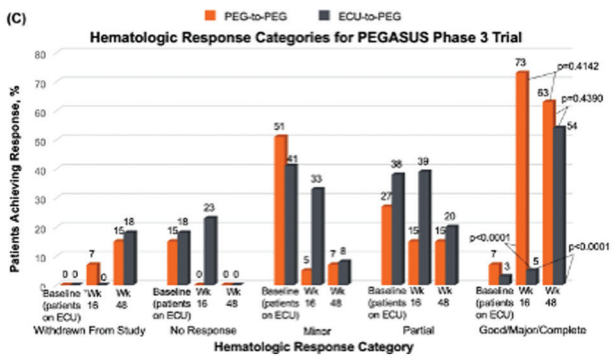
Results: Of 80 enrolled patients, 41 and 39 were randomized to the PEG-to-PEG and ECU-to-PEG study arms, respectively (Figure A). Mean Hb levels for each arm at baseline, Week 16, and Week 48 are shown below (Figure B). At baseline, 7% (PEG-to-PEG) and 3% (ECU-to-PEG) of patients exhibited a Good/Major/Complete hematologic response. At Week 16, 73% (PEG-to-PEG) and 5% (ECU-to-PEG) of patients exhibited this response (p<0.0001), while the proportion of patients who achieved this response was similar between arms at Week 48 (p=0.4390). In total at Week 48, 63% of patients in the PEG-to-PEG arm (p=0.4142 vs. Week 16) and 54% of patients in the ECU-to-PEG arm (p<0.0001 vs. Week 16) achieved a Good/Major/Complete hematologic response, demonstrating a significant increase in the percent of ECU-to-PEG patients achieving at least a Good response after switching to PEG (Figure C).
Overall, 13 left the study; 12 patients discontinued PEG: 3 in the randomized controlled period, 8 in the open label period due to TEAEs (6 in ECU-to-PEG, 2 in PEG-to-PEG), and one during follow-up; one additional patient withdrew due to physician decision. These 13 patients (12 discontinuations and 1 withdrawal) were not included in statistical analyses.

(A)



(B) Mean Hemoglobin Levels for Each Study Arm at Baseline, Week 16, and Week 48

	PEG-to-PEG			ECU-to-PEG		
	Baseline	Week 16	Week 48	Baseline	Week 16	Week 48
Hb level, g/dL; NRR, 12.0-18.0 g/dL Mean (SD)*	8.7 (1.1)	11.5 (2.0)	11.3 (1.8)	8.7 (0.9)	8.6 (1.0)	11.6 (2.2)

*NRR: normal reference range

(C)

Summary/Conclusion: In this post-hoc analysis of the PEGASUS study, PEG treatment resulted in a significantly greater proportion of patients with Good or better hematologic responses after switching from ECU treatment. These results further support that proximal complement inhibition, by preventing EVH in addition to controlling IVH, leads to clinical and hematologic improvement in PNH treatment.

PB1478 ASSOCIATION BETWEEN HLA AND BONE MARROW FAILURE DISEASES

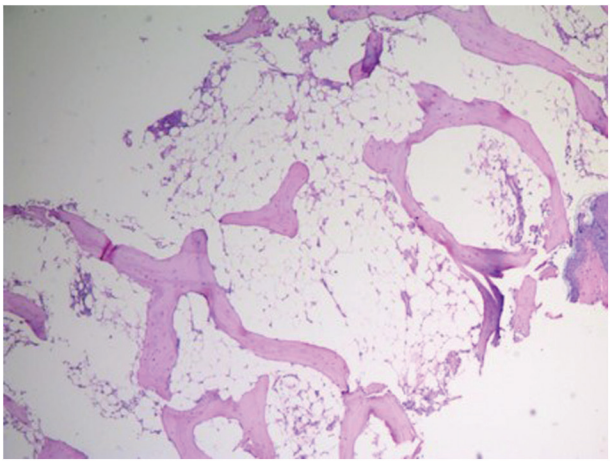
R. Fu [1], Y. Shao [1,*], B. Liu [1], X. Pan [1], C. Liu [1]

[1]*Tianjin Medical University General Hospital, Tianjin, China*

Background: The bone marrow failure diseases include a group of disorders that can be either inherited or acquired, involving either 1 cell line or all of the cell lines. Acquired aplastic anemia and myelodysplastic syndrome are common diseases, manifested as bone marrow failure. Acquired aplastic anemia (aAA) is thought to be driven by Human Leukocyte Antigen (HLA)-restricted T cell immunity, with earlier studies favoring HLA class II-mediated pathways. Owing to the association of autoimmune disease with pathognomonic HLA, we hypothesized that part of the MDS and aAA patients could associate with HLA genotype and thus those patients are prone to develop bone marrow failure diseases.
Aims: To characterize the association between HLA genotype and bone marrow failure disease, we therefore designed a study to investigate the association of HLA genotype and its correlation with bone marrow failure disease.
Methods: A total of 12 patients with acquired severe aplastic anemia (aSAA) and 10 patients with myelodysplastic anemia (MDS) were enrolled in this study, as well as 10 health controls. The enrolled patients were diagnosed in our department from 2019.07 to 2020.12. All subjects underwent blood sampling on EDTA as anti-coagulant for DNA extraction. We used a next-generation sequencer (MiSeq, Illumina, CA, USA) to identify the HLA of HLA-A, HLA-B, HLA-C, HLA-DR, HLA-DP, and HLA-DQ genes in each patient and heath control. Informed consent was obtained from the study participants for the genetic analyses. The diagnosis and severity of AA and MDS were determined according to standard criteria. Tests of proportions were used to compare allelic frequencies.
Results: We found HLA-C*14:02:01, HLA-C*04:01:01, HLA-DQB1*06:01:01 might be involved in the pathogenesis in bone marrow failure diseases (all $p<0.05$). As for HLA-C*14:02:01, frequency of this gene in MDS and SAA is 20% and 0%, respectively. ($p=0.0357$) This serotype of HLA-C might be a biomarker to distinguish MDS from SAA. As for HLA-C*04:01:01, frequency of this gene in SAA and HC is 0% and 20%, respectively. ($p=0.0357$) This serotype of HLA-C might be a major protective factor in the pathogenesis of aSAA. Similarly, the frequency of HLA-DQB1*06:01:01 in SAA and HC is 4.17% and 30%, respectively. ($p=0.0353$) This serotype of HLA-DQ might be a major protective factor in the pathogenesis of aSAA (Table 1). Supporting by previous study, we found high risk HLA-DR alleles such as DRB1*15:01 is highly expressed in patients with MDS or SAA (35%, 41.6%, respectively), compared with health control (25%). However, we did not find a statistical significance between three groups.

Table 1. Identified genotype with statistical significance

	Frequency in MDS	Frequency in aSAA	Frequency in HC	p1	p2	p3
C*14:02:01	4	0	1	0.3416	0.4545	0.0357
C*04:01:01	2	0	4	0.6614	0.0357	0.2008
DQB1:06:01:01	3	1	6	0.4506	0.0353	0.3155
	Note: p1:MDS compared with HC; p2: SAA compared with HC; p3: MDS compared with aSAA					



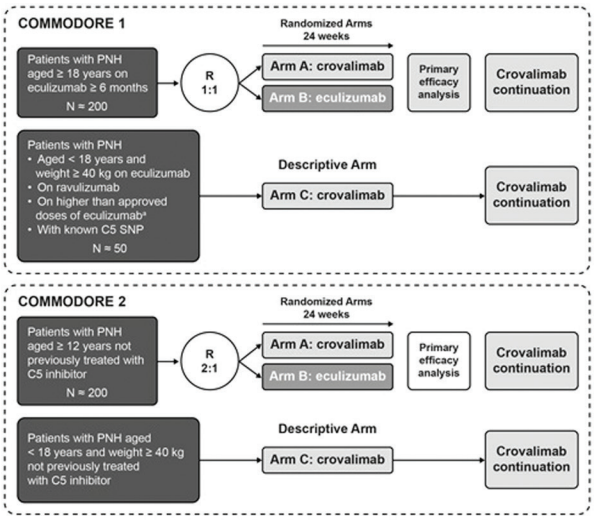
Summary/Conclusion: HLA genotype could be a surrogate marker to monitor the disease severity and predisposition to bone marrow failure disease.

PB1479 POST COVID 19 APLASTIC ANEMIA: CASE REPORT

O. Fahmy [1], A. Ayad [1], M. Marie [2], E. S. Saber [1], M. T. Hamza [3], D. El Demerdash [1,*]

[1]Clinical hematology unit, internal medicine, [2]Internal Medicine (Nephrology unit), Cairo university, [3]clinical pathology & hematology, Ain shams university, Cairo, Egypt

Background: The most common symptoms seen in COVID-19 patients are fever, fatigue, and dry cough, and dyspnea. Although there is comparatively few rising reports on the hematological sequelae. Hematological changes commonly described in patients with COVID-19, include reduced lymphocyte count and platelet count but normal white blood cell count. we present a case of pancytopenia and hypocellular marrow which is not a commonly known sequalae of COVID 19 infection.
Aims: To describe a novel case of coronavirus disease 2019 (COVID-19)-associated aplastic anemia in a patient known to have primary glomerulonephritis.
Methods: we described a case report of hematological sequalae of a COVID 19 case including the clinical presentation, management, and response to therapy
Results: A 25-year-old lady with a background of primary membranous glomerulonephritis with crescent formation required therapy with rituximab monoclonal anti CD20, presented with anemia, mucocutaneous bleeding. 25 days before her presentation she had subjective fever, cough, and dyspnea with radiological findings highly suspicious for COVID 19 and she tested positive for COVID-19 by PCR on nasopharyngeal swab. Isolation at home was recommended for her as she had mild-moderate COVID19 and her swab turned negative after 15 days of onset of the respiratory symptoms. she experienced pallor and muco-cutaneous bleeding in form of ecchymosis all over the body, wet purpura but the rest of her clinical examination was free, her CBC revealed hemoglobin: 6.9 g/dl; WBC: $2.67\times10^3/mm^3$; platelets: $10\times10^3/mm^3$. MCV 79 with reticulocytopenia, all immunological profiles as well as virology screening for HCV, HBV, HIV, CMV and EBV were negative. Bone marrow aspirate and biopsy revealed marked hypocellular marrow (cellularity 20%) with all bone marrow element were markedly depressed. Cyclosporine was prescribed for her as well as eltrombopag in the dose of 50 mg/day orally which titrated gradually according to platelet response to 100 mg/day PO with repeated irradiated packed RBCs and platelet transfusion during hospital stay.
During her hospital stay her liver enzymes (AST & ALT) were elevated so doses of cyclosporine and eltrombopag were decreased till the normalization of her liver enzymes then reiterated again according to the hematological response. She is maintained on this protocol now for 2 months with minimal hematological response. she prepared now for HLA matching and hematopoietic stem cell transplantation.



Summary/Conclusion: Further exploration of potential COVID-19-related hematological abnormalities is needed and requires extensive collaboration to collect large, organized data sets. The possibility of an immune-mediated process and its therapeutic implications also warrants greater study.

PB1480 TWO CURRENTLY RECRUITING PHASE III TRIALS: COMMODORE 1 AND 2 EVALUATING CROVALIMAB VS ECULIZUMAB IN PATIENTS WITH PAROXYSMAL NOCTURNAL HEMOGLOBINURIA WITH OR WITHOUT CURRENT ANTI–COMPLEMENT THERAPY

A. Kulasekararaj [1,*], A. Risitano [2,3], A. Röth [4], G. He [5], J. Pu [6,7], L. Wright [8], A. Appius [9], A. Sostelly [9], S. Sreckovic [9], S. F. Stanzel [9], T. Munir [10], J.-I. Nishimura [11]

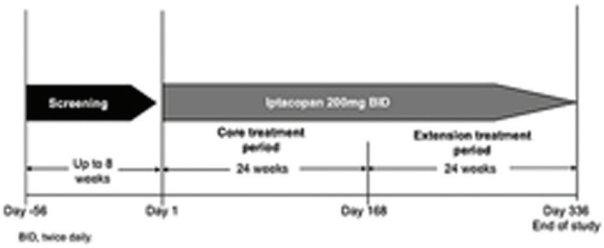
[1]Department of Haematological Medicine, King's College Hospital-NHS Foundation Trust, NIHR Wellcome Foundation Clinical Research Facility, King's College London, London, United Kingdom, [2]Hematology, Department of Clinical Medicine and Surgery, Federico II University, Naples, [3]Hematology and BMT Unit, AORN Moscati Avellino, Avellino, Italy, [4]Department of Hematology and Stem Cell Transplantation, University Hospital Essen, University of Duisburg-Essen, Essen, Germany, [5]Department of Hematology, The First Affiliated Hospital of Nanjing Medical University, Jiangsu Province Hospital, Jiangsu, China, [6]Hollings Cancer Center, The Medical University of South Carolina, Charleston, SC, [7]University of Arizona Cancer Center, Tucson, AZ, [8]Genentech, Inc., South San Francisco, CA, United States, [9]F. Hoffmann-La Roche Ltd., Basel, Switzerland, [10]Department of Haematology, St James's University Hospital, Leeds, United Kingdom, [11]Department of Hematology and Oncology, Osaka University Graduate School of Medicine, Suita, Osaka, Japan

Background: Crovalimab is a novel anti–complement C5 antibody currently being studied as a treatment for paroxysmal nocturnal hemoglobinuria (PNH), a life-threatening disease associated with hemolytic anemia and thrombosis. Treatment with approved C5 inhibitors eculizumab or ravulizumab is effective but can be limited by breakthrough hemolysis (BTH) due to unsustained C5 inhibition, inadequate efficacy in patients with C5 mutational variants and the requirement of regular intravenous (IV) infusions. Crovalimab is unique in that its properties allow for subcutaneous (SC) injections once every 4 weeks (Q4W) that can be self-administered. Additionally, crovalimab binds to C5 mutational variants. Promising results were obtained in the Phase I/II COMPOSER trial (NCT03157635; Röth et al, *Blood*. 2020) conducted in patients with PNH, with or without prior anti–C5 treatment.
Aims: The efficacy and safety of crovalimab vs eculizumab will be evaluated in two Phase III, randomized, open-label trials in patients with PNH, with or without current complement inhibition.
Methods: COMMODORE 1 (NCT04432584) will enroll patients who are receiving complement therapy. This trial is divided into 2 parts: 2 randomized arms (Arms A and B) for primary and secondary efficacy analyses and an exploratory descriptive arm (Arm C) (Figure). Patients eligible for the randomized arms will be randomized 1:1 to receive either crovalimab (Arm A) or eculizumab (Arm B). Arm A and C patients will receive crovalimab loading and subsequent SC Q4W maintenance dosing from week 5. Arm B patients will receive eculizumab IV maintenance dosing from D1 Q2W for a total of 24 weeks. Patients from each treatment arm can continue or switch to crovalimab after 24 weeks of treatment as determined by the treating physician. The primary efficacy objective is to determine the noninferiority of crovalimab vs eculizumab based on mean percent change in lactate dehydrogenase levels from baseline to week 25. Secondary efficacy objectives are to determine the proportion of patients who experience BTH, achieve transfusion avoidance (TA) or hemoglobin stabilization, as well as determine mean change in fatigue according to the Functional Assessment of Chronic Illness Therapy–Fatigue questionnaire from baseline to week 25. Safety and tolerability of crovalimab will also be evaluated along with pharmacokinetic, immunogenicity and health status utility objectives.
COMMODORE 2 (NCT04434092) will enroll patients not previously treated with complement inhibitors. This trial is also divided into 2 parts (Figure). Patients aged ≥ 12 years will be randomized 2:1 to receive either crovalimab (Arm A) or eculizumab (Arm B). Arm A and C patients will receive crovalimab loading and subsequent SC Q4W maintenance dosing from week 5. Arm B patients will receive induction doses of eculizumab IV QW for 4 weeks followed by maintenance dosing Q2W up to 24 weeks. Patients from each treatment arm can continue or switch to crovalimab as determined by the treating physician. The co-primary efficacy objectives are to determine the noninferiority of crovalimab vs eculizumab, based on the proportion of patients 1) who achieve TA from baseline to week 25 and 2) with hemolysis control from week 5-25. Safety and tolerability of crovalimab will also be evaluated along with pharmacokinetic, immunogenicity and health status utility objectives.
Results: COMMODORE 1 and 2 are now enrolling.

[a]Those receiving > 900 mg per dose and/more frequently than Q2W.
C5, complement component 5; PNH, paroxysmal nocturnal hemoglobinuria; Q2W, once every 2 weeks; R, randomized; SNP, single nucleotide polymorphism.

AK and AR are co-first authors. TM and J-IN are co-senior authors.

Summary/Conclusion: The COMMODORE 1 and 2 studies aim to assess the efficacy and safety of crovalimab in patients with PNH, compared with eculizumab, in patients with or without prior complement inhibition.



PB1481 PHASE 3 STUDY OF THE EFFICACY AND SAFETY OF IPTACOPAN (LNP023), AN ORAL FACTOR B INHIBITOR, IN ADULT PATIENTS WITH PAROXYSMAL NOCTURNAL HEMOGLOBINURIA (PNH) NAÏVE TO COMPLEMENT INHIBITOR THERAPY

R. Peffault de Latour [1,*], B. Han [2], J. Maciejewski [3], Y. Ueda [4], Y. Cheng [5], G. Bermann [6], M. Dahlke [6], A. M. Risitano [7,8]

[1]Saint-Louis Hospital, Paris, France, [2]Peking Union Medical College, Beijing, China, [3]Case Western Reserve University, Cleveland, United States, [4]Osaka University Graduate School of Medicine, Osaka, Japan, [5]China Novartis Institutes for BioMedical Research, Shanghai, China, [6]Novartis Pharma AG, Basel, Switzerland, [7]University of Naples Federico II, Naples, [8]AORN Moscati, Avellino, Italy

Background: The standard of care treatment (tx) in PNH is based on complement C5 inhibition with anti-C5 monoclonal antibodies (MAbs). Anti-C5 MAbs are generally effective at treating intravascular hemolysis (IVH) but unmet medical needs remain. Hematological responses to anti-C5 antibody tx can be heterogenous and a substantial number of pts experience residual anemia associated with breakthrough hemolysis (BTH). Anti-C5 MAbs are also not available in all countries and, where available, pt access can be limited. Iptacopan (LNP023) is a first-in-class, oral, small-molecule, selective, and reversible complement factor B inhibitor that inhibits both IVH and extravascular hemolysis (EVH). In an ongoing Ph2 study (NCT03439839), iptacopan has demonstrated improvements in both hematological response and biomarkers of disease activity in adult pts with PNH who had active hemolysis despite tx with eculizumab. These findings warrant further Ph3 studies to assess the efficacy of iptacopan in a wider population of pts with PNH, including those who are naïve to anti-C5 MAbs tx.
Aims: The Ph3, single-arm, open-label APPOINT-PNH study (CLNP023C12301) will assess the efficacy and safety of iptacopan in adult pts with PNH who are naïve to complement inhibitor therapy, including anti-C5 MAbs.
Methods: The study comprises an ≤8-wk screening period; a 24-wk, single-arm, open-label core tx period; and a 24-wk, open-label tx extension period (Fig. 1). On completion of the Wk 24 visit, pts who show benefit from iptacopan tx can enter the extension period. Eligible adult pts (N≈40; ≥18 years old) must have a confirmed diagnosis of PNH (red blood cells [RBCs] and white blood cells [granulocyte/monocyte] clone size ≥10%); anemia (mean Hb <10g/dL) and active hemolysis (lactate dehydrogenase [LDH] >1.5×upper limit of normal). Key exclusion criteria: prior tx with a complement inhibitor; known or suspected hereditary complement deficiency; history of hematopoietic stem cell transplantation; laboratory evidence of bone marrow failure; active, systemic infection ≤14 days preceding study drug tx; and history of recurrent, invasive infections caused by encapsulated microorganisms. The primary objective is to assess hematologic response, defined as achieving a sustained increase in Hb levels ≥2g/dL (in the absence of RBC transfusions). The primary endpoint is to evaluate the proportion of pts achieving an increase from baseline (BL) in Hb levels ≥2g/dL, between D126–D168 (in the absence of RBC transfusions between D14–D168). The analysis of the primary endpoint will be a logistic regression model including BL covariates: sex, age (categorical), Hb >8g/dL, and presence of transfusion dependence at enrollment. Secondary endpoints include: proportion of pts reaching Hb levels ≥12g/dL; absence of RBC transfusions; changes from BL in Hb levels; changes in patient-reported fatigue scores (FACIT-Fatigue); changes from BL in reticulocytes; % change from BL in LDH; occurrence of BTH; occurrence of major adverse vascular events (including thrombosis). Additional analyses include safety assessments; evolution of PNH clone size and C3d deposition on RBCs; and other PROs (PGI-S, EORTC QLQ-C30, EQ-5D-5L).
Results: NA.

Figure 1: APPOINT-PNH design

Summary/Conclusion: Ph2 study data suggest that iptacopan may control EVH and IVH, thereby reducing anemia in pts with PNH previously treated with anti-C5 MAbs. Data from a further Ph2 study of iptacopan in patients with treatment-naïve PNH (NCT03896152) are awaited. Ph3 studies to assess the efficacy of iptacopan in a wider population of pts with PNH are planned.

PB1482 PHENOTYPE-GENOTYPE RELATIONSHIP IN PATIENTS WITH FANCONI ANEMIA AND VACTERL-H ASSOCIATION FREQUENCY

C. Albayrak [1,*], D. Albayrak [2]

[1]Pediatric Hematology, Ondokuz mayıs university Medical Faculty, [2]Pediatric Hematology, Samsun Medicalpark Hospital, Samsun, Turkey

Background: Fanconi anemia is mainly an autosomal recessive syndrome and more than 60% of the patients have physical anomalies. In the follow-up of the patients, bone marrow failure, AML and solid tumors develop. Pathological changes have been identified in at least 22 genes. FANCA 60%, FANCC 14% and FANCG 10% genes have been identified most frequently. VATER association, in its broader form, is an abbreviation of VACTERL or VACTERL-H, vertebral anomaly, anal atresia, cardiac anomalies, trecea-esophageal fistula, renal anomaly, extremity (radius and thumb) anomaly and hydrocephalus. It is a disease defined by a combination of three or more. It is seen sporadically and its frequency is reported as one in ten thousand or forty thousand in the general population. The probability of being diagnosed with Fanconi anemia simultaneously or later with VACTERL-H association has been reported to be 5-30%. In these patients, the risk of early-onset midline brain tumors, Wilms' tumors and AML is greatly increased.
Aims:
Our aim is to investigate the phenotype-genotype relationship of our patients with Fanconi anemia.
Methods: In our department, the phenotype-genotype relationship was investigated by studying the genetic mutations of patients diagnosed with Fanconi anemia with clinical, laboratory and mitomycin C test positivity. Our patients were evaluated especially in terms of VACTERL-H association.
Results: Mutations were detected in 14 patients out of 40 Fanconi anemia followed in our clinic. Four of our patients were male and other was female. Their age was between 2-21 and the median age was 10. Two siblings were identified in three families. Mutations were detected in the FANCA gene of 13 patients. Compound heterozygosity was detected in four patients, large homozygous deletion in six patients, and homozygous missense mutation in three patients. Eleven different pathological alleles were shown in the FANCA gene. In a patient with VACTERL-H association, c.2504+1G> C homozygous mutation was found in the FANCG gene.

Summary/Conclusion: Fanconi anemia is common in our country. However, genotype determination studies have started in recent years. Fanconi anemia are the results of this study genotype the first reported from Turkey. By obtaining genotype results in more of our patients, the frequency of Fanconi genotype in our country should be determined and its relation with phenotype should be investigated. In addition, patients with VACTERL-H association should be evaluated in terms of Fanconi anemia.

PB1483 DIAGNOSIS OF HEMATOPOIETIC MALIGNANCIES WITH GERMLINE PREDISPOSITION: A FILTERED WHOLE EXOME SEQUENCING APPROACH

R. Fernandez Carazo [1,*], B. Koopmansch, [1], B. Charloteaux [1], L. Palmeira [1], F. Lambert [1]

[1]Genetics, CHU Liege, Liège, Belgium

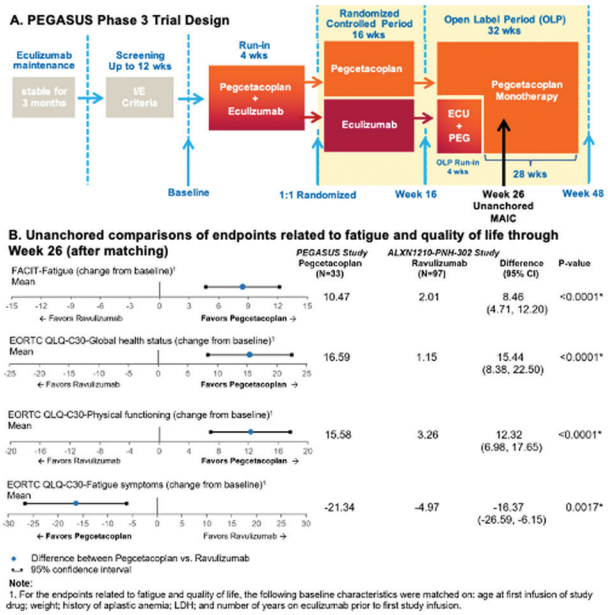
Background: Inherited Haematological Malignancies are a heterogeneous group of malignancies not yet fully understood and in constant evolution.
Patients suffering of suspected inherited malignancies are often faced to poor access to rapid diagnosis due to a restricted number of analytical sites or the current use of non-comprehensive targeted panels.
Aims: We aim at developing a new NGS panel for the analysis of several haematological diseases based on a filtered whole exome sequencing approach.
Haematological diseases incorporated in the panel include myelodysplasic syndromes, acute myeloid leukemia, inherited bone marrow failure syndromes, Fanconi anemia, Diamond Blackfan anemia, dyskeratosis congenita, Telomeropathies and severe congenital neutropenia.
Methods: Clinical exome is sequenced with the SureSelect Hulan Exome V6, recovering information for about 20k genes, representing ca. 180k exons. A newly designed variant filter based on an in-house pipeline tree (Alissa Interpret) for the flagging of retained variants, allows for the selection and labeling of ca. 100 variants per patient. Variants are categorized following the ACMG guidelines for the interpretation of inherited variants and reported in the context of the patient malignancies.
The set of genes has been selected from a deep insight to the most recent literature and guidelines and covers 85 full (exonic) genes. The ncRNA gene TERC and intronic regions from RETL1 are also included in the set.
The analytical pipeline considers the analysis of single patients, corroboration of relevant inherited germline mutations from fibroblasts and/or trio analysis including first or second relatives. Applications cover from simple diagnostic from single patients to familiar studies or donor compatibility analysis.
Results: The proposed analytical method provides a solution for the detection of mutations in a large panel of genes involved in the cited haematological diseases. Due to the constant evolution and updates in this malignancies area, flexibility is a key concept to avoid analytical obsolescence. Due to the wide range of genes covered by the WES approach, significant genes could be further updated, with a minimal effort, to the panel.
Summary/Conclusion: We therefore aim to provide physicians with a comprehensive diagnostic panel for the diagnostic work-up of patients affected (or suspected to be affected) by inherited haematological malignancies, and related diseases enhancing the patient's chances to benefit from a personalized medicine approach; together with a view to increase the knowledge about those (rare) conditions.

PB1484 REAL WORLD SINGLE CENTRE EXPERIENCE OF USE OF ELTROMBOPAG ADDED TO STANDARD IMMUNOSUPPRESSION AMONG INDIAN PATIENTS WITH APLASTIC ANEMIA

R. K. K [1,*]

[1]Clinical Haematology, Nizam's institute of Medical Sciences, Hyderabad, India

Background: Acquired aplastic anemia results from immune-mediated destruction of haematopoietic stem cells of bonemarrow. Immunosuppressive therapies are effective, but reduced numbers of residual stem cells may limit their efficacy. In patients with aplastic anemia that was refractory to immunosuppression, eltrombopag, a synthetic thrombopoietin-receptor agonist, led to clinically significant increases in blood counts in almost half the patients. We combined standard immunosuppressive therapy with eltrombopag in previously untreated patients with severe aplastic anemia.
Aims: To evaluate the Effectivness and Safety of Eltrombopag, Added to Standard Immunosuppression in Indian patients with Acquired Aplastic Anemia.
Methods: Patients (>5 years) of either gender with Acquired Aplastic Anaemia, who had received Eltrombopag, in addition to standard Immunosuppression with ATG/Cyclosporin from Jul-2019 to Oct-2020, at Department of Clinical Hematology, Nizam's Institute of Medical Sciences, Hyderabad, India, were included. The primary outcome was complete/partial hematologic response at 6 months. Secondary end points included overall response, survival, adverse events{platelet response (platelet count: ≥50000/μL).}
Results: Of 17 patients, majority (%) were females. The mean age was… years. Seven (…%) patients had severe Aplastic Anaemia, two (12.5%) had non-severe aplastic Anaemia, 6 (37.5%) had Megakaryocytic thrombocytopenia. For newly diagnosed patients, the frontline use of eltrombopag (concomitant medications: anti-thymocyte globulin, ATG, and cyclosporin, N = 4; cyclosporin, N = 5; nil, N = 1) at a median maximum dose of 150 (50–300) mg/day led to an overall response rate (ORR) of 90% (trilineage: 60%; neutrophil: 20%; platelet: 10%). Adverse effects included dyspepsia, and liver function derangement. Eltrombopag was well tolerated without significant side-effects mandating drug withdrawal.
Summary/Conclusion: In a routine haematological practice, the use of eltrombopag in AA patients was feasible, safe, and associated with favourable responses.



PB1485 COMPARATIVE EFFECTIVENESS OF PEGCETACOPLAN VERSUS RAVULIZUMAB IN PATIENTS WITH PAROXYSMAL NOCTURNAL HEMOGLOBINURIA: A MATCHING-ADJUSTED INDIRECT COMPARISON USING 26 WEEK PEGASUS PHASE 3 TRIAL DATA

R. Bhak [1,*], N. Mody-Patel [2], S. Baver [2], C. Kunzweiler [1], C. Yee [1], S. Sundaresan [1], N. Swartz [1], M. S. Duh [1], S. Krishnan [2], S. Sarda [2]

[1]Analysis Group, Boston, MA, [2]Apellis Pharmaceuticals, Inc, Waltham, MA, United States

Background: Pegcetacoplan (PEG), a PEGylated peptide targeting proximal complement protein C3, can control both intravascular and extravascular hemolysis. In the PEGASUS trial (NCT03500549), a phase 3, randomized, open-label, active-comparator controlled study, PEG was shown to be superior to the C5 inhibitor eculizumab (ECU) after 16 weeks, improving hemoglobin (Hb) levels and clinical outcomes in patients with PNH (*Hillmen P et al., EHA 2020*).
Aims: We assessed the comparative effectiveness of PEG to the C5 inhibitor ravulizumab (RAV) using matching-adjusted indirect comparison (MAIC) methodology to conduct cross-trial comparisons.
Methods: Individual patient data from PEGASUS were used to adjust for baseline differences compared to aggregate, published results from the randomized ALXN1210-PNH-302 ("302") study (NCT03056040) which compared RAV and ECU at 26 weeks among patients with PNH with previous ECU treatment (Kulasekararaj et al., *Blood* 2019). In PEGASUS, patients completed a 16-week randomized controlled period (RCP) with 1:1 PEG and ECU randomization followed by PEG monotherapy for all patients for 28 weeks (Figure A). PEGASUS and 302 had similar eligibility criteria; however, PEGASUS required Hb <10.5 g/dL and absolute reticulocyte count >1x upper limit of normal while 302 did not. Propensity score weighting was used to balance demographic and clinical characteristics between the PEG arm from the PEGASUS trial and the RAV arm from the 302 trial. To compare to RAV results at Week 26, unanchored MAIC was used for PEGASUS patients from the RCP PEG group, using a proxy for Week 26 (mean of Week 24 and Week 28). Mean change from baseline (CFB) was calculated for Functional Assessment of Chronic Illness Therapy (FACIT)-Fatigue score and for European Organisation for Research and Treatment of Cancer Quality of Life Questionnaire-Core 30 Scale (EORTC QLQ-C30) global health status, physical functioning, and fatigue symptoms questionnaires. Weighted Wald tests and 95% confidence intervals (CIs) were computed for comparisons of categorical and continuous outcomes.
Results: Thirty-three PEG patients from PEGASUS and 97 RAV patients from the 302 study were included. At Week 26, PEG patients experienced a clinically meaningful (>3 points) improvement in FACIT-Fatigue (higher score indicates less fatigue; mean CFB: 10.47 [95% CI: 6.98-13.95]) that was significantly greater (P<0.001) than the improvement for RAV patients (2.01 [95% CI: 0.64-3.38]) (Figure B). PEG patients also experienced clinically meaningful (>10 points) improvement in

EORTC QLQ-30 global health status (higher score indicates improved patient health; mean CFB: 16.59 [95% CI: 10.34-22.84]) that was greater than in RAV patients (mean CFB: 1.15 [95% CI: -2.14-4.44], P<0.001). Similarly, PEG patients showed clinically meaningful (>10 pts) improvement in EORTC QLQ-30 physical functioning (mean CFB: 15.58 [95% CI: 10.53-20.62]), but RAV patients did not (mean CFB: 3.26 [95% CI: 1.53-4.99], P<0.001), indicating that PEG patients experienced higher levels of physical functioning. For EORTC QLQ-30 fatigue symptoms, in which a negative score indicates a decrease in fatigue, PEG patients experienced a clinically meaningful (>10 points) decrease in levels of fatigue (mean CFB: -21.34 [95% CI: -30.96 to -11.72]), but RAV patients did not (mean CFB: -4.97 [95% CI: -8.40 to -1.54], P<0.010).

Summary/Conclusion: MAIC results indicated that when compared with RAV, PEG treatment is associated with improvements in FACIT-Fatigue and EORTC QoL scores, evidencing an improvement in fatigue, physical functioning, global health, and quality of life.

PB1486 TRIAL IN PROGRESS: QUANTIFYING THE HUMANISTIC AND SOCIOECONOMIC BURDEN OF PAROXYSMAL NOCTURNAL HEMOGLOBINURIA IN THE COMMODORE BURDEN OF ILLNESS STUDY

R. James Hampton [1,*], P. Katz [1], A. Shang [1], H. Dhillon [2], H. Hubberstey [2]

[1]F. Hoffmann-La Roche Ltd, Basel, Switzerland, [2]HCD Economics, The Innovation Centre, Daresbury, Cheshire, United Kingdom

Background: Paroxysmal nocturnal hemoglobinuria (PNH) is a rare disease associated with major complications such as thrombotic events and impaired renal function. Prior to the introduction of C5 inhibitors in 2007, PNH had been fatal in about 35% of patients within 5 years of diagnosis; yet this fatality rate continues in countries without access to these medications. Worldwide access to the C5 inhibitor eculizumab is hindered by the unavailability of treatment, and in places where treatment is approved, cost of treatment, reimbursement issues, infrastructure, or patient restrictions may further impede access (Risitano et al, *Am J Hematol*. 2018; Risitano et al, *Front Immunol*. 2019). PNH treatment places a significant economic burden on healthcare systems. In many countries, this has resulted in negative health technology appraisals (HTAs), indicating that optimal care and resource utilization are not being achieved (Coyle et al, *Med Decis Making*. 2014). New therapies with more convenient modes of administration may improve how PNH is clinically treated and positively impact access to C5 inhibitors globally. Further, treatments that allow for home administration may reduce patient and healthcare systems costs. Robust data on the real-life burden and cost of PNH are needed to assess the impact of current therapies and establish a baseline for new therapeutic approaches. Data derived from this study, which to our knowledge is the first socioeconomic study in PNH, will be used to support HTA processes and inform the value of new PNH therapies.

Aims: The COMMODORE burden of illness (BOI) study will quantify the direct medical costs (eg, treatment and hospitalization), direct nonmedical costs (eg, travel), and indirect costs (eg, impact on work productivity and family burden) associated with PNH for patients and care providers and determine the impact of PNH on health-related quality of life (HRQOL).
Methods: This is an international, prevalence-based, bottom-up, BOI study containing both retrospective and prospective data collection. The study will be overseen by an expert reference group consisting of multidisciplinary stakeholders. The study protocol and materials will be submitted for ethical approval to the University of Chester in the United Kingdom. Physicians will provide information on sociodemographic, clinical, and medical resource utilization using electronic case record forms (eCRFs). Through patient and public involvement and engagement, patients, after giving informed consent, will provide further information on the economic and HRQOL impact of PNH by completing patient-reported outcome surveys. Patients from France, Germany, the United Kingdom, and China will be included.
The aim is to recruit 94 physicians who will report 350 patient eCRFs with an expected return of 140 patient surveys and longitudinal data collection after 6-12 months for each patient. Mean per-patient costs, including direct medical and nonmedical costs, and indirect resource utilization will be calculated by multiplying the individual resource utilization by country-specific unit costs. National economic burden will be extrapolated by applying national prevalence estimates of PNH. Additionally, the impact of PNH on patient HRQOL will be assessed.
Results: Final results are expected in spring 2022.
Summary/Conclusion: The COMMODORE BOI study aims to characterize current PNH treatment via quantification of the humanistic and socioeconomic burden at the patient, healthcare system, and societal level to enhance the evidence base for treatment and decision-making in this community.

PB1487 EPIDEMIOLOGY OF ACQUIRED APLASTIC ANEMIA: A RETROSPECTIVE 10-YEAR SINGLE CENTRE EXPERIENCE

L. Seraj [1,*]

[1]Hematology, University hospital center Mother Teresa of Tirana, Tirana, Albania

Background: Aplastic Anemia (AA) is a syndrome characterized by peripheral blood pancytopenia with hypo cellular marrow. Acquired idiopathic AA is still the most common variety. Aplastic anemia's incidence varies in different geographic areas. In Albania the epidemiology of Acquired AA has not been identified by any study up to now.
Aims: The aim of this study is to identify and describe the epidemiology, including the incidence of Acquired AA in Albania.
Methods: The following study is a retrospective study. Patients diagnosed for the first time between January 2010 and December 2020, at the University Hospital Center (UHC) 'Mother Teresa' Tirana, Albania, aged 14 years old and up, were included in this study. The diagnosis of AA patients was confirmed by the bone marrow biopsy hypo-cellularity (less than 25% of cellularity), immunohistochemistry, and by the peripheral blood cytopenias (ANC, Hgb, Plt). The patients were classified into three severity subgroups using the International Aplastic Anemia Study Group. Statistical analysis for this study was performed using SPSS. Categorical and continuous parameters were analyzed using the x^2 test and the T test respectively.
Results: A total of 35 patients were diagnosed as Aplastic Anemia between 2010-2020. The median age was 51 (15-80) years, and 19 (54.3%) were females. Males' age was slightly higher than the females, mean 54.7 and 49.4 years old respectively. Most of the cases fell under the Non-severe AA group and the Very-severe AA group, 16 and 12 patients respectively. Out of the 35 patients, two were lost to follow, 5 died within the first year following the diagnosis. The incidence of Acquired Aplastic Anemia in Albania is 1.35 per million inhabitants.

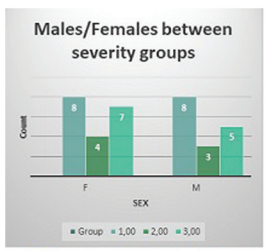


Figure 1. Bar chart showing the distribution of men and women between the three groups.Left to right 1st group NSAA; 2nd group SAA; 3rd group VSAA.

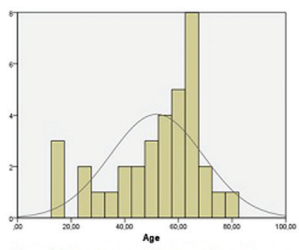

Figure 2. Histogram of the age distribution of the AA patients.

Summary/Conclusion: The incidence of AA in Albania is lower compared to other studies performed in Europe. In this study the median age of the AA patients was 51 years old, which could be due to environmental factors, whereas other studies have reported a younger median age varying between 19 to 35 years of age. In this study females' numbers were slightly higher compared to males. In other studies, males were predominant.

PB1488 RETROSPECTIVE ANALYSIS OF ROMIPLOSTIN IN SEVERE MEDULLARY APLASIA

A. R. Carranco Falcón [1,*], B. Díaz Roldán [1], E. Gil Esparraga [1]

[1]Hematología y hemoterapia, Hospital Juan Ramón Jiménez, Huelva, Spain

Background: Thrombopoietin analogs (aTPO) are used due to effectiveness in megakaryocytes stimulus and bone marrow multipotent hematopoietic progenitor cells. Thus, are widely used as second row treatment in patients with refractory medullary aplasia. Currently, it could be used as first contact treatment with immunosuppressive therapy enhacing in order to increase the response to treatment.
Aims: Analyze of Romiplostim use after inmunosuppressive therapy in patients with severe medullary aplasia.
Methods: Data analysis of all the patients diagnosed with medullary aplasia between 2019 - 2021 and with Romiplostim treatment has been done taking into account the effiency of the treatment in two terms:
- Parcially response to treatment: neutrophils higher than 0.5x10e9/L, platelets higher than 20x10e9/L and haemoglobin higher than 8 g/dL.
- Complete response to treatment: neutrophils higher than 1.5x10e9/L, platelets higher than 150x10e9/L and haemoglobin higher than 12-13 g/dL.
Results: In table 1 below, characteristics of 4 patients treated with Romiplostim has been shown. Three of them had platelets lower than 20x10e9/L with transfusional dependency and neutrophils lower than 1x10e9/L. All of them had have immunosuppressive therapy + Eltrombopag without response. Two of them had refraction to platelets transfusion. One of them only had been received previous treatment with Eltrombopag. After 6,5 months of tracking, all the patients treated with Romiplostim achieve parcially response to treatment without serious complications.

Summary/Conclusion: Adjuvant use of Romiplostim with patients without immunosuppressive therapy response must be taken into account. This option decrease transfunctional needs and improve all the blood series (hemoperipheral level) without serious complications.

PB1489 BONE MARROW METASTASIS: A CASE SERIES

S. L. Chong [1,*], R. J. Fann [1,2], K. W. Ngan [3], A. W. Ahmad Asnawi [1,4], V. Selvaratnam [1], S. M. Tan [1]

[1]Haematology Department, Ampang Hospital, [2]Faculty of Medicine and Health Sciences, Universiti Tunku Abdul Rahman, [3]Pathology Department, Serdang Hospital, Selangor, [4]Faculty of Medicine and Health Sciences, Universiti Sains Islam Malaysia, Seremban, Malaysia

Background: In bone marrow metastasis, the search of primary tumor is important as prompt treatment dictates prognosis of patient. However, site of primary tumor remains elusive in 10-30% of metastatic cancer despite extensive search.
Aims: At Clinical Referral Haematology Laboratory, Hospital Ampang, which is the tertiary referral laboratory for all hospitals within the Ministry of Health in Malaysia, we performed a retrospective review on the cases with a trephine diagnosis of metastatic carcinoma between 2010-2020.
Methods: A bone marrow trephine biopsy was performed based on patients' clinical presentation and cytopenia from full blood count. We analyzed each report individually and extracted the patients' clinical data from our cases and report, including the primary tumor and or possible metastasis site as well as survival rates.
Results: There were 14 cases of tumors metastatic to the bone marrow comprising of 9 women and 5 men, with median age of 60.3-year-old. Metastasis was made upon a bone marrow trephine biopsy was performed. Preliminary of 6 cases who we manage to identify the site of primary tumor whereas the rest of the cases with unknown primary bone marrow metastasis.
Summary/Conclusion: Bone marrow metastasis is an infrequent event. Close collaboration between clinician and pathologist is essential for diagnosis, identification of tumour subtype and even primary site of tumour for management and prognostication for cancer of unknown

Table 1. Characteristics of patients treated with Romiplostim.

Pacient	Age	Gender	Diagnosis	Immunosuppressive therapy	Refractariedad plaquetaria	Eltrombopag treatment
1	73	F	Severe medullary aplasia	YES	YES	YES (No response)
2	52	F	Severe medullary aplasia	YES	YES	YES (No response)
3	68	M	Severe medullary aplasia	YES	NO	YES (No response)
4	33	M	Severe medullary aplasia	YES	NO	NO

primary. Outcome of unfavourable cancer of unknown primary is poor even with recommended treatment.

Chronic lymphocytic leukemia and related disorders - Biology & Translational Research

PB1490 GENETIC LESIONS IN CLL PATIENTS WITH STEREOTYPE ANTIGENIC RECEPTORS MOST COMMON IN RUSSIA.

B. Biderman [1,*], E. Likold [1], N. Severina [1], A. Sudarikov [1]

[1]*Molecular Hematology Lab., National Research Center for Hematology, Moscow, Russian Federation*

Background: Tumor B-cells in chronic lymphocytic leukemia possess extreme narrowing of the IGHV gene repertoire comparing to other lymphoproliferative diseases. B-cell receptors with a highly homologous structure (SARs) - account for more than 40% of all CLL cases, with 29 such most common subgroups accounting for more than 13% of all CLL cases. CLL#1, CLL#2, and CLL#8 SARs are associated with an extremely aggressive course of the disease, while CLL#4 - with indolent. It was also suggested that tumor cells expressing certain SARs may also differ in the frequency and patterns of genetic lesions.
Aims: To determine the frequency of TP53, NOTCH1, and SF3B1 gene mutations in CLL#1, CLL#6, CLL#3, CLL#99, and CLL#28A subgroups of patients from the Russian cohort.
Methods: The study included 88 CLL patients admitted to the National Research Center for Hematology (Moscow, Russia) from 2012 to 2020. Rearranged IGHV gene sequences and SARs were determined according to the procedure recommended by ERIC. NOTCH1 gene (exon 34) mutations were studied by fragment analysis or by NGS as described by Campregher et al. TP53 gene mutations (exons 2-11 exons) were determined by NGS according to Pavlova et al. SF3B1 gene (exons 14-16) mutations were assessed by NGS.
Results: Peripheral blood DNA samples from CLL#1 (N=32), CLL#6 (N=17), CLL#3 (N=15), CLL#99 (N=12), and CLL#28A (N=12) patients were studied. TP53 gene mutations were detected with a high frequency in the CLL #6, CLL#1, CLL#99, and CLL#28A subgroups in 6 (35.3%), 11 (34.3%), 4 (33.3%) and 2 (16%) cases respectively. It should be noted that in all patients with CLL#99 and CLL#28A, only minor VAF (<5%) mutations were found. Most CLL#1 and CLL#6 patients have VAF>10%. Two patients with CLL#6 and one with CLL#99 had 2 clones simultaneously. In the CLL#3 subgroup, only 2 cases with mutations in this gene were identified, however one had 2 clones, and the other - 4. Mutations in the NOTCH1 gene were detected in patients with CLL#99, CLL#6, CLL#1, CLL#28A, and CLL#3 with a frequency of 3 (25%), 4 (23.5%), 7 (21.8%), 2 (16%) and 2 (13%) respectively. In most cases, the widespread c.7544_7545delCT mutation was detected. Also, c.7558_7561delCTTC and p.Q2444X mutations were found in two cases with CLL#1 and c.7547_7551del deletion in a patient with CLL#28A. SF3B1 gene mutations were detected in 8 (53.3%) CLL#3 patients. In CLL#6 (11 patients studied), CLL#99, and CLL#28A no SF3B1 gene mutations were found and in CLL#1 subgroup these mutations have not been assessed yet.

	CLL#1	CLL#99	CLL#28	CLL#3	CLL#6	CLL in general
IGHV	Clan I	Clan I	IGHV1-2	IGHV1-69	IGHV1-69	--
U-CLL	100%	100%	100%	100%	100%	50-60%
TP53 mutation	34,3%	33,3%	16%	13,3%	35,3%	7-10%
NOTCH1 mutation	21,8%	25%	16%	13,3%	23,5%	4-10%
SF3B1 mutation	--	0	0	53,3%	0	4-10%

Table 1. Genetic lesions frequency in Russian CLL subsets studied and in CLL in general

Summary/Conclusion: Here we present the data concerning the higher frequency of mutations in CLL#1, CLL#6, and CLL#3 subgroups than have been reported so far. Perhaps this is since some of our patients were tested after they already received FCR treatment and subsequently relapsed. It should be noted that CDR3 in subgroups CLL#1 and #99 have a similar motif, differ only by 1 amino acid, and are formed using the IGHV genes of the clan 1 (mostly IGHV1-2). CLL#28A is also based on IGHV1-2, and CLL#3 and CLL#6 are based on IGHV1-69. In the CLL#99 subgroup, as well as in the CLL#1 subgroup of a similar receptor structure, mutations in the TP53 gene are abnormally common, but with low VAF, which currently has no proven negative clinical significance. Interestingly, the two SARS subgroups with the IGHV1-69 gene usage demonstrate an opposite TP53, NOTCH1, and SF3B1 gene mutation pattern. Further study of genetic lesions in diverse SARs subgroups CLL patients should help to improve understanding of the pathogenesis, prognostication, and therapy of the disease.

PB1491 TARGETED MULTIGENE PANEL: NEXT-GENERATION SEQUENCING IN CHRONIC LYMPHOCYTIC LEUKEMIA

M. Mikhaleva [1,*], I. Martynkevich [1], E. Motyko [1], A. Kuvshinov [1], S. Petrov [1], I. Buldakov [1], A. Chechetkin [1], S. Voloshin [1,2,3]

[1]*Federal State Budget Institution "Russian Scientific and Research Institute of Hematology and Transfusiology of Federal Medical Biological Agency", [2]North-Western State Medical University named after I.I. Mechnikov, [3]Military Medical Academy named after S.M. Kirov, Saint-Petersburg, Russian Federation*

Background: Next-generation sequencing (NGS) technologies have revolutionized approaches in molecular genetic studies making possible to spell out the mutational status, the genetic and epigenetic variability of chronic lymphocytic leukemia (CLL). The driver mutation's identification allows for a deep understanding the pathogenesis of CLL, stratifying patients (pts) into prognostic groups and select the appropriate treatment matching it with the genetic lesions.
Aims: We aimed to develop the Lymphoid Targeted NGS Panel for assessing the mutations of pts with CLL and to study the possible correlation of the mutational status with the clinical characteristics of the disease.
Methods: In study were enrolled 26 pts with CLL: treatment-naïve (n=18) and relapsed/refractory (n=8). All cases were diagnosed according to iwCLL criteria (iwCLL, Hallek et al., 2018). According to cytogenetic assay, pts were divided into 3 prognostic groups: favorable (n=16), neutral (n=2) and unfavorable (n=8). Although, 20/26 pts were divided into 2 prognostic groups taking into account the data on the mutational status of *IGHV*: favorable (n=8) and unfavorable (n=12). Six patients have no available data of *IGHV* mutational status. Treatment regimens: standard rituximab-containing (n=15) and targeted drugs (n=11). The Lymphoid Targeted NGS Panel was designed as a comprehensive gene panel and covered 117 genes, part of which plays a core role in cellular pathways. DNA samples were extracted from peripheral B-cell lymphocytes via the standard phenol-chloroform method. An average reading depth of 1000x is produced on a MiSeq platform (Illumina, USA). The 2% threshold of allele frequency (VAF) was used. The clinical significance of mutations was established using the following databases: COSMIC, ClinVar, gnomAD with application *in silico* analysis (Cscape, Cancer Genome Interpreter, SNPs&Go).
Results: Sequencing of 15 pts samples was performed. Genetic aberrations were detected in all DNA samples. We identified 722 variants in 83/117 genes. Frequent mutations were *FAT1* (13.9%), *KMT2C* (13.6%) and *RYR1* (4.4%). The clinical significance of 82% of variants was identified as likely benign (n=348) and benign (n=244), 16.2% (n=116) of the mutations was uncertain. Regarding associations, pathogenic and likely pathogenic mutations were identified in 80% pts (12/15) with an unfavorable prognosis. The pathogenic mutations 1.7% (n=12): *SF3B1* K700E (n=3), *SF3B1* G742D, *TP53* Lys120Glu, *NOTCH1* P2514fs*4, *BRAF* D594G, *BRAF* K601N, *PTEN* (c.1321-2A>T),*MGA* R1246X, *JAK3* V722L, *IDH2* T352P. Likely pathogenic variants (n=2) were *ATM* Y2080C and *NF1* M2217V. The detected variant of the mutation Lys120Glu in the *TP53* gene was associated with the presence of del17p13, and correlated with the unfavorable clinical course of the disease in patient CLL-024. Three pts with del13q14 had *SF3B1* K700E pathogenic mutation, which accelerated the development of CLL by alternative splicing of RNA and activation mTORC1. It should be noted that 2 pts (CLL-023, CLL-024) with unfavorable prognosis had mutations both in *BCR* and *NOTCH2* genes of uncertain significance. The existing approach to the interpretation of the results does not allow making an unambiguous conclusion about the clinical significance of variants in the *IDH2* and *JAK3* genes, despite its pathogenic effect.
Summary/Conclusion: The obtained data demonstrate the possibility of applying NGS in clinical practice and the approbation of The Lymphoid

Targeted NGS Panel. Whereas the clinical significance of some mutations is currently uncertain, further research using NGS technology is required.

Chronic lymphocytic leukemia and related disorders - Clinical

PB1492 CLINICAL FEATURES OF LARGE GRANULAR LYMPHOCYTIC LEUKEMIA-ASSOCIATED PURE RED CELL APLASIA: RESULTS FROM A SINGLE CENTER IN CHINA

M. Ge [1,*], J. Huang [1], J. Huo [1], Y. Shao [1], Y. Zheng [1]

[1]State Key Laboratory of Experimental Hematology, National Clinical Research Center for Blood Diseases, Institute of Hematology & Blood Diseases Hospital, Chinese Academy of Medical Science & Peking Union Medical College, Tianjin, China

Background: Large granular lymphocyte leukemia (LGLL)-associated pure red cell aplasia (PRCA) is a rare lymphoproliferative disorder. Only a few case series have been reported in the literature. so that the features and optimal treatment of the disease remains unclear.
Aims: We conducted this retrospective study to assess clinical features, immunological profiles and the outcome of treatment in patients with LGLL-associated PRCA.
Methods: A cohort of 20 patients with LGLL-associated PRCA who referred to our hospital from January 2013 to April 2020 was reviewed.
Results: The clinical characteristics of 20 patients included in this study showed that no differences were evident based on sex. The median age of the patients was 50 years old (range, 28-76 years). Splenomegaly was observed in 45% of cases, most of which were characterized by mild to moderate enlargement. By contrast, hepatomegaly was rare (10%). Our study identified increased percentage and absolute number of $CD3^+CD8^+$ T cells, meanwhile decreased $CD3^+CD4^+$ T cells, $CD3^-CD16/CD56^+$ NK, $CD19^+$ B cells and CD4/CD8 ratio (Table 1). For treatment (Table 1), cyclosporine A (CSA) in combination with methylprednisolone (MP) was administered in 6 patients, with an complete and partial remission (CR+PR) of 50.0% (3/6). A novel immunosuppressive strategy of cyclosporine (CSA), low dose methylprednisolone (MP) and danazol(DNZ), which we named CMD regimen, was administrated orally with an initial dose of CSA 3mg/kg/day, MP 0.25–0.5 mg/kg/day, and DNZ 5.0-10.0 mg/kg daily as first-line therapy for 13 patients, of which ten responded positively(76.9%). One patient received antithymocyte globulin (ATG), resulting in no response (NR). Among the three patients who failed to respond and two relapse to first-line therapy of CSA and MP, four patients received the second-line therapy of CMD regimen, with an CR+PR of 60%. Another patient received ATG, and achieved complete remission (CR). Among the three patients who failed to respond and two relapse to first-line therapy of CMD regimen, three patient responded to the second-line therapy of CMD regimen plus methotrexate (MTX). Adverse events were uncommon, one patient had impairment of liver function with transaminase values up to 110 U/L.

Table 1 Immunological profiles and response to treatment of all patients

Immunological profiles (N=20)	Min	Max	Mean	SD	Reference range	Low ,N	Normal ,N	High ,N
$CD3^+T$(%)	85.3	98.5	94.2	3.4	56-86	0	1	19
$CD3^+CD4^+T$(%)	15.3	51.0	30.3	10.7	33-58	12	8	0
$CD3^+CD8^+T$(%)	22.4	80.5	57.2	15.4	13-39	0	1	19
CD4/CD8 ratio	0.2	1.3	0.6	0.4				
$CD3^-CD16/CD56^+$ NK(%)	0	6.4	1.7	1.9	5-26	18	2	0
$CD19^+B$(%)	0.6	9.2	2.6	2.6	5-22	17	3	0

Treatment	First-line therapy, n(%)			Second-line therapy, n(%)	
	N	CR+PR(%)	Relapse	N	CR+PR(%)
CSA+MP	6	2+1 (50.0%)	2 (66.7%)		
ATG	1	0+0 (0%)		1	1+0(100.0%)
CSA+MP+DNZ	13	7+3 (76.9%)	2(20.0%)	5	2+1(60.0%)
CSA+MP+DNZ+MTX	0			5	2+1(60.0%)

CsA cyclosporine A; MP methylprednisolone; ATG antithymocyte globulin; DNZ danazol; MTX methotrexate; CR complete remission; PR partial remission; NR no response;

Summary/Conclusion: This study provides new information regarding the clinical features and therapeutic strategies for LGLL-associated PRCA, which demonstrated that the CMD regimen could be a promising strategy for patients with LGLL-associated PRCA.The multiple-center clinical trial need to initiate to validate this conclusion.

PB1493 A RETROSPECTIVE ANALYSIS OF PATIENTS WITH CHRONIC LYMPHOCYTIC LEUKEMIA (CLL) TREATED WITH VENETOCLAX IN THE REAL-LIFE SETTING IN SPAIN (VENARES)

C. Ferra [1,*], P. Baltasar [2], M. J. Terol [3], S. Osorio [4], J. Loscertales [5], J. A. Garcia Marco [6], M. Ortiz [7], S. Iraheta [8], A. Smucler [9], D. Moreno [10]

[1]Institut Català d'Oncologia-H. Germans Trias i Pujol, Badalona, [2]H. U. La Paz, Madrid, [3]H.U. Clínico de Valencia, Valencia, [4]H. General U. Gregorio Marañón, [5]H. U. La Princesa, [6]H.Puerta deHierro-Majadahonda, Madrid, [7]H. U. Carlos Haya, Malaga, [8]H. Universitario de Canarias, Tenerife, [9]H. del Bierzo, Leon, [10]Abbvie, Madrid, Spain

Background: Pivotal clinical trials have shown Venetoclax (Ven; BCL inhibitor) good efficacy and safety profile. Studies in real life setting are limited as Ven is commercially available in Spain since April 2018.
Aims: To evaluate the effectiveness of Ven in adult CLL pts by the overall response rate (ORR) at 9 months (mo) after the first Ven dose administration, as assessed by the treating physician.
Methods: This is a Spanish non-interventional, retrospective, national, multicenter, post-marketing, observational study. Eligible subjects were adult pts with CLL who initiated Ven at least 9 mo before inclusion. Subjects in Early Access Program from Jan 2017 were included.
Data from approximately 100 pts is planned to be collected from 30 Spanish sites. Data of pts are retrospectively reviewed until the date of last follow-up or death.
Results: 48 pts were included in the interim study: 32 pts (66.7%) were male, the median age was 74.5 years (67.5-78), pts had received a median of 4 prior lines of therapy (range 1-10 lines). 15 pts had unmutated IGHV (88%), 10 pts (33.3%) had del(17p), 10 pts (33.3%) had TP53 mut. In 42 pts, median time from CLL diagnosis to Ven initiation was 78.5 m (38-125). 81.2% of pts received Ven monotherapy, 4.2% combined with rituximab, 2% with obinutuzumab,12.5% with other agents. Objective response was evaluated in 23/39 pts treated with Ven monotherapy.
48 pts (100.0%)had dose modifications, 19 (39.6%), dose interruptions, 19 (39.6%) discontinued Ven. 26 (54.2%) had TLS greater risk before Ven initiation, 22 pts were hospitalized during ramp-up.
14pts (29.2%) presented at least 1 SAE, 10 (20.8%) presented at least 1 SAE related to Ven. 6 pts (12.5%) presented 1 AE related to Ven that led to drug withdrawal. Percentages of Specific AEs were neutropenia (43.7%), febrile neutropenia (12.5%), serious infection (18.8%), TLS in 6.3% (2 laboratory,1 clinical) and Richter transformation (RT) (6.3%). Related to Ven were 4 febrile neutropenia (8.3%) and 1 lab TLS(2.1%).

Table: Outcomes with Venetoclax monotherapy	
Patients, n	39
Overall response rate in evaluable pts (23)	
CR/Cri	8 (34.8%)
PR/nPR	9 (39.1%)
ORR	17 (73.9%)
PFS est 24 mo	75.9% (56.2-87.6)
uMRD ($<10^{-4}$) in assessed pts, (%,n)	22.2% (2/9)

Summary/Conclusion: This preliminary effectiveness data suggest overall outcomes are similar to those in the pivotal clinical trials. Safety assessment show AEs reported were consistent with the safety profile seen in prior VEN studies and did not reveal unexpected AEs.

PB1494 COMPREHENSIVE CARDIAC EVALUATION REVEALS NO INCREASE IN VENTRICULAR ARRHYTHMIAS IN PATIENTS ON CHRONIC IBRUTINIB THERAPY – A STUDY OF KROHEM, THE CROATIAN COOPERATIVE GROUP FOR HEMATOLOGIC DISEASES

M. Kolacevic Zeljkovic [1], N. Bulj [1,2], S. Basic-Kinda [3], V. Milunovic [4], D. Carzavec [5], O. Jaksic [6], M. Vodanovic [3], S. Ostojic-Kolonic [2,4], P. Gacina [5,7], D. Dujmovic [3], I. Zeljkovic [1], V. Pejsa [2,6], I. Aurer [2,3,*]

[1]Department of Cardiology, University Hospital Centre Sisters of Mercy, [2]Medical School, University of Zagreb, [3]Division of Hematology, Department of Internal Medicine, University Hospital Centre Zagreb, [4]Division of Hematology, Department of Internal Medicine, University Hospital Merkur, [5]Division of Hematology, Department of Internal Medicine, University Hospital Centre Sisters of Mercy, [6]Division of Hematology, Department of Internal Medicine, University Hospital Dubrava, [7]School of Dental Medicine, University of Zagreb, Zagreb, Croatia

Background: Ibrutinib is increasingly used for treatment of various B-cell malignancies. It's generally well tolerated, but has cardiovascular side-effect including hypertension and arrhythmias, most frequently atrial fibrillation (AFib). Data on the dynamics of frequency and severity of arrhythmias in patients on chronic ibrutinib treatment are lacking.
Aims: We initiated this prospective study to determine the impact of chronic ibrutinib therapy on incidence of supraventricular (SPB) and ventricular premature beats (VPB).
Methods: This was a multicentre, prospective, observational cohort study. Consecutive patients with hematologic malignancies starting ibrutinib therapy and without structural heart disease and clinically significant arrhythmias were included in the study. Cardiologic work-up included echocardiography and 24h-Holter-ECG. Diagnostic assessment was carried out before and repeated at 3, 6 and 12 months after the introduction of ibrutinib therapy. Primary endpoint was the number of VPBs on 24h-Holter-ECG; secondary endpoints were: number of SPBs on 24h-Holter-ECG, systolic left ventricular function, occurrence of AFib and newly diagnosed or worsened hypertension.
Results: 35 patients recruited from 4 hospitals were included in the study during 2019 and 2020 (Table 1). The most common indication for treatment was chronic lymphocytic leukaemia in 31 (89%) patients. Median age was 66 years (range 58-73), 54% were female. The most prevalent cardiovascular comorbidity was hypertension (45%), followed by smoking (29%). The remaining risk factors, including diabetes mellitus, stroke and coronary artery disease had a prevalence of <10%. Mean left ventricle ejection fraction was 60%, left atrial diameter 40±4 mm and volume 53±7 mL.After a median follow-up of 6 months, there was no significant increase in the number of VPBs (428±320 vs. 170±110, p=.19) or SPBs (245±104 vs. 532±305, p=.09). Hypertension was newly diagnosed or worsened in 8 patients (23%), and 2 patients developed paroxysmal AFib (6%). Ibrutinib was temporarily discontinued or its dose was adjusted in 3 patients due to non-cardiovascular side-effects.

Table 1. Baseline characteristics

	Total (N= 35)
Demographics	
Age (years)	66 (58-73)
Male sex (% (n))	46 (16)
BMI (kg/m^2)	27.3 ± 4.5
History (% (n))	
Hypertension	46 (16)
Diabetes mellitus	20 (7)
Hyperlipidaemia	23 (8)
Smoking	29 (10)
Stroke / TIA	0
Coronary artery disease	6 (2)
Chronic kidney disease	14 (5)
COPD/Asthma	6 (2)
CHA_2DS_2VASc score	2.35 ± 1.5
HAS BLED score	0.3 ± 0.45
Hemato-oncologic disease	
Chronic lymphocytic leukemia	88 (31)
Waldenstrom macroglobulinemia	6 (2)
Mantle-cell lymphoma	6 (2)
Echocardiography	
LVED diameter (mm)	47 ± 3
LA diameter (in PLAX) (mm)	40 ± 4
LA volume (mL)	53 ± 7
LVEF (%)	60 ± 3
TAPSE (mm)	21 ± 2
TAP (mmHg)	20 ± 2
Electrocardiogram	
Heart frequency	78 (72-85)
Sinus rhythm (yes/no)	100 (35)
Atrial premature beats	36 (7-141)
Ventricular premature beats	9 (2-49)

Summary/Conclusion: Prolonged treatment with ibrutinib had no significant impact on number of VPBs or SPBs. Our study suggests that ibrutinib does not significantly increase the propensity to develop dangerous cardiac arrhythmias in patients who do not have clinically important structural heart disease or arrhythmias prior to treatment start and stresses the importance of hypertension control in this group of patients.

PB1495 PROGNOSTIC VALUE OF IGHV MUTATIONAL STATE AT DIAGNOSIS FOR PATIENTS WITH CHRONIC LYMPHOCYTIC LEUKEMIA

A. Suarez-Cabrera [1], D. V. Fiallo-Suárez [1], R. Stuckey [1], Y. Florido Ortega [1], M. L. Uroz-de la Iglesia [1], M. Á. Perera-Álvarez [1], H. Luzardo-Henriquez [1], H. de la Nuez [1], P. Fernandez-Caldas [1], A. Lemes-Castellano [1], S. de la Iglesia [1], T. Molero-Labarta [1], M. T. Gómez-Casares [1], C. Bilbao-Sieyro [1,*]

[1]*Hematology, Hospital Universitario de Gran Canaria Dr. Negrín, Las Palmas de Gran Canaria, Spain*

Background: Chronic lymphocytic leukemia (CLL) is a pathology with a variable clinical evolution; some patients remain indolent for many years while others require treatment, including shortly after diagnosis. Although molecular and genetic markers with prognostic value have been described, the current International Workshop on Chronic Lymphocytic Leukemia (iwCLL) guidelines only recommends their analysis prior to commencing treatment.
Aims: In this retrospective study, we analyzed the prognostic impact of molecular and genetic markers on CLL patients at diagnosis.
Methods: A consecutive series of 217 patients with CLL diagnosed in our hospital between 2008 and 2018 was analyzed. Clinical, molecular (*IGHV* and *TP53*) and cytogenetic data were collected at diagnosis.
Results: Our series confirmed the prognostic value of the CLL-IPI index for OS (p=0.003, Log-Rank test) and time to first treatment (TFT, p<0.001). In accordance with previously published results, Kaplan-Meier survival analyses identified an association between *IGHV* unmutated (p<0.022) (Figure 1**A** and **1B**) and shorter OS and TFT (p≤0.001). The variables age >65 years (p<0.001), β_2-microglobulin >3.5 mg/dL (p<0.001) and advanced Binet/Rai clinical stage (p=0.001) were also associated with shorter OS and TFT, while the presence of mutation/deletion of *TP53* (p=0.001) and deletion of 11q (p<0.001) were associated with shorter TFT. Unmutated *IGHV,* advanced clinical stage and age (albeit marginally) also showed independent prognostic value for OS as determined by multivariate analysis (**Table 1**, p=0.01, 0.033, and 0.072 respectively). For TFT, only unmutated *IGHV* and clinical stage (albeit marginally) had prognostic impact (p=0.001 and 0.081, respectively). Importantly, when only patients in the early stages were selected (RAI 0-2/ BINET A), *IGHV* mutation maintained prognostic value for both OS and TFT in the multivariate analysis (OS: OR 6.16, p=0.01/OR 5.96, p=0.009; TFT: OR 13.58, p=0.001/OR 14.08, p=0.001) and Kaplan-Meier survival analyses (OS: p=0.013, TFT: p<0.001) (Figure 1**C** and **1D**). The loss of prognostic value of β_2-microglobulin levels might be explained by the statistically significant association observed in our series between unmutated *IGHV* and β_2-microglobulin levels > 3.5 mg/dL (p = 0.002, Pearson's χ^2) as well as advanced age (p = 0.024, Pearson's χ^2). Chromosomal alterations, such as deletion/mutation of *TP53* and deletion of 11q, were not included in the multivariate analysis due to their low incidence in our series. A larger series would be required to evaluate their prognostic impact.

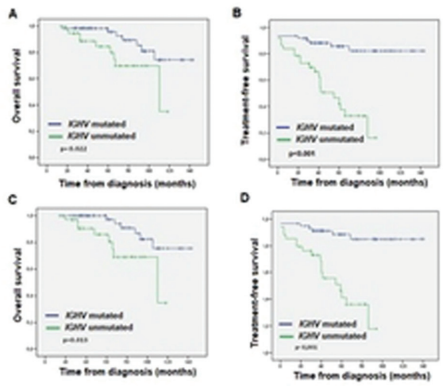

Figure 1. Kaplan-Meier survival curves according to *IGHV* mutational state. **A)** Overall survival (OS) in the whole series, **B)** Time to first treatment (TFT) in the whole series, **C)** OS in RAI stages 0-2, **D)** TFT in RAI stages 0-2.

Summary/Conclusion: *IGHV* mutational state was the only prognostic marker to have independent prognostic value for both OS and TFT, for the whole series as well as patients in the early stages. Our results indicate that the determination of *IGHV* mutational state at diagnosis informs the risk stratification of patients with CLL.

PB1496 FEATURES OF THE DIRECT ANTIGLOBULIN TEST AND THEIR ROLE IN THE DEVELOPMENT OF IMMUNE HEMOLYSIS IN PATIENTS WITH CHRONIC LYMPHOCYTIC LEUKEMIA

E. Poponina [1,*], E. Butina [1], A. Yovdiy [1], O. Maksimov [1]

[1]Federal State Budget Institution of Science "Kirov research Institute of Hematology and Blood Transfusion of the Federal Medical and Biological Agency of Russia", Kirov, Russian Federation

Background: The course of chronic lymphocytic leukemia (CLL) is often complicated by autoimmune disorders, including autoimmune hemolytic anemia (AIHA). The direct antiglobulin test (DAT) is playing an important role in the diagnostic of autoimmune hemolysis. The modern capabilities of the DAT make it possible to detect the presence of autoantibodies and complement on the surface of red blood cells (RBC), as well as to determine the class and subclass of antibodies involved in the pathological process.
Aims: The aim of this study was to explore the frequency and features of positive DAT in patients with CLL and its possibilities to prognose AIHA.
Methods: DAT was carried out using equipment (automatic immunohematological analyzer IH-1000) and reagents from Bio-Rad (USA). DiaMed-ID-LISS/Coombs Anti-IgG + C3d cards were used for screening. Upon receiving a positive DAT, immunoglobulin classes, complement components, IgG subclasses were detected using DC-Screening I and DAT IgG1/IgG3 cards (Bio-Rad (USA)). The presence of hemolytic anemia was determined according the usual clinical and laboratory criteria. The levels of hemoglobin, RBC, reticulocytes, total and indirect bilirubin were investigated by conventional methods. DAT results were analyzed in 104 patients with CLL. The median age of the cohort was 65 years (range 53 to 85 years).
Results: Positive DAT was detected in 15.4% patients with CLL (16 out of 104 examined). The intensity of the reaction was: (+) - in 3 patients (18.8%), (++) - in 6 (37.5%), (+++) - in 5 (31.3%), (++++) - in 2 (12.5%). Positive DAT was due to fixation on RBC IgG 2/4 - in 37.5% of the examined, IgG1 — in 18.8%, IgG1 in combination with the complement component C3d — in 18.8%, IgG1 + IgG3 + IgA + C3d — in 12.5%, only C3d — in 12.5%.
Hemolysis was observed in 9 people (56.3%) among 16 patients with a positive DAT. Patients with positive DAT due to IgG2,4, showed no signs of hemolysis. The detection of C3d both independently and in combination with IgG1, IgG3, IgA, in all cases was associated with signs of hemolysis. IgG1 fixation on RBC was found in 3 patients with CLL, hemolytic anemia developed in 2 of them (66.7%).
Summary/Conclusion: Positive DAT was detected in 15.4% of patients with CLL, hemolytic anemia was found in more than half of them (56.3%). The detection of the complement component C3d on the surface of RBC, as well as the combination of C3d with IgG1, IgG1+IgG3+IgA, in 100% of cases was associated with the AIHA. Fixation of IgG1 alone led to AIHA in 66.7% of cases. The role of IgG 2,4 in the development of hemolysis has not been proven.

PB1497 COMPARATIVE ASSESSMENT OF PROGNOSTIC MODELS FOR ASYMPTOMATIC CHRONIC LYMPHOCYTIC LEUKEMIA PATIENTS IN BINET STAGE A: EVALUATION IN CHINESE HAN COHORT

Y. Sha [1,2], H. Shen [1,2], W. Wu [1,2], Y. Xia [1,2], Y. Miao [1,3], L. Cao [1,2], L. Wang [1,2], L. Fan [1,2], W. Xu [1,2], J. Li [1,2], H. Zhu [1,2,*]

[1]Hematology, The First Affiliated Hospital of Nanjing Medical University, [2]Pukou CLL Center, Pukou division of Jiangsu Province Hospital, Nanjing, China, [3]Hematology, Pukou CLL Center, Pukou division of Jiangsu Province Hospital, Nanjing, China

Background: Clinical course of CLL is heterogeneous and asymptomatic patients with early stage should receive active surveillance until there is evidence for progression. Several molecular, genetic and clinical prognostic markers were demonstrated to be capable of predicting the probability of treatment and various prognostic models have been proposed to predict time to first treatment (TTFT).
Aims: To explored the potency of four proposed models (IPS-E, CLL-IPI, CLL1-PM and Barcelona-Brno prognostic model) to predict TTFT using our Han cohort. All four models were initially based on western population. Considering the significant difference of CLL between Western and Asian population, the models should be validated and discussed thoroughly among all ethnics prior to its broader implementation.
Methods: From the database of Department of Hematology and Pukou CLL Center, The First Affiliated Hospital of Nanjing Medical University, a total of 110 newly diagnosed Binet stage A CLL patients without indication for treatment from Jun, 2009 and to Jan, 2020 were enrolled in our cohort. The diagnosis of CLL and stage of disease was strictly in line with the updated guidelines from iwCLL. All included patients underwent active surveillance as initial management, defined as no treatment need within the first 3 months after diagnosis and patients who didn't meet the indication for treatment were censored at date of statistical analysis. The endpoint was TTFT, which was defined as the time interval between diagnosis and start of treatment due to disease progression. We collected all parameters at diagnosis as mentioned in previous four prognostic models: (1) clinical manifestation (age, Binet and Rai stage and lymph nodes size); (2) absolute lymphocyte count (ALC) and lymphocyte doubling time (LDT); (3) b2-Microglobulin (β2-MG); (4) del [17p], del [11q] analyzed by FISH; (5) IGHV mutation status.
Results: 110 asymptomatic Binet A patients were included in our study; the median age was 58 years old (25-84). The median follow-up time was 35 months (4-189 months), 57 patients (51.8%) met the indication for treatment due to disease symptomatic progression during follow-up. Log-rank test was performed to analyze the independent risk factors associated with TTFT. Seven variables were found to be independently associated with TTFT including Rai stage, ALC > 15×10^9/L, palpable lymph node ≥ 1 cm, β2-MG > 3.5 mg/L, unmutated IGHV, TP53 disruption and 11q deletion (Figure 1). However, age older than 60 years old and LDT<12 months, as proposed in CLL1-PM model, failed to show correlation with shorter TTFT (p=0.383 and p=0.087, respectively) in our cohort. Stratification of patients according to IPS-E, CLL-IPI, CLL1-PM and Barcelona-Brno prognostic model all showed significant difference in terms of TTFT (Figure 2). The predictive power of four prognostic models was further assessed by Harrell's C-index and AIC. C-index was highest in CLL1-PM, followed by CLL-IPI, IPS-E and Barcelona-Brno prognostic model. The AIC values were lowest in CLL1-PM, followed by CLL-IPI, Barcelona-Brno and IPS-E (**Table 1**).

Figure 1. Log-rank Analysis for Time to First Treatment (TTFT).

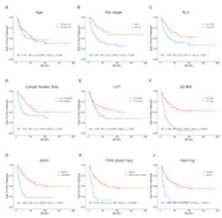

Figure 2. Kaplan-Meier Analysis Comparing TTFT According to (A) IPS-E; (B) CLL1-PM; (C) CLL-IPI; (D) Barcelona-Brno prognostic model.

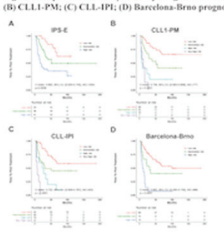

Table 1. Comparison of IPS-E, CLL-IPI, CLL1-PM and Barcelona-Brno prognostic model for prediction of time to first treatment (TTFT).

The cohort of our Binet A CLL patients (n=110)		
	C-index (95% CI)	AIC
IPS-E	0.683 (0.620-0.745)	1004
CLL-IPI	0.722 (0.656-0.787)	933
CLL1-PM	0.736 (0.663-0.808)	777
Barcelona-Brno	0.663 (0.595-0.730)	986

Abbreviations: C-index, Harrell's concordance index. AIC, Akaike information criterion

Summary/Conclusion: All four prognostic models had their efficacy in prediction of TTFT. IPS-E might be an ideal model for patients who undergo basic clinical examination so that fundamental evaluation could be conducted to guide clinical surveillance. For patients yearn for active assessment, FISH and NGS were recommended and CLL-IPI could be used to predict their prognosis more accurately and comprehensively.

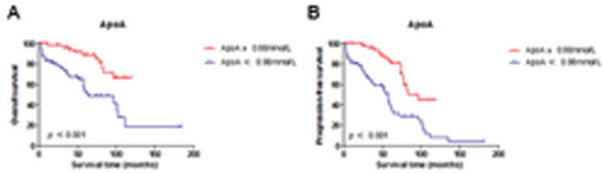
PB1498 FEASIBILITY OF MEASURING ADHERENCE TO ORAL ONCOLYTICS IN ROUTINE CLINICAL PRACTICE: A PILOT STUDY IN OLDER ADULTS WITH LYMPHOID DISORDERS

O. S. Akhtar [1,*], E. R. Gage-Bouchard [1], D. Carozza [1], T. M. Wildes [2], S. Chowdhry [3], S. Sundaram [1], P. Ghione [1], F. J. Hernandez-Ilizaliturri [1], P. Torka [1]

[1]Roswell Park Comprehensive Cancer Center, Buffalo, [2]Unaffiliated, St. Louis, [3]Jacobs School of Medicine, Buffalo, United States

Background: Oral targeted therapies (OTT) have transformed the treatment of chronic lymphocytic leukemia (CLL). Prior studies in cancer patients (pts) have reported variable adherence rates (12-100%) to OTT with suboptimal adherence associated with inferior outcomes. Data from studies in CLL suggest that even brief treatment interruptions can lead to lower survival rates. However, defining optimal adherence and routine measurement of adherence in clinical practice is challenging. Techniques for measuring adherence include self-reporting, pill counts, electronic monitoring systems, prescription database analysis and assessment of serum/urine drug levels. We conducted a pilot study to evaluate

the performance of multiple strategies for measuring adherence in a busy oncology practice caring for older adults (OA) with CLL.
Aims: The aims of this study were three-fold:
1. To compare the utilization of self-report [brief adherence rating scale (BARS)], pill count and Medical Event Monitoring System (MEMS) Cap (an electronic bottle cap) to measure adherence to OTT in OA with CLL.
2. To determine the adherence rate and factors impacting adherence.
3. To correlate adherence rate with disease outcomes.
Methods: Pts ≥70 years (yrs) with CLL and other lymphoid disorders on OTT were followed monthly for the first 3 months (mos), then every 3 mos for 1 year. Nursing home residents were excluded. Pt, disease and treatment characteristics [including a geriatric assessment (GA)] were recorded at baseline. Adherence was measured at every visit with BARS, pill count and MEMS Cap. Data on adverse events and disease outcomes were also collected.
Results: Of the 54 pts screened, 25 were enrolled. Median age was 77 yrs (71-93 yrs), 21 pts had CLL, 3 had mantle cell lymphoma and 1 had marginal zone lymphoma. Geriatric syndromes (GS) detected at baseline included cognitive impairment (28%), depression (24%), polypharmacy (92%) and recent falls (12%); 48% pts had ≥2 GS. Most frequently used OTT were ibrutinib (n=17) and venetoclax (n=5). So far, pts have completed a total of 63 visits (30 virtual, 33 in-person) with median follow up of 3.3 mos. BARS was the most consistently used measure of adherence (63/63 visits, 100%). MEMS cap data was obtained on 13% of total visits. Pill package incompatibility (68%), refusal to use MEMS cap (8%) and clinical trial participation (4%) precluded use of MEMS cap in 80% (*n*=20) of pts. Pill counts could be performed at only 8% of visits due to increasing usage of telehealth (51%), unavailability of pill packaging (32%) or logistic issues (17%). Median adherence using both BARS and MEMS cap was 100% (range, 70%>100% for BARS; 82-100% for MEMS cap). Only 4 pts had less than 100% adherence at any visit. Patient's self-report accurately reflected MEMS cap measured adherence in these instances. Five pts (20%) required dose interruptions, mostly due to adverse events. Six pts discontinued therapy and 2 pts died of unrelated causes. Chronological age and presence GS were not associated with adherence rate or outcomes.
Summary/Conclusion: Objective measurement of adherence to oral therapies remains challenging with poor applicability of electronic pill bottle cap devices due to pill package incompatibility and increasing use of virtual/tele visits. Despite its limitations, self-report remains a feasible tool to measure adherence in routine clinical practice. Abbreviated adherence scales and other electronic monitoring technologies may be able to overcome existing challenges and warrant further study.



PB1499 PROGNOSTIC VALUE OF APOLIPOPROTEIN A IN CHRONIC LYMPHOCYTIC LEUKEMIA

X. Yun [1,*], Y. Zhang [1], X. Sun [1], X. Hu [1], H. Zhang [1], Z. Yin [1], X. Zhang [1], M. Liu [1], X. Wang [1]

[1]*Shandong Provincial Hospital, Jinan, China*

Background: The improvement of risk stratification and novel therapeutic targets of chronic lymphocytic leukemia (CLL) are urgently needed. Lipid metabolism is related to the prognosis of hematologic tumors and a potential target for novel therapies of some hematologic malignancies. Apolipoprotein A (ApoA), the major protein of high-density lipoprotein, takes effect on lipid transportation and immunity. Nevertheless, the role of ApoA in CLL has not been explored.
Aims: This study aimed to investigate the potential role of ApoA in the prognosis of CLL patients.
Methods: A total of 150 newly diagnosed CLL patients from January 2010 to December 2019 were enrolled in this study. Survival analyses were performed by Kaplan-Meier curves and univariate and multivariate Cox proportion hazard regression models. Pearson tests, Spearman tests and Chi-square tests were performed to evaluate the correlation between ApoA and other clinical and laboratory parameters.
Results: Kaplan-Meier curves revealed that increased ApoA was associated with longer overall survival (OS) (χ^2=14.985; p<0.001; shown in Figure 1A) and progression-free survival (PFS) (χ^2=16.190; p<0.001; shown in Figure 1B). Univariate and multivariate Cox regression revealed that ApoA was a significant independent prognostic factor of OS (p=0.028) and PFS (p<0.001). ApoA was related to advanced stages (p<0.001), β2-microglobulin (r=-0.447, p<0.001) and C-reactive protein (r=-0.508, p<0.001).

Figure 1

Summary/Conclusion: Our study indicates the prognostic value of ApoA in CLL patients for the first time. ApoA was a favorable prognostic biomarker of OS and PFS in CLL patients. The novel prognostic biomarker may increase prognostic accuracy of CLL.

PB1500 THE EFFICACY OF FRONT-LINE CHEMOIMMUNOTHERAPY WITH FLUDARABINE, CYCLOPHOSPHAMIDE, AND RITUXIMAB (FCR) IN PATIENTS WITH CHRONIC LYMPHOCYTIC LEUKEMIA IN REAL CLINICAL PRACTICE

E. Kataeva [1,*], E. Klinushkina [1], A. Golenkov [1], J. Tchuxina [1], T. Mitina [1], E. Trifonova [1], J. Chernykh [1], K. Belousov [1], S. Zakharov [1], L. Visotskaya [1], R. Vardanyan [1], Z. Kharasova [1]

[1]*of Haematology, Moscow Regional Research and Clinical Institute, Moscow, Russian Federation*

Background: Treatment of chronic lymphocytic leukemia remains a significant challenge in gematology. Despite the large number of innovative targeted drugs used, the FCR program is used in many randomized trials as a reference for comparison, which indicates its importance not only for scientific tasks, but also for modern clinical practice, as it remains one of the most accessible. To date, the FCR program is included in the modern algorithm of the 1st line treatment of patients with CLL younger than 65 years with intact TP53, regardless of the mutated IGHV genes. This is based on data from randomized trials of the GCLLSG. In the CLL8 study, the standard FCR-program cycle was 28 days. There are not enough studies proving the efficacy of such treatment in patients with high comorbidity.
Aims: The aim of the study was to investigate the clinical efficacy of front-line FCR program treatment in CLL patients within a clinical model integrated into real practice.
Methods: The study included 108 previously untreated patients with CD20-positive chronic lymphocytic leukemia. The stage of the disease was assessed according to the Rai classification, the functional state was determined on the ECOG scale, and the comorbidity was assessed on the SIRS - G scale. The 17p13/TP53 deletion was calculated using the FISH method, and the IGHV-status observed through PCR. The FCR program consisting of 6 standard courses was being conducted over a longer period of time, which extended the induction period and reduced treatment density. Minimal residual disease (MRD) was assessed according to the international standardized protocol (Rawstron, 2007) by 4-color flow cytometry. Some patients were receiving maintenance treatment with Rituximab for 2 years, compared to the group of patients without maintenance therapy. The main control points of the analysis were PFS and OS. The OS was evaluated according to the intent-to-treat principle.
Results: The Me of the comorbidity index was 5(0-12). The Me of creatinine clearance was 60.4 ml / min (43-121). We have introduced the concept of treatment density (the ratio of the duration of the standard cycle to the original one) in real clinical practice. The drug doses were not reduced in our study. The Me of the FCR cycle in our study was 50 days. Accordingly, the Me duration of the induction treatment period increased to 9 months, and the treatment density decreased to 0.6. The clinical efficacy of the treatment was evaluated according to the iWCLL 2008. The overall respons rate was 92.6%, complete remission (CR) was detected in 53.9% patients. 52.8% patients had undetectable MRD (UMRD) in the peripheral blood and 39.3% patients had UMRD in the bone marrow. The Me follow-up was of 51 months (range 8-150). The Me of PFS from the beginning of FCR induction was 42 months. PFS was significantly longer in patients who achieved CR (p=0,0001), with comorbidity in patients below 5 index (p=0,02), and with achievement of UMRD (p=0,002). Reduced treatment density and maintenance therapy with Rituximab did not affect the duration of PFS. OS from the beginning of FCR-induction was 120 months in 60% of patients.
Summary/Conclusion: The study showed that the decrease in the density of the FCR program induction in real clinical practice in patients with CLL was accompanied by high efficacy and did not lead to a significant decrease in the PFS compared to patients who received the standard program.

PB1501 PATIENT PERSPECTIVES OF CHRONIC LYMPHOCYTIC LEUKEMIA & DISEASE RELATED OUTCOMES – A QUALITATIVE STUDY

D. HS [1,*], S. Surve [1]

[1]*Medical Affairs, AstraZeneca Pharma India Ltd, Bangalore, India*

Background: Chronic lymphocytic leukemia (CLL) is a B-cell hematological malignancy of elderly population with varied presentation and multiple therapeutic options available for disease management. There are lack of studies on patient journeys in India which would provide key insights about the disease, impact the current management and quality of life of patients.
Aims: This study aims to leverage the benefits to provide the patient perspective of CLL in India which may help mitigate the current gaps and expectations regarding comprehensive care.
Methods: A focused group discussion was conducted on an online platform using a semi-structured discussion guide, with four CLL patients and two caregivers of CLL patients, of India. The duration of the meeting was 90 minutes. The discussions were focused on understanding the symptoms, diagnosis, treatment, follow up and quality of life of CLL patients. The information obtained was analyzed to identify the common trends and patterns related to the patient's health, emotional state and challenges encountered throughout the clinical course of the disease.
Results: Common symptoms observed by patients that led to primary care physician visits were unexplained weight loss, fever, fatigue, breathlessness and repetitive infections. The first point of contact were primary care physicians where patient were treated and there was a delay of 6-7 months from onset of symptoms to diagnosis of CLL and reaching specialist. Patients were anxious about the disease progression despite of completing treatment and there were psychological, emotional and financial burden associated with the disease which lead to treatment discontinuation and impact in patient morale. There is a need for psychological counselling, guidance and patient advocacy group support, peer to peer interaction, disease awareness initiatives and cost effective treatment options to improve the patient related outcomes in CLL.
Summary/Conclusion: The present study highlights the need for disease education, support to reduce diagnosis time, recurrence of disease and additionally patients support groups and counseling to improve patient's morale and adherence to treatment thus enhancing the quality of life in CLL patients.

PB1502 OUTCOMES IN PATIENTS WITH FOLLICULAR LYMPHOMA AND CHRONIC LYMPHOID LEUKEMIA RECEIVING OBINUTUZUMAB, IN THE SETTING OF COVID19 INFECTION

A. Perolla [1], N. Çollaku [1,*], A. Cili [1], E. Çalliku [1], T. Caja [1], P. Pulluqi [1], A. Ivanaj [1]

[1]*Hematology, UHC " Mother Teresa", Tirana, Albania*

Background: Obinutuzumab is a type II humanized anti-CD20 antibody of the IgG1 subclass that mediates B-cell lysis by direct cell death and by antibody-dependent cell -mediated toxicity. The treatment with GA 101 (single agent or combined) causes a potent overall B-cell depletion that may compromise the antiviral immunity and augment the tendency to severe pulmonary complications.
Aims: We conducted a one year retrospective study of all the patients hospitalized in our Service of Hematology, (Department of internal Medicine, UHC " Mother Teresa") being diagnosed with Follicular Lymphoma and Chronic Lymphoid Leukemia under treatment with Obinutuzumab to evaluate and identify all the COVID-19 positive patients and to evaluate their outcome.
Methods: We reviewed the data of all the patients >18 years old, diagnosed with Follicular Lymphoma and Chronic Lymphoid Leukemia, hospitalized in our Service of Hematology from January 2020 to January 2021 under treatment with Obinutuzumab (single agent or combined). The positivity of COVID-19 infection was demonstrated through positive PCR- based test (nasopharyngeal swab). Chest scan was performed to access the severity of pulmonary involvement from SARS-COV-2.
Results: A total number of 25 (100%) patients on Obinutuzumab treatment were identified. 20 (80%) patients were diagnosed with CLL and 5 (20%) patients were diagnosed with FL. The median age for CLL patients resulted 61,8 years (18-80 yrs) and the median age for FL resulted 50,8 years (18-80 yrs). 14 (70%) of CLL patients were classified as high- risk CLL and 6 (30%) as intermediate-risk CLL. All the FL were classified as high -risk FL. 60% of all the patients were without comorbidities at the moment of the diagnosis (11 CLL and 4 FL patients) and 40% has two or more comorbidities at diagnosis. 6 CLL patients and 4 FL patients were on 1st line Obinutuzumab, 10 CLL patients and 1 FL patient were on 2nd line Obinutuzumab, and 4 CLL patients were on 3rd line Obinutuzumab. All the patient were at the moment of starting the treatment with Obinutuzumab with ECOG 0-1. No therapy related complications were found. 32% (8) of all the patients receiving Obinutuzumab were without comorbidities and ECOG 0-1 at the moment of getting infected with SARS-COV-2 (5 high-risk CLL patients and 3 FL patients) and developed severe COVID-19 pneumonia 5 to 9 days after getting infected with rapid critically severe clinical picture evolution. The median age of the patients infected with COVID-19 resulted 55,6 years (24- 67years), and the male:female ratio resulted 1,6:1. They were all treated in the ICU and unfortunately none of them survived more than 30 days-hospitalization time. The COVID-19 mortality in this cohort was 100%.
Summary/Conclusion: The introduction of new anti-CD20 antibodies as Obinutuzumab in the treatment of CLL and Follicular Lymphoma undoubtedly is a milestone in the treatment history of Lymphoid Neoplasms, being 1,5 to 2,5 times more effective than Rituximab, prolonging the overall survival of the patients and giving a great impact on the decourse of the disease. With our study (a very small cohort study) we demonstrate that getting infected with SARS-COV-2 is not related to the treatment with Obinutuzumab or other chemotherapies, but the patients treated with Obinutuzumab (single agent or combined) develop a very severe COVID-19 clinic. If this is biologically caused or is just a casualty finding is still to be studied. Previous studies have demonstrated almost the same results but further studies are needed to evaluate this findings.

PB1503 ATYPICAL CHRONIC LYMPHOCYTIC LEUKEMIA: A COMPARATIVE MORPHOLOGICAL AND IMMUNOPHENOTYPIC STUDY

I. Davidkova [1], R. Vladimirova [1], M. Jagurinoski [1], B. Spassov [2], G. Balatzenko [3], M. Guenova [1,*]

[1]*Laboratory of Hematopathology and Immunology,* [2]*Haematology Clinic,* [3]*Laboratory of Medical Genetics, National Specialised Hospital for Active Treatment of Hematological Diseases, Sofia, Bulgaria*

Background: Chronic lymphocytic leukemia (CLL) is the most common leukemia in the Western world, which is characterized by monomorphic clonal B-cell lymphocytosis, low expression of B-cell markers, combined with CD5 and CD23. A proportion of cases show less common laboratory features and the adjective atypical has been introduced firstly in regard to the presence of morphological heterogeneity and then – to describe forms with an uncommon phenotype. Some data suggest that the distinction between CLL and aCLL is clinically relevant, however, the concept of atypical CLL is still applied differently.
Aims: To conduct a comparative study of the morphological and immunophenotypic variants of CLL and to compare them by main clinical and laboratory parameters.
Methods: A total of 123 men and 104 women at a mean age of 65.6±11.7 years with clinical and laboratory CLL features were included in the study. Morphological assessment of the lymphocyte population and flow cytometric immunophenotyping were performed in all samples.
Results: According to WHO criteria, 35 of the patients (15.4%) were defined as "atypical CLL" with >15% atypical cells on microscopic examination, while deviations from the typical CLL immunophenotype occurred in 9.7% with high expression of CD20 (6%), CD79b (2%), CD22 (4%), and/or negative expression of CD23 (7%), defined as immunophenotypic atypical cases. The analysis revealed that the presence of atypical morphological features did not correlate significantly with immunophenotypic parameters, except the fact that 33.3% of CD23(-) CLL had atypical morphology vs 14.15% of CD23(+) (p=0.04) and 37.5% of CD38(+) cases revealed different morphological

characteristics compared to 26.6% of CD38(-) (p=0.023). On the other hand, phenotypically atypical CLL had a significantly higher incidence of CD38 (28% vs 5% in CLL with a typical immunophenotype) (p=0.002), CD49d (80% vs 23%) (p=0.001), and sIgM (33% vs 4%) (p=0.02) and lower expression of CD43 (40% vs 93% in CLL with a typical immunophenotype) (p<0.001), while CD27, CD62L, CD81 and CD200 had a similar incidence.Only 3.08% of the patients demonstrated both atypical morphology and immunophenotype, however, no significant associations with the main biological and laboratory parameters were found, except for the significantly lower relative number of Gumprecht shadows (4.5±1.8% vs 22.7-31%). There were no differences in time to treatment (TTT) and overall survival (OS) depending on morphological and/or immunophenotypic atypia.
Summary/Conclusion: In conclusion,microscopic and flow cytometric studies of leukemic cells in CLL define the disease as heterogeneous, however, the combined morphological and immunophenotypic atypia is a rare event. Further studies integrating molecular and genomic approaches are needed to shed light on the underlying causes and the potential clinical significance of atypical variants.

PB1504 PROSID STUDY: EVALUATING EFFICACY AND SAFETY OF INTRAVENOUS IMMUNOGLOBULIN (IVIG) 10% IN PRIMARY INFECTION PROPHYLAXIS IN PATIENTS WITH CHRONIC LYMPHOCYTIC LEUKEMIA – STUDY DESIGN

O. Cornely [1,*], A. Mato [2], T. Robak [3], D. Wei [4], S. Mellinghoff [1], T. Lavrova [5]

[1]CECAD Cluster of Excellence & Dep of Internal Medicine, University Hospital of Cologne, Cologne, Germany, [2]Memorial Sloan Kettering Cancer Center, New York, United States, [3]Department of Hematology, Medical University of Lodz, Copernicus Memorial Hospital, Lodz, Poland, [4]Mayo Foundation for Medical Education and Research, Rochester, United States, [5]Octapharma Pharm.Prod.ges.m.b.H, Vienna, Austria

Background: Secondary immunodeficiency (SID) occurs as a consequence of hematological malignancies (HM), most commonly in chronic lymphocytic leukemia (CLL) and multiple myeloma. About 25% of patients present with SID at diagnosis of CLL and this incidence may increase to 85% during the course of disease. Recent advances in CLL therapy also lead to cumulative immunosuppression. Infections are the main cause of morbidity and mortality in CLL patients, causing between 30% and 50% of deaths within the first year after diagnosis. Intravenous immunoglobulin (IVIg) is established as secondary prophylaxis to reduce infection rates in patients with HM with hypogammaglobulinemia. No large randomized study has established efficacy of IVIg as primary prophylaxis in CLL patients with hypogammaglobulinemia yet, although several small studies suggest an up-to 4-fold reduction of infection rates.
Aims: The primary objective is to demonstrate the benefit of IVIg 10% compared to placebo as primary infection prophylaxis in patients with CLL and SID who undergo antineoplastic therapy.
Methods: This study is planned as a prospective, double-blind, randomized, placebo controlled, multicenter, interventional phase 3 study and will be conducted in approximately 50 centers in North America and Europe (EUDRA-CT #: 2019-004375-40). A minimum of 240 adults with a diagnosis of CLL will be enrolled and allocated 1:1 to either IVIg 10% (0.4 g/kg) plus standard of care (SoC) prophylaxis or placebo plus SoC prophylaxis. Patients will receive up to 13 infusions of IVIg in 4-weekly intervals. Total duration will be up to 55 weeks consisting of up to 3 weeks for screening, 48 weeks of treatment and 4 weeks of follow-up. Main inclusion criteria are CLL diagnosis according to International Workshop on CLL (iwCLL) criteria, undergoing CLL antineoplastic treatment, and hypogammaglobulinemia with IgG levels <500 mg/dL (5 g/L). Main exclusion criteria are IgG treatment within the last 3 months, antibiotic prophylaxis and/or treatment within 7 days prior to current CLL treatment start, as well as current major infection or ˃1 major infection in the previous 6 months before baseline. The primary efficacy outcome will be the occurrence of at least one major infection defined as (□) bacterial or viral infection resulting in death, (□) microbiologically or clinically documented bacterial or viral infection requiring treatment with anti-infectives, or (□) fever of unknown origin requiring hospitalization or hospitalization prolongation. Secondary outcomes include overall infection rate, frequency of SoC prophylaxis with anti-infectives, duration of anti-infective prophylaxis. Exploratory outcomes include quality of life measured by EQ-5D, IVIg PK profiles, and resource utilization. The primary efficacy evaluation is based on the comparison of major infections in CLL patients with or without primary infection prophylaxis with IVIg. The difference between these proportions will be statistically tested in the intent-to-treat (ITT) population. The Z approximation will be used for statistical comparison of the proportions observed. One-sided 97.5% confidence interval will be provided.
Results: Interim analysis will be conducted once at least 100 patients are available for evaluation of the primary endpoint in the ITT population).
Summary/Conclusion: This study will evaluate the efficacy and safety of IVIg 10% as primary prophylaxis of infections inCLL patients with SID in a large clinical setting for the first time.

PB1505 PRETREATMENT NEUTROPENIA IN CLL PATIENTS IS ASSOCIATED WITH HIGH INFECTION RISK AND PREDICTS TREATMENT INITIATION WITHIN ONE YEAR.

O. Gutwein [1,2,*], O. Bairey [1,3], G. Itchaki [1,3], Y. Herishanu [1,4], M. Koren-Michowitz [1,2]

[1]Sackler Faculty of Medicine, Tel Aviv University, Tel Aviv, [2]Department of Hematology, Shamir medical center, Zerifin, [3]Institute of Hematology, Rabin Medical Center, Petah-Tiqva, [4]Department of Hematology, Tel Aviv Sourasky Medical Center, Tel Aviv, Israel

Background: CLL (Chronic Lymphocytic Leukemia) activity is frequently manifested as anemia and/or thrombocytopenia, either as a result of bone marrow infiltration or autoimmunity, but CLL-related neutropenia is not common and it's effect on disease course is rarely reported. However, the development of neutropenia, especially when considering the underlying immune dysfunction of CLL patients, might contribute to infection risk and influence treatment decisions.
Aims: To study clinical characteristics, complications and treatment outcomes of CLL patients manifesting pre-treatment CLL-related neutropenia.
Methods: Cases were retrospectively collected from members of the Israeli CLL Study Group. Patients with a diagnosis of CLL/SLL (Small lymphocytic lymphoma) and neutropenia of < 1000/μL before initiating CLL directed therapy were included. Patients who developed neutropenia while receiving CLL directed therapy or following treatment were excluded.
Results: We identified 12 treatment-naïve CLL/SLL patients with neutropenia<1000/μL (CLL n=11, SLL n=1) (Table 1). Three patients presented with neutropenia concurrently with CLL/SLL diagnosis and nine developed neutropenia during CLL follow up, with median time of 2.2 years (0.5-11.7) post CLL diagnosis. Median neutrophils count at the time of first neutropenia was 600/μL (0-900). At the time of first neutropenia, six patients had isolated neutropenia without anemia or thrombocytopenia. Bone marrow biopsy was done in 11 patients, nine patients had diffuse infiltration pattern and two non- diffuse infiltration pattern. Nine patients had splenomegaly. Direct Coombs test was positive in six patients but no patient had clinically significant AIHA (Autoimmune hemolytic anemia) or ITP (Immune thrombocytopenia). Anti-neutrophils antibody test was done in one patient and was found negative. Low IgG level (<700 mg/dL) was present in four patients, low IgA (<70 mg/dL) in two and low IgM (<40 mg/dL) in five. Six treatment naive neutropenic patients developed Grade 3 or 4 infection (50% of the study cohort). The most common infection site was the skin and soft tissues (n=3), other infection sites include the oral cavity, gastrointestinal tract, urinary tract and lungs. Among the six patients with neutropenia and significant infection, four had low IgG levels. Supportive care with GCSF was administered in eight patients. Four patients received a course of steroids, concurrently with GCSF in three. CLL directed therapy was initiated in nine patients with median time from first neutropenia to CLL directed therapy of 104 days (Range, 6-490), eight patients received CLL-directed therapy within a year (Table 2). Treatment was chemoimmunotherapy in five patients, ibrutinib in two and venetoclax-obinutuzumab in two. Data on treatment toxicity is available for seven patients, among those- two patients developed neutropenic fever following cycle one of treatment and none had neutropenic fever during cycles 2-6 of treatment. Three patients on chemoimmunotherapy needed dose reduction due to treatment toxicity. No dose reduction was reported in patients on novel agents.

Table 1

Patient Characteristics	N=12
Gender: Male/Female	7/5
Age (years) at CLL diagnosis, median (range)	63 (42–88)
Neutropenia at CLL diagnosis	3
Neutropenia developed during CLL follow up	9
Time (years) from CLL diagnosis to first neutropenia, median (range)	2.2 (0.5-11.7)
IGHV gene unmutated , n/n tested	4/6
Unfavorable FISH (11q- or 17p-), n/n tested	2/9
BINET stage A/B/C at time of first neutropenia	1/4/6
Splenomegaly	9
Bone marrow involvement, n/n tested	
Diffuse pattern	9/11
Non Diffuse pattern	2/11
Neutrophils/µL at time of first neutropenia, median (range)	600 (0-900)
Lymphocytes/µL at time of first neutropenia, median (range)	21300 (500-261000)
Hemoglobin g/dL at time of first neutropenia, median (range)	11.4 (8.4-13.3)
Platelet/µL at time of first neutropenia, median (range)	106500 (82000-279000)
Elevated LDH	2
IgG mg/dL, at time of first neutropenia, median (range)	1150 (267-2700)

Summary/Conclusion: Neutropenia in treatment naïve CLL patients is accompanied by diffuse bone marrow involvement in most patients, although anemia and/or thrombocytopenia might be absent. Neutropenia can predispose patients to significant infections. Some patients will be managed solely with GSCF and/or steroids, but most patients will need CLL-directed therapy within a year.

PB1506 SUBCUTANEOUS IMMUNOGLOBULINS USE IN IMMUNODEFICIENCY SECONDARY TO CHRONIC LYMPHOCYTIC LEUKAEMIA: MONOCENTRIC EXPERIENCE IN COVID-19 ERA

I. Innocenti [1,*], F. Autore [1], A. Tomasso [2], G. Benintende [2], A. Fresa [2], F. Vuono [1], E. Galli [1], F. Sorà [3], L. Laurenti [3]

[1]Sezione di Ematologia, Dipartimento di Diagnostica per Immagini, Radioterapia Oncologica ed Ematologia, Fondazione Policlinico Universitario A. Gemelli IRCCS, [2]Sezione di Ematologia, Dipartimento di Diagnostica per Immagini, Radioterapia Oncologica ed Ematologia, Università Cattolica del Sacro Cuore, [3]Sezione di Ematologia, Dipartimento di Diagnostica per Immagini, Radioterapia Oncologica ed Ematologia, Fondazione Policlinico Universitario A. Gemelli IRCCS, Università Cattolica del Sacro Cuore, ROMA, Italy

Background: Secondary antibody deficiency (SAD) is a typical manifestation of haematological malignancies such as chronic lymphocytic leukaemia (CLL), or a side effect of their treatment. Immunological defects are observed in 25-85% of CLL patients (pts) and increases the risk of infections, with overall higher morbidity and mortality. Antibiotics administration and vaccinations are recommended as risk-reduction strategies in those pts. No real guidelines are available to recommend eligibility for prophylaxis, but many indications warrant immunoglobulins replacement therapy (IgRT) in selected pts with low IgG (<5g/l) or with more than 3 infective episodes per year despite antibiotic treatment and timely vaccination. No clear indications are available regarding the delivery method (intravenous or subcutaneous), dosage, frequency of administration and duration of IgRT.
Aims: The aim of this study is to assess the efficacy and safety of subcutaneous IgRT (SCIg) and its impact on quality of life (QoL) on CLL pts in Covid-19 era.
Methods: Ten CLL pts, have been treated with SCIg from October 2019 to December 2020. Median age and body weight were 66 years (56-88) and 68 Kg (52-86). Comorbidities were present in 5 pts (hypertension, diabetes mellitus, lung diseases). 5 pts had unmutated IgVH and 1 had 17p deletion. The median number of prior therapies was 2 (IBR, BR, Chl-antiCD20, FCR, in 5, 4, 4, 3 pts respectively). At that time, 7 pts were on therapy (IBR, Ven, Alkylating Agent in 4, 1, 2 pts respectively). None presented neutropenia. All pts underwent antibiotic prophylaxis with trimetroprin-cotimoxazole, sometimes associated with clarithromycin, and influenza vaccinations. Median baseline IgG level was 485 mg/dl (118-817), with a media of 3 infection/year (1-5; pneumonia, UTI). All pts received 10 g total dose hyaluronidase-free SCIg over a 1h double-needle subcutaneous infusion every 15 days over one year, independently from their body weight. After the first dose, administered in a hospital setting to make the patient comfortable with their personal pump, the next doses were self-administered at home. The IgG level and CD4/CD8, CD19 and CD16/56 (natural killer, NK) lymphocytes subset were recorded both at baseline and during the observation period to monitor the immunological reconstitution as the therapy went on.
Results: No patient experienced infectious events during the SCIg therapy nor Covid-19 mediated interstitial pneumonia. All patients tolerated the therapy: nobody interrupted the treatment and only one patient presented a skin rash (grade 2). Both dosage and administration schedule have been stable over time. Dealing with humoral immunity, IgG levels arose from a median of 485 mg/dl (118-817) to a stable median value >600 mg/dl from 6 months onward. About cellular immunity, T-cells including CD4 and CD8 and NK cells displayed a stable fashion until 6 months. On the other hand, the CD19 B cells values reflect both the disease status and the ongoing treatment effects. Results were in Table 1. Finally we observed advantages on both QoL and costs, since pts did not need to go to the hospital with the help of a care-giver, rather they could comfortably get their SCIg at home without any assistance.

Table 1. Results

Parameter Normal range	Baseline Median value	1° month Median value	3° months Median value	6° months Median value	9° months Median value	12° months Median value
Gamma % (10-18)	7 (2-11)	7 (4-11)	7 (6-12)	8 (7-12)	9 (8-12)	9 (7-11)
IgG mg/dl (700-1600)	485 (118-817)	491 (259-808)	471 (436-818)	615 (436-865)	621 (578-839)	602 (538-915)
IgA mg/dl (70-400)	32 (2-85)	26 (2-55)	29 (5-84)	32 (2-82)	39 (2-73)	60 (5-71)
IgM mg/dl (40-230)	17 (9-28)	16 (9-28)	15 (6-48)	18 (7-80)	25 (11-78)	10 (9-46)
CD4 x10^9/L (630-1400)	429 (292-1056)	458 (262-962)	448 (434-463)	430 (373-487)	nd	nd
CD8 x10^9/L (350-810)	854 (227-1539)	888 (218-1220)	889 (600-1179)	966 (523-1410)	nd	nd
CD19 x10^9/L (100-410)	202 (2-52488)	55 (4-2847)	43 (3-3060)	11 (8-8926)	nd	nd
CD16/56 x10^9/L (140-420)	180 (61-541)	303 (59-383)	107 (67-353)	107 (104-330)	nd	nd

Summary/Conclusion: SCIg administration in CLL pts is safe and efficacious as infectious prophylaxis, with higher median IgG levels, thanks to its pharmacokinetic advantages and improved adherence to treatment. Especially in the Covid-19 era, the subcutaneous route is preferred to the intravenous one, because of the self-administration at home and the granted availability to the drug itself.

PB1507 EVALUATION OF ADVERSE EFFECTS OF IBRUTINIB: EXPERIENCE FROM A NORTHERN HOSPITAL OF SPAIN

L. Escalada González [1,*], P. López de Ugarriza [1], M. Á. Fernández Rodríguez [1], Á. Ramírez Páyer [1]

[1]Haematology and hemotherapy service, Hospital Universitario Central de Asturias, Oviedo, Spain

Background: Ibrutinib has emerged as an effective therapeutic alternative with proven clinical benefit in several lymphoid neoplasms such as Chronic Lymphatic Leukemia (CLL), Mantle Cell Lymphoma (MCL), and Waldenström's Macroglobulinemia (WM). However, it can produce adverse effects that may limit its use.
Aims: To evaluate the clinical impact and adverse effects/toxicity of Ibrutinib in patients diagnosed with CLL, MCL and WM, who were treated with this drug between 2015 and 2020 at our hospital.
Methods: An observational study in which 41 patients diagnosed with CLL, MCL and WM and treated with Ibrutinib, were included.
Results: 41 people were enrolled: 36 CLL (88%), 4 MCL (10%) and 1 WM (2%). 63% were men and 49% were patients aged >74 years. From the total number of patients, 8 (20%) have died (5 LLC, 2 LCM and 1 WM).
Comorbidities at diagnosis were: 18 patients (44%) had arterial hypertension, 7 (17%) had diabetes mellitus, and 5 (12%) had dyslipidemia. 6 patients had cardiovascular alterations: 3 (7%) Atrial Fibrillation (AF), 2 (5%) dilated cardiomyopathy and 1 (2%) heart failure; 8 patients (19%) had respiratory disorders and 5 (12%) previous tumors (3 malignant and 2 benign).
In the subgroup of patients with CLL, 25% were Rai-Binet advanced stage and 42% had high-risk cytogenetic alterations (del17p / TP53 / del11q). 36% received Ibrutinib as the first line and 64% had relapsed CLL. The median duration of treatment in these patients was 19.5 months (range from 3 to 36 months). 5 CLL have received post-Ibrutinib treatment because of the progression of the disease.
Patients with MCL were all stage IV: 75% received Ibrutinib in the second line and 25% received it in the third line (25%). The patient with WM received Ibrutinib in the second line.
ADVERSE EFFECTS

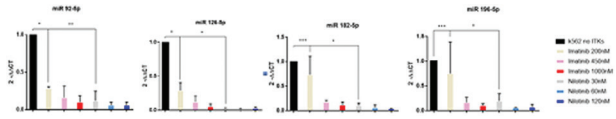
17 patients (41%) had infectious complications (mostly relapsing CLL): 10 respiratory (3 of them were severe because of *H. influenzae*, *K. pneumoniae* and Varicella-Zoster Virus (VZV). 3 encephalitis (1 tuberculous, 1 viral because of VZV and 1 case in which the implicated microorganism was not identified), 2 urinary (E. coli), 1 digestive (Campylobacter jejuni) and 1 cutaneous (cellulitis due to S. pyogenes). In 4 CLL (24%), these infections led to the temporary suspension of the drug for an average of 13.5 days (range: 10-16 days) and in 2 CLL (12%), the infections caused the definitive suspension by the appearance of CNS involvement. 3 patients have suffered grade IV bleeding complications: 2 CLL required temporary suspension and 1 WM required definitive suspension because of subdural hematomas.
1 CLL and 1 WM developed AF, 1 CLL grade II hyponatremia and 1 CLL and 1 MCL, grade IV hyponatremia (definitive suspension). 1 LLC required a temporary suspension of Ibrutinib due to grade IV pancytopenia and edema. There was 1 CLL that developed a secondary lung neoplasm.
In conclusion, in 7 patients (17%) it was necessary to discontinue the drug (2 of them required a dose adjustment when restarting the drug) and in 5 patients (12%), Ibrutinib was permanently suspended.
8 patients died (all of them were older than 75 years and had comorbidities). 5 died due to adverse effects: 3 infectious complications (2 CLL and 1 MCL), 1 WM with grade IV hemorrhage, and 1 CLL due to secondary carcinoma.
Summary/Conclusion: In our experience, infectious complications were the most frequent and caused discontinuations and temporary suspensions of Ibrutinib in most cases. However, there was little impact of bleeding complications, hematological adverse effects and new cases of AF. Generally, Ibrutinib is a well-tolerated and effective drug.

PB1508 CD38 EXPRESSION AND CD19/CD5 CO-EXPRESSION IN CLL PATIENTS WITH DIFFERENT RESPONSES TO IMMUNOCHEMOTHERAPY

T. Perekhrestenko [1,*], S. Vydyborets [1], U. Melnyk [2]

[1]Department of Hematology and Transfusiology, Shupik National Healthcare University of Ukraine, [2]Blood Disease, Kyiv Municipal Hospital N9, Kyiv, Ukraine

Background: To date, great success has been achieved in the study of B-CLL oncogenetics, according to which the nature of the clinical course of the disease, the effectiveness of using various methods of therapy and predicting pathology is determined, in particular, by the features of pathogenesis, affecting certain structural components of the genome of malignant cells. Despite this, the principles of the genetic determination of B-CLL in the dynamics of the development of pathology are still largely unclear, which complicates the use of expression indicators of CD-marker molecules as diagnostic and prognostic criteria for the disease.
Aims: to monitor the expression of CD38 and the co-expression of CD19 and CD5 on lymphocytes of CLL patients with the determination of the relationship between their quantitative changes and the clinical course.
Methods: We included 11 CLL patients in the study. The median age was 57.3 years (range 44-68). The expression of CD38 markers and the co-expression of CD19 and CD5 were studied in peripheral blood before initiating therapy and during the treatment. None of the patients had a del17p13, del11q23, del13q14. Patients up to 65 years of age received FCR regimen, after 65 RB or ChlR regimes were administered. Antigen expression monitoring was carried out after the 2nd, 3th, 4th courses of therapy. Expression of CD38, co-expression of CD19/CD5 was determined by flow cytometry in the direct immunofluorescence test using monoclonal antibodies.
Results: It was noted that in 7 patients with a positive clinical and hematological effect after the second and subsequent courses of therapy, the expression of the CD38 antigen was either not observed or did not exceed 16%. Five of these patients received FCR regimen, two patients were administered RB. In 5 patients over 65 years of age and who did not receive the FCR regimen, pronounced tumor mass or hyperleukocytosis remained after the second and third courses of therapy. Three of them showed hyperexpression of CD38 + cells, amounting to (69.3 ± 7.1)%. As for the co-expression of CD19 and CD5, it did not differ in 7 patients who responded to therapy and in 5 refractory patients and was (79.5 ± 6.7)% and (80.6 ± 9.4)% after 2 courses, respectively. Similar results were observed in the dynamics of the study. Two patients, who received the RB regimen and were infected with COVID-19, unfortunately died from complications of this viral infection. They did not have any previous cardiovascular pathology or diabetes mellitus. Both patients had overexpression of the CD38 antigen, which was 69% and 74%. Perhaps, besides the negative effect of rituximab and bendamustine on the course of COVID-19, an additional negative role is played by overexpression of the CD38 molecule, which, being a marker of activation, also provides adhesion of lymphocytes to the vascular endothelium, enhances their adhesive-aggregation properties.
Summary/Conclusion: Overexpression of the CD 38 antigen is associated with resistance to immunochemotherapy, and also, possibly, has a negative effect on the course of COVID-19 in CLL patients, which requires further research. Coexpression of CD19/CD5 antigens in our study did not change in patients with different responses to immunochemotherapy.



Chronic myeloid leukemia - Biology & Translational Research

PB1509 TYROSINE KINASE INHIBITORS DOWNREGULATE MIRNA EXPRESSION IN K562 CELL LINE

J. M. Freue [1,*], M. S. Ruiz [1], M. B. Sanchez [1], M. Bianchini [1]

[1]Centro de Investigaciones Oncologigas Alexander Fleming, Buenos Aires, Argentina

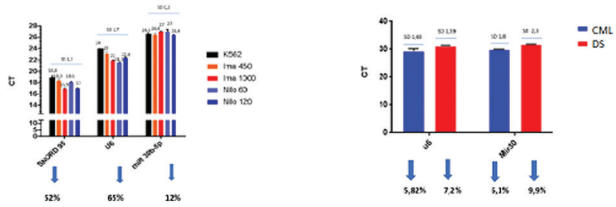
Background:: Chronic myeloid leukemia is a clonal disease of the bone marrow characterized by a genetic marker: the t (9; 22) translocation. This genetic event produces an oncoprotein (BCR-ABL1) with constitutive tyrosine kinase activity which, through the phosphorylation of adapter proteins, leads to an increase in proliferation and decrease in apoptosis of hematopoietic precursors.
Although this genetic translocation was believed to be the only responsible for the pathology, nowadays, other additional molecular events are being investigated. Such events could be an alteration in the expression of microRNAs since t (9; 22) generates genomic instability and consequently additional genetic alterations to BCR-ABL1. It is well known that miRNAs are dysregulated in many types of cancer and they are being studied as potential biomarkers. Moreover, dysregulation in miRNAs expression could be independent from the activity of the BCR-ABL1.
Aims: To evaluate the dependence of miRNAs expression from BCR-ABL1 activity in vitro
Methods: mirVana miRNA Isolation Kit (Ambion®) was used for RNA extraction from K562 CML cell line which was previously incubated with either imatinib 1000nM, 450nM and 200nM or nilotinib 120nM, 60nM and 30nM according to calculated IC50 using MTT assay. To confirm inhibition of the BCR-ABL1 pathway a western blot for phospho-CRKL was performed. For qPCR a protocol that is designed to specifically amplify and quantify miRNAs using stem-loop primers was used. The following miRNAs were evaluated: hsa-miR-196a-5p, hsa-miR-92b-3p, hsa-miR-126-5p, hsa-miR-125a-5p, hsa-miR-2355-5p, hsa-miR-10a-5p, hsa-miR-132-3p, hsa-let-7a-5p and hsa-miR-182-5p. This panel was based on previous experiments from our group which assessed miRNAs expression in CML patients (leukemic stem cells vs hematopoietic stem cells) by next generation sequencing. Statistical analysis was done with GraphPad v6.0. T-Student test was used to calculate statistical significance between samples.
Results: Imatinib at a concentration of 200nM did not inhibit p-CRKL by western blot. The expression of all miRNAs aforementioned but for miR2355 was downregulated after incubation for 48hs with both TKIs. This effect was more powerful with nilotinib than imatinib. When incubated with imatinib hsa-miR-126-5p, hsa-miR-182-5p hsa-miR-92b-5p and hsa-miR-196a-5p showed a dose dependent inhibition (Figure 1).
*p< 0,01 ** p< 0,05 ***p> 0,05

Summary/Conclusion: In K562 cell line, a down regulation of miRNA expression was observed when exposed to both drugs, with a dose-dependent effect confirmed for some miRNAs incubated with imatinib. More studies should be done to evaluate if this effect is also observed in vivo. Eventually, miRNAs could be used as a biomarker of response to TKIs in CML patients.
The fact that imatinib 200nM did not inhibited BCR-ABL1 but miR92 and miR 126 where still dowregulated could be explained by off target effect of TKIs.

PB1510 PATTERN OF MINIMAL RESIDUAL DISEASE IN TUNISIAN CHRONIC MYELOID LEUKEMIA PATIENTS

R. Frikha [1,*], M. Elloumi [2], H. Kamoun [1]

[1]Department of Medical Genetics, [2]Department of Hematology, Faculty of Medicine and University Hospital of Sfax, Sfax, Tunisia



Background: The efficacy of Tyrosine Kinase inhibitors (TKI) treatment can be accurately evaluated by a molecular monitoring based on the quantification of *BCR-ABL1*.
Aims: This study was carried out to assess the minimal residual disease in Tunisian patients with chronic myeloid leukemia (CML) treated with TKI therapy in routine clinical practice in Tunisia to identify potentially eligible for treatment discontinuation, based on a molecular response (MR) on the international scale (IS).
Methods: A five-year retrospective study was carried out in the Hospital University of Sfax, south of Tunisia including all CML patients in the chronic phase at diagnosis, treated with TKI for a minimum duration of 6 months. Quantitative assessment of the BCR-ABL transcript was performed using the Cepheid Xpert BCR-ABL ultra assay. Molecular response and outcome were evaluated; according to the European Leukemia Net guidelines.
Results: A total of 162 CML patients were carried out. The median age was 50 years, the sex ratio M/F was 1.62. The rate of cumulative EMR; MMR and DMR was 80.8%; 73.8% and 55.9% respectively. According to the ELN criteria, 141 CML patients were evaluable. Optimal, sub-optimal response, and failure were noted in 81 (57.4%), 33(23.4%) and 27(19.1%) patients, respectively. Overall survival (OS) and progression-free survival (PFS) was 96.3% and 85%. Risk factors for event (death/progression) were lack of EMR, MMR and DMR (P<0.05). Among 149 patients with sustained DMR; 14 (8.6%) CML patients have discontinued TKI therapy.
Summary/Conclusion: Despite the limit of our study (duration and size), the available real-life molecular responses with TKI therapy should be considered to identify potentially CML patients eligible for discontinuation of TKI therapy.

PB1511 MI-30-B AS A HOUSEKEEPING GENE POR MIRNA QPCR QUANTIFICATION IN CHRONIC MYELOID LEUKEMIA

J. M. Freue [1,*], M. S. Ruiz [1], M. B. Sanchez [1], M. Bianchini [1]

[1]Centro de Investigaciones Oncologigas Alexander Fleming, Buenos Aires, Argentina

Background: Quantitative polymerase chain reaction (qPCR) is a rapid and sensitive approach to identify miRNA expression. However, because of the shorter PCR products, very few reference genes have been identified for the quantitative analysis of miRNA. Different internal reference genes are needed to normalize the expression of miRNAs and mRNA genes respectively. Therefore, it is particularly important to select the suitable common reference genes for normalization of qPCR of miRNA. In CML there is not a standard control gene, both U6 and SNORD95 have been evaluated with discordant results. So, its mandatory to evaluate another housekeeping gene to use in these pathology.
Aims: To evaluate Mir-30-b as housekeeping gene in miRNA qPCR in CML cell line and patient´s samples
Methods: mirVana miRNA Isolation Kit (Ambion®) was used for RNA extraction from peripheral blood mononuclear cells (PBMCs) from 5 patients at diagnosis and 4 healthy donors' samples (DS) and K562 CML cell line previously incubated with either imatinib 1000nM and 450nM or nilotinib 120nM or 60nM according to calculated IC50 using MTT assay. For qPCR a protocol that is designed to specifically amplify and quantify miRNAs using stem-loop primers was used. SNORD95, U6 and Mir-30-b were compared.
Results: in human samples U6 and miR30-b had acceptable values to be used as control gene: standard derivation (SD) was 1,38 and 1,48 for U6 and 1,8 and 2,3 for mIR-30 in CML samples and DS respectively; while coefficient of variation (CV) was 5,8% for U6 and 6,1% for Mir-30 CML samples and 7,2% and 9,9% for DS respectively. Two-way anova comparison between CML and DS was not statistically significant neither was it comparing each ARN group individually. (p> 0,05)
In K562 cell line SD was 1,2 for SNORD95; 1,7 for U6; and 0,2 for Mir-30. CV was 52% for SNORD 95, 65% for U6, and 12% for mir-30. Tukey's multiple comparisons test of each group of RNA with different treatment showed statistical significance difference (p<0,001)

Summary/Conclusion: In conclusion, miR-30 is a suitable control gene when evaluating miRNAs expresión in K562 cell line and for human samples. To confirm this findings, a bigger cohort should be evaluated. U6 was a good control gene in human samples but not in CML cell line.

PB1512 STUDY OF TELOMERE LENGTH IN PATIENTS WITH CHRONIC MYELOLEUKOSIS

A. Lyamkina [1,*], P. Orlov [2], V. Maximov [2], E. Voropaeva [2], T. Pospelova [1]

[1]Therapy, hematology and transfusiology, Novosibirsk State Medical University, [2]Research Institute of Therapy and Preventive Medicine, Federal Research Center Institute of Cytology and Genetics, Siberian Branch of the Russian Academy of Sciences, Novosibirsk, Russian Federation

Background: The emergence of inhibitors of atypical tyrosine kinase changed the prognosis of the course of the disease in patients with CML. This type of therapy is comparable to allogeneic hematopoietic stem cell transplantation in terms of efficiency, and radically surpasses it in terms of safety. The success of imatinib therapy may be partly due to the increase in average telomere length. Recent studies have shown a permanent decrease in telomere length in CML patients in sustained complete cytogenetic remission, virtually regardless of what therapy was used to induce remission. This finding may indicate a pre-existing shortage of telomere length in CML patients (and a potential predisposition to CML) prior to the development of BCR / ABL positive hematopoiesis.
Aims: to reseche the dependence of the length telomeric fragments of chromosome on the presence of chronic myeloid leukemia in the person.
Methods: We have studied of the length telomeric fragments of chromosome in a group of 27 patients with chronic myeloid leukemia. The group was consisted of 15 women (55.6%), average age 53.93 years and 12 men (44.4%), average age 50.54 years. The group of women was more homogeneous: 5 patients achieved a major molecular response (MMR), 3 - only a cytogenetic response (CR), MMR have not obtained, and 4 patients were newly diagnosed in the chronic phase of the disease. In the group of men, MMR was achieved in 1 patient, only CR - in 2, chronic phase, no CR was obtained in 3, primary patients in the chronic phase - 3 and progressive phase of the disease, terminal stage (blast crisis) - in 3 patients. The study of telomere length have stadied out on DNA material isolated from blood cells using quantitative PCR (qPCR) in real time based on the method of R.T. Cawthon et al. (2002) with modifications.
Results: The average level of blood telomere length (TL) was 1.185 ± 1.037 (min. 0.188 / max. 5.681, median 0.960) in the group of CML patients, and 1.388 ± 0.417 (min. 0.440 / max. 2.780, median 1.340) in the group of subjects without hemoblastosis., that is, the length of blood telomeres was shorter in patients with CML. According to the one-sample Kolmogorov-Smirnov test, the distribution did not correspond to the normal one; therefore, nonparametric tests were used for comparison. We have compared telomere lengths separately in the groups of women and men with CML and men and women from the comparison group. The length of leukocyte telomeres was significantly less in the group of women with CML, compared to the control (p <0.001; asymptotic significance (2-sided) in the Mann-Whitney test). There were no significant differences in men. In women with CML, TL 0.984 ± 0.552 (median 0.917), in the control group TL 1.442 ± 0.426) (median 1.376). In men with CML TL was 1.419 ± 1.405 (median 1.047), in the control group TL 1.317 ± 0.397 (median 1.287). The presence of an aggressive clone of lecosis cells in men with progressive stages of CML can explain the absence of significant differences and even the excess of TL (1.419 ± 1.405) compared with the control group (1.317 ± 0.397). At the same time, the median TL in men with CML is less than in the control group (1.047 and 1.287, respectively).
Summary/Conclusion: Investigation of telomere length is an important diagnostic technique in determining the predisposition to the development of CML and determining the prognosis of the deasese

Chronic myeloid leukemia – Clinical

PB1513 PULMONARY HYPERTENSION IN NEWLY DIAGNOSED AND TYROSINE KINASE INHIBITOR-TREATED PATIENTS WITH CHRONIC MYELOGENOUS LEUKEMIA: A SINGLE-CENTER RETROSPECTIVE ANALYSIS

I.-C. Song [1,*], M.-W. Lee [1], H. Ryu [1], H.-J. Lee [1], H.-J. Yun [1], B. J. Sun [1], J.-O. Jeong [1], D.-Y. Jo [1]

[1]*Department of Internal Medicine, College of Medicine, Chungnam National University, Daejeon, Korea, Republic Of*

Background: Dasatinib, a tyrosine kinase inhibitor (TKI), is known to induce pulmonary hypertension (PH) in patients with chronic myelogenous leukemia (CML). Although PH is usually reversed on discontinuation of dasatinib, this is based mainly on case reports and small case series. It remains unclear whether other TKIs, such as imatinib or nilotinib, are also linked to PH. In addition, there have been few reports on PH in newly diagnosed CML patients.
Aims: In this study, we analyzed the prevalence of PH and its clinical implications in both newly diagnosed and TKI-treated CML patients.
Methods: The medical records of newly diagnosed CML patients who underwent transthoracic echocardiographic examination (TTE) at diagnosis, and of TKI-treated patients who underwent TTE at least once during treatment at Chungnam National University Hospital from January 2003 to June 2020, were analyzed retrospectively. The TTE results were reviewed by two cardiologists and a diagnosis of PH was made when the PH probability was "high" according to the European Society of Cardiology/European Respiratory Society (ESC/ERS) guidelines.
Results: Of 189 CML patients diagnosed and/or treated during the study period, 57 (30.2%) and 112 (59.3%) underwent TTE at the time of CML diagnosis and during TKI treatment, respectively, and were therefore enrolled in the study. The majority of patients underwent TTE more recently; 40 (70.2%) of the 57 newly diagnosed patients and 92 (82.1%) of the 112 TKI-treated patients underwent TTE between January 2017 and June 2020, respectively. The majority of patients underwent TTE to screen for PH; only 7 (12.3%) of the 57 newly diagnosed patients and 11 (9.8%) of the 112 TKI-treated patients underwent TTE due to cardiopulmonary symptoms. Among the 57 newly diagnosed patients, 4 (7.0%) had PH. PH resolved in three (75.0%) of those four patients after TKI treatment (imatinib in two patients and nilotinib in one patient). PH continued for 8 years in a male patient (aged 61 years at CML diagnosis) despite changes in the TKI (from imatinib to nilotinib, and then to dasatinib); he had no specific PH-related symptoms. In TKI-treated patients, the median TKI treatment time was 40.4 months (range: 0.1–167.2 months). PH was found in 12 (10.7%) of the 112 TKI-treated patients, most frequently in the dasatinib-treated patients [i.e., in 3 (7.5%) of 40 in the imatinib-treated group, 1 (3.1%) of 32 in the nilotinib-treated group, and 8 (21.6%) of 37 in the dasatinib-treated group]. In multivariate logistic regression analyses, age > 60 years (OR, 12.3; 95% CI, 1.1–142.1, p = 0.044), dasatinib treatment (OR, 8.2; 95% CI, 1.3–50.6, p = 0.026), and positive cardiopulmonary symptoms/signs at the time of undergoing TTE (OR, 36.1; 95% CI, 5.3–247.3, p = 0.001) were statistically significant risk factors for developing PH. PH resolved in five (62.5%) of the eight dasatinib-treated patients after discontinuation of the agent. However, PH persisted in three patients, i.e., in one since CML diagnosis and in two despite discontinuing dasatinib; one of those patients had exertional dyspnea. All three imatinib-treated patients recovered from PH: one after the TKI was changed and two despite continuing imatinib. One nilotinib-treated patient also recovered from PH after the TKI was changed.
Summary/Conclusion: PH is common in CML patients treated with dasatinib; however, it is also observed in patients treated with imatinib or nilotinib, and even in newly diagnosed patients. Careful screening for PH both at the time of diagnosis and during any TKI treatment is warranted in patients with CML.

PB1514 KARYOTYPING CML PATIENTS IN TANZANIA USING DRY SPOT CARDS: A FEASIBLE AND NECESSARY DIAGNOSTIC PERFORMANCE FOR BETTER TREATMENT OUTCOME

O. Henke [1,*], E. Mkwizu [1], T. Haferlach [2], M. Meggendorfer [3]

[1]*Cancer Care Centre, Kilimanjaro Christian Medical Centre, Moshi, Tanzania, United Republic of,* [2]*MLL Münchner Leukämie Labor, München,* [3]*MLL Münchner Leukämie Labor, Munich, Germany*

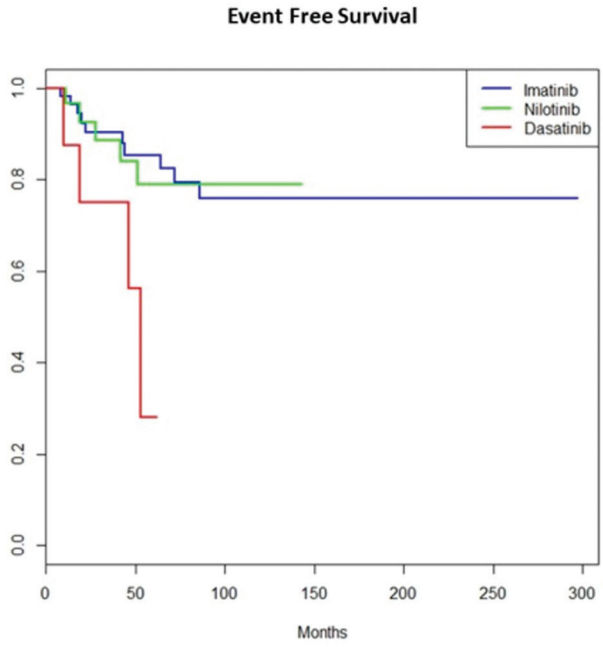
Background: CML is the result of the chromosome translocation t(9;22), which leads to the fusion gene between ABL1 proto-oncogen and BCR gene [1]. The resulting product is an active tyrosine kinase leading to uncontrolled proliferation of different cell lineages and eventually to leukaemia.The crude annual incidence of CML in Europe ranges between 0.7–1.0/100,000 with a median age at diagnosis of 57-60 years [2]. WHO suggests no association with race or ethnicity [3]. Due to lack of reliable data for Low-and-middle-income countries (LMIC), numbers remain an estimation, but taking existing data for extrapolation, the global annual incidence would be above 100,000 [3]. Few studies on treatment outcome in LMIC suggest a lower response rate to TKI [4,5], despite following international treatment guidelines. Assessment of additional chromosomal aberrations (ACA) is no criterion according to the ELN staging recommendation, but one criterion for accelerated phase in the WHO recommendations. However, it is not routinely assessed in LMIC due to unavailability of karyotyping diagnostics, challenges in timely transportation of samples and costs.
Aims: To assess the possibility of obtaining high quality results in karyotyping of CML patients by using dry spot cards for sample collection and storage in a resource poor setting.
Methods: 9 peripheral blood samples of newly diagnosed CML patients have been collected and stored between 1 and 5 months before analysed by array-CGH (aCGH). Storage and transportation of the samples were performed on dry spot cards. ELN and WHO criteria for CML phases were applied to all patients. aCGH analyses were carried out for all cases (4x180K microarray slides, Agilent Technologies, Santa Clara, CA). Images were analyzed using the DEVA Software v1.2.1 (Roche Nimblegen) and Nexus Copy Number 6.1 (Biodiscovery, Inc., El Segundo, CA). ACA were evaluated in each sample using BioDiscovery's Fast Adaptive States Segmentation Technique (FASST2) algorithm. Targeted NGS sequencing was performed with the TruSeq DNA library Prep (Illumina, San Diego, USA) followed by a hybridization capture workflow (IDT, Coralville, USA) for enrichment of a myeloid 34 gene panel including a CNV spike-in panel.
Results: 8 patients were in CP, 1 in AP (ELN criteria) and all 9 patients in AP (WHO criteria). All specimen for karyotyping were evaluable and 7/9 showed ACA, mainly small deletions which are cytogenetically cryptic and thus only detectable using aCGH. 2 cases showed larger chromosomal aberrations, one patient showed a trisomy 8, while another one showed a deletion 7q and gain of 8q, resulting for both in an unfavourable prognosis. Interestingly, no gene mutation was identified within the 34 analysed genes. The NGS CNV panel confirmed all larger chromosomal changes.
Summary/Conclusion: Applying ELN criteria for CML phases without karyotyping might lead to underdosing and eventually treatment failure. Our small cohort shows that 7 out of 8 patients diagnosed in CML-CP by ELN criteria, have ACA and need higher dosages of Imatinib or 2nd line TKI (CML-AP by WHO criteria). The results provide a likely explanation for the general poorer outcome of standard dose treatment in LMIC. Using dry spot cards for storage and transportation of blood samples is a simple to apply technique for clinicians and delivers DNA for standard molecular genetic diagnostics like information about chromosomal copy number changes as well as mutation analyses. These information allow further risk stratification of these patients. This approach can overcome current challenges of sample shipment and storage in LMIC.

PB1515 E13A2, E14A2 TRANSCRIPTS: DO THEY HAVE A DIFFERENT IMPACT ON OUTCOME IN PATIENTS WITH CHRONIC MYELOID LEUKEMIA?

M. Garofalaki [1,*], E. Tziotziou [1], E. Nikolou [1], I. Tsonis [2], M. Dellatola [2], Z. Mellios [2], M. Psyllaki [3], E. Grispou [1], S. Delimpassi [2], I. Baltadakis [2], S. Gigantes [2], D. Karakasis [2], N. Harhalakis [4], T. Karmiris [2], M. Pagoni [2]

[1]*Molecular Biology Lab, Haematology-Lymphomas Dpt and BMT Unit,* [2]*Haematology-Lymphomas Dpt and BMT Unit, Evaggelismos Hospital, Athens,* [3]*Haematology Dpt, University Hospital of Heraklion, Heraklion,* [4]*Haematology Dpt, Metropolitan Hospital, Athens, Greece*

Background: Most patients with Chronic Myeloid Leukemia (CML) express the *BCR-ABL* fusion gene that generates a 210 kDa/p210 tyrosine kinase protein that promotes leukemic metamorphosis. P210 is encoded by both transcripts that are created when the breakpoint in the *BCR* gene occurs in a region called M-bcr, leading to the formation of the transcripts e13a2/ "b2a2" and e14a2/ "b3a2". The difference of both e13a2 and e14a2 transcripts is the absence and presence of exon 14 of the *BCR* gene respectively. The different effect of e13a2 and



e14a2 transcripts on leukemic phenotype and disease outcome has been debated for many years.
Aims: The purpose of this retrospective study is to investigate the impact of different transcripts on the achievement of EMR, MMR and MR4.0 in patients who received Tyrosine Kinase Inhibitor (TKI) as first line treatment from 2005 to 2020 in Greece.
Methods: This study involved 261 patients with chronic phase CML treated with TKI and assessed for response to treatment according to ELN guidelines. Transcript type was identified by RT-PCR at diagnosis. RT-qPCR standardized by the EAC (Europe Against Cancer) protocol was assessed to determine *BCR-ABL* levels using *ABL* as the reference gene. All results are expressed according to International scale / IS.
Results: 168 patients with *BCR-ABL* known transcripts, either e13a2 or e14a2, were included in the analyses. Sixty-four (38.1%) carried the transcript e13a2, while 12 expressed also e1a2 transcript. A hundred and four patients (61.9%) carried e14a2 transcript, only two (1.2%) co-expressed e13a2, while 23 (22.1%) expressed also e1a2 transcript. Hematological parameters were comparable between patients with different transcripts. Regarding the achievement of EMR there are no data for 14 out of 64 (21.8%) and 22 out of 104 (24.15%) patients with e13a2 and e14a2 transcripts respectively. Out of the 50 with e13a2, 23 (46%) did not achieve EMR compared to 21 out of 82 (25.61%) of patients with e14a2 transcript. Data at the timepoint of MMR and MR4 achievement are available for 141 and 148 out of 168 patients respectively. Six out of 48 (12.5%) patients with e13a2 and 4 out of 93 (4.3%) patients with e14a2, and also 15 out of 52 (28.8%) with e13a2 and 13 out of 96 (13.5%) with e14a2 did not achieve MMR (p=0.0895) and MR4.0 (p=0.0288) respectively. Patients with e13a2 and e14a2 achieved MMR at an average time of 782.35 days (median 469) and 1021.9 days (median 275), respectively. MR4.0 was achieved in 1535.8 days on average (median 882.5) and 1505.63 days (median 609) for e13a2 and e14a2 respectively.
Summary/Conclusion: Our data suggest that a larger percentage of patients with e14a2 transcript achieve EMR compared to patients with e13a2 (74.4% *vs* 54%). More patients with e14a2 transcripts (95.7% *vs* 87.5%) achieve MMR in shorter time than patients with e13a2. Failure to achieve MR4.0 was observed in patients with e13a2 more commonly versus those with e14a2 transcript. The transcript could serve as a prognostic indicator and/or as a treatment selection criterion. At present the bibliographic data are contradictory and need further study. We plan to study their importance in a larger number of patients in combination with other features of the disease and the selected TKI.

PB1516 CHRONIC MYELOID LEUKEMIA – THE CHALLENGE OF FRONTLINE TKI SELECTION 20 YEARS AFTER IMATINIB

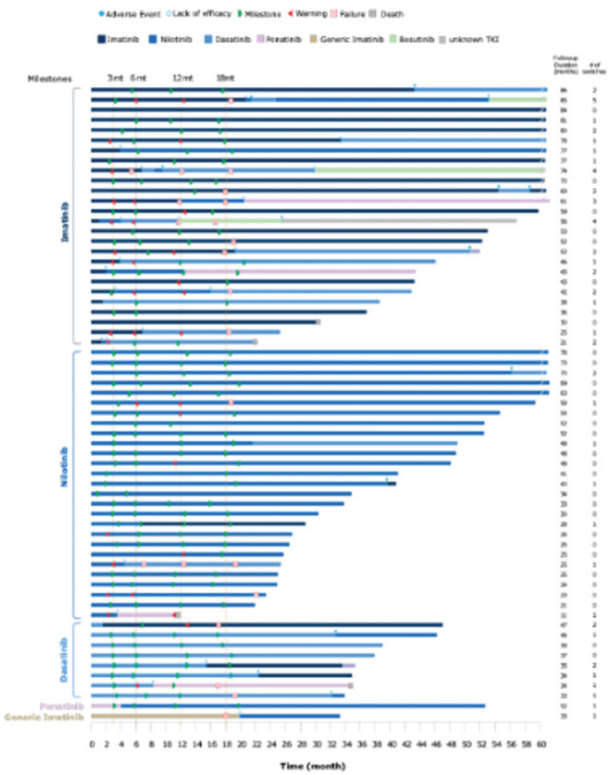
Background: The introduction of Imatinib in the treatment of Chronic Myeloid Leukemia (CML) changed radically the outcome of patients, transforming a fatal disease to a disease compatible with normal lifespan. Currently, 4 tyrosine kinase inhibitors (TKIs) have been approved for the treatment of newly diagnosed CML patients in chronic phase (CP). Treatment goal is the deepest molecular response. However, the optimal time for this achievement that results in the best long-term outcome and the best chance for treatment free remission remains under discussion. Patients that do not achieve early molecular response (EMR) define a group with unfavorable prognosis. The optimal choice of TKI in terms of both effectiveness and safety remains a challenge.
Aims: In this retrospective real-world study, our goal is to investigate the role of EMR in the long-term outcome in regard to the TKI that was administered as first line treatment.
Methods: 261 patients with CML-CP that were diagnosed between 2005-2020 were included. Patients were treated with either 1st or 2nd generation TKI according to treating physician's choice and availability at the time of diagnosis. Regular evaluation of molecular response with RQ-PCR was done according to ELN guidelines. EMR (≤10% IS at 3 months) and the cumulative incidence (CI) of achievement of MMR and MR4.0 in regard to selected TKI were estimated. Event free survival (EFS) was defined as the time from treatment onset to death, disease progression, treatment failure or treatment change.
Results: Data for EMR were available for 148 patients and were included in the analysis. First line TKI was imatinib (IM) in 94, nilotinib (NIL) in 44 and dasatinib (DAS) in 10 cases. Prior to completion of three consecutive months of treatment 6 patients changed TKI due to intolerance/toxicities (IM, n=4 due to pyrexia, myalgias, edema, toxic epidermal necrolysis – NIL, n=1 due to heart failure – DAS, n=1 due to pulmonary hypertension). EMR was evaluated to the remaining 142 patients. Overall, EMR achieved 76.6%, 80.9% and 100% of patients on IM, NIL and DAS respectively (p=NS). Of 113 patients that achieved EMR 107 were on the same TKI 12 months after diagnosis. All TKI changes prior to 12 months were made due to grade ≥3 toxicities (IM, n=5 due to rash, edema, myalgias and NIL, n=1 due to gout and rash). At this timepoint, the CI of MMR was 67.7%, 70.6% and 90% for IM, NIL and DAS, respectively (p=0.06). On the same TKI remained at least for 18 consecutive months 103 patients. Three patients were switched due to toxicities (rash on IM, myocardial infarction on NIL, pleural effusion on DAS) and one patient due to not optimal treatment response on NIL according to ELN2020 (*BCR/ABL* 0.52% IS). The CI of MR4.0 at this timepoint was 45.4%, 50.9% and 73.3% on IM, NIL and DAS, respectively (p=0.16). After a median follow-up of 70.6 months the median has not been reached. At 60 months the EFS was 85.3%, 78.9% and 28.1% for IM, NIL and DAS, respectively (p=0.02). Of note, 69.9% of patients in our initial cohort achieved EMR and remained on treatment with IM for ≥18 months.



Summary/Conclusion: Long-term EFS depends on both the effectiveness and the safety profile of the TKI. In terms of effectiveness, EMR can provide guidance at an early timepoint. Although more potent TKIs are available, IM still appears to be satisfactory as frontline treatment choice taking into consideration the long term safety profile.

PB1517 A MULTICENTER REAL-WORD EVIDENCE STUDY IN THE SWISS TREATMENT LANDSCAPE OF CHRONIC MYELOID LEUKEMIA

S. Balabanov [1,*], N. Cantoni [2], R. Sommavilla [3], P. Seitz [3], E. Kulenkampff [3], J.-F. Lambert [4], A. Schmidt [5], R. Zenhaeusern [6]

[1]Department of Medical Oncology and Hematology, University Hospital of Zürich, Zürich, [2]Kantonsspital Aarau, Aarau, [3]Novartis Pharma Schweiz, Rotkreuz, [4]Hôpital de Nyon, Nyon, [5]Stadtspital Waid and Triemli, Zürich, [6]Spitalzentrum Oberwallis, Brig, Switzerland

Background: The availability of real-world data of patients with chronic myeloid leukemia (CML) collected outside the context of clinical trials is limited.
Aims: To describe the use and choice of tyrosine kinase inhibitors (TKIs), the achievement of response per European LeukemiaNet (ELN) criteria as well as adherence to ELN recommendations in this unselected patient population in Switzerland.
Methods: This non-interventional, multicenter, retrospective chart review analyzed data from patients with newly diagnosed CML treated at six Swiss hospitals. Written informed consent was obtained from all individual participants before data collection. Included patients had received front-line TKI and were solely treated with TKIs between 2010–2015, with a minimum follow-up of 18 months. Treatment efficacy was evaluated according to ELN 2013 milestone achievements at predefined time points (3, 6, 12 and 18 months, last follow-up).
Results: Data from 63 patients treated with TKIs were collected (first-line imatinib [n = 27], nilotinib [n = 27], dasatinib [n = 8], or ponatinib [n = 1]); 56% of patients were men, and the median age at diagnosis was 55 years. A high frequency of TKI therapy switches (49 times) and treatment changes (dose adjustment, dose interruption or re-initiation; 165 times) due to intolerance or insufficient response were recorded. First-line treatment with nilotinib or dasatinib compared with imatinib consistently resulted in a higher proportion of patients achieving an ELN-defined optimal response at every timepoint, irrespective of subsequent TKI therapy. A major molecular response (BCR-ABL^{IS} ≤ 0.1%) was not reached at last visit for 18% of patients irrespective of TKI and for 24% of patients treated with imatinib as first-line therapy. A higher percentage of patients in the nilotinib and dasatinib groups versus the imatinib group reached a deep molecular response (BCR-ABL1^{IS} ≤ 0.01%) at 12 months (32% and 25%, respectively, vs. 23%) and 18 months (42% and 38%, respectively, vs 27%). Patients who received nilotinib or dasatinib as front-line TKI switched therapies less frequently compared with patients treated with first-line imatinib, irrespective of subsequent TKI therapy.

Summary/Conclusion: This study confirms that in a real-world patient population ELN guidelines are generally implemented in Switzerland. While TKI use involves all approved inhibitors, with a large proportion of patients achieving ELN milestones, an unexpectedly high number of TKI therapy switches suggests a clear difference in TKI use between registration trials and clinical practice.

PB1518 IMPACT OF LOW-DOSES TKIS IN THE RESPONSE OF CHRONIC PHASE CML PATIENTS: A 20-YEAR RETROSPECTIVE ANALYSIS.

L. Martínez Tobar [1,*], B. De La Cruz Benito [1], D. Zagrean [1], R. de Paz Arias [1], A. Ramírez López [1], P. Lázaro del Campo [1], I. García Bosque [1], R. Yarza Barrio [2], M. A. Canales Albendea [1], V. M. Jiménez Yuste [1]

[1]Hematology Department, La Paz University Hospital, [2]Oncology Department, 12 de Octubre University Hospital, Madrid, Spain

Background: Long-term survival in chronic myeloid leukemia (CML) has been achieved with the advent of the BCR-ABL tyrosine kinase inhibitors (TKIs), which represent the standard treatment of this disease nowadays. However, almost 20 % of LMC patients present TKIs intolerance, and finding the right dose while maintaining an optimal response, without therapy-related adverse events, is challenging.
Aims: The aim of our study was to retrospectively analyze the impact of low dose TKIs on the deep molecular response (MR) in the group of patients who required a dose reduction due to adverse effects or in order to prevent long-term toxicities, in comparison with those who maintained standard dose.
Methods: We analyzed 82 patients diagnosed with chronic phase of CML from January 2000 to December 2020, who started treatment with TKIs.
Results: Among the population of study, 47 (58,02%) were male and 35 (42,6%) female, with a median age of 50 years (range 13-87ys), at the moment of diagnosis.
Standard dose of Imatinib (400mg/day) was the first line TKI in 63 (76,8%) patients, Nilotinib (600mg/day) in 4 (4,87%) and Dasatinib (100mg/day) in 3 (3.65%). We had 5 patients with Imatinib (800/day), 1 with Bosutinib (500mg/day) and 1 with Bosutinib (400/day), all included in a clinical trial. Low-dose TKIs was started in 6 patients due to age (median age of 78.3, range 50-87); and comorbidities. 4 patients (4,94%) took Imatinib 300mg/day and 2 (2,47%), Imatinib 200mg/day. The main comorbidities for low initial dose were ischemic heart disease, atrial fibrillation, renal failure and vasculopathy. We lost follow up of 4 patients, finally analyzing the response to treatment only in 72 patients, standard dose versus patients who required adjustment the following years.
During this period, 33 (40,2%) patients, with a median age of 66.44 years, required TKIs dose reduction: 17 (51.6%) due to toxicity, and 16 of them (48.4%) in order to prevent long term toxicities once they achieved a MR ≥ 4.
Although 41 patients (50%) presented toxicities, only 17 required dose adjustment. We found mild-to-moderate events: diarrhea in 5 patients, arthromyalgia in 4, hematological toxicity in 3, cutaneous in 5, mainly skin rash, acute pulmonary edema in 1 patient and edema in another one. Ten patients from the initial population required to change first-line TKI treatment due to toxicities: 8 patients received a different TKI as a second-line treatment, whereas 2 of them changed to cytoreductive therapy.
In **table 1**, we describe the proportion of patients who lost response (MR<4): 21.21% in the group of low dose and 20.51% in the group of standard dose. When comparing TKIs dose reduction group with the group which maintained standard dose, we found no statistically differences in terms of loss of response (MR<4), using the Fisher's exact test (p 0.94).

	No. patients (N= 72)	Maintenance of response (MR≥4)	Loss of response (MR<4)	p value*
TKI standard doses	39	31 (79,49%)	8 (20,51%)	0.94
TKI dose reduction	33	26 (78,79%)	7 (21,21%)	

Table 1. Loss of response as an outcome among patients with maintenance of standard doses of TKI versus reduced dose. ***p value for Pearson's chi squared test***

Summary/Conclusion: Even if only 33 patients required a dose reduction, 26 (78.79%) maintained the depth of the molecular response (MR≥4). We can conclude that, if required, due to adverse events or in order to reduce long-term toxicities, the reduction of TKI has a clear clinical benefit and an impact on life quality, without the lost of a deep molecular response.

PB1520 RETROSPECTIVE REAL-WORLD COMPARISON OF CLINICAL AND ECONOMIC BURDEN BETWEEN FIRST-GENERATION AND SECOND-GENERATION TYROSINE KINASE INHIBITORS (TKIS) IN CHRONIC MYELOID LEUKEMIA (CML)

T. A. Russell-Smith [1,*], S. Verma [2], Y. Liu [2], S. Sikirica [1], N. Janjan [2]

[1]Pfizer Inc, New York, [2]STATinMED Research, Plano, United States

Background: TKIs are the standard of care for the treatment of chronic phase CML under National Comprehensive Cancer Network (NCCN) guidelines. Imatinib is recommended as a first-generation TKI (1GTKI), and bosutinib, dasatinib, nilotinib, and ponatinib are recommended as second-generation TKIs (2GTKIs). TKIs are associated with high healthcare resource utilization (HRU) and costs, although literature is limited comparing 1GTKI and 2GTKIs in a U.S. population.
Aims: To assess clinical and economic burden of first-generation and second-generation TKIs in CML patients
Methods: Using the Veteran's Health Administration (VHA) database between April 1, 2013 and March 31, 2018, the study included patients aged ≥18 years with ≥1 medical claim for CML and ≥1 prescription claim for a TKI on or after the initial CML diagnosis date during the identification period (October 1, 2014 to September 30, 2017); the first TKI prescription claim was defined as the index date. Inverse probability of treatment weighting (IPTW) minimized potential confounding; included variables were age, race, Quan-Charlson Comorbidity Index (CCI) score, and CHA2DS2-VASc Score. Medication possession ratio (MPR) assessed adherence to index TKI; optimal adherence was defined as MPR ≥80%.
Results: 944 patients were included: 78.9% on 1GTKI and 21.1% on 2GTKI. Mean age was 62.21 years (SD:18.8); 77.2% were white. At baseline, patients on 1GTKI had a higher comorbidity burden than 2GTKIs: COPD (19.7% vs. 8%; p<0.01), anemia (17.7% vs. 11.1%; p=0.02), GI symptoms (28.5% vs. 18.6%; p<0.01), cardiac dysrhythmias (15.6% vs. 7.5%; p<0.01), coronary artery disease (26.3% vs. 13.6%; p<0.01), hypertension (55.7% vs. 43.2%; p<0.01) and CHA2DS2-VASc Score (2.2 vs 1.6; p<0.01). Optimal adherence was higher with 1GTKI (69.6% vs. 62.2%; p=0.04), although this was not statistically significant when mean MPR was compared. During follow-up, no difference between 1GTKI and 2GTKIs patients occurred with cardiac-related risk factors or CHA2DS2-VASc Score. Compared to 1GTKI, 2GTKIs had lower medical (inpatient and outpatient) costs ($3,162 vs. $3,906; p=0.04) but higher all-cause pharmacy cost ($7,214 vs. $3,895; p<0.01) due to imatinib becoming a generic drug during the study period. CML-related ($2,260 vs. $1,640, p<0.01) and cardiac-related medical costs ($1,365 vs. $665, p<0.01) were significantly higher in 1GTKI vs. 2GTKIs patients.
Summary/Conclusion: Adherence to TKI therapy was suboptimal for both 1GTKI and 2GTKIs. 2GTKIs incurred lower medical cost in comparison to 1GTKI. Differences in total all-cause cost was primarily driven by pharmacy cost of TKIs. These results show that, beyond the cost of the TKI, using a 2GTKIs in the first-line can lead to cost offsets when compared to imatinib.

PB1521 TREATMENT SELECTION IN CML: EFFECT OF ONLINE EDUCATION ON CLINICIAN KNOWLEDGE AND CONFIDENCE

A. Taylor [1,*], S. Koekkoek [1], C. Scot-Smith [1], J. Apperley [2]

[1]Medscape Education Global, New York, United States, [2]Imperial College London, London, United Kingdom

Background: Despite the improvement in patient outcomes with the implementation of TKIs, patients still relapse on or are intolerant of initial treatment and an associated impact on quality of life. Physician choice of 2nd and 3rd line treatment is currently essentially limited to the same TKIs as are available for front-line treatment, with the exception of ponatinib. Thus physician's choice of 2nd or 3rd line therapy is not only predicated on patient disease, social and clinical characteristics, but also by which TKI the patient received previously, challenging them to make choices from a decreasing pool of options.
Aims: This study determined whether online continuing medical education could improve the knowledge and confidence of clinicians in best-practice sequencing strategies for patients with CML after front line therapy with a tyrosine kinase inhibitor (TKI), using a case-based approach.
Methods: A 30-minute online video panel discussion was launched for countries outside the USA in June 2020. Data were collected to September 2020. Educational effect assessed with repeated-pairs pre-/post-activity, where individual participants served as their own control. 3 multiple-choice, knowledge questions and 1 self-efficacy, 5-point Likert scale confidence question were analyzed. Chi-squared test assessed pre- to post-activity change (5% significance level, P <.05). Magnitude of change in total number of correct responses overall, and for each question, were determined with Cramer's V (<.06=Modest, 0.06- 0.15=Noticeable, .16-.26=Considerable, >.26=Extensive).
Results: 52 hematologist/oncologists completed pre- and post-activity questions. A considerable educational effect was observed (V=.181, P<.0001) with average % of correct responses increasing from 34 to 52%. Clinicians with 3/3 answers correct increased post-activity (4 to 12%) and for 2/3 answers correct post-activity (29-46%). Improvements in % of correct responses post-activity were seen for questions on: the patient population with the best outcomes related to clinical trials data, the application of the ELN guideline recommendations for defining response to TKI treatment, and the selection of an appropriate alternative TKI for a patient case (relative improvements, 25%, 56%, and 85%). 52% of haematologist/oncologist responses were improved or reinforced post-activity. 48% of all participants stated they would modify treatment plans. 31% had a measurable increase in confidence in selecting an appropriate BCR-ABL TKI for individual patients with CML who have failed prior lines of therapy with a total average confidence shift of 9.6%.
Summary/Conclusion: This on-demand, online video panel discussion resulted in a considerable educational impact. Online medical education is valuable in improving knowledge and confidence, as well as identifying areas of continued educational need and potentially improving patient outcomes, of particular importance during the COVID-19 pandemic where in-person conference learning is inaccessible.

