Methods: A contemporary US-based dataset of patients with MM who were refractory to anti-CD38 MoAb (MAMMOTH study) was utilized to identify patients who would meet eligibility for CARTITUDE-1 and who received conventional therapy. Analyses were performed on the intent-to-treat (ITT) population in CARTITUDE-1, defined as patients who underwent apheresis (N=113), and a modified ITT (mITT) population, defined as the subset of patients who received cilta-cel at the recommended phase 2 dose (N=97). From the MAMMOTH dataset, we identified a population corresponding to CARTITUDE-1 ITT (N=190) and a mITT population, patients without death or progression within 47 days (median time between apheresis and cilta-cel infusion) from onset of therapy (N=122). Propensity scores (PS) were calculated with demographics, number of prior therapies, cytogenetics, and refractoriness to MM agents as covariates. Nearest neighbor 1:1 PS matching was performed by an analyst who was blinded to outcomes. The overall response rate (ORR), progression-free survival (PFS), and overall survival (OS) were evaluated for ITT and mITT populations in CARTITUDE-1 vs. matching MAMMOTH cohorts.
Results: A total of 95 ITT (75 received bridging therapy, 82 received cilta-cel) and 69 mITT (54 received bridging) CARTITUDE-1 patients matched MAMMOTH patients (Table). Among the patients in the MAMMOTH ITT cohort, 34% had received pomalidomide, 24% anti-CD38 MoAb, 19% carfilzomib, and 35% cytotoxic chemotherapy in next therapy. ORR in the ITT cohorts was higher in CARTITUDE-1 than in MAMMOTH (84% vs. 28%). Compared with their MAMMOTH counterparts, patients in CARTITUDE-1 ITT cohort had improved PFS (12 months, 73% vs. 12%) and OS (12 months, 83% vs. 39%). Between the mITT cohorts, CARTITUDE-1 patients had superior ORR (96% vs. 30%), PFS (12 months, 79% vs. 15%), and OS (12 months, 88% vs. 41%).

	ITT (apheresis) CARTITUDE-1 (N=95)	ITT matches, MAMMOTH (N=95)		mITT (treated) CARTITUDE-1 (N=69)	mITT matches, MAMMOTH (N=69)	
Mean Age -years (sd)	62.4 (8.5)	62 (8.5)		62.6 (7.7)	62.7 (9.4)	
High cytogenetic risk	22%	24%		25%	23%	
Mean N lines of therapy (sd)	6.2 (3.0)	6.3 (2.4)		5.9 (2.9)	6 (1.9)	
Triple-class refractory	97%	96%		96%	96%	
Penta exposed	80%	76%		75%	75%	
Penta refractory	43%	42%		35%	42%	
ORR	84%	28%	P<0.001	96%	30%	P<0.001
PFS	HR=0.11, 95% C.I. 0.05-0.22		P<0.001	HR=0.02, 95% C.I. 0.01-0.14		P<0.001
OS	HR=0.20, 95% C.I. 0.10-0.39		P<0.001	HR=0.05, 95% C.I. 0.01-0.22		P<0.001

C.I., confidence interval; HR, hazard ratio; ITT, intent-to-treat; mITT, modified intent-to-treat; N, number; ORR, overall response rate; OS, overall survival; PFS, progression free survival; sd, standard deviation.

Summary/Conclusion: In patients with RRMM beyond therapy with IMiD, PI, and anti-CD38 MoAb, treatment with cilta-cel is associated with higher response rate and superior PFS and OS when compared with conventional treatment.

EP992 A MULTINATIONAL CHART REVIEW OF REAL-WORLD TREATMENT PATTERNS AND CLINICAL OUTCOMES IN PATIENTS WITH RELAPSED/REFRACTORY MULTIPLE MYELOMA

K. M. Kortum [1,*], S. P. Nagar [2], E. Singh [3], K. L. Davis [2], P. L. Lin [3]

[1]Department of Internal Medicine II, University Hospital of Würzburg, Würzburg, Germany, [2]RTI Health Solutions, Research Triangle Park, NC, [3]Sanofi, Cambridge, MA, United States

Background: Approvals of new agents have changed the treatment landscape for multiple myeloma (MM) in recent years, but real-world (RW) data on treatment patterns and clinical outcomes in patients with relapsed/refractory multiple myeloma (RRMM) outside of clinical trial settings remain limited.
Aims: To assess RW treatment patterns and clinical outcomes of patients with RRMM in Canada, France, Spain, and UK.
Methods: This retrospective, observational chart abstraction study recruited oncologists, hematologists and hemato-oncologists in Canada, France, Spain and the UK, who reviewed deidentified medical records from adult patients with a diagnosis of RRMM between Jan 1, 2012–Dec 31, 2016. RRMM was defined by disease progression during or after first-line (1L) therapy for MM (date of 1L MM progression was study index). Treatment regimens were described, and progression-free survival (PFS) and overall survival (OS) were assessed by Kaplan–Meier estimation from start of each line of therapy (LoT), 1L–3L.
Results: A total of 412 patient records were included (Canada: n=101; France: n=101; Spain: n=104; UK: n=106). Mean (SD) age of patients at index was 65.4 (10.5) years, 59.2% of participants were male, median duration of follow-up from index was 37.7 months; and median number of LoT received was 3. At index, a higher proportion of patients in the UK (53.8%) had at least one gene translocation associated with high risk MM including del(17/17p), t(4;14), t(14;16), t(14;20), compared with other countries (34.6–39.6%). Median Charlson Comorbidity Index score at index was 1.0 in Canada, France and the UK, and 2.0 in Spain. Rates of MM-related symptoms were broadly comparable but with some country variation for some symptoms: proportion of patients with anaemia ranged from 24.8–51.9%, renal impairment from 5.9–24.0%, hypercalcemia 6.6–12.5%, and skeletal-related events 4.7–22.1%. Bortezomib-based regimens were most frequently used in 1L (**Table**), both in patients who did and who did not have stem cell transplant (SCT). Lenalidomide-based regimens were frequently used in 2L (particularly Rd, KRd, VRd, and NRd); carfilzomib (KRd, Kd) and daratumumab (DaraVd) were among the most frequently used regimens in 2L in France and Spain, but not Canada and the UK. In the 3L setting, pomalidomide (Pd, PCd), carfilzomib (Kd), and daratumumab (Dara monotherapy, DaraVd) were frequently used in most countries except the UK. Following 1st relapse, almost all patients received 2L therapy (>93% in all countries); while a lower proportion received 3L therapy following 2nd relapse (36.6%–64.2%). Median PFS ranged from 20.7 months (UK) to 33.9 months (Canada) in 2L, and from 12.0 months (France) to 22.5 months (UK) in 3L. Median OS was not reached for any LoT from 1L–3L. From start of 2L, 2-y OS rate ranged from 82% (Spain) to 92% (UK); from start of 3L, 2-y OS ranged from 65% (Spain) to 89% (UK).

Table: Most frequent treatment regimens and survival outcomes in 1L–3L.

	Canada (N=101)	France (N=101)	Spain (N=104)	UK (N=106)

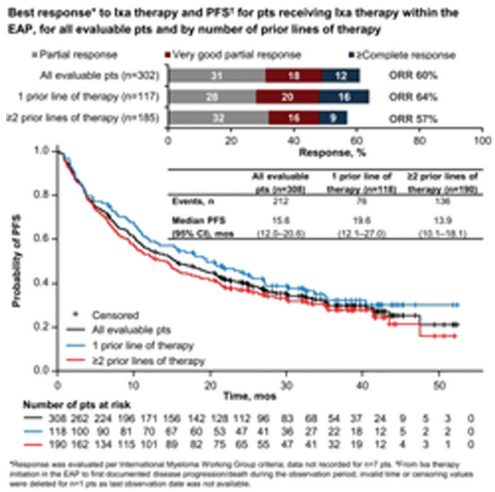
Summary/Conclusion: Newer therapies for RRMM began to be commonly used in 2L and became more frequent in 3L. Following first relapse, a substantial proportion of patients with RRMM received 2L but not 3L therapies. PFS in 2L and 3L was longer than in clinical trials but comparable with other RW studies, suggesting that patients with RRMM have longer than expected treatment-free interval instead of continuous treatment until disease progression. These findings also suggest there may be country variations in the implementation of approved new therapies in routine clinical practice.

EP993 PULMONARY FUNCTION TESTS REVEAL UNRECOGNIZED LUNG DYSFUNCTION AND HAVE INDEPENDENT PROGNOSTIC SIGNIFICANCE IN PATIENTS WITH SYSTEMIC AL AMYLOIDOSIS

D. Fotiou [1,*], G. Trakada [2], A. Kallianos [1], F. Theodorakakou [1], I. Ntanasis-Stathopoulos [1], M. Migkou [1], P. Malandrakis [1], N. Kanellias [1], E. Eleutherakis-Papaiakovou [1], I. Dialoupi [1], M. Gavriatopoulou [1], E. Terpos [1], M. A. Dimopoulos [1], E. Kastritis [1]

[1]Department of Clinical Therapeutics, Alexandra Hospital, [2]National and Kapodistrian University of Athens, School of Medicine, Athens, Greece

Background: Dyspnea in patients with AL amyloidosis is a common symptom usually attributed to cardiac dysfunction. Lung involvement is not a common feature of the disease and requires histopathological verification and a symptomatic presentation or typical radiographic changes of diffuse interstitial lung disease. However, post-mortem data and some retrospective studies suggest that lung involvement is likely underrecognized. A systematic functional approach of lung function in these patients is lacking.
Aims: To perform a comprehensive evaluation of lung function in consecutive patients with newly diagnosed AL amyloidosis.
Methods: This non-interventional, prospective study included 139 consecutive patients with systemic AL amyloidosis treated in the Department of Clinical Therapeutics (Athens, Greece). Patients with localized lung amyloidosis were excluded. Pulmonary function tests (PFTs) were performed in a Master screen Body (Jaeger, Germany). Spirometry, lung volume measurements, carbon monoxide diffusion capacity (DLCO) corrected for hemoglobin, maximal expiratory (Pe) and inspiratory (Pi) pressures were measured in a sitting position. Patient's age, height and weight were recorded for use in the calculation of reference values.
Results: Median age was 65 years, 59% of patients were male; 65% had renal, 79% cardiac, 24% liver, 22% peripheral/autonomic and 2% lung involvement. Mayo stage distribution was as follows; 10% stage I, 52% stage II, 31% stage IIIa and 7% stage IIIb. Among patients, 68% had a normal breathing pattern, 9% obstructive and 23% restrictive. A restrictive pattern was associated with advanced Mayo stage (p=0.034); there was no association with free light chain (FLC) levels. One-year mortality for patients with a normal pattern was 14% versus 18% with obstructive and 38% for patients with a restrictive pattern. In univariate analysis, a restrictive breathing pattern was associated with worse survival (28.6 vs 76 months for patients with obstructive/normal pattern, p=0.002) and remained significant even after adjustment for Mayo stage (HR: 2.01, p=0.034). Certain indices of PFTs which reflect neuromuscular fitness and not breathing pattern (Pi and Pe), were severely affected in the majority of patients (93% for Pi and 61% for Pe had <80% of predicted values). Among PFT indices, FEV%, FVC1%, TLC, DLCO and Pe% were all associated with survival. Importantly, each of FEV1%<80%, FVC1%<80% and Pe% <80% of predicted remained significant for survival when adjusted individually for Mayo stage (FEV1%<80%, HR:2.1, p=0.016, FVC1%<80% HR:2.8, p<0.001, Pe% <80%, HR: 4.6, p=0.002). Low Pe% remained an independent prognostic factor for survival (HR 3.1, p=0.005) even when adjusted for the breathing pattern (restrictive versus normal/obstructive). Furthermore, among patients with stage IIIb disease, a low Pe% could further identify and ultra-high risk subgroup with even worse outcome (p=0.033).



Summary/Conclusion: In this comprehensive evaluation of lung function by PFTs we found that a restrictive breathing pattern is common in patients with systemic AL amyloidosis. Importantly, indices of PFTs associated with neuromuscular function are severely affected in most patients and are associated with prognosis, independently of the degree of cardiac dysfunction. Our results point to the presence of unrecognized pulmonary dysfunction, despite the absence of typical imaging findings, with prognostic and potentially therapeutic implications.

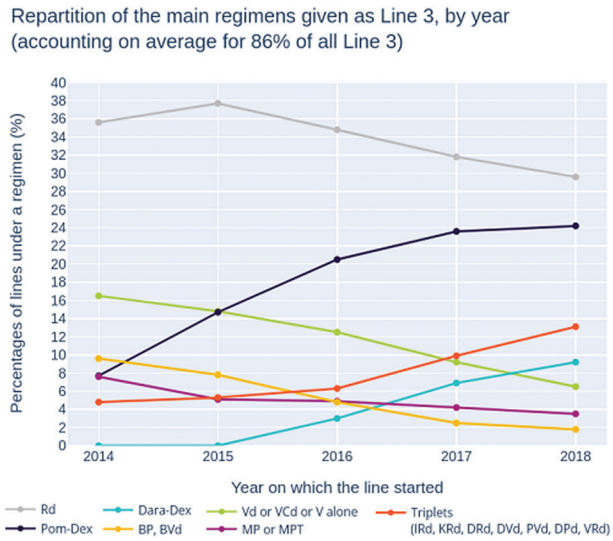
EP994 EFFECTIVENESS AND SAFETY OF IXAZOMIB-BASED THERAPY IN RELAPSED/REFRACTORY MULTIPLE MYELOMA (MM) OUTSIDE OF A CLINICAL TRIAL: FINAL ANALYSIS OF THE 'USE VIA EARLY ACCESS TO IXAZOMIB' (UVEA IXA) STUDY

H. Ludwig [1,*], E. Terpos [2], M.-V. Mateos [3], M. Boccadoro [4], B. Kishore [5], K. Ramasamy [6], P. Krhovska [7], M. Streetly [8], V. Gergely [9], M. Ladicka [10], S. Fernandez [11], L. Simoni [11], N. Bent-Ennakhil [12], A. Zomas [12], F. Gavini [12], R. Hájek [13]

[1]Wilhelminen Cancer Research Institute, c/o 1st Department of Medicine, Center for Oncology and Hematology, Clinic Ottakring, Vienna, Austria, [2]Department of Clinical Therapeutics, National and Kapodistrian University of Athens, School of Medicine, Athens, Greece, [3]Department of Hematology, University Hospital of Salamanca, IBSAL, CIC, IBMCC (USAL-CSIC), Salamanca, Spain, [4]Division of Hematology, University of Torino, Torino, Italy, [5]Heart of England/University Hospitals Birmingham NHS Foundation Trust, Birmingham, [6]Oxford University Hospitals NHS Foundation Trust, Oxford, United Kingdom, [7]Department of Hemato-oncology, University Hospital Olomouc, Olomouc, Czech Republic, [8]Guys and St Thomas' NHS Foundation Trust, London, United Kingdom, [9]Faculty of Medicine Department of Internal Medicine and Haematology, Semmelweis University, Budapest, Hungary, [10]National Cancer Institute, Bratislava, Slovakia, [11]MediNeos, Observational Research, Modena, Italy, [12]Takeda Pharmaceuticals International AG, Zurich, Switzerland, [13]Department of Hemato-oncology, University Hospital Ostrava, and Faculty of Medicine, University of Ostrava, Ostrava, Czech Republic

Background: In MM treatment, it is important to improve our understanding of routine clinical practice and the effectiveness of new agents outside of clinical trials. Ixazomib (Ixa) is approved for MM patients (pts) who have received ≥1 prior therapy on the basis of TOURMALINE-MM1 study data.
Aims: Report data from the final analysis of UVEA-IXA, a European, multicenter, observational, longitudinal cohort study of pts receiving Ixa via an Early Access Program (EAP) in the Czech Republic, Greece, Hungary, Italy, Slovakia, Slovenia, Spain, and United Kingdom.
Methods: UVEA-IXA comprised a retrospective chart review from Ixa therapy initiation in the EAP and a prospective 1-year (yr) follow-up period from chart review initiation, with quarterly data capture. Eligible pts were in biochemical and/or symptomatic relapse after 1–3 prior lines of therapy, had not received anti-MM therapy for >3 cycles (except steroids) at the start of Ixa therapy, and had an Eastern Cooperative Oncology Group performance status (ECOG PS) of 0–2. Lenalidomide (R)- or proteasome inhibitor-refractory pts were ineligible. Primary endpoints were response and progression-free survival (PFS).
Results: 309/357 enrolled pts were evaluable; 54% were male; median age at enrollment was 68 yrs (range 36–92), 40% aged ≥70 yrs. At the start of Ixa therapy, 37/123 pts (30%; n=186 unknown [unk]) had International Staging System (ISS) stage III MM, 62/308 (20%; n=1 unk) had ECOG PS 2, and 13/279 (5%; n=30 unk) had an estimated glomerular filtration rate (eGFR) <30 mL/min. Of 309 pts, 61% had ≥1 comorbidity, including hypertension (26%), renal disease (23%), and diabetes (9%). Median time from diagnosis was 37.2 months (mos; range 4.9–232.8); 39%, 43%, and 18% of pts had received 1, 2, and 3 prior lines of therapy, respectively. Median observation period (n=306; n=3 not available) was 25.5 mos (range 0.8–54.1). Pts received Ixa for a median of 10.5 mos (range 0.2–52.3); most pts also received R (98%) and dexamethasone (97%). Overall response rate (ORR) on Ixa therapy was 60%; median PFS (mPFS) was 15.6 mos (Figure). Risk of progression/death was significantly greater in pts with ECOG 2 vs 0–1: 87% vs 64% had PFS events (p=0.0004). Overall, median time to next therapy after stopping Ixa was 21.4 mos. Median overall survival was 35.5 mos (95% confidence interval [CI] 28.0–44.4) overall, and 43.1 vs 31.4 mos (95% CI 31.2–not evaluable vs 21.5–47.5) in pts with 1 vs ≥2 prior lines of therapy. Ixa dose was reduced in 57/307 pts (19%; n=2 not recorded); 246/309 pts (80%) discontinued Ixa, most frequently due to: progression in 37% of pts, adverse events (AEs) in 19%, and loss/lack of response in 10%. Among 215 pts who received ≥4 cycles of Ixa, rates of any-grade (G) and G≥3 AEs were 62% and 37%; most common any-G AEs were thrombocytopenia (15%) and diarrhea (13%); the most common G≥3 AE was thrombocytopenia (6%).

Summary/Conclusion: UVEA-IXA data show that Ixa therapy is an effective, tolerable treatment option outside the clinical trial setting. Outcomes were favorable in pts with 1 vs ≥2 prior lines of therapy and ECOG PS 0–1 vs 2. Although UVEA-IXA data derive from retrospective chart review/infrequent prospective data capture and thus cannot be directly compared to clinical trial data, compared with TOURMALINE-MM1 pts (Ixa arm; ORR 78%, mPFS 20.6 mos), UVEA-IXA pts had higher rates of ECOG PS 2 (20 vs 5%), ISS stage III MM (30 vs 12%), and eGFR <30 mL/min (5 vs 1%), and had received more prior lines of therapy (61 vs 38% had ≥2). Most common AEs were gastrointestinal and hematologic, consistent with the safety profile in TOURMALINE-MM1.



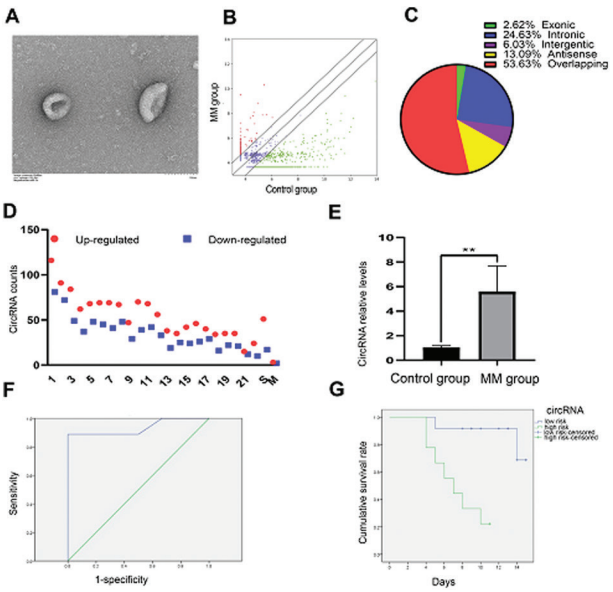
EP995 OVERVIEW AND EVOLUTION OF TREATMENT LINES IN MULTIPLE MYELOMA FROM 2014 TO 2018: A RETROSPECTIVE STUDY USING THE FRENCH NATIONAL CLAIM DATABASE (SNDS)

A. Perrot [1,*], V. Augusto [2], M. Pierres [3], M. Javelot [3], C. Guilmet [3], M. Prodel [4], L. Lamarsalle [4], M. Laurent [4], I. Borget [5], C. Touzeau [6]

[1]Institut Universitaire du Cancer Toulouse – Oncopole, Toulouse, [2]Center for Biomedical and Healthcare Engineering Mines, Saint-Etienne, [3]Janssen-cilag

France, Issy-les-moulineaux, [4]HEVA, Lyon, [5]Department of Biostatistics and Epidemiology, Gustave Roussy, University Paris-Saclay, Villejuif, France, Oncostat U1018, Inserm, Université Paris-Saclay, Équipe Labellisée Ligue Contre le Cancer, Villejuif, France, GRADES, Université Paris-Saclay, Chatenay-Malabry, [6]Centre Hospitalier Universitaire de Nantes, Nantes, France

Background: Multiple Myeloma (MM) disease course is a succession of remissions and relapses, which define lines of treatment. For each line, several regimens can be used. Although guidelines provide recommendations on the disease management, real world data are missing to describe which regimens are used in the daily practice. Regarding recent changes due to the introduction of new drugs (e.g., daratumumab, carfilzomib and ixazomib), an accurate and updated overview of MM treatment management is needed. This study provides a comprehensive overview of these recent changes based on the nationwide French National Health Insurance (NHI) databases, called SNDS ("Système National des Données de Santé"). These databases include hospital records, primary and secondary care of 66 million people.
Aims: To describe the evolution over time of MM treatment management by line and treatment sequencing in practice in France, in the context of a new therapeutic landscape.
Methods: This is a retrospective observational cohort study including all cases of multiple myeloma from 2014 to 2018 identified through the French NHI databases (SNDS). Cases were detected using a validated algorithm which was expanded to consider recent evolutions of MM therapeutic management. Treatment lines were re-constructed through ATLAS, a published adaptation of the Smith-Waterman alignment sequence algorithm, by scanning day-by-day patient claims. This innovative algorithm gave the temporal flexibility needed, and impossible with a solely rule-based identification, to identify lines considering the possible deviations between theoretical regimens and patient reality, and between reality and claim data. For each year (2014-2018) and for each line, the number and percentage of patients starting a regimen was assessed and protocols detailed.
Results: 36,208 prevalent patients treated for a MM between 2014 and 2018 were included. As expected, the main regimen for L1 without transplant changed from VMP (2014: 32%) to Rd (2018: 30%), the place of VRd regimen rapidly increased (2017: 4%, 2018: 10%), whereas MPT and MP regimens decreased (together, 2014: 19%, 2018: 4%). For L1 with transplant, VTd remains the main regimen (2014: 59%; 2018: 61%). Same for Rd on L2 and L3 (L2 - 2014: 47%, 2018: 54%; L3 - 2014: 36%; 2018: 30%), although we observed a shifting of some standards from doublet to triplet therapy (IRd, KRd, DRd, DVd, DPd, PVd, and VRd) with the newest drugs, as presented in the attached figure. Moreover, L4+ landscape is broadly evolving with a main regimen changed from Pom-Dex (2014: 21%) to Dara-Dex (2018: 21%). The rapidly acquired place of Pom-Dex in L3 (2018: 24%) can be related to the shift to the use of lenalidomide in earlier lines (L1, L2), hence inducing more lenalidomide-refractory patients. Regarding treatment sequences, the main course of patients having a L4+ in 2018 was as follows: L1: V-based regimen (VMP for non-transplant; VTd for transplant); L2: Rd; L3: Pom-Dex; L4+: Dara-Dex. All these results will be updated (Q2-2021) and presented with 2019 data.



Summary/Conclusion: This study demonstrates the fast evolution of treatment management of MM patients, due to new drug marketing authorizations. The study also showed that real-world data are a powerful tool to study treatment lines at a national scale and lead the way to more precise analyses of optimal therapeutic sequences, including their impact on the overall survival.

EP996 EXOSOMAL CIRCRNA CACNG2 IS A NOVEL BIOMARKER FOR MM-RELATED CARDIAC DISEASES

M. Yu [1,*], X. Cui [2]

[1]Shandong University of traditional Chinese medicine, [2]Affiliated Hospital of Shandong University of traditional Chinese medicine, Jinan, China

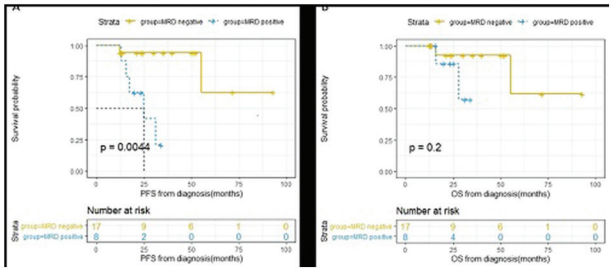
Background: Cardiac disease is one of the most common complications of multiple myeloma (MM), which seriously affects the survival and prognosis of patients. Several studies have revealed that circular RNAs (circRNAs) might play some roles in the initiation and progression of MM. Exosomes participate in the growth and drug resistance of many tumors via delivering bioactive molecules contained in them. However, the clinical significance of most serum exosome-derived circRNAs (exo-circRNAs) in MM-related cardiac complications is rarely studied.
Aims: To provide evidence for exo-circRNAs as novel potential diagnostic and therapeutic targets for MM-related cardiac diseases.
Methods: We collected serum samples from 21 MM patients which cardiac complications and 5 matched healthy control people as total samples. Then, we used the ExoQuick exosome precipitation kit to separate the exosomes, after which transmission electron microscopy (TEM) was applied to observe the precipitates. Subsequently, 6 serum samples from MM patients and 5 control samples were sent for high-throughput sequencing. According to p value and fold changes, the top 6 significantly up-regulated and 10 down-regulated exo-circRNAs were selected for quantitative real-time PCR (qRT-PCR) in total samples. Finally, we statistically analyzed the data with SPSS STATISTICS 26.0. ROC curves and Kaplan Meier survival curves were performed to evaluate the diagnostic and prognostic performance of the relative circRNA in MM-related cardiac diseases.
Results: 1.Characterization of serum exosomes
Under the TEM, oval extracellular vesicles less than 100 nm diameter were observed (Fig 1A), which demonstrated that the separated granules were true exosomes.
2. High throughput RNA sequencing
We identified 16106 differentially expressed exo-circRNAs via high-throughput sequencing. Taking FC ≥ 2.0 and $P \leq 0.05$ as the criteria, 2,052 exo-circRNAs were selected with significant differences compared with the control group. Then they were visualized by a Scatter plot (Fig 1B). Further analysis showed that most of the up-regulated ones were sense overlapping, while most of the down-regulated ones were exonic (Fig 1C), and they were widely distributed in 22 pairs of autosomes, sex chromosomes and mitochondria (Fig 1D).
3.qRT-PCR validation
The results showed that one of the up-regulated circRNAs chr22: 37076154-37076351 - was derived from the intron of CACNG2 locus, named it as "circ-CACNG2", with the data of 5.55 ± 2.15 in MM, which was more than five times that in the control group (Fig 1E, $P<0.01$). It proved that circ-CACNG2 was highly expressed in the exosomes of MM patients.
4.Correlation between circ-CACNG2 and clinicopathological characteristics
The receiver operating characteristic curve (ROC) analysis indicated that circ-CACNG2 had high sensitivity and specificity as a prognostic indicator. The area under the ROC curve (AUC) was 0.935 (P=0.001, Fig 1F), and the optimal critical value of circ-CACNG2 is 4.95 (sensitivity = 88.9% and specificity =100%, Fig 1F). Furthermore, Kaplan Meier survival curve analysis demonstrated that there was a significant difference in survival time between circ-CACNG2 high risk (≥ 4.95) and low risk (< 4.95) (P = 0.001, Fig 1G).

Summary/Conclusion: Exosome-derived circ-CACNG2 has the potential to be a novel independent diagnostic factor and prognostic indicator of MM-related cardiac diseases. And it may be an effective therapeutic target in the future.

EP997 AUTOLOGOUS TRANSPLANT IN MULTIPLE MYELOMA: IMPROVEMENT IN IMMEDIATE RESULTS USING NON-CRYOPRESERVED STEM CELLS

P. Dutari [1,*], E. Colombo [1], M. Alvarez Bollea [1], S. Jarchum [1], D. Minoldo [1], M. Lavarda [1], L. Rizzi [1], G. Jarchum [1]

[1]*Hematology, Sanatorio Allende, Cordoba, Argentina*



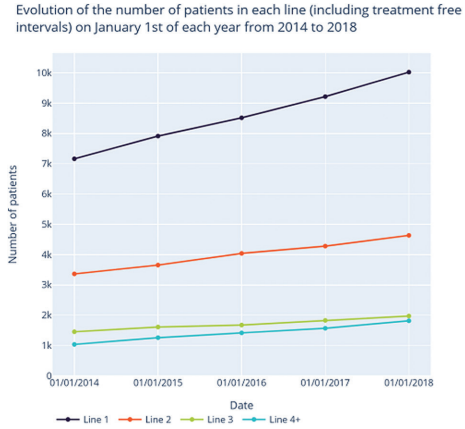
Background: Patients with diagnosis of multiple myeloma (MM) who are candidates to receive an autologous hematopoietic stem cell transplant (Auto-HSCT) are stimulated to harvest stem cells from the peripheral blood. These cells can be either cryopreserved with Dimethyl sulfoxide (DMS) for later use or stored in liquid state at 4ºC for up to 5 days to be reinfused after a 48-hours- conditioning regimen with a total dose of 200mg/m2 of Melphalan. Potential advantages of non-cryopreserved stem cells are a decrease in apoptotic progenitors, the avoidance of DMS toxicity, and a reduction in the use of economic resources.
Aims: To compare acute complication, transfusional requirement, and time to hematologic recovery between patients with MM that receive cryopreserved (CRYO) and non-cryopreserved (non-CRYO) autologous stem cells.
Methods: Observational, retrospective trial that included pacientes with MM who received Auto-HSCT between January 2018 to January 2021 at a high complexity center.
Results: 62 pacientes received transplant on the study period. 4 were excluded due to missing important data. 21 patients received non-CRYO cells whereas 37 received CRYO products. Median age was 55±9.53 years; 59% were males. Median number of chemotherapy cycles was 6 cycles; 47% were on complete remission, 21% very good partial remission, and 33% on partial remission. Before harvesting, 52% versus 75% patients require addition of plerixafor in the non-CRYO and CRYO groups, respectively (p=0.72). The mean amount of CD34+/kg infused cells was 7.7±1.6 x106 for the non-CRYO patients versus 6.6±2.4 x106 for the CRYO group (p=0.44).
Incidence of febrile neutropenia was 61% non-CRYO vs 91% CRYO (p=0.01). There were no cases of severe sepsis nor dialysis requirements. Incidence of grade IV mucositis was 19% non-CRYO vs 45% CRYO (p=0.08). Requirement of parental nutricion was 42% non-CRYO vs 78% CRYO (p=0.01).
Platelet transfusion requirement was 10.05±10.70 units for non-CRYO and 11.68±8.27 units for the CRYO group (p=0.18). The median amount of red blood cells units was 0.67±2.22 units in the non-CRYO group versus 0.62±1.52units in the CRYO group (p=0.55).
Time in days to neutrophil recovery (>500/mm3 for 2 consecutive days) was 10.52±1.29 non-CRYO vs 12.89±2.23 CRYO (p>0.001). In the case of platelet recovery (>30.000/mm3 without transfusion in the last 3 days), it took 13.14±7.25 days non-CRYO versus 15.51±4.19 days CRYO (p<0.001). Median hospital stay was 13 ±2.55 non CRYO versus 16±4.11 CRYO (p<0.001). There were no transplant-related deaths in either group.
Summary/Conclusion: Auto-HSCT in MM using non-cryopreserved cells is a safe and effective technique associated with a decrease in febrile neutropenia incidence, lower parenteral nutrition requirement, faster hematologic recovery and shorter hospital stay, making it more cost-effective. Besides, it showed a tendency to a lower incidence of severe mucositis. There was no significant impact on transfusion requirement and on mortality associated with the transplant. Further studies are needed to evaluate long-term outcomes.

EP998 CLINICAL VALUE OF MINIMAL RESIDUAL DISEASE ASSESSED BY MULTIPARAMETER FLOW CYTOMETRY IN AMYLOID LIGHT CHAIN AMYLOIDOSIS

X. Li [1], J. Li [1,*]

[1]*The department of hematology, The first affiliated hospital of Sun yat-sen university, Guangzhou, China*

Background: Amyloid light chain (AL) amyloidosis, as a clonal plasma cell disorder, is characterized by organ dysfunction secondary to deposition of misfolded monoclonal light chains and most commonly involves the heart, kidney, and liver. AL amyloidosis is typically associated with a lower indolent clonal plasma cell burden within the bone marrow than multiple myeloma (MM). However, even low levels of unstable light chains secreted by these plasma cells can deposit in organs, resulting in organ dysfunction. Thus, the treatment of the disease aims to target the plasma cell clone and completely eliminate toxic light chain production. With the development of novel therapies, deep responses, as assessed by serum- or urine-based methods such as immunofixation electrophoresis and free light chain (FLC) quantification, can be achieved in a significant proportion of patients with AL amyloidosis. However, there are several limitations inherent to FLC assays and immunofixation electrophoresis. Hematologic relapses still occur, and organ function may continue to deteriorate due to small residual clones. The small amounts of light chains produced by these plasma clones may not be detectable by conventional techniques. In MM, multiparameter flow cytometry (MFC) is being used to detect the presence of minimal residual disease (MRD), and the absence of detectable MRD has been associated with improved survival outcomes across different therapeutic regimens and lines of therapy. Such data are sparse in patients with AL amyloidosis. Some studies have shown that the absence of MRD detected by MFC is associated with superior outcomes in patients with AL amyloidosis, but these studies have limitations given the heterogeneity of patients tested and the lack of predefined time points for MRD assessment.
Aims: To assess the feasibility and prognostic value of minimal residual disease (MRD) evaluated by multiparameter flow cytometry (MFC) in newly diagnosed amyloid light chain (AL) amyloidosis patients.
Methods: Clinical data from 25 consecutive newly diagnosed AL amyloidosis patients with MRD data tested 3 months after first-line therapy completion were retrospectively analyzed in a single center from 2012 to 2019. First-line therapy included 8 courses of VD or 4 courses of VD and sequential autologous stem cell transplantation (ASCT), both without maintenance therapy.
Results: Of 25 patients with very good partial response (VGPR) or better, 19 (76%) achieved MRD negativity. There were no differences in baseline characteristics between MRD-negative and MRD-positive patients. More ASCT patients than non-ASCT patients (90.0% vs 53.3%, P=0.043) achieved MRD negativity. In the MRD-negative and MRD-positive groups, renal response was observed in 82% vs 50% (P=0.116), cardiac response in 93% vs 25% (P=0.019), liver response in 100% vs 50% (p=0.286), and any organ response in 94% vs 50% (P=0.023) of patients. At a median follow-up of 25.1 months, MRD-negative patients showed significantly longer progression-free survival (PFS) from diagnosis than MRD-positive patients (24.52 vs 76.39 months, P= 0.004) (Figure 1).



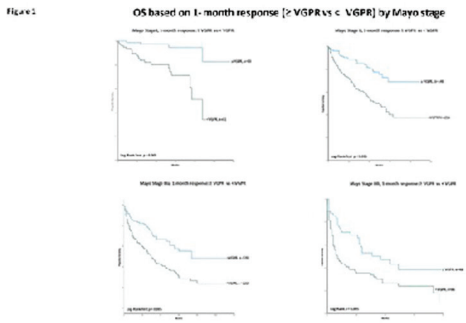
Summary/Conclusion: MRD negativity measured by MFC at 3 months after first-line therapy completion in patients with AL amyloidosis is measurable and associated with improved organ response rates and PFS over a long follow-up.

EP999 EPIDEMIOLOGY OF MULTIPLE MYELOMA: DATA FROM THE FRENCH NATIONAL HEALTH INSURANCE DATABASE (SNDS)

C. Touzeau [1,*], M. Pierres [2], M. Javelot [2], C. Guilmet [2], L. Lamarsalle [3], F. Raguideau [3], I. Borget [4], V. Augusto [5], A. Perrot [6]

[1]Centre Hospitalier Universitaire de Nantes, Nantes, [2]Janssen-cilag France, Issy-les-moulineaux, [3]HEVA, Lyon, [4]Department of Biostatistics and Epidemiology, Gustave Roussy, University Paris-Saclay, Villejuif, France, Oncostat U1018, Inserm, Université Paris-Saclay, Équipe Labellisée Ligue Contre le Cancer, Villejuif, France, GRADES, Université Paris-Saclay, Chatenay-Malabry, [5]Center for Biomedical and Healthcare Engineering Mines, Saint-Etienne, [6]Institut Universitaire du Cancer Toulouse – Oncopole, Toulouse, France

Background: Multiple myeloma (MM) is considered as an incurable hematologic disease. Net cancer-specific survival at 5 years after diagnosis of MM was estimated at 47% between 2005 and 2010. Thanks to significant improvements of the MM therapeutic management in the past decades, the overall survival of MM patients tends to increase, and some patients now achieve long-term remission. This directly impacts the dynamic of MM epidemiology. The world age-standardized MM incidence rate in France was estimated at 4.1/100 000/year in 2020, based on extrapolations from available regional data. For the first time, this study provides updated and comprehensive epidemiological data by line of treatments based on the nationwide French National Health Insurance (NHI) databases, called SNDS ("Système National des Données de Santé"). These databases include hospital records, primary and secondary care for 66 million people.
Aims: To estimate incidence, prevalence of multiple myeloma and mortality of these patients, each year and for each line from 2014 to 2018, based on secondary use of data from the French NHI databases.
Methods: This is a retrospective observational cohort study of multiple myeloma patients identified through the French NHI databases, SNDS from 2014 to 2018. To identify patients with MM, a published algorithm was used as a base and was expanded to consider recent evolutions of MM therapeutic management. The rates were standardized using the age distribution in the world population. Treatment lines were re-constructed through ATLAS, a published adaptation of the Smith-Waterman alignment sequence algorithm, by scanning day-by-day patient claims.
Results: 56,247 prevalent MM patients were identified from 2014 to 2018. Among them, 36,208 patients (64.4%) were treated for MM. The world age-standardized prevalence rates tend to regularly increase every year (from 19.6/100,000/year in 2014 to 23.6 in 2017, 2018 to be consolidated). In 2017, the 23,496 prevalent patients presented a median age of 70 years old. In average, they started their first treatment for MM 3.2 years (+/- 2.9) ago. The standardized incidence rate tends to increase over the years from 2014 to 2017. In 2017 the incidence rate was 4.7 (4.5-4.8)/100 000 person-years and was slightly higher among men (5.4 (5.2-5.6)) than women (4.0 (3.8-4.2)), and much higher in patients ≥ 65 years old (31.7 (30.6-32.9)). Standardized mortality rate was estimated at 3.2 (2.5-3.9) in 2017, respectively 3.6 (2.5-4.6) in men and 2.8 (1.9-3.6) in women, with a tendency to decrease slowly over the years. Moreover, as displayed on the figure attached, the number of treated patients for each line tends to increase overtime going for instance from 7,163 in 2014 to 10,022 in 2018 for patients in L1. The number of patients receiving a L4+ increased between 2014 (N=1040) and 2018 (N=1818).



Summary/Conclusion: This study expands existing epidemiological data on MM patients in France and is the first to present recent nationwide results by line of treatment. Incidence rates are in accordance with the estimations from French network of cancer registries confirming that the French health insurance databases are a valuable source of data to further study the therapeutic management of multiple myeloma.

EP1000 IMPACT OF EARLY RESPONSE ON OUTCOMES IN AL AMYLOIDOSIS FOLLOWING TREATMENT WITH FRONTLINE BORTEZOMIB

S. Ravichandran [1,*], O. Cohen [1], S. Law [1], D. Foard [1], M. Fontana [1], A. Martinez-Nahharo [1], C. Whelan [1], J. Gillmore [1], H. Lachmann [1], S. Sachchithanantham [1], S. Mahmood [1], P. Hawkins [1], A. Wechalekar [1]

[1]National Amyloidosis Centre, University College London, London, United Kingdom

Background: The outcomes in systemic AL amyloidosis are dependent on the depth of haematologic response. However, there is limited data on the impact of the speed response on outcomes.
Aims: Here we report the impact of speed of response in a cohort of AL patients treated with upfront Bortezomib.
Methods: Patients seen from February 2010 until August 2019 are included in the present analysis.
Results: 1194 & 1133 patients comprised the ITT and 1-month landmark cohorts. In the landmark cohort, 137 (11.5%), 270 (22.6%), 252 (21.1%), and 352 (31.1%) patients had a CR, VGPR, PR and NR at 1-month. Patients with ≥ VGPR at 1-month had significantly better survival (median not reached; at the end of 1, 2, 5,10 years, 87%/92%, 83%/87%, 68%/72% & 63%/58% of patients in CR/VGPR respectively were alive) compared to those with a PR (median OS 60 months) or NR (median OS 32 months) (p<0.005). At 1-month, patients with CR and iFLC < 20 mg/l had a significantly better survival compared to CR and iFLC > 20 mg/l (p=0.005). Reaching ≥ VGPR at 1-month significantly improved survival in all Mayo disease stages.

Summary/Conclusion: In conclusion, patients achieving an early deep haematologic response have a significantly superior survival irrespective of cardiac involvement.

EP1001 RELATIONSHIP BETWEEN CORNEAL EXAM FINDINGS, BEST-CORRECTED VISUAL ACUITY (BCVA), AND OCULAR SYMPTOMS IN PATIENTS WITH RELAPSED OR REFRACTORY MULTIPLE MYELOMA (RRMM) RECEIVING BELANTAMAB MAFODOTIN

E. Terpos [1,*], A. Badros [2], R. Popat [3], P. Rodriguez-Otero [4], A. Farooq [5], B. Jeng [2], S. Degli Esposti [6], E. Lewis [7], I. Gupta [8], J. Opalinska [8], A. Palumbo [9], S. Trudel [10]

[1]National and Kapodistrian University of Athens School of Medicine, Athens, Greece, [2]University of Maryland School of Medicine, Baltimore, MD, United States, [3]University College London Hospitals, NHS Foundation Trust, London, United Kingdom, [4]Clinica Universidad de Navarra, Instituto de Investigación Sanitaria de Navarra, Navarra, Spain, [5]University of Chicago Medical Center, Chicago, United States, [6]NIHR Biomedical Research Centre at Moorfields Eye Hospital NHS Foundation Trust and UCL Institute of Ophthalmology, London, United Kingdom, [7]GlaxoSmithKline, Research Triangle Park, NC, [8]GlaxoSmithKline, Upper Providence, PA, United States, [9]GlaxoSmithKline, Zug, Switzerland, [10]Princess Margaret Cancer Centre, Toronto, Canada

Background: Belantamab mafodotin (GSK2857916; belamaf) is a B-cell maturation antigen (BCMA)-targeting antibody–drug conjugate approved in the US and EU as a monotherapy for the treatment of adult patients with RRMM. Ocular events (OEs) during the pivotal DREAMM-2 trial (NCT03525678) included corneal exam findings (punctate keratopathy and microcyst-like epithelial changes), BCVA changes, and ocular symptoms. Dose reductions or delays based on corneal exam findings and BCVA were used to manage OEs. Here we performed a *post hoc* investigation of relationships between corneal exam findings, BCVA changes, and patient-reported ocular symptoms to explore if BCVA changes and symptoms could guide dosing, rather than corneal exams.

Aims:.

Methods: Eye evaluations (including a corneal exam and BCVA assessment of Snellen visual acuity) were performed on all patients receiving single-agent belamaf (2.5 mg/kg) by ophthalmologists at baseline and prior to each belamaf dose. Changes in the corneal epithelium (Ker) and BCVA were both assessed as per protocol-defined criteria and assessment of grade (Gr) was based on the worse eye. BCVA grading was relative to baseline. Patient-reported ocular symptoms were reported as per the Common Terminology Criteria for Adverse Events.

Results: In 12.5% of eye evaluations Gr 3–4 Ker was associated with minimal or no (Gr ≤1) BCVA changes. When patient-reported ocular symptoms were also considered, only 7.5% of evaluations found Gr 3–4 Ker with Gr ≤1 BCVA changes or ocular symptoms. Mild or no (Gr ≤2) Ker was associated with Gr ≤1 BCVA changes in 59.5% of evaluations, or in 38.8% of evaluations with no ocular symptoms reported. Overall, Gr 3–4 Ker were found in 24.9% of evaluations; by contrast, patients had Gr 2–4 BCVA changes or ocular symptoms in 53.7% of evaluations.

Table. Association of corneal epithelium changes (Ker) with BCVA changes and ocular symptoms

Ker + BCVA changes only (evaluations, n=773); n (%)	
Gr 3–4 Ker & Gr ≤1 BCVA	97 (12.5)
Gr 3–4 Ker & Gr 2–4 BCVA	96 (12.4)
Gr ≤2 Ker & Gr ≤1 BCVA	460 (59.5)
Gr ≤2 Ker & Gr 2–4 BCVA	120 (15.5)
Ker + BCVA changes or ocular symptoms (evaluations, n=773); n (%)	
Gr 3–4 Ker & (Gr ≤1 BCVA, no symptoms)	58 (7.5)
Gr 3–4 Ker & (Gr 2–4 BCVA, or symptoms)	135 (17.4)
Gr ≤2 Ker & (Gr ≤1 BCVA, no symptoms)	300 (38.8)
Gr ≤2 Ker & (Gr 2–4 BCVA, or symptoms)	280 (36.2)

Summary/Conclusion: These findings highlight that BCVA changes and ocular symptoms should be further investigated to determine if they can be used as alternatives (eg, frequency of eye examinations based on symptoms) for the management of belamaf dosing to potentially reduce the burden on patients and healthcare professionals.

Background: Exportin 1 (XPO1) mediates the nuclear export and functional inactivation of tumor suppressor proteins. XPO1 is required for multiple myeloma (MM) cell growth, is associated with poor prognosis and mediates resistance to standard MM therapies. Selinexor (SEL) is a first-in-class, oral selective inhibitor of nuclear export (SINE) compound approved in combination with dexamethasone (dex) ± bortezomib for patients (pts) with previously treated MM. Once MM becomes refractory to anti-CD38 monoclonal antibodies (αCD38 mAb), pts have limited effective treatment options and poor prognoses. With standard therapies, overall response rate (ORR) to the first regimen after refractoriness to an αCD38 mAb is 31%, median progression-free survival (PFS) is 3.4 months and median overall survival (OS) is 8.6 months (Gandhi et al, *Leukemia*, 2019). The doublet SEL-dex (Xd) has shown ORR ~26% in triple-class (IMID, PI, αCD38 mAb) refractory MM and improved OS over matched cohorts in community (Richardson et al, *eJHaem*, 2021) and academic (Cornell et al, *AJH*, 2020) settings. SEL-based triplets could be more effective in this triple class treated population.

Aims: To retrospectively analyze the efficacy and safety of SEL-containing triplets in pts in the STOMP study previously treated with αCD38 mAbs.

Methods: STOMP is a multi-arm, open-label, Phase 1b/2 study evaluating SEL in various triplet combinations (ClinicalTrials.gov: NCT02343042). Pts who entered the study received Xd plus pomalidomide (XPd, n=19), bortezomib (XVd, n=4), lenalidomide (XRd, n=4), daratumumab (XDd, n=2) or carfilzomib (XKd, n=18). ORR, OS, PFS and adverse events (AEs) were analyzed.

Results: Among the 47 pts, median age 64 yrs, female 53%, median time from diagnosis 5.1 yrs, median number of prior regimens 5 (range, 2–11). Prior daratumumab (96%), isatuximab (4%); 96% had MM documented to be refractory to αCD38 mAb, 81% had triple-class refractory MM, 74% and 47% were quad- and penta-treated, 43% (20/47) and 15% (7/47) had quad- and penta-refractory MM. αCD38 mAb was included in the immediate prior regimen of 57% of pts and median duration from end of most recent αCD38 mAb therapy to first dose of study treatment was 6.9 weeks (range, 2.6-114.9). ORR was 51% among the 45 evaluable pts; 59% in the XPd arm (n=17; 2 pts were not efficacy evaluable) and 67% in the XKd arm. ORR was 47% (9/19) among efficacy evaluable pts with quad-refractory MM. Among all evaluable pts, median PFS was 8.8 months (95% CI: 4.9, NE) and median OS was 20.4 months (95% CI: 9.6, NE). Among the 25 pts with αCD38 mAb in their immediate prior regimen, efficacy of SEL-containing triplets was similar to that of the prior regimen: ORR 52% vs. 45%, median PFS 8.8 vs. 9.3 months. The most common treatment emergent AEs were nausea (72%), anemia (64%), thrombocytopenia (60%), fatigue (57%), which were managed with standard

supportive care and dose modifications; cytopenias were infrequently symptomatic.
Summary/Conclusion: SEL-containing triplets in pts with MM previously treated with αCD38 mAbs, most of whom had triple-class refractory MM, exhibit tolerability and comparable effectiveness to their most recent αCD38 mAb-containing regimens. Compared to historical controls who received regimens with agents with which they were previously treated, OS on the SEL-containing triplets was much higher. These results suggest that the use of SEL-containing triplets can provide prolonged disease control with good tolerability rather than recycling previously utilized drugs/mechanisms. Further investigation is warranted.

EP1003 INCIDENCE, MITIGATION, AND MANAGEMENT OF NEUROLOGIC ADVERSE EVENTS IN THE PHASE 2 CARTITUDE-2 STUDY OF CILTACABTAGENE AUTOLEUCEL IN PATIENTS WITH MULTIPLE MYELOMA

H. Einsele [1,*], S. Parekh [2], D. Madduri [2], B. Santomasso [3], J. Gállego Pérez-Larraya [4], N. van de Donk [5], B. Arnulf [6], M.-V. Mateos [7], K. De Braganca [8], H. Varsos [8], M. Carrasco-Alfonso [9], M. Akram [9], N. Lendvai [8], C. Jackson [8], Y. Olyslager [10], E. Zudaire [11], C. Li [11], D. Geng [9], A. Jakubowiak [12], A. Cohen [13]

[1]Universitätsklinikum Würzburg, Medizinische Klinik und Poliklinik II, Würzburg, Germany, [2]Mount Sinai Medical Center, [3]Memorial Sloan Kettering Cancer Center, New York, United States, [4]Clínica Universidad de Navarra, Pamplona, Spain, [5]Department of Hematology, Cancer Center Amsterdam, Amsterdam UMC, Vrije Universiteit Amsterdam, Amsterdam, Netherlands, [6]Saint-Louis University Hospital AP-HP, Paris, France, [7]Institute of Cancer Molecular and Cellular Biology, University Hospital of Salamanca, Salamanca, Spain, [8]Janssen R&D, Raritan, [9]Legend Biotech USA, Inc., Piscataway, United States, [10]Janssen R&D, Beerse, Belgium, [11]Janssen R&D, Spring House, [12]University of Chicago, Chicago, [13]Abramson Cancer Center, University of Pennsylvania, Philadelphia, United States

Background: Ciltacabtagene autoleucel (Cilta-cel or JNJ-68284528) is a chimeric antigen receptor T (CAR-T) cell therapy with two B-cell maturation antigen (BCMA)-targeting, single-domain antibodies designed to confer high avidity binding. In the phase 2, multicohort, open-label CARTITUDE-2 (NCT04133636) study, the efficacy and safety of cilta-cel in patients with multiple myeloma (MM) were assessed in various clinical settings.
Aims: To describe the mitigation and management strategies implemented in order to identify and reduce the risk for neurologic adverse events (AEs) in Cohort A patients (progressive MM after 1–3 prior lines of therapy).
Methods: Eligible patients (≥18 years of age) had MM per International Myeloma Working Group criteria, measurable disease, Eastern Cooperative Oncology Group performance status ≤1, progressive MM after 1–3 prior lines of therapy (including a proteasome inhibitor and immunomodulatory drug), and were lenalidomide refractory (no prior BCMA-targeting agent). All patients provided informed consent prior to enrollment in the study. Patients received cilta-cel (0.75×10^6 [range: $0.5–1.0\times10^6$] CAR+ viable T cells/kg) as a single infusion 5–7 days after start of lymphodepletion (cyclophosphamide 300 mg/m^2 + fludarabine 30 mg/m^2 daily for 3 days). Monitoring and mitigation strategies for neurologic AEs included providing more effective bridging therapy to reduce tumor burden prior to lymphodepletion, frequent assessment of CAR-T-related immune effector cell-associated neurotoxicity syndrome (ICANS) using the immune effector cell-associated encephalopathy tool, regular handwriting assessments to detect micrographia, and neuroimaging (brain MRI) and EEG for patients with prior neurologic disease. Management strategies included evaluation of infectious and paraneoplastic etiologies upon observation of ICANS ≥ grade 1, administration of tocilizumab (if concurrent cytokine release syndrome [CRS], all grade of ICANS) and/or dexamethasone (grade 2/3) or methylprednisolone (grade 4). ICANS and CRS were graded by American Society for Transplantation and Cellular Therapy criteria; neurotoxicities not classified as ICANS were graded per Common Terminology Criteria for Adverse Events version 5.0.
Results: As of 15 Jan 2021 (median follow-up: 5.8 months [range: 2.5–9.8 months]), 20 patients in Cohort A received cilta-cel. The median age was 60 years (range: 38–75) and 65% of patients were male. Neurotoxicities occurred in 4 patients (20%). Three patients had ICANS (grade 1/2); the median time to onset of symptoms was 8 days (range: 7–11), and the median duration was 2 days (range: 1–2). Two of the 3 patients received supportive measures to treat ICANS, including levetiracetam and steroids; all 3 had concurrent CRS and all recovered. One patient developed isolated grade 2 facial paralysis on Day 29 after ciltacel infusion and recovered 51 days after the onset of event following treatment with dexamethasone for 28 days. No movement or neurocognitive disorders were reported.
Summary/Conclusion: Neurologic AEs were generally manageable in patients with MM following treatment with cilta-cel. With a median follow-up of 5.8 months, there were no movement or neurocognitive disorders in patients with progressive MM who had received 1–3 prior lines of therapy (Cohort A). These results suggest that early detection and management of neurologic AEs can lead to better treatment outcomes.

EP1004 VACCINATION AGAINST SEASONAL INFLUENZA AND PNEUMONIA IMPROVES CLINICAL OUTCOME IN MULTIPLE MYELOMA PATIENTS RECEIVING CONTINUOUS TREATMENT WITH LENALIDOMIDE: A REAL-LIFE SURVEY

A. Bulla [1,*], A. Romano [2], M. La Morella [3], C. Bellofiore [1], A. Curtopelle [1], V. Del Fabro [4], U. Markovic [1], F. Puglisi [3], F. Di Raimondo [5], C. Conticello [3]

[1]Division of Hematology, Azienda Policlinico-OVE, University of Catania, Italy, Postgraduate School of Hematology, University of Catania, Italy, [2]Department of General Surgery and Medical Surgical Specialties, University of Catania, Italy, [3]Division of Hematology, Azienda Policlinico-OVE, University of Catania, Italy, Catania, Italy, [4]Division of Hematology, Azienda Policlinico-OVE, University of Catania, Italy, Division of Hematology, Azienda Policlinico-OVE, University of Catania, Italy, [5]Division of Hematology, Azienda Policlinico-OVE, University of Catania, Italy, Department of General Surgery and Medical Surgical Specialties, University of Catania, Italy, Catania, Italy

Background: Respiratory infections are common complications of multiple myeloma(MM),leading to increased risk of death within first 90 days from diagnosis.Despite proven efficacy of vaccination and guidelines,this supportive care is underutilized in MM patients.
Aims:
We report the results of a single-center, retrospective evaluation of rate of
hospitalization and infection in patients undergoing vaccination after start of anti-MM treatment,
based on lenalidomide or proteasome inhibitors, alone or in combination with monoclonal
antibodies.
We report results of a single-center, retrospective evaluation of rate of hospitalization and infection in patients undergoing vaccination after start of anti-MM treatment based on lenalidomide or proteasome inhibitors,alone or in combination with monoclonal antibodies.
Methods: We have retrospectively evaluated 290 consecutive MM patients from September 2019,distinguished in three cohorts: active disease requiring anti-MM treatment(group A, N=120),not active disease controlled by maintenance/continuous therapy(group B, N=107), and off-therapy due to stable disease remission(group C, N=63),who received vaccination against seasonal flu(FV)and/or pneumococcus(PV). We monitored the number of infections requiring hospitalization, including COVID-19,OS at 12 months,and MM and not-MM related factors associated to early death.
Results: Of 290 patients, 71% received FV and 45% PV, 44% both. FV was performed in A, B and C groups, respectively in 71%, 72% and 71% patients. Among group A, B and C 45%, 48% and 40% patients respectively received PV.The rates of infections at 12 months in A, B and C groups were respectively 40%, 20% and 6%. The rates of hospitalization for infections at 12 months among group A, B and C were respectively 18%, 4% and 27%.In A group, factors associated to development of infection were age>65 years(OR, 3.95, p=0.005),male gender(OR, 4.46, p=0.0004),high-risk FISH(OR, 5.68, p=0.0039),ALC<1100 cells/mmc(OR, 3.82, p=0.0085),ANC<1500 cells/mmc(OR, 26.42, p=0.03),and IgM<40(OR 2.78, p=0.006).Factors associated to hospitalization for infection were age>65 years(OR, 9.50, p=0.03), male gender (OR, 8.71, p=0.005), ALC<1100 cells/mmc (OR, 10.91, p=0.03),and IgM<40 (OR 5.71, p=0.007).Continuous treatment with lenalidomide based regimens was associated to increased infection(OR, 3.70, p=0.004)and hospitalization rates(OR, 21.11, p=0.0036).FV was associated to reduced number of infections at one year in patients

carrying high-risk cytogenetics or undergoing continuous treatment with daratumumab.PV reduced number of infections in patients carrying high-risk cytogenetics, ALC<1100/mmc, ANC<1500/mmc or who received ASCT before study entry. 29 patients(10%)died(6 for infection,23 for disease progression).Predictors at study entry of shorter 12-mOS were age≥65 yo(p=0.009), frailty score≥1(p=0.03),ANC<1500/mmc(p=0.0002),IgM<40mg/dL(p=0.01),active disease(p<0.0001),previous ASCT(p=0.002),occurrence of hospitalization(p<0.0001)or/and infections(p=0.001).Continuous therapy,including lenalidomide maintenance or daratumumab exposure did not affect 12-mOS in our cohort. In multivariable analysis active disease(HR 71.5, 95% CI 1.97 - 25.93, p=0.0028) and hospitalization for infection(HR 38.1,95% CI 1.27–11.37,p=0.0167)significantly impact on OS.

Summary/Conclusion: Vaccination coverage does not protect from infections patients with active MM, particularly when treated with lenalidomide.

EP1005 REAL-WORLD TREATMENT PATTERNS AND CLINICAL OUTCOMES IN MULTIPLE MYELOMA PATIENTS REFRACTORY TO LENALIDOMIDE

X. Leleu [1,*], A. Chandak [2], A.-L. Vataire [3], G. Gusto [4], R. Kapnang [4], R. Casciano [2], P. L. Lin [5]

[1]University Hospital of Lille, Lille, France, [2]Certara, New York, NY, United States, [3]Sanofi, Gentilly, [4]Certara, Paris, France, [5]Sanofi, Cambridge, MA, United States

Background: In recent years, lenalidomide (LEN) has become an increasingly common therapy of multiple myeloma (MM). However, once patients become refractory to LEN, they are generally considered harder to treat, with fewer treatment options available. Real world (RW) evidence on clinical management of LEN-refractory patients is lacking.

Aims: To describe clinical characteristics, treatment patterns, and clinical outcomes across lines of therapy (LoT) in patients who were refractory to LEN therapy for MM.

Methods: Using the Système National des Données de Santé in France, we identified a cohort of adult patients with an initial diagnosis of MM (index date) between Jan 1, 2010–Dec 31, 2018 who received at least one LoT for MM. Within this cohort, patients who were refractory to LEN (defined as having received only 1 LEN-based LoT, with no LEN in any subsequent LoT, and having initiated a new, non-LEN-based treatment regimen within 60 days of the LEN-containing LoT) were assessed. Baseline patient characteristics were captured in the 12 months before index, and symptoms and comorbidities within the 6 months prior to each LoT. The most frequently used regimens following the LEN-refractory LoT were described. Median overall survival (OS), duration of treatment (DoT) and time to next treatment (TTNT) from the start of each LEN-refractory LoT was assessed by Kaplan–Meier method, and 1–5-year landmark survival rates were calculated.

Results: In total, 25,323 patients received ≥1 LoT for MM, of whom 1907 patients were identified as having experienced a LEN-refractory LOT. During the study follow-up period (2010–2018), LEN-based regimens were among the most frequently used regimens in the overall cohort of MM patients, accounting for 14.9% of the 5 most common 1L regimens and 45.7% of the 5 most common 2L regimens. In recent years (2016–2018), LEN-based regimens accounted for 24.7% and 30.6% of the 5 most frequent regimens in 1L and 2L, respectively. Among patients who were refractory to LEN, mean (SD) age was 67.3 (10.7) years at index, and 70.5 (10.5) years when patients became LEN-refractory; 50.9% of LEN-refractory patients were male. Most patients (90.2%) had their LEN-refractory encounter in 2L–4L. The proportion of patients with CRAB symptoms and the median Charlson Comorbidity Index remained consistent across LoTs. After a LEN-refractory LoT, the most frequently used subsequent regimens were generally POM-based (**Table**). In LEN refractory patients, DoT continued to decrease across LoT (1L: 9.7 months; 2L: 8.4 months; 3L: 6.7 months; 4L: 6.7 months; 5L 7.2 months); similarly, TTNT decreased with advancing LoT (1L–2L: 18.0 months; 2L–3L: 12.0 months; 3L–4L: 9.0 months; 4L–5L: 9.0 months). Survival outcomes in patients following a refractory LEN regimen were poor, with a median OS ranging from 10.4–12.2 months across LoT. Less than a third of patients survived for at least 2 years following a LEN-refractory LoT.

Table. Survival outcomes and subsequent treatment regimens in patients who were LEN-refractory

	2L (n=498)	3L (n=652)	4L (n=388)	5L (n=118)
Most frequent regimens after LEN-refractory LoT, %				
1	POM (17.1)	POM (18.4)	POM (23.2)	POM (24.6)
2	BEN (10.2)	BOR (13.2)	CYCLO+POM (11.3)	DARA (7.6)
3	DARA (8.4)	CYCLO+POM (10.3)	DARA (9.3)	CYCLO+POM (7.6)
Median OS, months (95% CI)	13.4 (11.9–16.1)	13.6 (12.1–15.0)	12.4 (10.3–13.5)	12.4 (9.1–18.7)
1–y OS, % (95% CI)	54.6 (49.7–59.2)	54 (49.8–58)	50.9 (45.4–56)	53.2 (43.1–62.4)
2–y OS, % (95% CI)	33.7 (28.6–38.7)	33.8 (29.5–38.2)	26.5 (21.1–32.1)	30.3 (20.1–41.1)
3–y OS, % (95% CI)	25.9 (20.8–31.2)	20.6 (16.3–25.2)	14.5 (9.6–20.5)	17.4 (7.6–30.5)
4–y OS, % (95% CI)	21 (15.7–26.7)	15.6 (11.1–20.9)	9.7 (4.9–16.6)	11.6 (3–26.6)
5–y OS, % (95% CI)	15.2 (9.5–22.1)	9.3 (4.6–16)	9.7 (4.9–16.6)	Could not be estimated

BEN, Bendamustine; BOR, Bortezomib; CYCLO, Cyclophosphamide; DARA, Daratumumab; POM, Pomalidomide.

Summary/Conclusion: This large, national health database analysis demonstrated that in French RW clinical practice, LEN was frequently used as 1L and 2L therapy for MM, and use of LEN has increased in recent years. After becoming LEN-refractory, patients generally receive POM-based therapy. However, survival outcomes after LEN-refractory regimens were poor, with median survival of around a year and few patients surviving beyond 2 years, regardless of the LEN-refractory LoT. These observations highlight the need for new, efficacious LEN-free treatment options for this hard-to-treat patient population.

EP1006 ISATUXIMAB PLUS CARFILZOMIB AND DEXAMETHASONE IN EAST ASIAN PATIENTS WITH RELAPSED MULTIPLE MYELOMA: IKEMA SUBGROUP ANALYSIS

K. Kim [1,*], C.-K. Min [2], Y. Koh [3], K. Ishizawa [4], S.-H. Kim [5], S. Ito [6], J. Tanaka [7], M. Uchiyama [8], Y. Kawano [9], J. S. Kim [10], P. Moreau [11], T. Martin [12], Y. Dong [13], M.-L. Risse [14], K. Suzuki [15]

[1]Hematology-Oncology, Samsung Medical Center, Sungkyunkwan University School of Medicine, [2]Department of Hematology, Seoul St Mary's Hospital, [3]Department of Internal Medicine, Seoul National University Hospital, Seoul, Korea, Republic Of, [4]Department of Hematology and Cell Therapy, Yamagata University, Yamagata, Japan, [5]Department of Internal Medicine, Dong-A University College of Medicine, Busan, Korea, Republic Of, [6]Division of Hematology & Oncology, Department of Internal Medicine, Iwate Medical University School of Medicine, Yahaba, [7]Department of Hematology, Tokyo Women's Medical University, Tokyo, [8]Department of Hematology, Japanese Red Cross Society, Suwa Hospital, Suwa, [9]Department of Hematology, Kumamoto University Hospital, Kumamoto, Japan, [10]Department of Hematology, Severance Hospital, Seoul, Korea, Republic Of, [11]Department of Hematology, University Hospital of Nantes, Nantes, France, [12]Department of Medicine, University of California, San Francisco, San Francisco, United States, [13]Sanofi Research and Development, Sanofi, Beijing, China, [14]Research and Development, Sanofi, Vitry-Sur-Seine, France, [15]Myeloma/Amyloidosis Center, Japanese Red Cross Medical Center, Tokyo, Japan

Background: The Phase 3 IKEMA study (NCT03275285) demonstrated that isatuximab (Isa) plus carfilzomib and dexamethasone (Kd) significantly improved progression-free survival (PFS) compared with Kd in patients (pts) with relapsed multiple myeloma (RMM) (hazard ratio [HR] 0.53; 99% confidence interval [CI] 0.32–0.89; *P*=0.0007).

Aims: To evaluate the efficacy and safety of Isa-Kd in the East Asian patients (19 Japanese, 27 Korean).

Methods: RMM pts who received 1-3 prior lines of therapy were stratified to receive Isa-Kd or Kd. Isa-Kd arm received Isa (10 mg/kg intravenously) weekly for 4 weeks, then every 2 weeks. Both arms received K (20 mg/m^2 days 1-2, 56 mg/m^2 thereafter) twice-weekly for 3 of 4 weeks, and d (20 mg) twice-weekly. Treatment continued until disease progression or unacceptable adverse events (AE). The primary endpoint was prolongation of PFS. Key secondary endpoints included; very good partial response or better (≥VGPR), complete response (CR) rate and minimal residual disease negativity (MRD–) rate.

Results: East Asian pts (25 Isa-Kd, 21 Kd) were randomized. Pt characteristics were similar in the East Asian subgroup compared with the intent to treat (ITT) population (N=302). Median age (Isa-Kd 64.0 [range 45–83] years vs Kd 60.0 [range 33–73] years); median prior lines Isa-Kd 2.0 (range 1–3) vs Kd 1.0 (range 1–3); refractory

to lenalidomide 16.0% Isa-Kd vs 47.6% Kd; refractory to PI 20.0% Isa-Kd vs 33.3% Kd; high-risk cytogenetics 48.0% Isa-Kd vs 42.9% Kd. After a median follow-up of 20.7 months, the addition of Isa to Kd improved ≥VGPR, CR and MRD– rates (Table). The HR 0.64 (95%CI: 0.231-1.764) for disease progression or death favored Isa-Kd. Grade ≥3 AEs were observed in 79.2% Isa-Kd vs 55.0% Kd pts, serious TEAEs in 45.8% Isa-Kd vs 50.0% Kd; TEAEs leading to treatment discontinuation were lower in the Isa-Kd group (4.2% Isa-Kd vs 10.0% Kd). Overall, 64.0% Isa-Kd vs 42.9% Kd pts were still receiving treatment.

	East Asia		ITT	
	Isa-Kd n=25	Kd n=21	Isa-Kd n=179	Kd n=123
PFS HR	0.638 (95% CI: 0.231-1.764)		0.531 (99% CI:0.318–0.889)	
≥VGPR rate, n (%)	20 (80.0)	11 (52.4)	130 (72.6)	69 (56.9)
CR rate, n (%)	11 (44.0)	5 (23.8)	71 (39.7)	34 (27.6)
MRD– rate, n (%)	11 (44.0)	2 (9.5)	53 (29.6)	16 (13.0)
≥Grade 3 TEAE, n (%)	19 (79.2)*	11 (55.0)**	136 (76.8)†	82 (67.2)††
Serious TEAE, n (%)	11 (45.8)*	10 (50.0)**	105 (59.3)‡	70 (57.4)††
Fatal TEAE, n (%)	0*	1 (5.0)**	6 (3.4)†	4 (3.3)††

*n=2, **n=20, †n=177, ††n=122

Summary/Conclusion: Efficacy and safety results of Isa-Kd in East Asian pts are consistent with the results of the overall IKEMA population, in which significantly better efficacy (PFS, CR, ≥VGPR and MRD– rate) was reported in favor of Isa-Kd without an increase in the number of patients with serious TEAEs or discontinuations. Isa-Kd is a potential treatment option for East Asian pts with RMM.

EP1007 TUMOR CHARACTERISTICS OF DISEASE PROGRESSION AFTER BCMA-CART TREATMENT OF RELAPSED AND REFRACTORY MULTIPLE MYELOMA WITH EXTRAMEDULLARY LESIONS

Y. Guo [1,*], K. Hu [1], X. Ke [1]

[1]*Beijing Boren Hospital, Beijing, China*

Background: Although protease inhibitors, immunomodulators, and hematopoietic stem cell transplantation prolong the survival of patients with multiple myeloma, the disease is still incurable. BCMA-CART treatment can make patients with relapsed and refractory multiple myeloma (RR MM) obtain Re-remission, but RR MM patients with extramedullary lesions are prone to relapse or progress again after BCMA-CART. Exploring the mechanism of relapse and progress in these patients is conducive to the selection of maintenance programs after CART to prolong survival.
Aims: The purpose of this study is to explore the disease characteristics of the disease progression of RR MM with extramedullary lesions after BCMA-CART treatment, so as to clarify the mechanism of recurrence or progression in this type of patients, and provide evidence for the selection of the maintenance plan for the patients who are in remission after the BCMA-CART treatment.
Methods: The clinical and molecular characteristics of patients with RR MM with extramedullary lesions who underwent BCMA-CART treatment in our hospital from January 2019 to December 2020 were collected, For disease remission, compare the flow cytometry and immunohistochemical changes of tumor tissue in patients with extramedullary lesions before BCMA-CART treatment and after recurrence or progression, and compare the molecular characteristics of patients with different prognosis to clarify the mechanism of disease recurrence or progression.
Results: From January 2019 to December 2020, a total of 8 patients with RR MM with extramedullary lesions were treated in our department. Of the 8 patients with extramedullary recurrence, 6 (75%) patients relapsed or progressed within 1 year after BCMA-CART treatment. The 6 patients with recurrence or progression had a curative effect assessment of 1 at 3 months after BCMA-CART treatment. 1 case (16.7%) CR, 4 cases (66.7%) PR, 1 case (16.7%) SD; 2 cases of patients who did not relapse and progressed within 1 year after BCMA-CART had CR (3 months after BCMA-CART). 100%). The recurrence or progression sites were bone marrow, cerebrospinal fluid, right psoas major and erector spinae muscles, right eyelid mass, right shoulder soft tissue and elevated serum M protein;
Before treatment, 8 patients underwent flow cytometry and immunohistochemical BCMA antigen detection of tumor tissues. The results showed that BCMA antigen expression was positive, and 4 of the 6 patients who relapsed or progressed were re-exposed to BCMA of tumor cells. Antigen detection of the first patient with bone marrow recurrence showed negative BCMA by bone marrow flow cytometry; the second patient with recurrence of right psoas major and erector spinae had negative tumor tissue flow BCMA, and immunohistochemistry showed weak BCMA positive; Three patients had new lesions on the right eyelid. The tumor tissue flow cytometry showed negative BCMA, and immunohistochemistry showed weak BCMA; the fifth patient had a progression of the right shoulder tumor, and the tissue flow cytometry showed negative BCMA, and puncture tumor immunity histochemistry was negative for BCMA.
Summary/Conclusion: In patients with RR MM with extramedullary lesions, the negative or weak expression of tumor cell surface antigens after BCMA-CART treatment may be one of the mechanisms of disease recurrence or progression; if not achieving deep remission 3 months after BCMA-CART treatment, the possibility of recurrence or progression after 1 year is high.
Key words:
RR MM with extramedullary lesions, BCMA-CART, extramedullary lesions

EP1008 ORAL SELINEXOR, POMALIDOMIDE, AND DEXAMETHASONE (XPD) AT RECOMMENDED PHASE 2 DOSE IN RELAPSED/REFRACTORY MULTIPLE MYELOMA (MM)

Background: Exportin 1 (XPO1) mediates the nuclear export and functional inactivation of tumor suppressor proteins (TSPs), is associated with poor prognosis in MM, and contributes to proteasome inhibitor (PI) and immunomodulatory drug (IMiD) resistance. Selinexor (SEL) is a novel, oral, first-in-class selective inhibitor of nuclear export (SINE) compound that blocks XPO1, forcing the nuclear retention and activation of TSPs. SEL is approved with low-dose dexamethasone (dex) ± bortezomib (BOR) for patients (pts) with previously treated MM. In the Phase 3 BOSTON study, once weekly (QW) SEL, QW BOR, and dex (XVd) significantly increased progression-free survival (PFS) and overall response rate (ORR) with marked reduction of peripheral neuropathy as compared to standard twice weekly BOR/dex (Vd), despite XVd utilizing 40% less BOR and 25% less dex than Vd. Pomalidomide (POM) plus dex (Pd) has an ORR of 31% and median PFS (mPFS) of 4 months in MM pts refractory to BOR and lenalidomide (LEN).
Aims: To determine if the addition of once weekly SEL to Pd (XPd) would be an active, all-oral combination with an acceptable safety profile in pts with LEN- and BOR-treated MM.
Methods: In the XPd arm of the multi-arm Phase 1b/2 STOMP study, SEL was evaluated at 60, 80, or 100 mg QW or 60 or 80 mg twice weekly in combination with Pd. Study objectives were to determine the maximum tolerated dose and recommended Phase 2 dose (RP2D) and to assess the safety and activity of the XPd regimen overall and at the RP2D.

Results: As of 4 Jan 2021, 65 pts (33 male) were enrolled with median age of 64 years (range 37-85 years) and median of 3 (range 1-10) prior lines of therapy. Previously treated/refractory rates were LEN 100%/85%, BOR 92%/49%, carfilzomib 43%/37%, POM 31%/29%, and daratumumab (dara) 26%/26%. RP2D was SEL 60 mg QW, POM 4 mg (days 1-21), dex 40 mg QW.

Common hematologic, treatment-related adverse events (TRAEs) included (all grades, grades ≥3) neutropenia (63%, 55%), anemia (58%, 32%), and thrombocytopenia (54%, 31%) which were typically asymptomatic. Non-hematologic TRAEs were reversible and included nausea (62%, 2%), fatigue (55%, 11%), and decreased appetite (45%, 2%).

Among pts with POM naïve or nonrefractory MM (N=44), ORR was 57% (1 sCR, 1 CR, 8 VGPR, 15 PR); mPFS was 12.2 months. In pts treated with RP2D (N=20), ORR was 65% (1 sCR, 5 VGPR, 7 PR); mPFS was not reached with a median follow-up time of 3.9 months. In pts with POM-refractory MM and those with prior dara, ORRs were 44% (7/16) and 60% (9/15), respectively.

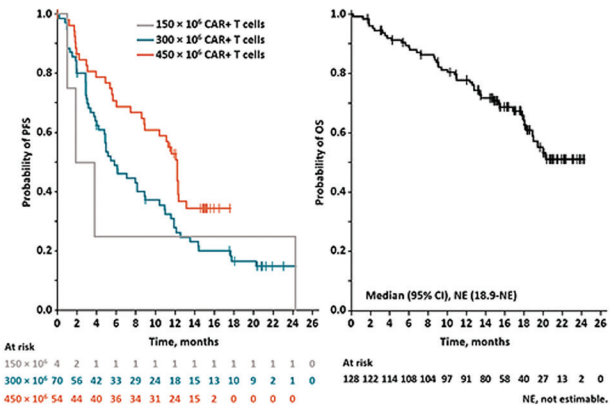
Summary/Conclusion: SEL, once weekly, can be safely combined with Pd in pts with heavily pretreated MM. No new safety signals were identified. The all-oral combination of XPd is highly active with an ORR of 65% at RP2D (compared to expected ORR ~30% for Pd) and produces durable responses with a mPFS of 12.2 months overall. These data support a planned Phase 3 study with an all-oral combination of XPd vs elotuzumab-Pd in pts who have been previously treated with LEN, a PI, and an anti-CD38 mAb.

EP1009 IDECABTAGENE VICLEUCEL (IDE-CEL, BB2121), A BCMA-DIRECTED CAR T CELL THERAPY, IN PATIENTS WITH RELAPSED AND REFRACTORY MULTIPLE MYELOMA: UPDATED KARMMA RESULTS

Weisel [12], A. Rambaldi [13], D. Reece [14], P. Rodríguez-Otero [2], F. Petrocca [15], J. N. Connarn [16], P. Patel [16], L. Huang [16], T. B. Campbell [16], K. Hege [16], N. C. Munshi [17]

[1]Institut Josep Carreras and Institut Català d'Oncologia, Hospital Germans Trias i Pujol, Badalona, [2]Clinical Universidad de Navarra, Navarra, Spain, [3]Simmons Comprehensive Cancer Center, UT Southwestern Medical Center, Dallas, [4]Mount Sinai Hospital, New York, [5]University of California San Francisco, San Francisco, United States, [6]Centre Hospitalier Universitaire de Nantes, Nantes, [7]CHU de Lille, Univ Lille, INSERM U1286, Infinite, Lille, France, [8]University Hospital Leuven, Leuven, Belgium, [9]Bologna University School of Medicine, Bologna, Italy, [10]University Hospital Würzburg, Würzburg, [11]University Hospital Heidelberg, Heidelberg, [12]University Medical Center of Hamburg-Eppendorf, Hamburg, Germany, [13]University of Milan and ASST Papa Giovanni XXII, Bergamo, Italy, [14]Princess Margaret Cancer Centre, Toronto, Canada, [15]bluebird bio, Cambridge, [16]Bristol Myers Squibb, Princeton, [17]The LeBow Institute for Myeloma Therapeutics and Jerome Lipper Multiple Myeloma Center, Dana-Farber Cancer Institute, Harvard Medical School, Boston, United States

Background: Patients with relapsed and refractory multiple myeloma (RRMM) previously exposed to immunomodulatory agents, proteasome inhibitors (PIs), and anti-CD38 monoclonal antibodies (mAbs) have poor outcomes with subsequent treatments. In the pivotal KarMMa trial, ide-cel, a BCMA-directed CAR T cell therapy, showed frequent, deep, and durable responses in heavily pretreated patients with RRMM (Munshi NC, et al. *N Engl J Med* 2021;384:705-716).



Aims: To report updated efficacy and safety data from the phase 2 KarMMa trial (NCT03361748).

Methods: Eligible patients had received ≥ 3 prior regimens (including an immunomodulatory agent, a PI, and an anti-CD38 mAb) and were refractory to their last regimen per IMWG criteria. After 3 days of lymphodepletion (cyclophosphamide 300 mg/m^2 + fludarabine 30 mg/m^2), patients received 150—450 × 10^6 CAR+ T cells (target dose levels). The primary endpoint was overall response rate (ORR). The key secondary endpoints included complete response (CR) rate (CR + stringent CR [sCR]). Other secondary endpoints included duration of response (DOR), progression-free survival (PFS), overall survival (OS), and safety.

Results: Of the 140 patients enrolled in KarMMa, 128 received ide-cel. Data are presented for the treated patients, who had a median age of 61 years and had received a median of 6 (range, 3-16) prior regimens; 84% were triple-class refractory, and 26% were penta-refractory (lenalidomide, pomalidomide, bortezomib, carfilzomib, and daratumumab). Most patients (88%) had received bridging therapy. At the data cutoff (7 April 2020), the median follow-up was 15.4 months. The ORR was 73% and the median PFS was 8.8 months; both increased with higher dose (**Table**). At the highest target dose (450 × 10^6 CAR+ T cells), the ORR was 81%, the CR rate was 39%, and the median PFS increased to 12.2 months with longer follow-up. Responses were observed in all subgroups, including difficult-to-treat subsets (eg, high tumor burden [ORR, 71%], extramedullary disease [70%], and R-ISS stage III disease [48%]). OS continues to mature, and the median has not been reached (**Figure**); the estimated 15-month OS rate was 71%. The most common any-grade toxicities were cytopenia (97%) and cytokine release syndrome (CRS; 84%). CRS was mostly grade 1/2; 5 patients (4%) had grade 3, 1 had grade 4 (at 300 × 10^6), and 1 had grade 5 (at 300 × 10^6) events. Investigator-identified neurotoxicity was reported in 23 patients (18%); 4 patients (3%) had grade 3 and 0 had grade ≥ 4 events. Tocilizumab was used in 67 and 3 patients with CRS and neurotoxicity, respectively. Similarly, steroids were used in 19 and 10 patients with CRS and neurotoxicity, respectively.

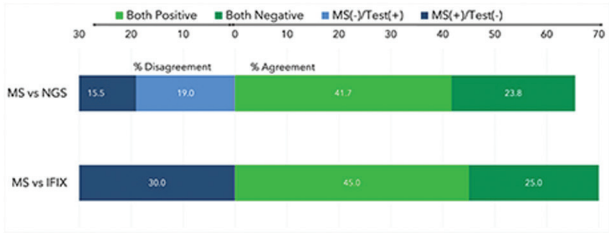
Dose, × 10^6 CAR+ T cells	150 (n = 4)	300 (n = 70)	450 (n = 54)	300-450 (n = 124)	Total (N = 128)
ORR, n (%)	2 (50)	48 (69)	44 (81)	92 (74)	94 (73)
CR/sCR, n (%)	1 (25)	20 (29)	21 (39)	41 (33)	42 (33)
Median DOR, mo*	†	9.9	11.3	10.7	10.7
Median PFS, mo*	†	5.8	12.2	8.8	8.8

*Kaplan-Meier estimate. †Not reported due to small n.

Summary/Conclusion: Updated results from the KarMMa trial continue to demonstrate deep, durable responses with ide-cel in heavily pretreated, triple-class–exposed patients with RRMM. Efficacy and safety reflect prior reports and support a favorable clinical benefit-risk profile for ide-cel across the target dose levels.

EP1010 ANALYSIS OF A PHASE 2 MINIMAL RESIDUAL DISEASE (MRD)-ADAPTIVE TRIAL OF ELOTUZUMAB, CARFILZOMIB, LENALIDOMIDE, AND DEXAMETHASONE (ELO-KRD) FOR NEWLY DIAGNOSED MULTIPLE MYELOMA (MM)

B. A. Derman [1,*], J. Zonder [2], A. Kansagra [3], D. Grinblatt [4], S. Narula [1], S. Rayani [1], L. D. Anderson, Jr. [3], A. Kin [2], A. Stefka [1], K. Jiang [1], S. Major [1], B. Wolfe [1], M. Whelan [1], B. Libao [1], A. McIver [1], E. Andreatos [1], R. Malloy [1], D. Juergens [1], L. Alcantar [1], T. Karrison [1], S. Kosuri [1], M. Bishop [1], J. Jasielec [1], A. Jakubowiak [1]



[1]University of Chicago, Chicago, Illinois, [2]Wayne State University Karmanos Cancer Institute, Detroit, Michigan, [3]University of Texas Southwestern, Dallas, Texas, [4]NorthShore University Health Systems, Evanston, Illinois, United States

Background: The addition of a monoclonal antibody to triplet induction regimens in patients (pts) with MM with intent for autologous stem cell transplant (ASCT) has resulted in higher overall and deep response rates.

Aims: In this MRD-guided treatment design, we are investigating the impact of the addition of Elo to KRd on complete response (CR) and/or MRD-negative rates in newly diagnosed MM regardless of transplant eligibility.

Methods: Enrollment was completed from four MM Research Consortium sites into this phase 2 study. All patients receive 12 cycles of Elo-KRd in 28-day cycles: Elo per standard dosing, K 20/56/70 mg/m^2 days 1, 8 and 15, R 25 mg days 1-21, and dexamethasone 40 mg days 1, 8, 15, 22. ASCT eligible candidates can undergo stem cell collection after cycle 4 and then resume treatment; pts who elect to proceed to ASCT are censored for response at that time. Pts MRD(-) (<10^{-5}) by NGS after cycles 8 (C8) and 12 (C12) proceed to Elo-Rd until progression. Patients who convert from MRD(+) to MRD(-) between C8 and C12 receive an additional 6 cycles of Elo-KRd (total 18 cycles) followed by Elo-Rd, and pts MRD(+) after C12 receive an additional 12 cycles of Elo-KRd (total 24) followed by Elo-Rd. The primary endpoint of the study is sCR and/or MRD(-) rate after C8 E-KRd. MRD status was determined by ClonoSEQ next generation sequencing (NGS, <10^{-5}) [Adaptive Biotechnologies]. An improvement in the sCR and/or MRD(-) rate by NGS from a historical 30% to 50% at the end of C8 will be considered promising. Liquid chromatography mass spectrometry (MS) was also performed (Bristol Myers Squibb) from peripheral blood samples on an experimental basis to help distinguish elotuzumab from IgG Kappa paraprotein seen on immunofixation (IFIX).

Results: 44 pts are enrolled, 39 of whom are evaluable for response (cutoff Jan 10 2021). 6 pts (14%) are Black, with 30 (68%) White pts and 8 (18%) with race unreported. Median age is 62 years (range 43-81, 23% age ≥70) and 23 (52%) have IMWG high-risk cytogenetic abnormalities (HRCA) including 13 (30%) with ≥2 high-risk abnormalities (6 pts unknown cytogenetics). 24 pts (55%) have a monoclonal IgG Kappa isotype at baseline. 34/39 (87%) have MRD trackable by clonoSEQ. The rate of sCR and/or MRD(-) by NGS at the end of C8 is 19/33 (58%), meeting the statistical threshold for efficacy (2 pts censored for elective ASCT before C8 and 4 pts on therapy but have not reached C8). For those reaching MRD(-), the median time to MRD(-) is 8 cycles (range 4-18). At the primary endpoint, there was 70% agreement between IFIX and MS amongst 20 paired samples with 6 discordant cases all MS(+)/IFIX(-). There was 65% agreement between MS and NGS across all timepoints, with 13/84 (15%) MS(+)/NGS(-) and 16/84 (19%) MS(-)/NGS(+). With a median follow-up of 24 months, estimated 2-year progression free survival is 87% (100% for standard risk, 79% for HRCA) and estimated 2-year overall survival is 89% (82% for HRCA). No pt who was MRD(-) by NGS after C8 has progressed, including 6 pts with HRCA. Serious adverse events occurred in 30 pts (68%). 89% experienced treatment emergent AEs, the most common (>10%) of which was pneumonia (14%). One pt had grade 5 myocardial infarction.

Summary/Conclusion: Elo-KRd demonstrates tolerability consistent with known toxicities of these agents and met the primary endpoint of sCR and/or MRD(-) of >50% after 8 cycles. MS and NGS are complementary in defining deep responses. With longer follow-up, the study may validate that an MRD-adaptive design for de-escalation of therapy in MM can generate deep responses while reducing treatment exposure.

EP1011 REAL-WORLD DATA ON PATIENT CHARACTERISTICS AND TREATMENT PATTERNS FOR 3000 PATIENTS WITH SYSTEMIC AL AMYLOIDOSIS IN EUROPE BETWEEN 2011 AND 2018: A RETROSPECTIVE STUDY BY THE EUROPEAN MYELOMA NETWORK

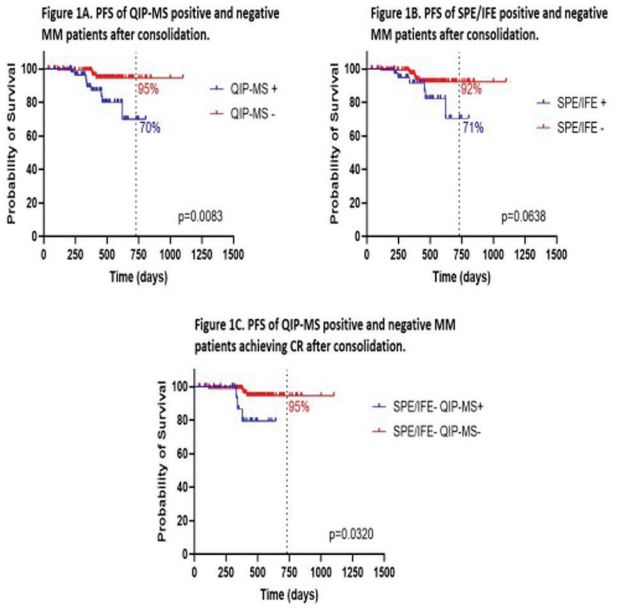
Background: Systemic light chain (AL) amyloidosis is a serious plasma cell disorder where amyloid is deposited in various organs and tissues throughout the body, disrupting their function, and severely affecting the quality of life of the patients (pts). Therapeutic regimens have been used off-label until very recently, therefore leading to differences in treatment patterns across Europe.

Aims: The current analysis aims to describe differences in patient characteristics and treatment strategies among different European countries in the recent years.

Methods: EMN23 is an ongoing, retrospective, multicenter study aiming to enroll 5000 pts in 13 Sites from 10 European countries. Eligibility criteria include diagnosis of systemic AL amyloidosis, and first-line treatment initiation between 2004 and 2018. This report focuses on the most recent period and presents demographic and clinical characteristics as well as first- and second-line regimens for patients starting first line treatment between 2011 and 2018. Treatment information and efficacy outcomes for patients who participated in an interventional clinical trial have been excluded from the analysis.

Results: Overall, 3064 pts have been included from Austria (1.9%), Czech Republic (0.6%), France (5.8%), Germany (13.8%), Greece (5.8%), Italy (27.0%), the Netherlands (3.6%), Portugal (0.6%), Spain (2.9%), and UK (38.0%). The majority of pts were male (59%). Median age was 66 years, with 29% of the pts below 60 and 17% over 75 years. Heart (70%) and kidney (66%) were the organs most commonly involved and 17%, 35%, 28%, and 16% of the pts were at cardiac stage I, II, IIIA, and IIIB, respectively. Bortezomib-based (Bor-B) therapies were administered to 75% of pts at first line, without differences in age groups (74% in ages <65 years, 76% in ages ≥65), but they were more frequently used with more severe disease (65%, 73%, 81%, and 82% for pts of stage I, II, IIIA, and IIIB). Chemo-based regimens were administered to 9% of pts at first line, regardless of the cardiac stage but more frequently in older pts (5% vs 12%, for pts younger and older than 65, respectively). ASCT was used in 10% of those younger than 65, only in 2% those older than 65, and mostly to patients at earlier cardiac stage (14%, 4%, 3%, and 1% for stage I, II, IIIA, and IIIB). Overall, 984 pts received treatment at second line. Approximately half of the pts (48%) who received Bor-B therapy at first line received immunomodulatory-based (IMiD) at second line, 12% received chemo, 12% ASCT, and 14% were re-treated with Bor-B. About half of the pts (51%) who received chemo at first line continued with Bor-B at second line, 26% with IMiD, none received ASCT, and 3% proceeded with chemo again. Pts who received ASCT at first line continued with IMiD (40%), second ASCT (25%), Bor-B (8%), and chemo (4%). Median overall survival (OS) was 67, 31, and 4 months for pts of stages II, IIIA, and IIIB, and not reached for stage I pts (figure); for pts of revised stages (Mayo 2012) II, III, IV the median OS was 89.4, 29.6, and 14.3 months, and not reached for revised stage I pts.



Summary/Conclusion: Bortezomib-based regimens are the most commonly used in the period 2011-2018, across all patients groups, irrespectively of age or cardiac stage. ASCT and chemotherapy-based are used only in a minority of patients in Europe and seldom in patients with advanced cardiac disease. The dismal prognosis of stage IIIB pts even in recent years shows that there is an urgent medical need for more efficacious treatments and new strategies for these patients.

EP1012 ASSESSMENT OF TREATMENT RESPONSE BY MASS SPECTROMETRY IN NEWLY DIAGNOSED MULTIPLE MYELOMA PATIENTS FROM THE GEM2012MENOS65 CLINICAL TRIAL: COMPARISON WITH STANDARD SPEP/IFE

Background: Various studies have demonstrated that Mass Spectrometry (MS) could be a more sensitive method than protein electrophoresis (SPEP) and immunofixation (IFE) for detecting the monoclonal component (MC) in serum in multiple myeloma (MM) patients.
Aims: To compare MS performance against conventional techniques (SPEP and IFE) for the detection of the MC in MM patients enrolled in the PETHEMA/GEM2012MENOS65 clinical trial.
Methods: Newly diagnosed MM patients enrolled in the PETHEMA/GEM2012MENOS65 received six induction cycles of bortezomib, lenalidomide, and dexamethasone (VRD), high-dose therapy (melphalan 200 or busulfan and melphalan) followed by autologous stem cell transplantation (ASCT) and two further cycles of consolidation with VRD. MC in serum was evaluated by conventional techniques (SPEP and IFE) and by Quantitative Immunoprecipitation Mass Spectrometry (QIP-MS) using IgG/A/M, kappa, lambda, free kappa and free lambda isotypic specific beads, both after induction (post-Ind), at day 100 after ASCT (post-ASCT), and after consolidation (post-Cons). The first 186 patients out of the 458 recruited were included in this study.
Results: QIP-MS identified the MC in 118/186 (63%) patients post-Ind, 80/173 (46%) post-ASCT and 61/168 (36%) post-Cons. By contrast, SPEP/IFE detected the MC in 97/186 (52%) post-Ind, 62/173 (36%) post-ASCT and 41/168 (24%) post-Cons. The percentage of discordant cases decreased from 18% post-Ind to 14% post-ASCT and 13% post-Cons. Most discordances were due to samples positive by QIP-MS and negative by SPEP/IFE (15% post-Ind, 12% post-ASCT and 13% post-Cons). In a minority of cases, the MC was exclusively detected by SPEP/IFE: 6/186 (3%) post-Ind, 3/173 (2%) post-ASCT, and 1/168 (1%) post-Cons. Most discrepancies occurred early during monitoring or after ASCT, and could represent false-positives due to gel interpretation issues and/or the presence of oligoclonal bands. Of note, none of these latter discrepant cases (QIP-MS neg/SPEP/IFE+) have relapsed so far.
Once confirmed the higher ability of MS to detect the MC as compared to standard methods, we decided to compare their respective clinical value in terms of progression free survival (PFS) at the completion of the treatment (post-Cons, Figure 1). The probability of PFS at 2 years post-Cons was 95% for QIP-MS- patients vs 70% for those QIP-MS+ (p=0.0083, HR=4.677; fig. 1A). By contrast, the differences in PFS at 2 years post-Cons between SPEP/IFE- vs SPEP/IFE+ cases did not reach statistical significance (92% vs 71%, p=0.0638; fig. 1B). Investigating the 127 patients achieving CR post-Cons, we found out that QIP-MS was able to identify the presence of a MC in 21 of them (16.5%); further, the identification of the MC by QIP-MS in this group of patients in standard CR (SPEP/IFE-) was associated with a significantly shorter PFS (p=0.0320; HR=10.07; fig. 1C).

Summary/Conclusion: As compared to standard methods to detect the MC in serum, in this study QIP-MS: 1) identified the presence of the paraprotein in a higher proportion of cases throughout monitoring; 2) was able to discriminate 2 groups of patients with different PFS at treatment completion and 3) identified residual disease in a cohort of patients in standard CR but at increased risk of progression.

EP1013 A META-ANALYSIS OF EFFICACY OF POMALIDOMIDE-BASED REGIMENS FOR THE TREATMENT OF RELAPSED OR REFRACTORY MULTIPLE MYELOMA AFTER LENALIDOMIDE EXPOSURE

F. E. Davies [1,*], X. Leleu [2], P. Vogel [3], S. Dhanasiri [3], P. Le Nouveau [4], K. Weisel [5]

[1]NYU Grossman School of Medicine, Clinical Myeloma Program, Perlmutter Cancer Center, New York, United States, [2]Service d'Hématologie et Thérapie Cellulaire,

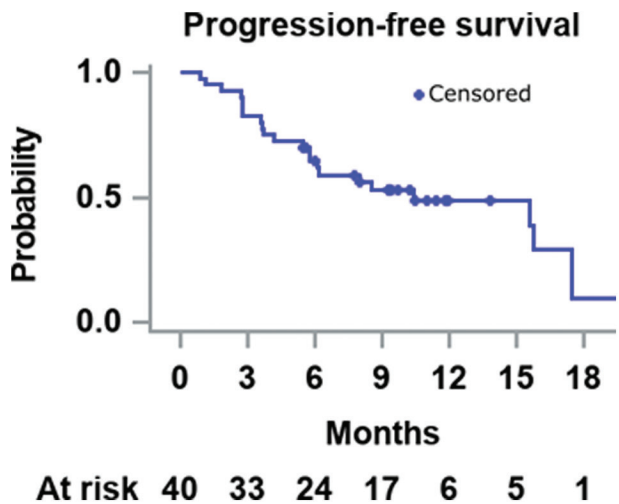
Hôpital La Milétrie, CHU, Poitiers, France, [3]Celgene International Sàrl, a Bristol-Myers Squibb Company, Boudry, Switzerland, [4]Amaris Consulting, Levallois-Perret, France, [5]Universitätsklinikum Tübingen, Hamburg, Germany

Background: Pomalidomide (POM)-based combination(s) are a standard therapy for patients with lenalidomide (LEN)-exposed relapsed or refractory multiple myeloma (RRMM). Multiple studies have assessed the efficacy and risk profile of POM-containing regimens, leading to the approval of regimens such as PVd, DPd, and EloPd.
Aims: To conduct a meta-analysis of progression-free survival (PFS) outcomes reported for POM-based combination regimens and generate a pooled efficacy estimate.
Methods: A targeted search was conducted to identify studies between 2016 and 2020 in patients previously treated with LEN. Trials had to include a POM-based combination with proteasome inhibitors (PVd, KPd), monoclonal antibodies (EloPd, DPd, IsaPd) or an alkylating agent (PCd). Kaplan-Meier curves reported in publications were digitized to reconstruct the individual patient data (IPD) through the Guyot algorithm. Reconstructed IPD were then used to generate survival analyses and obtain a detailed description of individual survival curves. Individual curves were pooled using a random-effects model and the DerSimonian and Laird method. The I2 statistic was used to test for heterogeneity between the studies, with 0% suggesting the lowest level of heterogeneity. Heterogeneity was observed between studies in terms of patient characteristics and number of prior lines of therapies. Three unadjusted analyses were performed: a meta-analysis to obtain a pooled median PFS based on all the studies, independent of the number of prior lines; a meta-analysis restricted to studies that included 2L patients (2L+); and a meta-analysis of PFS reported in 2L patients only. The 1- and 2-year PFS rates were then extracted.
Results: Five randomized controlled trials (RCTs) (OPTIMISMM—PVd vs Vd, APOLLO—DPd vs Pd, ELOQUENT-3—EloPd vs Pd, ICARIA-MM—IsaPd vs Pd, and NCT01432600—Cd vs Pd) and 6 single-arm trials (MM-014—DPd, MMRC—KPd, NCT02185820—KPd, NCT02176213—PCd, EMN1—KPd, and IFM2013—PCd) were identified. Eleven, 7, and 3 trials were included, with heterogeneity levels estimated at 15.3%, 13.2% and 0.0%, respectively. The overall population was found to have a median PFS of 14.1 months (**Table**). The unadjusted pooled median PFS in trials including 2L+ patients was 16.9 months. Finally, when considering only 2L patients, the pooled median PFS was 21.3 months. The PFS rates at 1 and 2 years were 57% and 30%, respectively, in the overall population, 62% and 39% for trials including 2L+ patients, and 74% and 42% when considering only 2L patients. Although unadjusted, the pooled estimated median PFS highlighted that POM-based combinations seem to have better efficacy when used in early treatment lines.

Table PFS rates at 1 and 2 years in the overall population, 2L+ patients, and only 2L patients

Analysis	Median PFS, mo	PFS rate at 1 year (95% CI), %	PFS rate at 2 years (95% CI), %
Overall population	14.1	57 (49–65)	30 (23–41)
Overall population (trials including 2L patients)	16.9	62 (52–73)	39 (30–50)
2L patients only	21.3	74 (66–83)	42 (31–56)

2L, second line; PFS, progression-free survival.



Summary/Conclusion: POM-based combinations have been an effective treatment strategy in RRMM post LEN. The efficacy associated with these combinations was found to be higher for patients treated in earlier lines (second line) compared with the overall population of previously treated patients. POM delivered consistent efficacy and synergy in combinations with protease inhibitors and monoclonal antibodies. These data suggest that class switch may not always be necessary when making treatment decisions.

EP1014 SAFETY AND EFFICACY OF DARATUMUMAB WITH IXAZOMIB AND DEXAMETHASONE IN PATIENTS WITH ONE PRIOR LENALIDOMIDE-BASED REGIMEN: THE DARIA STUDY

E. Terpos [1,*], M. Gavriatopoulou [1], E. Katodritou [2], E. Hatjiharissi [3], I. Dialoupi [1], E. Verrou [2], A. Leonidakis [4], M. Migkou [1], S. Delimpasi [5], A. Symeonidis [6], E. Kastritis [1], M. A. Dimopoulos [1]

[1]Department of Clinical Therapeutics, National and Kapodistrian University of Athens, School of Medicine, Athens, [2]Department of Hematology, Theagenio Cancer Hospital, [3]First Department of Internal Medicine, Division of Haematology, AHEPA University Hospital, Aristotle University of Thessaloniki, Thessaloniki, [4]Health Data Specialists, [5]Department of Hematology and Bone Marrow Transplantation Unit, Evangelismos Hospital, Athens, [6]Hematology Division, Department of Internal Medicine, University of Patras Medical School, Patras, Greece

Background: Second-line treatment of patients (pts) with multiple myeloma (MM), who are refractory to, or have relapsed after frontline lenalidomide-based therapy is challenging. Daratumumab (DARA), an anti-CD38 monoclonal antibody, has shown significant clinical activity and an acceptable safety profile in pts with relapsed/refractory multiple myeloma (RRMM) as monotherapy or in combination with other agents. Ixazomib, the first oral proteasome inhibitor, has also been shown to be efficacious and with a positive safety profile in newly diagnosed MM pts.
Aims: This study aims to evaluate the effectiveness of DARA in combination with ixazomib and dexamethasone (DId) as second-line therapy in pts with RRMM who have previously been treated with a lenalidomide-based regimen.
Methods: DARIA is an ongoing, prospective, open-label, multicenter, phase 2 study. Eligible adult pts with RRMM had measurable disease after 1 prior line with a lenalidomide-based regimen and a Karnofsky Performance Status (KPS) score of ≥70. Exclusion criteria included previous DARA or anti-CD38 or ixazomib treatment. Treatment with DId comprises an induction phase of 9 cycles (each of 28 days in duration) and a maintenance phase. In induction, pts received DARA 16mg/kg (weekly for cycles 1–2, every 2 weeks for cycles 3–6, and every 4 weeks thereafter) administered intravenously until November 2020 and subcutaneously at a fixed dose of 1800 mg thereafter; 4mg oral ixazomib (days 1, 8, and 15 of each cycle); and 40mg oral dexamethasone (weekly, each cycle). In maintenance, DARA and ixazomib are administered every 4 weeks until disease progression or unacceptable toxicity, with dexamethasone being discontinued. The primary endpoint is overall response rate (ORR). This report presents results for pts who received the first dose at least 6 months prior to the cut-off date (31/12/2020).
Results: This analysis includes 40 pts (median age: 69.0 years; male: 52.5%). At screening, 75.0% of pts had a KPS score of ≥90. 50.0%, 32.5%, and 17.5% had an International Staging System (ISS) stage of 1, 2, and 3, respectively; and 37.5%, 52.5%, and 7.5% had a revised ISS of 1, 2, and 3, respectively. 70.0% of pts were refractory to lenalidomide, and 37.5% of them had received prior autologous stem cell transplantation. The median time from diagnosis to first study dose was 2.1 years. Up to the cut-off date, pts received a median of 9 treatment cycles. ORR was 57.5% (complete response: 2.5%, VGPR: 30.0%, and PR: 25.0%). The median time from first DId dose until first response (PR or better) was 0.9 months. The median PFS was 10.4 months (figure), and 37.5% of the pts were still on treatment by the cut-off date. Of all pts, 62.5% discontinued treatment (40% due to progressive disease, 12.5% due to physician's decision, and 10% due to a safety event). Overall, 40% of the pts had ≥1 AE grade 3/4, the most common being thrombocytopenia (n=8, 20.0%), and 25.0% (n=10) had ≥1 serious adverse event, the most common being acute kidney injury (n=2, 5.0%) and pneumonia (n=2, 5.0%, one of which fatal). In total, there were 3 fatal SAE, the other 2 being infection and a lower respiratory tract infection.

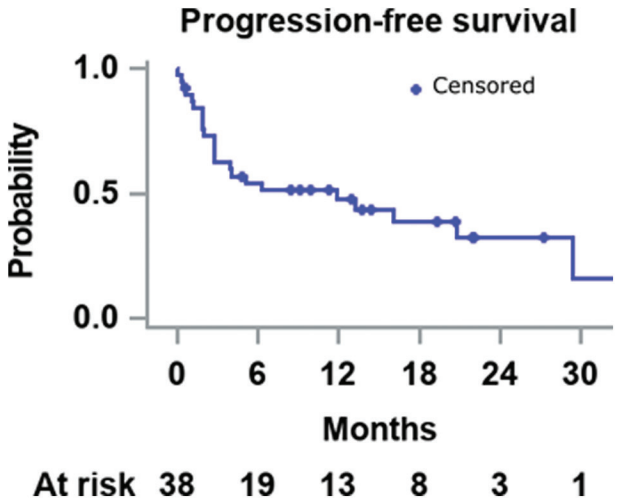
Summary/Conclusion: Second-line treatment with DId in pts with RRMM who were previously treated with a lenalidomide-based regimen resulted in rapid (median time to PR or better was less than a month)

and deep responses (about a third of pts exhibited VGPR or better). The safety profile of DId was very good, and the majority of pts (60%) did not experience grade 3/4 AE, whereas 25% of them experienced a SAE.

EP1015 EARLY INTENSIVE CONSOLIDATION WITH AUTOLOGOUS HEMATOPOIETIC CELL TRANSPLANTATION IN NEWLY DIAGNOSED HIGH-RISK MULTIPLE MYELOMA: A SYSTEMATIC REVIEW AND META-ANALYSIS OF RANDOMIZED CONTROLLED TRIALS

S. Gupta [1,*], R. Siddiqi [2], I. Riaz [3], M. Husnain [4], M. Aljama [5], F. Anwar [6], N. Asghar [7], R. Chakraborty [8]

[1]Internal Medicine, University of Oklahoma Health Science Center, oklahoma city, United States, [2]Internal Medicine, Dow University of Health Sciences, Karachi, Pakistan, [3]Department of Medicine, Hematology Oncology, Mayo Clinic, Rochester, [4]Department of Medicine, Hematology and Oncology, University of Arizona, Tucson, United States, [5]Division of Malignant Hematology, Department of Oncology, McMaster University, Hamilton, Canada, [6]Department of Hematology and Medical Oncology, Cleveland Clinic, Cleveland Clinic, Cleveland, United States, [7]Internal medicine, Dow Medical College, Karachi, Pakistan, [8]Multiple Myeloma and Amyloidosis Program, Herbert Irving Comprehensive Cancer Center, New York, United States



Background: In patients with newly diagnosed multiple myeloma, early intensive consolidation with high dose therapy-autologous hematopoietic cell transplantation (HDT-AHCT) leads to a superior progression-free survival (PFS) compared to standard dose therapy (SDT). However, whether patients with high-risk cytogenetics benefit from early HDT-AHCT remains unclear. To answer this question, we performed a systematic review and meta-analysis of randomized controlled trials (RCTs) comparing consolidation with HDT-AHCT versus SDT in the era of proteasome inhibitor (PI) and/or immunomodulatory drug (IMiD)-based induction therapy.
Aims: The primary objective of this study was to evaluate the association of HDT-AHCT with PFS in newly diagnosed high-risk myeloma, with overall survival (OS) being the secondary objective.
Methods: Standard electronic databases were searched for citations of phase 3 RCTs comparing HDT-AHCT with SDT in newly diagnosed myeloma. High-risk myeloma was defined as subjects with adverse-risk cytogenetics, as specified by individual study protocol. Efficacy data was extracted using hazard ratios (HRs) for PFS and OS. We used DerSimonian-Laird random effects model to pool log HRs, and applied Hartung-Knapp adjustment as the total number of trials was small. Heterogeneity was assessed using the Cochran Q and the I^2 statistic.
Results: After screening all citations, a total of 17 RCTs were retrieved, of whom, 4 RCTs were deemed eligible for inclusion in the meta-analysis. An additional RCT was included after searching conference abstracts and grey literature. The included RCTs were as follows: IFM 2009 (Attal *et al*. NEJM. 2017), EMN02/HOVON 95 (Cavo *et al*. Lancet Haem. 2020 and Cavo *et al*. ASH 2020), RV-MM-EMN-441 (Gay *et al*. Lancet Oncol. 2015), RV-MM-PI-209 (Palumbo *et al*. NEJM. 2014), and FORTE (Gay *et al*. ASH. 2020). The induction regimens used were VRD (bortezomib-lenalidomide-dexamethasone; n=1), KRD (carfilzomib-lenalidomide-dexamethasone; n=1), VCD (bortezomib-cyclophosphamide-dexamethasone; n=1), and RD (lenalidomide-dexamethasone; n=2). Patients underwent a single HDT-AHCT in 2 trials, tandem in 2 trials and a combination of single or tandem in 1, with the conditioning regimen being melphalan 200 mg/m^2 in all RCTs. Three RCTs (IFM 2009, EMN02/HIVON95, and RV-MM-EMN-441) included post-transplant lenalidomide maintenance in all patients and 2 RCTs (RV-MM-PI-209 and FORTE) randomized patients to lenalidomide versus observation or carfilzomib-lenalidomide respectively. Early intensive consolidation with HDT-AHCT led to superior PFS compared to SDT, with the benefit consistent in both high-risk (Pooled HR, 0.50 [0.27-0.94]) and standard-risk (Pooled HR, 0.58 [0.46-0.73]) subrgoups (p-value for interaction=0.32). A subset of 3 RCTs (EMN02/HOVON95, RV-MM-EMN-441, and RV-MM-PI-209) reported OS in cytogenetic risk subgroups. Patients with high-risk cytogenetics had a greater OS benefit with early HDT-AHCT (Pooled HR, 0.59 [0.47-0.74]) compared to standard-risk (Pooled HR, 0.82 [0.63-1.07]) patients (p-value for interaction<0.01).
Summary/Conclusion: In patients with newly diagnosed myeloma undergoing induction therapy with PIs +/- IMiDs, early intensive consolidation with HDT-AHCT is associated with a superior PFS compared to SDT, with benefit being consistent in both high-risk and standard-risk subgroups. Furthermore, although HDT-AHCT leads to an OS benefit overall, high-risk patients derive greater benefit compared to standard-risk. HDT-AHCT should not be delayed in patients with high-risk myeloma outside of well designed clinical trials.

EP1016 RESULTS ON EFFICACY AND SAFETY OF DARATUMUMAB WITH DEXAMETHASONE IN PATIENTS WITH RELAPSED/REFRACTORY MULTIPLE MYELOMA AND SEVERE RENAL IMPAIRMENT: THE DARE STUDY

E. Kastritis [1,*], E. Terpos [1], A. Symeonidis [2], S. Delimpasi [3], M. Cavo [4], E. Zamagni [4], E. Katodritou [5], E. Rivolti [6], M.-C. Kyrtsonis [7], M. Gavriatopoulou [1], M. Roussou [1], D. Fotiou [1], E. Hatjiharissi [8], N. Kanellias [1], M. Migkou [1], M. A. Dimopoulos [1]

[1]Department of Clinical Therapeutics, National and Kapodistrian University of Athens, School of Medicine, Athens, [2]Hematology Division, Department of Internal Medicine, University of Patras Medical School, Patras, [3]Department of Hematology and Bone Marrow Transplantation Unit, Evangelismos Hospital, Athens, Greece, [4]Seragnoli Institute of Hematology, Bologna University School of Medicine, Bologna, Italy, [5]Department of Hematology, Theagenio Cancer Hospital, Thessaloniki, Greece, [6]Azienda USL-IRCCS di Reggio Emilia, Reggio Emilia, Italy, [7]First Department of Propedeutic Internal Medicine, National and Kapodistrian University of Athens, School of Medicine, Athens, [8]First Department of Internal Medicine, Aristotle University of Thessaloniki, School of Medicine, AHEPA University Hospital, Thessaloniki, Greece

Background: Severe renal impairment (RI) is a common myeloma (MM) complication. For patients with relapsed/refractory MM (RRMM) there is a need for effective therapies with low or minimal risk of renal toxicity. Daratumumab (DARA), an IgG1κ human monoclonal antibody that targets CD38, has shown durable responses and a favorable safety profile in heavily pretreated patients (pts) with RRMM. However, there is limited data on the safety and efficacy of DARA in pts with RRMM and severe RI.
Aims: DARE study aims to assess the safety and efficacy of DARA with dexamethasone in pts with RRMM and severe RI.
Methods: DARE is a prospective, open-label, multicenter, phase 2 study conducted in 7 sites in Greece and Italy, and has completed enrolment. Eligible adult pts had documented RRMM and severe RI (estimated glomerular filtration rate [eGFR] <30 mL/min/1.73m^2 or requiring dialysis), who had ≥2 previous treatments of both bortezomib- and lenalidomide-based regimens, had progressive disease after their last treatment and Eastern Cooperative Oncology Group performance status (ECOG PS) ≤2. Exclusion criteria included previous daratumumab or other anti-CD38 therapy. Pts received 28-day treatment cycles with 16 mg/kg intravenous daratumumab (weekly for cycles 1–2, every 2 weeks for cycles 3–6, and every 4 weeks thereafter) and oral dexamethasone (40 mg weekly). The primary endpoint is progression-free survival (PFS). Secondary endpoints include overall response rate (ORR; partial response [PR] or better), renal response rate (RRR; best response of renal partial response or better), and safety. All responses were based on investigators' assessment as per IMWG criteria.
Results: In total, 38 pts (male: 76.3%; median age: 72 years; median time from diagnosis to study entry: 4.2 years) were included. The median number of prior therapies was 3, and 34.2% had undergone autologous stem cell transplantation. At study entry, 10.5% and 89.5% of pts had International Staging System (ISS) 2 and 3 disease, median eGFR was 13 mL/min/1.73 m^2, and 44.7% were on dialysis. The median follow-up is 10 months, and pts received a median of 8 cycles of DARA with dexamethasone. The 6-month and median PFS is 54% and 11.8 months respectively (Figure). The ORR was 47.4% (very good partial response: 34.2%, PR: 13.2%), and the ORR for pts on dialysis (n=17) was 47.1%. The median time from the first study treatment dose to first response (PR or better) was 0.9 months. The RRR was 15.8%. By the cut-off date (31/12/2020) 31.6% of pts were still receiving protocol therapy; 68.4% had discontinued treatment (progressive disease: 36.8%; lost to follow-up: 7.9%; patient choice 5.2%, and SAE: 18.4%). Overall, 50% of pts had ≥1 adverse event (AE) grade 3/4 (most common were anemia [15.8%] and hyperglycemia [13.2%]), and 26.3% (n=10) had ≥1 serious adverse event (SAE), mostly infectious complications: septic shock (n=3, all fatal), pneumonia, peritonitis (fatal), lower respiratory tract infection (fatal), ECOG PS worsened (fatal), cerebrovascular accident, myocardial infarction (fatal), acute kidney injury, and hyperkalemia (n=1 each).

Summary/Conclusion: DARA and dexamethasone is an effective treatment for RRMM with severe renal dysfunction or requiring dialysis, associated with rapid and high rates of hematologic and respectable rates of renal responses in this heavily pretreated population. Notably, responses were similar in pts regardless of being on dialysis or not. No new safety signals were observed but antibiotic prophylaxis may potentially reduce infection risk.

EP1017 SAFETY AND TOLERABILITY OF CAEL-101 IN COMBINATION WITH CYCLOPHOSPHAMIDE-BORTEZOMIB-DEXAMETHASONE AND DARATUMUMAB IN PATIENTS WITH AL AMYLOIDOISIS

J. Valent [1,*], J. Zonder [2], M. Liedtke [3], J. Silowsky [4], M. Kurman [5], E. Daniel [4], J. Jobes [4], M. Harnett [6], M. Ziola [4], J. Raviwong [4], M. Spector [4], S. Sobolov [4]

Background: Amyloid light-chain (AL) amyloidosis is a rare, potentially life-threatening disorder, caused by a plasma cell dyscrasia (PCD) that results in overproduction of immunoglobulin light chains, which misfold and aggregate to form amyloid fibrils. These deposit in tissues and/or organs, such as heart and kidneys, causing significant morbidity and mortality.

MedDRA Preferred Term	Part A CAEL-101 + CyBorD N=13	Part B CAEL-101 + CyBorD + daratumumab N=9	Overall (Part A+B) N=22
At least one TEAE	13 (100%)	5 (55.6%)	18 (81.8%)
At least one TEAE considered to be at least possibly related to study drug[1]	3 (23.1)	0	3 (13.6%)
At least one Grade 3 or higher TEAE	1 (7.7%)	3 (33.3%)	4 (18.2%)
At least one treatment-emergent SAE	2 (15.4%)	1 (11.1%)	3 (13.6%)
TEAEs leading to study discontinuation	0	0	0
TEAEs leading to death	0	1 (11.1%)	1 (4.5%)
Most Common TEAEs (≥9%)			
Nausea	4 (30.8%)	1 (11.1%)	5 (22.7%)
Constipation	2 (15.4%)	3 (33.3 %)	5 (22.7%)
Rash	2 (15.4%)	2 (22.2%)	4 (18.2%)
Fatigue	2 (15.4%)	2 (22.2%)	4 (18.2%)

Diarrhea	3 (23.1%)	0	3 (13.6%)
Vomiting	1 (7.7%)	1 (11.1%)	2 (9.1%)
Anaemia	2 (15.4%)	0	2 (9.1%)
Hypokalaemia	0	2 (22.2%)	2 (9.1%)
Headache	2 (15.4%)	0	2 (9.1%)

Abbreviations: TEAE=treatment-emergent adverse event. A TEAE was defined as an adverse event occurring during or after study drug administration. SAE=Serious TEAE. DLT=Dose-limiting-toxicity.
[1] At least possibly related TEAEs were defined as TEAEs with relationship of possibly or related
Note: Patients experiencing more than 1 TEAE were only counted once under the greatest severity and causality.

Current treatments target the underlying PCD to arrest formation of additional misfolded light chains; there are no treatments currently available that target the removal of fibrils and amyloid deposited in organs. CAEL-101, a chimeric immunoglobulin that reacts specifically with light chain fibrils but not with the native form, is believed to inhibit fibril formation and improve outcomes by facilitating removal of amyloid deposited in tissues. Results of the dose selection part (Part A) of this Phase 2 study found that CAEL-101 in combination with cyclophosphamide-bortezomib-dexamethasone (CyBorD) was safe and well tolerated in doses up to 1000 mg/m^2 (Valent et al., ASH 2020).

Aims: To define the safety and tolerability through 4 weeks of treatment with CAEL-101+CyBorD (Part A) and CAEL-101+CyBorD+daratumumab (Part B) in patients with AL amyloidosis.

Methods: This ongoing multicenter, open-label, sequential cohort, dose-selection study of CAEL-101 in Mayo Stage I, Stage II and Stage IIIa AL amyloidosis patients was divided into two parts (NCT #NCT04304144). Staging was based on the European modification to the Mayo 2004 staging system (Wechalekar et al., 2013). Part A consisted of a 3 + 3 dose escalation design to determine the recommended dose for the Phase 3 study in combination with CyBorD. Part B studied 1000 mg/m^2 CAEL-101+CyBorD+daratumumab. The study included an initial 4-week dose limiting toxicity (DLT; Part A) and safety observation (Part B) period; patients are continuing to receive CAEL-101 until end of study or discontinuation. All patients in Parts A and B received CAEL-101 q1wk for the first 4 infusions, followed by CAEL-101 q2wk. Key inclusion criteria were adults ≥18 years old with a minimum life expectancy of 6 months and histopathological diagnosis of AL amyloidosis. Key exclusion criteria included any other amyloidosis, multiple myeloma, or supine systolic blood pressure <90 mmHg or symptomatic orthostatic hypotension. Outcomes for safety and tolerability are presented through the first 4 weeks of treatment.

Results: Of the 22 patients enrolled to date, 13 received 1000 mg/m^2 CAEL-101+CyBorD in Part A and 9 received 1000 mg/m^2 CAEL-101+CyBorD+daratumumab in Part B. Mean age was 65.1 years (range 47.6–79.6 years); the majority were male (72.7%) and white (90.9%), with Mayo stage I (9.1%), II (68.2%), and IIIa (22.7%). 72.7% had cardiac involvement and 68.2% had at least one prior PCD treatment. During the 4-week DLT/safety observation period, the most common TEAEs were nausea (22.7%), constipation (22.7%), rash (18.2%), and fatigue (18.2%). One death occurred in the setting of septic pneumonia during this study that was not considered related to study drug.

Summary/Conclusion: Safety data from this ongoing phase 2 study indicate that 1000mg/m^2 of CAEL-101 in combination with CyBorD alone or CyBorD+daratumumab is well tolerated in patients with AL amyloidosis during the first 4 weeks of treatment. Two Phase 3 trials, one enrolling Mayo Stage IIIa (NCT# 04512235) and Mayo Stage IIIb patients (NCT# 04504825), have been initiated to study the safety and efficacy of 1000 mg/m^2 CAEL-101.

EP1018 SAFETY AND TOLERABILITY OF CAEL-101 IN PATIENTS WITH AL AMYLOIDOSIS IN A PHASE 2 STUDY FOR A MEDIAN OF 38 WEEKS

J. Valent [1,*], J. Zonder [2], M. Liedtke [3], J. Silowsky [4], M. Kurman [5], E. Daniel [4], J. Jobes [4], M. Harnett [6], M. Ziola [4], J. Raviwong [4], M. Spector [4], S. Sobolov [4]

[1]Taussig Cancer Institute, Cleveland Clinic, Cleveland, [2]Karmanos Cancer Center, Detroit, [3]Stanford University Medical Center, Palo Alto, [4]Caelum Biosciences, Bordentown, [5]Michael Kurman Consulting, LLC, Wyckoff, [6]Caelum Biosciences, Stow, United States

Background: AL amyloidosis is a rare, progressive disorder caused by misfolded immunoglobulin light chains that aggregate into amyloid fibrils which can deposit in tissues and organs, such as the heart, causing significant mortality and morbidity. Cardiomyopathy impacts prognosis, hence cardiac biomarkers are used in the Mayo staging system for AL amyloidosis (Dispenzieri et al., 2015). Median overall survival for patients with Mayo Stage II, IIIa, and IIIb is 54 months (m), 24 m, and 4 m, respectively (Dittrich et al., 2020).

Current treatment strategies do not directly target the amyloid deposited in organs. CAEL-101 is a chimeric immunoglobulin that binds specifically to misfolded light chain fibrils and is believed to facilitate removal

of amyloid deposited in tissues. Results from the dose limiting toxicity period of a phase 2 study with CAEL-101 in combination with cyclophosphamide-bortezomib-dexamethasone (CyBorD) demonstrated that CAEL-101 up to 1000 mg/m^2 was well tolerated and is the recommended dose for future studies (Valent et al., ASH 2020). Here we report results to date from this study.

Aims: To define the safety and tolerability of CAEL-101+CyBorD in patients with AL amyloidosis.

Methods: In this ongoing multicenter, open-label, sequential cohort, dose-selection study of CAEL-101 in AL amyloidosis patients (NCT #NCT04304144), a 3+3 dose escalation design was used to determine the recommended dose for Phase 3 studies. All patients received CAEL-101 q1wk for the first 4 infusions, after which patients receive CAEL-101 q2wk. Key inclusion criteria were adults ≥18 years old with a minimum life expectancy of 6 m, measurable hematological disease (dFLC > 5mg/dL or FLC >5mg/dL with abnormal ratio or SPEP M-spike >0.5 g/dL) and histopathological diagnosis of AL amyloidosis. Key exclusion criteria included any other amyloidosis, multiple myeloma, or supine systolic blood pressure <90 mmHg or symptomatic orthostatic hypotension. Assessments include clinical laboratory tests, echocardiograms, vital signs, physical exams and, treatment emergent adverse events (TEAEs).

Results: The 13 patients enrolled had a mean age of 65.2 years (range 47.6–79.6 years), were diagnosed with AL amyloidosis on average 29.4 m (range 2.7–163 m) prior to study enrollment, and were mostly male (76.9%) and white (84.6%). At baseline, 61.5% of patients had cardiac involvement with Mayo stage II (69.2%) and IIIa (23.1%). A majority (69.2%) had at least one prior PCD treatment; commonly reported prior treatments were bortezomib (61.5%), daratumumab (53.8%), cyclophosphamide (53.8%), melphalan (15.4%), carfilzomib (15.4%), lenalidomide (15.4%).

This study is ongoing with a current median treatment duration of 38 weeks (wk) (range 12 wk–48 wk), with most patients having had ≥20 infusions of CAEL-101. The most common TEAEs reported include diarrhea (46.2%), nausea (46.2%), rash (38.5%), and anaemia (38.5%). Using NT-proBNP and cTnT values to assess changes in Mayo staging, no patients have progressed from their baseline disease staging and none have died through a median of 38 wk of treatment.

MedDRA Preferred Term	CAEL-101 + CyBorD N=13
At least one TEAE	13 (100%)
At least one TEAE considered to be at least possibly related to study drug[1]	6 (46.2%)
At least one Grade 3 or higher TEAE	2 (15.4%)
At least one treatment-emergent SAE	2 (15.4%)
TEAEs leading to study discontinuation	0
TEAEs leading to death	0
Most Common TEAEs (≥15%)	
Diarrhea	6 (46.2%)
Nausea	6 (46.2%)
Rash	5 (38.5%)
Anaemia	5 (38.5%)
Constipation	4 (30.8%)
Fatigue	4 (30.8%)
Cough	4 (30.8%)
Insomnia	3 (23.1%)
Dyspnoea	3 (23.1%)
Hypertension	3 (23.1%)
Hyperkalaemia	2 (15.4%)
Vomiting	2 (15.4%)
Headache	2 (15.4%)
Pleural Effusion	2 (15.4%)
Arthralgia	2 (15.4%)

Abbreviations: TEAE=treatment-emergent adverse event. A TEAE was defined as an adverse event occurring during or after study drug administration. SAE=Serious TEAE. DLT=Dose-limiting-toxicity.
[1] At least possibly related TEAEs were defined as TEAEs with relationship of possibly or related.
Note: Patients experiencing more than 1 TEAE were only counted once under the greatest severity and causality.

Summary/Conclusion: These data suggest that treatment with CAEL-101+CyBorD through ~8.8 m is generally well tolerated, with possible stabilization of cardiac disease as assessed by Mayo staging. Additional data from this ongoing Phase 2 study, as well as from the two currently enrolling Phase 3 studies (NCT# 04512235 and 04504825) in patients with Mayo Stage IIIa and IIIb, will further evaluate the safety and efficacy of CAEL-101 in patients with AL amyloidosis.

EP1019 POMALIDOMIDE, DEXAMETHASONE, AND DARATUMUMAB IN RELAPSED REFRACTORY MULTIPLE MYELOMA (MM-014 PHASE 2 TRIAL): A SUBANALYSIS OF PATIENTS PREVIOUSLY TREATED WITH LENALIDOMIDE AND A PROTEASOME INHIBITOR

Background: Lenalidomide (LEN) with or without a proteasome inhibitor (PI) administered until disease progression is a standard treatment (Tx) approach for patients with newly diagnosed multiple myeloma (MM). However, recent clinical trials investigating triplet therapies did not have a large representation of patients whose disease has relapsed or become refractory to LEN after early-line Tx. The phase 2 MM-014 trial (NCT01946477) was designed to investigate the outcomes with sequencing pomalidomide (POM)-based therapy immediately after first- or second-line LEN-based Tx failure in patients with relapsed refractory MM (RRMM). In an earlier report of the intention-to-treat population (N = 112) from cohort B of this trial, POM + dexamethasone (DEX) + daratumumab (DARA) demonstrated promising efficacy and safety with an overall response rate (ORR) of 77.7%, and median progression-free survival (PFS) of 30.8 months (Siegel DS, et al. *Blood* 2020;136[suppl 1]: 16–17).

Aims: To report the efficacy and safety of POM + DEX + DARA immediately after LEN-based Tx failure in a subgroup of cohort B patients who received prior LEN + PI.

Methods: Patients with RRMM treated with 1-2 prior Tx lines, LEN-based Tx for ≥ 2 consecutive cycles as their most recent regimen, and progressive disease during or after their last line of Tx received POM + DEX + DARA. POM 4 mg/d was given orally on days 1-21; DEX 40 mg/d (20 mg/d in patients aged > 75 years) was given orally on days 1, 8, 15, and 22; and DARA 16 mg/kg was given intravenously on days 1, 8, 15, and 22 of cycles 1 and 2, days 1 and 15 for cycles 3-6, and day 1 for cycles 7+. The primary endpoint was ORR; secondary endpoints included PFS and safety.

Results: In cohort B, 89 of 112 patients (79%; median age, 65.0 years) had received prior LEN + PI. Among this patient subgroup, 67 patients (75.3%) had LEN-refractory MM and 22 (24.7%) had MM that relapsed after LEN Tx; most patients (52 [58.4%]) received 1 vs 2 (37 [41.6%]) prior Tx lines. Median duration of treatment of POM, DEX, and DARA was 15.9. 14.0, and 16.1 months, respectively. At data cutoff (March 24, 2020), the ORR was 78.7% (≥ very good partial response [VGPR], 55.1%); median follow-up of 28.3 months. The ORR was 80.8% (≥ VGPR, 63.5%) and 75.7% (≥ VGPR, 43.2%) in patients with 1 vs 2 prior lines of treatment, respectively. Median duration of response and median PFS were not yet reached (Figure; 1-year PFS rate, 74.1%). Infusion-related reactions occurred in 28.1% of patients and were primarily low grade. Overall, 97.8% of patients had ≥ 1 grade 3/4 Tx-emergent adverse event. The most common grade 3/4 hematologic events were neutropenia (64.0%; febrile, 12.4%), anemia (19.1%), and thrombocytopenia (13.5%). Grade 3/4 infections occurred in 40.4% of patients, including 15.7% with grade 3/4 pneumonia.

Figure. Progression-free survival in the prior LEN + PI subgroup (n = 89)

Summary/Conclusion: In this subanalysis, POM + DEX + DARA administered immediately after LEN failure in a subgroup of patients previously treated with LEN + PI demonstrated a high response rate and a safety profile consistent with that in the overall cohort B population. The results support the use of POM-based therapy, integrating the monoclonal antibody DARA as early as second line in patients with RRMM, potentially immediately after LEN Tx failure. Furthermore, these data support subsequent Tx with the same immunomodulatory agent class in a patient population with LEN-relapsed or -refractory disease.

EP1020 EARLY MORTALITY AMONG PATIENTS WITH NEWLY DIAGNOSED MULTIPLE MYELOMA IN THE NETHERLANDS: A POPULATION-BASED STUDY

M. Brink [1,*], K. Groen [2], P. Sonnveld [3], M. C. Minnema [4], A. Broyl [3], A. G. Dinmohamed [1,2,5], E. van der Spek [6], M.-D. Levin [7], P. F. Ypma [8], E. de Waal [9], E. F. W. Posthuma [10], S. Zweegman [2], N. W. van de Donk [2]

[1]Department of Research and Development, Netherlands Comprehensive Cancer Organisation, Utrecht, [2]Department of Hematology, Amsterdam UMC, Vrije Universiteit Amsterdam, Cancer Center Amsterdam, Amsterdam, [3]Department of Hematology, Erasmus MC Cancer Institute, Rotterdam, [4]Department of Hematology, University Medical Center Utrecht, Utrecht, [5]Department of Public Health, Erasmus University Medical Center, Rotterdam, [6]6Department of Internal Medicine, Rijnstate Hospital, Arnhem, [7]Department of Internal Medicine, Albert Schweitzer Hospital, Dordrecht, [8]Department of Hematology, Haga Teaching Hospital, The Hague, [9]Department of Internal Medicine, Medical Center Leeuwarden, Leeuwarden, [10]Department of Internal Medicine, Reinier de Graaf Group, Delft, Netherlands

Background: The introduction of novel agents and autologous stem cell transplantation improved the population-level survival of patients with multiple myeloma (MM). However, early mortality (EM) remains a major clinical issue. Identification of risk factors of EM may contribute to more rigorous supportive care measures or different therapeutic approaches in patients at risk for EM.
Aims: This population-based study aimed to assess trends in and risk factors of EM among MM patients diagnosed in the Netherlands during a 30-year period.
Methods: All MM patients diagnosed between 1989-2018 were identified in the Netherlands Cancer Registry, with survival follow-up through 2020. Data on primary therapy, i.e. no therapy and anti-neoplastic therapy were available for all patients. Patients were categorized into three calendar periods (1989-1998, 1999-2008, 2009-2018) and four age groups (≤65, 66-70, 71-80, >80 years). The impact of age, sex, period of diagnosis, hospital type at diagnosis, and prior malignancies, for EM was evaluated using uni- and multivariable Cox regression analyses. Moreover, for patients diagnosed in 2014-2018, detailed data on plasma cell percentage, cytogenetic risk, type of M-protein, levels of β2-microglobulin and albumin, as well as presence of thrombocytopenia, hypercalcemia, renal impairment, anemia, and bone lesions, type and number of novel agents (bortezomib, lenalidomide and/or thalidomide) was evaluated. EM was defined as the date from MM diagnosis to all-cause death ≤180 days.
Results: Our analytical cohort included 28,328 MM patients (median age 70 years; 55% males; 88% diagnosed in non-academic centers; 13% prior malignancies). EM for patients ≤65 was 11%, 11%, and 6% (P<0.001) in 1989-1998, 1999-2008, and 2009-2018, respectively. The corresponding proportions for patients aged 66-70 were 19%, 16%, and 8% (P<0.001), for patients 71-80, 25%, 22%, and 15% (P<0.001), and for patients >80, 40%, 41%, and 31% (P<0.001). EM was significantly lower among patients who received anti-neoplastic therapy as compared to patients who did not receive first-line therapy (13% vs. 29%; P<0.001) and EM decreased for both groups over time. When simultaneously adjusted for calendar period, sex, age, hospital type at diagnosis, prior malignancies, and treatment, patients diagnosed in 2009-2018 had a 42% lower risk of mortality as compared with patients diagnosed in 1989-1998 (hazard ratio, 0.58; P<0.001) with an adverse effect of older age, and prior malignancies.
In 2014-2018, 6,380 MM patients were diagnosed of whom 780 (12%) patients died ≤180 days post-diagnosis. For patients ≤70 years, EM was 6% for patients treated with bortezomib, 5% for lenalidomide, 3% for thalidomide as well as for treatment with two novel drugs (*P*=0.013). EM was similar for patients >70 years treated with bortezomib, lenalidomide, or thalidomide (12%, 15%, 14%, respectively; *P*=0.441). For patients >70 years treated with a combination of two novel drugs, none died ≤180 days. Albumin <35 g/L, β2-microglobulin ≥3.5 mg/L, thrombocytopenia, hypercalcemia, and poor renal function have an adverse effect on EM for patients ≤70 (Table). In addition, anemia and bone lesions have an adverse effect on EM for patients >70.

Table 1. Impact of various diagnostic parameters on risk of EM in 2014-2018 stratified by age.

	18-65 years				66-70 years				>70 years

Abbreviations: HR, hazard ratio; CI, confidence interval. P-values in bold indicate statistical significance

Summary/Conclusion: In summary, EM among MM patients improved from 1999 onwards. Nevertheless, EM remains high, especially for patients aged >70 years. Patients at risk for EM may benefit from better supportive care or individualized anti-MM therapy.

EP1021 IMPACT OF T(11;14) ACCORDING TO INDUCTION REGIMEN IN NEWLY DIAGNOSED TRANSPLANT-ELIGIBLE MULTIPLE MYELOMA PATIENTS: LONG TERM FOLLOW-UP OF GEM05MENOS65 PETHEMA/GEM STUDY

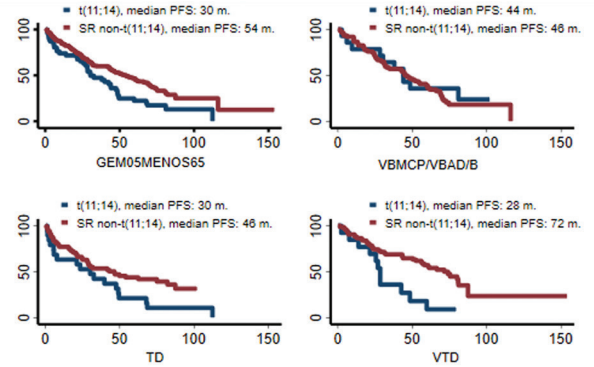

Figure 1. Progression free survival between patients with t(11;14) and SR non-t(11;14) in the GEM05MENOS65 global series and according to treatment arms.

Background: t(11;14) is the most frequently IgH rearrangement in multiple myeloma (MM) with a 15-20% prevalence and is considered a standard-risk cytogenetic abnormality (SR). However, t(11;14) is controversial since recent reports describe inferior outcomes in contrast to other SR patients.
Aims: To analyze the long-term outcome of t(11;14) compared with the remaining SR population in transplant-eligible (TE) patients included in the GEM05MENOS65 study.
Methods: From April 2006 to August 2009, 386 TE patients with newly diagnosed symptomatic MM were randomized to receive three induction regimens: six 4-week cycles of TD (thalidomide 200 mg daily; dexamethasone 40 mg on days 1-4 and 9-12) vs. six 4-week cycles of VTD (TD at identical doses plus iv bortezomib 1.3 mg/m2 on days 1, 4, 8 and 11) vs. combination chemotherapy plus bortezomib (4 cycles of alternating VBMCP and VBAD chemotherapy followed by two cycles of iv bortezomib). All patients were planned to undergo autologous stem cell transplant (ASCT) with MEL-200 followed by maintenance therapy with thalidomide/bortezomib vs. thalidomide vs. alfa-2b-interferon for 3 years.
Results: A total of 53 (16%) patients were positive for t(11;14) but 7 patients harboring concomitant high-risk abnormalities were excluded. SR excluding t(11;14) were found in 215 (66%) patients. There were no differences in baseline characteristics among groups. In the overall series, there were no differences in overall response rate (ORR) after induction between patients with t(11;14) compared to SR (78 vs. 87%, p=0.1). However, the ≥VGPR and MRD negativity rates were lower in patients with t(11;14) (17 vs. 33%; p=0.03 and 6 vs. 33%; p=0.002). In the VBMCP/VBAD/B arm, there were no significant differences in ORR or CR rate after induction between patients with t(11;14) or SR. However, patients with t(11;14) treated with VTD had lower ORR and CR rates after induction than SR patients (ORR 85 vs. 97%, p=0.04; CR 15 vs. 38%, p=0.1). Patients with t(11;14) treated with TD had lower ORR and CR rates although the differences were not statistically significant (ORR 63 vs. 78%, p=0.2, CR 5 vs. 11%, p=0.4). In the overall series, on an intention-to-treat basis, the ORR after ASCT (65% vs 76%, p=0.1) as well as the CR and MRD negativity rates were lower for patients with t(11;14) (CR 28 vs. 45%; p=0.04, MRD negative 20 vs. 42%; p=0.01).
With a median follow-up of 63.4 months, median progression free survival (PFS) in the overall series was shorter for patients with t(11;14) (30 vs. 54 months; p=0.004). No differences in median PFS were observed in the VBMCP/VBAD/B arm (44 vs. 46 months; p=0.7). However, shorter PFS was observed in patients with t(11;14) in the TD (30 vs. 46 months; p=0.03) and VTD arms (28 vs. 72 months; p=0.003) (Figure 1). In the overall series, there were no differences in the overall survival (OS) between t(11;14) and SR patients. However, patients with t(11;14) treated in the VBMCP/VBAD/B arm showed shorter median OS than SR patients (66 months vs. not reached; p=0.03). In contrast, median OS was not reached in patients with t(11;14) or SR in both, TD and VTD arms.
Summary/Conclusion: In our study, bortezomib and thalidomide-based induction regimens (VTD/TD) are suboptimal in patients with t(11;14) concerning response rates and PFS than SR patients, although this does not impact on OS. Patients with t(11;14) receiving induction with chemotherapy have the same response and PFS than SR patients but display a shorter OS. These results should be confirmed in larger series.

EP1022 RISK OF MULTIPLE MYELOMA AND OTHER MALIGNANCIES AMONG FIRST- AND SECOND-DEGREE RELATIVES; A POPULATION BASED STUDY OF10035 PATIENTS IN NORWAY WITH MULTIPLE MYELOMA

Ø. Langseth [1,2,*], T. Å. Myklebust [3,4], T. B. Johannesen [5], Ø. Hjertner [1,6], A. Waage [1,6]

[1]IKOM, Norwegian University of Science and Technology (NTNU), [2]The Cancer Clinic, St Olavs Hospital, Trondheim, [3]Department of Registration, Cancer Registry Norway, Oslo, [4]Department of Research and Innovation, Møre and Romsdal Hospital Trust, Ålesund, [5]Department of Registration, Cancer Registry of Norway, Oslo, [6]Dep of Hematology, St Olavs Hospital, Trondheim, Norway

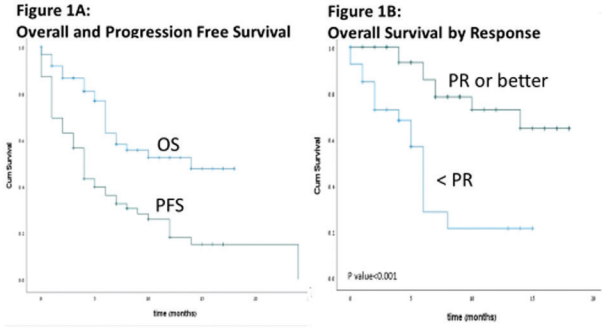
Background: The occurrence of two or more cases of multiple myeloma (MM) in the same family has been decribed in several countries whereas population-based studies on MM and other malignancies beyond first-degree relatives are scarce.
Aims: We wanted to investigate the risk of multiple myeloma (MM) and other malignancies in first- and second-degree relatives of MM patients based on information from the Cancer Registry of Norway (CRN).
Methods: All cases of MM diagnosed between January 1, 1982 and December 31, 2013 were retrieved. Population based control probands were retrieved in 4:1 and matched by year of birth, sex and county of residence. First-degree relatives for a given proband consisted of parents, siblings, and children. Second-degree relatives consisted of grand-parents, uncles and aunts, nephews and nieces, and grandchildren.
We used a Cox proportional hazards model to estimate the risk, denoted by the hazard ratio (HR), for MM and other malignancies in relatives of MM patients versus relatives of controls. An individual became at risk for a given cancer diagnosis after the date of birth or at the start of cancer registration (1953). Follow-up ended at the date of diagnosis of the cancer of interest, date of emigration, date of death, or end of study December 31, 2015. We adjusted for sex of the relatives, sex of the proband, and 15-y calendar period of birth in all analyses. The association between exposure and a diagnosis of MM was evaluated in all relatives. For MM, associations in subtypes of first- and second-degree were assessed. HR with 95% confidence intervals not including one were considered statistically significant.
Results: We included 7487 of 10035 MM patients diagnosed between January 1, 1982 and December 31, 2013 and 26 511 matched controls. The actual study population of relatives consisted 65 168 relatives of MM-patients and 223 643 relatives of matched controls.

Table 1.Hazard ratios for MM in relatives of MM patients vs. relatives of controls

	Cases‡	HR† (95% CI)
All relatives	101/182	1.89(1.40-2.57)*
All first-degree relatives	91/167	1.89(1.37-2.61)*
Offspring	31/49	1.90 (1.20-2.98)*
Siblings	17/27	2.29 (1.09-4.84)*
Parents	43/91	1.77 (1.23-2.55)*
All second-degree relatives	10/15	1.99(0.86-4.57)
Grandchildren	1/4	0.68 (0.07-6.20)
Grandparents	1/4	0.81 (0.09-7.31)
Uncles/aunts	3/4	2.25 (0.53-9.63)
Nieces/nephews	5/3	4.76 (1.19-18.9)*

* †Adusted for sex of the relatives, sex of the proband and 15y calendar period of birth,‡ Cases in 65 168 relatives of MM patients/cases in 223 643 relatives of controls,* 95% confidence interval not including one

First-degree relative of MM patients had approximately 2-fold increased risk for a MM diagnosis.
In second-degree relatives of MM-patients, no overall significant association with an MM diagnosis was observed. However, for nieces or nephews of MM patients, a significant association was found.
Summary/Conclusion: Overall, being a first-degree relative of MM patients was associated an approximately 2-fold increased risk for acquiring a MM diagnosis compared to relatives of controls. In second-degree relatives of MM-patients, no overall significant association with an MM diagnosis was observed. This was also true for subgroups, except for nieces or nephews of MM patients who had an icreased risk based on small numbers.



EP1023 BELANTAMAB MAFODOTIN TREATMENT FOR PATIENTS WITH RELAPSED/REFRACTORY MYELOMA VIA GSK EXPANDED ACCESS PROGRAM: REAL-WORLD DATA

Davidoff Cancer Center, Rabin Medical Center, Petah-Tikva, [12]Hematology, Bnai-zion medical center, Haifa, [13]Hematology, Assuta university hospital, Ashdod, [14]Faculty of health science, Ben-Gurion university of the Negev, Beer-Sheva, [15]Hematology, Shamir medical Center, Rishon-Lezion, Israel

Background: Belantamab mafodotin (GSK2857916), an immuno-conjugate targeting B-cell maturation antigen, showed single-agent activity in the phase 1 and 2 studies in heavily pre-treated patients, and was recently approved for patients with relapsed/refractory multiple myeloma (RRMM) after 4 lines of therapy, including a proteosome inhibitor, immunomodulatory agent and an anti-CD38 monoclonal antibody. Real-world data and long-term follow-up are lacking.
Aims: To assess safety and efficacy of belantamb mafodotin therapy administered via the GSK expanded access compassionate care program for treatment of RRMM patients in a multi-site real-world setting.
Methods: All consecutive RRMM patients who received at least two doses of belantamab mafoditin under the expanded access compassionate care program in 9 Israeli centers were included. Data were extracted from medical charts focusing on demographics, disease characteristics, prior treatment, safety including ocular toxicity and disease responses. Primary endpoint was progression free survival (PFS), secondary endpoints included safety with focus on ocular toxicity, overall response rate (ORR), overall survival (OS), safety and tolerability.
Results: Sixty-seven RRMM patients, treated with belantamab mafodotin between July 2019 and February 2021 were included. Median follow-up was 16.1 (95% confidence interval [CI] 11.2-20.9) months. Median age was 70 (range 36-88) years. Forty-seven percent had a high-risk cytogenetic profile, including t(4;14), t(14;16), t(14;20), del17p and +1q). Patients were heavily pretreated with a median of 5 [IQR 4-7] prior therapy lines. Exposure rates to bortezomib, carfilzomib, lenalidomide, pomalidomide and daratumumab were 100%, 73%, 91%, 77% and 92%, respectively. Sixty-five percent and 23% were triple and penta- refractory, respectively. Median number of cycles was 4 (range 2-17) per patient. The maximal dose was 3.4 mg/kg and 2.5 mg/kg in 36% and in 56% of patients, respectively. Twenty-five percent (n=73) of the cycles beyond inital dose were delayed. Reasons for delays were mainly ocular toxicity (65%) followed by hematological (11%) toxicity and infections (5%). Ocular toxicity (keratopathy) occurred in 41 of 62 evaluable patients (66%). Worst ocular toxicity was grade 1, 2 and 3 in 10%, 23% and 32%, respectively. Resolution of grade ≥2 ocular toxicity to grade 1/0 was documented in 74% of the patients. Hematologic side effects included thrombocytopenia (39%, grade≥3: 31%), neutropenia (13%, grade≥3.9%) and anemia (9%, grade≥3.6%). Two grade 3 bleedings (epistaxis and upper gastrointestinal bleeding) were reported among patients with thrombocytopenia grade 3-4. Frequent non-hematologic adverse events included infection (10%, grade≥3: 6%) and elevation of liver enzymes (10%, grade≥3: 4%). Four patients (6%) discontinued therapy due to toxicity (ocular in all cases). ORR was 54%. Best response rates were: complete response, very good partial response, partial response, minor response, stable disease and progressive disease in 6%, 23%,25%,11%,14%, 20% of the patients, respectively. Median PFS was 4.4 (95% CI 3.3-5.5) months in the entire cohort and 8.8 (95% CI 6.2-11.3) months among responders (patients achieving PR or better, **figure 1A**). Median OS was 14 (95% CI NE) months. Among responders, median OS was not reached vs. 6 (95% CI 5.2-6.7) months in non-responders (p<0.001, **figure 1B**).

Summary/Conclusion: Belantamab mafodotin shows significant anti-myeloma activity in heavily pre-treated patients with RRMM in a real-world setting with a manageable safety profile.

EP1024 PHASE 3 STUDY OF DARATUMUMAB, BORTEZOMIB, MELPHALAN, AND PREDNISONE (D-VMP) VERSUS BORTEZOMIB, MELPHALAN, AND PREDNISONE (VMP) IN ASIAN PATIENTS WITH NEWLY DIAGNOSED MULTIPLE MYELOMA (NDMM): OCTANS

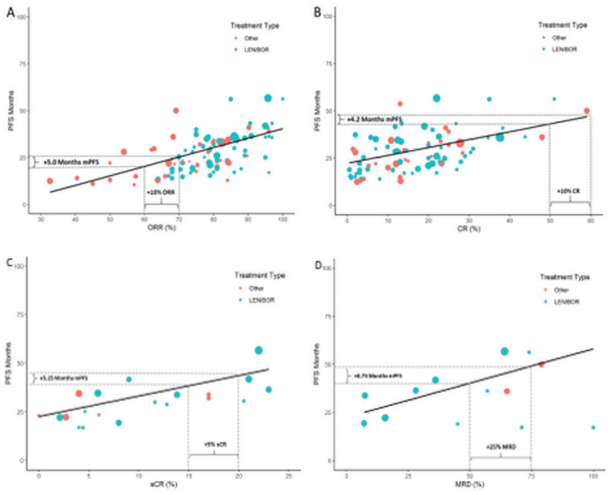
[1]Department of Hematology, Renji Hospital Shanghai Jiaotong University School of Medicine, [2]Shanghai Changzheng Hospital, Shanghai, China, [3]Seoul National University Bundang Hospital, Seongnam, [4]Department of Medicine, Samsung Medical Center, Sungkyunkwan University School of Medicine, Seoul, Korea, Republic Of, [5]Department of Hematology at the Oncology Center, The First Hospital of Jilin University, Changchun, [6]Institute of Hematology & Blood Diseases Hospital, Chinese Academy of Medical Sciences & Peking Union Medical College, Tianjin, China, [7]Department of Hematology-Oncology, Chonnam National University Medical School, Hwasun, Jeollanamdo, Korea, Republic Of, [8]The First Affiliated Hospital of Zhejiang University, College of Medicine, Hangzhou, Zhejiang, [9]Tianjin Cancer Hospital, Tianjin, China, [10]Queen Mary Hospital, University of Hong Kong, Hong Kong, Hong Kong, [11]Janssen Research & Development, LLC, Spring House, PA, [12]Janssen Research & Development, LLC, Raritan, NJ, United States, [13]Janssen Research & Development, LLC, Beijing, [14]Janssen Research & Development, LLC, Shanghai, China

Background: Daratumumab (DARA), a human IgGκ monoclonal antibody that targets CD38, is approved for the treatment of NDMM in combination with standard-of-care regimens, including in combination with VMP based on results of the phase 3 ALCYONE trial. The phase 3 study OCTANS investigated the efficacy, safety, and pharmacokinetics (PK) of D-VMP in Asian NDMM patients.
Aims: To compare the efficacy, safety, and PK of D-VMP versus VMP in Asian and Chinese-only patients (NCT03217812).
Methods: Asian patients (from the following countries/regions: China, Hong Kong SAR, Taiwan, Korea, and Malaysia) with NDMM who were ineligible for autologous stem cell transplant were randomized (2:1) to D-VMP or VMP. Patients received 9 (42-day) cycles of bortezomib (1.3 mg/m^2 SC) twice weekly in Cycle 1 (Weeks 1, 2, 4, 5) then once weekly in Cycles 2-9 (Weeks 1, 2, 4, 5); melphalan (9 mg/m^2 PO) and prednisone (60 mg/m^2 PO) once daily on Days 1-4 of each cycle. Patients in the D-VMP arm received DARA (16 mg/kg IV) once weekly in Cycle 1, once every three weeks in Cycles 2-9, and once every four weeks thereafter until disease progression or unacceptable toxicity. The primary endpoint was the rate of very good partial response or better (≥VGPR). Key secondary endpoints included progression-free survival (PFS), overall response rate (ORR), and safety. DARA PK and minimal residual disease (MRD) negativity rates were exploratory endpoints.
Results: A total of 220 patients (Chinese patients, n=167) were randomized to D-VMP (n=146) or VMP (n=74). Baseline characteristics were well balanced between arms; median age was 69 (range, 57-84) years and 48 (21.9%) patients had high-risk cytogenetics. At the time of data analysis (clinical cutoff 02 Jul 2020), 51 patients (35.4%) in the D-VMP arm completed 9 treatment cycles and received DARA monotherapy; 20 (28.2%) patients in the VMP arm had completed all 9 cycles of treatment. After a median follow-up of 12.3 (range, 0.0-29.3) months, ≥VGPR rate was significantly improved with D-VMP versus VMP overall (74.0% vs 43.2%; odds ratio 3.57; 95% CI 1.99-6.43; *P*<0.0001) and among Chinese patients (74.6% vs 45.3%; odds ratio 3.51; 95% CI 1.76-7.00; *P*=0.0003). ORR was 88.4% with D-VMP and 78.4% with VMP. Median PFS was not reached in the D-VMP arm and was 18.2 months in the VMP arm (HR 0.43; 95% CI 0.24-0.77; *P*=0.0033); the estimated 12-month PFS rate was 84.2% in the D-VMP arm versus 64.6% in the VMP arm. PK results for DARA (overall population n=144; Chinese patients n=114) were comparable between the overall population and Chinese patients. The most frequent (≥10%) grade 3/4 TEAEs for the D-VMP/VMP arms were thrombocytopenia (46.5%/45.1%),

neutropenia (39.6%/50.7%), leukopenia (31.3%/36.6%), lymphopenia (30.6%/22.5%), pneumonia (29.2%/14.1%), anemia (24.3%/26.8%), and hypokalemia (13.2%/2.8%). TEAEs occurred at a similar rate in Chinese patients. Infusion-related reactions were observed in 44 patients (30.6%); the vast majority (n=41) were mild (grade 1 or 2). A total of 8 TEAE-related deaths (D-VMP, n=5; VMP, n=3) were reported. Additional data including the MRD negativity rate (10^{-5} threshold) will be presented.

Summary/Conclusion: The addition of DARA to VMP significantly improved efficacy outcomes for Asian patients with NDMM, consistent with results from the global ALCYONE trial. Safety profiles of D-VMP in an Asian population were also consistent with previously reported trials and no new safety concerns were identified. These data support the use of DARA plus VMP for the treatment of Asian and Chinese NDMM patients.



EP1025 OVERALL, COMPLETE, AND STRINGENT COMPLETE RESPONSE RATES AND MINIMAL RESIDUAL DISEASE AS POTENTIAL SURROGATES FOR PROGRESSION-FREE SURVIVAL IN NEWLY DIAGNOSED MULTIPLE MYELOMA

P. Daniele [1,*], C. Mamolo [2], J. C. Cappelleri [2], T. Bell [3], A. Neuhof [3], G. Tremblay [1], M. Musat [4], A. Forsythe [4]

[1]Purple Squirrel Economics, Montreal, Canada, [2]Pfizer, Inc, Groton, [3]Pfizer, Inc, [4]Purple Squirrel Economics, New York, United States

Background: The armamentarium of treatment for newly diagnosed multiple myeloma (NDMM) has recently expanded. Yet MM remains largely incurable and all patients inevitably relapse or fail treatment. Progression-free survival (PFS) is a common primary endpoint in NDMM trials; however, demonstrating improvements in PFS requires a larger sample size and longer follow-up compared with other endpoints.
Aims: Endpoints such as overall response rate (ORR), complete response (CR), stringent complete response (sCR), and minimal residual disease (MRD) may be clinically relevant surrogate endpoints; this study investigated their role as surrogates for PFS in NDMM.
Methods: Medline, Embase, and Cochrane databases were systematically searched for randomized controlled trials (RCT) studies published from 2010 to July 2020. Additionally, relevant congress abstracts from 2018 to 2020 were reviewed. Studies that reported ORR, CR, sCR, or MRD and median PFS were extracted. The correlations between PFS and ORR, CR, sCR, or MRD were estimated using Pearson's correlation weighted by sample size in each study arm. Surrogacy for PFS was evaluated using unadjusted and adjusted weighted linear regression models to estimate the gain in median PFS associated with each surrogate. Factors considered for adjustment included study year, age, sex, International Staging System risk stage, eligibility for transplant, and treatment type (lenalidomide/bortezomib [LEN/BOR] vs other). Optimal adjusted models were selected based on model fit statistics. Separately, a review of real-world evidence (RWE) studies was conducted following similar parameters to further investigate the association of MRD with survival.
Results: Seventy-five RCTs studies were identified with 101 study arms reporting median PFS. Final analysis datasets were developed that included study arms with valid pairs of median PFS with ORR (N=89), CR (N=87), sCR (N=20), and MRD (N=14). Moderate-to-strong significant correlations were observed for PFS with ORR (Pearson r=0.59), CR (r=0.48), sCR (r=0.68), and MRD (r=0.69). The unadjusted analysis models estimated an average increase of 0.50 (95% confidence interval [CI]: 0.36, 0.64), 0.42 (95% CI: 0.25, 0.58), 1.05 (95% CI: 0.58, 1.52), and 0.35 (95% CI: 0.12, 0.58) months of median PFS per percentage point increase in ORR, CR, sCR, and MRD, respectively (Figure 1). Following adjustment for age, and treatment type in the ORR model, and ISS risk stage in the CR model, the associations remained significant but were attenuated to 0.35 (95% CI: 0.21, 0.49) and 0.29 (95% CI: 0.16, 0.41) months of median PFS for each point of ORR and CR, respectively. Adjusted models could not be constructed for sCR or MRD models due to small sample size. The systematic review of RWE revealed 20 studies investigating the association between survival and MRD; 12 found significant ($p < 0.05$) survival benefit associated with MRD-negativity.

Figure 1. Scatterplots of ORR, CR, sCR, and MRD

Unadjusted linear model overlayed over raw data for A, ORR (%) vs PFS (months); B, CR (%) vs PFS (months); C, sCR (%) vs PFS (months); and D, MRD (%) vs PFS (months).
Note: Point size relates to the sample size of each study arm.
BOR: bortezomib; CR: complete response; LEN: lenalidomide; mPFS: median progression-free survival; MRD: minimal residual disease; ORR: overall response rate; sCR: stringent complete response

Summary/Conclusion: We demonstrated significant associations of PFS with ORR, CR, sCR, and MRD in NDMM, which may justify their use as surrogate endpoints to estimate PFS benefit in this population. Adjusted models estimate a 10% increase in ORR or CR is associated with 3.5 and 2.9-month increases in median PFS, respectively. The results of the exploratory MRD analyses of this study and RWE complement recent publications which have suggested that MRD-negativity is a viable surrogate endpoint for PFS in MM. The accumulation of evidence from multiple methodologies strengthens the argument that MRD is a suitable surrogate for PFS in NDMM.

EP1026 CHARACTERIZATION OF OCULAR ADVERSE EVENTS IN PATIENTS RECEIVING BELANTAMAB MAFADOTIN FOR ≥12 MONTHS: POST-HOC ANALYSIS OF DREAMM-2 STUDY IN RELAPSED/REFRACTORY MULTIPLE MYELOMA

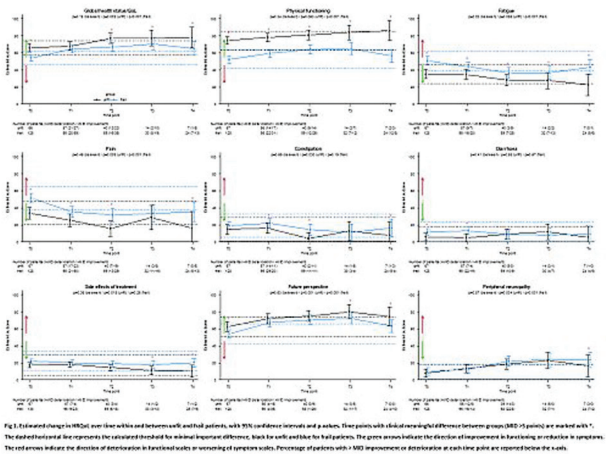
Background: The B-cell maturation antigen–targeting antibody–drug conjugate belantamab mafodotin (belamaf; GSK2857916) is approved for the treatment of patients with heavily pretreated relapsed or refractory multiple myeloma (RRMM). Ocular symptoms (eg, dry eye, blurred vision, etc) and eye examination findings including keratopathy (superficial punctate keratopathy and/or microcyst-like epithelial changes) and changes in visual acuity are common with belamaf. These may be managed with dose modification (reduction and/or delay) or treatment discontinuation. Durable responses have been observed despite dose modifications. The safety profile of belamaf and longer-term management of ocular events need to be characterized more fully to optimize clinical care.



Aims: To characterize the safety profile of belamaf in patients treated for ≥12 months, in a *post-hoc* analysis of the 2.5 mg/kg Q3W arm of the open-label, Phase 2 DREAMM-2 study at 13-month follow-up.
Methods: Patients with RRMM who had ≥3 prior therapies and were refractory to an immunomodulatory agent and proteasome inhibitor and refractory and/or intolerant to an anti-CD38 monoclonal antibody received single-agent belamaf. Eye exams, including a corneal exam and assessment of best corrected visual acuity (BCVA) change, were conducted at baseline and prior to each dose. Dose modifications (delays/reductions) were made based on the most severe Keratopathy and Visual Acuity scale grading, which considers corneal exam findings and BCVA changes from baseline. Recovery was defined as Grade 1 exam findings/no exam findings, and ≤1-line decline in BCVA vs baseline. Patient-reported ocular symptoms were graded per CTCAE version 4.03.
Results: Of 97 patients randomized to the belamaf 2.5 mg/kg cohort, the clinical benefit rate (minimal response or better) was 36% at the 13-month cut-off. A total of 14 patients (15%) had received ≥12 months of treatment with 2.5 mg/kg Q3W belamaf at data cut-off. All 14 patients had experienced ≥1 ocular event (maximum grade of 2 [14%], 3 [79%], or 4 [7%]), and required ≥2 dose delays, with dose reduction (to 1.92 mg/kg) in 12 patients (86%). Dose delay or reduction permitted recovery of ocular events so that treatment could be restarted in all 14 patients. Patients underwent a mean of 3.6 dose delays over the ≥12 months of belamaf treatment (median: 3.5, range: 2–6). Median duration of dose delays was 41 days (range: 4–212). Ten patients (71%) required dose delays of >63 days. In general in this subset of 14 patients, long delays did not appear to negatively impact clinical response to belamaf: 12 (86%) had a clinical response (partial response or better; 11 [79%] for ≥6 months). In the subset of 14 patients analyzed here, all 14 had keratopathy. Ocular symptoms occurred in 13 patients (93%), most commonly blurred vision (57%), dry eye (36%), visual acuity reduced (21%), and photophobia (21%). No patients had permanent complete vision loss.
Summary/Conclusion: In this subset of patients receiving belamaf treatment for ≥12 months, dose modification was effective in managing ocular symptoms and decreasing findings at eye examination, and allowed patients the clinical benefit gained from continuing treatment with belamaf. The safety profile of belamaf will be further characterized in ongoing analyses and studies.

Background: Frailty in non-transplant eligible (NTE) newly diagnosed multiple myeloma (NDMM) patients is associated with non-hematological toxicity which can negatively affect physical functioning (PF). Older patients increasingly prefer quality of life (QoL) and physical independence over length of life, highlighting the importance of health-related (HR)QoL assessment to take into account for treatment guidance. We here present the HRQoL results of the HOVON 123 trial. In addition to previous reports on HRQOL with MPV, we here present results by frailty level and also after completion of treatment for the first time.
Aims: To evaluate 2 year HRQoL in unfit and frail patients treated with MPV in the HOVON123 trial.
Methods: In this prospective phase 2 trial patients ≥75 years were treated with 9 dose-adjusted cycles MPV. Two HRQoL instruments (EORTC QLQ-C30 and MY20) were obtained at baseline (T0), after 3 (T1) and 9 (T2) cycles and after 6 (T3) and 12 (T4) months of follow-up for patients on protocol. Nine (3 functional; 6 symptom) subscales were presented as concepts relevant to patients: global QoL (GHS), PF, future perspective; fatigue, pain, constipation, diarrhoea, treatment side effects, and neuropathy (PNP, based on "tingling hands/feet" Q13 MY20). Baseline differences were analysed with independent t-tests, changes over time with linear mixed models. Minimal important difference (MID) from T0 within groups was defined as a score change of ≥1 SEM for multi-item scales or ≥0.5xSD for single-item scales. Cross-sectional clinically relevant superiority of one group was defined as MID≥5 between groups. HRQOL changes/differences were reported only when both statistically significant and clinically relevant (>MID). Analyses were based on only unfit and frail patients (based on IMWG-frailty index (Palumbo et al, 2015)).
Results: Of 238 included patients, 71 (30%) were unfit and 130 (55%) frail. Of those, 67 (94%) and 130 (100%) completed a baseline questionnaire. Compliance during T1-T4 was comparable between unfit and frail, ranging from 59-92%. At baseline, HRQoL was generally superior in unfit vs frail patients, which remained over time (Fig 1). In contrast, there was no difference in constipation, side effects and PNP between unfit and frail (Fig 1). When looking at unfit and frail patients separately, we observed that GHS, future perspective and pain improved, whereas PNP deteriorated in both groups. In addition, in frail patients also PF and fatigue improved, and in unfit patients constipation improved. Improvement in GHS, future perspective, pain, PF and fatigue was reached earlier in frail as compared to unfit patients (Fig 1). Importantly, these improvements were sustained after treatment completion. However, in frail patients a decrease in PF, fatigue and future perspective as compared to earlier time points was observed at T4 but still superior compared to baseline. With respect to PNP, a clinically relevant worsening was observed in both unfit and frail patients from T2 onwards.

Summary/Conclusion: In this first study reporting HRQoL in NDMM patients by frailty level, we show that unfit had a superior HRQoL as

compared to frail, both at baseline and follow-up. A HRQoL improvement over time was not only observed in unfit (4/9 scales) but importantly, also in the frail (5/9 scales) patients, who even showed an improvement at earlier time points. Only PNP worsened over time in both groups, as expected because of bortezomib treatment, however not negatively affecting physical functioning in those patients who completed 9 MPV-cycles.

EP1028 BRIDGE (OP-107): A PHASE 2 PHARMACOKINETIC STUDY OF MELFLUFEN PLUS DEXAMETHASONE IN PATIENTS WITH RELAPSED/REFRACTORY MULTIPLE MYELOMA AND IMPAIRED RENAL FUNCTION

L. Pour [1,*], S. Delimpasi [2], W. Legiec [3], J. Minarik [4], I. Spicka [5], S. Grosicki [6], M. Rymko [7], J. Najda [8], A. Symeonidis [9], B. Andersson [10], M. Jerling [10], H. Xie [10], J. Aschan [10], M.-A. Dimopoulos [11]

Background: Melphalan flufenamide (melflufen) is an investigational first-in-class peptide-drug conjugate (PDC) that leverages aminopeptidases and thereby rapidly delivers and releases alkylating agents inside tumor cells. It has shown promising clinical activity in relapsed/refractory multiple myeloma (RRMM). In cells, melflufen is rapidly metabolised to produce additional alkylating agents, including melphalan. Since melphalan, in contrast to melflufen, is partially cleared by renal elimination, it is important to assess the impact of renal impairment on melphalan pharmacokinetics (PK), particularly because impaired renal function is a common complication of RRMM.

Aims: The BRIDGE study aims to assess the relationship between renal function and the PK of melphalan in patients (pts) receiving melflufen for RRMM (NCT03639610).

Methods: BRIDGE is a phase 2, multicentre, open-label, single-arm study of pts with RRMM (following 2–4 lines of prior therapy). Informed written consent was obtained from pts with an estimated glomerular filtration rate (eGFR) of ≥30 to <45 ml/min/1.73m^2, who received 30 or 40 mg melflufen intravenously on Day 1, and 40 mg oral dexamethasone (20 mg for pts ≥75 yrs) on Days 1, 8, 15, and 22 of each 28-day cycle. PK sampling was performed 3 times in the first 2 cycles: 5–10 mins, 2–3 hrs, and 5–7 hrs after each melflufen infusion. Primary outcome measures were maximum observed concentration (C_{max}), area under the concentration versus time curve from 0 hrs to infinity (AUC_{inf}), and elimination phase half-life ($t_{½}$) of melphalan assessed using non-compartmental methods, and safety. Efficacy and renal function over time were also assessed.

Results: At data cut off (Nov 17, 2020), 31 pts had received melflufen (median age 71 yrs [range 52–85]; 52% male; median eGFR 35 mL/min/1.73m^2). Eighteen pts were evaluable for PK analysis. Dose-adjusted AUC_{inf} negatively correlated with eGFR ($p = 0.020$, $r^2 = 0.17$; Figure) and body surface area (BSA; $p = 0.006$, $r^2 = 0.23$; combined $r^2 = 0.44$). Dose-adjusted C_{max} negatively correlated with BSA ($p = 0.0009$, $r^2 = 0.32$) and $t_{½}$ negatively correlated with eGFR. 77% of pts had ≥1 Grade 3/4 treatment-emergent adverse event (TEAE), most commonly thrombocytopenia (58%), neutropenia (42%), and anemia (35%). Seven (23%) pts had ≥1 melflufen-related serious TEAE and 7 (23%) pts had TEAEs leading to melflufen discontinuation. Overall response rate was 48% and clinical benefit rate was 58%. Renal function remained stable; median pre-dose eGFR at Cycle 2 was 42 mL/min/1.73m^2.

Summary/Conclusion: For pts receiving melflufen in BRIDGE, exposure to melphalan increased with reduced eGFR, similar to what is observed during treatment with melphalan. The overall toxicity profile was as expected for melflufen and dexamethasone and no new safety signals were observed, supporting the use of melflufen in pts with moderate renal impairment. The optimal melflufen dose for pts with impaired renal function will be determined following recruitment of a second cohort of pts with severe renal impairment.

EP1029 PROGNOSTIC FACTORS AND OUTCOMES OF MULTIPLE MYELOMA PATIENTS WITH CHRONIC KIDNEY DISEASE STAGE 5 OR UNDER DIALYSIS

Background: About one-third of the multiple myeloma (MM) patient are recognized to have renal impairment (RI) at initial diagnosis of MM and up to 10% of the patients present with RI severe enough to require dialysis. The prognosis of MM with RI has improved significantly over the past decade owing to the availability of new agents (including proteasome inhibitors and immunomodulatory drugs) and improvement of the supportive care measures. A recent data revealed an upward movement of survival curves after the introduction of bortezomib into the MM treatment. However, conventional staging systems are insufficient to prognosticate MM patient with RI.

Aims: This study aimed to investigate the prognostic factors and treatment outcomes in multiple myeloma patients with chronic kidney disease (CKD) 5 or patients under dialysis.

Methods: Patients who were confirmed multiple myeloma between January, 2001 to December, 2016 and had an estimated glomerular

filtration rate (eGFR) of less than 15 ml/min/1.73m^2 at the time of multiple myeloma diagnosis or receiving hemo- or peritoneal dialysis at the time of multiple myeloma diagnosis were included into the study. A total of 248 patients from 17 centers participating Korean multiple myeloma working party were analyzed. Renal reversibility was defined by international myeloma working group recommendation: renal complete response (CRrenal) as best eGFR of ≥ 60 ml/min/1.73m^2, renal partial response (PRrenal) of 30-59 ml/min/1.73m^2, and renal minor response of 15-29 ml/min/1.73m^2. Overall survival (OS) was defined by the date of MM diagnosis to the date of death by any cause or follow-up loss.

Results: Median age was 63.5 years (range, 32-91 years) and median eGFR was 8.9 ml/min/1.73m^2 (1.0- 40.0 ml/min/1.73m^2). 126 (50.8%) of the analyzed patients were under dialysis or were dialysated just after the diagnosis of MM. 79.4% of the patients received bortezomib and/or thalidomide (new agents group) as an induction regimen and 35.1% of the analyzed cohort underwent autologous stem cell transplantation (auto-SCT group). Dialysis stop rates were higher in the new agents group compared with no new agent group (49.5% versus 27.8%, P=0.088) and in the auto-SCT group compared with no auto-SCT group (77.6% versus 40.4%, P=0.000). With a median follow-up duration of 24.42 months (range, 0.20-134.93 months), the median OS in the total cohort was 46.83 months (95% confidence interval, CI, 29.39-64.27 months). OS was not different between the groups with or without new agents incorporated into the induction chemotherapy, but auto-SCT group showed a significantly prolonged OS compared with no auto-SCT group: 67.63 (95% CI, 36.07-99.19) vs. 40.60 months (28.94 - 52.26 months) (P=0.001). By the conventional international staging system (ISS) or revised international staging system (R-ISS), OS was not different between the groups. However, age (65 years or more), Eastern cooperative group performance status (2 or more), high risk cytogenetics by fluorescent in situ hybridization (FISH), and C-reactive protein (CRP) 1.0 mg/dL or more significantly affected OS by both univariate and multivariate analysis (Table 1).

< 1.0 mg/dL				
≥ 1.0 mg/dL	1.684 (1.099-2.580)	0.017	1.838 (1.020-1.313)	0.043

Abbreviation: ECOG PS, Eastern Cooperative Group performance status; BMI, body mass index; LDH, lactate dehydrogenase; FISH, fluorescent in situ hybridization; ISS, international staging system; R-ISS, revised international staging system; CRP, C-reactive protein

Summary/Conclusion: Autologous stem cell transplantation in MM patients with CKD5 or under dialysis is able to effectively reverse renal function and prolong overall survival. Conventional ISS or R-ISS was insufficient to predict survival outcome in this cohort. Other prognostic markers incorporating age, performance status, cytogenetics by FISH, and CRP should be considered for patients with poor renal function.

EP1030 A PHASE IA STUDY OF BISTHIANOSTAT, A NOVEL PAN-HDAC INHIBITOR IN PATIENTS WITH RELAPSED/REFRACTORY MULTIPLE MYELOMA (RRMM): UPDATED RESULTS OF CH-020PI STUDY

H.-H. Huang [1,*], J. Hou [1], Y.-M. Zhang [2,3], Y.-B. Zhou [2,3], Y.-F. Zhang [2,4], F. Xiao [1], X.-F. Han [1], L.-J. Shen [1], J. Li [2,3], F.-J. Nan [2,3]

[1]Department of Hematology, Ren Ji Hospital, Shanghai Jiao Tong University School of Medicine, [2]National Center for New Drug Screening, State Key Laboratory of Drug Research, Shanghai Institute of Materia Medica, Chinese Academy of Sciences, Shanghai, [3]University of Chinese Academy of Sciences, Beijing, [4]Shanghai Center for Drug Metabolism and Pharmacokinetics Research, Shanghai, China

Background: Bisthianostat is a novel Histone deacetylase inhibitor (HDACi), derived by systematic optimizations on the basis of the thiazole-thiazoline core structure in natural HDACi Largazole (Nan et al., ACS Med Chem Lett. 2014). It displayed potent anti-MM activity as single agents and good synergistic effect with bortezomib both in vitro and in vivo. Herein, we presented our updated in-patient findings from CH-020PI study, an ongoing dose-escalating phase 1a study of bisthianostat in patients(pts) with RRMM(NCT03618602).

Aims: To investigate the safety, tolerability, pharmacokinetics, and efficacy of single-agent bisthianostat in pts with RRMM.

Methods: Adult pts with RRMM who had received ≥2 prior regimens were enrolled. Bisthianostat was administered orally on a twice-weekly schedule, in 4-week cycles, until progressive disease or unacceptable toxicities. The criteria of dose escalation were based on a modified Fibonacci method with dose increased by 100mg, 200mg, 400mg, and 600mg, respectively.

Results: As of Dec 29, 2020, 15 pts were enrolled at 4 dose levels from 100 to 600mg. The median age at enrollment was 60 years (range, 49-70 years). The median number of previous lines of therapy was 3 (range, 2-9) and included treatment with bortezomib (100%), ixazomib (13.3%), immunomodulatory drugs (lenalidomide/thalidomide, 93.3%). Among all treated pts (N=15), 93.3% of pts had treatment-emergent adverse events (TEAEs), which were mostly grade 1-2 (66.7%). Most common TEAEs (any grade, ≥20%) were: neutropenia (66.7%), urinary tract infection (33.3%), fever (20%), ECG QTc interval prolonged (20%) and diarrhea (20%). Grade 3/4 TEAEs were neutropenia (20%), anemia (6.7%) and pneumonitis (6.7%). Only one TEAE led to permanent treatment discontinuation in patient 009 (400mg cohort), who experienced QTc prolongation and was assessed as dose-limiting toxicity (DLT) per protocol. Later investigation indicated that this patient had QTc prolongation within 6 months prior enrollment. No further case of DLT or MTD was observed in cohort of 400mg and 600mg.

In the pharmacokinetic evaluation, for all of the 15 pts tested at day 1, the peak concentration of bisthianostat was reached within 0.5-2.25 h; half life time were 4.28-9.48 h; the mean C_{max} was 0.599, 1.11, 1.16, and 0.996 mg/mL at dose levels of 100, 200, 400 and 600 mg, respectively, and the mean $AUC_{0-\infty}$ was 2.07, 3.76, 5.53, and 4.68 h·mg /mL, respectively. The $AUC_{0-\infty}$ and C_{max} exhibited dose proportionality over the range of 100-200 mg, but they increased lower than dose-proportional manner from 200 to 400 mg. The exposure of bisthianostat at 600 mg was comparable to that at 400 mg. Similar results were found following multiple doses administration. Bisthianostat was not accumulated following a twice-weekly treatment.

The single-agent efficacy was modest. Of the 14 efficacy evaluable pts, seven pts (50%) experienced stable disease as their best response. One patient (004, 200mg cohort) remained stable for up to 6.5 months.

Summary/Conclusion: Bisthianostat proved to be well absorbed and tolerated. It exhibited modest anti-tumor efficacy in our cohort of RRMM pts. According to pharmacokinetic evaluation data, dose escalation will not proceed and a triple-weekly oral administration schedule is currently ongoing, Future trials in the combination with established MM therapy will be investigated in phase 1b study to enhance its efficacy via synergistic effect.

EP1031 TREATMENT OF PATIENTS WITH RELAPSED/REFRACTORY MULTIPLE MYELOMA WITH POMALIDOMIDE AND DEXAMETHASONE WITH OR WITHOUT SUBCUTANEOUS DARATUMUMAB: PATIENT-REPORTED OUTCOMES FROM APOLLO

D. M. Dimopoulos [1,*], E. Terpos [1], M. Boccadoro [2], S. Delimpasi [3], M. Beksac [4], E. Katodritou [5], P. Moreau [6], L. Baldini [7], A. Symeonidis [8], J. Bila [9], A. Oriol [10], M.-V. Mateos [11], H. Einsele [12], I. Orfanidis [13], K. S. Gries [14], J. Fastenau [14], T. Kampfenkel [15], Y. Qiu [16], H. Amin [14], P. Sonneveld [17]

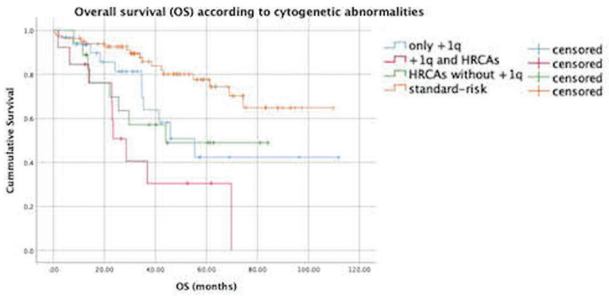
Background: Patients with relapsed/refractory multiple myeloma (RRMM) have a reduced health-related quality of life (HRQoL) compared with age- and sex-matched populations. In the phase 3 APOLLO study (NCT03180736), patients with RRMM who had received ≥1 prior line of therapy, including lenalidomide with a proteasome inhibitor, were treated with pomalidomide and dexamethasone (Pd) with or without subcutaneous daratumumab (D-Pd; 1800 mg, co-formulated with recombinant human hyaluronidase PH20 in 15 mL). The rate of progression or death was significantly lower with D-Pd (by 37%) vs Pd (median follow up, 16.9 months).
Aims: To present patient-reported outcomes (PROs) from the APOLLO study.
Methods: Patients were randomly assigned 1:1 to receive D-Pd or Pd in 28-day cycles until disease progression or unacceptable toxicity. Written informed consent was obtained from all patients. Using the European Organization for Research and Treatment of Cancer Quality of Life Questionnaire Core 30 item (EORTC QLQ-C30), EORTC QLQ Multiple Myeloma Module 20 item (MY20), and EQ 5D, PROs were assessed on Day 1 of each cycle. Intent-to-treat population with baseline and ≥1 postbaseline assessment were evaluated. Time to worsening was estimated using the Kaplan-Meier method, and treatment effect was evaluated using a mixed effects model with repeated measures.
Results: Overall, 304 patients (D-Pd: n=151, pd: n=153) were eligible. The median duration of treatment was 11.5 and 6.6 months in the D-Pd and Pd groups, respectively. At Cycle 16, 63 patients in the D-Pd group and 40 patients in the Pd group continued to be on treatment. The PRO compliance rates were similarly high in both groups. As measured with the EORTC QLQ-C30, pain reduced in D-Pd-treated patients (maximum improvement: 6.8 points at Cycle 12), and no mean change was observed in disease symptoms or treatment side effect subscales of the EORTC QLQ-MY20. Group mean physical and emotional functioning worsened from baseline in the Pd group (maximum worsening: 6.4 points at Cycle 4 and 9.1 points at Cycle 14) but was unaltered in the D-Pd group. A greater proportion of patients had a meaningful improvement from baseline with D-Pd vs Pd for disease symptoms (55.0% vs 49.0%), physical functioning (43.0% vs 35.3%), and emotional functioning (41.7% vs 31.4%). The median time to worsening was approximately 4 months, except for disease symptoms subscale, where the median time to worsening was approximately 10 months. No differences were observed between groups.
Summary/Conclusion: Combining daratumumab with Pd for the treatment of RRMM did not lead to any decrements in HRQoL. Some patients benefited from the combination through reduction in pain and clinically meaningful improvements in symptoms and emotional/physical function. These findings complement the clinical benefits of D-Pd in patients with RRMM and further support its use in this population



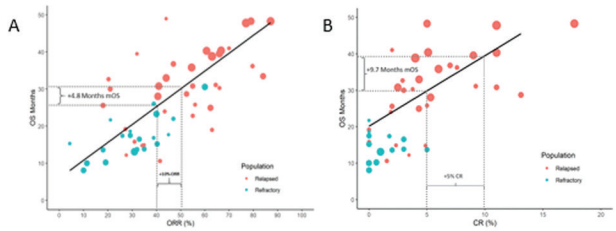
EP1032 GAIN IN CHROMOSOME 1 SIGNIFICANTLY IMPACTS SURVIVAL IN TRANSPLANT-ELIGIBLE MULTIPLE MYELOMA PATIENTS

I. Paulos Mesquita [1,*], J. Vieira [1], S. Durão [1], E. Espada [1], H. Martins [1], I. Franco [2], C. Duarte [2], J. Raposo [1], G. Esteves [1]

[1]Department of Hematology and Bone Marrow Transplant, [2]Department of Clinical Pathology, Hospital de Santa Maria, Centro Hospitalar Universitário de Lisboa Norte, Lisbon, Portugal

Background: Gain in chromosome 1q (+1q) is one of the most common recurrent cytogenetic abnormalities in multiple myeloma (MM). Previous studies indicate an association with inferior outcomes, but there is uncertainty about the prognostic impact of this abnormality relative to other high risk cytogenetic abnormalities (HRCAs).
Aims: To evaluate clinical characteristics, response to treatment and survival outcomes in newly diagnosed transplant-eligible MM patients (pts) with +1q
Methods: Single centre retrospective study including newly diagnosed transplant-eligible MM pts treated between January 2012 and December 2020, who had cytogenetic analysis by fluorescence in situ hybridization (FISH) performed at diagnosis. FISH abnormalities included +1q, del17p, t(11;14), t(4;14), t(14;16) and hyperdiploidy. +1q was defined by ≥3 copies of CKS1B locus (1q21), with a threshold of 3-5%. Clinical data were obtained by review of electronic medical records. Response evaluation was according to the International Myeloma Working Group (IMWG) criteria. HRCAs as defined by the Revised-International Staging System (R-ISS): del17p, t(4;14) and/or t(14;16).
Results: This cohort included 150 pts, with a median age of 60 years (range 35-72); 53.3% were male. 30.6% of the pts had documented +1q and 20.8% expressed HRCAs. All patients received bortezomib-based induction regimens, 42.0% in association with an immunomodulatory drug (IMiD) (thalidomide in 25.3% of the pts, lenalidomide in 16.7%), 52.0% with an alkylating agent and 4.0% with an anthracycline, followed by single autologous stem-cell transplantation (ASCT) in 74.0% and tandem ASCT in 16.0%. Median follow-up (FU) was 34.6 months (mo). Baseline clinical characteristics were similar in pts with +1q (gr 1) and without +1q (gr 2). There were also no differences in overall response rates to induction therapy between gr 1 and 2 (93.3% vs 89.9%; p=0.37). Overall survival (OS) and progression free survival (PFS) were compared between gr 1 and 2, and four other subgroups: standard risk cytogenetics (gr 3), presence of +1q alone (gr 4), presence of ≥1 HRCAs (gr 5) and presence of +1q and ≥1 HRCAs (gr 6). At median FU, OS was significantly lower in gr 1 compared with gr 2 (60.5% vs. 82.3%; p= 0.001), as was PFS (24.6% vs. 56.8%; p<0.001). OS was also lower in gr 4, 5 and 6, when compared with gr 3 [69.8% (vs 87.7%; p=0.019), 57.1% (vs. 87.7%; p<0.01) and 40.6% (vs. 87.7%; p=0.02), respectively], as well as PFS [23.0% (vs 67.0% p<0.001), 23.4% (vs. 67.0%; p=0.011) and 34.4% (vs. 67.0% p=0.032), respectively]. When comparing gr 1 and 2 according to induction regimen (IMiD vs non-IMiD), there was lower OS in gr 1 (56.0% vs. 80.9%; p=0.003) with non-IMiD-based regimens, but no difference with IMiD-based regimens (76.7% vs. 83.4%; p=0.288). In multivariate Cox-regression analyses including age, presence of HRCAs, presence of +1q, and IMiD-based induction regimens, +1q remained a significant and independent adverse factor for OS [HR 2.46 (95% CI 1.34-4.52); p=0.004] and PFS [2.13 (95% CI 1.34-3.38); p=0.001], whereas HRCAs only significantly impacted OS [3.03 (95% CI 1.61-5.72); p=0.001].

Summary/Conclusion: Our results corroborate the high prevalence of +1q in MM, although we found no association with any specific clinical characteristics at diagnosis. +1q had a significant negative impact in OS and PFS. IMiD-based regimens may have a beneficial effect in terms of survival in this subgroup of patients.



EP1033 OVERALL AND COMPLETE RESPONSE RATES AS POTENTIAL SURROGATES FOR OVERALL SURVIVAL IN RELAPSED REFRACTORY MULTIPLE MYELOMA

P. Daniele [1,*], C. Mamolo [2], J. C. Cappelleri [2], T. Bell [3], A. Neuhof [3], G. Tremblay [1], M. Musat [4], A. Forsythe [4]

[1]Purple Squirrel Economics, Montreal, Canada, [2]Pfizer Inc, Groton, [3]Pfizer Inc, [4]Purple Squirrel Economics, New York, United States

Background: Several recent clinical trials in relapsed refractory multiple myeloma (RRMM) have demonstrated significant improvements in overall response rates (ORR), complete response (CR), and progression-free survival (PFS); however, few have reported improvement in overall survival (OS). As the "gold standard" for measuring the clinical benefits of a cancer drug, OS requires larger patient cohorts and longer follow-ups compared with other clinical trial endpoints.
Aims: The surrogacy of PFS for OS has been previously reported in RRMM; however, these analyses did not include most recent studies. This analysis aimed to investigate ORR and CR as potential surrogate endpoints for OS.
Methods: A systematic literature review of randomized controlled trials (RCTs) and single-arm studies in RRMM was conducted to identify studies that reported ORR or CR in addition to median OS. Medline, Embase, and Cochrane databases were systematically searched for randomized controlled trials published from 2010 to Jul 2020. Relevant congress abstracts from 2018 to 2020 were also reviewed. Correlations of OS with ORR and with CR were evaluated using Pearson's product–moment correlation weighted by study sample size. Unadjusted and adjusted weighted linear regression models were constructed to estimate the gain in median OS associated with each surrogate endpoint. Optimal adjusted models considered age, sex, study year, MM type, International Staging System risk stage, prior stem cell transplant, prior lines of therapy, and treatment type.
Results: Sixty-five studies were identified, including 55 treatment arms from 33 RCTs. Moderate-to-strong significant correlations were observed for median OS with ORR (Pearson r=0.79) and CR (r=0.57). The unadjusted absolute analysis models estimated an increase of 0.48 (95% CI: 0.39, 0.57) and 1.94 (95% CI: 1.36, 2.51) months of median OS on average for every additional percentage point of ORR and CR, respectively (Figure 1). Following adjustment for age, relapsed vs refractory MM, and study year, the association was essentially unchanged at 0.46 (95% CI: 0.34, 0.58) and attenuated to 1.17 (95% CI: 0.65, 1.69) months of median OS for each additional point of ORR and CR, respectively.

Figure 1. Scatterplots of ORR and CR with Unadjusted Linear Model

Unadjusted linear model overlayed over raw data for A, ORR (%) vs OS (months; and B, CR (%) vs OS (months).
Note: Point size relates to the sample size of each study arm.
CR: complete response; ORR: overall response rate; OS: overall survival; mOS: median overall survival

Summary/Conclusion: We demonstrated significant associations of median OS with ORR and CR, supporting the use of ORR and CR as surrogate endpoints for OS benefit in RRMM. Because MM is considered incurable, increasing survival is a key endpoint from both a clinical standpoint and a humanistic standpoint. Being able to predict survival outcomes through endpoints available earlier in a trial may help expedite the approval of novel therapeutics to address this unmet need. In addition, based on unadjusted analysis, there is a clear trend towards higher ORR and CR rates and longer survival among patients with relapsed disease compared with patients with refractory disease. Adjusted models estimated that a 10% increase in ORR predicts a 4.6 month increase in median OS, and a 5% increase in CR predicts a 5.85 month increase in median OS. Often, early phase trials provide initial evidence of treatment benefit, but the follow-up is not long enough to calculate OS. These results suggest that ORR results in initial trials can be used to project survival outcomes, thus potentially informing the design of subsequent trials and accelerating patient care and treatment.

EP1034 BENDAMUSTINE-BORTEZOMIB-DEXAMETHASONE (BVD) IN HEAVILY PRETREATED MULTIPLE MYELOMA: OLD/NEW IN NOVEL AGENTS' ERA

C. Cerchione [1,*], L. Catalano [2], D. Nappi [3], S. Rocco [4], S. Palmieri [4], A. E. Pareto [5], G. Musuraca [1], A. Lucchesi [1], S. Ronconi [1], M. Ceccolini [1], F. Pane [2], F. Ferrara [4], G. Martinelli [1]

[1]Hematology Unit, Istituto Scientifico Romagnolo per lo Studio e la Cura dei Tumori (IRST) IRCCS, Meldola (FC), [2]Hematology, AOU Federico II, Napoli, [3]Hematology, Bolzano Hospital, Bolzano, [4]Hematology, AORN Cardarelli, Napoli, [5]Hematology, San Giuliano, Giugliano (NA), Italy

Background: Bendamustine is an old bi-functional alkylating agent which has proved to be effective in relapsed, refractory and in new diagnosed Multiple Myeloma (MM).
Aims: Thus, aiming to provide further insights in this field, also in novel agents'era, we present here a retrospective, real-life analysis of patients with relapsed/refractory MM (rrMM), who had received salvage therapy with bendamustine in combination with bortezomib and dexamethasone (BVD)
Methods: 81 patients (44 M/37 F), with rrMM, median age at diagnosis 59.4 years (r. 36-82), median age at start of treatment 63.6 years (r.37-86) treated with several lines of treatments (median 6, r. 2-11), every refractory to all the drugs previously received (also Bortezomib), received BVD (B 90 mg/sqm days 1,2; V 1.3 mg/sqm days 1,4,8,11, D 20 mg days 1,2,4,5,8,9,11,12, Pegfilgrastim day +4) every 28 days, until progression. All patients had previously received bortezomib-based and IMIDs-based treatments, and 32% (26/81) had also received radiotherapy. 69% (56/81) had undergone single or double autologous and three (2%) allogeneic stem cell transplant. All patients were relapsed and refractory to last therapies received before BVD.
Results: Bendamustine was well tolerated, with grade 3-4 transfusion-dependent anemia in 56% (46/81) of patients, and 43% (35/81) grade 3-4 neutropenia (no ospedalization was required, no septic shocks were observed). No severe extrahematologic toxicity was observed, only grade 1 gastrointestinal side effect (nausea), treated by common antiemetic drugs. According to IMWG, ORR was 63% (51/81: 7 CR, 18 VGPR, 15 PR, 11 MR) with 11 PD and 19 patients in SD, which can be considered as an impressive result in this subset of rrMM patients. In particular, for 11 patients, BVD was, after having achieved at least

a PR, a bridge to second auSCT, and for two patients a bridge to allo-SCT. Eight patients have surprisingly achieved a notable PR after failure of novel agents (i.e. Carfilzomib, Daratumumab and Pomalidomide). Median time to response was 1.3 months (r.1-3), median OS from diagnosis was 67.3 months (r.6-151), median OS from start of Bendamustine was 9.6 months (r.2-36).

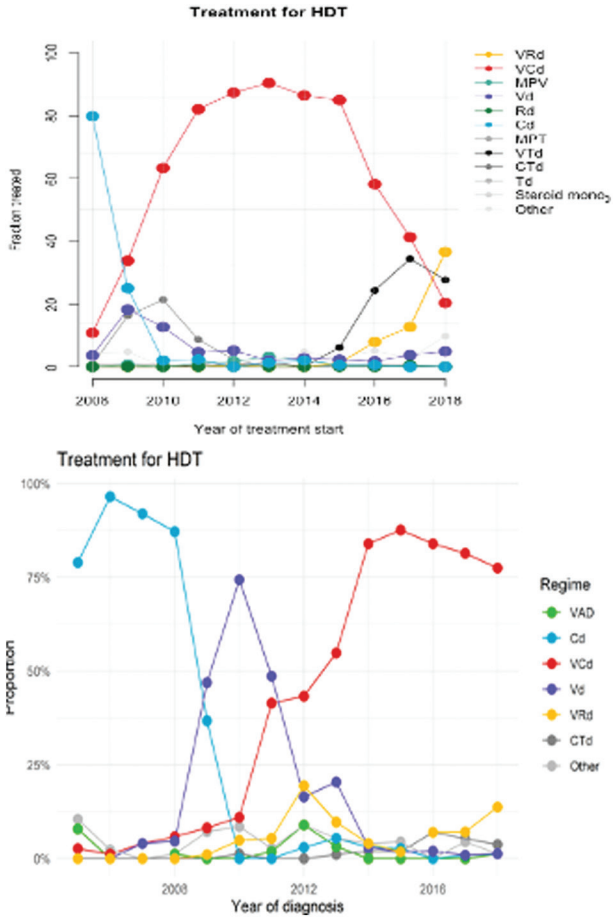
Summary/Conclusion: The triplet Bendamustine-Bortezomib-Dexamethasone has shown significant efficacy in a particularly severe setting of patients, relapsed and refractory to all available therapeutic resources, and, in particular cases, it could be considered as a bridge to a second autologous or allogenic SCT, also after failure of novel agents.

EP1035 RAPID IMPLEMENTATION NATIONWIDE OF NEW TREATMENTS IN MULTIPLE MYELOMA, EXPERIENCE FROM MORE THAN 10.000 PATIENTS IN THE DANISH AND SWEDISH NATIONAL REGISTRIES.

C. Hveding Blimark [1,*], A. Juul Vangsted [2], T. W. Klausen [3], H. Gregersen [4], A. Gyula Szabo [5], E. Hermansen [6], G. Wålinder [7], D. Knut-Bojanowska [8], C. Zang [9], I. Turesson [10]

[1]1Department of Hematology, Sahlgrenska University Hospital, Institution of Internal Medicine, Sahlgrenska Academy at the University of Gothenburg, Gothenburg, Sweden, [2]Department of Hematology, Rigshospitalet, Copenhagen, [3]Department of Haematology, Herlev Hospital, Herlev, [4]Department of Haematology, Aalborg University Hospital, Aalborg, [5]Department of Haematology, Vejle Hospital, Vejle, [6]Department of Haematology, Zealand University Hospital, Roskilde, Denmark, [7]Department of hematology Karolinska University Hospital Huddinge, Karolinska Institute, Stockholm, [8]Department of Haematology, Uddevalla sjukhus, Uddevalla, [9]Regional Cancer Centre West, Sahlgrenska University Hospital and Institution of Internal Medicine, Sahlgrenska Academy at the University of Gothenburg, Gothenburg, [10]Department of Haematology, Skåne University Hospital, Malmö, Sweden

Background: National registers including all multiple myeloma (MM) patients can give fast information on the implementation and effect of new treatment strategies. In Denmark ans Sweden MM patients have been registered at diagnosis of MM since 2005 and 2008, respectively. Data in characteristics, treatment and outcome is collected and the coverage is close to 100% coverage.



Aims: By merging the national databases in Sweden and Denmark where drug access and treatment guidelines are comparable and MM care universal, we study the implementation of guidelines and the effect of treatments in the real world.

Methods: We present treatment data from 10.062 patients annotated in the Danish Multiple Myeloma Registry (DMMR; n=4177) in the calendar period 2005 to 2018 and the Swedish Myeloma registry (SMR; n=5885) in the calendar period 2008-2018. Induction treatments for patients undergoing high-dose melphalan and autologous stem cell transplant, and first line treatment for patients with non-HDM/ASCT is presented.

Results: In both countries, 30% of newly diagnosed patients received HDM/ASCT upfront. Figure 1 A (above) and B (below) illustrate the use of induction treatment preceding HDT/ASCT for 1791 in Sweden, and 1281 patients in Denmark, respectively. Before 2010, induction treatment consisted of two-drug combinations of either cyclophosphamide/dexamethasone (Cydex) or bortezomib/dexamethasone (Vd) in both countries. Later, the 3-drug combination bortezomib/cyclophosphamide/dexamethasone (VCD) soon became a commonly used induction treatment. From 2015 an increasing proportion received 3-drug combinations containing an immunomodulatory drug (IMiD), a proteasome inhibitor (PI) and dexamethasone. In 2017-2018, the proportion of patients receiving induction treatment with VCD, thalidomide combinations and VRD was 79.8 %, 4.7% and 9.8 % in Denmark and VCD, VTd and VRD 32%, 32%, and 22% in Sweden, respectively.

In elderly patients, the use of 2-drug alkylator-based regimens melphalan/prednisone (MP) in Sweden and MP or CyDex in Denmark gradually shifted towards 2- or 3-drug combinations with an IMiD or a PI. In Sweden the use of MP decreased from 50 % in 2008 to 5 % in 2017-2018 and was replaced first by the combination of melphalan/thalidomide/prednisone (MPT) and later by melphalan/bortezomib/prednisone (MPV). In Denmark, a similar decrease in the use of MP was observed with a shift from MP to MPT followed by MPV. After 2015 an increasing proportion in both countries were treated with the combinations Vd and VCD while the use of lenalidomide-based combinations differed, with more patients treated with VRd in Denmark. In 2017-2018 the proportion of elderly patients treated with VD, VCD, Rd or VRD in 1st line were 13.1%, 20.7%, 8.7%, 15.0% in Denmark and 21%, 11%, 10%, and 7% in Sweden, respectively.

In the DMMR we show an increase in 5-year OS in patients ≤65 year from 59.8% in the calendar period 2008-2013 to 73.4% in the calendar period 2014-2019. In the same calendar periods an increase in 5-years OS was also noted for patients > 65 years from 27.5% (2008-2013) to 39.8% (2014-2019)(www.myeloma.dk). Similarly, in the SMR, in all patients diagnosed 2008-2019, the 5-year OS is now reaching 70% in patients ≤65 and 35% in patients >65 years (www.cancercentrum.se/Årsrapport2020).

Summary/Conclusion: National registries that include all MM patients are an important source of knowledge on treatment and outcome. Our data show that new treatment strategies are rapidly implemented in both countries in parallel with increased OS for all patient groups.

EP1036 DARATUMUMAB MONOTHERAPY IN NEWLY DIAGNOSED PATIENTS WITH STAGE 3B LIGHT CHAIN (AL) AMYLOIDOSIS: A PHASE II MULTICENTER STUDY BY THE EUROPEAN MYELOMA NETWORK

E. Kastritis [1,*], M. C. Minnema [2], M. A. Dimopoulos [1], G. Merlini [3], F. Theodorakakou [1], D. Fotiou [1], A. Huart [4], K. Belhadj [5], P. Sonneveld [6], G. Palladini [3]

[1]Department of Clinical Therapeutics, National and Kapodistrian University of Athens, School of Medicine, Athens, Greece, [2]Department of Hematology, University Medical Center Utrecht, Utrecht, Netherlands, [3]Amyloidosis Research and Treatment Center, University of Pavia, Pavia, Italy, [4]Department of Nephrology and transplantation, Rangueil University Hospital, Toulouse, [5]Lymphoid Malignancies Unit, Henri Mondor Hospital, Créteil, France, [6]Erasmus University Medical Center, Rotterdam, Netherlands

Background: Light chain (AL) amyloidosis is a plasma cell disorder where amyloid deposition occurs in various tissues and organs. Heart is affected in most patients and cardiac dysfunction is the leading cause of death. Cardiobiomarker-based staging identifies patients with extremely

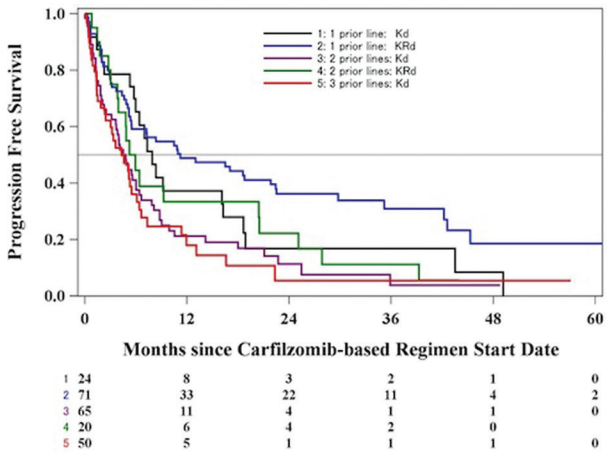
poor outcomes. These patients with stage 3B disease have a dismal prognosis of just a few months which despite recent advances has not been improved, mainly due to delays in hematologic responses and treatment-related toxicities. Daratumumab (DARA), a human IgG1κ monoclonal antibody which targets CD38, has shown rapid, deep, and high rates of response in patients with AL amyloidosis, and with a favorable safety profile.
Aims: The present analysis aims to evaluate the safety profile of DARA monotherapy in this high-risk population.
Methods: EMN22 is an open-label, multicenter, Phase 2 study aiming to enroll approximately 40 pts from 4 countries (Greece, the Netherlands, Italy, and France) with newly diagnosed stage 3B AL amyloidosis (i.e., with both a high sensitivity Troponin T (hsTnT) >54 pg/ml and NTproBNP ≥8500 pg/ml) who will receive primary therapy with DARA monotherapy. Pts initially received intravenous DARA, but from 2/2020 receive subcutaneous DARA at a fixed dose of 1800 mg, weekly for Cycles 1–2, every 2 weeks for Cycles 3–6, and every 4 weeks thereafter. Treatment continues until disease progression according to Major Organ Deterioration Progression-Free Survival (MOD-PFS) criteria, initiation of subsequent therapy, or a maximum of 2 years. Pts who do not achieve at least a hematologic VGPR, or hematologic PR with cardiac or renal response, may receive at Investigator's discretion additional treatment with Bortezomib (weekly for a maximum of 6 months) and low dose dexamethasone from Cycle 4. The current analysis includes pts who received the first dose of treatment at least 6 months prior to the cut-off date (31/01/2021).
Results: Overall, 7 pts were included. Median age was 65 years, and the majority were male (6 pts). Median baseline NT-proBNP and hsTnT levels were 33,442 and 166 pg/mL, respectively. ECOG Performance Status was 1 for 4 pts, 2 for 2 pts and 3 for 1 pt. Pts have received a median of 13 cycles, and until the cut-off date 4 pts are still on treatment; 3 pts died due to complications of the disease; no patient died due to treatment-related cardiac complications. In total, 6 pts had ≥1 adverse event (AE) grade 3 or 4, and 5 pts experienced ≥1 serious adverse event (SAE). No IRRs were reported. Most common grade 3/4 AEs were dyspnea (3 pts), atrial fibrillation (2 pts), and peripheral edema (2 pts). There were 10 SAEs reported: congestive heart failure (n=2, one of them fatal), dyspnea (n=2), atrial fibrillation, intracranial hemorrhage, muscle hemorrhage, sepsis (fatal), septic shock, and sudden death (1 pt each). Overall, 4 pts achieved a hematologic response (median time to first response <1 month), with 1 pt reaching PR, 2 pts VGPR, and 1 pt CR (also MRD negative). From the deceased pts, one died while in unconfirmed hematologic response while 2 pts had already discontinued treatment due to hematologic progression and major organ deterioration. The 6-month OS rate was 57.1%.
Summary/Conclusion: This early analysis shows that DARA monotherapy is safe with no treatment-related safety events or any signal of cardiac toxicity in patients with stage 3B disease. The enrollment in the study continues and more data will be available on safety and efficacy with the inclusion of additional patients in the updated analysis.

EP1037 PREDICTIVE FACTORS RELATED TO DISEASE PROGRESSION IN PATIENTS WITH MONOCLONAL GAMMOPATHY OF UNDETERMINED SIGNIFICANCE IN A SINGLE CENTER DURING 9 YEARS

J. Zhao [1], J. Zhuang [1,*]

[1]*Department of Hematology, Peking Union Medical College Hospital, Beijing, China*

Background: MGUS is the asymptomatic state of multiple myeloma and other plasma cell diseases.
Aims: To explore the disease progression rate and related factors in patients with monoclonal gammopathy of undetermined significance (MGUS).
Methods: NLP natural language processing technology and RegEx regular expression technology were used to mine clinical data from the medical hospital information system (HIS) of Peking Union Medical College Hospital and manage unstructured data. MGUS patients diagnosed from January 1, 2012 to January 31, 2021 were included, and demographic information, clinical data and follow-up results were recorded. A Cox regression model was established to evaluate the hazard ratio (HR) of various factors to the progression of multiple myeloma and other plasma cell diseases. According to the screened risk factors, a risk-stratification model was established to calculate the risk of disease progression (PD) under different risk strata.
Results: 1. A total of 1288 patients with MGUS were enrolled with a median age of 65 years (21-100), majority over 50 years old (86.3%). During a median follow-up of 41 months (3-127), 74 cases developed into plasma cell diseases such as multiple myeloma, Waldenström macroglobulinemia, POEMS syndrome and amyloidosis, with an average annual progression rate of 0.54%.
2. Univariate analysis of Cox regression model showed that a history of cancer (HR 5.260, P< 0.001), Fanconi syndrome (HR 5.268, P=0.021) and abnormal ratio of serum free light chain (sFLC) (HR 1.347, P=0.013) were risk factors for the disease progression of MGUS. Multivariate analysis suggested that serum M protein ≥15g/L (HR=2.778,95%CI 1.464-5.271, p=0.00176) and IgG M protein (HR=1.847,95%CI 1.006-3.391, p=0.04778) were risk factors for PD.
3. The Cox model was used to establish a risk stratification model. If two risk factors (M protein ≥15g/L, IgG type) were included, compared with the low-risk group (M protein <15g/L, non-IgG type), the relative risk (RR) of PD in the intermediate-risk group (1 risk factor) and high-risk group (2 risk factors) were 1.51 and 4.15, respectively. If three risk factors (a history of cancer was added) were included, compared with the low-risk group (none), the relative risk (RR) of progression in low-intermediate-risk, intermediate-high-risk and high-risk groups (1,2 and 3 risk factors, respectively) were 1.43,3.80 and 11.40, respectively.
Summary/Conclusion: During past 9 years, the disease progression rate of MGUS in our center is 0.54% per year. Serum level of M protein ≥15g/L, IgG M protein, a history of cancer are the predictive factors of disease progression. The annual disease progression rate of Asian MGUS is lower than that of European and American data.



EP1038 CARFILZOMIB-CONTAINING REGIMENS FOR RELAPSED MULTIPLE MYELOMA IN A REAL-WORLD SETTING: A MULTI-INSTITUTIONAL REPORT FROM THE CANADIAN MYELOMA RESEARCH GROUP (CMRG)

A. McCurdy [1,*], M. Louzada [2], C. P. Venner [3], E. Masih-Khan [4], V. H. Jiminez-Zepeda [5], R. LeBlanc [6], M. Sebag [7], K. Song [8], D. White [9], H. Mian [10], E. Atenafu [11], J. Stakiw [12], A. Reiman [13], M. Aslam [14], R. Kotb [15], E. Gul [11], D. Reece [16]

Background: Carfilzomib is approved for relapsed multiple myeloma (RRMM) based on 2 randomized controlled trials (RCTs). The ASPIRE trial of KRd after 1-3 prior lines (PLs) of therapy showed a progression-free survival (PFS) of 26.3 and overall survival (OS) of 48.3 mo,[1] while the ENDEAVOR trial of Kd reported a PFS of 18.7 and OS of 47.6 mo.[2] A recent analysis showed that >75% of patients (pts) with RRMM in routine practice would have been ineligible for pivotal RCTs.[3] Therefore, evaluation of the real-world (RW) efficacy of these regimens is needed.[4]
Aims: To evaluate the efficacy of carfilzomib-based regimens in a RW data set of pts with RRMM and 1-3 PLs of therapy.
Methods: We performed a retrospective study using the Canadian Myeloma Research Group Database (CMRG-DB), which includes >7500 MM pts from 15 Canadian sites and legacy data from 2007. All RRMM pts treated with approved carfilzomib-based therapies after 1-3 PLs analyzed up to 31/10/2020 were included. Primary outcome was PFS with each therapy; overall response rate (ORR), ≥very good partial response rate (VGPR), and OS were secondary outcomes. Survival was estimated using Kaplan-Meier methods.
Results: A total of 235 pts were identified: 139 treated with Kd and 96 with KRd. In the Kd group, 131 (94.2%) had prior PI and 93 (66.9%) had prior IMiD. For the KRd group, 93 (96.9%) had prior PI, and 19 (19.8%) had prior IMiD. In the Kd cohort, 24 (17.3%) of pts had 1 PL, 65 (46.8%) had two PLs, and 50 (36.0%) had three PLs of therapy. In

the KRd group, 71 (74%), 20 (20.8%) and 5 (5.2%) had one, two, or three PLs, respectively.
The ORR of the entire Kd cohort was 49.6%, with ≥VGPR in 27.0%. Median PFS was 5.2 mo and OS was 16.7 mo. By PL of treatment in the Kd cohort: ORR was 69.6%, ≥VGPR was 30.4%, median PFS was 7.92 mo and OS was 34.0 mo for pts with 1 PL; ORR was 48.1%, ≥VGPR was 28.9%, median PFS was 4.80 mo and OS was 19.69 mo for pts with two PLs; and ORR was 38.9%, ≥ VGPR was 22.2%, median PFS was 4.31 mo, and OS was 12.39 mo for pts with three PLs.
The ORR of the entire KRd cohort was 67.1%, with 53.2% of pts achieving ≥VGPR. The median PFS was 10.49 mo and OS was 42.84 mo. For 1PL, ORR was 66.1%, ≥VGPR was 50%, PFS was 11.21 mo, and OS was 42.84 mo; for 2PLs, ORR was 54.6%, ≥VGPR was 27.3%, median PFS was 5.61 mo, and OS was 15.52 mo. The 5 pts with three PLs were too few to evaluate separately.

Summary/Conclusion: In this real-world observational study, the responses and efficacy were less than that demonstrated in prospective RCTs. However, our findings are consistent with those reported by Chari et al in 208 patients with relapsed MM treated with KRd after a median of 2 PLs who experienced a median TTNT of 9.5 months[5] and in other real-world observational studies of carfilzomib-based regimens.[6,7] An improved understanding of the reasons underlying the difference in effectiveness, such as recent availability of more potent initial treatments, may lead to improved clinical decision-making and translate into better real-world outcomes.

EP1039 MULTIPLE MYELOMA TREATMENT PATTERNS AND OUTCOMES IN THE PUBLIC AND PRIVATE HEALTHCARE SYSTEMS IN BRAZIL: ONE COUNTRY, TWO WORLDS - MMYBRAVE STUDY

V. T. D. M. Hungria [1,*], R. I. Bittencourt [2], G. A. Martinez [3], J. D. A. Santos [4], D. R. Almeida [5], V. L. D. P. Figueiredo [6], D. L. C. Farias [7], K. R. Zanella [8], L. B. Muniz [9], D. Mendonça [10], R. M. Abreu [10], J. Senra [10], É. R. Mattos [11]

[1]Clínica São Germano, São Paulo, [2]Hospital de Clínicas of Porto Alegre (HCPA), Universidade Federal do Rio Grande do Sul, Porto Alegre, [3]Hospital das Clínicas, Faculdade de Medicina of Universidade de São Paulo, São Paulo, [4]CEHON – Centro de Hematologia e Oncologia, Salvador, [5]Hospital São Vicente de Paulo, Passo Fundo, [6]Hospital do Servidor Público de São Paulo, São Paulo, [7]Hospital das Clinicas, Universidade Federal de Goiás, Goiania, [8]CEPON - Centro de Pesquisas Oncológicas, Florianópolis, [9]Casa de Saúde Santa Marcelina, [10]Medical Affairs, Takeda Distribuidora Ltda., São Paulo, [11]Centro de Ensino e Pesquisas, Fundação Dr. Amaral Carvalho, Jaú, Brazil

Background: Over the past two decades, the approval of several novel drugs has broadened therapeutic options for multiple myeloma (MM) patients, but has also raised concerns about increasing drug expenses and healthcare costs in general. Access to these treatments in public and private settings in Brazil differs significantly and it is unknown if shortcomings in treatment availability affect patient outcomes.
Aims: To understand the patient characteristics, treatment patterns and MM patient outcomes in private and public settings in Brazil.
Methods: MMyBrave is an observational, retrospective study with no control group. Eligible patients were diagnosed with active MM between January 1, 2008 and December 31, 2016 (cut-off date), at 17 public and private medical centers in Brazil. The MM diagnosis was performed at the discretion of the investigator. The data collection started on June 2018, after ethical approval, and progressed until August 2019. Sites with patients from both private and public sectors were considered hybrid centers.
Results: A total of 943 patients were included. Private, public and hybrid centers accounted for 49.3, 43.7 and 7.0% of patients, respectively. The mean age and male percentage at private, public and hybrid centers were 68.6, 68.5 and 66.0 years and 56.3, 51.2 and 50.0%, respectively. The International Staging System stages I, II and III and unknown stages were: 24.7, 24.1, 26.7 and 24.5 at private centers; 14.3, 18.4, 24.3 and 43.0 at public centers, and; 12.1, 19.7, 40.9 and 27.3% at hybrid centers. A total of 47.9% (41.8% public, 50.4% private and 7.7% hybrid) were eligible for stem cell transplantation (SCT). Proteasome inhibitor (PI) regimens (mainly regimens with bortezomib) were used by 50% at private centers (56% in SCT eligible (TE); and 44% in SCT ineligible (TI)), 11% at public centers (46% TE and 54% TI) and 8% at hybrid centers (80% TE and 20% TI). Regarding immunomodulator regimens (mainly thalidomide and rarely lenalidomide), 39% at private centers (53% TE and 47% TI), 71% at public centers (53% TE and 47% TI) and 80% at hybrid centers (58% TE and 42% TI). PI-immunomodulator regimens were used by 4% at private centers (93% TE and 7% TI) and 2% at public centres (17% TE and 83% TI). During the second-line treatment, PI regimens accounted for 46% at private centers, 31% at public centers and 17% at hybrid centers; immunomodulator regimens accounted for 27% at private centers (96% thalidomide and 4% lenalidomide), 57% at public centers (99% thalidomide and 1% lenalidomide) and 61% at hybrid centers (100% thalidomide). PI-immunomodulator regimens accounted for 16% at private centers and 3.0% at public centers. Less than 1% of patients have been treated with carfilzomib, daratumumab, ixazomib and pomalidomide. The median OS was 6.4 and 4.8 years ($p = 0.001$) for patients in the private and public systems; 8.2 and 4.3 years for TE (intention-to-treat population) and TI ($p < 0.0001$), respectively.

Figure 1: Kaplan-Meier overall survival curves for MM patients, eligible for SCT and ineligible (A) and private and public healthcare system (B).

Summary/Conclusion: Real-world MM patient outcomes at private and public institutions in Brazil were quite different. The superior OS among patients in the private healthcare system may be due, at least in part, to a wider availability of therapies enabling individualized management of MM patients.

EP1040 THE USE OF NON-CRYOPRESERVED AND CRYOPRESERVED HEMATOPOIETIC STEM CELLS FOR AUTOTRANSPLANTATION IN MULTIPLE MYELOMA.

A. Garifullin [1,*], S. Voloshin [1,2,3], S. Linnikov [1], A. Kuzyaeva [1], V. Balashova [1], Z. Chebukina [1]

[1]Russian Research Institute of Hematology and Transfusiology, [2]Military Medical Academy named after S.M. Kirov, [3]North-Western State Medical University named after I.I. Mechnikov, Saint-Petersburg, Russian Federation

Background: Bone marrow (peripheral blood stem cells (PBSCs)) autologous transplantation is the standard care for transplant-eligible patients with multiple myeloma. This treatment option is somewhat limited due to the high consumption of economic resources and the access to

Cryobank. We performed a retrospective analysis of multiple myeloma patients who underwent autologous transplantation using non-cryopreserved and cryopreserved grafts at our institution from March 2016 to April 2020.
Aims: Compare the results of autologous transplantation using non-cryopreserved and cryopreserved hematopoietic stem cells (HSC).
Methods: 78 patients with MM were included in the study (male/female ratio 1.3:1).
All patients got the standard immunochemotherapy programs. They had remission (≥partial response) till the auto-HSCT. Patients were divided in two groups depending on the technique of HSC storage: non-CRYO (n=35) and CRYO (n=43). Cryopreservation is a standard method of storage of HSC suspension. In our work we used the native HSC suspension which was saved from +4 °C to +6 °C during 72 hours.
An effectivity and safety were evaluated in such parameters as the number of CD34+ and 7AAD- cells, colony-forming ability (CFA). All of these were made after apheresis and before reinfusion of HSC.
Additionally, the effectiveness of therapy was assessed according to the IMWG and MRD response criteria before SCT and on day +100.
Results: There were no differences in the total number of CD34 + cells x 10^6/kg, or in the level of 7AAD– cells, or in the total CFA. However, there was a significant difference in the percentage of loss of CD34+ cells from the moment of apheresis to the moment of reinfusion. We suppose it was caused adverse effects by temperature changes in CRYO group. In both groups, there were no severe infusion reactions on day 0. The adverse events were absent in the non-CRYO group. But 29/43 (67.4%) patients had such symptoms in the CRYO group on day 0 (nausea and vomiting – 7 patients (16,3%), tachycardia – 16 patients (37,2%), stenocardia – 3 patients (7,0%), arterial hypertension – 6 patients (13,9%), increased total bilirubin and indicator liver enzymes – 5 patients (11,6%)).
All patients had full recovery of hematopoiesis till discharge from the hospital. Neutrophil recovery was achieved at 11th day (range 9-14) and platelets at 12th day (range 8-19) in the non-CRYO group, and 10th day (range 8-14) and 12th day (range 8 -20) in the CRYO group, respectively.
The frequency of achieving a partial response before autoHSCT was 37% (13/35), a very good partial response - 40% (14/35), a complete response - 23% (8/35) in the non-CRYO group and 72% (31/43), 14% (6/43) and 14% (6/43) in the CRIO group, respectively. HSCT was improved the efficiency of treatment as well as the frequency of complete and MRD-negative responses in both groups. Partial response after autoHSCT was achieved in 23% (8/35) patients, very good partial response in 40% (14/35), complete response in 37% (13/35) in the non-CRYO group compared to the CRYO group (47% (20/43), 21% (9/43) and 32% (14/43), respectively).
The MRD status was assessed before and after autoHSCT in 48 patients. The frequency of MRD-negative response before autoHSCT was 37,5%, after transplantation – 54,5% in the non-CRYO group and 16% and 33% in the CRYO group, respectively.

Tab. 1. The results are presented in the comparison table of the evaluated parameters.

Parameters	Non-CRYO (n=35)	CRYO (n=43)	p
CD34 + (apheresis) x10^5 / kg	5,48±3,13	5,1±2,98	0,59
CD34 + (reinfusion) x10^5 / kg	2,71±1,36	2,49±1,17	0,44
7-AAD - (apheresis), %	98,65±1,64	99,11±1,35	**0,002**
7-AAD - (reinfusion), %	93,07±4,64	90,58±7,32	0,08
CFA, colonies 10^5/l (apheresis)	404,97±80,62	420,86±89,05	0,46
CFA, colonies 10^5/l (reinfusion)	306,71±138,66	257,55±126,46	0,14
Platelet transfusions, doses	4 (2-8)	4 (1-8)	0,35
Red blood cell transfusions, doses	1 (0-6)	1 (0-3)	0,18
Duration of hospital stay after HSCT, days	17 (13-26)	16 (11-24)	0,59
Febrile neutropenia, episodes	13 (37%)	21 (49%)	0,15
Enteropathy, cases	20 (57%)	13 (30%)	**0,02**
Mucositis, cases	15 (42%)	20 (46%)	0,37
Sepsis/bacteremia	0 (0%)	2 (5%)	
Pneumonia, cases	2 (6%)	2 (5%)	0,41
Mortality within 100 days after transplantation (%)	0 (0%)	0 (0%)	
No complications, number of patients (%)	6 (17%)	6 (14%)	0,35

Summary/Conclusion: The method of storage of PBSCs without cryopreserved is equal to traditional method controlled freezing with Dimethyl sulfoxide and can be used in hospitals which have no a Cryobank in their composition.

EP1041 MAINTAINING DELIVERY OF HIGH QUALITY SPECIALIZED CARE IN PATIENTS WITH MYELOMA DURING THE COVID-19 PANDEMIC: COMPARING 2019 TO 2020

E. Kastritis [1,*], M. Gavriatopoulou [1], M. Roussou [1], E. Eleutherakis-Papaiakovou [1], M. Migkou [1], N. Kanellias [1], D. Fotiou [1], I. Ntanasis-Stathopoulos [1], F. Theodorakakou [1], P. Malandrakis [1], E. Terpos [1], M. A. Dimopoulos [1]

[1]*Department of Clinical Therapeutics, National and Kapodistrian University of Athens, School of Medicine, Athens, Greece*

Background: The SARS-CoV-2 pandemic has caused innumerable social and economic consequences, has stressed health care systems, affecting the delivery of health care and raising concerns that many patients may have suffered delays in therapy and in the diagnosis of serious conditions, such as hematologic and other malignancies. This effect may be more pronounced in older patients, who are at higher risk for COVID-19 complications, but which may also be affected by social isolation and distancing, difficulties in reaching health care facilities and fear of acquiring the infection. Myeloma patients are a vulnerable, mostly elderly population who may have been affected in terms of diagnosis and treatment delivery during the pandemic. There is a concern that diagnosis may be delayed, potentially presenting with more advanced disease or more often with severe complications.
Aims: To provide evidence for the care of patients with myeloma, during the COVID-19 era, we compared the characteristics of newly diagnosed patients during 2020 and 2019 (i.e pre COVID-19 pandemic).
Methods: We compared baseline characteristics and short-term outcomes of newly diagnosed MM patients who were diagnosed and started therapy in a tertiary referral center (Department of Clinical Therapeutics, Athens) during two calendar periods, 2019 and 2020. Initial restrictive measures were first implemented in Greece in mid-February 2020 and national lockdown in mid-March. Data were collected through our prospectively maintained database that includes all patients with a diagnosis of myeloma in our center. Since the beginning of the pandemic in Greece, our department implemented preventive measures and operating procedures to ensure continuous delivery of care and reduce the risk of COVID-19 infection.
Results: In 2019, 125 MM patients with a new diagnosis of symptomatic disease started therapy vs 101 in 2020. The distribution of new cases per month was similar between the two years (p=0.542). Gender distribution was similar, but patients diagnosed in 2020 were slightly older (median 69 vs 66 years for 2019, p=0.084). There were no differences in baseline anemia, renal function, need for dialysis or ISS stage; however, slightly more patients had high risk cytogenetics in 2020 vs 2019 (37% vs 27%, p=0.129). The median time from the first test for the diagnosis to start of therapy was 15 days in 2019 vs 8 days in 2020. First line therapies were similar with the majority receiving a PI plus IMiD combination (mostly VRD: 70% in 2019 vs 76% in 2020). Radiotherapy due to MM-related complications was required in 2.4% vs 4% of patients in 2019 and 2020 respectively. Early mortality (death <3 months from start of therapy) was 2.4% in 2019 and 5% in 2020 (p=0.314). The number of autologous transplants was slightly smaller in 2020 vs 2019 (54 vs 61). Infection rates during induction, which may have been affected by the use of social distancing and protective measures, was similar (15% vs 16%); however, less patients required hospitalization for infection management in 2020 (in 8% vs 16% in 2019). Very few cases of COVID-19 occurred among our MM patients and in only one newly diagnosed MM patient.
Summary/Conclusion: Despite the pandemic, we did not observe significant delays or changes in the characteristics of patients that were diagnosed with myeloma between 2019 and 2020 in our center, neither in the short-term outcomes of our patients. Despite the pandemic it is possible to maintain delivery of high-quality specialized care in patients with myeloma.

EP1042 IXAZOMIB, LENALIDOMIDE AND DEXAMETHASONE IN ROUTINE PRACTICE: EXTENDED SUBGROUP ANALYSIS

J. Minarik [1,*], J. Radocha [2], A. Jungova [3], J. Straub [4], T. Jelinek [5], T. Pika [6], L. Pour [7], P. Pavlicek [8], M. Mistrik [9], L. Brozova [10], P. Krhovska [1], V. Maisnar [2], R. Hajek [5]

[1]Department of Hemato-Oncology, University Hospital Olomouc, Olomouc, [2]4th Department of Internal Medicine – Hematology, Faculty Hospital and Charles University in Hradec Kralove, Hradec Kralove, [3]Hematology and Oncology Department, Charles University Hospital Pilsen, Pilsen, [4]1st Medical Department – Clinical Department of Haematology, First Faculty of Medicine and General Teaching Hospital Charles University, Prague, [5]Department of Hematooncology, University Hospital Ostrava and Faculty of Medicine University of Ostrava, Ostrava, [6]Department of Hematooncology, University Hospital Olomouc, Olomouc, [7]Department of Internal Medicine, Hematology and Oncology, University Hospital Brno and Faculty of Medicine Masaryk University, Brno, [8]Department of Internal Medicine and Hematology, 3rd Faculty of Medicine, Charles University and Faculty Hospital Kralovske Vinohrady, Prague, Czech Republic, [9]Department of Hematology and Transfusiology, Faculty of Medicine, University Hospital Bratislava, Bratislava, Slovakia, [10]Institute of Biostatistics and Analyses, Ltd., Brno, Czech Republic

Background: Ixazomib, lenalidomide and dexamethasone (IRD) provide an efficient treatment for relapsed and/or refractory multiple myeloma (MM) based on the results of the TOURMALINE-MM1 study. Our recent analysis[1] showed that the IRD combination has a survival benefit over lenalidomide and dexamethasone alone (RD) in the routine practice.
In the registration trial, the subgroups with greater benefit included patients with 2 or 3 prior therapies, or 1 prior therapy without transplant. Our analysis showed better results in the first relapse with no adverse impact of previous autologous stem cell transplant (ASCT) on the outcome.
Aims: The aim of the present analysis was to determine which subgroups had adverse outcomes regardless of treatment used.
Methods: We assessed a group of 127 patients with relapsed and/or refractory MM treated with IRD and 217 patients with RD regimen. With known data on PFS (17,5 vs 11,5 months) and OS (36,6 vs 26,0 months) we looked for the subgroups who did not benefit from either therapy.
The analyzed parameters were: age (≤65, 66-75, >75 years), ISS stage, cytogenetics, presence of extramedullary disease (EM), line of treatment, maximal treatment response, pretreatment by proteasome inhibitors (PI), immunomodulatory drugs (IMiDs) or ASCT, disease status (relapsed vs relapsed and refractory).
Results: We previously reported adverse impact of EM in both IRD and RD arms (PFS 6,5 and 10,5 months), decreasing PFS with number of prior lines (1 line 32.7 vs 14.8 months, 2 lines 23.1 vs 9.3 months, 3 lines 9.7 vs 9.0 months and ≥4 lines 5.0 vs 9.9 months), with increasing age (≤65 years: 23.0 vs 10.8 months, 66-75 years: 17.8 vs 11.5 months, >75 years: 11.1 vs 11.7 years), more advanced disease by ISS stage (ISS 1 32.7 vs 17.1 months, ISS 2 25.8 vs 9.7 months, ISS 3 9.9 vs 6.4 months), and that there was no adverse impact of previous ASCT – patients after ASCT did better in IRD than RD arm (PFS 23.0 vs 9.7 months).[1]
The subsequent subgroup analysis showed following results: There was only a limited number of patients with known high-risk cytogenetics (IRD 15, RD 19), still, with a trend to negative impact on PFS (7,3 and 9,9 months). Pretreatment with PIs did not significantly affect the outcomes. There was, however, negative impact of exposure to IMiDs in both IRD (PFS 11,3 months vs not reached) and RD arms (PFS 9,3 vs 18,0 months). Patients who were relapsed and refractory did worse to those who were relapsed only in both IRD (PFS 9,7 months vs not reached) and RD arms (PFS 6,0 vs 14,8 months).
Summary/Conclusion: Most of the subgroups that do not benefit with either treatment, correlate with either patient´s overall condition or the aggressiveness of the disease itself. Groups with worse outcomes were as follows: later relapse (≥4), higher age (≥75 years), the presence of high risk features – extramedullary disease, high-risk cytogenetics, higher stage (ISS 3) and refractory status in the previous line. We did not find an adverse impact of pretreatment by PIs or ASCT but patients with previous IMiDs had worse outcomes in both IRD and RD arms.

EP1043 RESPONSE-ADJUSTED ISS SCORE IN TRANSPLANT INELIGIBLE PATIENTS WITH MULTIPLE MYELOMA: DOES IT MATTER?

A. Sretenovic [1,2,*], M. Mitrovic [1], V. Djurasinovic [1,2], D. Antic [1,2], M. Todorovic Balint [1,2], B. Mihaljevic [1,2], J. Bila [1,2]

[1]Clinic of Hematology, University Clinical Center of Serbia, [2]Medical Faculty, University of Belgrade, Belgrade, Serbia

Background: Achievement of the complete remission (CR) represents one of the most powerful prognostic indicators in patients (pts) with multiple myeloma, along with prognostic indices as International Staging System (ISS) and recently established Revised ISS score (R-ISS).
Aims: The aim of study was to analyze prognostic significance of Response-adjusted ISS (RaISS) in transplant ineligible MM pts.
Methods: The study included 257 newly diagnosed, transplant ineligible MM, diagnosed during period 2009-2020 (129 male; 128 female, mean age 66 yrs, range 35-85 yrs). The IgG myeloma was diagnosed in 155pts (60.3%), IgA in 50 (19.5%), BJ in 43 (16.7%), IgD in 3 (1.2%) and IgM in 1pt (0.4%). According to the clinical stage (CS, Durie-Salmon), patients were distributed as follows: III 207pts (80.5%); II 38pts (14.8%); and I CS 10pts (3.9%). Renal impairment was present in 82pts (31.9%) and elevated LDH in 58pts (22.6%). Regarding ISS score, the group included: ISS1 had 55pts (21.4%), ISS2 65pts (25.3%) and 137pts (53.3%) had ISS3. According to the Revised ISS (R-ISS) score, R-ISS1 was found in 40pts (15.6%), R-ISS2 in 164pts (63.8%), while R-ISS3 was present in 53pts (20.6%). Treatment with triple thalidomide (Thal) based chemotherapy (HT) was applied in 129pts (50.2%) with standard risk features (R-ISS1), while bortezomib (Bz) based triplets were applied in 95pts (37%) with high risk features (R-ISS2 and R-ISS3). Standard HT was applied in 33pts (12.9%).
Results: Considering RaISS score, the group of pts treated with Thal-based HT, consisted of: 15pts (11.6%) with low risk (RaISS 0-1); 65pts (50.4%) with intermediate risk (RaISS 2-3); and 49pts (40.3%) with high risk (RaISS 4). There was significant difference in PFS (Log Rank 7.197; p=0.027), and, even more pronounced, in OS (log Rank 22.192; p=0.000) between low risk pts (RaISS 0-1), and intermediate or high risk pts (RaISS 2-3; RaISS 4), treated with Thal-based HT. The distribution according the RaISS score in the pts group treated with Bz-based combos was as follows: low risk - 11pts (11.6%); intermediate - risk 36pts (37.9%); high risk- 48pts (50.5%). Although there was no difference in PFS (Log Rank 3.307; p=0.191), pts of low risk, with RaISS score 0-1, had significantly longer OS (Log Rank 13.894; p=0.001) in comparison to the pts of intermediate and high risk (RaISS ≥2), treated with Bz-based triplets. There was no difference in PFS (Log Rank 0.008; p=0.930) or OS (Log Rank 0.502; p=0.479) between pts with RaISS 4, and pts with R-ISS 3 (Log Rank 0.008; p=0.930) treated with Thal-based HT. Likewise, no difference was found considering PFS (Log Rank 0.168; p=0.682) and OS (Log Rank 0.923; p=0.337) in patients treated with Bz-based triplets with RaISS 4 in comparison to the pts with R-ISS3.
Summary/Conclusion: RaISS score represents simple and powerful prognostic tool. Compared to R-ISS scoryng system, it seems that tailored treatment approach according to the R-ISS, overcomes high-risk features in patients with multiple myeloma.

EP1044 CHARACTERISTICS AND OUTCOME OF TRANSPLANT INELIGIBLE MYELOMA PATIENTS ACHIEVING SUSTAINED PARTIAL RESPONSE VS. THOSE EXHIBITING COMPLETE REMISSION AFTER 1ST LINE THERAPY: SINGLE CENTER REAL-WORLD DATA

T. Triantafyllou [1,*], V. Palaska [1], K. Tsirou [1], E. Verrou [1], A. Sevastoudi [1], G. Douganiotis [1], K. Keramidioti [1], I. Diamanti [1], D. Markala [1], E. Yiannaki [1], P. Xirou [1], S. Barbanis [1], B. Christoforidou [1], A. Christoforidou [1], A. Papanikolaou [2], P. Konstantinidou [1], E. Terpos [3], E. Katodritou [1]

[1]THEAGENIO CANCER HOSPITAL, THESSALONIKI, [2]EVANGELISMOS GENERAL HOSPITAL, [3]NATIONAL AND KAPODISTRIAN UNIVERSITY OF ATHENS, ALEXANDRA HOSPITAL, ATHENS, Greece

Background: Complete remission (CR) is an important prognostic factor for overall survival (OS) in Multiple Myeloma (MM). The prognostic significance of sustained partial response (sPR) defined as PR >24

months, however, may be a sufficient goal in MM patients, ineligible for transplant (NTE). The characteristics of NTE MM patients who achieve sPR and its prognostic role has not been sufficiently explored.
Aims: Herein, we investigated the characteristics, the prognostic impact and OS rates of NTE patients achieving sPR, compared with those who achieve CR after induction therapy.
Methods: We studied 255 patients (M/F: 130/125, median age: 68, range: 43-83, IgG: 151. IgA: 64, light chain: 31, non-secretory: 9), who were considered eligible for analysis among 487 consecutive NTE MM diagnosed and treated in our department between 2001-2019; 62 fulfilled the criteria of sPR whereas the rest (n=193) achieved CR after induction treatment. Importantly, patients in CR were considered as eligible for analysis if OS exceeded 24 months. The 2 groups were compared for standard prognostic factors such as age, International Staging System (ISS) and revised ISS (RISS), β2 microglobulin (β2M), lactate dehydrogenase (LDH), hemoglobin (Hb) and estimated glomerular filtration rate (eGFR). Comparisons were performed with Pearson's x^2 test, Mann-Whitney-*U*-test and One-Way ANOVA. Prognostic factors for the type of response (sPR vs. CR) were evaluated with binary logistic regression analysis; OS was plotted with Kaplan-Meier; $p<0.05$ was considered as statistically significant boundary.
Results: Median age at diagnosis was higher in the sPR group. Patients with sPR had better performance status, higher eGFR and less often anemia, abnormal LDH, and advanced stage (ISS3/RISS3) at diagnosis ($p<0.05$). With regard to molecular cytogenetics overall, high-risk features were less common in the sPR group ($p<0.05$); in particular, t(4;14) was not detected in any patient with sPR vs. 10% in the CR group, whereas del17p was found in 2% of patients with sPR vs. 14% in the CR group ($p<0.05$); the rate of t(14;16) or 1q+ did not differ between groups ($p>0.05$); 71% of patients with sPR was treated upfront with novel agents compared with 24% of those in the CR group ($p<0.05$). Overall, 65% of the studied population received 2nd line therapy (sPR vs. CR group: 51% vs. 69%; $p<0.05$). Age >65, RISS1/2 and absence of anemia (Hb<10g/dL) were independent predictors for achieving sPR vs. CR ($p<0.05$). In the univariate analysis for OS, established markers such as ISS, RISS and LDH confirmed their prognostic value for the whole study population ($p<0.05$). In addition, type of response (sPR vs. CR) was an independent prognostic factor for OS after adjustment for the type of initial therapy (HR: 0.59; p=0.009). Patients who achieved sPR exhibited significantly longer OS compared with those achieving CR (84 months vs. 59 months; p=0.008). In the multivariate analysis, RISS was the strongest prognostic factor for OS (HR: 0.32; p=0.002).
Summary/Conclusion: Patients who achieve sPR represent a unique group of NTE MM patients with higher age and favorable prognostic characteristics. Achievement of sPR was a positive prognostic factor for OS, which led to 41% reduction of the risk of death; this latter finding supports that probably in a subgroup of NTE MM patients with favorable features, therapeutic strategy should not always aim for CR, at the expense of safety and quality of life.

EP1045 EFFICACY AND SAFETY OF DARATUMUMAB FOR THE TREATMENT OF MULTIPLE MYELOMA: A SERIES OF COCHRANE REVIEWS

C. Hirsch [1,*], V. Piechotta [1], P. Langer [1], C. Scheid [2], L. John [3], N. Skoetz [4]

[1]Cochrane Haematology, Department I of Internal Medicine, Center for Integrated Oncology Aachen Bonn Cologne Duesseldorf, Faculty of Medicine and University Hospital, University of Cologne, [2]Department I of Internal Medicine, Center for Integrated Oncology Aachen Bonn Cologne Duesseldorf, Stem Cell Transplantation Program, Faculty of Medicine and University Hospital, University of Cologne, Cologne, [3]Department of Hematology, Oncology and Rheumatology, University Hospital Heidelberg, Heidelberg, [4]Cochrane Cancer, Department I of Internal Medicine, Center for Integrated Oncology Aachen Bonn Cologne Duesseldorf, Faculty of Medicine and University Hospital, University of Cologne, Cologne, Germany

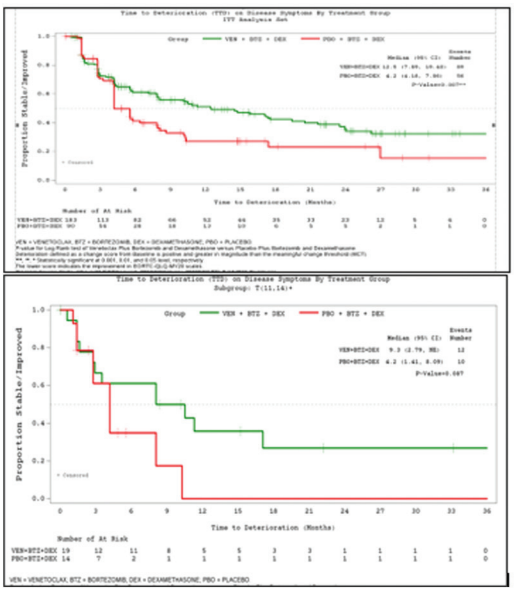
Background: Daratumumab has approved indications for the treatment of patients with newly diagnosed multiple myeloma (NDMM) both eligible and ineligible for transplant and treatment of relapsed or refractory multiple myeloma (RRMM).
Aims: To evaluate the efficacy and safety of daratumumab for transplant-ineligible NDMM patients (PICO 1), transplant eligible NDMM patients (PICO 2), and for RRMM patients (PICO 3).
Methods: For each PICO we conduct one Cochrane review according to the standard methodology as outlined in the Cochrane Handbook for Systematic Reviews of Interventions, and assess the certainty in the evidence using the Grading of Recommendations Assessment, Development and Evaluation (GRADE) approach. Our prioritised outcomes were overall survival, adverse events (CTCAE grade ≥3), serious adverse events, and quality of life.
Results:
Transplant-ineligible NDMM (PICO 1): We identified two RCTs (MAIA, ALCYONE) reporting on 1443 patients. Treatment with daratumumab probably increases overall survival (HR 0.67, 95% CI 0.5 to 0.85, I^2 39%, moderate-certainty evidence), results in a slight increase of adverse events (grade ≥3) (RR 1.05, 95% CI 1.0 to 1.11, I^2 26%, high-certainty evidence) and may increase serious adverse events (RR 1.14, 95% CI 0.86 to 1.51, I^2 85%, very low-certainty evidence) compared to treatment without daratumumab. More people receiving daratumumab probably gain at least 10 points of global health status after start of treatment when compared to people receiving no daratumumab (RR 1.13, 95% CI 1.13 to 1.23, I^2 0%, moderate-certainty evidence).
Transplant-ineligible NDMM (PICO 2): We identified two RCTs (CASSIOPEIA, GRIFFIN) reporting on 1292 patients. GRIFFIN included 207 patients, but did not report any of our crucial outcomes. Treatment with daratumumab may increase overall survival (HR 0.52, 95% CI 0.33 to 0.82, low-certainty evidence), results in a slight increase of adverse events (grade ≥3) (RR 1.06, 95% CI 1.0 to 1.13, high-certainty evidence) and people may experience less serious adverse events (RR 0.91, 95% CI 0.73 to 1.14, I^2 52%, low-certainty evidence) when compared to treatment without daratumumab. More people receiving daratumumab may gain at least 10 points of global health status after start of treatment compared to people receiving no daratumumab (RR 1.07, 95% CI 0.91 to 1.24, low-certainty evidence) at 9.0 months after start of treatment.
RRMM (PICO 3): We identified four RCTs (CANDOR, CASTOR, LEPUS, POLLUX) reporting on 1717 patients. Treatment with daratumumab probably increases overall survival when compared to treatment without daratumumab (HR 0.62, 95% CI 0.49 to 0.79, I^2 7%, moderate-certainty evidence). Two studies reported safety outcomes for 1044 patients. Treatment with daratumumab probably results in a slight increase of adverse events (grade ≥3) (RR 1.17, 95% CI 1.04 to 1.31, I^2 64%, moderate-certainty evidence) and probably increases serious adverse events when compared to treatment without daratumumab (RR 1.21, 95% CI 1.09 to 1.35, I^2 0%, moderate-certainty evidence). More people receiving daratumumab may gain at least 10 points of global health status after start of treatment compared to people receiving no daratumumab (RR 1.07, 95% CI 1.07 to 1.22, I^2 0%, low-certainty evidence) at 9 months after start of treatment.
Summary/Conclusion: Treatment with daratumumab is likely to retrieve gain in survival, but increases the risk of grade ≥3 and serious adverse events and may contribute to a clinically important improvement of quality of life compared to treatment without daratumumab.

EP1046 ASSESSING TIME TO DETERIORATION IN HRQOL IN PATIENTS WITH MULTIPLE MYELOMA USING VENETOCLAX IN COMBINATION WITH BORTEZOMIB AND DEXAMETHASONE COMPARED WITH PATIENTS USING BORTEZOMIB AND DEXAMETHASONE

P. Moreau [1,*], R. Popat [2], S. Kumar [3], M. Cavo [4], J. de la Rubia [5], V. Hungria [6], H. Salwender [7], I. Kim [8], S. Harrison [9], J. Muhammad [10], A. Melhem Bertrandt [10], R. F. Cornell [10], S. Karve [10], K. Fitzgerald [10], R. Kamalakar [10], J. Devine [11]

[1]CHU de Nantes, Nantes, France, [2]University College Hospitals, London, United Kingdom, [3]Mayo Clinic, Rochester, United States, [4]Seragnoli Institute of Hematology,, Bologna, Italy, [5]University Hospital La Fe,, Valencia, Spain, [6]Clinica Sao Germano, Sao Paulo, Brazil, [7]Asklepios Klinik Altona, Hamburg, Germany, [8]Japanese Red Cross Medical Center,, Tokyo,, Japan, [9]Peter MacCallum Cancer Centre,, Melbourne, Australia, [10]AbbVie, Mettawa, [11]Genentech,, South San Francisco, United States

Background: Patients with MM experience treatment and disease-related symptoms that impact their daily living and health-related quality of life. Among patients with MM the commonly reported disease symptoms that impact patient daily life include pain, and fatigue (Gonzalez-McQuire, MDM Policy Pract. 2019). BELLINI (M14-031, NCT01794520) phase



3 double-blind randomized clinical trial compared venetoclax (ven) in combination with bortezomib (bort) and dexamethasone (dex) compared with placebo (pbo), bort and dex. The primary study results readout in 2019 reported that the primary endpoint of PFS (HR 0.63, 95% CI=0.44-0.89) was achieved but higher risk of death (HR 2.027, 95% CI=1.04-3.95) was observed in the treatment (trt) arm compared with pbo arm (survival data not yet mature; Kumar, S et al. EHA Library. Jun 16 2019;273254:LB2601).

Aims: The current analysis compared time to deterioration (TTD) in patient-reported outcomes (PROs) as measured by the EORTC QLQ-C30 and EORTC QLQ-MY20 questionnaires (PROs assessed at Cycles 1, 3, 5, 7 and every other cycle starting cycle 9) between the M14-031 study groups

Methods: BELLINI enrolled adult patients with RR MM with exposure to 1-3 prior lines of therapy. For current analysis, meaningful change thresholds (MCTs) for the EORTC-QLQ-C30 (Osoba et al 1998), and EORTC-QLQ-MY20 (Sully et. al 2019) measures were defined using published literature. For each PRO domain, meaningful deterioration was defined as a change of at least one unit of the scale specific MCT at any time point after the baseline observation. Kaplan-Meier (KM) curves and corresponding nominal log-rank P-value were used to assess differences between trt arms (reported for the overall and t(11;14) positive sub-group).

Results: The intention-to-treat (ITT) dataset included 194 pts (≥65 years: 56%; 2-3 prior lines: 46.1%) in the trt group and 97 pts (≥65 years: 54%; 2-3 prior lines: 51.5%) in the pbo group. The t(11;14) positive sub-group included 35 patients of which 20 were in the ven arm and 15 in the pbo arm. For the ITT population, delay in TTD was observed for the EORTC QLQ-MY20 disease symptom domain (e.g., bone aches or pain, back pain, hip pain) in the trt group compared with the pbo group (12.5 vs. 4.2 Months; P = 0.042; Figure 1). TTD in EORTC QLQ-MY20 disease symptom domain was longer but not statistically significantly in the trt group compared with the pbo group in the t(11;14) MM sub-group (Figure 1). KM analysis for the EORTC QLQ-C30 domains indicated delay in cognitive functioning deterioration for the trt group versus the pbo group (4.6 vs. 4.2 months; P = 0.042). No statistically significant differences were observed in TTD between the two study groups for the EORTC QLQ-C30 emotional (P = 0.437), physical (P = 0.754), role (P = 0.623) functioning domains, fatigue (P = 0.829) and global health status/quality of life (P = 0.623) domains.. In multivariate Cox proportional hazard model, reduction in the risk of deterioration in EORTC QLQ-MY20 disease symptoms domain was estimated at 38% (hazard ratio;95% CI: 0.62; 0.44 - 0.88) in the trt group compared with the pbo group.

Figure 1: Time to Deterioration on Disease Symptoms Measures Using EORTC QLC-MY20, Overall and t(11;14) Sub-Group

Summary/Conclusion: In this analysis of the M14-031 PRO data, delays in TTD were observed in in the ven-based trt arm compared with the pbo group for the myeloma-specific disease symptom domain. This finding was consistent in the overall ITT population and positive trend in the t(11;14) sub-group. Smaller sample size for the t(11;14) positive sub-group likely limits drawing meaningful inferences.

EP1047 DISCREPANCIES IN ETHNIC DIVERSITY OF PATIENTS ENROLLED INTO UK MULTIPLE MYELOMA CLINICAL TRIALS

S. Asher [1,*], A. Kazantzi [1], F. Dekaj [1], L. Steventon [2], A. Khatun [2], N. Rabin [3], A. Wechalekar [3], J. Sive [3], C. Kyriakou [3], X. Papanikolaou [3], K. Xu [3], S. Mahmood [3], B. Wisniowski [3], L. Lee [3], K. Yong [3], R. Popat [1,3]

[1]National Institute for Health Research Clinical Research Facility, [2]Cancer Clinical Trials Unit, [3]Department of Haematology, University College London Hospitals NHS Trust, London, United Kingdom

Background: The incidence of multiple myeloma (MM) varies with ethnicity with black patients (pts) approximately twice as likely to develop MM to white pts or Asians (males, black: white 2.9; females, black: white: 2.2 (median, source: CRUK)). Despite this, a lower proportion of black pts have been reported to be enrolled into clinical trials. In some countries, survival may be inferior and appear to be linked to access to treatments and other socio-economic factors. If these are corrected, survival appears to be similar to white pts. However, it is unknown if these discrepancies exist in a state funded health care system with intended equitable access to treatments.

Aims: The primary aim was to assess the proportions of ethnic groups enrolled into clinical trials in the UK National Health Service (NHS). Secondary aims were to determine differences in patients enrolled into early phase vs late phase trials by ethnicity, sex and age; to assess the ethnic diversity of MM pts attending MM clinics and compare if the same diversity was observed in clinical trial enrolment, to assess the overall survival (OS) of patients enrolled into clinical trials by ethnic group.

Methods: Cross-sectional population-based analysis was assessed in participants enrolled into MM clinical trials from 2014 to 2021 in a large specialist MM centre receiving referrals from across the UK. Age, sex and ethnicity was determined by electronic health records. Ethnicity was divided by White, Black, Asian and Mixed/Other. Statistical analysis was performed by one-way ANOVA, Fisher's exact test and Chi-squared (GraphPad Prism version 9).

Results: 182 pts (Phase I/II: 57; Phase II/III: 125) from 25 clinical trials were assessed. The ethnicity was: white 143 (79%), black 23 (13%), Asian 8 (4%), mixed/ other 7 (4%). The black: white ratio was 0.16 . This discrepancy was more marked for Phase I/II trials: white 49 (86%), black 5 (9%), Asian 2 (4%), mixed/other 0 (0%); black: white 0.10 than Phase II/III trials: white 94 (75%), black 18 (14%), asian 6 (5%), mixed/ other 7 (6%); black: white 0.19. Male: female ratio was 1.38 in keeping with incidence of MM by sex. The median age of patients enrolled was 65 years (range 38-85) which is lower than expected for the population. Within the MM clinics (n=192 over a 4 week period), ethnicity was again skewed to white pts but less so than trial enrolment: white 124 (65%), black 32 (17%), Asian 15 (8%), mixed/ other 19 (10%); black: white 0.25. Comparing ethnicity within clinics and clinical trial enrolment, there was a lower proportion of non-white pts enrolled into trials, p=0.0038 and this was particularly observed for Phase I/II trials, p=0.0014. However, there was no significant difference in white: non-white pts between clinic and Phase II/III trial enrolment, p=0.0804. There was also a lower proportion of mixed/ other pts enrolled into clinical trials, p= 0.0247.

Despite these differences, the OS for those pts enrolled into clinical trials by ethnicity was not significantly different (p=0.4352). OS (years): white: 10.9, black: 11.8, Asian 15.1, mixed/ other 13.5.

Summary/Conclusion: The proportion of ethnic minorities enrolled into MM clinical trials was lower than expected compared to the incidence of MM in the UK. This was particularly apparent in Phase I/II clinical trials where patients are referred from a wider geographical area. Further research is required to understand and improve ethnic diversity into MM trials in state funded health care systems.

EP1048 DETECTION OF CIRCULATING TUMOR CELLS IN MULTIPLE MIELOMA BY FLOW CYTOMETRY AND CLINICAL SIGNIFICANCE

J. Tchuxina [1,1,*], K. Belousov [1], T. Mitina [1], A. Golenkov [1], E. Kataeva [1]

[1]of Hematology, Moscow Regional Research and Clinical Institute named M.F.Vladimirskij, Moscow, Russian Federation

Background: The improvement and practical application of high-sensitive molecular biological assays to detect of tumor cells has made it possible not only to determine the circulating tumor cells (CTCs) in the peripheral blood and to measure them quantitatively, but also to analyze their morphological and immunophenotypic characteristics. The use of multi-color flow cytometry makes it possible to characterize the biological features of tumor myeloma cells not only in the bone marrow, but also to identify the population of such cells in the peripheral blood.
Aims: The aim of the study was to investigate the immunophenotypic features of bone marrow tumor plasma cells (BM PLCs) and circulating tumor plasma cells in multiple myeloma (CTC MM) in comparison with the clinical features of the disease.
Methods:: A parallel immunophenotypic study of bone marrow (BM) and peripheral blood (PB) samples was performed in 34 patients with a newly diagnosed MM by 4-color flow cytometry (FACSCalibur (Becton Dickinson, USA). Bone and extramedullary plasmocytomas were detected in 10 MM patients with stage III disease, and chronic renal failure (CRF) was detected in 24 patients. The isolation of tumor PLCs was carried out from a gate of CD38-positive (bright) plasma cells against a lateral light scattering (SSC) signal, and at least 500,000 events were included in the analysis. The expression of CD138, CD45, CD56, CD19, CD20, CD79b, CD11c, CD33, CD28, CD117 was determined. Quantitative assessment of PLCs was carried out by the content of CD38+(bright) cells in terms of all nucleated cells of BM and/or PB.
Results: In all patients with newly diagnosed MM, CTCs MM was characterized by significantly lower expression of CD138, CD56, CD28, and CD79b compared to BM PLCs.
The immunophenotypic profile of CTCs compared to BM PLCs in patients with plasmocytomas was characterized by a significant decrease (p=0.0003) in the expression of syndecan-1 (CD138), and a significant (p=0.0004) increase in the content of CD138-negative and CD19-positive PLCs in the population. In patients with MM, not complicated by plasmocytomas, a significant (p=0.03) decrease in the expression of CD138 and CD28 (p=0.02) in the CTCs compartment was revealed. CD79b expression on CTCs MM was significantly more frequently detected in extramedullary plasmocytomas. When comparing BM PLCs in MM patients with or without kidney lesions, no significant differences in the frequency of antigens were obtained. The high content of PLCs positive for CD138, CD56, CD11c, CD28, CD79b was noted. CTCs MM in patients with renal lesions were characterized by the same phenotype as BM PLCs, as well as significantly more frequent positive expression of CD56. CTCs MM in patients with MM without impaired renal function were characterized by reduced expression of CD138, CD28. Thus, in the case of kidney damage in patients with MM, a large number of cells positive for CD138, CD56, CD28 enter the circulation, which is not observed in the absence of this complication.
Summary/Conclusion: Our study has shown that in MM with a complicated course, the identified CTCs subclone has a unique immunophenotypic protein expression profile, characterized by a less "mature" phenotype and variable expression of adhesive molecules (CD138, CD56), which increases their ability to enter the peripheral blood from the bone marrow and cause extramedullary lesions. The data obtained are consistent with the literature data on the significant role of CD138-negative cells in MM, less "mature" phenotype, and resistance to chemotherapy.

EP1049 CILTACABTAGENE AUTOLEUCEL VERSUS SELINEXOR + DEXAMETHASONE IN PATIENTS WITH RELAPSED/REFRACTORY MULTIPLE MYELOMA (RRMM) TREATED WITH ≥3 LINES OF PRIOR THERAPY: A MATCHING ADJUSTED INDIRECT COMPARISON

T. Martin [1,*], A. Krishnan [2], K. Yong [3], J. M. Schecter [4], M. Vogel [5], C. C. Jackson [4], W. Deraedt [6], H. Tian [4], T.-M. Yeh [4], A. Banerjee [7], M. J. Carrasco-Alfonso [8], X. Wu [8], T. Nesheiwat [8], S. Van Sanden [5], J. Diels [5], S. Valluri [5], S. Z. Usmani [9], J. G. Berdeja [10], S. Jagannath [11], K. Weisel [12]

[1]UCSF Helen Diller Family Comprehensive Cancer Center, San Francisco, [2]Judy and Bernard Briskin Center for Multiple Myeloma Research, City of Hope, Duarte, United States, [3]University College Hospital, London, United Kingdom, [4]Janssen R&D, [5]Janssen Global Services, LLC, Raritan, United States, [6]Janssen R&D, Beerse, Belgium, [7]Janssen R&D, Spring House, [8]Legend Biotech USA, Inc, Piscataway, [9]Levine Cancer Institute-Atrium Health, Charlotte, [10]Sarah Cannon Research Institute, Nashville, [11]Mount Sinai Medical Center, New York, United States, [12]University Medical Center Hamburg-Eppendorf, Hamburg, Germany

Background: Multiple myeloma (MM) remains incurable and relapses are common despite new treatment options. Most patients eventually progress despite an increasing armamentarium of anti-myeloma drugs such as proteasome inhibitors (PIs), immunomodulatory drugs (IMiDs), and anti-CD38 monoclonal antibodies. Recycling of previous treatment regimens is often the only alternative available for these patients, which highlights the need for new drug targets and treatment options. The chimeric antigen receptor (CAR) T-cell therapy ciltacabtagene autoleucel (cilta-cel; JNJ-68284528) has two BCMA–targeting single-domain antibodies designed to confer avidity. Initial results from the phase 1b/2 CARTITUDE-1 study (NCT03548207) have shown that a single infusion of cilta-cel yielded early, deep, and durable responses with a manageable safety profile in patients with heavily pretreated RRMM. To date, cilta-cel has not been directly compared with other therapies in development for RRMM in clinical trials. A systematic literature review using PRISMA guidelines identified selinexor + dexamethasone as a potential non-BCMA-targeting comparator in the triple-class exposed RRMM patient population.
Aims: To compare efficacy outcomes in patients who received cilta-cel in CARTITUDE-1 to those who received selinexor + dexamethasone in the STORM trial (Part 2; NCT02336815).
Methods: CARTITUDE-1 included triple-class exposed patients who received ≥3 prior lines of therapy or were double refractory to an IMiD and PI, had ECOG score of ≤1, and disease progression ≤12 months after the last line of therapy. Unanchored matching-adjusted indirect treatment (MAIC) comparisons were performed based on individual patient-level data from 97 infused patients in CARTITUDE-1 and published aggregate-level data from STORM Part 2 (N=122). Patients from CARTITUDE-1 (N=73) who matched the eligibility criteria for STORM Part 2 (penta-drug exposed, ≥ triple-class refractory, and refractory to daratumumab and last line of treatment) were included in the analysis. Individual patient data for time-to-event outcomes from STORM Part 2 were simulated based on the published Kaplan-Meier curves. CARTITUDE-1 patients were matched to the modified intent-to-treat population from STORM Part 2 on available prognostic factors identified from the literature and based on clinical expertise using propensity score weighting methods. Outcomes included overall response rate (ORR), complete response or better (≥CR), progression-free survival (PFS), and overall survival (OS). For ORR and ≥CR, the relative effects of cilta-cel versus selinexor + dexamethasone were quantified using odds ratios (OR) and 95% confidence intervals (CI) derived from a weighted logistic regression analysis, while time to event endpoints were analyzed using a weighted Cox proportional hazards model. A similar comparative analysis was performed which included all enrolled patients in CARTITUDE-1.
Results: Cilta-cel was associated with statistically significant improvements in ORR, ≥CR, PFS, and OS versus selinexor + dexamethasone in a population matched to STORM Part 2 (Table). Similarly, cilta-cel was associated with higher efficacy in the comparative analysis which included all patients enrolled in CARTITUDE-1.

Outcome*	Cilta-cel vs. selinexor + dexamethasone mITT
ORR, OR (95% CI)	121.17 (34.16, 429.83)†
≥CR, OR (95% CI)	111.13 (24.09, 512.60)†
PFS, HR (95% CI)	0.16 (0.09, 0.31)†
OS, HR (95% CI)	0.24 (0.12, 0.49)†

*Patient populations from CARTITUDE-1 (N=73; penta-drug exposed, ≥ triple-class refractory, and refractory to daratumumab and last line of treatment) and STORM Part 2 (N=122) were matched on refractory status, cytogenetic risk, and R-ISS; †P<0.0001.
CR, complete response; CI, confidence interval; HR, hazard ratio; mITT, modified intent-to-treat; OR, odds ratio; OS, overall survival; PFS, progression-free survival; R-ISS, revised international staging system.

Summary/Conclusion: These analyses demonstrated improved efficacy with cilta-cel versus selinexor + dexamethasone for ORR, ≥CR, PFS, and OS, highlighting its potential in patients with heavily pretreated RRMM.

EP1050 IXAZOMIB VERSUS LENALIDOMIDE OR IXAZOMIB AND LENALIDOMIDE COMBINATION AS MAINTENANCE REGIMEN FOR PATIENTS WITH MULTIPLE MYELOMA: INTERIM ANALYSIS OF A MULTI-CENTER PROSPECTIVE STUDY IN CHINA

Z. Zhuang [1], Q. Liu [2], D. Zou [3], L. Shi [4], Y. Tian [5], H. Yu [6], F. Dong [7], S. Liu [1], H. Jing [7], R. Fu [6], W. Chen [5], Y. Wu [5], L. Bao [4], W. Sun [3], J. Zhuang [1,*]

[1]Department of Hematology, Peking Union Medical College Hospital, Chinese Academy of Medical Sciences, Beijing, [2]Department of Hematology, The First Affiliated Hospital of Anhui Medical University, Hefei, [3]Department of Hematology,

Xuanwu Hospital of Capital Medical University, [4]Department of Hematology, Beijing Jishuitan Hospital, [5]Department of Hematology, Beijing Chao-Yang Hospital of Capital Medical University, Beijing, [6]Department of Hematology, Tianjin Medical University General Hospital, Tianjin, [7]Department of Hematology, Peking University Third Hospital, Beijing, China

Background: Maintenance therapy deepens response and prolongs progression free survival (PFS) in patients with newly diagnosed multiple myeloma (NDMM) after frontline regimens. Ixazomib, a 2nd generation oral proteasome inhibitor (PI), has been approved for maintenance therapy because of the convenience and tolerability.
Aims: We conducted this prospective multi-center study to compare the efficacy and safety of Ixazomib (I-MT) or Ixazomib plus Lenalidomide (IL-MT) to Lenalidomide (L-MT) as maintenance regimen in NDMM patients.
Methods: This study was approved by the Institutional Review Board of Peking Union Medical College Hospital and registered (NCT04217967). NDMM patients were enrolled from 7 centers of North China MM Registry, since September 2019. After 4 cycles of front-line induction therapy, patients reached partial response (PR) or above would receive autologous stem cell transplantation (ASCT) if eligible, or another up to 5 cycles of same regimens if ineligible, then started maintenance. Patients who did not achieve PR within 4 cycles would switch to second-line induction for 2-5 cycles and start maintenance once PR or above was achieved. For maintenance therapy, Ixazomib was given 4mg on day 1,8,15, and 25mg every other day for Lenalidomide on days 1–21 of 28day cycles. Patients in dual drug group were administrated with both Ixazomib and Lenalidomide. The primary endpoint was PFS from maintenance.
Results: A total of 85 patients were enrolled, including 37 in I-MT, 28 in L-MT and 20 in IL-MT. The demographic and clinical characteristics were comparable among three groups at baseline, including gender ratio, age, paraprotein isotype, ISS, R-ISS, and response evaluation before MT (Figure 1). Though patients on IL-MT were slightly younger. The proportions of patients with high-risk cytogenetic abnormalities (HRCAs), defined as amplification 1q21 (1q21+), deletion 17p (17p-), t(4,14) and t(14,16), were also comparable, as well as the ratios of each CA. However, L-MT cohort had a lower percentage of patients with double hit CA. The ratio of ASCT in L-MT cohort was also greater the others.
The median follow-up duration since maintenance was 4.0, 8.5 and 4.6 months in I-MT, L-MT and IL-MT groups, respectively. Disease progression was recorded in 2 patients (5.4%) on I-MT, 3 (10.7%) on L-MT and 2 (7.1%) on IL-MT. The median PFS was not reached (NR) in all groups. Meanwhile, 6 patients (16.2%) on I, 2 (7.1%) on L and 6 (30%) on IL had improved response after maintenance. No mortality was recorded in all patients.
Peripheral neuropathy with grade 1 was observed in 4 patients (10.8%) on I-MT, 7 (35%) on IL-MT and 0 on L-MT. Gastrointestinal events occurred in 5 patients (13.5%) on I-MT, 5 (25%) on IL-MT and 0 on L-MT. The prevalence of hematologic toxicities was 2.7%, 10% and 7.1%, respectively. Whereas infection rate was 8.1%, 5% and 3.6%. The incidence of skin rashes was 2.7%, 5% and 10.7%, respectively. No patients have discontinued maintenance due to adverse events.

		Ixazomib N= 37	Lenalidomide N= 28	Combination N=20	p-value
Gender (male%)		22 (59.5%)	17 (60.7%)	12 (60%)	0.99
Age (ave±sd/yr)		62.0±9.3	63±2.8	57.5±9.1	0.07
Paraprotein isotype (%)	IgG	21 (56.8%)	12 (42.9%)	11 (55.0%)	0.72
	IgA	5 (13.5%)	7 (25.0%)	1 (5.0%)	
	IgD	0 (0)	0 (0)	2 (10.0%)	
	Light Chain	10 (27.0%)	8 (28.6%)	5 (25.0%)	
	Other or NA	1 (2.7%)	1 (3.5%)	1 (5.0%)	
ISS	I	7 (18.9%)	5 (17.9%)	2 (10.0%)	0.88
	II	11 (29.7%)	7 (25.0%)	9 (45.0%)	
	III	17 (45.9%)	14 (50.0%)	8 (40.0%)	
	Missing	2 (5.4%)	2 (7.1%)	1 (5.0%)	
R-ISS	I	4 (10.8%)	3 (10.7%)	1 (5.0%)	0.79
	II	22 (59.5%)	19 (67.9%)	16 (80.0%)	
	III	9 (24.3%)	4 (14.3%)	2 (10.0%)	
	Missing	2 (5.4%)	2 (7.1%)	1 (5.0%)	
HRCAs		18/31 (58.1%)	14/21 (66.7%)	9/14 (64.3%)	0.81
Cytogenetic abnormalities	Gain(1q21)	13/34 (38.2%)	12/23 (52.2%)	9/19 (47.4%)	0.57
	Del(17p)	2/26 (7.7%)	1/22 (4.5%)	1/13 (7.7%)	0.89
	t(4,14)	4/30 (13.3%)	1/23 (4.3%)	2/16 (12.5%)	0.53
	t(14,16)	5/28 (17.9%)	3/22 (13.6%)	3/15 (20%)	0.87
	Double Hit	6/31 (19.4%)	2/21 (9.5%)	4/14 (28.6%)	*0.049
Response prior to maintenance	sCR+CR	13 (35.1%)	16 (57.1%)	7 (35.0%)	0.30
	VGPR	13 (35.1%)	5 (17.9%)	6 (30.0%)	
	PR	11 (29.8%)	7 (25.0%)	7 (35.0%)	
ASCT before MT		2 (5.4%)	10 (35.7%)	3 (15.0%)	*0.006

ISS: international staging system; R-ISS: revised-ISS; HRCAs: high risk cytogenetic abnormalities. sCR: stringent complete response. CR: complete response. VGPR: very good partial response. PR: partial response.

Summary/Conclusion: Due to inadequate access to melphalan and low rate of ASCT in China, there is still a gap of PFS in NDMM patients with those in western countries. We herein design this multi-centered prospective study to evaluate if dual drug maintenance will further strengthen response and make up the gap. Though the primary endpoint--PFS has not been reached in all treatment groups, dual drug maintenance is quite tolerable. Clinicians prefer to administrate Ixazomib in patients with complex cytogenetic abnormalities in the real-world practice.

EP1051 ASSESSMENT OF CLINICAL USE PARAMETERS ASSOCIATED WITH A SWITCH FROM INTRAVENOUS TO SUBCUTANEOUS DARATUMUMAB ADMINISTRATION IN PATIENTS WITH MULTIPLE MYELOMA AT MAYO CLINIC

S. Soefje [1,*], C. Carpenter [2], K. Carlson [2], S. Awasthi [2], T. S. Lin [3], S. Kaila [3], D. Tarjan [2], N. Kayal [2], C. Kirkup [2], T. Wagner [2], K. Gray [3], S. Kumar [1]

[1]Department of Hematology, Mayo Clinic Rochester, Rochester, MN, [2]nference, Cambridge, MA, [3]Janssen Scientific Affairs, LLC, Horsham, PA, United States

Background: Subcutaneous daratumumab (DARA SC), which is approved for the treatment of multiple myeloma (MM), has efficacy comparable to intravenous (IV) DARA, but it takes only 3-5 min to administer vs 3-7 h for DARA IV and is associated with reduced rates of administration-related reactions (ARRs) in clinical studies. However, DARA IV to SC switch has not been studied, and ARR rates and patient management data (eg, time in/through clinic) associated with the switch are not well characterized.
Aims: To assess real-world evidence on chair time, post-administration observation time, and ARR rates in patients with MM switching from DARA IV to SC
Methods: Patients aged ≥18 years with an ICD-9/10 diagnosis code of MM and a first DARA treatment between April 1, 2017 and December 31, 2020 were identified in Mayo Clinic's Electronic Health Records database. A scheduling and pharmacy software that tracked patient movement through appointments at a Mayo Clinic infusion center was used for data extraction. Data from patients initiating DARA by a single administration route (IV or SC) and patients who received DARA IV for ≥2 doses before switching to SC within 6-60 days were evaluated. The primary objective of the study was to describe the characteristics of DARA administration. The incidence of ARRs was determined in patients who switched from DARA IV to SC using ARR-associated events, including treatment, ICD codes, or admission to emergency department (ED).
Results: Overall, 737 patients initiated DARA treatment for MM (IV, n=640; SC, n=97); 74 patients who initiated DARA IV switched to SC. The median total chair time for DARA SC was 2.4 to 3.4 h shorter compared with DARA IV across all doses (Table). The median observation time decreased from Dose 1 to Dose 3 by 3.0 h (70%) in the SC group and by 2.8 h (82%) in the IV to SC switch group. Among patients who switched from IV to SC, the ARR rate was 1.4% for Dose 1 and 0% for both Doses 2 and 3, with no ARRs leading to ED visits for any dose. The analysis was limited in terms of data completeness, past treatments, and other temporal confounding factors.

	Dose 1			Dose 2			Dose 3			Dose 4+		
	IV	SC	IV to SC+	IV	SC	IV to SC+	IV	SC	IV to SC+	IV	SC	IV to SC+
Evaluable patients, n[†]	424	97	72	419	93	64	402	91	57	455	83	46
Total chair time (incl. observation time), median (hr)[‡]	8.8	5.6	4.5	5.9	2.5	1.7	4.9	2.5	1.3	3.6	1.2	1.1
Observation time, median (hr)[§]	0.3	4.3[‖]	3.4[¶]	0.3	1.4	1.0	0.3	1.3	0.6	0.3	0.4	0.3
ARRs, n (%)[#]	-	-	1 (1.4)	-	-	0	-	-	0	-	-	2 (2.7)
ARRs leading to ED visits, n (%)	-	-	0	-	-	0	-	-	0	-	-	0

*Dose number reflects dose after switching to DARA SC. [†]Available data. [‡]Later of check out time/end of admin – infusion room entry time. [§]Mayo mandated observation time at Dose 1 was [‖]4 hr or [¶]3 hr. [#]ARR data collected only for IV to SC patients (n = 74).

Summary/Conclusion: A shorter median total chair time and low ARR rates were observed across all SC doses in this real-world study, based on which modification of the observation time after Dose 1 are being considered. This may lead to improved practice efficiency and support initiating DARA therapy with SC administration or switching from DARA IV to SC.

EP1052 QUANTIFYING THE BURDEN OF ILLNESS IN PATIENTS WITH NEWLY DIAGNOSED MULTIPLE MYELOMA, AND THEIR CAREGIVERS, IN THE FIRST YEAR AFTER DIAGNOSIS

X. Gatopoulou [1], W. Iraqi [2], K. Morgan [3], V. Spain [4], J. Redfearn [4], B. Gardiner [4,*]

[1]Health Economics and Market Access EMEA, Janssen, Athens, Greece, [2]Janssen Pharmaceuticals, Paris, France, [3]Myeloma Patients Europe AISBL, Brussels, Belgium, [4]Research Partnership Ltd, LONDON, United Kingdom

Background: Newly Diagnosed Multiple Myeloma (NDMM) is recognised as a source of significant morbidity and mortality. Though current therapies have been associated with substantial improvements in patient outcomes for both transplant eligible (TE) and non-transplant eligible (NTE) individuals, the magnitude of the burden of illness (BoI) among NDMM patients, and their caregivers, in the first year after diagnosis has yet to be defined.
Aims: To quantify the BoI in TE and NTE NDMM patients, and their caregivers at 3 timepoints: pre-treatment (TP0), at 3 months (TP3) and at 12 months post-treatment (TP12).
Methods: A prospective, longitudinal, observational NDMM study was conducted amongst TE and NTE patients, and their caregivers, from France, Germany, Italy, and Spain between January 2019 and January 2021. Participants were recruited through their haematologist/haemato-oncologist. A structured, online questionnaire incorporating standardised assessment tools for measuring disease burden, including direct costs, indirect costs, and health-related quality of life (HRQoL) was used. Where possible, respondents completed all timepoints; however, some additional recruits were included at TP3 and TP12 to account for drop-outs. Descriptive statistics were performed and informed consent was obtained.
Results: Across the 3 timepoints, 160-190 NDMM patients [majority older than 65 years of age; multimorbid; self-described as relatively healthy; not working; living with the caregiver] answered the questionnaire. Throughout the 12 months, patients progressively lost independence to perform daily activities [IADL scores]. Median 3-month direct medical costs peaked at 3 months, being significantly higher amongst TE patients than NTE patients, due to increased testing and overnight hospital stays. Specialist consultations and hospital admissions were the greatest cost component amongst TE and NTE patients, respectively. In addition, home adaptations raised out-of-pocket expenditures amongst some NTE patients. Although always a minority, the share of working patients declined across the 12 months; those still describing themselves as working spent a median zero hours in the office at all timepoints, with associated costs for the employer. After a partial recovery at TP3, the numeric rating of pain intensity (mean) raised, more significantly among NTE patients. Accordingly, opioid utilisation increased from TP0 to TP12, particularly for NTE patients. Despite this, overall health status and HRQoL [EORTC QLQ-C30] remained stable with average scores over time. Across timepoints, 122-131 caregivers [patient's partner or adult child; self-rated good health; not employed; caring for the patient more than 4 days a week] answered the questionnaire. Mean self-rated burden score rose over the 12 months. By TP12, half of caregivers developed stress, anxiety or depression related to the patient's NDMM. Though most employed caregivers continue to be able to work, productivity was low at TP0 with a trend to recovering at TP12. Caregivers of NDMM NTE patients reported greater time burden compared to TE individuals. As seen with the patients, caregivers' HRQoL remained stable over time [CarerQoL 7D score].
Summary/Conclusion: NDMM is highly burdensome for patients and caregivers in the first year after treatment initiation. NTE patients experience greater pain and are more dependent on caregivers than TE patients. Despite the economic, physical, and emotional burden, HRQoL remains stable possibly indicating resilience and illness adjustment amongst patients and caregivers.

EP1053 EVERY CLOUD HAS A SILVER LINING: EVEN AN EARLY HEMATOLOGICAL PARTIAL RESPONSE COULD IDENTIFY LONG-TERM SURVIVORS IN HIGH-RISK AL AMYLOIDOSIS PATIENTS. A SINGLE CENTER EXPERIENCE.

M. Riva [1,2,*], F. Adami [1], A. Branca [1], F. Lessi [1], G. Scapinello [1], A. Visentin [1], M. Fedrigo [3], F. Piazza [1], L. Trentin [1], T. Berno [1]

[1]Hematology and Clinical Immunology Unit, Padova University, azienda ospedaliera di Padova, Padova, [2]Cell Therapy and Hematology, San Bortolo Hospital, Vicenza, [3]Department of Cardiac, Thoracic and Vascular Sciences, Padova University Hospital, Padova, Italy

Background: Immunoglobulin light chain (AL) amyloidosis is a heterogeneous disease. The prognosis is highly related to the stage of the disease which, in turn, is dependent on the hearth involvement. At diagnosis, patients in Mayo stage III and IV represent the majority of AL amyloidosis, and are defined "high-risk" because their outcome is poor.
Aims: From 2003 to 2019, 111 patients were diagnosed with systemic AL amyloidosis in our Center; 52 patients were identified as "high risk". We retrospectively analyzed the impact of hematological responses (HeR) by day 30 on overall survival (OS). All patients underwent first line bortezomib-based chemotherapy (6 cycles, weekly administration).
Methods: Baseline characteristics are shown in Table 1. All patients had an initial dFLC >50 mg/L, and a NTproBNP value above the normal limit. Diagnosis of amyloidosis was biopsy-proven and amyloid typing was established by immunoelectron microscopy in all cases. Patients were considered to have cardiac amyloidosis based on the accepted criteria for the definition of organ involvement. Hematologic and organ responses (OR) were defined according to Palladini et al.
Results: By day 30 of treatment, 23 patients (44%) achieved a HeR (11 CR and 12 VGPR). Twenty-nine patients (56%) attained PR or NR (14 and 15 patients, respectively). At 6 months 21 out of 29 patients with an inadequate response at day 30 did not change their hematological status (7 and 14 of them were PR and NR respectively at day 30), and 8 out of these 21 patients experienced early (i.e., within 6 mo.) death. All these latter patients were NR at day 30. The remaining 8 patients (7 PR and 1 NR at day 30) achieved a VGPR with no treatment modification. Remarkably, 12 out of 14 PR patients at day 30 achieved an organ response at the end of treatment; 7 of them achieved a VGPR while in 5 the hematological status did not change. The median OS of patients achieving the HeR, PR and NR at day 30 were 43, 24, 11 months, respectively.
At univariate analysis, achieving a HeR and PR at day 30 significantly predicted survival, with respect to NR (respectively p=0.001 and p=0.007). These results were confirmed even in the final multivariate Cox model (HeR *vs* NR p=0.001 and PR *vs* NR p=0.04).
Summary/Conclusion: In this limited retrospective analysis, HeR (CR+VGPR) at day 30 confirmed its prognostic value. Nevertheless, patients who reached a suboptimal response (PR) at day 30 have reasonable chances of survival, and do not necessarily need a change in therapeutic strategy even in the face of permissive clinical conditions. Therefore we confirm that achieving a rapid HeR and, to a lesser extent, a PR to bortezomib at day 30 in patients in newly diagnosed high-risk AL amyloidosis, has a favorable prognostic value. On the other hand, an early identification of NR patients should prompt a shift in therapy trying to improve the well-known dismal prognosis of these patients.

EP1054 DARATUMUMAB (DARA), CYCLOPHOSPHAMIDE, THALIDOMIDE AND DEXAMETHASONE: A QUADRUPLET INTENSIFIED TREATMENT FOR TRANSPLANT ELIGIBLE NEWLY DIAGNOSED MULTIPLE MYELOMA (TE NDMM) PATIENTS

E. Crusoe [1,2,*], J. Santos [1], J. Leal [1], H. Santos [3], A. Santos [3], A. Almeida [4], L. Lucas [1], M. Santos [3], C. Fonseca [5], S. Queiroz [1], E. Adorno [5], L. Vieira [6], M. Chaves [7], D. Dourado [4], V. Hungria [8], M. Salvino [4], M. D. G. Arruda [1]

[1]Hematology, Instituto D'or de pesquisa e ensino (IDOR) and Clinica CEHON,, [2]Hematology, Federal University of Bahia- University hospital, [3]Immunology and Cytometry Lab, Federal University of Bahia, [4]Hematology and Bone Marrow Transplantation, Federal University of Bahia- University hospital, [5]Pharmacy school, Federal University of Bahia, [6]Nuclear Medicine, Instituto D'or de pesquisa e ensino (IDOR) and Clinica CEHON,, [7]Hemotherapy, Federal University of Bahia- University hospital, Salvador, [8]Hematolgy, Clinica Sao Germano, Sao Paulo, Brazil

Background: Newly drugs access for MM treatment still a challenge in some countries. One of the most available inductions for TE NDMM

patients (pts) worldwide is cyclophosphamide (C), thalidomide (T) and dexamethasone (d)- (CTd). Dara the first anti- CD38, had been combined with VCd, VTd and VRd and markedly increased the depth and duration of the response. We hypothesized that the combination of Dara and CTd could be safe and allow deeper activity as an alternative protocol.
Aims: The primary endpoint was to evaluate the VGPR after two consolidation cycles post-autologous stem cell transplantation (ASCT). Secondary endpoints were the overall response rate during all treatment phases and minimal residual disease (MRD), based on the International Myeloma Working Group (IMWG) criteria that includes the next-generation flow (NGF) by the EuroFlow® and PET-CT and the safety profile.
Methods: This is a phase II, open-label single-center clinical trial. The main inclusion criteria were: TE NDMM, creatinine clearance ≥ 30 ml/min, normal cardiac, renal and liver function and the Easter Cooperative Oncology Group (ECOG) performance status = 0 - 2. The protocol was Dara-CTd for up to four 28-day induction cycles: C-500mg oral (PO) on days 1,8 and 15, T at 100-200mg PO on days 1 to 28, (d) at 40mg PO on days 1,8,15 and 22 and Dara at 16mg/Kg/dose intravenous (IV) on days 1,8,15 and 22 during cycles 1 - 2 and every other week in cycles 3 – 4, followed by ASCT. All pts received up to four 28-day consolidation cycles that was started at D+30 after ASCT: Dara at 16mg/Kg and (d) at 40mg every other week, associated with T at 100mg PO on days 1 - 28. Dara at 16mg/Kg was used monthly as maintenance until progression or limiting toxicity. G-CSF was used for stem cell (SC) mobilization and plerixafor had been allowed whenever the pts need. All pts received antiviral, anti-pneumocystis and anti-thrombotic prophylaxis.
Results: The first pts was enrolled in November 2018. A total of 21 pts were included, the median age being 56 (range 37 – 67 years), 19 (90%) were non-white, 3 (14%) had an R-ISS = 1, 12 (57%) had an R-ISS = 2 and 3 (14%), an R-ISS = 3. Five (24%) pts had high-risk chromosomal abnormalities [del17p, t(4;14) or t(14;16)]. To date, all pts have completed induction, 19 have received transplant and 17 have completed D+90 post-transplant assessment. No SC mobilization failure was observed, and five (26%) pts needed plerixafor use. In an intention to treatment analysis, after the end of induction (cycle 4), 19 (90%) of the pts obtained > PR and 8 (38%) obtained ≥VGPR, including three MRD negativity by NGF. 17 pts have completed two consolidation cycles after transplant and 94% obtained ≥ VGPR as best response, 12 (70%) obtained MRD negativity by NGF and nine (53%) had negative PET-CT. Seven (41%) pts had both flow and PET-CT negativity. Three pts died from infection, one before transplant because of Covid infection, on post-transplant, considered not related to the investigational agent, and another after consolidation, related to the investigational agent. The most common nonhematological adverse events (AEs) grades 3 and 4 before ASCT were neuropathy (n = 6), infusion reaction (n = 7), infection (n = 2), hypertension (n = 1) and rash (n = 1).
Summary/Conclusion: This is the first study that combined Dara with CTd as induction for TE NDMM pts. This present data has shown that the association of Dara-CTd achieved the primary end point once ≥ 90% of the pts achieved VGPR after two consolidations cycles, and safety profile was acceptable. Clinical trial information: NCT03792620.

EP1055 INTERMITTENT TREATMENT OF NEWLY DIAGNOSED MULTIPLE MYELOMA PATIENTS: RESULTS OF A PHASE II TRIAL EVADING AUTOLOUGOS STEM CELL TRANSPLANT (ASCT)

M. salamoon [1,*], M. balti [2]

[1]*hematology, al bairouni university cancer center, damascus, Syrian Arab Republic,* [2]*hematology, hopital militaire principal d'instruction, tunis, Tunisia*

Background: ASCT is still the standard of care for newly diagnosed patients with MM; however, it carries a high toxicity profile compared with chemotherapy or/and new agents such as thalidomide, lenalidomeide and anti-CD38.
Aims: the study aims to evaluate the treatment of newly diagnosed patients with MM using an intermittent therapy rather than autologous stem cell transplantation
Methods: The study was carried out at Al Bairouni University Cancer Center in Damascus, Syria between 2012 and 2017 and concluded 123 patients received three lines: (thalidomide+bortizomib+dexamethasone)/(lenalidomide+dexamethasone) and (bortizomib+dexamethasone), 44, 53 and 26 patients respectively. Evaluated evry 3 months and treatment was ceased in complete responders after 6 months of treatment and restarted upon documented relapse.
Results: Complete response was documented in 55 (44.7%) patients at the end of the 3rd month versus 102 (82.9%) at the end of 6th month. All patients relapsed or progressed at different times of treatment then they were retreated with the same induction or switched to another protocol. 112 patients were still alive at 5 years with an overall survival of 91%. In a univariate analysis, factors associated with poor survival are: patients with spinal cord compression at presentation with an odds ratio (OR) of 0.33 (95% CI, 0.11-0.83) and p value 0.04, extramedullary localization with an OR of 0.66 (95% CI, 0.15-0.95) and p value 0.09 and acute renal failure at presentation with an OR 4.5 (95% CI,0.9-9.7) and p value 0.004. The toxicity profile was acceptable.
Summary/Conclusion: Though all patients progressed or relapsed; however, 65 patients (52.8%) re-experienced the same complete response for at least four times using the same protocol, while the remaining 58 patients were responded at least 2 times then switched to other protocols in 3 occasions. Those with renal failure were correlated with poor survival taking into account the inability to deliver zoledronic acide. The toxicity profile was well tolerated and most patients continued their daily life with a good quality.
Results are comparable to those treated with ASCT taking into account the safe toxicity profile. Intermittent therapy is well tolerated, less aggressive and it had a better impact on the psychiatric status of the recruited cohort; however, a phase III head to head with ASCT is warranted in future.

EP1056 THE RETROSPECTIVE ANALYSIS OF MULTIPLE MYELOMA PATIENT SURVIVAL IN ARMENIA

L. Sahakyan [1,*], N. Ghazaryan [1], S. Danelyan [1], Y. Hakobyan [1]

[1]*Armenian Haematology center aft.prof.R.Yeolyan, Yerevan, Armenia*

Background: It is well known that the increased incidence of hematological malignancies is mainly caused by the growth of non-Hodgkin's lymphoma and multiple myeloma (MM). MM is the second most commonly diagnosed hematological neoplasm over the world. The indicated annual increase of MM incidence in the world is 0.7%. MM primarily affects the elderly and is typically diagnosed between the ages of 65-74 years and characterized by severe bone, blood and renal complications, impacting therapy choices and quality of life.
Aims: The aim of the current study was a comprehensive analysis of MM, i.e., their prevalence, incidence and survival rates in Armenia for the period of 2006-2020.
Methods: The main data source for this study was outpatient and dispensary cards, hospitalization journals, as well as clinical data from the Register of Blood Diseases of the Hematology Center after. prof. R. Yeolyan. This information has been supplemented by the data from National Oncological Centre after V.A. Fanarjyan as well as from death registration service at Ministry of Justice RA. Demographic indicators were derived from the database of Statistical Committee of Armenia. Diagnosis of MM and the definition of the stage were carried out according to the criteria proposed by the International Myeloma Working Group. Survival (OS) was determined by the period between the date of diagnosis and the date of death. Direct method of adjustment was used for elimination of possible influence of changes in age structure of population through passage of fifteen years. The time series data was analyzed using least squares regression analysis.
Results: We analyzed the data of 589 (48.2% female and 51.8 male) patients with MM registered in Armenian Hematology Center of the Ministry of Health of the Republic of Armenia from 2006 to 2020. The median age was 60.6 years (range 31–89). Data analysis showed that during the reported time period the increase of the MM incidence was 1.23 per 100 000 population. In comparison to the results obtained for 1966-1971 and 1998-2004, a significant increase in incidence of MM (about 3.6 and 1.4) was found. The low five-year survival rates were beaten in groups of patients who initially refused therapy and / or were diagnosed already in higher ISS stage for this disease. Among patients receiving therapy, the best survival rates were beaten on MP, VAD protocols and VCD and transplantation. The median survival for ISS stage II disease was 26 months, stage III disease 7 months and stage I disease 20 months. The incidence rates for the MM increased during the analyzed period and male over 60 years old were particularly in the risk group.
Summary/Conclusion: In general, the results of treatment in the Armenian population with MM were comparable with the data of the total European cohort. The survival rate was lower in patients with higher ISS stage for this disease and untreated patients. Survival rate seems to be better among younger patients than in older ones even with lower ISS stage of this disease. The MM-related deaths prevailed in the first 5 year of MM therapy. The appropriate monitoring and therapy

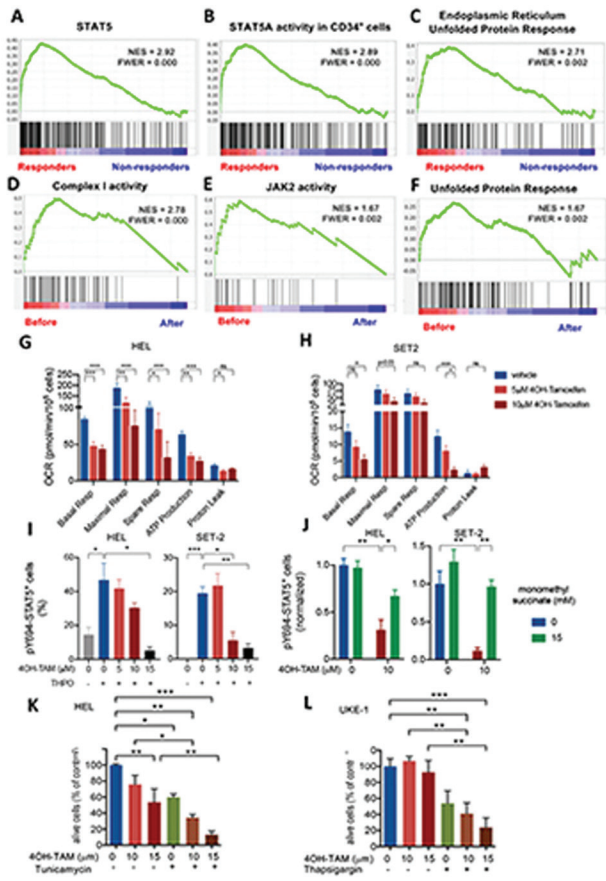
interventions during the first year of MM treatment are apparently important for the long-term treatment results

Myeloproliferative neoplasms - Biology & Translational Research

EP1057 ANTI-TMPRSS6 RNAI THERAPY AS A NOVEL TREATMENT OPTION FOR POLYCYTHAEMIA VERA

C. Bennett [1,*], A. Ng [1], T. Hayman [1], A. Pettikiriarachchi [1], W. Alexander [1], K. Burbury [2], U. Schaeper [3], S.-R. Pasricha [1]

[1]The Walter and Eliza Hall Institute of Medical Research, [2]Peter MacCallum Cancer Centre, Melbourne, Australia, [3]Silence Therapeutics GmbH, Berlin, Germany



Background: Polycythaemia Vera (PV) is a myeloproliferative neoplasm (MPN) in which overproduction of mature red cells renders patients at increased risk of serious thrombotic events. First line therapy includes periodical venesection (blood withdrawal) to reduce haematocrit, and thus risk of thrombosis, and induces whole body iron deficiency, which suppresses further red cell production. However, resulting systemic iron deficiency and fluid shifts lead to unwanted side effects including vaso-vagal complications, fatigue and cognitive dysfunction. Therefore, venesection is often poorly tolerated.
Hepcidin, the liver-derived hormone that regulates systemic iron homeostasis, is normally suppressed in iron deficiency (via decreased BMP/SMAD signalling) or by increased erythropoiesis (via increased erythroferrone expression) but is increased by inflammation (via IL6- STAT3 signalling). Interestingly, hepcidin levels are not suppressed in PV despite sustained increased erythropoiesis and iron deficiency, suggesting relative upregulation in this disease context.
Aims: We hypothesised that further upregulation of hepcidin in PV limits iron available for erythropoiesis. This would prevent patients from obtaining the high red cell counts that are incompatible with life. We aimed to discover whether therapeutically increasing endogenous hepcidin expression in PV through knock-down of its regulator, *Tmprss6*, could act as a therapeutic phlebotomy and decrease disease severity.
Methods: We developed a novel bone marrow transplant model of PV driven by the mutant human JAK2V617F allele. PV and control mice were subcutaneously administered anti-Tmprss6 siRNA or a non-targeting control siRNA once every 3 weeks for 3 doses. Mice were humanely euthanised and organs collected for downstream analysis.
Results: PV mice had comparable levels of hepcidin mRNA and protein as control mice, recapitulating what has previously been observed in patients. Mice administered anti-Tmprss6 siRNA showed ablated *Tmprss6* gene expression which resulted in sustained increase of endogenous hepatic hepcidin mRNA and serum protein levels, compared to mice given non-targeting siRNA. Increased serum hepcidin significantly decreased serum iron levels but did not cause iron deficiency in peripheral organs, as determined by liver iron content. PV animals administered anti-Tmprss6 siRNA had significantly lower haematocrit (45.9 vs 61.2%; P<0.0001), haemoglobin levels (12.0 vs 17.7g/dL; P<0.0001) and mean cell volume (36.1 vs 48.4fL, P<0.0001) than PV animals treated with control siRNA.
Summary/Conclusion: These data provide pre-clinical evidence that increasing endogenous hepcidin expression via anti-Tmprss6 RNAi could be a viable therapeutic avenue for treatment of PV. This treatment approach does not affect fluid levels and may reduce risk of systemic iron deficiency, the two concerns with conventional first line therapy. A related siRNA compound targeting TMPRSS6, SLN124, is in clinical development for hepcidin deficient anaemias. The inherent long-lasting duration of action coupled with patient friendly route of administration could provide benefit by decreasing the requirement for venesection and increasing comfort for patients with PV.

EP1058 TAMOXIFEN CAN REDUCE MITOCHONDRIAL RESPIRATION, ONCOGENIC JAK-STAT SIGNALING AND MUTANT ALLELE BURDEN IN A SUBSET OF PATIENTS WITH MYELOPROLIFERATIVE NEOPLASMS – RESULTS OF THE TAMARIN PHASE II STUDY

Z. Fang [1,*], G. C. Fattori [1], R. H. Boucher [2], M. Thomas [3], A. Jackson [2], R. S Fletcher [2], J.-E. Martin [1], S. Fox [2], J. Roberts [1], R. Glover [1], E. Harris [1], L. Grassi [1], A. Background: Myeloproliferative neoplasms (MPN) most frequently originate from mutations in hematopoietic stem and progenitor cells (HSPCs) affecting JAK2 or CALR. Tamoxifen restores normal apoptosis in mutated HSPCs in preclinical studies. The results of the TAMARIN Phase II study assessing tamoxifen's safety and activity in reducing molecular markers of disease burden in MPN have been recently reported (Blood 2020;136(Supplement 1):33-35).
Aims: Here we have investigated tamoxifen's mechanism of action in human MPN.
Methods: CD34+ HSPCs were isolated from peripheral blood at baseline, 12w and 24w after tamoxifen treatment for RNA-Seq, also performed on JAK2V617F-mutated human cell lines 4h after 4-hydroxytamoxifen (4OH-TAM) treatment. ATP generation from Oxidative phosphorylation (OXPHOS) and glycolysis was measured by Seahorse. STAT5-Y694 phosphorylation and apoptosis were measured by flow cytometry in Ba/F3 cells expressing erythropoietin receptor (EpoR) and WT or mutant JAK2, HEL, SET2 and UKE1 cells treated with different drugs including unfolded protein response (UPR) stressors thapsigargin and tunicamycin.
Results: Weighted correlation network analysis (WGCNA) revealed two gene modules with increased expression in HSPCs from responders at baseline. Gene-set enrichment analysis (GSEA) highlighted in responder HSPCs genes related to STAT3, STAT5, inflammation, apoptosis, reactive oxygen species (ROS), starvation or ATF response to UPR and cellular stress, suggesting that differential UPR determines sensitivity to tamoxifen. Indeed, nutrient deprivation or UPR stressors sensitised JAK2^{V617F+} cells to 4OH-TAM-induced cell death. 4OH-TAM-induced cell death was

more pronounced in Ba/F3 cells carrying the mutant human JAK2^{V617F}, supporting an increased activity of tamoxifen in the mutant cells. The expression of OXPHOS-related genes was high at baseline and specifically reduced by tamoxifen in responder HSPCs. This was mimicked by 4OH-TAM-sensitive and resistant cell lines. OXPHOS-derived ATP was markedly reduced by 4OH-TAM in sensitive cells including permeabilised cells, suggesting a direct inhibition of mitochondrial complex I. Complex II activators (succinate prodrug) protected from 4OH-TAM-induced cell death by rescuing ATP generation. Since ATP binding to the pseudokinase domain of JAK2 is critical for pathogenic activation of JAK2^{V617F}, but is not required for WT JAK2 activity, we hypothesized that reduced ATP generation might compromise pathogenic JAK2^{V617F}-STAT5 activation and possibly explain the selective proapoptotic effect of tamoxifen in mutant cells. STAT5-Y694 phosphorylation after Epo or Tpo stimulation was dose-dependently inhibited by 4OH-TAM. However, restoration of the mitochondrial electron transport and ATP generation by succinate prodrugs or cell-permeable ATP rescued pathogenic JAK2^{V617F}-STAT5 activation in 4OH-TAM-treated cells.
Summary/Conclusion: Longitudinal transcriptomic analysis of HSPCs from TAMARIN study patients and JAK2^{V617F}-mutated cells lines showed high UPR activity and expression of OXPHOS genes, specifically reduced by tamoxifen in sensitive cells. 4OH-TAM inhibits mitochondrial complex I and ensuing ATP synthesis, causing decreased pathogenic (but not WT) JAK2 signalling. These studies advocate for future studies on the transcriptomic and metabolic effects of selective oestrogen receptor modulators to target metabolic vulnerabilities in MPN with careful consideration of thrombotic risk.

EP1059 INVESTIGATION OF FEASIBILITY AND EFFICACY OF AN ANTI-INFLAMMATORY ANTI-IL-6 TREATMENT IN THE JAK2-V617F MOUSE MODEL

C. Baldauf [1,*], P. Müller [1], T. R. Haage [1], S. Adam-Frey [1], J. Lokau [2], C. Garbers [2], T. Fischer [1]

[1]Department of Hematology and Oncology, [2]Department of Pathology, Otto-von-Guericke University, Magdeburg, Germany

Background: The classic Philadelphia-chromosome negative chronic myeloproliferative neoplasms (CMN) are characterized by clonal proliferation of myeloid cells, increased thrombotic risk, inflammation and splenomegaly. Besides driver mutations (e.g. JAK2-V617F mutation), inflammation plays a key role in pathophysiology in CMN. Amongst other cytokines, IL-6 levels are elevated in CMN-patients. The pleiotropic cytokine IL-6 was described as a master cytokine due to its involvement in a wide range of physiological and pathological mechanisms. It was shown that IL-6 reduction by ruxolitinib correlates with improvement of symptom burden in CMN. Additionally, IL-6 and the downstream molecule STAT3 were described to link inflammation with malignant proliferation. Recently, pro-inflammatory cytokines are discussed as interesting anti-inflammatory targets in CMN treatment to inhibit inflammation driven transformation into myelofibrosis and/or acute leukemia.
Aims: This study aimed to investigate the impact of an anti-IL-6 treatment on disease specific parameters (e.g. cytokine levels in serum, hematocrit, and splenomegaly) in a polycythemia vera - like JAK2-V617F knock-in mouse model.
Methods: JAK2-V617F knock-in mice (11-13 weeks old) were treated (3x/week for three weeks) with anti-IL-6 antibody (clone MP5-20F3) and isotype IgG control, respectively. A wide panel of pro-inflammatory cytokines was measured in serum of treated mice by Eve Technologies Corporation (Mouse Cytokine Array/Chemokine Array 31-Plex; Calgary, AB, Canada). Blood parameters were analyzed by ADVIA®2120i Hematology System (Siemens Healthcare Diagnostics, Erlangen, Germany). For histopathologic analysis, hematoxylin-eosin staining was performed on isolated spleens sections.
Results: Reduced inflammatory cytokine levels (factor 0.3 – 0.8) were measured in serum of anti-IL-6 treated JAK2-V617F mice for CXCL1, CCL11, CXCL2, G-CSF, CXCL10, CXCL5, IL-13, CCL4 and CCL5. Interestingly, high dose isotype IgG control antibody also reduced levels of a number of these cytokines in JAK2-V617F mice.
The reduced inflammatory environment upon anti-IL-6 treatment did not result in improvement of hematological parameters. For example, hematocrit (82.0 % vs 76.0 %) and erythrocyte blood cell (20.8 Tpt/L vs 21.5 Tpt/L) were still significant elevated at the end of anti-IL-6 treatment. Another characteristic parameter of JAK2-V617F mice is a splenomegaly. The reduced cytokine levels showed no impact on the elevated spleen weight and size. In addition, there was no apparent amelioration of spleen histopathology.
Summary/Conclusion: Anti-IL-6 treatment was shown to reduce a number of pro-inflammatory cytokine levels in serum of JAK2-V617F mice. However, this change had no apparent impact on hematologic disease parameters. Furthermore, anti-IL6 treatment had no impact on extramedullary hematopoiesis presenting as splenomegaly and on histopathology of the spleen. This suggests that inhibition of IL-6 in CMN may be compensated by IL6-independent inflammatory pathways *in vivo* and may not be useful as a therapeutic approach in patients.

EP1060 EXOSOMES IN POLYCYTHEMIA VERA: "MINI PLATELETS" WITH ONCOGENIC AND THROMBOGENIC POTENTIAL

O. Uziel [1,*], K. R. Geiger [2], A. Shacham-Abulafia [3], G. Spectre [3], E. Ziv [2], Z. Sarsor [4], N. Ron [1], E. Beery [4], P. Raanani [3], U. Rozovski [3]

[1]Felsenstein Medical Research Center, Rabin Medical Center, Petah-Tikva, Israel; Sackler School of Medicine, Tel Aviv University, Tel Aviv, [2]Institute of Hematology, Rabin Medical Center, Petah-Tikva, [3]Institute of Hematology, Rabin Medical Center, Petah-Tikva, Israel; Sackler School of Medicine, Tel Aviv University, Tel Aviv, [4]Felsenstein Medical Research Center, Rabin Medical Center, Petah-Tikva, Israel

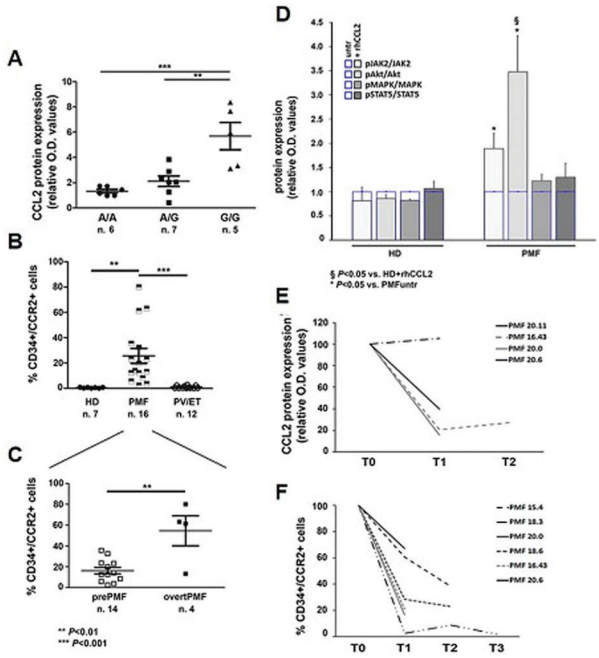
Background: Thrombotic complications across the vascular tree are frequent in patients with polycythemia vera (PV). These patients also have an increased risk of second primary malignancies. Although genetic predisposition may partially explain these links, whether and how the presence of PV-clonal cells induce pro-thrombotic and oncogenic environment is poorly understood. Secreted by all types of cells, exosomes are nano-scaled particles which carry a molecular cargo that reflects, *at least* partially the molecular makeup to their cell of origin. Exosomes travel in blood, may reach distant sites away from their cell of origin and affect various physiological and pathological processes. These features led us think that PV-derived exosomes (hereafter PV-exosomes) contribute to the thrombotic manifestations and oncogenic potential of our patients. Since mutated *JAK2* is present in virtually all patients with PV, we hypothesized that exosomes that are derived from a PV clone, carry the mutated *JAK2* oncogene and contribute to the increased incidence of thrombogenic complications and oncogenic risk.
Aims: 1) Determine whether PV-exosomes harbor mutated *JAK2* transcripts.
2) Determine whether PV-exosomes are pro-thrombotic.
3) Explore the oncogenic potential of PV-exosomes.
Methods: We isolated microparticles by serial ultracentrifugation, confirmed the presence of exosomes by NTA (Malvern) and imaged them by EM. We extracted RNA, generated cDNA (Invitrogen) and amplified a 465 bp long DNA segment within exon14 of JAK2 by PCR. Sanger sequencing was used to determine the JAK2 mutational status. We used thrombin generation assay to assess the thrombotic potential of PV-exosomes and Trans Epithelial Electric Resistance (TEER) assay to assess endothelial dysfunction. We measured exosomal uptake by HUVECS and keratinocytes by flow cytometry and assessed the oncogenic potential of these exosomes by the NIH/3T3 assay.
Results: To determine whether PV-exosomes carry mutated *JAK2* transcripts, we harvested exosomes from the peripheral blood of 21 patients with PV and 20 healthy individuals. Reverse-transcriptase PCR revealed the presence of mutated *JAK2* mRNA in all patients and the presence of wild type JAK2 in all healthy individuals. Because mutated *JAK2* induces endothelial dysfunction, we wondered whether JAK2^{mutated}-exosomes are taken up by endothelial cells and induce endothelial dysfunction. We stained PV-exosomes with the FM-1-43 dye and showed by flow cytometry that these exosomes are taken up by Human-Umbilical-Vein-derived-Endothelial-Cells (HUVECs) in a dose- and time- dependent manner, peaking at 24 hours. To assay the functional status of the endothelium, we measured the membranal resistance of HUVECS prior to and after exposure to PV-exomes for 24 hours. The resistance was dramatically decreased in the presence of PV-exosomes, indicating that the tight junction between adjacent cells was impaired implicating that PV-exosomes induce endothelial dysfunction. To assess the thrombogenic potential of PV-exomes, we measured the rate of thrombin generation in platelets poor plasma and recorded an increase in the peak thrombin concentration in the presence of PV-exosomes compared with exosomes from healthy individuals. Finally, using the NIH/3T3 platform we found that PV-exosome have the capacity to transform normal cells from various tissues.
Summary/Conclusion: Like their parental cells, PV-derived exosomes carry mutant JAK2 transcripts. These exosomes are pro thrombotic and have transforming potential both directly and indirectly through endothelial dysfunction.

EP1061 RUXOLITINIB DOWN-REGULATES SELECTIVELY-ACTIVATED CCL2/CCR2 SIGNALING AXIS IN PRIMARY MYELOFIBROSIS CELLS

E. Masselli [1,*], G. Pozzi [1], G. Gobbi [1], S. Bonomini [2], P. Mirandola [1], M. Vitale [1], C. Carubbi [1]

[1]Medicine and Surgery, University of Parma, [2]Hematology and BMT Unit, University Hospital of Parma, Parma, Italy

Background: Primary Myelofibrosis (PMF) represents the paradigm of onco-inflammatory disorders. In fact, although its pathogenesis is cell-intrinsic and triggered by acquired somatic mutations in specific myeloid genes, cell-extrinsic effects exerted by the malignant clone via inflammatory mediators result in systemic complications (Jutzi & Mullally, 2020). Moreover, chronic inflammation elicits clonal evolution, in a self-perpetrating vicious cycle (Hasselbalch, Mediators Inflamm 2015).



CCL2 (also known as Monocyte Chemoattractant Protein-1) is one of the most potent immune-modulatory cytokines known to be elevated in PMF and exerts its biological effects by preferentially engaging its cognate receptor CCR2, activating a downstream signaling which includes G-proteins, MAPK/ERK, PI3K/Akt and JAK/STAT pathways (Lim, Oncotarget 2016).

SNPs in the regulatory regions of *CCL2* gene account for the great inter-individual variability in CCL2 expression levels. Specifically, the rs1024611 (A>G) SNP of *CCL2* leads to higher chemokine production upon inflammatory noxa (Tam, PlosOne 2012). We recently demonstrated that homozygosity for the G allele variant of this SNP is associated to reduced survival in PMF (Masselli, ASH 2019 abs#1689).

Aims: Here we sought to prove the functional relevance of this finding by assessing expression and function of CCL2/CCR2 axis in PMF and its down-regulation induced by immunomodulatory therapy with ruxolitinib.

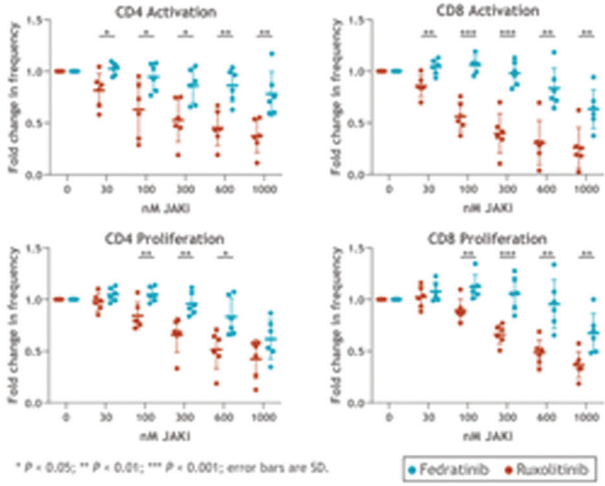
Methods: MNCs from therapy naïve PMF stratified according to the *CCL2* SNP (n. 25), and from PMF before (T0) and after Ruxolitinib start (T1→T3) (n. 6) were in part pelleted and in part cultured for 20h in 10% fetal bovine serum-enriched RPMI medium with 1.1 mg/ml of IL1-β as described (Rovin, BBRC 1999). Cells were then subjected to western blot for CCL2 expression. Immunomagnetically-isolated primary CD34+ cells from PMF and healthy donors (HD) were checked for CCR2 expression by flow cytometry and cultured for 24h in serum-free X-vivo medium with and without rhCCL2 (100 ng/mL). Cells were subjected to western blot to assess signaling pathways activation.

Results: The rs1024611 SNP is functionally relevant in PMF since the G allele exerts a dose-dependent effect on CCL2 expression, with G/G PMF significantly overexpressing CCL2 as compared to the other genotypes (panel A). We asked whether PMF hematopoietic progenitors could be a target of CCL2 and we found that PMF CD34+ cells uniquely display CCR2 (> 60 fold-higher expression as compared to HD and >26 fold-higher as compared to PV and ET, which share with PMF the same driver mutations) (panel B). Additionally, among PMF, overtPMF significantly overexpress CCR2 as compared to prePMF (panel C). When PMF CD34+ cells were stimulated with rhCCL2, a significant phosphorylation of JAK2 and Akt was detected. As control, CCR2-negative CD34+ cells were subject to the same treatment and do not display CCL2-mediated phosphorylation of JAK/STAT, Akt and MAP-kinase pathways (panel D). Finally, we proved that ruxolitinib is effective in turning-off CCL2/CCR2 signaling. In fact, MNCs from patients at 1, 3 and 6 months of therapy (T1→T3) display a significantly reduced capacity to produce CCL2 upon inflammatory stimulus as compared to T0 (before ruxo start). A significant and stable reduction of the chemokine receptor on PMF CD34+ was detected as well (panel E-F).

Summary/Conclusion: CCL2/CCR2 chemokine axis is selectively activated in PMF, boosting pro-survival signals induced by driver mutations. Ruxolitinib effectively counteracts CCL2 production and down-regulates CCR2 expression in PMF cells.

EP1062 FEDRATINIB DEMONSTRATES LIMITED SUPPRESSION OF T- AND NATURAL KILLER- (NK) CELL ACTIVITY EX VIVO COMPARED WITH RUXOLITINIB AT CLINICALLY RELEVANT DOSES

A. Ahsan [1,*], R. La Motte-Mohs [1], P. Hagner [1], A. Thakurta [1]



[1]Bristol Myers Squibb, Princeton, United States

Background: Myelofibrosis (MF) is a debilitating clonal myeloproliferative neoplasm characterized by anemia, splenomegaly, and constitutional symptoms, often presenting with activating Janus kinase 2 (*JAK2*) mutations. Two JAK inhibitors (JAKis), ruxolitinib (RUX) and fedratinib (FEDR), are approved for treatment (Tx) of intermediate- or high-risk MF, and others, such as momelotinib and pacritinib, are in late-stage clinical development. FEDR is an oral, selective inhibitor of wild-type and mutant JAK2 and fms related receptor tyrosine kinase 3 (FLT3) approved in the United States (US) and European Union (EU) for adult patients (pts) with intermediate-2 or high-risk primary or secondary MF. Ruxolitinib (RUX) is a multikinase inhibitor with broad activity against JAK family kinases including JAK1, JAK2, JAK3, and TYK2. RUX is approved in the US and EU for Tx of pts with intermediate or high-risk primary or secondary MF. Due to variations in JAK specificity, FEDR and RUX may have differential immunomodulation effects, which could have important clinical implications.

Aims: Determine the relative immunomodulatory activity of FEDR and RUX in human *ex vivo* culture model systems.

Methods: Peripheral blood mononuclear cells (PBMCs) were isolated from heathy subjects (n = 6) with standard Ficoll gradient centrifugation. Primary cells (PBMCs and CD56+ NK cells) and cell lines (Raji and K562) were co-cultured in triplicate with FEDR, RUX, or vehicle control

at different effector:target (E:T) ratios and assayed by flow cytometry. Activation was assessed by ELISA for interferon γ (IFNγ) secretion after Tx with 50 ng/mL *Staphylococcus* enterotoxin B (SEB). Though the recommended clinical dose of FEDR, 400 mg/day, is ~10-fold higher than the recommended RUX dosages of 30–50 mg/day (15–25 mg BID), the observed peak plasma concentrations for both are ~1–2 µM. Thus, FEDR and RUX activity were compared by using equal concentrations of drug at 30, 100, 300, 600, 1000 nM, or vehicle control. A two-parameter, unpaired Student's t-test was used to compare Tx groups.
Results: PBMCs were cultured with equal concentrations of FEDR or RUX. Overall, Tx with FEDR showed significantly reduced CD4+ and CD8+ T-cell suppression at clinically relevant doses compared with RUX. Compared with vehicle control, activation and proliferation of CD4+ T cells were suppressed with RUX Tx by 48% and 35%, respectively, and by 14% and 4% with FEDR Tx (each at 300 nM). Similarly, CD8+ T-cell activation was reduced by 60% and proliferation by 34% with RUX vs. control, compared with 2% and no reduction, with FEDR vs. control ($P > 0.01$) at 300 nM (**Figure**). In a co-culture system (E:T ratio, 3:1 NK:Raji cells) using 2 µg/mL rituximab (or isotype control) to tag CD20+ Raji cells, the reduction in NK-mediated antibody-dependent cellular cytotoxicity (ADCC) was significantly greater with RUX than FEDR after 4 hr. In assays of HLA-dependent cytotoxicity (E:T ratio, 20:1 NK:K562 cells; no antibody), FEDR showed limited inhibition of NK cells compared with RUX after 6 hr in 4/5 NK cell donor samples.

Summary/Conclusion: Overall, Tx with FEDR resulted in significantly lower suppression of T- and NK-cell proliferation and activation *ex vivo* when compared with RUX. FEDR also displayed limited suppression of NK-cell–mediated ADCC and HLA-dependent cytotoxicity in *ex vivo* model systems. These findings elucidate some of the variable immunomodulatory effects of JAKis and may aid in development of clinical trials combining FEDR with immunotherapies for MF and other neoplasms.

EP1063 DISTINCT GENE EXPRESSION PROFILES AND MOLECULAR MARKERS IN CD34+ CELLS FROM PATIENTS WITH MYELOPROLIFERATIVE NEOPLASMS

J. Baumeister [1,*], T. Maié [2], N. Chatain [1], B. Weinbergerova [3], M. A. S. de Toledo [1], J. Eschweiler [4], A. Maurer [1], J. Mayer [3], B. Kubesova [3], A. Schuppert [2], I. Costa [2], S. Koschmieder [1], T. H. Brümmendorf [1], D. Gezer [1]

[1]Department of Hematology, Oncology, Hemostaseology, and Stem Cell Transplantation, [2]Joint Research Center for Computational Biomedicine, Uniklinik RWTH Aachen, Aachen, Germany, [3]Department of Internal Medicine, Hematology and Oncology, Masaryk University and University Hospital Brno, Brno, Czech Republic, [4]Department of Orthopedic Surgery, Uniklinik RWTH Aachen, Aachen, Germany

Background: Myeloproliferative neoplasms (MPN) are hematological disorders of the myeloid lineage characterized by hyperproliferation of mature blood cells. In classical Ph$^-$ MPN, comprising polycythemia vera (PV), essential thrombocythemia (ET) and primary myelofibrosis (PMF), mutations in the genes of *JAK2*, *CALR* and *MPL* are frequently observed. The most commonly detected mutation is *JAK2*V617F, a gain-of-function mutation, that results in expansion of stem and progenitor cells. Mutations in additional genes have been identified as potential high molecular risk factors for progression. The prediction of clinical course and progression remains incompletely understood and new molecular components whose targeting might result in further improvement of risk stratification and therapeutic strategies are of high interest. Several CD34$^+$ gene expression studies have been conducted to investigate deregulated gene sets in MPN. However, most studies do not include all MPN subtypes, impeding a comparison, especially with regard to disease progression. Thus, further studies are necessary.
Aims: We conducted a CD34$^+$ gene expression study to identify signatures and potential biomarkers in the different MPN subtypes with the aim to identify new therapeutic targets and predict the transition of a rather benign, chronic to a more malignant, aggressive state.
Methods: In this study, we performed gene expression analysis (GEA) of CD34$^+$ peripheral blood and bone marrow (BM) mononuclear cells from MPN patients and healthy controls. A total cohort of 36 samples (6 ET, 11 PV, 9 PMF, 4 secondary myelofibrosis (SMF; post PV or post ET) patients and 6 healthy donors) were objected to Affymetrix GeneChip HTA 2.0 analysis.
Results: GEA revealed a variety of differentially regulated genes in the different MPN subtypes compared to healthy controls, with PMF (200 genes) and SMF (272) resulting in stronger differences than ET (132) and PV (121). PROGENγ analysis revealed the significant induction of NF-κB and TNFα signaling (particularly in SMF) and a reduction of estrogen signaling (PMF and SMF). We performed gene ontology (GO) enrichment analysis and discovered the induction of inflammatory pathways, particularly in PMF and SMF. Biological processes associated with RNA splicing were downregulated in PMF. Several potential marker genes that might be utilized as diagnostic or prognostic markers were identified such as *AREG*, *CYBB*, *DNTT*, *TIMD4*, *VCAM1* and members of the S100 family (*S100A4/8/9/10/12)*. S100 proteins are pro-inflammatory alarmins that might contribute to the high risk of leukemic transformation. RT-qPCR analysis in full BM cells revealed that the deregulation was mainly restricted to the CD34$^+$ compartment. 98 genes were deregulated solely in SMF and may be used to predict the progression into myelofibrosis. The strongest deregulated genes in this group included *CLEC1B*, *CMTM5*, *CXCL8*, *DACH1* and *RADX* that potentially play a role in MPN pathogenesis due to their described functions.
Summary/Conclusion: Our study is the first to provide gene expression signatures in CD34$^+$ stem and progenitor cells of all classical Ph$^-$ MPN subtypes ET, PV, PMF and SMF supporting the paradigm of early and late stage MPN. We identified a strong activation of inflammatory pathways in PMF and especially SMF. GO analysis revealed that the downregulation of RNA splicing pathways was restricted to PMF patients. Furthermore, we identified a variety of deregulated genes and pathways that might serve as molecular markers for diagnosis or prediction of disease transition and may lead to the development of new therapeutic modalities.

EP1064 CLONAL HAEMATOPOIESIS PROMOTES ADVERSE OUTCOMES IN CHRONIC KIDNEY DISEASE

A. Dawoud [1], W. Tapper [1], N. Cross [1,*]

[1]University of Southampton, Southampton, United Kingdom

Background: Age-related clonal haematopoiesis (CH) is a risk factor for atherosclerotic cardiovascular disease (CVD) and all-cause mortality. Chronic kidney disease (CKD) is a worldwide health problem associated with an elevated risk of CVD, but the relationship between CH and CKD is unknown.
Aims: To assess the relationship between CH and CKD in UK Biobank, a prospective, population-based cohort of UK subjects aged 40-69 years recruited between 2006-10.
Methods: We focused on subjects with both genomewide SNP array and WES data (n=200,361; median age = 58y, median follow up = 11y). Array allelic intensities were used to infer mosaic chromosome abnormalities (mCA), which were categorized as myeloid, lymphoid or other based on known cytogenetic associations. Likely somatic driver mutations were extracted from WES variant calls (DeepVariant) based on VAF, recurrency in COSMIC, CADD pathogenicity score and a binomial test against the mean VAF. Estimated Glomerular Filtration Rate (eGFR) was calculated using CKD-EPI formula using cystatin-C (eGFR.cys), creatinine (eGFR.creat), or both (eGFR.creat.cys). 10,144 participants were considered ineligible for analysis due to end stage kidney

disease (n=211), any eGFR score <15 (n=20) or missing biochemistry measures (n=9,913) at study entry. Linear and logistic regression models were used with kidney function defined as (i) a binary trait (CKD, eGFR <60; control, eGFR ≥60) or (ii) a continuous trait. A Cox proportional hazard model was used to assess the risk of developing adverse outcomes defined by death, myocardial infarction or stroke. All P values were corrected for false discovery rate

Results: CH, defined as the presence of any mCA and/or somatic mutation, was identified in 5,449 (2.9%) eligible subjects. CH was negatively associated with eGFR.cys (OR=0.44, P=5.9x10^{-5}), but not other eGFR scores, when tested as a continuous variable and was specifically associated with CKD defined by eGFR.cys <60 (n=5,449/185,038, OR=1.02, P=1.2x10^{-8}). Focusing on CH defined by mCA only (n=1,918), eGFR.cys was associated with myeloid mCA (n=176, OR=0.01, P=5.9x10^{-5}) and not lymphoid (n=229, P=0.13) or other mCA (n=1495, P=0.18). Similarly, for CH defined by somatic mutations (n=3,686), the association with eGFR.cys was due myeloid-malignancy related genes (n=3323, OR=0.26, P=1.2x10^{-7}), particularly *JAK2* V617F (n=139, OR=6.5x10^{-4}, P=1.6x10^{-9}) and *TET2* (n=788, OR=0.13, P=9.5x10^{-5}) but not *DNMT3A* or *ASXL1*. The link between myeloid malignancy and CKD is well established, and was replicated in our series, which included participants with a myeloid malignancy diagnosed prior to or within a year of study entry (n=320, OR= 3.9x10^{-3}, P=7.0x10^{-12}). Excluding these cases and also those with any prior history of CVD (n=8,459), we confirmed that myeloid CH was associated with adverse outcomes during follow up (RR=1.57, n=338/3,078, P=1.1x10^{-12}) compared to myeloid CH-free participants (n=9174/176,944). For subjects who had CKD, the risk of adverse outcomes was higher: RR=2, n=1,186/6,991 P=7.6x10^{-78} compared to CKD free participants (n=8326/173,031). Within the CKD group, the risk was further increased for subjects with myeloid CH (RR=1.63, n=59/226, P=1.5x10^{-3}) compared to those who were myeloid-CH free (n=1,127/6,765).

Summary/Conclusion: CH, and specifically myeloid CH, is associated with CKD defined by eGFR.cys. Myeloid CH promotes adverse outcomes in CKD, highlighting the importance of the interaction between intrinsic and extrinsic factors to define the health risk associated with CH.

EP1065 CDK4/CDK6-INHIBITION AS A POTENT APPROACH TO AUGMENT ANTI-NEOPLASTIC EFFECTS OF MIDOSTAURIN, AVAPRITINIB AND NINTEDANIB IN KIT D816V+ NEOPLASTIC MAST CELLS

M. Schneeweiss-Gleixner [1,2,3,*], G. Stefanzl [2], D. Berger [2], G. Eisenwort [1,2], G. Greiner [1,4], G. Hoermann [1,5], J. Schwaab [6], M. Jawhar [6], W. R. Sperr [1,2], A. Reiter [6], M. Arock [7], P. Valent [1,2], K. V. Gleixner [1,2]

[1]Ludwig Boltzmann Institute for Hematology and Oncology, [2]Department of Internal Medicine I, Division of Hematology and Hemostaseology, [3]Department of Internal Medicine III, Division of Gastroenterology and Hepatology, Medical University of Vienna, [4]Ihr Labor, Medical Diagnostic Laboratories, Vienna, Austria, [5]MLL Munich Leukemia Laboratory, Munich, [6]Department of Hematology and Oncology, University Medical Center Mannheim and Medical Faculty Mannheim, Heidelberg University, Mannheim, Germany, [7]Department of Hematological Biology, Pitié-Salpêtrière Hospital, Pierre et Marie Curie University (UPMC), Paris, France

Background: Advanced systemic mastocytosis (AdvSM), including aggressive SM (ASM), SM with an associated hematologic neoplasm (SM-AHN) and mast cell leukemia (MCL) are rare, KIT-driven malignancies with a grave prognosis. Although KIT D816V inhibitors, such as midostaurin or avapritinib, are available, most patients do not achieve a durable complete remission upon treatment with such drugs. Drug combinations may be an approach to improve the outcome of these patients. Cyclin-dependent kinase-4 (CDK4) and CDK6 contribute to cell cycle initiation and growth of normal and neoplastic cells. However, CDK4/CDK6 have not been analyzed as targets in AdvSM so far.

Aims: We aimed at elucidating the role of CDK4/CDK6 as therapeutic targets in AdvSM and evaluated anti-proliferative effects of CDK4/CDK6-inhibitors, alone or in combination with KIT D816V-targeting drugs, on neoplastic mast cells (MC).

Methods: Primary neoplastic cells were isolated from bone marrow (BM) samples of 21 patients [indolent SM (ISM; n=5), ASM (n=2), MCL (n=3) and SM-AHN (n=11)] and used in proliferation studies. mRNA was obtained from 70 additional patients with SM [ISM (n=45), SSM (n=2), ASM (n=7), SM-AHND (n=11), MCL (n=5)]. The MCL-like cell lines HMC-1.1 (lacking *KIT* D816V), HMC-1.2 (*KIT* D816V+), ROSA$^{KIT\ WT}$, ROSA$^{KIT\ D816V}$ and MCPV-1 (expressing RAS G12V, hTert and Large T) were also tested. Expression of CDK4, CDK6 and cyclins D1 and D2 was analyzed by qRT-PCR. Phosphorylation of the retinoblastoma gene product (RB1) was analyzed by Western blotting. The functional role of CDKs was evaluated by shRNA-mediated knockdown of CDK4 and/or CDK6 in HMC-1.2 cells. Proliferation was determined by measuring ^{3}H-thymidine uptake. Apoptosis was quantified by flow cytometry.

Results: CDK4, CDK6 and cyclins D1 and D2 were found to be overexpressed in BM samples from patients with AdvSM compared to samples of ISM patients. shRNA-mediated knockdown of both CDK4 and CDK6 resulted in a growth-arrest in HMC-1.2 cells, suggesting a functional role of CDK4/CDK6 in MC expansion. The pharmacologic CDK4/CDK6-inhibitors palbociclib, ribociclib and abemaciclib were found to suppress proliferation of HMC-1 cells and ROSA cells expressing or lacking *KIT* D816V, with reasonable IC_{50} values (<0.5 µM). In MCPV-1 cells, abemaciclib also induced growth-inhibition (IC_{50}: 1–3 µM), whereas no substantial growth-inhibitory effects were seen with palbociclib and ribociclib (IC_{50} >10 µM). However, neoplastic cells in all primary samples tested were found to be sensitive to palbociclib, ribociclib and abemaciclib (IC_{50}: <0.5 µM), with no differences seen between sub-types of SM. In the MCL-like cell lines, growth-inhibition was accompanied by apoptosis, cell cycle arrest and inhibition of phospho-RB1, the main target of CDK4/CDK6. CDK4/CDK6 inhibitors were also found to induce apoptosis in CD34^{+}/CD38^{-} stem cells obtained from 3 patients with AdvSM. Finally, cooperative effects of drug combinations involving CDK4/CDK6-inhibitors and KIT D816V-targeting drugs were assessed. In these experiments, palbociclib, ribociclib and abemaciclib were found to synergize with the KIT-inhibitors midostaurin, avapritinib and nintedanib in inducing growth inhibition in all MCL-like cell lines, including MCPV-1 as well as in primary neoplastic MC.

Summary/Conclusion: CDK4/CDK6 inhibition is a potent approach to block growth and survival of neoplastic MC and to potentiate anti-proliferative effects of KIT-targeting drugs in AdvSM. Whether such concepts can improve clinical outcomes in patients with drug-resistant AdvSM remains to be determined in clinical trials.

EP1066 TARGETING HDAC AS A NOVEL THERAPEUTIC APPROACH TO COUNTERACT GROWTH OF NEOPLASTIC MAST CELLS IN ADVANCED SYSTEMIC MASTOCYTOSIS

B. Peter [1,2,*], D. Berger [2], G. Stefanzl [2], G. Hoermann [1,3], S. Kubicek [4], M. Arock [5,6], P. Valent [1,2]

[1]Ludwig Boltzmann Institute for Hematology and Oncology, Medical University of Vienna, [2]Department for Internal Medicine I, Division of Hematology & Oncology, Medical University of Vienna, Vienna, Austria, [3]MLL Munich Leukemia Laboratory, Munich, Germany, Munich, Germany, [4]CeMM Research Center for Molecular Medicine of the Austrian Acadamy of Sciences, Vienna, Austria, [5]Laboratory of Hematology, Pitié-Salpêtrière Hospital, Paris, [6]Laboratoire de Biologie et Pharmacologie Appliquée, CNRS UMR 8113, Ecole Normale Superieure de Cachan, Cachan, France

Background: Systemic mastocytosis (SM) is a hematologic stem cell neoplasm characterized by uncontrolled growth and accumulation of neoplastic mast cells (MC) in one or more organs. In a majority of patients with SM, the D816V-mutated variant of *KIT* is detectable which induces resistance against a number of tyrosine kinase inhibitors (TKI), including imatinib. Midostaurin is a TKI which is known to target *KIT* D816V. This drug has been approved for the treatment of patients with advanced SM by the FDA and EMA. However, long-lasting hematologic remissions are rarely seen and patients treated with midostaurin may also relapse.

Aims: The aim of our study was to identify novel potential drug targets and associated targeted drugs to overcome mutant-induced drug resistance of neoplastic MC.

Methods: For this purpose, a robot-based high-throughput cell viability screen using 8 different MC lines, including the *KIT* D816V+ cell lines HMC-1.2 and ROSA$^{KIT\ D816V}$ was performed.

Results: We identified a number of drugs effectively blocking survival of *KIT* D816V+ MC lines. Among these, HDAC blockers were the most potent inhibitors. The two most promising HDAC blockers, panobinostat and quisinostat, were used in subsequent validation experiments. Both HDAC inhibitors were found to block proliferation of HMC-1.1 (IC_{50}: 5-25 nM), HMC-1.2 (IC_{50}: 2.5-25 nM), ROSA$^{KIT\ WT}$ (IC_{50}: 2.5-25 nM), and ROSA$^{KIT\ D816V}$ cells (IC_{50}: 5-50 nM) as well as the multi-drug resistant cell lines MCPV-1.1, MCPV-1.2, MCPV-1.3 and MCPV-1.4 (IC_{50}:

10-100 nM). Moreover, panobinostat and quisinostat were found to suppress proliferation of primary neoplastic MC obtained from patients with advanced SM (IC_{50}: <10 nM). The two HDAC inhibitors were also found to induce apoptosis in HMC-1 cells. Moreover, combinations of HDAC blockers (panobinostat or quisinostat) and KIT-targeting drugs (midostaurin or avapritinib) produced cooperative growth-inhibitory effects in both HMC-1 subclones as well as $ROSA^{KIT\ WT}$ and $ROSA^{KIT\ D816V}$ cells. As assessed by qPCR, all MC-lines tested as well as primary neoplastic MC obtained from patients with various types of SM were found to express HDAC1 and HDAC2 mRNA. Furthermore, all cell lines investigated were found to display HDAC1 and HDAC2 which was evaluated by immunocytochemistry. In Western blot experiments, both HDAC inhibitors were found to promote the expression of acetylated histone H3 and H4 in HMC-1 and ROSA cells. By contrast, no effects of these drugs on phosphorylation of KIT were seen.

Summary/Conclusion: HDAC inhibitors are novel potent inhibitors of growth of neoplastic MC. Whether HDAC inhibitors alone or in combination with midostaurin or avapritinib are also effective *in vivo* in patients with advanced SM remains to be determined in clinical trials.

EP1067 ONCOGENE-INDUCED MALADAPTIVE ACTIVATION OF TRAINED IMMUNITY IN THE PATHOGENESIS OF HUMAN INFLAMMATORY MYELOID NEOPLASM

E. Cantoni [1,*], R. Biavasco [2], R. Molteni [1], D. Stefanoni [1,3], M. Panigada [1], T. Nemkov [3], J. Domínguez-Andrés [4], R. J. Arts [4], I. Merelli [2,5], D. Mazza [1], S. Zambrano [1], I. Tengesdal [4,6], F. Piras [7], G. De Luca [8], L. Cassina [1], G. Distefano [1], A. Loffreda [1], D. Gnani [1], C. Doglioni [9], L. A. Joosten [4], A. Kajaste-Rudnitski [2], J. Haroche [10], L. Background: Trained immunity (TI) is a pro-inflammatory program induced in monocyte/macrophages upon sensing of specific pathogens, and characterized by immunometabolic and epigenetic changes enhancing cytokine production. Maladaptive activation of TI (*i.e.* in the absence of infection) might result in detrimental inflammation and disease development.

Aims: The present study aims at identifying the role and extent of inappropriate activation of TI in the pathogenesis of a human inflammatory myeloid neoplasm (Erdheim-Chester disease, ECD, characterized by the *BRAFV600E* oncogenic mutation in monocyte/macrophages and excess cytokine production).

Methods: Human monocytes engineered to express *BRAV600E* were investigated for the ability to recapitulate TI and ECD features by combining biochemical, genetic, metabolic, and functional approaches.

Results: Mechanistically, we provide evidence that, myeloid cells expressing *BRAFV600E* exhibit all molecular features of TI: activation of the AKT/mTOR signaling axis; increased glycolysis, glutaminolysis, and cholesterol synthesis; epigenetic changes on promoters of genes encoding cytokines; and enhanced cytokine production leading to hyper-inflammatory responses. In ECD patients, effective therapeutic strategies contrast this maladaptive TI phenotype; in addition, pharmacologic inhibition of immunometabolic changes underlying TI (i.e. glycolysis) effectively dampens cytokine production by myeloid cells.

Summary/Conclusion: This study reveals the deleterious potential of inappropriate activation of TI in the pathogenesis of human inflammatory myeloid neoplasms, and the opportunity for inhibition of TI in conditions characterized by maladaptive myeloid-driven inflammation.

EP1068 THE SYNTHETIC TRITERPENOID CDDO-ME BLOCKS SURVIVAL OF NEOPLASTIC MAST CELLS AND SYNERGIZES WITH KIT D816V-TARGETING DRUGS IN INDUCING GROWTH INHIBITION

M. V. John [1,*], M. Schneeweiß-Gleixner [1,2,3], G. Eisenwort [1,2], B. Peter [1,2], D. Berger [2], G. Stefanzl [1,2], M. Konopleva [4], M. Andreeff [4], W. R. Sperr [1,2], M. Arock [5], P. Valent [1,2], K. V. Gleixner [1,2]

[1]Department of Internal Medicine I, Division of Hematology and Hemostaseology, [2]Ludwig Boltzmann Institute for Hematology and Oncology, [3]Department of Internal Medicine III, Division of Gastroenterology and Hepatology, Medical University of Vienna, Vienna, Austria, [4]Department of Leukemia, University of Texas, Houston, Texas, United States, [5]Department of Hematology, Pitié-Salpêtrière Hospital, APHP Sorbonne University, Paris, France

Background: Contrasting indolent forms of systemic mastocytosis (SM), advanced SM, including aggressive SM (ASM), mast cell leukemia (MCL), and SM with an associated hematopoietic neoplasm (SM-AHN) are characterized by SM-induced organ damage, disease progression and a poor prognosis. In most patients, *KIT* D816V is detected and is considered to act as a disease-driver. Despite encouraging results obtained with KIT D816V-targeting tyrosine kinase inhibitors (TKI), such as midostaurin, most patients fail to achieve a durable remission. This may be explained by additional oncogenic pathways. Therefore, current efforts are focusing on the identification of suitable combination partners for KIT D816V-targeting TKI. The synthetic triterpenoid 2-cyano-3,12-dioxooleana-1,9-dien-28-oic acid methyl ester (CDDO-Me) acts anti-neoplastic in various malignancies.

Aims: The aim of the present study was to evaluate the anti-neoplastic potential of CDDO-Me, alone or in combination with KIT D816V-targeting TKI, in neoplastic mast cells (MC).

Methods: Primary bone marrow (BM) cells were obtained from 15 patients with SM (indolent SM, n=3; ASM, n=2; MCL, n=3; SM-AHN, n=7). Furthermore, we employed the MCL-like cell lines HMC-1.1 (lacking *KIT* D816V), HMC-1.2 (*KIT* D816V+), $ROSA^{KIT\ WT}$, $ROSA^{KIT\ D816V}$ and MCPV-1 (expressing RAS G12V, hTert and Large T). Proliferation was determined by measuring ^{3}H-thymidine uptake. Apoptosis was quantified by flow cytometry. Western blot experiments were performed to determine drug effects on expression and phosphorylation of target proteins.

Results: CDDO-Me was found to suppress the proliferation of HMC-1, ROSA and MCPV-1 cells, with comparable IC_{50} values (0.1-0.5 µM). Interestingly, no differences were seen between cells lacking or expressing *KIT* D816V or RAS G12V. Growth arrest was accompanied by induction of apoptosis in all cell lines tested. In addition, CDDO-Me was found to inhibit the proliferation of primary neoplastic MC, with IC_{50}-values ranging between 0.1 and 1 µM with no differences observed between SM variants and independent of previous

treatment with midostaurin. Anti-neoplastic effects of CDDO-Me were accompanied by suppression of KIT and AKT expression in HMC-1 cells. However, CDDO-Me also led to upregulation of heme oxygenase-1 (HO-1) in MC lines. Therefore, we combined CDDO-Me with the HO-1 inhibitor SMA-ZnPP. This combination resulted in synergistic effects in all cell lines tested. Finally, potential cooperative effects between CDDO-Me and the KIT D816V-targeting TKI midostaurin, avapritinib and nintedanib, were explored. In these experiments, CDDO-Me was found to synergize with KIT-targeting drugs in producing growth-inhibition in HMC-1 cells as well as in the multi drug-resistant cell line MCPV-1.
Summary/Conclusion: Together, we found that CDDO-Me counteracts growth and survival of various MCL-like cell lines and primary neoplastic MC in SM. CDDO-Me was found to potentiate anti-neoplastic effects of KIT D816V-targeting TKI and to synergize with the HO-1 blocker SMA-ZnPP in producing growth inhibition. Whether CDDO-Me is also effective *in vivo* in patients with ASM/MCL remains at present unknown.

EP1069 GENOMIC LANDSCAPE OF NON-DRIVER MUTATIONS IN MYELOPROLIFERATIVE NEOPLASMS - THE STANFORD EXPERIENCE

H. Robert [1,*]

[1]*Hematology, Government, Lahore, Pakistan*

Background: The myeloproliferative neoplasms (MPN) - polycythemia vera (PV), essential thrombocytosis (ET) and primary myelofibrosis (PMF) - are clonal hematopoietic stemcell disorders with acquired genetic mutations JAK2, CALR, and MPL, that constitutively activate the signal-transduction pathways. Recently, non-driver mutations in TET2, ASXL1, SRSF1 and U2AF1 were reported to be associated with the intiation and disease transformation, independent of the driver mutations in myeloproliferatuve neoplasms.
Aims: To define the genomic landscape of non-driver mutations in myeloproliferative neoplasms.
Methods: This study was conducted at Department of Pathology StanfordUniversity from April 2017 to January 2018. We studied the association of non-driver mutations with the presenting clinical and laboratory characteristics in a cohort of 71 subjects of MPN at the time of diagnosis including 15 polycythemia vera, 17 essential thrombocytosis and 39 subjects of primary myelofibrosis. We used targeted next generation sequencing panel (Illumina) to detect somantic mutations in 54 genes. Genomic DNA was extracted from peripheral blood or bone marrow. Libraries were prepared and sequencing performed on MiSeq. NextGen analysis software was used for alignment, variant calling, annotation and reporting.
Results: Among 71 patients 55(77%) harbored JAK2, 9(13%) CALR and 2(3%) MPL mutations while 5(7%) were triple negative. 36(51%) subjects had driver mutations JAK2, CALR and MPL with co-occuring non-driver mutations in PV, ET and PMF subjects (14 vs 17 vs 69%; *P*=0.001) at the time of diagnosis. The most frequent non-driver mutations are involved in epigenetic regulation, splicing, and signaling like TET2(23%), ASXL1(15%), SRSF2(13%) and U2AF1(7%) being most prevalent in PMF with leukemic transformation (69%; *P*=0.02). The results also indicate that MPNs primarily affects older male patients (median; 66 yrs, male; 69%). At initial diagnosis 36% displayed transfusion required anemia and 56% constitutional symptoms.
Summary/Conclusion: Targeted NGS has become more widely available for the detection of specific MPN associated mutations, allowing early detection of residual disease and leukemic transformation which in turn should lead to improved clinical outcomes for patients by early therapeutic intervention. We further conclude that MPNs have frequent presence of co-occuring non driver mutations, reported in literature to play a key role in the disease initiation, progression and prognosis.

EP1070 AVAPRITINIB AND NINTEDANIB INHIBIT GROWTH AND SURVIVAL OF KIT D816V+ HUMAN MAST CELLS

S. Gamperl [1,*], G. Stefanzl [1], A.-K. Schruef [1], G. Eisenwort [1,2], B. Peter [1,2], G. Greiner [2,3], E. Hadzijusufovic [1,2,4], J. Schwaab [5], K. V. Gleixner [1,2], W. R. Sperr [1,2], G. Hoermann [2,6], A. Reiter [5], M. Arock [7], P. Valent [1,2]

[1]*Deparmtent for Internal Medicine I, Division of Hematology and Hemostaseology,* [2]*Ludwig Boltzmann Institute for Hematology and Oncology, Medical University of Vienna,* [3]*Ihr Labor, Medical Diagnostic Laboratories,* [4]*Department/Hospital for Companion Animals and Horses, University Hospital for Small Animals, Internal Medicine Small Animals, University of Veterinary Medicine, Vienna, Austria,* [5]*Department of Hematology and Oncology, University Medical Centre Mannheim and Medical Faculty Mannheim, Heidelberg University, Heidelberg,* [6]*Munich Leukemia Laboratory (MLL), Munich, Germany,* [7]*Department of Hematological Biology, Pitié-Salpêtriére Hospital, Pierre et Marie Curie University (UPMC), Paris, France*

Background: Systemic mastocytosis (SM) is a hematopoietic neoplasm defined by abnormal growth and accumulation of neoplastic mast cells (MC) in various internal organs. Major drivers of SM are activating mutations in *KIT*, especially the D816V point mutation, which initiates ligand-independent signaling in MC.
Aims: Several tyrosine kinase inhibitors targeting KIT have already shown clinical activity. However, the D816V *KIT* mutation confers resistance against most KIT-targeting drugs.
Methods: We evaluated the effects of two novel KIT D816V-targeting drugs, avapritinib and nintedanib, on growth and function of neoplastic MC and compared their activity profiles with that of midostaurin.
Results: Avapritinib was found to suppress growth of HMC-1.1 (KIT V560G) and HMC-1.2 cells (KIT V560G+KIT D816V) with comparable IC_{50} values (0.1-0.25 µM). In addition, avapritinib was found to block proliferation of $ROSA^{KIT\ WT}$ (IC_{50}: 0.1-0.25 µM), $ROSA^{KIT\ D816V}$ (IC_{50}: 1-5 µM), and $ROSA^{KIT\ K509I}$ cells (IC_{50}: 0.1-0.25 µM). Even stronger effects were seen with nintedanib (IC_{50} in HMC-1.1: 0.001-0.01 µM; HMC-1.2: 0.25-0.5 µM; $ROSA^{KIT\ WT}$: 0.01-0.1 µM; $ROSA^{KIT\ D816V}$: 1-5 µM; $ROSA^{KIT\ K509I}$: 0.001-0.01 µM). Avapritinib and nintedanib also suppressed the growth of primary neoplastic MC in most patients with advanced SM (IC_{50} of avapritinib: 1-5 µM; IC_{50} of nintedanib: 0.1-5 µM). Growth-inhibitory drug effects were accompanied by signs of apoptosis and downregulation of activation-linked surface antigens CD63, CD71 and CD117 (KIT) in MC. Contrasting midostaurin, both drugs failed to inhibit IgE-dependent histamine release in MC or basophils.
Summary/Conclusion: Contrasting midostaurin, both drugs failed to inhibit IgE-dependent histamine release in MC or basophils. In conclusion, our data suggest that avapritinib and nintedanib are promising drugs for treatment of patients with advanced SM.

EP1071 CALR MUTATION CLEARANCE IN RUSSIAN PATIENTS WITH PHI-NEGATIVE MYELOPROLIFERATIVE NEOPLASMS TREATED WITH INTERFERON-ALPHA

S. Treglazova [1,*], E. Nikulina [1], T. Makarik [1], A. Abdullaev [1], I. Soubortseva [2], A. Melikyan [2], A. Sudarikov [1]

[1]*Molecular Hematology,* [2]*Outpatient Department, National Research Center for Hematology, Moscow, Russian Federation (Russia), Moscow, Russian Federation*

Background: Mutations in CALR gene exon 9 insertion/deletions along with JAK2 or MPL gene mutations are routine diagnostic markers in phi-negative myeloproliferative neoplasms (MPN). Interferon-α (IFN) selectively targets the malignant clone in MPN patients and can induce both hematological and molecular remissions. Quantitative measurement of JAK2 (V617F) mutation burden is routinely used for treatment monitoring in the therapy of MPN. The value of CALR mutation burden monitoring still controversial.
Aims: To evaluate CALR gene mutation clearance in Russian patients with phi- negative MPNs, treated with IFN.
Methods:. Patients diagnosed in accordance with the WHO (2017) classification and treated at the Outpatient Department of the National Research Center for Hematology from 2015 to 2020 were included in the study (n=27). Among 27 patients with MPNs 16 cases were essential thrombocythemia (ET), 10 cases - primary myelofibrosis (PMF), 1 unclassified MPNs. All cases were tested for the presence of JAK2 (V617F), CALR(exon 9), and MPL (W515L/K) gene mutations by means of allele-specific PCR or fragment analysis. All patients were CALR positive (type 1 or type 2), JAK2 (V617F) and MPL (W515L/K) mutation negative at the onset of disease. Out of 27 patients, 22 were females (81%), and the mean age at diagnosis was 34.6 years (range 18-70). The median of IFN treatment duration was 30,5 months (range 10-68).
Results: Only 2 ET patients with CALR mutation type 2 achieved a minimal or partial molecular response. Both of them had at onset an initial allele load level of no more than 45%. Patients with PMF did not achieve any molecular response. 2 ET patients with the allelic load of 45 and 49% at the onset did not achieve any molecular response despite long-term treatment (49 months or more). Molecular response in patients

with type 1 mutation was 7 out of 14 (50%) - 5 patients with ET and 2 – with PMF. Two PMF patients with molecular response to treatment had an allele load at onset of no more than 30%.

	Age at diagnosis	Sex	Type Mutation	%CALR (debut)	Month of treatment	%CALR	% decrease

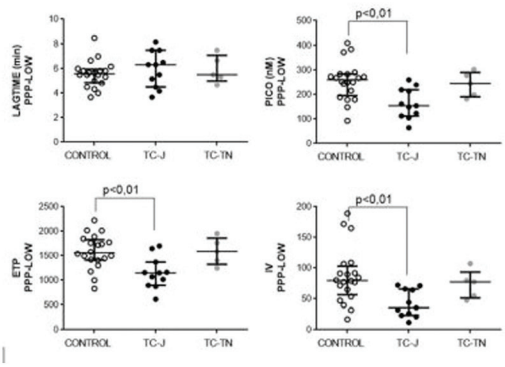
n-MPN patient							
1	19	m	Type 1	33	30	43	0

Summary/Conclusion: All patients in our study had more than 20% level of the mutant CALR allele at baseline, in contrast to patients with the JAK2 (V617F) mutation, who often carry low levels of mutant cells. Despite complete hematological remission achieved by all patients included in the study, clearance of mutated clone measured by PCR and fragment analysis of CALR mutation was only partial in some cases. One can speculate that IFN treatment may effectively control malignant cells with CALR mutations while not affecting more differentiated ones. However further studies with separated cell populations are required to support this point and to establish the value of CALR mutation monitoring in the therapy of MPNs.



EP1072 RELATIONSHIP BETWEEN MOLECULAR PROFILE AND PLATELET FUNCTION AND THROMBIN GENERATION IN PATIENTS WITH ESSENTIAL THROMBOCYTEMIA

M. Gasior Kabat [1,*], E. Monzón Manzano [1], P. Acuña Butta [1], M. T. Alvarez Román [1], E. García Arias Salgado [1], M. I. Rivas Pollmar [1], S. García barcenilla [1], E. González Zorrilla [1], F. Gómez Aguado [1], C. Ramos Castro [1], V. Jiménez Yuste [1], N. Butta Coll [1]

[1]*Hematology, Hospital Universitario La Paz, Madrid, Spain*

Background: Myeloproliferative neoplasms (MPNs) like Essential Thrombocythemia (ET) presents with higher platelet counts and driver mutations in JAK2, CALR or MPL. Thrombotic and hemorrhagic complications are main causes of morbidity/mortality. Platelet functional alterations have been previously reported in patients with ET, also higher reticulated platelet fraction and higher aggregation potential compared to healthy controls.
Aims: To investigate platelet activity and thrombin generation (TG) in patients with ET with different molecular mutations.
Methods: Twenty-two adult patients with ET according to 2017 WHO classification and 10 healthy controls were included. Patients did not receive cytoreductive treatment, and antiaggregant drugs were stopped 7 days prior to sample collection. Patients group included JAK2 mutations (n=11), CALR (n=3), MPL (n=1) and triple-negative (TN)(n=5). Platelet characteristics and functional assessment included flow cytometry and TGT using *Calibrated Automated Thrombogram (CAT) using* PPP-low as trigger.
Results: ET patients included 21 females and 1 male with median age of 51 years (24-76). Median platelet count was 631 x10^9/L (245-1102) and median platelet volume was 8,3fL (7,2-10,8). Fibrinogen receptors on platelets from JAK2+ patients had decreased capacity to be activation by agonists TRAP *(p<0.01) and ADP (p<0.01)*. Platelets from JAK2+ and TN patients exposed P-selectin levels similar to controls after agonist stimulation. Decreased CD63 exposure was noted on JAK2+ group after TRAP stimulation *(p<0.05)*.No significant differences in vWF receptor expression were detected among groups. Plasma from JAK2+ patients had less thrombogenic potential according to the reduced values of endogenous thrombin potential (ETP) *(p<0.01)*,peak (p=0.01) and Velocity index (VI) *(p=<0,01) (Figure 1)*. Platelets from patients with MPL mutation had less fibrinogen receptors with reduced capacity to be activated by TRAP and ADP. All evaluated activation markers were decreased in CALR+ platelets. In MPL+, basal exposure of P-selectin and of CD63 were increased compared to controls. vWF receptor level in CALR+ and MPL+ was similar to controls. TG capacity in CALR+ showed decrease in ETP, peak and VI similar to findings in JAK2+. In phospholipid-dependent TG, diminished ETP and activation index was observed in CALR+. TG depending on tissue factor on microparticles was similar to controls in CALR+.

Figure 1. Thrombin generation capacity in JAK2+ and triple negative patients and healthy controls triggered by PPP-Low reactive

Summary/Conclusion: Our results suggest that molecular profile in ET patients may influence platelet activity and TG. Some alterations were also found in CALR+ and MPL+ patients, but due to the small number of patients it´s no possible to conclude a characteristic pattern in these patients Studies increasing number of patients included should be performed to identify a characteristic pattern of haemostasis and coagulation for each mutation that could help to adjust antiaggregant treatment in ET patients.

EP1073 MECHANISTIC ABSORPTION PHYSIOLOGICALLY-BASED PHARMACOKINETIC (PBPK) MODEL FOR THE MURINE DOUBLE MINUTE 2 (MDM2) INHIBITOR KRT-232: PREDICTION OF FOOD AND PROTON PUMP INHIBITOR EFFECTS

J. Dong [1,*], G. Fraczkiewicz [1], S. Wong [2], T. Podoll [3], J. G. Slatter [2]

[1]*Simulations Plus Inc., Lancaster,* [2]*Kartos Therapeutics, Inc., Bellevue,* [3]*IV-PO, LLC., Seattle, United States*

Background: KRT-232 is a potent, selective, and orally bioavailable inhibitor of MDM2, a key negative regulator of the tumor suppressor protein, p53. KRT-232 restores p53 function resulting in apoptosis of malignant cells. Clinical trials investigating hematologic malignancies and solid tumors are ongoing. KRT-232 is a carboxylic acid that is metabolized primarily to an acyl glucuronide and undergoes enterohepatic recirculation. A 60 mg dose of KRT-232 given after a fast or a high-fat, high-calorie meal gave generally comparable KRT-232 pharmacokinetics (PK; Wong 2020). PBPK modeling was used to extrapolate this observation to higher doses and to define sensitivity of KRT-232 absorption to intrinsic and extrinsic factors.
Aims: 1) Develop an absorption PBPK model for KRT-232; 2) Use the model to characterize regional absorption and fraction absorbed (Fa) across doses; 3) Predict whether PK exposure will be sensitive to gastric pH, gastrointestinal transit times, or meal type.
Methods: The PBPK model was developed in GastroPlus v9.7 (Simulations Plus, Inc.), using KRT-232 physicochemical properties that were mainly measured in vitro. Single dose healthy volunteer PK data (N=30) were from a 60-mg single-dose crossover study that compared a new tablet formulation administered after fasting and after a high-fat, high-calorie meal (Wong 2020). The model was verified against the single-dose clinical PK data, which led to a clearance adjustment. The final model was validated against PK results from a single ascending dose study in patients with advanced solid tumors or multiple myeloma (Gluck 2020, Ma 2019).
Results: Model simulations using the final model were consistent with observed data from healthy volunteers (60-mg single tablet dose) and from fasted cancer patients (60–480-mg single tablet dose; **Table**).
The model accurately reflected the lack of a meaningful change in KRT-232 PK after administration of a 60-mg tablet with a high-fat,

high-calorie meal. KRT-232 Fa was near 100% and was not affected by dose or meal type. Absolute bioavailability was estimated to be ~73%, assuming UGT1A3 is the primary isoenzyme mediating KRT-232 metabolism. Under fasted conditions, most KRT-232 absorption occurred in the jejunum, with the relative amount of drug absorbed in the duodenum increasing slightly after a meal.

KRT-232 exposure was simulated for other meal types; Fa and AUC were not markedly affected. Over a physiologically-relevant range of values, sensitivity analyses showed that complete absorption of KRT-232 had little or no sensitivity to dose (≤ 480 mg), dissolution volume, stomach pH, or stomach transit time.

Simulated Fa of KRT-232 had little sensitivity to solubility from 1.6 µg/mL upwards past the reference solubility of the drug in Fasted and Fed State Simulated Intestinal Fluid (FaSSIF and FeSSIF, respectively [130 µg/mL]). Simulated fasted Fa was >90% with a mean particle radius almost 3-fold higher than that of the active pharmaceutical ingredient. Simulated Fa was even less sensitive to particle size under fed conditions.

Table. Simulated versus observed PK parameters for KRT-232 after 60-mg crossover tablet administration in healthy volunteers (N=30) under fasted or fed conditions (Treatments A1, A2, B) or fasted administration to cancer patients at 60-480-mg doses.

Healthy Volunteer PK

AUC, area under the curve; $AUC_{0\text{-}24}$, AUC during 24-hour period; $AUC_{0\text{-}inf}$, AUC to infinite time; C_{max}, maximum concentration; inf, infinity; nc, not calculated; NCA, noncompartmental analysis; Obs, observed; PK, pharmacokinetics; Sim, simulated; T_{max}, time of maximum concentration.
[a]Observed data are geometric means of individual values. [b]Observed data are medians of individual values. [c]Observed data are means of individual values. [d]Treatments A1 and A2 – New tablet fasted was measured in duplicate on separate occasions, Treatment B – New tablet – high fat/high calorie meal, [e]NCA PK parameter values were estimated with PKPlus™ software version 2.0 (Simulations Plus, Inc.) and are similar to Wong et al. *Blood*. 2020. [f]NCA PK parameter values are rounded from Gluck et al. *Invest New Drugs*. 2020.

Summary/Conclusion: The model adequately predicted KRT-232 PK under fasted and fed conditions. KRT-232 is completely absorbed across a wide range of doses, mainly from the jejunum. KRT-232 PK is not likely to be affected by proton pump inhibitor-mediated increases in gastric pH, in accord with its carboxylic acid structure. Because absorption is near 100% under most circumstances, major contributors to variability in KRT-232 PK will most likely be related to post-absorption intrinsic or extrinsic factors.

Myeloproliferative neoplasms - Clinical

EP1074 A PHASE 2 STUDY OF THE LSD1 INHIBITOR IMG-7289 (BOMEDEMSTAT) FOR THE TREATMENT OF ADVANCED MYELOFIBROSIS

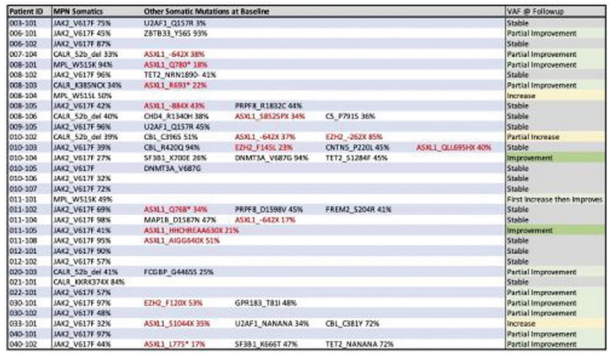
Background: Patients with myelofibrosis (MF) require treatment when the clinical benefits of JAK inhibitors are exhausted; there is a clear need for novel therapies. Lysine-specific demethylase-1 (LSD1) is an enzyme critical for malignant stem cells and the differentiation, e.g., LSD1 licenses maturation of megakaryocytes, a key cell in MF pathogenesis. IMG-7289 (bomedemstat) is an orally active LSD1 inhibitor that in mouse models of MPNs reduced peripheral cell counts, splenomegaly, inflammatory cytokines, marrow fibrosis and, importantly, mutant cell burdens (Jutzi *et al.* 2018).



Aims: IMG-7289-CTP-102 is an ongoing, multi-national, open-label, 24-week Phase 2 study of IMG-7289 taken once daily in MF patients resistant to all approved therapies. Key objectives are safety, and reduction a in spleen volume (SVR) and total symptoms scores (TSS). A platelet count ≥100k/µL is a key inclusion criterion. Bone marrow (BM) biopsies and imaging studies are read centrally. Dosing is individually tailored using platelet count as a biomarker targeting a platelet count of 50-100k/µL.

Methods: At the censoring date (15Feb2021), 62 patients had enrolled, 24 patients remain on study. The median duration of treatment is 98 days (14-567). Median age is 68 (35-88) with 50% males; 47% had PMF, 34%, PET-MF, 19%, PPV-MF. All but 6 patients were previously treated with ruxolitinib; 47% had received up to 3 additional treatments. 33% were transfusion-dependent. 58% were IPSS high-risk, 42% intermediate risk-2. Of driver mutations, 66% were *JAK2*, 27% *CALR*, 6% *MPL* and one triple-negative. Of a panel of 261 genes mutated in AML/MPN/MDS, 65% had ≥2 mutation, 46% had ≥1 HMR mutations, 94% were in *ASXL1*.

Results: Of all enrolled patients evaluable at 24 weeks for TSS (N=13), 85% recorded a reduction in TSS (mean change -31%; -81% to 21%) with 31% reporting >50% reduction. Of all patients evaluable for SVR after 24 weeks (N=19), 81% had a reduction in SV from baseline (mean SVR: -8%; -41% to +37%). 72% of evaluable patients (N=36) had stable or improved hemoglobin (>1 g/dL). 26% of evaluable patients had an improvement in fibrosis score by 1 grade while 43% were stable. Elevated serum LDH improved or resolved in 88%.

In 32 patients to date, mutant allele frequencies (MAF) in driver and HMR mutations were reduced in 42% and stable in 50%. All driver mutations showed sensitivity to bomedemstat; most *ASXL1* clones were subject to purifying selection by treatment. When MAFs in driver mutations were stable or decreased, SV and/or TSS was stable (n=2) or improved (n= 17). In subjects with excess blasts (N=12), 8 (67%) improved or resolved during therapy. There has been no progression to AML at up to 550 days. There was no obvious relationship among mutations, final optimal dose or response rates. Germline variants will be discussed. CN-LOH remains a strong driver of mutant gene dosage.

55 patients (89%) reported 1001 AEs of which 63 were SAEs. Eight SAEs, 6 Grade 3 and 2 Grade 2, each occurring once, were deemed related by Investigators to IMG-7289: painful splenomegaly, rectal hemorrhage, cardiac failure, headache, vertigo, gastrointestinal hemorrhage, anaemia and pyoderma gangrenosum. There have been no safety signals, DLTs, or deaths related to drug.

Summary/Conclusion: In this first clinical study of an LSD1 inhibitor in MF patients, IMG-7289 as monotherapy was well-tolerated, improved symptom burdens and reduced spleen volume without safety signals. Additionally, improvements in fibrosis scores, anemia and MAF have been observed.
The study is active and is enrolling in the US, UK, EU and Hong Kong.

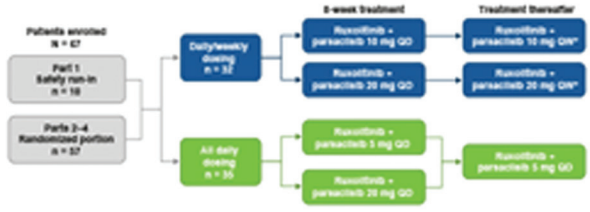
EP1075 ADD-ON PARSACLISIB (A PI3K-DELTA INHIBITOR) IN PATIENTS WITH MYELOFIBROSIS AND SUBOPTIMAL RESPONSE TO RUXOLITINIB: INTERIM ANALYSIS FROM A PHASE 2 STUDY

A. Yacoub [1,*], U. Borate [2], R. Rampal [3], H. Ali [4], E. Wang [5], A. Gerds [6], G. Hobbs [7], M. Kremyanskaya [8], E. Winton [9], C. O'Connell [10], S. Goel [11], S. Oh [12], G. Schiller [13], A. Assad [14], S. Erickson-Viitanen [14], X. Chen [14], F. Zhou [14], N. Daver [15]

[1]University of Kansas Cancer Center, Westwood, [2]Oregon Health & Science University, Portland, [3]Memorial Sloan Kettering Cancer Center, New York, [4]City of Hope National Medical Center, Duarte, [5]Roswell Park Cancer Institute, Buffalo, [6]Cleveland Clinic, Cleveland, [7]Massachusetts General Hospital, Boston, [8]Icahn School of Medicine at Mount Sinai, Manhattan, [9]Emory University, Atlanta, [10]University of Southern California, Los Angeles, [11]Montefiore Medical Center, Bronx, [12]Washington University School of Medicine, St Louis, [13]University of California Los Angeles, Los Angeles, [14]Incyte Corporation, Wilmington, [15]University of Texas MD Anderson Cancer Center, Houston, United States

Background: Ruxolitinib (rux) is highly effective in myelofibrosis (MF). Rux improves symptoms, reduces spleen size, and prolongs survival; however, suboptimal response may occur in a subset of patients (pts), potentially due to persistent PI3K/AKT pathway activation despite continued JAK inhibition. Parsaclisib (INCB050465) is a potent and highly selective next-generation PI3Kδ inhibitor. We hypothesized that adding parsaclisib would improve outcomes in pts with suboptimal response to stable rux treatment.
Aims: This phase 2 study (NCT02718300) evaluated optimal dosing, efficacy, and safety of add-on parsaclisib in pts with MF with a suboptimal response to rux.
Methods: Pts had primary, post–polycythemia vera, or post–essential thrombocythemia MF, ECOG performance status ≤2, and suboptimal response (palpable spleen >10 cm below left subcostal margin [LSM]; or palpable splenomegaly 5–10 cm below LSM and presence of 1 symptom score ≥5 or 2 symptom scores ≥3 each using the Screening Symptom Form) after ≥6 months of rux (5–25 mg twice daily; rux stable dose, ≥8 weeks [wks]). Pts remained on their stable rux dose and were randomized to receive add-on parsaclisib 10 mg or 20 mg once-daily (QD) for 8 wks and the same dose once-weekly (QW) thereafter (QD/QW group), or parsaclisib 5 mg or 20 mg QD for 8 wks and 5 mg QD thereafter (all QD group) (Figure 1). The primary endpoint was change in spleen volume from baseline to wk 12 by MRI/CT scan; other endpoints included change in spleen length and symptoms (Myelofibrosis-Symptoms Assessment Form Total Symptom Score [MFSAF-TSS]).
Results: At data cutoff (Aug 27, 2020) for this interim analysis, 32 pts received parsaclisib QD/QW and 35 received parsaclisib all QD. Median treatment duration was 213 days; median average daily dose was 5.0 mg/day for parsaclisib and 30.0 mg/day for rux. Baseline median spleen volume (cm^3) was 2414 in QD/QW (n=29) and 1885 in QD (n=29); median MFSAF-TSS was 10.8 (n=28) and 16.3 (n=26), respectively. Median percentage change in spleen volume at wk 12 was −1.9 (n=29) in QD/QW and −13.0 (n=27) in QD, and at wk 24 was −3.5 (n=23) and −21.8 (n=17), respectively (Figure 2: [A] spleen volume reduction; [B] palpable spleen length change). Median percentage change in MFSAF-TSS at wk 12 was −14.0 (n=21) in QD/QW and −37.4 (n=17) in QD.
Nonhematologic treatment-emergent adverse events (TEAEs) were primarily grade 1/2; grade 3/4 nonhematologic TEAEs occurring in >1 pt overall were urinary tract infection (n=3; all QD/QW), fall, increased alanine aminotransferase, increased aspartate aminotransferase, hypocalcemia, and hypertension (each n=2; all QD/QW), dyspnea (n=2; both QD), and fatigue and pneumonia (each n=2; each 1 QD/QW, 1 QD). New-onset grade 3 thrombocytopenia was observed in 6/32 (19%) pts in QD/QW and 9/35 (26%) pts in QD; grade 4 thrombocytopenia was observed in 6/32 (19%) pts in QD/QW and 1/35 (3%) pts in QD. TEAEs of special interest included grade ≥2 diarrhea (n=4) and grade ≥2 rash (n=1) (all QD/QW). No colitis was reported. TEAEs led to parsaclisib interruption in 18/32 pts in QD/QW and 18/35 pts in QD, and rux interruption in 6/32 and 8/35 pts, respectively; and to parsaclisib discontinuation in 7/32 pts in QD/QW and 3/35 pts in QD, and rux discontinuation in 2/32 and 1/35 pts, respectively.

Figure 1: Parsaclisib dosing schedules in combination with ruxolitinib



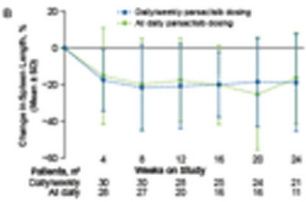


Figure 2: Spleen volume reduction at week 12 and 24 (A) and change in palpable spleen length over time (B), by parsaclisib dosing schedule

A.

Response Category, n (%)	Daily/Weekly Dosing	All Daily Dosing
Week 12	n = 29	n = 27
>10% to <25% reduction	8 (28)	11 (41)
≥25% to <35% reduction	1 (3)	3 (11)
≥35% reduction	0	1 (4)
Week 24	n = 23	n = 23
>10% to <25% reduction	2 (7)	6 (26)
≥25% to <35% reduction	3 (10)	5 (21)
≥35% reduction	1 (3)	2 (9)

Summary/Conclusion: Add-on parsaclisib showed preliminary efficacy in pts with MF experiencing suboptimal response to rux; QD dosing appeared more efficacious than QD/QW dosing. Combination therapy was generally well tolerated with limited grade 3/4 AEs and TEAE-related discontinuations.

Background: Following long-term interferon-α therapy for polycythaemia vera (PV), hematologic responses persist despite treatment discontinuation in some patients, demonstrating that operational cure can be achieved. Relapse-free discontinuation is more likely in patients who achieved a *JAK2*V617F mutation <10% prior to stopping treatment (Daltro De Oliveira R et al., Blood 2020) but prognostic factors for deep molecular responses to interferon-α are unknown.
Aims: To explore predictive baseline factors in patients who achieved a *JAK2*V617F allele burden <10% after 5 years' ropeginterferon alfa-2b (BESREMi®) therapy and to distinguish this population from patients with allele burden ≥10% regarding clinical outcome parameters.

Methods: Patients with PV diagnosed by WHO 2008 criteria who were cytoreduction-naïve or hydroxyurea (HU) pre-treated were randomised 1:1 to receive ropeginterferon alpha-2b or HU for one year in PROUD-PV. In CONTINUATION-PV, patients received long-term treatment in the study arms originally allocated. Efficacy assessments included complete haematological response (CHR) and *JAK2*V617F allele burden. Patients with a baseline *JAK2*V617F allele burden ≥10% who were treated with ropeginterferon alpha-2b for ≥5 years were analysed using univariate and multivariate logistic regression models to determine predictive baseline factors (including demographics, non-driver mutations, spleen size and PV-related symptoms) and Fisher's or Wilcoxon test to determine other associated factors (including 4-weekly dose level, CHR, duration of maintained CHR, splenomegaly and symptoms) for achieving a *JAK2*V617F allele burden <10% at 5 years.
Results: In CONTINUATION-PV, 66/95 patients enrolled in the ropeginterferon alfa-2b arm had a baseline *JAK2*V617F allele burden ≥10% and had been treated for ≥5 years at the time of analysis, of whom 37 achieved allele burden <10% at Month 60 (last observation carried forward).
Lower age and lower *JAK2*V617F allele burden were identified as predictive baseline factors for achieving a *JAK2*V617F allele burden <10% at 5 years (median age 54.0 years for patients with allele burden <10% vs. 63.0 years in those with allele burden ≥10%; univariate and multivariate analyses p=0.005 and p=0.002; median allele burden 36.8% vs. 46.3%, p=0.03 and p=0.02 respectively). Absence of non-driver mutations was predictive only in the univariate analysis (p=0.02). Time since PV diagnosis, PV-related symptoms and spleen size were not predictive.
Allele burden <10% was associated with a higher CHR rate at Month 60 (CHR in 86.5% of patients with allele burden <10% vs. 58.6% with allele burden >10%; p=0.02) and longer maintained CHR (median: 41.8 vs. 30.3 months respectively; p=0.03). All 37 patients with allele burden <10% had platelets <400 x 10^9/L and leukocytes <10 x 10^9/L at Month 60, but a few patients still required phlebotomy in the 5th year (n=6) or had mild splenomegaly (n=2; spleen size 14.9 cm and 13.4 cm) or pruritus (n=1). Dosing level had no impact on allele burden (p=0.9).
Operational cure defined as allele burden <10%, maintained CHR for the last ≥2 years, and no disease progression, thromboembolic events, or worsening of symptoms in the entire 5-year period was achieved in 27 patients.
Summary/Conclusion: A sizable proportion of patients with PV achieved operational cure after 5 years' ropeginterferon alfa-2b treatment. Lower age and lower allele burden at baseline predicted allele burden <10% at 5 years, suggesting that ropeginterferon alfa-2b should be initiated early in PV to achieve the greatest long-term benefit.

EP1077 PELABRESIB (CPI-0610) IMPROVED ANEMIA ASSOCIATED WITH MYELOFIBROSIS: INTERIM RESULTS FROM MANIFEST PHASE 2 STUDY

Background: Pelabresib (CPI-0610), a first-in-class, oral, small-molecule inhibitor of bromodomain and extraterminal domain (BET) proteins, has the potential to promote disease-modifying activity through altered gene regulation of key oncogenic, fibrotic, and inflammatory factors in the clonal disease cells of origin in myelofibrosis (MF). Furthermore, pelabresib promotes maturation and ex vivo differentiation of erythroid progenitors (Mertz, ASH 2020). Many MF patients (pts) treated with ruxolitinib (rux) develop worsening anemia and may become red blood cell (RBC) transfusion-dependent (TD) which represents a significant unmet medical need. Here we report improvement of anemia in advanced MF pts as evidenced by achievement of RBC-transfusion independence (TI) in TD pts or sustained mean hemoglobin (Hgb) increase of ≥1.5g/dL for 12 wks in non-transfusion dependent (non-TD) pts.
Aims: Evaluation of pelabresib monotherapy or as add-on to rux in advanced MF pts.
Methods: MANIFEST is an ongoing, open-label Phase 2 study. In Arm 1, pts that were refractory, intolerant or ineligible for JAKi were treated with pelabresib monotherapy. A washout of ≥2 wks since last systemic MF therapy was required. In Arm 2, pts receiving rux but not deriving adequate benefit were treated with pelabresib add-on to rux. Pts are stratified to cohorts 1A and 2A if they were TD (receiving ≥6U RBCs/12 wks) and into cohorts 1B and 2B as non-TD if they did not meet TD criteria. Primary endpoint was achievement of TI ≥12 wks in TD cohorts; ≥35% spleen volume reduction at wk 24 in non-TD cohorts.
Results: As of 29 Sep 2020, 19 TD pts and 27 non-TD pts were treated in Arm 1 (monotherapy). 76% of pts had baseline Hgb <10g/dL (Median: 9, range: 6-15). Median number of prior therapies was 2 (1-6). Median time since last rux dose in non-TD cohort was 9.2 mo (range 0.5-46 mo). In TD cohort, 21% (3/14) of pts achieved TI (median duration of transfusion-free period: 44 wk, range 32-50). In non-TD cohort, mean Hgb increase ≥ 1.5 g/dL sustained over a 12-wk transfusion-free period was achieved by 59.1% (13/22) of pts among which only 1 pt received rux within 4 months of study entry, suggesting the increase in Hgb was not a consequence of rebound due to rux discontinuation.
In Arm 2, 52 TD pts and 26 non-TD pts were treated with pelabresib as add-on to rux. 76% of pts had baseline Hgb <10g/dL (median: 9, range: 6-13). In TD cohort, 36% (13/36) of pts achieved TI (median duration of transfusion-free period: 39 wk, range 18-148). 17.4 % (4/23) of non-TD pts had mean Hgb increase ≥ 1.5 g/dL sustained over a 12-wks transfusion-free period.
In pts with an anemia response, the observed Hgb improvement or achievement of TI has been generally associated with an increase in reticulocyte count and/or increased CD71+ progenitor cells in the bone marrow, suggesting a positive pelabresib effect on erythroid differentiation.
Pelabresib was generally well tolerated. The most common treatment emergent adverse events include diarrhea (46%, ≥Gr3: 4%), thrombocytopenia (40%, ≥Gr3: 22%), nausea (36%, ≥Gr3: 2%), asthenic conditions (32%, ≥Gr3: 2%), respiratory tract infections (32%, ≥Gr3: 4%), dysgeusia (26%, ≥Gr3: 1%) and cough (25%, no ≥Gr3).

Table 1	Monotherapy Non-TD (1B)	Add-on to rux Non-TD (2B)	Monotherapy TD (1A)	Add-on to rux TD (2A)
Mean Hgb increase of ≥1.5 over 12 wks[1,2]	59.1% (13/22)	17.4% (4/23)	-	-
Achievement of TI ≥12 wks[3]	-	-	21% (3/14)	36% (13/36)

[1]Patients are evaluable if they received ≥12wks of treatment; baseline: the latest Hgb assessment prior to C1D1
[2]Post-baseline mean Hgb increase of at least 1.5g/dL is required for any 12 wks RBC transfusion free period
[3]Patients are evaluable for achievement of transfusion independent (TI) ≥12 wks if they have been on treatment for at least 24 weeks by the data cutoff date or if they have been on treatment for at least 12 weeks by the data cutoff day and have achieved the conversion or would have failed to achieve the conversion by week 24

Summary/Conclusion: Pelabresib monotherapy was associated with a mean increase in Hgb ≥ 1.5 g/dL in majority of non-TD pts and conversion of one-fifth of TD pts to TI in heavily pretreated MF pts in Arm 1. Addition of pelabresib to rux in Arm 2 pts with suboptimal response on stable doses of rux resulted in mean increase in Hgb ≥ 1.5 g/dL in 17% of non-TD pts and conversion to TI in more than one-third of TD pts.

EP1078 NAVITOCLAX AND RUXOLITINIB FOR PATIENTS WITH MYELOFIBROSIS AND JAK INHIBITOR EXPERIENCE: RESPONSE DURATION IN PHASE 2 STUDY

Background: Navitoclax (Nav) is an oral small-molecule inhibitor of antiapoptotic B-cell lymphoma 2 proteins (BCL-X_L, BCL-2, BCL-W) that has shown pronounced antitumor activity in xenograft models. Interim analyses of an ongoing, multicenter, Phase 2 trial (NCT03222609) of Nav plus the Janus kinase 1/2 (JAK1/2) inhibitor ruxolitinib (Rux) in 34 patients (pts) with myelofibrosis (MF) were previously reported (Pemmaraju et al. ASH 2020, #52).
Aims: To provide an update on the findings from this Phase 2 trial of Nav plus Rux in pts with MF.
Methods: Pts with primary or secondary MF who had previously received Rux for ≥12 weeks continued their current stable dose of Rux, and Nav was initiated at 50 mg/day and escalated to a maximum of 300 mg/day, as tolerated based on platelet count. The primary endpoint was spleen volume reduction of ≥35% (SVR_{35}) from baseline (BL) at Week (Wk) 24. Secondary endpoints included improvement in total symptom score (TSS, as measured by the Myelofibrosis Symptom Assessment Form v4.0), bone marrow fibrosis (BMF), anemia response (per International Working Group [IWG] criteria), and safety. Exploratory endpoints were duration of response (DOR) of SVR_{35}, and overall survival (OS).
Results: At the data cutoff, August 30, 2020, 34 pts with MF received ≥1 dose of Nav plus Rux. Median age was 68 years (range 42–86). At BL, the median spleen volume was 1,695 cm^3 (range 465–5,047). At BL, 9 pts were transfusion independent (TI) with hemoglobin (Hbg) <10g/dL and 2 pts were transfusion dependent per IWG criteria. Of 33 pts with BL testing, 79% and 21% had *JAK2* and *CALR* mutations (4/7 *CALR* type 1, 3/7 *CALR* type 2), respectively, and 19 pts had high molecular risk mutations (HMR); 17 pts had ≥3 genes mutated at enrollment. Median duration of Rux exposure prior to study was 82 wks (range 19–308).
Twenty-four (71%) pts received the maximum Nav dose of 300 mg/day. Median Nav exposure since study onset was 81 wks (range 4–126); 24 pts remain on-study and 17 pts remain on-treatment. Of 17 pts who discontinued Nav, the most common reasons were progressive disease (29%) and adverse events (AEs, 18%).
SVR_{35} from BL to Wk 24 was reported for 9 (27%) pts, independent of HMR, and SVR_{35} at any time was achieved in 15 (44%) pts; responses were seen at wk 12 in 6 (18%) pts. Median DOR of SVR_{35} was 13.8 months (95% confidence interval [CI]: 8.2–not reached), which was similar in pts with and without HMR. TSS was reduced by ≥50% in 6/20 (30%) pts who were evaluable at Wk 24. BMF improved by ≥1 grade at any time on study in 11/33 (33%) pts. Hgb levels improved on-study; 7/11 (64%) pts with Hgb <10 g/dL or transfusion dependency at BL had improvement in Hgb of ≥2 g/dL (n=6) or became TI (n=1). At a median follow-up of 105 wks, median OS was not reached (**Figure**); OS estimate at 24 months was 84% (95% CI: 63.0%–93.9%).
All pts experienced an AE, most common AEs were thrombocytopenia (88%), diarrhea (71%), and fatigue (62%), with most gastrointestinal AEs of Grade 1/2. Thirty (88%) pts experienced a Grade 3/4 AE, and 15 (44%) had a serious AE (SAE). The most common Grade ≥3 AEs were thrombocytopenia (without clinically significant bleeding; 56%) and anemia (32%), and the most common SAE was pneumonia (12%). Thrombocytopenia led to Nav dose reduction in 19 (56%) pts.

Figure. Kaplan-Meier Curve of Overall Survival

NE, not estimable NR, not reached; OS, overall survival

Summary/Conclusion: SVR was durable and encouraging, and improvement in TSS, anemia response, BMF, and OS were clinically meaningful. These data suggest that Nav plus Rux may exert disease-modifying activity in MF and warrant further testing in Phase 3 clinical studies.

EP1079 HIGH MOLECULAR RISK MUTATIONS ARE BIOMARKERS OF CLINICAL RESPONSE AND OUTCOME IN INTERMEDIATE-1 RISK MYELOFIBROSIS PATIENTS TREATED WITH RUXOLITINIB

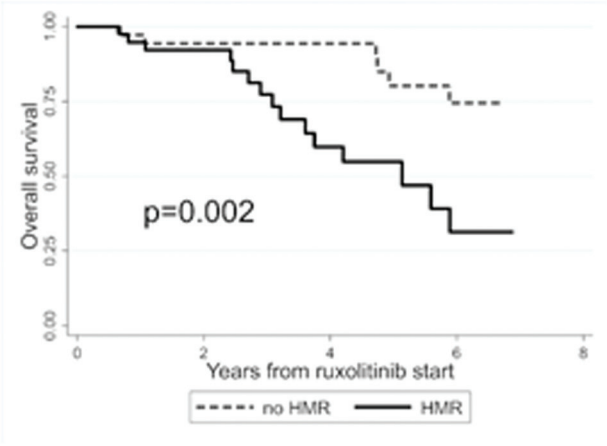
Ingrassia", University of Catania, Catania, Italy



Background: In intermediate (int)-2/high-risk patients (pts) with myelofibrosis (MF), presence of ≥3 high molecular risk (HMR) mutations (*IDH1/2*, *ASXL-1*, *SRSF2*, *EZH2*) was associated with lower response rates to ruxolitinib (RUX) (Newberry, Blood 2016). Although RUX is widely used in int-1 risk pts, the impact of HMR on response and outcome is unknown in this setting.
Aims: To investigate the impact of HMR mutations on treatment success and outcome in int-1 risk RUX-treated MF pts.
Methods: After IRB approval, the "RUX-MF" retrospective study collected 739 RUX-treated MF pts in 25 Hematology Centers. Overall, 361 (48.9%) pts received RUX while at int-1 risk according to DIPSS (primary MF, PMF) or to MYSEC-PM (secondary MF, SMF). In 79 int-1 pts, HMR status was evaluated by next generation sequencing (NGS) before or soon after RUX start. Clinical/laboratory characteristics and RUX starting dose were comparable in these 79 pts and in the 282 with no HMR data available. Spleen (SR) and symptoms (SyR) response were evaluated according to IWG-MRT criteria. Overall survival/RUX stop/blast phase (BP)/infection-free survival were estimated from RUX start to death/RUX stop/BP/infection or last contact and compared with the log-rank test.
Results: The characteristics of the 79 int-1 MF pts at RUX start were: median age 65.7y (24-83); males 55.7%; PMF 44.3%; *JAK2*, *CALR* and *MPL* mutated: 73.4%, 25.3% and 0 (1.3% triple negative), Hb<10 g/dl: 12.7%, PLT>200 x10^9/l: 76%; blast cells≥1%: 33%; spleen length >10 cm: 44.3%, TSS >20: 56.5%, time from MF diagnosis to RUX start >2y

in 46.8%. Starting and cumulative RUX dose >10 mg BID: 74.4% and 57.9%, respectively. Overall, ≥1 HMR was detected in 39 pts (49.4%) (≥2HMR in 12 pts). Specifically, *ASXL-1* was found in 33 pts, *IDH1* in 5, *IDH2* in 3, *SRSF2* in 6 and *EZH2* in 7. While *SRSF2* mutations were detected only in PMF (p=0.005), distributions of the other HMR mutations were comparable in PMF and SMF. HMR pts started RUX more frequently with large spleen (p=0.03) and lower PLT count (p=0.04) compared to no-HMR pts.