PB1522 CLINICAL CHARACTERISTICS, DISEASE EVOLUTION AND SURVIVAL IN PATIENTS WITH CHRONIC MYELOID LEUKEMIA, BCR-ABL-1+ AND MUTATION T315I

V. Goranova [1,*], H. Ivanov [2], A. Linev [2], I. Zheljazkov [2], V. Stojanova [2], Z. Grudeva-Popova [3]

[1]Hematology, [2]Medical genetics, [3]Medical oncology, Medical University of Plovdiv, University Hospital "Sv. Georgi", Plovdiv, Bulgaria

Background: Targeted inhibition of the mutant tyrosine kinase BCR-ABL-1 (Philadelphia chromosome fusion protein) is one of the brightest advances in medical science. Thanks to this fundamental discovery, patients with chronic myeloid leukemia (CML) today have a life expectancy comparable to that of people without CML. However, additional mutations in the kinase domain of the BCR-ABL-1 gene result in resistance to the effect of tyrosine kinase inhibitors (TKIs). Different TKIs cover a different spectrum of mutations, and T315I is one of the most difficult to manage.
Aims: To study the frequency of T315I mutation in patients with CML, BCR-ABL +; to analyze their clinical characteristics, disease evolution and median survival, and to compare with those of CML patients without established T315I mutation.
Methods: We studied 75 patients with CML, BCR-ABL1 + with suboptimal therapeutic response or loss of therapeutic respones. The detection and quantification of the T315I mutation was performed by digital droplet PCR (dd PCR). Molecular studies for detection and quantification of BCR - ABL 1 fusion transcripts were performed by RT-PCR and presented on the international scale, according to ELN criteria. In patients with established T315I mutation (CML, T315I +) a comparative analysis was performed by sex and age, disease phase, risk group, treatment, type and duration of molecular response and median survival compared to patients with CML without T315i mutation (CML T315i-). Statistical data were processed with descriptive analysis, correlation analysis and Independent Sample T-test for comparison of mean values, at a level of significance p <0.05. Survival analysis was performed by the Kaplan-Meier method with a log-rank test.
Results: The T315I mutation was detected in 11 (14.7%) of CML patients. The m / f ratio in the T315I (+) group was 2/3, mean age 49.27 +/- 13.5 years, with no statistical difference from the whole cohort and patients without the T315I mutation. No statistically significant difference was found in the baseline characteristics of the disease between the two groups - phase, risk group (according to Sokal and Hasford) and choice of first-line therapy. A significantly higher proportion of CML T315I + patients did not achieve a molecular response >3.5 log throughout the follow-up period, compared to patients with CML T315I-: 8 (72.7%) vs 22(34.4%), p = 0.023. The lowest mean BCR-ABL -1 expression levels reached were significantly higher in the CML T315I + group compared to the CML T315I - group: 12.1 +/- 6.0 versus 3.77 + / 1.28 (p = 0.009). In patients with CML T315I +, the mean number of treatment lines was 3.2 compared to 1.1 in the CML T315I- group. The median survival (MS) of CML T315I + patients was significantly shorter than

the MS of patients without the T315I- mutation: 73 months vs 175 months (p <0.0001).
Summary/Conclusion: Our data confirm the data from the accumulated world experience on the frequency of T315I mutation, as well as the unfavorable evolution, resistance to TKI treatment and short survival in patients with CML, T315I +. ddPCR is a highly sensitive and informative method for early detection of genetic mutations, even at low levels of expression. Timely detection of the T315I mutation, immediately after failure of first-line TKI therapy in patients with CML, gives the chance to choose effective treatment, improve their prognosis and long-term survival

PB1523 TREATMENT OF CHRONIC MYELOID LEUKEMIA IN CHILDREN WITH TYROSIN KINASE INHIBITORS

N. Karadaş [1,*], S. Onen Goktepe [1], I. Bas [1], D. Ece [1], H. Hekimci Ozdemir [1], C. Balkan [1], Y. Aydinok [1], D. Yilmaz Karapinar [1]

[1]Pediatric Hematology, Ege University School of Medicine, Izmir, Turkey

Background: Chronic myeloid leukemia (CML) is a myeloproliferative disorder. It is very rare during childhood. Tyrosine kinase inhibitors (TKI) changed those patients' treatment approach and prognosis. The most of the authors are in consensus to TKIs should be the first line treatment in CML patients. However, in children and young adults it may be concern. Although Bone Marrow Transplantation (BMT) is a curative approach, TKIs should continue as a life- long treatment.
Aims: In this single center series we aimed to evaluate the presenting symptoms, findings, treatment approaches, responses and prognosis of children with CML under the treatment of TKIs.
Methods: Single center retrospective study was approved by Local Ethic Committee. CML patients who were diagnosed at Ege University Pediatric Hematology Department between 1997 and 2020 were evaluated.
Results: Sixteen patients were diagnosed with CML during the study period. The median age of the patients was 9,5years (range 2-16 years), nine of them were girls.
5 patients were in blastic phase, 11 patients were in chronic phase of CML.
The predominant symptoms at presentation were asthenia (31%) and fever(31%). The most predominant clinical sign was splenomegaly (80%). The fever was seen in all patients in blastic phase. The mean WBC count at presentation was 205.000/mm^3. 50% of the patients the WBC count was above 200.000/mm^3. Only one patient with normal WBC count who was investigated for the reasons of thrombocytosis (1.820.000/mm^3) was diagnosed as CML.
Hydroxyurea treatment was given before the translocation (9;22) had been detected. One patient was given ARA-C and Interferon for 4 years since imatinib was not available. Imatinib treatment was given 15 patients as initiation treatment. Complete hematological response was documented in all patients between 20 and 68 days (median33 days) of treatment. The major molecular response was achieved in 14 of the patients within 6 months. Five patients with blastic crisis received both ALLIC BFM 2002 Chemotherapy protocol and imatinib.
7 patients received only imatinib. In 7 patients imatinib was switched to dasatinib as second line therapy. In 2 Patients nilotinib was started as third line treatment.
Two patients underwent BMT. The first patient achieved MMR at 12 months, but showed molecular relapse at 14 months of follow up, and the second patient developed blastic crisis at the 19 month of imatinib treatment.
TKI treatment was discontinued in 5 patients after a median of 7 years (range 5-10.5 years) treatment. Three of the patients were in MMR for seven years and one for 10,5 years. While no molecular relapse was seen until the last follow up, the median follow up period was 70 months. One patient who was on MMR for 5 years, molecular relapse developed nine months after the discontinuation of the treatment. TKI treatment was restarted.
The median follow up of whole study group is 109 months (range 19-522 months) and overall survival is 100%. BMT is needed in 2 patients (12.5%). Additionally 3 patients (18,7%) received only TKIs and succeded to discontinue TKIs without molecular relapse for a median period of 163 months.
Summary/Conclusion: In Conclusion, CML is a very rare disease during childhood. TKIs lead very good results in survival. In some patients, it is possible to discontinue TKIs without molecular relapse.

PB1524 QTC PROLONGATION AND SUDDEN CARDIAC DEATH AS A MANIFESTATION OF CARDIOTOXICITY

L. Makeeva [1,*], G. Gendlin [1], E. Emelina [1], I. Nikitin [1]

[1]NI Pirogov Russian National Research Medical University, Moscow, Russian Federation

Background: There are only few descriptions available in literature about the QTc prolongation and sudden cardiac death during treatment using BCR-ABL tyrosine kinase inhibitors.
Aims: Analysis of corrected interval QT (QTc) prolongation and sudden cardiac death of patients with chronic myeloid leukemia (CML) treated with BCR-ABL tyrosine kinase inhibitors (TKI).
Methods: The study was conducted on 114 patients who received nilotinibb, dasatinib or imatinib. All the patients underwent classical ECG monitoring and 24-hour Holter ECG monitoring with measuring of QTc duration. The trial excluded patients with severe heart diseases.
Results: Conducted comparative analysis shows statistically significant greater impact of nilotinib on the duration of QTc interval compared to other tyrosine kinase inhibitors. The maximum QTc was slightly longer than in patients treated with imatinib and dazatinib already at the early and middle stages (up to 36 months), but these differences are statistically insignificant. The main differences can be seen in patients taking nilotinib over 38 months, when these differences become statistically significant: median and interquartile range in patients on nilotinib therapy were 0.46 (0.44-0.47) s, n = 17 versus 0.43 (0.42-0.44) s in the group of patients taking dazatinib or imatinib (n=23), p=0.0004. After 7 years, we found out the fate of 110 examined patients. It turned out that 4 CML patients treated with ITK died suddenly. During analysis of the obtained data, it was found that the QTc duration in the ECG of the deceased did not differ from the survivors. At the same time, the QTc in 24-hour Holter ECG monitoring of 4 patients with sudden cardiac death was statistically significant longer than in the rest: 0.48 (0.48-0.505) s (n = 4) versus 0.45 (0.43-0.46) s (n = 110) (p=0.0003). Since all of the deceased were over the age of 52, the examination results of patients of this age were studied. A similar data was found in the group of patients older than 52 years: QTc duration of patients who died from sudden cardiac death - 0.48 (0.48-0.505) s, who are currently living or died from other reasons - 0.44 (0.43-0.46) s (n=56), p=0.001. All cases of sudden cardiac death occurred on nilotinib treatment (p=0.01), and the estimation of this indicator in the group of patients older than 52 years of age shows an identical trend with lower statistical significance (p=0.05).
Summary/Conclusion: 1. We have shown that in patients with CML taking nilotinib, the QTc duration is statistically significant longer than in similar patients receiving other TKI more than 38 months.
2. Despite the small number of groups and the small number of sudden deaths, they had a statistically significant QTc prolongation in 24-hour Holter ECG monitoring compared to those currently living or died from CML progression.
3. All CML patients treating with nilotinib are indicated to receive not only classical ECG, but also regular 24-hour Holter ECG monitoring with its greater sensitivity to detection of QTc prolongation.

PB1525 THE DIAGNOSIS, TREATMENT AND MONITORING OF PATIENTS WITH CHRONIC MYELOID LEUKAEMIA: THE IMPACT OF ELN GUIDELINES ON CLINICAL PRACTICE IN A DISTRICT GENERAL HOSPITAL

S. N. Nanayakkara [1], M. Sivakumaran [1,*]

[1]Haematology, Peterborough City Hospital, Peterborough, United Kingdom

Background: Tyrosine Kinase Inhibitors (TKI) have revolutionised the treatment and outcome of patients with Chronic Myeloid Leukaemia. This treatment, however, is associated with significant toxicity, in particular cardiovascular complications, and emergence of drug resistance. In order to optimise the TKI treatment pathway, European Leukaemia Net (ELN) published a Guidelines in 2013 (Baccarani et al, Blood. 2013;122:872–84). But the recent UK TARGET CML study carried out in the United Kingdom has identified significant variations in compliance with the above guidelines (Milojkovic et al, Br Haematol. Br J Haematol. 192(1):62-74).
Aims: We conducted an audit into the treatment pathway of all patients currently treated with a TKI in our hospital
Methods: Patient demographics, clinical features at presentation, diagnostics, clinical risk assessment, prognostic evaluation, treatment choice, frequency of response monitoring and interventions at treatment failures were analysed in a cohort of 51 (31 male and 20 female) patients.
Results: The age group of this patient population is 24-88 years (mean 59.4). Good clinical records documenting relevant clinical information are

available in 40/51 (78%) cases. Cardiac co-morbidities are recorded in 21/51 (41.2%) patients. These include type II diabetes mellitus (11.8%), hypertension (11.8%), cardiac arrhythmias (5.9%), obesity (21.6%), ischaemic heart disease (5.9%) and hyperlipidaemia (1.9%). Relevant clinical signs are recorded in 86% of the cases but this information is missing in 14% of the notes studied. Splenomegaly and hepatomegaly were noted at presentation in 14 (27.4%) and 1 (1.9%) patients respectively. All patients (100%) had bone marrow evaluation and cytogenetics done at diagnosis but prognostic scores are recorded only in 10 (19.6%) cases. The first line TKI was imatinib in 44/51 (86.2%), dasatinib in 4/51 (7.8%) and nilotinib in 3/51 (5.9%). The selection of TKI was appropriate in all 14 patients (100%) with known cardiac risk factor(s). A second generation TKI was selected on the basis of risk assessment in 3 patients. The reason for the selection of a second generation TKI in the other 4 cases was not recorded. 22/51 (43.1%) patients developed treatment failure at various time points. One patient opted for palliative care. Appropriate changes to treatment were made in 18/21 (85%) patients. However, there were delays in introducing changes to treatment in the remaining 3/21 cases (15%). Second line TKI treatment was dasatinib in 10 (47.6%), nilotinib in 6 (28.6%) and imatinib in 5 (23.8%) patients. The choice of second generation TKI was based on cardiovascular risk assessment in 18/21 (85.7%). Tyrosine Kinase Domain mutation analysis was carried out prior to changing TKI in 6/21 (28.6%). The test was not performed in 15/21 (71.4%) cases. The results of the current audit were compared with the previous audit conducted in 2011, prior to the introduction of ELN Guidelines.

Summary/Conclusion: The ELN Guidelines have had a positive impact on the CML treatment pathways in our institution with significant improvements in the diagnosis, clinical risk assessment, disease monitoring and drug selection at treatment failure. However, there is still room for further improvements, in particular, in areas of prognostic evaluation, risk-adapted drug choice and TKD mutation analysis at treatment failure.

PB1526 DOSE REDUCTION OF ITKS IN THE TREATMENT OF CHRONIC MYELOID LEUKEMIA. RETROSPECTIVE STUDY OF A SINGLE CENTER EXPERIENCE: SAFETY, EFFICIENCY AND ECONOMIC IMPACT.

F. Marco De Lucas [1,*], L. Martinez [2], L. Otaolea [3], J. Uriarte [1], Z. Díez Gallarreta [1], C. Barrenetxea [1], J. I. Rodríguez Gutiérrez [1], O. Arce Fernández [1], A. Blanco [1], L. Vidal Lartitegui [1], D. Caballero [1], S. Amandi [1], J. A. Márquez [1], S. Herráez [1], I. Leal [1], A. Mendizabal [1]

[1]Servicio de Hematologia del Hospital Universitario Basurto, Osakidetza. Biocruces, [2]Facultad de Medicina, UPV, [3]Servicio de Genética. HU Basurto, Osakidetza, Bilbao, Spain

Background: Discontinuation of TKIs has been gaining ground in recent years in the usual practice of CML treatment. Long-term dose reduction is another strategy shown in different publications that may in some cases contribute to improving the quality of life of patients without putting disease control at risk.

Aims: Evaluate in retrospect the clinical and analytical evolution of the cases of our service in which the doses of ITKs have been reduced in the treatment of patients with CML and make an estimate of the economic savings obtained by dose reduction.

Methods: We have reviewed the clinical and analytical course of patients with CML in follow-up in H.U. Basurto between June 2013 and April 2020. Among them we have selected 20 patients in which the dose of ITK was reduced below the standard dose and we have analyzed the evolution of its clinical course and various analytical data, including BCR-ABL/ABL (IS), blood count, glucose, cholesterol, AST, ALT and triglycerides, both before and after dose reduction of ITK. Economic savings were calculated by multiplying the monthly price of each drug by the number of months of reduction and the fraction of reduced dose.

Results: A total of 20 patients with dose reduction were identified, with a median age of 60 years (40-89). ITK distribution was 16 imatinib, 14 nilotinib, 5 dasatinib and 1 bosutinib. Twenty-six patients were under first-line treatment, 9 second-line treatment and 1 on third-line. A total of 36 dose reduction episodes were collected in the study. The average treatment time with ITK prior to reduction was 24.6 months (0-135 months). The reason for the reduction was toxicity in most cases, although in 4 cases with nilotinib it was to prevent cardiovascular toxicity and in 1 case it was by the patient's own decision. Pre- and post-reduction molecular response levels are listed in Table 1. No cases of blast crisis or accelerated phase was observed after the reduction. Of 26 reductions the molecular response worsened in 4 cases and only one loss of MMR was observed, which was subsequently rescued without increasing the dose. The improvement in toxicity symptomatology was greater than 80% with all drugs. A significant increase in Hb and cholesterol levels was observed following dose reduction of imatinib. The estimated overall economic savings from dose reduction of ITKs were 568,367€ (nilotinib 428.729 €, dasatinib: 136.153 €, bosutinib: 2.286 €, imatinib: 1.198 €).

		Post-reduction molecular response					
		N.A.	MR1	MR2	MMR	MR≥4.0	Total
Pre-reduction molecular response	N.A.	0	1	0	1	0	2
	MR2	1	0	3	1	0	5
	MMR	0	0	1	2	0	3
	MR≥4.0	1	0	0	3	22	26
	Total	2	1	4	7	22	36

Summary/Conclusion: Our series shows that dose reduction of ITKs in selected cases may reduce toxicity and improve the quality of life of patients with CML with little effect on treatment efficacy and a big impact on pharmaceutical cost.

PB1527 DISCONTINUATION OF TYROSINE KINASE INHIBITORS IN PATIENTS WITH CML WITH DEEP MOLECULAR RESPONSE IN SOUTH OF TUNISIA

R. Mallek [1,*], O. Kassar [1], R. Frikha [2], L. Khalifa [1], I. Turki [1], Y. Fakhfekh [1], I. Frikha [1], M. Medhaffer [1], F. Kallel [1], M. Charfi [1], I. Ben Amor [1], S. Hdiji [1], M. Elloumi [1]

[1]Department of Hematology, [2]Oncogenetic departement, Faculty of Medecine of Sfax, Sfax, Tunisia

Background: The therapeutic aim of chronic myeloid leukemia (CML) has profoundly changed over this decade from obtaining normal life expectancy to discontinuing medication for treatment-free remission (TFR). TKI discontinuation becomes an option for patients who achieve a stable and prolonged deep molecular response.

Aims: We report the experience of discontinuation of TKI in CML in South of Tunisia.

Methods: Our study was prospective. We included patients with CML followed at hematologic department in the south of Tunisia from October 2015 to December 2020. The criteria of inclusion suitable patients for discontinuation of TKI therapy were an age ≥18 years, a chronic phase CML with no prior history of accelerated or blast phase CML, non-high sokal-score at diagnosis, typical b2a2- or b3a2-bcr–abl1 transcripts, TKI therapy for at least 5 years, no history of resistant or progressive disease and stable deep molecular response (DMR) (*bcr-abl1* ≤0.0032% IS) for at least 2 years. After TKI discontinuation, hematological monitoring including a complete blood count and bcr-abl1 messenger RNA quantification by RT-PCR were done monthly during the first 6 months, every 2 months from 7 to 12 months, quarterly the second year and then every 3 to 6 months. Molecular relapse after TKI discontinuation was defined by loss of major molecular response (MMR) (bcr-abl1 >0.1% IS) and was an indicator for a resumption of TKI.

Results: Eleven patients out of 160 patients with CML (7%) were enrolled in our study. Seven patients were women and 4 were men. Median age at TKI discontinuation was 52 years (range 48-77 years). Sokal-score at diagnosis was low in 8 cases and intermediate in 3 cases. All patients were treated with Imatinib. Median period of TKI therapy was 117 months (range 60- 180 months). The average of length of DMR before TKI discontinuation was 45 months (range 24-72 months). The median period of follow-up after TKI discontinuation was 26 months (15-50 months). Molecular relapse occurred in 4 patients (36% of patients) in the first 3 months of discontinuation therapy. After the reintroduction of TKI, all of these patients obtained DMR again with 3.2 months (3 patients at 3 months and 1 at 4 months). The remaining 7 patients (63%) achieved a TFR.

Summary/Conclusion: In our study, the rate of TFR is 63% which is similar to literature results (40-60%). We conclude that TKI can be safely discontinued in our CML population fulfilling criteria of eligibility. To make more concrete conclusion, we must enlarge patient population and much longer follow up are needed.

PB1528 PARAPROTEINEMIA PREVALENCE AND CHARACTERISTICS IN PATIENTS WITH CHRONIC MYELOID LEUKEMIA

T. Berger [1,2,*], A. Shacham Abulafia [1,2], O. Pasvolsky [1,2], I. Vaxman [1,2,3], Y. Miron [1], S. Feldman [1], A. Leader [1,2], P. Raanani [1,2]

[1]Hematology division, Davidoff cancer center, Beilinson hospital, Rabin medical center, Petah Tikva, [2]Sackler Faculty of Medicine, Tel Aviv University, Tel Aviv, Israel, [3]Division of Hematology, Mayo Clinic, Rochester, MN, United States

Background: Chronic myeloid leukemia (CML) is a clonal disorder of myeloid origin. Paraproteinemias are a group of disorders arising from the clonal proliferation of a lymphoid origin leading to the production of a monoclonal (M-) protein. Though originating from different cell origins, there have been several reports describing patients with coexistence of CML and multiple myeloma (MM) or other paraproteinemias, mostly in patients treated with tyrosine kinase inhibitors (TKIs).
Aims: To determine whether the prevalence of paraproteinemia in a large cohort of CML patients is higher than in the general population in a tertiary medical center.
Methods: This is a cross sectional study among chronic phase CML patients treated in the Institute of Hematology at the Rabin Medical Center, a university affiliated tertiary medical center in Israel. Between February 2019 and Februray 2021 consecutive patients with a diagnosis of chronic phase CML, who gave their consent to the study, performed the following serum samples: protein electrophoresis & immunofixation (SPEP, IFIX), serum free light chains (FLC) and quantitative immunoglobulin (Ig) levels. The study's primary outcome was the prevalence of paraproteinemia among this cohort of CML patients. Secondary outcomes evaluated the correlations between paraproteinemia and various patient, disease and treatment-related variables. The study was approved by the Institutional Review Board.
Results: A total of 96 patients were recruited. Data for the analysis were available for 90 of them. Patients' characteristics are presented in Table 1. On SPEP - 18 patients (20%) had hypergammaglobulinemia, 14 patients (15.5%) had hypogammaglobulinemia and 58 patients (64.5%) had normal gammaglobulin fraction.
M-protein was detected on SPEP and IFIX in 6 patients (6.6%) with a median age of 71.5 years (range 46-74). Among them, two patients had also an abnormal FLC and elevated IgG or IgA levels with corresponding immunoparesis of the uninvolved Ig heavy chain. These patients underwent a bone marrow biopsy and skeletal imaging and were diagnosed with IgG-kappa and IgA-kappa smoldering multiple myeloma (SMM). The other four patients had normal FLCs and their characteristics were compatible with the diagnosis of low risk monoclonal gammopathy of undetermined significance (MGUS). None of the patients in our cohort was diagnosed with active MM.
All six patients with an M-protein are currently under observation for their newly-diagnosed paraproteinemia.
At enrollment, five of the six patients with a detectable M-protein were treated with a TKI [imatinib (n=2), dasatinib (n=2), bosutinib (n=1)] and one had been in TFR for two months, after 6 years of imatinib therapy.

Table 1 – cohort characteristics (n=90)

Variables	
Median age, year (range)	
At CML diagnosis	54.6 (23.9-90.4)
At enrollment & testing	64.3 (26-92)
Median time from CML diagnosis to enrollment & testing, year (range)	6.8 (0.1-23.5)
Gender, n (%)	
Male	44 (49)
CML treatment at enrollment, n (%)	
1st line TKI	48 (53.3)
2nd line TKI	37 (41.1)
3rd line TKI	2 (2.2)
Treatment free remission	3 (3.3)

Summary/Conclusion: To the best of our knowledge this is the largest study to describe the prevalence of paraproteinemia among CML patients. We found the prevalence of MGUS in chronic phase CML patients (4.4%) to be similar to that of the general population above the age of 50 years. Nonetheless, we found a non-negligible prevalence of SMM (2.2%), a relatively uncommon clinical entity. Based on these data, we recommend to consider screening for paraproteinemia coexistence in patients with CML, since this might have a clinical impact. Further studies, including extended follow up of the present cohort should elucidate the true clinical significance of our findings.

PB1530 CHRONIC MYELOID LEUKEMIA WITH THREE-WAY TRANSLOCATION T(4;9;22) AND MULTIPLE MYELOMA – A RARE CASE OF COMORBIDITY

N. Petkova [1,*], L. Grahlyova [2], R. Hristoskova [3], A. Nedeva [1], L. Mitev [2], J. Raynov [1]

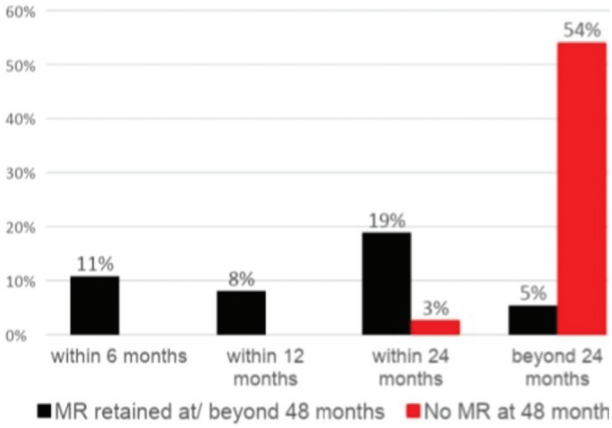
[1]Clinic of Hematology, [2]Laboratory of Cytogenetic and Molecular Biology, [3]Pathology Department, Military Medical Academy, Sofia, Bulgaria

Background: Chronic myeloid leukemia (CML) is a clonal myeloproliferative disorder of pluripotent hematopoietic stem cells, that is genetically characterized by Philadelphia (Ph') chromosome in 90% of cases, consisting of reciprocal t(9;22)(q34;q11) translocation. About 5-10% of CML patients develop variant translocations involving one or more chromosomes beside 9 and 22. Multiple myeloma (MM) is a monoclonal disorder of plasma cells which have differentiated from lymphoid B cells. Since different cell lines give rise to CML and MM, the occurrence of both MM and CML in the same patient is extremely rare.
Aims: We describe a rare case of a patient with CML with t(4;9;22)(q21;q34;q11) three-way translocation and MM diagnosed and treated in our Clinic.
Methods: Case report. Data was collected form medical history and clinical charts. Relevant literature was reviewed.
Results: We present a case of 71-year-old man with leukocytosis, mild anemia and splenomegaly, who was initially diagnosed with CML, chronic phase. The bone marrow aspirate was typical of CML with granulocyte hyperplasia and 1% myeloblasts. The cytogenetic analysis revealed the presence of an uncommon three-way translocation 46,XY,t(4;9;22)(q21;q34;q11) in all metaphases obtained from the bone marrow, confirmed with positive dual fusion FISH probe for t(9;22)BCR/ABL. The qRT-PCR detected BCR/ABL1 transcripts. Treatment with tyrosine kinase inhibitor (TKI), nilotinib (300mg bid), was started and the patient achieved a complete hematologic response and at 3 months – complete cytogenetic response with normal bone marrow karyotype and early molecular response.
Six months after initial therapy with TKI, mild anemia with a rise of total serum protein were detected and serum protein electrophoresis revealed a monoclonal IgG lambda M-spike of 27g/L. Bone marrow biopsy at that time showed 35-40% CD138+/CD56+ plasma cells infiltration, and no increased blast cells. FISH analysis for BCR/ABL of bone marrow was negative, but quantitative RT-PCR detected M-BCR/ABL with a level of expression of 0.63%. MM was diagnosed, in addition to CML. The revision of the bone marrow at initial CML diagnosis was negative for plasma cells. Chemotherapy with weekly bortezomib, cyclophosphamide and dexamethasone was preferred considering the risk of drug interactions and pancytopenia when combined with nilotinib for CML. The patient achieved complete response with 6 courses of chemotherapy for MM, deep molecular response (DMR) of CML at the first year of TKI therapy; therapy was well tolerated. One year later he developed myeloma relapse with anemia, while DMR of CML remained stable with nilotinib. The patient was treated for relapsed myeloma, but he experienced a complicated COVID-19 infection with pneumonia and renal failure, and had fatal outcome in few weeks.
Summary/Conclusion: While other than 9 and 22 chromosomes are frequently involved in three-way translocations, chromosome 4 is a very rare event in CML complex variant, with only seven cases with breakpoint 4q21 reported in cytogenetic databases. The coexistence of CML and MM is another extremely uncommon event with only ten patients described in medical literature diagnosed first as having CML, and then MM. This is for the first time that CML patient with three-way translocation t(4;9;22)(q21;q34;q11) is diagnosed with MM. Due to the rarity of coexistence of two hematological malignancy in the same patient, we have scarce data on treatment approach. Our case demonstrates that nilotinib combined with certain myeloma therapy can be considered safe and efficient in a case of CML and MM comorbidity.

PB1531 CHRONIC MYELOID LEUKEMIA AS A SECONDARY MALIGNANCY IN A PATIENT WITH SPLENIC MARGINAL ZONE LYMPHOMA: A CASE REPORT

Z.-H. Li [1], B.-W. Ni [1], F. Xiao [1], H.-H. Huang [1,*]

[1]Department of Hematology, Ren Ji Hospital, Shanghai Jiao Tong University School of Medicine, Shanghai, China



Background: Philadelphia chromosome-positive (Ph+) chronic myeloid leukemia (CML) occurring as a secondary malignancy is a rare clinical scenario, the publications on treatment-related CML (tr-CML) in lymphoma patients is limited by a few case reports.
Aims: To describe a unique case of an elderly patient who developed CML subsequent to splenic marginal zone lymphoma (SMZL). To our knowledge, CML as a secondary malignancy in a SMZL patient is hitherto unreported worldwide.
Methods: A case study.
Results: Male, 61-year-old, diagnosed with SMZL in February 2009. He had white blood cell count (WBC) of $33.1x10^9$/L, 86% lymphocytes in peripheral blood, immunophenotype with positive for HLA-DR, CD19, CD20, cCD79α, κ, negative for CD10, CD5, BCL-2, CD103, CD23, normal karyotype and splenomegaly. The patient was asymptomatic, so a watch-and-wait approach was used. Follow-up observation showed stable disease till 2012. From Jun 2012, chlorambucil was applied intermittently, due to thrombocytopenia and progressive enlargement of the spleen. Thereafter the disease was generally stable. In Aug 2014, the patient presented with an elevated WBC of $87.98x10^9$/L. Peripheral blood smear revealed increased immature granulocytes, with 4% promyelocyte, 12% myelocyte, 3% metamyelocyte. The BM smear identified the cellular hyperplasia and increased myeloid to erythroid ratio, with 61.5% marrow myelocytes and 31% marrow mature lymphocytes. Cytogenetic analysis revealed t (9;22) and RT-PCR analysis demonstrated *BCR/ABL* fusion transcript. Over six years after the initial diagnosis of SMZL, a diagnosis of CML in chronic phase was made. He started on imatinib (400mg daily), and was simultaneously treated with cyclophosphamide for the SMZL because he refused the anti-lymphoma immuno-targeting therapy. Imatinib treatment was switched to nilotinib (300mg, twice per day) after seven months due to recurrent skin rash and refractory mucous membrane ulcer, which were probably attributed to imatinib. As of Dec 2020, the patient is in sustained complete molecular response from CML, and the disease state of SMZL is stable.
Summary/Conclusion: In conclusion, we report a rare tr-CML case of an elderly patient treating with an alkylating agent for SMZL. Tr-CML is an infrequent complication after chemotherapy and/or radiotherapy, which may increase the risk of secondary malignancies by inducing genetic damage. Nilotinib, the second generation TKI, could show a favorable response in Ph+ tr-CML, similar to that in *de novo* CML.

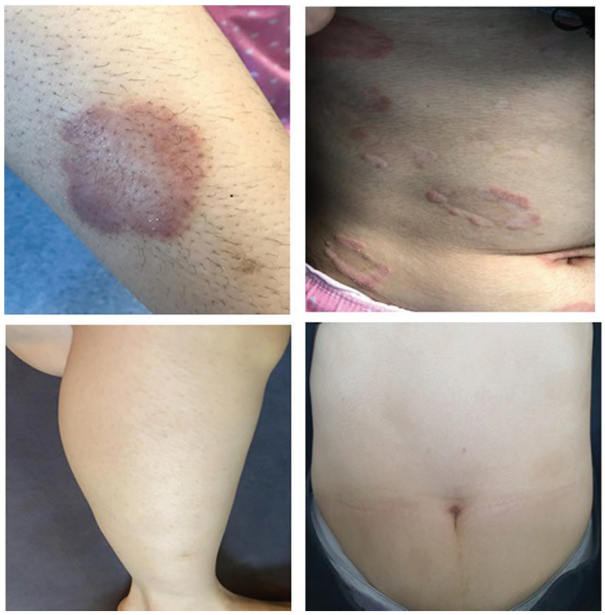
PB1532 FISH VERSUS REAL-TIME QUANTITATIVE PCR FOR MONITORING OF MINIMAL RESIDUAL DISEASE IN CHRONIC MYELOID LEUKAEMIA PATIENTS ON TYROSINE KINASE INHIBITOR THERAPY

A. M. haidary [1,2,*]

[1]Hematopathology, French medical institute for children and mother, Kabul, Afghanistan, [2]Pathology and Laboratory Medicine, Universiti Kebangsaan Malaysia, Kuala Lumpur, Malaysia

Background: BCR-ABL fusion gene, the oncogenic driver of CML, results from a translocation between short arms of chromosome 9 and 22. Monitoring of CML patients during treatment is essential, not only for tailoring the treatment but also to detect early relapse to enable timely intervention. Commonly used methods for detection of residual disease are conventional karyotyping, FISH and molecular methods. In this study, we compared FISH with QRT-PCR for detection of residual disease in CML.
Aims: To demonstrate correlation between FISH and Quantitative PCR for BCR ABL1
Methods: CML patients on tyrosine kinase inhibitor (TKI) therapy and on regular follow up at University Kebangsaan Malaysia Medical Center (UKMMC) were selected. A comparative study was conducted between FISH and QRT-PCR for BCR-ABL transcripts at diagnosis and during follow-up.
Results: There was good correlation between FISH and QRT-PCR for BCR-ABL. At 6th month of follow-up post diagnosis, FISH had a sensitivity of 83.3% and specificity of 65.2% (k >0.339, p<0.033). At 12th month, the sensitivity of FISH was 83% and the specificity was 59.1% (k >0.286, p <0.065). Similarly, at the 24th month, FISH had a sensitivity of 100% and specificity of 68.8% (k >0.642, p<0.000).

Summary/Conclusion: QRT-PCR was the most reliable and therefore the current gold-standard method to monitor residual disease in CML patients. In our study FISH analysis was demonstrated to be a reliable investigation that should be considered with QRT-PCR for BCR-ABL. It was also demonstrated that time to achievement of molecular and cytogenetic targets i.e. MMR and CCyR respectively, were reliable indicators to detect the long-term outcome of the disease.



PB1533 COMPLETE REMISSION OF PSORIASIS IN CML LADY TREATED WITH DASATINIB: JOYFUL EXPERIENCE

N. Eisa [1,2,*], M. Asiri [2], A. Alshehri [2]

[1]Clinical Hematology Unit, Internal Medicine Department, Faculty of Medicine, Mansoura University, Mansoura, Egypt, [2]Hematology and Oncology Unit, Internal Medicine Department, Aseer Central Hospital, Ministry of Health, Abha, Saudi Arabia

Background: Discovery of tyrosine Kinase inhibitors (TKIs) was a watershed moment in Chronic Myeloid Leukemia (CML) treatment. Adverse cutaneous reactions (ACRs) represent the most common non-hematological adverse reactions with TKIs. More with 1st generation TKIs (Imatinib), tend to be less severe with second-generation. Development of psoriasis during Imatinib and Nilotinib was reported in few cases. One reported case showed that Dasatinib causing worsening of Psoriasis vulgaris. To our knowledge, this is the first case showed complete remission of psoriasis after Treatment with Dasatinib.
Aims: To document a rare beneficial effect of dasatinib which is accidently discovered during treating female patient of CML.
Methods: Case Report: 27 years old Saudi Female, medically free before, presented in Jul 2019 to ED with abdominal pain mainly in epigastric region associated with heart burn and vomiting, this condition started 3 days ago. Preceded by fever mainly during night, night sweating and weight loss for 1 month. She also suffered from recurrent nose bleeds with headache. Clinical examination showed Huge splenomegaly reaching Umbilicus. Skin examination showed multiple ecchymotic patches with multiple skin lesions scattered all over the abdomen, back and lower limbs which were red in Colour with scaly patches.
Initial laboratory tests showed anemia (Hb 7.8 gm/dL), leukocytosis (WBC 537.00 x 109/L), with platelet count 327.00 x 109/L. The Peripheral blood smear showed picture of Chronic Myeloid Leukemia –chronic phase. The pelvi-abdominal ultrasound showed markedly enlarged splenomegaly 20 cm in size. Coagulation profile was with normal range. High LDH level [820 U/L]. ESR 1st hour was 100. PCR was positive for the BCR-ABL1 fusion transcript p210(85% IS score). July

2019 Back skin, Punch biopsy showed hyperkeratosis, parakeratosis, Munro's micro abscess, acanthosis, diminished granular layer, and tortuous dilated papillary capillaries which Consistent with annular non-pustular psoriasis.
Sockal score was calculated to be Intermediate. She had plan for marriage after 1 year from diagnosis. So, we started Dasatinib 100 mg once daily with optimum response at 3 months (BCR-ABL 1% IS score). But the amazing thing is that psoriatic lesions started to improve gradually without using any medications for psoriasis. During her last visit to Hematology Clinic on Feb 2021, she was very happy that psoriasis disappeared completely and got married with gentleman accompanied her to the clinic. She agreed to take photos for abdomen and Lower Limb.
Results: -

Summary/Conclusion: It is well known that tyrosine kinase inhibitors made a revolution in CML, but it can be hope for other difficult treating conditions as psoriasis.

PB1534 CHRONIC MYELOID LEUKEMIA: ATYPICAL PRESENTATION WITH ISOLATED EXTREME THROMBOCITOSIS

J. M. Freue [1,*], C. Enciso [1], A. Panizo [2], G. Dallasta [2], M. Narbaitz [3], R. Campestri [1]

[1]Hematology, [2]Tranfusional Medicine, Sanatorio Anchorena, [3]Hematology, IIHEMA Academia Nacional de Medicina, Buenos Aires, Argentina

Background: Chronic myeloid leukemia (CML) represents a common condition in the spectrum of myeloproliferative disorders. It classically exhibits leukocytosis, but rarely presents with isolated thrombocytosis. Severe thrombocytosis, with a platelet count of more than 1,000×109/L, is exceptionally rare to be found upon initial laboratory workup in newly diagnosed patients with CML. A systematic review done by Dawood Findakly et al only found 20 cases in PubMed, MEDLINE®, ScienceDirect, and Scopus for English-language articles for the period 2000-2020.
Aims: To describe a case of a patient with isolated thrombocytosis as initial manifestation of CML.
Methods: A 33 yo woman was admitted for spontaneous hematomas and extreme thrombocytosis. Laboratory was as follows: Hg 13gr/dl WBC 8400 (normal blood smear) Platelet 2 million/mm3. Factor VIII 61% V. Willebrand (VW) 70%, Ristocetin ccofactor 40%. Abdominal ultrasound showed no visceromegalies. A bone marrow biopsy was done: cellularity was 70% CD34+ cells 4% with marked hyperplasia. Hydroxyurea was initiated at an initial dose of 500mg BID and she was discharged. Essential thrombocytemia was the initial suspected diagnosis. 1 week after she was admitted again with headache and dizziness. Platelet count has risen to 3 million/mm3 despite an increase in hydroxyurea to 1gr every 8hs. Since she had neurological symptoms, she initiated platelet apheresis for 3 sessions achieving symptomatic relief and was discharged with a platelet count of 500000/mm3. Cytogenetic results were 46XX, t (9;22) and BCRABL p210 transcript by qPCR was positive. JAK2V16F was negative. CALR and MPL mutations were also negative
Results: With diagnosis of CML she iniated imatinib 400mg/daily achieving at month 6 mayor molecular response, normalization of platelet and VW factor. We present this case because of the rare incidence isolated thrombocytosis as manifestation of CML
Summary/Conclusion: This atypical CML presentation with an isolated thrombocytosis is a rare entity. Isolated thrombocytosis could lead to a misdiagnosis of essential thrombocythemia.

PB1535 COMPLEX CYTOGENETIC ABNORMALITIES IN CHRONIC MYELOID LEUKEMIA RESULTING IN EARLY PROGRESSION TO BLAST CRISIS: A CASE REPORT

A. M. haidary [1,2,*], S. Noor [3,4]

[1]Pathology and Laboratory Medicine, Universiti Kebangsaan Malaysia, Kuala Lumpur, Malaysia, [2]Hematopathology, French medical institute for children and mother, [3]Hemato-oncology, Jumhoriat hospital, [4]Oncology department, Ali Abad Hospital, Kabul, Afghanistan

Background: BCR-ABL1, resulting from t(9;22), is the oncogenic driver of chronic myeloid leukemia and the therapeutic target of the disease. Molecular studies have been the gold standard modality for patient assessment since the advent of tyrosine kinase inhibitor therapy. In spite of that, there are cytogenetic abnormalities that can render the disease unresponsive to conventional therapy, thus making cytogenetics an important component of patient management guidelines.
Aims: To present a novel karyotype in CML with impact on clinical outcome of the patient.
Methods: Conventional Karyotyping using Giemsa Banding
Results: We present a case of a Tajik, Afghan patient with chronic myeloid leukemia with del(6)(q23.3q27), t(9;22)(q34;q11.2), monosomy 11, monosomy 12, and marker chromosome who, despite having typical clinical and hematological disease with initial response to therapy, progressed to blast crisis very early and thus required special interventions.

Summary/Conclusion: Cytogenetic monitoring is an important pillar in the management of patients with chronic myeloidleukemia that cannot be ignored. It should therefore be a part of patient management not only during diagnosisbut also during management. We present an unusual cytogenetic abnormality in a patient with chronic myeloidleukemia that resulted in early disease progression.

Enzymopathies, membranopathies and other anemias

PB1536 NEXT-GENERATION OSMOTIC GRADIENT EKTACYTOMETRY: AN ESSENTIAL STEP FOR THE DIAGNOSIS OF RED BLOOD CELL MEMBRANE DISORDERS

A.-S. Adam [1,*], S. Benyaich [1], F. Cotton [1], B. Gulbis [1]

[1]Clinical Chemistry, LHUB-ULB, Brussels, Belgium

Background: During the last decade, next-generation osmotic gradient ektacytometry, which analyses the red blood cell (RBC) deformability under an osmotic gradient, has become a very useful tool for the

diagnosis of RBC membrane disorders, especially for hereditary spherocytosis (HS). The LHUB-ULB is currently the National Reference Center for RBC membrane disorders and ektacytometer is one of its tools.
Aims: The aim of this study was to improve our diagnosis of HS by using ektacytometry.
Methods: Between 2017 and 2020, a total of 124 consecutive EDTA samples from patients with chronic haemolytic anaemia were obtained from our routine workload. They were analyzed prospectively using the osmoscan module of an osmotic gradient ektacytometer. According to our diagnostic algorithm, 66 cases of HS, three hereditary elliptocytosis, one hereditary stomatocytosis, one congenital dyserythropoietic anemia type II and one Southeast Asian ovalocytosis were diagnosed. Finally, 52 patients were classified as "membranopathies excluded". Osmoscan parameters were expressed as percentage of change compared to the control sample of the day. Cut-off values for the most robust parameters for the diagnosis of HS were established using receiver operating characteristic (ROC) curve analysis.
Results: The best criteria for the diagnosis of HS were the combination of a decreased area under the curve (AUC) of more than 17.9% and an increased minimal osmolality point (Omin) of more than 18.3% compared to the control. Using these established cut-offs, osmotic gradient ektacytometry reported a sensitivity of 93.9 % and a specificity of 91.4% for the diagnosis of HS.
Summary/Conclusion: After more than three years of routine use in our laboratory, by using dedicated cut-offs for several parameters obtained by osmotic gradient ektacytometry, the next-generation ektacytometer confirmed its place as a powerful diagnostic tool for the diagnosis of RBC membrane disorders.

PB1537 DIAGNOSTIC IMPORTANCE OF BONE MARROW ASPIRATION IN CHILDREN WITH ANEMIA OF UNKNOWN ETIOLOGY

Z. mtvarelidze [1,2,*]

[1]Hematology Department, Children s New Clinic, [2]Hematology Department, G.Jvania Pediatric Clinic, Tbilisi, Georgia

Background: Anemia of unknown etiology is a major problem for hematologists and requires a wide range of studies. One of the main investigations at this time is bone marrow examination.
Aims: This study was designed to determine the diagnostic importance of bone marrow aspiration in children with anemia of unknown etiology during 5 years (2016-2020).Study place: Children's clinic, hematology department, Tbilisi, Georgia.
Methods: A total of 50 children, aged 2 month to 16 years presenting with anemia, whose cause cannot be established on detailed history, physical and routine laboratory examinations, were referred for bone marrow aspiration during the study period. Patients having malignancies, blast cells on peripheral blood film and other causes associated marrow suppression were excluded from the study.
Results: Out of 50 cases presenting with unexplained anemia, about 7 (14%) made up rare anemias: congenital form of vitamin B12 deficiency anemia-2 (1-Imerslund-Grasbeck syndrome), congenital dyserithropoietic anemia type II-1, pure red cell aplasia (Diamond-Blackfan syndrome)-2, congenital sideroblastic anemia-1, iron refractory iron deficiency anemia 1. It was also revealed bone marrow megaloblastic changes caused by a acquired forms of B12 deficiency-8 (16%), folic acid deficiency-2 (4%).13 cases were iron deficiency anemia (26%),6 cases were of anemia of chronic disease (12%),4 cases as hemolytic anemia unknown etiology (8%).About 5 cases as aplastic anemia (10%). 5 Cases of anemia remain undiagnosed (10%).
Summary/Conclusion: Research data analysis demonstrate that the bone marrow aspiration is essential and necessary and should be performed as soon as possible in all cases of unexplained anemia. This examination successfully provide diagnostic evolution and confirmation of anemia where cause cannot be found by routine laboratory investigations in most cases (90%).It gives us precise direction to conduct additional studies to confirm the diagnosis. Accurate examination of bone marrow is crucial in diagnosis of very rare anemias. The final morphological interpretation of bone marrow aspirate smears reveals specific abnormalities of various anemias and helps hematologists choose the right direction in disease management.

PB1538 CLINICAL MANIFESTATIONS AND COMPLICATIONS IN PEOPLE WITH HEMOGLOBIN C DISEASE

C. Mendes Pires [1], A. P. Martins Rocha Ribeiro [2,*],
J. C. Zambrano Contreras [2], C. Santos Silva [2],
I. Vasconcellos Nunes [2], C. Silva Andrade Costa [3], E. Cunha Pires [4],
J. de Bessa Jr. [2]

[1]Medicina, Escola Bahiana de Medicina e Saúde Pública, Salvador, [2]Medicina e Saúde Coletiva, [3]Medicina, UEFS, Feira de Santana, [4]Medicina, UFBA, Salvador, Brazil

Background: Hemoglobin C disease is a type of hemolytic anemia, like sickle cell disease, caused by a structural change on the beta globin gene, which provokes a tendency to hemoglobin cristalization.The disease manifests itself when the two genes in beta globin are altered (HbCC). It usually develops with mild to moderate hemolytic anemia, splenomegaly (most frequent symptom), target cells, HbC crystallization, reticulocytosis and low mean corpuscular volume (CMV).HbC has an affinity slightly reduced by oxygen and tends to crystallize in its oxygenated form, there are more dehydrated, dense, viscous and less deformable erythrocytes, which, however, does not lead to vaso-occlusive crises as occurs in the presence of HbS.There are few reports in the literature about its prevalence in the population and its clinical behavior.
Aims: Describe the clinical manifestations and complications in people with hemoglobin C disease assited in a sickle cell disease reference center in Feira de Santana (BA), Brazil and promote a critical reflection of the multidisciplinary team.
Methods: Descriptive observational study of a case series with 13 children with hemoglobin C disease diagnosed by electrophoresis. Interviews were conducted alongside medical record review to analyse the participants social and clinical variables, as well as laboratorial behavior through hemoglobin levels (Hb).
Results: The studied population consisted of children aged 2-18 years, with the majority of people being in the age group 5-7 years (46.2%).11 particpants were female with an average of 6.6±2.1 years old and 9 identified themselves as black or brown. Regarding the use of medications, 12 people reported use of folic acid, 3 used profilatic penicilin, 4 used painkillers because of painful episodes and 3 reported use of other medications. Concerning clinical manifestations, 1 person had splenomegaly; 5 reported mild to moderate painful episodes in the last 12 months; 7 reported acute chest syndrome (ATS) as complication; no one had any target-organ damage or had gone through blood transfusion in the last 12 months. The hemoglobin levels varied between 8.6-12.6g/dL with an average of 11.3±0.9 g/dL, 4 patients didn't have anemia, 3 had mild anemia and 3 others had moderate anemia.

Clinical and Sociodemographic Characteristics		N (13)	%

	Acute Chest Syndrome	7	53,8

In the last 12 months.

Summary/Conclusion: This study showed that people with hemoglobin C disease had mild clinical manifestations. Studies are needed to better understand it's pathophysiology as well as coohort studies to evaluate the clinical evolution of the disease and it's clinical manisfestions.That way, people with hemoglobina C disease will be able to receive a better defined and beneficial treatment, one that isn't based only on what is known and established for sickle cell anemia.

PB1539 PROSPECTIVE ANALYSIS OF NEWLY DIAGNOSED AUTOIMMUNE HEMOLYTIC ANEMIA: A SINGLE CENTER STUDY

D. Pulanic [1,*], M. Raos [2], G. Salai [3], M. Vodanovic [4], A. Boban [1], M. Mikulic [4], S. Basic Kinda [4], D. Dujmovic [4], P. Roncevic [4], J. Batinic [4], A. Ostojic [4], L. Desnica [4], I. Radman [4], R. Vrhovac [1], B. Golubic Cepulic [2], I. Aurer [1]

[1]Department of Internal Medicine, Division of Hematology, University Hospital Center Zagreb and School of Medicine, University of Zagreb, [2]Department of Transfusion Medicine, University Hospital Center Zagreb, [3]School of Medicine, University of Zagreb, [4]Department of Internal Medicine, Division of Hematology, University Hospital Center Zagreb, Zagreb, Croatia

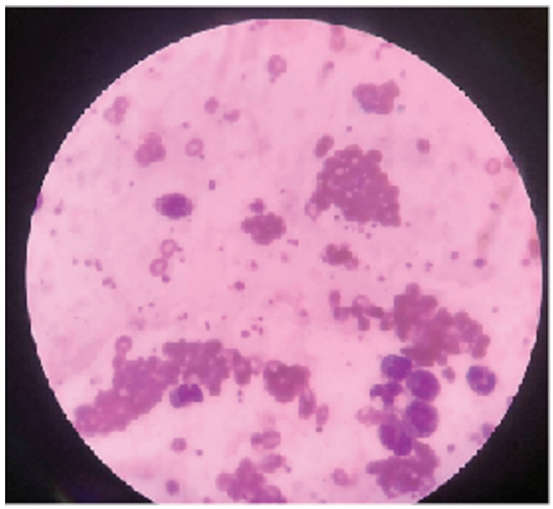
Background: Autoimmune hemolytic anemia (AIHA) is an autoimmune-mediated disease in which erythrocytes are destroyed through (auto)antibodies against their surface antigens, resulting in premature lysis. It is a rare disorder and data about characteristics of AIHA from clinical practice are rare, especially if collected prospectively.
Aims: This prospective study was conducted in order to analyze characteristics of patients with newly diagnosed AIHA.
Methods: A single-center prospective study was performed at the University Hospital Center Zagreb (UHC), a tertiary center and the largest Croatian hospital, which included all consecutive patients with a newly diagnosed direct antiglobulin test positive AIHA from 1st Jan 2019 to 31th Dec 2020. Study was approved by UHC Ethical Committee. Descriptive statistics were performed and results are reported as frequencies (percentage) for categorical and as means (±standard deviation) or medians (minimum-maximum), as appropriate, for continuous values.
Results: Data includes 17 patients (41% men), median age at diagnosis 52 (5-76) years. Majority of patients had secondary AIHA (14/17, 82%), mostly due to underlying lymphoproliferative malignant disease (7/14 patients, 50%). 4 had underlying autoimmune disorders, 1 solid cancer, 1 developed AIHA after allogeneic bone marrow transplantation, and 1 after *M. pneumoniae* infection. Median hemoglobin (Hb) at diagnosis was 74 (39-124) g/L; 12 (71%) patients required hospital care with admission Hb of 58 (39-124) g/L, and 10 (59%) received erythrocyte transfusion. 15 (88%) patients required therapy with corticosteroids, and 6 (35%) received rituximab (as the first line therapy in 3/6 (50%) of patients). Patients were followed with a median time of 474 (22-648) days during which 13 (76%) achieved complete remission (CR) without signs of hemolysis or anemia, 1 showed improvement but failed to achieve normal Hb levels, 1 was refractory to therapy, and 2 were lost to follow-up. Median time from diagnosis to best response was 137 (43-606) days. Of 13 patients in CR, 2 (15%) relapsed which was observed 260 and 363 days after remission. During follow up 2 patients suffered from COVID-19 infection, but neither showed signs of AIHA relapse. 2 patients died during follow-up due to AIHA-unrelated causes.
Summary/Conclusion: Although with relatively small number of patients, this prospective study of newly diagnosed AIHA patients showed increased percentage of rituximab administration (from 17.6% to 35%) comparing to our previous retrospective single-center analysis from 2014 to 2018 (EHA library: Pulanic D, et al. 2019;PB 1963.). This is probably due to the increase of rituximab availability due to lower costs and more experience with this treatment modality.

PB1540 EPIDEMIOLOGICAL CHARACTERS OF ADULT EGYPTIAN AUTO IMMUNE HEAMOLYTIC ANEMIA PATIENTS: A SINGLE CENTER EXPERIENCE

Y. Essam [1], M. Elbogdady [1,*], E. Jamal [1]

[1]Hematology, Oncology center Mansoura university - Mansoura university - Egypt, Mansoura, Egypt

Background: Auto immune Heamolytic anemia (AIHA) is a widely used title for a variety of anemia types which are mostly diagnosed by exclusion and comprises a lot of symptoms and signs with a myriad of complications. No age is immune with majority being middle-aged with a significant female predominance over male patients. It could be primary or secondary to many factors but mostly other immune disorders. The treatment may include a watch and wait strategy with regular tonics or the major used line corticosteroids and if the patient fails this immunosuppressive drugs might be added or replace corticosteroids with the increased use of monoclonal antibodies especially rituximab and splenectomy still remains an option for resistant cases with certain types of chemotherapeutic agents. The burden of such medications and their associated toxicities affect the patient adherence to therapy itself and follow up dates which requires meticulous and tailored treatment choices for each patient to decrease disease complications and treatment related adverse events and ensure the patient compliance.
Aims: The Aim of this study is to outline the Demographic characters of Egyptian AIHA patients on regular follow up at an adult academic hematology center in Egypt and the characters of their disease
Methods: This is a descriptive study regarding Adult (above the age of18) AIHA patients on follow up with the clinical hematology unit Oncology center Mansoura University, Dakahlia, Egypt who had recorded follow up visits on our System in the period between 2005 and 2021 regarding their age at diagnosis, sex, baseline criteria, presence of crisis or not method of diagnosis and their follow up regimen.
Results: By reviewing the data on our system over the period of 1-1-2005 and 1-1-2021 we found that we have 228 AIHA anemia patients with 25 males (10.8 %) and 203 females (89.2 %), The average age at diagnosis at our center was 45 years with the range of 16 – 72 years, The median follow up of our patients was 61 months (180 – 6).All patients with follow up under 6 months were excluded from final analysis. 77.9 % of our patients were primary AIHA while the remaining 22.1% were secondary from which 41.6% were secondary to Viral hepatitis, 16.6% to both of Myelodysplastic syndrome and Systemic lupus erythrmatosis and 8.3% to pregnancy, rheumatoid arthritis and Antiphospholipid syndrome.The average hemoglobin at diagnosis was 7 gm/dl with the range (3 – 12), average White blood cell count was 8 $x10^3$/ ml (3 - 67) and platelets average was 205 $x10^3$/ ml (5 - 387). 15.2% of our patients had immune thrombocytopenia and were considered to be having Evan's syndrome while the other 84.8 had normal platelets count. As regard direct coomb's test 91.5 % were positive while the remaining 8.5 % were negative while the indirect coomb's test was positive in 71.2 % and negative in 28.2 %. 75% of our patients required packed red blood cells transfusion during their course of the disease while the rest were not transfused.
Summary/Conclusion: Patients with AIHA need more care and psychological support with increasing the awarence regarding their disease characters and complications with an increased need for further progress in the treatments avaibale for them to ensure longer and more stable remissions



PB1541 HEMOLYTIC ANAEMIA COMPLICATING PREGNANCY

F. A. P. Karlath [1,*], P. V K [1], K. Beevi [1], H. M [1]

[1]Internal Medicine, Government Medical College Kannur, Pariyaram,Kannur, India

Background: Hemolytic anaemia and pneumonia are uncommon complications of pregnancy.Most common aetiological agents of pneumonia in pregnancy are typical bacterial pathogens,like Streptococcus pneumoniae,Haemophilus influenzae and atypical bacterial pathogens,like Mycoplasma pneumoniae,Chlamydia pneumoniae and Legionella pneumophilia.
Aims: Unfortunately,the incidence of Mycoplasma pneumonia in pregnant women and the probability of spontaneous abortion is unknown. Also,the association between risk for abortion in patients complicated by secondary autoimmune hemolytic anaemia is yet to be established.
Methods: A 31 year old woman,with no known comorbidities in the past,$G_2P_1L_1A_0$,at 12 weeks period of gestation,presented with fever,cough and breathlessness for 2 weeks.Upon physical examination,patient appeared ill,dyspnoeic,with significant pallor and icterus,had bilateral basal crepitations and 12-14 weeks relaxed uterus.Initial investigation reports revealed anaemia,indirect hyperbilirubinemia,elevated LDH and reticulocyte count,and,single live intrauterine gestation 11 weeks 4 days on USG abdomen.
Results: Positive direct coombs test,high cold agglutinin titer with anti-I specificity and peripheral smear examination (figure 1) showing agglutination of RBCs with normal platelets,increased number of WBCs without immature cells,pointed towards immune hemolytic anaemia,suggestive of cold agglutinin disease.Bone marrow biopsy was not indicative of any hematological malignancy.Though steroids,blood transfusion(O negative)and antibiotics were initiated,she developed bleeding per vagina and products of conception expelled with fetus.Acute hemolysis complicating Mycoplasma pneumoniae infection seemed the most likely diagnosis,which was confirmed serologically with positive

antimycoplasma IgM and high antibody titer by complement fixation. Chest X-ray showed high-density area in right lower lobe.Azithromycin was given along with steroids.Patient improved and she remains clinically well,with no recurrence of jaundice

Summary/Conclusion: We report a unique case of Mycoplasma pneumonia complicating pregnancy,resulting in spontaneous abortion and secondary autoimmune hemolytic anaemia.Though pneumonia in pregnancy can cause severe maternal morbidity and mortality,Mycoplasma pneumonia causing spontaneous abortion isn't a common clinical scenario.Moreover,our patient had severe hemolytic anaemia to such extent that cross matching for blood transfusion was not possible due to autoagglutination.There have been many instances where autoimmune hemolytic anaemias are not evaluated for any secondary causes.This could leave an asymptomatic infection or hematologic malignancy undetected unless progressed to an advanced stage.The infrequency with which it is encountered makes it a formidable diagnostic challenge.We emphasize the need for further studies on association,if any,between the risk of spontaneous abortion in Mycoplasma pneumoniae complicated by secondary autoimmune hemolytic anaemia.

Gene therapy, cellular immunotherapy and vaccination - Biology & Translational Research

PB1542 GENETICALLY ENGINEERED IPSC-DERIVED NK CELLS AS A PROMISING CLINICAL DRUG CANDIDATE FOR THE TREATMENT OF B CELL MALIGNANT LYMPHOMA

Y. Yue [1], X. Song [1], Y. Zhou [1], W. Xu [1], J. Xiong [1], L. Song [1], J. Wu [1], J. Xu [1], Q. Zhang [1], Z. Tian [1], L. Shen [1], Y. Lu [1], G. Li [1], L. Le [1], M. Yang [1], X. He [1], Y. Zhang [1], Y. Wang [2], Y. Hu [2], S. Tan [1], Y. Gao [1,*], H. Huang [2], L. Yang [1]

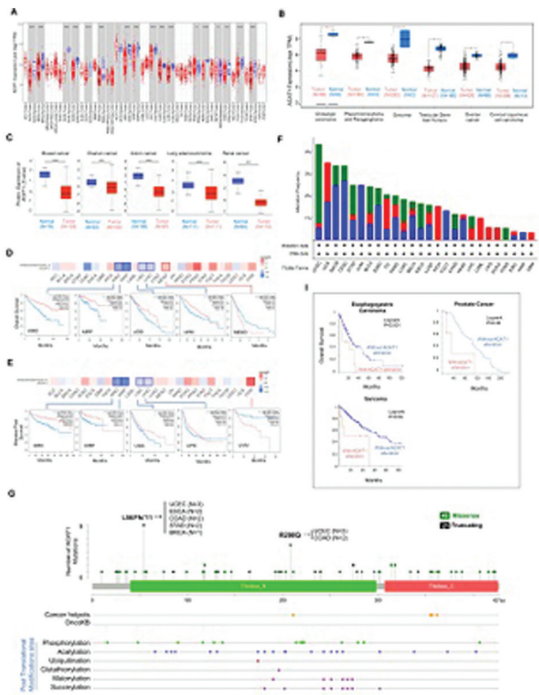
[1]Qihan Biotech, [2]The First Affiliated Hospital, School of Medicine, Zhejiang University, Hangzhou, China

Background: Chimeric antigen receptors (CARs) are synthetic transmembrane receptors designed to target tumor-associated antigen to treat human malignancies. CARs have been used to redirect the specificity of T cells and NK cells against several hematologic cancers with notable clinical responses. Despite their antitumor activity, autologous CAR-modified T cells have many limitations including clinical safety and manufacturing difficulties. NK cells that have been engineered to express a CAR are candidate effectors for cancer treatment. Unlike T cells, allogeneic NK cells do not cause GvHD and can be safely administered without the need of full HLA matching based on previous clinical trials. This eliminates the need to produce a unique, patient-specific CAR product for each patient. A major advantage of NK cells is that they are naturally "off-the-shelf" and can be manufactured centrally so that product is available on-demand and ready-to-use.
Aims: iPSCs, with their ease to be genetically engineered, indefinite expansion capacity in vitro and feasibility to be differentiated into NK cells, are attractive starting cell resources to produce therapeutic NK products.
Methods: Extensive genetic modifications on iPSCs can be achieved by engineering a population of iPSCs, followed by single-cell-derived clone expansion and screening. The resulting iPSC clones carrying homogeneous genetic composition can be used as the MCB for downstream manufacturing.
Results: Here we report some characteristics of NK019 cells, a genetically engineered iPSC-derived NK cell therapy candidate. NK019 cells were differentiated from a modified human iPSC single-cell clone carrying 3 transgenes, including a Chimeric Antigen Receptor (CAR) targeting CD19, a modified CD16 and an IL15 molecule. The 3 transgenes maintain stable expression before and after differentiation from iPSC into NK cells. In addition, NK019 cells display typical NK cell characteristics, with CD19 target-specific cytotoxicity, enhanced antibody-dependent cell-mediated cytotoxicity (ADCC) and constitutively activated IL15 signaling. Furthermore, NK019 cells also show promising in vivo antitumor activity in a Raji NCG mouse model.
Here we report some characteristics of NK019 cells, a genetically engineered iPSC-derived NK cell therapy candidate. NK019 cells were differentiated from a modified human iPSC single-cell clone carrying 3 transgenes, including a Chimeric Antigen Receptor (CAR) targeting CD19, a modified CD16 and an IL15 molecule. The 3 transgenes maintain stable expression before and after differentiation from iPSC into NK cells. In addition, NK019 cells display typical NK cell characteristics, with CD19 target-specific cytotoxicity, enhanced antibody-dependent cell-mediated cytotoxicity (ADCC) and constitutively activated IL15 signaling. Furthermore, NK019 cells also show promising *in vivo* anti-tumor activity in a Raji NCG mouse model. In summary, we have engineered iPSC-derived NK cells as a promising clinical drug candidate for the treatment of B cell malignant lymphoma.
Summary/Conclusion: In summary, we have engineered iPSC-derived NK cells as a promising clinical drug candidate for the treatment of B cell malignant lymphoma.

PB1543 LIR-1 EDUCATES EXPANDED HUMAN NK CELLS AND DEFINES A UNIQUE NK CELL SUBSET WITH POTENT ADCC CAPACITY ATTRACTIVE FOR CANCER IMMUNOTHERAPY ACROSS HLA BARRIERS

C. Leijonhufvud [1,*], R. Reger [2], F. Segerberg [1], J. Theorell [1], H. Schlums [1], Y. T. Bryceson [1], R. W. Childs [2], M. Carlsten [1]

[1]Department of Medicine, Huddinge, Karolinska Institutet, Stockholm, Sweden, [2]National Heart, Lung, and Blood Institute, National Inititutes of Health, Bethesda, United States



Background: NK cells are educated to stay responsive to cells with diminished HLA class I expression as a consequence of viral- or tumor-transformation. Inhibitory KIR and NKG2A receptors are known to educate human NK cells upon interaction with cells expressing their cognate HLA class I ligands.
Aims: To addressed if the inhibitory receptor LIR-1 (LILRB1/ILT2/CD85j) that is widely expressed on human NK cells and mediates inhibition via similar mechanisms as KIR and NKG2A, can mediate education and contribute to anti-tumor functions of NK cells.
Methods: NK cells were obtained from healthy donors and used resting, cytokine-activated or following ex vivo expansion. NK cell phenotype and activation were addressed using flow cytometry, while tumor cytotoxicity was assessed using ^{51}Cr-release assays with flow cytometry cell sorted NK cell subsets. Antibody-dependent cellular cytotoxicity was asses using the monoclonal antibody rituximab.
Results: LIR-1 can mediate NK cell education. This novel finding was exclusive to expanded NK cells and associated with high expression of granzyme B and DNAM-1, which both have been linked to NK cell education. Corroborating the rheostat education model, LIR-1 co-expression with an educating KIR further increased the responsiveness of expanded NK cells. Inversely, antibody masking of LIR-1 decreased the responsiveness. Using rituximab and a panel of CD20$^+$ target cells, LIR-1$^+$ expanded NK cells displayed high intrinsic ADCC that, in contrast to KIR and NKG2A, was not inhibited by HLA class I.
Summary/Conclusion: Overall, these findings define a unique NK cell subset attractive for adoptive cell therapy to treat cancer. Given that LIR-1 binds most HLA class I molecules, this subset may be utilized in both autologous and allogeneic settings to innately reject HLA class I$^-$ tumor cells as well as HLA class I$^+$ target cells when combined with anti-tumor antibodies. Further studies are warranted to explore the potential of this subset in clinical therapy.

PB1544 A PAN-CANCER ANALYSIS OF THE SUPPRESSOR ROLE OF ACETYL-COA ACETYLTRANSFERASE 1 IN TUMORS

X. Hu [1,*], Y. Zhang [1,2], Y. Han [1], X. Zhang [1], Z. Tian [1], X. Wang [1,2]

[1]Department of Hematology, Shandong Provincial Hospital, Cheeloo College of Medicine, Shandong University, [2]Department of Hematology, Shandong Provincial Hospital Affiliated to Shandong First Medical University, Jinan, China

Background: Acetyl-CoA acetyltransferase 1 (ACAT1) is an enzyme to catalyze the condensation of two acetyl-CoAs to make acetoacetyl-CoA as well as the reverse reaction. Recently, the abnormal ACAT1 enzyme activity in diverse cancer cell lines was recently reported. Yet, the roles of ACAT1 in malignant progression have been incompletely understood so far.
Aims: The aim of this study was to investigate the function and significance of ACAT1 in tumors.
Methods: In the present study, gene expression analysis is completed through the TIMER2 and GEPIA2 web, based on the combination of the HPA, GTEx, and FANTOM5 datasets. The data of protein expression is acquired from the CPTAC dataset. The statistical significance of survival prognosis is analyzed by log-rank test. Genetic alteration analysis is accomplished by cBioPortal web.
Results: Aberrantly alleviated expression of ACAT1 was detected in multiple tumors at mRNA level compared with normal cells, such as bladder urothelial carcinoma (BLCA), head and neck squamous cell carcinoma (HNSC) *et al* (Figure 1A). After including the normal tissue of the GTEx dataset as controls, we further evaluated the expression difference of ACAT1 between the normal tissues and tumor tissues of PCPG, SARC, TGCT, *et al*. ACAT1 expression levels were significantly downregulated (tumor versus normal) in above types of tumor (Figure 1B, P<0.05). Similarly, the outcome of decreased protein level of ACAT1 (tumor versus normal) could be obtained (Figure 1C, P<0.001). Next, we investigated the correlation of ACAT1 expression with the prognosis of patients with different tumors. Stratified $ACAT1^{low}$ patients were observed with significantly shorter overall survival (OS) versus the $ACAT1^{high}$ group in kidney renal clear cell carcinoma (KIRC, P<0.001), kidney renal papillary cell carcinoma (KIRP, P<0.001), brain lower grade glioma (LGG, P=0.019) and liver hepatocellular carcinoma (LIHC, P=0.004) (Figure 1D). Likewise, the shorter disease-free survival (DFS) was shown in $ACAT1^{low}$ patients (Figure 1E). Intriguingly, $ACAT1^{low}$ group showed a better OS and DFS than $ACAT1^{high}$ group in mesothelioma (MESA, P=0.02) and uveal melanoma (UVM, P=0.017), respectively. Then, we observed the genetic alteration status of ACAT1 in different tumor samples of the TCGA cohorts. As shown in Figure 1F, the highest alteration frequency of ACAT1 (>7%) appears for patients with uterine tumors. The types, sites, and case number of the ACAT1 genetic alteration are further presented in Figure 1G. We found that missense mutation of ACAT1 was the main type of genetic alteration (N=48). Additionally, we explored the potential association between genetic alteration of ACAT1 and the clinical survival prognosis of cases with different types of cancer. The data of Figure 1H indicated a better overall survival in cases without altered ACAT1 compared with cases with ACAT1 alteration in variety of malignant, such as esophagogastric carcinoma (P<0.001), prostate cancer (P=0.03) and sarcoma (P=0.04).

Summary/Conclusion: Taken together, the present study was the first pan-cancer analysis on the role of ACAT1 in tumors. ACAT1 was down-regulated and conferred independent prognostic significance, highlighting the effectiveness and potential of ACAT1 as a potential target for future therapeutic strategies.

PB1545 THE IMPLEMENTATION OF BLOOD CANCER BIOBANKING IN GALWAY UNIVERSITY HOSPITAL

A. Wrafter [1,*], J. Krawczyk [1], T. Cichocka [2], E. Szegezdi [2], M. Murray [1], R. Gilmore [1], M. O'Dwyer [1], A. Hayat [1], S. Ni Loingsigh [1], Y. Nunez [1], N. Keane [1], T. Meenaghan [1], M. Gurney [1], R. Faryal [1], C. Kelly [1], R. O'Doherty [1], A. Kwiatkowska [1], T. Steede [1]

[1]Department of Haematology, Galway University Hospital, [2]Blood Cancer Biobank, National University of Ireland, Galway, Galway, Ireland

Background: Galway University Hospital (GUH) is the designated cancer centre for the west of Ireland. It has strong links with the National University of Ireland, Galway (NUIG) for training and research. The Blood Cancer Network Ireland (BCNI) established a biobank in NUIG in 2017. With the collaboration of GUH and NUIG, biobanking of peripheral blood and bone marrow aspirate commenced in Galway that same year. Bone marrow procedures are carried out daily in GUH for the diagnosis of haematological disorders. After obtaining informed patient consent, additional bone marrow aspirate and peripheral blood samples for BCNI biobanking are collected at the patient bedside. These samples are transported to NUIG, then processed and stored in the BCNI biobank for future research.
Aims: To establish a blood cancer biobank for use in early phase clinical trials. To optimise sample collection and transport to ensure the integrity of the biobanked sample.
Methods: Implementation involved multidisciplinary collaborations including researchers, consultant haematologists, haematology registrars, advanced nurse practitioner and medical scientists at the BCNI, Galway and the Department of Haematology, GUH. Staff educational sessions were provided by the BCNI. Bone marrow procedures were performed by haematology registrars or the advanced nurse practitioner at GUH. Patient consent for biobanking was obtained prior to the bone marrow proceedure and informational leaflets provided to each patient. The medical scientist ensured that the bone marrow aspirate sample was adequate for the evaluation of the patient's haematological condition and then collected additional samples for biobanking. On return to the Haematology Laboratory the medical scientist arranged transport to the BCNI laboratory in a timely manner, to ensure sample integrity. Samples were processed and stored in the BCNI biobank at NUIG.
Results: Currently, 448 samples have been collected and stored in biobanks at BCNI sites across Ireland. Of these, 62 samples have been provided through the Department of Haematology, GUH. The majority of samples collected have been from patients with Acute Myeloid Leukaemia (AML).
Summary/Conclusion: The implementation of biobanking in GUH has been successful to date. Biobanking has now expanded to include the collection of samples from patients with Monoclonal Gammopathy of Undetermined Significance (MGUS). Additional educational sessions are required to increase awareness of biobanking to all relevant staff in GUH, in order to optimise the collection of samples. Improvement of quality control measures to ensure optimal transport and storage of cells from GUH to NUIG is also required.

Gene therapy, cellular immunotherapy and vaccination – Clinical

PB1546 REAL-WORLD DRUG USE AND COMPLEMENTARY AND ALTERNATIVE MEDICINES PRACTICE IN LYMPHOMA PATIENTS TREATED WITH CAR T CELLS IN A FRENCH UNIVERSITY HOSPITAL

J. BORSATO [1], V. SCHWIERTZ [1], F. RANCHON [1], A.-G. CAFFIN [1], P. SESQUES [2], E. FERRANT [2], V. SAFAR [2], C. GOLFIER [2], C. LEFORT [1], L. HUOT [3], G. SALLES [2], E. BACHY [2], H. GHESQUIERES [2], C. RIOUFOL [1,*]

[1]Clinical Oncology Pharmacy Unit, [2]Hematology, [3]Public Health Department, Hospices Civils de Lyon, PIERRE BENITE Cedex, France

Background: Genetically engineered CAR T cells represent a breakthrough therapeutic innovation for lymphoma patients in second or more relapse. Despite clinical trials, there is a lack of data, especially about drug use and Complementary and Alternative Medicines (CAM). Such data are necessary to optimize patient care and safety and to improve knowledge about this recent population.
Aims: We performed a prospective real-world study to evaluate drug use and CAM practice in lymphoma patients treated with axi-cel, tisa-cel and brexu-cel.
Methods: Data from patients who received CAR T cells between May and November 2020, outside of clinical trials, were prospectively collected and analyzed. Drug use and CAM were collected during an interview between a hospital pharmacist and the patient the day before lymphodepletion chemotherapy and at month 3 after CAR T cell infusion.
Results: 25 successive patients were infused among them 17 patients with DLBCL and one with mantle cell lymphoma were analysed. Patients were treated by axi-cel (11), tisa-cel (7) and brexu-cel (1). Six of the 18 patients were excluded from the study in the first 3 months (1 death, 3 progressions, 2 refusals).
The male/female sex ratio was 1.25 (10/18), and mean age at infusion 59 years [range, 20-77 years], with 100% of the patients with ECOG performance status ≤ 1. Median number of prior therapies was 2 [range, 2-4]. Median Charlson score was 2 [range, 0-5]. Half of the patients were unemployed or retired (n=9) at diagnosis. Some patients were polymedicated (n=9), using ≥ 5 daily prescribed drugs; the most frequent classes were anti-infectious (n=13), anti-ulcer drugs (n=10), cardiovascular drugs (n=4) as well as thromboprophylaxis agents (n=3). 16 patients used analgesics (prescription or self-medication). Psychotropic drugs were taken by 5 patients (28%) to manage stress, anxiety, sleep disorders or depression; 16/18 patients used at least one CAM with a mean of 3.3 [range, 1-12] (Table). No changes of drug use and CAM were observed through the first 3 months following the infusion of CAR T.

Type of CAM	Nb of patients using at least 1 CAM
Natural products	**16**
Herbal medicine	7
Essential oils	7
Vitamins and minerals	7
Other dietary supplements	6
Homeopathy	**4**
Mind and body practice	**5**
Massage therapy	4
Osteopathic manipulation	3
Acupuncture	2
Traditional healers	**4**
Magnetizer	4
Uthotherapy	2
Reason for using CAM	**Nb of patients using at least 1 CAM**
To manage symptoms and side effects	**11**
Pain	6
side effects of chemotherapy	5
asthenia	5
stress and anxiety	3
To improve health and treatment	**7**
to improve health status	5
to improve well being	4
to boost immunity	5
to drain organs	3

Summary/Conclusion: This study provides one of the first datasets on drug use and CAM in lymphoma patients treated by CAR T cells in real-life. Despite CAR T cells bring an innovative and expensive strategy, lymphoma patients continue using CAM to manage health disorders and to boost immunity as other cancer patients treated with chemotherapy. Such results should led us to investigate patients' representations about innovative anticancer drugs.

Hematopoiesis, stem cells and microenvironment

PB1547 SECONDARY HYPERPARATHYROIDISM AND ERYTHROPOETIN-STIMULATING-AGENT REFRACTORY ANEMIA: A CASE OF REVERSIBLE TRANSFUSION DEPENDENCE

B. Ashraf [1,*], I. Ibrahim [2], T. Bat [2]

[1]*Internal Medicine,* [2]*Hematology, UT Southwestern, Dallas, United States*

Background: Anemia is a universal complication of End Stage Renal Disease (ESRD). Erythropoiesis-stimulating agents (ESAs) have fundamentally changed the treatment of anemia of ESRD, greatly decreasing transfusion dependence. However, ESA-resistant anemia is not well studied and a difficult condition to manage. Among the most frequent causes of ESA-resistant anemia is secondary hyperparathyroidism (SHP), which is associated with bone marrow remodeling and bone marrow fibrosis. Treatment goals of SHP are centered on goal calcium, phosphorus and parathyroid hormone (PTH) levels determined largely by consensus, and not pathophysiology including hematologic effects.
Aims: Here we describe a patient with ESRD, SHP with reversible bone marrow changes and transfusion-dependent anemia, as well as descriptive findings of bone marrow changes in patients with anemia and ESRD in our center.
Methods: Using the EMR, the patient's data including demographics, progress notes, laboratoy values, and bone marrow findings were extracted. Subsequently, the EMR was interrogated to reveal all patients with anemia and ESRD, who had a bone marrow biopsy at out center. Data including demographics, laboratory values, bone marrow findings, and medications were extracted. Data was presented descriptively.
Results: A 67-year-old male with ESRD secondary to hypertension and type 2 diabetes was referred to our Hematology clinic for anemia of ESRD. He was receiving epoeitin 20,000 three times weekly. He was transfusion-dependent to maintain a hemoglobin of 6.3 g/dL, with a concomitant PTH of 400.5 pg/mL. Calcium and phosphorus were normal. Bone marrow biopsy revealed focal areas of bone marrow remodeling and reticulin fibrosis. Fluorescence in situ hybridization studies for myelodysplastic syndrome were negative, as were thyroid studies, serum protein electrophoresis (SPEP), and free light chain ratio. In conjunction with his Nephrologist, treatment of his SHP was optimized. His initial regimen was calcitriol 0.25 mcg once daily and calcium acetate 667 mg three times daily. Subsequently, cinacalcet 30 mg twice daily was added and calcium acetate was replaced with sevelamer 1600 mg three times daily. Following these changes, his hemoglobin remained stable in the range of 8-9 g/dL. He became transfusion independent, despite only a modest reduction in PTH to 311.2 pg/mL. Repeat bone marrow biopsy revealed no bone marrow remodeling or reticulin fibrosis.
Bone marrow findings for all patients in our center with ESRD and anemia are summarized in Table 1. The range of PTH for patients with bony remodeling was 183-16161.9 pg/mL versus 90.8-3283 pg/mL for those without bony remodeling. The range of PTH for patients with fibrotic changes was 183-2487 pg/mL versus 90.8-16161.9 pg/mL for those without fibrotic changes.

Table 1: Descriptive Bone Marrow Findings of Patients with ESRD and Anemia Versus PTH Levels

Age	Sex	Race	Ethnicity	Hemoglobin (g/dL)	PTH (pg/mL)	Bone Marrow Fibrosis	Bone Marrow Remodeling
32	F	Black	Non-Hispanic	7.2	2763	Marked Fibrosis	Yes
53	F	Other	Hispanic or Latino	8.6	207.8	None	No
20	F	Black	Non-Hispanic	8.2	246.7	None	No
47	F	White	Hispanic or Latino	8.1	156.4	None	No
74	M	White	Non-Hispanic	9.2	121	None	No
52	M	Black	Non-Hispanic	8.9	116.8	None	No
33	F	White	Hispanic or Latino	8.3	183.2	None	No

Summary/Conclusion: SHP is an increasingly defined cause of ESA-resistant anemia in ESRD. Here we describe a patient with modestly elevated PTH and reversibility of his transfusion-dependent anemia and bone marrow changes following optimized management of his SHP. The degree of reversible ESA-resistant anemia and transfusion dependence in the setting of a PTH elevation to 400.5 in this case is surprising. The great variability in PTH levels of both affected and unaffected patients (i.e. bone marrow changes) presented here indicates the relationship between SHP and anemia is complex. A single level for the whole dialysis population is not appropriate. It may be reasonable to attempt a trial of more aggressive management of SHP in patients with difficult to manage ESA-resistant anemia and only mild-moderate PTH elevation.

PB1548 A POSSIBLE NEW MUTATION IN DNMT3A AS A MARKER OF CLONAL HEMATOPOIESIS

P. Lipilkin [1,*], E. Kulaeva [2], T. Lipilkina [1], E. Mashkina [2], Y. Shatokhin [3]

[1]Biology and General Pathology, Don State Technical University, [2]Genetics, Southern Federal University, [3]Rostov State Medical University, Rostov-on-Don, Russian Federation

Background: DNMT3A is one of the most frequently mutated genes in adult hematological neoplasms, including myelodysplastic syndrome (MDS), acute myeloid leukemia (AML) and myeloproliferative neoplasms (MPN). Probably, the effect of mutations in this gene on disease progression is to destabilize the tetrameric form of DNMT3A and reduce the enzyme activity. Here we report the unexpected discovery of a new mutation in DNMT3A at the Fsp4HI restriction site (2:25234469 - 2:25234473), which was also located in the DNA sequence we examined during the development of a test to identify the most common R882H mutation in DNMT3A using the Fsp4HI restrictase.
Aims: This study was aimed to investigate the possibility of creating a simple restriction test system to diagnose the R882H mutation and determine the possible clinical significance of the new mutation.
Methods: From September 2019 to December 2020 we consecutively recruited 81 patients (43 male and 38 female) with the median age is 57 years (18-87) diagnosed at the Clinic of Rostov State Medical University and City hospital No 7 (Rostov-on-Don), with the following diagnoses: MDS = 31, OML = 30, MPN = 19 (chronic myeloid leukemia (CML) = 17, primary myelofibrosis (PM) = 2). We developed a specific restriction test using Fsp4HI restrictase and original primers. The sequence after PCR contained two Fsp4HI-recognition sites - the target site for R882H and the non-target site in positions (2:25234469 - 2:25234473).
Results: Despite the expected high frequency of R882H (12 to 14% according to different sources), we did not find this mutation in our study. But we did find 5 patients with a mutation in a non-targeted restrictase recognition site, which caused a length-specific unique bend on electrophoresis. We did not find mutations in this region by searching databases (e.g., COSMIC, GenBank), so we tend to believe that the DNMT3A region (2:25234469 - 2:25234473) contains a new mutation, which we plan to confirm by sequencing in the next stage of the study. We found this mutation in 5 (6,17%) patients from our sample (AML = 1, MDS = 1, CML = 2, PM = 1) with clonal hematopoiesis together with other mutations in JAK2 (V716F), BCR-ABL and FLT3/TKD, but not MPL (W515L, W515K).
Summary/Conclusion: During the development of a test system to detect the R882H mutation, we discovered a possible new mutation in the region (2:25234469 - 2:25234473) DNMT3A, which is a common marker for clonal hematopoiesis and is associated with other mutations and requires to determine the exact location and further research as a possible clinical marker.

PB1549 SPONTANEOUS APOPTOSIS IN THE CULTURE OF BONE MARROW`S MESENCHYMAL STROMAL CELLS

K. Vetoshkin [1], M. Butolina [1,*], N. Isaeva [1], N. Minaeva [1], N. Zorina [1]

[1]Kirov Research Institute of Hematology and Blood Transfusion, Kirov, Russian Federation

Background: Mesenchymal stromal cells (MSC) are one of the cell lines for potential use in the treatment of a number of hematological and non-hematological diseases. The basis of successful cultivation is the study of factors influencing the activity of culture's growth. It is known that apoptosis processes can affect the growth parameters of MSC. Apoptosis is programmed cell death resulting from the implementation of its genetic program in response to external signals. One of the universal methods for detecting apoptotic cells is the analysis of the lipid composition of their membrane. Phosphatidylserine molecules are found in large quantities on the surface of the cell membrane at the stage of apoptosis. It can be detected by flow cytometry. Currently, the method of studying programmed cell death by staining cells with annexin 5 conjugated with fluorescein isothiocyanate (AnxV-FITC) and vital DNA dyes (7-aminoactinomycin D (7-AAD) is widely used.
Aims: To assess the relationship between the growth activity of MSC cultures and the number of cells at the stage of apoptosis.
Methods: MSC were obtained from the donors bone marrow (n = 15), whose age ranged from 24 to 46 (median, 26.5) years. Cultivation of MSC was carried out on the surface of plastic flasks under conditions of 5% carbon dioxide at a temperature of 37 ° C. When confluent growth of cultures was achieved, the cells were detached from the plastic using a solution of trypsin. The growth activity of cell cultures was determined by the time the cells of primary seeding (PO) reached the confluent monolayer and the period of cell doubling at passage 1 (P1). Apoptotic cells were distinguished from necrotic cells by spontaneous binding to AnxV-FITC and lack of 7-AAD staining (AnxV-FITC+ 7-AAD-) by laser flow cytometry using a BD FACS Canto II analyzer.
Results: The relative number of MSC with the AnxV-FITC+ 7-AAD- characteristic in the primary culture ranged from 1.3 to 7.9 (median 2.3)% of the total number of MSC, P1 - from 1.7 to 6.0 (median 3.8)%. The period of reaching of confluent monolayer for the primary culture varied from 336 to 528 (median - 456) h, the time of cell doubling on P1 - from 53.4 to 63.3 (median - 58.9) h. A direct relationship between the number of AnxV-FITC+ 7 -AAD- MSC and the time the cells reached the confluent monolayer was found (Pearson's coefficient, r = 0.73). Also a direct correlation between the number of MSC with the characteristic AnxV-FITC+ 7-AAD- and the cell doubling time at P1 was determined (r = 0.83). With increasing of number cells with markers of apoptosis, the longer it takes to achieve confluent growth.
Summary/Conclusion: The number of apoptotic MSC spontaneously binding to AnxV-FITC and unstained with 7-AAD has a direct effect on the activity of culture growth.

Hodgkin lymphoma - Clinical

PB1550 LATE TOXICITIES IN CLASSICAL HODGKIN LYMPHOMA AND DIFFUSE LARGE B-CELL LYMPHOMA SURVIVORS AND LONG-TERM MONITORING: A SERIES OF SYSTEMATIC REVIEWS OF THE FONDAZIONE ITALIANA LINFOMI

C. Minoia [1,*], C. Gerardi [2], E. Allocati [2], V. De Sanctis [3], S. Viviani [4], G. Gini [5], L. Nassi [6], S. Franceschetti [7], A. Daniele [8], A. Bari [9], G. Loseto [1], S. Di Molfetta [10], A. Di Russo [11], V. Caccavari [12], A. Puzzovivo [13], S. Oliva [13], M. A. Annunziata [14], A. Guarini [1]

Ematologia, ASST Ovest Milanese, Legnano, [8]Experimental Oncology and Biobank Management Unit, IRCCS Istituto Tumori "Giovanni Paolo II", Bari, [9]UO Terapie Mirate in Oncoematologia ed Osteoncologia, Dipartimento di Scienze Mediche e Chirurgiche Materno-Infantili e dell'Adulto, Universita' di Modena e Reggio Emilia, Modena, [10]Department of Emergency and Organ Transplantation, Section of Internal Medicine, Endocrinology, Andrology and Metabolic Diseases, University of Bari Aldo Moro, Bari, [11]Radiotherapy Unit, Fondazione IRCCS Istituto Nazionale dei Tumori, [12]Assisted Reproduction Unit, Ilstituto Clinico Citta' Studi, Milan, [13]Cardiology Unit, IRCCS istituto tumori "Giovanni Paolo II", Bari, [14]Unit of Oncological Psychology, Centro di Riferimento Oncologico di Aviano (CRO), Aviano, Italy

Background: In the current years it is estimated that cancer survivors are more than 16 million and it is predicted to reach 22 million by 2030.The prevalence of long-term lymphoma survivors is steadily increasing, and includes mainly histotypes for which biological knowledge and treatments obtained better results. Up today there is a paucity of data on late toxicities affecting lymphoma survivors, thus we still need more data from literature to follow late sequelae of these patients and to set up an organized and evidence based follow-up strategy.
Aims: Researchers belonging to the Fondazione Italiana Linfomi drawn a series of systematic reviews with the aim to:i) evaluate available data and develop homogeneous indications for lymphoma survivors' monitoring using a systematic approach; ii) find a balance between the unmet medical need and the sustainability of healthcare system.
Methods: The research work was carried out by a multi-disciplinary team of 16 researchers of the Fondazione Italiana Linfomi under the methodological supervision of 3 Researchers of the Istituto di Ricerche Farmacologiche "Mario Negri", in Milan. The systematic reviews focused on six topics: cardiotoxicity, secondary cancers, endocrine-metabolic sequelae, fertility and neurological/ cognitive toxicities, healthy lifestyles. The following specific questions were analyzed, considering the population of classical Hodgkin lymphoma (cHL) and Diffuse large

B-cell lymphoma (DLBCL) survivors treated at adult age (≥ 18 years old): i) incidence of the long-term toxicity; ii) comparison with more recent therapies (e.i. modern radiation therapy); iii) best monitoringof long-term sequelae. The search was conducted on 3 bibliographic databases (PubMed, Embase and the Cochrane Library) with also hand searching up to December, 2020. Selection process and data extraction were conducted according to the Preferred Reporting Items for Systematic reviews and Meta-analyses (PRISMA) guidelines.
Results: Six independent systematic reviews were conducted according to the topics of research. A global number of 170 full text papers resulted eligible for data extraction and were included in the final sample. They concerned: cardiotoxicity (n=22), secondary cancers (n=21), endocrine-metabolic sequelae (n=9), fertility (n=46), neurologic and cognitive toxicity (n=62), healthy lifestyles (n=10). The incidence for cardiovascular disease, endocrine-metabolic sequelae, secondary cancers, neurological and anxiety and depression, infertility were calculated and related to risk factors. The optimal detection and monitoring was found out for: i) early left ventricular ejection fraction dysfunction, coronary artery disease, valvular heart disease; ii) secondary acute myeloid leukemias/myelodisplastic syndromes and solid tumors; iii) metabolic syndrome, thyroid, gonadal, and mineral bone disorders; iv) peripheral neuropathy, fatigue, cognitive impairment, anxiety and depression. Fertility preservation and correction of unhealthy lifestyles were also examined. The possible use of Survivorship Care Plans was introduced.
Summary/Conclusion: The final documents could be a reasonable bridge from evidence to decision in order to improve the clinical practice and customize the general follow-up approach of cHL and DLBCL survivors. Data emerged will suggest also direction of future research.

PB1551 RISK FACTORS FOR THE OCCURRENCE OF BLEOMYCIN-INDUCED LUNG TOXICITY IN THE ERA OF POSITRON EMISSION TOMOGRAPHY.

S. Jennane [1,*], M. Ababou [1], M. El Haddad [1], H. El Maaroufi [1], E. M. Mahtat [1], M. Mikdame [2], K. Doghmi [1]

[1]Service d'Hématologie Clinique, Hôpital Militaire d'Instruction Mohammed V, [2]Faculté de Médecine et de Pharmacie de Rabat, Rabat, Morocco

Background: Bleomycin is a major antimitotic agent in the first-line treatment for Hodgkin's lymphoma. The main limitation of its use is its pulmonary toxicity.
Aims: The objectives of this study are to find out the risk factors for the occurrence of bleomycin-induced lung toxicity in patients with Hodgkin's lymphoma, on the other hand to determine if positron emission tomography scan is a reliable means of early detection of this toxicity.
Methods: This is a retrospective study conducted in the clinical haematology department of Mohammed V Military Instruction Hospital of Rabat in Morocco. All patients with Hodgkin's lymphoma and treated with a bleomycin based chemotherapy were included.
Results: Among 124 patients included in the study, 18 (14.5%) patients experienced bleomycin-induced lung toxicity. On multivariate analysis, smoking (p: 0.038) and the use of the ABVD regimen (doxorubicin, bleomycin, vinblastine and dacarbazine) compared to the escalated BEACOPPe (bleomycin, etoposide, doxorubicin, cyclophosphamide, vincristine, procarbazine and prednisone) regimen (p: 0.018) were statistically significant risk factors.
After 2 and 4 courses of therapy, the positron emission tomography was able to predict the occurrence of bleomycin-induced lung toxicity before the appearance of clinical symptoms in 43.7 % and 12.5% of patients, respectively.
Summary/Conclusion: Researches to identify risk factors for the development of bleomycin-induced lung toxicity are crucial to reduce toxicity in the treatment of Hodgkin's lymphoma. However, 2- and 4-cycles positron emission tomography scans cannot be considered as a reliable means of early detection of this toxicity.

PB1552 PROGNOSTIC FACTORS OF WORSE SURVIVAL IN NEWLY DIAGNOSED ADVANCED-STAGE HODGKIN LYMPHOMA IN TAIWAN: A NATIONWIDE RETROSPECTIVE STUDY

T.-D. Tan [1,*], C.-L. J. Teng [2], Y.-W. Lin [3], Y.-Y. Pan [3], P.-W. Lien [4], H.-C. Chou [4], P.-H. Chen [4], F.-J. Lin [3]

[1]Department of Hematology and Medical Oncology, Koo Foundation Sun Yat-Sen Cancer Center, Taipei City, [2]Division of Hematology/Medical Oncology, Department of Medicine, Taichung Veterans General Hospital, Taichung City, [3]Graduate Institute of Clinical Pharmacy, College of Medicine, National Taiwan University, [4]Takeda Pharmaceuticals Taiwan, Taipei City, Taiwan, Republic of China

Background: While the majority of Hodgkin lymphoma (HL) patients are curable, some patients with advanced disease still relapse and have poor prognosis. Although the International Prognostic Score (IPS) or a modified IPS were developed to predict prognosis, therapeutic and imaging modalities of HL have improved over time and their impact among different risk groups has diminished nowadays. It is crucial to identify and assess new prognostic factors in advanced HL patients.
Aims: To identify and assess the prognostic factors for newly-diagnosed HL (NDHL) patients with stage III/IV in Taiwan.
Methods: This study used Taiwan's National Health Insurance Research Database and the Taiwan Cancer Registry. All NDHL patients with stage III/IV who underwent front-line therapy with ABVD or ABVD-like regimens (the standard of care) between 2009 and 2016 enrolled. We randomly split these patients into the development and validation samples by a ratio of 80:20. Cox proportional hazards models were used to identify prognostic factors for overall survival (OS) and time to next treatment (TTNT, as a surrogate for progression-free survival, PFS). Factors with a p-value <0.25 in the univariable model were included in the multivariable model. In the multivariable model, factors with a p-value <0.05 were considered significant, and adjusted hazard ratios (aHRs) with 95% confidence interval (CI) were estimated. Additionally, we used the time-dependent area under the receiver operating characteristic curve (AUC) to assess the model performance.
Results: A total of 459 NDHL patients with stage III/IV were included. At a median follow-up of 4.7 years, the OS was 76%. The median TTNT was 5.1 years. There were 359 and 100 patients in the development and validation samples, respectively. Age (45-59 years: aHR 2.4 [95% CI 1.2-4.7], 60 years or older: aHR 9.9 [5.9-16.8]; both compared to age <45) and extra-nodal disease (aHR 1.8 [1.1-2.9]) were significant factors associated with a shorter OS in the final model. The mean time-dependent AUC was 0.82 in the development sample and 0.81 in the validation sample. With regard to disease progression, patients with older age (45-59 years: aHR =1.2 [0.8-1.9], 60 years or older: aHR 2.3 [1.6-3.3]) and extra-nodal disease (aHR 1.5 [1.1-2.1]) also had significantly shorter TTNT. The mean time-dependent AUC was 0.61 in the development sample and 0.65 in the validation sample.
Summary/Conclusion: In NDHL patients with stage III/IV, older age and extra-nodal disease were important prognostic factors for both shorter OS and shorter TTNT. Furthermore, the discrimination ability of the OS model was excellent. Since laboratory data were not available in the present study, further studies that evaluate all HL-related clinical factors may be required to validate the findings and provide a more comprehensive evaluation.

PB1553 BRENTUXIMAB VEDOTIN IN COMBINATION WITH NIVOLUMAB, DOXORUBICIN, AND DACARBAZINE IN NEWLY DIAGNOSED PATIENTS WITH ADVANCED HODGKIN LYMPHOMA (SGN35-027, TRIAL IN PROGRESS)

I. Flinn [1,*], J. D. Friedman [2], L. Ho [3], H. J. Lee [4]

[1]Sarah Cannon Research Institute and Tennessee Oncology, Nashville, [2]University Hospitals Seidman Cancer Center, Cleveland, [3]Seagen Inc., Bothell, [4]MD Anderson Cancer Center, Houston, United States

Background: Brentuximab vedotin (BV, ADCETRIS®) is approved for the treatment of adults with treatment-naïve Stage III or IV classical Hodgkin lymphoma (cHL) in combination with doxorubicin, vinblastine, and dacarbazine (AVD) (Connors 2017). Nivolumab is approved for treatment of adults with relapsed/refractory cHL. Both agents have been well tolerated with promising activity when combined with multiagent chemotherapy. The combination of BV plus nivolumab was evaluated as a frontline treatment option for patients (pts) with cHL who are over 60 years and ineligible for or declined conventional combination chemotherapy (Yasenchak 2020). The ongoing study reported an overall response rate (ORR) of 82% in 11 pts and appears well tolerated in this population. In another trial in 93 pts in the first salvage setting, the combination produced a 67% complete response (CR) rate (Herrera 2018, Moskowitz 2019) and the majority of pts were able to undergo subsequent stem cell transplant. It is reasonable to expect that the combination of BV, nivolumab, A, and D (AN+AD) will result in high response rates and be well tolerated, with potentially less toxicity relative to A+AVD.

Aims: Part A will evaluate the efficacy and safety of A+AVD when administered with growth factor prophylaxis in pts with Stage III/IV cHL. Part B will evaluate the combination of AN+AD in pts with Stage I or II cHL with bulky mediastinal disease or Stage III or IV cHL. Part C will evaluate the efficacy and tolerability of AN+AD in pts with Stage I or II cHL without bulky disease. The primary objective of Parts B and C is to estimate the CR rate at end of treatment (EOT) in pts with treatment-naïve cHL.
Methods: SGN35-027 (EudraCT 2020-004027-17) is an open-label, multiple part, multicenter, phase 2 clinical trial. Approximately 240 pts will be enrolled in this study: approximately 40 in Part A, 50 in Part B, and 150 in Part C. Part A has completed enrollment, and Part B is fully enrolled. Pts in Parts B and C will be treated with BV 1.2 mg/kg, nivolumab 240 mg, doxorubicin 25 mg/m^2, and dacarbazine 375 mg/m^2, administered separately by IV infusion on Days 1 and 15 of each 28-day cycle. Pts in Part B will receive up to 6 cycles of treatment; pts in Part C will receive 4 cycles. Efficacy will be assessed by PET/CT scans at Cycle 2 and EOT; disease response and progression for Parts B and C will be assessed using the LYRIC modification of the Lugano Classification Revised Staging System for nodal non-Hodgkin and Hodgkin lymphomas (Cheson 2016). Pts will be followed for disease progression and overall survival for 5 years. Enrollment is ongoing in the US, with plans for rest-of-world expansion for Part C.
Results: N/A
Summary/Conclusion: N/A

PB1554 OUTCOMES AFTER INITIAL REFUSAL OF CURATIVE TREATMENT IN PATIENTS WITH HODGKIN LYMPHOMA IN BRITISH COLUMBIA

M. Chahal [1,*], A. Jiang [2], A. Hayden [3], K. Savage [4], D. Villa [4], D. Scott [4], A. Gerrie [4], A. Lo [5], M. Chan [5], T. Pickles [5], J. Connors [4], L. Sehn [4], C. Freeman [4]

[1]Medical Oncology, BC Cancer and the University of British Columbia, [2]2.British Columbia Cancer Research Centre, Vancouver, [3]Hematology, BC Cancer, Surrey, [4]Centre for Lymphoid Cancer and Division of Medical Oncology, BC Cancer and the University of British Columbia, [5]Division of Radiation Oncology, BC Cancer, Vancouver, Canada

Background: Classical Hodgkin lymphoma (cHL) is considered a highly curable cancer. With standard combination chemotherapy regimens, long-term survival exceeds 95% for limited-stage and 85% for advanced-stage patients. Despite these excellent outcomes some patients delay or decline conventional treatment for cHL. We retrospectively assessed the impact of initial treatment refusal on outcomes of patients with cHL in British Columbia (BC).
Aims: We retrospectively assessed the impact of initial treatment refusal on outcomes of patients with cHL in British Columbia (BC).
Methods: Using the BC Cancer Lymphoid Cancer Database, we identified all patients aged 18-70 diagnosed between 1st Jan 1999- 31st Dec 2020 that had documented treatment refusal at initial presentation ('refusers' defined as not receiving or delaying treatment > 16 weeks). We identified a control cohort (min. 3 controls/refuser) treated within 8 weeks of diagnosis, matched for age, stage, diagnosis date within 3 years, and blinded for outcome. All patients had centrally reviewed biopsies and were treated with ABVD or ABVD-like regimens +/- radiotherapy if appropriate. Patient and disease characteristics at baseline and at time of treatment were analyzed with Chi-squared test and one-way ANOVA test. The Kaplan-Meier method was used to assess progression-free survival (PFS) and overall survival (OS), and statistical significance between groups was determined using the log-rank test.
Results: We identified a cohort of 15 patients who initially refused treatment and 47 matched controls. The control cohort was well-matched, with no statistically significant differences in baseline characteristics (age, sex, Ann Arbor stage, B symptoms, International Prognostic Score (IPS) score, ECOG PS, and disease bulk) between groups. The most common reason for initial treatment refusal was to pursue alternative therapy (73%). 13 of 15 refusers eventually accepted treatment (mean time to treatment 76 weeks [range 26-214] vs. 5 weeks [range 1-8] for controls, $p < 0.001$). At time of treatment, the proportion of refusers with advanced-stage disease increased from 20% to 62% ($p = 0.03$) and had an associated alteration of treatment plan, and 62% of patients developed higher risk disease with increased IPS score ($p = 0.02$). At median follow-up of 5 years (0.4-21 years) for all living patients, estimated 5-year PFS was 65% vs 84%, and 5-year OS was 93% vs 98% for refusers and controls respectively. With extended follow up, 13% of refusers (1 late death at 8 years) compared to only 4% of controls died of cHL specifically.
Summary/Conclusion: This study highlights the impact of treatment refusal in this highly curable malignancy. Initial refusal of treatment is associated with progression of stage, worsening prognostic score, escalation to more prolonged treatment than required at diagnosis, and increased risk of death from cHL. This analysis may help to provide guidance to counselling physicians, as well as inform patients who may be considering alternatives to standard of care for cHL.

PB1555 RETROSPECTIVE STUDY TO DESCRIBE TREATMENT PATHWAYS, OUTCOMES, AND RESOURCE USE IN PATIENTS WITH CLASSICAL HODGKIN LYMPHOMA (B-HOLISTIC): RESULTS FROM THE SUBGROUP ANALYSIS OF PATIENTS FROM CHINA

Y. Song [1,*], T. Du [1]

[1]Peking University Cancer Hospital, Beijing, China

Background: Classical Hodgkin Lymphoma (cHL) constitutes 95% of all reported cases of HL and is often cured with chemotherapy. Approximately 10% to 20% of the patients progress to relapsed/refractory cHL (RRHL), requiring intense treatment with chemotherapy and hematopoietic stem cell transplantation (SCT). Differences in clinicopathological characteristics based on geographical and socioeconomic status are reported previously.
Aims: In this subgroup analysis of the B-CD30+ HOdgkin Lymphoma International Multicenter Retrospective Study of Treatment PractIces and OutComes (B-HOLISTIC) (NCT03327571) study, we report the treatment pathways and outcomes in patients from China with cHL and RRHL.
Methods: This retrospective, multicenter, observational study retrieved data from the medical records of patients (≥18 years) with a diagnosis of stage IIb-IV cHL between January 1, 2010 and December 31, 2013 who have received frontline treatment with chemotherapy with or without radiotherapy (Group 1) and of patients with a diagnosis of RRHL (Group 2). Patients who progressed from cHL to RRHL during the study period were included in both the groups. The primary end point was progression-free survival (PFS) in patients with RRHL and the secondary end points were overall survival (OS), best clinical response, and incidences of adverse events (AEs). Survival analysis (OS and PFS) was performed using Kaplan Meier method, and the differences in baseline factors were adjusted with multivariable analysis.
Results: In all, 93 and 34 Chinese patients were enrolled in the cHL and RRHL groups, respectively (27 patients in the cHL group progressed to RRHL and were included in both the groups). The median age (range) of patients at diagnosis in the cHL group was 33 (18-88) years, and 62/93 (66.7%) patients were males. The distribution of clinical stage (Ann Arbor staging) at cHL diagnosis was as follows: stage II, 18/93 (19.4%); stage III, 43/93 (46.2%); stage IV, 32/93 (34.4%). All patients in the cHL group received first-line chemotherapy, with doxorubicin, bleomycin, vinblastine, dacarbazine (ABVD; 78/93 [83.9%]) and bleomycin, etoposide, doxorubicin, cyclophosphamide, vincristine, procarbazine, prednisolone (BEACOPP; 17/93 [18.3%]) being the most prevalent chemotherapeutic regimen. A total of 12/93 (12.9%) patients in the cHL group also received consolidation radiotherapy. The median age (range) at diagnosis for patients in the RRHL group was 34 (20-73) years, and 20/34 (58.8%) were males. At RRHL diagnosis, intensive second-line chemotherapy was used in 31/34 (91.2%) patients: the common regimens used in second line were BEACOPP (5/34 [16.1%]), cyclophosphamide, doxorubicin, vincristine, prednisone (CHOP) (5/34 [16.1%]), and ABVD (4/34 [12.9%]). Of the 34 patients with RRHL, 28 (82.4%) were eligible for hematopoietic SCT at relapse/refractory diagnosis; Among the 34 patients, 13 patients (38.2%) patients underwent autologous SCT and 1 patient underwent allogenic SCT. Median PFS (95% confidence interval) for the RRHL group was 9.53 (3.84-20.43) months, with estimated 1-, 3-, and 5-year PFS rates of 43%, 29.8%, and 29.8%, respectively (Table 1). Median OS was not reached for both the groups. AEs were reported by 67/93 (72%) patients with cHL and 31/34 (91.2%) patients with RRHL.

Table 1. Clinical Outcomes for Chinese Patients

	cHL (n=93)[a]	RRHL (n=34)
Best clinical response, n (%)[b]		
Complete remission	50 (53.8)	6 (17.6)
Partial remission	27 (29)	16(47.1)
Unconfirmed complete remission	3 (3.2)	0
Stable disease	6 (6.5)	3 (8.8)
Progressive disease	6 (6.5)	8 (23.5)
Unknown[c]	4 (4.3)	1 (2.9)
PFS % (95% CI)		
1-year	81.6 (71.7, 88.3)	43 (25.6,59.3)
3-year	61.8 (49.9, 71.7)	29.8 (15, 46.1)
5-year	55.1 (42.3, 65.8)	29.8 (15, 46.1)
OS, % (95% CI)		
1-year	98.8 (91.5, 99.8)	96.9[d] (79.8, 99.6)
3-year	87.4 (77.1, 93.3)	77.9[d] (59.1, 88.8)
5-year	80.5 (68.6, 88.3)	66.5[d] (46.4, 80.5)

Abbreviations: cHL, classical Hodgkin lymphoma; CI, confidence interval; OS, overall survival; PFS, progression-free survival; RRHL, relapsed/refractory cHL.
[a] 27 patients with an initial diagnosis of cHL progressed to RRHL during the study period and were included in both the groups. [b] Best clinical response after completion of first-line treatment. [c] Unknown: there is no entry in the medical record or patient chart relating to an item as confirmed by the site. [d] OS from diagnosis of cHL.

Summary/Conclusion: Subgroup analyses of Chinese patients from the B-HOLISTIC study reveal that the PFS remains low in patients with RRHL in real-world clinical practice in China. This emphasizes the unmet need for novel targeted therapies to improve survival in patients with RRHL.

PB1556 THE PARTICULARITY OF MANAGEMENT OF PEDIATRIC HODGKIN LYMPHOMA IN TUNISIA: MONOCENTRIC STUDY

R. Mansouri [1,*], Y. KHAYATI [1], K. KACEM [1], D. Jabeur [1], E. BERRED [1], M. ACHOUR [1], S. Kefi [1], M. BCHIR [1], M. BAHRI [1], R. KHARRAT [1], H. BEN NEJI [1], Y. BEN ABDENNEBI [1], L. AISSAOUI [1], R. BEN LAKHAL [1], B. MEDDEB [1]

[1]Haematology, Aziza Othmana Hospital, Tunis, Tunisia

Background: The pediatric Hodgkin lymphoma (PHL) treatment particularity is to guarantee the efficacy with toxicity reduction. This was the objective of the first European protocol of PHL treatment: Euronet-PHL-C1. It consisted of the early FDG-PET response assessment. The indication for radiotherapy is based on early response evaluation by TEP scan. In Tunisia, the Euronet-PHL-C1 protocol has been used since 2012 with some modification because of the difficulty of the FDG-PET access. So, the early response assessment was based on whole body CT scan and the radiotherapy was maintained.
Aims: The objectives of the study were to analyze the characteristics of PHL and the therapeutic response.
Methods: A retrospective study was involving 49 patients, with PHL, treated with Euronet-PHL-C1 protocol modified, in the clinical hematology department of Aziza Othmana Hospital of Tunis, between 2013 and 2019.
Results: The median age was 13 years with a sex ratio of 1.59. Twenty-two children had less than 2 lymph nodes regions affected. Thirty-two patients didn't have B symptoms. Ten had a large mediastinum in the chest x-ray. Thirty- two had an ESR≥ 30mm. Localized stages represented the majority (67%). Twenty-two had a CHIPS score between 1 and 4 (i.e. 24%). Nine patients belonged to therapeutic groups TG1 group, 24 to TG2 group and 16 to TG3 group. All the three TG received two OEPA cycles. The TG2 and TG3 received after the both OEPA courses, 2 and 4 COPDAC courses, respectively. The radiotherapy of in-volved fields (IF) is done for all TG. The assessment is based on whole body CT scan. The overall response rate (ORR) after 2 OEPA courses was 100%. The ORR after 2 COPDAC regimens was 95%. The ORR after 4 COPDAC regimens was 100%. Forty among the 49 patients received a radiotherapy of involved fields. Four patients (8%) had a pro-gressive disease: two during the chemotherapy and two before the radiotherapy. These patients belonged to the high risk relapse group of the Euronet-PHL-C1 protocol (RG3) and were in indication for treatment intensification. The Overall survival rate (OS), the event free survival (EFS) and the relapse free survival (RFS) were respectively, 95%, 80% and 99%.
Summary/Conclusion: PHL had a good prognosis. To maintain these excellent results and to limit the long-term consequences by using the FDG-PET to omit the radiotherapy.

PB1557 LONG-TERM OUTCOME OF HODGKIN'S LYMPHOMA CASES IN A POPULATION-BASED CANCER CENTER

S. Alshemmari [1,*], S. Alottaibi [2], A. Akrama [2], A. Hamada [3], A. Alraihan [2]

[1]Kuwait University, [2]Kuwait University, Jabriya, [3]Hematology, Kuwait Cancer Center, Shuwaikh, Kuwait

Background: Background: Hodgkin's lymphoma (HL) is a common malignancy among a young population with a reported improved outcome. There has been major changes in the mamagement stratgies of HL over the past two decades; less chemotherapy and smaller RT filed and dosing. In the current study, we report the long-term outcome in a population-based cancer center after adotping the changes in management in our HL cases.
Aims: The aim of the study is to monitor the long-term outcomes of treatment strategies adopted from international studies thar were implemented in a community-based cancer senetr
Methods: Data from consecutive sets of patients diagnosed with HL between 2000-2016 were collected by ERIC and subjected to detailed statistical analysis. Collected variables included: demographics, stage at diagnosis, treatment, treatment response, and death. Early favorable-early stage HL cases were generally treated with abbreviated ABVD courses (2 cycles) followed by involved-field radiotherapy (IFRT). Unfavorable-early stage HL cases were treated with four courses of ABVD and IFRT (20 Gry). 6 courses treated advanced stage HL cases of ABVD.
Results: 186 cases are included in this analysis. The majority were males, representing 57.5% of the cases. The majority are adolescents and young adults, between 20-40 years, with a median age of 31. The most common histology is Nodular sclerosis, representing 59% of all diagnosed cases. The median progression-free survival (PFS) among the entire group is 159 (CI:144-175) months. The median survival among the early stages HL is 160(CI:8-144) months compared to 150 (12_125) months in the unfavorable early stages(P value=0.5). The advanced favorable HL PFS is 99 (CI:85-114), compared to 150 (12-125) months among the unfavorable group (p=0.06)

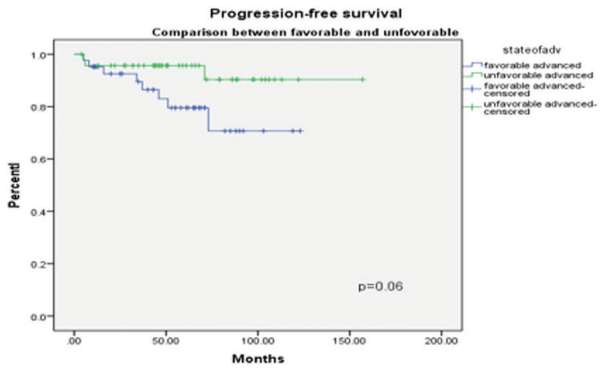

Figure 1: PFS among the advanced cases, comparing favorable vs. unfavorable.

Summary/Conclusion: We report the long-term survival among the local HL cohort from Kuwait. The cohort achieved long-term survival compared to the historical data. There is no difference between the favorable and the unfavorable early stages HL cases. The outcome represents a non-inferiority in the early favorable patients treated with short courses of ABVD and limited RT. There is no difference in survival among advanced stages HL; favorable vs. unfavorable. However, there a trend of lower survival among the favorable group. This finding warrants longer follow-up.
Key-words: Hodgkins lymphoma' outcome, lon-term

PB1558 HODGKIN'S LYMPHOMA IN ADOLESCENTS TREATED WITH ABVD

B. Sidi Mohamed El Amine [1,*], H. Asma [1], B. Soraya [1], Z. Zahia [1], O. Fouzia [1]

[1]Hematology department, Universitary Hospital Of Sidi Bel Abbes, Sidi Bel Abbés, Algeria

Background: The standard treatment for adolescent patients with Hodgkin lymphoma (HL) is not well defined, especially in the choice between pediatric and adult protocols.
Aims: To compare the risk factors and the therapeutic results of adolescents and young adults with HL treated with ABVD.
Methods: 98 patients treated in our department between 2000 and 2015 were analyzed: 33 adolescents aged between 15 and 21 years, and 65 young adults aged between 22 and 39 years. All patients received the

ABVD protocol as initial chemotherapy, followed in 65 (66.3%) by radiotherapy. We compared the characteristics of patients of the two populations using Fisher's exact test. Survival was estimated using the Kaplan and Meier method, and compared by the log rank test. A Cox proportional hazards model regression was used to assess prognostic factors in adolescent patients.
Results: Histologic type 2 as well as hypoalbuminaemia were more common in adolescent patients (P = 0.05, P = 0.02 respectively). The incidence of other risk factors is not significantly different between the two populations. With a median follow-up of 67 months, overall survival (OS) and 5-year event-free survival (EFS) rates are of 79% and 72% for all the patients. The overall complete remission rate (CR) is 87.8%, 84.8% for adolescents and 89% for young adults (P = 0.53). The log rank test showed no significant difference between the two age groups in OS (P = 0.31) or EFS (P = 0.51). At 5 years, the estimate of OS and EFS are of 77% and 74% for young adults, 73% and 68% for adolescents, respectively. After Cox model analysis, two factors were important for the prognosis of adolescent patients: massive tumor involvement (P = 0.008) and extranodal involvement (P = 0.04).
Summary/Conclusion: The prognosis and risk factors of adolescent and young adult patients with HL, treated with ABVD are comparable. These data suggest that adult treatment protocols are safe and an effective option for adolescent patients.

PB1559 EARLY DISEASE PROGRESSION PREDICTS SHORTER SURVIVAL IN PATIENTS TREATED FOR HODGKIN LYMPHOMA.

B. Sidi Mohamed El Amine [1,*], H. Asma [1], S. A. Nadjet [1], Z. Zahia [1]

[1]Hematology department, Universitary Hospital Of Sidi Bel Abbes, Sidi Bel Abbés, Algeria

Background: Early disease progression within two years of diagnosis (POD24) is linked to poor overall survival (OS) in follicular lymphoma but its prognostic role is less clear in Hodgkin lymphoma (HL).
Aims: In this study, we wanted to identify the prognostic factors associated with early progression of HL and to determine its impact on patient survival and outcome.
Methods: We analyzed the impact of POD 24 of patients followed for HL in our department, and who received initially ABVD, with or without radiotherapy. This study involved 96 patients followed between 2002 and 2012. We excluded from the analysis patients who, within 24 months of starting treatment, died without progression or were lost of follow-up without prior progression. OS was calculated from progression (for patients with early progression), and from 24 months after initiation of treatment for those without progression.
Results: Early progression was observed in 28 (29%) patients. The 10-year OS of patients with POD24 was 18%, while that of patients without early progression was 80% (p <0.0001). POD24 was correlated with the existence of an extranodal localization (p = 0.0008), an extended stage of the disease (p = 0.02), B symptoms (p = 0.02), as well as hypoalbuminemia (p = 0.04). The rate of relapses was higher in patients with POD24 (32%), compared to patients without POD (10%, p = 0.02). In multivariate analysis, two factors were predictive for the long-term survival of the patients: extranodal localization (p = 0.03), and POD24 (p <0.0001).
Summary/Conclusion: In patients with HL who have received first-line treatment, early disease progression is associated with poorer survival, and POD24 may represent a useful endpoint in future prospective clinical trials or assessments of responses. to treatment.

PB1560 INTERIM PET BASED OMISSION OF RADIOTHERAPY OR INTENSIFICATION OF CHEMOTHERAPY IN YOUNGER PATIENTS WITH LOCALIZED STAGE CLASSICAL HODGKIN LYMPHOMA: PRELIMINARY EXPERIENCE FROM A SINGLE REFERRAL CENTER

M. Belia [1,*], M. Angelopoulou [1], A. Liaskas [1], P. Rondogianni [2], J. Asimakopoulos [1], M. Arapaki [1], C. Chatzidimitriou [1], E. Konstantinou [1], D. Galopoulos [1], J. Vasilopoulos [1], S. Chatziioannou [3], E.-F. Triantafyllou [1], M. Dimou [4], V. Prassopoulos [5], M. Siakantaris [1], M.-C. Kirtsoni [4], E. Variami [6], N.-A. Viniou [6], M. Efstathopoulou [1], S. Chatzidavid [6], N. Giannakopoulou [6], T. Iliakis [4], V. Pardalis [4], E. Skoura [7], V. Bartzi [4], I. Datseris [2], M. Dimopoulou [1], V. Komninaka [1], P. Tsaftaridis [1], F. Panitsas [1], E. Plata [1], P. Panagiotidis [4], K. Konstantopoulos [1], T. Vassilakopoulos [1]

[1]Haematology and Bone Marrow Transplant Unit, National and Kapodistrian University of Athens, "Laikon" General Hospital, [2]Department of Nuclear Medicine, Evangelismos General Hospital, [3]Department of PET/CT, Biomedical Research Foundation of the Academy of Athens, [4]1st Department of Propaedeutic and Internal Medicine, "Laikon" General Hospital, [5]Department od Radiology and Nuclear Medicine, Hygeia Hospital, [6]1st Department of Internal Medicine, "Laikon" General Hospital, [7]Department of Nuclear Medicine, Bioiatriki Healthcare Group, Athens, Greece

Background: Combined modality therapy including ABVD and radiotherapy (RT) has been traditionally the treatment of choice for limited-stage Hodgkin lymphoma (HL) (I/II). The long-term side effects of RT are still notable and consist the main reason for the attempt to exclude it from the treatment algorithm in a group of patients that are mostly young and, thus, vulnerable to late-onset neoplastic and cardiovascular complications. Recently, in 2017, the EORTC H10 study demonstrated that RT can be safely omitted in case of a strictly negative interim PET (iPET) [roughly corresponding to Deauville-5-point scale score (D5PSS) 1-2], with a statistically significant but numerically negligible loss in disease control of about 2-3%, especially in patients with early unfavorable disease. On the contrary, in patients who remain iPET-positive, RT is preserved and chemotherapy can be intensified with excellent results.
Aims: The aim of this study was the initial evaluation of the results of the above strategy, which was adopted in our Center in 2018, as most of the relapses occur within the first 2 years from diagnosis and therefore, a preliminary assessment of the safety of RT omission in regard to disease control can be performed in a real-life setting.
Methods: 52 patients <50 years old with a median follow-up of 18 months were retrospectively evaluated. Since the beginning of 2018 we used the aforementioned therapeutic strategy in patients with favorable or unfavorable limited-stage disease with mediastinal involvement. On the other hand, RT was maintained in patients without mediastinal involvement, those with iPET D5PSS 3 as well as those with D5PSS 4-5, who received BEACOPP-escalated and RT, and in patients >50 years old, who are potentially less susceptible to long-term complications.
Results: *Patients <50 years with mediastinal involvement:* Among 41 patients included, 31 had early unfavorable and 10 early favorable HL according to EORTC. Among 24 patients who achieved D5PSS-1/2 (59%) only 3 received RT. The 2-year Progression-Free Survival (PFS) was 96% with only one event of primary refractory disease upon restaging that could not have been avoided with RT. Among 11 patients (27%) who achieved D5PSS 7 received RT with no relapses observed in this group so far. iPET remained positive with D5PSS-4/5 in 6 patients (15%), 5 of whom were switched to BEACOPP-esc and RT. The 1-year PFS was 50%. *Patients<50 years without mediastinal involvement:* Among 11 patients included, 10 had early favorable and 1 early unfavorable HL according to EORTC. Among 9 patients (82%) who achieved D5PSS-1/2/3, 8 received RT. No relapses were observed. iPET was positive with D5PSS-4/5 in 2 patients that were treated with BEACOPP-esc and RT without any relapse so far.
Summary/Conclusion: These initial results demonstrate that when RT is omitted following a strictly negative iPET, the relapse rate remains low and absolutely acceptable in the short-term, which is the highest-risk time period. In fact, in this situation the only observed failure event could not have been avoided with RT. However, the question whether RT remains necessary for patients with D5PSS-3 still exists. No safe conclusions can be made so far in regard to the intensification of therapy with BEACOPP-esc in the small subgroup with clearly positive iPET. These results encourage the continuation of this therapeutic strategy based on H10 study, in order to eliminate the long-term side effects of radiotherapy. Further observation and recruitment of much more patients in this real-life setting is scheduled.

PB1561 ACUTE NEUROLOGIC DETERIORATION FOLLOWING THREE DOSES OF BRENTUXIMAB-VEDOTIN IN A PATIENT WITH CHARCOT-MARIE-TOOTH DISEASE

H. De La Nuez Melián [1,*], H. Luzardo Henríquez [1], A. Suárez Cabrera [1], P. Fernández-Caldas González [1], C. Acosta Fleitas [1], N. Cruz Cruz [1], A. Borrero Borrego [1], J. F. López Rodríguez [1], A. Morales Curbelo [1], M. Cabezas de la Cruz [1], M. T. Gómez Casares [1]

[1]*Hematology, Doctor Negrín Hospital, Las Palmas de Gran Canaria, Spain*

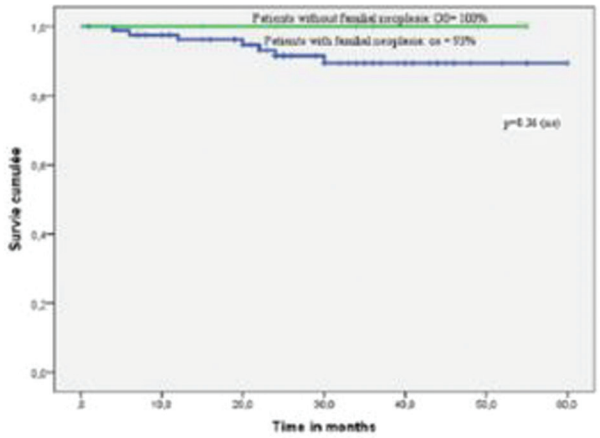
Background: Charcot-Marie-Tooth (CMT) disease represents a heterogeneous group of disorders of peripheral nerve, that is characterized by progressive weakness and atrophy of distal muscles, loss of tendon reflexes, mild sensory impairment and foot deformity.
Two major types of CMT can be differentiated: type I (IA chromosome 17p11.2 gen PMP22, IB chromosome 1q22-23 gen P0, IC unknown gen) more frequently (60%) and type II. Both types are inherited in an autosomal dominant pattern and generally show a benign and chronic clinical course.
Aims: To show severe and life-threatening neuropathic events in patients with hereditary neuropathies receiving Brentuximab-Vedotin (BV).
Methods: We report an unusual case of acute deterioration of CMT disease IA following three doses of BV.
Results: A 27-year-old male was diagnosed with Hodgkin's lymphoma in June 2020. He presented cervical lymphadenopathies. Definite histological diagnosis was made after lymph node removal. Further diagnostic studies revealed splenic and bone infiltration and he was staged IVA (Ann Arbor Classification). BV+AVD-chemotherapy (Adriamycin, Bleomycin, Vinblastine) was the chosen treatment; 120 mg was the BV dose administered in each cycle (1,2 mg/kg). At that point, the neurological status and clinical examination results showed no alterations. No family or personal history was notified.
He received two doses of BV without problems. The third dose was given on 11 September. Three days later, the patient started with neurological symptoms such as muscular weakness, both in the upper and lower limbs (power grade III), fingertips' paresthesia, bilateral sensory impairment of feet and lower legs. Symptoms worsened significantly resulting in dependency of a wheelchair. Finally, he was assessed by a neurologist and diagnostic studies were performed. He continued with the treatment for his lymphoma without BV and with a provisional diagnosis of severe BV-induced neuropathy. At this moment, his father revealed that he had a Charcot-Marie-Tooth disease.
Electrophysiological studies showed sensory-motor polyneuropathy with predominantly demyelinating. We searched his medical history from children's hospital and it was observed that he presented 17p11.2 duplication typical for CMT disease IA. While continuing chemotherapy without the use of BV, the patient's neurological symptoms slowly recovered with rehabilitation for four months.
Summary/Conclusion: Peripheral neuropathy induced by BV is a characteristic effect of cumulative exposure to this drug and it is reversible in most cases. As shown in our patient the coincidence of BV use and underlying CMT IA can lead to severe neurological impairment. If these symptoms are unusual or do not recover before the next dose of BV, diagnostic work-up for underlying hereditary neuropathy including nerve conduction velocity studies and sometimes molecular genetic analysis should be performed. No further use of BV or at least adequate dose reduction have also to be considered. However, we have not found cases like ours on bibliography. Only a few cases have been reported with the use of vincristine. We conclude that a detailed family history and careful clinical examination should be obtained before exposing patients to any kind of neurotoxic agents. Otherwise, consequences can be deleterious for the quality of patient's life.

PB1562 BULKY MEDIASTINAL DISEASE IN HODGKIN LYMPHOMA: THERAPEUTIC OUTCOMES OF ABVD VERSUS BEACOPP ESCALATED REGIMEN IN A SINGLE TUNISIAN CENTER

F. K. Sarbeji [1,*], F. kammoun [1], M. charfi [1], I. ben amor [1], Y. fakhfakh [1], O. kassar [1], I. frikha [1], L. khelifa [1], M. medhaffar [1], M. elloumi [1], S. hadiji [1]

[1]*hematology department, hedi chaker hospital, tunisia, Tunisia*

Background: Bulky mediastinal disease (BMD) is one of the prognostic factors in Hodgkin lymphoma (HL) usually associated with a poor prognosis. In order to improve treatment results for patients with BMD, the Tunisian group changed the national protocol based on ABVD (MDH2002)to BEACOPP escalated regimen(MDH2008 in 2008,then MDH2015 in 2015).
Aims: Our study aims to evaluate and compare the therapeutic results of these protocols in these patients.
Methods: Our study is retrospective interesting 71 newly diagnosed HL adults (<60 years old) with BMD (MTI ≥0.35) treated between January 2002 and June 2020 at the hematology department of Hedi Chaker hospital in Sfax, Tunisia with different versions of national protocols. A total of 20 patients were enrolled from January 2002 to December 2007 with the MDH2002. It is based on the use of the ABVD regimen: 6 cycles for unfavorable early stagesfollowed by involved field radiation therapy (IFRT), and 8 cycles for advanced stages followed by consolidative radiation therapy if there is a residual mass. The MDH2008 and MDH2015 protocol sare rather based on staging these patients in advanced stages and treating themwith intensive chemotherapy: the BEACOPP escalated regimen. Early assessment of response based on scanography is recommended after two cycles and de-escalation to ABVD is favored if the response is ≥75%(according to Cheson's criteria).MDH2015 differs from MDH2008 by reducing the number of cycles to six instead of eight in order to decrease toxicity. Our review determines therapeutic responses, the overall survival (OS), event-free survival (EFS), and factors forecast which influenced these survivals. It aims to compare these survivals using the ABVD regimen (MDH2002=P1) and BEACOPP regimen (MDH2008 and 2015 = P2).
Results: Median age at presentation was 24 years (range 16-51 years). The study included 44 females and 27 males. Forty-four percent(44 %) of patients presented with advanced disease. B-symptoms, more than three sites of involvement, and Bulky tumor were respectively recorded in 75%, 39.4%, and 43.7% of cases.The CR/CRu rate was 69% at the end of treatment (55% with P1 versus 74.5% with P2). PR was 11.3%(5% vs 13.7%). 19.7% of patients did not respond to treatment (40% vs 11.7%) either by a stable disease, progressive disease,or death before the end of chemotherapy.The difference in response between P1 and P2 was significant (p=0.023).With a median follow-up of 72months (range 1-232 months),3- year and 6-year OS rates were respectively 79.6% (65% vs 85.4%) and77.9% (60% vs 85%) with a statistically significant difference between the two groups (p=0.039). Median EFS was 40months. Three-year EFS was 59.7% (45% vs 65.6%), (p=0.01).
Summary/Conclusion: Our results show that the BEACOPP regimen is superior to ABVD for initial disease control and prolonged time to relapse in the treatment of patientswith BMD as described in the literature. However, it noted that BMD stills a poor prognosis factor for OS and EFS comparing to other cases of HL without BMD.



PB1563 IS THERE ANY CORRELATION BETWEEN THE HISTORY OF FAMILIAL NEOPLASIA AND THE DESCRIPTIVE AND PROGRESSIVE PROFILE OF HODGKIN LYMPHOMAS? 4-YEAR COHORT STUDY

T. Faiza [1,1,*], K. belateche [1], Y. ghassoul [1], M. dlilali [1], L. sahraoui [1], H. mansour [1], R. abbadi [1], A. nehab [1], K. djouadi [1]

[1]*hematology, military hospital, algiers, Algeria*

Background: malignant lymphoid hemopathies represent a heterogeneous group, many authors have reported a history of familial neoplasia in these patients, in particular, in case of Hodgkin lymphoma, non-Hodgkin lymphoma, chronic lymphocytic leukemia and multiple myeloma. The pathophysiology involves genetic factors since a close link with certain HLA groups is found. The data in the literature are contradictory, however, many studies indicate that these clinical forms have certain peculiarities: an older age at diagnosis compared to the sporadic forms, a predominance of the male sex, of the scleronodular type and Poppema and Lennert's paragranuloma, extensive stages and extra nodal involvement.
Aims: to analyze the clinical and progressive characteristics of patients with Hodgkin lymphoma and with a history of familial neoplasia (hematological or extra-hematological) and to seek a correlation between the observed data and this parameter over a period of 4 years.

Methods: we conducted a retrospective, single-center and descriptive study on 98 patients with Hodgkin lymphoma enrolled in the Hematology department of Centra Hospital during the period (2016-2019), a history of familial neoplasia is found. in 08 cases (8%).
Results: in 8/98 patients with HL with a history of familial neoplasia, we found a history of Hodgkin lymphoma in 1 case (in the brother), digestive cancer in 4 cases (cousins), breast cancer in 1 case (2 sisters), uterine neoplasia in 1 case and lung carcinoma in 1 case (father). The mean age at diagnosis is 35 years in the sporadic forms and 37.5 years in the forms with a history of familial neoplasia, p = 0.12 (ns). Three out of 5 patients are male in the group with familial neoplasia vs 53/90 in the sporadic group, p = 0.22 (ns).The scleronodular type is found in the 8 cases of LH with familial neoplasia vs 74/90 (in the sporadic forms), p = 0.09 (ns), only one patient in our cohort presents a Poppema and Lennert paragranuloma, it belongs to in the 1st group (with familial neoplasia), p = 0.0004 (s). Four out of 8 patients are classified as localized stages (I-II) versus 30/90 in the sporadic forms, p = 0.38 (ns), a bulky mass (diameter greater than 7cm and / or IMT> 0.35) is found in 6 out of 8 cases versus 34/90 in the 2nd group, p = 0.02 (s). Extra nodal location (contiguous to a lymph node involvement) is noted in 3 out of 8 cases in the forms with familial neoplasia vs. 18/90 in the sporadic forms, p = 0.12 (ns)
By applying the prognostic classification of the EORTC (European Organization for Research and Treatment of Cancer) in the localized stages and the IPS (international Prognostic Score) in the extended stages, all patients with HL with familial neoplasia are classified in the unfavorable group vs 58/90 in sporadic forms: p = 0.01 (s).We recorded, over a period of 4 years, 8 deaths in the sporadic forms (no deaths were noted in the group with familial neoplasia), p = 0.21 (ns). The 5-year overall survival (January 2016 to January 2021) is estimated at 91% all forms combined, this factor is not influenced by the family history of the patients (p = 0.32)

Summary/Conclusion: our results agree with the data in the literature: the family history of neoplasia gives patients with HL certain clinical characteristics, however, the impact of this factor on the evolution of patients is not confirmed in our study series.

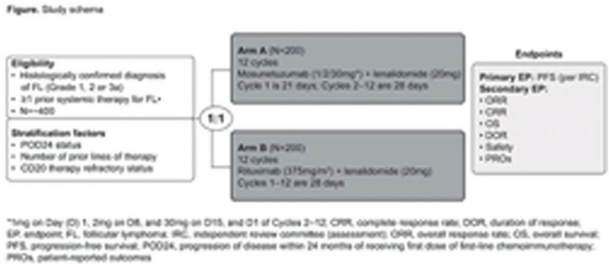
PB1564 THERAPEUTIC RESULTS OF A TUNISIAN PROSPECTIVE NON-RANDOMIZED ADULT HODGKIN LYMPHOMA STUDY: SINGLE-INSTITUTION EXPERIENCE ABOUT 73 ADULT PATIENTS

F. K. Sarbeji [1,*], F. kammoun [1], M. charfi [1], O. kassar [1], H. ben salah [2], N. toumi [3], Y. fakhfakh [1], I. frikha [1], I. ben amor [1], L. khelifa [1], M. medhaffar [1], J. daoud [4], A. khainfir [3], M. elloumi [1], S. hadiji [1]

[1]hematology department, hedi chaker hospital, tunisia, [2]radiotherapy department, habib bourguiba hospital, sfax, [3]oncology department, [4]radiotherapy department, habib bourguiba hospital, tunisia, Tunisia

Background: Hodgkin lymphoma (HL) is a hematologic malignancy with a high rate of curability. Several national and international groups have established management protocols for this disease. Since 1999, The Tunisian group has adopted four versions of the HL national protocol(MDH99, MDH2002, MDH2008, and MDH2015).
Aims: Our study aims to evaluate the therapeutic results of the fourth-protocol: MDH2015.
Methods: Our study is retrospectiveabout73newly diagnosed HL adult patients (<60 years old) treated between December 2015 and June 2020at the hematology department of HediChaker hospital Sfax, Tunisia, according to the MDH2015 protocol. The MDH2015recommends an early assessment of response based on scanography after 2 cycles of chemotherapy in each group. For favorable early stages (G1), ABVD regimen was used:two to three cycles followed by involved field radiation therapy (IFRT). For unfavorable early stages (G2), four cycles of ABVD were usedfollowed byIFRT. An escalation to BEACOPP escalated regimenwas recommended if the response was ≤75% (according to Cheson's criteria).For the advanced stages and localized stages with bulky mediastinal mass (BMM)(G3), treatment is based on six cycles of BEACOPP escalated regimen. De-escalation to four ABVD cycles is used if the response is ≥ 75%after two cycles.The date of point is in February 2021. Our study determines therapeutic responses, the overall survival (OS), event-free survival (EFS), and factorsthat affect the survivals.
Results: Median age at presentation was 33 years (range 16-57 years). There were 27 females and 46 males (M/F: 1.7). Fifty-three percent (53 %) of patients presented with advanced disease. Distribution by group was: G1(n=4), G2(n=20), and G3(n=49).B-symptoms, more than three sites of involvement, BMM, and peripheral bulky tumor were respectively recorded in 74%, 35.6%, 28.8%, and 45.2% of cases. The CR/CRu rate was 82.2% at the end of treatment. PR was 9.6%. The rest of the patients (8.2%) had stable disease. No progressive disease was noted. With a median follow-up of 37 months, one year and 3-year OS and EFS were respectively 97%, 83% and 81.5%, 74.2%. Therapeutic response at the end of treatment was a predictive adverse prognostic factor for OS (p=0.014) and EFS (p=0.0001) in multivariate analysis.
Summary/Conclusion: Our results with the MDH2015 protocol in both localized and advanced stages of the disease are encouraging either in initial therapeutic response or in OS and EFSwhich correlates favorably with previous findings of BEACOPP regimen results in the literature: more than 90% of survival in the first year, and more than 80% in three years.

Indolent and mantle-cell non-Hodgkin lymphoma - Clinical



PB1565 A PHASE III TRIAL (GO42909) EVALUATING MOSUNETUZUMAB IN COMBINATION WITH LENALIDOMIDE (M-LEN) VERSUS RITUXIMAB-LENALIDOMIDE (R-LEN) IN PATIENTS WITH RELAPSED/REFRACTORY (R/R) FOLLICULAR LYMPHOMA (FL)

C. W. Scholz [1,*], N. L. Bartlett [2], L. Nastoupil [3], M. C. Wei [4], C. O'Hear [4], A. Knapp [5], C. Granier [6], S. Pham [5], K. Sarouei [4], C.-C. Li [4], A. Bottos [4], E. Purev [4], F. Morschhauser [7]

[1]Department of Hematology and Oncology, Vivantes Klinikum Am Urban, Berlin, Germany, [2]Department of Medicine, Washington University School of Medicine, St. Louis, MO, [3]MD Anderson Cancer Center, Houston, TX, [4]Genentech, Inc., South San Francisco, CA, United States, [5]F. Hoffmann-La Roche Ltd, Basel, Switzerland, [6]F. Hoffmann-La Roche Ltd, Welwyn Garden City, United Kingdom, [7]Hôpital Claude Huriez and Centre Hospitalier Régional Universitaire de Lille, Lille, France

Background: Despite currently available therapies, FL is characterized by recurrent relapses, with increasing refractoriness and decreasing duration of response to subsequent lines of therapy. Mosunetuzumab is a full length, IgG1 CD20xCD3 bispecific antibody that redirects T cells to engage and eliminate malignant B cells. Mosunetuzumab monotherapy elicited high and consistent complete response (CR) and overall response rates (ORR) across high-risk FL subsets in an ongoing Phase I/Ib study (N=62; CR rate: 51.6%; ORR: 67.7%; NCT02500407; Assouline, et al. ASH 2020). Lenalidomide is a potent immunomodulatory agent that has been shown to enhance T-cell and natural killer-cell activity. As such, mosunetuzumab and lenalidomide have potential to exhibit synergistic activity. The combination of M-Len may afford further clinical benefit, providing a new treatment option for patients with R/R FL. Here we present details of a trial in progress assessing M-Len.
Aims: To evaluate the efficacy and safety of M-Len versus R-Len in patients with R/R FL.
Methods: GO42909 (NCT04712097) is a Phase III, open-label, multicenter, randomized controlled trial in patients with R/R FL. Eligible patients must have CD20-positive FL (excluding grade 3b and transformed FL) with an Eastern Cooperative Oncology Group Performance status ≤2, patients must also have received at least one prior systemic therapy, and require treatment according to Groupe d'Etude des Lymphomes

Folliculaires (GELF) criteria (Solal-Céligny, et al. J Clin Oncol 1998). Patients are randomized 1:1 to receive either M-Len or R-Len; randomization is stratified by progression of disease within 24 months of receiving the first dose of first-line immunochemotherapy, number of prior therapies, and CD20-refractoriness. Patients in the M-Len cohort receive mosunetuzumab intravenously (IV) as step-up doses in Cycle 1 (21-day cycle): 1mg on Day (D)1, 2mg on D8, and 30mg on D15, and D1 of Cycles 2–12 (28-day cycles). Lenalidomide (20mg) is administered orally, once daily on D1–21 of Cycles 2–12. Patients in the R-Len cohort receive 375mg/m^2 rituximab (IV) on D1, 8, 15 and 22 of Cycle 1, and on D1 of Cycles 3, 5, 7, 9 and 11 (28-day cycles); lenalidomide is administered once a day on D1–21 of Cycles 1–12 (Figure). The primary efficacy endpoint is progression-free survival as determined by an independent review committee using the 2014 Lugano response criteria (Cheson, et al. J Clin Oncol 2014). Key secondary efficacy endpoints include ORR, CR rate, and overall survival. Safety endpoints comprise incidence and severity of adverse events (NCI CTCAE v5.0) including cytokine release syndrome (ASTCT criteria; Lee, et al. Biol Blood Marrow Transplant 2019), change from baseline in targeted vital signs and clinical laboratory test results, and tolerability; an independent data monitoring committee will evaluate safety data periodically during the study. In addition, pharmacokinetic and biomarker endpoints will be explored.
Results: The study start date is planned for 2021, with an anticipated enrollment of around 400 patients from approximately 16 countries and at least 150 sites globally.

Summary/Conclusion: GO42909 is an ongoing study of M-Len versus R-Len in patients with R/R FL. Further study details will be presented.

PB1566 TRIAL IN PROGRESS: A PHASE 2, SINGLE-ARM, OPEN-LABEL, MULTICENTER STUDY OF TAZEMETOSTAT IN COMBINATION WITH RITUXIMAB FOR THE TREATMENT OF RELAPSED OR REFRACTORY FOLLICULAR LYMPHOMA

K. Patel [1,*], N. Bailey [1], J. Yang [2], T. Lingaraj [2], D. Adib [2], J. Pagel [1]

[1]Swedish Center Institute, Seattle, [2]Epizyme, Inc., Cambridge, United States

Background: Patients with follicular lymphoma (FL) who do not achieve a response after 2 or more prior lines of systemic therapy have a poor prognosis when treated with salvage chemotherapy alone or phosphoinositide 3-kinase (PI3K) inhibitors. Tazemetostat, a first-in-class, oral, selective enhancer of zeste homolog 2 (EZH2) inhibitor, has demonstrated single-agent antitumor activity and a favorable safety profile in patients with wild-type (WT) and mutant (MT) *EZH2* relapsed/refractory (R/R) FL who had received ≥2 prior lines of therapy. Rituximab, as a single agent or in combination, is often used in the second line or later in patients with FL. In preclinical studies, tazemetostat has shown synergistic activity when combined with rituximab. This, in addition to clinical study experience with the combination of tazemetostat and rituximab in patients with diffuse large B-cell lymphoma, support the evaluation of tazemetostat in combination with rituximab in patients with R/R FL.
Aims: To determine the efficacy and safety of tazemetostat in combination with rituximab for the treatment of R/R FL.
Methods: This trial (NCT04762160) is a phase 2, single-arm, open-label, multicenter study of tazemetostat in combination with rituximab in patients with R/R FL who have received ≥2 prior lines of systemic therapy, including an anti-CD20–based regimen. Patients eligible for inclusion are aged ≥18 years with grade 1 to 3A FL who have met Groupe d'Etude des Lymphomes Folliculaires (GELF) criteria to receive treatment, have an Eastern Cooperative Oncology Group (ECOG) performance score ≤2, and have not received any prior treatment with EZH2 inhibitors. Patients with transformed FL, a history of clinically significant gastrointestinal conditions, or any uncontrolled illness are excluded from this study. *EZH2* mutation testing will be performed during patient screening; however, the presence of an *EZH2* mutation is not required to be eligible for the study. Patients will receive tazemetostat 800 mg orally twice daily beginning on cycle 1 day 1 for continuous 28-day cycles until the end of cycle 24, for a total of 24 months of therapy. Patients will also receive rituximab 375 mg/m^2 intravenously (IV) on cycle 1 day 1, then 375 mg/m^2 IV or 1400 mg subcutaneously on days 8, 15, and 22 of cycle 1, and on day 1 of cycles 3, 4, 5, and 6, for a total of 8 doses of rituximab. The primary endpoint is the objective response rate (ORR; the proportion of patients with complete or partial response) in patients with WT *EZH2*. Key secondary endpoints include median progression free survival (PFS) in patients with WT *EZH2*; median PFS in all patients, regardless of mutational status; ORR in patients with MT *EZH2*; efficacy outcomes in rituximab-refractory patients; and incidence of adverse events. Efficacy and safety analyses will be performed on all patients who receive ≥1 dose of study drug. The evaluation of ORR will be based on Lugano 2014 response criteria and will be presented with corresponding 2-sided Clopper-Pearson 95% confidence intervals. The Kaplan-Meier method will be used to estimate PFS. Survival follow-up will be done following the study treatment period every 6 months for 2 years or until disease progression or death for all patients who complete the 24 months of tazemetostat therapy. As of February 2021, 1 site is recruiting patients in the United States, with 2 patients enrolled.
Results: N/A
Summary/Conclusion: N/A

PB1567 THE PROGNOSTIC NUTRITIONAL INDEX (PNI) IS AN INDEPENDENT PREDICTOR OF OVERALL SURVIVAL IN OLDER PATIENTS WITH FOLLICULAR LYMPHOMA

P. Mozas [1,*], A. Rivero [1], A. Rivas-Delgado [1], J.-G. Correa [1], M. Condom [1], F. Nadeu [2], E. Giné [1], J. Delgado [1], N. Villamor [1], E. Campo [1], P. Pérez-Galán [2], L. Magnano [1], A. López-Guillermo [1]

[1]Hospital Clínic de Barcelona, [2]IDIBAPS, BARCELONA, Spain

Background: Although outcomes in follicular lymphoma (FL) are generally good, some patients experience early relapse or histological transformation (HT), which compromise their life expectancy. The Prognostic Nutritional Index (PNI), a parameter combining the serum albumin concentration and the absolute lymphocyte count, was initially designed to estimate the prognosis of patients undergoing gastrointestinal surgery, but it has then been successfully applied to a wide range of solid and hematological cancer types. This index, a putative combined measure of the nutritional and inflammatory status and host's anti-tumor response, has not been well characterized in FL.
Aims: To evaluate the role of the PNI in a large single-center series of FL patients.
Methods: We studied 351 grade 1-3A FL patients (190 F / 160 M; median age, 61 years) diagnosed at a single institution between 2000 and 2018. The PNI (a unitless parameter) was calculated using the original formula (Buzby *et al*, Am J Surg, 1980): PNI = albumin (g/L) + [5 x absolute lymphocyte count (x10^9/L)]. Clinical characteristics, treatment modalities, response, progression-free (PFS) and overall survival (OS), risk of HT, and of second primary malignancies (SPM) were assessed and compared between patients with a PNI below and above 45, the most widespread cut-off.
Results: Forty-one patients (12%) had a PNI ≤45 (Table), who were older and showed adverse baseline features (poor ECOG PS, B symptoms, high LDH and/or β_2-microglobulin levels, anemia, and high-risk FLIPI score). Median follow-up was 5 years (range, 0.8–16.2 years). Frontline treatment and responses were comparable among groups. Globally, PFS did not significantly differ based on the PNI. When a subgroup analysis was performed, a PNI ≤45 was predictive of a lower PFS in patients >60 years, but not in those ≤60 years. Using competing risks of death, the 10-year cumulative incidence of lymphoma-related death (progressive FL or treatment-related complications) was significantly higher for patients with a PNI ≤45 (29 vs. 11% at 10 years, P = 0.0006, Figure A). A low PNI was associated with a shorter OS in the global series (10-year OS, 52% versus 74%, P = 0.0001, Figure B). In a 6-element multivariate model also including the presence of B symptoms and of a bulky mass, ECOG PS, FLIPI score, and β_2-microglobulin, the prognostic impact of the PNI on OS was confirmed for patients >60 years (HR = 3, P = 0.006). Finally, the PNI did not predict the risk of HT or SPM.

	Prognostic Nutritional Index		
	≤45	>45	P
Number of patients, n (%)	41 (12)	310 (88)	–
Age (median, range)	71 (33-91)	60 (26-86)	<0.001
Female sex, n (%)	25 (61)	166 (54)	NS
Charlson Comorbidity Index ≥2, n (%)	11 (27)	70 (23)	NS
Histological grade 1-2, n (%)	30 (75)	255 (84)	NS
ECOG PS ≥2, n (%)	10 (24)	14 (5)	<0.001
B symptoms, n (%)	11 (27)	30 (10)	0.001
Ann-Arbor stage III/IV, n (%)	33 (81)	231 (75)	NS
Secondary extranodal involvement, n (%)	30 (73)	193 (62)	NS
Bulky mass, n (%)	11 (27)	65 (21)	NS
Elevated serum LDH, n (%)	15 (37)	53 (17)	0.003
Elevated β2-microglobulin, n (%)	27 (73)	122 (40)	<0.001
Hemoglobin <120 g/L, n (%)	23 (56)	42 (14)	<0.001
High-risk FLIPI score, n (%)	20 (49)	69 (22)	<0.001
Frontline treatment with R-CHOP, n (%)	21 (55)	144 (54)	NS
CR rate, n (%)	27 (71)	201 (75)	NS
PFS, % at 10 y (95% CI)	46 (30-70)	53 (45-62)	NS
OS, % at 10 y (95% CI)	52 (35-78)	74 (68-82)	0.0001
Cumulative incidence of lymphoma-related death, % at 10 y (95% CI)	29 (14-45)	11 (7-16)	0.0006

Table. Baseline features of the 351 patients, globally and according to the PNI.
PNI, Prognostic Nutritional Index; ECOG PS, Eastern Cooperative Oncology Group Performance Status; LDH, lactate dehydrogenase; FLIPI, Follicular Lymphoma International Prognostic Index; ULN, upper limit of normal; NS, not statistically significant; CR, complete response; R-CHOP, rituximab, cyclophosphamide, doxorubicin, vincristine, and prednisone; CI, confidence interval; HT, histological transformation; FL, follicular lymphoma; NS, not statistically significant; PFS, progression-free survival; OS, overall survival; SM, second malignancies.

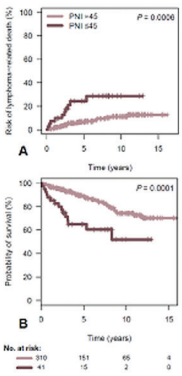


Figure. A. Cumulative incidence of lymphoma-related death according to the PNI. **B.** Overall survival according to the PNI.

Summary/Conclusion: The PNI is a readily accessible piece of information that can identify a small subset of FL patients with shorter survival, especially among the older age subgroup. Upon validation in other series, it could be a valuable tool to anticipate outcomes and identify patients who could have their nutritional status optimized before treatment initiation.

PB1568 PROGNOSTIC PERFORMANCE OF CLINICAL RISK SCORES IN FOLLICULAR LYMPHOMA: EVALUATION IN A SINGLE-CENTER SERIES

P. Mozas [1,*], A. Rivero [1], A. Rivas-Delgado [1], J.-G. Correa [1], M. Condom [1], F. Nadeu [2], E. Giné [1], J. Delgado [1], N. Villamor [1], E. Campo [1], L. Magnano [1], A. López-Guillermo [1]

[1]Hospital Clínic de Barcelona, [2]IDIBAPS, BARCELONA, Spain

Background: Most follicular lymphoma (FL) patients have prolonged survival. However, early progression (POD24) and histological transformation (HT) compromise their life expectancy. With the intention of identifying such individuals, different risk scores (RS) have been developed. Although FLIPI has gained the widest acceptance, none of the previous (IPI, ILI) or more recent indexes (FLIPI2, PRIMA-PI) has been clearly shown to outperform the others.
Aims: To evaluate the utility of the IPI, ILI, FLIPI, FLIPI2, and PRIMA-PI in a single-center series of FL patients.
Methods: We studied 414 grade 1-3A FL patients [230 F/184 M; median age, 60 years (range, 26–91)] who had available information about at least one of the five clinical RS (IPI, ILI, FLIPI, FLIPI2, PRIMA-PI), diagnosed at our institution between 2002 and 2018. Three hundred and ten patients (75%) had advanced-stage disease, and 250 (69%) received frontline treatment with R-CHOP or R-CVP. With a median follow-up of 5.9 years, 10-year overall survival (OS) was 71%.
Prognostic performance of each RS was evaluated in terms of calibration (Hosmer-Lemeshow goodness of fit), discrimination [Harrell's c-index, Akaike's information criterion (AIC), and Gönen & Heller's concordance probability estimate (CPE)], reclassification [net reclassification index (NRI)], and clinical utility [prediction of time to first treatment (TTFT), response, progression-free survival (PFS), OS, risk of lymphoma related death (LRD), and of HT].
Results: Performance metrics of the five RS are detailed in *Table 1*. Goodness of fit, Harrell's c-index, AIC, and CPE were similar across indexes. NRI did not show improvement of any RS in comparison with the existing ones. The proportion of patients allocated to the high-risk category by each RS was as follows: 7% (IPI), 27% (ILI), 28% (FLIPI), 30% (FLIPI2), and 27% (PRIMA-PI). Pairwise concordance (patients allocated to the same risk category by two RS, *Table 2*) was lowest between IPI-FLIPI2, ILI-FLIPI2, and ILI-PRIMA-PI (51%), and highest between IPI-FLIPI (67%). All five RS predicted TTFT (P <0.01). Using logistic regression, all five RS predicted for the absence of complete response, as well as for POD24.
All five RS were predictive of PFS (P <0.0001), OS (P <0.0001, Figure), and LRD (P <0.001). Ten-year OS estimates for each high-risk group were as follows: 16% (IPI), 46% (ILI), 46% (FLIPI), 48% (FLIPI2), 43% (PRIMA-PI). Although PRIMA-PI identified a high-risk group (B2M >3 mg/L), no significant differences in OS were found according to bone marrow infiltration (pairwise P = 0.7). FLIPI was the only RS to predict HT, with 10-y cumulative incidences of 3%, 8% and 10% for low-, intermediate-, and high-risk patients, respectively (P = 0.04).

Figure. Kaplan-Meier curves of overall survival according to the five risk scores.

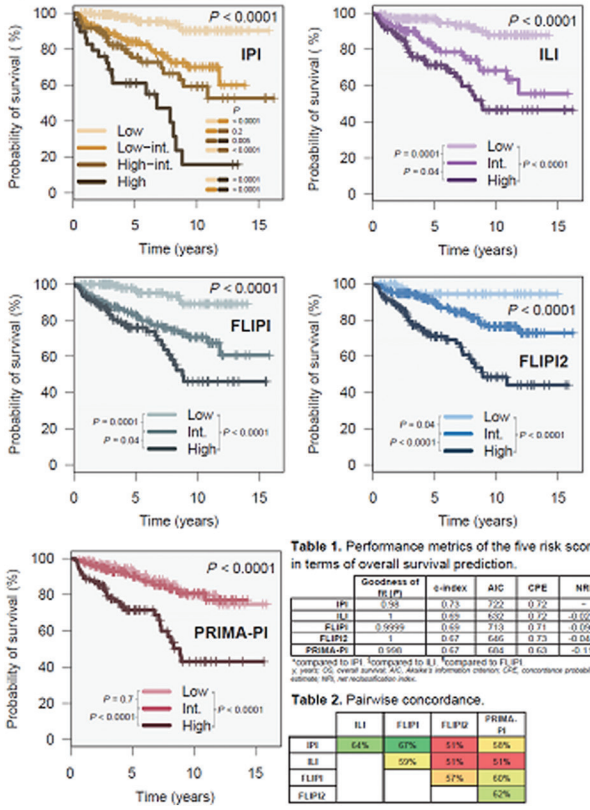

Table 1. Performance metrics of the five risk scores in terms of overall survival prediction.

	Goodness of fit (LR)	c-index	AIC	CPE	NRI
IPI	0.98	0.73	7222	0.72	–
ILI	1	0.69	6992	0.72	-0.022*
FLIPI	0.9999	0.69	713	0.71	-0.096†
FLIPI2	1	0.67	686	0.73	-0.044‡
PRIMA-PI	0.998	0.67	684	0.63	-0.11§

*compared to IPI. †compared to ILI. ‡compared to FLIPI.
y, years; OS, overall survival; AIC, Akaike's information criterion; CPE, concordance probability estimate; NRI, net reclassification index.

Table 2. Pairwise concordance.

	ILI	FLIPI	FLIPI2	PRIMA-PI
IPI	64%	67%	51%	58%
ILI		59%	51%	51%
FLIPI			57%	60%
FLIPI2				62%

Summary/Conclusion: The five RS exhibit very subtle differences in their performance metrics. All of them predict TTFT, response, POD24, PFS, OS, and the risk of LRD. IPI identifies a small subset of patients with dismal outcomes. Bone marrow involvement did not impact OS, questioning the prognostic discrimination of the low- and intermediate-risk PRIMA-PI categories. In our series, FLIPI was the only RS to predict HT. In summary, all available RS are similarly valid for prognostication. Their potential to aid in the decision of initiating treatment should be explored.