At 3 and 6 mos, 26.9% and 31.3% of pts achieved a SR, while 65.6% and 75% were in SyR, respectively. SR was less frequently achieved by HMR pts at both 3 (11.4% vs 43.8%, p=0.003) and 6 mos (18.8% vs 43.8%, p=0.03). SyR was not influenced by HMR status.

PLT count at 3 and 6 mos was always >50 x10^9/l in all cases but two. At 3 and 6 mos, in 33.3% and 29% of transfusion independent pts, Hb decreased <10 g/dl, while 18.7% and 19.7% became transfusion-dependent, respectively, regardless of HMR. At least one infection, mainly including lung (32.8%), urinary tract (11.7%) and gastrointestinal tract (7.6%) occurred in 28 pts, regardless of HMR (log-rank p=0.13).

After a median RUX exposure of 2.7y (0.1-7.7), 36 (45.6%) pts discontinued RUX, 4 (5.2%) progressed to BP and 22 (27.9%) died. In HMR pts, RUX discontinuation (38.9% vs 20.8% at 3y, log-rank p=0.01) and BP progression (10% vs 0 at 3y, log-rank p=0.04) were significantly higher. Overall survival was also significantly shorter for HMR pts (log-rank p=0.002) (**Fig.1**).

Summary/Conclusion: In int-1 pts treated with RUX, HMR mutations are associated with lower responses, increased BP progression and worse survival. HMR evaluation is crucial for personalized management of these pts.

EP1080 BET INHIBITOR PELABRESIB DECREASES INFLAMMATORY CYTOKINES, IMPROVES BONE MARROW FIBROSIS AND FUNCTION, AND DEMONSTRATES CLINICAL RESPONSE IRRESPECTIVE OF MUTATION STATUS IN MYELOFIBROSIS PATIENTS

P. Keller [1,*], J. Cui [1], J. Mertz [1], M. Salama [2], O. Zavidij [1], S. Verstovsek [3], C. Harrison [4], J. Mascarenhas [5], M. Talpaz [6], R. Mesa [7], A. Vannucchi [8], R. Rampal [9], S. Oh [10], G. Colak [1], K. Luptakova [1], J. Humphrey [1], J. Wang [1], P. Trojer [1]

Background: Myelofibrosis (MF) is characterized by abnormal megakaryopoeisis and overproduction of pro-inflammatory cytokines (Ck), which lead to bone marrow (BM) fibrosis, progressive anemia, and extramedullary hematopoiesis resulting in hepatosplenomegaly. Driver and high molecular risk mutations are well characterized and impact survival of MF patients (pts). Bromodomain and extraterminal domain (BET) proteins regulate neoplastic myeloproliferation and pro-inflammatory Ck expression mediated by nuclear factor kappa B (NF-κB), serving as a rational target for drug development in MF. Pelabresib (CPI-0610) is a potent, selective BET inhibitor under investigation in the ongoing Phase 2 MANIFEST trial (NCT02158858), given as a monotherapy to ruxolitinib (rux) intolerant/refractory MF pts in arm 1; as an 'add-on' to rux in MF pts who have suboptimal or lost response to rux in arm 2; and as combination therapy with rux in JAK inhibitor naïve MF pts in arm 3. Pelabresib demonstrated reductions in spleen volume and symptoms, improvements in hemoglobin levels, and conversions to transfusion independence.

Aims: Evaluation of translational studies from MANIFEST Phase 2 trial.

Methods: We assessed pharmacodynamic (PD) activity of pelabresib including changes in inflammatory Ck in blood, improvement of BM biology, including fibrosis (BMF), erythroid (Ery) progenitor and megakaryocyte (Mk) histotopography, and impact of mutations status on clinical response.

Results: Rapid PD response was demonstrated by 55% median reduction of blood *IL8* mRNA level compared to baseline (BL) 4 hours post the 1st dose of pelabresib in 101 pts, with similar reduction across arms. Elevated blood Ck levels were observed at BL across arms, consistent with prior MF studies. Reduction of NF-κB and non-NF-κB regulated inflammatory Ck was observed on cycle 1 day 14 (C1D14) across arms and maintained at C5D1 and C9D1.

BMF grading was assessed by local pathologists for BL and post-treatment (most at 24 weeks) biopsies available from 116 evaluable pts. Relative BMF improvement of ≥1 grade was observed in 33% (38/116) of all pts, with 21% (6/29) in arm 1, 41% (16/39) in arm 2 and 33% (16/48) in arm 3. BMF grade worsening was observed in only 6% (7/116) of pts. Exploratory analysis of Ery and Mk lineages by immunohistochemistry staining for CD71 and CD61 were conducted centrally on BM biopsy pairs collected at BL and week 24 for 37 pts. Semi-quantitative analysis revealed an increase in Ery progenitors in 59% (22/37) of pts. Tight clusters of Mk, characteristic in MF BM, were observed at BL, and improvement in Mk histotopography was observed in 65% (24/37) of pts.

Mutation analysis revealed similar mutation profiles at BL across arms, with *JAK2* (65%) and *ASXL1* (47%) as the most frequently mutated genes. The 14 most frequently mutated genes at BL were assessed for correlation with spleen volume reduction by ≥35% (SVR35) or ≥50% reduction of total symptom score (TSS50) at 24 weeks. SVR35 and TSS50 at 24 weeks were similar in pts regardless of mutational status for each of the 14 genes analyzed.

Summary/Conclusion: Our interim translational data demonstrate a robust PD effect of pelabresib in MF pts, indicate broad clinical responses of pelabresib monotherapy and combination with rux irrespective of mutation status, including *ASXL1*, and suggest at a disease-modifying potential of pelabresib by improving BM histotopography and function. MANIFEST-2; a global, randomized, double-blind phase 3 trial (NCT04603495) is currently underway evaluating combination of pelabresib with rux versus placebo with rux in JAK inhibitor treatment naïve MF pts.

EP1081 IMPROVED TRANSFUSION INDEPENDENCE RATES FOR MOMELOTINIB VS RUXOLITINIB IN ANEMIC JAKI NAÏVE MYELOFIBROSIS PATIENTS INDEPENDENT OF BASELINE PLATELET OR TRANSFUSION STATUS

Background: Momelotinib (MMB) is a potent JAK1, JAK2 and ACVR1 inhibitor with clinical activity against the hallmark features of myelofibrosis (MF), namely anemia, constitutional symptoms and splenomegaly, across the continuum of JAKi naïve or previously JAKi treated intermediate/high risk MF patients as demonstrated in the previously conducted Phase 3 SIMPLIFY-1 & -2 clinical trials (S1, S2). S1 was conducted in JAKi-naïve patients with MF (n=432) double-blind randomized 1:1 to MMB or ruxolitinib (RUX).
MMB demonstrated a statistically non-inferior splenic response rate (SRR) to RUX at the W24 landmark analysis in S1 but did not meet significance for total symptom score (TSS) response. Low SRR and TSS response was observed for RUX in patients with low platelets, while MMB elicited consistent SRR and TSS response across the platelet subsets, comparable to the response in the ITT. Transfusion independence (TI) at W24 was higher for MMB vs RUX patients across all PLT strata.
Aims: Progressive anemia is a common occurrence in MF with nearly all MF patients requiring transfusions as their disease advances. Given the prognostic importance of Hgb and transfusion status in MF patients including evidence that achieving or maintaining transfusion independence by Week 24 with momelotinib is associated with improved OS in S1 and S2, we expanded the previously reported retrospective platelet subset analysis.
Methods: Week 24 TI response rates for MMB and RUX randomized patients in S1 by baseline Hgb and PLT levels and transfusion status were explored.
Results: The data presented here suggest that the prognostically-important W24 TI rate was substantively higher in anemic patients receiving MMB versus RUX, irrespective of the degree of anemia. MMB is also more effective relative to RUX in achieving or maintaining TI in JAKi naïve patients irrespective of baseline PLT count or baseline transfusion status.

	TI Response at Week 24	
	MMB	RUX
ITT Population	67% (143/215)	49% (107/217)
Baseline Hgb Level		
Hgb <8	29% (8/28)	18% (4/22)
Hgb <10	47% (40/86)	27% (26/95)
Hgb <12	62% (99/159)	37% (61/164)
Hgb <14	67% (136/204)	45% (87/195)
Hgb ≥14	64% (7/11)	91% (20/22)
Baseline PLT Count		
PLTs <150	62% (29/47)	43% (24/56)
PLTs <300	68% (93/136)	48% (62/128)
PLTs ≥300	63% (50/79)	51% (45/89)
Baseline Transfusion Status		
TI	81% (119/147)	62% (94/152)
TR	53% (8/15)	31% (4/13)
TD	30% (16/53)	17% (9/52)

Hgb=hemoglobin, ITT=intent-to-treat, MMB=momelotinib, PLT=platelet, RUX=ruxolitinib, TD=transfusion dependent, TI=transfusion independent, TR=transfusion requiring

Summary/Conclusion: Together with data suggesting that TI response at W24 with momelotinib is associated with a survival advantage, these data further support the potential TI benefits of inhibiting ACVR1 in addition to JAK1 and JAK2 with MMB in MF patients.

EP1082 INTENSIVE AND NONINTENSIVE BLAST REDUCTION THERAPY IN ACCELERATED AND BLAST PHASE OF BCR-ABL NEGATIVE MPN

M. Davidson [1,*], J. Kennedy [2], C. McNamara [3], E. Smith [3], J.-M. Capo-Chichi [4], J. England [3], Y. Shi [5], T. Murphy [3], H. Sibai [3], D. Maze [3], K. Yee [3], A. Schuh [3], A. Schimmer [3], S. Chan [3], M. Minden [3], V. Gupta [3]

[1]Medical Oncology and Hematology, Princess Margaret Cancer Center, [2]Division of Medical Oncology and Hematology, Sunnybrook Health Sciences Centre, [3]Division of Medical Oncology and Hematology, Princess Margaret Cancer Center, [4]Department of Molecular Genetics, Toronto General Hospital, [5]Department of Biostatistics, Princess Margaret Cancer Center, Toronto, Canada

Background: Accelerated phase (AP) and/or blast phase (BP) of *BCR-ABL* negative myeloproliferative neoplasms (MPN) are associated with poor outcomes. Comparative efficacy of AML-type induction regimens versus non-intensive hypomethylating agent (HMA)-based regimens is not well studied. Further, the lack of standardized response criteria to evaluate the treatment of MPN-AP/BP poses challenges in understanding treatment efficacy between various studies.
Aims: To determine the efficacy of intensive and non-intensive blast-reduction therapy in patients with MPN-AP/BP using uniformly applied study-defined response criteria.
Methods: All patients with MPN-AP/BP assessed at Princess Margaret Hospital between 01/1998 and 12/2020 were identified from the program database. Only patients treated with intensive induction chemotherapy and non-intensive azacytidine (AZA)-based therapy were included.
Intensive treatment included 3+7 (daunorubicin 60 mg/m^2 IV day (d) 1-3; AraC 100-200 mg/m^2 d1-7), FLAG-IDA (fludarabine 30 mg/m^2 IV & AraC 2000 mg/m^2 IV day 1-5; idarubicin 10 mg/m^2 IV d1-3; granulocyte-colony stimulating agent SC d1-6), or NOVE-HiDAC (mitoxantrone 10 mg/m^2 IV & etoposide 100 mg/m^2 d1-5; AraC 1000-1500 mg/m^2 every 12 hours for d1-2).
Non-intensive therapy consisted of AZA or AZA with venetoclax (AV). Targeted sequencing with a myeloid gene panel was performed. The primary endpoint was overall survival (OS) (time of AP/BP transformation until death or last follow-up), and overall response (CR, CRi or reversion back to chronic phase of MPN), using study-defined criteria.
Results: All patients (n=124) with MPN-AP (n=27) and MPN-BP (n=97) treated with intensive chemotherapy (3+7 [n=31]; FLAG-IDA/NOVE-HiDAC [n=46]) or non-intensive therapy (AZA [n=36] AV [n=11]) were included. The proportion of patients >70 years old, with ECOG ≥2, adverse ELN risk, and AP was higher in the non-intensive group. In evaluable patients, higher overall response rates were observed in patients treated intensively (78% [60/77] vs 38% [17/45], p<0.001). There was a trend towards improved response with AV (55% [6/11]) over AZA (32% [11/34]). Similar response rates were observed in patients receiving upfront 3+7 (74% [23/31]) or FLAG-IDA/NOVE-HiDAC (80% [37/46], p=0.58). However, patients receiving upfront 3+7 required more second inductions (29% [9/31] vs 9% [4/46], p=0.03). No difference in HCT rates was observed between induction regimens (43% [9/21] in 3+7 vs 58% [21/36] in FLAG-IDA/NOVE-HiDAC, p=0.4). The median OS for the cohort was 9.7 months (95% CI 8.4-12). There was no difference in OS between the intensive and non-intensive groups (HR 1.13 [95% CI 0.75-1.72].
OS was improved among patients receiving HCT (HR 0.3 [95%CI 0.17-0.54]). Factors significantly associated with shorter OS in multivariable analysis included non-response, BP (vs AP), number of mutated genes, and TP53 mutation. Factors negatively associated with response in multivariable analysis were non-intensive therapy and TP53 mutation.

Outcome	Blast Reduction Therapy					
	INTENSIVE THERAPY			NON-INTENSIVE		
	3+7 (N=31)	FLAG-IDA or NOVE-HIDAC (N=46)	P-value	HMA (N=34)	HMA+Ven (N=11)	P-value#
Best Response* (%)						
CR	9 (29)	14 (30)		1 (3)	3 (27)	
CRi	1 (3)	5 (11)		0	0	
CMPN	13 (42)	18 (39)		10 (29)	3 (27)	
No response	3 (10)	3 (7)	NS	19 (56)	5 (45)	
Progressive Disease	3 (10)	1 (2)		1 (3)	0	
Early Death	2 (6)	5 (11)		3 (9)	0	
Composite Best Response (CR/CRi/CMPN)	23 (74)	37 (80)	NS	11 (32)	6 (55)	NA
Need for re-induction (%)	9 (29)	4(9)	<0.05			
HCT-Eligible‡ (≤70 yo in CR/CRi/CMPN1)	N=21	N=36		N=5	N=3	
HCT performed (%)	9 (43)	21 (58)	NS	3 (60)	3 (100)	NA

*assessed after 1-2 cycles of induction and at time of best response with HMA; NS: not statistically significant
#Intensive vs non-intensive NA: not applicable
‡ patients ≤70 years-old and in CR/CRi/CMPN1

Summary/Conclusion: In this observational study, more rapid responses were observed with higher dose AraC containing regimens FLAG-IDA or NOVE-HIDAC compared to 3+7 in MPN-AP/BP. Azacytidine and venetoclax combination therapy appear to have higher response rate in comparison to azacytidine alone, and merit prospective investigation.

EP1083 CLINICAL AND MOLECULAR FACTORS AFFECTING SURVIVAL AFTER JAK-INHIBITOR FAILURE IN MYELOFIBROSIS: LONG-TERM DATA FROM A MOLECULARLY ANNOTATED COHORT

J. England [1,*], C. McNamara [1], J. Kennedy [2], J.-M. Capo-Chichi [3], J. Huang [4], W. Xu [4], A. Arruda [4], S. Malik [1], V. Cheung [1], D. Maze [1], H. Sibai [1], V. Gupta [1]

[1]Hematology/Medical Oncology, Princess Margaret Cancer Centre, [2]Hematology/Medical Oncology, Sunnybrook Health Sciences Centre, [3]Department of Molecular Genetics, [4]University Health Network Research, University Health Network, Toronto, Canada

Background: JAK-inhibitor (JAKi) therapy has become standard of care for symptomatic patients with myelofibrosis. While effective in ameliorating symptoms of MF, JAKi therapy is limited by variable duration of therapeutic benefit. Survival following JAKi failure is short, and the impact of clinical and molecular factors at JAKi failure is not well studied.
Aims: To characterize the clinical and molecular factors that influence the outcomes of JAKi failure in a myelofibrosis cohort with mature follow-up.
Methods: We conducted a retrospective cohort study analyzing a well-curated dataset of 113 patients in chronic phase MF patients treated with first line ruxolitinib (n=85) or momelotinib (n=28) at the Princess Margaret Cancer Centre between 11/2009 and 02/2019. Patients were included if they had a sample available for targeted mutational profiling of clinically relevant genes in myeloid neoplasms prior to start of JAKi therapy. Paired samples were available for a subset of 55 patients at the time of JAKi failure (n=49), or after sustained clinical response >3 years (n=6). The Canadian MPN Group consensus criteria was used to define JAKi failure along with its pattern: loss or lack of spleen response, cytopenias, progression to acceleration/blast phase (AP/BP), second malignancy, or non-hematologic toxicity (Gupta et al, JCO Oncology Practice, 2020).
Results: Median follow-up in survivors was 74 (range 21-120) months. A total of 107 (95%) patients experienced JAKi failure, and cumulative incidence of JAKi failure at 1,3 and 5 years was 34%, 71%, 87%, respectively. JAKi therapy failure rates were similar for those treated with ruxolitinib or momelotinib. Median overall survival (OS) was 41.8 months after JAKi start and 13.6 months in 107 patients after first line JAKi failure. In multivariate analysis, survival after JAKi failure was associated with high DIPSS score (HR 4.06, 95%CI 1.61-10.21), ECOG ≥2 (HR 5.58, 95%CI 2.27-13.72) and transformation to AP/BP (HR 2.44 95%CI 1.04-5.7)
Paired samples were available for mutation analysis in 49 patients at time of failure, and 6 patients with ongoing clinical response. A total of 30 emergent mutations were observed in 20 (43%) patients with JAKi failure. The most common emergent mutations were in *KRAS* (n=4) and *ASXL1* (n=4); with *RAS* pathway genes (*KRAS*, *NRAS*, *CBL*, and *PTPN11*) the most common class of emergent mutations occurring in 9 (45%) patients. *RAS* pathway mutations at time of JAKi failure, including persistent (n=8) and emergent (n=9) mutations, were present in: 7/23 (30%) patients with spleen progression, 5/10 (50%) with AP/BP, and 1/10 (10%) with cytopenia, 2/4 (50%) with non-heme toxicity, and 1/2 (50%) with secondary malignancy. The presence of persistent or emergent *RAS* pathway (P=0.03, Figure 1), *TET2* (P=0.04), or high molecular risk (HMR; *ASXL1*, *EZH2*, *IDH1/2*, *SRSF2*, *U2AF1 Q157*)(p=0.009) mutations were associated with inferior survival.

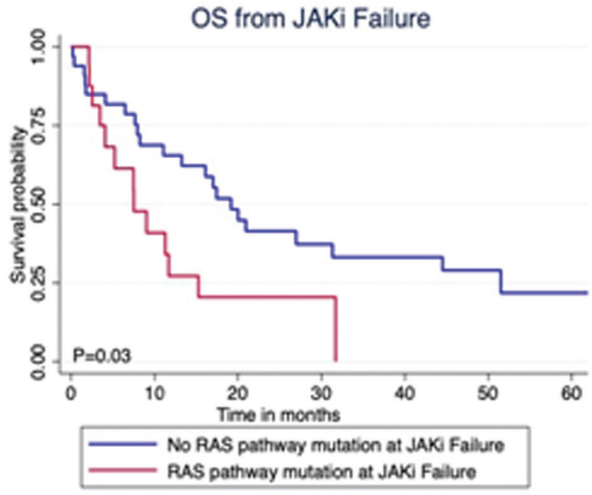

Figure 1: Overall survival following JAKi failure in patients with and without mutations in the *RAS* pathway (*NRAS/KRAS/CBL/PTPN11*)

Summary/Conclusion: Survival following first line JAKi failure is poor. Higher DIPSS/ECOG at time of failure and patients with disease transformation to AP/BP have worse survival compared to other types of JAKi therapy failure. *RAS* pathway gene mutations were the most common emergent mutations at JAKi therapy failure. The presence of persistent or emergent *RAS* pathway (Figure 1), *TET2*, or HMR mutations appear to predict inferior survival following JAKi failure.

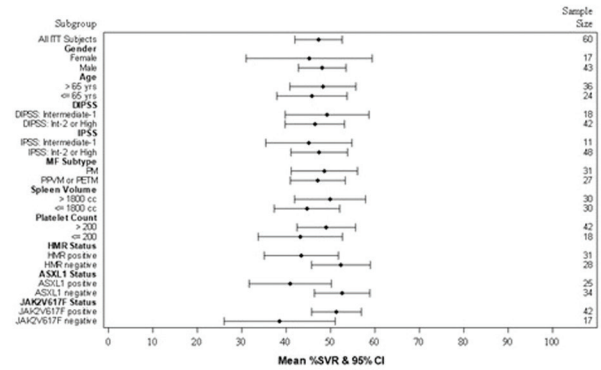
EP1084 GENOMIC PROFILING OF MYELOPROLIFERATIVE NEOPLASMS WITH SPLANCHNIC VEIN THROMBOSIS

M. Garrote [1,*], M. López-Guerra [1], E. Arellano-Rodrigo [2], M. Magaz [3], A. Triguero [4], V. Hernandez-Gea [3], F. Turon [3], A. Baiges [3], D. Colomer [1], J. C. García-Pagán [3], F. Cervantes [4], A. Alvarez-Larrán [4]

[1]Pathology Department, Hematopathology Unit, [2]Hemotherapy and Hemostasis Department, [3]Hepatology Department, [4]Hematology Department, Hospital Clínic de Barcelona, Barcelona, Spain

Background: Myeloproliferative neoplasms (MPN) are associated with an increased risk of thrombosis that can affect atypical sites, such as splanchnic vein thrombosis (SVT). In some cases, SVT precedes the MPN diagnosis whereas in other cases it occurs sometime after. MPN patients presenting with SVT are usually younger, have less abnormal blood counts and lower *JAK2V617F* allele burden than other MPN patients. However, it is unknown whether clinical and genetic characteristics are different according to SVT chronology.
Aims: The main aim of the present study is to describe the clinical and genomic profile of MPN associated with SVT occurring before, concurrent or after the diagnosis of MPN.
Methods: Ninety-two patients with MPN and SVT were selected. Cases were divided in three categories: Group 1 included patients diagnosed of SVT before MPN; group 2, cases with concurrent diagnoses of MPN and SVT; and group 3, patients with SVT being diagnosed after MPN. Next Generation Sequencing was performed and patients were classified according to the genomic classification proposed by Grinfeld.

Results: In 15 cases (16%) SVT was diagnosed before MPN, in 56 patients (61%) SVT and MPN were concurrently diagnosed and in 21 cases (23%) SVT was found after the diagnosis of MPN. Fifty-two patients (56.5%) were women. The median age was 51, 42 and 43 years in groups 1, 2, and 3, respectively.
Regarding their MPN, 52 cases (57%) fulfilled diagnostic criteria for polycythemia vera (PV), 23 cases (25%) for essential thrombocythemia and 2 (2%) for primary myelofibrosis. Thirteen cases (14%) were classified as MPN, unclassifiable (MPN-U). Group 1 was enriched in MPN-U cases (33% of group 1 cases vs 11.5% and 9.5% in groups 2 and 3, p=0.02), while group 2 was enriched with PV (69% of cases vs 47% and 43% in groups 1 and 3, p=0.02).
In comparison with group 2 and 3, group 1 patients had lower hematocrit value (median 41% vs 46% and 49%, p=0.02) and lower leukocyte count (5.8x10^9/L vs 9.9x10^9/L and 10.9 x10^9/L, p=0.02) whereas patients from group 3 showed higher platelet counts (630x10^9/L vs 339 x10^9/L and 410 x10^9/L in groups 1 and 2, respectively, p=0.02).
JAK2 gene was mutated in 85 patients: *V617F* mutation in 81 cases (88%), exon 12 mutation in 3 cases and non-canonical mutation in 1 case. *JAK2V617F* allele burden was higher in group 3 (43% vs 21% and 28% in groups 1 and 2, respectively, p=0.001). Genomic classification showed MPN with *TP53* disruption/aneuploidy, MPN with chromatin/spliceosome mutation, MPN with *CALR* mutation, MPN with homozygous *JAK2* and MPN with heterozygous *JAK2* mutation in 5%, 17%, 3%, 10%, and 61% of cases, respectively. Analysis according to SVT chronology showed that groups 1 and 2 were enriched in MPN with heterozygous *JAK2* mutation (60% and 77% of cases, respectively, vs 37% in group 3, p=0.01). MPN with *TP53* disruption/aneuploidy was observed in 0%, 7%, and 21%, of cases in groups 1, 2 and 3, respectively. MPN with chromatin/spliceosome mutation was detected in 20%, 15% and 26% of cases in groups 1, 2, and 3 respectively. A higher number of pathogenic mutations was observed in group 3 (median: 2; range:1-6) than in group 2 (median: 1; range: 1-3) or group 1 (median 1; range: 0-4) (p=0.001).
Summary/Conclusion: Patients developing SVT after the diagnosis of MPN have higher *JAK2V617F* allele burden and more genomic complexity than patients with SVT diagnosed before or at MPN diagnosis. Mild or absent hematological alterations due to low genomic complexity might explain the delay in MPN diagnosis in patients with SVT preceding MPN.



EP1085 CLINICAL BENEFIT OF PELABRESIB (CPI-0610) IN COMBINATION WITH RUXOLITINIB IN JAK INHIBITOR TREATMENT NAÏVE MYELOFIBROSIS PATIENTS: INTERIM EFFICACY SUBGROUP ANALYSIS FROM ARM 3 OF MANIFEST PH2 STUDY

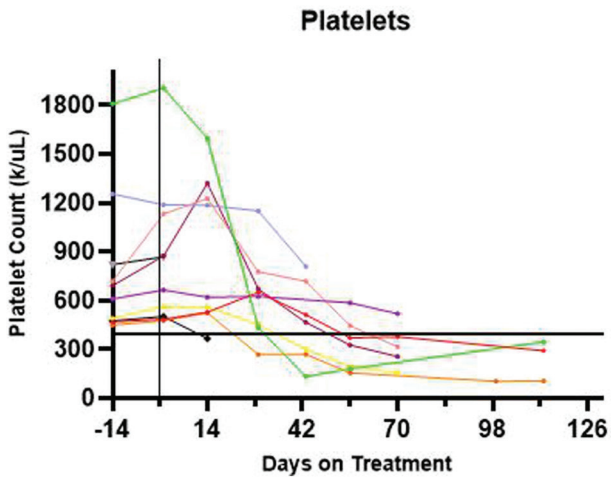
M. Kremyanskaya [1,*], J. Mascarenhas [1], A. Patriarca [2], V. Gupta [3], T. Devos [4], C. Harrison [5], F. Passamonti [6], R. Rampal [7], A. Mead [8], J. Scandura [9], G. Hobbs [10], M. Talpaz [11], N. Granacher [12], T. Somervaille [13], R. Hoffman [1], P. Bose [14], G. Colak [15], J. Shao [15], J. Cui [15], S. Bobba [15], K. Luptakova [15], S. Verstovsek [14], F. Palandri [16]

Seràgnoli", S. Orsola-Malpighi Bologna University Hospital, Bologna, Italy

Background: The bromodomain and extraterminal domain (BET) family of proteins bind to chromatin to regulate the transcription of target genes involved in multiple pro-fibrotic pathways and is a potential novel therapeutic target for reducing fibrosis in myelofibrosis (MF). Pelabresib (CPI-0610), a first-in-class, oral, small-molecule inhibitor of BET proteins (BETi), has potential to promote disease-modifying activity through altered gene regulation of key oncogenic, fibrotic, and inflammatory factors in the clonal disease cells of origin in MF. Treatment with JAK inhibitor (JAKi) ruxolitinib (rux) or fedratinib in the frontline setting is associated with approximately 30-40% splenic response defined as spleen volume reduction ≥ 35% (SVR35) at 6 months (Verstovsek 2012, Pardanani 2015). The BETi pelabresib monotherapy demonstrated clinical activity in heavily pretreated MF patients (pts) (Talpaz, ASH 2020). In preclinical MF models, the combination of a BETi and rux demonstrated synergistic reduction of splenomegaly (Kleppe 2018). Therefore, combination of pelabresib with rux is expected to achieve higher SVR35 response rate in JAKi treatment naïve MF pts.
Aims: Evaluation of pelabresib in combination with rux in JAKi treatment naïve MF pts.
Methods: Pts with MF who were not previously treated with JAKi were enrolled in Arm 3 of the MANIFEST study. Primary endpoint is SVR35 response (≥35% reduction in spleen volume) at wk 24. Pts were treated with pelabresib 125 mg daily on days 1-14 in a 21-day cycle, in combination with rux which was dosed based on the baseline platelet count.
Results: As of 29 September 2020, 78 pts were treated, and 66 pts were ongoing. Baseline characteristics were mean age: 67 yo; 72% male; primary MF: 54% pts; DIPSS ≥Int-2: 76% pts; IPSS ≥Int-2: 83%; Hgb <10g/dL: 65%; median platelet: 294 x 10^9/L (range: 100, 1849); median spleen volume: 1719 cc (range: 451, 4782); median TSS: 16 (range: 0, 38); high-molecular-risk mutations: 55%, *JAK2* mutation: 72%.
At wk 24, 67% (42/63) pts achieved SVR35 (median % change from baseline: -50%; range: -84.4%, 23.7%). Subgroup analysis showed that mean percentage change in spleen volume at wk 24 was consistent across subgroups based on gender, age, risk score, MF subtype, baseline platelet count and baseline spleen size (Fig. 1). Importantly, subgroup analysis based on molecular findings show a significant benefit regardless of the mutational status, including the presence of *ASXL1* mutation which generally carries a poor prognosis.
Pelabresib was generally well tolerated. The most common treatment emergent adverse events include anemia (33%, ≥Gr3: 30%), thrombocytopenia (32%, ≥Gr3: 8%), diarrhea (30%, no ≥Gr3), dysgeusia (19%, no ≥Gr3), and asthenic conditions (19%, no ≥Gr3).

Figure 1. Subgroup analysis of percentage reduction in spleen volume from baseline at wk 24

Summary/Conclusion: Pelabresib treatment in combination with rux in JAKi treatment naïve MF pts resulted in spleen volume reduction that was greater than what would be expected with rux alone, regardless of baseline patient disease and demographic characteristics.



EP1086 A PHASE 2 STUDY OF THE LSD1 INHIBITOR IMG-7289 (BOMEDEMSTAT) FOR THE TREATMENT OF ESSENTIAL THROMBOCYTHEMIA (ET)

Background: For patients with essential thrombocythaemia (ET) intolerant of or resistant to hydroxyurea (HU), interferon or anagrelide, there is a need for therapies with distinct MOAs that reduce thromboses, improve the patient experience and potentially offer distinct clinical benefits. Lysine-specific demethylase-1 (LSD1) is a histone H3K4 demethylase critical for the self-renewal potential of malignant myeloid cells and the differentiation of myeloid progenitors, *e.g.*, LSD1 licenses progenitors to mature into megakaryocytes, a cell central to the pathogenesis of ET. IMG-7289 (bomedemstat) is an orally active LSD1 inhibitor that reduced peripheral cell counts, splenomegaly, inflammatory cytokines, and mutant cell burdens in mouse models of MPNs (Jutzi *et al*. 2018). In an ongoing study of IMG-7289 for the treatment of myelofibrosis (MF) (NCT03136185), symptoms, platelets, neutrophils, mutant allele burdens and inflammatory cytokines were favorably impacted (Pettit *et al*. 2020).
Aims: IMG-7289-CTP-201 is an ongoing, multi-national, open-label, 24-week Phase 2b study of bomedemstat taken once daily in patients with ET who are resistant to or intolerant of at least one standard of care treatment (NCT04254978). Key objectives are safety and reduction in the platelet count to ≤400k/μL in the absence of thromboembolic events. Dosing is individually tailored targeting a platelet count between 200-400k/μL. All patients were started at a dose of 0.6mg/kg/d and titrated as needed to the target platelet count range.
Methods: At the censoring date (16 Feb 2021), 10 patients had enrolled. All patients remain on study. The median duration of treatment is 85 days (6-141).
Median age, 66 years (55-84), 20% males. 60% were deemed resistant to or intolerant of HU (by ELN criteria), 20% to anagrelide and 10% to interferon or busulfan. 40% had received at least one additional previous treatment. After a 14- to 28-day washout of prior ET treatment, the mean platelet and WBC counts at Day 1 were 866k/μL (477-1905) and 10.2k/μL (4.4-20.0), respectively.
Results: Of 7 patients who reached Day 71, the mean platelet count was 289k/μL (145-519k/μL), an overall -58% reduction from baseline (mean, -582k/μL). 86% achieved a platelet count of <400k/μL. (See Figure 1.) Mean WBC count at Day 71 was 7.8k/μL (6.8-9.5k/μL), a reduction of -24%. All patients had stable haemoglobins. At baseline, 2 patients had MPN10 TSS >10 (scale 0-100); at Week-12, both had a TSS reduction of >50% while the symptom scores of the remaining patients were stable at <5. There was no obvious relationship among driver mutations, starting platelet counts, final optimal dose or response rates. Germline variants, individual mutational burden and changes in mutant allele frequencies will be presented.
Eight patients have reported 67 AEs, all Grade 1/2. The most common related non-hematologic AEs were headache and diarrhoea, each reported by 2 patients with all instances Grade 1 in severity. There have been no SAEs. There have been no safety signals, DLTs, or deaths related to drug.

Summary/Conclusion: In this first clinical study of an LSD1 inhibitor in ET patients, IMG-7289 as monotherapy was generally well-tolerated, reduced platelets in all patients, moderated WBC counts, improved symptom scores and maintained haemoglobin levels without safety signals. The study is active and enrolling in the US, UK, EU, Australia and New Zealand.

EP1087 SAFETY AND EFFICACY OF MEPOLIZUMAB IN HYPEREOSINOPHILIC SYNDROME: AN OPEN-LABEL EXTENSION STUDY

F. Roufosse [1,*], J. Steinfeld [2], G. J. Gleich [3], G. Chupp [4], S. Faguer [5], A. Reiter [6], B. Walz [7], J. H. Bentley [8], E. S. Bradford [9], S. W. Yancey [9]

[1]Department of Internal Medicine, Hôpital Erasme, Université Libre de Bruxelles, Brussels, Belgium, [2]Respiratory Research & Development, GSK, Collegeville, PA, [3]School of Medicine, University of Utah, Salt Lake City, UT, [4]Department of Internal Medicine, Yale School of Medicine, New Haven, CT, United States, [5]Département de Néphrologie et Transplantation d'Organes, CHU de Toulouse, Toulouse, France, [6]Department of Hematology and Oncology, University Medical Centre Mannheim, Mannheim, [7]Department of Internal Medicine, Rheumatology and Immunology, University of Tübingen, Kirchheim-Teck, Germany, [8]Clinical Statistics, GSK, Uxbridge, Middlesex, United Kingdom, [9]Respiratory Therapeutic Area, GSK, Research Triangle Park, NC, United States

Background: Mepolizumab, an anti-interleukin-5 monoclonal antibody, has been shown to reduce disease flares and blood eosinophil counts (BEC) with a favorable safety profile in patients with uncontrolled *FIP1L1-PDGFRA*-negative hypereosinophilic syndrome (HES).
Aims: To further investigate the safety and efficacy of mepolizumab in patients who had previously completed the 32-week, randomized, double-blind, placebo-controlled, Phase III study, 200622 (NCT02836496).
Methods: In this open-label extension study (205203), patients who previously received mepolizumab or placebo during 200622 received 4-weekly mepolizumab 300 mg subcutaneously (SC) for 20 weeks, plus standard of care (SoC) adapted at their physicians' discretion. All patients provided written informed consent. Investigators and patients were blinded to BEC until Week 4. Primary safety endpoints included the number of patients with adverse events (AEs), serious AEs (SAEs), AEs of special interest (AESIs), and anti-drug antibodies (ADAs). Efficacy and pharmacodynamic endpoints included the annualized rate of flares (physician-identified based on worsening symptoms/BEC), plus changes from baseline in mean daily oral corticosteroid (OCS) dose and BEC.
Results: Of the 104 patients who completed 200622, 102 (98%) enrolled in 205203 (previous placebo n=52, previous mepolizumab n=50; 54% female; mean [SD] age 46.0 [15.5] years). Exposure to mepolizumab during both studies was 70.0 patient-years. Overall, 62 (61%) patients experienced on-treatment AEs (**Table**); the maximum severity was mild and moderate for 18% and 31% of patients, respectively. Treatment-related AEs were reported by 15 (15%) patients and one SAE was considered treatment-related; AESIs were uncommon and no events were fatal (**Table**). One patient was positive for ADAs at baseline (but negative thereafter) and no neutralizing antibodies were detected. The mean annualized rates of flares (95% confidence intervals) during 205203 were 0.37 (0.16, 0.86) and 0.14 (0.04, 0.49) events/year for the previous placebo and previous mepolizumab groups, respectively, versus a mean of 2.7 events for each treatment arm in the year preceding 200622. Of the 72 patients using OCS during Weeks 0–4, 20 (28%) achieved a ≥50% reduction in daily dose during Weeks 16–20 (**Table**). Reductions in BEC observed with mepolizumab in 200622 were maintained in 205203; for the previous placebo group, the adjusted mean reduction from baseline at Week 20 was 89%.

Table: Summary of safety and efficacy endpoints

	Mepolizumab 300 mg SC		
	Previous placebo (n=52)	Previous mepolizumab (n=50)	Total (n=102)
Safety endpoints, n (%) patients			
Any AEs	40 (77)	26 (52)	66 (65)
On-treatment AEs	38 (73)	24 (48)	62 (61)
Most frequent* on-treatment AEs, by preferred term			
Diarrhea	8 (15)	4 (8)	12 (12)
Pruritus	4 (8)	3 (6)	7 (7)
Headache	4 (8)	2 (4)	6 (6)
Vomiting	6 (12)	0	6 (6)
Treatment-related† AEs	11 (21)	4 (8)	15 (15)
Leading to study treatment discontinuation	1 (2)	0	1 (<1)
Leading to study withdrawal	1 (2)	0	1 (<1)
Any SAEs	6 (12)	3 (6)	9 (9)
On-treatment SAEs	6 (12)	2 (4)	8 (8)
Treatment-related† SAEs	1 (2)	0 (0)	1 (<1)
Fatal AEs/SAEs	0	0	0
Most frequent* AESIs			
All infections	18 (35)	18 (36)	36 (35)
Local injection site reactions	3 (6)	3 (6)	6 (6)
Efficacy/ pharmacodynamic endpoints			
Rate of HES flares, adjusted mean rate/year (95% CI)	0.37 (0.16, 0.86)	0.14 (0.04, 0.49)	0.26 (0.13, 0.52)
Patients achieving a mean daily OCS dose reduction ≥50%, n (%)‡	14 (37)	6 (18)	20 (28)
Week 20 LS mean ratio to baseline BEC, (95% CI)§	0.11 (0.08, 0.15)	0.52 (0.67, 1.26)¶	N/A

Reductions in mean daily OCS dose were calculated for patients with a mean OCS dose >0 mg/day at Weeks 0–4.
*Reported for >5% of patients overall; †as determined by the treating investigator; ‡in this analysis, n=38 in the previous placebo group and n=34 in the previous mepolizumab group; §in this analysis, n=50 in the previous placebo group and n=48 in the previous mepolizumab group. AE, adverse event; AESI, adverse event of special interest; BEC, blood eosinophil count; CI, confidence interval; HES, hypereosinophilic syndrome; LS, least squares; OCS, oral corticosteroid; SC, subcutaneous; SAE, serious adverse event

Summary/Conclusion: Mepolizumab 300mg SC plus SoC has a favorable safety profile without the development of neutralizing antibodies, and is associated with reductions in flares, OCS use, and BEC. These findings support previous safety and efficacy data for mepolizumab in patients with uncontrolled *FIP1L1-PDGFRA*-negative HES. Funding: GSK [205203/NCT03306043]

EP1088 INCREASED RISK OF PRETERM BIRTH IN PATIENTS WITH MYELOPROLIFERATIVE NEOPLASMS – A POPULATION BASED COHORT STUDY FROM SWEDEN

A. Ravn Landtblom [1,2,*], T. M.-L. Andersson [3], A. L. Johansson [3,4], J. Samuelsson [5], M. Björkholm [1], M. Hultcrantz [1,6]

[1]Department of Medicine, Solna, Karolinska Institutet, [2]Department of medicine, Division of Hematology, Stockholm South General Hospital, [3]Department of Medical Epidemiology and Biostatistics, Karolinska Institutet, Stockholm, Sweden, [4]Cancer Registry of Norway, Oslo, Norway, [5]Department of Hematology, University Hospital Linköping, Linköping, Sweden, [6]Department of Medicine, Myeloma Service, Memorial Sloan-Kettering Cancer Center, New York, United States

Background: A significant proportion, 10-15%, of patients with myeloproliferative neoplasms (MPNs) are of fertile age at diagnosis. Pregnancy in MPN patients is associated with increased risks of numerous complications, including bleeding, thrombosis, and fetal loss. Population-based studies of pregnancy outcomes in MPN patients are rare, and even less is known about risks for the child.
Aims: The aim of this study is to assess adverse pregnancy outcomes in patients with MPN in a population-based setting.
Methods: Patients with MPN were identified in the Swedish Cancer Register and Patient Registers, from 1953 to 2019. All pregnancies in these patients between 1973 and 2019 were identified from the Medical Birth Register, which captures all pregnancies in Sweden starting from gestational week 22 (before 2008 from week 28), thus only viable pregnancies at that gestational week are included in this study. Women with an MPN diagnosis prior to delivery or during the postpartum period (2 months) were included. From the general population, one pregnant control per pregnant MPN patient was randomly selected, matched by maternal age, year of delivery, maternal parity, and whether it was a singleton or duplex pregnancy. Main outcomes were stillbirth, birthweight, small-for-gestational-age, and preterm birth. The two-sided Fisher exact test was used to assess associations, with p-values <0.05 considered statistically significant. In the test comparison, only the first pregnancy after MPN was included.
Results: We identified 342 pregnancies in 229 women with MPN, and equally many in controls, 337 of these were singleton pregnancies and 5 duplex pregnancies, table. Among the 342 pregnancies in MPN patients, 43 were in patients with polycythemia vera, 238 in patients with essential thrombocythemia, 55 in patients with primary myelofibrosis and 6 in patients with MPN-unclassifiable. The mean maternal age at delivery among MPN patients and controls was 31.9 years, range 20-45. Mean birthweight was 3,378 g in children to MPN patients and 3,573 g in controls.

Table. Descriptive statistics and number and proportion of pregnancies in MPN patients and controls respectively with stillbirth, low birthweight, small for gestational age and prematurity. P-values are calculated with two-sided Fisher exact test, including only first pregnancy after MPN diagnosis.

	All identified pregnancies		First pregnancy after MPN diagnosis		
	Number of pregnancies in MPN patients (%)	Number of pregnancies in controls (%)	Number of pregnancies in MPN patients (%)	Number of pregnancies in controls (%)	p-value
Total	342	342	229	229	
Singleton	337	337	225	225	
Duplex	5	5	4	4	
Polycytemia vera	43 (13)	-	27 (12)	-	
Essential thrombocythemia	238 (70)	-	158 (69)	-	
Myelofibrosis	55 (16)	-	40 (17)	-	
MPN-Unclassifiable	6 (2)	-	4 (2)	-	
Stillbirth	2 (0.6)	0 (0)	1 (0.4)	0 (0)	1.0
Low birthweight <2500 g	29 (8)	11 (3)	22 (10)	10 (4)	0.042
Very low birthweight <1500 g	7 (2)	0 (0)	7 (3)	0 (0)	0.015
Small for gestational age	15 (4)	7 (2)	11 (5)	7 (3)	0.47
Preterm < week 37	42 (12)	14 (4)	33 (14)	10 (4)	<0.001
Moderate preterm, week 32-37	31 (9)	12 (4)	22 (10)	9 (4)	0.024
Very preterm, week 28-32	6 (2)	2 (0.6)	6 (3)	1 (0.4)	0.122
Extremely preterm, >week 28	5 (1)	0 (0)	5 (2)	0 (0)	0.061

When restricting to first pregnancy after MPN, there were 229 pregnancies. There was a significantly increased proportion of preterm birth (<37 weeks) in MPN patients (n=33, 14%) compared to controls (n=10, 4%). Furthermore, 11 deliveries were very (week 28-32) or extremely (<28 weeks) preterm in MPN patients, compared to 1 in the control group. The proportion of neonates with low birthweight was also significantly higher in MPN patients (n=22, 10%) versus in controls (n=10, 4%). No significant differences were observed in proportion of small-for-gestational-age or stillbirth, although very few events. There was one neonatal death in the MPN group and one in the control group, both on day 2.
Summary/Conclusion: This large register- and population-based study demonstrated a significantly increased risk of preterm birth in patients with MPN. The higher proportion of low birthweight in children of MPN patients was mainly but not solely driven by the higher proportion of preterm birth. Our novel findings indicate the need for further clarification of the underlying pathophysiology as well as identification of adequate preventative measures. Preterm birth may affect neonatal morbidity and mortality, and have consequences on future health and capabilities, therefore optimizing care in MPN pregnancies to prevent maternal and neonatal complications is of great importance.

EP1089 LONG-TERM FOLLOW-UP OF RECOVERED MPN PATIENTS WITH COVID-19

Background: To our knowledge, there is no information on long-term follow-up of recovered patients with chronic myeloproliferative neoplasms (MPN) with COVID-19. It can be hypothesized that cytokine storm of the acute phase and the post-COVID persistence of a residual inflammatory state may contribute to elicit hematopoietic stem cell insults and continuous vascular endothelial damage, leading to MPN disease progression and persistent high risk of thrombosis.
Aims: To describe sequelae of COVID-19 in surviving patients with MPN following COVID-19.
Methods: MPN-COVID study involved 38 European blood centers, and accrued 180 patients with MPN diagnosed with COVID-19 from Feb to Jun 2020, assessing mortality and incidence of thrombosis and bleeding during the acute phase of the pandemic [Barbui T et al. Leukemia. 2021;35(2):485-493. Barbui T et al. Blood Cancer J. 2021;11(2):21]. One-hundred-twenty-five (69%) of these patients survived and were followed up for at least 6 months. Centers were asked to update symptoms, treatments, hematological changes, major outcomes (i.e., thrombosis, disease evolution and death).
Results: Among the 125 surviving patients, all eligible for the follow-up update, with a median age 70 years (IQR: 58-79), the following phenotypes were registered: PV (n=38, 30%), ET (n=37, 30%), early PMF (n=14, 11%) and MF (n=36, 29%). During the acute phase of infection, 38 (30%) were managed at home, 80 (64%) in a regular ward and 7 (6%) in ICU.
Symptoms
(i)The 3 prevalent symptoms during the acute phase of the disease were fever (79%), cough (56%) and dyspnea (53%), while gastrointestinal, neurological, musculoskeletal symptoms, as well as fatigue and anosmia/dysgeusia, were present in a minor proportion, ranging from 1.6% to 17%.
(ii) In the post-acute COVID-19 phase, 36 of 125 patients (32%) declared the persistence of some of these symptoms, fatigue being the most frequent (19%), while none presented persistence of fever and only 10% of dyspnea.
Major outcomes
(i) Major thrombosis was documented in 5 patients and involved 3 patients with MF (one fatal intestinal ischemia, two non-fatal events: splenic infarction and peripheral artery thrombosis), one case in PV (acute myocardial infarction) and one with ET (DVT of the legs with pulmonary embolism). Age varied from 61 to 80 years. The first event occurred five months after COVID-19 recovery and the Kaplan Meier thrombosis-free survival probability after 9 months was 82%.
(ii) Acute myelogenous leukemia (AML) was ascertained in 3 patients (1 in MF, 1 in early-PMF, 1 in ET); one was fatal and occurred in a 49-year-old patient, the other 2 in 78- and 82-year-old patients, respectively. One non-Hodgkin´s lymphoma (in ET) and one progression of a previous parotid carcinoma (in MF) were seen in two patients aged 60 and 77 years, respectively.
(iii) Deaths were reported in 8 patients (6.4%), due to AML (n=1), thrombosis (n=1), progression to prior carcinoma (n=2, 1 suspected), multi organ failure (n=1) and heart failure (n=2); the cause was unknown in a single patient. Five deaths (63%) occurred in MF patients.
(iv) Overall, the event-free survival pooling together thrombosis, disease evolution and death reached 66% after 9 months from COVID-19 recovery, indicating that, during this time of observation, 1 out of 3 patients died or have experienced at least one of the other two severe events.
Summary/Conclusion: These results indicate that MPN patients who have survived SARS-CoV-2 infection continue to experience severe events suggesting an increased vigilance in the post-COVID period.

EP1090 AN EPIDEMIOLOGICAL STUDY OF THE CARDIOVASCULAR HEALTH AND THROMBOTIC RISK PROFILES OF PATIENTS WITH MYELOPROLIFERATIVE NEOPLASMS IN PRIMARY CARE ACROSS THE UNITED KINGDOM

F. Chen [1,*], A. Rabe [2,3,4], J. Were [2], G. Chiu [5], A. Liu [5]

[1]Barts Health NHS Trust, [2]Health iQ Limited, [3]Imperial College London, [4]Global Health Focus, London, [5]Novartis Pharmaceuticals UK Limited, Camberley, United Kingdom

Background: Patients with myeloproliferative neoplasms (MPN) are at increased risk of venous and arterial thromboembolic events (TEEs). Although MPN-specific treatment is generally delivered by specialist haematology centres in the United Kingdom (UK), cardiovascular risk is managed in the primary care setting. In the UK, primary care is provided by the government-funded National Health Service, and patient data is collected by the Clinical Practice Research Datalink (CPRD).
Aims: In this retrospective cohort study, we interrogated the CPRD, a centralized national dataset comprising clinical and prescription records for patients in primary care across the entire UK, for descriptive data on the cardiovascular health and thrombotic risk of all patients with MPN.
Methods: During the study period (1 Jan 2012–21 Aug 2019), adults were indexed at the date of first recorded diagnosis for polycythemia vera (PV), essential thrombocythemia (ET) and primary myelofibrosis (MF), with a ≥6-month pre-index lookback and ≥24-month post-index follow-up. The study objectives were to determine the MPN epidemiological landscape, extent of co-morbidities (using the Charlson score), thrombotic/cardiovascular risk profiles (before diagnosis) and occurrence of TEEs/cardiovascular events (CVEs) (after diagnosis). MPN diagnoses and co-morbidities were determined using medical and ICD-10 codes; medications were identified using product codes.
Results: Overall, 2,477 patients with MPN (PV, n=1,315; ET, n=336; MF, n=146; unspecified MPN, n=680) of the 19,474,733 patients in the CPRD were identified with a median age at diagnosis of 68 years (range 7 months–101 years); 56% were male. Among all MPN patients, 96.2% had a low Charlson co-morbidity score of 0–5. The prevalence of MPN was 12.72 per 100,000; PV was the most prevalent MPN subtype (6.75 per 100,000), followed by ET (1.73 per 100,000) and MF (0.75 per 100,000). In the total MPN population, the most prevalent pre-diagnosis risk factors were smoking (59.8%) and ischaemic heart disease (27.7%); few patients had hypertension (14.6%), diabetes (13.1%), dyslipidaemia (12.8%) or obesity (8.8%). For risk management, most hypertensive (88.9%), dyslipidemic (82.4%) and diabetic (77.9%) patients were prescribed appropriate medications for management of their blood pressure, dyslipidemia, and diabetes, respectively. Among the patient cohort, 372 TEEs/CVEs occurred after diagnosis (PV, 214 events; ET, 64 events; MF, 9 events; unspecified MPN, 85 events), the most common being stroke (27.2%), deep vein thrombosis (17.7%) and myocardial infarction (MI; 14.8%) (**Table**). Notably, the occurrence of MI was greater for patients with PV (15.9%) than for those with ET (10.9%) or MF (0%).

Table | Occurrence of TEEs and/or CVEs post-diagnosis in the total MPN population and by MPN subgroup.

TEE/CVE Category	Number of TEEs and/or CEEs by MPN subgroup – n (%)				
	All MPN (372 events)	PV (214 events)	ET (64 events)	MF (9 events)	Unspecified (85 events)
Myocardial Infarction	55 (14.8)	34 (15.9)	7 (10.9)	0 (0)	14 (16.5)
Stroke	101 (27.2)	57 (26.6)	15 (23.4)	4 (44.4)	25 (29.4)
Deep Vein Thrombosis	66 (17.7)	43 (20.1)	5 (7.8)	2 (22.2)	16 (18.8)
Peripheral Arterial Disease	8 (2.2)	4 (1.9)	2 (3.1)	0 (0)	2 (2.4)
Pulmonary Embolism	45 (12.1)	20 (9.3)	16 (25)	0 (0)	9 (10.6)
Splanchnic Vascular Thrombosis	9 (2.4)	1 (0.5)	1 (1.6)	1 (11.1)	6 (7.1)
Rare Site Venous Thrombosis	14 (3.8)	10 (4.7)	1 (1.6)	1 (11.1)	2 (2.4)
Migraine	49 (13.2)	29 (13.6)	14 (21.9)	0 (0)	6 (7.1)
Vascular Dementia	25 (6.7)	16 (7.5)	3 (4.7)	1 (11.1)	5 (5.9)

Summary/Conclusion: This study is the first of its kind to describe the cardiovascular health and thrombotic risk profiles of UK patients with MPN in primary care within the CPRD. The prevalence of PV and MF in this study was largely consistent with most known epidemiological reports, but the prevalence of ET was lower. However, MPN subtype was not specified in the CPRD for a sizeable proportion (680 of 2,477 patients). Importantly, in the UK MPN population, the majority were smokers and a considerable proportion of patients (11.1–22.1%) were not prescribed appropriate medications for management of co-morbidities associated with thrombotic risk (hypertension, dyslipidemia or diabetes), highlighting a potential unmet need for improved cardiovascular risk management and coordination between primary and secondary care.

EP1091 ANALYSIS OF THROMBOTIC AND BLEEDING COMPLICATIONS IN 1381 ESSENTIAL THROMBOCYTHEMIA PATIENTS ASSESSED BY R-IPSET THROMBOSIS RISK SCORE: A MULTICENTER RETROSPECTIVE STUDY

R. Stuckey [1], J.-C. Ianotto [2], M. Santoro [3], T. Wróbel [4], M. M. Pérez Encinas [5], M. T. Gómez-Casares [1], M. S. Noya Pereira [6], A. Kulikowska de Nałęcz [7], A. Gołos [8], K. Lewandowski [9], L. Szukalski [10], J. M. González-Martín [11], M. Sobas [12,*]

Background: Vascular complications such as thrombosis and hemorrhage are major causes of morbimortality in patients with essential thrombocythemia (ET). The 2016 revised IPSET-thrombosis (R-IPSET-thrombosis) score stratifies patients into very-low (VLR), low (LR), intermediate (IR) and high (HR) risk groups according to thrombosis history, age≥60 years and *JAK2*mut. Such stratification is important as lower risk patients receive less intensive treatment.
Aims: Confirm the prognostic impact of the R-IPSET-thrombosis risk score and other risk factors for thrombosis and major bleeding in a large cohort of adult patients with ET.
Methods: Medical records were retrospectively reviewed for data on thrombotic events, major hemorrhages; and anti-aggregation, anticoagulation, and cytoreductive treatment for 1381 adult ET from 1 French, 1 Italian, 3 Spanish and 5 Polish hospitals. Patients were treated according to local protocols. Statistical analyses were performed using R Core Team 2020 software v4.0.2.
Results: Patient median age was 62 years (54.4% ≥60 years). In terms of driver mutation, 898 were mutated in *JAK2* (65.0%), 264 (19.1%) in *CALR*, and 24 (1.7%) in *MPL*; 176 (12.7%) were triple negative (19 patients were negative for *JAK2* and *CALR* but *MPL* was not determined).
Data on thrombosis and major bleeding was available for 1378 and 1380 patients, respectively. With an average follow-up period of 87.7 months, a total of 91 hemorrhagic events (6.6%) were reported. Thrombotic events occurred in 260 patients (18.8%) before or at diagnosis (dx), and in 173 patients (12.6%) after dx. There were 88 deaths (6.4% of the study population).
Following distribution into risk groups according to the R-IPSET-thrombosis score, thrombosis-free survival (TFS) at 10 years for the VLR, LR, IR and HR groups was 99%, 88%, 83% and 75%, respectively (p<0.0001). Overall survival (OS) according to thrombosis risk group was 96%, 93%, 76% and 71%, respectively (p<0.0001) (**Figure 1**). Comparing the LR and VLR groups, the difference in TFS was significant (Fisher Exact test, p<0.001) but OS was not (HR 1.43, p=0.451).
Logistic regression univariate analysis confirmed the R-IPSET-thrombosis variables of age at dx, cardiovascular risk factors, thrombosis history, and *JAK2*mut as thrombotic risk factors (HR 2.5, 1.9, 2.3, and 1.6, respectively). *CALR*mut was a protective factor (HR 0.43, p=0.0021). In multivariate analysis, only age, previous thrombosis and *CALR*mut retained statistical significance. For thrombotic event prior to dx or at dx, *JAK2*mut was a risk factor (Fisher exact, OR 2.8, p<0.001) while *CALR*mut was a protective factor (OR 0.32, p<0.001); *MPL*mut was not a significant risk factor.
For major bleeding, leukocyte count was a significant risk factor while hemoglobin count was a significant protective factor in multivariate analysis.
Anti-aggregation after dx had a protective effect on thrombosis (HR 0.31, p=0.005) in multivariate analysis but was not protective for major bleeding (χ^2, p=0.708). Thrombosis at 10 years was not a significant risk factor (HR 1.3, p=0.35) for OS while severe bleeding was (HR 2.3, p=0.0011). Among the 249 patients in the VLR group, 12 had severe bleeding (4.8%), of which 9 received anti-aggregation (75%).

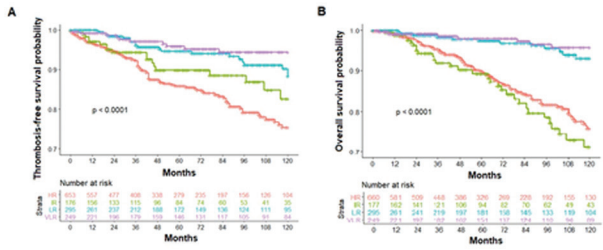

Figure 1. Kaplan-Meier survival curves for the high risk (HR), intermediate risk (IR), low risk (LR) and very-low risk (VLR) groups according to the R-IPSET score, for **A.** Thrombosis-free survival, and **B.** overall survival.

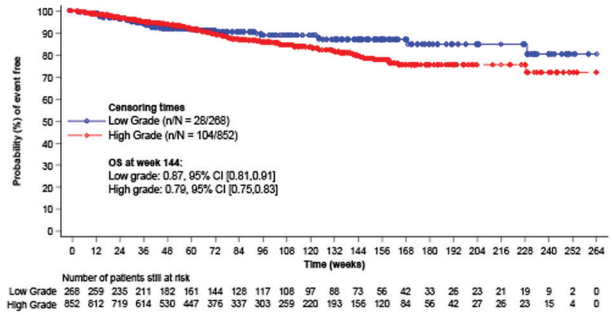
Summary/Conclusion: TFS was significantly different between the risk groups; specifically, the VLR group had a higher TFS than the LR group. Therefore, our results validate the R-IPSET score. Anti-aggregation after dx was protective for thrombosis but not for major bleeding. Major bleeding at 10 years was associated with mortality but thrombosis was not.



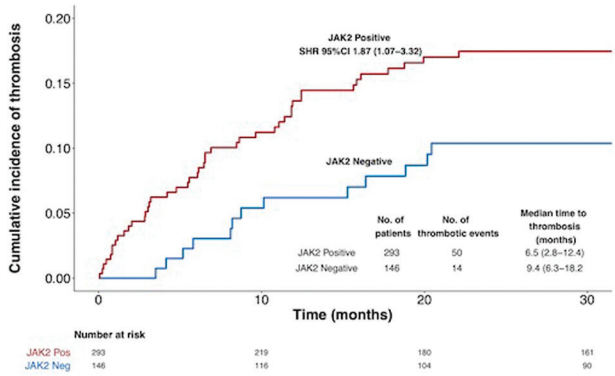
EP1092 IMPACT OF BONE MARROW FIBROSIS GRADE ON RESPONSE AND OUTCOME IN PATIENTS WITH PRIMARY MYELOFIBROSIS TREATED WITH RUXOLITINIB: A POST-HOC ANALYSIS OF THE JUMP STUDY

F. Palandri [1,*], H. K. Al-Ali [2], P. Guglielmelli [3], M. Zuurman [4], C. Paley [5], J. Han [5], V. Gupta [6]

[1]IRCCS Azienda Ospedaliero-Universitaria di Bologna, Istituto di Ematologia "Seràgnoli", Bologna, Italy, [2]University Hospital Halle, Halle, Germany, [3]University of Florence, Florence, Italy, [4]Novartis Pharma AG, Basel, Switzerland, [5]Novartis Pharmaceuticals Corporation, East Hanover, United States, [6]Princess Margaret Cancer Centre, Toronto, Canada

Background: Bone marrow (BM) fibrosis is one of the key histological features of myelofibrosis (MF); high-grade BM fibrosis is associated with worse outcome in patients (pts) with MF. Prefibrotic MF is characterized by low-grade BM fibrosis (0-1) and is described as a separate entity from overt MF in the WHO 2016 classification. Ruxolitinib (RUX) is a potent JAK1/JAK2 inhibitor that has shown improvement of MF-related symptoms and increased overall survival (OS) in pts with MF. The JUMP phase 3b, expanded-access trial (NCT01493414) assessed the safety and efficacy of RUX in pts with symptomatic MF without access to RUX outside of the clinical trial setting (N=2,233).
Aims: To investigate the impact of BM fibrosis grade on response and outcome in pts with primary MF (PMF) treated with RUX.
Methods: Pts ≥18 years (y) with PMF, and with an enlarged spleen (≥5 cm from costal margin) were included in this analysis. BM fibrosis was assessed locally by biopsy and graded 0 to 3. Although the primary endpoint of the study was safety, efficacy of RUX was assessed by secondary endpoints including changes in spleen length by palpation, progression-free survival (PFS), and OS. The present work is a post hoc analysis, and thus was not statistically powered.
Results: A total of 1,326/2,233 pts with PMF had a documented biopsy (grade 0, n=25; grade 1, n=243; grade 2, n=433; grade 3, n=419). The median age at baseline was 67 years (range, 18–89 years). Median time since initial diagnosis was similar between pts with lower grade fibrosis (LGF, grade 0-1; 31.8 months [range, 0.3–296.4]) and higher grade fibrosis (HGF, grade 2-3; 25.5 months [range, 0.1–456.0]). Pts with HGF had more cases of anemia and thrombocytopenia at baseline (HGF vs LGF: 46.4% vs 32.5% pts with hemoglobin <100 g/L; 8.6% vs 4.1% pts with platelets <100 x 10^9/L). Mean (SD) palpable spleen length (cm below costal margin) at baseline was similar between patient groups (LGF vs HGF: 11.3 [7.1] vs 12.9 [7.2]), as were mean FACIT – Fatigue and FACT – Lymphoma total scores (34.5 and 115.4 for pts with LGF vs 32.8 and 114.9 for pts with HGF, respectively).
A larger proportion of pts with LGF achieved a ≥50% spleen length reduction at week 24 (62.4% vs 55.1% in pts with HGF). Furthermore, a clear trend was observed between grade of fibrosis and spleen response at week 24 (66.7% for grade 0, 62.0% for grade 1, 59.5% for grade 2, and 50.2% for grade 3). Spleen response at week 24 was higher for pts who initiated RUX ≤2 y after diagnosis irrespective of fibrosis grade (64.0% vs 61.1% in >2 y in LGF; 61.5% vs 49.2% in >2 y in HGF).

PFS estimates at week 144 were 82% for pts with LGF and 70% for pts with HGF. LGF was associated with higher OS at week 144 (91% for grade 0, 87% for grade 1, 80% for grade 2, and 78% for grade 3). OS probability estimate at week 144 was 87% for pts with LGF (n=73), and 79% for pts with HGF (n=156); median OS was not achieved by either pt group (**Figure**). More deaths were recorded for pts with LGF who initiated RUX >2 y after diagnosis (death events: 12.4% vs 8.1% for pts ≤2 y); this effect was not observed in pts with HGF (death events: 11.4% vs 13.0% for pts ≤2 y).



Summary/Conclusion: PMF symptomatology and splenomegaly are comparable in LGF and HGF pts, suggesting an unmet need in LGF pts. RUX therapy is associated with improved spleen responses and survival in both cohorts, but more so in LGF pts; however, LGF could also be a marker of better clinical characteristics at baseline. Early treatment with RUX may improve clinical benefits for both LGF and HGF pts.

EP1093 CLINICAL AND MOLECULAR FACTORS ASSOCIATED WITH THROMBOSIS IN MYELOFIBROSIS

A. Bankar [1,*], E. Smith [1], V. Cheung [1], N. Siddiq [1], J. Claudio [1], A. Arruda [1], H. Tsui [2], J.-M. Capo-Chichi [1], J. Kennedy [3], C. Mcnamara [1], H. Sibai [1], D. Maze [1], W. Xu [4], V. Gupta [1]

[1]Hematology, Princess Margaret Cancer Centre, [2]Hematopathology, [3]Hematology, Sunnybrook Health Sciences Centre, [4]Biostatistics, Princess Margaret Cancer Centre, Toronto, Canada

Background: The clinical and molecular factors for thrombosis in myelofibrosis are not well studied.
Aims: To measure the association of molecular and clinical factors with thrombotic events in MF.
Methods: Design: Retrospective, single-centre study.
Study Population and Setting: All chronic phase MF patients from 2004 to 2018 seen at Princess Margaret Cancer Centre, Toronto, Canada.
Exposure: Our primary exposure variable was *JAK2* mutation; and *DNMT3A*, *ASXL1* and *TET* mutations in a subset with myeloid next generation sequencing availability. Clinical variables were age, sex, cardiovascular risk factors (smoking, hypertension, diabetes mellitus, and hypercholesterolemia), thrombosis prior to MF diagnosis, blood counts, DIPSS risk.
Outcomes and measures: The primary outcome was cumulative incidence of first thrombosis (arterial or venous) 30 days after diagnosis. The effect of covariates was measured as sub-distribution hazard ratio (SHR) using Fine-Gray method to account for competing risks from death.
Results: Total 439 MF patients were included in the study, 229 (52%) were primary, 153 (35%), secondary, and 57 (13%) pre-fibrotic. The median age was 68.6 years (SD 12.7), 59% were male. The median follow-up was 4.2 years (Range 0-18). *JAK2* mutations were detected in 293 patients (66.7%), *CALR* in 82 (18.6%), *MPL* in 26 (5.9%), and 38 (8.6%) were triple negative with no canonical MPN driver mutations. 228 (52%) had next generation myeloid sequencing results: 120 (52.6%) had at least 1 Tier I/II mutation in *ASXL1* (n = 83, 36.4%), *EZH2* (n = 22, 9.6%), *IDH1* (n = 3, 2.8%), *IDH2* (n = 2, 1.8%), *SRSF2* (n = 11, 10%); *DNMT3A* (n=18, 7.9%) or *TET2* (n=68, 29.8%).
There were 64 (14.6%) thrombotic events (37 venous, 27 arterial) after diagnosis. The median time to thrombosis was 8.1 months (IQR 3.1-15.6). The 1-year cumulative incidence of thrombosis was 11.2% (95% CI 8.3-14.5) [6.6% (95% CI 4.3-8.2) arterial and 6.7% (95% CI 5.1-8.1) venous]. The incidence rate ratios for thrombosis per 100 person-years for those with *JAK2* mutation compared to those without was 2.6 (1.9-4.9, p-value <0.001). The univariate Fine Gray analysis showed only *JAK2* mutation and prior thrombosis were associated with increased thrombosis risk (Figure 1) and also remained significant in the multivariable model [SHR: *JAK2* mutation 1.93, 95% CI 0 1.07-3.59; prior thrombosis 4.06, 95% CI 2.38-6.90]. For model validation, bootstrap cross-validation with 1000 samples was used. The Wolber's concordance index at 1-year was 0.65, suggesting adequate discrimination. The model showed good calibration graphically.
We then studied the influence of clonal hematopoiesis associated mutations (*DNMT3A*, *ASXL1*, *TET2*) on thrombosis in a subset cohort of 228 patients. Patients with *TET2* mutation had a significant association with thrombosis in univariate analysis; *DNMT3A* or *ASXL1* mutations did not. In the multivariable model, *TET* mutations did not show an independent effect on thrombotic risk. Patients with co-occurrence of *JAK2* and *TET2* mutations (SHR 4.95, 95% CI 1.8-13.7) had similar thrombotic risk compared to patients with *JAK2* (SHR 3.02, 95% CI 1.10-8.3) mutation alone (p-value 0.1). Prior thrombosis remained a significant variable in this model.

Summary/Conclusion: In MF, the 1-year cumulative incidence of thrombosis after diagnosis was 11.2%. *JAK2* mutation and prior thrombosis independently predicted a higher risk of thrombosis. *DNMT3A*, *TET2* or *ASXL1* did not show an independent effect on risk of thrombosis. These data provide useful information to further develop thrombo-prophylaxis strategies in MF patients.

EP1094 WHEN MYELOPROLIFERATIVE NEOPLASMS MEET COVID-19: INFLAMMATION, ENDOTHELIOPATHY AND COAGULOPATHY

R. Cacciola [1,*], E. Gentilini Cacciola [2], V. Vecchio [3], E. Cacciola [4]

[1]Experimental and Clinical Medicine, Haemostasis Unit - University of Catania, Catania, [2]Infectious Disaeses, La Sapienza University, Rome, [3]Medical School, [4]Med Sur Sci Advance Techno, University of Catania, Catania, Italy

Background: Myeloproliferative Neoplasms (MPNs) - polycythemia vera (PV), essential thrombocythemia (ET), and primary myelofibrosis (PMF) - are marked by thrombosis. COVID-19 infection is marked by thrombosis as reported in China and confirmed in autopsies of patients experiencing sudden death. The thrombosis in MPNs is related to inflammation and endotheliopathy. The thrombosis in COVID-19 may be related to devastating enhancement of inflammation ("cytokine storm") and profound endotheliopathy, known as COVID-19-associated coagulopathy (CAC). It is showed that patients with hematological malignancies and COVID-19 had worse outcomes. It is unclear if COVID-19 exerts additive or synergistic thrombotic effects.
Aims: Therefore, we evaluated Interleukin-6 (IL-6) and Tissue Factor (TF), as inflammatory and endothelial mediators, D-dimer (DD), thrombin antithrombin complex (TAT) and Fibrinogen (Fib), as coagulation activation mediators, platelet factor 4 (PF4), as platelet activation mediator, and whole blood viscoelastic analysis, as indicator of whole hemostatic activation.
Methods: The cohort study included 120 WHO-defined MPNs patients with COVID-19 ascertained by positive RT-PCR on nasopharyngeal swab (n= 40 PV, n= 40 ET, n= 40 PMF) (60 men, 60 women; mean age 51 years, range 32-60) and 90 WHO-defined MPNs patients without

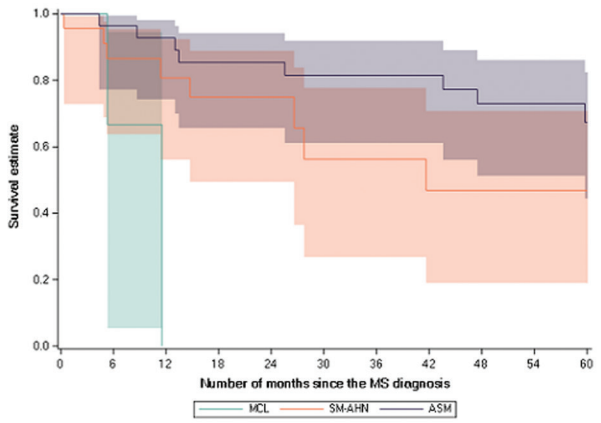
COVID-19 (n= 30 PV, n= 30 ET, n= 30 PMF) (45 men, 45 women, mean age 50 years, range 30-60). All patients gave written informed consent for study enrollment. The mean duration of disease was 12 years. All patients were on ASA 100 mg once daily. Concerning presentation and therapy, our MPNs patients with COVID-19 and without COVID-19 had not comorbidities and drug treatment was consistent with therapeutic standards (hydroxyurea, interferon, anagrelide, ruxolitinib). All patients were on ASA 100 mg once daily. IL-6 was measured by multiplex bead array (Millipore Sigma), TF and DD, and TAT by ELISA and Fib by Clauss method. PF4 was determined by ELISA. Whole blood viscoelastic analysis including clotting time (CT), and clot formation time (CFT) were measured by thomboelastometry method.

Results: MPNs with COVID-19 had high IL-6 and TF (50±12pg/ml and 1950±500 pg/ml) compared with MPNs without COVID-19 (3±2pg/ml and 19±2 pg/ml), as well as DD, TAT and Fib (549±100 □g/l, 69±10 □g/l and 590±20mg/dl) compared with MPNs without COVID-19 (59±5□g/l, 2±1□g/l and 149±10 mg/l). PF4 was elevated (150.1□62.7 IU/ml) in MPNs with COVID-19 compared with MPNs without COVID-19 (2□1 UI/ml). A positive correlation was found between inflammatory, endothelial and coagulation mediators. A p-value of <.05 was considered statistically significant. Shortened CT (CT, unit: s. n.v. 100-240 s) (40±20 s) and shortened CFT (CFT, unit: s, n.v. 30-160 s (14±10 s) there were in MPNs with COVID-19 compared with MPNs without COVID-19 (CT 99±10 s and CFT 39±5 s).

Summary/Conclusion: These data suggest that COVID-19 infection in MPNs patients may increase the thrombotic risk and get worse prognosis. In our opinion, this study can serve as a baseline study of COVID-19 thrombotic risk in MPNs and it is worthy of dissemination amongst patients and clinician communities.

EP1095 FIRST REAL-LIFE RESULTS ON PATIENTS WITH ADVANCED SYSTEMIC MASTOCYTOSIS TREATED WITH MIDOSTAURIN IN FRANCE

J. Rossignol [1,*], S. Nizard [2], A.-S. Blanc [2], A. Filipovics [2], F. Raguideau [3], G. Poinsot [3], A. Schmidt [3], O. Hermine [1]



[1]CEREMAST, Hôpital Necker-Enfants Malades, Paris, [2]Novartis, Rueil-Malmaison, [3]HEVA, Lyon, France

Background: Mastocytosis is a heterogeneous group of rare diseases related to the proliferation and/or abnormal accumulation of mast cells in one or more organs. The most common form, observed mostly in children, is cutaneous mastocytosis where the infiltration of mast cells is limited to the skin. When it reaches other organs, the disease is called systemic mastocytosis (SM). SM is frequently indolent with normal life expectancy but is life threatening in patients with advanced SM. In France, midostaurin, a tyrosine kinase inhibitor, is the only approved treatment for the three advanced SM subtypes [Aggressive Systemic Mastocytosis (ASM), Systemic Mastocytosis with Associated Haemotological Neoplasms (SM-AHN) and Mast Cell Leukemia (MCL)].

Aims: This study aimed to describe in real-life the characteristics and outcomes of patients treated with midostaurin for advanced systemic mastocytosis.

Methods: A retrospective cohort study was conducted using the French National Healthcare Database (SNDS). The study population included all adults patients with advanced SM treated with midostaurin between January 1, 2012 and September 30, 2018. Kaplan Meier model was used to assess survival and competing risk survival model was used to assess treatment duration, using death as competing risk. Survival analysis was realized on a sub-group of 61 patients exclusively affiliated to the French general insurance scheme.

Results: Overall, 81 patients treated with midostaurin for advanced SM were identified and their data collected, mainly from 2016 and later on (68%). The most frequent subtype was ASM (n=37), followed by SM-AHN (n=31) and MCL (n=4). The SM subtype was undetermined in 9 patients. The median age was 67 years and 64% of patients were men. Over the 11.4 months mean follow-up, median midostaurin treatment duration was 8.4 months and 28 patients were still on treatment at the end of the study. Discontinuation from the study was firstly due to a treatment discontinuation (42%) followed by the end of the study period (Dec 31, 2018, 35%), death (16%) and switch to another treatment (7%). The estimated overall survival (considering any deaths) from time since diagnosis was 83% at one year and 56% at five years. The overall survival in the different MS sub-types was statistically different (p=0.0095) with ASM>SM-AHN>MCL: 1-year overall survival was respectively 93% for ASM patients, 81% for SM-AHN patients and 0% for MCL patients. Over the follow-up period, 12 serious adverse events were identified, with the most frequent one being pneumonia (N=6 patients).

Summary/Conclusion: This study described for the first time the characteristics and outcomes of patients treated in real-life with midostaurin for advanced SM. It highlights that in routine clinical practice the characteristics of the patients, their disease management, treatment tolerance (treatment discontinuation) and survival were in line with previous published results (compassionate use and clinical trials). This study confirms the positive outcomes of midostaurin in AdvSM patients in France.

EP1096 OVERALL AND CAUSE SPECIFIC CHANGES IN MORTALITY OF PATIENTS WITH MYELOFIBROSIS OVER THE LAST 3 DECADES

L. Masarova [1,*], P. Bose [1], N. Pemmaraju [1], H. Chifotides [1], L. Zhou [1], Z. Estrov [1], H. Kantarjian [1], S. Verstovsek [1]

[1]Leukemia, MD Anderson Cancer Center, Houston, United States

Background: Patients with myelofibrosis (MF) have decreased overall survival with a median of 5 years. Leading causes of death are believed to be directly or indirectly related to MF progression or complications, including transformation to acute leukemia (AML) and infections.

Aims: We aimed to compare survival, mortality rate and causes of death of MF patients referred to our institution before (≤) and after the years of 2010.

Methods: This retrospective study included patients with MF diagnosed within one year prior to their presentation to our institution (between January 1990 and February 2020, 4% presented < year 2000). Patients with unknown cause of death or loss to follow-up were excluded (final cohort, n = 995). Causes of death were divided into groups: i) MF progression; ii) AML (≥ 20% blasts); iii) sudden multi-organ failure or vascular event (possibly related to MF, Vasc/MOF); iii) infections (MF had to be controlled or in remission); iv) other (unrelated medical conditions). We calculated crude mortality rate per 1000 person - years of observation (comparison by Poisson's regression) and overall survival (by Kaplan Meier method with log rank test). To account for variations in age groups (< 49; 50-59; 60-69; and 70+ years), we assessed age-adjusted mortality rates per 1000 person-years standardized for the entire cohort.

Results: The study included 378 and 617 patients ≤ and > 2010, respectively, 59% of which were males. Sixty-five percent of patients were ≥60 years. Distribution of age groups between periods was comparable, except for higher proportion of 70+ year old patients > 2010, counterbalanced by lower proportion of < 60 years.

Over the observation time of 1942 and 1608 person-years for ≤ and > 2010, 206 (55%) and 100 (16%) of patients died, respectively (p < 0.001, RR 0.54, CI 0.48-0.63). Crude, age-adjusted and cause-specific mortality per 1000 person-years in both periods is outlined in Table.

Overall mortality, both crude and age-adjusted, was significantly higher ≤ 2010 irrespectively of gender and age. As expected, crude mortality steadily increased with age in both periods. For each of the respective age groups, more patients died ≤ 2010 than > 2010. In both periods, males

had higher mortality than females; but it has decreased > 2010 for both genders. Whilst comparable death rate was observed between < 49 years males and females, it was significantly higher in males for all other ages regardless of periods.
Leading cause of mortality for all combined ages was AML, followed by MF, infections, Vasc/MOF and other causes. However, when MF related and possibly related causes of death (Vasc/MOF, or /i+iii/) were combined, this group was leading cause of mortality ≤ 2010, and was comparable to AML > 2010. Cause specific crude mortality has decreased > 2010 for all subcategories, except for AML, which remained unchanged between periods. MF and AML related cause of deaths were increasing with age irrespectively of periods (Table).

Mort. per 1000 person-years	All patients		< 49yo	50-69yo	60-69yo	70+yo
	< 2010	≥ 2010	< / ≥ 2010	< / ≥ 2010	< / ≥ 2010	< / ≥ 2010

Others, N (%)	24 (6)	7 (1)	2 (3)/0	2 (2)/1 (1)	10 (8)/4 (2)	10 (13)/2 (10)
Crude Mort.	12	4	5 / 0	3 / 3	16 / 7	35 / 5
Age Adj Mort.	12	3				

Summary/Conclusion: In our study, we provide specific details on overall and cause specific mortality for patients with MF and show declining rates in the last decade (> 2010). However, the leading cause of death still remain MF and AML, implying ongoing need for clinical research and novel therapies.

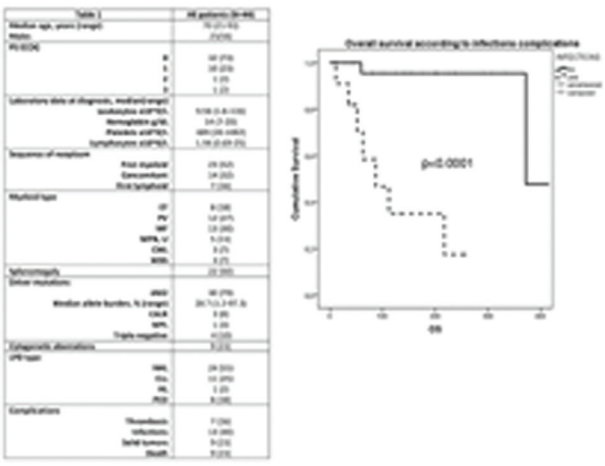
EP1098 ACQUIRED VON WILLEBRAND SYNDROME IN MYELOPROLIFERATIVE NEOPLASMS WITH EXTREME THROMBOCYTOSIS

C. Trotti [1,*], E. Sant'Antonio [2], D. Vanni [1], I. Casetti [1], O. Borsani [1], D. Pietra [3], V. V. Ferretti [4], C. Astori [3], L. Arcaini [1,3], E. Rumi [1,3]

[1]Molecular Medicine, University of Pavia, Pavia, [2]Hematology, USL Toscana Nord Ovest, Lucca, [3]Hematology, [4]Service of Clinical Epidemiology and Biometry, Fondazione IRCCS Policlinico San Matteo, Pavia, Italy

Background: Acquired von Willebrand syndrome (AvWS) is a rare bleeding disorder that resembles inherited von Willebrand disease. AvWS may be associated with myeloproliferative neoplasms (MPN), due to the adsorption of von Willebrand Factor (vWF) on platelets (PLT), and enhanced cleavage of vWF multimers. Current guidelines recommend to test VWF activity in MPN with PLT above 1000 x10^9/L. However, there is no convincing evidence that correlates PLT count, VWF activity and risk of bleeding.
Aims: We aimed to describe vWF parameters, in terms of antigen and functional activity, and correlate the frequency of AvWS with risk of bleeding in MPN patients with extreme thrombocytosis, considering different PLT thresholds and different severity of AvWS. Moreover, we analysed the impact of patients' genotype.
Methods: We interrogated our MPN database to identify patients affected with essential thrombocythemia and polycythemia vera and extreme thrombocytosis (PLT higher than 1.000 x10^9/L) and identified 58 patients (15 at diagnosis, 43 during follow-up), as reported in table. vWF testing included vWF antigen (vWF: ag) and vWF ristocetin cofactor activity (vWF:RCo). AvWS was diagnosed when vWF:RCo was below the normal range (50-200%), vWF:RCo / vWF: ag was below 0.7 and in the absence of a familial history. Analyses were performed in 3 clusters of PLT count (1000-1200, 1200-1400, >1400 x10^9/L, defined as mild, intermediate ad severe thrombocytosis respectively). Severe AvWS was diagnosed for vWF:RCo below 30%.
Results: We found an inverse relationship between PLT count and vWF:RCo (Spearman's Rho=-0.4 P 0.002). VWF:RCo was significantly different (*P* 0.022) in the 3 clusters of thrombocytosis, with a median of 44.4% (IQR 35.7-65.6) in mild thrombocytosis, 32.6% (IQR 26.9-38.2) in intermediate and 35.2% (IQR 29.8-44.9) in severe. Frequency of AvWS was higher among *JAK2* mutated patients (26/30, 86.7%) as compared to *CALR* mutated ones (5/24, 62.5%, *P* 0.056). Also median vWF:RCo was different according to genotypes (*P* 0.004), being 35.9% (IQR 27.9-44.4) in *JAK2* mutated patients, 44.2% (IQR 32.4-63.9) in *CALR* mutated patients, and 68.5% (IQR 67.4-76.6) in triple-negative ones. In a ROC analysis we found PLT ≥ 1211 x10^9/L and PLT ≥ 1153 x10^9/L as the better cut-offs to identify AvWS and severe AvWS, respectively. In bivariable logistic model, AvWS was associated with PLT ≥ 1211 x10^9/L (OR=16.8 P 0.012), adjusting for mutational profile (presence versus absence of *JAK2* mutation, OR=7.4 P 0.005). Similarly, severe AvWS was associated with PLT ≥ 1153 x10^9/L (OR=12 P 0.004), after adjusting for diagnosis (TE vs PV, OR=0.25 p=0.091). Of 58 patients, 23 (39.7%) experienced bleeding events (all mild and muco-cutaneous). We did not find association between bleeding and vWF level (P 0.632), also after adjusting for antiplatelet treatment (P 0.640). This result might be influenced by the introduction of cytoreduction (32 patients, 55.2%), that was coincident with vWF assessment (n= 10) or prescribed shortly after (n= 22). Accordingly, number of patients experiencing bleedings significantly decreased after starting cytoreduction: 35% (12/32) before compared to 6.3% (2/32) after therapy (P=0.002).

	n=58
Age, median (IQR)	43.1 (33.5-51.7)
Sex, n (%)	
female	35 (60.3%)
male	23 (39.7%)
MPN diagnosis	
ET	46 (79.3%)
PV	12 (20.7%)
Patients with PLT > 1000x10^9/L	
At diagnosis	15 (25.8%)
During follow-up	43 (74.2%)
Antiplatelet drugs at vWF assessment	50 (86.2%)
Genotype	
CALR	24 (41.4%)
CALR type 1	12 (20.7%)
CALR type 2	12 (20.7%)
JAK2	30 (51.7%)
Triple negative	4 (6.9%)
Plt, median (IQR)	1132 (1053-1301)
Plt, n (%)	
<1200	39 (67.2%)
1200-1400	13 (22.4%)
≥1400	6 (10.4%)
vWF antigen, median (IQR)	73.4 (55.3-89.5)
vWF:RCo, median (IQR)	38.6 (31.3-63.7)
vWF:RCo <50%, n (%)	41 (70.7%)
vWF:RCo <30%, n (%)	13 (22.4%)



Summary/Conclusion: vWF:RCo reduction is associated with PLT count and mutational profile. Extreme thrombocytosis is associated with muco-cutaneous bleedings, as expected in primary haemostasis defects. The introduction of cytoreduction significantly reduces the number of bleeding events.

EP1099 INFECTIOUS AND THROMBOTIC COMPLICATIONS AND THEIR PROGNOSTIC IMPACT IN PATIENTS WITH CONCOMITANT MYELOID AND LYMPHOID NEOPLASMS. A SINGLE-CENTER COHORT STUDY

C. Bucelli [1,*], B. Fattizzo [2], D. Cattaneo [1], J. A. Giannotta [1], K. Barbullushi [3], R. Pasquale [3], E. Barozzi [3], M. C. Barbanti [3], L. Pettine [3], F. G. Rossi [3], G. Reda [3], W. Barcellini [3], L. Baldini [4], A. Iurlo [3]

[1]Hematology Unit, Fondazione IRCCS Ca' Granda Ospedale Maggiore Policlinico, [2]Hematology Unit and Department of Oncology and Onco-hematology, University of Milan, Fondazione IRCCS Ca' Granda Ospedale Maggio Policlinico, [3]Hematology Unit, Fondazione IRCCS Ca' Granda Ospedale Maggiore Policlinico, [4]Hematology Unit and Department of Oncology and Onco-hematology University of Milan, Fondazione IRCCS Ca' Granda Ospedale Maggiore Policlinico, Milan, Italy

Background: patients with myeloproliferative neoplasms (MPNs) have an intrinsic risk of lymphoproliferative disease (LPD) compared to the general population, ranging from 2.79 to 3.44 folds increased as reported in literature. Less is known about the clinical characteristics of this setting of patients and their outcome in terms of infectious and thrombotic complications.
Aims: to assess the occurrence of infections and thrombosis in patients with concomitant myeloid and lymphoid neoplasms.
Methods: We retrospectively evaluated a single center cohort of 1351 myeloid neoplasms (930 MPN and 421 myelodysplastic syndromes [MDS]) followed up for a median of 9 (0.8-35) years. We evaluated the time from diagnosis to LPD development, LPD type, treatment requirement for both myeloid disorder and LPD, and the occurrence of infections, thrombosis, and overall survival (OS).
Results: A total of 44 patients developed an LPD after a median of 37 (0-318) months from myeloid disease, in 32% of patients myeloid and lymphoid neoplasms were diagnosed concomitantly. Table 1 shows clinical and laboratory characteristics: patients were mainly males, 61% >65 years, and all but 3 had a diagnosis of MPN. JAK2V617F-mutated patients were 30 (68%), while 25% and 11% were CALR- and MPL-mutated, respectively. Mutated patients showed a longer time to LPD development (mean 120±92 versus 31±17 months in unmutated, p=0.01).
As regards treatment, 29 MPN patients were on anti-platelet therapy, 2 on anticoagulants, 36 (82%) of MPN patients required myeloid specific treatment, the majority with hydroxyurea (71%). Lymphoid disease required treatment in 45.5% of cases, after a median time from diagnosis of 8 months (0-115). A thrombotic event was reported in seven patients (4 ET and 3 MF), and, unexpectedly, JAK2 resulted unmutated in more than half of the cases (57.1%). Thirteen patients (30%) experienced a grade ≥3 infectious episode (9 pneumonias, 3 urinary tract infection, and 1 sepsis), all due to bacterial agents, occurring mainly in elderly subjects (12/13, p=0.006).
Nine patients (20%) died due to solid tumor (4), leukemic progression (2), infectious complications (2), and brain bleeding (1). Deaths were more frequent among elderly patients (89%), ECOG ≥1 (42% versus 13%, p=0.02), and triple-negative status (50% versus 12.5%, p=0.02); deaths were also associated with a significantly shorter time to LPD development (37±8 versus 115±94 months, p=0.002) and with lymphoid treatment requirement (35% versus 9%, p=0.04). In addition, fatalities were more frequent in patients with infections (58% versus 6%, p=0.001). By Kaplan Meyer method, a longer OS was observed in younger patients (p=0.001), with better performance status (p=0.02) and with the presence of driver mutations (p=0.003). Contrarily, a worse survival was significantly associated with the occurrence of infections (p<0.0001). Multivariate analysis by Cox regression model showed that the occurrence of infections was the only independent predictor of worse survival within the cohort (HR 3.18, 95%CI 2.9-19, p=0.003).

Summary/Conclusion: The co-occurence of LPD and myeloid neoplasms was associated with a high rate of infectious complications (30%) being the latter the only independent predictor of shorter OS. Interestingly, our data support the adverse prognostic impact of triple-negative molecular status also in this specific setting.

EP1100 MYELOPROLIFERATIVE NEOPLASMS IN PEDIATRICS AND YOUNG ADULTS: GENOMIC FEATURES, CLINICAL OUTCOMES, PROGRESSION AND OVERALL SURVIVAL

Z. Harris [1,*], D. M. Williams [2], J. Spivak [2], L. Resar [2], A. Moliterno [2], E. Braunstein [2]

[1]Internal Medicine, Johns Hopkins Hospital, [2]Hematology, Johns Hopkins School of Medicine, BALTIMORE, United States

Background: The myeloproliferative neoplasms (MPN) comprise a group of hematological malignancies, consisting of essential thrombocytosis (ET), polycythemia vera (PV), and primary myelofibrosis (MF) which are diagnosed primarily in older adults (OA). MPN is characterized by clonal overproduction of mature blood cells and a driver mutation in the *JAK2*, *MPL*, or *CALR* gene. However, MPN in pediatric and young adults (PAYA) has not been well-described and optimal management is unknown.
Aims: We sought to compare genomic features, disease progression, and clinical outcomes between the PAYA and OA patient groups.
Methods: The Hopkins MPN cohort is comprised of 630 patients with an MPN enrolled between 2005-2015. All had driver mutation genotyping for *JAK2V617F*, *CALR*, and *MPL*. PAYA was defined as those diagnosed ≤39 years of age; OA were diagnosed at >40 years. STADA was used for statistical analysis. Familial MPN was defined as MPN with a 1st or 2nd degree relative with myeloid malignancy.
Results: Of 630 patients, 27% (n=171) were PAYA (average age 30 years; range 1 week-39 years) and 63% (n=459) were OA (average age 58 years; range 40-89 years). Females comprised the majority in both cohorts, but were more prevalent in PAYA (71% v. 58%; $p<0.05$). ET was more frequent in PAYA compared to OA (67% v. 39%; $p<0.05$), whereas PV [26% v. 46%; $p<0.05$) and MF [7% v. 16%; $p<0.05$) were less common. Mutations in *JAK2 V617F* (64% PAYA, 80% OA) or exon 12 mutations (2% PAYA, 1% OA) comprised 100% of PV for both groups, while *JAK2* mutations were less common in PAYA ET (55% v. 67%; $p<0.05$) and similar in MF (42% v. 66%). *CALR* mutations were similar in PAYA and OA in ET, but less common in PAYA MF (42% v. 16%; $p<0.05$). *MPL* mutations were more common in PAYA MF (42% v. 17%). Triple negative disease (absence of mutations in *JAK*, *CALR*, *MPL*) was more common in PAYA (9% v. 4%; $p<0.05$). Familial MPN was more prevalent (19% v. 9%; $p<0.05$). Cancer predisposition syndromes were rare in both cohorts (2 PAYA, 1 OA). Venous thromboses comprised the most frequent (n=39; 23%) complication in PAYA. Additional cancers, most frequently skin, developed in 9% of PAYA compared to 20% ($p<0.05$) of OA. In PAYA, 12.9% progressed to MF or AML, with majority progressing to MF (11%). In PAYA, ET progressed to MF (n=8, mean age 51 years, mean time to progression 22 years) and PV to MF (n=11, mean age 40 years, mean time to progression 10 years). Progression to AML occurred in 2% (3/171) PAYA, with average time to AML from original MPN diagnosis of 27 years, compared to OA, where AML occurred in 5% (25/459), with average time to AML progression of 11 years ($p<0.05$). There were fewer deaths in the PAYA v. OA (12% v. 39%; $p<0.05$). Overall survival was longer in PAYA (29 v. 12 years, $p<0.05$); however, average age of death was lower in the PAYA v. OA (60 v. 74 years; $p<0.05$).
Summary/Conclusion: PAYA comprised almost 1/3 of our MPN cohort and were more likely to present with lower-risk disease (ET), although almost 13% ultimately progressed to MF or AML. PAYA MPN had longer latency periods before progression and longer overall survival but earlier age of death compared OA MPN. The higher prevalence of familial MPN in PAYA and the secondary cancers suggest that an inherited predisposition to cancer may contribute to MPN development. Together, our findings suggest that PAYA patients should be followed closely for progression, venous thromboses, and possibly additional cancers. The long latency underscores the need to limit exposure to potentially genotoxic therapies.

EP1101 HEMORRHAGIC EVENTS BUT NOT THROMBOTIC EVENTS CONTRIBUTE TO WORSE SURVIVAL IN PATIENTS WITH ESSENTIAL THROMBOCYTHEMIA: A RETROSPECTIVE NATIONWIDE SURVEY IN JAPAN

Background: The treatment goals for essential thrombocythemia (ET) are to prevent thrombotic and hemorrhagic events, genetic transformation, and secondary malignancies. In recent years, the risk factors (including epigenetic mutations) of thrombosis and genetic transformation have been intensively investigated. However, the risk factors of hemorrhagic events have not been sufficiently investigated because the incidence of hemorrhagic events after diagnosis of ET is lower than that of thrombosis. Serious hemorrhagic events can lead to impaired activities of daily life and poor survival, and thus, prevention is of extreme importance.
Aims: We conducted a large-scale, nationwide retrospective study on Japanese patients with ET to investigate the clinical characteristics, survival rate, and incidence of thrombotic and hemorrhagic events and identify the risk factors of these events.
Methods: We included patients aged ≥20 years who were newly diagnosed with ET according to the World Health Organization's 2008 or 2017 criteria between April 2005 and March 2018. We reviewed data on patient characteristics including driver gene mutations, treatment, thrombotic and hemorrhagic events after diagnosis, genetic transformation, incidence of secondary malignancies, overall mortality, and the cause of death collected from patient medical records. This study was conducted by the Japanese Society of Hematology.
Results: In total, 1232 patients with ET were enrolled. Of these patients, 80 patients were excluded according to the selection criteria. The remaining 1152 patients were included in the analysis. At the time of diagnosis, the median patient age was 65 years old, the median platelet count was 832 × 10^9/L, and the positive mutation rates of *JAK2*V617F, *CALR*, and *MPL* were 62.8%, 25.1%, and 4.1%, respectively. The median follow-up period was 45 months (range: 0-188 months). During the study period, fifty-nine (5.1%) patients experienced hemorrhagic events. The hemorrhagic event-free survival rate was 94.2% and 89.4% at 5 and 10 years, respectively. There was no significant difference in hemorrhagic event-free survival among patients with different driver gene mutations (*JAK2*V617F, *CALR*, *MPL*, and triple-negative). In multivariate analysis, platelet count ≥1000 × 10^9/L (hazard ratio, 2.007), previous history of hemorrhage (hazard ratio, 3.793), and splenomegaly (hazard ratio, 2.888) were identified as risk factors for of hemorrhagic events. Furthermore, multivariate analysis with hemorrhagic events (hazard ratio, 7.180) as a time-dependent variable showed that hemorrhagic events were a life-threatening risk factor, and the same results were seen for landmark analysis.
Summary/Conclusion: In this large-scale retrospective study of Japanese ET patients, platelet count ≥1000 × 10^9/L, previous history of hemorrhage, and splenomegaly were risk factors of hemorrhagic events, and hemorrhagic events after diagnosis of ET was a risk factor of mortality. Since an increased platelet count is not a risk factor for thrombosis but for hemorrhagic events, appropriate cytoreductive therapy is required to prevent hemorrhagic events.

EP1102 JAK2V617F ALLELE BURDEN: AN INDEPENDENT PREDICTOR OF OVERT FIBROSIS IN PRIMARY MYELOFIBROSIS

S. Duarte [1,*], R. Gomes [1], C. Afonso [1], B. Marques [1], A. T. Simões [1], M. Coucelo [1], A. Roque [1,2], J. P. Carda [1,2], A. Crisóstomo [1]

[1]Clinical Hematology Department, University Hospital Center of Coimbra, [2]Faculty of Medicine, University of Coimbra, Coimbra, Portugal

Background: *JAK2V617F* mutation is on the genetic basis of myelofibrosis (MF) onset and the role of its mutant allele frequency (VAF) in disease evolution as well as survival remains controversial. Monocyte-derived fibrocytes are involved in MF pathogenesis. A recent study demonstrated that monocytes with higher *JAK2V617F* allele burden were associated with the onset of MF in patients with myeloproferative neoplasms harbouring *JAK2V617F*. In addition, it has been previously shown that *JAK2V617F* with ≥ 50% allele burden was associated with more advanced BM fibrosis.
Aims: To evaluate the association between *JAK2V617F* allele burden and MF disease presentation and prognosis.
Methods: Retrospective unicentric analysis of patients diagnosed with MF between January 2010 and December 2019. The cutoff value of *JAK2V617F* VAF was established applying a logistic regression ROC curve. All variables with p<0.05 in the univariate model were included in the multivariate analysis. The Cox regression model and Kaplan-Meier method were used for the analysis of progression free survival (PFS) and overall survival (OS).
Results: Sixty-four (71.1%) out of 90 patients newly diagnosed with MF harboured the *JAK2V617F* mutation. VAF was evaluated in 54 (60%) patients, with a median mutant allele burden of 33% (range, 1-95%). Median age in this sub-cohort was 66 years old and 64.8% were males. *JAK2V617F* allele burden did not correlate with levels of hemoglobin (Hb), platelets neither with the presence of constitutional symptoms (p=NS). Based on our sample, there was a statistically significant association between VAF and leucocytes, and as VAF increase, leukocytes increase (rs=0.51; p<0.001). The presence of splenomegaly is associated with higher median VAF (26 *versus* 47%; p=0.02). About half of the patients (51.9%) were in the overt fibrotic stage (FMF) at diagnosis, which is associated with a trend for higher VAF (26 *versus* 47%, for prefibrotic (PFMF) and FMF, respectively; p=0.08). Variable dichotomization for allele burden established VAF=40% has the cutoff value to distinguish between PFMF and FMF (sensibility 60.7%; specificity 76.9%; PPV 73.9%; NPV 64.6%), therefore demonstrating VAF>40% as a good predictor of FMF (OR 5.15, p=0.007), even after adjusting to the variables older age, Hb<10g/dL, leucocytes≥11x10^9/L, elevated lactate dehydrogenase and circulating blasts >1% (OR 9.33, p=0.003). VAF>40% associated with leucocytes >11x10^9/L (p=0.019) and splenomegaly (p=0.017), at presentation. VAF had no positive predictive value in estimating prognosis according to the International Prognostic Scoring System nor in predicting need of treatment or disease progression to acute leukemia (p=NS).
In our sample, median PFS and OS were identically estimated in 124.6 months. While median PFS and OS were not reached for PFMF patients, FMF patients reached a median PFS and OS of 50.2 (P=0.0196) and 51.7 months (0.0015), respectively. Contrastingly, *JAK2V617F VAF>40%* had no impact on both PFS (124.6 vs NR months; HR 0.890, p=0.826) and OS (124.6 vs 54.4 months; HR 1.169, p=0.782).
Summary/Conclusion: We showed that MF patients with overt fibrosis at diagnosis had worse survival times, compared to PFMF patients. Also, and although the allele burden of *JAK2V617F* had no impact on PFS and OS of patients with MF, we demonstrated that VAF>40% has an independent positive predictive value for diagnosis of FMF. Thus, our findings identify *JAK2V617F* allele burden as a valuable tool to discriminate between pre-fibrotic and overt fibrotic stages in MF and suggest higher *JAK2V617F* VAF as a useful non-invasive marker of fibrosis onset in MF.

EP1103 CLONAL MUTATION PATTERNS OF ESSENTIAL THROMBOCYTHEMIA REVEALED BY SINGLE-CELL TARGETED SEQUENCING

R. Fu [1,*], D. Liu [2], H. Xiong [2], H. Su [2], H. Li [1], X. Liu [1], F. Xue [1], S. Zhu [2], R. Yang [1], T. Cheng [1], L. Zhang [1]

[1]State Key Laboratory of Experimental Hematology, National Clinical Research Center for Blood Diseases, Institute of Hematology & Blood Diseases Hospital, Chinese Academy of Medical Sciences & Peking Union Medical College, Tianjin, [2]BGI-Shenzhen, Shenzhen, China

Background: Single-cell sequencing of hematopoietic stem cells (HSCs) provides an unprecedented opportunity to directly reveal origins of driver mutations in essential thrombocythemia (ET)–a unique model for dissecting clonal architecture of tumors.
Aims: The study aimed at revealing the clonal mutation patterns of ET with different driver mutations.
Methods: Whole-exome sequencing of bulk bone marrow cells from 33 ET patients were conducted, and targeted region sequencing of single

HSCs from two representative patients was performed, one with JAK2 V617F and the other one with the CALR mutation.
Results: Seventeen patients (51.5%) had the JAK2 V617F mutation, four (10.8%) harbored the CALR mutations, and one (3.0%) had the MPL mutation. More somatic non-silent mutations were observed in JAK2 V617F+ patients (median 13; range 5–94) than in CALR-mutated patients (median 8.5; range 2–10; P = 0.048). Mutations with known roles in myeloid neoplasms (e.g., mutations in DNMT3A, TET2, and ASXL1) were more likely to co-occur with JAK2 V617F, but not with CALR mutations. Single-HSC sequencing revealed that not every possible key mutation identified in bulk cells was an 'essential mutation'. Single-HSC sequencing revealed an unexpected complexity in genetic composition of the HSC pool. In the JAK2 V617F+ patient, tumor cells were oligoclonal in origin. The JAK2 V617F mutation occurred after the LIN54, TET2, and DNMT3A mutations. These pre-JAK2 mutations randomly occurred and continually accumulated in almost all cells from the HSC pool. JAK2 V617F occurred in cells with at least one of the pre-JAK2 mutations. As a consequence, a cluster of cells with these four mutations in every cell were emerged and acquired a growth advantage. Unlike JAK2 V617F, the CALR mutation was an early event, and the clone containing a single CALR mutation acquire a survival advantage. JAK2 V617F+ cell amplification mainly occurred in the HSC compartment in ET30, but CALR-mutated cells were mainly amplified in HPCs in ET35. This observation helps explain why JAK2 V617F causes erythrocytosis, granulocytosis, and thrombocytosis, while the CALR mutations mainly cause thrombocytosis.
Summary/Conclusion: Single-HSC sequencing provides direct evidence for revealing subject-specific key mutations and clonal evolution patterns in patients with ET.

EP1104 RECURRENT ACTIVATING STAT5B N642H MUTATION IN MYELOID NEOPLASMS: CLINICO-PATHOLOGIC AND GENOMIC CHARACTERIZATION

H. Mo [1,*], E. Margolskee [2], M. Routbort [1], K. Patel [1], G. Montalban-Bravo [3], G. Garcia-Manero [3], T. Kadia [3], S. Loghavi [1], G. Crane [4], C. Bueso-Ramos [1], L. J. Medeiros [1], R. Kanagal-Shamanna [1]

[1]Hematopathology, UT MD Anderson Cancer Center, Houston, [2]Pathology and Laboratory Medicine, Perelman School of Medicine University of Pennsylvania, Philadelphia, [3]Leukemia, UT MD Anderson Cancer Center, Houston, [4]Laboratory Medicine, Cleveland Clinic Foundation, Cleveland, United States

Background: Oncogenic activating *STAT5B* N642H driver mutation, observed recurrently in aggressive T-cell malignancies, was recently reported as a clonal biomarker in association with myeloid neoplasms (MNs) with eosinophilia. This mutation provides potential therapeutic opportunities using small molecule inhibitors (under development) and tyrosine kinase inhibitors.
Aims: In this study, we sought to characterize the frequency, clinicopathologic and genomic features, and outcomes of all MNs with *STAT5B* N642H mutation at a single-institution.
Methods: All patients (pts) with a myeloid malignancy with *STAT5B* N624H mutation detected by using next-generation sequencing and an 81-gene myeloid panel were included (2017-2019). Pts with concurrent T-cell neoplasms or aberrant T/NK cells detected by flow cytometry immunophenotypic analysis were excluded. Bone marrow (BM) morphologic features were reviewed. Clinicopathological data were collected by chart review.
Results: Of 4551 pts who underwent baseline NGS profiling, we identified 14 (0.3%) pts with MNs associated with *STAT5B* N642H mutations. These pts included 8 men and 6 women with a median age of 76 years (26-87). Using the WHO classification criteria, the diagnoses included myelodysplastic/myeloproliferative neoplasm (MDS/MPN, n=5), MDS (n=4), acute myeloid leukemia (AML, n=3), *CALR* mutated MPN (n=1) and chronic eosinophilic leukemia (CEL, n=1). Peripheral blood (PB) or BM eosinophilia was noted in 8 (57%) pts: 5 (36%) with PB hypereosinophilia (defined >1500/μL), 3 (21%) with PB eosinophilia (500-1500/μL). Five pts (36%) showed increased eosinophils in BM. Patients with increased eosinophils were negative for rearrangements involving *BCR/ABL1*, *PDGFRA*, *PDGFRB,* and *FGFR1* assessed by FISH. BM fibrosis (grade ≥ MF-2) was seen in 2 pts. Seven (50%) pts had normal diploid karyotypes; recurrent abnormalities included +8 and monosomy 7. The median variant allele frequency (VAF) of *STAT5B* mutation was 21% (range, 2-61). In 9 (64%) pts the mutation was dominant (defined as VAF >20%) and in 5 pts the mutation was sub-clonal. The median number of mutations per pt was 4 (range, 1-7). Frequent concurrent gene mutations included *U2AF1* (n=7, 50%), *ASXL1* (n=6, 42.9%) and *TET2* (n=5, 35.7%). Eleven of 14 (79%) pts had a concurrent mutation in a splicing factor gene. Using the molecular grouping scheme by Cross et al. (PMID: 30573779), 13 (93%) pts were in group 3 (with additional mutations, not *SF3B1*), 1 in group 2 (with *SF3B1* mutations). No cases belonged to group 1 (sole abnormality).
To compare molecular characteristics, we identified 9 pts with *STAT5B* N642H positive T-cell neoplasms (6 T-prolymphocytic leukemia, 2 T-lymphoblastic leukemia, 1 cytotoxic mature T-cell lymphoma) over the same time-period. Compared to MNs, T-cell malignancies showed a higher median *STAT5B* VAF [41% (3-72); p=0.25] and fewer concurrent mutations [median 3 (range, 1-4) mutations per pt.; p=0.001]. None showed splicing mutations.
Over a median of 20 months (range, 0-42), 7 (50%) pts died. Follow-up data were available for 11 pts. Six pts transformed to AML; all died except 1 pt with sub-clonal *STAT5B* mutation with concurrent *NPM1* and *FLT3* mutations. Four patients showed clearance of *STAT5B* mutation post therapy.
Summary/Conclusion: *STAT5* N642H mutations are recurrent in MNs. Although eosinophilia is frequent, this is the first study of an unbiased pt cohort showing that a substantial proportion [6 (43%)] of pts lack eosinophilia. Further investigation of these cases is warranted due to the potential targetable nature of *STAT5* N642H using small molecular inhibitors.

EP1105 A NATIONWIDE SURVEY OF JAPANESE PATIENTS WITH POLYCYTHEMIA VERA

Background: A nationwide survey of Japanese patients with Philadelphia-negative myeloproliferative neoplasms (MPNs) was reported in 2006, including 266 patients with polycythemia vera (PV) and 381 patients with essential thrombocythemia (ET). Since then,*JAK2* and other driver gene mutations have been found in MPNs, and new diagnostic criteria such as the World Health Organization (WHO) 2008 and 2017 classifications have emerged, warranting a new survey to obtain novel insights regarding Japanese patients with MPNs.
Aims: To analyze the clinical characteristics of patients with PV in Japan, we conducted a retrospective study.
Methods: Patients who were diagnosed with PV according to either the WHO 2008 or 2017 classification between April 2005 and March 2018 were enrolled. This study was conducted by the Japanese Society of Hematology.
Results: In total, 1867 patients with PV or ET from 41 institutions in Japan were registered. Among them, 596 patients with PV were analyzed. The median age was 65 years, including 5.2% and 16.8% of patients <40 and <50 years of age, respectively. *JAK2* V617F mutations

were detected in 83.1% (456/549) of patients. Thrombotic and hemorrhagic events before or at the time of diagnosis occurred in 16.2% and 3.7%, respectively.
During a median follow-up of 47 months (range: 0–182 months), 49 deaths (8.2%) occurred. The median overall survival was not reached, likely due to the short follow-up time. The major causes of death were secondary malignancies (n=11; 1.8%), leukemic transformation (n=6; 1.0%), non-leukemic progressive disease (n=5; 0.8%), thrombotic complications (n=3; 0.5%), and hemorrhagic complications (n=3; 0.5%). Progression to secondary myelofibrosis was observed in 17 cases (2.9%), which subsequently progressed to acute leukemia in 1 case. Thrombotic and hemorrhagic events occurred in 24 (4.0%) and 20 (3.4%) cases, respectively. While extreme thrombocytosis (≥1000 × 10^9/L) was a risk factor for survival, leukocytosis (≥10 × 10^9/L) was a risk factor for survival and thrombosis-free survival. Age >60 years was a risk factor for leukemic transformation. Interestingly, splenomegaly was a predictor of hemorrhagic events in univariate analysis. The international PV prognostic score (age, venous thrombosis, and leukocytosis) clearly distinguished the Japanese PV population into three distinct risk groups.
Summary/Conclusion: This was the largest study of Japanese patients with PV, showing that leukocytosis is a risk factor for survival and thrombosis, and splenomegaly is a risk factor for hemorrhagic complications. Although splenomegaly has been reported as a risk factor for hemorrhage in patients with ET or whole MPN, to the best of our knowledge, it has not been specifically predicted in patients with PV. While few hemorrhagic events occurred before or at the time of diagnosis of PV, the number of thrombotic and hemorrhagic events after diagnosis showed only a slight difference (24 and 20, respectively). Among the 20 patients with hemorrhagic complications, 14 received an anti-thrombotic drug. These findings suggest that instead of preventing thrombotic complications during PV treatment, many hemorrhagic events may occur as iatrogenic events. Both thrombotic and hemorrhagic complications are significantly correlated with survival; thus, the risk of both thrombotic and hemorrhagic complications should be considered in the treatment algorithm.

EP1106 IMETELSTAT DEMONSTRATES AN ACCEPTABLE SAFETY PROFILE IN MYELOID MALIGNANCIES

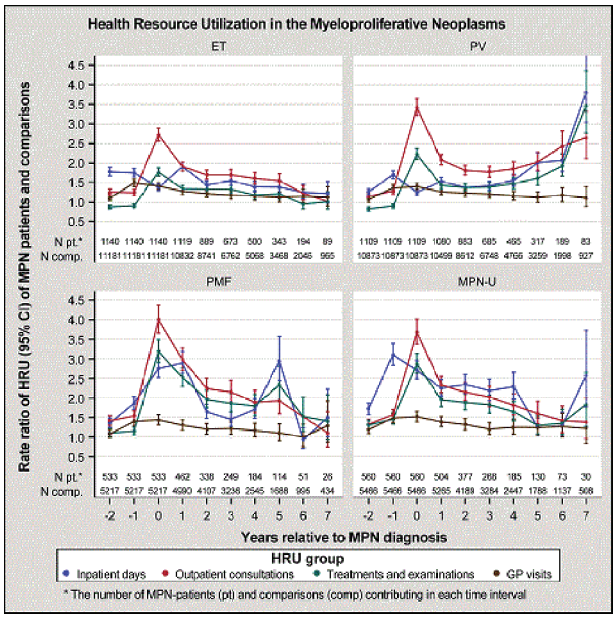
Background: Imetelstat is a first-in-class telomerase inhibitor that induces selective apoptosis of malignant hematopoietic stem and progenitor cells in the bone marrow. Imetelstat has shown clinical benefit in symptom response rate and a potential overall survival (OS) impact in Janus kinase (JAK) inhibitor relapsed and refractory (R/R) intermediate 2 (Int-2) and high risk (HR) myelofibrosis (MF) patients (pts) in the Phase 2 MYF2001 (IMbark) study, as well as meaningful and durable transfusion independence (TI) in high transfusion burden low risk (LR) and intermediate 1 (Int-1) risk myelodysplastic syndrome (MDS) pts R/R to erythropoiesis stimulating agents (ESAs) in the Phase 2 portion of the MDS3001 (IMerge) study. Clinical and biomarker data in both studies indicate potential disease-modifying activity of imetelstat. The most frequently reported adverse events (AEs) in both studies were manageable and reversible cytopenias, with limited clinical consequences, suggesting on-target activity of imetelstat (Platzbecker ASH 2020, Mascarenhas ASH 2020).
Aims: To further characterize hematologic and non-hematologic AEs, including the AEs of Interest (AEI), hepatic AEs and grade ≥3 liver function tests (LFTs) in these Phase 2 studies.
Methods: These safety analyses focus on MYF2001 study pts randomized to imetelsat 9.4 mg/kg IV q 3 weeks (wks) (N=59) as of 7 Feb 2020 and the Phase 2 of the MDS3001 study in LR/Int-1 non-del(5q) transfusion dependent ESA R/R MDS pts, all lenalidomide and hypomethylating agent-naïve (N=38), who received 7.5 mg/kg IV every 4 wks as of 21 Oct 2020. AEs were monitored and reported from the time of screening until 30 days after treatment discontinuation. Dose modification was performed based on protocol-defined criteria. An independent hepatic expert committee (HEC) reviewed all LFT and AEI data quarterly.
Results: On MYF2001 41% and 32% of pts had grade (G) ≥3 (G≥3) thrombocytopenia and neutropenia respectively and on MDS3001 61% and 55% of pts had G≥3 thrombocytopenia and neutropenia respectively. Median time to onset of these G≥ 3 cytopenias was 3 cycles in MF pts and approximately 1 cycle in MDS pts. Median duration of G≥3 cytopenias was <2 wks and >72% were reversible within 4 wks (Table 1). Median time to first dose reduction was 21 wks in MF and 11 wks in MDS. Cytopenias leading to treatment discontinuation occurred in 15% and 18% of MF and MDS pts, respectively. Importantly, clinical consequences of cytopenias including G≥3 hemorrhagic events or febrile neutropenia occurred in <10% of pts. Non-hematological AEs occurring in >20% pts in either study were nausea, diarrhea, abdominal pain, fatigue, asthenia, pyrexia, dyspnea, and back pain and were generally G1-2 events. One pt on each study experienced imetelstat related G3 AST increase that recovered with dose reduction. HEC reviews found no significant imetelstat-related liver injury.

Table 1: Characteristics of Cytopenias

	MYF2001 9.4 mg/kg q 3 weeks (n=59)		MDS3001 7.5 mg/kg q 4 weeks (n=38)	
	G3/4 Thrombocytopenia	G3/4 Neutropenia	G3/4 Thrombocytopenia	G3/4 Neutropenia
Median duration	2.0 weeks	1.3 weeks	1.1 weeks	1.7 weeks
Median time to onset	9.0 weeks (~3 cycles)	9.0 weeks (~3 cycles)	4.0 weeks (~1 cycle)	4.7 weeks (~1 cycle)
% Reversible within 4 weeks	47/65 events 72.3%	47/56 events 83.9%	86/95 events 90.5%	68/79 events 87.3%
Cytopenias leading to treatment discontinuation	6/59 (10%)	3/59 (5%)	6/38 (15.8%)	1/38 (2.6%)
Median time to first dose reduction	21.4 weeks (Cycle 6.5)		10.8 weeks (Cycle 3)	

Summary/Conclusion: Imetelstat related cytopenias are on-target effects based on the selective reduction of malignant cells through telomerase inhibition. Furthermore, they are of short duration, reversible and with limited clinical consequences when managed with the dose modification guidelines in the protocols. Pts in these two studies had no evidence of imetelstat-related liver injury. Differences in disease pathology (proliferation vs dysplasia) could account for the differences in toxicity profiles in MF vs MDS pts. Ongoing Phase 3 studies in MF and MDS will confirm the safety profile of imetelstat in a controlled setting.



EP1107 HEALTHCARE RESOURCE UTILIZATION IN PATIENTS WITH MYELOPROLIFERATIVE NEOPLASMS: A NATIONWIDE MATCHED COHORT STUDY

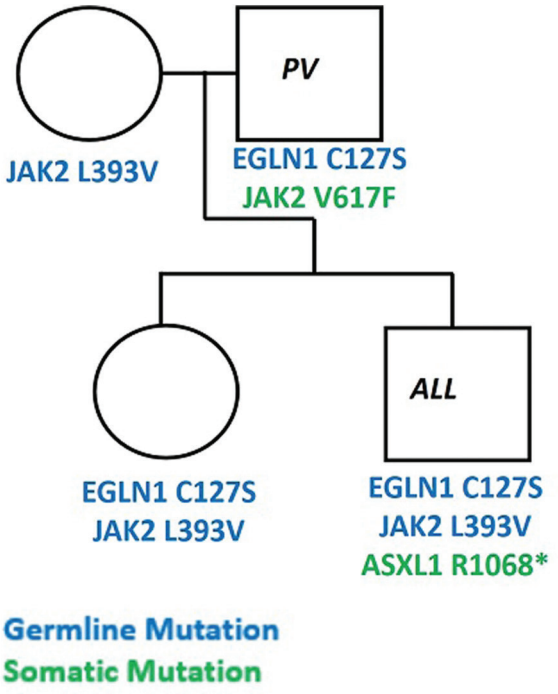
[5]Department of Hematology, Aarhus University Hospital, Aarhus, [6]Department of Hematology, Holstebro Hospital, Holstebro, [7]Department of Hematology, Aalborg University Hospital, Aalborg, [8]Department of Hematology, Hospital of South West Jutland, Esbjerg, [9]Department of Hematology, Odense University Hospital, Odense, Denmark

Background: Myeloproliferative neoplasms (MPNs) are associated with severe complications and a substantial symptom burden – frequently emerging several years before diagnosis. Due to the chronic nature of the diseases, MPN patients have a lifelong need for treatment and care. However, only few studies have assessed MPN healthcare resource utilization (HRU) compared with matched cohorts, and no detailed assessments of HRU in the years preceding MPN diagnosis exist.
Aims: To assess the pre- and post-diagnostic HRU of MPN patients compared with matched cohorts of $_{non}$MPN comparisons.
Methods: We conducted this descriptive, register-based nationwide cohort study, utilizing data from the Danish National Chronic Myeloid Neoplasia Registry on all MPN patients diagnosed between January 2010 and December 2016, and data on HRU from the Danish National Patient Registry and the Danish National Health Service Registry. Population-based cohorts of $_{non}$MPN comparisons were constructed by 1:10 matching on age, sex, level of education, and region of residence. Data were linked using the unique civil registration number, which identifies all Danish citizens. HRU was summarized over each year for all cohorts from two years before date of MPN diagnosis and until emigration, death, or end of study (31 December 2017). HRU was calculated as annual number of healthcare contacts (inpatient days, outpatient consultations, treatments and examinations, and general practitioner [GP] visits) divided by person-years at risk and compared using rate ratios with 95% CI.
Results: The study population included 3,342 MPN patients (1,140 essential thrombocythemia [ET]; 1,109 polycythemia vera [PV]; 533 primary myelofibrosis [PMF]; and 560 unspecified MPN [MPN-U]) and 32,737 $_{non}$MPN comparisons (11,181 $_{non}$ET; 10,873 $_{non}$PV; 5,217 $_{non}$PMF; and 5,466 $_{non}$MPN-U). The median age was 67 (ET), 69 (PV), 73 (PMF), and 72 years (MPN-U), and the mean follow-up was 3.8 (ET), 3.8 (PV), 3.1 (PMF), and 3.3 years (MPN-U). A total of 750 (22.4%) MPN patients and 4,627 (14.1%) $_{non}$MPN comparisons died during follow-up. In nearly all years of follow-up, MPN patients had a higher HRU than $_{non}$MPN comparisons (Figure, rate ratio>1). Rate ratios for *outpatient consultations* were largest at the time of diagnosis: ET, 2.7 (95%CI, 2.6-2.9); PV, 3.4 (95%CI, 3.2-3.6); PMF, 4.0 (95%CI, 3.7-4.4); and MPN-U, 3.7 (95%CI, 3.4-4.0). For most MPN subtypes, rate ratios also peaked at time of diagnosis for *treatment and examinations*. In contrast, the largest rate ratio for PV was in the last year of follow-up: 3.5 (95%CI, 2.8-4.3). Across MPN subtypes, rate ratios for *GP visits* varied from 1.0 to 1.5 during follow-up without any considerable fluctuations. Interestingly, increased rate ratios for *inpatients days* were evident 2 years before diagnosis: ET, 1.8 (95%CI, 1.7-1.9); PV, 1.3, (95%CI, 1.2-1.3); PMF, 1.4 (95%CI, 1.2-1.5); and MPN-U, 1.7 (95%CI, 1.6-1.9). During follow-up, notable increases in rate ratios were observed, e.g., PMF 3.0 (95%CI 2.4-3.6) and PV 3.8 (95%CI 3.0-4.8) in year 5 and 7, respectively.



Summary/Conclusion: Overall, compared with matched $_{non}$MPN comparisons, MPN patients had a higher HRU throughout the study period. This was consistent across MPN subtypes and HRU measures. Within the limitations of small numbers toward end of follow-up and lack of matching on comorbidity, our findings confirmed a consistent HRU burden after MPN diagnosis. Equally important, our study revealed substantial increases in HRU two years before MPN diagnosis, warranting further exploration of the pre-diagnostic period, including the potential benefits of early detection.

EP1108 ASSOCIATION OF JAK2 AND PHD2 MUTATIONS IN A FAMILY WITH ERYTHROCYTOSIS

G. Biagetti [1,*], A. Benetti [1], F. Polese [2], A. Lombardi [1], G. Ceolotto [1], M. L. Randi [1]

[1]Clinica Medica 1, University of Padua, Padova, [2]Transfusional Center of Mestre, Ospedale dell'Angelo - Mestre, Venezia, Italy

Background: Absolute erythrocytosis is characterized by persistently raised Haemoglobin (Hb) and haematocrit (Ht) levels. Polycythaemia Vera (PV) is a clonal disease associated in 95% of cases with *JAK2*V617F mutation, while familial erythrocytoses are poorly understood.
Idiopathic erythrocytosis (IE) has not a definite cause, even after an accurate diagnostic investigation. Recently, also HFE mutations have been observed frequently in erythrocytotic patients. The recent availability of NGS technique has offered us the possibility to recognize mutations in known and unknown genes involved in the pathogenesis of erythrocytosis.
Aims: We report a venetian family with erythrocytosis in whom we found an undescribed association of mutations all consistent with the clinical phenotype.
Methods: The family comprehends a man, his wife, and their two children, a male and a female. Hematocrit, ferritin at diagnosis and necessity of phlebotomies were recorded if available. An NGS panel constituted by *JAK 2, EGLN 1 (PHD2), HBB, HBA1, HBA2, ASXL1, HFE, HFE2, TFR2, HAMP, SLC40A1, SLC11A2, VHL, BPMG, EPAS1* was used.
Results: Results are showed in Table I.
Genealogic tree of the family is reported in Figure I.

Summary/Conclusion: In this study we show the presence of contemporary mutations involved in erythrocytosis in more members of the same family.
Father and the two children have the same germline mutation *(EGLN1 C127S)* among with a mutation in *JAK2* gene, somatic in the father (*V617F*) and germline in the two children *(L393V)*. The mother has also this *JAK2* germline mutation. The son has also a somatic mutation in *ASXL1* R1068*. Interestingly, the son developed an acute lymphoblastic

Member	Age	History	Somatic Mutations	Germline Mutations	HT (%)	Ferritin (μG/L)	Phlebotomies
Father	68	Treated for PV since 2014, symptomatic for chest pain when Ht is high, no coronaropathy.	JAK2V617F	EGLN1 C127S	56	n.a.	4/year since 2014, recently increasing
Mother	57	Asymptomatic	-	JAK2 L393V	40	n.a.	no
Son	26	Treated for acute lymphoblastic leukemia (ALL) in 2012 with high transfusion need and iron overload, developed erythrocytosis in 2017	ASXL1 R1068*	EGLN1 C127S JAK2 L393V	50	510	4/year since 2017
Daughter	30	Asymptomatic	-	EGLN1 C127S JAK2 L393V	n.a.	n.a.	no

leukemia (ALL) at the age of 18 and developed erythrocytosis after recovery. The daughter and the mother are still asymptomatic.
It has been hypothesized that *JAK2* germ line mutations may precede the acquisition of *JAK2V617F* lesion during the evolution of PV phenotype. The *PHD2* mutation of this family is frequently observed in Tibetans, that establish an escape mechanism against erythrocytosis at high altitude, while in conditions of normoxia, the *EGLN1 p.C127S* variant has still an unclear function. We surmise that the association of *PHD2* and *JAK2* mutations could be associated with a more significant increase in hematocrit in this family. Moreover, usually ASXL1 is an epigenetic modifier, a marker of high risk for shorter survival in primary myelofibrosis (PMF). IE patients during their clinical history do not usually evolve in overt PV, nor in PMF or AML, and the role of *ASXL1* mutation in these patients is therefore unknown.
In conclusion, the use of a specific NGS panel for erythrocytosis is a useful tool to explore new and combined genes variants and to study other members of the family to find the link between their haematological complications, in order to predict eventual clinical variations of the phenotype.

EP1109 DIAGNOSTICS OF ERYTHROCYTOSIS OFTEN STOPS AFTER POLYCYTHAEMIA VERA EXCLUSION

S. Anžej Doma [1,2,*], E. Drnovšek [2], A. Kristan [3], M. Sever [1,2], M. Fink [1], N. Debeljak [3], I. Preložnik Zupan [1,2]

[1]Hematology Department, UMC Ljubljana, [2]Medicine Faculty, University of Ljubljana, [3]Medical Centre for Molecular Biology, Faculty of Medicine, Institute of Biochemistry and Molecular Genetics, University of Ljubljana, Ljubljana, Slovenia

Background: Erythrocytosis is a condition of increased red cell mass, manifested by high haemoglobin (Hb) and/or haematocrit (Hct). Most frequently, it is secondary (SE) to hypoxia caused by various cardiac, pulmonary or renal diseases. Congenital causes are very rare. The only clonal erythrocytosis is polycythaemia vera (PV), almost uniformly associated with *JAK2* mutation. When no cause of erythrocytosis is identified, the erythrocytosis is idiopathic (IE). As thromboembolic events are frequent in PV, patients are usually treated with antiaggregation and cytoreduction. Management of all other types of erythrocytosis is less clear and differs according to the underlying cause of erythrocytosis
Aims: The aim of our study was to retrospectively analyze the etiology and management of patients with non-clonal erythrocytosis referred to an adult haematology outpatient clinic in an 8-year period.
Methods: First step was inclusion of patients with Hb> 185 g/L and/or Hct> 0.52 in men and Hb> 165 g/L and/or Hct> 0.48 in women on two visits ≥ two months apart, thus confirming absolute erythrocytosis. Secondly, PV was excluded by determination of *JAK2* mutation and erythropoietin level, sometimes also by bone marrow biopsy. Concomitantly, causes of SE were identified using various biochemistry and imaging techniques (iron stores, haemochromatosis testing, pulse oximetry, blood gas analysis with COHb determination, CT or ultrasound for detection of cardiac or pulmonary disease or origin of ectopic erythropoietin, polysomnography). Thirdly, IE patients were referred to targeted next-generation sequencing for congenital erythrocytosis. Informed consent was obtained from all participants.
Results: Between March 2011 and April 2019, 655 patients met the inclusion criteria for absolute erythrocytosis. After excluding PV 116 patients were evaluated for other causes of erythrocytosis; 75 (65%) were men and 41 (35%) women. Median age in men and women was 51.4 years (41.1 – 62.9, interquartile range), and 60.7 years (54.4 -68.2), respectively (p = 0.002). For 34/116 (29%) patients secondary causes of erythrocytosis were identified, namely obstructive sleep apnoea (38%), smoking (21%), lung (18%) and cardiovascular diseases (6%), neurological disorders affecting respiratory function (6%), kidney diseases (renal cell carcinoma, renal cysts, polycystic kidney disease) (12%), tumors with ectopic erythropoietin secretion (6%), hemochromatosis (3%) and drugs (6%). 15/116 (13%) patients remained idiopathic despite extensive diagnostics. 67/116 (58%) patients stayed incompletely characterized (ICE) due to insufficient diagnostics. Patients from all three groups were similarly treated, either with aspirin or phlebotomies. Differences in SE, IE and ICE patients are presented in Table 1. Thrombotic events were registered in 12%, 20% and 15% of SE, IE and ICE patients, respectively. Congenital erythrocytosis type 4 (ECYT4) was diagnosed in one patient, who had already suffered several thromboembolic complications.

Table 1. Characteristics of patients with secondary (SE), idiopathic (IE) and incompletely characterized (ICE) erythrocytosis (N=116).

Laboratory characteristics	Median (25% – 75%)			
	Patients with SE (N=34)	*Patients with IE (N=15)*	**p value** (SE vs IE)	*Patients with ICE (N=67)*
Age	57.7 (47.3 – 63.8)	41.1 (35.4 – 52.0)	**0.01**	58.0 (45.6 – 67.9)
Male /female	25/9	12/3	NS	38/29
Haemoglobin	189 (182 – 197)	182 (176 – 183)	**0.02**	180 (172 – 185)
Haematocrit	0.55 (0.53 – 0.58)	0.52 (0.52 – 0.53)	**0.002**	0.53 (0.51 – 0.54)
Erythropoietin	9.8 (7.6 – 17.2)	8.2 (6.1 – 12.5)	NS	8.6 (6.2 – 11.3)
Treatment with phlebotomies	19 (56%)	8 (53%)	NS	27 (40%)
Prescribed aspirin	25 (74%)	10 (67%)	NS	47 (70%)
Thrombotic events	4 (12%)	3 (20%)	NS	10 (15%)

Haemoglobin and haematocrit in the table reflect the patients' first measurements before phlebotomies.

Summary/Conclusion: Our study demonstrated that diagnostics of erythrocytosis often stopped after PV exclusion. Thromboembolic events were not rare among patients with non-clonal erythrocytosis, which could be attributable to yet unidentified causes of congenital erythrocytosis in the ICE group but also to inadequate management of secondary causes. The optimal management for each patient can be chosen only by identifying the etiology of erythrocytosis.

EP1110 IS MIR-155 USEFUL AS A MARKER OF CLONAL HEMOPOESIS IN MYELOID PROLIFERATION?

M. Stolyar [1,*], A. Gorbenko [1,2], V. Bakhtina [3,4], V. Babushkin [3], V. Prugova [5], E. Anisimova [3], M. Smelyanskaiya [5], M. Mikhalev [6], T. Olkhovik [6], I. Olkhovskiy [1,2]

[1]Department of Health, Krasnoyarsk branch of the National Research Center for Hematology, [2]Federal Research Center Krasnoyarsk Scientific Center of the Siberian Branch of the Russian Academy of Sciences, [3]Krasnoyarsk State Medical University named after Professor V.F. Vojno-Yasenetsky, [4]Krasnoyarsk regional clinic Hospital,, [5]Krasnoyarsk regional clinic Hospital, [6]Krasnoyarsk city Clinical Hospital № 7, Krasnoyarsk, Russian Federation

Background: MiR-155 is involved in various physiological processes in the cell, including hematopoiesis, immunity, inflammation and differentiation. Increased expression of miR-155 is observed in many malignant diseases, including lymphomas, acute myeloid leukemia and CLL (Morales-Martinez M., et.al., 2020). Earlier (Stolyar M.A., et.al.,2020) we have demonstrated an increased miR-155 level in patients with chronic Ph-negative myeloproliferative neoplasms (MPN). Both an increase (Long L., et.al., 2013) miR-155 in blood mononuclear cells

and a decrease (Kolarz B., et.al., 2020) in its level in the blood plasma of patients with rheumatoid arthritis have been described. At the same time, there are no results of a special study of miR-155 expression in reactive (non-clonal) leukocytosis.
Aims: To assess the diagnostic capability of determining miR-155 for the differentiation of non-clonal leukocytosis and MPN.
Methods: The study used anonymous (blind) EDTA venous blood samples from 107 patients with MPN (66-PV, 24-ET,17-PMF) and 20 patients with reactive neutrophilic leukocytosis above 12 * 10^9/μL, as well as 51 samples of voluntary blood donors. Determination of miR-155 in blood leukocytes was carried out by RT-PCR (Gene Formula Ltd.). The results were statistically evaluated using the R statistical package.
Results: In our study, the level of miR-155 in whole blood samples did not depend on the number of blood leukocytes. At the same time, its level in blood samples from patients without oncohematological disease does not significantly differ from the values typical for healthy people. On the contrary, in the group of patients with verified forms of MPN, the level of miR-155 in leukocytes was significantly increased (Table; p<0.001), although leukocytosis was less pronounced. There were no significant differences in the level of miR-155 between different variants of the MPN phenotype (PV, ET or PMF). Obviously, miR-155 overexpression is characteristic of cancer-transformed blood cells during myeloid proliferation.

Table. Characteristics of the studied groups

Patients		Leukocytosis Me*10^9/μL (C_{25}-C_{75})	miR-155 (relative units)	P-value
1	Blood donors	< 7,2	0,74 (0,28-1,48)	
2	With reactive (non-clonal) neutrophilic leukocytosis	17,4 (14,9-20,6)	0,25 (0,18-0,38)	0.001
3	With MPN	7,1 (5,3-10,1)	1,7 (0,9-2,9)	

Summary/Conclusion: The data obtained confirm the participation of miR-155 in the pathogenesis of MPN and suggest the possibility of using the miR-155 test as an additional diagnostic test for the differentiation of the clonal nature of the disease.

EP1111 A REAL-WORLD STUDY ON DIAGNOSIS AND TREATMENT STRATEGIES OF PEDIATRIC ESSENTIAL THROMBOCYTHEMIA IN CHINA

R. Fu [1,*], D. Zhang [1], H. Li [1], F. Xue [1], X. Liu [1], Y. Chen [1], W. Liu [1], R. Yang [1], L. Zhang [1]

[1]*State Key Laboratory of Experimental Hematology, National Clinical Research Center for Blood Diseases, Institute of Hematology & Blood Diseases Hospital, Chinese Academy of Medical Sciences & Peking Union Medical College, Tianjin, China*

Background: Essential thrombocythemia (ET) is rare in pediatric patients, with uncertain criteria for diagnosis, prognosis and treatment strategies in real-world clinical practice.
Aims: The study aimed at revealing the patterns of diagnosis, prognosis and treatment strategies in real-world clinical practice in a cohort of children diagnosed with ET in China, and trying to optimize the diagnostic and therapeutic regimens based on existing evidence.
Methods: A total of 86 pediatric patients (age≤16 years) with an initial diagnosis of ET according to the 2016 WHO diagnostic criterion were enrolled. A total of 137 genes associated with myeloid malignancies were analyzed in 55 children. The immunophenotype of bone marrow mononuclear cells was detected by flow cytometry. Informed consent was obtained from the guardians of the patients.
Results: The median age was 10 years (range 1-16 years). The JAK2 V617F mutation was positive in 16 patients (18.6%). The CALR mutations were found in 3 out of 62 (4.8%) patients. The MPL mutation was analyzed in 65 patients, and none of them was positive. Surprisingly, although bone marrow histology was consistent with a diagnosis of ET in all the 67 cases without driver molecular markers, a spontaneous normalization of the platelet count without cytoreductive therapy occurred in 7 cases (10.4%), after a median follow-up of 37 months (8-96 months). We found that several factors might be 'true ET'-specific, but rarely seen or absent in those with spontaneous recovery, including palpable splenomegaly, presence of immunophenotypic abnormality (mainly showing reduced CD38 expression on myeloid blast cells and reduced CD36 expression on nucleated red blood cells), positive endogenous erythroid colonies, subnormal erythropoietin, and presence of molecular markers other than JAK2, CALR or MPL mutations (such as mutations in NRAS, ASXL1). In 79 patients still with sustained thrombocytosis, 4 children (5.1%) displayed major thrombosis, and 3 (3.8%) evolved to myelofibrosis. The International Prognostic Score of thrombosis for adults was not applicable to childhood patients, and so does the International Prognostic Score of survival. We found that severe splenomegaly was a risk factor of myelofibrosis transformation in childhood patients. The Efficacy and safety between pegylated interferon and regular interferon were compared for the first time in childhood patients. Similar efficacy was seen between pegylated interferon and regular interferon, but better tolerance was seen in children using pegylated interferon. Furthermore, pegylated interferon was still effective and tolerant in 8 children that were resistant or intolerant for regular interferon.
Summary/Conclusion: Based on the 2016 WHO diagnostic criterion for ET, several 'true ET'-specific features might be considered for the diagnostic screening of childhood ET. Prognostic factors of thrombosis and survival in pegylated interferon were different from that in adult patients. Pegylated interferon has an extensive application prosperity for childhood ET.

EP1112 EFFECT OF DRIVER MUTATIONS ON THE PHENOTYPE OF ESSENTIAL THROMBOCYTHEMIA AND PRIMARY MYELOFIBROSIS

G. Alfia [1,*], Y. Tregubova [1], E. Nazarova [1], T. Rybolovleva [1], V. Ovsepyan [1]

[1]*The Federal State-Financed Scientific Institution Kirov Research Institute of Hematology and Blood Transfusion under the Federal Medical Biological Agence (KRIHBT), Kirov, Russian Federation, Kirov, Russian Federation*

Background: Myeloproliferative neoplasms (MPN) are a group of clonal hematological malignancies. In which there are three classic pathologies (WHO 2017): polycythemia vera, essential thrombocythemia (ET) and primary myelofibrosis (PMF). According to the accumulated data, it becomes clear that the traditional division of MPN into the above mentioned subtypes does not fully reflect the main biological heterogeneity of these diseases, and that their clinical and laboratory parameters are the result of the various genetic factors interaction. Somatic point mutations of genes encoding tyrosine kinase (*JAK2*), calreticulin protein (*CALR*), and thrombopoietin receptor (*MPL*) (driver mutations, DM) had a great influence on the diagnosis of this group of pathological conditions. However, the question of the each of the mutations influence on the fenotype remains open.
Aims: To determine the correlation of the gene mutations *JAK2, CALR, MPL* with the clinical and laboratory features of MPN.
Methods: Retro- and prospective study of the 192 ET and 141 PMF patient's medical histories were performed. All of them were observed at The Federal State-Financed Scientific Institution Kirov Research Institute of Hematology and Blood Transfusion under the Federal Medical Biological Agence from 1995 to 2019. Gene mutations *JAK2* V617F, *CALR*, and *MPL* W515L/K were determined using kits from GenoTechnologiya LLC (Moscow, Russia) by real-time PCR using TaqMan technology. The mutational status of the gene *CALR* included two like mutations - p.L367fs * 46 (52 bp deletion - type 1, or group *CALR1+*) and p.K385fs * 47 (5 bp insertion - type 2, or group *CALR2+*). Patients without DM were assigned to the triple negative group. The statistical significance of quantitative indicators differences was assessed by the Kruskal-Wallace test.
Results: JAK2-mutated (*JAK2+*) ET patients display a higher hemoglobin levels (median Hb levels are 147 (102-219) and 134 (93-176) g/l, respectively, p <0.0001). Patients with *CALR2+* had a higher number of platelets compared with those who did not have this mutation (median platelet counts 1197x10^9/l (676-3766) and 750x10^9/l (357-2074), respectively, p <0.0001). A comparative analysis of the data obtained showed that the *CALR2+* ET patients were significantly younger at the onset of the disease than the patients from other groups (medians of age 39 (31-78) and 57 (18-90) years, respectively, p = 0.001)
Patients with *JAK2* V617F mutated PMF also had higher hemoglobin levels (median Hb levels are 146 (125-162) and 114 (59-160) g/l, respectively, p <0.0001). The number of platelets in *CALR2+* mutation carriers was statistically significantly higher than their number in patients from other groups (median platelet counts are 1330x10^9/l (272-2529) and 487x10^9/l (38-2000), respectively, p = 0.01). The presence of a type 1 *CALR* gene mutation in patients was associated with a lower leukocyte count of the median leukocyte count of 6.3x10^9/l (3.35-13.64) and 12.2x10^9/l (2.3-49.1), respectively, p = 0.0004).

Summary/Conclusion: In patients with ET and PMF, the association of the gene *JAK2* V617F mutation with a higher hemoglobin level was confirmed. Patients with type 2/like gene *CALR* mutations in comparison with all other patients had the highest platelet count. In the case of PMF, it was found that the leukocyte count in patients with a type 1 gene *CALR* mutation was lower than in patients from other groups. A statistically significant difference in the age at the disease onset for ET was established.

EP1113 ACUTE CORONARY SYNDROME AND JAK2 V617F MUTATION POSITIVE MYELOPROLIFERATIVE NEOPLASMS: A CARDIOLOGICAL PERSPECTIVE

S. Cantoni [1,*], C. Colombo [2], F. Soriano [2], J. Oreglia [2], A. Sacco [2], A. Rubboli [3], R. Cairoli [1], N. Morici [2]

[1]Ematology, [2]Cardiology, Grande Ospedale Metropolitano Niguarda, Milano, [3]Cardiology, Ospedale S. Maria delle Croci, Ravenna, Ravenna, Italy

Background: In Polycythemia vera (PV) and essential thrombocythemia (ET) morbidity relates to thrombotic events. The JAK2 V617F mutation alters both the cellular and plasma compartments of hemostasis favoring a hypercoagulable state. Compared to a matched control population, PV/ET pts have a significantly increased rate of thrombotic events and this risk remains independent of gender and across all age groups. Conventional cardiovascular risk factors (CRF) add to the risk of acute coronary syndrome (ACS).
Aims: Since ACS can occur either as first clinical manifestation of PV/ET or it may complicate its course, we explored the possibility that differences may exist between these two settings.
Methods: Retrospective cohort study of 1,413 consecutive ACS performed at ASST Niguarda Hospital between Jan 2014 and Dec 2019. Patients were divided into 3 groups: *group 1*: patients diagnosed with JAK2+ PV/ET during the index hospitalization; *group 2:* patients with a known diagnosis of JAK2+ PV/ET; *group 3*: control group = ACS in myeloproliferative neoplasm (MPN) negative pts. Clinical and angiography data and outcome events were compared among the 3 groups.
Results: Data are summarized in the Table. Overall, MPN patients differed from MPN negative patients in terms of CRF and extension of coronary artery disease. These differences were even more prominent between MPN group 1 and group 2 patients. Specifically, incidence of CRF was lower and single-vessel disease was more prevalent among group 1 patients. Interestingly, a decreased incidence of long-term adverse cardiovascular events was observed in group 1 MPN patients. At a median follow-up of 18 months, the composite of overall mortality, myocardial infarction, stroke and bleeding events occurred in 2 (6.2%) patients in group 1, in 1 patient (7.7%) in group 2 and 188 patients (13.7%) in MPN-negative ACS patients.

	Group 1 (n = 32)	Group 2 (n = 13)	No MPS (n = 1368)	P value
Age, years	64±15	71±12	66±13	0.219

ACE-inhibitor/ARB, n (%)	23 (71.9)	9 (69.2)	889 (65.3)	0.713

Summary/Conclusion: ACS is a known complication of JAK2+ PV/ET. In this setting it displays peculiar angiography features according to time of clinical presentation with newly diagnosed PV/ET patients more often showing single-vessel involvement compared to patients with known PV/ET who have angiography features similar to the control group. CRF were also not significantly represented among these patients. It is tempting to hypothesize that mechanisms other than atherosclerotic plaque rupture may be relevant to ACS development when JAK2+ PV/ET occur. Considering the anatomical sites involved, it may be speculated that endothelial dysfunction associated with elevated shear stress may be the main inciting factor leading to thrombosis. In the setting of shear-induced endothelial dysfunction, the overall pro-coagulant features of circulating cells may give rise to thrombus formation even in the absence of underlying plaques. Recognition by the cardiologists of the peculiar angiography features associated with ACS as initial presentation of PV/ET should prompt hematologic counseling aimed at a tailored treatment strategy. Dual anti-platelet therapy alone may not protect from further thrombotic events and a more comprehensive therapeutic strategy, comprising hydroxycarbamide/phlebotomy, is be advisable in these patients.

EP1114 IPSS, DIPSS AND DIPSS-PLUS: PREDICTIVE VALUE FOR SURVIVAL IN PRIMARY MYELOFIBROSIS STAGES

R. S. Gomes [1,*], S. Duarte [1], C. Afonso [1], B. Marques [1], A. Roque [1], J. Carda [1], A. Crisóstomo [1]

[1]Hematology department, Coimbra University Hospital Centre, Coimbra, Portugal

Background: In the recent years, prognostic models have been validated for primary myelofibrosis (PMF), initially based exclusively on clinical variables, namely the *International Prognostic Scoring System-(IPSS)* and the *Dynamic IPSS-(DIPSS)*. Cytogenetics was incorporated in the most recent scores such as the DIPSS-plus. However, the applicability of PMF scoring systems in the recently recognized pre-fibrotic PMF (pre-PMF) has not been validated.
Aims: To assess the prognostic value of IPSS, DIPSS and DIPSS-plus in PMF stages: pre-PMF and overt-PMF.
Methods: Retrospective and unicentric analysis of records from patients (pts) diagnosed with PMF between January 2010 and December 2019. The diagnoses of pre-PMF and overt-PMF were reviewed according to WHO 2016 criteria. Prognostic scores were calculated considering clinical and laboratory information at diagnosis. Kaplan-Meier method were used for the analysis of progression free survival (PFS) and overall survival (OS). For multivariate analysis were included the variables with p<0.05 in the univariate analysis.
Results: We studied a total of 90 pts, with a median age of 68 years (range, 24-92 years old), 63.3% males. Forty-three (47.8%) pts were at pre-PMF stage.
The overall PFS in our cohort was 101.7 months. In addition to the variables included in the IPSS and DIPSS-plus, histological stage (HR 4.1; p=0.002), increased lactate dehydrogenase (LDH) (HR 9.7; p=0.026) and splenomegaly (HR 2.2; p=0.013) were predictors of PFS. In multivariate analysis, IPSS (HR 5.7; p<0.001), DIPSS (HR 4.5; p<0.001) and DIPSS-plus (HR 4.1; p=0.009) remained predictors of PFS. However, after sub-analysis for the histological stage, all the three scores were predictors of PFS in overt-PMF (HR 7.4, p=0.001; HR 6.8, p<0.001; HR 3.4, p=0.022, respectively) but not in pre-PMF (HR 3.1, p=0.202; HR 6.7, p=0.132; HR 2.5, p=0.237, respectively).
The overall OS was estimated in 124.6 months. Again, beyond the variables included in IPSS and DIPSS-plus, the histological stage (HR 6.2; p=0.001), elevated LDH (HR 8.8; p=0.033) and splenomegaly (HR 3.3 p=0.010) were also predictors of OS. In multivariate analysis, IPSS (HR 6.2; p<0.001), DIPSS (HR 4.5; p<0.001) and DIPSS-plus (HR 4.1; p=0.009) persisted as predictors of OS. However, upon sub-analysis for the histological stage, the aforementioned scores kept as predictors of OS in overt-PMF (HR 7.6, p=0.001; HR 6.1, p<0.001; HR 4.1, p=0.019, respectively) but not in pre-PMF (HR 3.1, p=0.200; HR 3.4, p=0.382; HR 7.9, p=0.988, respectively).
Summary/Conclusion: In our cohort, IPSS, DIPSS and DIPSS-plus were independent predictors of PFS and OS in overt-PMF, but did not in pre-PMF. These findings identify a flaw in prognostic stratification applying the available scoring systems and alarms for the need of validated scores specifically for pre-PMF pts.

EP1115 A POSSIBLE SYNERGISTIC EFFECT OF P SELECTIN GLYCOPROTEIN LIGAND 1 POLYMORPHISM AND ANTIPHOSHOLIPID ANTIBODIES ON THROMBOSIS IN MYELOPROLIFERATIVE NEOPLASIA PATIENTS

R. Dambrauskiene [1,*]

[1]*Department of Oncology and Hematology, Institute of Oncology, Kaunas, Lithuania, Lithuanian University of Health Sciences, Kaunas, Lithuania*

Background: The morbidity and mortality of BCR-ABL negative myeloproliferative neoplasms (polycythaemia vera, essential thrombocyhaemia and primary myelofibrosis) is highly dependent on thrombotic complications. In myeloproliferative neoplasia patients circulating platelets are already activated and they secrets higher levels of surface P-selectin and tissue factor. Anti-β2 glycoprotein 1 antibodies (β2GP1) bind to the β2GP1 receptors on the platelet surface, activating them that is important for thrombus formation. Antiphospholipid antibodies activates endothelial cells, whose dysfunction also plays an important role in the pathogenesis of thrombosis in BCR-ABL negative myeloproliferative neoplasia.
Aims: To evalute the antiphospholipid antibodies in relationship P Selectin Glycoprotein Ligand 1 (PSGL1) polymorphism on the development of thrombosis with other risk factors in patients with MPN.
Methods: A total of 105 MPN patients were included in this retrospective study. 58 of the MPN patients were diagnosed with essential thrombocythemia (ET), 41 with polycythemia vera (PV), 6 with myelofibrosis (MF). Clinical data about the development of thrombosis was collected. PSGL1 polymorphisms was determined from peripheral blood samples using PCR method. In electrophoresis the size of A allele was 558 bp, B allele – 528 bp. Data analysis was performed using "IBM SPSS Statistics 23". There were two different selective and one confirmatory test for the LA determination. The detection of antibodies against β2-glycoprotein-1 (β2GP1) was performed using a chemiluminescent method. The detection of antibodies against cardiolipin (aCL) was performed by ELISA using commercial Aeskulisa Cardiolipin-GM (AESKU.DIAGNOSTICS, Germany).The interdependence of qualitative attributes was evaluated by the criterion of the chi square ($\chi 2$), and the Stjudent t-test or the Mann-Whitney U test was used to compare the quantitative characteristics. The data was statistically reliable when $P<0.05$.
Results: Arterial thrombotic complications were present in 38 (42.2%) of those with MPN. These patients were diagnosed with transient ischaemic attack (TIA), ischaemic stroke or myocardial infarction. aPL together with PSGL1 polymorphism were significant more frequently found in arterial thrombosis MPN patients compared with MPN patients who didn't experienced thrombosis (21.1% and 5.8%; $p< 0.029$).
Summary/Conclusion: Myeloproliferative neoplasm´s patients with antiphospholipid antibodies and PSGL1 polymorphism may have the increased risk of thrombosis development.

EP1116 CHARACTERIZATION OF MYELOID MUTATIONS IN 21 PATIENTS WITH COEXISTING MYELOPROLIFERATIVE AND LYMPHOPROLIFERATIVE SYNDROMES

D. V. Fiallo Suárez [1,*], M. Tapia Torres [2], Y. Florido Ortega [1], R. Stuckey [1], A. Lemes Castellano [1], M. Lorenzo Perez [1], A. Suárez Cabrera [1], H. Luzardo Henrriquez [1], M. A. Perera Alvarez [1], M. Perera Alvarez [1], J. Benitez Jerez [1], M. J. Cruz Afonso [1], A. Borrero Borrego [1], I. Deniz Marrero [1], G. Santana Santana [1], E. Robaina Sanchez [1], B. Bolaños Mnrroy [1], M. T. Gomez Casares [1], C. Bilbao Sieyro [1]

[1]*Hematology, Hospital Universitario de GC. Dr. Negrin, Las Palmas GC,* [2]*Hematology, Hospital General de la Palma, Santa Cruz de la Palma, Spain*

Background: The coexistence of myeloproliferative neoplasms (MPN) and lymphoproliferative neoplasms (LPN) is a rare finding. However, studies have demonstrated that patients with MPN have approximately a 3-fold higher risk of developing an LPN than the general population. The clonal origin of these diseases has yet to be elucidated, although there are suggestions that their origin may lie in multipotent hematopoietic stem cells.
Aims: Use of next-generation sequencing (NGS) to identify myeloid mutations in separated cellular populations associated with the development of coexisting MPN/LPN syndromes.
Methods: All patients with a MPN or LPN diagnosis (dx) between 1997 and 2020 were retrospectively analyzed for concomitant MPN/LPN according to the WHO 2016 criteria. Of the 21 patients identified, informed consent was obtained from the live patients (n=13) for peripheral blood (PB) extraction. CD34+ (progenitor cells), CD15+ (granulocytes), and CD19+ (B lymphocytes) cell populations were separated using an autoMACS Pro. So far, genomic DNA of 5 patients has been analyzed by NGS with the MiSeq (Illumina) platform using the targeted panel Myeloid Solution™ (SOPHiA GENETICS). Only variants with VAF ≥1%, MAF<1% and described as having a pathogenic or probably pathogenic effect were considered.
Results: We report a series of 21 patients: 57% received an MPN dx first (average age at dx 66.4 years) then LPN, 28.5% received an LPN dx first (average age at dx 68.1 years) then MPN, while 14.5% had a concomitant dx (average age at dx 64.3 years). The most frequent LPN dx was chronic lymphocytic leukemia (CLL, 33%); the most frequent MPN dx was essential thrombocythemia (ET, 48%). Coexisting syndromes with the highest incidence were CLL-ET (28.6%) and PV-MGUS (14.3%). Patient characteristics are shown in Table 1.
Mutated MPN driver genes were *JAK2* and *CALR* for 81% (n=3, all V617F) and 10% (n=2, 1 Type 1, 1 Type 2), respectively; 10% of patients were triple negative (n=2). The MPN driver mutation was always detected in the CD34+ population, although the allelic frequency (VAF) was slightly inferior compared to PB in 2 cases. In 1 TN patient no mutation was found in PB but the *JAK2* mutation was detected in CD34+ cells (VAF 2.7%). In the CD19+ population, the MPN driver gene mutation was undetectable except for 1 patient who had a high VAF (*CALR* Type 1) in all cell populations and developed the LPN just one year after the initial MPN diagnosis. In the other 3 MPN-first cases, the LPN developed after 3-12 years.
With regard to other myeloid genes, *TET2* was mutated in 2 patients in SP and CD34+ cells, while 1 patient was mutated in both *DNMT3A* and *PTPN11*. None of these variants were detected in the CD19+ populations. The only alteration observed in CD19+ cells was a chromosome 21 deletion (also present in the CD34+ population but not in PB).

Table 1. Patient characteristics.

Patient	Age	Sex	LPN-MPN type	MPN driver mutation	Time between dx (years)	LPN treatment type	MPN treatment type	Treatment response LPN	Treatment response MPN	Concomitant follow up (years)

F: female, M: male, TN: triple negative, LPN: lymphoproliferative neoplasm, MPN: myeloproliferative neoplasm, ET: essential thrombocythemia, PV: polycythemia vera, PMF: primary myelofibrosis, CLL: chronic lymphocytic leukemia, BL: Burkitt lymphoma, AITL: angioimmunoblastic T-cell lymphoma, MALT: mucosa-associated lymphoid tissue, MGUS: monoclonal gammopathy of undetermined significance, HL: Hodgkin lymphoma, DLBCL: Diffuse large B-cell lymphoma, NHLB: B-cell non-Hodgkin lymphoma, SMZL: splenic marginal zone lymphoma, OBS: observation, HU: hydroxyurea, RIT: rituximab, RUX: ruxolitinib, R-CHOP: rituximab-cyclophosphamide-doxorubicin hydrochloride-vincristine sulphate,prednisone, R-CHOEP: rituximab-cyclophosphamide-doxorubicin hydrochloride-vincristine sulphate-etoposide-prednisone, ABVD: adriamycin-bleomycin-vinblastine-dacarbazine, SD: stable disease, CR: complete response, ND: not determined.

Summary/Conclusion: In 1 patient the MPN driver mutation was present in the CD19+ population and the LPN debuted only one year after the MPN dx. In this case, the mutation was developed in an immature cell preceding myeloid/lymphoid differentiation and could have had a role in the development of LPN. In the rest of the patients, LPN development seemed to be independent of the *JAK2/CALR* driver gene mutation. Our results show that the genetic analysis of CD34+ cells could help reveal the driver gene mutation in triple negative cases. The study of

myeloid and lymphoid separated populations gives us a better understanding of the mechanisms of concomitant MPN/LPN development.

EP1117 PULMONARY MANIFESTATIONS OF ERDHEIM-CHESTER DISEASE : CLINICAL CHARACTERISTICS, OUTCOMES AND COMPARISON WITH LANGERHANS CELL HISTIOCYTOSIS

J.-N. Wang [1,*], F.-D. Wang [2], J. Li [1], D.-B. Zhou [1], X. Tian [3], X.-X. Cao [1]

[1]Department of Hematology, [2]Department of Radiology, [3]Department of Pulmonary and Critical Care Medicine, Peking Union Medical College Hospital, Beijing, China

Background: Erdheim-Chester disease (ECD) is a rare form of non-Langerhans cell histiocytosis that typically affect many organs including lung and pleura. However, studies concerning pulmonary involvement are limited in ECD patients.
Aims: The aim of the study is to describe the clinical manifestations, radiological findings and treatment outcomes of ECD pulmonary involvement, explore its prognostic value, as well as compare the pulmonary involvement of our ECD cohort with the adult LCH patients in our center.
Methods: We performed a retrospective study of the clinical features, radiological characteristics and treatment outcomes of 54 consecutive ECD patients at Peking Union Medical College Hospital between January 2013 and October 2020. Data of adult Langerhans cell histiocytosis (LCH) patients with pulmonary involvement diagnosed from January 1990 to November 2019 in our center were also retrospectively analyzed. Clinical and radiological characteristics between these two cohorts were compared.
Results: The median age of diagnosis was 48 years (range 9-66 years) for the 54 ECD patients. 49 patients (91%) had pulmonary involvement, while 14 (25.9%) had respiratory symptoms. Chest computed tomography (CT) scans revealed lung involvement in 49 (91%) patients and pleura involvement in 34 (63%). 33 (61%) patients had interstitial lung disease (ILD) with varying degrees of interlobular septal thickening (57.4%), micronodules (55.6%), and ground-glass opacities (48.1%). Diffusion dysfunction was the most frequent pattern in pulmonary function test and the median diffusion lung capacity for carbon monoxide was 65.1% predicted (37.5-111% predicted). Patients with pulmonary involvement between ECD and LCH show significant differences in smoking status (10.3% VS 59.3%, P<0.001), respiratory symptoms (28.6% VS 57.5%, P=0.001) like cough, pneumothorax (0 VS 23.9%, P<0.001), and the radiological findings, including cysts (P<0.001), opacities (P<0.001), and pleural thickening (P<0.001). With the median follow-up duration of 24 months (range, 1–84 months), the estimated 3-year OS of this cohort were 90.2%. Patients with ILD tended to have worse PFS than those with no ILD (P = 0.29).
Summary/Conclusion: Pulmonary involvement is usually asymptomatic and therefore underestimated among ECD patients. Typical findings on CT scans include interlobular septal thickening, micronodules, ground-glass opacities, and pleural thickening. The pulmonary involvement of ECD is quite different from LCH in clinical and radiological manifestations.

EP1118 THE ROLE OF NEUTROPHIL LYMPHOCYTE RATIO AND PLATELET LYMPHOCYTE RATIO AS AN INDICATOR TO THROMBOSIS IN PHILADELPHIA NEGATIVE MYELOPROLIFERATIVE NEOPLASMS: PRELIMINARY DATA OF PROSPECTIVE COHORT

M. Abdelaziz [1,*], H. Nafady [1], S. Hussein [1], M. Thabet [2]

[1]clinical hematology unit, [2]Clinical Pathology, assiut university hospitals, Assiut, Egypt

Background: Major thrombotic events are devastating complications in the Philadelphia negative myeloproliferative diseases. The neutrophil-lymphocyte ratio (NLR) and the platelet- lymphocyte ratio (PLR) were found to be associated with the burden of thrombotic events.
Aims: Our objective is to determine the role of NLR, and PLR ratios detected at the diagnosis of the MPN diseases as an indicator to thrombosis in conjugation with the other risk factors and to illustrate the difference between the patients developed thrombosis at the diagnosis of MPN disease and patients who develop the thrombosis after the diagnosis.
Methods: The current study is a single-center observational prospective cohort (NCT03599700, Clinical Trials.gov) conducted in a university-affiliated hospital (Assiut University Hospital, Assiut, Egypt).
Subjects were enrolled if BCR-ABL negative myeloproliferative neoplasms e.g.: Polycythemia vera, Essential thrombocythemia, and Primary myelofibrosis and the age was more than 18 years.
Clinical and demographic data were collected. Laboratory assessment included complete blood count (CBC). Follow up for thrombotic events were planned for three years from the start of the study. The patients were divided to three groups according to the incidence of thrombosis either no thrombosis or thrombosis at diagnosis of the MPN or thrombosis after the diagnosis of the disease.
Results: Within 15 months of the study, we recruited 204 patients with 142 patients (69.6%) of whom showed no thrombosis and 42 patients (20.6%) of the patients affected by thrombosis at the diagnosis and 20 patients (9.8%) of the patients developed thrombosis during their follow up.
We found that thrombosis at and after diagnosis occurred in 42 patients (27%) at age <65 years while it occurred in 20 patients (40.8%) at age ≥ 65 years group (P=0.05).
PLR showed a significant difference between Patients without thrombosis group and both Patients with thrombosis at diagnosis and after diagnosis groups (P= 0.002).
NLR showed a significant difference between Patients without thrombosis group and the group of Patients with thrombosis at diagnosis and after diagnosis groups (P= 0.03).
Univariate analysis was done for the thrombosis risk factors: sex, BMI, diagnosis subclassification, presence of constitutional symptoms, JAK mutation, PLR, NLR, age ≥65 years and smoking status.
PLR, constitutional symptoms, smoking status, JAK mutation and MPN subclassification were the significant factors and incorporated into multivariate analysis.

	P -value	Odds ratio	95% CI: lower limit	95% CI: upper limit
PLR	0.032	1.002	1.001	1.004
constitutional symptoms	0.073	7.437	0.832	66.509
Smoking	0.006	3.323	1.410	7.831
JAK mutation	0.009	2.843	1.299	6.225
ET versus PMF	0.020	4.338	1.259	14.943
PRV versus PMF	0.015	3.917	1.306	11.746

Summary/Conclusion: In conclusion, PLR is a strong predictor for thrombosis in patients of MPNs while NLR appears to be higher in the group of patient suffering from thrombosis but not efficiently predict future events. This effect appears independently from other well known risk factors. JAK2 mutation, MPN sub classification and smoking are significantly associated to the burden of thrombotic risk.

EP1119 RUXOLITINIB-ASSOCIATED TUBERCULOSIS IN MYELOPROLIFERATIVE NEOPLASMS (MPN): SYSTEMATIC REVIEW AND META-ANALYSIS OF 26 CASE REPORTS

M.-A. Gaman [1,2,*], D. Coriu [1,2], I. Ursuleac [1,2]

[1]Faculty of Medicine, "Carol Davila" University of Medicine and Pharmacy, 8 Eroii Sanitari Boulevard, Bucharest 050474, [2]Hematology, Center of Hematology and Bone Marrow Transplantation, Fundeni Clinical Institute, 258 Fundeni Road, Bucharest 022328, Romania, Bucharest, Romania

Background: Despite significant benefits of ruxolitinib (RUX) in MPN management, e.g. primary (PMF) or secondary myelofibrosis and polycythemia vera (PV), the reports of opportunistic infections occurring during RUX treatment, particularly pulmonary (PTB) or disseminated tuberculosis (DTB), are increasing worldwide.

Aims: To identify PTB/DTB cases in RUX-treated MPN and report on epidemiology, clinical manifestations, RUX associations, outcomes.
Methods: Systematic search computed in PubMed/Medline, Web of Science, ScienceDirect, SCOPUS, from the inception of these databases until 15.11.2020. Relevant English-written articles were identified based on the Eligibility criteria: 1. Confirmed MPN diagnosis, 2. Confirmed diagnosis of PTB/DTB caused by *Mycobacterium tuberculosis*, 3. MPN managed with RUX. Exclusion criteria: reports of other mycobacteria apart from *M. tuberculosis*, RUX used in other disorders, *in vitro studies*, animal studies. The initial search identified 156 publications, of which 22 were selected based on title/abstract screening. Following full-text review, 20 publications depicting 26 distinct case reports were included in the systematic review and meta-analysis.
Results: 26 case reports were identified: 69.2% females, mean age 65.6 years, 80.8% PMF. JAK2V617F mutation was detected in 65.4% of cases. RUX mean dose was 35 mg/day (40.74% received 40 mg/day) and the average time from RUX initiation to TB diagnosis was 7 months. TB screening was performed only in 19.2% of subjects. DTB was more frequent *versus* PTB (65.4% versus 34.6%). PTB and DTP were observed primarily in PMF (80.8%) and less frequently in post-PV-MF (7.7%) or PV (3.85%). The most common presentations were fever (80.7%), peripheral lymphadenopathy (38.5%), night sweats (23.1%), fatigue/tiredness (19.2%), weight loss (15.4%), cough (11.54%) and shortness of breath (7.7%). All patients received 6, 9 or 12 months of antitubercular treatment (ATT), i.e. HRZE (isoniazid + rifampicin + pyrazinamide + ethambutol) or variants. RUX was discontinued in 69.2% of cases and maintained in 11.5% of cases in combination with ATT. RUX re-initiation was decided in 23.1% of patients. TB-related death occurred in 23.1% of the subjects involved. Most case reports did not report on follow-up visits, thus assessing TB resolution or relapse is difficult to pursue. The attached table details the case reports of RUX-associated TB included in our analysis (+ = Yes; – = No;? = Unknown/Unspecified/Unavailable; P-pulmonary, D-disseminated TB).

	Ref./Year	Age	Sex	PMF	JAK2 V617F	RUX dose mg/d	Δt [months]	TB	ATT, ΔATT [months]	RUX discontinuation	TB resolution	RUX reintroduction	TB relapse	Outcome

22	Feng/2020	66	M	+	+	40	2	D	12 HR, levofloxacin, cefuroxime, moxifloxacin	–	?	Not discontinued	?	Alive
23	Repelaer/2018	52	F	+	?	40	8	D	6 HRZE	+	+	+	?	Alive
24	Sakiyama/2020	76	M	PV	+	20	6	D	6 HRZE	+	+	–	–	Alive
25	Shamil/2015	78	F	+	?	?	?	D	12 HRZE	+	+	?	?	Alive
26	Tsukamoto/2020	73	M	+	+	40	6	D	HRZE	+	+	–	–	Alive

Summary/Conclusion: Opportunistic infections, including PTB/DTB, can develop during RUX treatment due to its immunosuppressive effects. Screening for TB is advised prior to RUX prescription by skin tests, IFN-γ releasing assays and (or) chest X-rays. Prophylaxis can be considered in TB-endemic areas.

EP1120 VARIABLES ASSOCIATED WITH PATIENT-REPORTED OUTCOMES IN PATIENTS WITH MYELOPROLIFERATIVE NEOPLASMS

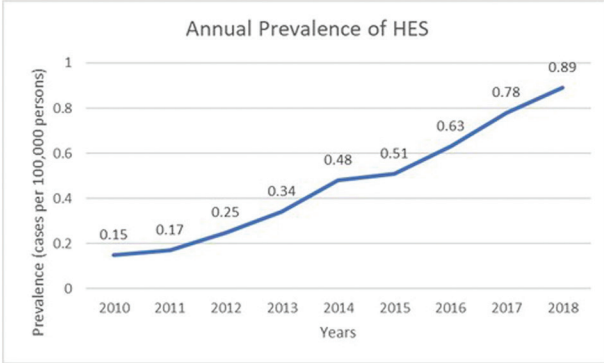
Background: The Philadelphia chromosome–negative myeloproliferative neoplasms (MPNs), including essential thrombocythemia (ET), polycythemia vera (PV), and myelofibrosis (MF), are characterized by clonal proliferation of myeloid–derived hematopoietic stem cells. Patient-reported outcomes (PROs) are an assessment of health outcomes including symptom status, physical function, mental health, social function, and well-being from the patients' perspective. Besides the life-threatening complications, patients with MPN also suffer from substantial symptom burden, which has aroused great attention in recent years. PROs other than symptom burden such as the impact on work productivity and daily living, satisfaction level with therapy, and health-related quality of life (HRQoL) were also studied in patients with MPN. However, there were limited data of PROs and their associated variables in MPN patients in the developing countries, as most of the published data were from western developed countries, and variables associated with PROs were not fully explored in those studies using multivariate analyses. With different socio-demographic status, financial status, health insurance policy, humanistic philosophy, and treatment pattern, MPN patients in the developing countries might have distinct PROs and different variables associated with them.
Aims: To explore PROs including symptom burden, impact on daily life and work, obstacles during therapy, satisfaction level with therapy, and HRQoL in patients with MPN in China, a representative of developing countries, and to identify variables associated with those PROs.
Methods: A multi-center, cross-sectional study was conducted in patients with MPN across China.
Results: Data from 1,500 respondents including ET (n = 707), PV (n = 316) and MF (n = 477) were analyzed. In multivariate analyses, *CALR* mutation [HR =0.4 (0.2-0.9); $P = 0.020$] was significantly-associated with lower MPN-10 scores in respondents with MF. Higher MPN-10 scores were significantly-associated with negative impact on daily life and work as well as lower satisfaction level in those with ET [HR = 3.9 (2.3-6.5); $P < 0.001$ and HR = 2.1 (1.2-3.9); $P = 0.016$], PV [HR = 3.2 (1.6-6.5); $P = 0.001$ and HR = 3.5 (1.4-8.5); $P = 0.007$] and MF [HR = 2.4 (1.4-4.2); $P = 0.002$ and HR = 3.9 (2.1-7.5); $P < 0.001$]. Receiving ruxolitinib was significantly-associated with high satisfaction and satisfaction in respondents with MF [HR = 0.09 (0.03-0.3); $P < 0.001$]. In addition, demographics and clinical variables including age, gender, household registration, marital status, education level, comorbidity burden, concomitant medication, splenomegaly, complete blood count and annual *out-of-pocket* costs were also impacting PROs.
Summary/Conclusion: Socio-demographic and clinical variables were significantly-associated with PROs in respondents with MPNs.

EP1121 USE OF RUXOLITINIB IN ELDERLY PATIENTS WITH PRIMARY MYELOFIBROSIS

S. Duarte [1,*], R. Gomes [1], C. Afonso [1], B. Marques [1], A. Roque [1,2], J. P. Carda [1,2], A. Crisóstomo [1]

[1]Clinical Hematology Department, University Hospital Center of Coimbra, [2]Faculty of Medicine, University of Coimbra, Coimbra, Portugal



Background: Ruxolitinib (Rx) is a Janus kinase (JAK) 1/JAK2 inhibitor with established efficacy in improving primary myelofibrosis (PMF)-related symptoms and survival. However, while aging is known to correlate with worse prognosis in PMF, real-life studies become essential to demonstrate the efficacy and safety of Rx in older populations.
Aims: To compare survival of elderly patients treated (Rx-t) *versus* non-treated (Rx-nt) with Rx.
Methods: Retrospective and unicentric analysis of records from elderly patients (age ≥65 years) diagnosed with PMF (WHO 2016) between January 2010 and December 2019.The Cox regression model and Kaplan-Meier method were used for the analysis of progression free survival (PFS) and overall survival (OS).
Results: We analysed a cohort of 70 patients, 70% males and with a median age of 74 years old (range, 65-92 years old). Thirteen patients (16.6%) had post-polycythemia vera (PV)/post-essential thrombocythemia (TE) MF. *JAK2V617F* mutation was identified in 71,4% of the patients, while 7,1% and 14.3% harboured a mutation in the *MPL* and *CALR* genes, respectively. Five patients (7.1%) were triple negative for those mutations.
About 87% of the patients required treatment in the course of the disease, 20% with ≥2 lines of therapy. Seventeen-percent were Rx-t. Rx-t patients were younger (69 *versus* 75 years old; p=0,011) and showed a higher incidence of MF post-PV/TE (50 *versus* 12%, p=0,002), compared to Rx-nt. The frequency of *JAK2V617F* mutation was equivalent in both groups (83 *versus* 69%; p=NS), however, the allele burden was higher in Rx-t patients (VAF 73 *versus* 33%; p=0,029). All Rx-t patients were at overt fibrotic stage (p=0,006). Blood tests at diagnosis demonstrated that the majority of the Rx-t presented with anaemia (Hb<12g/dL; p=0,034), however no significant differences were observed in leucocyte counts, LDH, circulating blasts or constitutional symptoms (CS), compared to Rx-nt. With no surprise, most patients selected for treatment with Rx presented with splenomegaly (92 *versus* 50%; p=0,008). There was no significant difference in the distribution through International Prognostic Scoring System (IPSS), dynamic IPSS (DIPSS) or DIPSS-*plus,* between Rx-t *versus* Rx-nt patients. PFS and OS in our cohort was estimated in 62,7 and 101,8 months, respectively.
In the univariate analysis, the variables age, anaemia, CS, circulating blasts, splenomegaly, IPSS and DIPSS intermediate-2/high-risk, were significantly associated with PFS; the same variables in addition to fibrosis grade ≥2, were related to OS. After Cox multivariate analysis and after adjusting for variables with impact on PFS and OS in the univariate analysis, we found that treatment with Rx improves PFS (HR 0,28, p=NS, IC95% 0,05-1,52) and OS (HR 0,05, p=0,009; IC95% 0,01-0,48).
Summary/Conclusion: In our cohort, Rx showed to have an independent beneficial impact in mortality of elderly patients with PMF, including patients with high risk IPSS and DIPSS score, therefore demonstrating that advanced age does not stand as a limitation for treatment with Rx.

EP1122 THE INCREASING INCIDENCE AND PREVALENCE OF HYPEREOSINOPHILIC SYNDROME (HES) IN THE UK

G. Requena 1,*, J. Logie 2, D. Gibbons 3, J. Steinfeld 4, M. Van Dyke 5

[1]Epidemiology, Value Evidence and Outcomes, Global R&D, GSK, Brentford, [2]Value Evidence and Outcomes Data, Methods and Analytics, Global Medical, GSK, London, [3]Value Evidence and Outcomes Data, Methods and Analytics, Global Medical, GSK, Uxbridge, United Kingdom, [4]Respiratory Research & Development, [5]Epidemiology, Value Evidence and Outcomes, Global R&D, GSK, Collegeville, United States

Background: Hypereosinophilic syndrome (HES) is a group of rare hematologic disorders of unknown etiology defined by sustained eosinophilia associated with organ damage. The burden of this rare condition is not yet well characterized. Reliable estimates of the incidence and/or prevalence of the disease are not readily available, since most publications are case reports without clear details of the population from which they are drawn.
Aims: To explore the incidence and prevalence of HES using UK real-world primary care data.
Methods: Primary care data from the UK Clinical Practice Research Datalink (CPRD) GOLD and Aurum databases, were analyzed. Patients of interest were identified using medical codes specific for HES and for chronic eosinophilic leukemia not otherwise specified (CEL-NOS) as a subtype. Annual incidence rates and prevalence were estimated for the years 2010 to 2018 (inclusive) based on the assumption that patients with diagnosed HES would be identified if they were followed for at least 365 days within CPRD. For calculations of incidence, patients with no records of HES within the first 365 days of observation were considered disease-free and hence "at risk" of developing HES in the future. For calculations of prevalence, HES patients were identified from the population of patients who were continually registered for the full calendar year of interest; their HES diagnosis could occur either during or at any time before the calendar year of interest. The impact of this assumption was tested in additional sensitivity analyses applying a minimum observation period of 730 days (two years) or 1035 days (three years) to identify existing prevalent cases.
Results: During the study period, 93 patients were identified with a first diagnosis of HES, 57% were male, with a mean (SD) age of 57.0 (19.3) years. Of these, 12 patients had a diagnosis of CEL-NOS; they were slightly older (average age of 67 years) and predominantly male (92%). From 2010 to 2018, the overall annual incidence rate of patients diagnosed with HES ranged from <0.04 to 0.17 per 100,000 person-years and the overall annual prevalence ranged from 0.15 to 0.89 cases per 100,000 persons (Figure 1). Sensitivity analyses based on minimum observation periods of two and three years gave similar results.

Summary/Conclusion: These results provide estimates of the burden of HES in the UK and indicate that whilst HES is a very rare disease, there is evidence that it is increasingly being recorded in UK primary care. We discuss potential explanations for the patterns seen.

EP1123 INTERLEUKIN-6 AND ITS RELATION TO CLINICAL AND LABORATORY CHARACTERISTICS OF PATIENTS WITH MYELOFIBROSIS

S. Dimitrova [1,2,*], I. Micheva [1,2]

[1]Clinic of Hematology, UMHAT Sveta Marina Varna, [2]Medical University, Varna, Bulgaria

Background: Myelofibrosis (MF) is a myeloproliferative disease, characterized by a heterogeneous clinical picture due to bone marrow fibrosis, ineffective extramedullary hematopoiesis and excessive splenomegaly. The pathogenesis of MF is multifactorial, determined by genetic profile of the patient, bone marrow microenvironment, response to inflammatory (cytokine) stimuli and age. Inflammatory cytokines are key mediators in the pathological relation between tumor microenvironment and the clonal hematopoiesis in MF. Interleukin-6 (IL-6) is a multifunctional, pleotropic, pro-inflammatory cytokine that is released by immune-competent cells as a result of infection and/or challenge to the immune system. It's a key participator in the tumor genesis of oncological and hematological neoplasms. IL-6 is involved in a number of pathophysiological mechanisms in MF development and is of major importance for the clinical manifestation, prognosis and progression of the disease.

Aims: The aim of the study is to analyze serum IL-6 levels in patients with MF and its relation to clinical and laboratory characteristics of patients.
Methods: We analyze 68 patients with MF (overt MF -27 patients, prefibrotic MF – 25 patients, post-polycythemia vera (post-PV) MF -9 patients and post-essential thrombocytemia (ET) MF- 7 patients) and 12 healthy controls. The mean age of the patients' group is 67,7 years; male: female ratio - 1,7:1. According to the Dynamic International Prognostic Scoring System (DIPSS) 6 patients are high risk; 35 patients are intermediate 2 risk; 22 patients are intermediate 1 risk and 5 patients are low risk. According to the number of transfusions that patients receive per month: 40 patients are transfusion-independent and patients, receiving an average of 1 blood unit/month (BU/m) are 5; 2 BUs/m – 7 patients; 3 BUs/m – 4 patients; 4 BUs/m - 7 patients; 5 BUs/m - 4 patients and > 6 BUs/m- 1 patient. Regarding treatment 26 patients are on best supportive therapy (BST); 26 patients are treated with cytoreductive treatment (Hydroxyurea-23 patients; Interferon α -3 patients) and 16 patients are treated with target therapy (Ruxolitinib). Degree of fibrosis in the bone marrow (grade 0-3), carrier of Jak2 V617F mutation, spleen size by ultrasound examination and peripheral blood count parameters (hemoglobin, leukocytes, platelets, MCV) are analyzed in all patients. We measure serum IL-6 levels by ELISA in all patients and healthy controls according to the manufacturer's operating instructions. Statistical analysis is performed with SPSS version 20.
Results: Levels of IL-6 are significantly higher in patients with MF compared to healthy controls (26.96 ± 46.73 pg/ml; -0.03 ± 1.68pg/ml; t = 1.99; p = 0.05). A significant difference is found between healthy controls, patients with overt MF (p = 0.036) and patients with post-PV MF (p = 0.028). IL-6 levels are significantly higher in patients with grade 3 fibrosis in comparison to the other grades (60.4 ± 77.3 pg /ml; p = 0.025). There is a strong significant correlation between IL-6 and the number of blood transfusions per month (r = 0.488; p <0.001). No correlation is found with hemoglobin, leukocyte count, MCV, spleen size, Jak2 mutation, DIPSS, symptomatic disease and treatment.
Summary/Conclusion: IL-6 is a key mediator in the pathogenesis and clinical evolution of MF. Its involvement in the establishment of a cytokine risk model of MF, makes it a potential target for therapeutic response, control and monitoring of the disease.

Platelets disorders

EP1124 THROMBOPOIETIN RECEPTOR AGONISTS (TPO-RA) INCREASE T REGULATORY AND T HELPER CELLS IN SPLEENS OF PRIMARY IMMUNE THROMBOCYTOPENIA

M. Pizzi [1,*], E. Sabattini [2], G. Binotto [1], F. D'amore [1], G. Carli [3], B. Famengo [4], N. Vianelli [5], G. Auteri [6], M. Sbaraglia [1], I. Nichele [3], J. Ceccato [1], E. S. G. D'amore [4], L. Trentin [1], A. P. Dei Tos [1], F. Vianello [1]

[1]Medicine, University of Padova, Padova, [2]Hemolynphopathology, Ospedale Policlinico S. Orsola - Malpighi, Bologna, [3]Hematology, [4]Anatomy and Istopathology, Ospedale San Bortolo, Vicenza, [5]Hematology, Ospedale Policlinico S. Orsola - Malpighi, [6]Diagnostic and Experimental Medicine, University of Bologna, Bologna, Italy

Background: Primary Immune Thrombocytopenia (ITP) is an autoimmune disorder, characterized by low platelets counts due to immune-mediated platelet destruction. The spleen plays a central role in the pathogenesis of ITP, as it is the main site of anti-platelet immune responses and platelet destruction. Thrombopoietin receptor agonists (TPO-RA) are a valid second-line therapy for ITP, being associated with increased platelet production and immune modulatory effects. Such immunological mechanisms are poorly characterized and nothing is known on the splenic effects of TPO-RA administration.
Aims: This study aimed at assessing: (i) the immunological effects of TPO-RA on ITP spleens; and (ii) the effects of TPO-RA administration on splenectomy outcome.
Methods: A clinically annotated series of 35 ITP spleens removed from therapeutic purposes was histologically assessed for the following parameters: (i) white pulp features (lymphoid follicle density and marginal zone width); (iii) subset of CD207/PD1 positive T-cells(which include T follicular helper (Tfh) cells; (iv) cytotoxic T cell density (as assessed by CD8 immunostain); (v) Th1 cell density (as assessed by tBet immunostain); (vi) Th2 cell density (as assessed by GATA3 immunostain); (vii) Treg cell density (as assessed by FOXP3 immunostain). Ten non-ITP spleens were used as controls. ITP patients were stratified into responders and non-responders to splenectomy, based on IWG consensus criteria. Statistical analysis was performed by non-parametric tests for quantitative (Mann-Whitney-Wilcoxon test) and qualitative (Fisher's exact test). Kaplan-Meyer and log rank methods were used for survival analyses. Differences between groups were considered statistically significant for *p*-values <0.05.
Results: The study population included 12/35 (34.3%) males and 23/35 (65.7%) females (M:F ratio: 0.5) with mean age at splenectomy of 41.0 years (range: 16.8 – 68.2 years). TPO-RAs were administered in 13/35 (37.1%) cases. The spleens of TPO-RA treated patients had higher Treg, Th1 and Th2 densities compared to TPO-RA untreated patients (Treg density: 73.7 cells/HPF *vs* 49.4 cells; Th1 density: 79.8 cells/HPF *vs* 49.8 cells/HPF; Th2 density: 281.6 cells/HPF *vs* 185.9 cells/HPF; p< 0.05; Figure 1A). No other differences were noted between TPO-RA treated and untreated cases. Splenic Treg, Th1 and Th2 densities of TPO-RA treated ITP were similar to those of non-ITP controls (p> 0.05). In ITP patients, the outcome of splenectomy was not influenced by prior TPO-RA treatment and/or splenic T cell patterns (Figure 1B).

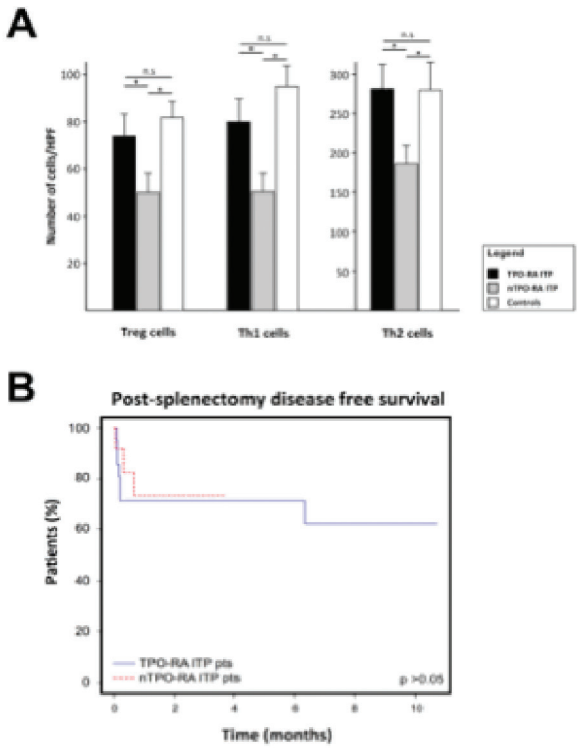

Figure 1. Effects of TPO-RA on ITP spleens.
A. TPO-RA treatment is associated with higher Treg, Th1 and Th2 cell density in ITP spleens. T cell density values are comparable with those of control spleens.
B. Disease free survival following splenectomy was not influenced by prior TPO-RA therapy (TPO-RA ITP pts= patients treated with TPO-RA; nTPO-RA ITP pts= patients not treated with

Summary/Conclusion: Treatment with TPO-RAs in ITP is associated with increased splenic Treg, Th1 and Th2 cells, at values comparable to those of healthy controls. TPO-RA does not influence the outcome of splenectomy in primary ITP.

EP1125 OFF-LABEL USE OF ELTROMBOPAG IN ADULT PATIENTS WITH IMMUNE THROMBOCYTOPENIA BEFORE SIX MONTHS OF DISEASE DURATION IN THE REAL-WORLD IN FRANCE. RESULTS OF THE ELEXTRA STUDY.

G. Moulis [1,2,*], J. Germain [2], M. Rueter [2], M. Lafaurie [2,3], T. Comont [4], M. Mahévas [5], J.-F. Viallard [6], M. Ebbo [7], S. Audia [8], S. Chèze [9], A. Sommet [2], O. Beyne-Rauzy [4], B. Godeau [5], M. Lapeyre-Mestre [2]

[1]Internal Medicine, [2]Clinical Investigation Center, [3]Clinical Pharmacology, Toulouse University Hospital, [4]Internal Medicine, Toulouse Oncopole, Toulouse, [5]Internal Medicine, Henri Mondor University Hospital, Créteil, [6]Internal Medicine, Bordeaux University Hospital, Bordeaux, [7]Internal Medicine, Marseille Universtiy Hospital, Marseille, [8]Internal Medicine, Dijon University Hospital, Dijon, [9]Hematology, Caen University Hospital, Caen, France

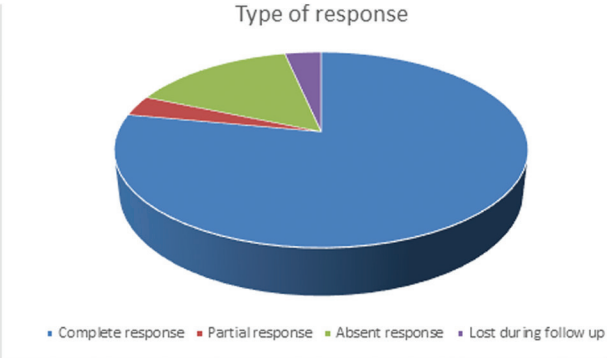
Background: Eltrombopag, a thrombopoietin receptor agonist (TPO-RA), has been available in Europe for the treatment of chronic primary immune thrombocytopenia (ITP) since 2010. Since 2019, it has been indicated in patients with primary ITP, lasting 6 months or longer from diagnosis and who are refractory to other treatments, aged 1 year and above. However, French ITP management guidelines published in 2017, as well as international guidelines updated in 2019 consider the use of second-line treatments earlier in the disease course, including TPO-RAs.
Aims: The ELEXTRA study has been designed to assess the use, the efficacy and the safety of eltrombopag in adult patients with ITP in the real world in France. The present study focused on patients treated with eltrombopag off label before 6 months of ITP duration.
Methods: The source of study population was the multicenter CARMEN-France registry, aimed at the prospective follow-up of adults with incident ITP in France. Patients included in the registry between 2013 and 2019 who were exposed to eltrombopag during the first 6 months of ITP course were selected. Efficacy was assessed in patients who had a platelet count <30 x 10^9/L at eltrombopag initiation. Overall and complete responses were defined by platelet counts ≥30 x 10^9/L and ≥100 x 10^9/L, respectively. Adverse drug reactions (ADRs) with a World Health Organization causality score at least as *"possible"* were described.
Results: Out of 799 patients included in the registry, 156 (19.5%) had been exposed to eltrombopag. Among them, 95 (60.9%) were treated off-label with eltrombopag during the first 6 months of ITP duration. Mean age was 60.5 years; 50 (52.6%) were men; 33 (34.7%) had at least one comorbidity of the Charlson Comorbidity Index; 56 (58.9%) had at least one cardiovascular risk factor (not including age and sex). At ITP diagnosis, the median platelet count was 7 x 10^9/L and 76 (80.0%) patients had bleeding. Median time from ITP onset to eltrombopag exposure was 1.6 months: 74 (77.9%) patients were exposed before 3 months and 21 (22.1%) between 3 and 6 months. Treatments before eltrombopag were: corticosteroids in 91 (95.8%) patients, intravenous immunoglobulin (IVIg) in 66 (69.5%), dapsone in 11 (11.6%), hydroxychloroquine in 6 (6.3%), rituximab in 5 (5.3%), romiplostim in 5 (5.3%), vinblastine in 5 (5.3%), danazol in 2 (2.1%); no patient was splenectomized. Eltrombopag was used as second-line and third-line agent in 41 (43.2%) and 32 (33.7%) patients, respectively. Among the 95 patients, 48 had a platelet count <30 x 10^9/L at eltrombopag initiation; among them, 39 (81.3%) achieved overall response and 35 (79.2%) complete response. Among the 39 patients who achieved overall response, 25 (64.1%) had a concomitant exposure to another ITP treatment at eltrombopag initiation (including steroids, IVIg in the past month or rituximab in the past 6 months). At last follow-up, 57 had stopped eltrombopag, including 17 for absence or loss of response, 15 for ADR and 9 for sustained complete response. Overall, 17 ADRs were reported in 16 (16.8%) patients: thrombocytosis (n=5), venous thrombosis (n=6: 4 pulmonary embolism, 1 deep vein thrombosis, 1 soleal vein thrombosis), rash (n=3), hepatitis, gastrointestinal discomfort, and diarrhea (n=1 each).
Summary/Conclusion: Eltrombopag was mostly used off-label before 6 months of ITP duration in the French real-world practice. Efficacy was similar to that observed in ITP lasting >6 months. The pattern of ADRs was in accordance with previous reports.