PB1569 COASTAL: A PHASE 3 STUDY OF THE PI3KΔ INHIBITOR ZANDELISIB WITH RITUXIMAB (R) VERSUS IMMUNOCHEMOTHERAPY IN PATIENTS WITH RELAPSED INDOLENT NON-HODGKIN'S LYMPHOMA (INHL)

W. Jurczak [1,*], P. L. Zinzani [2], D. Cunningham [3], S. Yavrom [4], W. Huang [4], I. Gorbatchevsky [4], V. Ribrag [5]

[1]Maria Skłodowska-Curie National Research Institute of Oncology, Krakow, Poland, [2]Institute of Hematology Seràgnoli, University of Bologna, Bologna, Italy, [3]Royal Marsden Hospital, NHS Foundation Trust, London, United Kingdom, [4]MEI Pharma Inc, San Diego, United States, [5]Institut Gustave Roussy, Villejuif, France

Background: Patients (pts) with iNHL treated with front-line immunochemotherapy may benefit from an alternative, chemotherapy-free regimen at relapse. Zandelisib, a potent, selective, and structurally differentiated oral PI3Kδ inhibitor, achieved an 87% response rate, with median duration of response not reached in iNHL when given as a monotherapy or in combination with R. A low rate (<10%) of Grade ≥ 3 immune-mediated adverse events of special interest associated with PI3kδ inhibitors is observed in patients administered zandelisib on an intermittent schedule (IS) (JCO 2020 38:15_suppl, 8016). An open-label, phase 2 study (TIDAL, NCT03768505) of zandelisib as monotherapy is ongoing in pts with relapsed/refractory follicular lymphoma (FL) and marginal zone lymphoma (MZL).
Aims: The COASTAL study is a randomized, open-label, controlled multicenter phase 3 trial to investigate the safety and efficacy of zandelisib in combination with R versus standard immunochemotherapy in pts with iNHL.
Methods: Key eligibility criteria: adults with relapsed or refractory FL or MZL who received ≥1 prior lines of therapy which must have included an anti-CD20 antibody in combination with chemotherapy or lenalidomide

(L); at least one bi-dimensionally measured lesion >1.5 cm; adequate bone marrow, renal and hepatic function; ECOG performance status score of 0 to 1. Key exclusion criteria: histologically confirmed diagnosis of FL grade 3b or transformed disease; administration of 2 prior immunochemotherapy regimens; prior PI3K inhibitor therapy; known lymphomatous involvement of the central nervous system. Subjects will be randomized 1:1 to receive R-zandelisib or immunochemotherapy (R-CHOP or R-B) and stratified by type and number of prior treatment regimens, histology, and duration of treatment-free interval after last therapy. Zandelisib will be given in a 28-day cycle comprising of daily dosing for 2 cycles followed by IS dosing on days 1-7 or each 28-day subsequent cycle for a duration of 2 years. Rituximab or immunochemotherapy will be given for a total of 6 cycles. Disease response will be assessed by an Independent Response Review Committee according to the modified Lugano Classification. Radiographic tumor assessment will be performed approximately every 12 weeks for the first 9 months, every 16 weeks for the next 12 months, and every 24 weeks thereafter. The primary efficacy endpoint is progression-free survival. The major secondary endpoints include ORR, complete response rate, overall survival, and safety.
Results: The trial will enroll approximately 534 pts in ~200 sites globally and will begin enrollment in mid-2021.
Summary/Conclusion: NCT04745832

PB1570 A PHASE 2 RANDOMIZED STUDY OF LONCASTUXIMAB TESIRINE VERSUS IDELALISIB IN PATIENTS WITH RELAPSED OR REFRACTORY FOLLICULAR LYMPHOMA (LOTIS-6)

C. Carlo-Stella [1,*], J. Depaus [2], B. T. Hess [3], E. Kingsley [4], P. L. Zinzani [5], D. Ungar [6], V. Dai [6], L. Wang [6], K. M. Ardeshna [7]

[1]Department of Oncology and Hematology, Humanitas Clinical and Research Center - IRCCS and Humanitas University, Rozzano, Milano, Italy, [2]Department of Hematology, CHU UCL Namur site Godinne, Yvoir, Belgium, [3]Department of Medicine, Division of Hematology and Medical Oncology, Medical University of South Carolina, Charleston, SC, [4]Comprehensive Cancer Centers of Nevada, Las Vegas, NV, United States, [5]Institute of Hematology "Seràgnoli", University of Bologna, Bologna, Italy, [6]Clinical Development, ADC Therapeutics America, Inc, Murray Hill, NJ, United States, [7]Department of Hematology, University College London Hospitals NHS Foundation Trust, London, United Kingdom

Background: Although many patients (pts) with follicular lymphoma (FL) respond to first-line therapy, most pts have a history of successive relapses and response duration shortens after each relapse; therefore, FL is considered incurable and an area of considerable unmet need. Loncastuximab tesirine (Lonca) is an antibody-drug conjugate comprising a humanized anti-CD19 monoclonal antibody conjugated to a pyrrolobenzodiazepine dimer (PBD) toxin. Single-agent Lonca demonstrated antitumor activity and a manageable safety profile in pts with relapsed/refractory (R/R) B-cell non-Hodgkin lymphoma, including FL, in a Phase 1 clinical trial (ADCT-402-101), and in heavily pretreated pts with R/R diffuse large B-cell lymphoma in a Phase 2 trial (ADCT-402-201). Idelalisib is an inhibitor of phosphatidylinositol 3-kinase, approved for pts with relapsed FL who had ≥2 prior systemic therapies.
Aims: The primary objective of this trial (NCT04699461) is to evaluate the efficacy of single-agent Lonca compared with idelalisib in R/R FL.
Methods: This is a prospective, randomized, two-arm, multicenter, open-label, Phase 2 study of Lonca versus idelalisib in pts with R/R FL. Key inclusion and exclusion criteria for the study are presented in **Table 1**. Informed consent will be obtained. Eligible pts will be randomized 2:1 to Lonca (intravenous infusion; 150 µg/kg every 3 weeks [Q3W] for 2 cycles then 75 µg/kg Q3W for subsequent cycles) or idelalisib (oral; 150 mg twice daily). Randomization will be stratified based on the time since last systemic therapy (ie, ≤2 years versus >2 years). The follow-up period will be up to 3 years after the end of treatment. Pts can continue treatment until disease progression, unacceptable toxicity, or other discontinuation criteria.
The primary endpoint is complete response rate (CRR) according to the 2014 Lugano Classification as determined by central review. CRR will be tested for the intent-to-treat population between the two treatment arms using the Cochran–Mantel–Haenszel method adjusted for stratification factors from the randomization list. The study is 99% powered for the primary efficacy endpoint, assuming a 55% CRR to Lonca and a 15% CRR to idelalisib, and the sample size for enrollment (approximately 150 pts) allows for a robust safety data set. Secondary endpoints include overall response rate (key secondary endpoint); progression-free survival; overall survival; duration of response; incidence and severity of adverse events (AEs) and serious AEs; change from baseline in laboratory values, vital signs, 12-lead electrocardiogram, and Eastern Cooperative Oncology Group performance status; concentration and pharmacokinetic parameters of Lonca total antibody, PBD-conjugated antibody, and unconjugated warhead (SG3199); anti-drug antibody titers; and patient-reported outcome (PRO) measures. PRO measures will include change from baseline in PROs, as measured by EuroQol–5 Dimensions–5 Levels and Functional Assessment of Cancer Therapy-Lymphoma, and the occurrence, severity, and interference of specific symptomatic AEs selected from the PROs version of the Common Terminology Criteria for AEs.
The trial is anticipated to open for recruitment in Quarter 1, 2021.
This study is sponsored by ADC Therapeutics SA.
Results: N/A

Table 1 : Key Inclusion and Exclusion Criteria

Key Inclusion Criteria	Key Exclusion Criteria
• Patients aged ≥18 years with a pathologic diagnosis of FL (Grade 1, 2, 3A) • Patients with R/R FL following ≥2 lines of therapy, at least 1 of which contained an anti-CD20 therapy • Patients who received prior CD19-directed therapy must have a biopsy showing CD19 expression after the CD19-directed therapy is completed • Presence of measurable disease as defined by the 2014 Lugano Classification • Eastern Cooperative Oncology Group performance status 0–2 • Adequate organ function	• Prior treatment with loncastuximab tesirine or idelalisib • Patients with FL that has transformed to diffuse large B-cell lymphoma or other aggressive lymphomas • Patients needing treatment or prophylaxis with a strong cytochrome P450 3A inhibitor, inducer, or sensitive substrate • Active or prior drug-induced pneumonitis or inflammatory bowel disease • A condition that could interfere with absorption/metabolism of idelalisib • Autologous or allogeneic stem cell transplant within 30 or 60 days, respectively, before the start of study treatment • Clinically significant third space fluid accumulation (ie, ascites requiring drainage or pleural effusion that is either requiring drainage or associated with shortness of breath) • Active Grade ≥3 infection requiring IV antibiotics, antiviral, or antifungal treatment

Summary/Conclusion: N/A

PB1571 CLINICAL OUTCOMES IN PATIENTS RELAPSED/REFRACTORY AFTER ≥ 2 PRIOR LINES OF THERAPY FOR FOLLICULAR LYMPHOMA: A SYSTEMATIC LITERATURE REVIEW AND META-ANALYSIS

S. Kanters [1,*], B. Kahl [2], A. Wiesinger [3], B. Gurung [4], E. Limbrick-Oldfield [1], A. Sudhindra [3], J. Snider [3], A. R. Patel [3]

[1]RainCity Analytics, Vancouver, Canada, [2]Oncology Division, Department of Medicine, Washington University School of Medicine, St. Louis, [3]Kite, A Gilead Company, Santa Monica, United States, [4]Health Economics & Outcomes Research, IQVIA, London, United Kingdom

Background: Patients with follicular lymphoma (FL) can have high response rates to early lines of treatment. However, among FL patients relapsed/refractory (r/r) after ≥2 prior lines of therapies (LOT), remission tends to be shorter. Moreover, there is limited guidance for treatment options among these patients.
Aims: This study sought to evaluate the clinical outcomes for r/r FL after ≥2 prior LOT using currently available treatment options.
Methods: Electronic databases were searched on 2nd June 2020. Eligible studies were comparative or non-comparative interventional or observational studies of systemic therapies among adults with FL r/r after ≥2 prior LOT. Prior LOT must have included anti-CD20 monoclonal antibodies and alkylating agents, in combination or separately. Overall response rate (ORR) and complete response (CR) were analyzed using inverse-variance weighting with Freeman-Tukey double-arcsine transformations. Kaplan-Meier (KM) analysis for progression-free survival (PFS) and overall survival (OS) were conducted using data from digitized curves and prepared using the Guyot algorithm. Survival analyses were stratified by ≥2 prior LOT and ≥3 prior LOT groups and were restricted to the observational cohorts as a sensitivity analysis.
Results: The meta-analysis included 12 studies published from 2014-2020, including three studies that were cohorts using mixed treatments representing currently available treatments. Sample size for response outcomes was 340, for survival outcomes with ≥2 prior LOT was 1024 and for ≥3 prior LOT was 502. The estimated ORR in the ≥2 prior LOT group was 56.0% (95% confidence interval [CI]: 47.2 – 64.5) and proportion of patients with CR was 12.2% (95% CI: 8.0 – 17.3). The median OS was 54.4 months (95% CI: 45.8 – 76.0) and median PFS was 10.3 months (95% CI: 9.3 – 11.1). The 24-month OS decreased from 66% in the ≥2 prior LOT group to 60% in the ≥3 prior LOT group (Table 1), with a similar trend in PFS at 24-month (28% vs 24%).

Table 1: Key outcomes

Population	Median OS months (95% CI)	Median PFS months (95% CI)	OS at 18m (95% CI)	PFS at 18m (95% CI)	OS at 24m (95% CI)	PFS at 24m (95% CI)
Full Analysis* ≥2 prior LOT	54.4 (45.8 – 76.0)	10.3 (9.3 – 11.1)	71% (68 – 74)	35% (33 – 38)	66% (63 – 69)	28% (26 – 30)
Full Analysis* ≥3 prior LOT	40.6 (32.6 – 52.1)	8.4 (7.5 – 9.5)	65% (61 – 70)	31% (28 – 35)	60% (55 – 64)	24% (21 – 27)
Cohorts ≥2 prior LOT	57.9 (46.6 – 78.4)	10.0 (8.6 – 11.1)	71% (68 – 74)	35% (33 – 38)	66% (63 – 70)	29% (26 – 31)
Cohorts ≥3 prior LOT	42.0 (34.8 – 55.3)	8.3 (7.1 – 9.6)	66% (61 – 70)	32% (28 – 35)	60% (56 – 65)	25% (22 – 28)

*Full analysis includes drug trials and cohorts; CI: confidence interval.

Summary/Conclusion: This study found that few r/r FL patients with ≥2 prior LOT achieve CR, and despite some benefit, approximately 1/3 of patients die within 24 months. The shorter median PFS with increasing prior LOT suggest treatment durability is suboptimal in later LOT. These findings indicate that patients are underserved by current treatments, demonstrating a need for new treatments that can achieve high rates of response that are durable in this disease.

PB1572 PHASE 3 STUDY OF TAFASITAMAB + LENALIDOMIDE AND RITUXIMAB VS PLACEBO + LENALIDOMIDE AND RITUXIMAB IN PATIENTS WITH RELAPSED/REFRACTORY FOLLICULAR LYMPHOMA (FL) OR MARGINAL ZONE LYMPHOMA (MZL): INMIND

Background: Most patients (pts) with the indolent non-Hodgkin lymphoma (NHL) subtypes FL or MZL respond to first-line treatment but relapse is common, and there is no single standard treatment for pts with relapsed/refractory (R/R) FL or MZL. Tafasitamab is an Fc-engineered humanized monoclonal antibody (mAb) against CD19 which is broadly expressed in FL and MZL, and regulates B-cell proliferation via B-cell receptor signaling. In preclinical studies, tafasitamab has shown activity against NHL cell lines in combination with rituximab (anti-CD20 mAb) and lenalidomide (LEN). Tafasitamab monotherapy has shown promising clinical activity in a phase 2a study in pts with R/R NHL (NCT01685008), with an ORR of 29% (n/N=10/34) in pts with FL and 33% (n/N=3/9) in pts with MZL. In an ongoing phase 2, single-arm study (L-MIND, NCT02399085), tafasitamab plus LEN followed by tafasitamab alone demonstrated an ORR of 57.5% (n/N=46/80) with CR of 40% (n/N=32/80) and median DOR of 34.6 months (95% CI: 26.1–NR), in pts with R/R diffuse large B-cell lymphoma (FDA approved indication). These preclinical and clinical observations from phase 2 trials suggest a potential clinical benefit of tafasitamab plus LEN and rituximab for pts with R/R FL or MZL.
Aims: This phase 3 double-blind, placebo-controlled, randomized study is designed to investigate whether tafasitamab plus LEN and rituximab provides improved clinical benefit compared with LEN and rituximab in pts with R/R FL or R/R MZL.
Methods: Pts will be randomized 1:1 to receive tafasitamab (12 mg/kg IV on days 1, 8, 15, and 22 of a 28-day cycle [cycles 1–3], then days 1 and 15 [cycles 4–12]) plus LEN (20 mg PO QD [or starting dose 10 mg PO QD if creatinine clearance ≥30 to <60 mL/minute], days 1–21/ cycle for 12 cycles) and rituximab (375 mg/m^2 IV on days 1, 8, 15, and 22 of cycle 1, then day 1 of cycles 2–5), or placebo (0.9% saline solution IV) plus LEN and rituximab. At randomization, stratification factors will include: progression of disease within 24 months (FL; yes vs no), refractoriness to prior anti-CD20 mAb therapy (FL; yes vs no), and number of prior lines of therapy (FL or MZL; <2 vs ≥2). Radiological (PET) assessment will be performed at baseline, every 12 (± 2) weeks in year 1, 16 (± 2) weeks in years 2–3, and 24 (± 3) weeks in years 4–6; additional assessment performed within 4 (± 2) weeks if progressive disease confirmed before end-of-treatment visit. The primary study endpoint is PFS (investigator assessed [INV] by Lugano 2014 criteria) for pts with FL. Key secondary endpoints are PFS (INV) in overall population (FL and MZL), PET-CR rate (INV) at end of treatment (4–8 weeks after last treatment) and OS in pts with FL. Inclusion criteria include age ≥18 y, histologically confirmed FL (grade 1, 2, or 3a) or MZL (nodal, splenic, or extranodal), documented R/R disease, ≥1 prior systemic anti-CD20 therapy (including anti-CD20 refractory disease), ECOG PS ≤2, adequate systemic organ function, and high tumor burden (per GELF criteria). Exclusion criteria include prior rituximab plus LEN treatment, history of radiotherapy for other diseases (≥25% of bone marrow), nonhematologic malignancy, congestive heart failure (LVEF <50%), active systemic infection, known CNS lymphoma, or severe immunocompromised state. inMIND (NCT04680052, EudraCT2020-004407-13) is currently enrolling pts; planned enrollment is 528 pts with R/R FL and 60–90 pts with R/R MZL. Centers across Europe, Asia Pacific and North America are expected to participate in this study.

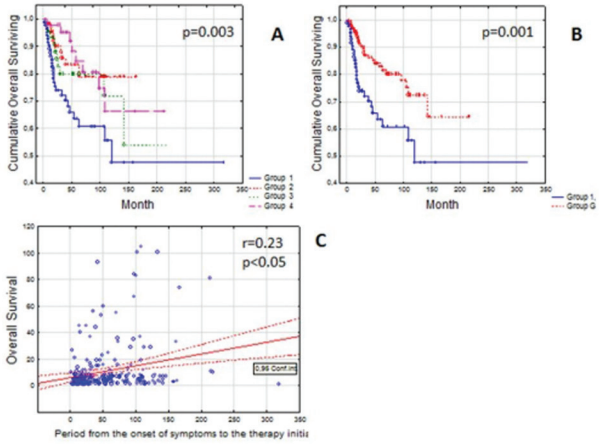
Summary/Conclusion: Not applicable

PB1573 OUTCOMES OF BENDAMUSTINE + RITUXIMAB FIRST-LINE THERAPY IN PATIENTS WITH INDOLENT NON-HODGKIN'S LYMPHOMA OR MANTLE CELL LYMPHOMA: REAL WORLD EXPERIENCE

R. Kotchetkov [1,2,*], D. Susman [3], E. DiMaria [1], L. Gerard [1], D. Nay [1]

[1]Medical Oncology, Royal Victoria Health Center, Barrie, [2]medicine, University of Toronto, Toronto, [3]medicine, University of Western Ontario, London, Canada

Background: Bendamustine plus rituximab (B+R) was established as a preferred first line therapy for patients with previously untreated indolent non-Hodgkin's lymphoma based on the BRIGHT and STIL trials. However, only few reports on efficacy and safety data of this combination in the real-world setting are available to-date.
Aims: To assess pattern of bendamustine + rituximab administration, efficacy and safety in non-clinical trial setting.
Methods: We conducted a retrospective review of patients who received therapy with B+R in our cancer center from June 2013 to dECEMBER 31, 2020. Patients with indolent non-Hodgkin's lymphoma (iNHL) and mantle cell lymphoma (MCL) who received at least one cycle of B+R were evaluated.
Results: Amongst a total of 201 patients 56% were males and 44% females. Median age at B+R initiation was 72 years (range 34-94). Follicular lymphoma (FL) (50.3%), marginal zone lymphoma (MZL) (19.4%), and lymphoplasmacytic lymphoma (LPL) (14.5%) were the most common iNHL. Stage 3 and 4 diseases represented 19.9% and 68.6% of patients. Extranodal disease was found in 35.8%. The proportion of patients with high-risk disease was 48.5% for FL (FLIPI score ≥3), 86.6% for LPL (WMISS score ≥2), and 80.5% for MCL (MIPI score ≥6.2). History of secondary malignancy was presented in 23.4% of patients; 88.6% had ECOG 1-2, and 11.4% ECOG 3. Most common indications for B+R initiation were bulky symptomatic lymphadenopathy (69.1%), cytopenia (36.8%) and constitutional symptoms (36.8%). Fifty-eight percent of patients had more than one indication for therapy. Median number of B+R cycles delivered was 6 (range: 1-6), median dose of bendamustine was 90 mg/m^2 (range: 45-90). Full doses of bendamustine were given in 66.7% of patients. In patients (33.3%) with dose reduction, the mean dose was 78.3 mg/m^2. A total of 50.8% completed 6 cycles with no delays; and 49.2% of treatment was delayed (mean delay time:1.8 weeks). Overall response was 94.5%, with 77.1% complete and 17.4% partial remission. Median follow-up duration was 35 months (range: 4-91). At the end of follow-up, event free survival (EFS) was 77.1% and overall survival (OS) was 79.6%. Six percent of patients relapsed. In total, 14.5% develop secondary malignancies (6.5% non-hematological and 8% hematological) including 14 cases (7%) of aggressive B-cell lymphoma and 2 cases of myelodysplastic syndroms. A total of 16.9% of patients required support with G-CSF. The total number of adverse events was the highest in cycle one and decreased consistently with each cycle. Grade 3-4 neutropenia was recorded in 17.4%, febrile neutropenia in 8.0%, grade 3-4 anemia in 8.0%, and grade 3-4 thrombocytopenia in 3.9% of patients. Rituximab-associated infusion reactions were the most common in cycle 1 (46%) and 2 (16%). The rate of skin rash, fatigue, nausea/vomiting and infections were similar in each cycle. A total of 84.6% of patients proceeded to rituximab maintenance.



Summary/Conclusion: B+R chemoimmunotherapy was feasible to administer and retained its efficacy in non-clinical trial (real world) setting. HIgehr than previously reported rate of aggressive B-cell lymphoma was noted. No new adverse events of secondary non-hematological malignancies were found.

PB1574 ASSOCIATION OF DISEASE HISTORY DURATION AND SURVIVAL RATES IN FOLLICULAR LYMPHOMA PATIENTS AS A NEW FACTOR OF UNFAVORABLE PROGNOSIS.

S. Kravchenko [1,*], K. Sychevskaya [1], A. Misurina [1], F. Babaeva [1]

[1]National Research Center for Hematology, Moscow, Russian Federation (Russia), Moscow, Russian Federation

Background: Indolent and aggressive lymphomas differ in clinical course with a short anamnesis and a rapid increase in tumor mass characterized for the latter. However, the factor oh the disease history duration (DHD) is not sufficiently studied within nosological forms. At present DHD as a factor of patient risk stratification is not included in any prognostic scale.
FL grade 3 is a very heterogeneous group of patients with different outcomes of the disease. So new stratification factors research is encouraged for FL grade 3 patients.
As genetic analysis is not readily available in general practice and, moreover, no key unfavorable genetic abnormalities have been identified for FL with an unfavorable prognosis, such a clinical parameter as DHD could be a feature reflecting the biological rate of tumor development.
Aims: To determine the prognostic value of DHD in patients with FL grade 3 and transformation of FL into large-cell lymphoma.
Methods: The medical histories of 257 patients with FL high-grade from 1998 to 2020 were analyzed. Based on DHD values the following groups of patients were formed: group 1, DHD less than 3 months (#85); group 2, DHD from 3 to 6 months (#72); group 3, DHD from 6 to 12 months (#49); group 4, DHD more than 12 months (#51). Statistical analysis was carried out in STATISTICA 12 software (StatSoft, USA). Pearson correlation, $\chi 2$ test, Kaplan-Meyer survival analysis, Log-Rank test were used. Overall (OS) and event-free (EFS) survival were studied as control points.
Results: When comparing four patients groups the lower OS and EFS in group 1 (Figure 1A) were noted. Survival rates in groups 2, 3, and 4 were almost identical, which allowed us to merge into them into general group G. The following statistically significant differences ($p<0.05$) were found between group 1 and group G: 3 year OS was 71% and 87%, and 10-year OS – 47% and 72%, respectively (Figure 1B). 3-year EFS in groups 1 and G were 38% and 61% and 10-year EFS –20% and 41%, respectively (are not illustrated).
The association of DHD and OS was also confirmed by the correlation analysis ($r=0.23$, $p<0.05$) (Figure 1C).
In the $\chi 2$ test, there were no differences between the groups in the following terms: FL grade, complete and partial remission or disease progression frequency, Ann-Arbor stage, bulky lymph nodes presence, bone marrow involvement, as well as immune chemotherapy regimen (high-dose therapy, CHOP, EPOCH and others). In group 1, the frequency of high risk FLIPI-1 values was slightly higher, but not statistically significant.
Thus, clinical features of patients groups with different DHD were comparable, which suggests a reliable association OS, EFS and DHD.

Summary/Conclusion: We suggest that the association of DHD and survival rates in FL patients is not only a clinical observation. Currently, the hematopoiesis chronology phenomenon is not sufficiently studied. This interesting area of hematology implies the existence of regular rhythms of cell differentiation. The tumor stem cell resting period and its proliferation activation time, in contrast to the normal precursor, are apparently individual and predetermined by the tumor genome. So DHD considered in the study may reflect this tumor chronological nature. In this regard, the relationship with patient survival rates becomes clear.
The practical result of this work is the identification of a new factor of unfavorable prognosis, which can potentially be used in FL prognostic scales design.

PB1575 TOWARDS PERSONALIZED MEDICINE FOR RELAPSED/REFRACTORY FOLLICULAR LYMPHOMA PATIENTS: THE CANTERA LUPIAE REGISTRY

M. de Valdecilla, Santander, Spain, [12]Hematology, University Medical Center, Groningen, Netherlands, [13]Hematology, National Cancer Institute, Kiev, Ukraine, [14]Hematology, Klinički Bolnički Centar Split, Split, Croatia, [15]Hematology, Amsterdam University Medical Center, Amsterdam, Netherlands, [16]Hematology/ CHIMINO, University of Modena and Reggio Emilia, Modena, Italy

Background: Follicular lymphoma (FL) is a highly heterogeneous entity with variable clinical outcomes. In some patients, the disease follows an indolent course with durable remissions after treatment, while in others transformation or aggressive and chemotherapy-resistant disease develops (Tan et al., Blood 2013). Especially early relapse within 2 years (POD24) identifies a poor-prognosis group of patients with an unmet medical need (Casulo et al., J Clin Oncol 2015). Current knowledge is insufficient to identify patients with high-risk disease, nor to guide treatment decisions.
Aims: In this study we aim to define the prognosis of refractory/relapsed FL after second line therapy, to report current treatment strategies, and to provide rationale for the design of novel treatments strategies. In addition, the project provides ground for an international network of young lymphoma researchers and promotes multicentric collaborations. We here present preliminary data on patient and disease characteristics at diagnosis and at relapse.
Methods: We initiated an international, prospective, observational registry to study the clinical course of relapsed/ refractory (R/R) FL (NCT04587388). Patients with histologically confirmed FL are registered in the study at the time of the first event after first-line treatment, documented by biopsy, imaging, or clinical evaluation. Primary and secondary outcome measures are: (1) rate of progression of disease within 24 months from start of second line treatment (second POD24),

(2) overall survival (OS), (3) progression-free survival after second line therapy (second PFS), and (4) complete response rate at 30 months (CR30) from start of second line treatment (second CR30). The study was approved by the Ethics Committee of all participating centers.
Results: The project was initiated in the Netherlands in 2019, and as of December 2020 46 consecutive R/R FL patients have been included at 11 sites in 6 countries. On 42 patients with available data, one third experienced relapse and one third progression of previously stable/ responding disease, while 13 events occurred during treatment (either induction or maintenance therapy). The median time between initial diagnosis and relapse/ progression was 34 months (range 1-245; n = 38); relapse/ progression occurred within 24 months (POD24) in 12 patients. Details on patients and disease characteristics are summarized in Table 1. Although the number of patients does not allow correlative analysis, various findings stand out, a.o.: (1) the variable use of the FDG-PET scan, especially at initial diagnosis (60%); (2) the differences in choice of chemo-immunotherapy regimen; and (3) more strikingly the variance in application of maintenance therapy after first-line treatment (yes: 51%).

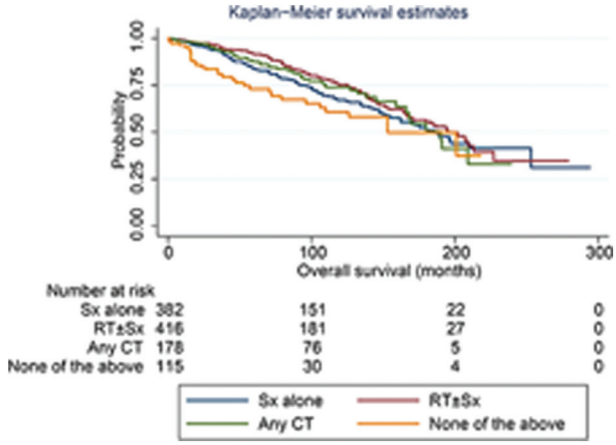
	PR	11/39 (28)	2/18 (11)
	PD	5/39 (13)	3/18 (17)



Summary/Conclusion: This is the first report on proceedings of the LUPIAE FL registry. Data on the first set of included patients confirm variability in diagnostic and therapeutic approaches in centers across Europe. We aim to further extend our registry (to 500 patients) to allow characterization of the clinical course of R/R FL. The ultimate goal is to understand the optimal management of patients with POD24 and use these data as a rationale for the design of an interventional trial for this group of patients. Ancillary biological studies will be planned depending on samples availability and enrolment.
Furthermore, this project has already shown the feasibility of a collaboration between junior hematologists across Europe, which will be the base for future initiatives. All hematologists (also from outside of Europe) are invited to join the project.

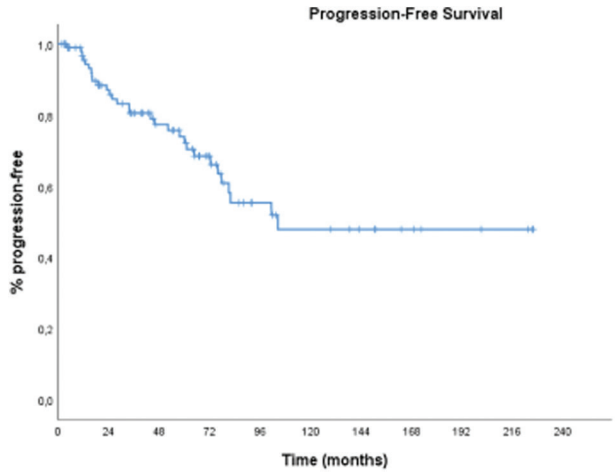
PB1576 CONVENTIONAL INTERVENTIONS FAILED TO PROVIDE SURVIVAL BENEFIT FOR EARLY-STAGE MAJOR SALIVARY GLAND MARGINAL ZONE LYMPHOMA

H. Liu [1], L. Cao [1], C. Yang [1], Y. Miao [1], X. Du [1], R. Huang [1], H. Zhu [1], X. Shi [1], W. Xu [1], J. Li [1], L. Fan [1,*]

[1]Department of Hematology, Jiangsu Province Hospital, The First Affiliated Hospital of Nanjing Medical University, Nanjing, China

Background: Major salivary gland marginal zone lymphoma (MSGMZL) is a rare malignant tumor with predominantly early-stage (I/II) lesions.
Aims: This study aims to identify prognostic factors in early-stage MSGMZL and compare long-term outcomes of conventional approaches.
Methods: We conducted a population-based cohort study utilizing the Surveillance Epidemiology and End Results (SEER) database and used log-rank test, Cox regression, and propensity score matching (PSM) analyses to explore the association of characteristics and therapeutic methods with survival.
Results: We identified 1,091 early-stage MSGMZL cases with a median follow-up of 81.0 months. Univariate and multivariate analyses indicated that age over 60 years at diagnosis, diagnosis before 2005, and coexisting malignancy were unfavorable independent predictors for overall survival; the former two also were adverse predictors for disease-specific survival. By PSM, we compared the effects of conventional interventions, including surgery, radiotherapy, and chemotherapy, and found no statistically significant differences between treatments after matching. In the subgroup analysis according to the above prognostic factors, there was inadequate data to identify any one of the conventional therapies as superior to the others. A notable one is patients diagnosed after 2005 had better survival curves than those diagnosed before 2005 with the same strategy, indicating that there might other therapy involved in the treatment of patients with early-stage MSGMZL. According to the literature, the anti-CD20 monoclonal antibody is the most promising drug responsible for improved survival.

Summary/Conclusion: In this retrospective study from a database, conventional interventions failed to provide any survival benefit for early-stage MSGMZL patients. A novel therapy might be a better alternative.



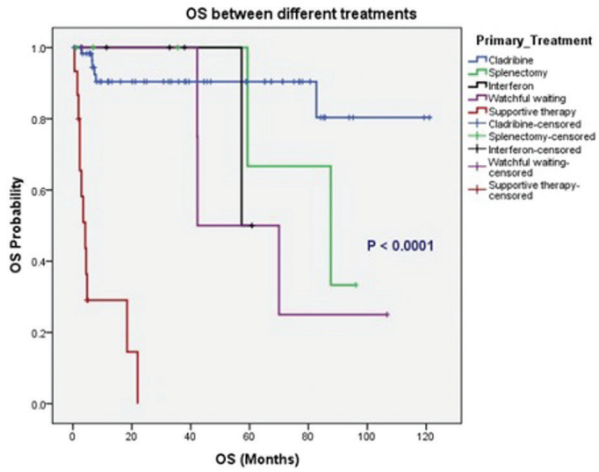
PB1577 EARLY STAGE FOLLICULAR LYMPHOMA: A CURABLE DISEASE? LONG-TERM FOLLOW-UP FROM A SINGLE UNIT.

S. Diavati [1,*], T. Giannikos [1], P. Tsirkinidis [1], M. P. Siakantaris [1], P. Tsaftaridis [1], E. Plata [1], J. V. Asimakopoulos [1], E. Konstantinou [1], D. Galopoulos [1], I. Vassilopoulos [1], E.-F. Triantafyllou [1], M. Belia [1], C. Chatzidimitriou [1], M. Efstathopoulou [1,2], G. Tsourouflis [3], M. Moschogiannis [2], S. Sachanas [2], X. Giakoumi [2], G. A. Pangalis [2], K. Konstantopoulos [1], T. P. Vassilakopoulos [1], M. K. Angelopoulou [1]

[1]Hematology and BMT Department, Laikon General Hospital, [2]Department of Hematology, Psychikon Branch, Iatriko Athinon, [3]2nd Department of Propaedeutic Surgery, Laikon General Hospital, Athens, Greece

Background: Early stage follicular lymphoma (FL) is considered a potentially curable disease. Involved-field radiotherapy (IFRT) ± immunotherapy/immunochemotherapy is the standard treatment approach by most centers, although few data exist from randomized clinical trials. Long-term follow-up is needed to rule out very late relapses.
Aims: The aim of the present study was to assess the long-term outcome and identify prognostic factors and best treatment approaches in a series of patients with localized FL treated in a single unit.
Methods: This is a retrospective analysis on 106 consecutive localized FL patients diagnosed between 2000 and 2020 from a single center. The mean follow-up of the patients is 82.3 months. The following parameters were evaluated as possible prognostic factors: stage, age, gender, histological grade, ki-67, hemoglobin, LDH, monocyte count, lymphocyte count, bulk (>/= 7cm), FLIPI score and type of treatment.
Results: Median patients' age was 56,4 years and 67 (63%) were females. 72 (68%) cases were histological grade 1/2 and the remaining 34 (32%) were grade 3A. 71 patients (67%) were Stage 1 and 35 (33%)

Stage 2; 94 patients (88,7%) had performance status 0. 14 patients (13.3%) has an elevated LDH and 19 (18.1%) had bulky disease. IFRT was delivered in 50 (47.6%) patients and anti CD20+ antibody (Ab) in 74 (70.5%). More specifically 21% received IFRT only, 29% received IFRT+Rituximab, 45% received anti CD20+ Ab+chemotherapy and 5% received chemotherapy only. Complete response was achieved in 92,3 %. 31 patients progressed (among these 35% within 24 months from initiation of treatment; 93% experienced limited stage disease at first relapse). Of note, there was a median progression free survival (PFS) of 104,39 months and a 5-and 10-year PFS of 74% and 48% respectively. Most importantly, a plateau in the PFS curve was observed at 8.7 years. At last follow up, 10 patients (9,4%) had expired but only 5 (4.7%) died due to lymphoma, resulting in a 10-year overall survival (OS) of 88% and a 10-year disease specific survival (DSS) of 95%. There was no significant difference in PFS, OS and DSS according to treatment. Bulky disease was the only poor prognostic factor for PFS, although with marginal significance, whereas stage, bulk and FLIPI score were prognostic for DSS.



Summary/Conclusion: With long follow-up, early stage FL is a curable disease for the majority of patients with no relapses observed after 8.7 years, irrespectively of treatment. Bulky disease seems to be the most important prognostic parameter.

PB1578 HAIRY CELL LEUKEMIA: SINGLE CENTER EXPERIENCE

A. Hamed [1,2], Z. Emarah [1,2,3,*], M. Zakia [4,5], N. Eisa [3,6,7], H. Ghazy [1,2,3]

[1]Medical Oncology Unit, Oncology Center, Mansoura University, [2]Medical Oncology Unit, Internal Medicine Department, Faculty of Medicine, Mansoura University, [3]Adult Bone Marrow Transplantation Unit, [4]Pathology Department, Oncology Center, Mansoura University, [5]Pathology Department, Faculty of Medicine, Mansoura University, [6]Clinical Hematology Unit, Oncology Center, Mansoura University, [7]Clinical Hematology Unit, Internal Medicine Department, Faculty of Medicine, Mansoura University, Mansoura, Egypt

Background: Hairy cell leukemia (HCL) is an uncommon chronic B cell lymphoproliferative disorder that represents approximately 2% of all leukemias and less than 1% of lymphoid neoplasms. The lack of large national and international registries on HCL has limited the ability to identify clear clinico-epidemiological characteristics in this rare disease.
Aims: To evaluate the hairy cell leukemia patients in Egyptian population as regard epidemiological, pathological, immunophenotypic, clinical data as well as treatment modalities and outcome.
Methods: This is a retrospective observational study in which 92 patients diagnosed with HCL were reviewed through the electronic health records between January 1, 2008 and December 31, 2019.
Results: Median age of patients was 50 years (23-81), patients have < 60 years represented 78.3%. Male to female ratio was 5.5:1. The prevalence of hepatitis c virus (HCV) infection was triple that of the general population and appeared to have no effect on overall survival (OS). Most patients (88%) had no comorbidities. The most common presentations were weakness and fatigue then B symptoms, 80% of patients had splenomegaly with a median of 21 cm (massive) and 19% had splenectomies. Hepatomegaly is reported in 40% of cases and uncommonly less than 2% of the cases had abdominal lymphadenopathy. Most of the patients had varying degree of cytopenia varying from pancytopenia (50%), bicytopenia (43.5%), thrombocytopenia (69.3%), leukopenia (53%) and anemia only (6.5%). Hairy cells in peripheral blood samples were observed in 18.5% of cases, dry bone marrow aspirates were in 40% and lymphoid aggregates in 79% of cases. Diffuse infiltrative pattern in bone marrow biopsies was observed in 75% of the patients and the pattern of infiltration posed no effect on overall survival. Regarding the therapeutic options; 61 patients received cladribine, five patients received interferon (INFa), six patients had palliative splenectomies, five patients were subjected to watchful waiting and 15 patients received supportive therapy. Irrespective of the received treatment; complete remission (CR) was achieved in 43.5% of the patients, 8.7% had partial remission (PR), 26.1% had stationary disease, 3.3% had progressive disease, 5.4% had treatment related mortality and 13% had disease related mortality. The presence of comorbidities, Age >60 years, fever, pancytopenia, hemoglobin level < 8 gm/dl and WBCs < 4 k/ml all inversely affected OS (p-value = 0.028, 0.002, 0.008, 0.03, 0.02, 0.02 respectively). After median follow up of 57 months, 68 cases (73.9%) were alive. The OS% of all the cases regardless of the treatment modality was 78% at 1 year, 65% at 5 years and 53% at 10 years. For the patients who received cladribine; 64% had CR and 11.5% had PR with a relapse rate of 19.5%. The OS with cladribine as first line was 91% at 5 years, 83% at 10 years. Treatment with cladribine improved OS in comparison to other treatment modalities (p < 0.0001).

Summary/Conclusion: HCL in Egypt is a rare NHL that have different clinicopathological features especially in association with hepatitis C infection that necessitate participation in international registries for HCL e.g. Hairy Cell Leukemia Foundation, to investigate the most optimal treatment strategies for these neoplasms in the real world population.

PB1579 MYD88 MUTATION IN WALDENSTROMSÖM MACROGLOBULINEMIA AND TREATMENT OUTCOME. A SINGLE CENTRE EXPERIENCE

A. Konenko [1,*], B. Hennessy [1], S. Kumar [1], D. Walsh [2], F. Quinn [3], E. Elhassadi [1]

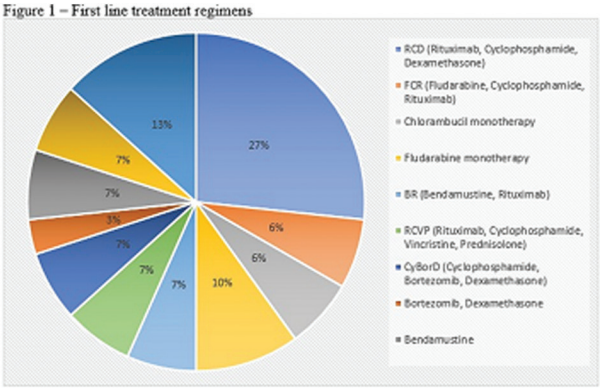
[1]Hematology, [2]Pharmacy, University Hospital Waterford, Waterford, [3]Cancer Molecular Diagnostics, St. James's Hospital, Dublin, Ireland

Background: Waldenstromsöm Macroglobulinemia (WSM) is an indolent mature B-cell neoplasm which accounts for 1 to 2% of all hematological malignancies. WSM is characterized by lymphoplasmacytic cells proliferation associated with a monoclonal immunoglobulin M (IgM). More than 90% of patients with WSM carry point mutation L265P in the MYD88 gene which is shown to be significant for diagnostic and risk stratification purposes.
Aims: This is a retrospective study to evaluate the treatment outcome of WSM patients treated at our institution between 2001 and 2021. Baseline demographic characteristics, clinical features, laboratory findings, including IgM levels and bone marrow findings at diagnosis, International Prognostic Score (IPSS-WM), treatment regimens, response to treatment were analysed. Survival outcomes according to MYD88 mutational status were assessed.
Methods: Patients were identified through our pathology database and data collected using patient's medical records and laboratory results and

patient informed consent obtained. All diagnostic BM aspirates were screened for evidence of MYD88 mutation and results correlated to patient's treatment outcome and survival.

Results: Thirty patients were included in this study, twenty (67%) male and ten (33%) female, with median age of 67years (range 50 – 86). At presentation 80% of patients had anaemia (20% at least grade 3), 60% had lymphadenopathy,30% had splenomegaly, and 30% of patients had IPSS-WM score 3 or greater. Four (13%) cases with bi-clonal B cell disorders (2 Multiple Myeloma, 1 Follicular lymphoma, and 1 Chronic lymphocytic Leukemia) and four patients with immune cytopenia (2 AIHA & 2 ITP). Twenty six patients (87%) received first line treatment (Figure 1). While the remainder four (13%) managed with watch & wait approach due to low disease burden or were not eligible for any treatment due to extreme frailty. Most of treated patients (92%) achieved either a good or very good partial response after first line therapy and only one patient achieved complete response (CR). Six patients (20%) had relapsed and received a second line therapy (1 FCR, 1 Chlorambucil, 1 Ibrutinib, 1 no further therapy due to extreme age, 1 patient with bi-clonal disease with CLL treated with Idelalisib and Rituximab and 1 moved to another institution). One patient underwent autologous stem cell transplant consolidation for relapsed disease after 4 lines of therapy. Twenty (67%) patients' diagnostic samples provide sufficient DNA materials suitable for MYD88 mutation screen. The majority (90%) of analysed samples were positive of MYD88 mutation and only two samples revealed wild-type MYD88 status. The median overall survival (OS) for the entire cohort was ~ 8.5 years (Figure 2). The OS at 36 months was 65%. At the time of the analysis, eighteen patients (60%) are still alive and either on treatment or on active surveillance. Twelve patient (40%) have died, the majority of deaths (67%) were unrelated to WSM but due to comorbidities, 17% related to treatment complications (sepsis) and two (17%) related to disease progression (both MYD88 mutated).

Figure 1 – First line treatment regimens



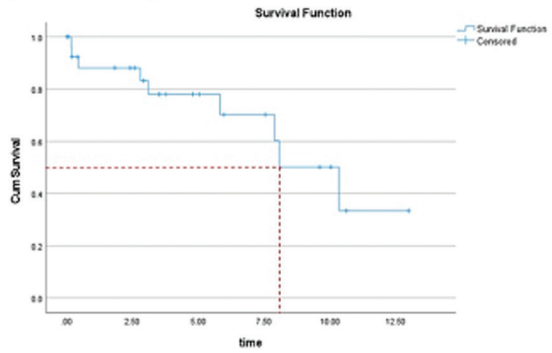


Figure 2 – Survival analysis

Summary/Conclusion: The frequency of MYD88 mutation in our study cohort is comparable with the reported literature. The overall survival in this study was 65% at 36 months and evaluating the MYD88 mutational status impact was limited due the small sample size and retrospective nature of this study. CXCR4 mutation screening for this study cohort is in progress and longer follow up will continue prospectively.

PB1580 RETROSPECTIVE STUDY ON MANTLE CELL LYMPHOMA (MCL) AND TREATMENT OUT-COME-A SINGLE CENTER EXPERIENCE.

E. Elhassadi [1,*], B. Hennessy [2], S. kumar [1], M. Nur [3], C. Shilling [3], L. Sutton [3], M. Catherwood [4]

[1]Haematology Department, [2]University Hospital Waterford, Waterford, Ireland, [3]Pathology Department, University Hospital Waterford, Waterford, Ireland, [4]Molecular Department, Belfast University Hospital, Belfast, United Kingdom

Background: Mantle Cell Lymphoma (MCL) is a rare type of non-Hodgkin lymphoma (NHL), with an aggressive clinical course. MCL is associated with poor prognosis and incurable disease in the majority of the patients. However, a minority of patients will not require any treatment for many years. Although MCL is initially responsive to different conventional chemotherapies, such a response is short-lived. The median overall survival in modern trials incorporating intensive therapy has improved accounting of 8 to 10 years. However *TP53* mutation continue to confers a dismal prognosis in MCL with a median survival of 1.3 years. Targeted therapy and recently more promising CAR-T therapy have revolutionized this disease out-come.

Aims: This is a single-centre, retrospective analysis of MCL patients treated over study period (2006-2020) to evaluate our MCL patients treatment out-come.

Methods: Using our MCL data-base, baseline patient's demographic characteristics, clinical features, laboratory findings, MIPI score, initial/subsequent treatment responses and survival were analysed. Patient's informed consent was obtained. Sub-set of patients have completed p53 disruption screen using both p53 expression on immuno-histochemistry (IHC) and mutational status and this genetic defect impact was evaluated here.

Results: Sixty-one patients were included in this study, with male predominance, median age 67 yrers and the majority with advanced disease. 50% presented with B symptoms and BM involvement in 35 (57%) patients (Table 1). Chemo-immunotherapy (CIT) remains the main treatment modality in our cohort (54/88% patients), resulted in an ORR of 79%, CR 55% and PR 24%, which compares well with the reported literature. 5 (8%) patients were not eligible for any treatment, one patient received IFRT only for early-stage disease and one patient had splenectomy. Rituximab maintenance was used in 29 (48%) and 3 (5%) patient had ASCT. 21 (39%) patients had relapsed disease,11(52%) patients treated with Ibrutinib as a second line, 7 (33%) patients treated with CIT, with one (5%) patient with HL relapse treated with ABVD and 2 (10%) patients were not suitable for further treatment. Eight (38%) experienced further disease relapse, 3 (14%) patients received Ibrutinib and 5 (23%) patient received CIT and 1 (1.6%) patient had Allo-SCT. At time of the study analysis, 40 (67%) patients were still alive and 23 (38%) patients had died. The median survival for all the cohort was 3 years (range 0-14 years). To date, 29 (46%) patient's samples screened for p53 disruptions, only 6 (10%) patient's sample demonstrate a high p53 expression and harboured deleterious *TP53* mutation by NGS sequencing. Most of MCL cases harbouring *TP53* mutations have an aggressive disease course with multiple disease relapses and lymphoma related deaths (80%). In sub-set analyses, the OS was only 4 years in *TP53* mutated disease and was not reached in wild-type *TP53* cohort (P value = 0.007, log rank test) which is comparable to the reported data. The median overall survival (OS) for the entire cohort was 7 years (Fig 1), according to disease sub-type classic vs blastic, the median survival were 8 years vs 2 years respectively.

Patient's Characteristics (61)	Patients No	%
Gender (M *vs* F)	44 *vs* 17	72% *vs* 28%
Median age	67	Range 36-88
Performance status (PS) = or > 2	17	28%
Early *vs* Advance stage	13 *vs* 48	20% *vs* 80%
Nodal *vs* Extra-nodal Disease	39 *vs* 16	64% *vs* 26%
Sub-Type Classical *vs* Blastic *vs* Indolent	54 *vs* 11 *vs* 5	74% *vs* 18% *vs* 8%
MIPI score High *vs* intermediate *vs* low	37 *vs* 12 *vs* 12	60% *vs* 20% *vs* 20%

Table 1 Patient's Characteristics

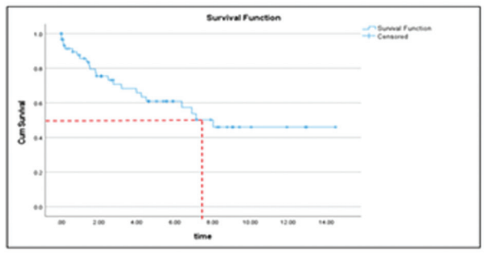

Figure 1 Entire Study Cohort KM OS survival curve

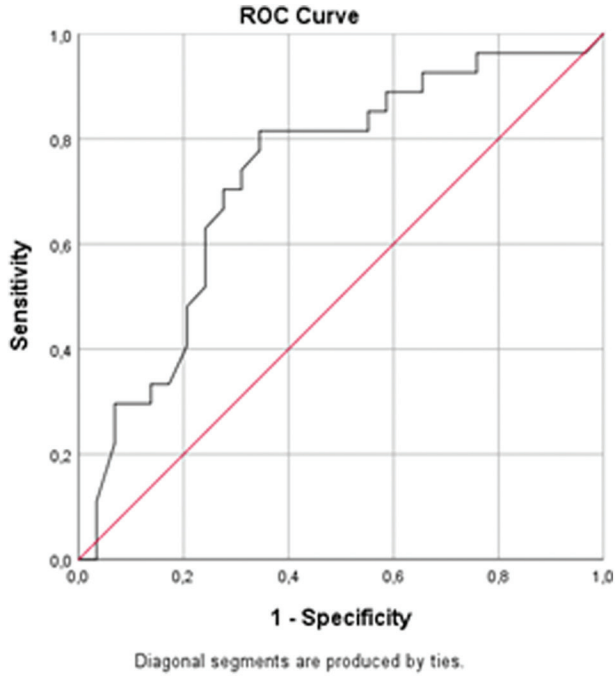
Summary/Conclusion: Mantle cell lymphoma (MCL) continue to be challenging disease to treat with a short lived treatment response and frequent relapses. Genetic risk stratification and clinical trials enrollement are of great importance. Our data showed comparable treatment outcome similar to the reported literatures.

Infections in hematology (incl. supportive care/therapy)

PB1581 PEGFILGRASTIM IN THE SUPPORTIVE CARE OF HEAVILY PRETREATED MULTIPLE MYELOMA IN POMALIDOMIDE-BASED TREATMENT

C. Cerchione [1,*], L. Catalano [2], D. Nappi [3], A. E. Pareto [4], G. Musuraca [1], A. Lucchesi [1], S. Ronconi [1], M. Ceccolini [1], F. Pane [2], G. Martinelli [1]

[1]Hematology Unit, Istituto Scientifico Romagnolo per lo Studio e la Cura dei Tumori (IRST) IRCCS, Meldola (FC), [2]Hematology, AOU Federico II, Napoli, [3]Hematology, Bolzano Hospital, Bolzano, [4]Hematology, San Giuliano, Giugliano (NA), Italy



Background: Pegfilgrastim is a pegylated long-acting recombinant form of G-CSF that extends the half-life and allows for once-per-cycle dosing, requiring less frequent dosing than nonpegylated G-CSF.
Aims: The objective of this study was to compare the efficacy and safety of pegfilgrastim in patients affected by heavily pretreated MM, treated with pomalidomide-dexamethasone, in order to determine whether a single subcutaneous injection of pegfilgrastim is as effective as daily injections of standard filgrastim, in terms of haematological toxicity, febrile neutropenic episodes, antibiotic usage and hospedalization duration.
Methods: 57 patients (31 M and 26 F) were enrolled, median age at diagnosis 69 years (r. 52-84), and median age at start of treatment 76 years (r.56-90) treated with several lines of treatments (median 7, r. 2-12), every refractory to all the drugs previously received, received Pomalidomide-Dexamethasone (P 4 mg for 21 days, D 40 mg days 1,8,15,22, pegfilgrastim day +8) every 28 days, until progression. Since first course, received in domestic setting, with a very good compliance, patients performed blood counts once weekly and received, from day +8 to day +19, prophylactic oral chinolonic antibiotics and anti-fungal drugs. During neutropenia after first cycle, Filgrastim (5 µgr/kg/day for 3 days) was given if neutrophils count was <1500 x 10^9 cells/L.
Results: Median number of filgrastim administrations was 4.6 (r. 3-6); nadir neutropenia was registered after a median of 10.4 days (r. 7-14); median of nadir neutrophil count was 1.13 x 10^9 cells/L (r.0.3 – 1.5), with maximum duration of 14 days. From the second course, all patients switched to prophylaxis with pegfilgrastim (6 mg), injected subcutaneously with a single administration on day +3 independently from the neutrophil count at that time. During pegfilgrastim, neutropenia was never longer than 8 days, with a consequent reduction of neutropenia-related infections. Median nadir neutrophil count, evaluated for every patients for at least three courses of therapy (r. 3-6) registered at day +11, was 1.28 (r.0.9-2.2). Only 4 patients needed a supplement of 3 administrations of filgrastim. Pegfilgrastim was well tolerated in all patients: main side effects in our patients were mild fever and bone pain (21.2%).
Summary/Conclusion: In patients affected by heavily pretreated MM treated with pomalidomide-dexamethasone, pegfilgrastim seems to reduce the incidence of severe neutropenia and infections and may increase the possibility to maintain the scheduled time of treatment.

PB1582 PROGNOSTIC SIGNIFICANCE OF NEUTROPHIL-TO-LYMPHOCYTE RATIO IN THE DETERMINATION OF SEVERE PROGNOSIS OF HEMATOLOGICAL PATIENTS WITH COVID-19 INFECTION. DATA OF MOLDOVAN HEMATOLOGICAL CENTER.

V. Tomacinschii [1,2,*], M. Robu [1], S. Buruiana [1], A. Golub [2], C. Dudnic [1], D. Urescu [1], V. Finciuc [1]

[1]Department of Hematology, Nicolae Testemitanu State University of Medicine and Pharmacy of the Republic of Moldova, [2]Department of Hematology, Institute of Oncology of Republic of Moldova, Chisinau, Moldova, Republic of

Background: COVID-19 infection represents a continuous challenge for the medical society. . Patients with hematologic disease and a COVID-19 infection were found to have a significantly worse prognosis compared to the ones infected with COVID-19 but without hematological cancer.
Aims: Evaluation of neutrophil-to-lymphocyte ratio(NLR) as a potential marker of the severity and morbidity of COVID-19 infection among hematological patients.
Methods: A retrospective study was conducted on 56 COVID positive patients who have been hospitalized between July 2020 and January 2021. Medical records of the cases are analyzed and compared retrospectively for demographic, clinical, laboratory data, and radiological findings. The standard deviation, receiver operating curve (ROC) and area under the curve (AUC) were calculated to compare the diagnostic performance NLR into the determination of the disease severity.
Results: Out of 56 examined patients 29 (51,2%) were females, the median age of infection was 57 years (21–84 years). The most frequent hematological malignancies among the studies group were: Non-Hodgkin lymphomas (46,2%), followed by multiple myeloma(16%), acute leukemias(10,7%), chronic lymphocytic leukemia (7,1%), and others. 35 out of 56 patients developed a severe form of COVID-19 infection(62,5%), out of them, 27(77,1%) necessitating access into an ICU unit. Medium severity was detected in 16 patients(28,6%), mild form being diagnosed in just 5 of them(8,9%). The mortality rate in the study group constitutes 35,7%(20 of 56 patients). NLR had a mean of 8,03±7,41, having a lower index in patients with mild to moderate COVID-19: 6.11±6,09 and higher in the group of patients with severe forms: 9.18±7,96. On receiver operating characteristic curve (ROC) analysis, the predictive ability of NLR to detect critical patients was significant (p= 0.003; AUC:0.729), with an optimal cut-off value of 8.375 having 82% sensitivity and 66.7% specificity to determine the severe COVID-19 cases among hematological patients.

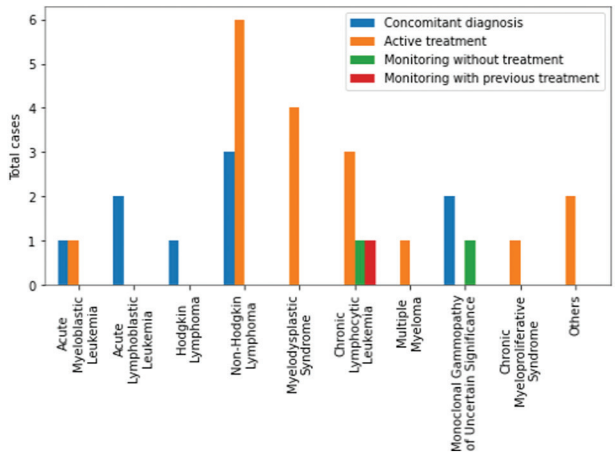
Summary/Conclusion: This study confirmed the high risk of mortality among hematological patients showed previously in the literature. Severe forms of COVID-19 were diagnosed in 62,5% of cases. The mortality rate in the study group constitutes 35,7%. NLR can be a useful tool in the prediction of severe cases of COVID-19 infection with quite high sensitivity (82%) but with a moderate specificity(66,7%).

PB1583 COVID-19 OUTCOMES OF PATIENTS WITH HEMATOLOGIC MALIGNANCIES: A SINGLE CENTER EXPERIENCE

N. Spyridis [1,*], D. Mallouri [1], T. Chatzikonstantinou [1], C. Demosthenous [1], N. Stavroyianni [1], A. Lalayanni [1], I. Batsis [1], I. Sakellari [1], A. Anagnostopoulos [1], D. Sotiropoulos [1]

[1]Hematology Department - HCT Unit, G.Papanikolaou Hospital, Thessaloniki, Greece

Background: SARS-CoV-2 is a novel coronavirus causing an infection, named Coronavirus Disease 2019 (COVID-19). As of February 22, 2021, the virus had affected more than 112 millions individuals and resulted in over 2,4 millions deaths worldwide. Mortality can be as high as 15% in elderly patients, and/or in patients with comorbidities. Data from studies suggest that patients with cancer have a higher incidence of severe events



after contacting the virus. Very few data are available on COVID-19 outcomes in patients with hematologic diseases who are highly immunocompromised due to their underlying disease and the treatments they receive, with high risk of morbidity and mortality from COVID-19.
Aims: The purpose of this study was to perform a review to quantify the outcomes (hospitalizations and deaths) of patients with hematologic malignancy and COVID-19.
Methods: Our department consists of Hematology Clinic and BMT Unit. We included patients with a hematologic disease, with laboratory-confirmed COVID-19 infection between October 2020 and February 2021. A confirmed case of COVID-19 was defined by a positive result on RT-PCR assay. We reviewed hematological medical records to collect demographic, clinical, and treatment data and outcomes of COVID-19. We evaluated 73 patients (43 male, 30 female, median age 61). Information extracted included total number of patients, coronavirus symptoms, hospital admission rate, death rate. Hematologic malignancy subtypes were: acquired bone marrow failure syndromes; acute leukemias; lymphomas; chronic lymphocytic leukemia; plasma cell dyscrasias; MPNs; other hematologic conditions; stem cell transplantation.
Results: According to our analysis, regarding COVID-19 symptoms at diagnosis, 47 of 73 pts (64%) presented fever, as single symptom or combined with at least one more symptom, 20 of 73 pts (27%) presented two or more symptoms, including anosmia, cough, shortness of breath, myalgias, fatigue, while 9 of 73 pts (12%) were asymptomatic and diagnosis confirmed only with positive PCR test. Patients presented with moderate or severe COVID-19 were 28 of 73 (38%), while 9 of 28 hospitalized pts (32%) required Intensive Care Unit (ICU) admission.
Data collected regarding hematologic malignancy subtype showed: lymphomas, non including CLL, 24 of 73 pts (33%), CLL, 17 of 73 pts (23%), acute leukemias, 7 of 73 pts (10%), MPNs, 8 of 73 pts (11%), acquired bone marrow failure syndromes, 5 of 73 pts (7%), multiple myeloma, 3 of 73 pts (4%), other hematologic conditions 5 of 73 (7%), while patients who underwent transplantation were 4 of 73 (5%). Regarding treatment, patients divided in two subgroups, 52 of 73 (71%) received anticancer therapy at some time in their lives, while 21 of 73 pts (29%) have never been on treatment.
Total death rate was 23% (17 of 73 pts), while among hospitalized pts was nearly 54% (15 of 28), with all patients requiring ICU not surviving (9 of 9, rate 100%). 2 of 17 pts (11%) died without hospitalization. Death rate in CLL pts was 41% (7 of 17 pts) with 2 of 17 (11%) not on treatment, in lymphomas 16% (4 of 24 pts), while in other hematologic subgroups were reported from 1 to 2 deaths per group.
Summary/Conclusion: Hematological patients appear to be a population very vulnerable to COVID-19 infection, with significant morbidity and mortality. More data are necessary in further surveys from more centers and larger number of patients. Hematology departments should remain COVID-19 free zones dedicated only to hematologic treatment and patients should strictly comply with social distancing.

PB1584 SARS-COV-2 INFECTION IN HAEMATOLOGICAL PATIENTS: DESCRIPTIVE COHORT STUDY OF HOSPITALIZED PATIENTS IN A TERTIARY CARE CENTER

A. M. Hoyos Brea [1,*], J. Á. Raposo Puglia [2], M. T. Fábregas Ruano [3], S. Chulián [4,5]

[1]Department of Hematology and Hemotherapy, Hospital Universitario Puerta del Mar, Cádiz, [2]Deparment of Hematology and Hemotherapy, Hospital Universitario Puerta del Mar, Cadiz, [3]Department of Internal Medicine, Hospital Universitario Puerta del Mar, Cádiz, [4]Biomedical Research and Innovation Institute of Cádiz (INiBICA), Hospital Universitario Puerta del Mar, Cadiz, [5]Department of Mathematics, Universidad de Cadiz, Puerto Real, Spain

Background: The novel coronavirus SARS-CoV-2 was officially detected in Spain on January 31, 2020. Since then, the health system has suffered 3 waves of healthcare pressure due to this pandemic infection. There was concern about the impact of Coronavirus 2019 disease (COVID-19) being significant in haematological patients.
Aims: Find out the mortality rate by COVID-19 in a cohort of hematological patients. Identify potential predictive parameters associated with poor outcome in patients with a diagnosis of haematological malignancy and COVID-19.
Methods: Retrospective and descriptive study of hospitalized patients in the Hematology Clinical Management Unit at our center, between February 12, 2020 and February 12, 2021. The patients had a diagnosis of a haematological malignancy and laboratory-confirmed COVID-19. We performed a Pearson correlation test on Phyton between variables of interest.
Results: 356 patients were admitted in the Hematology Unit in the referred period.
Of these, 30 had SARS-CoV-2 infection on arrival or during their hospital stay (10% nosocomial infection rate). We summarize in Table 1 total cases reported by diagnostic and state.
There was a male predominance (69%), with a median age of 67 years old [14-90]. Average days of symptom onset until admission: 7.81 days. Chest X-ray images at the diagnosis: bilateral pneumonia (37.9%), peripheral infiltrates (13.8%), unilateral infiltrates (17.2%).
Patients were treated according to local guidelines with high-dose corticosteroid pulses, remdesivir and interleukin inhibitors. Only 13,3% of them needed additional support in the Intensive Care Unit.
Mortality rate in our cohort was 30%. The mortality rate at our hospital for patients with COVID-19 and no haematological malignancy within the same period of time was 10%. By subgroups, non-Hodgkin's lymphoma (NHL) group was the neoplasm with largest number of deaths. 62.5% of these patients had a 4C Mortality Score between 1 and 8 points, ranking in the intermediate risk group. 55.56% (5/9) of them expired. Myelodysplastic syndrome (MDS) group had the highest 4C Mortality Score, with more than 10 points, placing itself in the high or very high-risk group. 50% (2/4) of them died.
We have found no correlation between the level of ferritin, Interleukin 6 (IL6), neutrophils, monocytes, platelets, D-dimer and successive clinical and radiological evolution in these patients, in contrast with other studies in the general population. We found a weakly positive relationship between the IL6 level at admission and the subsequent need to enter in the Intensive Care Unit ($r = 0.44$, $p<0.05$). We noticed a negative correlation between the IL6 level at admission and clinical improvement after treatment by protocol ($r = -0.21$ $p<0.05$), the day of symptom evolution at admission and age ($r = -0.58$ $p< 0.05$).

Summary/Conclusion:
- SARS-CoV2 infection incidence in our cohort was lower than expected, but the mortality rate was superior compared to hospitalized patients with no haematological malignancy.
- MDS group had the highest risk according to the 4C Mortality Score, with 50% of the patients dying due to the infection in our study. We think it may be related to older patients with more comorbidities. Mortality rate was also high in patients with NHL in spite of lower potential risk. Further prognostic scores should be developed in order to properly predict the risk of poor outcome in hematological patients.
- IL-6 seems to be a key component of the immune response to SARS-CoV-2 as well as clinical evolution, even in immunocompromised patients.

PB1585 CLINICAL CHARCTERISTICS AND RISK FACTORS OF SEVERITY OF COVID19 INFECTION IN PATIENTS WITH HEMATOLOGICAL MALIGNANCIES

R. El Fatmi [1,2,*], E. I. Saidi [1,2], R. Y. Kanoun [1,2], M. Bchir [1,2], M. Hamdoun [2,3], D. Jabr [1,2], M. Bahri [1,2], E. Berred [1,2], S. Kefi [1,2], R. Mansouri [1,2], Y. Meddeb [1,2]

[1]Clinical Hematology, Aziza Othmana Hospital, [2]Faculty of medicine of Tunis, University Tunis El Manar, [3]laboratory of Microbiology and Biochemistry, Aziza Othmana Hospital, Tunis, Tunisia

Background: Patients with hematologic malignancies are considered particularly vulnerable to COVID 19 infection due to their underlying malignancy and their anticancer therapy. However, there are still few data on risk factors of mortality in this population.
Aims: This study aimed to determine the clinical and biological characteristics of COVID-19 infection in hematologic patients and the risk factors of COVID-19 severity and mortality
Methods: This prospective study included all consecutives COVID 19 infected patients, treated for hematologic malignancies in the clinical hematology department of Aziza Othmana Hospital, between October 2020 and January 2021. Covid 19 infection was confirmed by PCR or rapid antigenic analysis of a nasopharyngal swab. We collected clinical, biological, radiological and outcomes data
Results: No cases of COVID 19 infection was diagnosed in our departement during the first COVID 19 wave. The first confirmed case was diagnosed on 12th october 2020. A total of 68 patients was included. Median age was 47 years with a sex ratio of 1.5. Twenty-nine (43%) patients were treated for acute leukemia, 24 (37%) for lymphoma, 6 (9%) for chronic lymphocytic leukemia, 6 (9%) for multiple myeloma and 3 (4%) for myelodysplastic syndrome. Forty-three patients (63%) had active disease (AD) while 37% were in remission (RD). Thirty-three patients (46%) had at last 1 comorbidity including diabetes (16%) and obesity (9%). The main symptoms of the infection were fever (63%), cough (49%), dyspnea (40%) and diarrhea (30%). Seventeen patients had a chest scanning, 12 of them (70%) had a damage greater than 25% of the surface area of the lungs (60% and 85% in the AD and RD groups respectively [p=0.15]). During the infection, 44% of patients had lymphopenia and 21% grade 4 neutropenia. Median dosage of C reactive Protein was of 154 mg/l [1.9-658].
Twenty (29%) patients developped severe infection (37% and 16% in the AD and RD groups respectively [p=0.09]). Seven (10%) of them required admission in an intensive care unit (14% and 4% of the AD and RD groups respectively[p=0.14]). Significant risk factors of the severity of the infection were: age >45 years (p= 0.008), the presence of at least 1comorbidity (p=0.009), dyspnea (p< 0.0001) and a dosage of C reactive protein superior to 150 mg/l (p =0.033). Twelve patients (18%) died from COVID19 infection (23% and 8% in the AD and RD groups respectively[p=0.11]). Dyspnea and grade 4 neutropenia were the independent risk factors of death (p=0.011 and p=0.049 respectively).
Summary/Conclusion: In this study of patients with hematological malignancies, high rates of COVID19 infection severity and associated mortality was noted especially in neutropenic patients. Although no difference was observed in the radiological severity between AD and RD groups, there was a trend to a more clinically severe infection in the AD group.

PB1586 BACTEREMIA IN PEDIATRIC PATIENTS WITH HEMATOLOGIC MALIGNANCIES

B. Achouro 1,*, M. Manel [2], A. Chalbaoui [1], A. Asma [3], E. Nihel [3], B. Emna [1], R. Haifa [1], B. Nesrine [1], K. Zahra [1], Z. Monia [1], B. Yosra [1], B. Jalel [2], K. Abderrahim [1]

[1]Hematology, [2]Microbiology, [3]Community Medecine, Farhat Hached Hospital, Sousse, Tunisia

Background: Bacteraemia adversely affect the outcome of pediatric patients with hematologic malignancies.
Aims: This study aimed to describe the epidemiology, outcome, and factor influencing mortality of bacteremia in children with hematologic malignancies.
Methods: This is a descriptive retrospective study. Data belonging to bacteraemia in pediatric (<16 years) patients with hematologic malignancies admitted in our department of hematology during the period spanning from January 2010 and November 2019 were analyzed. Risk factors with a P-value less than 0.20 were initially included in the binary logistic regression model to determine the independent risk factors for mortality Bloodstream infection in adult hematologic malignancies. Factors described in previous literature were also included in the model. Then the model was reduced by means of manual backward elimination. P values ≤ 0.05 were considered statistically significant.
Results: One hundred thirty nine bacteremia episodes among 110 patients were identified. Underlying diseases were acute lymphoblastic leukemia (ALL) 106(76.3%) which far exceeds acute myeloid leukemia (AML) 29 (20.9%). The bacteraemia occurred in 68 patients with uncontrolled/relapse or refractory disease. The majority of BSI episodes occurred in the presence of severe neutropenia (62.6%). Ninety-four (67.6%) of the culture isolates were Gram-negative bacteria and 45 (32.4%) were Gram-positive bacteria. Klebsiella species and Escherichia coli were the most common Gram-negative isolates. Staphylococcus aureus and staphylococcus epidermidis were the most common Gram-positive isolates. A multidrug-resistant bacteria was present in 31 (22.3%) cases. In 96 (69.1%) episodes, patients received an appropriate antibiotherapy. Complications occurred in 24 (17.3%) episodes of bacteremia. seven children died during bacteremia, giving a case-fatality rate of 5%. The independent risk Factor influencing mortality were: qSOFA>2 (P: 0.002).
Summary/Conclusion: Bacteremia in these patients was caused mainly by Gram-negative microorganisms and was associated with a low case-fatality rate. Factor influencing mortality was qSOFA>2.

PB1587 INCIDENCE OF CELL-MEDIATED IMMUNODEFICIENCY-RELATED INFECTIOUS DISEASES IN THE HEMATOLOGIC DEPARTMENT OF A COMMUNITY HOSPITAL: A SINGLE INSTITUTION RETROSPECTIVE ANALYSIS

N. Imoto [1,*], M. Watanabe [1], Y. Suzuki [1], S. Fujiwara [1], R. Ito [1], T. Sakai [1], I. Sugiura [1], S. Kurahashi [1]

[1]hematology, Toyohashi Municipal Hospital, Toyohashi, Japan

Background: Cell-mediated immunodeficiency-related infectious diseases occasionally occur in the hematologic department of our hospital, although with much lower incidence than neutropenia-related infections other than stem cell transplantation (SCT).
Aims: In this study, we explored which hematologic diseases (HD) and treatments are most likely to be associated with certain infectious diseases in our hospital.
Methods: We retrospectively extracted data on patients who were infected with specific cell-mediated immunodeficiency-related pathogens prior to December 31 2020 in the hematologic department. Target patients had been diagnosed between January 1 2010 and December 31 2019 with representative HD, which included leukemia, lymphoma, myeloma, myelodysplastic syndrome, myeloproliferative neoplasm, warm autoimmune hemolytic anemia (AIHA), immune thrombocytopenic purpura, and aplastic anemia. Patients who had more than one HD were categorized according to the predominant disease during infection. The pathogens of focus were Cytomegalovirus (CMV), *Cryptococcus* (Crypto), *Listeria* (Lis), *Nocardia* (Nocar), *Mycobacterium tuberculosis* (TB), *Mycobacterium* other than TB (AM), and *Pneumocystis jirovecii* (PC). These pathogens were selected based on the outbreak situation in our area, diagnostic facilities in the hospital, and pathogens that rarely occur in other immunodeficiency status like neutropenia or humoral immune defect. Infectious pathogens were defined by cell culture, pathology, or PCR and needed treatment. We excluded patients who were: (1) infected and treated before diagnosis of HD; (2) infected after SCT; (3) diagnosed in another hospital and admitted for treatment of the infectious disease; (4) only diagnosed by immunological or serological tests; (5) diagnosed with a rare HD, seen in fewer than one patient per year. Patient characteristics, type of infectious disease, underlying diseases, and treatment outcomes were analyzed.

Results: Of the 1,904 patients who were diagnosed with the HD during the specified period, 22 patients (1.2%) were infected with pathogens CMV (n = 3), Crypto (4), Lis (4), Nocar (1), TB (3), AM (3), and PC (4). Median age of the patients was 71 years (49–94 years). Primary sites of infection were identified as pulmonary for TB, PC, AM, and Nocar (n = 11), meningitis for Crypto and Lys (5), colitis for CMV (3), and sepsis for Lys (3). Types of treatment for HD undertaken at the time of infection were chemotherapy (n = 9) (cyclophosphamide plus steroid [2], R-CHOP [1], daratuzumab [1], anthracycline plus cytarabine [1], dasatinib plus steroid [1], and others [3]), steroid (7), and no treatment or completed (4). Two patients were diagnosed with infections at the time of HD diagnosis. Seventeen patients recovered from the infections, while five patients died during treatment. All deceased patients had poor control of their HD. HD associated with multiple infectious diseases were: AIHA (n = 5/21, 23.8%; Crypto [2], CMV [1], TB [1], AT [1]); angioimmunoblastic T-cell lymphoma (n = 3/29, 10.3%; Crypto [1], CMV [1], PC [1]); multiple myeloma (n = 3/186, 1.6%; PC [2], Lis [1]); acute lymphoblastic leukemia (n = 2/53, 3.8%; PC [1], TB [1]); and diffuse large B cell lymphoma (n = 2/465, 0.4%; TB [1], AM [1]).
Summary/Conclusion: Over 20% of AIHA patients were infected with cell-mediated immunodeficiency-related infectious diseases. Long-term steroid administration may have been the main contributing factor, although underlying diseases that cause immunodeficiency should also be considered.

PB1588 REAL-WORLD GLUCARPIDASE UTILIZATION IN MALIGNANT HEMATOLOGY PATIENTS RECEIVING HIGH-DOSE METHOTREXATE: A SINGLE INSTITUTION EXPERIENCE

M. Snyder [1], R. Caddell [1], M. Ruane [2], J. Chavez [3,*]

[1]Pharmacy, Moffitt Cancer Center, Tampa, [2]Duquesne School of Pharmacy, Pittsburgh, [3]Malignant Hematology, Moffitt Cancer Center, Tampa, United States

Background: High-dose methotrexate (MTX) is a key agent for several chemotherapy regimens for various disease states. Its main role relates to its ability to penetrate the central nervous system. Toxicity due to inefficient MTX clearance (Cl) can lead to significant morbidity and mortality. Glucarpidase (GP) is a recombinant enzyme that rapidly reduces MTX concentrations and is currently approved by the United States Food and Drug Administration for patients with toxic MTX concentrations associated with delayed Cl due to impaired renal function. Literature regarding its utilization in the off-trial setting is sparse and mainly limited to case reports. Available literature does not frequently address other issues which could concurrently impact MTX Cl and toxicity, such as supportive care measures or alternative causes of delayed drug elimination.
Aims: To assess the real-world utilization, safety, and efficacy of GP in malignant hematology patients receiving high-dose MTX at a single tertiary care cancer institution who developed MTX-related toxicity and delayed Cl.
Methods: A retrospective, single-center chart review of 19 adults with hematological malignancies who received GP after high-dose MTX-based therapy at Moffitt Cancer Center from January 1, 2012 to November 24, 2020 was conducted. Data collected was descriptive in nature and focused on patient demographics, GP utilization, supportive care measures, and outcomes.
Results: Patient demographics, GP utilization, and supportive care measures are featured in Table 1. Subjects received a median 5000 units (range 2000-7000 units) of GP at a median of 54 hours (range 40-86 hours) post-MTX initiation. Fifteen patients had drug levels available ~36-48 hours after MTX initiation (the remaining four's last MTX levels were well before this timeframe and would have skewed the comparison). GP resulted in a median 93% (range 15-97%) decrease in those concentrations at a median of 73 hours (range 61-84 hours) after enzyme administration. No significant adverse events related to GP occurred. The most common MTX-related toxicities included nephrotoxicity (N=19, 100%), neutropenia (N=6, 32%), hepatotoxicity (N=4, 21%), and infection (N=4, 21%). Serum creatinine (SCr) increased a median of 200% (range 38-700%) and renal recovery, defined as SCr return to within 50% above baseline SCr, occurred in fifteen patients (79%) at a median of 14 days (range 4-48 days). Median total duration of hospital stay (from initial admission to discharge) was 15 days (range 9-45 days), while median time to MTX Cl (level ≤ 0.1 µm/L) in the sixteen patients achieving that concentration was 12 days (range 5-19 days). One patient (5%) was rechallenged with MTX in the future and did not require GP. Three (16%) and four patients (21%) experienced 30- and 100-day mortality, respectively. Three subjects (15%) died of toxicity directly attributed to MTX.

Table 1: Patient Demographics, Glucarpidase Utilization, and Supportive Care Measures

Demographics	
Height, cm*	175 (158-199)
Weight, kg*	97 (55-132)
BMI, kg/m²*	30.9 (21-40.4)
BSA, m²*	2.14 (1.56-2.6)
Age, years*	66 (19-74)
Gender	
Male, N (%)	10 (53)

Cost of GP, $^&	199446 (79778-279224)
Supportive Care Measures	
Maximum Leucovorin Dose Used, mg/m²*	200 (20-1000)
Leucovorin Duration, days*	15 (8-26)
Urinary pH < 7 During Episode, N (%)	5 (26)
Maximum Maintenance Fluid Rate, mL/hour*	150 (100-250)
Dialysis Utilized, N (%)	1 (5)

*Reported as Median (Range); ^Not All Patients were Assessed – ECOG Performance Status – 13 of 19 assessed, KPS Scale – 15 of 19 assessed, If Received Prior High-Dose MTX, Number of Doses – 6 of 19 assessed, &Cost Estimate Based on Average Wholesale Price as of February 21, 2021
Abbreviations: BMI – Body Mass Index, BSA – Body Surface Area, ECOG – Eastern Cooperative Oncology Group, KPS – Karnofsky Performance Status, DLBCL – Diffuse Large B-Cell Lymphoma, PCNSL – Primary Central Nervous System Lymphoma, ALL – Acute Lymphoblastic Leukemia, CNS – Central Nervous System, MTX – Methotrexate, GP – Glucarpidase

Summary/Conclusion: In this single institution study of malignant hematology patients GP was safe and efficacious in reducing MTX concentrations in patients with delayed Cl, potentially decreasing MTX-related morbidity and mortality. This analysis provides an important insight on the use and activity of GP in the real-world setting for this feared situation. Further studies with larger numbers of patients will be needed in order to analyze factors that can accurately identify patients who will likely need GP.

PB1589 HEPATITIS B AND C IN ACUTE LYMPHOBLASTIC LEUKEMIA: A 2-YEAR STUDY 2015-2016 AT CHILDREN WELFARE TEACHING HOSPITAL

M. Al-Jadiry [1], S. Sahib [2], S. Fadhil [2], S. Faraj [3], H. Ghali [1], A. Al-Darraji [2], R. Al-Saeed [2], A. Sabhan [2], S. AL-Hadad [1,*]

[1]Pediatric hematology/oncology, College of Medicine, University of Baghdad / Children Welfare Teaching Hospital, Medical City, [2]Pediatric hematology/oncology, Children Welfare Teaching Hospital, Medical City, [3]Pediatric hematology/oncology, College of Medicine, University of Wasit / Children Welfare Teaching Hospital, Medical City, Baghdad, Iraq

Background: The risk of acquiring both hepatitis B virus (HBV) and hepatitis C virus (HCV) infections in patients with cancer has been documented. Risk of parenteral transmission of viral hepatitis has been well recognized, especially due to blood product transfusions.
Aims: Retrospectively collecting baseline and follow up data to determine the rate of hepatitis B and C infection in children with ALL. To determine the extent of liver toxicity in patients infected with hepatitis B and C compared to those who do not acquire the infections, and to recognize any relation between seroconversion and different variables.
Methods: The duration of the data collection and analysis of the study was from August 2018 till October 2019. A retrospective study included 92 children with Acute Lymphoblastic Leukemia diagnosed consecutively in a 2-year period; 2015-2016 at Oncology Unit in Children Welfare Teaching Hospital. Demographic information, treatment details, vaccination history and baseline hepatitis screen were documented. Follow up data during ALL therapy regarding the mass of blood products received by the patients, regular assessment of liver enzymes and bilirubin as well as hepatitis B and C testing was done every 3 months. Documentation of any interruption or omission of chemotherapy related to liver dysfunction and Neutropenia. Detection of seroconversion for HBV and HCV by serology and viral load if serology was positive, all taken in a chronological manner.
Results: At the time of diagnosis, all patients were serologically negative from HBV and HCV. During the follow up period, there were 19 (20.6%) patients infected with hepatitis by serological method; 18 with hepatitis C and one with hepatitis B. there was no significant correlation between seroconversion with hepatitis and liver dysfunction, blood product transfusions more than 10 times, chemotherapy delay due to liver dysfunction and risk group. The mean duration from date of diagnosis till date of last follow up was 43.7 months (range 28.6-56.2 months), while the duration from date of diagnosis till seroconversion with hepatitis was 44.2 months (range 6.9-56.4 months).
Summary/Conclusion: Low incidence of HBV and high incidence of HCV was noticed in this group of patients, there was no direct significant correlation to blood product transfusions. Primary and secondary prevention from infection as a WHO recommendation and Continuous regular screening for HCV for several years after discontinuation of chemotherapy to detect dormant infection is of paramount role.

PB1590 ETIOLOGICAL CHARACTERISTICS OF BLOODSTREAM INFECTION PATOGENS IN PATIENT WITH ACUTE MYELOID LEUKEMIA

M. Tsiarentsyeva [1,*], I. Iskrov [1], I. Stoma [2]

[1]Department of Hematology 3, Minsk Scientific and Practical Center for Surgery, Transplantology and Hematology, Minsk, [2]University rector, Gomel State Medical University, Gomel, Belarus

Background: Bacterial bloodstream infections (BSI) have a significant impact on treatment outcomes in patients with acute myeloid leukemia (AML). According to P. Kalaskar et al. the incidence of BSI during the induction phase is 27.8%, and during consolidation phase is about 25%.
Aims: To explore the epidemiological characteristics and risk factors of BSI in patients with AML, who develop agranulocytosis fever after chemotherapy.
Methods: A retrospective analysis of 221 patients with AML, 26 of which were diagnosed with AML for the first time in 2020, treated in the Department of Hematology of our hospital, was conducted from January 2020 to August 2020 to analyze the incidence of BSI, the distribution and types of pathogenic bacteria. We also determined whether various parameters are risk factors to BSI, including the patient age, gender, agranulocytosis time, the absolute value of neutrophils on the day of agranular fever.
Results: Among the 221 patients, 37 (16.7%) had agranulocytosis fever and were microbiologically confirmed as BSIs, including 17 (65.3%) who were diagnosed for the first time. The patients included 16 (43.3%) males and 21 (56.7%) females, with median age of 44 years (21-71).
Nine pathogens were detected in 37 patients, including 4 G-strains (86.4%) and 5 G+ bacteria (13.6%). Following pathogens were noted: K. pneumoniae - in 18 (48.6%), E. coli - in 12 (32.4%), A. baumannii - in 1 (2.7%), E. cloacae - in 1 (2.7%), S. Haemolyticus - in 1 (2.7%), S. hominis - in 1 (2.7%), S. epidermidis - in 2 (5.4%), S. aureus - in 1 (2.7 %), E. faecalis - in 1 (2.7%).
Also, in several patients, different pathogens of BSI were isolated during one hospitalization. Agranulocytosis was registered in all patients on the day of BSI, of which 34 (91.8%) had absolute value of neutrophils less than 0.2 * 10^9 / L.
As an empiric antibiotic therapy, in 29.7% of cases, a combination of a 4th generation cephalosporin (cefepime) with a 3rd generation aminoglycoside (amikacin) was used, and in 70.3% of cases, a combination of carbapenem (meropenem) with a 3rd generation aminoglycoside (amikacin), while empirical antibiotic therapy was rational in 35.1% of cases, escalation was required in 64.8% of cases.
In 86.4% of cases, the outcome of therapy showed stabilization of the patient's condition and in 13.6% of cases, a lethal outcome was registered.

Table 1 Characteristics of patients diagnosed with acute myeloid leukemia

Markers	AML patients with BSI, n=20	Newly diagnosed AML patients with BSI, n=17
1.Sex, n (%)		
male female	8 (40%) 12 (60%)	8 (47.1%) 9 (52.9%)
2. Age (mean, year)	45.4	42.4
the absolute value of neutrophils at the time of development of febrile neutropenia		
<0.2 >0.2	18 (90%) 2 (10%)	16 (94.2%) 1 (5.8%)
3. CRP at the time of development of febrile neutropenia, mean	105.8	90.4
4. Procalcitonin at the time of development of febrile neutropenia, mean	6.1	2.2
5. Status		
alive dead	17 3	15 2

Summary/Conclusion: 1. In the etiological spectrum of pathogens of bloodstream infections in patients with AML, gram-negative pathogens (86.4%) predominate, mainly of endogenous, most likely intestinal origin.
2. Repetitive cases of bloodstream infections caused by different pathogens during the same hospitalization were noted.
3. In more than 90% of patients with AML and bloodstream infection, this infectious complication was observed with absolute value of neutrophils below 0.2 * 10^9/ L.
95% CI was 91.9% (78.7% -97.2%)
4. All deceased patients had absolute value of neutrophils below 0.2 * 10^9/ L.

PB1591 A SCORING SYSTEM FOR PREDICTING THE PROGNOSIS OF LATE-ONSET SEVERE PNEUMONIA AFTER ALLOGENEIC HEMATOPOIETIC STEM CELL TRANSPLANTATION

L.-Q. Cao [1,*], J.-R. Zhou [1], X.-H. Zhang [2], L.-P. Xu [2], Y. Wang [2], Y.-H. Chen [2], H. Chen [2], Y. Chen [2], W. Han [2], C.-H. Yan [2], Y.-Y. Zhang [2], F.-R. Wang [2], J. Kong [2], Z.-D. Wang [2], Y.-F. Cheng [2], J.-Z. Wang [2], X.-D. Mo [2], T.-T. Han [2], X.-S. Zhao [2], Y.-J. Chang [2], K.-Y. Liu [2], X.-J. Huang [2], Y.-Q. Sun [2]

[1]Peking University People's Hospital, Peking University Institute of Hematology, National Clinical Research Center for Hematologic Disease, Beijing Key Laboratory of Hematopoietic Stem Cell Transplantation, [2]Peking University People's Hospital & Peking University Institute of Hematology, National Clinical Research Center for Hematologic Disease, Beijing Key Laboratory of Hematopoietic Stem Cell Transplantation, Beijing, China, Beijing, China

Background: Late-onset severe pneumonia (LOSP) is defined as severe pneumonia developed during the late phase of allogeneic hematopoietic stem cell transplantation (allo-HSCT). Patients with LOSP have high mortality, so it is important to identify prognostic factors.
Aims: In this study, we aimed to develop a risk score system with broad applicability that could help predict the risk of LOSP-associated mortality.
Methods: We retrospectively analyzed 100 patients with LOSP after allo-HSCT from June 2009 to July 2017. The assessment variables included immune, nutritional and metabolic parameters at the onset of LOSP.
Results: Of all 100 patients who suffered LOSP after allo-HSCT, 45 (45.0%) patients eventually died, and 55 (55.0%) patients were positive for pathogens, with the most common being viruses. In the multivariate analysis, higher monocyte (≥0.20 *vs.* <0.20×10^9/L, *P*=0.001), higher albumin (≥30.5 *vs.* <30.5 g/L, *P*=0.044), lower LDH (<250 *vs.* ≥250 U/L, *P*=0.008) and lower BUN (<7.2 *vs.* ≥7.2 mmol/L, *P*=0.026) levels at the onset of LOSP were significantly associated with better 60-day survival. A risk score system based on the above results showed that the probability of 60-day survival decreased with increasing risk factors and were 96.3% (low-risk group), 49.1% (intermediate-risk group) and 12.5% (high-risk group).
Summary/Conclusion: The results indicated that the scoring system including several variables could stratify patients with different probabilities of survival after LOSP, which is of great clinical significance.

PB1592 GEOTRICHUM CAPITATUM SEPTICEMIA IN NEUTOPENIC PATIENTS WITH ACUTE LEUKEMIA

I. Ben Amor [1,*], F. Kallel [1], I. Frikha [1], S. Néji [2], H. Trabelsi [2], A. Ayedi [2], M. Elloumi [1]

[1]Hematology, university Hospital Hédi Chaker, [2]laboratory of parasitology-mycology, university Hospital Habib Bourguiba, Sfax, Tunisia

Background: Geotrichum Capitatum (G.Capitatum) is uncommon but frequently fatal mycosis in immunocompromised patients.
Aims: We report our experience of systemic Geotrichum Capitatum infection in severe neutropenic patients who were receiving chemotherapy for acute leukemia in the hematology department of sfax in Tunisia.
Methods: It was a retrospective study of cases of G. capitatum septicemia diagnosed in patients followed for acute leukemia in the hematology department of sfax in Tunisia from January 2005 to december2020. G.Capitatum was identified in blood cultures performed in laboratory of Parasitology. For each patient, we collected epidemiological clinical and imaging data, microbiological results, antifungal treatment and evolution disease.
Results: Eleven cases of of G. capitatum septicemia were identified in 4 mens and 7 womens (sex ratio 0,7). The mean age was 35 years (5-55 years).
Nine patients were diagnosed with acute myeloid leukemia and two with acute lymphoblastic leukemia. At the time of infection, all patients had a prolonged profound neutropenia and had received broad-spectrum antibiotics before the onset of the septicemia. Five patient had a central venous catheter.
Disseminated infection were reported in all of patients and pulmonary localization is the most commun. The computed tomography scan showed pulmonary nodules and/or ground glass opacities, in all cases. A concomitant proven invasive pulmonary aspergillosis was noted in one patient and probable pulmonary aspergillosis was suggested in four patients with ground glass opacities in radiographic findings and a positive aspergillus Galactomannan antigenemia.
Involvement of other deep organs (liver, spleen) was reported in 5 patients (45%). Papulo-vesicular or purpuric skin lesions of the trunk and the members were observed in two cases.
In vitro susceptibility findings showed that all fungi were sensitive for amphotericin B and Voriconazol, high Caspofongine and Fluconazole MICs have been found for four and two patients respectively. Resistance has been noted to Caspofongine in 2 patients and to Fluconazol in one patient.
Differents antifungal therapy was proposed to our patients. Monotherapy antifungal for five patients: conventional Amphotericin B in 2 cases, Voriconazol in 2 cases, and Fluconazol in 1 case, the infection was controlled only in one patient receiving Voricnazol.
Five patients were treated by a combination of Amphotericin B and Voriconazole
with favorable outcome in 3 cases. One patient received two combinations of antifungal therapy and a splenectomy because of the extension lesions in the spleen with a fatal outcomes. The mortality rate in our study was 64%.
Summary/Conclusion: G. capitatum is an opportunistic fungus in leukemia patients mostly with acute myeloid leukemia like our patients.
Disseminated infection were reported in 100% of our patients. Pulmonary localizations is the most common reported in G.capitatum septicemia, but lung infiltrates by G.capitatum and Aspergillus may be indistinguishable each other in some cases, like four of our patients.
The optimal therapy for G.capitatum has not been established, the combination of amphotericin B and voriconazole seem to have favorable outcomes in our study.
Despite antifungal therapy, mortality rate exceeding 50%, (64% in our study).

PB1593 A NOVEL PREDICTIVE SCORING MODEL FOR PREDICTING INFECTION

C. Qian [1], M. Hong [2,*], L. Xia [3], Q. Wu [3]

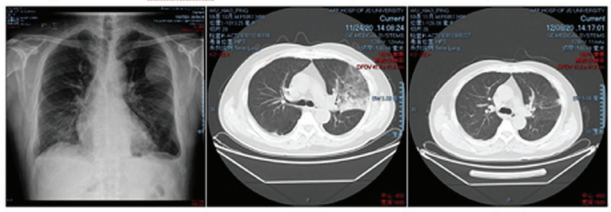
[1]Blood Research Institute, Union Hospital, Tongji Medical College, Huazhong University of Science and Technology, Wuhan, [2]Blood Research Institute, Union Hospital, Tongji Medical College, Huazhong University of Science and Technology, [3]Institute of Hematology, Union Hospital, Tongji Medical College of Huazhong University of Science and Technology, Wuhan, China

Background: Infections caused by carbapenem-resistant Gram-negative bacteria (CRGNB) have a negative impact on the outcome of hospitalized patients, especially in regions with a high prevalence of CRGNB. Implementation of infection control measures significantly reduces their spread among critically ill patients in endemic areas. Early identification of rectal carriers of hematologic malignancies CRGNB at risk for clinical infection will facilitate better management and optimal use of healthcare resources.A retrospective study was conducted in a tertiary care hospital in China to identify the main factors associated with clinical infection in rectal carriers of hematological malignancies CRGNB and to develop a model to predict patients with such infection early.
Aims: To investigate the factors contributing to clinical infection in rectal carriers of carbapenem-resistant gram-negative bacteria (CRGNB) in hospitalized patients with hematological malignancies (HM) to develop an effective model for early identification of cases progressing to severe clinical CRGNB infection.
Methods: This retrospective single-center case-control study included CRGNB rectal carriers hospitalized for hematological malignancies from January 2018 to June 2020. The distribution of strains and clinical infection rate were analyzed. Multivariate analysis was performed by logistic regression model to identify risk factors.
Results: In this retrospective case-control study, the top three species detected in the Department of Hematology of our hospital on 2018-2020 (the first two quarters) were: Klebsiella pneumoniae 137 (33.1%), Escherichia coli 72 (17.4%), and Baumannii 69 (16.7%); univariate analysis showed that patients induced remission chemotherapy, transplantation, mucositis, duration of particle deficiency, nutritional status (albumin), infectious drug exposure (such as carbapenems, aminoglycosides, chemotherapy, immunosuppressive agents, glucocorticoids,

antacids (PPIs), etc.); invasive procedures before infection (such as arterial/venous, sputum suction, catheterization, etc.), and the differences were statistically significant ($p < 0.05$). Multivariate logistic regression analysis indicated that remission induction chemotherapy, duration of particle deficiency, mucositis, and nutritional status (hypoalbuminemia) were independent risk factors for clinical infection in CRGNB rectal carriers. Among them, skin mucositis and particle gap time ≥ 15 days were the most important independent risk factors for clinical infection in CRGNB rectal carriers; the model for predicting CRGNB infection was effective, and the predictive efficacy of the risk prediction score table was validated by ROC curve, with an area under the characteristic curve of 0.697 (95% CI 0.647-0.747, $p < 0.05$).

Risk factors	Category	Regression coefficient	βi	Score
Mucocutaneous break		3.248		
	No			0
	Yes			2
Remission induction chemotherapy		1.921		
	No			0
	Yes			1
Particle deficiency state				
	0			0
	1-14	1.959		1
	≥15	2.651		2
Hypoproteinemia		1.837		
	No			0
	Yes			1

Summary/Conclusion: It can help early and accurately predict rectal carriers of hematologic malignancies CRGNB at risk for clinical infection. Patients in the high-risk group (>3.5) should take more effective prophylactic antibiotics and undergo more rigorous monitoring. The model showed excellent predictive performance and showed good discrimination.



PB1594 NEXT-GENERATION SEQUENCING RAPIDLY IDENTIFY PATHOGENIC MICROBE IN BRONCHOALVEOLAR LAVAGE LIQUID OBTAINED FROM PATIENTS FAILED MULTIPLE LINES OF EMPIRICAL ANTI-MICROBIAL TREATMENT

X. Fei [1,*], W. LU [1], X. YU [1], L. WANG [1], F. LEI [1]

[1]*Department of Hematlogoy, Affiliated Hospital of Jiangsu University, Zhenjiang, China*

Background: Pulmonary infections occur frequently during the management of patients with hematologic malignancies, and usually managed with empirical strategy before the responsible pathogen could be identified. However, conventional techniques such as culture are not sensitive enough and have a long turnaround time. If a patient failed multiple lines of anti-microbial treatment or had an exacerbation of infection, then a rapid and effective way to identify responsible pathogen is critical. Next-generation sequencing (NGS) has the potential to detect pathogenic microbe in a high throughout and rapid way, which is different from the conventional techniques in this respect. However, when and who to integrate NGS into management of pulmonary infection is currently unclear.
Aims: To explore the feasibility and effectiveness of next-generation sequencing (NGS) test to identify responsible microbial pathogens in bronchoscopic bronchoalveolar lavage (BAL) liquid, which was obtained from febrile patients who both failed multiple lines of antimicrobial therapy and had newly emerged pulmonary changes on X-rays or CT scan.
Methods: All the patients had received anti-cancer therapy of underlying hematologic malignancies before infections developed. If a patient developed febrile episodes and still had persistent or recurrent fever even with multiple lines of empirical anti-microbial treatment, once newly emerged pulmonary changes on X-rays or CT scan were documented, bronchoscopic bronchoalveolar lavage (BAL) liquid was then obtained for NGS test. When the definitive microbial pathogen is identified, specific antimicrobial strategy was employed accordingly.
Results: All four cases had been treated for underlying hematologic malignancies in our hospital, two of them for acute lymphoblastic leukemia and the other two cases for multiple myeloma. During the anti-malignancy treatment, all had febrile neutropenia (FN) and received multiple lines of antimicrobial treatment. Even with rigorous combined and multiple lines of antimicrobial agent treatment, three of them had persistent fever and the fourth had recurrent fever. All cases had baseline pulmonary imaging scan and a routine imaging follow-up was employed during anti-microbial treatment. As soon as a newly emerged change was confirmed by either X-rays or CT scan, bronchoscopic BAL liquid was obtained for NGS test in an attempt to identify responsible pathogen. All cases had negative blood and sputum culture, negative galactomannan (GM) and β-D-Glucan assay (G) test before bronchoscope. NGS test had positive findings in all four cases, the pathogens are Lautropia mirabilis, Aspergillus fumigates, Pneumocystis jirovecii and Aspergillus fumigates, respectively. Only one case had subsequent positive serum GM assay and sputum Aspergillus fumigates detection after NGS test. Every case had the antimicrobial agents adjusted according to NGS results, and fever resolved in all cases. Subsequent imaging showed significantly improved or resolved in all four cases.

Representative imagings at baseline, BAL liquid NGS test and post-treatment

Baseline Newly emerged changes post-treatment

Summary/Conclusion: In the management of refractory/recurrent pulmonary infection patients with hematological malignancies, NGS test of bronchoscopic BAL liquid should be considered if previous conventional test cannot identify pathogen, especially when there are newly emerged changes on X-rays or CT scan.

PB1595 REVIEW OF ANTIFUNGAL PROPHYLAXIS PRACTICES AND INCIDENCE OF BREATHROUGH FUNGAL INFECTIONS IN PATIENTS WITH HAEMATOLOGICAL MALIGNANCIES

J. Muscat [1,*], N. Aquilina [1], M. Farrugia [1], D. J. Camilleri [1]

[1]*Mater Dei Hospital, Mater Dei Hospital, Msida, Malta*

Background: Antifungal prophylaxis is routinely prescribed in patients with haematological malignancies receiving chemotherapy. Breakthrough fungal infections are still problematic in these patients and can be difficult to treat.
Aims: This review was conducted to determine the incidence of breakthrough fungal infections, and to assess the adequacy of current antifungal prophylactic practices in our Centre.
Methods: All patients admitted in the Haematology Ward at the Sir Anthony Mamo Oncology Centre (Malta) over a total of 19 months were included. Data about the underlying diagnosis and the incidence of fungal infections was obtained from medical notes.
Results: A total of 169 admitted patients with the following malignancies were admitted: 29.6% (n=50) with acute myeloid leukaemia (AML), 45% (n=76) with non-Hodgkin's lymphoma (NHL), 5.9% (n=10) with Hodgkin's lymphoma, 5.9% (n=10) with acute lymphoblastic leukaemia (ALL), 3% (n=5) with Burkitt's lymphoma, and 10.6% (n=18) being a mixture of myeloma, chronic lymphocytic leukaemia (CLL) or post allogeneic transplant patients.
From these 169 patients, 56.8% (n=96) were on fluconazole, with 8.3% (n=8) developing a localized fungal infection and another 8.3% developing a systemic infection. Of the 46 patients on itraconazole, 19.6% (n=9) developed a localized fungal infection and 17.3% (n=8) developed an invasive fungal infection. Three patients were on liposomal amphotericin prophylaxis – one developed a skin infection requiring topical treatment, and two developed an invasive fungal infection requiring escalation to voriconazole. Out of nine patients on Nystatin, there was one systemic fungal infection and no localized infections– only lymphoma patients were on this prophylactic drug.

The antifungal agent with the least incidence of breakthrough infections was posaconazole. 7.1% (n=12) of patients were prescribed this drug. No breakthrough infections were reported.
AML patients predominantly received itraconazole prophylaxis (68%, n=34), as did ALL patients (60%, n=6). Burkitt's lymphoma patients received fluconazole primarily (60%, n=3), with the one case of systemic candidaemia occurring on this drug. Fluconazole was the predominant prophylaxis in patients with NHL (78.9%, n=60), Hodgkin's lymphoma (90%, n=9) and plasma cell disorders (100%, n=11).
Breakthrough fungal infections occurred in 24.3% of admissions (n=41); 53.6% were systemic in nature (n=22). Half of these systemic infections occurred in AML patients (n=11), with five cases of candidaemia and 6 cases of aspergillosis. ALL patients made up 13.6% of these systemic infections (n=3), with one case each of aspergillosis, candidaemia and mucormycosis. The remaining systemic infections were as follows: 31.8% in NHL (n=7) and 5% in Burkitt's (n=1).
Summary/Conclusion: The patients at highest risk of breakthrough fungal infections are the AML group, with a significant incidence in ALL patients, despite itraconazole prophylaxis in these groups. Admitted NHL patients also had a high incidence of systemic fungal infections despite prophylaxis. Those on Nystatin did not seem to be at increased risk however; most likely these are low risk patients which did not receive intensive chemotherapy regimens. Liposomal amphotericin does not seem to provide adequate prophylaxis, as fungal infections still occurred with a 100% rate. Our analysis suggests that posaconazole is the most effective prophylactic antifungal agent prescribed locally.

PB1596 THROMBOELASTOMETRY AND CONVENTIONAL COAGULATION TESTS AS PREDICTORS OF PROGRESSION TO CRITICAL PHASE IN PATIENTS IN THE FEBRILE PHASE OF DENGUE FEVER: A PRELIMINARY PROSPECTIVE CASE CONTROL STUDY

A. Sivashangar [1,*], M. Wimalachandra [1], T. Perera [1], P. Karunanayake [2], R. Arya [3], L. Gooneratne [1]

[1]Department of Pathology, [2]Department of Clinical Medicine, University of Colombo, Colombo 08, Sri Lanka, [3]King's Thombosis Centre, King's College Hospital, Denmark Hill, United Kingdom

Background: Dengue fever is a viral infection caused by four distinct serotypes of the dengue virus, transmitted to humans by female mosquitos of Aedes species. It is the most critical mosquito-borne disease globally. Infection leads to clinical manifestations ranging from undifferentiated fever to dengue haemorrhagic fever (DHF) and dengue shock syndrome. DHF has three stages namely febrile phase, critical phase and convalescent phase. Plasma leakage and abnormal haemostasis are the two key characteristic pathophysiological features of DHF. Identifying patients likely to progress to the critical phase, as soon as possible, would be a major advantage in initiating management early.
Aims: Several factors associated with progression to critical phase have been described. The usefulness of ROTEM in predicting which patient will go to critical phase has not been hitherto reported. The main objective of this study was to assess if conventional coagulation tests (CCT) and ROTEM parameters are useful predictors of progression to critical phase in patients in febrile phase of dengue fever.
Methods: A prospective case control study was performed in medical units at National Hospital of Sri Lanka on patients with fever and a positive dengue NS1 antigen test. CCT (PT, APTT & Clauss fibrinogen assay) and ROTEM (EXTEM & INTEM) were performed in patients in febrile phase, on 3rd day of fever, if the platelet count > 100 x 10^9/L and no features of plasma leakage. Patients enrolled were followed up and if they progressed into critical phase were categorized as "cases" and if they did not (recovered from the febrile phase) categorized as "controls".
Results: A prospective case control study was performed in medical units at National Hospital of Sri Lanka on patients with fever and a positive dengue NS1 antigen test. CCT (PT, APTT & Clauss fibrinogen assay) and ROTEM (EXTEM & INTEM) were performed in patients in febrile phase, on 3rd day of fever, if the platelet count > 100 x 10^9/L and no features of plasma leakage. Patients enrolled were followed up and if they progressed into critical phase were categorized as "cases" and if they did not (recovered from the febrile phase) categorized as "controls".
Summary/Conclusion: Conventional coagulation tests were not useful in predicting progression to the critical phase. ROTEM parameters CT & CFT of EXTEM and CFT of INTEM, which can be ascertained at point of care, even in an outpatient setting, in about 10-15 minutes, appeared to be useful in predicting which patient is likely to progress to the critical phase from the febrile phase of dengue fever. When combined, specific cut-off values for each of these 3 parameters gave a NPV of >80% in patients in the febrile phase of dengue fever, on the 3rd day of fever. This preliminary study suggests that a larger study looking at ROTEM parameters, not only on the 3rd day, but also on 4th and 5th days of fever may be useful in predicting which patient with dengue fever is likely to progress to the critical phase.

PB1597 COVID-19 AND MALIGNANT HEMOPATHIES: EXPERIENCE OF THE CLINICAL HEMATOLOGY SERVICE OF THE UNIVERSITY HOSPITAL CENTER IBN SINA IN RABAT

K. Hajar [1,*], F. safae [1], M. alaoui [1], C. yasmine [1], C. wyssal [1], B. sami [1], B. majdouline [1], H. soukayna [1], A. wafae [2], M. mouna [1], H. hicham [1], A. mohammed [1], T.-M. zoubida[1]

[1]internal medecine and clinical hematology, [2]university hospital centre IBN SINA, faculty of medecine and pharmacy of RABAT, university Mohammed V of Rabat, rabat, Morocco

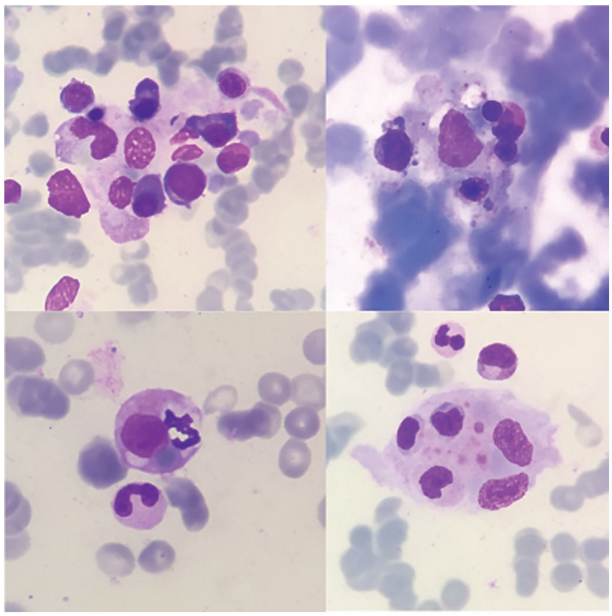
Background: Since September 2020, Morocco has experienced the 2nd wave of covid-19 infection explaining the high daily rate of new infections and deaths from this infection
Aims: the aims is to describe the state of play of this infection in patients followed for malignant hematologic disease
Methods: This is a retrospective and observational study during the 2nd wave of the COVID-19 pandemic in Morocco (from September 2019 to February 2021) carried out at the clinical hematology service of the Ibn Sina University Hospital center in Rabat concerning patients followed for active malignant hemopathy who presented with COVID-19 infection
Results: we have collected 25 cases. The average age estimated as: 40 years (18-65 years), sex ratio: 1.27 (14 M / 11F). We objectified 40% of patients with large B cell lymphoma, 8% with acute leukemia, 40% with multiple myeloma, 2% with myelodysplasia, and 5% with CLL. At the time of COVID - 19 infection, 80% of patients were on chemotherapy, and another 20%) had not yet started chemotherapy. 9 patients presented with comorbidities: arterial hypertension in 12% of cases, diabetes in 8% of cases, and obesity (BMI> 30) in 16% of cases. The main symptoms of COVID-19 in our patients were: Asthenia (80%) dyspnea (81%), and cough (50%), none of our patients presented neurological, digestive, cutaneous vasculitis, myocarditis,or ORL signs. lymphopenia was noted in 90% of cases, an inflammatory syndrome in 30% of cases. hepatic tests were normal in all patients. 8% of patients had chronic renal failure. D-Dimers were elevated in 40% of patients. thoracic CT revealed pulmonary lesions of the corads 4 and 5 type in 75% of cases, extended between 25-50% of lung surface in 90% of cases, no thrombosis or pulmonary embolism were observed. 18% of patients were paucisymptomatic for COVID-19 infection, 70% of patients had moderate symptoms, and 12% of patients had severe respiratory-type symptoms. 80% of patients had normal initial AAS with 97% O2, 10% had presented respiratory distress with AAS <90% O2. they received oxygen therapy by the high concentration O2 mask, optiflow and CPAP as needed. 16% of patients were hospitalized in intensive care for NIV. All the patients received the anti-covid treatment according to the Moroccan national protocol: azithromycin and vitamin therapy (vit C, D, zinc) in 100% of the patients, and hydroxychloroquine in 70% of the patients. No patient received lopinavir / ritonavir, anakinra or tociluzimab, or remdesivir. because of severe sepsis on bronchopulmonary infection, we used broad-spectrum antibiotics in 8.3% cases. (80%) of patients received corticosteroid therapy (dexamethasone) and 90% had an enoxaparin at a preventive anticoagulant dose. because of the Covid-19 infection, chemotherapy was postponed or not started (2-3 weeks).
ARDS was present in 16%. The average length of stay in hospital was 15 days (10-40 days). All of our patients have recovered from their Covid-19 infection. We deplore 12% of deaths linked to the progression of hemopathy. No patient experienced spontaneous recovery from their hemopathies after infection with Covid-19. 1 patient (4%) followed for CLL under ibrutinib maintained a normal lymphocytosis at 4400/ mm3 persistent after 6 months of evolution. We noted an early relapse of the Covid -19 infection on day 22 of the 1st infection in 4% of patients with hypogammaglobulinemia.

Summary/Conclusion: The COVID-19 pandemic had a significant negative impact on the care of patients with malignant hemopathy, limiting patients' access to chemotherapy.

PB1598 HEMATOLOGIC PARAMETERS IN ASYMPTOMATIC PATIENTS WITH ACTIVE COVID-19 INFECTION.

M. Ababou [1,2,*], S. Jennane [1], M. Mahtat [1], H. El Maaroufi [1], A. Terfay [1], O. Mourafiq [2,3], N. Messaoudi [4], B. Chaguar [2,3], K. Doghmi [1]

[1]Clinical Hematology, Military hospital Mohammed v, Rabat, Morocco, Rabat, [2]Sidi Yahya El Gharb field Hospital, Sidi Yahya El Gharb field Hospital, Sidi Yahya El Gharb, [3]Traumatology orthopidics, [4]Hematology and Immuno-Hematology Departement, Military hospital Mohammed v, Rabat, Morocco, Rabat, Morocco



Background: In December 2019, coronavirus disease 2019 (COVID-19) was first found in Wuhan, China caused by severe acute respiratory syndrome coronavirus 2 (SARS-CoV-2). It is currently a pandemic infection reported all around the world. It was previously highlighted that laboratory medicine plays an essential role in the early detection, diagnosis and management of many diseases. Complete blood count is the most available, efficient and economic examination. We compared the data of complete blood count betwen COVID19 pateints and a conrol group.
Aims: This study aims to retrospect and analyze the complete blood count of asymptomatic patients with active COVID-19 infection diagnosed by polymerase chain reaction (PCR) in order to obtain possible indirect key indicators of active disease in asymptomatic patients.
Methods: Sidi Yahya El Gharb Hospital is a field Hospital for asymptomatic patients diagnosed with COVID-19 infection mainly during contact cases screening. Confirmed cases were based on polymerase chain reaction (PCR) nucleic acid testing for SARS-CoV-2 infection. We collected patients from June 20 to July 13, 2020, all of them were isolated and treated according to a national regiment. Patients received hydroxychloroquine 200 mg three times daily for 07 days and azithromycin 500mg once daily for three days. We compared the data of complete blood count, the neutrophil lymphocyte ratio (NLR), the mastocyte lymphocyte ration (MLR) and the platelet lymphocyte ratio (PLR) of our patients with a data of a control group from the Hematologic Laboratory in the Military Hospital Mohammed V of Rabat. The analysis of the data was done using the JAMOVI 1.6.8 statistical programs.
Results: COVID-19 infection was confirmed in 220 patients, no one was febrile. Comparisons made with a control group including 220. The sex ratio was 0,23 vs 0,44. The median values of Leucocytes, neutrophils, lymphocytes, monocytes, eosinophils, basophils, hemoglobin, platelet, the neutrophil lymphocyte ratio (NLR), the mastocyte lymphocyte ration (MLR) and the platelet lymphocyte ratio (PLR) between the COVID-19 group and the control one was as following: 7110[5495-8683] vs 6500[5375-8000], 3200[2165-4400]vs 3700[2775-2500], 2800[2257-3305]vs 2000[1600-2500], 615[460-780] vs500[400-700], 140[70-230]vs 100[100-200], 50[40-72] vs 0[0-100], 13,1[12,2-13,9] vs 13,2[12,3-14,1], 282500[224000-353250]vs234000[196000-297750], 1,12[0,765-1,69] vs 1,42[1,19-2,19], 0,207[0,152-0,277] vs0,212[0,211-0,316] and 103[79-126]vs105[97,9-156].Comparisons made between the two groups revealed a significant difference regarding neutrophils, lymphocyts, basophils, NLR, MLR and PLR ($p < 0.05$).
Summary/Conclusion: Neutrophil, lymphocyts, basophils, NLR, MLR and PLR can be used to predict n COVID-19 infection in asymptomatic patients.

PB1599 BENEFIT OF TREATMENT WITH TOCILIZUMAB IN HEMOPHAGOCYTIC LYMPHYSTIOCYTOSIS SECONDARY TO VISCERAL LEISHMANIASIS INFECTION.

M. E. Cornejo Calvo [1,*], J. A. Perez Gonzalez [1], A. Martinez Hellin [1], F. Anguita Santos [2]

[1]Hematology, [2]Infectious Diseases, Hospital Universitario Clínico San Cecilio, Granada, Spain

Background: Visceral Leishmaniasis (VL) is a zoonotic infection produced by the Leishmania spp parasite transmitted through the bite of the Phlebotomus or Lutzomya mosquito. It is more frequent in endemic areas and a common, although underdiagnosed, cause of secondary hemophagocytic lymphohistiocytosis (HHL), consisting of a dysregulation of T lymphocytes and NK cells and uncontrolled macrophage activation. The generated cytokines storm (IFN-gamma, IL-1, 6, 10, 12, and 18) and uncontrolled hemophagocytosis result in a life-threatening hyperinflammatory state. The clinical-analytical manifestations between HLH and VL may overlap, making diagnosis difficult. Amphotericin B is the treatment of choice, together with corticosteroids and immunoglobulins in case of LHHs and no response to initial treatment.
Aims: To express the importance of controlling the cytokine storm in Hemophagocytic Lymphohistiocytosis to avoid the development of the hyperinflammation state.
Methods: Description of clinical case and sample of response to treatment with Tocilizumab. The follow-up was carried out until January 31, 2021.
Results: A 51-year-old man with a personal history of psoriasis arthritis treated with Adalimumab and Methotrexate and cutaneous leishmaniasis on the pinna in February 2019, untreated. Consultation in the Emergency Service for a 2-week fever and general malaise, presenting progressive pancytopenia without remarkable findings in the peripheral blood smear. Viral serologies and PCR for SARS-CoV2 were negative; antigenuria for Leishmania was positive. Abdominal CT showed mild hepatomegaly and splenomegaly of 19 cm. Treatment is started with Liposomal Amphotericin B. The subsequent analytical study showed CRP 77.4 mg/L, IL-6 19.2 pg/mL, Ferritin> 4,500 ng/mL, triglycerides 217 mg/dL, AST/ALT 221/135 U/L and CD25s> 7500 U/mL. A bone marrow aspirate was performed which, together with a positive Leishmania PCR in peripheral blood and bone marrow and HScore with a probability of 94% HLH-2004 score with 6/8 items completed, LHHs to LV were diagnosed, adding Dexamethasone according to the HLH-2004 protocol and Gammaglobulin. Despite the instaured measures, pancytopenia, fever> 38°C, liver involvement and hyperinflammatory status with IL-6 87.5 pg/mL persisted, deciding to administer a single dose of Tocilizumab 8 mg/Kg. The fever disappeared and the laboratory abnormalities were normalized in 1.5 months. Dexamethasone decrease was performed according to protocol. Currently Adalimumab has been restarted and continues with monthly doses of Amphotericin B.

Summary/Conclusion: There is little scientific evidence about the targeted management of the cytokine storm generated in LHHs.
Blocking the action of IL-6 with Tocilizumab at standard doses allowed adequate management of the pro-inflammatory state and the infection, without side effects and with good tolerance.
Experience with Tocilizumab in LV LHHs is extremely limited. Understanding the pathophysiology of this entity and its similarity to other states of hyperactivation and immune dysregulation will allow better therapeutic regimens to be established.
There is little scientific evidence about the targeted management of the cytokine storm generated in LHHs. Blocking the action of IL-6 with Tocilizumab at standard doses allowed adequate management of the pro-inflammatory state and the infection, without side effects. Experience

with Tocilizumab in LV LHHs is extremely limited. Understanding the pathophysiology of this entity and its similarity to other states of hyper-activation and immune dysregulation will allow to establish better therapeutic regimens.

PB1600 INFECTION PROFILE AND OUTCOMES OF ADULT ACUTE LEUKEMIA PATIENTS DEVELOPING CHEMOTHERAPY-ASSOCIATED FEBRILE NEUTROPENIA AT THE PHILIPPINE GENERAL HOSPITAL

C. A. Tanchanco [1,*], M. P. Reyes-Montecillo [2], A. Mirasol [1], K. E. Henson [2]

[1]Division of Hematology, University of the Philippines- Philippine General Hospital, [2]Division of Infectious Diseases, University of the Philippines - Philippine General Hospital, Manila, Philippines

Background: Chemotherapy induced myelosuppression is one of the major dose-limiting toxicities of systemic chemotherapy. It results to dose reductions and treatment delays hence compromising treatment-efficacy and long-term clinical outcomes. Moreover, the burden of these complications to patients as well to their caregivers could be economically troublesome and would require substantial resource allocation.
Aims: This study determined the infection profile and outcomes of adult acute leukemia patients developing chemotherapy-associated febrile neutropenia and identified the antimicrobial sensitivity patterns of the bacterial blood isolates.
Methods: This was a single-center retrospective study which reviewed medical records of 100 adult acute leukemia patients who developed chemotherapy-associated febrile neutropenia. Descriptive statistics was used to summarize demographic and clinical characteristics. Independent Sample T-test, Mann-Whitney U-test and Fisher's Exact/Chi-square test determined difference of mean, rank and frequency between AML and ALL. STATA 13.1 was used for data analysis.
Results: There were 106 microbiological isolates. Most commonly isolated were *Escherichia coli (ESBL-48.39%)*, *Klebsiella pneumoniae (ESBL-61.90%)* and coagulase-negative *Staphylococcus (CoNS)*. Organisms were isolated from blood (57.55%), sputum (15.09%), urine (12.26%), and stool (7.55%). More ALL patients had *Klebsiella pneumoniae* isolates (p-value: <0.001). Presence of Carbapenemase-producing *Klebsiella* was statistically significant in the mortality group (p-value: 0.018). Susceptibility patterns show: (1) *E. coli*susceptible to Carbapenems, Cefepime and Aminoglycosides (2) *K. pneumoniae* to Carbapenems and Aminoglycosides (3) CoNS to Vancomycin.
Summary/Conclusion: This study emphasized the need to identify the most commonly isolated pathogens to aid physicians decide on the appropriate empiric antibiotic/s to use during chemotherapy-associated febrile neutropenia to avoid serious morbidity and mortality. Proper coordination between clinician and microbiological laboratory for prompt pathogen identification and monitoring of microbial susceptibility patterns is vital to provide the best treatment option for this patient population.

Iron metabolism, deficiency and overload

PB1601 SET UP OF A GENE PANEL FOR NEXT GENERATION SEQUENCING IN THE CAUSES OF ERYTHROCYTOSIS

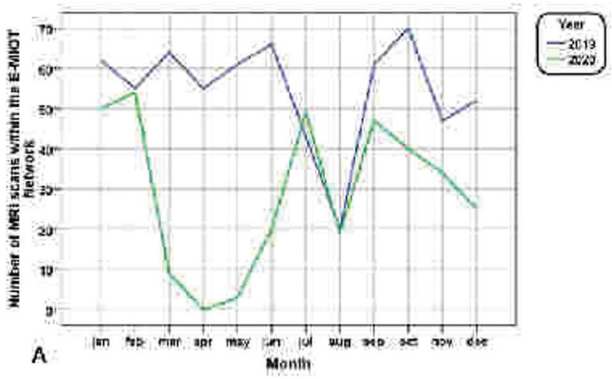
A. Benetti [1,*], G. Biagetti [1], A. M. Lombardi [1], G. Ceolotto [2], M. L. Randi [1]

[1]DIMED - Clinica Medica 1, [2]DIMED - Campus Biomedico Pietro D'Abano, University of Padua, Padua, Italy

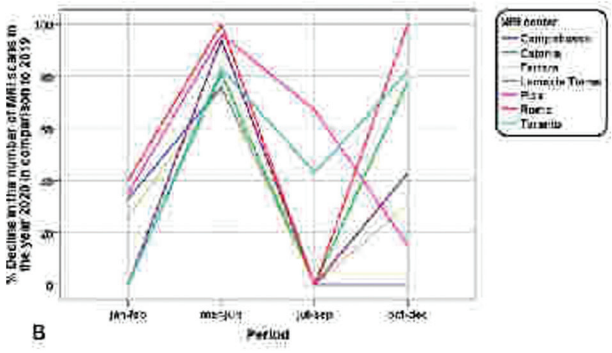
Background: Persistently raised hemoglobin (Hb) and hematocrit (Ht) levels characterize Erythrocytosis which cause in some cases is not recognized despite a careful study. In these patients a diagnosis of Idiopathic Erythrocytosis (IE) is carried out.
Recent observations suggest that some IE patients carry mutations or polymorphisms of HFE gene. This gene is involved in the Iron Metabolism regulation and these data suggest that some other cases of IE may be due to an alteration of Iron Mechanism involved genes.
Aims: We constructed a genes panel for Next Generation Sequencing (NGS) to search mutations of already known genes involved in Erythrocytosis and in those involved in Iron Metabolism in patients with increased Ht of not defined origin.
Methods: Fifteen genes composed the panel designed for NGS: JAK2, EGLN1 (PHD2), EPOR, FTL, FTH, ASXL1, HFE, HFE2, TFR2, HAMP, SLC40A1, SLC11A2, VHL, BPMG, EPAS1. All the exons part of the 15 genes were analyzed. The approach used for the library preparation was a multiplexing PCR and data were analyzed by bioinformatics tools. In all patients, the mutations found were confirmed with Sanger Sequencing.
Results: We studied 68 patients with erythrocytosis not carrying any JAK2 somatic mutation. We found 44 patients carrying at least one germline mutation in the genes of the panel. The germline mutations found in this study are reported in Table 1: 17 interest oxygen sensing pathway, 4 EPOR, 2 ASXL1 and 5 JAK2 genes. Moreover, we found 25 patients with at least one missense mutation in HFE gene and 7 patients with a mutation in TFR2 gene.

GENE	MUTATION	PATIENTS WITH MUTATION		
		N	alone	multiple
EGLN1	Cys127Ser	6	2	4
	Gln157His	5	2	3
	Ile269Thr	1	1	0
	Cys127Ser + Arg370Gly	1	0	1
EPOR	Ala99Val	1	0	1
	Asp398Glu	1	1	0
	Asn487Ser	1	1	0
	Glu181Asp	1	0	1
VHL	Pro25Leu	3	1	2
HFE	His63Asp	17	10	7
	Cys282Tyr	5	4	1
	Ser65Cys	1	0	1
	His63Asp + Ser65Cys	1	0	1
	His63Asp + Cys282Tyr	1	0	1
TFR2	Arg752His	4	2	2
	Asp602fs	1	1	0
	Ala182Glu	1	0	1
	Asp648Tyr	1	0	1
JAK2	Leu113Val	1	0	1
	Gly571Ser	1	1	0
	Leu393Val	1	0	1
	Gly48Glu	1	0	1
	Asn1108Ser	1	0	1
ASXL1	Pro873Leu	1	0	1
	Gly1102Asp	1	0	1
EPAS1	Phe374Thr	1	0	1

Summary/Conclusion: Our data show the validity of the chosen NGS panel. The use of this panel allowed us to found mutations already known to be related to erythrocytosis, and also to find some cases characterized by mutations of iron metabolism genes, as we previously found with sequencing method. The NGS genes panel evaluated offers the possibility to easily recognize new mutations explaining IE. The researchers have to consider iron metabolism to be possibly involved in the etiology of IE.



PB1602 IMPACT OF THE COVID-19 PANDEMIC IN THE MR AVAILABILITY FOR IRON OVERLOADED PATIENTS



A. Meloni [1,*], L. Pistoia [1], R. Righi [2], M. Missere [3], S. Renne [4], A. Vallone [5], A. Riva [6], P. Fina [7], D. Maddaloni [8], A. Ermini [9], V. Spadola [10], A. Pepe [1]

[1]Fondazione G. Monasterio CNR-Regione Toscana, Pisa, [2]Ospedale del Delta, Lagosanto (FE), [3]Fondazione di Ricerca e Cura "Giovanni Paolo II", Campobasso, [4]Presidio Ospedaliero "Giovanni Paolo II", Lamezia Terme (CZ), [5]Azienda Ospedaliera "Garibaldi" Presidio Ospedaliero Nesima, Catania, [6]Ospedale "SS. Annunziata", Taranto, [7]Ospedale "Sandro Pertini", Roma, [8]Ospedale "Engles Profili", Fabriano, [9]Ospedale S. Maria Annunziata, Bagno a Ripoli (FI), [10]Azienda Ospedaliera Civile - O.M.P.A. Ragusa, Ragusa, Italy

Background: The T2* magnetic resonance imaging (MRI) technique for the noninvasive quantification of iron overload has significantly improved the survival of patients with hemoglobinopathies by tailoring the chelation therapy. In Italy, the E-MIOT (Extension-Myocardial Iron Overload in Thalassemia) Network, a collaborative project among MRI and hematological centers, has assured high-quality quantification of iron in vital organs such as heart, liver, and pancreas. The COVID-19 pandemic has disrupted healthcare services around the world, also leading to postpone or delete deferable diagnostic evaluations.
Aims: We evaluated the impact of the COVID-19 pandemic on MRI services for iron overload quantification in Italy.

Methods: The activity of the MRI centers of the E-MIOT Network in the year 2020 was compared to the activity in the same months of 2019. A specific survey was filled out by the MRI operators to evaluate if the availability of MRI slots for patients with hemoglobinothies was reduced and the reasons.
Results: In comparison with the year 2019, in 2020 there was a significant reduction in the number of T2* MRIs performed (350 vs 656; P<0.0001). The comparison month by month between the two years highlighted a marked decline (86.9%) in the four-month period March-June 2020, a reduction in the gap between the two years in the three-month period July-September, and a new decline (41.4%) in the three-month period October-December (Figure 1A). No patient with hemoglobinopathy could undergo an MRI scan during the Italian lockdown (9 March-10 May 2020).
Figure 1B shows the percentage of decline (year 2020 vs 2019) in the number of T2*MRI scans for each MRI center. If no decline or an increase were present, the vertical axis was set at 0. All centers experienced a significant drop in the number of the T2* MRIs in the four-month period March-June (from 75 to 100%). In the three-month period July-September only the centers of Pisa and Taranto dropped the number of T2* MRIs due to the rescheduling of the other MRI appointments deleted during the lockdown. In the three-month period October-December a reduction of the T2* MRI scans was experienced by all centers, except for Campobasso. In the centers of Ferrara and Lamezia Terme the reduction was the consequence of the general reduction in the number of the total MRIs scheduled per day for the sanitation procedures. In the other centers, the availability for T2* MRI scans was unchanged in comparison to 2019, but the patients refused the MRI follow up for fear of getting sick of COVID.

Summary/Conclusion: The COVID-19 pandemic is having a strong negative impact on the quantification of iron overload by MRI, which may seriously worsen the prognosis of patients with hemoglobinopathies. Strategies to ensure proved lifesaving MRI exam and to reassure patients about the health safety of the hospitals are recommended.

PB1603 PROSPECTIVE ANALYSIS OF DIFFERENT ORAL IRON POSOLOGY ON CLINICAL FINDINGS AND SERUM IRON PARAMETERS INCLUDING HEPCIDIN IN PATIENTS WITH IRON DEFICIENCY ANEMIA

M. Yüksel [1], Ö. Doğan [2], M. Kurt Yüksel [3,*]

[1]Ankara University Faculty of Medicine Internal Medicine Department, [2]Ankara University Faculty of Medicine Biochemistry Department, [3]Ankara University Faculty of Medicine, Department of Hematology, Ankara, Turkey

Background: Iron Deficiency Anemia (IDA) is a common health problem in daily clinical practice. A better understanding of iron metabolism in recent years; has created the need for revising treatment regimens in the treatment of IDA.
Aims: Based on these data, we aimed to evaluate the effectiveness of oral ferrous sulfate treatment at different doses, and posologies in premenopausal women diagnosed with IDA, and its relationship with hepcidin, treatment compliance, and gastrointestinal side effects in this study.
Methods: This is a prospective observational study including premenopausal female patients median age 36 (18-50) diagnosed with IDA. This study was approved by local ethic committe and sponsored by Ankara University School of Medicine Scientific Research Projects(BAP proje number 20L0230012) All patients recieved po ferrous sulfate (FS) 80 mg elemental iron) for three months. Patients were classified into three group according to FS dose: Group 1: 2x1/day; Group 2: 1x1/day; Group 3: 1x1every other day. At the time of enrollment, thereafter at the second week of FS and at the third month: Hb level, transferrin saturation(%TS), total iron binding capacity were recorded. Blood was drawn and stored at -20 temperature for hepcidin analysis from patiens who signed informed consent.
Results: We intent to analyse 50 patients for each group, however as a consequence of COVID-19 pandemic, neither patients could come to hospitals nor we could visit them. The patients in each group, ages and results are shown Table At the end of the second week a significant increase in Hb level was observed ($p < 0.01$) and the mean Hb level increased by 1.38 ± 1.04 and 1.03 ± 0.48 in the first and second groups respectively and ≥ 1 g / dl while in the group given every other day it remained <1 g / dl with an increase of 0.69 ± 0.36. ($p = 0.020$, $p = 0.019$, respectively). Comparing the ferritin levels within the three group, it was seen that the ferritin increased significantly in the first group compared to the second and third group ($p < 0.05$). There was no difference between group 2 and group 3 in terms of increase in ferritin level ($p > 0.05$). The increase in TS% and decrease in total iron binding capacity were similar in all three group at the end of the treatment ($p > 0.05$). The change between the second week and the initial hepcidin was mostly observed in the second group ($p = 0.024$) and the change between the three group were similar ($p = 0.708$). Gastrointestinal side effects were observed more in the first group who received 2*1 daily than in the second and third group ($p < 0.05$). While a similar increase in appetite and weight was observed in the patients in group 1 and 2 at the end of the treatment ($p > 0.05$) and there was no increase in appetite and weight in group 3.

	Median Age	Basal Hb g/dl	Sekond Week Hb g/dl	Third Month Hb g/dl	Basal Hepcidin pg/ml	Sekond Week Hepcidin pg/ml	Basal %TS	Third Month % TS	Basal Ferritin ng/ml	Third Month Ferritin ng/ml
Group 1 n=28	35.6 (19-50)	9.42	10.81	13.34	125.53	147.68	5.92	26.54	4.64	25.78
Group 2 n=30	36.8 (22-48)	9.96	10.99	13.75	130.51	192.88	4.70	26.13	2.85	13.74
Group 3 n=32	36.7 (22-50)	10.16	10.79	13.74	117.03	158.46	6.23	23.62	3.84	14.02

Summary/Conclusion: Hb level increase at the end of second week was ≥1 g / dl in the first and second group and <1 g / dl in the third treatment group. However, at the end of the treatment third month anemia was significantly improved in all three group and the increase in Hb level was similar. We consider, 1*1 daily or 1*1 every other day posology

would be more appropriate instead of 2*1 daily due to the significant gastrointestinal side effects in the first group. In addition, we believe in that, the evaluation of Hb response in the second week is too early to decide treatment outcome due to the slower Hb increase in the other day group and serial Hepcidin measurements will give a better idea to better understand the kinetics.

PB1604 THROMBOCYTOPENIA AS AN INITIAL FINDING IN IRON DEFICIENCY ANEMIA

E. A. Winsnes [1,*], P. M. Garcia Cereijo [1], O. Dominguez Muñiz [1], L. Gonzalez Rodriguez [1], C. Fonte Feal [1], A. Santamaria Lopez [1], M. D. C. Albo Lopez [1]

[1]Hematology, Hospital Álvaro Cunqueiro, Vigo, Spain

Background: Iron deficiency anemia (IDA) is typically associated with either normal or elevated platelet counts, likely due to a low iron content in the bone marrow that induces a bias toward megakaryocyte commitment in the megakaryocyte-erythroid progenitors. A much less frequent presentation is iron deficiency-associated thrombocytopenia (IDAT), be it at the time of diagnosis or secondary to iron replacement therapy.
Aims: Given the rarity of these findings, as well as the limited literature available, these cases can lead to diagnostic confusion and unnecessary invasive procedures. Here we present the case of a severe IDA and thrombocytopenia with subsequent progression of the thrombocytopenia after initiation of iron replacement therapy.
Methods: A qualitative case study from the authors' institution diagnosed with the help of standard hematological parameters.
Results: A 45 year old woman was referred to the Emergency Department because of severe anemia (Hemoglobin 4.3 g/dL) and thrombocytopenia (PLT 85 x10^3/µL) in a routine analysis. Her medical history showed an earlier untreated episode of IDA due to menorrhagia, but at the moment the patient reported normal menstruations. The complete blood count showed a microcytic, hypochromic pattern (MCV 62.5 fL, MCHC 28.4 g/dL, RDW 22.1%, WBC 4.14 x10^3/µL), without alterations in the rest of the work-up (no fever, LDH 142 UI/L, total bilirubin 0.56 mg/dL, DAT negative, reticulocytes 20.40 x10^3/µL, creatinine 0.69 mg/dL, no schistocytes in peripheral blood smear). The patient was hospitalized in the department of Internal Medicine for further study and treatment, initiating blood transfusion and intravenous iron replacement therapy the same day. The iron studies showed a ferritin level of <1 ng/mL, total serum iron 8 µg/dL, transferrin 406 mg/dL, and transferrin saturation index 1%. Further diagnostic procedures included abdominal ecography, gastroscopy, colonoscopy, thoracoabdominal CT, bone marrow aspirate, and gynecological work-up, all without alterations. The patient was discharged after 13 days of hospitalization, continuing with oral iron supplementation. The blood parameters during the hospitalization and at 45 days can be seen in the figure.

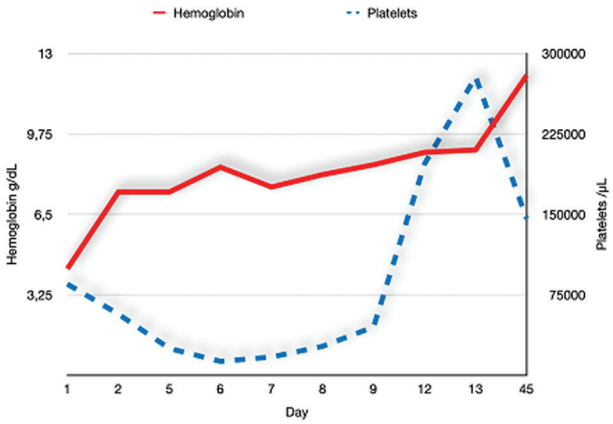


Figure 1. Hemoglobin and platelet-levels from day 1 to 45. Intravenous iron supplementation was initiated at day 1, together with transfusion of red blood cells. Oral iron supplementation was initiated at hospital discharge at day 13.

Summary/Conclusion: This case illustrates how easily the differential diagnosis of an IDA can be complicated by the association of a thrombocytopenia. Discarding hemolysis, thrombotic thrombocytopenic purpura and hemolytic uremic syndrome can usually be done within the Emergency Deparment, but other pathologies like malignancy or IDA secondary to bleeding caused by immune thrombocytopenia (ITP) can be more challenging without being well aware of this uncommon presentation. Studies comparing IDAT and ITP have found that the former usually present with more profound anemia and less severe thrombocytopenia, as well as significantly shorter platelet recovery time. Excluding malignancy, on the other hand, requires invasive procedures that might well be avoided if an early suspicion of IDAT is being addressed. Women of childbearing age with a history of menorrhagia fits the bill in this regard, as they also comprise the majority of the previously reported cases. As demonstrated, the rapid response to intravenous iron replacement therapy, even with an initial worsening of the platelet-count, obviates other invasive diagnostic procedures.

PB1605 THE ANALYSIS OF THE FIRST HEMATOLOGICAL CONSULTATIONS IN CROATIAN HEMATOLOGY OUTPATIENT CLINICS - A KROHEM STUDY

M. Vodanovic [1,2,*], D. Pulanić [2,3], I. Radman [1,2], I. Krečak [4], H. Holik [5], A. Racetin [3], V. Gverić-Krečak [4], B. Coha [5], R. Flegarić-Babok [6], M. Marjanović [7], I. Aurer [2,3]

[1]University of applied Health Sciences, [2]Department of Internal Medicine, Division of Hematology, UHC Zagreb, [3]School of Medicine, University of Zagreb, Zagreb, [4]Division of Internal Medicine, General Hospital Šibenik, Šibenik, [5]Division of Hematology and Oncology, General Hospital "Josip Benčević" Slavonski Brod, Slavonski Brod, [6]Division of Hematology, Oncology and Clinical Immunology, General hospital Varaždin, Varaždin, [7]Division of Internal Medicine, General Hospital Bjelovar, Bjelovar, Croatia

Background: Patients with anemia are often referred to hematologists and anemia is one of the most common diagnosis in hematological clinics.
Aims: The aim of of this cross-sectional study is to determine the prevalence of anemia among all first examinations in hematological clinics, prevalence of individual types of anemia and specializations of referring physicians who request anemia testing with hematology consultation.
Methods: A multi-center cross-sectional study was performed at five Croatian outpatient hematology clinics which included all patients reffered to hematologists for the first consultation and anemia testing from different specialists from 1st Mar 2019 to 30th Jun 2019. Study was approved by Ethical Committee of each Hospital. Patients completed an appropriate questionnaire and signed informed consent. Descriptive statistics were performed and results are reported as frequencies (percentage) for categorical and as means (±standard deviation) or medians (minimum-maximum), as appropriate, for continuous values.
Results: Data includes 965 patients referred to the hematologist for the first consultation, and total of 280 patients (29 %) were with a referral diagnosis of anemia, 72 men (25.7%) and 208 women (74.3%) median age at diagnosis 51.5 (18 – 94) years. There were 46.8% of patients younger than 50 years and 53.2% older than 50 years. The male to female anemia ratio is 12: 1 within the younger group. The most common referral diagnosis was iron deficiency anemia in 76 % of patients. After hematological consultation and anemia testing, the actual diagnosis of anemia was consistent with referral diagnosis in 63.4% of patients. Anemia of other causes was most common in younger male group (80%), and iron deficiency was the cause of anemia in 90% of women in younger group due to reproductive age. Among women iron deficiency anemia is the most common (72.5%), while in men all other causes of anemia (megaloblastic are more common (61%). In older group other causes of anemia (megaloblastic anemia, MDS, malignancies, hemolytic anemias etc.) are more common among the causes of anemia (53%). Physicians of fifteen different specializations referred patients to hematologists for the anemia testing, most often general practicioners (82 %).
Summary/Conclusion: Iron deficiency anemia is the most prevalent anemia (90 %) among younger women, whereas iron deficiency is the cause of anemia in 63 % of all patients. Among older population other causes of anemias are more frequent than iron deficiency. General practicioners referred most common patients to hematologists for the first examination and anemia testing.

PB1606 AGE AND IRON STATUS IN PATIENTS WITH HFE MUTATIONS AT FIRST TIME REFERRAL TO PHLEBOTOMY

M. Sandnes [1,*], M. Vorland [2], R. Ulvik [1], H. Reikvam [1,3]

[1]Department of Clinical Science, University of Bergen, [2]Department of Medical Biochemistry, [3]Department of Medicine, Haukeland University Hospital, Bergen, Norway

Background: *HFE* hemochromatosis is characterized by iron overload due to increased iron absorption. Serum ferritin (SF) reflects total body storage iron, and the combination of elevated SF levels and an elevated transferrin saturation (Tsat) offers an easy and inexpensive screening method to detect candidates for *HFE* genetic testing. Overt disease is mainly associated with the C282Y homozygote genotype, and recommendations regarding phlebotomy to achieve iron depletion in these patients are well established. Fewer studies have focused on SF levels and its association with iron overload in other *HFE* genotypes, and accordingly to the controversy regarding risk of a significant iron overload developing in non-C282Y homozygotes, recommendations regarding management of these patients differ.
Aims: Based on these considerations, we wanted to investigate distribution and phenotypic expression of C282Y and H63D *HFE* mutations in patients referred to first time therapeutic phlebotomy, based on clinical suspicion of hemochromatosis or biochemical findings indicating iron overload.
Methods: We conducted a monocenter, cross-sectional study and retrospectively reviewed hospital records of patients who had positive genetic testing for C282Y and/or H63D *HFE* mutations over a 7-year period, and who were referred by their general practitioner to a tertiary referral center upon suspected hereditary hemochromatosis. 431 men and 97 women referred to first time therapeutic phlebotomy by the treating physician were included in the final analysis. Age at referral and last set of laboratory parameters prior to initiation of phlebotomy were obtained, including the following: SF, Tsat, hemoglobin (Hb), leukocyte particle concentration (LPK), thrombocyte particle concentration (TPK) and C-reactive protein (CRP).
Results: Median age at referral was 47.8 years in men and 57.1 years in women ($p < .001$). C282Y homozygosity was the most prevalent while H63D homozygosity was the least prevalent genotype in both genders (fig. 1). C282Y homozygotes represented the youngest group in both men (median 40.1 years, range 18.9 to 76.8) and women (median 53.8 years, range 25.1 to 79.5) ($p < .001$) (fig. 2). In men, H63D heterozygotes had the highest age at referral (median 50.7 years), while H63D homozygotes showed the highest age at referral among women (median 65.7 years). Finally, SF levels were lower in women (median 625 µg/L) than men (median 706 µg/L) ($p < .001$).
Only 10.8% of men and 3.8% of women exhibited SF levels ≥ 1000 µg/L in combination with Tsat level ≥ 50%. C282Y homozygosity was the most prevalent genotype of this group, although other genotypes were also represented. Additionally, 37% of men and 16% of women exhibiting Tsat levels ≥ 50% were non-C282Y homozygotes.

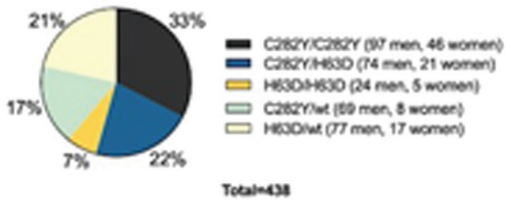

Figure 1. Distribution of *HFE* genotypes in the study population.

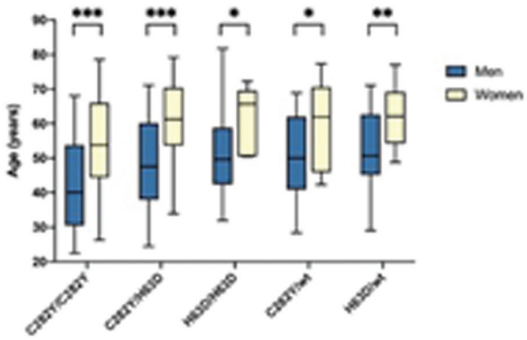

Figure 2. Age at referral for first time phlebotomy. Whiskers represent the 5th and 95th percentile. Men and women of each genotype were compared using Mann-Whitney U test, *p < .05, **p < .01, ***p < .001.

Summary/Conclusion: Our results are in line with previous observations regarding elevated iron indices compatible with iron overload not only in the C282Y homozygous state, but also in other *HFE* genotypes. Clinical practice regarding therapeutic phlebotomy in non-C282Y homozygotes is often restrictive, as risk of complications due to iron overload in these individuals is generally considered as low. Nevertheless, iron overload is not independently dependent on *HFE* mutations status, as environmental and host risk factors may modulate expression and contribute to a variable clinical presentation. Hence, phlebotomy ought to be considered in non-C282Y homozygote patients with persistent hyperferritinemia and suspected iron overload, particularly when other risk factors are present and further assessment is unwarranted.

PB1607 HYPERFERRITINEMIA IN HETEROZYGOUS H63D AND HYPERTRIGLYCERIDEMIA

M. A. Molina-Arrebola [1,*], C. Porrino-Herrera [2], I. M. Portell-Rigo [2], C. Avivar-Oyonarte [3]

[1]Haematology and Haemotherapy. Biotechnology Department, [2]Clinical Analysis Unit; Biotechnology Department, [3]Biotechnology Department, Poniente Hospital Public Health Agency, El Ejido, Spain

Background: Hereditary hemochromatosis (HH) is the most prevalent form of iron overload in Caucasians and comprises a group of disorders that lead to abnormalities in iron homeostasis, increasing intestinal absorption of iron and tissue deposition. If not treated, the accumulated iron can result in tissue damage such as liver cirrhosis, diabetes mellitus, arthropathy, myocardiopathy, endocrine disorders and hepatocarcinoma. Variants C282Y and H63D of the HFE gene (chromosome 6p21.3) are the two polymorphisms most frequently associated with HH. Studies of allele frequencies in northern European populations have reported 10–15% C282Y heterozygotes, 0.25–1.0% C282Y homozygotes, 20–30% H63D heterozygotes and 2% C282Y/H63D compound heterozygotes. The iron-loading risk profile for the possible genotypes is described: C282Y/C282Y >>> C282Y/H63D > C282Y/-, H63D/H63D, H63D/-. Non-C282Y homozygotes with significant iron loading should be investigated for rare iron-loading genotypes. Hypertriglyceridemia (HTG) is a common and important lipid abnormality in Western societies. Approximately 18% of adults have triglycerides over 200mg/dl, defining HTG. The HFE locus is associated with primary HTG, and in approximately 5% of cases, the HFE genotype could play a role in their pathogenesis. It is supposed thatincreased iron deposits associated with certain HFE genotypes induce an overproduction of liver triglycerides in predisposed individuals. In one study, this synergic effect seems to be especially relevant in C282Y/H63D compound heterozygotes; subjects with this genotype are at low risk of iron overload in the general population but, in the presence of HTG, iron overload penetrance seems to be much higher. On the other hand, phlebotomies significantly decreased triglycerides, especially in subjects with basal HTG.
Aims: To describe the characteristics of a patient with hyperferritinemia, H63D heterozygous and hypertriglyceridemia and the evolution after a phlebotomy regimen.
Methods: Case description.
Results: A 44-year-old male was referred to us because of hyperferritinemia. Body mass index 22.86, No toxic habits, including alcohol consumption. High blood pressure diagnosed at 35. Familiar hypertriglyceridemia. Nephritic colic, renal lithiasis and chronic uric acid nephropathy. He was taking carvedilol, manidipine, doxazosin, ezetimibe+atorvastatin, levetiracetam and omega 3. Abdominal ultrasound showed moderate hepatomegaly of left predominance, with no other abnormalities. Abdominal Angio-TC showed bilateral double renal artery.
Since H63D heterozygous is not supposed to justify the intense hyperferritinemia, rare iron loading genotypes were investigated, showing negative results for SLC40A1, TFR2, HFE2 or HAMP mutations.
The outstanding values of the analysis, and the comparison after the 3 phlebotomies are shown in the table.

Summary/Conclusion: H63D heterozygous patients, considered at low risk of iron overload in the general population, can express much higher iron overload penetrance in the presence of hypertriglyceridemia (HTG). Phlebotomies, even in a low number, led to normalization of the ferritin level, improved hypertriglyceridemia and the hepatic impact of the iron overload (leukopenia, macrocytosis, high liver enzymes) was normalized. Along with the specific treatment, this case suggests that therapeutic phlebotomy could be a useful therapeutic approach in patients with HTG and iron overload.

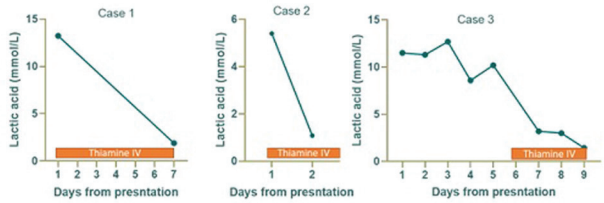
PB1608 EXTRAVASATION OF INTRAVENOUS IRON INFUSION: A CASE REPORT

E. Vetsiou [1,*], N. Youakim [2], C. Michailidou [3], S. Theodoridou [4], E. Vlachaki [5]

[1]coventry, [2]University Hospital Coventry and Warwickshire, Coventry, United Kingdom, [3]Hematological Laboratory, [4]Thalassemia Prevention Unit, Hippokration Hospital, [5]Thalassemia Unit, Aristotle University, Thessaloniki, Greece

Background: Iron deficiency anaemia is the most common anaemia worldwide. Parenteral iron administration (Intramuscular or intravascular) is used when per os administration is contraindicated or is insufficient. Intramuscular (IM) iron administration is rarely used because it is painful and can stain the skin. Intravenous (IV) iron administration is time-consuming and anaphylactic-type reactions, including fatalities, have followed the parenteral administration of iron dextran injection. A new iron formulation such as sodium ferric gluconate complex and iron sucrose has led intravenous administration to gain ground over iron deficiency anaemia treatment during the last years. It can be administered in a short time with rare adverse events. Despite that, extravasation of iron solution although rare, may happen, leading to permanent skin hyperpigmentation.
Aims: Herein, a case report of iron extravasation among 200 infusions in 15 years, is reported.
Methods: A 51year-old woman with 3 children, Christian in religion with limited meat consumption throughout the year and regular menstruation, presented complaining of tiredness and headache. The laboratory exams revealed iron deficiency anaemia (Hb8gr/dl, MCV70fl, serum ferritin level 4ng/ml). Initially, she was prescribed sulphate iron per os, but she complained of epigastric pain and nausea a few days later. Thus, it was decided to be administered iron IV (Ferric Carboxymaltose). A few minutes after the initiation of the infusion, the woman complained of left arm oedema. The infusion was immediately stopped, and prevention measures were taken.
Results: Six months later, the skin hyperpigmentation in her left arm persists (photo 1).

Summary/Conclusion: Conclusion: Patients who are candidates to receive IV iron administration should be informed about this rare complication. Furthermore, nurses and physicians should be aware of possible iron extravasation and monitor the patient carefully throughout the infusion process; that way, it can be interrupted early if required. As spontaneous regressions of iron skin hyperpigmentation are rarely reported, there is no sufficient data regarding treatment options. Laser therapy could be beneficial in such cases.



Lymphoma Biology & Translational Research

PB1609 THIAMINE REVERSAL OF LACTIC ACIDOSIS IN HIGH BURDEN HEMATOLOGICAL MALIGNANCY: CASE SERIES

K. Alzahrani [1,*], A. Alrajhi [2], M. Marei [1], S. Z. Zaidi [1], I. Tailor [1], S. Altaf [1], F. Alnajjar [2], A. Alnakhli [2], M. Alnoamani [1], I. Motabi [1], N. AlShehry [1], M. Alfayez [1]

[1]Adult Hematology and BMT, [2]Department of Pharmacy, King Fahad Medical City, Riyadh, Saudi Arabia

Background: A malignancy-induced lactic acidosis is a rare event that is largely associated with hematologic malignancies (leukemias and lymphomas). It is a subset of type B lactic acidosis that is mediated without evidence of tissue hypoperfusion, pathophysiology that is centered around the Warburg effect and is associated with poor outcomes. Thiamine pyrophosphate is a vital cofactor for pyruvate dehydrogenase, which irreversibly converts pyruvate to acetyl-CoA, committing the pathway in a way that it cannot be reversed back to anaerobic respiration. We hypothesize in the presence of a high level of cofactors responsible for this step, the glycolysis pathway might be skewed to an otherwise anaerobic preference.
Aims: To evaluate if high dose thiamine can reverse malignancy-induced lactic acidosis in patients with hematological malignancies.
Methods: Retrospective-single center review of malignancy-induced lactic acidosis that has been treated empirically with high dose thiamine between 2015 and 2020. Patients with not enough data on the lactic acid level, or an alternative explanation for the lactic acidosis is present, were excluded.
Results: *Case 1:* 19-year-old male with a history of Classical Hodgkin's Lymphoma 3 years before his presentation with symptoms of fatigue and shortness of breath. His CBC revealed pancytopenia with ANC 0.3 x109/L and platelets of 9 x 109/L. Metabolic acidosis was noted on presentation with bicarbonate 9.5 mmol/L and lactic acid of 13.23 mmol/L. PET scan showed above and below diagram lymphadenopathy with cutaneous and subcutaneous and bone marrow activity. He was given thiamine 100 mg IV TID for 7 days pending the establishment of diagnosis by biopsy. Lactate normalized during this time, with only cofounding agent been steroids. The final diagnosis was T-cell lymphoma with Ki67 of more than 90% with bone marrow showing evidence of hemophagocytic lymphohistiocytosis [Figure].
Case 2: 15-year-old female with no past medical history who presented with gum bleeding and abdominal pain for 7 days. CBC revealed WBC of 10 x109/L and platelets of 12 x109/L. Biochemistry showed metabolic acidosis with bicarbonate of 11 mmol/L and lactic acid of 5.4 mmol/L. LDH was more than the upper limit of detection (>2000). The patient was started on thiamine 100 mg TID for 2 days with normalization of lactate in 36 hours. Bone marrow biopsy was difficult to aspirate and biopsy showed 100% cellularity with 70% blast. Diagnosis of Philadelphia negative B-ALL was made, and the patient was treated on pediatric ALL protocol [Figure].
Case 3: 22-year-old male with no past medical history presented with epistaxis, shortness of breath, scrotal and generalized edema. He had hepatosplenomegaly on the exam with a tender spleen. Imagining revealed renal hypodensities with ascites and bilateral pleural effusion. CBC showed WBC of 16 x109/L and platelets of 8 x109/L. Biochemistry showed LDH of 1123 U/L with a picture of metabolic acidosis. Bicarbonate was 16 mmol/L and lactic acid was 8.6-12.8 mmol/L for four days before starting on thiamine 100 mg IV TID with normalization of lactate in 3 days. The patient's bone marrow showed 100% cellularity with 75% blast. The diagnosis of Philadelphia negative B-ALL was made, and the patient was started on pediatric-inspired protocol [Figure].

Summary/Conclusion: Malignancy-induced lactic acidosis related to the Warburg effect or thiamine pyrophosphate deficiency at a cellular level, high dose thiamine, and/or other cofactors like riboflavin, might be useful in treating this disorder, meriting further investigation.

PB1610 CLONALITY ANALYSIS IN FOLLOW-UP OF PATIENTS WITH NON-HODGKIN LYMPHOMA

I.Ković [1,*], V. Vogrič [1], P. Škerl [1], S. Novaković [1]

[1]Department of Molecular Diagnostics, Institute of Oncology Ljubljana, Ljubljana, Slovenia

Background: Clonal immunoglobulin and T cell receptor gene rearrangements can be used as tumor-specific markers in patients with non-Hodgkin lymphoma.
Aims: The aim of our study was to evaluate the applicative value of standardized BIOMED-2 gene clonality assay protocols for monitoring of lymphoma recurrence.
Methods: With this purpose, 448 specimens from 93 patients with non-Hodgkin lymphoma submitted for initial diagnosis, post-treatment monitoring and evaluation of lymphoma progression or recurrence from 2011-2020 were retrospectively analyzed. According to the initial diagnosis, our series comprised 65 samples from 23 patients with B-cell lymphomas and 383 samples from 70 patients with non-Hodgkin T-cell lymphomas. Clonality testing and determination of amplicon sizes was performed using the BIOMED-2 clonality assays.
Results: We detected clonal immunoglobulin heavy chain gene (IGH) rearrangements with amplicons of same sizes as at initial diagnosis in all follow-up samples from patients with B cell non-Hodgkin lymphoma (100%). In a group of T cell lymphomas we detected clonal T cell receptor beta (TCRB) or gamma (TCRG) gene rearrangements with amplicons of same sizes as at initial diagnosis in 376 follow-up samples from 62 patients (95.6%).
Summary/Conclusion: In the present study, we confirmed the utility of standardized BIOMED-2 clonality assays not only for initial diagnosis of wide range of lymphoid proliferations but also for post-treatment monitoring and evaluation of lymphoma progression or recurrence.

PB1611 TUMOR-NONSPECIFIC METHYLATION OF THE MIR-145 GENE IN DIFFUSE LARGE B-CELL LYMPHOMA

E. Voropaeva [1,*], T. Pospelova [2], M. Churkina [2], V. Maximov [1], A. Gurageva [1]

[1]Research Institute of Internal and Preventive Medicine - Branch of the Federal State Budget Scientific Institution The Federal Research Center Institute of Cytology and Genetics of Siberian Branch of the Russian Academy of Sciences, [2]Novosibirsk State Medical University, Novosibirsk, Russian Federation

Background: The p53 protein (a product of the TP53 gene) is known to regulate a whole class of micro-RNAs. The direct target of p53, through which it implements its oncosuppressive effects, is miR-145. This microRNA interacts with the 3/ - untranslated mRNA sequence of oncogenes c-MYC and individual cyclinkinases.
Several mechanisms of impaired expression of oncosuppressive microRNAs have been described, among which the methylation of promoters and enhancers encoding their genes is important. It is known that the frequency of methylation of the MIR-145 gene differs in various oncological processes. Thus, in patients with prostate cancer and non-small cell lung cancer, the frequency of methylation of this gene is about 50.0 % (Zaman M. S., 2011; Zhiqiang Y., 2015), and in colon cancer – more than 80.0 % (Pekow J., 2015).
It has been shown that a decrease in miR-145 expression is not only associated with the occurrence of lymphomas, but also a predictor of their more aggressive clinical course (Poli V., 2020). However, studies of the methylation status of MIR-145 in diffuse B-large cell lymphoma (DLBCL) have not been previously conducted.
Aims: To evaluate the frequency of methylation of the MIR-145 gene in the tumor tissue of Diffuse Large B-cell Lymphoma.
Methods: Genomic DNA was isolated by phenol-chloroform extraction using guanidine from paraffinized blocks of biopsy samples of tumor lymph nodes and extranodal lesions of patients with DLBCL. The DNA of a healthy donor was used to assess the specificity of methylation. The Human Methylated and Unmethylated DNA Control Kit (Zymo Research, USA) was used as a controls. Bisulfite DNA conversion was performed using the EZ DNA Methylation-Gold Kit (Zymo Research, USA). The methylation status of the gene was determined by the method of methyl-specific PCR using pairs of primers to the methylated and unmethylated sequences.
Results: Currently, 25 DNA samples have been analyzed. It was shown that the frequency of methylation of the MIR-145 gene was 23\25 (92%). In the healthy tissue MIR-145 was also in the methylated state.
Summary/Conclusion: The results obtained indicate that the methylation of the MIR-145 gene in the lymphoid tissue of patients with DLBCL is not tumor-nonspecific.

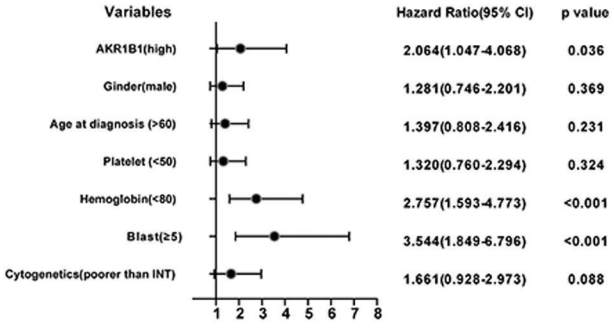
Myelodysplastic syndromes - Biology & Translational Research

PB1612 COMBINING FLOW CYTOMETRY AND MOLECULAR GENETICS FOR PROGNOSIS IN MYELODYSPLASTIC SYNDROME

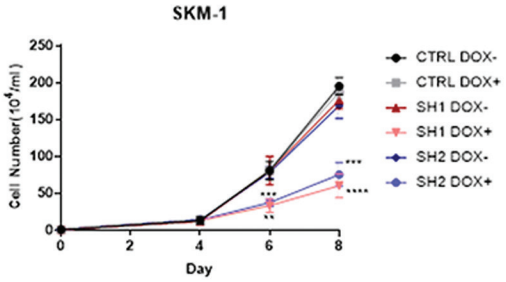
N. Tcvetkov [1,*], E. Morozova [1], O. Epifanovskaya [1], A. Parfenenkova [2], E. Babenko [1], E. Izmailova [1], A. Shakirova [1], I. Barkhatov [1], M. Barabanshikova [1], K. Lepik [1], E. Bakin [1], J. Vlasova [1], A. Smirnova [1], I. Moiseev [1]

[1]RM Gorbacheva Research Institute, Pavlov University, [2]St. Petersburg University, Saint-Petersburg, Russian Federation

Background: Refinement of prognosis is crucial for improvement of outcome in patients with myelodyslastic syndrome (MDS). Flow cytometry and molecular genetics can be used for this purpose.
Aims: In our study we tried to combine these two approaches to define subgroups of MDS patients with different clinical course.
Methods: We performed flow cytometry to quantitatively assess T- and NK-cells, myeloid progenitors, T-regulators, myeloid-derived suppressor cells in bone marrow of 38 adult MDS patients after signing informed consent for participation in research. In each cell population we measured expression of PD-1, PD-L1, PD-L2, CD80, CTLA-4, LAG3, TIM3, ICOS-L. In 23 patients we carried out Sanger sequencing of SF3B1, DNMT3A, RUNX1, ASXL1, TP53 genes. We tracked the 2-year outcome of the included patients regarding the defined flow and molecular parameters. This work was supported by Russian Science Foundation, grant No 17-75-20145-П.
Results: We observed significant role of PD-L1 expressing regulatory T-cells (PDL1-Tregs) subpopulation level. Patients with PDL1-Tregs higher than 0.003% of all nucleated cells showed lower 2-year overall (OS2) and relapse-free (RFS2) survival (41.3% and 35.8% vs. 85.7% and 85.7% in those with PDL1-Tregs lower than 0.003%, respectively, $p<0.05$). The number of mutations significantly influenced OS2 (80%, 60%, and 0% for 0, 1, and 2 mutations, respectively, $p<0.05$) and RFS2 (72.2%, 60%, and 0% for 0, 1, and 2 mutations, respectively, $p<0.05$). When combining these results we managed to derive the compound index consisting of two binary variables: PDL1-Tregs higher or lower than 0.003% of all nucleated cells and presence or absence of at least one molecular mutation obtaining 4 subgroups of MDS patients with significantly different OS2 and RFS2. Thus, in lower PDL1-Tregs without mutations, lower PDL1-Tregs with mutations, higher PDL1-Tregs without mutations, and higher PDL1-Tregs with mutations OS2 was 100%, 50%, 72%, and 0% ($p<0.05$), respectively, and RFS2 was 100%, 50%, 80%, and 0% ($p<0.05$), respectively.
Summary/Conclusion: Our preliminary results underline the importance of using parallel approaches and new methods for prognosis in MDS patients. Further studies are warranted.



PB1613 SUPPRESSION OF AKR1B1 REDUCES CELL PROLIFERATION AND ENHANCES SENSITIVITY TO HYPOMETHYLATING AGENTS BY INHIBITING MTORC1 SIGNALING PATHWAY IN HIGH-RISK MYELODYSPLASTIC SYNDROME



H. Tong [1,*], S. Zhu [1]

[1]department of hematology, The first affiliated hospital Zhejiang university school of medicine, Hangzhou, China

Background: High-risk myelodysplastic syndrome (HR-MDS) patients have a short survival time and a poor prognosis. Moreover, there is dearth of therapeutic targets for treatment of this malignancy. Aldo-keto reductase AKR1B1 was reported to be highly expressed in a variety of tumors and promote the tumor cell proliferation.
Aims: The main objective was the identification of the role of the AKR1B1 axis in the progression of HR-MDS and its druggable potential
Methods: Kaplan Meier curve was used to evaluate the relationship of AKR1B1 expression level and overall survival in HR-MDS. The effect of AKR1B1 knockdown and overexpression and the effect of AKR1B1 inhibitor epalrestat was studied in cell viability. To evaluate the combined effect of epalrestat and hypomethylating agents (HMAs), data were analyzed by the CalcuSyn software. The related signaling pathways

of AKR1B1 in MDS were investigated by gene set enrichment analysis (GSEA) and verified by Western blot. Co-immunoprecipitation (Co-IP) was performed to detect proteins that interact with AKR1B1.
Results: AKR1B1 was upregulated in high-risk MDS, not low-risk MDS. AKR1B1 expression was increased in EZH2 mutant MDS patients. In the hematopoietic stem and progenitor cells (HSPCs), AKR1B1 was barely expressed. High expression of AKR1B1 was associated with shorter OS and EFS in HR-MDS. Multivariate analysis revealed that higher AKR1B1 expression was an independent, unfavourable prognostic factor for OS in HR-MDS, not in the total MDS.
Genetic or pharmacological inhibition of AKR1B1 markedly decreased cell viability of MDS cell lines. Similar results were obtained in primary MDS cells. SKM-1 cells overexpressing AKR1B1 had a higher proliferation rate under serum starvation. Epalrestat enhances the toxicity of HMA in MDS cell line and primary MDS cells.
GSEA results suggested that AKR1B1 might participate in the mTORC1 signaling pathway, which was confirmed by Westernblot. Mechanistically, AKR1B1 interacted with RHEB to regulate the phosphorylation of mTOR.

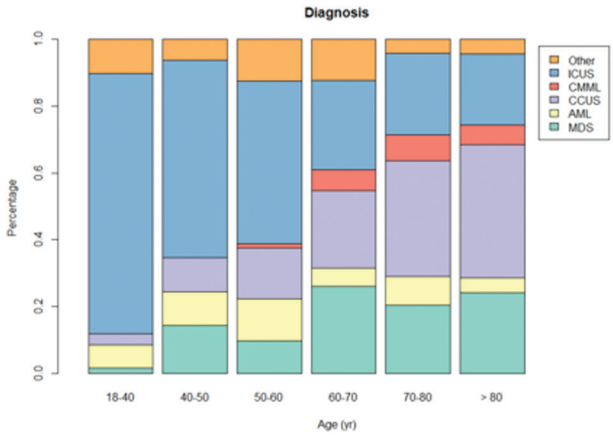
Summary/Conclusion: AKR1B1 is negatively correlated with overall survival in HR-MDS. Inhibition of AKR1B1 not only suppressed the proliferation of MDS cells but also increase the drug susceptibility to HMAs. AKR1B1 interacts with RHEB to modulate mTORC1 activity. In conclusion, suppression of AKR1B1 reduces cell proliferation and enhances sensitivity to HMAs by inhibiting mTORC1 signaling pathway in HR-MDS.

PB1614 U2AF1 MUTATION PROMOTES TUMORIGENICITY THROUGH FACILITATING AUTOPHAGY FLUX MEDIATED BY FOXO3A ACTIVATION IN MYELODYSPLASTIC SYNDROMES

Y. Zhu [1], F. Xu [1], C. Chang [2], Q. He [1], L. Wu [1,*]

[1]Hematology, Shanghai Sixth People's Hospital, [2]Hematology, Shanghai Sixth People's Hospital, Shanghai, China

Background: Mutations in the U2 small nuclear RNA auxiliary factor 1 (U2AF1) gene are the common feature of a major subset in myelodysplastic syndromes (MDS). However, the genetic landscape and molecular pathogenesis of oncogenic U2AF1S34F mutation in MDS are not totally understood.
Aims: To explore the molecular pathogenesis of oncogenic U2AF1S34F mutation in MDS, we carried out the current study.
Methods: We performed comprehensive analysis for prognostic significance of U2AF1 mutations in acute myeloid leukemia (AML) cohort based on The Cancer Genome Atlas (TCGA) database. Functional analysis of U2AF1S34F mutation was performed in vitro. Differentially expressed genes (DEGs) and significantly enriched pathways were identified by RNA-sequencing. The forkhead box protein O3a (FOXO3a) was investigated to mediate the function of U2AF1S34F mutation in cell models using lentivirus. Chromatin immunoprecipitation, immunoblotting analyses and immunofluorescence assays were also conducted.
Results: U2AF1 mutations were associated with poor prognosis in MDS and AML samples, which significantly inhibited cell proliferation and induced cellular apoptosis in cell models. Our data identified that U2AF1-mutant cell lines undergo FOXO3a-dependent apoptosis and NLRP3 inflammasome activation, which induces pyroptotic cell death. Particularly, an increase in the level of FOXO3a promoted the progression of MDS in association with restored autophagy program leading to NLRP3 inflammasome activation in response to U2AF1S34F mutation. Based on the result that U2AF1S34F mutation promoted the transcriptional activity of Bim through up-regulating FOXO3a with transactivation of cell cycle regulators p21Cip1 and p27Kip1, FoxO3a, a potentially cancer-associated transcription factor, was identified as the key molecule on which these pathways converge. death. Particularly, an increase in the level of FOXO3a promoted the progression of MDS in association with restored autophagy program leading to NLRP3 inflammasome activation in response to U2AF1S34F mutation. Based on the result that U2AF1S34F mutation promoted the transcriptional activity of Bim through up-regulating FOXO3a with transactivation of cell cycle regulators p21Cip1 and p27Kip1, FoxO3a, a potentially cancer-associated transcription factor, was identified as the key molecule on which these pathways converge.
Summary/Conclusion: Overall, our studies provide new insights that U2AF1S34F mutation functions the crucial roles in mediating MDS disease progression via FOXO3a activation, and demonstrate novel targets of U2AF1 mutations to the pathogenesis of MDS.



PB1615 THE UTILITY AND OUTCOME OF NEXT GENERATION SEQUENCING IN THE DIAGNOSTIC WORK UP OF PATIENTS WITH UNEXPLAINED CYTOPENIA AT A PRIMARY REFERRAL CENTER

D. Træden [1,2,3,*], M. Tulstrup [1,2,3], J. B. Cowland [4], K. Grønbæk [1,2,3], M. Klarskov Andersen [4], J. Werner Hansen [1,2,3]

[1]Department of Hematology, Rigshospitalet, [2]Biotech Research and Innovation Centre, Faculty of Health and Medical Sciences, [3]The Danish Stem Cell Center (Danstem), Faculty of Health and Medical Sciences, University of Copenhagen, [4]Department of Clinical Genetics, Rigshospitalet, Copenhagen, Denmark

Background: With increasing availability, next generation sequencing (NGS) is becoming a useful supplement in the diagnostic work up of patients with cytopenia.
Aims: This study aimed to improve the rational use of NGS by analyzing the occurrence of mutations in 593 patients with cytopenias from 2015-2020, referred for primary work up for a suspected hematological malignancy.
Methods: NGS of 20 genes associated with myeloid malignancies was performed in all patients, and 97% and 88% had a bone marrow biopsy and cytogenetics performed, respectively.
Results: Mutations were found in 311 (52.4%) patients and the most commonly mutated genes were *TET2*, *DNMT3A*, *ASXL1*, *SRSF2* and *SF3B1*. Among patients with mutations, the most prominent diagnosis was CCUS (45%) followed by MDS (30%), AML (11%) and CMML (9%). The presence of one or more mutations increased the risk of having a malignant disorder diagnosed on the bone marrow (OR: 4.48, $p < 0.0001$). The median number of mutations per patient was one (range 0-12). High variant allele frequency was associated with abnormal bone marrow ($p < 0.0001$) with median VAF for MDS patients being 37% (IQR: 23%>44%), whereas patients with CCUS had a median VAF of 22% (9%>40%). Most patients presented with isolated cytopenia (42.7%), while 37.6% and 20.7% had bicytopenia and pancytopenia, respectively. The highest risk of mutations was in patients with bicytopenia, where 58.5% had at least one mutation. ICUS patients were the youngest, with a median age of 58 years (IQR: 43-70 yr) compared to 66 (51-73), 70 (64-77), 73 (67-78) and 71 (68-76) for AML, MDS, CCUS and CMML, respectively. We found a positive correlation between age and the risk of having a mutation, as the amount of patients with 1 or more mutations increased from 22% to 66%, regardless of final diagnosis, in age groups < 60 years and ≥ 60, respectively (OR: 7.0, $p < 0.0001$). In the age group above 60 years, CCUS was the most prominent

diagnosis (32%), and 37% received a malignant hematological diagnosis (MDS, AML or CMML).

Summary/Conclusion: In conclusion, NGS can be a valuable tool in the diagnostic work up of patients with cytopenia, and CCUS is the most common disease in patients above 60 years referred due to unexplained cytopenia.

PB1616 MUTATIONAL PROFILE AND IMMUNOPHENOTYPIC CHANGES IN BONE MARROW COMPARTMENTS OF CHRONIC MYELOMONOCYTIC LEUKEMIA PATIENTS

J. Gaião Santos [1,*], C. Barros Lima [1], M. Coucelo [1,2,3], A. T Simões [1], A. L. Santos [4], M. Pereira [1,2,3,5], J. Azevedo [1,2,5], A. B. Sarmento-Ribeiro [1,2,3,5,6], A. I. Crisóstomo [1], A. Paiva [2,3,4]

[1]Clinical Hematology, Coimbra University Hospital Centre, [2]Coimbra Institute for Clinical and Biomedical Research, Group of Environment Genetics and Oncobiology, [3]Center for Innovative Biomedicine and Biotechnology, [4]Flow Cytometry Unit, Coimbra University Hospital Centre, [5]Laboratory of Oncobiology and Hematology, University Clinic of Hematology, Faculty of Medicine - University of Coimbra, [6]Clinical Academic Center of Coimbra, Coimbra, Portugal

Background: Chronic Myelomonocytic Leukemia (CMML) is a heterogeneous disease, with overlapping features of myelodysplastic and myeloproliferative syndromes. Both immunophenotypic alterations and recurrent somatic mutations are found in CMML patients and can provide useful information on diagnosis and prognosis.
Aims: Immunophenotypic characterization of bone marrow compartments and its correlation with genetic alterations in a group of CMML patients (WHO2016).
Methods: Retrospective immunophenotypic analysis was performed according to EuroFlow panels and the Mean Fluorescence Intensity (MFI) from bone marrow (BM) granulocyte, monocyte and erythroid compartments of CMML patients (n=47) and from a normal BM (healthy group HG, n=16) was recorded. In 33 patients, targeted gene sequencing of 45 genes recurrently mutated in myeloid malignancies was performed on an Ion S5 (Thermo Fisher). Statistical analysis was done using SPSSv26.
Results: CMML patients were 70% male, median age 72y. WHO Classification: 42% CMML-0; 42% CMML-1; 16% CMML-2. FAB-Classification: 40% proliferative, 60% dysplastic. AML progression occurred in 13%, with a median time of 15 months. Mutations were identified in 97% of patients, with a median of 3 (0-7). *ASXL1* (55%), *TET2* (52%) and *RAS* pathway (22%) were the most frequently mutated genes. CPSS-Mol risk score was: 14% low; 20% int-1; 33% int-2; 33% high. Mutations in epigenetic modifiers genes alone (group A) were found in 21% and simultaneously with signal transduction genes (group B) in 36% of patients. Patients with mutated epigenetic modifiers had lower hemoglobin levels ($p<0.05$). We found an association between *ASXL1* mutations and increased leukocyte count and between *ASXL1* and *RAS* mutations with proliferative-CMML ($p<0.05$).
Flow cytometry analysis of CMML BM revealed statistically significant differences in MFI in granulocyte (CD10, CD13, CD45), monocyte (CD11b, CD36, CD45, HLA-DR) and erythroid (CD45, CD105, CD117) maturation, compared with HG. Both genetic groups A and B showed an increased MFI in CD45 in granulocyte and CD36, CD45, HLA-DR in monocyte maturation when compared to HG and increased CD11b MFI in monocyte maturation on group B. Decreased MFI in CD10, CD13 in granulocyte and CD45, CD105, CD117 in erythroid maturation also occurred in both groups. The more pronounced changes found in erythroid maturation in group A patients could be related to their lower hemoglobin levels, but further studies are required.
We observed no differences in MFI in the analysed markers among WHO classification or CPSS-Mol Score groups, but progression to AML was associated with increased MFI in CD45, CD11b, CD13 in granulocyte and CD45, HLA-DR in monocyte maturation ($p<0.05$).
Summary/Conclusion: In CMML, there seems to be a specific immunophenotypic expression pattern in granulocyte, monocyte and erythroid maturation. Contrary to the remaining CMML BM, patients with mutations in epigenetic modifiers genes alone did not show a significant increase in CD11b expression in monocyte maturation.
In our cohort, progression to AML was associated with specific immunophenotypic changes.
Detailed immunophenotyping of different BM maturation compartments can further improve our understanding of CMML and help to better refine risk and prognosis classification of such heterogeneous disease.

PB1617 AKT KINASE REGULATES TIM-3 EXPRESSION IN MYELOID NEOPLASMS

A. Parfenenkova [1,*], I. Barkhatov [2], O. Epifanovskaya [2], A. Shakirova [2], N. Tcvetkov [2], E. Babenko [2], K. Lepik [2], E. Morozova [2], I. Moiseev [2]

[1]Biological faculty, Saint-Petersburg State University, [2]RM Gorbacheva Research Institute, Pavlov University, St. Petersburg, Russian Federation

Background: Myelodysplastic syndrome (MDS) is a heterogeneous clonal disease characterized by the presence of cytopenia in the peripheral blood and dysplasia in the bone marrow. The rate of progression to acute myeloid leukemia (AML) is significant and median time to progression varies from months to years according to biological and clinical feature. Recent preclinical and clinical research indicated the significance of TIM3 signaling checkpoint pathways in progression of MDS and AML and showed the utility of TIM3 inhibition by monoclonal antidotes in inducing clinical remission.
Aims: To investigate the potential targets for therapy of myeloid neoplasms.
Methods: The ability of signaling pathway inhibitors to decrease the expression level of TIM-3 on the membrane surface was tested using the THP-1 cell line of the M2 variant of AML. We tested the panAKT inhibitor MK-2206, mTOR (Rapamycin), PKC (Enzastaurin), RAF (Sorafenib) and ERK (PD98,059). Also the patient's bone marrow with transformation into AML was plated with a 1:20 dilution in RPMI-1640 medium with/without the inhibitor. The surface expression of TIM-3 was assessed by flow cytometry after incubation for 24 and 48h. Additionally, fresh cells from the bone marrow was cultivated only with MK-2206 for 24h.
Results: We found that after the addition of panAKT inhibitor MK-2206 to THP-1 cells and its cultivation for 24 hours, the percentage of TIM-3+ cells decreased from 96.4% to 27.5% at 5 µm and to 16.5% at 10 µm. After 48 hours of cultivation, the sustained decrease persisted up to 40% and 43.2%, respectively. No difference in TIM3 expression after THP-1 cultivation with other inhibitors was observed ($p> 0.05$). The same pattern was observed in native MDS bone marrow: after its cultivation with 10 µm MK-2206, the percentage of TIM-3+ cells decreased from an average of 10.7% to 5.9%.
Summary/Conclusion: A promising direction for further research in AML and MDS is not only blockage of TIM3 signaling by monoclonal antibodies, but also elucidation of pathways leading to TIM3 expression on malignant cells. Further research is required to identify the mechanisms of Akt-mediated TIM3 downregulation.

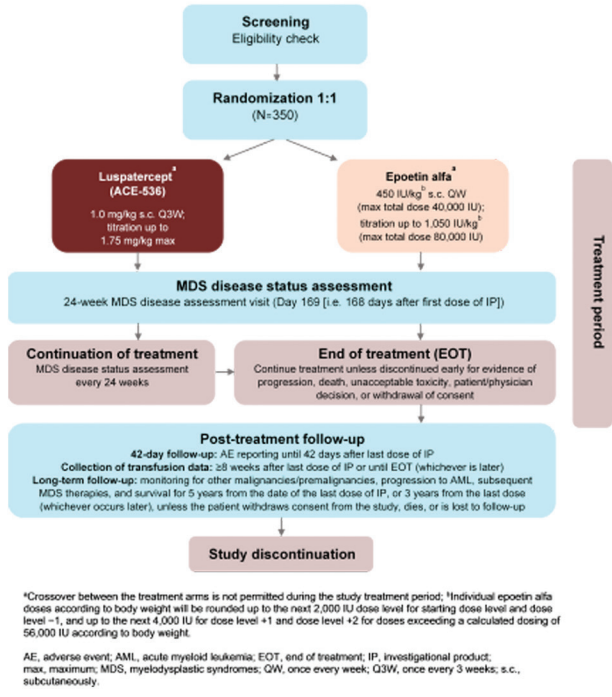
PB1618 POLYMORPHISM OF GSTM1, GSTT1 AND CYTOKINE GENES IN PATIENTS WITH MYELODYSPLASTIC SYNDROME

Z. Sidorova [1,*], S. Svitina [1], J. Drijun [1], I. Kostroma [2], S. Gritsaev [2], S. Kapustin [1]

[1]Laboratory of biochemistry, [2]Hematological Clinic, FSBI "Russian Research Institute of Hematology and Transfusiology of FMBA", St.Petersburg, Russian Federation

Background: Cytokine and cytokine receptors are important regulators of hematopoiesis. Overexpression of cytokine are observed in multiple myeloid diseases such as myelodysplastic syndrome (MDS). Glutathione S-transferases (GST) modulate the effects of exposure to various cytotoxic and genotoxic agents, including those associated with increased risks of the myelodysplastic syndrome. Polymorphisms in carcinogen-metabolizing genes may affect enzyme activity and subsequently influence carcinogen activation.
Aims: The aim of this study was to assess the features of alleles and genotypes distributions of GSTM1, GSTT1 and cytokine genes in MDS patients.
Methods: Thirty-nine patients with MDS (17 men and 22 women, mean age 62.4 yrs) and 150 healthy controls (HC) (cancer-free 102 men and 48 women, mean age 52.1 yrs) from North-Western Russia were genotyped for the GSTM1, GSTT1, IL-6 G174C, TNF-α G308A, IL-1β T31C polymorphisms by PCR and PCR-RFLP technique. The differences in allele and genotype frequencies between patient and HC groups were assessed by Fisher's exact test with computation of odds ratios (OR), their 95% confidence intervals (CI) and p-values.
Results: The frequencies of the *null* alleles GSTM1 and GSTT1 differed slightly in both patients with MDS and in the control group. At the same time, the simultaneous presence of the IL-6 174C allele and GSTM1 *null* allele was more often detected in male MDS group compared to male HC group (58.8% vs. 26.4%, OR=3.9, 95%CI: 1.4-11.5, p=0.011), in female MDS patients was not different to female HC group (36.3%, vs. 33.3%, respectively). The frequency of the IL-1β 31C allele in patients MDS with GSTM1 *null* allele was nearly 2-fold higher, than in those HC group (41% vs 23,3 % respectively, OR=2.3, 95% CI: 1.1-4.8, p=0.04), In contrast, IL-1β 31C allele was observed 5.5 -fold higher in men HC group compared in men MDS group with undeleted GSTM1 allele (33.3% vs 5,9 %, OR=8.0, 95% CI: 1.0-63.0, p=0.022). At availability genotype IL-6 174CC with GSTT1 *null* allele in the male patients MDS were found more often than the same male group HC (11,8% vs 1%, OR=13.5, 95% CI: 1.1-157, p=0.053, respectively). Genotype IL-1β T31C in the presence undeleted GSTT1 allele was more often in female MDS group compared to female HC group (50% vs. 22,9%, OR=3.4, 95%CI: 1.1-9.8, p=0.03). TNF-α G308A polymorphism in patients were not statistically different from those in HC group.
Summary/Conclusion: We believe that the distribution of alleles and genotypes of the GSTM1, GSTT1 and cytokine genes in patients with MDS is multifactorial and requires further study to identify risk factors for the development of the disease and explain the causes of their occurrence.

Myelodysplastic syndromes - Clinical



PB1619 A PHASE 3 STUDY OF THE EFFICACY AND SAFETY OF LUSPATERCEPT VERSUS EPOETIN ALFA FOR THE TREATMENT OF ANEMIA DUE TO LOWER-RISK MDS IN ESA-NAIVE PATIENTS REQUIRING RBC TRANSFUSIONS (THE COMMANDS TRIAL)

M. Della Porta [1,2,*], U. Platzbecker [3], V. Santini [4], G. Garcia-Manero [5], R. S. Komrokji [6], R. Ito [7], P. Fenaux [8]

[1]Cancer Center IRCCS Humanitas Research Hospital, [2]Department of Biomedical Sciences, Humanitas University, Milan, Italy, [3]Medical Clinic and Policlinic 1, Hematology and Cellular Therapy, University Hospital Leipzig, Leipzig, Germany, [4]MDS Unit, Azienda Ospedaliero-Universitaria Careggi, University of Florence, Florence, Italy, [5]Department of Leukemia, The University of Texas MD Anderson Cancer Center, Houston, TX, [6]Moffitt Cancer Center, Tampa, FL, [7]Bristol Myers Squibb, Princeton, NJ, United States, [8]Service d'Hématologie Séniors, Hôpital Saint-Louis, Université Paris 7, Paris, France

Background: Patients (pts) with myelodysplastic syndromes (MDS) often suffer from anemia and other consequences of regular red blood cell (RBC) transfusions. Erythropoiesis-stimulating agents (ESAs) are a standard of care for pts with lower-risk MDS (LR-MDS). Epoetin alfa and darbepoetin alfa have shown efficacy among pts with LR-MDS, but the pt population in whom a clinically significant effect is seen may be limited. An important clinical benefit in this LR-MDS pt population would be to increase the frequency of response and the duration of RBC transfusion independence (TI). Luspatercept, a first-in-class erythroid maturation agent with a mechanism of action distinct from ESAs, is now approved in both the EU and the USA for pts with LR-MDS with ring sideroblasts (RS) who require RBC transfusions and are refractory, intolerant, or ineligible to receive ESAs. Luspatercept may also be beneficial in treating anemia in pts with ESA-naive, LR-MDS who require RBC transfusions. In a phase 2 study in anemic pts with LR-MDS, 63% of pts receiving luspatercept (0.75–1.75 mg/kg) achieved a modified hematologic improvement–erythroid (mHI-E) response; when analyzed by RS status, 69% of pts with ≥15% RS and 43% of pts with <15% RS achieved mHI-E response (Platzbecker U, et al. *Lancet Oncol* 2017;18:1338–1347).
Aims: The COMMANDS is a phase 3, open-label, randomized trial comparing the efficacy and safety of luspatercept vs epoetin alfa in anemic pts with IPSS-R-defined LR-MDS, with or without ≥15% RS, who are ESA naive, and who require regular RBC transfusions.
Methods: To be eligible, pts must be ≥18 years old, have a diagnosis of IPSS-R-defined LR-MDS with <5% blasts in the bone marrow, serum erythropoietin (sEPO) levels <500 U/L, and require RBC transfusions (defined as transfusion requirement of 2–6 RBC units/8 weeks for ≥8 weeks immediately prior to randomization). Exclusion criteria include prior use of ESAs (≤2 doses of prior epoetin alfa permitted if ≥8 weeks from randomization date and sEPO confirmed as ≤ 500 U/L), granulocyte colony-stimulating factor or granulocyte-macrophage colony-stimulating factor, unless administered for treatment of febrile neutropenia; disease-modifying agents (e.g. lenalidomide), or hypomethylating agents; and presence of del(5q) cytogenetic abnormality. Eligible pts (N≈350) will be stratified and randomized 1:1 to either luspatercept (starting dose 1.0 mg/kg with titration up to 1.75 mg/kg) subcutaneously (s.c.) once every 3 weeks or epoetin alfa (starting dose 450 IU/kg with titration up to 1,050 IU/kg) s.c. once every week, for a minimum of 24 weeks (Figure). Best supportive care, including RBC transfusions, is permitted in combination with study treatment in both arms. Stratification factors include: baseline RBC transfusion burden (<4 vs ≥4 RBC units/8 weeks), baseline sEPO level (≤200 U/L vs >200 U/L), and RS status (with RS+ defined as RS ≥15%, or ≥5% [but <15%] if *SF3B1* mutation is present). Additionally, ≥40% and ≤60% of randomized pts will be RS+, and ≥25% will have sEPO >200 U/L.
Results: The primary endpoint is defined as achievement of RBC-TI for 12 weeks during Weeks 1–24 of study, with a concurrent mean hemoglobin (Hb) increase of ≥1.5 g/dL compared to baseline. Key secondary endpoints include duration of RBC-TI, change in Hb levels, achievement of HI-E (per International Working Group [IWG] 2006), and safety.

Figure. Design of the COMMANDS trial

[a]Crossover between the treatment arms is not permitted during the study treatment period; [b]Individual epoetin alfa doses according to body weight will be rounded up to the next 2,000 IU dose level for starting dose level and dose level −1, and up to the next 4,000 IU for dose level +1 and dose level +2 for doses exceeding a calculated dosing of 56,000 IU according to body weight.

AE, adverse event; AML, acute myeloid leukemia; EOT, end of treatment; IP, investigational product; max, maximum; MDS, myelodysplastic syndromes; QW, once every week; Q3W, once every 3 weeks; s.c., subcutaneously.

Summary/Conclusion: The COMMANDS trial is registered at EudraCT (number 2017-003190-34) and ClinicalTrials.gov (NCT03682536). This abstract was presented previously (Della Porta et al. *Blood* 2020;136(suppl 1):1–2).

PB1621 MUTATIONAL ANALYSIS IN LOW RISK MYELODYSPLASTIC SYNDROMES: A SINGLE CENTER REPORT

G. Cassanello [1,*], G. V. Levati [1], J. A. Giannotta [2], W. Barcellini [2], B. Fattizzo [1]

[1]Hematology, University of Milan, [2]Hematology, Fondazione IRCCS Ca' Granda Policlinico Hospital, Milan, Italy

Background: Myelodysplastic syndromes (LR-MDS) are a very heterogeneous group of diseases ranging from mild forms to life-treathening cytopenias. Recently, a deeper knowledge of LR MDS molecular landscape paved the way to novel treatments, such as luspatercept for SF3B1 mutated patients with ring sideroblasts. Less is known about the prevalence and type of other mutations in LR-MDS and their clinical significance.

Aims: To evaluate the prevalence of somatic mutations of myeloid genes in LR-MDS patients and their relationship with clinical/laboratory features and outcome.

Methods: Fifty out of 160 LR-MDS patients regularly followed at a tertiary hematologic center have been evaluated by next generation sequence (NGS) technology (Ion Torrents5) Ion Reporters software 5.2 which evaluates mutational status of 69 potentially oncogenic genes present in the Oncomine Myeloid Research Assay diagnostic panel, including hotspot genes, full genes, and fusion transcripts. Only variants with an allelic frequency (VAF) > 5% were reported. NGS results were matched with clinical and hematologic variables that have been retrospectively collected

Results: Table 1 shows the clinical features in mutated and unmutated patients. Seventy-two % of cases showed at least one mutation involving SF3B1 (N=16), TET2 (N=10), DNMT3A (N=4), SRSF2 (N=6), ASXL1 (N=5), ZRSR2 (N=3), IDH2 (N=3), IDH1 (N=2), SH2B3 (N=2), U2AF1 (N=4), P53 (N=1), ETV6 (N=1), PHF6 (N=2), STAG2 (N=1), RUNX1 (N=2), JAK2 V617F (N=2), FLT3 (N=1). The median VAF was 30%, and 15 patients showed 1 mutation, 10 patients 2 mutations, and 11 patients 3 or more. Subjects harbouring at least one mutation were older as compared to NGS negative cases (p<0.01), and more frequently displayed a normo/hypercellular bone marrow (p=0.01). Interestingly, mutated cases showed a higher response rate to recombinant erythropoietin (70.3% versus 50%), although not significantly. Subsequent analyses were made according to the number and type of genetic defects: harbouring 2 or more mutations was associated with older age [76 (41-86) versus 71 (48-85) years, p< 0.05], lower neutrophil counts at diagnosis [1.47 (0.4-4.2) versus 2.71 (0.4-5.8) x10^9/L, p<0.01], and to shorter time to response to recombinant EPO [2.2 (1.5-8.8) months versus 6.3 (1.5-16) months, p=0.06]. Neutropenia was even more marked in patients with 3 or more mutations [1.1 (0.2-2) versus 2.6 (1.9-5.2) x10^9/L, p<0.01]. Mutations involving the splicing pathway (i.e. SF3B1, U2AF1, and ZRSR2) were the most common, and correlated with older age (76 versus 71, p=0.01), increased bone marrow cellularity [50 (25-90) versus 40 (20-50)%, p<0.01], higher platelet [209 (41-564) versus 105 (20-332) x10^9/L, p=0.02] and neutrophil counts [2.8 (0.37-5.8 versus 1.8 (0.4-3.5) x10^9/L, p=0.03].

Time to response, months	5.3 (2.3-9.4)	5.9 (1.4-11.21)

*p=0.03, **p=0.01

Summary/Conclusion: Somatic mutations involving myeloid genes were frequent in patients with LR-MDS and mainly correlated with older age and deeper cytopenias. The latter worsened along with the increase of mutations number. Considering mutation types, expectedly, those involving splicing pathway correlated with a more proliferative phenotype. Interestingly, somatic mutations did not negatively impact on response to recombinant erythropoietin

PB1624 MAGROLIMAB + AZACITIDINE VERSUS AZACITIDINE + PLACEBO IN UNTREATED, HIGHER-RISK (HR) MYELODYSPLASTIC SYNDROME: THE PHASE 3, RANDOMIZED, ENHANCE STUDY

G. Garcia-Manero [1,*], N. G. Daver [1], J. Xu [2], M. Chao [2], T. Chung [2], A. Tan [2], V. Wang [2], A. H. Wei [3], P. Vyas [4], D. A. Sallman [5]

[1]The University of Texas MD Anderson Cancer Center, Houston, [2]Gilead Sciences, Inc., Foster City, United States, [3]The Alfred Hospital and Monash University, Melbourne, Australia, [4]University of Oxford, Oxford, United Kingdom, [5]Moffitt Cancer Center, Tampa, United States

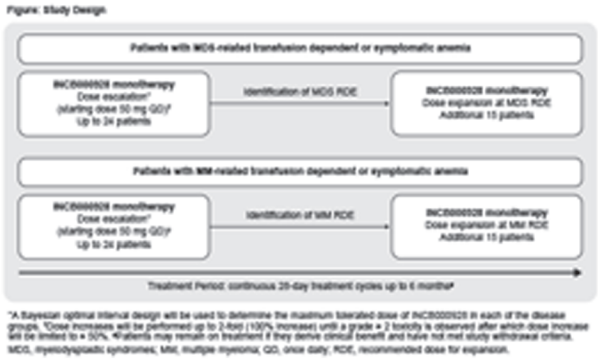
Background: Myelodysplastic syndrome (MDS) is a clonal myeloid disorder characterized by cytopenia and ineffective hematopoiesis. The median age of diagnosis is approximately 70 years of age, and prognosis and treatment are guided by the Revised International Prognostic Scoring System (IPSS-R) criteria. Patients with intermediate, high, and very high risk MDS have a median overall survival (OS) of 0.8 to 3.7 years. Despite the high unmet need in this patient population, azacitidine (AZA) is the only approved therapy for HR-MDS that has improved OS in clinical trials to date. However, these agents lead to low complete response (CR) rates (10-17%) with limited OS (<2 years), indicating a need for alternative therapy. Magrolimab (Magro) is a first-in-class monoclonal antibody that blocks the macrophage inhibitory immune checkpoint CD47, a "do not eat me" signal overexpressed on tumor cells. Binding of Magro to CD47 leads to phagocytosis of tumor cells. AZA increases expression of prophagocytic "eat me" signals, facilitating synergy with Magro. In an ongoing phase 1b study, the combination of Magro+AZA led to high response rates (objective response rate 91%, with a CR of 42%) and an acceptable safety profile without significant immune-related adverse events.
Aims: ENHANCE (NCT04313881) is a phase 3 trial to compare the efficacy and safety of Magro+AZA with that of AZA+placebo (PBO) in previously untreated patients with HR-MDS.
Methods: Patients ≥18 years old with previously untreated intermediate to very high risk-MDS by IPSS-R are eligible for ENHANCE. Randomization is 1:1 to Magro+AZA or AZA+PBO with no crossover allowed. Magro or PBO is administered intravenously (IV) with an initial 1 mg/kg priming dose to mitigate on-target anemia. An intrapatient dose-escalation regimen up to 30 mg/kg is then administered through Cycle 1, 30 mg/kg weekly dosing in Cycle 2, with 30 mg/kg dosing every 2 weeks in Cycle 3 and beyond. AZA is administered per regional prescribing information. Patients may remain on treatment until disease progression, relapse, loss of clinical benefit, or until unacceptable toxicities occur. Two primary efficacy endpoints are CR rate and OS. For patients undergoing allogeneic stem cell transplantation (ASCT), data for the CR rate will be censored at the time of ASCT and OS will be censored at the last known alive date. Secondary efficacy endpoints include red blood cell transfusion independence rate, event-free survival, minimal residual disease-negative rate, time to acute myeloid leukemia transformation, and patient-reported Functional Assessment of Cancer Therapy (FACT)–Anemia response rate. Biomarkers of immune cell recruitment, immune cell signaling, and bone marrow penetration of Magro will also be explored. Planned enrollment is approximately 520 patients globally, which began in September 2020.
Results: Trial in progress.
Summary/Conclusion: Accrual is ongoing.

PB1625 TREATMENTS AND OUTCOMES FOR PATIENTS WITH MYELODYSPLASTIC SYNDROME (MDS) BY REVISED INTERNATIONAL PROGNOSTIC SCORING SYSTEM (IPSS-R) SCORES AT THE HUNTSMAN CANCER INSTITUTE

C. Willis [1,*], M. Tan [1], H. Bauer [1], T. Au [1], S. Tantravahi [2], J. Gilreath [3], T. Kovacsovics [2], X. Cao [4], I. Sadek [4], D. Stenehjem [5]

[1]Pharmacotherapy, University Utah, [2]Hematology, [3]Pharmacy Services, Huntsman Cancer Institute, Salt Lake City, [4]Novartis Pharmaceuticals, East Hanover, [5]Pharmacy Practice and Pharmaceutical Sciences, University of Minnesota, Duluth, United States

Background: IPSS-R is used to classify risk of disease progression & guide treatment decisions for patients with MDS. Recent data shows mutational profiling may improve the prognostic stratification of MDS. Minimal real-world evidence exists for this population.
Aims: Primary objectives were to assess treatment patterns & clinical outcomes in patients with MDS by IPSS-R risk scores.
Methods: A retrospective cohort study assessed real-world, patient-level data from adults diagnosed with MDS between 2010-2019 at the Huntsman Cancer Institute (HCI), a NCCN, NCI-designated Comprehensive Cancer Center. All data were obtained via chart review from electronic medical records. IPSS-R scores were manually calculated from lab & cytogenetic data derived within 30 days of diagnosis. Patients with an intermediate to very-high IPSS-R score comprised the higher risk (HR) cohort; those with low or very low-risk IPSS-R comprised the lower risk (LR) cohort.
Results: Of the 259 MDS patients at HCI, 90 had an available IPSS-R score at diagnosis (ANC results were missing for 64% of cohort). After excluding clinical trial participants, 65 patients were included. Distribution of IPSS-R scores was: 15% (n=10) very low, 28% (n=18) low, 22% (n=14) intermediate, 23% (n=15) high, & 12% (n=8) very high. The average age of subjects was 68 years. 52% (n=34) of patients were female, 91% (n=59) were white, 8% (n=5) had autoimmune disorders, & 5% (n=3) had cerebrovascular disease. Twelve percent of NGS-tested patients had *TP53* alterations (n=7), while the most frequently altered gene for both cohorts was *DNMT3A* (19%, n=11). In the HR cohort, HMAs were used to treat 62% (n=23) of patients (median 2 cycles), while 27% (n=10) received no MDS-directed therapy, & 11% (n=4) received other MDS-related medications. In the LR cohort HMAs were used to treat 54% (n=15) (median 5.5 cycles), 39% (n=11) received no MDS-related medications, & 7% (n=2) received lenalidomide. Second-line treatment was received by 8% (n=5) of patients across both cohorts. Stem-cell transplant (SCT) was received more frequently (n=13, 35%) & sooner (median 4.8 months from diagnosis) by HR patients compared to LR patients (18%, n=5; median 15.0 months from diagnosis). Complete or partial response was achieved by 17% (n=4) of HR patients treated with a HMA versus 7% (n=1) of LR patients treated with a HMA. Transfusion independence was achieved by 60% (n=3) & 100% (n=4) of HR & LR HMA-treated patients that received PLT or pRBC prior to treatment initiation, respectively. Disease progression or death occurred in 82% (n=53) of patients during the study period with a median progression free survival (PFS) of 8.3 months & 25.3 months for HR & LR patients, respectively. PFS was significantly shorter for patients with *TP53* alterations compared to wild-type (HR: 3.07, 95% CI: 1.13-8.28), while controlling for IPSS-R using multivariable cox regression. Median overall survival was 18.8 & 31.0 months for HR & LR patients, respectively.
Summary/Conclusion: These results show that patients with MDS have a low likelihood of achieving & maintaining complete remission. In addition, few patients receive second-line therapy, revealing a large unmet need. Real world data are further limited by the reduction of patients with calculable IPSS-R scores at diagnosis. Specific genetic profiles may indicate the need for more aggressive treatments & management of relevant comorbidities. Updated results will be presented, including economic outcomes.



PB1626 A PHASE 1/2, OPEN-LABEL, MULTICENTER STUDY OF INCB000928 MONOTHERAPY IN PATIENTS WITH ANEMIA DUE TO MYELODYSPLASTIC SYNDROMES OR MULTIPLE MYELOMA

J.-M. Michot [1,*], M. G. Della Porta [2], E. Asatiani [3], F. Seguy [3], F. Zhou [4], G. Garcia-Manero [5]

[1]Gustave Roussy Cancer Center, Villejuif, France, [2]Humanitas University, Pieve Emanuele MI, Italy, [3]Incyte Biosciences International Sàrl, Morgues, Switzerland, [4]Incyte Corporation, Wilmington, [5]MD Anderson Cancer Center, Houston, United States

Background: Disease-related anemia presents a therapeutic challenge in patients (pts) with myelodysplastic syndromes (MDS) or multiple myeloma (MM). Regular red blood cell (RBC) transfusions in pts with MDS can lead to iron overload with potential clinical consequences, and one-third of pts with MM do not respond to erythropoietin-stimulating agents (ESAs). Activin receptor-like kinase-2 (ALK2) is an upstream regulator of hepcidin, the key regulatory hormone in iron homeostasis. Disrupted hepcidin homeostasis or elevated serum hepcidin levels can contribute to anemia in pts with MDS or MM. INCB000928, a selective ALK2 inhibitor, reduced hepcidin-induced anemia in preclinical models.
Aims: INCB 00928-105 (NCT04582539) is a phase 1/2, open-label, multicenter dose-escalation and dose-expansion study evaluating INCB000928 as monotherapy for pts with MDS- or MM-related anemia. The primary objective is to evaluate the safety and tolerability of INCB000928 monotherapy in pts with MDS or MM who present with

transfusion-dependent or symptomatic anemia. Secondary objectives are to determine efficacy and pharmacokinetics of INCB000928, and effects of INCB000928 treatment on iron homeostasis and erythropoiesis parameters in pts with MDS or MM.
Methods: Pts aged ≥18 years with histologically confirmed MDS (or chronic myelomonocytic leukemia or unclassifiable MDS/myeloproliferative neoplasm [MPN] overlap syndrome) or MM who present with transfusion-dependent (RBC transfusion ≥4 units during 28 days pretreatment, or ≥4 units during 8 weeks pretreatment with hemoglobin [Hgb] <8.5 g/dL) or symptomatic anemia (baseline Hgb <10 g/dL on 3 separate occasions ≥7 days apart) are eligible to enroll. Other key inclusion criteria are: ineligibility for or lack of response to standard anemia treatments including ESAs; failure of standard MM treatments including alkylating agents, glucocorticoids, immunomodulators, proteasome inhibitors, daratumumab; ECOG PS ≤1 (dose-escalation) or ≤2 (dose-expansion); and life expectancy >6 months. Key exclusion criteria are: presence of MDS with ring sideroblasts or with atypical chronic myeloid leukemia, juvenile myelomonocytic leukemia, or MDS/MPN overlap syndromes with ring sideroblasts and thrombocytosis; MDS requiring cytoreductive treatment other than hydroxyurea; MDS with bone marrow and peripheral blood myeloblast count ≥10%; platelet count <50 × 10^9/L; or prior allogeneic stem cell transplantation. Treatment with oral INCB000928 monotherapy will start at 50 mg once daily in 28-day cycles (Figure). Dose escalation will follow a Bayesian optimal-interval design, independently and in parallel in each group, to determine the maximum tolerated doses; recommended doses for expansion (RDE) for each group will be based on safety and PK/PD data. Dose increases will be performed up to 2-fold until a dose-limiting toxicity is observed; subsequent increases will be limited to ≤50% of the prior dose. It is expected that up to 24 pts will be treated in each dose-escalation, and an additional 15 pts at the RDE in each dose-expansion. Pts will receive treatment for up to 6 months and may continue if deriving clinical benefit and no progression occurs. Sites are opening in the United States, France, and Italy.
Results: Not applicable

Summary/Conclusion: Not applicable

PB1627 SWITCHING TO AN ALTERNATIVE RECOMBINANT ERYTHROPOIETIN AGENT MAY BE EFFECTIVE IN PATIENTS WITH MYELODYSPLASTIC SYNDROME

B. Fattizzo [1,*], L. Rizzo [2], J. A. Giannotta [3], W. Barcellini [3], M. Riva [2]

[1]*Hematology, University of Milan,* [2]*Hematology, Ospedale Niguarda Ca' Granda,* [3]*Hematology, Fondazione IRCCS Ca' Granda Policlinico Hospital, Milan, Italy*

Background: Low risk myelodysplastic syndromes (MDS) are a heterogeneous group of diseases that mainly present with anemia. The latter ranges from mild/asymptomatic to transfusion dependent and benefits from recombinant erythropoietin (rEPO) treatment in about 70% of cases. Several types of rEPO are available, and it is a matter of debate which one is the most effective and at what dose. Moreover, median duration of response is limited, and subsequent therapeutic options are scanty, so that most subjects would finally become transfusion dependent.
Aims: To evaluate the efficacy of an alternative rEPO product in patients with MDS refractory or relapsed after the first rEPO course.
Methods: MDS patients followed at two tertiary hematologic centers in Milan, Italy, subsequently treated with two different rEPO products have been included. Hematologic parameters, including endogenous EPO (eEPO) and transfusion dependence have been analysed before each rEPO course and response rates have been evaluated according to the International Working Group 2006 criteria.
Results: A total of 25 patients (14 males/15 females), with a median age of 74 years (59-85), followed for a median of 51 months (12-225) have been included. The majority suffered from MDS with ring sideroblasts (N=13) followed by MDS with multi-lineage dysplasia (N=7), single lineage dysplasia (N=2), 5q deletion (N=2), and excess of blasts type 1 (N=1); 15 cases had a low and 11 an intermediate-1 IPSS score. Bone marrow was hyper/normocellular in all cases but one, 10 patients showed reticulin fibrosis (MF-0), and 4 subjects harboured a cytogenetic aberration (including 5q and 11q23 deletions, and trisomy 8). Table 1 shows rEPO agents used and the relative doses/responses. Considering the first course, median eEPO pre-dose was 59 U/L (3-257) and 12 patients were transfusion dependent with a median need of 4 units/8 weeks (2-7). The first product utilized was mainly epoetin alpha (N=16, biosimilar in 9), followed by epoetin zeta (N=4), beta (N=3), and darbepoietin (N=2), with a median initial dose of 40,000 U/week, resulting in an overall response rate of 60% after 2.4 months (0.8-18). Median treatment duration was 20 months (2.4-81) with the first product, and patients were switched to an alternative compound due to loss of response (N=15), inefficacy (N=8), and toxicity (N=2). All had been increased to the maximal dose before switching. At the beginning of the second rEPO course 14 patients were transfusion dependant, and pre-dose eEPO was 142 U/L (43-390). Most patients started the alternative rEPO at high dose (80,000 U/w) and mainly shifted from alpha biosimilar to epoetin alpha (N=9) or vice versa (N=2), from alpha to zeta (N=4) or vice versa (N=4), from beta to alpha (N=3) or vice vera (N=1), and from darbepoietin to alpha (N=2). 44% of patients responded after a median of 1.9 months (0.7-5.2) from the switch, including 3 cases refractory to the first rEPO. Interestingly, 10/11 responders had been switched to epoetin alpha (p=0.03), 1 to the biosimilar, and only 27% were transfusion dependent before the switch (versus 78% in non-responders p=0.01). At the last follow up, 3 patients were still on rEPO, whilst 8 stopped it due to loss of response (N=6) or intolerance (N=2) after a median of 15.8 months (11.6-17.5).

Patient	First EPO type	Dose/week	Response	Second EPO type	Dose/week	Response
1	Darbepoietin alpha	40,000	0	Epoetin alpha	40,000	1
2	Darbepoietin alpha	500	1	Epoetin alpha	40,000	1
3	Epoetin alpha	80,000	0	Epoetin zeta	80,000	0
4	Epoetin alpha	40,000	1	Epoetin zeta	40,000	0
5	Epoetin alpha	40,000	0	Epoetin zeta	40,000	0
6	Epoetin alpha	40,000	0	Epoetin zeta	40,000	
7	Epoetin alpha	40,000	0	Epoetin alpha biosimilar	80,000	0
8	Epoetin alpha	3,000	0	Epoetin beta	80,000	0
9	Epoetin alpha	80,000	0	Epoetin alpha biosimilar	80,000	0
10	Epoetin alpha biosimilar	40,000	1	Epoetin alpha	80,000	0
11	Epoetin alpha biosimilar	40,000	1	Epoetin alpha	80,000	1
12	Epoetin alpha biosimilar	40,000	1	Epoetin alpha	80,000	1
13	Epoetin alpha biosimilar	40,000	1	Epoetin alpha	80,000	1
14	Epoetin alpha biosimilar	40,000	1	Epoetin alpha	80,000	0
15	Epoetin alpha biosimilar	40,000	0	Epoetin alpha	80,000	0
16	Epoetin alpha biosimilar	40,000	1	Epoetin alpha	80,000	0
17	Epoetin alpha biosimilar	80,000	0	Epoetin alpha	80,000	0
18	Epoteina alpha biosimilar	40,000	1	Epoetin alpha	80,000	0
19	Epoetin beta	30,000	1	Epoetin alpha biosimilar	80,000	1
20	Epoetin beta	30,000	1	Epoetin alpha	80,000	0
21	Epoetin beta	30,000	1	Epoetin alpha	80,000	1
22	Epoetin zeta	40,000	1	Epoetin alpha	80,000	1
23	Epoetin zeta	40,000	0	Epoetin alpha	80,000	1
24	Epoetin zeta	40,000	1	Epoetin alpha	80,000	1
25	Epoetin zeta	40,000	1	Epoetin alpha	40,000	1

Summary/Conclusion: Switching to an alternative rEPO was effective in 44% of cases, particularly in transfusion independent patients shifted to epoetin alpha. These results may suggest a try of an alternative rEPO product in both primary refractory MDS patients and in those relapsing after a first agent.

PB1628 A CLINICAL STUDY ON MYELODYSPLASTIC SYNDROMES

A. Perolla [1,*], A. Cili [1], E. Çalliku [1], P. Pulluqi [1], T. Caja [1], A. Ivanaj [1]

[1]*Hematology, UHC " Mother Teresa", Tirana, Albania*

Background: Myelodysplastic Syndromes (MDS) compound a heterogeneous group of malignant hematological diseases presenting an

ineffective hematopoiesis and a tendency of evolution to acute myeloblastic leukemia. The natural course of MDS is very different among the subgroups emphasizing the importance of the correct stratification / subclassification of those patients to better diagnose and treat them.
Aims: To study the incidence of Myelodysplastic Syndromes (MDS), risk factors, concomitant diseases, genetic abnormalities at the moment of the diagnosis.Our study aims to evaluate the median survival and the overall survival of MDS patients, the evolution in the acute myeloblastic leukemia of MDS patients and to evaluate the effect of different etiological factors on it.
Methods: Our study is a case-control study of 294 patients diagnosed with MDS from January 1999 to 2013 and followed up until 5 years after the moment of the diagnosis. Data were analyzed with IBM SPSS Statistics version 24, MedCal Software BVBA and Wizard Pro statistical software. In all the tests $p < 0,05$ was considered statistically important.
Results: Median incidence of MDS during the interval of time from 1999 to 2013 in the Albanian population resulted in 0,65 /100,000 inhabitants, 19-20 new cases/year. The median age at the moment of the diagnosis resulted in 61.5 ±15.08years (17 to 88-years). 65% of the patients diagnosed with MDS were at the moment of the diagnosis ≧ 60 years, with a ratio F: M ~1:1.39. 92,5% of the patients were diagnosed with primary MDS and only 7,5% were secondary MDS. According to the FAB classification, 173 patients studied retrospectively during the interval of time from 1999 to 2008 resulted: 91(53%) AREB, 28(16,2%) RA, 24(about 14%) AREB-T, 10 (5,8%) RARS, and the same result for CMML, and 9(5,2%) t- MDS. Only one patient was diagnosed with MDS-U. During the prospective phase were diagnosed 121 pacients with MDS classified according to WHO 2008: 31(25,4%) RCMD, 29(23.8%) AREB-1, 20(16.4%)AREB-2, and 12(9,8%) t- MDS. Only two patients were diagnosed with isolated del 5q-, one patient was diagnosed with RARS and 3 (2,5%) RCMD-RS. RA were 13,9% of all the patients with MDS. OS resulted 4,6 years (95%CI 3.837 to5.441). The role of karyotype in OS (years) resulted in highly significative $P < 0.001$. All the MDS patients classified as higher risk (N=56/64) evolved in Acute Leukemia within 2,8 years, meanwhile, in the lower risk, MDS group resulted in 7,29 years. The presence of concomitant diseases at the moment of the diagnosis is an independent prognostic factor P =0,016 for the median survival (years) of MDS patients, but data shown no evidence of prediction in the evolution on acute myeloblastic leukemia of those patients(P=0.3346).
Summary/Conclusion: Myelodysplastic syndromes represent a heterogeneous group of malignant diseases characterized of an ineffective hematopoiesis and a tendency of evolution to acute myeloblastic leukemia. The incidence of MDS increases significantly with the age and is more frequent in males than females over 60 years old. The natural course of MDS is very different among the subgroups emphasizing the importance of the stratification and of the subclassification of those patients according to IPSS to better diagnose and treat the MDS patients.

PB1629 ALLOGENEIC STEM CELL TRANSPLANTATION IN 34 PATIENTS WITH MYELODYSPLASTIC SYNDROME

S. Akhrouf [1,*], M. Benakli [1], A. Talbi [1], I. Abderrahim [1], R. Benouatas [1], F. Mehdid [1], N. Rahmoune [1], M. Baazizi [1], R. Belhadj [1], D. Ait ouali [1], H. Bouarab [1], S. Zerkout [1], F. Louar [1], R.-M. Hamladji [1], R. Ahmed Nacer [1]

[1]Hematology-Bone marrow transplantation, Pierre and Marie Curie Center, Algiers, Algeria

Background: Myelodysplastic syndromes (MDS) are clonal hematopoietic disorders of pluripotent stem cells, characterized by ineffective hematopoiesis, richmarrow dysplasia resulting in cytopenias. In addition, MDS frequently progresses to acute myeloid leukemia and is the most common preleukemic state in adults. Allogeneic hematopoietic stem cell transplantation (HSCT) currently is the only potentially curative therapy for MDS. It can be performed in patients (pts) aged less than 60 years from an HLA compatible or haplo-identical donor.
Aims: Long term series study
Methods: Between May 2001 to March 2019 (18 years period), thirty four pts with MDS underwent allogeneic HSCT (geno-identical: 31 pts, haplo-identical: 3 pts). The median age of the pts is 36 years (4 - 58), the Sex ratio is 1,42 (20M/14F). Median time from diagnosis to allogeneic HSCT was 11 months (2-81). The pre-transplant status of pts according to the WHO 2016 classification is (MDS with unilineage dysplasia: 4 including 2 with ring sideroblasts and 1 with isolated del 5q, MDS with multilineage dysplasia: 30 including 07 with excess blasts-1 and 09 with excess blasts -2). The treatments received before the transplant are: Ciclosporin: 07 pts, EPO: 07 pts, Danazol: 03 pts, Revlimid: 02 pts, Azacytidine: 01 pt, Aracytine: 01 pt, Rituximab: 01 pt and 33 pts were transfusion-dependent before the graft with an average of 32 RBC unit/pt (3 - 135). All the patients received myeloablative conditioning [classic MAC: 13 pts (Santos, TUTSHKA, Haplo); Flu-Bu4: 21 pts]. GVHD prophylaxis consisted on association of Cyclosporin and Methotrexate according to the Seattle protocol in 31 pts of which 10 pts received anti thymocyte globulin; Post-transplant Endoxan and Mycophenolate mofetil without Methotrexate for 3 pts. All pts received G-CSF alone mobilised peripheral blood stem cells, with a median CD34+ cell count: $7,62.10^6$ / kg (3.18-19.9). In addition to the CSP graft, one patient received a bone marrow graft.
Results: Neutropenia occured in all pts and the median duration of aplasia was14 (7-31) days. Median time to achieve neutrophils count > $0,5.10^9$/l: 14 days (11-25) and platelets > 20.10^9/l: 13 days (9-35). Thirty pts (88%) required red blood cells transfusion (8.7 unit/pt) and 31 pts (91%) needed platelet transfusions (6.6 units/pt). Three pts (8.8%) presented VOD, one of which was severe. Grade II-IV acute GVHD was observed in 08/26 pts (30.7%) and chronic GVHD in 11/20 pts (55%) of whom 5 with an extensive form. Relapse was observed in 2/26 pts (7.6%) within 4 and 20 months post transplant. At July 31, 2020, the median follow-up is 94.5 months (16-202), 16 pts (47%) are still alive (15 pts in complete remission and 1 pts in relapse on Azacytidine), 18 pts (53%) are died including 17 pts (50%) of TRM (early infection: 06, VOD: 01, thrombotic microangiopathy: 1, acute GVHD: 04, pneumopathy: 02, fulminant hepatitis: 01, metabolic disorders: 02) and 1 pt of relapse. The overall survival (OS) is 47%, relapse-free survival (EFS) 44%, and GVHD-free and relapse-free survival (GRFS) 32%.
Summary/Conclusion: Allogeneic HSCT, in our study, was a curative option in 44% of patients with MDS with 16 years of follow-up. Thirty-two% are alive with a good quality of life.

Myeloma and other monoclonal gammopathies - Biology & Translational Research

PB1630 UNRAVELLING RESISTANCE MECHANISMS TO PROTEASOME INHIBITORS IN MULTIPLE MYELOMA

C. Afonso [1,*], D. Roque [2], R. Alves [2,3,4,5], N. Magalhães [2], M. I. Costa [2], E. Gomes [2], D. Figueiredo [2], J. Jorge [2,3,4,5], B. Lapa [2,3,4,5], A. C. Gonçalves [2,3,4,5], J. Nascimento-Costa [3,4,5,6], C. Geraldes [1,2,3,4,5], A. B. Sarmento-Ribeiro [1,2,3,4,5]

[1]Department of Clinical Hematology, Centro Hospitalar e Universitário de Coimbra, [2]Laboratory of Oncobiology and Hematology (LOH), University Clinic of Hematology, Faculty of Medicine - University of Coimbra (FMUC), [3]Coimbra Institute for Clinical and Biomedical Research (iCBR) - Group of Environment Genetics and Oncobiology (CIMAGO), [4]Center for Innovative Biomedicine and Biotechnology (CIBB), [5]Clinical Academic Center of Coimbra (CACC), [6]University Clinic of Oncology, Faculty of Medicine - University of Coimbra (FMUC), Coimbra, Portugal

Background: The development of proteasome inhibitors (PI) – Bortezomib (BTZ), Carfilzomib (CFZ), Ixazomib (IXA) - for the treatment of multiple myeloma (MM) has dramatically increased treatment responses and improved patient outcomes. However, the acquisition of resistance is a major limitation in PI therapy. Many mechanisms have been proposed for PI resistance, including genetic mutations in proteasome subunits, alterations in drug efflux transporters and antioxidant response pathways, among others.
Aims: In this study, we investigate the molecular mechanisms of PI resistance and the existence of cross-resistance between the three PI. Additionally, we explore potential strategies to overcome PI resistance.
Methods: Three PI-resistant MM cell lines were established by chronic exposure of PI-sensitive cells (NCI-H929) to non-lethal doses of BTZ (H929-BTZ cells), CFZ (H929-CFZ cells) and IXA (H929-IXA cells). The validation of the PI resistant models, the evaluation of the potential cross-resistance between PIs and the efficacy of the immunomodulatory drugs (IMiDs), lenalidomide (LEN) and pomalidomide (POM), were assessed using the fluorometric microculture cytotoxicity assay (FMCA). Expression and activity of ATP Binding Cassette (ABC) family efflux transporters (P-glycoprotein; multidrug resistance protein 1 (MRP1) and MRP2; breast cancer resistance protein (BCRP)) were analysed by flow cytometry. Gene expression analysis (Nuclear Factor, Erythroid 2 Like 2 (NFE2L2; Kelch Like ECH Associated Protein 1 (KEAP1), Nuclear Factor Kappa B Subunit 1 (NFKB1); ABC Subfamily B Member 1 (ABCB1); ABC Subfamily G Member 2 (ABCG2); ABC Subfamily

C Member 1 (ABCC1) and ABCC2) was performed by qPCR assay. A p-value of 0,05 was used as cut-off for significance.
Results: The confirmation of the resistance of the three PI-resistant MM cell lines was shown by the increase of the half maximal inhibitory concentration (IC50) by 4.7 folds (H929-BTZ IC50 2.8nM), 6.7 folds (H929-CFZ IC50 2.0nM) and 10.5 folds (H929-IXA IC50 20nM) compared to the IC50 value of sensitive cells (IC50 BTZ 0.6nM, IC50 CFZ 0.3nM and IC50 IXA 1.9Nm, respectively). BTZ-resistant cells displayed cross-resistance to CFZ; however, cells resistant to these two PI did not display cross-resistance to IXA (H929-BTZ IC50 IXA 0.5nM; H929-CFZ IC50 IXA 1.9nM). H929-CFZ showed an increased expression of *ABCB1* and *ABCG2* genes. There were not statistically significant differences in the expression levels of the other evaluated genes (*NFE2L2, KEAP1, NFKB1, ABCC1, ABCC2*) in PI-resistant cell lines compared to PI-sensitive cell lines. Expression levels of protein efflux transporters were also similar between all cell lines; however, the activity of MRP1/2 in all PI-resistant cell lines was significantly higher than in sensitive cells. The association of IMiDs with PI was effective to overcome PI resistance.
Summary/Conclusion: Our results suggest that PI resistance may be mediated by an increased activity of MRP1/2. The absence of cross-resistance between IXA and the other two PI suggest that IXA can be effective even in the presence of resistance to BTZ and/or to CFZ. The association of IMiDs with PI appears effective in overcoming PI resistance. Additional studies are required for a better understanding of the mechanisms of PI-resistance in MM, in order to improve novel therapeutic strategies for refractory and relapsed patients.

PB1631 EFFECTS OF DARATUMUMAB(DARA), CYCLOPHOSPHAMIDE (C), THALIDOMIDE (T) AND DEXAMETHASONE (D) COMBINATION ON LYMPHOCYTE POPULATIONS OF TRANSPLANT ELIGIBLE NEWLY DIAGNOSE MULTIPLE MYELOMA PATIENTS

A. Santos [1,*], H. Santos [1], M. Salvino [2], J. Santos [3], S. Queiroz [3], L. Lucas [3], A. Almeida [2], M. Santos [1], A. Torres [1], M. D. G. Arruda [3], E. Crusoe [3,4]

[1]Immunology and Cytometry Lab, Federal University of Bahia, [2]Hematology and Bone Marrow Transplantation, Federal University of Bahia- University hospital, [3]hematology, Instituto D'or de pesquisa e ensino (IDOR) and Clinica CEHON, [4]hematology, Federal University of Bahia- University hospital, Salvador, Brazil

Background: The CTD combination have both an immunomodulatory and immunosuppressive activity on multiple myeloma (MM) patients (pts) treatment. The advance of immunotherapy has been demonstrated by the development of new agents like anti CD38-antibody Dara, that are increasing the overall and progression-free survival of MM pts. Dara effect on the immune system was already described, but few studies analyzed specifically lymphocytes population. We hypothesized that Dara-CTD combination could impact on lymphocytes subsets during treatment.
Aims: The primary endpoint was to quantify subpopulations of lymphocytes in pts with newly diagnosed multiple myeloma (NDMM) transplant eligible (TE) pts, during Dara-CTD treatment phases (induction, consolidation and maintenance). Secondary endpoint was to describe B cells subsets during the same phases
Methods: Peripheral blood of 14 pts at four different time points was collected: at diagnose, after four cycles of Dara-CTD, after two consolidation cycles post-autologous stem cell transplantation (ASCT) and before maintenance therapy. Flow cytometry was used to detect lymphocyte surface molecules including CD3, CD4, CD5, CD8, CD16, CD19, CD20, CD38, CD45 and CD56 in the scatter plot. B cells were isolated and subpopulations (naïve B cells, non-class switched memory B cells, class switched memory B cells, IgD-CD27- memory B cells and plasmablasts) were detected by CD20, CD24, CD27, CD38, CD45 and IgD. Statistics was performed using the SPSS® v25.0
Results: The pts median age was 55 range (41-65) years old, and 57% were female. The median of T, B and NK lymphocytes subsets at diagnosis were 1153 x 10^3/µL, 205x 10^3/µL and 284 x 10^3/µL cells, respectively. After four cycles of Dara-CTD the median of T, B and NK cells dropped significantly to 889 x 10^3/µL, 12 x 10^3/µL and 11 x 10^3/µL, respectively ($p \leq 0.05$). The number of the cells after two consolidation cycles post-ASCT, showed T cells full recovery (1087 x 10^3/µL) while B and NK cells had weakly reconstitution (15 x 10^3/µL and 34 x 10^3/µL, respectively). Before maintenance therapy, the median of T, B and NK cells were 1456 x 10^3/µL, 24 x 10^3/µL and 33 x 10^3/µL, respectively. Regarding B cell population, the median of naïve B cell decreased after 4 induction cycles from 32 x 10^3/µL to 1 x 10^3/µL. Then, after two consolidation cycles post-ASCT the number of B cell increased to 14 x 10^3/µL and to 18 x 10^3/µL before maintenance
Summary/Conclusion: Lymphopenia have been shown with different protocols using Dara as single agent or in combination. The present study confirmed that there is a decrease in the number of different lymphocytes populations (T, B and NK) after induction therapy with Dara-CTD. The T cells number recovery after two consolidation cycles post-ASCT, but B and NK cells remain low after the same period. There was a slowly but continuously recovering of B and NK cells, suggesting that Dara-CTD combination allows lymphocytes reconstitution. Analyzing the B cells subpopulations, the naive B cell was the first to show a more significant recovery, although it was below the reference range (33 – 259). In conclusion, this is the first study that report the lymphocyte profile during Dara-CTD treatment. This preliminary data suggest that Dara-CTD induces general lymphopenia on (T, B and NK) populations after induction phase. It was identified that T cells recovery was complete after two consolidations cycles while the recovery of B and NK cells was slowly but continuously.

PB1633 ROLE OF PROTEIN KINASE CK1 ALPHA AND LENALIDOMIDE IN THE INTERACTIONS BETWEEN MULTIPLE MYELOMA PLASMA CELLS AND BONE MARROW STROMAL CELLS: THERAPEUTIC IMPLICATIONS

A. Fregnani [1,2,*], L. Quotti Tubi [1,2], Z. Spinello [1,2], G. Barilà [1,2], R. Zambello [1,2], D. Toscani [3], N. Giuliani [3], G. Semenzato [1,2], L. Trentin [1,2], F. Piazza [1,2], S. Manni [1,2]

[1]Department of Medicine, University of Padova, [2]Veneto Institute of Molecular Medicine, Padova, [3]Department of Clinical and Experimental Medicine, University of Parma, Parma, Italy

Background: Multiple myeloma (MM) plasma cells (PC) growth and the associated bone disease is tightly dependent on bone marrow (BM) microenvironment. Survival pathways, such as NF-κB, Hedgehog and Wnt/β-catenin, support the MM clone and bone homeostasis imbalance. The Wnt/β-catenin pathway is pivotal for bone formation since it stimulates *RUNX2* expression, the master gene regulator of osteoblastogenesis. It has been shown that MM PC cells inhibit RUNX2 activity in mesenchymal stromal cells (MSC). Moreover, RUNX2 overexpression in MM cells is also associated to osteoblastogenesis inhibition. Protein kinase CK1α supports MM PC growth and it is a known target of Lenalidomide (Lena). Our preliminary data show that CK1α gene silencing in MSC sustains *RUNX2* gene expression, favoring the osteogenic program.
It is known that Lena works through a novel drug mechanism, modulating Cereblon E3 ubiquitin ligase. It induces the ubiquitination and the subsequent proteasomal degradation of Ikaros, Aiolos and CK1α leading to MM cells death. The effects of the Lena-CK1a axis on the MSC osteogenic potential and the MM BM-dependent growth are unknown.
Aims: To investigate the effects of Lena-induced CK1α degradation in MSC on: 1) cell survival. 2) the MSC osteoblastic phenotype, including *RUNX2* and *ALP* expression.
To study the impact of Lena in a MSC-MM PC crosstalk BM microenvironment culture model on: 1) MM PC growth/survival 2) the MM PC-induced anti-osteogenic phenotype.
Methods: Cell lines and cultures: the IL-6 dependent INA-6 MM cell line and the MSC-hTERT stromal cell line have been used. A BM microenvironment model was obtained by plating INA-6 on a layer of MSC-hTERT cells. MM cells and MSC pure populations were obtained by cell sorting since MSC express GFP. Primary BM stromal cells were isolated from MM and MGUS sample patients. All the experiments were performed adding Lena to the culture medium. The rate of apoptosis was detected through Annexin V and Propidium Iodide staining. qRT-PCR and WB analysis were used to analyze mRNA and protein level expression of CK1α, RUNX2 and other osteogenic markers.
Results: Lena treatment did not change MSC viability, while it induced MM cells apoptosis. CK1α protein level was reduced after Lena treatment, not only in MM cells, but also in MSC cultured alone or with PC. Surprisingly, despite CK1α degradation, both *RUNX2* and *ALP* mRNA expression was reduced in MSC-hTERT and preliminarly in primary MSC, suggesting a negative effect of Lena on osteogenic differentiation. In the MM-BM stromal cells co-culture model, we found reduced RUNX2 expression levels both in MM cells and in MSC

Summary/Conclusion: Lena induced CK1α reduction does not seem to be sufficient to recover the MSC osteogenic program, while it is sufficient to reduce RUNX2 expression in MM cells, inducing cell death. Further studies will be necessary to investigate if combining CK1α silencing/chemical inhibition to Lena, in the co-culture model system, could be promising not only to cause PC death, but also to rescue the MSC osteoblastic phenotype.

PB1634 THE FIRST MYELOMA PATIENT DERIVED XENOGRAFT FROM TREATMENT REFRACTORY HUMAN MYELOMA CELLS IN SWEDEN AND THE EFFECT OF BROMODOMAIN-INHIBITORS ON MYELOMA CELLS IN VIVO

D. Jansson [1,2,*], J. Nilsson [1,3], L. Nilsson [1,3], C. Hveding Blimark [2]

[1]Sahlgrenska Center for Cancer Research, Institute of Clinical Research, Dept of Surgery, University of Gothenburg, [2]Department of Hematology, Sahlgrenska University Hospital, Institution of Internal Medicine, Sahlgrenska Academy at the University of Gothenburg, Gothenburg, Sweden, [3]Harry Perkins Institute of Medical Research,, Melanoma Discovery Laboratory, University of Western Australia, Nedlands/Pert, Perth, Australia

Background: Multiple myeloma is a plasma cell malignancy and the second most common haematological cancer in Sweden. *In vivo* studies of myeloma in mice are usually done by injecting commercial cell lines intravenously. If we could successfully transplant treatment refractory human myeloma cells intratibially it would be a substantial benefit to test novel treatments and predict clinical outcome in patients. The bromodomain inhibitors (BETi), which inhibit reading of epigenetic modifications and block transcriptional activity, have sparked a lot of interest and showed promising results in animal studies of myeloma. An in-house compound under development called BETi-1 has shown promising results *in vitro* on commercial cell lines exhibiting at minimum equal potency as the widely-used compound JQ1 (data not yet published).
Aims: The primary objective of this project was to investigate whether it is possible to develop a patient derived xenograft (PDX) from human bone marrow aspirates of treatment refractory multiple myeloma. Secondary objectives were to examine if BETi affect the viability of myeloma cells *in vivo*.
Methods: In this translational study, biobank material consisting of cryopreserved bone marrow samples acquired from patients receiving treatments at Sahlgrenska University Hospital between 2017 and 2020 with relapsed/refractory multiple myeloma (RRMM), were thawed and transplanted intratibially on immunodeficient mice (NOD-SCID-IL2 receptor gamma knockout, NOG/NSG) to develop a patient-derived xenograft (PDX). Tumour progression was monitored with lambda- and kappa ELISA every other week. When progression was confirmed, the mice received either vehicle or treatment with BETi-1. At sacrifice, long bones and sternum were analysed with immunohistochemistry and FACS to verify presence of clonal plasma cells. All experiments were approved by the regional Ethical Committees in Gothenburg.
Results: We show a successfully established and serially transplanted myeloma PDX from human treatment refractory myeloma cells verified by two independent methods exhibiting clonal plasma cells with the ability to disseminate in NOG/NSG mice. *In vivo* experiment with BETi-1 treatment is still ongoing and will be presented in due time

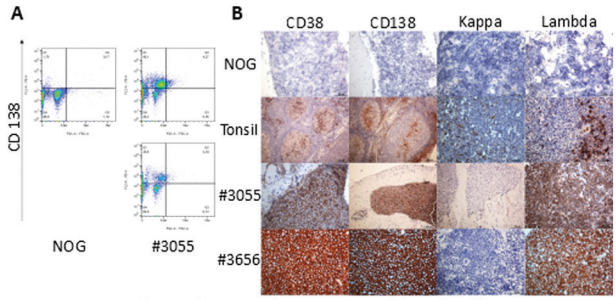


Figure 1. FACS-analysis with CD138 of negative control (NOG) and bone marrow extracted from the injection site of #3055 (lower) and contralateral tibia (upper) upon sacrifice (A). Staining for CD38, CD138, Kappa and Lambda on NOG (negative control), Tonsil (positive control), #3055 (mouse with hindleg paralysis) and #3656 (transplanted with cells from #3055) identifies human tumour cells in #3055 and #3656, thus confirm a successful serially transplanted patient -derived xenograft (B). Cells not stained are blue and cells with positive staining are brown.

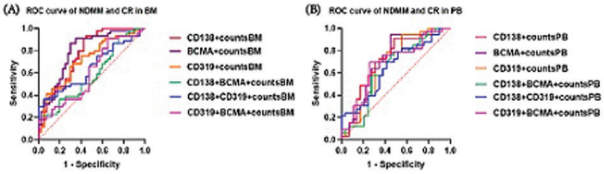
Summary/Conclusion: In this translational study we have established a multiple myeloma PDX model from human treatment refractory myeloma cells and thus developed a platform for examining new treatment options in multiple myeloma.

PB1635 CYTOKINE GENE POLYMORPHISMS AND AUTOLOGICAL TRANSPLANTATION OF HEMATOPOIETIC STEM CELLS IN PATIENTS WITH MULTIPLE MYELOMA

S. Svitina [1,*], Z. Sidorova [1], I. Kostroma [2], A. Zhernyakova [2], S. Gritsaev [2], S. Bessmeltsev [3], S. Kapustin [1]

[1]Laboratory of biochemistry, [2]Hematological Clinic, [3]FSBI "Russian Research Institute of Hematology and Transfusiology of FMBA", Saint Petersburg, Russian Federation

Background: Important role of certain cytokines in the regulation of hematopoiesis and immune response in multiple myeloma (MM) patients has been established. The lack of improvement in the quality of response after autologous hematopoietic stem cell transplantation (auto-HSCT), which is observed in some patients, may lead to decrease in the effectiveness of treatment. There is a little data on the significance of immune genes variations in predicting the effect of auto-HSCT in patients with MM.
Aims: To assess effect of several immune system genes (IL-6, TNF-A, IL-1B, IL-10) polymorphisms in patients with MM during auto-HSCT.
Methods: We included 28 MM patients (15 men and 13 women, mean age 53.7 ± 6.8 years) who underwent auto-HSCT in the study. Improvement in the quality of response after the first auto-HSCT was observed in 16 (57.1%) patients, whereas other 12 (42.9%) patients did not achieve such improvement. Genotyping for the IL-6 -174G/C, TNF-A -308G/A, IL-1B -31T/C, IL-10 -592C/A polymorphisms was performed by PCR-RFLP. Odds ratios (OR) and p-values were determined by Fisher's exact test to characterize intergroup differences in distributions of genotypes and their combinations.
Results: Genotype frequencies for the TNF-A, IL-1B and IL-10 polymorphisms were not significantly different between the groups of patients with or without improvement in the quality of response after the first auto-HSCT. However, the frequency of homozygotes for the rare -592A allele of the IL-10 gene was almost 3 times higher in patients with improved quality of response than in those without improvement (20.0% vs 8.3%, respectively; p=0.12; OR=3.3). The frequency of the IL-1B -31TT genotype was also increased in patients with effective auto-HSCT when compared to "no improvement" group (37.5% vs 16.7%, respectively; p=0.4; OR=3.0). Finally, proportion of the IL-6 -174C allele carriers among patients with improved response was almost 2-fold higher (81.3% vs 41.6% in the group with no improvement in the quality of response; p=0.05; OR=6.1).
Summary/Conclusion: In this study, we observed possible association between the IL-6 -174G/C gene polymorphism and effectiveness of the first auto-HSCT in patients with MM. Further studies are needed to clarify the significance of immune genes variations in predicting the effect of auto-HSCT in patients with MM.



PB1636 THE POTENTIAL DIAGNOSTIC ROLE OF CD138+/BCMA+/CD319+ MICROPARTICLES FROM THE PLASMA CELL IN MULTIPLE MYELOMA CLINICAL MONITORING BY FLOW CYTOMETRY

N. Meng [1], Z. Liu [1,*], R. Fu [1]

[1]Department of Hematology, Tianjin Medical University General Hospital, Tianjin, China

Background: Multiple myeloma (MM) is malignant tumor with abnormal proliferation of bone marrow plasma cells. The existing clinical tools used to determine treatment response and minimal residual disease (MRD) are affected by focal distribution of myeloma cell in bone marrow and the quantity of sample. In our previous study, we demonstrated that the counts of $CD138^+$microparticles (MPs) in BM showed to be a potential marker to monitor the load of MM. On this basis, we further investigated the feasibility of $BCMA^+$MPs and $CD319^+$MPs to monitor MM load.
Aims: 1.The number of MPs produced by a single myeloma cell.
2.If $CD138^+$/$BCMA^+$/$CD319^+$MPs can monitor the load of multiple myeloma.

Methods: Peripheral blood and bone marrow of MM patients and healthy donors were collected. Microparticles were isolated by differential centrifugation, and MPs were immunolabeled and detected by flow cytometry (Cyto-FLEX). Mann-Whitney (U) test was conducted for the nonparametric data. New diagnosed MM (NDMM) patients and CR patients were compared, and ROC curves were used to identify cutoff points with optimal sensitivity and specificity concerning the counts of MPs in BM and PB.

pared
+MPs
l; The
which
nts in

Summary/Conclusion: Our research showed that similar to CD138, the counts of BCMA$^+$MPs and CD319$^+$MPs was also a powerful marker for monitoring MM cell, and the accuracy of monitoring MM using BCMA$^+$MPs was higher than CD138; MM-MPs from the plasma provided support for a potential monitoring biomarker of MM.

PB1637 GLOBAL DNA METHYLATION AND PROMOTER GENE METHYLATION IN MGUS AND DIFFERENT STAGES OF MULTIPLE MYELOMA

P. Flodrova [1,*], J. Minarik [2], P. Krhovska [2], K. Smesny Trtkova [1,3]

[1]Department of Clinical and Molecular Pathology, Palacky University Olomouc, [2]Department of Haemato-oncology, University Hospital Olomouc, [3]Institute of Molecular and Translational Medicine, Palacky University Olomouc, Olomouc, Czech Republic

Background: Multiple myeloma is biologically heterogenic disease with wide spectrum of genetic and epigenetic changes. Global hypomethylation and gene-specific promoter hypermethylation are supposed to be included in mechanism in myelomagenesis.
Aims: The study is focused on global DNA methylation assessment and its relationship to methylation level of promoter and 1. exon sequences of *PDLIM4* and *CDKN2B* genes.
Methods: The set of 94 un-sorted samples of bone marrow aspirate from patients with MGUS and multiple myeloma (MM) in different disease stages (smoldering myeloma, MM diagnosis, MM remission, MM relapse), were examined in our study. An informed consent from all patient was obtained. For determination of the global DNA methylation level, the Luminometric Methylation Analysis (LUMA) was newly implemented. Methylation analysis of particular gene sequences was performed by bisulfite pyrosequencing.
Results: While *CDKN2B* gene methylation level was generally low (median between 4 % and 5,5 % in first exon and between 1 % and 4 % in promotor), the increased promoter *PDLIM4* methylation was determined in newly diagnosed patients with multiple myeloma (median 19 %). The highest global DNA methylation level was detected in MGUS samples (76,5 %), and its gradual decreasing during myeloma progression was observed (medians: 73,1 % in smoldering myeloma, 72,5 % in MM diagnosis and 69,4% MM relapse). In the subgroup of myeloma remission patients, the level of global DNA methylation showed an upward trend (median 73,4 %).
Summary/Conclusion: The LUMA method proved to be an effective procedure and ease to perform. Our results of global DNA methylation assessment are in accordance with literature data relating to haemato-oncological malignancies. Further, the use of a bone marrow of the un-sorted cell population could be an advantage of the method procedure. Moreover, our data support an important role of the *PDLIM4* gene in the onset and progression of multiple myeloma disease. In contrast with some other studies, we did not confirm any methylation changes in CDKN2B gene analysed sequences, which indicates its unmethylated state.

PB1638 PROGNOSTIC ROLE OF MONOMERIC C-REACTIVE PROTEIN IN NEWLY DIAGNOSED MULTIPLE MYELOMA AS A MARKER OF THE BONE LOSS DEGREE

S. Semochkin [1,*], M. Zvereva [2], I. Melnikov [2], O. Saburova [2], A. Cherkasova [3], Z. Gabbasov [2]

[1]P. Hertsen Moscow Oncology Research Institute, National Medical Research Radiological Centre, Pirogov Russian National Research Medical University, [2]Cell hemostasis laboratory, National Medical Research Center of Cardiology, [3]Pirogov Russian National Research Medical University, Moscow, Russian Federation

Background: C-reactive protein (CRP) is the most used clinical indicator of inflammation, which under certain circumstances can dissociate into insoluble monomers (mCRP). A recent study identified that mCRP can increase the number of osteoclasts in the culture medium. It is known that osteolytic lesions are a hallmark of MM, causing severe bone pain and pathological fractures. The malignant plasma cells induce bone resorption by activating osteoclasts. On the other hand, a Renal impairment (RI) is others common in MM)], with up to 40% of the patients experiencing this complication. RI increases risk of early death and affects disease management in multiple ways, as it may complicate treatment options and dosing, and render pts more susceptible to infections and prolonged hospitalizations. In addition, in the case of RI, traditional prognostic markers such as albumin and beta2-microglobulin are less accurate in terms of disease prevalence and tumor volume.
Aims: The target was to study the importance of mCRP as a marker of bone resorption for this kind of patients.
Methods: Blood samples were collected from patients before starting chemotherapy. To distinguish between mCRP and pentameric CRP, we combined the FITC-labeled monoclonal antibody to pCRP (mAb to pCRP), clone 372 (ImTek, Moscow, Russia), and PE-labeled mAb to mCRP with cross-reactivity to pCRP (mAb to mCRP), clone 328 (ImTek, Moscow, Russia). We used a non-specific FITC-labeled mouse IgG as a negative control. In each test at least 10,000 events were registered. We prospectively evaluated 15 patients with newly diagnosed MM (median age at diagnosis 67 years, range 55-74 years, female-9/male-6). A feature of our population of patients was a severe renal failure with a median of CKD-EPI 6.3 [Q25 5.2; Q75 12.3] ml/min/1.73 m2.
Results: The degree of bone destruction was assessed using X-ray, based on which, the patients were divided into 2 groups. For patients with limited bone loss (corresponds to stages Durie-Salmon 1-2, Groupe I, n=6), the median of mCRP was 47.6 [35.3; 62.5] versus 112.6 [75.6; 183.2] ng/ml (p = 0.02) for advanced lytic bone lesions (DS stage 3, Groupe B, n=9). This is much more than healthy people who have an mCRP level of 1 ng/ml. Only the concentration of mCRP, but not CRP, Ca2+, albumin, β2-microglobulin or NT-proBNP, correlated with bone destruction (Table 1).

Table 1. Analysis of the predictive value of individual biological markers by matching groups

Parameters	CKD-EPI, ml/min/1.73 m2	NT-proBNP, pg/ml	hs-CRP, mg/l	mCRP, ng/ml	Ca2+, mmol/l	Albumin, g/l	β2-MG, mg/l
Groupe I (n=6)							
Median	7.7	2483	6.50	**47.6**	2.25	36.8	17.8
Range	3.0 – 14.9	1082 - 35000	2.26 – 26.2	**26.4 – 64.9**	2.02 – 2.82	29.5 – 39.7	12.0 – 19.0
Groupe II (n=9)							
Median	6.0	5500	15.9	**112.2**	2.51	36.3	19.0
Range	2.1 – 26.0	560 - 35000	1.95 – 134,0	**42.2 – 260.6**	1.90 – 3.49	27.5 – 45.3	10.6 – 19.7
F (χ2)	0.07	0.48	2.27	**4.48**	1.50	1.03	0.21
P value	0.79	0.83	0.16	**0.05**	0.25	0.33	0.66

Abbreviations: hs-CRP - high-sensitivity C-reactive protein; β2-MG – β2-microglobulin; mCRP – monomeric C-reactive protein; CKD-EPI - Chronic Kidney Disease Epidemiology Collaboration; NT-proBNP – N-terminal pro-brain natriuretic peptide.

Summary/Conclusion: Thus, we concluded that there is a relationship between the degree of bone destruction and mCRP concentration. Hence mCRP plays an important role in the increase in the number of osteoclasts and increasing their activity, it can serve as a good marker of bone resorption.

PB1639 VALIDATION OF ALGORITHMS TO IDENTIFY FIRST-LINE THERAPY (INDUCTION AND MAINTENANCE) FOR MULTIPLE MYELOMA FOR USE IN ELECTRONIC HEALTHCARE DATABASES

A. Berger [1,*], S. Ailawadhi [2], S. Shah [1], K. Fraeman [3], D. Saragoussi [4], R. Buus [5], B. Nguyen [6], D. Cherepanov [7], D. Romanus [7]

[1]Data Analytics, Evidera, Waltham, [2]Division of Hematology/Oncology, Department of Medicine, Mayo Clinic, Jacksonville, [3]Data Analytics, Evidera, Bethesda, United States, [4]Non-Interventional Studies, Evidera, Paris, France, [5]Non-Interventional Studies, Evidera, [6]Global Product Development, Oncology, PPD, Bethesda, [7]Global Outcomes Research, Takeda Pharmaceuticals, Cambridge, United States

Background: Treatment for multiple myeloma (MM) is complex, involving several agents that may be used to induce and/or maintain response. While large electronic health databases (claims or electronic medical records [EMR]) represent sources of rich information on real-world use of these therapies and associated outcomes, they lack sufficient clinical detail needed to determine lines of therapy (LOTs) or treatment intent. Clinically robust and validated algorithms are required in order to use these data to identify LOTs—including when maintenance therapy (MT) is used and its constituent medication(s)—in MM.
Aims: To develop and assess performance of algorithms to identify LOTs among MM patients.
Methods: Algorithms for LOT identification were previously developed with hematologists/oncologists and in accordance with guidelines (Table). Validation of the algorithms was conducted using data from the Henry Ford Health System (HFHS). We identified adults with MM enrolled in the HFHS Health Alliance Plan (HAP) between January 1, 2006 and December 31, 2017. Patients whose HAP enrollment coincided with available medical chart data, and who had evidence of ≥1 "CRAB" (i.e., hypercalcemia, renal insufficiency, anemia, bone lesions) symptoms, were included. Starting from the date of the initial MM diagnosis, agents used to treat MM were identified in claims and EMR data. LOTs were then constituted based on the algorithms. First, individual agents were combined into small "mini-LOTs" using a series of defined rules (e.g., concomitant drugs) dependent on medications received. Next, mini-LOTs were combined into final LOTs based on additional rules that included: (1) receipt of ≥1 "new" agents of interest (not received in prior mini-LOT), including switches/augmentation; (2) days between mini-LOTs; (3) duration of prior mini-LOTs; and (4) whether the patient had undergone frontline stem-cell transplant (SCT). Attention was focused on the first LOT following diagnosis (LOT1). Use of MT within LOT1 was determined based on specific criteria, including duration and composition of mini-LOTs and SCT status. LOTs derived by these algorithms were then validated via review of all relevant clinical data in patients' medical records by two independent hematologists/oncologists, with discordant cases adjudicated by a third arbitrator. Sensitivity, specificity, positive predictive value (PPV), and accuracy were estimated.
Results: A total of 133 patients (89 non-SCT [nSCT]; 44 SCT) were identified. Mean (standard deviation) age was 67.5 (11.6) years, 53.4% were male, and 60.9% were African American; 24.8%, 57.1%, 84.2%, and 39.1% had hypercalcemia, renal insufficiency, anemia, and bone lesions, respectively. The 3 most commonly used LOT1 regimens (Table) collectively represented 74.4% of patients. Overall accuracy of algorithms to identify LOT1 was 85.0% (88.8% nSCT; 77.3% SCT). For MT, it was 85.7% (87.6% nSCT; 81.8% SCT). PPVs for the most commonly used regimens ranged between 90.9%>92.9% for nSCT patients and 70.6%>100.0% for SCT patients. See the Table for validation statistics by regimens.

Table. LOT Algorithm Performance, by SCT Status

	Regimen	nSCT Cohort, N=89					SCT Cohort, N=44

*Oral preparations only

Abbreviations: LOT = line of therapy; SCT = stem cell transplant; nSCT = non SCT; sens = sensitivity; spec = specificity; PPV = positive predictive value; acc = accuracy; V = bortezomib; R = lenalidomide; M = melphalan; T = thalidomide; Cyclo = cyclophosphamide + bortezomib; A = doxorubicin; Vin = vincristine; K = carfilzomib; Cy = cyclophosphamide; Int = interferon; NA = not applicable

NOTE: Sensitivity was estimated by dividing the number of true positives by the total number of patients who received the regimen (true positives + false negatives); specificity by dividing the number of true negatives by the total number of patients who did not receive the regimen (true negatives + false positives); PPV by dividing the number of true positives by the total number of patients who were allocated to the regimen by the algorithm (true positives + false positives); and accuracy by dividing the number of patients correctly allocated by the algorithm (true positives + true negatives) by the total number of patients to whom the algorithm was applied.

Algorithms for LOT identification were previously developed with hematologists/oncologists and in accordance with published guidelines and literature (References: 1. Rajkumar SV, *et al. Blood. 2015 May 5;125(20):3069-3*; 2.NCCN.org [Internet].2020. Available from: www.nccn.org/professionals/physician_gls/pdf/myeloma.pdf ; 3. Rajkumar SV, *et al. Blood. 2015 Aug 13;126(7):922-2*.

Summary/Conclusion: Algorithms to identify LOT1 and use of MT therein performed well, with an overall accuracy of 85.0% among patients with newly diagnosed MM. The algorithms performed numerically better in nSCT patients than SCT patients, although the latter had relatively smaller sample size. Further study in other large electronic healthcare databases is warranted to determine the consistency with which these algorithms can accurately constitute LOTs for the treatment of MM.

PB1640 COMPARISON OF THE EXPRESSION PROFILE AND PROMOTER GENE METHYLATION OF SELECTED TUMOR-SUPPRESSOR GENES IN MYELOMA CELLS

K. Smesny Trtkova [1,2,*], E. Gottwaldova [1], D. Weiser Drozdkova [1], P. Luzna [1], P. Flodrova [1], J. Minarik [3]

[1]Department of Clinical and Molecular Pathology, [2]Institute of Molecular and Translational Medicine, Palacky University Olomouc, [3]Department of Haemato-oncology, University Hospital Olomouc, Olomouc, Czech Republic

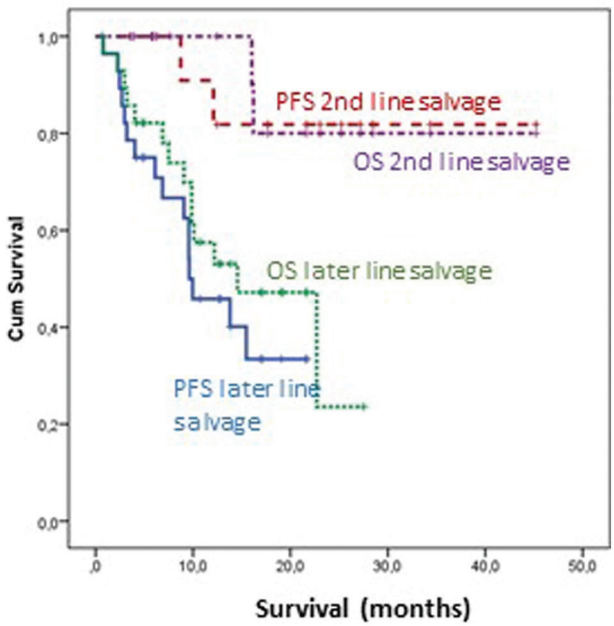
Background: Epigenetic regulations play an important role in the etiopathogenesis of multifactorial diseases such as multiple myeloma. DNA methylation is the most studied epigenetic modification and has an impact on gene expression and genome stability.
Aims: The gene expression profile was compared with DNA methylation level in selected promoter regions of two tumor suppressor genes.
Methods: 5 samples of bone marrow aspirates (after sorting of $CD138^+$ cells) were used for quantification of *RBP1* and *GPX3* genes expressions followed by pyrosequencing methylation analysis of the promoter gene sequence. These expression and methylation analysis of studied tumor suppressor genes were also performed in myeloma cell lines KMS12-BM and KMS12-PE after their treatment with demethylation agents, 5-aza-2´-deoxycytidine and 5-azacytidine.
Results: In $CD138^+$ sorted patient samples, strong negative correlation (r = -0,635) between *GPX3* gene expression and its promoter gene sequence methylation was determined, and the low negative correlation was detected in two from three analysed promoter sequences of *RBP1* gene (r = -0,304 for As11; r = -0,154 for As10; r = 0,207 for As12). In comparison to untreated cells, the re-expression and/or increased expression of *RBP1* and *GPX3* genes after their demethylation treatment of both KMS12-BM and KMS12-PE cell lines was found.
Summary/Conclusion: Negative correlation between gene expression and promoter gene methylation of both studied *GPX3* and *RBP1* genes indicates DNA methylation impact on expression of these tumor suppressors, which could play an important role in myelomagenesis.

Myeloma and other monoclonal gammopathies - Clinical

PB1641 EFFICACY AND SAFETY OF VENETOCLAX COMBINATIONS IN T(11;14) MULTIPLE MYELOMA: REAL WORLD DATA OF 50 PATIENTS COLLECTED FROM 7 HUNGARIAN CENTERS

V. R. Szita [1,*], G. Mikala [2], J. Fábián [2], A. Hardi [2], H. Alizadeh [3], P. Rajnics [4], L. Rejtő [5], T. Szendrei [6], L. Váróczy [7], Á. Illés [7], T. Masszi [1], G. Varga [1]

[1]Department of Internal Medicine and Haematology, Semmelweis University, [2]Department of Hematology and Stem Cell Transplantation, South Pest Central Hospital, National Institute for Hematology and Infectious Diseases, Budapest, [3]1st Department of Internal Medicine, University of Pécs, Pécs, [4]Department of Haematology, Somogy County Kaposi Mór Teaching Hospital, Kaposvár, [5]Department of Haematology, Jósa András Teaching Hospital, Nyíregyháza, [6]Department of Haematology, Teaching Hospital Markusovszky, Szombathely, [7]Department of Haematology, Institute for Medicine, Clinical Center, University of Debrecen, Debrecen, Hungary



Background: Venetoclax, a selective bcl-2 inhibitor first approved for CLL has been investigated for the treatment of relapsed myeloma patients, and although it failed to show benefit for myeloma patients as a whole, t(11;14) patients demonstrated exceptional responses in the Bellini trial (Lancet Oncol 2020; 21:1630), thus paving the way towards the first genetically targeted treatment in myeloma.
Aims: Off label use of venetoclax is on the rise, even though clinicians have to face unanswered questions regarding the right dosage and length of therapy, as well as the potential for adverse events (AEs), especially infections. Real world data could help to elucidate its optimal use, but is very limited as of yet.
Methods: We addressed all Hungarian centers treating myeloma to evaluate the efficacy and safety of venetoclax in their practice treating t(11;14) myeloma, collecting data about the treatment duration, AEs, dose modifications and treatment discontinuations, and analyzed response rates as well as progression free and overall survivals (PFS, OS).
Results: 50 patients were reported from 7 Hungarian sites. 33 patients were relapsed and heavily pretreated with an average of 4.8 prior lines, whereas 17 patients received venetoclax after a suboptimal initial response to their first line treatment (8 PR, 7 SD, 2 PD) as planned

pre-transplantation salvage. Most patients had venetoclax in combination with a proteasome inhibitor and dexamethasone. The response rate was remarkably high given the refractoriness of this cohort: all but two patients responded, with 28% CRs, 38% VGPRs and 30% PRs. The median PFS and OS calculated from initiation of venetoclax dosing were 15.5 and 24 months, respectively, Figure 1. shows the PFS and OS curves of the 2nd line and late line cohorts. The most common AEs were cytopenias, gastrointestinal toxicities and infections, reported in 8, 9 and 10 patients with 1 fatal infection. Two patients had COVID-19 related hospitalization, both recovered.

An important point to emphasize is the very high risk nature of this cohort. 13 out of the 47 patients had deletion 17p before venetoclax dosing was initiated, explaining their refractoriness to standard treatments. Notably, of these patients 2 reached CR, 9 VGPR, 1 PR, and only one progressed while on venetoclax treatment. The median PFS and OS were 9.6 and 10 months, respectively. Five patients had plasma cell leukaemia and 1 CNS involvement, the PFS and OS of these ultra-high risk patients were 10 and 12 months.

Another important aspect of our analysis was the question of venetoclax dosing, as the appropriate dose in this indication is not yet clear. Reflecting this uncertainty, as well as funding difficulties with this off-label drug, only 2 patients received the 800 mg dose as seen in the Bellini trial; one received 600 mg daily, with all others taking 400 mg or less. To counteract this many centers employed a combination with either clarithromycin or fluconazole, CYP3A inhibitors known to increase venetoclax serum levels two- to threefold. Where available, serum venetoclax levels were monitored to ensure serum levels comparable to regular dosing.

Figure 1. Overall and progression free survival of 11;14 translocated multiple myeloma patients treated with venetoclax based therapy

Summary/Conclusion: Our results highlight the importance of targeted treatments in multiple myeloma. We experienced lasting responses in quadruple-refractory patients, many with other high risk features. In the newly diagnosed group, where the depth of pre-ASCT response has great impact on PFS, venetoclax may have a role converting suboptimal responses into CRs by eliminating residual disease.

PB1642 FIRST CASE OF SYSTEMIC LIGHT CHAIN (AL) AMYLOIDOSIS TREATED WITH ANTI-B CELL MATURATION ANTIGEN -CAR T CELLS

Background: Chimeric antigen receptor T cell (CART) therapy is a groundbreaking approach in the treatment of relapsed/refractory hematological malignancies. Given that multiple myeloma (MM) remains an incurable disease to current standard of care therapies, several investigational CAR-T constructs are in development in clinical trials. However, some MM patients may evolve to light-chain (AL) amyloidosis which is currently an exclusion criterion for these trials.

Aims: We present the first case reported of a patient with systemic AL amyloidosis, evolved from a MM, and successfully treated with CART therapy.

Methods: Our institution has developed an academic second generation humanized 41BB-based CART targeting B cell maturation antigen (BCMA), called ARI-0002h, which is currently being tested on the CARTBCMA-HCP-01 clinical trial for patients with relapsed/refractory MM. The patient underwent treatment with ARI-0002h as a compassionate use after approval by the local Health Care Ethics Committee and the Spanish Drugs Agency. An informed consent form was obtained. Lymphodepletion was performed with fludarabine (90 mg/m^2) and cyclophosphamide (900 mg/m^2), followed by infusion of 3 x10^6 ARI-0002h cells/kg in a fractionated manner (3 doses). Patient medical records were collected for analysis.

Results: A 61-year-old woman was diagnosed with an IgA-lambda symptomatic MM in 2014. She received several lines of treatment including an autologous stem cell transplantation, proteasome inhibitors, immunomodulatory drugs and the CD38-targeted antibody daratumumab. Despite the previous therapies, the patient relapsed with a serum M-protein of 20.7 g/L, kappa/lambda serum-free light-chain of 2/231 mg/L and bone marrow infiltration by 23% plasma cells (normal FISH), without evidence of extramedullary disease by PET-CT or other CRAB signs. However, she developed edema and significant non-selective albuminuria (24-hour proteinuria of 2626 mg with urinary M-protein of 307 mg). Therefore, subcutaneous fat aspirate and renal biopsy were performed showing amyloid deposits of lambda type. Diagnosis of systemic AL amyloidosis with renal involvement (revised Mayo Stage II) was stablished. Cardiac involvement was ruled out. BCMA expression in bone marrow plasma cells before CART infusion was 23%. The patient received ARI-0002h after lymphodepletion, developing a grade I cytokine release syndrome, treatment-related grade 4 neutropenia and grade 2 thrombocytopenia, with no evidence of neurotoxicity. On day +28 the patient had achieved a hematological complete response (CR) with negative minimal residual disease (MRD) in the bone marrow by next generation flow cytometry. Six months later, the patient remained in MRD negative CR and had achieved a renal response, with a 78% decrease of proteinuria (Figure 1). Renal response at 3 months was not assessable due to a BK virus hemorrhagic cystitis. The highest peak of ARI-0002h expansion was detected at +21 days after infusion and was detectable until day +107 by either flow cytometry and quantitative RT-PCR techniques (Figure 1).

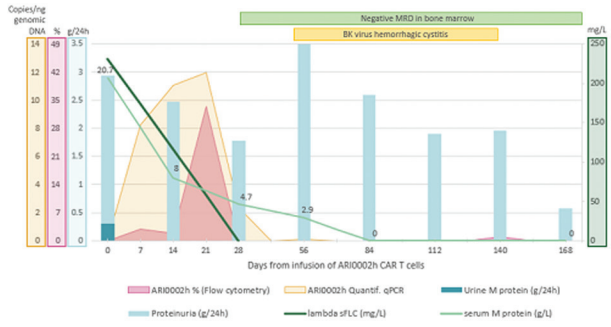

Figure 1. Evolution of clinical and laboratory findings after infusion of ARI-0002h. In the first six months after infusion of ARI-0002h a progressive decline in serum M-protein and lambda serum free light chain (sFLC) was observed. MRD was negative on day +28 and remains negative at 6 months. A renal response with a 78% decrease in proteinuria was observed at six months with an intermediate period in which, due to hemorrhagic cystitis, proteinuria is not assessable. Expansion of CART cells by either flow cytometry and qRT-PCR are also represented, with a peak at day +21.

Summary/Conclusion: We report the first case to our knowledge of a patient diagnosed with light-chain amyloidosis successfully treated with BCMA-CART therapy. Despite the fact that only a low proportion of clonal plasma cells expressed BCMA, the patient achieved a hematologic CR on day 28 and a renal response at 6 months after CART infusion. Considering the importance of obtaining fast and deep hematologic responses in this disease, CART cells could be a promising therapeutic strategy in AL amyloidosis.

PB1643 OUTCOMES OF DARATUMUMAB-CONTAINING REGIMENS IN THE TREATMENT OF RELAPSED MULTIPLE MYELOMA: REAL-WORLD DATA FROM THE CANADIAN MYELOMA RESEARCH GROUP DATABASE

R. LeBlanc [1,*], H. Mian [2], D. Reece [3], E. Masih-Khan [4], E. Atenafu [5], V. H. Jimenez-Zepeda [6], A. McCurdy [7], K. Song [8], M. Sebag [9], M. Louzada [10], D. White [11], J. Stakiw [12], R. Kotb [13], A. Reiman [14], M. Aslam [15], E. Gul [5], C. P. Venner [16]

Background: Multiple myeloma (MM) remains an incurable disease with significant morbidity and mortality. Daratumumab (Dara)-containing regimens, both in monotherapy and in combinations with other agents, have significantly altered the therapeutic landscape of MM especially in the relapsed setting.
Aims: The aim of this study was to evaluate the outcomes of Dara-containing regimens in the Canadian real-world setting among MM patients, many of whom may have been ineligible for the landmark trials.
Methods: We performed a retrospective study using the Canadian Myeloma Research Group Database (CMRG-DB), containing real-world data on myeloma outcomes in Canadian academic centers. We identified 798 patients previously exposed to Dara up to 31/08/2020, of which 710 were treated in the relapsed setting. This includes patients for whom Dara was added within 6 months from initiation of a treatment and considered the same line of therapy. Objectives were to evaluate progression-free survival (PFS) and overall survival (OS) using 6 different Dara-based regimens (in monotherapy, with cyclophosphamide, with bortezomib, with lenalidomide, with pomalidomide ± cyclophosphamide), considering median prior lines of therapy.
Results: Of the 710 MM patients receiving Dara-based therapy in ^{3} 2nd-line treatment, 58.5% were male, 18% had high-risk [del17p, t(4;14) and/or t(14;16)] cytogenetic disease and 34% were ISS 3. Overall, the median number of prior lines of therapy was 3 (range 2-11). After a median follow-up of 13 months, the median PFS and median OS for the entire cohort were 13 months (95% CI 11-15) and 38 months (95% CI 31-72), with 23 months and not reached (NR) in 2nd-line, 14 and 38 months in 3rd-line, and 8 and 20 months in 4th-line treatment, respectively. Additional demographic and outcome data stratified by different Dara-containing regimens are shown in Table 1. Dara in monotherapy ± corticosteroids after a median of 5 prior lines of therapy resulted in a median PFS of 3.7 months and median OS of 20.6 months, similar to the SIRIUS trial (Lonial et al. Lancet 2016). The inclusion of cyclophosphamide with Dara after a median of 3 prior lines of therapy resulted in a median PFS of 15.8 months (median OS NR). DVd, after a median of 3 prior lines of therapy, resulted in a median PFS of 7.8 months and median OS of 27.8 months -- significantly less than the results in the latest CASTOR trial update (Mateos et al. Clin Lymphoma Myeloma Leuk 2020) although their patients were less pre-treated. DRd, after a median of 2 prior lines of therapy, resulted in a median PFS of 26.6 months and median OS of 32.9 months which is significantly inferior to results of the last update of the POLLUX trial (Bahlis et al. Leukemia 2020) although their patients were also less pre-treated. DPd, used after a median of 3 prior lines of therapy, resulted in a median PFS of 9.7 months and median OS of 31.3 months similar to what is expected from the EQUULEUS (Chari et al. Blood 2017) and APOLLO trials (Dimopoulos et al. ASH 2020) after a median of 4 and 2 prior lines of therapy, respectively. The addition of cyclophosphamide to Dara and pomalidomide significantly increased the median PFS (22.7 months) and OS (median NR).

Table 1. Patient information grouped by daratumumab-based regimens

	Dara ± steroids	DCd	DVd	DRd	DPd	DPCd
N	100	49	143	263	77	45
Age in years; median (range)	66 (36-85)	64 (47-87)	69 (43-88)	70 (39-88)	63 (40-85)	65 (44-82)
Male n (%)	57 (57)	23 (47)	89 (62)	150 (57)	48 (62)	26 (58)

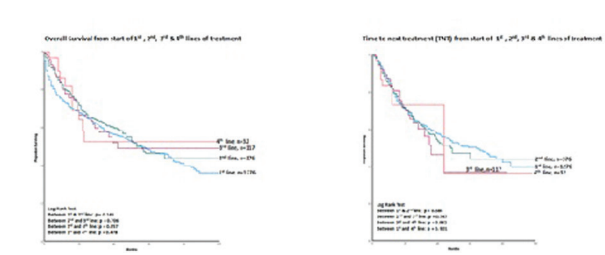
TTNT in days; median (range)	204 (27-802)	336 (22-902)	155 (59-671)	239 (29-930)	319 (56-1028)	462 (62-868)
ORR n (%)	38 (45.24)	33 (71.74)	69 (57.98)	198 (84.98)	47 (66.20)	40 (88.89)
≥VGPR n (%)	18 (21.43)	20 (43.48)	34 (28.57)	137 (58.80)	27 (38.03)	32 (71.11)
Prior PI (%)	100	98	87	97	94	100
Prior IMID (%)	96	73	66	37	71	69
Prior ASCT (%)	71	84	68	56	78	80
Median follow-up (months)	13.7 (0.1-71.5)	20.7 (1.6-44.2)	8.9 (0.5-27.8)	11.8 (0.1-73.5)	19.3 (0.5-47.8)	23.9 (1.4-32.9)
Median PFS months (95% CI)	3.7 (2.9-4.6)	15.8 (9.7-23.4)	7.8 (5.9-9.5)	26.6 (20.7-62.8)	9.7 (7.6-13.8)	22.7 (12.9-NR)
Median OS months (95% CI)	20.6 (15.1-37.9)	NR	27.8 (17.2-27.8)	32.9 (27.1-NR)	31.3 (18.2-NR)	NR

Abbreviation: ASCT: autologous stem cell transplantation; Dara: daratumumab; DCd: daratumumab-cyclophosphamide-dexamethasone; DoT: duration of therapy; DPd: daratumumab-pomalidomide-dexamethasone; DPCd: daratumumab-pomalidomide-cyclophosphamide-dexamethasone; DRd: daratumumab-lenalidomide-dexamethasone; DVd: daratumumab-bortezomib-dexamethasone; HR: high-risk; IMiD: immunomodulator; ISS: international staging system; NR: not reached; ORR: overall response rate; OS: overall survival; PFS: progression-free survival; PI: proteasome inhibitor; TTNT: time to next treatment; Tx: treatment; VGPR: very good partial response



Summary/Conclusion: Our results demonstrate that Dara-based therapy is effective in relapsed MM patients even in real-world practice. Our observations suggest that the addition of oral cyclophosphamide to Dara-based therapy results in more favourable outcomes and deserves further evaluation.

PB1644 THE NATURAL HISTORY OF SYSTEMIC AL AMYLOIDOSIS FOLLOWING UPFRONT TREATMENT WITH BORTEZOMIB: AN ANALYSIS OF REAL-WORLD LONGITUDINAL DATA

S. Ravichandran [1,*], O. Cohen [1], S. Law [1], D. Foard [1], M. Fontana [1], A. Martinez-Nahharo [1], C. Whelan [1], J. Gillmore [1], H. Lachmann [1], S. Sachchithanantham [1], S. Mahmood [1], P. Hawkins [1], A. Wechalekar [1]

[1]National Amyloidosis Centre, University College London, London, United Kingdom

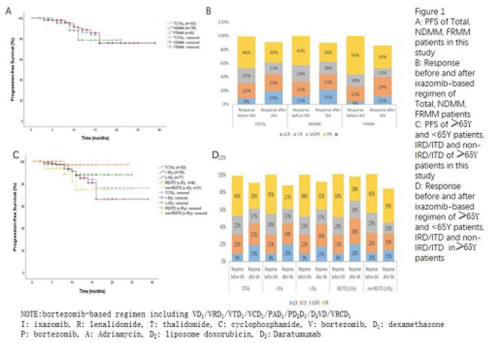
Background: AL amyloidosis is an incurable disorder. The real natural history of this condition is incompletely understood.
Aims: In this study, we describe the natural history of the disease based on analysis of real-world longitudinal data.
Methods: All patients seen at the National amyloidosis Centre, the UK between Feb 2010 and Aug 2019 and treated with upfront Bortezomib are included in this analysis.
Results: 1276 patients received 1st line treatment. 26% of patients had died within 12 months of 1st line treatment. 376 (29.5%), 117 (9.2%), 32 (2.5%), 8 (0.6%) and 2 (0.2%) patients had received 2nd, 3rd, 4th, 5th and six lines of treatment, respectively. 77.2% of patients who required more than one line of treatment received the 2nd line within the first two years of 1st line treatment. There was no significant difference in survival from 1st, 2nd, 3^{rd,} and 4th lines of treatment (p=.478). The OS from 1st, 2nd, 3^{rd,} and 4th lines treatment was 56 month, 53 months, 42 months and not reached, respectively (Figure 1). There was no significant difference in TNT from 1st, 2nd, 3rd, and 4th lines of treatment (p=.901). The TNT from 1st, 2nd, 3^{rd,} and 4th lines of treatment was 64 months, 48 months, 36 months, and 44 months, respectively (Figure 1).

Summary/Conclusion: AL Amyloidosis is an incurable disease, and most patients require further treatment. However, even multiply relapsed AL patients have a good outcome and prolonged remission periods. Prospective trials are needed to refine treatments in the patients with relapsed AL amyloidosis.

PB1645 A CLINICAL-DECISION TOOL TO IMPROVE THE STRATEGY OF MULTIPLE MYELOMA TREATMENT

A. Luchinin [1,*], O. Kolupaev [2]

[1]Kirov Scientific Research Institute of Hematology and Blood Transfusion of the Medical-Biological Agency, Kirov, Russian Federation, [2]UNC Chapel Hill, Lineberger Comprehensive Cancer Center, Chapel Hill, United States



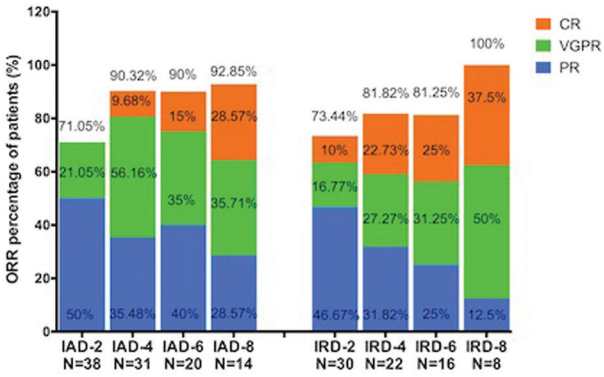
Background: Multiple myeloma (MM) is one of the most common hematologic malignancies with more than 30,000 cases diagnosed in the US alone. This incurable disease is characterized by a high heterogeneity and complex pathophysiology. A tremendous progress in our ability to treat this disease has been made in the last two decades by introduction of new therapeutic modalities. Today, there are dozens of interventions that include radiation therapy, cell therapy and drug combinations available. Unfortunately, direct head-to-head comparisons between treatment regiments in MM are often available due to the high cost and time-consuming nature of additional clinical trials.
Aims: Here we describe a method for prediction of several (clinical) parameters of responses to MM therapy that uses statistical and machine learning approaches.
Methods: Clinical data including names of treatment options, response rates, progressive-free survival (PFS) and other parameters were extracted from scientific publications that described results of clinical trials and real-world practice in the management of patients with MM. We used a very good partial response (VGPR) and PFS as outcomes for the prediction. The prognosis of VGPR was calculated as follows: 1) we calculated inverse percentages for each clinical study and treatment method, 2) added all inverse percentages for a given treatment method to get an average rate, 3) VGPR rates between the two treatment options were compared by using Odds Ratio (OR). The prediction of PFS is based on a machine-learning algorithm - random forests for survival which uses VGPR, line of therapy and stem cell transplantation as predictors. All statistical analyses were done using R version 3.6.0. and the "shiny", "epiR", "survminer", "survival", "ranger", "ggplot2" packages.
Results: More than 300 publications were identified by a systematic literature review and 100 treatment options with a total of 40334 patients with MM were selected. The data from this corpus of publications were analyzed using open-source R software, and visualized via an interactive web app. The functions of the app include: 1) calculation VGPR or better for selected treatment options, 2) therapy response comparison with calculation of statistical significance (OR, p-value), 3) PFS prediction with interactive graphs of survival curves (Hazard ratio, p-value). The Harrell's c-index for the model of PFS prediction is 0.81. The app is available at https://luchinin.shinyapps.io/MM_Therapy_Analyzer/. All treatment options are divided into two categories: "newly diagnosed MM" and "relapsed and refractory MM". Current version of the web app provides an additional reference point for making a decision about the treatment strategy in patients with MM. The tool also helps to estimate efficacy of the therapy in relation to another for categories of clinical cases.
Summary/Conclusion: We developed an interactive digital tool and web app to aid selection of strategy for multiple myeloma treatment. We used machine learning and general statistics to calculate and predict key outcomes of therapy in patients with MM based on a systematic review of 300+ clinical publications. To the best of our knowledge, this is the first publication describing this approach combined with a user-friendly publicly available tool. Future work will extend this approach and explore the potential for integration into hematology clinical decision-support systems.

PB1646 IN-CLASS TRANSITION FROM INTRAVENOUS TO ORAL PROTEASOME INHIBITOR AS LONG PROTEASOME INHIBITION IN NEWLY DIAGNOSED AND FIRST RELAPSED MULTIPLE MYELOMA PATIENTS IN CHINA: A REAL-WORLD STUDY

A. Liu [1], R. Fu [2], Z. Zhu [3], J. Zhuang [4], Z. Li [5], Y. Ma [6], L. Bao [7], W. Chen [1,*]

[1]Hematology, Beijing Chaoyang Hospital afflicated to Capital Medical University, Beijing, [2]Hematology, Tianjin Medical University General hospital, Tianjin, [3]Hematology, Henan Provincial people's hospital, Zhengzhou, [4]Hematology, Peking Union Medical Hospital, [5]Hematology, China-Japan Friendship Hospital, Beijing, [6]Hematology, Second hospital of Shanxi Medical University, Taiyuan, [7]Hematology, Beijing Jishuitan Hospital, Beijing, China

Background: Bortezomib, as an intravenous proteasome inhibitor (PI) is important in the treatment of multiple myeloma (MM), but it always discontinued by adverse event (AE).
Aims: Assessing in-class transition (iCT) from intravenous bortezomib-based induction to all-oral ixazomib-based regimen is a good method for improving PI-based continuous therapy with efficiency, safety and convenience.
Methods: In this real-world retrospective study from Chinese seven hospitals during Oct, 2017-Jan, 2021, we analysed newly diagnosed multiple myeloma (NDMM) and first relapsed multiple myeloma (FRMM) patients without transplantation, who achieved at least partial response of bortezomib-based introduction and then received ixazomib-based regimen for 2 years or until progression/intolerant toxicity. Primary endpoint: progression-free survival (PFS). Key second endpoints included response rate, therapy duration and AE.
Results: 183 patients were enrolled in this study (NDMM 76%, FRMM 24%, median age 63 years; 42% ≥ 65 years; 10% ≥ 75 years; 51% male; IgG/IgA/IgD/light chain /non-secretory/others 50%/22%/2%/22%/1%/3%; ISS stage I/II/III 16%/37%/47%; R-ISS stage was estimated in 107 patients, stage I/II/III 9%/54%/37%). 48% high risk (HR,59/123) and 52% standard risk (SR,64/123) were tested by metaphase fluorescence in situ hybridization (M-FISH) according to Mayo clinic risk stratification.
183 patients received median 4 cycles (1-14) of bortezomib-based regimen, and median 4 cycles (1-20) of iCT regimen including I/ ID1/IRD1/ITD1/ ICD1. Median duration of total PI therapy was 10 months and of iCT regimen was 4 months. With 13 months median follow-up, 18 month PFS rate was 80% (95% confidence interval,67-93) from the start of bortezomib-based induction and 78% (95% confidence interval,70-94) from the start of iCT (Figure 1A), 66% patients remain on therapy at data cutoff. There's no significance in PFS between NDMM and FRMM, between HR and SR MM patients (P=0.419, P=0.105, Figure 1A, Figure 1C). Before iCT, ORR rate was 100% (sCR 9%; CR 22%; VGPR 22%; PR 47%) and 90% (sCR 19%; CR 25%; VGPR 19%; PR 27%) after iCT. There were 50 PR improved to more than VGPR (Figure 1B). ORR of HR and SR patients were 100% and 83%, 100% and 94%, before and after iCT, respectively (Figure 1D).
Among 113 patients who transited to IRD1/ITD1 regimen, medium duration of total PI therapy was 9 months and of iCT regimen was 3 months, 77% of patients remain on therapy (Figure 1C). ORR rate was 100% and 92% before and after iCT, respectively (Figure 1D). ORR of HR (23/52), of SR patients (29/52) patients were 100% and 96%, 100% and 86% before and after iCT, respectively. For those non-transplantation-eligible (NTE, ≥65 years old) patients, medium duration of total PI therapy was 9 months and of iCT regimen was 4 months (Figure 1E). PFS and ORR rate of IRD1/ITD1 group are better than non-IRD1/ITD1 group (P=0.023, Figure 1E; ORR rate still 98% after iCT, Figure 1F).
The ixazomib-safety profile was consistent with previous clinical trial data. 54% of patients had any grade AEs. In which, the most frequent grade <=2 AEs were peripheral neuropathy (PN) (37%, 50 patients began before iCT), nausea and vomiting (16%), diarrhea (13%). Grade 3/4 AEs were agranulocytosis (1%), rash (1%), pneumonia (1%), PN (1%). The most often treatment discontinued AEs is PN.



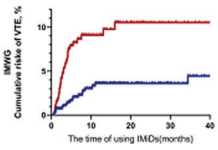
Summary/Conclusion: In real-world China MM population, NDMM and FRMM patients are sensitive to PI-based continuous therapy with satisfied response rate; iCT can permit prolonged PI-based therapy with promising efficacy and tolerated adverse events.

PB1647 EFFICACY AND SAFETY OF INDUCTION THERAPY WITH IAD VERSUS IRD REGIMEN IN FRAGILE ELDERLY PATIENTS WITH NEWLY DIAGNOSED MULTIPLE MYELOMA-RESULTS OF PROSPECTIVE MULTICENTER CLINICAL TRAIL

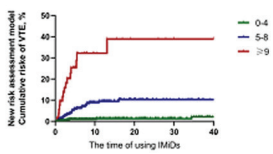
M.-Q. Lu [1], P. Liu [2], J.-L. Zhuang [3], M. Zhang [4], Z.-J. Xia [5], Z.-L. Li [6], H.-M. Jing [7], Y. Wu [8], H.-B. Zhou [9], Y.-P. Gong [10], R. Fu [11], W.-R. Huang [12], B. Chu [1], Y.-T. Wang [1], Y.-Q. Zhang [13], L. Bao [1,*]

[1]hematology, Beijing Jishuitan Hospital,the Fourth Medical College of Peking University, Beijing, [2]hematology, Zhongshan Hospital,Fudan University, Shanghai, [3]hematology, Peking Union Medical College Hospital, Chinese Academy of Medical Sciences, Beijing, [4]hematology, The First Affiliated Hospital of Xi'an Jiaotong University, Xian, [5]Hematologic Oncology, Sun Yat-sen University Cancer Center, Guangzhou, [6]Hematology, China-Japan Friendship Hospital, [7]Hematology, Third Hospital of Peking University, [8]Hematology, Beijing Chao Yang Hospital, Capital Medical University, [9]Hematology, Beijing Luhe Hospital,Capital Medical University, Beijing, [10]Hematology, West China Hospital, Sichuan University, Chengdu, [11]Hematology, Tianjin Medical University General Hospital, Tianjin, [12]Hematology, the First Medical Center of Chinese People's Liberation Army General Hospital, [13]Hematology, The Eighth Medical Center of Chinese PLA General Hospital, Beijing, China

Background: Fragile elderly patients with multiple myeloma(MM) have poor efficacy and low survival rate due to many factors including complications, poor tolerance and compliance, high rate of treatment discontinuation.
Aims: This is a prospective multicenter non-randomized controlled study, design to compare efficacy and safety of ixazomib in combination with lenalidomide and dexamethasone versus ixazomib in combination with liposome doxorubicin and dexamethasone. (ClinicalTrials.gov number, chiCTR1900024917)
Methods: This multicenter trial was conducted in 13 hospitals. Inclusion criteria was patient age≥65 and IMWG geriatric scoring system (GA)≥2 points or Mayo geriatric vulnerability scoring system defined as vulnerable. No exclusion criteria. Scheme include: IAd regimen (Ixa 4mg d1,8,15, liposome doxorubicin 40mg d1, dexamethasone 20mg d1,8,15,22); IRd regimen (Ixa 4mg d1,8,15, lenalidomide 25mg d1-14, dexamethasone 20mg d1,8,15,22) 4 weeks a cycle. The assessment of response conducted post four 28-day cycles. The consolidation therapy of previous regimen recommended 2 cycles for ≥VGPR and 4 cycles for PR &MR. Id (Ixa 4mg d1,8,15, dexamethasone 20mg d1,8,15,22) regimen maintenance initiated until progression. Primary endpoint is overall response rate (ORR). The secondary endpoints are progression free survival (PFS), overall survival (OS), tolerability, toxicity, health-related Qol. This study is designed for 3 years, 120 patients in-total, 60 each group.
Results: From Oct 2019 to Jan 2021, 79 cases were enrolled without intervention, 29.1%(23/79) of them were aged≥75. 15.2%(12/79) cases with renal insufficiency, including 9 severe renal failure (eGFR<30mL/min), 2 dialysis. 7 cases were complicated with paraplegia. Efficacy could be evaluated in 68 cases, 11 cases could not be evaluated, of them, 4 had not completed a cycle chemotherapy, 5 had given up, and 2 died in the 1st treatment course. Most if not all cases with renal failure, bedridden and thrombosis enter the IAd group. The total ORR was 82.35%, with 84.21% (32/38) in the IAd and 80.0% (24/30) in the IRd group, $p>0.05$. 53 cases (77.9%) completed 4 cycles (IAd group of 31, the IRd group 22); 22 cases (32.4%) completed 8 cycles (IAd group of 14, the IRd group 8).16 cases (23.5%) are in maintenance treatment (10 of IAd group, the IRd 6). The median follow-up period was 8 months (1-16m), the median PFS and OS were not achieved either, with OS of 85.7% at 12th months. According to IMWG risk stratification, OS in high-risk group was significantly shorter than that in standard risk group,14.0m vs not reached, respectively ($p=0.022$).
To date, 15 death occurred, including 4 early deaths within 60 days, 7 by disease progression, 3 individually gave up and 1 unexplained sudden death. During induction chemotherapy,11.8% (8/68) of cases experience hematology above grade 3, 11(16.2%) cases with pneumonia (8 of IAd and 3 of IRd), 13(19.1%) cases developed gastrointestinal AE above grade 3 (10 cases in the IAd group and 3 cases in the IRd group), among which 4 cases developed AE above grade 4.



Summary/Conclusion: The results showed in the interim observation, both three-drug combination regimen of ixazomib was effective, with overall response rate of 82.35% and 12-month OS of 85.7%. The adverse reactions were tolerable. As AE rate and the interim mortality rate are comparably high in fragile elderly MM patients, it is still a challenge for treatment. Drugs and regimens with low toxicity and high efficacy are needed to continuously explore.



PB1648 RISK ASSESSMENT MODEL FOR IMMUNOMODULATORY DRUG-ASSOCIATED VENOUS THROMBOSIS AMONG PATIENTS WITH MULTIPLE MYELOMA IN CHINA

X. Li [1], X. Sun [2], B. Fang [3], Y. Leng [4], F. Sun [2], Y. Wang [3], Q. Wang [5], J. Jin [6], M. Yang [6], B. Xu [7], Z. Fang [7], L. Chen [8], Z. Chen [8], Q. Yang [9], K. Zhang [10], Y. Ye [10], H. Geng [11], Z. Sun [12], D. Hao [12], H. Huang [13], X. Wang [14], H. Jing [15], L. Ma [15], X. Pan [16], W. Chen [4], J. Li [1,*]

Background: Venous thromboembolism (VTE) is a significant complication for patients with multiple myeloma (MM) receiving immunomodulatory drugs (IMiDs). The International Myeloma Working Group (IMWG) developed guidelines recommending primary thromboprophylaxis in those identified to be at high risk of VTE according to the presence of risk factors. However, these guidelines lack validation and do not take ethnic differences into account. There is no validated clinical model predicting VTE in this population in China.
Aims: This study aimed to assess the frequency of VTE and associated risk factors and derive a new risk assessment model for IMiD-associated VTE in Chinese MM patients.
Methods: Patients with MM receiving IMiDs were selected from 16 centres in China between 2010 and 2020. We assessed the incidence of VTE and the associated clinical parameters. The primary endpoint was the rate of symptomatic VTE. Secondary endpoints were associations between VTE and clinical factors, including age, sex, disease characteristics and duration, history of VTE, immobilization, comorbidities, treatment regimens, and laboratory parameters.
A multivariable cause-specific Cox regression model was used for model development.
Results: A total of 1137 myeloma patients were followed up for a median of 8.51 months (range 0.46-180.01 months), and 52 (4.6%) developed VTE, which was lower than the rate found in Western countries. In addition, 41 patients developed VTE within 6 months of treatment with IMiDs. The sites for VTE included the lungs (6%), lower extremities (71%), upper extremities (11%), and central venous catheter (12%). Thromboprophylaxis with aspirin or warfarin did not reduce the risk of VTE; the rates of VTE with or without aspirin or warfarin treatment were 5.2% and 4.1% (p=0.377), respectively. Multivariate analysis determined that an ECOG score≥2, history of VTE, D-dimer>2.42 mg/L, use of IMiDs during induction therapy, diabetes and the use of lenalidomide, dexamethasone, anthracyclines or erythropoietin were significant risk factors for VTE. We derived a new risk assessment model that included these 9 clinical variables. The model stratified approximately 32.1% of patients as high-risk. In contrast, the IMWG stratification method only classified 9.1% of patients as high-risk. A high-risk group for VTE among MM patients receiving IMiDs was identified, and a larger study is needed to confirm these findings.

Summary/Conclusion: The new risk assessment model score outperformed the current IMWG guidelines in the risk stratification of patients with MM receiving IMiD therapy in China. A high-risk group for VTE among MM patients receiving IMiDs was identified, and a larger study is needed to confirm these findings.

PB1649 REAL-LIFE DATA ON THE SAFETY AND EFFICACY OF CARFILZOMIB AND LENALIDOMIDE PLUS DEXAMETHASONE (KRD) IN 149 PATIENTS WITH RELAPSED/REFRACTORY MULTIPLE MYELOMA: A RETROSPECTIVE ANALYSIS OF GEMMAC GROUP.

A. Garcia-Guiñon [1,*], P. Charry [2], M. Jimenez [3], I. Delgado [1], L. Segura de la Torre [4], M. Garcia-Pintos [5], Y. Gonzalez [6], A. Senin [7], C. Motllo [8], E. Abella [9], M. Granell [10], M. J. Herranz [11], Y. Seres [1], M. Gironella [3], S. Joan Alfons [4], R. Ben Azaiz [9], C. Fernandez de Larrea [2]

[1]Hematology deparment, Hospital Universitari Arnau de Vilanova, Lleida, [2]Hematology deparment, Hospital Clínic and IDIBAPS, [3]Hematology deparment, Hospital Universitari Vall Hebron, Barcelona, [4]Hematology deparment, Hospital Universitari Parc Tauli, Sabadell, [5]Hematology deparment, Consorci Sanitari Terrassa, Terrassa, [6]Hematology deparment, Hospital Universiari Josep Trueta-ICO Girona, Girona, [7]Hematology deparment, Hospital Universitari Germans Trias I Pujol-ICO Can Ruti, Badalona, [8]Hematology deparment, Hospital Sant Joan de Deu-Althaia, Manresa, [9]Hematology deparment, Hospital del Mar, [10]Hematology deparment, Hospital de la Santa Creu i Sant Pau, Barcelona, [11]Hematology deparment, Hospital del Vendrell - Xarxa Santa Tecla, Tarragona, Spain

Background: Carfilzomib, a second-generation proteasome inhibitor, in combination with lenalidomide plus dexamethasone (KRD) is approved for the treatment of patients with relapsed/refractory multiple mm (RRMM) after 1-3 prior lines.
Aims: Our objective was aimed to analyse the efficacy and safety of KRD in a real-life cohort in eleven hospitals from Catalonia.
Methods: A real-life retrospective analysis of RRMM patients treated with KRD at hospitals in GEMMAC group from January 2016 until May 2020. KRd was administrated at standard schedule (carfilzomib 27mg/m2, d1,2,8,9,15,16; lenalidomide 25mg/d,d1-21 (adjusted by renal clearance); dexamethasone 20-40mg,d1,8,15, 22). Response rate was assessed using IMWG criteria. Progression free survival (PFS) and overall survival (OS) were calculated from the start of KRD treatment using Kaplan-Meier method. Cytogenetic high-risk (HR) included t(4;14), t(14;16) or del(17p) vs. Standard risk (SR).
Results: We included 149 patients with a median age of 66 years (range:40-88); 56% were male. Forty-four (29%), 57(38%) and 42(28%) patients were ISS1, ISS2 and ISS3, respectively. Ninety-seven (65%) patients had cytogenetic information by FISH at diagnosis, thirty-six (37%) of them had HR cytogenetic. Median prior lines of therapy were 1 (range: 1-4), 120(80%) patients had received only one prior line. All patients had previously received bortezomib and 61(41%) thalidomide. Seventeen (11%) patients had been exposed to lenalidomide previously. The overall response rate (ORR) was 75% (53% ≥VGPR, 38% ≥CR) with a median time to best response of 4 months. Median time on treatment was 6 (1-46) months. One hundred one (68%) patients discontinued treatment, mainly due to progression and toxicity: 49 (33%) and 17(11%) patients, respectively. Twenty-one (14%) patients received consolidation with autologous transplantation (ASCT) and 7 (5%) patients with allogeneic transplantation (AlloSCT). After a median of 18 months of follow-up, median PFS and OS were 26 (95% CI, 20-33) and 42 (95% CI, 34-50) months, respectively. Median PFS and OS at 1st, 2nd and subsequent relapse were 28 (95%CI, 22-34), 22 (95%CI, 1-46) and 1 (95%CI,1-4) months (p=0,004) and 50 (95%CI, 30-70), 37 (95%CI, 0-79) and 4 (95%CI, 0-8) (p=0,014) months, respectively. PFS was shorter in HR cytogenetic group patients but did not achieve statistically significance (HR: 12 [95%CI, 1-27] months vs SR: 25 [95%CI, 15-34] months, p=0.15). OS was either not significantly different in this group (OS: HR: not reached vs SR: 50 months, p=0,15). Median PFS and OS in a subgroup of patients who consolidated with ASCT or AlloSCT (28 [19%]) were longer [PFS: not reached vs 20 (95%CI,9-31) months, p=0.001; OS: not reached vs 42 (95%CI,29-55) months, p=0.007]. The most common adverse effects (incidence >10%) were hematological [anemia (41%), leukopenia (36%) and thrombocytopenia (34%)], infection (32%), asthenia (25%), gastrointestinal (19%) and cutaneous (10%). Fifteen (10%) patients discontinued carfilzomib due to toxicity, 6 (4%) of them by cardiovascular toxicity.
Summary/Conclusion: Our cohort shows that KRD is especially effective (ORR: 82%) in patients at first or second relapses after bortezomib- or thalidomide-based regimen. In patients who were candidates for transplantation (ASCT or AlloSCT) KRD was an effective salvage treatment. The most frequent toxicities were haematological and infectious complications. Cardiac toxicity, even not frequent, was the main cause of carfilzomib discontinuation. In conclusion, this data shows that KRD is an effective and safe regimen in patients with RRMM.

PB1650 HIGH LEVELS OF GALECTIN-3 AND IMMUNOGLOBULIN LIGHT CHAINS AS MARKERS OF THE RISK OF PROGRESSION OF MONOCLONAL GAMMOPATHY OF UNDETERMINED SIGNIFICANCE IN RESIDENTS OF GOMEL REGION OF BELARUS

Z. Kozich [1,*], V. Martinkov [2], J. Pugacheva [3], D. Blizin [4], L. Smirnova [5]

[1]Hematology, [2]Laboratory of Molecular Genetics, [3]Clinical and diagnostic laboratory, [4]The Republican Research Center for Radiation Medicine and Human Ecology, Gomel, [5]Belarusian Medical Academy Of Postgraduate Education, Minsk, Belarus

Background: Monoclonal gammopathy of undetermined significance (MGUS) is asymptomatic in most cases, but there is an increased risk of developing multiple myeloma (MM) or other lymphoproliferative disorders. There is very little information about the markers that lead to the development of MM.
Galectin-3 (Gal-3) is one of the members of lectin family expressed in the human body. It plays an important role in many biological processes, it is involved in the suppression of apoptosis and proliferation processes.
We presented the results of a study of Gal-3, immunoglobulins, and other blood indicators and their impact on the MM progression in MGUS patients of Gomel region, Belarus.
Aims: To study risk markers of MGUS progression in residents of Gomel region, Belarus.
Methods: The study included 22 MGUS patients who underwent examination in the period 2020-2021 in RRCRM&HE, Gomel (Belarus) The diagnosis was confirmed by the presence of abnormal immunoglobulin in the blood and/or urine and the tumor immunophenotype of the plasma cells of the bone marrow. All patients underwent assessment of renal function (study of creatinine clearance and estimated glomerular filtration rate). Determination of the level of Galectin-3 in blood serum was carried out by the CMIA method on ARCHITECT 12000SR analyzer. Results were assessed at the time of detecting MGUS and after 8 months of the study. The number of clonal plasma cells in the bone marrow averaged 2.4%. MGUS was more common in women (72.2%). The median age was 60 years.
Results: At the first stage, we examined immunoglobulins and renal function, and then the level of Gal-3 and B2-microglobulin.
Pathological protein in patients was represented by IgG (22.7%), IgA (22.7%), IgM (9%), two Ig (18.2%), and light chain secretion (27.4%).
An increase in the level of B2- microglobulin was detected in 16 patients (72.2%) (in 2 patients it was not associated with impaired renal function). Renal dysfunction was detected in 6 patients (27.4%), an increased Gal-3 level was found in 4 patients (18.2%).
The study revealed a significant excess of the Gal-3 level in patients with secretion of immunoglobulin light chains ($p = 0.0001$).
In our study, high levels of B2-microglobulin were revealed in patients with renal dysfunction and a high level of Gal-3. It is 1.52 times more frequent than in patients with normal Gal-3 levels ($p = 0.051$).
During the follow-up period, MM developed in two patients with secretion of light chains, high Gal-3 levels, renal dysfunction, and high levels of B2-microglobulin.
Summary/Conclusion: Despite a very short follow-up period and a small number of cases, our study identified patients with a high Gal-3 level, the presence of immunoglobulin light chains, a high level of B2-microglobulin, and kidney damage that progressed within a year. We supposed that these indicators as a whole at the initial stage of diagnosis can be considered as unfavorable prognostic markers with a high risk of developing MM in MGUS patients.

PB1651 ANALYSIS OF DELAY IN THE DIAGNOSIS OF MULTIPLE MYELOMA IN A SANITARY REGION OF SOUTHERN SPAIN.

F. J. Cabrera Ruiz [1], L. Sanz Rekalde [1,*], M. Conde Ausin [1], G. Moreno Carrasco [1], M. Rodríguez González [1], R. E. Orozco Colon [1], R. García Sánchez [1], R. García Delgado [1]

[1]*Hematology, Hospital Universitario Virgen de la Victoria, Málaga, Spain*

Background: Multiple myeloma (MM) is a bone marrow neoplasm that accounts for 1% of all cancers. Besides, it also constitutes a 10% of haematological malignancies. Nowadays, MM continues to be an incurable disease that affects the elderly. It is not a well-known disease by general practitioners and its symptoms are also common in many other conditions which make it difficult to suspect MM as the underlying cause. Longer time to diagnosis is associated with more complications and irretrievable consequences.
Aims: Assessing the delay in the diagnosis of MM, number of visits in different health units, reasons for consultation and possible consequences.
Methods: We have carried out a retrospective study and we have analysed all new diagnoses of MM patients between 1st January 2017 and 31th December 2020 in our centre. Patients with monoclonal gammopathy of undetermined significance (MGUS), previous or another centre diagnosis were excluded. We define "delay in diagnosis" as the time that elapses from the first consultation of the patient for any symptom or sign related to the disease until the final diagnosis of MM by bone marrow aspiration.
Results: In total, 61 patients were diagnosed as de novo MM, between 2017 and 2020. Median age was 68 years (range 30-85 years). 41% (25 patients) were females and 59% (36) were males. IgG was the most frequent type of MM (47.5%) and more than a half of patients were stage two by MM international staging system (ISS). Characteristics of patients are in table 1A and the results of sample in table 1B.
The average delay in diagnosis was 81 days (range 2-321 days) and in 27 patients (44.3%) the retardation between the first claim for a MM symptom and diagnosis was equal or less than 60 days. However, 11 patients (18%) were diagnosed within more than two months and equal or less than four months and the delay was more than 120 days in 23 patients (37.7%). Besides, almost 20% of patients waited for more than 6 months to be diagnosed.
The first consultation for any sign or symptom was in primary care centres (49.2%), emergency services (37.7%) or another specialist hospital consultation (17%) and low back pain was the reason in almost half of the patients (45.9%).
Two visits (range 0-12) were the median in care centres but 40.9% of patients needed more than two and 9 people (14.7%) went more than five times. Also, the median was two visits (range 0-7) in emergencies, although 42.5% of patients were three times or more. In consultation with another specialist (nephrology, traumatology, internal medicine…) median of visits was one (range 0-4).
Twenty-five patients (41%) were admitted without diagnosis to the hospital by internal medicine. At diagnosis, anemia was presented in 67.2% of patients, kidney failure in 42.6%, hyperkalaemia in 13.1%, bone fractures in 37.7% and 6.6% of patients had spinal cord compression.

Table 1A: Characteristics of patients

Sex	41% (25) Females /59% (36) Males
Age	Median: 68 years (range 30-85 years).
Multiple Myeloma type	IgG: 47.6% (29) Light chains: 24.6% (15) IgA: 26.2%(16) IgD: 1.6% (1)
Serum monoclonal protein	Mean: 2.85 g/dl (range 0 – 7.06 g/dl)
Urinary monoclonal protein	Mean: 1147 mg per 24h (range 0 – 12850 mg per 24h).
Serum free light chain ratio	Mean: 242.14 [0.01 – 1869.05].
Bone marrow plasma cells	Mean: 30.9% [range 10 - 95%]
ISS	I: 8.2% (5) II: 52.5% (32) III: 24% (39.9%)

Table 1B: Results

Diagnostic delay Median: 81 days (range 2 – 321 days).	≤ 60 days (2 months): 44.3% (27) ≤ 120 days (4 months): 18% (11) ≤ 180 days (6 months): 18% (11) ≤ 240 days (8 months): 11.5% (7) ≤ 300 days (10 months): 6.6% (4) > 300 days: 1.6% (1)
First consultation for any reason caused by multiple myeloma	
Where?: Primary care center: 49.2% (30) Emergency department: 37.7% (23) Medical specialist consultation: 13.1% (8)	**Why?:** Low back pain: 45.9% (28) Other bone pain:11.5% (7) Renal failure: 9.8% (6%) Anemia: 14.8% (9) Lesions on imaging test: 3.3% (2) Other sign/symptom: 14.8% (9)
Number of consults:	Primary health care center. Median: 2 (range 0-12) Emergency unit. Median: 2 (range 0-7) Medical specialist consultation. Median: 1 (range 0-4)
Hospitalization without diagnosis	Yes: 41% (25) / No: 31.1% (19)
Signs at diagnosis	Anemia: 67.2% (41) Renal failure: 42.6% (26) Hypercalcemia: 13.1% (8) Bone fractures: 37.7% (23) Spinal cord compression: 6.6% (4)

Summary/Conclusion: We believe that there is a significant delay in the diagnosis of patients with MM. There are probably many reasons for this, but we think that one of the most important is the lack of knowledge about this pathology outside the haematology units. Based on these data, we are going to implement a protocol for the early diagnosis of myeloma, in collaboration with the emergency department, other hospital specialties and the primary care centres in our health area. The protocol is already written and it is approved by the hospital's medical management. With the implementation of the protocol, our objective is to reduce the delay in the diagnosis of these type of patients.

PB1652 REAL-WORLD EVIDENCE OF CARFILZOMIB USE AMONG MULTIPLE MYELOMA PATIENTS WITH AT LEAST ONE PRIOR THERAPY ACROSS 4 COUNTRIES IN CENTRAL EASTERN EUROPE AND ISRAEL

Y. Cohen [1,2,*], I. Spicka [3], V. Maisnar [4], K. Simeonova [5], K. Björklöf [6], A. Iordan [7], V. Ianakieva [8], S. N. Badelita [9]

[1]*Tel Aviv Sourasky Medical Center (TASMC),*, [2]*Sackler Faculty of Medicine, Tel Aviv University, Tel Aviv, Israel,* [3]*First Department of Medicine – Department of Hematology, First Faculty of Medicine, Charles University and General Hospital, Prague,* [4]*Fourth Department of Medicine-Hematology, Charles University Hospital and Faculty of Medicine, Hradec Kralove, Czech Republic,* [5]*National Specialised Hospital for Active Treatment of Hematological Diseases, Sofia, Bulgaria,* [6]*Amgen (Europe North East), Rotkreuz, Switzerland,* [7]*Amgen, Bucharest, Romania,* [8]*Amgen, Sofia, Bulgaria,* [9]*Hematology and Bone Marrow Transplant Department, Fundeni Clinical Institute, Bucharest, Romania*

Background: Carfilzomib (K) was approved in combination with dexamethasone (d), i.e. Kd, or with lenalidomide (R) and d, i.e. KRd, in Europe during a large, prospective, observational study (NCT03091127) that included 701 patients (pts) with relapsed or refractory multiple myeloma (RRMM) across 10 European countries and Israel.
However, in participating Central Eastern European (CEE) countries and Israel, usage of K-based regimens was restricted in routine practice: in Bulgaria and Romania, Kd was reimbursed for use in second line of therapy (LoT) and KRd access was limited by R availability for private purchase; in Czech Republic (CZ), only KRd was reimbursed. In Israel, KRd was reimbursed in second LoT, and Kd in third LoT.
Aims: To understand effectiveness, safety and usage of K-based regimens according to routine practice in selected CEE countries and Israel during study NCT03091127.
Methods: Adults with ≥1 prior LoT (pLoT) and ≥1 K dose received in routine care were eligible. Data were collected and analysed as previously described (Terpos et al., *Blood* 2020. 136 [Suppl_1]: 38-39).
Results: Of the 144 pts enrolled in CEE and Israel, 63% received Kd and 32% KRd. The remaining 5% received other K-based triplets (Kd+cyclophosphamide, Kd+thalidomide) not further described here. Pts characteristics and results are summarized in Table. Across countries, Kd was mainly used, except for CZ (KRd only). Median pts age was comparable in Kd and KRd cohorts (64 vs 63 years).
Kd pts had received a median of 2 pLoTs, 36% had a prior autologous stem cell transplantation (ASCT). Nearly all Kd pts were exposed to bortezomib (V) in a pLoT and over half (53%) of them were V-refractory. Over one-fifth (23%) were exposed to R and 81% of these were R-refractory.
KRd pts had received a median of 1 pLoT and 72% had a prior ASCT. All KRd pts had a prior V-exposure with one-third being V-refractory. Prior R-exposure was reported in 22% of pts, of whom 40% were R-refractory. In this population, overall response rates (ORRs) were high regardless of K-based regimen (Kd: 80%; KRd: 87%).
The mean K dose intensity received relative to EU label for Kd (20/56 mg/m^2 twice weekly [Q2W] for K) and KRd (20/27 mg/m^{2}Q2W for K) was 81% and 83%, respectively. The Kaplan-Meier median estimate of treatment duration was 9.7 months (95% CI: 7.2, 12.0) for Kd and 13.6 months (95% CI: 8.8, 16.6) for KRd.
Treatment-related adverse events (TRAEs) of grade 3 or above (Gr3+) were reported in 13% of Kd and 35% of KRd pts, including 9% and 13% of serious TRAEs, respectively. The most frequent Gr3+ TRAEs were blood cytopenias (2% Kd, 24% KRd), infections (3% Kd, 11% KRd), respiratory and vascular disorders (2% Kd, 4% KRd). Of the fatal events (8 Kd and 1 KRd), none were considered treatment related.

Table: Patient Characteristics at K initiation and Response by Planned K Regimen

	Kd (N=91)	KRd (N=46)
Distribution of K-based regimens by country[a], n (%) (n=144)		
Bulgaria (n=22)	17 (77)	4 (18)
Czech Republic (n=27)	0 (0)	27 (100)
Israel (n=18)	11 (61)	3 (17)
Romania (n=77)	63 (82)	12 (16)
Median (IQR) age at K initiation, years	64 (59, 70)	63 (55, 68)
ISS stage, n (%)[b]	***N=46***	***N=21***
I	17 (37)	9 (43)
II	13 (28)	7 (33)
III	16 (35)	5 (24)
Derived frailty score, n (%)[b]	***N=74***	***N=39***
Fit	6 (8)	11 (28)
Intermediate	29 (39)	16 (41)
Frail	39 (53)	12 (31)
Cytogenetic risk, n (%)		
High risk	2 (2)	4 (9)
Normal/intermediate risk	4 (4)	16 (35)
Unknown/missing/not done	85 (93)	26 (57)
Previous therapies of interest, n (%)		
ASCT	33 (36)	33 (72)
Bortezomib	91 (100)	45 (98)
Lenalidomide	21 (23)	10 (22)
Monoclonal antibodies	6 (7)	3 (7)
Patients with evaluable best response, n (%)[b]	***N=88***	***N=45***
ORR [95% CI]	**70 (80)** [69.6, 87.4]	**39 (87)** [73.2, 94.9]
CR or better	15 (17)	17 (38)
VGPR	36 (41)	12 (27)
PR	19 (22)	10 (22)
Adverse events of Grade 3 or above, n (%)		
Overall adverse events	29 (32)	23 (50)
TRAEs	12 (13)	16 (35)
Serious TRAEs	8 (9)	6(13)
Fatal TRAEs	0 (0)	0 (0)

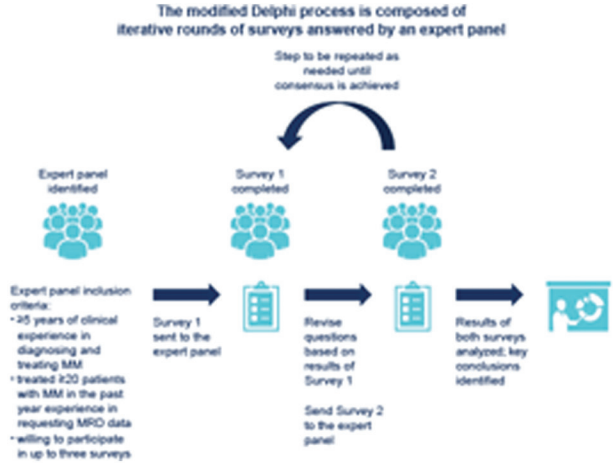
[a]Percentages of Kd and KRd are listed, other K-based triplets account for those missing to total number of patients in the respective country/region. [b]Percentages based on reported data

ASCT, autologous stem cell transplantation; CI, confidence interval; CR, complete response; IQR, interquartile range; ISS, international staging system; K, carfilzomib; Kd, carfilzomib and dexamethasone; KRd, carfilzomib, lenalidomide and dexamethasone; ORR, overall response rate (partial response or better); PR, partial response; TRAEs, treatment-related adverse events; VGPR, very good partial response

Summary/Conclusion: In CEE and Israel, usage of K-based regimens (32% KRd, 63% Kd) differed from that in the overall study population (55% KRd, 39% Kd) probably due to country-specific reimbursement regulations at time of study. Compared with the overall study population, pts enrolled in CEE and Israel were generally younger (Kd: 64 vs 68; KRd: 63 vs 65) and Kd was used in earlier lines (median number of pLoTs: 2 vs 3). Irrespective of K-based regimens, high response rates (over 80%) and deep responses (≥VGPR: Kd 58%, KRd 64%) were achieved over long treatment durations. K-based regimens were well tolerated (TRAE G3+: 13% Kd, 35% KRd).

PB1653 MODIFIED DELPHI CONSENSUS ON THE RELEVANCE OF MINIMAL RESIDUAL TESTING IN MULTIPLE MYELOMA IN THE CLINICAL PRACTICE

K. Ramasamy [1,*], H. Avet-Loiseau [2], C. Hveding Blimark [3], M. Delforge [4], F. Gay [5], S. Manier [6], J. Martinez-Lopez [7], M. V. Mateos [8], M. Mohty [9], N. W. van de Donk [10], K. Weisel [11]



[1]Oxford University Hospitals NHS Foundation Trust & Oxford University, Oxford, United Kingdom, [2]University Institute of Cancer Toulouse & University Hospital of Toulouse, Toulouse, France, [3]Sahlgrenska University Hospital, Gothenburg, Sweden, [4]University Hospital Leuven, Leuven, Belgium, [5]University of Torino, Turin, Italy, [6]University of Lille, Lille, France, [7]12 de Octubre University Hospital, Madrid, [8]Univeristy Hospital of Salamanca & Salamanca Biomedical Research Institute, Salamanca, Spain, [9]Hospital Saint-Antoine & Sorbonne University, Paris, France, [10]VU University Medical Center, Amsterdam, Netherlands, [11]University Medical Center Hamburg-Eppendorf, Hamburg, Germany

Background: Results from clinical trials in patients newly diagnosed with multiple myeloma (MM) or those with relapsed/refractory MM (including trials investigating add-on monoclonal antibodies to standard of care regimens), as well as retrospective analyses from clinical practice, have demonstrated a consistent association between minimal residual disease (MRD) negativity in MM and sustained clinical response to therapies. In these studies, depth of clinical response as measured by MRD predicted progression-free survival and overall survival. While these data indicate that MRD status is prognostic in clinical practice and may represent a valuable surrogate efficacy endpoint in clinical trials, to date, results from large-scale randomized clinical trials of MRD-directed therapy are lacking. In the absence of these data, a Delphi survey to establish consensus regarding the clinical practice utility of MRD in MM may serve as a bridge to help close this knowledge gap. Here we describe the interim results of a modified Delphi analysis conducted among representative experts in the field of MM across Europe.

Aims: To establish whether there is consensus on the relevance of determining MRD status in MM clinical practice in assessing and confirming response to therapy, and to assist physicians in implementing MRD assessment in the management of patients with MM.

Methods: The modified Delphi process is composed of two or more rounds of surveys answered by an expert panel. The expert panel comprises invited, currently practicing, hematological oncologists who fit all inclusion criteria (see Figure). A panel of 11 advisors across 8 European countries developed the questionnaires, identified and invited expert panel members, completed the surveys, and analyzed the results. Questions from Survey 1 were divided into 6 categories: screening and respondent demographics; perceptions regarding the potential use of MRD in clinical practice; actual use of MRD; barriers to routine MRD assessment; guidelines concerning the use of MRD; and educational needs concerning the use of MRD in MM. Advisors defined consensus *a priori* as 75% agreement or disagreement by the expert panel. Participants' contact details and survey data were handled in accordance with local regulatory requirements. This analysis focuses on the results from the categories on guidelines and educational needs concerning the use of MRD in MM (as stated in the categories above).

Results: Sixty-one experts (11 advisors; 50 invited) from 16 Western European countries completed Survey 1. Half (50%) reported that MRD was covered in either the prognostic, treatment, or both guidelines that they used. 64% felt suitably informed regarding the use of MRD in MM and were confident using it in a variety of clinical situations, while only 16% felt other clinicians in their country were suitably informed. There was consensus among the experts that clinicians in their country would benefit from education/resources in the use of MRD in informing treatment decisions (92%), and guidelines on the use of MRD in MM (75%).

Summary/Conclusion: As the treatment of MM continues to evolve, guidelines on using MRD in the clinic are increasingly necessary. Results from a Delphi survey of expert MM clinicians suggest a lack of MRD practice guidelines, and consensus that clinicians across Europe were not suitably informed regarding the clinical use of MRD in MM. These preliminary results highlight the importance of establishing guidelines and providing education on MRD in MM; final Delphi results will provide areas of expert consensus on MRD utility in clinical practice.

PB1654 A RETROSPECTIVE TWO-CENTRE COHORT STUDY OF THE EFFICACY AND SAFETY OF DARATUMUMAB WITH BORTEZOMIB AND DEXAMETHASONE THERAPY FOR PREVIOUSLY TREATED MULTIPLE MYELOMA

I. Sanchez [1,2,*], J. Aspa [1], P. Garcia [1], G. Milner [2], I. El-Najjar [2], S. Sachchithanantham [2], M. Gleeson [2], M. Kazmi [2], K. Bailey [3], R. Benjamin [3], K. Cuthill [3], L. Yuen [4], J. Garcia [1], M. Streetly [2]

[1]Haematology, Hospital Universitario Principe de Asturias, Alcala de Henares, Spain, [2]Haematology, Guy's and St Thomas' NHS Foundation Trust, [3]Haematological Medicine, King's College Hospital, [4]Pharmacy, Guy's and St Thomas' NHS Foundation Trust, London, United Kingdom

Background: Daratumumab, bortezomib and dexamethasone (DVd) is a therapy that has demonstrated significant clinical activity in relapsed/

refractory multiple myeloma (RRMM). In April 2017, DVd was approved by the European Medicines Agency (EMA). In June 2020, subcutaneous (SC) daratumumab gained EMA approval.
Aims: To analyze the clinical characteristics, response rates and treatment emergent toxicity of DVd combined therapy in two European centres.
Methods: This two-centre retrospective study includes 25 RRMM patients who started DVd therapy between July 2018 and November 2020 at Guy's Hospital (London) or Hospital Principe de Asturias (Madrid). The patients' data were reviewed using electronic records. Response outcomes were assessed for patients who received ≥1 cycles.
Results: The median age at the start of therapy was 62 (range 42-86), with 15 (60%) male patients. Clinical characteristics are shown in Table 1. Twenty (80%) patients had 1 previous line of therapy: 5 (25%) VMP (bortezomib, melphalan, prednisone), 5 (25%) VTd (bortezomib, thalidomide, dexamethasone), 3 (15%) VCd (bortezomib, cyclophosphamide, dexamethasone), 1 (5%) Vd (bortezomib, dexamethasone), 1 (5%) CRd (carfilzomib, lenalidomide, dexamethasone) and 4 (20%) a clinical trial. Five (20%) patients had 2 prior lines. Fourteen (56%) had undergone autologous stem cell transplant. Overall, 21/25 (84%) patients had been exposed to bortezomib: overall response rate (ORR) was 90.5% and 1 (4.8%) was bortezomib-refractory in 1st line. Median progression free survival (PFS) was 43.1 months (m) and median treatment-free interval was 33.2 m.
All patients had disease progression and 1 (4%) extramedullary disease prior to starting DVd. Median time on treatment was 9.6 m (0.2-29.4), with a median number of cycles of 12 (2-33). Seven (28%) patients discontinued therapy: 5 (71.4%) due to progressive disease, 1 (14.3%) for patient's choice and 1 (14.3%) died on treatment (due to SARs-CoV2-related pneumonia).
At a median follow-up of 11 m (1.8-29.4), 24 (95.2%) patients have completed ≥1 cycles. ORR is 83.3%, with very good partial response (VGPR) in 10/24 (41.7%) patients; only 2 (8.3%) patients had no response. The patient who was bortezomib-refractory in 1st line has a partial response (PR) so far. Median time to PR in the population is 36 days (15-120). PFS and overall survival (OS) rates are 73.7% and 90% at 11 m.
Daratumumab administration was SC in 6 (24%) patients, and was switched from intravenous (IV) to SC in 8 (32%) patients. Eight (32%) patients had a first-dose infusion related reaction (IRR) with daratumumab, in all cases being IV. In 3 (12%) it had grade 3 (hypertension) and infusion could be resumed.
Common (≥15%) AEs were: lymphopenia (76%), anaemia (64%), thrombocytopenia (60%), neutropenia (20%), peripheral sensory neuropathy (32%) and infections (36%), most of them SARs-CoV2 related (44.4%).
Grade ≥3 AEs occurred in 12 (48%) patients. Three (25%) developed thrombocytopenia, 1 (8.3%) anaemia, 3 (25%) neutropenia and 6 (50%) lymphopenia. Moreover, 3 (25%) patients had SARs-CoV2-related pneumonia (in 1 leading to death), 1 (8.3%) neutropenic sepsis secondary to pneumonia (causing death), 1 (8.3%) sepsis secondary to jaw infection and 1 (8.3%) non-pneumonic respiratory tract infection.

Table 1. Clinical characteristics of the population.

Characteristics (n=21)		Overall data (%)
MM type	- IgG	16/21 (76.2%)
	- IgA	2/21 (9.5%)
	- Bence-Jones	2/21 (9.5%)
	- Non-secretory	1 (4.8%)
ISS stage at diagnosis	- I	11/21 (52.4%)
	- II	6/21 (28.6%)
	- III	4/21 (19%)
ISS-R stage at diagnosis	- I	6/21 (28.6%)
	- II	7/21 (33.3%)
	- III	2/21 (9.5%)
	- Unknown	6/21 (28.6%)
Cytogenetics at diagnosis*	- Non-high risk	15/21 (71.4%)
	- High risk	1/21 (4.8%)
	- Unknown	5/21 (23.8%)
ECOG performance scale ≤2		21/21 (100%)

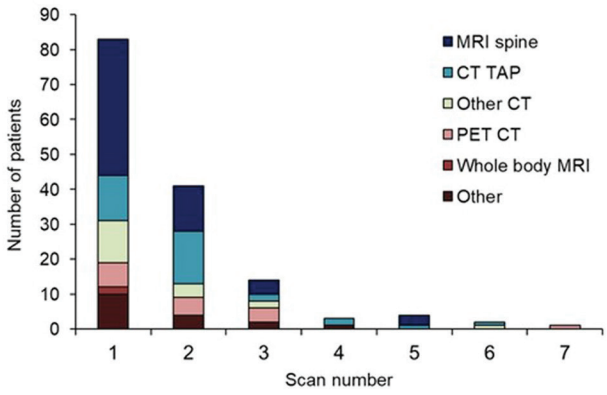
Abbreviations: MM: Multiple myeloma. ISS: International Staging System. ISS-R: Revised International Staging System. ECOG: Eastern Cooperative Oncology Group. *High risk cytogenetics at diagnosis: t(4;14), del(17/17p), t(14;16).

Summary/Conclusion: Daratumumab combined with bortezomib and dexamethasone as salvage therapy in MM demonstrates encouraging outcome results in our population, similar to those exposed in the analysis of the phase III CASTOR study. It shows an acceptable safety profile, with no IRRs to the moment since the introduction of SC daratumumab.