EP1126 EFFECTIVENESS OF ROMIPLOSTIM ON PLATELET ENDPOINTS AMONG PATIENTS WITH NEWLY DIAGNOSED, PERSISTENT AND CHRONIC IMMUNE THROMBOCYTOPENIA IN ROUTINE CLINICAL PRACTICE IN DENMARK, SWEDEN, AND NORWAY

C. F. Christiansen [1,*], N. Risbo [1], W. Ghanima [2,3], M. Linder [4], S. Bahmanyar [4], A. Seesaghur [5], M. Clouser [6], M. Nørgaard [1], H. T. Sørensen [1]

[1]Department of Clinical Epidemiology, Aarhus University Hospital, Aarhus N, Denmark, [2]Department of Medicine, Østfold Hospital Trust, Grålum, [3]Department of Hematology, Institute of Clinical Medicine, University of Oslo, Oslo, Norway, [4]Clinical Epidemiology Division & Centre for Pharmacoepidemiology, Department of Medicine, Karolinska Institutet, Stockholm, Sweden, [5]Center for Observational Research, Amgen, Uxbridge, United Kingdom, [6]Center for Observational Research, Amgen, Thousand Oaks, United States

Background: Romiplostim is approved for the treatment of chronic immune thrombocytopenia (ITP for ≥12 months) in adults who are refractory to other treatments such as steroids and intravenous immunoglobulin. In 2021, the romiplostim indication was expanded to also cover adult patients with ITP for <12 months duration.
Aims: To examine baseline characteristics, dosage, and platelet endpoints after initiation of romiplostim in newly diagnosed (ITP duration <3 months), persistent (ITP duration 3-12 months) and chronic (ITP duration >12 months) ITP patients treated in routine clinical practice in Denmark, Sweden and Norway.
Methods: From the population-based Nordic Country Patient Registry for Romiplostim, we included all adult (≥18 years) romiplostim-exposed patients with ITP for at least 6 months between 1 April 2009 and 31 December 2018. We disaggregated the cohort according to time from ITP diagnosis to romiplostim initiation into newly diagnosed, persistent, and chronic ITP. For each exposure group, we described patient characteristics at romiplostim initiation, romiplostim dosage, duration of romiplostim treatment, platelet count during and after romiplostim treatment, and durable platelet response (defined as ≥75% of all recorded platelet count measurements ≥50 x 10^9/L during weeks 14 through 24 after date of first romiplostim administration).
Results: Among the 262 patients initiating romiplostim, 77 had newly diagnosed, 41 had persistent, and 144 had chronic ITP. The proportions aged 70+ years were 26%, 42% and 29% in the three groups, and 13%, 15%, and 16% had Charlson Comorbidity Index Score ≥3, respectively. The three groups had similar proportions of patients with a platelet count <50x10^9/L within 90 days before romiplostim initiation (91%, 88%, and 90%, respectively). The proportions of patients with <2 recorded ITP medication within 6 months prior to romiplostim were 33%, 37%, and 43% in the three groups, respectively. The median of first romiplostim doses were also similar (1.1, 1.1, 1.1 µg/kg, respectively), while there were slight differences in last maintenance romiplostim doses (3.6, 2.5, 2.9 µg/kg, respectively). The median [quartile (Q) Q1,Q3] duration of romiplostim exposure was 19 [3,59], 17 [7,59], and 35 [8,125] weeks, respectively.
The median [Q1, Q3] time to first recorded platelet count ≥50x10^9/L within 2 to 24 weeks after romiplostim initiation was 24 [19,34] days for newly diagnosed ITP and 21 [19,34] days for persistent or chronic ITP. The median [Q1,Q3] platelet count (x10^9/L) during romiplostim treatment was 71 [23,154] in newly diagnosed, 75 [41,133] in persistent, and 76 [33,153] in chronic ITP. The median [Q1, Q3] of the last platelet count within 31-100 days after discontinuing romiplostim among 47, 16, and 51 in patients not receiving any ITP treatment in the period was 171 [107,297], 120 [59,259], and 120 [47,249), respectively. Durable platelet response was achieved in 66%, 53%, and 54% of patients with newly diagnosed, persistent, and chronic ITP, respectively.
Summary/Conclusion: Baseline characteristics and platelet-based outcomes were comparable among newly diagnosed, persistent, and chronic ITP groups treated with romiplostim in routine clinical care of patients with at least six months history of ITP. This suggests that initiation of romiplostim is not guided by ITP duration but rather by patient and disease characteristics.



EP1127 OFF-LABEL USE OF ELTROMBOPAG IN A PEDIATRIC POPULATION WITH NEWLY-DIAGNOSED/PERSISTENT IMMUNE THROMBOCYTOPENIC PURPURA

V. Clemente [1], G. Ceglie [2,*], F. de Gennaro [3], C. Mascolo [3], G. Nocentini [3], J. Pianese [2], G. Palumbo [2]

[1]University Department of Pediatrics, Bambino Gesù Children's Hospital, University of Rome Tor Vergata, Rome, Italy, Tor Vergata, Roma, [2]Department of Pediatric Hematology and Oncology, Cell and Gene Therapy, IRCCS Bambino Gesù Children's Hospital, [3]University Department of Pediatrics, Bambino Gesù Children's Hospital, University of Rome Tor Vergata, Rome, Italy

Background: Immune Thrombocytopenic Purpura (ITP) is an immune mediated disorder characterized by an isolated decrease of the platelet count. Symptoms are usually mild, with cutaneous and/or mucosal bleeding, rarely serious symptoms occur, such as intracranial hemorrhage. ITP is classified into 3 groups: newly diagnosed (within 3 months from the onset), persistent (3 to 12 months from the onset), chronic (after 12 months from the onset). Infusion of immunoglobulin or steroid therapy are the first line of treatment. Current guidelines suggest the use of thrombopoietin receptor agonists (TPO-RAs), such as Eltrombopag (EPAG), in patients with persistent thrombocytopenia. They stimulate thrombopoiesis through the activation of the thrombopoietin receptors, furthermore TPO-RAs can influence platelet antibody production and T regulatory cell count. EPAG is an effective and safe therapy, although its

use is currently approved in patients with ITP after at least 6 months from the diagnosis. Some studies, in the adult setting, have already described the safety and efficacy of EPAG in patients before the 6th month from the onset (off label use).Currently there are no studies on the use of EPAG in the same setting in a cohort of pediatric patients with ITP.
Aims: Evaluate the safety and efficacy of the use of EPAG within 6 months from the onset on a cohort of pediatric patients with ITP.
Methods: *Study population:* 59 patients aged between 1 and 18 years were enrolled from February 2013 and December 2020.
Response evaluation: We evaluated the type of response based on the platelet count: complete if the platelet count was at least > 100.000 in one determination, partial if the platelet count was at least once between 30.000 and 100.000, absent if the platelet count never overcame 30.000. We also defined the persistent response as a platelet count constantly over 30.000, in the absence of symptoms nor rescue therapies over a follow-up of at least 1 year.
Results: We enrolled 59 patients, 39 with newly diagnosed ITP and 20 with persistent ITP. 46 patients had a complete response (80,7%), 2 patients (3,5%) had a partial response, 9 patients did not respond to EPAG. 2 patients were lost at follow-up. 39 of the 49 patients who responded to the treatment with EPAG had a follow-up longer than 1 year, allowing the evaluation of the persistence of the response. 29 patients (74,4%) had a persistent response, with no differences between the group with newly diagnosed ITP and persistent ITP. 14 patients (23,7%) had at least one adverse event. 3 patients presented with significant thrombocytosis (over 1.000.000) that promptly resolved after a temporary, brief suspension of the treatment. Other adverse events were hypertransaminasemia, nausea, hypoferritinemia with or without anemia. In one patient who had grade 3 hypertransaminasemia and acydosis EPAG was suspended.

Summary/Conclusion: This study is, to the best of our knowledge, the first reporting on the use of EPAG in a pediatric population with newly diagnosed or persistent (3-6 months) ITP. Our data highlight the efficacy of this therapy and its safety, with only a small proportion of patients reporting reversible adverse events. Therefore, given the difficulties to treat patients who do not respond to the first line therapy or who have an early relapse, EPAG could be an option.
We believe further studies are needed to explore the use of EPAG in these contexts.

EP1129 CLINICAL-PATHOLOGICAL PREDICTORS OF SPLENECTOMY RESPONSE IN PRIMARY IMMUNE THROMBOCYTOPENIA: A MULTI-CENTER ITALIAN STUDY.

M. Pizzi [1,*], G. Binotto [1], F. D'amore [1], I. Bertozzi [1], S. Zoletto [1], G. Carli [2], B. Famengo [3], N. Vianelli [4], M. Sbaraglia [1], I. Nichele [2], E. Sabattini [5], G. Auteri [6], J. Ceccato [1], E. S. G. D'amore [3], L. Trentin [1], A. P. Dei Tos [1], F. Vianello [1]

[1]Medicine, University of Padova, Padova, [2]Hematology, [3]Anatomy and Istopathology, Ospedale San Bortolo, Vicenza, [4]Hematology, [5]Hemolynphopathology, Ospedale Policlinico S. Orsola - Malpighi, [6]Diagnostic and Experimental Medicine, University of Bologna, Bologna, Italy

Background: Splenectomy is a valuable second-line therapy for primary Immune Thrombocytopenia (ITP), with response rates exceeding 60% of cases. It is nonetheless an invasive procedure with potentially severe side effects (thrombotic events, major bleeding and life-threatening infections). At present, there are no validated predictors of splenectomy response in ITP. Their identification may nonetheless help identify ITP patients with the highest chances of benefitting from this procedure.
Aims: This study was aimed at identifying possible clinical-pathological predictors of splenectomy outcome in primary adult ITP.
Methods: A discovery set of 27 clinically-annotated ITP spleens from Padua University Hospital (Padua – Italy) was histologically assessed for the following parameters: (i) density of lymphoid follicles; (ii) width of peri-follicular marginal zones; (iii) density of T regulatory, Th1, Th2, cytotoxic T cells and Cd207/PD1-positive T-cells (which include T follicular helper cells; (iv) width of perivascular T cell sheaths; and (v) red pulp features (plasma cell, histiocyte and sinusoid density). Splenectomized ITP patients were stratified into responder and non-responder subgroups based on IWG consensus criteria and clinical-pathological data were matched to identify possible predictors of surgical outcome. The obtained results were validated in an additional set of 31 ITP patients from Sant'Orsola University Hospital (Bologna – Italy) and San Bortolo Hospital (Vicenza - Italy). Statistical analysis was performed by non-parametric tests for quantitative (Mann-Whitney-Wilcoxon test) and qualitative (Fisher's exact test) variables. Kaplan-Meyer and log rank methods were used for survival analyses. Differences between groups were considered statistically significant for *p*-values <0.05.
Results: The discovery set consisted of 9/27 (33.3%) males and 18/27 (66.7%) females with mean age at surgery of 36 years (range: 18-67 years). Histological evaluation of ITP spleens documented heterogeneous morphology, spanning from white pulp hyperplasia to marked lymphoid atrophy. No single clinical-pathological parameter predicted splenectomy outcome. However, the combination of multiple variables (*i.e.* age at surgery >45 years; concurrent autoimmune diseases and/or high ANA counts; low splenic Cd207/PD1-positive T-cell density (which include T follicular helper cells); low splenic marginal zone width) efficiently stratified patients into splenectomy response groups. Indeed, the occurrence of ≥2 clinical-pathological (left upper panel) or ≥1 clinical risk factors (left lower panel) was associated with significantly worse splenectomy outcome (p <0.05;). These results were confirmed in a validation set of 31 ITP cases, which included 14/31 (45.2) males and 17/31 (54.8%) females with mean age at surgery 33 years (range: 19-69 years) (Right panels). Splenectomy response did not correlate with prior medical therapies.

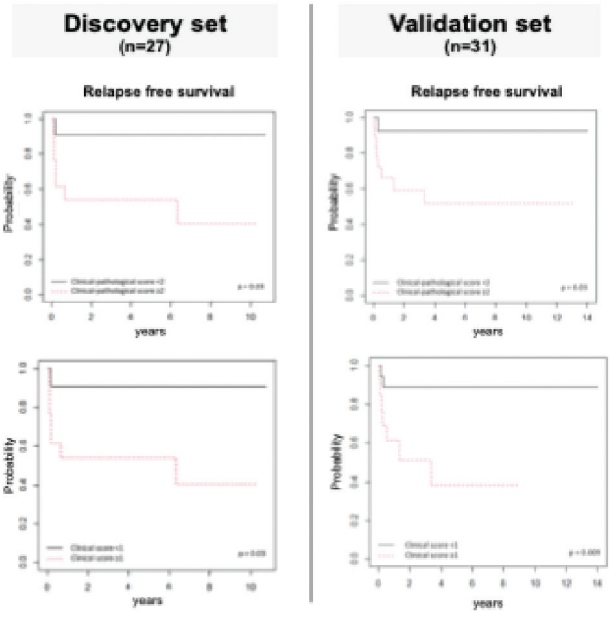


Figure 1. Disease free survival curves of the discovery set and validation set.
The curves stratifying patients according to clinical-pathological risk factors (*upper panels*) included the following variables: (i) age at surgery >45 years; (ii) concurrent autoimmune diseases and/or high ANA counts; (iii) low splenic T follicular help cell density; (iv) low splenic marginal zone width. The curves stratifying patients based on clinical risk factors only (*lower panels*) included: (i) age at surgery >45 years; (ii) concurrent autoimmune diseases and/or high ANA counts.

Summary/Conclusion: The integration of clinical-pathological parameters may predict splenectomy outcome, contributing to the management of ITP patients.

EP1130 TREATMENT OF IMMUNE THROMBOCYTOPENIA IN THE COVID-19 ERA: FOSTAMATINIB, AN ORAL SPLEEN TYROSINE KINASE INHIBITOR

N. Cooper [1,*], A. Charania [2], A. Hart [3], C. Ademokun [4], R. Numerof [5]

[1]*Imperial College Healthcare NHS Trust, Hammersmith Hospital, London,* [2]*Epsom and St Helier University Hospitals NHS Trust, Carshalton,* [3]*Imperial College NHS Trust,* [4]*Imperial College Healthcare Trust, London, United Kingdom,* [5]*Medical Affairs, Rigel Pharmaceuticals, Inc, South San Francisco, United States*

ITP is an autoimmune disease primarily mediated by spleen tyrosine kinase (SYK) signaling-dependent phagocytosis of autoantibody-bound platelets by macrophages. Fostamatinib is a potent SYK inhibitor, is approved for ITP in the US, Canada, and Europe, and has been shown to elevate platelet counts and decrease bleeding. Fostamatinib may also abrogate thrombosis by mitigating SYK signaling in platelets. Furthermore, preclinical studies in rodents showed that R406 (the active metabolite of fostamatinib) is not immunosuppressive, preserving both the innate and humoral responses to immune challenges.[1]

Background: Management of immune thrombocytopenia (ITP) has become increasingly challenging during the COVID-19 pandemic. Immunosuppressive treatments used to treat ITP can increase the susceptibility of patients to develop COVID-19. Additionally, therapies which increase the risk of thrombosis may not be optimal due to the hypercoagulable state also observed in patients with COVID-19 infection. The need to minimize office visits, to limit potential exposure to the virus, renders therapies requiring intravenous administration or injections as well as treatments requiring frequent titration less suitable. Consequently, ITP management requires careful patient-centric consideration during the pandemic.
Aims: To evaluate fostamatinib as an ITP treatment during the COVID-19 era
Methods: Review of the safety data from the phase 3 studies for fostamatinib in ITP as well as titration and mode of administration.
Results: Patients (n=146) in the trials had a median age of 53 years (range 20-88), a median of 5 prior ITP treatments, and 229 years of fostamatinib exposure. An increase in platelet count ≥50,000/μL was observed in 54% of patients on fostamatinib treatment. These patients maintained their response to treatment for 86% of treatment days. In the placebo-controlled phase, there was a 2.4-fold difference in duration of exposure to fostamatinib vs. placebo (29 vs. 12 patient-exposure years, respectively). Consequently, the incidence of infections with fostamatinib was somewhat higher than with placebo (27% vs. 21%). The incidence of overall adverse events was similarly higher with fostamatinib vs placebo (83% vs 75%). No patients had opportunistic infections.
Office visits can be minimized due to oral administration of fostamatinib and simplified titration. Fostamatinib dosing is initiated at 100mg BID in patients and increased to 150mg BID after 4 weeks if needed. Titration visits are also minimized due to the low incidence of thrombocytosis (1.4% over 5 years).
ITP patients have an increased risk of thrombotic events, which may be due to SYK-dependent platelet activation in patients with ITP.[2] In the randomized fostamatinib studies, 87% of patients had at least one risk factor for thrombosis, and 58% had multiple risk factors. Over the 62-month study, one (0.7%) thrombotic event was reported: a patient with pre-existing atherosclerosis had a mild transient ischemic attack, which resolved spontaneously. This rate is lower than seen in long-term ITP clinical trials (2-8 years duration), which ranged from 2.6% to 8.9%.
Summary/Conclusion: Fostamatinib is an immunomodulatory treatment that elevates platelet counts and may lower the risk of thrombosis in ITP. There is also a reduced need for office visits due to oral administration, simplified titration, and infrequency of thrombocytosis. Fostamatinib is an appropriate therapeutic option for the treatment of ITP in the COVID-19 era.

Background: Inherited platelet disorders (IPD) are a heterogeneous group of rare diseases, whose functional and molecular diagnosis has traditionally been complex. Although, high-throughput sequencing (HTS) has allowed us to increase the number of patients with an accurate genetic diagnosis, there are many specific and/or syndromic IPD patients with unknown underlying molecular variations. So, it is probably challenging by the limitation to identify large and complex deletions or amplifications of DNA segments between 50bp and 1kb, called Copy Number Variations (CNV). Comparative Genetic Hybridization array (aCGH) or Multiplex Ligation-dependent Probe Amplification (MLPA) has become the gold standard for constitutional genetic diagnosis of CNV and big structural chromosomal variants, translocations and aneuploidy. The application of HTS to detect CNV is being studied in IPD.
Aims: To identify CNVs using a custom HTS panel in patients with specific and/or syndromic IPDs.
Methods: Custom HTS panel was designed using the SureDesign Studio (Agilent Technologies, Santa Clara, CA, USA) with 57,070 probes, including coding regions for 108 genes with relevance in inherited bleeding disorders, which also allowed to detect CNVs. Regions of interest were enriched for each library following the SureSelectQXT-Target-Enrichment protocol (Agilent), and finally were sequenced on an Illumina NextSeq platform, with a read length of 2x150 nucleotides. Data were processed using an in-house pipeline. CNV analysis were made using depth-of-coverage method, which assumes a linear correlation between the coverage depth and the number of copies. Lower reading depth than expected represented losses or deletions, while higher depth represented gains or amplifications.
Results: CNVs were detected in 5 patients whose, clinical and laboratory phenotypes were included in Table 1. For CNV analysis an average of $1{,}8x10^6$ reads per sample was obtained with a minimum mean coverage of 300X that allowed detecting deletions in the following genes: *RBM8A, GP1BB, TBX1, RUNX1 and VWF*. In patient 1 (P1), thrombocytopenia-absent radius syndrome was previously diagnosed and HTS allowed us to identify a low frequency SNP which affects the 5'UTR region of RBM8A (c.-21 G>A; rs139428292) and a deletion on chromosome 1q. The latter was validated with aCGH showing a microdeletion at chromosome band 1q21.1. In P2, Di George syndrome (DGS) was diagnosed and deletion of *GP1BB* and *TBX1* confirmed a del22q. Additionally, in P3, a syndromic thrombocytopenia (table 1) was suspected and a deletion of *GP1BB* and *TBX1* was detected related to incomplete DGS. In these 2 patients, deletions were validated with MLPA and aCGH, respectively. A deletion on chromosome 21q which involved *RUNX1* was identified in P4 with syndromic thrombocytopenia. Finally, a homozygous deletion of 3 exons (14-16) of *VWF*, was detected in P5 (von Willebrand disease type 3) (Figure 1).

Table 1. Clinical and biological phenotype of patients with IPD in whom CNVs have been analyzed.

Case	Age / gender / BS	Clinical symptoms	Laboratory phenotype	Suspected / final IPD	CNVs
1	45 y, female / 2; heavy menstrual bleeding	Bicuspid aortic valve and cow's milk intolerance, bilateral radioulnar agenesis, hip dysplasia, other skeletal and facial malformations	P=84x10³/mm³ MPV=13,8 fl. BF: large platelets	Thrombocytopenia with absent radius syndrome	*RBM8A* deletion, del1q, and SNP which affects 5'UTR region
2	13 y, male / 0	Hypertelorism, prognathism, dental mal-occlusion, short stature, psychomotor retardation, bicuspid aortic valve, umbilical hernia	P=135x10³/mm³ VPM=13.7 fl. BF: large platelets	DiGeorge syndrome	*GP1BB* and *TBX1* deletion, del22q
3	14 y, male / 0	Hypertelorism, short stature, learning difficulties, hearing loss, infections, situs solitus	P=79x10³/mm³ MPV=12.8 fl. BF: large platelets	Syndromic thrombocytopenia / incomplete DGS	*GP1BB* and *TBX1* deletion, del22q
4	1 y, male / 2; epistaxis and ecchymosis	Bilateral sensorineural deafness, corpus callosum hypoplasia, cardiac and facial malformations	P=35x10³/mm³ MPV=8 fl. BF: dysmorphic cells	Syndromic thrombocytopenia	*RUNX1* deletion del21q
5	5 y, male / 9	Consanguinity, epistaxis, ecchimosis, bleeding after dental extraction, hemartroses	Normal platelet count Severely reduced VWF:Rco and Ag	VWD type 3	Homozygous deletion *VWF* (exons 14-16)

Abbreviations: P: platelet counts; MPV: mean platelet volume; BF: blood film; DGS: DiGeorge syndrome; VWD: von Willebrand disease ; BS: bleeding score according to ISTH-BAT.

Figure 1. Representation of CNVs identified in 5 patients with specific and/or syndromic IPDs.

Summary/Conclusion: Our custom HTS panel has allowed us not only identify single-nucleotide variants but also CNVs. CNV analysis is particularly useful in IPDs patients with specific phenotype with unknow underlying genetic variants and/or a syndromic thrombocytopenias.

EP1132 CLINICAL APPLICATION OF GENETIC TESTING IN PATIENTS WITH NOT ACQUIRED THROMBOCYTOPENIA: ONE CENTER EXPERIENCE

P. Silva De Tena [1,*], M. Argüello de Tomás [1], C. Pascual Izquierdo [1,2], J. L. Diez-Martín [1,2,3], C. Martinez Laperche [1,2,3], G. Perez Rus [1,2]

[1]Hematology, [2]Health Researh Institute, Hospital General Universitario Gregorio Marañón, [3]Medicine, Universidad Complutense, Madrid, Spain

Background: Misdiagnosed thrombocytopenia, mainly autoimmune forms, could lead to inadequate treatments with eventual development of side effects. Recently, the knowledge about inherited thrombocytopenia has expanded offering a new field of research and a new diagnostic, prognostic and therapeutic approach for these patients.
Aims: To evaluate the applicability and utility of a next generation sequencing (NGS) based gene panel in the diagnostic of suspected inherited thrombocytopenia in the clinical practice.
Methods: This prospective descriptive study included patients with a previous diagnosis of not specified thrombocytopenia who fulfilled inclusion criteria: not acquired thrombocytopenia (no previous normal range platelets count) and not known secondary causes of thrombocytopenia. A family history of thrombocytopenia and lack of response to immunosuppressive treatment were also recorded.
All participants underwent a complete medical and family history, a physical examination and several laboratory tests including a complete blood count, blood chemistry and a peripheral blood smear. A total of 200 platelets were evaluated in every blood smear and platelet size, granulation and vacuolization were described. Platelets larger than half a red blood cell were considered large forms. Bone marrow was recorded if it was previously studied. The NGS gene panel was performed to all the patients. Data are presented as medians, maximum, minimum and percentages. Informed consents were required for all patients.
Results: Thirty patients were included in the study. They were 51 (22-86) year old by median and showed a median platelet count of 76000/µl (10000 to 120000) and a median platelet volume of 11.7fl (8.3-13.9) at the time of the inclusion. Almost half of subjects (47%) had family history of thrombocytopenia and only 1 patients (3%) had family history of hematologic malignancy: one brother with an unknown type of acute leukaemia. None of the patients presented known syndromic disorder. Nine patients (30%) referred previous haemorrhagic complications, in most cases with mild symptoms. Ten (33%) participants received previous treatment for immune thrombocytopenia without response. Six (20%), 3 (10%) and 5 (17%) of the peripheral blood smear samples showed large, hypogranular and vacuolated platelets respectively. The NGS panel proved that 12 out of the 30 patients (40%) presented some genetic mutation related to inherited thrombocytopenia (see table 1). In total, 15 gene alterations were identified. It is remarkable that all the patients who showed large platelets in blood smear matched with some type of gene mutation.

Patients (n = 30)	
Age, years	51 (22-86)
Sex (number, %)	
- Male	13 (43%)
- Female	17 (57%)
Family background (number, %)	
Thrombocytopenia	14 (47%)
Hematologic malignancy	1 (3%)
Haemorrhagic symptoms (number, %)	9 (30%)
Platelet count (platelet/µL)	76000 (10000-126000)
Platelet volume (fl)	11,7 (8,3-13,9)
Previous treatment (number, %)	
- Yes	10 (33%)
- No	20 (67%)
Type of treatment (number, %)	10 (33%)
Glucocorticoids	20 (67%)
Intravenous Immunoglobulins	5 (17%)
Splenectomy	0 (0%)
Rituximab	3 (10%)
Thrombopoietin analogs	1 (3%)
Others	3 (10%)
Peripheral blood smear (number, %)	
- Large/giant platelets	6 (20%)
- Hypogranular platelets	3 (10%)
- Vacuolated platelets	5 (17%)
Patients with NGS gene mutation (number, %)	12 (40%)
Gene alterations (number, %)	15
- ITGA2B/ITGB3	4 (27%)
- RUNX1	2 (13%)
- MYH9	2 (13%)
- GFI1B	2 (13%)
- NBEAL2	2 (13%)
- GP1BA	1 (7%)
- TUBB1	1 (7%)
- ADAMST13	1 (7%)

Summary/Conclusion: In this one center experience, the application of a NGS based gene panel allowed to diagnose a considerable amount of patients with suspected inherited thrombocytopenia. Identifying these patients is important to avoid useless treatments (up 33% in our series) and to recognize some forms that can develop secondary diseases requiring follow-up in clinical practice.

EP1133 COGNITIVE IMPAIRMENT IN PATIENTS WITH IMMUNE THROMBOCYTOPENIA

C. Vladescu [1,*], A. Hart [1,2], G. Adams [1,3], D. Paul [1], R. M. Szydlo [2], C. Ademokun [1], N. Cooper [1,2]

[1]Non-malignant Haematology, Imperial College NHS Trust, [2]Department of Immunology and Inflammation, [3]Department of Life Sciences, Imperial College, London, United Kingdom

Background: Immune thrombocytopenia (ITP) is an autoimmune condition characterised by a low platelet count (<100 x 10^9/L). Patients with ITP have an increased risk of bruising and bleeding. However, a few studies have shown that they also suffer from other symptoms (e.g. memory and concentration problems) that are not related to bleeding, suggesting that ITP patients might suffer from cognitive impairment.
Aims: The study hypothesis was that patients with ITP suffer from cognitive impairment. The aims were to establish what cognitive domains are impaired and what the prevalence of cognitive impairment in this population is. The secondary objective was to investigate the link between ITP disease parameters and cognitive impairment.
Methods: Seventy patients with ITP and a nadir platelet count ≤ 30 x 10^9/L were recruited to the study and were then invited to Hammersmith Hospital, London, for the following procedures: cognitive testing using an automated neuropsychological test battery (CANTAB), completion of SMOG bleeding questionnaire and full blood count. CANTAB is a validated automated software used in clinical practice and research to assess cognitive impairment. Five key cognitive domains (episodic memory, executive function, processing speed, working memory and attention) were assessed using different CANTAB tasks. The scores for each test were automatically processed by the software, and z-scores standardized for age, sex and education level were generated. Based on the z-scores, the patients' cognitive performance was categorised as impaired or not impaired. The patients' clinical metadata (including date of diagnosis, lowest platelet count recorded during the course of the disease, number of types of ITP treatments received and co-morbidities) was collected from paper and electronic medical records.
Results: The summary of the patients' demographics and clinical characteristics is presented in Table 1.

Table 1. Demographics and clinical characteristics of the population studied

	Median (range)
Age at the time of cognitive test, years	40 (19, 88)
Age at the time of ITP diagnosis, years	40 (4, 83)
Female, n (%)	46 (65.7)
Duration of disease, months	67.5 (1, 535)
Nadir platelet count, x 10^9/L	5 (0, 30)
Number of types of ITP treatments received during the course of the disease	4 (0, 14)
Platelet count at the time of test, x 10^9/L	93 (4, 653)
Patients receiving ITP treatment at the time of cognitive test, n (%)	36 (51)
Patients with co-morbidities, n (%)	46 (65.7)

Of the 70 patients tested, 50% (95 % CI [37.8%, 63.2%]) had at least one impaired cognitive domain: 30% had impairment in one domain, 17% in two domains and 3% in three domains. The frequency of cognitive impairment per domain is illustrated in Figure 1.
Organ bleeding was found to be associated with impaired episodic memory (p = 0.017). No other disease parameters were associated with impaired cognition.

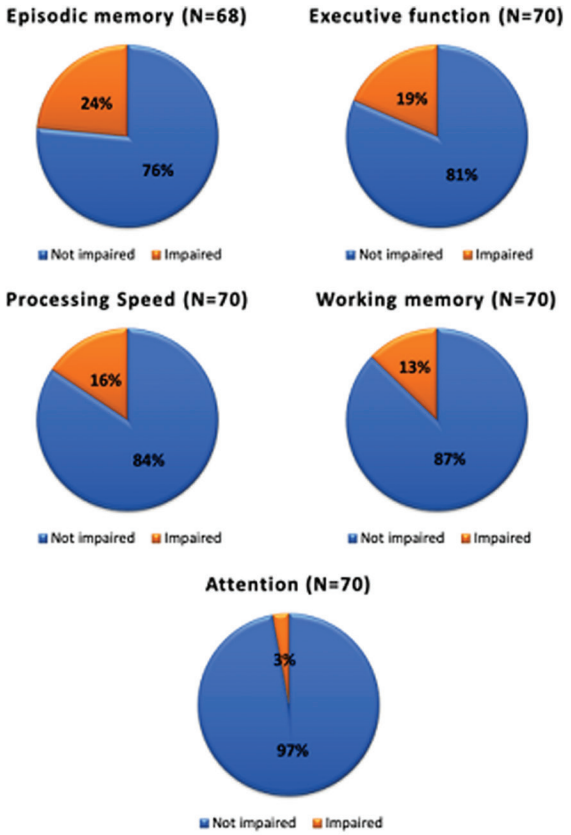

Figure 1. Pie charts showing the percentage of patients with cognitive impairment per domain
Episodic memory 95% CI [14.1, 35.4]; Executive function 95 %CI [10.3,29.7]; Processing speed 95 %CI [8.1, 26.4]; Working memory 95 %CI [6.1, 23]; Attention 95% CI [0.3,9.9].

Summary/Conclusion: Fifty percent of patients with ITP were found to have impaired cognition. Patients with higher organ bleeding scores were more likely to have impaired episodic memory. No other disease parameters, including duration of disease, or platelet count were associated with impaired cognition. These results suggest that ITP is not just a 'low platelet' disease.

EP1134 EFFECTIVENESS AND SAFETY OF ROMIPLOSTIM AMONG PATIENTS WITH NEWLY DIAGNOSED, PERSISTENT AND CHRONIC ITP IN ROUTINE CENTRAL AND EASTERN EUROPEAN CLINICAL PRACTICE: AN ANALYSIS OF THE PLATON STUDY

B. Skopec [1,2,*], Z. Sninska [3], N. Tsvetkov [4], V. Ivanushkin [5], K. Bjorklof [6], J. Hippenmeyer [7], G. Mihaylov [8]

[1]Department of Hematology, University Medical Center Ljubljana, [2]Medical Faculty, University of Ljubljana, Ljubljana, Slovenia, [3]Department of Hematology and Blood Transfusion, University Hospital St. Cyril and Metod, Bratislava, Slovakia, [4]Clinic of Hematology, University Multiprofile Hospital for Active Treatment "Dr. Georgi Stranski" EAD, Pleven, Bulgaria, [5]Department of Biostatistics, Quartesian, Kharkov, Ukraine, [6]Medical Affairs, Amgen (Europe North East), [7]Medical Affairs, Amgen (Europe) GmbH, Rotkreuz, Switzerland, [8]Clinic of Hematology, Specialized Hospital for Active Treatment of Hematology Diseases AD, Sofia, Bulgaria

Background: Immune thrombocytopenia (ITP) is a rare immune-related condition characterized by low platelet counts and an increased haemorrhagic tendency. Romiplostim is a thrombopoietin receptor agonist (TPO-RA) used to treat ITP. Recent guidelines have recommended the earlier use of TPO-RAs following first-line therapy with corticosteroids, including in patients with ITP <1 year since diagnosis. However, outcomes of romiplostim treatment by ITP duration at initiation in real-world practice are required to strengthen the evidence in this setting.
Aims: We assessed effectiveness and safety of romiplostim within 24 weeks after initiation by duration of ITP: <3 ("newly diagnosed"), 3-12 ("persistent"), and >12 ("chronic") months according to the updated product label. Real-world data collected between December 2010 and July 2017 in five Central and Eastern European countries were analysed.
Methods: This was a post-hoc analysis of the PLATON single arm, observational cohort study of adults receiving ≥1 dose of romiplostim within the indication approved at the time of study conduct (i.e. as second-line therapy after failure of other interventions, or where surgery was contraindicated). The planned observation period was 24 months. Durable platelet response was achieved if ≥75% of platelet count measurements during weeks 14-24 after romiplostim initiation were ≥50 x 10^9/L and no rescue therapy was administered. Overall platelet response was defined as at least one platelet measurement ≥50x10^9/L during weeks 2-24 after romiplostim initiation. Other outcomes included rescue therapy, bleeding, discontinuation of other ITP medications and adverse drug reactions (ADR). Patient and disease history were retrospectively collected at enrolment, prospective follow-up began at the first romiplostim dose and ended at the earliest of 24 months, loss to follow-up, censoring, or death.
Results: Of 100 patients, 22 (22%) were classified as newly diagnosed, 17 (17%) as persistent, and 61 (61%) as chronic at romiplostim initiation. The proportion of patients with splenectomy at initiation was highest in chronic patients (33%). Durable platelet response was achieved in 50% (CI: 28-72%) of newly diagnosed patients, 35% (CI: 14-62%) of patients with persistent ITP, and 31% (CI: 20-44%) of those with chronic ITP. Overall platelet response was achieved in >80% of patients across all strata. More newly diagnosed than persistent or chronic ITP patients discontinued all other concomitant ITP medications. Safety was comparable across ITP strata; the incidence of thrombotic ADRs was low and no occurrences of bone marrow ADRs were reported (Table).

Table. Characteristics of patients initiating romiplostim (2010-2017) and effectiveness and safety endpoints in routine clinical practice

	Duration of ITP		
	<3 months (N=22)	3–12 months (N=17)	>12 months (N=61)
Patient characteristics			
Median (IQR) ITP duration, years	0.1 (0.1, 0.1)	0.5 (0.3, 0.7)	4.7 (2.5, 14.0)
Median (IQR) platelet count, 10^9 cells/L	8 (4, 16)	19 (7, 45)	26 (14, 42)
Prior splenectomy, n (%)	1 (5)	2 (12)	20 (33)
Number of prior ITP therapies[a], n (%)			
0	1 (5)	0	1 (2)
1	9 (41)	5 (29)	18 (30)
2	4 (18)	2 (12)	11 (18)
≥3	8 (36)	10 (59)	31 (51)
Prior bleeding events[b], n (%)	15 (68.2)	7 (41.2)	18 (29.5)
Duration of romiplostim exposure, months			
Mean (SD)	14.13 (10.27)	17.31 (9.26)	17.62 (8.59)
Median (range)	18.60 (0.5, 24.4)	23.92 (0.7, 24.4)	23.69 (0.9, 24.4)
Efficacy outcomes, estimates [95% CI]			
Overall platelet response, %	82 [60, 95]	88 [64, 99]	85 [74, 93]
Durable platelet response, %	50 [28, 72]	35 [14, 62]	31 [20, 44]
KM median time to first platelet response (after day 7)[c], days	27 [15, 86]	15 [15, 57]	22 [15, 22]
Discontinuation of all non-romiplostim ITP treatments, %	32 [14, 55]	18 [4, 43]	16 [8, 28]
Any rescue therapy, %	14 [3, 35]	12 [2, 36]	10 [4, 20]
Specific types of bleeding[d], %	5 [0, 23]	0	3 [0, 11]
Bleeding requiring emergency treatment, %	14 [3, 35]	6 [0, 29]	5 [1, 14]
Incidence of ADR[e] [95% CI]			
Any adverse drug reaction	15.4 [4.2, 39.5]	32.6 [14.1, 64.3]	4.5 [1.2, 11.4]
Thrombotic adverse drug reaction	0	0	1.1 [0.0, 6.2]
Bone marrow fibrosis	0	0	0

CI, confidence interval of percentage; IQR, interquartile range; ITP, immune thrombocytopenia; KM, Kaplan-Meier estimates
[a]Prior medications include those that have ended prior to initiation of romiplostim.
[b]Patients experiencing bleeding events within 6 months prior to romiplostim initiation.
[c]Time to first platelet count ≥ 50 x 10^9/L during weeks 2 through 24 after index date, in the absence of rescue therapy.
[d]Abnormal vaginal bleeding, central nervous system bleeding with neurologic symptoms, hematemesis, haematuria, and/or melena.
[e]Exposure-adjusted incidence of adverse drug reactions per 100 patient years.

Summary/Conclusion: In this real-world study in Central and Eastern Europe, platelet response to romiplostim was consistent between the early (newly diagnosed / persistent) and chronic ITP settings. ADRs were infrequent and similar across strata of ITP duration. These findings support the utilisation of romiplostim in patients with newly diagnosed and persistent ITP in accordance with recent guidelines and according to the romiplostim label extension for these patients.

EP1135 UNUSUAL LABORATORY FEATURES AND CLINICAL COURSE OF HEPARIN INDUCED THROMBOCYTOPENIA IN CARDIOPULMONARY PATIENTS.

K. Ali [1], N. PalomoLopez [2], V. jeyakumar [1], A. HurtadoDoce [2], M. Mangi [1,*]

[1]Haematology, [2]ICU, Royal Brompton and Harefield NHS-GSTT, LONDON, United Kingdom

Background: Heparin induced thrombocytopenia (HIT) is characterised by a rapid fall in the platelet count normally 5-10 days after starting

heparin therapy with or without thromboembolic complications and commonly seen in the cardiac population. For laboratory diagnosis of HIT antibodies, both antigen assays and platelet activation (functional) assays are available. Both tests are very sensitive (high negative predictive value) but specificity is problematic, especially for the antigen assays, which also detect non-pathogenic immunoglobulins. Functional tests including the Serotonin release assay (SRA) and heparin induced platelet activation (HIPA) are more specific but only available in specialised laboratories.
Aims: 1. To assess the laboratory diagnosis for detecting anti-PF4/heparin antibodies and assays in cardiopulmonary bypass (CPB) cardio thoracic intensive care unit (ICU) patients. **2**.To evaluates the positive and negative predictive value of various HIT laboratory tests and assess any correlation between HIT, the underlying diagnosis, underlying procedure, valve replacement and cardiac devices.
Methods: This is a retrospective 1-year study in CPB patients from a single cardiothoracic ICU centre. The '4 T's' (*T*hrombocytopenia, *T*iming of platelet count fall, *T*hrombosis and exclude other causes for *T*hrombocytopenia,) was used for the clinical diagnosis of HIT. Two laboratory diagnostic tests were performed, the pan specific screening test which includes pan specific antibodies IgG, IgA and IgM, followed by confirmatory HIT specific IgG ELISA. Functional assays, the SRA and HIPA were not available in our laboratories. Clinical details were obtained from ICU-ICCA[7*] system.
Results: Total N=80 patients (F:23, M:57) had HIT probability "4 T" score >4. Total N=38 patients (48%) were HiT screen pan specific IgGAM negative and n=40 (50%) were HIT pan specific positive. Only n=14 patients (17%) were panspecific and HIT IgG ELISA positive and 2 cases were inconclusive. All HIT positive acute patients received Argatroban except one who received Fondaparinux. There were 5 unusual cases. One patient had Eosinophilic myocarditis and was HIT ELISA IgG neg but the 4-T score was >6 and patient received Argatroban and responded with platelet recovery and no further thrombosis. One patient with Sarcoidosis had aggressive course and received IV IG but succumbed secondary to bleeding. One patient progressed to gut ischemia and had surgical intervention but perished. Two patients with mechanical valves were on Argatroban/Warfarin but relapsed during ICU stepdown stage and received and responded to IV immunoglobulin. It is observed that 9/16 (>50%) HIT+patients had valve replacement or cardiac devices.

Table 1. Details of Cardiothoracic diagnosis of HIT-Positive patients

Pt no:	Age/sex	Diagnosis
1	54/M	Cardiomyopathy
2	63/M	t-MVR+AVR
3	67/M	m-MVR/AVR
4	57/M	VAD
6	30/M	VAD
7	53/M	t-MVR
8	67/M	Bilateral lung transplant
9	45/M	m-AVR
9	66/M	Late presentation STEMI, PCI, not suitable for heart transplant/for alternative treatment
10	75/F	Type A aortic dissection, ascending aorta (28mmHaemashield graft) and re-suspension of the Aortic Valve
11	74/M	Aortic+mitral+tricuspid repair and CABG
12	56/M	t-MVR
13	55/M	Sarcoidosis-cardiac transplant
14	56/F	Eosinophilic Myocarditis
15	56/F	Aortic intramural haematoma repair and m-AVR
16	55/M	t-AVR and CABG

1. HIT=Heparin Induced thrombocytopenia/thrombosis (HITT).
2. VAD= ventricular assisted device, MVR=mitral valve replacement.
3. AVR=Aortic valve replacement, t=tissue and m=mechanical.
4. CABG=Coronary artery bypass graft, STEMI=ST elevation myocardial infarction.
5. ECMO= Extracorporeal Membrane Oxygenation.
6. PCI=Percutaneous coronary intervention.
7. *ICCA=IntelliSpace Critical Care and Anaesthesia, Critical care information system.

Summary/Conclusion: 1. 80% of thrombocytopenia in ICU patients was secondary and not HIT related. 2. Pan specific HIT antibody test had positive predictive value of only 35% and Argatroban treatment based on pan specific antibody positivity may be uncertain and may lead to complications. 3.The autoimmune diseases patients like sarcoidosis and eosinophilic myocardits course varies in pathogenic and non-pathogenic HIT antibody production and clinical severity. The functional assays SRA or HIPA would be more useful in these cases. 4. Patients underlying diagnosis as well as underlying surgical procedures do play a key role in the incidence and severity of HIT and thrombosis 5. It may simply be a selected patients caseload surgery practice or an indication that patients with valve replacement and cardiac devices showed relatively higher HIT incidence and this requires larger studies and further investigations.

EP1136 CAPLACIZUMAB FOR ACQUIRED THROMBOTIC THROMBOCYTOPENIC PURPURA: A SINGLE-INSTITUTION EXPERIENCE

C. N. Logothetis [1,*], A. Patel [2], D. A. Laber [2]

[1]Department of Internal Medicine, University of South Florida, [2]Section of Satellite and Community Oncology, H. Lee Moffitt Cancer Center and Research Institute, Tampa, United States

Background: Acquired thrombotic thrombocytopenic purpura (aTTP) is caused by a deficiency in a von Willebrand factor (vWF) cleaving protease called ADAMTS13. Caplacizumab (C) is a monoclonal antibody that targets the A1 domain of vWF preventing platelet adhesion. The clinical trials that lead to the approval of C in aTTP have demonstrated improved outcomes. Experience outside clinical trials has been limited as many centers have never used this agent.
Aims: We report our single institution experience with C since it became commercially available. The aim of this study was to examine the efficacy and toxicity of C in patients with aTTP in standard practice.
Methods: This retrospective study included all patients admitted at our institution that were diagnosed with aTTP and received C since its approval. We used the following definitions through our data collection and analysis. Response: platelet count (PC) more than 150,000/uL and LDH less than 2 times the upper limit of normal (ULN). Exacerbation: aTTP event occurring within 30 days after end of plasma exchange (PLEX). Complete Response (CR): response without exacerbation. Relapse: aTTP event occurring more than 30 days after the end of PLEX. Day 1 was the first day of PLEX.
Results: Patient characteristics: Ten patients with aTTP received C at our institution in 2019-2020. The median age of diagnosis was 52 years. Five (50%) patients were white, 3 (30%) were African American and 2 (20%) were Hispanic. Nobody had fever. Five (50%) subjects had neurologic symptoms (weakness, numbness, and altered mental status). Six (60%) patients had refractory aTTP while 4 (40%) had newly diagnosed aTTP at the time of starting C. Prior to receiving PLEX and C, 2 (20%) patients had bleeding events, one in the form of hematuria and another with severe anemia with a drop in hemoglobin of 2.0 g/dL in 24 hours requiring blood transfusion post thoracic aortic aneurysm repair. Two (20%) patients had a thrombotic stroke. Median (range) laboratory values prior to PLEX and C demonstrated: PC 29/uL (9-61), LDH 518 U/L (182-1850), ADAMTS13 activity 3.0% (3.0-82.0) and ADAMTS13 inhibitor 1.4 BU (0.5-32.0).
Treatments: All subjects received glucocorticoids, rituximab, PLEX and C. The median number of PLEX was 12 (1-33) days. C was started at a median of 5 (2-34) days after the start of PLEX and continued for median treatment duration of 33 (8-108) days with 3 patients still on C. Two patients received vincristine.
Efficacy: Time to normalized PC, LDH and ADAMTS13 activity in days were 5 (3-50), 3.5 (0-146), and 32.5 (0-89), respectively. The median event free survival from the start of PLEX was 75.5 (16-576) days. Six (60%) patients achieved CR, 3 (30%) had refractory disease and 1 (10%) had relapsed aTTP. No one had a major bleeding or major thrombotic event while taking C and no one died. The reason for C discontinuation was normalization of ADAMTS13 in 1 patient and completion of the prescribed course in the rest of our cohort.

Table 1. Labs and Treatment Outcomes

Treatment Response	Patient Cohort (N=10) Median (Range) Count (%)
Baseline Labs before PLEX	
Platelet (/uL) [N=10]	29.0 (9.0-61.0)
LDH (U/L) [N=9]	518 (182-1850)
AST (U/L) [N=9]	26 (3-111)
ALT (U/L) [N=9]	20 (17-33)
Bilirubin (mg/dL) [N=9]	1.8 (0.70-4.0)
Creatinine (mg/dL) [N=10]	1.0 (0.70-2.5)
ADAMTS13 Inhibitor (IU) [N=7]	1.40 (0.50-32.0)
ADAMTS13 Activity (%) [N=9]	3.0(3.0-82.0)
Baseline Labs before Caplacizumab	
Platelet (/uL) [N=10]	95.5 (7.0-314.0)
LDH (U/L) [N=9]	255 (182-562)
AST (U/L) [N=9]	20 (11-36)
ALT (U/L) [N=9]	19 (13-49)
Bilirubin (mg/dL) [N=9]	0.70 (0.30-4.70)
Creatinine (mg/dL) [N=10]	0.9 (0.70-2.5)
ADAMTS13 Inhibitor (IU) [N=7]	4.30 (1.90-32.0)
ADAMTS13 Activity (%) [N=9]	3.0 (3.0-82.0)
Complete Remission	6 (60%)
Refractory	3 (30%)
Relapse	1 (10%)
Event Free Survival from Initiation of PLEX in days (N=10)	75.5 (16-578)
Event Free Survival from the End of Caplacizumab in Days (N=5)	433 (9.0-541)
Event Free Survival from the Start of PLEX in Days (N=10)	433 (9-541)
Number of Patients Hospitalized	10 (100%)
Duration of Hospitalization in Days	10.5 (4.0-37.0)
Number of Patients with an ICU Stay	2 (20%)
Duration of ICU Stay in Days	6.5 (3.0-10.0)
Adverse Events while on Caplacizumab	
Thrombotic Event	0 (0%)
Bleeding Event	0 (0%)
Other	0 (0%)
Reason for Drug Discontinuation (N=10)	
Normalization of ADAMTS13	1(10%)
Completion of Prescribed Course	6 (60%)
Patients still on Caplacizumab (N=10)	3 (30%)

Summary/Conclusion: Our study demonstrates that C is safe and effective at treating aTTP. C was associated with a short time to platelet normalization and number of PLEX days. No patient had a major bleeding event. While our population is small due to the rarity of aTTP, our data is important since it was derived from real-world experience and included all unselected patients. Finally, our data is consistent with clinical trial findings reported in the literature.

EP1138 BICYTOPENIA AND PANCYTOPENIA IN NEONATES: PREVALENCE, RISK FACTORS, AND OUTCOME

E. Tüsüz Önata [1], M. Üstkaya Sungur [2], F. Tüzün [2], Ö. Tüfekçi [3], N. Duman [2], S. Yılmaz [3], H. Ören [3,*]

[1]Pediatrics, [2]Neonatology, [3]Pediatric Hematology, Dokuz Eylül University Faculty of Medicine, İzmir, Turkey

Background: Neonatal anemia, neutropenia, and thrombocytopenia are common hematological problems in neonatal intensive care units. In the literature, there are studies evaluating neonatal anemia, thrombocytopenia, and neutropenia; but to date, no study has investigated the prevalance, risk factors, and outcome of neonatal bicytopenia and pancytopenia.
Aims: In our study, we aimed to evaluate the prevalence, risk factors, and outcome of bicytopenia and pancytopenia in neonates.
Methods: A retrospective analysis was conducted on the medical records of 2672 neonates hospitalized at neonatal intensive care unit between January 1, 2015 and January 1, 2019 and those with bicytopenia or pancytopenia were enrolled. Hemoglobin, neutrophil, and platelet counts were obtained from a whole blood EDTA sample taken from newborns for routine medical treatment. A hemoglobin concentration <7 gr/dL was accepted as severe anemia. Platelet count <50,000/mm^3 was accepted as severe thrombocytopenia. An absolute neutrophil count of <500/μL was accepted as severe neutropenia. The study was approved by the local ethics committee.
Results: Bicytopenia or pancytopenia was detected in 103 (3.8%) of 2672 newborns. The prevalence of bicytopenia and pancytopenia was 3.4% and 0.4%, respectively. The most common clinical findings in both pancytopenic and bicytopenic patients were pallor (63.6% and 53%, respectively) and bleeding (45.4% and 35%, respectively). Anemia and thrombocytopenia were found in 69.6% of bicytopenic patients, neutropenia and thrombocytopenia in 25%, and anemia and neutropenia in 5.4%. When prenatal risk factors were investigated, it was observed that bicytopenia and pancytopenia were more common in preterm babies compared to term babies (p<0.0001, p=0.02, respectively) and preterm infants with very low birth weight had increased risk for development of bicytopenia and pancytopenia (p=0.008, p=0.046, respectively). Asphytic delivery and gestational hypertension were found to be significant risk factors for development of bicytopenia (p<0.0001, p<0.0001). Sepsis (42.2%) and congenital heart anomaly (21.5%) were the two most common underlying diseases in neonates with bicytopenia; sepsis was also found to be the most common underlying disease in neonates with pancytopenia. Mean postnatal age of detection of bicytopenia was 8±7.3 days, nadir was 9±7.6 days, and resolving day was 5±4.6 days. Mean postnatal age of detection of pancytopenia was 7±6.4 days, nadir was 9±7.2 days, and resolving day was 7±6.4 days. Blood product transfusion was given to 76% of bicytopenic patients and 100% of pancytopenic patients. Bicytopenia or pancytopenia recurred in 4.9% of the patients within the first month. Among newborns with bicytopenia or pancytopenia, 4.8% had severe anemia and 32% had severe thrombocytopenia. The presence of severe anemia, severe thrombocytopenia, and the need for mechanical ventilation were found to be poor prognostic factors leading to a prolonged recovery period. Death occurred in 15.2% of bicytopenic patients and 27.3% of pancytopenic patients. Sepsis was the most common cause of death in these patients.
Summary/Conclusion: This study showed that prematurity, asphytic delivery, and gestational hypertension are important prenatal risk factors for development of neonatal bicytopenia and pancytopenia. Sepsis was the most common underlying disease and cause of death in these newborns. Poor outcome due to neonatal bicytopenia and pancytopenia may be improved by eliminating preventable risk factors.

EP1139 IMMUNE THROMBOCYTOPENIA AND COVID-19: A SINGLE CENTRE EXPERIENCE

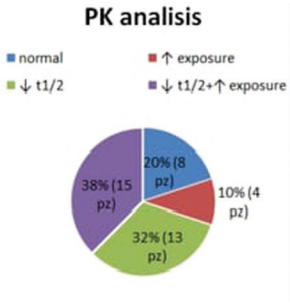
M. Moreno Carbonell [1,*], E. González Gómez [1], N. Espinosa Lara [1], A. Gómez Martínez [1], C. Hernández Mata [1], S. Martín-Consuegra Ramos [1], M. Civeira Marín [1], A. López Peña [1], C. Rodríguez Lefler [1], A. J. García Ortego [1], S. F. Pinzón Mariño [2], I. Izquierdo García [1]

[1]Haematology, Hospital Universitario Miguel Servet, Zaragoza, [2]Haematology, Hospital del Mar, Barcelona, Spain

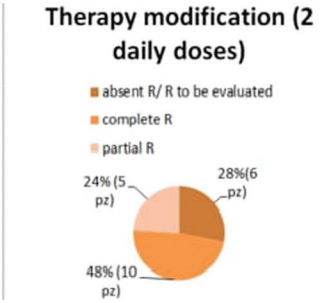
Background: Immune thrombocytopenia (ITP) is an acquired autoimmune disorder defined by a platelet count <100×10^9/L without explanation. This laboratory parameter has emerged as an important complication and have been shown to correlate with severe course in the coronavirus disease (COVID-19) caused by novel coronavirus SARS-CoV-2.
Aims: To analyze the clinical characteristics, diagnostic, blood count parameters, therapeutic strategies and outcomes in patients admitted with COVID-19 infection with acquired ITP.
Methods: An observational, longitudinal, descriptive and retrospective study was performed on all patients who were COVID-19 positive and platelet count < 100×10^9/L admitted to hospital between March 1 2020 and January 31 2021 at our centre. All patients were laboratory confirmed COVID-19 positive with a positive nasopharyngeal swab. Clinical and demographic data were collected for each patient, including age, gender, nadir platelet count, bleeding symptoms, time to recovery from start of treatment and clinical outcomes. Patients with previous hematological pathologies or thrombocytopenia were excluded. Mild COVID-19 disease was defined by presence of fever and cough only. Moderate disease was defined by presence of unilateral pneumonia by radiological evidence and/or clinical worsening. Severe disease was defined by presence of bilateral pneumonia by radiological evidence, admission to intensive care unit (ICU) during admission or met criteria for ARDS. Response to treatment was defined by documentation of platelet doubling or platelet count reaching at least > 30 × 10^9 /L (partial response-PR) or level reached > 100 × 10^9 /L or up to baseline count of that patient (complete response-CR). The results are expressed in percentages for qualitative variables, and in means and interquartilic ranges for continuous variables. The data were included in an Excel database

(Microsoft®) and the IBM SPSS Statistics® 20 program was used for their analysis.
Results: A total of 27 patients were identified, 17 males (62.96%) and 10 females (37.03%). The mean age at the time of the event was 78 years old (interquartile range-IQR-: 28 years). Attending to severity, 15 had severe disease (55.5%), 9 moderate and only 3 patients (11%) had a mild presentation.
The mean time from first COVID-19 manifestations to first ITP expression was 5 days (0–23). and in most of our patients was an incidental finding, presenting only 22% haemorragic clinic associated.
The majority of patients in our study did not receive a specific treatment for suspected ITP (e.g. only 6 were treated with intravenous immunoglobulins which were needed due to bleeding). But most patients were already treated with low doses of steroids as part of their treatment for COVID-19. The response rate was about 63% (PR and CR), with a mean of response of six days (IQR of 6.5 days).
Patients with severe disease and those who died at the end of the study, had lower platelet count than survivors and patients with moderate disease. However, our differences were not statisticaly significant.

			Average (%)
N		27	100
Gender	Male	17	63
	Female	10	37
Defeated		11	40.7
Severity	Sever	15	55.5
	Moderate	9	33.3
	Mild	3	11.11
Response	Complete response	12	44.4
	Partial response	5	18.6
	No response	10	37
Haemorrage		6	22.2



Summary/Conclusion: In our study, ITP was more frequent in severe COVID-19, with lower nadir platelet count, as described in literature. Bleeding events were infrequent. Glucocorticoids were used as a treatment for COVID-19 disease, only used in few patients as ITP specific treatment. The results should be confirmed with prospective randomized controlled studies.



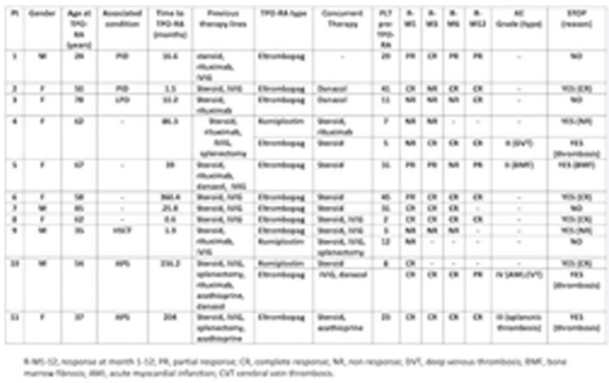
EP1140 PHARMACOKINETIC EVALUATION OF ELTROMBOPAG IN A COHORT OF PEDIATRIC PATIENTS WITH IMMUNE THROMBOCYTOPENIC PURPURA

F. de Gennaro [1,*], M. Dionisi [2], S. Cairoli [2], B. M. Goffredo [2], G. Ceglie [3], V. Clemente [4], C. Mascolo [1], G. Palumbo [3]

[1]University Department of Pediatrics, Bambino Gesù Children's Hospital, University of Rome Tor Vergata, [2]DEPARTMENT OF PEDIATRIC MEDICINE, LABORATORY OF METABOLIC BIOCHEMISTRY UNIT, [3]Department of Pediatric Hematology and Oncology, Cell and Gene Therapy, IRCCS Bambino Gesù Children's Hospital, Rome, [4]University Department of Pediatrics, Bambino Gesù Children's Hospital, University of Rome Tor Vergata, Rome, Italy, Tor Vergata, Roma, Italy

Background: Immune thrombocytopenic purpura (ITP) is an immune mediated acquired disorder characterized by decreased platelet count and increased risk of bleeding. The disease is classified into 3 categories according to the time from diagnosis: newly-diagnosed (within 3 months of onset), persistent (between 3 and 12 months), chronic (beyond 12 months). Eltrombopag (EPAG) is an orally TPO-RA (Thrombopoietin-Receptor Agonist), approved for patients with pediatric chronic ITP older than 1 year, refractory to first line therapy. In two Randomized Controlled Trials conducted in pediatric age, EPAG led to an improvement of platelet counts and a reduction in bleeding severity. In addition, in some studies conducted on adults with newly-diagnosed ITP the use off-label of EPAG has also shown good results. However, there is still a significant proportion (about 20%) of pediatric patients who do not show a response to EPAG. Scarce data are currently available regarding the pharmacokinetics of EPAG in children: the estimated median plasma EPAG time to maximum plasma concentration (Tmax) and geometric mean plasma EPAG half-life (t1/2) values are consistent with the adult values, respectively 4 hours and 47-51 hours. The area under plasma concentration-time curve over a dosing interval at steady-state (AUC(0-t)) and maximum plasma concentration (Cmax) values were similar between adolescents and adults while children have higher dose normalized AUC(0-t) and Cmax.
Aims: Explore potential variability of EPAG pharmacokinetic in a cohort of pediatric patients affected by refractory ITP with no or variable response to EPAG or who experienced significant side effects.
Methods: Subjects aged 0 to 18 years were enrolled for pharmacokinetic assessment. Blood samples were obtained at 0, 2, 4 and 8 hours after the administration. Patients had started EPAG at least since 2 weeks. Analysis of EPAG plasma concentration was performed by mass spectrometry coupled with UHPLC (Ultra High Performance Liquid Chromatography) platform.
Results: We performed 40 PK analysis (24 Females, 16 Males). Patients who started therapy at different stages of the disease were considered (16 newly diagnosed, 12 persistent, 12 chronic). The median dose of EPAG given once daily was 50 mg, ranging from 12.5 mg (n subjects=3) to 150 mg (n subject=1). Overall, EPAG peak (Tmax) occured between 2 and 4 hours with a population Cmax of 50 ug/mL and t1/2 of 25 hours. Our cohort of patients therefore showed a Tmax consistent with the literature values, on the other hand, t1/2 appeared to be reduced when compared to known data. Moreover, 32% (13 patients) of our population had an extremely short half-life with values below 12 hours. With regard to exposure, 47.5% of patients (19 patients) have higher Cmax and AUC(0-t) values compared to literature. Based on these results, we tried to change the time of administration of EPAG in about 21 patients, who had shortened t1/2 and/or increased exposure, dividing the daily dose into 2 administrations. 15 patients showed a response, 10 showed a complete response (PLTs >100.000), 5 a partial response (PLTs 30.000-100.000), although 2 patients did not maintain the response in the follow-up and 1 had a fluctuating response.

Summary/Conclusion: These data highlight the need to further explore variability of EPAG exposure and its pharmacokinetic/pharmacodynamic profile in the pediatric population. Our results also suggest the possibility of improving the response to EPAG by modifying the administration although further studies are needed.



EP1141 EFFICACY OF THROMBOPOIETIN RECEPTOR AGONISTS IN EVANS SYNDROME: A SINGLE CENTER SERIES

N. Cecchi [1,*], J. A. Giannotta [2], M. Capecchi [3], W. Barcellini [2], B. Fattizzo [1]

[1]Hematology, University of Milan, [2]Hematology, Fondazione IRCCS Ca' Granda Ospedale Maggiore Policlinico, [3]University of Milan, Milan, Italy

Background: Evans syndrome (ES) is a rare condition, defined as the presence of two autoimmune cytopenias (AIC), more frequently autoimmune hemolytic anemia (AIHA) and immune thrombocytopenia (ITP), and rarely autoimmune neutropenia (AIN). ES can be classified as primary or secondary to various conditions, including lymphoproliferative disease (LPD), primary immune deficiencies (PID) or other systemic autoimmune diseases (AID). ES onset may be acute and life-threatening, whilst its clinical course is usually chronic and marked by several relapses of AIHA, ITP or both. First line therapy is based on steroids +/- intravenous immunoglobulins (IVIG), followed by rituximab and splenectomy in refractory/relapsing cases. Concerning ITP, splenectomy is not always feasible, and rituximab is poorly effective on the long term. Thrombopoietin receptors agonists (TPO-RA), such as romiplostim

(ROMI) and eltrombopag (EPAG), are highly effective in primary ITP, whilst their use in ES has never been systematically studied.
Aims: to evaluate the efficacy and safety of TPO-RA in a cohort of patients with ES.
Methods: ES patients treated with TPO-RA out of a cohort of 46 cases followed at a tertiary hematologic hospital were retrospectively evaluated. Baseline hematologic parameters, associated conditions, previous/concomitant treatments were assessed. The time from diagnosis to first TPO-RA was collected. Response rates were evaluated at 1, 3, 6, and 12 months, and classified as partial (PR) or complete (CR), for platelets >30x10^9/L or >100x10^9/L, respectively. Treatment emergent adverse events (TEAEs) were registered and graded according to CTCAE.
Results: As shown in Table 1, 11 patients have been evaluated: 4 males and 6 females, with a median age at the start of TPO-RA of 55.6 years (24-85). Six patients suffered from secondary ES: 2 PID, 2 antiphospholipid syndrome (APS), 1 post allogenic stem cells transplant (SCT), and 1 LPD. All patients had received steroids +/- IVIG, and the majority at least one further line including rituximab (N=6), splenectomy (N=3), azathioprine (N=2), and danazol (N=1). The median time from diagnosis to TPO-RA was 25.8 months (0.6-360.4). Response rates to the first TPO-RA (9 EPAG and 2 ROMI) were: 72% at month 1 (45% CR, 27% PR, N=11), 60% at month 3 (50% CR, 10% PR, N=10); 66% at month 6 (55% CR 11% PR, N=9); 100% at 12 months (71% CR, 28% PR, N=7). Of note, 91% of patients required concomitant therapies, including steroids +/- IVIG (N=10), danazol (N=3), rituximab, splenectomy and azathioprine (N=1 each). Interestingly, 3 patients switched to the alternative TPO-RA (2 ROMI to EPAG and 1 vice versa) mainly because of no response (NR); two out of 3 responded. Four out of 11 (36%) patients developed at least one TEAE: 3 venous thromboses (1 deep venous thrombosis, 1 cerebral vein thrombosis CVT, and 1 splanchnic thrombosis) and 1 acute myocardial infarction (in the same APS patient experiencing CVT). Four patients are still receiving TPO-RA, whilst the other stopped because of persistent CR (N=3), thrombosis (N=3), or increase in bone marrow reticulin fibrosis (N=1).

Summary/Conclusion: TPO-RA were effective in about 70% of ES patients, even heavily pre-treated, but required a concomitant therapy in the majority of them. Moreover, TPO-RA use was complicated by a high occurrence of thrombotic events that may be also favored by underlying conditions. These findings highlight that ES is sustained by a profound immune dysregulation where autoimmune platelet destruction cannot be completely overcome by bone marrow stimulation.

EP1142 ELTROMBOPAG PLUS RHTPO VERSUS ELTROMBOPAG FOR ITP DURING THE COVID-19 PANDEMIC (ELABORATE-19)

Z.-Y. An [1,2,3,*], Y. He [1,2,3], X.-L. Zhu [1,2,3], H.-X. Fu [1,2,3], T.-T. Han [1,2,3], X.-Y. Zhao [1,2,3], X.-L. Dou [1,2,3], Y.-J. Chang [1,2,3], X.-H. Zhang [1,2,3]

[1]Peking University Institute of Hematology, Peking University People's Hospital, [2]Collaborative Innovation Center of Hematology, Peking University, [3]National Clinical Research Center for Hematologic Disease, Beijing, China

Background: Immune thrombocytopenia (ITP) is an acquired thrombocytopenia caused by immune-mediated platelet destruction and impaired platelet production. Recombinant human thrombopoietin (rhTPO) and Eltrombopag, a small molecule agonist of thrombopoietin receptor (TPO-RA), are both recommended as the subsequent treatment for ITP patients, which also already showed robust efficacy. They increase the number of platelets through different mechanisms, and previous studies demonstrated that they might exert synergic effect. During the COVID-19 pandemic, the classical subsequent treatment regimen for ITP of immunosuppressants and/or steroids might increase patients' susceptibility of virus infections. The investigators hypothesized that the combination of these two agents could be a promising option for ITP treatment during the COVID-19 pandemic. To minimize ITP patients' risk during the COVID-19 global crisis and to improve treatment efficacy, this treatment regimen of Eltrombopag plus rhTPO should be investigated. This trial is registered with ClinicalTrials.gov, number NCT01667263.
Aims: This study aimed to evaluate the sustained responses at 6 months and safety of Eltrombopag plus rhTPO as treatment for corticosteroid-resistant or relapsed ITP patients during the COVID-19 pandemic.
Methods: In this open-label, randomized, phase 2 trial, we enrolled confirmed corticosteroid-resistant or relapsed adult ITP patients from 5 different tertiary medical centers in China. They were randomly assigned 1:1 with an interactive web-based response system to receive either Eltrombopag 25-75 mg oral daily according to platelet response plus rh-TPO 300U/kg subcutaneous injection once daily for 7 consecutive days, followed by a tapering dose in maintenance therapy or Eltrombopag monotherapy for 12 weeks (Figure 1). The primary endpoint was 6-month sustained response (SR) defined as platelet counts maintained > 30×10^9/L and at least a doubling of baseline platelet count. Key secondary endpoints were initial response by day 14, duration of response (DOR), TTR, bleeding scores, and adverse events (AEs).
Results: Between August 2020, and March 2021, 60 patients were randomly allocated into either rh-TPO plus Eltrombopag (n=30) or Eltrombopag monotherapy (n=30). At the 6-month follow-up, the proportion of patients with SR was significantly higher in the rh-TPO plus Eltrombopag group than in the Eltrombopag monotherapy group (66.7% vs 36.7%, p= 0.020). The combination of rh-TPO and Eltrombopag resulted in a higher incidence of initial response by day 14 compared with Eltrombopag monotherapy (76.7% vs 60%, p= 0.165). Throughout the follow-up period, overall DOR was greater in the combination group, estimated by the Kaplan-Meier analysis. Bleeding was more effectively controlled in the rh-TPO plus Eltrombopag arm, with fewer bleeding events and lower bleeding scores. There was no difference between the 2 groups in terms of rescue treatments. All subjects tolerated the treatment well, and no grade 4 adverse events or treatment-related death were reported. No statistically significant differences were observed in the incidence of treatment-related AEs between the two groups.
Summary/Conclusion: Rh-TPO plus Eltrombopag is an effective and safe treatment for corticosteroid-resistant or relapsed ITP patients during the COVID-19 pandemic. (NCT04516837)

EP1143 IMMUNE THROMBOCYTOPENIA ASSOCIATED WITH LYMPHOID MALIGNANCIES: REPORT FROM A FRENCH PROSPECTIVE REGISTER.

N. Grienay [1], M. Mounier [2], C. Rossi [3], O. Casasnovas [3], D. Caillot [3], M. Maynadié [2], B. Bonnotte [1], S. Audia [1,*]

[1]Internal Medicine and Clinical Immunology, Referral Center for Autoimmune Cytopenia, [2]Register of hematological malignancies of Côte d'Or, [3]Hematology department, University Hospital of Dijon, Burgundy University, Dijon, France

Background: The incidence of immune thrombocytopenia (ITP) is around 3/100,000 person-years. ITP is associated to another disease in 15-20% of the cases, mostly systemic auto-immune diseases, or hematological malignancies. For the latter, the association is principally reported with chronic lymphoid leukemia (CLL), large granular leukemia (LGL) and Hodgkin lymphoma (HL). As data have been derived from cohorts from tertiary centers with a possible selection bias, the accurate incidence rate of lymphoid malignancies (LM)-related ITP remains elusive.
Aims: Determination of the frequency, clinical characteristics and evolution of LM-related ITP based on the prospective data collected in the register of hematological malignancies of Côte d'Or (RHEMCO), a population-based register recording all incident hematological malignancies occurring in a restricted geographical area of 532,886 inhabitants.
Methods: Patients included in RHEMCO between January 1995 and December 2015 (n=3499) were analyzed to calculate incidences. The medical records of ITP patients referred to our tertiary hospital during the same period were also considered for the clinical description and the evolution of LM-related ITP. ITP was defined as a thrombocytopenia

<100 G/L after exclusion of other causes. Response was defined as a platelet count >30 G/L with at least a 2-fold increase of baseline level.
Results: Based on RHEMCO, the frequency of ITP during LM was 1.06% (n=37/3499): 3.46% for T cell lymphoma, 1.21% for CLL, 0.82% for B cell lymphoma and 0.36% for HL. The frequency of Evans' syndrome (ES) was 0.29% (n=10/3499) in the whole cohort: 0.44% during CLL, 0.43% for T cell lymphoma, and 0.24% for B cell lymphoma.
From RHEMCO and medical records, 76 patients with secondary ITP were identified, among which 17 with ES. For ITP, the median age at diagnosis was 69.5 [interquartile range (IQR): 19-94] years and 59% were male. For ES, the median age was 62 [IQR: 29-85] and 76% were male. Among all LM-related ITP, CLL and indolent B cell lymphoma were the most represented (29% each), followed by T cell lymphoma (20%), aggressive B cell lymphoma (18.5%) and HL (3.5%). ES was mostly associated with indolent B cell lymphoma (47%) or CLL (41%), T cell lymphoma or HL representing only 6% each. LM occurred before ITP in 46% of the cases, with a median delay of 3 [IQR: 0.5-18.4] years and in 65% for ES with a delay of 5.1 [IQR: 0.3-10.1] years. LM and ITP were simultaneous (≤ 3 months) in 44% for ITP and 29% for ES. Bleedings were reported in 45% and splenomegaly in 29% of the cases. The median platelet count at diagnosis was 30 [IQR: 1-96] G/L.
All the patients were treated: 84% received specific medications for ITP and 91.5% for LM. Responses to ITP treatments were 63% for steroids and IVIg, 79% for rituximab and 80% for thrombopoietin receptor agonists. After 4.4-year follow-up, ITP was considered in remission in 53%.
Summary/Conclusion: LM-related ITP is a rare condition, with an incidence of 0.073/100,000 person-years for CLL, 0.072/100,000 for B cell lymphoma and 0.059/100,000 for T cell lymphoma. The diagnosis of LM precedes or is concomitant of ITP in most of the cases (90%). Responses rates to usual ITP therapies seem to be lower than in primary ITP, with a remission rate of 50%.

EP1144 A MULTICENTER U.S. STUDY OF AVATROMBOPAG SWITCH THERAPY FOLLOWING PRIOR ELTROMBOPAG OR ROMIPLOSTIM

H. Al-Samkari [1,2,*], D. Jiang [3,4], T. Gernsheimer [3,4], H. Liebman [5], S. Lee [5], M. Wojdyla [6], M. Vredenburg [6], A. Cuker [7]

Background: Avatrombopag (AVA) is an oral thrombopoietin receptor agonist (TPO-RA) approved for treatment of chronic immune thrombocytopenia (ITP). Data describing effectiveness of AVA following treatment with other TPO-RAs is limited.
Aims: Evaluate ITP treatment outcomes in patients who switched from romiplostim or eltrombopag (ROMI/ELT) to AVA.
Methods: We retrospectively evaluated all adults with ITP switched from ROMI/ELT to AVA at four U.S. tertiary ITP referral centers from July 2019 through December 2020 who were treated with AVA for at least two months by the data cutoff date.
Results: *Patient Characteristics:* 45 patients were included, with a median (range) age of 60 (21-87) years; 53% were female. Mean treatment duration with ROMI/ELT prior to switch was 26.4 months and mean AVA treatment duration was 9 months. At AVA initiation, patients had ITP for a mean of 8.3 years with a mean (range) of 4.8 (2-10) unique prior ITP treatments. The reason for switching to AVA was convenience in 23 patients (51%), ineffectiveness of ROMI/ELT in 14 (31%), and adverse event on ROMI/ELT in 8 (18%). The TPO-RA prior to switch was ROMI in 33 patients (73%), ELT in 11 (24%) and both simultaneously in 1 (2%).
Platelet Outcomes: In all patients, the median platelet count (Plt) on ROMI/ELT was 45×10^9/L vs. 114×10^9/L on AVA ($P<0.0001$); in patients switched for ineffectiveness of ROMI/ELT, it was 28×10^9/L on ROMI/ELT vs. 88×10^9/L on AVA ($P=0.025$), **FIGURE**. On AVA, in the absence of rescue therapy (>8 weeks from rescue corticosteroids or >4 weeks from rescue IVIG), Plt ≥50×10^9/L was achieved by 42/45 patients (93%), including 12/14 (86%) switched due to ineffectiveness of ROMI/ELT; Plt ≥100×10^9/L (complete response) was achieved by 39/45 patients (87%), including 10/14 (71%) switched due to ineffectiveness of ROMI/ELT.
AVA Dosing: The median total weekly AVA dose was 140 mg (20 mg daily) in all patients and 280 mg (40 mg daily) in patients switching due to ROMI/ELT ineffectiveness.
Concomitant Medications/Rescue Therapy: Of the 19 patients who required concomitant corticosteroids while on ROMI/ELT, 12 (63%) were able to discontinue steroids, 6 (32%) reduced steroid dose, and none increased steroid dose after switching to AVA. 15 patients (33%) required rescue in the year prior to switching versus 9 (20%) following the switch; this included 4 patients who had also required rescue on ROMI/ELT and 5 who had not previously required rescue. 11 patients requiring rescue on ROMI/ELT did not require rescue after the switch to AVA.
AVA Discontinuation: 7 patients (16%) discontinued AVA, including 2 patients (4%) for adverse events (headache, portal vein thrombosis), 1 (2%) for lack of response, 1 for patient preference, 1 for achievement of remission, 1 for transition to rituximab to treat concomitant hemolytic anemia (patient with Evans syndrome), and 1 due to lack of the medication on a formulary.

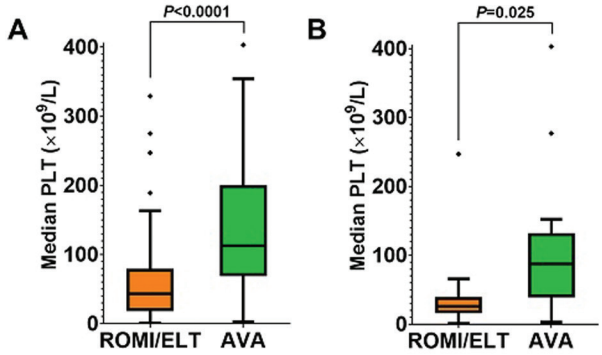

Figure. Median platelet counts for each patient prior to switch (during treatment with romiplostim or eltrombopag) vs. following the switch to avatrombopag. For each patient, the median platelet count is the median of the most recent 3 platelet counts measured while receiving that agent. **(A)** All patients (N=45). **(B)** Patients switched due to ineffectiveness of romiplostim or eltrombopag (N=14). One patient with median Plt 585×10^9/L on avatrombopag omitted from both graphs to preserve graph resolution.

Summary/Conclusion: In a heavily pretreated chronic ITP population, AVA was effective following therapy with ROMI/ELT, with high response rates even in patients with inadequate response to a prior TPO-RA.

EP1145 EPIDEMIOLOGY, TREATMENT PATTERNS, AND CLINICAL OUTCOMES AMONG PATIENTS WITH ACQUIRED THROMBOTIC THROMBOCYTOPENIC PURPURA (ATTP) IN THE UNITED STATES: AN ELECTRONIC HEALTH RECORDS ANALYSIS

A. Adeyemi [1,*], F. Callewaert [2], F. Razakariasa [3], R. de Passos Sousa [4]

[1]Sanofi, Cambridge, United States, [2]Sanofi, Diegem, Belgium, [3]Quinten France, Paris, France, [4]Sanofi, Lisbon, Portugal

Background: aTTP is an ultra-rare and potentially life-threatening thrombotic microangiopathy (TMA). Owing to the rarity of the disease, data on epidemiology, disease management, and clinical outcomes are scarce and often heterogeneous.
Aims: To assess the epidemiology, disease management, and clinical outcomes in patients with aTTP.
Methods: A longitudinal, retrospective observational study identified patients with an aTTP diagnosis from October 2015 to December 2019 in the Optum-Humedica database. Patients were eligible if they had ≥1 documented ADAMTS13 (a disintegrin and metalloproteinase with a thrombospondin type 1 motif, member 13) test result <10% or ≥1 aTTP episode, defined as having ≥1 inpatient stay with an International Classification of Diseases (ICD) diagnosis of TMA (ICD, Ninth Revision [ICD-9], dx: 446.6; ICD, Tenth Revision [ICD-10], dx: M31.1) and ≥1 therapeutic plasma exchange (TPE) procedure (Current Procedural Terminology-4 code: 36514; ICD-10: 6A551Z3) during the same

inpatient stay. Patients with a diagnosis of hemolytic uremic syndrome, *Escherichia coli* infection, human immunodeficiency virus, organ/stem cell transplant, systemic infection, and malignancy ≤6 months before or at index date were excluded. Index date was defined as the date of the earliest occurrence of an ADAMTS13 test result <10% or first TMA+TPE-related hospitalization during the study period. Index aTTP episode was defined as the first occurrence of TMA+TPE-related hospitalization. Patients were followed from the index date until the loss to follow-up, end of study period, or death, whichever occurred first. Incidence of aTTP, demographic, and clinical characteristics of patients, treatment patterns, and clinical outcomes were descriptively analyzed.

Results: A total of 666 patients met inclusion criteria for aTTP diagnosis. Among these, 302 (45%) patients had ≥1 reported aTTP episode (TMA+TPE-related hospitalization). Patient demographics are summarized in the **Table**. The annual proportion of patients with documented aTTP (ADAMTS13 <10% or an aTTP episode) was 3.43/million, while the annual incidence of ≥1 aTTP episode was 1.81/million (averaged over 2016–2019).

Patients with ≥1 aTTP episode received a mean of 16.7 TPE sessions (standard deviation, 22.3); 86%, 59%, and 7% of patients received corticosteroids, rituximab, and other immunosuppressant treatments, respectively. The therapies received among all patients with aTTP diagnosis are summarized in the **Table**.

Exacerbations (rehospitalizations for TPE within the first 30 days following discharge for any aTTP episode) occurred in 17% (52/302) of patients with ≥1 episode. Relapse (new aTTP episode >30 days after discharge for the index episode) was reported in 11% (34/302) of these patients.

Mortality rate during follow-up among all patients with aTTP diagnosis was 25% (167/666), with 77% (129/167) of deaths occurring within 6 months of the index date. For patients with ≥1 aTTP episode, 14% (41/302) died, with 51% (21/41) of deaths occurring within 45 days of the index episode. Among all patients with aTTP diagnosis, 21% (139/666) of patients had ≥1 thromboembolic event (TE); of 193 total TEs reported, the most common were cerebral infarction (CI [55%]) and myocardial infarction (MI [19%]). For patients with ≥1 aTTP episode, 34% (103/302) had ≥1 TE; of the 152 TEs reported, CI (51%) and MI (21%) were the most common (**Table**).

Table. Demographics, treatment patterns, and clinical outcomes of patients with aTTP in the post-index period

	All patients with aTTP diagnosis (n=666)	Patients with ≥1 aTTP episode (n=302)
Demographic characteristics		
Mean (SD) age, years	49.2 (18.7)	46.2 (16.2)
Females, n (%)	421 (63)	219 (73)
Race, n (%)		
Caucasian	380 (57)	150 (50)
African American	214 (32)	116 (38)
Asian	10 (2)	5 (2)
Other or unknown	62 (9)	31 (10)
Mean (SD) BMI, kg/m^2	29.1 (7.0)	30.2 (6.7)
Treatments received		
TPE, n (%)	329 (49)	302 (100)
Mean (SD) number of TPE per patient	15.9 (21.7)	16.7 (22.3)
Corticosteroids, n (%)	406 (61)	260 (86)
Rituximab, n (%)	210 (32)	178 (59)
Other immunosuppressant medications, n (%)	14 (2)	10 (3)
Outcomes		
Exacerbation, n (%)	N/A	52 (17)
Relapse, n (%)	N/A	34 (11)
Number of patients with ≥1 TE event, %	139 (21)	103 (34)
Total number of TEs, %	193	152
TE type, n (%; of total number of TEs)		
Arterial embolism	7 (4)	7 (5)
Cerebral infarction	106 (55)	77 (51)
Deep vein thrombosis	2 (1)	2 (1)
Mesenteric vein embolism	1 (1)	1 (1)
Myocardial infarction	37 (19)	32 (21)
Portal vein obstruction	5 (3)	4 (3)
Pulmonary embolism	15 (8)	12 (8)
Vascular syndromes	20 (10)	17 (11)
Number of deaths (%)	167 (25)	41 (14)
Time of death, n (%; of total number of deaths)		
Within 45 days of index aTTP episode	21 (13)	21 (51)
0–6 months from the index date	129 (77)	29 (71)

aTTP, acquired thrombotic thrombocytopenic purpura; BMI, body mass index; N/A, not applicable; TE, thromboembolic event; TPE, therapeutic plasma exchange.

Summary/Conclusion: Despite treatment with TPE and immunosuppressants, the high mortality and morbidity observed in this patient population demonstrates the need for more effective therapies to improve clinical outcomes.

EP1146 STYDY OF FAS, CASPASE-8 (CASP8) AND -10 (CASP10) POLYMORPHISMS IN CHILDREN AND ADOLESCENTS WITH IMMUNE THROMBOCYTOPENIA

E.-D. Ampazoglou [1,*], M. Lourou [1], M. Zervou [2], I. Pelagiadis [1], N. Katzilakis [1], G. Goulielmos [2], E. Stiakaki [1]

[1]Pediatric Hematology-Oncology, School of Medicine University of Crete, University Hospital of Heraklion, [2]Molecular Pathology and Human Genetics Section, School of Medicine, University of Crete, Heraklion, Greece

Background: Immune thrombocytopenia (ITP) is a relatively common acquired bleeding disorder in childhood. ITP is characterized by a low circulating platelet count due to the production of autoantibodies against platelet glycoproteins, followed by their destruction via the reticuloendothelial system. Apoptosis is a physiologic mechanism of programmed cell death, crucial for controlling the cell number during development and for the entire lifespan of an organism. Deregulation of the apoptosis signalling may compromise the homeostasis of an organism and cause a wide range of diseases. Fas is a transmembrane molecule belonging to the tumor necrosis factor (TNF) receptor superfamily. Fas ligation by FasL induces programmed cell death in several lymphoid cell lines and may play a role in immune response control, lymphocyte life span regulation and induction of peripheral tolerance. Caspases are cysteine proteases that play a central role in apoptosis. Caspase-8 and caspase-10 are the first enzymes in the proteolytic cascade that are activated by Fas ligand and TNF. According to the literature, mutations in either CASP8 or CASP10 influence immune surveillance of malignancies and cause lymphoproliferation (ALPS).

Aims: The aim of this study was to identify whether polymorphisms of FAS, CASP8 and CASP10 play a role in the pathophysiology of ITP in children and adolescents.

Methods: In this study 30 children and adolescents with ITP and 60 healthy individuals as control group were included. At first, extraction of the DNA from peripheral blood cells was performed and then analysed by PCR. The PCR was followed by digestion using selected restricted enzymes in order to genotype individuals for the SNPs under study. For the *FAS* (rs2234767) and *CASP8* (rs1045485), the restriction enzyme *BstU*I was applied while for the *CASP10* (rs13006529), the enzyme *Ssp*I. Digestion products were analysed by agarose gel electrophoresis and statistical analysis was performed using the GraphPad Prism (GraphPad Software, San Diego, CA, USA) program.

Results: Statistical analysis of data showed that allele T of *CASP10* rs13006529 SNP was associated with the diagnosis of ITP. However, no association for the studied SNPs of *FAS* and *CASP8* genes was detected.

Summary/Conclusion: Allele T of *CASP10* rs13006529 SNP appeared has a statistically significant difference between patients and controls, thus suggesting its role in the development of ITP. Its effect may be related to the role of caspase 10 in the endogenous pathway of apoptosis as well as its involvement in the process of autophagy. As regards with the *FAS* (rs2234767) and *CASP8* (rs1045485) SNPs no association with ITP was observed. However, these results are considered as early due to the small number of samples examined. Further analysis of a higher number of samples is needed in order to clarify the role of the SNPs under study in children and adolescents with ITP.

EP1147 DARATUMUMAB, AN ORIGINAL APPROACH FOR TREATING REFRACTORY AUTOIMMUNE CYTOPENIA

E. Crickx [1,*], S. Audia [2], A. Robbins [3], D. Boutboul [4], T. Comont [5], M. Cheminant [6], E. Oksenhendler [4], B. Godeau [1], M. Michel [1], M. Mahevas [1]

[1]Service de Médecine Interne, Centre national de référence des cytopénies auto-immunes de l'adulte, Hôpital Henri Mondor, APHP, Creteil, [2]Service de Médecine Interne et d'Immunologie Clinique, Hôpital François Mitterrand, CHU de Dijon, Dijon, [3]Service de médecine interne, CHU de Reims, Reims, [4]Service d'Immunologie Clinique, Hôpital Saint Louis, APHP, Paris, [5]Service de Médecine Interne et Immunopathologie, Institut Universitaire du Cancer Toulouse – Oncopôle, Toulouse, [6]Service d'hématologie, hôpital Necker, APHP, Paris, France

Background: Patients with autoimmune cytopenias failing first- or second-line treatments have an increased morbidity and mortality, and therapeutic alternatives are needed. Daratumumab, an anti-CD38 monoclonal antibody developed for multiple myeloma, could target long-lived autoreactive plasma cells.
Aims: The aim of the study was to assess safety and efficacy of daratumumab given for refractory autoimmune cytopenias.
Methods: We conducted an observational, retrospective, multicenter study throughout the network of the French reference center for adult' immune cytopenias including patients receiving compassionate off-label treatment by daratumumab for either refractory immune thrombocytopenia (ITP) or warm autoimmune hemolytic anemia (wAIHA) between 2020 and 2021. Response was assessed according to international criteria. Patients who required any other treatment more than six weeks after first daratumumab infusion were considered non-responders.
Results: Eight patients (5 female) with a median age of 45 years [range 34-70] were included in the study. Treatment by daratumumab was given for ITP (5 patients), wAIHA (2 patients), and acquired Glanzmann thrombastenia complicating ITP (1 patient) with a median disease duration of 84.5 months [range 18-174]. Five patients had underlying Evans syndrome and one patient had ITP secondary to antiphospholipid syndrome. Five patients were splenectomized and all 8 patients failed to respond to rituximab (median time from last infusion of 11 months [3-98]). Patients received a median number of 6 [range 4-11] weekly infusions of daratumumab at 16mg/kg of body weight with dexamethasone premedication.
Median follow up after daratumumab was 6 months [range 3-9]. Three patients had a minor reaction at first daratumumab infusion. Two patients had infectious events during follow up (one bacterial pneumonia and one COVID-19 pneumonia). After exclusion of 2 patients who received regular intravenous immunoglobulin, hypogammaglobulinemia (i.e., gammaglobulins <6g/L) was observed in 5/6 patients. Median concentration of gammaglobulins was 7.1 g/L [4.8-16.2] before treatment, versus 4.2 g/L [3.5-7.6] at 3 months and 6.1g/L [6-15.5] at 9 months.
Five patients were given daratumumab for ITP with low platelet counts (median 11 x10^9/L, [range 0-21]). Two achieved a CR after respectively 3 and 4 infusions, including one of who relapsed after 3 months. Anti-β2GP1 antibodies and lupus anticoagulant disappeared upon treatment in the patient with antiphospholipid syndrome. Another steroid dependent patient required a transient increase in corticosteroid doses one month after daratumumab, but with a definite weaning at 6 months. The remaining 2 patients had no response.
Two patients had wAIHA and a positive IgG DAT (no C3). One patient received 4 daratumumab infusions associated with corticosteroids tapered during 6 weeks, resulting in a CR that lasted 9 months. The other patient had no response. Daratumumab had no clinical efficacy in the patient with an ITP that had acquired Glanzmann thrombastenia with bleeding symptoms despite normal platelet counts.
Summary/Conclusion: Overall, these data suggest that daratumumab may be effective in a subset of patients with autoimmune cytopenia refractory to standard therapy. The response appears transient as some patients with CR eventually relapsed during the follow-up. As most patients experienced transient hypogammaglobulinemia, the risk of infection should be weighted in the therapeutic decision. Prospective studies are needed to confirm these preliminary data.

EP1148 DURABILITY OF PLATELET COUNT RESPONSE IN PATIENTS TREATED WITH AVATROMBOPAG FOR IMMUNE THROMBOCYTOPENIA (ITP): POST-HOC RESULTS FROM THE PHASE 3 CORE AND OPEN-LABEL EXTENSION STUDY

S. Jain [1], M. Wojdyla [2], C. Bernheisel [2], S. Kolodny [2], M. Vredenburg [2,*], T. Gernsheimer [3]

[1]Department of Hematology/Oncology, Rush University Medical Center, Chicago, [2]Dova Pharmaceuticals, Durham, [3]Department of Hematology, University of Washington, Seattle, United States

Background: The clinical management of ITP has been evolving. Thrombopoietin receptor agonists (TPO-RAs) have become widely utilized as second-line treatments, and the 2019 ASH guidelines recommend their use over rituximab to achieve a durable response. Avatrombopag (AVA) is an oral TPO-RA approved in 2019 for patients (Pts) with ITP. A high proportion of Pts (~90%) respond to AVA; but limited information is available regarding the durability of response over time utilizing clinically relevant loss of response (LOR) definitions.
Aims: To understand the time it took Pts to experience their first LOR and the overall percent of treatment days a response level platelet (PC) was achieved.
Methods: A Phase 3 study (NCT01438840) enrolled 32 AVA and 17 placebo-treated (PBO) Pts with ITP. The core study design included a 6-week study drug titration period, 12-week concomitant ITP medication reduction period, and an 8-week maintenance period. Subjects who completed the maintenance phase of the core or discontinued early because of lack of treatment effect were eligible for the Extension Phase. These Pts all received open-label 20 mg AVA once daily and underwent a 6-week conversion period, and a 90-week maintenance period.
For this post-hoc analysis, we assessed how many days it took for Pts randomized to AVA who responded in the Core and continued into the extension to experience their first LOR or reach study conclusion. After the initial PC ≥50,000/μL was noted, we also examined the percentage of remaining treatment time that initial response was maintained.
Response was defined as the first time achieving a PC ≥50,000/μL. LOR was defined as a Pt experiencing a PC <30,000/μL for 4 consecutive weeks (LOR-4wk), or in a more conservative manner, Pts experiencing a PC <30,000/μL on 2 consecutive scheduled visits (LOR-2vis). During the Core, visits were weekly or biweekly depending on the phase of the study with 21 visits occurring over 26 weeks. In the Extension, visits were every 3-4 days, weekly, bi-weekly, or monthly depending on the phase with 31 planned over 96 weeks. The protocol was amended to end the study on 3/10/2014 when the last patient exited the Core Study.
When a LOR was observed, the date of the first PC <30,000/μL was used for subsequent calculations with a return of response defined as a PC exceeding ≥30,000/μL again. Pts who required rescue therapy (n=4) were included in the analyses and the first date of administration was used for the LOR date. Pts requiring corticosteroids (n=3) as rescue therapy were considered non-responders for a minimum of 8 weeks and Pts receiving a platelet transfusion (n=1) for a minimum of 1 week.
Results: 32 Pts were randomized to AVA, 29 responded, and 21 continued into the Extension Phase and were evaluated here.
61.9% (13/21) and 42.9% (9/21) of AVA-responsive Pts never experienced a LOR-4wk or LOR-2vis, respectively. The average number of months until all Pts experienced their first LOR-4wk, discontinued, or completed the study was 8.2 months (median 9.4) and 6.9 months (median 4.8) for the LOR-2vis analysis. Pts maintained their initial response on average for 83.5% (median 100%) of their remaining time in the study for LOR-4wk and for 79.3% (median 100%) in the LOR-2vis analyses (Table 1).

Table 1: Durability of Initial Avatrombopag Response

	Months Patient in Core + Extension From 1st PC ≥ 50	Months Until 1st Loss of Response	% of Time with Response
4 Consecutive Weeks <30 = Loss of Response			
ALL PATIENTS (n=21)			
Mean (SD)	11.2 (2.9)	8.2 (5.0)	83.5% (26.7)
Median (min, max)	10.8 (6.2, 16.8)	9.4 (0.5, 16.8)	100% (11.0, 100)
NO RESCUE ONLY (n=17)			
Mean (SD)	11.2 (2.8)	9.6 (4.5)	90.8% (20.1%)
Median (min, max)	10.8 (6.2, 16.8)	10.4 (0.5, 16.8)	100% (31.4, 100)
RESCUE ONLY (n=4)			
Mean (SD)	11.1 (3.3)	2.2 (1.7)	52.6% (29.0)
Median (min, max)	11.3 (7.1, 14.7)	1.6 (0.5, 5.1)	57.0% (11.0, 85.3)
2 Consecutive Scheduled Visits <30 = Loss of Response			
ALL PATIENTS (n=21)			
Mean (SD)	11.2 (2.9)	6.9 (5.5)	79.3% (27.5)
Median (min, max)	10.8 (6.2, 16.8)	4.8 (0.5, 16.8)	93.6% (11.0, 100)
NO RESCUE ONLY (n=17)			
Mean (SD)	11.2 (2.8)	8.0 (5.5)	86.6% (22.5%)
Median (min, max)	10.8 (6.2, 16.8)	10.4 (0.5, 16.8)	100% (18.6, 100)
RESCUE ONLY (n=4)			
Mean (SD)	11.1 (3.3)	2.0 (1.4)	48.4% (25.1)
Median (min, max)	11.3 (7.1, 14.7)	1.6 (0.5, 4.4)	52.8% (11.0, 76.9)

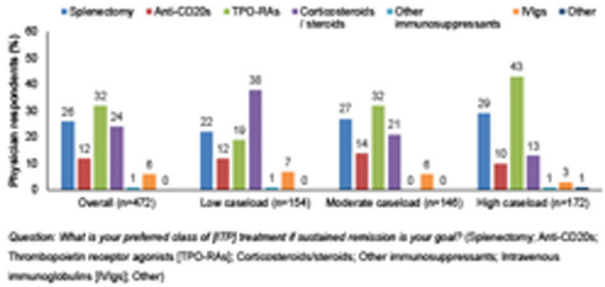
Summary/Conclusion: These data suggest that the initial response to AVA is durable, with up to 62% of Pts never experiencing a LOR in the core or extension, and stable with Pts maintaining a response on average for up to 84% of the time despite the planned objective of reducing concomitant medications and required AVA starting dose in the extension.

EP1149 SERUM COMPLEMENT LEVELS IN IMMUNE THROMBOCYTOPENIA: RELATION WITH CLINICAL PRESENTATION AND TREATMENT RESPONSE.

S. Pérez -León [1,*], B. Galmés [1], G. Puguet [1], M. Canaro [1]

[1]*Hematology, Son Espases University Hospital, Palma de Mallorca, Spain*

Background: The complement system activation is one of the mechanisms behind platelet destruction in immune thrombocytopenia, but its role in the clinical setting is still limited.
Aims: Characterized C3, C4, and CH50 levels from ITP patients and its relation with the clinical presentation and treatment response.
Methods: A retrospective observational study in a teaching hospital with specific ITP outpatient consults. Complement levels were measured in any moment of the disease course through turbidimetric immunoassays. The relations between complements levels and characteristics of the disease and the response to treatments were evaluated with regression analysis
Results: Forty-three ITP patients with complement C3, C4, CH50 were included. Medium age was 44 years (16.99). In the moment when complement levels were measured 70% of patients were not receiving any treatment. There were 16% of previously splenectomized patients. Medium C3: 103,5 (34-28), medium C4: 14,5 (4-171), with 75% of the patients with levels of C4 below the normal range. Medium CH50 49 (12-95). Not responders to first line treatment had lower C3 levels (p: 0,018). Patients receiving treatment had lower mean C4 (p: 0,039) and lower C3 (p: 0,065). In multivariable analyses patients receiving TPO agonist had lower levels of C3, C4, and CH50 (p: 0,024; 0,019 y 0,054). There were no relation between complement level and severity of bleeding, refractory disease or splenectomy status.
Summary/Conclusion: ITP patients had lower levels of C4, especially those on active treatment. Patients not responders to first line treatments had lower levels of C3. Those on treatment with thrombopoietin receptor agonists had lower levels of C3,C4, y CH50. Further prospective studies are needed to evaluate the role of complement in the current clinical practice and with the emergent complement- directed therapies.



EP1150 GEOGRAPHIC DISTRIBUTION OF PATIENT AND PHYSICIAN ITP TREATMENT PREFERENCES AND EFFECT OF PHYSICIAN CASELOAD ON TREATMENT PRACTICES: RESULTS FROM THE ITP WORLD IMPACT SURVEY (I-WISH)

N. Cooper [1,*], C. Kruse [2], M. Michel [3], T. Bailey [4], J. Haenig [5], J. B. Bussel [6]

[1]*Hammersmith Hospital, Imperial College London, London, United Kingdom,* [2]*Platelet Disorder Support Association, Cleveland, United States,* [3]*Henri Mondor University Hospital, Créteil, France,* [4]*Adelphi Real World, Bollington, United Kingdom,* [5]*Novartis Pharma AG, Basel, Switzerland,* [6]*Division of Hematology/Oncology, Weill Cornell Medical College, New York, United States*

Background: American Society of Hematology 2019 guidelines for immune thrombocytopenia (ITP) recommend considering individual patient (pt) preference when selecting second-line therapy in adults with ITP. We previously reported pts' and physicians' (MDs') perspectives on ITP treatments (txs) across all countries included in the ITP World Impact Survey (I-WISh), which examined ITP's burden and impact on quality of life (QoL). A better understanding of the geographic differences in pts' and MDs' tx preferences and the effects of MD caseload may reveal areas in which additional discussion and education might be beneficial.
Aims: Using I-WISh data, define the geographic distribution of pt and MD tx preferences and the effect of MDs' ITP caseload on their tx practices and attitudes.
Methods: I-WISh was an exploratory, cross-sectional 30-minute survey of 1507 pts with ITP and 472 ITP-treating MDs conducted in 13 countries (Dec 2017-Aug 2018). Pts were recruited via MDs and pt advocacy groups (PAGs). A steering group of expert ITP clinicians and PAG leads developed the survey. Pts' and MDs' preferences on tx modalities were evaluated through responses to specific questions. MD caseload was defined as 'low' (≤10 pts currently treated), 'medium' (11-29), or 'high' (≥30). Differences in responses between 'low' and 'high' caseload status were considered meaningful if they differed by >10 percentage points.
Results: Mean pt age was 47 years; 65% were female. MDs had a mean caseload of 34 current pts with ITP; MDs with 'low', 'moderate', and 'high' caseload status had mean caseloads of 7, 19, and 70 current pts with ITP, respectively.
Most pts (90%; n=1360/1507) had a preference for orally administered ITP txs (once [83%] or twice [7%] daily) over an injection; pt preference for oral ITP tx was >85% in countries excluding France (80%), Turkey (77%), and Germany (70%). MDs' (first-choice) preference for orally administered ITP txs (versus subcutaneous [SC] or intravenous [IV] tx) was broadly aligned with that of pts, and was selected by 77% of all MDs (n=365/472).
There were distinct geographical differences in MDs' preferred ITP txs when pursuing a tx goal of 'sustained remission': splenectomy was the preferred tx class in Canada (70%), Colombia (48%), and the USA (36%); corticosteroids (CSs) in China (56%) and India (33%); and thrombopoietin-receptor agonists (TPO-RAs) in Egypt (70%), Turkey (57%), the UK (55%), Spain (48%), Italy (43%), France (41%), Japan (39%), and Germany (27%).
For pts with persistent/chronic/recurrent ITP, MDs' first-choice preference for oral (vs SC or IV) ITP tx appeared to increase with rising caseload ('low', 'moderate', and 'high' caseload: 68%, 77%, and 87%, respectively). As MDs' caseload increased, shifts in the preferred tx class for the goal of 'sustained remission' were also seen; preference for TPO-RAs increased (19%→43%) whereas CSs decreased (38%→13%).TPO-RAs were the overall preferred tx class (Fig. 1).

Figure 1. Physicians' preferred immune thrombocytopenia (ITP) treatment class if 'sustained remission' is the goal (overall and by caseload status)

Question: What is your preferred class of [ITP] treatment if sustained remission is your goal? (Splenectomy; Anti-CD20s; Thrombopoietin receptor agonists [TPO-RAs]; Corticosteroids/steroids; Other immunosuppressants; Intravenous immunoglobulins [IVIgs]; Other)

Summary/Conclusion: Both pts and MDs appeared to demonstrate a preference for oral ITP txs over an injection (SC/IV) option, with some geographic differences in preferences. There were also apparent shifts in MD tx preferences with changes in ITP caseload in approaching sustained clinical remission. An important limitation was question phraseology, which did not include factors such as substantial dietary restrictions for oral medications. Also, country sample sizes varied, and data were collected prior to the COVID-19 pandemic: tx preferences may have changed subsequently. Nonetheless, these findings warrant confirmation.

EP1151 LENGTH OF THROMBOPOIETIN RECEPTOR AGONIST (TPO-RA) TREATMENT AND PERSISTENCE IN IMMUNE THROMBOCYTOPENIA (ITP): REAL WORLD UNITED STATES CLAIMS ANALYSES

M. Vredenburg [1,*], S. Kolodny [1], M. Wojdyla [1], T. Darden [1], H. Boyer [1]

[1]*Dova Pharmaceuticals, Durham, United States*

Background: The recent ASH Guidelines[1] and International Consensus Report[2] for the management of ITP suggest consideration of TPO-RAs as subsequent therapy following an insufficient response to first-line treatments, especially if seeking a durable platelet response. Avatrombopag (AVA), a TPO-RA which was FDA approved in 2019, also recently received EMA approval for adults suffering with chronic ITP. AVA is orally-administered, does not have food type restrictions, nor carry a boxed warning for hepatoxicity or requires liver function monitoring.
Aims: To understand length of therapy (LOT) and persistence (PER) of treatment in adult ITP patients in US, treated with an FDA-approved TPO-RA (AVA, eltrombopag (ELT) or romiplostim (ROMI).
Methods: The Symphony Health Claims Database[3] was used to understand LOT and PER for ELT and ROMI in US adult ITP patients. Claims data were evaluated and inclusion in the analyses required a D69.3 or D69.49 ICD-10 diagnostic code for ITP, and ≥ 1 first-initiated claim for ELT or ROMI during the 2019 calendar year. Due to AVA claims not being available in the Symphony Database, data from a closed system of specialty pharmacies (CVS, Accredo, Biologics, Kroger, PharmaCord, Panther) accounting for ~78% of AVA prescriptions were used. Adult patients with a D69.3 or D69.49 diagnostic code, receiving ≥ 1 initial shipment of AVA from August 2019 through December 2019 were included in the evaluation, with LOT and PER calculated over the first 365 days following initial shipment of AVA from the specialty pharmacy. Days of supply were considered to be 7 days per administration for ROMI and were provided specifically in each claim for ELT, with no cap on supply. Days of supply for AVA were provided by the pharmacy with a maximum of 90 days per shipment.
LOT for each TPO-RA was determined by calculating the time between the first claim/shipment date and the last claim/shipment date, while adding on the number of days of supply provided in the last claim/shipment (e.g. 30 day supply).
PER for each TPO-RA were determined by claims occurring in specific months (e.g. a patient with a claim on January 31st and another on February 1st would have 2 months of persistence). For each therapy, gaps in claims/shipments were allowed, with no max duration between data points. Unlike LOT, PER did not add the number of days of supply to the last evaluable claim/shipment.
Results: LOT and PER for AVA, ELT and ROMI are shown below (Table 1). 171 unique AVA patients were captured via specialty pharmacy data, while 1,400 ELT and 1,283 ROMI patients had evaluable claims. LOT was highest in AVA patients, regardless of whether a conservative single claim/shipment, or ≥ 2 claims/shipments were used for inclusion, with a max of 9.3 months of therapy administered over a potential max 12-month time frame. PER for each individual month reached was highest for AVA, with the median AVA patient reaching 10 months of treatment.

Table 1: Length of Therapy (LOT) and Persistence of Treatment (PER) for TPO-RAs in Adult ITP

Length of Therapy (LOT)		
TPO-RA	Months of Therapy (1 claim/shipment)	Months of Therapy (2+ claims/shipments)
AVA (n=171)	7.7	9.3
ELT (n=1,400)	6.5	8.2
ROMI (n=1,283)	5.5	6.4

Persistence of Treatment (PER)												
	Proportion (%) of Patients by Month Reached											
TPO-RA	1	2	3	4	5	6	7	8	9	10	11	12
AVA (n=171)	100	80	71	66	63	60	57	56	52	51	47	43
ELT (n=1,400)	100	75	66	60	55	50	47	43	40	37	34	29
ROMI (n=1,283)	100	78	63	55	51	46	42	38	35	32	30	28

References:

1. Neunert C, et al. *Blood Adv*. 2019;3(23):3829-66.
2. Provan D, et al. *Blood Adv*. 2019;3(23):3780-3817.
3. Symphony Health, PatientSource®, January 2018 – December 2020.

Summary/Conclusion: These data suggest that AVA has greater length of treatment and higher rates of persistence than other TPO-RAs, which may be due to a variety of variables including 1) route of administration, 2) convenience, 3) patient preference, 4) efficacy, 5) side effects, 6) insurance coverage. These results should be interpreted with caution. Claims data using matched methodologies were utilized to calculate LOT and PER for each TPO-RA, however due to AVA's commercial availability occurring in July 2019, slightly different time frames were evaluated. Also, different sources of data capture were necessary due to lack of a consistent source.

EP1152 IMMUNE THROMBOCYTOPENIA DURING COVID-19 PANDEMIC: AN ITALIAN MONOCENTRIC EXPERIENCE

G. Lapietra [1,*], A. Ferretti [1], E. Baldacci [1], M. L. De Luca [1], S. M. Aprile [1], F. Barone [1], S. Olivieri [1], A. Chistolini [1], C. Santoro [1]

[1]*Hematology, Translational and Precision Medicine, Sapienza, University of Rome-Policlinico Umberto I, Rome, Italy*

Background: Immune thrombocytopenia (ITP) is an acquired immune disorder characterised by a platelet count < $100x10^9$/L, leading to an increased bleeding risk. Infectious diseases, especially from viral agents, may potentially cause ITP. Since the novel pandemic caused by severe acute respiratory syndrome coronavirus-2(SARS-CoV2), known as COVID-19, has started in February 2020, different cases of ITP in patients affected by SARS-CoV2 have been reported. The management of COVID-19 in patients with simultaneous or previous ITP can be challenging because of the great involvement of the haemostatic system in this viral infection.
Aims: To describe the management and outcome of patients with newly diagnosed (ND), chronic and previous ITP, infected by COVID-19.
Methods: Data were collected from clinical charts and updated through telephone contacts. All patients expressed their agreement to participate to the study.
Results: Seventeen patients had RT-PCR confirmed SARS-CoV2 infection on a nasopharyngeal swab (October 2020-January 2021). Six patients were male (35.3%) and 11 female (64.7%). The median age was 57 years (range 30-90). At the time of the COVID-19 infection, as regards ITP, patients were grouped as follows: 3 had simultaneous ND ITP (17.6%) and 1 experienced a relapse (5.8%) (median platelet count $5.5x10^9$/L; range 2-$30x10^9$/L); 7 had chronic ITP on treatment (41.2%) (eltrombopag, n=5; romiplostim, n=1; prednisone, n=1) and 2 patients had stable chronic ITP off-therapy (11.8%) (median platelet count $63x10^9$/L; range 30-$100x10^9$/L); 4 patients had a previous ITP on follow-up (FU) (23.6%) (platelet count >$100x10^9$/L). Fever, anosmia, dysgeusia, articular pain and mild-to-moderate respiratory distress were considered typically COVID19-related symptoms. Overall, 15 patients were symptomatic: 11 had only COVID19-related symptoms (64.8%), 1 presented with isolated mucocutaneous bleeding (5.8%) and 3 reported both (17.6%). Two patients did not refer any symptoms throughout the course of the infection (11.8%). Six cases required hospitalization (35.3%): 3 for acute decrease of platelet count and bleeding symptoms (17.6%) (ND ITP=2; ITP relapse=1); 3 for pneumonia (17.6%) (ND ITP=1; chronic ITP on treatment=1; ITP on FU=1). Patients with bleeding symptoms were responsive to dexamethasone (40 mg/day, days 1-4) and immunoglobulins (1 g/kg). Patients with pneumonia were successfully treated with antibiotics and oral corticosteroids. The median duration of stay in the hospital was 10.5 days (range 3-20). Eleven patients recovered at home without any bleeding; they did not show any significant change in the platelet count at the first evaluation after quarantine (64.7%). Twelve patients had previously received either steroids (n=8) or steroid+splenectomy (n=4) (70.5%). Serious respiratory distress, requiring mechanic ventilation, was not recorded. Anti-thrombotic prophylaxis of COVID-related thromboembolism was not used and no cases of thrombosis were observed. The viral seroconversion was observed in all patients and no death occurred.
Summary/Conclusion: In our experience, ND ITP triggered by COVID-19 has been responsive to immunoglobulins and steroids. Overall outcome has been favourable also for COVID-19 patients with a stable off-therapy or on treatment ITP.

EP1153 IMPACT OF AUTOIMMUNE ANTIBODIES IN PATIENTS WITH PRIMARY IMMUNE THROMBOCYTOPENIA: REAL WORLD RETROSPECTIVE STUDY FROM THE ITP REGISTRY OF THE HELLENIC SOCIETY OF HEMATOLOGY

Background: Background: Previous reports have suggested an increased frequency of autoantibodies (AutoAbs) in patients (pts) with ITP. However, the features of those ITP pts bearing AutoAbs have not been fully elucidated thus far.
Aims: Aims: To describe real world characteristics at diagnosis and evaluate disease outcome in pts with primary ITP and elevated at least one of antinuclear antibodies (ANA), rheumatoid factor (RF), antiphospholipid (APL) Abs or antithyroid Abs. Data from the national database (ITP registry) operated under the auspices of the Hellenic Society of Hematology was used.
Methods: Methods: The Greek ITP registry recruits pts (n=1514, to date) nationally through a network of 26 sites. In the present study we retrospectively analyzed data from pts with primary ITP aged over 18 years, who were diagnosed from 1979 to 2020
Results: Results: The total number of evaluable pts was 554. Pts were excluded from the study if they had a diagnosis of systemic lupus erythematosus, rheumatoid arthritis, thyroid disorder or antiphospholipid syndrome at the time of ITP initial presentation Of the 420 pts tested for ANA, 94 (22.4%) were positive with a titer of ≥ 1/160. There was no difference in age, sex or frequency of concurrently used medications between ANA^+ and ANA^- pts. However, the median platelet count at diagnosis was significantly lower in ANA^+ pts ($21.8x10^9$/L, interquartile range: 5.7-30.5x10^9/L; P=0.048) than in ANA^- pts ($28.2x10^9$/L, interquartile range: 8-43.3x10^9/L; P=0.048). Furthermore in ANA^+ pts epistaxis and oral cavity bleeding were more frequently observed than in ANA^- pts (P=0.0477 and P=0.0008; respectively). Of the 416 pts tested for RF, 20 (4.9%) were positive. RF^+ and RF^- pts had similar age and sex distribution as well as frequency of concurrently used medications and platelet counts at diagnosis. However, epistaxis and oral cavity bleeding were more frequently observed in RF^+ pts than in RF^- ones (P=0.021 and P=0.0445; respectively). Of the 208 pts tested for APL antibodies and of the 75 pts tested for antithyroid Abs, 24 (11.5%) and 19 (25%) were positive, respectively. Neither APL Ab^+ nor antithyroid Ab^+ pts had distinctive features in terms of age, sex, frequency of concurrently used medications platelet count at diagnosis or location of bleeding, as compared to APL Ab^- and antithyroid Ab^- pts, respectively. The frequency of antiplatelet Ab positivity, the overall response to treatment and the frequency of chronic ITP development did differ between positive and negative patients for any of the aforementioned autoimmune markers.
Summary/Conclusion: Summary/Conclusion: The presence of elevated ANA or RF characterizes ITP patients with distinct presentation. However neither response to treatment nor the development of chronic disease seems to be influenced by these autoAbs. On the other hand neither the presence of APL Abs nor antithyroid Abs did seems to affect the clinical profile of the pts. Additional studies are warranted to confirm our results and probe more deeply in the significance of autoimmune markers in ITP

EP1154 SLEEP HEALTH IN ADULTS WITH IMMUNE THROMBOCYTOPENIA: QUALITY OF LIFE DATA FROM THE PLATELET DISORDER SUPPORT ASSOCIATION (PDSA) PATIENT REGISTRY

J. DiRaimo [1,*], C. Kruse [1], D. Arnold [2], A. Kruse [1,3]

[1]Platelet Disorder Support Association, Cleveland, United States, [2]Department of Medicine, McMaster Centre for Transfusion Research, McMaster University and Canadian Blood Services, Hamilton, Canada, [3]Tulane University School of Medicine, New Orleans, United States

Background: While poor sleep health has been documented in several autoimmune diseases, it's never been evaluated in patients with immune thrombocytopenia (ITP), an autoimmune bleeding disorder. In this study, sleep health refers to participants' overall satisfaction with their sleep, sleep quality, effort it takes to fall asleep, and problems sleeping.
Aims: We reviewed data from the ITP Natural History Patient Registry on sleep health among adults with ITP to examine the extent of sleep disruption in ITP patients and whether overall sleep health is worse among those receiving treatment, particularly a corticosteroid.
Methods: Adults ≥18 years with ITP completed both a demographic and a Quality of Life (QoL) survey regarding their symptoms within the last seven days.
Results: Within the 310 respondents, 248 were female (80%), 260 from the USA (83%), 180 were employed (58%), 288 insured (93%), and 235 were under the age of 65 (76%, range 18-100 years). Overall, 249 (80%) reported they had problems sleeping, 217 (70%) reported they were not very satisfied with their sleep, 155 (50%) worried about falling asleep, and 180 (58%) reported difficulties falling asleep. When asked about the quality of their sleep, 162 (52%) reported fair/poor sleep quality and 244 (79%) indicated their sleep was restless. Only 100 (32%) respondents indicated their sleep was refreshing.
Of the 310 respondents, 129 (42%) were receiving treatment for ITP. Among those, 102 (79%) reported they had problems sleeping, 92 (71%) were not very satisfied with their sleep, 68 (53%) worried about falling asleep, and 80 (62%) reported difficulties falling asleep. When asked about the quality of their sleep, 72 (56%) reported fair/poor sleep quality and 107 (83%) indicated their sleep was restless. Only 40 (31%) respondents reported their sleep was refreshing. Sleep health was not significantly worse in the treatment group compared to the non-treatment group despite high levels of poor sleep health.
Within the 129 respondents on treatment, 30 (10%) were receiving corticosteroids. Among those, 28 (90%) reported problems sleeping, 25 (84%) were not very satisfied with their sleep, 19 (64%) worried about falling asleep, 22 (74%) reported difficulties falling asleep, 20 (67%) reported fair/poor quality of sleep, 28 (90%) reported restless sleeping, and 16 (53%) reported their sleep was refreshing. Corticosteroid users reported more problems sleeping than those receiving a non-corticosteroid treatment and this difference was significant (p=.033, p<.05). Corticosteroid users also reported more restless sleep compared to the 181 respondents not receiving any treatment and this difference was found to be significant (p=0.044, p<.05). No other significant differences in sleep health were identified between corticosteroid users and non-corticosteroid users, or between corticosteroid-users and those not receiving treatment.
Summary/Conclusion: Overall, adults with ITP reported high levels of poor sleep health above what is expected from general population data, particularly among those receiving corticosteroids. Certain elements of sleep health were significantly worse among corticosteroid users, whereas other elements did not appear to be related to treatment for ITP. These results could be due to the low sample of participants currently taking corticosteroids in the study. Further work is needed to understand

what additional factors aside from corticosteroids may be influencing poor sleep health in this patient population.

EP1155 ASSOCIATION OF IMMUNE THROMBOCYTOPENIA AND INFLAMMATORY BOWEL DISEASE IN CHILDREN

Background: Many extraintestinal autoimmune manifestations are reported in inflammatory bowel disease (IBD): Immune thrombocytopenia (ITP) can be associated: only a few patients are of pediatric age.
Aims: In this retrospective study we analyzed the largest series of children affected by both ITP and IBD. The coexistence of both diseases was investigated in children diagnosed from January 1th 2000 to December 31th 2019.
Methods: This retrospective study was designed by the Coagulation Defects Study Group of A.I.E.O.P. (Associazione Italiana Emato-Oncologia Pediatrica). Informed consent was obtained from the parents or the legal guardians of all patients. Clinical characteristics of both IBD and ITP, onset of disorders and patient's response to treatment were collected through a structured form sent to 55 Italian pediatric referring centers for hematological disorders. IBDs were classified as Crohn disease (CD), Ulcerative colitis (UC) and Inflammatory bowel *disease unclassified* (IBDU). ITP was defined as *newly diagnosed* (within 3 months from diagnosis), *persistent* (between 3 and 12 months from diagnosis) and *chronic* (cITP, lasting for more than 12 months). The ITP bleeding score was defined as *Type A: asymptomatic-paucisymptomatic ITP*, clinical symptoms ranging from no bleeding to few petechiae and some bruises without mucosal hemorrhages; *type B: intermediate ITP,* clinical picture with more petechiae, bruising and mucosal hemorrhages; *type C: severe ITP,* clinical picture with severe cutaneous and mucosal bleeding symptoms. As timing of diagnosis the patients were classified as: 1) *IBD first*: IBD was diagnosed before ITP; 2) *ITP first*: ITP was diagnosed before IBD; 3) *Simultaneous diagnosis*: the second disease (IBD or ITP) was diagnosed during hospitalization or initial ascertainment for the other disorder.
Results: Centers responded to the survey and reported the coexistence of IBD and ITP in 14 children. The most relevant clinical features of this cohort are shown in table I. The first diagnosis was ITP in 57.1% and IBD in 35.7% of patients: it was simultaneous in 7.1%. IBD was classified as UC (57.1%), CD (35.7%) and *IBDU* (7.1%). The bleeding score was A in 71.4% and B in 28.6% of patients. ITP turned to be persistent in 9/14 patients (64.3%) and chronic in 7/14 (50%). At ITP onset 4/14 of the patients (28.6%) were not treated (wait&see), 8/14 (57.1%) received iv immunoglobulin (IVIG) and 2/14 (14.3%) oral prednisone. Subsequent rescue therapies for ITP were attempted in 7 patients (50.0%). At the last follow up 5/14 patients (35.8%) were still presenting cITP and 3 patients were still on treatment. No therapy for ITP other than steroids had any effect on IBD and vice versa. Colectomy resulted in recovery from ITP in 1 of the 2 patients surgically treated. At the last FUP 35.8% of patients were still presenting cITP and 3 patients were still on treatment (with eltrombopag).

Table 1. Characteristics of study population

Sex (F%)	50%
IBD diagnosis (years, median)	8.4
ITP diagnosis (years, median)	7.6
Platelets (median) at ITP diagnosis	31,500/mmc
Familiarity for autoimmune diseases	28.6%
Extraintestinal disorders	28.6%
IBD type	UC: 57.1% CD: 35.7% IBDU: 7.1%
ITP score bleeding	score A: 71.4% score B: 28.6%
Timing of diagnosis	ITP first: 57.1% IBD first: 35.7% Simultaneous: 7.1%
Persistent ITP at 3 months	64.3%
Chronic ITP at 12 months	50.0%
Chronic ITP at last FUP	35.8%
First line therapy for ITP	IVIG: 57.1% Wait&see: 28.6% Oral prednisone: 14.3%
FUP from ITP diagnosis (median, years)	6.2
FUP from IBD diagnosis (median, years)	3.7

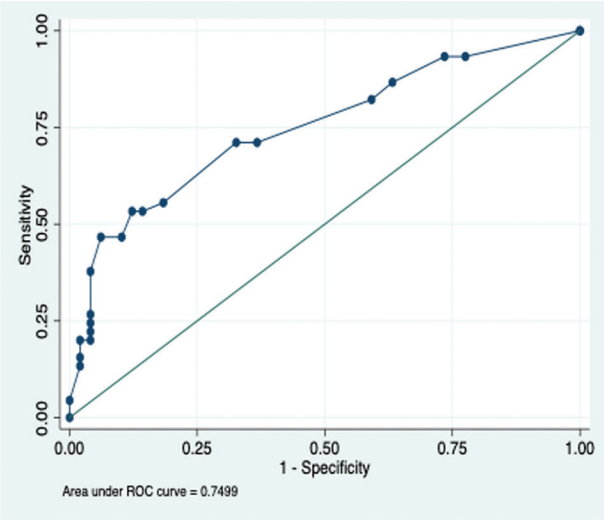
IBD: inflammatory bowel disease; ITP: immune thrombocytopenia; CD: Crohn disease; UC: Ulcerative colitis; IBDU: inflammatory bowel disease unclassified; FUP: Follow Up; IVIG: iv immunoglobulin.

Summary/Conclusion: We present the largest case series reported to date of children affected by both IBD and ITP. In all patients ITP was mild without any evident impact on IBD severity. It seems that UC is the type of IBD more commonly associated to ITP and that incidence of cITP (50%) is higher than what usually reported in pediatric age. Colectomy can occasionally result in ITP recovery and steroids can be effective in both diseases. Finally eltrombopag retains its high efficiency also in pediatric ITPs associated to IBD.

EP1156 DEVELOPMENT AND VALIDATION OF THE C-SCORE, A SCORE OF DIAGNOSIS A SEVERE THROMBOCYTOPENIA OR OTHER CYTOPENIAS IN HEPATIC CIRRHOSIS

F. G. Marquez Villegas [1,*], E. I. Apodaca Chávez [1], A. Almeida Arvizu [1], A. Hernández Frausto [2], M. R. Demichelis Gómez [1]

[1]Hematologia y oncologia, [2]Radiologia e Imagen, Instituto Nacional de Ciencias Medicas y Nutrición Salvador Zubiran, Mexico, Mexico



Background: Patient's cirrhosis develops thrombocytopenia or other cytopenias from multiple factors, including hypersplenism, because it has no unique clinical or laboratory features to distinguish cytopenias is due cirrhosis or from other diseases.
Aims: This study was conducted to develop a diagnostic score for severe cytopenias in patients with hepatic cirrhosis.
Methods: In one referral center in Mexico City retrospective cohort of 95 patients with hepatitic cirrhosis of any etiology with thrombocytopenia or other cytopenia, (hematologic disease were excluded in hematologist evaluation and with bone marrow aspiration and biopsy), was used to construct the severe cytopenias in hepatic cirrhosis diagnostic score, called the C-score. We divide two groups according to severity of cytopenias: severe (absolute neutrophil count ≤1000 cells/μL or platelet count ≤ 50X10 /μL) and no severe cytopenias. Six variables were evaluated for their association with diagnosis of cytopenias in hepatic cirrhosis and logistic regression was used to calculate the weight of each criterion included in the score.
Results: The group of severe cytopenias included 45 patients, no difference was observed in patient characteristics, included age, sex, etiology of cirrhosis, Child-Pugh Score, presence of esophageal varices, hemoglobin levels, lactate dehydrogenase, INR, creatinine. Six variables: 2 clinical (ascites and state of cirrhosis), 2 laboratory (lymphocytes and hemoglobin) and one radiological (spleen size, measured by the same radiologist) and one prognostic (MELD-Na), were used in the development the C-score. The possible number of points assigned to each variable ranged from 0 to – 3 for hemoglobin to 0-12 for spleen size and ascites (table 1). The area under the ROC curve for the C-Score was 0.74 (CI 95%, 0.65-0.84, P *0.05*), indicating excellent discrimination

(figure 1). The pseudo R^2 statistic for the model was 0.15. The best cutoff value for de C-Score was ≥15, corresponding to a sensitivity of 71.11%, a specificity of 67.35%, positive predictive value of 66.67%, negative predictive value of 71.74% and accurate classification of 69.15% of the patients. The probability of having severe cytopenias in hepatic cirrhosis ranged from 30.22 % with a score of 5 to 89% with score of 40. We perform internal validation with the area under the ROC curve of 0.752 (min: 0.673, max 0.840).ç

Table 1.The C-Score

Parameter	Points
Spleen Size (cm)	
<14	0
≥14	12
Lymphocytes (cells/µL)	
>800	0
≤800	6
Ascites	
No	0
Mild	1

MELD-Na	
<14	0
≥14	7
Cirrhosis stage	
Compensated	0
Decompensated	5

Figure 1. Area under the receiver operating characteristic curve for C-Score

Summary/Conclusion: Discussion: Severe cytopenias are frequently in patients with cirrhosis, with multifactorial pathogenesis, difficult diagnosis and many of the times the patient undergoes unnecessary diagnostic workup. The C-Score is the first for the diagnosis of severe cytopenias in patients with cirrhosis, C-Score has limitations, was developed using a retrospective study population and in this initial study we focus on the development of the score, since we do not have a cohort for external validation, we perform internal validation by bootstrap, prospective validation of the score in other samples of patients is needed before it is recommended for widespread use.

Conclusion: The C-Score can be used to estimate the patients risks of having severe cytopenias in hepatic cirrhosis and it can help the clinician to make adequate diagnosis and treatment decisions in clinical practice.

EP1157 EFFECTIVENESS AND SAFETY OF ROMIPLOSTIM IN PATIENTS WITH NEWLY DIAGNOSED, PERSISTENT AND CHRONIC PRIMARY IMMUNE THROMBOCYTOPENIA IN GERMAN ROUTINE CLINICAL PRACTICE: THE OBSERVATIONAL PLATEAU STUDY

M. Reiser [1,*], K. M. Josten [2], H. Dietzfelbinger [3], A. Seesaghur [4], M. Schill [5], J. Hippenmeyer [6], M. Welslau [7]

[1]Praxis Internistische Onkologie und Hämatologie (PIOH), Köln, [2]Praxis Haematologie/Onkologie, Wiesbaden, [3]Hämatologisch-onkologische Schwerpunktpraxis, Herrsching, Germany, [4]Amgen Ltd, London, United Kingdom, [5]Amgen GmbH, München, Germany, [6]Amgen, Rotkreuz, Switzerland, [7]Onkologie Aschaffenburg, Aschaffenburg, Germany

Background: Immune thrombocytopenia (ITP) is a rare autoimmune disease characterised by low platelet counts. Romiplostim is a thrombopoietin-receptor agonist (TPO-RA) that increases platelet production and is indicated in Europe for the treatment of primary ITP in adult patients (pts) who are refractory to other treatments (e.g. corticosteroids/immunoglobulins). In 2021, romiplostim was approved for use in all phases of ITP, i.e. newly diagnosed (0–3 months [M]), persistent (>3–12M) and chronic ITP (>12M). This is in line with current European guidelines to switch adult pts earlier from corticosteroids to TPO-RAs. Although romiplostim was previously restricted to chronic ITP, there has been clinical evidence supporting the use of romiplostim in earlier disease phases (Kuter, Br J Haematol 2019; Newland, Br J Haematol 2016). Real-world data on the routine use of romiplostim in pts with ITP duration of ≤12M can help guide current and future clinical practice.
Aims: To assess the effectiveness and safety of romiplostim in adults with primary ITP, according to ITP phase, in routine clinical practice in Germany.
Methods: This was a *post-hoc* analysis of the single-arm, prospective, observational PLATEAU study. Data were collected from adult pts (≥18 years of age) who received ≥1 dose of romiplostim in haemato-oncological centres across Germany during the years 2010–2016. After the first romiplostim dose, follow-up data were collected for up to 2 years or until loss to follow up/death. Retrospective data were collected for bleeding events for up to 6M prior to romiplostim. Overall platelet response was defined as ≥1 platelet count measurement ≥50 x 10^9/L during weeks 2–24 after romiplostim initiation. Durable platelet response was achieved if ≥75% of all platelet count measurements were ≥50 x 10^9/L during weeks 14–24 after romiplostim initiation. Other outcomes included patient demographics, romiplostim use, and adverse drug reactions (ADRs). Subgroup analyses were performed according to ITP phases (time from diagnosis to romiplostim initiation: <3M; 3–12M; >12M).
Results: A total of 96 pts were included in the analysis. At the time of romiplostim initiation, 18 (18.8%) were newly diagnosed, 25 (26.0%) had persistent ITP, and 53 (55.2%) had chronic ITP (**Table**). The median (Q1–Q3) time from ITP diagnosis to romiplostim initiation was 14.9M (4.3–54.2). The proportion of pts who were non-splenectomised at treatment initiation was 87.5%. No newly diagnosed pts were splenectomised (versus 12.0% and 11.3% of pts with persistent or chronic ITP, respectively). Overall platelet response was achieved in 100% of pts with newly diagnosed and persistent ITP, and in 96.2% of pts with chronic ITP. Durable platelet response was achieved in 88.2% of newly diagnosed pts, 65.0% of pts with persistent ITP, and 69.4% of pts with chronic ITP. The median time to first platelet response was 8.5 days (newly diagnosed), and 7 days (for both persistent and chronic ITP). Safety was comparable across all ITP phases; there were two occurrences of bone marrow ADRs, both in pts with chronic ITP, and no thrombotic ADRs.

Table. Characteristics, effectiveness and safety of romiplostim treatment, for patients (N=96) with newly diagnosed, persistent and chronic primary ITP in German routine clinical practice (2010 –2016)

	Phases of ITP (time from ITP diagnosis to romiplostim initiation)		
	Newly diagnosed <3 months n=18 (18.8%)	Persistent 3–12 months n=25 (26.0%)	Chronic >12 months n=53 (55.2%)
Patient characteristics at the time of romiplostim initiation			
Male, n (%)	13 (72.2)	14 (56.0)	23 (43.4)
Age, years*	64 (56–76)	70 (56–79)	67 (55–72)
Time from ITP diagnosis to romiplostim initiation, months*	1.0 (0.5–1.4)	5.8 (4.7–9.0)	51.0 (26.4–100.5)
Platelet count, x10^9/L*	32 (21–50)	28 (19–78)	29 (15–45)
Prior splenectomy, n (%) †	0	3 (12.0)	6 (11.3)
≥1 prior ITP therapies, n (%) ‡	13 (72.2)	23 (92.0)	49 (92.5)
Prior bleeding events§, n (%)	7 (38.9)	10 (40.0)	16 (30.2)
Type III or IV (transfusion required)	*1 (5.6)*	*0*	*0*
Prior bone marrow biopsy, n (%) †	11 (61.1)	18 (72.0)	29 (54.7)
Duration of romiplostim exposure, weeks			
Mean (SD)	82.1 (33.9)	66.3 (41.6)	81.9 (35.7)
Median (Q1–Q3)	102.2 (65.1–104.4)	87.3 (13.6–104.0)	104.1 (50.4–104.4)
Effectiveness outcomes during 24 -week follow-up period			
Overall platelet response, % (95% CI)¶	100.0 (81.5–100)	100.0 (86.3–100)	96.2 (87.0–99.5)
Durable platelet response, % (95% CI)¶	88.2 (63.6–98.5)	65.0 (40.8–84.6)	69.4 (54.6–81.7)
Time to first platelet response ≥50 x 10^9/L, days*	8.5 (7–14)	7 (7–13)	7 (7–14)
≥1 ITP therapy since initiation of romiplostim, n (%)	11 (61.1)	7 (28.0)	21 (39.6)
Bleeding events since initiation of romiplostim, n (%)	6 (33.3)	9 (36.0)	25 (47.2)
Type III or IV (transfusion required)	*3 (16.7)*	*0*	*1 (1.9)*
No transfusion since the initiation of romiplostim, n (%) ‖	13 (72.2)	23 (92.0)	43 (81.1)
ADRs during the 2-year follow-up period			
Total number of ADRs, n	38	14	46
Patients with any ADR, n (%)	6 (33.3)	6 (24.0)	19 (35.8)
Thrombotic ADR, n	0	0	0
Bone marrow fibrosis ADR, n (%)	0	0	2 (3.8)

ADR, adverse drug reaction; CI, confidence interval; ITP, immune thrombocytopenia; SD, standard deviation
*Median (Q1–Q3); †2 patients with persistent ITP and 1 patient with chronic ITP had missing data; ‡1 patient with newly diagnosed ITP had missing data; §Within 6 months prior to romiplostim initiation; ¶Patients for whom there was no data on the number of platelets or the timing of the platelet measurement were censored; ‖Including platelet transfusions, red blood cell transfusions, and other types of blood transfusions

Summary/Conclusion: In this observational study, clinically meaningful platelet responses were achieved by romiplostim-treated pts in all ITP phases. Romiplostim was well tolerated. This cohort, representative of routine clinical practice in Germany, supports the effectiveness and safety of romiplostim in pts with newly diagnosed and persistent ITP in routine clinical practice, in line with recent guidelines.

Background: Coeliac disease (CD) is often associated with other autoimmune disorders: the association with Immune Thrombocytopenia (ITP) has been investigated in some cohorts and case reports with contradictory results especially about gluten-free diet efficacy on ITP. No study aimed to describe the specific features of this association in pediatric age.
Aims: The aim of this study was to characterize the association of Cd and ITP in Italian children.

Methods: This is a multicenter retrospective study investigating the coexistence of CD and ITP in 28 children diagnosed from January 1th 2000 to December 31th 2019. A case report form was sent to all 55 A.I.E.O.P. Centers collecting information about patients up to 18 years of age with both CD and ITP. Informed consent was obtained from the parents or the legal guardians of all patients. CD was classified as *classic* (presence of symptoms of malabsorption, positive CD specific antibodies and biopsy, and symptoms resolution on a gluten-free diet), *silent* (positive CD specific antibodies, HLA DQ2 or DQ8 and biopsy without symptoms), *latent* (presence of HLA DQ2 or DQ8 and histological alterations typical of CD in duodenal biopsy at some point of their life, but neither symptoms nor positive antibodies) and *potential* (positive CD-specific antibodies and HLA without histological abnormalities in duodenal biopsies). ITP was defined as *newly diagnosed* (within 3 months from diagnosis), *persistent* (between 3 and 12 months from diagnosis) and *chronic* (cITP, lasting for more than 12 months). The ITP bleeding score was defined as *Type A: asymptomatic-paucisymptomatic ITP*, clinical symptoms ranging from no bleeding to few petechiae and some bruises without mucosal hemorrhages; *type B: intermediate ITP*, clinical picture with more petechiae, bruising and mucosal hemorrhages; *type C: severe ITP*, clinical picture with severe cutaneous and mucosal bleeding symptoms. As timing of diagnosis the patients were classified as *CD first*: CD was diagnosed before ITP; *ITP first*: ITP was diagnosed before CD; *Simultaneous diagnosis*: the second disease (CD or ITP) was diagnosed during hospitalization or initial ascertainment for the other disorder.
Results: The most relevant clinical features of this cohort are shown in table I. The first diagnosis was ITP in 16 (57.2%) and CD in 9 patients (32.1%) respectively. In 3 patients (10.7%) the two diagnosis were simultaneous. The bleeding score of ITP was A in 67.9% and B in 32.1% of patients. ITP turned to be persistent in 44.4% and chronic in 40%. At the last FUP 28.6% of patients were still presenting cITP. The CD was classified as classical in 60.7% of children, silent in 25%, latent in 7.1% and potential in 7.1%. At ITP onset 21.4% of the patients were not treated (wait&see), 64.3% received iv immunoglobulin (IVIG) and 14.3% oral prednisone. Subsequent rescue therapies for ITP were attempted in 12 patients (42.9%). All the potential and silent CDs in our cohort were diagnosed in the 2 groups of *ITP first* or *simultaneous diagnosis*. In all children ITP was mild and in 2 out of 8 patients not recovered from ITP at the time of CD diagnosis a normalization of platelet counts (> 100,000/mmc) occurred after 3 and 5 months from starting gluten free diet.

Table 1. Characteristics of the patients

Median age at CD diagnosis (years)	6.2 (range 0.6-27.6)
Median age at ITP diagnosis (years)	5.8 (range 0.5-15.1)
Median PLTs at ITP diagnosis	19,500/mmc (range 1,000-96,000/mmc)
Familiarity for autoimmune diseases	55.6%
Extaintestinal disorders	14.8%
CD type	Latent: 7.1% Potential: 7.1% Silent: 25% Classic: 60.7%
ITP score bleeding	score A: 67.9% score B: 32.1%
Time of diagnosis	ITP first: 57.2% CD first: 32.1% Simultaneous: 10.7%
Gluten-free diet efficacy on ITP	NR: 77.8% CR: 22.2%
cITP at 12 months	40%
First line therapy for ITP	IVIG: 64.3% Wait&see: 21.4% Oral prednisone: 14.3%
First rescue therapy for ITP	42.9%
Second rescue therapy for ITP	21.4%
Median FUP from ITP diagnosis (years)	4.4 (range 0.2-16.5)
Median FUP from CD diagnosis (years)	2.3 (range 0.02-15.2)

CD: coeliac disease; ITP: immune thrombocytopenia; FUP: Follow UP; PLTs: platelets; NR: no response; CR: complete response; cITP: chronic immune thrombocytopenia; IVIG: iv immunoglobulin.

Summary/Conclusion: We think that screening for celiac disease should be considered in children with ITP, regardless the presence of

gastrointestinal symptoms. About one fourth of patients recover from ITP after starting gluten-free diet.

EP1159 EPIDEMIOLOGY AND MANAGEMENT OF IMMUNE THROMBOCYTOPENIA IN ADULT PATIENTS IN ALGERIA

Background: Immune thrombocytopenia (ITP) affects 2–4/100,000 adults globally. Recent ASH and ICR guidelines recommend short duration (<6 weeks) corticosteroids as first-line therapy for ITP, and thrombopoietin receptor agonists (TPO-RAs) and rituximab as second-line therapy before splenectomy. There are limited data on the epidemiology and management of ITP patients (pts) in Algeria.

Aims: Here we investigate the epidemiology and management of ITP pts treated in public hospitals in Algeria from September 2017–August 2018.

Methods: This was a non-interventional, longitudinal, nationwide estimation study of ITP pts ≥16 years (y) of age, either previously (before 1 September 2017) or newly (September 2017–August 2018) diagnosed with ITP. Assessments included pt characteristics, disease etiology, ITP incidence (by age, sex, diagnosis stage, and Algeria province), ITP prevalence, and ITP treatment regimens.

Results: Overall 1746 pts were listed of whom 587 did not provide consent; 1159 were included in the analysis. Among eligible pts, 895 (77.2%) were women, 173 (14.9%) were newly diagnosed, and 986 (85.1%) were previously diagnosed with ITP. A total of 966 pts (83.3%) had no comorbidities conferring bleeding risk. Etiological investigations for diagnosis showed that a majority of pts were evaluated for autoimmune disease (79.9%) and/or lymphoid hemopathy (75.9%) (Table). At diagnosis, median age was 36y (range 0–94y), and platelet counts (10^3/mm^3) were 0–30 in 124 pts (71.7%), 30–50 in 20 pts (11.6%), 50–100 in 28 pts (16.2%), and >100 in 1 (0.6%) pt. Khellaf score was ≤8 for 45 (26.0%) pts, >8 for 8 (4.6%) pts, and missing for 120 (69.4%) pts. Bleeding risk was grade 0 (low), 1, 2, 3, and 4 for 50 (28.9%), 24 (13.9%), 34 (19.7%), 52 (30.1%), and 13 (7.5%) pts, respectively; 55 (31.8%) pts were asymptomatic, 58 (33.5%) ecchymotic, and 60 (34.7%) severely hemorrhagic.

The incidence (95% CI) of ITP was 0.85 (0.75, 0.96) per 100,000 inhabitants, increasing with age from 0.5 (0.43, 0.68) for pts 15–35y old to 2.4 (1.60, 3.51) for pts ≥75y old. Women had a higher incidence of ITP than men (1.2 [1.02, 1.37] vs 0.5 [0.43, 0.67]). Incidence of ITP varied with diagnosis stage (asymptomatic: 0.4 [0.31, 0.45]; ecchymosis: 0.1 [0.10, 0.19]; severe hemorrhage: 0.1 [0.06, 0.13]), and Algeria province (lowest in a public site in Tebessa: 0.1 [0.02, 0.92], highest in a public site in Sidi Bel Abbès: 1.6 [0.93, 2.89]). The prevalence (95% CI) of ITP was 5.7 (5.39, 5.93) per 100,000 inhabitants, increasing with age from 3.2 (2.78, 3.67) for pts 15–25y old to 11.9 (9.68, 13.08) for pts 65–75y old, and then decreasing to 7.6 (4.79, 12.06) for pts ≥85y old. Women had a higher prevalence of ITP than men (8.8 [8.33, 9.29]) vs 2.6 [2.34, 2.85]). Corticosteroids were the primary treatment for new (136 [78.6%]) and previously (795 [80.7%]) diagnosed pts. Last/ongoing treatments at study inclusion were corticosteroids (712 [72.2%]), rituximab (56 [5.7%]), immunoglobulins (30 [3.0%]), TPO-RA (romiplostim: 19 [1.9%]), and antibacterials (4 [0.4%]). Among previously diagnosed pts, 172 (17.4%) had splenectomy with a median time of 19 months from ITP diagnosis.

Table. Summary of Etiological Investigations of ITP Patients in Algeria

Test done	Total N = 1159
Autoimmune disease, n (%)	
Done	925 (79.9)
Missing	1 (0.09)
Not Done	233 (20.1)
Lymphoid hemopathy, n (%)	
Done	879 (75.9)
Missing	1 (0.09)
Not Done	279 (24.1)
Viral hepatitis serologies, n (%)	
Done	850 (73.4)
Missing	1 (0.09)
Not done	308 (26.6)
HIV serology, n (%)	
Done	848 (73.2)
Missing	1 (0.09)
Not Done	310 (26.8)
Helicobacter pylori infection, n (%)	
Done	161 (13.9)
Missing	1 (0.09)
Not Done	997 (86.1)
Viral infections preceding thrombocytopenia (sore throat, flu, other), n (%)	
Done	30 (2.6)
Missing	6 (0.5)
Not done	1123 (97.4)

HIV, human immuno-deficiency virus; ITP, immune thrombocytopenia.

Summary/Conclusion: The incidence and prevalence of ITP in Algeria increased with age, and both were higher in women than men, conforming to global trends. The results highlight the need to reduce corticosteroid treatment duration and improve second-line therapy options such as TPO-RAs before splenectomy (in line with the recently updated ASH and ICR guidelines) for management of adult ITP pts in Algeria.

EP1160 THE CLINICAL UTILITY OF ALINITY HQ STANDARD AND RESEARCH CBC PARAMETERS IN THE DIFFERENTIAL DIAGNOSIS OF ITP

S. M. Hwang [1,*], G. Lakos [2]

[1]Seoul National University Bundang Hospital, Seongnam, Korea, Republic Of, [2]Abbott laboratories, Santa Clara, United States

Background: Immune thrombocytopenia (ITP) is diagnosed in patients with a platelet (PLT) count below 100 x 10^9/L in whom other causes of thrombocytopenia have been ruled out. Myelodysplastic syndrome (MDS), aplastic anemia, myeloproliferative and lymphoproliferative diseases are among the main causes that are considered in the differential diagnosis.

Aims: As complete blood count (CBC) is one of the first tests that is performed on any patient who presents with clinical symptoms, our goal was to evaluate if standard and research CBC and reticulocyte parameters reported by Alinity hq can help differentiating ITP from other forms of thrombocytopenia.

Methods: The patient population (n=117) was selected to include samples with a PLT count of < 100 x 10^9/L. The cohort included 38 unique samples from patients with ITP and 79 samples with other forms of thrombocytopenia, such as MDS, aplastic anemia, primary myelofibrosis and idiopathic cytopenia of undetermined significance, among others. CBC and reticulocyte results were generated with the Abbott Alinity hq hematology analyzer. Hematological parameters were compared between the two thrombocytopenic groups by the Mann-Whitney test. The effectiveness of standard and research CBC parameters and mathematical formulas to differentiate ITP for other forms of thrombocytopenia was assessed by ROC analysis. Patients who have received RBC

transfusion in the past eight weeks were excluded from the analysis of RBC and reticulocyte parameters.
Results: PLT counts were not significantly different between ITP and the other thrombocytopenia group (medians: 55.3 vs 46.9 x 10^9/L). Several CBC parameters demonstrated significant differences between the two populations.
The five parameters that showed the largest difference between the two groups (MPV, RBC, RDW-MATH SD, %HPO and HDW) produced area under the curve (AUC) values ranging from 0.676 (MPV) to 0.828 (HDW). Several mathematical formulas also demonstrated good performance. The formula of (RBC / HDW x MPV) resulted in an AUC of 0.848, and a sensitivity of 80.6% and specificity of 81.4% for differentiating ITP from other forms of thrombocytopenia.

Measurand	Other thrombocytopenia	ITP	p value
	Median and interquartile range		
MPV (Mean platelet volume)	7.9 (7.0-8.9)	9.0 (8.0-10.2)	0.0001
Absolute neutrophil count	1.58 (0.81-2.66)	2.66 (1.79-3.80)	0.0007
RBC (Red blood cell count)	3.41 (2.74-3.84)	4.12 (3.76-4.63)	<0.0001
RDW (Red cell distribution width)	12.7 (11.6-15.3)	11.5 (11.2-12.6)	0.001
RDW-MATH SD (RDW expressed as standard deviation)	13.3 (12.0-14.7)	11.3 (10.7-12.4)	<0.0001
%MAC (% macrocytic RBC)	10.8 (3.7-22.1)	2.6 (1.0-8.4)	0.0007
%HPO (%hypochromic RBC)	11.2 (4.7-16.1)	2.1 (0.9-4.4)	<0.0001
HDW (HGB distribution width)	10.1 (7.9-11.8)	6.3 (5.9-7.7)	<0.0001
IRF (Immature reticulocyte fraction)	0.39 (0.31-0.46)	0.32 (0.31-0.36)	0.0002

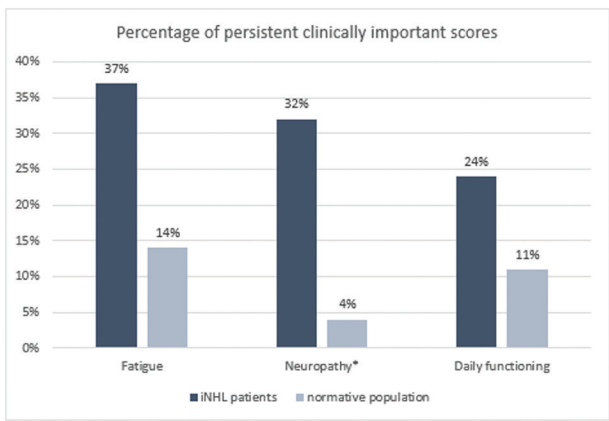
Summary/Conclusion: Several Alinity hq standard and research CBC and reticulocyte parameters have demonstrated significant differences between ITP and other forms of thrombocytopenia. These differences are likely related to the fact that erythropoiesis and myelopoiesis are commonly affected in many forms of thrombocytopenia such as MDS or aplastic anemia, while they are not impacted in ITP. In addition, accelerated thrombopoiesis is present in ITP, but usually not in other types of thrombocytopenia. These results demonstrate the clinical utility of Alinity hq standard and research hematology parameters in the differential diagnosis of ITP.

EP1161 CHANGES IN THE EXPRESSION OF PROTEINS INVOLVED IN THE CA2+ HOMEOSTASIS IN NEONATE PLATELETS.

A. Berna-Erro [1], E. Delgado [2], A. J. Corbacho [2], M. P. Granados [3], J. Perez [4], F. Ferrer-Marin [5], P. C. Redondo [1,*]

[1]Physiology, University of Extremadura, Cáceres, [2]Extremadura county blood and tissue bank, Merida, [3]Serradilla medical Health center, [4]Heme research group, University of Extremadura, Caceres, [5]5.Hematology and Medical Oncology Unit, Hospital Morales-Meseguer, IMIB-Arrixaca, Murcia, Spain

Background: Calcium homeostasis is crucial for platelet function and Store Operated Calcium Entry was found to be the main Ca^{2+} entry mechanism in non-excitable like in platelets[1]. SOCE relays in the association of the DTS, STIM1, and the plasma membrane calcium channels, Orais and TRCPs[2]. Changes in the Ca^{2+} homeostasis of neonate platelets were early described[3], but most of the main components of SOCE were unknown by that time[1,2], which has been revisited in the present research work
Aims: The aim of the present work is to investigate the possible alteration in the regulatory proteins involved in the intracellular calcium homeostasis in human platelets from neonates respect adults.
Methods: Upon platelet isolation they were subjected to either protein- and mRNA isolation protocols and alternatively were used in functional experiments as well as for analysis of intracellular calcium homeostasis using fura2.
Results: mRNA analysis and protein evaluation by Western blotting revealed interesting differences between neonate platelets and platelets from adults like the one shown in the Figure representing STIM1 and SARAF (Fig A), which are relevant for SOCE and therefore, those changes may explain the physiological and functional changes in neonate platelets previously described by others (Fig B and C)[4].
Summary/Conclusion: Here, we describe some of these key proteins involved in Ca^{2+} entry through SOCE that are modify in neonate platelets.



Quality of life, palliative care, ethics and health economics

EP1162 PERSISTENT CLINICALLY IMPORTANT OUTCOMES OF FATIGUE, NEUROPATHY AND PROBLEMS WITH DAILY FUNCTIONING AMONG INDOLENT NON-HODGKIN LYMPHOMA SURVIVORS.

A. Ekels [1,2,*], L. V. van de Poll-Franse [1,2,3], E. F. M. Posthuma [4], L. Tick [5], S. Oerlemans [1]

[1]Department of Research and Development, Netherlands Comprehensive Cancer Organisation (IKNL), Utrecht, [2]Division of Psychosocial Research and Epidemiology, Netherlands Cancer Institute, Amsterdam, [3]Department of Medical and Clinical Psychology, Center of Research on Psychological and Somatic Disorders (CoRPS), Tilburg University, Tilburg, [4]Department of Internal Medicine, Reinier de Graaf Group, Delft, [5]Department of Internal Medicine, Máxima Medical Centre, Veldhoven, Netherlands

Background: Clinical outcomes and survival rates for indolent Non-Hodgkin Lymphoma (iNHL) have greatly improved in the past two decades. It, however, does not necessarily mean that these survivors live in good health. Patients often experience relapses of their disease and need to undergo several treatment lines. They are therefore at risk for adverse physical and psychosocial effects, such as fatigue, neuropathy and anxiety. To date, most information has been obtained from clinical trials and cross-sectional studies and little is known about persistent (long-term) symptoms and problems in a population-based setting.
Aims: (1) To evaluate the course of symptoms and daily functioning among iNHL patients, up to ten years after diagnosis in a prospective observational population-based cohort, (2) to determine the number of patients with persistent fatigue, neuropathy and problems in daily functioning and (3) to identify sociodemographic, clinical and psychological factors associated with this.
Methods: Patients diagnosed with iNHL between 1999 and 2014, 18 years and older, were invited for a longitudinal population-based survey. Patients received subsequent questionnaires every six months (≤ three years after diagnosis) and once a year (> three years after diagnosis), starting from the time of enrollment until spring 2019. Data collection was done within the PROFILES registry. Sociodemographic and clinical data were obtained from the Netherlands Cancer Registry. The EORTC QLQ-C30 was used to assess daily (role) functioning and fatigue and the CLL-16 was used for neuropathy. Psychological distress was measured with the Hospital Anxiety and Depression Scale. Persistent symptoms and problems in daily functioning were defined with the thresholds for clinical importance of the QLQ-C30. Data of patients were compared to an age- and sex-matched normative population. Individual Growth Curve models with maximum likelihood estimation and Generalized Estimating Equation analysis were performed using SPSS.

*No longitudinal neuropathy data was available for the normative population, this neuropathy score was therefore based on a cross-sectional measurement.

Results: 669 iNHL patients were included who completed on average 4 measurements. Patients had a mean age of 64.8 years at inclusion and 60% were male. Mean survival time at inclusion was 3.6 years [range 0.4-10.5 years]. Primary treatment was watchful waiting (52%), chemotherapy (29%) or radiotherapy (14%). The growth model shows that the course of symptoms and daily functioning remains stable up to 10 years after diagnosis. Respectively, 37% reported persistent fatigue, 32% persistent neuropathy and 24% persistent problems in daily functioning. This was 2-3 times higher than the normative population. Factors associated with worse persistent outcomes were: receiving chemotherapy as primary treatment, having comorbidities, lower education, not having a partner and experiencing psychological distress (all p's <0,05).
Summary/Conclusion: A quarter to one-third of iNHL patients experiences persistent fatigue, neuropathy and problems with daily functioning. To organize early detection and supportive care for those in need, further research is needed to better understand the underlying mechanisms of symptoms and daily functioning (e.g. the role of physiological and biological factors). Additionally, it will lead to better expectation management and informed decision-making for iNHL patients.

EP1163 QUALITY OF LIFE WITH REGN5458 IN PATIENTS WITH RELAPSED/REFRACTORY MULTIPLE MYELOMA (RRMM): PATIENT-REPORTED OUTCOMES (PROS) FROM THE FIRST-IN-HUMAN PHASE 1/2 TRIAL

N. Bumma [1,*], R. G. W. Quek [2], J. Brayer [3], J. A. Zonder [4], J. E. Hoffman [5], W. I. Bensinger [6], M. V. Dhodapkar [7], S. Lentzsch [8], D. Cooper [9], J. J. Maly [10], L. Xu [11], J. Li [11], K. R. Lorenc [12], M. Sharma [13], D. Madduri [14], S. Jagannath [14]

[1]Division of Hematology, The Ohio State University Comprehensive Cancer Centre, Columbus, [2]Health Economics and Outcomes Research, Regeneron Pharmaceuticals, Inc, Tarrytown, [3]Hematology/Oncology, H. Lee Moffitt Cancer Centre, Tampa, [4]Hematology/Oncology, Karmanos Cancer Institute, Detroit, [5]Hematology/Oncology, University of Miami Health System, Miami, [6]Hematology/Oncology, Swedish Center for Blood Disorders and Stem Cell Transplants, Seattle, [7]Hematology and Medical Oncology, Emory University School of Medicine, Atlanta, [8]Division of Hematology/Oncology, Columbia University Medical Center, New York, [9]Medical Oncology, Rutgers Cancer Institute of New Jersey, New Brunswick, [10]Oncology, Norton Cancer Institute, Louisville, [11]Statistics, [12]Program Direction, [13]Clinical Sciences, Regeneron Pharmaceuticals, Inc, Tarrytown, [14]Hematology and Medical Oncology, Icahn School of Medicine at Mount Sinai, New York, United States

Background: The phase 1 portion of the phase 1/2 trial of REGN5458, a B-cell maturation antigen (BCMA) x CD3 bispecific antibody, demonstrated an acceptable safety and tolerability profile with early, deep and durable efficacy in heavily pre-treated patients with RRMM (NCT03761108).[1]
Aims: To report the effects of REGN5458 on patient-reported outcomes (PROs).
Methods: Patients with progressive RRMM (≥3 prior lines of systemic therapy, including a proteasome inhibitor, an immunomodulatory agent, and an anti-CD38 antibody) were enrolled in the study. Patients received weekly doses of REGN5458, followed by continuous dosing, administered every 2 weeks. A modified 3+3 dose escalation design (4+3) was used. PROs were assessed using multiple instruments including the European Organisation for Research and Treatment of Cancer Quality of Life Questionnaire Core 30 (EORTC QLQ-C30). Analyses were performed on patients (N=49) who received REGN5458, pooled across dose levels 1 to 6, at baseline and Weeks 4, 8, 12 and 24. These included A) descriptive mean scores at each assessment, B) change from baseline scores over time and C) estimated overall change from baseline using mixed-effects model for repeated measures analysis [and 95% confidence intervals (CI)] in the global health status/quality of life (GHS/QoL), and all functional and symptom scales from the EORTC QLQ-C30. No multiplicity adjustments were made, and findings are exploratory. Clinically meaningful change was defined as a ≥10-point change from baseline, statistical significance was interpreted using 95% CIs of change from the baseline.
Results: At baseline, patients had a median of five prior lines of therapy. Statistically significant and clinically meaningful overall improvements from baseline in GHS/QoL (10.7 [95% CI: 6.2, 15.1]) and patient-reported pain symptoms (-10.2 [95% CI: -16.2, -4.2]) were observed with REGN5458. Statistically significant overall improvements from baseline in emotional functioning (7.6 [95% CI: 3.4, 11.7]) and social functioning (8.9 [95% CI: 1.6, 16.3]) were also seen. Across remaining EORTC QLQ-C30 functional (Figure 1A) and symptom (Figure 1B) scales, improved trends were observed, with the exception of physical functioning (-0.2 [95% CI: -5.0, 4.6]), fatigue (0.3 [95% CI: -4.0, 4.6]), and appetite loss (3.0 [95% CI: -2.6, 8.5]).

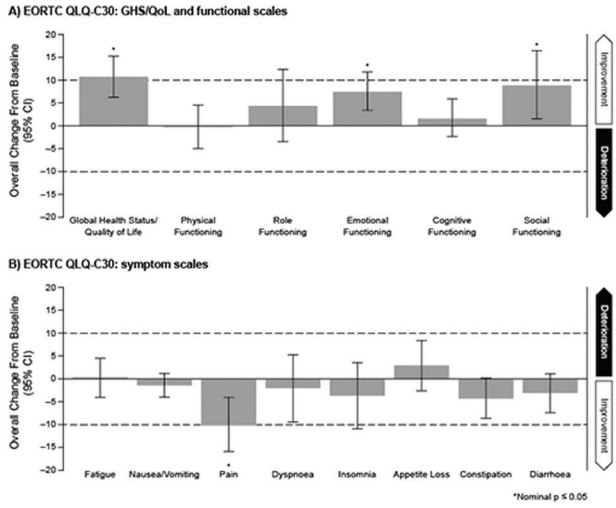


Figure 1 Overall change from baseline (repeated-measures mixed-effect model) (A) EORTC QLQ-C30: GHS/QoL and functional scales (B) EORTC QLQ-C30: symptom scales

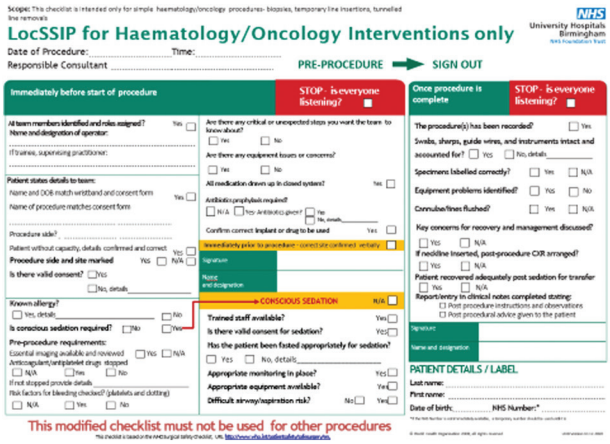

Summary/Conclusion: Patients who received REGN5458 showed statistically significant and clinically meaningful overall improvements in GHS/QoL and pain symptoms. Furthermore, there was no statistically significant overall deterioration in PROs even in a heavily pre-treated population. Additional and longer follow-up PRO data are warranted to confirm the benefit-risk profile of REGN5458 in heavily pre-treated patients with RRMM. 1. Madduri D et al. ASH 2020. O291

EP1164 LOCAL SAFETY STANDARDS FOR INVASIVE PROCEDURES (LOCSSIPS) IN HAEMATOLOGY

Z. Ahmed [1,*], R. Purmessur [1], K. Sheldon [2], J. King [1], M. Stewart [1], R. Steyn [1], T. Graham [1]

[1]Clinical Governance, [2]Haematology, University Hospitals Birmingham Foundation Trust, Birmingham, United Kingdom

Background: A study in 2009 demonstrated there were a number of preventable serious incidents occurring in hospitals around the UK. These were termed Never Events(NE). In 2015, as a way to mitigate these serious incidents, the National Patient Safety Agency(NPSA) released a report, recommending the creation and implementation of National Safety Standards for Invasive Procedures(NatSSIPs), which at a local level would be named Local Safety Standards for Invasive Procedures(LocSSIPs). In 2017, University Hospitals Birmingham(UHB) NHS Foundation Trust set up a LocSSIP steering committee, with the commitment to create and implement LocSSIPs across the trust.
Aims: Our aim was to create and develop LocSSIPs within the haematology department and audit its implementation.
Methods: The project plan was divided into 4 phases: scoping, development, implementation and maintenance and monitoring. We identified a LocSSIP 'champion' within haematology and identified key procedures which would require LocSSIPs. Our safety standards were framed on NPSA guidance and standards of the WHO checklist but tailored for procedures within haematology. Following implementation, compliance was audited.
Results: The LocSSIP checklist was successfully developed and approved for implementation. Pre-procedure and sign-out sections were created to allow safety checks before and after the procedures whilst allowing for efficiency and effective use. All questions were tailored to haematology such as bone marrow biopsies, lumbar punctures, and line insertions. Additionally, key safety questions for conscious sedation were created in line with local Trust and NICE guidance. Compliance of haematology LocSSIPs was 93.5% involving 31 procedures.
Informal feedback overall mentioned that staff members felt safer using LocSSIPs. Standardisation further facilitated patient safety following redeployment of staff due to the pandemic and recent merger of Trusts.

LocSSIP for Haematology/Oncology Interventions only

University Hospitals Birmingham NHS Foundation Trust

Date of Procedure: Time:

Responsible Consultant

PRE-PROCEDURE → SIGN OUT

Immediately before start of procedure — STOP - is everyone listening?

Once procedure is complete — STOP - is everyone listening?

All team members identified and roles assigned? Name and designation of operator:

If trainee, supervising practitioner:

Patient states details to team:

Name and DOB match wristband and consent form

Name of procedure matches consent form

Procedure site?

Patient without capacity, details confirmed and correct

Procedure side and site marked

Is there valid consent?

Known allergy?

Is conscious sedation required?

Pre-procedure requirements:

Essential imaging available and reviewed

Anticoagulant/antiplatelet drugs stopped

If not stopped provide details

Risk factors for bleeding checked? (platelets and clotting)

Are there any critical or unexpected steps you want the team to know about?

Are there any equipment issues or concerns?

All medication drawn up in closed system?

Antibiotic prophylaxis required?

Confirm correct implant or drug to be used

Immediately prior to procedure - correct site confirmed - verbally

Signature

Name and designation

CONSCIOUS SEDATION

Trained staff available?

Is there valid consent for sedation?

Has the patient been fasted appropriately for sedation?

Appropriate monitoring in place?

Appropriate equipment available?

Difficult airway/aspiration risk?

The procedure(s) has been recorded?

Swabs, sharps, guide wires, and instruments intact and accounted for?

Specimens labelled correctly?

Equipment problems identified?

Cannulae/lines flushed?

Key concerns for recovery and management discussed?

If nexidine inserted, post-procedure CXR arranged?

Patient recovered adequately post sedation for transfer

Report/entry in clinical notes completed stating:

- Post procedure instructions and observations
- Post procedural advice given to the patient

Signature

Name and designation

PATIENT DETAILS / LABEL

Last name:

First name:

Date of birth: NHS Number:*

This modified checklist must not be used for other procedures

Summary/Conclusion: We have successfully demonstrated implementation and compliance of a LocSSIP in haematology. As with every quality improvement project, the work is longitudinal and the troubleshooting process is still ongoing. Continuous auditing and monitoring of their use is required as well as the long term effects on serious incidents.

EP1165 SYSTEMATIC LITERATURE REVIEW (SLR) OF THE EFFICACY AND SAFETY OF SECOND-LINE (2L) TREATMENTS FOR RELAPSED OR REFRACTORY (R/R) LARGE B-CELL LYMPHOMA (LBCL)

F. F. Liu [1,*], A. Oliva Ramirez [2], E. Worthington [2], C. Parker [3]

[1]Worldwide Health Economics and Outcomes Research, Bristol Myers Squibb, Summit, United States, [2]Value & Evidence Division, Marketing and Market Access, EVERSANA, Burlington, Ontario, Canada, [3]Worldwide Health Economics and Outcomes Research, Bristol Myers Squibb, Uxbridge, United Kingdom

Background: More than one-third of patients with diffuse LBCL, the most common LBCL subtype, relapse after standard first-line therapy. Standard of care (SoC) in 2L R/R LBCL is salvage chemotherapy (CTx), followed by high-dose CTx (HDCT) and hematopoietic stem cell transplantation (HSCT) in eligible patients. However, only roughly 30% of R/R patients eventually proceed to HSCT. High-risk patients with early first-line relapse obtain only a limited survival advantage with HSCT.
Aims: We conducted an SLR to identify clinical evidence regarding the efficacy and safety of therapies used in the treatment of patients with 2L R/R LBCL, including transplant-eligible (TE) and transplant non-eligible (TNE) patients.
Methods: The Population, Intervention, Comparator, Outcome, and Study (PICOS) framework was used for the search strategy for identifying English-language publications from January 2003 to July 2020. Articles were searched in MEDLINE, Embase, and the Cochrane Library databases; abstracts were identified from key congresses (2017–2020). Selection criteria included (but were not limited to) 2L R/R LBCL, ≥25 participants per treatment arm or ≥50 per study, single- or multiagent chemotherapy or immunotherapy, chemoimmunotherapy, CAR T cell therapy, HSCT, and efficacy (overall response rate [ORR], overall survival [OS], and progression-free survival [PFS]).
Results: Of 3417 records screened, 68 were included (28 publications, 37 conference abstracts, and 3 trial records), representing 55 unique studies. Most were observational studies (n=36), followed by randomized controlled trials (n=8), single-arm trials (n=7), and nonrandomized controlled trials (n=4). Exclusions included studies that were preclinical, duplicates, or studies with incomplete data. The study populations included TE (n=15), TNE (n=9), and mixed/unspecified (n=31). Salvage CTx (with or without HSCT) was the most common treatment (n=42), followed by HSCT (n=3) and CAR T cell therapy (n=1); 6 observational studies had no specified treatment and 3 were prognostic. ORR with salvage CTx ranged from 37%–69% for TE patients (with an outlier reporting an ORR of 23% due to a high-risk population) and from 48%–74% for TNE patients. Interim efficacy data for a CAR T cell therapy in TNE patients were reported from one ongoing phase 2 trial: an ORR of 89% and a complete response rate of 56% were observed in 27 patients who received lisocabtagene maraleucel. Median OS was reported in 18 studies, ranging from 13.2–16.7 months in the intent-to-treat population of TE patients and 8.7–24.2 months in TNE patients. Median OS with HSCT in 3 studies ranged from 12.4–36.7 months.
Summary/Conclusion: Most studies in 2L LBCL explored salvage treatment regimens with intent of HDCT/HSCT follow-up treatment. Despite limited data, this SLR identified a lack of a clear SoC in TNE populations who have a dismal prognosis. Historically, ~30% of patients proceed to receive HSCT, indicating a critical need for effective therapeutic options that are more broadly accessible to all 2L patients, with a greater long-term benefit in high-risk subgroups.

EP1166 ERECTILE DYSFUNCTION (ED) IN PATIENTS WITH LIGHT-CHAIN AMYLOIDOSIS (AL): DIAGNOSIS AND CORRELATION WITH THE HEMATOLOGIC DISEASE.

C. Giordano [1,*], G. Cerciello [1], N. Pugliese [1], D. De Novellis [1], A. D'Ambrosio [1], A. Salemme [1], A. Vincenzi [1], F. Garifalos [2], R. Pivonello [2], M. Picardi [1], F. Pane [1]

[1]Department of Clinical Medicine and Surgery, Hematology Unit, Federico II University Medical School, Via Sergio Pansini, 5, Naples, 80131, Italy;, [2]Department of Clinical Medicine and Surgery, Endocrinology Unit, Federico II University Medical School, Via Sergio Pansini, 5, Naples, 80131, Italy;, Università Federico II di Napoli, Napoli, Italy

Background: AL is caused by the amyloid deposition of a misfolded protein responsible for organ damage. In men, ED can be an early disease related feature, but the real incidence and pathogenesis is not well established. ED can be psychogenic or organic.
Aims: Our aim is to investigate the incidence and evaluate the presence and possible causes of ED in male patients with AL.
Methods: All male adult patients with a confirmed diagnosis of AL attending the Haematology Department of Federico II University were enrolled in the study, from July to November 2020. Patients older than 70 years and/or with ECOG ≥ 2 were excluded. All patients underwent a diagnostic work up, comprehensive of hematologic and andrological assessments. Andrological assessment, performed by G.F and P.R, consisted in physical examination, power doppler ultra-sound (PDUS) evaluation and a structured questionnaire concerning sexual activity [International Index of Erectile Function (IIEF-15)]. Mayo clinic staging assessment was reported for all patients at diagnosis and enrolment (Table).
Results: A total of 13 patients were included (Table): five patients were enrolled at AL diagnosis ("treatment naïve") while eight patients were in follow-up after Bortezomib-based treatment ("Off-therapy"). In the latter group, hematologic complete response and Very Good Partial Response were observed in 5/8 and 3/8 patients, respectively (median 38 and 57 months, respectively); complete organ response was recorded in all patients. Assessments of hormonal dosages resulted within the reference limit for all patients and nobody resulted suffering from pathological depression according to our psychologist consultant (S.A). ED prevalence was 92.3% (12/13): 9 subjects with severe ED, 1 with moderate ED, and 2 with mild ED (the patient with localized AL was the only one not suffering from ED). The flowmetric indices showed a reduction of peak systolic value (PSV) in 76.9% of patients and a pathological acceleration (Acc) in 4/13. The population was analyzed based on both andrological and haematologic characteristics. Patients with pathological Acc showed a higher age (p=0.05) and worse scores at IIEF-TOT (p=0.006), at Desire Function (p=0.011), at Overall Satisfaction (p=0.034); patients with severe ED showed a higher age (p value = 0,003) and a pathological left Acc value (p value= 0,04); patients with mild ED and patient with normal erectile function (localized AL) showed normal right PSV (P value = 0,004) and normal left PSV (p value= 0,006) in comparison with patients with moderate and severe ED. Overall, no statistical difference was found for the two groups of patients: ED prevalence and ED stage was homogenous as the flowmetric characteristics. In the "off-therapy" group no differences were found according to hematologic response.

Table 1: Patients clinical and haematologic characteristics

	Treatment naive group (n=5)	Off-therapy group (n=8)	p value
Age, median (range)	53 (41-62)	61 (55-69)	0,49
Time from diagnosis, median (range)	5 days (2-8)	66 months (10-112)	
Characteristics at AL diagnosis			
Localized AL	1 (0,2)	0	
Lambda isotype	2 (0,4)	6 (0,75)	0,28
Monoclonal component g/l, median (range)	3 (4,1-12,3)	4 (3,5-7,2)	0,63
Dflc mg/l, median (range)	223,4 (2,7-560)	77,9 (0,32-248)	0,17
Cardiac involvement	4 (0,7)	5 (0,6)	0,21
Revised Mayo clinic stage III	1 (0,2)	2 (0,25)	
Revised Mayo clinic stage IV	3 (0,6)	3 (0,37)	0,47
Troponin (median, ng/l)	96 (10-100)	90 (20-420)	0,93
NT-ProBNP (median, ng/l)	6037 (80-9588)	4829 (80-29133)	0,92
Renal involvement	3 (0,6)	7 (0,87)	0,07
Proteinuria g/24h, median (range)	1474 (140-14250)	5169 (30-7193)	0,01
Neurological involvement	0	1 (0,12)	
Liver involvement	1 (0,2)	0	
Gastrointestinal involvement	0	1 (0,12)	
Number of organs involved			
1 organ	3 (0,6)	2 (0,25)	
2 organs	0	5 (0,6)	0,04
3 organs	2 (0,4)	1 (0,12)	

Values are n (%) unless otherwise specified

Summary/Conclusion: In our study a strong association between arterial inflow deficit, penile hemodynamic alteration, and ED was outlined. Having ruled out all possible causes for secondary ED, an arteriogenic cause, sustained by a possible cardiotoxic effect of extracellular light chain, was disclosed by the presence of early endothelial dysfunction in systemic AL patients independently of AL treatment received, time from AL diagnosis and organ involvement (the patient with localized AL was the only one not suffering from ED). A possible indication our study may provide is that any patient seeking medical advice for unexplained ED (common secondary ED causes ruled out) should undergo AL screening with QPE and FLC assay.

EP1167 COST-EFFECTIVENESS ANALYSIS OF AXICABTAGENE CILOLEUCEL VS TISAGENLECLEUCEL FOR THE MANAGEMENT OF DIFFUSE LARGE B-CELL LYMPHOMA IN SPAIN

M. Bastos-Oreiro [1], M. Presa [2], A. de las Heras [2], M. Á. Casado [2], C. Pardo [3,*], V. Martín-Escudero [3], A. Sureda [4]

[1]Hematology, Hospital Universitario Gregorio Marañón, [2]Pharmacoeconomics, Pharmacoeconomics&Outcomes Research Iberia (PORIB), [3]Market Access, Gilead Sciences, Madrid, [4]Hematology, Institut Català d'Oncologia-Hospitalet, IDIBELL, Universitat de Barcelona, Barcelona, Spain

Background: Diffuse large B-cell lymphoma (DLBCL) represents approximately 30% of non-Hodgkin lymphomas, identified as one of its most common and aggressive forms. The recent inclusion of chimeric antigen receptor T-cell (CAR-T) treatments into the therapeutic scheme of DLBCL has been recognised as a change of paradigm in terms of survival and safety. Axicabtagene ciloleucel (axi-cel) and tisagenlecleucel (tisa-cel) are CAR-T therapies approved in Spain for the treatment of relapsed/refractory (R/R) DLBCL after ≥2 lines of systemic therapy in adult patients.
Aims: The aim of the study was to compare the cost-effectiveness of axi-cel vs tisa-cel for the treatment of adult patients with R/R DLBCL after ≥2 lines of systemic therapy, from the Spanish National Health System (NHS) perspective.
Methods: A lifetime partitioned survival mixture cure model, which comprises of pre-progression, post-progression, and death partitioned states, was used in the base case to estimate the accumulated costs and outcomes in terms of life years (LY) and quality-adjusted life years (QALY). Long-term survival with both therapies was estimated through a matching-adjusted indirect comparison (MAIC) that aligned the patient characteristics for the pivotal trials, fitting the patient-level data of ZUMA-1 trial for axi-cel to the aggregate-level data of JULIET trial for tisa-cel (Oluwole et al, Biol Blood Marrow Transplant, 2020). Utility values were extracted from EQ-5D data from ZUMA-1. The analysis was performed from the NHS perspective, thus only direct costs were included. Drug costs were estimated based on ex-factory prices with national mandatory deduction applied. Costs related to administration and monitoring of CAR-T therapy, apheresis, conditioning chemotherapy, disease management, stem cell transplant, hospitalisation and adverse events were derived from local cost databases and literature. A 3% annual discount rate was applied for costs and outcomes. Efficiency was expressed as incremental cost-effectiveness ratio (ICER; incremental cost vs effectiveness measured as LY), and incremental cost-utility ratio (ICUR; incremental cost vs effectiveness measured as QALY). One-way sensitivity analyses (OWSA) were carried out modifying discount rate, unitary costs, utilities, days of hospitalisation and simulating alternative scenarios such as naïve comparison without MAIC and partitioned survival model. A probabilistic sensitivity analysis (PSA) was also developed.
Results: In the base case, discounted results are as follows: axi-cel provides 9.45 LY and 7.47 QALY (7.24 in the pre-progression and 0.23 post-progression states), compared to 6.71 LY and 5.16 QALY (4.87 in pre-progression and 0.29 in post-progression) with tisa-cel. Thus, axi-cel generates 2.31 incremental QALY with an additional cost of €30,135 vs tisa-cel. The higher costs with axi-cel are mainly attributed to a longer progression-free survival, implying higher disease management costs in the pre-progression state. Hence, the ICER and ICUR are €10,999/LY and €13,049/QALY, respectively. OWSA and alternative scenario analyses show that the results are robust. The most influential parameters are the utility in the pre-progression state and the naïve comparison without MAIC. In the PSA, ICUR is ≤€22,000/QALY and ≤€60,000/QALY in 92.3% and 99.2% of the iterations, respectively.
Summary/Conclusion: Considering the frequently assumed willingness-to-pay thresholds in Spain, axi-cel is likely to be a cost-effective treatment vs tisa-cel for adult patients with R/R DLBCL in Spain.

EP1168 IMPLEMENTATION OF A HOSPITAL-AT-HOME (HAH) UNIT FOR HEMATOLOGICAL PATIENTS DURING THE COVID-19 PANDEMIC: SAFENESS AND FEASIBILITY.

I. Gómez-Centurión [1,2,*], G. Oarbeascoa [1,2], M. C. Garcia [2,3], M. C. López Fresneña [2,3], M. J. Martínez Carreño [2,3], V. Escudero Vilaplana [2,4], E. González-Haba [2,4], R. Bailén [1,2], N. Dorado [1,2], L. M. Juárez [1,2], G. Rodríguez Macías [1,2], P. Font López [1,2], C. Encinas [1,2], M. Bastos Oreiro [1,2], J. Anguita [1,2], A. Herranz [2,4], J. L. Díez-Martin [1,2], M. Kwon [1,2]

[1]Hematology, Hospital General Universitario Gregorio Marañón, [2]Instituto de Investigación Sanitaria Gregorio Marañón, [3]Nursing, [4]Pharmacy, Hospital General Universitario Gregorio Marañón, Madrid, Spain

Background: COVID-19 fatality can be as high as 30% in patients with hematological malignancies and hematopoietic stem cell transplant (HSCT) recipients.
Hospital-at-home (HAH) programs have significantly spread out in the last years and have demonstrated to improve patients satisfaction, avoid unnecessary hospital admissions and reduce healthcare costs.
Aims: To describe the implementation of an HAH unit for patients with hematological malignancies and HSCT recipients during the COVID-19 pandemic.
Methods: We retrospectively analysed the implementation of an HAH unit for caring hematological patients in our centre. In January 2020, we started our HAH unit, initially created for specific programs: at-home autologous HSCT for patients with multiple myeloma (MM), at-home consolidation treatment for patients with acute leukemia and intravenous treatment delivery. During March and April, simultaneously with the highest peak of the pandemic, the program expanded to other areas as part of our department strategy to ensure safe and high quality care for our patients. Besides, prevention measures were adopted to avoid cross-infection between patients and nurses.
At-home episode was defined as any time a patient was included in the HAH unit for a specific program previously described until patient was discharged.
Results: One hundred and five patients were included in the HAH unit between January 2020 and November 2020, with a total of 204 at-home episodes (Table 1). Nine at-home autologous HSCT were performed in 8 patients with MM (1 patient received a tandem transplant). All patients were discharged the day after infusion, except one with persistent vomiting, later discharged on day +5. Engraftment was achieved in a median time of 17 days (range 14-29) after transplant. Febrile neutropenia and engraftment syndrome rate was 0%.
Three patients were included in the at-home consolidation treatment program: 2 patients with AML and 1 with high-risk acute promyelocytic leukemia (APL). They were discharged from the hematology ward the day after cytarabine was fully administered.
Clinical and analytical monitoring or electrolyte replacement was performed at home in 32 patients (43 episodes). Five of these patients were autologous recipients who were discharged from HSCT unit before achieving engraftment, 15 were allogeneic HSCT recipients and 2 had received CAR-T cells therapy.
Azacitidine was administered at home to 22 patients (83 episodes), bortezomib to 22 patients (34 episodes) and carfilzomib to 8 patients (12 episodes).
Other episodes are described in Table 1.
Overall, more than 1000 visits were made to patients homes by nurses from the HAH unit, a median of 17 (IQR 13-19) days of admission per patient and a total of 239 visits to the hematology day-care hospital were avoided.
In summary, 28 patients (14% of all episodes) needed admission to the hospital while being treated by HAH unit, 4 of them because of SARS-CoV-2 related pneumonia. None of the nurses from the HAH unit

developed SARS-CoV-2 infection while being actively caring patients at home, thus cross-transmission was discarded.

Table 1. Main characteristics of patients and at-home episodes.

Patients, n	105
Episodes, n	204
Median age, years (range)	63 (20-92)
Female, n (%)	50 (47%)
Diagnosis, n (%)	
MM	35 (33%)
AML	27 (26%)
NHL	16 (15%)
MDS	15 (14%)
ALL	5 (5%)
Others	7 (7%)
Program, episodes (%)	
Admission avoidance programs	
At home autologous HSCT	9 (5%)
At home consolidation in acute leukemia	3 (1.5%)
Monitoring and electrolyte replacement (early discharge)	43 (21%)
Antimicrobial drugs delivery	16 (8%)
Venetoclax dose ramp-up	4 (2%)
Day-hospital avoidance programs	
Azacitidine	83 (40%)
Bortezomib	34 (16.5%)
Carfilzomib	12 (6%)
Re-admissions, n (%)	
SARS-CoV-2 related pneumonia	4 (2%)
Other causes	24 (12%)

Summary/Conclusion: Implementation of a hematology HAH unit was feasible, safe and provided a thorough advanced care to a high risk population. Admissions and visits to day hospital were significantly reduced and SARS-CoV-2 infection rate was low and probably not related to cross-transmission between patients and nurses from the unit. In our experience, the use of advanced care at-home resulted crucial during times of COVID-19 to minimize treatment interruptions and reduce the risk of cross-infections.

EP1169 USE OF CHIMERIC ANTIGEN RECEPTOR T CELL THERAPIES IN PATIENTS WITH LARGE B-CELL LYMPHOMA IN THE REAL-WORLD SETTING: SYSTEMATIC LITERATURE REVIEW

F. F. Liu [1,*], K. Hofer [2], G. S. Ardekani [2], C. Parker [3]

[1]Worldwide Health Economics and Outcomes Research, Bristol Myers Squibb, Summit, United States, [2]Health Economics and Outcomes Research, Evidinno Outcomes Research Inc., Vancouver, BC, Canada, [3]Worldwide Health Economics and Outcomes Research, Bristol Myers Squibb, Uxbridge, United Kingdom

Background: Use of chimeric antigen receptor (CAR) T cell therapies for relapsed/refractory (R/R) large B-cell lymphoma (LBCL) was first approved by the United States (US) Food and Drug Administration in 2017 (with lisocabtagene maraleucel approved in 2021) and by the European Medicines Agency in 2018. A growing body of evidence has been published recently on the effectiveness and safety of CAR T cell therapies in the real-world (RW) clinical setting. The landscape of this evidence is of particular interest to clinicians and researchers.
Aims: This systematic literature review was designed to identify and characterize the effectiveness, safety, and quality of life (QOL) of tisagenlecleucel and axicabtagene ciloleucel (axi-cel) in the treatment of R/R LBCL in the RW setting.
Methods: Study eligibility criteria were defined using the PICO (Population, Intervention, Comparators, and Outcomes) framework. Embase, MEDLINE, and relevant conference proceedings were searched from database inception to November 23, 2020. Interventional or observational studies with RW data on specific survival, response, safety, and QOL outcomes in patients with LBCL treated with tisagenlecleucel and axi-cel were included. Study quality was assessed using the Newcastle-Ottawa Scale for non-randomized studies.
Results: After study selection, 68 publications pertaining to 67 unique studies were included, comprising 21 full-text articles and 46 conference abstracts. The majority of the studies were conducted in the US (n=49), followed by the United Kingdom (n=6), Germany (n=6), France (n=4), Spain (n=1), and the US and Canada (n=1). Fifty-two (78%) studies had a sample size of <100 patients. Ten (15%) studies had >1-year follow-up, 37 (55%) had ≤6-month follow-up. Median age ranged from 50–72 years, with median or mean prior lines of therapy ranging from 3–5. Diffuse LBCL (de novo) was the most common disease histology. Use of bridging therapy varied widely from 2%–98% where reported (17 studies). Overall response rates and complete response rates ranged from 32%–84% and 12%–80%, respectively, at 3 months. Median progression-free survival (PFS) ranged from 0.8–13.8 months; median overall survival (OS) ranged from 7.9–35.0 months. PFS at 6 and 12 months ranged from 29%–60% and 20%–47%, respectively; OS ranged from 50%–100% and 56%–80%, respectively. Cytokine release syndrome (CRS) and neurological events (NEs) were reported in 49 (72%) and 47 (69%) studies, respectively. While synthesis of CRS and NE rates was limited by differences in data collection between studies, the reported rates of grade ≥3 CRS and NEs ranged from 0%–43% and 3%–41%, respectively. Only 1 study of 29 patients reported QOL outcomes (Short Form-36 QOL questionnaire), in which authors observed nonsignificant (P > .05) improvements from baseline to 90 days post-treatment with axi-cel in both the physical health and mental health components.
Summary/Conclusion: The RW evidence on the effectiveness and safety of commercially available CAR T cell therapies is growing, and a large number of observational studies on axi-cel and tisagenlecleucel in LBCL have been conducted, particularly those investigating axi-cel. The RW evidence suggests CAR T cell therapy is generally effective, based on survival and response outcomes, and safety is similar to that of clinical trials. Additionally, data on QOL are severely limited. Future prospective RW studies with large populations and incorporation of patient-reported outcomes are warranted.

EP1170 OUR EXPERIENCE OF NEGATIVE SYNERGISM BETWEEN STEROIDS AND LMWH IN PATIENTS WITH AGGRESSIVE LNH ON SKELETAL EVENTS (BONE FRACTURES)

L. Pezzullo [1,*], M. D'addona [1], C. Martorelli [1], L. Mettivier [1], I. Ferrara [1], R. Fontana [1], R. Guariglia [1], B. Serio [1], S. Luponio [1], V. Giudice [1], C. Selleri [1]

[1]hematology Division, University of Salerno, Salerno, Italy

Background: Low molecular weight heparins (LMWH) are widely used in thrombosis prophylaxis in treated lymphoma patients with central peripheral venous device (PVD). The negative effect of heparin on osteogenesis is known, it is not clear how anticoagulants vit K inhibitors act while the role of LMWH is controversial. The negative effect of steroids on osteogenesis is also documented but there are no data on negative synergy related to the simultaneous intake of steroids and LMWH.
Aims: The aim of our study is to evaluate the bone events (bone fractures) observed retrospectively in a consecutive cohort of lymphoma patients treated with chemotherapy (with or without steroids) from January 2014 to January 2021 with at least 6 months of follow-up.
Methods: From January 2014 to January 2021 we observed 197 patients with a median follow-up of 38 months (range 6-85 months); 90 with aggressive NHL treated with CHOP or similar 34 f and 56 m with a median age of 59 years (range 23-77 years); 53 with indolent NHL treated with bendamustine based therapy; 23 f and 30 m with median age of 65 years (range 42-81 years) and 54 with HD treated with ABVD or similar; 26 f and 28 m with a median age of 34 years (range 16-75 years). All patients with PVD and all treated in prophylaxis with LMWH (enoxaparin or nadroparin) 4000 U / day.
Results: In the NHL group treated with steroids and LMWH the observed bone events (fractures) were 13/90 patients (14.5%), 6 M and 7 F with a mean age of 63 years (range 39-73 years) all patients had vertebral involvement, while in 2 patients, in addition to the vertebral, with the femur involvement were documented. In the NHL group treated with LMWH but non-steroids, the observed bone events were 3/53 patients (5.5%) all female with a mean age of 66 years, while in the HD group it was 2/54 patients (3.8%) all females with a mean age of 72 years, all with vertebral involvement only.
Summary/Conclusion: These data show a higher incidence of bone events in patients receiving steroid and LMWH therapy. This evidence suggests a negative synergism between the association of steroids and

LMWH on bone metabolism and also probably confirms that vitamin D metabolism in patients with aggressive NHL may be implicated in the prognosis of these lymphomas.
This evidence suggests the need to integrate vit D with or without calcifying into the therapy of patients with aggressive NHL and to evaluate the possibility of proposing prophylaxis for thrombosis not with LMWH but with the new oral anticoagulants.
A prospective study is needed which also includes the study of calcium metabolism and bone mineralization both at diagnosis and over time in the various subtypes of NHL and which supportive treatments they have received.

EP1171 LANDSCAPE REVIEW OF THE PATIENT-REPORTED OUTCOMES VERSION OF THE COMMON TERMINOLOGY CRITERIA FOR ADVERSE EVENTS (PRO-CTCAE) IN ONCOLOGY: ADOPTION AND RECENT LEARNINGS

A. Regnault [1,*], S. Quéré [1], B. Gorsh [2], S. Sapra [2], A. Loubert [1], R. Davis [2], L. Nelsen [2], A. Cardellino [2], L. Eliason [2]

[1]Modus Outcomes, Lyon, France, [2]GlaxoSmithKline, Upper Providence, United States

Background: The PRO-CTCAE is a patient-reported outcome measure of symptomatic toxicity in oncology trials designed to complement CTCAE criteria (clinician's measure of adverse events [AEs]). Items for evaluation are selected from 78 symptomatic toxicities in the CTCAE. PRO-CTCAE uptake and use has not been uniformly assessed; understanding how to best analyze and present PRO-CTCAE data is important.
Aims: We reviewed literature on clinical trials reporting the PRO-CTCAE to ascertain its use and current analytical methods to inform future analyses.
Methods: A review of the literature and ongoing oncology trials using PubMed, oncology and outcomes research conferences (ASCO, ASH, ISOQOL, ISPOR), and ClinicalTrials.gov was completed August 2019; updated November 2020. Selected literature included guidance on: item selection; analytical methods; PRO-CTCAE data/endpoint use in clinical trials. Analytical and visualization methods from the literature were used to inform the specification of PRO-CTCAE analyses conducted on data from the DREAMM-2 (NCT03525678) trial of single-agent belantamab mafodotin (belamaf), a B-cell maturation antigen–binding antibody–drug conjugate, in relapsed/refractory multiple myeloma.
Results: After screening (n=197), 45 articles were reviewed: 13 related to recommendations for use/analysis, 7 to item selection, and 25 to examples of PRO-CTCAE use. 118 completed/ongoing trials reported PRO-CTCAE use (17 [14%] Phase I or I/II; 73 [62%] Phase II, II/III, or III; 3 [3%] Phase IV; 25 had no phase reported). Most (92/118, 78%) trials included the PRO-CTCAE as a secondary endpoint. The number of trials using the PRO-CTCAE increased from 3 in 2015 to 30 in 2020. PRO-CTCAE data in the literature were reported descriptively using tables (maximum post-baseline ratings; mean change over time; ratings higher than a predefined cutoff) and graphs (line graphs; stacked bar charts; heatmaps). These and more sophisticated analyses were applied to DREAMM-2 data to best capture the dynamics of patient-reported AEs over time, or control for baseline PRO-CTCAE ratings (eg, Toxicity over Time approach; ordinal log-linear models).
Summary/Conclusion: The importance of tolerability and symptomatic AEs for patients is increasingly recognized, particularly for new therapies. This landscape review demonstrates recent growth in interest and adoption of PRO-CTCAE. There are few existing standards for analysis; this research increases understanding of existing methods and further evaluates ways of analyzing and presenting PRO-CTCAE data over time. Additional research exploring innovative methods to analyze PRO-CTCAE data and address its challenges is needed.