PB1655 LIGHTHOUSE (OP-108): A PHASE 3 STUDY OF MELFLUFEN IN COMBINATION WITH DEXAMETHASONE AND DARATUMUMAB VS DARATUMUMAB IN PATIENTS WITH RELAPSED/REFRACTORY MULTIPLE MYELOMA

M.-V. Mateos [1,*], L. Pour [2], E. M. Ocio [3], P. Sonneveld [4], C. Jansson Blixt [5], K. Larsson [5], L. Palmér [5], P. G. Richardson [6]

[1]Hospital Clínico Universitario de Salamanca/IBSAL/CIC, Salamanca, Spain, [2]University Hospital Brno, Brno, Czech Republic, [3]University Hospital Marqués de Valdecilla (IDIVAL), University of Cantabria, Santander, Spain, [4]Erasmus MC Cancer Institute, Rotterdam, Netherlands, [5]Oncopeptides AB, Stockholm, Sweden, [6]Dana-Farber Cancer Institute, Harvard Medical School, Boston, United States



Background: Melphalan flufenamide (melflufen) is a first-in-class peptide-drug conjugate (PDC) that leverages aminopeptidases and thereby delivers and rapidly releases alkylating agents inside tumor cells. In the phase 2 HORIZON study, melflufen plus dexamethasone showed clinical efficacy and was well tolerated in patients with heavily pretreated relapsed/refractory multiple myeloma (RRMM; Richardson et al. *J Clin Oncol.* 2020 Dec 9 [Epub]). The ongoing phase 1/2 ANCHOR study (OP-104) established the optimal dose for melflufen plus dexamethasone and daratumumab, showing meaningful clinical activity and manageable safety at both melflufen doses tested in patients with RRMM (Ocio et al. ASH 2020. Oral 417).
Aims: LIGHTHOUSE (OP-108; NCT04649060) is a randomized, open-label, multicenter, phase 3 study designed to evaluate the efficacy and safety of melflufen plus dexamethasone and daratumumab vs daratumumab alone in patients with RRMM previously treated with an IMiD and a proteasome inhibitor (PI).
Methods: Patient enrollment has begun, with N=240 patients planned for enrollment. The patient population is similar to that of the indication for daratumumab monotherapy. Key inclusion criteria are age ≥18 years, double refractory to (or intolerant of) an IMiD and a PI or having had ≥3 prior lines of therapy including an IMiD and a PI, have measurable disease, and Eastern Cooperative Oncology Group performance status ≤2. Patients with primary refractory disease and refractoriness to an anti-CD38 antibody are excluded. Patients will be randomized 1:1 to open-label melflufen plus dexamethasone and daratumumab (Arm A) or single-agent daratumumab (Arm B) and stratified by number of prior lines of therapy. Patients will receive therapy until progressive disease (PD) or unacceptable toxicity. In Arm A, patients will receive melflufen 30 mg intravenously on day 1 of each 28-day cycle; dexamethasone 40 mg weekly orally (20 mg if aged ≥ 75 years); daratumumab 1800 mg subcutaneously on days 1, 8, 15, and 22 of cycles 1 and 2, days 1 and 15 of cycles 3-6, and day 1 of cycles 7+. In Arm B, patients will receive daratumumab at the same dosage as in Arm A. Patients in Arm B with PD can opt to receive triplet therapy as in Arm A.
The primary objective of the study is to show superiority of progression-free survival (PFS) in patients treated with triplet therapy vs daratumumab alone (*P* value from the 2-sided statistical test <0.05; upper limit of the 2-sided 95% CI for the hazard ratio <1). An estimated sample of 240 patients with 160 expected events (PD or death) and 15% assumed dropout rate would provide 90% power at a 2-sided log rank test at 5% significance level to detect a hazard ratio for death of 0.6. Key secondary endpoints are overall response rate (ORR; ≥ partial response [PR]), duration of response, and safety. Response will be assessed by a blinded independent review committee based on International Myeloma Working Group response criteria. Other secondary endpoints include clinical benefit rate (≥ minimal response), time to response, time to progression, time to next treatment, and overall survival. Exploratory endpoints include minimal residual disease in patients achieving ≥ very good PR, PFS following next line of treatment (PFS-2), patient-reported outcomes, pharmacokinetics, translational biomarkers, response rate in patients with extramedullary disease, and efficacy (including ORR) in patients in Arm B who receive triplet therapy as in Arm A after PD.
Results:.
Summary/Conclusion:.

PB1656 WHOLE BODY MRI IS A FEASIBLE AND COST-EFFECTIVE IMAGING MODALITY FOR WORK-UP OF SUSPECTED OR NEWLY DIAGNOSED MULTIPLE MEYLOMA: A RETROSPECTIVE, SINGLE CENTRE COHORT STUDY

R. Buka [1,*], S. Gaba [2], K. Karunanithi [1]

[1]Clinical Haematology, [2]Radiology, University Hospital North Midlands, Stoke-on-Trent, United Kingdom

Background: The detection of bone disease has important prognostic implications in multiple myeloma and can influence the diagnostic classification and the urgency of instituting treatment. Whole body magnetic resonance imaging (WB-MRI) is the most sensitive imaging technique and there are a number of advantages over other modalities. WB-MRI is able to detect axial and extra-axial disease, other solid organ malignancies, and has superior resolution and sensitivity for focal bone lesions. However, its use is restrained by a lack of local availability, paucity of radiological expertise in reporting, long acquisition time, and other factors. In this study, we hypothesised that more widespread use of WB-MRI would decrease the total number of scans, improve the patient journey and be cost effective.
Aims: The primary aim was to ascertain the feasibility, service impact and potential for cost-saving of instituting WB-MRI as the first-line skeletal imaging technique for patients with suspected or proven multiple myeloma in a large teaching hospital.
Methods: Electronic records of 88 consecutive patients with newly diagnosed multiple myeloma in the University Hospitals North Midlands NHS trust between 1st November 2018 and 31st October 2020 were studied. For the purposes of our analyses, a label of suspected myeloma was assigned when an abnormal protein electrophoresis or serum free light chain result was available. Confirmed myeloma was assigned when results of bone marrow showing >10% plasma cells was available. Data were anonymised and stored using Microsoft Excel on password-protected trust computers.
Results: 83 (94%) patients had imaging performed, with a total of 213 imaging procedures during the time period. Diagnostic imaging is summarised in figure 1 which includes all imaging performed prior, and up to, the achievement of a formal diagnosis of multiple myeloma (not follow-up scans). 43/83 (52%) had focal skeletal disease. Imaging triggered upstaging from smouldering myeloma to multiple myeloma in 7 (8%) patients. Where scans were performed for suspected or confirmed myeloma, 18 patients had in total 28 scans that could have been avoided if we had performed at the earliest realistic opportunity, 70 WB-MRI instead of 43 MRI whole spine, 12 computed tomography (CT) thorax, abdomen, and pelvis, 4 other CT scans, 8 positron emission tomography (PET) CT scans, and 3 other MRI scans. This equates to a direct cost saving of £11,428 (€13,177) over two-year period - a cost saving of £130 (€149) per patient – and the opportunity to redirect valuable scanner time for other cases.

Summary/Conclusion: As myeloma is a rare disease, patients arrive at the diagnosis through a variety of circuitous routes. It is therefore not feasible to perform WB-MRI in all patients as firstline imaging. However, it is reasonable to perform WB-MRI where myeloma is suspected or confirmed in place of other imaging. We have calculated direct cost savings but there are likely to be myriad benefits for the patient journey relating to improved diagnostic sensitivity and speed, fewer hospital visits, decreased exposure to radiation, and timely access to treatment where appropriate. Our findings support UK recommendations for WB-MRI as the first-line imaging modality. Radiology services should focus on expanding expertise in the delivery of this service and identifying patients who can benefit. Clinicians should be encouraged to utilise WB-MRI wherever possible.

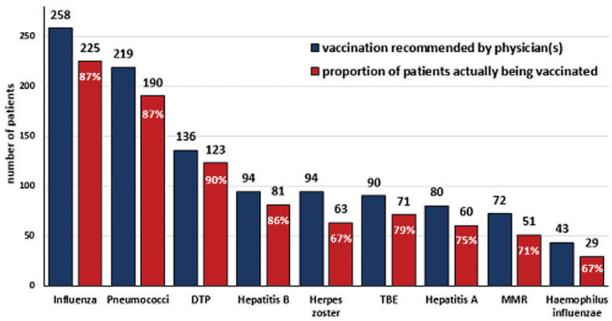
PB1657 AL AMYLOIDOSIS SURVIVAL EVOLUTION IN NEW AGENTS ERA: A REAL LIFE EXPERIENCE

O. Rizzo [1,*], J. Avci [1], J. Dallemagne [2], M. Vercruyssen [1], V. Dewilde [2], N. Meuleman [1]

[1]Hematology, Institut Jules Bordet, ULB, [2]Hematology, Hôpital Erasme, Brussels, Belgium

Background: Light chain amyloidosis (AL) is a rare but severe disease due to deposition of misfolded protein in tissues leading to progressive organ failure. Its prognosis is mostly due to the degree of cardiac involvement at diagnosis. In the past years, thanks to the introduction of new agents, such as Daratumumab, a huge improvement of the prognosis has been observed due to better efficacy and less toxicity as well.
Aims: This retrospective review aimed to evaluate the reported improvement in a real life population. For this purpose, we looked at our entire AL patients population during the past 15 years.
Methods: We collected the data of 42 AL patients from two hospitals in Brussels from 2006 until 2019 and separated them into two cohorts: 2006-2015 and 2016-2019, before and after the introduction of Daratumumab. We looked into and then compared baseline characteristics, treatments, overall survival (OS), response rate, toxicities but also time from first symptoms to diagnosis between the two cohorts.
Results:
The median age at diagnosis was 62.3 62 (58-72) years, 45% were females, and 23% of patients had an ECOG performance status ≥ 3. Basics characteristics of the two groups were comparable no difference regarding the number of organ involvement and their severity (stage 4 revised Mayo Clinic 23 vs 25% respectively, p=1). No improvement concerning the time to establish the diagnosis from first symptoms described by patients was observed (109,5 months versus 181 months, p=0.3) between the two periods of time. In the second cohort, an increase of Bortezomib-based regimens use was observed (71 vs 59%) and 12 patients were treated by Daratumumab in the relapse setting. The hematological overall RR was 65%, with high-quality response (≥ very good partial remission)in 41% of the patients. There was no difference in the RR between the two periods. Median OS was 33 months for the whole cohort. However, an improvement in overall survival is neat between the two cohorts with median OS (mOS) of 7 months for the first period of time compared to a mOS that was not reached yet in the second cohort (p=0.01). As expected, concerning the whole population, the mOS was significantly and hugly better in patients with PS 0-2 comparing to those with PS 3-4 (116 vs 8,9 months; p=0,009.). Moreover, median mOS according to stage of Mayo Clinic was 55,1 months for stage 1-2 and 32,1 months for stage 3-4 (HR 0.58). Within the specific population treated by Daratumumab(N=12), we described a significant improvement of mOS compared to other treatments (7 months versus not reached; p=0,01). Moreover, less toxicities were described with 25% of infectious and 17% of haematological complications of > grade 2.
Summary/Conclusion: We observed a significant improvement in overall survival as described in other recent and larger publications. These encouraging results are mostly due to the introduction of new agents, especially Daratumumab in the relapse setting. Also, new guidelines recommending to switch treatment quickly if no satisfactory response is reached, are part of this success. However, even if a massive effort has been done in the recent past years by scientific authorities to improve the time to diagnosis (recommendation of MGUS screening i.e.), no difference was observed in the time needed to establish the diagnosis and hence, in the amount of severe cases at diagnosis between the two periods of time.
Finally, according to recent studies, Daratumumab is well tolerated and extremely efficient in AL amyloidosis.

PB1658 RECOMMENDATIONS FOR VACCINATION GIVEN TO PATIENTS WITH MULTIPLE MYELOMA IN REAL-WORLD CLINICAL PRACTICE AND PATIENTS` COMPLIANCE WITH THEM



H. Ludwig [1,*], A. Meckl [1], M. Engelhardt [2]

[1]Wilhelminen Cancer Research Institute, Vienna, Austria, [2]Medical Department, Hematology, Oncology, and Stem Cell Transplantation, University Hospital Freiburg, Faculty of Freiburg, Freiburg, Germany

Background: Infections are the second leading cause of death in multiple myeloma (MM). All available measures to curb this complication should be exploited, including vaccination against several bacteria and viruses.

Aims: In this study, we examined the recommendations for vaccination given to patients (pts) with MM in real-world clinical practice and pts' compliance with them. We also analyzed the incidence of infections before and after diagnosis, and pts' willingness to be vaccinated against COVID-19.
Methods: 335 pts with MM from Germany, Switzerland, and Austria participated in this survey. A questionnaire was designed in cooperation with pts groups to assess the vaccination recommendations given to them from their treating physicians, to evaluate their compliance with the advice received, to capture the infection rate of pts in the year before and the first six months after start of therapy, and to assess pts' willingness to be vaccinated against COVID-19. The invitation to participate in this electronic survey was distributed by 31 participating myeloma support groups. In addition, 500 hardcopy questionnaires were mailed directly to pts, reaching out to approximately 2,000 pts.
Results: Pts' median age was 65 years; 23.0% had 1, 34.8% 2-3, and 42.3% ≥ 4 lines of prior treatment. Pts' responses were similar between respondents to the online and printed version of the questionnaire. The number of pts who received recommendations for the various vaccinations and the proportion of pts who actually received the vaccine is shown in Figure 1. Influenza was the most frequently recommended vaccine (77.0%), followed by pneumococci (65.4%). Pts' compliance with their physicians' advice varied between 67% and 90%.
At least one infectious period in the year preceding the diagnosis of MM was reported by 51.9% of the 322 responding pts, and by 42.4% of the 314 responding pts during the first six months after initiation of first-line therapy. Eighty-three percent of pts declared their willingness to be vaccinated against COVID-19, while 17% stated that they objected to it. Reasons for refusing SARS-CoV-2 vaccination were lack of long-term experience (76.6%), concerns regarding late effects (60.9%), insufficient confidence in the pharmaceutical industry (26.7%), and concerns that the vaccine will not be protective (15.6%).

Figure 1: Types of vaccinations recommended, number of pts with vaccination advice, and proportion of patients who actually received the vaccine

DTP – diphtheria, tetanus, pertussis; TBE – tick borne encephalitis; MMR – measles, mumps, rubella

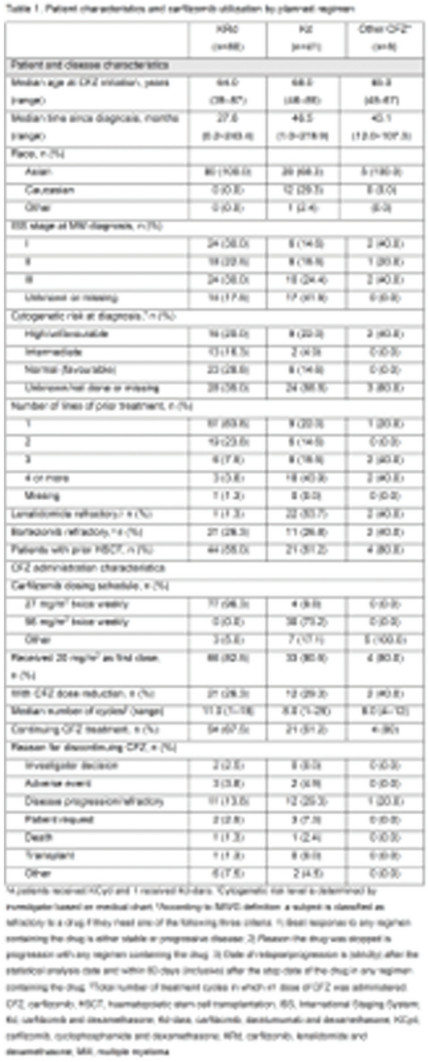
Summary/Conclusion: The vaccination recommendations varied widely depending on the type of vaccine, but compliance with these recommendations was remarkably high (>80%) for influenza, pneumococci, hepatitis B, and DTP. The high rates of recommendations for influenza and pneumococci seem to reflect the high prevalence of upper and lower respiratory tract infections in MM. Of note, 51.9% of pts reported a least one infectious episode in the year before, and 42.4% during the first six months after initiation of treatment. As 75.4% of pts did receive prior ASCT, vaccinations with DTP and MMR were recommended to substantial pt numbers. In contrast, fewer than expected pts were advised to get vaccinated against VZV (28%) and against Haemophilus influenzae (12.8%). Tick borne encephalitis is endemic in the some areas of the participating countries, which possibly explains the high compliance rate (78.8%) in the 26.8% of pts who were advised to be vaccinated.
The high readiness of MM pts to get vaccinated with a SARS-CoV-2 vaccine (83%) seems remarkable and much higher than that of the general population. A possible explanation for this proactive attitude is the preferential participation of well-informed pts in this study.

PB1659 COVID-19 MORTALITY IN CONCURRENT MULTIPLE MYELOMA (MM) – A PROSPECTIVE AND COMPARATIVE CASE SERIES THROUGH THE FIRST AND SECOND WAVE OF THE SARS-COV-2 PANDEMIC IN A UK TERTIARY HAEMATOLOGY CENTRE

S. Shaya [1,*], S. Choudhuri [1]

[1]*Northern Care Alliance, Manchester, United Kingdom*

Background: The Sars-CoV-2 pandemic has markedly disrupted haemato-oncology services in the UK in balancing Covid-19 infection risk with MM management. New light has been shed on risk factors for mortality in hospitalised Covid-19 patients with concurrent MM. However, reported mortality rates for Covid-19 in MM patients show significant heterogeneity between countries, and do not examine for changes to mortality despite huge shifts in Covid-19 management throughout the pandemic.
Aims: 1) Record patient demographics and medical risk factors of all MM patients hospitalised with Covid-19 between March 2020 to January 2021 in the NCA (catchment population of ~1,000,000 patients), UK.
2) Compare patient factors and outcomes between the first and second wave of the Sars-CoV-2 pandemic to characterise more currently reflective demographic and outcome data for Covid-19 in MM patients.
Methods: All patients with a previous diagnosis of MM who were admitted Covid-19 treatment were included. Covid-19 diagnosis was defined as a positive nasopharyngeal PCR swab 7 days before or after admission. Admissions during the 01/03/2020 to 30/06/2020 and 01/07/2020 to 07/01/2021 were included, and classified as the first and second wave, respectively. Patient demographics, myeloma therapy before admission, medical co-morbidities, and 28-day mortality from Covid-19 test positivity was recorded and analysed. Statistical comparison of mortality rate was applied between the first and second wave.
Results: 6 patients were admitted in the first wave of whom 6 (100%) died. 6 patients were admitted in the second wave, of whom 2 (33.3%) died. The change in mortality between waves approached, but fell short of, statistical significance (p=0.061). The average age in both waves was 79 and both had heterogeneous but comparable medical co-morbidities. Gender did not correlate to mortality, and gender ratios were comparable between both groups. 10 of 12 patients had medical therapy for MM prior to their admission, 7 of which were bortezomib based, two lenalidomide-Ixazomib based, and one receiving pomalidomide monotherapy. No correlation was detected between specific MM therapy or therapy line, on pandemic wave or mortality.
Summary/Conclusion: This study seeks to define more up to date Covid-19 outcomes in MM patients compared to previous outcome data which uses both early and current Covid-19 outcome data, homogenously. Our findings are strictly limited by sample size and power but display a large difference in Covid-19 mortality rate between the first and second wave in the NCA. Due to comparable patient and medical characteristics, and near statistical significance, these findings suggest a significant reduction in mortality of Covid-19 in MM patients between the first and second Sars-CoV-2 wave in the UK and is a novel finding which warrants further study to confirm or refute this. A more representative set of outcome statistics for Covid-19 infection in MM patients would represent today's pandemic and may shed light on the impact of previously implemented changes in MM management as well as advances in Covid-19 inpatient care. Finally, an accurate representation of today's Covid-19 outcomes in MM patients would set the benchmark for comparing interventional outcomes going forward.



PB1660 CARFILZOMIB USE AMONG PATIENTS WITH RELAPSED/REFRACTORY MULTIPLE MYELOMA IN THE ASIA PACIFIC REGION: AN INTERIM ANALYSIS FROM A PROSPECTIVE, REAL-WORLD STUDY

J. S. Kim [1], S.-S. Yoon [2], K. Kim [3], J. H. Lee [4], C. Nagarajan [5], P. J. Ho [6], M. Low [7], W. H. Huang [8], R. Wong [9], N. Liao [10], S. Chai [11], J. Li [11], H. Lin [11], H. Quach [12,*]

[1]*Severance Hospital, Yonsei University College of Medicine,* [2]*Seoul National University Hospital,* [3]*Department of Medicine, Sungkyunkwan University School of Medicine, Samsung Medical Center, Seoul,* [4]*Dong-A University College of Medicine, Busan, Korea, Republic Of,* [5]*SingHealth Duke-NUS Blood Cancer Center and Singapore General Hospital, Singapore, Singapore,* [6]*Royal Prince Alfred Hospital, Sydney,* [7]*Monash Medical Centre, Melbourne, Australia,* [8]*Hualien Tzu Chi Hospital, Buddhist Tzu Chi Medical Foundation, Hualien City, Taiwan, Republic of China,* [9]*Prince of Wales Hospital, Hong Kong, Hong Kong,* [10]*Parexel International, Taipei, Taiwan, Republic of China,* [11]*Amgen Asia Holding Limited, Hong Kong, China,* [12]*University of Melbourne, St Vincent's Hospital, Melbourne, Australia*

Background: Carfilzomib (CFZ) is a next-generation proteasome inhibitor currently approved in combination with lenalidomide and dexamethasone (KRd) or with dexamethasone alone (Kd) for treatment of multiple myeloma (MM) patients with at least one prior line of therapy in the Asia Pacific (APAC) region. Real-world evidence is crucial to understanding how CFZ-based regimens are used in practice.
Aims: To describe utilization of KRd and Kd in routine clinical practice in APAC, including treatment patterns, patient profile and reasons for discontinuation.

Methods: This prospective, single-arm cohort study recruited adults with relapsed or refractory MM who received ≥1 dose of CFZ in either a combination or monotherapy regimen and had received ≥1 prior line of MM treatment prior to CFZ initiation. Between July 2019 and June 2021, approximately 300 patients are anticipated to be enrolled in this study, with 25–100 patients from each included country/region. Medical history, patient characteristics and clinical data will be collected at baseline and throughout the 2-year observation period or until death, withdrawal of consent or loss of follow-up. Follow-up data will be collected through chart reviews every 3 months. Adverse events (AEs) leading to treatment discontinuation will be collected. The last patient record for the analysis will be collected no later than Q1, 2023.
Results: The first patient was enrolled on 10 July 2019. As of 10 September 2020, 126 patients have been included from five countries/regions: Australia (n=15), Hong Kong (n=2), Korea (n=95), Singapore (n=10) and Taiwan (n=4). To date, the regimens prescribed were KRd (63%), Kd (33%) and other CFZ-based regimens (4%), including triplet combinations with cyclophosphamide (n=4) and daratumumab (n=1). Overall, 29% of patients reported a history of hypertension, 9% of cardiac disorders, 8% of diabetes mellitus and 1% of pulmonary embolism, prior to CFZ initiation. On average, patients prescribed KRd were slightly younger than patients prescribed Kd. The majority of KRd patients (63.8%) had received one prior line of treatment, whereas nearly half of Kd patients (43.9%) had received ≥4 lines of prior treatment. Similar proportions of KRd (26.3%) and Kd (26.8%) populations were bortezomib refractory; 53.7% of Kd patients were lenalidomide refractory. For nearly all KRd patients (96.3%) and almost three-quarters of Kd patients (73.2%), the initial prescribed therapeutic CFZ dose was in accordance with the local product information: 27 and 56 mg/m^2 twice weekly, respectively. As of September 2020, 67.5% and 51.2% of KRd and Kd patients, respectively, remained on CFZ treatment. The most common reason for CFZ discontinuation was disease progression/refractory disease (See Table). Overall, only five patients discontinued CFZ for treatment-related AEs.

Summary/Conclusion: This study investigates the real-world use of CFZ for relapsed/refractory MM in a predominantly Asian patient population from across the APAC region. Interim results confirm that the standard dosing schedules for KRd and Kd are well tolerated in real-world practice and suggest a very low rate of discontinuation due to CFZ-related AEs, even in the very late stages of MM. Further prospective data collection of patients in routine practice is ongoing to assess patterns of longer-term patient management, response, survival outcome and AEs, which will inform optimal use of CFZ.

PB1661 BCMA-DIRECTED THERAPY IN MULTIPLE MYELOMA: EFFECT OF ONLINE EDUCATION ON CLINICIAN KNOWLEDGE AND CONFIDENCE

A. Taylor [1,*], S. Koekkoek [1], J. Vandenbroucque [1], R. Popat [2]

[1]Medscape Education Global, New York, United States, [2]University College London Hospitals NHS Foundation Trust, London, United Kingdom

Background: BCMA-directed modalities including CAR T-cell therapy, bispecific antibodies and antibody-directed cytotoxic agents are potentially transformative next steps in managing patients with multiple myeloma. However, beyond expert centres physicians have little experience of such agents to date.
Aims: This study aimed to determine whether online continuing medical education could improve the knowledge and confidence of clinicians in their understanding of the rationale for and clinical aspects of different BCMA-directed therapies
Methods: Three educational activities were launched for physicians outside the USA during 2020 to a target audience of hematologist/oncologists and ophthalmologists. Activities comprised a 30-minute video lecture, a 15-minute video collegial discussion, and a 30-minute online video panel discussion. Data were collected March to June 2020. For each activity educational effect was assessed with repeated-pairs pre-/post-activity, where individual participants served as their own control. 3 multiple-choice, knowledge questions and 1 self-efficacy, 5-point Likert scale confidence question were analyzed. Data were subsequently combined and analyzed to provide a summative overview of the effect of the education across the combined knowledge-based learning objectives and confidence questions from the three programs. A McNemar's test was conducted to assess statistical significance of changes from pre- to post-assessment.
Results: Between 66 and 103 hematologist/oncologists (combined total n=259) and 39-41 ophthalmologists (combined total n=121) completed pre- and post-activity questions. A statistically significant effect was observed for hematologist/oncologists across all 3 learning objectives (P<0.05-P<0.001) with a relative improvement in % of correct responses ranging from 10-44%. Furthermore, there was an overall improvement in confidence, with a 72% gain in confidence in those reporting increased confidence. The education had less impact on ophthalmologists; while some improvements were noted in individual activities, in the summative overview the greatest improvement was noted in knowledge of AEs associated with BCMA-directed therapies. The summative overview revealed that hematologists/oncologists demonstrated improvements in knowledge across the 3 learning objectives: 10% (P<0.05) regarding rationale and types of BCMA-directed therapies, 44% (P<0.001) regarding AEs associated with BCMA-directed therapies, and 29% (P<0.001) regarding BCMA clinical trials data. Ophthalmologists showed knowledge changes of -2% (NS) regarding knowledge of clinical data and the rationale and type of BCMA-directed therapy, and a 41% (P<0.05) improvement in knowledge of BMCA-therapy associated AEs. In combined self-assessed confidence questions, 51% of hematologist/oncologists had a measurable increase in and 46% maintained confidence. Thirty-three percent of ophthalmologists had a measurable increase in and 59% maintained confidence. All changes in confidence were significant (P<0.01 or P<0.001). At the individual activity level, ~50% of all participants stated that they would modify treatment plans and ~90% were committed to those changes.
Summary/Conclusion: These three educational activities resulted in a considerable educational impact, particularly for hematologist/oncologists. Online medical education is valuable in improving knowledge and confidence, as well as identifying areas of continued educational need and potentially improving patient outcomes, of particular importance during the COVID-19 pandemic where in-person conference learning is inaccessible.

PB1662 A DESCRIPTIVE COST-ANALYSIS OF MYX.1/MCRN003 - A PHASE 2 CLINICAL TRIAL EVALUATING HIGH-DOSE WEEKLY CARFILZOMIB, CYCLOPHOSPHAMIDE, AND DEXAMETHASONE IN RELAPSED AND REFRACTORY MULTIPLE MYELOMA

B. E. Monteith [1,*], C. P. Venner [2], M. C. Cheung [3], J. Pater [4], L. Shepherd [5], H. Richardson [6], D. Reece [7], E. Gul [8], M. Lalancette [9], V. Castonquay [9], V. Kukreti [7], R. Tiedemann [7], C. Phua [10], S. Bhella [7], J. Dudebout [4], M. Sherry [11], H. Yen [11], B. E. Chen [11], A. E. Hay [1]

[1]Medicine, Queen's University, Kingston, [2]Medicine, Cross Cancer Institute, Edmonton, [3]Medicine, Odette Cancer Center, Toronto, [4]Oncology, [5]Pathology, [6]Health Sciences, Queen's University, Kingston, [7]Medicine, Princess Margaret Cancer Center, Toronto, [8]Canada Myeloma Research Group, Markham, [9]Medicine, Universite Laval, Quebec City, [10]Medicine, Western University, London, [11]Queen's University, Kingston, Canada

Background: The prevalence of multiple myeloma is increasing and there is a need to evaluate the associated escalating therapy costs(1). The MYX.1 phase II trial showed that high-dose weekly carfilzomib, cyclophosphamide, and dexamethasone (wKCD) is efficacious in relapsed and refractory disease (2,3). We conducted a descriptive cost analysis, from the perspective of the Canadian public healthcare system, using trial data.
Aims: The goal of this secondary analysis was to determine the total cost of wKCD per patient with a description of per cycle costs and estimated annual costs.
Methods: The primary outcome was the mean total cost per patient. Resource utilization data were collected from all 75 patients enrolled in the MYX.1 trial over a trial time horizon. Costs are presented in Canadian dollars (2020).
Results: The cost of treatment was calculated from the time of patient enrollment until the time of the second data lock in June 2019. The mean total cost per patient was $203,336.08 (range $17,891.27 – $505,583.55) Canadian dollars (CAD, where 1 CAD = 0.65 Euro (EUR)). The median number of cycles was 15. The mean cost per patient per cycle was $14,081.45. The predominant cost driver was the cost of chemotherapy accounting for an average of $179,332.78 per patient or $12,419.17 per patient per cycle. Carfilzomib acquisition accounted for the majority of chemotherapy costs – $162,471.65 total per patient or $11,251.50 per patient per cycle. Fifty-six percent (56%) of patients had at least one hospitalization during the trial period with an average cost of $12,657.86 per hospitalization. The average cost to treat each patient with thrombotic microangiopathy (TMA) was $18,863.32 including the cost of hospitalizations and therapeutic plasma exchange.
Summary/Conclusion: High-dose wKCD is an active triplet regimen for RRMM associated with reduced total cost compared with twice weekly regimens.

PB1663 RACIAL DISPARITIES OF OUTCOME IN MULTIPLE MYELOMA COMPARATIVE ANALYSIS OF VARIED ETHNIC GROUPS IN GALILEE, ISRAEL

N. Dally [1,2,*], A. Breaster [3,4], M. kashlikov [1], K. tarabeh [1], L. akria [3,4], C. suriu [3], M. baranes [4]

[1]Hematology Institute and Blood Bank, Ziv Medical Center, [2]Hematology, Azreili Faculty of medicine Bar -Ilan univesity, Safed, [3]Hematology Institute and Blood Bank, Galilee Medical Center, Nahariyya, [4]Hematology, Azrieli Faculty of medicine Bar-Ilan university, Safed, Israel

Background: Multiple Myeloma is a malignant bone marrow disorder with plasma cell proliferation. The average survival is about 4 years. There are 19,900 new cases of Multiple Myeloma (MM) every year in the United States and 10,700 deaths from the disease annually. Multiple myeloma is about 1% of all cancers and about 10% of the hematologic malignancies. Monoclonal gammopathy of undetermined significance (MGUS) is the most common form of the pre-cancerous stage of MM. MGUS is characterized by the absence of clinical symptoms and low fraction of a monoclonal antibody (less than 3 g/dl) In addition less than 10% of the plasma cells in the bone marrow.MGUS prevalence is 2-3 times higher in Afro-Americans. There are differences in disease presentation and epidemiology of MM and MGUS between patients from different ethnic groups (Caucasian, Afro-Americans and Asian.). the difference between the incidence of phenomena in different ethnic groups implies a genetic basis for the disease. In Israel it is estimated that 400 to 500 new cases of MM are diagnosed annually.
Aims: Various studies have been conducted around the world examining the relationship between ethnic origin and the prognosis of multiple myeloma by comparing different indicators such as the survival index. The survival index differs among MM patients depending on their ethnic origin. Thus, the treatment of multiple myeloma may be tailored based on their background and ethnicity. For instance, studies conducted in the United States compared Caucasians to African Americans and other ethnic groups such as Asians and Hispanics. These studies indicate that the prognosis differs between populations and show a relationship between survival rates and patients' ethnicity. The aim of this study is to assess the relationship between ethnic origin and the prognosis of MM among various populations in Israel, particularly in the Galilee region
Methods: A retrospective study was performed in order to analyze the medical records of MM patients treated in the Galilee region, exploring the relationship between prognosis and ethnicity. For this purpose, data was collected from medical files of MM patients treated at Ziv medical center and Galilee Medical center between 2008-2018.Patients were divided according to their ethnicity and survival was compared between different ethnic groups. Statistical analysis: Statistics are described using averages and standard deviations, median, and range. Qualitative data was described through prevalence and percentages. Differences in measures between the ethnic groups were thought of by the T or ANOVA tests. Results with $p<0.05$ were considered statistically significant
Results: A mortality rate of 48.9%, was found in the study, regardless of population origin. There was no difference in PFS (progression free survival) and OS (overall survival) between the different ethnic groups. The stage of the disease at the time of diagnosis is lower in Jews compared to patients of Arab origin with statistical significance ($p\leq0.008$),34% of the patients were diagnosed in Stage I, 70.6% of them were Jewish compared to 29.4% of patients of Arab origin. 51.4% of patients were diagnosed in advanced stage III disease were from Arab ethnicity versus 39.4% of all patients
Summary/Conclusion: There was no statistically significant difference in survival between populations of different ethnicity. A difference was found in the stage of the disease at the time of diagnosis. The patients of Arab origin were diagnosed at a more advanced stage than the patients of Jewish origin

PB1664 TREATMENT FOR NEWLY DIAGNOSED, FIT AND YOUNG PATIENTS WITH MULTIPLE MYELOMA: "ONE SIZE FITS ALL" OR PERSONALIZED TREATMENT APPROACHES SHOULD BE CONSIDERED?

F. Abdulla [1,*], P. Kaloyannidis [1], E. Mutahar [1], H. Hashim [1], S. Harbi [1], A. Estanislao [1], J. Bacal [1], K. Al Anezi [1], H. Al Hashmi [1]

[1]Adult Hematology & Stem Cell Transplantation Department, King Fahad Specialist Hospital, Dammam, Saudi Arabia

Background: Multiple myeloma (MM) is considered a disease of elderlies with only 15% of cases occurring in patients (pts) ≤55 years (ys) old. Despite the improvements on response and survival rates after treatment with the novel agents combinations, the disease still remains incurable. Focusing on younger pts, although they succeed better outcomes, a considerable number of them (25-35%) succumb to MM, within 5 years after diagnosis. Therefore, even in the novel agents era, an efficient treatment approach for young and fit pts remains a goal to be fulfilled.
Aims: In this retrospective study we evaluated the overall survival (OS) and the potentially related risk factors, in newly diagnosed MM pts aged ≤55 years. We also designed a scoring system with predictive value on their long-term outcome.
Methods: We reviewed the medical records of 122 pts who were treated in our center from 2010-2020 and received either combinations with 2 (n=21) or 3 (n=91) agents of Velcade, Cyclophosphamide, Thalidomide, Lenalidomide and Dexamethasone, or other regimens (n=10), and had also adequate data regarding their age, disease stage (according to ISS), response to the treatment (according to the latest IMWG criteria) and long-term outcome. Pts diagnosed with amyloidosis or smoldering MM were excluded from the study. Student's t-test, Kaplan-Meir and Cox regression methods, were used for the statistical analysis.
Results: Based on the whole cohort's median age (55 ys, range, 38-80), we divided our pts in two groups: those of ≤55 ys (group A, n=63) and those of >55ys (group B, n: 59). Cytogenetic analysis was feasible in 75 (60%) and only 7/75 pts found to have high risk features. No significant differences were noticed between the two groups in terms of disease stage, cytogenetic abnormalities and response rates after induction remission treatment. Autologous stem cell transplantation (ASCT) was performed in 69 pts [51 (81%) from group A and 18 (30%) from group B, p< .001]. After a median follow up of 28 months, the 10-year OS was better for group A

(75% vs 50%) and the median OS was not reached in group A vs 6,5 ys in group B (p: 0,01). With regard to younger pts, we observed that approximately 25% died within 5 years after MM diagnosis, even if combinations of novel agents plus ASCT (either as induction or as salvage treatment) had been used. Three factors adversely affected the outcome of group A pts: advanced stage, less than VGPR achievement after induction treatment and presence of extramedullary disease at diagnosis. Based on these 3 factors we created an easily applicable scoring system. Due to the insufficient number of pts with chromosomal analysis, the cytogenetic abnormalities were not incorporated in the scoring system. Pts with 0-1 factors had significantly better prolonged OS rates as compared to those with 2-3 factors (82% vs. 55% p=0.02). Also, in multivariate analysis, our proposed scoring system was found to be independent risk factor for prolonged survival.
Summary/Conclusion: The heterogeneity in the outcomes among the MM pts, denotes that the "one size fits all" approach, probably is not efficient enough at least for selected young pts with adverse disease features. Currently, the plethora of the available novel treatment agents, highlights the unmet need to establish appropriate criteria for personalized and more efficient treatment approaches for MM pts, especially for the younger ones. In this study, using an easily applicable scoring system, we were able to identify pts ≤55 ys who might need more intensive treatment approaches aiming at prolonged survival rates.

PB1665 MULTIPLE MYELOMA TREATMENT DECISIONS FROM THE PATIENT PERSPECTIVE

M. Lyall [1,*], A. Heyes [1], T. Bell [2], C. Mamolo [3], A. Neuhof [4], C. Levy [1], R. Crawford [1]

[1]RTI Health Solutions, Manchester, United Kingdom, [2]Pfizer Inc., New York, [3]Pfizer Inc., Groton, United States, [4]Pfizer Pharma GmbH, Berlin, Germany

Background: Multiple myeloma (MM) is an incurable hematological malignancy, and during the illness course, patients face a range of disease symptoms and treatment side effects, making therapeutic management a challenging process. There is currently a shortage of data on the treatment decision-making process from the patient perspective, and published literature and patient-reported information (PRI) shared on social media could be a potential source for this evidence.
Aims: A combined research methods approach using a review of published literature and social media posts was conducted to better understand treatment decisions associated with MM from the patient perspective.
Methods: Targeted searches of PubMed and PsycINFO were conducted from 2010 to November 2020 to identify articles covering the patient voice of the burden and treatment of MM. Titles and abstracts were screened for relevance by 2 experienced reviewers with the most relevant full-text articles selected for inclusion in the review. To supplement this, searches for PRI were conducted of relevant patient advocacy websites (e.g., Patient Power, The Patient Story, Cure Today) and YouTube. Posts were included for review if shared by adults with a self-reported diagnosis of MM and had content relating to the patient experience of MM and its treatment. Demographic and disease characteristics at the time of the post were recorded where available.
Results: From a total of 374 articles identified in the literature search and 2,575 posts identified in the social media search, 27 articles and 138 posts were included in the review. Of these, 3 articles and social media posts from 19 patients reported information on patient views regarding treatment decision making. Patients with newly diagnosed MM (N = 7) reported feeling that their life and independence were being taken away and expressed shock at the number of therapeutic decisions. Evidence from the literature (3 articles) stated that a high percentage of patients expressed a desire to be included in treatment decisions but results from the social media posts (N = 5 patients) showed that some felt that they were not consulted by the treating physician before being assigned therapy. In the literature, patients (all treatment lines) reported that finding the most capable specialist and having trust in their health care provider was key (2 articles). From the PRI sources, patients receiving later lines of therapy (N = 10) stated that communication of comprehensive information was important and valued engagement in shared decision making; in this group, treatment effectiveness had the greatest influence on choice. Side effects were a lower concern for patients who had been on therapy for a long time versus patients receiving induction therapy (1 article). Despite this, patients on social media (N = 2 patients) valued the flexibility of being able to decide when to start or break from treatment to fit in with other life events such as holidays or important family occasions.
Summary/Conclusion: The patient perspective on participation in treatment decisions is an important factor in the MM patient journey, and our research showed that, in published literature and on social media, patients appreciate involvement in deciding treatment options. Our review highlights the importance of further understanding patient perspectives on their role and input into treatment decision making with the health care professional; patients value inclusion in the process, and this is an area that is important for improving the overall quality of care for the patient.

PB1666 BORTEZOMIB, LENALIDOMIDE, AND DEXAMETHASONE (VRD) AS FIRST LINE THERAPY IN MULTIPLE MYELOMA PATIENTS. REAL LIFE EXPERIENCE IN A SINGLE INSTITUTION.

D. De Miguel Llorente [1,*], B. Merchan [1], I. Nuevo [1], A. Gil [1], M. Mora [1], N. Golbano [1], A. Vazquez [1], H. Guillen [1], A. B. Santos [1]

[1]Hematologia, H.U. Guadalajara, Guadalajara, Spain

Background: Achieving and maintaining high-quality response is the treatment goal for patients with newly diagnosed multiple myeloma (NDMM). Nowaday different schedaules of bortezomib, lenalidomida and dexamethasone are using. The phase 3 PETHEMA/GEM2012 study, in ≤ 65 years old with NDMM, is evaluating bortezomib (subcutaneous) + lenalidomide + dexamethasone (VRD) for 6 cycles. The ≥ very good partial response rates were 70.4% after induction. The complete response rate of 33.4% after induction in the intent-to-treat (ITT) population. Rates of undetectable minimal residual disease (median 3 × 10–6 sensitivity) in the ITT population was 28.8%.
Aims: We want to know the efficacy and safety of the induction therapy with VRD schedule in frail and fit NDMM patients in our institution.
Methods: we reported 34 NDMM patients who received VRD induction therapy since september 2015 until november 2020. All patients received first line treatment with VRD, which consisted of bortezomib 1.3 mg/m2 (subcutaneous) on days 1, 4, 8, and 11 of each cycle; lenalidomide 25 mg/day on days 1 to 21; and dexamethasone 40 mg on days 1 to 4 and 9 to 12 at 4-week intervals for 6 cycles (maximum or until better response). Thromboprophylaxis with low molecular weight heparin was mandatory. Antiviral prophylaxis was also required. MRD (median limit of detection, 3 × 10–6) was analyzed after induction using next generation flow following EuroFlow standard operation protocols as defined by the IMWG. Demographic characteristics are shown in Figure 1.
Results: Results of efficacy and safety are shown in Figure 1. High-risk cytogenetics, defined as t(4;14), t(14;16), gain 1p, and/or del(17p) (p53 deletion), were reported in 9 patients.

N= 34 (evaluable 31)	Follow up median 20 months (5-66)
Age (median)	62 (39-80) > 75 years old (29%) >70 years old (34%)
High risk Cytogenetic*	9 (26%)
Received Cycles (median)	4 (2-6)
Overall response	100%
Response	MRD—^ 6 (27 %) (after induction therapy) Very Good partial response (VGPR) 9 (29%) Complete response (CR) 22 (71%)
Progression free survival (PFS)	High Risk: 13 months (7-26 m) Overall: no reached (NR)
Dose Modifications	5% cycles (Peripheral neuropathy G3, Neutropenia G4, Diarrhea, infection, thrombosis)

Summary/Conclusion: 1) VRD is an effective and well-tolerated regimen for induction in NDMM with deepening response throughout induction.
2) VRD was well tolerated in transplant-ineligible patients.
3) High risk cytogenetic patients responded to treatment, but they need a long time better strategy.

PB1667 THE IMPACT OF COVID-19 ON PATIENT DISEASE EXPERIENCE: INSIGHTS FROM SOCIAL MEDIA POSTS CONTRIBUTED BY PATIENTS WITH MULTIPLE MYELOMA

R. Crawford [1,*], T. Bell [2], C. Levy [1], C. Mamolo [3], M. Lyall [1], A. Neuhof [4], A. Heyes [1]

[1]RTI Health Solutions, Manchester, United Kingdom, [2]Pfizer Inc., New York, [3]Pfizer Inc., Groton, United States, [4]Pfizer Pharma GmbH, Berlin, Germany

Background: Coronavirus disease 2019 (COVID-19) is rapidly spreading; high infection and mortality rates have resulted in extreme restrictions on individuals' liberties and freedom of movement, which are particularly salient for individuals with pre-existing conditions affecting health related quality of life. Patient-reported information (PRI) shared on social media provides an opportunity to access real-time data to better understand patients' perspectives outside the formal research context.
Aims: The aim of this study was to explore the impact of COVID-19 on patients, focusing on analyzing relevant social media posts to better understand the patient experience of multiple myeloma (MM) during the COVID-19 pandemic.
Methods: Searches were conducted of two patient advocacy websites (Patient Power, Myeloma Crowd) and YouTube to identify individual social media posts. English-language posts were reviewed if shared by adults with a self-reported MM diagnosis, with content relevant to the impact of COVID-19 on their experiences of MM. A pragmatic literature review was also conducted to identify articles on the impact of COVID-19 on general patient disease experience and use of social media for research during the pandemic.
Results: Six social media posts (9 individuals [4 male/5 female]) were identified that met the review criteria (7 individuals provided >1 source of data). Four articles were identified as pertinent to humanistic challenges associated with disease management and use of social media for research during the pandemic. Patients with MM encounter additional challenges associated with the pandemic. The PRI data highlighted exacerbation of the psychosocial impact of MM by the pandemic; patients expressed concern about increased vulnerability to infection due to previous treatment toxicities, plus fear and anxiety regarding possible virus transmission. PRI data reported that patients with MM took additional precautions to limit physical contact while attempting to maintain social interactions; already restricted by MM. Both data sources identified that patients encountered disruption/delays to their medical management and treatments. Although the pandemic has been a catalyst for development of telemedicine strategies to provide efficient management, delays/restrictions on treatments (e.g., transplants for MM) and suspension of development of innovative treatments may have deleterious effects for disease management. However, COVID-19 has also provided positive opportunities. Patients' previous experience of MM treatment–related immunosuppression had provided preparation for dealing with COVID-19. Articles reporting on patients' experiences in general noted that medication adherence during the pandemic has reportedly improved for patients with respiratory conditions. Social media has been utilized as a strategy for patient research during the pandemic, resulting in the formation of research groups—i.e., the COVID-19 Global Rheumatology Alliance—as a way of studying the effects of COVID-19 on patients with rheumatic disease.
Summary/Conclusion: PRI can provide timely access to preliminary information on changes to the patient disease experience not easily accessed by traditional research methods. Findings from the targeted search of patients in general and social media posts from patients with MM illustrated that patients with pre-existing diseases encounter challenges due to COVID-19 that can further disrupt their daily lives (e.g., social functioning, medical management) and impact their psychological well-being (e.g., anxiety, fear).

PB1668 THE PATIENT EXPERIENCE OF MULTIPLE MYELOMA: SYMPTOMS AND HEALTH-RELATED QUALITY OF LIFE

C. Levy [1,*], T. Bell [2], M. Lyall [1], C. Mamolo [3], A. Neuhof [4], R. Crawford [1], A. Heyes [1]

[1]RTI Health Solutions, Manchester, United Kingdom, [2]Pfizer Inc., New York, [3]Pfizer Inc., Groton, United States, [4]Pfizer Pharma GmbH, Berlin, Germany

Background: Patients with multiple myeloma (MM) report considerable disease- and treatment-related impacts on their health-related quality of life (HRQOL) despite improvements in treatment strategies over the past 5 years. Patient-reported information (PRI) shared on social media provides a unique opportunity to explore unsolicited patient data to understand patients' perspectives outside of the formal research context.
Aims: A combined research methods approach was conducted of a review of published literature and social media posts to better understand the MM patient disease and treatment experience.
Methods: Targeted searches of PubMed and PsycINFO were conducted from 2010 to November 2020 to identify articles describing the humanistic burden of MM and its treatment from the patient perspective. Titles and abstracts were screened for relevance by two experienced reviewers, with relevant articles included in the review. In parallel, PRI derived from social media posts from five patient advocacy websites and YouTube were included. English-language posts were reviewed if shared by adults with a self-reported MM diagnosis and content was relevant to patient MM and treatment experience. Patients' demographic and disease characteristics were extracted from posts (where available), and the posts were analyzed thematically.
Results: A total of 27 articles and 138 posts were included in the final review (79 videos/58 blog posts/1 podcast). The review included PRI from 76 individuals (38 males/38 females). Seven contributors provided more than one source of data (i.e., blog and/or video). Key symptoms reported by the PRI: pain (n = 24), fatigue (n = 10), fractures (n = 9), and infections (n = 6). Substantial impairments to patients' HRQOL were reported in terms of patients' physical functioning (n = 11), emotional and psychological well-being (n = 26), relationships (n = 13), and work (n = 8). Patients with MM tend to experience multiple treatments during their MM journey in pursuit of remission. Patients reported that the impact of their MM treatments can often be more detrimental to their HRQOL than the disease itself (n = 2). Patients can experience a range of long-lasting and durable side effects from their different MM treatments, including neuropathy (n = 3), fatigue (n = 3), nausea (n = 2), and cognitive dysfunction (n = 2). Steroids (n =7) were particularly burdensome for patients due to the numerous and sometimes severe side effects, including sleep disturbances, weight gain, and the detrimental effect on patients' mood. Treatment expectations were reported by 6 patients in the PRI: hopes and expectations of delaying disease progression and prolonging life are often counterbalanced by the negative consequences and burden of therapies (e.g., side effects/social isolation/financial impact).
Summary/Conclusion: The combination of published literature and PRI provided valuable and rich information on the patient experience and perceptions of MM and its treatment. Frequently reported themes in PRI included the symptom burden and HRQOL impact of MM as well as the burden associated with treatment. These key issues were also illustrated by results of the literature review. The data highlighted that the MM patient journey is multifaceted; patients' HRQOL is impeded not only by the disease but also by the treatment-related side effects, which can have a substantial and long-lasting impact on patients' lives.

PB1670 PHASE 2 MARCH STUDY OF ORAL ATG-010 PLUS LOW DOSE DEXAMETHASONE IN CHINESE PATIENTS WITH RELAPSED/REFRACTORY MULTIPLE MYELOMA PREVIOUSLY EXPOSED TO AN IMMUNOMODULATORY AGENT AND A PROTEASOME INHIBITOR

W. Fu [1,*], Z. Xia [2], C. Fu [3], W. Chen [4], G. An [5], Z. Cai [6], B. Fang [7], H. Jing [8], Y. Wei [9], J. Weng [10], C. Chang [11], L. Chen [12], S. Gao [13], X. Chen [14], F. Li [15], Z. Liu [16], J. Liu [17], Y. Jiao [18], A. Wang [19], Z. Yu [19], L. Qiu [20]

[1]Shangai Changzheng Hospital, Shanghai, [2]Sun Yat-sen University Cancer Center, Guangzhou, [3]The First Affiliated Hospital of Soochow University, Suzhou, [4]Beijing Chao-Yang Hospital, Beijing, [5]Institute of Hematology and Blood Diseases Hospital, Tianjin, [6]The First Affiliated Hospital, College of Medicine, Zhejiang University, Hangzhou, [7]Henan Cancer Hospital, Zhengzhou, [8] Peking University Third Hospital, Beijing, [9]Nanfang Hospital, Southern Medical University, [10] Guangdong Provincial People's Hospital, Guangzhou, [11]Shanghai Jiao Tong University Affiliated Sixth People's Hospital, Shanghai, [12]Jiangsu Province Hospital, First Affiliated Hospital of Nanjing Medical University, Nanjing, [13]the First Affiliated Hospital of Jilin University, Changchun, [14]Xi Jing Hospital affiliated to the Fourth Military Medical University, Xi'An, [15] the First Affiliated Hospital of Nanchang University, Nanchang, [16]Shengjing Hospital of China Medical University, Shenyang, [17]the Third Xiangya Hospital of Central South University, Changsha, [18]Antengene Therapeutics Ltd., Beijing, [19] Antengene Therapeutics Ltd., Shanghai, [20]Institute of Hematology and Blood Diseases Hospital, Chinese Academy of Medical Science and Peking Union Medical College, Tianjin, China

Background: ATG-010 (Selinexor) is a novel, oral selective inhibitor of nuclear export inhibiting exportin 1. In preclinical and clinical studies, ATG-010 has demonstrated activity against multiple myeloma (MM). ATG-010 (80 mg biweekly) plus dexamethasone (20 mg biweekly) (Sd) was approved by US FDA for treatment of patients(pts) with penta-refractory MM in 2019 based on the STORM study. MARCH is a single arm, Phase 2 study to assess efficacy and safety of Sd in Chinese pts with relapsed/refractory MM (RRMM) (NCT03944057).
Aims: To evaluate efficacy and safety of oral ATG-010 plus low dose dexamethasone in Chinese pts with RRMM.
Methods: Enrolled pts have been previously treated with and refractory to proteasome (PI), immunomodulatory agent (IMiD), and the last line of therapy. Sd is administered in 4-week cycles. Primary endpoint

is overall response rate (ORR) per independent review committee. The total planned enrollment of 82 pts provides ~80% power to test against H_0 of 15% ORR at one-sided α of 0.025. This abstract provides data from a planned analysis of the first 60 treated pts.
Results: As of 13 Oct 2020, 18 (30%) of the 60 pts were on treatment. Median follow-up was 9.5 months (mo) (range: 1.9-12.8).
Median age was 61 years (range 43-82; 42% > 65). Pts had received a median of 5 (range 1-16) prior MM regimens, with following baseline risk factors: 72% R-ISS II/III, 70% cytogenetic abnormalities, 22% del (17p13),20% renal impairment, 15% prior CAR-T therapy, and 25% pre-treated with daratumumab (considered 'triple-class exposed').
ORR was 26.7% (95% CI: 16.1, 39.7). Median DOR was 4.6 mo (95% CI: 1.42, NE). Median PFS was 3.7 mo (95% CI: 1.92, 4.66). Median OS was not reached; 9-mo OS rate was 68.5%. ORR was 33.3% in triple-class-exposed pts, and 44.4% in pts with prior CAR-T. ORR was generally consistent across subgroups.
Common TEAEs of any grade included: thrombocytopenia (87%), nausea (87%), leukopenia (85%), anemia (85%), lymphopenia (78%), neutropenia (73%), weight loss (72%), hyponatremia (65%), decreased appetite (63%), asthenia (62%)/fatigue (17%), hyperglycemia (53%), vomiting (52%), hypocalcemia (38%), hypokalemia (30%), diarrhea (30%), pneumonia (27%). Common TEAEs of Grade ≥ 3 included: anemia (60%), thrombocytopenia (55%), leukopenia (42%), lymphopenia (42%), neutropenia (38%), hyponatremia (28%), and pneumonia (23%). Thirty pts (50%) had TESAEs, including (>3%): thrombocytopenia (15%), pneumonia (15%), anemia (6.7%), hyponatremia (3.3%). Eight pts (13.3%) had TEAEs leading to treatment discontinuation, including (>2%): thrombocytopenia (5%) and pneumonia (3%). Three fatal TEAEs were pneumonia, intracranial hemorrhage and sudden death (1 each).
Summary/Conclusion: In Chinese RRMM pts refractory to both IMiD and PI, with a highly unmet medical need, MARCH confirms the efficacy of Sd as a promising new oral therapeutic option with a manageable safety profile, which is consistent with STORM.

PB1671 VALIDATION OF THE MYRADS REPORTING CRITERIA USING DATA FROM A PROSPECTIVE IMAGING STUDY IN PLASMA CELL DYSCRASIAS (LOOMIS).

G. Nador [1,*], S. Gooding [2], C. Rodgers [3], C. Pereira [2], N. Patel [2], M. K. Javaid [2], H. Getu [4], R. Soundarajan [2], R. Mills [2], J. Kothari [1], S. Varghese [1], R. Brouwer [1], D. Peppercorn [5], A. Shah [5], K. Ramasamy [1]

[1]Oxford University Hospitals NHS Foundation Trust, [2]University of Oxford, Oxford, [3]University of Cambridge, Cambridge, [4]Oxford University Hospitals, Oxford, [5]Hampshire Hospitals NHS Foundation Trust, Basingstoke, United Kingdom

Background: Cross-sectional MRI imaging has a growing importance in the classification of plasma cell dyscrasias, and in the definition of multiple myeloma (MM) response or progression (Dimopoulos 2015, Chantry 2017). High sensitivity of a diffusion-weighted whole body MRI (DW-WBMRI) in the early detection of bone marrow changes has been acknowledged in the revised IMWG diagnostic criteria (Rajkumar et al, 2014). A multidisciplinary imaging and haematologist expert panel has supported the measurement of cell density using an apparent diffusion coefficient (ADC) for the early diagnosis of changes in bone marrow infiltration and myeloma focal lesions (Messiou 2019). Recommendations for myeloma diagnosis and response assessment has been published (MYRADS) recently. We used data from a prospective plasma cell dyscrasias imaging study (NCT03951220) to validate these recommendations.
Aims: This prospective imaging study used a DW-MRI protocol to quantify longitudinal changes in tumour burden and bone disease. To improve sensitivity of bone marrow lesion identification healthy volunteers (HV) were also recruited. One of the study aims is to validate MYRADS protocol recommendations.
Methods: To validate the recommendations in the MYRADS protocol we took an unselected population of 18 MM pts, 12 MGUS pts and 6 HVs recruited between April 2018 and January 2019. See Table 1 for participants' characteristics. After enrolment patients had a DW-WBMRI abbreviated protocol on the 3T Avanto MRI scanner (Siemens, Germany). In 18 participants with MM and MGUS the scan was repeated after 6 months using the same protocol. Qualitative assessment of bone marrow changes were made using the MYRADS recommendations. In each positive scan (Myeloma patients) we used the changes in ADC value (quantitative) of a single lytic lesion (MYRADS response assessment categories) and matched them with the serological parameters of disease.
Results: All 36 participants safely completed the protocol at baseline. Ten scans (28%) were positive for vertebral fractures (1 to 8 vertebral bodies involved); pathological fractures were associated with known active myeloma only (2 NDMM, 2 RRMM; new fractures in 3/4 cases). Focal lesions were identified in 7 (19%) baseline scans (3 NDMM, 3 RRMM, 1 MGUS), mostly affecting spine and pelvis. Other findings included extraskeletal involvement (2/36), cord compression (1/36) and previous vertebral interventions (3/36 vertebroplasty, 1/36 stabilisation, 1/36 radiotherapy). Bone marrow appearance was normal in all HV scans, focal in 1/12 MGUS scans and otherwise normal, whereas a focal infiltrative pattern and an indeterminate pattern were demonstrated in 2/9 SMM cases. 4/9 of active myeloma cases showed a focal infiltrative pattern. For response assessment, no change was noticed in the patients with normal bone marrow pattern at baseline. No change was noticed in a patient with focal infiltrative pattern who received anti-myeloma treatment with lack of serological response, whereas two patients achieving a complete serological response were in the "highly likely to respond" category based on the change in bone marrow pattern and ADC measurement.

Table 1. Study population

n= 36	
Age *(median)*	40-82 *(65)*
Gender *(%)*	21 M *(58)* 15 F *(42)*
Diagnosis *(%)*	12 MGUS *(33)* 9 SMM *(25)* 5 NDMM *(14)* 4 RRMM *(11)* 6 Healthy volunteers *(17)*
Diagnosis date	April 2014 – February 2019
ISS at diagnosis *(%)* – myeloma cases	10 ISS I *(56)* 8 ISS II *(44)*
Paraprotein/light chain type *(%)* – myeloma, MGUS cases	22 IgG *(74)* 5 IgA *(17)* 1 IgM *(3)* 1 kappa *(3)* 1 lambda *(3)*
Calcium levels at baseline *(%)* – myeloma, MGUS cases Normal range 2.2-2·6 mmol/L	25 normal *(83)* 3 high *(10)* 2 low *(7)*
Alkaline phosphatase levels at baseline *(%)* – myeloma, MGUS cases Normal range 30 – 130 IU/L	28 normal *(93)* 2 low *(7)*

Summary/Conclusion: Using MYRADS recommendations, WB DW MRI serves as a good qualitative discriminator between HV/MGUS and myeloma patient cohorts. In the myeloma cohort, we validated MYRADS recommendations to demonstrate patterns of disease infiltration and disease response categorisation. We aim to report results at the meeting from a larger cohort in the ongoing study.

PB1672 REDEFINING OUTCOMES IN MULTIPLE MYELOMA IN COVID-19 INFECTED PATIENTS. RECONSIDERING THE THROMBOSIS AND INFECTIVE RISK.

H. Fernandez-Leyva [1,*]

[1]Haematology, NHS, North Warnborough, United Kingdom

Background: There role and factors about susceptibility to the outcome of acute respiratory syndrome coronavirus 2 (SARS-CoV-2) infected patients with multiple myeloma (MM) with a thrombotic event presents numerous challenges. As MM is a disease of the elderly, characterised by immunosupresion, hence, patients with MM might be considered more susceptible to severe complications from COVID-19.
Aims: To evaluate the outcomes in the COVID myeloma hospitalised population.
Methods: We undertook this retrospective study to characterise the baseline and outcome data of COVID-19 infection in 50 patients with plasma cell disorders, collected by two different Trust institutional analysis to identify potential predictors of outcome. Apart from the specific MM-related symptoms, most patients display Infections and thrombosis as more common disease complications, and unfortunately remain a major cause of death.
Patients with MM and confirmed COVID-19 diagnosed between January 2020 to January 2021, Furthermore, corticosteroids, and especially dexamethasone, are used as for hospitalised MM patients.
Results: The 39% presented with severe COVID-19 (need of oxygen and/or intensive care support - admission). Severe COVID-19 was associated

with more advanced age (≥65 years) (odds ratio 3.72 [95% CI 1.79-7.71]). 39.7% with severe COVID-19 were receiving or had recent (≤ 12 months) treatment for MM at the time of COVID-19 versus (patients with mild stable disease. Hospitalisation rate for severe COVID-19 was lower ($p < 0.05$) for patients on oral regimen (IMIDs) and good control paraprotein versus those on other regimens or off treatment.
the median age was 71 years, and all patients received at least one line of previous treatment. Approximately 36% were recently diagnosed (2019-2020), and only 32% of patients were receiving first-line therapy. The mortality associated to admission were approximately 6 % of hospitalised patients. More of the half of the patient (54%) had at leat one previous cardiovascular positive past medical history. In addition, patients were long hospitalised or partially immobilised or 23% patients received previous ESAs (EPO) or severe renal impairment. The principal thrombotic event were segmental pulmonary embolism and in less proportion STEMI, renal infarct or stroke. In the mean time they received LMWH prophylaxis was 4.7 months. After reevaluation of thrombotic risk, most of the patients maintained LMWH with more strict control and in the group with good outcomes switched to DOAC. There were no cases of severe bleeding complications with the use of adequate thromboprophylaxis. Univariate analysis identified age, International Staging System stage III (ISS-III), renal disease, high-cytogenetics risk disease, delays (toxicities) or suboptimal myeloma control (active or progressive disease), and more than two co-morbidities as risk factors for higher rates of death. Neither history of transplant, including within a year of diagnosis, nor other anti-MM treatments were associated with outcomes.
Summary/Conclusion: Age and co-morbidities did impact on mortality, alluding to a relevant role of MM and immunodeficiency. Among hospitalised patients, We did not observe any significant correlation between active PI, IMiD, anti-CD38 monoclonal antibody, alkylating agents, steroids, or other treatments and the COVID-19 outcome.
The management of MM in the era of COVID-19 requires careful consideration of individual approach- and disease-related factors to decrease the risk of acquiring COVID-19 infection, while not compromising disease control through appropriate MM treatment.

PB1673 REAL-WORLD TREATMENT PATTERNS AND CLINICAL OUTCOMES IN PATIENTS WITH MULTIPLE MYELOMA IN DIFFERENT GEOGRAPHICAL REGIONS: FINDINGS FROM A SYSTEMATIC LITERATURE REVIEW

E. Zamagni [1,*], F. E. Davies [2], R. Chawla [3], S. Dhanasiri [4]

[1]Univeristy of Bologna, Bologna, Italy, [2]NYU Grossman School of Medicine, Clinical Myeloma Program, Perlmutter Cancer Center, New York, United States, [3]Accuscript Consultancy, Ludhiana, Punjab, India, [4]Celgene International Sàrl, a Bristol-Myers Squibb Company, Boudry, Switzerland

Background: The introduction of new agents and classes of therapy has improved outcomes in patients with multiple myeloma (MM). However, there is limited understanding of the variations in use of new therapies across different geographical regions and the extent to which these variations translate into improved outcomes.
Aims: To perform a systematic literature review (SLR) to investigate trends in MM treatment patterns and clinical outcomes reported in published real-world studies.
Methods: Searches were performed in PubMed and EMBASE from January 2010 to November 2020 to identify English-language publications reporting the efficacy and safety of therapies for patients with newly diagnosed MM (NDMM) and relapsed or refractory MM (RRMM) in any geographical region. Relevant conferences in 2019 and 2020 were also searched. The citations were systematically screened in 3 stages following predefined eligibility criteria (PICOs). Data were analysed in MS excel and the relevant data extracted for further interpretation.
Results: A total of 472 publications were identified; 60% were published in 2016 or later. Most reported findings for studies conducted in Europe (n=180 [38%]), North America (n=98 [21%]), or Asia (n=171 [36%]). Almost half (n=222 [47%]) involved patients with RRMM, 41% (n=195) included patients with NDMM and 12% (n=55) had a mix of MM populations. A total of 149 publications described multicentre/claims database/registry studies involving >50 patients. Of these, 28 reported median OS and 23 reported median PFS data. Median OS was 5.2–60.0 months in patients with NDMM and 5.4–41.9 months in patients with RRMM. Median PFS was 10.3–33.6 months in patients with NDMM and 4.9–27.6 months in patients with RRMM. Differences in the most commonly cited regimens were noted between geographical regions (**Table**). In studies reporting outcomes in patients with NDMM, bortezomib-based regimens predominated in Europe and Asia, whereas in US studies, lenalidomide + dexamethasone (Rd)–based regimens and bortezomib-based regimens were equally described. The most commonly described bortezomib-based regimens in Europe and Asia were bortezomib + dexamethasone (Vd), VCd, VMP, and VTD. In studies reporting outcomes in patients receiving treatment for RRMM, Rd and Rd-based triplets (including RVd, KRd, and IRd) were the most commonly used regimens across the 3 regions. Bortezomib-based regimens described in >4 European studies included Vd, VCd, and VTD. Few US or Asian studies described bortezomib-based regimens. Differences in efficacy outcomes according to geographical regions will be presented.

Table. Number of studies [n=109] reporting outcomes with different regimens per geographical region

Regimen	NDMM				RRMM		
	North America	Europe	Australia + Asia	Latin America	North America	Europe	Australia + Asia
Lenalidomide-based							
Rd	5	3	1	0	0	16	6
RVd	6	0	2	0	2	3	0
KRd	0	0	1	0	3	5	0
IRd	0	0	1	0	1	4	1
Bortezomib-based							
Vd	5	7	9	0	1	10	2
CyBorD	1	0	2	2	0	0	0
VCd	3	6	5	1	1	4	1
VMP	0	6	7	0	0	2	0
VTD	2	6	6	2	0	6	1
PAD	0	3	6	0	0	3	0
Others							
KPd	0	0	0	0	1	0	1
Kd	0	0	1	0	2	2	1
DARA	0	0	0	0	2	3	0
CTD	0	5	3	0	0	2	2
MPT	0	4	3	0	0	1	2
VAD	1	6	11	0	0	2	2

CyBorD, cyclophosphamide-bortezomib-dexamethasone; CTD, cyclophosphamide-thalidomide-dexamethasone; DARA, daratumumab; IRd, isazomib-lenalidomide-dexamethasone; Kd, carfilzomib-dexamethasone; KPd, carfilzomib-pomalidomide-dexamethasone; KRd, carfilzomib-lenalidomide-dexamethasone; MPT, melphalan-prednisolone-thalidomide; PAD, bortezomib-doxorubicin-dexamethasone; Rd, lenalidomide-dexamethasone; RVd, lenalidomide-bortezomib-dexamethasone; VAD, vincristine-doxorubicin-dexamethasone; VCd, bortezomib-cyclophosphamide-dexamethasone; Vd, bortezomib-dexamethasone; VMP, bortezomib-melphalan-prednisone; VTD, bortezomib-thalidomide-dexamethasone.

Summary/Conclusion: The findings from the SLR indicate that, over the last 10–15 years, there have been differences in the reported use of the new therapies and regimens in different geographical regions, particularly between North America vs Europe and Asia. Reported survival outcomes differ widely between different studies, possibly reflecting differences in regimens used and patient management. Understanding these differences in real-world clinical practice and their outcomes will help inform clinicians of the optimal use of available treatments, identify unmet needs, and help further improve long-term outcomes for patients.

PB1674 PARATHYROID HORMONE LEVELS AND PROGNOSIS IN MULTIPLE MYELOMA?

J. S. L. Tung [1,*], G. Vassiliou [1]

[1]Department of Haematology, Cambridge University Trust, Cambridge, United Kingdom

Background: Based on anecdotal reports of raised serum parathyroid hormone (PTH) levels in some patients with multiple myeloma, we set out to investigate if this is a common finding.
Aims: To establish if parathyroid hormone levels act as predictors of outcome in multiple myeloma.
Methods: Patients with newly diagnosed multiple myeloma at Cambridge University Hospitals between 2015 and 2021 were identified from electronic records (EPIC). Blood parameters including paraprotein, PTH, beta-2 microglobulin (β2M), albumin and others, recorded near the time of diagnosis were collected. We use the International Staging System (ISS), defined as, ISS stage I: β2M < 3.5 mg/L and albumin ≥ 35 g/dL, ISS stage II: neither I or III, ISS stage III: β2M ≥ 5.5 mg/L and our novel 'ISS+PTH' score, calculated from a sum of: β2M < 3.5 mg/L (0), ≥ 3.5 mg/L (1); PTH < 10 pmol/l (0), ≥ 10 pmol/l (1); albumin < 35 g/dL (1), ≥ 35 g/dL (0). We use Pearson correlation and Kaplan-Meier survival analyses to investigate factors that correlate with PTH levels and assess their impact on prognosis.
Results: We identified 1066 patients with multiple myeloma (640 men/426 women). Median age at diagnosis was 70 years and median survival was 832 days. Of these, 182 had PTH levels assayed at diagnosis. Median serum PTH level was 4.77 pmol/l (range 0-103.3 pmol/l) and 35 patients had PTH >10 pmol/l. Median survival for those with PTH >10 pmol/l was 859 days, compared to those with PTH <10 pmol/l, with a median survival of 1495 days ($p<0.229$). PTH level significantly correlated with creatinine and other parameters (Table 1A).

To understand if PTH levels can enhance the predictive power of the International Staging System (ISS), we compared the performance of the ISS score to a modified score including PTH as a variable, applied to participants for whom all relevant tests were available. We noted that β2M and albumin levels correlated significantly to each other (r=-0.37), raising the possibility that additional variables could be used to refine prognosis. Therefore, we tested if PTH could be added to ISS and re-stratified patients into 4 categories (Table 1B). Upon incorporation of PTH, we found that distribution across the classes was similar, but the worse prognostic group faired significantly worse (Table 1B). As noted by the mean survival differences between ISS and ISS+PTH, we observed better separation of the categories on survival curves by the latter. Of particular note, 17 patients with a very high PTH (>15 pmol/l) had a significantly poorer mean survival of 368 days and high median values for albumin (28.5 g/L), β2M (12.2 mg/L), creatinine (258 umol/L) and Corrected Calcium (2.35 mmol/L).

(A) Significant Correlations to PTH	R value	Unsignificant Correlations to PTH	R value
Creatinine	0.520**	Phosphate	0.110
Urea	0.439**	Age at diagnosis	0.079
Potassium	0.326**	ALP	0.043
β2M & Lambda free light chain	0.192*	Sodium	0.033
Vitamin D	-0.185*	Albumin	0.015
Adjusted calcium	-0.222*	Kappa/Lambda ratio	-0.023
Paraprotein	-0.226*	Survival	-0.128
(B)		Number of patients	Mean survival
Score (ISS)	I	67 (23.8%)	1651
	II	192 (68.3%)	1360
	III	22 (7.8%)	1152
Total score (ISS+PTH)	0	50 (27.6%)	1480
	1	65 (35.9%)	1712
	2	54 (29.8%)	1108
	3	12 (6.6%)	823

Table 1: Comparison of ISS and ISS-PTH prognostic scores
A. Correlations to PTH, * significant. **B.** Numbers per class and mean survival (days) for patients classified using the ISS and ISS+PTH scores.

Summary/Conclusion: Collectively, our findings show that PTH levels correlate with other parameters and do not significantly improve the prognostic ability of the ISS score overall, but do identify a group with particularly poor prognosis. PTH has a very short half-life of 5 minutes, as it is rapidly cleared by the liver and kidney, so the correlation with creatinine and urea may allude to renal failure being at least partially responsible for PTH accumulation. In addition, our findings show that PTH levels in multiple myeloma are often inappropriately elevated in relation to the prevailing calcium level, a factor that can contribute to the cytokine-driven myeloma bone disease. Therefore, will next investigate the impact of inappropriately raised PTH on myeloma bone disease per se and any clinical/therapeutic implications this may have on patient management.

PB1675 DEMOGRAPHIC, CLINICAL, AND PROGNOSTIC CHARACTERISTICS OF PRIMARY PLASMA CELL LEUKEMIA IN LATIN AMERICA, A STUDY OF GELAMM GROUP.

C. Peña [1], M. Roa [1,*], N. Schutz [2], E. Riva [3], J. Vasquez [4], C. Seehaus [2], A. Ramírez [5], R. Vengoa [6], Y. Figueredo [7], P. Ochoa [8], P. Duarte [9], H. Martinez-Cordero [10], O. Ríos [11], J. Ramírez [12], V. Bove [13], M. Espinoza [14], G. Rodriguez [15], G. Remaggi [16], M. E. Enciso [17], D. del Carpio [18], D. Fantl [2]

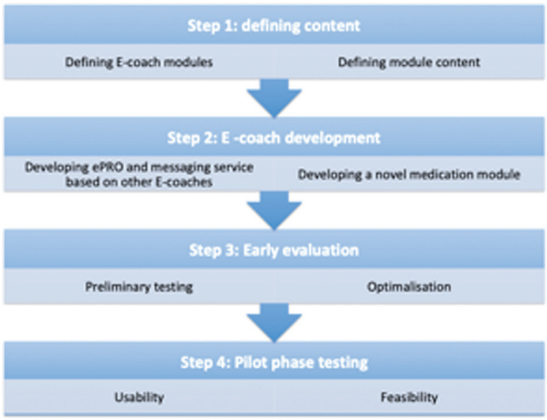
Background: Primary plasma cell leukemia (pPCL) is an infrequent plasma cell disorder that accounts for 1.3%–3.4% of all plasma cell dyscrasias. Its prognosis is poor, with a median survival of 36 months, even after the use of novel drugs. The ideal treatment is not well established. There is scarce data on this disorder in Latin America (LA).

Aims: The aim of this study was to describe demographic, clinical and prognostic characteristics of newly diagnosed pPCL in LA.
Methods: This is a retrospective, multicentric observational study. Patients from 9 countries of LA with diagnosis of pPCL between 2012 and 2020 according to current definition were included. Demographic and clinical data were collected from clinical records. Survival curves were estimated using the Kaplan–Meier method. Uni- and multivariable Cox proportional hazards models were used to assess risk factors.
Results: Sixty patients from Chile, Argentina, Ecuador, Cuba, Perú, México, Paraguay, Colombia and Uruguay were included. Median age was 55 years (range 28 to 92), 53% were male. Anemia was present in 83% at diagnosis (mean 8.1 g/dL), hypercalcemia in 47% (mean 11 mg/dL), renal failure in 50% (mean 2,6 mg/dL of creatinine), thrombocytopenia in 53% (mean 105.000/mm^3) bone lytic lesions in 80%. High LDH was observed in 72%. Extramedullary disease was reported in 28% of patients, 3 of them with CNS involvement. Type of paraprotein was IgG in 33%, IgA in 13%, light chain in 45% (55% Kappa), and not reported in 9%. Flow cytometry was performed in 78% of patients, and FISH and conventional cytogenetics in 28%.
Five patients died before receiving any specific treatment. Most patients (83%) were classified as eligible for transplant and received at least 1 cycle of treatment. Thirty-two patients received a bortezomib-based induction, and 17 an intensive chemotherapy-based approach, like VTD-PACE. The most used regimens were CyBorD in 26%, VTD-PACE in 22%, VAD in 16%, and CTD in 14%. Only 1 patient received daratumumab-based therapy. Five patients died during induction, and 12 achieved a complete remission. Twelve patients (24%) received an autologous transplant as consolidation, in 7 cases with tandem modality, and 19% had maintenance therapy. Eleven patients relapsed.
With a median follow up of 16 months, 35 patients (58%) died, and 12 patients remained in complete remission. Median progression free survival (PFS) was 11 months (CI95% 4-18) for the whole cohort, while in patients that receive a bortezomib-based treatment median PFS was 22 months (CI95% 8-73). Median overall survival (OS) was 18 months (CI95% 9-59), and not reached for patients with bortezomib-based induction.
In the multivariate analysis (Table 1) only proteosome inhibitor (PI)-based induction was an independent factor of improved OS.

	Overall Survival – Univariate Analysis			Multivariate Analysis		
Variable	HR	95% CI	p Value	HR	95% CI	p Value
Age > 60 years	1.18	0.58 - 2.39	0.645	1.54	0.66 – 3.60	0.315
Female Sex	1.62	0.82 – 3.20	0.163			
PS ECOG > 2	1.28	0.59 - 2.79	0.525			
Extramedullary Disease	**2.27**	**1.05 – 4.93**	**0.036**	1.09	0.44 – 2.71	0.843
Renal Failure (Cr > 2 mg/dl)	1.11	0.56 – 2.23	0.750			
Anemia (Hb < 10 g/dl)	2.02	0.70 – 5.81	0.191			
PC in peripheral blood > 20.000/mm3	1.26	0.54 – 2.95	0.584			
Platelets < 100.000/ mm3	1.58	0.78 – 3.23	0.202			
Calcium > 11 mg/dl	0.85	0.42 – 1.71	0.654			
High LDH	1.61	0.71 – 3.60	0.247			
Albumin < 3.5 g/dl	**2.90**	**1.34 – 6.25**	**0.007**	2.18	0.84 – 5.68	0.109
PI-based treatment	**0.35**	**0.17 – 0.74**	**0.006**	**0.40**	**0.17 – 0.94**	**0.036**
Maintenance treatment	**0.25**	**0.09 – 0.68**	**0.007**	0.32	0.10 – 0.99	0.32
CR or better	**0.26**	**0.08 - 0.89**	**0.032**	0.28	0.07 – 1.10	0.07

Summary/Conclusion: As reported internationally, LA patients with pPCL were younger than myeloma patients, and clinical features at diagnosis show a more aggressive disease. Of notice, they show more bone lesions than classically described. Reasons for this finding have not been addressed in this analysis. Whether this can be attributed to the use of more sensible imaging techniques or to late diagnosis remain to be elucidated. Frontline therapies were heterogeneous, and autologous transplant were performed in only one quarter of patients. Reasons for 76% of potential candidates not being transplanted merit further analysis. OS is still very poor. Bortezomib-based therapies were associated to improved OS.



PB1676 DEVELOPING A MULTI-MODULE E-HEALTH APPLICATION FOR PATIENTS WITH MULTIPLE MYELOMA RECEIVING COMPLICATED TREATMENT REGIMENS.

P. Geerts [1,*], J. Eijsink [2], P. ter Horst [2], C. Boersma [3], M. Postma [3]

[1]Internal medicine, [2]Clinical Pharmacy, Isala, Zwolle, [3]Department of Health Sciences, University Medical Centre Groningen, Groningen, Netherlands

Background: Digital applications in healthcare (e-health) are increasingly used. In solid oncology, implementing electronic patient-reported symptom monitoring was associated with improved survival. Currently, medication support applications are not available. Patients with multiple myeloma are faced with complicated treatment regimens. They may receive various treatment lines containing several anti-myeloma and

supportive care medications. Treatment is based on tumor and patient characteristics, but also on patient preferences and side effects.
Aims: To explore the needs of patients with Multiple Myeloma and their health care providers, with regard to supportive care using eHealth. Additionally, to design an eHealth application to address these needs and evaluate its usability and feasibility.
Methods: This study was performed in a large non-academic hospital, collaborating with an experienced E-Coach developer. First, to define the current standard of care the Multiple Myeloma treatment pathway was identified within a value based healthcare (VBHC) trajectory. Second, health care providers' (physicians, nurses, pharmacists and supportive staff) needs were explored during five focus group sessions. Patients and their spouses participated in the third session. The focus group topic agenda was based on the VBHC trajectory outcome and on two surveys amongst 18 patients with Multiple Myeloma. The first survey explored the current experience with care delivery and the needs for the eHealth application. The second evaluated potential patient reported outcomes (PROs), based on the EORTC QLQ-C30, MARS-5 and patient reported experience measures (PREMs). Finally, the application, called the 'E-Coach', was developed in a multi step process (figure 1): step 1, defining content; step 2, e-coach development; step 3, early evaluation; and step 4, pilot phase testing.
Results: Two sets of PROs were defined. First, a large set of PROMs and PREMs to perform periodic evaluations at large intervals (e.g.: 3 or 6 months). Second, a short list of PROs and one blank space for personal suggestions to prepare outpatient clinic visits. The participants expressed a need for medication support and overview and for a messaging service. The application was developed, using several modules. The messaging and PRO questionnaire modules were integrated in already existing application modules. Additionally, the medication module was developed during an iterative process with the health care providers. Then, a first version of the Multiple Myeloma E-coach was tested in a pilot study. During eight weeks, the application was used by twenty patients and a clinical multidisciplinary team (clinicians, nurses and pharmacists). Eighty-three percent of participants were satisfied using the E-coach. Fifteen recommendations were done for improvements, such as individualizing the built-in tool to check when medicines had been taken. Some patients preferred to check every medicine they took; others preferred to check several at the same time. The health care providers recommended creating a dashboard, for overview of all PROs and medication adherence. Based on all recommendations, the E-coach was adapted.

Summary/Conclusion: Using an approach that involved all relevant stakeholders, we developed a multi-module E-coach for patients with Multiple Myeloma receiving complicated treatment regimens. Most notable, we developed a medication module for support and overview of medication. To further evaluate the E-coach, a randomized controlled trial is planned to compare implementation of the E-coach with regular care (EudraCT 2020-005267-31).

PB1677 IMMUNOPHENOTYPIC PROFILE AND CLINICAL CHARACTERISTICS OF PRIMARY AND SECONDARY PLASMA CELL LEUKEMIA

R. Bezděková [1,*], T. Jelinek [2], M. Stork [3], P. Polackova [1], L. Brozova [4], M. Almasi [5], I. Boichuk [3], M. Penka [1], P. Ludek [3], Z. Knechtova [3], S. Sevcikova [1], L. Rihova [1]

[1]Dept. of Clinical Hematology, University Hospital Brno, Brno, [2]Dept. of Clinical Hematooncology, University Hospital Ostrava, Ostrava, [3]Department of Internal Medicine, Hematology and Oncology, University Hospital Brno, [4]Institute of Biostatistics and Analyses, Faculty of Medicine, Masaryk University, [5]Dept. of Clinical Hematology, University Hospital Ostrava, Brno, Czech Republic

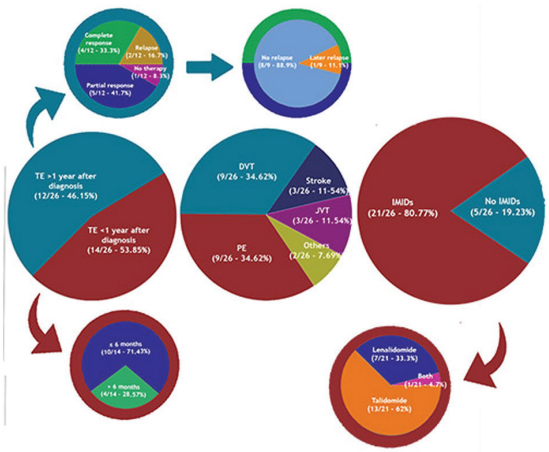
Background: Plasma cell leukemia (PCL) is rare, aggressive plasma cell (PC) disorder, characterized by presence of circulating PC (cPC) in peripheral blood (PB). PCL can be divided in 2 groups - primary PCL (pPCL) which originates *de novo* and secondary PCL (sPCL), a leukemic transformation of MM. Detection of cPC by flow cytometry (FC) is important for early diagnostics and for distinguishing PCL from reactive plasmacytosis as well, but less about PCs phenotype profile is known.
Aims: Analyses of differences in number and phenotypic profile PCs between pPCL and sPCL aiming at their association with clinical outcomes and evaluation of the prognostic value of PCs immunophenotype.
Methods: Investigation of PB and/or bone marrow (BM) of 18 pPCL and 15 sPCL patients was done by FC. Expression of surface antigens (CD19, CD20, CD27, CD28, CD44, CD56, CD81, CD117 and CD200) with intracellular nestin was studied. Medians of relative expression and positivity (cut-off 20%) were used.
Results: There were found no significant differences in clinical characteristics of pPCL and sPCL patients except increased level of platelets in pPCL compared to sPCL (median 129.5 vs 49.1x10^9L, p=0.004, respectively). Median OS was 17.6 months in pPCL, 0.9 months in sPCL; (p<0.001). Significantly higher number of cPCs was identified by FC when compared to morphology (26.7 vs 13.5%, p=0.02). The number of cPCs was lower in pPCL than in sPCL (25.1% vs. 30.2%), the number of PCs in BM was significantly lower in pPCL than in sPCL (39.2% vs. 64.9%; p=0.02).
Phenotypic profile of pPCL was very close to sPCL in PB and/or BM, although there were some alterations. Unlike pPCL, no CD19 and CD20 positive patients were detected in sPCL. Interestingly, co-expression of CD28 and CD56 with no expression of CD117 was observed in 75% (3/4) $CD20^+$ pPCL cases. Low level of expression and similar positivity of CD27, CD28, CD81, and CD117 were found in PB and/or BM of both PCLs. On the other hand, missing CD56 was not a dominating event in both PCLs, although its decreased expression was found in PB when compared to BM. Lower CD200 expression was found in sPCL when compared to pPCL in PB (51.5% vs 99.7%) and similarly in BM. Positivity of nestin was similar for both PCL, but lower expression was found in PB of pPCL (9.3% vs. 32.0%). Total lack of CD20 and higher difference in number of $CD81^+$ PC in BM compared to PB was associated with higher risk of death. Patients with platelets below 70x10^9/l had 3.9 times higher risk of death, patients with ECOG 2–3 had three times higher risk of death compared to patients with ECOG 0–1.
Summary/Conclusion: Even when limited number of PCL patients was analyzed, it was proved that polychromatic FC analysis of cPCs is more accurate than morphology assessment and should be used diagnostics of all patients suspected with PCL. Phenotype differences were mostly not significant in both PCLs, but lack of CD20 and decreased CD81 in PB seems to be risk factors of shorter survival.
Supported by grant AZV NV18-03-00203.

PB1678 CARFILZOMIB-LENALIDOMIDE-DEXAMETHASONE IN THE MANAGEMENT OF LENALIDOMIDE-REFRACTORY MULTIPLE MYELOMA

C. Cerchione [1,*], L. Catalano [2], D. Nappi [3], A. E. Pareto [4], G. Musuraca [1], A. Lucchesi [1], S. Ronconi [1], M. Ceccolini [1], F. Pane [2], G. Martinelli [1]

[1]Hematology Unit, Istituto Scientifico Romagnolo per lo Studio e la Cura dei Tumori (IRST) IRCCS, Meldola (FC), [2]Hematology, AOU Federico II, Napoli, [3]Hematology, Bolzano Hospital, Bolzano, [4]Hematology, San Giuliano, Giugliano (NA), Italy

Background: Carfilzomib is an epoxyketone proteasome inhibitor of second generation, proved to be effective and safe in relapsed and refractory Multiple Myeloma (rrMM), in combination with dexamethasone or lenalidomide and dexamethasone.
Aims: In this retrospective observational trial, it has been evaluated efficacy and safety of carfilzomib, in combination with lenalidomide-dexamethasone (KRD) as salvage regimen in patients with rrMM, refractory to lenalidomide, where lenalidomide-based regimens have no proven efficacy.
Methods: 41 patients (23 M/18 F), with rrMM, median age at diagnosis 63.7 years (r. 43-82), median age at start of treatment 67 years (r. 48-84) previously treated with several lines of treatments (median 3, r. 2-11), underwent to KRD regimen (ASPIRE trial schedule) for a median treatment cycles of 8 (r 2-18). ISS was equally distributed, and all patients had previously



been treated with bortezomib and IMIDs, and were refractory to this agents. 61% (19/31) of them had undergone at least to a single ASCT.
Results: According to IMWG criteria, after a median follow-up of 9 months (r. 2-18), ORR was 68,2% (28/41: 9 CR, 12 VGPR, 7 PR) with 5 progressive diseases (PD) and 8 patients in stable disease (SD): this can be considered as an impressive result in this subset of rrMM patients, refractory to lenalidomide. In particular, for 11 patients, KRD was, after having achieved at least a PR, a bridge to second/third autologous SCT. Median time to response was 1.3 months (r.1-4), median OS from diagnosis was 62 months (r. 9-170), median OS from start of Carfilzomib was 11 months (r. 2-18). Carfilzomib was well tolerated, with grade 2 anemia in 39%(16/41) of patients, successfully managed by ESAs, without necessity of blood transfusions; 29% (12/41) grade 3-4 neutropenia (pegfilgrastim in primary prophylaxis was given, no ospedalization was required, no septic shocks were observed); 34% (14/41) grade 2, 21% (9/41) grade 3 and 12% (5/41) grade 4 thrombocytopenia, without hemorrhagic events and transfusion-dependency. Moreover, it was observed pneumonia in 39% (16/41) of patients, treated by common antibiotic drugs and always solved. A cardiac monitoring was performed for all patients: hypertension (grade 2-3) in 34% (14/41) of patients; fatigue in 39% (16/31) of patients.
Summary/Conclusion: Carfilzomib-Lenalidomide-Dexamethasone has shown significant efficacy in a particularly severe setting of patients, relapsed and refractory to all available therapeutic resources, also lenalidomide, and it could be considered as a bridge to a second autologous or allogenic SCT.

PB1679 PREVALENCE OF THROMBOTIC EVENTS IN PATIENTS WITH MULTIPLE MYELOMA TREATED WITH IMIDS.

P. Tenorio [1,*], P. Rios Rull [1], J. Breña [1], J. De Ramos [1], M. T. Busnego [1], L. Uribe [1], P. Hillebrand [1], A. Marín [1], A. Sánchez [1], C. Marrero [1], A. León [1], C. Notario [1], M. C. Mesa [1]

[1]Hematology, HUNSC, Santa Cruz de Tenerife, Spain

Background: Multiple myeloma (MM) induces a hypercoagulability state which increases the occurrence of thrombotic events (TE). The common usage of immunmodulatory imide drugs (IMIDs) has had a relevant prognostic impact in patients with multiple myeloma, although a major risk of TE has been detected throughout the years. Besides, therapeutic strategies including high-dose corticosteroids, central venous catheters and comorbidities already present at the usual age of debut of the disease (such as diabetes, high blood pressure, obesity, dyslipidemia or coexistence of previous neoplasms) also cast an increased risk of TE.
Aims: Describe the incidence of thrombotic events in MM patients treated with IMIDs in our hospital.
Methods: 287 patients diagnosed from 2014 to 2021 were reviewed. Further risk factors, lines of therapy and antithrombotic prophylactic measures were also included.
Results: Of all the patients reviewed (287), 26 developed TE (9.06%). Out of these events, 14 occurred in the first year after the diagnosis (53.85%). Of all these cases, 19 (73.08%) featured more than one additional risk factor. Furthermore, 21 (80.77%) had received IMID-based therapies. Most common events were pulmonary embolism (9 - 34.62%), deep vein thrombosis (9 - 34.62%), strokes (3- 11.54%) and jugular venous thrombosis (3 - 11.54%) followed by other events (2 - 7.69%).

Summary/Conclusion: Prevalence of TE in MM patients in our institution is 9.06%, with a high proportion of them (80.77%) receiving IMID-based therapies and occurring in the first year after the diagnosis (53.85%).
Most of the events developed despite the usage of prophylactic antithrombotic measures, hence early high-risk prophylactic measures should be mandatory in MM patients treated with IMID-based therapies.

PB1680 RENAL IMPAIRMENT IN MULTIPLE MYELOMA: CHARACTERISTICS AND OUTCOMES OF 55 MOROCCAN PATIENTS

E. M. Mahtat [1,*], K. Hassani [2], S. Jennane [1], H. El Maaroufi [1], D. Kebbaj [2], K. Doghmi [1]

[1]Clinical Hematology, [2]Nephrology, Hôpital Militaire Mohamed V Rabat, Rabat, Morocco

Background: Renal impairment occurs in 20 to 50% of newly diagnosed multiple myeloma (NDMM) patients. It is associated with worse outcome of the disease. The recent use of new agents and the development of novel techniques of light chain removal have been associated with improved renal and patient outcomes in MM patients. Nevertheless, dialysis-dependent patients with MM have higher mortality than other dialysis patients.
Aims: The aim of this study was to describe renal impairment in patients with MM at time of diagnosis and to investigate renal response factors and overall survival.
Methods: This retrospective study analyzed the medical records of all patients newly diagnosed with MM between January 2008 to November 2020 at the Nephrology department of the military Hospital in Morocco. Diagnosis of MM was based on the IMWG 2014 criteria. We collected patients' data as age, sex, presenting symptoms, hematological and laboratory features. Renal impairment was defined as serum creatinine >2 mg/dl or eGFR<60 ml/min/1,73 m^2 and/ or elevated proteinuria/ creatinuria (>0,5 g/g). We reported renal biopsy results, anti-myeloma treatment. We evaluated the hematological and renal response and overall survival. Descriptive statistics of continuous variables were presented as medians. Survival curves were constructed according to the Kaplan-Meier method, and the curves were compared using log-rank test. Cox proportional hazard analysis was used to identify factors influencing the overall survival.
Results: Fifty-five NDMM patients with initial RI were included. The median age was 60 years. Sex ratio was 2,6. Sixteen patients (29.1%) had light chain Lambda myeloma, 15 (27.3%) had monoclonal IgG kappa MM. Thirty patients had stage 5 CKD and 44 (80%) had serum creatinine 2>mg/dl. Seventeen (35.5%) patients required dialysis at the diagnosis. Twenty seven (49%) patients had a kidney biopsy. Cast nephropathy was reported in 15 cases, Randall-type monoclonal immunoglobulin deposition disease in 7 patients and renal amyloidosis was found in 5 patients. The treatment regimens included a CTD in 19 patients (35.8%), VTD in 13 patients (24.5%) and VAD in 12 patients. Seven patients were referred for stem cell transplantation. Hematologic and renal responses were observed in 31 patients (76.5%) and 34 patients (60.7%) respectively. Dialysis was withdrawn in one patient only. Patient sub-groups with and without renal response were similar in age, gender distribution, LDH levels, thrombocytopenia and histological type. Serum creatinine was >2 mg/dl in 60% of patients who did not achieve renal response versus 40% in patients achieving renal response (p=0.02). The renal response rate in the group treated with bortezomib based regimens was slightly superior compared with the group not treated with bortezomib (p=0,07). Only multivariate analysis only female sex and Bortezomib use appear to be associated with renal response. In a mean follow-up of 17 months 25 patients died (51.9%). The median overall survival from diagnosis was estimated at 35 months. In a univariate analysis, age, gender, thrombocytopenia, LDH, renal response and treatment with bortezomib were not found to influence OS. In multivariate analysis a serum creatinine > 2 mg/dl was significantly associated with decreased OS (p=0.03).
Summary/Conclusion: Our study showed a dismal outcome and a short survival in of NDMM with RI in our center. Mainly because a large proportion of our patients did not receive new agents in front line therapy and only a few were transplanted. This study emphasise also the importance of bortezomib based regimens in this setting.

PB1681 FIRST-LINE TREATMENT OF OLDER PATIENTS WITH MULTIPLE MYELOMA (MM) WITH BORTEZOMIB, CYCLOPHOSPHAMIDE AND DEXAMETHASONE (VCD)

K. Liapis [1,*], F. Panitsas [2], S. Hatzileontiadou [3], S. Papadakis [4], I. Liapis [4], G. Vrachiolias [1], A. Bouchla [5], E. Hatzimichael [6], N. Gianakoulas [7], E. Hatziharisi [3], A. Bilalis [8], C. Misidou [1], A. Sherif Damadoglou [1], G. Melissinidis [1], E. Mpogatsa [1], C. Roubakis [1], I. Xilouri [4], V. Pappa [5], E. Papadaki [4], M. Papaioannou [3], I. Kotsianidis [1], E. Spanoudakis [1]

[1]Department of Hematology, Democritus University of Thrace Medical School, Alexandroupolis, [2]Department of Hematology, Laikon General Hospital, National and Kapodistrian University of Athens, Athens, [3]Department of Hematology, AHEPA University Hospital, Thessaloniki, [4]University General Hospital of Heraklion, Voutes, Heraklion, [5]Second Department of Internal Medicine, Hematology Unit, Attikon University General Hospital, Athens, [6]University Hospital of Ioannina, Ioannina, [7]Department of Hematology, University Hospital of Larissa, Larissa, [8]Hematology Department, General Oncology Hospital of Kifissia "Agioi Anargiroi", Athens, Greece

Background: First-line treatment with VCD is well-studied in transplantation-eligible younger patients with MM (overall response rate [ORR] 83%, with 56% achieving ≥VGPR). Although VCD has not been approved by the European Medicines Agency for untreated older patients with MM, its use is recognized in the current ESMO guidelines. There have been few systematic studies of VCD in older patients with MM and data on its efficacy and safety is limited.
Aims: We did a retrospective, multicenter, cohort study of newly-diagnosed older patients with MM treated with VCD.
Methods: We identified all newly-diagnosed patients with MM aged ≥70 who were treated with VCD in six Greek hospitals between 2007-2020. We used Kaplan-Meier curves and Cox regression for the primary outcomes (overall survival [OS] and progression-free survival [PFS]).
Results: A total of 99 patients (52 men; 47 women) were included in our study. Median age was 76 years (range, 70-92). 16 patients (16.2%) aged ≥80 years. Performance status (PS) was ≥2 in 44 patients (50%). The median Charlson Comorbidity Index (CCI) was 4 (range, 2–9); 51.6% had multimorbidity (CCI≥4). 46 patients (54.8%) had ISS 3 and 37 (37.8%) had high LDH. Renal impairment was seen in 27 patients (27.3%). Median follow-up was 25.3 months (IQR 8.9–49.4), during which 25 (25.2%) patients died. The median number of VCD cycles received was 6 (IQR 4–7). Most patients received weekly VCD (61.2%). Bi-weekly VCD was given in 38.8%, mainly as initial treatment (cycles 1-2). 22 patients (23.1%) received ≥8 cycles. Maintenance therapy was given in 24.7%. ORR was 83.6%, including CR 25.3% (23/91), VGPR 28.6% (26/91), and PR 29.7% (27/91). Stable disease occurred in 11% (10/91) and progressive disease in 5.5% (5/91). VCD produced rapid responses (median time to ≥PR: 2 cycles [range, 1-6]). We saw no difference in ORR in patients aged ≤75 vs. >75 years (P=0.845). Median OS was 62.7 months (IQR 28.9–98.4); 2-year OS was 80.4%. Median PFS was 26.6 months (IQR 9.7–46.6) and 18-month PFS 58.8%. We noted no difference in PFS between patients ≤75 years vs. > 75 years (P=0.999), ISS 3 vs. 1-2 (P=0.99), LDH (P=0.57), and CCI (P=0.70). Significant baseline risk-factors associated with OS in the multivariate analysis included ISS (HR 4.46, 95% CI 1.35–14.7; P=0.014), PS (3.19, 1.02–10; P=0.047), LDH (5.3, 1.16–24.2; P=0.031), plasmacytomas (7.4, 1.8–30.6; P=0.006), and amyloidosis (8.5, 1.37–53; P=0.021). Subjectively VCD was well tolerated (7 patients discontinued VCD). Bortezomib dose was reduced in 23.9% (22/92). Grade ≥2 peripheral neuropathy occurred in 19.3% (19/98), grade 3/4 myelosuppression in 4.4% (4/91). Systematic G-CSF was used in 2 patients (2.2%). 42.4% of patients relapsed after VCD. Lenalidomide-dexamethasone was the most common second-line regimen (ORR 58.3%).
Summary/Conclusion: Our results show that VCD is a safe, feasible triplet for older patients with MM. It enables a high proportion of patients to achieve ≥VGPR (53%) and can be continued for >8 cycles for enhanced disease control. It is associated with long remissions (PFS 26.6 months) and may be given by nonintravenous route, which is particularly important for older patients.

PB1682 SKELETAL RELATED EVENTS IN MULTIPLE MYELOMA: A RETROSPECTIVE SINGLE CENTRE ANALYSIS

D. Farrugia [1,*], E. Sultana [1], M. Cutajar [1], F. Micallef [1], L. Gauci [1], D. J. Camilleri [1], A. Gatt [1], M. Grech [1]

[1]Haematology Dept, Mater Dei Hospital, Msida, Malta, MSD 2090, Msida, Malta

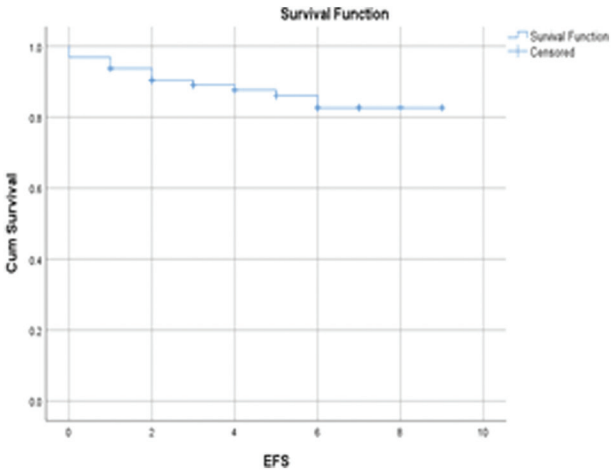
Background: A risk-adapted algorithm for mitigation of skeletal-related events (SREs) in myeloma can help guide intensity and duration of bisphosphonate (BP) therapy.
Aims: The aim of study was to investigate characteristics of SREs and associate clinical with any laboratory factors which might predict a higher SRE risk in plasma cell dyscrasias.
Methods: Patients receiving treatment for plasma cell disorders between January 2016 and December 2020 were retrospectively identified. SREs were identified and defined as: humeral, femoral, vertebral, rib and other fractures, skeletal and pain-related procedures. Skeletal events were divided into 5 periods: A: occurring between presentation and induction; B: occurring from initiation to end of induction; C: from end of induction till biochemical relapse, D: from biochemical relapse/progression to second-line therapy; E: second-line therapy onwards.
Results: Included were 113 patients, with a median age of 66 years (range 28–83 years) of whom 44 were female and 69 were male. The diagnoses were: 108 active myeloma, 3 solitary plasmacytomas, 2 plasma cell leukaemia and 1 POEMS. Ninety (79.6%) patients received zoledronic acid, 6 (5.3%) received pamidronate, 5 (4.4%) received both drugs. Twelve (10.6%) patients did not receive BP.
There were 128 SREs identified during follow-up, with a median of 1 SRE per patient. Sixty-four (56.6%) patients experienced SREs: 23 (20.4%) had 1 SRE, 26 (23.0%) had 2 SREs, nine (8.0%) had three SREs, four (3.5%) had four SREs and two (1.8%) patients had five SREs. These occurred as follows: Period A: 53 (41.4%) SREs; Period B: 45 (35.2%), Period C: 22 (17.2%), Period D: 2 (1.6%) and Period E: 6 (4.7%) events. SREs included: 60 (46.9%) vertebral fractures, 21 (16.4%) radiotherapy treatments, 13 (10.2%) hospitalisations with bone pain, 8 (6.25%) rib fractures, and 11 (8.6%) orthopaedic and pain procedures. Three (2.7%) had cord compression, comprising 2.3% of SREs.There was no significant difference in the interval between diagnosis and administration of first dose of BP between the patients with SREs and those without.
Patients with SREs likely to be younger (median age 63.5 years vs 69 years, ***P*=0.002**), have light chain myeloma (***P*=0.025**) and more than 4 lytic lesions on baseline imaging (**P<0.001**). There was no significant difference with respect to gender, immunoglobulin isotype, light chain type, ISS stage, cytogenetics, presence of hypercalcaemia, anaemia or renal impairment at diagnosis, and baseline alkaline phosphatase level. There was no difference in OS between those experiencing SREs and those who did not (***P*=0.555**).
Summary/Conclusion: Our study found an SRE rate comparable to other European countries. Most occurred early following diagnosis. Baseline characteristics associated with increased risk of SREs include younger age, light chain myeloma and more than four lytic lesions on imaging. Identification of baseline risk factors for SREs may help us move towards a risk-adapted strategy.

PB1683 FREQUENCY AND PROGNOSTIC SIGNIFICANCE OF MEDITERRANEAN FEVER GENE MUTATIONS IN MULTIPLE MYELOMA AND OTHER PLASMA CELL NEOPLASMS

I. Kaygusuz Atagunduz [1,*], M. Azizy [2], T. Toptas [1], F. Eren [3], D. Yılmaz [3], T. Tolu [2], F. Arıkan [1], F. Yilmaz [1], T. Firatli Tuglular [1]

[1]Heamatology, [2]Internal Medicine, [3]Medical Biology, Marmara University Pendik Training and Research Hospital, Istanbul, Turkey

Background: Mediterranean FeVer (MEFV) gene, a member of a highly conserved gene family that regulates embryonic development, hematopoiesis, oncogenesis, and inflammation, encodes pyrin protein, an important regulator of apoptosis, inflammation and communication between cytokines. The relationship of MEFV gene mutations with malignancies is an intriguing issue. It is suggested that MEFV gene mutations may cause a decrease in apoptosis, increase in inflammation and nuclear factor-kappa B (NF-kB) activity by disrupting the structure of normal pyrin protein and its interaction with other proteins. The role of increased NF-kB activity in the pathogenesis of multiple myeloma (MM) is well defined. However, there is no information that MEFV mutations may play a role in the pathogenesis of MM through a decrease in apoptosis and an increase in NF-kB activity.
Aims: In our study, we aimed to investigate the frequency of MEFV gene mutations in MM and the effect of these mutations on the disease prognosis.
Methods: Sixty-five patients diagnosed with plasma cell neoplasia followed in our hematology department were included in the study. MEFV



gene mutation analyzes were performed from the blood samples of all patients. The gene mutation frequency was compared with the results of 186 healthy individuals. The clinical characteristics and survival rates of patients with and without mutations were compared by evaluating the data obtained from the patient files.
Results: Fifty five patients diagnosed with multiple myeloma, and ten patients diagnosed with monoclonal gamopathy of undetermined significance, solitary plasmacytoma, smoldering myeloma and amyloidosis were included in our study. MEFV gene mutation was observed in 11 (16.92%) patients in all patient group and it was found that the frequency did not increase compared to the control group. Nine MEFV gene mutations were found in eight patients (14.54%) in the MM group and it was observed that the frequency did not increase compared to the control group. However, it was found that the frequency of E148Q mutations decreased significantly compared to the control group (1.88 % versus 10.71 %), but the difference remained within the statistical significance limit (p=0.0524). When the clinical data of patients with and without mutations in the MM patient group were compared, it was observed that there was no significant difference between the two groups in terms of International Staging System (ISS) stages, anemia and the frequency of renal involvement. In the survival analysis, there was no statistically significant difference between the 2 groups in terms of 3-year progression-free survival and overall survival rates.
Summary/Conclusion: In our study we found that there is no increase in the frequency of MEFV gene mutations in MM patients compared to the control group. However, the frequency of the E148Q mutation was significantly reduced in the patient group compared to the healthy control. We also observe that carrying the MEFV gene mutation does not have a significant effect on the clinical course and survival of the disease. However, due to the low number of patients with mutations, it seems necessary to conduct studies involving more patients for a more accurate evaluation. The fact that the frequency of E148Q mutations is significantly lower in MM patients compared to the healthy control group seems to be an area that needs to be investigated and confirmed by studies involving more patients, especially in order to understand the role of this gene mutation in the malignant transformation process.

PB1684 DARATUMUMAB IN TREATMENT OF RELAPSED/REFRACTORY MULTIPLE MYELOMA – EXPERIENCES OF THE CROATIAN COOPERATIVE GROUP FOR HEMATOLOGIC DISEASES (KROHEM)

J. Batinić [1,*], D. Radić Krišto [2], V. Blaslov [3], M. Jakić Bubalo [3], M. Ivić [4], M. Piršić [4], D. Deak [5], G. Rinčić [5], V. Periša 6 7, S. P. Jasminka [6], H. Holik [8], V. L. Ivana [8], M. P. Martina [9], I. Zekanović [9], I. Krečak [10], P. Berneš [11], I. Romić [12], L. Kužat [13], T. Valković [14], D. Dujmović [1], S. Bašić-Kinda [1], I. Aurer [1,15]

[1]Hematology, University Hospital Centre Zagreb, [2]Hematology, Clinical Hospital Merkur, Zagreb, [3]Hematology, University Hospital Center Split, Split, [4]Hematology, Clinical Hospital Dubrava, [5]Hematology, Clinical Hospital Centre "Sisters of Charity", Zagreb, [6]Hematology, Clinical Medical Center Osijek, [7]Faculty of Medicine; University in Osijek, Osijek, [8]Hematology, General Hospital "dr. Josip Benčević", Slavonski Brod, [9]Hematology, General Hospital Zadar, Zadar, [10]Hematology, General Hospital Šibenik, Šibenik, [11]Hematology, General Hospital Pula, Pula, [12]Hematology, General Hospital Dubrovnik, Dubrovnik, [13]Hematology, County Hospital Čakovec, Čakovec, [14]Hematology, Clinical Hospital Centre Rijeka, Rijeka, [15]School of Medicine, University of Zagreb, Zagreb, Croatia

Background: Multiple myeloma (MM) remains uncurable disease, with multiple relapses and clone evolution leading to refractoriness. However, recently significant therapeutical advancements were achieved leading to improvement of patient's survival.
Aims: The aim of this analysis was to show real world data on treating multiple myeloma patients with relapsed/refractory (RR) disease with daratumumab.
Methods: We performed a retrospective analysis of outcomes of MM patients treated with daratumumab, in combination with bortezomib and dexamethasone (DVd) or lenalidomide and dexamethasone (DRd) in 13 Croatian hematology centers in the period between June 2019 and February 2020 (daratumumab available and reimbursed since June 2019).
Results: A total of 96 patients with RR myeloma were included. Median age at the start of daratumumab treatment was 66.5 years (range 41 – 86). There were 41 male and 57 female subjects. Median number of previous lines of therapies was 3 (range 2 – 8). 49 patients (51%) previously underwent autologous stem cell transplantation (ASCT) in the first line of treatment (12 patients received tandem ASCT) and 16 patients (17%) as salvage ASCT (6 patients had tandem ASCT). 57 patients (59%) were bortezomib exposed and 31 (32%) lenalidomide exposed. DVd was administered to 36 patients (38%) and DRd to 60 patients (62%). In the DVd group response rate (better or equal to partial response; PR) was 72%, while in the DRd group response rate was 76%. After a median follow up of 6 months, median progression free survival (PFS) was not reached in both groups. During the study, hematologic toxicities were reported for the entire group: anemia, thrombocytopenia and neutropenia in 30, 27 and 26 patients, respectively. Infective complications were reported in 21 patients in total. During the study 12 patients died.

Summary/Conclusion: This real-world data analysis confirms that in the setting of RR MM daratumumab has significant efficacy with acceptable and manageable toxicities. Our data support previously reported clinical trials data.

PB1685 LENALIDOMIDE VERSUS THALIDOMIDE OR BORTEZOMIB AS MAINTENANCE REGIMEN FOR NON-TRANSPLANT PATIENTS WITH MULTIPLE MYELOMA: MULTI-CENTER REAL WORLD EXPERIENCES IN CHINA

Z. Zhuang [1], L. Shi [2], Y. Tian [3], D. Zou [4], R. Feng [5], F. Dong [6], S. Liu [1], H. Jing [6], H. Liu [5], W. Sun [4], W. Chen [3], Y. Wu [3], L. Bao [2], J. Zhuang [1,*]

[1]Department of Hematology, Peking Union Medical College Hospital, Chinese Academy of Medical Sciences, [2]Department of Hematology, Beijing Jishuitan Hospital, [3]Department of Hematology, Beijing Chao-Yang Hospital of Capital Medical University, [4]Department of Hematology, Xuanwu Hospital of Capital Medical University, [5]Department of Hematology, Beijing Hospital, National Center of Gerontology, Institute of Geriatric Medicine, Chinese Academy of Medical Science, [6]Department of Hematology, Peking University Third Hospital, Beijing, China

Background: The current situation of maintenance (MT) after front-line therapy in non-transplant patients with multiple myeloma (MM) is not adequate in China.
Aims: We conducted this multi-centered retrospective real-world study on efficacy and safety of the mainstream maintenance regimens, thalidomide (T-MT), lenalidomide (L-MT) and bortezomib (B-MT).
Methods: Clinical data of newly diagnosed MM patients were collected from 6 centers of North China MM Registry from January 2010 to May 2020. The progression-free (PFS) and overall survival (OS) from maintenance, and drug toxicities were compared in T-MT, L-MT and B-MT groups.
Results: A total of 291 patients were enrolled, including 153 in T-MT, 101 in L-MT and 37 in B-MT. At baseline, the gender ratio, paraprotein isotype, ISS and R-ISS, as well as response evaluation before MT were comparable (Figure 1). Patients on L-MT were older than the other groups. Meanwhile, greater proportions of patients on L-MT and B-MT had high-risk cytogenetic abnormalities (HRCA), defined as amplification 1q21 (1q21+), deletion 17p (17p-), t(4,14), t(14,16), or dual HRCAs (double hit).
The median follow-up duration since maintenance was 35.6, 19.4 and 17.3 months (m) in T-MT, L-MT and B-MT groups, respectively. Disease progression was recorded in 95 patients (62.1%) with T-MT, 49 (48.5%) with L-MT and 13 (35.1%) with B-MT. While mortality was 43(28.1%),

20(19.8%) and 2(5.4%), respectively. The median PFS was 22.5m in T-MT, as compared with 20.0m in L-MT and 37.0m in B-MT (p=0.61). Median OS was 79.5m in T-MT, whereas not reached (NR) in the others (p=0.21). Patients reaching complete response (CR) or stringent CR (sCR) before MT had significantly prolonged PFS compared to those with very good partial response (VGPR) or less in T-MT (28.0m vs 16.1m, p=0.02) and L-MT groups (27.0M vs 13.2M, p=0.01), while comparable in B-MT (NR vs 16.5m, p=0.36). Meanwhile, patients in each cohort had similar OS despite of different response before MT.

Patients with 1q21+ on T-MT had shorter median PFS compared to those without (16.1m vs 22.5m, p=0.14), so did impaired median OS (52.3m vs 96.5m, p= 0.003). While PFS was similar in patients with 1q21+ or without in L-MT group (33.5m vs 17.9m, p=0.29), and 4-year estimated OS was 52% and 51%(p=0.99). 1q21+ or not did not affect PFS in B-MT (15.2m vs 16.5m, p=0.89), and OS was not reached.Only a few patients with 17p- in T-MT and B-MT, yet presented remarkably inferior PFS (6.7m vs 22.5m, p=0.007) and OS (39.6m vs 79.5m, p=0.02) with T-MT. As for L-MT, PFS (15.4m vs 27.0 m, p=0.33) and OS (37.6m vs NR, p=0.99) were not of discrepancy between 17p- or without.In patients with any adverse CA, T-MT resulted in impaired PFS (11.9m vs 20.9m, p=0.06) and OS (52.3m vs NR, p < 0.01). In contrast, PFS and OS were both comparable in L-MT or B-MT, no matter with HRCA or not.

The main reason of maintenance withdrawal was disease progression. Adverse event related discontinuation was seen in 5.3%, 6.1% and 0 patients in T-MT, L-MT and B-MT.

		Thalidomide N= 153	Lenalidomide N= 101	Bortezomib N= 37	p-value
Gender (male%)		89 (58.2%)	55 (54.5%)	16 (43.2%)	0.26
Age (ave±sd/yr)		58.0±12.3	64.4±6.8	56.6±12.9	*0.001
Paraprotein isotype (%)	IgG	71 (46.4%)	44 (43.6%)	15 (34.1%)	0.64
	IgA	34 (22.0%)	23 (22.8%)	6 (13.6%)

	II	54/77 (70.1%)	28/45 (62.2%)	14/20 (70%)	
	III	11/77 (14.3%)	11/45 (24.4%)	3/20 (15%)	
HRCAs		39/94 (37.2%)	43/65 (66.2%)	15/26(57.7%)	*0.01
Cytogenetic abnormalities	Gain(1q21)	30/106 (28.3%)	33/70 (47.1%)	10/26 (38.5%)	*0.04
	Del(17p)	7/106 (6.6%)	14/63 (22.2%)	3/25 (12%)	*0.01
	t(4,14)	0/89 (0)	7/56 (12.5%)	3/22 (13.6%)	*0.002
	t(14,16)	1/89 (1.1%)	8/56 (14.3%)	3/22 (13.6%)	*0.005
	Double HIT	3/94 (3.2%)	13/65 (20.0%)	5/26 (19.2%)	*0.002
Response prior to maintenance	sCR+CR	33.6%	36.8%	43.2%	0.10
	VGPR	45.5%	33.3%	13.5%	
	PR	14.9%	24.1%	24.3%	
	MR	2.2%	1.1%	2.7%	
	SD	3.7%	4.6%	13.5%	

ISS: international staging system; R-ISS: revised-ISS; HRCAs: high risk cytogenetic abnormalities.

Summary/Conclusion: In this multi-centered real-world study, thalidomide, lenalidomide or bortezomib as maintenance after front-line therapy in non-transplant NDMM patients suggest that a response of CR or better predicts superior PFS. HRCAs drag down survival in T-MT, while L-MT and B-MT mostly reverse the negative effects. Although patients on L-MT and B-MT have greater proportion of HRCAs, PFS in three groups are comparable. Clinicians in real practice prefer to select lenalidomide or bortezomib as maintenance in high-risk patients.

PB1686 CONVENTIONAL CYTOGENETIC ANALYSIS IN PATIENTS WITH MULTIPLE MYELOMA – SINGLE CENTER STUDY

R. Lukanov [1,2,*], S. Dimitrova [1,2], V. Miteva [2,3], I. Micheva [1,2]

[1]Clinic of Hematology, UMHAT "Sveta Marina", [2]MU Varna Prof. Dr Paraskev Stoyanov, [3]Laboratory of medical genetics, UMHAT "Sveta Marina", Varna, Bulgaria

Background: Multiple myeloma (MM) is a clonal malignant hematological disease characterized by a broad range of genetic abnormalities that contribute to the disease course, treatment outcome and overall survival. Metaphase cytogenetics requires proliferating cells and is not sensitive for the detection of primary or secondary cytogenetic abnormalities. Nevertheless, any finding of a metaphase-detected abnormality is probably associated with more proliferative and aggressive form of MM.

Aims: The aim of the study is to define the role of conventional cytogenetics in the disease phenotype, time to next treatment (TNT) and overall survival (OS).

Methods: We analyzed 103 patients with newly diagnosed MM between February 2012 – December 2020. Mean age of the group is 62,3; male:female ratio - 1,06:1. According to ISS: 25,2% (n=26) are stage I; 18,4% (n=19) - stage II and 56,3% (n=58) - stage III. 36,5% are IgG kappa, 15,5% gG lambda, 10,7% IgA kappa, 6,8% IgA lambda, 22,3% FLC myeloma, 2,9% non secretory myeloma and 1,9% biclonal myeloma, 2,9% plasma cell leukemia. Regarding lines of therapy, 54,4% received 1, 23,3% - 2, 13,6% - 3, 3,9% - 4 lines of therapy and 4,9% did not receive any treatment. G-banding was performed on bone marrow samples. The cytogenetic risk was determined according to the Mayo Algorithmic Approach for Stratification of Myeloma and Risk-Adapted Therapy (mSMART) classification v.3.0. Patients with high risk are 8,7%, standard risk-82,5%. In 8,7% metaphases for cytogenetics are not obtained. Patients are distributed in 8 groups based on karyotype: normal karyotype-74,8%, hypodiploids-6,8%, hyperdiploids-2,9%, diploid-1,9%, high risk deletions-2,9%. One patient is with pseudodiploid karyotype and one is with complex karyotype. Statistical analysis is performed with SPSS v.19.

Results: By crosstab descriptive analysis approximately half of the patients with standard cytogenetic risk are stratified in ISS 3-54,1% (n=46). In the high risk group 81,8% are categorized in ISS 3. Regarding the karyotype classification, in ISS 1, 20 of the patients are with normal karyotype and only 2 have pathological karyotype: one is hypodiploid and one is with del(21)(q22). In the ISS 2, from 19 patients 17 are with normal karyotype and 1 is hyperdiploid. In ISS 3 the distribution is heterogeneous with normal karyotype in 40; hypodiploids in 6; hylerdiploid in 2, pseiudodiploid in 1, diploid in 2, high risk deletions in 2 and complex karyotype in one patient. The mean OS of the whole group is 39,7±4,2 months. We found significant difference in the mean OS based on the cytogenetic risk - 40,8±4,4 months in standard risk and 19,6±6,9 in high risk group (p<0,05). We found a significant difference in the time to third treatment (TTT) within the cytogenetic risk groups (p<0,001). The mean TTT in patients with standard risk is 2,1±5,2 months compared to 0 months in high risk group. We found a tendency showing that patients with standard risk have longer time to second treatment (TST) compared to those with high risk (12,9±18,8 months; 4,5±9 months; p=0,6). There is no difference between number of therapies, cytogenetic profile and myeloma type according to the karyotype.

Summary/Conclusion: The cytogenetic profile in MM is of utmost importance for risk stratification. Deviations from the normal karyotype detected by G-banding are found in approximately 20% of patients. Despite the importance of FISH-based risk stratification of MM, the role of conventional cytogenetics should not be underestimated, giving the opportunity of detecting a vast majority of cytogenetic abnormalities.

PB1687 COMPARISON OF 140MG/M2 VS 200MG/M2 DOSE OF MELPHALAN IN MYELOMA AUTOGRAFT – A SINGLE CENTER EXPERIENCE FROM CHENNAI, INDIA.

K. Kumar [1,*], C. Subash [1]

[1]Haematology, MIOT Hospital, Chennai, India

Background: Melphalan at a dose of 200mg/m^2 is considered the standard autograft dose in patients with multiple myeloma without major co-morbidity. This was formulated in early years before the era of novel agent induction and maintenance. Considering the deeper remission achieved by novel agents and prevailing refractory gram negative sepsis in most Indian setups.

Aims: We compared 140mg/m^2 (MEL140) vs 200mg/m^2(MEL200) of Melphalan in Indian myeloma patients who achieved a complete remission before transplant without having any major co-morbidity.

Methods: We analyzed myeloma autograft patients from September 2014 to February 2018. 49 patients received MEL200 and 51 patients received MEL140. These patients were clinically randomized. Diabetes on oral medications was randomized equally on both sides. The median age of patients in MEL200 was 52 years and MEL140 was 53.6 years. There were 60% and 55% males in MEL200 vs MEL140 respectively. ISS-III patients were 48% and 49% in MEL200 vs MEL140 respectively. The standard induction regimen was three to four cycles of RvD chemotherapy. Around 16% patients in MEL140 group had a creatinine clearance between 30-50ml/min. The mobilization regimen followed was

5 days of GCSF based mobilization. The stem cell cut-off was kept to a minimum of 2 x 10^6/CD34+ve cells/kg bodyweight.
Results: In outcome analysis, there was no transplant related mortality in both groups. The mean day of engraftment was around Day +9 in MEL140 vs Day +11 in MEL200. The rate of Gram Negative Bacilli sepsis was around 14% in MEL140 vs 27% in Mel200 (p 0.02). This reflected in use of high end antibiotics like Colistin and Fosfomycin in such patients and there was a delay in engraftment which may have been confounded by sepsis. The median progression free survival was 26.1 months in MEL200and 27.2 months in MEL140 group. The cumulative incidence of relapse at 3 years was not significantly different between the Mel200 (36.3%) and Mel140 (37.9%) groups. The adjusted HR for relapse was 0.98. Subgroup analysis suggests that in overall survival, progression-free survival, and cumulative incidence of relapse there was no significant advantage associated with melphalan 200 mg/m^2.
We formulated to compare a lower dose melphalan to prevent a stormy post-transplant course and prevent patients succumbing to sepsis. This may not be an issue in western countries where gram negative sepsis rates are lower. The biggest worry for us is not to compromise the myeloma outcome due to lower doses of Melphalan in fit patients who achieve complete remission. This study concluded that there is not much of a difference in overall survival, Progression free survival and cumulative incidence of relapse at three years among MEL200 vs MEL140.
Summary/Conclusion: We conclude that Melphalan autograft at a dose 140mg/m^2 can achieve comparable responses to 200mg/m^2 in Indian myeloma patients who are taken to transplant post complete remission. We need a bigger multicentric study and a longer follow up to recommend MEL140 as standard of care in Indian setting.

PB1688 CLINICAL OUTCOMES OF IXAZOMIB-BASED REGIMENS IN CHINESE PATIENTS WITH MULTIPLE MYELOMA PREVIOUSLY RECEIVING BORTEZOMIB-BASED INDUCTION REGIMEN: PROTOCOL FOR MODIFY STUDY

L. Li [1], W. Chen [2,*]

[1]Takeda (China) International Trading Co, Ltd, [2]Beijing Chao-yang hospital, capital medical university, Beijing, China

Background: Bortezomib-based triple drug regimen is the standard of care in Chinese multiple myeloma (MM) patient in front line setting, but there is huge economic and disease burden, and toxicity to bortezomib-based regimen. Oral regimen offers convenience to the patients, especially in China, because of the scarcity of top tier MM center and the community healthcare service system is not well established. Hence frequent communication between home and hospital is a burden for patients and their family. The feasibility of the in-class transition from a bortezomib-based treatment to an all oral ixazomib treatment has previously been demonstrated. Relatively good safety profiles of ixazomib make it possible for switching from a bortezomib-based induction regimen to an ixazomib-based regimen.
Aims: To assess the effectiveness of all oral ixazomib-based regimen in Chinese patients with MM, who had at the least a partial response (PR), after receiving bortezomib-based regimens as initial treatment.
Methods: This study will be an open-label, single-arm, multicenter, observational study among Chinese patients with MM in real world clinical setting. Patients (aged ≥18 years) who have been newly diagnosed with MM (NDMM) using International Myeloma Working Group criteria and have received a bortezomib-based triple-drug regimens for more than 2 cycles as initial therapy including bortezomib, cyclophosphamide and dexamethasone (VCD) or lenalidomide, bortezomib, and dexamethasone (VRD) or bortezomib, doxorubicin and dexamethasone (PAD) or bortezomib, thalidomide, and dexamethasone (VTD) will be enrolled in this study. At the time of enrollment, patient must achieve at least PR as defined by IMWG criteria. Approximately 320 eligible patients at 15 top MM hospitals in China will be treated with ixazomib-based regimens. All patients will be followed for 24 months once every 3 months unless withdraw of informed consent form, death or lost to follow-up, termination of the study by the sponsor, whichever comes first.
Results: This study will assess the progression free survival (PFS) at 2 years for Chinese NDMM patients switched from a bortezomib-based induction regimen to ixazomib-based regimens as primary endpoint. The clinical effectiveness, safety and tolerability, patient-reported outcomes and heath economic/resource utilization will be evaluated as secondary endpoint. Meanwhile, we propose to get more available data to exploratorily evaluate minimal residual disease, influence on medication adherence and impact factors for clinical outcome.
Summary/Conclusion: The available clinical data has been confirmed that long-term therapies are necessary for MM
patients to improve disease control compared with fixed-duration treatment. The results of this
study may provide evidences to verify the benefits of switching from bortezomib-based induction regimen to ixazomib-based regimens in Chinese NDMM patients in real world clinical setting. Meanwhile, we hope the study could provide treatment ideas in clinical practice to ensure clinical efficacy while reducing burden of disease and toxicity which will help to achieve the goals of maximal benefit with long term treatment in MM patients.

PB1689 CLINICAL CHARACTERISTICS AND OUTCOMES, OF REFRACTORY OR RELAPSED MULTIPLE MYELOMA PATIENTS TREATED WITH ANTI-CD38 MONOCLONAL ANTIBODIES

I. Zamanillo Herreros [1,*], R. De la Puerta Paula [2], R. Gil Manso [1], J. M. Sánchez Pina [1], R. Alonso [1], C. Cuellar Pérez-Ávila [1], M. Calbacho Robles [1], M. T. Cedena Romero [1], M. L. Paciello Coronel [1], J. Martinez-Lopez [1]

[1]Hematology, Hospital Universitario 12 de Octubre, Madrid, [2]Hematology, Hospital Universitario Politecnico la Fe, Valencia, Spain

Background: Anti-CD38 monoclonal antibodies (Mab) used in treatment of multiple myeloma (MM) patients have high response rates both in combination with other drugs and in monotherapy. However, a proportion of patients will eventually be resistant or relapsed (R/R). Patients R/R to anti-CD38 Mab present dismal prognosis and constitute a group for which therapeutic needs are still not defined.
Aims: In this study we aimed to describe the clinical and biological features as well as outcome of daratumumab R/R MM patients.
Methods: This is a retrospective analysis of 54 MM patients R/R to Daratumumab. Refractoriness was defined as progression within the first two months of treatment. Clinical and analytic data were collected from medical history. We used chi-square test to compare categorical variables and the Kaplan-Meier method and log rank test for the survival analysis. We performed multivariable analysis using logistic regression. IBM SPSS (v25.0) was used for the statistical analysis.
Results: The median age was 66 years; R(36-85), 57.4% were female. The cohort received a median of 4 lines of treatment; R(1-12). 70.4% had been previously treated with lenalidomide, 81.1% with bortezomib and 64.8% with both. Daratumumab was used as a first line therapy in 7 patients (14.8%), and as third or later line in 32 (59.3%). The median time to daratumumab progression was 6 months; R(1-53). 18 patients (33.3%) were primary refractory to daratumumab and 21 patients (38%) achieved very good partial response (VGPR) or better response. The median overall survival (OS) was 20 months; R(0-73). The most frequent combinations were with lenalidomide (DRd; 11%), bortezomib (DVd; 16%), bortezomib and melphalan (D-VMP; 13%) and with carfilzomib (KDd; 27%). 26% received daratumumab in monotherapy or with corticosteroids.
Only high cytogenetic risk (p=0,001) and treatment outside a clinical trial (p=0.003) were predictors of primary refractoriness to daratumumab. High cytogenetic risk remained statistically significant in the multivariable analysis (p=0.007). Patients with primary refractoriness to daratumumab had significantly shorter OS, with a median of 3 months vs 47 months in patients with eventual progression to Daratumumab (p=0,0001), as well as patients not treated within a clinical trial (p=0.0001) and patients treated in monotherapy (p=0.006). Interestingly, Daratumumab-resistant patients had longer OS when treated with regimens containing pomalidomide (median survival of 13 vs 46 months; p=0.021).
Resistance to daratumumab as a first line treatment was observed in 7 patients. The median OS in this group was 52 months and the median time of response to daratumumab was 12 months with 1 patient presenting refractoriness. All of them were treated within a clinical trial and none had high risk cytogenetics.

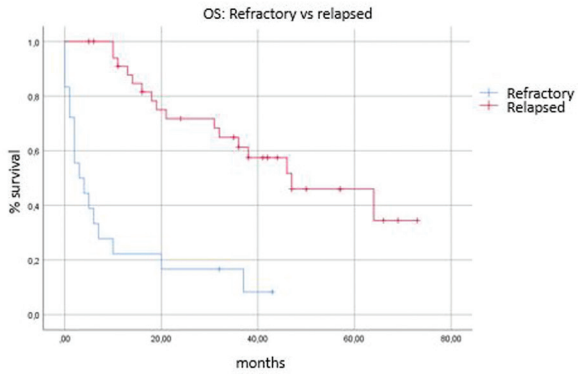

Figure 1. Survival in anti-CD38 monoclonal antibody refractory vs relapsed patients.

Summary/Conclusion: Patients R/R to CD-38 targeted monoclonal antibodies present dismal prognosis, with a median OS of 20 months. Only high cytogenetic risk was predictive of primary refractoriness according to the literature. Patients who received anti-CD38 Mab as a first line treatment had longer responses and OS, although the differences did not reach statistical significance, suggesting that even in this poor prognosis setting, patients benefit from using potent treatments as a first line. Particularly, the cohort treated with pomalidomide after daratumumab progression reached a longer OS, indicating that new drugs may represent an interesting approach for this subgroup of patients. Studies describing mechanisms of resistance to anti-cD38 Mab are essential to select the best option for each patient.

PB1690 THERAPEUTIC RESULTS OF BORTEZOMIB MULTIPLE MYELOMA TREATMENT: A MONOCENTRIC STUDY

F. K. Sarbeji [1,*], N. siala [1], M. charfi [1], Y. fakhfakh [1], D. belloumi [2], L. khelifa [1], O. kassar [1], I. frikha [1], I. ben amor [1], M. ghorbel [1], S. hadiji [1], T. ben othmen [2], M. medhaffar [1], M. elloumi [1]

[1]hematology department, hedi chaker hospital, sfax, [2]hematology department, national center of graft, tunis, Tunisia

Background: Multiple myeloma (MM) is an incurable pathology whose treatment has progressed over time. Bortezomib is now considered as a treatment that improves the prognosis of the disease in all stages. Given that Tunisia is a country with limited resources, the use of Bortezomib as a treatment for MM has only begun in 2016 as a part of a prospective protocol and could be administered only for high-risk patients (pts).
Aims: Our study aims to report the therapeutic results of pts with MM from southern Tunisia treated with Bortezomib.
Methods: It is a retrospective study over 4 years (2016-2019) which included young patients (<65 years old) with high-risk myeloma (ISS at 3, renal failure, and cytogenetic abnormalities with poor prognosis) and treated at the hematology department of Hedi Chaker Hospital Sfax, Tunisia with Bortezomib according to the 2016 national MM treatment guidelines. The treatment consists of 4 VTD courses every 21-day followed by an autograft. If autograft is not possible, consolidation at the base of 4 other CT courses should be received. Point-date is January 2021. We are interested in the response to treatment, overall survival (OS), and progression-free survival (PFS).
Results: Thirty-eight patients were treated with VTD. The reason for treatment was an ISS score at 3, a renal failure, and a high-risk cytogenetic abnormality were recorded in respectively 28, 21, and 9 pts (2pts with 17p del and 7pts with t (4,14)). Evaluation after 3 courses showed a complete remission (CR) in 8 pts(21%), a very good partial response(VGPR) in 11 pts(28.9%), a partial response (PR) in 9 pts(23.6%), a minor response (MR) in 2 pts(5.26%), a stable disease (SD) in 2 pts(5.26%), and progression in 6 pts(15.7%). Autograft of hematopoietic stem cells was performed in 10 pts. After autograft, CR, VGPR, PR rates were respectively 20%, 70%, and 10%. Twenty-eight patients did not benefit from autograft either for early death, severe comorbidities or because of the limitation of hospitalization at the national bone marrow transplant center in Tunis because of Covid 19 pandemic. Among un-grafted patients, 17 have received a consolidation treatment, the rest either progressed (10.7%) or died (28.5%) before consolidation. The median survival was 26 months and two-year OS was 84.5%. OS was 100% for autografted pts and 84% for those who received consolidation with significant difference (p=0.003). PFS was 61.6% at 24 months with PFS equal to 76% for autografted patients and 51.8% for those who received consolidation (p=0.021). Response after 3 courses influenced significantly the OS (p=0.027) in a multivariate analysis.
Summary/Conclusion: Despite its high cost, Bortezomib has been a major breakthrough in the treatment of severe forms of MM. Although in our review we obtained an OS equal to 84.5% and an OR equal to 73.6% which remains lower than the results found in the literature (OS at 24 months better than 90% and OR varies between 85 and 100%) which is explained by the use of Bortezomib only for high-risk patients and by the unavailability of autograft for all patients by its non-feasibility in our center, it is still better than results obtained by the old therapeutic protocol used in Tunisia based on DT, this prompts us to use this product for all patients and not only for high-risk ones and to generalize autograft.

PB1691 VCD VERSUS VRD-BASED REGIMENS AS INDUCTION THERAPIES IN NEWLY DIAGNOSED PATIENTS WITH MULTIPLE MYELOMA (MM): UPDATED UKRAINIAN RETROSPECTIVE MULTICENTER ANALYSIS

O. Novosad [1,1,*], I. Kryachok [1], Y. Pastushenko [1], O. Gorbach [2], O. Kostiukevych [3], L. Mykhalska [4], O. Kindrakevych [4], U. Melnyk [5], V. Sieriedin [5], N. Kostiukova [6], O. Tkachenko [6], V. Timofeev [7]

[1]Oncohematology, [2]Experimental Oncology, National Cancer Institute, [3]Hematology, State Institution of Science 'Research and Practical Centre of Preventive and Clinical Medicine, [4]Center of Hematology, Clinical Hospital "Feofaniya", [5]Hematology #1, City Clinical Hospital #9, [6]Oncohematology of preparation for bone marrow transplantation, Center of Bone Marrow Transplantation, Kiev, [7]Hematology, Ambulance hospital, Chernivtsi, Ukraine

Background: Recently more effective induction chemotherapy regimens have been developed and patients treated with these new regimens are able to achieve higher and deeper responses than those previously treated on older regimens. But there are still discussions about which regimen in the first line of therapy is the priority.
We studied the difference between the median of VCd regimen progression-free survival (PFS) and the PFS of VRd treatment used as initial therapy for MM.
Aims: The primary endpoint was to study the best response to VCd/VRd treatment at the time of early response, as well as PFS of newly diagnosed patients with MM.
Methods: Between 2011 and 2021, we analyzed 98 newly diagnosed patients with MM (males:51, females:47) at 6 Ukrainian centers. 70.4% and 29.5% of patients received VCd and VRd regimens, respectively (p<0.05). The response was evaluated at the end of 3-4 cycles and the end of treatment, as per IMWG criteria. The patients' characteristics were similar in both groups according to ISS stage (ISS III –VRd: 29%, VCd: 24.4%), and median age (VRd -51.5 y.o; VCd-54.5 y.o).
Results: Both VRd and VCd groups ORR was high, (79.3% and 81.1%, respectively). Patients in both groups achieved similar rates ≥VGPR (44.9% VCd vs 51.7% VRd). CR/sCR rates were superior in the VRd arm; 37.9 % vs 28.9%, p< 0.05.
We compared the median of rapid early response with VCd regimen, taking in consideration a larger percentage of CR achievement in the patient group with Lenalidomide-containing regimen. However, we could not obtain an accurate result as the median of rapid response was similar in both groups: 3.1 months for VRd vs 3.2 months for VCd.
The mean of PFS median was 31.93 months, and the OS median was not reached. The PFS was correlated with therapy response. Patients who achieved ≥VGPR vs MR/progression, (84% vs 20%, p<0.0001), had a significantly longer 5-year PFS.
It is interesting to note that during our patient cohort analysis, we discovered a significant risk mitigation of disease relapse in the near 5 years when using a VRd regimen compared to the VCd one, (5-year PFS 50% vs 35%, log-rank test, p<0.0001). The OS level remains nevertheless the same and does not constitute a statistically important result.
Summary/Conclusion: Our data suggest that the response to therapy affects the prediction of clinical outcome in patients with MM. Other than OS or PFS, alternative primary endpoints need to be developed for an adequate future assessment of treatment efficiency using VRd and VCd regimens in order to determine the therapy "leader" in newly diagnosed patients with multiple myeloma.

PB1692 THE HIGH-RISK CYTOGENETIC (HRC) INFLUENCES IN THE OUTCOME OF THE NEWLY DIAGNOSED MULTIPLE MYELOMA (NDMM).

M. I. Nuevo López [1,*], B. Merchan Muñoz [1], A. Gil Perez [1], H. Guillen Garcia [1], M. Argumanez [1], A. Vazquez Ramo [1], A. B. Santos [1], N. Golbano [1], S. Herrero Martín [1], J. Arbeteta Juanis [1], D. Morales [1], M. Diaz Morfa [1], D. Subirá [1], D. De Miguel Llorente [1]

[1]*Hematology, Hospital, Guadalajara, Spain*

Background: MM is the 2nd most common hematologic malignancy. It has different overall survival (OS) and progression-free survival (PFS) depending on cytogenetic abnormalities. A 15% of NDMM has an HRC, which supposes an aggressive behaviour, with frequent relapses, until it becomes refractory. There are drugs that partly overcome the adverse effect of HRC on PFS and OS.
Aims: 1. Evaluate efficacy and number of relapses until achieving a good treatment response or death. 2. Prognostic impact of clinical-biochemical diagnosis data in a heterogeneous NDMM HRC`s cohort.
Methods: Unicentric, descriptive and retrospective analysis, using clinical and analytical NDMM HRC patient's data from 2009 to 2020 at Guadalajara University Hospital. HRC is defined by fluorescence in situ hybridization (FISH): mutations on chromosome 1, del17p, t(4;14), t(14;16), t(14;20) or plasmablastic leukemia. Survival data or Cox regression were used. Risk measures; Hazard Ratio (HR) with 95% CI. Negative binomial regression to analyze count variables. P value <0.05 was considered significant.
Results: We identified 53 patients (pts) with HRC NDMM, whose clinical characteristics and treatment (tt) data are listed in Table 1. NDMM HRC first-line tt was chosen, regardless of the FISH results: 90,6% of the pts received bortezomib (V) - based induction, of them 35% (n=17) were treated with alkylating agents, 48% (n=23) received immunomodulatory drugs and 17% (n=8) V with dexamethasone (d). Whereas 24,5% (n=13) received a nonintensive tt as Vd, melphalan-d or lenalidomide-d, because they were older than 70 years and the tt was chosen before 2017. Twenty-one pts (39,6%) underwent autologous stem-cell transplantation (ASCT) as part of first-line tt, the vast majority under 65 years. Overall response rate (ORR) after induction was 37%; and declined in subsequent treatment lines, 49% achieved ≥ very good partial response (VGPR).
Median follow-up for surviving patients was 47,25 months (IQ 23,8 – 97, 58). The PFS was 50.26 months (IQ 16.37 - 68.70). 18 pts deceased during the time of the follow-up.
In multivariate analysis to predict OS rate: being a woman (HR: 1.036; p = 0.948) and age >65 years (HR: 1.053; p = 0.087) was associated with a risk factor, but no data showed a statistically significant association.
Equal characteristics such as age, sex, ISS, D&S and analytical data, the only variable that was independently associated with the relapse rate during the follow-up time was ISS-2 versus ISS-1, multiplying by 1,86 the number of times the event appears. Relapse rate: 1.86; p = 0.037) (figure 1).
Summary/Conclusion: Our case series presents a longer survival compared to those commented in other studies. It describes similar % cytogenetic abnormalities as in the literature, except for del(17p), which has an incidence of 28.3%. Most frequent combination was the one between 1q gain among pts with del(17p). Our study validates the ISS as the factor with the greatest impact on its prognosis. A longer follow-up and higher HRC NDMM pts`s recruitment will be necessary to better define the response to tt regimens based on individual cytogenetic groups.

PB1693 REAL-LIFE OUTCOMES OF DARATUMUMAB TREATMENT IN PATIENTS WITH RELAPSED AND/OR REFRACTORY MULTIPLE MYELOMA: EXPERIENCE FROM A SMALL PERIPHERAL HOSPITAL

D. Rochate [1,*], C. Pavão [1], A. R. Leal [1], A. Moreira [1], J. Oliveira [1], A. R. Dias [1], F. Oliveira [1], C. Viveiros [1], A. L. Araújo [1], C. Fraga [1]

[1]*Department of Hematology, Hospital do Divino Espírito Santo de Ponta Delgada, PONTA DELGADA, Portugal*

Background: Multiple myeloma (MM) is the second most common hematological cancer worldwide. Although it is still considered an incurable disease, MM might be controlled for long periods of time. Notwithstanding the therapeutic approach to MM is guided by eligibility to autologous stem cell transplantation (ASCT), treatment was markedly improved with the availability of agents approved in the last 15 years, leading patients with MM to improvements in 5 to 10 year survival rates. Daratumumab (Dara) is a CD38 monoclonal antibody approved in Portugal in monotherapy or in combination with bortezomib (DVd), Lenalidomide (DRd) with dexamethasone, for the treatment of relapsed or refractory myeloma (RRMM).
Aims: The aim of this study was to characterize a portuguese RRMM population of a small center treated with Daratumumab in different regimens.
Methods: We performed a retrospective observational cohort study of 55 adult MM patients diagnosed between 2010 and 2019 and analyzed a subpopulation of 11 RRMM patients treated with Daratumumab regimens. We assessed response according to IMWG criteria and progression free survival (PFS) was determined using Kaplan-Meier analysis.
Results: Of 55 MM patients, 20% received regimens with Daratumumab (N=11/55). In this subgroup of patients 36% (n=4/11) had relapsed MM and 64% (n=7/11) presented MM refractory to one or more previous treatment lines. Amongst Dara associations, 63,6% patients (n=7/11) received DRd, 18% (n=2/11) received DKd, one patient received Daratumumab in monotherapy and one patient received DVd (Daratumumab, Bortezomib, Dexamethasone). The median age at diagnosis was 59 years (range 41-69). The median time to initiation of Dara from diagnosis was 4 years (range 1-8). Patients had received a median 2 prior lines of therapy (range 1-3). Seven patients (64%, n=7/11) had previously undergone single or tandem ASCT. In the Rd-and Kd-groups all patients were previously exposed to bortezomib. In the Kd-group and Vd-group patients were exposed to Lenalidomide. The median number of administered cycles was 15 (range 2-27) in the Rd-group, 5 (range 1-9) in the Kd-group and 45 cycles in the Vd-group. The regimens were well tolerated with few grade adverse events (AE). Grade 3/4 neutropenia and thrombocytopenia (18%) were the most common AE. One patient developed toxidermia to Lenalidomide. When treated with Dara regimens, clinical relapse was observed in two patients (18%) and death in 6%. One patient was on hemodialysis as renal failure related to MM, and during DRd treatment there was vital improvement in renal functional with hemodialysis independency. Regarding to response,

in the Rd-group CR was achieved in 71% and VGPR in 14%, in the Kd-group CR was achieved in 100% and in Vd-group VGPR was achieved in 100%. Stable disease after Daratumumab was achieved by 7 patients (64%). OS was 65,8 months (range 17-120). Median PFS on Dara was 18 months (range 2-40, 95%>IC) in Rd-group, 13 months (range 1-25) in the Kd-group and in the Vd-group 39 months. Patients with extra medullary disease had poorer median PFS than those without.

Summary/Conclusion: Current MM prevalence is expected to increase since incidence is higher than mortality and new pharmacological treatments have been reshaping the market and the treatment landscape. These small real-life results are lined up with the results of POLLUX trial and demonstrate that in daily practice, Daratumumab regimens are safe, well-tolerated with benefits on PFS and OS in RRMM.

PB1694 REAL WORLD TWO-CENTER EXPERIENCE OF DARATUMUMAB MONOTHERAPY IN HEAVILY PRETREATED RELAPSED/ REFRACTORY MULTIPLE MYELOMA

I. Sanchez [1,2,*], J. Aspa [2], H. P. J. Lam [1], G. Milner [1], I. El-Najjar [1], S. Sachchithanantham [1], M. Gleeson [1], M. Kazmi [1], K. Bailey [3], R. Benjamin [3], K. Cuthill [3], L. Yuen [4], J. Garcia [2], M. Streetly [1]

[1]Haematology, Guy's and St Thomas' NHS Foundation Trust, London, United Kingdom, [2]Haematology, Hospital Universitario Principe de Asturias, Alcala de Henares, Spain, [3]Haematological Medicine, King's College Hospital, [4]Pharmacy, Guy's and St Thomas' NHS Foundation Trust, London, United Kingdom

Background: Daratumumab, an anti-CD38 monoclonal antibody, was approved in May 2016 by the European Medicines Agency (EMA) for relapsed/refractory multiple myeloma (RRMM) patients whose previous therapies included a proteasome inhibitor (PI) and an immunomodulatory drug (IMiD). In June 2020, subcutaneous (SC) daratumumab gained EMA approval.

Aims: To assess clinical characteristics, response rates and toxicity profile of RRMM patients treated with daratumumab monotherapy in 2 European centers.

Methods: This two-center retrospective study included 25 RRMM patients who started daratumumab monotherapy between 05/2018 and 09/2020 at Guy's Hospital (London) or Hospital Príncipe de Asturias (Madrid). Patients' data were reviewed from electronic records. Patients who completed ≥1 cycles were included in response analysis. Kaplan-Meier was used for survival outcomes.

Results: Median age at the start of daratumumab was 65 (range 47-91); 11 (44%) patients were male. Clinical characteristics are summarised in Table 1. All patients had previous exposure to a PI (bortezomib 100%, ixazomib 48%, carfilzomib 8%) and an IMiD (lenalidomide 100%, thalidomide 76%, pomalidomide 16%). Two (8%) were bortezomib-refractory, 1 (4%) was lenalidomide-refractory; another (4%) patient was refractory to both VTd (bortezomib, thalidomide, dexamethasone) and IRd (ixazomib, lenalidomide, dexamethasone) therapies. Twelve (50%) patients had undergone autologous stem cell transplant. Six (25%) had been included in a clinical trial (with no anti-CD38).

All patients had progression before starting daratumumab, with extramedullary disease in 4 (16%) patients. Median treatment duration was 4.3 months (m) (0.7-22.7) and median number of doses given was 28 (3-35). Seventeen (68%) patients discontinued therapy: 12 (70.6%) due to progressive disease and 5 (29.4%) died. Two deaths were due to refractory myeloma, 2 as a result of bleeding complications with thrombocytopenia grade≥3 and 1 sepsis-related.

At median follow-up of 8.7 months (0.7-23), 23 patients completed ≥1 cycles. Overall response rate (ORR) was 39.1% (9/23), with very good partial response (VGPR) in 17.4% (4/23). Median time to partial response (PR) was 2.3 m (2-3.6). Median progression-free survival (PFS) is 5.5 m, with longer PFS associated with completion of ≥1 cycle (median 6.5 months) and with deeper response (VGPR vs. PR or less, 15.3 vs. 3.9 m (p 0.012)). Median overall survival (OS) is 15.5 m.

Administration was SC in 4 (16%) patients and was converted from intravenous (IV) to SC in 4 (16%) others. First-dose infusion related reactions (IRR) occurred in 9 (36%) patients; 8/9 (88.9%) were associated with IV daratumumab and 3 were classified as grade ≥3 (including hypertension, fevers, desaturation and vomiting).

Common (≥15%) AEs were anaemia (92%), lymphopenia (80%), thrombocytopenia (72%), neutropenia (32%) and infections in 11 (44%), the majority being non-severe respiratory infections (45.4%).

Grade ≥3 AEs were found in 13 (52%) patients. Grade ≥3 thrombocytopenia was seen in 5 (20%), anaemia in 7 (28%), lymphopenia in 7 (28%) and neutropenia in 1 (4%). Grade ≥3 new proven infections after daratumumab start happened in 4/13 (30.8%) patients: sepsis related to Gram negative bacteriaemia leading to death, sepsis of unknown origin, pneumonia and urinary tract infection.

Table 1. Clinical characteristics of the population.

Characteristics (n=25)	Overall data (%)
Multiple myeloma type	
- IgG	15/25 (60%)
- IgA	5/25 (20%)
- Bence-Jones	5/25 (20%)
ISS stage at diagnosis	
- I	8/25 (32%)
- II	4/25 (16%)
- III	10/25 (40%)
- Unknown	3/25 (12%)
ISS-R stage at diagnosis	
- I	6/25 (24%)
- II	6/25 (24%)
- III	3/25 (12%)
- Unknown	10/25 (40%)
Cytogenetics at diagnosis*	
- Non-high risk	10/25 (40%)
- High risk	5/25 (20%)
- Unknown	10/25 (40%)
ECOG performance scale ≤2	20/25 (80%)

*Abbreviations: ISS: International Staging System. ISS-R: Revised International Staging System. ECOG: Eastern Cooperative Oncology Group. *High risk cytogenetics at diagnosis: t(4;14), del(17/17p), t(14;16).*

Summary/Conclusion: In summary, our experience with daratumumab monotherapy demonstrates encouraging response rates in heavily pretreated patients, similar to those reported in a pooled analysis of GEN501 and SIRIUS phase 1-2 trials. It shows an acceptable safety profile.

PB1695 POMALIDOMIDE-DEXAMETHASONE IN THE MANAGEMENT OF RELAPSED/REFRACTORY MULTIPLE MYELOMA

C. Cerchione [1,*], L. Catalano [2], D. Nappi [3], A. E. Pareto [4], G. Musuraca [1], A. Lucchesi [1], S. Ronconi [1], M. Ceccolini [1], F. Pane [2], G. Martinelli [1]

[1]Hematology Unit, Istituto Scientifico Romagnolo per lo Studio e la Cura dei Tumori (IRST) IRCCS, Meldola (FC), [2]Hematology, AOU Federico II, Napoli, [3]Hematology, Bolzano Hospital, Bolzano, [4]Hematology, San Giuliano, Giugliano (NA), Italy

Background: Pomalidomide is a new generation IMID, with a very good compliance, thanks to oral administration, which can be used also in heavily pretreated patients, in a domestic setting.

Aims: In this retrospective observational trial, It has been evaluated efficacy and tolerance of pomalidomide plus dexamethasone (PD) as salvage regimen in heavily pretreated patients with relapsed and refractory MM (rrMM), whose prognosis is particularly severe.

Methods: 57 patients (31 M/26 F), with rrMM, median age at diagnosis 69 years (r. 52-86), and median age at start of treatment 76 years (r.56-90) treated with several lines of treatments (median 7, r. 2-11), every refractory to all the drugs previously received (also Bortezomib, Thalidomide and Lenalidomide), received Pomalidomide-Dexamethasone (Pomalidomide 4 mg for 21 days, Dexamethasone 40 mg days 1,8,15,22, pegfilgrastim day +8) every 28 days, until progression. ISS was equally distributed, and cytogenetic at relapse was evaluable in 14 patients. All the patients had previously been treated with schedule containing bortezomib and IMIDs. 63% (36/57) had undergone at least to a single ASCT. All patients were relapsed and refractory to last therapies received before PD.

Results: Pomalidomide was well tolerated, with grade 3-4 transfusion-dependent anemia in 58% (33/57) of patients, 44% (23/57) grade 3-4 neutropenia (pegfilgrastim in primary prophylaxis was given, no hospitalization was required, no septic shocks were observed), 40% (23/57) grade 3-4 thrombocytopenia without hemorrhagic events and transfusion-dependence. No severe extra-hematologic toxicity was observed. According to IMWG, ORR1 (≥PR) was 47.3% (27/57: 5 CR, 11 VGPR,

7 PR, 4 MR), but, considering that we are evaluating a cohort of heavily pretreated patients, with poor prognosis, another parameter should be considered, ORR2 (≥SD), considering stable disease as a successful result in progressive MM. ORR2 was 77.1% (17 SD). These can be considered as impressive result in this subset of patients. Oral treatment gives a really good compliance, in frail and unfit patients, and response, when present, is always really fast (median time to response: 2 months (r.1-6)), median OS from diagnosis was 94 months (range 21-234), median OS from start of pomalidomide was 9 months (range 1-25). Nine patients have surprisingly achieved a notable response (3 VGPR, 4 PR, 2 MR) after failure of novel agents (i.e. Carfilzomib, Daratumumab and Pomalidomide).

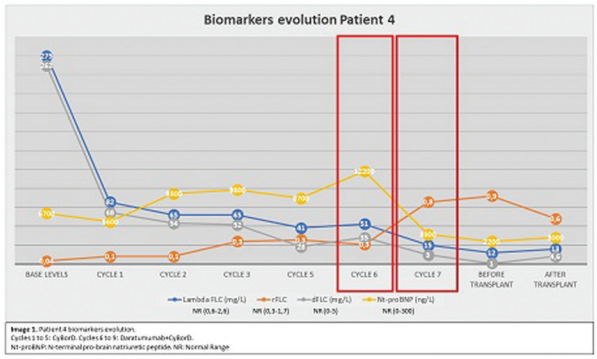
Summary/Conclusion: Pomalidomide-dexamethasone has shown significant efficacy and a very good compliance, thanks to oral administration, in a particularly severe setting of heavily pretreated patients, relapsed and refractory to all available therapeutic resources, also after failure of novel agents.

PB1696 FOUR PATIENTS DIAGNOSED OF AL AMYLOIDOSIS WITH SEVERE ORGAN DAMAGE WHO UNDERWENT AN AUTOLOGOUS STEM CELL TRANSPLANTATION (ASCT) FOLLOWING AN INDUCTION TREATMENT: EXPERIENCE IN A THIRD LEVEL HOSPITAL

N. Alba [1,*], C. Encinas [1,2], I. Regalado-Artamendi [1], M. Argüello-Tomás [1], G. Oarbeascoa [1,2], E. Zataraín [2,3], I. A. Gómez-Centurión [1,2], J. Badiola [1,2], S. Monsalvo [1,2], L. Solán [1], M. Kwon [1,2], J. L. Díez-Martín [1,2]

[1]Hematology Departament Hospital General Universitario Gregorio Marañón, [2]Instituto de Investigación Sanitaria Gregorio Marañón (IiSGM), [3]Cardiology Department Hospital General Universitario Gregorio Marañón, Madrid, Spain

Background: The organ damage at the time of AL amyloidosis diagnosis infers a high morbi-mortality and a poor prognosis. Most patients have some degree of cardiac involvement and the stringent selection criteria for ASCT exclude many of them despite an appropriate age, making upfront ASCT not a suitable option. The novel agent-based schemes (Palladini et al. Ash publications Blood 2020) with an excellent toxicity profile and efficacy may allow to undergo ASCT due to a better hematologic and organic response.



Aims: To describe our experience in patients treated in our center who are not eligible for ASCT (Kumar et al. J. Clin. Oncol. 2012) with an in induction treatment based on immunomodulator (IMID) and proteasome inhibitor (PI), with Daratumumab in one, allowing them to undergo ASCT later.

Methods: Descriptive and retrospective analysis of four cases of AL Amyloidosis, diagnosed and treated in our center between 2010 and 2020.

Results: Baseline characteristics are described in Table 1A. The induction treatment, hematologic and organ response and the patient´s evolution are presented in table 1B. Patients 1, 2 and 4 presented severe cardiac damage and patient 3 has subacute liver failure (bilirubin 30 mg/dL). All the patients had a Mayo Clinic 2012 stage II or superior, so their survival prognosis was less than 1 year. After the induction treatment, we could perform an ASCT in all patients. Image 1 shows the evolution of the free light chains (FLC) of patient 4 with severe cardiac damage, and we present how the improvement of the hematologic response (to get dFLC less than 10 mg/L), allowed the organ response, and she could undergo a transplant. With a median follow-up of 23,5 months, all patients are currently alive and maintain a hematologic and organ response.

Tabla 1A. Patient

	1	2	3	4
Age (years)/Gender	61/Female	47/Female	54/Male	49/Female
rFLC/dFLC (mg/L)	0.1/81.8	0.092/-	40/480	0.04/262.5
Creatinine (mg/dL)/24h urine protein (mg/dL)	0.61/126	-/70	2.5/570	0.65/3054
Nt-proBNP (ng/L)/TnT (ng/L)	2236/60	10055/normal	8231/50	6700/47.2
ECOG/NYHA	3/III	3/III	3/I	3/III
LVEF (%)/thickness ventricular wall (mm)	55/16	45/14	65/17	45/17
Bilirrubine (mg/dL)	0.4	-	29.5	0.9
Mayo Stage 2012	III	II	III	IIIB

Summary/Conclusion: In our experience, patients with the diagnosis of AL amyloidosis and severe organ damage who underwent a ASCT after an induction therapy using new agents outlived their initial poor prognosis.

PB1697 REAL WORLD EVIDENCE OF CARFILZOMIB IN RELAPSED REFRACTORY MULTIPLE MYELOMA (RRMM)

V. Douka [1,*], M. Iskas [1], A. Giannakopoulou [1], S. Tagara [1], S. Dimou-Besikli [1], C. Lalayanni [1], M. Papathanasiou [1], C. Vadikoliou [1], G. Papaioannou [1], A. Papalexandri [1], A. Anagnostopoulos [1]

[1]Hematology & HCT Unit, General Hospital "George Papanikolaou", Thessaloniki, Greece

Background: Duration of response in multiple myeloma patients has significantly ameliorated due to introduction of new drugs, such as proteasome inhibitors, immunomolulatory agents and monoclonal antibodies. Carfilzomib is an approved treatment option beyond first line.
Aims: The aim of our study is the efficacy and safety of carfilzomib in daily practice.
Methods: In a cohort of 30 patients since 2017, 21 received carfilzomib in combination with lenalidomide and dexamethasone (KRd), 9 with dexamethasone only (Kd). The study cohort consists of 11 male and 19 female patients with median age 68 (41-80) years old, 17 IgG, 10 IgA, 3 free light chain disease. Carfilzomib was administered as 2nd line treatment in 12 patients, as 3rd in 5, as 4th in 8, as 5th in 3 and as 6th in 2 patients. Patients received a median of 8 (1-51) treatment cycles. Left ventricular ejection fraction (LVEF%) was determined by heart ultrasound prior to treatment initiation in all patients. Median LVEF% value was 65% (55%>80%).
Results: Serum creatinine and markers of hemolysis (reticulocyte count, LDH, bilirubin) remained constantly within normal ranges. Platelet count did not deviate from baseline throughout treatment. No schistocytosis or microangiopathy occurred. One female patient developed new onset hypertension during the 6th KRd cycle and one Kd patient was in need of antihypertensive regimen modifications upon treatment initiation. All patients underwent LVEF reevaluation by echocardiogram beyond 6-mo treatment and q6mo thereafter. Reduction in LVEF more than 10% comparing to baseline was noted in 3/20 (15%) evaluated patients. Two sudden deaths occurred in two patients without cardiac history, one 72 y-o male patient during cycle 7 and one 75 y-o female upon treatment initiation. Death was attributed to physical causes and no autopsy was performed. Disease assessment was performed in 29 patients. At least partial response (PR) was achieved in 22 (76%) patients, 7 (32%) in VGPR. Median progression free survival (PFS) and overall survival (OS) was 15 (1-31) and 34 (18-50) months respectively. Median PFS and 3-year PFS was significantly higher in patients with 1-3 vs >3 prior treatment lines 37 (19-54) vs 9 (8-10) months and 40% vs 0% respectively, p<0.001. A trend for improved OS and 3-year OS was evident in patients with 1-2 vs >2 prior treatment lines, not reached vs 22 months and 61% vs 19% respectively, p=0.06. For lenalidomide refractory patients receiving Kd vs lenalidomide naïve KRd patients, median PFS was 9 (4-14) mo vs 28 (21-35) mo (p<0.001). Twelve-month PFS and 36-mo PFS was, 27% vs 69% and 39% vs 0% respectively.
Summary/Conclusion: In conclusion, carfilzomib administration in relapsed/refractory multiple myeloma exhibits adequate efficacy. Cardiovascular assessment is mandatory prior to treatment initiation and during treatment cycles. Quality and duration of response was augmented when integrated in 1st or 2nd relapse treatment plan.

PB1698 DREAMM-5 PLATFORM TRIAL: BELANTAMAB MAFODOTIN (BELAMAF) IN COMBINATION WITH FIVE DIFFERENT NOVEL AGENTS IN PATIENTS WITH RELAPSED/REFRACTORY MULTIPLE MYELOMA (RRMM)

P. G. Richardson [1,*], S. Trudel [2], N. Callander [3], A. Nooka [4], K. Song [5], K. Uttervall [6], M. C. Minnema [7], P. Rodriguez-Otero [8], D. Routledge [9], J. Khan [10], H. Struemper [11], A. Yeakey [12], R. Montes de Oca [13], L. M. Smith [14], N. Jackson [15], M. Kaisermann [12], E. Im [13], F. G. Basile [16], C. M. Ahlers [13], B. Holkova [13], I. Gupta [13], B. E. Kremer [13], H. Quach [17]

Background: Single-agent belamaf (GSK2857916, BLENREP), a B-cell maturation antigen–targeting antibody-drug conjugate, induced durable responses in patients with RRMM, with a manageable safety profile with 13 months of follow-up (DREAMM-2; NCT03525678). The unique multimodal mechanisms of action (MoAs) of belamaf in combination with MoAs of selected agents, have the potential to achieve synergistic effects in RRMM to further enhance the benefit-risk profile. The DREAMM-5 study (NCT04126200), a platform trial, allows for efficient evaluation of belamaf in combination with other anti-tumor agents, including a humanized wild-type immunoglobulin (Ig)G1 anti-OX40 agonist, an IgG4-inducible T-cell co-stimulator (ICOS) agonist (feladilimab), a gamma-secretase inhibitor (nirogacestat), a humanized programmed cell death (PD)-1 antagonist (dostarlimab), and a humanized wild-type IgG1 CD38 antagonist (isatuximab).
Aims:.
Methods: DREAMM-5 is a Phase I/II study that utilizes a master protocol with separate sub-studies comprised of sequential dose-exploration (DE) and cohort-expansion (CE) phases, to identify promising, effective belamaf combinations when compared with a shared single-agent belamaf control arm (CE phase only). The DE phase consists of multiple dosing cohorts with belamaf combinations in which patients are assigned to treatment slots by a predetermined algorithmic approach (N≤10 per cohort). A recommended Phase II dose (RP2D) for each combination treatment will be identified based on the safety and preliminary efficacy in the DE phase. At the end of the DE phase, an interim analysis of safety, pharmacokinetic, biomarker, and efficacy data will also be performed for each sub-study treatment combination to determine whether the combination should move forward at the RP2D to the CE phase. Patients in the CE phase (N≥35 per cohort) will be randomized to a sub-study, and within a sub-study to either combination treatment or the belamaf monotherapy control arm shared across sub-studies; patients will also be stratified by number of prior therapies. Eligible patients will have RRMM and will have received ≥3 prior therapy lines, which includes a prior immunomodulatory agent, proteasome inhibitor, and anti-CD38 antibody; all patients will provide informed consent for participation. The primary objectives of the study are to identify the RP2D (DE phase) and the overall response rate (≥partial response, CE phase), along with safety and tolerability, for each combination treatment.
Sub-study 1 (combination with GSK3174998, OX40 agonist antibody) is no longer open to enrollment. Sub-studies 2 (combination with GSK3359609, feladilimab, anti-ICOS agonist), 3 (combination with nirogacestat [PF-03084014; SpringWorks Therapeutics], gamma-secretase inhibitor), and 4 (combination with dostarlimab, PD-1 antagonist antibody) are currently open to enrollment. Sub-study 5 (combination with isatuximab [Sanofi], CD38 antagonist antibody) will be open to enrollment soon. Additional sub-studies will be explored based on scientific rationale and/or preclinical combination data available.
Results:.
Summary/Conclusion:.
Funding: GSK (Study 208887, NCT04126200); belamaf drug linker technology licensed from Seagen Inc; belamaf monoclonal antibody produced using POTELLIGENT Technology licensed from BioWa; nirogacestat gamma-secretase inhibitor produced by and used in collaboration with SpringWorks Therapeutics and isatuximab produced by and used in collaboration with Sanofi.

PB1699 A RAPID RESPONSE WITH DARATUMUMAB, LENALIDOMIDE AND DEXAMETHASONE COMBINATION IN A PATIENT WITH CASTLEMAN VARIANT OF POEMS SYNDROME

Y. G. Mutlu [1,*], B. Balık Aydın [1], Ö. G. Sevindik [1]

[1]Department of Hematology, Medipol University, İstanbul, Turkey

Background: POEMS syndrome (POEMS) is a rare paraneoplastic syndrome of an underlying plasma cell disorder (PCD). Castleman disease (CD),itself,can also cause symptoms or signs of polyneuropathy,volume overload,cytokine release,but only those with peripheral neuropathy and a plasma cell clone can be classified as classical POEMS.
Aims: Both classical POEMS syndrome with CD and castleman disease variant of POEMS syndrome(CD-POEMS),literature lacks a standardized treatment approach.
Methods: Here we present a case who is diagnosed with CD-POEMS and successfully treated with a combination of Daratumumab, Lenalidomide and Dexamethasone (DRd).
Results: A 54-yr-old man had admitted to our department of neurology with weakness of both arms and legs. Three years ago,patient developed tingling on legs and ataxia. He needed assistance for walking. The

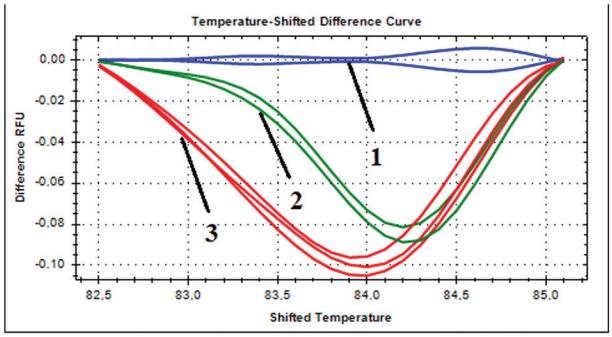
neurological examination showed bilateral upper and lower limb muscle weakness especially dominant on distal parts of the extremities on admission. There was an evident atrophy on distal part of the extremities. Stocking-glove pattern for loss of vibration and pinprick sensation was found. Romberg sign was present. The rest of the neurological examination was normal. Electrodiagnostic study showed that sensory nerve action potential,compound muscle action potential is diminished on bilateral upper and lower extremities. To exclude a possible accompanying plasma cell disorder,serum protein electrophoresis,serum immunofixation electrophoresis, serum free kappa and lambda light chains were odered and revealed no monoclonal protein. But further urine immunofixation electrophoresis revealed a lambda monoclonal protein in urine. Then serum VEGF and IL6 levels were ordered. At the same time because of a previous CT scan showing multiple mediastinal masses, a PET scan was ordered to document any FDG avid masses. Serum VEGF level was 531 pg/ml (<96 pg/ml) and serum IL-6 level was measured as 24.75 pg/ml (<7 pg/ml) PET scan revealed axillary, paraaortic and aorta-caval masses with a biggest dimension of 5x4 cm and a maximum SUVmax of 3.5. Excisional biopsy of the most FDG avid mass was reported as hyalin vascular type Castleman Disease. He also suffered from coronary artery disease and a chronic subdural hematoma, which are now regarded as the vascular complications of PCD. The patient was diagnosed as CD-POEMS and a combination of Daratumumab – Lenalidomide – Dexamethasone was initiated with a protocol of weekly Daratumumab 16 mg/m2 for first 2 cycles, then once in every two weeks for 4 cycles and then once in a month with the same dose, Lenalidomide 25 mg po 21/28 and dexamethasone 20 mgs per day D1,2 D8,9 D15,16 /28. The aforementioned triple combination was well tolerated. After the 1st cycle of the treatment a VEGF response was achieved, and serum VEGF level was declined to 27.2 pg/ml. Also the serum IL-6 level was decreased and measured as 6.31 pg/ml. The patient was able to stand up and walk with the help of two walking sticks. The PET scan revealed a complete response regarding the Castleman component of the disease. At the third cycle of DRd combination he also underwent a successful revascularization of coronary arteries for the treatment of coronary artery disease. He is now on the 6th Cycle of the treatment with an ongoing and even deepening hematological and neurological response and able to walk without any support.

Summary/Conclusion: This case should serve as a proof of consept among the efficacy and safety of Daratumumab-Lenalidomide-Dexamethasone combination in the treatment of castleman variant of POEMS syndrome.

Myeloproliferative neoplasms - Clinical

PB1700 SCREENING OF SOMATIC MUTATIONS IN THE CALR GENE BY HIGH-RESOLUTION MELTING CURVE ANALYSIS

D. Kurochkin [1,*], T. Subbotina [1], A. Khazieva [2], E. Dunaeva [3], K. Mironov [3]



[1]Siberian Federal University, [2]Regional Clinical Hospital, Krasnoyarsk, [3]Central Research Institute of Epidemiology of The Federal Service on Customers Rights Protection and Human Well-being Surveillance, Moscow, Russian Federation

Background: In accordance with the WHO clinical guidelines, the analysis of somatic mutations in the CALR gene, as well as mutations in the JAK2 and MPL genes, are included in the list of criteria for the Ph-myeloproliferative neoplasms (Ph-MPN) diagnosis. More than 50 different mutation variants have been found in the CALR gene, among which the most frequent are a 52 bp deletion (p.L367fs*46), also called type 1, and a 5 bp insertion (p.K385fs*47), also called type 2 (88%). The remaining 12% are other type less frequent indels or combinations. Therefore, it is important to develop an inexpensive screening test that can detect any mutations in the analyzed DNA fragment of the CALR gene.

Aims: The aim of this study was to screen CALR mutation by HRM analysis using the CFX96 thermocycler and the Precision Melt Analysis software (Bio-Rad, USA) for patients with Ph-MPN.

Methods: 5 CALR«+» DNA samples from MPN patients were included in this study. HRM analysis was performed using a Precision Melt Supermix reagent kit in the presence of Eva Green dye (Bio-Rad, USA). PCR with an additional high-resolution melting step was carried out on a CFX96 device (Bio-Rad, USA) according to the following program: denaturation at 95 ° C for 2 minutes, then 40 cycles at 95 ° C for 10 seconds, 57 ° C in for 30 seconds and 72 ° C for 30 seconds. The high resolution melting program consisted of denaturation at 95 ° C for 30 seconds, renaturation at 60 ° C for 1 minute, and melting at 65 ° C to 95 ° C with a 0.2 ° C gradient in 10 seconds. For the most common CALR mutations (c.1092_1143del and c.1154_1155insTTGTC), a threshold determination of the mutant allele presence was analyzed. To analyze the threshold for determining the proportion of the mutant allele, dilution of cloned wild-type and mutated samples was performed to obtain samples with different levels of allelic loads 100%, 50%, 25%, 12.5%, 6.25%, 3.13%

Results: The results of CALR«+» samples analysis after processing in the "Precision Melt Analysis" program are shown in Figure 1. According to the figure, all melting curves of amplification products from CALR«+» DNA samples are clearly divided into two clusters relative to samples without mutations (cluster No 1). So, two out of five CALR«+» samples (the sample with a classical mutation of type 2 (c.1154_1155insTTGTC) and the sample with a combined mutation (c.1128_1129insCTTTGCT; c.1131_1133delAGA)) were assigned to one cluster (cluster No 2). The three other samples with type 1 mutation (c.1092_1143del) were assigned also to one cluster (cluster No 3). The detection thresholds in case of the c.1092_1143del and c.1154_1155insTTGTC mutation analysis are 12.5% of the presence of the mutant allele in the samples.

Summary/Conclusion: Therefore, the HRM analysis that was conducted on the CFX96 allows screening of highly specific mutation for the diagnosis of Ph-MPN in the exon 9 of the CALR gene. The inclusion of this screening research in the laboratory testing algorithm improves the efficiency and accessibility of molecular genetic technologies in the diagnosis of Ph-MPN.

PB1701 SYSTEMIC MASTOCYTOSIS: A RETROSPECTIVE STUDY OF A SINGLE-CENTER'S EXPERIENCE ON A RARE DISEASE

C. Campos-Costa [1,*], F. Vasconcelos [1], F. Cubal [1], F. Seixas [1], I. Fernandes [2,3,4], R. Cabral [2,4,5], M. Lima [2,4,6], M. Guerra [1], M. Cunha [1]

[1]Hematology Department, Centro Hospitalar de Trás-os-Montes e Alto Douro, Vila Real, [2]Unidade Multidisciplinar de Investigação Biomédica, Instituto Ciências Biomédicas Abel Salazar, Universidade do Porto (UMIB/ICBAS/UP), [3]Dermatology Department, [4]Consulta Multidisciplinar de Linfomas Cutâneos e Mastocitoses, [5]Hematology Department, [6]Laboratório de Citometria, Unidade de Diagnóstico Hematológico, Serviço de Hematologia, Centro Hospitalar e Universitário do Porto, Porto, Portugal

Background: Systemic Mastocytosis (SM) is a rare and heterogeneous disease characterized by the proliferation and accumulation of neoplastic mast cells in one or more organ systems. Its manifestations range from an indolent disease, to a highly aggressive neoplasm with associated multiorgan failure. Due to its rarity and wide range of symptoms, SM can be challenging to diagnose so a high index of suspicion should be maintained throughout the course of investigation of these patients.

Aims: To describe a single-center's experience on the diagnosis and management of SM with special emphasis on its presenting manifestations and symptoms.

Methods: A retrospective revision of adult patients referred to our department and diagnosed with SM was performed. The diagnosis of SM followed the 2016 WHO classification criteria. Laboratory/diagnostic

findings and patient management was carried out in collaboration with a specialized center.

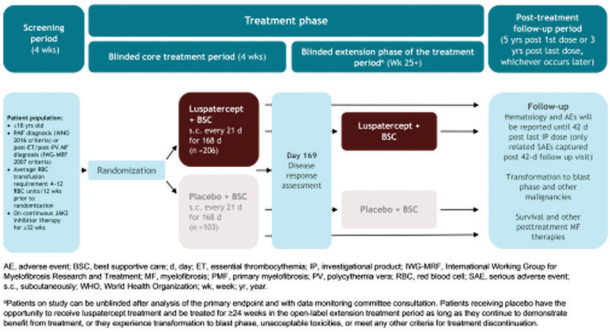
Results: Eleven patients were diagnosed with SM at our institution, 5 females (45%) and 6 males (55%), with a median age at diagnosis of 52 years (range 38-68). Most patients (n=9, 82%) were referred to our clinic from other departments at our institution, while 2 patients (18%) were referred directly from their General Practitioner. Four patients (36%) presented with cutaneous manifestations, had a previous skin biopsy which confirmed mastocytosis in the skin, and were referred to exclude SM; 3 patients (27%) had previous severe anaphylaxis requiring hospitalization, 1 with cardiac arrest and admission to an Intensive Care Unit; 1 patient (9%) was referred for suspicion of an acute leukemia; the remainder 3 patients (27%) were referred for investigation of splenomegaly, polycythemia and eosinophilia. Regarding the diagnostic approach, all patients performed a complete blood count and basic biochemical evaluation, serum tryptase level measurement, bone marrow biopsy with morphologic and immunophenotypic study of mast cells. Nine patients (82%) had a *KIT D816V* mutation analysis. The presence of B and C findings was also evaluated. Hence 7 patients (64%) were diagnosed with Indolent SM (ISM) and 4 patients were diagnosed with other forms of SM, 1 case (9%) each: Smoldering SM (SSM); Aggressive SM (ASM); Mast Cell Leukemia (MCL); and SM with an associated hematological neoplasm (SM-AHN). The median time from first symptoms to diagnosis was 4 years, ranging from 3 months to 38 years. The main symptoms of our cohort are presented on Table 1. All patients received symptomatic treatment according to their needs, with H1 and H2 anti-histamines, sodium cromoglycate, biphosphonates, bee/wasp immunotherapy, omalizumab, among others. The patient with ASM received several cytoreductive therapies (pegylated interferon-α, cladribine, dasatinib), but only after initiation of midostaurin was the disease stabilized. The MCL patient was treated with cladribine with poor response, dying from refractory disease 1 month after diagnosis. All the remaining patients are still alive and under clinical surveillance.

Table 1: Clinical Manifestations

	Total	ISM	SSM	ASM	MCL	SM-AHN
Number	11 (100%)	7 (63,6%)	1 (9,1%)	1 (9,1%)	1 (9,1%)	1 (9,1%)
Clinical Manifestations						
Cutaneous	9 (81,8%)	6 (85,7%)	1 (100%)	1 (100%)	0	1 (100%)
Anaphylaxis	4 (36,3%)	3 (42,9%)	0	1 (100%)	0	0
Hymenoptera venom	3 (27,3%)	3 (42,9%)		0		
Food/Drugs	1 (9,1%)	0		1 (100%)		
Gastrointestinal	6 (54,5%)	4 (57,1%)	1 (100%)	1 (100%)	0	0
Nausea/Vomiting	2 (18,2%)	1 (14,3%)	0	1 (100%)		
Gastritis	4 (36,4%)	3 (42,9%)	1 (100%)	0		
Diarrhea	2 (18,2%)	1 (14,3%)	0	1 (100%)		
Cardiovascular	2 (18,2%)	1 (14,3%)	0	1 (100%)	0	0
Syncope	1 (9,1%)	0		1 (100%)		
Flushing	1 (9,1%)	1 (14,3%)		0		
Neurological	4 (36,3%)	4 (57,1%)	0	0	0	0
Brain fog	2 (18,2%)	2 (28,6%)				
Depression	2 (18,2%)	2 (28,6%)				
Headache	1 (9,1%)	1 (14,3%)				
Musculoskeletal	3 (27,3%)	1 (14,3%)	1 (100%)	1 (100%)	0	0
Osteopenia/porosis	3 (27,3%)	1 (14,3%)	1 (100%)	1 (100%)		
Osteolysis	1 (9,1%)	0	0	1 (100%)		
Bone pain	3 (27,3%)	1 (14,3%)	1 (100%)	1 (100%)		
Constitutional	3 (27,3%)	0	0	1 (100%)	1 (100%)	1 (100%)
Organopathy	3 (27,3%)	0	1 (100%)	1 (100%)	1 (100%)	0
Hepatomegaly	2 (18,2%)		0	1 (100%)	1 (100%)	
Splenomegaly	3 (27,3%)		1 (100%)	1 (100%)	1 (100%)	
Cytopenias	2 (18,2%)		0	1 (100%)	1 (100%)	

ISM: Indolent Systemic Mastocytosis; SSM: Smoldering Systemic Mastocytosis; ASM: Aggressive Systemic Mastocytosis; MCL: Mast Cell Leukemia; SM-AHN: Systemic Mastocytosis with an Associated Hematological Neoplasm

Summary/Conclusion: Our data illustrates the heterogenicity of the clinical manifestations of SM. Patients range from nearly asymptomatic to severely ill, with a wide array of symptoms that can mimic other diseases. A multidisciplinary approach is of utmost importance for an earlier diagnosis of this rare condition and for a correct approach on the treatment options for these patients. Furthermore, an international collaborative work would certainly help further understand the clinical course of this disease and would be beneficial for the development of novel treatment strategies.



PB1702 EFFICACY AND SAFETY OF LUSPATERCEPT VERSUS PLACEBO IN PATIENTS WITH MYELOPROLIFERATIVE NEOPLASM-ASSOCIATED MYELOFIBROSIS ON JAK2 INHIBITOR THERAPY AND REQUIRING RBC TRANSFUSIONS (INDEPENDENCE TRIAL)

R. Mesa [1,*], G. Barosi [2], C. Harrison [3], J.-J. Kiladjian [4], S. Verstovsek [5], T. G. Gerike [6], V. Chia [6], J. K. Shetty [7], Y. Wang [6], H. Marks [6], F. Passamonti [8]

[1]Mays Cancer Center, UT Health San Antonio Cancer Center, San Antonio, TX, United States, [2]IRCCS Policlinico San Matteo Foundation, Pavia, Italy, [3]Guy's and St Thomas' NHS Foundation Trust, London, United Kingdom, [4]Hôpital Saint-Louis et Université Paris Diderot, Paris, France, [5]Department of Leukemia, The University of Texas MD Anderson Cancer Center, Houston, TX, [6]Bristol Myers Squibb, Princeton, NJ, United States, [7]Celgene International Sàrl, a Bristol-Myers Squibb Company, Boudry, Switzerland, [8]Department of Medicine and Surgery, University of Insubria, Varese, Italy

Background: Myeloproliferative neoplasm (MPN)-associated myelofibrosis (MF) is a clonal myeloid neoplasm characterized by defective bone marrow (BM) function, BM fibrosis, ineffective erythropoiesis, and increased risk of progression to acute myeloid leukemia (AML). Up to 60% of patients (pts) with MF present with anemia at diagnosis, and eventually all pts go on to develop anemia. Anemia associated with transfusion-dependent MF is associated with poor survival and there are limited treatment options. Luspatercept is a first and only erythroid maturation agent approved in both the EU and the USA for treatment of anemia in pts with β-thalassemia who require red blood cell (RBC) transfusions and in pts with lower-risk myelodysplastic syndromes with ring sideroblasts who failed erythropoiesis-stimulating agent (ESA) treatment and require RBC transfusions. In a preliminary analysis of a phase 2 trial evaluating luspatercept in pts with MF-associated anemia (NCT03194542), 27% of pts achieved at least one ≥12-week (wk) episode of RBC transfusion independence (TI) with luspatercept within the first 24 wks of treatment (Gerds et al. *Blood* 2020;136(suppl 1):47–48).
Aims: This trials-in-progress abstract details eligibility criteria and trial design of the currently enrolling phase 3 INDEPENDENCE trial.
Methods: INDEPENDENCE is a phase 3, double-blind, randomized trial to evaluate the efficacy and safety of luspatercept versus placebo in pts with MPN-associated MF receiving concomitant JAK2 inhibitor therapy who require RBC transfusions. Eligible pts must be ≥18 years old, have a documented diagnosis of primary MF, post-essential thrombocythemia MF or post-polycythemia MF, require regular RBC transfusions (defined as 4–12 RBC units/12 wks prior to randomization), and receiving JAK2 inhibitor therapy for ≥32 wks (on stable daily dose for ≥16 wks) prior to randomization. Exclusion criteria include presence of anemia due to causes other than MPN-associated MF or JAK2 inhibitor therapy, and prior use of hydroxyurea, immunomodulatory compounds (pomalidomide, thalidomide), ESAs, androgenic steroids, or other drugs with potential effects on hematopoiesis ≤8 weeks before randomization. Following screening, ~309 pts will be randomized 2:1 to either luspatercept (starting at 1.33 mg/kg with titration up to 1.75 mg/kg) subcutaneously every 3 wks, or placebo (Figure). Best supportive care, including RBC transfusions, iron chelation therapy, antibiotic, antiviral, and/or antifungal therapy, is permitted in both treatment arms. Stratification factors include RBC transfusion burden and Dynamic International Prognostic Scoring System (DIPSS) score at baseline.
Results: Clinical benefit (CB) will be assessed after 24 wks of treatment, and is defined as RBC-TI for any consecutive ≥12-wk period during Wks 1–24 of study, a reduction in RBC transfusion burden by ≥50% and by ≥4 units for ≥12 wks during Wks 1–24, or an incomplete duration of response, defined as being free from RBC transfusions for ≥4 wks immediately up to the end of 24 wks. Pts achieving CB can continue luspatercept treatment as long as they continue to benefit, or until progression to AML, unacceptable toxicities, withdrawal of consent, or until meeting any other criteria for treatment discontinuation. Primary endpoint of the study is the proportion of pts who become RBC-transfusion free over any consecutive 12-wk period starting from randomization up to and including Wk 24.

Figure. The INDEPENDENCE trial design

AE, adverse event; BSC, best supportive care; d, day; ET, essential thrombocythemia; IP, investigational product; IWG-MRF, International Working Group for Myelofibrosis Research and Treatment; MF, myelofibrosis; PMF, primary myelofibrosis; PV, polycythemia vera; RBC, red blood cell; SAE, serious adverse event; s.c., subcutaneously; WHO, World Health Organization; wk, week; yr, year.

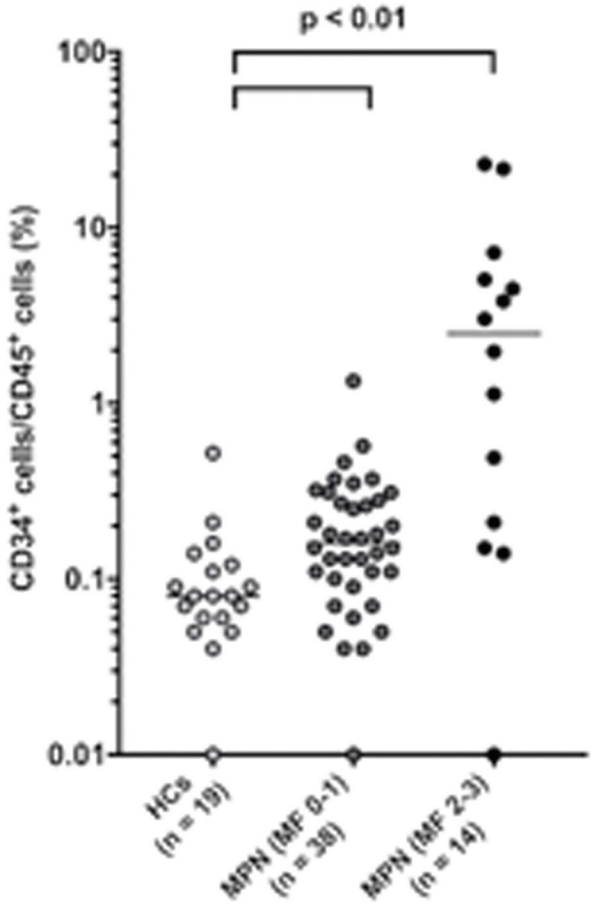
*Patients on study can be unblinded after analysis of the primary endpoint and with data monitoring committee consultation. Patients receiving placebo have the opportunity to receive luspatercept treatment and be treated for ≥24 weeks in the open-label extension treatment period as long as they continue to demonstrate benefit from treatment, or they experience transformation to blast phase, unacceptable toxicities, or meet any other criteria for treatment discontinuation.

Summary/Conclusion: The INDEPENDENCE trial is registered at EudraCT (2020-000607-36) and ClinicalTrials.gov (NCT04717414).

PB1703 THE FREQUENCY OF CD34+ CELLS PER CD45+ CELLS IN PERIPHERAL BLOOD ENUMERATED BY AUTOMATED METHOD IS EFFECTIVE AS A NON-INVASIVE MARKER OF MYELOFIBROSIS IN THE PATIENTS WITH MYELOPROLIFERATIVE NEOPLASMS

T. Maekawa [1,*], H. Ogata [1], T. Kawamura [1], S. Kato [1], Y. Osawa [1], A. Kobayashi [1], S. Kobayashi [1], F. Kimura [1]

[1]Department of Internal Medicine, Division of hematology, National Defense Medical College, Tokorozawa, Japan



Background: The CD34+ cells in peripheral blood (PB) increased in myeloproliferative neoplasm (MPN) patients with myelofibrosis (MF) compared with MPN patients without MF, and were significantly correlated with disease duration, spleen volume, liver volume and risk classification. Further, the CD34+ cells in PB could be useful as a biomarker for prognosis and follow-up in the allo-SCT setting in MPN patients with MF.

Flow cytometric applications for CD34+ cell enumeration provide a rapid, quantitative, and reproducible method. However, significant site-to-site variation has been reported. Moreover, the variability associated with hematology-derived absolute counts is quite considerable. Single-platform flow cytometric absolute cell counting protocols have been shown to provide increased robustness of CD34+ enumeration. Enumeration of the cell populations in this study is obtained using an automated method for gating and analysis.

Aims: This study aimed to investigate the correlation between the frequency of CD34+ cells per CD45+ cells in PB (CD34+ cells/CD45+ cells) and MF progression, splenomegaly or cytokine levels.

Methods: We measured CD34+ cells/CD45+ cells of 19 healthy controls (HCs) and 52 MPN patients without ruxolitinib (Rux) treatment using BD™ Stem Cell Enumeration Kit®. The MPN patients with Rux treatment were excluded from this study because these patients had already been diagnosed MF before Rux treatment and Rux could affect the cytokine profiles and splenomegaly. The bone marrow biopsy was also performed at the same time as the PB sample collection. We also examined the concentration of 24 cytokines in the serum of 52 MPN patients using Human Luminex® Assays. Thereafter, we assessed the correlations between CD34+ cells/CD45+ cells and MF onset, splenomegaly or cytokine levels.

Results: The median percentage of CD34+ cells/CD45+ cells of HCs (n = 19), MPN patients with MF grade 0-1 (n = 38) and MPN patients with MF grade 2-3 (n = 14) were 0.08%, 0.16%, and 2.49%, respectively. Compared with HCs and MPN patients with MF grade 0-1, CD34+ cells/CD45+ cells of MPN patients with MF grade 2-3 significantly increased ($p < 0.01$). Further, MPN patients with MF grade 2-3 had significantly higher CD34+ cells/CD45+ cells than MPN patients with MF grade 0-1 ($p < 0.01$). For the ROC curve, the sensitivity and specificity for classifying MF grade 2-3 were 71.4% and 94.7% with the cutoff set to > 0.5%. Moreover, the sensitivity for detecting MF progression of CD34+ cells/CD45+ cells (71.4%) was approximately two times higher than that of the blast emergence in hemogram (35.7%). On the other hand, the median percentage of CD34+ cells/CD45+ cells of MPN patients without splenomegaly (n = 41) and MPN patients with splenomegaly (n = 11) were 0.17% and 3.81%. MPN patients with splenomegaly had significantly higher CD34+ cells/CD45+ cells than those without splenomegaly ($p < 0.01$). For the ROC curve, the sensitivity and specificity for classifying splenomegaly onset were 72.7% and 95.1% with the cutoff set to > 1.0%. In addition, TNF-a, IL-8 and CXCL1 showed significant correlations with CD34+ cells/CD45+ cells ($R^2 = 0.538$, 0.435 and 0.260, respectively).

Summary/Conclusion: In our study, CD34+ cells/CD45+ cells in PB elevated in MPN patients with MF grade 2-3, and was significantly correlated with MF grade, splenomegaly, TNF-a, IL-8 and CXCL1. It would be worth evaluating the efficacy of CD34+ cells/CD45+ cells as non-invasive markers of MF progression in a prospective study.

PB1704 CLINICAL BENEFIT IN REAL LIVE OF ALTERNATIVE RUXOLITINIB DOSING REGIME IN MYELOFIBROSIS PATIENTS

F. Hernandez Mohedo [1,*], E. Masana Flores [1], A. Pardo Vela [1], M. Bernal Sanchez [1], M. García Valdés [2], J. M. Puerta Puerta [1], A. Jiménez Morales [2], M. Jurado Chacón [1]

[1]Hematology, [2]Pharmacy, Hospital Universitario Virgen de las Nieves, GRANADA, Spain

Background: Despite ruxolitinib is considered the standard of care for patients with myelofibrosis (PMF and post-ET/post-PV MF) in not allogeneic stem-cell transplant candidates with Intermediate or High-risk IPSS, is necessary to confirm in real live the clinical benefit, in spleen, symptomatic responses and overall survival (OS) outcomes, achieved in COMFORT-I and -II trials. In the other hand, nearly half of the patients develop grade 3/4 anemia or thrombocytopenia, that usually lead to a dose reduction, that can have a negative impact on its efficacy.

Aims: We conducted this study to evaluate the differences on clinical benefit of alternative rusolitinib dosing regime in real live.

Methods: 6-year observational retrospective study of 53 patients with myelofibrosis (years 2013 -2019), 41 of them, not allogeneic stem-cell transplant candidates on ruxolitinib therapy, stratified by IPSS, DIPSS-PLUS and MIPSS 70+ v.2.0, and divided into 2 arms according to the maximum dose reached of ruxolitinib (A ≥ 15 mg BID and B <15 mg BID). We evaluated the rate of response according to IWG-MRT-2013 criteria, and we perform a survival analysis.

Results: 41 not candidates for transplantation on Ruxolitinib therapy (median age 62 year; 11 PMF and 30 Post-ET and Post-PV). Group A ≥

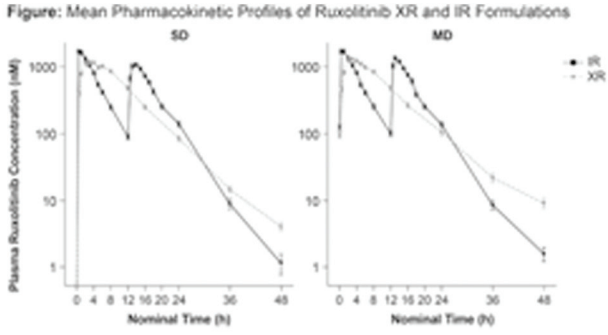
15 mg BID (N=19) and B <15 mg BID (N=22). With a median follow-up of 19 months (9,5-45), we observe a similar duration of treatment, IPSS and DIPSS-Plus score in both arms, although the MIPSS70+ high score was more frequent in B arm (66,7% vs. 15,4%; p=0.026). We did not observe statistically significant differences in spleen response (A 52,9% vs. B 25,0%; p=0.081), symptomatic responses (A 84,2% vs. B 63,6%; p=0.138) or 5-years OS (A 89.5% vs. B 75.1%; P=0.300), although the hematological improvement is more frequent in arm A (63.5% vs. 22.7%; p=0.009).
Summary/Conclusion: Despite the observed trend of lower spleen and symptomatic responses in arm B (ruxolitinib <15 mg BID), these are not statistically significant, and these do not translate into differences in OS in real live. High-risk MIPSS 70+ more frequently need dose reduction of Ruxolitinib, due to their baseline cytopenias, and probably this factor is the most important for evaluation of clinical benefit of Ruxolitinib in real live.

PB1705 REAL-LIFE RUXOLITINIB EXPERIENCE IN AN INTERMEDIATE-1 RISK PREDOMINANT COHORT

T. Toptas [1,*], F. Arikan [1], T. Ercan [1], O. Oruc [1], F. Yilmaz [1], I. Kaygusuz Atagunduz [1], T. Tuglular [1]

[1]Hematology, Marmara University, Istanbul, Turkey

Background: Data regarding ruxolitinib safety and efficacy in intermediate-1 risk patients are scarce.
Aims: In this retrospective study, we aimed to document a real-life clinical experience with ruxolitinib in predominantly intermediate risk primary and secondary MF patients.
Methods: Fifty six patients who received ruxolitinib were included into the analyses. All patients were at least 18 years of age and they had INT-1/2 or high risk disease according to DIPSS-plus risk classification.
Results: Patients
The median age of patients was 58 (23-80) years. Overall, 50.9% of patients were male and 49.2 % had PMF. Patient assignment according to DIPSS-plus risk categories goes as follows: 33 patients (57.9 %) in INT-1, 23 patients (40.4 %) in INT-2, 1 patients (1.8%) in high-risk. Hydroxyurea was used previously by 91.2% of the patients before ruxolitinib. JAK2 was obtained positive in 71.9% of the patients.
Efficacy
Overall, a spleen size reduction of at least 35% (spleen response) was achieved in 56.6% of patients (30/53) at any time. A spleen response at 6 months was observed in 41.5 % of patients. Only 36.6 % (11/30) of the patients in INT-1 myelofibrosis group achieved a spleen response at 6 months.
Twenty three patients had MPN-SAF TSS during the course of the treatment. Five patients (21.7%) had at least 50% reductions in myelofibrosis associated symptoms. In 10 patients (43.5%), a 20-50% reduction in symptom score was observed. Four patients (17.4%) had only mild (5-10%) symptom responses.
Safety
Median duration of exposure to ruxolitinib was 22 months (range: 1-80 months). Forty-two patients (%73.7) were still receiving ruxolitinib. Initial dose of ruxolitinib was 20 mg bid in 67% of the patients.
Fifty two out of 57 (91%) experienced any kind of hematologic side effect. Most common hematologic adverse events were anemia (all grades, 84.2%; grade 3-4, 42.1%) and thrombocytopenia (all grades, 38.6%; grade 3-4, 17.5%). Cytopenias were more prominent within the first three months.
A total of 27 out of 57 patients experienced non-hematologic side effects, which were generally grade 1-2. Most common non-hematologic adverse events were fatigue, pneumonia, and elevated liver enzymes. Pulmonary embolism was observed in two patients who had pneumonia. Herpes zoster infection, hepatitis B virus (HBV) reactivation, and urinary tract infection were noted. Overall, three patients diagnosed with cancer including pancreas adenocarcinoma, squamous cell carcinoma of the skin and metastatic neuroendocrine tumor. Patients with INT-1 risk had the similar safety profile.
Survival
A total of 17 (29.8%) deaths occurred during a median follow-up of 22 months. Causes of death were as follows: transformation to acute myeloid leukemia (n=5), disease progression (n=11), and pancreas adenocarcinoma (n=1). In all cohort, overall survival probability at 24 months was 75.1% (95% CI: 59.8% to 85.3%). Median overall survival was not reached.
Since previous studies claim that basal hemoglobin levels lower than 10 g / dL was associated with worse survival outcomes, we stratified survival probabilities according to basal hemoglobin levels as well. Median survival was not reached in both group with Hb< 10 g / dL and Hb ≥ 10 g / dL during the first 2 years, patients with a Hb ≥ 10 g / dL seem to have a better survival. Two year survival probabilities were 58.5 % (95% CI: 34.5 to 76.4%) versus 87.5 % (95% CI: 65.5% to 95.9%), respectively. However, survival curves merged at month 33 and beyond (p=0.15).
Summary/Conclusion: Ruxolitinib is safe and effective in all risk groups of patients with myelofibrosis.



PB1706 BIOEQUIVALENCE OF 50 MG ONCE-DAILY RUXOLITINIB EXTENDED RELEASE (XR) TABLETS COMPARED TO 25 MG TWICE-DAILY RUXOLITINIB IMMEDIATE RELEASE (IR) TABLETS

X. Gong [1,*], N. Punwani [1], E. Cimino [1], B. Yuska [1], X. Liu [1], K. Rockich [2], J. Getsy [1], S. Yeleswaram [1]

[1]Incyte Research Institute, Incyte Corporation, [2]Incyte Corporation, Wilmington, United States

Background: Ruxolitinib is currently dosed twice-daily (BID) using an immediate release (IR) formulation for the treatment of myelofibrosis, polycythemia vera, and acute graft-versus-host disease. An extended release (XR) formulation of ruxolitinib was developed to allow once-daily (QD) dosing. Five XR tablet strengths were developed, containing 10, 20, 30, 40, and 50 mg of ruxolitinib, free base equivalent.
Aims: To establish the bioequivalence of the highest strength of ruxolitinib XR tablets (50 mg) dosed QD to the highest strength of ruxolitinib IR tablets (25 mg) dosed BID, following a single dose and at steady-state.
Methods: This phase 1, open-label, randomized, 2-period, 2-way crossover study in 60 healthy adult participants evaluated single-dose and steady-state bioequivalence of ruxolitinib 50 mg XR tablets compared to ruxolitinib 25 mg IR tablets. In treatment period 1, participants were randomly assigned to receive ruxolitinib XR or ruxolitinib IR; following a 9-day washout period, participants entered treatment period 2 and crossed over to receive the other formulation (IR or XR, respectively). Each treatment period consisted of single-dose and multiple-dose parts. In the single-dose part of the study, participants received either ruxolitinib XR 50 mg as a single dose or ruxolitinib IR as 2 doses of 25 mg each administered 12 hours apart; in the multiple-dose part of the study, participants received ruxolitinib XR 50 mg QD or ruxolitinib IR 25 mg BID for 4 days (4 doses and 8 doses, respectively). Standard non-compartmental pharmacokinetic (PK) analysis methods were used to calculate PK parameters. Average bioequivalence analysis was performed for the determination of geometric mean ratio (GMR) and 90% confidence interval (CI) for the comparison of PK parameters between the test formulation (XR) and the reference formulation (IR). Bioequivalence criteria required the point estimate and 90% CI limits to lie within the range of 0.8-1.25. The measures used for bioequivalence evaluation included C_{max}, C_{24h}, AUC_{0-t}, and $AUC_{0-\infty}$ from the single-dose part, and $C_{max,ss}$, C_{24h}, and AUC_{0-24h} from the multiple-dose part. Safety and tolerability were assessed by monitoring the frequency and severity of adverse events; performing physical examinations; and collecting vital signs, 12-lead electrocardiograms, and clinical laboratory data.
Results: The PK profiles of ruxolitinib XR and IR for single dose and multiple-dose parts are shown in Figure 1. The 50 mg ruxolitinib XR tablet formulation met the bioequivalence criteria for AUC parameters both following a single dose and at steady-state; bioequivalence was not achieved for C_{max} or C_{24h}. All treatments were well tolerated and no new safety findings were observed with administration of ruxolitinib XR.

Figure: Mean Pharmacokinetic Profiles of Ruxolitinib XR and IR Formulations

IR, immediate release; MD, multiple-dose; SD, single dose; XR, extended release.
Error bars represent ±1 × standard error.

Summary/Conclusion: Ruxolitinib XR 50 mg tablets dosed QD is bioequivalent to 25 mg IR tablets dosed BID, based on AUC parameters. No new safety concerns were observed with ruxolitinib XR.

PB1707 ESSENTIAL THROMBOCYTHEMIA AND THE RISK OF POLYPHARMACY: ASSESSMENT OF POTENTIAL DRUG-DRUG AND FOOD-DRUG INTERACTIONS

M.-A. Gaman [1,2,*], A. M. Gaman [3,4], C. C. Diaconu [5,6]

[1]Faculty of Medicine, "Carol Davila" University of Medicine and Pharmacy, 8 Eroii Sanitari Boulevard, Bucharest 050474, [2]Hematology, Center of Hematology and Bone Marrow Transplantation, Fundeni Clinical Institute, 258 Fundeni Road, Bucharest 022328, Romania, Bucharest, [3]Pathophysiology, University of Medicine and Pharmacy, [4]Clinic of Hematology, Filantropia City Hospital, Craiova, [5]Internal Medicine, "Carol Davila" University of Medicine and Pharmacy, 8 Eroii Sanitari Boulevard, Bucharest 050474, [6]Internal Medicine Clinic, Clinical Emergency Hospital of Bucharest, Bucharest, Romania

Background: Polypharmacy is defined as the concurrent use of 5 or more medications/day by a single subject. As the lifespan increases worldwide, patients diagnosed with essential thrombocythemia (ET) are often exposed to polypharmacy due to age-related comorbidities and lifelong ET management.
Aims: Identify polypharmacy use and the risk of potential drug-drug (DDI)/food-drug interactions (FDI) in ET patients on risk-adapted therapy.
Methods: The electronic medical records of the Internal Medicine Clinic, Clinical Emergency Hospital of Bucharest, Bucharest, Romania, were searched from inception (available since August 2014) to February 2021. We included all ET patients who received risk-adapted therapy, had signed the written informed consent for participation in medical research and for whom information regarding prescribed medications was available. The study was approved by the hospital's ethics council (35552/22.10.2020). DDI/FDI were evaluated using an online drugs interaction checker.
Results: We identified 15 ET patients, median age 65 years, range 41-80 years, 60.0% females. Cytoreductive therapy was based predominantly on hydroxycarbamide (73.3%), anagrelide (13.3%) or their combination (13.4%). Due to thrombotic risk and associated comorbidities, most patients received antiplatelet drugs (acetylsalicylic acid 13.3%, clopidogrel 13.3%) or systemic anticoagulation alone (acenocoumarol 20.0%, dalteparin 13.3%) or their combination (acetylsalicylic acid + acenocoumarol 6.67%, clopidogrel + rivaroxaban 6.67%). Polypharmacy was detected in 66.67% of ET cases, all patients receiving at least 3 drugs/day. The mean number of prescribed drugs, DDI and FDI were 6.67±2.91 (range 3-12), 4.40±5.83 (range 0-24) and 1.87±1.82 (range 0-8). We recorded 66 DDI (20 major, 1.33±1.81/patient; 36 moderate, 2.40±3.44/patient; 10 minor, 0.67±0.87/patient) and 28 FDI (6 major, 0.40±0.61/patient; 20 moderate, 1.33±1.49/patient; 2 minor, 0.13±0.34/patient). Hydroxycarbamide led to 2 major DDI with infliximab and 1 moderate DDI with *Saccharomyces boulardii*. Anagrelide led to 5 major DDI with amiodarone, ciprofloxacin, dalteparin, ivabradine and rivaroxaban, and 2 moderate DDI with carvedilol and omeprazole. The main DDI and the drugs which led to FDI are reported in the attached tabel. The mean number of drugs prescribed correlated with the number of DDI (r=+0.887, P<0.001), major DDI (r=+0.743, P=0.002), moderate DDI (r=+0.834, P<0.001), minor DDI (r=+0.706, P=0.003), FDI (r=+0.735, P=0.002), moderate FDI (r=+0.731, P=0.002), but not with the number of major/minor FDI (P=0.207 and P=0.242, respectively). The number of DDI-per-patient also correlated with the number of FDI-per-patient (r=+0.879, P<0.001), major (r=+0.548, P=0.035) and moderate (r=+0.785, P=0.001) FDI, but not minor FDI (P=0.179). Surprisingly, there was no correlation between the age of ET patients and the number of drugs prescribed/DDI/FDI or major/moderate/minor FDI/DDI.
Summary/Conclusion: Risk-adapted therapy remains safe in ET, yet due to age-related comorbidities and increased risk of polypharmacy, these patients should be closely monitored to avoid DDI and FDI and reduce medication burden. To our knowledge, this is the first assessment of polypharmacy and DDI/FDI in ET. However, since there was no correlation of the number of drugs prescribed or of the DDI/FDI with the age of the participants, this might signal that polypharmacy is emerging as a public health issue irrespective of age and points out that the multidisciplinary team involved in the management of ET patients could also include clinical pharmacists/pharmacologists.

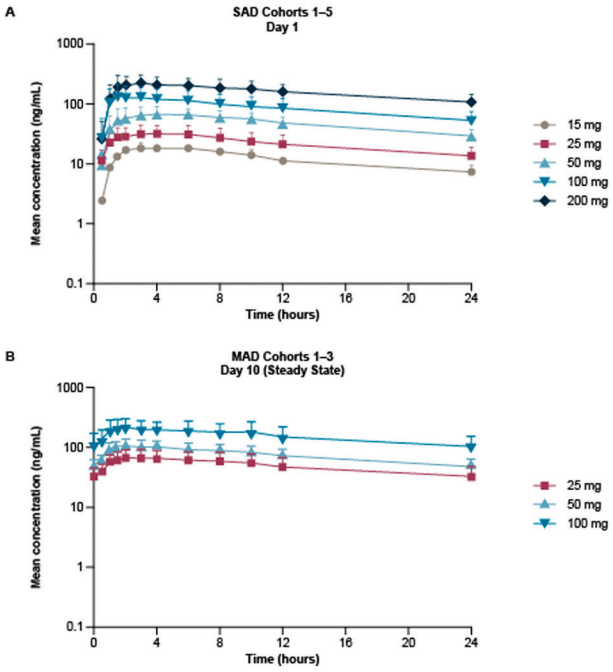
PB1708 LYMPHOPENIA IS HIGHLY PREVALENT IN OVERT MYELOFIBROSIS AT DIAGNOSIS AND ASSOCIATED WITH THE DEGREE OF ANEMIA AND THROMBOCYTOPENIA.

N.-M. Messerich [1], S. Cogliatti [2], T. Lehmann [3], A. Holbro [4], L. Graf [5], T. Silzle [3,*]

[1]Department of General Internal Medicine, [2]Department of Pathology, [3]Department of Medical Oncology and Hematology, Cantonal Hospital St. Gallen, St. Gallen, [4]Division of Hematology, University Hospital of Basel, Basel, [5]Centre for Laboratory Medicine, St. Gallen, Switzerland

Background: Lymphopenia is common in a variety of malignancies, including lymphoma and myelodysplastic syndromes. Little is known about its prevalence in BCR-ABL1-negative myeloproliferative neoplasms (MPN) and its association to prognostic factors or systemic inflammation.
Aims: To evaluate the prevalence of lymphopenia in BCR-ABL-negative MPN at diagnosis and its possible association with disease-related or prognostic factors.
Methods: Patients diagnosed with a BCR-ABL1-negative MPN between 2010-2020 and having given informed consent were evaluated for the absolute lymphocyte count (ALC) at diagnosis. In addition, parameters of the DIPSS-(plus)-Score and markers of systemic inflammation (albumin, CRP) were retrospectively collected from hospital records. The study was approved by the local ethics committee.
Results: 116 patients were included into this preliminary analysis. The median ALC was significantly lower in overt Myelofibrosis (MF) compared to Essential Thrombocythemia (ET), Polycythemia Vera (PV) and prefibrotic PMF (1.3x10^9/L versus 1.8x10^9/L, 2.05x10^9/L and 1.9 x10^9/L, respectively; p=0.005).
An absolute lymphopenia (defined as ALC <1.0x10^9/L) was observed in 10/35 patients with overt MF (29%; primary MF n=24, post-ET MF n=3, post-PV MF n=8), 2/35 with ET (6%) and not seen in PV (0/30) and prefibrotic PMF (0/16).
Regarding the single factors of the DIPSS-(plus), the ALC was significantly lower in patients with a hemoglobin < 10 g/l and with platelets < 100x10^9/L (1.1 vs. 1.6x10^9/L; p=0.019; and 0.75 vs. 1.5 x10^9/L; p=0.036, respectively). Patients with leukocytes > 25x10^9/L (n=3) had higher lymphocyte counts (median 2.5 vs. 1.3 x10^9/L; p=0.02). For transfusion-dependency, a trend towards a lower ALC was observed (median 0.9 vs. 1.5x10^9/L, p=0.134). No significant differences of the median ALC were observed for absence/presence of constitutional symptoms, age ≤/> 65 years and peripheral blasts 9/L, intermediate-1 [n=12] 1.4x10^9/L, intermediate-2 [n=14] 1.2x10^9/L and high-risk [n=5] 1.9 x10^9/L; p=0.876). Since metaphase cytogenetics were available in a minority of patients only, the DIPSS-plus could not be evaluated.
Patients with a CRP > ULN (5 mg/l) or an albumin-concentration <35 g/l did not differ in regard to their median ALC (1.5 vs. 1.2x10^9/L, p=0.32 and 1.4 vs. 1.3x10^9/L, p=0.886). In addition, there was no difference of the median ALC between the different risk groups of the Glasgow Prognostic Score (GPS), which combines CRP >10mg/l and albumin < 35 g/l (GPS 0 [n=19]: 1.5 x10^9/L; GPS 1 [n=8]: 1.4 x10^9/L, GPS 2 [n=3] 1.1x10^9/L; p=0.927).
Summary/Conclusion: Within our MPN cohort, lymphopenia at diagnosis was largely restricted to patients with overt myelofibrosis with considerable prevalence in this entity. Its association with a lower hemoglobin concentration and lower platelet counts points towards a causal relationship of lymphopenia and the pathobiology of the MF-associated bone marrow failure. We were not able to show any influence of systemic inflammation on the ALC or any association of lymphopenia with disease-risk according to DIPSS. However, interpretation of our data is considerably hampered by



the low patient numbers and the retrospective nature of the analysis. Given the rarity of the disease, evaluation of larger (prospective) multicentric patient cohorts would be desirable in order to identify factors related to lymphopenia and to further elucidate its prognostic impact.

PB1709 SAFETY AND PHARMACOKINETICS OF BLU-263, A NEXT GENERATION KIT INHIBITOR, IN NORMAL HEALTHY VOLUNTEERS

N. Dave [1,*], M. Devlin [1], J. Rodstrom [1], B. Yu [1], M. Foley [1], K. He [1], S. Rassmussen [2], A. Boral [1], T. Dong Si [1]

[1]Blueprint Medicines Corporation, Cambridge, MA, [2]Celerion, Inc, Lincoln, NE, United States

Background: BLU-263 is an investigational, potent, and selective oral small molecule inhibitor of KIT with sub-nanomolar potency against D816V-mutant KIT. Systemic mastocytosis is driven by the *KIT* D816V mutation in approximately 95% of cases and is vulnerable to KIT D816V inhibition. BLU-263 was highly active in a murine model of mastocytosis and was well tolerated with minimal central nervous system penetration in preclinical species.
Aims: Here we report the safety, tolerability, and pharmacokinetics (PK) of BLU-263 in an ongoing Phase 1, randomized, double-blind, placebo-controlled single ascending dose (SAD) and multiple ascending dose (MAD) study.
Methods: In the SAD portion of the study, cohorts of eight normal healthy volunteers aged ≥19 years received either oral placebo (n=2/cohort) or single oral doses of BLU-263 (n=6/cohort) of 15, 25, 50, 100, or 200 mg. In the MAD portion of the study, normal healthy volunteer cohorts received either oral placebo or BLU-263 at 25, 50, or 100 mg once daily (QD) on each of 10 consecutive days. Blood plasma samples were collected for PK analyses at pre-dose and 0.5, 1, 1.5, 2, 3, 4, 6, 8, 10, 12, 24, 48, 72, and 96 hours post-dose in SAD cohorts, and the same post-dose time points after dosing on days 1 and 10 in the MAD cohorts. Safety was assessed according to incidence and severity of adverse events (AEs) in recipients of BLU-263 as compared with placebo.
Results: BLU-263 was well tolerated across the five BLU-263 SAD cohorts and three MAD cohorts. Only Grade 1 AEs were reported, and most were assessed as not related to the study drug by the investigator. These AEs included pain at the blood-sampling site, headache, dry/itchy skin, nausea, and stomachache. No serious AEs were reported, and there were no clinically relevant findings in laboratory, electrocardiogram, or vital signs parameters. After administration of BLU-263 at single doses, the median time to maximum concentration ranged from 1.5 to 6 hours post-dose. The mean half-life of BLU-263 ranged from 20 hours to 28 hours, indicating that steady-state would be reached by Day 7, supporting QD dosing. After 10 days of repeated oral administration of 25 to 100 mg BLU-263, the geometric mean accumulation ratio for area under the curve ranged from 1.6 to 1.8. The geometric mean apparent volume of distribution ranged from 753 to 973 L, indicating wide tissue distribution. Overall, a dose-proportional increase in systemic exposure to BLU-263 was observed across the SAD and MAD cohorts (Figure).
Summary/Conclusion: BLU-263, a next-generation investigational KIT inhibitor, was well tolerated across all SAD and MAD cohorts in normal healthy volunteers. The PK of BLU-263 were linear across the dose ranges in SAD and MAD cohorts and support QD dosing. These data support the continued development of BLU-263 in patients with systemic mastocytosis and other mast cell disorders.

PB1710 GENERAL CHARACTERISTICS AND OUTCOME OF RENAL EXTRAMEDULLARY HEMATOPOIESIS IN PATIENTS WITH MYELOPROLIFERATIVE NEOPLASMS-A LITERATURE REVIEW

S. Mohamed [1,*], M. Yassin [2], M. Alkhateeb [3], A. Abdalhadi [3], A. Nashwan [4], K. Obeidat [3], Y. Imam [3]

[1]Leukemia, MD Anderson, Houston, United States, [2]Hematology, NCCCR, [3]Medicine, [4]Research, HMC, DOHA, Qatar

Background: Extramedullary hematopoiesis (EMH) is hematopoiesis in organs outside the bone marrow.It occurs with several hematological conditions such as hereditary anemias,leukemias and myeloproliferative neoplasms (MPNs) such as myelofibrosis (MF), polycythemia vera (PV), essential thrombocytosis (ET) and chronic myeloid leukemias (CML). The sites of EMH include: Lymph nodes, thyroid, spinal, lung pericardium, pancreas.kidneys are a rare site to be involved. There are several theories with cytokines and growth factor production playing a central role in most. The spleen filter theory is an interesting one, where it is observed that in splenectomized patients, the kidneys will compensate as an EMH organ. Another theory speculates that haematopoietic cells are derived from resident kidney mesenchymal pluripotent cells that could proliferate as a response to a disease-related simulating factor.EMH can originate in the renal interstitium or could be perirenal, this leads to different clinical presentation such as proteinuria, nephrotic syndrome, and renal failure.
Aims: The objective is to review cases of EMH affecting the kidneys, focusing on demographics, clinical manifestations, treatment, follow up and outcomes.
Methods: We reviewed the literature using PubMed, Scopus, and Google scholar databases. Our search included all English language cited studies including case series and case reports that reported on renal EMH with a primary or background diagnosis of MPNs from 1990-2020
Results: forty-three patients (79 % males) were retrieved. The mean age of the cohort was 65 years (range 49-87years). Most of the cohort was white Caucasian 91 %. The type of MPNs was mostly MF, seen in 35 patients (81.4%), while PV was seen in 5 patients (11.6%), ET and CML were seen in 2(4.7%) and 1 (2.3%) patient, respectively.The most common renal manifestation was renal failure and nephrotic syndrome in 39.5 % of the cases, followed by renal failure alone 37.2 % and nephrotic syndrome only in 9.3 % and interestingly a renal mass was found 9% of the patient on imaging. Splenomegaly was found in 58 % of the patient while 14 % have already underwent Splenectomy. The average duration to developing EMH from time of diagnosis was 7.8 years (0- 20 years).Four patients developed EMH post-transplant, 3 of them allogenic while one autologous.The JAK mutation was reported in 7 patients and CALR mutation in one patient.Patient were treated with different medication including diuretics, anti-hypertensive (mainly ACE inhibitors) and steroids. However, for MPNs 25 % received HU, 14 % received Thalidomide or Thalidomide analogue while 16 % received JAK inhibitors; Ruxolitinib. The CML case was treated with Imatinib.The average duration of Follow up was 19 months with 42.5% death rate by the end of follow up.Kidney function improved in 31 % of patients, with Ruxolitinib administration correlating with improved kidney function and survival (6 out of 7 patients)
Summary/Conclusion: Kidneys are a rare but serious site for EMH. Unexplained Increase in renal function or proteinuria or kidney mass should raise the suspicion of this diagnosis among hematologist and nephrologist. We suspect there is underreporting in the hematology literature as there is lack of information on cytogenetics, types of mutations and risk stratifications.There is currently no consensus or guidelines on management of such cases. Ruxolitinib with the limitations of the small numbers treated may offer some benefit, however further studies and exploration of this drug and others in well-constructed prospective studies is needed

PB1711 PACIFICA: A RANDOMIZED, CONTROLLED PHASE 3 STUDY OF PACRITINIB VERSUS PHYSICIAN'S CHOICE IN PATIENTS WITH PRIMARY OR SECONDARY MYELOFIBROSIS AND SEVERE THROMBOCYTOPENIA

J. Mascarenhas [1,*], A. Gerds [2], J.-J. Kiladjian [3], K. Döhner [4], S. Buckley [5], J. Smith [5], A. Craig [5], S. Singh [5], S. Verstovsek [6], C. Harrison [7]

[1]Icahn School of Medicine at Mount Sinai, New York, [2]Cleveland Clinic Taussig Cancer Institute, Cleveland, United States, [3]Saint-Louis Hospital, Paris, France, [4]Ulm University Hospital, Ulm, Germany, [5]CTI BioPharma Corp., Seattle, [6]MD Anderson Cancer Cente, Houston, United States, [7]Guy's and St Thomas' NHS Foundation Trust, London, United Kingdom

Background: Myelofibrosis (MF) is a serious and life-threatening myeloproliferative neoplasm (MPN) due to clonal proliferation of myeloid cells. Patients with MF and severe thrombocytopenia (platelet counts <50 x 10^9/L) are generally older and have more advanced disease with increased risk of bleeding, higher rates of anemia, higher rates of complex or unfavorable cytogenetics and shortened overall survival (~15 months) compared to those with higher platelet counts. Currently approved JAK inhibitors, ruxolitinib (RUX) and fedratinib (FED), were not studied in this high-risk population and neither drug has a recommended starting dose for the treatment of patients with severe thrombocytopenia. RUX often requires dose reductions for patients with platelet counts <100,000/mL, due to thrombocytopenia. Such dose reductions impair efficacy compared to higher doses. NCCN guidelines and ELN recommendations suggest enrollment in clinical trials for such patients due to limited therapeutic options. Pacritinib (PAC) is an oral JAK2/IRAK1 inhibitor that has demonstrated clinical activity in MF patients in prior phase 3 studies (PERSIST-1, PERSIST-2) and a phase 2 dose-finding study (PAC203), including in patients with severe thrombocytopenia.
Aims: The PACIFICA trial (NCT03165734) was designed to evaluate the efficacy and safety of PAC 200 mg twice daily (BID) vs physician's choice (P/C) therapy in patients with MF and severe thrombocytopenia.
Methods: PACIFICA is a multinational, multicenter, randomized, controlled phase 3 trial of PAC vs P/C in adult patients with primary or secondary MF who are not candidates for stem cell transplant, with DIPSS intermediate- or high-risk disease, ECOG PS 0-2, and platelet counts <50 x 10^9/L, who have had limited prior JAK2 inhibitor treatment or are JAK2 inhibitor-naïve. Additional exclusion criteria include recent cardiac or hemorrhagic events, ejection fraction <50%, QTc >450 msec, or use of medications that increase the risk of hemorrhage or QT prolongation. Patients in the PAC arm receive continuous PAC 200 mg BID. Patients in the P/C arm receive one of the following agents as selected prior to randomization: low-dose ruxolitinib, danazol, corticosteroids, or hydroxyurea. The primary objective is to compare the efficacy of PAC vs P/C as assessed by the proportion of patients achieving a ≥35% spleen volume reduction (SVR) from baseline to week 24. Secondary objectives include comparisons of the proportion of patients achieving a ≥50% reduction in total symptom score (TSS) at week 24, overall survival, safety, and proportion of patients who self-assess as "very much improved" or "much improved" as measured by the Patient Global Impression of Change (PGIC). Tertiary endpoints include leukemia-free survival, alternative SVR analyses, hematologic improvement (transfusion independence and improvement in hemoglobin and platelet levels), fatigue improvement as measured by the PROMIS v.1.0 - Fatigue - Short form 7a, and changes in biomarkers and gene expression. The study will enroll approximately 348 patients in a 2:1 ratio (PAC to P/C). The primary analysis (for SVR) will be based on approximately 168 patients, while the secondary analyses (for TSS) will be based on the full sample size. PACIFICA is currently enrolling, with approximately 140 sites worldwide (US, Australia, Europe, Canada, Middle East, Asia, Russia).

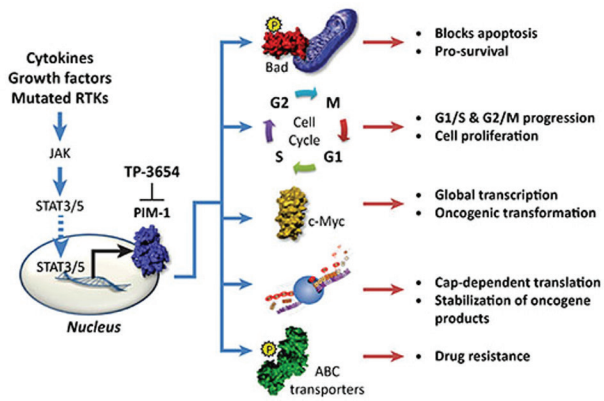
Summary/Conclusion: N/A



PB1712 A PHASE 1 STUDY OF TP-3654, AN ORAL PIM KINASE INHIBITOR, IN PATIENTS WITH INTERMEDIATE-2 OR HIGH-RISK PRIMARY OR SECONDARY MYELOFIBROSIS

C. Lebedinsky [1,*], S. Kabir [1], S. Warner [2], G. Mohi [3], H. Yang [1], J. Mei [1], E. Braendle [1]

[1]Sumitomo Dainippon Pharma Oncology, Inc., Cambridge, [2]Sumitomo Dainippon Pharma Oncology, Inc., Lehi, [3]University of Virginia School of Medicine, Charlottesville, United States

Background: Myelofibrosis (MF) is characterized by bone marrow fibrosis (BMF), ineffective hematopoiesis, splenomegaly, and debilitating symptoms. An activating Janus kinase 2 (JAK2) mutation (JAK2 V617F) has been frequently observed in MF. Ruxolitinib and fedratinib, approved JAK inhibitors, have been shown to reduce splenomegaly and improve constitutional symptoms in MF patients, but with a modest reduction of BMF. Patients (pts) with MF who progressed on, are intolerant to, or are ineligible for JAK inhibitors have limited treatment options. Proviral integration site of Moloney murine leukemia virus (PIM) serine/threonine kinases are downstream targets of the JAK/STAT signaling pathway (**Figure**). Expression of PIM1 is significantly elevated in MF primary hematopoietic cells. Therefore, PIM kinase is a potential therapeutic target for MF. TP-3654, an oral, small molecule, investigational PIM kinase inhibitor, has been shown to inhibit proliferation and increase apoptosis in murine and human hematopoietic cells expressing JAK2 V617F mutation. TP-3654, alone and in combination with ruxolitinib, improves leukocyte counts, reduces spleen size, and reduces BMF in a JAK2 V617F murine MF model (Nath D, et al. *Blood.* 2018;132(suppl 1):54).
Aims: To evaluate TP-3654 monotherapy in pts with MF.
Methods: This phase I, multicenter, open-label, dose-escalation study is evaluating TP-3654 monotherapy in pts with MF who previously failed or are ineligible to receive a JAK inhibitor (ruxolitinib or fedratinib) (NCT04176198). Primary objectives are to determine the maximum tolerated dose (MTD) and/or to identify the recommended phase II dose (RP2D) of TP-3654 monotherapy. Secondary objectives are to assess preliminary activity (spleen volume reduction, symptom improvement, and BMF reduction), determine QT interval changes, and establish the pharmacokinetic profile. Exploratory objectives are to study pharmacodynamic markers in peripheral blood and bone marrow (BM) biopsy samples. Eligible pts have primary or secondary MF (post-polycythemia vera-MF/post-essential thrombocythemia-MF); intermediate-2/high-risk MF by the Dynamic International Prognostic Scoring System (DIPSS); previously failed or are ineligible to receive treatment with a JAK inhibitor; grade ≥2 MF, as confirmed by BM biopsy ≤12 weeks prior to screening; have a platelet count ≥50x10^9/L, absolute neutrophil count ≥1x10^9/L, hemoglobin level ≥8 g/L, peripheral blood blast counts <10%, ECOG performance status ≤2, life expectancy ≥3 months, and adequate renal and hepatic function; have spleen length ≥5 cm by palpation or spleen volume ≥450 cm^3 by CT/MRI, and show ≥2 measurable symptoms per the MF Symptom Assessment Form, version 4.0. Pts must not have had splenic irradiation ≤6 months prior to screening; have acute myeloid leukemia or myelodysplastic syndrome; or had prior stem cell transplantation (SCT) or be eligible for allogeneic BM or SCT. Enrollment of approximately 50 pts with MF is planned. Pts will receive oral TP-3654. Dose escalation will be performed using a Bayesian Logistic Regression Model (BLRM) with Escalation with Overdose Control (EWOC). Adverse events occurring during the first cycle will be considered in the determination of the MTD. Dose escalation will continue until identification of the MTD and/or a suitable RP2D. This study is currently recruiting pts. Informed consent is being obtained for each participant/potential participant in this trial, in accordance with the International Conference on Harmonization-Good Clinical Practice.

PB1713 A PHASE 1/2 STUDY OF INCB000928 AS MONOTHERAPY OR IN COMBINATION WITH RUXOLITINIB IN PATIENTS WITH ANEMIA DUE TO MYELOFIBROSIS (INCB 00928-104)

S. Oh [1,*], J.-J. Kiladjian [2], F. Palandri [3], J. Gotlib [4], S. Mohan [5], H. Ali [6], E. Asatiani [7], F. Seguy [7], F. Zhou [8], S. Verstovsek [9]

[1]Washington University School of Medicine, St. Louis, United States, [2]Hôpital Saint-Louis, Assitance Publique - Hôpitaux de Paris, Université de Paris, Inserm, Paris, France, [3]IRCCS Azienda Ospedaliero-Universitaria di Bologna, Bologna, Italy, [4]Stanford Cancer Institute, Stanford, [5]Vanderbilt University Medical Center, Nashville, [6]City of Hope Medical Center, Duarte, United States, [7]Incyte Biosciences International Sàrl, Morgues, Switzerland, [8]Incyte Corporation, Wilmington, [9]University of Texas MD Anderson Cancer Center, Houston, United States

Background: Anemia represents a therapeutic challenge in patients with myelofibrosis (MF). Activin receptor-like kinase-2 (ALK2) activation is associated with elevated hepcidin, which may contribute to anemia of chronic disease and anemia due to hematologic malignancies, and is associated with increased transfusion rate and reduced overall survival.
Aims: This phase 1/2, open-label, multicenter, dose-escalation/dose-expansion study will evaluate the safety and tolerability of INCB000928, a potent, highly selective, ALK2 inhibitor, as monotherapy or combined with ruxolitinib in patients with anemia due to MF (INCB 00928-104; NCT04455841).
Methods: Patients with histologically confirmed primary or secondary MF presenting with symptomatic anemia or transfusion dependence will receive oral INCB000928 either alone (treatment group [TG] A) or combined with ruxolitinib (TGB; Figure). In TGA, patients must have intermediate (INT)-2 or high-risk (per Dynamic International Prognostic Scoring System [DIPSS]) disease that is intolerant, resistant, refractory, or has lost response to prior JAK inhibitor therapy (≥12 weeks). In TGB, patients must have received stable ruxolitinib therapy for ≥12 consecutive weeks before first dose and have INT-1/INT-2, or high-risk disease. Eligibility also requires age ≥18 years, platelet count ≥75 × 10^9/L, ECOG PS 0–1 (dose-escalation) or 0–2 (dose-expansion), life expectancy >6 months, no other hematologic malignancy, no prior stem cell transplantation, no major surgery within 28 days, and no prior disease-directed therapy within 5 half-lives or 28 days of first dose. In part 1 (dose escalation), TGA will receive INCB000928 monotherapy starting at 50 mg/day (28-day cycles) (Figure). Dose-escalation will follow a Bayesian optimal-interval design to determine the maximum tolerated dose (MTD) and/or recommended dose for expansion (RDE). Dose increases not exceeding 2-fold will continue until grade ≥2 treatment-related toxicity occurs. TGB will receive INCB000928 plus ruxolitinib; INCB000928 dose escalation will start 2 dose levels below the highest dose determined to be safe and tolerable in TGA. In part 2 (dose expansion), the RDE in TGB will be evaluated in combination with ruxolitinib in ~25 patients; treatment will continue for ≤12 months, and may continue if clinically beneficial and no progression occurs. Primary objective is to determine the safety and tolerability of INCB000928 as monotherapy or combined with ruxolitinib. Secondary objectives are to determine the efficacy of INCB000928 as monotherapy or combined with ruxolitinib (anemia response, duration of anemia response, mean change from baseline in hemoglobin, and RBC transfusion rate through weeks 24 and 48); evaluate INCB000928 pharmacokinetics; and evaluate effects of INCB000928 as monotherapy or combined with ruxolitinib on hepcidin levels and other measures of iron homeostasis and erythropoiesis. Sites are opening in the United States and Europe.

PB1714 A TWO-PART PHASE 2 STUDY OF ITACITINIB IMMEDIATE RELEASE IN PATIENTS WITH PRIMARY OR SECONDARY MYELOFIBROSIS WHO HAVE RECEIVED PRIOR RUXOLITINIB AND/OR FEDRATINIB MONOTHERAPY

A. Kuykendall [1,*], L. Burke [2], M. Lakshminarayanan [2], P. Colucci [2]

[1]Department of Malignant Hematology, Moffitt Cancer Center, Tampa, [2]Incyte Corporation, Wilmington, United States

Background: Ruxolitinib (JAK1/JAK2 inhibitor) and fedratinib (JAK2/FLT3 inhibitor) are indicated in the United States for myelofibrosis (MF); however, some patients fail to achieve adequate/sustained response to initial JAK-inhibitor therapy. Itacitinib is a potent JAK inhibitor selective for JAK1 over JAK2 when administered as a once-daily sustained-release (SR) formulation. In a prior clinical trial, the SR formulation improved MF-related symptoms but had less effect with respect to spleen volume reduction (Mascarenhas JO, et al. Haematologica. 2017;102(2):327–335). When dosed as a twice-daily (BID) immediate release (IR) formulation, itacitinib, a selective JAK1 inhibitor, may attain sufficient JAK2 inhibition to better address the JAK2-mediated myeloproliferative features of the disease.
Aims: This open-label phase 2 study is designed to determine a tolerable and safe dose of itacitinib IR and whether that dose results in clinically significant reductions in symptoms and spleen volume in patients with MF who have previously received ruxolitinib and/or fedratinib monotherapy (INCB 39110-213; NCT04629508).
Methods: Eligible patients are aged ≥18 years, diagnosed with at least INT-1–risk (Dynamic International Prognostic Scoring System [Passamonti F, et al. Blood. 2010;115(9):1703–1708]) primary or secondary (post-polycythemia vera or post-essential thrombocythemia) MF and have received ruxolitinib and/or fedratinib monotherapy. Patients must also have palpable splenomegaly and platelets ≥50×10^9/L at screening. Exclusion criteria include receipt of a JAK inhibitor other than ruxolitinib or fedratinib, ≥10% myeloid blasts in peripheral blood or bone marrow, or inability to taper ruxolitinib/fedratinib over 14 days without use of other agents.
Two itacitinib IR dose levels (DLs) will be evaluated in part 1 following a Bayesian optimal interval design algorithm: 3–9 patients will be enrolled at DL1 (300 mg BID) and observed for 28 days for dose-limiting toxicity before enrollment at DL2 (600 mg BID) (Figure). Part 2 will enroll ~55 patients at the recommended phase 2 dose (RP2D) determined in part 1. Patients may remain on treatment until week 48 if they are receiving clinical benefit and have not met study withdrawal criteria. A safety follow-up will occur 30 days after treatment completion.
Primary objectives: part 1 - evaluate safety and tolerability of itacitinib IR and select the RP2D; part 2 - evaluate efficacy of itacitinib IR at the RP2D based on spleen volume reduction at week 24. Secondary objectives (part 2 only): evaluate safety and tolerability of itacitinib IR at the RP2D; evaluate efficacy of itacitinib IR at the RP2D with respect to MF symptom improvement at week 24 in patients with baseline total symptom score ≥10, quality-of-life improvement, and patient global impression of change. Sites are opening in the United States and Europe.

PB1715 A RANDOMIZED, DOUBLE-BLIND, PLACEBO-CONTROLLED PHASE 3 STUDY OF ADD-ON PARSACLISIB IN PATIENTS WITH MYELOFIBROSIS WHO HAVE SUBOPTIMAL RESPONSE TO RUXOLITINIB

A. Yacoub [1,*], M. Stouffs [2], F. Zhou [2], A. Assad [2]

[1]University of Kansas Medical Center, Westwood Campus, Westwood, [2]Incyte Corporation, Wilmington, United States

Background: Ruxolitinib (JAK1/JAK2 inhibitor) is indicated for the treatment of adults with intermediate (INT) or high-risk myelofibrosis (MF), including primary MF, post-polycythemia vera MF, and post-essential thrombocythemia MF, but a subset of patients may exhibit a suboptimal response due to possible persistent PI3K/AKT activation. Targeting PI3K/AKT signaling may therefore have clinically relevant effects on MF disease burden.
Aims: This phase 3, randomized, double-blind, placebo-controlled study will determine the effect of add-on parsaclisib, a highly selective PI3Kδ inhibitor, on signs and symptoms of MF in patients with suboptimal or declining response to stable ruxolitinib treatment (INCB 50465-304; NCT04551053).
Methods: Eligible patients are aged ≥18 years with a diagnosis of at least INT-1–risk (according to the Dynamic International Prognostic Scoring System [DIPSS]; Passamonti F, et al. Blood. 2010;115(9):1703–1708) primary or secondary (post-polycythemia vera or post-essential thrombocythemia) MF, have received ruxolitinib for ≥3 months with a stable dose (5–25 mg twice daily) for ≥8 weeks prior to receiving the first dose of study drug (day 1), have evidence of suboptimal response to ruxolitinib (palpable spleen ≥5 cm below left subcostal margin, and total symptom score ≥10), and ECOG PS ≤2. Patients are excluded if they received prior therapy with any PI3K inhibitor, experimental or standard drug therapy for MF (except ruxolitinib) within 3 months of starting study drug, or have platelet count <50×10^9/L, recent history of inadequate bone marrow reserve, or inadequate liver or renal function at screening. Approximately 212 patients on a stable dose of ruxolitinib will be randomized (1:1) to receive add-on parsaclisib 5 mg daily or matching placebo beginning on day 1, with stratification by platelet count (≥100×10^9/L or 50 to <100×10^9/L) and DIPSS risk category (high, INT-2, or INT-1) at randomization. Treatment will continue as long as tolerated and discontinuation criteria are not met. When a patient has completed 24 weeks of treatment, he/she will be unblinded and if found to be randomized to ruxolitinib plus placebo with adequate hematology parameters, the patient will be able to crossover to receive ruxolitinib plus add-on parsaclisib. The primary objective is to evaluate and compare the efficacy of add-on parsaclisib versus placebo on spleen volume at Week 24. Secondary objectives are to evaluate and compare the effect of add-on parsaclisib versus placebo on: patient-reported MF symptoms, overall survival, time to onset and duration of spleen volume response, and safety and tolerability. Sites are opening throughout North America, Europe, Asia, and Oceania.
Results: Not applicable
Summary/Conclusion: Not applicable

PB1716 A PHASE 3, RANDOMIZED, DOUBLE-BLIND, PLACEBO-CONTROLLED STUDY OF RUXOLITINIB PLUS PARSACLISIB IN PATIENTS WITH JAK- AND PI3K-INHIBITOR TREATMENT–NAÏVE MYELOFIBROSIS

A. Yacoub [1,*], S. Erickson-Viitanen [2], F. Zhou [2], A. Assad [2]

[1]*University of Kansas Medical Center, Westwood Campus, Westwood,* [2]*Incyte Corporation, Wilmington, United States*

Background: Ruxolitinib (JAK1/JAK2 inhibitor) significantly improves outcomes in patients with myelofibrosis (MF); however, a subset of patients may experience a suboptimal response. Recent phase 2 data showed that addition of the PI3Kδ inhibitor parsaclisib to ruxolitinib monotherapy resulted in additional alleviation of MF symptoms and splenomegaly in patients with MF (Yacoub. EHA2020. S216).
Aims: This phase 3, randomized, double-blind study (INCB 50465-313; NCT04551066), evaluates the combination of ruxolitinib and parsaclisib in patients with MF who are naive to Janus kinase (JAK) and PI3K inhibitor therapies.
Methods: Eligible patients are aged ≥18 years with a diagnosis of primary MF, post-polycythemia vera MF, or post-essential thrombocythemia MF, have a Dynamic International Prognostic Scoring System (DIPSS; Passamonti F, et al. Blood. 2010;115(9):1703–1708) risk of at least Intermediate (INT)-1, palpable spleen ≥5 cm below left subcostal margin, total symptom score ≥10 at screening, ECOG PS 0–2, and life expectancy ≥24 weeks. Patients will be excluded if they previously received therapy with any JAK inhibitor, any PI3K inhibitor, any experimental or standard drug therapy for MF≤ 3 months of first study dose and/or lack of recovery from all toxicities related to previous therapies to grade ≤1, have recent history of inadequate bone marrow reserve (eg, platelet count <50×10^9/L), or have inadequate liver or renal function at screening. Approximately 440 patients will be randomized (1:1) to ruxolitinib plus parsaclisib 5 mg QD or ruxolitinib plus matching placebo, with stratification at randomization by DIPSS risk category (high vs INT-2 vs INT-1) and platelet count (≥100×10^9/L vs 50 to <100×10^9/L inclusive). Treatment will begin on day 1, with starting ruxolitinib dose level determined by baseline platelet count, and will continue as long as treatment is tolerated and discontinuation criteria are not met. When the last enrolled patient has completed 24 weeks of treatment, the study will be unblinded and patients randomized to ruxolitinib plus placebo who have adequate hematology parameters will be able to crossover to receive parsaclisib together with continued ruxolitinib. The primary objective is the evaluation and comparison of spleen volume at week 24 for patients who received ruxolitinib plus parsaclisib versus ruxolitinib plus placebo. Secondary objectives include evaluation and comparison of patient-reported MF symptoms, overall survival, time to onset and duration of response in spleen volume, and safety and tolerability of ruxolitinib plus parsaclisib versus ruxolitinib plus placebo. Sites are opening across the United States, Europe, Asia, and New Zealand.

Summary/Conclusion: Not applicable

PB1717 RELATIVE BIOAVAILABILITY AND DOSE LINEARITY OF FIVE STRENGTHS OF RUXOLITINIB EXTENDED RELEASE (XR) TABLETS

X. Gong [1,*], N. Punwani [1], E. Cimino [1], Z. Xun [1], B. Yuska [1], X. Liu [1], K. Rockich [2], J. Getsy [1], S. Yeleswaram [1]

[1]*Incyte Research Institute, Incyte Corporation,* [2]*Incyte Corporation, Wilmington, United States*

Background: Ruxolitinib is currently dosed twice-daily using an immediate release (IR) formulation for the treatment of myelofibrosis, polycythemia vera, and acute graft-versus-host disease. An extended release (XR) formulation of ruxolitinib was developed to allow once-daily dosing. Five XR tablet strengths were developed, containing 10, 20, 30, 40, and 50 mg of ruxolitinib, free base equivalent.
Aims: To study the linearity in the pharmacokinetics (PK) of ruxolitinib following a single dose of each of the five strengths of ruxolitinib XR tablets.
Methods: This open-label, randomized, crossover study was conducted in healthy adult participants (n=12–15 per cohort) to evaluate the dose proportionality of the ruxolitinib XR formulation. The study also assessed the effect of a high-fat meal. Standard non-compartmental PK analysis was used. Dose proportionality of the ruxolitinib XR formulation was assessed by comparing dose-normalized, log transformed PK parameters (C_{max}, AUC_{0-t}, and $AUC_{0-\infty}$). Food effect was evaluated by analysis of variance using a mixed effects model. Safety and tolerability were assessed by monitoring the frequency and severity of adverse events; performing physical examinations; and collecting vital signs, 12-lead electrocardiograms, and clinical laboratory data.
Results: The results of ruxolitinib XR dose proportionality analysis are summarized in Table 1. The geometric mean ratios with 90% CI (fed with a high-fat meal vs fasted) were estimated at 1.627 (1.367, 1.936), 0.903 (0.841, 0.970), and 0.912 (0.848, 0.981) for C_{max}, AUC_{0-t}, and $AUC_{0-\infty}$, respectively. The treatments were well tolerated and no new safety findings were observed with administration of ruxolitinib XR.

Table: Dose Proportionality Analysis Results of Ruxolitinib XR Tablets

Relative Bioavailability of Ruxolitinib XR Tablet Strengths Compared to 50 mg XR Tablet (Geometric Mean Ratios with 90% CI)			
	C_{max} (nM)	AUC_{0-t} (h*nM)	$AUC_{0-\infty}$ (h*nM)
10 mg XR	0.918 (0.773, 1.090)	1.026 (0.943, 1.118)	1.033 (0.949, 1.124)
20 mg XR	0.884 (0.745, 1.048)	1.034 (0.950, 1.126)	1.038 (0.954, 1.129)
30 mg XR	0.891 (0.755, 1.051)	0.958 (0.883, 1.040)	0.962 (0.889, 1.042)
40 mg XR	0.952 (0.803, 1.128)	1.000 (0.919, 1.088)	0.999 (0.920, 1.084)
Exponent (90% CI) on Dose from a Power Function Regression			
	1.069 (0.954, 1.164)	0.983 (0.935, 1.031)	0.978 (0.931, 1.026)

AUC_{0-t}, area under the plasma concentration-time curve from time zero to last quantifiable concentration; $AUC_{0-\infty}$, area under the plasma concentration-time curve from time zero to infinity; CI, confidence interval; C_{max}, maximum plasma drug concentration; XR, extended release.

Summary/Conclusion: Dosage strength proportionality has been demonstrated across all five ruxolitinib XR tablet strengths (10 mg, 20 mg, 30 mg, 40 mg, and 50 mg), and they can be dosed without regard to food. No new safety concerns were observed with ruxolitinib XR.

PB1718 TUBERCULOSIS REACTIVATION FOLLOWING RUXOLITINIB THERAPY FOR MYELOFIBROSIS

A. Aribandi [1,*], R. K. CS [1], R. M. Gottipati [2]

[1]Haematology & BMT, American Oncology Institute, Hyderabad, [2]Haematology & BMT, American Oncology Institute, Vijayawada, India

Background: Myelofibrosis is an uncommon myeloproliferative neoplasm, characterized by stem cell-derived clonal proliferation that is often accompanied by JAK2, CALR, or MPL mutations. It presents with marrow fibrosis, variable degree of splenomegaly, cytopaenias and constitutional symptoms, that significantly impact on quality of life and survival.
Aims: Ruxolitinib is a JAK 1/2 inhibitor that can decrease spleen size, relieve constitutional symptoms, reduce transfusion requirement and prolongs survival in some patients. Uncommon adverse reaction of Ruxolitinib includes reactivation of tuberculosis infection.
Methods: We are describing 4 patients of myelofibrosis who have had reactivation of tuberculosis, whilst on Ruxolitinib. Data was collected retrospectively. Patients were followed up actively during antituberculous treatment
Results: Age (yr) sex Diagnosis JAK2 CALR Ruxolitinib initi TB reactivation Site of reactivation ATT outcome
53 F SMF/PV + - Dec, 2013 15 months Abdominal 6 month Alive
33 F PMF + - Feb, 2016 14 months Pulmonary 6 months Alive 40 M PMF - + Apr, 2017 4 months Lymphnode 6 months Alive 54 M PMF + - Mar, 2017 11 months Pulmonary 6 months Alive
Summary/Conclusion: Tuberculosis infection was observed in 4 patients who were being treated with Ruxolitinib. This case series highlights the importance of screening for latent tuberculosis in patients from highly endemic areas before commencing on Ruxolitinib.

PB1719 A CASE OF POLYCYTHAEMIA VERA TREATED WITH ROPEGINTERFERON-2B DURING PREGNANCY

I. Sanchez [1,*], G. Durgam [2], C. Woodley [1], N. Curto-Garcia [1], J. O'Sullivan [1], S. Robinson [1], S. Ali [1], D. McLornan [1], C. Harrison [1]

[1]Haematology, Guy's and St Thomas' NHS Foundation Trust, London, [2]Haematology, Arrowe Park Hospital, Wirral, United Kingdom

Background: Polycythaemia Vera (PV), a myeloproliferative neoplasm (MPN), is usually diagnosed in patients ≥60 years. However, 15-20% of PV patients are less than 40 years of age at diagnosis. MPN patients have increased risk for pregnancy-related complications (miscarriage, thrombosis, haemorrhage, intrauterine growth restriction, pre-eclampsia and stillbirths). Hence the importance of a correct management during this time, including the employment of aspirin, low molecular weight heparin (LMWH), venesection and cytoreductive therapy when needed. When cytoreduction is necessary, in PV patients wishing to conceive, interferon alfa is the choice. The development of pegylated formulations, including ropeginterferon alfa-2b (Besremi®), has resulted in improved tolerability and easier administration.
Aims: To describe the clinical and analitical evolution of a PV patient treated with novel ropeginterferon alfa-2b during pregnancy.
Methods: We present the case of a 32-year-old woman diagnosed of PV in December 2018 and followed up at Guy's Hospital, who was on ropeginterferon alpha-2b during pregnancy, with adequate control and no complications.
Results: In December 2018, at the age of 29, she presented with numbness and intermittent paraesthesia in the right side of her face and body. She had had previous history of skin rash and bilateral conjunctival congestion. She had no history of thrombotic events. Neurological causes of her hyperviscosity syndrome were ruled out. Her leukocyte count was 25.2 $\times 10^9$/L (neutrophils 22.2 $\times 10^9$/L), with haemoglobin (Hb) of 175 g/L, haematocrit (Hct) of 0.57 and platelets of 859 $\times 10^9$/L. Abdominal ultrasound scan showed splenomegaly (16 cm). JAK2 V617F mutation was detected and PV, with bone marrow (BM) features of panmyelosis, no immature precursors and grade 1 fibrosis, was diagnosed according to WHO criteria.
She had several venesections and started aspirin 150 mg/day. Due to myeloproliferative features, treatment with peginterferon alfa-2a (Pegasys®), 90 mcg weekly, was added, with later increases up to 225 mcg weekly.
As she had no major response to peginterferon alfa-2a, with persistent high leukocyte and platelet counts (leukocytes 23.8 $\times 10^9$/L, neutrophils 21.2 $\times 10^9$/L, Hb 107 g/L, Hct 0.38 and platelets 926 $\times 10^9$/L), teardrop cells in the blood film and enlarged spleen (23 cm), in February 2020 another BM was performed, excluding progression to myelofibrosis. During this time she had the desire to concieve, but could not become pregnant. She was then switched to ropeginterferon alfa-2b, 350 mcg every other week.
In March 2020 she conceived, continuing ropeginterferon alfa-2b, as well as thromboprophylaxis with aspirin and enoxaparin 40 mg/day. She had several venesections during pregnancy, in order to maintain Hct <0.38 per BSH guidelines. She underwent local follow up with no special symptoms or signs of abnormal fetal development. Ultrasound scan in the third trimester demonstrated stability in spleen size.
The baby was delivered on 14th December 2020, at 38 weeks of gestation (weight 2.8 kg). The patient's most recent blood control in January 2021, after delivery, showed a leukocyte count of 19.1 $\times 10^9$/L (neutrophils 15.7 $\times 10^9$/L), Hb of 119 g/L, Hct of 0.42 and platelet count of 855 $\times 10^9$/L.

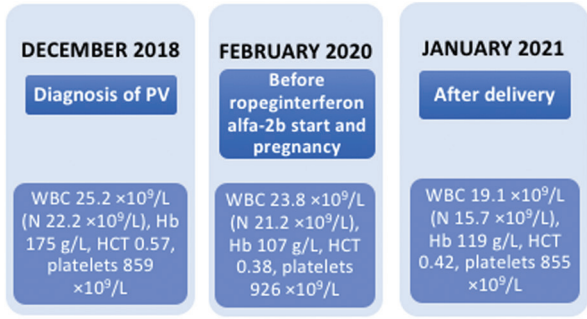

***Figure 1.** Evolution of blood counts since diagnosis of polycythaemia vera. Abbreviations: PV: polycythaemia vera. WBC: white blood cells. N: neutrophils. Hb: haemoglobin. HCT: haematocrit.*

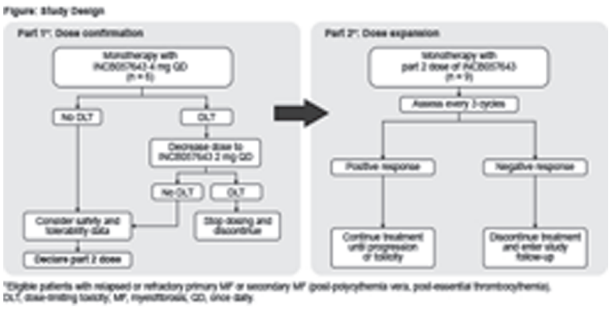
Summary/Conclusion: To our knowledge, this is the first case in which ropeginterferon alfa-2b is used in a pregnant PV patient and also the first reported case where a patient with inadequate disease control with peginterferon alfa-2a attained sufficient response with ropeginterferon alfa-2b. An informed consent has been obtained from the patient to write this abstract.



PB1720 A PHASE 1 STUDY OF INCB057643 MONOTHERAPY IN PATIENTS WITH RELAPSED OR REFRACTORY MYELOFIBROSIS (INCB 57643-103)

J. Watts [1,*], E. Curran [2], B. Reeves [3], E. Winton [4], C. Lihou [5], G. Zhou [5], F. Zheng [5], P. Vachhani [6]

[1]University of Miami Sylvester Comprehensive Cancer Center, Miami, [2]University of Cincinnati Cancer Institute, Cincinnati, [3]University of North Carolina at Chapel Hill, Chapel Hill, [4]Winship Cancer Institute of Emory University, Atlanta, [5]Incyte Corporation, Wilmington, [6]UAB Division of Hematology/Oncology, O'Neal Comprehensive Cancer Center at the UAB, Birmingham, United States

Background: Many neoplasms including myelofibrosis (MF) are associated with activation of transcription factors that regulate oncogenic processes. These may respond to inhibition of bromodomain and extra-terminal domain (BET) protein. In the first-in-human study INCB 57643-101, the BET inhibitor INCB057643 was generally safe and tolerable as monotherapy, and demonstrated preliminary efficacy in a small number of patients with MF, as monotherapy or combined with the JAK inhibitor, ruxolitinib (Falchook G, et al. *Clin Cancer Res.* 2020).
Aims: This phase 1, open-label, two-part dose confirmation and expansion study further evaluates the safety and tolerability of INCB057643 monotherapy in patients with relapsed/refractory MF (INCB 57643-103; NCT04279847).
Methods: Eligible patients must be aged ≥18 years with histologically confirmed primary or secondary (post-polycythemia vera, post-essential thrombocythemia) MF, have received ≥1 prior therapy including ruxolitinib, have no known clinically beneficial therapy available, have intermediate-2/high risk disease by Dynamic International Prognostic Scoring System, have ECOG PS 0–2, life expectancy ≥24 weeks, and willing to provide a bone marrow biopsy and/or aspirate at baseline (or archival sample obtained after most recent therapy). Exclusion criteria include prior BET inhibitor or anticancer treatment within specified intervals before first dose; concurrent anticancer therapy; allogeneic hematopoietic stem cell

transplant (allo-HSCT) ≤6 months before enrollment; active graft versus host disease or immunosuppressive therapy after allo-HSCT ≤2 weeks before first-dose; significant and uncontrolled disease (eg, gastrointestinal, cardiovascular); history of bleeding disorders, high risk of bleeding, or abnormal hematologic, hepatic, renal, coagulation, or metabolic laboratory values. In part 1, ≤6 patients will receive oral INCB057643 4 mg once-daily continuously (Figure). Doses will be deemed tolerable if ≤2 patients experience dose-limiting toxicities (DLTs) and ≤2 patients discontinue due to treatment-related adverse events (TRAEs) during the DLT evaluation period. Part 2 will further characterize safety and tolerability as well as evaluate preliminary efficacy of INCB057643 in ≤9 patients. The starting dose will be 4 mg once-daily if tolerated in part 1, and 2 mg once-daily if not. Treatment may continue if clinically beneficial and discontinuation criteria are not met. The primary objective is to determine the safety and tolerability of INCB057643 monotherapy. Secondary objectives are to evaluate anemia response by International Working Group-Myeloproliferative Neoplasms Research and Treatment (IWG-MRT) and European LeukemiaNet Consensus Report (ELN), transfusion dependence, spleen volume, rate and duration of spleen response by IWG-MRT and ELN, and impact on quality of life. Patients will be assessed every 3 cycles and will receive follow-up for safety for 30–35 days after last dose. Sites are opening in the United States and Europe.

Summary/Conclusion: Not applicable

PB1721 CONSECUTIVE OCCURRENCE OF ACUTE MYELOID LEUKEMIA, CHRONIC LYMPHOCYTIC LEUKEMIA AND POLYCYTHEMIA VERA; EMERGENCE OF DRIVER MUTATIONS IN A CONTEXT OF CLONAL HEMOPOIESIS OF INDETERMINATE POTENTIAL.

V. Douka [1,*], A. Papalexandri [1], T. Testa [1], A. Giannakopoulou [1], I. Eftychidis [1], M. Iskas [1], T. Touloumenidou [1], A. Athanasiadou [1], G. Papaioannou [1], A. Tsompanakou [1], A. Anagnostopoulos [1]

[1]*Hematology & HCT Unit, General Hospital "George Papanikolaou", Thessaloniki, Greece*

Background: Asynchronous occurrence of myeloid/lymphoid malignancies has been previously described. Multiple malignant clones can arise from a cancer cell but accumulation of genetic events is not fully elucidated. We describe a rare case of consecutive AML, CLL and PV in which extended genetic profiling has been performed.
Aims: To report the concurrent presence of three hematologic malignancies in the same patient
Methods: Flow cytometry, cytogenetics and molecular analysis.
Results: A 69 years old male presented 5 years ago with lymphocytosis (ALC 15.0 K/ul). His medical history revealed acute myeloid leukemia (AML) M2 FAB, diagnosed 20 years earlier. He had received intensive chemotherapy and achieved complete response. Karyotype was not performed at that time. Lymphocytosis investigation was initiated and flow cytometry revealed a clonal B cell population expressing CD5+, CD23+, CD43+, CD200+, ROR1+, CD20dim, FMC7-, CD79b- and weak surface light chain immunoglobulin. Hemoglobin and platelet counts were within normal range. There were no palpable spleen, liver or B symptoms. Small axillar lymph nodes were present and patient was diagnosed with chronic lymphocytic leukemia (CLL), stage Rai I, Binet A. Cytogenetic analysis demonstrated 47,XY,+del(5)(q13q33)[2]/46,XY [21]. No NOTCH1 or TP53 mutations were present. IGHV genes were 88.8% mutated bearing the VDJ rearrangement IGHV1-3/IGHD2-15/IGHJ3. Del(13)(q) was detected by FISH in 61% of the cells, while here was no 17p or 11q deletion or trisomy 12. Within two years the patient developed progressive splenomegaly and subsequently received 6 cycles of chemo-immunochemotherapy with Obinutuzumab-chlorambucil. He achieved partial response (marrow MRD 1.9%, splenomegaly partially resolved). During regular follow-up visits, gradual increase in hemoglobin was noted (RBC 6.65 x 10^9 K/ul, Hb=17.1 g/dl, Ht=51.4%). Polycythemia Vera was suspected and JAK2 V617F mutation was found. Bone marrow biopsy revealed 75% cellularity, erythroid and megakaryocyte hyperplasia with groups of megakaryocytes, and blasts <5%. A 10% B lymphocyte infiltration was also noted. No BCR/ABL transcript was found. He was put on hydroxyurea and salicylic acid. Concurrent follicular thyroid cancer was diagnosed. NGS analysis was performed with Sophia Genetics Myeloid Panel on 3 subsequent samples from: (i)AML (ii) CLL and (iii) PV diagnosis and the results are as follows: (i) FLT3-ITD, NPM1 type A and IDH2 Arg140Gln mutations, (ii) the AML mutations disappeared, KRAS and DNMT3A mutations and a 3% JAK2V617F clone emerged and (iii) KRAS, DNMT3A and JAK2V617F clones expanded contributed probably to the PV phenotype. Interestingly, 2 TET2 and CEBPA mutations were stable in all three timepoints, possibly as CHIP, indicating a single cell of origin.
Summary/Conclusion: Herein, for the first time to our knowledge, we report the concurrent presence of three hematologic malignancies in the same patient. Common genetic background with clonal hematopoiesis may confer genetic instability, upon which distinct driver mutations arise, contributing to distinct phenotype.

PB1722 ESSENTIAL THROMBOCYTEMIA IN THE YOUNG PATIENT: EXPERIENCE OF A SECONDARY HOSPITAL

M. D. M. Romero Gónzalez [1], I. Gardelegui Perez de Villarreal [1], M. R. Arcas Vega [1,*]

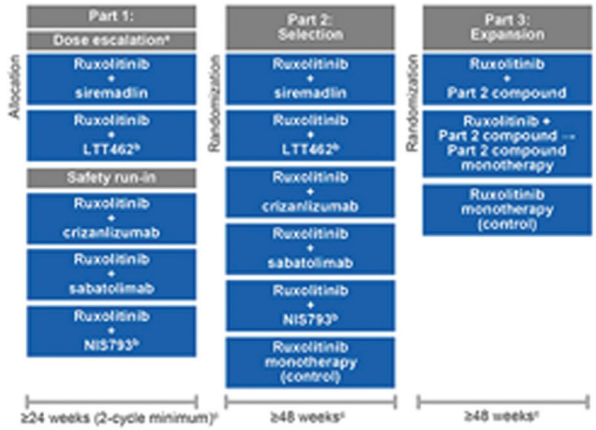
[1]*HEMATOLOGÍA Y HEMOTERAPIA, SAS LA LINEA, La Línea de la Concepción, Spain*

Background: Essential Thrombocythemia (ET) is a Philadelphia negative myeloproliferative neoplasia, which presents with persistent thrombocytosis, megakaryocytic hyperplasia in bone marrow and a tendency to both hemorrhagic and thrombotic complications. It predominates in female patients with a mean age of 60 years, with 15% being less than 40 years old.
Aims: The goal of our study was to describe our experience in patients with ET ≤ 40 years at diagnosis (dx).
Methods: A retrospective analysis was conducted based on the review of medical records of the adult patients diagnosed of TE in our centre from 2005 to 2020. Clinical and biological data were recorded.
Results: A total of 8 cases were detected (1 man and 7 women). in 38 total cases, which represents 21% (higher than that described in the literature). Mean age at dx: 34.5 [31-40] years.
- Reasons Consultation: Thrombocytosis + paresthesias (2), isolated thrombocytosis (5), thrombocytosis + headaches (1).
- Mutational status: CARL + (2), JAK-2 V617F + (4), not filiated (2).
- Thrombotic events (4/8): Abortion (2), PE (1), Portal Thrombosis (1).
- Thrombophilia study: MTHFR with increased Homocysteine (1), Gen 20210 Prothrombin (1). IPSET ET: High Risk (5), Low Risk (2), Intermediate (1).
- Treatment received: Hydrea + maintenance interferon (1/8), Anagrelide + antiplatelet (5/8), antiplatelet (ASA) (3/8), interferon due to pregnancy (1/8).
- Side effect: Heartburn + pain in lower limbs + headaches + heavy menstruation (1), hives + headaches + palpitations + asthenia + nausea (1), palpitations + dizziness + headaches + bruising + increased menstrual bleeding + pulmonary hypertension + pain in lower limbs (1), increased menstrual bleeding + alopecia + tachycardia (1) and nausea + headaches +palpitations (1).
- Intra-treatment thrombotic events (0/5).
- Treatment suspension (0/5).
- Evolution: Exitus due to breast neoplasia with metastases in a patient with previous Hydrea treatment (1/8).

Patient	Age	Sex	Reason for consultation	Mutational status	Treatment	Side effect	Thrombotic event	Thrombophilia study	IPSET ET
N° 1	31	Man	Thrombosis	JAK2	ASA	None	No	No	Interm
N° 2	32	Woman	Thrombosis	JAK2 - Rest of mutations not affiliated	Anagrelide + ASA	• Headache • Increased menstrual bleeding • Heartburn • Pain in lower limbs	Portal thrombosis	Homozygous MTHFR	High
N° 3	33	Woman	Thrombosis	JAK2	ASA	None	No	No	Low
N° 4	34	Woman	Thrombosis + headaches	JAK2	Anagrelide + ASA	• Headache • Palpitations • Hives • Asthenia • Nausea	No	No	High
N° 5	35	Woman	Thrombosis + Paraesthesia	CARL	Anagrelide + ASA	• Headache • Palpitations • Increased menstrual bleeding • Pain in lower limbs • Bruises • Dizziness • PH	Abortion	Heterozygous G20210A	High
N° 6	35	Woman	Thrombosis	CARL	Anagrelide/ Interferon + ASA	• Palpitations • Increased menstrual bleeding • Alopecia	Abortion	No	High
N° 7	36	Woman	Thrombosis	JAK2	Anagrelide + ASA	• Headache • Palpitations • Nausea	PE	Heterozygous MTHFR	High
N° 8	40	Woman	Thrombosis	Not affiliated	Hydrea/ Interferon + ASA	Not registered	No	No	Low

Abbreviations: ASA: acetylsalicylic acid, PE: pulmonary embolism, PH: pulmonary hypertension

Summary/Conclusion: - In our series 37.5% of the patients presented some thrombotic event / abortion as a precedent, the only etiology being ET 12.5%, given that the rest of the events were associated with prothrombotic mutations coinciding with the chronic myeloproliferative disorders.
- The common reason for consultation was thrombocytosis.
- Anagrelide therapy was acceptably tolerated, not being necessary to suspend treatment, and managed with dose adjustment.
- The most frequent side effects were: bleeding tendency, palpitations. The most serious side effect was pulmonary hypertension.



PB1723 ADORE: A RANDOMIZED, OPEN-LABEL, PHASE 1/2 OPEN-PLATFORM STUDY EVALUATING SAFETY AND EFFICACY OF NOVEL RUXOLITINIB COMBINATIONS IN PATIENTS WITH MYELOFIBROSIS

D. Ross [1,*], F. Heidel [2], A. Perkins [3], K. Burbury [4], T. Lehmann [5], V. Gupta [6], C. Harrison [7], J.-J. Kiladjian [8], A. Vannucchi [9], M. Wondergem [10], R. Pack [11], M. Wroclawska [11], C. Wilke [11], A. Zhang [11], A. Reiter [12]

[1]Royal Adelaide Hospital, Adelaide, Australia, [2]Universitätsklinikum Greifswald, Greifswald, Germany, [3]Australian Centre for Blood Diseases, Monash University, [4]Peter MacCallum Cancer Centre, Melbourne, Australia, [5]Kantonsspital St. Gallen, St. Gallen, Switzerland, [6]Princess Margaret Cancer Centre, Toronto, Canada, [7]Guy's and St Thomas' NHS Foundation Trust, London, United Kingdom, [8]Hôpital Saint-Louis & Université de Paris, Paris, France, [9]Center Research and Innovation of Myeloproliferative Neoplasms - CRIMM, Azienda Ospedaliera Universitaria Careggi, University of Florence, Florence, Italy, [10]Amsterdam University Medical Centers, Amsterdam, Netherlands, [11]Novartis Pharma AG, Basel, Switzerland, [12]Universitätsklinikum Mannheim, Mannheim, Germany

Background: Myelofibrosis (MF) is a myeloproliferative neoplasm (MPN) that can develop de novo (primary MF) or from the progression of antecedent MPNs, in particular polycythemia vera (PPV-MF) or essential thrombocythemia (PET-MF). Ruxolitinib (RUX), a first-in-class JAK1/JAK2 inhibitor, is the standard of care for MF and demonstrated superiority over placebo (COMFORT-I) and best available therapy (COMFORT-II). However, RUX is not curative, cytopenias remain a challenge and some patients (pts) lose response or discontinue treatment due to adverse events. RUX combined with novel agents may offer superior disease control and transformative clinical benefits.
Aims: ADORE (NCT04097821) is a 3-part, open-label, multicenter, phase 1/2, platform study that will assess the safety and efficacy of RUX in combination with 5 novel compounds for the treatment of MF: siremadlin (HDM2 inhibitor), crizanlizumab (P-selectin inhibitor), sabatolimab (TIM-3 inhibitor) and, recently added to the study, LTT462 (ERK1/2 inhibitor) and NIS793 (anti-TGFβ antibody).
Methods: The study includes pts ≥18 years with primary MF, PPV-MF, or PET-MF, splenomegaly (a palpable spleen ≥5 cm from the left costal margin or spleen volume ≥450 cm^3 by MRI or CT scan), hemoglobin level <11 g/dL, and platelet count ≥75 × 10^9/L (≥50 × 10^9/L in Parts 2/3). Pts must have received RUX for ≥24 weeks and at a stable dose for ≥8 weeks prior to study entry.
Part 1 (phase 1b; Safety) includes a dose escalation arm to determine the recommended phase 2 dose for siremadlin + RUX and LTT462 + RUX, and a safety run-in for RUX + crizanlizumab, RUX + sabatolimab and RUX + NIS793. RUX will be administered at the same stable dose used prior to study entry. Pts will be treated for ≥24 weeks (8 cycles in NIS793 arm or 6 cycles in other arms). Part 1 primary endpoint is the incidence of dose-limiting toxicities within the first 2 cycles. Combinations evaluated as safe and tolerable in Part 1 may be selected for Part 2.
In Part 2 (phase 2; Selection), pts will be randomized to one of the selected combinations or RUX monotherapy (control) and treated for ≥48 weeks. After all Part 2 pts have completed 24 weeks of treatment, a futility interim analysis will determine which treatment will proceed to Part 3.
In Part 3 (phase 2; Expansion), pts will be randomized to the combination treatment, RUX cessation, or RUX monotherapy and treated for ≥48 weeks. Pts in the RUX cessation arm will be treated with combination therapy for 12 weeks, followed by novel agent monotherapy.
The primary endpoint for Parts 2 and 3 is the response rate (a composite of anemia improvement [increase in hemoglobin of ≥1.5 g/dL], no spleen volume progression, and no symptom worsening) at the end of cycle 8 (NIS793 arms) or cycle 6 (other arms) (24 weeks). The study will end 24 months after the last pt has initiated Part 3. A total of 240 patients are planned to be enrolled.
Results: Trial in progress.

Figure. ADORE Study Design

[a] Dose escalation required to determine Phase 2 dose for siremadlin and LTT462 arms.
[b] LTT462 and NIS793 added to study protocol in November 2020.
[c] NIS793 has a 21-day cycle; all other arms have 28-day cycles.
Part 1 dosing: ruxolitinib, 5 to 25 mg administered orally twice daily; siremadlin, 20 mg starting dose administered orally once daily on days 1 to 5 of a 28-day cycle; LTT462, 200 mg starting dose orally once daily in 28-day cycles; crizanlizumab, 5 mg/kg intravenously every 4 weeks; sabatolimab, 800 mg intravenously every 4 weeks; NIS793, 2100 mg intravenously every 3 weeks. Part 2/3: as per Part 1 except siremadlin and LTT462 which will use recommended Phase 2 dose established in Part 1.

Summary/Conclusion: As of January 2021, the study is open for enrolling into Part 1.

PB1724 CLINICAL CHARACTERISTICS AND SURVIVAL OF PATIENTS WITH PH NEGATIVE MYELOPROLIFERATIVE NEOPLASMS TREATED IN A REFERRAL HOSPITAL IN MEXICO CITY

G. Montero [1,*], G. I. Barranco Lampón [1,2], S. Rivas [1], R. Castillo [1]

[1]Hematology, Instituto Nacional de Cancerología, [2]Hematology, Hospital General de México Dr. Eduardo Liceaga, Mexico City, Mexico

Background: Myeloproliferative neoplasms (MPNs) are heterogenous myeloid malignancies that include essential thrombocythemia (ET), polycythemia vera (PV), and myelofibrosis (MF). There are few Latin American studies focused on these diseases.
Aims: In this work, we describe the clinical characteristics and frequency of the JAK2 V617F mutation, as well as the treatment patterns and survival of patients with the most frequent Philadelphia MPN neoplasms treated in a referral hospital in Mexico City.
Methods: A retrospective analysis of the medical history of patients with Ph negative myeloproliferative neoplasms treated at the National Cancer Institute of Mexico City was carried out to describe the variables considered for inclusion.
Results: Among the patients with essential thrombocythemia, 53% were men and 47% women, with a mean age of 51 years, 67% underwent

bone marrow biopsy, the JAK2 V671F mutation was detected in 47%, the mean platelet count at diagnosis was 1 016 x10^9/L (±SD 68 x10^9/L), 80% received treatment cytoreductive with hydroxyurea.
50% of the patients with polycythemia vera were women, the mean age at diagnosis was 63 years, 100% had a bone marrow biopsy, the JAK2 V617F mutation was found in 75%, the mean hemoglobin level at diagnosis was 18.6 g/dL (± SD 2.6 g/dL), 100% received treatment with hydroxyurea plus a low dose of aspirin.
Most of the patients with myelofibrosis were women (67%) and had a mean age at diagnosis of 68 years, a bone marrow biopsy was performed in 100% and the JAK2 V617F mutation was found in 67%, the mean hemoglobin level at diagnosis was 10.7 g / dL (± SD 4 g / dL), mean platelet count at diagnosis was 333 x109 / L (± SD 275 x109 / l), only 33% received treatment with JAK2 inhibitors.
Summary/Conclusion: Myeloproliferative neoplasms are rare in our environment, however, they present a behavior similar to that reported in other parts of the world. Efforts should be made to identify molecular alterations in our patients that could imply an improvement in access to novel treatments. Although our study has many limitations, it is expected to serve as the basis for the creation of a national registry that will help improve the study of patients with myeloproliferative neoplasms.

PB1725 SUCCESSFUL PREGNANCY OUTCOME IN ESSENTIAL THROMBOCYTAEMIA PATIENT AFTER MULTIPLE MISCARRIAGES WITH PLT NORMALISATION INDUCED BY GESTATIONAL THROMBOCYTOPENIA

I. Vaide [1,2,3,*], V. Aabrams [2], E. Laane [1,3]

[1]Tartu University. Institute for Clinical Medicine. Hematology-Oncology Clinic, Tartu, [2]Pärnu Hospital, Pärnu, [3]Kuressaare Hospital, Kuressaare, Estonia

Background: Essential thrombocythaemia (ET) is a clonal stem cell disorder presented with elevated platelet counts. ET in young women can be challenging due to their childbearing potential. There can be increased risk of fetal and maternal complications. The most common pregnancy-related complication is spontaneous abortion during the first trimester.
Aims: We present here a high-risk ET patient 38y old with successful pregnancy and with gestational thrombocytopenia
Methods: Chart review of the case records of the hospital
Results: The patient has been followed by Hematologist since 2014 due to four miscarriages (2013, 2015, 2017 and 2018) but had normal pregnancy with healthy boy born in 2002. Her platelet (PLT) count started to increase from 2010 and in 2014 JAK2 positive ET was diagnosed. In 2017 patient reported heavy metrorrhagia caused by acquired von Willebrand disease with loss of high weight vWF multimers. Hemostasis analyses: APTT 47.7s (28-40), PT-INR 1.28 (0.8-1.2), fibrinogen 1.3 g/L (1.6-3.5), D-dimers 0.28 µg/l (<0.5), FVIII 37% (60-150), vWFAg 61% (50-160), vWFac 34% (46-146), vWFAg/ac ratio 0.55 (>0.7). Patient was consulted by genetics, prothrombin and factor V Leiden mutation were negative.
The highest PLT count was 1604x10^9/L before the last 6th pregnancy in 2019. During the first and second trimester PLT count was in range of 600x10^9/L and decreased to normal reference range before delivery (PLT 398x10^9/L). Patient was treated with LMW heparin Enoxaparin sodium and low-dose Aspirin (75mg) during the 2nd-3rd trimester and after delivery for 10 days. PLT count at week (w) 12 was 1122 x109/L, w22 600 x10^9/L, w36 475 x10^9/L and w39 398 x10^9/L. Hemostasis analyses in w36: APTT 31.6s (28-40), PT-INR 1.1 (0.8-1.2), fibrinogen 3.6 g/L (1.6-3.5), D-dimers 0.64 µg/l (<0.5), FVIII 122% (60-150), vWF 257% (50-160), vWFac 182% (46-146). Five weeks after the delivery PLT count increased again to 1099x109/L Patient had no bleeds during pregnancy and blood loss was 300 ml during delivery.
Summary/Conclusion: We conclude that the patient had pregnancy associated thrombocytopenia due to PLT count decrease of the 70% from base value. It has been reported PLT decrease up to 20% in patients with ET during pregnancy. However, PLT count decrease could also be a side effect of Enoxaparin treatment but PLT decrease was profound, more than 30-50% in which observed PLT change was unlikely caused by Enoxaparin treatment. Furthermore, clinical findings do not support drug-induced thrombocytopenia. Pregnancy outcome was successful without initially planned alfa-interferon therapy. VWF level normalized and during pregnancy increased to thrombosis state, but VWF was still dysfunctional with lack of high molecular weight multimers. Clinically there was no reports of bleeding during delivery and Enoxaparin therapy after the childbirth. Our patient's case refers to the need of individual person and situation specific guiding of pregnancy in patients with myeloproliferative neoplasms which can be challenging.

PB1726 MYELOFIBROSIS TREATMENT WITH RUXOLITINIB IN CLINICAL PRACTICE: AN ANALYSIS OF EFFICACY AND SAFETY OF A SINGLE CENTER

R. Brito [1,*], S. Gonçalves Pereira [1], C. J. Saunders [1], M. Martins [1], P. Sousa e Santos [1], P. Ribeiro [1]

[1]Hematology, Santo António dos Capuchos Hospital, CHULC, Lisboa, Portugal

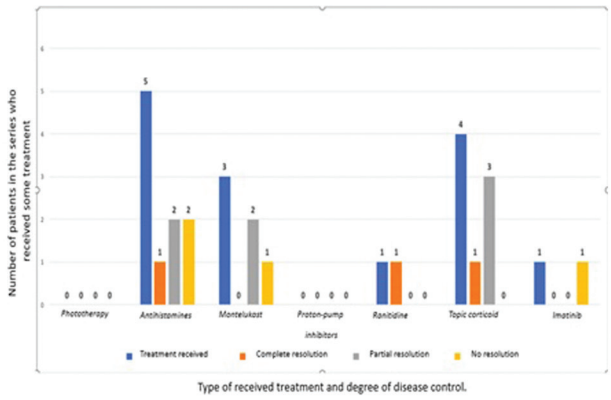
Background: ruxolitinib is a potent *Janus Associated Kinase* (JAK) inhibitor that mediates the signaling of a number of cytokines and growth factors that are important for hematopoiesis and immune function. It acts by inhibiting dysregulated JAK signaling associated with myelofibrosis (MF). Also, it has been shown to be an effective drug in alleviating systemic symptoms and reducing spleen size with significant improvement in patients (pts) quality of life.
Aims: report the efficacy and safety of ruxolitinib in a cohort of MF pts treated in routine clinical practice.
Methods: we retrospectively analyzed a total of 16 pts with MF treated with ruxolitinib in our hospital, between 2015 and 2020. For toxicity grading (gr) we used CTCAE criteria v5.0.
Results: 62.5% were males and the median age at diagnosis was 69.5 years (22-77). Ten pts (62.5%) were diagnosed as primary MF, 4 (25%) as post-essential thrombocythemia MF and 2 (12.5%) as post-polycythemia vera MF. Ten pts (62.5%) were JAK2 V617F mutated, 1 (6.3%) was CALR and 5 (31.3%) were triple negative. When analyzing risk stratification, 50% were DIPSS intermediate II and 25% high risk. Indications for treatment were constitutional symptoms plus splenomegaly in 10 (62.5%) pts, splenomegaly alone in 5 (31.3%) and intolerance to hydroxycarbamide in 1 (6.25%). Median time from diagnosis to start of ruxolitinib was 32.9 months with a median initial dose of 30mg/day. At baseline of treatment, 75% pts experienced constitutional symptoms among which 58.3% had complete symptomatic resolution. An average reduction in the spleen length of 60.6%, with almost all patients having a spleen reduction, was observed. Seven pts (53.8%) required a dose reduction: 3 (42.9%) due to anemia gr4, 1 (14.3%) due to thrombocytopenia gr2 and 2 (28.6%) due to both anemia and thrombocytopenia gr3. Five pts (25%) discontinued ruxolitinib, 2 due to leukemic transformation, 2 due to anemia g4 and gr5 and 1 due to no response.
Summary/Conclusion: our analysis confirms the efficacy and safety of ruxolitinib outside clinical trials with more than half of treated pts achieving and maintaining a clinical benefit and most of them reporting relief from symptoms. Clinicians are usually more alert towards thrombocytopenia but in our series, anemia was the most frequent and serious toxicity having occurred in more than half of the cases. Although, we consider that it is manageable, we would like to propose more strict indications for ruxolitinib dose adjustment according to the hemoglobin cut-off value.

PB1727 RUXOLITINIB TREATMENT IN PATIENTS WITH MYELOPROLIFERATIVE DISORDERS (MPD) – A UNICENTER STUDY.

V. Pereira [1,*], J. Santos [1], A. António [1], A. Neves [1]

[1]Oncology, Centro Hospitalar de Setúbal, Setúbal, Portugal

Background: Ruxolitinib (RXL) is an inhibitor of JAK 1 and 2, used in the management of patients with MPD, leading to improvements in splenomegaly and constitutional symptoms.
Aims: to characterize the efficacy and toxicity of RXL in patients with MPD treated in our center.
Methods: retrospective analysis of the patients treated with RXL during the previous 5 years.
Results: 13 patients were included, 10 (71%) males, median age 63.5 yo (min 52; max 78). 7 (54%) patients had primary myelofibrosis (PMF); 4 (30%) patients had secondary myelofibrosis (SMF) - 1 post Polycythemia Vera (PV) and 3 post Essential Thrombocytosis (ET); 1 (8%) patient with PV and 1 (8%) patient with ET. Results are presented as follows:
PMF – at diagnosis 3 (43%) patients presented with intermediate-2 DIPSS score, 3 patients with intermediate-1 DIPSS score and 1 (14%) patient had low risk DIPSS. 4 patients were JAK2V617F+. As first line treatment, 3 patients were treated with ESA, 2 with HU and 1 patient received first line treatment with RXL. RXL was offered as 2nd line treatment in 3 patients, and as 3rd line treatment in 3 patients. Median duration of



treatment with RXL was 15 months (min-9; max-54). No patient had PMF-related symptoms. Splenomegaly was present in 4 (57%) patients: 1 received RXL as first line treatment, 2 received RXL after 2nd line HU therapy and 1 received RXL as 3rd line of treatment (after HU and subsequent therapy with thalidomide + PDN). Response to RXL, including spleen reduction, was observed in the patient who received treatment as 1st line treatment, in 1 patient after 2º line treatment and in the patient treated as 3rd line of treatment. Overall, 4 (57%) patients had hematological toxicities and 1 (14%) patient had gastrointestinal adverse effects.
SMF – 3 patients had post ET myelofibrosis, all had received cytoreductive therapy as first line treatment; only 1 patient were JAK2V617F+ and had splenomegaly, and RXL was effective in reducing splenomegaly in this patient; the 2 other patients had no splenomegaly or JAK2V617F+ mutation and evolved with splenomegaly despite RXL therapy. Mean duration of treatment was 18 months (min 3; max 33). Hematological toxicity was registered in 2 patients. 1 patient had post PV myelofibrosis, was JAK2V617F+ and had splenomegaly responding to RXL treatment. There was no toxicity registered after a treatment duration of 10 months.
PV – 1 patient with PV received RXL due to intolerance to cytoreductive therapy; he was JAK2V617F+ and had splenomegaly at diagnosis. RXL was no able to reduce splenomegaly after 20 months of treatment. Hematological toxicity as thrombocytopenia has occurred.
ET – 1 patient with ET received RXL due to resistance to hydroxyurea; he was JAK2V617F+; had symptoms related to thrombocytosis, but no splenomegaly. RXL was effective in reducing symptoms but had no effect on the platelet count. No hematological toxicity was registered after 12 months of treatment with RXL.
Summary/Conclusion: Overall, response to RXL measured as spleen reduction or symptomatic control, was verified in 6 patients (46%) and 8 (61,5%) patients suffered toxicity, mainly hematological.

PB1728 CHARACTERIZATION OF ADULTS SERIES OF MASTOCYTOSIS CASES IN A HEALTH CARE CENTER IN CALI

J. L. Zambrano Urbano [1,*], R. Gomez Gutierrez [1]

[1]*Valle del Cauca, Universidad Libre Cali -Colombia, Colombia, Colombia*

Background: Mastocytosis are neoplastic diseases of the myeloid line. They are characterized by pathological increase and accumulation of mast cells in one or more organs, most frequently involving the skin, bone marrow, liver and gastrointestinal tract. They may present as cutaneous mastocytosis (CM), systemic mastocytosis (SM), and localized mast-cell tumors. An annual incidence of up to 0.89 cases per 100,000 inhabitants has been reported for SM. There is no clarity on the therapeutic strategies, and several experimental treatments are still underway. In Colombia, there are only case reports; and so far, there are no more extensive studies.
Aims: To characterize a series of 7 patients with mastocytosis (both cutaneous and systemic cases) describing their clinical manifestations, paraclinical behavior and response to the medical treatment established in a reference center in the city of Cali (Colombia, South America).
Methods: A descriptive study of a series of cases in which it was carried out an active search for patients with a diagnosis of mastocytosis, whether cutaneous or systemic, from the total number of consultations in the period between June 2004 and June 2019, in the hematology-oncology reference center ("mastocytosis") in Cali. A total of 7 patients were found; their informed consent was obtained in accordance with the guidelines of the local ethics committee and the Helsinki act. Compliance with diagnostic criteria was verified according to existing WHO guidelines. The different sociodemographic, clinical, paraclinical and response to treatment variables were characterized, according to data from the clinical history. Qualitative variables were analyzed by frequencies and proportions, quantitative variables were measured by frequencies, averages and ranges.
Results: A total of 4 cases of CM and 3 cases of SM were identified. The most frequent clinical manifestations were skin lesions, which occurred in 100% of the patients; of these, the most frequent finding was hyper-pigmentary macules. 67% (2/3) of the SM patients presented gastrointestinal symptoms. Elevated serum tryptase (ST) levels were found in 67% (2/3) of MS patients. Both ST levels and the average absolute eosinophils values were higher in SM patients. The C-KIT mutation (D842B) was requested in only one patient (MC) in the series; this was positive. Only 28% (2/7) of the patients had complete resolution of symptoms with antihistamine treatment.

Summary/Conclusion: Regardless its presentations, mastocytosis is a rare disease, with little evidence to guide its diagnosis and management. A higher frequency of extracutaneous involvement, high levels of ST and eosinophils were found in SM patients; and in general, (there was) a very poor response to the established management in the two groups. The findings of this series are comparable to those reported in the world literature.

Platelets disorders

PB1729 OVERVIEW OF IMMUNE THROMBOCYTOPENIA MANAGEMENT IN CHILDREN, A SINGLE INSTITUTE EXPERIENCE

A. Al-Darraji [1], K. Auda [1], H. Ghali [2], M. Al-Jadiry [2], S. Faraj [3], R. Al-Saeed [1], A. Sabhan [1], S. Fadhil [1], S. AL-Hadad [2,*]

[1]*Pediatric hematology/oncology, Children Welfare Teaching Hospital, Medical City,* [2]*Pediatric hematology/oncology, College of Medicine, University of Baghdad / Children Welfare Teaching Hospital, Medical City,* [3]*Pediatric hematology/oncology, College of Medicine, University of Wasit / Children Welfare Teaching Hospital, Medical City, Baghdad, Iraq*

Background: Immune thrombocytopenia (ITP) during childhood is usually characterized by acute onset of thrombocytopenia with around 75% of children having spontaneous remission within 6 months. Most children experience only mild bleeding in the form of bruising and Petechiae, with severe bleeding being rare even in children with persistent disease
Aims: To study demography, clinical, laboratory and treatment options of patients who were newly registered cases of immune thrombocytopenia referred to Children Welfare Teaching Hospital, Medical City, Baghdad.
Methods: A retro-prospective descriptive study was done on a newly diagnosed patients with ITP who were referred to Children's Welfare Teaching Hospital (CWTH) / Medical City / Baghdad from January 1, 2019 to April 30, 2020. The period of data collection and follow up started in September 2019 till December 2020
Results: A total of 107 patients were identified as having a presumptive newly diagnosed Immune Thrombocytopenia. Seven patients were excluded after being diagnosed as secondary ITP or other causes of thrombocytopenia during observation period. The mean age was 5.6 years (range 3 months-13.5 years). There were 56 (52.3%) boys, with a M:F ratio was 1.09:1. The mean duration of symptoms is 62 days. Sixty-four (59.8%) patients were managed as an outpatient only.
Sole cutaneous bleeding was reported in 55 (51.4%) patients while wet purpura was the leading cause of mucosal bleeding occur in 25 (23.3%) patients followed by epistaxis in 24 (22.4%) patients. According to grading, grade I/II was seen in 55(51.4%). The mean platelet's count was $15.7x10^9$/L, Platelet's count of <30 $x10^9$/L in 92 (86%) patients.
Seventy-eight patients (72.9%) reached CWTH without receiving any treatment while 29 (27.1%) patients received treatment elsewhere. The total number of patients kept under watchful waiting strategy was 44 (41.1%).
The mean and median platelets count at both time of diagnosis and time of last contact in the observation group were higher than that of the treatment group (24&19 vs 9.9&7 x 10^9/L at time of diagnosis; 210.6&246 vs 204.8&214 at time of last contact). There was significant

statistical correlation between each group and classification of grading (P value 0.0001).
Comparing severe thrombocytopenia (platelet's count < 30 x 10^9/L) and bleeding score among 2 groups; there was significant statistical correlation between bleeding grade at time of diagnosis and at time of last contact (P value 0.004).
Summary/Conclusion: The result of this study confirms the result of last year study in the same center which encourages the successful management of ITP by observation only and support the consensus that ITP is a benign and self-limited condition for the majority of affected children. The incidence on intracranial bleeding was 0.9%. The study observations support the emerging trend toward reserving drug therapy for ITP patients with major bleeding manifestations or troublesome impairment of quality of life.

PB1730 DENTOALVEOLAR PROCEDURES IN IMMUNE THROMBOCYTOPENIA; SYSTEMATIC REVIEW AND PRACTICAL RECOMMENDATIONS

W. E. M. Van Dijk [1,*], R. J. J. van Es [2], M. E. P. Correa [3], R. E. G. Schutgens [1], K. P. M. van Galen [1]

[1]Van Creveldkliniek, [2]Department of Head and Neck Surgical Oncology, University Medical Center Utrecht, Utrecht, Netherlands, [3]Oral Medicine Ambulatory, Haematology and Haemotherapy Centre, University of Campinas, Campinas, Brazil

Background: Dentoalveolar procedures in immune thrombocytopenia (ITP) pose a risk of bleeding, due to thrombocytopenia, and infection, due to immunosuppressive treatments.
Aims: To systematically review the safety and management of dentoalveolar procedures in ITP patients in order to create practical recommendations.
Methods: Pubmed, Embase, Cochrane and Cinahl were searched. All original studies with surgical and non-surgical dentoalveolar procedures (including tooth extractions, scaling, and periodontal and endodontic surgery) in adult and pediatric patients with known primary ITP at the time of procedure were included. Details on bleeding- and infection-related outcomes were recorded, including the therapeutic strategies. Clinically relevant bleeding was defined as needing treatment or medical attention.
Results: Eighteen articles were included, of which twelve case reports/series. Overall, the quality of the available evidence was poor. Outcomes and administered therapies (including hemostatic therapies and prophylactic antibiotics) were not systematically reported. At least 118 dentoalveolar procedures in 94 ITP patients were described. The range of preoperative platelet count was 2-412*10^9/L. Two clinically relevant bleedings were reported in the same patient, of which one life-threatening. Strategies used to minimalize the risk of bleeding were heterogeneous and included therapies to increase platelet count, antifibrinolytics, local measures and minimal invasive techniques. Reports on the occurrence of bleedings due to anesthetics or infection were lacking.
Summary/Conclusion: It appears that clinically relevant bleeding complications after dentoalveolar procedures in ITP patients occur rarely, based on low quality data. Reported therapeutic strategies to prevent bleedings are heterogeneous. Prospective and controlled studies are needed to evaluate safety of dentoalveolar procedures in patients with low platelet counts and to investigate the efficacy of therapeutic interventions. We propose practical recommendations to manage dentoalveolar procedures in ITP patients based on the best available evidence and our single-center clinical experience.

PB1731 CLINICAL AND BIOLOGICAL PREDICTORS OF CHRONICITY OF IMMUNE THROMBOCYTOPENIA IN ADULTS

M. Bchir [1,*], E. berred [1], R. berred [1], Y. selmi [1], S. kefi [1], L. issaoui [1], B. meddeb [1]

[1]hematology department, Tunis El Manar University, Faculty of medecine of Tunis,Aziza Othmana Hospital., Tunis, Tunisia

Background: Immune thrombocytopenia (ITP) in adults is an auto-immune disease treated in first- line by corticosteroids and polyvalent immunoglobulins. This disease has frequently a chronic evolution. Risk factors for chronicity are not well defined and were explored in only a few studies.
Aims: The aims of this study were to report the clinical features of adult ITP, and to identify the clinical and biological risk factors predicting chronicity.
Methods: This was a monocentric retrospective study that collected data from adult patients followed for newly diagnosed ITP over a six year-period (2011 - 2017). Patients with platelets inferior to 30000/mm^3 were initially treated with corticosteroids. Second-line treatment consisted of splenectomy or danazol. Thrombopoeitin receptor agonists were not available in Tunisia during the period of the study.
Results: One hundred and fifty patients were included, with a median age of 43 (16-79). The median platelet count was 15000/mm^3 (0-88000). Response to corticosteroids was observed in 84,6% of patients with 71,5% of complete response. But recurrence of thrombocytopenia occurred in 27,2% of these patients.Chronic ITP was noted in 32,4%of patients, while newly diagnosed and persistent ITP were noted in 59,3% and 8,3% respectively.
Clinical and biological predictors of chronicity were studied. Clinical factors studied were: age, sex, the presence of bleeding symptoms,Khellaf score, the corticosteroid resistance, the time to response to corticosteroids, the duration between the response to corticosteroids and the recurrence of ITP. Biological factors studied were: the mean platelets count at baseline, the presence of antinuclear antibodies, the presence of antiphospholipid antibodies, the platelet-to-lymphocyte ratio at baseline (PLR). Only the presence of bleeding symptoms at diagnosis (p=0,033), the corticosteroid resistance (p=0,000) and the PLR <0.86 (p=0,031) were associated with a significant risk of progression to chronic ITP.
Summary/Conclusion: The progression to chronic ITP is frequent. The predictive markers of chronicity can be used to introduce promptly a second-line treatment and avoid prolonged courses of corticosteroids.

PB1732 NOT YET TO BE BORN – A CLINICAL CASE OF PSEUDOTHROMBOCYTOPENIA IN A PREGNANT WOMAN

A. C. B. Marques [1,*], A. V. D. Barros [1], J. S. Matias [1], M. Manaças [1], F. Carriço [1], A. Miranda [1]

[1]Clinical Pathology Department, Hospital de Santa Maria, Centro Hospitalar Universitário Lisboa Norte, Lisboa, Portugal

Background: Pseudothrombocytopenia (PTCP) is a platelet count (PC) erroneously below the reference value, usually under 150x10^9/L, due to platelet aggregation or platelet satellitism that happens *in vitro* triggered by the presence of an anticoagulant, mostly seen with EDTA. This phenomenon happens due to the binding of autoantibodies to glycoprotein IIb/IIIa in the presence of EDTA.
Aims: The authors present a clinical case of pseudothrombocytopenia.
Methods: 32-year-old pregnant woman, gesta 5, para 4, at 36 weeks and 2 days was admitted to the Obstetrics Emergency Room (OER) with complains of low back pain, cramps, chills, vomiting and nausea with 1 day evolution. The patient denied fever, cough, respiratory difficulty or urinary symptoms. There was no known epidemiological context for SARS-CoV-2 infection. Obstetric past history of 4 previous eutocic deliveries, 2 of them were preterm labours at 27th and 34th week of gestation. She had been medicated in outpatient care with vaginal progesterone. At clinical observation in the OER the patient was hemodynamically stable with no significant clinical changes, only showing a dubious right Murphy sign. Analytically, revealed thrombocytopenia of 126x10^9/L, lymphopenia of 0,34 x10^9/L and C-RP: 3,93mg/dL; the remaining inflammatory parameters were within reference values as well as renal function and liver damage analytes. Urine dipstick test revealed Ketone bodies: 150mg/dL; Proteins: 25mg/dL; Leucocytes: 100 cell/µL; Erythrocytes: 10 cell/µL; Nitrites: negative. SARS-CoV-2 RT-PCR test was positive. Cardiotocography (CTG) showed a normal pattern, with fetal heart rate of 150-160 bpm and irregular and sparse uterine contractility. The patient was proposed for hospitalization with CTG monitoring and started empirical antibiotherapy with cefuroxime for a presumed acute pyelonephritis. Prophylactic enoxaparin was started on the 2nd day. The pregnant woman remained clinically stable, analytically highlighting a progressive decrease in PC from the 2nd day on, with PC of 85x10^9/L. On the 4th day of hospitalization with thrombocytopenia of 11x10^9/L, a blood smear and the sFlt-1/PlGF ratio ongoing, a variety of different diagnosis were raised, such as pre-eclampsia, HELLP syndrome, autoimmune disorders, idiopathic thrombocytopenic purpura, heparin induced thrombocytopenia (HIT) or COVID-19-induced thrombocytopenia. At this point, our laboratory was contacted in order to confirm the low PC, since a labour induction was a possibility.
Results: HIT test proved to be negative and the blood smear revealed many and huge platelet aggregations. To confirm the PC our laboratory advised a new blood collection in a trisodium citrate solution (S-Monovette® *Citrate*) and in Mg^{2+} compound (S-Monovette® *ThromboExact*) collection tubes, which revealed a PC of 31x10^9/L and 123x10^9/L, respectively. On the 5th day she was discharged. After COVID-19 infection cure, the PC values remained significantly different

when measured in an EDTA and in Mg^{2+} compound collection tubes. The delivery happened, later, at 39 weeks of gestation.
Summary/Conclusion: The identification of a PTCP allowed us to avoid an iatrogenic preterm labour. When confronted with a patient with no signs or symptoms of bleeding or haemorrhagic dyscrasia and no past history of thrombocytopenia, PTCP should be considered as one of the differential diagnosis. It is estimated that approximately 0.1% of the whole population has antiplatelet autoantibodies triggered by EDTA. Early detection of this phenomenon may avoid an extensive investigation and unnecessary therapeutic procedures.

PB1733 PHASE III MULTICENTER, DOUBLE-BLIND, RANDOMIZED, PLACEBO-CONTROLLED STUDY OF RILZABRUTINIB, ORAL BTK INHIBITOR, IN ADULTS AND ADOLESCENTS WITH PERSISTENT OR CHRONIC IMMUNE THROMBOCYTOPENIA

D. J. Kuter [1,*], J. B. Bussel [2], N. Cooper [3], T. Gernsheimer [4], M. P. Lambert [5], H. A. Liebman [6], M. D. Tarantino [7], O. Bandman [8], P. Arora [8], A. Neale [8], R. Burns [8], H. Guo [9], W. Ghanima [10]

[1]Hematology Division, Massachusetts General Hospital, Harvard Medical School, Boston, [2]Division of Hematology/Oncology, Department of Pediatrics, Weill Cornell Medicine, New York, United States, [3]Department of Medicine, Hammersmith Hospital, London, United Kingdom, [4]University of Washington Medical Center, Seattle, [5]Division of Hematology, The Children's Hospital of Philadelphia, Philadelphia, [6]Jane Anne Nohl Division of Hematology, Keck School of Medicine. University of Southern California, Los Angeles, [7]The Bleeding and Clotting Disorders Institute, University of Illinois College of Medicine-Peoria, Peoria, [8]Principia Biopharma Inc, a Sanofi Company, South San Francisco, [9]Biostatistics, Sanofi US Services Inc., Bridgewater, United States, [10]Ostfold Hospital Foundation, Gralum, Norway

Background: Immune thrombocytopenia (ITP) is an autoimmune disorder characterized by immune-mediated platelet destruction and impaired production, leading to thrombocytopenia, a predisposition to bleeding, and diminished quality of life. Although initial response rates to standard therapy are generally high, long-term tolerability and durable remission remain elusive. Rilzabrutinib is an oral, reversible Bruton tyrosine kinase (BTK) inhibitor targeting mechanisms driving ITP. Preclinical studies of rilzabrutinib showed simultaneous rapid anti-inflammatory effects, along with neutralization and prevention of autoantibody signaling. In an ongoing phase I/II study of rilzabrutinib (± concomitant ITP therapy), 400 mg BID was identified as the optimal dose in patients with relapsed or refractory ITP. Preliminary results showed rapid, durable platelet response increases with a well-tolerated safety profile.
Aims: LUNA3 is a multicenter, randomized phase III study with open-label extension evaluating the efficacy and safety of rilzabrutinib vs placebo in adult and adolescent patients with persistent or chronic ITP (CT.gov: NCT04562766; EudraCT: 2020-002063-60).
Methods: Eligible patients must have primary ITP for a duration of >6 mo for adolescents (ages 12-17 y) or >3 mo for adults (age ≥18 y) and an average of 2 platelet counts <30×10^9/L (no single count >35×10^9/L) within 2 wk prior to treatment. Eligible patients should have a previous response (platelet count ≥50×10^9/L) to intravenous immunoglobulin/anti-D or corticosteroids that was insufficient or not sustained, or documented intolerance or insufficient response to any appropriate courses of standard-of-care ITP therapy. Randomization is carried out separately for the 2 age groups (12-17 y and ≥18 y). Within the 2 age groups, patients are stratified by splenectomy status (yes/no) and thrombocytopenia severity (platelet counts <15×10^9/L or ≥15×10^9/L). Patients are randomized 2:1 to oral rilzabrutinib 400 mg BID or placebo to receive double-blind treatment for up to 24 wk, followed by open-label treatment for 28 wk, and then a 4-wk safety follow-up. After 12 wk of double-blind treatment, non-responders will be given the option to receive open-label rilzabrutinib or discontinue from the study. Concomitant stable doses (maintained for at least 2 wk prior to study day 1) of ITP medication (corticosteroids and/or thrombopoietin-receptor agonists) are permitted. Patients who receive rescue medication may continue study treatment. The primary endpoint is the achievement of platelet counts ≥50×10^9/L for ≥8 of the last 12 weeks of the 24-week blinded treatment period in the absence of rescue medication. Secondary endpoints include safety, duration of and time to platelet responses, rescue therapy use, and changes from baseline in bleeding scores (per ITP-BAT assessment). Responders may enter an additional 12-mo long-term extension.
Results: This is a recently-initiated, global clinical trial with the goal of enrolling approximately 194 patients.
Summary/Conclusion: The LUNA3 multicenter, phase III pivotal study is designed to evaluate the efficacy and safety of oral rilzabrutinib (± concomitant ITP therapy) vs placebo in adults and adolescents with persistent or chronic ITP who had insufficient response or were intolerant to previous ITP therapy. These study results will provide further support for a unique treatment mechanism via BTK inhibition to target the underlying pathology of ITP.

PB1734 REVISION OVER 15 YEARS EXPERIENCE OF MULTIPLE AUTOINMUNE CYTOPENIAS IN HEMATOLOGICAL AND NON-HEMATOLOGICAL DISORDERS

P. Melero Valentín [1,*], E. Fernández Melid [2], A. Abuin Blanco [2], A. Peleteiro Raíndo [1], M. Cid López [1], M. D. Vilariño Lopez [2], E. Fontanes Trabazo [2], L. Bao Perez [2], M. J. Rabuñal Martinez [2], Á. Bendaña López [2], M. M. Perez Encinas [2], R. Ferreiro Ferro [2], M. S. González Pérez [2], N. Alonso Vence [2], J. L. Bello López [3]

[1]Hematology, Residente, [2]Hematology, Adjunto, [3]Hematology, Jefe, Santiago de Compostela, Spain

Background: Inmune cytopenias (IC) are a frecuent finding that may occur either isolated or associated with autoimmune, neoplasic or infectious diseases. Anemia and thrombocytopenia are the most usual concomitant cytopenias and they even constitute a syndrome (Evans Syndrome-ES) themselves with specific characteristics and prognostic implications. Futhermore, when they are related with another medical condition, the presence of IC may affect unfavorably its treatment and evolution. However, it is not unusual that in some mild onsets this coexistence may be not detected until long time evolution because, for example, haemolytic activity is well-balanced and no anemia or thrombocytopenia are detected or neutropenia is unstable.
Aims: Get a global perspective of the variety of entities with multiple IC that had been referred to Haematology department for assessment and treatment evaluation. Identify those which fulfill classical ES criteria and their treatment and evolution.
Methods: We included 13 adult patients studied between 2006-2020 with autoimmune hemolytic anemia (AIHA) and/or immune thrombocytopenia (ITP) and/or immune neutropenia (IN) in the absence of any underlying cause. A revision of the diagnosis criteria and response to therapy was made according to International Consensus for Adult AIHA and the American Society of Hematology 2019 guidelines for inmune thrombocytopenia. Inmune neutropenia was define by neutrophil count <1,5x10E9/L on at least 2 separate determinations. Finally we defined ES as the concomitant or sequential confirmed presence of 2 of them: AIHA, ITP or IN.
Results: Thirteen patients with confirmed IC were included, 6 males and 7 females with a median age of 42 years at the diagnosis, and a median of 9 years of monitoring. Only 4 patients developed simultaneous cytopenias (2 ITP+IN, 2 ITP+AIHA) and the median of time between one cytopenia and another was 2'5 years. The most frecuent combination found was AIHA+ITP in 12 patients, with lower counts for ITP.
All AIHA were mediated by warm antibodies and antiglobulin test (DAT) IgG1+C3d in 85% of cases with only 1 case IgG+IgA. ITP presentation was moderated to severe in 12 cases. IN was not clinically relevant with a neutrophils nadir over 300x10E9 for all patients, and no recurrent or opportunist infections were documented even though there was 38% cases with significative hipogammaglobulinemia.
Additionally we detected antinuclear positive antibodies in 7 patients, and other types of autoimmune antibodies in 2 patients (antiphospholid and thyroid peroxidase antibodies) with higher titles in those with deeper cytopenias, specially AIHA, and mild to low titles in the rest.
ES criteria were accomplished by 8 patients, 5 AHAI+ITP, 3 ITP+IN. We describe their association with or without an underlying disorder as well as the therapeutic management in Table 1.
Finally, there was not any death related to this autoimmune disorder and 1 patient with secondary ES associated with lung cancer has died for this neoplasic disease.

	CYTOPENIA	1°/2	SIMUTANEOUS YES/NO	YEARS	ACUTE TREATMENT	CHRONIC TREATMENT	RESPONSE
Patient 1	AHAI+ITP	2°	No (1° ITP)	2'5	Corticosteroids+Igs+ Rituximab	No	Complete
Patient 2	AHA+ITP	2°	No (1° AHAI)	3	Corticosteroids+Igs+ Rituximab	Corticosteroids low doses	Complete
Patient 3	AHAI+ITP	2°	No (1°AHAI)	4'5	Corticosteroids+Igs	Revolade+ Corticosteroids low doses	Complete
Patient 4	AHAI+ITP	2°	No (1° ITP)	9	Corticosteroids+Igs	Romiplostin+ Corticosteroids low doses	Complete
Patient 5	AHAI+ITP	2°	N0 (1°ITP)	0'5	Corticosteroids+Igs+ Chemotherapy	Mycophenolate	Complete
Patient 6	ITP+IN	1°	Yes	-	Corticosteroids+G-CSF	No	Complete
Patient 7	ITP+IN	2°	Yes	-	Corticosteroids	Mycophenolate	Partial
Patient 8	ITP+IN	2°	No (1° ITP)	4	Corticosteroids+Igs	Revolade	Complete

Summary/Conclusion: ES in a rare and probably undiagnosed condition with a treatment traditionally based on corticosteroids. Nowadays combination with TPO-agonists is changing the rules and the prognosis of these patients.

Quality of life, palliative care, ethics and health economics

PB1735 HEALTH-RELATED QUALITY OF LIFE AMONG REFRACTORY/RELAPSED B-CELL PRECURSOR ACUTE LYMPHOBLASTIC LEUKEMIA PATIENTS TREATED WITH KTE-X19: PHASE 2 RESULTS FROM ZUMA-3 TRIAL

B. Shah [1], C. Solem [2,*], C. Feng [3], G. Maglinte [3], W.-J. Wang [2], T. Shen [3], R. Vezan [3], B. Kharabi Masouleh [3], R. Houot [4]

[1]Moffitt Cancer Center, Tampa, FL, [2]Patient Centered Outcomes, Pharmerit- an OPEN Health Company, Bethesda, MD, [3]Kite Pharma, A Gilead Company, Santa Monica, CA, United States, [4]CHU Rennes, Rennes, France

Background: Refractory/relapsed B-cell precursor acute lymphoblastic leukemia (r/r ALL) is an acute disease with poor prognosis with standard of care. The value of chimeric antigen receptor (CAR) T-cell therapies on not only overall survival but also health-related quality of life in r/r ALL warrants further study. The ZUMA-3 open-label, phase 1/2 multicenter trial (NCT02614066) was designed to evaluate the safety and efficacy of KTE-X19 in adult subjects with r/r ALL.
Aims: This analysis aimed to evaluate health-related quality of life as measured by the EQ-5D within the ZUMA-3 trial and how scores changed after treatment with KTE-X19 as compared to before treatment.
Methods: The EQ-5D 5 level version (EQ-5D-5L) was used to assess quality of life among patients in the Phase 2 portion of the ZUMA-3 trial at Screening, Day 28, Month 3, and every 3 months during long-term follow-up (up to 12 months). The EQ-5D visual analog scale (VAS) and Index scores (calculated using the US value set, with sensitivity analyses using crosswalk of UK, German, and French value sets) were described at screening, Day 28 and Months 3, 6, 9, and 12 with changes in scores from screening compared to thresholds for meaningful change (7 for VAS, 0.05 for EQ-5D indices). To handle missing survey response data, mixed-effects models with repeated measures (MMRMs) using a categorical variable for visit were applied under the missing-at-random assumption to estimate changes in scores in the full study population.
Results: Among 55 treated subjects in the Phase 2 modified intent to treat (mITT) study population, 51 patients completed the EQ-5D-5L survey at screening, 42 (41 for Index) at Day 28, 26 (25 for Index) at Month 3, 25 at Month 6, 10 at Month 9 and 14 at Month 12. Mean (SD) VAS scores at Screening, Day 28, Month 3, Month 6, Month 9, and Month 12 were 68.2 (21.8), 74.7 (17.9), 79.7 (12.2), 81.0 (17.6), 81.7 (23.1), and 86.9 (10.0) respectively. Most patients (min 70.0%, max 92.9%) had stable or improved VAS scores after treatment with KTE-X19.
Mean (SD) EQ-5D Index scores (US value set) were 0.82 (0.19) at screening with the highest score at Month 12 (0.91 [0.13]). Most patients had stable or improved EQ-5D Index scores after treatment with KTE-X19 (min: 57.5% [Day 28] max: 80.0% [Month 9]). Results were similar using UK, German, and French EQ-5D-5L index value sets. Based on MMRMs, estimated mean change in VAS exceeded clinically meaningful thresholds at Month 3 (mean [95% CI]: 9.6 [2.6, 16.5]), Month 6 (9.4 [2.5, 16.3]), and Month 12 (14.8 [7.0, 22.6]). Estimated mean change in EQ-5D-5L indices exceeded clinically meaningful thresholds at Month 12 (0.078 [-0.009, 0.164]) but confidence intervals overlapped 0. Similar to other patient outcome survey studies, results should be interpreted with caution due to missing follow-up data for some patients and small sample size.
Summary/Conclusion: Results showed that among R/R ALL patients participating in ZUMA-3, the majority of patients experienced improved or stable health-related quality of life as assessed by the EQ-5D scores, and this was more pronounced with the VAS score.

PB1737 PSYCHOLOGICAL DISTRESS IN OUTPATIENTS WITH LYMPHOMA DURING THE COVID-19 PANDEMIC

C. Minoia [1,*], F. Romito [2], G. Loseto [1], C. Cormio [2], G. Opinto [1], A. Guarini [1]

[1]Hematology Unit, [2]Psycho-Oncology Unit, IRCCS Istituto Tumori "Giovanni Paolo II", Bari, Italy

Background: Cancer patients are a population at high risk of contracting COVID-19 and, also of developing severe complications due to the infection, which is especially true when they are undergoing immunosuppressive treatment. Despite this, they had still to go to hospital to receive chemotherapy during lockdown.
Aims: In this context, we have evaluated the psychological status of onco-hematological outpatients receiving infusion and not deferrable anti-neoplastic treatment for lymphoproliferative neoplasms, with the aim of both measuring the levels of post-traumatic symptoms, depression, and anxiety during the pandemic and also of investigating the perception of risk of potential nosocomial infection.
Methods: The Impact of Event Scale-Revised (IES-R) and the Hospital Anxiety and Depression Scale (HADS) were administered to all patients. Moreover, patients were investigated about their worries regarding the impact of COVID-19 on their lives as onco-hematologic patients.
Since the 2nd to the 29th April 2020 (during the first phase of the lockdown period in Italy) outpatients affected by lymphoma and needing an infusional chemotherapy/ immunetherapy were evaluated in the study. A multi-disciplinary approach to the patient was then activated, in order to provide a psychological support during the next phases of pandemy.
Results: 77 outpatients were prospectively evaluated. The mean age was 56.6 (range 22–85); 39 (50.6 %) were male and 38 (49.4 %) female. Diagnoses were distributed as: cHL n. 25 (32.5%); aggressive NHLS n. 15 (19.5%), of whom n. 9 had diffuse large B-cell lymphoma (DLBCL), n 5 mantle cell lymphoma (MCL), and n. 1 primary mediastinal large B-cell lymphoma; indolent NHLs n. 37 (48%), distributed as follicular lymphoma (FL) n. 28, marginal zone lymphoma (MZL) n. 3, hairy cell leukemia (HCL) n. 3, lymphoplasmacytic lymphoma n. 1, CLL/SLL n. 3. N. 6 (7.8%) were treated inside of a clinical trial. N. 52 (67.5%) of patients received infusion chemotherapy or immune-chemotherapy and n. 25 (32.5%) received immunotherapy. According to the line of treatment, n. 38 (49.3%) received induction therapy, n. 6 (7.8%) second line therapy, n. 13 (16.9%) were at the third or higher line, and n. 20 (26%) were receiving maintenance therapy.The mean age was 56.6 (range 22-85). Authors found that 36% of patients had anxiety (HADS-A), 31% depression (HADS-D), and 43% were above the cut-off for the HADS-General Scale; 36% fulfilled the diagnostic criteria for post-traumatic stress disorder (PTSD). Women and younger patients were found to be more vulnerable to anxiety and PTSD.
In the subsequent months, Authors planned a more structured psychological support, based on a screening offered to outpatients with lymphoma.
Summary/Conclusion: The study firstly analyzes the psychological impact of the COVID-19 pandemic on the frail population of patients affected by lymphoproliferative neoplasms, to underly the importance of screening patients for emotional and distress conditions and then offering them psychological support.

PB1738 REAL-WORLD COSTS OF FRONT-LINE TREATMENT FOR PERIPHERAL T-CELL LYMPHOMA IN FRANCE, GERMANY, AND THE UNITED KINGDOM

C. Fox [1], A. Ashaye [2,*], R. Shah [3], S. Corman [3], M. Dalal [2], L. Trumper [4]

[1]Nottingham University Hospitals NHS Trust, Nottingham, United Kingdom, [2]Millennium Pharmaceuticals Inc., a wholly owned subsidiary of Takeda Pharmaceutical Company Ltd, Cambridge, MA, [3]Pharmerit - an OPEN Health Company, Bethesda, MD, United States, [4]University Medicine, Georg-August-University, Goettingen, Germany

Background: Peripheral T cell lymphomas (PTCL) are a rare and heterogenous group of aggressive non-Hodgkin lymphomas (NHL) that develop from mature T- and natural killer cells. They comprise approximately 10% of all newly diagnosed cases of NHL in Western populations
Aims: To estimate the cost of first-line treatment in patients with PTCL, from the government payer perspective, in France, Germany, and the UK
Methods: A cost calculator was designed to apply country-specific unit costs to treatments and other healthcare resource use collected in a retrospective medical chart review study conducted in France, Germany, and the UK. The study included PTCL patients diagnosed between January 1,

2014 and December 31, 2016, who received at least front-line treatment for PTCL. Medical chart data, including PTCL treatments, adjunctive therapies (e.g., antibiotics, antivirals, granulocyte-colony stimulating factor), radiotherapy, laboratory tests, inpatient and outpatient visits, and ancillary care, were collected. Unit costs for each type of resource used were sourced from tariffs in each country, and adjusted to 2020 values. Resource use was then multiplied by the corresponding unit cost to calculate the total cost by resource type, and the mean cost per patient was calculated. Results were stratified by country, PTCL subtype, front-line treatment regimen, age, and receipt of stem cell transplant.
Results: Data for a total of 165 patients (France, 53; Germany, 56; UK, 56) were collected in the chart review. The median age at diagnosis was 62 years, 81 % of patients had an ECOG status of 0-1 at diagnosis, and 72% had stage III/IV disease. Total costs of first-line therapy were €12,257 per patient in France, €22,392 in Germany, and €32,461 in the UK. The greatest proportion of costs was attributed to adjunctive therapies in France (€4,509) and Germany (€11,539), and stem cell transplant in the UK (€13,419). Of note, patients in the UK were more likely to have received a stem cell transplant (44.6%) compared to France (13.2%) and Germany (19.6%).
Summary/Conclusion: Adjunctive therapies and stem cell transplants are major cost drivers in patients with PTCL receiving front-line treatment.

PB1739 DETERMINING SATISFACTION WITH INTERPERSONAL RELATIONSHIP WITH NAVIGATOR MEASURE AMONG CAREGIVERS OF FILIPINO CHILDREN WITH CANCER IN A TERTIARY REFERRAL CENTER: A PATIENT NAVIGATION RESEARCH STUDY

T. Chu [1,*]

[1]Department of Pediatrics, West Visayas State University, Iloilo City, Philippines

Background: Patient Navigators are trained to provide support and guidance to patients throughout the cancer care continuum. They help "navigate" through the maze of doctors' clinics, outpatient centers, insurance and payment systems, patient-support organizations, and other components of the health care system. Yet, there is no existing patient satisfaction tool to assess the patient navigation program in the Philippines for pediatric cancer.
Aims: This study aims to evaluate satisfaction with the patient navigation program using a validated Satisfaction with Interpersonal Relationship with Navigator (SN-I-Ph) Measure among Filipino caregivers in a tertiary referral center for childhood cancer.
Methods: The tool was first translated for cultural appropriateness, translated and back translated into Filipino and the content validity and internal consistency were tested. Caregivers of Filipino children with cancer were then recruited to answer the survey and the results analyzed.
Results: The SN-I-Ph was modified for cultural appropriateness; content validity for all 9 items was acceptable with score of 4.5-5 and internal consistency showed satisfactory results with cronbach alpha of 0.9067. A total of 202 participants were recruited to join the survey. Results showed mean±SD of 42.6±7.8. All of the 9 items showed excellent satisfaction. The socio-demographic and clinical factors showed no clinical significance with p value showing >0.05.

Table 9. Socio-Demographic and Clinical Factors associated with Satisfaction among Caregivers of Filipino Children with Cancer

Factors	Very Satisfied (N = 187)	Somehow Satisfied (N = 15)	Odds Ratio	P-Value
Age (years)	36.8±8.9	35.6±7.3	1.01	0.594
Gender				
Female	157 (84.0%)	12 (80.0%)	Reference	Reference
Male	30 (16.0%)	3 (20.0%)	0.76	0.691
Relationship to the Patient				
Mother	151 (80.8%)	12 (80.0%)	Reference	Reference
Father	28 (15.0%)	3 (20.0%)	0.74	0.659
Others	8 (4.2%)	0	-	-
Educational Attainment				
College Level	79 (42.3%)	5 (33.3%)	0.58	0.351
Secondary Level	93 (49.7%)	10 (66.7%)	Reference	Reference
Primary Level	15 (8.0%)	0	-	-
Language Preference				
Bilingual (English/Filipino)	110 (58.8%)	5 (33.3%)	Reference	Reference
Filipino only	77 (41.2%)	10 (66.7%)	0.35	0.064
Employment Status				
Employed	42 (22.5%)	5 (33.3%)	0.58	0.342
Unemployed	145 (77.5%)	10 (66.7%)	Reference	Reference
Monthly Income				
Less than P 5000	152 (81.3%)	10 (66.7%)	Reference	Reference
More than P 5000	35 (18.7%)	5 (33.3%)	0.46	0.188
Health Insurance				
With Health Insurance	173 (92.5%)	15 (100.0%)	Reference	Reference
Without Health Insurance	14 (7.5%)	0	-	-
Diagnosis				
Hematologic Malignancy	138 (73.8%)	12 (80.0%)	Reference	Reference
Solid Tumor	49 (26.2%)	3 (20.0%)	0.70	0.599
Year of Diagnosis				
2013-2014	24 (12.8%)	3 (20.0%)	2.94	0.255
2015-2016	47 (25.1%)	2 (13.3%)	1.45	0.593
2017-2018	116 (62.1%)	10 (66.7%)	Reference	Reference

Summary/Conclusion: This study showed good satisfaction with the interpersonal relationship of the navigators among caregivers. Participants enrolled in the patient navigation program reported a positive overall experience with the medical care.