EP1172 THE PSYCHOSOCIAL IMPACT OF HAEMATOPOIETIC STEM CELL TRANSPLANTATION ON ADULT PATIENTS WITH LYMPHOMA, LEUKAEMIA OR MYELODYSPLASTIC SYNDROMES – A LITERATURE REVIEW

P. Frank [1,*], R. Ramos [2], E. Sasse [1]

[1]Novartis Pharma AG, Basel, Switzerland, [2]Novartis Pharmaceuticals Corporation, East Hanover, United States

Background: Haematopoietic stem cell transplantation (HSCT) using multipotent haematopoietic stem cells from either the patient (autologous) or a donor (allogeneic) is often the only potentially curative treatment for haematological malignancies such as lymphoma, leukaemia and myelodysplastic syndromes. In addition to the physical effects exerted by the transplantation procedure and the underlying disease, HSCT may have a psychosocial impact on patients, families and carers.
Aims: To identify the areas of psychosocial impact experienced and reported by adult patients with lymphoma, leukaemia or myelodysplastic syndromes who have undergone HSCT.
Methods: A targeted literature search was conducted to identify relevant research published between 1 January 2009 and 30 January 2021 by searching CINAHL, EMBASE, IPA, MEDLINE, and PsycINFO using combinations of search terms referring to HSCT, the disease areas of interest, and phrases related to psychosocial impact (e.g. patient experience). Abstracts and full text articles were screened for relevance by two independent researchers, and the PRISMA statement was followed for this literature review.
Results: Our search retrieved 868 unique records; 826 records were excluded through abstract and full-text screening. The 42 remaining articles were deemed relevant and included in our analysis. Using meta-ethnography, a method for synthesising qualitative research and interpreting findings across multiple studies, we identified three key themes ("feelings about transplantation", "changes in psychosocial functioning after transplantation", "coping") and eight associated categories that describe the impact of HSCT. Among these categories, psychological distress was most frequently discussed, suggesting it contributes considerably to the psychosocial burden. This category includes issues such as anxiety that can be experienced by both patients and caregivers, occurring with greater intensity at certain stages of the treatment journey and potentially lasting for years post-transplantation. Altered relationships was the second most discussed category, when patients are being drawn nearer to or pushed away from others. Expectations of survivorship and lack of preparedness was the next most discussed category, where patients are confronted with the reality of life after transplantation, as they often experience persistent health effects and do not return to their lives pre-diagnosis as hoped.
Summary/Conclusion: HSCT exerts a considerable psychosocial impact on patients, their families and carers. Psychological distress – the most frequently mentioned experience – is not restricted to the period of transplantation but can persist for many years after transplantation. Patients feel unprepared for the journey ahead of them and are required to make significant adjustments at the survivorship stage. Furthering our understanding of this burden might contribute to improved patient support systems, and knowledge of both the psychosocial and physical burden of HSCT could potentially enable patients to make more informed treatment decisions when comparing transplantation with other treatment options.

EP1173 COST EFFECTIVENESS COMPARISON OF BELANTAMAB MAFODOTIN AND SELINEXOR IN RELAPSED REFRACTORY MULTIPLE MYELOMA

A. Kansagra [1,*], P. Ramakrishnan [1], G. Kaur [1], J. Trivedi [2], E. Hu [3], L. D. Anderson Jr [1], K. Kapinos [3]

[1]Hematology Oncology, [2]Pharmacy, [3]Population and Data Science, University of Texas Southwestern Medical Center, Dallas, United States

Background: Highly effective drugs have significantly affected the outcomes of multiple myeloma, with a five-year survival improving from

34.6 % in 1998 to 53.9% in 2016. Since 2009 alone, more than a dozen new treatments have been approved by FDA continuing to improve quantity and quality of life in pts with MM. However, these drugs come at a huge financial cost and cost effectiveness analysis is commonly used tool to study economic impact of novel treatments.
Aims: Multiple drugs are being developed and approved for R/R Multiple Myeloma that has been treated with Immunomodulatory drugs, Proteasome Inhibitor and anti-CD38 monoclonal antibody (TCE). We aim to study economic evidence for FDA approved therapies in TCE Multiple Myeloma
Methods: Using survival probabilities by three response groups (partial or complete response; stable disease; and progressive disease) from clinical trials for Selinexor (STORM) and Belantamab mafodotin (DREAMM-2), we estimated incremental cost effectiveness ratios from a healthcare sector perspective comparing the two treatments. We modeled 12-month treatment and severe adverse effects costs, life-years gained, and an incremental cost-effectiveness ratio among a hypothetical cohort of adults age 40 to 80 using a Markov model.
Results: The expected value of the 12-month treatment costs per life gained were $251,211 and $239,749 for Selinexor and Belantamab, respectively. Extrapolating response rates for the hypothetical cohort over a longer period suggested Selinexor treatment costs $96,170 per discounted quality-adjusted life-year (QALY) and Belantamab costs $89,521 per discounted QALY.
Summary/Conclusion: Outcomes for patients with TCE Myeloma is poor with limited therapeutic options and carry a significant cost burden. With scientific advances, we are at verge of paradigm shift with anticipated regulatory approval of therapeutic options agents like novel alkylating agents, newer immunomodulatory drugs, CAR T-cell and Bispecific Antibodies. Our study is the first to provide critically required economical perspective in choosing appropriate agents in TCE Multiple Myeloma.

EP1174 COST-EFFECTIVENESS OF ZANUBRUTINIB VERSUS IBRUTINIB IN ADULT PATIENTS WITH WALDENSTRÖM MACROGLOBULINEMIA

J. Castillo [1,*], K. Yang [2], R. Liu [3], Y. Wang [4], A. Cohen [2], T. Zimmerman [2], Q. Zhao [5], G. van de Wetering [6], X. Gao [3], B. Tang [2]

[1]Dana-Farber Cancer Institute, Boston, [2]Beigene, San Mateo, [3]Pharmerit-an Open Health Company, Bethesda, United States, [4]Beigene, [5]Pharmerit-an Open Health Company, Shanghai, China, [6]Pharmerit-an Open Health Company, Rotterdam, Netherlands

Background: The efficacy of zanubrutinib and ibrutinib was examined in the randomized ASPEN trial (NCT03053440) in adult patients with Waldenström macroglobulinemia (WM).
Aims: This analysis aimed to assess the cost-effectiveness of zanubrutinib versus ibrutinib in this population from a US payer perspective.
Methods: A 3-state (pre-progression, post-progression, and death) partitioned survival model was used to estimate the life years (LYs), quality-adjusted life years (QALYs), and costs for each treatment over a 30-year lifetime horizon. Overall survival (OS), progression-free survival (PFS), and time-to-discontinuation (TTD) curves were fitted using parametric distributions to extrapolate long-term outcomes. Selection of the parametric models for each outcome and treatment was based on assessments of 1) the proportional hazard assumption, 2) goodness-of-fit, and 3) clinical plausibility of extrapolated mean OS and associated hazard patterns (based on literature and US clinical expert input) and the alignment between PFS and TTD. Background US mortality was accounted for in the model. Utilities were based on the ASPEN EQ-5D data and literature. Costs (2020 US$) included drug (wholesale acquisition cost from RED BOOK) and adverse event management (Healthcare Cost and Utilization Project) for zanubrutinib and ibrutinib, routine care, and terminal care. Sensitivity analyses were conducted to evaluate the impact of parameter uncertainty. All outcomes were discounted at 3% annually.
Results: In the base case analyses using the dependent exponential model for all outcomes over a 30-year time horizon, zanubrutinib led to 0.94 LY and 0.84 QALY gained with an additional total cost of $11,132. This additional cost was primarily driven by patients staying on zanubrutinib treatment longer as zanubrutinib has longer time to treatment failure. However, this is partially offset by zanubrutinib's lower monthly drug acquisition, reduced cost of routine care (–$2,935) and terminal care (–$2,964) than ibrutinib. The incremental cost-effectiveness ratio (ICER) of zanubrutinib was $13,205 per QALY gained. The deterministic sensitivity analyses showed that ICER was most sensitive to the monthly costs of routine care. The probabilistic sensitivity analyses showed that the mean probabilistic ICER was $16,804, and that the probability of zanubrutinib being cost-effective was 61% at a willingness-to-pay threshold of $100,000 per QALY gained. Varying the time horizon to 5, 10, or 15 years consistently led to zanubrutinib being dominant (i.e., greater QALYs but lower costs).

CE results

	Zanubrutinib	Ibrutinib	Incremental
LY	11.33	10.39	0.94
QALY	8.75	7.90	0.84
Costs	$1,547,630	$1,536,498	$11,132
Cost/LY gained	-	-	$13,205
Cost/QALY gained	-	-	$11,806

Summary/Conclusion: Zanubrutinib appears to be cost-effective compared with ibrutinib for the treatment of patients with WM in the US.

EP1175 QUANTIFYING PATIENT PREFERENCES FOR TYROSINE KINASE INHIBITORS IN CHRONIC MYELOID LEUKEMIA: A DISCRETE-CHOICE EXPERIMENT

B. Mason [1,*], A. Russell-Smith [2], P. Hallworth [3], A. Gater [1], S. Sikirica [2], T. Gardner [3], J. Anand [2], O. Hughes [3], C. Mamolo [4], J. C. Cappelleri [4]

[1]Adelphi Values Ltd, Cheshire, United Kingdom, [2]Pfizer Inc, New York, United States, [3]Adelphi Research, Cheshire, United Kingdom, [4]Pfizer Inc, Groton, United States

Background: Currently available second and third generation tyrosine kinase inhibitors (TKIs), offer a variety of treatment options for chronic-phase chronic myeloid leukemia (CP-CML) patients and prescribing physicians. Indirect comparisons suggest the efficacy of these TKIs are similar, however each have distinct dosing requirements and safety profiles. Patient preferences for TKI dosing and safety have yet to be quantified, but are valuable for optimizing healthcare decisions and outcomes.
Aims: The aim of this study was to quantify CP-CML patient preferences and perspectives regarding treatment attributes for TKI therapies.
Methods: US-based patients (N=200) with self-reported CP-CML completed an online discrete choice experiment. Choice tasks were based on key treatment attributes: 1) dosing requirements (number of tablets and consumption with/without food), and incidence of 2) nausea, 3) fatigue, 4) pain in muscles and/or joints, 5) diarrhea, 6) blockage to a major blood vessel and 7) pleural effusion. Attributes were identified from the published literature, approved TKI labels, qualitative interviews with CML patients (N=12) and consultation with clinical experts. Hierarchical Bayesian estimation was used to calculate part-worth utilities to estimate relative importance (RI) and category-level preference of each attribute. Latent class analysis investigated preference patterns among patients.
Results: The sample included 149 females and 51 males (median age 54 years). Patients had been diagnosed for <1 year (n=31), 1-5 years (n=74), >5-10 years (n=47) and >10 years (n=48). Current treatments included dasatinib (n=62), imatinib (n=61), nilotinib (n=43), bosutinib (n=16) and ponatinib (n=1). Blockage to a major blood vessel emerged with the highest RI: 34%. RI of remaining attributes were comparable: pleural effusion (12%); fatigue (12%); pain in muscles and/or joints (11%); dosing requirements (11%); diarrhea (10%); nausea (9%). Similar findings were observed in demographic (gender, age) and clinical characteristic (time since diagnosis, current TKI) subgroups. Evaluation of mean part-worth utilities for individual attribute levels indicated preference for once daily dosing compared with twice daily dosing on an empty stomach. Lower incidences of diarrhea (20% vs 85%) were preferred, but duration of diarrhea (1-5 days vs 10+ days) had limited impact on preferences. Latent class analysis identified a number of distinct groups of participants which varied with respect to those attributes driving preferences in each group. Blockage to a major blood vessel was important in all groups, but was not always the most important attribute.

Summary/Conclusion: The likelihood of experiencing serious adverse events (blockage to a major blood vessel) was a key driver of CP-CML treatment preferences. However, heterogeneity in treatment preference patterns highlight the importance of discussions regarding dosing and treatment toxicities for optimizing individual treatment decisions.

EP1176 A NEW OPTION IN PAIN PREVENTION WITH BLISS©, A THERAPEUTIC VIRTUAL REALITY SOLUTION IN BONE MARROW CONTEXT: RESULTS OF A FRENCH OPEN-LABEL MULTICENTER RANDOMIZED PHASE II/III STUDY (REVEH TRIAL)

K. Le Dû [1,*], A.-L. Septans [2], F. Maloisel [3], H. Vanquaethem [4], A. Schmitt [5], M. Le Goff [6], M.-P. Moles-Moreau [7], M. Zinger [8], H. Bourgeois [9], M. Peron [10], F. DENIS [11], S. Bouchard [12]

[1]Hematology, Institut Inter-régional de Cancérologie, Centre Jean Bernard/ Clinique Victor Hugo, [2]ILC Jean Bernard, Weprom, LE MANS, [3]Hematology, Clinique Saint-Anne, Strasbourg, [4]Internal Medicine, Hôpital d'Instruction des Armées de Bégin, Saint-Mande, [5]hematology, institut Bergonié, Bordeaux, [6]hematology, ILC Jean Bernard, LE MANS, [7]hematology, CHU Angers, ANGERS, [8]medecine, Clinique Victor Hugo, [9]oncology, ILC Jean Bernard, LE MANS, [10]Effet Papillon Society, LAVAL, [11]radiotherapy, ILC Jean Bernard, LE MANS, France, [12]Psychoeducation and Psychology, Université du Québec en Outaouais, Gatineau, Canada

Background: The prevention of care-induced pain is a central concern for all healthcare teams in hematology units. Use of MEOPA (Oxygen + Nitrous Oxide) is today a standard of care for relaxation procedure. Distraction through immersion in virtual reality (VR) has already documented its analgesic effects in several phase II trials but comparison with standard treatments in a large randomized study is needed.
Aims: We assessed the safety and efficacy of a new therapeutic virtual reality solution for pain distraction, Bliss©, in prevention of pain and anxiety before performing a bone marrow biopsy.
Methods: We conducted an open-label multicenter randomized phase II/III trial (ClinicalTrials.gov identifier: NCT03483194) in 5 sites in France. Bliss© is a VR software with four imaginary interactive environments in three dimensions. Binaural sound and specific music programs were created to promote immersion and relaxation. The program runs on a smartphone and a GearVR head-mounted display. Efficacy was evaluated by pain intensity with visual analog scale (score from 0 to 10) just after the biopsy and anxiety by 2 questionnaires (fear of pain before the biopsy and revised STAI questionnaire before and after the biopsy). The primary end point was patient-assessed pain intensity after the bone marrow procedure. Statistical analysis was performed with modified intention to treat (Fisher test).
Results: A total of 126 patients were enrolled with previously untreated malignant hemopathy or suspected between September 6, 2018 and May 18, 2020. They were randomly assigned in a 1:1 ratio to receive pain prevention with MEOPA (n=63) or Bliss© (n=63) before and during their bone marrow biopsy. All patients received a local anesthesia with lidocaïne before the biopsy. In addition, patients, nurses and physicians performed efficacy and safety measures during a 1-month follow-up assessment.
Median age of the study population was 65.5 years old (range 18 to 87) and 54.2% were men. The average pain intensity was 3.5 (standard deviation 2.6) for the MEOPA group and 3.0 (SD 2.4) for the VR group (p=0.26), without any significant difference according to age, gender or hemopathy. Concerning anxiety, 67.5% of patients were afraid before the biopsy and anxiety scores were moderate to very high in 26.3% of patients before the biopsy (STAI questionnaire) and 9.0% after the biopsy for all patients without any significant difference between the 2 groups (17.3% of reduction in anxiety for the MEOPA group and 17.2% for the VR group, p=0,83). Immersion in VR was well tolerated in 100% of patients included in the VR group. Physicans were very satisfied by the relaxation procedure in 64.9% of cases (52.5% in the MEOPA group and 77.6% in the VR group, p=0,01) and recommended re-use of the technique in 54.2% in the MEOPA group and 79.1% in the VR group (p=0,02).

Summary/Conclusion: The intensity of pain did not significantly differ in both arms. Bliss©-based relaxation method was well tolerated and the satisfaction of patients and physicians was very high in VR group. This study validates the use of immersion in VR with Bliss© as a new digital therapeutics and support the integration of the software in the panel of supportive care.

EP1177 A CROSS-SECTIONAL STUDY EXAMINING THE IMPACT OF AGEING ON THE PSYCHOSOCIAL EXPERIENCES OF PATIENTS WITH LYMPHOMA

N. Dren [1,*], O. Bamigbola [1], L. Warwick [2]

[1]Research, [2]Management, Lymphoma Coalition, Mississauga, Canada

Background: Patients with lymphoma face various emotional consequences as a result of their diagnosis and treatment. Progress in providing high-quality care for the psychosocial impacts of lymphoma has not matched the advances in lymphoma detection and treatment. Patients in different life stages may experience different psychosocial issues or varying intensities of psychosocial issues because of their lymphoma.
Aims: Using data from the Lymphoma Coalition (LC) 2020 Global Patient Survey (GPS) on Lymphomas and CLL, this study examines the impact of ageing on the psychosocial experiences of patients with lymphoma.
Methods: Globally, 11,878 respondents including 9,179 patients and 2,699 caregivers took part in the LC 2020 GPS. There were 9,078 patients included in this analysis who self-identified their age. These patients were grouped into five age groups for analysis: 18-29 (n=638), 30-39 (n=1,196), 40-59 (n=3,261), 60-69 (n=2,216), and 70+ (n=1,767). Demographics of the five age groups were examined, and descriptive analyses for all questions relating to psychosocial issues were performed in IBM SPSS v27.
Results: The five age groups differed significantly ($p< 0.001$) in all the demographic categories examined. These categories included lymphoma subtype, sex, area of residence, education level, employment status, and household status.
Patients were asked which psychosocial issues they had experienced over the last 12 months because of their lymphoma diagnosis. The oldest age group (70+) reported the lowest prevalence of every psychosocial issue listed (table 1). The oldest age group (70+) also reported the highest prevalence of experiencing no psychosocial issues ('none')(39%). In all cases, each psychosocial issue was most prevalent in the youngest age groups (18-29 and 30-39), with prevalence decreasing with increasing age (table 1).
Patients who reported experiencing symptoms of lymphoma/CLL were asked how these symptoms impacted their life, including everyday activities, employment, social life, and relationships (table 1). The lowest prevalence for each of these impact categories was observed in the oldest age group (70+) (table 1). The highest prevalence for each category, except for social life, was observed in the youngest age group (18-29) (table 1).
Patients who reported experiencing treatment-related side effects were asked how these side effects impacted their life, including everyday activities, employment, social life, and relationships (table 1). The lowest prevalence for each of these impact categories was observed in the oldest age group (70+) (table 1). In all cases, the greatest prevalence of each

impact was observed in the youngest age groups (18-29 and 30-39), with the prevalence of each issue decreasing with increasing age (table 1).

Table 1. Quality of life issues that patients with lymphoma reported experiencing due to their disease and treatment by age group

	Prevalence of issues by age group					
Psychosocial issues experienced in the last 12 months	18-29 %	30-39 %	40-59 %	60-69 %	70+ %	X^2 (p-value)
Loss of self-esteem	43	38	25	14	7	578.10 (p< 0.001)
Concerns about body image	51	45	28	20	14	497.18 (p< 0.001)
Changes in relationships	34	30	19	11	8	379.57 (p< 0.001)
Isolation	29	24	20	15	10	156.86 (p< 0.001)
Depression	48	39	33	24	17	298.96 (p< 0.001)
Anxiety	51	51	37	24	14	559.45 (p< 0.001)
Fear of cancer relapse	68	69	56	41	29	474.69 (p< 0.001)
Fear of lymphoma progression	39	42	41	41	31	49.60 (p< 0.001)
None	9	9	15	24	39	512.98 (p< 0.001)
How lymphoma/CLL symptoms affected day-to-day life (those who strongly agree or agree)	18-29 %	30-39 %	40-59 %	60-69 %	70+ %	X^2 (p-value)*
Negative impact on everyday activities	60	53	56	53	47	146.49 (p< 0.001)
Unable to work/change job or working pattern	50	49	48	38	18	632.39 (p< 0.001)
Negative impact on social life	50	49	51	43	33	254.50 (p< 0.001)
Created problems with partner, friends, relatives	44	43	37	23	14	574.02 (p< 0.001)
How treatment-related side effects affected day-to-day life (those who strongly agree or agree)	18-29 %	30-39 %	40-59 %	60-69 %	70+ %	X^2 (p-value)*
Negative impact on everday activities	68	66	63	56	49	212.17 (p< 0.001)
Unable to work/change job or working pattern	59	57	53	38	16	781.49 (p< 0.001)
Negative impact on social life	59	61	54	45	34	353.27 (p< 0.001)
Created problems with partner, friends, relatives	43	45	34	21	13	537.56 (p< 0.001)

*Chi square values calculated based on the inclusion of all question response options, though only the percentages for those who strongly agree or agree are displayed in the table.

Summary/Conclusion: This analysis revealed that compared to the mid to oldest patient groups, younger patients with lymphoma are disproportionately affected by psychosocial issues resulting from their disease and treatment. These psychosocial issues can negatively impact quality of life. Psychosocial assessment and intervention should be high priority for all patients with lymphoma; however, younger patients may require additional attention and support. In the future, LC would like to explore how demographic differences may have confounded results.

EP1178 TARGETED LANDSCAPE REVIEW FOR UNDERSTANDING LYMPHOMA PATIENT-REPORTED OUTCOME ASSESSMENT IN THE ERA OF EMERGING THERAPIES

S. Hudgens [1,*], A. Guobyte [2], E. Yucel [3], J. Braverman [3], A. Hayes [4], F. F. Liu [3], C. Bacon [5], A. Stevenson [2], J. W. Shaw [3]

[1]Regulatory and Access, Clinical Outcomes Solutions, Tucson, [2]Clinical Outcome Assessments, Clinical Outcomes Solutions, Chicago, [3]Worldwide Health Economics and Outcomes Research, Bristol Myers Squibb, Princeton, United States, [4]Clinical Outcome Assessments, Clinical Outcomes Solutions, Folkestone, [5]HTA and Payer Insight, Fingerpost Consulting, Poynton, United Kingdom

Background: The lymphoma treatment landscape is changing with the introduction of chimeric antigen receptor (CAR) T cell therapies and there is a need to better understand the patient experience. During development of new therapies, patient-reported outcome measures (PROMs) provide useful information on clinical outcomes from the patient perspective. A targeted landscape review of data from published literature, clinical trial databases, and health technology assessment (HTA) reviews is a traditionally required step to identify appropriate PROMs to inform clinical development programs of new treatment options.

Aims: This landscape review aimed to identify and summarize evidence on the use of PROMs in lymphoma based on publicly available literature, product labels for medications approved by the United States Food and Drug Administration and/or the European Medicines Agency (EMA) for the treatment of lymphoma, and existing HTA information (eg, clinical effectiveness, safety, patient and social aspects) for lymphoma.

Methods: We conducted a targeted literature search using the Ovid platform and clinical trial registries from 2009–2020. English-language titles, abstracts, and clinical trial outcome measure descriptions that focused on lymphoma were reviewed, and those that mentioned the use of a PROM were deemed eligible for inclusion. Product labels were reviewed for 7 medications approved for the treatment of adult lymphoma (ie, brentuximab vedotin, lenalidomide, idelalisib, axicabtagene ciloleucel, tisagenlecleucel, pembrolizumab, pixantrone), and a review of HTA reports was carried out for non-Hodgkin lymphoma indications in 9 countries and regions over the last 5 years.

Results: A total of 1683 articles and conference abstracts were identified and screened from the Ovid platform, of which 78 were considered eligible for inclusion. In addition, 1541 clinical trials were identified and reviewed, of which 129 reported PROM use. Among literature included, a total of 67 different PROMs were identified. The most used PROMs were Functional Assessment of Cancer Therapy – Lymphoma (FACT-Lym), European Organization for Research and Treatment of Cancer Quality of Life Questionnaire – 30 items (EORTC QLQ-C30), and EQ-5D (See Table). The most frequently cited PROMs evaluated fatigue, pain, sleep, dermatological symptoms, and neurotoxicity. Out of 7 medications approved for adult lymphoma, brentuximab vedotin was the only one that included PROMs in its EMA labeling (EORTC QLQ-C30, EQ-5D, FACT-General); however, no clinically meaningful difference between treatment arms was reported. According to the HTA review of the 7 medications, the FACT-Lym, 36-Item Short Form Health Survey (SF-36), and Skindex-29 were all consistently accepted as relevant, validated measures to capture PRO assessments for lymphoma indications. However, treatment benefit reported by PRO data was limited by an absence of comparative data, exploratory analyses, low number of patients, and a short length of follow-up.

Table. Frequency of use of PROMs in publications and clinical trials.

Measure	No. of times found in the literature	
	Publications	EU and US clinical trials
FACT-Lym	13 (1 CAR T cell therapy)	41 (2 CAR T cell therapy)
EORTC-QLQ-C30	19 (0 CAR T cell therapy)	77 (6 CAR T cell therapy)
EQ-5D	19 (0 CAR T cell therapy)	54 (5 CAR T cell therapy)

Summary/Conclusion: A multitude of PROMs have been employed in assessing patient burden in lymphoma. Health authorities and HTA centers recognize sensitive, validated, and reliable PROMs that report on lymphoma-specific symptom burden and patients' health-related quality of life and well-being as critical for assessing treatment benefit and interpreting patient burden. With appropriate study design and robust PRO data collection (eg, comparative data, validated instruments), PROMs should be considered in assessing patients' quality of life for emerging lymphoma therapies.

EP1179 CLINICALLY IMPORTANT CHANGE IN FACIT-FATIGUE SCORE FOR PATIENTS WITH COLD AGGLUTININ DISEASE: AN ANALYSIS USING THE PHASE 3 CARDINAL AND CADENZA STUDIES

Q. A. Hill [1,*], A. Röth [2], B. Jilma [3], C. M. Broome [4], S. Berentsen [5], A. A. Rizio [6], F. Joly [7], P. DasMahapatra [8], X. Jiang [8], F. Shafer [8], M. Iglesias-Rodriguez [8], J. Su [9], M. Kosinski [6], D. Cella [10]

[1]Department of Haematology, St James University Hospital, Leeds, United Kingdom, [2]Department of Hematology and Stem Cell Transplantation, West German Cancer Center, University Hospital Essen, University of Duisburg-Essen, Essen, Germany, [3]Department of Clinical Pharmacology, Medical University of Vienna, Vienna, Austria, [4]Division of Hematology, MedStar Georgetown University Hospital, Washington, DC, United States, [5]Department of Research and Innovation, Haugesund Hospital, Haugesund, Norway, [6]QualityMetric Incorporated LLC, Johnston, RI, United States, [7]Sanofi, Chilly-Mazarin, France, [8]Sanofi, [9]Sanofi, Employee at time of study, Cambridge, MA, [10]Department of Medical Social Sciences, Northwestern University, Chicago, IL, United States

Background: Sutimlimab (formerly BIVV009) is a humanized monoclonal anti-C1s antibody with a clinical trial program to support its development as a treatment for cold agglutinin disease (CAD). CARDINAL (NCT03347396) and CADENZA (NCT03347422) are Phase 3 clinical trials for sutimlimab in patients with CAD. As fatigue is one of the most common symptoms of CAD (Su et al. ASH 2020; 2484), one of the secondary aims of CARDINAL and CADENZA was to examine treatment-related change in fatigue using the Functional Assessment of Chronic Illness Therapy (FACIT)-Fatigue outcome measure.

Aims: To estimate the clinically important change (CIC) for FACIT-Fatigue in patients with CAD using pooled data from CARDINAL and CADENZA. The CIC reflects the smallest score change that indicates a meaningful treatment benefit for individual patients.

Methods: CARDINAL is an open-label, single-arm, multicenter study in patients with CAD with a recent blood transfusion. CADENZA is a randomized, double-blinded, placebo-controlled study in patients with CAD without a recent blood transfusion. Data from the Part A, 26-week component of both studies were combined for these analyses. Anchor- and distribution-based analyses were performed to estimate the CIC. Anchor-based approaches (mean change and model-based) examined the relationship between change in FACIT-Fatigue scores and change in related anchor variables from baseline to Week 26. The independent variable was change in FACIT-Fatigue score and dependent variables were binary (improvement vs. no improvement). The anchor variables were change in self-assessed general health perceptions (as measured through change in response to the general health scale [GH01] of the Short Form 12-Item (version 2)® Health Survey [SF-12v2]), change in Patient Global Impression of (fatigue) Severity (PGI-S), Patient Global Impression of Change (PGIC), and change in hemoglobin levels.
Results: Fifty-five patients were included from CARDINAL (n=17) and CADENZA (n=38 [n=19 placebo, n=19 sutimlimab]). The median (range) age was 70 (46–88) years and 76% (n=42) were female. Mean FACIT-Fatigue score rose from 32.6 at baseline to 39.3 at Week 26, an improvement of 6.7 points. Correlations between FACIT-Fatigue scores and GH01, PGI-S, and PGIC exceeded 0.40, indicating moderately strong associations (**Table 1**). When using an anchor-based approach that evaluates mean change in FACIT-Fatigue score, CIC estimates ranged from 9.20 (PGIC) to 15.69 (PGI-S). Results from the two model-based anchor approaches that estimate CICs using receiver operating characteristic–based and logistic regression–based analyses ranged from 2 (hemoglobin) to 8.87 (GH01) (**Table 2**). CIC estimates generated from the anchor-based approaches ranged from 2 to 16 (interquartile range [IQR], 5–10). Distribution-based analyses determined the CIC to be 5.62 when based on one-half standard deviation of FACIT-Fatigue at baseline, and 2.78 when based on the standard error of the measure. The empirically determined CIC for patients with CAD for FACIT-Fatigue was 5, a median estimate produced by model-based analyses that falls within the IQR of all anchor-based analyses and converges with estimates produced by distribution-based analyses.

Table 1. Polychoric correlation coefficient between FACIT-Fatigue and anchors

Anchors		N	FACIT-Fatigue at baseline	FACIT-Fatigue at Week 26	Change in FACIT-Fatigue
GH01	Baseline	53	0.63	–	–
	Week 26	53	–	0.78	–
	Change	53	–	–	0.64
PGI-S	Baseline	35	0.83	–	–
	Week 26	35	–	0.87	–
	Change	35	–	–	0.80
PGIC	Week 26	53	–	–	0.56
Hemoglobin	Baseline	55	0.20	–	–
	Week 26	55	–	0.41	–
	Change	55	–	–	0.54

Table 2. Results of ROC-based and logistic regression–based analyses

				ROC-based analyses				Logistic regression–based analyses
Anchors	N, total	N, improved	Percentage with improvement	AUC	Sensitivity	Specificity	CIC	CIC
GH01	53	21	39.62	0.79	0.71	0.78	8	8.87
PGI-S	35	15	42.86	0.93	0.87	0.85	5	7.01
PGIC	53	34	64.15	0.74	0.68	0.74	4	4.15
Hemoglobin	55	30	54.55	0.73	0.73	0.68	2	5.66

AUC, area under the receiver operating characteristic curve; FACIT-Fatigue, Functional Assessment of Chronic Illness Therapy-Fatigue; GH01, general item of the 12-item Short Form Health Survey; CIC, clinically important change; PGIC, Patient Global Impression of Change; PGI-S, Patient Global Impression of (Fatigue) Severity; ROC, receiver operating characteristic.

Summary/Conclusion: This study estimated a CIC of 5 for FACIT-Fatigue in patients with CAD, a CIC consistent with estimates for other disease areas (eg, rheumatoid arthritis, systemic lupus erythematosus, anemia related to cancer). This analysis demonstrated that the FACIT-Fatigue Scale may be an appropriate and interpretable assessment of fatigue among patients with CAD.

EP1180 INCREASED ANTIDEPRESSANT USE AMONG NEWLY DIAGNOSED PATIENTS WITH COLD AGGLUTININ DISEASE COMPARED WITH OTHER PATIENTS IN A LARGE US HEALTHCARE SYSTEM

C. M. Broome [1,*], P. Patel [2], X. Jiang [3], M. Iglesias-Rodriguez [2], J. Fryzek [3]

[1]Division of Hematology, MedStar Georgetown University Hospital, Washington DC, [2]Sanofi, Cambridge, MA, [3]EpidStrategies, Rockville, MD, United States

Background: Cold agglutinin disease (CAD) is a rare form of autoimmune hemolytic anemia (AIHA) that accounts for approximately 20% of all AIHA and is characterized by classical complement pathway–mediated hemolysis. Clinical manifestations of CAD can include complement-mediated chronic hemolytic anemia, profound fatigue, as well as transient agglutination-mediated circulatory symptoms (Swiecicki et al. *Blood* 2013). CAD (formerly primary CAD) is clinically distinct from secondary cold agglutinin syndrome (CAS), which is caused because of an underlying condition (coexisting diagnosis of overt malignancy or infection). Recent research has shown that patients with anemia are more likely to develop depression and anxiety (Shafi et al. *J Coll Physicians Surg Pak* 2018; Vulser et al. *Acta Psychiatr Scand* 2016); however, this has not been studied in patients with CAD.
Aims: To determine the antidepressant (AD) use in patients with CAD (includes patients with both primary CAD and secondary CAS) versus those without CAD in a large United States (US) healthcare system.
Methods: We conducted a matched-cohort comparison study evaluating AD use in patients with and without CAD. All patients with CAD were identified in the Optum Claims-Clinical database by reviewing clinical notes for CAD terms. Patients with CAD were matched (1:10) to patients without CAD by age (±3 years), sex, race, region of residence, and active time and season and year of entry date in the Optum health plan. Patients ≥25 years of age with no history of anxiety or depression were included in the study. Patients were considered to be on ADs if they had at least three medication codes recorded in the database on different dates. Cox regression models were built to estimate time to first medication use, adjusted for age, sex, race, region, comorbidity score, and cluster (matched CAD and non-CAD cohorts). A subset analysis was also performed in patients with primary CAD. Medication use was further described using univariate analyses.
Results: A total of 317 patients with CAD (mean [standard deviation (SD)] age, 70.1 [12.7] years) and 1965 patients without CAD (comparison; mean [SD] age, 69.9 [12.4] years) were identified between 2006 and 2016 and included in the study. Patients with CAD were twice as likely to have medically attended anxiety and depression than their comparisons (hazard ratio [HR], 1.69; 95% confidence interval [CI], 1.03–2.75). On average, patients with CAD with medically attended anxiety and depression started ADs 15 months (SD, 17 months) after diagnosis. The top three ADs used in patients with CAD and medically attended anxiety and depression included benzodiazepines (76%), antipsychotics (24%), and selective serotonin reuptake inhibitors (SSRI; 10%). A similar pattern was seen for comparisons, but the proportion using benzodiazepines was less versus patients with CAD (76% vs 60%). Comparisons used more SSRIs versus patients with CAD (31% vs 10%). Patients with and without CAD used a similar proportion of antipsychotics (24% vs 21%, respectively). Sub-analysis of patients with primary CAD reported a higher risk for AD use versus those without CAD (HR, 2.37; 95% CI, 1.34–4.20). A similar pattern for the specific AD use was also reported.
Summary/Conclusion: Our study indicates that ADs are used more often in patients with CAD versus patients without CAD. These findings suggest that patients with CAD may experience extra-hematologic manifestations of the disease that potentially have a broader impact on their overall mental health, physical health, and quality of life. Further investigation on this topic is warranted.

EP1181 A MACHINE LEARNING APPROACH TO IDENTIFICATION OF CLINICALLY RELEVANT HEMATOLOGY-ONCOLOGY RESEARCH PUBLICATIONS

A. Luchinin [1,*], O. Kolupaev [2]

[1]Kirov Scientific Research Institute of Hematology and Blood Transfusion of the Medical-Biological Agency, Kirov, Russian Federation, [2]UNC Chapel Hill, Lineberger Comprehensive Cancer Center, Chapel Hill, United States

Background: In the last 10 years, the amount of clinical research published in the field of oncology has grown dramatically due to accelerated pace of drug development and increased use of combination treatments. Concurrently, the problem of finding high-quality clinical research publications to develop evidence-based treatment plans for individual patients has become more challenging. Commonly used solutions primarily rely on bibliographic metadata and expert curation. Here, we describe a tool for fast automatic identification of clinically relevant publications that does not use the tags associated with the publication or curation.
Aims: Here, we describe a tool for fast automatic identification of clinically relevant publications that does not use the tags associated with the publication or curation.
Methods: We used a machine learning approach, trained on the titles of PubMed publications downloaded to the database through OncoTriage.com service. Papers predominantly describing clinical trials in hematological malignancies and clinical cases were used in the analysis. Balanced training data included texts cited in expert-curated sources to form a "*relevant*" dataset (i.e., high quality publications describing treatment of hematologic malignancy), and an "*irrelevant*" dataset that did not include data relevant to therapy. We used a Bayes approach with a binary classification. Briefly, 26,667 texts were processed to get a document-term matrix representation of both the training and the test set (80/20 split).
Results: Our model for "*irrelevant*" detection classified papers in the test dataset with AUC 0.859 accuracy (95%CI 0.853-0.865, p<0.0001), with sensitivity 0.93 and specificity 0.72. The balance of the model was biased towards the sensitivity. We speculate that our training dataset for the model was skewed towards publications describing clinical trials. Therefore, several clinically relevant categories of publications describing treatments were labeled as "irrelevant". An expert examination of the false positives has revealed that these publications included therapy reviews, single center practices and observational studies that nonetheless are informative for clinical practice. We plan to address these drawbacks in future iterations of the model by incorporating supervised or reinforcement learning approaches. The interactive web app is available at https://luchinin.shinyapps.io/PubMed_Triage/
Summary/Conclusion: Machine learning is an effective approach for a large-scale automaticidentification of clinically relevant publications from a variety of databases, such asPubMed and conference abstracts. The use of machine learning techniques as one of the filtersto build a database tailored for clinicians. In the future tools using this database may help tominimize the time clinicians spend finding high-quality publications that fit their patient's profile.In addition, it can be used as a clean-up step for getting a list of publications for further curationby the subject matter experts. Future work will extend this approach and may be integrated intodecision support systems and knowledge management databases.

EP1182 HEALTH-RELATED QUALITY OF LIFE (HRQOL) IN PATIENTS (PTS) WITH MYELODYSPLASTIC SYNDROMES (MDS) IN THE CONNECT® MYELOID DISEASE REGISTRY

D. A. Revicki [1,*], D. L. Grinblatt [2], R. S. Komrokji [3], G. Garcia-Manero [4], M. R. Savona [5], B. L. Scott [6], M. A. Sekeres [7], E. D. Flick [8], A. Y. Makinde [8], P. Kiselev [8], C. U. Louis [8], M. Nifenecker [8], I. S. DeGutis [8], C. R. Cogle [9]

[1]Outcomes Research Consulting, Sarasota, FL, [2]NorthShore University Health System, Evanston, IL, [3]H. Lee Moffitt Cancer Center, Tampa, FL, [4]The University of Texas MD Anderson Cancer Center, Houston, TX, [5]Vanderbilt-Ingram Cancer Center, Vanderbilt University School of Medicine, Nashville, TN, [6]Fred Hutchinson Cancer Research Center, Seattle, WA, [7]Sylvester Comprehensive Cancer Center, University of Miami Health System, Miami, FL, [8]Bristol Myers Squibb, Princeton, NJ, [9]University of Florida, Gainesville, FL, United States

Background: At diagnosis, disease risk and transfusion burden (TB) can impact HRQoL in pts with MDS. The impact of disease status and higher transfusion requirements on HRQoL has not been well studied.
Aims: We used data from the Connect® Myeloid Disease Registry, an ongoing, prospective, observational cohort study that includes adult pts with lower-risk (LR) and higher-risk (HR) MDS, to investigate factors influencing baseline (BL) and subsequent HRQoL.
Methods: BL and Month 6 (M6) data from pts enrolled from Dec 12, 2013 to Mar 6, 2020 (data cutoff) were analyzed. Pts were stratified by International Prognostic Scoring System (IPSS) risk (LR, HR), treatment (Tx) within 45 days post-enrollment (no Tx, best supportive care [BSC], active Tx), and TB 16 weeks post-BL (non-transfusion dependent [NTD], low TB [LTB]; 1–3 transfusions, high TB [HTB]: ≥4 transfusions). Pts completed EuroQol 5 dimensions (EQ-5D), Functional Assessment of Cancer Therapy-Anemia (FACT-An) trial outcome index (TOI), and FACT-Fatigue (FACT-F) questionnaires at BL and quarterly thereafter. Clinically meaningful change, based on minimally important differences, was defined as a change of ±0.07 for EQ-5D, ±6 for FACT-An TOI, and ±3 for FACT-F.
Results: At data cutoff, 830 (489 LR, 341 HR) pts were enrolled. Median age was 74 years. 278 pts received no initial Tx, 161 BSC, and 378 active Tx. At BL, 470 were NTD, 197 LTB, and 163 HTB. Of 670 pts still on-study at M6, 462 completed the questionnaires at both BL and M6.
At BL, clinically meaningful differences were observed in FACT-An TOI and FACT-F scores, but not EQ-5D, between LR- and HR-MDS and the Tx subgroups. From BL to M6, no clinically meaningful changes were observed in mean scores for each questionnaire. For the TB subgroups, meaningful differences were observed at BL in FACT-An TOI and FACT-F scores, but not EQ-5D (Table). From BL to M6, meaningful decreases in scores were reported by 26%, 30%, and 35% of NTD, LTB, and HTB pts in EQ-5D, 41%, 43%, and 48% for FACT-An TOI, and 40%, 42%, and 48% for FACT-F; increases were reported by 19%, 19%, and 20% pts for EQ-5D, 31%, 32%, and 39% for FACT-An TOI, and 30%, 39%, and 40% for FACT-F.

Table. Mean HRQoL scores in pts with MDS

		EQ-5D		FACT-An TOI		FACT-F	
		BL (n=807)	M6 (n=459)	BL (n=803)	M6 (n=463)	BL (n=810)	M6 (n=464)
IPSS risk	LR	0.80	0.79	92.3	92.4	23.4	24.1
	HR	0.75	0.79	83.9	87.5	20.5	22.2
Tx	None	0.81	0.80	96.0	95.9	25.6	25.9
	BSC	0.78	0.77	87.2	88.2	20.3	21.7
	Active	0.76	0.78	84.3	87.3	20.6	22.2
TB	NTD	0.80	0.81	92.9	95.9	24.2	25.7
	LTB	0.75	0.75	83.6	82.0	19.4	19.6
	HTB	0.76	0.75	83.6	84.3	19.8	20.8

BL, baseline; BSC, best supportive care; EQ-5D, EuroQol 5 dimensions; FACT-An, Functional Assessment of Cancer Therapy-Anemia; FACT-F, Functional Assessment of Cancer Therapy-Fatigue; HRQoL, health-related quality of life; IPSS, International Prognostic Scoring System; HTB, high transfusion burden; LTB, low transfusion burden; M6, Month 6; MDS, myelodysplastic syndromes; NTD, non-transfusion dependent; pt, patient; TB, transfusion burden; TOI, trial outcome index; Tx, treatment.

Summary/Conclusion: This preliminary analysis suggests that pts with HR-MDS, and transfusion-dependent pts, generally had worse HRQoL at BL, providing further support to initiating active Tx in pts with TB. Possible limitations of the analysis are lower completion rates in pts with more severe disease, and EQ-5D may not capture changes in these subgroups at M6. A longer follow-up may help delineate the impact of Tx on HRQoL assessments in pts with MDS.

[1]Haematology and Haemotherapy, [2]Clinical Analysis Unit; Biotechnology Department, [3]Biotechnology Department, Poniente Hospital Public Health Agency, El Ejido, Spain

Background: Point-of-care testing (POCT or bedside testing) provide faster results than those obtained in hospital laboratory analyzers, but should not compromise quality and safety. Compared to arterial and venous blood, capillary blood can be easily collected from the fingertip and does not require a skilled worker. Therefore, it has excellent potential as an ideal blood source for disease diagnosis and health monitoring. In coagulation, these systems are very useful in obtaining the INR test for the monitoring of vitamin K antagonist (VKA) oral anticoagulants therapy. Xprecia Xtride™, Siemens®, is a POC system, with an ergonomic design, touch screen and intuitive software that, after performing an automatic calibration and two quality control checked on each test strip, provides INR after analyzing a sample of 6 µl of capillary blood, reporting data between 0.8 and 8. It uses Innovin® reagent with ISI 1. It is stablished that a POC device should be assessed for reproducibility against a central laboratory analyser, since INR is essential for proper management of oral anticoagulation. Regarding to NCCLS guidelines, statistically there is an equivalence of INRs obtained from POC systems that are within 0.4 at a target INR of 2.5 and 0.7 at a target INR of 3.5. Results exceeding an INR of 5.0 generally have reduced trueness, precision, and linearity, both in POC and laboratory-based testing.
Aims: This is a comparative study of INRs obtained by a POC system (POC-INR) compared to INRs obtained from plasma of venous samples collected in citrate tubes (P-INR), both from the same patient at the time. In previous studies of our own we found linearity between both methods and no statistically significant differences. In this study, our intention was to demonstrate if there was such correlation exclusively in supra-therapeutic INR results.
Methods: POC-INR was obtained from capillary sample analyzed with POC Xprecia Xtride™, Siemens®. If INR was superior to 3.0, a venous citrated sample was recolected and P-INR was obtained from ACL-TOP500 hospital analyser, Werfen®, using as reagent Hemosil Recombiplastin® ISI 1. The results were compared with the statistical package Medcalc to calculate Pearson correlation coefficient and non-parametric Passing-Bablok regression analysis, suitable for method comparison studies.
Results: We obtained 215 samples of POC-INR higher than 3.0 and P-INR from the same patients at the time. A correlation coefficient r=0.7698 with a 95% confidence interval (0.7091 to 0.8192) was obtained, with the regression equation y=0.160+0.967 X, where y=P-INR, x=POC-INR: a=0.160 CI 95% (-0.4238 to 0.6581), b=0.9667 CI 95% (0.8762 to 1.0692) with a value of p=0.73, being evident that there are no significant differences regarding the deviation of the linearity between both techniques.
Summary/Conclusion:
POCT Xprecia Xtride™ system, Siemens®, offers INR results statistically comparable to those obtained from plasma in a laboratory analyzer, even with supra-therapeutic INR values.
POCT allows the accessibility of the patient for the monitoring of VKA oral anticoagulant therapy; with the transmission of results via web, the decentralization of the control in the Health Centers is facilitated, allowing the validation and dosage from the hospital.
It offers a valid alternative to the historical pattern in which testing was mostly confined to the medical laboratory and provides continuous improvement in patient care quality.

EP1184 FERTILITY PRESERVATION IN LYMPHOMA PATIENTS TREATED WITH IMMUNOCHEMOTHERAPY WITH OR WITHOUT RADIOTHERAPY: RESULTS OF A RETROSPECTIVE MULTICENTER STUDY OF THE FONDAZIONE ITALIANA LINFOMI (FERTY CARE).

Background: In the last decades, a significant improvement in overall survival (OS) of patients (Pts) affected by lymphoma has been observed. Fertility and gonadal function represent one of the most important aspects for long-term lymphoma survivors.
Aims: We designed this retrospective, multicentric, observational study, with the primary end point to describe the application in real-life of different methods of fertility preservation during treatment in lymphoma pts afferent to the Fondazione Italiana Linfomi (FIL) centers participating. Other end points were: to determine amenorrhea rate after first and subsequent lines of treatment and possible risk factors in young female lymphoma patients and to record rate of pregnancy and miscarriage after treatment in this population.
Methods: All female pts, aged from 18 to 40 years old, diagnosed with Hodgkin (HL) or non-Hodgkin's lymphoma (NHL) in the timeframe between Oct 1st/2010 and May 31st/2018, treated with chemoimmunotherapy (CHT) regimens and/or radiotherapy (RT) were included in the analysis. Histology included were: HL, primary mediastinal B-cell (PMBCL), diffuse large B-cell (DLBCL), follicular (FL), mantle cell (MCL) and T-cell Lymphoma.
Results: A total of 414 women were enrolled in the study. Median age was 28 years old (range 18-40), histology were: HL 308 (74%), PMBCL 56 (13%), DLBCL 43 (10%), FL plus MCL plus T-cell lymphoma 7 (3%). Advanced Ann Arbor stage III-IV was seen in 164 (40%) of pts. First line treatment were: ABVD in 295 (71%), R-CHOP like in 102 (25%), higher intensity regimens (BEACOPP/high dose chemotherapy plus autologous stem cell transplantation (ASCT) in 17 (4%) cases. 203 (49%) patients received RT. A relapsed/refractory disease was observed in 48 (11%) cases, and 52% of them received ASCT. Pretreatment data recorded: regular period in 80%, previous pregnancy in 26%, previous miscarriage in 9%. Overall, 76% of the ptsreceived GnRH analogues during chemotherapy; 10% took OCs and 14% nothing. Oocytes and ovarian tissue cryopreservation were performed in 55 and 42 pts, respectively (23%). In 7 pts were proposed with cryopreservation but not performed for therapy urgency. Post treatment data were transient amenorrhea in 216 (75%), premature ovarian failure (POF) in 33 (9%), a restored regular period was observed in 293 (90%) on cases. After treatment were recorded 43 (10%) pregnancies and 17 (4%) miscarriages. Most pregnancies (88%) were observed in women under 30 years of age and subjected to a single line of therapy. Median age of menopause onset was 34.5 ± 7.8 years old (19.0-47.0). In multivariate analysis median age at diagnosis and number of lines of treatment correlate with higher rate of amenorrhea, risk of POF and menopause. No protective effect of GnRHa administration of amenorrhea, POF and menopause was observed. Even if 23% of pts performed oocytes and ovarian tissue cryopreservation, this was not used in any case.
Summary/Conclusion: Pregnancy in long term lymphoma survivors should be considered possible and safe. Median age at diagnosis and number of treatment lines correlate with amenorrhea, POF rate and menopause. The use of GnRHa and OCs not seem protective for fertility. Our study confirm the need to a correct and multidisciplinary approach to fertility preservation in young lymphoma patients for a correct strategy in relation to the patient's age, type of disease and chemotherapy treatment

EP1185 IMPACT OF THE COVID-19 PANDEMIC ON HEALTH-RELATED QUALITY OF LIFE AND ANXIETY IN PEDIATRIC HEMATOLOGY/ONCOLOGY PATIENTS: A SINGLE EGYPTIAN CENTER EXPERIENCE

E. Hassan [1], D. Nagui Rizk [2], N. Aly [3], Y. El Chazli [1,*]

[1]Pediatrics, [2]Neuropsychiatry, [3]Pediatric Dentistry and Dental Public Health, Alexandria University, Alexandria, Egypt

Background: Since the World Health Organization declared coronavirus disease 2019 (COVID-19) pandemic, the strain on healthcare services affected patients suffering from various comorbidities and added to the psychological burden.
Aims: To assess anxiety level and it's impact on the health-related quality of life (HRQoL) of pediatric Hematology/Oncology patients during the COVID-19 pandemic.

Methods: A cross-sectional study on convenience sample of 292 children with chronic hematological/oncological disorders attending Alexandria University Children's Hospital with their parents/guardians available were included. Patients' recruitment was done from May to June 2020 during the peak of the pandemic in Egypt. A Three groups were included: Patients with bleeding/coagulation disorders, transfusion-dependent patients, and patients receiving chemotherapy. HRQoL was assessed using a validated Arabic version of Parent proxy-report of Pediatric Quality of Life Inventory ™ (PedsQL™ 4.0 Generic Core Scales). Anxiety was assessed using the Arabic version of the Spence Children's Anxiety Scale (SCAS). The preschool (PAS) and parent versions of the scale (SCAS-P) were completed by the caregivers. The preschool anxiety scale was used to measure anxiety in children aged 2.5-6.9 years.
Results: The mean age was 8.72 ± 3.66 years, 52.4% were males and 65.4% were transfusion-dependent patients. Almost 60% of children were aware of the pandemic and 60.3% had blood transfusion difficulties. Males had lower anxiety levels than females ($p < 0.001$), and transfusion-dependent patients had lower anxiety levels than patients receiving chemotherapy ($p < 0.001$). Children who were aware of the COVID-19 pandemic had lower anxiety levels than those who were not ($p = 0.006$), while those suffering from fewer clinic days had higher anxiety levels ($p = 0.02$). Anxiety significantly reduced the three HRQoL domains ($p < 0.001$).
Summary/Conclusion: The present study demonstrated the degree of anxiety and HRQoL affection during the COVID-19 pandemic in children with chronic hematological/oncological diseases and malignancies. The anxiety score was highest in patients receiving chemotherapy, while the HRQoL was lowest in patients with bleeding/coagulation disorders. These findings help a better understanding of the psychological impact of the pandemic on the studied group as a crucial step in guiding policies and interventions to maintain their psychological wellbeing.

EP1186 THE IMPACT OF COVID-19 ON A RURAL HEMATOLOGY OUTREACH SERVICE, AN AUSTRALIAN EXPERIENCE

H. Cashman [1,2,*], S. Sushil [2], S. Milliken [1], N. Hamad [1,2,3,4]

[1]Department of Haematology and Bone Marrow Transplant, St Vincent's Hospital, [2]St Vincent's Clinical School, University of New South Wales, Sydney, [3]Murrumbidgee Local Health District, Griffith, [4]School of Medicine, University of Notre Dame, Sydney, Australia

Background: The COVID-19 pandemic has had widespread and drastic impacts on healthcare delivery across the world, aside from the direct effects of the virus itself. Patients in rural areas represent a particularly vulnerable population who may be heavily impacted by changes to healthcare provision.
Griffith is a regional city in New South Wales, Australia with a fortnightly outpatient outreach hematology service provided by visiting hematologists travelling by plane from St Vincent's Hospital in Sydney. Hematologists were abruptly unable to continue regular in-person visits to Griffith after the COVID-19 pandemic caused flight disruptions and travel bans in April 2020. Rapid shifts to telemedicine consultations for remote specialist patient management were imposed due to the travel changes, supported by a pre-existing hematology-specific integrated and unified electronic health record between the two sites as previously reported[1]. This system offered the ability to continue the safe prescribing, monitoring and multidisciplinary management of haematology patients including those with malignant diseases.
Aims: To review the impacts of the COVID-19 pandemic on a rural hematology outreach service, including on clinical service activity and patient transfer rates to the metropolitan tertiary referral centre.
Methods: We reviewed the Griffith hematology outreach service activity for the 12 month period before and following the COVID-19 pandemic began significantly impacting rural Australian health services by causing flight cancellations and reliance on telemedicine reviews alone. Data was collected for the time periods April 2019-March 2020 and April 2020-March 2021 inclusive [remaining data to be presented]. Clinical service activity and patient admission rates to the metropolitan tertiary referral centre were assessed.
Results: Prior to the pandemic, an average of 39 patients were seen in the Griffith clinic each month, compared to an average of 47 per month after the change to telemedicine, Figure 1. The number of new patient consultations performed increased over time, from 64 new patient reviews to 79 from April 2020. The St Vincent's Hospital hematology clinic service was similarly able to sustain it's activity with increases seen in both total and new patient reviews, increasing by 12% and 15% respectively.
There was no increase seen in the number of hematology patients from the Griffith region needing treatment at the tertiary referral centre due to disruptions in care. In the 12 months prior to the service disruption (April 2019- March 2020), 18 patients were treated or required hematological investigation at the tertiary referral centre at St Vincent's Hospital in Sydney, compared to nine patient over the 10 month period following.

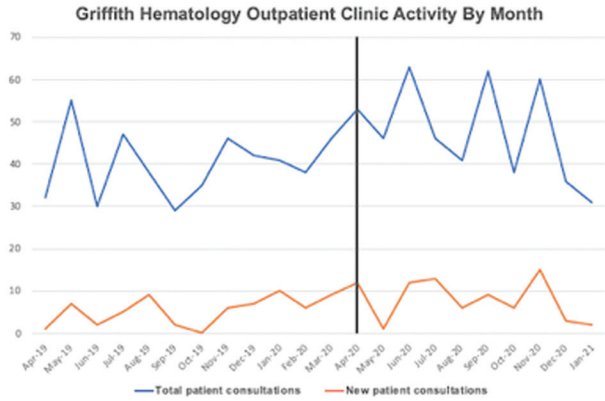

Figure 1: Griffith hematology outpatient clinic activity by month, April 2019-January 2021.
The black line denotes the change to telemedicine consultations due to flight disruptions.

Summary/Conclusion: We demonstrate how a rural outreach hematology service was able to continue with minimal disruption after the COVID-19 pandemic caused an abrupt transition to exclusively remote patient reviews and chemotherapy management. The use of an integrated digital platform shared between the two sites allowed the remote telehealth service to be maintained. Significant increases in rural patients requiring transfer or admission to the tertiary referral centre in Sydney were not seen. With continued uncertainty and unpredictable flight changes, we demonstrate long term and sustainable adjustments are feasible and necessary to serve rural populations from potentially detrimental changes to already fragile health services.

EP1187 APPRAISAL OF THE CONSISTENT USE AND REPORTING OF PATIENT-REPORTED OUTCOMES IN MULTIPLE MYELOMA CLINICAL TRIALS: DOES IT MATTER?

E. Laane [1,*], T. Ionova [2], E. N. Oliva [3], M. Andreas [4], N. Kreuzberger [4], V. Piechotta [4], I. Monsef [4], N. Skoetz [4], S. Salek [5]

[1]Department of Hematology and Oncology, University of Tartu, Tartu, Estonia, [2]St.Petersburg State University Hospital, Saint-Petersburg, Russian Federation, [3]Grande Ospedale Metropolitano Bianchi Melacrino Morelli, Reggio Calabria, Italy, [4]Evidence-based Oncology, Department I of Internal Medicine, Center for Integrated Oncology Aachen Bonn Cologne Duesseldorf, Faculty of Medicine and University Hospital Cologne, University of Cologne, Cologne, Germany, [5]School of Life and Medical Sciences, University of Hertfordshire, Hatfield, United Kingdom

Background: The treatment landscape for the management of multiple myeloma (MM) has substantially evolved over the past decade. Inclusion of humanistic outcomes reported by patients (PROs) to supplement the clinical outcomes is becoming increasingly important in MM clinical trials to ensure the intended benefits based on patients' perspective. For patients with MM, PRO measurement is essential to understand the impact of treatment on their physical and psychosocial functional behaviour and evaluate the benefit-risk balance of specific treatments. However, it is unclear which PRO instruments are utilized in multiple myeloma trials, how often they are used and whether results are consistently reported.
Aims: The aim of this project was to explore the use and frequency of PRO instruments in randomized controlled trials (RCTs) for MM and to assess the consistency of their reporting.
Methods: Under the auspices of the European Hematology Association (EHA), development of guidelines for the use of PROs in adult patients with hematological malignancies was conceptualised. MEDLINE and CENTRAL were systematically searched for RCTs investigating multiple myeloma between 2015 and 2020. Study design, disease and treatment characteristics, primary outcome, PRO instrument(s) as well as the methods of their reporting were extracted using a pre-defined template. To assess the consistency of PRO reporting, study registries were compared

with publications, study protocol and Health Technology Assessment (HTA) reports, where available.
Results: Overall, 10,707 records were found. Following screening for RCTs, 283 ongoing, completed or published studies were included for review. 118 studies planned the use of PROs. The most frequently used PRO instrument (92 studies) was the EORTC QLQ-30 measuring health-related quality-of-life (HRQoL) in cancer patients. The disease-specific questionnaire EORTC-MY20 was also frequently used (50 studies). Likewise, the HRQoL instrument EQ-5D was used in 50 studies. Overall, 38 different PRO instruments were reported. In 39 studies for which a study protocol was found, only 19 reported PRO instruments consistently with the trial registry for the study. In addition, in 30 studies for which a publication reported PRO results (58 overall), the information on PRO instruments differed between publication and the trial registry. Further, information on PRO in HTA reports was available for 26 studies of which 18 reports were consistent with the trial registries.
Summary/Conclusion: The findings indicate that despite the general agreement on the importance of measurement of PROs in multiple myeloma RCTs, they remain under-utilized and under-reported. While most studies identified in this review comply with the recommendations for incorporating PROs into adult oncology trials, they are often inconsistently reported. Thus, guidelines for the appropriate use of PROs are needed to ensure standardisation in selection and reporting of PROs.

EP1188 FERTILITY ANALYSIS IN MALE PATIENTS LONG SURVIVING BY HODGKIN'S LYMPHOMA

F. Gaudio [1,*], P. Masciopinto [1], C. Nardelli [2], M. P. Vacca [2], E. Cicinelli [2], P. Musto [1]

[1]Unit of Hematology and Stem Cell Transplantation, AOUC Policlinico, [2]Unit of Second Unit of Obstetrics and Gynecology, AOUC Policlinico, Bari, Italy

Background: The outcome of patients with Hodgkin's lymphoma (HL) has greatly improved in recent years, which is why the attention of doctors and researchers has increasingly been diverted towards the well-being of these young patients. Consistent with this, the study aimed to analyze the influence of HL and its treatment on the fertility status of young males and detect new predictors affecting the likelihood of parenthood.
Aims: Consistent with this, the study aimed to analyze the influence of HL and its treatment on the fertility status of young males and detect new predictors affecting the likelihood of parenthood.
Methods: In this retrospective study, the fertility status of 42 male patients (mean age 25 years) with HL treated at the University Hospital of Bari (Italy) between 2008 and 2016 was studied. All were assessed for fertility at diagnosis, while 24 had post-treatment fertility status checks. All patients underwent ABVD as first-line chemotherapy, of them 6 patients with relapsed/ refractory disease underwent autologous hematopoietic stem cell transplantation (ASCT).
Results: At the time of diagnosis, we found that 15 (35%) patients had normozoospermia, 19 (45%) oligozoospermia (of these 14 had other despermias), and 8 (19%) only other despermic conditions. After treatment, 17% of patients had azoospermia (all had undergone ASCT). Of the 9 normozoospermic patients at the time of diagnosis, 5 (55.5%) maintained that condition after treatment, while 4 (45.5%) developed azoospermia associated with other types of despermia (all undergoing ASCT). Of 11 patients with oligozoospermia and other types of despermia at the time of diagnosis treated with first line alone (no ASCT group), 6 (54%) normalized the fertility status after treatment; in the same group, 5 of 6 patients (83%) with normozoospermia at diagnosis maintained the status after treatment. Furthermore, in patients who received first-line treatment only, the mean sperm concentration was increased post-treatment (5.53 x10e7 at diagnosis vs 4.02 x10e7 after treatment).
We also found that 4/6 patients undergoing ASCT had azoospermia and despermia in the post-treatment control. On the other hand, 2 of the 3 patients, who had oligozoospermia before treatment, became normozoospermic after therapy. Furthermore, in univariate analysis, we found that patients undergoing ASCT were associated with severe impairment of fertility in terms of sperm motility (74% at diagnosis versus 22% after ASCT; p = 0.025, Fig. 1). In patients not undergoing ASCT we found a statistically significant improvement in fertility in terms of motility (35% at diagnosis versus 50% after treatment; p = 0.009, fig. 1)

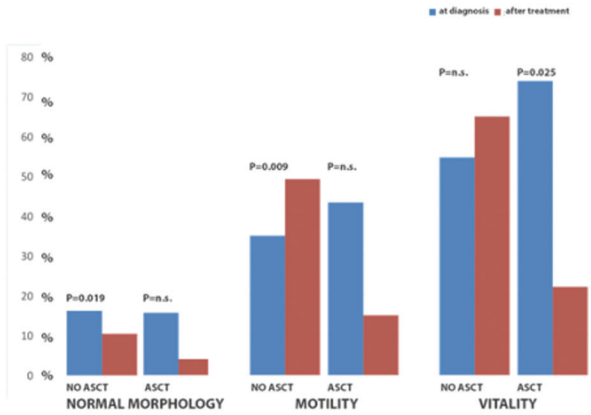

Figure 1: percentage of spermatoza normal morphology, motility and vitality at time of diagnosis and of post treatment control.

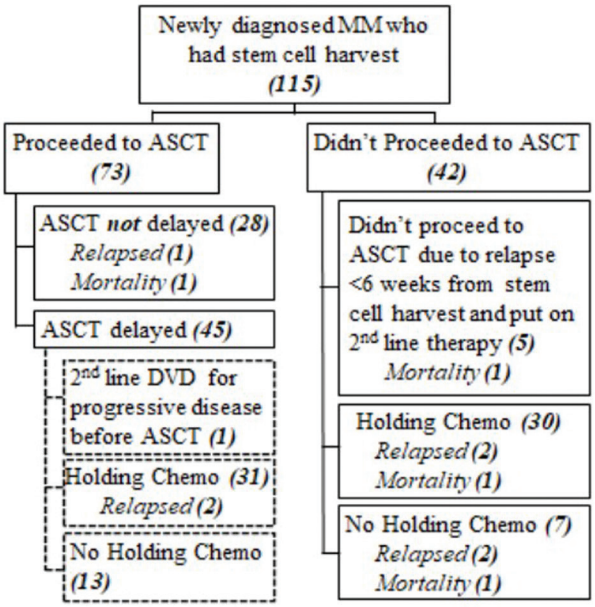
Summary/Conclusion: In this study we found that ASCT induces infertility in the majority of male patients with HL and that first-line treatment could improve the fertility status caused by the disease. Further studies are needed in a larger case series to investigate risk factors for impaired fertility at diagnosis and after treatment.



EP1189 IMPACT OF COVID-19 ON AUTOLOGOUS STEM CELL TRANSPLANTATION (ASCT) IN MULTIPLE MYELOMA (MM) PATIENTS: A SINGLE-CENTRE, QUALITATIVE EVALUATION STUDY

M. Camilleri [1,*], G. Bekris [2], G. Sidhu [3], C. Buck [4], E. Elsden [2], O. McCourt [1], J. Horder [5], F. Newrick [5], N. Rabin [5], K. Yong [1], A. Fisher [2]

[1]Haematology, Cancer Institute, [2]Institute of Epidemiology and Health Care, University College London, London, [3]Public Health, North East Lincolnshire Council, Leeds, [4]Department of Social Science, University College London, [5]Haematology, University College London Hospitals NHS Foundation Trust, London, United Kingdom

Background: ASCT is standard of care in biologically fit, newly diagnosed MM (NDMM) patients (pts), offering deeper responses with prolonged progression free/overall survival and improved quality of life (QOL). However, with the UK's 1st national lockdown on 23/03/2020, several guidelines recommended deferring ASCT for MM due to risks of infection, with resource limitations forcing some units to suspend ASCT entirely. Such changes to pts' treatment plans inevitably altered their lived experience during these uncertain times with expected impact on QOL.
Aims: To provide a snapshot of how COVID-19 affected the MM ASCT service in a single UK institution, including changes to chemotherapy treatment plans, timing, and prioritisation of ASCT. To gain insight into MM pts' understanding of their disease, initial therapy and ASCT, and their response to therapy changes.
Methods: We collected data on 115 NDMM pts who had a stem cell harvest (PBSCH) for upfront ASCT from December 2019–January 2021. During this time, 3 national lockdowns led to the ASCT service being suspended twice (March–June 2020 and January–February 2021). 25 pts within this cohort underwent a semi-structured interview via telephone. Inductive and deductive framework analysis was utilised to determine key themes and subthemes.
Results: Pts were discussed in multidisciplinary meetings and decisions taken to delay or defer ASCT based on pt fitness, disease risk and depth of response. 73 (63%) proceeded to ASCT and 42 (37%) were deferred indefinitely ($ASCT^{def}$). The 2 groups were similar in terms of gender, age and ISS, but there were more pts with adverse risk cytogenetics in the ASCT group (26% *vs* 12%). Both groups were predominantly treated with bortezomib-based induction; in 11/73 (15%) ASCT and 7/42 (16.7%) $ASCT^{def}$ pts treatment was changed to an oral, lenalidomide-based regimen to reduce hospital attendances for parenteral therapy. Overall response to induction in the 2 groups was similar; 97.3% and 95.2% and ^{3}VGPR 59% and 52.4% in ASCT and $ASCT^{def}$ pts respectively. 28/73 ASCT pts had no delay to ASCT and none received

bridging chemotherapy; 45/73 had delayed ASCT (median 11 months [5–17] from start of induction) of whom 31 were put on bridging chemotherapy. In the 42 ASCT^{def} pts, 5 relapsed within ≤6 weeks of PBSCH and received 2nd line therapy, 30 were put on holding chemotherapy (previously not offered in the UK) as per NHS England COVID-19 interim guidance and 7 remained treatment-free post-induction.
Thematic analysis identified 6 overarching themes: a) psychological response to diagnosis and initial therapy, b) beliefs and opinions about the benefits of ASCT, c) perceptions of information provided about MM and ASCT, d) high levels of fear and anxiety around COVID-19 and e) feelings about ASCT disruption or delay due to COVID-19 f) perceptions of care. Example subthemes were beliefs that ASCT would provide a long-remission/best chance of normality including freedom from chemotherapy and associated side-effects, disappointment and devastation at COVID-related treatment delays (in spite of high anxiety about infection) and exceptionally high levels of trust in the transplant team.

Summary/Conclusion: New COVID-19-adapted guidelines, and new ways of perceiving and balancing risks of ASCT, led to a substantial proportion of MM pts having a delayed or indefinitely deferred ASCT. Such enforced changes gave us an opportunity to explore pts' attitudes, perceptions, and expectations around MM and ASCT. Insights gained will help us adjust our service and counselling approaches to be more in tune with pts' priorities and expectations.

EP1190 OUTCOMES OF BRENTUXIMAB VEDOTIN AS ≥3 LINE TREATMENT IN PATIENTS WITH RELAPSED/REFRACTORY CLASSICAL HODGKIN LYMPHOMA: PHYSICIAN'S AND PATIENT'S PERSPECTIVE

T. Ionova [1,2,*], M. Andrievskikh [3], A. Amdiev [4], E. Baryakh [5], V. Chang [6], A. Endakova [7], N. Fadeeva [3], G. Husainova [8], V. Ivanov [9], K. Kaplanov [10], O. Kaverina [11], M. Pirogov National Medical Surgical Center, [18]N.N. Burdenko Main Military Clinical Hospital, Moscow, [19]Clinic of Professional Pathology and Hematology named after V.Ya. Shustov, Saratov State Medical University, Saratov, [20]Regional Clinical Hospital, Krasnoyarsk, [21]Tula Regional Clinical Hospital, Tula, Russian Federation

Background: For patients with relapsed/refractory classical Hodgkin Lymphoma (R/R cHL) who are ineligible for auto-SCT, or who are relapsed after auto-SCT, one of promising treatment options is brentuximab vedotin (BV). Real-world data about risks/benefits of this treatment are limited. Comprehensive evaluation of effects of BV, including patient-reported outcomes, in this patients population is worthwhile.
Aims: Here we demonstrate the results of multicenter observational study aimed to evaluate clinical and patient-reported outcomes in R/R cHL pts receiving BV as ≥3rd treatment line in the real world setting.
Methods: Pts with R/R cHL receiving BV 1.8 mg/kg q3w as ≥3rd treatment line were included in the real-world study. Treatment response was assessed using RECIST criteria v. 1.1. Duration of response (DOR) and progression free survival (PFS) were evaluated by Kaplan-Meier analysis. Adverse events (AEs) were evaluated in accordance with NCI CTCAE v. 4.0. For QoL and symptom assessment pts filled out RAND SF-36 and ESAS-R, accordingly. Generalized Estimating Equations (GEE), Friedman ANOVA and McNemar's test were used for statistical analysis.
Results: In total, 62 pts with R/R cHL (median age – 31 yrs, range 18–67, 53% males) were recruited in the study: 69% pts had advanced stage (III–IV) at diagnosis; 66% pts – B-symptoms; 18% pts – ECOG 2-3; 29% – comorbidities. All pts received 2-10 previous treatment lines (median – 3); 98% pts were primary refractory/relapsed, among them 19% relapsed after auto-SCT. Before BV treatment start 60% pts had severe/critical QoL impairment. All the pts experienced symptoms; 88.7% pts had moderate-to-severe symptoms, more than half pts had moderate-to-severe worse wellbeing (76%), tiredness (67%), drowsiness (60%), depression and lack of appetite (each 53%). At median follow-up of 8 mo (5.3–15 mo) one patient died at 2 mo after treatment start not because of HL, one patient was lost. For the entire follow-up period 68.3% pts achieved/maintained the objective response (OR). Among them 40% pts achieved the best response in terms of complete remission, 28.3% pts – partial remission. Median of DOR in 41 pts with OR was 11 mo (95% CI: 0.8– -).The median PFS was 10.6 mo (95% CI: 7.4-12.9). Most common AEs were peripheral neuropathy (55%) and fatigue (38%), AEs of grades III-IV were reported in 1.6% pts. SAE was reported in one case (sepsis, respiratory insufficiency due to agranulocytosis, BV was temporary stopped). During 15 mo of BV treatment significant QoL improvement was revealed for all SF-36 scales (GEE, p<.01). The most pronounced meaningful improvement was found for role physical functioning (Δ=60 scores), role emotional functioning (Δ=44) and vitality (Δ=28). Proportion of pts with severe/critical QoL impairment dramatically decreased during BV treatment (at 9, 12 and 15 mo, p<.05). The severity of all symptoms by ESAS-R decreased (p≤.001). Total Symptom Score by ESAS-R became significantly less after treatment start: 36.5 at baseline vs 5.6 at 15 mo (p<.001).
Summary/Conclusion: The results of this multicenter real world study confirm notable effectiveness and good tolerability of BV as a treatment modality for R/R cHL pts. Median PFS was 10.6 mo; 68.3% pts achieved OR (CR – 40%). Treatment toxicity is comparable with clinical data; AEs of grades III-IV – in 1.6% pts. BV treatment is accompanied with dramatical QoL improvement and significant decrease of symptom burden.

EP1191 PAROXYSMAL NOCTURNAL HEMOGLOBINURIA'S HUMANISTIC AND ECONOMIC BURDEN IN PATIENTS RECEIVING C5 INHIBITORS IN EUROPE

J. Panse [1,*], J. E. Matos [2], T. Mnif [3], K. Lehrhaupt [2], S. P. Sarda [4], S. B. Baver [4], J. Fishman [4], Z. Hakimi [5], J. Nazir [5], E. Persson [5], J. C. Birkmose [5]

[1]Department of Hematology, Oncology, Hemostaseology and Stem Cell Transplantation, University Hospital RWTH Aachen, Aachen, Germany, [2]Health Division, Kantar, New York, United States, [3]Health Division, Kantar, Paris, France,

[4]Apellis Pharmaceuticals, Inc, Waltham, MA, United States, [5]Sobi, Stockholm, Sweden

Background: Paroxysmal nocturnal hemoglobinuria (PNH) is a rare acquired and potentially life-threatening hematologic disease, characterized by hemolytic anemia, thrombosis and impaired bone marrow function. Treatment with the C5 inhibitors has resulted in a reduction in intravascular hemolysis and improvements in morbidity and mortality. Despite the clinical benefit for PNH patients (pts), real world evidence studies indicate that pts treated with C5 inhibitors eculizumab (ECU) and ravulizumab (RAV) experience continued impairment in productivity and overall quality-of-life (QoL), and that a significant proportion of pts, besides being anemic continues to experience fatigue and other symptoms.[1]
Aims: Assess the burden of illness in European PNH pts currently treated with C5 inhibitors, from a clinical, humanistic and economic perspective. Here, we present interim results to specifically, assess the impact of PNH on QoL and work productivity in a subgroup of pts receiving ECU in Germany, France, and the United Kingdom (UK), or RAV (Germany only).
Methods: A cross-sectional online survey administered to pts with self-reported PNH diagnosis. The survey, initiated in February 2021, aims to recruit 90 pts. Following a Central Institutional Review Board exemption, convenience sampling was used to recruit pts through patient advocacy groups in each country. Inclusion criteria required a self-reported PNH diagnosis, age ≥18 years, current treatment with ECU or RAV and agreement to informed consent and adverse event reporting. To assess the burden of illness in these pts, Work Productivity and Activity Impairment–General Health questionnaire, Functional Assessment of Chronic Illness Therapy (FACIT)-Fatigue scale (total score range: 0-52), and European Organization for Research and Treatment of Cancer QoL Questionnaire (EORTC-QLQ-C30; total score range: 0-100) were analyzed. For the interim analyses reported here, descriptive statistics are presented.
Results: In February 2021, 37 pts were included in the study, among which 21 were residing in Germany, 4 in France, and 12 in the UK. Pts with self-reported PNH diagnosis had a median age of 43 years (range 19-74) and most were female (70%). There were 32% pts on ECU, and 68% pts on RAV; all pts had been on treatment for at least 3 months and most for at least 1 year (96% ECU and 83% RAV). The FACIT-Fatigue total score (mean[±SD]: 35[±13]) was lower than the general population mean (~44, determined in a German population); and the EORTC-QLQ-C30 global health status score (67[±18]) was also below the mean of the European general population (~76). Furthermore, the EORTC-QLC-C30 physical functioning score mean (84[±15]) averaged lower than the general population mean (~93). Pts also reported 35%[±29] impairment in normal daily activities in the prior 7 days (37%[±31] ECU, 32%[±26] RAV). The 22 pts (60%) employed at the time of the study reported 6%[±22] absenteeism (proportion of work time lost due to being absent; ECU: 10% [±28], RAV: 1%[±4]) and 20%[±24] presenteeism (productivity impairment while working; ECU: 21%±[26], RAV: 19%[±23]). Total work productivity impairment was 29%[±32] (ECU: 48%[±34], RAV: 19%[±23]).
Summary/Conclusion: This burden of illness interim analysis among European PNH pts indicates a substantial unmet need in regards to economic burden and QoL as the results show relevant work-related productivity loss, diminished ability to work, limitations in daily life activities, and reduced QoL, despite treatment with ECU or RAV.

EP1192 DEVELOPING TREATMENT ATTRIBUTES FOR A PATIENT PREFERENCE SURVEY: A QUALITATIVE MULTINATIONAL STUDY IN MULTIPLE MYELOMA

R. Janssens [1,*], T. Lang [2], A. Vallejo [2], J. Galinsky [2], A. Plate [2], K. Morgan [2], E. Cabezudo [3], R. Silvennoinen [4], D. Coriu [5], S. Badelita [6], R. Irimia [5], M. Anttonen [7], R.-L. Manninen [7], E. Schoefs [1], M. Vandebroek [8], A. Vanhellemont [9], M. Delforge [9], H. Stevens [10], S. Simoens [1], I. Huys [1]

[1]*Department of Pharmaceutical and Pharmacological Sciences, KU Leuven, Leuven,* [2]*Myeloma Patients Europe, Brussels, Belgium,* [3]*Department of Haematology, H. Moises Broggi / ICO-Hospitalet, Barcelona, Spain,* [4]*Department of Hematology, Helsinki University Hospital Comprehensive Cancer Center and University of Helsinki, Helsinki, Finland,* [5]*"Carol Davila" University of Medicine and Pharmacy and Fundeni Clinical Institute,* [6]*Fundeni Clinical Institute, Bucharest, Romania,* [7]*Association of Cancer Patients in Finland, Helsinki, Finland,* [8]*Faculty of Economics and Business, KU Leuven,* [9]*University Hospital Leuven, Leuven,* [10]*Institute for Interdisciplinary Innovation in healthcare (I3h), Université Libre de Bruxelles (ULB), Brussels, Belgium*

Background: Patient preferences have become an important focus for inclusion in the drug development, regulatory, and reimbursement process for multiple myeloma (MM) treatments (Postmus et al, 2018; Fifer et al, 2020). Over the last decade there has been a rapid development of new medicines for MM, all with varying safety and efficacy profiles. Therefore, the need for a clear and standardized methodology for collection of patient preference data is important.
Aims: This study aimed to understand which characteristics of treatment MM patients find most important and should be included as attributes in a subsequent (quantitative) preference survey.
Methods: This research incorporates a literature review and qualitative discussions with patients to formulate attributes for inclusion in a subsequent quantitative patient preference survey. This qualitative study involved: i) a scoping literature review, ii) discussions with MM patients (n=24) in Belgium, Finland, Romania, and Spain using *Nominal Group Technique (NGT)*, and iii) a qualitative thematic analysis with multi-stakeholder discussions.
Results: After completion of the literature review, a patient consensus on MM treatment attributes was reached using *NGT*. Thematic analysis generated the following treatment attributes for inclusion in the subsequent quantitative patient preference survey: i) life expectancy, ii) life-threatening side-effects (such as the development of another cancer), iii) treatment response (i.e., a reduction of cancer signs), iv) nerve or bone problems affecting movement (such as fractures), v) thinking problems (such as concentration problems), vi) increased susceptibility to infections, vii) reduced energy, viii) pain (such as bone pain), ix) emotional problems (such as mood changes), x) eating and digestive problems (such as incontinence), and xi) vision problems (such as blurred vision).
Summary/Conclusion: Obtaining patient insights for inclusion in subsequent quantitative preference studies requires several steps. This study highlights the importance of the incorporation of the qualitative portion of a patient preference study, to ensure sensitive and appropriate attribute selection. This study illustrates that patients focus not only on treatment efficacy, but also value a reduction of MM-related symptoms and side effects.

EP1193 HEALTHCARE RESOURCE UTILIZATION AMONG PATIENTS WITH COLD AGGLUTININ DISEASE IN DENMARK

E. K. Vágó [1,*], G. Nicholson [2], E. Horváth-Puhó [1], N. Hooda [2], J. P. Fryzek [2], J. Su [3]

[1]*Department of Clinical Epidemiology, Aarhus University, Aarhus, Denmark,* [2]*EpidStrategies, Rockville, MD,* [3]*Sanofi, Employee at time of study, Cambridge, MA, United States*

Background: Cold agglutinin disease (CAD) is a rare, chronic type of autoimmune hemolytic anemia characterized by classical complement pathway–mediated hemolysis. Clinical manifestations may include chronic hemolytic anemia, profound fatigue, and transient agglutination-mediated circulatory symptoms. CAD (formerly primary CAD) is clinically distinct from secondary cold agglutinin syndrome, which is caused by an underlying condition (coexisting diagnosis of overt malignancy or infection). Healthcare resource utilization (HRU) for patients with CAD in Europe is unknown.
Aims: Compare overall and CAD-related HRU in patients with CAD versus matched comparators in Denmark.
Methods: Nationwide patient registries were used to identify newly diagnosed cases of CAD (International Classification of Diseases, Tenth Revision, code: D591A) in Denmark between January 1, 1999 and June 30, 2016. Each patient with CAD was matched 10:1 to a comparison patient from the general population by birth year, gender, and comorbidities. Inpatient, outpatient, and emergency room (ER) visits and transfusion use were assessed 6 months before and 12 months after the date of the first CAD diagnosis/index date. Descriptive statistics, conditional logistic regression, mixed-effect negative binomial regression, and zero-inflated binomial mixed model were used to compare HRU among patients with CAD versus matched comparators. CAD-related inpatient and outpatient visits were also assessed.
Results: A total of 104 patients with CAD and 1003 comparison cohort members were included. Women comprised over half of the cohorts (53% CAD; 52% comparator), and 60% were ≥70 years of age (59%

comparator). Nearly half of the cohort had ≥2 comorbidities (45% CAD; 43% comparator). At 6 months before CAD diagnosis/index date, 31% of patients with CAD experienced an inpatient hospitalization versus 13% of matched comparators (P<0.001). Outpatient and ER visits were experienced by 80% (vs 47% comparators; P<0.001) and 19% (vs 5% comparators; P<0.001) of patients with CAD, respectively. At 12 months after CAD diagnosis/index date, 53% of patients with CAD had an inpatient hospitalization (vs 23% comparators; P<0.001), 95% had an outpatient hospitalization (vs 59% comparators; P<0.001), and 19% had an ER visit (vs 14% comparators; P=0.231). Overall, 67% of inpatient hospitalizations for patients with CAD were due to anemia and pneumonia. Patients with CAD had significantly higher mean inpatient length of stay (10.6 vs 2.7 days; P=0.001). Analyses limited to inpatient hospitalizations or outpatient clinic visits associated specifically with CAD showed similar but stronger results for patients with CAD versus matched comparators during the 12-month post-diagnosis period (**Table**). Transfusion use was significantly greater for patients with CAD versus comparators (43% vs 1%; P<0.0001). Up to 5 years after diagnosis, relative risk remained high for patients with CAD compared with their matched comparators for an ER visit (1.36–2.18 from Years 1 to 5), an inpatient visit (2.30–2.36 from Years 1 to 5) and an outpatient visit (1.61–1.60 from Years 1 to 5). Sensitivity analysis for patients with primary CAD (representing 82% of identified patients with CAD) showed similar findings of significantly increased overall and CAD-related HRU versus matched comparators.

Table. Annualized overall and CAD-related HRU of the CAD and matched comparison cohorts within 12 months after the index date

	Overall HRU		CAD-related HRU	
	CAD (N=504)	Matched comparison (N=5000)	CAD (N=504)	Matched comparison (N=5000)
Inpatient hospitalizations				
Number of patients				
Cohort, n (%)	55 (53)	227 (34)	34 (33)	36 (4)
OR (95% CI)	3.9 (2.5–6.0)		15.3 (8.3–28.2)	
P value	<0.0001		<0.0001	
Number of admissions per patient				
Mean	1.8	0.5	1.0	0.1
Median (IQR)	1 (0–3)	0 (0–0)	0 (0–1)	0 (0–0)
RR[2] (95% CI)	5.1 (3.6–7.3)		40.1 (18.2–88.6)	
P value	<0.0001		<0.0001	
Number of hospital days per patient				
Mean	10.6	2.7	6.8	0.7
Median (IQR)	1.5 (0–14)	0 (0–0)	0 (0–6.5)	0 (0–0)
P value[1]	0.001		0.331	
Outpatient clinic visits				
Number of patients				
Cohort, n (%)	99 (95)	590 (59)	57 (95)	93 (9)
OR[1] (95% CI)	17.2 (6.8–43.1)		36.4 (18.2–72.7)	
P value	<0.0001		<0.0001	
Number of admissions per patient				
Mean	14.2	3.7	6.3	0.7
Median (IQR)	10 (4.5–19.5)	1 (0–4)	2 (0–9)	0 (0–0)
RR[2] (95% CI)	5.3 (4.1–6.8)		180.9 (88.9–368.1)	
P value[1]	<0.0001		<0.0001	

CAD, cold agglutinin disease; CI, confidence interval; HRU, healthcare resource utilization; IQR, interquartile range; OR, odds ratio; RR, rate ratio.
[1]OR estimated with conditional logistic regression.
[2]RR estimated with mixed-effect negative binomial regression.
[1]Zero-inflated negative binomial model, with significance test for the negative binomial part of the model.

Summary/Conclusion: Patients with CAD used significantly more healthcare services than matched comparators, both before and after their diagnosis. Current management of CAD has a substantial impact on HRU, placing a burden on patients and healthcare systems.

EP1194 THE LIFETIME ECONOMIC BURDEN OF PYRUVATE KINASE DEFICIENCY IN THE UNITED STATES

W. Su [1], J. van Stiphout [2], K. H. M. Kuo [3], R. F. Grace [4], S. Chonat [5], H. Yaish [6], Y. Ravindranath [7], E. Zagadailov [8,*]

[1]Xcenda, Carrollton, TX, United States, [2]Xcenda, Basel, Switzerland, [3]Division of Hematology, University of Toronto, Toronto, Canada, [4]Dana-Farber/Boston Children's Cancer and Blood Disorder Center, Boston, MA, [5]Department of Pediatrics, Emory University, Atlanta, GA, [6]Department of Hematology, University of Utah, Salt Lake City, UT, [7]School of Medicine, Wayne State University, Detroit, MI, [8]Agios Pharmaceuticals, Cambridge, MA, United States

Background: Pyruvate kinase (PK) deficiency is a rare, inherited disorder caused by autosomal recessive mutations in the *PKLR* gene, whereby a glycolytic defect causes reduced adenosine triphosphate levels and leads to hemolytic anemia. Patients with PK deficiency can experience serious complications associated with the disease and its treatment, including perinatal complications, iron overload, bone fractures, pulmonary hypertension, and liver cirrhosis. The current standard of care for PK deficiency is supportive, including blood transfusions, splenectomy, cholecystectomy, iron chelation therapy, and/or interventions for other disease-related morbidity. Recent studies have demonstrated that iron overload and need for chelation is common even in patients that do not require regular transfusions. There is no approved drug therapy for this condition. Although the clinical burden in patients with PK deficiency is well documented, the economic burden of long-term disease management, procedures, and clinical complications has not been investigated and is unknown.
Aims: This study aimed to estimate the lifetime burden of patients with PK deficiency, from the perspective of the healthcare payer, in the United States (US).
Methods: A micro-costing method was employed to determine the direct costs associated with the diagnosis, treatment and monitoring of PK deficiency, and complications over a patient's lifetime. The occurrences and frequency of complications and monitoring were derived from scientific literature and verified with clinical experts. Patient mortality was based on a previously published report of the PK deficiency population. Cost inputs were derived from public databases (eg, Medicare physician fee schedule, Healthcare Cost and Utilization Project [HCUP]) and economic literature from a US payer perspective. Total costs were calculated as the sum of early pediatric (0–5 y), late pediatric (6–17 y), and adult phases. Adult patients were grouped based on transfusion status (RT, regularly transfused [≥6 transfusions per year]; NRT, not regularly transfused; NT, never transfused). A univariate sensitivity analysis, at 10% variance, was conducted to identify major cost drivers.
Results: The mean lifetime direct cost of a patient with PK deficiency is $3.3 million with the majority of the costs occurring during the adult phase ($3.0 million). The mean lifetime cost varied by transfusion status with lifetime costs of $4.4 million, $2.8 million, and $2.4 million for RT, NRT, and NT patients, respectively (Table). Although transfusion and chelation costs were higher in those with a greater transfusion burden, the costs of complications, particularly from iron overload, were higher in the NRT and NT populations. The main cost-drivers overall were the adoption rate and cost of chelation therapies, the cost and frequency of transfusions, and the cost associated with complications.

Total Lifetime Direct Costs by Subgroup (2020 USD)

	RT	NRT	NT
Diagnosis	$10,689	$10,689	$10,689
Monitoring	$432,242	$129,470	$97,437
Transfusion	$1,076,923	$203,786	$94,644*
Chelation Therapy	$1,849,451	$1,030,223	$750,685
Procedures	$44,640	$42,263	$37,833
Disease Complications	$752,676	$1,187,667	$1,186,958
End of Life Care	$227,243	$227,243	$227,243
Total	**$4,393,864**	**$2,831,341**	**$2,405,489**

*Transfusion cost before adulthood
RT=regularly transfused (≥6 transfusions per year), NRT= not regularly transfused, NT=never transfused, USD=United States dollar

Summary/Conclusion: The results of this study suggest that the lifetime economic burden of PK deficiency, from the perspective of the healthcare payer, is substantial. A large proportion of the direct cost of PK deficiency comes from transfusion and chelation therapies. Although the model provides a foundation for further economic evaluations, additional research regarding real-world healthcare resource utilization and indirect costs would further improve our understanding of the economic burden.

EP1195 "SHEFAA" AN ITP PATIENT ADVOCACY GROUP: AN EGYPTIAN SINGLE CENTER EXPERIENCE

M. Mattar [1], D. El Demerdash [1,*]

[1]Clinical hematology unit, internal medicine, Cairo university, Cairo, Egypt

Background: The patient is the main constant in the delivery of health care throughout the world, patient advocacy organizations play a critical role in increasing public awareness of a specific disease and in demanding

improvement in approaches to treatment. Patients advocacy group also enables patients to make informed decisions about their disease and to be responsible members of the health care team. To do this, patients must be informed about their condition and their treatment options, and given the opportunity to express their understanding, values and beliefs. They must be given the time and encouragement to ask questions, raise concerns, and express their feelings about what is happening to them.
Aims: We aimed to raise the awareness of Immune thrombocytopenia being not uncommon disease anymore
Methods: we targeted ITP patients as well as their families, friends and normal populations through regular direct group meetings, webinars, telemedicine and Facebook page in order to increase the awareness of ITP, correct the wrong believes about the disease which may leads to wrong behaviors.
Results: Our patient advocacy group was initiated in 2017 by doing many patients regular meetings explaining disease in simple Arabic language in collaboration with different medical specialties like gynecology, nutrition and psychiatry teams, raising the awareness of the disease by celebrating the ITP awareness month in September each year with patients and their families, also we became part of ITP global group actively participating in their activities. We initiated Facebook campaign supported by Novartis pharama. Our campaign achieved in 4 months duration (from august 2020 to December 2020) 155.537 followers, with 673.157 post engagements, 78% of the followers were female (68% of them were between 25-45 years old), 126.031 were Egyptian followers but other followers were from middle east countries as Saudi Arabia, Libya, UAE, Kuwait, Algeria, Jordon and morocco. All information about ITP were discussed in native simple language especially the nature of ITP, clinical pictures, diagnosis, goals for treatment, models of treatment, potential difficulties in adherence to treatment and Plan how to overcome these difficulties Most interaction were noticed in posts about COVID19 and ITP especially vaccination issue. Regarding questions which were asked frequently; "how to know that I have thrombocytopenia" "what to do in pregnancy" and "what are the symptoms of ITP".

Summary/Conclusion: Patient–health professional relationships which are grounded in effective communication, trust, reciprocal information, mutual understanding and respect are a foundation, and even a prerequisite for effective and efficient care

EP1196 CHRONIC MYELOID LEUKEMIA ACCESS TO TYROSINE KINASE INHIBITORS AND POLYMERASE CHAIN REACTION TESTING IN CENTRAL AND EASTERN EUROPE AND WEST ASIA REGION: A PATIENT ADVOCACY PERSPECTIVE.

J. Čugurović [1,*], Š. Narbutas [1], J. Pelouchová [1], D. Costello [1], C. Marin [1]

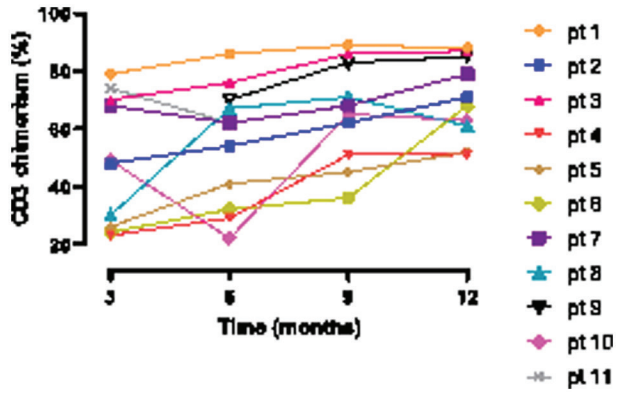
[1]*CML Advocates Network, Bern 7, Switzerland*

Background: Chronic myeloid leukemia (CML) patient organisation representing countries of the CML Advocates Network Easter Europe and West Asia region have come to conclusion that they share similar issues in access to treatment and monitoring tools. The reason is the lack of a common database with the relevant information about CML.
Aims: The goal was to create the CML Atlas of Central and Eastern Europe and West Asia region to showcase the most relevant data on CML about access to tyrosine kinase inhibitors (TKIs) and monitoring tools to support CML patient organisations' advocacy in those countries.
Methods: An European online survey was conducted, recruiting CML patient advocates and doctors from 19 countries, representing over 26.000 CML patients from Armenia, Croatia, Czech Republic, Georgia, Hungary, Kazakhstan, Kosovo, Kyrgyzstan, Lithuania, Moldova, North Macedonia, Poland, Russia, Serbia, Slovenia, Tajikistan, Turkey, Ukraine and Uzbekistan. The survey started on 1st December 2019 and lasted until 31st March 2020 covering the following topics: CML general information, availability of TKIs and PCR testing, clinical trials and treatment free remission data. Presented data as of 1st July 2020.
Results: 19 countries reported Imatinib available, 13 of them on insurance. Collected data show that in Armenia, Georgia, Kyrgyzstan, Moldova, Tajikistan and Uzbekistan availability was managed by donations; in Kazakhstan, Imatinib was available both on insurance and donations and no countries reported its availability in clinical trials.
18 countries reported Nilotinib available, with the exception of Kosovo, although 12 countries declared it was just on insurance. Data from Armenia, Georgia, Kyrgyzstan, Moldova, Tajikistan and Uzbekistan show that Nilotinib was available on donations and no countries reported its use in clinical trials.
16 countries informed on Dasatinib availability: the drug was obtainable on insurance in 10 of them, and through donations in Armenia, Kyrgyzstan, Moldova, North Macedonia, Serbia and Tajikistan. No countries reported access to Dasatinib through clinical trials.
9 countries reported that Bosutinib was available on insurance. Therefore, in 10 countries of the region, this drug was not available for CML patients.
Ponatinib reported as an available drug on insurance in 6 countries as well as on donations, while in 2 countries was reported as available in clinical trials. This medicine was not available in 6 countries of the region.
Collected data about testing demonstrate that PCR was available in all countries participating in the survey, except Kosovo. In the majority of countries, price of PCR is covered by public insurance. However, in countries as Armenia, Kyrgyzstan and Tajikistan access to PCR testing is provided through donations.

Note: Kosovo* is not presented as PCR is not available in the country.

Figure 1. PCR test data in the CML Advocates Network Easter Europe and West Asia region. July 2020.

Summary/Conclusion: There are important differences in access to TKIs to treat CML patients between countries of the Central and Eastern Europe and West Asia region. While five TKIs are available on these countries, the majority of them are just available on insurance and/or donations. Access to free PCR testing for CML patients is not ensured in all countries. There are opportunities to improve access to high-quality and safe therapies and effective monitoring tools for CML patients in the region.



Sickle cell disease

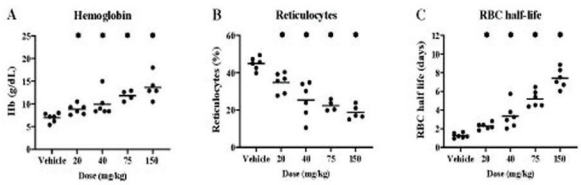
EP1197 ADDING AZATHIOPRINE/HYDROXYUREA PRECONDITIONING TO ALEMTUZUMAB/TBI MAY REDUCE RISK OF GRAFT FAILURE IN MATCHED SIBLING DONOR ALLOGENEIC HSCT IN ADULT SICKLE CELL PATIENTS

E. Dovern [1,*], M. Hazenberg [1], M. W. Tang [1], C. Rutten [1], L. Suijk [1], C. van Tuijn [1], S. Zeerleder [2], B. Biemond [1], E. Nur [1,3]

[1]Dep. of Hematology, Amsterdam University Medical Centers, AMC, Amsterdam, Netherlands, [2]Dep. of Hematology, University Hospital, University of Bern, Bern, Switzerland, [3]Dep. of Blood Cell Research, Sanquin Research and Landsteiner Laboratory, Amsterdam, Netherlands

Background: Sickle cell disease (SCD) is a severe, inherited hemoglobinopathy, resulting in poor quality of life and reduced life expectancy. Allogeneic hematopoietic stem cell transplantation (HSCT) is currently the only established curative treatment option for SCD. In adults, myeloablative conditioning is associated with significant toxicity. Matched sibling donor (MSD) transplantation with non-myeloablative conditioning (alemtuzumab/3Gy total body irradiation (TBI)) has shown promising results in adult SCD patients. Patients treated with this regimen had their sickle cell phenotype corrected with only mild complications and no reports of graft-versus-host disease (GvHD). However, a large part of these patients reached very low donor T-cell chimerism, resulting in 13% graft failure and necessitating chronic use of immunosuppression to avoid graft failure. We hypothesized that adding azathioprine (suppressing patient T-cells) and hydroxyurea (reducing bone marrow expansion) as preconditioning to the alemtuzumab/TBI regimen might improve donor chimerism and reduce risk of graft failure.
Aims: In this study we prospectively investigate the effects of azathioprine/hydroxyurea preconditioning on donor chimerism and graft failure in patients receiving non-myeloablative MSD HSCT for SCD.
Methods: Adult SCD patients with an MSD were eligible for this treatment. After 3 months of azathioprine 150mg qd and hydroxyurea 25mg/kg qd, erythrocyte exchange transfusion was performed on day −10. Alemtuzumab/TBI conditioning was started on day −7, as described by Hsieh et al (NEJM, 2009). Graft-vs-host-disease (GvHD) prophylaxis consisted of sirolimus.
Results: As of august 2020, eleven SCD patients (median age 26 (range 19-49) years) were transplanted. All patients engrafted successfully. After a median follow-up of 22 months, median donor myeloid and T-cell chimerism were 100% (range 84%>100%) and 68% (range 51%>88%), respectively. These donor chimerism percentages are higher than previously reported with alemtuzumab/TBI only. All patients had a corrected SCD phenotype with normalized hemoglobin levels. Patients reaching one year post-transplantation were able to stop sirolimus without decreases in chimerism. Only one patient developed acute grade II intestinal GvHD, that responded well to steroids. There were no viral reactivations or signs of macrophage activation syndrome.

Summary/Conclusion: Azathioprine/hydroxyurea preconditioning prior to alemtuzumab/TBI results in improved donor chimerism, potentially reducing risk of graft failure after non-myeloablatieve MSD transplantation in SCD patients. Importantly, in contrast to earlier studies, all patients in this study were able to stop sirolimus as scheduled. Adding azathioprine/hydroxyurea preconditioning renders the alemtuzumab/TBI non-myeloablative HSCT, with low risk of transplantation-related toxicity, a viable alternative for adult SCD patients.



EP1198 GBT021601 IMPROVES THE PATHOPHYSIOLOGY OF SICKLE CELL DISEASE IN A MURINE MODEL

K. Dufu [1,*], C. Alt [1], S. Strutt [1], T. Tang [1], H. Liao-Zou [1], Y. Yuan [1], B. Cathers [1], D. Oksenberg [1]

[1]Global Blood Therapeutics, South San Francisco, United States

Background: Sickle cell disease (SCD) is a genetic disorder caused by the inheritance of two alleles bearing a single nucleotide change in the β globin gene coding sequence. The pathophysiologic mechanism of SCD involves polymerization of intracellular sickle hemoglobin (HbS) following deoxygenation in the microvasculature, leading to decreased red blood cell (RBC) deformability, morphologic sickling of RBCs, decreased RBC survival, microvascular obstruction, and clinical complications. Voxelotor, a HbS polymerization inhibitor recently approved for the treatment of SCD in the United States, is an allosteric modifier of hemoglobin (Hb) that increases the proportion of oxygenated Hb in all RBCs. In clinical studies in patients with SCD, voxelotor demonstrated that doses of up to 1500 mg daily achieved Hb modifications of ~27%, was well tolerated and resulted in reduced hemolytic anemia. GBT021601 is a potent second generation HbS polymerization inhibitor with the potential to achieve even higher Hb modification in patients with SCD at lower doses and therefore with less pill burden.
Aims: To evaluate the effect of GBT021601, a second generation HbS polymerization inhibitor, in mouse model of SCD.
Methods: To evaluate its effect on the pathophysiology of SCD, GBT021601 was orally administered at 20, 40, 75, and 150 mg/kg once-daily doses for 21 days in Townes SCD mice (SS mice).
Results: At steady state, GBT021601-treated SS mice achieved Hb occupancies (at minimum concentration in plasma) of 6%, 12%, 21%, and 29% corresponding to 20, 40, 75, and 150 mg/kg doses, respectively. This resulted in a dose-dependent reduction in p50, partial pressure of oxygen at 50% Hb saturation, of SS mouse blood from ~28 mmHg (vehicle-treated) to 11 mmHg at the highest dose tested. Consequently, GBT021601 significantly reduced in vivo circulating sickled cells and ex vivo sickling of SS mouse blood under hypoxic conditions (pO_2, 20 mmHg). Consistent with its anti-polymerization activity, GBT021601 reduced hemolysis as demonstrated by: 1.) an increase in Hb of up to 6.7 g/dL (Figure 1A), thereby achieving the normal range for wildtype mice, and 2.) a reduction in the percentage of reticulocytes of up to 58% relative to vehicle-treated SS mice (Figure 1B). Additionally, GBT021601 treatment increased the percentage of mature RBCs, reduced the percentage of mitochondria-containing RBCs, and improved RBC deformability, collectively indicating an overall improvement in RBC health. Consistent with improved Hb levels, reduced hemolysis, and improved RBC health, GBT021601 dose-dependently increased RBC half-life from 1.3 days in vehicle-treated SS mice to 7.4 days in SS mice treated with 150 mg/kg GBT021601 (Figure 1C). Furthermore, treatment of SS mice with GBT021601 for 21 days led to a significant reduction in spleen weight, indicating an improvement in splenic blood flow and organ function. Lastly, GBT021601 treatment for longer than 21 days (up to 42 days) indicated a dose-duration dependent improvement in hemolysis markers including Hb level and reticulocyte count.

Figure 1. GBT021601 Treatment Was Associated With Dose-Dependent Changes in Hb, Reticulocytes, and RBC Half-Life.

Individual animal data and means are shown.
Data were analyzed by Student's t test and Hochberg's method for multiple testing. *$P<0.05$.
Hb, hemoglobin; RBC, red blood cell.

Summary/Conclusion: Together, these data demonstrate that GBT021601, a next generation HbS polymerization inhibitor, normalized Hb, reduced hemolysis, and significantly improved RBC health, RBC half-life, and organ function in a mouse model of SCD. These data support clinical development of GBT021601 as a potential best-in-class HbS polymerization inhibitor for patients with SCD.

EP1199 ELIGIBILITY FOR EMERGING THERAPIES IN SICKLE CELL DISEASE

S. M. Vora [1,*], E. R. Jackson [2], N. D. Denny [3], N. Paterson [1], P. Lux [1], N. B. Roy [3,4,5], S. Lugthart [1]

[1]Department of Haematology, University Hospitals Bristol and Weston NHS Foundation Trust, Bristol UK, [2]School of Medicine, University of Bristol, Bristol, [3]Department of Haematology, Oxford University Hospitals NHS Foundation Trust, [4]Department of Haematology, NIHR BRC Blood Theme, [5]Department of Haematology, Oxford Myeloma Centre for Translational Research, Oxford, United Kingdom

Background: Management of patients with sickle cell disease (SCD) in the UK relies largely on transfusion therapy and hydroxycarbamide alongside supportive care. New therapies to improve morbidity and mortality are needed. Two new therapies undergoing NICE technology appraisal are Crizanlizumab and Voxelotor. Crizanlizumab, a p-selectin inhibitor, has been shown to reduce the frequency of vaso-occlusive crisis in patients aged 16 or over in a randomised, placebo-controlled phase 2 trial (SUSTAIN)[1]. Voxelotor is an HbS polymerisation inhibitor and showed increased haemoglobin levels with reduced markers of haemolysis in a phase 3 trial (HOPE)[2]. Both were approved by the FDA in November 2019.

Aims: The eligibility criteria used in the SUSTAIN and HOPE trials have been compared against the Bristol Haematology and Oncology Centre and Oxford University Hospitals SCD cohorts to identify those patients who would be eligible for these emerging therapies.

Methods: The patient databases were cross-referenced with electronic notes to identify eligibility data. Vaso-occlusive crises (VOC) were determined by calls to the haemoglobinopathy team or helpline, attendance at the Acute Haematology Unit or admission. Electronic blood results were checked to ensure haemoglobin fell within the specified ranges.

Results: Results of analysis of SCD patient database according to eligibility criteria for Crizanlizumab and Voxelotor as described in the SUSTAIN and HOPE trials [1,2] are shown in Table 1. Results show that, out of 158 patients with eligible sickle cell disorders, only 7 (4.4%) were eligible for both therapies. 8 (5.1%) were eligible for Voxelotor only, and 2 (1.3%) were only eligible for Crizanlizumab. Patients with no VOC in 12 months were ineligible for either therapy (n=75, 47.5%) and just under half of these patients had a baseline haemoglobin over the range of eligibility for Voxelotor (n=37, 23.4%). 5 patients with a single VOC in 12 months had an Hb out of range for Voxelotor (3.2%). Regular transfusion therapy was the second most common exclusion (n=29, 18.3%). Age over 65 excluded 8 (5.1%) of our patients, and 6 (3.8%) had significant comorbidity that rendered them ineligible. 15 (9.5%) of our patients had moved out of area so estimates of VOC per year are likely to be inaccurate. Other reasons for exclusion included titration of hydroxycarbamide and family planning.

	Bristol	Oxford	Total
Ineligible for analysis	9	6	15 (9.5%)
Excluded - age	5	3	8 (5.1%)
Excluded – RCE	14	15	29 (18.4%)
Excluded – comorbidity	2	4	6 (3.8%)
Excluded – other	1	2	3 (1.9%)
Hb>105g/dL + insufficient no. VOC p.a.	22	15	37 (23.4%)
Insufficient no. VOC p.a.	26	12	38 (24.1%)
Eligible for both therapies	3	4	7 (4.4%)
Eligible for Crizanlizumab only	2	0	2 (1.3%)
Eligible for Voxelotor only	6	2	8 (5.1%)
Insufficient no. VOC p.a. for Crizanlizumab, Hb out of range for Voxelotor	5	0	5 (3.2%)
Total	95	63	158

Table 1: Results of analysis of SCD patient database according to eligibility criteria for Crizanlizumab and Voxelotor as described in the SUSTAIN and HOPE trials [1,2] (no. = number, p.a.= per annum)

Summary/Conclusion: Though new therapies are being developed for prevention of VOC in SCD, few patients in our cohort are eligible for these. Incidence of severe VOC may be underestimated as patients self-manage at home, particularly in the current Covid-19 pandemic. This should be kept under review and closer liaison with patients about their VOC may help identify eligible patients. Strict adherence to eligibility based on that of clinical trials is likely to result in very few patients benefitting from these new therapies.

EP1200 HEMOPEXIN PROTECTS HUMAN ENDOTHELIAL CELLS FROM HEME-DRIVEN ACTIVATION AND DAMAGE IN VITRO

J. Adam [1,*], L. Ventrici [1], V. Verdon [1], T. Gentinetta [1], S. Diditchenko [1], A. Schaub [1], G. Kato [2], N. Brinkman [3], A. Zuercher [1]

[1]Research and Development, CSL Behring AG, Bern, Switzerland, [2]Clinical Research & Development, CSL Behring, King of Prussia, [3]Research and Development, CSL Behring, Kankakee, United States

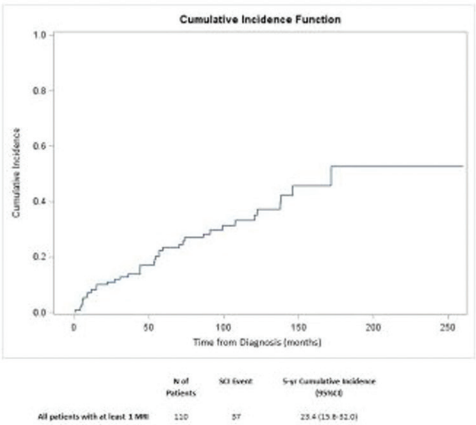
Background: One of the most abundant proteins in the human body is Hemoglobin (Hb). Upon rupture of red blood cells, cell-free Hb may initiate adverse pathophysiological reactions. A well characterized example of Hb-triggered pathophysiological disorders is sickle cell disease (SCD). SCD is characterized by a single nucleotide mutation of the β-globin gene resulting in Hemoglobin-S (HbS) instead of the normal HbA. Polymerization of HbS shortens the lifespan of sickle red blood cells and promotes intra- and extravascular hemolysis. In cell-free Hb ferrous Hb (Fe^{2+}) is oxidized into ferric Hb (Fe^{3+}) promoting the dissociation and transfer of heme into lipid compartments where the generation of cytotoxic and pro-inflammatory reaction products are triggered. These processes eventually lead to endothelial cell activation and damage. The natural plasma protein hemopexin (Hpx) is a heme scavenger and binds heme in a 1:1 binding ratio with highest affinity. Hpx-bound heme is rendered relatively non-reactive and is delivered safely to hepatocytes for endocytosis and degradation.

Aims: Investigating the protective function of Hpx on endothelial cells exposed to elevated levels of cell-free heme.

Methods: Human umbilical vein endothelial cells (HUVEC) were exposed in vitro to heme in the presence or absence of different Hpx doses. As a read-out, different markers for endothelial cell activation were analyzed by Western Blot, multiplexed particle-based flow cytometry (Luminex), flow cytometry or on mRNA levels by qRT-PCR. Briefly, confluent HUVEC were preincubated with Hpx at different concentrations for 5 min before stimulation with heme for various lengths of time. Following stimulation cells were analyzed by Western Blot for the expression of HO-1, a sensitive marker for heme exposure. Expression of pro-inflammatory cytokines IL-6 and IL-8, cell adhesion molecule VCAM-1 and blood glycoprotein von Willebrand factor (vWF) were analyzed on mRNA levels by qRT-PCR or in cell culture supernatants by Luminex. All these investigated proteins are well known markers for endothelial cell activation.
Alternatively, heme stimulation of Hpx-preincubated HUVEC was conducted for 25 min and cells were analyzed by flow cytometry for membrane bound P-Selectin expression, another robust endothelial cell activation marker.

Results: In the absence of Hpx, Heme consistently showed strong stimulatory capacity on HUVEC reflected in a robust upregulation of pro-inflammatory cytokines, VCAM-1, vWF, HO-1 and P-Selectin. Increasing Hpx concentrations during heme-mediated stimulation led to a dose-dependent reduction in HUVEC activation markers and once an equimolar ratio between heme and Hpx had been reached, the expression of HO-1, P-Selectin, VCAM-1, vWF and pro-inflammatory cytokines was lowered to background levels.

Summary/Conclusion: The presented data underlines on the one hand the stimulatory capacity of heme on endothelial cells and demonstrates on the other hand the efficient heme scavenging potential of Hpx. Hpx-bound heme molecules are rendered non-reactive and consequently, Hpx potently prevents the pro-inflammatory effect of heme on endothelial cells. This effect results in a strongly reduced expression of endothelial activation markers in heme-stimulated cells under an equimolar ratio of heme and Hpx. Hence, our study suggests a protective role of Hpx for endothelial cells exposed to elevated levels of cell-free heme due to intravascular hemolysis, a phenomenon seen in Hb-triggered pathophysiological disorders such as SCD.



EP1201 SILENT CEREBRAL INFARCTS IN A PEDIATRIC SICKLE CELL DISEASE NATURAL HISTORY COHORT: TOO MANY, TOO SOON?

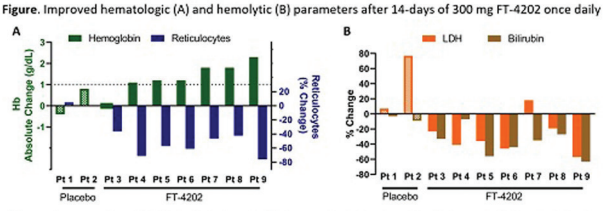
G. Reggiani [1], B. Coppadoro [1], V. Munaretto [1], R. Manara [2], I. Agodoa [3], A. Beaubrun [3], A. Biffi [1], L. Sainati [1], R. Colombatti [1,*]

[1]Clinic of Pediatric Hematology Oncology, Department of Woman's and Child's Health, Azienda Ospedale-Università di Padova, Padua, Italy, [2]Azienda Ospedale-Università di Padova, Padua, Italy, [3]Global Blood Therapeutics, San Francisco, United States

Background: Cerebrovascular complications cause significant morbidity from childhood in patients with sickle cell disease (SCD). Stroke and large vessel vasculopathy are the most severe manifestations, but silent cerebral infarcts (SCI) are more common and impact neurocognitive development and quality of life. Routine use of Magnetic Resonance Imaging/Angiography (MRI/MRA) as a screening tool since childhood is suggested in some European guidelines. Risk factors for SCIs are known, but real-world studies documenting contemporary rates of SCI and evaluating the association between hemoglobin (Hb) levels and the incidence of SCIs are limited.
Aims: To determine the incidence and evolution of SCIs in a pediatric natural history cohort in Italy and investigate the correlation between hematological variables, treatment and SCI.
Methods: A retrospective analysis was performed in a cohort of children with SCD prospectively enrolled in a natural history study from Oct 2007 to Dec 2020. The standard care includes annual TCD from age 2, MRI/MRA from 6 years old, every 2 years; Hydroxyurea (HU), Chronic Red Blood Cell Transfusion and Bone Marrow Transplantation (BMT) are prescribed according to national guidelines. Two-sample t-test and Welch t- test for unequal variances were used to compare means of Hb values and hemolysis markers in patients with and without SCIs. Cumulative incidence function (CIF) estimated incidence of SCI occurrence. Patients were censored at the moment of BMT, death or loss to follow-up.
Results: Of the 182 SCD patients identified, 110 (60%) underwent 1 evaluable MRI/MRA. 51% were male; 81% HbSS, 6% HbSβthal^0, 12% HbSC, 1% HbSβthal$^+$, 80% were from Sub-Saharian Africa, 11% from Europe, 5% from North Africa. Median age at diagnosis was 25.4 months (IQR 8.4-59.3); 48% were diagnosed before 24 months. Median follow-up time was 113.9 months (range 6.2-301.0)(IQR 79.2-153.3). Overall, 55.5% received HU, 11% chronic transfusion, 19% HU and transfusion (only 4 in combination for recurrent VOCs or switch protocol, the remaining in sequence), 14.5% received no disease modifying therapy; 17% underwent BMT. Mean age of HU start was 92 months (range 10.1-236.9). Median age at first MRI was 6.5 years (IQR 4.64-10.01). SCIs occurred in 33.6% of patients with a MRI test performed with no difference between genotypes. A SCI was detected at first MRI in 78.3% of patients, with mean lesion burden of 1550.1 mm3 (range 60.6-5916). 22/37 had follow up MRIs evaluable in this analysis; in 6 patients the lesion burden increased (mean +290 mm3): 4/6 were teenagers with poor adherence to HU treatment or behavioural risk factors (cigarette smoke), 1/6 had large vessel vasculopathy, 1/6 had epilepsy.Patients with SCIs had lower Hb (8.3 vs 9 g/dl), higher indirect bilirubin (42.8 vs 34.9 umol/L) and reticulocytes (291932 vs 249719/mm3) compared to patients without SCIs (p ≤0.0001).The overall cumulative incidence of SCIs at 5 years from SCD diagnosis was 23.4 (95%CI 15.6-23.0) [Figure 1] generally increasing over time, and the 5-year cumulative incidence was 63.4 (95%CI 43.7-77.9) among patients with no therapy administered.

FIGURE 1. Cumulative Incidence of Silent Cerebral Infarcts in the Pediatric Sickle Cell Disease Population [Time from SCD diagnosis]

Summary/Conclusion: Our real-world analysis demonstrates that even in pediatric SCD patients who undergo regular screening and have access to treatments, SCI burden is still high, but could be stabilized with early therapy and additional interventions. Given the observed differences in markers among patients with and without SCIs, hematological or behavioral risk factors should be considered in screening programs.



EP1202 FT-4202 IMPROVES HEMATOLOGIC AND HEMOLYTIC PARAMETERS IN A PHASE 1 STUDY OF PATIENTS WITH SICKLE CELL DISEASE

R. C. Brown [1,*], S. Saraf [2], K. Cruz [3], A. Kutlar [4], G. Konis [5], T. Kalfa [6], F. Kuypers [7], J. Estepp [8], M. Ribadeneira [9], S. Forsyth [9], P. Schroeder [9], E. Wu [9], P. Kelly [9], M. Telen [10]

[1]Children's Healthcare of Atlanta, Atlanta, [2]University of Illinois, Chicago, Chicago, [3]Advanced Pharma, Miami, [4]Augusta University, Augusta, [5]Woodland International Research Group, Little Rock, [6]Cincinnati Children's Hospital Medical Center, Cincinnati, [7]Children's Hospital Oakland Research Institute, Oakland, [8]St. Jude Children's Research Hospital, Memphis, [9]Forma Therapeutics, Inc., Watertown, [10]Duke University Medical Center, Durham, United States

Background: Polymerization of deoxygenated hemoglobin S (HbS) is the precipitating event leading to red blood cell (RBC) sickling, hemolysis, and vaso-occlusion. The pathogenesis of sickle cell disease (SCD) is exacerbated by increased levels of 2,3-DPG, which decrease O_2 affinity, and decreased levels of ATP, which impact RBC function. FT-4202 is a small molecule activator of erythrocyte pyruvate kinase (PKR) that decreases 2,3-DPG and increases ATP in RBCs. In healthy volunteers (HVs), FT-4202 was well tolerated in both single ascending dose (SD) and 14-day (2wk) once daily (QD) multiple ascending dose (MD) cohorts (Kalfa, 2019). In patients (pts) with SCD, a SD of FT-4202 was well tolerated and demonstrated similar pharmacokinetic (PK) and pharmacodynamic (PD) responses as in HVs (Estepp, 2020). Based on these initial results, two 2wk SCD MD cohorts (SCD MD1 [300mg FT-4202/placebo (P)] and SCD MD2 [600mg FT-4202/P]) were initiated in pts with SCD. The unblinded results of the SCD MD1 cohort are described here; data from the ongoing SCD MD2 and 12wk open label SCD MD (400mg FT-4202 QD) cohorts will be presented [NCT03815695].
Aims: To evaluate the safety and PK/PD of FT-4202 in HVs and pts with SCD.
Methods: In each 2wk SCD MD cohort, a minimum of 9 pts, randomized 7:2 to FT-4202:P, were required for safety/dose escalation decisions. Safety included treatment (Tx)-emergent adverse events (AEs), vital signs, ECGs and laboratory parameters. Blood sampling for PK and PD (RBC 2,3-DPG and ATP) was performed for up to 7 days after end of treatment (EOT). Exploratory studies included P_{50} and RBC deformability with controlled deoxygenation/reoxygenation and varying osmolality (Lorrca® oxygenscan and osmoscan).
Results: In the SCD MD1 cohort, of 9 pts (8 Hb SS; 1 SB+ thal) randomized 7:2 to FT-4202:P, 6 pts were on hydroxyurea. Eighteen AEs were reported in 7 pts (6 FT-4202, 1 P) with 16/18 AEs unrelated to study Tx; related AEs were headache and nausea (n=1 each). All AEs occurring in FT-4202 pts were ≤ grade 2. Three uncomplicated sickle pain events reported in 2 FT-4202 pts were consistent with SCD history and managed with standard home pain medications (no SAE/no hospitalization). Consistent with expected PD effects of PKR activation, rapid and sustained pharmacological activity was observed. In FT-4202 pts, 2,3-DPG levels decreased within 24h (p=0.031), while ATP levels increased through Tx day 7 (p=0.031). Both effects were sustained through the 2wk Tx period. In FT-4202 pts, Hb O_2 affinity was increased as demonstrated by decreased P_{50} (p=0.031), reaching comparable values to untreated HVs. The increased O_2 affinity and ATP were associated with improved sickle RBC deformability across an O_2 or osmotic gradient; this improvement persisted for up to 7 days post-Tx in some pts. After 2wks, Hb increased (median +1.2 g/dL, p=0.031), with 6/7 pts having a maximum increase of >1 g/dL, occurring at EOT in 5/6 pts. Significant decreases in reticulocyte count (median -57%, p=0.016), LDH (median -36%, p=0.031), and bilirubin (median -35%, p=0.016) were also observed (Figure).

Figure. Improved hematologic (A) and hemolytic (B) parameters after 14-days of 300 mg FT-4202 once daily

(A) In patients receiving FT-4202, 6 of 7 had a > 1 g/dL increase in Hb (median: 1.2 g/dL [range 0, 2.3]) and all 7 had a decrease in reticulocytes (median: -57% [range -36%, -76%]) over baseline. **(B)** In patients receiving FT-4202, 6 of 7 had a decrease in LDH (median: -36% [range +18%, -57%]) and all 7 had a decrease in total bilirubin (median: -35% [range -7%, -63%]) over baseline. Hb = hemoglobin; LDH = lactate dehydrogenase.

Summary/Conclusion: FT-4202 demonstrated a favorable safety profile in SCD pts when dosed at 300mg QD for 2wks. Consistent with PKR activation, FT-4202 decreased 2,3-DPG and increased ATP in RBCs, which correlated with increased RBC O_2 affinity and improved RBC deformability. FT-4202 improved hematologic and hemolytic parameters, with best responses often observed at the end of the 2wk Tx period. Data from the ongoing 2wk SCD MD2 (600mg FT-4202/P) and 12wk open label SCD MD (400mg FT-4202) cohorts will be presented.

EP1203 CYTOKINE MAPPING IN PAEDIATRIC SICKLE CELL DISEASE: ARE DIFFERENT SIGNATURES ASSOCIATED WITH DIFFERENT PHENOTYPES?

G. Ceglie [1,*], S. Marchesani [2], L. Antonucci [3], Z. Abbaszadeh [3], L. Sabatini [2], M. Di Mauro [2], M. Petrone [2], L. Schettini [2], C. Quintarelli [3], G. Palumbo [3]

[1]Department of Pediatric Hematology and Oncology, Cell and Gene Therapy, IRCCS Bambino Gesù Children's Hospital, Roma, [2]University Department of Pediatrics, Bambino Gesù Children's Hospital, University of Rome Tor Vergata, [3]Department of Pediatric Hematology and Oncology, Cell and Gene Therapy, IRCCS Bambino Gesù Children's Hospital, Rome, Italy

Background: The mutation of the beta-globin gene that causes sickle cell disease (SCD), results in pleiotropic effects, such as haemolysis and vaso-occlusive crisis (VOC) that can induce inflammatory mechanisms with deleterious consequences on the organism. In fact, the activation of inflammatory cells (endothelial activation followed by a monocytic-neutrophilic response) and their intracellular pathways yield the production and secretion of numerous molecules that promote inflammation, including cytokines, chemokines, and growth factors. Few studies are currently available that evaluate the circulating levels of these molecules in a pediatric population.
Aims: The aim of this study is to identify a cytokine signature in a pediatric SCD population associated with specific clinical correlations.
Methods: This study includes 35 patients with SCD (23 males and 12 females, medium age 9.3 years, range 0-20 years) at steady state (no current haemolytic crises or VOC or other acute complications) and 10 healthy controls matched for age and ethnicity. A panel of 42 serum cytokines was measured using Luminex Performance Human XL-Cytokine-Discovery-Magnetic-Panel following the manufacturers' instructions (see table 1 for the list of analytes). These results were statistically related to clinical (age, gender, number of VOC per year, number of transfusions per year, pharmacological therapy) and laboratory data, such as hemoglobin (Hb)S, HbF and erythropoietin (EPO). Statistical analysis was performed to compare and correlate data. Data considered with statistical significance were those with p-value <0.05 and are therefore the ones presented in the results section.
Results: Significantly lower levels of IL-3, IL-4, IL-5, IL-7, IL-10, G-CSF and GM-CSF with higher levels of CXCL-2, CXCL-10, CCL-3, CCL-19 were observed in patients with SCD, compared to healthy donors. Furthermore, the group of patients who experienced VOC with higher frequency (1 or more crisis per year versus less than 1 crisis per year), showed lower levels of IL-3, IL-4 and IL-7. On the other hand, patients who underwent more frequently transfusion procedures (2 or more transfusions per year versus less than 2 transfusions per year) showed higher levels of IL-8, CCL-2, programmed death-ligand 1 (PD-L1), tumor necrosis factor-related apoptosis-inducing ligand (TRAIL) and TGF-alpha. We also related cytokines levels to laboratory data, finding a direct correlation between HbS concentration, EGF and CXCL-2; an inverse relation was observed between HbF and CCL-2. Also, a positive correlation was found between EPO, IL-3 and PD-L1.

IL-1 alpha	IL-6	IL-17A	CCL-3	CXCL-2	EGF
IL-1 beta	IL-7	IL-17E	CCL-4	CXCL-10	TGF-alpha
IL-1 RA	IL-8	IL-33	CCL-5	CX3CL-1	TNF-alpha
IL-2	IL-10	IFN-alpha	CCL-11	FLT3LG	TRAIL
IL-3	IL-12 p70	INF-beta	CCL-19	G-CSF	PD-L1
IL-4	IL-13	IFN-gamma	CCL-20	GM-CSF	CD40L
IL-5	IL-15	CCL-2	CXCL-1	VEGF	Granzyme B

Summary/Conclusion: These results showed that our population of patients with SCD displayed higher levels of specific chemokines compared to HDs and lower levels of cytokines related to a Th2 response, cytokines involved in bone marrow omeostasis (IL-3 and IL-7) and growth factors, possibly related to bone marrow exhaustion. Moreover, we interestingly found that different phenotypes of patients displayed different signatures of cytokines: in particular patients who experienced more VOC showed lower levels of Th2 related cytokines with lower concentration of IL-3 and IL-7 as well; on the other hand, patients with greater transfusion needs, expressed higher levels of cytokines related to apoptosis control and specific chemokines, as CCL-2; coherently, we observed that increased concentrations of EPO are related to higher levels of PD-L1.

EP1204 DISTINCTIVE EFFECTS OF SYSTEMIC IRON RESTRICTION BY FERROPORTIN INHIBITION THROUGH VIT-2763 AND DIETARY IRON LIMITATION IN A SCD MODEL

G. Ingoglia [1,*], N. Nyffenegger [1], A. Flace [1], N. Kalleda [1], C. Doucerain [1], F. Dürrenberger [1], V. Manolova [1]

[1]CPRD, Vifor (International) AG, St. Gallen, Switzerland

Background: In sickle cell disease (SCD) a point mutation in the β-globin gene leads to synthesis of sickle hemoglobin (HbS) in erythrocytes. Upon deoxygenation in capillary blood vessels, HbS polymerizes in rigid fibers causing red blood cell (RBC) membrane distortion, intravascular hemolysis, increased endothelial adhesion and inflammation that might lead to vaso-occlusion (VO) and painful crisis. The kinetics of HbS polymerization is strongly dependent on the intracellular HbS concentration and a relatively small reduction of the cellular HbS concentration might prevent HbS polymerization and its sequelae. Clinical cases showed that iron deficiency in SCD patients decreases the mean corpuscular HbS concentration, intravascular hemolysis and pain crisis. A recent publication using the Townes mouse model of SCD showed that dietary iron restriction in juvenile mice (3 weeks old), fed low iron diet (LID) immediately after weaning, improved hemolysis, hematological and endothelial cell activation markers. Despite the promising effect in the mouse model, dietary iron restriction is not readily implemented in a compliant way for SCD patients. We have previously shown that iron restriction by inhibition of ferroportin, the unique iron transporter in mammals, reduced hemolysis, improved hemodynamics and prevented VO events in the Townes model of SCD.
Aims: To compare the effects of pharmacological iron restriction by the oral ferroportin inhibitor VIT-2763 to dietary iron restriction induced by low iron diet (LID) in adult Townes mice.
Methods: Townes mice (7 weeks old) engineered to synthesise exclusively human HbS were orally administered either the ferroportin inhibitor VIT-2763 (60 mg/kg bidaily) or vehicle for 6 weeks and received dietary iron corresponding to standard rodent diet (250 ppm iron). Dietary iron restriction was achieved by feeding Townes mice LID (10 ppm iron) for 6 weeks. Hematological parameters, hemolysis and vascular and systemic inflammation markers were evaluated at the study end.
Results: RBCs of Townes mice treated with VIT-2763, but not mice fed LID, showed hematological parameters indicating iron-restricted erythropoiesis: reductions in mean corpuscular volume (MCV), mean corpuscular Hb (MCH) and reticulocyte Hb content, whereas percentages of hypochromic and microcytic RBCs were increased with preserved RBC counts. Importantly, the intracellular HbS concentration, as measured by the corpuscular Hb concentration mean (CHCM) was significantly reduced in Townes mice receiving VIT-2763, but not in mice fed LID. In agreement with the determining effect of HbS concentration on intravascular hemolysis, mice treated with VIT-2763, but not mice fed LID, showed lower markers of intravascular hemolysis and endothelial dysfunction. Iron restriction by VIT-2763 but not via LID decreased blood leukocyte counts and circulating chemokines such as CCL5, suggesting the potential of VIT-2763 to reduce systemic inflammation in Townes mice. Iron restriction via LID, but not by VIT-2763, increased significantly erythropoietin (EPO) plasma levels, suggesting a feedback response to iron deficiency, which might further stimulate erythropoiesis.
Summary/Conclusion: This data demonstrated that VIT-2763 induced iron-restricted erythropoiesis and reduced vascular and systemic inflammation in adult Townes mice. The differential effects of VIT-2763 and LID in adult Townes mice highlight the role of systemic ferroportin inhibition for efficient iron restriction and therapeutic benefit.

EP1205 SYSTEMATIC, POINT-OF-CARE NEWBORN SCREENING FOR SICKLE CELL DISEASE IN RURAL MALI, WEST AFRICA

A. Anderson [1,2,*], J. Kamate [3], A. Guindo [4], B. Maclean [5], D. Diallo [4]

[1]Pediatrics, Prisma Health-Upstate, [2]University of South Carolina School of Medicine, South Carolina, United States, [3]Pediatrics, Koutiala Women's and Children's Hospital, Koutiala, [4]Pediatrics, National Sickle Cell Disease Research and Control Centre, Bamako, Mali, [5]Pediatrics, Global Partners in Hope, Nebraska, United States

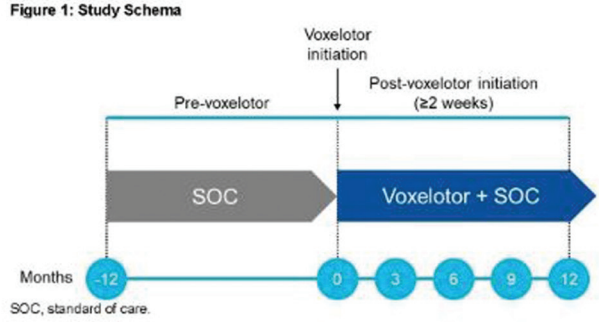
Background: Sickle cell disease (SCD) is highly prevalent across sub-Saharan Africa and is a significant source of under-5 mortality. However, accurate characterization of the prevalence is difficult to determine due to the absence of systematic newborn screening in most African countries. Mali is a land-locked West African country with a high burden of sickle cell disease. Despite the critical need for early diagnosis of SCD to improve survival, wide scale diagnostic efforts utilizing isoelectric focusing (IEF) or high-performance liquid chromatography (HPLC) in sub-Saharan Africa have been limited by a paucity of laboratory equipment and trained personnel, unreliable supply chain for consumables, and overall expense. Point-of-Care (POC) testing for SCD is advancing rapidly and has the potential to reduce these barriers.
Aims: The objective of this study was to assess the feasibility and efficacy of systematic, POC newborn screening for SCD at a rural hospital in Mali, West Africa.
Methods: Between March 2019 and Jan 2021, all newborns at Koutiala Women's and Children's Hospital were offered screening for SCD with the Hemotype SC™ POC test kit (Silver Lake Research, Azusa, California, USA). Each kit included a plastic test tube, blood sampling device, and Elisa-based test strip. Verbal consent was obtained and heel-stick samples were procured within the first day of life. The samples were processed according to the package insert. The testing required 6 drops of unfiltered tap water. No other reagents or equipment were necessary. The results were available within 10 minutes and were provided to the caregiver prior to discharge. Newborns who were found to have sickle cell disease were referred to the SCD outpatient treatment program for ongoing management. Families of those with HbS trait or HbC trait received appropriate genetic counseling.
Results: 4822 infants were born over the study period and 4774 (99%) received POC screening. Screening results revealed Hemoglobin S trait; n=461(9.7%), Hemoglobin C trait; n=539 (11.3%), Hemoglobin SS; n=40 (0.84%), Hemoglobin SC; n=55 (1.2%), and homozygous C; n=16 (0.33%). In all, 95 infants (2.04%) were found to have sickle cell disease and were referred to the SCD outpatient treatment program. In addition, 22% of infants were found to be carriers of either HbC trait or HbS trait. The POC testing results were directly compared to historical pilot data of IEF-based SCD newborn screening at Koutiala Hospital between 2011-2014 (Table 1).

Table 1:

Newborn Screening Results Koutiala, Mali	Number of Infants 3/2019-1/2021	Incidence of Hemoglobin sub-type (POC)	Number of Infants 3/2011-6/2014	Incidence of Hemoglobin sub-type (IEF) **
Sickle Cell Trait	461	9.7%	414	9.5%
thal	40	0.84%	43	0.98%
Hemoglobin SC	55	1.2%	46	1.1%
Hemoglobin C trait	539	11.3%	386	8.81%
Homozygous C	16	0.33%	12	0.27%
SCD (any type)	95	2.04%	89	2.08%
Normal	3568	77.7%	3479	79.4%
Total Infants Screened	4774 (99%)		4380 (46%)	

** Pilot study data from IEF-based screening at Koutiala Hospital between 2011-2014 included to show the reliability of the POC testing platform.
This data was presented in abstract form at the Global SCD Network Symposium 2014, Rio de Janeiro, Brazil.

Summary/Conclusion: This pilot study is the first to examine the impact of systematic POC infant screening for SCD in Mali, West Africa. The rapidity of the POC testing resulted in a high newborn screening rate and increased the percentage of SCD-affected infants who successfully transitioned into the outpatient treatment program at the hospital. The POC testing results were very comparable and highly feasible when reviewed alongside historical IEF-based screening at Koutiala Hospital. While the incidence of hemoglobin abnormalities discovered by newborn screening was very similar between these different testing strategies, the percentage of evaluable births that were screened was much higher in this POC cohort than in the IEF pilot study (99% vs 46%). Overall, the low cost (<$2/test), ease of use, and reliability of the Hemotype SC™ POC test has the potential to make it a more desirable option for wider scale screening efforts in the future.



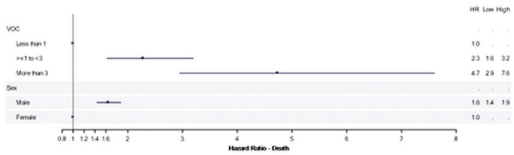
EP1206 REAL-WORLD EXPERIENCE OF PATIENTS WITH SICKLE CELL DISEASE TREATED WITH VOXELOTOR: A MULTICENTER, RETROSPECTIVE STUDY

B. Andemariam [1,*], M. Achebe [2], E. L. Jerome Clay [3], R. Drachtman [4], A. Nero [5], I. Osunkwo [6], A. U. Zaidi [7], M. Idowu [8], S. Curtis [9], C. Minniti [9]

[1]New England Sickle Cell Institute, University of Connecticut Health, Farmington, CT, [2]Brigham and Women's Hospital, Boston, MA, [3]Johns Hopkins All Children's Hospital, Johns Hopkins University, St. Petersburg, FL, [4]Rutgers Robert Wood Johnson Medical School, New Brunswick, NJ, [5]University of Texas Southwestern Medical Center, Dallas, TX, [6]Levine Cancer Institute, Charlotte, NC, [7]Division of Pediatric Hematology/Oncology, Central Michigan University, Detroit, MI, [8]University of Texas Health, Houston, TX, [9]Montefiore Medical Center, Bronx, NY, United States

Background: Sickle cell disease (SCD) is an inherited disorder in which sickle hemoglobin (HbS) polymerization triggers red blood cell sickling, chronic hemolysis, anemia, and episodic vaso-occlusion. In addition to acute life-threatening events, SCD-related complications also include cumulative organ damage and early mortality. Voxelotor is an oral HbS polymerization inhibitor that increases hemoglobin (Hb) levels and reduces markers of hemolysis, and is approved in the United States for treatment of SCD in patients ≥12 years of age.
Aims: To characterize the real-world hematologic and clinical responses to voxelotor treatment in a multicenter, retrospective series of patients with SCD.
Methods: We collected and aggregated real-world, retrospective laboratory and clinical data on adolescents and adults (aged ≥12 years) with SCD treated with voxelotor as part of their usual care at multiple clinical centers in the United States. Laboratory and clinical data were collected 12 months before initiation of voxelotor and compared to similarly collected post-treatment data outcomes (Figure 1). Included patients received voxelotor for ≥2 consecutive weeks. Only data that were available from the patients' medical records and other secondary data sources were collected. Study data from 1 year before and up to 1 year after the first dose of voxelotor were entered in de-identified case report forms via an electronic data capture system.
Results: Approximately 300 patients have been treated across the 9 clinical centers participating in this study. Changes from the pre-voxelotor treatment period in Hb, hemolysis markers, and iron overload will be summarized descriptively. Changes in the annualized incidence rates of significant SCD-related clinical events from the pre-voxelotor treatment period will be reported, including vaso-occlusive crises, acute chest syndrome, priapism, cerebral infarcts (overt and silent), transient ischemic attack, leg ulcers, and measures of cardiac function, renal function, and tricuspid regurgitation velocity/pulmonary hypertension. The associations between changes in Hb, markers of hemolysis, and incidences of SCD-related clinical events will be evaluated. Health resource utilization changes from the pre-voxelotor treatment period will be reported, including acute clinic visits, emergency department visits, hospitalizations, acute and chronic transfusions, and home oxygen supplementation. Changes in health-related quality-of-life measures collected as part of usual care will be summarized descriptively. Adverse events by severity and relationship to voxelotor will be collected and tabulated.

Figure 1: Study Schema



Summary/Conclusion: This study is the first to examine the real-world effectiveness of voxelotor in a multicenter, retrospective study and describe the observed changes in laboratory and clinical outcomes after at least 2 weeks of therapy in up to 300 patients.

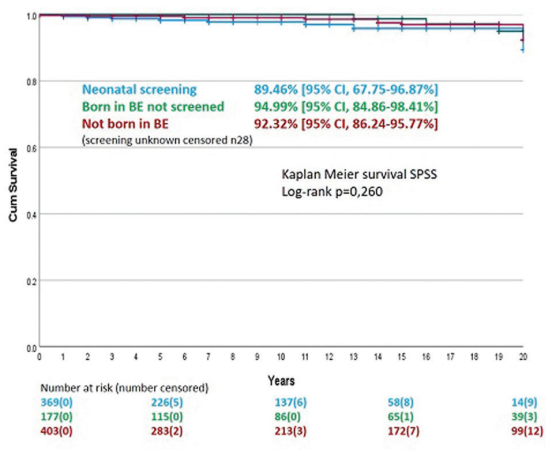
EP1207 ASSOCIATION BETWEEN HOSPITALISED VASO-OCCLUSIVE CRISES AND MORTALITY IN SICKLE CELL DISEASE PATIENTS AGED 16 YEARS AND OLDER USING THE FRENCH NATIONAL HEALTH INSURANCE DATABASE (SNDS)

J.-B. Arlet [1,*], H. Lennon [2], M. Bailey [3], E. Herquelot [2], L. Lamarsalle [4], F. Raguideau [2], P. Bartolucci [5]

[1]Médecine interne, Hôpital Européen Georges-Pompidou, Paris, [2]Méthodes et Statistiques, HEVA, Lyon, France, [3]Gene therapies, Novartis, Bannockburn, IL, United States, [4]HEVA, Lyon, [5]Hopitâl Henri-Mondor, Créteil, France

Background: Patients with sickle cell disease (SCD) experience a wide range of complications thought to be due to the systemic impact of chronically inflamed vasculature, ongoing haemolysis, multi-cellular adhesion and ischemic damage. One of the most impactful complications is the vaso-occlusive crisis (VOC). An early study suggested a relationship between VOC occurrence and increased mortality. Reviewing this possible relationship, now that SCD management has improved, is important.
Aims: To assess the association between hospitalised VOCs and mortality, in SCD patients.
Methods: This study was a retrospective observational cohort study using the French national health insurance's claims database. This database gathers information on hospital records, primary and secondary care, and cause of death. Between 01-01-2012 and 12-31-2018, all 16 years and older patients identified as suffering from SCD (with either a hospital record or Long-Term Disease status with diagnostic ICD-10 codes D57.0-2) were included in the study. The index date was defined as the first interaction with the healthcare system (whether it was related to their SCD or not). Participants were followed-up for at least one year and until the end of the study (12-31-2018).
A hospitalised VOC was defined as a hospital stay of at least one night with a primary or related diagnosis of sickle-cell anaemia with crisis (D57.0), preceded by a transit through the emergency room (to avoid capturing SCD-related hospital stays for reasons other than VOCs).
The hospitalized VOC annual rate was defined as the total number of hospitalized VOCs during the follow-up divided by the number of follow-up years. Patients were categorised by the annual rate of VOCs they experienced into three groups: <1; 1 to <3; ≥3 VOCs per year.
Cox proportional hazards models using age as the time scale were used to study the effect of the cumulative rate of hospitalised VOCs on the risk of death, adjusted for gender.
Results: A total of 17,726 SCD patients were included in the study, of which 65.3% were females —a high proportion partly due to several hospitalizations found in women while pregnant. Ages ranged from 16 to 99 years and the average age was 35.0 years (±17.8, median 32.0).
Each calendar year, 86–89%, 9–10%, and 2–4% of patients experienced <1, 1 to <3, and ≥3 hospitalised VOCs, respectively. The mean age in increasing VOC groups was 36.3 (±15.8), 23.8 (±9.0), and 21.3 years old (±7.1), respectively. The proportion of women was 66.7%, 51.8% and 52.9%, respectively. The median time between two hospitalised VOCs was 37 days (Q1–Q3 22–96).
Over a median follow up of 7 years, 914 (5.2%) patients died; 75% died at the hospital. The mean age at death was 60.1 years (±19.7).
Patients with an average of ≥3 hospitalised VOCs per year over the follow-up were 4.73 times [2.95;7.61] more at risk of death during the follow-up period than patients with <1 hospitalised VOC per year.

Summary/Conclusion: Our study confirms, in a nationwide cohort in France in a real-life setting, that patients frequently experiencing hospitalised VOCs are at higher risk of death compared to patients seldom experiencing VOCs. The highest risk of hospitalized VOC recurrence was within 100 days of a prior hospitalized VOC. Therefore, patients with recurring VOCs are at greatest need for innovative therapies that could reduce or prevent these events. Patients who are able to reduce their annual number of VOCs may live longer.



EP1208 BELGIAN SICKLE CELL DISEASE REGISTRY: DIVERSITY IN PRACTICE BUT LOW MORTALITY

S. Wambacq [1,*], B. Gulbis [2], S. Benghiat [3], B. Bénédicte [4], A. Bruwier [5], L. Dedeken [1], B. De Wilde [6], M.-F. Dresse [7], A. Efira [8], C. Heijmans [1,9], V. Labarque [10], P. Q. Le [1,11], P. Maes [12], P. Philippet [13], A. Vanderfaeillie [14], A. Ferster [1]

Background: The Belgian sickle cell disease registry (BSR) was initiated in 2008 and updated in 2018 to be a more user-friendly and easy-operable application.
Aims: To evaluate if disease modifying treatment (DMT) practice across centres participating in BSR is similar and what the mortality rate is among patients with sickle cell disease (SCD) included in the BSR.
Methods: All data from the initial 2008 database cohort were retrospectively encoded in the updated database format. All new data are recorded prospectively from neonatal screening or first contact until last annual follow-up (FU) or death. The data collected included diagnosis, demography, treatment and outcome data. Data were extracted from the database in January 2021 and were registered by 13 different centres.
Results: There were 977 patients registered with a median FU of 9 years (1-53 y). Median age at last FU was 13 (0-60 y). 654 (87,5%) have a severe phenotype (SS or Sβ°) and 51% are female. Among them, 546 (56%) were born in Belgium of which 369 (68%) were diagnosed by neonatal screening. In the absence of a neonatal screening, median age at diagnosis was 1 year (range 0-18). At last follow-up, 707 patients (72.3%) receive DMT: 523 patients receive hydroxyurea (HU), 126 underwent hematopoietic stem cell transplantation (HSCT), 53 are chronically transfused, 5 participate to a study with crizanlizumab.
Among not transplanted patients, the proportion of those receiving HU is significantly different among centres (46% to 75%; p<0,0001). The median age at which HU was initiated was also significantly different among the centres (4y to 21y; p<0,0001).
Most of HSCT were performed in two main centres i.e., 66 and 58, respectively. Median age at HSCT was significantly different between both centres (8y (2-15) versus 5y (0-19); p=0,004).
Twenty-four (2.5%) patients died which account for a mortality rate of 0.22/100 patients-years (PY) and a trend to increase with age (0,18/100PY < 18 years, 0.39/100PY 18 -40 years and 0.63/100PY > 40 years; p=0.056).
Kaplan-Meier estimate of survival at 20 years is similar regardless of the mode of diagnosis (89%, 95%, 92% respectively for neonatal screening, not screened and not born in Belgium; p=0.260)(Figure 1).

Overal survival cohort per screening group

Summary/Conclusion: Among the patient cohort recorded in the BSR, the proportion of patients receiving DMT, the age at start of HU and the

age at HSCT is significantly different between centres. A detailed analysis of practices based at least on demographic criteria, severity of the disease, etc. is needed to understand their causes. Mortality remains low but with a trend to increase with age. The absence of a national neonatal screening program, deaths occurring before diagnosis and no inclusion in the registry, represent a bias in the interpretation of the mortality. Survival status might be impacted by the proportion of patients that consented to participate to the BSR and could be different between the neonatal screening, born in Belgium not screened, and born abroad groups.

EP1209 REAL-WORLD EXPERIENCE OF VOXELOTOR FOR THE TREATMENT OF PATIENTS WITH SICKLE CELL DISEASE – A SINGLE-CENTER STUDY

K. Muschick [1], T. Fuqua [1], C. Stoker-Postier [1], A. R. Anderson [2,*]

[1]Prisma Health – Upstate Comprehensive SCD Program, [2]Prisma Health – Upstate Comprehensive SCD Program, University of South Carolina School of Medicine, Greenville, United States

Background: Sickle cell disease (SCD) is an inherited disorder of the red blood cells (RBC) in which sickle hemoglobin (HbS) polymerizes and leads to a detrimental shape change in the RBC. This change, known as sickling, can trigger serious consequences including chronic hemolysis, anemia, and episodic vaso-occlusion and often leads to complications such as cumulative organ damage, disability, and accelerated mortality. Voxelotor is a first-in-class therapy that interferes with sickle cell polymerization, increases hemoglobin (Hb) levels, and reduces hemolysis. It is FDA approved for the treatment of SCD in patients 12 years of age and older.
Aims: The objective of this study was to quantify the clinical response to voxelotor treatment in a single-center series of 73 adult and adolescent patients with SCD.
Methods: We collected real-world clinical data from 73 adult and adolescent patients with SCD at the Prisma Health – Upstate Comprehensive SCD Program, Greenville, South Carolina, USA, under a data collection protocol for standard-of-care clinical data. Laboratory data were collected before initiation of voxelotor and were compared to the most recent laboratory value collected during treatment. All patients included in the analysis had received voxelotor for at least 2 consecutive weeks. Data from 13 patients were not included in the analysis, 7 patients who received less than 2 weeks of treatment, 3 after reporting adverse events (hypersensitivity reaction [n=2], diarrhea [n=1]), and 6 additional patients who did not receive medications due to insurance issues.
Results: Sixty patients were included in the current analysis. The age range was 12 to 70 years, average (SD) age was 31.1 years (15.36), and 61.7% were female. SCD genotypes represented included HbSS (85%), HbSC (6.7%), and HbSβ0 (6.7%). Mean baseline Hb was 8.2 g/dL. A stable dose of hydroxyurea (HU) was reported in 80.0% of patients at the time of voxelotor initiation and 26.7% of patients received exogenous erythropoietin (EPO) treatment plus HU. At the time of this analysis, patients received voxelotor for an average (range) of 3.9 months (0.5-13.6 months). Levels of Hb increased (post- vs pre-voxelotor, mean [SD]) by 2.0 g/dL (1.02 g/dL); whereas reticulocyte percentage decreased by 4.6% (3.7%), and total bilirubin decreased by 1.4 mg/dL (2.2 mg/dL). All patients who received exogenous EPO were able to either discontinue (n=11) or reduce the frequency (n=5) of EPO therapy after voxelotor initiation. The clinical improvements reported by patients included increased energy, improved activity tolerance, decreased pain symptoms, and reduced scleral icterus. The most common reported side effects were diarrhea, nausea, and rash. These side effects were mild and self-limited in most patients. Dose modification from 1500 mg to 1000 mg was only necessary in 3 patients with diarrhea.
Summary/Conclusion: The effects of voxelotor on Hb, reticulocyte percentage, and total bilirubin were of similar magnitude to values reported in the HOPE trial. In addition, consistent evidence of improved clinical status was associated with a robust hematologic response, including a reduction in EPO therapy. In summary, our study suggests that patients with SCD achieve meaningful clinical benefit with voxelotor therapy.

EP1210 PHARMACOKINETIC PROPERTIES OF A HUMAN PLASMA DERIVED HEMOPEXIN DRUG PRODUCT (CSL889) IN TOWNES HBSS-, WILD-TYPE MICE, RATS AND CYNOMOLGUS MONKEYS FOR THE TREATMENT OF ACUTE VOC IN SICKLE CELL DISEASE

G. Hoebarth [1,*], T. Ruthsatz [1], J. Bain [2], M. Mischnik [2], T. Gentinetta [3], M. Edler [3], M. Pelzing [4], H. Lioe [4], K. Martin [4], K. Patel [4], D. Schu [2], G. J. Kato [5], E. Herzog [5]

[1]CSL Behring GmbH, Vienna, Austria, [2]CSL Behring GmbH, Marburg, Germany, [3]CSL Behring AG, Bern, Switzerland, [4]CSL Innovation, Melbourne, Australia, [5]CSL Behring, King of Prussia, United States

Background: Sickle cell disease (SCD) is an inherited, autosomal recessive disorder that leads to hemolytic anemia and vascular disease, with a range of acute and chronic complications driven by self-perpetuating cycle of vaso-occlusion and vaso-occlusive crises (VOCs).
Aims: CSL889, a human plasma derived hemopexin, is being developed as a novel pharmacologic therapy to scavenge cell free toxic heme in patients with VOC, with the goal of reducing the duration and severity of acute VOC in adults and children with SCD.
Methods: In order to evaluate the pharmacokinetics (PK) of CSL889, single-dose PK studies were performed following intravenous (IV) administration in Townes HbSS mice, a model for sickle cell disease, (*Hbb*$^{tm2(HBG1,HBB*)Tow}$), wild type C57BL6 (WT) mice and rats at a dose of 35 mg/kg, and in cynomolgus monkeys at doses of 50, 150 and 500 mg/kg BW. Additionally, a PK following repeated dosing (up to 3 repeat doses each 4 hours apart at a dose of 500 mg/kg IV) in Townes HbSS mice was conducted. In addition to CSL889, the concentration-time profiles of hemopexin:heme complex and total heme were described. Townes HbSS mice were used because they express the human HbSS and mimic the major features of the human SCD (eg. sickled red blood cells (RBCs) with a half-life of 2.4 days vs normal RBCs with a half-life of 15.7 days in healthy mice). Quantification of total human hemopexin (CSL889) in mouse, rat and cynomolgus monkey was performed using LC-MS/MS.
Results: In comparison to WT mice, Townes HbSS mice showed a markedly decreased C_{max} (0.41 mg/mL vs 0.70 mg/mL) associated with a markedly increased clearance (23.0 vs 1.6 mL/kg/h) and consequently decreased half-life (7 vs 58 h) and mean residence time (MRT; 5 vs 81 h) following IV administration of CSL889. Similarly, the area under the curve (AUC_{0-inf}) was 14-fold higher in WT- compared to Townes HbSS mice (21.8 vs. 1.52 h*mg/mL). PK parameters of CSL889 in rats were comparable to that in WT mice - C_{max} (0.74 mg/mL), clearance (1.78 mL/kg/h), half-life (58 h) and AUC_{0-inf} (19.6 h*mg/mL).
For hemopexin, following repeated IV administration, plasma levels accumulated up to the 3rd dose, reached a plateau and declined subsequently over the following 24 hours. AUC_{0-inf} was 345 h*mg/mL, MRT 21.4 h, half-life 13.7 h and IVR 93%. For hemopexin:heme complex, the highest plasma levels were measurable at 5 min after the first dose of CSL889. Levels declined slightly until they reached a steady state after the last dose up to the last time-point measured. Total heme plasma concentrations first declined slightly and showed an increase to the end of the concentration-time profile (Figure 1).
In monkeys, C_{max} and AUC of CSL889 increased slightly less than dose-proportionally over the dose range of 50-500 mg/kg (C_{max} from 1.6 to 10.4 mg/mL and AUC_{0-inf} from 84.4 to 587 h*mg/mL). A slightly higher total clearance (Cl) [0.85 vs 0.66 vs. 0.61 mL/h/kg] was observed at the high dose compared to the intermediate and low dose. The terminal half-life following IV administration increased with dose from 80 to 103 h.

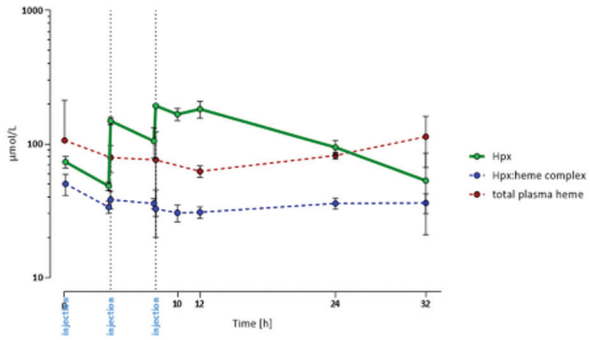

Figure 1: Hemopexin plasma concentration-time profile. For hemopexin (green solid line) plasma levels accumulated up to the 3rd dose, reached a plateau and declined subsequently over the following 24 hours. For hemopexin:heme complex (blue dotted line), the highest plasma levels were measurable at 5 min after the first dose of CSL889. Levels declined slightly until they reached a steady state after the last dose up to the last timepoint measured. Total heme plasma concentrations (red dotted line) first declined slightly and showed an increase to the end of the concentration-time profile. Baseline levels for hemopexin in plasma were below the LLOQ and for hemopexin:heme complex were slightly above the LLOQ.

Summary/Conclusion: Townes HbSS mice tested at 35 mg/kg showed a shorter half-life compared to the healthy rodent species (7 h vs. 58 h) suggesting an increased binding of CSL889 to accessible heme in SCD. Following repeated dosing in Townes HbSS mice increasing hemopexin concentration levels correlate with decreasing total heme plasma levels. The increase of total heme towards the end is most probably due to the saturation of the clearance mechanism and ongoing hemolysis.

EP1211 REAL-WORLD DATA FROM THE CRIZANLIZUMAB MANAGED ACCESS PROGRAM (MAP): BASELINE DISEASE BURDEN AND PRIOR TREATMENTS FOR PATIENTS WITH SICKLE CELL DISEASE (SCD) AND RECURRENT VASO-OCCLUSIVE CRISES (VOCS)

A. C. Silva-Pinto [1,*], E. Marturano [2], L. DeBonnett [3], R. D. Cançado [4]

[1]Regional Blood Center, Department of Medical Imaging, Hematology and Oncology, Ribeirão Preto School of Medicine, University of São Paulo, São Paulo, Brazil, [2]Novartis Pharma AG, Basel, Switzerland, [3]Novartis Pharmaceuticals Corporation, East Hanover, United States, [4]Department of Hematology and Oncology, Santa Casa de São Paulo School of Medicine, São Paulo, Brazil

Background: VOCs are the most common cause of SCD-related hospitalization and can lead to serious complications. Hydroxyurea (HU) has historically been a mainstay for VOC prevention, but new therapies are now available. Crizanlizumab is an anti-P-selectin monoclonal antibody approved in several regions to prevent/reduce VOC burden for SCD patients aged ≥16 years. Early access to crizanlizumab is possible before health authority approval in some countries via a MAP (NCT03720626). Baseline patient data are collected to assess their eligibility for MAP participation. We conducted a descriptive analysis of aggregated baseline data for patients eligible to enter the MAP in countries where publication of these data was allowed.
Aims: We analyzed baseline SCD characteristics and treatment history for patients participating in the MAP to assess real-world disease burden prior to receipt of crizanlizumab. The data set primarily included patients in Brazil, but also included those in Canada, Israel, Italy and Spain.
Methods: The MAP was designed to provide access to crizanlizumab for patients with serious or life-threatening disease for which no comparable or satisfactory alternative to crizanlizumab was available as treatment in their country. Crizanlizumab access was sought via independent request by each patient's physician. Other patient eligibility criteria were: age 16–70 years (18–70 years in Italy); confirmed SCD (any genotype); history of VOCs as assessed by the treating physician (including recurrent VOCs while receiving preventative therapies like HU); not eligible for a crizanlizumab clinical trial; and not participating in a chronic transfusion program (simple or exchange).
Results: As of 31 January 2021, baseline data were available for 124 patients eligible for this analysis. Median age was 33 years, 60% were female and 83% were from Brazil (Table). In the year before entering the MAP, 122 patients (98%) had experienced ≥1 home-managed VOC (median 6, interquartile range [IQR] 4–10), 118 (95%) had experienced ≥1 healthcare-managed VOC (median 4, IQR 2–5) and 106 (85%) had been hospitalized for SCD-related reasons (median 3, IQR 2–4).
Opioids had been taken by 118 patients (95%) in the year before entering the MAP; all of them took opioids for VOC-related pain. Of the 118 patients who took opioids, 47% took them <4 times a month, but 31% took them more than once a day (Table). Some physicians chose to provide specific HU-use information, for 93 patients, to help better characterize those patients' medical history. Of these patients, 24 (26%) had never taken HU and 69 (74%) had, either ongoing at baseline or at any prior point. Of those 69 patients, 66 (96%) reported opioid use in the year prior to MAP entry. Of those 66 patients, 55% took opioids <4 times a month, but 26% took opioids more than once a day (Table).

Table. Baseline characteristics and treatment history for patients eligible for the crizanlizumab MAP

Characteristic	Patients N=124
Median age, years (IQR)	33 (25–40)
Country, n (%)	
Brazil	103 (83)
Israel	8 (6)
Italy	6 (5)
Spain	6 (5)
Canada	1 (1)
Gender, n (%)	
Female	74 (60)
Male	50 (40)
Race/ethnicity, n (%)	
African American	64 (52)
Hispanic/Latino	20 (16)
Caucasian	15 (12)
Other	25 (20)
SCD genotype, n (%)	
HbSS	100 (81)
HbSβ°	10 (8)
HbSC	7 (6)
HbSβ+	6 (5)
Other	1 (1)
Taken opioids in the year before entering the MAP	**Patients N=118**
Frequency of opioid use	
Fewer than four times a month	56 (47)
More than once a day	36 (31)
More than once a week	13 (11)
Once a week	7 (6)
Once a day	6 (5)
Taken HU at some point (either currently or previously) and taken opioids in the year before entering the MAP	**Patients N=66**
Frequency of opioid use	
Fewer than four times a month	36 (55)
More than once a day	17 (26)
Once a day	6 (9)
More than once a week	5 (8)
Once a week	2 (3)

Summary/Conclusion: By analyzing baseline characteristics in this patient population prior to crizanlizumab treatment in the MAP, we observed a high burden of home- and healthcare-managed VOCs and SCD-related hospitalization. This high disease burden was seen despite many patients reporting use of HU and/or opioids, which illustrates their unmet medical need, hence their request to participate in the MAP. These real-world data demonstrate the need for alternative treatments targeting VOC burden for SCD patients, beyond HU. Reduction in VOC frequency would also be expected to reduce the need for opioids to manage acute pain. Additional data are required to assess if these observations are replicated in other SCD patient populations.

EP1212 COMPLICATIONS OF SICKLE CELL DISEASE IN EAST LONDON NEWBORN COHORT PATIENTS OVER THE YEARS 2015-2018

M. Soriano [1,*], C. Sangarappillai [1], W. Hann [2], K. Wieczorek [1], R. Nzouakou [2], B. Kaya [2], F. Barroso [2], S. Bennett [2], P. Telfer [1]

[1]Centre of Genomics and Child Health, Queen Mary University of London, [2]Haematology, Barts Heath NHS Trust, London, United Kingdom

Background: Hydroxyurea (HU) and chronic transfusion therapy (CTT) are the only treatments currently available in the UK to modify the course of sickle cell disease (SCD), while haematopoietic stem cell transplant (HSCT) is only available to a small minority with HLA-matched sibling donor. Numerous studies have shown reduction in acute vaso-occlusive and neurological complications (particularly ischaemic stroke) with these therapies. New therapies under development are expected to further improve outcomes, but there remains uncertainty towards the degree to which morbidity and mortality could be improved and how to evaluate their health economic potential. There is, therefore, a need for accurate, long-term follow-up studies demonstrating the range of complications, residual morbidity and early mortality. The East London Newborn Cohort Study aims to study long-term outcomes of patients with SCD in the UK. Outcomes have previously been reported up to the end of 2005 (Telfer et al, Haematologica, 2007). Here, we report on follow-up during the years 2015-2018 when HU and CTT were widely available to children and adults according to national and international guidelines.
Aims: To compare impact of current standard therapies on rates of acute complications.
Methods: Eligible patients were born in a designated local region, diagnosed by newborn screening between 1983-2018 and followed in our Specialist Centre. The age distribution in this cohort is currently paediatric and young adult. Recruitment was at birth, before any SCD complications could occur and represent the full spectrum of disease severity, avoiding any selection bias from clinical phenotype. For this study, we restricted the analysis to children and adults with HbSS and HbS beta thalassaemia who were followed in our centre during the period 2015-2018. Patients were categorised according to treatment received during follow-up (HU, CTT or no treatment), where duration was at least 6 months. Patients who switched were allocated according to the longest duration of therapy in follow-up. Data on all acute complications requiring hospital treatment (in patient, emergency department, or day unit) were collected. Sickle cell complications included acute (pain, chest syndrome, ischaemic stroke, hepatic/splenic sequestration), aplastic crisis, dactylitis, girdle syndrome, and priapism. Chi-squared tests were used to test for associations between categorical variables, and the Kruskal Wallis test for comparisons of continuous variables between the three treatment groups.
Results: 175 patients were included; 91 (52.0%) were female. Median age at study entry was 11.6 years (range 0.2 to 31.4 years). 47 (26.9%) patients were treated with HU, 53 (30.8%) with CTT, 72 (41.9%) were not treated, 2 (1.1%) died, and 1 (0.6%) received HSCT. There was a total of 695 patient-years of follow-up. Data on acute complications are presented in the table. More than one-third of the patients had a relatively mild phenotype and had not been treated with HU or CTT. This group had the lowest rate of acute SCD-related complications, while patients on HU had the highest rates of pain, acute chest syndrome, and sickle complications.

	HU N=47 Years of follow-up: 188	CTT N=53 Years of follow-up: 212	No Therapy N=72 Years of follow-up: 288	P value
Acute painful crisis[1]				
Patients with ≥1 episode	39 (83.0%)	31 (58.5%)	41 (56.9%)	X2=9.6 2 df, P=0.008[2]
Number of episodes	413	233	174	
Episodes per patient-year Median (range)	0.50 (0 - 54.25)	0.25 (0 - 13.50)	0.25 (0 - 7.50)	X2=10.3, 2 df P=0.006 [3]
Acute Chest Syndrome[1]				
Patients with ≥1 episode	10 (21.3%)	11 (20.8%)	8 (11.1%)	X2=2.9, 2 df, P=0.2[2]
Number of episodes	18	14	15	
Episodes per patient-year Median (range)	0 (0 - 1)	0 (0 - 0.75)	0 (0 - 1.25)	X2=2.8, 2 df, P=0.2[3]
All sickle related acute episodes[1]				
Patients with ≥1 episode	39 (83.0%)	34 (64.2%)	45 (62.5%)	X2=6.2, 2 df, P=0.04[2]
Number of episodes	451	275	199	
Episodes per patient-year Median (range)	0.75 (0 - 54.5)	0.50 (0 - 13.50)	0.25 (0 - 8.75)	X2=11.4, 2 df, P=0.003[3]
All non-sickle related acute episodes[1]				
Patients with ≥1 episode	22 (46.8%)	21 (39.6%)	28 (38.9%)	X2=0.82 2 df, P=0.7[2]
Number of episodes	52	42	66	
Episodes per patient-year Median (range)	0 (0 - 3.25)	0 (0 - 1.50)	0 (0 - 1.75)	X2=0.67 2 df, P=0.7[3]

[1]Applies to the 4 year period of follow-up 2015-2018, [2]Chi-Square test, [3]Kruskal Wallis Test

Summary/Conclusion: The results confirm that current standard therapies are only partially effective in controlling acute complications of SCD. There remains a significant unmet need for effective disease modifying or curative therapies for patients with more severe phenotype.

EP1213 LOW SARS-COV-2 SEROPREVALENCE IN A COHORT OF SICKLE CELL DISEASE (SCD) PATIENTS: POSSIBLE EFFECTS OF EMPHASIS ON SOCIAL ISOLATION FOR A POPULATION INITIALLY CONSIDERED TO BE AT VERY HIGH RISK

L. Francisco Trafane [1,*], V. A. da Costa [1], A. da Silva Santos Duarte [1], A. Basso Zangirolami [1], J. L. Proenca-Modena [2], P. de Melo Campos [1], S. de Souza Medina [1], S. T. Olalla Saad [1], M. Addas Carvalho [1], B. Deltreggia Benites [1]

[1]Hematology and Transfusion Medicine Center, [2]Laboratory of Emerging Viruses (LEVE), Department of Genetics, Evolution, Microbiology and Immunology, Institute of Biology, University of Campinas, Campinas, Brazil

Background: Although initially considered at higher risk for severe presentations of COVID-19, observational studies with SCD patients have mostly pointed to clinical severity similar to the general population. However, the level of vulnerability of these individuals to become infected and the determinants for their contagion are still uncertain.
Aims: To assess the prevalence of SARS-Cov-2 antibodies in SCD patients followed at a Brazilian center and its correlation with phenotypic and socioeconomic determinants.
Methods: A questionnaire was applied regarding demographics, socioeconomic status, use of Hydroxyurea, working status and income, COVID-19 symptoms, and the perceptions about social isolation measures. Blood samples were taken for chemoluminescence IgG (anti-N) and IgM (anti-S) anti-SARS-CoV-2 tests (Abbott Architect™, Ireland); specific neutralizing antibody titers were accessed observing the cytopathic effect in cells incubated with patient serum-virus mixture.
Results: From Jul/20 to Jan/21, 214 serological tests were performed on 135 patients (86% of SCD patients registered at the center): 82 HbSS (61%), 41HbSC (30%), 8Sβ+ (6%), 4Sβ0 (3%); 57% male and median age 42 (19-74). 66% were using Hydroxyurea and 4% were on chronic transfusion. In the analyzed period, 61 (45%) patients had vasoocclusive crises; 37 (27%) had symptoms suggestive of COVID-19, but only 2 patients had a positive PCR for SARS-Cov-2. When questioned, only 12% of patients did not consider themselves vulnerable to infection, and only 17% believed that individual and collective protection measures were expendable. In fact, 91% stated that they were able to adopt basic social distance measures, with 76% reporting cancellation of social events and 64% managed to reduce the use of public transport, but only 44% could work or study remotely. Regarding serological evaluation, 57 patients (42%) were tested more than 1 time during this period: 46 with 2 tests, 11 with ≥ 3 tests. Among all patients, 15 had positive results: 9 IgG/IgM+ and 6 IgG+ only, therefore with an overall seroprevalence of 11%. Seroconversion was documented for only 1 patient during the study period and, interestingly, with no signs and symptoms of infection. Moreover, 2 patients lost positivity for IgG 3 months after the initial positive test. The search for functionally neutralizing antibodies resulted in 9 patients with low titers (□1:40) and only 3 patients with remarkably high titers (≥1:640). There were no correlations between test positivity and education, income, number of household contacts and maintenance of work outside the home; however, serological positivity was associated with older age (40.3 x 22.9, p<.001) and regular use of public transport (Fisher exact test, p=0.02). Only 1 patient in this cohort needed hospitalization for COVID-19, including mechanical ventilation and exchange transfusions, but was discharged after 14 days
Summary/Conclusion: These data attest to the effectiveness of social distancing instructions given to patients in our SCD clinic throughout the pandemic, considering the low overall positivity and only 1 seroconversion during the study period. The fact that only 1 patient in our center had severe disease agrees with other reports showing less severity for SCD than initially expected. In fact, the transient positivity of serological tests and the low levels of functional neutralizing antibodies in SCD patients may indicate the acquisition of protective immune responses that are not dependent on antibodies and that still need to be better evaluated.

EP1214 EVALUATION OF DIFFERENT ESTIMATED GLOMERULAR FILTRATION RATE AS RELIABLE MEASURES OF RENAL FUNCTION IN CHILDREN WITH SICKLE CELL DISEASE

I. Liguoro [1,*], B. Inusa [2], B. Tayo [3], C. Booth [4], C. Turner [5], N. Dalton [5]

[1]Department of Medicine, Division of Pediatrics, University of Udine, Udine (UD), Italy, [2]Paediatric Haematology, Evelina London Children's Hospital, Guy's & St Thomas' NHS Foundation Trust, London, United Kingdom, [3]Department of Public Health Sciences, Parkinson School of Health Sciences and Public Health, Loyola University, Chicago, United States, [4]Department of Nephrology, [5]WellChild Laboratory, Evelina London Children's Hospital, Guy's and St Thomas NHS Foundation Trust, London, United Kingdom

Background: Renal complications can occur throughout the life of a patient with sickle cell disease (SCD), starting with hyperfiltration and impaired urinary concentration in early childhood, leading to chronic kidney disease (CKD) with advancing age. As patients with SCD survive longer, the risk of these changes progressing to end-organ damage rises. Currently, there is no reliable marker for detecting early renal disease in childhood. Routine estimation of glomerular filtration rate (GFR) in children is derived from the height/plasma creatinine formula and is dependent on the accuracy of the creatinine analytical method used.
Aims: The aim of this study was to evaluate different equation methods for estimating GFR in comparison to the gold standard measure of GFR using clinical and demographic variables and markers of renal function, including creatinine.
Methods: Children aged 5-16 years followed for SCD (homozygous HbSS and $HbSb_0/b^+$) were prospectively recruited. Specific renal biomarkers were measured: formal GFR was measured using plasma disappearance of Inutest/Ihexol, plasma creatinine was measured either by standard laboratory method or by tandem mass spectrometry (MS). Estimated GFR was then calculated by using the "Bedside Schwartz method" with the formula: [(constant × height) ÷ plasma creatinine].
Results: A total of 79 patients (39 males, mean age 9.8±4.0 years) were enrolled. Anthropometric measures were collected: the mean height, weight and body surface area were 135.4±20.9 cm, 34±15 kg, and 1.1±0.3 m^2, respectively. Height/plasma creatinine was significantly correlated with Inutest GFR, r=0.86 (p<0.001). A revised eGFR constant was calculated for Schwartz equation from the slope of the plot of height/plasma creatinine versus GFR forced through zero. The new constant was determined as 30.86, or 31 for convenience. Standard renal measurements were available for all children. Mean values for GFR and laboratory plasma creatinine were 132.7±32.1 ml/min/1.73m^2 and 38.5±17.8 µmol/l, respectively. Mean values for eGFR derived from standard plasma creatinine was 122.4 ± 31.7 ml/min, with significant difference in comparison to GFR values (p=0.002). MS eGFR was calculated for 44 children, resulting with a mean of 120.5±34.4 ml/min, and there was no significant difference in comparison to GFR values (p=0.239).
Summary/Conclusion: In conclusion, in children with SCD the formula to calculate eGFR based on height and plasma creatinine determined with MS traceable creatinine methods provides a more reliable estimation of renal function in comparison to standard laboratory plasma creatinine derived values, as a possible effect of the hyperfiltration state of these patients.

EP1215 PRECLINICAL SAFETY AND TOXICITY ASSESSMENT OF A HUMAN PLASMA DERIVED HEMOPEXIN DRUG PRODUCT (CSL889) FOR THE TREATMENT OF ACUTE VOC IN SICKLE CELL DISEASE

T. Ruthsatz [1,*], G. Hoebarth [1], J. Bain [2], T. Gentinetta [3], K. Martin [4], R. Davis [4], D. Schu [2], G. J. Kato [5], E. Herzog [5]

[1]CSL Behring GmbH, Vienna, Austria, [2]CSL Behring GmbH, Marburg, Germany, [3]CSL Behring AG, Bern, Switzerland, [4]CSL Innovation, Melbourne, Australia, [5]CSL Behring, King of Prussia, United States

Background: Sickle cell disease (SCD) is an inherited, autosomal recessive disorder that leads to hemolytic anemia and vascular disease, with a range of acute and chronic complications driven by self-perpetuating cycle of vaso-occlusion and vaso-occlusive crises (VOCs).
Aims: CSL889, a human plasma-derived hemopexin, is being developed as a novel pharmacologic therapy to reduce toxic cell-free heme in patients with VOC, with the goal of reducing the duration and severity of acute VOC in adults and children with SCD.
Methods: The *in-vivo* toxicological program included 2-week repeat-dose tolerability studies in wild-type (C57BL/6) and Townes HbSS sickle cell mice (*Hbb*$^{tm2(HBG1,HBB*)Tow}$), a 2-week repeat-dose toxicity study in rats and a 2-week repeat-dose toxicity study in cynomolgus monkeys including cardiovascular safety pharmacology. The latter studies included a treatment free period of 7 days. A single dose safety pharmacology study in rats assessed effects on respiratory parameters. CSL889 was administered intravenously (IV) at dose levels of 50 to 500 mg/kg. All studies were conducted under applicable animal welfare standards and regulatory approvals.
Results: Repeat-dose administration of CSL889 every other day over two weeks was well-tolerated in cynomolgus monkeys and rats. There were no mortalities or adverse findings regarding clinical observations, body weights, ophthalmoscopy, electrocardiography, blood pressure, respiratory rate, clinical pathology, urine analysis, organ weights, gross pathology or histopathology attributable to treatment with CSL889. Non-adverse and transient effects which returned to baseline levels after the 7-day recovery period included an increase of the beta-globulin serum levels in cynomolgus monkeys, an increase of the alkaline phosphatase (ALP) serum levels which did not clearly follow the dose-response principle in rats, and a small but statistically significant decrease from baseline activated partial thromboplastin time (aPTT). The observed formation of anti-drug antibodies (ADAs) against CSL889 in both species is an expected immune reaction after repeated application of the heterologous human protein to animals and is not considered predictive for the clinical situation. ADA formation did not have an impact on safety or exposure of the study animals. Safety pharmacology evaluation did not show any deleterious effects of CSL889 on cardiovascular and respiratory functions in cynomolgus monkeys and rats. The NOAEL for rats and cynomolgus monkeys was at least 500 mg/kg under the conditions of the study.
Daily IV administrations of hemopexin for two weeks to wildtype mice was well tolerated and produced no adverse clinical signs at 160 mg/kg. While there were no findings after the first dosing occasions, high dose animals (500 mg/kg) showed a short-lived, transient clinical reaction, ie reduced mobility and body temperature to the treatment on Day 8. There was no clear evidence of treatment-related changes to hematology or clinical chemistry parameters in any dose group at the end of the dosing period.
Daily IV administration of hemopexin for two weeks or six days (500 mg/kg only) to Townes HbSS mice was generally tolerated. Similar to the reaction observed in wildtype mice immunological reactions were observed in some dosing groups after repeat administration, which are assessed as a result of the application of the heterologous human protein.
Summary/Conclusion: The toxicological program demonstrated that CSL889 has a favorable safety profile and supports the clinical development of hemopexin for the treatment of acute VOC in sickle cell disease.

EP1216 ATTITUDES TOWARD THE MANAGEMENT OF SICKLE CELL DISEASE: RESULTS FROM TURKISH REGISTRY

Background: Sickle cell disease (SCD) is a significant health problem for Turkey. The official register of the Ministry of Health includes 1200 patients with SCD residents in Turkey. However, there has been no data including the demographic and clinical features of this cohort
Aims: The National Hemoglobinopathy Register of the Turkish Society of Hematology (TSH) aims, to evaluate the geographic distribution and disease characteristics of patients with SCD and the need for delivering a standard of care to the patients.
Methods: Thirty-five hemoglobinopathy centers entered a total of 656 patients' data, 627 of whom were alive, into the web-based system from the hospital records. The database was composed of 480 SCD (75%), 160 (25%) HbSB patients, and only 16 HbS with other abnormal beta-globin chain variants. The 640 of 656 registered patients were born in Turkey, and 80% were born in only three provinces (Adana, Hatay, and Mersin).
Results: The patients (305 males, 335 females) were 32 ± 15 years-old. The mean age of diagnosis was 11±10.7 months (HbSS; 10±8.2, HbSB; 23±14). The physicians prescribed penicillin prophylaxis for 46.5% of patients at the mean age of 15±14 months. The pneumococcal, meningococcal, and Hib vaccination was administered to 91.7%, 66.8%, and 54.6%, respectively, and 48.5% of those received booster dose of pneumococcal vaccine. 75% of patients were receiving hydroxyurea, the last amount used was mean 15 ± 6.7 mg/kg/day, the physician reported compliance with the treatment was 69%.
The 33% of patients received simple transfusions for anemia (63%) or controlling painful crises (20%) in the last year. The 8.4% of the patients were on chronic exchange programs. Erythrocytapheresis was the method of choice in the majority of those (81.4%). The rate of transfusion with ABO, Rh(CcDEe), Kell compatible products was 23%. Iron chelation therapy (ICT) has been initiated in 22% of the patients at the mean age of 7.7±11.2 years, with a median serum ferritin level of 2500±470 ug/L. Deferasirox was the first-line iron chelator in 52.5% of the patients. Deferasirox use increased to 85.6% among patients on ICT over the years. The median serum ferritin decreased to 1400±176 ug/L in the last year. The patients who had at least one acute chest syndrome and stroke were 16% and 9.5%, respectively. At least one painful crisis was recorded in 81% of patients in the last year
Summary/Conclusion: Current treatment options for reducing morbidity and mortality in SCD are limited to adherence to penicillin prophylaxis and recommended vaccination schedule, using hydroxyurea, erythrocyte transfusions, and ICT whenever indicated. The data showed, starting hydroxyurea and providing patients' compliance to the therapy were our positive aspects. However, the physicians should reconsider the adjustment of the hydroxyurea dose. The initiating penicillin prophylaxis, use of ABO, Rh(CcDEe), Kell compatible erythrocyte transfusions, and timely initiation of ICT were the aspects we needed to improve delivering a standard of care to the patients.

EP1217 ASSESSING TRANSITION OUTCOMES IN SICKLE CELL DISEASE (SCD) PRIOR TO IMPLEMENTATION OF A FORMAL TRANSITION PROGRAM

S. Sheppard [1,*], G. Hellemann, PhD [2], J. Kanter, MD [3]

[1]University of Alabama at Birmingham School of Medicine, [2]Biostatistics, School of Public Health, [3]Hematology/Oncology, University of Alabama at Birmingham, Birmingham, United States

Background: From newborn screening to vaccinations to disease-modifying therapies, the evolution of medicine has potentiated the livelihood of children and adolescents with Sickle Cell Disease (SCD). Over 90% of children with SCD now survive into adulthood in high resource

countries—however, mortality rates have not improved in young adults. Challenges in continuing care emerge as they transition from a heavily contiguous pediatric healthcare model to an increasingly self-reliant adult healthcare model.
Aims: The goal of this study is to identify potential facilitators and barriers to a successful transition in care.
Methods: The Comprehensive Sickle Cell Center at UAB serves a large area of Alabama, including many surrounding cities. The pediatric program is housed in Birmingham, AL but has outreach clinics in Montgomery, Opelika, and Tuscaloosa, AL. It provides care for approximately 900 children with SCD. The adult program only has one clinic located in Birmingham, AL. With IRB approval, we performed a retrospective medical chart review of all individuals with SCD (all genotypes) aged 18-24 (as of January 31, 2019) who were previously treated by hematology at Children's of Alabama. To be included, patients must have been seen at least twice prior to turning 18 years old and have confirmed SCD. Charts were reviewed for demographics, insurance at last known visit, SCD genotype, use disease-modifying therapy (hydroxyurea or transfusion therapy) at last pediatric visit, location of pediatric SCD clinic, and transition status. Based on these characteristics, analyses were done to determine if there were differences in genotype, pre-transition treatment, or demographics between those who had become lost-to-follow-up and those who had successfully transitioned (defined as coming to an appointment with an adult hematologist at UAB or with a community hematologist-oncologist).
Results: The total sample included 544 individuals. Of this group: 234 were lost-to-follow-up, 189 transitioned to adult care, 36 moved, and 15 died before 18 years of age. Seventy patients have not yet transitioned and thus, were excluded from study. Sixty-eight percent of patients (n=127) that successfully transitioned to an adult provider had their last pediatric visit at the Birmingham clinic, compared to only 32% (n=61) that were followed in outreach (non-Birmingham clinics) (P<.01). Patients were also more likely to have successfully transitioned if they had sickle cell anemia versus those with hbSC/hbSß+ (p<.01) and if they were receiving hydroxyurea or chronic transfusion therapy (p<.01).
Summary/Conclusion: Our results suggest that geography, genotype, and the use of disease-modifying therapy are strong predictors for a successful transition to adult care in SCD. Novel strategies to improve transition of care for patients living outside of Birmingham are clearly needed. Potential care improvements include telehealth and developing relationships with local primary care providers or developing affiliate clinics in more rural areas. People with hbSC and hbSß+ disease (compared to hbSS) often have less severe disease complications as children. It may be necessary to enhance engagement in care for these patients to ensure they do not become lost to follow-up. Further, increasing early discussion about the necessity of lifespan care may help patients and families plan for adult care at earlier ages. Beyond our institution, this information could serve as a potential framework for evidence-based guidelines in SCD Transition Care.

EP1218 CHRONIC COMPLICATIONS OF SICKLE CELL DISEASE PATIENTS IN TURKEY

S. Ünal [1,*], E. Gürkan [2], N. Tiftik [1], H. Özdoğu [3], S. Aydın Köker [4], G. İlhan [5], N. Soyer [6], Z. Karakaş [7], B. İnce [8], A. Özcan [9], T. Celkan [10], A. Şahin [11], F. azık [12], C. Acıpayam [13], M. Türker [14], M. Evim [15], M. Şöker [16], Ö. Bör [17], S. Ünal [18], M. Akcan [19], Ö. Gür Kırkaş [20], I. İnce [21], A. Canbolat [22], Y. Aydınok [23]

[1]Mersin University faculty of Medicine, Mersin, [2]Çukurova University, [3]Başkanet University Faculty of medicine, Adana, [4]Hatay Public Hospital, [5]Mustafa Kemal University faculty of Medicine, Hatay, [6]Ege University Faculty of Medicine, İzmir, [7]İstanbul University Faculty of Medicine, İstanbul, [8]Adana Public Hospital, Adana, [9]Erciyes University Faculty of Medicine, Kayseri, [10]Cerrahpaşa University Faculty of Medicine, İstanbul, [11]Yüzüncü Yıl University Faculty Of Medicine, Van, [12]-, Sırrı Koçman University Faculty Of Medicine, Muğla, [13]-, Kahramanmaraş University, Kahramanmaraş, [14]-, Tepecik Public Hospital, İzmir, [15]-, Uludağ University Faculty of Medicine, Bursa, [16]-, Dicle University Faculty Of Medicine, Diyarbakır, [17]-, Osmangazi University Faculty of Medicine, Eskişehir, [18]-, Hacettepe University Faculty Of Medicine, Ankara, [19]-, Adnan Menderes University Faculty of Medicine, Aydın, [20]-, Bursa Dörtçelik Public Hospital, Bursa, [21]-, Gaziantep Ersin Arslan Public Hospital, Gaziantep, [22]-, İstanbul Medeniyet University Faculty of Medicine, İstanbul, [23]-, Ege University Faculty of Medicine, İzmir, Turkey

Background: With the advances in sickle cell disease (SCD), the patients' life expectancy has increased, and chronic disease complications have become more prominent.
Aims: The National Hemoglobinopathy Register of the Turkish Society of Hematology (TSH) aims to evaulate the frequency of chronic complications and long term outcomes of the patients with SCD in Turkey.
Methods: The physicians from 35 hemoglobinopathy centers registered 480 SCD (75%) and 160 (25%) HbSB patients' hospital records into the web-based system.
Results: The patients (305 males, 335 females) were 32 ± 15 years-old. Musculoskeletal disorders (44%), osteopenia (42%), and avascular necrosis (34%) were the most common complications. Musculoskeletal complications were significantly higher in patients with HbSS (48.5%) than the patients with HBSB (34.8%) (p = 0.006). Infectious complications affected 26.5% of patients, and 3.4% of patients suffered from sepsis. Overall, 3.8% of the patients had transfusion-transmitted infections, and the majority (90%) was Hepatitis-C virus infection. 17% of patients with SCD had liver and gall bladder complications. The biopsy-proven cirrhosis was 1.6%. The cardiovascular complications, including heart failure, thromboembolism, arrhythmia, and pulmonary hypertension, affected 4.9%, 4.4%, 3.2%, 1.5% of the patients, respectively. Each of the urogenital and cerebrovascular complications affected 9.5% of the patients. 2.3% of the patients showed chronic renal failure. Endocrine complications were more prominent in patients with HbSB than SS (14.7% versus 6.5%; p = 0.006). 38% of patients aged >18 years got married at the mean age of 26.7 ± 5.2 years (range 18-48). In 11.3% of these marriages, the couples were the patients with hemoglobinopathy. 85.7% of patients with a healthy partner had at least one child indicating patients' reproductive potential. Three patients had breast cancer, non-Hodgkin lymphoma, and neurofibromatosis type 1, one in each. Twenty-seven patients (4.2%) died of SCD-related complications at the mean age of 38.9± 15.4 years (range 10-67). Among the causes of death, cardiovascular complications were the most common (22%), followed by infections (18.5%) and thromboembolic events (11%). Nine patients aged between 4 and 32 years vof age had bone marrow transplantation (BMT) from a matched sibling (n=7) and unrelated (n=2) donors. All transplanted patients alive, and all but one had BMT from an unrelated donor were disease-free.
Summary/Conclusion: As the data showed, adolescents and young adults are composed of most SCD population in Turkey. It indicates the need for consideration of an effective transitioning program from pediatric to adult care. The organization of specialized centers for patients with SCD and improving access to these centers for regular and comprehensive follow-up should positively impact the patients' survival by controlling the disease's life-threatening complications.

EP1219 A LONGITUDINAL OBSERVATIONAL STUDY TO EVALUATE THE PSYCHOMETRIC PROPERTIES OF A DAILY DIARY FOR ADOLESCENTS AND ADULTS WITH SICKLE CELL DISEASE

R. C. Brown [1,*], X. Lin [2], A. A. Rizio [2], J. Han [3], E. Marturano [4], K. I. Ataga [5]

[1]Aflac Cancer and Blood Disorders Center, Emory - Children's Pediatric Institute, Atlanta, [2]QualityMetric Incorporated LLC, Johnston, [3]Novartis Pharmaceuticals Corporation, East Hanover, United States, [4]Novartis Pharma AG, Basel, Switzerland, [5]UTHSC Center for Sickle Cell Disease, Memphis, United States

Background: Vaso-occlusive crises (VOCs) are one of the most serious clinical features of sickle cell disease (SCD), impacting mortality, morbidity, and health-related quality of life (HRQoL). Existing patient-reported outcome measures (PROs) aim to assess the overall impact of SCD, and are typically administered at fixed intervals several days or weeks apart. However, such PROs are unable to accurately capture the full impact of VOCs, which occur sporadically and unpredictably. The Sickle Cell Pain Diary – Self Report (SCPD-S) was developed to address this measurement gap, assessing the impact of VOCs in adolescents and adults. Administered daily, the diary was designed with patient input to evaluate the severity of SCD-related pain during and outside of a VOC, and to capture the impact of pain on patient-relevant HRQoL concepts.
Aims: To develop a longitudinal observational study to assess the psychometric properties of the SCPD-S.
Methods: Study plans include enrolling 328 patients from 3 countries with a high burden of SCD: the United States (US), United Kingdom (UK), and Kingdom of Saudi Arabia. Participants with a verified diagnosis of SCD who were ≥12 years old were recruited through participant panels, advocacy groups, and clinician referrals. Participants were asked to complete the SCPD-S every day through a mobile application. On days that a VOC was experienced, participants reported on the impact of the VOC; if a VOC was not experienced, they reported on the

impact of SCD on their daily life. The assessments occurred for at least 3 months, increasing the likelihood that participants would experience at least 1 VOC during the study. Anticipating that participants may not have perfect diary completion, it was determined that to be included in the planned analyses, participants must complete at least 25 of 30 daily assessments for at least one month and experience a VOC during that month. One criterion measure was administered daily (single item global impression of severity), while the remainder were administered the day after a VOC in order to reduce respondent burden during a crisis. Planned analyses include factor analysis to confirm the structure of the SCPD-S, which is hypothesized to assess a unidimensional construct of VOC impact. Multiple scoring systems will be explored to provide users flexibility in evaluating diary responses. Psychometric analyses will be conducted to examine the reliability (test-retest and internal consistency reliability), validity (convergent, divergent, and known-groups validity), and responsiveness of the instrument.

Results: After 11 weeks of recruitment in the UK, 81 participants have been enrolled. After 30 weeks of recruitment in the US, a total of 135 participants have been enrolled in the study. Of these, 9 were lost to follow-up, leaving 126 active participants. Only 1 participant missed more than 5 daily assessments for each month of their participation; 8 participants are still in their first month of the study. One hundred nine (93%) of the 117 remaining participants who have completed at least one month of the study have reported at least 1 VOC throughout their participation.

Summary/Conclusion: This study takes a unique approach to the psychometric validation of an SCD-specific PRO that was designed to collect information on sporadic and unpredictable events. Once the psychometric properties of the SCPD-S have been documented, the diary could be used in clinical practice to describe patients' experiences during VOCs and capture responses to treatment.