PB1740 DANISH PATIENTS WITH MULTIPLE MYELOMA REPORT NO CHANGE IN QUALITY OF LIFE DURING THE COVID-19 PANDEMIC

L. Redder [1,*], S. Möller [2,3], H. R. Eshoj [1], M. Jarden [4], C. Lykkegaard Andersen [5], H. Frederiksen [1], H. Gregersen [6], A. Klostergaard [7], M. S. Steffensen [8], P. T. Pedersen [9], M. Hinge [10], M. Frederiksen [11], B. A. Jensen [12], C. Helleberg [12], A. K. Mylin [4], N. Abildgaard [1], L. K. Nielsen [1,13]

[1]Quality of Life Research Center, Department of Haematology, [2]OPEN, Odense Patient data Explorative Network, Odense University Hospital, [3]Department of Clinical Research, University of Southern Denmark, Odense, [4]Department of Haematology, Copenhagen University Hospital, Copenhagen, [5]Department of Haematology, Zealand University Hospital, Roskilde, [6]Department of Haematology, Aalborg University Hospital, Aalborg, [7]Department of Haematology, Aarhus University Hospital, Aarhus, [8]Department of Haematology, Regional Hospital West Jutland, Holstebro, [9]Department of Haematology, South West Jutland Hospital, Esbjerg, [10]Department of Haematology, Vejle Hospital, Denmark, Vejle, [11]Department of Haematology, Hospital of Southern Jutland, Aabenraa, [12]Department of Haematology, Herlev Hospital, Denmark, Herlev, [13]Research Unit for Multimorbidity, Department of Internal Medicine and Cardiology, Regional Hospital Viborg, Viborg, Denmark

Background: In December 2019, the severe acute respiratory syndrome coronavirus 2 (SARS-CoV-2) was detected for the first time in Wuhan, China, causing the coronavirus disease 2019 (COVID-19). Mortality rate in patients with multiple myeloma (MM) hospitalized due to COVID-19 has been reported to be 50% higher compared to non-cancer patients. The COVID-19 pandemic has resulted in adaption of myeloma care recommendations including key principles of limiting hospital visits by use of telemedicine communication and to use oral agents as much as possible and/or allowing treatment breaks. To mitigate the risk of COVID-19 spreading, extensive national lockdowns have been practiced and patients and caregivers have been encouraged to practice social distancing.
Aims: The aim was to investigate the impact of the first and second wave of the COVID-19 pandemic on quality of life (QoL) in Danish patients with MM.
Methods: The study was designed as a cross-sectional study comparing QoL in patients with MM using data obtained the year before the pandemic (pre-COVID) as a reference in comparison to the COVID period. In a Danish context, first wave was defined as April to June 2020 and the second wave as November 2020 to January 2021. The survey data originates from an ongoing cohort study, "Quality of life in Danish Multiple Myeloma patients" (QoL-MM), which is a Danish prospective, nationwide, observational survey, initiated in February 2017. Survey data are obtained at enrolment and subsequently at 12 follow-up time points over a two-year period including 24 QoL domains assessed by the European Organisation for Research and Treatment of Cancer Quality of life QLQ-C30, the Multiple Myeloma module QLQ-MY20, the Chemotherapy-Induced Peripheral Neuropathy module and the Short-form health survey version 2. The QoL data was analysed using mixed effects linear regression, with a year-period-interaction. Pre-COVID versus COVID mean domain score difference was considered evident, if the difference was *both* statistically significant (p-value <0.05) and clinical relevant using minimal important difference defined as 0.3 standard deviation of the mean score of all included 2019 answers. For data validation, the mean scores of the pre-COVID period were compared to the mean scores for 2018.
Results: In the study, 616 patients was included (63% newly diagnosed and 37% relapsed) with a mean age of 68.2 years (standard deviation 9.2). Females represent 40% of the population. Seventy-six percent were married/cohabiting, 24% single. The completion rates during the investigated periods were between 94% to 97%, and a total of 2,576 completed sets of questionnaires were included in the analyses. The Danish MM patients reported no statistical significant and clinical relevant difference in QoL during the first or second wave of the COVID-19 pandemic compared to one year earlier.
Summary/Conclusion: Patients with MM infected by COVID-19 are in increased risk of dying and the pandemic has to some extent affected the usual clinical care program and caused restrictions in their everyday living. However, the pandemic does not seem to impact the patients´ reporting's of QoL. A limitation, however, may be that the questionnaires used are not validated to capture psychosocial health during a pandemic. Still, our results is important as it documents that QoL collected in clinical trials during the pandemic allow interpretation without adjusting for the impacts of the pandemic.

PB1742 DISPARITIES IN ACCESS TO HOSPITAL-AT-HOME FACILITIES FOR MULTIPLE MYELOMA PATIENTS TREATED AS OUTPATIENTS WITH INJECTABLE CHEMOTHERAPY IN FRANCE – A NATIONAL HOSPITAL DISCHARGE DATABASE STUDY.

U. Rodts [1,*], G. Mercier [1], G. Desamericq [2], J.-V. Chauny [2], V. Coisne [2], L. Vincent [3]

[1]KanopyMed, Clapiers, [2]Amgen France, Boulogne Billancourt, [3]Montpellier University Hospital, Montpellier, France

Background: Multiple myeloma (MM) is the second most frequent hematologic malignancy. In the past few years, the approval of new drugs has significantly modified the management of this disease allowing outpatient care either in hospital-at-home or in outpatient hospital settings. However, little is known about the real-world management of MM patients in France and the factors influencing patients' orientation and use of the different hospital care facilities available.
Aims: To describe the real-world management of MM patients treated as outpatients with injectable chemotherapy. To assess determinants of being treated in each setting including patients related features and organization related features.
Methods: Methods: We conducted an observational, retrospective, cross-sectional study using the exhaustive national French hospital discharge database (PMSI). All myeloma patients with MM diagnosis (ICD-10 code=C90.0) having received at least one chemotherapy injection either in hospital at home or in outpatient hospital, in a hospital center offering both modalities of care, were included. The primary outcome was the proportion of patients having received at least one chemotherapy injection in the hospital at home setting in 2018. The following variables were collected: patient's age and gender, Charlson comorbidity index, time from MM diagnosis, distance from home to the hospital, number of inhabitants and median pre-tax annual income of the patient's city of residence, name of the chemotherapy when data available. To quantify the respective influence of each factor on access to hospital at home facilities, a logistic regression model was run on a 90% training set and assessed on a 10% test set.
Results: In 2018, 12,493 MM patients received at least one chemotherapy injection in France. 623 were excluded because of missing data and 8,245 because they had not been treated in center offering hospital at home chemotherapy. In total, 3,625 MM outpatients from 21 centers were included, of whom 1,180 (32.6%) had at least one chemotherapy injection delivered in the hospital at home setting. On average, those patients were 68 years (SD 11.3) old. Charlson comorbidity index was 5.5 (SD 2.6). Patients lived 26 kilometers (SD 29) away from the hospital. Time from MM diagnosis was 20.6 months (SD 14.9). The average size of the city of residence was 51,283 inhabitants (SD 67,097) and the median annual income was 22,702 Euros (SD 5,007). These patients were treated in 21 different centers, among which 9 teaching hospitals; 2,192 patients (60.5%) received bortezomib and 253 (7%) received carfilzomib.
After adjustment, the probability of having received at least one chemotherapy injection in the hospital at home setting was significantly higher for patients treated by bortezomib versus not treated by bortezomib (OR=21.3; 95IC=16.4-28.2) and living in more affluent cities (OR=1.07; 95IC=1.05-1.09). This probability was significantly lower for patients living further from the hospital (OR=0.99; 95IC=0.98-1.00) and in larger cities (OR=0.98; 95IC=0.97-0.98). The overall model fit was good (area under the ROC curve=0.83).
Summary/Conclusion: In this observational, retrospective, nationwide, real-world study in France, MM patients getting access to injectable chemotherapy in hospital at home facilities are more frequently treated by bortezomib and live closer to the hospital, in smaller and richer cities. These results suggest that organizational interventions could help reducing the observed disparities in access to hospital at home facilities.

PB1743 EXPERIENCES AND SUPPORT NEEDS OF CAREGIVERS OF PATIENTS WITH HIGHER-RISK MDS: QUALITATIVE INSIGHTS VIA ONLINE BULLETIN BOARD IN THE US, UK, AND CANADA

P. Frank MSc [1,*], A. S. Olshan [2], T. Iraca [3], C. Anthony [4], S. Wintrich [5], E. Sasse MD [1]

[1]Novartis Pharma AG, Basel, Switzerland, [2]Olshan Patient Relations Inc, Stamford, [3]Myelodysplastic Syndromes Foundation US, Yardville, United States, [4]Aplastic Anemia & Myelodysplasia Association, Ontario, Canada, [5]MDS UK Patient Support Group, London, United Kingdom

Background: Higher-risk MDS pts and caregivers face many challenges in the course of disease management. Pts with advanced cancer and their caregivers can experience physical, emotional, social, financial, and functional issues. Research on the burden of caring for advanced cancer pts suggests that there is insufficient support for caregivers, likely due to the lack of knowledge about their needs and burdens. The overall experience of caregivers for MDS pts has not been evaluated to date.
Aims: Identify key challenges for caregivers of higher-risk MDS pts in the (1) caregiver role before, during, and after diagnosis; and along the disease journey; (2) Impact on the caregiver's life and well-being; consequently their areas of need for support; (3) Impact of decisions made, including treatments.
Methods: The OBB was the qualitative research methodology used. OBB enables data collection via a web-based platform. This innovative type of online focus group can generate more meaningful and impactful insights compared to traditional focus groups. A mix of moderator-led Q&A and participant discussion provides the caregiver insights as online dialogue. OBB is advantageous when participants are located in various geographic locations, time zones, and availabilities. Additionally, such a virtual platform meant the research was not disrupted despite being conducted during the COVID-19 pandemic. Inclusion criteria: (1) caregiver of adult pt with high- or very high-risk MDS as diagnosed per IPSS-R category or high-risk MDS as per IPSS, or intermediate-risk pts on hypomethylating agents, and (2) Proficiency in written English. Exclusion criteria: (1) Caregiver of pt with lower-risk MDS; (2) caregiver of pt in a clinical trial; and (3) Paid caregiver.
Results: 16 caregivers participated: 5 from the US, 6 from the UK, and 5 from Canada. A content analysis identified 7 key themes where caregiver burden was significant (Table).

Table: 7 Key Themes Experienced by Caregivers of Patients With Intermediate and Higher-Risk MDS

Themes	Categories That Fall Within the Theme
Caregiver role & burden	Adjusting to caregiver role, Adapting to patient's care needs, Boundary, Physical impact, Logistical burden, Financial impact, COVID-19 impact
Mental health	Emotional stress, Mindfulness, Masking, Adapting to life change, Coping mechanisms, Self-care, Social support networks
Family dynamics	Adjusting to new roles, Patient-caregiver dynamics, Co-caregiver dynamics, Impact on family relationships
Disease experience	Diagnosis, Prognosis, Watch and wait, Quality of life
Treatment experience	Treatment options, Decision-making, Experience of treatment
HCP interactions	Physician relationship, Physician communication, HCP care experience
Information & education	Disease awareness, HCP education, Sources of information/education

Abstract abbreviations: HCP, health care professional; IPSS-R, International Prognostic Scoring System-Revised; MDS, myelodysplastic syndrome; OBB, online bulletin board; Pts, patients.

Summary/Conclusion: The findings highlight a significant impact and burden on caregivers of pts with higher-risk MDS, which varies depending on the stage of the disease, the choice (or lack of choice) of treatments, and the personal situation of the caregiver. For example, although the caregiver role for more recently diagnosed pts is perceived as minimal effort, their role increases significantly if a stem cell transplant occurs, and/or if there are changes in the pt's health status (eg, infection, medication change, managing side effects). Emotional stress is pervasive, especially at diagnosis and prognosis stage, and when told to "watch and wait." This is amplified when HCPs are perceived to lack knowledge/expertise about MDS, resulting in additional burden to pts and caregivers as they seek more appropriate care. There is a strong need for mental health support for both pt and caregiver. The extent required depends on the personal situation and dynamics of the pt and caregiver. Additional stress factors include the uncertainty of employment and financial burden; the time burden when balancing other commitments; and the impact on their own health, particularly if they have their own health issues to manage. Most caregivers can manage the physical and functional aspects of care; however, many state that the bigger unmet need for both pt and caregiver is emotional support, which has not typically been part of the standard of care provided to MDS pts. There is thus an opportunity for healthcare systems to provide better support in these areas of emotional burden.

PB1744 'A DIFFERENT PERSON ENTIRELY': ADOLESCENT AND YOUNG ADULTS' EXPERIENCES RETURNING TO EDUCATION AFTER TREATMENT FOR HAEMATOLOGICAL MALIGNANCIES

C. Magrath [1,*], D. Critoph [2], L. Smith [3], H. Hatcher [4]

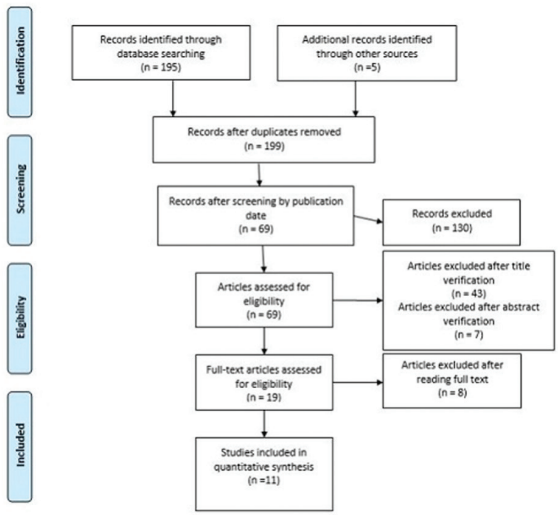
[1]School of Clinical Medicine, [2]Clinical Communication Skills, School of Clinical Medicine, University of Cambridge, [3]North West Anglia NHS Foundation Trust, [4]Department of Oncology, Cambridge University Hospitals NHS Foundation Trust, Cambridge, United Kingdom

Background: Adolescent and Young Adults (AYAs) establish their independent, adult identities as part of their psychosocial development, a process largely informed by educational experiences. Not only is a cancer diagnosis disruptive to this process but AYA cancer survivors (AYACs) face barriers as they attempt to reintegrate into educational systems. .
Aims: This study explores the experiences of AYACs as they return to education. We do this to better understand the challenges they face, identify resources already available to this patient population and make recommendations that facilitate return of AYACs to education.
Methods: In-depth semi-structured interviews were conducted with AYA cancer survivors (n=8), aged 16-19 at time of diagnosis and 18-27 at time of interview. Interviews were transcribed verbatim and analysed using the principles of Giorgi's phenomenological analysis.
Results: Most participants were survivors of haematological malignancies (n=7, image 1). Four major themes were identified: AYAC survivors suffer from debilitating late effects (theme 1) post-treatment as they adjust to a loss of normality and other fundamental losses (theme 2) associated with a cancer diagnosis, such as irrecoverable future plans. The educational systems (theme 3) to which they return can be both accommodating, capable of making allowances, and uncompromising, unable to adapt to AYAC survivors' needs. Support (theme 4) is vital for successful return to education.

Table 1. Participant Demographics Table

AYA Participant	Gender	Age at diagnosis	Age at interview	Diagnosis
Pre-COVID lockdown measures: interviews conducted face-to-face				
AYA1	Male	17	21	Burkitt's lymphoma
AYA2	Male	19	22	Brain tumour
AYA3	Male	17	18	Hodgkin's lymphoma
AYA4	Female	18	25	Acute lymphoblastic leukaemia
Post-COVID lockdown measures: interviews conducted via online video calls				
AYA5	Female	19	21	Hodgkin's lymphoma
AYA6	Male	18	20	Hodgkin's lymphoma
AYA7	Female	17	27	Hodgkin's lymphoma
AYA8	Female	16	20	Lymphoblastic lymphoma

Summary/Conclusion: This study supports previous findings that late effects and systemic barriers can hinder return to education but further research focused on this age group is required. We believe that treating clinicians and specialist services can facilitate the return of AYAs to education by providing warning and comprehensive information about late effects, as early as possible prior to treatment completion, as well as effective information-sharing with educational institutions.



PB1745 SPIRITUALITY AND ITS INFLUENCE IN QUALITY OF LIFE IN HEMATOLOGICAL PATIENTS: A SYSTEMATIC REVIEW

C. B. C. D. Carmo [1,*], D. D. F. B. Rêgo [1], M. M. D. Lucena [1], G. A. D. S. Xavier [1], M. J. D. A. Rezende [1], P. J. B. D. Camargo [1], T. D. A. Nunes [1], E. M. B. D. Souza [1], I. L. O. D. Oliveira [1], I. V. D. Bastos [1], W. O. Santos [1], G. P. Gutierres [1], G. C. Vieira [1], J. P. A. Silva [1], L. P. Monteiro [1], A. T. O. Raab [1], L. D. Carvalho [1], A. B. Rassi [2]

[1]Curso de Medicina, Universidade Católica de Brasília, [2]Departamento de Hematologia, Hospital Sírio Libanês, Brasília, Brazil

Background: Studies indicate that spirituality and religious practices can result in positive impacts in the quality of life (QOL) in many pathologies. From decreased anxiety or depression symptoms to a greater sense of peace and acceptance.
Aims: It is then questioned the spirituality impact in hematological patients QOL.
Methods: This systematic review included studies on the impact spirituality has in the QOL of hematological patients. Three electronic databases (SciELO, LILACS, PubMed) were consulted in search for articles published in the last ten years, in English, Spanish and Portuguese, using the following keywords searched in DeCs/ MeSH: spirituality, quality of life and hematology and its correlates in Portuguese and Spanish.
The initial online search led to the retrieval of 195 references and reviewers extracted data independently. A total of 11 articles were used in the review. The checklist of 27 items and 4-step flow chart (Table 1) indicated by the PRISMA methodology were used.
Results: It was observed that spirituality and religiosity have been associated with a better quality of life (QOL) in hematological patients. The study by Sirilla J, (2013) reported an improvement in QOL in patients who underwent bone marrow transplantation, as well as in the studies by Durner J, (2013), demonstrating improvement in patients with multiple myeloma and Thomas ML. (2012) in myelodysplastic syndromes. Rodin G. et al. (2013) found that spirituality is related to less symptoms of post-traumatic stress in patients with acute leukemia and Bediako SM et al. (2011) observed fewer hospital admissions among adults with sickle cell disease.
The study by Maheri A, et al. (2016) in adults with thalassemia affirms that spiritual growth is one of the most significant predictive factors of QOL, and emphasizes the importance of including spirituality in health care. Abdol Jabbari M, et al. (2018), observed that among parents of children diagnosed with cancer had developed spiritual tactics to deal with the disease, even under stressful conditions. According to Jabbari, reaching a certain spiritual level provided greater adherence to treatment and raised the hope.
Sheikhzakaryaee, et al. (2018) also explores the experiences of parents with children with cancer and their spiritual strategies. The results obtained were reduction of anxiety, depression and loneliness of patients and increase in QOL, with an expansion in positive and pleasure feelings.
The research carried out by Prince, et al. (2015) reports that patients subjected to allogeneic hematopoietic stem cell transplantation with greater spiritual well-being achieved a better QOL, while those who reported lower spiritual well-being affirmed emotional and QOL damage.
The study by Kiyancicek, (2017) with family members who assisted cancer patients obtained the following results: of 230 participants, 47.1% believed exercising spirituality helped them to deal with stress; 35% affirmed that after the diagnosis they dedicated more time to spiritual practices. In contrast, 30% affirmed that they spent less time exercising spirituality and 35.6% said nothing had changed.

Table 1 - PRISMA 4-step flow chart

Summary/Conclusion: The analyzed studies showed that spirituality has great potential in improving QOL for hematological patients and their relatives. However, despite the fact that complementary medicine has been gaining ground in helping various hematological diseases treatments, for spirituality to be truly added in daily practices, further studies should be strongly considered. In addition, health professionals must recognize the value of patients' psycho spiritual well being.

PB1746 EFFECTS OF ISOLATION DURING THE COVID-19 PANDEMIC ON TEENAGERS WITH SICKLE CELL DISEASE IN ITALY: THE EXPERIENCE OF A DEDICATED TELEPHONE SERVICE FOR PSYCHOLOGICAL SUPPORT

M. Perdibon [1], E. Maran [1], V. Munaretto [2], G. Reggiani [2], C. Marin [2], A. Biffi [2], R. Colombatti [2,*], L. Sainati [1]

[1]Department of Woman's and Child's Health, Azienda Ospedale-Università di Padova, [2]University of Padova, Padova, Italy

Background: In the past year the COVID19 Pandemic and the repeated lockdown measures have disrupted people's life. Teenagers with chronic illness, such as Sickle Cell Disease (SCD) present special health care and educational needs during the delicate phase of transition to adulthood compared to their peers. The Veneto Region, in North East Italy, was one of the first red zones areas in Europe since February 26th 2020 with Phase 1 of strict lockdown until April 30th 2020; Phase 2 with progressive reopening of activities during the summer; Phase 3 since September 2020 with initial high school opening but successive implementation of risk zones across the country with regional limitation of movements, economical activities, social life and education according to the diffusion of COVID19 in the area. Since November 2020 high school students were forced to stay at home and perform virtual classes; only individual sports were allowed.
Aims: We analyzed the psychological impact of the restrictions and isolation measures on teenagers and young adults with SCD in the Veneto Region of Northern Italy during the 3 different phases of lockdown while offering a dedicated telephone service of psychological support.
Methods: A dedicated telephone service was organized since March 2020 by a Psychologist of the SCD Team to contact families and offer support. Adolescents and young adults were contacted directly. Telephone calls occurred during Phase 1 (strict isolation), phase 2 (progressive reopening) and the current phase 3 (alternation of openings and closures) and were characterized by a set of standardized questions tailored to the phase followed by an open dialogue. A qualitative description is presented.
Results: 28 adolescents responded to the phone calls and agreed to be called again. Psychological experiences differed according to the phase of the lockdown. In phase 1, in which the limits to personal freedom were high, they felt equal to the general population and felt confident that this painful period would soon end. In phase 2, due to loosen restrictions, greater concerns and anxiety emerged: the need to coexist with the virus and the continuous changing of the rules generated a greater perception that a sudden painful event could break into their life at any time, increasing personal discomfort and undermining the quality of life. Phase 3 showed further different responses. 23/28 stated that they resumed school or work activities, although in different ways (virtual classes or smart working). All reported feeling accustomed to, and therefore less anxious, about covid-19. All claimed to respect the rules, to know them well, and to apply them. 20/28 patients reported spending most of their time at home, were not interested in going out and didn't have social interactions. 6/28 teenagers requested specific psychological support in the form of weekly phone calls or zoom calls with the SCD psychologist, which is still ongoing. Most of them are girls who asked for help in managing their anxiety and the fear that they won't be able to realize their expectation in professional or family life.
Summary/Conclusion: The dedicated telephone service for psychological support was well received by teenagers with SCD with a subgroup requesting a repeated intervention. The qualitative results of our experience demonstrate the need for psychological support during the pandemic in patients with chronic disease; remote support has proven to be an effective tool.

PB1747 USE OF THE EUROPEAN ORGANISATION FOR RESEARCH AND TREATMENT OF CANCER QUALITY OF LIFE MULTIPLE MYELOMA QUESTIONNAIRE (EORTC QLQ-MY20): A REVIEW OF THE LITERATURE 25 YEARS AFTER DEVELOPMENT.

I. Mcmillan [1], K. Cocks [2], J. Wells [1], S. Bristogiannis [3], Y. Lwin [4], C. Kyriakou [5,*]

[1]Patient-Centered Outcomes, Adelphi Values, Bollington, Cheshire, [2]Patient-Centered Outcomes, Adelphi Values, Bollington, Cheshire, [3]Haematology, Hillingdon Hospital, [4]Haematology, Kings College Hospital, [5]Haematology, University College London Hospital, London, United Kingdom

Background: The EORTC QLQ-MY20 was originally developed in 1996 to assess health-related QoL (HRQoL) in multiple myeloma (MM) patients. Since its development, the use of multiple new myeloma treatment options has had a major impact on prolong survival in MM patients. The continuous introduction of new Myeloma combination agents is likely to have further implications on HRQoL outcomes and its measurement.
Aims: In the era of new therapies the aim of this review was to explore the use and performance of the QLQ-MY20 in clinical studies, the population characteristics (i.e the number of treatment lines patients had received), therapy types, positioning to support randomised controlled trial (RCT) endpoints and psychometric performance.
Methods: Original research (1996-June 2020) that used the QLQ-MY20 in a clinical study or that assessed the psychometric properties of the questionnaire was identified through an electronic database search. Abstracts were screened to remove irrelevant results and duplicates. Data were extracted from full text publications/conference abstracts and checked by a second rater.
Results: 66 clinical studies and 9 validation studies were identified. The QLQ-MY20 had been used in RCTs (n=19, 29%), clinical trial-single arm (n=3, 5%), cross-sectional observational (n=26, 39%), and longitudinal/cohort observational (n=18, 27%) studies. The publication of QLQ-MY20 data in clinical trials increased over time from 2006-2010 (n=1), 2011-2015 (n=8) and 2016-2020 (n=13). Clinical trials most frequently included relapsed MM patients (n=15, 68%), and assessed a range of combinations therapies with Steroids (n=18, 82%), Proteasome inhibitors (n=13, 59%), immunomodulatory IMiDS (n=12, 55%) and Chemotherapeutic drugs (n=10, 46%). QLQ-MY20 subscales were most frequently defined as secondary (n=12, 55%) or exploratory (n=7, 32%) trial endpoints. The subscales most frequently used to support trial endpoints were Disease Symptoms (DS; n=16, 72%) and Side Effects (SE; n=16, 72%). Validation articles demonstrated that all domains were performing well in terms of internal consistency reliability (>0.7), test-reset reliability (intraclass correlation coefficient >=0.85) and internal and external convergent and discriminant validity. The DS, SE and Future Perspectives (FP) domains were performing well with respect to floor and ceiling effects however four articles reported a high percentage of ceiling effects in the Body Image (BI) domain.
Summary/Conclusion: Overall the results showed that the EORTC QLQ-MY20 remains a widely used and psychometrically robust instrument. An update to prospectively optimize this EORTC QLQ MY20 is currently underway in a European trial, to keep up the conceptual relevance in reporting QOL with survival outcomes using new therapies.

PB1748 INPATIENT CARE OF PATIENTS WITH EARLY-RELAPSED DIFFUSE B-CELL LYMPHOMA (DLBCL): AN ECONOMIC PERSPECTIVE

B. Moertl [1,*], M. Dreyling [1], E. Hoster [1], C. Schmidt [1], W. Schoel [2], M. von Bergwelt-Baildon [1], K. Berger [1]

[1]Haematology/Oncology (MED III), [2]Stabsstelle Käufmännisches Controlling und Entgelte, LMU Klinikum, Munich, Germany

Background: Immunochemotherapy-regime R-CHOP is the standard firstline (1L) treatment for patients (pts) with diffuse large B-cell lymphoma, approximately 30 - 50% of pts will not be cured by 1L. Especially pts with an early relapse <12 months (m) after 1L have a poor prognosis for cure. Only limited information exists on clinical outcomes, treatment patterns, resource consumption and costs in routine care of early-relapsed DLBCL-pts in Germany.
Aims: Therefore, we initiated a study to provide information on aforementioned variables.
Methods: Retrospective single center observational feasibility study. Data sources were claims data and data from medical records (2007-2018) from a German tertiary teaching hospital. Early relapse was defined as <17m after initial diagnosis (ID). Treatment-patterns were analyzed in regimens per line. Outcome-parameter: resource-use (inpatient stay; cumulated over patient career), costs (cumulated over patient career) and documented death (dd). Costs were evaluated from statutory health insurance perspective. Inclusion criteria: age ≥18 years, diagnosis of relapsed DLBCL (ICD: C83.3). Exclusion criteria: age <18 years, additional active malignancies.
Results: We identified 84 pts with relapse after 1L. In total 44 pts (52%) relapsed within 17 m after ID. Mean age at ID: 59 y (median: 63); n = 26 (59%) were male. Ann-Abor stage at ID: 15 pts I-II; 29 pts III-IV. 28 pts were in 2L; 14 pts received 3L, 1 pt in 4L and 1 pt 5L. Outcomes for 2L pts: 17 in complete remission incl. follow-up (CR), 11 documented deaths (dd). 3L pts: n=8 in CR, 6 dd. 4L: n=1 in CR. 5L: n=1 dd. Mean duration of inpatient stay per patient (ppt) in 2L was 45 days (median:

43; range 3 – 132); in 3L: 74d (80; 33 – 122); 4L: 137d; 5L: 183d. Following treatment-patterns refer on pts in 2L (n=28): 10 pts received Immuno-chemotherapy (I-chemo), 6 pts I-chemo + autologous-stem cell transplantation (auto-SCT), 4 pts a chemo, 4 pts a radiation, 2pts a chemo + auto-SCT and 2 pts a I-chemo + radiation. Mean total costs (€) ppt in 2L: 47.300 (median: 40.300; 6.500 – 166.000); 85.000 for 3L pts (77.300; 33.700 – 214.000); 4L: 200.000 and 5L: 163.000.
Summary/Conclusion: The results show that an early-relapse results in a high patient and economic burden: various therapies, long inpatient-stay, significant costs and documented deaths. The highly individual treatment approaches or the huge ranges in costs are indicators that it is difficult to calculate DLBCL-treatment with averages in variables. Comprehensive cost and outcome analyses in DLBCL treatment are needed. The presented costs may underestimate the total hospital costs for patients with DLBCL treatment, because exclusively inpatient claims data from the hematology/oncology department were taken into consideration. Costs from the radiation center and the outpatient center are not included.

PB1749 HEALTH –RELATED QUALITY OF LIFE OF PATIENTS WITH ACUTE MYELOID LEUKEMIA

M. Bchir [1,*], H. ben neji [1], R. kharrat [1], S. kefi [1], R. mansouri [1], R. el fatmi [1], B. meddeb [1]

[1]hematology department, Tunis El Manar University, Faculty of medecine of Tunis,Aziza Othmana Hospital, Tunis, Tunisia

Background: Patients with acute myeloid leukemia are treated with intensive chemotherapy, and usually have long hospitalizations and severe treatment side effects that may have a negative influence on the health-related quality of life.
Aims: The aim of this work was to study the health –related quality of life of acute myeloid leukemia survivors in complete remission.
Methods: Arabic translations of the SF-36 and the Hospital-Anxiety-Depression Scale (HADS) questionnaires were used. The patients replied to these questionnaires during their medical consultation.
Results: Thirty –nine patients were included in the study with a median age of 42. Twenty one patients had acute myeloid leukemia (AML) and 18 patients had acute promyelocytic leukemia (APL). The median duration after the diagnosis was 74 months (13-190). All these patients were in complete remission. The SF-36 results showed no difference in physical or mental scales compared to the population norms. The mean physical score found was 71,5. The mean mental score was 70,9. The scores of the different domains were also similar to the population norms, ranging between 61,6 and 85,8. The lowest score was associated with the domain of fatigue.
The HADS questionnaire results showed a pathologic score (>= 11) in 14% of patients in the domain of anxiety. The anxiety score was doubtful (ranging from 8 to 10) in 17% of patients. No pathologic results were found in the domain of depression, but the score was doubtful in 17% of patients.
Summary/Conclusion: Survivors of acute myeloid leukemia have normal global health-related quality of life. But they suffer often from anxiety disorders and still require counseling.

PB1750 COST-EFFECTIVENESS OF RUXOLITINIB FOR PATIENTS WITH MYELOFIBROSIS: A REVIEW OF THE LITERATURE

G. Karakuleli [1,*], L. Barham [2]

[1]Scientific Education Support, Richmond, [2]Learna Ltd in partnership with the University of South Wales, London, United Kingdom

Background: Myelofibrosis (MF) is a rare (annual incidence estimated to be 1/100,000 in Europe), chronic hematologic disorder associated with morbidity and mortality as well as the risk of evolution to acute myeloid leukemia. Ruxolitinib (Jakavi®, Novartis) is the first JAK 1/2 inhibitor approved by the Food and Drug Administration (FDA) and the European Medicines Agency (EMA) in 2011 for the treatment of patients with MF. Ruxolitinib is considered a high-cost and life-time treatment. UK-based estimates of the cost of treatment are in the region of £43,000 per patient, per year. The work was completed in partial fulfilment of an MSc in Applied Economics for Healthcare Decision Making from the University of South Wales. The research was deemed as low risk and as such was reviewed by the Low Risk Ethical procedure at the Faculty of Life Science and Education, University of South Wales and granted approval.
Aims: Against the background of the challenge of treatments for rare diseases reaching cost-effectiveness thresholds, this study identified, synthesized and appraised the available evidence on the cost-effectiveness of ruxolitinib in the treatment of MF.
Methods: A systematic approach was taken to conducting the literature review. Databases searched included PubMed, EMBASE, MEDLINE, and the Cochrane Library based on search terms informed by Population, Intervention, Comparator and Outcomes (PICO): myelofibrosis, ruxolitinib, best available therapy/standard of care, and cost-effectiveness/cost-utility/pharmacoeconomics. The search was limited to studies published in the English language. Narrative synthesis was used to evaluate included studies and the CHEERS checklist to explore quality of reporting of the cost-effectiveness analysis.
Results: The narrative synthesis included five studies conducted in the UK, Portugal, Chile, Canada, and Finland. All cost-effectiveness analyses used data obtained from the same two large, randomized controlled, double-blind, phase III studies (COMFORT-I and -II) that led to the regulatory approval of ruxolitinib. Ruxolitinib was compared to best available therapy (BAT), including hydroxyurea, no medication, and prednisone/prednisolone. Perspectives and included costs varied among analyses. Markov models and discrete state cohort models were used to evaluate cost-effectiveness and clinical benefit was measured in quality-adjusted life years (QALY) or life years (LY) gained.
These analyses estimated the base case incremental cost-effectiveness ratios (ICER) per QALY of (converted into USD, if appropriate, at the historic average annual exchange rate) 44,905 GBP in the UK (in 2013; USD 70,2262), 40,000 EUR in Portugal (in 2016; USD 44,272), 54,500 USD in Chile (in 2016), 61,444 CAD in Canada (in 2012; USD 61,474), and 42,367 EUR in Finland (in 2015; USD 42,027). Based upon the cost-effectiveness thresholds applied in each of these countries, ruxolitinib was found to be universally cost-effective, albeit with price adjustments as part of the wider pricing and reimbursement processes used in these countries.

	Wade et al., 2017[4]	Vandewalle et al., 2016[7]	Rojas et al., 2016[8]	El Ouagari et al., 2012[9]	Hahl et al., 2015[10]
Country	The UK	Portugal	Chile	Canada	Finland
Publication type	Full-text	Full-text	Abstract	Poster	Abstract
Comparator	BAT	BAT	BAT	BAT	BAT

Time horizon	35 years	Lifetime	Lifetime	Lifetime	Lifetime
Discount rate	3.5%	5%	3%	NA	3%
Types of costs included	Drug acquisition costs, disease management costs, adverse event costs, costs associated with leukemic transformation, end of life costs	Treatment costs, AE costs, costs related to AML transformation, splenic irradiation, splenectomy, resource use	NA	Costs related to drug administration, the management of AEs, other medical costs, and indirect costs	Drug costs and healthcare resource cost
Perspective	NHS and PSS	National health service	NA	Societal	Payer
Incremental cost	NA	€97,052 (Ruxolitinib: €188,967 BAT: €91,915)	$54,856 (Ruxolitinib: $101,926, BAT: $47,070)	CAD 73,104 (Ruxolitinib: CAD 494,859, BAT: CAD 421,755)	€102,802
Incremental QALY with ruxolitinib	+2.51 (Ruxolitinib: 3.99 BAT: 1.48)	+2.43 (Ruxolitinib: 5.39 LY BAT: 2.96)	+0.98	+1.19 (Ruxolitinib: 4.01 BAT: 2.82)	+2.43
ICER	£44,905/QALY	€40,000/LY	USD 54,500/QALY	CAD 61,444/QALY	€42,367/QALY
Sensitivity analysis	Probabilistic sensitivity analysis: £44,625/QALY gained The probability of being cost-effective £30,000: 0.33% £50,000: 95.02%	Probabilistic sensitivity analysis: The probability of being cost-effective €50,000: > 95%	The probability of being cost-effective $20,000: 0% $60,000: 73.6%	One-way sensitivity analysis and probabilistic sensitivity analysis: The mean ICER was CAD 59,216/QALY	The model was found to be robust to changes in inputs based on sensitivity analysis
Conclusion	Cost-effective at a £50,000 threshold	Cost-effective option with a WTP of €50,000	Cost-effective option with a discount	Cost-effective option at a threshold of CAD 100,000	Acceptable QALYs and costs

AE, adverse event; AML, acute myeloid leukaemia; BAT, best available therapy; ICER, incremental cost-effectiveness ratio; LY, life years MF, myelofibrosis; NA, not available; NHS, National Health Service; NICE, The National Institute for Health and Care Excellence; PSS, Personal Social Services; QALY, quality-adjusted life-year; TTO, time-trade-off; UK, United Kingdom; WTP, willingness-to-pay

Summary/Conclusion: Ruxolitinib was found to be cost-effective for the treatment of patients with myelofibrosis informed by different types of models and from different perspectives; however, there was some uncertainty around available data due to a very limited data source.

PB1751 THAI-VERSION OF THE MD ANDERSON SYMPTOMS INVENTORY FOR ACUTE MYELOID LEUKEMIA/ MYELODYSPLASTIC SYNDROME (MDASI-AML/MDS): THE PSYCHOMETRIC PROPERTIES INVESTIGATION IN ADULT AML PATIENTS

T. Rattanathammethee [1,*], O. Wongkhut [2], P. Piriyakhuntorn [1], S. Huntrakool [1], C. Chai-Adisaksopha [1], E. Rattaritamrong [1], A. Tantiworawit [1], L. Norasetthada [1]

[1]Division of Hematology, Department of Internal Medicine, Faculty of Medicine, [2]Department of Internal Medicine, Faculty of Medicine, Chiang Mai University, Chiang Mai, Thailand

Background: The MD Anderson Symptoms Inventory for acute myeloid leukemia/myelodysplastic syndrome (MDASI-AML/MDS) is one of the specific patient-reported outcome measure (PROM) and widely used to assess the quality of life of acute myeloid leukemia (AML) patients. We translated the original version into Thai (Thai MDASI-AML/MDS) and evaluated its psychometric properties.
Aims: To evaluate the psychometric properties of Thai MDASI-AML/MDS in AML patients.
Methods: After receiving permission, the original MDASI-AML/MDS was translated and cross-culturally adapted to Thai. Sixteen of AML patients were included in the study. Internal consistency was evaluated using Cronbach's alpha and test-retest reliability was analyzed using intraclass correlation coefficient (ICC). Spearman's rank correlation was used to investigate among the subscales of Thai MDASI-AML/MDS and Thai EQ-5D-5L.
Results: All subscales of Thai MDASI-AML/MDS showed an acceptable Cronbach's alpha (0.64-0.92). The test-retest reliability of each subscale was good (ICC = 0.89-0.98). The core symptoms subscale in the Thai MDASI-AML/MDS strongly correlated to the anxiety/ depression subscale in the Thai EQ-5D-5L (r = 0.65, p = 0.0044). The strong correlation was demonstrated between the interference's subscale of the Thai MDASI-AML/MDS and the usual activities subscale of Thai EQ-5D-5L (r = 0.79, p = 0.0002). A weak correlation was found between the MDS/AML specific symptoms subscale in the Thai MDASI-AML/MDS and the pain subscale in the Thai EQ-5D-5L (r = 0.59, p = 0.0121). The Thai MDASI-AML/MDS had strong correlation with Thai EQ-5D-5L (r = 0.76, p = 0.0005).
Summary/Conclusion: The Thai MDASI-AML/MDS provides adequate internal consistency in all subscales as well as good construct validity and reliability for Thai patients.

PB1752 ECO-HEALTH LITERACY ASSOCIATED WITH LEUKEMIA AMONG TUNISIAN YOUTHS AND PROSPECTS FOR EMPOWERMENT

F. Maaoui [1,2,*], I. Moumni [2], F. Arboix-Calas [3], I. Safra [2], S. Mnif [2]

[1]ISEFC, Virtual University of Tunis, [2]Cellular and molecular hematology, Pasteur Institute of Tunis, Tunis, Tunisia, [3]Faculté d'Education Montpellier, Université de Montpellier, Montpellier, France

Background: Given the increasing blood cancer incidence in Tunisia and recent discoveries proving the involvement of environmental factors, the empowerment of youths to the complexity and multi-causality of this disease constitute an essential objective of health promotion and education.
Aims: This study examined the eco-health literacy of Tunisian secondary school students concerning blood cancer, their interest in knowing about it, and their emotional and behavioral attitudes towards leukemia risk.
Methods: This is a quantitative study; a cross-sectional survey was conducted among Tunisian youths. Data collection took place in five representative public secondary schools in the north, center, and south of Tunisia. Students completed a paper and pencil questionnaire and described their literacy level about blood cancer, as well as their attitudes and interest in the disease. Statistical software (SPSS, v.25.0) was used to analyze the data.
Results: The results indicate low eco-health literacy scores concerning leukemia. Lack of knowledge and confusion about the causes, symptoms, and diagnosis of leukemia is a common finding at all school levels surveyed. Most youths failed to identify all the carcinogenic (except tobacco) and non-carcinogenic risk factors. Pesticide use and exposure to electromagnetic radiation are not considered risk factors. Living in a polluted urban area or near a roadway in high traffic does not constitute a real risk situation for youths. The leukemia risk perception and the fear level differed according to gender, with higher sensitivity among teenage girls. Despite these low scores, most participants were interested in having more information about leukemia and cancers in general.
Summary/Conclusion: This investigation shows a lack of knowledge about leukemia and these environmental factors. Low scores, interest, and an information need for expressed by youths who should incite educational actors and curriculum designers to optimize content and innovate ICT adapted to this eco-health challenge.

PB1753 UNCERTAINTY ABOUT THE FUTURE: INSIGHTS FROM OLDER PATIENTS WITH ACUTE MYELOID LEUKAEMIA (AML) ON DIFFERENT TREATMENT PATHS

R. B. Walter [1,*], D. Maze [2], D. Merino Vega [3], T. J. Bell [4], J. Stein [5], K. Amer [6], L. Morgan [5], F. Peloquin [7], L. Hernandez-Aldama [8], J. Healy [7], C. Panter [5], V. Welch [4], A. Gater [5], R. Hohman [3], L. O'Hara [5], A. Brown [7], T. W. LeBlanc [9], N. H. Russell [10]

[1]Fred Hutchinson Cancer Research Center, Seattle, United States, [2]Department of Medical Oncology and Hematology, Princess Margaret Cancer Centre, Ontario, Canada, [3]Friends of Cancer Research, Washington, [4]Pfizer Inc, New York, United States, [5]Adelphi Values Ltd, Bollington, [6]Pfizer Ltd, Tadworth, United Kingdom, [7]Pfizer Canada ULC, Kirkland, Canada, [8]ArmorUp for LIFE, Philadelphia, [9]Division of Hematological Malignancies and Cellular Therapy, Department of Medicine, Duke University School of Medicine, Durham, United States, [10]Department of Haematology, Guy's Hospital, London, United Kingdom

Background: AML is a haematologic cancer primarily affecting older people (median age 68 at diagnosis). Prognosis is poor, with median survival ranging from 2 to 10 months from diagnosis, depending on patient health, age, and treatment path. Some patients described struggling with uncertainty about the future, but it is unclear how this differs across patients and treatment paths.
Aims: This study explored the experiences of AML patients (≥65 years old, not receiving intensive chemotherapy), their close relatives, and independent clinicians. Specifically, patient expectations for the future and how these varied by treatment path and by time since diagnosis were investigated.
Methods: A total of 28 AML patients (aged 65-83; median 74), 25 relatives, and 10 clinicians from the US, UK, and Canada each took part in a 60-minute, semi-structured telephone interview. Open-ended questions were used to elicit spontaneous content, followed by focused questions when needed.
Results: Patients had diverse treatment histories: 13 no treatment, 14 with experience of non-intensive chemotherapy (NIC) including 3 who discontinued treatment, and 1 on best supportive care (BSC). At time of interview the mean time since diagnosis was 5 (range 2 to 9) months for patients with no treatment experience, and 8 (range 2 to 19) months for those with treatment experience. The BSC patient was diagnosed 9 months prior to interview.
Patients discussed positive and negative expectations for the future related to: physical functioning; treatment; life expectancy; ability to do hobbies, spend time with family, and go on vacation. In the no treatment group, there was evidence that expectations about the future became more negative over time. Few patients (n=4/13) recalled having negative expectations about the future at diagnosis, while most (n=10/13) did at time of interview. In contrast, patients with treatment experience appeared to have increasingly positive expectations. Most of these patients (n=11/14) recalled negative expectations when diagnosed, whereas at interview most (n=9/14) felt hopeful about future events. Further, of patients with treatment experience, almost all those diagnosed ≥6 months prior to interview had positive expectations about their future (n=6/7), while under half of those diagnosed <6 months prior (n=3/7) did. Clinicians (n=7/10) further highlighted that patient expectations changed over time depending on treatment success.
Additionally, patients (n=15/28) and relatives (n=15/25) discussed feeling uncertain throughout the AML journey, reporting unknowns around life expectancy, what they would be able to accomplish, and future plans. Uncertainty was a consistent experience regardless of treatment history, with similar proportions of patients not on treatment (n=7/13) and those with NIC experience (n=7/14) reporting the sentiment. Additionally, recently interviewed patients (n=7/13) and relatives (n=7/10) noted that the ongoing COVID-19 pandemic contributed to experiences of uncertainty and difficulties planning for the future.
Summary/Conclusion: There were key differences between patients not on treatment and those with experience of NIC, as patients with treatment experience demonstrated more hope for the future. Regardless, uncertainty is a key element of the AML journey. For some patients, this was exacerbated by the COVID-19 pandemic. These findings highlight

the importance of ensuring all patients are provided with emotional and spiritual support to help them process their diagnosis and plan for the future, both during this pandemic and beyond.

PB1754 MEASURING HEALTH RELATED QUALITY OF LIFE OF CHRONIC MYELOID LEUKEMIA PATIENTS ON NEWER GENERATION TKIS USING THE FILIPINO VERSION OF THE FACT-LEU QUESTIONNAIRE

C. A. Tanchanco [1,*], K. K. Tobias [2], T. Dumagay [2]

[1]Division of Hematology, University of the Philippines- Philippine General Hospital, [2]Division of Hematology, University of the Philippines - Philippine General Hospital, Manila, Philippines

Background: Significant attention has been placed on recognizing impact of symptom burden and treatment-related toxicities on patients' health-related quality of life (HRQoL) since these would have an effect on treatment tolerability and adherence. In the Philippines, the only locally available TKIs are Imatinib and Nilotinib. Access and sustainability for the newer TKIs such as Dasatinib, Ponatinib and Bosutinib as second- or third-line agents is made possible with the help of The Max Foundation via their Max Access Solutions (MAS). There is paucity of published local data on HRQoL outcomes on Filipino CML patients treated with newer-generation tyrosine kinase inhibitors (TKIs).
Aims: This study determined the HRQoL of Chronic Myeloid Leukemia (CML) patients on newer-generation TKIs using the Filipino-version of the Functional Assessment of Cancer Therapy-Leukemia (FACT-Leu) Questionnaire©.
Methods: A single-center, cross-sectional study included CML patients, aged 19, with stable comorbidities, taking newer-generation-TKIs as second-or-third line treatment (Dasatinib, Ponatinib and Bosutinib) for 3 months. HRQoL was assessed using the Filipino-version of the FACT-Leu© questionnaire. Descriptive statistics was used to summarize patients' demographic and clinical characteristics. Independent sample T-test and one-way analysis of variance was used to test significant difference between groups. STATA 13.1 was used for data analysis.
Results: All 33 patients were in chronic-phase. Newer-generation TKIs used were: Dasatinib (54.55%), Bosutinib (30.30%) and Ponatinib (15.15%). Mean scores: Trial Outcomes Index (106.15 ± 12.27), FACT-G score (94.79 ± 10.74) and FACT-Leu score (151.58 ± 17.25) showed good HRQoL. There was no significant difference between HRQOL with sex, marital status, educational attainment, employment, adverse drug event with concomitant dose adjustment and newer-generation TKI used (p-value 0.786, 0.764, 0.764, 0.944, 0.864, 0.554); and insufficient evidence to conclude a correlation between overall FACT-Leu score to age, CML and treatment duration (p-value 0.7389, 0.4738, 0.6984).
Summary/Conclusion: HRQoL evaluation is a vital part of disease management. This study demonstrated that Filipino CML patients using newer-generation TKIs as second or third-line therapy showed good HRQoL regardless of age, sex, marital status, educational attainment, employment, CML duration, treatment duration, presence or absence of adverse drug event with concomitant dose adjustment and newer-generation TKI used.

PB1755 NATIONAL REGISTRY-BASED SURVEILLANCE ON HEMOGLOBINOPATHIES IN TURKEY

Y. Aydinok [1,*], Z. Karakas [2], E. Gürkan [3], B. Akinci [4], H. Tokgoz [5], M. Turker [6], S. Akbayram [7], T. İleri [8], N. Tiftik [9], A. Kupesiz [10], N. Yarali [11], A. Meral [12], A. Background: The National Hemoglobinopathy Registry of the Turkish Society of Hematology (TSH) includes all resident patients in Turkey.
Aims: It aims to assess the efficacy of the national hemoglobinopathy control program (HCP), the changing pattern of the epidemiology, and the standardization of high-quality health care overall in Turkey.
Methods: The registry has been approved by the ethics committee of the Ege University. Participating physicians recorded patients' data into the database after receiving informed consent from the patients/legal representatives. The data collected during the last 18 months were extracted onto an Excel spreadsheet for analysis in January 2021.
Results: The table shows the characteristics of the 3554 patients. Overall, 81.5% of patients had thalassemia, and 18.5% sickle-cell disorders (SCD). A comprehensive HCP was activated, in Turkey, in 2002. A total of 1262 affected births were registered in the database since 2003. While 40% of the parents of affected births had a pre-marital screening, only 50% of those couples stated having appropriate genetic counseling. Eighty percent of couples having genetic counseling did not get a prenatal diagnosis (PND). The rest (20%) gave birth to affected babies despite PND. Notably, 30% of patients had at least one affected sibling born before the patient's birth, and 24% of patients had at least one affected sibling after the patient's birth. Although there has been a 33% reduction in the number of affected subjects (~52/year) since 2015, compared to the prior 5-year cohort (~80/year), the rate is still high, and this declining pattern requires further confirmation. The registry also includes 428 affected children from refugee families, of whom 30% were born in Turkey during the last decade. Overall, 295 patients (13 refugees) with thalassemia and 9 (1 refugee) with SCD, aged 8.7±5.4 (median 7.0), had bone marrow transplantation (BMT). The majority (82%) of BMTs were performed after 2010. The 2-year overall survival was 98%, and event-free survival was found 89% in those (MSD 179, MFD 29, UD 29) followed at least 2-years after BMT. Cardiac failure and arrhythmias were the most common causes of death in thalassemia until the last decade. The rate of cardiac deaths in the "at-risk" population significantly decreased, while the mean age of deaths was increased in the decades following (p=0.02), and infections, particularly in association with transplantation, have replaced cardiac deaths in the period between 2010-2019. Cardiac and infectious complications were also the leading causes of death in patients with SCD. Acute chest syndrome, renal failure, and thrombosis comprised other frequent causes of death in this group. Survival analysis of patients with thalassemia & SCD by 10-year intervals demonstrated that >90% of patients were alive in each 10-year cohort since 1960.

Table. Demographics of patients with Thalassemia and SCD in Turkey

Hemoglobinopathies	All	Thalassemia	SCD
Number of patients	3554	2898	656
Turkish	3126	2486	640
F/M	1554/1572	1219/1267	335/305
Age ± SD (year)	23 ± 14	20 ± 12	32 ± 15
DT <2003	1864 (60%)	1338 (54%)	526 (82%)
DT≥2003	1262 (40%)	1148 (46%)	114 (18%)
*Refugees**	428	412	16

Summary/Conclusion: Turkey is a country with a high young patient burden of hemoglobinopathies. As shown by the present data, these

patients will survive by using the advantages of full access to conventional treatment. Despite good outcomes, BMT as a curative approach has remained limited to a suitable donor. Therefore, a more effective HCP should be in place to reduce the economic burden on the healthcare system. The program should offer prenatal testing in couples of the immigrant population. The longitudinal hemoglobinopathy registry is needed for national surveillance to organize healthcare resources properly.

PB1756 PRIORITISATION OF RELEVANT COCHRANE REVIEW TOPICS IN THE FIELD OF HAEMATOLOGY

C. Hirsch [1,*], T. Jakob [1], E. Tomlinson [2], L. J. Estcourt [3], S. Theurich [4], S. Ocheni [5], N. Skoetz [6], V. Piechotta [1]

[1]Cochrane Haematology, Department I of Internal Medicine, Center for Integrated Oncology Aachen Bonn Cologne Duesseldorf, Faculty of Medicine and University Hospital, University of Cologne, Cologne, Germany, [2]Cochrane Cancer Network, Royal United Hospital, Bath, [3]Cochrane Haematology, Haematology/Transfusion Medicine, NHS Blood and Transplant, Oxford, United Kingdom, [4]Department of Medicine III, University Hospital LMU, Ludwig-Maximilians-Universität München, Munich, Germany, [5]Department of Haematology & Immunology, University of Nigeria, Ituku-Ozalla Campus, Enugu, Nigeria, [6]Cochrane Cancer, Department I of Internal Medicine, Center for Integrated Oncology Aachen Bonn Cologne Duesseldorf, Faculty of Medicine and University Hospital, University of Cologne, Cologne, Germany

Background: Cochrane Haematology produces, publishes and maintains systematic reviews in the field of haematology. The group wants to ensure that their limited resources and efforts are being used to produce Cochrane reviews addressing topics that are of utmost importance to their end-users. According to one of Cochrane's key principle 'striving for relevance' the group initialised their first priority setting exercise engaging stakeholders worldwide to identify the top priority topics for Cochrane Haematology reviews.
Aims: To identify the top ten priority topics for review updates and the top five priority topics for new Cochrane Haematology reviews as part of Cochrane Haematology's priority setting exercise.
Methods: The priority setting exercise consisted of two phases. In phase one, potential priority topics were generated by identifying trends (analysing review metrics) and gaps (screening for priority topics of the American Society of Hematology (ASH), the European Hematology Association (EHA), the German Society for Hematology and Oncology (DGHO) and the James Lind Alliance (JLA) in the field of hematology) in the current review portfolio. In the second phase, the identified topics were then prioritised by various stakeholders in an online survey. Respondents were asked to select the topics they deemed to be of high priority and rank them afterwards from highest to lowest priority. An average score was then calculated for each ranked topic. Topics with the highest average score were identified as being the top priority topics.
Results: The online survey was open between July 6th 2020 to August 28th 2020. A total of 160 responses were collected, of which 63 respondents (39%) provided complete responses. Most of the respondents identified themselves as physician (34%), someone who is or has been affected by haematological disease (31%), or researcher (24%) and were distributed across 21 countries. The highest number of respondents resided in the United Kingdom (n = 72), Germany (n = 20) and Canada (n = 11). The top ten priority topics for reviews that need updating were related to interventions in multiple myeloma, hodgkin lymphoma and topics from the areas of stem cell transplantation and supportive care for haematological diseases. The top five priority topics for new reviews addressed mainly myelodysplastic syndrome (MDS), relapse of disease post-haematopoietic stem cell transplant and long-term survival in cancer.
Summary/Conclusion: The priority setting process engaged various stakeholders and identified the most relevant review topics, published on Cochrane Haematology's website. These topics, some of them are open to new authors, will now guide the group's future scope of work and ensure that the most important reviews are updated. New priority reviews will close gaps within the review portfolio of Cochrane Haematology.

PB1757 ENHANCING THE ACCESS OF COAGULATION FACTORS TO PATIENTS WITH HAEMOPHILIA IN ESTONIA

K. Kaare [1], I. Vaide [2,3,4,*], K. Karp [5], E. Laane [2,3]

[1]Estonian Haemophilia Society, [2]Tartu University. Institute for Clinical Medicine. Hematology-Oncology Clinic, Tartu, [3]Kuressaare Hospital, [4]Estonian Haemophilia Society, Kuressaare, [5]Estonian Haemophilia Society, Tallinn, Estonia

Background: Estonia, located in the shores of Baltic Sea has a population of 1,3 million with population density of 29,8 inhabitants per km^2 (2011). There are 2 major islands which are accessible from mainland by ferry or airplane. After the restruction of the hospital network 19 hospitals remained, incl. 3 regional, 4 central and 11 county hospitals.
Aims: Patients with haemophilia live everywhere. Replacement factors are distributed from regional hospitals, two are located in Tallinn (population 500 000) and one in Tartu (population 100 000). The network of retail pharmacies is very well established. The social support in rural parts of the country is suboptimal; from the other hand the pharmacy services are developing rapidly, including the door-to-door deliveries.
Methods: It was one of Kreuth III recommendations to establish a national roundtables to develop the treatment of coagulation disorders. Estonian Hemophilia Society (EHS) initiated a meeting in September 2013 where high-level stakeholders – from Ministry of Social Affairs, Health Insurance Fund, Estonian Hematology Society's working group on coagulation disorders – supported the improvement in treatment access. It was proposed that 20% of the coagulation factors will remain for hospital use in case of emergencies and surgeries and 80% will be included to the reimbursement list and can be obtained from retail pharmacies as prescription drugs.
Results: Some of the coagulation factors were included to the reimbursement list and became available in retail pharmacies in early 2015. However, as the regional hospitals had economically favorable tender contracts which tied the sale of the donated plasma to the purchase of plasma-derived factors, the system change was not fully implemented. EHS continued the work for better access. National tender and better access to replacement factors was supported by WHF-EHC-EAHAD joint visit to Estonia in October 2015. The major breakthrough took place in July 2019 when new medicines were included to the reimbmursement list by Health Insurance Fund. Also all plasma derived products, long acting coagulation factors, recombinant factors, aPCC are included to the list, which are prescribed electronically by physicians.
Summary/Conclusion: The delivery to pharmacies takes place within 24 hours. The door-to-door delivery to patients is developing as well. The new coagulation factor delivery system has reduced patients' financial burden, travel time and has brought high satisfaction among Haemophilia community in Estonia.

PB1758 A PRECEDE - PROCEED MODEL APPROACH IN ESTABLISHING A HEMOPHILIA CENTER IN A TERTIARY MEDICAL INSTITUTION: A DESCRIPTIVE STUDY.

P. B. Nuqui [1,*]

[1]Pediatric Hematology, University of Santo Tomas, Manila, Philippines

Background: Hemophilia is an inherited bleeding disorder due to "clotting factor" deficiency which requires lifelong management and support. This is the first study created to address the needs of this special population of patients in the country.
Aims: To provide a comprehensive framework that can be offered for hemophilia care.
Methods: The researcher used the PRECEDE-PROCEED framework to assess the current status of hemophilia care by evaluating the epidemiology, beliefs, environmental factors, including medical, surgical, psycho-social aspects based on the retrospective data evaluation in the PRECEDE phase. The Haemo-HQOL questionnaire was used to evaluate the current status of patients as part of the PROCEED phase.
Results: A total of 202 patients were seen in the institution over the past three years. Important factors identified were the ability to manage bleeding episodes at home, challenges due to limited supply of factor concentrate and cost of treatment. The availability of patient support groups and provision of donated factor concentrates provided improvement in the care of persons with hemophilia (PWH).

The PROCEED phase evaluated the current status of care with the use of a validated Haemo-HQOL which showed the different dimensions of interest according to age group.
Summary/Conclusion: The study provided a comprehensive framework of care and service that can be offered to PWH. Evidences regarding the importance of creating a specialized treatment center to cater hemophilia patients despite the difficult political, socio-economic, behavioural and environmental problems of PWH confirmed that interventions may improve the quality of life of this population. Moreover, continuous monitoring and reevaluation will provide a good system to guide our pediatric hematologists regarding the practice of treating hemophilia patients.

PB1759 THE IMPACT OF COVID-19 ON PATIENTS WITH HEMATOLOGICAL MALIGNANCIES: THE MIXED-METHOD ANALYSIS OF AN ISRAELI NATIONAL SURVEY

I. Levy [1,2,*], G. Sharf [3], S. Norman [4], T. Tadmor [1,2]

[1]Hematology, Bnai Zion Medical Center, [2]Faculty of Medicine, Technion- Israel Institute of Technology, Haifa, [3]Halil Haor non-profit organization for patients with Leukemia and Lymphoma, Halil Haor non-profit organization for patients with Leukemia and Lymphoma, [4]AMEN, Israeli Association of Myeloma Patients, AMEN, Israeli Association of Myeloma Patients, Tel Aviv, Israel

Background: The COVID-19 pandemic required reevaluation of the therapeutic approach and added emotional stress for patients with hematological malignancies at high risk of contracting the virus.
Aims: We aimed to evaluate how it affected such patients during the second lockdown in Israel.
Methods: This national survey included Hebrew-speaking patients with hematological malignancy. This included three tools with 28 items of socio-demographic and medical baseline characteristics, management of hematological disease, and evaluation of emotional coping during COVID-19 pandemic; the Hebrew version of the Patient Health Questionnaire 9; and 3 qualitative open-ended questions. Data was analyzed by mixed methods which combined both quantitative and qualitative thematic analyses.
Results: 408 patients responded to the survey. The management of their hematological disease included a decrease in the number of visits to the hematology clinic (37.0%), delay of some treatment schedules (9.1%), and prescription of replacement therapies permitting less visits to the clinic (2.2%). The frequency and intensity of "feeling afraid" regarding COVID-19 infection was increased (mean±SD: 4±1 to 5±2 in a 1-7 Likert scale), and a high rate of depression was recorded, which appeared to be more evident in patients with chronic myeloid leukemia (CML) ($p<0.001$).
Summary/Conclusion: The management of hematological malignancies during pandemics should always take into consideration patients' fears, as well as the development of depression related to isolation and loneliness, in addition to the high risk of severe disease. Patients with CML had a high rate of depression which obviously needs to be managed very carefully during and after the COVID-19 pandemic.

Sickle cell disease

PB1760 THE PHARMACOKINETIC PROFILE OF DEFERIPRONE IN PATIENTS WITH SICKLE CELL DISEASE

D. Soulières [1,*], J. Mercier-Ross [1], C. Fradette [2], Y. Chung Tsang [3], A. Rozova [4], F. Tricta [2]

[1]Department of Hematology and Oncology, University of Montreal Hospital Center, Montreal, [2]Hematology/Immunology, Chiesi Canada Corporation, [3]Biopharmaceutics & Biostatistics, Apotex Inc., [4]Medical Safety, Chiesi Canada Corporation, Toronto, Canada

Background: Repeated blood transfusions are a mainstay treatment for the management of sickle cell disease (SCD), but often cause transfusion-dependent iron overload (TDI) in patients. Deferiprone (Ferriprox®) is an oral iron chelator indicated for the treatment of TDI due to thalassemia and has been investigated as a treatment for TDI in patients with SCD and other anemias. Unlike other chelation therapies, deferiprone is well tolerated in patients with decreased renal function, a common complication in SCD patients (Nath and Hebbel 2015). Previous studies in healthy adult volunteers have characterized the pharmacokinetic (PK) and safety profiles of deferiprone and its metabolite, deferiprone 3-O glucuronide, but the PK of deferiprone in SCD patients has not been established.
Aims: The present study aims to characterize the PK profile of deferiprone in patients with SCD and evaluate whether alterations in its metabolism and excretion necessitate dosing adjustments.
Methods: In this phase I, single-center, non-randomized, open-label, single-dose study (NCT01835496), patients with a diagnosis of SCD were administered a single 1500 mg dose of deferiprone under fasting conditions. Blood and urine samples were collected pre-dose and over a 10-hour post-dose period for PK assessments of deferiprone and deferiprone 3-O glucuronide. Patients were monitored throughout the study for adverse events (AEs) and returned to the study site 7 ± 3 days for a final follow-up and safety assessment.
Results: Eight patients with SCD (3 males and 5 females) were enrolled and completed the study. All patients were black, with a mean ± SD age of 33.0 ± 5.9 years. Following drug administration, serum levels of deferiprone and deferiprone 3-O-glucuronide rose rapidly with maximum concentrations (C_{max}) reached at 1.0 and 2.8 hours post-dose, respectively. The mean ± SD C_{max} for deferiprone was 17.6 ± 5.8 mg/mL and for deferiprone 3-O- glucuronide was 33.0 ± 11.8 mg/mL. The peak in serum levels of deferiprone and deferiprone 3-O-glucuronide were followed by a rapid decline with a half-life of 1.5 and 1.6 hours, respectively. Less than 4% of administered drug was excreted unchanged in urine samples, while the majority was metabolized and excreted as deferiprone 3-O-glucuronide. Two patients reported mild AEs. One patient experienced sore throat, headache, fatigue, and fever and the other patient reported abdominal pain. None of the AEs were considered related to the study drug. Furthermore, vital sign measurements and laboratory test results found no indications of clinical concern.
Summary/Conclusion: The pharmacokinetics of deferiprone in SCD patients were consistent with values reported in previous PK studies in healthy adult volunteers, suggesting no special dosing adjustments are indicated. The safety profile of deferiprone and deferiprone 3-O glucuronide, was found to be favorable with no safety concerns. Because the sample size is small the latter results should be interpreted with caution. However, these findings provide insight for the treatment of TDI in SCD patients with limited chelation therapy treatment options.

PB1761 GBT1118, A VOXELOTOR ANALOG PROTECTS RED CELLS FROM POLYMERIZATION-INDUCED DAMAGE DURING SEVERE HYPOXIA

M. Tarasev [1,*], A. Herppich [1], M. Ferranti [1], C. Allen [1], P. Hines [1]

[1]Functional Fludics, Detroit, United States

Background: In Sickle Cell Disease (SCD) sickle hemoglobin (HbS) can polymerize in its deoxygenated form, leading to perturbations of Red Blood Cells (RBC) biochemical, morphological, and mechanical properties. RBC membrane damage due to hypoxia-induced polymerization causes hemolysis leading to hemolytic anemia and other complications linked to elevated cell-free Hb levels and heme toxicity.
Aims: The FDA recently approved voxelotor (Oxbryta; Global Blood Therapeutics) for treatment of SCD in patients 12 years of age and older, shown to increase patient Hb levels in a pivotal phase 3 trial. In this study, we assessed the effect of GBT1118, a voxelotor (Oxbryta) analog on hypoxia-induced RBC membrane damage (lethal and sublethal) using standardized assays.
Methods: Blood was from steady state homozygous SS SCD patients of Children's Hospital of Michigan (n=4; HbS=62-85%). Informed consent was obtained per protocol approved by Wayne State University IRB. RBC Mechanical Fragility (MF), a metric indicative of existing RBC membrane damage and prospective hemolysis, was measured using a proprietary system comprising an electromagnetic bead mill and fiber-optic spectrophotometry detection. Non-invasive probing of sample agitated with a magnetic bead at 5 Hz allowed determination of MF indices (MFI), representative of RBC resistance to induced hemolysis. MFIs were assessed for most labile RBC fraction (induced hemolysis ab. 20%, MFI_1) and for total induced hemolysis over 10 minutes agitation time (MFI_10). RBCs were assessed at normoxia, before and after three cycles of hypoxia, with deoxygenation induced via protocatechuate/protocatechuate dioxygenase oxygen scavenging system (< 5% oxygenated-Hb) and re-oxygenation under normoxic conditions (close to 100% RBC recovery).

Results: Whole blood samples supplemented with 1mM GBT1118 in DMSO (0.9% final concentration) were compared *in-vitro* to those with equal volume of DMSO-containing buffer. For control samples, three cycles of hypoxia with follow-up reoxygenation resulted in significant increase in RBC MF indices (MFI) for all samples with changes for labile fraction being more pronounced. Supplementation with GBT1118 did not result in statistically significant changes in RBC MFI_1 or MFI_10 as compared to control samples pre-hypoxia. Following GBT1118 treatment, MFI_1 and MFI_10 showed significantly less increase after the hypoxia-reoxygenation cycles with the averages unchanged from MFIs' pre-hypoxia values. (Figure 1). Average (mean ±SD), for the 4 samples, percent change from pre-hypoxia after the 3 cycles of hypoxia was 47%±28% (MFI_1) and 25%±20% (MFI_10) for the control samples compared to 0%±20% (MF_1) and 5%±7% for (MFI_10) for samples supplemented with GBT1118. Changes in pre-existing (existing prior to stress application) sample hemolysis due to hypoxia cycles were not significant for any of the samples.

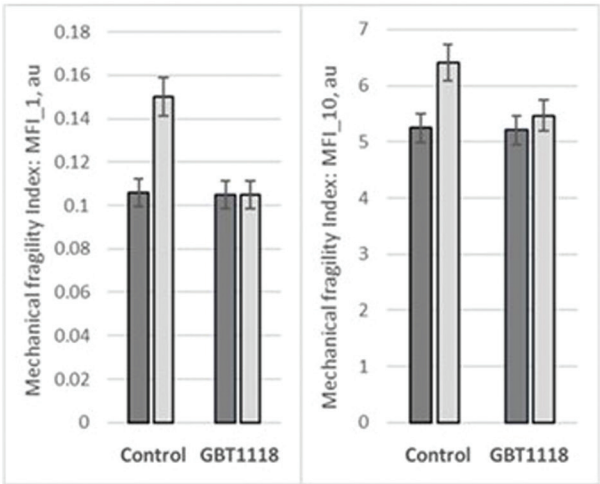

Fig.1 RBC MF at normoxia before (■) and after (□) three cycles of hypoxia with and without GBT1118.

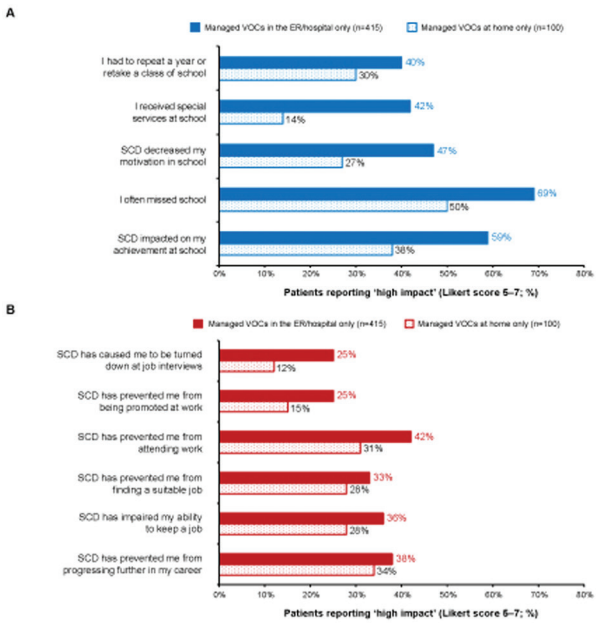
Summary/Conclusion: Cycles of severe hypoxia followed significantly damage RBC membranes making cells more susceptible to lysis under flow-induced mechanical stress. With no history of hypoxia, GBT1118 did not affect membrane stability under normoxic conditions. However, when present during hypoxia, GBT1118 significantly reduced membrane damage as shown by reduced RBC propensity to lyse. That highlights the potential of GBT1118, a voxelotor (Oxbryta) analog, to prevent sub-lethal RBC membrane damage likely leading in increased RBC survival in circulation

PB1762 IMPACT OF SICKLE CELL DISEASE ON DAILY LIFE IN PATIENTS MANAGING VASO-OCCLUSIVE CRISES AT HOME VS THE EMERGENCY ROOM/HOSPITAL: RESULTS FROM THE INTERNATIONAL SICKLE CELL WORLD ASSESSMENT SURVEY (SWAY)

E. Nur [1,*], J. James [2], B. Andemariam [3], B. Inusa [4], F. El Rassi [5], B. Francis-Gibson [6], C. Minniti [7], C. Trimnell [8], M. R. Abboud [9], J.-B. Arlet [10], R. Colombatti [11], M. de Montalembert [12], S. Jain [13], W. Jastaniah [14], M. Pita [15], E. Marturano [16], T. Bailey [17], O. Rajkovic-Hooley [17], I. Osunkwo [18]

[1]Department of Clinical Hematology, Amsterdam University Medical Centers, Academic Medical Center, Amsterdam, Netherlands, [2]Sickle Cell Society, London, United Kingdom, [3]New England Sickle Cell Institute, Division of Hematology-Oncology, Neag Comprehensive Cancer Center, UCONN Health, University of Connecticut, Farmington, United States, [4]Paediatric Haematology, Evelina Children's Hospital, Guy's and St Thomas' Hospital, London, United Kingdom, [5]Department of Hematology and Medical Oncology, Emory University School of Medicine and Georgia Comprehensive Sickle Cell Center at Grady Health System, Atlanta, [6]Sickle Cell Disease Association of America, Baltimore, [7]Montefiore Health System, Albert Einstein College of Medicine, New York, [8]Sickle Cell 101, San Jose, United States, [9]American University of Beirut Medical Center, Beirut, Lebanon, [10]Hôpital Européen Georges-Pompidou, Paris, France, [11]Clinica di Oncoematologia Pediatrica, Dipartimento della Salute della Donna e del Bambino Azienda Ospedaliera, Università di Padova, Padova, Italy, [12]Hôpital Universitaire Necker-Enfants Malades, Paris, France, [13]Thalassemia And Sickle Cell Society, Hyderabad, India, [14]College of Medicine, Umm Al-Qura University, Mecca, Saudi Arabia, [15]Department of Hematology and BMT, Samaritano Hospital, São Paulo, Brazil, [16]Novartis Pharma AG, Basel, Switzerland, [17]Adelphi Real World, Bollington, United Kingdom, [18]Sickle Cell Disease Enterprise at The Levine Cancer Institute/ Atrium Health, Charlotte, United States



Background: Sickle cell disease (SCD) is a group of blood disorders with a range of clinical complications, mostly driven by hemolytic anemia and vaso-occlusion. Vaso-occlusive crises (VOCs) are the hallmark of SCD and the most common cause of patient (pt) hospitalization. Despite the potential severe consequences of VOCs, many pts manage them at home. Previous reports from SWAY showed that 24% of pts managed their VOCs at home (not exclusively), primarily because of a poor prior experience in the emergency room (ER)/hospital (Osunkwo I *et al.* ASH 2019; abstract 2297).

Aims: To assess whether pt-reported impact of SCD on daily life in SWAY differs between pts who reported managing their VOCs exclusively in the ER/hospital vs exclusively at home in the 12 months prior to survey completion.

Methods: SWAY was developed by international SCD experts, pt advocacy groups and Novartis. Pts with SCD aged ≥6 years completed the survey between April and October 2019 (completion by proxy [parent/guardian/caregiver] was required for pts aged 6–11 years, optional for older pts). In SWAY, VOCs were defined as 'severe pain crises' and were self-reported by the pt or relevant proxy. Responses to questions on the impact of SCD on daily life were classified on a 1–7 Likert scale (1=not severe/strongly disagree, 7=worst imaginable/strongly agree; 5–7 indicated high impact/agreement).

Results: 2145 pts from 16 countries across six regions were included in SWAY; 11,317 VOCs were reported in the 12 months prior to survey completion. Of these pts, 29% (n=629) reported managing their VOCs in the ER/hospital (mean age, 24.6 [SD 12.4] years; female, n=331 [53%]; median of 3 [IQR 1–4] VOCs) and 6% (n=134) reported managing VOCs at home (mean age, 27.5 [SD 13.6] years; female, n=71 [53%]; median of 2 [IQR 1–4] VOCs). A greater proportion of pts who reported managing their VOCs in the ER/hospital (n=629) vs at home (n=134) reported a high negative impact of SCD on their emotional wellbeing (61% vs 49%). Of pts managing their VOCs in the ER/hospital, 49%, 45% and 49% rated their level of agreement with the statements *'I feel stressed'*, *'I feel depressed'* and *'I worry about dying'*, respectively, in the high impact range, compared with 37%, 33% and 36% of pts who managed their VOCs at home. A greater proportion of pts who reported managing their VOCs in the ER/hospital vs at home reported a high impact of SCD on aspects of their daily life, including family/social life (37% vs 27%), relationship with their spouse/partner (33% vs 17%), sexual desire/activity (33% vs 19%) and, to a lesser extent, household daily activities (eg housework, childcare; 32% vs 25%). Self-reported impact of SCD on aspects of schooling and employment also appeared to be higher in pts who managed their VOCs in the ER/hospital vs at home (Figure).

Figure. Proportion of pts reporting a high impact (Likert score 5–7) of SCD on their schooling (A) and careers (B) stratified by VOC management location

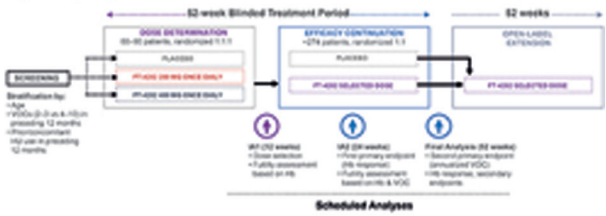
Summary/Conclusion: Pts managing their VOCs in the ER/hospital reported a greater impact of SCD on daily life than pts who managed them at home. This may indicate that pts visited the ER/hospital because their pain was too severe to manage at home. Pts experiencing a high impact of SCD on daily life may also seek ER/hospital care for VOCs for psychological support. Equally, visiting the ER/hospital for VOC management may itself be a detriment to pts' daily lives. Differences in access to healthcare facilities amongst participating countries in SWAY, as well as differing numbers of pts who managed VOCs in the ER/hospital vs at home – possibly influenced by pts' varied geographic location – may also contribute to the observed differences in this analysis.

PB1763 IMPACT OF COVID-19 ON SICKLE CELL DISEASE IN LEBANON; MILD DISEASE AND ONE CASE OF DEEP VEIN THROMBOSIS.

N. El Hariri [1,*], G. Siblany [1], R. Hanna Wakim [1], F. Haddad [2], G. Dbaibo [1], S. Khafaja [1], M. R. Abboud [1]

[1]pediatrics, [2]AUBMC, Beirut, Lebanon

Background: Novel coronavirus SARS-CoV-2, COVID-19, infection was first reported in December 2019, and then spread dramatically around the world. Sickle cell disease is caused by a mutation in the beta globin gene resulting in the production of sickled hemoglobin that alters its shape upon deoxygenation to form an elongated rigid sickled erythrocyte that leads to vaso-occlusion. To date, there have been limited published data on how COVID-19 may affect morbidity and mortality in SCD patients. A review of the literature showed that SARS-CoV-2 infection should be considered to be an important triggering factor of sickle cell crisis. Most investigators report mild disease in children and moderate disease in many SCD adults.
Aims: The aim of this report is to describe the clinical features of 11 confirmed cases of COVID-19 in patients with SCD in Lebanon.
Methods: 11 SCD patients, were infected with COVID-19. Data concerning the age, gender, weight, and genotype were collected. In addition to medications received and chronic transfusion. Information about the course of COVID-19 is reported regarding: complications, type and duration of symptoms as well as therapy.
Results: In this series median age was 22.2 years (range 14-40 years), only 2 are females and 8 patients had HbSS, 2 HbS beta + thalassemia, and 1 HbSC. 3 patients weighed >70kg the others were all below 70 kg. Ten patients were on long term hydroxyurea (HU) and in one it was initiated for only 1 week before infection. 1 patient was receiving Voxelotor and 1 Crizanlizumab in addition to HU. None were on chronic transfusion. Two patients had previously been started on Aspirin. One was on acencoumarolum, for a previous pulmonary embolism. One patient had asthma and was a smoker. Nine patients had moderate to severe symptoms and 2 had mild symptoms. 2 patients underwent PRBC transfusion for pain and anemia and one had erythrocytopherisis to control severe pain. Three patients required oxygen but none were admitted to a critical care unit. The mean number of days with symptoms was 14.1 days. Of the 11 patients 7 experienced pain crisis. None developed acute chest syndrome. 3 patients received corticosteroids and 5 patients received low molecular weight heparin (LMWH) 2 received therapeutic dose and 3 prophylactic dose.
A 16 years old male with HbSS genotype developed multi system inflammatory syndrome and was admitted to regular floor for 26 days. He had prolonged high grade fever, epigastric pain, sore throat in addition to maculopapular rash. He had elevated D-Dimers >3000 ng/ml. He received PRBC transfusion, IVIG, corticosteroids, LMWH and antibiotics. Another 18 year old male with HbSS, developed extensive right lower limb deep vein thrombosis (DVT) 20 days after recovering from very mild COVID-19 infection. This patient had been on aspirin for 6 years after recovering from a catheter provoked DVT.
Summary/Conclusion: This is one of the first reports on COVID-19 in patients who are not of African descent. In our patients COVID-19 was manifested mainly as fever and pain crises. Most patients required transfusions. Overall the symptoms were mild or moderate, similar to what was reported by others. Of concern were the development of multi system inflammatory syndrome in one patient and the development of delayed extensive DVT in another.



PB1764 HIBISCUS, AN ADAPTIVE, RANDOMIZED, PLACEBO-CONTROLLED, DOUBLE-BLIND, MULTICENTER STUDY OF ORAL FT-4202, A PYRUVATE KINASE ACTIVATOR IN PATIENTS WITH SICKLE CELL DISEASE

K. Ataga [1,*], K. Wood [2], J. Geib [2], E. Wu [2], J. Berlin [2], I. Webster [2], J. Howard [3], J. H. Estepp [4], J. Brevard [2], M. J. Telen [5]

[1]University of Tennessee Health Science Center, Memphis, [2]Forma Therapeutics, Inc., Watertown, United States, [3]Guy's and St. Thomas' Hospital, London, United Kingdom, [4]St. Jude Children's Research Hospital, Memphis, [5]Duke University Medical Center, Durham, United States

Background: The hallmark of sickle cell disease (SCD) is hemoglobin S (HbS) polymerization upon deoxygenation, resulting in red blood cell (RBC) sickling, hemolysis, and vaso-occlusion. Exacerbating the pathogenesis of SCD, the HbS RBC has increased (↑) levels of 2,3-diphosphoglycerate (2,3-DPG), resulting in reduced (↓) Hb oxygen affinity (↑P50), and ↓ATP, essential for RBC homeostasis. FT-4202 is a selective, and orally bioavailable allosteric activator of erythrocyte pyruvate kinase (PKR) that increases PKR activity, resulting in ↓2,3-DPG levels and ↑ATP levels in RBCs. Preliminary data from an ongoing phase 1 study (NCT03815695) indicate that FT 4202 is well-tolerated, has no effect on steroidogenesis, and exhibits linear and time-independent pharmacokinetics and associated pharmacodynamic responses (↓2,3-DPG and ↑ATP). Treatment of patients with SCD for 14 days with once-daily FT-4202 resulted in ↑Hb O2 affinity, ↓RBC sickling, improved RBC deformability, and improved hematologic and hemolytic parameters (Brown, ASH2020_ abstract_#134269).
Aims: Hibiscus (NCT04624659) is a phase 2/3, randomized, double-blind, placebo-controlled global study to investigate the safety and efficacy of FT-4202 in patients with SCD.
Methods: Adult and adolescent patients with SCD (all genotypes) will be enrolled in a Dose Determination (DD) group and an Efficacy Continuation (EC) group using an adaptive design. Eligible patients must have had ≥2 vaso-occlusive crises (VOCs) in the past year, baseline Hb ≥5.5 and ≤10 g/dL, and if receiving hydroxyurea (HU), be on stable therapy for the previous 90 days. Patients with >10 VOCs in the past year, hospitalized for sickle cell crisis/other vaso-occlusive event within 14 days of consent, receiving routine RBC transfusions, significant hepatic/renal dysfunction, history of unstable or deteriorating cardiac or pulmonary disease, or overt stroke within 2 years will be excluded. Co-primary endpoints are Hb response rate (RR) at Week 24 (increase from baseline >1 g/dL) measured as the percentage of treated population achieving the endpoint, and annualized VOC rate during the blinded treatment period based on adjudicated VOC review. Secondary endpoints include measures of hemolysis, time to first VOC, and the Patient Reported Outcome Measurement Information System fatigue scale. Safety endpoints will also be assessed. Patients will be stratified by number of VOCs in the preceding 12 months, prior/concomitant HU use and age, and randomized 1:1:1 to 200 or 400 mg (once-daily) FT-4202, or placebo in the DD group. At interim analysis (IA) 1, one FT-4202 dose level will be selected based on safety and Hb RR at Week 12 in the first 60 patients. EC group patients will be randomized 1:1 to the selected FT-4202 dose or placebo. Once 110 patients randomized to the selected dose or placebo complete 24-weeks blinded treatment or drop out, IA2 will assess Hb RR (first primary endpoint). At final analysis (52-weeks blinded treatment) annualized VOC (second primary endpoint), 24-week Hb RR and all secondary endpoints will be evaluated. Patients may then enter a 52-week open-label extension period at the selected FT-4202 dose. Futility assessments will be conducted (Weeks 12 and 24).
Results: Recruitment is ongoing; planned enrolment: ~344 patients with SCD (DD group, n=60–90; EC group, n~274).

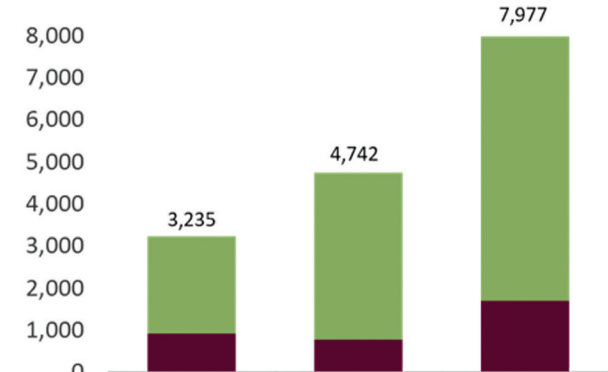
Figure: Study Design

Summary/Conclusion: This study will evaluate the safety and efficacy of oral, once-daily FT-4202 in adult and adolescent patients with SCD.

PB1765 ECOCARDIOGRAPHIC EVALUATION OF CARDIOVASCULAR COMPLICATIONS IN PEDIATRIC SICKLE CELL DISEASE PATIENTS: MORE THAN MEETS THE EYE?

G. Ceglie [1,*], L. Sabatini [2], M. Chinali [3], A. Franceschini [3], S. Marchesani [2], M. Di Mauro [2], M. Cossutta [2], G. Arcuri [2], G. Palumbo [1]

[1]Department of Pediatric Hematology and Oncology, Cell and Gene Therapy, IRCCS Bambino Gesù Children's Hospital, [2]University Department of Pediatrics, Bambino Gesù Children's Hospital, University of Rome Tor Vergata, [3]Department of Pediatric Cardiology, IRCCS Bambino Gesù Children's Hospital, Rome, Italy



Background: Sickle cell disease (SCD) is an inherited blood disorder caused by a mutation in the gene encoding the hemoglobin subunit β. The number of SCD cases is expected to increase in the next decades and new therapies led to an increase in patients' life expectancy. Thus, it has become essential to define screening and prevention programs for the long-term complications. Among these, cardiovascular involvement has a significant impact on morbidity and mortality in SCD. Although cardiovascular complications have been well described in the adult population, few studies are currently available regarding the pediatric setting.
Aims: This study aims to investigate the impact of cardiac complications in a pediatric cohort and the role of clinical and laboratory markers as predictors factors to identify at-risk patients.
Methods: This is a retrospective observational monocentric study on a pediatric SCD population followed at the Bambino Gesù Childrens' Hospital in the last 5 years (2015–2020). We have analyzed the data regarding 64 SCD patients (37 Males and 27 Females, median age 10) who undergone a routine transthoracic echocardiogram. Echocardiograpic evaluations were performed by a pediatric cardiologist, blinded to the clinical status and biological data. We collected personal information, medical history, and laboratory data referring to 2 years prior to echocardiogram. Statistical analysis was performed and data considered with statistical significance were those with p-value <0.05 and are therefore the ones presented in the results section.
Results: Globally, 46 (72%) patients had at least one cardiac abnormality. Left atrial dilatation (LAD) was present in 41 (65%) patients and left ventricular hypertrophy (LVH) was found in 29 (45%) patients. Only 5 patients had systolic disfunction, and no patient had indirect signs of pulmonary hypertension. No differences were found in the different age groups. Patients with LAD showed lower median Hb level (p=0,009), higher absolute reticulocyte count (p=0,04), higher conjugate bilirubin level (p=0,01) and alanine transaminase level (p=0,009). LVH was negatively correlated with median Hb value (p=0,006) and positively with reticulocyte count (p=0,03). Interestingly, we found that patients with cardiac anomalies had a higher transfusion needs and a lower frequency of pain crises. Among other complications, we found a correlation between left ventricular hypertrophy and splenectomy (p=0,03).
Summary/Conclusion: In our setting, cardiac involvement has a high prevalence in a pediatric cohort, involving the majority of patients. In the adult setting it's known that elevated right ventricular pressure and left diastolic dysfunction are independent predictors of worst clinical course and early death. As suggested from other studies, left diastolic dysfunction, the prominent echocardiographic finding in adult, may take time to develop. Our findings suggest that cardiac complications are not only associated with specific laboratory findings, but also with a specific clinical phenotype, characterized by chronic significant hemolysis, severe anemia, high transfusion need and other complications related to chronic volume overload due to chronic anemia. The current guidelines do not recommend a screening echocardiogram in the asymptomatic pediatric population, we think further studies are needed on the impact of cardiac anomalies in the young age since their burden and clinical significance may be currently understated.

PB1766 THE GREATALYS (GENERATING REAL WORLD EVIDENCE ACROSS ITALY IN SCD): EPIDEMIOLOGY AND DISEASE BURDEN IN ITALY

C. Castiglioni [1], C. Condorelli [1], D. Valsecchi [1], E. Premoli [1], V. Perrone [2], L. Degli Esposti [2], L. De Franceschi [3], G. L. Forni [4], C. A. Fiocchi [1,*]

[1]Novartis Farma SpA, Origgio, [2]Clicon S.r.l. Health Economics and outcome Research, Bologna, [3]Department of Medicine, University of Verona, Verona, [4]Centro della Microcitemia e Anemie Congenite, Ospedale Galliera, Genoa, Italy

Background: Epidemiological 2010-2050 predictions of increasing global burden, make SCD an emerging problem of public health. The distribution of SCD patients in Italy has severely changed in the last decade due to a combination of migration fluxes and increased survival of the endemic population.
Aims: To understand the evolution of SCD disease burden in Italy, we designed a non-interventional retrospective cohort study with secondary use of administrative data (GREATalyS; CSEG101AIT01). Our objective is to collect representative data generalizable to the total Italian population to estimate prevalence and incidence rates of SCD in clinical practice settings.
Methods: An observational retrospective analysis was conducted by integrating administrative NHS databases for healthcare resources consumption from a geographically distributed sample of Italian Regions and Local Health Units (LHUs) comprising approximately 15.3 million health-assisted subjects (about 25% of the whole Italian population). Patients with at least one hospitalization (day hospital or regular admission) with a main or secondary discharge SCD diagnosis (identified by ICD-9-CM codes) were included in the analyses (period: January 2010-December 2018). Analyses of prevalence and incidence were stratified by age, sex and presence/absence of crisis (based on diagnosis at inclusion). Data were then projected to the total Italian population.
Results: Out of 15.3 million health-assisted subjects, 2,347 patients fulfilled the inclusion criteria during the full study period. The calculated SCD prevalence in 2018 was around 13 cases per 100,000 health-assisted subjects (around 11 cases per 100,000 males and 15 per 100,000 females were observed). SCD prevalence in young (<18 years old) and adult population was 17.2 and 12.4 cases per 100,000 health-assisted individuals, respectively. When projected to the total Italian population, 7,977 SCD patients were estimated in 2018 (1,690 young and 6,287 adult patients) (Figure 1).
Incidence rates slightly fluctuate over the years (from 2.00 per 100,000 health assisted in 2011 to 0.93 per 100,000 in 2018 corresponding to 567 new diagnosis in 2018).
Approximately two third (74%) of the patients had at least one hospitalization during study without a concomitant diagnosis of crisis (5,894 without/1,279 with, 804 unspecified), thus suggestive of a high disease burden beyond severe VOC. SCD "With crisis" prevalence was higher in patients aged <45 years, ranging from 2.45 (age group 35-44) to 3.04 (age group 25-29) and decreased significantly after 54 years to a minimum of 0.34 in patients aged 75-84 years. Geographical stratification showed a "population without crisis" almost doubled in the Southern areas (12.44 cases per 100,000) compared to the North (6.93 cases per 100,000) and Center (4.34 cases per 100,000) areas.

	M	F	TOT
>=18 yy	2,316	3,971	6,287
<18 yy	919	771	1,690
Total	3,235	4,742	7,977

Summary/Conclusion: GREATalyS identified a high SCD incidence and prevalence resulting in a total of 7,977 Italian SCD patients estimated in 2018, when considering the long observation period. The discrepancy between the prevalence herein reported with previous SCD epidemiology analysis (around 2,000 SCD patients in Italy) might be explained by the real world setting of our analysis which considers also patients not referred to specialist centers, potentially underreported in Italy. Hence, this data represents the highly variable presentation of SCD and shed light on the management of patients not generally described in the literature.

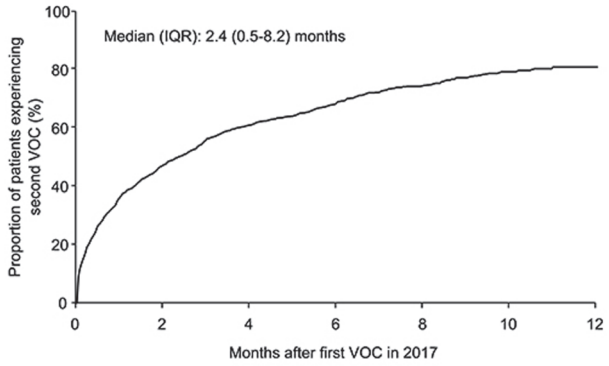
PB1767 IN SICKLE CELL DISEASE WITH CHRONIC RETINAL COMPLICATION CAN HAEMATOLOGICAL PARAMETERS BE USEFUL AS A STRATIFYING RISK TOOL?

C. J. Saunders [1,*], R. Serras Pereira [2], F. Saraiva [1], E. Araújo [3], R. Anjos [2], R. Flores [2], A. Monteiro [1], M. Silva [1]

[1]Haematology, [2]Ophtalmology, Hospital dos Capuchos, [3]Transfusional Medicine, Hospital São José, Lisboa, Portugal

Background: Sickle cell associated retinopathy is a well established chronic complication in sickle cell disease. There can be proliferative retinopathy (PR) and non-proliferative retinopathy (NPR). Although the risk of retinal changes is higher in heterozygotes SC (SC) disease followed by sickle-beta-thalassemia disease (S-tal) and homozygous sickle cell disease (SS), its exact incidence is unknown since most patients are asymptomatic.
Aims: Our study's goals are, firstly to characterise sickle cell retinopathy in patients with SS, SC and S-tal disease and secondly understand if haematological parameters (such as hemoglobin level, haematocrit, mean corpuscular volume and percentage of haemoglobin S and F) can be used as a stratifying risk tool regarding presence of NPR and PR in SS patients.
Methods: We included 106 patients followed between January/2017 and December/2019. Retinal evaluation was performed with binocular indirect ophthalmoscopy, fluorescein angiography (FA) and optical coherence tomography angiography (OCTA). In order to compare haematological parameters in the PR and NPR groups, we carried out a descriptive analysis of the variables and verification of normality. We resorted to the t-test of 2 independent samples for normal variables and the Mann-Whitney U test for variables without normal distribution. Subsequently, the existence of variables with an impact on the type of retinopathy was analysed through logistic regression
Results: We found 26 from 35 patients asymptomatic, however 13 (37.1%) had already fundoscopic changes, whilst 22 (62.9%) had no changes. Further ophthalmological evaluation with FA and OCTA, found that 29 patients (82.9%) had retinopathy. According to the Goldberg's classification, 17 patients (58.6%) had NPR and 12 (41.4%) had PR. These patients included all with SC and S-tal disease (5 and 2, respectively) and 22 (78.6%) with SS disease.
Regarding the SS retinopathy group, these patients had higher levels of Hb S (69.2% vs. 67.21%) and lower levels of Hb F (9.54% vs. 13.47%). Statistical analyses revealed that the two populations PR and NPR, are similar, without significant statistical differences and with no specific associated parameters.

Summary/Conclusion: Our preliminary results reinforce that retinopathy is frequently clinically silent. Unfortunately, it is a well established under-diagnosed complication in sickle cell disease. Retinal complications should always be stratified with ophthalmological imaging techniques, since haematological parameters apparently are not a good stratifying risk tool. There is a minor difference regarding the amount of Hb S and F, but further work with a larger cohort of patient is needed. Therefore, our preliminary results reinforced that periodic ophthalmological evaluation is mandatory for all sickle cell disease patients and not only for the high-risk group sickle cell associated retinopathy.



PB1768 CLINICAL CHARACTERISTICS AND THE RISK OF VASO-OCCLUSIVE CRISES IN PATIENTS WITH SICKLE CELL DISEASE

S. Tzivelekis [1,*], E. Swallow [2], A. Briggs [2], M. L. Zichlin [2], B. Mellgård [3]

[1]Shire Human Genetic Therapies, Inc., a Takeda company, Cambridge, [2]Analysis Group, Inc., Boston, [3]Baxalta US Inc., a Takeda company, Cambridge, United States

Background: Sickle cell disease (SCD) is an inherited disorder affecting the red blood cells that causes lifelong complications. Vaso-occlusive crises (VOCs), which result from blood vessel obstruction, are clinical hallmarks of SCD. VOCs are associated with intense pain and can lead to potentially irreversible organ damage, and thus can represent a significant clinical burden.
Aims: To assess the risk of VOC by age in patients with SCD using data from a retrospective database analysis.
Methods: The IBM MarketScan Commercial Claims and Medicare Supplemental Claims databases (July 1, 2013 to June 30, 2018) were used for a retrospective analysis of patients with SCD. Patients with ≥2 SCD diagnoses (ICD-9 CM and ICD-10 CM) on separate claims between July 1, 2013 and January 1, 2017, who were ≥6 years of age on January 1, 2017, and had continuous enrollment throughout a 1-year analysis period (January 1, 2017 to December 31, 2017) were included in this analysis. Patients with >100 inpatient or outpatient VOC-related days, as of January 1, 2017, were excluded from the analysis. Patient demographics and clinical characteristics were assessed using descriptive statistics. In addition, the monthly VOC risk by age, proportion of VOCs experienced by clinical setting, and time to second VOC were evaluated.
Results: All inclusion criteria were met by 8174 patients. The median (interquartile range) age was 42 (24–55) years and 36.5% of the patients were male. A total of 1659 (20.3%) patients had ≥1 VOC diagnosis during the 1-year study period. The mean (SD) Charlson Comorbidity Index was 0.6 (1.3) and the most common component conditions were chronic pulmonary disease (n=1117 [13.7%]), mild to moderate diabetes (n=608 [7.4%]), renal disease (n=445 [5.4%]), and cerebrovascular disease (n=438 [5.4%]). Patients experienced VOCs in both the outpatient and inpatient setting, and the mean (SD) proportion of VOCs experienced in an outpatient setting was 0.74 (0.34). The mean (SD) monthly VOC risk was 0.07 (0.19). Patients aged ≥20 and <30 years (n=939) had the highest mean (SD) monthly VOC risk (0.16 [0.28]). Among the 1659 patients with ≥1 VOC, 1161 (70.0%) experienced a second VOC during the study period. The time from first to second VOC for all patients with ≥1 VOC within the 1-year study period is shown in Figure 1.

Figure 1. Time from first to second VOC in patients experiencing ≥1 VOC from January 1, 2017 through December 31, 2017

Number of patients experiencing second VOC						
0	766	968	1065	1124	1156	1161
Number of patients at risk						
1659	818	530	358	217	100	3

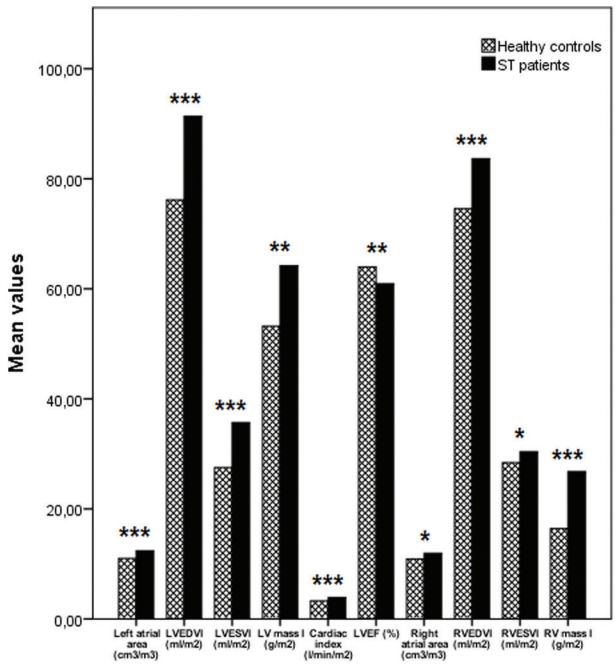
Abbreviations: IQR, interquartile range; VOC, vaso-occlusive crisis.
Second instance of a VOC during the study period was defined as the second instance of a VOC (defined by diagnosis codes) in 2017 after the first VOC experienced on or after January 1, 2017.

Summary/Conclusion: The findings of this study show that patients with SCD often experience recurring VOCs and that younger patients appear to be at greater risk of VOC events.

PB1769 PEDIATRIC PATIENT REPORTED OUTCOMES IN PATIENTS RECEIVING VOXELOTOR FOR SICKLE CELL DISEASE

C. Brown [1,*], O. Moshkovich [2], K. Lipman [2], R. Murphy [2], A. Beaubrun [3], I. Agodoa [3]

[1]Children's Healthcare of Atlanta, United States, Atlanta, Georgia, [2]ICON, United States, Gaithersburg, MD, [3]Global Blood Therapeutics, San Francisco, United States



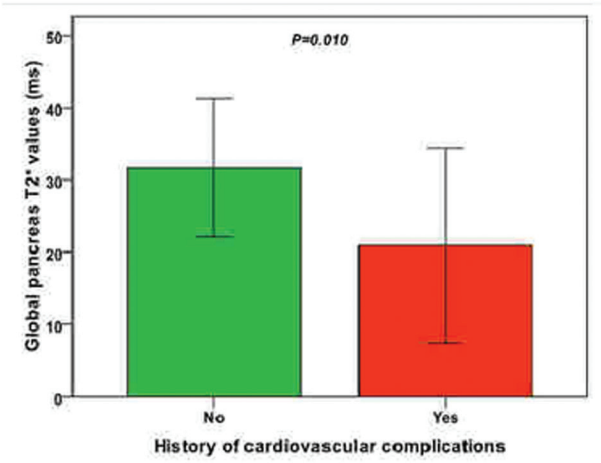
Background: Sickle cell disease (SCD) describes a group of chronic, inherited blood disorders resulting from mutations that reduce or abolish normal hemoglobin production. The most common clinical manifestations of SCD are related to hemolytic anemia and vaso-occlusion, which can cause acute and chronic pain and end-organ damage. Voxelotor is a first-in-class sickle hemoglobin–polymerization inhibitor, FDA approved for patients with SCD aged ≥12 years, that modulates hemoglobin oxygen-affinity, prevents sickling of red blood cells, and possibly interrupts the molecular pathogenesis of the disease. It is currently being investigated in patients aged 4-11 years. Incorporating the patient voice into drug development is increasingly important to regulators; thus, collecting qualitative data to gain patient and caregiver insights alongside clinical data can aid in understanding treatment benefits in this patient population.
Aims: The purpose of this study is to collect qualitative data to understand patient experiences with voxelotor, as reported by pediatric patients and their caregivers. Specifically, the study aims to understand how the treatment affects symptoms and related impacts, and overall health-related quality of life (HRQOL).
Methods: This qualitative study will involve interviewing children with SCD (aged 4-11 years) and their caregivers to be recruited from multiple sites in the US. Eligible patients will have been taking voxelotor for ≥4 weeks at the time of the interview. Concept elicitation interviews are to be conducted via telephone by experienced qualitative researchers using a semi-structured interview guide. Interview transcripts will be analyzed with MAXQDA software. This will allow theme identification using an induction-abduction approach, enabling the analysis to remain grounded in the data. Inter-coder reliability will be established early in the coding process by having two analysts independently code the same transcript.
Results: The interviews are ongoing. Changes in symptoms, effects on daily life, and other impacts to HRQOL reported by patients and their caregivers will be presented.
Summary/Conclusion: This will be the first study to report qualitative experiences of pediatric patients treated with voxelotor.

PB1770 CARDIAC INVOLVEMENT IN SICKLE Β-THALASSEMIA PATIENTS BY MAGNETIC RESONANCE IMAGING

L. Pistoia [1], A. Meloni [1,*], V. Carrai [2], E. Facchini [3], S. Bagnato [4], F. Sorrentino [5], A. Quarta [6], S. Renne [7], M. Zerbini [8], L. Barbuto [9], V. Positano [1], A. Pepe [1]

[1]Fondazione G. Monasterio CNR-Regione Toscana, Pisa, [2]Azienda Ospedaliero - Universitaria Careggi, Firenze, [3]Azienda Ospedaliero-Universitaria di Bologna - Policlinico "S. Orsola-Malpighi", Bologna, [4]Presidio Ospedaliero Lentini - ASP 8 Siracusa, Lentini (SR), [5]Ospedale "Sant'Eugenio", Roma Eur, [6]Ospedale "A. Perrino", Brindisi, [7]Presidio Ospedaliero "Giovanni Paolo II", Lamezia Terme (CZ), [8]Ospedale del Delta, Lagosanto (FE), [9]Azienda Ospedaliera di Rilievo Nazionale Antonio Cardarelli, Napoli, Italy

Background: Sickle β-thalassemia (Sβ-thal) is a hereditary hemoglobinopathy resulting from the combined heterozygosity for sickle cell and β-thalassemia genes. Cardiac involvement in Sβ-thal patients has been poorly investigated.
Aims: We aimed to evaluate myocardial iron overload and cardiac function by cardiovascular magnetic resonance (CMR) in patients with Sβ-thal.
Methods: One hundred and eleven Sβ-thal patients consecutively enrolled in the Myocardial Iron Overload in Thalassemia (MIOT) network were studied and compared with 46 sickle cell disease (SCD) patients. Bi-atrial and biventricular function CMR parameters of Sβ-thal patients were compared with those of 111 healthy volunteers, matched by gender and age. Myocardial iron overload (MIO) was assessed by T2* technique. Cine images were acquired to quantify biventricular function. Macroscopic myocardial fibrosis was evaluated by late gadolinium enhancement (LGE) technique.
Results: In Sβ-thal and SCD patients morphological and functional MR parameters were not significantly different, except for left atrial area and SVI (p = 0.023 and p = 0.048, respectively) that were significantly higher in SCD patients. No significant differences between the two groups were found in terms of myocardial iron overload and macroscopic myocardial fibrosis. When compared to healthy subjects, Sβ-thal patients showed significantly higher bi-atrial and biventricular parameters except for LVEF that was significantly lower (Fig.1).



Summary/Conclusion: The CMR analysis confirmed that Sβ-thal and SCD patients are phenotypically similar. Since Sβ-thal patients showed markedly different morphological and functional indices from healthy subjects, it would be useful to identify Sβ-thal/SCD-specific bi-atrial and biventricular reference values.

PB1771 PANCREATIC IRON IS A MARKER OF CARDIOVASCULAR COMPLICATIONS AND IN SICKLE CELL DISEASE

A. Meloni [1,*], L. Pistoia [1], I. Fotzi [2], L. Rigoli [3], V. Carrai [4], C. Argento [5], L. Tedesco [6], V. Vinci [7], R. Righi [8], P. Fina [9], V. Positano [1], A. Pepe [1]

[1]Fondazione G. Monasterio CNR-Regione Toscana, Pisa, [2]Ospedale "Meyer", Firenze, [3]Policlinico "G. Martino", Messina, [4]Azienda Ospedaliero - Universitaria Careggi, Firenze, [5]Ospedale "San Giovanni Di Dio", Agrigento, [6]Presidio Ospedaliero Locri - A.S.P di Reggio Calabria, Locri (RC), [7]Azienda Ospedaliera "Garibaldi" Presidio Ospedaliero Nesima, Catania, [8]Ospedale del Delta, Lagosanto (FE), [9]Ospedale "Sandro Pertini", Roma, Italy

Background: A strong association between pancreatic iron burden and cardiac complications was found in patients with thalassemia major. There is no study evaluating this issue in sickle cell disease (SCD).
Aims: The objective of this multicenter study was to systematically explore the link between pancreatic iron and cardiovascular complications in a cohort SCD patients enrolled at baseline in the prospective Extension-Myocardial Iron Overload in Thalassaemia (E-MIOT) project.
Methods: We considered consecutively enrolled 63 patients: 44 with sickle beta thalassemia, 18 with sickle cell anemia (SCA), and one with hemoglobin SC disease (HbSC). Mean age was 36.6±14.4 years and 29 patients were females. T2* measurements were performed over pancreatic head, body and tail and global value was the mean. Myocardial iron overload (MIO) was quantified using a T2* segmental approach.
Results: SCA and sickle beta thalassemia patients were comparable for age, sex, hematochemical parameters, and cardiac and pancreatic T2* values.
Transfusion dependent (TD; N=44) and no-TD patients showed comparable global pancreas T2* values (29.8±11.4 ms vs 32.2±8.0 ms; P=0.414), but were more frequently chelated (79.1% vs 52.6%; P=0.034).
Nineteen patients (30.2%) showed a pathological global pancreas T2* value (<26 ms) while no patient had significant myocardial iron overload (global heart T2*<20 ms).
Seven patients (11.1%) had at least one cardiovascular complication: two supraventricular arrhythmias, one heart failure, one heart failure + pulmonary hypertension, one myocardial infarction, one deep vein thrombosis, and one leg ulcer. Frequency of cardiovascular complications was comparable among the forms of SCD, but all complications occurred in regularly transfused patients.
Patients with cardiovascular complications showed significantly lower global pancreas T2* values than patients free of cardiovascular complications (20.9±13.5 ms vs 31.7±9.6 ms; P=0.010) (Figure 1) but comparable global heart T2* values (38.4±5.6 ms vs 40.6±4.7 ms; P=0.257). Patients with pancreatic iron overload were more likely to have cardiovascular complications [odds ratio=7.5 (95%confidence intervals=1.3-43.1); P=0.024].

Summary/Conclusion: Pancreatic iron overload is associated with an increased risk of cardiovascular complications in SCD patients. If a patient has pancreatic iron overload, it would be prudent to start or intensify iron chelation therapy to prospectively prevent cardiac damage.

PB1772 EFFECT OF HYDROXYUREA ON ADHESION MOLECULES IN YOUNG PATIENTS WITH SICKLE CELL BETA THALASSEMIA

H. Papadopoulou [1], A. Teli [1,*], A. Taparkou [1], E. Farmaki [1], M. Economou [1]

[1]1st Pediatric Department, School of Medicine, Faculty of Health Sciences, Aristotle University of Thessaloniki, Thessaloniki, Greece

Background: Hydroxyurea (HU) is a cytotoxic drug that is used in sickle cell disease (SCD) in order to ameliorate disease's severity. Induction of HbF is reported as the main mechanism of action, however, other mechanisms contribute to its beneficial effect, given that some patients present with clinical improvement without an HbF increase. Sickle erythrocytes and activated circulating neutrophils contribute to vaso-occlusion by adhering to inflamed endothelium. B2-Integrins (CD11a, CD11b, CD11c and CD18), which are transmembrane adhesion receptors, are expressed exclusively on leukocytes. A number of studies have shown that HU decreases leucocyte adhesion, but the role of HU on B2 integrins expression has not been clarified. Moreover, there is conflicting data on the role of HU in decreasing CD36 - an adhesion receptor with increased expression on sickle reticulocytes and immature sickle erythrocytes.
Aims: Aim of present study was to evaluate the effect of HU on erythrocyte and leukocyte adhesion molecules in young patients with Sickle cell beta thalassemia.
Methods: Eleven young patients with Sickle cell beta thalassemia aged 3.5-18 years participated in the study. HU was given at a daily dose that ranged from 14.5 to 19 mg/kg, with a mean of 16.3mg/kg, for a 3year period. Expression of CD11a, CD11b, CD11c and CD18 on neutrophils, and of CD36 on reticulocytes was evaluated by flow cytometry.
Results: Before HU initiation all patients presented with normal expression of the CD11a, CD11b, CD11c and CD18 integrin subunits and increased expression of CD36. Following 3 years of therapy, expression of CD11a, CD11b and CD18 integrin, as well CD36 expression, were not found to be significantly altered. Of interest is the finding of a significant increase in the expression of the CD11c integrin subunit (p=0.034) (Table 1).

	Prior to HU initiation	Following HU treatment	p-value
CD11a (%)	94.70±3.67	94.46±5.06	0.859
CD11b (%)	94.42±4.35	96.28±4.03	0.091
CD11c (%)	85.97±7.34	90.64±8.75	**0.034**
CD18 (%)	99.43±1.33	99.90±0.1	0.952
CD36 (%)	0.97±0.46	0.91±0.99	0.213

Summary/Conclusion: The present study failed to reveal an effect of HU on most of the adhesion molecules studied. In order to better interpret study results, evaluation in larger cohorts of Sickle cell beta thalassemia patients is warranted.

PB1773 EPIDEMIOLOGICAL CHARACTERS OF ADULT: EGYPTIAN SICKLE CELL ANEMIA PATIENTS: A SINGLE CENTER EXPERIENCE

M. Elbogdady [1,*], Y. Essam [1]

[1]Hematology, Oncology center Mansoura university - Mansoura university - Egypt, Mansoura, Egypt

Background: Sickle cell anemia (SCA) is a chronic problem with growing with ages consequences. It starts with birth & continues to add complication throughout the patient's life. During his childhood the patient develop a psychological bond with his treating team which makes it traumatic to him when he is transferred to adult hematology service

which might lead to loss of interest in receiving treatment and skipping follow up visits which eventually leads to increased complications and either stopping treatment or developing treatment related adverse events.
Aims:
This is a descriptive study regarding Adult (above the age of 18) SCA patients on follow up with the clinical hematology unit Oncology center Mansoura University, Dakahlia, Egypt who had recorded follow up visits on our System in the period between 2005 and 2020 regarding their age at diagnosis, sex, baseline criteria, presence of crisis or not method of diagnosis and their follow up regimen.
To outline the Demographic characters of Egyptian SCA patients on regular follow up at an adult academic hematology center in Egypt and the characters of their disease
Methods: This is a descriptive study regarding Adult (above the age of18) SCA patients on follow up with the clinical hematology unit Oncology center Mansoura University, Dakahlia, Egypt who had recorded follow up visits on our System in the period between 2005 and 2021 regarding their age at diagnosis, sex, baseline criteria, presence of crisis or not method of diagnosis and their follow up regimen.
By reviewing the data on our system over the period of 1-1-2005 and 1-1-2020 we found that we have 39 SCD anemia patients with 19 males (48.7%) and 20 females (51.3%) as shown in figure 1, Four patients had a less than six months follow up so they were excluded from the final analysis.By reviewing the data on our system over the period of 1-1-2005and 1-1-2020 we found that we have 39 SCD anemia patients with 19 males(48.7%) and 20 females (51.3%) as shown in figure 1, Four patients had aless than six months follow up so they were excluded from the final analysis.
Results: By reviewing the data on our system over the period of 1-1-2005 and 1-1-2021 we found that we have 39 SCD anemia patients with 19 males (48.7%) and 20 females (51.3%), The average age at referral to our center was 24 years with the range of 14.6 – 37.4 years, The median follow up of our patients was 114.8 months (357 – 6).Out of our 35 patients twenty five (71.4 %) were referred to us from the pediatric service while the remaining ten (28.6 %) were newly diagnosed at our unit. Using Hemoglobin electrophoresis twenty eight patients (71.8 %) had done this investigation which showed that 11 (39 %) had sickle-thalassemia while the rest were pure SCA. Spleen was surgically removed in 7 (17.9 %), Non-visualized in 8 (20.6 %) while the remaining 22 had spleen measurable by ultrasonography. 12 (30.7 %) patients had HCV infection, Twenty four (61.5 %) were non transfusion dependent while the remaining 11 (28.2 %) required monthly transfusion. As regard all our 39 patients were accounted for at the time of data analysis
Summary/Conclusion:
Children with SCA need a more smooth transfer from their pediatric service to adult service to help them to be more adherent Children with SCA need a more smooth transfer fromtheir pediatric service to adult service to help them to be more adherent to follow up instead of showing up when they have a problem, require transfusion or in need of a grave intervention and on the other hand all SCA patients require more thorough chelation therapy and supportive measures to avoid end organ damage.

Stem cell transplantation - Clinical

PB1774 THE RELATIONSHIP OF SERUM GROWTH DIFFERENTIATING FACTOR 15(GDF15) TO HEPCIDIN IN POST TRANSPLANT ADULT EGYPTIAN PATIENTS AND ITS PROGNOSTIC SIGNIFICANCE

M. Azzazi [1,*], A. AlAfifi [1], H. Hegab [1], A. El-Ghammaz [1], M. ElRazzaz [1], M. Shazly [1]

[1]Hematology and Bone marrow transplantation, internal medicine, Faculty of Medicine, Ain Shams University, Cairo, Egypt

Background: Hepcidin is a small peptide that is produced in the liver that is most likely the major regulator of iron. Based upon the importance of iron, multiple mechanisms exist for the regulation of hepcidin. Iron levels, inflammation, erythropoiesis and the combined effects of several proteins expressed on hepatocyte membranes are involved. Growth differentiation factor 15 (GDF15) is a member of the transforming growth factor-b (TGF-b).GDF15 expression level is usually low in resting cells but may be substantially increased following response to diverse cellular stress signals, such as hypoxia, inflammation, acute tissue injury and during cancer progression
Aims: The aim was to assess the relationship of serum Growth Differentiating factor 15(GDF15) to hepcidin in post transplant adult Egyptian patients as an assessment for iron overload and their relationship to post transplantation complications
Methods: Serum GDF15 and hepcidin were measured using ELISA in 45 post allogenic(23 patients) and autologous(22 patients) bone marrow transplanted patients 1 year posttransplantation in comparison to 15 healthy controls recruited from Bone Marrow Transplantation Unit, Ain Shams University Hospitals
Results: Serum level of GDF15 and hepcidin level were elevated 1 year post allogenic and autologous transplantation in comparison to control group with a statistically significant difference between patients and control($P<0.001$). GDF15 and hepcidin were positively correlated with ferritin level($p<0.001$). GDF15 and ferritin were positively correlated with acute GVHD and chronic GVHD($P=0.004$ and 0.002 respectively), but hepcidin did not show any significant correlation with acute GVHD(($P=0.110$). Also, GDF15, hepcidin and ferritin were positively correlated with serum levels of ALT and AST in both autologous and allogenic transplanted patients. But, GDF15, hepcidin and ferritin were not correlated with bacterial or viral infections in both allogenic and autologous group of patients
Summary/Conclusion: Both GDF15 and hepcidin are useful biomarkers for iron overload late post allogenic and autologous bone marrow transplantation and both can be used as a predictor for posttransplantation complications

PB1775 SYSMEX XN 1000 CAN PREDICT THE TIME OF STEM CELL COLLECTION WITH NEW COMPLETE BLOOD COUNT PARAMETERS: SINGLE CENTER EXPERIENCE FROM TURKEY

E. Gunduz [1,*], E. Kocaturk [2], H. Kayadibi [2], H. Uskudar Teke [1]

[1]Hematology, [2]Biochemistry, Osmangazi University School of Medicine, Eskisehir, Turkey

Background: Hematopoietic stem cell transplantation is widely perfomed for the treatment of hematological malignancies. Hematopoietic stem cells are mostly collected from peripheral blood. A minimum of $2x10^6$ CD34+ cells/kg is needed for a successful transplant. The amount of CD34+ cells in peripheral blood must be 20/µl in order to collect this amount. The optimal time for stem cell collection varies between patients and the time of initiating stem cell collection should be determined according to peripheral blood stem cell count. The gold standard method for determining the amount of peripheral blood stem cells is flow cytometry. However, this method is expensive and time laboring. In Sysmex XN 1000 (Sysmex Corporation, Kobe, Japan) automatic complete blood count (CBC) analyzers; immature granulocytes(IG) are counted in white blood cell differential (WDF) channel and nucleated red blood cells (NRBC) are counted in white cell nucleated (WNR) channel with fluorescent flow cytometry method. IG is expressed as the sum of metamyelocytes, myelocytes and promyelocytes and NRBC reflects the increase in erythropoietic activity.
Aims: In this sudy; we compared IG and NRBC counts, the routine components of our CBC parameters,with peripheral blood CD34+ cell counts and aimed to find the role of these parameters in determining the time of stem cell collection.
Methods: 86 patients who underwent stem cell mobilization between October 2018 and August 2020 were included in the study. Mobilization and stem cell collection records were evaluated retrospectively. Peripheral blood CD34+ cells were analyzed with flow cytometer (Becton Dickinson Biosciences FACS Calibur, California,US) according to ISHAGE guidelines. The time of analyzes were determined according to white blood cell count.(WBC) IG and NRBC analyzes were performed by Sysmex XN 1000 (Sysmex Corporation, Kobe, Japan) on the same day with flow cytometry which was also the first day of stem cell collection. Patients were divided into 2 groups according to periheral blood CD 34+ cell count/µl (≤20= group 1 vs >20= group 2). IG ratio was calculated with the formula of IG count x 100 / WBC count and NRBC ratio was calculated with the formula of NRBC count x 100 / RBC count.
Results: The median age was 56 years and 48.8% were female. The diagnosis were multiple myeloma in 56, non Hodgkin lymphoma in 18, Hodgkin lymphoma in 8, plasma cell leukemia in 2, amyloidosis in 1 and

multiple plasmositoma in 1 of the patients. Mobilization regimens were cyclophosphamide + G-CSF in 55, DHAP + G-CSF in 7, ICE + G-CSF in 12, hyperCVAD + G-CSF in 5, plerixafor + G-CSF in 2, G-CSF alone in 4 and etoposide + G-CSF in 1 of the patients. When we compared CBC parameters we found that only IG ratio, NRBC ratio and NRBC counts were different between 2 groups ($p< 0.001$, $p= 0.011$ and $p= 0.012$, respectively). IG ratio, NRBC ratio and NRBC counts were positively correlated with peripheral blood CD34+ cell counts. The index formulated with multivariate logistic regression analysis was -1.7 + (IG% x 0.12) + (NRBC% x 2) and the cut off was zero. According to these results, the parameter with the highest diagnostic accuracy was the new index with an AUC of 0.766 (0.665 – 0.867). The sensitivity of the index was 76% and specifity was 72% with a cut off of zero.
Summary/Conclusion: In conclusion, the new index formulated from the CBC parameters can predict the time for beginning stem cell collection with a more fast and less expensive way compared with the gold standard flow cytometry. However, this data must be validated with larger multicenter prospective studies.

PB1777 PATIENT-CENTERED FACTORS IN EVALUATION OF ELIGIBILITY AND PROGNOSTICATION IN HEMATOPOIETIC STEM CELL TRANSPLANTATION IN OLDER PATIENTS WITH HEMATOLOGIC MALIGNANCIES – A SYSTEMATIC REVIEW

S. Koeck [1,*], F. Prader [1], I. Stojkov [2], K. Koinig [1], R. Stauder [1]

[1]Internal Medicine V, Hematology/Oncology, Medical University of Innsbruck, Innsbruck, [2]Department of Public Health, Health Services Research and Health Technology Assessment, UMIT - University for Health Sciences, Medical Informatics and Technology, Hall in Tirol, Austria

Background: Hematopoietic stem cell transplantation (HSCT) represents a cornerstone in individualized treatment algorithms in blood cancer. However, assessment of eligibility and outcome prediction remains challenging, particularly at advanced age.
Aims: This systematic review investigates the relevance of patient-orientated scores in decision-making in HSCT.
Methods: We performed a systematic review with a literature search on MEDLINE and Web of Science on the use and prognostic relevance of patient-centered scores in allogeneic and autologous HSCT in adult patients with hematologic malignancies.
Results: After screening 2326 studies, we identified 59 studies using at least one validated score to determine eligibility for HSCT, including 57 studies assessing performance status (PS) and three studies using comorbidity scores. Prognostic relevance of comorbidities was analysed in 128 studies, of PS in 67, of functional activities in three, of nutritional status in ten and of health-related quality of life (HRQOL) in six studies. Based on uni-/multivariate analyses, predictors of overall survival in allogeneic HSCT included comorbidities in 42/72 (58%) and in 39/58 (67%), PS in 20/33 (61%) and 30/37 (81%), nutritional status in 1/3 and 3/5, functional activities in 2/3 and 2/2 and HRQOL in 2/3 and 2/2, respectively. Likewise, comorbidities were predictors of reduced survival in autologous HSCT in 3/9 (33%) and 4/7 (57%) and PS in 4/5 (80%) and 4/6 (67%), respectively.
Summary/Conclusion: To date, validated patient-centered scores have been rarely used to evaluate eligibility for HSCT. The prognostic impact of comorbidities and of PS was demonstrated in a relevant proportion of studies and the results for the relevance of functional activities and HRQOL are encouraging. Thus, the relevance and further integration of patient-orientated scoring in decision-making in HSCT is underlined.

PB1778 IS THE USE OF DEFIBROTID EFFECTIVE ON GRAFT VERSUS DISEASE (GVHD) IN ALLOGENEIC STEM CELL TRANSPLANTATION?

A. Turgutkaya [1,*], I. Yavaşoğlu [1], H. Eroğlu Küçükdiler [1], G. Kadıköylü [2], G. Sargın [3], A. Z. Bolaman [1]

[1]Hematology, Adnan Menderes University Medicine Faculty, Aydın, [2]Hematology, Kent Hospital Department of Hematology and Bone Marrow Transplantation, İzmir, [3]Rheumatology and Immunology, Adnan Menderes University Medicine Faculty, Aydın, Turkey

Background: Hepatic sinusoidal obstruction syndrome (SOS) is one of the complications of allogeneic stem cell transplantation (allo-SCT) due to endothelial dysfunction. Defibrotide (DF) is used effectively in SOS prophylaxis and treatment because of its endothelial protective and thrombocytic-fibrinolytic regulatory effects. On the other hand, graft versus host disease (GVHD), regardless of whether acute chronic or overlap syndrome, is the most important cause of morbidity and mortality in ASCT.
Aims: Here, we retrospectively investigated the use of DF and its effect on the development of GVHD in our allogeneic transplant patients.
Methods: Eighty-one patients with various diagnoses (including myeloid and lymphoid hematological malignancies and aplastic anemia), who underwent allo-SCT at the Hematology Department of Adnan Menderes University between 2014-2020 were included. Of the patients, 34 used DF as a prophylaxis (25mg/kg/day, intravenously, 21 days) while 47 patients did not. Acute and chronic GVHD and overlap syndrome assessment were performed at +30/100th day and throughout the life of the patient, respectively. The data were evaluated using SPSS 21 software program (Chicago, IL, USA). Chi-square test was used to demonstrate the difference between categorical variables. A p value below 0, 05 was the cutoff for statistical significance.
Results: The results for the patients are presented in Table 1. Thirteen patients (38%) in the DF group and 16 patients (34%) in the non-DF group received myeloablative conditioning regimens containing busulfan. The rest of the patients in both groups received non-myeloablative or reduced intensity conditioning regimens. Acute GVHD was more common in patients who received DF, compared to patients who did not receive it (82% vs 61%). Although rates of chronic GVHD differ among DF users compared to non-users (31% vs 19%); it did not reach a statistically significant value (p: 0,274). While no patient died in the group that did not use DF, 5 patients died in the first 100 days in the group using DF. Overlap GVHD was observed in 4 patients. We observed that 1 patient in the non-DF group developed SOS according to the European Bone Marrow Transplantation (EBMT) criteria.

	DF (+) N: 34	DF(-) N:47	p

-with	9	9	
Overlap GVHD	2	2	
SOS development	-	1	

Table 1: Comparison of patients according to defibrotide use

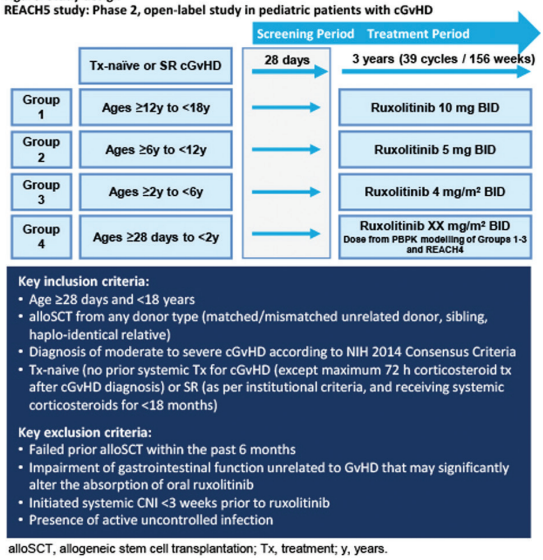
Summary/Conclusion: In our study, DF use was evaluated in terms of the development of acute and chronic GVHD and we noted the development of more acute GVHD with the use of DF. There was no difference in the development of chronic GVHD. There are few studies in the literature evaluating the relationship between DF use and GVHD. In an in vitro study on mice, DF use was shown to be effective in acute GVHD through T lymphocyte and neutrophil interaction. In another experimental study, it was shown to suppress acute GVHD by inhibiting the "endothelial cell line" activation. In contrast to our study, acute GVHD was less common in another clinical study by Tekgündüz et al (46, 5% vs 82%). To the best of our knowledge, this is the first study evaluating the effect of DF on both acute and chronic GVHD in the adult population. The use of DF for prophylaxis is mostly preferred in high risk patients. Development of GVHD is also important for this risk group. These risks may explain the higher rate of acute GVHD in the DF group in our study. The effects of DF use on GVHD will be clarified with studies in which both the use of DF and risk subgroups of GVHD development are evaluated using a high and homogeneous number of patients.

PB1779 CLINICO-HEMATOLOGICAL PREDICTORS OF RESPONSE DEEPENING AFTER STEM CELL TRANSPLANTATION IN PATIENTS WITH MULTIPLE MYELOMA

I. Kostroma [1,*], A. Zhernjakova [1], R. Sabitova [1], E. Stepchenkova [1], S. Bessmel'tsev [1], S. Gritsaev [1]

[1]Bone marrow transplantation, Russian Research Institute of Hematology and Transfusiology, S.Petersburg, Russian Federation

Background: The effectiveness of multiple myeloma (MM) patients' treatment is dependent on the response to therapy including the stage of autologous stem cell transplantation (AutoSCT). The importance of predictors associated with the quality of response after AutoSCT is due to the possibility to change the option and intensity of condiioning regimen and/or posttransplantation consolidation.
Aims: To determine the frequency of MM cases without the improving of response after AutoSCT and evaluate the possibility to predict the effectivence of AutoSCT using clinical and hematological parameters.
Methods: Retrospective analyses of 84 patients' data have been done. Total number of performed AutoSCT was 112 including 84 the first and 28 the second transplantation. The response was determined according to IMWG criteria.
Results: Before the first AutoSCT the number of patients with complete (CR), very good partial (VGPR) and partial (PR) response were 31, 19 and 33 accordingly. One patient has MM stabilisation. Improving of the response depth after the first AutoSCT was recorded in 29/53 (54.7%) patients. Frequency of CR was higher in patients with previus VGPR than PR: 11/19 (57.9%) vs 6/33 (18.2%); p=0.005; OR=6.19, 95%CI 1.7-22. In the group without improving of response the number of patients received additional drugs to standard schemes with bortezomib and lenalidomide was higher than in the group with depeening of response: 29.2% vs 13.8%; difference not significant. The same situation was in relation to Mel200 conditioning regimen: 65.6% vs 79.3%.: difference not significant. The effectiveness of the second AutoSCT was evaluated in 2 patients with VGPR and 6 patients with PR. All patients with VGPR and 1 patient with PR had CR and 1 patient with PR reached VGPR. 4 patients with PR did not improve their response after the seconf AutoSCT.
Summary/Conclusion: Reaching of CR after AutoSCT in patients with MM is dependent on the quality of previous response, scope of induction therapy and intensity of conditioning regimen.



PB1780 A PHASE 2 OPEN-LABEL, SINGLE-ARM, MULTICENTER STUDY OF RUXOLITINIB ADDED TO CORTICOSTEROIDS IN PEDIATRIC SUBJECTS WITH MODERATE/SEVERE CHRONIC GVHD AFTER ALLOGENEIC STEM CELL TRANSPLANTATION (REACH5)

C. Diaz-de-Heredia [1,*], K. Koh [2], S. Bhat [3], Y. Takahashi [4], A. Zhang [5], C. Rosko [6], Y. Smith [7], T. Stefanelli [5], F. Locatelli [8]

[1]Hospital Universitari Vall d'Hebron, Barcelona, Spain, [2]Saitama Children's Medical Center, Saitama, Japan, [3]Mazumdar-Shaw Medical Center, Bangalore, India, [4]Nagoya University Graduate School of Medicine, Nagoya, Japan, [5]Novartis Pharma AG, Basel, Switzerland, [6]Novartis Pharmaceuticals Corporation, East Hanover, United States, [7]Novartis Ireland Limited, Dublin, Ireland, [8]Sapienza, University of Rome and IRCCS Ospedale Pediatrico Bambino Gesù, Rome, Italy

Background: Graft-vs-host disease (GvHD) may significantly impair the success rate of allogeneic stem cell transplantation. In pediatric patients, chronic GvHD (cGvHD) can lead to considerable morbidity, impaired quality of life and transplant-related mortality (Inagaki 2015). Although systemic corticosteroids are the standard of care in initial stages of moderate to severe cGvHD, there is little controlled trial evidence to indicate the best initial or second-line treatment strategy. In recently reported data from the phase 3 REACH3 study, ruxolitinib improved overall response rate (ORR) versus best available therapy in adults and adolescents (≥12 years of age) with steroid-refractory (SR) or steroid-dependent cGvHD (Zeiser ASH 2020 [abstract 77]; NCT03112603). Furthermore, ruxolitinib has demonstrated encouraging activity in SR cGvHD pediatric patients in case series and a single center study (González Vicent 2019, Moiseev 2020). These data, combined with knowledge of the role played by janus kinase-signal transducer and activator of transcription (JAK-STAT) signaling in cGvHD pathophysiology, support the investigation of ruxolitinib in the pediatric cGvHD patients.
Aims: The REACH5 study will assess the safety, efficacy, and pharmacokinetics (PK) of ruxolitinib in pediatric patients with moderate to severe treatment-naive or SR cGvHD.
Methods: REACH5 is a Phase 2 open-label, single-arm, multicenter study of pediatric patients aged ≥28 days to <18 years divided into four age groups (see **Figure** for details). Patients are eligible for inclusion if diagnosed with moderate to severe cGvHD (National Institutes of Health [NIH] 2014 Consensus Criteria) and are either treatment-naïve or SR (as per institutional criteria and still receiving systemic corticosteroids). Patients will be treated for up to approximately 3 years (39 cycles/Week 156). The primary objective is to evaluate the activity of ruxolitinib twice daily (BID) added to corticosteroids +/- calcineurin inhibitor (CNI) measured by ORR at Week 24. Secondary endpoints include ruxolitinib safety, PK in treatment-naive and SR cGVHD, percentage of participants with ≥50% reduction from baseline in daily corticosteroid dose at Cycle 7 Day 1, duration of response, best overall response and failure-free survival. The study will enroll a minimum of 5 evaluable patients in Groups 1, 2 and 3, no minimum number of evaluable subjects in Group 4, and no cap to enrollment in any group. Group 1 patients will be treated at 10 mg BID, which is already considered the recommended phase 2 dose for this age group. Based on a review of PK data in the same aged group of patients treated in the pediatric acute GvHD study REACH4 [NCT03491215], the Group 2 dose has been confirmed at 5 mg BID and Group 3 dose at 4 mg/m² BID. Enrollment initiation into Group 4 will be subject to the availability of data in this age group from REACH4, as well as a review of available PK, safety, and activity data generated from Groups 1 to 3 in the current study.
Results: Trial in progress.

Figure. Study design
REACH5 study: Phase 2, open-label study in pediatric patients with cGvHD

alloSCT, allogeneic stem cell transplantation; Tx, treatment; y, years.

Summary/Conclusion: As of February 2021, 25 patients have been enrolled. Enrollment is ongoing for Groups 1 and 2, with Group 3 opening in 2021 (ClinicalTrials.gov: NCT03774082).

PB1781 EFFECT OF CYP3A5 GENE POLYMORPHISMS ON TACROLIMUS CONCENTRATION AND ADVERSE EVENTS IN PATIENTS UNDERGOING ALLOGENEIC HEMATOPOIETIC STEM CELL

X. chen [1,*], R. zhang [1], W. zhai [1], Q. ma [1], A. pang [1], D. yang [1], Y. he [1], J. wei [1], E. jiang [1], S. feng [1], M. han [1]

[1]cell transplant center, Chinese Academy of Medical Sciences Institute of Hematology and Blood Disease, tianjin, China

Background: Acute graft-versus-host disease (aGVHD) is one of the major life-threatening complications after HSCT. Prevention of severe aGVHD is crucial to the success of HSCT.
Aims: To investigate the relationship between CYP3A5 gene polymorphisms and tacrolimus concentration and acute graft versus host disease (GVHD) in patients undergoing hematopoietic stem cell transplantation (HSCT).

Methods: Retrospective analysis the clinical data of 35 Chinese adult patients received allo-HSCT from 2019.7 to 2020.2. Bone marrow samples were collected before transplantation for CYP3A5 genotyping. Intravenous infusion of tacrolimus and short course of methotrexate (MTX) ± mycophenolate were used to prevent GVHD. The initial concentration was monitored on the second or third day of tacrolimus administration, followed by 2-3 times a week. The drug dose was adjusted according to the target blood concentration (10-15ng / ml). The incidence of III-IV aGVHD in patients with CYP3A5*1 alleles was higher than that in patients with CYP3A5*3/*3 gene (26.3+10.1% vs 6.2+6.1%, P=0.115).
Results: In 16 HSCT patients with CYP3A5 * 3 / * 3 gene, the initial concentration of tacrolimus (9.82 vs 8.53 ng / ml), the initial concentration / dose (C / D) ratio (5.72 vs 4.26 ng / ml / mg), and the median C / D ratio in the first two weeks after HSCT (5.29 vs 4.61 ng / ml / Mg, 5.65 vs 4.56 ng / ml / mg) were significantly higher than 19 patients with at least one CYP3A5 * 1 allele (P = 0.026, 0.001, 0.037, 0.045).
Summary/Conclusion: CYP3A5 genotype directed administration may help to achieve the target blood concentration of tacrolimus after HSCT more quickly, reduce the incidence of severe aGVHD and improve the efficacy of transplantation.

PB1782 ANTIGENIC DIVERSITY OF THE MAJOR HISTOCOMPATIBILITY COMPLEX AMONG RECIPIENTS, RELATED DONORS AND HEMATOPOIETIC STEM CELL DONORS OF THE REGISTRY OF THE REPUBLIC OF BELARUS

A. Hlaz [1,*], A. Uss [2]

[1]HSC donor registry, [2]Director of Hematology and bone marrow transplantation, Minsk Scientific and Practical Center for Surgery, Transplantology and Hematology, Minsk, Belarus

Background: Modern trends in hematopoietic stem cell transplantation with high donor requirements (10/10 HLA-matching of donor and recipient, infectious status, young donor age) require new approaches to the operation of registries and donor centers. There are various strategies not only to attract more potential HSC donors, but also to increase the diversity of HLA phenotypes. The allele frequencies of the HLA system are specific for populations, which limits the number of different phenotypes that we obtain when typing new potential donors.
Aims: to analyze antigenic diversity in the population of siblings, patients and HSC donors of the registry.
Methods: The analysis included the results of HLA typing of 216 patients and 289 siblings, 27 885 phenotypes HSC donor of the registry of the Republic of Belarus.
Results: The results of the study of the frequency of occurrence of antigens in patients, siblings and HSC donors of the registry presented in Table 1.

Table 1
Comparison of the frequency of occurrence of antigens in the phenotypes of patients, siblings and HSC donors of the registry.

	patient	sibling	registry	p-value corrected for multiple comparisons		
				patient vs sibling	patient vs registry	sibling vs registry
A26	14 (3,2)	18 (3,1)	5581 (5,5)	>0,99	0,103	0,045
A33	13 (3)	11 (1,9)	1119 (1,1)	0,346	0,001	0,207
A68	15 (3,5)	19 (3,3)	553 (0,5)	>0,99	<0,001	<0,001
B14	13 (3)	18 (3,1)	1720 (1,6)	>0,99	0,078	0,026
B15	26 (6)	37 (6,4)	1348 (1,3)	0,918	<0,001	<0,001
B40	28 (6,5)	55 (9,5)	1284 (1,2)	0,108	<0,001	<0,001

Summary/Conclusion: Taking into account the results obtained, it can be concluded that there are differences in the phenotypes of related and unrelated HSC donors. The revealed differences in the frequency of occurrence of antigens suggest the formation of unique phenotypes that differ from the general population, the inclusion of which in the information base will increase the antigenic diversity of the main histocompatibility complex in the population of HSC donors of the registry, which will increase the number of suitable donor-recipient pairs.

PB1783 COMPARATIVE EFFECTIVENESS OF DIFFERENT CONDITIONING REGIMENS WHEN PERFORMING AUTOLOGOUS STEM CELL TRANSPLANTATION IN MULTIPLE MYELOMA PATIENTS

I. Kostroma [1,*], A. Zhernjakova [1], R. Sabitova [1], Z. Sidorova [1], S. Bessmel'tsev [1], S. Gritsaev [1]

[1]Bone marrow transplantation, Russian Research Institute of Hematology and Transfusiology, S.Petersburg, Russian Federation

Background: The principal role of autologous stem cell transplantation (AutoSCT) in patients with multiple myeloma (MM) is dependent primarilly on cytoreductive action of conditioning regimen (CR). There are different approaches to strengthen antimyeloma exposure of CR and one of them is adding a new drug to standard used melphalan
Aims: The aim was to compare the effectiveness of standard used CR with melphalan (Mel) monotherapy with combination of Mel with thiotepa (Mel/Thio) and combination of Mel with carfilzomib (Mel/Carfil). Progression free survavl (PFS) was chosen as a measure of CR effectiveness
Methods: Response to therapy before AutoSCT was identified with IWG criteria. PFS was calculared from the data of AutoSCT in patients without MM progression during the first 3 months. Thre groups of patients were formed: the first group of 27 patients with CR Mel200/140, the second group of 9 patients with CR Mel/Thio and the third one of 8 patients with CR Mel/Carfil
Results: Median age of patients in the group one, two and three was 54y, 59y and 57.5 y accordingly. The number of patients with comple, very good partial and partial response was 10, 7 and 10 in the first group, 1, 4 and 1 in the second group and 1, 1 and 6 in the third group. The patients' follow-up period was 14 (3-40), 13 (10-26) and 11.5 (3-18) months in the groups accordingly. The median PFS was 40 mo, 13 mo and not achived in the groups accordingly: p=0.833. Difference in the data of PFS between indidvidual groups has not been found too
Summary/Conclusion: Despite the lack of distinction, the trend towards improved PFS in the group with the pre-eminent number of MM patients with partial response treated with regimen Mel/Carfil possibly reflects a more pronounced antimyeloma effect of this CR. A longer period of observation is needed for the final conclusion

PB1784 USE OF RECOMBINANT SUPEROXIDE DISMUTASE IS THE EFFECTIVE METHOD TO REDUCE TOXIC COMPLICATIONS IN PATIENTS WITH MULTIPLE MYELOMA AFTER AUTOLOGOUS STEM CELL TRANSPLANTATION

A. Zhernjakova [1,*], I. Churilova [2], I. Kostroma [1], N. Leonova [2], R. Sabitova [1], Z. Sidorova [1], S. Bessmel'tsev [1], S. Gritsaev [1]

[1]Bone marrow transplantation, Russian Research Institute of Hematology and Transfusiology, [2]Biochemical Laboratory, Research Institute of Highly Pure Biopreparations, S.Petersburg, Russian Federation

Background: It is well known that high dose chemotherapy may lead to the strengthening of oxidative stress that may be an additional factor of internal injuries and deteriorating of the patients' condition. It has been shown previously that increased oxidative stress after conditioning regimen with melphalan in patients with multiple myeloma (MM) can be considered as a reason of worthening of quality of life too.
Aims: To evaluate the influence of recombinant superoxide dismutase (Rexod®) (SOD) on some parameters of oxidative stress in MM patients during autologous stem cell transplantation (AutoSCT).
Methods: 6 VV patients with median of age 50 y (39-60) were included in the trial after signing the informed consent. Levels of SOD, total SH-groups, active oxigen species, malondialdehide (MDA) were studied. 9.6 - 16x10/6/U of recombinant SOD was infused IV within 10-15 minutes at -2, +1, +7 and +14 days.
Results: Baseline level of SOD was reduced in 2 and more times compared to the norm. Futher decline of SOD was fixed on +7 day in 4 patients. Level of SOD did not change in 2 other patients. Baseline level of active oxygen species was increased (by maximum of 20 times) or decreased (by 1.3-1.8 times) in 5 patients. Levels of MDA and SH-groups did not differ from the norm. Postinduction reactions were not fixed in any case. One episode of febrile neutropenia took place in (16%) patient. Short-term

elevation of transaminases of grade 1 was detected in 2 (33%) patients. Median time of neutrophils and platelets engraftment was 12 (10-15) and 14.5 (13-17) day accordingly. On day +14 restoring of SOD and active oxygen species levels to the indicators corresponding to AutoSCT were fixed. Despite the positive dynamics of significant markers of oxidative stress, they did not reach the norm in any patient.
Summary/Conclusion: The use of Rexod®, which has anti-inflamatory properties, leads to a decrease in undesirable toxic effects. It is possible that an increase in the dose and duration of Rexod® using will give a more pronounced positive effect.

PB1785 THE RESULTS OF THERAPY IN PATIENTS WITH B-CELL LYMPHOID MALIGNANCIES WITH MUTATIONS IN THE TP53 GENE

E. Zvonkov [1,*], D. Koroleva [1], N. Gabeeva [1], M. Drokov [2], O. Gavrilina [3], A. Smol'yaninova [1], O. Shchetsova [1], S. Tatarnikova [1], A. Belyayeva [1], A. Garmash [1], D. Badmazhapova [1], A. Chelmakov [1], D. Rogozhkina [1], O. Koroleva [2], N. Popova [2], V. Vasilieva [2], B. Biderman [4], A. Gubkin [5], A. Sudarikov [6], L. Kuzmina [7], E. Parovichnikova [2], V. Savchenko [8]

[1]Department of intensive high-dose chemotherapy for lymphomas, [2]Department of hemoblastosis and BMT, [3] Department of Chemotherapy of Hematological malignancies and Hematopoietic Depressions and Bone Marrow Transplantatio, [4], Laboratory of Molecular Hematology, National Research Center for Hematology, [5]Central Clinical Hospital No 2 named Semashko, [6]Laboratory of Molecular Hematology, [7]Department of Chemotherapy of Hematological malignancies and Hematopoietic Depressions and Bone Marrow Transplantatio, [8]National Research Center for Hematology, Moscow, Russian Federation

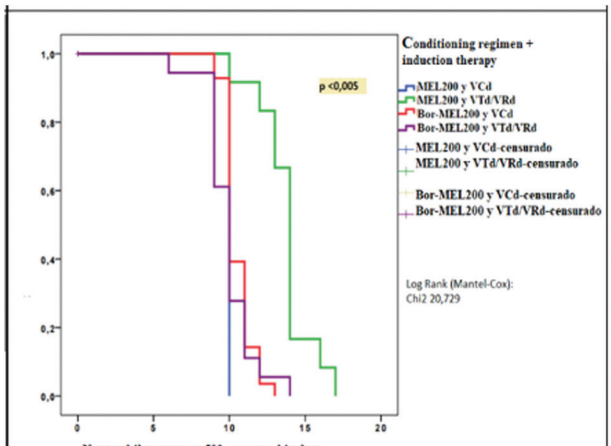
Background: Mutations in the *TP53* gene in lymphoid malignancies occur in about 19,3% of cases. Patients are carrying mutations in *TP53* do not benefit from intensive chemotherapy regimen and have poor prognosis. The only approach to achieve long-term remission is to use cell therapy in the first line: allogeneic hematopoietic cell transplantation and CAR-T cell therapy. The use of targeted therapy does not allow achieving long-term remissions and is justified only as a bridge to cell therapy.
Aims: To evaluate the prognostic value of mutations in the *TP53* gene in patients with B-cell lymphoid malignancies and the results of therapy in this group of patients.
Methods: During the period from 2016 to 2021, 95 patients with B-cell lymphoid malignancies were included in the prospective study: 47 pts - mantle cell lymphoma, 16 pts - primary mediastinal lymphoma, 12 pts - diffuse large B-cell lymphoma, 8 pts - "double-hit" lymphoma, 7 pts - follicular lymphoma grade 3, 3 pts - Burkitt's lymphoma, 1 pt – plasmablastic lymphoma, 1 pt - chronic lymphocytic leukemia. Sanger DNA sequencing and NGS carried out analysis of mutations in the *TP53* gene.
Results: *TP53* mutations were detected in 18 of 95 patients (19%): 11 pts – mantle cell lymphoma, 2 - diffuse large B-cell lymphoma, 1 pt - "double-hit" lymphoma, 1 pt - Burkitt's lymphoma, 1 pt - primary mediastinal lymphoma and 1 pt – plasmablastic lymphoma. In our study of eight patients with mutations in the *TP53* gene underwent haploidentical (4), matched unrelated (3), mismatched related (1) allo-HCT between 2016 and 2021.
Five out of 8 patients before allo-HCT received targeted therapy: 4 patients as a bridge to allo-HCT after previous chemotherapy (3 pt - MCL, 1 pt – DLBCL), 1 pt with PL - in combination with induction chemotherapy (mNHL-BFM-90 + lenalidomide) and 1 patient with CLL - in as a first-line therapy ibrutinib with venetoclax was administered before allo-HCT.
Five out of 8 patients remain in complete remission of the disease without signs of GVHD with follow-up from 1 to 52 months: 3 pt – mantle cell lymphoma, 1 pt - plasmablastic lymphoma, 1 pt - chronic lymphocytic leukemia.
Three out of 8 patients died after allo-HCT: 1 pt - due to severe toxic and infectious complications (DLBCL), 2 pt – due to progression disease (MCL).
One patient with «double-hit» lymphoma underwent CAR-T cell therapy. With a follow-up period of 6 months, the patient remain in complete remission.
Among other patients five died of disease progression (4 pts – MCL, 1 pt – BL, 1 pt – PML), despite the use of various chemotherapy regimens and targeted therapy. Four patients are currently undergoing therapy.
Summary/Conclusion: The presence of mutations in the *TP53* gene is characterized by an extremely unfavorable impact on the prognosis and survival of patient with lymphoid malignancies. *TP53* mutations should be considered for risk models in all B-cell lymphoid malignancies. Allo-HCT improves outcomes for patients with mutant *TP53*. CAR-T cell therapy can serve as an alternative approach to the therapy of patients with B-cell lymphoid malignancies with mutations in the *TP53* gene.

PB1786 PREEMPTIVE VS SALVAGE RUXOLITINIB TREATMENT FOR STEROID-INSENSITIVE ACUTE GRAFT-VERSUS-HOST-DISEASE (SI-AGVHD): WHICH APPROACH IMPROVES CLINICAL OUTCOMES?

J. Ren [1], K. Lin [1], J. Xu [1], Q. Lu [1], Y. Luo [1], J. Lu [1], Y. Weng [1], Y. Zhang [1], M. Chen [1], Z. Chen [1], R. P. Gale [1], J. Hu [1], T. Yang [1,*]

[1]Department of Hematology, Fujian Medical University Union Hospital, Fuzhou, China

Background: Ruxolitinib (RUX) has been approved for second line treatment of acute graft-versus-host disease (aGVHD). However, the optimal timing for steroid-insensitive aGVHD (SI-aGvHD) remains unclear.
Aims: In this context, our multi-center retrospective study aimed to assess the benefits and risks of initiating RUX treatment for aGvHD poorly responsive to corticosteroid therapy within 7 days (preemptive strategy) compared to that longer than 7 days (salvage strategy).
Methods: The study was a multi-center retrospective study to compare the efficacy and safety profiles of preemptive versus salvage RUX treatment. A total of 49 patients were included, with 32 receiving preemptive RUX within 7 days when fail response to prior steroid and 17 patients treated with salvage RUX longer than 7 days.
Results: The two cohorts were well-matched demographically. Although the baseline condition of aGVHD in both groups were more than half are stage II and mainly with skin involvement, more patients (71.9% vs 35.3%, p==0.015) achieve CR in preemptive cohort which also led to a better survival outcome. The median time to response was shorter in patients treated with preemptive RUX (7 days vs 14 days, p=0.157). The risk of adverse events was comparable between the two groups (SAEs: 25% vs 24%, symptom of Cytopenia:43.8% vs 35.3%, viral reactivation:50% vs 23.5%). No adverse events led to treatment discontinuation and no viral infections had been documented. The mortality rates were low in 2 cohorts (21.9% vs 23.5%, P=0.582), mainly due to opportunistic infections and aGVHD progression.
Summary/Conclusion: It became more common to prompt RUX intervention for patients with SI-GVHD in clinical practice. Consistent with expectations, preemptive strategy was associated with significant better outcomes and rapid improvement in this patient populations. Further prospective trials will be important to confirm the preemptive impact.



PB1787 BORTEZOMIB + HIGH-DOSE MELPHALAN (BORMEL200) VERSUS MEL200 AS A CONDITIONING REGIMEN FOR AUTOLOGOUS HEMATOPOIETIC PROGENITORS TRANSPLANTATION (TAPH) IN NEWLY DIAGNOSED MULTIPLE MYELOMA (NDMM).

M. I. Nuevo López [1,*], B. Merchan Muñoz [1], A. Gil Perez [1], H. Guillen Garcia [1], M. Argumanez [1], A. Vazquez Ramo [1], A. B. Santos [1], N. Golbano [1], S. Herrero Martín [1], J. Arbeteta Juanis [1], D. Morales [1], M. Diaz Morfa [1], D. Subirá [1], D. De Miguel Llorente [1]

[1]Hematology, Hospital, Guadalajara, Spain

Background: Therapeutic strategy for transplant-eligible NDMM patients (pts) is triplet-based induction scheme, with novel therapeutic agents (immunomodulators (IMIDs), proteasome inhibitors (IP) and even monoclonal antibodies as Daratumumab), to obtain better responses prior to conditioning regimen and TAPH. The standard of conditioning is MEL200. BORMEL200 vs MEL200 conditioning has been proposed, with better responses, similar toxicity, and prolonged progression-free survival (PFS) and overall survival (OS).

Aims: To analyse efficacy and toxicity depending on the administered conditioning: BORMEL200 vs MEL200 and VCd induction vs VTd / VRd.
Methods: Unicentric, descriptive and retrospective study carried out at Guadalajara University Hospital, from February 2010 to June 2020, using clinical and analytical NDMM pts data with ≥ partial response in the 1st line of treatment (tt). From February 2010 to July 2019, pts received BORMEL200: Bor sc (1mg/m2) days -6, -3, +1, +4 + MEL200 iv (200mg/m2) day -2, with G -CSF from day +7. From July 2019 to present, MEL200 iv, without G-CSF. In each conditioning, induction subgroups were analyzed: VCd vs VTd / VRd.
Results: We identified 61 pts whose clinical characteristics and treatment (tt) data are listed in Table 1. 48 (78,7%) received BORMEL200 and 13 (21,3%) MEL200. In general, pts received bortezomib (V) - based induction, of them 51% (n=31) were treated with alkylating agents and 49% (n=30) received immunomodulatory drugs.
In the group of BORMEL200, after a median follow-up of 9,7 years, the PFS and OS median for VCd and for VTd/VRd was 4,2 years and 9,7 years vs 4,7 years and not reached, respectively. In a PFS multivariable analysis, were included as independent variables: sex, age >65 years old, use of IMIDs (VTd/VRd), ISS, preTAPH response, high risk cytogenetic and infused CD34/kg quantity. It was associated independently to relapse: IMID use (HR 0.119; p = 0.003), age> 65 years (HR 0.832; p <0.001), ISS-2 vs ISS-1 (HR 62.2; p <0.001), ISS-3 vs ISS-1 (HR 36.3; p = 0.004).
In the MEL200 group, statistical data is not offered due to the few pts treated in both arms and short follow-up period.
Regarding toxicity, the median of platelet recovery >20,000 was similar in both conditioning regimens. It was only found a significant association in the time till recovery neutrophils >500/ul, being superior in pts who received G-CSF during TAPH (Figure 1).

Neutrophils recovery >500, measured in days

Conditioning regimen + induction therapy	Median CI 95%		Median	
	Lower limit	Upper limit	Estimate	Error típico
MEL200 y VCd	.	.	10,000	.
MEL200 y VTd/VRd	13,578	14,422	14,000	,215
Bor-MEL200 y VCd	9,662	10,338	10,000	,172
Bor-MEL200 y VTd/VRd	9,379	10,621	10,000	,317
Global	9,545	10,455	10,000	,232

Figure 1. Toxicity results. Comparison of both condicioning regimens and its subgroups, Neutrophils >500/uL and platelets >20,000/uL recovery.

Summary/Conclusion: Among the patients with BORMEL200, the use of IMIDs does not provide better SLP in our series. BORMEL200 with VTd/VRd gets better postTAPH responses. An early recovery of neutrophils in conditioning with G-CSF is observed, with the clinical and socioeconomic implications associated. More patients need to be included in both treatment branches and a better follow-up and monitoring so that data may be confirmed.

PB1788 RESULTS OF SECOND ALLOGENEIC HEMATOPOIETIC STEM CELL TRANSPLANTATION IN PATIENTS WITH HEMATOLOGICAL DISEASES: RETROSPECTIVE ANALYSIS OF OUR HOSPITAL

E. Paumard Rodríguez [1,*], C. Aparicio Pérez [1], M. S. Vázquez Díaz [1], E. García Torres [1], R. Rojas Contreras [1], J. R. Molina Hurtado [1], A. Rodríguez Villa [1], J. Serrano López [1], S. Tabares Carrasco [1], C. Martín Calvo [1]

[1]Hematology and Hemotherapy, Reina Sofía Hospital, Córdoba, Spain, Córdoba, Spain

Background: Performing a 2nd Hematopoietic Stem Cell Transplantation (HSCT) after the relapse of the underlying disease is one of the therapeutic strategies in patients who achieve a response after relapse.
Aims: The aim of our study is to analyze the results and prognostic factors in patients who underwent a 2nd allogeneic HSCT.
Methods: We studied 126 patients who received a 2nd allogeneic HSCT in our center between 1995-2019, the 1st HSCT being autologous or allogeneic. Two groups were established: 1st: 1st autologous-2nd allogeneic / 2nd: 1st allogeneic-2nd allogeneic. Patient's characteristics are shown in Table1.
Results: With a median follow-up of 96 months (range: 21-300), the probabilities of overall survival (OS), progression-free survival (PFS), and probability of relapse (RP) at 5 and 10 years are 44.5 ± 5% (5 years); 31±5% (10 years), 38.9± 5% (5 years); 29.2± 5% (10 years) and 38 ± 6% (5 years); 46.2±7% (10 years) in the 1st group and 35.1±9% (5 years); 30±9% (10 years), 38.9± 9% (5 and 10 years) and 53.7±10% (5 and 10 years) in the 2nd group, respectively.
Transplant-related mortality in the first 100 days (TRM100) and global TRM are 23.4% and 39.4% in the 1st group and 12.5% and 18.8% in the 2nd group, respectively. There are no differences in the TRM100 or global TRM according to the intensity of the 2nd HSCT conditioning.
PFS is higher in patients transplanted in complete response: 43±7% vs 23.5±6% (p= 0.17). This advantage in PFS reached statistical significance in the 1st group: 45 ± 7.8% vs 16 ± 6%, p = 0.05. (Figure 1)
The presence of acute GVHD did not influence significantly OS, PFS or PR in any of the groups. The presence of chronic GVHD decreases PR and increases PFS and OS, but without being statistically significant.
We did not observe differences in OS, PFS or PR depending on whether the same or different donor was used in the 2nd HSTC, or whether the relapse was early or late.
Summary/Conclusion: Carrying out a 2nd HSCT in patients who relapse after a 1st HSCT is a feasible treatment option that offers a survival of 53 ± 4.4% at 5 years and 34.6 ± 4.6% at 10 years, being the main influencing factor the disease status at the 2nd HSCT.