EP1220 ECONOMIC BURDEN OF SICKLE CELL DISEASE IN THE MIDDLE EAST

H. Ezzat [1,2,3,*], I. Alghaithi [4], S. Alkindi [5], H. Almudaiheem [6], H. Al Saeed [7], J. Altooq [8], S. Basu [9], N. Dani [10], O. Gharaibeh [11], W. Jastaniah [12], H. Malhan [13], O. Mohamed [14], A. Taher [15], A. Tantawy [16], T. Wagdy [8], A. Inati [17]

Background: Sickle cell disease (SCD) is a haematological disorder caused by a mutation in the β-globin gene (HbS) and is characterized by multisystem clinical manifestations, which result in varied acute and chronic SCD-related complications. The most common complication is vaso-occlusive crisis (VOC). In the Middle East (ME), SCD prevalence varies from (0.04%>0.5%) and is localized in certain pockets within countries and is contributed by consanguinity, environmental factors, large sibship size and migration. The increased prevalence together with the complexity in its management, may lead to high utilization of healthcare resources posing a considerable economic burden on the healthcare system, patients, and the society. The paucity of literature on SCD burden, lack of systematic disease registry/databases and structured costs data in the ME challenges the understanding of the scope of the public health concern that SCD poses.

Aims: To estimate the economic burden associated with SCD management in Bahrain, Egypt, Kingdom of Saudi Arabia (KSA), Lebanon, and Oman.

Methods: An excel-based micro-costing analysis was carried out, to estimate the direct and indirect costs associated with SCD management in the countries of interest over a one-year period both from a payer and societal perspective. Data inputs included epidemiology data with health state (defined in model as acute and chronic events consuming resources during the year) and unit costs for SCD management. Data sources included an exhaustive literature review followed by a clinician survey (using Delphi method) which included 41 experts. All findings were further validated by a steering committee of 12 multidisciplinary experts representing the studied countries. The model structure and inputs have been elaborated in the figure. The total annual direct and indirect costs associated with SCD and VOC were calculated. Subgroup analyses were also performed for age groups (paediatrics, adolescents, and adults) and VOC frequencies per year (0, 1-2, 3-4, ≥5 VOCs).

Results: The overall economic SCD burden from Payer's perspectives, across all ages, ranged from USD $1.3 Mn in Egypt to as high as USD $395 Mn in KSA for the management of 1,000 and 94,455 SCD patients, respectively. The model showed that the SCD societal burden in ME ranged from USD $1.79 Mn in Egypt to as high as $1.4 Bn in KSA mostly driven by productivity losses due to SCD. On average and across ME countries, the acute complications represented approximatively 75% of the total SCD burden, of these 58% were attributed to the VOC management costs. In terms of healthcare resources utilization, hospital visits (inpatients, outpatients, and emergency room (ER)) were the main utilized health service contributing, on average, 54% to the total burden. Patients with ≥5 VOC per year incurred the highest annual cost per patient across all countries. The table summarizes the main results per country as well as the overall average.

Total burden	KSA	Oman	Bahrain	Egypt	Lebanon	Average across all countries
Payer's perspective (USD $)	$ 395,141,455	$ 40,305,740	$ 38,416,736	$ 1,289,762	$ 6,211,427	$ 96,273,024
Societal perspective (USD $)	$ 1,443,683,729	$ 68,068,957	$ 55,370,288	$ 1,789,672	$ 6,433,453	$ 3,15,069,216
Number of SCD patients	94,455	7,500	8,800	1,000	850	22,521
Cost of Acute complications as % of total burden (payer's perspective)	93%	89%	73%	68%	47%	74%
Cost of VOC events as % of total burden (payer's perspective)	75%	70%	64%	38%	40%	57%
Cost of hospital visits (inpatients, outpatients and ER) as % of total burden	59%	55%	62%	62%	36%	55%
Average annual cost per patient with ≥5VOC annually (USD $)	$ 14,706	$ 10,390	$ 18,507	$ 5,126	$ 28,654	$ 15,476

Summary/Conclusion: The findings highlighted the extensive utilization of healthcare resources associated with the management of SCD and its substantial impact on patients' work productivity, across the studied countries. Patients with acute complications, primarily VOC events incurred the majority of the economic burden due to the need for hospital visits. The higher the number of VOC events per year the higher the need for medical care hence healthcare resources utilization. This study emphasizes the need for innovative and cost-efficient therapies for the prevention of VOCs and/or reduction of VOCs frequency.

EP1221 THE VALUE OF THE YEARS CLINICAL DECISION ALGORITHM TO RULE OUT PULMONARY EMBOLISM IN PATIENTS WITH SICKLE CELL DISEASE: A RETROSPECTIVE EVALUATION.

A. Gaartman [1,*], A. Strijdhorst [1], M. W. Tang [1], N. van Es [1], B. Biemond [1], E. Nur [1]

[1]Hematology, Amsterdam University medical Center, Amsterdam, Netherlands

Background: Sickle cell disease (SCD) is recognized as a hypercoagulable state and associated with an increased incidence of thromboembolic events. SCD patients presenting with vaso-occlusive crisis (VOC)

frequently have symptoms also suspected of pulmonary embolism (PE) (i.e. thoracic pain, dyspnea, decreased O2 saturation). To compute the pretest probability of PE, the YEARS decision rule is used. This algorithm uses the presence of three clinical criteria (1. signs of deep venous thrombosis, 2. Hemoptysis, 3. PE most probable diagnosis) in combination with D-dimer cut off values. A D-dimer level of ≥ 0.5 mg/L (and 1 or more positive criteria), or ≥ 1mg/L (and no positive criteria) indicates a high probability of PE and would justify performing a computed tomography pulmonary angiogram (CTPA) for a definitive diagnosis. Being a hypercoagulable disease, SCD is associated with increased D-dimer levels. The YEARS decision rule is not validated for SCD patients.
We questioned whether the use of the YEARS criteria with its current D-dimer cut off values is able to rule out PE in SCD patients.
Aims: To validate the Years criteria with its current D-dimer cut off values to rule out PE in SCD patients.
Methods: We performed a single-center retrospective cohort study in the Amsterdam University Medical Centres, a tertiary hospital in the Netherlands. Consecutive D-dimer samples of patients (≥18y) with a confirmed diagnosis of SCD and sickle cell trait (HbAS) were eligible for inclusion if D-dimers were measured to exclude suspected PE. D-dimer samples that were measured to exclude deep venous thrombosis or in other settings were excluded. Laboratory values including D-dimer levels, medical history, the proportion of indicated CTPA examinations based on the YEARS decision rule, the incidence of PE and other diagnoses were documented and compared between groups.
Results: A total of 76 patients with 94 D-dimer samples were eligible for inclusion. Sixty (79%) participants had SCD, while 16 (21%) had HbAS. Plasma D-dimer levels were significantly higher in SCD patients compared to individuals with HbAS (2.88 mg/L [1.56-4.43] vs. 1.01 mg/L [0.49-4.03]; *P*=0.004). Sixty-seven (89%) of SCD patients and 10 (53%) of individuals with HbAS had D-dimer levels in excess of 1,0 mg/L. In patients with the severe genotype (HbSS and HbS-β^0-thalassemia), 94% had D-dimer levels ≥ 1.0 mg/L. CTPA was performed in 88% of SCD patients and 69% of individuals with HbAS. PE was confirmed in 8 (9%) patients without significant differences between patients with SCD and those with HbAS (n=5 (7%) vs n=3 (16%); *P*=0.203, respectively). No differences in D-dimer levels were found in SCD patients with PE compared to those without PE (3.62 mg/L [2.54-8.59] vs 2.76 mg/L [1.52-4.39), *P*=0.293).

Table 2. Hospital characteristics of SCD patients and HbAS patients

	SCD (n=75)		P[1]	HbAS (n=19)	P[2]
	Severe (n=51)	Mild (n=24)			
D-dimer, mg/L	2.88 (1.99-4.02)*	2.86 (1.18-10.98)*	0.654[4]	1.01 (0.49-4.03)*	0.004[4]
D-dimer ≥ 1,0 mg/L	48 (94)	19 (79)	0.050[3]	10 (53)	0.000[3]
CTPA	49 (96)	17 (71)	0.002[3]	13 (69)	0.037[3]
Diagnosis					
PE	3 (6)	2 (8)	0.691[3]	3 (16)	0.203[3]
Pneumonia/ACS	13 (26)	2 (8)	0.083[3]	2 (11)	0.338[3]
Pleural effusion	5 (10)	1 (4)	0.401[3]	0	0.203[3]

Abbreviations: SCD, Sickle cell disease; CTPA, computed tomography pulmonary angiogram; PE, pulmonary embolism; ACS, acute chest syndrome
**Median and inter quartile range; [3] Pearson's Chi Square; [4] Mann-Whitney-U test*
[1] Statistical analysis between severe and mild genotypes [2] Statistical analysis between all SCD patients and HbAS patients

Summary/Conclusion: In this study, 89% of analyzed D-dimer values in SCD patients were > 1 mg/L. This was 94% for the severe genotypes. This translated into a high percentage of CTPA that then had a low yield (7%) of PE in SCD patients. The rate of indication for CTPA for SCD patients in this study was much higher than the 20-30% previously reported for the YEARS algorithm. These data indicate that the specificity of the YEARS algorithm is very low in SCD patients and might lead to over imaging in this patient group.

EP1222 FACTORS ASSOCIATED WITH HOSPITAL ADMISSION DUE TO VASO-OCCLUSIVE CRISIS IN PATIENTS WITH SICKLE CELL DISEASE: RETROSPECTIVE ANALYSIS OF 3-YEAR OBSERVATIONAL STUDY DATA

M. M. Heeney [1,*], T. Pattipaka [2], E. Marturano [2], J. M. Fermont [2]

[1]Dana-Farber/Boston Children's Cancer and Blood Disorders Center, Boston, United States, [2]Novartis Pharma AG, Basel, Switzerland

Background: Sickle cell disease (SCD) is a global health burden that has been largely neglected. Despite improvements in diagnosis, treatment and management over the past few decades, SCD morbidity including vaso-occlusive crises (VOCs) remains high. VOCs, the hallmark of SCD, are the primary cause of hospitalization for SCD patients, and are associated with significant morbidity and mortality. Evidence regarding potential risk factors for hospitalization due to VOC (H-VOC) including commonly measured blood markers is limited.
Aims: To assess whether selected factors are associated with the rate of H-VOC and hospital length of stay by performing a retrospective analysis of data collected prospectively during a 3-year, multicenter, observational US study (NCT01220115) that aimed to better understand disease burden and management of SCD in patients aged ≥2 years.
Methods: Out of a total of 498 recruited patients, 202 aged ≥16 years and for whom patient-reported hospital admission data were available were included in this analysis. Negative binomial regression (adjusted for age, sex, and SCD genotype) was used to examine the association of selected baseline characteristics (ie body mass index, hemoglobin, ferritin, transaminases, and any history [received in the preceding 12 months] of opioids, hydroxyurea, transfusion, and H-VOC) with the frequency and length of stay of H-VOC in SCD patients.
Results: Overall, 71% of patients had a HbSS genotype, 98% were Black or African American and 51% were female. The median age of the cohort was 31 years (interquartile range [IQR] 22–41). At baseline, 36% of patients had received opioids, 14% had received hydroxyurea and 51% had received transfusions in the previous 12 months, comprising 30% who had received 1–5 transfusions and 21% who had received ≥6 transfusions. During the 3-year follow-up period, 55% of patients experienced at least one H-VOC with a median length of stay of 16 (IQR 6–45) days. History of H-VOC was significantly associated with a higher rate of subsequent H-VOC (incidence rate ratio [IRR] 4.32, 95% confidence interval [CI] 2.86 to 6.61, *P*<0.001) and a longer stay (IRR 5.37, 95% CI 3.00 to 9.77, *P*<0.001; Table). Transfusion history was also significantly associated with a higher rate of subsequent H-VOC (IRR 1.58, 95% CI 1.05 to 2.38, *P*=0.030) and a longer stay (IRR 3.79, 95% CI 2.03 to 7.06, *P*<0.001; Table). However, further analysis to investigate the effect of transfusion frequency (ie chronic versus rescue transfusions) is needed. Secondary analysis, including hospitalized patients only (n=112), found a HbSC or HbSβ-thalassemia genotype, a body mass index of <18.5 kg/m^2 (ie underweight), a higher aspartate aminotransferase level and transfusion history were associated with a longer stay. Older age, males, and history of opioid use were associated with a shorter stay (Table).

Table: Selected baseline factors assessed for association with rate and duration of H-VOC

Factors	Multivariable analysis* IRR (95% CI)	Stepwise regression† IRR (95% CI)	*P* value
H-VOC rate (n=202)			
Age (per 1-year increase)	1.00 (0.98 to 1.02)	1.00 (0.98 to 1.01)	0.760
Sex (male)	1.22 (0.79 to 1.90)	1.04 (0.69 to 1.55)	0.864
Genotype (HbSC or HbSβ-thalassemia)‡	0.90 (0.56 to 1.46)	1.18 (0.75 to 1.85)	0.478
History of H-VOC (in preceding 12 months)	4.56 (3.03 to 6.97)	4.32 (2.86 to 6.61)	<0.001
History of blood transfusion (in preceding 12 months)	1.88 (1.22 to 2.93)	1.58 (1.05 to 2.38)	0.030
H-VOC duration (n=202)			
Age (per 1-year increase)	0.99 (0.97 to 1.02)	1.00 (0.97 to 1.02)	0.731
Sex (male)	1.56 (0.82 to 2.99)	1.27 (0.70 to 2.28)	0.411
Genotype (HbSC or HbSβ-thalassemia)‡	0.62 (0.32 to 1.30)	1.55 (0.83 to 3.01)	0.165
History of H-VOC (in preceding 12 months)	6.16 (3.12 to 12.71)	5.37 (3.00 to 9.77)	<0.001
History of blood transfusion (in preceding 12 months)	5.41 (2.92 to 9.98)	3.79 (2.03 to 7.06)	<0.001
Initial H-VOC duration, hospitalized patients only (n=112)			
Age (per 1-year increase)	0.99 (0.97 to 1.00)	0.98 (0.97 to 0.99)	0.008
Sex (male)	0.80 (0.56 to 1.16)	0.69 (0.49 to 0.97)	0.030
Genotype (HbSC or HbSβ-thalassemia)‡	1.55 (1.04 to 2.34)	1.72 (1.18 to 2.51)	0.006
BMI (<18.5 kg/m^2)	3.27 (1.65 to 7.22)	2.46 (1.29 to 5.06)	0.013
AST (per 1-unit increase)	1.01 (1.00 to 1.01)	1.01 1.00 to 1.01)	0.011
History of opioids (in preceding 12 months)	0.60 (0.43 to 0.84)	0.73 (0.53 to 1.00)	0.045
History of blood transfusion (in preceding 12 months)	2.24 (1.60 to 3.14)	1.95 (1.39 to 2.73)	<0.001

*Adjusted for age, sex and genotype.
†Only factors significantly associated with rate or duration of H-VOC in the multivariable analysis were included in the stepwise regression.
‡Versus HbSS.
AST, aspartate aminotransferase; BMI, body mass index; CI, confidence interval; H-VOC, hospitalization related to vaso-occlusive crisis; IRR, incidence rate ratio; NA, not applicable.

Summary/Conclusion: Our results demonstrate that history of H-VOC within the preceding 12 months was significantly associated with a higher rate of subsequent H-VOC and increased length of stay in our cohort, independently of age, sex and genotype. Our data have limited statistical power and generalizability. Therefore, future studies in larger cohorts and/or different geographical populations are needed. However, in combination with the widely accepted impact that VOCs have on morbidity and mortality, these findings further support the need to reduce/prevent VOCs in SCD patients.

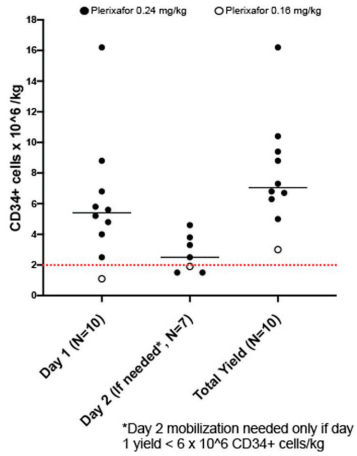
Stem cell transplantation - Clinical

EP1223 ALLOGENEIC HEMATOPOIETIC STEM CELL TRANSPLANTATION FOR REFRACTORY/RELAPSED T-CELL ACUTE LYMPHOBLASTIC LEUKEMIA/LYMPHOMA AFTER ALLOGENEIC CD7-CART CELL THERAPY

Z. Li [1,*], J. Pan [2], X. Wen [1], J. Li [1], X. Peng [1], Y. Song [1], T. Wu [1]

[1]Department of Bone Marrow Transplantation, [2]Department of Hematology, BEIJING BOREN HOSPITAL, Beijing, China

Background: The prognosis of refractory/relapsed T-cell acute lymphoblastic leukemia/lymphoma (T-ALL/T-LBL) was extremely poor. In our previous clinical study (unpublished data), more than 90% complete remission (CR) has been obtained with allogeneic CD7-CART therapy in refractory/relapsed T-ALL/T-LBL, but hematopoiesis reconstitution is crucial for long-term disease-free survival (DFS) in this setting.
Aims: A clinical trial was designed to examine the safety and efficacy of allogeneic hematopoietic stem cell transplantation (allo-HSCT) after allogeneic CD7-CART for refractory/relapsed T-ALL/T-LBL.
Methods: From October 2020 to January 2021, 7 patients with refractory/relapsed T-ALL/T-LBL (refractory in 1, relapsed in 6; with extramedullary disease (EMD) in 4) after allogeneic CD7-CART therapy followed by allo-HSCT from the same donor were enrolled. The median age was 12 (3-44) years old. The median blasts in bone marrow (BM) were 35 (15-90) % before CD7-CART. Before allo-HSCT, minimal residual disease (MRD) in BM and cerebrospinal fluid was negative in all cases, and EMDs were detectable in 3 patients but with much smaller sizes. Pancytopenia was seen in all cases before HSCT. The median time from CART cell infusion to allo-HSCT was 32 (29-36) days. The types of HSCT were haploidentical in 5 cases and identical sibling in 2 cases. Conditioning regimens were busulfan/fludarabine-based (6 cases) or TBI/fludarabine-based (1 case). ATG (rabbit anti-human T-lymphocyte immunoglobulin 10mg/kg in 4, rabbit anti-human Thymocyte globulin 6mg/kg in 1) was applied in haploidentical transplants. Cyclosporine, MMF and short-term MTX were employed for GVHD prophylaxis. Chimerism was analyzed by STR. MRD was detected by flow cytometry (FCM) and PCR, and EMD was evaluated by PET-CT. CART cells were monitored by FCM and PCR.
Results: Before HSCT, all patients were with mixed chimerism. The median percentage of chimerism in BM and peripheral blood were 58.05 (1.57-73.42) %, 92.34 (35.11-98) %, respectively. The median time of neutrophil engraftment was 19 (12-21) days. The median time of platelet engraftment was 21 (6-100) days. At one month post-transplant, all patients achieved MRD^- CR without EMD, and full donor chimerism in $CD3^+$ lymphocytes and BM was detected in all cases. Acute graft-versus-host disease (aGVHD) was mild with only grade I in 2 patients, and no chronic GVHD was noted. Bacterial infections occurred in some patients (perianal infection in 1, sepsis in 1, intestinal infections in 3). Four cases developed CMV viremia and 1 patient had CMV retinitis. Hemorrhagic cystitis occurred in 2 patients. One case had post-transplant lymphoproliferative disease and resolved with rituximab and chemotherapy. One patient died from multi-organ failure on days 14 after HSCT. With the median follow-up 61 (25-151) days, no recurrence was found, 6/7 cases have been survived free of diseases. The median time of CART cell detectable was 39 (28-60) days post-HSCT. The median CART cell percentage was 0.52 (0.17-3.62) %.
Summary/Conclusion: With our protocol, hematopoiesis reconstitution has been achieved in all patients. Allogeneic CD7-CART combined with allo-HSCT has shown powerful anti-T-ALL/T-LBL effects and good safety profile. The existence of CD7-CART early after transplant had no influence on engraftment and may contribute to prolonged anti-tumor effect. Infections are main complications in this setting, therefore, appropriate dosages of immunosuppressants and the timing bridge to allo-HSCT need to be further investigated. This trial is still ongoing.



EP1224 PHASE 2 STUDY OF MGTA-145 + PLERIXAFOR FOR RAPID AND RELIABLE HEMATOPOIETIC STEM CELL (HSC) MOBILIZATION FOR AUTOLOGOUS STEM CELL TRANSPLANT IN MULTIPLE MYELOMA

S. Sidana [1,*], A. Bankova [1], H. Hosoya [1], L. Muffly [1], S. Kumar [2], L. Johnston [1], R. Lowsky [1], E. Meyer [1], A. Rezvani [1], W.-K. Weng [1], S. Arai [1], M. Frank [1], P. Shiraz [1], H. Howell [3], K. Goncalves [3], V. Schmelmer [3], J. Davis [3], J. Shizuru [1], D. Miklos [1]

[1]Division of BMT and Cell Therapy, Stanford University, Stanford, [2]Division of Hematology, Mayo Clinic, Rochester, [3]Magenta Therapeutics, Boston, United States

Background: MGTA-145 (GroβT), a CXCR2 agonist, has shown promising activity for HSC mobilization with plerixafor in pre-clinical models & healthy volunteers. It has the potential to become a GCSF free regimen for reliable, same day stem cell mobilization/apheresis in preparation for transplant, with fewer side effects, better patient experience and optimal resource utilization.
Aims: This phase 2 single center study evaluates HSC mobilization with MGTA-145 + plerixafor and same day apheresis in patients with multiple myeloma (NCT04552743). Primary endpoint is collection of 2 x 10^6 CD34+ cells/kg in 2 days of mobilization/apheresis. Secondary endpoints are collection of 4 and 6 x 10^6 CD34+ cells/kg and engraftment after transplant.
Methods: Patients with myeloma 18-70 years of age, within 1 year of treatment start and creatinine clearance ≥ 30 ml/min were eligible. Patients received plerixafor 0.24 mg/kg (0.16 mg/kg if renal dysfunction) SQ, followed 2 hours later by MGTA-145 (0.03 mg/kg) IV over 3-10 minutes and apheresis within 30 minutes. Mobilization was repeated for a second day if day 1 yield was < 6 x 10^6 CD34+ cells/kg. This interim analysis reports on mobilization in 10 patients (of 25 planned), including safety cohort of first 6 patients completing transplant.
Results: Median age was 63 years (range: 46-68), 50% were female, 22% had ISS stage 3 & 50% had high-risk FISH. Induction therapy was VRD in 7 and daratumumab + VRD in 3 patients; median induction duration: 4 months (3-6) & median lenalidomide exposure: 6 cycles (4-6), with ≥ VGPR in 70%.
Plerixafor 0.24 mg/kg was used in 9 patients and 0.16 mg/kg in 1 (renal dosing). Median total stem cell yield (CD34+ cells/kg x 10^6) was 7.1 (3-16.2), day 1 yield was 5.4 (1.1-16.2) & yield per apheresis session was 4 (1.1-16.2) **(Fig).** 100% patients met the primary endpoint of collecting sufficient HSCs in ≤ 2 days of mobilization + apheresis to proceed to transplant, 90% in 1 day (2 x 10^6 CD34+ cells/kg). Secondary endpoints of 4 and 6 x 10^6 CD34+ cells/kg in ≤ 2 days were met in 90% & 80% patients. Overall, 30% patients underwent 1 apheresis, while 70% underwent 2 sessions (if day 1 yield < 6x10^6 CD34+ cells/kg).
MGTA-145 was well tolerated. At least 1 adverse event (AE) was seen in 90% of patients, 20% had grade 2 AEs (anemia, hypokalemia) and 20% had grade 3 AEs (worsening of baseline grade 3 anemia; hypocalcemia); all resolved. Acute & transient bone pain was seen in 40% of patients (back-2, hip-1, sternum-1), all grade 1, all on day 1, & resolved without intervention after 6 minutes (3-10).
All 6 patients in the safety cohort have completed transplant with melphalan 200 mg/m^2. Median of 4.1 (3.4-5.6) x 10^6 CD34+ cells/kg were infused. All patients have engrafted timely (DiPersio Blood 2009); median time to neutrophil engraftment: 12 days (11-13) & platelet engraftment: 17 days (16-19). Apheresis graft analysis is available in these 6 patients. Grafts with MGTA-145+plerixafor showed high enrichment for CD90+CD45RA- among CD34+ cells, a CD34 subset of long term engrafting HSCs (median: 31% of CD34+ cells, 27-52), higher than seen with G-CSF (6%, Goncalves TCT 2021). 67% of grafts were minimal residual disease negative with next generation flow cytometry.

Figure: Stem Cell Yields with Same Day MGTA-145 and Plerixafor Mobilization in Multiple Myeloma

Summary/Conclusion:
This is the first study to evaluate the novel regimen of MGTA-145 + plerixafor for same day stem cell mobilization & collection in myeloma/hematologic malignancies, with 100% efficacy in interim analysis and the first to demonstrate successful engraftment in patients with cells collected with this GCSF free regimen.

EP1225 FIRST-IN-HUMAN CLINICAL TRIALOF BCMA-CD19 COMPOUND CAR IN THE REDUCTION OF DONOR-SPECIFIC ANTIBODY IN HAPLOIDENTICAL HEMATOPOIETIC STEM CELL TRANSPLANTATION

F. Liu [1,*], X. Wang [1], G. He [1], Y. Xiong [1], Y. Cao [2], Y. Ma [3], M. Wada [2], Y. Su [1], Y. Ma [2]

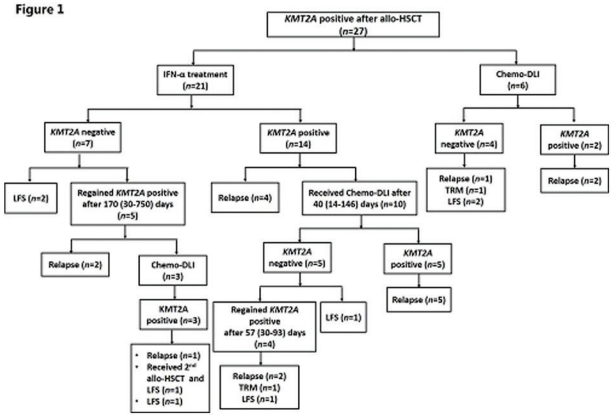
[1]Hematology, The General Hospital of Western Theater Command, Chengdu, China, [2]Research & Development Division, iCell Gene Therapeutics LLC, Stony Brook, NY, United States, [3] Manufactory Division, iCAR Bio Therapeutics Ltd, Zhongshan, China

Background: Donor-specific anti-HLA antibodies (DSAs) are antibodies in the recipient directed against donor class I/II HLA antigens. The existence of DSAs before HLA mismatched allogenic hematopoietic stem cell transplantation (allo-HCT) are known to cause primary graft failure. Currently, there is no established method of desensitization for DSAs due to the long half-life of plasma cells.
Aims: To evaluate the toxicity and efficacy of the BCMA-CD19 cCAR in the reduction of Donor-Specific Antibody (DSA) in haploidentical hematopoietic stem cell transplantation(haplo-HCT).
Methods: We have generated a BCMA-CD19 cCAR bearing 2 complete CAR constructs connected by a cleavable linker, P2A. CAR T cells were manufactured in a cGMP facility. The in vitro and in vivo activity of the cCAR were detected by co-culture assays and in mouse model studies. Between May 2019 and Sep 2020, 4 haploidentical HCT candidates with high titers of DSA were enrolled. All patients received conditioning (fludarabine 30 mg/m^2/d and cyclophosphamide 300 mg/m^2/d for 3 days). CAR-T cells were given by a dose escalation at 2~4.5×10^6/kg with a single dose. Study endpoints include the safety of the CAR, the reduction of DSA and engraftment after haplo-HCT.
Results: In co-culture assays, BCMA-CD19 CAR-T cells exhibited robust cytotoxic activity against the K562 cells engineered to express either CD19 or BCMA. In mouse model studies, cCAR-T cells were able to eliminate tumor in mice injected with MM.1S cells and REH cells, indicating the ability of the cCAR to specifically lyse both BCMA and CD19 expressing target cells in vitro and in vivo.
Of the 4 patients who have received CAR-T cell infusion, 1 was acute lymphoblastic leukemia(ALL), 2 were acute myeloid leukemia(AML), 1 was aplastic anemia-paroxysmal nocturnal hemoglobinuria (AA-PNH) syndrome. The age was from 21 to 48 years old, all patients had high DSA levels (MFI >5,000). CAR-T dose were from 2-4.5×10^6/kg.
Cytokine release syndrome (CRS) occurred in 3 patients (1 grade I, 2 grade II). No Neurotoxicity and other severe organ toxicity occurred in all the patients.
Bone marrow B cells and plasma cells were depleted at 4 weeks post CAR-T therapy in all patients. DSA dropped to low levels (MFI <5,000) for all patients, of them, plasma exchange was combined in 2 patients due to the emergency of HCT. The reduction percent ranged from 62.3% to 100%. All patients received a haplo-HCT 49-135 days post CAR-T therapy, and were successfully engrafted with a persistent full chimerism. (Figure 1)

	Age/sex Dx	CAR-T Dose (x10^6/kg)	B/plasma cells% in BM at 4 weeks	Days of HSCT	MFI of DSA before CAR	MFI of DSA before HCT	Combined methods
P1	48/F B-ALL	2	0/0	102	7820	1573	No
P2	21/F AA/PNH	2.7	0/0	135	12492/ 9663	0	No
P3	35/F AML	4.5	0/0	49	11547/ 11477	4343/ 2310	PE×3
P4	34/F AML	2	0/0	90	19180	3756	PE×1

	DSA reduction % before HCT	Donor HLA compatibility	Neutrophil engraftment	Platelet engraftment	Donor chimerism	Months post HCT	Status
P1	79.8%	6/12	d11	d10	full	17	alive
P2	100%	6/12	d16	d23	full	5	alive
P3	62.3%/ 79.8%	8/12	d12	d13	full	7	alive
P4	80.4%	6/12	d10	d11	full	1	alive

Summary/Conclusion: Our first in human clinical trial on BCMA-CD19 cCAR demonstrated profound efficacy in reducing DSA levels in an allo-HCT candidate. There was strong clinical evidence of depletion of antibody-producing roots, B-cells and plasma cells in the patients. Our results further suggested that BCMA-CD19 cCAR has the potential to benefit patients receiving solid organ transplants or those with other antibody-mediated diseases.



EP1226 MINIMAL RESIDUAL DISEASE MONITORING AND PREEMPTIVE IMMUNOTHERAPIES FOR FREQUENT 11Q23 REARRANGED ACUTE LEUKEMIA AFTER ALLOGENEIC HEMATOPOIETIC STEM CELL TRANSPLANTATION

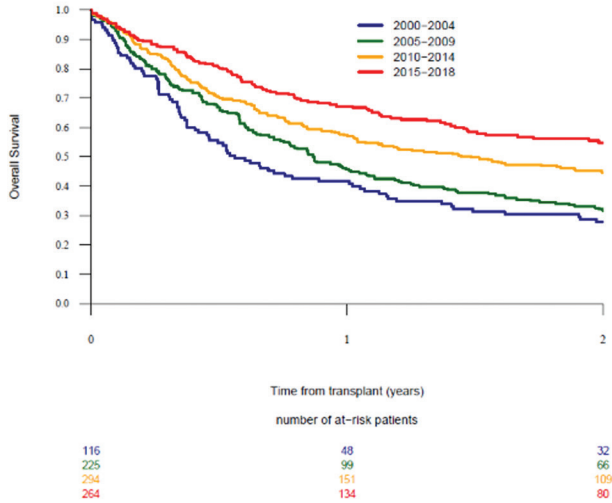
J. Liu [1,*], X.-H. Zhang [1], L.-P. Xu [1], Y. Wang [1], C.-H. Yan [1], H. Chen [1], Y.-H. Chen [1], W. Han [1], F.-R. Wang [1], J.-Z. Wang [1], Y.-F. Cheng [1], Y.-Z. Qin [1], K.-Y. Liu [1], X.-J. Huang [1], X.-S. Zhao [1], X.-D. Mo [1]

[1]Peking University Institute of Hematology, Peking University People's Hospital, Beijing, China

Background: The prognosis of *11q23/KMT2A* rearranged (*KMT2A*-r) acute leukemia (AL) after allogeneic hematopoietic stem cell transplantation (allo-HSCT) was poor. Minimal residual disease (MRD) was an important prognostic factor for relapse.MRD directed preemptive immunotherapy was effective to prevent relapse after allo-HSCT in AL. However, no study had identified the efficacy of these methods in a disease-specific population of patients with *KMT2A*-r AL, and whether commonly used preemptive immunotherapies could clear the MRD in these patients was unknown.
Aims: We aimed to identify the evolution of *KMT2A* before and after allo-HSCT and the efficacy of preemptive immunotherapies for *KMT2A*-r AL patients receiving allo-HSCT.
Methods: *KMT2A* expression was determined through TaqMan-based RQ-PCR technology. Preemptive immunotherapies included interferon-α and donor lymphocyte infusion. We collected 1751 bone marrow samples from 177 consecutive *KMT2A*-r AL patients.The SPSS 23 and the R software package were used for data analyses.
Results: Pre-HSCT *KMT2A* positive was correlated with post-HSCT *KMT2A* positive (correlation coefficient=0.371, P<0.001). The rates of *KMT2A* achieving negative after allo-HSCT were 96.6%, 92.9%, and 68.8% in the pre-HSCT low (>0, <0.1%)-, intermediate (≥ 0.1%, <1%)-, and high-level (≥1%) groups, respectively. The rates of regaining *KMT2A* positive after allo-HSCT were 7.7%, 35.7%, 38.5%, and 45.5%, respectively, for pre-HSCT *KMT2A* negative, low-, intermediate-, and high-level groups (P<0.001). The 4-year cumulative incidence of relapse after allo-HSCT was as high as 53.7% in pre-HSCT *KMT2A* expression ≥ 0.1% group, which was comparable between the *KMT2A* negative (15.1%) and *KMT2A* <0.1% group (31.2%). The clinical outcomes of patients with post-HSCT *KMT2A* positive were poorer than those with persistent *KMT2A* negative.
Thirty patients showed *KMT2A* positive after allo-HSCT, and the detail of *KMT2A*-directed immunotherapies were showed in Figure 1. In total, 27 KMT2A patients (25 AML and 2 ALL) received preemptive immunotherapies. Twenty-one patients received preemptive IFN-α treatment. Seven patients (33.3%) achieved *KMT2A* negative; however, 5 of them regained *KMT2A* positive, and only 2 patients (9.5%) achieved persistent LFS after IFN-α treatment. Nineteen patients received preemptive Chemo-DLI. Nine patients (47.4%) achieved *KMT2A* negative. In addition, only the patients with very low-level *KMT2A* gene expression might benefit from this treatment (rate of *KMT2A* achieving negative: *KMT2A* <0.01% vs. ≥ 0.01% before IFN-α treatment, 75.0% vs. 23.5%, P=0.088). Thirteen patients (68.4%) experienced relapsed and 5 patients (26.3%) achieved persistent LFS. The level of *KMT2A* gene expression before Chemo-DLI did not influence the rate of *KMT2A* achieving negative (<0.1% vs. ≥ 0.1% before Chemo-DLI, 75.0% vs. 46.2%, P=0.576).

Figure 1

Summary/Conclusion: Pre-HSCT *KMT2A* positive were significantly associated with post-HSCT *KMT2A* positive. The clinical outcomes of patients with post-HSCT *KMT2A* positive was poor. Although post-HSCT preemptive immunotherapies might help to achieve *KMT2A* negative, the long-term efficacy was unsatisfactory.



EP1228 SURVIVAL TRENDS OF ADULT PATIENTS WITH RELAPSED PHILADELPHIA POSITIVE ACUTE LYMPHOBLASTIC LEUKEMIA POST ALLOGENEIC HEMATOPOIETIC CELL TRANSPLANTATION OVER 20 YEARS: AN ALWP-EBMT ANALYSIS

A. Bazarbachi [1,†,*], M. Labopin [2], M. Aljurf [3], R. Niittyvuopio [4], H. Labussière-Wallet [5], D. Blaise [6], I. Yakoub-Agha [7], A. Grassi [8], C. Reinhardt [9], S. Lenhoff [10], P. Background: Allogeneic hematopoietic cell transplantation (allo-HCT) in patients with Philadelphia positive (Ph+) acute lymphoblastic leukemia (ALL) in first complete remission (CR1) has improved survival outcomes, even after the advent of tyrosine kinase inhibitors (TKI). However, relapses post allo-HCT still occur in up to 30% of transplanted patients, and pose a real challenge. While historically, available treatment options involved reduction/withdrawal of immunosuppression, cytotoxic chemotherapy, donor lymphocyte infusion, and a second allo-HCT, currently there is an increased use of newer generation TKI, monoclonal antibodies such blinatumomab and inotuzumab, as well as CAR T cell therapy.
Aims: The aim of this study was to assess the impact of the post-transplant relapse therapeutic evolution on survival outcomes over the years.
Methods: We selected all adult patients from the EBMT database with a diagnosis of Ph+ ALL who had morphologic relapse between 2000 and 2019 after allo-HCT performed in CR1, regardless of type of conditioning, donor type, stem cell source and prior TKI treatment. We analyzed survival outcomes using the Kaplan Meier method, and predictive factors by univariate and multivariate analysis. Median follow up for alive patients was 56 months.
Results: We identified 899 patients with a median age at transplant and at relapse of 44 and 45.4 years, respectively. Overall, 116 patients relapsed between 2000-2004, 225 between 2005-2009, 294 between 2010-2014, and 264 between 2015-2019. Patient and transplant characteristics were similar over the 4 time periods except for a progressive increase in the use of matched unrelated donor (from 34.5% between 2000-2004 to 55.7% between 2015-2019; p=0.0002), peripheral blood stem cells (from 60.3% to 84.5%; p<0.0001), reduced intensity conditioning (RIC) (from 16.4% to 34.5%; p=0.004), and *in vivo* T cell depletion (TCD) (from 27.9% to 62.4%; p=0.0001) as well as a progressive decrease in the use of total body irradiation (TBI) (from 73.3% to 53%; p=0.0002), respectively. The 2-year overall survival (OS) after relapse was 41.5 % (95% CI: 38 - 44.9). Original disease was the cause of death in 68.5% of patients. Importantly, the 2-year OS after relapse increased from 27.8% for patients relapsing between 2000-2004 to 31.7% for 2005-2009, 44.5% for 2010-2014 and 54.8% for 2015-2019 (p=0.001) (Figure 1). A second allo-HCT within 2 years after relapse was performed in 13.9% of patients resulting in a 2-year OS of 35.9%. The incidence of second allo-HCT was 21.7%, 12.8%, 9.9% and 15.7% for the same time periods (p=0.027). In multivariate analysis, factors that influenced positively the OS were a longer time from transplant to relapse (>median:7.1 months; hazard ratio [HR] 0.71, p=0.0007) and the year of relapse (reference 2000-2004; HR 0.68, p<0.013 for patients relapsing from 2005-2009; HR 0.72; p<0.008 for patients relapsing from 2010-2014, and HR=0.72; p=0.016 for patients relapsing from 2015-2019). Other patient, donor and transplant characteristics had no significant effect on outcomes.

OS after relapse – Ph–pos B ALL

Summary/Conclusion: We observe a major progressive improvement in OS from post-transplant relapse for patients with Ph+ ALL, likely reflecting the efficacy of post-transplant therapeutic strategies. This large-scale real-world data can serve as a reference for future studies investigating novel agents in this setting.

EP1229 COMPARISON OF OUTCOMES OF SINGLE CORD BLOOD TRANSPLANTATION AND HLA 1-3 ANTIGEN-MISMATCHED RELATED STEM CELL TRANSPLANTATION USING LOW-DOSE ANTITHYMOCYTE GLOBULIN FOR HEMATOLOGICAL MALIGNANCIES

Background: Cord blood transplantation (CBT) and HLA-mismatched transplantation has become established alternative stem cell sources for patients with hematological malignancies. HLA-mismatched transplantation with post-transplant cyclophosphamide has spread rapidly and demonstrated favorable outcomes. Likewise, several studies indicated the potential of HLA-haploidentical transplantation with low-dose antithymocyte globulin, especially for high-risk diseases. On the other hand, significant progress in the management of CBT has led to comparable outcomes of HLA-matched and mismatched unrelated transplantation, showing better outcomes for patients with minimal residual disease.
Aims: To compare the outcomes of CBT and HLA-mismatched transplantation using low-dose ATG, we performed a retrospective study using data from the Japanese registry.
Methods: A total of 7899 patients aged 0-70 years with hematological malignancies who received their first allogeneic hematopoietic cell transplantation between 2009-2018 were eligible. A total of 7034 and 865 patients who underwent single CBT and HLA 1-3 antigen-mismatched related stem cell transplantation using ATG (mismatched-ATG) were included. The primary endpoint was overall survival (OS) and secondary endpoints were relapse-free survival (RFS), GVHD-relapse-free survival (GRFS), non-relapse mortality (NRM), relapse, neutrophil engraftment, platelet engraftment, grade II-IV acute GVHD, grade III-IV acute GVHD, chronic GVHD and extensive chronic GVHD.
Results: The median age in the CBT and mismatched-ATG groups were 53 and 47 years, respectively (p<0.001). High risk diseases and reduced-intensity condition were more frequent in the mismatched-ATG group (43.4% vs 66.1% and 36.6% vs 66.2%). In the mismatched-ATG group, the most common combination of GVHD prophylaxis was ATG plus cyclosporine A (CsA) or tacrolimus (TAC), and steroid (66.6%), whereas it was CsA or TAC plus methotrexate (MTX) in the CBT group (66.5%). In the mismatched-ATG group, 1 antigen mismatched transplant was included (16.5%) and median total dose of ATG was 2.5 (0.42-10.0) mg/kg. Median follow-up time in survivors was 3.3 and 3.4 years in the CBT and mismatched-ATG groups, respectively. OS after CBT was significantly higher than that of mismatched-ATG (3-year OS: 47.2%, 32.4%, P<0.001 and adjusted hazard ratio (aHR) 0.76, P<0.001). RFS and GRFS of CBT were also higher than mismatched-ATG (aHR 0.79, p<0.001 and aHR 0.70, p<0.001). Neutrophil and platelet engraftment were significantly lower (85% vs 94.8% and 60.2% vs 65.2%), whereas the incidence of grade III to IV acute GVHD and extensive chronic GVHD was significantly lower in the CBT group (aHR 0.44, p<0.001 and aHR 0.62, p<0.001). In the subgroup analysis, superiority of CBT to mismatched-ATG was observed in each disease group (AML: aHR 0.87, 95% confidence interval (CI) 0.75-1.00, ALL: aHR 0.70, 95% CI 0.55-0.89, MDS: aHR 0.79, 95%CI 0.52-1.19, and lymphoma: aHR 0.64, 95%CI 0.52-0.79). Favorable OS of CBT was confirmed regardless the disease risk (standard risk: aHR 0.63, 95%CI 0.53-0.75, high risk: aHR 0.83, 95%CI 0.73-0.93) and HLA mismatch (0-1: aHR 0.85, 95%CI 0.67-1.08, 2-3: aHR 0.74, 95%CI 0.67-0.83).
Summary/Conclusion: We observed favorable outcomes of CBT compared to mismatched-ATG, consistently the same according to the patient generations, disease, and disease risk. CBT may be the better choice alternative to HLA mismatched related transplant using low-dose ATG.

EP1230 OUTCOMES FOLLOWING UNMANIPULATED HAPLOIDENTICAL HEMATOPOIETIC STEM CELL TRANSPLANTATION AMONG 111 MIXED-PHENOTYPE ACUTE LEUKEMIA PATIENTS AT A SINGLE CENTER

Y.-L. Zhao [1,*], X.-Y. Cao [1], R.-J. Sun [1], D.-Y. Liu [1], J.-R. Zhou [1], Y. Lu [1], M. Xiong [1], Z.-J. Wei [1], J.-P. Zhang [1], H. Wang [2], P.-H. Lu [3], D.-P. Lu [1]

[1]Bone Marrow Transplantation, [2]Hematopathology, [3]Hematology and Immunology, Hebei Yanda Ludaopei Hospital, Langfang, China

Background: Mixed phenotype acute leukemia (MPAL) is rare and generally associated with a poor prognosis. Optimal treatment for patients with MPAL and the role of allogeneic hematopoietic stem cell transplant (allo-SCT) remain unclear. Most prior case series included only modest numbers of transplanted patients, among which haploidentical transplant (haplo-SCT) were rarely included.
Aims: We tried to evaluate the safety and efficacy of haplo-SCT for MPAL patients and attempted to define factors that confer high-risk disease.
Methods: We retrospectively analyzed clinical results among MPAL diagnosed patients, defined by the 2017 World Health Organization (WHO) criteria. All patients included underwent a transplant at the Lu Daopei Hospital between July 2012 and December 2020. The latest follow-up date was December 2020.
Results: MPAL accounted for 3.1% (131 out of 4212) of all acute leukemias. Our analysis included the 111 MPAL patients who underwent unmanipulated haplo-HSCT with antithymocyte globulin [AA1] (ATG). Median age at transplant was 15 years (range: 1- 60 years of age). Patients had one of three immunophenotypes: 61 patients had leukemia with B/myeloid marker, 65 with T/myeloid marker, and 5 had B/T/myeloid markers. Fifteen patients harbored a BCR-ABL1 rearrangement and five had KMT2A-rearranged MPAL. Seventy-nine patients were in first complete remission (CR1), 31 in CR2 and 23 were in none remission (NR). Myeloablative regimens were used in all patients, among which 80 cases were body irradiation-based (TBI, 2Gy×5~6) and 41 busulfan-based (3.2 mg/kg/day×4). Cyclosporine, short-term methotrexate, and mycophenolate mofetil were used for graft versus host disease (GVHD) prophylaxis. Median total mononuclear cell count (MNC) and the infused CD34+ cell count was 9.0 $\times10^8$/kg (range: 3.94-19.13 $\times10^8$/kg) and 4.72 $\times10^6$/kg (range: 1.27-12.57$\times10^6$/kg). Except for two patients transplanted in advanced status both of whom died of sepsis on Day 2, all patients received neutrophil engraftment at a median 14 days (range: 9-34 days) post-transplant[AA2]. One hundred and four patients achieved platelet engraftment at a median 13 days post-transplant (6-73 days). Up to the latest follow-up date, the median survival time was 34 months (range: 1 - 93 months). The 3-year relapse rate was 12.1% (95% CI 5.4%>18.8%) and the 3-year non-relapse mortality (NRM) rate was 20.7%
(95% CI 12.7-28.7%). The 3-year overall survival (OS) and 3-year leukemia-free survival (LFS) were 69.5% (95% CI 60.5-78.5%) and 69.6% (95% CI 60.8-78.4%), respectively. The 3-year LFS of patients in CR1 and ≥CR2 and those with advanced disease were 75.4% (95% CI 64.2-86.6%), 70.1% (95% CI 52.7-87.5%), and 52.5% (95% CI 31.1-73.9%), respectively (CR1vs.≥CR2 p=0.416; CR1 vs. advanced disease p=0.024; CR2 vs. advanced disease p=0.213). There were no differences in relapse rate, NRM, OS or LFS among patients in the three different immunophenotype groups (B/myeloid vs. T/myeloid), nor by age (<13 years vs. ≥14years), conditioning regimes (TBI-based vs. Bu-based), or date of transplant (2012-2017 vs. 2018-2020). In multivariate analyses, status before transplant was the only predictor of relapse rate (hazard ratio [HR] 2.151; 95% CI, 1.058-4.375; p=0.034), OS (HR 1.598; 95%CI, 1.048-2.435; p=0.033) and LFS (HR 1.574; 95%CI, 1.044-2.375; p=0.031).

Summary/Conclusion: Haplo-SCT is a promising treatment option for patients with MPAL with encouraging low rates of relapse and long-term survival. Patients who undergo transplantation at an earlier stage of disease may have better safety and efficacy outcomes.

EP1231 CURRENT ROLE OF ALLOGENEIC STEM CELL TRANSPLANTATION (ALLO-SCT) IN MANTLE CELL LYMPHOMA (MCL) IN THE ERA OF NEW IMMUNOTHERAPEUTIC AND TARGETED THERAPIES. THE GETH/GELTAMO EXPERIENCE.

[1]Hospital Son Espases, Palma, [2]Hospital Sant Pau, [3]Hospital Clinic, Barcelona, [4]Hospital Gregorio Marañon, Madrid, [5]Hospital Clinico de Valencia, Valencia, [6]Clinica de Navarra, Pamplona, [7]Hospital Morales Meseguer, Murcia, [8]Hospital La Fe, Valencia, [9]Hospital Canruti, [10]Hospital de Bellvitge, Barcelona, [11]Hospital de Córdoba, Córdoba, [12]Hospital La Arrixaca, Murcia, [13]Hospital de Valdecilla, Santander, [14]Hospital Virgen del Rocio, Sevilla, [15]Hospital de Asturias, Oviedo, [16]Hospital Ramon y Cajal, Madrid, [17]Hospital Juan Canalejo, La Coruña, [18]Hospital de Salamanca, Salamanca, Spain

Background: MCL has been associated with poor prognosis, chemorefractoriness and older median age at diagnosis. For transplant-eligible patients, clinical outcome improves using intensive cytarabine-based induction, followed by autologous stem cell transplant (ASCT). Recently, new approaches with anti-CD20 maintenance, new target drugs or new ways of immunotherapy such as CARTs are changing the therapeutic landscape. Allo-SCT is a curative option for selected patients but with significant non-relapse mortality (NRM).
Aims: Our objective was to analyze long-term results in patients receiving allo-SCT in Spain.
Methods: We performed a retrospective multicenter study including patients from centers of GETH/GELTAMO with relapsed/refractory (R/R) MCL treated with allo-SCT from March 1995 to February 2020. The primary endpoints were event-free survival (EFS), overall survival (OS), NRM and cumulative incidence (CI) of relapse and graft versus host disease (GVHD).
Results: We included one-hundred and thirty-five patients with R/R MCL that fulfilled the inclusion criteria (Table 1). Median age was 56 years (27% >60 years); 49% had previous ASCT and median number of previous lines of therapy were 2 (1-8). Disease status at allo-SCT was complete response (CR) in 64%, partial response (PR) in 26% and stable/progressive disease (SD/PD) in 10%. Most patients (85%) received reduced intensity conditioning (RIC). After a median follow-up of 68 months (2-247), 5-year EFS and OS were 47% and 50%. NRM at day 100 and 5 years were 20% and 44%, respectively. Overall and CR rates on day 100 were 86% and 80%, respectively. The main causes of death were secondary to NRM: 32% GVHD, 32% infection, 3% veno-oclussive disease (VOD), 3% thrombotic microangiopathy and 15% others. Progression was the cause of death in only 14%. CI of relapse at 1 and 5 years were 9% and 16%, respectively. CI of grade 3-4 acute GVHD (aGVHD) at day 100 and moderate/severe chronic GVHD at 5 years were 29% and 42%, respectively. In the multivariate analysis we found the following independent factors: ECOG PS > 1 (HR 3.2; p=0.017) and donor mismatch (HR 2.2; p=0.007) for EFS; ECOG PS>1 (HR 3.1; p=0.018) and previous ASCT (HR 2.1; p=0.004) for OS; and grade 3-4 aGVHD (RR 7.1; p<0.001) for NRM.

Table 1. Characteristics of patients

Median age at allo-SCT (range)	56 (32-70)
Donor type:	
- HLA-id sibling	74 (55%)
- Matched unrelated	29 (21%)
- Mismatch unrelated	14 (10%)
- Haploidentical	18 (13%)
Median donor age (range)	46 (19-72)
ECOG at allo-SCT:	
- 0	74 (60%)
- 1	43 (35%)
- 2-4	6 (5%)
HCT-CI:	
- 0-1	70 (56%)
- 2	28 (23%)
- 3 or more	26 (21%)
Status at allo-SCT:	
- CR	86 (64%)
- PR	35 (26%)
- SD/PD	13 (10%)
Conditioning type:	
- Myeloablative	20 (15%)
- Reduced intensity conditioning	115 (85%)
Median months from diagnosis to allo-SCT (range)	33 (3-164)
Previous ibrutinib	19 (14%)
Previous rituximab maintenance	6 (4%)

Summary/Conclusion: Our data confirmed that allo-SCT may be a curative option in R/R MCL with low CI of relapse, although NRM is still high, mainly secondary to aGVHD. Results are better for fit patients, using HLA-identical donor (related or unrelated) and without previous ASCT. However, in the era of new immunotherapy and target drugs, allo-SCT should only be considered in selected patients failing these new approaches.

EP1232 DYNAMIC ASSESSMENT OF PERIPHERAL PERFUSION IN ALLOGENEIC HEMATOPOIETIC CELL TRANSPLANTATION SURVIVORS

E. Gavriilaki [1,*], I. Sakellari [1], P. Anyfanti [2], I. Batsis [1], A. Vardi [1], Z. Bousiou [1], D. Mallouri [1], A. Lazaridis [2], B. Nikolaidou [2], N. Koletsos [2], M. Gavriilaki [2], I. Zarifis [2], M. Masmanidou [1], S. Douma [2], A. Anagnostopoulos [1]

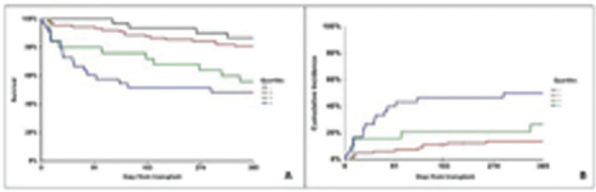
[1]G. Papanicolaou Hospital, [2]Aristotle University of Thessaloniki, Thessaloniki, Greece

Background: Allogeneic hematopoietic cell transplantation (alloHCT) survivors have been recently recognized as patients at increased cardiovascular risk. Although impaired microcirculation dynamics are currently considered an important component of the pathophysiology of CV disease, their role has not been studied in alloHCT.
Aims: We hypothesized that microcirculation dynamics are impaired in alloHCT, independently of traditional cardiovascular risk factors.
Methods: We enrolled consecutive adult alloHCT survivors and otherwise healthy control individuals (January 2019-March 2020), matched for traditional cardiovascular risk factors. Microvascular dysfunction was dynamically assessed by Laser Speckle Contrast Analysis (LASCA); pulse-wave velocity (PWV) and intima media thickness (IMT) were assessed as surrogate markers of cardiovascular disease.
Results: We studied 75 alloHCT survivors after a median of 3.2 (range 2.1-4.9) years from alloHCT, who had suffered from grade 2-3 acute (20%) and/or moderate/severe chronic GVHD (42%), and 75 controls. Although traditional cardiovascular risk factors and surrogate markers of cardiovascular disease did not differ between groups, alloHCT survivors showed significantly impaired microvascular response (Table). Among them, occlusion flux and baseline to occlusion change independently predicted alloHCT status in the multivariate model.
Baseline, occlusion, time to peak, and base to peak change were also significantly impaired in patients with a hypertension diagnosis. Baseline flux was associated with age (r^2=0.191, p=0.020), office DBP (r^2=0.225, p=0.009), and PWV (r^2=0.034, p=0.050). Time to peak had an association with BMI (r^2=-0.189, p=0.034), office systolic BP (r^2=-0.186, p=0.038), heart rate (r^2=-0.375, p<0.001), and PWV (r^2=-0.314, p=0.014). Baseline to occlusion change was associated with office DBP (r^2=0.225, p=0.009), and PWV (r^2=0.335, p=0.001). Baseline to peak change was associated only with office DBP (r^2=-0.299, p=0.009). No significant associations were observed in LASCA indices and studied transplant characteristics.
Taking into account the univariate associations of LASCA indices, we further performed multivariate analyses to determine independent predictors. Only factors with significant univariate associations with the dependent variable were included in the multivariate model. The only independent predictor of baseline flux and baseline to occlusion change was the history of alloHCT (p=0.002 and p=0.022 respectively). Regarding time to peak change, heart rate and history of alloHCT independently predicted time to peak change in the multivariate model (p=0.044 and p=0.037 respectively).

Table . Markers of vascular dysfunction in alloHCT survivors and matched controls

	alloHCT (n=75)	Controls (n=75)	p-value
Surrogate markers of cardiovascular disease			
Pulse-wave velocity (m/s)	5.8 (3.3)	5.9 (1.6)	0.715
Left Carotid IMT (mm)	0.57 (0.18)	0.59 (0.16)	0.694
Right Carotid IMT (mm)	0.55 (0.15)	0.54 (0.12)	0.397
Laser Speckle Contrast Analysis			
Baseline flux (PU)	47.7 (16.0)	42.9 (13.0)	**0.031**
Occlusion flux (PU)	12.4±8.0	3.8±6.1	**<0.001**
Peak flux (PU)	116.1±29.6	114.2±20.8	0.693
Time to peak (sec)	9.3 (6.1)	11.8 (6.0)	**0.004**
Base to peak (%change)	76.8±65.8	130.8±80.4	**<0.001**
Baseline to occlusion (%change)	74.2 (15.6)	70.8 (166.1)	**<0.001**
PORH amplitude	0.75±0.33	0.78±0.24	0.675

alloHCT: allogeneic hematopoietic cell transplantation; IMT: intima media thickness; CVC: Cutaneous Vascular Conductance; PORH: post-occlusive reactive hyperemia. Continuous variables are presented as means±SD or median (interquartile range) according to normality tests.



Summary/Conclusion: Our study shows for the first time impaired indices of dynamic microcirculation assessment in adult alloHCT survivors, as this is reflected by LASCA, independently of traditional CV risk factors. Furthermore, we were able to identify occlusion flux and baseline to occlusion change as the most significant predictors. Lastly, our findings confirm that patients with hypertension are at higher risk of microvascular dysfunction. Additional studies are needed to address the role of novel markers in cardiovascular risk prediction, as well as the effects of disease type, phase, and pre-transplant treatments.

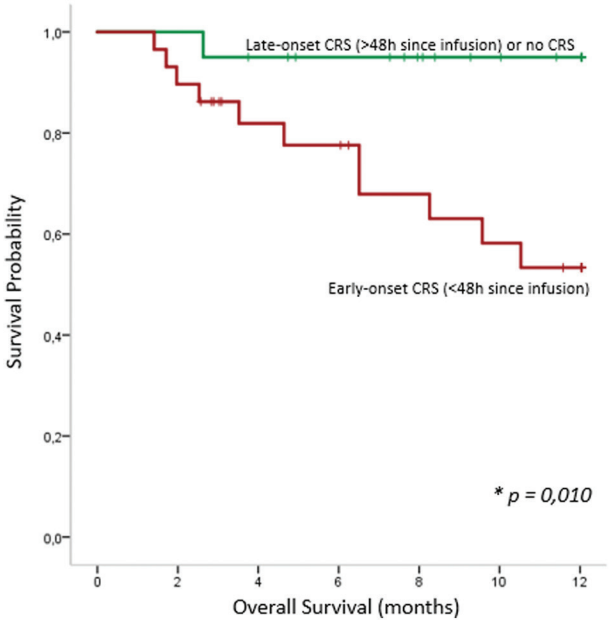
EP1233 DAY 0 EASIX SCORE MIGHT PREDICT OVERALL SURVIVAL AND TRANSPLANT RELATED MORTALITY AFTER ALLOGENEIC STEM CELL TRANSPLANTATION: SINGLE CENTRE EXPERIENCE.

E. Metafuni [1,*], S. Giammarco [1], S. Bellesi [1], F. Sorà [1], L. Laurenti [1], A. Bacigalupo [1], S. Sica [1], P. Chiusolo [1]

[1]Hematology Department, Fondazione policlinico Universitario Agostino gemelli-IRCCS, Rome, Italy

Background: Recently, Endothelial Activation and Stress Index (EASIX), calculated at the onset of acute GvHD, was reported as reliable predictor of survival in patients receiving reduced intensity conditioning at transplant. We wondered if an early evaluation of the EASIX score might be able to predict survival regardless of GvHD development.
Aims: We evaluate EASIX score at day 0 in a cohort of three consecutive years patients submitted to allogeneic stem cell transplantation in our department matching data with pot-transplant outcomes.
Methods: We enrolled 179 patients consecutively submitted to allogeneic stem cell transplantation (HSCT) in our centre from January 2017 to November 2019. The most frequent diagnosis was leukemia (n=104), followed by myeloproliferative disease (n=32), myelodysplastic syndrome (n=19), lymphoma (n=22) and SAA (n=2). Median age was of 53 years (range, 14-72). Twenty patients received a mismatched donor, 72 a haploidentical donor and 87 a matched donor. Donor was unrelated in 60 patients and a relative in the others. Stem cell source was cord blood in 7 patients, bone marrow in 76 patients and peripheral blood in the other 96. Seventy-nine patients received a myeloablative conditioning and 100 a reduced intensity conditioning. EASIX score (lactate dehydrogenase U/L x creatinine mg/dl / platelets x 10^9/L) was calculated at day 0 before stem cell infusion (EASIX-0). No log transformation was applied.
Results: Median level of EASIX-0 was of 1.67 (95% CI 1.39-1.96) for surviving patients and 4.64 (95% CI 2.36-8.59) for patients dying after HSCT (p<0.0001). Multivariate analysis for survival confirmed EASIX-0 (HR 1.01, 95% CI 1.00-1.02, p=0.01) as predictive factor for mortality together with relapse occurrence (HR 2.92, 95% CI 1.3-4.92, p=0.0001). One-year overall survival (OS) according to EASIX-0 was as follows: <25th quartile (n=31) 86.9% (95% CI 74.9-98.9), 25th-50th quartile (n=90) 80.9% (95% CI 72.8-89.1), 50th-75th quartile (n=25) 56% (95% CI 36.2-75.5) and >75th quartile (n=33) 48.5% (95% CI 31.4-65.5) (p<0.0001, Figure 1A). Moreover, EASIX-0 was significantly associated to the cumulative incidence of transplant related mortality (TRM): HR 1.01 (95% CI 1.00-1.02) (p=0.004). Multivariate analysis confirmed EASIX-0 (HR 1.06, 95% CI 1.01-1.12, p=0.01) as predictive factor for TRM together with grade 2-4 acute GvHD occurrence (HR 8.05, 95% CI 1.92-33.80, p=0.004). One-years cumulative incidence of TRM was as follows: <25th quartile 0%, 25th-50th quartile 13.6% (95% CI 7.9-23.6), 50th-75th quartile 26.3% (95% CI 12.4-55.8) and >75th quartile 50% (95% CI 35-71.5) (p<0.0001, Figure 1B). No association was found for relapse incidence.
Figure 1. A) One-year OS survival according to Day 0 EASIX score quartiles; B) One-year TRM according to Day 0 EASIX score quartiles.

Summary/Conclusion: Early EASIX score, calculated at day 0 of transplant, appeared to be a reliable prognostic score of survival after allogeneic stem cell transplantation. We plan to enlarge the study cohort to confirm our data.



EP1234 EARLY-ONSET CYTOKINE RELEASE SYNDROME FOLLOWING ALLOGENEIC HAPLOIDENTICAL PERIPHERAL BLOOD STEM CELL TRANSPLANTATION MIGHT DECREASE OVERALL SURVIVAL

A. Hernandez-Sanchez [1,*], A. Cabero [1], B. Puertas [1], S. P. Gómez-Úbeda [1], D. Caballero [2], P. Lázaro [3], L. G. Román [1], R. Azibeiro [1], M. Fonseca [1], A. Avendaño [1], M. Baile [1], A. Á. Martín [1], E. Pérez [1], M. Cabrero [1], M. López-Parra [1], M. M. Salinero [1], Á. Rodríguez [1], M. D. Caballero [1], L. López-Corral [1]

[1]Hematology, Hospital Universitario de Salamanca, Salamanca, [2]Hematology, Hospital Universitario de Basurto, Bilbao, [3]Hematology, Hospital Universitario La Paz, Madrid, Spain

Background: Haploidentical HLA stem cell transplantation (haplo-HSCT) is increasingly being used as part of the treatment of hematological malignancies lacking a suitable HLA-matched donor. Cytokine release syndrome (CRS) is a systemic inflammatory response with aberrant immune activation and hyperstimulation which has been described in a number of clinical settings, including haplo-HSCT. However, clinical impact of CRS on these patients is controversial.
During COVID-19 pandemic, graft cryopreservation in haplo-HSCT has increased in our centre. As a result, we clinically noticed a change in CRS onset in these patients.
Aims: To identify novel CRS features that might have a prognostic impact on haplo-HSCT, as well as to determine if graft cryopreservation might influence any of those features.
Methods: A cohort of 154 patients undergoing allogeneic stem cell transplantation in 2019 and 2020 in our centre, from which 51 patients receiving peripheral blood haplo-HSCT from 1st February 2019 to 31st December 2020 were selected. Two of them were excluded for the CRS analysis due to relevant microbiological isolation close to the infusion date and impossibility to distinguish between infectious and CRS fever. CRS was graded according to the ASBMT consensus.
Results: The median age was 51 years (range 17-72), 59% were male. Median follow-up was 359 days for alive patients. Hematopoietic Cell Transplantation Comorbidity Index (HCT-CI) was low risk in 45%, intermediate risk in 22% and high risk in 33%. Most patients (71%) had an intermediate Disease Risk Index (DRI). Conditioning regimen was myeloablative in 12 (24%). 84% of the patients presented with CRS after haplo-HSCT (71% of them occurred in the first 48 hours after infusion). CRS was mild in most patients (grade 1 in 29 (71%) and grade 2 in 12 (29%); no grade 3 CRS or further occurred. Graft cryopreservation accounted for 13 (25%) patients.
Early-onset CRS (<48h since stem cell infusion) **was associated with lower overall survival** (Figure 1, p=0,01), **as well as lower event free survival** (relapse or death, p=0,03) when compared with the remaining patients in a univariate analysis. Non-myeloablative conditioning was associated with a higher proportion of early-onset CRS (74% vs 9%, p<0,001) as well as age >60 years (80% vs 45% p=0,014). It should be noted that age >60 years did not impact on overall survival in the first year following haplo-HSCT in our patients (p=0,485). We also found an **interesting trend between graft cryopreservation and early-onset CRS** (only 38% of patients with graft cryopreservation presented early-onset CRS, whereas 67% of patients with fresh graft did so, p=0,075).
Cryopreservation was related to less proportion of CRS grade ≥2 (0% vs 33%, p=0,014) and it did not impact on engraftment, overall survival nor graft versus receptor disease rate or severity in our patients. Patients with refractory disease prior to transplantation presented higher rates of CRS grade ≥2 (75% vs 20%, p=0,041). Moreover, a trend was observed for mononucleated cell count >8 x 10^8 (37% vs 14%, p=0,067). However, CRS grade ≥2 did not impact on overall survival in our patients (p=0,251).

Figure 1. Early-onset CRS is associated with less overall survival after allogeneic haploidentical peripheral blood stem cell transplantation

Summary/Conclusion: Early-onset CRS is associated with less overall survival and less event-free survival following the first year after haplo-HSCT. Cryopreservation is associated with less CRS grade ≥2 probability and might also reduce the chance of developing early-onset CRS.

EP1235 TRIAL OF AB-205 (E-CEL® CELLS) IN ADULTS WITH SYSTEMIC LYMPHOMA UNDERGOING HIGH-DOSE THERAPY AND AUTOLOGOUS HEMATOPOIETIC CELL TRANSPLANTATION (HDT-AHCT) RESULTS OF AB-205-001 BY AGE SUBGROUP

M. Abedi [1,*], M. Scordo [2], L. E. Budde [3], C. Mulroney [4], B. Fakhri [5], A. Pawarode [6], B. Dholaria [7], E. Kavalerchik [8], S. K. Aggarwal [8], M. Qazilbash [9], P. Finnegan [8], S. Giralt [2]

[1]Hematology and Oncology, University of California Davis, Davis, CA, [2]Medicine, Adult Bone Marrow Transplant Service, Memorial Sloan Kettering Cancer Center, New York, [3]Hematology and Hematopoietic Cell Transplantation, City of Hope National Medical Center, Duarte, CA, [4]Medicine, Blood and Marrow Transplantation, University of California San Diego, San Diego, [5]Medicine, Blood and Marrow Transplantation, University of California San Francisco, San Francisco, [6]Medicine, Blood and Marrow Transplantation, University of Michigan, Ann Arbor, [7]Medicine, Division of Hematology and Oncology, Vanderbilt University, Nashville, [8]Clinical Development, Angiocrine Bioscience, San Diego, [9]Stem Cell Transplantation and Cellular Therapy, The University of Texas MD Anderson Cancer Center, Houston, United States

Background: Improvements in supportive care and HCT practices have led to increasing use of HDT-AHCT for patients with chemosensitive lymphomas, with a growing interest of treating older patients (pts). However, HDT is associated with high rates of severe regimen-related toxicities (SRRT), especially in older adults, (Dahi 2018) and the risk of life-threatening SRRT may preclude older pts or pts with co-morbidities from this potentially curative treatment.
SRRT is thought to result from diffuse injury to the microvasculature forming the organ vascular stem cell niches caused by off-target cytotoxic effects of HDT. SRRT involves virtually all organ systems, but is most evident in organs with high cell turnover such as oral-gastrointestinal (oral/GI) tract and bone marrow. While the hematopoietic system is rescued by AHCT, there are no effective therapies to repair damage to other organs.
AB-205 is a novel experimental engineered-cell therapy. AB-205 contains E-CEL® cells: allogeneic *E4*$^{+}$ human cord endothelial cells. E-CEL cells express multiple angiocrine factors in a dynamic, paracrine manner.
Aims: AB-205-001 objectives included assessing initial safety and efficacy.
Methods: Subjects with chemosensitive lymphomas eligible for HDT-AHCT were enrolled. AB-205 was administered IV after AHCT in dose-escalated cohorts: 5, 10 and 20x10^{6} cells/kg, either as single or divided (D0, D2) dose. Supportive care therapies were administered as per site institutional guidelines. Oral/GI SRRT was defined as NCI-CTCAEv5.0 grade (G)≥3 oral mucositis, nausea, vomiting or diarrhea. A retrospective chart review (n=45) at a participating site served as a contemporary control.
Results: Overall results have been presented previously [ASH 2020, TCT 2021, EBMT 2021]. Here we present data from pts treated with 20x10^{6} cells/kg by age.
29 systemic lymphoma subjects were treated with AB-205 with a median (range) follow up of 271 (179, 566) days. MTD was not reached. AEs were generally mild/moderate and as expected with HDT-AHCT.
AB-205 therapy demonstrated dose-dependent reduction of oral/GI SRRT. No (0%) oral/GI SRRT were reported for any subjects (n=18) receiving the recommended AB-205 dose, including the subjects ≥60 yo (n=7). In contrast, the control cohort reported 16/25 (64%) oral/GI SRRT rate ≥60 yo, while those <60 yo had 9/20 (45%).
Median time to neutrophil engraftment, platelet engraftment and number of hospitalization days (from AHCT) were numerically lower with AB-205 than in the control cohort by approximately 2, 7 and 3 days respectively (Table). The benefits with AB-205 treatment were consistent across age subgroups.
As of the cutoff date, there have been no reports of SRRT affecting the pulmonary, cardiac, renal or hepatic systems. No detrimental effect on PFS or OS was observed. There were no deaths by day 100.

	Age <60		Age ≥60	
	AB-205	Control	AB-205	Control
N	11	20	7	25
Age, Median (range), years	47 (25, 59)	40 (21, 59)	66 (61, 73)	66 (60, 73)
Male (%)	55	65	57	80
Diagnosis HL/NHL (%)	27/73	55/40	29/71	8/92
Lines of Therapy, median (range)	2 (1, 4)	2 (1, 3)	2 (2, 2)	2 (1,4)
HDT BEAM/BeEAM (%)	91/9	95/5	86/14	96/4
CD34+ cells x10^{6}/kg, median (range)	4.2 (2.8, 16.7)	5.3 (3.2, 7.9)	6.3 (4.5, 8.4)	3.2 (2.0, 7.2)
Oral/GI SRRT, n (%)	0	9 (45)	0	16 (64)
Neutrophil engraftment, median, days	10	12	10	13
Platelet engraftment, median, days	11	21	11	18
Number of hospitalization days from AHCT, median, days	13	16	12	16

Summary/Conclusion: 20x10^{6} cells/kg of AB-205 eliminated the occurrence of oral/GI SRRT including in subjects 60 yo. In contrast, 64% event rates were seen in pts ≥60 yo in a contemporary control cohort. AB-205 has potential to make HDT-AHCT substantially safer for older pts and may enable physicians to consider this potentially curative therapy for high-risk patients currently considered ineligible for HCT.

EP1236 DEMOGRAPHIC, CLINICAL CHARACTERISTICS AND MORTALITY OF ADULT HEMATOLOGICAL CANCER PATIENTS WITH VENO-OCCLUSIVE DISEASE IN ENGLAND, 2010 TO 2020

I. U. Doobaree [1,*], A. Khachatryan [1], R. Kelly [2]

[1]Pharmaco-epidemiology, Certara, London, [2]Leeds Teaching Hospitals NHS Trust, Leeds, United Kingdom

Background: Veno-occlusive disease (VOD), or sinusoidal obstruction syndrome, is a rare liver disorder which is associated with high morbidity and mortality. Patients with hematological malignancies are at particularly high risk of developing VOD following antineoplastic treatment, especially among those who had hemopoietic stem cell transplantation (HSCT).
Aims: To apply an adapted algorithm based on the Seattle/Baltimore diagnostic criteria to identify VOD patients among adult hematological cancer patients and a subcohort of patients with leukemia in England, and to describe their demographic, clinical characteristics, and mortality.
Methods: This retrospective observational study utilized the Hospital Episode Statistics (HES) inpatients, outpatients, and critical care 'pseudonymized' datasets (NHS Digital, England) as its source of adult hematological cancer patients, including a subcohort with leukemia, identified between 1/1/2010 and 31/3/2020. An algorithm to identify VOD was applied based on the Baltimore/Seattle diagnostic criteria and other clinical features of the disease (with a breakdown of its components shown in Table 1); adults with chronic graft-versus-host disease (GVHD) or total parenteral nutrition (TPN) cholestasis were not included. Patients with VOD were followed up from diagnosis of VOD (index date) until the earliest occurrence of death or end of study period.
Results: A total of 386,174 adults with hematological cancers (mean age: 67.9; males: 57.9%), including a subcohort of 80,081 patients with

leukemia (mean age: 70.7; males: 60.4%), were identified within the HES datasets during study period. Overall, the adapted algorithm identified 323 (8 per 10,000; mean age: 51.0; males: 55.1%) patients with VOD in the hematological cancer cohort, and 68 (8 per 10,000; mean age: 53.9; males: 50.0%) in the leukemia subcohort (Table 1). The majority (~41%) developed VOD between 45 and 64 years of age. Overall, prior systemic antineoplastic therapies (inc. chemotherapy), radiotherapy and HSCT were received by 79.3%, 11.2% and 67.5% of hematological cancer patients and 89.7%, 20.6% and 73.5% of leukemia patients, respectively. Antineoplastic treatments were received by 282 hematological cancer patients who developed VOD and among them 218 (77.3%) had prior HSCT. Within the leukemia subcohort, 50 of 64 (78.1%) VOD patients had prior HSCT. Among patients with VOD, 56.7% (hematological cancer patients) and 55.9% (leukemia patients) died within 100 days of developing the disease. The mortality rates following VOD were 68.8 and 94.0 per 100 person-years, among hematological cancer patients and leukemia subcohort, respectively.

Table 1. Characteristics of hematological and leukemia patients with VOD

	Hematological cancer patients (N=386,174)	Among patients with leukemia (N=80,081)
	VOD (n=323)	VOD (n=68)
All VOD[£], n (%)[^]	323 (100.0)	68 (100.0)
K76.5 or K71.8	128 (39.6)	23 (33.8)
Hepatic VOD (ICD 10 K76.5)	108 (33.4)	20 (29.4)
Toxic liver disease with other liver disorders (ICD 10 K71.8)	21 (6.5)	3 (4.4)
Symptoms of VOD within 60 days of HSCT	9 (2.8)	0 (0.00)
Multi-organ failure with liver failure within 60 days of HSCT	147 (45.5)	35 (51.5)
Other hepatic vein occlusion or necrosis within 60 days of HSCT	72 (22.3)	14 (20.6)
Male n (%)	178 (55.1)	34 (50.0)
Age at first VOD event in years, n (%)		
Mean (SE)	51.0 (16.3)	53.9 (16.3)
Median (IQR)	54.1 (36.7, 64.6)	56.7 (42.3, 65.8)

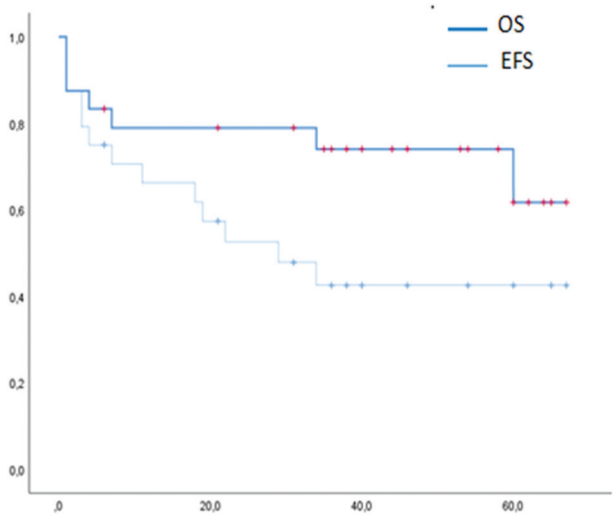
[£] after applying selection criteria (patients with graft-versus-host disease or total parental nutrition cholestasis removed) and categorized into components as per adapted algorithm. To note, use of defibrotide could not be identified in order to use as proxy to define VOD
[^] unique number of patients after accounting those who were under more than one criterion
*Some patients may have received more than one treatment modality (e.g. chemotherapy, radiotherapy or HSCT)
[#]Data request to NHS Digital was for adult patients only
HSCT, hemopoietic stem cell transplant; ICD, international classification of diseases; IQR, inter-quartile range; n/a, not applicable; SE, standard error; VOD, veno-occlusive disease

Summary/Conclusion: This study identified a similar proportion of VOD patients (8 per 10,000) in the overall hematological cancer cohort as in the leukemia subcohort. It should be noted that the incidence of VOD is representative of the calculations that were based on this study's adapted algorithm. Among patients who were treated for their hematological cancers and subsequently developed VOD, this particular algorithm identified that three quarters had prior HSCT in their treatment strategies. The high mortality rate among patients with VOD in England suggests a clear need to focus research and clinical efforts to identify the disease promptly, develop risk-profiling methodology and improve patients' survival.

EP1237 PHASE II CLINICAL TRIAL (EMN-ALLORIC 2010) OF ALLOGENEIC STEM CELL TRANSPLANTATION FOR HIGH RISK (HR) MULTIPLE MYELOMA (MM) FOLLOWED BY MAINTENANCE WITH BORTEZOMIB AND LENALIDOMIDE. UPDATED ANALYSIS.

M. Reinoso Segura [1,2,*], J. Martín Sánchez [1,2], P. Herrera [3], F. Patriarca [4], B. Bruno [5], H. Einsele [6], H. Nahi [7], G. Gahrton [7], L. López Corral [8], M. Granell [9], T. Caballero-Velázquez [1,2], J. A. Pérez-Simón [1,2,10,11,12]



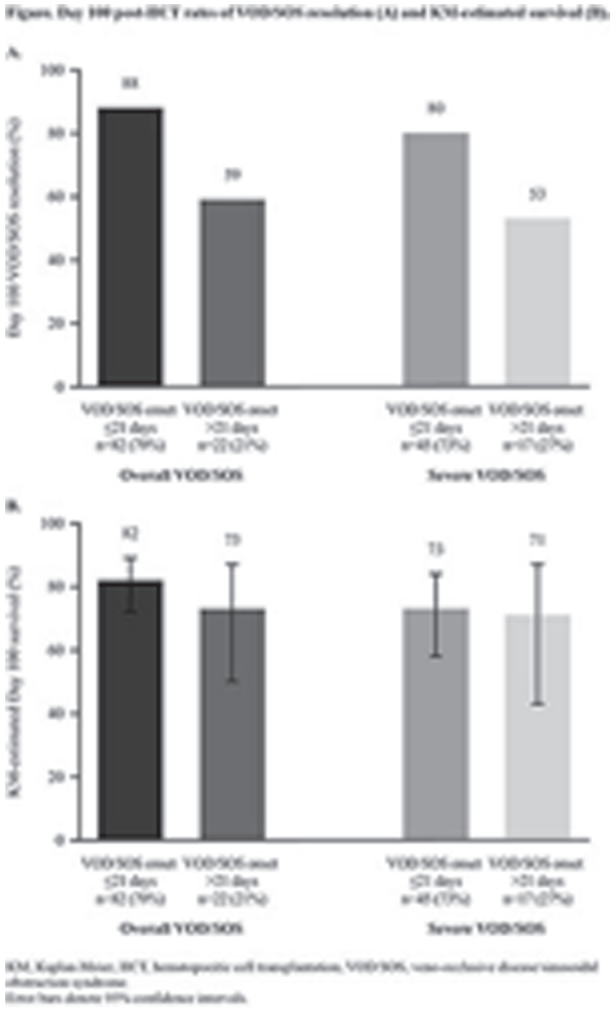
[1]Hospital Universitario Virgen del Rocío, [2]Instituto de Biomedicina, Universidad de Sevilla, Sevilla, [3]Hospital Ramón y Cajal, Madrid, Spain, [4]Azienda Ospedaliera Universitaria, Udine, [5]AOU Città della Salute e della Scienza, Torino, Italy, [6]Medizinische Klinik and Poliklinik II University Hospital, Würzburg, Germany, [7]Karolinska University Hospital, Huddinge, Sweden, [8]Hospital Clínico Universitario, Salamanca, [9]Hospital Sant Pau, Barcelona, [10]Grupo Español de Trasplante Hematopoyético, [11]European Bone Marrow Transplantation, [12]European Myeloma Network, Sevilla, Spain

Background: Maintenance treatment with lenalidomide (Len) after autologous SCT in MM patients has demonstrated 2.5 years improvement in overall survival(OS). Its role after alloSCT is controversial because of an increased risk of graft versus host disease (GVHD), and prospective trials are lacking. AlloSCT can be a curative option in MM patients, but relapse is the main cause of treatment failure, especially after reduced intensity conditioning regimens (RIC), although they are the preferred option due to lower non-relapse mortality (NRM). The use of Bz within the conditioning regimen was demonstrated to be safe and allowed to obtain a high response rate after RIC alloSCT in a previous phase I trial. In an attempt to decrease the risk of relapse, this phase II was planned adding maintenance with Bz and Len.

Aims: Evaluate the toxicity and efficacy of a RIC with Bz and postransplant maintenance with Bz and Len in HR MM patients. Updated analysis of relapse rate (RR), acute and chronic GVHD, event free survival (EFS) and OS. To analyse inmune subpopulations and the effect of Len in immune recovery.

Methods: Multicenter, phase II trial. All patients provided written informed consent. RIC included Bz 1.3 mg/m2 iv on days -9 and -2; fludarabine 30 mg/m2 iv on days –6 to –4 and melphalan 140 mg/m2 iv on d –3. GvHD prophylaxis was based on Bz 1.3 mg/m2 iv on d +1, +4 and +7 plus methotrexate 15 mg/m2 on d+1 and 10 mg/m2 on d +3, +6 and +11 and tacrolimus. For maintenance therapy, all patients received Bz 1,3 mg/m2 iv on d 1, 8 and 15 in 28 days cycles starting on d+70 postransplant. Based on disease status at d +100, patients received six cycles of Bz (1.3 mg/m2 iv on d 1, 8, 15) every 56 days (if complete response(CR) or nCR) or four cycles of Bz (1.3 mg/m2 iv on d 1, 8, 15), Len (15 mg on days 1 to 21) and dex (10 mg on d 1 to 4 and 8 to 11) followed by same treatment regimen specified for patients in CR. Len was started on day +180 (5 mg pd until relapse or toxicity).Different subpopulations of the immune system were evaluated on peripheral blood by flow cytometry (FC) on days +100, +180, +270, and +365.

Results: 24 patients were included. All had previously received treatment with proteasome inhibitors and immunomodulatory drugs, 87% had received a previous autoSCT. Cumulative incidence (CI) of grade 2-4 and 3-4 aGvHD at 100d was 39% (CI 95%: 15.5%>56.1%) and 21.7% (CI 95%: 7.7%>40.4%). CI of overall cGVHD at 1y was 22.7% (CI 95%: 7.9%>42%) and moderate-severe 18.1% (CI 95%: 5.4%>36.8%). 7 patients died (5 due to aGvHD), CI NRM was 21.1% (95% CI 0.074-0.394) at 1y. With a median follow up of 39m (range 1-67), median EFS was 29m (95% CI 8.1%>49.8) (not reached for patients with at least VGPR at d100 postransplant); median OS was not reached. EFS and OS at 3y were 42,48% (95% CI 21.9%>61.7%) and 74% (95% CI 50.8%>87.45%). CI of relapse was 13.6% (95% CI: 3.2%>31.3%) at 1y. Out of 20 patients evaluable for maintenance therapy, 15 patients stopped it before relapse or death due to GvHD (9), infection (1), citopenia (1), neuropathy (2) and patient/physician´s choice (2). Upon comparing inmune recovery between patients included in the phase II or the phase I trial (who did not received maintenance), several differences emerged in different immune cell sub-populations (non classical monocytes, lymphocytes).



Summary/Conclusion: Combination of alloSCT with novel drugs could improve the efficacy of the procedure in MM.
Maintenance treatment with Len and Bz leads to a low risk of relapse. Although the risk of cGVHD did not increase, Len was stopped in a significant proportion of patients.

EP1238 LATE-ONSET VENO-OCCLUSIVE DISEASE/ SINUSOIDAL OBSTRUCTION SYNDROME (VOD/SOS) AFTER HEMATOPOIETIC CELL TRANSPLANTATION (HCT): OUTCOMES OF DEFIBROTIDE-TREATED PATIENTS FROM THE EBMT PASS REGISTRY STUDY

M. Mohty [1,*], I. Yakoub-Agha [2], M. Lisa Battista [3], D. Blaise [4], E. Calore [5], V. Amber [6], R. J. Ryan [7], K. Perruccio [8]

[1]Department of Clinical Haematology and Cellular Therapy, Hôpital St Antoine, Sorbonne University, INSERM UMRs 938, Paris, [2]CHU de Lille, University of Lille, INSERM U1286, Infinite, Lille, France, [3]Hematology Clinic, University of Udine, Udine, Italy, [4]Institut Paoli Calmettes, Aix Marseille University, CNRS, INSERM, CRCM, Marseille, France, [5]Department of Pediatric Hematology-Oncology, Azienda Ospedale, Università di Padova, Padova, Italy, [6]Clinical Development, Jazz Pharmaceuticals, Oxford, United Kingdom, [7]Biostatistics, Jazz Pharmaceuticals, Philadelphia, PA, United States, [8]Mother and Child Health, Santa Maria della Misericordia Hospital, Perugia, Italy

Background: Severe hepatic VOD/SOS is a potentially fatal complication of HCT conditioning. Signs and symptoms of VOD/SOS often peak within 14 days of HCT but in a large, prospective study, late-onset (beyond Day 21) VOD/SOS occurred in 26% of patients and was more common in adults than pediatric patients. Defibrotide is approved for severe hepatic VOD/SOS post-HCT in patients aged >1 month in the European Union.
Aims: This subgroup analysis of defibrotide-treated patients from the EBMT PASS evaluated outcomes in patients with VOD/SOS onset ≤21 days or >21 days post-HCT.
Methods: This multicenter, multinational, prospective, observational study (NCT03032016; EBMT PASS), enrolled defibrotide-treated patients from April 2015 to July 2018. Investigators diagnosed VOD/SOS using classical/standard criteria (including, but not limited to, hyperbilirubinemia, hepatomegaly, ascites, and weight gain >5%). Severity grading criteria were not predefined in the protocol; investigators graded VOD/SOS severity based on clinical expertise. Multiorgan dysfunction/failure (MOD/MOF) was diagnosed by the investigator based on renal, pulmonary, or cerebral dysfunction/failure.
Results: Of 104 defibrotide-treated patients with VOD/SOS post-HCT, 82 (79%) had onset ≤21 days (41% were adults) and 22 (21%) had onset >21 days post-HCT (50% were adults). Median time to VOD/SOS onset was 10.5 (range: 1, 21) days in patients with onset ≤21 days and 32.0 (range: 22, 122) days in those with onset >21 days. Median age was 14.0 (range: 0, 69) years and 19.0 (range: 1, 65) years in patients with onset ≤21 days and >21 days, respectively. Severe VOD/SOS occurred in 62 of the 104 patients with VOD/SOS post-HCT; in patients with severe VOD/SOS, 45 (73%) and 17 (27%) patients had VOD/SOS onset ≤21 days and >21 days, respectively. Among patients with severe VOD/SOS, MOD/MOF at baseline was observed in 25 (56%) patients with onset ≤21 days and 11 (65%) patients with onset >21 days.
In the overall population, the rates of VOD/SOS resolution (**Figure [A]**) and Kaplan-Meier–estimated survival (**Figure [B]**) at Day 100 were numerically lower in patients with late-onset VOD/SOS. Overall, the Kaplan-Meier–estimated survival rate at 1 year post-HCT was 65% in patients with onset ≤21 days and 41% in those with onset >21 days; among patients with severe VOD/SOS, 1-year post-HCT survival rates were 53% and 41%, respectively. In patients with severe VOD/SOS, the MOD/MOF resolution rate was 56% in patients with onset ≤21 days and 46% in those with onset >21 days.
Serious adverse events (SAEs) of interest occurred in 29% of patients with onset ≤21 days and 23% of those with onset >21 days; among patients with severe VOD/SOS, incidence of SAEs was 33% and 29%, respectively. The most common categories of SAEs in the overall population were infections (onset ≤21 days: 22%; onset >21 days: 14%) and bleeding events (onset ≤21 days: 11%; onset >21 days: 14%); corresponding values among patients with severe VOD/SOS were 27% and 18% for infections and 11% and 18% for bleeding events.

Summary/Conclusion: In this analysis of post-HCT VOD/SOS patients, approximately 20% developed VOD/SOS >21 days post-HCT, highlighting the need for continued vigilance for VOD/SOS beyond the usual window of development. Given that patients with late-onset VOD/SOS are likely to begin treatment later post-HCT than those with onset ≤21 days, caution must be taken when interpreting rates of Day 100 post-HCT VOD/SOS resolution and survival. The safety of defibrotide in this real-world setting was consistent with previous studies.

EP1239 OPTIMOB STUDY: INTERIM ANALYSIS OF THIS NON-INTERVENTIONAL TRIAL IN GERMANY TO EVALUATE THE MOBILIZATION AND COLLECTION OF HEMATOPOIETIC STEM CELLS IN POOR MOBILIZERS

M. Bittrich [1], K. Kriegsmann [2], C. Tietze-Bürger [3], M. Grube [4], V. Vucinic [5], D. Wehler [6], A. Burchert [7], M. Schmidt-Hieber [8], H. A. Dürk [9], C. Kunz [10,*], N. Kröger [11]

[1]University Hospital Würzburg, Würzburg, [2]University Hospital Heidelberg, Heidelberg, [3]University Hospital Charité, Berlin, [4]University Hospital Regensburg, Regensburg, [5]University Hospital Leipzig, Leipzig, [6]University Hospital Mainz, Mainz, [7]University Hospital Gießen und Marburg GmbH, Marburg, [8]Carl-Thiem-Hospital Cottbus GmbH, Cottbus, [9]St. Barbara Hospital Hamm – location St. Josef, Hamm, [10]Westpfalz-Hospital Kaiserslautern, Kaiserslautern, [11]University Hospital Hamburg-Eppendorf, Hamburg, Germany

Background: Although most of the patients with multiple myeloma (MM) or lymphoma eligible for autologous stem cell transplantation (ASCT) mobilize enough hematopoietic stem cells (HSCs), there are also

patients in which mobilization is more difficult and several apheresis (aph) sessions are needed. For those poor mobilizers (PMs), data will be collected across Germany and adequate mobilization strategies will be established.
Aims: Aim of the OPTIMOB study is to assess the current approach of HSC mobilization and collection, and ASCT in PM patients in Germany to eventually improve mobilization and transplantation strategies, especially in PM patients.
Methods: The OPTIMOB study is an ongoing, prospective, non-interventional study including patients having MM or lymphoma who are eligible for ASCT. PMs are categorized as follows: (1) patient never achieved ≥ 20 $CD34^+$ cells / µL before 1st aph (PM-A), (2) patient received plerixafor (PLX) at any time point of mobilization (PM-B), (3) the initially planned HSC yield had to be reduced (PM-C), or (4) patients have not received aph due to low $CD34^+$ count in peripheral blood (PM-D).
Results: Until data cut-off in November 2020, 461 patients participated in the study, of whom 37.6% were classified as PMs. Most patients (67%) suffered from MM. Notable, the share of PMs was nearly the same in both entities, MM and lymphoma. In general, PMs were older, mostly male and had a poorer Karnofsky score. 68.2% of the PMs received plerixafor during mobilization, mainly in combination with chemotherapy and/or G-CSF (granulocyte-colony stimulating factor). PLX administration led to a notably increase of $CD34^+$ cells in peripheral blood in PM patients (at least two-fold). Until data cut-off, 84.4% of the PMs were able to undergo aph. In general, patients with PLX supported mobilization had a higher mean total $CD34^+$ collection result than PM patients without PLX administration (7.5 x10^6 cells/kg body weight (BW) [SD: ± 7.46] vs 5.2 x10^6 cells/kg BW [SD: ± 3.70]). Further, 72% of the PM patients treated with PLX (n=104) reached the total planned $CD34^+$ collection target (median 6.0 x10^6 cells/kg BW) during aph whereas in patients without PLX administration, only 45.5% of the patients achieved this goal. ASCT was feasible in 66.5% of the PM patients until data cut-off.
Summary/Conclusion: The ongoing OPTIMOB study provides comprehensive data of the current situation of MM and lymphoma patients classified as PMs in Germany. Data support that additive administration of PLX to established mobilization strategies leads to a sufficient mobilization and collection of HSCs PM patients.
This non-interventional study is sponsored by Sanofi.

EP1240 CO-REACTIVATION OF CYTOMEGALOVIRUS AND EPSTEIN-BARR VIRUS WAS ASSOCIATED WITH POOR PROGNOSIS AFTER ALLOGENEIC STEM CELL TRANSPLANTATION

J.-R. Zhou [1,*], Y.-Q. Sun [1,2], D.-Y. Shi [1], R. Wei [1], Y. Wang [1,2], C.-H. Yan [1,2], X.-H. Zhang [1,2], L.-P. Xu [1,2], K.-Y. Liu [1,2], X.-J. Huang [1,2,3]

[1]Peking University People's Hospital, Peking University Institute of Hematology, National Clinical Research Center for Treatment of Hematological Disease, Beijing, China, [2]Beijing Key Laboratory of Hematopoietic Stem Cell Transplantation for the Treatment of Hematological Diseases, Beijing, China, [3]Peking-Tsinghua Center for Life Sciences, Beijing, China

Background: Reactivation of cytomegalovirus (CMV) or Epstein-Barr virus (EBV) is common after hematopoietic stem cell transplantation (HSCT). Previous researches have demonstrated that either CMV or EBV reactivation is associated with poor outcomes of HSCT. However, few studies investigate the impact of CMV and EBV co-reactivation after HSCT.
Aims: Our aim was to described clinical characteristics of patients with co-reactivation of CMV and EBV (defined as CMV and EBV viremia occur at the same period of time), research the impact of such co-reactivation on prognosis and identify associated risk factors.
Methods: We conducted a longitudinal study of 247 patients who underwent first HSCT in our center between July 2015 and June 2016. Of these 247 patients, different conditioning regimen were performed according to their different underlying disease. They received uniform CMV and EBV monitoring and therapy, as well as graft-versus-host disease (GVHD) prophylaxis. Peripheral blood samples were collected from the recipients at 30, 60 and 90 days after HSCT for immunophenotyping. Co-reactivation of CMV and EBV was defined as the detection of EBV or CMV viremia during CMV or EBV viremia, respectively. The time of co-reactivation was defined as the day when viremia of the first virus was identified. Univariate and multivariate analysis and survival analysis were performed to elucidate the impact of such co-reactivation on prognosis and identify associated risk factors.
Results: A total of 24 (9.7%) patients had CMV and EBV co-reactivation of these 247 patients. These patients showed higher incidence of viral pneumonitis (P=0.005). Patients with CMV and EBV co-reactivation had significant lower 1-year overall survival (OS) (P=0.004) and lower 1-year leukemia free survival (LFS) (P=0.016). Our further analysis suggested that duration of CMV (P=0.014), EBV (P<0.001), and CD4+CD25+ T cell counts at day 30 post-transplantation (P=0.05) are independent risk factors of virus co-reactivation.

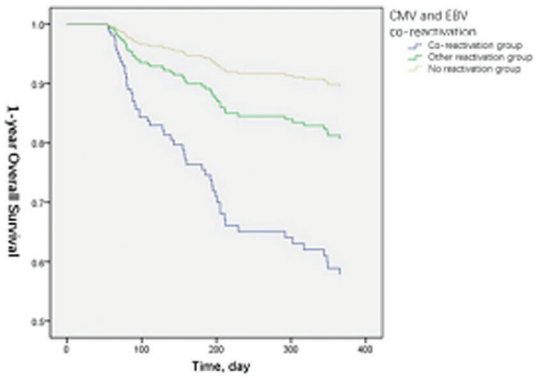


Figure 1 CMV and EBV co-reactivation was identified as one of the independent risk factors for 1-year overall survival. (P=0.004)

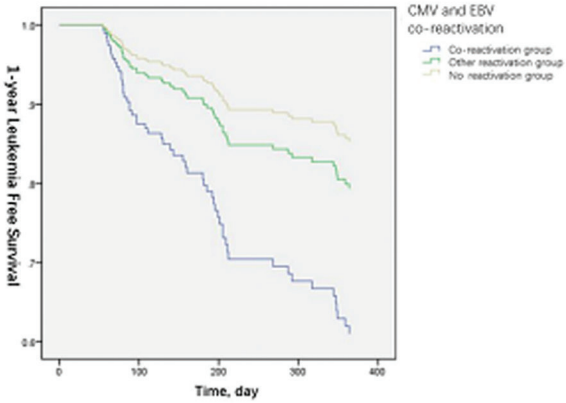

Figure 2 CMV and EBV co-reactivation was identified as one of the independent risk factors for 1-year leukemia free survival. (P=0.016)

Summary/Conclusion: Patients who developed co-reactivation of CMV and EBV had poor prognosis in terms of lower 1-year OS and LFS, and the CMV and EBV co-reactivation was associated with prolonged CMV or EBV duration and poor CD4+CD25+ T cell reconstitution at day 30 post-transplantation, which may provide an alternative way to prevent CMV and EBV reactivation in HSCT patients.

EP1241 IMPACT OF IMMUNE STATUS ON HOSPITAL READMISSION AFTER ALLO-HSCT

I. Galtseva [1,*], D. Mikhail [1], Y. Davydova [1], K. Nikiforova [1], N. Kapranov [1], E. Michaltsova [1], L. Kuzmina [1], T. Gaponova [1], E. Parovichnikova [1], V. Savchenko [1]

[1]Research Center for Hematology, Moscow, Russia, Moscow, Russian Federation

Background: Allo-HSCT is accompanied by different complications including infections, graft-versus-host disease (GVHD) that require constant follow-up. Increased rate of HLA-mismatched allo-HSCT may be associated with higher hospital readmissions rate.
Aims: We studied the impact of immune status (T-, B- and natural killer lymphocytes, or NK-cells) in patients (pts) after allo-HSCT within the period from +6 to +12 months (mths) after transplantation for assessment of hospital readmission risk.
Methods: 51 pts were included in the study (male=23, female=28). Median age 41 (min – 20, max – 70). Pts had diagnosis: AMLs (n=28), ALLs (n=10), NHLs (n=5), CLL (n=1), primary myelofibrosis (n=2), MDS (n=3), aplastic anemia (n=2). 8 pts (16%) had mismatched unrelated donors, 19 pts (37%) had mismatched related donors, 6 pts (12%) had haploidentical, 18 pts (35%) had matched related donors. 24 pts were transplanted with PBSC, 27 - with bone marrow. Myeloablative or reduced-intensity conditioning regimens were performed in 14 (27%) and 37 (73%) pts, respectively. Flow cytometry analysis was performed on BD FACS Canto II device (Becton Dickinson, USA) with BD Multitest™ 6-color TBNK kit to define T-cells, T-helpers, cytotoxic T-lymphocytes, NK-cells and B-cells on +6, +9, +12 mths. The two-platform method was used to determine an absolute lymphocytic subpopulation count. Mann–Whitney U test used for nonparametric data analysis. A p-value was less than cutoff 0.05 was considered significant. ROC-analysis was performed to determine parameters, which affect readmission rate. Multivariate analysis (MVA) was used to determine the relating probability of readmission with gender, age of pts, type of donors, type of grafts, GVHDs, numbers of T-helpers, B-cells, NKs.
Results: From +6 to +9 mths 11 pts (29.7%) were hospitalized due to GVHD, 4 pts (10.8%) were hospitalized due to infections and 22 pts (59.5%) due to other reasons. From +9 to +12 mths hospital readmissions causes were: chronic GVHD (n=13, 41.9%), infections (n=2, 6.5%), relapses (n=4, 12.9%) and other reasons (n=12, 38.7%).
According to thresholds determined by ROC analysis pts were divided into two groups. The probability of readmissions in the period from +6 to +9 mths were: 55% for pts with the absolute number of T-helpers less than 180/μL and 23% for pts with the absolute number of T-helpers more than 180/μL (p=0.0144); 58% for pts with B-cells less than 50/μL and 27% for pts with B-cells more than 50/μL (p=0.0079). The probability of readmissions in the period from +9 to +12 mths were: 72% for pts with the absolute number of T-helpers less than 225/μL and 16% for pts with the absolute number of T-helpers more than 225/μL (p<0.0001); 52% for pts with NKs less than 175/μL and 18% for pts with NKs less than 175/μL (p=0.0033) (figure 1).

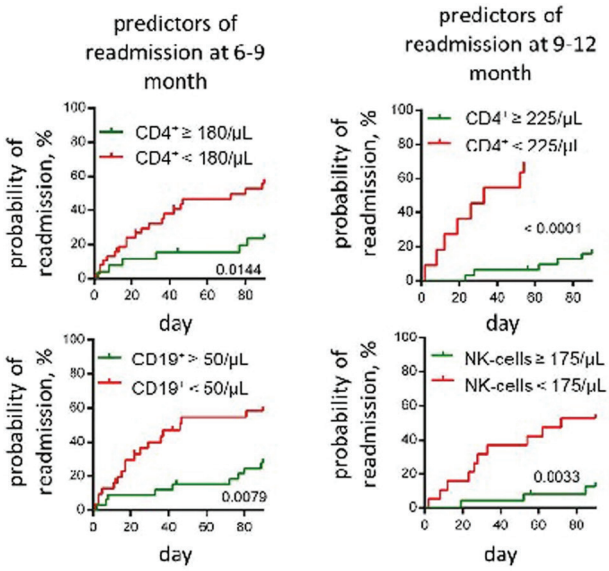

figure 1. The probability of hospital readmission depending on some parameters of the lymphocytes subpopulation

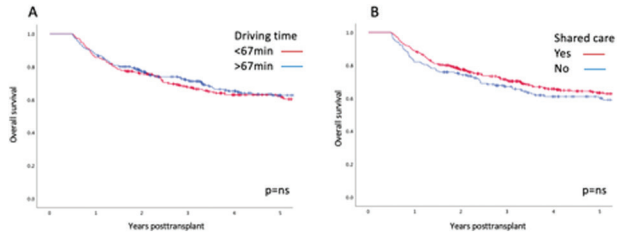
In MVA probability of readmissions weren't related to gender, age of pts, donor's type, graft type, GVHD. But probability of readmissions at +9 mths was significantly associated with the absolute number of T-helpers (for pts with the absolute number of CD4<180/μL at +6 mths (p=0.0435) and for pts with the absolute number of CD4<180/μL at +9 mths (p=0.0157)) and B-cells (p = 0.0184 for pts with the absolute number of CD19<50/μL at +9 mths).
Summary/Conclusion: The absolute number of NK cells, B-cells and T-helpers can reflect the quality of immune reconstitution after allo-HSCT. The low level of these cells may predict high readmission risk in the post-engraftment period after allo-HSCT at different time points disregarding gender, age of pts, donor's type, graft type, GVHD.

EP1242 ASSOCIATION OF TRAVEL TIME TO TRANSPLANT CENTER AND POST-TRANSPLANT CARE MODEL WITH OUTCOME PARAMETERS AFTER ALLOGENEIC TRANSPLANTATION



R. Peter [1,*], J. Halter [2], D. Heim [2], M. Medinger [2], T. Pabst [3], G. Stussi [4], J. Passweg [2], S. Gerull [2]

[1]University of Basel Medical School, [2]Division of Hematology, University Hospital Basel, Basel, [3]Department of Medical Oncology, Inselspital, University Hospital and University of Bern, Bern, [4]Division of Hematology, Oncology Institute of Southern Switzerland, Bellinzona, Switzerland

Background: Allogeneic hematopoietic cell transplantation is a well-established treatment modality for multiple hematological diseases, however a significant risk of complications remains. It is performed only in specialized centers and patients necessitate intense follow-up care posttransplant which is usually performed at the transplant center, in turn leading to long travel times for patients. It is conceivable that travel burden could impair the quality of posttransplant care, as has been shown in other healthcare settings. Previous retrospective studies conducted in North America have shown contrasting results regarding the impact of travel distance on outcome. To reduce the burden of travel time to our center, whenever possible we offer shared care posttransplant meaning that patients can receive some or in selected cases all follow-up visits with other health care providers with which we have an established collaboration.
Aims: Due to the situation at our center with long travel times on the one hand and an established shared care model posttransplant on the other hand, we were interested in analyzing the impact of distance and posttransplant care model on outcome parameters.
Methods: We conducted a retrospective analysis of 678 patients who received a first allogeneic transplantation at the University Hospital of Basel between January 2008 and December 2017. Pediatric patients were excluded. All study participants gave written informed consent. Since the intention to provide shared care posttransplant was not collected prospectively, patients who did not receive shared care presumably also included those that died before they could continue to outpatient care or were considered too sick. For this reason, we performed selected analyses in a landmark population of patients alive at day 180.
Results: Median age at transplant was 53y (range 19-75), 416 (61%) were male. The most common disease was acute leukemia (n=329, 49%). The majority of patients had an unrelated donor (n=379, 56%) and a myeloablative conditioning regimen (n=467, 69%). The median follow-up of survivors was 1750 days while 57% of the patients were still alive after 3 years.
Median travel time by car and public transport to the transplant center was 67min and 112min respectively, and 56% and 78% of patients had a travel time of over 1h by car and public transport respectively.
Of the patients in the landmark population alive at day 180 (n=553), 375 (68%) received shared care, and 277 (91%) of those with a driving time >1h. There was no difference in overall survival (OS) for patients with driving time over or under the median or for those

receiving shared care posttransplant versus not (Figure 1). A multivariable analysis including patient and transplant characteristics confirmed the lack of association between driving time and receiving shared care with OS in the landmark population. Patients alive at one year receiving shared care had significantly less visits at the transplant center with a median of 12 versus 22 visits (p<0.001) between day 100 and day 365.

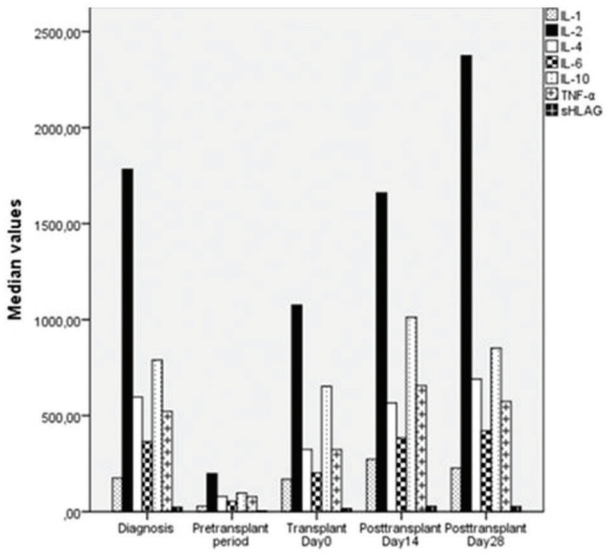
Figure 1

Summary/Conclusion: Our study demonstrates that within the framework of shared care, increasing distance to the transplant center does not negatively impact outcome and that the burden of prolonged travel time for patients can be significantly reduced. While acknowledging the limits of a retrospective analysis, to our knowledge, this is the first such study performed in Europe, and we believe it will help optimize post-transplant follow-up and is an important contribution to the growing field of health services research.

EP1243 THE ADDITION OF ATG TO NON-MYELOABLATIVE ALLOGENEIC STEM CELL TRANSPLANTATION WITH FLUDARABINE AND CYCLOPHOSPHAMIDE REDUCES GVHD AT THE EXPENSE OF HIGHER RELAPSE RATES AND POORER OVERALL SURVIVAL.

M. Rawicki [1,2,*], R. M. Koo [1,3], R. Koldej [1,2], D. Ritchie [1,2,3], E. Wong [1,2,3,4]

[1]ACRF Translational Research Laboratory, Royal Melbourne Hospital, [2]Faculty of Medicine, Dentistry and Health Sciences, University of Melbourne, [3]Clinical Haematology, Peter MacCallum Cancer Centre–Royal Melbourne Hospital, [4]Department of Clinical Haematology, Austin Health, Melbourne, Australia



Background: The use of anti-thymocyte globulin (ATG) for graft versus host disease (GVHD) prophylaxis has been demonstrated to reduce acute GVHD (aGVHD) and chronic GVHD (cGVHD) following myeloablative HLA matched related and unrelated allogeneic stem cell transplantation (alloSCT). However, its use in non-myeloablative (NMA) alloSCT is less well described with concerns for graft loss or poor donor chimerism due to prolonged lymphocyte depleting effects.
Aims: To analyse the impact of ATG on post-transplant outcomes following unrelated donor alloSCT using NMA conditioning with fludarabine and cyclophosphamide
Methods: We reviewed patients treated at our centre that received alloSCT from an unrelated donor (n=58) between 2000 and 2020 with (n=35) or without ATG (n= 23) for the treatment of haematological malignancies. All patients received either fludarabine (90mg/m2) and low-dose cyclophosphamide (2250mg/m2) or fludarabine (125mg/m2) and high dose cyclophosphamide (120mg/kg). The primary outcomes were the incidence and severity of aGVHD, cGVHD and T-cell chimerism within the first 100 days following transplantation. Secondary outcomes included rates of non-engraftment, overall survival (OS), and GVHD-free relapse free survival (GRFS).
Results: The ATG cohort was older (median 59 vs 55 years) with more female participants (48.6% vs 30.4%) but had similar disease characteristics and conditioning to the non-ATG group. All patients engrafted with faster neutrophil and platelet engraftment in the ATG cohort with a median recovery time of 16 days (range: 8-23) vs 19 days (range: 9-34) [P = 0.03] and 18 days (range: 10-35) vs 20 days (range: 8-33) [P = 0.47] respectively. There was no difference in median T-cell chimerism at day 30, 60 or 100 for either group although more patients in the ATG cohort had chimerism less than 50% (37.1 vs 17.4%, p = 0.080) at day 100. At 80 months follow-up post-transplant, the cumulative incidence (CI) of cGVHD (0.20 vs 0.52; P = 0.0076) and moderate to severe cGVHD (0.11 vs 0.35; P = 0.048) was lower in the ATG cohort however there was a higher incidence of relapse (0.60 vs 0.17; P = 0.015). There were no significant differences in the incidence of aGVHD (0.20 vs 0.26; P = 0.53) or non-relapse mortality (0.14 vs 0.087; P = 0.50). OS for the ATG group was significantly lower (42.9% vs 82.6%; P = 0.0026), with a lower relapse free survival (25.7% vs 73.9%, P = 0.12) and GRFS (20% vs 48.9%, P = 0.69).
Summary/Conclusion: The addition of ATG to NMA conditioning alloSCT with fludarabine and cyclophosphamide was associated with a reduced incidence of GVHD but with no significant difference in T-cell chimerism or engraftment. There was a greater likelihood of disease relapse leading to inferior OS with the use of ATG.

EP1244 EVALUATION OF SOLUBL HLA-G AND CYTOKINE LEVELS IN CHILDREN WITH ACUTE LEUKEMIA UNDERGOING ALLOGENEIC STEM CELL TRANSPLANTATION.

Z. Kaya [1,*], D. Yüce [2], S. Kirkiz [1], Ü. Koçak [1], F. Özmen [3]

[1]Pediatric Hematology, Gazi University School of Medicine, [2]Preventive Oncology, [3]Basic Oncology, Hacettepe University Cancer Institute, ANKARA, Turkey

Background: There are few studies about cytokines and soluble human leukocyte antigen-G (sHLA-G) levels in patients with acute leukemia undergoing allogeneic stem cell transplantation (allo-SCT). Proinflammatory and antiinflammatory cytokines maintain a balance between hematopoietic stem cell and lineage spesific cell in a healthy marrow; however, this balance is disrupted in case of leukemic transformation. In addition, HLA-G expressed in leukemic cells contributes to the uncontrolled proliferation of the leukemic cell by protecting the leukemic cell from NK-mediated lysis and apoptosis. Few studies have been reported that the balance of inflammation during allo-SCT is also mediated by cytokines, which stimulate inflammation by proinflammatory cytokines as well as suppress inflammation by anti-inflammatory cytokines and sHLA-G.
Aims: The aim of the present study was to investigate the role of cytokines and sHLA-G levels measured at five different time points in children with acute leukemia undergoing allo-SCT.
Methods: This was a prospective longitudinal cohort study. A total of 41 patients with acute leukemia were recruited in this study. Among them, 26 consecutive patients were examined during the diagnosis of acute leukemia and in the remission period before transplantation (PreTx). The remaining 15 patients were included on the day of transplantation (Tx_0). A total of 41 patients with acute leukemia were also examined on the 14th ($PostTx_{14}$) and 28th ($PostTx_{28}$) days after transplantation. Serum levels of pro-inflammatory (IL-1, IL-2, IL-6, TNF-α), anti-inflammatory (IL-4, IL-10) cytokines and sHLA-G were measured by ELISA (Bioassay Technology, China). This study was approved by the Institutional Review Board. All statistical analyses were performed using SPSS 15.0 program.
Results: The median cytokine and sHLA-G levels in leukemia diagnosis and post-transplantation periods (Tx_0, $PostTx_{14}$, $PostTx_{28}$) were found

to be significantly higher than the cytokine and sHLA-G levels in the pre-transplantation period (p<0.05). Serum IL-1, IL-4, IL-10, and sHLA-G levels at diagnosis were significantly higher in children with relapse acute lymphoblastic leukemia (ALL) than in children without relapse ALL (p<0.05). Compared with patients who had pre-B-ALL and acute myeloblastic leukemia, median serum IL-2, IL-10, and sHLA-G levels were significantly higher in patients with T-ALL (p<0.05 for all). The sHLA-G serum level was strongly correlated with serum IL-4 (r=0.94) and IL-10 (r=0.92) levels (p<0.05). In the Tx_0 and $PostTx_{14}$ days, transplantation related complications, relapse, and mortality risk were found to be approximately 2.5 times higher in patients with elevated cytokines and sHLA-G levels.
Summary/Conclusion: Our results indicate that elevated anti-inflammatory cytokines and sHLA-G levels at diagnosis can be associated with relapse in pediatric ALL, and also elevated cytokines and sHLA-G levels during transplantation have a negative effect on survival in leukemia.

EP1245 SUBMYELOABLATIVE TBI-BASED CONDITIONING AND ALLOGENEIC HEMATOPOETIC CELL TRANSPLANTATION IN HIGH-RISK MYELOMA WITH EARLY PROGRESSION POST AUTOLOGOUS TRANSPLANTATION

E. K. Mai [1,*], T. Schmitt [1], A. Radujkovic [1], L. Koenig [2], H. Goldschmidt [1,3], A. D. Ho [1], T. Luft [1], C. Mueller-Tidow [1], P. Dreger [1], U. Hegenbart [1], S. O. Schoenland [1]

[1]Internal Medicine V, [2]Department of Radiation Oncology, University Hospital Heidelberg, [3]National Center for Tumor Diseases (NCT) Heidelberg, Heidelberg, Germany

Background: Allogeneic stem cell transplantation (alloSCT) in multiple myeloma (MM) is considered a treatment option in relapsed MM, especially in the presence of high-risk disease as indicated by early progression post upfront autologous transplantation (ASCT) or adverse cytogenetics.
Aims: There is no standard conditioning regimen, especially in patients considered to be melphalan-refractory and data on alloSCT in relapsed MM consist of heterogenous patient populations. We aimed to study a TBI-based submyeloablative conditioing regimen in relapsed high-risk MM.
Methods: Between September 2009 and December 2017, we investigated a submyeloablative conditioning regimen consisting of 8 Gy total body irradiation (TBI) and cyclophosphamide (total 80mg/kg bodyweight) followed by alloSCT in 32 consecutive patients with early progression post upfront ASCT.
Results: 90.6% of patients initially received novel agent-based induction therapy prior to ASCT. 58.3% had adverse cytogenetics (deletion17p, t(4;14), t(14;16) or gain 1q21 > 3 copies) and 79.2% had high-risk MM disease as defined by either International Staging System stage III, elevated LDH (above upper limit of the normal) or adverse cytogenetics and all patients had early disease progression (<24 months) post ASCT (median time to progression post ASCT: 300 days, range 52–664). Median lines of therapy prior to alloSCT reinduction was 1 (range 1-8) with a rate of very good partial response or better (≥VGPR) of 37.5%. Median time of hospitalization for conditioning and alloSCT was 29 days (range: 21 – 64 days). Toxicity of alloSCT during hospitalization was low and acceptable with only one early death (febrile neutropenia with multi-organ failure). Median days to engraftment of neutrophils and platelets of 14 days (range: 11 – 27 days) and 11 days (range: 8 – 34 days), respectively. Acute graft-versus-host disease (GvHD) occurred in 15 patients (20.0% ≥3 grade) and chronic GvHD in 18 patients (mild: 44.4%, moderate: 38.9%, severe: 16.7%). Response rates post alloSCT (between days 100-180) were ≥VGPR in 41.4% of patients. Maintenance therapy post alloSCT was applied in only 10.7% of patients. After a median follow-up of 76.7 months, median progression-free (PFS) and overall survival (OS) from alloSCT were 9.4 (95% CI: 5.2 – 13.7 months) and 28.8 months (95% CI: 8.0 - 49.5 months), 3- and 5-year OS rates were 50% and 30%, respectively. Non-relapse mortality (NRM) was 12.5% at 1 and 3 years (95% CIs: 4 - 27% each).
Summary/Conclusion: Our study demonstrated an acceptable toxicity profile, low NRM and a small fraction of high-risk patients achieving long-term disease control with 8 Gy TBI / cyclophosphamide conditioning prior to alloSCT in a homogenous cohort of MM with early relapse post upfront ASCT. The role of alloSCT in high-risk, relapsed MM deserves further investigation with optimized reinduction, conditioning and maintenance therapies.

EP1246 G-CSF-PRIMED PERIPHERAL BLOOD STEM CELL HAPLOIDENTICAL TRANSPLANTATION COULD ACHIEVE SATISFACTORY CLINICAL OUTCOMES FOR ACUTE LEUKEMIA PATIENTS IN THE FIRST COMPLETE REMISSION: A REGISTERED STUDY

Y. Ma [1,*], X. Mo [2], X. Huang [3]

[1]Hematology, Peking University, Peking University of People's hospital, Peking University Institute of Hematology, [2]Hematology, Peking University, Peking University Institute of Hematology, Beijing, [3]Hematology, Peking University, Peking University Institute of Hematology, Beijing, China

Background: G-CSF-mobilized peripheral blood (G-PB) harvest is the predominant graft for identical sibling donor and unrelated donor allogeneic hematopoietic stem cell transplantation (HSCT) recipients, but it was controversial in haploidentical related donor (HID) HSCT.
Aims: In this registry study, we aimed to identify the efficacy of HID G-PB HSCT (HID-PBSCT) for acute leukemia (AL) patients in first complete remission (CR1). Also, we reported the outcomes for the use of G-PB grafts in comparison with the combination of G-BM and G-PB grafts in HID HSCT recipients.
Methods: Sixty-seven AL patients in CR1 who received HID-PBSCT were recruited at Institute of Hematology, Peking University. Patients who received haploidentical HSCT using the combination of G-BM and G-PB harvests in the same period were enrolled as controls (n=392).
Results: The median time from HSCT to neutrophil and platelet engraftment was 12 days (range, 9-19 days) and 12 days (range, 8-171 days), respectively. The 28-day cumulative incidence of neutrophil and platelet engraftment after HSCT was 98.5% and 95.5%, respectively. The cumulative incidences of grade II-IV and grade III-IV acute graft-versus-host disease (GVHD) were 29.9% (95%CI 18.8%>40.9%) and 7.5% (95%CI 1.1%>13.8%), respectively. The cumulative incidences of total and moderate-severe chronic GVHD were 54.9% (95%CI 40.9%>68.8%) and 17.4% (95%CI 6.7%>28.0%), respectively. The cumulative incidences of relapse and non-relapse mortality were 13.9% (95%CI 5.4%>22.5%) and 3.4% (95%CI 0-8.1%), respectively. The probabilities of overall survival (OS) and leukemia-free survival (LFS) were 84.7% (95%CI 74.7%>94.7%) and 82.7% (95%CI 73.3%>92.1%) respectively. Compared with the HID HSCT recipients using the combination of G-BM and G-PB grafts, the engraftments of neutrophil and platelet were both significantly faster for the G-PB group, and the other clinical outcomes were all comparable between the groups. In multivariate analysis, graft types did not influence the clinical outcomes.
Summary/Conclusion: Overall, for the patients with AL CR1, G-PB graft could be considered an acceptable graft for HID HSCT recipients.

EP1247 MAINTENANCE THERAPY AFTER ALLOGENEIC HEMATOPOIETIC TRANSPLANT FOR ACUTE MYELOID LEUKEMIA: A SYSTEMATIC REVIEW AND META-ANALYSIS

O. Pasvolsky [1,2,*], S. Shimony [1], M. Yeshurun [1], L. Shargian [1], O. Wolach [1], P. Raanani [1], A. Gafter-Gvili [1], R. Gurion [1]

[1]Hematology, Beilinson Hospital, Petah Tikva, [2]Sackler School of Medicine, Tel Aviv University, Tel Aviv, Israel

Background: Allogeneic hematopoietic stem cell transplant (HSCT) is a standard therapy for patients with acute myeloid leukemia (AML), when the risk for relapse overweighs projected transplant related morbidity and mortality. Disease relapse remains the most common reason for transplant failure and patient death, and treatment of relapse remains extremely challenging. Reducing the risk of post-transplant relapse without unwanted toxicity by means of post-transplant maintenance therapy has recently been studied in several prospective studies.
Aims: We aimed to evaluate the efficacy and safety of maintenance therapy for AML after allogeneic HSCT.
Methods: Systematic review and meta-analysis of randomized controlled trials which compared maintenance therapy with observation or placebo in AML patients after allogeneic HSCT. The Cochrane Library, Pubmed, conference proceedings and references were searched until February 2021. Two reviewers appraised the quality of trials and extracted data. Primary outcome was overall survival (OS). Secondary outcomes

included relapse free survival (RFS), relapse rate and safety (including adverse events and GVHD).
Results: Our search yielded five trials conducted between the years 2009 and 2018, including 736 patients, all published in peer-reviewed journals. Maintenance therapy was comprised of tyrosine kinase inhibitors (TKI): sorafenib - 2 studies; midostaurin - 1 study, and hypomethylating agents (HMAs): decitabine and azacytidine - one study each. Characteristics of included trials are presented in Table 1. Data from four trials were available for analysis of OS. Maintenance after allogeneic HSCT was associated with an improved OS, HR=0.61 (95% CI 0.47-0.80, I^2=2%, 547 patients). Subgroup analyses by type of maintenance therapy also revealed advantage in OS with either TKI or HMA maintenance [HR=0.50 (95% CI 0.33-0.77, 3 trials, 345 patients) and HR=0.69 (95% CI 0.49-0.98, 2 trials, 391 patients), respectively]. Data from five trials were available for RFS analysis and showed improved RFS in the maintenance group compared with the control arm HR=0.51 [95% CI 0.40 - 0.66]. Relapse rate was significantly decreased in the maintenance arm compared to the control arm, RR=0.41 (95% CI 0.20-0.88, 4 trials, 668 patients).
Regarding safety, three trials reported grade 3 or 4 adverse events. The risk of any grade 3 or 4 adverse events did not increase with the addition of maintenance after allogeneic HSCT, RR=1.0 (95% CI 0.83-1.20, 464 patients). There was no difference between the maintenance and control arms in the rate of all infections or grade 3 or 4 infections [(RR=0.98 (95% CI 0.83-1.16, I2=0%, 3 trials, 585 patients) and (RR=0.96 (95% CI 0.68-1.36, 3 trials, 464 patients), respectively]. There was no difference between the two arms in grade 3 or 4 thrombocytopenia or in grade 3 or 4 neutropenia. No difference was noted between the two arms regarding grade 2-4 acute GVHD, mild-moderate chronic GVHD or severe chronic GVHD.

Table 1. Characteristics of included trials

Study	AML type eligibility criteria	Start of maintenance post transplant (days)	Primary endpoint	Length of follow up (months)	Treatment regimen	Num. of patients included	Age (Median, range)	Sex (male, %)
Burchert 2020	Flt3-ITD mutated AML	60-100	RFS	42	sorafenib	43	54 (24-75)	42%
					placebo	40	54 (19-76)	58%
Maziarz 2020	Flt3-ITD mutated AML	28-60	RFS	24	midostaurin	30	48 (20-61)	53%
					SOC	30	6 (20-68)5	60%
Xuan 2020	Flt3-ITD mutated AML	30-60	relapse rate	21	sorafenib	100	35 (26-42)	50%
					SOC	102	35 (26-43)	51%
Gao 2020	High risk AML	60-100	relapse rate	28	decitabine + GCSF	102	30 (3-62)	56%
					SOC	102	28 (2-52)	60%
Oran 2020	High risk AML/MDS	42-100	RFS	52	azacitidine	93	57 (19-72)	59%
					SOC	94	58 (20-75)	61%

AML – acute myeloid leukemia; RFS – relapse free survival; GCSF - granulocyte colony stimulating factor; SOC – standard of care; MDS – myelodysplatic syndrome.

Summary/Conclusion: Our meta-analysis shows that post-transplant maintenance therapy in AML patients is effective in decreasing relapse rate and improving RFS and OS, with a satisfactory safety profile.

EP1248 OUTCOME OF ALLOGENEIC HEMATOPOIETIC STEM CELL TRANSPLANTATION FOR AML PATIENTS WITH 11P15/NUP98 REARRANGEMENT

S. Yan [1,*], D. Liu [1], Y. Zhao [1], J. Zhang [1], J. Zhou [1], R. Sun [1], Z. Wei [1], M. Xiong [1], Y. Lu [1], X. Cao [1]

[1]BMT, Hebei Yanda Lu Daopei Hospital, Yan Jiao economic development zone,lang fang, China

Background: Patients with acute myeloid leukemia and 11p15/NUP98 gene rearrangement (NUP98-r AML) treated with chemotherapy alone generally show poor overall survival (OS) and prognosis, with less than 50% OS and leukemia-free survival; some reports with median OS of less than 1 year. In cases of NUP98-r AML with co-existing FLT3 mutation, treatment with chemotherapy alone has demonstrated poor prognosis, with only 28% of 3-year OS.
Aims: To study clinical outcome of patients with NUP98-r AML after allogeneic hematopoietic stem cell transplantation (HSCT).
Methods: We conducted retrospective assessment and outcome analysis in a cohort of 34 patients with NUP98-r AML treated with allogeneic HSCT at the Hebei Yanda Lu Daopei Hospital (from July 1, 2019 to February 1, 2021). Six types of NUP98 fusion gene partners were identified by PCR/FISH as follows: NSD1 (n=23), HOXA9 (n=5), KDM5A (n=4), HOXD13 (n=1), and LNP1 (n=1); 18 cases were identified with FT3 mutation. Median age was 16 years old (range from 1 to 61 years). Majority of patients underwent haplo-identical HSCT (n=31), while the rest received matched sibling donor HSCT (n=3). The conditioning regimens were based on Bu/Cy (n=31) and TBI/Cy (n=3). Patients received antithymocyte globulin, cyclosporine, mycophenolate mofetil, or methotrexate for graft-versus-host disease (GVHD) prophylaxis. Dosage of infused mononuclear cells and CD34+ cells were 10.5±3.2x10^8 /Kg and 5.5±2.3 x10^6 /Kg, respectively.
Results: In this study, the median follow-up time was 9 months (3-30). All 34 patients in this cohort achieved myeloid engraftment with median time for ANC above 0.5x10^9 /L on Day 14 (10-23). The median time for platelet count to exceed 20x10^9 /L was Day 13 (7-58) in 32 patients, with 2 patients remained thrombocytopenic. The incidence of acute GVHD (n=9) and chronic GVHD (n=7) was 26% and 20.5%, respectively. The average survival rate was 24±2 months (95% CI=19-27 months). Two-year OS and LFS were 75.9+7.5% and 75.6± 7.6%, respectively. In this cohort of NUP98-r AML patients, the subgroup with co-existing FLT3 mutation (n=18) has demonstrated an OS of 71.3 ± 10.9%, as compared to 81.3±9.8% in the subgroup without FLT3-mutation (n=16). Our data showed better survival of FLT3-positive patients in NUP98-rAML after allogeneic HSCT as compared to anecdotal survival data with chemotherapy alone. The OS of the subgroup without minimal residual disease (MRD negative, n=13) was 84.6±10.0%, versus 70.3±10.3% in the group with positive MRD (n=21). In this cohort of NUP98-r AML patients, the mortality rate within 100 days after HSCT was 11.7% (n=4). The causes of death (total of 8 patients) include relapse of disease (n=4), Grade IV GVHD (n=3), thrombotic microangiopathy (n=1) and subdural hemorrhage (n=1). Among the 5 patients developed relapse of disease, one with molecular relapse and responded well after chemotherapy and second allogeneic HSCT, while the other 4 relapsed patients expired.
Summary/Conclusion: This study has demonstrated encouraging clinical outcomes for NUP98-r AML patients after treatment with allogeneic HSCT, as compared to anecdotal data with chemotherapy alone in the literature, particularly in the clinical setting of coexisting FLT3 mutation. Larger clinical study is required to confirm this result.

EP1249 EFFECT OF HEMATOPOIETIC STEM CELL TRANSPLANTATION(HSCT)IN SEVERE CONGENITAL NEUTROPENIA

S. Zhou [1], M. xiong [1,*], J. zhu [1], G. wang [1], H. wang [1], W. ling [1]

[1]Hebei Yanda Ludaopei Hospital, LangFang, China

Background: Severe congenital neutropenia(SCN) is a preleukemic bone marrow failure syndrome.Patients are at considerable risk of infections and evolving into leukemia or myelodysplastic syndrome (MDS). According to the reports of international that allogeneic hematopoietic stem cell transplantation (HSCT) is the curative treatment of SCN, but data on outcome about that are scarce in our country.
Aims: The aim of the present study is to clarify the cficacy of HSCT on patients with severe congenital neutropenia(SCN).
Methods: We retrospectively analyzed clinical characteristics about total 11 patients with SCN who underwent HSCT in our hospital from April 2015 to July 2020. ALL patients with EL. ANE-gene mutation. The median age was 3 (1-14) years. Male to female was 7:4.The median discase course from diagnosis to transplant was 37 (8-165) months.Six patients received umbilical cord blood-HSCT,the conditioning regimen was:Fludarabine(40mg/m^2/d×5days)+Ara-c(2g/m^2/d×5days)+Bu(0.8mg-1.2mg/KgQ6h×4days)+cyclophosphamide(1.8g/m^2/d×2days)+ATG(Thymoglobuline,SANOFI,1.25mg/Kg/d×2days).Two patients underwent matched unrelated donor(MUD)-HSCT,two patients underwent Haplo-HSCT,and another one were sibling donor-HSCT,the conditioning regimen was:Ara-c(3g/m^2/d×3days)+Bu(0.8mg-1.2mg/Kg Q6h×4days)+Fludarabine(40mg/m^2/d×4days)+ATG(ATG-Fresenius S,4mg/Kg/d×4days or p-ALG 20mg/Kg/d×2days for sibling donor-HSCT).For GVHD prophylaxis,CsA/tacrolimus plus MTX were used.
Results: All of the 11 patients tolerated pretreatment successfully. the total implantation rate was 100%.The median time of neutrophil sngraftment was 11 (9-16) days;the median time of platelet engraftment was 12(9-36)days.During the median follow-up period of 25 (range,3-70 months) months:the incidence of CMV was 72.7%;EBV DNA load of all patients who infected with EBV were undetectable after transplant. Grade II-IVaGVHD occurred in 4 cases,the probability was 36.3%. Two cases had cGVHD. Two patients died of GVHD,and the rest of the patients survived, with an overall survival rate (OS) were 81.81%.
Summary/Conclusion: Our results have shown that HSCT has higher implantationrate and overall survival rate,and may become a viable therapeutic option. Nevertheless, because of the transplant-related

death, a careful selection of HSCT candidates and the time point for HSCT should be undertaken.

EP1250 OUTPATIENT PROGRAM BASED ON TELEMEDICINE IS A GOOD OPTION TO MANAGE PRE-ENGRAFTMENT PHASE IN MYELOMA MULTIPLE PATIENTS UNDERGOING AUTOLOGOUS STEM CELL TRANSPLANTATION

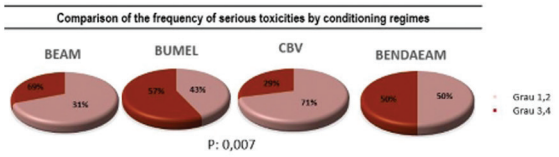
P. Gonzalez-Sierra [1,*], E. López Fernández [1], S. de Linares Fernández [1], L. Moratalla Lopez [1], J. Muñoz Ballester [1], Z. Mesa Morales [1], M. Jurado Chacón [1]

[1]*Hematology, Uniiversity Hospital Virgen de las Nieves of Granada, Granada, Spain*

Background: Autologous Hematopoietic Stem Cell Transplantation (ASCT) is a therapeutic procedure used as consolidation therapy in different acute hemopathies, especially Multiple Myeloma (MM) and Lymphomas.
There are centers with experience in home care programs that avoid hospital admission partially (aplasia phase) or total (conditioning and infussion day include). This model of attencion requires the support of visits from health personnel, mainly home nursing.
In our center we have designed a mixed care model based on telemedicine and visits to an outpatient clinic twice a week, named e-outpatient. For monitoring during the stay at home we have developed a mobile app (THAD® app) with different utilities (registry of constants, treatment adherence, videoconference) that allows us to control the patient's condition twentyfour hours/seven days.
Aims: Our main objective is to describe the efficacy and safety of this type of care in MM patients undergoing ASCT included in the e-outpatient program.
Methods: A one center retrospective study, with data obtained from the electronic clinical history, in our center from 2015 to 2020. Statistical analysis has been performed with IBM SPSS.19.
Results: During the study period, 112 patients with a diagnosis of MM underwent ASCT, 43 of them (38.4%) were included in the e-outpatient program. The characteristics of the patients are listed in Table 1.
The median days of hospital admission for the included patients was 5 (0-25). The median neutrophil and platelet engraftment was 13 and 15 days. Median red blood cell and platelet concentrates were 0 and 2 respectively. None of the patients required parenteral nutrition during the procedure. The hospital readmission rate was 27.9%. The causes of readmission were mainly fever (58.3%) and Grade III-IV gastrointestinal toxicity (41.7%).
The incidence of febrile syndrome in our series was 65.1% (28/43). The median number of empirical antibiotics used was 0 (0-3). The infectious syndromes reported were febrile neutropenia without focus (25 episodes), pulmonary aspergillosis (1 episode), Escherichia Coli bacteremia (1 episode) and soft tissue infection (1 episode). No deaths have been registered.

Table 1. Characteristics of patients included in e-outpatient program (n=43)

Gender (Male)	81.8%
Mean age (years)	57.1 (40-69)
Response pre-ASCT	
• Complete Response	12 (27.9%)
• Very Good Partial Response	19 (44.1%)
• Partial Response	9 (20.9%)
• Stable Disease	3 (7.1%)
ISS	
• Stage I	13 (30.2%)
• Stage II	16 (37.2%)
• Stage II	14 (32.6%)
Mean of Cells Infused	3.01(2.02-5.20)
Conditioning	
• MEL200	28 (65.1%)
• MEL140	12 (27.9%)
• BUMEL	3 (7%)



Summary/Conclusion: 1. The use of telemedicine in home care programs is an opportunity to reduce the need for health support resources at home.
2. Our e-outpatient program shows a significant reduction in the days of admission (median 5) compared to conventional hospitalization (3 weeks), allowing less exposure to nosocomial germs, a lower cost associated with admission and a better emotional adaptation to the process of the patient and their caregiver.
3. The safety profile is adequate, with an acceptable incidence of infectious complications, with a transplant-related mortality of 0%.
4. Readmission rate (28.9%) is relatively high compared to similar outpatient programs. The combination of technological tools with home care can be a good option to reduce hospital readmissions.

EP1251 INCIDENCE OF EARLY TOXICITIES AND MORTALITY AFTER 4 TYPES OF CONDITIONING REGIMENS FOR AUTOLOGOUS HEMATOPOIETIC STEM CELL TRANSPLANTATION IN PATIENTS WITH LYMPHOMAS: A RETROSPECTIVE ANALYSIS.

J. M. Carranza Jara [1,*], A. Costa Cordeiro [1], A. Meneses Ferreira [1], I. Goncalves Ramos [1], L. Netto Chaer [1], M. Junqueira Atanazio [1], L. Caroline Mariano [1], V. Rocha [1]

[1]*Division of Hematology. Transfusion and Cell Therapy. University of São Paulo, Hospital das Clínicas, São paulo, Brazil*

Background: High-dose therapy (HDT) followed by autologous stem cell transplantation (ASCT) is the standard treatment for relapsed or refractory lymphomas. Until recently, carmustine, etoposide, cytarabine and melphalan (BEAM) was the most used conditioning regimen in this setting, given its acceptable efficacy and tolerability. Recent supply and cost issues for this agent have created an urgent need for alternative conditioning regimens. Toxicity evaluation of alternative conditioning regimens to BEAM may guide the choice of a regimen equally effective and at least equally tolerated, achieving adequate lymphoma control, resulting in similar overall survival.
Aims: To compare toxicities of BEAM (Carmustine, Etoposide, Citarabina, Melphalan), CBV (Carmustine, Etoposide, Cyclophosphamide), BendaEAM (Bendamustine, Etoposide, Citarabina, Melphalan) and BuMel (Busulfan, Melphalan) conditioning regimens used for ASCT in patients with relapsed/refractory non-Hodgkin (NHL) and Hodgkin lymphomas(HL).
Methods: From January 2014 to December 2020, we included patients aged 18 years or older, diagnosed with NHL or HL who underwent ASCT at Hospital das Clinicas da Faculdade de Medicina de Sao Paulo, Brazil. Frequencies of serious toxicities (Grade III-IV CTCAE v4.0) among conditioning schemes were compared using the Fisher's exact test. For the toxicity analysis, a univariate logistic regression model was conducted, and the effect size was presented as odds ratio. Overall survival curves at 100 days and 1 year were determined using the Kaplan Meier method. The assessment of risk factors for mortality was conducted using the multivariate Cox regression method, the effect size on the outcome was presented as a hazard ratio.
Results: Two hundred and thirteen patients were included (BuMel 42, BendaEAM 38, CBV 65 BEAM 68), of which 56% were men, with a median age of 43 years (IQR 19-74), 93% had a KPS> 80%, and 75% had a complete response prior ASCT. Regarding toxicities grade III and IV: Mucositis was frequently observed in the BuMel regimen 50% and BendaEAM 25%, compared to CBV 10% and BEAM 20%. Diarrhea was present in 30% in the BendaEAM, 28% in the CBV and less frequent in the other groups (BEAM 18% and BuMel 11%); renal toxicity was only presented in the BendaEAM (50%). Febril neutropenia was observed in all the regimens, mainly in the BendaEAM (92%) and BEAM (81%) compared with CBV (76%) and BuMel 67%. In the univariate logistic regression, there was an association of grade III- IV toxicities with type of conditioning regimens (p=0.007) In fact, BuMel (OR 2,984 P0.007) and BendaEAM (OR 2.23 P 0.054) were associated with a greater probability of developing grade III-IV toxicity (Figure 1). Median follow-up of the cohort was 27.51 months (0,75-81,40). Estimated overall survival was 95% at 100 days and 79% at 1 year. The following factors were associated with an increased risk of one year mortality: Ann Arbor stage IV at diagnosis (HR 1.81; P=0.028), disease response at transplant (CR>2) or second partial remission (PR) (HR 3.94; P=0.004) and the use of BendaEAM conditioning (HR 2.86; P=0.05).

Univariate logistic regression Any grade 3 and 4 toxicity (oral mucositis, nausea, vomiting, diarrhea, liver and kidney toxicity)

	OR	p-value	IC 95%	Sig
BEAM	1			
BuMel	2.984	0.007	1.342-6.634	***
CBV	0.924	0.836	0.44-1.941	
BendaEAM	2.238	0.054	0.988-5.071	*

*** p<.01, ** p<.05, * p<.1

Summary/Conclusion: BuMel and BendaEAM were associated with higher rate of grade III and IV toxicity however type of conditioning regimen was not ass associated with early mortality Carmustine based conditioning regimens appear to be less toxic and safer. BendaEAM was associated with an increased risk for death at 1 year after autologous transplantation for LNH and LH, but probably related to relapse Longer follow-up is needed to draw definitive conclusions on the use of BendaEAM to control lymphoma relapse.

EP1252 DEVELOPMENT AND VALIDATION OF A RISK SCORE SYSTEM FOR SKIN AND SOFT TISSUE INFECTIONS IN ALLOGENEIC HAEMATOPOIETIC STEM CELL TRANSPLANTATION RECIPIENTS

S. Chong [1,2,3,4,*], Y. He [1,2,3,4], X.-L. Zhu [1,2,3,4], H.-X. Fu [1,2,3,4], F.-R. Wang [1,2,3,4], X.-D. Mo [1,2,3,4], Y. Wang [1,2,3,4], X.-Y. Zhao [1,2,3,4], W. Han [1,2,3,4], Y.-Y. [1]Peking University Institute of Hematology, Peking University People's Hospital, [2]Collaborative Innovation Center of Hematology, Peking University, [3]Beijing Key Laboratory of Hematopoietic Stem Cell Transplantation, [4]National Clinical Research Center for Hematologic Disease, Beijing, China

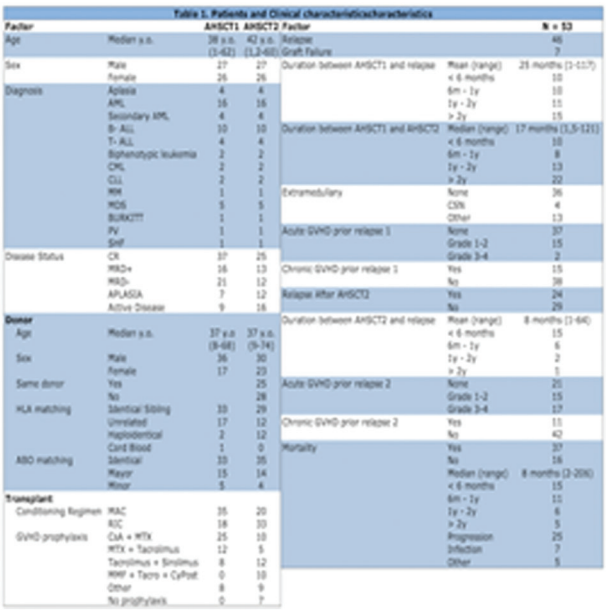
Background: Skin and soft tissue infections (SSTIs) refer to infections occurring in the skin, subcutaneous tissue, fascia and muscle. As immunocompromised hosts, transplantation patients are more likely to develop SSTIs. According to the Infectious Diseases Society of America (IDSA), SSTIs in immunocompromised patients should all be classified as severe. Several previous studies have analysed the epidemiology and risk factors of SSTIs in solid organ transplantation (OST) recipients. However, to date, no study has focused on SSTIs in haematopoietic stem cell transplantation (HSCT) recipients. The common pathogens, occurrence periods and anatomic sites and clinical outcomes of SSTIs in HSCT population remain unclear.
Aims: This retrospective study investigated the frequency, occurrence time, common anatomic locations, comorbidities and clinical outcomes of allo-HSCT recipients with SSTIs. Moreover, a prognostic model for allo-HSCT recipients with SSTIs was developed.
Methods: Allo-HSCT recipients developing SSTIs from pretreatment to 180 days after transplantation were included in our study. Pathogens including bacterium, fungus and virus were all involved. The patients' baseline characteristics, infection profiles, synchronous comorbidities and clinical outcomes were recorded in. Comorbidity referred to diseases occurring within 7 days before and after the SSTI course. Acute kidney injury was defined as serum creatinine increased 1.5–1.9 times baseline or ≥0.3 mg/dl, or urine output <0.5 ml/kg/h for over 6 hours. Patients involved were divided into two groups according to their outcome: survivors and nonsurvivors at 12 months after HSCT. We compared the differences between the two groups and developed a prognostic model.
Results: Two hundred twelve allo-HSCT recipients with 231 SSTIs were included from January 2005 to December 2019 at the Peking University Institute of Haematology, with a 12-month mortality of 27.4% (58/221). The median onset time of SSTI after transplantation was 10 days (from -9 to 179). Anal infection was the most common (19.4%, 45/231), while maxillofacial infection ranked second (18.6%, 43/231) and infection due to vascular devices ranked third (16.5%, 38/231). Pneumonia was the most common comorbidity of SSTI (23.8%, 55/231). Recipients who had undergone allo-HSCT after January 2014 were grouped as the derivation cohort, while others were grouped as the validation cohort. Failure of platelet engraftment, newly acquired or developed pneumonia and combined acute kidney injury were independent risk factors for 12-month death. According to the modelling coefficient magnitude of each factor, a risk score system was established (Table 1). The risk score was 1×failure of platelet engraftment+1.5×acute kidney injury+1×pneumonia. The patients' 12-month mortality rose with the score increasing. The 12-month mortality rates at 0 points, 1 point and 1.5 points were 12.1%, 44.7% and 77.8%, respectively. The bootstrap internal and external validation showed good discrimination power with AUCs of 0.817 (95CI: 0.692-0.866) and 0.749 (95CI: 0.625-0.855) in the derivation and validation cohorts, respectively. Additionally, the calibration plot demonstrated high agreement between the estimated and observed risks of 12-month death in the study population. Furthermore, decision curve analysis indicated considerable clinical benefit for patients.

Table 1. Coefficients and points for the rate risk score system for SSTIs in allo-HSCT recipients using independent variables in the derivation cohort.

Variables	Multivariable analysis			
	OR (95% CI)	P	Coefficients	Points
Failure of platelet engraftment	4.935 (1.668~14.600)	0.004	1.596	1
Acute kidney injury	12.943 (2.299~72.873)	0.004	2.561	1.5
Newly acquired or developed pneumonia	5.408 (2.023~14.456)	0.001	1.688	1

Summary/Conclusion: SSTIs are common complications in allo-HSCT recipients. Failure of platelet engraftment, combined pneumonia and acute kidney injury can predict the prognosis of patients.



EP1253 SECOND ALLOGENEIC HEMATOPOIETIC STEM CELL TRANSPLANTATION: SINGLE CENTER EXPERIENCE IN SALAMANCA, SPAIN.

F. Peña Muñoz [1,*], M. Lopez Parra [1], E. Perez Lopez [1], M. Cabrero Calvo [1], A. Martin Lopez [1], L. Vazquez Lopez [1], F. Sanchez-Guijo Martin [1], L. G. Roman Molano [1], D. Palomino Mendoza [1], M. Baile Gonzalez [1], M. Cortes Rodriguez [1], A. Cabero Martinez [1], A. Avendaño Pita [1], A. Navarro Bailon [1], L. Lopez Corral [1], D. Caballero [1]

[1]Hematology, Hospital Clinico de Salamanca, Salamanca, Spain

Background: Allogeneic hematopoietic stem cell transplantation (AHSCT) is a curative option in hematological malignancies. However, relapse is the first cause of transplant failure. Risk of relapse depends on disease and transplant characteristics [1-4].
The best approach after relapse hasn´t been defined and as prognosis is so poor, AHSCT2 is considered for some patients mainly if relapse after 6 months and are fit enough. Many questions remain regarding the best strategy for AHSCT2.
Aims: The aim of this study was to analyze our center´s experience in patients receiving AHSCT2 in order to identify possible factors to improve management and OS in these patients.
Methods: From 1995, 1119 patients have received an AHSCT in our Unit. Of them, 53 (4.7%) received AHSCT2. A retrospective analysis of data included in our Transplant data base was performed. Statistical analysis was performed with SPSS.
Results: Patients' characteristics are summarized in Table 1. Median age at AHSCT2 was 35 years old (range 1 to 65). Mean time between AHSCT1 and relapse was 25 months (range 1 to 117) and median time between AHSCTs was 17 months (range 1.5 to 121) Cause of AHSCT2 was relapse for 46/53 (87%) patients and graft failure for 7/53 (13%), of this latter 6/7 (86%) are still alive with graft recovery.
Most frequent diagnosis was primary acute leukemia (57%) (AML= 30%, B- ALL= 20% and T- ALL= 7%). Disease status at AHSCT2 was CR 25/53 (47%) (12/25 (48%) MRD negative), aplasia 12/53 (23%) and active disease (AD) in 16/53 (30%) respectively. Conditioning regimen was Myeloablative (MAC) in 35/53 (66%) for AHSCT 1 and in 20/53 (38%) of the patients for AHSCT2.
Donor was the same in 25/53 (47%) of the transplants. Donor was HLA identical sibling in 29/53 (55%), unrelated in 12/53 (23%) and haploidentical in 12/53 (23%) respectively.

With a median follow-up of 11 months (range 2 to 253) and 54 months (range 3 to 253) for surviving patients, 37 patients have died and 16 (30%) are still alive, 15/16 (94%) disease free. 12/37 patients die due to causes different from progression with Non relapse mortality of 32%.
The 2- and 4-years OS was 39% (SD ± 0.070) and 34% (SD ± 0.069) and the 2- and 4- years PFS was 35% (SD ± 0.067) and 33% (SD ± 0.066) respectively.
Thirty- two (60%) patients presented acute GVHD (aGVHD), 97% involving skin and/or gut. 11/53 (21%) presented Chronic GVDH after AHSCT2.
In the multivariate analysis, the variables which influenced OS were CR vs AD at AHSCT2 (HR 7.96, 95% CI: 2.67–23.78, p <0.001), MAC vs RIC (HR 7.79, 95% CI: 2.55–23.85, p <0.001) and relapse <25 months vs >25 months after AHSCT1 (HR 18.16, 95% CI: 2.03–162.178, p=0.009). HLA matching had no statistically significant impact on OS Identical sibling vs Haploidentical (HR 2.32, 95% CI: 0.581–9.26, p= 0.234), possibly related with our small sample.

Summary/Conclusion: Our results in more than 1000 transplant demonstrated that AHSCT2 is rarely indicated and confirm the poor prognosis reported by multicenter and single center experiences. Despite new management strategies for allogeneic transplants, mortality and relapse rates after AHSCT2 remain high. However, is a good treatment option for patients with late relapses and for those who achieve CR before second transplant. For earlier relapses and no chemosensitive patients, other options are required. Efforts should be made in identifying new strategies for these patients.

EP1254 THE IMPACT OF MEASURABLE RESIDUAL DISEASE POSITIVITY BEFORE ALLOGENEIC HEMATOPOIETIC CELL TRANSPLANTATION IN PATIENTS WITH PH(-) ACUTE LYMPHOBLASTIC LEUKEMIA: A SINGLE CENTER EXPERIENCE

V. Douka [1], A. Papalexandri [1,*], D. Mallouri [1], M. Iskas [1], E. Gavriilaki [1], A. Lazaridou [1], C. Demosthenoous [1], S. Dimou [1], S. Finitsis [2], R. Avramidou [1], M. Papathanasiou [1], A. Syrigou [1], I. Batsis [1], A. Marvaki [1], T. Touloumenidou [1], V. Tachynopoulou [1], A. Lalayanni [1], C. Vadikolia [1], I. Sakellari [1], A. Anagnostopoulos [1]

[1]Hematology Department and BMT Unit, G.Papanikolaou Hospital, [2]Aristotle University of Thessaloniki, Thessaloniki, Greece

Background: Measurable Residual Disease (MRD) in Ph negative (-) Acute Lymphoblastic Leukemia (ALL) patients before allogeneic hematopoietic cell transplantation (allo-HCT) has been proposed as a major risk factor for imminent relapse.
Aims: To study the prognostic value of pre-transplantation (pre-HCT) MRD in Ph(-) ALL adjusted to other disease characteristics.
Methods: Sixty-seven consecutive patients who underwent allo-HCT in our JACIE center between 2009-2020 for B- (39), T- (24) ALL or Mixed phenotype acute leukemia (MPAL,4) were evaluated. Eight color flow cytometry (FC) MRD analysis was performed pre-HCT and post-HCT in 3-month intervals. FC-MRD was considered positive if >=0.01%. In case of positive MRD pre-HCT, further treatment, mostly chemotherapy, was administered. In case of post-HCT MRD positivity, immunosuppression was reduced promptly.
Results: Thirty-one out of 67 transplants were matched unrelated, 27 sibling and 9 alternative ones. Most patients received 14,4 Gy total body irradiation (TBI) in conditioning regimen (53/67). Median age was 31 (14-57) years and patients were transplanted in first CR1,44/67 or >CR1, 23/67. Median follow-up was 26 (2-138) months.Overall, 8 presented hematological relapse out of 16 patients with positive MRD post-HCT,successfully reversed by immunotherapeutic intervention. On univariate analysis positive pre-HCT MRD was associated with shorter Time To Progression (TTP) (HR: 8.75 CI95%: 2.06-37.06, p=0.03), shorter Relapse Free Survival (RFS) (HR: 2.33 CI95%: 1.05-5.18, p<0.05) but not Overall Survival (OS). On multivariate analysis adjusted for transplant characteristics only the association with TTP persisted. We also studied the interaction between pre-HCT MRD and other transplant characteristics (age, type of transplant, cytogenetics, disease phase at transplant and conditioning regimen) on TTP, RFS and OS. We found that in the subgroup with disease phase >CR1, patients with positive pre-HCT MRD had shorter TTP (HR: 11.5, CI95%:1.78-74.21%, p=0.01) and shorter RFS (HR: 5.42, CI95%:1.61-18.18%, p=0.006) compared to patients with negative pre-HCT MRD. These associations did not occur in the subgroup transplanted in CR1. Comparing outcome of patients in CR1 vs >CR1, 4-year RFS and OS were: 61.4% [CI95%:44.5-74.5] and 61.4% [CI95%:44.5-74.5%] for CR1 and 44.2% [CI95%:20.6-65.6%] and 56.1% [CI95%:26.3-77.9%] for >CR1 respectively.
Summary/Conclusion: Detectable pre-HCT MRD in patients transplanted in >CR1 is associated to worse outcomes and remains a major failure barrier for transplant. In our small study population, it seems that allo-HCT may overcome the chemo-resistance of residual disease in CR1 performed transplants, as outcome is not related to pre-HCT MRD status. MRD post-HCT is an important tool and its monitoring with sensitive techniques could detect potentially high-risk patients who may benefit from abrupt cessation of immunosuppression. In the current era, the role of novel agents should be defined in large prospective studies in order to optimize the transplant outcome.

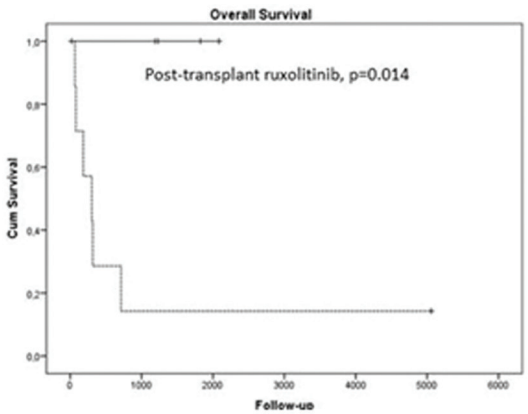
EP1255 PERIPHERAL BLOOD STEM CELL APHERESIS IN LOW-WEIGHT HEALTHY DONORS: A SINGLE CENTRE EXPERIENCE

M. Benakli [1,*], F. Mehdid [1], N. Rahmoune [1], M. Baazizi [1], D. Ait Ouali [1], R. Belhadj [1], H. Bouarab [1], F. Harieche [1], R.-M. Hamladji [1], R. Ahmed Nacer [1]

[1]Hematology-Bone marrow transplantation, Pierre and Marie Curie Center, Algiers, Algeria

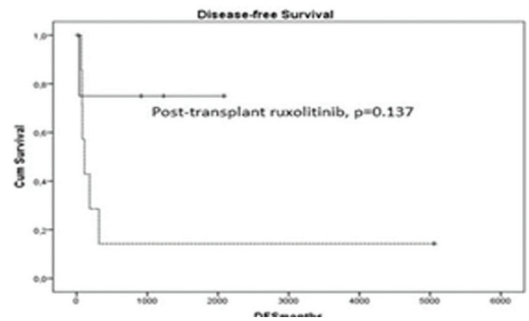
Background: The peripheral blood stem cells (PBSC) are the source of haematopoietic stem cells (HSC) currently most used in the allograft of malignant and non malignant haematological diseases in our practice. The procedure of mobilization and collection is similar for adult and children. However, many technical sides must be taken into account in the paediatric apheresis because of extracorporal volume related to the weak weight of the donors.
Aims: We report our experience of collection of PBSC in pediatric sibling donors weighing 20 kg or less over one 14 years period for allogeneic stem cell transplantation.
Methods: From January 2005 to December 2018, 29 children donors (17 boys and 12 girls) weighing 20 kg or less had a collection of PBSC by technic of apheresis after parental consent. The median age and weight at the time of apheresis were 5 years (range:3-9) and 18 kg (range: 13-20), respectively. Stem cell mobilization was obtained by once-daily subcutaneous injections of G-CSF (10µg/kg/day) for five consecutive days. PBSC were collected using a continuous flow blood cell separator (Cobe spectra or Optia) at the 5th day and repeated, if necessary, at the 6th and 7th days.
Results: A total of 54 PBSC were performed. Insertion of a femoral catheter was avoided in 58,6% of children. A single apheresis was sufficient to obtain the required cell number in 10 cases (34,4%). Two apheresis were performed on consecutive days in 13 cases (44,8%) and 3 apheresis were performed in 6 cases (20,6%). Five donors (17%) received transfusion of red blood cells before the second or third harvests. Insertion

of a femoral central venous line was necessary in 17 children (58,6%). No child experienced any collection-related occlusion or infection. The median duration of the apheresis per donor, was 223 mn (range: 115-351) with a median blood flow rate of 25 ml/mn (range: 20-50) using a median ACD-A of 375 ml (range: 128-717). The median cell yield per apheresis was 5,9×106 CD34+cells/kg (0,58–24,64) recipient body weight (RBW) of whom 18 donors (62%) achieved the target CD34+ cell dose more than 4.106/kg. Males had a higher mean collected CD34+ cell yields (≥ 4.106/kg) than females (82% vs 33%). The mean ratio between donor and recipient (D/R) body weight was 0,74 (0,25-1,36). Donors with this ratio < 1 failed to reach CD34+ cell dose > 4.106/kg. Morbidity related to PBSC collections was low and 26 children (90%) expressed their willingness to donate again.
Summary/Conclusion: The results suggest that G-CSF mobilization and harvesting of PBSCs are safe and effective in low-weight pediatric donors. An efficient and well-experienced team of physicians and nurses involved in CVC positioning and apheresis is crucial to perform a safe PBSC collection in children donors weighing 20 kg or less. Males and D/R body weight ≥ 1 have a higher mean collected CD34+ cell yields.



EP1256 IMPROVED SURVIVAL IN MYELOFIBROSIS PATIENTS RECEIVING RUXOLITINIB POST ALLOGENEIC HEMATOPOIETIC CELL TRANSPLANTATION

I. Sakellari [1], E. Gavriilaki [1,*], D. Mallouri [1], A. Vardi [1], Z. Boussiou [1], A. Panteliadou [1], C. Varelas [1], A. Lazaridou [1], M. Masmanidou [1], D. Sotiropoulos [1], I. Mpatsis [1], A. Anagnostopoulos [1]



[1]Hematology & HCT Unit, General Hospital "George Papanikolaou", Thessaloniki, Greece, Thessaloniki, Greece

Background: Allogeneic hematopoietic cell transplantation (alloHCT) remains the only curative option of myelofibrosis. Despite intensified efforts to broaden alloHCT indications with better patient stratification, treating physicians are reluctant to refer patients for alloHCT in the era of JAK2 inihibitors.
Aims: We investigated the long-term safety and efficacy of alloHCT in patients with myelofibrosis
Methods: We retrospectively enrolled consecutive adult alloHCT recipients transplanted for myelofibrosis over the last two decades (2000-2020) at our JACIE-accredited center. We excluded patients transplanted with acute myeloid leukemia progression post myelofibrosis. Factors included in the analysis were: age, type of myelofibrosis (primary or secondary due to polycythemia vera/essential thrombocytosis), dynamic IPSS score, donor (sibling/unrelated), HLA matching, graft failure, acute (grade II-III) and chronic (according to NIH classification) GVHD, relapse, second alloHCT, bacterial, viral or fungal infections, spleen size and ruxolitinib administration before/after alloHCT.
Results: We studied 12 alloHCT recipients aged 53 (31-66) years, after a median of 42.8 (range 4.1-421) months from alloHCT. Median DIPSS was 3 (range 2-4). Seven patients suffered from primary myelofibrosis, while five from secondary. Eight were transplanted from a sibling donor, and 4 from an unrelated (2 matched and 2 mis-matched donors). All patients received peripheral blood stem cells graft, after myeloablative (5) or reduced intensity (7) conditioning regimens. Neutrophil engraftment was achieved in all patients (median 13, range 9-23 days), while platelet engraftment in 11/12 (median 16, range 10-146 days). Two patients developed graft failure and received second alloHCT with reduced intensity regimens.
Splenectomy was performed before alloHCT in 2 patients, and 7 months post-transplant in 1. Incidence of acute GVHD (grade 2-3) was 33% patients, while cumulative incidence of moderate chronic GVHD reached 58%. Two-year cumulative incidence of treatment-related mortality (TRM) was 34.6% Ruxolitinib was administered in patients transplanted after 2015: before alloHCT in 6/6 patients, and after alloHCT in 4/6 (2 for relapsed disease, 1 for splenomegaly and thrombocytopenia despite involved field radiation therapy, and 1 for moderate chronic GVHD). Patients that received ruxolitinib post-transplant did not suffer from TRM. Additionally, 2-year disease-free survival was 75% for patients that received ruxolitinib post-transplant, compared to 14.3% for those that did not (p=0.137, Figure). Importantly, 2-year overall survival was significantly improved in patients with post-transplant ruxolitinib (100% compared to 13.1%, p=0.014, Figure).
Summary/Conclusion: Our real-world cohort indicates that the use of ruxolitinib has optimized outcomes of alloHCT. Especially after alloHCT, our results suggest a significant benefit of a personalized approach in ruxolitinib administration. Given the safety of alloHCT, further studies are needed to guide this personalized approach.

Overall Survival

Disease-free Survival

EP1257 A MODIFIED BUSULFAN/CYCLOPHOSPHAMIDE CONDITIONING REGIMEN INCORPORATING CLADRIBINE FOR AUTOLOGOUS HEMATOPOIETIC STEM CELL TRANSPLANTATION IN ACUTE MYELOID LEUKEMIA

Y. Shi [1,*], G. Zhang [1], Y. He [1], M. Han [1], S. Feng [1], R. Zhang [1], E. Jiang [1]

[1]State Key Laboratory of Experimental Hematology, National Clinical Research Center for Blood Diseases, Instituteof Hematology & Blood Diseases Hospital, Chinese Academy of Medical Sciences & Peking Union Medical College, tianjin, China

Background: How to reduce the recurrence of autologous hematopoietic stem cell transplantation in patients with acute myeloid leukemia is very important to improve the efficacy of transplantation.
Aims: To investigate the safety and efficacy of a modified busulfan(Bu)/cyclophosphamide(Cy) conditioning regimen incorporating cladribine(CLAD) for autologous hematopoietic stem cell transplantation(auto-HSCT) in acute myeloid leukemia(AML).
Methods: We retrospectively evaluated the clinical outcomes of patients with AML who had received auto-HSCT with conditioning incorporating CLAD at the Institute of Hematology and Blood Disease Hospital.
Results: Between September 2016 and February 2021, 20 adult patients with AML were enrolled including 13 males and 7 females with a median age of 32(range, 15 to 54) years. The median courses of chemotherapy before auto-HSCT were 4 courses(range, 3 to 9) and all patients were minimal residual disease(MRD) negative before auto-HSCT. Twelve out of the 20 AML patients received myeloablative conditioning regimens including:Bu 3.2 mg/kg/d*3, Cy 40mg/kg/d*2, CLAD 5mg/m^2/d*3, cytarabine(Ara-c) 2g/m^2/d*3 or idarubicin 12mg/m^2/d*3. The other 8 patients with AML received the similar modified conditioning regimens as above mentioned but CLAD and Ara-c were administered for 5 days while Cy was abandoned for its adverse cardiovascular reactions. All the 20 patients received peripheral blood stem cells for auto-HSCT. The median amount of infused mononuclear cell and CD34$^+$ stem cell were 9.05×10^8/kg(range, 2.88 to 20.97) and 1.99×10^6/kg(range, 1.59 to 10.44), respectively. All the 20 patients achieved neutrophil and platelet engraftment with a median time of 13(range, 10 to 34) days and 27(range, 14 to

113) days, respectively. Three patients suffered from septicemia during neutropenia stage, 2 patients suffered from pulmonary infection, the others suffered from mild to moderate infection or gastrointestinal reaction after conditioning and all were relieved by anti-infection and other supportive treatment. None of the patients died of transplant related complications. From 2 months after auto-HSCT, the maintenance therapy with interleukin-2, interferon or azacitidine was performed for 7 patients with FLT3- ITD mutation negative, sorafeni were performed for 2 patient with FLT3 -ITD mutation positive. At a median follow-up of 25.5(range, 2.5 to 52.5) months,four patients relapsed after auto-HSCT at a median time of 8(range, 0.5 to 18.5) months. One patients died due to leukemia relapse at 18 months after auto-HSCT, the other 19 patients were all alive including 16 patients with MRD negative and the other 3 patients achieved MRD negative after allogeneic HSCT or maintenance therapy. The estimated 2-year survival, relapse, and disease-free survival rates were 93.3%, 22.9% and 77.1%, respectively.

Summary/Conclusion: The modified conditioning incorporating CLAD was safe and effective for auto-HSCT in acute myeloid leukemia which might be confirmed by more clinical studies.

EP1258 INCIDENCE OF VENO-OCCLUSIVE DISEASE/ SINUSOIDAL OBSTRUCTION SYNDROME AFTER HEMATOPOIETIC CELL TRANSPLANTATION IN ENGLAND BASED ON HEALTHCARE RESOURCE GROUP CODES AND HOSPITAL EPISODE STATISTICS© DATA

J. Angus [1,*], P. O'Donohoe [1], M. Evans [2], T. Ellison [2]

[1]Jazz Pharmaceuticals, Oxford, [2]Harvey Walsh, Runcorn, United Kingdom

Background: Hepatic veno-occlusive disease/sinusoidal obstruction syndrome (VOD/SOS) is a potentially fatal complication that occurs after hematopoietic cell transplantation (HCT) conditioning or chemotherapy. The most severe form of VOD/SOS is associated with multi-organ dysfunction/failure and a mortality rate of >80% if untreated. Defibrotide is approved in the EU for severe hepatic VOD/SOS post-HCT in patients aged >1 month. Based on the number of patients undergoing HCT reported to the British Society of Bone and Marrow Transplantation (BSBMT) and available commissioned defibrotide use data from National Health Service (NHS) England, the estimated incidence of severe VOD/SOS in patients with first HCT (allogeneic or autologous) in England from 2019-2020 was ~2.5%. Within the NHS Hospital Episode Statistics (HES) database, healthcare resource group (HRG) codes are applied to patient events that have been judged to consume a similar level of resource.

Aims: This analysis used HRG codes to evaluate the incidence of post-HCT VOD/SOS in England and provide details on the effect of HCT and donor type on risk for VOD/SOS.

Methods: In this retrospective analysis, data for patients with first HCT as an inpatient between April 2010 and March 2020 were obtained from the HES database (copyright 2021; reused with the permission of NHS Digital; all rights reserved), a data warehouse containing details of admissions, outpatient appointments, and accident/emergency department attendances at NHS hospitals. Patients were coded for VOD/SOS using ICD-10 diagnostic codes. HRG codes were used to summarize age (≤18 years vs ≥19 years), HCT modality (allogeneic vs autologous) and allogeneic donor type.

Results: Of the 32,147 identified patients who underwent HCT, 31,387 had evaluable HRG data; 330 (1.05%) of these patients were coded for VOD/SOS (any severity) within 100 days post-HCT. Among the 3,679 pediatric patients (≤18 years) who received HCT, 2,582 (70.2%) received allogeneic HCT and 232 (6.3%) were coded for VOD/SOS. Among the 26,886 adult (≥19 years) patients who received HCT, 8,893 (33.1%) received allogeneic HCT and 82 (0.3%) were coded for VOD/SOS. Age was unknown in 822 patients, 16 of whom were coded for VOD/SOS. VOD/SOS in pediatric patients was primarily reported in the autologous setting (56.9%), in contrast to adults where most VOD/SOS cases were reported in the allogeneic setting (90.2%; **Table**). There appeared to be a trend to higher VOD/SOS prevalence in groups with increased allogenicity of the donor source but this was not borne out by statistical analyses (**Table**); among 133 patients with syngeneic HCT, no cases of VOD/SOS were reported.

Table. Incidence of VOD/SOS by HCT modality and donor source.

HCT modality and donor source	Pediatric patients		Adult patients	
	n	VOD/SOS incidence, %* (95% CI)	n	VOD/SOS incidence, %† (95% CI)
All allogeneic	100	43.1 (36.64, 49.75)	74	90.2 (81.68, 95.69)
VUD	25	10.8 (7.1, 15.5)	20	24.4 (15.58, 35.12)
Sibling	24	10.3 (6.74, 15)	6	7.3 (2.73, 15.25)
Cord blood	12	5.2 (2.7, 8.86)	6	7.3 (2.73, 15.25)
Haplo-identical	2	0.9 (0.1, 3.08)	1	1.2 (0.03, 6.61)
Syngeneic	0	0 (0, 1.58)	0	0 (0, 4.4)
Unspecified	37	15.9 (11.48, 21.31)	41	50.0 (38.75, 61.25)
Autologous	132	56.9 (50.25, 63.36)	8	9.8 (4.31, 18.32)

VOD/SOS, veno-occlusive disease/sinusoidal obstruction syndrome; HCT, hematopoietic cell transplantation; CI, confidence interval; VUD, volunteer unrelated donor.
*Denominator is the number of pediatric patients coded for VOD/SOS (n=232).
†Denominator is the number of adult patients coded for VOD/SOS (n=82).

Summary/Conclusion: The incidence of VOD/SOS in this analysis of HRG codes was lower (1.05%) than the ~2.5% incidence rate for severe VOD/SOS obtained from NHS England commissioning data, suggesting that VOD/SOS may be undercoded in the HES database. Limitations of the analysis include restriction to the data available in the HES database, underrecording of haplo-identical HCT in the HES database versus BSBMT returns and the small sample size. In this analysis, there appeared to be higher rates of VOD/SOS in pediatric patients versus adults. VOD/SOS was observed more frequently in the autologous setting in pediatric patients and in the allogeneic setting in adults. These observations suggest that, for allogeneic transplants, there may be a possible relationship between allogenicity of the HCT donor source and incidence of VOD/SOS; further investigation is needed to explore this potential relationship.

EP1259 THE EFFECT OF MYELOMA INDUCTION THERAPY TYPE AND DURATION ON PERIPHERAL BLOOD STEM CELL HARVEST FOR AUTOLOGOUS STEM CELL TRANSPLANTATION

C. Pawlyn [1,*], T. Menzies [2], F. Davies [3], G. Cook [2], M. Jenner [4], J. Jones [5], M. Kaiser [1], R. Owen [6], M. Drayson [7], D. Cairns [2], G. Morgan [3], G. Jackson [8]

[1]The Institute of Cancer Research, London, [2]Clinical Trials Research Unit, Leeds Institute of Clinical Trials Research, University of Leeds, Leeds, United Kingdom, [3]Perlmutter Cancer Center, NYU Langone Health, New York, United States, [4]University Hospital Southampton NHS Foundation Trust, Southampton, [5]Brighton and Sussex Medical School, Brighton, [6]HMDS, Leeds Cancer Centre, Leeds Teaching Hospitals NHS Trust, Leeds, [7]Institute of Immunology and Immunotherapy, University of Birmingham, Birmingham, [8]Department of Haematology, University of Newcastle, Newcastle, United Kingdom

Background: Autologous stem cell transplant (ASCT) remains standard of care for eligible newly diagnosed myeloma patients (TE NDMM). Induction prior to ASCT frequently includes lenalidomide, reported to have an adverse effect on peripheal blood stem cell (PBSC) harvest in some studies.

Aims: The UK NCRI Myeloma XI/+ study compared induction combinations including thalidomide or lenalidomide giving the opportunity to compare PBSC harvests between patients treated with different immunomodulatory agents.

Methods: TE NDMM patients were randomised to triplet combinations, thalidomide or lenalidomide plus dexamethasone and cyclophosphamide (Tdc/Rdc) or the quadruplet combination carfilzomib+Rdc (KRdc). Induction was given for a min. of 4 cycles but continued to max. response. Patients who received Tdc/Rdc and achieved a max. response less than VGPR underwent response-adapted intensification therapy.

PBSC harvest was planned to occur after the completion of induction+/-intensification. Stem cell mobilisation and harvest was performed according to local practice with advice to aim for the collection of sufficient cells for at least two transplants.

The median number of CD34+ cells harvested was compared between patients randomised to Tdc, Rdc and KRdc and those who received 4, 5-6 or >6 cycles of induction. Mann-Whitney U Tests were used to compare groups. Only patients achieving >=VGPR to initial induction, completing >=4 cycles and proceeding directly to ASCT were included in this analysis to avoid any impact of response or intensification therapy on harvest outcome.

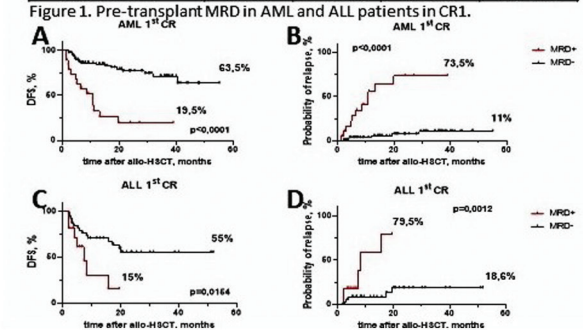
Results: Of the 1543 patients included, 521 had received Tdc (51.0% of all patients randomised to Tdc), 610 Rdc (59.7%), 412 KRdc (78.3%). Of these patients 88.4% underwent harvest (Tdc 86.9%, Rdc 87.5%, KRdc 91.5%).

The median number of CD34+ cells harvested was lower for those who had received lenalidomide compared to thalidomide. Patients who received Tdc harvested a median 4.6x10^6/kg CD34+ cells, Rdc 4.1, KRdc 4.2 (Rdc vs Tdc p=0.0002, KRdc vs Rdc p=0.1766, KRdc vs Tdc p=0.0210). There was also a reduction in the median CD34+ cells harvested for patients requiring >6 cycles of induction to achieve

maximum response prior to harvest. 4 cycles 4.5 x10^6/kg CD34+ cells, 5-6 cycles 4.2, >6 cycles 4.1 (4 vs 5-6 p=0.1212, 5-6 vs >6 p=0.1839, 4 vs >6 p=0.0262).
The reduction in CD34+ cells with increasing number of induction cycles appeared greater for those patients who received lenalidomide induction. Tdc: 4 cycles 4.9 x10^6/kg CD34+ cells, 5-6 cycles 4.6, >6 cycles 4.6. Rdc: 4 cycles 4.4, 5-6 cycles 4.0, >6 cycles 3.5. KRdc: 4 cycles 4.4, 5-6 cycles 4.1, >6 cycles 3.9. This corresponded to a reduction in the proportion of patients meeting the threshold for two ASCTs both between therapies and with increasing cycles. Tdc: 4 cycles 63.0%, 5-6 cycles 60.2%, >6 cycles 61.4%. Rdc: 4 cycles 54.3%, 5-6 cycles 47.4%, >6 cycles 46.2%. KRdc: 4 cycles 60.9%, 5-6 cycles 49.3%, >6 cycles 41.7%.
Despite these differences, more than 96% of patients in all groups were considered to have enough stem cells and proceeded to first ASCT within the trial, with no differences between treatment groups.
Summary/Conclusion: Lenalidomide-based induction therapy was associated with lower median CD34+ cells harvested than thalidomide-based induction. This had no impact on the proportion of patients able to undergo first ASCT. The reduction in median CD34+ cells with lenalidomide was most marked when >4 cycles were administered. This should be considered when planning the timing of harvests, especially if storage of sufficient cells for two ASCTs is desired.

EP1260 ADVERSE IMPACT OF PRE-TRANSPLANT MINIMAL RESIDUAL DISEASE ON OUTCOMES OF ALLOGENEIC HEMATOPOIETIC STEM CELL TRANSPLANTATION IN ACUTE LEUKEMIA PATIENTS.

Z. Konova [1,*], E. Parovichnikova [1], I. Galtseva [2], M. Drokov [1], J. Davydova [2], N. Kapranov [2], N. Popova [1], U. Maslikova [1], F. Omarova [1], E. Mikhaltsova [1], O. Koroleva [1], A. Dmitrova [1], M. Dovydenko [1], O. Starikova [1], D. Dubnyak [1], E. Kolgaeva [1], M. Akhmedov [1], V. Vasilyeva [1], L. Kuzmina [1], V. Savchenko [1]



[1]BMT, [2]Immunophenotyping Laboratory, National Research Center for Hematology, Moscow, Russian Federation

Background: Allogeneic hematopoietic stem cell transplantation (allo-HSCT) is a curative option for high-risk acute leukemias. But one of the main causes of treatment failure after allo-HSCT for acute leukemia (AL) is still the disease relapse. Currently, minimal residual disease (MRD), detected by multiparameter flow cytometry (MPC), is widely used to identify patients at high risk of relapse due to its availability and the ability to obtain results in a short time frame.
Aims: To assess the predictive value of pre-transplant MRD status.
Methods: We included 207 patients: 122 patients AML and 85 patients with ALL, who underwent allo-HSCT National Research Center for Hematology between September 2015 and December 2020. Patient characteristics are summarized in Table 1. All patients were in complete morphological remission (CR) at the time of allo-HSCT. The median follow-up was 17 (1,5-55) months for AML and 11,7 (1-64) months for ALL. 6-color MFC was performed on bone marrow samples obtained before allo-HSCT. MRD was detected using a combination of the "different-from-normal" and LAIP methods. The probabilities of DFS and relapse were estimated using the Kaplan–Meier method for all patients. The value of $p < 0.05$ was considered as significant. Statistical analysis was performed using SPSS ver. 23 (IBM, Chicago, Ill., USA). Cox proportional hazards model was used to assess the influence of various independent factors on the probability of relapse/death from any cause. The factors included in the model: disease status, donor type, conditioning regimen, source of graft, pre-transplant MRD status, age, acute or chronic graft versus host disease (GVHD).
Results: In univariate analysis, the DFS of MRD+ patients with AL in the 1st CR was significantly worse than MRD- (AML: 19,5% vs 63,5%, p <0.0001 (Fig.1A), ALL: 15% vs 55%, p = 0.0154(Fig.1C)), and the probability of relapse in MRD+ patients was significantly higher (AML: 73,5% vs 11%, p <0,0001 (Fig.1B), ALL: 79,5% vs 18,6%, p = 0,0012 (Fig.1C)). Pre-transplant MRD status was not prognostically significant for AL-patients in the 2nd and 3rd remission. In our study, the presence of MRD before allo-HSCT has been shown to be an independent factor influencing the probability of relapse/death (HR = 3,673 [2,185- 6,174], p<0,0001). In turn, it was noted that the development of chronic GVHD reduces post-transplant mortality if it does not require systemic therapy with glucocorticosteroides (HR = 0,183 [0,065-0,516], p=0,001).

Table 1. Patient's characteristics.

	AML (n=122)		ALL (n=85)	
	MRD+ (n=29)	MRD- (n=93)	MRD+ (n=20)	MRD- (n=65)
Age (median, interval)	36 (21-61)	38 (18-66)	35 (18-61)	30 (19-63)
Disease status, n (%)				
• 1st CR	19 (65,5%)	84 (90,3%)	11 (55%)	41 (63,1%)
• 2nd and 3rd CR	10 (34,5%)	9 (9,7%)	9 (45%)	24 (36,9%)
Donor type, n (%)				
• related matched	8 (27,6%)	33 (35,5%)	5 (25%)	10 (15,4%)
• unrelated matched	9 (31%)	24 (25,8%)	4 (20%)	18 (27,7%)
• unrelated mismatched	7 (24,1%)	16 (17,2%)	4 (20%)	14 (21,5%)
• haplo	5 (17,3%)	20 (21,5%)	7 (35%)	23 (35,4%)
Conditioning regimen, n (%)				
• myeloablative	6 (20,7%)	28 (30,1%)	6 (30%)	25 (38,5%)
• reduced intensity	23 (79,3%)	65 (69,9%)	14 (70%)	40 (61,5%)
Source of stem cells, n (%)				
• bone marrow	9 (31%)	43 (46,2%)	4 (20%)	20 (30,8%)
• peripheral blood	20 (69%)	50 (53,8%)	16 (80%)	45 (69,2%)

Figure 1. Pre-transplant MRD in AML and ALL patients in CR1.

Summary/Conclusion: Pre-transplant MRD is an independent factor of a poor prognosis. Testing for MRD before allo-HSCT is extremely important to stratify the risk of allo-HSCT and identify patients with AML or ALL who need early interventions such as withdrawal of immune suppression, donor lymphocyte infusion or preemptive chemotherapy in order to prevent the disease relapse.

EP1261 RELATIONSHIP OF HLA ALLELES AND THE RISK OF CYTOMEGALOVIRUS (CMV) REACTIVATION FOLLOWING ALLOGENEIC HEMATOPOIETIC STEM CELL TRANSPLANTATION (ALLO-HSCT)

S. Prem [1,*], M. Remberger [2], W. Lam [1], A. Alotaibi [1], R. Kumar [1], A. Viswabandya [1], A. Law [1], F. Michelis [1], J. Lipton [1], J. Mattsson [1], D. Kim [1], C. Ellison [3]

[1]Allo-BMT Program, Princess Margaret Cancer Centre, Toronto, Canada, [2]Uppsala University Hospital, Uppasala, Sweden, [3]HLA Laboratory, Lab Medicine Program, University Health Network, Toronto, Canada

Background: Evidence is emerging to support an association between certain HLA alleles, and the risk of CMV reactivation post-allo-HSCT. HLA alleles associated with resistance to CMV reactivation have been referred to as "CMV immunodominant alleles", and are thought to present viral antigen to T lymphocytes more effectively.
Aims: We aimed to identify HLA alleles associated with either resistance or susceptibility to CMV reactivation.
Methods: We studied 586 adults who underwent allo-HSCT. We included patients who had engrafted successfully, and had been typed at HLA-A, B, C, DRB1 and DQB1 loci by next-generation sequencing. Weekly CMV monitoring by PCR was done on whole blood, and anti-viral treatment was initiated for levels more than 200 IU/ml.
The primary outcome measure was the occurrence of CMV reactivation needing treatment, with or without CMV disease. Hazard ratios were calculated by Cox regression analyses, for HLA alleles and other variables significantly associated with CMV reactivation. We analysed only HLA Class I and II alleles that were observed at a frequency of >5% in donor or recipient cohorts, and adjusted for the effect of multiple comparisons.
Results: The median patient age was 57 years. AML was the most common diagnosis (51.5% patients). Donor types were as follows: matched unrelated (MUD; 52.5%); matched related (19%); mismatched unrelated (MMUD; 18%); and haploidentical (11%) donors. Eighty nine percent received a T-cell depleting agent during conditioning.
The cumulative incidence of CMV reactivation in the entire cohort at 6 months was 55% (95%CI 51%>59%).
This was significantly higher in recipients of MMUD and haploidentical grafts, and in those with a pre-transplant CMV IgG serostatus either donor positive/recipient positive or donor negative/recipient positive.

The one-year overall survival in patients with and without CMV reactivation were 54% and 63%
respectively (p=0.01). The univariate analysis indicated that alleles HLA A*01:01 (HR 0.62, 95% CI 0.48-0.83), A*02:01 (HR-0.77, 95% CI 0.59-0.93), and B*07:02 (HR 0.59, 95% CI 0.40-0.83) were associated with protection against CMV (Table 1). Other factors impacting risk of CMV reactivation on univariate analysis were increasing recipient age, use of T-cell depletion, mismatched donor (haploidentical or MMUD), and pre-transplant CMV serostatus. These factors, along with the significantly associated HLA alleles were included in a multivariable model. Mismatched donor (HR 1.23, 95% CI 1.02-1.63) and increasing age (HR 1.09, 95% CI 1.007-1.18) were independently associated with increased risk of CMV reactivation, whereas donor negative/recipient negative
serostatus (HR 0.05, 95% CI 0.02-0.11), donor positive/recipient negative serostatus (HR 0.35, 95% CI 0.20-0.59), and HLA B*07:02 (HR 0.63, 95% CI 0.44-0.88) were independently associated with protection against CMV reactivation.
Patients who developed CMV reactivation had lower overall survival (HR 0.62, 95% CI 0.46-0.82), higher transplant related mortality (TRM; HR 1.72, 95% CI 1.25-2.36), lower relapse (HR 0.58, 95% CI 0.41-0.82) and similar relapse free survival (RFS) when compared to those who did not develop CMV reactivation. The number of CMV reactivations had no effect on TRM.

Variable	Hazard ratio	95% CI	P-value
Associated with decreased risk			
A 0101	0.62	0.48-0.83	0.001
A 0201	0.77	0.59-0.93	0.01
B 0702	0.59	0.40-0.83	0.001
Donor neg/Recipient neg serostatus	0.05	0.02-0.11	<0.001
Donor pos/Recipient neg serostatus	0.35	0.2-0.59	0.001
Associated with increased risk			
Increasing age	1.09	1.007-1.18	0.033
Mis-matched donor (haplo/MMUD)	1.23	1.02-1.63	0.034

Table 1. Key risk factors for CMV infection (n=586)

Summary/Conclusion: HLA B*07:02 was associated with protection against CMV reactivation post-transplant. Although CMV reactivation was associated with increased TRM, it was also associated with decreased relapse rates, resulting in similar RFS post-transplant compared to patients not developing CMV reactivation.

EP1262 SURVIVAL AFTER SEQUENTIAL FLAMSA-BU CONDITIONING REGIMEN IS HIGHLY DEPENDENT ON PRE-HSCT MRD STATUS IN HIGH-RISK MYELOID NEOPLASM

G. Le Meur [1,*], A. Plesa [2], M. Balsat [1], H. Labussière-Wallet [1], M. Renault [1], M. V. Larcher [1], G. Fossard [1], F. Barraco [1], S. Ducastelle-Lepretre [1], L. Gilis [1], X. Thomas [1], H. Ghesquières [1], M. Heiblig [1]

[1]Service d'hématologie clinique, [2]Service d'hématologie biologique, Hospices civils de Lyon, Pierre-Bénite, France

Background: Historically, sequential transplant regimen using fludarabine/cytosine arabinoside/amsacrine (FLAMSA) cytoreduction followed by busulfan (Bu) based regimen has been associated with improved outcome in high-risk myeloid neoplasms (Schmid et al. J Clin Oncol 2005). Recently, Craddock et al. showed prospectively that FLAMSA-RIC was not associated with survival benefit compared to classical reduced intensity conditioning (RIC) regimens, especially in patients who experienced positive minimal residual disease (MRD) prior hematopoietic stem cell transplantation (HSCT)(Craddock et al. Blood 2020).
Aims: In this monocentric study, we aimed to evaluate retrospectively the outcome of patients receiving FLAMSA-Bu based conditioning regimens for high-risk myeloid neoplasms.

Methods: We analyzed 203 patients who received FLAMSA-Bu based conditioning regiments for high-risk AML (N=165), myelodysplastic syndrome (MDS)(N=32) or MDS/myeloproliferative neoplasms (MPN) (N=6), between October 2011 and June 2020. In AML setting, flow cytometry minimal residual disease (MRD) was available in 151/165 patient prior transplant and based on leukemia associated immunophenotype (LAIP) using ELN recommendations (bulk lyses, and at least 500 000 live cells to achieve a sensitivity of 0.1%). MRD flow was performed in bone marrow samples using 8 color panel.
Results: The median follow-up post HSCT time was 32,2 months (0.0—98 months). At 3 years, overall survival (OS) was 56% and 39.8% in AML and MDS settings respectively. In the AML cohort, ELN 2013 classification was not predictive for survival or cumulative incidence of relapse (CIR). When available, results were similar regarding ELN 2017 classification. For patients in CR1 (1st complete remission) at the time of HSCT, median OS was not reached. For those in > CR1 or refractory at the time of HSCT, median OS was 34.3 and 25.6 months respectively (p=0.56). For AML patients in CR1, pre-HSCT MRD+ (defined positive when ≥ 0.1%) was highly predictive for relapse, which reached 57.3% at 3 years. For pre-HSCT MRD- patients, median OS was not reached either patients where in CR1 or more. However, median OS was not statistically different for pre-HSCT MRD+ patients whatever was the pre-HSCT CR status (refractory excluded) (figure). Finally, MRD- patients receiving myeloablative (Bu4) regimen (MAC) has superior outcome compared to RIC (Bu2). However, neither MAC or RIC abrogated negative impact of pre-HSCT MRD positivity. Post-transplant, neither acute GVHD, chronic GVHD, prophylactic donor lymphocyte infusion or partial chimerism (at day+30, +60 or +90) were associated with survival. Regarding donor type, TRM was 14,1%, 29% and 37.3%, whereas cytologic relapse occurred in 32%, 20.3% and 15.1% cases in HLA-identical, matched-unrelated (MUD) and mismatched unrelated donor (MMUD) respectively. TRM was significantly higher in patients aged over 55 years old (38%) compared to younger ones (age < 45 = 14.9%, age 46-55 = 22%) (p=0.03). In multivariate analysis, only prior HSCT MRD status and age remained of statistical significance regarding survival in AML patients.

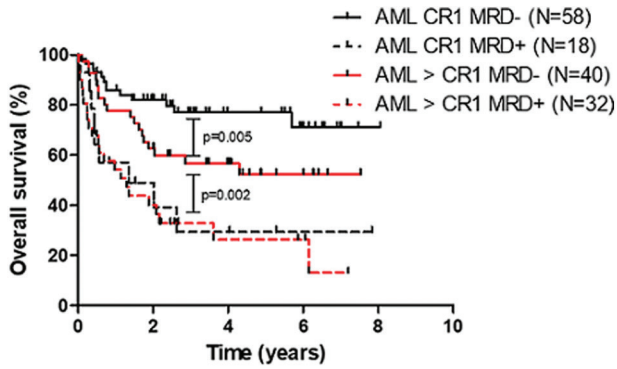


Figure : overall survival among AML patients according to the pre-transplant MRD status (assessed by flow cytometry)

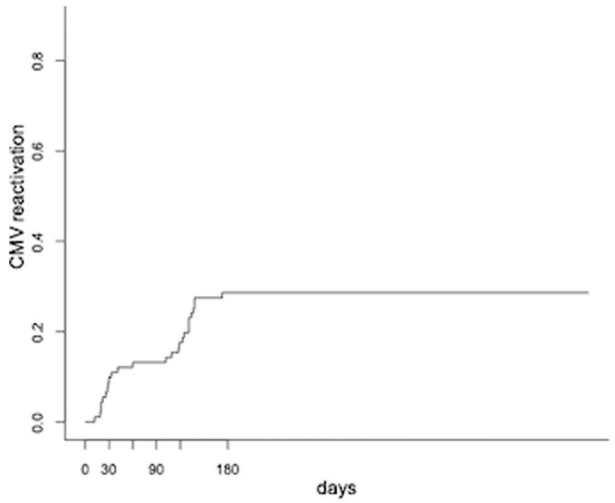
Summary/Conclusion: Our results emphasize that FLAMSA conditioning regimen is an interesting strategy in high-risk myeloid neoplasm, even in refractory AML patients. Despite abrogating the impact of ELN risk groups in AML settings, pre-HSCT MRD status remains the main detrimental factor for relapse probability. Moreover, advanced age was associated with high rate of TRM suggesting that such strategy should be avoided, especially in adults aged over 55 years old.