PB1789 ALLOGENEIC HEMATOPOIETIC STEM CELL TRANSPLANT FOR CHRONIC GRANULOMATOUS DISEASE: A SINGLE-CENTER 10-YEAR RETROSPECTIVE SERIES

A. I. Marques [1,*], C. Pinho Vaz [2], G. Brás [2], L. Leite [2], R. Branca [2], S. Roncon [3], A. Campos [2]

[1]Serviço de Onco-Hematologia, [2]Serviço de Transplantação de Medula Óssea, [3]Serviço de Terapia Celular, IPO Porto, Porto, Portugal

Background: Chronic Granulomatous Disease (CGD) is an inherited congenital disorder characterized by severe recurrent infections and inflammatory complications due to defects in phagocyte oxidative function. Allogeneic hematopoietic stem cell transplantation (alloHSCT) is currently the only established curative treatment, but it remains a challenge to decide which patients (and when) should proceed to transplant. Historically, alloHSCT in these patients was associated with greater risk of graft failure, low donor chimerism, and mortality due to previous organ dysfunction, compared to other primary immunodeficiency disorders.
Aims: To describe baseline characteristics and outcomes of patients with CGD treated with alloHSCT in our Institution.
Methods: Retrospective descriptive analysis of patients with CGD who received an alloHSCT in our Institution between 2009 and 2018.
Results: In the 10-year period considered in this study, 5 patients (4 boys and one girl) were referred to our Institution and received an alloHSCT for CGD. All had severe and recurrent infections and most (n=4) had also inflammatory conditions (most frequently granulomatous colitis) leading to diagnosis, which was confirmed at a median age of 8 months (5 months-13 years). Most (n=3) had an X-linked genotype (CYBB gene mutation) and 2 had an autosomal recessive genotype (CYBA and NCF1 gene mutations).
Median age at transplant was 7 years (1-15 years). Two patients received a matched sibling transplant from peripheral blood progenitors, and the remainder received a matched unrelated donor transplant from bone marrow (n=2) and cord blood (n=1) progenitors. There was no documented active infection at time of transplant. Most patients (n=4) received a myeloablative conditioning regimen with busulfan+cyclophosphamide,

and additional anti-thymocyte globulin in 2 cases. Median time of in-patient care during peri-transplant period was 29 days (25-74 days). All patients had febrile neutropenia during the pre-engraftment period controlled with large spectrum antimicrobials.
Median time to engraftment was 17 days (13-55 days). Acute graft-versus-host disease (GVHD) was documented in 2 patients (grades 1 and 2). Full donor chimerism was attained in 3 patients at a median time of 41 days (32-54 days). Mixed and falling donor chimerism was observed in the other 2 patients, who had received bone marrow reduced-intensity conditioning and cord blood HSCT. They had secondary graft failure and proceeded to a second alloHSCT, at 8 and 17 months after the first transplant (from different matched unrelated donors, graft source was peripheral blood in both cases).
With a median follow-up time from first alloHSCT of approximately 8 years (1.7-10.7 years), 4 patients are alive and without manifestations of CGD. Three patients have developed chronic GVHD, mostly cutaneous and mild. CMV reactivation was documented in 4 patients and one had post-transplant EBV-related lymphoproliferative disease successfully treated with rituximab. One patient died at 3 months after second alloHSCT from associated complications.
Summary/Conclusion: CGD patients remain a challenge in the alloHSCT setting due to susceptibility to infectious and inflammatory complications. However, improvement of conditioning regimens and peri-transplant supportive care have contributed to better outcomes in this population.

PB1790 EXTRACORPOREAL PHOTOPHERESIS IN THE TREATMENT OF ACUTE OR CHRONIC GRAFT VERSUS HOST DISEASE (GVHD) IN PEDIATRIC PATIENTS: MONOCENTRIC EXPERIENCE

D. De Novellis [1,*], I. Varsi [1], F. Cacace [1], V. Caprioli [1], M. Iannalfo [2], M. R. D'Amico [1], G. De Simone [1], A. De Martino [1], F. P. Tambaro [1]

[1]Pediatric Onco-Hematology department, AORN Santobono-Pausilipon, [2]Hematology department, AOU Federico II, Naples, Italy

Background: Steroid refractory (SR) and dependent (SD) acute or chronic Graft versus Host Disease (aGvHD/cGvHD) are severe complications of allogenic Hematopoietic Stem Cell Transplantation (HSCT) with high morbidity and mortality rates.
Extracorporeal Photopheresis (ECP) is a therapeutic option with T-cell immunoregulatory activity but without ImmunoSuppressive (IS) effects.
Aims: We retrospectively evaluated efficacy and safety of ECP in our pediatric population.
Methods: We reviewed data from 23 children with SR or SD GvHD followed at our Institution since 2010.
ECP was performed by COBE Spectra™and Therakos CELLEX™ systems; the schedule consisted of 2 consecutive days each week for 4-12 weeks with tapering to biweekly/monthly regimens, adjusted by patient response.
Complete and partial responses (CR and PR) were defined by resolution of all signs and symptoms of GvHD in every organ and by 1 grade improvement in 1 organ without any progression, respectively.
Results: Patients, HSCT, GvHD and treatment characteristics are summarized in Table.
Twenty-two (96%) and 14 (61%) children were diagnosed with aGvHD and cGvHD, respectively. Acute GvHD involved skin, gut and liver in 22 (96%), 8 (35%) and 5 (22%) cases; 4 (17%), 4 (17%) and 1 (4%) patients had a simultaneous involvement of skin+liver+gut, skin+liver and skin+gut, respectively. Grade I-II and III-IV aGvHD was observed in 13 (57%) and 9 (39%) children, respectively.
Among patients with cGvHD, involvement of skin, gut, liver, lung, mouth and eyes was detected in 11 (79%), 3 (21%), 8 (57%), 1(7%), 2 (14%) and 4 (29%) cases, respectively. Chronic GvHD was classified as mild, moderate and severe in 1 (7%), 10 (72%) and 3 (21%) patients.
ECP therapy was started in 10 (43%) patients for aGvHD and 13 (57%) for cGvHD.
Median ECP treatment duration was 3 months (1-29), with a median number of 16 ECP (2-74). ECP was associated with a new IS (MMF-Tacrolimus-Sirolimus), Jak2 inhibitor (Ruxolitinib), monoclonal antibodies (Rituximab or Basiliximab) and anti-TNFα in 11 (48%), 1 (4%), 5 (22%), in 5 (22%) patients, respectively. Overall response rates (ORR) evaluated at 1, 3 and 6 months were 78%, 83%, 74% and 67%,88%,100% for aGvHD and cGvHD respectively.
Infectious complications consisted of viral reactivations bacterial, fungal infections in 4 (17%)(1 CMV, 2 ADV, 1 ADV+EBV), 10 (43%) and 1 (4%) patients, respectively. No relapse of underlying disease occurred and only 1 (4%) child with positive minimal measurable disease (MRD) responded to tyrosine kinase inhibitor.
Median overall survival (mOS) was not correlated with grade for aGvHD [grade I-II vs III-IV; not reached (NR) vs 24 months;HR:2.6;p=0.14) or cGvHD (mild+moderate vs severe; NR vs 24 months; HR.4.6;p=0.09) while for involvement of gut in aGvHD [18 months vs NR;HR:3.26;p=0.06] and liver in cGvHD [50 months vs NR;HR:61.3;p=0.056] there was a trend with shorter mOS.
There were 12 (52%) and 11 (48%) patients with absolute lymphocyte count (ALC)<0.5 and ≥0.5 x10^3/μL, respectively; ALC ≥0.5 x10^3/μL was significantly correlated with higher 1-month ORR [100%vs64%;p=0.04] and longer mOS (NR vs 24 months; HR:0.2; p=0.02) while 3 and 6 month-ORR were not influenced (100% vs 80%; p=0.31; 100% vs 89%; p=0.44).

<0.5x10^3/μL:1-3-6 months ORR	7/11 (63) 8/10 (80) 8/9 (88)
≥0.5 x10^3/μL:1-3-6 months ORR	11/11(100)-11/11(100)-10/10(100)
Median OS, months (range)	62 (1-169)

Summary/Conclusion: ECP treatment is a safe and effective treatment for aGvHD and cGVHD in our pediatric population with superior ORR, decreased infection complications, and disease relapse compared to IS combination treatment for clinical practice as reported in the literature. Prospective trials are needed to validate our observation and further investigate the correlation of ALC with outcomes

PB1791 BENDAMUSTINE IMMEDIATELY BEFORE MOBILIZATION MAY DIFFICULT THE COLLECTION OF HEMATOPOIETIC STEM CELLS IN LYMPHOMA.

M. Bastos-Oreiro [1,*], V. Delgado [1], R. Cordoba Macuñano [2], A. Jimenez-Ubieta [3], D. García Belmonte [4], J. García-Arroba Peinado [5], J. Anguita Velasco [1], J. M. Sancho [6]

[1]Hematology, Hospital General Universitario Gregorio Marañón, [2]Hematology, Fundación Jimenez Díaz, [3]Hematology, Hospital Universitario 12 de Octubre,

[4]Hematology, Hospital de la Zarzuela, Madrid, [5]Hematology, Hospital Joan XXIII, Tarragona, [6]Hematology, Hospital Germans Trias y Pujol, Badalona, Cataluña, Spain

Background: Bendamustine is one of the chemotherapy agents widely used today in patients with lymphoma. Its impact on the yield of peripheral blood stem cells is not well known.
Aims: The aim of this study was to evaluate the influence of bendamustine as the last previous regimen used before hematopoietic stem cell (HSC) mobilization on HSC collected in patients with lymphoma, and to compare them with a group that has not received bendamustine.
Methods: This is a retrospective, multicenter study, which includes patients from 6 different centers in Spain. Nineteen patients who received bendamustine followed immediately by stem cell mobilization (SCM) were included. A single-center control group of consecutive patients was included, matched by histology, age and number of previous lines.
Results: Table 1 shows the characteristics of the included patients and the control group. Both groups are adequately balanced. No patients received previous lenalidomide, and none patient had previous transplant. The median number of bendamustine cycles was 3.6 (range 2-6). In most of the patients, the mobilization scheme was G-CSF 10 mg/Kg every 24 hours, although 7 patients in the bendamustine group received G-CSF 10 mg/Kg erery 12 hours, and 3 patients in each group were mobilized with G-CS plus chemotherapy. Median days of apheresis with the first attempt was 1.7 in the bendamustine group vs 1,4 in the control group, however in bendamustine group 3 patients didn't go to apheresis due to a low CD34 cell count in peripheral blood. Plerixafor was needed in 3 cases in the bendamustine group on the first attempt of mobilization, and in other 3 in the second attempt, but in any patient in the control group. In the bendamustine group, 7 patients required a second mobilization attempt (p= 0.003), 3 collected with the 2nd attempt and 1 with the 3rd, and 3 patients were unable to mobilize, none in the control group (p= 0.008). The median number of mobilized CD34 cells obtained with the first apheresis was 3.64x10^6/kg (range 0-9.6 64x10^6/kg) in the bendamustine group and 5.5x10^6/kg (range 1.1-10.4 64x10^6/kg) in the control (p = 0.003). No relationship was found between lymphoma histology, stage, doses, or number of cycles of bendamustine administered with the need of a second attempt or mobilization failure.

Patient characteristics	Benda. (n=19)	No Benda. (n=19)	p
Median age, years	53 (24-70)	50 (30-72)	*0.29*
Sex (male)	57%	68%	*0.45*
Diagnosis	FL 7	9	*0.11*
	MCL 4	2	
	HL 4	3	
	Others 4	5	
Stage at diagnosis	Localized 4	4	*0.6*
	Advanced 15	15	
BM involvement at diagnosis	47%	57%	*0.19*
Previous chemo lines, median (range)	2 (1-3)	2 (1-3)	*0.91*
Pre-apheresis leucocytes, x10^9/L	5.3 (1.6-12.3)	8.3 (1.5-20)	*0.31*
Pre-apheresis hemoglobin, g/dl	11.8 (9-12.3)	11.3 (8.9-13.1)	*0.26*

Benda. bendamustine. FL follicular lymphoma. MCL mantle cell lymphoma. HL Hodgkin lymphoma

Summary/Conclusion: Based on our results, we can conclude that bendamustine used immediately prior to mobilization could negatively affect the collection of HSC in lymphoma patients. We are expanding our series to confirm these results.

PB1792 COMPARISON OF VIABILITY AND HEMATOLOGIC RECOVERY AFTER ALLOGENEIC TRANSPLANTATIONS WITH FRESH OR FROZEN IN 5% DIMETHYLSULPHOXIDE (DMSO) HEMATOPOIETIC STEM CELLS (HSC)

I. Tonev [1,*], M. MIncheff [1]

[1]National Hospital For Active Treatment Of Hematological Diseases, Sofia, Bulgaria

Background: In allogeneic transplantation the usual approach is to synchronize the conditioning of the patient with stem cell harvesting in order to infuse fresh cell products. The EBMT COVID-19 guidelines recommend cryopreservation of the graft to be considered if there is a concern that the donor is at risk of infection after the patient's conditioning is initiated.
Aims: We analyzed if cell viability or hematological recovery is affected in case stem cells are previously frozen.
Methods: Results from two groups of patients, each comprising of 16 males and 8 females, were analyzed. HSC from the first group were non-programmed frozen and stored at –80°C in a cryoprotective solution with a final 5% DMSO, 3.6% hydroxyethyl amylopectin (HES, Mw 450 000 Da) and 3% human serum albumin (HSA) concentrations. Platelets and plasma were removed from stem cell harvest prior to the addition of the cryoprotectant. The HSCs from the second group were transplanted without freezing. Fresh cell viability or viability after thawing (trypan blue exclusion test) and hematological recovery (neutrophils and platelets) of patients receiving cryopreserved cells or fresh cells were analyzed.
Results: The average viability was 98,67 % (SD ±1,633) for fresh HSCs and 91,63% (SD ±8,021) for cryopreserved cells. The average time for hematological recovery for the neutrophils, was 17,96(SD ±4,601) for fresh cells and 16,46 (SD ± 4,530) for frozen cells. The average time for hematological recovery for the platelets, was 15,25 (SD ± 4,590) for fresh cells and 16,26 (SD ± 6,032) for frozen cells. There was no statistically significant difference between the two groups for hematological recovery.
Summary/Conclusion: Use of fresh HSCs is the first choice for allogeneic stem cell transplantation. In cases of pandemics, such as the Covid-19 one, use of cells harvested and frozen prior to initiation of the condioning regimen is preferred. Cryopreservation of HSCs with a cryoprotective solution with low (5%) DMSO concentration and extracellular agents (hydroxyethyl amylopectin and HSA) is safe and well tolerated and gives excellent post thaw viability and post-transplant hematological recovery results.

PB1793 ESTABLISHING A TRANSPLANT SHARING PROGRAM

I. Luts Khoroz [1,*], M. Calbacho [2], A. Lerma [1], J. Churruca [3], M. Martínez [1], J. Sanchez-Pina [2], M. Ustariz [1], M. Gracia Vela [1], A. Jimenez [2], S. del Valle [1], J. Hernandez-Rivas [3], J. Martínez-Lopez [2], F. Solano [1], J. Lahuerta [2]

[1]Hematology, Hospital Nuestra Señora del Prado de Talavera de la reina, Talavera de la reina, [2]Hematology, HU 12 de Octubre, [3]Hematology, H. Infanta Leonor, Madrid, Spain

Background: Autologous stem-cell transplantation (ASCT) is a prevalent therapy with firmly established efficacy and safety indices. However, to perform this procedure is necessary to transfer patients to referral centers with obvious implications for patients and their relatives. Besides, the increasing demand of autologous and allogeneic transplants may cause transplant delays.
Aims: Based on previous studies carried out in Canadian centers (Crump. Bone Marrow Transplant. 1992), an autologous transplant sharing program has been set between 3 centers in Spain to increase the availability of ASCT, avoid transplant delays and improve patient and family comfort.
Methods: Retrospective, observational and analytical study of the ASCT enrolled in this program between July 2017 and October 2019. Selected ASCT candidates for multiple myeloma (MM), lymphoma and acute myeloid leukemia (AML) from Infanta Leonor (ILH) and Nuestra Señora del Prado Hospitals (NSPH) were included after signing the informed consent. Uniform clinical protocols were used between the 3 hospitals. A clinical transplant update program for nurses and physicians was set up before the program started. The program is divided into 2 stages: First stage: Pre-transplant patient evaluation, stem-cell apheresis collection and cryopreservation as well as administration of high-dose therapy and hematopoietic stem-cell infusion were performed at 12 de Octubre hospital (H12O). Second stage: in absence of significant clinical events patients were transferred to the referring center (NSPH and ILH) on day +1 for supportive care.
Results:
Population: 12 patients (4 female, 8 male). Median age: 58 years (23-71). Diagnosis: multiple myeloma (MM): 9, acute promyelocytic leukemia (APL): 1, follicular lymphoma: 2. Conditioning regimens: Melfalan 200 (75%), CyBU (8%), BEAM (17%) All patients received standard prophylaxis with acyclovir, fluconazole and cotrimoxazole. G-CSF was allowed from day +5.

- **HSCT and engraftment:** no patient needed an additional bridge therapy because of transplant delay. All 12 patients were transferred on day +1. Median time to neutrophil (> 0.5x10^9/l) and platelets (> 20x10^9/l) engraftment was 11 days (10-14) and 12 days (11-20) respectively. Secondary graft failure: 1/12 patients.
- **Adverse events:** Febrile neutropenia was observed in all patients with microbiological documentation in 42%. Documented pathogens: bloodstream infections due to *Pseudomonas Aeruginosa*, *Enterobacter cloacae* and *Streptococcus gallolyticus*. Urinary tract infection: *Klebsiella pneumoniae*. 1 infectious colitis caused by *Campylobacter jejuni*. Engraftment syndrome was observed in 2 patients (17%) and grade ≥ 3 mucositis in 6 patients (50%). 7 patients (58%) required parenteral nutrition.
- **Results:** 11 patients were successfully discharged. 1 patient died due to secondary graft failure. Follow up was provided as needed in the referring center. Patients were reviewed in H12O on day +100 and annually therafter.

Summary/Conclusion: The sharing transplant program is a feasible and safe network that eases the access of patients to this therapy avoiding delays and prolonged stays in reference centers, with the consequent psychological and social benefit for patients and their families. Outcome and adverse events were according to literature. This is a pilot study that aims to extend to other centers within the PETHEMA group.

PB1794 ECULIZUMAB FOR TREATMENT OF TRANSPLANT-ASSOCIATED THROMBOTIC MICROANGIOPATHY IN OUR CENTRE

P. M. Garcia Cereijo [1,*], A. Nieto Vázquez [1], Ó. Domínguez Muñiz [1], E. A. Winsnes [1], L. González Rodríguez [1], T. Torrado Chedas [1], A. Santamaría López [1], M. D. C. Albo López [1]

[1]*Hematology, Hospital Álvaro Cunqueiro, Vigo, Spain*

Background: TA-TMA is a rare complication of HSCT that remains difficult to address due its significant morbimortality, lack of standard diagnostic criteria and limited therapeutic options. It is caused by endothelial injury and complement activation. It is further more common after allo-HSCT. Higher risk is in those patients with calcineurin inhibitors (CI), high dose chemotherapy or radiation, infections,GvHD, HLA mismatch or mutations in the complement system. Gold standard for diagnosis is the biopsy of the affected organ, but in the last years laboratory and clinical criteria were also developed. Kidneys, lungs and gastrointestinal tract are the most common affected organs. First-line management includes withdrawal of the CI, treatment of co-existing infections and GvHD and hypertension control. There are no clear recommendations about optimal specific treatment. Eculizumab, though off-label, is one of the most used drugs due to the promising results reported by various studies.
Aims: To evaluate the characteristics and results of the patients diagnosed of TA-TMA and treated with eculizumab in our centre.
Methods: Case reports of patients diagnosed of TA-TMA and treated with eculizumab in our centre between 2018 and 2019.
Results: Case reports of 7 patients. Most of them women (4). Age 51.9±11.7 years old. All caucasic. Indications for transplant: lymphoma (3), MDS (2) and leukemia (2). All of them allo-HSCT with MTX and TCR as GvHD prophylaxis. 5 donors were unrelated (4 10/10, 1 9/10) and 2 were related with HLAid. Day at diagnosis: 162.8±154.4. Most common affected organs: kidneys (4) and CNS (3). All had trombocytopenia, high LDH and anemia at diagnosis; >1% squistocytes (9), proteinuria (6) and hypertension (6). Biopsy was not performed. Mutations and C5b-C9 levels were not studied. Anti-factor H antibodies and ADAMTS13 levels were normal. Almost all the patients (6) had concomitant GvHD or infection (8). First-line treatment was withdrawal of TCR and control of the co-existing conditions; 1 patient received TPE and 2 rituximab prior eculizumab. Eculizumab was initiated 9.9±9.3 days after TA-TMA diagnosis. Almost half of the patients (3) reached CR after induction therapy (6 doses), but only 2 are still alive. Most common cause of exitus was septic shock.
Summary/Conclusion: As previously reported cases, all of our patients treated with eculizumab underwent allogeneic HSCT and received a calcineurin inhibitor as prophylaxis for GVHD. Affected organs and laboratory findings also correlated with previous literature. None of them responded to withdrawal of tacrolimus and most of them had concomitant infection or GvHD, which are known adverse risk factors. Begin of the disorder in our patients was later than common and less than a half happened before day 100 after the transplant. Following protocols in our centre we used TPE or rituximab while waiting for eculizumab approval in our centre. Similar to previous reports, 71% of patients reached complete response after its initiation and those who did not often died because of infection complications. However, given the small amount of patients, further studies with alleatory design are required to recommend eculizumab as an effective therapy of TA-TMA that not respond to supportive treatment and to evaluate the associated risks and prognostic factors.

PB1795 A SINGLE SUBCUTANEOUS INJECTION OF PLERIXAFOR IN COMBINATION WITH G-CSF INCREASE THE MOBILIZATION EFFICIENCY AND FACILITATE THE CELLULAR PHENOTYPING AND FUNCTION OF HEMATOPOIETIC STEM CELLS

Y. Zhang [1], J. Gu [1], Z. Zheng [1], J. Ren [1], X. Luo [1], Z. Chen [1], J. Hu [1], T. Yang [1,*]

[1]*Department of Hematology, Fujian Medical University Union Hospital, Fuzhou, China*

Background: Plerixafor, a selective inhibitor of CXCR4, can effectively mobilize the hematopoietic stem cells (HSC) depending on the dose and the study. It demonstrated also the alteration of the cellular phenotype and function of HSC compared to that with G-CSF in the animal experiments, while rare in clinical studies.
Aims: To investigate the potential influence of Plerixafor in combination with G-CSF and G-CSF alone on the mobilization efficiency, and also the phenotype and function of mobilized stem cells.
Methods: 12 patients diagnosed with NHL and MM were prospectively analyzed. Patients were randomly divided into two groups (6 in G-CSF only (G) group and 6 in G-CSF plus Plerixafor (G+P) group). Patients in G group were receiving 10 μg/Kg of G-CSF for 5 days consecutively while in combine with a single dose of 240 μg/kg Plerixafor at day 5 in the G+P group. The end point of apheresis was to collect at least 2x10^6 CD34+ cells/kg. The cellular phenotype of mobilized peripheral blood stem cells (PBSCs) and harvest stem cells was analyzed by Flow cytometry. The gene expression profiling of CD34+ cells were analyzed by Illumina High-throughput sequencing.
Results: Plerixafor reduced the number of apheresis sessions. The mean numbers leukapheresis per person was 1.50 in G+P group and 2.17 in the G group. The median CD34+ cell counts in peripheral blood increased 7.88 times after the administration of Plerixafor in G+P group as compared prior-Plerixafor, While 1.69 times increase in G group at the time of apheresis. Compared with G-CSF alone, there was a trend towards higher level of monocytes ($p = 0.031$) and lymphocytes ($p = 0.095$) and lower level of granulocytes ($p = 0.076$) in the mobilized PBSCs in G+P group, particularly a significantly higher percentage of B cells ($p = 0.045$) and Treg cells ($p = 0.079$). The gene expression profiling involved in cell proliferation ($p<0.0001$) and hematopoiesis($p<0.0001$) were significantly increased in G+P group, which associated with better engraftment.
Summary/Conclusion: A single dose of Plerixafor in combination with G-CSF increase the mobilization efficiency and facilitate the cellular phenotyping and function of hematopoietic stem cells compared to that with G-CSF alone, which may promote a superior and long-term engraftment.

PB1796 OUTCOME OF HAPLOIDENTICAL HEMATOPOIETIC STEM CELL TRANSPLANTATION WITH A DONOR AND RECIPIENT WITH SARS-COV2 INFECTION.

G. Ali [1,*], M. Altareb [1], N. Chaudhri [1]

[1]*Oncology departement, King Faisal Specialist Hospital and research Centre - Riyadh, Saudia Arabia, Riyadh, Saudi Arabia*

Background: COVID-19 disease is an infectious disease caused by the most recently discovered SARS Coronavirus 2 (SARS- CoV-2). This new virus and disease were unknown before the outbreak began in Wuhan, China, in December 2019. The WHO classified COVID-19 a pandemic on March 11.[3] Although elderly and people with comorbidities patients are the most affected by the severe manifestations of the disease, patients undergoing hematopoietic stem cell transplantation (HCT) are a group of patients with special immunocompromised situation and could have potentially devastating outcome if they infected with SARS-CoV-2. Although the majority of infected patients have mild disease, critical illness occurs in about 6.1% of affected patients.[4] People at risk of severe outcome and death include those older than 60 years and those with comorbid disease states such as hypertension (HTN), chronic respiratory disease, chronic kidney disease

(CKD), cardiovascular disease, diabetes mellitus (DM), cancer and immunosuppressed patients [5]. Data emerging about cancer patients show that these patients have an increased risk of complications and intensive care unit (ICU) admissions.[6] Hematopoietic cell transplant (HCT) patients are severely immune-compromised and their course with COVID-19 disease is expected to be complicated. The patient that is reported here developed SARS-CoV-2 post HCT who received stem cells from donor diagnosed with SARS-CoV2 by Nasopharyngeal swab on the day of the HCT. It is possible that this might be one of the rarest cases during the pandemic.
Aims: case report
Methods: case report
Results: case report
Summary/Conclusion: During this COVID-19 pandemic era, any patient for whom an allogeneic transplant is planned should be tested with nasopharyngeal swab for SARS-CoV-2 infection especially prior to hospital admission.If the result for SARS-CoV-2 infection proves negative, the transplant procedure should be pursued as planned. Donors with SARS-CoV-2 detected in a respiratory sample are considered ineligible to donate. However, an ineligible donor may be collected in certain situations where delay is not possible or unavoidable.
Post-transplant care in HCT recipients with COVID-19 infection is feasible in regular transplant units, provided the patient does not present with respiratory symptoms or failure. Early and repeated testing for SARS-CoV-2 in post-transplant patients with concomitant infection mitigation strategies should be considered in patients who develop fever, respiratory symptoms and/or gastrointestinal symptoms to control the spread of COVID-19 both in patients and healthcare workers in hospital environments.
Clinical decision making and team work is crucial for patient survival in the COVID-19 pandemic era.
This case of an asymptomatic SARS-CoV-2 positive recipient, stem cell transplantation was pursued as planned from an asymptomatic SARS-CoV-2 positive stem cell donor with no significant adverse CRS or infection-related outcome in the recipient.

PB1797 LOW-DOSE PTCY PLUS HAPLO-INDENTICAL TRANSPLANTATION A FEASIBLE AND SAFE CONSOLIDATION STRATEGY FOR CAR T-CELL SALVAGED REFRACTORY/ RELAPSED B-CELL ACUTE LYMPHOBLASTIC LEUKEMIA------ THREE CASE REPORT

X. Fei [1,*], X. Yu [1], L. Wang [1], F. Lei [1], W. Lu [1]

[1]*Department of Hematlogoy, Affiliated Hospital of Jiangsu University, Zhenjiang, China*

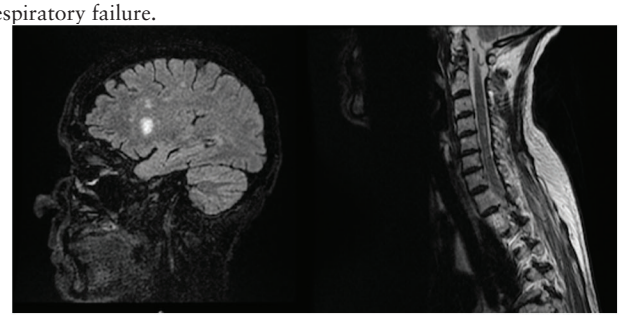
Background: Although chimeric antigen receptor (CAR) T-cell is highly-effective in remission induction for relapsed/refractory B-cell acute lymphoblastic leukemia (R/R B-ALL), a substantial proportion of responded patients will eventually relapse. Haplo-identical allogeneic hematopoietic stem cell transplantation (allo-HSCT) is considered one of subsequent consolidation options post CAR T-cell salvage, especially for those without marched related or unrelated donors. However, haplo-identical HSCT is usually associated with higher rate of graft-versus-host-disease (GVHD), so how to reduce the rates and degree of GVHD which maintain graft-versus-leukemia capacity, is an active field of exploration in this setting. Post-transplant cyclophosphomide (PTCY) was showed to be promising GVHD prophylaxis for allo-HSCT, and recently there were several reports showed low-dose PTCT could achieve similar outcome.
Aims: CAR T-cell has been approved for the salvage for refractory/ relapsed (R/R) acute lymphoblastic leukemia, and a proportion of salvaged ALL patients can further consolidated by allo-HSCT. Here we reported three cases of CD19-targeted CAR T-cell salvaged R/R-ALL patients who intended for haplo-identical allo-HSCT.
Methods: There are three cases of R/R B-ALL in our institute, in whom two of them are Philadelphia chromosome-positive (ph-positive) B-ALL patients. All of them have already identified related haplo-identical donors prior to CAR-T salvage. Once patient achieved complete remission post CAR-T salvage, then proceeded to haplo-HSCT as soon as possible. Unmanipulated mobilized peripheral blood stem cell (MPBSC) from related haplo-identical donor was employed as a stem cell source, and GIAC protocol plus low-dose PTCY was employed for haplo-identical allo-HSCT.
Results: All of three cases achieved CR post CAR T-cell salvage. During the preparation of HSCT, one case ph-positive ALL relapsed and did not proceed to allo-HSCT, and the other two cases successfully proceeded to haplo-identical allo-HSCT by GIAC protocol plus low-dose PTCY. Both patients had a rapid graft engraftment and achieved complete chimerism (CC) after MPBSC infusion, one case had grade II aGVHD which resolved rapidly with mono-steroid treatment. Both of them are leukemia-free and GVHD-free at the last follow-up.
Summary/Conclusion: Low-dose PTCY plus GIAC protocol with MPBSC is a feasible consolidation for CAR T-cell salvaged B-ALL patients, however, for patients with rapid relapse post CAR T-cell salvage, it is still an unmet clinical need.

PB1798 DONOR LYMPHOCYTE INFUSION (DLI). A STRATEGY TO PREVENT OR TREAT RELAPSE FOLLOWING ALLOGENEIC STEM CELL TRANSPLANTATION. ONE SINGLE CENTER EXPERIENCE.

P. Fernández-Caldas González [1,*], M. K. Torres Ochando [1], H. de La Nuez Melián [1], C. Acosta Fleitas [1], M. Perera Álvarez [1], L. Guerra Domínguez [1], L. González Pinedo [1], L. M. González del Castillo [1], A. Borrero Borrego [1], J. F. López Rodríguez [1], M. Cabezas De La Cruz [1], A. Morales Curbelo [1], M. T. Gómez Casares [1]

[1]*Hospital Universitario de Gran Canaria Doctor Negrín, LAS PALMAS DE GRAN CANARIA, Spain*

Background: Despite improvements in stem cell transplantation of patients with acute leukemia, relapse is still one of the main causes of mortality. DLI is one of the strategies used in high risk patients, allowing us to rescue 30-55% of the patients. It also reduces risk 2.3 times when it is used as a preemptive strategy.
Aims: Analyse our experience in the use of DLI as a prophylaxis, preemptive or treatment strategy.
Methods: A retrospective cohort study was performed among adult recipients of allogeneic HSCT between 2016 and 2019 who subsequently underwent DLI as a prophylaxis, preemptive or treatment strategy.
Results: A total of 10 patients were included. The median age was 52 (24-69), 70% were women (7) and 30% men (3). Underlying diseases: 7 Acute Myeloid Leukemia (70%), 2 Acute Lymphoid Leukemia (20%) and 1 Myelodysplastic Syndrome (10%). Patients received ASCT from related HLA-identical (10%), haploidentical (80%) and unrelated donors (10%). Disease status prior HSCT: 2 persistent disease (20%), 7 complete response (CR), 4 of them presented negative minimal residual disease (MRD) and the other 3 had positive MRD (molecular, cytogenetics or immunophenotypic markers). 1 patient with MDS had not received any previous treatment. At day +30: 90% presented CR, 4 of them complete chimerism (CC) and the other 6 mixed chimerism (MC). The patient with MDS presented persistent disease. One of the patients underwent a 2nd alloHSCT and received DLI after both transplants.
The median time for immunesuppressive treatment's interruption was 91 days (45-147). The median time to DLI indication was 137 days (114-475). The indications for DLI were: 4 (36.4%) as treatment (3 relapse diseases and 1 refractory), 4 (34.4%) prophylaxis because of high risk disease and 3 (27.2%) preemptive because of positive MRD or CC. The median DLI dose was 3 (1-4).
In the treatment group, 75% received DLI in combination with Azacitidine (1 of them in combination with Sorafenib) and 1 in monotherapy. In the prophylaxis group, 50% received it in combination with azacitidine and sorafenib or sorafenib only and the other 50% in monotherapy. In the preemptive group, 67% in combination with Azacitidine and 33% in monotherapy.
Related to response after DLI, in the treatment group: 75% refractory, 25% CR with positive MRD and MC. In prophylaxis group: 75% CR, negative MDR and CC, 25% CR and MC. In preemptive group: 67% CR, negative MRD and CC, 33% negative MRD and MC.
Therefore, 45.4% of all patients achieved CR, negative MRD and CC and the other 27.3% presented refractoriness.
GVHD rate was 50%. After a median time of follow-up of 4 years (1-4), 40% are still in remission. 4 patients died, 2 of them due to relapse (20%) and the other two because of infections
Summary/Conclusion: DLI represents an useful and safe preemptive and prophylactic strategy in patients with high risk of relapse. We achieved remission in 30-40% of patients. On the other hand, there was a limited response in patients with treatment indication, being necessary to individualize and to associate targeted therapies. In most of these cases,



it has been necessary the use of intensive therapies with a decrease in survival.

PB1799 CENTRAL NERVOUS SYSTEM (CNS) INVOLVEMENT OF GRAFT VERSUS HOST DISEASE (GVHD) AFTER ALLOGENEIC HEMATOPOIETIC STEM CELL TRANSPLANTATION (HSCT)

A. Puchol [1,*], G. Reig [2], A. Figuera [1], B. Aguado [1]

[1]Haematology and hemotherapy, [2]Neurology, Hospital La Princesa, Madrid, Spain

Background: CNS-GvHD remains a very uncommon entity after allo-HSCT and should be considered in absence of other diseases that justify neurological symptoms. CNS-GvHD criteria were described at Consensus Conference on Clinical Practice in chronic GvHD in 2010.
Aims: To describe a case of CNS-GvHD, a very rare entity still under-reported. We believe all cases should be reported to properly detect and treat this entity.
Methods: A 61-year-old woman diagnosed of mixed phenotype acute myeloid leukemia (AML) in June-20. After chemotherapy, on first remission MRD+, she underwent haploidentical HSCT, after fludarabine and busulfan conditioning; GvHD prophylaxis with cyclophosphamide, cyclosporine A (CsA) and mycophenolate mofetil (MMF). Acute skin GvHD grade IV on day +17, treated with systemic steroids with complete response. On day +59 she was admitted to emergency room with progressive inferior limbs motor deficit and hyperalgesia, followed by confusion, somnolence and visual hallucinations. No fever; adequate adherence to acyclovir, posaconazole and cotrimoxazole prophylaxis. Physical examination: decreased strength in lower limbs, dysesthetic alterations and vivid myotatic reflexes.
Laboratory findings: no toxic-metabolic abnormalities, normal B12, folic acid and CK levels. Autoimmunity: negative. No schistocytes in blood smear. Nevertheless, CsA was discontinued and MMF started. Cerebrospinal fluid (CSF): no pleocytosis, erythrocytes, nor oligoclonal bands; slight protein elevation (62.1 mg/dL). Microbiological analysis: CMV reactivation in blood sample and positive microarray for HHV-7 in CSF (negative in blood sample). Clinical relevance of HHV-7 was evaluated by neurologists, discarding it as the cause of the picture. Both viruses were covered with foscarnet since admittance, completing 4 weeks treatment. No evidence of EBV, HSV, VZV, HHV-6, HHV-8, polyomavirus, enterovirus, coxackie, toxoplasma, bacterial or fungal infection in CSF. Broad spectrum antibiotics and amphotericin B were also started. AML relapse was ruled out with marrow full donor chimerism and normal immunophenotype in CSF. Electromyography: motor polyneuropathy without demyelination. Cervical spine MRI: hyperintense lesion in T2 at C4-C5 affecting posterior cords; brain MRI: multiple hyperintense lesions in T2 affecting both hemispheres.
During hospitalization she developed gastrointestinal GvHD grade II, so we started methylprednisolone, with partial response. Simultaneously, neurological picture deteriorated with progressively impaired motor function, bradypsychia and dysphagia. New brain MRI showed lesions exacerbation.
Results: Methylprednisolone was substituted for dexamethasone, adding immunoglobulins, with improvement of consciousness, language and dysphagia within 48h; more discreet improvement of motor impairment. Dexamethasone was tapered with sustained neurological effect. A month later, under posaconazole prophylaxis, she developed fungal pneumonia without response to amphotericin B and isavuconazole and died due to respiratory failure.

Summary/Conclusion: Neurological complications after allo-HSCT present a wide variety of symptoms, associating high morbi-mortality. Our case exhibits CNS and peripheral nervous symptoms, not classifiable in any entity, with infectious, toxic or vascular etiologies as well as AML relapse discarded. Our patient met mandatory criteria for CNS-GvHD, with neurological worsening concurring in time with exacerbation of intestinal GvHD, and 3 facultative criteria, showing a rapid symptoms improvement after starting dexamethasone, so we assumed it as a neurological manifestation of GvHD.

Stem cell transplantation - Experimental

PB1800 EFFECT OF THE DURATION OF CRYOPRESERVATION ON THE VIABILITY AND PROLIFERATIVE POTENTIAL OF HSCS DURING AUTOGRAFT HARVESTING IN PATIENTS WITH MM

V. Balashova [1], N. Semenova [1,*], Z. Chubukina [1], I. Kostroma [1], Z. Artyukhina [1], A. Zhernyakova [1], S. Bessmeltsev [1], A. Chechetkin [1], S. Gritsaev [1]

[1]Russian research institute hematology and transfusiology, Saint-Petersburg, Russian Federation

Background: Autotransplantation of hematopoietic stem cells (HSC) (AutoHSCT) is the standard of therapy for young and middle-aged patients with multiple myeloma (MM) and is performed in order to restore hematopoiesis. Mandatory step AutoHSCT is the cryopreservation of HSC on the time required for high-dose chemotherapy or to re-AutoHSCT. The quality of the autograft depends on the speed of solving postsimulation aplasia of the bone marrow. Markers of autograft quality are the number of CD34+cells and the proliferative potential of HSCs, which can be judged by their colony-forming ability (CFA). When evaluating CFA, three indicators are taken into account separately: the number of granulocyte-macrophage colony-forming units (CFU-GM), erythroid burst-forming units (BFU-E), and total colony-forming units (CFU-total).
Aims: To evaluate the viability and proliferative potential of HSCs prepared for AutoHSCT in MM patients by the number of CD34+cells and CFA HSCs, depending on the timing of their cryopreservation.
Methods: CFA HSCs were evaluated based on the results of 12-14 days of cell culture in MethoCult H4435. CD34+cells were determined on a Cytomics FC500 flow laser cytofluorometer using a set of Stem Kit Reagents.
A retrospective analysis of autograft parameters during harvesting and subsequent transplantation, depending on the timing of cell cryopreservation, was performed in MM patients aged 32 to 68 years. The duration of cryopreservation ranged from 2 weeks to 1.5 years, with a median of 6 months. Depending on the shelf life, patients were divided into 3 groups: group 1 - shelf life from 1 to 5.9 months (n=83); group 2 - from 6 to 10 months (n=34); and group 3 - ≥ 10 months (n=10). The data of 91 MM patients were analyzed, the total number of analyzed cases was 127.
Results: The number of total CFU in group 1 is reduced to 66% of the original, in the second group to 60%, in group 3 to 44%. In groups 1 and 2, there was a proportional decrease in both CFU-GM and BFU-E. However, in group 3, with cryopreservation periods of more than 10 months, a statistically significant decrease in the number of BFU-E was shown; p=0.01. In the same group, patients with longer platelet recovery periods were noted.
The number of CD34+cells after cryopreservation is reduced to 77 % in group 1, 39% in group 2 and 49% in group 3. No statistically significant correlations with the shelf life were found, probably due to the wide range of values in all groups, but a significant decrease in the number of CD34+cells was shown. Even in group 1 with a minimum shelf life, the number of cells decreased by almost a third. The CFA results obtained are comparable to the reduced number of CD34+cells in the samples.
Summary/Conclusion: The data obtained by us indicate a reduction in the number of CD34+cells and a decrease in their proliferative potential according to the CFA data already in the group with a minimum shelf life. The lowest values were found in the group with a shelf life of more than 10 months. The results of the study show the expediency of earlier preparation of the autograft, eliminating the possibility of a negative impact of previous induction therapy, in order to obtain a cell suspension with the maximum content of HSC, especially when planning tandem or repeated AutoHSCT in patients with newly diagnosed MM.

PB1801 CYCLOSPORINE CAN INHIBIT INTESTINAL AGVHD BY REGULATING MITOCHONDRIAL APOPTOSIS

S. Li [1,*], X. Cui [2]

[1]Shandong University of Traditional Chinese Medicine, [2]Affiliated Hospital of Shandong University of Traditional Chinese Medicine, Jinan, China

Background: Acute graft-versus-host disease (aGVHD) limits the success rate of allogeneic hematopoietic stem cell transplantation (allo HSCT),which is a major complication and remains a significant cause of morbidity and mortality.Cyclosporine can inhibit the induction of MPTP by Ca2 + and ROS, protect the integrity of mitochondrial cristae junction and intima, and reduce the level of ROS and the formation of autophagy.It can regulate the expression of Bax and Bcl-2, reduce the oxidative damage and apoptosis induced by oxidative stress (OS).Low plasma CsA concentrations early following allo-HSCT is associated with an increased risk of developing aGVHD.Conversely, Higher therapeutic CsA levels early post transplantation reduce risk of aGVHD and improves survival.In the absence of specific drugs, the correct understanding and optimization of cyclosporine treatment has important clinical significance for the prevention and treatment of aGVHD.
Aims: To investigate the therapeutic effects of cyclosporine on gastrointestinal aGVHD and the regulatory mechanisms at the level of abnormal mitochondrial apoptosis in the intestine.
Methods: After were irradiated by 60co X rays,CB6F1 mice were transplated by using the mononuclear cells suspension (bone marrow + spleen) of Balb/c mice infused into the tail vein.The model group was administrated with 0.9% sodium chloride intragastrically,and the treatment group was administrated with intragastrically 5mg/kg cyclosporine. After 28 days, the clinical score of aGVHD and the pathological inflammation score of small intestinal mucosal were evaluated,respectively.The small intestinal mucosal mitochondria were observed by using transmission electron microscopy (TEM). Western blotting and immunofluorescence were used to detect the expression of apoptosis related proteins (bcl2 and bax)in two groups.
Results: 1. The differences of clinical aGVHD scores between the two groups are significant(P<0.01)(Fig 1 C).
2. The treatment effect of cyclosporine on intestinal aGVHD. The observation of HE staining showed that, compared with blank group, intestine tissue of the mice in treated group were improved (Fig 1 A and B), which indicated the treatment effect of cyclosporine in improving intestinal aGVHD is obvious. In addition, the pathological inflammation score between the two groups differed statistically significantly.(P<0.1)(Fig 1 G).
3. The expression levels of mitochondrial apoptosis related proteins tested by immunofluorescence. Found that compared with the blank group, cyclosporine not only can increase the intestinal Bcl2 expression level, but also decrease the Bax expression level.(Fig 1 D).
5. Bcl2 and Bax level tested by western blotting. Cyclosporine corrected the aberrant levels of apoptotic proteins, increased Bcl2 expression and decreased Bax expression levels after transplantation (Fig 1 K), all of which were statistically significant(P<0.01) (Fig 1 H and I).There was a significant difference in the relative expression levels, i.e., BCL2 / Bax of the two groups. (P<0.01)(Fig 1 J).
4. Mitochondrial structure was observation by TEM. After transplantation, mitochondrial structure swelling, broken membrane structure. However, in the treated group,mitochondria structure was relatively intact.(Fig 1 E and F).

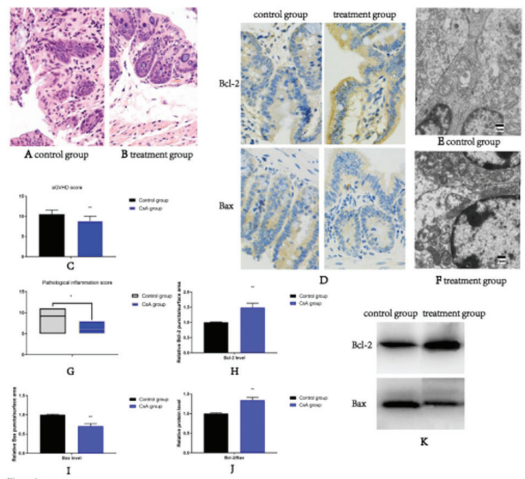


Figure 1
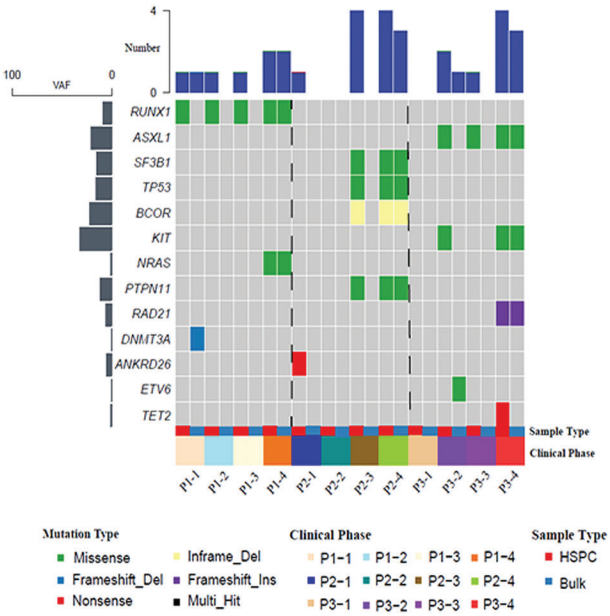
A,B:Small bowel pathological observation of mice in each group (×200).
C:The expression of apoptosis related proteins in small intestinal mitochondria was detected by immunofluorescence(×400).
E,F:Cell structure was observed by transmission electron microscope (×1650).



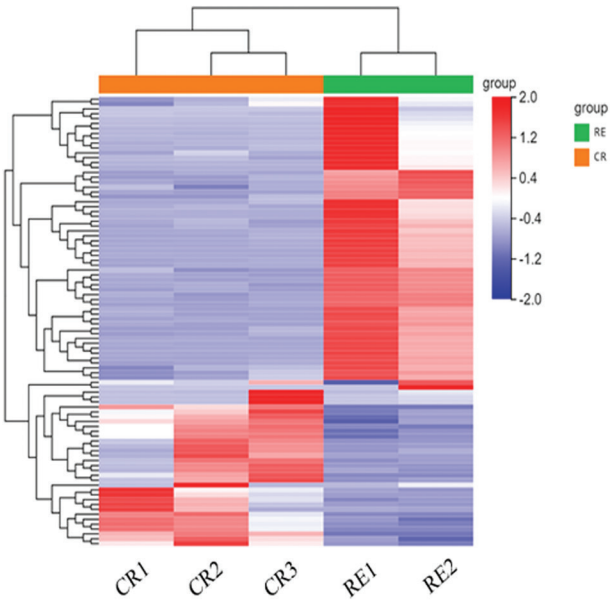
Summary/Conclusion: Cyclosporine can reduce apoptosis and protect intestinal mucosal barrier by inhibiting the activity of T lymphocytes, protecting the structure and function of the mitochondrial membrane, thereby reducing the incidence of intestinal aGVHD after transplantation.

PB1802 NEXT-GENERATION SEQUENCING-DEFINED MINIMAL RESIDUAL DISEASE AT THE STEM/PROGENITOR CELL LEVEL PREDICT POST-TRANSPLANTATION RELAPSE IN ACUTE MYELOID LEUKEMIA

F. Zhao [1,*], E. Jiang [1]

[1]State Key Laboratory of Experimental Hematology, National Clinical Research Center for Blood Diseases, Institute of Hematology & Blood Diseases Hospital, Chinese Academy of Medical Sciences & Peking Union Medical College, TianJin, China

Background: Allogeneic hematopoietic cell transplantation (allo-HSCT) is the most effective curative therapy in patients with acute myeloid leukemia (AML). However, relapse from the original disease is still one of the main causes of treatment failure. Thus high-sensitivity methods to detect minimal residual disease (MRD) in AML after transplantation are crucial. Single cell sequencing indicated that higher clonal diversity at the stem/progenitor cell level (HSPC) in AML, but the significance of MRD monitoring at the HSPC level is unclear.
Aims: To evaluate the value of MRD monitoring based on the stem cell level in predicting post-transplantation relapse.
Methods: DNA was extracted from cells collected from bone marrow (BM) samples. Genetic profiling included the targeted sequencing of 37 genes, which had been selected based on their known or potential involvement in the pathogenesis of acute myelogenous leukemia. Multiplexed libraries were sequenced with Illumina NovaSeq6000 and average raw sequencing depth on target per sample ≥10000×. The mutation variant allele frequency (VAF) ≥1% was considered as MRD positive criterion.
Results: We performed next-generation sequencing (NGS) to profile the mutation status in three AML patients (P1-P3) with relapse after transplantation. For each patient, two BM samples including bulk BM and CD34+ HSPC were collected at post-HSCT at day30 day60 day90 and relapse, respectively. Compared to bulk BM and multidimensional flow cytometry (MFC), MRD monitoring based on the HSPC level is likely more sensitive to predict relapse after transplantation (Figure 1). One of the patients was detectable as MRD positive at post-HSCT day30. Moreover, we observed that some hotspot mutations might be detected only in the HSPC sample.



Summary/Conclusion: Our study unveiled that phenotypically normal CD34+ HSPC possess some genetic abnormalities in cases with negative MCF MRD. NGS-defined MRD at the HSPC level in AML patients is feasible and can predict post-transplantation relapse much earlier.

PB1803 THE STUDY OF MICRORNAS IN CD34+ HSPCS FROM AML PATIENTS WITH RELAPSE AFTER ALLOGENEIC TRANSPLANTATION

F. Zhao [1,*], X. Pei [1], D. Yang [1], M. Han [1]

[1]State Key Laboratory of Experimental Hematology, National Clinical Research Center for Blood Diseases, Institute of Hematology & Blood Diseases Hospital, Chinese Academy of Medical Sciences & Peking Union Medical College, TianJin, China

Background: Relapse of the original disease is a major cause of death after allogeneic hematopoietic cell transplantation for acute myeloid leukemia (AML). It has been established that AML is driven by a subpopulation of rare cells with intrinsically defined stem cell properties. However, the mechanism of post-transplantation relapses at the stem cell level is not clear.
Aims: To describe role of microRNA (miRNA) in CD34+ hematopoietic stem/progenitor cells (HSPCs) from AML patients with relapse after allogeneic transplantation.
Methods: Bone marrow samples from 5 AML patients who received allogeneic hematopoietic cell transplantation, of which 2 patients relapsed after transplantation (RE) and 3 patients remained complete remission (CR). CD34+ HSPCs were sorted by CD34+ microbeads and analyzed by RNA-sequencing on an Illumina Hiseq 2500 platform to characterized all of miRNAs. Gene expression levels between groups of CD34+ HSPCs were compared with degeR to find out differential miRNAs. We performed the GO (Gene Ontology) and KEGG (Kyoto Encyclopedia of Genes and Genomes) enrichment analysis for the target gene candidates of differential miRNAs to predict the potential function of relapsed specific microRNAs. A value of P<0.05 (2-sided) was considered to be statistically significant.
Results: Compared with CR patients, we found that 61 miRNA were upregulated and 31 are significantly downregulated. The analysis showed the total of 92 miRNAs to be signifcantly altered as shown in the heatmap in Figure 1. The target gene candidates of differential miRNAs were enriched in numerous Go biological process including: immune system process, cell cycle, apoptotic process, protein transport, intracellular signal transduction, protein phosphorylation and so on. The top 10 signifcantly (P< 0.05) affected pathways identified by GO analysis.

Summary/Conclusion: The present study proved that miRNAs play an important role in AML patients with relapse after transplantation. The result may improved understanding of the special molecular alterations in relapse after transplantation and may provide potential targets for future clinical applications.

Thalassemias

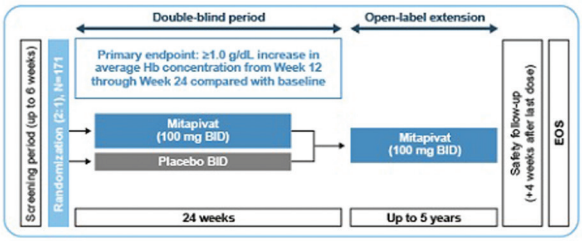
PB1804 HEMOGLOBINOPATHIES AND COVID-19: THE EXPERIENCE OF A CENTER IN NORTHERN GREECE

C. Varelas [1,*], E. Gavriilaki [1], I. Sakellari [1], F. Klonizakis [2], A. Anagnostopoulos [1], A. Tsapas [2], E. Vlachaki [2]

[1]Hematology & HCT Unit, General Hospital "George Papanikolaou", Thessaloniki, Greece, [2]Adults Thalassemia Unit, 2nd Department of Internal Medicine, Hippokration Hospital, Thessaloniki, Greece

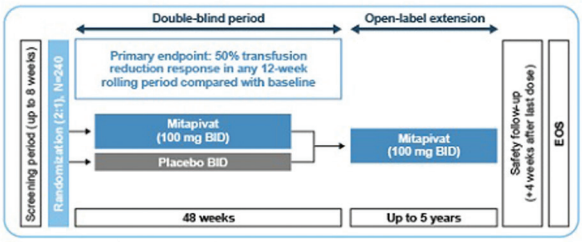
Background: Healthcare systems around the globe are still facing the evolving threat of the corovavirus-19 (COVID-19) pandemic. Hemoglobinopathies include a group of genetic disorders, with the two main pillars being thalassemias and sickle cell disease (SCD). Due to their immunocompromised status, such patients (pts) have been protected as extremely vulnerable to COVID-19 infection. Despite limited data in literature, recent reports present conflicting results
Aims: We prospectively investigated the incidence and outcomes of COVID-19 in pts with hemoglobinopathies and correlated them to their coexistent comorbidities.
Methods: We studied pts with different hemoglobinopathies, consecutively monitored at our Center, who were infected with SARS-COV 2 during the first and second "waves" of the pandemic in Greece (March - December 2020). The following factors were studied: age, employment, blood type, liver and heart hemosiderosis, splenectomy, concomitant endocrine disorders and transfusion dependency.
Results: Among 250 pts regularly followed-up at our Center (7 with HbH hemoglobinopathy 150 with Thalassemia major, 53 with SCD and 41 with non transfusion dependent thalassemia), 9 (3.4%) were infected with COVID-19 (5 male: 4 female). COVID-19 pts' age range was 20-46 (median 35.1). During the same time period the prevalence of COVID-19 infection in Greece's general population, regarding the same age groups, was 1.89%. Two pts had HbH hemoglobinopathy, 1 Sickle Cell Disease (SCD), and 6 transfusion dependent β-thalassemia (TDT). In total, 7/9 pts were transfusion dependent (TD). Blood type was A+ in 55.5%, B+ in 11.1%, AB+ in 11.1% and O+ in 22.2% of pts. The range of ferritin levels at the time of infection was 180-992 ng/ml (median 434). Seven out of 9 pts had median MRI T2* liver iron concentration (LIC) of 1.696 g/dw and median MRIT2* of the heart 33.7 tms. However, their ejection fracture (EF) was >50% at all cases. Two pts were splenectomized and 1 had functional asplenia. Only 2 pts had concomitant endocrine disorders (hypothyroidism and hypogonadism). These pts were on hormone replacement therapy. All TD pts were on iron chelation therapy (5 on deferasirox and 1 on both deroxamine and deferiprone). Three pts were healthcare employees.Six out of 9 pts required hospitalization for a median time of 5.8 days (1 with HbH, 1 with SCD during crisis and 4 with TDT), but no one required Intensive Care Unit (ICU) monitoring, intubation or intensive ventilation support. All pts presented with fever (3 with febrile neutropenia), while 2 TDT pts had ground-glass opacities. All hospitalized pts received wide-range antibiotics plus azithromycin (as did 1 TDT pt who stayed at home). Heparin was administered in the SCD pt and in 1 of the TDT pts. One pt with HbH also received hydroxychloroquine and 1 with TDT dexamethasone. At the end of follow-up (median of 3.5 months, range 1.2-4.2), all pts are alive. On the contrary, mortality of the general Greek population in the same age group and time period was 1%.
Summary/Conclusion: Our real-world data suggest that the prevalence of COVID-19 in pts with hemoglobinopathies is slightly increased compared to the general population. Considering that these pts are more strictly monitored, we could hypothesize that self-applied precautions are effective. No death or severe pulmonary disease requiring intubation was observed. In compliance with recent data, our findings do not indicate increased mortality and morbidity of COVID-19 in pts with hemoglobinopathies, followed in a Specialized Center. However, more data are needed for a safe conclusion to be extracted.

PB1805 ENERGIZE AND ENERGIZE-T: TWO PHASE 3, RANDOMIZED, DOUBLE-BLIND, PLACEBO-CONTROLLED STUDIES OF MITAPIVAT IN ADULTS WITH NON–TRANSFUSION-DEPENDENT OR TRANSFUSION-DEPENDENT ALPHA- OR BETA-THALASSEMIA



K. H. Kuo [1,*], D. M. Layton [2], H. Al-Samkari [3], A. Kattamis [4], S. Sheth [5], A. Taher [6], V. Viprakasit [7], C. X. Chamberlain [8], L. Czapla [8], S. Gheuens [8], L. Jiang [8], M. Lynch [8], B. Tong [8], K. Uhlig [8], M. D. Cappellini [9]

[1]Division of Hematology, University of Toronto, Toronto, Canada, [2]Hammersmith Hospital, Imperial College Healthcare NHS Trust, London, United Kingdom, [3]Massachusetts General Hospital, Harvard Medical School, Boston, MA, United



States, [4]First Department of Pediatrics, National and Kapodistrian University of Athens BR, Athens, Greece, [5]Weill Cornell Medical College, New York, NY, United States, [6]American University of Beirut, Beirut, Lebanon, [7]Siriraj Hospital, Mahidol University, Bangkok, Thailand, [8]Agios Pharmaceuticals, Inc., Cambridge, MA, United States, [9]University of Milan, Milan, Italy

Background: Thalassemias are characterized by imbalanced globin-chain production resulting in excess α- or β-globin precipitation, hemolytic anemia, and ineffective erythropoiesis. Adenosine triphosphate (ATP) levels are reduced in thalassemic red blood cells (RBCs), despite increased energy demands. Mitapivat (AG-348) is an oral activator of RBC pyruvate kinase (PKR), a glycolytic enzyme that regulates ATP production. In a phase 2 study of patients (pts) with α- or β-non–transfusion-dependent thalassemia (NTDT), twice-daily (BID) dosing with mitapivat increased hemoglobin (Hb) levels by ≥1.0 g/dL in 80% of pts, supporting the broadening of mitapivat's development in thalassemia.
Aims: To report the study designs of ENERGIZE (EudraCT: 2021-000211-23) and ENERGIZE-T (EudraCT: 2021-000212-34), two phase 3 trials to assess the efficacy and safety of mitapivat in adults with α- or β-NTDT or transfusion-dependent thalassemia (TDT), respectively.
Methods: Both studies are phase 3, multicenter, randomized, double-blind, placebo-controlled trials. In ENERGIZE, approximately 171 eligible adults with NTDT will be randomized (2:1) to receive 100 mg mitapivat BID or placebo for 24 weeks (wks). Upon completion, eligible pts can transition to a 5-year, open-label extension. Key inclusion criteria: documented diagnosis of thalassemia (β-thalassemia ± α-globin mutations, Hb E β-thalassemia, or α-thalassemia [Hb H disease]), Hb concentration ≤10.0 g/dL, and NTDT defined as ≤5 RBC units during the 24-wk period before randomization and no RBC transfusion ≤8 wks prior. The primary endpoint is an Hb response defined as a ≥1.0 g/dL increase in average Hb concentration from Wk 12 through 24 compared with baseline (BL). Secondary endpoints include pt-reported outcomes, changes in Hb, markers of hemolysis and erythropoiesis, and safety. In ENERGIZE-T, approximately 240 eligible adults with TDT will be randomized (2:1) to receive 100 mg mitapivat BID or placebo for 48 wks. Upon completion, eligible pts can transition to a 5-year, open-label extension. Key inclusion criteria: documented diagnosis of thalassemia (same genotypes as detailed for the ENERGIZE study), and TDT defined as 6–20 RBC units transfused and no transfusion-free period ≥6 wks during the 24 wks before randomization. The primary endpoint is a transfusion reduction response, defined as a ≥50% reduction in transfused RBC units with a reduction of ≥2 units of transfused RBCs in any consecutive 12-wk period through Wk 48 compared with BL. Secondary endpoints include additional measures of transfusion burden, changes in iron markers, and safety.
Results: Not yet available.

ENERGIZE: Phase 3 randomized clinical trial for adults with α- or β-non–transfusion-dependent thalassemia

ENERGIZE-T: Phase 3 randomized clinical trial for adults with α- or β-transfusion-dependent thalassemia

BID=twice daily; EOS=end of study; Hb=hemoglobin.

Summary/Conclusion: ENERGIZE and ENERGIZE-T are the first pivotal studies to assess a potential treatment across a broad spectrum of pts with thalassemia (ie, pts with TDT and NTDT; α- and β-thalassemias). This phase 3 program will evaluate the efficacy and safety of mitapivat, a novel, first-in-class oral activator of PKR. Both studies will start enrollment in 2021.

PB1806 DESIGN AND DEVELOPMENT OF A MACHINE LEARNING-BASED PREDICTIVE MODELLING TOOL TO ACCURATELY PREDICT THALASSEMIA CARRIER STATE USING FULL BLOOD COUNT INDICES AND HAEMOGLOBIN VARIANTS

C. Kolambage [1,*], H. Goonasekera [1], R. Hewapathirana [1]

[1]Human Genetics Unit, Faculty of Medicine, University of Colombo, Sri Lanka

Background: An effective screening programme to detect Thalassemia carriers is a vital part of Thalassemia prevention. There are many challenges to an effective screening programme, especially in low-resource settings. Machine learning (ML) has been instrumentalized in a range of prognostic and diagnostic medical tasks to overcome domain-specific and technical challenges. This study attempted to apply an ML-based tool to Thalassemia screening to accurately predict the Alpha thalassemia carrier state from a simple blood test. An effective screening programme to detect Thalassemia carriers is a vital part of Thalassemia prevention. There are many challenges to an effective screening programme,especially in low-resource settings. Considering alpha-thalassemia, genetic testing is needed for a confirmatory diagnosis of a carrier, which is expensive and not widely available. In this era of big data and exponentially increasing computing power, machine learning (ML) is being increasingly used in a range of prognostic and diagnostic medical tasks to overcome domain-specific challenges.
Aims: This study attempted to apply modern machine learning algorithms to alpha-thalassemia screening data, and develop a cost-effective and time-saving ML tool which can accurately predict the alpha thalassemia carrier state using simple blood tests. This tool can then be used in circumstances where there are constraints to genetic testing, and can act as a complimentary diagnostic tool which can identify high risk individuals who need to undergo confirmatory genetic testing.
Methods: Ethical clearance was obtained from the Ethics Review Committee of Postgraduate Institute of Medicine, University of Colombo. A database of 288 cases from the Human Genetics Unit (HGU) of the Faculty of Medicine, Colombo was used to train and test the ML tool. Three different models were formulated and tested on a validation set. Random Forest Algorithm, and an Artificial Neural Network (ANN) with four hidden layers were used to train each of the models. The relative performances of the algorithms on each model were compared in terms of overall accuracy and F1 score, which is a measure of sensitivity and positive predictive value.
Results: Dataset included predominantly alpha-thalassemia carriers (n = 149), but also individuals with normal red cell indices (n = 55), iron deficiency anaemia (n = 21) and beta-thalassemia carriers (n = 17). Model 1 was trained to differentiate between alpha-thalassemia carriers and normal individuals, and the Random Forest outperformed the ANN with an Accuracy of 93.5% and an F1 score of 87.5%. Model 2 differentiated between alpha-thalassemia silent carriers and alpha-thalassemia traits, and the Random Forest again showed a superior performance with an accuracy of 88.8% and an F1 score of 86.3%. Both models showed a satisfactory performance in all categories in the confusion matrix which plotted the true labels against predicted labels. Model 3 was developed to differentiate between thalassemia carriers, iron deficiency and normal individuals. Although ANN showed a superior performance with an overall accuracy and F1 score of 83.3% on model 3, the model only correctly classified one of the three iron deficiency cases in the validation set.

Summary of the Results obtained in the three predictive models

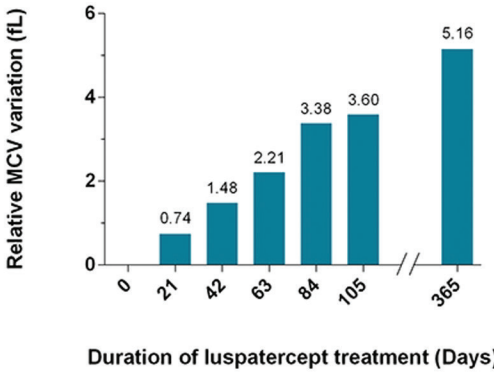
Model	Input Variables (Predictors)	Output (Target) Categories	Performance of the best model on test set	Most Important Feature (via Decision Tree visualisation)
Differentiating alpha thalassemia carriers from 'normal' individuals (Model 1)	Full Blood Count MCV, MCH, MCHC, Hb, PCV Haemoglobin Variants HbA	• Alpha thalassemia carrier • 'Normal' Individuals	*Random Forest :* Accuracy – 93.5% F1 score – 87.5%	MCV ≤ 80fL
Differentiating between two types of alpha thalassemia carriers (Model 2)	Full Blood Count MCV, MCH Hb, PCV, RDW, RBC Haemoglobin Variants HbA, HbA2	• Alpha trait • Alpha Silent carrier • 'Normal' Individuals	*Random Forest :* Accuracy – 88.88% F1 score – 86.36%	MCH ≤ 21pg
Differentiating between thalassemia, iron deficiency and 'normal' individuals(Model 3)	Full Blood Count MCV, MCH, MCHC, Hb, PCV Haemoglobin Variants HbA	• Thalassemia • Iron Deficiency • 'Normal' Individuals	*Neural Network:* Accuracy – 83.33% F1 score – 83.3%	MCV ≤ 80fL

Summary/Conclusion: Model 1 and 2 showed satisfactory performance, while model 3 did not. Model 1 and 2 can be combined to a diagnostic tool to identify alpha-thalassemia carrier states. The tool could be used in situations where there are constraints to genetic testing after being validated prospectively with a larger dataset.

PB1807 RETROSPECTIVE ANALYSIS OF OGTT IN PATIENTS WITH TRANSFUSION-DEPENDENT B-THALASSEMIA DURING THEIR SECOND DECADE OF LIFE

M. Dritsa [1], A. Teli [2], V. Perifanis [3], M. Economou [2,*], A. Christoforidis [2]

[1]Aristotle University of Thessaloniki, [2]1st Pediatric Department, [3]1st Propedeutic Department of Internal Medicine, School of Medicine, Faculty of Health Sciences, Aristotle University of Thessaloniki, Greece, Thessaloniki, Greece



Background: Current guidelines recommend yearly evaluation of glucose metabolism with Oral Glucose Tolerance Test (OGTT) in patients with transfusion-dependent thalassemia from their 10th year of age onwards.
Aims: To retrospectively analyse all the OGTT tests performed in a single pediatric center during the last decade and evaluate the necessity of yearly performed OGTT in patients with transfusion-dependent b-thalassemia during the second decade of life.
Methods: One hundred and seventy tests performed in 39 patients (24 boys) were included in the analysis. Mean age at the time of each OGTT was 14.15 ± 2.79 years.
Results: Seventeen tests (10%) in 8 patients (5 boys) were characterized as Impaired Glucose Tolerance (IGT) with a 2-hour glucose value above 140 mg/dl but below 200 mg/dl. In 20 tests (87.06%) fasting glucose values were between 100-125 mg/dl (Impaired Fasting Glucose, IFG), whereas in 2 tests (1.18%) fasting glucose values were above 200 mg/dl (Diabetes Mellitus, DM). These 22 abnormal fasting glucose values were belonged to 12 patients (8 boys). Acknowledging the fact that there could be sporadic technical errors, especially in fasting glucose abnormal values, we selectively separated patients with either IGT and abnormal HOMA, MATSUDA or QUICKI indices or persistent IFG or IGT. With these criteria, 7 patients (4 boys) were identified. When compared with the rest 32 patients, these 7 patients with a definite abnormal glucose metabolism did not significantly differ regarding their age, anthropometric parameters or ferritin levels. In order to address selection criteria for performing OGTT but without missing a single patient with a definite glucose intolerance, these criteria should include: i) a first OGTT test at the initiation of puberty, ii) OGTT in any patient with a fasting glucose above 100 mg/dl and iii) OGTT in any patient with a HOMA-IR index above 1.85 and yearly onwards. By adopting these criteria in our cohort of patients, not a single patient with consistent abnormal glucose metabolism would have been missed, while, on the other hand, total OGTT tests performed could have been reduced from 170 to only 91, translating to a significant reduction of 46.47%.
Summary/Conclusion: Only a small percentage of young patients with transfusion-dependent b-thalassemia exhibit abnormal glucose metabolism during their second decade of life. By adopting specific selection criteria, one may avoid the performing of this time- and money-consuming test in a significant proportion of patients, albeit, without sacrificing timely detection and intervention.

PB1808 MCV VARIATION AS AN EARLY PREDICTOR OF RESPONSE TO LUSPATERCEPT IN NTDT PATIENTS: PRELIMINARY DATA

A. Piolatto [1,*], P. Berchialla [1], N. Tesio [1], M. Boschero [1], V. Sciannameo [2], F. Longo [1], G. B. Ferrero [1], A. Piga [1]

[1]Department Of Clinical and Biological Sciences, University of Torino, Orbassano (TO), [2]Unit of Biostatistics, Epidemiology and Public Health, Department of Cardiac, Thoracic, Vascular Sciences and Public Health, University of Padova, Padova, Italy

Background: Beta-thalassemia is characterized by ineffective erythropoiesis, leading to a decreased number of mature and functional RBC, resulting in mild to severe anemia. Luspatercept is the first approved disease-modifying drug, currently indicated for Transfusion-Dependent Thalassemia (TDT) and in advanced trials for Non Transfusion-Dependent Thalassemia (NTDT). The response to luspatercept is quantified by the increase in total hemoglobin (Hb) in NTDT and by the decrease in transfusional need for TDT, but both changes require a long time to be consistently assessed.
Aims: To explore the hypothesis that early modifications in red blood cell indices could have a predictive value of response to luspatercept.
Methods: As reference Centre for Hemoglobinopathies of University of Torino we took part of luspatercept phase II/III clinical trials (NCT01749540, NCT02268409, NCT02604433, NCT03342404, NCT04064060). In this analysis we considered only local blood tests for all our patients that received luspatercept; patients or time frames on placebo were excluded. Responders and non responders were defined according to published clinical trial protocols: specifically, an increase in Hb ≥ 1.5 g/dL (NTDT) or a reduction in RBC transfusion need ≥ 33% (TDT) from baseline in weeks 13 to 24.
A generalized least-square regression model was used to ascertain whether the interaction between groups and time with respect to Hb, MCV, MCH, MCHC, RDW and Reticulocytes count was significant. A correlation structure was specified to account for repeated measures over time on the same patient with a continuous-time autoregressive of order 1 correlation structure. A recursive partitioning tree model was further developed to identify biomarkers time-dependent thresholds associated with heterogeneous treatment effects.
Results: The overall time of luspatercept treatment has been 32.0 years. The median duration for NTDT was 2.4 years (range 0.2-6.0) and for TDT 1.7 years (range 0.3-6.0) for each patient. We reviewed 1024 blood tests of 14 NTDT patients (9 responders, 5 non-responders) and 1968 blood tests of 14 TDT patients (10 responders and 4 non-responders).
No predictor of response was identified in blood test indices of TDT patients.
In NTDT patients, beyond the hemoglobin that defines the response, the index with better discriminative power was the MCV. A statistically significant trend difference in MCV was observed between responders and non-responders (p=0.03). Although the difference between groups is significant from 27 weeks after treatment start, responders show a relative increase in MCV compared to non-responders from the first weeks of treatment, reaching a mean variation of +5.16 fL at one year (see figure). The change remains long term. At baseline responders and non responders did not differ for age, genotype and total Hb, whereas mean baseline MCV was lower in responders (66.1 vs 72.3 fL), but this difference was not significant.

Relative MCV variation during treatment with luspatercept for the responders group, calculated as difference from MCV values of non-responders and normalized for baseline. Reported values represent the mean prediction of the statistical model based on clinical data. N(patient)=14, N(observations)=1024. P=0.03.

Summary/Conclusion: NTDT patients who respond to luspatercept treatment show an early increase in MCV; this change keeps up to 6 years. In part, this could be due to the rise in reticulocytes. In our data, a variation of reticulocytes alone is not sufficient to predict the response, but this could be due to the small sample size. More likely the MCV improvement could be the result of the not fully understood effects of luspatercept in regulating the late-stage RBC maturation.
These data need verification on a large set. If confirmed, the early MCV change may be easily applied in the clinical setting to predict long-term response to luspatercept among NTDT patients.

PB1809 THE PATIENTS WITH THALASSEMIA MAJOR MAY STILL DISPLAY GROWTH HORMONE DEFICIENCY DESPITE OPTIMUM TRANSFUSION AND IRON CHELATION THERAPY.

Y. Aydinok [1,*], V. Samedli [1], N. Karadas [1], O. Hamiyet [1], B. Yurekli [2]

[1]Department of Pediatric Hematology, [2]Department of Endocrinology, Ege University, Faculty of Medicine, Izmir, Turkey

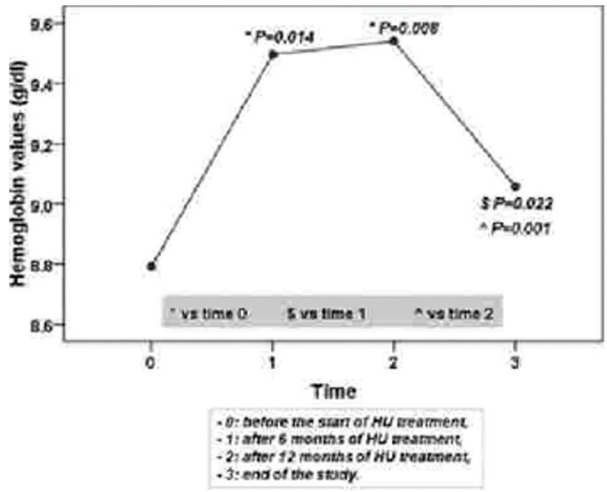
Background: Growth retardation (GR) and pubertal disorders are the earliest consequences of iron toxicity resulting from the pituitary iron deposition in children and adolescents with thalassemia major (TM). It is suggested that appropriate transfusion and iron chelation therapy (ICT) support proper growth and development.
Aims: The purpose of this study was to evaluate if the current treatment protocols may support a normal growth progression and sexual development in patients (pts) with TM.
Methods: We recruited male (M) and female (F) TM pts born after 2000. The pts with an acute or chronic illness that may interfere with growth and development or stem cell transplantation recipients were excluded. The Ethical Committee of Clinical Investigation (19.02.2020, 20-2.1T/2) approved this study. Transfused packed red cell units (pRBC) and average pre-transfusion hemoglobin (Hb) per year were recorded. Serum ferritin (SF) was monitored monthly (m). Myocardial (T2*) and liver (R2) iron were assessed by magnetic resonance imaging (MRI) after 8-years (y) of age. Annual median SF, prescribed chelator(s), mean chelator doses were recorded. Transfusional iron intake (TII) was estimated and expressed as mg/ kg b.w./days. Height (H) and weight (W) assessments were performed using the Harpenden stadiometer, and puberty was evaluated by Tanner staging at 3 monthly. H-standard deviation scores (h-SDS) were calculated. All pts were assessed annually for bone mineral density (BMD) after 8 y. The mean SDS of the lumbar spine (L1-4) BMD between -1 and -2.5 was defined as osteopenia and <-2.5 as osteoporosis. Growth hormone (GH) secretion was assessed by L-dopa and insulin tests in those with standing-H below the –2 SD. Pts whose GH response to both stimulation tests (STs) was less than 5 ng/ml with the monoclonal assay was defined as GH deficiency (GHD).
Results: We evaluated 30 TM (28 β/β, 1 β/δβ, 1 HbH) pts (13 F and 17 M) with the mean age of 12,5 ± 4,5 y. All pts have received pRBC for 11,1 ± 4,4 y and maintained pre-transfusion Hb> 9 g/dl. The patients started ICT by the SF of 1430 ± 795 ug/L and maintained ≤1500 ug/L at all times during 9 ± 4.2 y. Twenty-four pts received only Deferasirox (DFX) chelation while 6 were initiated ICT by Deferoxamine (DFO) and continued with DFX. Liver iron concentration (LIC) and myocardial T2* (mT2*) in 22 pts were between 0.9-5.4 (2.1 ± 1.3 SD) mg Fe/g d.w. and 19.4-43.5 (28 ± 6.7 SD) ms, respectively, in all assessments. The puberty initiated at 12.8 ± 1.1 y in M (n=12) & 11.2 ± 1.3 y in F (n=12) and progressed without hormone replacement in all. Overall, growth velocity reduced compared to the non-thalassemic population after 8 y with clear evidence of growth catch-up by the onset of puberty. Five pts (16.5%) developed h-SDS< -2 at 10-12 y-old when all but one had S1/2 puberty and displayed GHD. All pts received GH therapy. The pt no 4 was entirely unresponsive to GH-STs, developed GR at 1 y-old, and has remained unresponsive to GH therapy (Table). The 14 (%58) and 5 (21%) of 24 pts demonstrated osteopenia and osteoporosis, respectively. The BMD-SDS improved following pubertal spurt.

Table. The growth progression by GH treatment in thalassemia major patients with GR and GH deficiency

Pts no	Iron chelator		Max SF (ug/L)	Target h-SDS	Prior GH therapy			1st y of GH		Final G & D		
	I	FU			P	B-/C-age (y)	h-SDS	P	GV (cm)	P	C-age (y)	h-SDS
1	DFO	DFX	*4725	-1,41	S1	11,5/13	-2,46	S2	7,1	S5	18	-1,68
2	DFO	DFX	*2465	0,24	S1	10/13,2	-3,10	S2	8,9	S5	18	-0,19
3	DFX	DFX	1528	0,66	S2	11/12,7	-3,16	S3	9,2	S5	16	-1,64
4	DFX	DFX	1580	0,21	S1	6/10,7	-3,41	S1	3,2	S3	16	-4,30
5	DFX	DFX	1183	-0,54	S1	7,5/11,5	-2,31	S1	6,8	S1	13	-1,90

I: Initial, FU: Follow-up, B-age: Bone-age, C-age; Chronological-age, GV; Growth velocity, GH; Growth hormone,GR; Growth retardation, DFO; Deferoxamine, DFX; Deferasirox, G&D; Growth and Development
*The max. SF reached during 1st years on DFO then SF normalized around 1000 ug/L

Summary/Conclusion: The high prevalence of GHD in TM patients receiving an optimum transfusion and ICT throughout their life was disappointed. The most probable explanation is, growth patterns and bone-maturation in TM pts might differ from the non-thalassemic population, and the GH-STs may lead to overdiagnosis of GH deficiency in this distinct population.



PB1810 THE USE OF HYDROXYUREA IN THE REAL LIFE OF MIOT NETWORK: AN OBSERVATIONAL STUDY

P. Ricchi [1], A. Meloni [2,*], P. Rigano [3], L. Pistoia [2], A. Spasiano [1], M. Allò [4], G. Messina [5], A. Quarta [6], R. Rosso [7], A. Quota [8], A. Filosa [1], A. Maggio [3], A. Pepe [2]

[1]Azienda Ospedaliera di Rilievo Nazionale "A. Cardarelli, Napoli, [2]Fondazione G. Monasterio CNR-Regione Toscana, Pisa, [3]Ospedale "V. Cervello", Palermo, [4]Ospedale San Giovanni di Dio – ASP Crotone, Crotone, [5]Grande Ospedale Metropolitano "Bianchi-Melacrino-Morelli", Reggio Calabria, [6]Ospedale "A. Perrino", Brindisi, [7]Azienda Ospedaliero-Universitaria Policlinico "Vittorio Emanuele", Catania, [8]Ospedale "V. Emanuele III", Gela (CL), Italy

Background: Hydroxyurea (HU) has been widely used in clinical practice to manage patients with non-transfusion dependent thalassaemia (NTDT). Few data are available about the effects of its administration in Italian patients.
Aims: This multicenter study aimed to assess haematological and non-haematological outcomes following short- and long-term exposure to HU.
Methods: Among the 79 NTDT patients (<4 transfusions per year) consecutively enrolled in the Myocardial Iron Overload in Thalassaemia (MIOT) network, we considered 71 patients (30 females) treated for >12 months with HU. Patients were followed prospectively until September 2019.
Results: Patients started the treatment with HU at a mean age of 37.0±12.1 years and anemia was the indication in the 88.6% of the cases. The mean duration of HU treatment was 8.2±5.8 years.
After 12 months of therapy a significant increase in hemoglobin and mean corpuscular volume values and a significant decrease in the number of white blood cells, indirect bilirubin, nucleated red blood cells, and platelets, in uric acid levels, and in soluble transferrin receptor values were detected. We defined responders the 28 patients who achieved a ≥1.0 g/dl increase in haemoglobin levels after 12 months. Responders received a significantly higher dose of HU and showed significantly lower pre-treatment haemoglobin values. At receiving operating curve analysis, a dosage greater than 16.6 mg/dl discriminated the responders with acceptable sensitivity and good specificity (59.3% and 85.7%, respectively) and with an area under the curve of 0.75 (P<0.0001). The responders experienced a significantly higher decrease in white blood cells after 12 months of treatment.
The hematological response dropped in long-term treatment (see Figure).

During the HU treatment we did not detect significant changes in the frequency of dyspnea, asthenia, atrial dilatations, cardiovascular complications (pulmonary hypertension, arrhythmias, ulcers, and deep vein thrombosis), extramedullary hematopotesis (EMH), and fibroadipose involution of the EMH masses.

Summary/Conclusion: This study seems to suggest that not only for the hematological responder patients, but also for those affected by specific complications, HU could be still a valid option to limit the advance of the overall clinical burden disease without carrying significant adverse events and increase in mortality.

PB1811 MICRO-RNA 451 EXPRESSION AS A HEMOLYTIC MARKER IN EGYPTIAN CHILDREN WITH BETA-THALASSEMIA

Y. El Chazli [1,*], S. Imbaby [2], N. Eldabah [2]

[1]Pediatrics, [2]Clinical Pathology, Alexandria University, Alexandria, Egypt

Background: Beta-thalassemia (BT) is a genetic hematological disorder due to defect in beta globin gene, with extravascular hemolysis being a major feature of the disease. BT is the most common genetically inherited hemoglobin disorder in Egypt with a carrier rate reaching 10%. miRNA-451, an erythroid cell-specific miRNA, is upregulated during erythroid maturation, and could serve as a useful non-invasive biomarker for various diseases.
Aims: To investigate whether plasma miRNA-451can be considered as a hemolytic marker.
Methods: This cross-sectional study was conducted on 29 patients with BT attending the Alexandria University Children's Hospital Hematology outpatient clinic, Alexandria, Egypt. Patients were approached during their routine visits at the clinic and consecutively recruited if they accepted to participate and matched inclusion criteria, which were having BT (major or intermedia phenotype), being aged between 1 and 18 years, and having no known organ dysfunction (as renal or liver impairment). Ten age and sex-matched healthy chidlren were included as a control group provided they had a normal hemoglobin and RBCs indices for age. The BT patients were categorized as transfusion-dependent (TDT) if they had been receiving at least 8 packed red blood cells (PRBCs) transfusions per year, while patients receiving no or occasional transfusions were classified as non-transfusion dependent (NTDT). Complete blood counts, aspartate aminotransferase, total bilirubin, and lactate dehydrogenase where measured. Real-time quantitative PCR for miRNA was performed to detect the expression levels of miRNA-451. miRNA 134-2p was used as internal control. We compared the expression of miRNA-451 in the patients' plasma of patients to that of healthy controls.
Results: Among the 29 included patients, 16 had NTDT (age ranged from 3.2 to 17.6 years) and 13 had TDT (age from 4.5 to 14.8 years) and ten controls aged 3 to 14 years old. Plasma miRNA 451 expression was higher among β-thalassemia patients (median=0.7) when compared to controls (median=0.53) but not statistically significant, (p = 0.272). Similarly, there was an increased expression levels among TDT subgroup when compared to NTDT subgroup, (p = 0.288). The level of miRNA-451 was higher among severe cases than mild and moderate cases, (p = 0.301). There was also a higher miRNA-451 expression among splenectomized patients, (p = 0.10). In order to evaluate the diagnostic value of plasma miR-451, the $2^{-\Delta\Delta Ct}$ values of miRNA-451 from the patients' group were used to construct a ROC curve. Plasma miR-451 did not confidently discriminate between normal controls and patients (AUC = 0.621; p = 0.26). In controls, the Hb, RBCs and platelet count were all significantly correlating with the plasma miR-451 (p = 0.03, 0.008, 0.008, respectively). While in the patients' group, among the hemolytic markers only the ALP was significantly correlating with the plasma miR-451 (p = 0.007), as well as the BMI Z score among clinical parameters (p <0.001).
Summary/Conclusion: In order to investigate whether plasma miRNA-451can be considered as a hemolytic marker, we measured the expression of miRNA-451 in the plasma of Egyptian children with BT patients and compared it to healthy controls. miRNA-451 was more expressed in TDT patients compared to NTDT patients and controls, but this was not statistically significant. Plasma miR-451 failed to discriminate between normal controls and patients.

PB1812 CHELATION THERAPY WITH THE TWO DEFERASIROX FORMULATIONS IN TRANSFUSION-DEPENDENT THALASSEMIA CHILDREN OVER THE PAST TWO DECADES: A SINGLE CENTER EXPERIENCE

A. Adramerina [1,*], A. Teli [1], S. Simeonidis [1], C. Sidira [1], H. Papadopoulou [1], M. Economou [1]

[1]1st Pediatric Department, School of Medicine, Faculty of Health Sciences, Aristotle University of Thessaloniki, Thessaloniki, Greece

Background: Deferasirox (DFX) is once-daily oral iron chelator that was developed out of need for a long-acting chelator for patients with chronic iron overload. The first marketed formulation was a dispersible tablet (DT) thathad to be mixed inalarge amount of liquid and to be taken on an empty stomach. In addition to being unpalatable, it was commonly related to gastrointestinal symptoms. In that context, a new formulationin in the form of film coated tablet (FCT) was developed. FCT is still given once-daily, but can be taken with a light meal and differs with regards to excipients, offering improved palatability and tolerance.
Aims: To retrospectively report on the long-term experience of DFX use in transfusion-dependent thalassemia (TDT) children followed at a single Unit and to present a comparison between its two formulations.
Methods: Medical records of patients who received DFX were retrospectively evaluated. Data regarding demographics, duration and dose of chelation, renal and liver function, ferritin levels, and clinical adverse events were recorded. Statistical analysis was performed using the Wilcoxon test.
Results: A total of 44 patients treated with DFX DT were identified, between 2003 and 2016. Mean age at time of DFX DT exposure was 7.6(2– 15.3) years. Mean duration of exposure was 58.3 (3-141) months and mean daily dose 23.4(10-40)mg/kg. Prior to initiation, mean ferritin levels were 1094.7 (114–2760) ng/ml and at end of study 1149.1 (216-3184) ng/ml(P=0.6). At study entry mean creatinine levels were 0.49 (0.34-0.84) mg/dl and at end of study 0.7 (0.37-1.06) mg/dl (P<0.0001). During follow up 26/44 patients (59%) temporarily interrupted treatment, at one or more time points, on account of the following: 7/26 patients(26.9%) due to increased liver enzyme levels, 4/26(15,4%) due to renal dysfunction including increased creatinine levels and/or increased protein or calcium output, 4/26(15.4%) due to abnormal liver enzyme levels and concurrent renal dysfunction,, 2/26(7.7%) due to epigastralgia, and 1/26 (3.8%) due to either rash, epigastralgia or pregnancy. In 17/44 patients (38.6%) a switch to another chelator was decided due to recurrent adverse events after drug re-initiation.
A total of 27 children received DFX FCT after it was marketed in September 2017 until February 2021. Mean age at initiation was 12.9 (2 –18) years. Mean exposure time was 27.15 (8-40) months and mean daily dose was 16.4 (10-27.5) mg/kg. Prior to DFX FCT mean ferritin levels were 1197.2 (438–2094) ng/ml and mean creatinine levels 0.66 (0.4-0.98) mg/dl. At end of study mean ferritin and creatinine levels were 1300 (515-2829) ng/ml (P=0.75) and 0.7 (0.38-0.96) mg/dl (P=0.15), respectively.
During follow up 5/27 patients (18.5%) temporarily interrupted treatment due to increased liver enzyme levels (4/5,80%) or increased creatinine levels (1/5,20%). In total, 6/27 patients (22.2%) switched to other chelationregimens.
Summary/Conclusion: DFX demonstrated an adequately efficacious and safe profile in a pediatric thalassemia cohort over almost 2 decades. Although experience with DFX FCT is comparably limited, results are encouraging, especially in terms of number of related renal adverse

events. The new formulation's favorable safety profile along with its improved palatability may offer, in the long run, better adherence and optimal control of iron overload-related complications.

PB1813 ROLE OF TELEMEDICINE IN MANAGEMENT OF ADULT EGYPTIAN THALASSAEMIA PATIENTS DURING COVID-19 PANDEMIC; PATIENTS SURVEY

R. Rawi [1,*], N. M El Husseiny [1], N. Tawfik [1], M. Salah [1], M. Mattar [1]

[1]Hematology unit,Internal medicine department, Kasr Al Ainy hospital, Cairo university, Cairo, Egypt

Background: COVID-19 caused a massive damage to the whole world. Telemedicine (TM) is an excellent, safe,effective method to follow Adult B-thalassemia patients which are experiencing a chronic morbidity.
Aims: Evaluating medical service administrated to Adult B-thalassemia patients after 3 months of online follow up.
Methods: Since April 2020, follow up of our patients done via audio visual calls & whats app group which was created during the pandemic to follow thalassemia patients.Our clinic serves patients in an area range of about 1000 Km^2, and out of 100 adult B-thalassemia (major and intermedia) who are regularly following in haematology clinic only 30 patients were able to connect through whats app group with the physician.
After Three months (in July 2020) a simple Arabic questionnaire was given to our patients. Questionnaire asked about gender, degree of education, and whether the patient from urban or rural area.
The patients were asked if the application was easy to use & time saving, and was the online consultations were effective.They were asked about the new labs they performed and if their treatment was modified accordingly, & how often this happened. Whether their condition required attendance to casuality & for what reason.
Regarding COVID-19, patients were asked if the pandemic affected their routine medical service and receiving their treatment. In addition there were inquiries about any suspicious symptoms they suffered from since the start of the pandemic, if they notified the physician once they have these symptoms, if they performed COVID-19 swab,and what is the treatment they were prescribed.
Finally, we have asked about attendance to the hospital despite of TM service and for what reason.
Results: Thirty patients included in this study, 24(80%) females & 6(20%) males with median age of 29.5(17-50) years. Twenty-five (83%) patients were educated to higher school or more while 5 of patients were not educated. Twenty (67%) patients lived in urban areas &10 (33%) patients lived in rural areas.
Twenty-eight (93.3%) patients found the application easy while 2(6.7%) patients found it difficult. The application was time saving & consultations were efficient for 29 (97%) patients while it was not in only 1(3%) patient. Twenty-four (80%) patients didn't attend the casuality department while 6(20%) patients attended for blood transfusion.
Nineteen (63.3%) patients were asked to do new labs. Five (16.6%) patients needed to change their treatment, 2 of them changed it one time and 3 patients changed it more than one time. Twenty-five (83.4%) patients contacted consultant more than one time.TM consultations increased since the start of whats app group for 25 (83.4%)patients with no change in 4(13.3%) patients while it decreased in one (3.3%) patient only.
As regard to COVID-19, Ten(33.3%) patients had suspicious symptoms as fever or sore throat, 8 of them notified their consultant with description of Azithromycin to all of them. Despite TM, 21(70%) patients attended to the hospital, 14 of them to get monthly treatment, 6 patients for examination & treatment, and one patient for examination only.
About 70 consultations had been sent through whats app group before the survey and about 115 laboratory results sent during the 3 months of online follow up.
Summary/Conclusion: Current evidence supports that telemedicine can be a fast, safe, and effective tool to increase care for adult thalassemia patients during pandemic time.

PB1814 DISTINCTION BETWEEN IRON DEFICIENCY ANEMIA AND MINOR B-THALASSEMIA: DETERMINATION OF CUT-OFF OPTIMAL VALUES OF TEN HEMATOLOGICAL FORMULAS

M. Ben Ayed [1,*], A. Chakroun [1], S. Saffar [1], A. Jabri [1], M. Chelly [1], H. Baccouche [1], S. Mahjoub [1], N. Ben Romdhane [1]

[1]Hematology, La Rabta Hospital, Tunis, Tunisia

Background: Anemia is a public health problem. Two etiologies of microcytic anemia are relatively common in our country: iron deficiency anemia (IDA) and minor β-thalassemia (βTM). To guide the clinician in discriminating IDA from βTM, several studies have developed indices and formulas based on cells blood count parameters determined by hematology analyzers.
Aims: The aim of our study was to study the performance of these formulas to discriminate βTM and IDA and to identify the cut-off values adapted to our population for each formula.
Methods: After reviewing the records of adult patients with IDA and βTM, two groups were formed (IDA (n=172) and βTM group (n=69)). Demographic and cells blood count data were recorded. Performances of ten formulas and indices reported in the literature in the discrimination between IDA and βTM were studied. Statistical analysis was performed using SPSS 19.0. Sensitivity, specificity, Likelihood ratios, predictive values and analysis of ROC curves were carried out. Optimal cut-off values were determined according to calculation of Youden Index (J).
Results: Among CBC parameters, the hemoglobin rate, the erythrocyte count and the IDR-SD parameter showed an excellent discriminating power (respectively; AUC= 0.913, 0.971 and 0.968). Performance assessment of the various original cut-off indices, three of them were reliable: Green King index (Se= 71.01%, Sp= 97.67%; AUC=0.96), RDWI (Se= 78.26%, Sp=97.67%; AUC=0.95), and Sirdah index (Se=76.81%, Sp=97.67%; AUC=0.965). At the new cut-off, the England and Fraser index, the Green King index, the Sirdah index and the RDWI were the most effective in diagnosing βTM. At these new thresholds, only England and Fraser index and Sirdah index showed a gain in sensitivity and accuracy.
Summary/Conclusion: The use of formulas and indices to distinguish βTM from IDA is a considerable decision support tool for the clinician, however the adoption of population-specific cut-offs helps to improve the performance of these formulas and indices. The technology deployed by hematology analyzers and some clinical data would be necessary for optimal diagnostic guidance.

PB1815 USE OF RED BLOOD CELL AND RETICULOCYTE PARAMETERS FOR THE SCREENING OF MICROCYTIC ANAEMIA

A.-S. Adam [1,*], S. Benyaich [1], S. Eeckhoudt [2], F. Cotton [1], B. Gulbis [1]

[1]Clinical Chemistry, [2]Haematology, LHUB-ULB, Brussels, Belgium

Background: Anaemia is a global public health problem that affects almost one-third of the world population. Thalassaemia and iron deficiency anaemia are the most common causes of microcytic anaemia, with similar clinical and laboratory features, making their diagnostic often complicated. During the last decade, cell counter-based formulae and algorithms have been proposed in the differential diagnosis of microcytic anaemias. Unfortunately, only a few studies take into account certain not so rare clinical situations where microcytic anaemia may occur.
Aims: The aim of this study was to develop an algorithm as first tier screening tool in the differential diagnosis of microcytic anaemias.
Methods: We retrospectively analyzed results of complete red blood cells (RBCs) and reticulocyte (RET) counts obtained on the Sysmex XN-9000 of 280 adults, divided into 5 different groups: iron deficiency anaemia (n=56), β-thalassaemia minor (n=68), heterozygous haemoglobinopathies (n=24), hereditary spherocytosis (n=14) and other patients (n=118). A Classification and Regression Tree (CART) analysis was performed to obtain an algorithm in order to predict these groups.
Results: Four parameters were selected by the CART analysis: the percentage of microcytic RBCs (%MicroR), the %MicroR to percentage of hypochormic RBCs ratio (%MicroR/%Hypo-He), the reticulocyte haemoglobin content (RET-He) and the reticulocyte count to immature reticulocyte fraction ratio (RET/IRF). When applying the algorithm, 93/106 of the hereditary RBC disorder patients and 41/56 iron deficiency anaemia patients were corectly screened. The correct overall classification rate reached 83.6%. The best sensitivity and specificity were obtain for the screening of β-thalassaemia minor, with 92.6% and 94.8% respectively.
Summary/Conclusion: We proposed a costless, affordable, easy to use and effective algorithm that can be used routinely for the differential diagnosis of microcytic anaemias. The latter is based on erythrocyte and reticulocyte parameters offered by the most recent generation of the Sysmex analyzers, the XN-9000.

PB1816 IMMUNE PROFILE EVALUATION IN PEDIATRIC PATIENTS WITH TRANSFUSION DEPENDENT THALASSEMIA

A. Teli [1], A. Adramerina [1], S. Simeonidis [1], D. Adamidou [2], V. Tzimouli [1], M. Trachana [1], M. Economou [1,*]

[1]1st Pediatric Department, School of Medicine, Faculty of Health Sciences, Aristotle University of Thessaloniki, [2] Blood Bank Centre, Hippokration General Hospital, Thessaloniki, Greece

Background: Transfusions, oxidative stress splenectomy, as well as iron overload have been correlated to immune defects in transfusion dependent thalassemia patients. However, literature reports on immunoglobulin levels in this patient population remain contradictory. On the other hand, hyper reaction to constant immune challenges has also been a topic of controversy.
Aims: To evaluate the immune profile of pediatric multi - transfused patients with beta thalassemia.
Methods: The study group consisted of pediatric transfusion dependent thalassemia patients followed at a single Pediatric Hematology Department. Patients with a history of splenectomy, active autoimmune disease, active severe infection or any systemic condition that could affect the immune profile were excluded. Blood samples were collected from all subjects for evaluation of immunoglobin levels, C3 and C4 complement factors, red cell auto-antibodies, as well as antinuclear (ANA), and anti-double stranded DNA (anti-sdDNA), anti-thyroid peroxidase (anti-TPO) and anti-thyroglobulin (anti-TG) antibodies. Clinical and laboratory data were obtained from chart reviews, including demographics, presence of severe infections, duration of transfusion, history of allo-immunization, chelation therapy, heart T2* MRI and Liver Iron Concentration (LIC), as well as mean annual hemoglobin and ferritin levels.
Results: In total, 24 patients enrolled in the study. Mean patient age was 13.3 (2–19) years and 18/24 (75%) were males. No record of severe infection was noted. Mean annual pre-transfusion hemoglobin level was 9.5±0.48 (8.5-10.3) g/dl and mean annual ferritin level 1,228±538 (409-2,627) ng/ml. Mean duration of transfusion therapy was 9.6±5 (1.5–18) years. All except one patient were on chelation therapy. In specific, 12/23 patients (52.1%) were on deferasirox, 4/23 (17.3%) on deferiprone, 2/23 (8.6%) on deferoxamine 4/23 (17.3%) on deferoxamine / deferiprone combination and 1/23 (4.3%) on deferasirox / deferiprone combination. In 21/24 patients an annual MRI evaluation was available, with a mean heart T2* value of 32.01±6.19 (22.3-49) ms and a mean LIC of 8.05± 9.3 (1.28-32.9) mg/gdw.
With respect to immunoglobulin levels, mean IgG levels were 9.94±2.7 (6.3–15.1) gr/l with 7/24 (29.1%) patients presenting with lower than normal values, mean IgM levels were 1.1±0.6 (0.47 – 2.2) gr/l with 5/24 (20.8%) patients presenting with lower than normal values and mean IgA levels were 1.56±0.7 (0.6-3.38)gr/l with 2/24 (8.3%) patients presenting with lower and 2/24 patients (8.3%) with higher than normal levels. In total 10/24 patients (41.6%) and 1/24 (4.1%) had lower C3 and C4, respectively, with mean values of 0.77±0.14 (0.53 – 1.06) gr/l and 0.17±0.05 (0.09 – 0.28) gr/l. Positive ANA titres of ≥ 1:80 were found in 7/24 patients (29.1%) whereas no patient presented with positive anti-ds DNA, anti – TPO, anti- TG or red cell auto-antibodies. In total, 4/24 (16.6%) patients presented with a positive indirect Coombs test. No significant correlation was found between immunoglobulin levels, complement factors levels or autoantibody presence with age, duration of transfusion, allo-immunization, chelation therapy or iron overload.
Summary/Conclusion: The present study revealed an abnormal immune profile in a number of transfusion dependent pediatric patients, although no correlation to parameters studied was made. Larger prospective studies are needed in order to identify clinical relevance of the reported findings.

PB1817 KNOWLEDGE ON THALASSAEMIA AMONG STUDENTS AGED BETWEEN 14-17YRS IN KURUNEGALA DISTRICT, SRI LANKA

R. Warushahennadi [1,*], W. P. Angurukankanamge [1], D. Wanasundara [2], J. Nilam [1], A. Abeysekara [1]

[1]National Thalassaemia Center, [2]National Thalassaemia Centrer, Teaching hospital, Kurunegala, Sri Lanka

Background: Prevention and control of thalassemia in a country needs public education to prevent marriages between carriers. Correct message has to be delivered to the community so that the public will understand the importance of prevention. Kurunegala is one of the districts in Sri Lanka where thalassaemia is highly prevalent.
Aims: The aim of this study was to assess the knowledge on thalassemia of school children aged 14-17 years in Kurunegala district, Sri Lanka.
Methods: Descriptive cross-sectional study. Using probability proportional to size sampling technique, 55 clusters of 30 students in the age range 14-17 years each, were selected from all the schools in Kurunegala district. Within each selected school, the required number of children was selected randomly.
Results: Out of the participants (n=1821), majority (92.6%) had heard of thalassaemia before. Majority (83.4%) of participants showed high knowledge score regarding thalassaemia. Age, gender, ethnicity and the type of school correlated with knowledge score.
Summary/Conclusion: Based on study findings, students of Kurunegla district, showed satisfactory level of knowledge regarding thalassaemia. Good knowledge in young generation regarding the disease, diagnosis and prevention will reduce the incidence of thalassaemia in Kurunegala district in the future.

PB1818 GENETIC VARIATIONS OF IRON REGULATORY PROTEINS: FERROPORTIN-1(-8CG), TMPRSS6 (RS855791) AND HEMOJUVELIN (I222N AND G320V) WITHIN B-THALASSEMIA MAJOR PATIENTS

N. El-Gharbawi [1], I. Shaheen [1,*], M. Hamdy [2], S. Elgawhary [1], M. Samir [3], B. M. H. Matta Hanna [2], E. Yousief Ali [4], E. A. Youssef [1]

[1]Clinical and chemical pathology, [2]Pediatrics, [3]Cardiology, Cairo University, Cairo, [4]Clinical and chemical pathology, Fayoum University, Fayoum, Egypt

Background: β-thalassemia represents one of the most common human genetic disorders. The standard line of therapy is to combine regular blood transfusion with effective iron chelation, however iron overload remains a major cause of morbidity and mortality. Iron regulatory proteins and their genetic variants together with changes in hepcidin levels in thalassemic patients could affect the disease manifestations.
Aims: The aim of this work was to study genetic variations of ferroportin-1(-8CG), TMPRSS6 (rs855791) and hemojuvelin (HJV I222N and G320V) within β-thalassemia major patients.
Methods: tial
Polymerase chain reaction Restriction Fragment Length Polymorphism (PCR RFLP) analysis was used to study the four mentioned polymorphisms in comparison to fifty normal control subjects, to assess their poten
Results: Liver Iron Concentration (LIC) was significantly higher in patients harboring the homomutant FPN1 (GG) genotype compared to those with the wild genotype, Pulmonary artery pressure (PAP) was significantly higher in patients harboring the mutant FPN1 genotypes. MRI cardiac T2* was significantly lower among patients with the homomutant HJV I222N (AA) genotype.
Summary/Conclusion: Our results suggest that genetic variants in iron regulatory proteins could alter the manifestations of iron overload thus resulting in different clinical phenotypes of thalassemic patients.

PB1819 HB MARUCHI [ALPHA165 (E14) ALA> PRO; HBA1: C.196G> C]: A NEW THALASSEMIA HEMOGLOBINOPATHY RELATED TO THE ALPHA1 GLOBIN GENE

P. Ropero [1,*], J. M. Nieto [1], F. A. González [1], A. Villegas [1], A. Alfayate [1], M. Menéndez [1], D. Cubillas [1], B. Colás [1], A. Calo [1], M. Gómez [1], C. Benavente [1]

[1]Hematology, Hospital Clínico San Carlos, Madrid, Spain

Background: In thalassemias there are structural variants that, however, present a phenotype of α-thalassemia called thalassemic hemoglobinopathies, they are included in the so-called α-thalassemia no deletion. Non-deletion thalassemia represents 12% of all α-thalassemia in our country and 36% is due to thalassemic hemoglobinopathies
Aims: We present a new mutation in CD65 of the HBA1 gene, where the change AAG>TAG (Ala>Pro) generates a thalassemic hemoglobinopathy.
Methods: The propositus, a 37-year-old man from Madrid, was studied because he presented sustained microcytosis without iron deficiency. Hb A2 and Hb F levels were measured by ion exchange HPLC (VARIANT II). Hemoglobin was studied by capillary zone electrophoresis and ion exchange HPLC. The most frequent α-thalassemia mutations were ruled

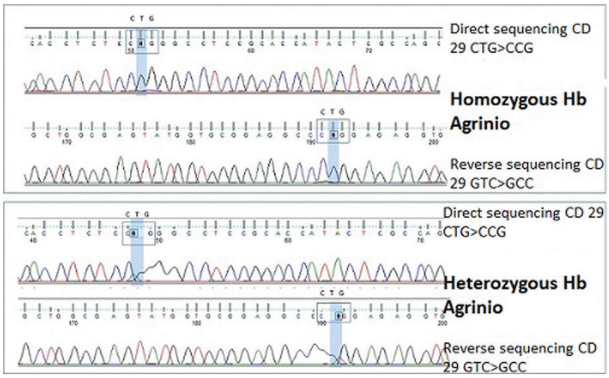
out by multiplex PCR (Alpha-Globin StripAssay kit) and molecular characterization was performed by automatic sequencing of the α globin genes.
Results: The propositus presented microcytosis (MCV 78.3 fL) with hypochromia (HCM 26.3 pg), without anemia (Hb 14.1 g /dL) and normal reticulocytes (1.01%). No abnormal hemoglobins were detected and Hb A2 and Hb F levels were within normality (2.6% and 0.8% respectively). Molecular characterization of the globin α1 gene, by automatic sequencing, identified a new HBA1: c.196G>C transversion mutation, which resulted in an amino acid change from Ala>Pro at codon 65 of exon 2 in the heterozygous state [α165(E14)Ala>Pro;HBA1:c.196G>C] which we have named Hb Maruchi.
Summary/Conclusion: The binding of heme to globin involves a very specific stereochemical adjustment that helps stabilize the tertiary conformation of the subunit. The heme group inserts into a cleft between the E and F helices. While the vinyl groups are asymmetrically located in the hydrophobic interior of the cleft, the propionic acids of porphyrin are oriented toward the hydrophilic surface, interacting with certain nonpolar amino acids in the CD, E, F and FG regions of the α and β globin chains. Most of these nonpolar amino acids are invariant residues. Therefore, it is not surprising that substitutions of any of the residues located in these regions can result in a decrease in the stability of the heme-globin bond and, subsequently, of the globin chain. The CD65 of the HBA1 gene encodes an Ala corresponding to position E14 of the α1 globin chain, located inside the pocket of the heme group. In Hb Maruchi this Ala is replaced by a Pro, which causes instability of the α1 globin chain, this instability is enhanced by the fact that Pro is an amino acid that cannot participate in the configuration of the alpha helix of the secondary structure deforming said structure. This new variant causes thalassemia instead of hemolysis because its α chains are unstable, catabolizing very rapidly before the formation of αβ dimers. The α1Maruchi gene does not produce functional α chains, hence the thalassemia phenotype. This variant is so unstable and catabolizes so rapidly that its detection by electrophoretic and chromatographic methods is impossible. The diagnosis of this type of mutations is important because the association with α0-thalassemia can lead to more severe forms such as Hb H disease or hydrops fetalis.

PB1820 EVALUATION OF IMMUNE FUNCTIONS IN TRANSFUSION-DEPENDENT THALASSEMIA PATIENTS WITH ALLOIMMUNIZATION

N. Ö. Gökçe [1], T. H. Karapınar [1,*], S. Okur Acar [1], Y. Ayhan [2], N. Gülez [3], Y. Oymak [1], F. Genel [3]

[1]Pediatric Hematology and Oncology, [2]Transfusion Center, [3]immunology, Dr. Behcet Uz Children Training and Research Hospital, Izmir, Turkey

Background: It is suggested that alloimmunization develops due to erythrocyte antigen differences between the blood donor and the recipient, the immune status of the recipient and the immune modulatory effects of repeated allogeneic blood transfusions on the immune system of the recipient. Understanding the immune regulators responsible for alloantibody development in transfusion dependent thalassemia patients will provide appropriate data for the reduction and / or prevention of alloimmunization rate.
Aims: We aimed to evaluate the association of alloimmunization and basic immune functions in transfusion-dependent thalassemia patients.
Methods: Fifty-four patients with a diagnosis of transfusion-dependent thalassemia between the ages of 1-24 who were regularly monitored in the Thalassemia Unit were retrospectively evaluated. In these patients, the frequency and types of alloantibodies and the basic immune functions tests and demographic characteristics that affect their formation were examined.
Results: The rate of alloantibody detection was 29.6%, and clinical alloimmunization was detected in 24% of the patients. The most common type of alloantibody is against the Rhesus system (70%) and secondly against the Kell system (23%) and Lutherian system (7%).
When the relationship between regular transfusion initiation age and development of alloantibody was examined; it is found out that while in 38 patients without alloantibody development the median age was 11.5 months (4-32 months), in 16 patients with alloantibody development the median age was 15 months (6-54 months). The age of initiation of regular transfusion was statistically significantly late in patients with alloantibody development (p=0.03). The frequency of transfusion between the groups was compared, and it was found that due to development of alloantibody, the need for transfusion, and therefore, more frequent transfusions increased significantly (p<0.001). Direct coombs positivity was detected in 8 (50%) of 16 patients with alloantibody development. Direct coombs was found positive in 5 (13.2%) of 38 patients without alloantibody development, and a statistically significant relationship was found between alloantibody development and direct coombs positivity (p=0.01). The 5 patients without alloantibody development but with direct coombs positivity mentioned here are patients with splenectomy.
No significant difference was found between the groups in terms of IgG, IgA, and IgM values (p=0.403, p=0.747, p=0.272). Similarly, there is no statistical significance between C3 level and development of alloantibody (p=1.00). Serum C4 levels were found to be low in 8 (14.8%) of 54 patients, 6 of these 8 patients were found to be alloantibody positive. There was no significant difference between the total lymphocyte count, $CD3^+$, $CD4^+$, $CD8^+$, and NK cells in the two groups whose lymphocyte panel results were evaluated (p=0.270, p=0.291, p=0.05, p=1.00, p=0.483). However, $CD19^+$ B cells were lower in the alloantibody present group (p=0.02). In addition, serum C4 level was found to be statistically significantly lower in patients with alloantibody development (p=0.006).
Summary/Conclusion: In this study, we found a strong relationship between alloantibody development and D. coombs positivity, low C4 and low $CD19^+$ B cell numbers.We believe that studies at molecular level should be increased and studies should be conducted with a larger number of patients in order to elucidate the immune pathogenesis of alloimmunization and determine the markers that will enable early recognition.



PB1821 A RARE CASE OF SEVERE ANAEMIA SINCE BIRTH: HAEMOGLOBIN AGRINIO.

M. Moreno Carbonell [1,*], Y. Aguilar [2], C. Rodríguez-Vigil [2], P. Ropero [3], A. Gómez Martínez [1], C. Hernández Mata [1], E. González Gómez [1], S. Martín-Consuegra Ramos [1], M. Civeira Marín [1], A. López Peña [1], C. Rodríguez Lefler [1], A. J. García Ortego [1], S. F. Pinzón Mariño [4], I. Izquierdo García [1], Á. Montañés Gracia [1], M. D. V. Recasens Flores [1]

[1]Haematology, [2]Pediatrics, Hospital Universitario Miguel Servet, Zaragoza, [3]Haematology, Hospital Universitario San Carlos, Madrid, [4]Haematology, Hospital del Mar, Barcelona, Spain

Background: Alpha thalassemia is characterized by the reduced or absence synthesis of alpha globin chains, most commonly due to delectional mutations. Hemoglobin Agrinio [α29(B10) Leu→Pro, CTG>CCG (α2)], is an infrequent nondelectional alfa thalasemia (α-Thal).
Aims: To describe an unusual case of neonatal anaemia and its diagnostical and therapeutical approach.
Methods: A systematic research of PubMed's Medline was done, using de words Agrinio, neonatal and Thalassemia. Then, we analysed the case using electronic health records of our centre (previous parents informed consent), for history taking and laboratory data collection.
Results: Case description: A newborn girl was admitted to the neonatal intensive care unit because of respiratory distress showing severe microcytic anemia (haemoglobin 67 g/L, MCV 70.5 fl) and increased lactate dehydrogenase (6630 U/L, reference range 225-660 U/L). Rest of hemolysis parameters were normal. All the obstetric control had been passed with no incident, except for the finding of mild pericardial effusion and cardiomegaly in the third trimester ultrasound. Delivery proceed without incidence.
During her admission, moderate pulmonary hypertension (corrected at first 48 hours), and patent foramen ovale were found. Toxic, infectious diseases and RH/ABO incompatibility were ruled out. Peripheral blood smear only showed significant anisopoikilocytosis with the presence of microcytosis, hypochromic red blood cells, target cells, helmet red blood cells, and reticulocytes. Capillary electrophoresis of haemoglobin was normal.
At sixteen days of life, she was discharged with supportive oral iron. In the next two months, she needed to be admitted twice, due to hyporexia, rejection of feeds and general decline in general appearance, with severe anemia and moderate transfusion dependence.
Given the consanguinity of the parents, both of gypsy ethnicity, and the suspicion of possible congenital haemolytic anaemia, thalassemia genetic study was requested to our reference centre, Hospital San Carlos, Madrid. After analysis, they concluded that the patient was a homozygous carrier of the CTG> CCG mutation in codon 29 of the first exon of the alpha 2 gene, which determines the change from leucine to proline

at position 10 of the B helix of the alpha chain (haemoglobin Agrinio). Both parents were studied with diagnosis of heterozygous carriers of this mutation. None of her older siblings presented this mutation, so an HLA compatibility study has been carried out to consider the possibility of hematopoietic progenitors transplant in the future.

Summary/Conclusion: Discussion: Cases like the one presented, even today, pose a diagnostic and therapeutic challenge. Clinical suspicion (more in cases of the severity of ours), should guide us towards carrying out complementary tests quickly in order to be able to provide adequate treatment in time.
Agrinio haemoglobin is an unknown hemoglobinopathy, but molecular characterization of entities like this and the communication of results could help us make these patients increasingly less challenging in clinical practice.
Conclusion: In cases like the one presented, clinical suspicion is vital, and guided by this suspicion, genetic techniques and molecular diagnosis will be key to the definitive diagnostic orientation and the subsequent therapeutic approach.

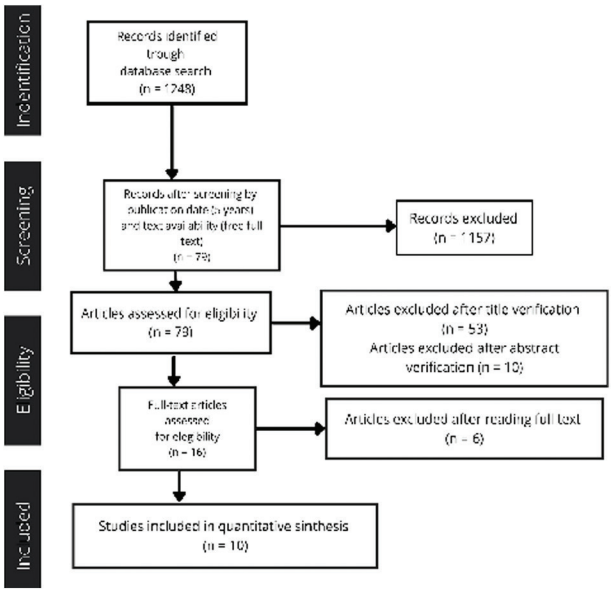
Thrombosis and vascular biology - Biology & Translational Research

PB1822 DIAGNOSIS OF THROMBOPHILIA IN YOUNG PATIENTS AND THE EFFICIENCY OF SECONDARY PREVENTION OF THROMBOSIS WITH DIRECT ORAL ANTICOAGULANTS

V. Voitsekhovsky [1,*], T. Zabolotskikh [1], I. Sayapina [1], O. Prikhodko [1], I. Menshikova [1]

[1]Amur State Medical Academy, Blagoveshchensk, Russian Federation

Background: The term "thrombophilia" means a tendency to thrombosis with an early age onset, family history, severity of thrombosis, disproportionate to the known causative factor and episodes of recurrent thrombosis.
Aims: To examine young patients who had a registered fact of thrombosis of various localization, in the absence of an obvious causative agent, for markers of hematogenous thrombophilia, to assess the possibilities of direct oral anticoagulants for the secondary prevention of thrombus formation.
Methods: Examination of 81 patients (men - 50, women - 31) between the ages of 17 and 45 was carried out. Somatic diseases in which the secondary thrombophilia, complicated by thrombosis may occur were excluded. The age structure of the examined: 5 patients aged 17 - 20 years, 28: 21 - 30, 38: 31 - 40, 10: 41 - 50 years. In 32 patients (38%), the disease debuted with pulmonary embolism; in 11 cases (14%) - ischemic stroke; in 3 (5%) - myocardial infarction; in 35 (43%) - pathology of the veins of the lower extremities. Relapses of vascular complications were already registered in 30 patients at the time of diagnosis.
Results: The following thrombophilia markers were found in 72 patients (men - 43, women - 29): F5 Leiden mutations - in 30 patients, prothrombin F2 G20210A - in 15, MTHFR - in 25, antithrombin III deficiency - in 6 and protein C - in 13, hyperhomocysteinemia - in 30, primary antiphospholipid syndrome (APS) - in 20 patients. In six patients, only one gene mutation took place, in other cases a combined form of thrombophilia was diagnosed. In 55 cases, there was heredity due to pathological thrombus formation.
Acute thrombosis was treated in accordance with national and international guidelines. For the purpose of the secondary prevention of thrombus formation, the drug Dabigatrana etexilate was prescribed to 37 patients; duration of drug administration was from 12 months to 9 years; the dose of the drug was selected individually from 150 to 300 mg per day. The drug Rivaroxaban was prescribed to 25 patients, the duration of drug administration was from 12 months to 6 years; the dose of the drug is 10 - 20 mg per day. The drug Apixaban was prescribed to 10 patients (30 - 50 years old), the duration of drug administration was from 6 months up to 2 years, the dosage - 5-10 mg per day. Only one patient after the administration of Dabigatrana etexilate had a relapse of PE due to low adherence to treatment. The rest had no recurrence of thrombotic complications. No hemorrhagic complications were diagnosed with the use of dabigatran and apixaban. In 5 patients receiving rivaroxaban, there were minor nosebleeds; in three cases they stopped when the dose was reduced from 20 to 15-10 mg, two patients were transferred to dabigatran. No life-threatening bleeding has been reported. Angiovitis was prescribed in case of hyperhomocysteinemia. Replacement therapy was used in the congenital deficiencies of protein C and antithrombin III.
Summary/Conclusion: Timely diagnosis of the variant of hematogenous thrombophilia in young patients with thrombosis and the appointment of adequate therapy contribute to the relapse-free course of the disease.



PB1823 EFFECTS OF DIABETES MELLITUS ON HEMOSTATIC CHANGES, A SYSTEMATIC REVEW

C. B. Carvalho do Carmo [1], I. L. Onofre de Oliveira [1], I. V. de Bastos [1], W. O. Santos [1], G. P. Gutierres [1], G. C. Vieira [1], J. P. Aniceto Silva [1], D. D. F. Britto Rêgo [1], M. M. de Lucena [2], G. A. de Santana Xavier [1], M. J. de Andrade Rezende [1], P. J. Braga de Camargo [1], T. D. A. Nunes [1], E. M. Bitencourt de Souza [1], L. P. Monteiro [1], A. T. Oppelt Raab [1,*], J. A. de Santana [3]

[1]Medicina, [2] Medicina, Universidade Católica de Brasília, [3]Departamento de Ginecologia e Obstetrícia, HAPVIDA, Brasília, Brazil

Background: Diabetes is a metabolic syndrome that generates an increase in glucose levels, so diabetic patients have been associated with the development of hemostatic complications, such as endothelial and platelet dysfunctions, coagulation factors, natural anticoagulants and the fibrinolytic system. They are also more prone to hypercoagulability cases.
Aims: This systematic review aims on how diabetes mellitus affects hemostatic changes.
Methods: Three electronic databases (SciELO, LILACS, PubMed) were consulted in search for articles, published in the last five years, using the following keywords searched in DeCs/MeSH: diabetes mellitus, hemostasis, blood disease.
The initial online search led to the retrieval of 1.248 references and reviewers extracted data independently. A total of 10 articles were used in the review. The checklist of 27 items and 4-step flow chart (Table 1) indicated by the PRISMA methodology were used.
Results: The study by Wieczór, R. et al. (2019) evaluated patients with symptomatic peripheral arterial disease and demonstrated that the concomitance of this disease with DM2 contributes to an increase in the concentration of fibrinogen in the blood. Pretorius, Thomson et al (2018) also reported that the presence of amyloid fibrin, the increase in circulating inflammatory biomarkers and a hyperglycemic state contributes to blood hypercoagulability. Greenhalgh, KA, et al. (2017) shows a brief connection between a variant of fibrinogen present in diabetics and significant changes in the structure of the clot and fibrinolysis, resulting in dense fibrin networks, difficult to lyse.
It is observed in the study by Sumaya, W et al. (2020) that individuals with diabetes may have changes in their lipid profile, converging to cases of lipotoxicity and changes in fibrinolysis. According to IS Sobzkak and Stewart, A (2019) 80% of patients with diabetes die from cardiovascular events. The randomized test conducted by Bratsheth, V et al. (2017) shows that physical exercise in one year was not able to bring greater control over pro-coagulant disorders and more serious diseases, such as albuminuria and acute myocardial infarction. However, research by Patti, G., Cavallari, I., Andreotti, F. et al. (2019) shows that more aggressive antithrombotic strategies can be indicated for diabetics with cardiovascular diseases.
The study by Gajos, G., Siniarski, A., et al. (2018) analyzed patients with DM2 and concluded that inadequate glycemic control, with increased platelet activation and oxidative stress, causes an increase in the formation of polyhedrocytes in contracted blood clots.
Newman, JD et al. (2017) evidenced that the glucose concentrations in the patient with DM potentiate the activation of the platelet-megakaryocyte hemostatic axis allowing the inorganic arsenic to cause atherothrombotic risk in diabetic patients.

The study by Bryk, AH, et al. (2019) showed that the markers of extracellular neutrophil traps in circulating plasma are related to glycemic control, so that the detectable increase refers to a prothrombotic state, especially hypofibrinolysis in patients with DM2.

Summary/Conclusion: The analyzed articles call attention to the changes in the coagulation patterns and in the lipid profile of the diabetic, situations that may imply the occurrence of cardiovascular and atherothrombotic events, responsible for increasing the population's morbidity and mortality.

PB1824 EVALUATION OF D-DIMERS CONCENTRATIONS IN PATIENTS UNDERGOING CARDIOPULMONARY BYPASS SURGERY

M. Sonia [1,*], E. Hammami [1], F. Ghedira [2], A. chamekh [2], A. chakroun [2], N. ben Romdhane [2], R. Denguir [2]

[1]hematology, [2]Hopital La rabta, Hopital La rabta, Tunis, Tunisia

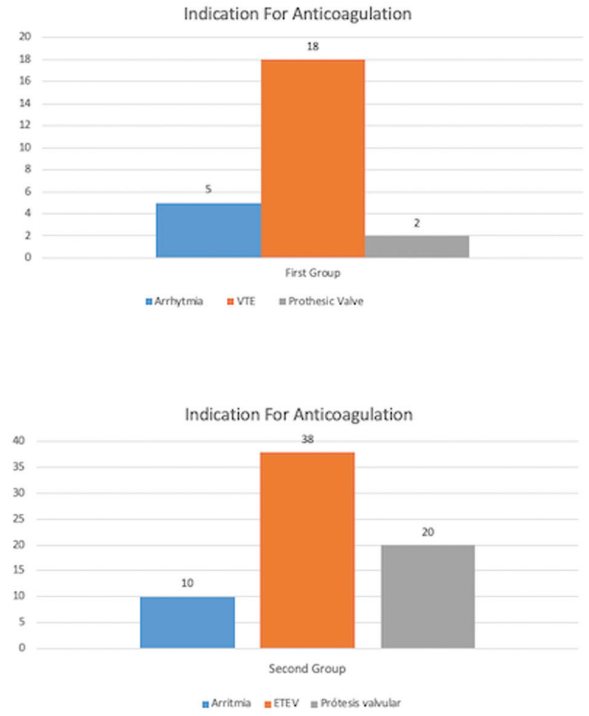
Background: Cardiac surgery under cardiopulmonary bypass (CBP) still involve major bleeding of which platelet injury is generally believed to be its primary nonsurgical cause. However, in some patients, excessive fibrinolysis may be the primary etiology of blood loss in postoperative period. The D-dimer assay, a measure of cross-linked fibrin degradation product, constitutes a specific test for fibrinolysis.
Aims: In this present study, we sought to assess the changes of D-dimers concentrations in cardiac patients before and after CBP and whether the D-dimers formation correlates with postoperative bleeding.
Methods: A total of 30 patients undergoing cardiac surgery under CBP were included in a prospective observational study. Patients' variables, postoperative bleeding volume, transfusions during the operation and 24 hours after, laboratory variables in preoperative, intraoperative and postoperative period (hemoglobin, hematocrit, platelet count, prothrombin rate, activated partial thromboplastin time, fibrinogen level) were registered. D-dimers concentration was measured using an enzyme-linked immunosorbent assay (ELISA) technique VIDAS before CBP and 5 minutes after heparin neutralization.
Results: There were 30 patients with an average age of 54.4 years old (18-79 years old).Based on the surgery indication, Patients were split up into three groups: coronary insufficiency (P)(N=12), valvulopathy (V)(N=14) and other reasons (C) (N=4). The mean preoperative D-dimers concentration was 509ng/ml ranging from 150ng/ml to 2200ng/ml. Among groups, the mean D-dimers levels were estimated as follows: 438ng/ml in group P, 625ng/ml in group V and 314ng/ml in group C. In postoperative time, D-dimers levels were significantly increased (p=0.01).In fact, the mean D-dimers concentration were 889ng/ml ranging from 270ng/ml to 3940ng/ml. Regarding groups, the D-dimers levels were respectively 527ng/ml, 1320ng/ml and 468ng/ml in group P, group V and group C with a statistically significant difference (p=0.05).Therefore, group V showed the highest increase of D-dimers level after CBP. This latter group consisted predominantly of female patients (H/F=4/10), showed the longest aortic cross clamp time (65.5min), had the highest mean number of red blood cell units transfused within and after surgery (1±0.96 and 1±1.24 units respectively) and the highest mean number of fresh frozen plasma transfused (2±2.9 units). On the other side, based on the median value of the rate of fall of hemoglobin between preoperative and postoperative time which was estimated at 2.5 g/dl, we defined two groups (N=15).There was no statistically significant difference in the mean D-dimers levels in the two groups (P=0.08) contrary to preoperative hemoglobin level and postoperative bleeding volume 24 hours after surgery. Furthermore, our study didn't demonstrate a correlation between D-dimers concentration and postoperative bleeding loss.
Summary/Conclusion: In summary, our results indicate, in small number, that there is an activation of fibrinolysis in patients undergoing CBP surgery as shown by the elevation of D-dimers level in the early postoperative period. A large study is desirable to study fibrinolysis in patients undergoing CBP, its pathophysiological implications and its correlation with hemorrhage complications

PB1825 A RARE CASE OF BI-ATRIAL THROMBI IN A STAGE IV PANCREATIC CANCER PATIENT WITH ATRIAL FIBRILLATION ON WARFARIN

K. Y. Kim [1,*], N. H. Kim [1], T. Alrifai [2]

[1]Amita Health St Joseph Hospital Chicago, [2]Rush University Medical Center, Chicago, United States

Background: Atrial fibrillation (AF) is the most common arrhythmia and can result in adverse consequences of reduced cardiac output or formation of atrial thrombus. AF-related systemic thromboembolic events are the leading cause of mortality and morbidity in AF patients. Thus patients are placed on anticoagulants after risk stratification.
Aims: We present an unusual case of a 78-year old male with Stage IV pancreatic cancer and underlying AF who was found to have bi-atrial thrombi while on warfarin therapy.
Methods: Case report with information extracted from patient chart per CARE (CAse REport) guidelines
Results: CT abdomen and pelvis for routine surveillance revealed small thrombi within the right atrium and left atrial appendage, which was new compared to his most recent CT imaging performed 3 months prior. At the time of imaging, the patient was noted to have supra-therapeutic prothrombin time-international normalized ratio(PT-INR) of 3.3. The patient was admitted and initiated on unfractionated heparin infusion. He declined transitioning to low molecular weight heparin therapy as this regimen required daily subcutaneous injections. He was instead discharged home on apixaban.
Summary/Conclusion: Pancreatic cancer is associated with a hypercoagulable state; the development of thrombi despite being on anticoagulation highlights the significance of clinical awareness of thromboembolism in patients with cancer regardless of therapeutic warfarin anticoagulation. The choice of an ideal anticoagulant in patients with concomitant AF and cancer remains a controversy. Traditionally, warfarin has been the mainstay of anticoagulation therapy for stroke and systemic thromboembolism prevention in patients with AF. However, our case of failed anticoagulation with warfarin suggests that this agent may be a less ideal choice in patients with underlying malignancy, particularly in the setting of hepatic dysfunction. Recent clinical evidence suggests that a number of direct oral anticoagulants (DOACs) can effectively prevent thrombotic events with comparable safety index in cancer patients to conventional therapy. Prudent consideration of multidisciplinary factors (thrombotic and bleeding risk, drug-drug interactions, patient's renal and hepatic function, nutritional status, patient preferences) is required in order to deliver individualised, safe, and effective anticoagulation therapy.



PB1826 EXPERIENCE IN THE USE OF BIOSIMILAR ENOXAPARIN SODIUM FOR PROPHYLAXIS AND TREATMENT OF VENOUS THROMBOEMBOLIC DISEASE IN OUR HOSPITAL

A. Garcia Ruiz [1,*], E. Morente Constantín [1], G. Salas Camacho [1], M. Jurado Chacon [1]

[1]Servicio Hematología y Hemoterapia, Hospital Universitario Virgen de las Nieves, Granada, Spain

Background: A biosimilar is a medicine of biotechnological origin, produced according to specific requirements established by the European Medicines Agency (EMA) regarding quality, efficacy and safety.
Aims: The main objective is to evaluate the efficacy and safety of using enoxaparin sodium biosimilar (Inhixa ®) available in our center, for the

prophylaxis of venous thromboembolic disease and the treatment of deep vein thrombosis, as well as hemorrhagic or thrombotic complications.
Methods: We evaluated two groups of patients with enoxaparin sodium biosimilar:
First group: Patients continuously anticoagulated at full doses, who were suspended oral anticoagulation due to recurrent hemorrhagic diathesis, active cancer under chemotherapy treatment and / or thrombosis.
- 25 patients treated with heparin at weight adapted doses once a day, as a starting dose, and then subsequently, according to anti-Xa levels.
- Ages between 50 and 88 years old.
- Indication of main anticoagulation: 5 arrhythmia, 18 VTE and 2 prosthetic valves.
- Most of the cases presented several associated diagnoses, and 75% of them comorbidities.
Second group: Anticoagulated patients with VKA with high thromboembolic risk, who have required bridging therapy at full doses.
- 98 patients. Bridging therapy consisted of suspending VKA from 4 (acenocoumarol) to 6 days (warfarin) before the procedure and substitution with biosimilar enoxaparin sodium: 1.5 mg / kg / 24 h, and administration of a prophylactic dose 4,000 IU, 12 hours before of the procedure, and another dose 6-12 hours after it, depending on the risk of bleeding from the intervention and the thrombotic risk of the patient's underlying disease.
- The ages ranged from 21 to 87 years.
- Indication for main anticoagulation: 10 arrhythmias, 58 VTE (with or without thrombophilia) and 30 prosthetic valves.
Results: In patients who had secondary bleeding to VKA, it totally disappeared with heparin. As side effects, only 3 patients had complications, being allergic reaction to heparin. There were no bleeding or thrombotic phenomena. There were 6 cases of hematomas at the heparin puncture sites.

Summary/Conclusion: Although these are few cases, the results obtained confirm the efficacy, safety and cost-effectiveness of the continuous use of enoxaparin sodium biosimilar in the prevention of VTE in patients requiring anticoagulation, when VKA are contraindicated and and DOACs cannot be managed. Anti-Xa levels are very useful for dose adjustment when necessary. Biosimilar enoxaparin sodium administered at therapeutic doses in the perioperative period, according to the scheme described, is associated with a low incidence of VTE recurrence and bleeding. Treatment should be personalized according to each patient and factors related to the surgical intervention. Further studies will provide more confirmatory data. Biosimilar drugs have the potential to offer the National Health System cost savings and expand access to therapeutic innovations.

PB1827 STUDIES OF GEOGRAPHIC VARIATIONS IN RISK FACTORS ASSOCIATED WITH THROMBOPHILIA AND ITS POSSIBLE IMPACT ON DISEASE MANAGEMENT PLANNING

Z. Iqbal [1], S. AlMukhaylid [1,*], M. AlMajed [1], B. AlShehab [1], N. AlMutairi [1], K. Rashid [1], N. Alanazi [1,2]

[1]*Clinical Laboratory Sciences, College of Applied Medical Sciences (CoAMS-A), King Saud Bin Abdulaziz University for Health Sciences / KAIMRC/ SSBMT,* [2]*Pediatric Hematology / Oncology Division, Department of Pediatrics, King Abdulaziz Hospital, Al-Ahsa, Saudi Arabia*

Background: Thrombophilia is a hypercoagulability disease that gives rise to clot formation in the blood leading to stroke, deep vein thrombosis, or pulmonary embolism. The prevalence of different risk factors associated with thrombophilia varies in different regions of the world that may impact its clinical management. However, no studies have been conducted in Al Ahsa concerning thrombophilia. Therefore, the aim of this study is to find out the risk factors associated with thrombophilia in Al-Ahsa.
Aims: Therefore, the aim of this study is to find out the risk factors associated with thrombophilia in Al-Ahsa and its comparison with other regions of the world.
Methods: This was retrospective cross-sectional study. It included 329 thrombophilia patients attending King Abdulaziz Hospital (KAH) from 2015-20. Patient data was retrieved from BestCare and was analyzed using SPSS version 20.
Results: Thrombophilia was significantly more prevalent in females than males. It was most common in the age group 44-54 years (44.7%). The main risk factors associated with thrombophilia were anti-phospholipid syndrome (52.3%), Protein S deficiency (17.9%), Protein C deficiency (13.4%), anti-thrombin deficiency (7.6%), familial predisposition (4.3%) and lupus anticoagulant (0.3%). Frequencies of thrombophilia-associated risk factors in Al-Ahsa region was significantly different from Korean population ($p<0.05$) (Figure 5).

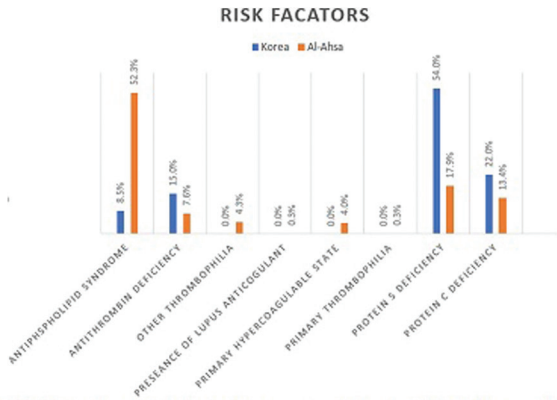


Figure 5: Multiple Bar chart displaying the percentage of thrombophilia risk factors in Al Ahsa and in Korea [12].

Summary/Conclusion: In our studies, female gender, anti-phospholipid syndrome, Protein S deficiency, Protein C deficiency, anti-thrombin deficiency and familial predisposition were found to be major risk factors associated with thrombophilia, respectively, that showed significant difference from other populations. These geographic variations in frequencies of different risk factors associated with thrombophilia may be attributed to different lifestyle, nutritional habits, genetic make-up and other ethnic differences in various geographical regions of the world. Strategies related to clinically manage thrombophilia in any clinical settings should consider prevalence of different genetic and non-genetic risk factors in that region.

PB1828 THE USEFUL OF TESTING DIRECT ORAL ANTICOAGULANTS

G. Garcia-Donas [1,*], M. Bonete [1], M. García [1], A. Rodríguez [1]

[1]*Hematology, Hospital Universitario Virgen Macarena, SEVILLA, Spain*

Background: Direct oral anticoagulants (DOAC) do not require routine laboratory monitoring, but it is useful to know the impact on coagulation

assays in order to interpret the results specially in emergency situations as bleeding or urgent perioperative management.
Aims: The objective of our study is to determnine de DOAC concentration with specific test in control patients under different DOAC treatment and compare the results with routine coagulation assays in different moments, plasma concentration at peak (3 hours after drug intake) and through (just before intake).
Methods: Samples from volunteers patients with non-valvular atrial fibrillation (NVAF) under DOAC treatmente were collected at peak and through plasma concentrations. For all samples prothrombine time (PT) with Tromborel and activated partial thromboplastin time (APTT) with Actin-FS were measured. For anti-Xa DOAC also anti-Xa activity (heparin calibrated) with Innovance Heparine and plasma concentration with STA-Liquid anti-Xa (Stago) was quantified anf for Dabigatran thrombin time (TT) with Thromboclotin and the specific test STA-ECAII (Stago) were used.
Results: 30 patients were included (59% males, median age 71 [IQR 41-88] years. 3 Dabigatran 150 mg/12 hours, 2 Dabigatran 110 mg/12 hours, 8 Rivaroxaban 20 mg/24 hours, 2 Rivaroxaban 15 mg/hours, 14 Apixaban 5 mg/12 hours and 1 Apixaban 2,5 mg/12 hours. The results for different test at peak and through are seen in Table 1. Under Dabigatran TT was uncoagulable for all samples, and all PT and APTT results were pathological. The most statistical correlation test with DOAC level (Apixaban and Rivaroxaban) was anti-Xa (heparin calibrated) specially at throug moment with a P<0.0001

Table 1 Results of coagulaion test at throuh and peak moments under DOAC treatment

	APIXABAN n:15 Median (25th-75th percentile)		RIVAROXABAN n:10 Median (25th-75th percentile)		DABIGATRAN n:5 Median (25th-75th percentile)	
	Through	Peak	Through	Peak	Through	Peak
PT sec (normal range 10-14)	13.1 (12.5-13.5)	14.3 (13.5-14.8)	12.8 (11.7-16.5)	16.1 (15.5-24.2)	15.6 (15.1-15.7)	16.6 (16.3-17.8)
APTT ratio (normal range 0.8-1.2)	1.15 (1.1-1.3)	1.2 (1.1-1.2)	1.1 (1.0-1.4)	1.4 (1.3-1.7)	1.7 (1.6-1.9)	2.1 (1.8-2.2)
Anti-Xa IU/mL (heparin calibrated)	0.56 (0.36-0.78)	1.79 (1.25-2.01)	0.25 (0.05-0.73)	1.70 (1.63-1.75)		
Concentration ng/mL	82 (66-106)	223 (157-303)	31 (11-73)	228 (170-338)	190 (158-205)	300 (245-335)

Summary/Conclusion: The results of DOAC concentration at peak and through are similar to literature except for Dabigatran that in our study are higher perhaps because there are few samples. Similar to other studies Dabigatran is the DOAC that most modifies coagulation assays specially APTT also at through moments and Apixaban is the DOAC that nearly no prolongs PT neither APTT on-therapy concentrations. For these reasons PT and APTT are not recommended to know coagulation state under DOAC treatment. The quatification of DOAC levels in plasma is more informative and useful tan other coagulation parameter so in case to measure low plasma concentrations in special circumstances specific test calibrated are required but if these are not available for direct FXa inhibitors a heparin-calibrated chromogenic assay can be indicative of clinically relevant levels of a ditrect FXa inhibitor.

PB1829 DEEP VEIN THROMBOSIS AND PULMONARY EMBOLISM IN AN ADOLESCENT WITH SARS-COV-2 INFECTION

A. Dettoraki [1,*], A. Michalopoulou [1], L. Ioannidou [1], M. Noni [2], D. Koukou [2], E. Botsa [3], A. Michos [2], V. Spoulou [2], Z. Kapsimali [1], C. Kanaka-Gantenbein [4], H. Pergantou [1]

[1]Hemophilia Centre and Hemostasis and Thrombosis Unit, "Aghia Sophia" Children's Hospital, Athens, Greece, [2]Division of Infectious Diseases, First Department of Pediatrics, Medical School, [3]First Department of Pediatrics, Medical School, "Aghia Sophia" Children's Hospital, National and Kapodistrian University, Athens,Greece, [4]Division of Endocrinology, Diabetes and Metabolism, First Department of Pediatrics, Medical School, "Aghia Sophia" Children's Hospital, National and Kapodistrian University, Athens, Greece

Background: Pulmonary embolism (PE) is reported in around 2.6–8.9% of COVID-19 hospitalized adult patients, but it is very rare in children and adolescents with symptomatic infection from SARS-CoV-2.
Aims: This is the case of a 15-year-old male patient with COVID-19 complicated by deep vein thrombosis (DVT) who developed PE.
Methods: The patient presented with fever and a four-day history of pain and swelling of the right lower limb, without any history of injury. It is notable that 15 days before admission, he experienced diarrhea, vomiting and low-grade fever for 48 hours. The adolescent boy had short stature and was rather overweighted for his age and gender (body mass index: 25.2 kg/m^2), while over the last two years he was receiving anastrozole (aromatase inhibitor), for height increase.
Results: On admission, due to pain, limited mobility of the right limb and edema of the ipsilateral knee, a triplex ultrasound was performed that revealed DVT extended from the right iliac to the popliteal vein. RT-PCR for SARS-CoV-2 was positive, while the rest of the laboratory results showed a prolongation in prothrombin time (16.3 seconds, normal values: 10-14 sec), elevated d-dimers (10 mg/dl, n.v.: < 0.5 mg/dl), high levels of factor VIII (214 IU/dl, n.v: 50-150 IU/dl), low levels of antithrombin (36 IU/ml, n.v.: 80-120 IU/ml) and increased ferritin (346 µg/L, n.v.: 10-150 µg/L). Initial management consisted of antibiotic therapy plus anticoagulation with subcutaneous low molecular weight heparin (LMWH) i.e. tinzaparin in therapeutic dose. Soon after admission the patient developed severe hypotension with low diastolic blood pressure, refractive to IV normal saline boluses while his oxygen saturation dropped to 94% few hours later. A CT pulmonary angiogram (CTPA) was performed revealing a big thrombus with longitudinal diameter of 3 cm, in the left pulmonary artery, establishing the diagnosis of PE on the ground of DVT. After PE diagnosis, the patient was transferred to the intensive care unit (ICU) for 48 hours, and subsequently at the special SARS-CoV-2 ward for 4 weeks. He completed a ten-day course of intravenous dexamethasone and anticoagulation treatment was switched to oral warfarin, after completion of three weeks of LWMH. Apart from COVID-19 whose hypercoagulable physis is already well-established the patient had additional risk factors predisposing to thromboembolic episodes. More precisely, he was overweight and under aromatase inhibitor therapy (which can be procoagulant by increasing testosterone levels). Moreover, the preexisting symptoms from the gastrointestinal system, could have predisposed him to DVT in view of dehydration and increased viscosity. On top of it, it is noteworthy that the patient had excessive screen time for his tele-education the last three weeks prior to the onset of VTE, meaning there were long periods of immobilization. Additionally, during the course of COVID-19 infection he had low levels of antithrombin, a serious prothrombotic condition attributed to the disease.
Summary/Conclusion: This case underlines the fact that pediatric patients with COVID-19, are predisposed to the development of thromboembolic events, especially in the presence of preexisting prothrombotic risk factors. Larger studies in pediatric population with SARS-CoV-2 infection are needed, for the establishment of recommendations regarding risk evaluation, hemostatic monitoring and application of anticoagulation in outpatient, as well as hospitalized patients.

PB1830 COVID-19 ASSOCIATED THROMBOTIC THROMBOCYTOPENIC PURPURA (TTP); A CASE SERIES AND MINI-REVIEW

S. Haghighi [1], H. Azhdari Tehrani [1,*], M. Darnahal [1]

[1]Hematology and Medical Oncology, Shahid Beheheshti University of Medical Sciences, Tehran, IRAN, Taleghani Hospital, Tehran, Iran, Islamic Republic Of

Background: Thrombotic microangiopathies are a group of disorders that are mainly related to endothelial dysfunction. This category of endothelial dysfunction results of several imbalances between platelets, endothelium and immune system, also cytokine production
Aims: To report cases with thrombotic thrombocytopenic purpura (TTP) and COVID-19 and review COVID-19 endothelial dysfunction literature.
Methods: Primary laboratory data, peripheral blood smear, ADAMTS13 antigen activity level, and antibody ordered for each of these four patients. Treatments for COVID-19 administered for all patients. Traditional treatments for TTP also were administered.

Results: There were numerous schistocytes (more than 5%) in peripheral blood smears for each patient. ADAMTS13 antigen activity level was below 10%, and ADAMTS13 antibody was elevated for each patient. COVID-19 PCR was positive for all patients, and CT-Scans were indicative of the involvement of COVID-19.
Summary/Conclusion: Conclusion: In this case series, we reported four COVID-19 patients who presented with signs and symptoms of anemia and thrombocytopenia, resulting in thrombotic thrombocytopenic purpura.

PB1832 A YOUNG WOMEN WITH LIGNEOUS MEMBRANES WHO WANTS TO BE PREGNANT

A. G. Kacar [1,*], S. Fenercioglu [2], T. T. Celkan [1]

[1]Pediatric Hematology and Oncology, Cerrahpasa Medical Faculty, [2]Gynecology and Obstetrics, Istanbul Fertility Center, Istanbul, Turkey

Background: Plasminogen deficiency is a rare condition with autosomal recessive inheritance. Severe hypoplasminogenemia is associated with 'ligneous' lesions on each mucous membranes especialy eye, ear, mouth, pharynx, respiratory and female genital tract; cervix and endometrium. Furthermore, plasminogen deficient women complained from infertility. These kind of patient's diagnosis remained elusive for years.
Aims: We want to share this young women in order to take attention and form a greater familiarity with the clinical and histopathologic features of this condition among gynecologists.
Methods: Data from the files of a 32 year -old nulliparous young woman with intractable gingivitis and dental problems and a history of persistent conjuctivitis is documented.
Results: She was refered to a gynaecologist due to infertility and cervicitis. Colposcopic and ultrasound examination of the uterus revealed, woody membraneous lesion which cover the inner site of the uterine cavity. We decided to give fresh frozen plasma (FFP) infusions both IV and locally to the uterine cavity after diagnosis of plasminogen deficiency. Heparine added FFP (50ml) also 5mg recombinant plazminogen activator (rt-PA, Actilyse^{R})remained in the cavity for 2-4 hours. Although a regular cavity view was achieved after FFP replacement therapy and local application, freeze embrional transfer was performed without a proper pregnancy achievement.
Summary/Conclusion: Gynecologists and clinicians who are familiar with this bizarre disease's clinical and histopathologic features will diagnose timely and manage properly.

PB1833 AN AUDIT OF DIAGNOSIS AND MANAGEMENT OF PE IN DGH AND LITERATURE REVIEW.

T. Memon [1,*], S. Ullah [1], K. Memon [2]

[1]Medicine, Weston Supermare Hospital NHS Trust, Weston Supermare, [2]Trauma and Orthopaedics, WWL NHS Hospital Trust, Wigan, United Kingdom

Background: Pulmonary embolism remains a worldwide major health problem.**1** It is among the most common causes of vascular death after myocardial infarction and stroke, and is the leading preventable cause of death in patients in hospital. Pulmonary embolism (PE) is a life-threatening condition resulting from dislodged thrombi occluding the pulmonary vasculature; right heart failure and cardiac arrest may ensue if not aggressively treated.
Common clinical features include dyspnoea, pleuritic chest pain, and hypoxaemia. There may also be evidence of a concurrent deep vein thrombosis. Hypotension, syncope, tachycardia, and signs of right heart failure are less common signs but are important to recognise as they suggest a high-risk PE with a larger clot burden and a higher mortality rate. Clinical probability, assessed by a validated prediction rule and clinical judgement, is the basis for all diagnostic strategies for PE. Computed tomographic pulmonary angiography is the definitive diagnostic investigation..Haemodynamically unstable patients require urgent primary reperfusion (usually thrombolysis), anticoagulation, and supportive care. Those at intermediate risk of a poor outcome require anticoagulation and ongoing monitoring; rescue reperfusion should be used if patients become haemodynamically unstable.
Aims: Objectives of this audit was to determine compliance rates with NICE CG 144 in diagnosing PE and Re-audited after 1 year to assess improvement in practice
Methods: - **First Loop –** Notes of 100 patients who were referred for CTPA to radiology department was taken and analysed for clinical features and documentation of wells score and results of CTPA during 2017. Subsequently results were presented in medical grand round and recommendations were dissipated to medial teams and published in hospital news bulletin. In first loop only in 3% patients Wells score was calculated. While incidence of PE was 14%
- **Second loop –** Notes of 50 patients who were referred for CTPA to radiology department was taken and analysed for clinical features and documentation of wells score and results of CTPA during 2018. Again results were presented in medical grand round and recommendations were dissipated to medial teams and published in hospital news bulletin. In 2nd loop wells score was calculated in only 18% of patients and incidence of PE was 22%.
Results: Clinical features of PE in descending order (as per NICE)
- Dyspnoea (70% of patients). 1st 67. 2nd 72. Tachypnoea (RR >20). Pleuritic Chest pain. 47% 50%
- Apprehension. Tachycardia (HR >100). 1% -8%. Cough. 1st 7% 2nd 16 %
- Haemoptysis.1st 2% 2nd 8%. Leg Pain. Clinical evidence of DVT (10% of patients). Dizziness 1%>2%
- Majority of patients presented with mix symptoms.

Good clinical history and examination are key factors to establish the diagnosis followed by an appropriate investigation depending on risk stratification
Summary/Conclusion: Difficult to know how many patients warranted CTPA. Can assume unnecessary CTPAs have been performed. Costly investigation. Radiation – one CTPA = 350 CXRs Slight increase in compliance with NICE guidelines (from 3% to 18%).

Transfusion medicine

PB1834 ERYTHROCYTE AND PLATELET TRANSFUSION PRACTISES IN PEDIATRIC HEMATOLOGY AND ONCOLOGY PATIENTS AND INVESTIGATION OF THEIR EFFECTS ON OUTCOME

S. Uysal Ateş [1], Ö. Tüfekçi [2], S. Yılmaz [2], D. İnce [3], E. Çeçen [3], N. Olgun [3], H. Ören [2,*]

[1]Pediatrics, [2]Pediatric Hematology, Dokuz Eylül University Faculty of Medicine, [3]Pediatric Oncology, Dokuz Eylül University Institute of Oncology, İzmir, Turkey

Background: Supportive treatments have vital importance in pediatric oncology patients, besides the treatment intended to cancer.
Aims: We aimed to define the frequency and thresholds of erythrocyte and platelet transfusions which are administered to pediatric hematology and oncology patients and to investigate the effects of transfusions on outcome.
Methods: Eighty leukemia (31.6%) and 173 lymphoma or solid tumor (68.4%) patients who were diagnosed and treated in Dokuz Eylül University Pediatric Hematology and Oncology Departments between the January 1, 2013 and January 1, 2018 and transfused with erythrocyte and/or platelet suspension at least for one time period in the course of their treatments are involved in this study. The data of the patients were scanned by clinical follow-up records and DEU Hospital Blood Bank records, retrospectively.
Results: A total of 1389 units of erythrocyte suspension (ES) and 1357 units of platelet suspension (PS) were administered to the leukemia group; 1604 units of erythrocyte suspension and 1243 units of platelet suspension were administered to the lymphoma and solid tumor group. A significant difference was detected between the leukemia and solid tumor groups in terms of ES and PS transfusion numbers; as the leukemia group had more transfusions ($p<0.001$). Pretransfusion mean hemoglobin and platelet values were 7.3±0.69 (6.2-11.7) g/dL and 22.8±6.95 (10.5-53.3)x10^9/L in leukemia patients and 8.2±1.21 (5-13.9) g/dL and 30±30.86 (4.3-260) x10^9/L in lymphoma and solid tumor patients, respectively. A positive correlation was detected between platelet values at initial diagnosis and total number of PS transfusion numbers of leukemia patients ($p<0.001$). There was no relation between Hb value at diagnosis and ES transfusion numbers. In lymphoma or solid tumor patients; negative correlation was found between Hb levels at diagnosis and ES transfusion numbers ($p=0.005$). When the patients were compared in terms of survival rates as classified according to pretransfusion mean Hb and platelet values, the overall survival rate was found to be shorter in leukemia patients whose pretransfusion mean hemoglobin and platelet values were above 7.5 gr/dL and 30 x10^9/L, respectively (Log rank $p=0.044$ and 0.046). Event free survival rates were also

negatively affected in leukemia patients whose pretransfusion hemoglobin was above 7.5 gr/dL (Log rank p=0.006). There was no significant association between pretransfusion values and survival rates in patients with lymphoma and solid tumors.
Summary/Conclusion: Total ES and PS transfusion numbers were higher in patients with leukemia in comparison with patients with lymphoma and solid tumors. On the other hand, pretransfusion Hb and platelet thresholds were found to be higher in the lymphoma and solid tumor patients in comparison with the leukemia group. Leukemia patients with higher pretransfusion Hb and platelet thresholds were found to have lower survival rates; however, studies including more homogeneous and extensive patient groups are needed to demonstrate this association more clearly.

PB1835 FREQUENCY OF DIFFERENT BLOOD GROUPS AND ITS ASSOCIATION WITH BODY MASS INDEX AND BLOOD PRESSURE AMONG TWO-THOUSAND-EIGHT-HUNDRED-EIGHTY-THREE BLOOD DONORS

T. Faiza [1,*], D. Damerdji [2]

[1]hematology, military hospital, [2]hematology, blood trnsfusion station, algiers, Algeria

Background: The association of hypertension and obesity with blood group "B" was reported by many researchers. Recognition of a positive relation with blood group might reflect increased susceptibility to hypertension wich is still required to be explored by new researches.
Aims: to determine the frequency of different blood groups among blood transfusion post donors and find the association of blood groups and body mass index with blood pressure.
Methods: this cross-sectional study was performed at blood donors transfusion post, from january 2018 to December 2019, participants were divided into groups on the basis of their ABO blood groups, rhesus D and on body mass index criteria. Blood groups were determined by simple conventional slide method. Blood pressure was estimated by manual auscultatory technique with a mercury sphygmomanometer. Data was analysed using SPPS .16
Results: there were 2883 blood donors with an overall mean age of 37± 10,27 years (range: 17-66 years), 288 female and 2595 male, sex-ratio M/F = 9,01. Blood group O was the predominant group (1284→44,5%), besides, 2561 (89%) subject were rhesus positive. The overall mean values for weight, height and BMI were: 80±14.49 kg (50-150), 173.07 ± 7.50 (150-198) and 27,13 ± 4,42 kg/m^2 (16.01-54.09): according to the blood group and BMI, our donors are distributed as follows: blood group A (+): n= 891, the average BMI = 27,12 ± 4,46 kg/m^2 (17,28-50,78), A (-): n= 103, the average BMI is = 18,40 ± 5,02 kg/m^2 (18,3-54,69), blood group AB (-): n= 22, the average BMI = 26,78 ± 2,23 kg/m^2 (20,68- 34,66), blood group AB (+): n=116, the average BMI = 26,69± 4,26 kg/m^2 (17,99- 39,63), blood group B (-): n= 47, the average BMI = 26,90 ± 5,16 kg/m^2 (18,29- 39,27), blood group B (+): n= 420, the average BMI = 26,97 ± 4,34 kg/m^2 (17,36- 44,44), blood group O (-): n= 145, the average BMI = 27,01 ± 4,66 kg/m^2 (18,59- 44,18), blood group O (+): n= 1139, the average BMI = 27,14 ± 4,72 kg/m^2 (16,07- 46,30). Moreover 314 subjects (1%) were pre-hypertensive: blood group A: n= 184 (6%), blood group AB: n=26 (0,9%), blood group B: n=79 (2,7%), blood group O: n= 25 (0,9%). Relative risk of hypertension for obese was grater than non obese: AUC=0.459 (p=0.009), body mass index was associated with both systolic pressure (p=0.001), on the other hand, in our study, no significant differences were observed in the mean SBP (systolic blood pressure) and diastolic blood pressure (DBP) among the ABO study groups: AUC: 0,276, p=0.067 and AUC = 0, 429, p=0,156 for the two evaluations respectively
Summary/Conclusion: blood group O was the most common blood group, it is strongly correlated with the risk of obesity, but in contrast to some researches, regression analysis of the present data did not find any significant association of blood groups with DBP and SBP

PB1836 THE PREVALENCE OF MNS, KIDD, DUFFY BLOOD GROUP SYSTEMS PHENOTYPES IN BLOOD DONORS LIVING IN THE EUROPEAN PART OF RUSSIAN FEDERATION

A. Yovdiy [1,*], E. Butina [1], E. Poponina [1], P. Sherstnev [1]

[1]The Federal State-Financed Scientific Institution Kirov Research Institute of Hematology and Blood Transfusion under the Federal Medical Biological Agence, Kirov, Russian Federation

Background: Patients with hematological disorders are at high risk of developing post-transfusion complications. The possibility of alloimmunization to red blood cell antigens grows with an increase in the number of transfusions.The incidence of alloantibodies in patients ofour hematology clinic is 1.8%. A register of blood donors typed for a wide range of transfusion-dangerous antigens was created to select compatible red blood cells.
Aims: The aim was to study the prevalence of MNS, Kidd, Duffy blood group systems phenotypes in blood donors living inthe European part of Russian Federation and to compare with them in Caucasoids of Europe and America.
Methods: Immunohematological tests were carried out using equipment and reagents from BioRad (USA).
Results: The register currently includes 327 donors of blood components. The prevalence of phenotypes is shown in the table.

Table. The prevalence of red blood cells antigens

System	Phenotype	Prevalence (%)	
		Blood donors of European territory of Russia	Caucasoids of Europe and America (Shaz B.H., 2013)
MNS	M+N-S+s-	6,7	6
	M+N-S+s+	13,2	14
	M+N-S-s+	11,3	10
	M+N+S+s-	6,4	4
	M+N+S+s+	20,2	22
	M+N+S-s+	22,9	23
	M-N+S+s-	0,6	1
	M-N+S+s+	4,6	6
	M-N+S-s+	14,1	15
	M+N-S-s-	0	0
	M+N+S-s-	0	0
	M-N+S-s-	0	0
Kidd	Jk(a+b-)	22,2	26
	Jk(a-b+)	24,5	23
	Jk(a+b+)	53,3	50
Duffy	Fy(a+b-)	22,0	17
	Fy(a-b+)	27,5	34
	Fy(a+b+)	50,5	49

Summary/Conclusion: No significant difference was found in the prevalence of MNS, Kidd, Duffy phenotypes in blood donors living inthe European part of Russian Federation and with them in Caucasoids of Europe and America.