EP1263 LETERMOVIR FOR CMV PROPHYLAXIS AFTER ALLOGENEIC STEM CELL TRANSPLANTATION - CLINICAL "REAL WORLD" EXPERIENCE

L. Desnica [1,*], Z. Peric [1], N. Durakovic [1], R. Serventi Seiwerth [1], D. Sertic [1], M. Mikulic [1], P. Roncevic [1], D. Pulanic [1], N. Rustan [1], R. Vrhovac [1]

[1]Hematology, UHC Zagreb, Zagreb, Croatia

Background: CMV reactivation continues to be a significant clinical problem after allogeneic stem cell transplantation (allo-HSCT).



CMV (IgG) seropositivity before allo-HSCT is an important risk factor for CMV reactivation and CMV disease. Without prophylaxis, CMV infections occur in approximately 60-80% patients after allo-HSCT, usually in the early post-transplant period. Any level of CMV viremia is associated with increased non-relapse mortality in the first year post allo-HSCT. In 2019 at UHC Zagreb the preemptive CMV treatment approach was substituted with letermovir prophylaxis

Aims: The aim of this study was to analyse the population of patients who received letermovir, and to compare them with historical controls.

Methods: We retrospectively analysed 90 consecutive patients who underwent allo-HSCT between mid-2019 and mid-2020 in our Center.

Results: Median age of patients was 52.5 years, 49% of them were female and only 8.9% CMV seronegative. The most frequent indication for transplantation was acute leukaemia (53%) with peripheral blood stem cells (88%) from unrelated donor (62%) being the most common source of stem cells. Conditioning was of reduced intensity in most of the cases (86%). The patients received letermovir prophylaxis starting from a median of 18.5 days (range 5-28) after allo-HSCT during 90 or until CMV reactivation. With a median follow-up of 385 days (range 152-636), 26 patients (29%) experienced CMV breakthrough while on letermovir, 12 within 100 days, and 14 after day 100 post allo-HSCT. In 22 patients preemptive treatment was started and two patients developed CMV disease (pneumonitis). In one patient muscle and joint pain occurred, possibly related to letermovir, no other adverse events were noticed.

Cumulative incidence of CMV reactivation at day 180 was lower in letermovir group: 29% (95% CI 20-38; median 105 days, range 12-173) compared to historical group (with similar demographic characteristics): 61% (95% CI 53-68; median 27 days, range 1-131). Patients with detectable virus level <137 IU/ml were also started on letermovir prophylaxis, and were found to have higher cumulative incidence of CMV reactivation 53% (95% CI 26-7), compared to patients who were CMV DNA negative 23% (95% CI 14-33), p=0.002. At day 500 overall survival was 76% (95% CI 65-88) in patients without CMV reactivation compared to 75% (95%CI 53-100) with CMV reactivation.

Summary/Conclusion: Our "real-world" experience confirms the efficacy of letermovir in CMV prophylaxis, its favourable safety profile and lack of negative impact on engraftment. We showed a striking decrease in the incidence of CMV reactivation in patients on letermovir prophylaxis compared to similar patient cohort from the same institution during the "preemptive treatment" era, justifying the prophylactic approach. Given the connection between CMV reactivation and NRM, clinicians should be encouraged to use different anti-CMV options available to prevent or at least delay CMV reactivation and CMV disease in transplanted patients. Patients with low, but detectable CMV levels (<137 IU/mL) and patients with the highest risk of CMV reactivation (such as patients with GvHD receiving corticosteroids, or patients who received ATG) might need a specifically tailored anti-CMV approach. Further studies addressing these questions are warranted.

EP1264 THE PRELIMINARY RESULTS OF EFFICACY OF UPFRONT HIGH-DOSE CHEMOTHERAPY WITH AUTOLOGOUS STEM CELL TRANSPLANTATION FOR IV STAGE AND HIGH-INTERMEDIATE/HIGH IPI RISK GROUPS DLBCL.

A. Koviazin 1,*, L. Filatova 1,2, I. Zyuzgin 1, E. Cherkasova 1, Y. Chudinovskikh 1, S. Sergey 1, I. Ishmatova 1, A. Zverkova 1, M. Ghanzin 1, S. Volchenkov 1, M. Motalkina 1, Y. Oleinik 1, D. Burda 3, I. Poliatskin 3, A. Artemyeva 3, T. Semiglazova 2,4

[1]Department of Hematology and Chemotherapy with intensive care unit, NMRC of Oncology named after N.N.Petrov of MoH of Russia, [2]North-Western State Medical University named after I.I.Mechnikov, [3]Department of Pathology, [4]Department of Innovative Methods in Therapeutic Oncology and Rehablitation, NMRC of Oncology named after N.N.Petrov of MoH of Russia, Saint-Petersburg, Russian Federation

Background: Approximately 30% of patients(pts) with high-intermediate/high IPI risk groups (IPI ≥2) diffuse large B-cell lymphoma (DLBCL) have relapsed after the frontline regimens. High-dose chemotherapy (HDCT) with autologous hematopoietic stem cell transplantation (auto-HSCT) in the first remission can be an effective option to decrease the relapse rate in these patients.

Aims: Preliminary evaluation of the efficacy of the HDCT with auto-HSCT in the first remission for stage IV DLBCL patients with IPI ≥2.

Methods: 108 pts, which fit the following criteria: DLBCL NOS, age 18-65, stage IV, IPI ≥2, treated by x6 CHOP/EPOCH/H-CVAD + R in frontline from 01.01.2010 to 31.12.2019 at NMRC of Oncology named after N.N.Petrov of MoH of Russia were retrospectively analyzed.

If patients achieved complete response (CR) or partial response (PR) after frontline, they enrolled into upfront HDCT with auto-HSCT group (Group 1, n=38) or follow-up group (Group 2, n=70) based on multidisciplinary team (MDT) decision.

High LDH had 84% (32/38) pts in Group 1 and 81,4% (57/70) pts in Group 2; more than one extranodal involvement had 78,9% (30/38) pts in Group 1 and 75,7% (53/70) pts in Group 2. MYC and BCL-2 coexpression were analyzed in 84% (32/38) pts samples in Group 1 and 65,7% (46/70) in Group 2 and were present in 46,8% (15/32) pts samples in Group 1 and 28,2% (13/46) in Group 2.

An independent two-sample T-test and one-tailed p-value were used to determine the difference in relapse rate between Group 1 and Group 2.

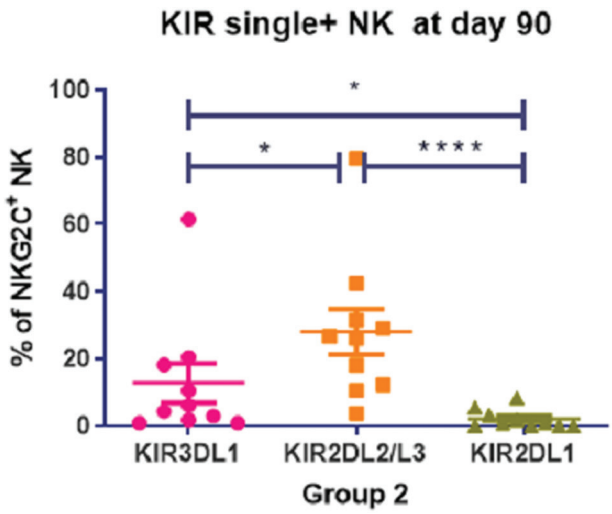
Results: CR after induction was achieved in 61% (23/38) pts in Group 1. After HDCT with auto-HSCT, the CR rate increased to 97% (37/38) and continues for a median of 30 (7-56) months in 87% (33/38) pts. It demonstrates the statistically significant difference - $t\alpha = 4,42$ ($p \leq 0,00001$). Early relapses were diagnosed in 6% (2/38) pts, late relapses in 6% (2/38) pts. HDCT associated mortality (infection) has occurred in 3% (1/38) pts.

Group 2 patients achieved CR in 81% (57/70) cases. CR continues for median 38 (8-73) months in 67% (47/70) pts. Group 2 patients have 14% (14/70) early and 6% (4/70) late relapse rate. No treatment-related deaths occurred.

Early relapse rate was significantly higher in Group 2 if the patient had initially high LDH (Group 1 – 3,1% (1/32), Group 2 – 15,8% (9/57)) - $t\alpha = 2,21$ ($p = 0.014865$); more than one initial extranodal site (Group 1 – 3,3% (1/30), Group 2 – 17,0% (9/53)) - $t\alpha = 2,23$ ($p = 0.014257$). MYC and BCL-2 coexpression was statistically significant in terms of both early (Group 1 – 6,6% (1/15), Group 2 – 38,4% (5/13)) - $t\alpha = 2,13$ ($p = 0.0214$) and all relapses (Group 1 – 6,6% (1/15), Group 2 – 46,1% (6/13)) - $t\alpha = 2,59$ ($p = 0.007761$). The early relapse rate in Group 2 was significantly higher if the combination of initially high LDH, more than 1 extranodal site, MYC and BCL-2 coexpression were present (Group 1 – 12,5% (1/8), Group 2 – 55.5% (5/9)) - $t\alpha = 2,12$ ($p = 0.025547$).

Summary/Conclusion:

1. CR rate significantly increased for DLBCL NOS pts with stage IV, IPI ≥2 treated by upfront HDCT with auto-HSCT.



2. Upfront HDCT with auto-HSCT significantly decreases early relapse rate for DLBCL NOS pts with stage IV, IPI ≥2 if high LDH, more than one extranodal site, and MYC and BCL-2 coexpression are present.

EP1265 KIR2DL2/L3 SINGLE POSITIVE/NKG2C+ NK CELLS SIGNIFICANTLY EXPAND IN NKG2C+ NK CELLS DURING EDUCATION AFTER HEMATOPOIETIC STEM CELL TRANSPLANTATION

W. Zuo [1,*], X.-Y. Zhao [1,2], X.-X. Yu [1], X.-F. Liu [1], X.-S. Zhao [1], Y.-J. Chang [1], Y. Wang [1], X.-H. Zhang [1], L.-P. Xu [1], Y.-K. Liu [1], X.-J. Huang [1,2]

[1]Peking University People's Hospital, Peking University Institute of Hematology, National Clinical Research Center for Hematologic Disease, Beijing Key Laboratory of Hematopoietic Stem Cell Transplantation, [2]Peking-Tsinghua Center for Life Sciences, beijing, China

Background: NK education plays a vital role in leukemia control and infection prevention after hematopoietic stem cell transplantation (HSCT), which is affected by interaction of human leukocyte antigen (HLA)-I/killer immunoglobulin receptor (KIR). However, different HLA-I/KIR interactions on NK education for intrinsic responsiveness is still conflicting. Recent studies showed that obvious NKG2C+ NK cell expansions are dominated by specific single KIR clones, mainly encoded by the centromeric part of group A haplotypes under cytomegalovirus (CMV) infection. However, the effect of HLA-I/KIR interactions on NKG2C+ NK education post HSCT were still unknown.
Aims: To figure out what KIR/HLA-I interaction has a main effect on the expansion and reactivity of NKG2C+ NK cells in NK education after HSCT.
Methods: We prospectively studied 114 patients with malignant hematologic disease who underwent HSCT at the Peking University People's Hospital between May 2016 and April 2017. All patients and donors provided written informed consent. Patient and donor DNA was prepared from peripheral blood mononuclear cells (PBMCs) for HLA, NKG2C and KIR genotyping test.The expansion, expression of cell surface molecules and function of three single KIR positive/NKG2C+ NK cells (KIR2DL1, KIR2DL2/L3 and KIR3DL1) at day 30, 90 and 180 are tested by flow cytometric analyses and cytotoxicity assays. Statistical analysis was performed by nonparametric test, Pearson correlation test and Chi-squared Test.
Results: It was shown that KIR2DL2/L3 single positive NKG2C+ cells significantly expanded in NKG2C+ NK cells than KIR2DL1 and KIR3DL1, in group1 where donor and recipient were both HLA-C1C1, and group2 where donor and recipient are both HLA -C1BW4, at day 90 (group1:P<0.0001, P=0.0001; group2:P<0.0001, P=0.0232) and 180(group1:P<0.0001; group2:P=0.0003, P=0.2581). In group3, where donor and recipient are both HLA-C1C2BW4, the proportion of KIR2DL2/L3 and KIR2DL1 single positive/NKG2C+ were both higher than KIR3DL1 (Day90:P<0.0001, P=0.0023; Day180:P<0.0001, P=0.0007). MFI of NKp30 expression on KIR2DL2/L3 single positive/NKG2C+ NK cells was significantly higher than KIR2DL1/NKG2C+ and KIR3DL1/NKG2C+, in group1, group2 and group3. Additionally, we found that KIR2DL2/L3 single positive cells showed more significant proliferation in NKG2C+ NK cells than NKG2A- NK cells at day 30, 90 and 180. NKG2C genotype (*NKG2C*$^{wt/del}$ or *NKG2C*$^{wt/wt}$) of donor cells had no effect on the significant expansion of KIR2DL2/L3 single positive/NKG2C+ NK cells at day 30, 90 and 180. Moreover, we observed that KIR CenA/A genotype may induce strong expansion of NKG2C+ NK cells and KIR2DL2/L3 single positive/NKG2C+ NK cells. Besides, it was observed that the frequencies of KIR2DL2/L3 single positive/NKG2C+ NK cells showed significant consistent correlation with the proportion of NKG2C+ NK cells among NK cells only at day 90 (P=0.0417). However, the proportion of KIR2DL2/L3/NKG2C+ was irrelevant with CMV infection type (refractory reactivation or not), clinical outcomes (relapse or not) and duration of viremia. Finally, the data revealed that the number of KIRs and KIR ligands shared by donors and recipients has no effect on NKG2C+ NK cells.
Summary/Conclusion: Interaction between KIR and HLA-C can modulate the education of NKG2C+ NK cells, characterized by KIR2DL2/L3 single positive/NKG2C+ NK cells clonal expansion, with NKp30 increasing expression, dominated by the combination of KIR2DL2/L3 and HLA-C1.

EP1266 DOWN-REGULATION OF HLA EXPRESSION IN ACUTE LEUKEMIA PATIENTS RELAPSED POST TRANSPLANTATION CORRELATED WITH MRD DURATION

M. GONG [1], A. WANG [1], X. WU [1], J. ZHEN [1], M. CHEN [1], Q. DU [1], H. Wang [1,*]

[1]clinical laboratory, Hebei Yanda Ludaopei Hospital, Langfang, China

Background: Allogeneic hematopoietic stem cell transplantation (HSCT) is an important treatment for the hematological malignancies. Relapse is the leading cause after transplantation. The immunological principle of recurrence is different, but HLA down regulation may be important.
Aims: study the change of HLA expression when relapse post allogeneic hematopoietic stem cell transplantation, and the relationship of HLA down regulation with MRD duration.
Methods: A total of 2581 patients received allogeneic hematopoietic stem cell transplantation(allo-HSCT) in Hebei Yanda Ludopei Hospital from 2018 to 2020, of which 32 patients with recurrent acute leukemia after transplantation were selected for HLA antigen expression analysis. Male: female was 23:9, median age was 17 years old (2-51 years old), including 18 cases of AML, 7 cases of B-ALL, 5 cases of T-ALL and 2 cases of MPAL. Among them, there were 23 cases of haplo-identical transplantation, 5 cases of related matched transplantation and 4 cases of unrelated matched transplantation. Bone marrow samples were taken at the time of initial diagnosis and recurrence, and the expression of HLA-II proteins (HLA-DR and/or HLA-DRDPDQ) in tumor cells were detected by multi-parameter flow cytometry. HLA-I proteins HLA-ABC were detected in 6 cases simultaneously. 52 kinds of common fusion genes and 58 kinds of gene mutation were monitored at the same time for all patients by real-time quantitative polymerase chain reaction (RT-PCR) and next generation sequencing (NGS), as well as chromosome examination. 34% (11/32) of the patients were analyzed for HLA gene sites in the HLA region by NGS or PCR according to the proportion of tumor cells at relapse. Median follow-up were 722 days (0-1950 days), and MRDs were detected using multicolor flow cytometry at regular intervals. SPSS 25 software was used to analyze the changes in HLA antigen expression intensity between initial diagnose and relapse after transplantation, as well as the correlation between HLA expression and persistence of MRD.
Results: Among the 32 patients, the median recurrence time was 239 days (30-1290 days). Compared with the initial diagnose, the HLA-II antigen expression was down-regulated in 43.75% of patients after transplantation (P=0.01), which was consistent with the results of NGS. And the down-regulated degree of HLA-II was positively correlated with the duration of MRD (R2=0.9996). 50% (5/10) of AML involved chromosome 3 at initial diagnose, and such patients were more prone to down-regulation of HLA class II protein expression. 77% of patients with relapse after transplantation were associated with new chromosomal abnormalities, but flow cytometry showed no correlation between down-regulation of HLA-II antigen expression and new chromosomal abnormalities after the relapses, and no significant correlation with gene mutation and fusion genes. Due to the small number of cases, no correlation was found between ALL. Three patients showed HLA-loss, including one case of HLA-I (haplo-allo-HSCT), one case of HLA II

(haplo-allo-HSCT), and one case of loss of both HLA II and class I sites (related matched allo-HSCT).

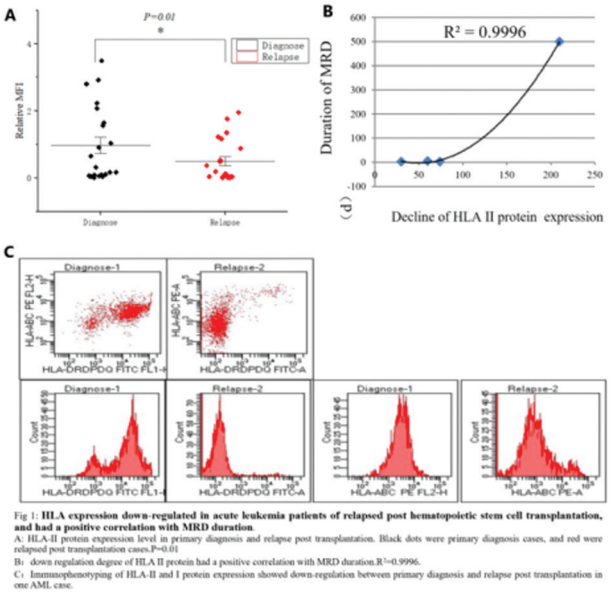


Fig 1: **HLA expression down-regulated in acute leukemia patients of relapsed post hematopoietic stem cell transplantation, and had a positive correlation with MRD duration.**
A: HLA-II protein expression level in primary diagnosis and relapse post transplantation. Black dots were primary diagnosis cases, and red were relapsed post transplantation cases.P=0.01
B: down regulation degree of HLA II protein had a positive correlation with MRD duration.R^2=0.9996.
C: Immunophenotyping of HLA-II and I protein expression showed down-regulation between primary diagnosis and relapse post transplantation in one AML case.

Summary/Conclusion: The HLA-II protein expression is prone to be down-regulated in relapsed patients after transplantation, which may be one of the important immunological reasons for the recurrence of hematologic tumors. The down-regulation degree of HLA II protein level is significantly positively correlated with the duration of MRD. Patients with AML that initially involved chromosome 3 were more likely to have down-regulated HLA class II protein expression.

EP1267 DONOR LYMPHOCYTE INFUSION AFTER ALLOGENEIC HEMATOPOIETIC STEM CELL TRANSPLANTATION: RESULTS FROM A RETROSPECTIVE MULTICENTER STUDY

B. De Marco [1,*], M. Malagola [2], L. Gandolfi [2], I. Cavattoni [3], D. Russo [2], A. Billio [3], M. Krampera [1], F. Benedetti [1], C. Tecchio [1]

[1]Dipartimento di Medicina, Sezione di Ematologia e Centro Trapianti Midollo Osseo, Azienda Ospedaliera Universitaria Integrata di Verona, Verona, [2]Dipartimento di Medicina, Sezione Centro Trapianti Midollo Adulti, ASST degli Spedali Civili di Brescia, Brescia, [3]Ematologia e Centro Trapianti Midollo Osseo, Azienda Sanitaria dell'Alto Adige, Bolzano, Italy

Background: Allogeneic hematopoietic stem cell transplantation (alloHSCT) is a curative therapy for several hematological malignancies. However, a major cause of alloHSCT therapeutic failure is represented by the underlying disease relapse. Donor lymphocyte infusion (DLI) is a powerful adoptive immunotherapy that can be used after alloHSCT in patients with high-risk disease (prophylaxis), mixed donor chimerism or minimal residual disease (preemptive), and relapse (therapeutic). DLI exploits donor derived graft versus tumor effects to induce a durable remission.
Aims: To evaluate DLI characteristics, outcomes and adverse events in a series of patients treated in three Bone Marrow Transplant Units of Northern Italy between January 2010 and June 2020.
Methods: Among 938 alloHSCT patients, 119 (12.7%) underwent DLI. Median age was 48.7 years (18-70). Patients were affected by acute myeloid leukemia (AML) (n=56), acute lymphoblastic leukemia (n=18), multiple myeloma (n=10), chronic myeloproliferative disease (n=10), Hodgkin lymphoma (n=7), myelodysplastic syndrome (n=6), non-Hodgkin lymphoma (n=5), chronic lymphocytic leukemia (n=4), mixed phenotype leukemia (n=1), severe aplastic anemia (n=1), and large granular lymphocytic leukemia (n=1). Conditioning was myeloablative in 57 (47.9%) patients, reduced-intensity in 62 (52.1%). Thirty-six (30%) donors were HLA-matched, 13 (11%) haploidentical, 70 (59%) HLA-matched unrelated. DLIs were prophylactic in 18 (15%) patients, preemptive in 43 (36%). Fifty-eight patients (49%) underwent therapeutic DLIs, 35 (60%) in combination with other drugs. DLI was administered in escalated schedule, from $1x10^5$ to $1x10^7$ CD3+ cells/Kg. Disease free survival (DFS) was calculated from the first DLI to relapse or last follow-up.
Results: The median number of DLIs was 4.6 (1-49), the median dose of total CD3+ cells infused was $2.9x10^7$/Kg (0.03-19.7). The median time elapsed between alloHSCT and the first DLI was 19 months (2-122). Complete remission (CR) was maintained in 13/18 (72%) patients undergoing prophylactic DLIs. Patients who received preemptive and therapeutic DLIs achieved CR in 30/43 (70%) and 22/58 (38%) cases, respectively. The median DFS was undefined in patients undergoing prophylactic or preemptive DLIs, 0.5 months (0-187) in those receiving therapeutic DLIs (p=<0.001). In the largest group of patients (i.e., AML), prophylactic, preemptive and therapeutic DLIs maintained or induced CR in 6/8 (75%), 12/20 (60%), and 10/28 (36%) cases, respectively.
Overall, 27/119 patients (23%) developed graft-versus-host-disease (GVHD). No significant differences were observed in terms of number of DLIs and donor type between patients with and without GVHD. Patients with GVHD received a slightly higher total number of CD3+ cells/Kg than those without ($3.31x10^7$ vs $2.74x10^7$, p=ns), though in a lower time frame (4.8 vs 5.2 months). GVHD was associated to a significantly higher CR rate (78% vs 48%, p=0.006), however, 3/27 (11.1%) patients died of GVHD. None of patients experienced bone-marrow aplasia following DLI. Overall, with a median follow-up of 38 months (0.3-189), 56/119 (47%) patients are currently alive in CR.
Summary/Conclusion: Although with the limits of a relatively small and heterogeneous series, our study indicates that DLI is an effective prophylactic and preemptive treatment option in alloHSCT patients. Prospective studies on homogeneous patient cohorts in terms of disease type and drug combination are awaited in order to address and ameliorate the effectiveness of DLI in therapeutic settings.

EP1268 FEASIBILITY OF ALLOGENEIC STEM-CELL TRANSPLANTATION WITH CONDITIONING REGIMEN OF 5-DAY DECITABINE IN MDS AND MDS/MPN : A MULTICENTER PROSPECTIVE COHORT STUDY IN CHINA

Y. Cao [1,*], E. Jiang [1]

[1]Hematopoietic Stem Cell Transplantation Center, Institute of Hematology and Blood Diseases Hospital, Peking Union Medical College and Chinese Academy of Medical Sciences, Tianjin, China

Background: Allogeneic stem-cell transplantation (allo-HSCT) is the only curative treatment in myelodysplastic syndromes (MDS) and MDS/myeloproliferative neoplasm (MPN). Post-HSCT relapse remains a major cause of treatment failure.
Aims: In our retrospective group, the addition of a 5-day schedule of decitabine conditioning regimen was proven to be feasible and effective.
Methods: We conducted a multicenter study to prospectively evaluate the feasibility of allo-HSCT with conditioning regimen of 5-day decitabine in 61 patients with a MDS, 6 with chronic myelomonocytic leukemia (CMML), and 9 with secondary acute myeloid leukemia (sAML) after MDS or CMML. Patients received Dec 20 mg/m^2/day on days -9 to -5, combined with a Bu/Cy/ Flu/ Ara-c modified preparative regimen.
Results: At a median follow-up of 563 (range: 8-1265) days, the overall survival (OS) was 82.9±4.5%, relapse incidence was 7.9±3.4%, and non-relapse mortality was 13.1±4.1%. Transplant related mortality(TRM) was assessed at 13% on the whole cohort. 6.5% has no engraftment for a total of 5 patients. A neutrophil count of >0.5 × 10^9/L was achieved at a median of 12 days (range, 6–21 days) and a platelet count of >20 × 10^9/L within 16 days (10–103 days) post-transplant. The incidence of severe acute (grade III/IV) graft-versus-host disease (GVHD) was 25.0% and that of chronic GVHD was 26.4%. At 2 years, OS was 78.8%,91.7% and 87.5%, respectively, for MDS patients with high risk, very high risk and sAML. Survival was promising in patients with poor-risk mutations, such as TP53 and ASXL1 (76.0%), and in those with ≥3 gene mutations (87.1%).
Summary/Conclusion: This new regimen was associated with a low relapse rate, low incidence and severity of GVHD, and satisfactory survival for allo-HSCT patients with MDS and MDS/MPN.

EP1269 DONOR-DERIVED ACTIVATED NK CELLS IN MANAGEMENT OF RELAPSE AFTER ALLOGENEIC HEMATOPOIETIC STEM CELL TRANSPLANTATION FOR ACUTE MYELOID LEUKEMIA

Z. Li [1,*], B. Deng [2], X. Wen [1], Y. Zhou [1], T. Wu [1]

[1]Department of Bone Marrow Transplantation, [2]Department of Cytology Laboratory, BEIJING BOREN HOSPITAL, Beijing, China

Background: Relapse remains the main cause of failure for hematopoietic stem cell transplantation (HSCT) in acute myeloid leukemia (AML). In some cases, leukemia cells may develop HLA loss which would result in poor response to conventional immunotherapy such as donor lymphocyte infusion (DLI) and thus NK cell therapy would be appropriate treatment.
Aims: In present clinical study, the safety and efficacy of donor-derived activated NK cells in management of relapse after allogeneic HSCT in AML were examined.
Methods: Between October 2019 and January 2021, 7 AML patients with hematologic relapse or minimal residual disease (MRD) positive after allogeneic HSCT and then received donor-derived activated NK cell therapy were enrolled. The median age was 10 (3-41) years old. Seven patients were with fusion genes (MLL-AF6 in 1, MLL-PTD in 1, CBFβ-MYH11 in 1, AML1-ETO in 4). The disease status before transplant was CR1 in 2 cases, CR2 in 3 and non-remission in 2. All transplants were from haploientical donors. Conditioning regimen was busulfan/fludarabine-based. Cyclosporine, MMF and short-term MTX were employed for GVHD prophylaxis. Isolated peripheral blood mononuclear cells (PBMCs) from original donors were co-cultured with cryopreserved-thawed irradiated genetically engineered (GE)_K562 feeder cells (a gift of Alex H. Chang, Shanghai YaKe Biotechnology Ltd., China) at a ratio of 2:1 (PBMCs:GE_K562) in SCGM media, with 100ul/ml IL-2 and donor serum for 8-9 days. Escalated dosages of NK cells were infused starting with 1×10^5 cells/kg (recipient's body weight) with or without IL-2 injection. The patients with hematologic relapse received NK cells 3 days later after chemotherapy. The disease status before NK cell therapy was hematologic relapse in 2 and MRD^+ in 5, and 2 cases with hematologic relapse failed to chemotherapy combined with DLI before NK cell therapy.
Results: The purity of donor-derived ex-vivo activated NK cells was 80-90%. Compared with our original culture system, the modified culture system enhanced approximately 20% to 40% of the purity and 3 to 6 fold in number of NK cells by day 8-9. The median NK cells infused were 5 (1-100) $\times10^5$ cells/kg with four-week interval. No transfusion-related side effects were noted. Five cases had response to NK cell therapy. Two cases with hematologic relapse all had response (CR) to NK cell therapy. For 5 cases with MDR^+, 1 case had a complete response, 2 cases had 1 log reduction in fusion gene, and 2 cases had no response. With the median follow-up192 (22-510) days, 7 cases have been survived, 5/7 cases have been survived free of diseases. Two patients relapsed.
Summary/Conclusion: Our preliminary results have demonstrated that donor-derived ex-vivo activated NK cells are safe and effective treatment in relapse after allogeneic HSCT in AML patients who even failed to chemotherapy combined with DLI. Optimal culture system with cryopreserved-thawed irradiated genetically engineered (GE)_K562 feeder cells has improved not only NK cell's purity and number but also clinical efficacy compared with our previous study.

EP1270 RESULTS OF AUTOLOGOUS STEM CELL TRANSPLANTATION IN MULTIPLE MYELOMA PATIENTS WITH RENAL FAILURE: A RETROSPECTIVE SINGLE-CENTER STUDY

M. Firsova [1,*], L. Mendeleeva [1], M. Solovev [1], V. Savchenko [2]

[1]Department of High-dose Therapy of Paraproteinemic Hemoblastoses, [2]National Research Center for Hematology, Moscow, Russian Federation

Background: According to the Russian register renal impairment at the time of diagnosis was noted in every fifth patient with multiple myeloma (MM). Timely induction therapy followed by autologous stem cell transplantation (ASCT) in some cases contributes to the reversibility of renal failure
Aims: To study the efficacy and safety of high dose therapy followed by ASCT in patients with MM and renal failure
Methods: A retrospective single-center study was performed, including 64 (30 males, 34 females) MM patients with renal failure at the time of diagnosis aged 19 to 65 years (median 54) underwent ASCT during a period from 2013 to 2019. At the time of diagnosis median of serum creatinine level was 462 μmol/L, and median of glomerular filtration rate was 10 ml/min/1.73 m^2 (CKD-EPI). 23 patients (36%) were dialysis-dependent at the time of diagnosis. Induction therapy included bortezomib-containing regimens in all patients, immunomodulatory drugs were used in 20% of cases. Before ASCT the overall response rate (CR, VGPR, PR) was documented in 91% of cases, CR was achieved in 45% of patients. Renal response was achieved in 80% of patients (complete response – 28%). In 13 of 23 cases (57%) dialysis was stopped after induction therapy. 10 patients were dialysis-dependent at the time of ASCT. 47 patients (73%) underwent a single and 17 patients (27%) underwent a tandem ASCT (Mel 140-200 mg/m^2). The analysis of complications, a requirement for transfusion therapy was carried out in 2 subgroups: subgroup A - patients without dialysis at the time of ASCT (n = 54), subgroup B - dialysis-dependent patients at the time of ASCT (n = 10).
Results: Reactivation of a herpesvirus infection was developed significantly more often in the subgroup B patients compared to the subgroup A patients (30% versus 6%, p = 0.04). Reversible toxic encephalopathy was developed significantly more often in the subgroup B patients comparison with the subgroup A patients (20% versus 0, p = 0.02).In subgroup B patients compared to subgroup A patients significant differences were observed in a requirement of the red blood cell transfusions (100% vs 37%, p = 0.001).100 days after ASCT the achievement of the overall response rate increased from 91 to 96%, the percentage of CR increased from 45% to 64%. After auto-HSCT, there was an increase in the rate of achieving complete renal responses - from 28% to 34%, however, the rate of total renal response remained within 80% (fig.1). In one case dialysis was stopped after the transplantation. So, at the time of diagnosis 23 patients were dependent on the renal replacement therapy. As a result of the treatment (induction therapy with auto-HSCT), 14 patients (61%) became hemodialysis-independent. Follow-up of these patients lasts from 1.5 to 7 years. There was no transplant-related mortality. After a median follow-up of 48 months 5-year overall survival (OS) was 70%, and 5-year progression-free survival (PFS) was 42%. We were analyzed OS and PFS depending on the dose of melphalan (140 versus 200), no statistically significant difference was obtained

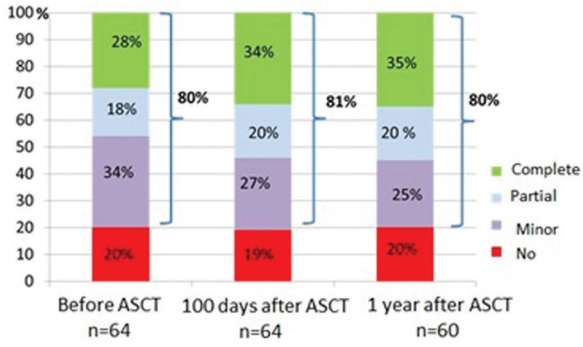

Fig. 1. Renal response in MM patients

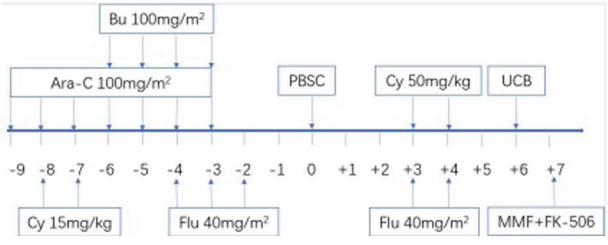
Summary/Conclusion: ASCT is feasible, safe and effective method of the treatment in MM patients with severe kidney injury. Induction therapy followed by ASCT allowed reducing a requirement of dialysis from 36% at the time of diagnosis to 14% after ASCT. In our study 14 of 23 patients (61%) became dialysis independent. Overall, this work confirmed dialysis-dependent MM patients should not be excluded from high dose therapy followed by ASCT

EP1271 POST-TRANSPLANTATION FLUDARABINE AND CYCLOPHOSPHAMIDE SELECTED AND PROMOTED UNRELATED UCB IMPLANTATION IN COMBINED TRANSPLANTION OF HALPOID AND UCB STEM CELLS FOR TREATMENT OF PEDIATRIC LEUKEMIA

X. Feng [1,*], S. Liu [2], Y. He [1], Y. Xiao [1], L. Chen [1], X. Liu [1], Y. Ruan [1], Y. Ren [1]



[1]Pediatrics, Nanfang Hospital, Southern Medical University, Guangzhou, [2]Hematology, Shenzhen Children Hospital, Shenzhen, China

Background: For patients without HLA matched donor, PTCY in haploid stem cell transplantation has relatively higher risk of relapse and severe GVHD. Umbilical cord blood (UCB) are readily available and has helped expand the donor pool to almost all patients requiring a transplant. Meanwhile UCB transplant improves outcomes in leukaemia with lower risk of relapse and GVHD.However, the clinical application of UCB is limited due to their small cell numbers and lower implantation rate than other sources of hematopoietic stem cells(HSC).

Aims: This clinical study is to explore the feasibility and efficacy of post-transplantation fludarabine and cyclophosphamide to select and promote the unrelated UCB to engraft in combined transplantation of haploid and UCB stem cells for the treatment of childhood and adolescent leukemia.

Methods: Total 27 children and adolescent patients with leukemia in Nanfang Hospital and Shenzhen Children's Hospital enrolled this study from Sept.2019 to Feb.2021. These patients were diagnosed as AML (3 secondary AML, 3 relapsed AML, 11 HR, 3 IR), ALL(2 relapsed, 2 HR),JMML(2) and MDS(1) with a median age of 10 years (range 1-17 years). Only one patient is BM PR before HSCT. The haploid stem cell was 5/10-9/10 mismatched and UCB was selected as 6/10-10/10 HLA matched or mismatched. The condition regimen was busulfan+fludarabine+CY+Ara-C. Haploid PBSC was infused in day0. All received PTCy 50 mg/kg and posttransplantation fludarabine 40mg/m^2 on days 3 and 4 along with tacrolimus or cyclosporine and mycophenolate mofetil for prophylaxis of acute graft-versus-host disease(GVHD). UCB was infused in day6. A median of haploid stem cells of 11.08×10^6/kg(1.51-23.20) of CD34+ cells/kg was infused while a median of UCB cells of 1.80×10^5/kg(0.40-4.80) of CD34+ cells/kg was infused.

Results: At a median follow-up of 6 months (range 2-17), all patients are alive and leukemia free. Among these patients, 25/27(92.6%, *95%CI*: 0.820~1.032)of patients achieved complete chimerism of unrelated UCB cells and 2/27(7.4%, *95%CI*: -0.032~0.180) of patients achieved high-level mixed chimerism of unrelated UCB cells rather than haploid cells. Two recent patients had primary poor graft function around posttransplantation of 70days. Neutrophil reconstitution was achieved in 25/27 patients with a median time of 30 days (range 17-44 days)without G-CSF after transplantation. Platelet recovery was achieved in 25/27 patients with a median time of 39 days (range 8-92 days).The incidence of grade I and grade II GVHD was 37% and 37% respectively (*95%CI*: 0.176~0.565). There was no grade III-IV GVHD and no extensive chronic GVHD. The incidence of chronic limited GVHD was 6/22(27.3%, *95%CI*: 0.071~0.475). Fourteen of 27 (51.9%, *95%CI*: 0.317~0.720) patients experienced clinically significant CMV reactivations or infections. One of 27 (3.7%,*95%CI*: -0.039~0.113) patients experienced EB virus reactivation.

Summary/Conclusion: In our primary clinical study, post-transplantation fludarabine and cyclophosphamide could effectively selecte and promote the unrelated UCB to implant rather than haploid cells in combined transplantion of halpoid and UCB stem cells even if the dose of CD34+ cells of UCB as little as less than 1.00×10^5/kg. Although acute GVHD was common but just milder degree and with lower incidence of EB virus reactivation. This new strategy has the potential to promote the wilder clinical use of unrelated UCB in the treatment of leukemia.

EP1272 RELAPSED/REFRACTORY (R/R) HODGKIN LYMPHOMA (HL): WHO SHOULD RECEIVE CONSOLIDATION TREATMENT AFTER AUTOLOGOUS STEM CELL TRANSPLANTATION (ASCT)? EXPERIENCE OUTSIDE CLINICAL TRIALS.

D. Galopoulos [1,*], T. P. Vassilakopoulos [1], M. Moschogiannis [2], P. Tsirkinidis [1], G. A. Pangalis [2], M. Efstathopoulou [1,2], E.-F. Triantafyllou [1], T. Giannikos [1], P. Petsa [1], E. Chatzidimitriou [1], I. Drandakis [1], A. Georgopoulou [1], E. Konstantinou [1], A. Kopsaftopoulou [1], M.-A. Lefaki [1], A. Machairas [1], A. Piperidou [1], I. Vassilopoulos [1], K. Konstantopoulos [1], M. K. Angelopoulou [1]

[1]Hematology and BMT Department, Laikon General Hospital, [2]Department of Hematology, Psychikon Branch, Iatriko Athinon, Athens, Greece

Background: Salvage chemotherapy followed by high-dose chemotherapy and ASCT is the standard treatment approach for R/R HL patients. This strategy leads to cure of almost half of the patients. Several HL study groups suggest various prognostic factors that identify patients at high risk for failing ASCT. These patients benefit from brentuximab vedotin (BV) consolidation treatment, as suggested by the AETHERA trial.

Aims: The identification of prognostic factors and the construction of an algorithm, to identify individuals at high-risk for progressing after ASCT from a series of consecutive R/R HL patients, treated in a single Unit.

Methods: A total of 189 patients who received ASCT between 1996 and 2020 were retrospectively analysed with a median follow-up of 106 (range 9-369) months, median age: 32 years, 110 males. The following factors were studied: age, sex, histologic type, stage, number of involved fields, extranodal, bulky disease, B-symptoms at diagnosis and at relapse, anemia at relapse (Hb<13 g/dl (males) and <12 g/dl (females), response to 1st line and salvage chemotherapy regimens, number of therapies before ASCT, use of radiotherapy, and disease status pre-transplant as assessed by computed tomography (CT) and positron emission tomography (PET), as well as by a composite score integrating both CT and PET. The primary endpoint was 5-year freedom from progression (FFP). Univariate Kaplan Meier analysis was conducted, followed by multivariate analysis using the Cox Proportional-Hazards Model.

Results: Univariate Analysis revealed the following significant factors for FFP: Response after 1st line and 1st salvage, Early (including primary refractory) vs late relapse, B-symptoms and anemia at relapse, disease status pre-transplant, as assessed by CT, PET and the composite PET and CT score. The latter was the factor with the highest significance (p<0.001), that could stratify patients into three groups with different outcomes. The 1st group included patients with complete remission (CR) by CT and PET up to Deauville 5-point scale (D5PS) of 4, and those with partial remission (PR) by CT and PET D5PS 1-3; the 2nd group included patients in PR by CT and PET D5PS 4-5, and those with stable disease (SD) by CT regardless of PET; finally the 3rd group included patients with progressive disease (PD) by CT, regardless of PET.

By multivariate Cox Regression analysis 2 factors remained significant: 1. The composite PET and CT score pre-transplant showed that patients of group 2 and 3 are more likely to relapse after ASCT, compared to those of group 1, (p=0.002, <0.001, hazard ratio 3.45 and 9.49, respectively), 2. Anemia at relapse; patients presenting without anemia at relapse had 51% less risk of progression (p= 0.033). PD and PR after 1st line of treatment show almost double, but marginally significant (p= 0.046 and 0.055, respectively) risk for progression, and SD was insignificant(p=0.99), but few cases were included (N=8).

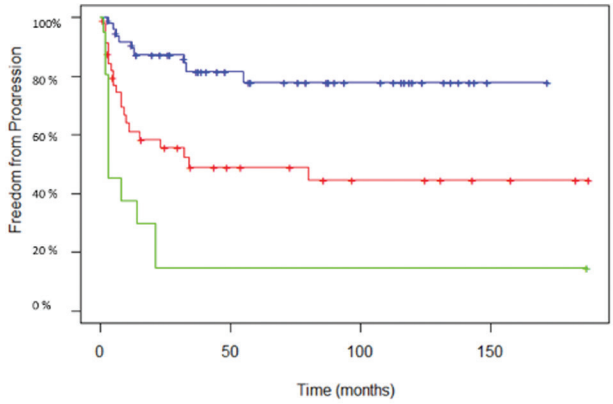


Figure 1: Freedom from Progression Survival Curves for the three groups, adjusted for gender, anemia and response to first line of treatment

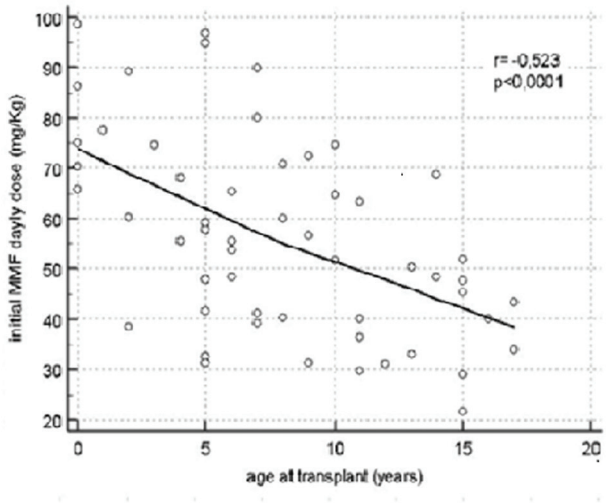
Groups	5 year FFP	Total Events/ Number of cases#	Log rank test p value
Group 1: CR by CT and PET D5PS: 1-4, PR by CT and PET D5PS:1-3	78%	9/50	<0.001
Group 2: PR by CT and PET D5PS: 4-5, SD by CT, regardless of PET D5PS*	49.1%	21/40	
Group 3: PD by CT, regardless of PET D5PS	19%	14/15	

*Three patients CR by CT and PET D5PS:5 were also included in Group 2
the number of cases is smaller, as these with missing values were excluded from multivariate analysis

Summary/Conclusion: Analysis of real world data showed that disease status assessment using both CT and PET prior to transplant can direct therapeutic strategy in R/R HL patients undergoing ASCT. Patients with PD do not benefit from the procedure and should be treated with alternative treatment. Patients with CR by CT and PET up to D5PS of 4 or these with PR by CT and PET up to D5PS 3, show excellent prognosis and do not need consolidation treatment post ASCT. The remaining ones representing 25% of the population are those who may benefit from BV maintenance. This strategy is currently adopted by our center.



EP1273 AREA UNDER THE CURVE BASED MYCOPHENOLATE MOFETIL DOSAGE REDUCED THE INCIDENCE OF GVHD AFTER ALLOGENIC HSCT IN PEDIATRIC PATIENTS: ONE FACILITY'S EIGHT-YEAR EXPERIENCE

A. Grasso [1,*], G. Carlone [2], R. Simenone [3], M. Baraldo [4], A. Maestro [1], D. Zanon [1], B. Egidio [1,2], M. Natalia [1]

[1]Institute for Maternal and Child Health-IRCCS Burlo Garofolo, [2]University of Trieste, [3]Department of Transfusion Medicine, Trieste, [4]Department of Medicine (DAME), Udine, Italy

Background: Use of mycophenolate mofetil (MMF) has been developed with different prophylactic regimens to obtain effective immunosuppression in combination with calcineurin inhibitors (FK506 or cyclosporine (CsA)) and/or serotherapy (anti-thymocyte immunoglobulin or alemtuzumab). However, the drug presents a significant inter and intra-patient variation that could lead to an inadequate GvHD prophylaxis or, on the contrary, excessive immunosuppression.
Aims: Study of the pharmacokinetics of MMF (MPA AUC) may help to correctly adequate dose and efficacy of GvHD prophylaxis but only a few data are available in pediatric population. Our study aims to find the correct balance in drug dosage to maximize the GvhD prophylaxis without impairing the process of immune recostitution.
Methods: We conducted a retrospective single-centre study at IRCCS "Burlo Garofolo". The primary goal was to analyze whether FK506 plus MMF prophylactic regimen, with MMF administered dose based on MPA AUC, reduces the incidence of acute and chronic GvHD in pediatric patients comparing with a control historical cohort. Inclusion criteria were age under 18 years, first HSCT, myeloablative conditioning regimen, and at least twelve-month follow-up after HSCT. Control group consisted of CsA and short-course of MTX or CsA and MMF at a standard daily dose of 30 mg/kg with pre-dose plasma level monitoring. All patients in the study group received FK506 and MMF as GvHD prophylaxis. The initial daily dose of MMF in this group was a minimum of 30 mg/kg and subjected to therapeutic drug monitoring (TDM) through MPA AUC.

Results: The two populations considered were 55 pts (study group) that received HSCT from 01/11 and 12/19 and 57 patients (control group) from 01/02 to 12/10. The demographics, clinical and HSCT features of the two groups were comparable. (table 1) After a twelve-month follow-up period, we observed a statistically significant difference either in overall acute GvHD (13% vs 69% p<0.0001) and overall chronic GvHD (5% vs 18% p<0.05). Comparing the incidence of different grades of GVHD in the study and the control group, we found statistically significant differences of the rate of acute GvHD I-II grade, acute GvHD III-IV grade, and acute GvHD III-IV grade with donor lymphocyte infusion (DLI)-related onset (45% vs 9%p<0.0001; 22% vs 5% p<0.001, 20% vs 2% p<0.0001, respectively). AUC of MMF leads to change drug dosage one time during the 28 days post-transplant prophylaxis with an increase of dosage mainly under six years of age and a strong inverse correlation (r= -0,523, p<0.0001) between initial daily MMF dose and age at transplant. (figure 1) Finally, no difference was shown in term of relapsed disease in the study group versus the control historical group (20% and 21.3%, respectively).

Summary/Conclusion: In our study using a drug monitoring of MMF through the calculation of MPA AUC shows a significant reduction of acute and chronic GvHD incidence. Furthermore, analyzing AUC curves, we saw that patients under six years of age need a significantly higher dose of daily MMF due to greater drug clearance than in older children. Due to the limitation of a retrospective, monocentric study furtherinvestigations are warranted to define efficacy and safety of FK506/MMF prophylaxis.

EP1274 EBMT, RPAM AND EASIX SCORES – IS THERE A BETTER PREDICTOR OF SURVIVAL AFTER ALLOGENEIC HEMATOPOIETIC STEM CELL TRANSPLANTATION FOR ACUTE MYELOID LEUKEMIA?

C. Afonso [1,*], C. Rodrigues [2], J. Pimenta [3], R. B. Ferreira [4], L. Leite [4], G. Brás [4], P. Coelho [4], C. Pinho Vaz [4], A. Campos Jr [4]

[1]Department of Clinical Hematology, Centro Hospitalar e Universitário de Coimbra, Coimbra, [2]Department of Clinical Hematology, Centro Hospitalar Tondela-Viseu, Viseu, [3]Department of Oncology, Centro Hospitalar de Trás-os-Montes e Alto Douro, Vila Real, [4]Department of Bone Marrow Transplantation, Instituto Português de Oncologia do Porto Francisco Gentil, Porto, Portugal

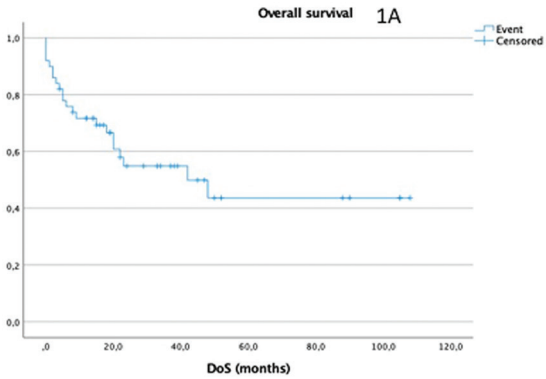
Background: Several scoring systems have been developed to predict the clinical outcome in hematopoietic stem cell transplantation (HSCT). The score of the European Society for Blood and Marrow Transplantation (EBMT) and the revised Pretransplantation Assessment of Mortality (rPAM) score include clinical characteristics of the patient, donor and disease status. Most recently, the Endothelial Activation and Stress Index (EASIx), a laboratory biomarker-based formula including serum creatinine, lactate dehydrogenase, and platelet count, was developed as a predictor of mortality after allogeneic HSCT (allo-HSCT). Data regarding the comparative performance of these scores are lacking.

Aims: To compare the performance of 3 scoring systems in a cohort of patients (pts) with acute myeloid leukemia (AML) undergoing allo-HSCT.
Methods: Retrospective analysis of 95 adult AML patients (pts) who underwent allo-HSCT between January 2015 and December 2019 in a single institution. EBMT and rPAM scores and EASIx prior to conditioning (EASIx-pre) were calculated for each patient. Using Cox regression, the predictive ability of each score for non-relapse mortality (NRM), relapse free survival (RFS), overall survival (OS), and acute graft versus host disease (aGvHD) was assessed.
Results: The median age at HSCT was 49 years (22-65), and 55% of pts were male. Seventy-five pts (80%) were in first complete remission at the time of allo-HSCT. Fifty-four pts (57%) were treated with myeloablative conditioning (MAC) regimens while the remaining pts received reduced intensity conditioning (RIC). Donors were a matched sibling in 53% of pts, a fully matched unrelated donor in 28%, and a partial matched unrelated donor in 17%. The stem cell source was peripheral blood in the majority of the pts (98%). The incidence of aGvHD was 55%, and the median time to onset of aGvHD was 33 days (8-211). The median OS and RFS for the whole cohort was 26 months and not reached (NR), respectively. NRM rate for the whole cohort was 24%. EASIx-pre predicted OS (HR 1.04; p= 0,021); however, its predictive ability did not remain after adjustment for other variables (age, donor type, conditioning intensity and disease status). RFS, NRM and aGvHD were not predicted by EASIx-pre. Revised PAM score predicted the occurrence of aGvHD (p=0,038); however, this score did not predict OS, RFS and NRM. EBMT score did not predict the assessed outcomes.
Summary/Conclusion: In our cohort, EASIx-pre was the only score predicting OS; however, the association between EASIx-pre and OS lost its significance in multivariate analysis, suggesting that EASIx-pre is not an independent predictor of OS. Neither rPAM nor EBMT score could predict survival outcomes. Interestingly, rPAM had a statistically significant association with aGvHD. Our results suggest that new scoring systems relying on biomarkers may improve predictive ability of survival after allo-HSCT for AML.

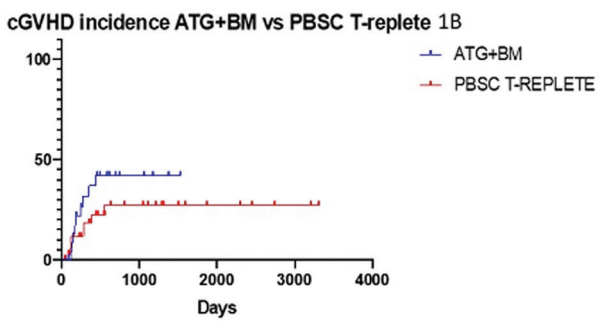
EP1275 PREVALENCE OF PURE RED CELL APLASIA AFTER HEMATOPOIETIC TRANSPLANTATION USING MAJOR ABO-INCOMPATIBLE UNMANIPULATED PERIPHERAL BLOOD STEM CELLS

P. Zhu [1], Y. Wu [1], J. Shi [1], J. Yu [1], Y. Zhao [1], X. Lai [1], H. Huang [1], Y. Luo [1,*]

[1]Bone Marrow Transplantation Center, the First Affiliated Hospital, Zhejiang University School of Medicine, Hangzhou, China



Background: Pure red cell aplasia (PRCA) is considered an uncommon but critical complication after ABO-incompatible allogeneic hematopoietic stem cell transplantation (HSCT). Previous studies have demonstrated several risk factors for post-HSCT PRCA, such as anti-A isohemagglutinins against donor red blood cells (RBC) and reduced-intensity conditioning regimens.
Aims: We intended to evaluate the clinical outcomes in the context of ABO-incompatible transplantation using peripheral blood stem cells.
Methods: We carried out a prospective nested case-control study to determine the prevalence and factors associated with PRCA following major ABO-incompatible peripheral blood stem cell transplantation (PBSCT) between August 1, 2014 and June 30, 2020. A total of 478 patients receiving ABO-incompatible PBSCT were observed and divided into 3 cohorts, including 196 with major grafts, 214 with minor grafts, and 68 with bidirectional grafts. The nested case-control study enrolled 187 patients after major ABO-incompatible PBSCT for the detailed analysis.
Results: A total of 13 out of 187 patients developed PRCA. The factors associated with PRCA were the patient's age, donor type, and the use of anti-T-lymphocyte globulin (ATG). Haploidentical related donor (HRD) was the only independent factor for PRCA after HSCT in the multivariate analysis (HR=0.029, 95%CI 0.004-0.231, P<0.001). The presence of PRCA did not influence overall survival (OS), disease-free survival (DFS), acute or chronic graft-versus-host disease (GVHD), non-relapse mortality (NRM), and relapse rate after HSCT.
Summary/Conclusion: The incidence of PRCA was 7% (95% CI, 3.9%>11.9%) after major ABO-incompatible PBSCT and low dose ATG-based haploidentical transplantation can significantly decrease the development of PRCA post-HSCT.

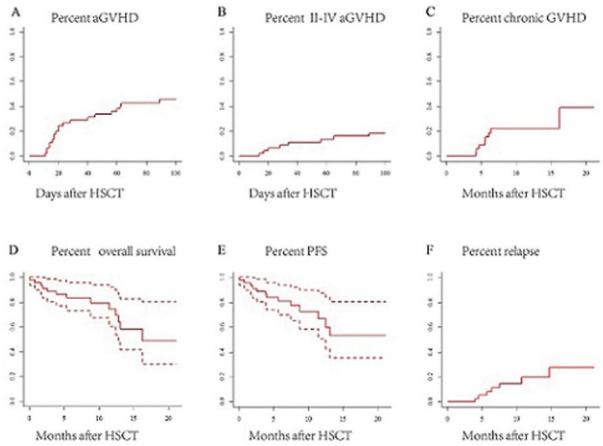


EP1276 EXCELLENT COMPARABLE OUTCOMES OF HAPLO-HSCT IN HIGH RISK MYELOID MALIGNANCIES USING MYELOABLATIVE OR REDUCED INTENSITY CONDITIONING WITH LOW RISK OF CGVHD IN RECIPIENTS OF PERIPHERAL BLOOD STEM CELL

D. Avenoso [1,*], M. Hassanein [1], R. El Fakih [2], P. Krishnamurthy [1], W. Rasheed [2], V. Mehra [1], S. Ahmed [2], H. De Lavallade [1], M. Shaheen [2], A. Kulasekararaj [1], M. Aljurf [3], S. Gandhi [1], M. Altareb [2], A. Pagliuca [1], F. Dazzi [1], M. Kenion [1], S. Ware [1], Y. T. Leung [1], V. Potter [1]

[1]Haematological Medicine, King's College Hospital, London, United Kingdom, [2]King Faisal Specialist Hospital and Research Centre, Riyadh, Saudi Arabia, [3]King Faisal Specialist Hospital and Research Centre, Riyad, United Kingdom

Background: Haploidentical haematopoietic stem cell transplant (haplo-HSCT) is a potentially curative option for patients with myeloid malignancies lacking an HLA identical donor. Although the original platform was based on bone marrow (BM) as cellular source, many transplant centres now use G-CSF mobilised peripheral blood stem cells (PBSC). Chronic graft versus host disease (cGVHD) is a complication that can jeopardize the transplant outcome; for that reason, some centres still prefer BM or use t-depletion with ATG. Relapse rates are also of concern, and the optimal intensity of conditioning (MA vs RIC) in haplo-HSCT for patient with acute myeloid leukaemia (AML) and myelodysplastic syndrome (MDS) remains unclear.
Aims: The aim of this paper is to compare results of two different haplo-HSCT approaches (BM vs PBSC and MA vs RIC) in patients affected by AML and MDS at King's College Hospital (KCH) in London and King Faisal Hospital (KFH) in Riyadh.
Methods: Between August 2010 and March 2020, 50 patients with a median age of 46 (14-60yrs) and a high-risk myeloid malignancy were identified (AML n=34, MDS n=16). At KCH, haplo-HSCT (n=23) was performed with G-CSF mobilized PBSC with FluCyTBI protocol (Cy 14.5 mg/kg/ days -6, -5, fludarabine 30 mg/m2/ days -6 to -2, and 200 cGy Total Body Irradiation day -1). At KFH 27 patients had t-deplete BM with TBF regimen (thiotepa 5 mg/kg days -8, -7, fludara 50 mg/m2 days -6, -5, -4, busulphan 3.2 mg/kg days -6, -5, -4, rabbit ATG 1 mg/Kg day -3, -2). GVHD prophylaxis was with post-transplant cyclophosphamide



(50 mg/kg day +3 and +4 at KCH; day +3 and +5 at KFH), mycophenolate and tacrolimus. All patients were in morphological complete remission prior to HSCT. A median 4,8x10^6 (1,5-14) CD34+/Kg was infused.
Results: At 24 months 55% of patients were alive and in CR, with median overall survival (OS) not reached (Fig 1A) and no differences between the two cohorts. Two septic deaths before engraftment and 3 primary graft failure were noted. Among 45 evaluable patients, median time to neutrophils □ 1000/□L was 17 days (13-42), and 25 days (14-44) to platelets □ 20.000/□L. Median CD3 and CD 15 chimerism at day 100 was 100%. Overall incidence of acute GVHD was 35% (grade I-II 76%; grade III-IV 24%) with no differences between t-replete PBSC and t-deplete BM. cGVHD rate was 26% (30% mild, 13% moderate, 56% severe) and significantly different between the two cohorts (in the PBSC cohort the incidence was 25% vs 40% in the t-deplete BM population (p 0.05 – Fig 1B)). CMV reactivation occurred in 77% of patients, at a median of 42 days after transplant (10-415); 74% patients of KFH had detectable CMV within 4 weeks whereas 54% of KCH's patients developed CMV reactivation; no cases of CMV disease were noted. The relapse rate at 4 years was 26% for both t-deplete BM and t-replete PBSC (p not significant). Overall, 18 patients (36%) died; cause of death were relapse (57%), GVHD (10%) and sepsis (33%).
Summary/Conclusion: this retrospective analysis demonstrated good OS in AML and MDS. The use of a haploidentical protocol with PBSC resulted in a low rate of cGVHD compared to a MA approach that utilised BM with the addition of ATG. Whilst noting the inherent limitations of retrospective data we conclude that PBSC is a safe and effective cell source for haploidentical transplants. Future strategies directed at relapse prevention either via further optimisation of the conditioning, post-HSCT maintenance or cellular therapy will be important for the optimal delivery of the RIC PSBC haplo-HSCT.

EP1277 CLINICAL EXPERIENCE OF VENETOCLAX THERAPY AS A BRIDGE TO ALLOGENEIC HEMATOPOIETIC STEM CELL TRANSPLANTATION FOR LEUKEMIA AND OTHER HEMATOLOGIC MALIGNANCIES: A MULTI-CENTER RETROSPECTIVE STUDY

T. Yang [1,2,3,4,*], X. Song [5], Y. Zhao [1,2,3,4], B. Ye [6], Y. Luo [1,2,3,4], H. Xiao [7], Y. Chen [8], H. Fu [1,2,3,4], J. Yu [1,2,3,4], L. Liu [1,2,3,4], X. Lai [1,2,3,4], J. Lan [5], H. Huang [1,2,3,4], J. Shi [1,2,3,4]

[1]Bone Marrow Transplantation Center, The First Affiliated Hospital, Zhejiang University School of Medicine, [2]Institute of Hematology, Zhejiang University, [3]Zhejiang Province Engineering Laboratory for Stem Cell and Immunity Therapy, [4]Liangzhu Laboratory, Zhejiang University Medical Center, [5]Department of Hematology, Zhejiang Provincial People's Hospital, [6]Department of Hematology, The First Hospital Affiliated to Zhejiang Chinese Medical University, [7]Department of Hematology, Sir Run Run Shaw Hospital, Zhejiang University School of Medicine, Hangzhou, [8]Department of Hematology, The First Affiliated Hospital of Wenzhou Medical University, Wenzhou, China

Background: The use of Bcl-2 inhibitor venetoclax (Ven) combined with hypomethylating agents or chemotherapy has shown promising results in treating Acute myeloid leukemia (AML) and other hematologic malignancies as frontline treatment and for relapse. However, studies regarding the effect of Ven therapy on subsequent HSCT are limited.
Aims: Aiming to evaluate the outcome of patients undergoing allogeneic hematopoietic stem cell transplantation (allo-HSCT) after Ven therapy, we retrospectively collected data from patients treated at four transplant centers in Zhejiang Province, China.
Methods: Patients who had received ≥1 cycle of Ven combinations prior to undergoing HSCT were included. Conditioning regimens included myeloablative regimens and nonmyeloablative regimens, which were determined by the individual transplant physician based upon disease- and transplant-related considerations.
Results: Forty-five patients who underwent HSCT after Ven therapy were enrolled between November 2018 and November 2020. Thirty-one patients were diagnosed with AML (28 were de novo AML, 3 were secondary for MDS), 6 with MDS, 3 with ALL, 2 with CMML, and 2 others. The majority (75.6%) of patients received Ven for treatment of relapse (40.0%) or induction failure (35.6%), 5(11.1%) were treated as initial treatment, and 6(13.3%) patients who were already in CR received Ven for further consolidation or deep remission before HSCT. Thirty-three (73.3%) patients were in complete remission at the time of HSCT. The median time of neutropenia and platelet engraftment were 12 days and 13 days, respectively. Day +100 cumulative incidences of acute graft-vs-host disease (aGVHD) and grade II-IV aGVHD was 42.9% and 15.9%. Of 39 evaluable patients, 38.9% developed chronic GVHD developed. The 100-day cytomegalovirus (CMV) reactivation occurred in 74.4% of patients; Epstein-Barr virus (EBV) reactivation in 38.1% of patients. With a median follow-up of 9.5 months, one-year overall survival, progression-free survival and relapse incidence were

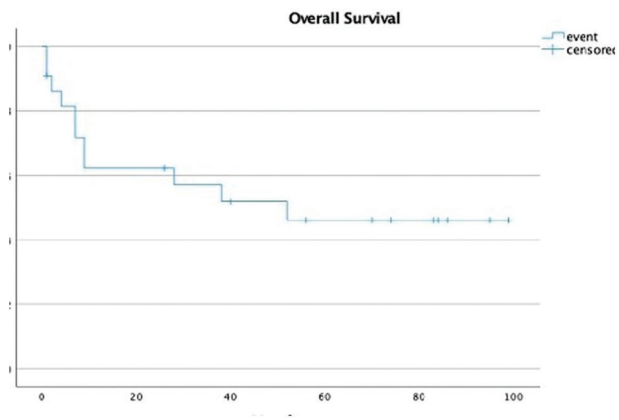
74.5%, 56.9% and 19.8%, respectively.
Summary/Conclusion: Our multicenter results showed that patients receiving HSCT after Ven therapy had favorable transplant outcomes with low aGVHD and relapse incidence, suggesting the feasibility of Ven proceeding to HSCT. Meanwhile, virus reactivation monitor should be paid attention.

EP1278 INCIDENCE, ETIOLOGY AND PROGNOSTIC IMPACT OF ATYPICAL ELECTROPHORETIC PROFILES IN PATIENTS RECEIVING ALLOGENEIC HEMATOPOIETIC STEM CELL TRANSPLANTATION

H. Kaies [1,*], C. Valentin [1], C. Amandine [2], C. Sandrine [3], G. Antoine [1], B. Thomas [4], A. Caulier [5], S. Chloé [1]

[1]Biochemistry laboratory, [2]Hematology department, [3]virology laboratory, [4]Hematology laboratory, Centre Hospitalio-universitaire Amiens France, [5]hematology department, Amiens University Hospital Center City, Amiens, France

Background: Atypical electrophoretic profiles (AEP) may appear in patients who required allogeneic hematopoietic stem cell transplantation (allo-HSCT). Nevertheless, their clinical significance remains unkown. AEP combine either monoclonal and oligoclonal components, suspected on serum protein electrophoresis and confirmed by immunofixation.
Aims: The purpose of the study is to analyze the incidence, etiology and prognosis of AEP in patients who received allo-HSCT for myeloid malignancies.
Methods: In this retrospective study, we recruited 117 patients with myeloid disease who received an allo-HSCT between 2012 and 2018. We excluded patients with lymphoid malignancies, multiple myeloma, patients with AEP before transplantation, and patients who died within 100 days after transplantation.
Results: AEP occurred in 42.7% of patients. The cumulative incidence of AEP was significantly higher in patients with acute Graft Versus Host Disease (GVHD, p=0.019) and in patients with CMV reactivation (p=0.0017). Noticeably, we showed for the first time that AEP mainly appeared in patients transplanted from a CMV+ donor (p=0.031). CMV reactivation preceded the onset of AEP in most patients. In patients with AEP, we observed a significantly longer time to relapse (486 vs 189 days, p=0.006) and a better overall survival (OS; 33.1 months vs 28.3 months, p=0.049). The presence of an AEP was the only factor that significantly improves OS in both univariate and multivariate analyses.
Summary/Conclusion: The occurrence of an AEP, after allo-HSCT, may result from an adapted post-transplant immune response, as an anti-CMV clonal expansion from pre-immunized donor cells. These atypical profiles could reflect both GVH and GVL activity, leading to favourable outcomes. This study provides new insights for clinicians that monoclonal or



oligoclonal components on protein electrophoresis are common, benign and associated with an improved prognosis after allo-HSCT.

EP1279 GOOD OUTCOME OF HIGH-RISK MYELOFIBROSIS IN ELDERLY RECIPIENTS AFTER FULL INTENSITY T-DEPLETE CONDITIONING WITH FLUDARABINE, BUSULFAN, WITH SINGLE AGENT CICLOSPORIN AS GVHD PROPHYLAXIS.

D. Avenoso [1,*], M. Hassanein [1], M. de Farias [1], P. Krishnamurthy [1], V. Mehra [1], H. De Lavallade [1], A. Kulasekararaj [1], S. Gandhi [1], A. Pagliuca [1], F. Dazzi [1], M. Kenyon [1], S. Ware [1], Y. T. Leung [1], V. Potter [1]

[1]Haematological medicine, King's College Hospital, London, United Kingdom

Background: The expected median survival of intermediate risk and high-risk myelofibrosis (MF) defined by dynamic international prognostic staging system (DIPSS) is of 2.9 and 1.3 years, respectively.
For that reason, allogeneic hematopoietic stem cell transplant (HSCT) is still considered the only curative option for those patients that are eligible for it.
The use of peripheral blood stem cell (PBSC) as graft source is allowing a fast engraftment, but there is still uncertainty among different centres about the most appropriate conditioning regimen in MF and the maximum age limit for myeloablative (MA) conditioning.
Aims: Herein we report the outcome of myeloablative HSCT in patients older than55 with high-risk MF as defined by DIPSS.
Methods: Between April 2012 and December 2018, 22 patients (10 high risk, 12 intermediate-2) with a median age of 61 (range 44-68 years) had full matched allogeneic stem cell transplant. HSCT was performed with GCSF mobilised PBSC. Conditioning protocol was with fludarabine 15 mg/m^2 days -9, -8, -7, -6, -5, busulfan 3.2 mg/Kg days -6, -5, -4, -3; graft versus host disease (GVHD) prophylaxis consisted of thymoglobulin before transplant (ATG 5.5 mg/Kg until January 2015; ATG 5 mg/Kg since March 2016) and single agent ciclosporin 1.5 mg/Kg (therapeutic level of 200) until d+90 and then tapered. A median of 5x10^6 CD34+/Kg was infused (3.2 – 6). Donors were: 10 siblings, 11 unrelated donor, 1 mismatched unrelated donor.
Results: at 24 months 60% of patients were alive and in complete remission, median overall survival was not reached (figure 1). No septic death before engraftment or primary graft failure were noted. Only 1 patient never had platelets engraftment and subsequently developed secondary graft failure four months after HSCT. Median time to neutrophils ^{3} 1000/mL was 13 days (11-56), and 19 days (12-161) to platelets ^{3} 20.000/mL. Median CD3 and CD15 chimerism at day 100 were 97% and 99%, respectively. Overall incidence of acute GVHD was 54% (grade I-II 50%, grade III-IV 50%); chronic GVHD rate was 31% (mild 57%, moderate 28%, severe 15%). CMV reactivation occurred in 40% of patients, at a median of 50 days after transplant (29 - 165). Incidence of venous occlusive disease (VOD) was 13%. Overall, 11 patients died (50%); cause of death were GVHD (3), PTLD (1), sepsis (2), VOD (1), donor derived acute myeloid leukaemia (1), relapse (1), unknown (1).
Summary/Conclusion: In this retrospective study we demonstrated a good

OS for high-risk MF. The use of MA conditioning and PBSC allowed a fast engraftment. Despite the small population, few cases of VOD were recorded as expected. The use of single agent ciclosporin as GVHD prophylaxis was not enough to avoid high rate of GVHD despite the use of in vivo T-cell depletion with ATG. In conclusion, MA HSCT seems a promising and safe curative option for high-risk MF in patients older than 55 years, but more strategies are needed to optimise the GVHD prophylaxis without increasing the rate of opportunistic infection or relapse.

EP1280 THE RELATIONSHIP BETWEEN THE CONCENTRATION OF VITAMIN A, C AND E, CYTOKINES AND THE OCCURRENCE AND SEVERITY OF MUCOSITIS IN PATIENTS WITH HEMATOLOGICAL MALIGNANCIES UNDERGOING AHSCT

A. Szymczyk [1,*], J. Mańko [1,2], A. Szymańska [1], A. Bojarska-Junak [1], A. Walter-Croneck [1], W. Legieć [1], D. Jawniak [1], J. Roliński [1], M. Hus [1], I. Hus [1,2]

[1]Medical University of Lublin, Lublin, [2]Institute of Hematology and Transfusion Medicine, Warsaw, Poland

Background: Hematopoietic stem cell transplantation (HSCT) that is currently the standard treatment for many hematological diseases is associated with high risk of mucositis. Recent studies showed that vitamins A, C and E play critical role in enhancing immune function and their low concentration in serum can be associated with higher frequency of mucositis and poor outcomes in patients with infectious complications. Relationship between antioxidative vitamines concentration and their inhibitory effect on the expression of proinflammatory cytokines were also described.
Aims: The aim of the study was to analyze the relationship between concentration of vitamins A, C and E and cytokines and the frequency and severity of mucositis in patients with hematological malignancies undergoing autologous HSCT (AHSCT).
Methods: The study group consisted of 57 patients aged 18-70 years (52.3 ± 13.4 years) who underwent high dose therapy (HDT) and HSCT. Eleven patients were diagnosed with Hodgkin's lymphoma (HL), 15 with non-Hodgkin lymphoma (NHL), 30 patients with MM (multiple myeloma) and 1 patient with amyloidosis. The severity of mucositis was assessed according to CTCAE v5.0. Serum concentrations of cytokines (IFN-gamma, IL-3, IL-6, IL-10, IL-1β) and vitamins A, C, E were evaluated before HDT/AHSCT and at the time of hematopoietic recovery (10 - 38 days after HDT/AHSCT) using the traditional ELISA method. A commercial was used according to the manufacturer's instructions.
Results: Mucositis was diagnosed in 26 patients, including eleven patients with grade 1, four with grade 2, six with grade 3, and five with grade 4 according to CTCAE v5.0. Frequency of mucositis was higher in the patients with lymphoma than in the MM patients (17 vs. 9 cases; 29.8% vs. 15.8%). The concentration of vitamin C and E was significantly lower ($p < 0.05$) after HDT/AHSCT comparing to the pretreatment values in the whole studied group(14748.4±9262.5 vs. 9875.1±8072.6 and 50.9±524.5 vs. 44.6±20.1, respectively).
There was no correlation between the frequency and severity of mucositis and the concentration of vitamin A, C and E before transplantation ($p>0.05$). After AHSCT concentration of vitamin C was significantly lower (7664.7±6919.5 vs. 12196.1±8701.8) and concentration of vitamin A was significantly higher (0.0025±0.0033 vs. 0.0040±0.0035) in patients with mucositis than in patients without mucositis. Pretreatment concentration of IL-3, IL1β, IL-6 were significant lower in the group of patients with mucositis after HDT/AHSCT: 15.4±45.8 vs. 24.1±65.3, 0.37±0.48 vs. 0.60±0.60 and 5.6±8.6 vs. 6.8±4.9, respectively. There was a positive correlation between the concentration of vitamin A and IL-3 and between the concentration of vitamin C and IL-3, IL-6, IL1β ($p<0.05$) before AHSCT ($p>0.05$).
Summary/Conclusion: Assessment concentrations of cytokines and antioxidative vitamin may allow to determine the factors predisposing to mucositis after HDT/AHSCT. Supplementation of antioxidative vitamins could be also beneficial to the recovery of the immune system in these patients, but further studies are necessary for a larger group of patients and assessing a larger number of parameters.

EP1281 PROGNOSTIC FACTORS AND OUTCOME OF CYTOMEGALOVIRUS INFECTION IN POST-ALLOGENEIC STEM CELL RECIPIENTS. FIVE YEARS RETROSPECTIVE STUDY.

M. Quintela [1,*], C. Pinho Vaz [2], D. Fonseca e Silva [3], R. Pinho Peixeiro [4], P. Silva Coelho [2], G. Brás [2], L. Leite [2], R. Branca [2], S. Roncon [5], I. Baldaque [3], A. Campos [2]

[1]Onco-Hematology, [2]Bone Marrow Transplantation Unit, [3]Virology Service, Instituto Português de Oncologia do Porto IPO Porto, [4]Hematology, Centro Hospitalar e

Universitário do Porto, [5]Cellular Therapy, Instituto Português de Oncologia do Porto IPO Porto, Porto, Portugal

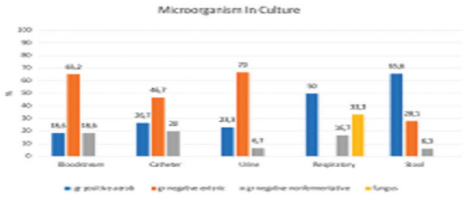
Background: Cytomegalovirus (CMV) infection is one of the major cause of morbidity and non-relapse mortality in allogeneic hematopoietic stem cell transplantation (aHSCT). There are many recognized risk factors for CMV infection or reactivation after aHSCT, being the most important CMV donor/recipient (D/R) serostatus and ocurrence of acute graft versus host disease (aGvHD). CMV infection can affect almost any organ, however, the most important clinical entities are pneumonia, gastroenteritis and retinitis.
Although some studies have shown that novel antiviral drugs should have a role in a prophylactic strategy, our current strategy is yet preemptive, based on regular pp65 antigenemia assays or qPCR.
Aims: The primary objective was to recognize and characterize prognostic factors related to CMV infection in post-transplant recipients. Moreover, we analyzed the impact of CMV infection in HSCT outcomes, respecting overall survival and non-relapse mortality.
Methods: A retrospective unicenter study was conducted in a cohort of 326 patients with hematological disease who underwent allogeneic stem cell transplant between January 2014 and December 2018. Analysis of survival and statistical comparison was made using the SPSS26® platform
Results: The median follow up time of our study was 26 months. Our cohort showed a male predominance (55% n=178) and a median age of 43 years, with 51 pediatric patients. The primary diseases were hematological malignancies in 89,6% (n=293). There was an almost even distribution of donor type (related 50% n=163, unrelated (MUD) 50% N=163) and conditioning regimen (mieloablative 47% n= 154 and reduced-intensity 53% N=172). Matched HLA donors constituted 73% (n=238) and mismatched donors were 27% (n=83) (26% HLA 9/10 or 8/10 and 1% haploidentical). Recipients were mostly seropositive for CMV infection (87% n=284) as well as donors (66% n=217). In respect to D/R serostatus the most frequent was D+/R+ (60,7%) followed by D-/R+ (26.4%), D+/R- (8.9%) and D-/R- (4%).
The incidence of aGvHD and chronic GvHD in this study was 51% (n=167) (91% with grade ≥ 2) and 32.5% (n=106), respectively.
CMV infection occurred in 46% of our cohort, with a median time to infection of 36 days (3-391d) and a median first infection time of 19 days (3-129d). Prognostic factors that impact the risk of infection were donor type (MUD – odds ratio (OR) 1.3 p=0.014), donor (IgG- OR 1.58 p=0.006) and recipient CMV seropositivity (IgG+ 1.18 p=0.000), D/R status (D-/R+ OR 2.09 p=0.000) and development of aGvHD (OR 1.9 p=0.000).
In our study, relapse was observed in 16% (n=51) of the cohort and 5% (n=17) of the sample died without evaluation of primary disease status. CMV infection has an impact on overall survival (2yOS 46.2% with infection vs 66.1% without, (with infection OR 1.51, p=0.001) and non-relapse mortality (2yOS 56% with infection vs 81.5% without infection (with infection OR 1.82, p=0.000).
Summary/Conclusion: CMV is still a major cause of morbidity and mortality in patients post allogeneic transplant and is of greater importance to recognize prognostic factors that increase the risk of reactivation. Our study confirms the role of classical risk factors in CMV infection. Despite the expected impact of prophylactic therapy in the incidence of CMV infection is still important to search for the best donor available regarding a multiplicity of factors as well CMV D/R status.

EP1282 THE IMPACT OF HEMATOPOIETIC STEM CELLS QUANTITY AND QUALITY ON HEMATOPOIETIC RECOVERY AFTER AUTOLOGOUS OR ALLOGENIC GRAFT: A TWO YEARS MULTICENTRIC RETROSPECTIVE STUDY

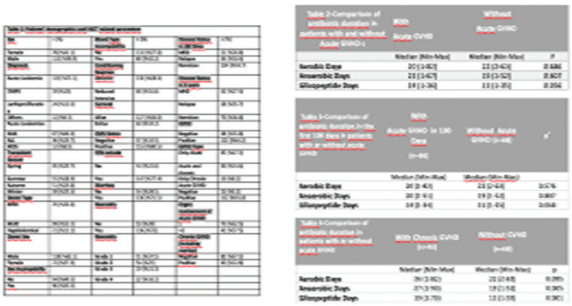
C. De Oliveira [1,*], C. Bercher [1], F. Benoit [1], J. Larghero [1,2,3], L. Faivre [1,3], A. Desnoyer [1], A. Cras [1,3], J. Nasone [1], M. Mebarki [1,3]

[1]Unité de Thérapie Cellulaire, [2]Centre MEARY de Thérapie Cellulaire, [3]INSERM U976 et Centre d'investigation clinique de Biothérapies CBT501, AP-HP, Hôpital Saint-Louis, Paris, France

Background: Hematopoietic Stem Cells (HSCs) transplantation is a therapeutic alternative for several malignant blood diseases and hemoglobinopathies. HSCs can be harvested from peripheral blood (PB), bone marrow (BM) or cord blood. The number of transplanted HSCs (CD34+ cells) represents the principal indicator of graft quality [1]. Usually, 2x106 CD34+/kg is the minimal required dose, 4x106 CD34+/kg is the target dose and over 8x106 CD34+/kg the benefice is highly speculative [1]. While autologous HSCs are systematically frozen and cryopreserved for later use, allogeneic HSCs are usually freshly transplanted after a possible manipulation including volume reduction, plasma removal or erythrocyte depletion. These processes may impact HSCs quantity and/or quality.
[1] Carreras et al., *The EBMT Handbook*.
Aims: The aims of our work were to evaluate (i) the correlation between hematopietic recovery and HSCs quantity and/or quality and (ii) the impact of HSCs manipulations on the hematopoietic recovery objectified by the delay of polynuclear neutrophils (PN) and platelet (PLT) engrafment.
Methods: We realized a retrospective multicentric study including 367 autologous HSCs from PB and 450 allogeneic HSCs (312 from PB and 138 from BM), over the period 2018-2019. The PN and PLT recovery were defined as the first day (d) of PN ≥ $0.5x10^9$/L and PLT ≥ 20 $x10^9$/L over 3 consecutive values and at least 7d after the last transfusion [1]. Statistical analyses were performed on GraphPad Prism® V8.4 and results expressed as mean ± standard deviation. Mann-Whitney, Kruskal-Wallis and Spearman's tests were used.
Results: CD34+ cell dose as well as total nucleated cell (TNC) dose were not correlated to PN (r=-0.066; r=-0.016, p>0.05) nor to PLT recovery (r=0.06054; r=0.027, p>0.05) for allogeneic HSCs from PB neither from BM (r=0.073; r=0.080 for PN and r=-0.049; -0.066 for PLT, p>0.05). In addition, hematopoietic recovery was independent of the CD34+ range doses ($x10^6$/kg): < 4, 4 - 8 and > 8 (p>0.05). However, BM volume reduction delayed the PN recovery comparing to the unmanipulated BM (21.9 ± 6.1 d *versus* 18.6 ± 4.0 d, p<0.05). This may be explained by the reduction of HSCs clonogenicity after this process (6.7% *versus* 25.3%, p<0.001).
Analysis of autologous graft showed a significant correlation between CD34+ cell dose and PN (r= -0.3086, p<0.0001) and PLT recovery (r= -0.1617, p<0.01). CD34+ cell dose > $4x10^6$/kg reduced time to PN recovery (13.6 ± 3.5 d *versus* 12.1 ± 2.5 d, p<0.001), whereas dose > $8x10^6$/kg reduced PLT recovery (12.9 ± 5.4 d *versus* 9.2 ± 4.0 d, p<0.001). Interestingly, the TNC dose was correlated to the PLT recovery (r=0.246, p<0.0001).
Summary/Conclusion: Our results showed a significant impact of CD34+ cell dose on the PN and PLT recovery for autografts. CD34+ cell dose > $4x10^6$/kg reduced time to PN recovery whereas dose > $8x10^6$/kg decreased delay to PLT recovery. For allograft, no correlation was found. This difference could be explained by a better quality of HSCs harvested from healthy donors. Indeed, we showed that the decrease of HSCs functionality might delay the hematopoietic recovery. To better understand these mechanisms, we will analyze biological and clinical risk factors of engrafment failure after autologous and allogeneic HSCs transplantation. Finally, it is important to notice that our study was indepedent of pathology and clinical factors. A more specific analysis will be performed.



EP1283 THE DURATION OF ANTIBIOTICS WITH DIFFERENT SPECTRUMS ADMINISTERED DURING ALLOGENEIC HEMATOPOEITIC STEM CELL TRANSPLANTATION CAN PREDICT GVHD.

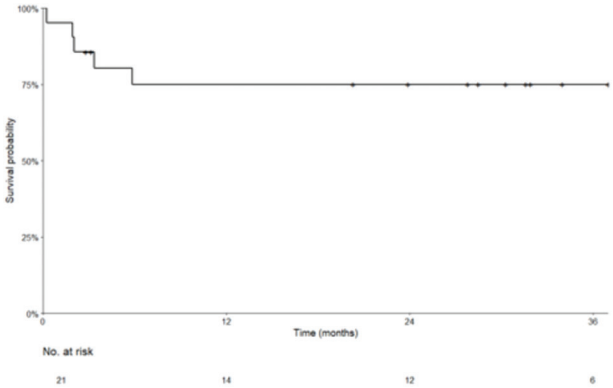


M. Kurt Yüksel [1,*], F. Doğan [2], G. Çınar [3], M. Yüksel [2], N. Öztürk [1], T. Şen [1], A. Azap [3]

[1]Ankara University Faculty of Medicine, Department of Hematology, [2]Ankara University Faculty of Medicine Internal Medicine Department, [3]Ankara University Faculty of Medicine, Department of Infectious Diseases, Ankara, Turkey

Background: The microbiome is a hot topic in recent years. It is severely disrupted by the antimicrobials during Allogeneic Hematopoietic Stem Cell Transplantation (AHSCT), resulting in a change in outcome.
Aims: This study evaluates the relationship between the usage of antibiotics with different spectrums in the first 100 days of AHSCT and GVHD incidence.
Methods: 190 patients who underwent AHSCT between March 2015 and January 2020 were retrospectively evaluated. Patients demographics and pretransplant features are shown in table-1. The antibiotics were grouped into three according to the spectrum of action: 1 -Aerobic (Levofloxacin, ciprofloxacin, amikacin, colistin, amoxicillin moxifloxacin); 2-Anaerobic (piperacillin-tazobactam, meropenem, imipenem, metronidazole, tigecycline, fosfomycin, linezolid); 3-Gram+tives (teicoplanin, vancomycin, moxifloxacin). All the patients received the same antimicrobial prophylaxis.
Results: Among the 190 patients, n=122(64.2%) developed GVHD.

The development of AGVHD in the first 100 days and one year is median 37 days (9-100) and 148.5 days (103-360), respectively. The development of chronic GVHD(including overlaps) is median six months (2-16 months). There was no difference in terms of documented microorganisms in patients with or without GVHD. In figure 1, we show the documented microorganisms in the culture in 100 days. The relationship between the duration of antibiotic usage and the development of GVHD is shown in tables 2, 3, 4. There was no relationship between the involvement of different organ GVHD, underlying diseases, and antibiotic groups. However, AHSCT from a match-related donor (MRD) had shorter usage of anti-aerobic antibiotics than match unrelated (MUD) and haploidentical donor; p=0.02, and p=0.014 respectively. However, anti-anaerobic duration was shorter in MRD compared with haploidentical donors (p=0.02) but not with MUD or MUD vs. haplo. Glycopeptide duration was longer in haploidentical donors than MRD and MUD, P=0.017 and p=0.018, respectively.
In the multivariate logistic regression analysis, patients who developed chronic GVHD had more prolonged glycopeptide usage (p<0.001). The threshold for chronic GVHD development is >14.5 days, the risk increase by 6.7 times.



Summary/Conclusion: Many parameters can affect the outcome of HSCT. As a consequence of this study, the antibiotic's spectrum should also be considered in terms of GVHD, particularly in haploidentical transplantations.

EP1284 EXCELLENT ENGRAFTMENT AND LOW RELAPSE RATE AFTER ALLOGENEIC STEM CELL TRANSPLANTATION FOR MYELOFIBROSIS AFTER CONDITIONING WITH FLUDARABINE, TREOSULFAN AND ATG: A RETROSPECTIVE SINGLE CENTER STUDY

R. van Weissenbruch [1], G. Choi [1], L. Morsink [1], E. Ammatuna [1], M. de Groot [1], J. Hilberink [1], B. Span [1], G. Huls [1], C. Hazenberg [1,*]

[1]*Department of Hematology, University Medical Center Groningen, Groningen, Netherlands*

Background: Allogeneic hematopoietic stem cell transplantation is the only curative therapy for myelofibrosis but is often complicated by graft failure and high rates of relapse. The optimal conditioning regimen has not been well determined. In order to improve outcomes, our center has transplanted patients with myelofibrosis with a conditioning regimen consisting of fludarabine, treosulfan and ATG, a regiment that was previously used for second transplant after primary graft failure.
Aims: The aim of this study was to analyze the outcomes of allogeneic hematopoietic stem cell transplantation after conditioning with fludarabine, treosulfan and ATG, in terms of engraftment, relapse, non-relapse mortality, relapse-free-graft-versus-host-free survival and overall survival.
Methods: We analyzed outcomes in patients with myelofibrosis (n = 21) after allogeneic stem cell transplantation preceded by fludarabine, treosulfan and ATG (anti-thymocyte thymoglobulin) conditioning, in a retrospective single center cohort study.
Results: Patients were transplanted with stem cells from siblings (n = 4), HLA 10/10 matched unrelated donors (n=15) or HLA 9/10 mismatched unrelated donors (n = 2) between the years 2014 and 2020. The median follow-up was 2.3 years for all patients (range 0.3 - 6,1).
Median time of engraftment was 17 days and all patients were engrafted within 32 days. Mean donor chimerism at day 30-35 was 99% (T-cell and mononuclear cells). Incidence of grade III-IV acute graft versus host disease (GVHD) was 25%, of whom 60% of patients achieved complete remission with prednisolone, tacrolimus and/or ruxolitinib. Incidence of chronic GVHD was 39%, of which 71% classified as NIH stage mild. We observed high rates of EBV reactivation (86%, all responsive to rituximab) and CMV reactivation (43%), the latter often followed by development of acute GVHD. Non-relapse mortality at 1 year was 19%. The 2-year progression-free survival was 92%, the 2-year relapse-free-graft-versus-host-disease-free survival was 38%. 1 year overall survival was 76%.

Summary/Conclusion: Our results indicate that conditioning with fludarabine, treosulfan and prior to allogeneic hematopoietic stem cell transplantation for myelofibrosis results in excellent engraftment and low rates of relapse and non-relapse mortality, leading to a high overall survival.

EP1285 THE IMPACT OF PRETRANSPLANT BODY MASS INDEX ON OUTCOMES OF ALLOGENEIC STEM CELL TRANSPLANTATION

S. Mekni [1,*], B. A. Nour [1], L. Amel [1], B. Dorra [1], T. Lamia [1], L. Saloua [1], B. O. Tarek [1]

[1]*service d'Hématologie et de Greffe, Centre National De Greffe de Moelle Osseuse, Tunis, Tunisia*

Background: The impact of obesity on outcomes of allogeneic stem cell transplantation (ASCT) is controversial.
Aims: The aim of this study is to evaluate the impact of pretransplant body mass index (BMI) on overall survival (OS),relapse free survival (RFS),non -relapse mortality (NRM),documented infectious complications and graft- versus host disease (GVHD).
Methods: We performed a retrospective study in patients who underwent ASCT from HLA-identical sibling donors between June 2015 and December 2018. Conditioning regimen consisted of Busulfex and Cyclophosphamide (Bu/Cy) or Fludarabine and Busulfex (F/Bu) in myeloid malignancies, TBI or thiotepa-based regimen in lymphoid malignancies and thymoglobuline and cyclophosphamide with or without fludarabine in aplastic anemia. Graft-versus host disease (GVHD) prophylaxis consisted of cyclosporine and short course of methotrexate. Patients were stratified according to pretransplantation BMI values: underweight (BMI<18 kg/m2); normal BMI (BMI 18 -25 kg/m2); overweight (BMI 25-30 kg/m2); obese(BMI 30 kg/m2).
Results: One hundred and nineteen patients were included (71 males and 48 females).The median age was 34 years (7-49y).Diseases were acute myeloid leukemia (n=37,31%),acute lymphoblastic leukemia (n=31,26%),aplastic anemia (n=27,22.7%),chronic myeloid leukemia or myeloproliferative neoplasms (n=16,13,5%),myelodysplastic syndrome (n=4,3.4%),NHL (n=4,3.4%).
According to the pretransplant BMI values,56% of patients have a normal BMI,13% were obese,23% were in overweight and 18% were in underweight.

There was no statistically significant association between pretransplant BMI and incidence of acute or chronic disease,acute infectious complications and relapse rate (p=074,p=0.15 and p=0.93 respectively).
However, obese patients have a significantly lower OS compared with other patients (78% vs 92%, p=0.004) without impact on RFS (72% vs 84%)between the two groups with p= 0.37).
The NRM was 12,5 % and it was not statistically different between the four groups(p=0.7)
Summary/Conclusion: Pretransplant obesity was associated with inferior OS after ASCT without impacting treatment related complications.

EP1286 IMPACT OF DARATUMUMAB (DARA) ADMINISTRATION DURING TRANSPLANT- ELIGIBLE NEWLY DIAGNOSED MULTIPLE MYELOMA (TE NDMM) INDUCTION ON STEM CELL (SC) MOBILIZATION COUNT AND POST-TRANSPLANT ENGRAFTMENT.

E. Crusoe [1,2,*], A. Moura [3], M. Chaves [4], M. Salvino [3], J. Nicanor [4], J. Leal [2], H. Santos [5], A. Santos [5], V. Guimaraes [1], C. Souza [4], D. Dourado [3], L. Lucas [2], M. Santos [5], J. Santos [2], M. D. G. Arruda [2]

[1]Hematology, Federal University of Bahia- University hospital, [2]Hematology, Instituto D'or de pesquisa e ensino (IDOR), Clinica CEHON, [3]Hematology and Bone Marrow Transplantation, [4]Hemotherapy, Federal University of Bahia- University hospital, [5]Cytometry and Immunology Lab, Federal University of Bahia, Salvador, Brazil

Background: The combination of an anti-CD38 monoclonal antibody, Dara, to the main induction protocols (VRd, VTd, VCd) significantly improved the response rate of TE NDMM before transplantation. However, there is a concern regarding the possible interference in the SC collection and bone marrow engraftment, since SC, to some degree, express CD38 on their surface. In the MAX Dara study, Dara-CTd protocol was used sequentially close to the pre- and post-autologous stem cell transplantation-(ASCT) (D-30 and D + 30), in order to take advantage of the molecule's action as an *in vivo* purge.
Aims: In this analysis, we examine the impact of the number of Dara doses administered pre-mobilization on CD34 cell count, SC apheresis yield, and post-ASCT engraftment.
Methods: This is a phase II, open-label single-center clinical trial. The original protocol was Dara-CTd for up to four 28-day induction cycles and Dara-Td for up to four 28 days consolidation cycles. C-1500mg oral (PO) per cycle, during cycles 1 to 4, T at 100-200mg PO on days 1 to 28, during cycles 1-8, (d) at 160mg PO per cycle, during cycles 1 - 8 and Dara at 16mg/Kg/dose intravenous (IV) on days 1,8,15 and 22 during cycles 1 - 2 and every other week in cycles 3 – 8. Because of the COVID pandemic we had to adapted the protocol and moving 5-6 consolidation cycles to be used as induction, increasing the total dose of Dara from 12 to 16 and the number of cycles from 4 to 6 before ASCT. Granulocyte colony-stimulating factor (G-CSF) was administered alone for SC mobilization and plerixafor added based on day 4 pre-harvest peripheral blood CD34 counts. The target of SC collection was to enable the performance of one ASCT (≥2,5 x 10^6/kg). PMN and platelet engraftment post-ASCT was defined as the first day with sustained PMN count >1000 x 10^6/L and independence from platelet transfusion in the preceding 7 days with a count >20 x 10^9/L, respectively
Results: From a total of 21 pts that were included, 19 pts completed mobilization. 12 pts received 12 and 7 pts received 16 induction Dara doses, respectively. The median number (range) of days between the last dose of Dara infusion and SC harvest was 23 (16-63) days. A total of five (26%) pts received plerixafor during mobilization. More pts from Dara 16 doses needed plerixafor comparing with Dara 12 doses (42% vs 16%), but without difference between the groups. Pts underwent a median (range) of 1 (1-2) days of apheresis. The median number of $CD34^+$ cells collected in the total group was 3.94×10^6/kg, and no difference was found between Dara 12 vs 16 doses (3.61×10^6/kg vs 4.01x10^6/kg), p=0.27. There was no difference in the number of SC collected considering the response rate after induction ≥ or < VGPR, and the last day of Dara use ≥ or < 30 days, before SC harvesting. Hematopoietic reconstitution rates were similar for Dara 12 vs 16 doses, a median (range) of 11.0 (9-13) vs 11.0 (11-14) days was required to achieve sustained ANC > 1000 cells/mm^3, and a median (range) of 12.0 (9-14) vs 11.0 (8-16) days was required to achieve sustained platelets > 20,000 cells/mm^3 without transfusion, respectively.
Summary/Conclusion: SC mobilization was feasible with Dara-CTd induction. Despite the more doses of Dara use before mobilization increases the need of plerixafor use, the SC number difference was not significant comparing Dara 12 vs 16 doses (p = 0.3). The infusion of Dara close to harvest did not interfere with SC collection. Adding DARA to CTd allowed successful transplantation in pts with TE NDMM.

EP1287 ALLOGENEIC STEM CELL TRANSPLANTATION OF PATIENTS WITH MYELOFIBROSIS AT UNIVERSITY HOSPITAL CENTRE ZAGREB FROM 2010 TO 2020

R. Vrhovac [1,*], Z. Peric [1], T. Taborsak [1], R. Serventi-Seiwerth [1], N. Durakovic [1], L. Desnica [1], M. Mikulic [1], I. Bojanic [2], Z. Grubic [3]

[1]Haematology, [2]Transfusion Medicine, [3]Tissue Typing, University Hospital Centre Zagreb, ZAGREB, Croatia

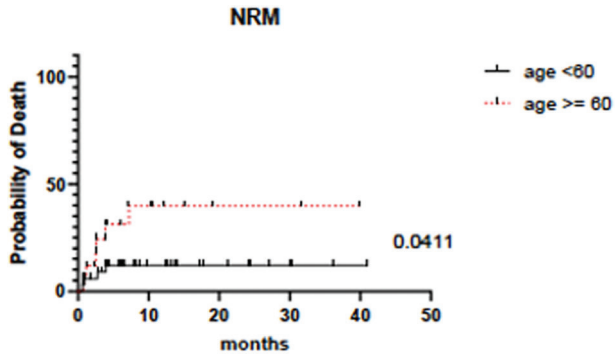
Background: Allogeneic stem cell transplantation (HSCT) remains the only curative option for patients with myelofibrosis (MF).
Aims: Investigate the influence of peritransplant variables on transplantation outcomes in patients with MF.
Methods: Retrospective analysis of patients treated with HSCT from 2010 to 2020 in the Department of Haematology at University Hospital Centre Zagreb.
Results: A total of 41 patients (14 women and 27 men) were transplanted, ranging in age from 32 to 65 years (median 54). Thirty (73.2%) had primary and 11 (26.8%) secondary MF. Most of the patients had intermediate or high-risk disease. Eleven patients (26.8%) received stem cells from a related, 28 (68.3%) from an unrelated, and 2 (4.9%) from a haploidentical donor. Except for 5 patients who received myeloablative conditioning (MAC), all others (36 patients, 87.8%) received reduced-intensity conditioning (RIC), in most cases FluBu3ATG. Only 2 patients received bone marrow stem cells, while others received peripheral blood stem cells. The median number of infused CD34+ cells was 6.02x10^6/kg BW (range 1.93–28.65). A total of 23 patients (56.1%) received ruxolitinib prior to transplantation, and 8 (19.5%) patients received the drug sometime during the post-transplantation period. The cumulative overall survival (OS) after a median follow-up of 574 days (range 18–3834) was 58.9% for the whole group. One patient transplanted from a haploidentical donor died of sepsis in the first weeks after transplantation and another one a year after transplantation after a series of infectious complications. Although not reaching statistical significance, patients transplanted from related donors had a better outcome than those who received a transplant from unrelated donors (OS 81.8% vs 60.7%, p=0.2), patients without splenomegaly pre-transplant compared to those with palpable spleens (OS 81.8% vs 59.3%, p=0.17), and patients who were fit enough to receive MAC compared to the large majority who received RIC (OS 100% vs 58.3%, p=0.07). Neither the diagnosis (primary or secondary MF) nor the number of CD34+ cells infused - over or below the median of 6.36x10^6/kg BW, had significant effects on outcomes (OS 58.7% vs 56%, p=0.85 and 61.2% vs 54.5%, p=0.9, respectively). Patients with chronic graft-versus-host disease had superior OS compared to patients not experiencing this transplant complication (OS 81.3% vs 54.2%, p=0.04).
Summary/Conclusion: Although wider donor availability and JAK inhibitors are making HSCT, the only available curative option for MF accesible to a larger number of patients, efforts should be made to further improve transplantation outcomes. Transplant candidates should be carefully selected with therapeutic interventions before and after transplantation tailored according to specific clinical situations. Trials addressing specific clinical scenarios are warranted.

EP1288 ALLOGENEIC HEMATOPOIETIC CELL TRANSPLANTATION WITH TBI-BASED REDUCED INTENSITY CONDITIONING FOLLOWED BY POST-TRANSPLANT CYCLOPHOSPHAMIDE FOR RELAPSED/REFRACTORY LYMPHOMA PATIENTS.

M. Griselli [1,*], S. Tricarico [1], S. Bonato [1], F. Marzuttini [1], V. Viglione [1], S. Saldi [2], T. Zei [1], C. Aristei [2], R. Iacucci Ostili [1], A. Terenzi [1], O. Minelli [1], L. Ruggeri [1], A. Velardi [1], A. Pierini [1], A. Carotti [1]

[1]medicine, Section of Hematology and Clinical immunology, [2]Sciences and biomedical Sciences, Radiotherapy, Perugia, Italy

Background: Allogeneic hematopoietic cell transplantation (Allo-HCT) is a potentially curative treatment for patients with relapsed/refractory (R/R) lymphomas. Patients with R/R lymphomas usually reach allo-HCT after several lines of treatment and are often affected by comorbidities. Therefore, these patients are often unsuitable for high intensity



myeloablative conditioning regimen. Historically, reduced intensity conditioning (RIC) regimens are feasible in this subset of patients, but they are complicated by high rate of graft versus host disease (GvHD) and disease relapse. The more recent introduction of post-transplant cyclophosphamide (PT-Cy) for GvHD prophylaxis reduced acute and chronic GvHD rates and transplant-related mortality (TRM) in comparison to allo-HCT with conventional immune suppressive (IS) regimens. In particular, haploidentical (haplo) allo-HCT with PT-Cy showed acceptable rate of TRM and good progression free survival (PFS) in Hodgkin lymphoma patients (Castagna et al 2017). We have recently introduced total body irradiation (TBI)-based RIC followed by PT-Cy for R/R lymphoma patients. We adopted such strategy across all the different donor/recipient HLA-matching combinations.
Aims: To evaluate safety and feasibility of TBI-based RIC allo-HCT followed by PT-Cy prophylaxis for R/R lymphoma patients at our center.
Methods: We adopted TBI-based RIC allo-HCT followed by PT-Cy for R/R lymphoma patients starting in April 2016. We collected data until December 2020. Conditioning regimen to transplant was based on fludarabine (150mg/m2 in 5 days) and cyclophosphamide (14.5 mg/kg for 2 days) followed by TBI (2-4 Gy). PT-Cy dose was 50mg/kg for 2 days at day 3 and 4 after allo-HCT. GvHD prophylaxis consisted also of Tacrolimus and Mycophenolate Mofetil in patients with matched unrelated donors (MUD) or haplo donors (haplo) and Cyclosporine alone in patients with matched related donors (MRD).
Results: Since April 2016 we transplanted 27 patients with R/R lymphoma using TBI-based reduced-intensity conditioning and PT-Cy based GvHD prophylaxis. Median age at transplant was 48 years (range 25-62). Median number of previous lines of therapy was 5. Thirteen patients were affected by Hodgkin Lymphoma and 14 by Non-Hodgkin Lymphoma (7 B lymphomas, 7 T lymphomas). Twelve patients were transplanted in hematological complete remission, while 15 had active disease at transplant. All but one patient received unmanipulated G-CSF primed peripheral blood hematopoietic stem cells. Six patients received MRD allo-HCT, 1 MUD, and 20 haplo. All patients achieved primary engraftment. Acute GvHD grade ≥ II developed in 4/27 patients reaching a cumulative incidence (CI) of 15%. Two patients developed chronic GvHD. TRM occurred in 3/27 patients (CI: 11%). Causes of death were aGvHD in 1, and infective pneumonia in 2. Eight patients relapsed (CI: 30%) so far. Seven of them had active disease at transplant. The 2-year PFS is 63% and the probability of GvHD-free/relapse-free survival (GRFS) is 52% at a median follow up of 32 months (range 1.5m-5y) with 17/27 patients alive and lymphoma-free to date.
Summary/Conclusion: Here, we show that RIC allo-HCT with PT-Cy is a safe procedure with low rates of GvHD and TRM in a small series of patients. Despite the majority of patients had active disease at transplant, relapse rate appears not to be superior to the one reported after allo-HCT with myeloablative conditioning and/or with conventional IS regimens (e.g. Sureda et al. 2008). In conclusion, TBI-based RIC allo-HCT with PT-Cy ensured good PFS and GRFS in R/R lymphoma patients.

EP1289 T-REPLETE HAPLOIDENTICAL STEM CELL TRANSPLANTION UTILISING POST-TRANSPLANT CYCLOPHOSPHAMIDE IS ASSOCIATED WITH INCREASED NON-RELAPSE MORTALITY IN PATIENTS OVER THE AGE OF 60

H. Mediwake [1,2,*], D. K. Morris [3], D. C. Curley [3], D. G. Kennedy [3]

[1]Haematology and Bone Marrow Transplant, Royal Brisbane and Women's Hospital, Herson, [2]School of Medicine, University of Queensland, St Lucia, [3]Haematology and Bone Marrow Transplant, Royal Brisbane and Women's Hospital, Herston, Australia

Background: Haploidentical stem cell transplants (Haplo-SCT) with post-transplant cyclophosphamide (PTCy) are increasing in application due to donor availability and simplicity. However, factors predictive of non-relapse mortality (NRM) in PTCy remain relatively poorly defined.
Aims: To evaluate factors predictive of NRM in patients undergoing T-replete PTCy Haplo-SCT at our centre.
Methods: Consecutive patients undertaking PTCy Haplo-SCT between January 2017 and October 2020 were identified from an institutional database and outcomes retrospectively determined from review of individual medical records. Conditioning regimens included myeloablative (MAB; Fludarabine / 12Gy TBI), reduced intensity (RIC; Melphalan/ Fludarabine/ 2Gy TBI) and non-myeloablative (NMA; Fludarabine / Cyclophosphamide / 2Gy TBI +/- rabbit ATG) regimens. All grafts were T-replete PBPC with patients commencing immunosuppression with MMF and tacrolimus post completion of PTCy.
Results: 51 patients underwent PTCy Haplo-SCT with PTCy during the time period under review. Median age at transplant was 50yrs (range 19-74yrs), with 18 patients (35%) aged ≥60yrs. Indication for SCT included AML in 26 patients (51%), MDS/ MPN in 10 (20%), B-ALL in 7 (14%), LPD in 6 (12%) and SAA in 2 (4%). Conditioning regimens were MAB in 16 (31%), RIC in 25 (49%) and NMA in 10 (20%). Haplo donors utilized included parents in 7 (14%), siblings in 15 (29%) and children in 29 (57%). Overall incidence of grade II-IV and III-IV acute GVHD was 27% and 14% respectively, with 12% of patients surviving post D100 developing extensive stage chronic GVHD. At median follow-up for survivors of 12mths 1yr OS, PFS, and NRM was 76%, 67%, and 21% respectively. In univariate analyses, factors associated with NRM included recipient age (≥60yrs) and occurrence of ICANS post PBPC infusion, which occurred in 8 (16%) of patients (n=4 ≥ grade 3). Recipient age (≥60yrs) remained predictive of NRM, with NRM of 12% in patients <60yrs vs 40% in those ≥60yrs respectively (p=0.041; see Figure). Conditioning regimen and HCT-CI score did not predict for NRM.

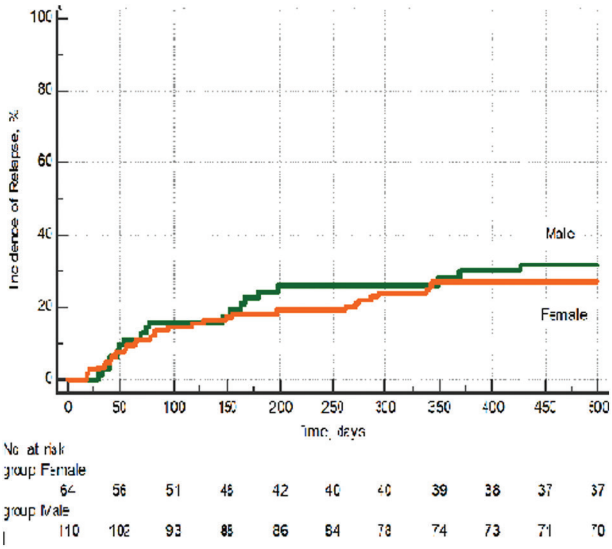
Summary/Conclusion: PTCy Haplo-SCT is associated with significant NRM in patients ≥60yrs. Further studies evaluating less toxic regimens is needed for this group of patients.

EP1290 IMPACT OF FLT3 INTERNAL TANDEM DUPLICATION ON THE OUTCOME OF ALLOGENEIC STEM CELL TRANSPLANTATION FOR ACUTE MYELOID LEUKEMIA

C. Afonso [1,*], C. Rodrigues [2], J. Pimenta [3], R. B. Ferreira [4], L. Leite [4], G. Brás [4], P. Coelho [4], C. Pinho Vaz [4], A. Campos Jr [4]

[1]Department of Clinical Hematology, Centro Hospitalar e Universitário de Coimbra, Coimbra, [2]Department of Clinical Hematology, Centro Hospitalar Tondela-Viseu, Viseu, [3]Department of Oncology, Centro Hospitalar de Trás-os-Montes e Alto Douro, Vila Real, [4]Department of Bone Marrow Transplantation, Instituto Português de Oncologia do Porto Francisco Gentil, Porto, Portugal

Background: FMS-like tyrosine kinase 3 (FLT3) gene internal tandem duplication (ITD) occur in 20%-30% of adult acute myeloid leukemia (AML) patients. FLT3-ITD is widely accepted as an independent adverse prognostic factor associated with high relapse and poor survival rates. Therefore, allogeneic hematopoietic stem cell transplantation (allo-HSCT) is generally accepted as the standard of care for AML patients with FLT3-ITD. Whether this mutation also affects outcome after allo-HSCT is controversial.
Aims: To determine the impact of FLT3-ITD on the outcome of allo-HSCT for adult AML.
Methods: Retrospective analysis of 95 adult AML patients (pts) who underwent allo-HSCT between January 2015 and December 2019 in a transplant center from north of Portugal. Clinical characteristics and outcomes were evaluated. The Kaplan-Meier method was used to describe time-to-event end points. The log rank test was used to compare the survival distribution of different groups.
Results: FLT3-ITD was detected in 17 pts (29%). Among these, 53% were female; median age at diagnosis was 43 years (22-60). Fifteen pts (88%) were transplanted in first remission, 1 in second remission and 1 in a more advanced stage of the disease. Donors were a matched sibling in eight pts (47%), a fully matched unrelated donor in six pts (35%), and a partial



matched unrelated donor in 3 pts (18%). The stem cell source was peripheral blood in the majority of pts (n=16; 94%). Eight pts (47%) were treated with myeloablative conditioning (MAC) regimens while the remaining pts received reduced intensity conditioning (RIC). MAC regimens consisted of busulphan plus cyclophosphamide (BuCy), whereas RIC consisted of fludarabine with reduced doses of busulfan (FluBu); antithymocyte globulin (ATG) was added to the conditioning regimen for unrelated transplantations. Grade ≥ 2 acute graft versus host disease (GvHD) occurred in 5 pts (31%), at a median time of 32 days (12-81) after allo-HSCT. Five pts experienced chronic GVHD; in 3 pts chronic GVHD evolved from acute GVHD. There were no statistically significant differences between FLT3-ITD-positive and -negative patients with respect to clinical characteristics (age, gender, disease status, donor type, stem cell source and conditioning), and GvHD (incidence and overall grade). The 1-year relapse-free survival (RFS) rates for FLT3-ITD-positive and -negative patients were 58% vs 79%, respectively (HR 1.19; p=0.276); the 1-year overall survival (OS) rates were 71% vs 69%, respectively (HR 0.64; p=0.423).
Summary/Conclusion: In our cohort, there was no difference in the outcomes of allo-HSCT between AML patients with FLT3-ITD and those without the mutation. Although in the absence of allo-HSCT the FLT3-ITD mutation is predictive of a short OS, our results suggest that in patients who undergo allo-HSCT, the FLT3-ITD mutation status loses its predictive value.

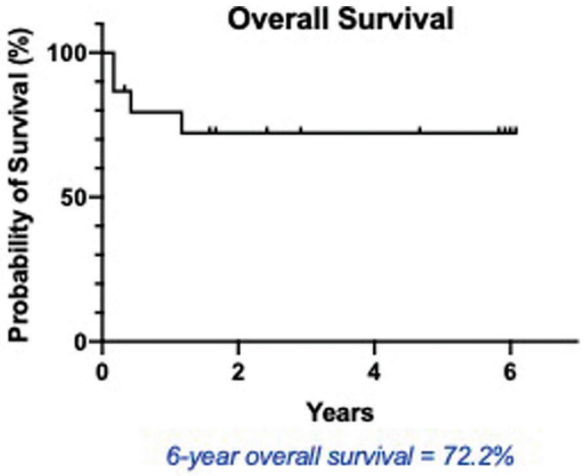
EP1291 PEDIATRIC MALES RECEIVING HEMATOPOIETIC STEM CELL TRANSPLANT SHOW AN EXTRA BENEFIT FROM THE PROCEDURE'S HORMONE IMPAIRMENT: A RETROSPECTIVE COHORT OBSERVATIONAL STUDY

L. De Nardi [1,*], A. Grasso [2], R. Simeone [3], L. Torelli [1], A. Maestro [2], D. Zanon [2], E. Barbi [1,2], N. Maximova [2]

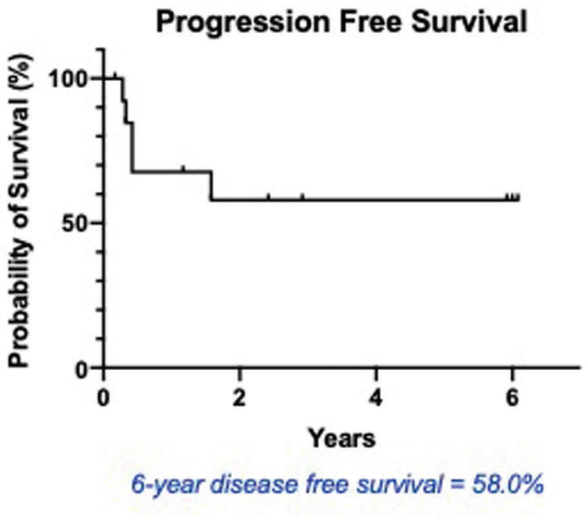
[1]Department of Medicine, Surgery and Health Sciences, University of Trieste, Piazzale Europa 1, 34127 Trieste, Italy, [2]Institute for Maternal and Child Health-IRCCS Burlo Garofolo, Via dell'Istria 65/1, 34137 Trieste, Italy;, [3]Department of Transfusion Medicine, ASUGI, Piazza dell'Ospitale 1, 34129 Trieste, Italy;, Trieste, Italy

Background: Sex differences play a relevant role in cancer susceptibility, incidence and survival, with male patients being at higher risk. Genetic, epigenetic and hormonal factors are involved in such differences, and a better understanding of their close interplay in the mechanisms of cancer could improve its prevention and therapy. However, assessing the actual weight of each one of these factors is challenging.
Aims: This study aims to explore sex differences in first and advanced-line therapy outcomes in pediatric oncology. In particular, we investigated whether the known sex differences occurring after first-line therapy, and leading to a higher number of male patients requiring Hematopoietic Stem Cells Trasplantation (HSCT), persist after transplant.This study setting may represent an experimental human model that reveals the possible effects of the impairment of gonadal hormones on cancer progression, which is poorly explored in the literature.
Methods: The study is a Single-center retrospective cohort observational study. Population of the study are pediatric patients between 0 and 18 years of age admitted for hematological malignances between 2000 and 2018 who underwent allogeneic or autologous HSCT at the pediatric Department of Oncology of the Institute for Maternal and Child Health of Trieste. As part of the HSCT course, participants underwent a conditioning regimen either with high-dose (myeloablative) chemotherapy or with total body irradiation (TBI), both of which exert a substantial impairment on gonadal function.
Results: Out of a total of 485 patients (280 males, 205 females) admitted for malignant diseases between 2000 and 2018, 174 patients (111 males and 63 females) had a high-risk form of acute lymphatic leukemia, acute myeloid leukemia, myelodysplasia or solid tumors requiring HSCT. Among these patients 15 males (9%) and 6 females (3%) died from primary disease relapse, providing a DRM of 12%. Fourteen males (8%) and 13 females (7%) died from transplant-related causes, providing a TRM of 15%. No statistically significant differences between males and females were found in terms of DRM and TRM ($P > .05$). The OS was 72%, including 82 male and 44 females. One hundred eleven patients (64%) showed a disease-free survival (DFS), including 72 males and 39 females. The Cumulative Relapse Incidence (CRI) was 21%, with 25 males and 11 females having a primary disease relapse. In addition, we analyzed differences in OS, EFS, early death, TRM, DRM, and the need for a further HSCT by comparing donor-recipient pairs matched and mismatched for sex and by comparing two age groups (<12 years, >12 years). No statistically significant differences for HSCT-related complications (mucositis, gastrointestinal, hepatic, lung and kidney toxicity, and GvHD) were found between donor-recipient pairs matched and mismatched for sex. ($P > .05$) Similarly, no statistically significant differences in HSCT complications were found between males and females when comparing two age groups (<12 years, >12 years)

Summary/Conclusion: While the number of males needing HSCT was almost double that of females, confirming the well-known "male disadvantage" with respect to cancer reported in the literature, no sex-related differences in terms of overall survival, cancer relapse, or complications were reported after HSCT exposure. These findings suggest that the existing sex differences in cancer risk ab initio can be modified by HSCT and its preliminary conditioning regimen, implicating a role of hormonal factors in cancer mechanisms and management.



EP1292 ALLOGENEIC STEM CELL TRANSPLANTATION FOR CUTANEOUS T-CELL LYMPHOMA



D. Angelov [1,*], J. Dillon [1], L. Mellerick [2], E. Pender [1], L. Bacon [1], G. Lee [1], L. Higgins [1], H. McCarty [3], C. Gillham [4], J. Quinn [5], N. Leonard [2], M. McMenamin [2], E. Vandenberghe [1]

[1]National Adult Stem cell Transplant Unit, [2]Department of Histopathology, St. James's Hospital, Dublin, Ireland, [3]Department of Radiation Oncology, Northern Ireland Cancer Centre, Belfast, United Kingdom, [4]Department of Radiation Oncology, St. James's Hospital, [5]Department of Haematology, Beaumont Hospital, Dublin, Ireland

Background: Cutaneous T-cell lymphomas (CTCL) are a heterogenous group of T-cell non-Hodgkin lymphomas with a variable prognosis. Patients with mycosis fungoides (MF) can have indolent disease, however transformed MF and Sezary Syndrome (SS) have an aggressive clinical course. CTCL are incurable with systemic chemotherapy but can achieve durable remissions with allogeneic stem cell transplantation (allo-SCT) and an SCT program was initiated for this group of poor prognosis patients in 2004 at a National allo-SCT Centre.
Aims: To review outcomes of consecutive patients with CTCL undergoing allo-SCT.
Methods: Patient demographics, disease characteristics, and outcome data were collected on consecutive CTCL patients transplanted from 2010 - 2020 at the Republic of Ireland (ROI) National allo-SCT Unit using 3 conditioning regimens; transformed MF <45 years received Cy-TBI, patients willing to travel outside ROI for Total Skin Electron Beam therapy (TSEBT) received TSEBT, total nodal irradiation, Anti-Thymocyte Globulin (ATG) and mycophenolate mofetil (Stanford) conditioning and the remaining patients received standard reduced intensity conditioning

(RIC) with Flu-Mel-ATG. Graft versus host disease (GVHD) prophylaxis with ciclosporin (+/- methotrexate) was used.
Results: Fifteen patients (10 male, 5 female) underwent allo-SCT with a median age at transplant of 49 years (range 21-64). Eight patients had SS, while 4 of 7 patients with MF had transformed disease. All four transformed MF patients [one of whom received pre-transplant brentuximab vedotin (BV)] expressed CD30. Ten patients had Stage IV disease (revised ISCL/EORTC criteria) and 7 patients had a raised LDH at referral for allo-SCT. Eleven patients (7 MF, 4 SS) received systemic chemotherapy (range 1-3 lines) pre allo-SCT; remission status pre-transplant consisted of 2 complete remissions, 10 partial remissions and 3 stable disease. Five MF patients recieved Cy/TBI conditioning, 4 SS patients received Stanford, and 6 patients (4 SS, 2 MF) received Flu-Mel-ATG conditioning. Neutrophil and platelet engraftment occurred at a median of 15 and 14.5 days respectively. Acute GVHD occurred in 13 patients, all of whom had grade 3 skin GVHD, while 5 patients had concomitant gut GVHD (grade 1-3). Early treatment-related mortality (TRM) occurred in 2 patients; one from CMV pneumonitis following Stanford conditioning and one from pneumonia following Cy-TBI. One patient progressed following Cy-TBI at 102 days and died 5 months post allo-SCT, one patient died 14 months post allo-SCT from viral pneumonitis. There were 4 overt relapses at a range of 4-19 months; 3 received donor lymphocyte infusion (DLI) and 1 had immunosuppression weaned; all 4 are in CR with a median follow up of 42 months. OS and PFS at 6 years were 72.2% and 58.0% respectively.
Summary/Conclusion: OS and PFS in this allo-SCT cohort of 15 CTCL patients was 72.2% and 58% with 4 patients achieving meaningful remissions with DLI despite post allo-SCT relapses. SS patients referred early in the disease course, had a good outcome with one post allo-SCT relapse. There were no relapses in SS patients receiving Stanford conditioning. MF patients did less well, but were referred for allo-SCT with advanced/transformed disease and may benefit (1) from earlier transplant referral and (2) from BV treatment if CD30 positive pre allo-SCT. Allo-SCT is an appropriate treatment for advanced CTCL, however improving referral timelines and conditioning in MF and reducing the incidence of skin GVHD remain challenges.

EP1293 HAPLOIDENTICAL STEM CELL TRANSPLANTATION FOR PEDIATRIC PATIENTS WITH HIGH DONOR-SPECIFIC ANTIBODY (DSA) TITERS USING A DESENSITIZING CONDITIONING REGIMEN

U. Yu [1,*], X. Wang [1], X. Zhang [1], C. Wang [1], C. Yang [1], Y. Li [1], X. Zhou [1], S. Liu [1]

[1]Department of Hematology and Oncology, Shenzhen Children's Hospital, Shenzhen, China

Background: The application of haploidentical stem cell transplantation (haplo-SCT) greatly broadens the choice of donor pools for recipients of hematopoietic stem cell transplantation (HSCT). Recent evidence suggests that high donor-specific antibody (DSA) titer is one of the leading causes of graft failure that may contribute to higher transplant-related mortality and modality. Several approaches have been developed to reduce DSA. However, there is no available consensus or standard guidelines for the reduction of DSA for HSCT recipients due to limited evidence in published data.
Aims: Our aims are to investigate the outcomes of pediatric haplo-SCT recipients with high DSA titers using a desensitizing conditioning chemotherapy regimen.
Methods: Fourteen candidates of haplo-SCT aged 2 to 17 (median 8 years of age) were tested to have high DSA titers (HLA type I and/or HLA type II, MFI≥4000) between January 2020 and September 2020. Primary diseases included thalassemia major (13 in 14 patients) and severe aplastic anemia (1 in 14 patients). The conditioning protocol consisted of a cyclophosphamide-busulfan-based myeloablative regimen and was selectively given one or more approaches to reduce DSA titer, including high-dose intravenous immunoglobulin, rituximab, bortezomib, and plasma exchange. The GVHD prophylaxis consisted of post-transplant cyclophosphamide, mycophenolate mofetil, and tacrolimus.
Results: Clinical data of 2 girls and 12 boys were analyzed. Haplo grafts were collected from the siblings (5/14), fathers (8/14), and mothers (1/14). The mean $CD34^+$ cell dose was 12.52×10^6/kg. Neutrophil and platelet engraftment was achieved at a median of 20 days (range, 8-33 days) and 20 days (range, 8-40 days), respectively. No patients had graft failure nor had developed poor graft function. Only two patients developed grade I-II acute graft-versus-host disease (GVHD), and no chronic GVHD was observed. Viremia of cytomegalovirus (CMV) and Epstein-Barr virus was observed in three and two patients, respectively. However, none of these patients had CMV diseases or post-transplantation lymphoproliferative disorder. No other transplant-related complications were observed. All patients were alive without chronic complications at the time of last follow-up (median follow-up period 243 days, range 164 to 334 days).
Summary/Conclusion: This preliminary data suggest that our approach to use a desensitizing conditioning regimen for pediatric recipients of haplo-SCT is safe and practical to limit graft failure and transplant-related complications and may contribute to a larger cohort study in the future.

EP1294 PD-1 INHIBITOR SIGNIFICANTLY INCREASES ACUTE GRAFT-VERSUS-HOST DISEASE AFTER ALLOGENEIC HEMATOPOIETIC STEM CELL TRANSPLANTATION IN PEDIATRIC REFRACTORY/RELAPSED B-CELL ACUTE LYMPHOBLASTIC LEUKEMIA

Y. Song [1,*], J. Pan [2], Z. Li [1], T. Wu [1]

[1]Department of Bone Marrow Transplantation, [2]Department of Pediatric Hematology, Beijing Boren Hospital, Beijing, China

Background: More than 90% complete remission (CR) can be achieved in relapsed/refractory B-cell acute lymphoblastic leukemia (r/r B-ALL) with chimeric antigen receptor T cell (CART) therapy. However, a small portion of patients still cannot obtain CR or minimal residual disease (MRD) negative by CART therapy. Programmed cell death protein 1 (PD-1) inhibitor can enhance anti-leukemia effect of CART cells, but increased early

immune toxicity has been reported in allogeneic hematopoietic stem cell transplantation (allo-HSCT) after PD-1blockade in lymphoma patients.
Aims: In present study, the influence of prior application of PD-1inhibitor on acute graft-versus-host disease (aGVHD) after allo-HSCT for r/r B-ALL patients who achieved CR with CART was investigated.
Methods: Five pediatric r/r B-ALL patients who achieved CR by CART combined with PD-1 inhibitor and then underwent allo-HSCT were analyzed retrospectively. The median age was 4 (3-9) years old. Three cases were with normal cytogenetics and molecular genetics, and 2 cases were with both complex karyotypes and E2A/PBX1 (one of them also with TP53 mutation). Before allo-HSCT, all patients achieved CR (MRD^- in 3, MRD^+ in 2) by CART combined with PD-1 inhibitor. CD19-CART and/CD22-CART were used. Toripalimab at 3mg/kg was applied for one (n=4) or two (n=1) doses if CR or MRD^- was not achieved two weeks after CART therapy. All patients underwent allo-HSCT from haploidentical donors with myeloablative conditioning regimens (TBI/fludarabine/ATG in 2, busulfan/fludarabine/ATG in 3). Cyclosporine, MMF and short-term MTX were employed for GVHD prophylaxis. Interval between last PD-1 treatment and HSCT was 45 (14-60) days.
Results: All patients achieved durable engraftment. Two patients developed hyper-acute GVHD with a noninfectious febrile syndrome and severe liver dysfunction and resolved with multiple immunosuppressants including methylprednisolone (up to 4mg/kg), cyclosporine, MMF, basiliximab, ruxolitinib, and MTX. Much higher incidences of overall aGVHD and severe aGVHD were noted in this cohort compared with our previous study that r/r B-ALL patients achieved CR with CART then bridge to allo-HSCT without prior PD-1 treatment (Zhang Y, et al. Br J of Haematol. 2020;189:146-52). Two cases had chronic GVHD. No severe hemorrhagic cystitis and other infections were found. Three patients relapsed at 3, 5, 6 months and died from relapse at 10, 12, 12 months after HSCT. One patient died from severe aGVHD and transplant-associated thrombotic microangiopathy (TA-TMA) at 4 months post-transplant. One patient has been surviving free of disease.
Summary/Conclusion: Our preliminary clinical results has shown that PD-1 inhibitor significantly increases the incidence and severity of aGVHD after allo-HSCT in pediatric r/r B-ALL patients who obtained CR with CART. Severe hyper-acute GVHD has been seen that needs to use multiply immunosuppressants timely to prevent from multi-organ failure via cytokine storm. It suggests that PD-1 inhibitor should be avoided as possible if allo-HSCT is scheduled later.

Stem cell transplantation - Experimental

EP1295 HUC-MSC-EVS-ATO REDUCES ACUTE GVHD VIA RESETTING INFLAMMATORY MACROPHAGES TOWARD M2 PHENOTYPE THAT IS MEDIATED BY AUTOPHAGY

Y. Su [1,2,3,4,*], X.-Y. Sun [1,2,3,4], L.-P. Yang [1,2,3,4], G.-C. Zhang [1,2,3,4], Q.-S. Huang [1,2,3,4], X.-H. Zhang [1,2,3,4]

[1]Peking University Institute of Hematology, Peking University People's Hospital, [2]Collaborative innovation Center of Hematology, [3]Beijing Key Laboratory of Hematopoietic Stem Cell Transplantation, [4]National Clinical Research Center for Hematologic Disease, Beijing, China

Background: Acute graft-versus-host disease (aGVHD), a serious complication, frequently occurs following allogeneic hematopoietic stem cell transplantation (allo-HSCT). Mesenchymal stem cell-derived extracellular vesicles (MSC-EVs) are considered promising candidates for treating GVHD, primarily due to their immunomodulation ability and safety. Recently, EVs have been exploited for delivery of exogenous therapeutic agents and internalized by macrophages, leading to a switch from the M1 to M2 phenotype (Mol Ther. 2010; Stem Cells Transl Med. 2017). Arsenic trioxide (As_2O_3), a promising regent for dysregulated immune diseases. In our previous study, we found that As_2O_3 prolonged the survival of aGVHD mice by polarizing macrophages toward the M2 status (Sci China Life Sci. 2020). Autophagy is a conserved cellular degradation pathway that maintains intracellular homeostasis. It has been elucidated that downregulation of autophagy levels limits repolarization of M2 to M1 (Nat Rev Immunol.2019). Based on this knowledge, herein, we hypothesized that EVs loaded with As_2O_3 could reset the M1 to M2 phenotype through autophagy for a greater therapeutic response against aGVHD.
Aims: To investigate the therapeutic effect of hUC-MSC-EVs-ATO in aGVHD mouse model and explore the immune mechanism of hUC-MSC-EVs-ATO in vivo and vitro.
Methods: hUC-MSC-EVs-ATO was injected intravenouslly at the onset of the murine aGVHD model. Moreover, we administered clodronate liposomes by intraperitoneal injection to deplete mouse macrophages before using hUC-MSC-EVs-ATO. We also established a murine GVL model with supplementation of A20 leukemia cells. At the experimental endpoint, mice were sacrificed, and target organs were extracted to analyses the phenotypic alterations in macrophages by enzyme-linked immunosorbent assay, flow cytometry, and immunohistochemistry. Finally, mTOR, p-mTOR, p62, LC3-I and LC3-II in BMDM-M1 and RAW264.7-M1 cells with or without hUC-MSC-EVs-ATO treatment were analyzed by western blot, and autophagic vacuoles were observed by electron microscopy.
Results: The severity and histological score of aGVHD were significantly reduced in response to hUC-MSC-EVs-ATO treatment. Mice receiving hUC-MSC-EVs-ATO exhibited longer lives compared to control mice. hUC-MSC-EVs-ATO reduced the number of Th1 and Th17 cells, while anti-inflammatory M2 and Treg cells were increased in aGVHD target organs liver and spleen. Notably, depletion of macrophages blocked these therapeutic effects and the effects on T-cells by hUC-MSC-EVs-ATO. In vitro, hUC-MSC-EVs-ATO repolarized inflammatory M1 macrophages to the anti-inflammatory M2 phenotype in both LPS/IFN-γ-conditioned bone marrow-derived and RAW264.7 macrophages. Furthermore, we demonstrated that hUC-MSC-EVs-ATO repolarized M2 to M1 macrophages partly through induction of autophagic flux by suppressing mammalian target of rapamycin (mTOR) activity. The mTOR signaling pathway activator MHY1485 reduced autophagy and repolarized M1 to M2 macrophages. Specifically, using murine model graft-versus-leukemia effects (GVL), we show here that treatment not only reduces aGVHD but also preserves GVL.
Summary/Conclusion: hUC-MSC-EVs-ATO alleviated aGVHD by switching the M1 phenotype to the M2 phenotype through inducing autophagy. Our findings demonstrate that hUC-MSC-EVs-ATO represents a potential therapeutic agent against GVHD, while preserving GVL activity.

EP1296 MICRORNA SERUM PROFILES AND CHRONIC GRAFT VERSUS HOST DISEASE FOR PATIENTS RECEIVING ALLOGENEIC HEMATOPOIETIC STEM CELL TRANSPLANTATION

H. Reikvam [1,2,*], A. K. Vo [1,2], A. Lodvir Hemsing [1,2], M. Solheim [1], K. A. Mosevoll [1,2], T. H. Anderson Tvedt [2], K. Hatfield [1]

[1]Insitute of Clinical Science, University of Bergen, [2]Departemnt of Medicine, Haukeland University Hospital, Bergen, Norway

Background: Chronic graft versus host disease (cGVHD) is the most common long-term complication of allogenic hematopoietic stem cell transplantation (allo-HSCT), associated with increased mortality, high disease burden and significant reduced quality of life for patients. The pathophysiology behind the disease is complex and insufficiently understood. The last decade has brought interest to single stranded noncoding RNA molecules; microRNAs (miRNAs), as important components in the pathophysiological process of cGVHD. However, their role in development of cGVHD and the possibilities of utilizing them as biomarkers are mainly unknown.
Aims: The objectives of this study were to investigate a broad specter of serum miRNAs from allografted patients and investigate associations between individual miRNAs and miRNA profiles, and cGVHD and their use as potential biomarkers for patients with cGVHD.
Methods: The study included 79 consecutively allotransplanted adults, 46 men and 33 women with median age of 49 years (range 15-71 years). Patients were transplanted with peripheral blood stem cells (PBSCs) derived from human leukocyte antigen (HLA)-matched family donors. Serum samples were obtained one year after the allo-HSCT, and stored under standard procedures before serum miRNA-seq analysis was performed using QIAGEN CLC Genomics Server v20.0.4 for all 79 patients.
Results: 50 of the 79 patients (63%) had signs of cGVHD at the one-year post-allo-HSCT control. The affected organ systems were; liver/bile duct (n=26), skin (n=22), gastrointestinal tract (n=21), eyes (n=21), mouth (n=17), lungs (n=3), urogenital tract (n=3), and musculoskeletal (n=1). miRNA-seq analysis revealed 1380 different miRNAs detected for at least one patient, while 233 miRNAs (17%) were detected in more than 70 patients. After corrections for age and by searching for discriminative miRNAs, we identified 29 microRNAs that differed significantly between patients with and without cGVHD (p-values <0.02), and 21 of these 29 miRNAs were detected for ≥ 70 of the patients. Among these 21 miRNAs, 12 were in particular differentially expressed (p-values <0.007). The results indicate that the difference in serum miRNA profiles between the two groups was considerable, and cGVHD appeared to have a profound impact on circulating miRNAs. Furthermore, five distinct miRNAs;

miR-365-3p, miR-148-3p, miR-122-3p, miR-378-3p, and miR-192-5p, were found to be highly associated with cGVHD in our analysis, and validated by receiver operating characteristics (ROC) analysis. Based on these five miRNAs, we developed a miRNA signature which by bioinformatic approaches and linear regression model utterly improved our prediction model for cGVHD. Finally, literature reviews support the association between individual microRNAs and cGVHD and inflammation.
Summary/Conclusion: To conclude, the present miRNA profiling study was conducted to identify serum miRNA signatures associated with cGVHD, and our observations suggest that cGVHD is associated with significant and profound alterations in miRNA serum profiles. We conclude that miRNAs are differently expressed among patients with and without cGVHD, although further and larger studies are needed to validate our present findings and investigate the potential diagnostic and prognostic impact of circulating miRNAs among allo-HSCT recipients.

EP1297 TRANSCRIPTOME ANALYSIS OF HAEMATOPOIETIC STEM CELLS AFTER MOBILIZATION WITH CYTARABINE AND CYCLOPHOSPHAMIDE

L. Huvarova [1,2,*], T. Sevcikova [3], D. Zihala [3], L. Cerna [1], J. Vrana [3], V. Kapustova [1], O. Venglar [1,2], T. Jelinek [1,3], R. Hajek [1,3], Z. Koristek [1,3]

[1]Department of Haematooncology, University Hospital Ostrava, [2]Department of Biology and Ecology, [3]Department of Clinical Studies, University of Ostrava, Ostrava, Czech Republic

Background: High dose chemotherapy with melphalan 200mg/m2 followed by autologous haematopoietic stem cell transplantation (ASCT) represents a standard of care for patients with multiple myeloma. Most transplant centers use for mobilization combination of cyclophosphamide (Cy) and granulocyte-colony stimulating factor (G-CSF). Recently our group and others demonstrated that alternative mobilization regimen with cytarabine (AraC), is safe and more effective (more than 2 times higher median of CD34+ yield) (Jelinek et al., 2018). The exact mechanism why is AraC more effective than Cy is largely unknown. To shed light into these processes we have performed transcriptome analysis of sorted haematopoietic stem cells after mobilization with AraC and Cy from apheresis product.
Aims: To find differences in transcriptome of haematiopoietic stem cells after mobilization with Cy or AraC in patients with newly diagnosed multiple myeloma.
Methods: Sorted CD34+ haematopoietic stem cells (HSCs) from 14 MM patients were used for the analysis. Nine patients were mobilized with cytarabine (AraC 400 mg/m2/12h day 1-2 followed by G-CSF) and 5 patients with cyclophosphamide (Cy 2,5 g/m2 day 1 followed by G-CSF). CD34+ HSCs were sorted from 1ml of apheresis product using FACS Arria III. RNA libraries were prepared using SMARTer Stranded Total RNA-Seq Kit v2 and sequenced aiming at 30 Mbp per sample. Raw reads were trimmed with TrimGalore. rRNA reads were filtered by sortmerna and the rest mapped and quantified by Salmon. Differential gene expression was evaluated using Deseq2.
Results: We have identified 190 significantly deregulated genes with more than 2 fold-change between groups of haematopoietic stem cell (HSC) samples mobilized by AraC or Cy. Unsupervised clustering showed distinct cluster including 3 Cy samples and second cluster with all AraC and 2 Cy samples. Pathway analysis of 171 down-regulated genes in AraC samples revealed immune system Gene Ontology term or chemokine signaling and osteoclast differentiation among the most deregulated KEGG categories. Besides, down-regulation of integrins (ITGB3, ITGAM, ITGA7) and chemokine receptors and ligands (CXCR2, CXCL16, CCR2, CCR1) suggest decreased cell homing in AraC group, however, the expression of some of the main homing molecules was not altered. E.g. CXCR4 was not markedly downregulated (FDR 0,09), chemokine ligand CXCL12 was not expressed at all. Among the top downregulated genes in AraC group was PAX5 transcription factor, which is responsible for the differentiation of B-cell lineage, though the level of expression of this gene was relatively low in both groups. We detected several histone genes to be upregulated in AraC group as well as multiple long non-coding RNAs including lncRNA for PSMF1 coding antisense RNA for the immunoproteasome inhibitor hP131 subunit suggesting potential upregulation of immunoproteasome in AraC group.
Summary/Conclusion: Our analysis focuses, for the first time, on the alteration of transcriptome after application of different mobilization agents (AraC and Cy) on HSC. Down-regulation of a number of genes involved in homing could explain increased mobilization efficacy after AraC regimen. On the other hand, pathways important for the haematopoietic stem cell function and metabolism were not deregulated and also their potential to differentiate into mature cell types was not significantly altered. The role of several long non-coding RNAs elevated in AraC group needs to be elucidated.

EP1298 EXPLOITING THE HEMATOPOIETIC SUPPORTIVE ACTIVITY OF MESENCHYMAL STROMAL CELLS TO IMPROVE THE TRANSPLANTATION OUTCOME OF GENE-EDITED HSPCS.

S. Crippa [1,*], A. Conti [1], V. Vavassori [1], S. Rivis [2], R. Bosotti [1], S. Scala [1], S. Pirroni [3], R. Jofra-Hernandez [1], L. Santi [1], L. Basso-Ricci [1], G. Schiroli [4], P. Genovese [5], A. Aiuti [6], R. Di Micco [6], L. Naldini [6], M. E. Bernardo [6]

[1]San Raffaele Telethon Institute for Gene Therapy (SR-Tiget), Ospedale San Raffaele, Milan, Italy, [2]Laboratory of Tumor Inflammation and Angiogenesis, VIB-KULeuven, Leuven, Belgium, [3]Divisione di Anatomia e Isologia Patologica, Presidio San Giovanni Di Dio, Cagliari, Italy, [4]Massachusetts General Hospital, [5]4Dana-Farber/Boston Children's Cancer and Blood Disorders Center, Boston, United States, [6]San Raffaele Telethon Institute for Gene Therapy, Ospedale San Raffaele, Milan, Italy

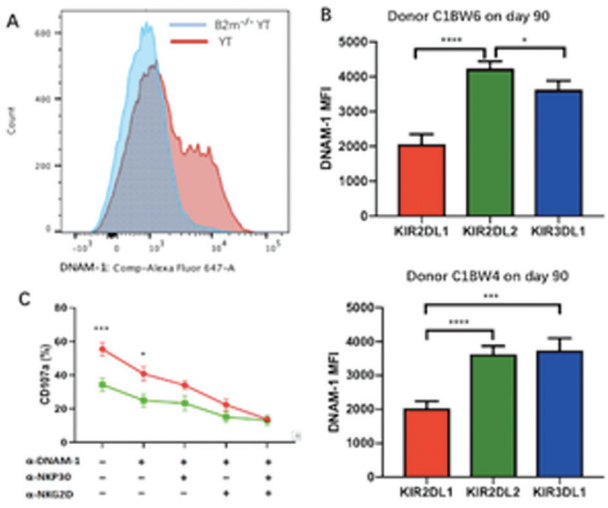
Background: Hematopoietic Stem and Progenitor Cells (HSPCs) reside in a specialized microenvironment in the bone marrow (BM), named the hematopoietic niche. Mesenchymal Stromal Cells (MSCs) are key elements of the BM niche, regulating HSPC function by direct contact and through the release of paracrine factors. Due to these properties, MSCs have been employed *in vitro* to support HSPC expansion, and *in-vivo* to promote HSPC engraftment and hematopoietic reconstitution in preclinical models and clinical trials of HSPC transplantation (HSCT).
Aims: Based on these studies, in our work we aimed to improve the outcome of HSCT with CRISPR-Cas9 gene-edited (GE)-HSPCs, whose efficiency equires further advancement to fully exploit its therapeutic potential. Indeed, GE-HSPCs activate a DNA damage cascade in response to nuclease-induced double strand break and delivery of DNA repair template, which constrains HSPC proliferation and long-term repopulating capacity.
Methods: To this aim, we developed a novel MSC-based *in-vitro* approach to expand and recover GE-HSPCs. We analyzed the GE-HSPC phenotype by flow cytometry and the activation of a DNA stress response in GE-HSPCs by immunohistochemistry. We further evaluated the cell-cycle state, the level of inflammation and apoptosis by flow-cytometry and gene expression analysis. The fitness of HSPCs gene-editd according to standard procedures were compared to HSPCs gene-edited in the presence of MSCs (+MSCs). Preclinical mouse models of HSCT were used to prove the superior capability of GE-HSPCs + MSCs to long-term engraft and favor hematological reconstitution.
Results: We show that MSCs produced several hematopoietic supportive and anti-inflammatory factors, capable to reduce the proliferation arrest, and mitigate the apoptotic and inflammatory programs activated in GE-HSPCs, ultimately improving GE-HSPC expansion and clonogenic potential. This resulted into a superior GE-HSPC engraftment and hematological reconstitution in transplanted mice. Moreover, we demonstrated that MSCs favored the engraftment of limited doses of GE-HSPCs when co-transplanted *in vivo*.
Summary/Conclusion: In conclusion, our work poses the basis for the clinical use of MSCs as a novel, safe and efficient strategy to preserve the long-term repopulating capacity and promote engraftment of CRISPR-Cas9 gene corrected HSPCs.

EP1299 EFFECT OF CD34+ DERIVED MICROPARTICLES ON THE CLONOGENIC POTENTIAL OF MONONUCLEAR CELLS FROM CORD BLOOD

A. Xagorari [1,*], K. Sianidou [2], D. Papaioannou [1], A. Kouvatsi [2], A. Anagnostopoulos [1], D. Sotiropoulos [1]

[1]Public Cord Blood Bank, Hematology Department, G.H.G.Papanicolaou, [2]Biology Department, Aristotelian University of Thessaloniki, Thessaloniki, Greece

Background: Umbilical cord blood is a source of hematopoietic stem cell (HSC) and is used in hematopoietic cell transplantation. The HSC



engraft in the bone marrow and differentiate to progenitor and mature blood cells. The dynamic of the HSC can be evaluated by hematopoietic colony-forming unit (CFU) assays using methylcellulose-based medium. From the plasma membrane of hematopoietic cells, like other cells, extracellular vesicles of 0.1–1μm in size germinate, called microparticles (MPs). MPs can affect normal cell functions. Our previous study showed that there are MPs derived from hematopoietic stem cells in umbilical cord blood and they carry the surface antigen CD34+ (CD34+ MPs).
Aims: The objective of this study was to analyze the role of CD34+MPs in the differentiation program of hematopoietic progenitor cells.
Methods: Umbilical cord blood units (UCB) were collected after informed consent. The low volume units were used in this study, as not appropriate for transplantation. CD34+MPs were isolated from the plasma of UCBs by centrifugation and purified using magnetic bead based technology (Miltenyi Biotec). Their number was estimated by flow cytometry using CD34-PE and Annexin V-FITC Abs. Mononuclear cells (MNCs) were isolated from UCB by ficoll density centrifugation. MNCs were cultured in liquid culture without growth factors for 24 hours with or without CD34+MPs. Furthermore, MNCs cultured in liquid culture without growth factors for 1 or 24 hours with or without CD34+MPs and then were seeded in semisolid cultures in the presence of a cocktail of growth factors for colony-forming unit-granulocyte/macrophage (CFU-GM), erythroid burst-forming units (BFU-E), colony-forming unit-granulocyte, erythrocyte, macrophage, megakaryocyte (CFU-GEMM) colony growth.
Results: The number of MNCs cultured in the presence of CD34+MPs was reduced by 15.1% compared to mononuclear cells cultured in the absence of CD34+MPs (Control) in liquid cultures of 24 hrs. In order to analyze the effect of CD34+MPs in the differentiation and proliferation of hematopoietic cells, CFU assays were performed. First MNCs were incubated for 1 hr or 24 hrs with 500, 1000 and 2000 CD34+MPs and then were seeded in semisolid culture. CFU colony numbers were decreased by 21,7% and 70,2% respectively when MNCs co-incubated for 1h with 1000 and 2000 CD34+MPs. When MNCs were incubated for 24 hrs with 500 CD34+MPs, the number of CFU colonies was increased by 26,6%, while co-incubation with 2000 CD34+MPs decreased the number by 44,2%. Furthermore, comparison between 1 and 24 hrs incubation of MNCs with CD34+MPs in liquid culture before plating in semisolid medium has shown, an increase by 77,87% and 32,8% in CFU-GEMM and CFU-GM respectively in the presence of 500 CD34+MPs while CFU-GEMM and CFU-GM colonies decreased by 11,88% and 27,3% with 1000 CD34+MPs and 73,8 and 53,1% with 2000 CD34+MPs respectively.
Summary/Conclusion: In this study we have evaluated the negative effect of CD34+MPs in the viability of MNC from cord blood. CD34+MPs were associated with CFU growth in a dose- and time- dependent manner. Low number of CD34+MPs acts beneficially for CFU viability whereas the high number of CD34+MPs decreases the number of CFU-GM and CFU-GEMM.

EP1300 COSTIMULATORY MOLECULE DNAM-1 EXPRESSION ON NK CELLS IS DETERMINED BY HLA AND CORRELATED WITH NK CELL EDUCATION POST ALLOGENEIC HEMATOPOIETIC STEM CELL TRANSPLANTATION

S. Qiannan [1,2,*], Y. Xingxing [1,2], L. Meng [1], C. Xunhong [1], L. Xuefei [1,2], X. Zhengli [1], C. Yingjun [1], Z. Xiaosu [1], W. Yu [1], Z. Xiaohui [1], X. Lanping [1], H. Xiaojun [1], Z. Xiangyu [1]

[1]Peking University People's Hospital, [2]Peking-Tsinghua Center for Life Sciences, Beijing, China

Background: NK cell education is a fateful process to acquire strong responsibility through inhibitory receptors bound with MHC-I on autologous cells during NK cell development. DNAM-1 (DNAX accessory molecule-1, CD226) is a costimulatory molecule expressed by NK cells and CD8+ T cells. Interaction between DNAM-1 and its ligands on target cells triggers cell-mediated cytotoxicity and cytokine production. Previous studies illuminated the expression of DNAM-1 on NK cells was associated with inhibitory receptors KIR/NKG2A. Our previous studies have demonstrated that when both donors and recipients present all the KIR ligands for donor KIRs, reconstituted NK cells would achieve better functional education in patients post allogeneic hematopoietic stem cell transplantation (allo-HSCT). However, the mechanism that regulates DNAM-1 expression is unclear.
Aims: To explore the regulation of MHC-I on DNAM-1 expression using YT cell lines. And to investigate the influence of donor and recipient HLA on DNAM-1 expression during NK cell reconstitution and education based on the setting of allo-HSCT.
Methods: Firstly, we used crispr-cas9 to knock out HLA-I on YT cell line to study the effect of MHC-I to DNAM-1 expression. Then, we investigated the correlation of DNAM-1 expression and NK cell education during a dynamic reconstitute state in patients who had acute leukemia and underwent allo-HSCT at days 30, 90 and 180 post-HSCT. And further analyzed the relationship of donor, recipients and both HLA with DNAM-1 expression. Finally, we blocked DNAM-1 in vitro to explore whether DNAM-1 expression determined educated NK stronger function.
Results: 1. $B2m^{-/-}$ YT cells, which had lower surface HLA-I expression, showed obviously decreased DNAM-1 expression.
2. In patients post allo-HSCT, educated NK cells displayed higher DNAM-1 expression than uneducated NK cells considering no matter donors, recipients or both HLA genotypes. DNAM-1 expression on sole-recipient HLA educated NK cells was higher than sole-donor HLA educated NK cells, indicating that recipients affected more than donors for NK education. Therefore, there was a close correlation of DNAM-1 expressions and NK education post transplantation.
3. DNAM-1 expression was positively related with inhibitory KIR/NKG2A numbers when patients presented all HLA(C1C2BW4) post-HSCT.
4. Only when DNAM-1, NKp30 and NKG2D receptors were blocked simultaneously, the function of educated and uneducated NK cells would be decreased to a similar level. So, activating receptors could be synergistic with DNAM-1 to determine NK function.

Summary/Conclusion: Both the donor or/and recipient could regulate the expression of DNAM-1 through HLA-I for patients post-HSCT. DNAM-1 collaborating with NKP30 and NKG2D determined hyperresponsiveness of educated NK cells.

Thalassemias

EP1301 INTERIM RESULTS OF BETIBEGLOGENE AUTOTEMCEL GENE THERAPY IN PEDIATRIC PATIENTS WITH TRANSFUSION-DEPENDENT B-THALASSEMIA (TDT) TREATED IN THE PHASE 3 NORTHSTAR-2 AND NORTHSTAR-3 STUDIES.

A. E. Kulozik [1,*], I. Thuret [2], J. L. Kwiatkowski [3], A. A. Thompson [4], J. B. Porter [5], S. Hongeng [6], E. Yannaki [7], M. Sauer [8], A. J. Thrasher [9], A. Lal [10], R. Guo [11], W. Liu [11], R. A. Colvin [11], M. C. Walters [12], F. Locatelli [13]

[1]University Medical Center for Children and Adolescents, Heidelberg University, Heidelberg, Germany, [2]Department of Pediatric Hematology, Marseille University, Marseille, France, [3]Division of Hematology, The Children's Hospital of Philadelphia, Philadelphia, [4]Hematology Section, Feinberg School of Medicine, Chicago, United States, [5]Department of Haematology, University College London, London, United Kingdom, [6]Department of Pediatrics, Faculty of Medicine Ramathibodi Hospital, Bangkok, Thailand, [7]Gene and Cell Therapy Center of the Hematology Dept / Hematopoietic Cell Transplantation Unit, Papanicolaou Hospital, Thessaloniki, Greece, [8]Pediatric Hematology and Oncology, Medical University of Hannover, Hannover, Germany, [9]Great Ormond Street Hospital for Children, London, United Kingdom, [10]UCSF Benioff Children's Hospital, Oakland, [11]bluebird bio, inc., Cambridge, [12]University of California San Francisco, San Francisco, United States, [13]Sapienza University of Rome, Rome, Italy

Background: Phase 3 studies evaluating betibeglogene autotemcel (beti-cel; LentiGlobin for β-thalassemia) gene therapy in patients with TDT, HGB-207 (non-β^0/β^0 genotypes; NCT02906202) and HGB-212 (β^0/β^0, $\beta^0/\beta^{+IVS\text{-}I\text{-}110}$, $\beta^{+IVS\text{-}I\text{-}110}/\beta^{+IVS\text{-}I\text{-}110}$ genotypes; NCT03207009), demonstrated positive outcomes in adults.
Aims: Therefore, the studies were expanded to include patients <18 years of age. We report interim results in these pediatric patients.
Methods: Autologous CD34+ cells were transduced ex vivo with BB305 lentiviral vector to produce beti-cel. Patients underwent pharmacokinetic-adjusted busulfan-based myeloablation followed by beti-cel infusion. Transfusion independence (TI; weighted average hemoglobin [Hb] ≥9 g/dL without packed red blood cell transfusions for ≥12 months) was the HGB-207 and HGB-212 (as of protocol amendment dated Oct 8, 2020) primary endpoint. Data are presented as median (min–max).
Results: As of 30 November 2020, 27 pediatric patients were treated and followed for 23.1 (0.9–35.5) months, including 16 patients <12 years (HGB-207: n=8; HGB-212: n=8) and 11 patients ≥12–<18 years at assent (HGB-207: n=6; HGB-212: n=5). The youngest patients were 4 years of age (n=3). TI was achieved in 9/11 evaluable patients <12 years and 10/10 evaluable patients ≥12–<18 years. The median duration of ongoing TI was 19.5 (12.3–32.0) months. Pediatric patients achieved TI at a similar rate to adults (90.5% [19/21] vs 84.6% [11/13] in patients > 18 years).
Weighted average Hb during TI in patients <12 years and ≥12–<18 years was 10.0 (9.5–11.4) g/dL and 11.5 (9.6–13.0) g/dL, respectively. At last visit, gene therapy-derived HbA^{T87Q} levels in these patients were 8.4 (5.0–10.1) g/dL (n=9) and 9.1 (4.4–10.8) g/dL (n=10), respectively. These data are comparable to those recorded in patients ≥18 years who achieved TI; weighted average Hb was 12.6 (9.9 – 13.6) g/dL and HbA^{T87Q} at last visit was 9.9 (6.3 – 13.4) g/dL (n=11). The median nadir lymphocytes within the first month post-infusion for patients <18 years was 0.48 x10^9/L (min – max: 0.02 – 1.7 x10^9/L) (n=27).
Non-hematologic ≥ Grade 3 adverse events in ≥3 patients <18 years were stomatitis (n=14), febrile neutropenia (n=13), epistaxis (n=6), decreased appetite (n=5), increased alanine aminotransferase (n=3), hypoxia (n=3), and pyrexia (n=3). Grade 4 veno-occlusive liver disease occurred in 2 patients ≥12–<18 years and one grade 2 event occurred in a patient <12 years; all events resolved after treatment with defibrotide. Drug-product related AEs as per investigators opinion were reported in 2 patients < 12 years of age (thrombocytopenia, tachycardia) and 2 patients 12-18 years of age (abdominal pain (2)). No replication-competent lentivirus was reported. All patients had polyclonal vector integration; no integration site contributed >3% of all integration sites at last assessment (n=22).

Table 1. Patient, drug product, engraftment characteristics (median [min–max])

		<12 years (N=16)	≥12–<18 years (N=11)
Age, years		8 (4–11)	15 (12–17)
Genotype	β^0/β^+	8 (50)	3 (27)
	β^0/β^0	6 (38)	4 (36)
	β^+/β^+	1 (6)	4 (36)
	β^E/β^0	1 (6)	0
Drug product			
Vector copies/diploid genome		2.9 (1.9–7.0)	3.3 (1.2–6.0)
Transduced cells, %		71 (34–94)	82 (34–90)
Cell dose, x 10^6 cells/kg		10.2 (6.1–42.1)	7.4 (5.0–19.4)
Neutrophil engraftment		26 (17–39)	26 (16–38)
Platelet engraftment		50 (13–94)*	50.0 (25–84)

*1 patient with <3 months follow-up had not yet achieved platelet engraftment.

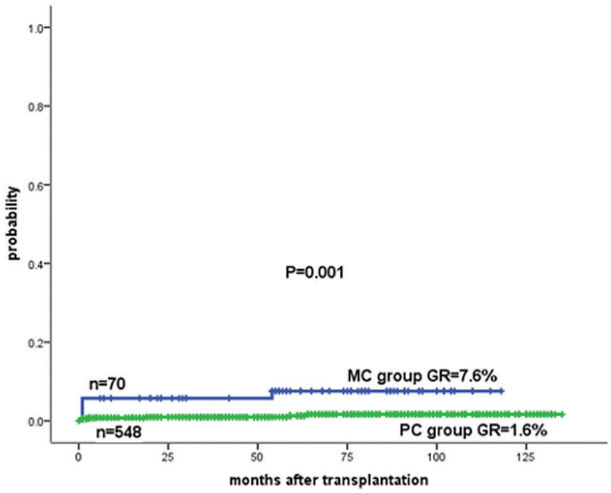
Summary/Conclusion: Pediatric patients with diverse TDT genotypes achieved TI rates comparable to adults after beti-cel gene therapy, suggesting that beti-cel is a viable treatment option for patients with TDT of all ages. The treatment regimen had a safety profile consistent with busulfan myeloablation.

EP1302 TFR2-HAPLOINSUFFICIENCY IMPROVES THE PHENOTYPE IN A MURINE MODEL OF TRANSFUSION-DEPENDENT B-THALASSEMIA

S. M. Di Modica [1,*], O. Violante [2], M. Pettinato [2], M. R. Lidonnici [3], A. Pagani [1], G. Ferrari [3], L. Silvestri [1], A. Nai [1]

[1]Division of Genetics and Cellular Biology, [2]Vita-Salute San Raffaele University, [3]San Raffaele Telethon Institute for Gene Therapy (SR-TIGET), IRCCS San Raffaele Scientific Institute, Milan, Italy

Background: β-thalassemia is a genetic disorder characterized by anemia, ineffective erythropoiesis and iron overload. Patients affected by the most severe form of the disease, transfusion-dependent thalassemia (TDT), require lifelong blood transfusion and an iron chelation therapy, symptomatic treatments that affect the quality of life. The only well-established curative therapy is allogenic bone marrow (BM) transplantation, but it is applicable only to a minority of patients because of the scarcity of suitable donors. Other recently approved treatments (i.e. gene therapy and luspatercept), despite promising, are only partially effective and/or suitable for selected patients. For these reasons, the identification of novel therapeutic approaches is a clinical need. We have already proved that the selective BM deletion of transferrin receptor 2 (TFR2), a partner of Erythropoietin receptor, improves erythropoiesis and ameliorates anemia in a non-transfusion-dependent thalassemia murine model, despite the persistence of the genetic defect (Artuso et al., *Blood* 2018; Casu, Pettinato et al., *Blood* 2020).
Aims: Here, we investigate whether *Tfr2* targeting might represent a therapeutic option for TDT.
Methods: TDT mice ($Hbb^{th1/th2}$) with BM *Tfr2* heterozygous deletion ($Tfr2^{BMhetero}/Hbb^{th1/th2}$) were generated by transplantation of fetal liver cells (FLT) harvested from day 14.5 $Tfr2^{+/-}/Hbb^{th1/th2}$ (or $Hbb^{th1/th2}$ as a control) embryos. Two x 10^6 fetal liver cells were retro-orbitally injected into lethally irradiated 8-week-old C57BL/6-Ly-5.1 wild-type male mice. Complete blood count was evaluated 8 and 12 weeks after FLT, when mice were sacrificed, before the onset of blood transfusion requirement. A full phenotypic analysis was performed to analyze the hematological parameters, erythropoiesis and the iron phenotype.
Results: Twelve weeks after FLT, chimerism was superior to 90% in all mice and the mortality rate was consistently higher among $Hbb^{th1/th2}$ than $Tfr2^{BMhetero}/Hbb^{th1/th2}$ mice (50% and 20%, respectively). BM *Tfr2* haploinsufficiency was sufficient to increase RBC count, Hb levels and hematocrit, despite the attenuation of the beneficial effect over time due to the worsening of anemia. *Tfr2* heterozygous deletion decreased the total amount of $Ter119^+$ cells and of polychromatic erythroblasts in the BM, showing a partial improvement of ineffective erythropoiesis. As expected, splenomegaly was not alleviated, while hepatic iron overload was reduced. Moreover, BM *Tfr2* haploinsufficiency partially corrected cardiomegaly, a secondary TDT complication caused by chronic anemia and iron overload, and attenuated the endoplasmic reticulum stress in the BM, preventing the activation of the unfolded protein response. However, whether this effect is directly due to the deletion of *Tfr2* or it



is an indirect consequence of the improved cell fitness is still unknown and worth to be assessed.
Summary/Conclusion: Overall our data show that *Tfr2* targeting might represent a valuable therapeutic option for the most severe form of β-thalassemia, ameliorating several features of the disease. However, the effect of full BM *Tfr2* inactivation, that we expect more efficient in correcting anemia and ineffective erythropoiesis, and the potential role of *Tfr2* deletion in the reduction of blood transfusion requirement, the standard treatment for TDT but correlated to several complications, remain to be evaluated.

EP1303 POSSIBLE CORRELATION OF MIXED CHIMERISM WITH POST-TRANSPLANT OUTCOME IN PATIENTS WITH B THALASSEMIA:RISK OF GRAFT FAILURE

W. Tan [1,*], Y. He [1], X. Feng [1], X. Wu [1], C. Li [2], J. Liao [2], H. Liu [2], X. Liu [1], F. Pei [1], Q. Liu [1], Y. Ruan [1], Y. Ren [1]

[1]Pediatrics, Nanfang Hospital,Southern Medical University, Guangzhou, [2]Nanfang-Chunfu Children's Institute of Hematology, Taixin Hospital, DongGuan, China

Background: Secondary graft failure (SGF) is a major obstacle in allogeneic hematopoietic stem cell transplantation for patients with thalassemia major (TM). However, the impact of the persisting mixed chimerism (MC) on transplant outcome remains controversial.
Aims: To assess risk factors of mixed chimerism and to evaluate possible correlations between mixed chimerism and transplantation outcomes.
Methods: A total of 618 patients with thalassemia major (TM) underwent allogeneic HSCT from December2008 until December 2019 were identified with median age of 6 years old (1-23) and median follow up time of 70 months(1-135), from HLA-identical sibling donors (SD) (n=212; 34.3%), unrelated donors (UD, n=313; 50.6%),sibling Cord blood(CB, n=49,7.9%)and parent donors (PD, n=44,7.1%). Source of graft were 538 (87.1%) from peripheral stem cells, 32(5.2%) from bone marrow and 48(7.8%)from sibling cord blood. Cy+Bu+Flu+TT+ATG conditioning regimen was used in 416 pts while a reduced conditioning regimen Cy+Bu+Flu+ATG was used for 167pts and Cy+Bu+Flu for the other 35 pts.
Results: Overall Survival (OS), Thalassemia-Free survival (TFS), Transplantation-related mortality (TRM) and graft rejection (GR) for the entire group were 94.8%, 92.7%,5.2% and 2.4% respectively. MC was presented in 70 pts, with median present time 4 months (1-59 months). The cumulative incidence MC was 12.4%.
No significant difference was observed in OS and Thalassemia-Free survival (TFS) between MC and full donor chimerism (FC) pts. The cumulative probability of OS, TFS between MC pts and FC pts was 97.1% vs. 94.4% (P=0.343) and 89.6% vs. 93.2% (P=0.272),respectively. However, the incidence of MC was significantly associated with the development of graft failure/rejection. Graft failure occurred in 5 pts in the MC group vs.7 pts in the FC group, the corresponding incidence were 7.6% vs. 1.6 % respectively. (P =0.001, Figure).
Acute GVHD incidence was much lower in MC pts than in FC pts (2.9% vs. 12.7%, P=0.022,), whereas MC pts had significantly higher chronic GVHD(16.8% vs. 4.2%, P=0.000).MC was associated with an increased risk of chronic GVHD, mostly were DLI derived
Patients receiving stem cells from cord blood of matched sibling donors had a high risk of MC.MC incidence of stem cell source from peripheral blood(PB), bone marrow(BM), cord blood (CB)were 10.6%, 10%, 34.2% respectively.(P=0.000).Unrelated donors had a lower risk of MC than sibling donors. Incidence of MC from unrelated donors was 9.5% vs. 16.1% from sibling donors (P=0.007).
Intravenous Thiotepa (TT) in combination with Busulfan (Bu), cyclophosphamide (Cy) anti-thymocyte globulin (ATG) on HSCT could reduce the risk of MC. The corresponding incidence of MC in Cy+Bu+Flu+TT+ATG, Cy+Bu+Flu+ATG, Cy+Bu+Flu conditioning regimen were 9.2%,15.9%,40.9% resepectively(P=0.000).
There was also a significant difference in chimerism based on donor-recipient gender pairing (P = 0.041): male grafts into male patients having the greatest risk of MC and female grafts into female patients having the least. Patients who under 9 years old had a higher risk of MC than that of pts>9 years old (P=0.018).

Summary/Conclusion: Our results show that patients who presented mixed chimerism showed a similar post-transplant outcome in OS and TFS but was associated with higher risk of graft failue.Patients receiving stem cells from CB had a high risk of MC than from PBSC. Reduced nonmyeloablative approach capable of achieving allogeneic mixed hematopoietic chimerism. Our data suggests that Cy+Bu+Flu+TT+ATG is a preferred conditioning regimenfor TM patients could reduce the risk of mixed chimerism.

EP1304 FEWER RED BLOOD CELL TRANSFUSION UNITS AND VISITS ACROSS BASELINE TRANSFUSION BURDEN LEVELS IN PATIENTS WITH BETA-THALASSEMIA TREATED WITH LUSPATERCEPT IN THE PHASE 3 BELIEVE TRIAL

A. T. Taher [1,*], J. B. Porter [2], O. Hermine [3,4], A. Piga [5], T. D. Coates [6,7], A. Kattamis [8], A. Khelif [9], F. Shah [10], Y. Aydinok [11], R. Zoffoli [12], D. Miteva [13], J. K. Shetty [13], L. Bueno [13], A. Yucel [14], M. D. Cappellini [15]

Background: β-thalassemia is a genetic blood disorder marked by ineffective erythropoiesis and anemia. The first-in-class erythroid maturation agent, luspatercept, enhances late-stage erythroid hematopoiesis. Luspatercept was shown to be effective in reducing red blood cell (RBC) transfusion burden (TB) in adult patients (pts) with β-thalassemia requiring regular RBC transfusions in the phase 3, double-blind, randomized, placebo-controlled BELIEVE trial (NCT02604433). The effect of luspatercept treatment on RBC TB warrants further investigation.
Aims: To assess the mean cumulative number of RBC transfusion visits and units across baseline (BL) low, medium, and high TB levels among pts with β-thalassemia in the BELIEVE trial.
Methods: Eligible pts were aged ≥18 years with β-thalassemia or hemoglobin (Hb) E/β-thalassemia (compound β-thalassemia mutation and/or multiplication of α-globin genes was allowed) and required regular RBC transfusions (defined as 6–20 RBC units in the 24 weeks (wks) prior to randomization with no transfusion-free period >35 days). Pts were randomized 2:1 to luspatercept 1.0 mg/kg (up to 1.25 mg/kg allowed) or placebo subcutaneously every 3 wks for 48 wks during the double-blind period. After study unblinding, pts randomized to placebo were eligible to cross over to receive luspatercept in an open-label phase.

Luspatercept responders (n = 47; 21%) were defined as pts who achieved the primary endpoint of RBC TB reduction of ≥33% during Wks 13–24 from BL (≥2 RBC units). BL low, medium, and high TB were defined as receipt of ≤10, >10–≤15, and >15 RBC units/24 wks, respectively. The mean cumulative number of RBC transfusion units and visits was assessed per pt in luspatercept responders and placebo-treated pts up to Wk 48, and in luspatercept responders and non-responders up to Wk 120, excluding pts who crossed over from placebo. Cumulative mean numbers of RBC transfusion units and visits were estimated using the Nelson-Aalen nonparametric estimator with robust variance estimate. The data cutoff was July 1, 2019.

Results: Luspatercept responders had fewer RBC units transfused vs placebo up to Wk 48 and vs luspatercept non-responders up to Wk 120, across BL TB levels (Table). Up to Wk 120, the mean cumulative number (95% confidence interval [CI]) of RBC units transfused per pt for luspatercept responders vs non-responders was 15.2 (9.0–25.5) vs 34.5 (30.6–38.8) for low BL TB, 37.8 (33.1–43.3) vs 53.2 (50.6–55.9) for medium BL TB, and 56.4 (50.0–63.6) vs 71.1 (67.3–75.1) for high BL TB.

Luspatercept responders also had fewer RBC transfusion visits vs placebo up to Wk 48 and vs luspatercept non-responders up to Wk 120, regardless of TB at BL (Table). Up to Wk 120, the mean cumulative number (95% CI) of RBC transfusion visits per pt for luspatercept responders vs non-responders was 13.5 (7.9–23.1) and 29.6 (26.5–33.0) for low BL TB, 28.3 (24.6–32.4) and 33.8 (32.1–35.6) for medium BL TB, and 35.1 (31.6–38.9) and 35.9 (34.0–37.9.) for high BL TB.

Table. Mean cumulative number of RBCT units and visits per pt for luspatercept responders, luspatercept non-responders, and placebo-treated pts across BL TB levels

Low BL TB[a]	Mean RBCT units per pt (95% CI)			Mean RBCT visits per pt (95% CI)		
	Responders[b]	Non-responders	Placebo	Responders[b]	Non-responders	Placebo
Up to Wk 48	n = 9	n = 22	n = 14	n = 9	n = 22	n = 14
	7 (4.3–11.5)	14.8 (13.0–16.9)	18.9 (16.4-21.7)	6.1 (3.7–10.1)	12.4 (11.2–13.6)	15.0 (13.2–17.0)
Up to Wk 120	n = 6	n = 12	n = 0	n = 6	n = 12	n = 0
	15.2 (9.0–25.5)	34.5 (30.6–38.8)		13.5 (7.9–23.1)	29.6 (26.5–33.0)	
Medium BL TB[a]	**Mean RBCT units per pt (95% CI)**			**Mean RBCT visits per pt (95% CI)**		
	Responders[b]	Non-responders	Placebo	Responders[b]	Non-responders	Placebo
Up to Wk 48	n = 21	n = 68	n = 39	n = 21	n = 68	n = 39
	17.4 (15.5–19.5)	23.6 (22.6–24.7)	27.5 (26.0–29.0)	12.9 (11.5–14.6)	14.6 (13.9–15.3)	14.3 (13.4–15.2)
Up to Wk 120	n = 12	n = 32	n = 0	n = 12	n = 32	n = 0
	37.8 (33.1–43.3)	53.2 (50.6–55.9)		28.3 (24.6–32.4)	33.8 (32.1–35.6)	
High BL TB[a]	**Mean RBCT units per pt (95% CI)**			**Mean RBCT visits per pt (95% CI)**		
	Responders[b]	Non-responders	Placebo	Responders[b]	Non-responders	Placebo
Up to Wk 48	n = 16	n = 65	n = 43	n = 16	n = 65	n = 43
	22.8 (20.2–25.8)	31.1 (29.5–32.7)	34.8 (33.3–36.4)	14.1 (12.6–15.8)	15.4 (14.6–16.3)	16.6 (15.6–17.7)
Up to Wk 120	n = 13	n = 29	n= 0	n = 13	n = 29	n = 0
	56.4 (50.0–63.6)	71.1 (67.3–75.1)		35.1 (31.6–38.9)	35.9 (34.0–37.9)	

[a]BL low, medium, and high TB were defined as receipt of ≤10, >10–≤15, and >15 RBC units/24 wks, respectively; [b]Luspatercept responders were defined as patients who achieved an RBC TB reduction of ≥33% during Wks 13–24 from BL (≥2 RBC units).
BL, baseline; CI, confidence interval; patients, pts; RBC, red blood cell; RBCT, RBC transfusion; TB, transfusion burden; wk, week.

Summary/Conclusion: These findings show that luspatercept responders in the BELIEVE trial had reduced numbers of RBC units transfused and transfusion visits over 120 wks, regardless of BL TB. The observed reduction in TB in pts with β-thalassemia treated with luspatercept may have a positive impact on clinical and economic outcomes.

EP1305 LONG-TERM EFFICACY AND SAFETY OUTCOMES IN THE PHASE 2 STUDY OF LUSPATERCEPT IN B-THALASSEMIA

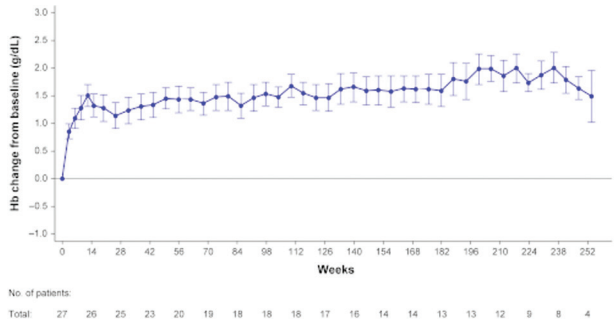
A. Piga [1,*], I. Tartaglione [2], R. Gamberini [3], E. Voskaridou [4], P. Ricchi [5], V. Caruso [6], A. Pietrangelo [7], X. Zhang [8], J. K. Shetty [9], K. M. Attie [10]

[1]Turin University, Turin, [2]Università della Campania "L. Vanvitelli", Naples, [3]Arcispedale S. Anna, Cona, Ferrara, Italy, [4]Thalassemia and Sickle Cell Center, Laiko General Hospital, Athens, Greece, [5]AORN "A. Cardarelli", Naples, [6]ARNAS Garibaldi, Catania, [7]CEMEF, Medicina 2, Modena, Italy, [8]Acceleron Pharma, Cambridge, MA, [9]Bristol Myers Squibb, Princeton, NJ, [10]Formerly Acceleron Pharma, Cambridge, MA, United States

Background: β-thalassemia is a hereditary anemia characterized by ineffective erythropoiesis. Luspatercept binds to selected TGF-β superfamily ligands, reducing aberrant Smad2/3 signaling and promoting late-stage erythroid maturation. Luspatercept is approved by the EMA and FDA for the treatment of adult patients (pts) with transfusion-dependent (TD) β-thalassemia. In a phase 2 study in pts with either TD or non-transfusion dependent (NTD) β-thalassemia, luspatercept increased hemoglobin (Hb) levels in NTD pts, reduced transfusion burden in TD pts, was well tolerated (Piga et al., *Blood* 2019;133(12):1279–89), and allowed the design of a 5-yr extension study.

Aims: To evaluate long-term efficacy and safety in pts enrolled in the phase 2 open-label study of luspatercept in β-thalassemia.

Methods: Eligible pts were ≥18 yrs old and either NTD (<4 red blood cell [RBC] U/8 wks prior to first dose with baseline Hb <10 g/dL) or TD (≥4 RBC U/8 wks prior to first dose, confirmed over 6 months). Pts received luspatercept for up to 3 months in the base study (NCT01749540); pts were then eligible for treatment for up to 5 additional yrs in the extension study at a starting dose of 0.8 mg/kg (with dose titration up to 1.25 mg/kg) every 3 wks subcutaneously (NCT02268409).



Results: As of 18 June 2020, 51 (80%) of the 64 pts from the base study continued onto the extension study. Of the 51 pts, 27 were NTD and 24 TD; median (range) age was 37 (22–62) yrs; 62.7% had prior splenectomy. For NTD pts, at baseline, median (range) Hb was 8.65 (7.6–9.8) g/dL; mean (SD) serum ferritin was 635.1 (387.3) µg/L. For TD pts, at baseline, median (range) transfusion burden was 8 (4–15) U/12 wks; mean (SD) serum ferritin was 1011.6 (795.5) µg/L.

Of the 27 NTD pts, 21 (78%) achieved a mean Hb increase ≥1.0 g/dL, and 17 (63%) achieved a mean Hb increase ≥1.5 g/dL over any 12 wks vs baseline. Mean Hb increase in NTD pts exceeded 1.0 g/dL by Wk 6 and was sustained throughout the extension study (Figure); mean (SD) duration of consecutive 12-wk periods of response was 1147.0 (637.5) days. Improvement in FACIT-Fatigue score in NTD pts correlated with change in Hb level at Wk 24 (r=0.71, *P*=0.0015). Improvement in 6-minute walk distance in NTD pts trended with change in Hb level at Wk 48 (r=0.64, *P*=0.0658).

Of the 24 TD pts, 20 (83%) achieved a ≥33% reduction in transfusion burden over any 12-wk interval vs baseline; mean (SD) duration of consecutive 12-wk periods of response was 462.5 (579.9) days. 12/24 (50%) TD pts achieved ≥33% reduction in transfusion burden over a fixed 12-wk interval (Wks 13–24) compared to baseline, and 8/24 (33%) responded during Wks 37–48. There was a trend for decreased mean serum ferritin levels from baseline for NTD and TD pts treated in the extension study which was maintained at Wk 252 (4.8 yrs after start).

Luspatercept had a tolerable safety profile across all pts in the extension study; 1 (2%) pt experienced a serious adverse event (AE) related to study drug (grade 3 biliary colic) and 5 (10%) pts experienced treatment-emergent AEs leading to study discontinuation (1 pt each: hemolytic anemia, musculoskeletal cerebrovascular accident, paresthesia, priapism, and pulmonary embolism).

Figure 1. Mean change in Hb level from baseline for NTD pts treated in the extension study (N=27). Error bars represent standard deviation.

Summary/Conclusion: In this assessment of longer-term outcomes in pts with β-thalassemia, luspatercept treatment was associated with sustained increases in Hb levels in NTD pts, and sustained decreases in transfusion burden in TD pts. There was a trend for a decrease in mean serum ferritin levels in NTD and TD pts. Luspatercept was associated with a tolerable safety profile over the extended observation period.

EP1306 BENEFIT OF CONTINUING THERAPY WITH LUSPATERCEPT IN PATIENTS WITH BETA-THALASSEMIA WHO DO NOT ACHIEVE ≥33% REDUCTION IN RED BLOOD CELL (RBC) TRANSFUSION BURDEN (TB) IN WEEKS 13–24 IN THE BELIEVE TRIAL

A. Piga [1,*], M. D. Cappellini [2], J. B. Porter [3], O. Hermine [4,5], K. H. M. Kuo [6], T. D. Coates [7,8], A. Kattamis [9], F. Shah [10], A. Khelif [11], Y. Aydinok [12], G. Zhang [13], J. K. Shetty [14], D. Miteva [14], T. Zinger [14], L. Bueno [14], A. Yucel [13], D. Tang [13], A. T. Taher [15]

Background: β-thalassemia is characterized by anemia and ineffective erythropoiesis. Appropriate schemes of RBC transfusions (RBCT) are the backbone of effective anemia treatment, but at the cost of progressive iron overload and iron-related complications. In the BELIEVE trial (NCT02604433), a phase 3, double-blind, multicenter, placebo-controlled study, the safety and efficacy of luspatercept, a first-in-class erythroid maturation agent, was evaluated in adult patients (pts) with β-thalassemia receiving RBCT. Luspatercept significantly reduced TB vs placebo (primary endpoint ≥33% reduction in RBCT in Weeks (Wks) 13–24 from baseline [≥2 RBC units]). As per protocol, pts that did not fully achieve the primary endpoint were defined as non-responders. In this group, the potential clinical benefit of treatment continuation with luspatercept has not yet been explored.
Aims: To evaluate the treatment benefit of continuing luspatercept therapy in pts who did not achieve the primary endpoint.
Methods: The BELIEVE trial enrolled pts aged ≥18 years with β-thalassemia or hemoglobin (Hb) E/β-thalassemia (including compound β-thalassemia mutation and/or multiplication of α-globin genes was allowed) and required regular RBCT (6–20 RBC units in the 24 wks prior to randomization, no RBCT-free period >35 days). Pts were randomized 2:1 to luspatercept 1.0 mg/kg (up to 1.25 mg/kg allowed) or placebo subcutaneously every 3 wks for 48 wks during the double-blind period. Pts in both treatment arms continued to receive best supportive care, including RBCT to maintain target Hb levels and iron chelation therapy adjusted to iron overload level. In this analysis, pts who did not achieve the primary endpoint during Wks 13–24 were followed until Wk 48. The data cutoff for this analysis was July 1, 2019.
Results: Of 224 pts who received luspatercept, 177 (79%) did not fully achieve the primary endpoint and were defined as non-responders. Of 163 luspatercept non-responders who continued treatment in Wks 25–48, 112 (68.7%) achieved a subsequent reduction in RBCT units from baseline vs 26/97 (26.8%) pts in the placebo arm (Table). For RBC units transfused, luspatercept non-responders had a mean change from baseline of –1.85 RBC units/24 wks vs +0.21 RBC units/24 wks in placebo-treated pts during Wks 25–48. For RBCT visits, luspatercept non-responders experienced a mean change of –0.38 RBCT visits/24 wks vs +0.14 RBCT visits/24 wks in placebo-treated pts during Wks 25–48.
In any 12-wk period during Wks 1–48, a reduction of ≥33% RBCT units from baseline was achieved by 119/163 (73.0%) luspatercept non-responders vs 33/97 (34.0%) pts in the placebo arm. A reduction of ≥50% RBCT units from baseline was achieved by 62/163 (38.0%) luspatercept non-responders vs 6/97 (6.2%) pts in the placebo arm.
In Wks 25–48, 97/163 (59.5%) luspatercept non-responders achieved a reduction in serum ferritin (SF) from baseline vs 36/97 (37.1%) pts in the placebo arm. For non-responders, the mean change in SF from baseline was –203.34 mg/L (–8.07%). Of 103 non-responders with baseline mean SF ≥1,000 µg/L, 20 (19.4%) achieved post-baseline mean SF <1,000 µg/L in Wks 25–48.

Table. RBCT burden in Wks 25–48 in pts treated with luspatercept who did not achieve the primary endpoint and pts who received placebo

Wks 25–48	Luspatercept non-responders[a]	Placebo-treated pts
Reduction in RBCT units from baseline, n (%)	n = 163	n = 97
	112 (68.7)	26 (26.8)
Mean change from baseline in RBC units transfused, RBC units/24 wks	n = 155	n = 96
	–1.85	+0.21
LS mean difference[b] (95% CI)	–2.07 (–2.71, –1.42); $P < 0.0001$	
Mean change from baseline in RBCT visits, RBCT visits/24 wks	n = 155	n = 96
	–0.38	+0.14
LS mean difference[b] (95% CI)	–0.43 (–0.76, –0.11); $P < 0.01$	

[a]Non-responders were defined as pts who did not fully achieve the primary endpoint of ≥33% reduction in RBCT in Wks 13–24 from baseline [≥2 RBC units]); [b]Calculated as placebo minus luspatercept. Estimates are based on an ANCOVA model with geographical regions defined at randomization and baseline transfusion burden as covariates.
ANCOVA, analysis of covariance; CI, confidence interval; LS, least squares; pt, patient; RBC, red blood cell; RBCT, RBC transfusion; wk, week.

Summary/Conclusion: Most pts with β-thalassemia who did not meet the primary endpoint during the BELIEVE trial and were defined as non-responders to luspatercept had clinical benefit from continuing therapy. Pts received fewer RBC units, had fewer hospital visits due to RBCT administration, and had lower SF levels.

EP1307 COVID-19 PREVALENCE AND MORTALITY IN A LARGE ITALIAN HEMOGLOBINOPATHIES COHORT

Background: Data on SARS-CoV-2 infection in Hemoglobinopathies are still scarce and controversial. Since March 2020, we, as Italian Society for Thalassemia and Hemoglobinopathies (SITE), recommended close monitoring and set up an Italian survey to verify the impact of SARS-CoV-2 infection on patients with Hemoglobinopathies (EMO AER COVID-19 NCT04746066) among Italian Centers.
Aims: To explore the hypothesis of an increased vulnerability of Hemoglobinopathies to SARS-COV2 infection.
Methods: After SITE proposal and Ethics Committee approval, each participating Center entered data on a specific electronic Case Report Form (eCRF) (https://covid19.site-italia.org). Inclusion criteria included positive swab or serology and at least 15 days of follow-up from either the onset of symptoms or SARS-CoV2 positivity. This cut-off is updated to February 15, 2021.

Results: Twenty-seven Centers that provide care to 6121 patients with Hemoglobinopathy (65% of the Italian population) recorded a total of 275 SARS-CoV2 infections (overall, prevalence 4.5%), in 191 transfusion-dependent thalassemia cases (TDT, prevalence 5.8%), 36 non-transfusion-dependent thalassemia (NTDT, prevalence 2.3%) and 48 sickle cell disease patients (SCD, prevalence 3.7%). Median age was 41 years (IQR: 30-48, range: 9 months-85 year). Twenty-eight patients (10 %) were pediatrics (median age: 6.5 years, IQR: 4-11). Most patients (72%) had comorbidities; 134 (49%) had splenectomy or functional asplenia. We observed a broad spectrum of disease severity, ranging from no symptoms in 65 patients (24%) to multisystem organ failure and death in 5 patients: 2 TDT (age: 49 and 56 years), 1 NTDT (age: 45 years), 2 SCD (age: 57 years both). Overall, 56 (20%) patients required hospitalization, 12 in high-intensity care unit; 10 required support by oxygen, 11 needed more intensive ventilation support with continuous positive airway pressure (CPAP), and 7 required intubation. Nine patients required ad hoc transfusion or more than scheduled. Two SCD patients of 9 and 20 months of age, respectively, recovered after a long and life-treating disease. One TDT patient experienced reinfection after 3 months from the first; one 30w-pregnant SCD woman developed COVID-19 without consequences for herself and the fetus. Overall clinical severity has been higher in SCD than in thalassemia patients.
Summary/Conclusion: The prevalence of COVID-19 in Hemoglobinopathies apparently overlaps the general population (4.5% vs 4.6%), however, these patients are more strictly observed and we could postulate that the precautions suggested or self-applied by the patients were effective. The overall mortality is 1.8% vs 3.4% and the difference may be due to the younger age of patients with Hemoglobinopathies. Our data confirm the higher risk of severe disease and death in SCD.

EP1308 HIGHLY EFFICIENT THERAPEUTIC GENOME EDITING OF HEMATOPOIETIC STEM AND PROGENITOR CELLS TO CURE SICKLE CELL DISEASE AND THALASSEMIA

H. Verhagen [1,*], C. Kuijk [1], S. Heshusius [1], S. van der Meulen [1], L. Rutgers [1], A. Kokke [1], B. Biemond [2], C. Voermans [1], E. van den Akker [1]

[1]Hematopoiesis, Sanquin, [2]Hematology, AMC, Amsterdam, Netherlands

Background: Sickle cell disease and β-thalassemia are globally the most common monogenic diseases. The common feature is mutations within the beta-globin gene leading to aberrant expression or protein function. Allogeneic stem cell transplantation is currently the only potential curative option, however, donor matching as well as post transplantation complications significantly hamper the success rate of this therapy. With the most recent developments in the CRISPR/Cas9 field we aim to develop a genome editing strategy on HSPCs that allow for autologous stem cell transplantations for both hemoglobinopathies. Our objective is to re-express gamma-globin(g) at the expense of the mutated beta-globin. Gamma-globin is normally only expressed during fetal development and the first 1-3 years after birth. It is widely accepted that 25% fetal hemoglobin (g2a2) expression in erythrocytes is sufficient for patients to remain symptom free as indicated by asymptomatic individuals with beta globin mutations but with concomitant high levels of fetal hemoglobin. Gamma-globin expression is controlled by the master regulator BCL11A. However, downregulation of this gene should be performed with great precision since it also exerts a critical role in B-cell development and hematopoietic stem cells homeostasis.
Aims: Developing a gene therapy to cure sickle cell disease and thalassemia
Methods: We and others have identified intronic erythroid specific enhancer elements in *BCL11A* using ATAC sequencing to which multiple guides where developed disrupting specific element regions. We have setup a viral free highly optimized CRISPR/Cas9 ribonucleoprotein (RNP) nucleofection that allows for knockout efficiencies up to 80% in human HSPCs. Furthermore, we have developed a novel transfection buffer that results in reduced toxicity for HSPCs.
Results: We demonstrate a fast and efficient method for gRNA selection and to genome edit HSPCs. We report knockout efficiencies up to 80% in human CD34+ HSPCs. Editing efficiency was similar between the different CD34+ progenitor and stem cell subpopulation including the immature CD34+CD38- subpopulation, which is enriched for hematopoietic stem cells. Ribonucleoprotein (RNP)-induced genome editing in human CD34+ HSPCs does not affect cell proliferation, differentiation or in vitro hematopoietic lineage commitment nor upregulated P21 expression. Deletion of various regions within the BCL11A erythroid specific enhancer element led to variable induction of fetal hemoglobin expression, up to 60%, that could be correlated to the specific transcription factors bound to the respective edited regions.
Summary/Conclusion: Making modifications in the BCL11A enhancer results in fetal hemoglobin levels that exceed the minimum clinical limit to cure SCD and thalassemia. In general, we show that mutations created in HSPCs are stable and we do not observe major toxic effects. Targeting specific sites that are occupied by erythroid restrictive transcriptional regulators may prevent collateral BCL11A knockout in other lineages. These data pave the road towards transplanting genome edited HSPCs to allow for autologous stem cell transplantations and thereby bypass current limitations.

EP1309 A RETROSPECTIVE DATABASE STUDY OF DISEASE COURSE AND CLINICAL OUTCOMES IN PATIENTS WITH TRANSFUSION-DEPENDENT THALASSEMIA (TDT) IN ITALY

A. Vitrano [1], A. Meloni [2], V. Di Marco [3], A. Filosa [4], P. Ricchi [4], A. Ceci [5], A. Pepe [2], S. Scondotto [6], G. Dardanoni [6], F. Bonifazi [5], A. Maggio [1,*]

Monasterio CNR-Regione Toscana, Pisa, [3]Sezione di Gastroenterologia e Epatologia, Dipartimento Biomedico di Medicina Interna e Specialistica, University of Palermo, Palermo, [4]"Cardarelli" Hospital, Rare Blood Cell Disease Unit, Naples, [5]Fondazione per la Ricerca Farmacologica Gianni Benzi Onlus, Valenzano (BA), [6]D.A.S.O.E, Regione Siciliana, Palermo, Italy

Background: β-thalassemia confers a substantial burden on both patients and the healthcare system.
Aims: We systematically quantified the outcomes and disease burden in 2,520 patients with transfusion-dependent thalassemia (TDT) or thalassemia major (TM) receiving regular treatment with red blood cell (RBC) transfusions and iron chelation therapy (ICT).
Methods: The data for this study came from the International Health Repository (IHR) protocol (EudraCT and Sponsor Protocol Code Numbers: 2017-004457-17 and 143AOR2017). This cross-sectional study focused on 3,106 patients with thalassemia presenting at 5 centers in Italy between July 2000 and July 2018, and employed retrospective, cross-sectional analyses of individual patient data at a given date during this timeframe. Here, we present a subgroup analysis of the 2,520 patients in the cohort with TDT.
Results: Of the 2,520 TDT patients included in the analysis 1,107 had a known genotype; in particular, 401 (36.2%) had a β^0/β^0 genotype, 237 (21.4%) had a IVS-1-110/β^0 genotype, 93 (8.4%) had a IVS-1-110/β^+ genotype, 133 (12.0%) had a IVS-1-110/IVS-1-110 genotype, 201 (18.2%) were β^0/β^+, and 42 (3.8%) were β^+/β^+. The percentage of patients with IVS-1-110 genotype was 41.8%, corresponding to 12.0% homozygous and 29.8% heterozygous patients. The mean age of patients was 36.8 (±10.7) years (range, 2.6-74.0), and 52.6% were females. The mean (range) age at diagnosis, initiation of RBC transfusions, and initiation of ICT was 1.1 (±1.2) years (0.08-13), 2.1 (±2.9) (0.08-43), and 5.1 (±5.1) (0.6-65), respectively.
The median (range) transfusion requirement for TDT patients was 175.0 mg/dL/year (100.7-417), the median of the mean hemoglobin (Hb) level was 9.5 g/L (6-20), and the median serum ferritin was 1003 ng/ml (37.6-12484). More patients (31.7%) underwent chelation with desferrioxamine (DFO), whereas deferiprone (DFP) and deferasirox (DFX) were used in 18.5% and 23.1% of patients, respectively. Furthermore, 19.3% of patients underwent sequential or combined DFO-DFP, 0.6% sequential or combined DFO-DFX, and 0.4% sequential or combined DFP-DFX. Chelation data were not available for 164 patients (6.5%).
Median (range) alanine transaminase (ALT) and aspartate transaminase (AST) levels in TDT patients were 29 IU/L (6-381) and 29 IU/L (7-320), respectively. The median (range) of the cardiac ejection fraction, liver T2*, and cardiac T2* was 64% (24-97), 7.5 ms (0.2-49.6), and 38 ms (0-64), respectively.
Eighty-two percent of TDT patients experienced one or more thalassemia-related complication, with 533 (21.1%) experiencing one complication, 486 (19.3%) experiencing two complications, 424 (16.8%) experiencing three complications, and nearly a quarter (625 patients (24.4%)) experiencing four or more complications. Eighteen percent of patients experienced no complications. The most frequently observed complications were liver complications, followed by splenectomy, osteoporosis, hypogonadism, cardiac complications, hypothyroidism,

diabetes, hypoparathyroidism, lung complications, infections, and cancer (Table 1).

Table 1: Number of complications in TM patients by diagnosis

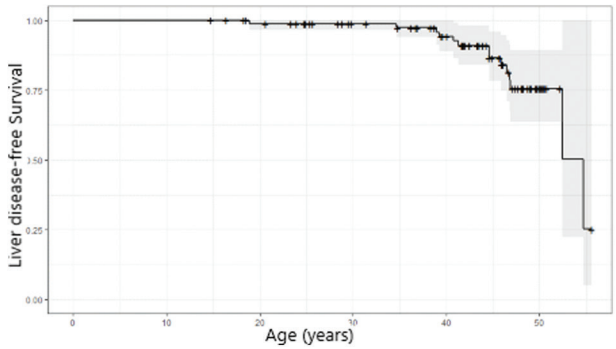
Complications	Number of patients
Liver complications	1397
Splenectomy	1264
Osteoporosis	829
Hypogonadism	780
Cardiac complications	464
Hypothyroidism	429
Diabetes	221
Hypoparathyroidism	120
Lung complications	100
Infections	76
Cancer	35

Summary/Conclusion: In this study, more than 80% of TDT patients experienced one or more disease-related complication, with nearly a quarter of patients experiencing four or more complications. This high rate of complications occurred despite well-managed serum transferrin levels in this patient group. This demonstrates that patients with TDT experience a significant burden of disease, even with appropriate iron chelation.

EP1310 AUDITORY CORTEX HYPOPERFUSION: A METABOLIC HALLMARK IN BETA THALASSEMIA

I. Tartaglione [1,*], S. Ponticorvo [2], M. R. Barillari [3], G. Costa [3], D. Brotto [4], R. Di Concilio [5], A. Ciancio [6], E. De Michele [7], D. troisi [7], F. Ammendola [8], R. Carfora [9], M. S. Valentino [9], E. Inserra [8], S. perrotta [8], R. Manara [10]

[1]Dipartimento della Donna, del Bambino e della Chirurgia generale e specialistica, Università della Campania "Luigi Vanvitelli", napoli, [2]Università di Salerno, Salerno, [3]Università della Campania "Luigi Vanvitelli", [4]Università di Padova, napoli, [5]ospedale Umberto I, Nocera Inferiore, [6]Ospedale santa maria delle grazie, matera, [7]ospedale san giovanni di dio e ruggi d'Aragona, salerno, [8]Università degli Studi della Campania, [9]Università degli studi della campania "luigi Vanvitelli", Napoli, [10]Università di Padova, Padova, Italy



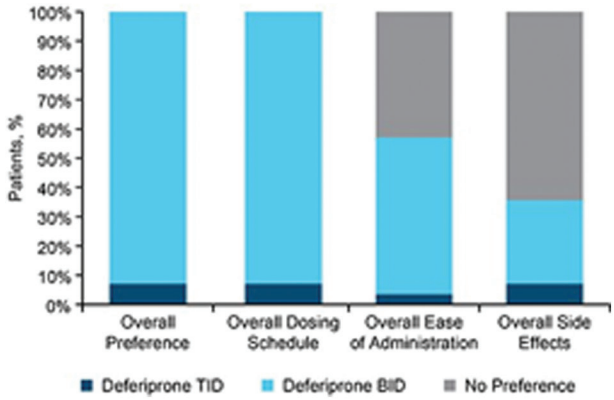
Background: Sensorineural hearing loss in beta-thalassemia is common and it is generally associated with iron chelation therapy. However, data are scarce, especially on adult populations, and a possible involvement of the central auditory areas has not been investigated yet.
Aims: We aimed at investigating the metabolism of the cerebral auditory areas in thalassemia, trying also exploratively to assess if this may correlate with the cognitive impairment previously shown in this disease.
Methods: We performed a multicenter cross-sectional audiological and single-center 3Tesla brain perfusion MRI study enrolling 77 transfusion-dependent/non transfusion-dependent adult patients and 56 healthy controls. Pure tone audiometry, demographics, clinical/laboratory and cognitive functioning data were recorded.
Results: Half of patients (52%) presented with high-frequency hearing deficit, with overt hypoacusia (Pure Tone Average (PTA)>25dB) in 35%, irrespective of iron chelation or clinical phenotype. Bilateral voxel clusters of significant relative hypoperfusion were found in the auditory cortex of beta-thalassemia patients, regardless of clinical phenotype. In controls and transfusion-dependent (but not in non-transfusion-dependent) patients, the relative auditory cortex perfusion values increased linearly with age ($p<0.04$). Relative auditory cortex perfusion values showed a significant U-shaped correlation with PTA values among hearing loss patients, and a linear correlation with the full scale intelligence quotient (right side p=0.01, left side p=0.02) with its domain related to communication skills (right side p=0.04, left side p=0.07) in controls but not in beta-thalassemia patients. Audiometric test results did not correlate to cognitive test scores in any subgroup.
Summary/Conclusion: In conclusion, primary auditory cortex perfusion changes are a metabolic hallmark of adult beta-thalassemia, thus suggesting complex remodeling of the hearing function, that occurs regardless of chelation therapy and before clinically manifest hearing loss. The cognitive impact of perfusion changes is intriguing but requires further investigations.

EP1311 THE VALUE OF EARLY HISTOLOGICAL FINDINGS IN PREDICTING SEVERE HEPATIC EVENTS IN B-THALASSEMIA

K. Koumasi [1,*], E. Nitsa [1], P. Delaporta [1], M. Moraki [1], N. Ioakeimidou [1], D. Kyriakopoulou [1], V. Ladis [1], C. Kattamis [1], A. Kattamis [1]

[1]Thalassemia Unit, First Department of Pediatrics, Aghia Sophia Childrens' Hospital, National and Kapodistrian University of Athens, Athens, Greece

Background: Current therapeutic modalities has rendered thalassemia a chronic disease. With patients' advanced age, previously unknown complications are observed with increasing frequency. Among them, liver disease and hepatocellular carcinoma(HCC) are on the rise. Viral hepatitis, mainly hepatitis C, and chronic iron overload are the main causes of liver disease, presenting as significant fibrosis, cirrhosis and/or HCC. Direct histological examination of hepatic tissue obtained by biopsy, remains highly sensitive and specific for the diagnosis of liver disease, but its predictive value is not established.
Aims: To evaluate the predictive value of histological findings of liver biopsy in the long-term liver-related morbidity and mortality in patients with β-thalassemia.
Methods: A retrospective analysis was performed in a group of Transfusion-Dependent (TDT) or Non-Transfusion-Dependent (NTDT) β-Thalassemia patients, who had undergone liver biopsy from 1992 to 2005, and were followed till 31/12/2020 in a single institution. Severe hepatic events were defined as either liver cirrhosis, HCC or death due to liver disease.Kaplan-Meier estimator was used to estimate disease-free survival (DFS). Cox proportional hazards model or Peto&Peto modification of the Gehan-Wilcoxon test were used to investigate risk factors. Time-To-Event (TTE) was performed from the date of: (1) birth or (2) biopsy, to the date of the liver event or of last follow up for censored records. The association of siderosis burden with ferritin was assessed through the Mann-Whitney U test. Statistical analysis was conducted using RStudio v. 3.6.3.
Results: In total, 87 patients (54 males, 79 TDT) had undergone liver biopsy at the age of 21.8±6.1 years and were monitored for 19.4 (IQR; 14.3-27.9) years. Forty-eight patients (55.2%) had viral hepatitis C. Histology evaluation showed low siderosis (grade:0-2 in a scale of 0-4) in 34 (39.1%) and high siderosis (grade: 3-4) in 50 (57.5%) patients, while it was not reported in 3 (3.4%). Mild fibrosis (grade: 0-2 in a scale of 0-6, as per Ishak classification) was observed in 22 (25.3%) patients, advanced fibrosis (grade 3-6) in 62 (71.3%), while in 3 patients was not recorded. We identified 14 (16.1%) events (all in TDT patients);7 developed HCC, 4 liver cirrhosis and 3 died from other liver-related causes. At 50 years of age DFS was 75% (figure 1), while 25% of patients developed liver disease in 24.4 years after the date of biopsy.High siderosis carries a greater risk for developing liver disease compared to group with low siderosis, Hazard Ratio (HR) 3.00 (95% CI:1.01-8.95, p=0.05), adjusted for age (aHR) 2.9 (95% CI: 0.90 – 9.01, p=0.07). An increase of 50 μg/L in ferritin level at time of biopsy is associated with an increased risk of developing liver disease (aHR 1.02, 95% CI:1.00-1.03, p=0.03). A statistically significant correlation was observed between high serum ferritin levels and high siderosis at the date of biopsy (1712(IQR;1000-2985) vs 3715(IQR;1721-5197.5),p=0.0003). No statistically significant correlation in the development of liver disease was observed between gender, HCV and degree of fibrosis at time of biopsy, p=0.2, p=0.3 and p=0.2, respectively.



Summary/Conclusion: The occurrence of liver-disease is increasing after the 4th decade of life. Serum ferritin and liver siderosis at the time of biopsy was found to be statistically significant risk factors for the progression of the disease. Degree of liver fibrosis does not seem to be related to progression, which may be due to stabilization and/or reversal of fibrosis achieved with current chelation therapy.

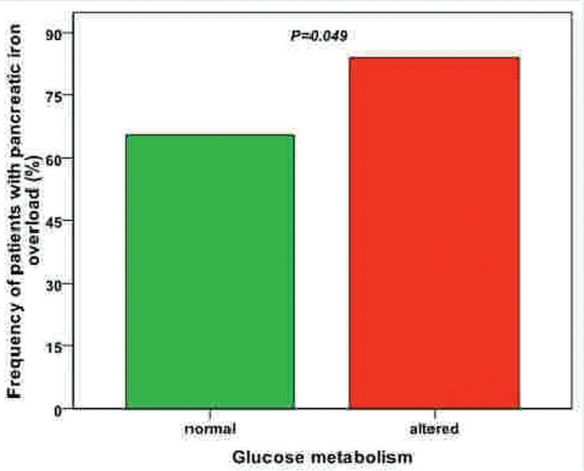
EP1312 A MULTICENTER OPEN-LABEL STUDY ON THE SAFETY AND ACCEPTABILITY OF TWICE-DAILY DEFERIPRONE TABLETS AMONG PATIENTS WITH TRANSFUSION-DEPENDENT THALASSEMIA AND SYSTEMIC IRON OVERLOAD

A. Kattamis [1,*], S. Badawy [2], H. Ezzat [3], F. Zhao [4], F. Tricta [5], S. Sheth [6], C. Fradette [7], A. G. Piga [8]

[1]Division of Pediatric Hematology-Oncology, National and Kapodistrian Univeristy of Athens, Athens, Greece, [2]Pediatrics, Ann & Robert H. Lurie Children's Hospital of Chicago, Chicago, United States, [3]Division of Hematology, St. Paul's Hospital, Vancouver, Vancouver BC, [4]Medical Affairs, [5]Hematology & Immunology Programs, Chiesi Canada Corporation, Toronto, Canada, [6]Pediatrics, New York Presbyterian Hospital/Weill Cornell Medical Center, New York, United States, [7]Hematology/Immunology, Chiesi Canada Corporation, Toronto, Canada, [8]Dipartimento di Scienze Cliniche e Biologiche, University of Turin, San Luigi Gonzaga University Hospital, Orbassano, Italy

Background: Adherence with life-long iron chelation therapy is critical for the survival of transfusion-dependent patients. Deferiprone is an orally absorbed bidentate hydroxypyridinone iron chelator with high efficacy in binding excess intracellular iron to reduce iron toxicity and is approved for the treatment of iron overload. The current formulation of deferiprone is immediate release (IR) and requires three-times-daily (TID) administration, which may result in decreased adherence in some patients.
Aims: A twice-daily (BID) deferiprone formulation was developed as a more convenient dosing regimen to improve patient adherence. In the current study, we evaluated the safety, tolerability, and acceptability of deferiprone BID tablets in a cohort of patients with transfusion-dependent thalassemia (TDT).
Methods: TWICE (NCT03802916) was a multicenter, open-label, switch-over study of 30 adult patients with TDT who were taking deferiprone IR TID, and the first study where patients with iron overload were administered deferiprone BID. The currently approved dosage of deferiprone IR TID is 75-99 mg/kg/d. To assess the impact of the BID formulation within the approved dosage range on adverse events (AEs), an equal number of patients were enrolled into either a "low-end standard dose" (LSD; ~75 mg/kg/d) or "high-end standard dose" (HSD; ~100 mg/kg/d) group based on their deferiprone IR TID dosage. At the end-of-study visit (day 28 of treatment), patients completed a preference questionnaire on the acceptability of the BID versus the IR TID formulation.
Results: The study enrolled 30 patients with TDT; 1 patient in the HSD group withdrew before receiving deferiprone BID. The study population consisted of 29 participants (44.8% female) with a mean age of 41.1 (SD: 8.4) years. Nineteen patients (10 in the LSD and 9 in the HSD group), experienced a total of 49 AEs; 41% were classified as mild, 57% moderate, and 2% severe. The most common AEs, irrespective of a causal relationship with therapy, were headache (21%), arthralgia (14%), and diarrhea (10%). 13 AEs (27%) were considered "at least possibly related" to therapy; those which were reported in 2 or more patients included diarrhea (n=3, HSD) and arthralgia (n=1, LSD; n=1, HSD). One patient in the LSD group experienced a severe AE of arthralgia (elbow pain) that resolved without interruption of therapy. All episodes of diarrhea were transient and resolved without interruption of therapy. One patient in the HSD group withdrew after experiencing a mild AE of renal colic, which was considered "possibly related" to therapy. Serious AEs previously ascribed to deferiprone IR TID (ie, agranulocytosis, neutropenia, or clinically concerning increases in liver enzymes) were not observed with deferiprone BID. The mean adherence to the deferiprone BID dosing regimen was 99.3% in the LSD and 98.5% in the HSD group. At the end-of-study visit, most patients (92.9%) indicated their strong preference for the deferiprone BID formulation over the IR TID formulation (Figure).

Summary/Conclusion: The new formulation of deferiprone BID tablets was safe and well-tolerated among patients with TDT. Most AEs were mild or moderate, and none of the serious AEs previously observed with deferiprone IR TID were reported. Patients reported high adherence to the deferiprone BID formulation and most (92.9%) preferred the deferiprone BID formulation over the IR TID, suggesting the BID formulation has the potential to improve patient adherence.



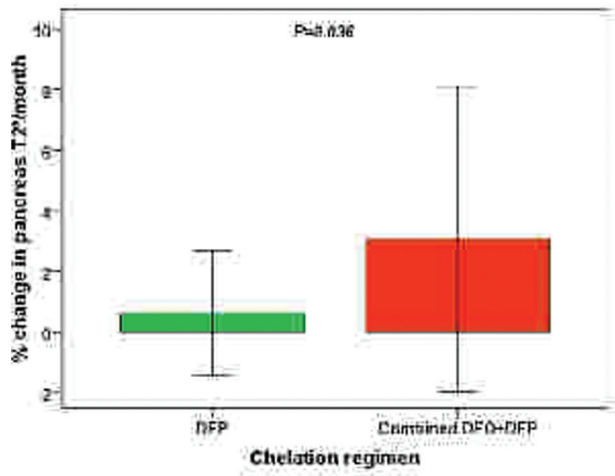
EP1313 PANCREATIC IRON CORRELATES WITH ALTERATIONS OF GLUCOSE METABOLISM AND CARDIAC IRON IN REGULARLY TRANSFUSED THALASSEMIA INTERMEDIA PATIENTS

A. Meloni [1,*], L. Pistoia [1], M. R. Gamberini [2], S. Armari [3], F. M. Pasin [4], P. Giovangrossi [5], M. Serra [6], G. Restaino [7], A. Vallone [8], A. Riva [9], V. Positano [1], A. Pepe [1]

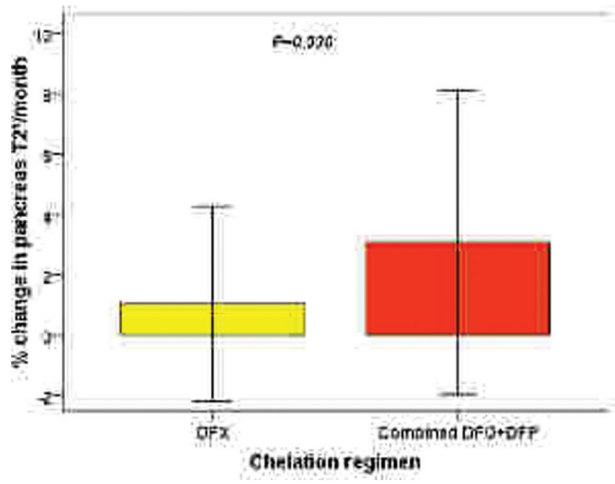
[1]Fondazione G. Monasterio CNR-Regione Toscana, Pisa, [2]Azienda Ospedaliero-Universitaria "S. Anna", Ferrara, [3]Azienda Ospedaliera di Legnago, Legnago (VR), [4]Ospedale S. Pertini, Roma, [5]Ospedale S. M. Goretti, Latina, [6]Ospedale "V. Fazzi", Lecce, [7]Fondazione di Ricerca e Cura "Giovanni Paolo II", Campobasso, [8]Azienda Ospedaliera "Garibaldi" Presidio Ospedaliero Nesima, Catania, [9]Ospedale "SS. Annunziata", Taranto, Italy

Background: In thalassemia major pancreatic iron was shown to be correlated to splenectomy, hepatitis C virus (HCV) infection, altered glucose metabolism, hepatic and cardiac iron, biventricular function, and myocardial fibrosis.
Aims: In the present multicenter study we explored the clinical correlates of pancreatic T2* in a cohort of patients with thalassemia intermedia (TI) under regular transfusion therapy.
Methods: We considered 150 patients (85 F, mean age 42.3±13.7 years) consecutively enrolled in the E-MIOT (Extension-Myocardial Iron Overload in Thalassemia) project. Magnetic Resonance Imaging (MRI) was performed to quantify hepatic, cardiac, and pancreatic iron overload by the T2* technique, to evaluate biventricular function parameters by cine images and to detect replacement myocardial fibrosis by late gadolinium enhancement (LGE) technique. To assess the disturbances of glucose metabolism, patients non already diagnosed with diabetes performed an oral glucose tolerance test (OGTT).
Results: Global pancreas T2* values were not correlated to age or gender. One-hundred and three patients (68.7%) showed a pathologic pancreas T2* value (<26 ms).
Splenectomised patients (76%) showed significantly lower global pancreas T2* than patients with the spleen (18.4±11.2 ms vs 23.8±13.4; P=0.017). Patients with an active or eradicated HCV infection (34.9%) had significantly lower global pancreas T2* values than negative patients (17.1±10.6 ms vs 22.6±12.6; P=0.021).
Patients with an altered OGTT (23%) showed a significant higher frequency of pancreatic iron overload than patients with a normal OGTT (83.9% vs 65.4%; P=0.049) (Figure 1). In non-diabetic patients global pancreatic T2* values were inversely correlated with glucose levels fasting (R=-0.366; P<0.0001) and 1-hr after OGTT (R=-0.308; P=0.016) and positively associated with the HOMA of β-cell function index (R=0.391; P=0.001).
Pancreas T2* values showed a negative correlation with MRI liver iron concentration values (R=-0.255; P=0.002) and a positive correlation

with cardiac T2* values (R=0.184; P=0.024) and all the 6 patients with global heart T2*<20 ms had also pancreatic iron load.
Global pancreas T2* values were not correlated to biventricular volumes and ejection fraction and were comparable between patients without and with replacement myocardial fibrosis.



Summary/Conclusion: In regularly transfused TI patients higher pancreatic siderosis was found in splenectomised patients, in patients with an history of HCV infection, and in patients with altered glucose metabolism. Moreover, a normal pancreas T2* showed a negative predictive value of 100% for cardiac iron. These data support for starting or intensifying iron chelation therapy in TI patients with pancreatic iron overload. By this way it may be prospectively possible to prevent both alterations of glucose metabolism and cardiac iron accumulation rather than wait for the manifestation of overt diabetes and cardiac complications.



EP1314 PROSPECTIVE COMPARISON ON PANCREATIC IRON BY MAGNETIC RESONANCE IN THALASSEMIA MAJOR PATIENTS TREATED WITH COMBINATION DEFERIPRONE–DESFERRIOXAMINE VERSUS DEFERIPRONE AND DEFERASIROX IN MONOTHERAPY

A. Meloni [1,*], P. Ricchi [2], L. Pistoia [1], S. Gentili [3], D. Visceglie [4], E. Facchini [5], A. Cossu [6], G. Peritore [7], M. Missere [8], F. Pezzullo [2], V. Positano [1], A. Pepe [1]

[1]Fondazione G. Monasterio CNR-Regione Toscana, Pisa, [2]Azienda Ospedaliera di Rilievo Nazionale "A. Cardarelli", Napoli, [3]Ospedale "San Donato", Arezzo, [4]Ospedale "Di Venere", Bari, [5]Azienda Ospedaliero-Universitaria di Bologna - Policlinico "S. Orsola-Malpighi", Bologna, [6]Presidio Ospedaliero "San Francesco", Nuoro, [7]"ARNAS" Civico, Di Cristina Benfratelli, Palermo, [8]Fondazione di Ricerca e Cura "Giovanni Paolo II", Campobasso, Italy

Background: The combination therapy with deferiprone (DFP) and desferrioxamine (DFO) was associated with an overall improvement in glucose metabolism disorders in β-thalassaemia, but no data are available about its efficacy in removing pancreatic iron.
Aims: The aim of this multi-center study, conducted in a large clinical observational setting of thalassemia major (TM) patients, was to prospectively evaluate the effects of combined DFO+DFP therapy versus both oral iron-chelators in monotherapy on pancreatic iron over a follow-up of 18 months.
Methods: Among the first 1176 TM patients consecutively enrolled in the E-MIOT (Extension-Myocardial Iron Overload in Thalassemia) network, 416 patients had a FU at 18±3 months. We selected those who had been received combined regimen (N=28) or DFP (N=61) and deferasirox-DFX (N=159) monotherapies between the two MRI scans. Pancreatic iron overload was quantified by multi-slice multiecho T2* technique; measurements were performed over pancreatic head, body and tail and global value was the mean.
Results: The comparison was restricted to patients with a normal baseline global pancreatic cut off value (T2*<26 ms): 28 in the combined DFO+DFP group, 54 in the DFP group and 129 in the DFX group.
The dosages were: 1) DFP in combined regimen 84.8±14.9 mg/kg body weight per day with a frequency of 6.9±0.6 days/week and DFO in combined regimen 37.9±7.8 mg/kg body weight per day with a frequency of 3.9±1.7 days/week; 2) DFP in monotherapy 84.5±14.3 mg/kg body per day; 3) DFX in monotherapy 24.9±7.1 mg/kg body per day if in dispersible tablets (N=98) and 18.3±4.4 mg/kg body per day if in film-coated tablets (N=31). The percentage of patients with excellent/good levels of compliance to the active chelation treatment was significantly lower in the combined DFP+DFO group versus both the DFP group (82.1% vs 98.1%; P=0.016) and the DFX group (82.1% vs 99.2%; P=0.001).
Global pancreatic T2* values were significantly lower in the combined DFO+DFP group compared to both DFP and DFX groups. A significant negative association was detected between changes in global pancreas T2* values and baseline global pancreas T2* values (R=-0.192; P=0.005). So, the % changes in global pancreas T2* values, normalized for the baseline values, were considered.
In no treatment group there was a correlation between the % changes in global pancreas T2* values and the iron chelator dosage.
The % changes in global pancreas T2* values were significantly higher in the combined DFO+DFP group versus both DFP (P=0.036) and DFX groups (P=0.030) (Figure 1).

Summary/Conclusion: Prospectively in TM patients at the dosages used in the real world, combined DFP+DFO was significantly more effective in reducing pancreatic iron versus both DFP and DFX in monotherapy.

EP1315 QUANTIFYING THE HEALTHCARE RESOURCE USE AND CLINICAL OUTCOMES OF PATIENTS WITH BETA THALASSAEMIA IN ENGLAND

J. Farrell [1,*], A. Farrer [2], L. Maher [3], A. Yucel [4], M. Chevli [3]

[1]HEOR, Bristol Myers Squibb, Uxbridge, [2]HealthIQ, London, [3]Bristol Myers Squibb, Uxbridge, United Kingdom, [4]Bristol Myers Squibb, New Jersey, United States

Background: Beta-thalassaemias are a group of hereditary haemoglobin disorders characterized by anomalies in the synthesis of the beta chains

of adult haemoglobin resulting in ineffective erythropoiesis (IE) and anaemia. Beta-thalassaemia (BT) is classified clinically as transfusion-dependent (TD) or non-transfusion-dependent (NTD) based on patients red blood cell transfusion (RBCT) needs. IE, anaemia and RBCT treatment can lead to iron overload and various morbidities such as endocrine, liver and cardiac complications.
The Hospital Episodes Statistics (HES) database in England contains universal coverage of secondary care data from NHS hospitals, covering three main patient groups: 1) inpatient patient care; 2) Outpatient appointments and attendances (OP); and 3) Emergency Room (ER) visits with approximately 17 million episodes recorded each year.
Aims: To describe patients diagnosed with BT in England in terms of demographics and clinical characteristics and to quantify the associated healthcare resource use (HCRU) and tariffs for this patient cohort including inpatient, day case, outpatient, and A&E care.
Methods: All data within an observation period between 01 January 2015- 31 December 2019, to include baseline characteristics for patients with ICD10 diagnosis code of D561 or D565 (BT) were extracted from HES and presented as crude counts. Descriptive statistics including frequency and percentage were calculated as categorical variables; whereas, mean, median and interquartile range (IQR) were calculated for continuous variables. Length of follow-up was calculated as the total number of days between diagnosis date (index date) and end of study period. Tariffs were derived based on case mix; a method of classifying patient care based on expected clinical resource use for the provision of that care.
Results: Overall 1,986 patients (mean age at inclusion 28 years [youngest; <1, oldest; 95]; 49.65% female) were identified. During a mean observation period of 35 months (IQR 54), 585 (29.46%) patients experienced a disorder of iron metabolism, 222 (11.18%) suffered from sepsis and 157 (7.91%) from heart failure.
2 (0.10%) patients had no inpatient admissions. For those who had ≥1 inpatient admissions, the mean number of inpatient blood transfusion visits per-patient-per-year was 11.31 (IQR 11.22), the mean number of outpatient blood transfusion visits per-patient-per-year was 17 (IQR 0.84). 1,032 patients (55.81%) had ≥12 blood transfusion visits per year.
Overall HCRU is split by inpatient and outpatient care and ER attendance. In the inpatient setting there were a mean of 14.9 admissions per-patient-per-year, of which 97.57% were elective (resulting in a mean of 4.34 bed days per-patient-per-year). In the outpatient setting there were a mean of 8.9 appointments per-patient-per-year. There were a mean of 5.81 ER visits per-patient-per-year.
Overall tariff costs on the health service per-patient-per-year were £23,120 (inpatient tariff £10,563, outpatient tariff £1,506, transfusion £10,200, ER visits £851).
Summary/Conclusion: The results of this database analysis with a large number of patients offer insights into the real-world management of patients with BT in England and the high HCRU associated with its management. A burden on patients and the healthcare system has been identified due to the frequent hospitalisations and secondary care visits. This highlights the need for novel treatment options in the management of BT.

EP1316 THE DATA FROM NATIONAL REGISTER FOR SURVEILLANCE OF STANDARD OF CARE IN THALASSEMIA IN TURKEY

Background: The National Hemoglobinopathy Registry of the Turkish Society of Hematology (TSH) records the data of hemoglobinopathy patients (pts) in Turkey. In the modern era, there has been a marked improvement in the standard of care in thalassemia.
Aims: We analyzed the conventional treatment indicators of disease to assess the delivery of high-quality care all over Turkey.
Methods: The registry has Ethical approval. Participating physicians recorded patients' data into the database after receiving informed consent from the patients/legal representatives. We extracted the data onto an Excel spreadsheet for analysis in January 2021.
Results: The register included 3554 pts' data entered by 56 thalassemia centers. There were 1998 pts with beta-thalassemia major (B-TM) and 415 pts with beta-thalassemia intermedia (B-TI).
The mean hemoglobin (Hb) at starting regular transfusion remained the same over the decades in B-TM pts. The mean Hb was 8.8±0.8 (median 9.0) g/dl in B-TM and 8.7±1.4 (range 6-13.5) g/dl in B-TI pts previous year. Overall, 4.6% and 7.0% of patients with B-TM and B-TI, respectively, were alloimmunized. 39% of non-immunized and 84.5% of alloimmunized pts were receiving ABO-RhEeDCc-Kell compatible pRBCs. Alloimmunization was significantly higher in patients who started regular Tx after the age of one year (3.9 vs. 10.0%) (p<0.0001). Transfusion transmitted infections affected 3% of the B-TM and 1% of the B-TI. Overall, 51 of 63 (80%) were HCV, in which 40% of those were reported as having chronic HCV infection. HCV-associated hepatocellular carcinoma was the cause of death in one.
Overall, 87% of pts with B-TM were on iron chelation therapy (ICT). Physicians prescribed ICT to 22% of pts with B-TI. Overall, 90% of pts were receiving chelator as monotherapy, and 90% of monotherapies were composed of Deferasirox (DFX). The combination was the choice in 1 of the 10th pts, and DFX & Deferiprone was the most prevalent (58.5% of the combined regimens). The data showed a gradually increasing trend towards monotherapy and the DFX use by each 10-year birth cohort. The median serum ferritin (SF) at starting ICT improved gradually by each 10-year birth cohort since 1960 from 2600 ug/L to as low as 1479 ug/L in the last cohort. Overall, median SF in B-TM pts settled down to 1200 ug/L in the previous year. Only 30% of B-TM patients had access to myocardial (T2*) MRI. The mean age of the first MRI assessment was 19±9 years. The majority (70%) had an mT2*of >20 ms, while 16.3% showed an mT2*of 10-20 ms and 6.7% an mT2* of <10 ms. Although SF was significantly correlated with the severity of cardiac siderosis, the pts' age was not.
In each 10-year birth cohort, 78% of pts with B-TM born between 1960-1990, and 54% of those born between 1990-2000 had a splenectomy. Further, half of those patients in each cohort had undergone splenectomy <10 years-old. The rate of splenectomy was lower (14%) in patients of the 2000-2010 cohort. It seems likely that the rate will less than that of the previous decades. Splenectomized patients showed less

pRBC consumption than the non-splenectomized ones (median 125 vs. 173 ml/kg/y, p<0001). Although SF has not markedly differed in splenectomized and non-splenectomized patients, myocardial siderosis was higher in patients with splenectomy (25.7±11.0 vs. 29.2±8.5, p<0.001).

Table. Transfusion and chelation indicators of patients with beta-thalassemia major (B-TM) and intermedia (B-TI)

Patients	B-TM	B-TI
n	1998	415
Age ± SD (year)	19 ± 11	24 ± 15
F/M	952/1046	226/189
Age of diagnosis (*year*)	1.2±2.1 (0.6)*	5.7±7.6 (3.2)*
Age of 1st transfusion (year)	1.1±2.0 (0.7)*	6.4 ±9.4 (3.8)*
Hb at 1st transfusion (g/dl)	6.6 ±1.1 (6.4)*	*NA*
Age of chelation start (year)	4.2±4.9 (2.8)*	11.9±9.8 (8.4)
SF at chelation start (ug/L)	1946±1402 (1594)*	1624±1127 (1318)*
Hb at previous year (g/dl)	8.8±0.8 (9.0)*	8.7±1.4 (8.5)*
SF at previous year (ug/L)	1760±1852 (1200)*	1087±729 (974)*
Splenectomy (%)	38	38

**mean±SD (median), NA; not applicable*

Summary/Conclusion: The register's data demonstrated the current status of a standard of care in thalassemia that still needs to achieve higher standards in this relatively young cohort in Turkey.

EP1317 THE PATIENTS WITH THALASSEMIA MAJOR MAY STILL DISPLAY GROWTH HORMONE DEFICIENCY DESPITE OPTIMUM TRANSFUSION AND IRON CHELATION THERAPY

Y. Aydinok [1,*], V. Samedli [1], N. Karadas [1], H. Ozdemir [1], B. Yurekli [2]

[1]Ege University Hospital, Department of Pediatric Hematology, [2]Ege University Hospital, Department of Endocrinology, İzmir, Turkey

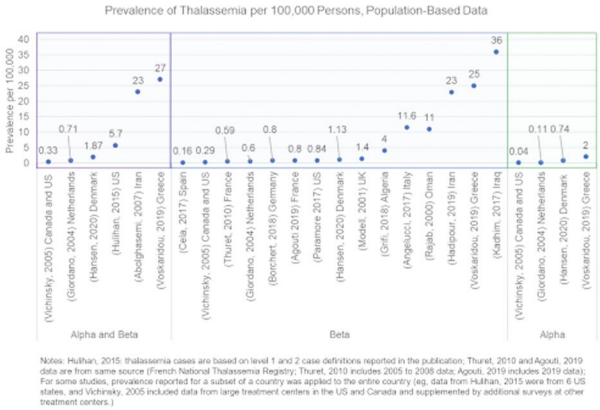
Background: Growth retardation (GR) and pubertal disorders are the earliest consequences of iron toxicity resulting from the pituitary iron deposition in children and adolescents with thalassemia major (TM). It is suggested that appropriate transfusion and iron chelation therapy (ICT) may achieve growth and development in TM.
Aims: The purpose of this study was to evaluate if the current transfusion and ICT protocols may support a normal growth progression and sexual development in patients (pts) with TM.
Methods: We recruited male (M) and female (F) TM pts born after 2000. The pts with an acute or chronic illness that may interfere with growth and development were excluded. The Ethical Committee of Clinical Investigation (19.02.2020, 20-2.1T/2) approved this study. Transfused packed red cell units (pRBC) and average pre-transfusion hemoglobin (Hb) per year were recorded. Serum ferritin (SF) was monitored monthly (m). Myocardial (T2*) and liver (R2) iron were assessed by magnetic resonance imaging (MRI) after 8-years (y) of age. Annual median SF, prescribed chelator(s), mean chelator doses were recorded. Transfusional iron intake (TII) was estimated and expressed as mg/kg b.w./days. Height (H) and weight (W) assessments were performed using the Harpenden stadiometer, and puberty was evaluated by Tanner staging at 3 m. H-standard deviation scores (h-SDS) were calculated. All pts were evaluated annually for bone mineral density (BMD) after 8 y. The mean SDS of the lumbar spine (L1-4) BMD between -1 and -2.5 was defined as osteopenia and <-2.5 as osteoporosis. Growth hormone (GH) secretion was assessed by L-dopa and insulin tests in those with standing-H below the –2 SD. Pts whose GH response to both stimulation tests were less than 5 ng/ml with the monoclonal assay was defined as GH deficient.
Results: We evaluated 30 TM (28 β/β, 1 β/δβ, and 1 non-deletional HbH) pts (13 F and 17 M) with the mean age of 12,5 ± 4,5 y. All pts have received pRBC for 11,1 ± 4,4 y and maintained pre-transfusion Hb> 9 g/dl. The patients started ICT by the SF of 1430 ± 795 ug/L and maintained ≤1500 ug/L at all times during 9 ± 4.2 y. Twenty-four pts received only Deferasirox (DFX) chelation while 6 were initiated ICT by Deferoxamine (DFO) and continued with DFX. Liver iron concentration (LIC) and myocardial T2* (mT2*) in 22 pts were between 0.9-5.4 (2.1 ± 1.3 SD) mg Fe/g d.w. and 19.4-43.5 (28 ± 6.7 SD) ms, respectively, in all assessments. The puberty initiated at 12.8 ± 1.1 y in M (n=12) & 11.2 ± 1.3 y in F (n=12) and progressed without hormone replacement in all. Overall, growth velocity reduced compared to the non-thalassemic population after 8 y with clear evidence of growth catch-up by the onset of puberty. Five pts (16.5%) developed h-SDS< -2 at 10-12 y-old when all but one had S1/2 puberty and displayed GH deficiency. All pts received GH therapy. The pt no 4 was entirely unresponsive to GH stimulation tests, developed GR at 1 y-old, and has remained unresponsive to GH therapy (Table). The 14 (%58) and 5 (21%) of 24 pts demonstrated osteopenia and osteoporosis, respectively. The BMD-SDS improved following pubertal spurt.

Table. The growth progression by GH treatment in thalassemia major patients with GR and GH deficiency

Pts no	Iron chelator		Max SF (ug/L)	Target h-SDS	Prior GH therapy			1st y of GH		Final G & D		
	I	FU			P	B-/C-age (y)	h-SDS	P	GV (cm)	P	C-age (y)	h-SDS
1	DFO	DFX	*4725	-1,41	S1	11,5/13	-2,46	S2	7,1	S5	18	-1,68
2	DFO	DFX	*2465	0,24	S1	10/13,2	-3,10	S2	8,9	S5	18	-0,19
3	DFX	DFX	1528	0,66	S2	11/12,7	-3,16	S3	9,2	S5	16	-1,64
4	DFX	DFX	1580	0,21	S1	6/10,7	-3,41	S1	3,2	S3	16	-4,30
5	DFX	DFX	1183	-0,54	S1	7,5/11,5	-2,31	S1	6,8	S1	13	-1,90

I: Initial, FU: Follow-up, B-age: Bone-age, C-age: Chronological-age, GV: Growth velocity, DFO; Deferoxamine, DFX; Deferasirox, G&D; Growth and Development
*The max. SF reached during 1st years on DFO then SF normalized around 1000 ug/L

Summary/Conclusion: The high prevalence of the diagnosis of GH deficiency in TM patients receiving an optimum transfusion and ICT throughout their life was disappointed. Either the growth pattern and bone-maturation in TM pts might differ from the non-thalassemic population, and the GH stimulation tests may lead to overdiagnosis of GH deficiency or the current chelation modalities may not prevent iron toxicity in pts with TM.



EP1318 GLOBAL THALASSEMIA EPIDEMIOLOGY: A SYSTEMATIC LITERATURE REVIEW

C. X. Chamberlain [1,*], E. Zagadailov [1], K. Kistler [2], J. A. Colby [2], K. Ruiz [2]

[1]Agios, Cambridge, [2]Xcenda, Palm Harbor, United States

Background: Alpha and beta-thalassemia are characterized by imbalanced globin chain production, resulting in ineffective erythropoiesis and hemolytic anemia. Patients with thalassemia intermedia or major may experience serious complications including iron overload, osteoporosis, thrombosis and increased mortality. While thalassemias are common in areas historically endemic to malaria, the global epidemiology is changing due to factors such as population screening, improved survival rates, and migration. Comprehensive understanding of the global prevalence particularly with region- and subtype-specific estimates is limited.
Aims: To determine the global prevalence of alpha- and beta-thalassemia (excluding minor/trait types), and to identify critical evidence gaps.
Methods: A systematic literature review (SLR) was conducted. Excerpta Medica database (Embase), PubMed (via MEDLINE), and the Cochrane Library (Database of Systematic Reviews) were searched to identify real-world observational studies published from Jan. 1, 2000 to Jun. 15, 2020 reporting on the incidence and/or prevalence of thalassemia. Dual independent screening was performed with disagreements resolved by a third researcher. Data extraction was performed by a single reviewer with full validation by a second reviewer. Prevalence per 100,000 people was estimated based on dates of data collection from respective included publications. Results were also extrapolated to estimate the number of patients with thalassemia in European countries and the United States (US).
Results: Of 1,900 records screened, 58 publications met the protocol-defined selection criteria for inclusion in the SLR.
Population-based prevalence data were reported in 17 studies (see Figure) from North America, Europe, the Middle East, and North Africa. In the US, the estimated population-based prevalence of alpha- and beta-thalassemia combined was 5.7/100,000. Among other countries with population-based studies, prevalence data were predominantly reported for beta-thalassemia only. In Europe, the estimated beta-thalassemia prevalence (9 studies) ranged from 0.16/100,000 in Spain to 25/100,000 in Greece; alpha-thalassemia prevalence (3 studies) was low, ranging from 0.11/100,000 in the Netherlands to 2/100,000 in Greece. In a single population-based analysis from North Africa, the prevalence of beta-thalassemia was 4/100,000 in Algeria, and across the Middle East (3 studies), the prevalence of beta-thalassemia ranged from 11/100,000 in Oman to 36/100,000 in Iraq.
Thalassemia prevalence data from Africa, Asia, and South America were mainly limited to specific sites or study samples that may not be generalizable to their respective countries. Further, the prevalence results ranged widely, indicating potential selection bias in these non-population-based studies.

Key evidence gaps in the published literature included incomplete reporting of thalassemia subtypes, lack of diagnosis confirmation, and a paucity of recent, population-based analyses, including from countries with thalassemia registries.

Notes: Hulihan, 2015: thalassemia cases are based on level 1 and 2 case definitions reported in the publication; Thuret, 2010 and Agouti, 2019 data are from same source (French National Thalassemia Registry; Thuret, 2010 includes 2005 to 2008 data; Agouti, 2019 includes 2019 data); For some studies, prevalence reported for a subset of a country was applied to the entire country (eg, data from Hulihan, 2015 were from 6 US states, and Vichinsky, 2005 included data from large treatment centers in the US and Canada and supplemented by additional surveys at other treatment centers.)

Summary/Conclusion: Based on available published data, the estimated prevalence of thalassemia (excluding minor/trait types) varied globally, with highest prevalence in Greece and the Middle East, and lowest prevalence in the Netherlands, Spain, France and Germany. There is limited prevalence data in non-Western countries, and in alpha-thalassemia in general. Additional studies, including global and country-specific thalassemia registries, are needed to better understand the current prevalence of this condition.

Thrombosis and vascular biology - Biology & Translational Research

EP1319 DIRECT ORAL ANTICOAGULANTS FOR THE SECONDARY PROPHYLAXIS OF VENOUS THROMBOEMBOLISM: COMPARISON BETWEEN PATIENTS WITH MAJOR CONGENITAL THROMBOPHILIA AND NON-THROMBOFILIC PATIENTS

A. Serrao [1,*], G. M. Assanto [1], C. Santoro [1], A. Pallotta [1], F. Barone [1], A. Chistolini [1]

[1]Sapienza, Roma, Rome, Italy

Background: Direct oral anticoagulants (DOACs) are widely used for the treatment and secondary prophylaxis of venous thromboembolism (VTE). Congenital thrombophilia is a condition that predisposes to a higher incidence of VTE, more frequent VTE recurrences, some also in atypical sites, and often require long-term anticoagulation for secondary prevention. It is less clear whether DOACs have the same effectiveness in patients with major thrombophilia than in non-thrombophilic patients for the prevention of VTE recurrences.
Aims: The aim of our study was to evaluate the efficacy, in terms of VTE prevention, and safety, in terms of absence of bleeding complications, in patients with major thrombophilia compared to non- thrombophilic patients candidate to long-term anticoagulation for recurrent VTE.
Methods: We evaluated consecutive patients who required long-term anticoagulation for recurrent VTE, treated with DOACs, and compared the outcomes between patients affected by major thrombophilia and non-thrombophilic patients. All patients presented at least 2 thrombotic events. Major thrombophilia was defined as the presence of physiologic inhibitors deficiency (protein C [PC], protein S [PS], and antithrombin (AT); homozygous Factor V Leiden, homozygous Factor II G20210A, combined heterozygosity of these defects. After DOACs start, patients were checked every 6 months for blood count, renal and liver function, coagulation, and for the onset of thrombotic and hemorrhagic adverse events.
Results: The examined patients were 167: 72 (43.4%) with major thrombophilia and 94 (66.6%) non-thrombophilic. Patients with major thrombophilia were younger than non-thrombophilic: median age 42 years (range 18-91 years) vs 56 years (range 18-94 years) (p <0.0001). All patients' characteristics are specified in table 1. The median time of DOACS therapy was 32 months (range 6-90) in the group with major thrombophilia; 20 months (range 6-80) in the other group. Two (2.8%) thrombotic events were observed in the subset affected by major congenital thrombophilia and 4 (4.3%) in the non-thrombophilic group (p 0.4). Five (6.8%) minor bleedings were reported in the group of major thrombophilia; 13 (14%) hemorrhagic adverse events were observed in the other group: 10 minor and 3 clinical relevant non-major bleedings (p 0.14).

Table I. Population Characteristics

Patients under DOAC 167	Patients with thrombophilia	Control Patients	p value*
Number of patients	72	94	
Sex (Male/Female)	39/33	62/32	0.12
Body Mass Index (median)	24,6 (range 16.8-45)	27 (range 20-39)	0.007
Age at start of therapy (median years)	42,4 (range 18-91)	55,9 (range 18-94)	<0,0001
Platelets at start of therapy (Median10^3/mmc)	228 (range 148-380)	234 (range 130-600)	0.24
Creatinine at start of therapy (median mg/dl)	0,8 (range 0.2-1.50)	0.93 (range 0.2-1.53)	0.005
DOAC administered			
Rivaroxaban	29 (40.3%)	26 (27.7%)	
Edoxaban	7 (9.7%)	20 (21.3%)	
Apixaban	28 (38.9%)	43 (45.7%)	
Dabigatran	8 (11.1%)	5 (5.3%)	
Thrombophilia			
Protein C Deficiency	7 (9.6%)		
Protein S Deficiency	20 (27.4%)		
Antithrombin Deficiency	12 (16.4%)		
FV Leiden Homozygous Mutated	18 (24.7%)		
FII G20210A Homozygous Mutated	5 (6.8%)		
Double Heterozygous mutation	10 (13.7%)		

*When appropriate, Chi-square and Mann-Whitney tests were performed

DOAC= direct oral anticoagulants; FV= factor V; FII= factor II

Summary/Conclusion: Although major thrombophilia predisposes to a higher incidence of VTE, our data suggest that in this setting of patients, DOACs are effective and safe, with comparable results to non-thrombophilic patients.

EP1320 COMPARISON OF DIFFERENT CLINICAL RISK ASSESSMENT MODELS (RAMS) FOR THROMBOSIS IN AMBULATORY CANCER PATIENTS RECEIVING CHEMOTHERAPY FROM THE SECOND COHORT ONCOTHROMB 12-01 STUDY

M. Ruiz [1,*], A. J. Muñoz [2], L. Ortega [2], C. Font [3], E. Segui [3], M. García de Herreros [3], V. E. Castellón [4], J. Rubio [5], A. Ferrer [6], J. Martínez-Galán [7], M. Salgado [8], I. García-Escobar [7], I. Fernández [9], E. Martínez de Castro [10], V. Pachón [11], T. Quintanar [12], I. Gras [2], M. C. Viñuelas [1], A. Cardenas [13], E. Salas [13], J. M. Soria [13]

[1]Department of Medicine, Faculty of Medicine Universidad Complutense, [2]Oncology, Hospital General Universitario Gregorio Marañón, Madrid, [3]Oncology, Hospital Clinic, Barcelona, [4]Oncology, Hospital Torrecárdenas, Almeria, [5]Oncology, Fundación Jiménez Díaz, Madrid, [6]Oncology, Hospital Obispo Polanco, Teruel, [7]Oncology, Hospital Universitario Virgen de las Nieves, Granada, [8]Oncology, Complejo Hospitalario Universitario de Ourense, Orense, [9]Oncology, Hospital Alvaro Cunqueiro, Vigo, [10]Oncology, Hospital Marqués de Valdecilla, Santander, [11]Oncology, Hospital Ramón y Cajal, Madrid, [12]Oncology, Hospital General de Elche, Elche, [13]Unidad de Genómica de Enfermedades Complejas, Institut de Recerca Hospital Santa Creu i Sant Pau, Barcelona, Spain

Background: The identification of ambulatory patients with cancer at a high-risk of thrombosis and candidates for thromboprophylaxis remains challenging as several risk assessments models (RAMs) have been developed but none of them are routinely used in clinical practice by oncologists.
Aims: To evaluate in a prospective validation cohort (Oncothromb12-01) the predictive capacity of the Khorana, PROTECHT, CONKO, Vienna-CATS modified without P-selectin and Pabinger's nomogram risk scores.

Methods: Multicenter, prospective, observational cohort study in Spain. The second cohort started in 2018 and includes outpatients with lung, central nervous system, colorectal, pancreatic, biliary tract, and gastric cancer naïve for systemic anti-tumor therapy and scheduled for initial treatment. The primary endpoint was the diagnosis of a symptomatic or incidental VTE episode within 12 months of follow up. The predictive power of each RAMs was analyzed by means of calculation of sensitivity, specificity, positive predictive value (PPV), negative predictive value (NPV), positive and negative likelihood ratios, and area under the ROC curve (AUC).
Results: 126 patients, median age 64 y.o. Gender male/female 54/72. Tumor types: pancreas 42,1 %, colorectal 21,4%, gastric 11,9%, biliary tract 9,5%, lung 9,5%, CNS 3,2%, esophagus 1,6% and pancreas + colorectal 0,8%. 57,9% stage IV, 10,3% ECOG ≥ 2. Thirty-four (27%) developed VTE during follow-up. PE 12 (35,3%), DVT 8(23,5%), central venous catheter thrombosis 1 (35,3%), visceral VTE 15 (44,1%). Incidental VTE 24 (70,5%). Overall mortality rate at 12 months 43%. Mortality rate of patients with VTE 65%. 79% of patients with VTE had tumor persistence within 12 months. The positive threshold of 3 points was determined for high-risk category in the RAMs (> 10% for Nomogram). Performance of clinical RAMs is summarized in Table 1.

Table 1. Performance of clinical RAMs

	Khorana			PROTECHT			CONKO			Viena-CATS (D-dimer)			Nomogram		
	All	Inc	Sympt	All	Inc	Sympt	All	Inc	Sympt	All	Inc	Sympt	All	Inc	Sympt
AUC	0,522	0,51	0,52	0,551	0,60	0,57	0,515	0,50	0,53	0,53	0,50	0,58	0,60	0,54	0,71
P value	0,598	0,66	0,72	0,311	0,05	0,33	0,735	0,91	0,60	0,591	0,95	0,37	0,06	0,43	0,01
Sensitivity	79,4%	79,2%	80%	55,9%	66,7%	70%	75,8%	73,9%	80%	38,4%	33,3%	50%	38,5%	27,8%	62,5%
Specificity	25%	25%	25%	54,3%	54,3%	45,7%	27,3%	27,3%	27,3%	64,7%	67,4%	67,4%	81,4%	81,4%	81,4%
LR+	1,06	1,06	1,07	1,22	1,46	1,29	1,04	1,02	1,1	1,18	1,02	1,54	2,07	1,49	3,36
LR-	0,82	0,83	0,8	0,81	0,61	0,6	0,89	0,96	0,73	0,91	0,99	0,74	0,76	0,89	0,46

All= all VTE events; Inc = incidental; Sympt= Symptomatic

Summary/Conclusion: All clinical RAMs tested in this study performed poorly in this high-risk population. We suggest the inclusion of other parameters in the RAMs as genomic o molecular variables to improve the predictive capacity.

EP1321 NON-THROMBOTIC COMPLICATIONS OF ANTIPHOSPHOLIPID SYNDROME

S. Khoduleva [1,*], I. Novikova [2], I. Malishevskaya [3], L. Korotaeva [3], A. Demidenko [3], I. Romashevskaya [3], E. Mitsura [3], E. Repchenko [3]

[1]chair of internal medicine, [2]Gomel state medical university, [3]RRCRM&HE, Gomel, Belarus

Background: Currently, antiphospholipid syndrome (APS) is recognized as one of the most important causes of acquired immune thrombophilia. Vascular accidents associated with the presence of antiphospholipid antibodies contribute greatly to morbidity and mortality. In addition, it is expected that APS, as an autoimmune disease, can lead to the development of a number of severe complications not associated with the risk of thrombosis.
Aims: To assess the nature of non-thrombotic complications of antiphospholipid syndrome.
Methods: The study included 55 patients aged from 14 to 61 years diagnosed with APS. The average age of patients was 36 ± 7.92 years, women predominated - 85.45%. The follow-up period ranged from 6 months to 7 years. The diagnosis was verified in accordance with the Sydney classification criteria of APS (2006). Antibodies (AB) to cardiolipin and to β2-glycoprotein-1 (β2-GP-1) of the IgM and G classes were determined by enzyme-linked immunosorbent assay (ELISA). Plasma hemostasis indicators and lupus anticoagulant were determined using an ACL Elite pro coagulometer. In order to exclude congenital thrombophilia, the activity of antithrombin III, proteins C and S, and the level of homocysteine were assessed. Molecular genetic testing (by PCR) for the presence of thrombogenic mutations was also carried out.
Results: The primary APS was identified in 90.9%. Among the clinical manifestations, obstetric pathology prevailed - 60% of cases. 23.6% of patients were diagnosed with thrombosis of various localization was diagnosed in: thromboembolism of the pulmonary arteries - 30.8%; vein thrombosis of the lower extremities - 30.8%; thrombosis of atypical localization (transverse sinus of the brain, portal vein) - 7.7%; ischemic cerebral circulation disorder - 16.5% of cases. In 4 patients (7.3%), the APS manifested with immune thrombocytopenia. Antibodies to β2-GP-1 of Ig M class were detected more often (36.4%); in 16.3% - antibodies to cardiolipin of the Ig M class and to β2-GP-1 of the IgG class. Highly positive APS was diagnosed in 27% of patients (n = 15), 60% of them developed complications within 2 to 3 years of follow-up, mainly due to the autoimmune mechanism of APS development. The most severe of them are aplastic anemia and aseptic necrosis of the heads of the pelvic bones, diagnosed in one patient at the age of 32 years. In two cases, the course of APS was complicated by the renal-cutaneous form of hemorrhagic vasculitis with the development of glomerulonephritis. The most common complication (44%) was autoimmune coagulopathy with pronounced decrease in plasma coagulation factors FVIII and FIX due to the presence of inhibitors to them. In one case, autoimmune hemolytic anemia was diagnosed against the background of APS.
Summary/Conclusion: The course of APS can be clinically manifested not only by thrombotic, but also by severe hematological complications, such as aplastic anemia, autoimmune coagulopathy, hemorrhagic vasculitis, autoimmune hemolytic anemia, and immune thrombocytopenia. In this regard, the diagnosis of primary APS should be considered much wider than the range of acquired thrombophilia.

EP1322 HIGH RATE OF BLEEDING AND ARTERIAL THROMBOSIS IN COVID-19: SAUDI MULTICENTER STUDY

A. al Raizah [1,*], A. Hejazi [1], M. Al Zahrani [1], N. Shaheen [2], K. Aldosari [1], M. Alnahdi [1], M. Luhanga [1], A. Basendwah [3], T. Alshuaibi [4], E. Alrayes [5], M. Almegren [6], A. Al Askar [1]

[1]Oncology, Ministry of National Guard-Health Affairs. King Abdullah International Medical Research Center. King Saud bin Abdulaziz University of Health Sciences, [2]Biostatistics and Bioinformatics, King Abdullah International Medical Research Center. King Saud bin Abdulaziz University of Health Sciences, Riyadh, [3]medicine, King Fahad Armed Forces Hospital, Jeddah, [4]medicine, King Fahd Hospital, Jeddah, [5]medicine, Prince Mohammed Bin Abdulaziz Hospital, [6]medicine, College of Medicine, Imam Mohammad Ibn Saud Islamic University, Riyadh, Saudi Arabia

Background: Several observational studies have reported the rate of venous and arterial thrombotic events in patients infected with COVID-19, with conflicting results.
Aims: The aim of this study was to estimate the rate of thrombotic and bleeding events in hospitalized patients diagnosed with Coronavirus disease 2019 (COVID-19).
Methods: This was a multicenter study of 636 patients admitted between 20 March 2020 and 31 May 2020 with confirmed COVID-19 in four hospitals. Patients were excluded if they were transferred in or out from one of these four hospital to another hospitals. Patients also excluded is they were admitted for less than 24 hours. Venous thromboembolism (VTE) included all symptomatic or incidentally diagnosed cases of pulmonary embolism (PE), deep vein thrombosis (DVT) and thrombosis in unusual sites (cerebral, mesenteric, portal, splenic, hepatic, and renal veins). All VTEs were confirmed radiographically by appropriate imaging. Screening for VTE in asymptomatic patients was not performed. Arterial events included cerebrovascular accidents (CVAs), mesenteric ischemia, limb ischemia and myocardial infarction (MI) were confirmed by the appropriate clinical, laboratory and imaging modality. Bleeding events were classified as major and nonmajor based on the definition of International Society of Thrombosis and Haemostasis (ISTH). The rates of VTE, bleeding, arterial are summarized as proportions, with the corresponding 95% confidence intervals (CIs). Statistical analyses were performed using SAS version 9.4 (SAS Institute, Cary, NC, USA). Informed consent was waived.
Results: The majority of patients (90%, n=573) and more than 99% of those in the ICU group received pharmacological prophylaxis according to local hospital practice. The most frequently prescribed regimen was enoxaparin (40 mg once daily) (59.2%). Over a median length of stay in the non-ICU group of 7 days and of 19 days in the ICU group, twelve patients were diagnosed with Venous thromboembolism (VTE) (1.8%) (95% CI, 1.1–3). The rate in the non-ICU group was 0.19% (95% CI, 0.04–0.84), and that in the ICU group was 10.3% (95% CI, 6.4–16.2). Two patients were not on prophylaxis prior to the event, 3 were on enoxaparin (40 mg once daily), 3 were on UFH (5000 IU twice daily), 2 were on UFH (5000 IU TID), one was on enoxaparin (40 mg twice daily), and one was on fondaparinux (2.5 mg once daily).The overall rate of arterial event is 2.2% (95% CI, 1.4–3.3). The rates in the non-ICU and ICU groups were 0.94% (95% CI, 0.46–0.1.9) and 8.4% (95% CI, 5.0–14.0). The overall rate of bleeding is 1.7% (95% CI, 1.0–2.8). The bleeding rate in the non-ICU group was 0.19% (95% CI, 0.04–0.84),

and that in the ICU group was 9.4% (95% CI, 5.7–15.1). At the time of bleeding, six patients were on enoxparin 40 mg once, 2 were on UFH(Unfractionated heparin)5000 IU TID, 1 was on enoxparin 40 BID, 1 was on asprin and one was on full dose UFH.

Table 1. Demographics and Baseline Characteristics of the Population

	Overall n=636	Non-ICU n=530	ICU n=106	p-value
Age (mean ±SD)	49±16	47±16	59±14	<0.0001
Male n (%)	456 (71.7)	371 (70)	85 (80.2)	0.033
BMI (mean ±SD)	28.4±6.0	28.1±5.5	17.3±7.8	0.075
^^Any comorbidities n (%)	303(47)	205(38)	98(92)	<0.0001
Active Cancer n (%)	12 (1.9)	9 (1.7)	3 (2.8)	0.432
History of Thrombophilia n (%)	3 (0.47)	1 (0.19)	2 (1.8)	0.073
History of DVT/PE n (%)	6 (0.94)	5 (0.95)	1 (0.94)	1.00

^^ Comorbidities: DM, hypertension, coronary artery disease, stroke, bronchial asthma, COPD, heart failure, and ESRD.

Table 2. Outcome Data

Variable	Overall	Non-ICU	ICU	P value
VTE % (95% CI)	1.8 (1.1–3)	0.19 (0.04–0.84)	10.3 (6.4–16.2)	<0.0001
PE n	8	0	8	
DVT n	5	0	5	
Proximal upper n	1	0	1	
Proximal lower n	4	0	4	
Other VTE n	2	1	1	
Arterial % (95% CI)	2.2 (1.4–3.3)	0.94 (0.46–1.9)	8.4 (5.0–14.0)	<0.0001
CVA n	10	4	6	
MI n	4	1	3	
Bleeding % (95% CI)	1.7 (1.0–2.8)	0.19 (0.04–0.84)	9.4 (5.7-15.1)	<0.0001
Major bleeding n	5	1	4	
Other bleeding n	6	0	6	

Summary/Conclusion: In this study, we found that the VTE rates in hospitalized patients with COVID-19 might not be higher than expected. In contrast to the risk of VTE, we found a high rate of arterial and bleeding complications in patients admitted to the ICU. Given the high rate of bleeding, the current study suggests that the intensification of anticoagulation therapy in COVID-19 patients beyond the standard of care be pursued with caution and would best be evaluated in a randomized controlled study.

EP1323 PLATELET COUNT AND MEAN VOLUME IN ACUTE STROKE: A SYSTEMATIC REVIEW AND META-ANALYSIS

D. F. Sadeghi [1,*], A. Shemirani [2]

[1]University of Debrecen, Clinical Laboratory Research Division, Debrecen, [2]University of Debrecen, Satoraljaujhely, Hungary

Background: Incidence of stroke in Europe is 95 to 290/100,000 per year and it is the fourth cause of death in the United States. The important role of platelets in the pathogenesis of the acute stroke (AS) (atherothrombosis and ischemic) has been documented. Mean platelet volume (MPV) is regarded as a marker of platelet turnover. More immature, thereby larger platelets usually contain more granules, thus releasing more chemokines promoting further platelet aggregation as well as activation. Elevated MPV simultaneously with the elevated PC increases the risk of thrombosis. Significant increased MPV in patients with deep vein thrombosis and isolated elevated platelet count (PC) in patients with pulmonary embolism has been revealed.
Modification of platelet function and consequently a hypercoagulable state has been suggested in patients with both ischemic and hemorrhagic strokes. It has been shown that PC and MPV are independent predictors for poor outcome in primary intracerebral hemorrhage (PICH). There has also been a body of interest for PC and MPV in stroke patients. However, these studies have yielded inconsistent findings. Some groups reported that patients with AS had significantly increased MPV or PC compared with controls, whereas other studies found decreased MPV or PC values in AS patients. Additionally, some studies have observed no association between these parameters and AS.
Aims: Taking these inconsistent findings into consideration, we undertook a meta-analysis to investigate the association between MPV, PC and AS.
Methods: Studies were included in accordance with Patient Population or Problem, Intervention, Comparison, Outcomes, and Setting framework. The PRISMA strategy was used to report findings. Risk of bias was assessed with the Newcastle-Ottawa Scale.
Results: We included 34 eligible articles retrieved from the literature. PC was significantly lower in AS patients [standardized mean difference (SMD) = – 0.30, (95%CI: – 0.49 – – 0.11), N = 2492, P = 0.002] compared with controls (N = 3615). The MPV was significantly higher [SMD = 0.52, (95%CI: 0.28 – 0.76), N = 2739, P < 0.001] compared with controls (N = 3810). Subgroup analyses showed significantly lower PC in both ischemic stroke (Difference SMD = – 0.18, 95%CI: – 0.35 – 0.01) and hemorrhagic stroke (– 0.94, – 1.62 – – 0.25), but only samples by citrate anticoagulant showed significantly lower result for patients compared to controls (– 0.36, – 0.68 – – 0.04). Ischemic stroke patients had higher MPV (0.57, 0.31 – 0.83), and samples by Ethylenediaminetetraacetic acid (EDTA) anticoagulant showed significantly higher result for patients compared to controls (0.86, 0.55 – 1.17).
Summary/Conclusion: PC and MPV appeared to be significantly different between patients with AS and control populations. MPV was significantly higher in ischemic stroke and PC was significantly lower in both ischemic and hemorrhagic strokes. These characteristics might be related to AS and associated with it. It is advisable to pay attention to elapsed time between phlebotomy and hematology analysis, anticoagulant and hemocytometer types in AS.

EP1324 PROGNOSTIC VALUE OF SONORRHEOMETRY IN COAGULOPATHY IN COVID-19 PATIENTS.

F. J. López Jaime [1,*], A. Doblas-Márquez [1], S. Martín-Téllez [1], I. Márquez-Gómez [2], M. Pérez-Raya [1], A. M. Mena Santano [1], D. F. Muñoz-López [1], A. Pérez-Gómez [3], J. M. Reguera-Iglesias [2], M. I. Muñoz-Pérez [1], A. Montaño [1]

[1]Unidad de Hemostasia y Trombosis, Hospital Universitario Regional de Málaga, IBIMA, Málaga, Spain, [2]Servicio de Enfermedades Infecciosas, Hospital Universitario Regional de Málaga, Málaga, Spain., Málaga, [3]Unidad Clínica de Enfermedades Infecciosas, Microbiología y Medicina Preventiva Instituto de Biomedicina de Sevilla – IbiS, Campus del Hospital Universitario Virgen del Rocío., Sevilla, Spain

Background: COVID-19 is a severe respiratory disease caused by the SARS-CoV-2 that manifests severely in a high number of patients, leading to hospitalization of many of them and in the worst case to death. Recent studies have shown a high incidence of thrombotic complications in these patients, especially in those with poor prognosis, and confer special interest to D-dimer as an indicator of poor prognosis. However, the diagnostic value of D-dimer is limited by the long analysis times and that it only reflects the final part of the physiological process of hemostasis. Therefore, the identification of other parameters is needed to allow a rapid and reliable characterization of the hemostatic status of the patient. Viscoelastic testing allows a global analysis of coagulation and have already proven their usefulness in the study of other infectious diseases. The application of viscoelastic tests in COVID-19 patients would therefore be very useful to quickly determine the hemostatic status of patients and thus identify predictors of poor prognosis.
Aims: To characterize the hemostatic status of COVID-19 patients with standard and viscoelastic testings, and identification of poor prognosis variables.
Methods: Prospective, observational, single-centre study. A total of 50 patients requiring hospitalization were included in the study. The next-generation viscoelastic testing "Quantra Hemostasis Analyzer" (HemoSonics) was used to determine the coagulation profile of patients. Blood samples at the time of hospitalization were taken to determine the parameters reported by Quantra (QStat and QPlus cartridges). Correlation study using a heat map of our Spearman partial correlation matrix with a confidence interval of 95%.
Results: As described, a high percentage of COVID-19 patients admitted to hospital showed increased levels of fibrinogen (81.6%), D-dimer (61.9%), IL-6 (70.3%) and increased clot stiffness measured by CS, FCS and PCS parameters (63.6%), while clotting times were normal in almost 100% of patients. Age (>65 years), together with elevated levels of D-dimer, LDH and clot firmness were associated with the presence

of an adverse event during admission, including the need for mechanical ventilation, ICU admission or death (p=0.007/0.030/0.010/0.002). Increased D-dimer levels were significantly recurrent in patients >65 years (p=0.031). A significant difference was observed between the median of these parameters between patients who experienced an adverse event and those who did not: fibrinogen (750 vs 532, p=0.010), D-dimer (779 vs 560, p=0.005), LDH (309 vs 227, p=0.027), CTH (131.5 vs 123, p=0.042), CS (38.15 vs 25, p=0.042), PCS (30.85 vs 20.7, p=0.042) and FCS (7.45 vs 3.9, p=0.027). Multiple correlation study using HeatMap representation revealed independence between clot firmness, age, LDH and D-dimer levels.

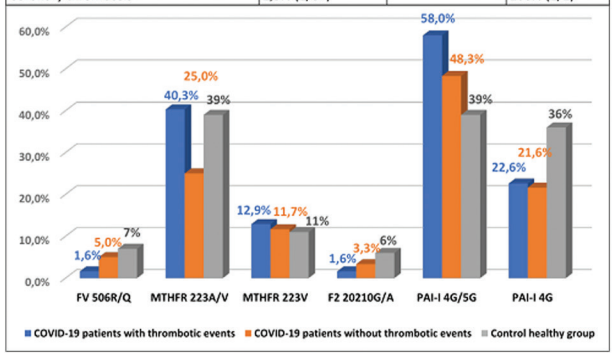
Summary/Conclusion: The study of global hemostatic status using Quantra can be a powerful tool for the analysis of COVID-19 patients at admission and thereby predict risk by identifying markers of poor prognosis. Increased levels of parameters measuring clot stiffness are associated with the presence of an adverse event in patients and can be considered as new independent prognostic markers.

EP1325 THROMBOTIC EVENTS AND THE PROFILE OF HEREDITARY THROMBOPHILIA FACTORS IN COVID-19 PATIENTS

A. Abdullaev [1,*], I. Fevraleva [1], A. Odilov [2], A. Volkov [2], I. Babichenko [2], A. Sudarikov [1]

[1]Laboratory of Molecular Hematology, National Research Center for Hematology, [2]Department of Pathological Anatomy, Peoples' Friendship University of Russia (RUDN University), Moscow, Russian Federation

Background: The leading cause of mortality in more than 2.5 million COVID-19 patients is the development of acute respiratory distress syndrome and multiple organ failure associated with thrombotic events (TE). However, information on the nature of TE and the pathogenetic significance of hereditary thrombophilia factors in patients with COVID-19 is still not completely understood.



Aims: To study possible correlation of TE with the profile of FV 506R/Q, MTHFR 223A/V, F2 20210G/A, and PAI-1 4G/5G mutations in patients with COVID-19.

Methods: Autopsy studies of 179 COVID-19 patients were performed from April to July 2020. Median age of the patients was 73 (range 37 to 99).Control healthy group was 71 individuals with median age of 56 (range 25 to 71). DNAs were isolated from formalin-fixed and paraffin-embedded spleen tissues using a QIAamp DNA FFPE Tissue Kit (QIAGEN, USA) according to the manufacturer's instructions. FV 506R/Q, MTHFR 223A/V, F2 20210G/A, and PAI-1 4G/5G alleles were assessed by an allele-specific real-time polymerase chain reaction.

Results: According to the results of postmortem examinations, 87 patients with TE were identified (see Figure 1). Pulmonary artery thrombosis was detected in 37.9% (33/87) of cases. Pulmonary embolism (PE) was detected in 27.6% (24/87) of cases, of which 87.5% (21/24) PE was combined with deep vein thrombosis (DVT) of the lower extremities, in two patients - with intracardiac thrombi, and in one case - both with DVT and intracardiac thrombi. The frequency of PE in women was twice as high. The incidence of pulmonary vein thrombosis was 18.4%, with a predominance in men (62.5% vs. 37.5%). Isolated intracardiac thrombi were found in 11.5% (10/87) of patients, with a predominance in women. Hepatic vein thrombosis was 4.6% (4/87) of cases. Cerebral artery, coronary vessels, and mesenteric veins thrombosis was detected in 2.3% (2/87) of cases. FV 506R/Q, MTHFR 223A/V, F2 20210G/A, and PAI-1 4G/5G allele patterns were identified for 122 cases 62 of which had TE (see Figure 1). The group of patients with TE revealed a higher incidence of heterozygous genotypes MTHFR 223A/V compared to those without TE (40.3% versus 25%), but relatively similar to the control healthy group (40.3% vs. 39%), and higher incidence of heterozygous PAI-1 4G/5G compared to both groups (58% vs. 48.3% vs. 39%). On the contrary, the incidence of FV 506R/Q and F2 20210G/A heterozygotes was lower compared to the group without TE, and control healthy group. The incidence of homozygous MTHFR 223V and PAI-I 4G did not differ significantly between COVID-19 patients groups, however the latter genotype incidence was lower compared to control healthy group.

Figure 1. Types and frequencies of vascular TE, and profile of the hereditary thrombophilia factors

Vascular TE	General (n=87)	Males (n=38)	Females (n=49)
Pulmonary artery thrombosis	37,9% (33/87)	48,5% (16/33)	51,5% (17/33)
Pulmonary embolism (PE)	27,6% (24/87)	29,2% (7/24)	70,8% (17/24)
PE associated with deep vein thrombosis	21/24	33,3% (7/21)	66,7% (14/21)
PE associated with intracardiac thrombi	3/24	33,3% (1/3)	66,7% (2/3)
Pulmonary vein thrombosis	18,4% (16/87)	62,5% (10/16)	37,5% (6/16)
Isolated intracardiac thrombi	11,5% (10/87)	40% (4/10)	60% (6/10)
Hepatic vein thrombosis	4,6% (4/87)	75% (3/4)	25% (1/4)
Cerebral artery thrombosis	2,3% (2/87)	100% (2/2)	-
Mesenteric venous thrombosis	2,3% (2/87)	-	100% (2/2)
Coronary thrombosis	2,3% (2/87)	-	100% (2/2)

Summary/Conclusion: Thrombosis and thromboembolism of arteries and veins of vital organs are detected in about half of patients who died from COVID-19. No significant trends in the distribution of genotypes of predisposition to thrombophilia between groups of COVID-19 patients with TE and without them, and the control healthy group have been revealed. This is quite unexpected that patients who died from thrombotic complications do not show any signs of hereditary predisposition to thrombophilia. Especially concerning no bias in PAI-4G allele incidence. Probably we do not have enough sample strength to reveal possible differences. Therefore, establishing the role of hereditary thrombophilia factors in the development of COVID-19 associated TE requires further studies with an extended cohort of patients.

EP1326 ROTATIONAL THROMBOELASTOMETRY (ROTEM) PROFILING OF COVID–19 PATIENTS

N. Sabljic [1,*], M. Mitrovic [1,2], Z. Cvetkovic [2,3], N. Pantic [1], Z. Bukumiric [4], M. Virijevic [1,2], I. Milosevic [2,5], Z. Pravdic [1], N. Suvajdzic-Vukovic [1,2], J. Fareed [6], D. Antic [1,2]

[1]Clinic of Hematology, University Clinical Center of Serbia, [2]Faculty of Medicine, University of Belgrade, [3]Clinical Hospital Center Zemun, [4]Institute for Medical Statistics and Informatics, University of Belgrade, [5]Clinic for Infectious and Tropical Disease, University Clinical Center of Serbia, Belgrade, Serbia, [6]Departments of Pathology and Pharmacology, Loyola University Center, Maywood, United States

Background: Thrombosis is frequently diagnosed in patients with Coronavirus disease (COVID - 19), despite the use of a standard-dose thromboprophylaxis in all hospitalized. Since conventional coagulation tests (CCTs) reflect only limited parts of the coagulation system and are insufficient to assess hypercoagulability, rotational thromboelastometry (ROTEM) could be more effective in identifying hypercoagulable pattern and patient in high-risk of thrombosis.

Aims: 1. To analyze ROTEM parameters across the entire clinical COVID-19 pneumonia spectrum, from moderate to critical. 2. To determine the incidence of hypercoagulable ROTEM patterns and improve risk stratification.

Methods: We evaluated coagulation abnormalities via CCTs and ROTEM in a group of 94 patients with confirmed SARS-CoV-2 infection and different severity of pneumonia (34 moderate, 25 severe, 35 critical). Shorter than normal clotting time (CT) and higher than normal maximum clot firmness (MCF) in both extrinsic pathway (EXTEM) and fibrinogen pathway (FIBTEM), as well as shorter than normal EXTEM clot formation time (CFT) and higher than normal α-angle were classified as markers of hypercoagulable state.

Results: At least one hypercoagulable ROTEM parameter had 62 (66%) patients. Increment in the number of patients with ≥ 2 hypercoagulable parameters, higher EXTEM MCF (P = 0.0001), higher FIBTEM MCF (P = 0.0001) and decrement in maximum lysis (P = 0.002) were observed

with increment in disease severity (P = 0.0001). Significant positive correlations between interleukine - 6 (IL6) and CT EXTEM (P = 0.003), MCF EXTEM (P = 0.033), MCF FIBTEM (P = 0.01) as well as negative with ML EXTEM (P = 0.006) were seen. Contrary to hypercoagulable ROTEM pattern which was not predictive for death, hypocoagulability represented by prolonged EXTEM CT (P = 0.0001) and CFT (P = 0.0001), smaller α angle (P = 0.014) and a prolonged FIBTEM CT (P = .0001) was a predictor.

Summary/Conclusion: Our findings confirmed that a hypercoagulable ROTEM pattern characterized by clot formation acceleration, high clot strength, and reduced fibrinolysis was more frequent in advanced disease groups and patients with high IL6. These results support the need for different thromboprophylaxis approaches for different severity groups.

EP1327 INCIDENCE OF THROMBOHAEMORRHAGIC COMPLICATIONS IN THE PERIPROCEDURAL OF ORAL ANTICOAGULANT TREATMENT WITH VITAMIN K ANTAGONISTS

M. Argüello Marina [1,*], I. Gutiérrez Jomarrón [1], L. Castilla García [1], E. Flores Ballester [1], I. Sánchez Prieto [1], S. Valenciano Martínez [1], J. M. Aspa Cilleruelo [1], C. Martínez Vázquez [1], G. López de Hontanar Torres [1], P. A. Rodríguez Barquero [1], M. López Rubio [1], J. García Suárez [1]

[1]*Hematology, Hospital Universitario Príncipe de Asturias, Alcalá de Henares, Spain*

Background: During the follow-up of oral anticoagulation therapy (OAT) with vitamin K antagonists (VKA), the patient undergo invasive procedures. The decision wether to withdraw or maintain the OAT, as well as the needing or not to implement low molecular weight heparin (LMWH) as bridge therapy, will be determined by the patient's thrombotic risk (TR) and the haemorrhagic risk (HR) of the surgery.

Aims: To determine the incidence of thrombohemorrhagic complications in the periprocedural of the patient with OAT, limiting the use of LMWH to patients at high TR looking for decreasing bleeding events related to surgery.

Methods: Prospective, unicentric and observational study including 200 patients with OAT who had had surgery between December 2019 and February 2021, with a subsequent follow-up of 4 weeks. The periprocedural management of the OAT was carried out in the anticoagulation consultation according to the hospital protocol approved in the Thrombosis Committee, which classifies patients according to TR (High TR: Prosthetic heart valves, atrial fibrillation (AF) with CHA2DS2-VASc score 7-9, Severe rheumatic mitral valvulopathy, Venous Thromboembolism less tan 3 months ago and Severe thrombophilia, define as Leyden's factor V in homozygosis, 20210 prothrombin mutation, protein C, S or antithrombin III deficiency, múltiples deficiencys or Antiphospholipid Syndrome), and surgeries in three groups according to HR. Thus, the VKA is suspended 3 days before the intervention and resumed 24 hours after. The use of LMWH as bridge therapy (BT) is reserved for patients with high TR or suspected active cancer. It starts the moment OAT is suspended and it is reintroduced along with it 24 hours after surgery for 3 days (if there are no bleeding complications). The dose of LMWH is therapeutic (as patients requiring BT are high TR).

Given the coagulopathy inherent to COVID infection, no positive COVID patients were included.

Results: The median age of the population is 73 (range 33-93). The main reason for anticoagulation is AF (64.5%). Most patients are low TR and HR on the CHADs-VASc and HAS-BLED scales (76% and 64% respectively). 26.5% of the patients had personal history (PH) of thrombosis and 5.5% had PH of Hemorrhagic Diathesis.

Table 1 shows the interventions performed and clinical events during the follow-up period. 10 post-surgical haemorrhagic events (5%) are described. Three of them (hemoperitoneum after cholecystectomy, hemoperitoneum after laparoscopic tubular gastrectomy, and haematoma of the anterior rectus abdominis muscle with secondary anemization after ventral hernia repair) required hospitalisation for management, all of which were solved with conservative treatment. The other 7 were mild events that were handled outpatiently. In addition, intra-procedure bleeding during bronchoscopy is described in patient with BT, that was controlled on the spot with amchafibrin and adrenaline. No thrombotic events were recorded. Generally, OAT was re-induced the day after surgery in patients undergoing minimal and low HR interventions, being the percentage somewhat lower in patients undergoing high HR interventions, both in high or low TR patients.

Table 1. Incidence of haemorrhagic and thrombotic complications according to the TR of the patient and the HR of the intervention.

Thrombotic Risk of the patient		Haemorrhagic risk of the surgery		Haemorrhagic Complications	Thrombotic Complications	OAT re-induced the day after surgery
High TR: Bridge therapy with LMWH	72 (36%)	Hihg/moderate HR	25 (12.5%)	5 (2.5%)	0%	19 (76%)
		Low HR	18 (9%)	1 (0.5%)		17 (94.4%)
		Minimum HR	29 (14.5%)	0 (0%)		28 (96.6%)
Low RT: Without bridge therapy	128 (64%)	Hihg/moderate HR	59 (29.5%)	3 (1.5%)		49 (83.1%)
		Low HR	25 (12.5%)	2 (1%)		23 (92%)
		Minimum HR	44 (22%)	0 (0%)		42 (95.4%)

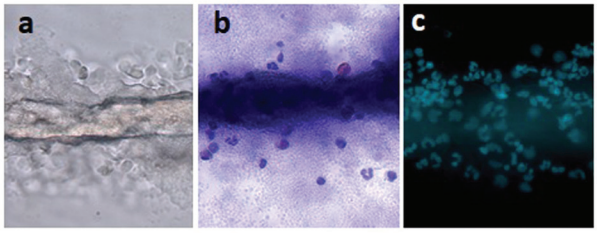
TR: thrombotic risk; HR: haemorrhagic risk; LMWH: low molecular weight heparin.

Summary/Conclusion: Standardization by means of a periprocedural management protocol of the OAT that adjusts BT with LMWH according to the risk factors of each patient, results in a reduction of the incidence of haemorrhagic complications without secondary increase of thromboembolic events. This study demonstrates the importance of centralizing unified periprocedural management using an established protocol.

EP1328 PLATELET ADHESION, VON WILLEBRAND FACTOR ACTIVATION AND LEUKOCYTES RECRUITMENT AT HIGH SHEAR RATES

Y. Avtaeva [1,*], I. Melnikov [1], O. Saburova [1], Z. Gabbasov [1]

[1]*Laboratory of cellular hemostasis, National Medical Research Centre of Cardiology of the Ministry of Health of the Russian Federation, Moscow, Russian Federation*



Background: Platelet adhesion is an important process in primary haemostasis and thrombus formation. Von Willebrand factor (VWF) is a key mediator of platelet adhesion at sites of vascular injury under high shear rates. Recent studies showed that VWF becomes highly reactive with platelets and leukocytes upon unfolding into a stretched conformation, at shear rates above the critical value, which occur at sites of arterial stenosis and injury. Activated VWF and platelets, adhered to injured vessel wall, may serve as sites of leukocyte recruitment under flow conditions and predispose to the propagation of inflammation and thrombosis.

Aims: The aim of the study was to investigate platelet adhesion and leukocyte recruitment in whole blood under high shear rates.

Methods: Venous blood from 7 healthy volunteers was collected from the cubital vein into PPACK solution at final concentration of 100 μM or into EDTA (1.6 mg/ml). To study the kinetics of cell adhesion to collagen we developed a laser optical system that utilizes special optical and microfluidic techniques. The microfluidic optical system consists of a cell assembly with a disposable flow chamber, a specialised optical prism system with a semiconductor laser and a photodetector. Shear stress-induced adhesion of blood cells to type I collagen-coated surface of a perfusion chamber was registered during 15 minutes of circulation of whole blood samples at shear rate of 2300 s^{-1}. After 15 minutes of perfusion flow chambers were fixed with 1% formalin solution, stained by Giemsa staining and 4′,6-diamidino-2-phenylindole (DAPI). Platelet GP Ib and GP IIb/IIIa receptors were blocked using monoclonal antibodies.

Results: Cell adhesion was quantified by measuring the intensity of scattered light after 15 min of perfusion and was 0.35±0.10 V in control samples, 0.25±0.08 V in samples after addition of anti-GP Ib and 0.07±0.03 V after addition of anti-GP IIb/IIIa antibodies (p=0.002). In blood samples with EDTA the intensity of scattered light was 0.06±0.02. Microscopy of perfusion chambers revealed large protein structures in the form of long strands. They were attached to a collagen surface and stretched along the streamline (Fig. 1a). Microscopy of perfusion chambers after Giemsa staining revealed that the protein structures were co-localized with leukocytes and platelets (Fig. 1b). Fluorescence microscopy of samples after staining with DAPI confirmed that there are leukocytes in this structure (fig. 1c).

Figure 1. Platelet adhesion and leukocyte recruitment to a collagen-coated surface at shear rate of 2300 s-1. (a) Transmitted optical microscopy; (b) Microscopy with Giemsa staining; (d) staining with 4′,6-diamidino-2-phenylindole (DAPI).

Summary/Conclusion: Our data demonstrate that platelet adhesion and leukocyte recruitment to collagen coated surface at high shear rates is mediated by the complex interaction of von Willebrand factor and platelet GP receptors.

EP1329 EXPERIENCE WITH DIRECT ORAL ANTICOAGULANTS (DOACS) FOR THE TREATMENT OF CANCER ASSOCIATED THROMBOSIS

C. Aguilar [1,*], M. Valles [2], D. Condori [2], A. B. Dueñas [1], F. Sevil [1], C. Domínguez [1]

[1]Haematology, [2]Oncology, Hospital General Santa Bárbara, Soria, Spain

Background: Low molecular weight heparins (LMWH) have long been the gold standard of the treatment of cancer associated thrombosis (CAT). However the growing use of DOACs as currently recommended by most international guidelines is gradually changing the treatment paradigm in this setting

Aims: To report some real-world experience on the efficacy and safety of DOACs for the treatment of CAT in a community hospital in Spain

Methods: Patients evaluated had been diagnosed with CAT, were referred from the Oncology to the Haematology Department for management of anticoagulant treatment and agreed to start on a DOAC. All patients had active cancer and underwent regular outpatient follow-up in order to make decisions on DOAC treatment duration, perform dose adjustments as required and evaluate any episodes of recurrent VTE or bleeding. DOACs are licensed but not reimbursed in Spain for the treatment of venous thromboembolism (VTE)

Results: Twenty three patients (12 male/11 female) fulfilled criteria mentioned above. Patients were affected by cancers as shown in Table 1. Over 60% (60.8%; 14 patients) had metastatic disease and almost 2 out of 3 (65.2%) were on some type of chemotherapy when VTE was diagnosed. Median age and duration of DOAC therapy were 68 years (range 49-87) and 103 days (range 27-740) respectively; 43.4% (10 cases) were treated for over 6 months. Twenty three patients had received a LMWH (tinzaparin 13, enoxaparin 7) following diagnosis of CAT for a median of 3 months (range 0-15) before switching to a DOAC. Rivaroxaban was the most commonly prescribed DOAC (20 patients; 87%). Edoxaban (2 cases) and apixaban (1 case) accounted for the rest of DOAC prescriptions. Most cases (69.5%) were sorted as having low thrombotic risk according to Khorana score 0-1 and the diagnosis of VTE was incidental in 14 cases (60.8%), this is, all cases of PE and 1 of portal/mesenteric venous thrombosis (Table 1). Only 2 individuals (8.7%) had a prior history of VTE.

Two patients (8.7%) with lung cancer showed thrombotic recurrence during follow-up in association with recurrent and/or locally advanced tumor progression.

No major bleeding episodes (ISTH criteria) were reported throughout the follow-up period. Four patients (17.3%) presented with some episode of clinically relevant non-major bleeding at a median of 2 months (range 1-4) from DOAC start: 3 cases of haematuria (1 patient on rivaroxaban with a urine bladder tumour, and 2 cases of lung cancer) and 1 case of haemoptisis (in a patient on edoxaban with lung metastases of a gynaecological cancer; incidence 1.2 per 100 patients-year). Nine patients (39.1%) died during the follow-up after a median of 88 days of DOAC therapy (range 54-740); in all cases cancer progression was the cause of death

Summary/Conclusion: Our real-world experience in an unfavourable-profile cancer patient setting confirms that DOACs are efficient and safe for the treatment of CAT even when prescribed for longer periods than those reported in clinical trials. Although initial treatment with a LMWH before patient referral and DOAC start may bias our results these are clinically applicable. Thus, incidence of thrombotic recurrence was consistent with that reported in pivotal trials of direct factor Xa inhibitors for the treatment of CAT and linked to cancer progression in our experience. Bleeding was always easily manageable with no major bleeding episodes being reported; incidence of other bleeding complications was also consistent with that reported in clinical trials of DOAC treatment for CAT

EP1330 THE EFFECTS OF AMBIENT PARTICULATE MATTER AIR POLLUTION ON HEMOSTASIS: A REPEATED-MEASURES ANALYSIS

S. Hantrakool [1,*], M. Sriwichai [2], B. Shaengkhamnang [2], N. Leetrakool [2], P. Niprapan [1], S. Kawichai [3], R. Natesirinilkul [4], P. Koonyosying [5], P. Phinyo [6,7], P. Piriyakhuntorn [1], T. Rattanathammethee [1], C. Chai-Adisaksopha [1], E. Rattarittamrong [1], A. Tantiworawit [1], L. Norasetthada [1], S. Srichairatanakool [5]

[1]Division of Hematology, Department of Internal Medicine, Faculty of Medicine, [2]Blood Bank Section, Faculty of Medicine, [3]The Chiang Mai University Research Institute for Health Sciences (CMU-RIHES), [4]Division of Hematology/Oncology, Department of Pediatrics, Faculty of Medicine, [5]Department of Biochemistry, Faculty of Medicine, [6]Center for Clinical Epidemiology and Clinical Statistics, Faculty of Medicine, [7]Department of Family Medicine, Faculty of Medicine, Chiang Mai University, Chiang Mai, Thailand

Background: High level of ambient air pollution significantly increases thrombotic risk, stroke, myocardial infarction and mortality rates. Furthermore, fine particulate matter size less than 2.5 and 10 microns ($PM_{2.5}$ and PM_{10}) were associated with disseminated intravascular coagulation (DIC) in animal models. This study describes the hemostatic changes in adults during the seasonal variations of air pollution.

Aims: This study aims to evaluate the short-term effects of high levels of $PM_{2.5}$ and PM_{10} on the coagulation tests in the same healthy individuals across the seasonal variations of ambient air pollution.

Methods: This is a prospective study. The data were collected from 30 platelet apheresis donors, during February and July 2020 at The Blood Bank Center, Maharaj Nakorn Chiang Mai Hospital, Thailand. The blood samples were obtained repeatedly at the time of donation, once every 4 weeks for 4 visits. The complete blood count and various coagulation tests, including PT, aPTT, vWF antigen, ristocetin cofactor assay, P-selectin and platelet function analysis, were done. Data of the ambient air pollution was recorded at the central air-quality monitoring station, one kilometer from the hospital center. Mixed effect model was used to analyze the impact of high $PM_{2.5}$ and PM_{10} on the blood cell count and the hemostatic tests.

Results: There were 30 healthy volunteers, 29 (96.7%) were men. Mean age was 38.9±8.2 years old. The median levels of $PM_{2.5}$ at the first, second, third and the fourth visits were 68.4, 35.25, 14.36 and 6.21 µg/m^3, and the PM_{10} levels during each visit were 98.09, 52.13, 25.92 and 15.96 µg/m^3, respectively. The hematocrit value was correlated with the $PM_{2.5}$ and PM_{10} levels. The white blood cell and platelet count were not affected. P-selectin was significantly associated with the levels of $PM_{2.5}$ and PM_{10}. The platelet function showed no correlation with the particulate matter level. The elevated $PM_{2.5}$ and PM_{10} levels were associated with the shortening of prothrombin time. This effect was not seen in aPTT. The values of $PM_{2.5}$ and PM_{10} markedly correlated with the increased von Willebrand function, whereas the von Willebrand antigen remained unchanged.

Summary/Conclusion: The elevated $PM_{2.5}$ and PM_{10} levels affect coagulation tests, including the shortening of prothrombin time and increased von Willebrand function. These findings wound play a key role in pathogenesis of ambient air pollution-related thrombosis.

EP1331 VALUE OF LABORATORY PARAMETERS IN THE CLINICAL MONITORING OF PATIENTS WITH SARS-COV-2 INFECTION (COVID-19).

M. Moreno Carbonell [1,*], E. González Gómez [1], A. Gómez Martínez [1], C. Hernández Mata [1], S. Martín-Consuegra Ramos [1], M. Civeira Marín [1], A. López Peña [1], C. Rodríguez Lefler [1], A. J. García Ortego [1], S. F. Pinzón Mariño [2], N. Fernández Mosteirín [1], J. M. Calvo Villas [1]

[1]Haematology, Hospital Miguel Servet, Zaragoza, [2]Haematology, Hospital del Mar, Barcelona, Spain

Background: Association between some analytical parameters and clinical evolution of patients infected by SARS-COV-2 is a controversial issue.
Aims: Review the relationship between laboratory parameters and severity and/or lethality of the COVID-19.
Methods: Observational, cross-sectional and retrospective study. Data obtained from electronic health record of patients over 18 years of age admitted in our hospital, between March and May 2020 with suspected SARS-COV-2 infection. After descriptive statistical study, we did an inferential analysis using Mann-Whitney U test for independent samples, in order to verify association between the results of analytical parameters and the clinical severity (defined by hospitalization in conventional ward vs. intensive care units (ICU)) and/or lethality (alive vs. death at the end of the study).
Results: 668 patients were included, 345 men (52%) and 323 women (48%), with a median age of 70 years. 80% of patients had previous comorbidities, 10% were admitted to the ICU, and 17% died.
Differences were found in hematimetric parameter between the different groups: leukocytes (10^3/µl): 8.3 in ICU patients vs. 6.5 in those admitted to the ward; platelet count (10^3/µl) of 182l in death patients vs. 223 in survivors; hemostasis parameters: D-dimer (DD) (µg/L) of 1379 and 1236 in deceased and admitted to the ICU respectively, compared to 734 and 786 in survivors and not admitted to ICU; and biochemical figures (increase in C-reactive protein (CRP), lactate dehydrogenase (LDH) or cardiac enzymes, the latter, especially, in patients who were deceased, with a median ultrasensitive troponin I (ng/L) of 34.75 vs. 7.1 in survivors. The differences were statistically significant (p value <0.01).

Figure 1. ICU vs. Ward admitted/ Defeated vs survival. *Inferential Statistics.*

All analytical data expressed as median (standard deviation). 1. Reference values in our laboratory 2. Units of measurement. 3. D-dimer. 4. Prothrombin time. 5. Activated partial thromboplastin time. 6. Lactic dehydrogenase. 7. Interleukin 6. 8. C-reactive protein. 9. Procalcitonin. 10. Troponin I.

Summary/Conclusion: Correlation exist between severity of infection and the increase in leukocytes, neutrophils, DD, CRP and LDH, and lymphopenia, in our sample. Decrease in the platelet count and the increase in cardiac enzymes were associated with an increased risk of mortality.

EP1332 FACTOR XII 46 C/T GENE POLYMORPHISM COULD BE ASSOCIATED WITH THE RISK OF LATE-ONSET VENOUS THROMBOEMBOLISM IN PATIENTS FROM THE NORTH-WESTERN RUSSIA

A. Chechulova [1,*], S. Kapustin [2], V. Soldatenkov [3], L. Papayan [2], V. Soroka [1]

[1]Vascular surgery, Dzhanelidze Research Institute of Emergency Medicine, St. Petersburg, [2]Russian Research Institute of Hematology and Transfusiology, St. Petersburg, Russian Federation, [3]Vascular surgery, Russian Research Institute of Hematology and Transfusiology, St. Petersburg, Russian Federation

Background: The Hageman factor (factor XII, FXII) is involved in initiation of internal blood coagulation pathway, regulation of fibrinolysis and kallikrein-kinin system, and activates coagulation factors VII and XI. The 46 C/T polymorphism in the gene coding for FXII is associated with decrease of both level and activity of this factor in blood plasma. However, the role of the FXII 46 C/T polymorphism in venous thromboembolism (VTE) development is not yet clear.
Aims: To assess the role of the FXII 46 C/T polymorphism in VTE development in patients from the North-Western region of Russia.
Methods: We examined 600 patients (294 men and 306 women, mean age – 43.6±15.3 years) with VTE. In 400 patients, the first episode of VTE was diagnosed at age 45 years or less. Other 200 patients composed the group with late-onset VTE. The control group (CG) consisted of 200 age- and sex-matched healthy individuals. All individuals originated from the North-Western region of Russia and gave informed consent for participation in the study. Genotyping for the FXII 46 C/T polymorphism was performed by PCR-RFLP. The differences in genotypes distribution between the groups were estimated by Fisher`s exact test.
Results: Comparative analysis of gene variants distribution for the FXII 46 C/T polymorphism in VTE patients and CG did not reveal any statistically significant difference. Frequencies for the CC, CT and TT genotypes were 48.2%, 43.0%, 8.8% in patients, and 48.0%, 45.5%, 6.5% in controls, respectively. Interestingly, the presence of 46T allele was more frequently detected in patients with late-onset VT (58.0% vs. 48.8% in young patients; OR=1.5; 95% CI: 1.0-2.0; p=0.038). Homozygosity for the 46T allele was found in 24 (12.0%) patients with late-onset VT and 29 (7.3%) young patients (OR=1.7; 95% CI: 1.0-3.1; p=0.066). When compared to CG, the frequency of 46TT genotype was almost 2-fold increased in patients with VT manifested after 45 years old (12.0% vs. 6.5%, respectively; OR=2.0; 95% CI: 1.0-4.0; p=0.083).
Summary/Conclusion: Our data suggest that the FXII 46 C/T gene polymorphism could influence the risk of late-onset VT development in patients from the North-Western region of Russia. Further studies are needed to confirm this association.

EP1333 VKORC1 -1639AA GENOTYPE COULD BE A POSSIBLE PROTECTIVE FACTOR FOR VENOUS THROMBOEMBOLISM DEVELOPMENT IN PATIENTS WITH FII G20210A MUTATION FROM NORTH-WESTERN RUSSIA

S. Kapustin [1,*], A. Chechulova [2], S. Svitina [1], J. Sidorova [1], J. Drijun [1], V. Burakov [1], V. Soldatenkov [1], V. Soroka [2], L. Papayan [1]

[1]Russian Research Institute of Hematology and Tranfusiology, [2]Dzhanelidze Research Institute of Emergency Medicine, Saint-Petersburg, Russian Federation

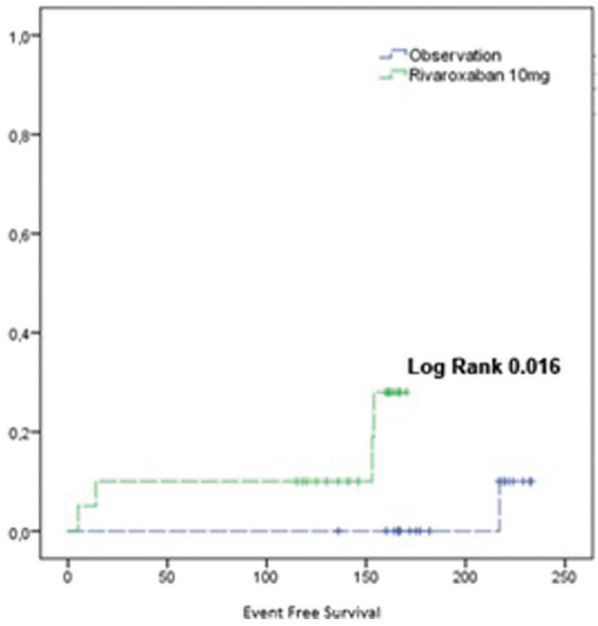
Background: Vitamin K plays a crucial role in hemostasis by activating both procoagulant (FII, VII, IX, X) and anticoagulant (proteins C, S, Z) factors. Vitamin K-epoxide reductase 1 (VKORC1) G-1639A gene polymorphism is known to affect an enzyme activity and bioavailability of vitamin K. To date, there is a little data on the role of VKORC1 G-1639A variation in venous thromboembolism (VTE) development, in particular, in patients with inherited thrombophilia.
Aims: To assess effect of the VKORC1 G-1639A gene polymorphism on the risk of VTE development in patients from North-Western Russia.
Methods: We included 600 VTE patients (294 men and 306 women, mean age 43.6±15.3 years) originated from the North-Western region of Russia in the study. The control group (CG) consisted of 200 healthy individuals of the same origin. Genotyping for the VKORC1 G-1639A, FII G20210A and FV G1691A variations was performed by PCR-RFLP. Odds ratios (OR) with 95% confidence intervals (CI) and p-values were determined by Fisher's exact test to characterize intergroup differences in distributions of genotypes and their combinations. The study was approved by the local ethical committee.
Results: Allele and genotype frequencies for the VKORC1 G-1639A polymorphism were similar in both VTE patients and controls. At the same time, we observed significant differences for the VKORC1 genotypes distribution between the groups of VTE patients with or without classical markers of inherited thrombophilia. The frequency of the -1639AA genotype in patients with FV 1691A variant (FV Leiden)

was 4-fold higher than in those having FII G20210A mutation (19.6% vs. 4.4%, respectively; OR=5.2; 95%CI: 1.2-23.6; p=0.021). In the group of patients without FII and FV gene mutations, the frequency of the VKORC1 -1639AA genotype was almost equal to that in CG (17.1% vs. 16.5%, respectively). When compared to CG, the VKORC1 -1639AA variant was significantly underrepresented in patients with the FII G20210A gene mutation (4.4% vs. 16.5%, respectively; OR=0.2; 95%CI: 0.1-1.0; p=0.035).
Summary/Conclusion: Genotype VKORC1 -1639AA could have protective effect on VTE development in patients with FII G20210A mutation from North-Western Russia. Further studies are needed to confirm this finding.

EP1334 GENES OF THROMBOPHILIA AND PROTHROMBOTIC CONDITIONS BY WOMEN WITH REPRODUCTIVE FAILURE IN ANAMNESIS

A. Kiseleva [1,*], E. Butina [2]

[1]laboratory of cellular and molecular immunology, [2]Laboratory of immunohematology, KRIHBT, Kirov, Russian Federation



Background: Inherited thrombophilia is one of the leading causes of coagulating disorders. Prothrombotic disorders are considered to be risk factors for many obstetric complications of placental origin starting with the implantation process and ending with the formation of the placenta (stillbirth, intrauterine growth retardation, severe preeclampsia, and placental abruption, recurrent pregnancy loss).
Aims: To assess the distribution of genes of thrombophilia and prothrombotic conditions (*F2: 20210 G>A, F5: 1691 G>A, F7: 10976 G>A, F13: 103 (163) G>T, FGB: -455 G>A, ITGA2: 807 C>T, ITGB3: 1565 T>C, PAI-1: -675 5G>4G*) by women with reproductive failure in anamnesis and by healthy women.
Methods: Genes of thrombophilia and prothrombotic conditions genes were carried out by polymerase chain reaction in real time on the detecting amplifier DT-96 (DNA Technology, Russia). The crtiterion X2 was used for statistical data processing. Depending on the diagnosis eastablished in the hospital on the basis of the international classification of diseases (ICD-10), 367 examined women were devided into such groups: group 1 - female infertility, unspecified (ICD-10: N97.9), n=9; group 2 - female infertility of other origin (ICD-10: N97.8), n=175; group 3 - two complete or unspecified abortions, without complications (ICD-10: O03.9), n=19; group 4 - habitual aborter (ICD-10: N96), n=59; comparison group - no problems with the onset and gestation of pregnancy, two or more children, n=105.
Results: The data of the performed study showed, that the C allele of the *ITGB3: 1565 T>C* gene was more common in women with other forms of female infertility (ICD-10: N97.8) (34.9% to 22.9% in the comparison group, p<0.05). Polymorphism of the remaining genes (*F2: 20210 G>A, F5: 1691 G>A, F7: 10976 G>A, F13: 103 (163) G>T, FGB: -455 G>A, ITGA2: 807 C>T, PAI-1: -675 5G>4G*) was detected with comparable frequency in women with and without pathology of pregnancy.
Summary/Conclusion: The presence of the allele C of the ITGB3:1565 T>C gene predosposes to female infertility.

EP1335 EFFECT OF RIVAROXABAN (10MG) VERSUS OBSERVATION ON THE RISK OF THROMBOSIS AT DISCHARGE IN INDIVIDUALS WITH COVID-19.

C. Ramos [1,*], E. Madera [1], A. Majlufc [2], A. Cabrera [3], D. Macedo [1], U. Valencia [4], C. Balderas [4], E. Camargo [5], M. Bejarano [6], C. Martínez [7], E. Rosas [6]

[1]Hematology, Hospital Regional de Ixtapaluca, [2]Hematology, Instituto Mexicano del Seguro Social, [3]Hemartology, Hospital Regional de Ixtapaluca, [4]Hematology, Hospital Regional Ixtapaluca, [5]Hematoogy, Hospital Regional de Ixtapaluca, [6]Nutrition Research, [7]Hematology, Hospital General de Mexico, Mexico City, Mexico

Background: Coagulopathy associated with COVID-19 is one of the main complications, especially in individuals with risk factors. Simultaneously, the use of low molecular weight heparin is the recommended strategy in hospitalized individuals, but the usefulness of other strategies such as DOACs in outpatients is still unknown.
Aims: Describe the benefit of the use of rivaroxaban at discharge on the risk of thrombosis in patients discharged from COVID-19.Identify the behavior of Dimero-D at discharge and its modification with anticoagulant therapy.
Methods: Randomized 1: 1 study (Rivaroxaban 10mg for 14 days versus observation) at discharge in individuals with COVID-19 who have not required mechanical ventilation. D-dimer was evaluated at 14 and 30 days after discharge in conjunction with a CT angiography at four weeks after hospital discharge. The protocol was developed in the Hospital Regional de Alta Especialidad de Ixtapaluca, authorized by the ethics committee with registration number NR-19-2020. The study is identified in ClinicalTrials.gov with the following registry NCT04508439
Results: Forty individuals were evaluated (20 in each arm) with follow-up greater than 100 days. Gender distribution was equitable in each arm, with a mean age of 50 years (21 to 74 years), 40% (n = 16) were older than 55 years, 27.5% (n = 11) had hypertension and 20% (n = 8) had diabetes. The mean length of hospital stay was 10.5 days (6 to 23 days) treated with oxygen and low molecular weight heparin. At discharge, treatment was started with rivaroxaban 10mg x 14d vs. observation; in the rivaroxaban group, four events were identified (3 hemorrhages / 1 thrombosis), this difference being significant (Log Rank 0.016). Only one thrombosis event (pulmonary embolism) was identified in the rivaroxaban group at eight treatment days. Compared to the diagnosis, DD levels were lower at both 14 and 30 days (p = 0.000, 95% CI, 440.8-1164.9) without finding a difference in those treated with rivaroxaban or observation (p = 0.721, 95% CI, -68.48 to 241.18).

Summary/Conclusion: The use of DOACs at discharge does not benefit from an increased risk of hemorrhagic events; the anticoagulant strategy should be individualized, focused only on those patients at very high risk of thrombosis.

Transfusion medicine

EP1337 RAVULIZUMAB AND ECULIZUMAB REDUCE TRANSFUSIONS IN ADULT PATIENTS WITH PAROXYSMAL NOCTURNAL HEMOGLOBINURIA: EVIDENCE FROM THREE REAL-WORLD DATABASES: TRINETX US EMR, TRINETX US CLAIMS AND KOMODO HEALTH

S. Nagalla [1], A. Hill [2], M. Royston [3], I. Tomazos [3,*]

[1]Miami Cancer Institute, Miami, FL, United States, [2]Alexion Pharmaceuticals, Inc., Leeds, United Kingdom, [3]Alexion Pharmaceuticals, Inc., Boston, MA, United States

Background: Results from the International PNH Registry have shown that eculizumab reduced the number of transfusions by 50% in patients (pts) with PNH with transfusion history. Ravulizumab, the new standard of care for PNH, was non-inferior to eculizumab in 2 large clinical trials; 77% and 87% of pts treated with ravulizumab achieved transfusion avoidance at 1 year. Collecting real world data on the proportion of pts with PNH requiring transfusions whilst on ravulizumab, or after switching from eculizumab to ravulizumab (E-R switch) is important

and valuable. Electronic medical records (EMR) and claims databases provide valuable real-world insight.
Aims: Determine proportion of pts with PNH receiving transfusions before and after initiating treatment with eculizumab, ravulizumab or E-R switch by using large-scale US EMR and claims databases.
Methods: TriNetX is a global health research network that integrates data from a variety of sources to create longitudinal real-world data, which can be sourced from EMR or claims. KOMODO Health is a comprehensive claims database in the US. The study population was identified using records with ICD-10 codes for PNH. Pts were grouped into three cohorts: received eculizumab but never ravulizumab (eculizumab-only), received ravulizumab but never eculizumab (ravulizumab-only), and an E-R switch. The TriNetX platform was used to access data up to 10/Feb/21 from two TriNetX networks: the US EMR and US Claims networks. Analyses for these databases were conducted at 6-month intervals: 6-months (mos) to 1 day pre-treatment, 0-6-mos post-treatment and continued at 6-month intervals thereafter until 18-24 mos in ravulizumab and E-R switch cohorts, and 42–48 mos in the eculizumab cohort. From the KOMODO Health database, claims data were sourced from 01/Jan/15 to 31/Dec/19. Analyses were conducted at 3-month intervals: 3 mos to 0-days pre-treatment, day of treatment (index date) to 3 mos post-treatment and at 3-month intervals until 6 mos for the ravulizumab and E-R switch cohorts, and 24 mos for the eculizumab cohort. Proportion of pts receiving transfusions at each interval was assessed.
Results: A total of 295, 804 and 231 pts with PNH that met the analysis criteria were identified from TriNetX EMR, TriNetX Claims and KOMODO, respectively (**Figure 1**). Proportion of pts receiving transfusions prior to index date in the eculizumab-only cohort was higher in all 3 databases. In the eculizumab-only cohort, the proportion of pts receiving transfusions decreased from 23–37% pre-treatment to 8–15% at the end of the study period. In the ravulizumab-only cohort, proportion of pts receiving transfusions decreased from 10–15% pre-treatment to 0% in the TriNetX Claims and KOMODO cohorts, and 8% in the TriNetX EMR cohort at the end of the study period. In the E-R switch cohort, proportion of pts receiving transfusions decreased from 9–17% pre-switch, to 0% in TriNetX Claims and TriNetX EMR cohorts and 8% in the KOMODO cohort at the end of study period after switching to ravulizumab. A limitation of this study was the small ravulizumab sample size.

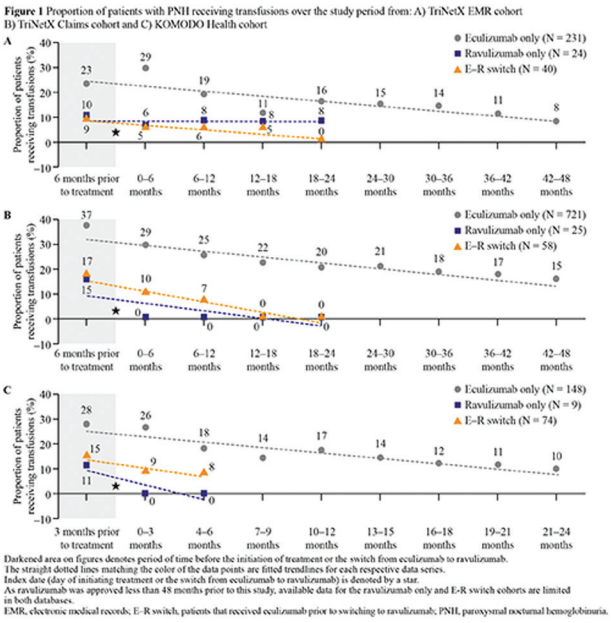


Figure 1 Proportion of patients with PNH receiving transfusions over the study period from: A) TriNetX EMR cohort B) TriNetX Claims cohort and C) KOMODO Health cohort

Darkened area on figures denotes period of time before the initiation of treatment or the switch from eculizumab to ravulizumab.
The straight dotted lines matching the color of the data points are fitted trendlines for each respective data series.
Index date (day of initiating treatment or the switch from eculizumab to ravulizumab) is denoted by a star.
As ravulizumab was approved less than 48 months prior to this study, available data for the ravulizumab only and E-R switch cohorts are limited in both databases.
EMR, electronic medical records; E-R switch, patients that received eculizumab prior to switching to ravulizumab; PNH, paroxysmal nocturnal hemoglobinuria.

Summary/Conclusion: Results of this real-world study demonstrate that the proportion of pts with PNH requiring blood transfusions was substantially reduced with eculizumab or ravulizumab monotherapy or after the E-R switch, with similar trends noted between treatment groups. This real-world data demonstrates the low transfusion dependence in pts with PNH treated with eculizumab or ravulizumab, or pts switched to ravulizumab.

EP1338 EVALUATION OF RED BLOOD CELL AUTOANTIBODIES AND ASSOCIATED THROMBOTIC RISK IN A TERTIARY CARE CENTRE IN SPAIN

C. Jimenez-Chillon [1,*], M. Tenorio-Nuñez [1], C. Nuñez-Torron [1], B. Astibia [1], L. Perez-Lamas [1], M. G. Moreno-Jimenez [1], F. J. Lopez-Jimenez [1]

[1]*Hematology, Hospital Universitario Ramon y Cajal, Madrid, Spain*

Background: Autoimmune hemolytic anemia (AIHA) is characterized by the presence of anti-red blood cell (RBC) autoantibodies with active hemolysis. Several studies have described a higher thrombotic risk compared to healthy subjects, possibly related to a combination of autoimmune features and hemolysis. However, the relationship between presence of anti-erythrocyte autoantibody and risk of thrombosis has not yet been explored.
Aims: The aim of this study is to identify whether the elevated thrombotic risk in AIHA could be associated with anti-RBC autoantibody presence regardless of the existence of active hemolysis.
Methods: We conducted a retrospective research in a single-center cohort selecting patients with an identified anti-RBC autoantibody and then evaluating the presence of hemolysis and the incidence of thrombotic events.
Laboratory methods to identify autoantibodies included direct antiglobulin test (polyspecific and monospecific anti-IgG and C3d, Menarini reagents) and elution tests (acid glycine elution with ELU-KIT Immucor or 56ºC elution) were also undertaken. Measured parameters for hemolysis were indirect bilirubin, LDH and reticulocytes.
Patients with AIHA were recorded from 2009, and those without active hemolysis were registered during part of this follow-up period. We also assessed associated diseases and features of the autoantibody. Prothrombotic characteristics (elderly, active cancer, previous VTE, known thrombophilic condition, recent trauma/surgery, infection/rheumatologic disorder and hormonal treatment) were registered in order to identify bias. Reduced mobility could not be evaluated due to lack of data.
Results: 105 patients with an anti-RBC autoantibody were identified, 5 were excluded due to lack of information. Among these 100 patients, 59 showed active hemolysis (AIHA). There was no difference in gender, age or associated diseases (idiopathic, lymphoproliferative, autoimmune disorders or others) between both groups. Patients without hemolysis showed more frequently warm autoantibody features (p=0.025) and less commonly mixed characteristics (p=0.039). Median follow up in AIHA patients was higher (33 vs 16 months; p=0.025). Prothrombotic factors were comparable among both groups, except for recent trauma/surgery (p=0.008), which was more frequent in patients without hemolytic features. We found a thrombosis incidence in AIHA patients of 17.2%; which is consistent with previous studies and comparable to those without hemolytic features (17.2% vs 9.8%; p=0.39. We dismissed the presence of confounding factors (trauma/surgery, warm or mixed autoantibodies) through stratified analysis, finding no statistical significance (p>0.14) on the incidence of thrombosis between AIHA and patients without hemolysis.
Median time to thrombosis from autoantibody identification was shorter in AIHA patients (2 vs 19 months; p=0.16) as 4 of them presented venous thromboembolism (VTE) at diagnosis. VTE in AIHA and patients without hemolysis were pulmonary embolism (5 vs 2); deep vein thrombosis (3 vs 2); and portal vein thrombosis (2 vs 0).

Table 1. Baseline characteristics of patients with an identified anti-RBC autoantibody.

	AIHA (n=59)	Autoantibody without hemolysis (n=41)	p
Baseline characteristics			
Gender, female; n (%)	34 (57.6)	23 (56.1)	.879
Median age (IQR)	72 (56-82)	67 (55-81)	.950
Median follow up, months (IQR)	33 (7-83)	16 (8.5-36)	**.025**
Associated disease, n (%)			
Idiopathic	28 (47.5)	25 (61)	.322
Lymphoproliferative	14 (25.7)	7 (17.1)	.546
Autoimmune disease	10 (16.9)	8 (19.5)	.634
Others (Immunodeficiency, neoplasm)	7 (11.9)	1 (2.4)	.136
Autoantibody characteristics, n (%)			
Warm autoantibodies	48 (81.4)	40 (97.6)	**.025**
Mixed autoantibodies	7 (11.9)	0 (0)	**.039**
Cold agglutinin	2 (3.4)	1 (2.4)	1
Others	2 (3.4)	0 (0)	.511
Prothrombotic characteristics; n (%)			
Elderly age (≥70 years)	30 (50.8)	19 (46.3)	.658
Active cancer	12 (20.7)	8 (19.5)	.886
Previous VTE	1 (1.7)	5 (12.2)	.079
Known thrombophilia	1 (1.7)	3 (7.3)	.304
Recent (≤1 month trauma/surgery)	1 (1.7)	7 (17.1)	**.008**
Acute infection/rheumatologic disorder	12 (20.7)	9 (22)	.880
Obesity (BMI≥30)	16 (27.6)	12 (29.3)	.855
Ongoing hormonal treatment	0 (0)	1 (2.4)	.414
Complications			
Thrombosis; n (%)	10 (17.2)	4 (9.8)	.385
Median time to thrombosis, months (IQR)	2 (0-45)	19 (17.5-21.5)	.161

Summary/Conclusion: Thrombotic events among patients with anti-RBC autoantibody were similar, regardless of the presence of active hemolysis (AIHA). Despite AIHA features and even in the absence of hemolysis, patients with anti-RBC autoantibodies may benefit from a closer follow up in order to prevent thrombosis. Further studies are needed to clear the significance of these autoantibodies in the pathogeny of AIHA related thrombosis.

EP1339 THE CONSEQUENCES OF UNNECESSARY REQUESTING AND REPORTING OF THE DIRECT ANTIGLOBLIN TEST IN NEONATES.

S. Bonney [1,*], E. Pannikodu [2], S. Samani [2], P. Belcher [3], J. McNulty [1], U. Chunara [1]

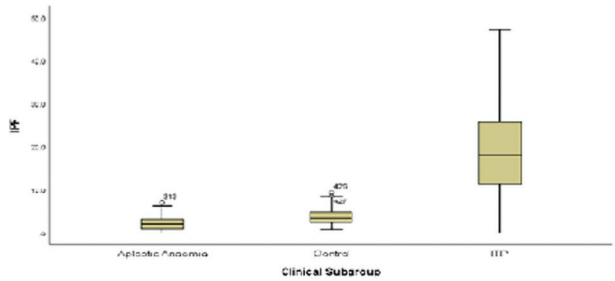
[1]haematolgy and Blood Transfusion Laboratory, [2]Paediatrics, St Helens and Knowsley Teaching Hosptials NHS Trust, St Helens, [3]Paediatrics, Southport and Ormskirk Hospitals NHS Trust, Lanchashire, United Kingdom

Background: BSH (British Society of Haematology) guidelines recommend that the Direct Antiglobulin Test (DAT) is only requested when clinically indicated in neonates. Prophylactic anti-D (PAD) administered routinely to Rh D Negative mothers during pregnancy can cause a positive DAT in the neonate that is not clinically relevant as PAD does not cause significant haemolysis (Dillon *et al.*, 2011, Maayan-Metzger *et al.*, 2001). However, it is common practice for clinicians to request 'Group and DAT' on all cord/heel prick samples that they send to the Transfusion Laboratory.
Aims: To analyse data on DAT testing in neonates performed by the Transfuision Laboratory Service at St Helens and Knowsley Teaching Hosptials NHS Trust (STHK) over a 12 month period. The aim was to establish if the test was clinically indicated and what further intervention a positive result prompted.
Methods: A list of all DATs performened on neonates (< 4 months of age) by the STHK transfusion service from 1st January 2020 to 31st December 2020 was retrospectively gathered. Postive DATs were further investigated to establish the impact of the positive result; clinical indication, additional blood tests, phototherapy, length of stay, folic acid administration and pardiatric consultation/review.
Results: During the audit period, 1745 DATs were performed on neonates at STHK. Of these, 10% (n=169) were postiive. In 80 of the postive cases (47%), the DAT was clinically indicated due to maternal antibodies or neonatal anaemia/jaundice. In over half of the positive DATs (53%) a clinical indication for the tests could not be found in the patients notes yet the mother was Rh D Negative and had recieved PAD during pregnancy. A vast majority of these DAT results were very weakly positive (97%). Half of the neonates with a non-clinically indicated but postive DAT recieved at least one intervention. Interventions included SBR and FBC teasting, folic acid administration, phototherapy, paediatric consult or 2 week review at a paediatirc out patient department.
Summary/Conclusion: The reporting of non-clinically indicated DATs in neonates of mothers who have recieved PAD is a financial burden and leads to unnecessary interventions, such as additional venepuncture and folic acid administration in non-syptomatic neonates. Additional teaching sessions and better policies need to be introduced to reduce this practice. Laboratory staff should also be empowered to question the clinical relevance of DATs if requesters fails to provide clinical details.

EP1340 FACILITATED IMMUNOGLOBULIN (FSCIG) USE IN PATIENTS WITH SECONDARY IMMUNODEFICIENCY DISEASES: TWO-YEAR INTERIM RESULTS FROM THE FIGARO STUDY

M. Dimou [1], D. Huscher [2], C. Hermann [3,*], D. Pittrow [4], M. Speletas [5], M. Borte [6]

[1]First Department of Propaedeutic Internal Medicine, National & Kapodistrian University of Athens Medical School, General Hospital "LAIKO,", Athens, Greece, [2]Institute of Biometry and Clinical Epidemiology, Charité-Universitätsmedizin Berlin, Berlin, Germany, [3]Baxalta Innovations GmbH, a Takeda company, Vienna, Austria, [4]Institute for Clinical Pharmacology, Medical Faculty, Technical University of Dresden, Dresden, Germany, [5]School of Health Sciences Faculty of Medicine, Department of Immunology and Histocompatibility, Medical School Campus - University of Thessaly, Thessaly, Greece, [6]Hospital for Children and Adolescents, St. Georg Hospital; Academic Teaching Hospital of the University of Leipzig, Leipzig, Germany



Background: Secondary immunodeficiency diseases (SID) commonly affect patients with hematological malignancies such as chronic lymphocytic leukemia (CLL) and lymphoma. Immunoglobulin replacement therapy (IGRT) is an important therapeutic option for preventing severe, recurrent, or persistent infections in patients with hematologic malignancies and SID. Facilitated subcutaneous immunoglobulin (fSCIG) is a dual-vial unit of immunoglobulin G (IgG) 10% and recombinant human hyaluronidase (rHuPH20) approved in the European Union as an IGRT for patients with SID. rHuPH20 depolymerizes hyaluronan in the extracellular matrix to transiently increase local subcutaneous tissue permeability, allowing for fSCIG infusion at rates, volumes, and frequencies comparable to intravenous immunoglobulin (IVIG) with better systemic tolerability.
Aims: To assess fSCIG usage and tolerability over time in patients with SID treated in routine clinical practice.
Methods: FIGARO (NCT03054181) is a European multicenter, prospective, observational study. Patients were eligible if they received ≥1 fSCIG infusion for primary immunodeficiency diseases or SID and provided informed consent. Patients are being followed for up to 3 years. An interim analysis (data cut-off date: February 2, 2021) was conducted to evaluate fSCIG usage and tolerability over the first 2 years of follow up in the subgroup of patients with SID.
Results: Of the 156 patients enrolled, 31 (mean [range] age: 61 [3–88] y) had SID and are included in the baseline (inclusion visit) analysis. At interim analysis, 1- and 2-year follow-up data were available for 23 and 12 patients, respectively. Indications for IGRT were CLL (n=20), non-Hodgkin lymphoma (n=6), SID due to immunosuppressive therapy (n=3), and Hodgkin lymphoma (n=2). At the inclusion visit, fSCIG (median total monthly dose: 30.0 g) was most recently infused at home (61%) or at a hospital (36%) by the patient (58%) or a nurse (42%). Most patients received fSCIG every 4 weeks (68%), infused into a single site. The median maximum infusion rate was consistent over the 2-year follow up: 290 mL/h at inclusion, 268 mL/h at 1 year, and 300 mL/h at 2 years. The median infusion volume was 300 mL across all visits to 2 years, with all patients receiving the full dose as planned. Two patients each reported 1 adverse drug reaction (ADR; erythema and headache) at the inclusion visit, with no ADRs reported at any of the follow-up visits. One patient changed to IVIG by 12 months.
Summary/Conclusion: In patients with SID primarily due to hematologic malignancies, fSCIG was tolerated over 2-years' follow up in routine clinical practice and offered the flexibility of administration at home or in a hospital setting, either by the patient or a nurse. Infusion parameters remained consistent over time.

EP1341 ASSESSMENT OF IPF% AS A PREDICTIVE BIOMARKER AND ITS USE IN PREDICTING PLATELET RECOVERY IN THROMBOCYTOPENIC PATIENTS

E. Elhassadi [1,1], A. Hourigan [1,*], B. Hennessy [2], S. kumar [1], D. Murray [1]

[1]Haematology Department, [2]University Hospital Waterford, Waterford, Ireland

Background: Patients with haematological malignancies more commonly present with thrombocytopenia than any other cohort. Early identification of the cause of thrombocytopenia is important to provide timely intervention to decrease the risk of life-threatening bleeding. Sysmex XN analysers allow for the measurement of immature platelet fraction (IPF%), differentiating mature from immature platelets. IPF% has the ability to distinguish between the causes of thrombocytopenia, differentiating decreased platelet production from increased platelet destruction. IPF% also has the ability to predict platelet recovery, reducing unnecessary platelet transfusions in patients where the platelet count would recover without intervention.
Aims: The aim of this project was to determine the efficacy in IPF% in determining the cause of thrombocytopenia and to determine the ability of IPF% to predict platelet recovery in thrombocytopenic patients in UHW.
Methods: 87 thrombocytopenic patients were included over a 13-month period. Patients were divided into two groups; decreased platelet production (n=53) and increased platelet destruction (n=34). Patients with normal FBC parameters (n=100) were included to establish a reference range for IPF%, represented using the 2.5th and 97.5th percentile. Comparison of IPF% amongst each group was carried out using Mann-Whitney U test. Reproducibility of IPF% was assessed by coefficient of variation (CV%) analysis. 14 patients were followed daily through platelet count and IPF% to determine the ability of IPF% to predict platelet recovery. ROC curve analysis was performed to determine the diagnostic cut off point of IPF% in differentiating between ITP and aplastic anaemia. ROC curve analysis was also used to determine the optimal value of IPF% for the prediction of platelet recovery.
Results: IPF% was assessed in patients with ITP, aplastic anaemia and a control group. A statistically significant different in IPF% between ITP and AA patients ($p<0.05$) and the control group ($p<0.05$) was found. ROC curve analysis determined a cut of point of 6.8% for differentiating ITP from AA with a sensitivity of 87% and specificity of 92.9%. To determine the sensitivity and specificity of IPF% in predicting imminent platelet recovery, ROC curve analysis was used. The increase in IPF% for ROC curve analysis was defined as the increase in IPF% from platelet nadir to the peak IPF% prior to platelet recovery. An increase of 2.1% was found to have a sensitivity and specificity of 92% and 96% respectively in predicting platelet recovery within 2 days of increase in IPF%.

Summary/Conclusion: Extensive analysis of the data obtained for this study has shown the benefits to IPF% as a clinical biomarker. Implementation of IPF% as a routine parameter would be beneficial to clinicians in UHW. As a non-invasive biomarker, IPF% would allow clinicians to gain an insight into the cause of thrombocytopenia allowing for prompt decisions regarding treatment strategies without the need for invasive procedures. IPF% as a predictive biomarker would also allow clinicians to defer platelet transfusion if platelet recovery is imminent, avoiding unwarranted platelet transfusions.

EP1342 PEDIATRIC TRAUMA: BLOOD PRODUCT TRANSFUSION CHARACTERISTICS IN A PEDIATRIC EMERGENCY DEPARTMENT

N. Şık [1], A. Uzun [1], A. Öztürk [1], Ö. Tüfekçi [2], S. Yılmaz [2], D. Yılmaz [1], H. Ören [2,*], M. Duman [1]

[1]Pediatric Emergency Care, [2]Pediatric Hematology, Dokuz Eylül University Faculty of Medicine, İzmir, Turkey

Background: Trauma is the leading cause of preventable death in children. Severely injured cases may require transfusion of blood products but no consensus exists regarding optimal blood product use and clear indications for pediatric massive transfusion (MT) activation.
Aims: In this study, it was aimed to investigate clinical and laboratory data, management, and outcomes of pediatric trauma patients who initially received blood product transfusion.
Methods: Children aged 0 to 18 years who presented to the pediatric emergency department due to trauma and underwent and blood product transfusion within 24 hours of arrival between January 2011 and January 2021 were included. Demographics, initial vital signs, clinical findings, laboratory, and radiologic results were recorded. Injury Severity Score (ISS), total volume of transfused blood products and crystalloid boluses in 24 hours were calculated. Patients were divided into two groups according to the fresh frozen plasma (FFP): packed red blood cell (PRBC) ratio: low ratio group as <1:2 and high ratio group as ≥1:2. Massive transfusion was defined as transfusion of ≥40 mL/kg of all blood products in 24 hours. Length of stay in the pediatric intensive care unit (PICU), stay in the hospital and 30-day mortality were recorded.
Results: Thirty-two patients [median age 8.8 years (IQR 2.0-15.1), 20 males (62.5%)] were enrolled. In addition to crystalloid boluses and PRBC transfusion, 19 (59.3%) cases received FFP and among them, 12 cases were transfused with high and 7 cases with low FFP: PRBC ratio. Eight (25.0%) patients met MT threshold criteria. Length of PICU stay, length of mechanical ventilation (MV) and transfusion complication rates were higher for cases who received MT although there was no difference for age, ISS scores, the volume of crystalloid boluses, length of hospital stay, and 4 h, 24 h or 30-day mortality between MT (+) and (-) groups. Children who received transfusion with a high FFP: PRBC ratio were older in age and had a higher ISS score than those who received a low ratio but there was no difference for length of hospital stay or mortality rates between groups. Total volume of crystalloid boluses was higher in patients who died than those who survived but the volume of blood products was similar for two groups. To predict 30-day mortality, multivariable analysis was performed and among parameters of a Glasgow Coma Scale (GCS) score of ≤8, an ISS score of ≥25, having received MT and crystalloid bolus ≥40 mL/kg, a GCS score of ≤8 was identified as a predictor (OR = 21.700, 95% CI: 1.951-243.498, p: 0.012). When we added activated partial thromboplastin time (APTT) to these parameters, then an APTT value of >37.5 seconds was identified as a predictor of 30-day mortality (OR = 48.000, 95% CI: 3.704-621.998, p: 0.003), respectively.
Summary/Conclusion: Children who received MT had longer duration of MV and PICU stay, and higher transfusion complication rates than those who did not receive but there was no significance for ISS scores, the volume of crystalloid boluses, hospital stay or mortality between two groups. Total volume of crystalloid boluses was higher in patients who resulted in death than those who survived although the volume of blood products was similar for two groups. The GCS score and APTT can be used to predict 30-day mortality in pediatric trauma patients.

EP1343 RELATION OF ABO BLOOD GROUP WITH SURVIVAL IN COVID-19 PATIENTS ADMITTED IN HOSPITAL CENTRAL DE LA DEFENSA, MADRID, SPAIN.

M.-T. Calderon-Lopez [1,*], A. M. Sologuren-Sanchez-Ferragut [1], L. Romeralo-Calvo [2], Y. Paredes-Muñoz [2], C. Rojo-Vidal [2], S. Haro-Cañada [2], E. Toledo-Hernandez [2], M. J. Contreras-Agudo [2], S. Gomez-Arevalillo [2], S. Ferro-Perez de Guzman [1], C. Gonzalez-Haro [1], A. Matilla-Garcia [1]

[1]Hematology and Hemotherapy, [2]Blood Bank, Hospital Central de la Defensa Gomez Ulla, Madrid, Spain

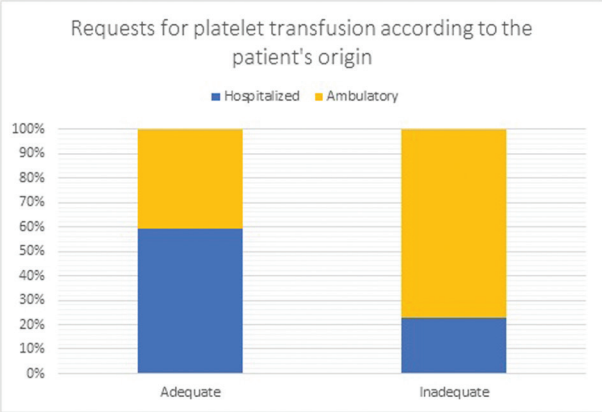
Background: There are some papers reporting a possible link between blood group type and susceptibility to SARS-CoV2 (COVID-19) infection and perhaps even with mortality. They describe a higher risk to develop COVID-19 in individuals with blood type A, whereas those with blood type O would have a lower susceptibility to COVID-19 infection.
Aims: To describe the distribution of the blood groups among the COVID-19 patients admitted in our hospital during the worse pandemic months in our country (March to May) and their relation with survival.
Methods: From March 1st to May 31st 1299 Covid-19 patients were admitted in our hospital (a 520-bed institution); a 27% died. We had the

blood group testing performed in 297 out of the 1299 patients. Those records were in our blood bank software (Delphy®) because of a previous transfusion or a transfusion during the COVID-19 hospitalization. We examined the ABO types among these patients and we compared this data with the frequency observed in the Spanish healthy population according to the Red Cross records of blood donors. Statistical study was performed using the Chi square test (χ^2) and Kaplan-Meier survival curves, by SPSS software.
Results: In the 297 COVID-19 patients admitted in our Hospital with ABO blood type recorded, the 55.2% were men, 44.8% women; median age was 79 (21-103).
We found a higher percentage of blood type A and a lower of O among the COVID-19 patients, compared with the prevalence of those blood groups in Spanish healthy population, but that difference was not statistically significant. Regarding survival curves among different blood groups, we found a decreased mortality in patients with O blood type (25.2%) compared with the rest of groups (34.5%). That difference was close to be statistically significant (p 0.08), showing a clear tendency that could be maybe significant with a bigger group of patients.
Summary/Conclusion: The distribution of the blood group in COVID-19 admitted patients in our hospital is similar to data already published: a higher rate of COVID-19 infection in patients with blood type A and a lower rate of type O. We also found lower mortality in our patients with O blood type; with a special signification when we compare O with the rest of blood groups together. There are some literature describing that anti-A antibodies could be protective against COVID-19 infection; this could explain the tendency we found of better survival in patients with O blood type.

EP1344 BLOOD DONATION AND IRON SUPPLEMENTATION IN NIGERIA THE RANFERON STUDY

T. Nwagha [1,*], A. Ugwu [1], H. Okoye [1]

[1]Haematology & Immunology, University of Nigeria Teaching Hospital, Enugu, Nigeria



Background: Regular blood donation depletes Iron. Uncompensated iron loss may eventually lead to iron deficiency anaemia. Approximately 25 to 35% of blood donors who donate blood 3-4 times yearly become iron depleted. Iron deficiency anaemia is an important limiting factor to a sustainable supply of blood units especially in LMIC. Blood transfusion practice in Nigeria is poorly developed and structured with paucity of non-remunerated blood donors and high rate of donor deferrals resulting from transfusion transmitted infections and low haemoglobin levels. There is need to protect the donor pool to meet the blood needs in resource poor countries.
Aims: We aimed to assess the effect of daily supplementation of iron using Ranferon-12 on RBC indices, Iron level, ferritin level and Hb recovery in blood donors in Nigeria.
Methods: We carried out an interventional study at the University of Nigeria Teaching Hospital blood transfusion center from March to July 2020. Study participants (blood donors) were randomized into two groups. Group A (control group): blood donor who did not donate a unit of blood and did not receive iron supplementation. Group B (experimental group): blood donors who donated a unit of blood and received iron supplementation (Daily Ranferon capsules containing 100mg elemental iron; iron fumarate) and 100mg of tablet vitamin C for 6 weeks. The primary outcome measure were levels of Haemoglobin (Hb), Packed cell volume (PCV), red cell indices (Mythic 22 haematology analyzer) Serum ferritin (Abbott 1000isr), Total body iron Beckman Coulter AU680) Soluble transferrin receptor (sTfR), and percentage iron saturation was calculated
Secondary outcome measure were adherence/compliance and tolerance to daily iron supplementation using Ranferon using Modified Morisky scale and investigator designed pretested, pre validated questionnaire, respectively.
The study was approved by UNTH REC with ethical approval number NHREC/05/01/2008B-FWA00002458-1RB00002323
Results: A total of 90 blood donors participated in the study, 30 was randomized to the control group and 60 to the experimental group. Majority (52.2%) were less than 24 years and Most (95.6%) were males. Only the mean difference in mean cell haemoglobin concentration (MCHC) and soluble transferrin receptor (sTfR) before and after iron supplementation were statistically significance with p values of 0.030 and<0.001, respectively.
The relationship between only the mean difference in red cell count (RCC), packed cell volume PCV), red cell indices, % iron saturation and soluble transferrin receptor (sTfR) and iron supplementation were statistically significant with p values <0.001.
Percentage recovery of the parameters after 6 weeks of daily Ranferon range from 89 to > 100%. The percentage recovery of Hb level was 89% while others were more than 89%.
Six participants (10%) were iron replete before the intervention with daly Ranferon with only one participant (1%) remaining iron replete after the intervention.
Only one participant (1.7%) reported GIT intolerance while on daily iron supplementationwith Ranferon. Majority, (95%), (93.3%) responded NO to "the participant takes less/more medicine than instructed" and NEVER to "The participant alters the dose of his/her medicine."
Summary/Conclusion: Iron supplementation using Ranferon capsule daily for 6 weeks enhanced the recovery of haemoglobin (Hb), red cell indices post blood donation with attainment of benchmark haemoglobin levels for donation.

EP1345 AUDIT OF PLATELET TRANSFUSION IN A LARGE UNIVERSITY HOSPITAL: HOW CAN WE IMPROVE PLATELET TRANSFUSION?

P. López De Ugarriza [1,*], A. Porro Camarero [1], M. Á. Fernández Rodríguez [1], E. Martínez Revuelta [1], J. M. García Gala [1]

[1]Haematology and hemotherapy, Hospital Universitario Central de Asturias, Oviedo, Spain

Background: According to the literature, up to 20% of platelet transfusions are considered inadequate, increasing platelet consumption and exposure to patients at risk.
Aims: The objective of this study is to know the incidence of inadequate platelet transfusion in our center and to determine areas of improvement.
Methods: Platelet transfusions performed in November 2020 at our center were reviewed retrospectively. Each transfusion was considered independently. Intra-operating room requests were excluded. Criteria of appropriate platelet transfusion set in the Guide on the Transfusion of Blood Components and Plasma Derivatives of the Spanish Society of Blood Transfusion and Cell Therapy (5th ed) were used: stable patients with central thrombocytopenia and platelet <10x10^9/L, platelets <20x10^9/L in non-stable patients (> 38 Celsius degrees fever, signs of ≥ WHO grade 2 haemorrhage), platelets < 50x109/L in patients who will undergo major surgical and/or invasive procedures or have signs of ≥ WHO grade 3 bleeding and platelets is < 80x10^9/L in case of central nervous system or eye involvement.
Results: Our center is a tertiary University Hospital with a large Stem Cell Transplantation program and important cardiac surgery department. 335 transfusion episodes were reviewed in 86 patients with mean age of 55 years (0-90). It involved 476 units of platelets. 49.4% were women (165/335), 78.5% (263/335) were indicated by the Hematology service and 11.4% (38/335) because of surgical procedures. 283 transfusions (84.4%) were performed in hospitalized patients compared to 52 (15.5%) outpatients. In 5 patients (5.8%) tranexamic acid was associated. 86% (288/335) of platelet transfusions were correctly indicated while 14% (47/335) did not meet the criteria described above, 29 patients (33%) were inadequately transfused with 49 platelet units (10,6% of total). No significant differences were found with respect to the requesting service. The main indication of platelet transfusion was stable thrombocytopenias with platelet values between 10x10^9/L and 20x10^9/L and it is this indication that has the highest frequency of inadequate transfusion. A significant difference was observed in the percentage of units suitable indications in outpatients versus admitted (40% vs 12%, p <0.005).

Summary/Conclusion: There is a high percentage of inadequate platelet transfusions, similar to the incidence referred in the literature. The main area of improvement is transfusion in outpatients. The development of training programmes and prescription aid systems can help to improve these outcomes.

EP1346 CONVALESCENT PLASMA FOR COVID-19. OUR EXPERIENCE.

D. Cubillas [1,*], M. I. Saez [1], M. P. Martin [1], E. Bolaños [1], B. Iñigo [1], F. Medina [1], A. Alfayate [1], M. Menendez [1], M. A. Mora [1], C. Benavente [1]

[1]Hospital Clinico San Carlos, Madrid, Spain

Background: Passive immunotherapy has been widely used previously to treat severe acute respiratory syndrome (SARS), Middle East respiratory syndrome, Influenza A and Ebola virus disease with encouraging results. The use of convalescent plasma against SARS-CoV-2 has been suggested as one of the treatments of patients with coronavirus disease 19 (Covid-19), specially as an early intervention.
Aims: We assess the security and efectivity of the treatment with CP in severe or potentially severe covid-19 disease.
Methods: We collect the data of all patients with Covid-19 who were treated with covalescent plasma (CP) in our hospital from April 2020 to February 2021. First of all, we assess the security of CP transfusion and then, we assess the efectivity of the CP transfusion.
We assess the mortality rate in this patients by precocity of plasma transfusión, sex and WHO Ordinal Scale for Clinical Improvement.
Results: Between April 2020 and February 2021, a total of 44 patients with Covid-19 were treated with CP in our hospital. 77.27% (n=34) were male and 22.73% (n=10) were female with a median age of 65 (28-92). Mortality rate by sex was 32.35% (n=11) in male and 30% (n=3) in female. In terms of security one of the patiens developed a mild rash that was managed with antihistamine and had a complete resolution.
In terms of precocity of CP administration we separated the patients into two different groups. The first one, with those patients who had an early CP transfusion (ten days or less after symptom onsent) and the second one, with patients who had a late CP transfusion (more than ten days after symptom onsent). 56.80% (n=25) had and early CP administration, while 43.20% (n=19) of the patients had a late one. Mortality rate in the first group was 16% (n=4) and 52.63% (n=11) in the second one. According to the WHO Ordinal Scale for Clinical Improvement, patients with a score of 6 (intubated or mechanical ventilation) or higher were 12; patients with a score of 5 (non-invasive ventilation or high-flow oxygen) were 13, and patients with a score of 4 (oxygen by mask or nasal prongs) were 19. In our center, the mortality rate of these groups of patients was 50% (n=6), 38% (n=5) and 16% (n=3) respectively.
Summary/Conclusion: In this 44 patients group, the administration of CP has had an adverse event rate very low, similar to non convalescent plasma trasfusion adverse event rate.
In those patients who had an early CP transfusion, the mortality rate is much lower than those who had a late CP transfusion. Possibly the elapsed time from symtom onset is the most important factor to assess efectivity.
Mortality rate by WHO Ordinal Scale for Clinical Improvement shows differences between groups. Those patients with a higher score present higher mortality rates, probably similar to patients with Covid-19 treated with other therapeutic options.
The mortality rate by sex was similar in both groups as we can observe in other studies.
An early CP administration could be a therapeutic option in severe patients with Covid-19 considering that is a safe procedure that can improve survival rates.

EP1347 THE RESULTS OF SCREENING AND IDENTIFICATION OF RED BLOOD CELLS ANTIBODIES IN HEMATOLOGICAL PATIENTS AND BLOOD DONORS

E. Butina [1,*], E. Poponina [1], A. Yovdiy [1], F. Sherstnev [2]

[1]immunohaematology, [2]Tranfusiology, Federal State Institute of Science "Kirov research Institute of Hematology and Blood Transfusion of the Federal Medical and Biological Agency of Russia", Kirov, Russian Federation

Background: Alloimmunization to antigens of red blood cells (RBC) can cause the development of post-transfusion complications and hemolytic disease of the fetus and newborn. Prevention of the emergence of alloantibodies during transfusion of blood components consists in the selection of RBC that are compatible with the recipient by phenotype. Since 2013, the Russian Federation has regulated the selection of RBC for all patients with diseases of the blood system for antigens ABO, RhD, C, c, E, c, K.
Aims: Determine the level of RBC alloimmunization of the healthy population (donors of blood components) and patients of the hematological hospital; to establish the value of donor selection for Rhesus antigens for the prevention of alloimmunization of recipients.
Methods: The analysis of the results of screening and identification of RBC antibodies was carried out in 2546 donors who first came to the blood center and 2729 patients who were first admitted to the hematology clinic in 2014-2020. Non-Hodgkin lymphoma (NHL) was diagnosed in 560 patients, acute leukemia (AL) - in 472, multiple myeloma (MM) - in 398, chronic lymphocytic leukemia (CLL) - in 188, aplastic anemia (AA) - in 100, chronic myeloid leukemia (CML) - in 92, MDS - in 78, hemophilia - in 65, other hematological diseases - in 776. Immunohematological studies were performed using equipment and reagents from BioRad (USA).
Results: RBC alloantibodies were detected in 0.98% of blood donors: in 0.24% of men and in 1.69% of women ($p < 0.01$). Alloantibodies were distributed according to specificity as follows: anti-D (0.27%) > -Le^a (0.20%) > -DC (0.16%) > -C^w(0.08%) > Jk^a (0.04%), -Jk^b (0.04%), -Fy^a (0.04%), -M (0.04%), -S (0.04%), -P_1 (0.04%).
Specific alloantibodies were diagnosed in 1.80% of hematological patients: in 1.26% of men, in 3.14% of women, and in 0.50% of children ($p < 0.01$). Alloimmunization was established in 5.43% of patients with CML, in 4.62% - hemophilia, in 3.85% - MDS, in 2.75% - OL, in 1.76% - MM, 1.61% - NHL, 1.06% - CLL, 0% - AA, in 0.9% of patients with other blood diseases.
The scale of the occurrence of specific antibodies in patients is as follows: anti-E (0.26%) > -M (0.22%)> -K (0.18%) > -DC (0.15%), -Le^a (0.15%) > -D (0.11%), -Jk^a (0.11%), -Lu^a (0.11%) > -C (0.07%), -c (0.07%), -Fy^a (0.07%), -S (0.07%), -Le^b (0.07%) > -Jk^b (0.04%), -C^w (0.04%), -s (0.04%), -P_1 (0.04%).
When comparing the data obtained with the results of our previous studies, a decrease in the level of alloimmunization of patients of the hematological clinic was found from 2.31% (in 2007 - 2013) to 1.80% (in 2014 - 2020), which is associated with the beginning of the mandatory selection of RBC for hematological patients for antigens C, c, E, c of the Rhesus system since 2014.
Summary/Conclusion: The frequency of detection of alloantibodies in patients of the hematology clinic remains high, twice as high as the level of alloimmunization in healthy individuals. Phenotypic selection of RBC is an effective method of preventing the formation of antibodies, which reduces the percentage of alloimmunization in hematological patients.

EP1348 REMOTE MONITORING OF VITAL AND ACTIVITY PARAMETERS IN CHRONIC TRANSFUSION DEPENDENT PATIENTS – A CASE-CROSSOVER PILOT USING WEARABLE BIOSENSORS

R. Tonino [1,2,3,*], M. Tweardy [4], S. Wegerich [4], J. J. Zwaginga [1], M. Schipperus [2,5]

[1]Hematology, LUMC, Leiden, [2]Hematology, HagaZiekenhuis, Den Haag, [3]TRIP, Leiden, Netherlands, [4]Physiq, Chicago, United States, [5]Hematology, UMCG, Groningen, Netherlands

Background: Optimising red cell transfusion requires an understanding of both the risks and the benefits. Adverse events of red cell transfusions, like transfusion reactions and iron overload are reasons for considering a restrictive transfusion strategy. However, there are no completed trials in the outpatient setting for chronic transfusion-dependent patients, and little data in general about the value of outpatient transfusions. With no objective parameters to measure the benefits of red cell transfusions, a restrictive transfusion strategy may not be optimal for patients who require RBCT on a regular basis. Transfusions are ordered primarily based on haemoglobin concentrations and a subjective interpretation of symptoms of anaemia. Endpoints that may be more clinically relevant include quality of life measurements, vital signs, functional activity and cognition. To date, there has been little systematic assessment of tools that assess these measures and no published trials that have examined the impact of transfusions on functional outcomes in transfusion-dependent patients.
Aims: The aim of this study is to understand how wearable devices and web-based testing can be used to measure physiological changes and functional activity in a cohort of transfusion-dependent patients.
Methods: We monitored 5 patients who chronically receive transfusions during one transfusion cycle with the VitalPatch® and Withings Steel HR. Patients completed CANTAB cognitive tasks, QUALMS and PROMIS quality of life questionnaires through web-based testing. Outcomes were first the quality and usability of data. Second, we leveraged mixed models to evaluate transfusion-induced changes in 1) heart rate, 2) activity, 3) sustained attention, and 4) patient-reported quality of life.
Results: Captured data was 97,8% high quality and usable for the VitalPatch; 98,9% for the Withings Steel HR. The sent out web-based CANTAB tasks and questionnaires were all completed on the appointed days. Heart rate and sustained attention are significantly and reversibly affected by RBC transfusions, corrected for predefined confounders (Fig. 1): Mean daytime heart rate was 76.5±2.8 bpm before and 72.3±2.8 after transfusion (*P*=0.002). Sustained attention (RVPA) increased from 8586±140 to 9141±183 after transfusion (*P*=0.004). Activity and quality of life measures did not yield transfusion-induced changes. The measured activity data may not be representative as the study was conducted during the COVID-19 induced lockdown.

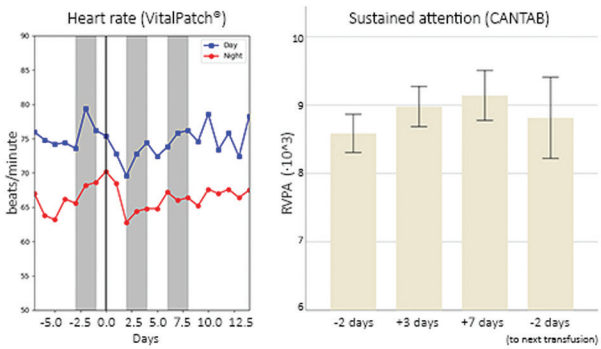


Figure 1. Mean heart rate as measured by the VitalPatch® per day/night (left) and mean RVPA per visit (right). A reversible transfusion-induced effect on heart rate and cognition is depicted. No data beyond day 14 is shown because 2/5 patients received another transfusion at day 15. Data summarized as visits for mixed models are shown as grey areas, transfusion is at day 0. CANTAB web-based cognitive tests (RVPA) were completed on the 4 appointed visits.

Summary/Conclusion: AccelerateIQ™, Withings Steel HR and the CANTAB platform are usable for extracting and analysing data. Red cell transfusions significantly and reversibly decrease heart rate and increase sustained attention in our cohort of 5 red cell transfusion-dependent patients.

EP1349 PHENOTYPIC AND FUNCTIONAL AGGREGATION FEATURES OF LEUKOCYTE-DEPLETED PATHOGEN-REDUCED PLATELETS OBTAINED BY AUTOMATIC APHERESIS

V. Verameeva [1,*], E. Dashkevich [1], J. Peshnyak [1], N. Goncharova [1], L. Moroz [1], N. Bukhvald [1], O. Bondaruk [1]

[1]*RSPC for Transfusiology and Medical Biotechnologies, Minsk, Belarus*

Background: Any technological procedure influences the functional activity of platelets. Therefore, to standardize the quality of platelet components (PLTCs), it is important to assess its phenotypic and aggregation properties. According to the immunophenotypic profile of platelets, one can judge its structural integrity and functional activity.
Aims: To study some phenotypic and functional features of leukocyte-depleted (LD) pathogen-reduced platelets obtained by automatic apheresis.
Methods: Phenotypic and functional characteristics were studied on 64 samples obtained from 32 donors of PLTCs. Platelet samples obtained from wholeblood before apheresis, prepared with 3.8% sodium citrate (n = 32) and obtained by automatic apheresis, pathogen-reduced LD (INTERCEPT (n = 23) and MIRASOL (n= 9)) were studied. The expression of adhesion molecules CD 62P, integrin complex (CD41 / CD61) and platelet activation marker CD36 was assessed using flow cytometry. The studies of the functional aggregation activity of platelets were carried out by theturbidimetric method. Statistical analysis was performed using the STATISTICA v.10software. To assess the quality of the functional aggregation activity of platelets by an opticalturbidimetric method, LD pathogen-reduced PLTCs obtained by automatic apheresiswere diluted to a standard platelet concentration (200-250 thousand / μL) with a poolof platelet-free universal plasma obtained from male donors AB (IV) blood groupRhesus (D)-negative in a ratio of 1: 3 (PLTCs: AB (IV) Rh (D)-negative (diluent))and incubated for 20-30 min.
Results: The ADP-induced (2.5 μM; 5 μM) platelets aggregation activity before apheresis was 48.1 (36.5; 65.8)% and 66.9 (55.6; 75.7)% respectively, which was significantly higher ($p < 0.05$) than one on the 1st day in LD pathogen-reduced platelets obtained by the method of automatic apheresis. The ADP-induced platelets aggregation activity of that PLTC was 7.5 (1.2; 12.3)% for plain and 10 (7.0; 15.4)% for diluted PLTC in case of 2.5 μM ADP and 15.7 (7.1; 20.1)% for plain and 19.4(14.3; 27.1)% for diluted PLTC in case of 5 μM ADPA statistically significant positive correlation was found in platelet samples from whole blood before apheresis between indicators of the ADP-induced (5 μM) platelet aggregation activity 66.9 (55.6; 75.7)% and the relative number of cells expressing CD62P 13.1 (6.4; 20.7)% ($R = 0.82$, $p = 0$). A similar positive correlation was determined in LD pathogen-reduced PLTCs afterapheresis which were stored for one day in a thermal shaker at 22 ± 20 C diluted with plasma. In that case ADP-induced (5 μM) platelet aggregation activity was 19.4(14.3; 27.1))% and the relative number of cells expressing CD62P 13.9 (8.0; 19.1)% ($R = 0.36$, $p = 0.003$)
Summary/Conclusion: Thus, a positive statistically significant correlation was revealed in ADP-induced (5 μM) platelet aggregation activity and the relative number of cells expressing P-selectin (CD62P) for LD pathogen-reduced PLTCs after apheresis after dilution with plasma and one day storage. The data obtained allow us to consider indicators for assessing the aggregation activity of platelets as one of thecharacteristics of quality control of platelet components.

Acute lymphoblastic leukemia - Biology & Translational Research

PB1350 NRF2 AS A THERAPEUTIC TARGET IN ACUTE LEUCEMIA – IN VITRO STUDIES WITH OLTIPRAZ

N. Magalhães [1,2], D. Figueiredo [2], R. Alves [2,3,4,5,*], D. Roque [1,2], M. I. Costa [2], E. Gomes [2], J. Jorge [2,3,4,5], B. Lapa [2,3,4], J. Nascimento Costa [3,4,5,6], A. C. Gonçalves [2,3,4,5], A. B. Sarmento-Ribeiro [2,3,4,5,7]

[1]Chemistry Department, Faculty of Science and Technology, University of Coimbra (FCTUC), [2]Laboratory of Oncobiology and Hematology, [3]Coimbra Institute for Clinical and Biomedical Research (iCBR) – Group of Environment, Genetics and Oncobiology (CIMAGO), Faculty of Medicine, University of Coimbra (FMUC), [4]Center for Innovative Biomedicine and Biotechnology (CIBB), University of Coimbra (UC), [5]Clinical Academic Center of Coimbra (CACC), [6]University Clinic of Oncology, Faculty of Medicine, University of Coimbra (FMUC), [7]Clinical Hematology Department, Centro Hospitalar e Universitário de Coimbra (CHUC), Coimbra, Portugal

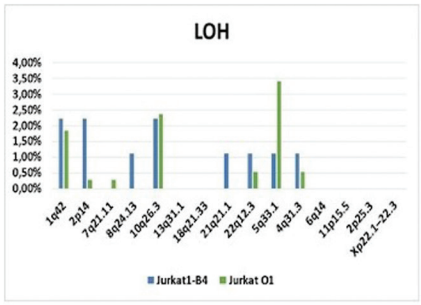
Background: Acute leukemias are a group of hematological neoplasias characterized by a dysregulation in cell proliferation and/or an arrest in the differentiation process of hematopoietic stem cells. Oxidative stress (OS) has been referred as one of the mechanisms involved in the pathophysiology of these diseases. The OS state consists in an unbalance between the production of reactive oxygen species (ROS) and the ability to neutralize them by antioxidant defenses. The nuclear factor erythroid 2–related factor 2, NRF2, is a transcription factor (TF) that regulates the expression of several antioxidants and detoxification systems and works as a protective mechanism in normal cells against malignant transformation. However, during the tumorigenic process, NRF2 protects tumor cells from OS effects compromising the therapeutic efficacy. Based on this, the modulation of this transcription factor may represent a therapeutic approach in acute leukemias.
Aims: The aim of this study was to investigate the therapeutical potential of the NRF2 modulator Oltipraz (Olt) in acute lymphoblastic leukemia (ALL) and acute myeloblastic leukemia (AML) cell lines.
Methods: To this propose, 3 ALLs cell lines, two from T lineage (CEM and MOLT-4 cells) and one B lineage (KOPN8 cells), and two AML (HEL and NB4 cells) were incubated in the absence and presence of Oltipraz in several concentrations for 72h. Metabolic activity was evaluated by resazurin assay. Cell death was assessed by flow cytometry (FC), using the Annexin V and 7-AAD double staining, and by optic microscopy (May-Grünwald-Giemsa staining). Cell cycle analysis was evaluated by FC using a PI/RNAse solution. The intracellular levels of ROS and GSH were quantified by FC (DCFH2-DA, DHE, and MO probes). JC-1 probe was used to determine the mitochondrial membrane potential (Y_{mit}) by FC. The statistical analysis was performed, considering a significance level of 95%.
Results: Oltipraz reduced metabolic activity in a time, dose, and cell line-dependent manner. After 72h of incubation, B-ALL cell line was the most sensitive to Olt (KOPN8 IC_{50}= 4.5µM) comparing to T-ALL (MOLT-4 IC_{50}= 87.4µM; CEM IC_{50}= 40.4µM) and AML (HEL IC_{50}= 63µM, NB4 IC_{50}= 21µM) models. This drug induced a cytotoxic effect mediated by apoptosis in AML cells. It was also observed a cytostatic effect in B-ALL cells, with a cell cycle arrest in G_0/G_1 phase, and in AML cell lines with a cell cycle arrest in S phase. Moreover, Olt increased the intracellular levels of ROS and ROS/GSH ratio and decreased the mitochondrial membrane potential (□mit) in all cell lines. These results support the role of OS and mitochondria dysfunction in the therapeutic effects mediated by Oltipraz in acute leukemias.
Summary/Conclusion: Our results demonstrate that lymphoid and myeloid acute leukemias were sensitive to NRF2 modulation using Oltipraz, suggesting that this drug may constitute a new therapeutic approach in these hematological neoplasms. However, the drug efficacy is cell type dependent and could be also related with molecular/genetic characteristics of the leukemia.
This work was supported by FMUC, CIMAGO and FCT (SFRH/BD/145531/2019).

PB1351 THE ROLE OF CASPASE-8 (CASP8) AND -10 (CASP10) GENE POLYMORPHISMS IN CHILDREN AND ADOLESCENTS WITH ACUTE LYMPHOBLASTIC LEUKEMIA

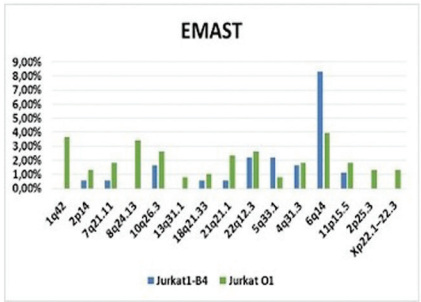
M. Lourou [1,*], M. Zervou [2], E. Ampazoglou [1], I. Pelagiadis [1], N. Katzilakis [1], G. Goulielmos [2], E. Stiakaki [1]

[1]Pediatric Hematology-Oncology, School of Medicine, University of Crete, University Hospital of Heraklion, [2]Molecular Pathology and Human Genetics Section, School of Medicine University of Crete, Heraklion, Greece

Background: In the past 50 years great advances have been achieved in the management and prognosis of Acute Lymphoblastic Leukemia (ALL) in children, resulting in improved treatment outcome of up to 90%. However ALL still remains a major cause of morbidity and mortality in children, specially in disease relapse.Major progress has been made in the last decade in understanding the biology of ALL, the genetic basis of leukemogenesis and the response to treatment. Epidemiological studies of possible risk factors in acute leukemia, proved that genetic factors play a crucial role in leukemogenesis. Alterations in the regulation of apoptosis and the deregulation of expression or function of caspase antagonists' pathways seem to play an important role in the pathogenesis and progression of hematological malignancies. Caspases are a family of cysteine proteases whose functions are strongly associated with programmed cell death. Polymorphisms in the apoptotic genes may enhance the risk of disease, as implicated by the strong link between genetic diversity and susceptibility to ALL. Caspase 8 plays an important role in apoptosis and several studies have been performed to identify the relationship between polymorphisms in *Casp8* gene and different types of cancer. Caspase 10 is the only caspase that shares homologous death–effector domains with caspase 8, while somatic mutations in *Casp10* gene have been observed in many cancers.
Aims: The purpose of the present study was to investigate the incidence of rs1045485 polymorphism in exon 10 of the caspase 8 gene and rs13006529 in exon 10 of the caspase 10 gene in children and adolescents with Acute Lymphoblastic Leukemia compared with healthy individuals.
Methods: The patient group consisted of 50 children and adolescents (1.5 to 17.5 years) with ALL and the control group consisted of 100 healthy individuals. Genomic DNA was isolated from periphral blood of participants and the genetic regions harboring the single nucleotide polymorphisms (SNPs) under investigation were amplified with Polymerase Chain Reaction. The PCR product was then digested with the appropriate restriction enzymes (*BstU*I for rs1045485, *Ssp*I for rs13006529). Statistical analysis was performed by using the GraphPad Prism (GraphPad Software, San Diego, CA, USA) program.
Results: Statistic analysis showed an association between the G allele of *Casp8* rs1045485 SNP and ALL (p=0.0002, OR=0.381, 95% 0.229-0.633). Statistically significant differences were found between AT and TT genotypes of rs13006529 SNP of *Casp10* and ALL (p=0.011, OR=4, CI 95% 1.382-11.380 and p=0.048, OR=0.346, CI 95% 0.127-0.937, respectively), as well as between T allele of the same SNP and ALL (p<0.0001, OR=0.345, CI 95% 0.205-0.578).
Summary/Conclusion: The present study showed that both rs1045485 SNP of *Casp8* and rs13006529 SNP of *Casp10* are associated with the diagnosis of ALL. Further study of these polymorphisms in children and adolescents with ALL would be of great interest, in order to confirm whether they are associated with the disease in the population of Greece.



PB1352 ¬HIGH FREQUENCY OF SPONTANEOUS LOSS OF HETEROZYGOSITY AND ELEVATED MICROSATELLITE ALTERATION AT SELECTED TETRANUCLEOTIDES IN LEUKEMIA CELLS STR-PROFILES: IN-VITRO TESTING OF LYMPHOBLASTOID CELL LINES



N. Risinskaya [1,*], O. Glinshchikova [1], T. Makarik [1], Y. Kozhevnikova [2], A. Borisova [1], T. Obukhova [1], A. Sudarikov [1]

[1]National Research Center for Hematology, [2]School of Medicine, Lomonosov Moscow State University, Moscow, Russian Federation

Background: The frequency of spontaneous mutagenesis of tetranucleotide microsatellites (STR) in the human population is less than 0.3% for most of STR loci [https://strbase.nist.gov/str_fact.htm]. The frequency of these events during leukemia cell development could hardly be measured by means of testing clinical specimens. However, these data could be assessed

by in vitro culturing and cloning experiments with common lymphoblastoid cell lines and could be useful for investigating possible associations of instability in certain chromosomal loci with the disease features in ALL.
Aims: To evaluate frequency of STR profile mutations during long term culturing of Jurkat and WIL2-S cell lines after cloning by limiting dilutions.
Methods: Jurkat is an immortalized T lymphocyte cell line originally obtained from the peripheral blood of T cell leukemia patient. WIL2-S is an immortalized B lymphoblast cell line derived from the spleen of the patient with hereditary spherocytosis. Cell lines were cultured in RPMI 1640 medium. Cells were cloned by the method of limiting dilutions; 21 individual clones of WIL2-S and 18 Jurkat clones were taken for STR profiling. Clone WIL2-S #11 was karyotyped, further cloned and 350 subclones were STR profiled. Jurkat1-B4 clones (with stable STR-profile comparing with STR-profile of Jurkat cell line) and Jurkat-O1 (Y loss and 12p13.2 LOH in relation to Jurkat cell line) were also karyotyped, further cloned and 180 subclones of Jurkat1-B4 and 381 subclones of Jurkat-O1 were STR profiled. STR-profiles were assessed by PCR with COrDIS Plus multiplex kit for amplification of 19 polymorphic STR-markers and amelogenin loci (Gordiz Ltd, Russia). The fragment analysis was performed on ABI 3130 Genetic Analyzer. The data processing was accomplished using GeneMapper v.4-0 software.
Results: Out of 18 Jurkat clones, 7 have marker loss on Y-chromosome (amelogenin locus); 5 have LOH on 12p13.2 (3 of these clones also have amelogenin Y loss) one clone - LOH on 4q; one — on 5q33.1; and one - on 8q. Elevated Microsatellite Alteration at Selected Tetranucleotides (EMAST- change in the length of STR markers) was found in 10 clones. Only 4 clones retained exactly the same STR profile of initial Jurkat stock sample. Out of 21 WIL2-S clones, EMAST was found in 4 clones only. One clone lost the amelogenin Y marker. Out of 350 subclones of WIL2-S STR-stable clone #11, only two (0.57%) were found to lose the Y-chromosome amelogenin marker. One LOH at 10q26.3 was seen in one of 350 clones (0.29%) only. For Jurkat line LOH was seen in 26 from 180 Jurkat1-B4 subclones (14.4%) and in 35 from 381 Jurkat-O1 clones (9,1%). EMAST was found in 45 from 180 (25%) B4 and 111 from 381 O1 subclones (29%) respectively. While EMAST appears uniformely along different STR-markers, LOH frequency for distinct STR-loci differs and seems to be a feature of certain acute T-cell leukemia (See Fig.1 LOH and EMAST frequencies for different loci in Jurkat 1-B4 and Jurkat-O1 subclones. *STR loci at 3p21.31, 5q23.2, 16q24.1, 12p13.31 are homozygous in Jurkat cell line). Only 60% of Jurkat1-B4 and 64% Jurkat-O1 subclones were found STR-stable. No significant difference was found in mutation frequencies in stable initially Jurkat1-B4 and mutated Jurkat-O1 clones.

STR-marker	Locus
D1S1656	1q42
D2S441	2p14
D3S1358	3p21.31
D5S818	5q23.2
D7S820	7q21.11
D8S1179	8q24.13
D10S1248	10q26.3
D12S391	12p13.2
D13S317	13q31.1
D16S539	16q24.1
D18S51	18q21.33
D21S11	21q21.1
D22S1045	22q12.3
CSF1PO	5q33.1
FGA	4q31.3
SE33	6q14
TH01	11p15.5
TPOX	2p25.3
VWA	12p13.31
Amelogenin X	Xp22.1–22.3
Amelogenin Y	Yp11.2

Summary/Conclusion: Jurkat T lymphocyte leukemia cell line demonstrated a high level of spontaneous LOH in selected loci and EMAST spreading equally through genome. More detailed STR profile testing on extended samples of in vitro cultured cell clones might identify more detailed patterns of spontaneous chromosomal instability in lymphoblastoid cells.

PB1353 PATHOGENETIC ROLE OF TUMOR NECROSIS FACTOR (TNF) AND TRANSFORMING GROWTH FACTOR B1 (TGFB1) IN THE CHANGING OF ADHESIVE PROPERTIES OF VASCULAR ENDOTHELIUM (VE) IN ACUTE LEUKEMIA (AL)

V. Barilka [1,*], V. Matlan [1], S. Prymak [1], O. Shalay [1]

[1]*Laboratory of Immunology and Cytogenetics of Blood Neoplasms, SI "Institute of Blood Pathology and Transfusion Medicine of National Academy of Medical Science of Ukraine", LVIV, Ukraine*

Background: Adhesion of acute leukemic cells (blasts) to the VE was significantly influenced by TNF and TGFβ1. TNF and TGFβ1 often accumulated in the blood of AL pts and correlated with the negative course of the AL. The pathogenetic role of cytokines in the spread of the AL has not been definitively established.
Aims: The aim of our investigation was to determine the role of TNF and TGFβ1 in changing the adhesive properties of the VE in 9 primary patients (pts) with AL (6 pts with ALL and 3 - AML).
Methods: Median of pts age was 68 years. The number of blasts in peripheral blood - 58,62±10,53%. We identified the attachment of labeled by ^{3}H-thymidine cells lines K562, L1210 to the monolayer of human umbilical vein endothelial cells (HUVECs) *in vitro* after treated of plasma or 24 h-conditional mediums (CM) of blasts from blood pts, and to compare obtained data with concentration of TNF and TGFβ1 in the experimental samples. We also evaluated the effect of different doses of rhTGFβ1, rhTNF on the adhesive properties of HUVECs. Doses of rhTNF and rhTGFβ1 were selected according to the determined in plasma and CM of blasts from AL pts. The level of TNF and TGFβ1 was detected by bioassays using L929 and CCL64 in accordance. The attachment of K562, L1210 to HUVECs was estimated by the index of adhesion (IA). K562, L1210 were not activated before the investigation.
Results: TNF and TGFβ1 levels in plasma of AL pts were higher than in healthy donors (p<0,001). Plasma showed more strong influence on adhesion to HUVECs of K562 cells (IA=2,37±0,24), in comparison to L1210 (IA=1,28±0,8; p<0,05). Nevertheless TGFβ1 levels in CM of blasts AL pts was two-fold higher than in plasma of AL pts and inversely correlated with blasts number (r= - 0,40). Blasts of AL pts influenced on adhesive activity of HUVECs to K562 and L1210 (IA=1,99±0,38 and 1,92±0,24, respectively). CM of blasts secreted higher level of TGFβ1, than it was in plasma pts (p<0,05) We found that low concentrations (0,01 up to 2,40 ng/ml) of rhTGFβ1 stimulated significantly the adhesive properties of HUVECs. rhTGFβ1 in the ranges from 3,60 ng/ml up to 8,30 ng/ml inhibited adhesion of K562 cells (IA<1,00) but in the higher doses it stimulated adhesive properties of HUVECs again (IA>1,00). On the other hand we found that low concentrations of rhTNF (0,001 up to 0,01 ng/ml) correlated inversely with adhesion of K562 to HUVECs (IA from 4,33 to 1,0). rhTNF in the range 0,01 up to 0,1 ng/ml didn't stimulate the attachment of K562 to HUVECs. Incubation of HUVECs with rhTNF in concentrations 0,8 up to 4,1 ng/ml resulted in significant increase of K562 adhesion (IA>1,0). After influence of rhTNF (0,001 up to 0,024 ng/ml) HUVECs demonstrated considerable adhesiveness to L1210 (IA from 1,42 to 3,02). rhTNF in range 0,03 up to 0,06 ng/ml diminished the attachment of L1210 (IA<1,0), but in the range (0,07 up to 2,03 ng/ml) it significantly induced the adhesion of L1210 again. Pretreatment of HUVECs by rhTNF more than 3,12 ng/ml didn't induce any adhesion, perhaps via its cytotoxic influence on EC monolayer.
Summary/Conclusion:.
Blasts were the powerful source of cytokines secretion that was able to modulated the adhesive properties of VE and may pathogenetically influence on spreading of AL.
TNF and TGFβ1 can affect different types of leukemia cells in different ways. On the other hand rhTNF and rhTGFβ1 *in vitro* changes the adhesive properties of HUVECs in a dose-dependent manner. Therefore, the adjustment of cytokine levels in the blood of AL pts may be an important step in the treatment of AL.

PB1354 EVALUATION OF BIOMATRICA'S RNASTABLE (BRS) AND NOVEL STABILIZER (CPHD1) TO PRESERVE IVT-RNA AT ROOM TEMPERATURE(RT) TO BE USED FOR CALIBRATION OF THE CEPHEID XPERT® BCR-ABL ULTRA P190 PROTOTYPE‡ ASSAY

T. Tran [1,*], Y. Liu [1], A. Aslam [1], J. Dosanjh [1], L. Yuan [1], P. Nguyen [1], G.-J. Day [1]

[1]*Oncology R&D, Cepheid, Sunnyvale, United States*

Background: Reliance on RNA usage is integral in many scientific fields. For many applications, RNA integrity is required and must be maintained during storage. Current gold standard for RNA storage at -80°C[1] may still jeopardize RNA integrity due to ribozyme activity[2]. An alternative method for RNA preservation is essential in these growing fields, where the use of RNA is imperative. BRS (Biomatrica, San Diego, CA), is a unique RNA preservative that has demonstrated RT stability for up to 12 years in accelerated aging studies[3].
Aims: BRS has shown excellent stability at 50°C for total RNA; however, BRS IVT-RNA stability data has not been published. We evaluated preservation of e1a2 IVT-RNA in BRS and CPHD1 for calibration of the Cepheid Xpert BCR-ABL Ultra p190 Prototype Assay, which is designed as a ≤ 2.5 hour test, to monitor minimal residual disease in Ph+ ALL patients.
Methods: e1a2 IVT-RNA was prepared in DEPC-treated water or in CPDH1 at 200pg/µL in *E.coli* tRNA. 10 µL of the IVT-RNA mixture was added to BRS or CPDH1 and dried in a laminar flow hood for ~24 hours. Completely dried IVT-RNA tubes were placed into moisture barrier bags with desiccant packets, heat sealed, and stored at RT (19°C-23°C) or 50°C. The IVT-RNA in DEPC-treated water controls were aliquoted into microfuge tubes and stored at -80°C. At designated time points, aliquots from each condition were diluted in assay buffer and tested with the Xpert BCR-ABL Ultra p190 Prototype Assay and with digital droplet PCR (ddPCR) on the BioRad QX-200 ddPCR systems (BioRad, Hercules, CA).
Results: Storage of IVT-RNA in BRS at RT and 50°C show excellent stability, comparable to the gold standard (-80°C) through the duration of the study. A general linear model (GLM) was fit to evaluate the effect of time, storage temperature, and IVT-RNA input level on measured e1a2 transcript (a2 Ct). Significant value was set at 0.01, according to Bonferroni correction method. All non-significant two-factor interaction and second-order terms were dropped from the analysis, yielding a general regression equation which predicts an increase of 0.43 Ct over 36 weeks. The reduced model ANOVA table showed no significant difference in e1a2 Ct between storage temperature with p-value = 0.73. E1a2 copy number was monitored in parallel, for the two lowest input levels (0.1fg and 1fg) with ddPCR. A GLM was similarly run to generate a regression equation to predict copy number (CN). Reduced model ANOVA from Design Of Experiment for CN show non-statistically significant for storage temperature with p-value = 0.296. At 36 weeks, e1a2 IVT-RNA performs remarkably well at 50°C, comparable to T0 baseline. Cycle threshold, endpoint fluorescent and CN comparability are indicators of excellent stability (Table 1). Preliminary data for the CPHD1 RNA show promising results after dried storage at RT for 20 days + 16 days at 50°C.

Table 1: RT-PCR data from Xpert BCR-ABL Ultra p190 and BioRad ddPCR data for e1a2 IVT-RNA stored in BRS for RT and 50°C and stored in DEPC-treated water for -80°C at 36 weeks compared to Time 0 week (T0).

Summary/Conclusion: BRS is an effective IVT-RNA storage formula at 50°C for up to the evaluated duration of 36 weeks, equivalent to 5 years at RT based on accelerated aging. Future timepoints up to 24 months will be monitored. The study goal was to determine storage stability of e1a2 IVT-RNA for usage in the Xpert BCR-ABL Ultra p190 Prototype Assay. However, during the initial evaluation, BRS production was discontinued and Cepheid has consequently developed an alternative formula (CPHD1) to store IVT RNA at RT. Preliminary data for CPHD1 show promising results. Further studies will need to be performed to elucidate the effectiveness of the CPHD1 RNA stable reagent for storage at RT.

PB1355 DEVELOPMENT OF ASSAY CALIBRATION MEHTHODOLOGY FOR CEPHEID XPERT® BCR-ABL ULTRA P190 PROTOTYPE‡ ASSAY

Y. L. Cepheid [1,*], T. Tran [1], P. Nguyen [1], V. Kadiyala [1], J. Dosanjh [1], A. Aslam [1], H. Wei [1], L. Yuan [1]

[1]*Oncology, Cepheid, Sunnyvale, United States*

Background: Currently, no International Standards are available for the quantitation of the e1a2 p190 transcript for both CML and ALL, posing a challenge when developing a quantitative assay to monitor the e1a2 p190 transcript levels.
Aims: Implementation of a primary control material, containing *in vitro* transcribed RNA (IVT-RNA) of ABL and BCR-ABL e1a2, for standardization of ABL and BCR-ABL e1a2 quantifications through copy number (CN) calibration was used to develop an assay calibration methodology at Cepheid. This process allows generation of in-house RNA control materials as secondary standard (SS) mimicking clinical samples, for calibration and standardization of the Xpert BCR-ABL Ultra p190 Prototype Assay.
Methods: Titration studies were performed with Cepheid's IVT-RNA, containing e1a2 and ABL, to derive CN calibration curves of the target genes relative to the corresponding Cycle Threshold (Ct) for both e1a2 and ABL in the background of PAXgene human whole blood. The calibrated standard curves assigned the BCR-ABL e1a2/ABL% values to a 4-member in-house control material (SS) ranging from ~10% to 0.02% generated by spiking BCR-ABL e1a2 total RNA and ABL total RNA (HL60) in PAXgene blood. A lot-specific curve of delta Ct vs BCR-ABL e1a2/ABL% value was generated from the secondary standard for the BCR-ABL p190 Prototype Assay providing an Efficiency Value ($E_{\Delta\Delta Ct}$) and a lot-specific scaling factor (*SF*). The BCR-ABL e1a2/ABL% value of any given clinical sample was calculated with $E_{\Delta\Delta Ct}$ and *SF*. A 4-assay comparison study was performed to validate the assay calibration methodology with contrived clinical samples.
Results: Based on the observation of constant delta Ct between e1a2 and ABL from IVT-RNA, the ABL standard curve was generated by BCR-ABL e1a2 standard curve. Through the BCR-ABL e1a2 and ABL calibration curves generated from IVT-RNA PAXgene blood background, the BCR-ABL e1a2/ABL % value of the SS was assigned. The $E_{\Delta\Delta Ct}$ and *SF* of 4 lots of BCR-ABL Ultra p190 kit were generated. BCR-ABL e1a2/ABL % values of contrived clinical samples in EDTA whole blood and PAXgene whole blood from BCR-ABL Ultra p190 Prototype Assay were consistent with those from three other comparator assays, RT-ddPCR, Asuragen, and Ipsogen (Table 1).

Table 1: Four assay comparison data for the same EDTA sample and PAXgene blood sample.

Sample background	Assay	Reported BCR-ABL/ABL %
EDTA Blood	BCR-ABL Ultra p190	2.69
	RT-ddPCR	N/A
	Asuragen	2.80
	Ipsogen	2.380
PAXgene Blood	BCR-ABL Ultra p190	0.026
	RT-ddPCR	0.020
	Asuragen	0.025
	Ipsogen	0.037

Summary/Conclusion: In conclusion, implementing a primary control material of IVT-RNA, allowed linkage of known RNA CN to corresponding Ct, thus providing a methodology to assign BCR-ABL e1a2/ABL % value to a human whole blood-based secondary standard. A lot-specific $E_{\Delta\Delta Ct}$ and *SF* for BCR-ABL Ultra p190 Prototype Assay was generated from the secondary standard and was utilized to calculate the BCR-ABL e1a2/ABL % value for a given clinical sample. Data from 4-assay comparison suggested that we achieved the goal of establishing a successful assay calibration methodology with IVT-RNA in human blood background as primary standard and the BCR-ABL e1a2/ABL % value reported by BCR-ABL Ultra p190 Prototype Assay was compatible with other comparator assays.

PB1356 BCR-ABL P190 QUANTITATION EVALUATED BY COMMERCIALLY AVAILABLE ASSAYS AND THE CEPHEID XPERT® BCR-ABL ULTRA P190 PROTOTYPE‡ASSAY

A. Aslam [1,*], T. Tran [1], V. Kadiyala [1], P. Nguyen [1], J. Dosanjh [1], Y. Liu [1], L. Yuan [1]

[1]Oncology R&D, Cepheid, Sunnyvale, United States

Background: BCR-ABL is a constitutively active tyrosine kinase formed by the t(9;22) reciprocal translocation, with the p190 transcript being the most frequent variant in Ph+ ALL[1]. Tyrosine kinase inhibitor (TKI) resistance develops in a significant number of Ph+ ALL patients over the course of treatment[2,3,4]. As 15-20% of children, and about half of adults treated for Ph+ ALL ultimately relapse, there is need for a more sensitive and easier to use molecular test with a shorter time-to-result (TTR) for the monitoring of MRD and treatment response in p190-positive patients[3,5,6].
Aims: The objective of this study was to compare the performance of the novel Cepheid Xpert BCR-ABL Ultra p190 Prototype Assay to the Asuragen QuantideX® qPCR BCR-ABL minor Kit, the Qiagen ipsogen® BCR-ABL1 mbcr Kit, and an in-house developed reverse transcriptase digital droplet PCR (RT-ddPCR) assay using samples contrived using Philadelphia chromosome-positive (Ph+) ALL patient peripheral blood. Our goal was to create a fast and easy to use quantitative assay with higher sensitivity than currently available assays for use in the monitoring of treatment efficacy and minimal residual disease (MRD) in Ph+ ALL patients.
Methods: Three p190-positive ALL total RNA samples were spiked into p190-negative EDTA whole blood lysate matrix diluents and serially diluted to target %BCR-ABL p190/ABL outputs from approximately 25% (LR [log reduction] 0.60) to near the assays expected limit of detection (LoD), approximately 0.005% (LR 4.30). A subset of each level underwent sample preparation, total RNA extraction, and RT-qPCR all in the Cepheid GeneXpert automated cartridge system, and another subset had total RNA extracted using the Zymo Direct-zol™ RNA Miniprep Plus Kit. RNA was qualified and quantified using the Thermo Scientific NanoDrop™ 2000 Spectrophotometer before being tested per the comparator assay vendors' recommendations. The Cepheid Prototype assay utilized 4.5mL of lysate, whereas the Asuragen assay used 1-2 µg of RNA per test, and the Qiagen and RT-ddPCR assays used 1 µg of RNA per test. The Cepheid Prototype assay was evaluated against the three comparator assays using Deming regressions with regression confidence intervals determined using jackknife resampling. Bland-Altman plots were utilized to evaluate bias between assay quantitation outputs. Hit-rates were assessed to compare the LoD between assays.
Results: Deming regressions and associated Bland-Altman plots showed a high degree of correlation and agreement between comparator assays and the Cepheid Prototype assay. Replicates that did not detect p190 were not included in this analysis. Dropout rates at low target %BCR-ABL p190/ABL levels were compared between assays. The Cepheid Prototype assay had the best performance in terms of hit-rate, followed by the Asuragen, RT-ddPCR, and Qiagen assays (**Table 1**).

Table 1. For levels containing at least one drop-out in any given assay, hit rate is given by %BCR-ABL p190/ABL level, as determined by the mean RT-ddPCR output ratio for the corresponding level. Misses were only included in this analysis if sufficient ABL background was detected.

Assay	Hit Rate by RT-ddPCR Determined %BCR-ABL p190/ABL Levels				
	0.006%	0.013%	0.020%	0.041%	0.068%
Xpert BCR-ABL Ultra p190 Prototype Assay	3/3	3/3	3/3	3/3	3/3
Asuragen QuantideX® qPCR BCR-ABL minor Kit	2/3	3/3	3/3	3/3	3/3
Qiagen ipsogen® BCR-ABL1 mbcr Kit	0/4	0/4	3/4	3/4	3/4
RT-ddPCR	2/3	2/3	3/3	3/3	3/3

Summary/Conclusion: The novel Cepheid Prototype assay showed a high level of agreement with the three comparator assays and gave the lowest LoD overall in this study using samples contrived from Ph+ ALL patient peripheral blood. TTR was minimized in the Cepheid Prototype assay to 130 minutes, while the comparator assays all had a TTR of approximately five hours or greater. While RNA extraction is performed within Cepheid Prototype assay cartridge and is included in the 130-minute TTR, the comparator assays require additional expensive and labor-intensive extraction steps that can last one-hour to multiple days, which are not included in the five-hour TTR estimate.

PB1357 CGH ARRAYS REVEAL ADDITIONAL CLINICALLY RELEVANT CHROMOSOME ABNORMALITIES IN POSITIVE PHILADELPHIA ACUTE LIMPHOBLASTIC LEUKEMIA: A CASE STUDY

A. Pansa [1,*], R. Silipigni [1], M. Sciumè [2], G. Sovena [1], P. De Leonardis [1], P. Trevisanutto [1], N. S. Fracchiolla [2], S. Guerneri [1]

[1]Laboratory of Medical Genetics, [2]Hematology Division, Fondazione IRCCS Ca' Granda Ospedale Maggiore Policlinico, Milan, Italy

Background: Screening at onset for BCR-ABL1 fusion gene by FISH/RT-PCR and chromosome banding analysis is mandatory and routinely tested for a rapid diagnosis in Acute Limphoblastic Leukemia (ALL). Philadelphia chromosome in adult ALL patients was associated with an unfavorable prognosis before the introduction of tyrosin kinase inhibitors. However, a proportion of patients still have an unfavorable prognosis, suggesting that additional biological mechanisms, like additional chromosomal abnormalities (ACAs), other than the BCR-ABL1 driver lesion, are involved. The application of high-resolution genome wide methods is useful for understanding the molecular bases of these mechanisms.
We report the case of a 42 years old male with Ph+ ALL confirmed by RT-PCR ($p190^{BCR-ABL}$) with a normal karyotype in all the observed metaphases and an abnormal FISH signal pattern (four fusion signals) detected only in nuclei.
Aims: To assess the real nature of an atypical cytogenetically undetectable rearrangement of BCR-ABL1 in a ALL patient we investigated his bone marrow sample with a microarray-based approach.
Methods: DNA obtained from bone marrow of the patient was analyzed by Comparative Genomic Hybridization (CGH) 60K oligonucleotide array. Fluorescence in situ hybridization (FISH) was performed to confirm the result obtained.
Results: CGH array detected a clone (20% of cells) with an additional X chromosome, trisomy of chromosomes 4, 5, 20, and 21 and a 3.8 MB interstitial deletion of short arm of chromosome 9. This region contains several genes including CDKN2A/2B, recently emerged as very strong prognostic marker in Ph+ ALL adult patients. Moreover, our analysis showed a gain of two copies of 9q34-qter and 22pter-q11.2 regions suggesting the presence of two additional Philadelphia chromosomes. This abnormal clone was confined to nuclei, as confirmed by FISH. Karyotype analysis needs the presence of mitotic cells that have been arrested in the metaphase. In this case probably only normal cells were actively dividing. This explains the normal karyotype displayed by the cytogenetic analysis. At the present time the patient, at day 45 from therapy start, is responding to the induction therapy with imatinib and prednisone, with minimal residual disease persistence.
Summary/Conclusion: Most of ACAs, frequently observed in Ph+ ALL, are detectable by chromosome analysis. The presence of ACAs in adult Ph+ ALL seems to negatively influence the prognosis and consequently the efficacy of TKI combined with chemotherapy and hematopoietic stem cell transplantation.
When a normal karyotype is detected, screening for recurrent fusion genes and rapid diagnosis for clinically relevant anomalies by FISH or RT-PCR represent the gold standard methods in genetic analysis of ALL. Anyway, these methods may not be able to detect cryptic genetic lesions. It is well known that a normal karyotype can hide a more complex condition. This is due to the low resolution of the cytogenetic analysis and to the different clone proliferation leading to cell selection. This case underlines that to overcome these limitations may be useful to include microarray-based genome wide test in the diagnostic workup that could provide insight into the molecular pathogenesis of Ph+ ALL and help to define more accurately prognostic groups.
In particular, CGH array can easily identify small and very often cytogenetically undetectable CDKN2A/2B deletions that recently emerged as a new strong and independent prognostic marker in Ph+ ALL adult patients.

PB1358 CHROMOSOMAL ABNORMALITIES DURING THE CLINICAL COURSE OF ADULT ACUTE LYMPHOBLASTIC LEUKEMIA

O. Zotova [1,*], A. Lukianova [2], M. Valchuk [1], O. Shalay [1], V. Loginsky [1]

[1]SI «Institute of Blood Pathology and Transfusion Medicine, NAMS of Ukraine», Lviv, [2]Medical Biology Centre «Genom», Kyiv, Ukraine

Background: Using conventional cytogenetics, an abnormal karyotype can be detected in 60-85% of adult acute lymphoblastic leukemia (ALL) patients. Taking into consideration the identified cytogenetic abnormalities ALL patients are currently classified into three risk groups: favorable, intermediate and adverse. These genetic abnormalities are the most important factors in determining response to chemotherapy as well as outcome in ALL.
Aims: Aim of this study was to detect the diagnostic and prognostic significance of chromosomal abnormalities in leukemic cells at different

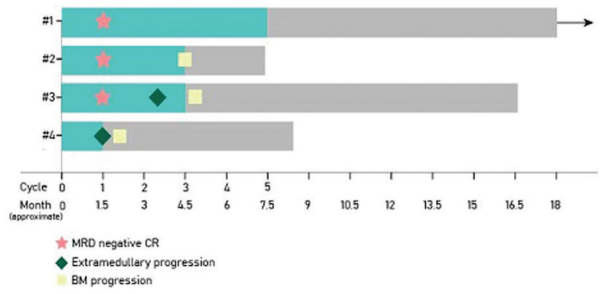
phases of ALL and to determine the frequencies of clonal evolution at ALL relapse.
Methods: Cytogenetic investigations of bone marrow and/or peripheral blood cells from 54 adult patients were performed during clinical evolution of ALL: in newly diagnosed patients, in remission and at relapse. The methods of conventional cytogenetics (GTG) and fluorescence *in situ* hybridization (FISH) were used. Cytogenetic methods were performed using standard techniques and karyotypes were described according to the International System for Human Cytogenetic Nomenclature.
Results: Cytogenetic investigations of 50 adult ALL patients were performed in newly diagnosed patients, in remission and at relapse. Structural (t(9;22)(q34;q11), 11q23 rearrangements, t(12;21)(p13;q22), del(17p), del(7q) and others) and numerical (monosomies, trisomies, tetrasomies, hyperdiploidy, hypodiploidy) chromosomal abnormalities in leukemic cells were found. Some genetic abnormalities (*BCR/ABL* and *AF4/MLL* fusion genes) were detected by molecular genetic methods (FISH). Spectrum of cytogenetic abnormalities had an important diagnostic and prognostic significance. Diagnosis of ALL was possible due to the presence of specific genetic markers that can confirm some types of ALL (ALL with t(9;22)(q34;q11), *BCR/ABL* gene, t(4;11)(q21;q23), hyperdiploidy, hypodiploidy). Taking into consideration the identified cytogenetic abnormalities ALL patients were classified by risk groups: the group of patients with adverse cytogenetic markers (hypodiploidy, t(4;11)(q21;q23), t(9;22)(q34;q11), multiple changes (≥3)), the intermediate risk group without significant prognostic markers and the group with favorable prognostic factors (t(12;21)(p13;q22), high hyperdiploidy). In remission cytogenetic investigations showed a normal karyotype without cytogenetically visible changes in all patients. Cytogenetic investigations at relapse were performed in 9 of 50 ALL cases. Presence of the additional/secondary chromosomal aberrations in leukemic cells or new cells clones with multiple structural and numerical changes at relapse was detected in 5 (56%) patients. This is the one sign of clonal evolution and progression of the disease.
Summary/Conclusion: Cytogenetic investigations had an important significance for diagnosis, prognosis and selection the optimal treatment strategy of ALL. Besides the analysis of chromosome banding patterns it is necessary for patients with ALL to apply molecular genetic studies, namely FISH and polymerase chain reaction (PCR). Taking into consideration the identified cytogenetic abnormalities ALL patients were classified by risk groups. Presence of the additional/secondary chromosomal aberrations in leukemic cells or new cells clones with multiple structural and numerical changes at ALL relapse is the one sign of clonal evolution and progression of disease.

Acute lymphoblastic leukemia - Clinical

PB1360 MAINTENANCE TREATMENT WITH LOW-DOSE DECITABINE AFTER ALLOGENEIC HEMATOPOIETIC STEM CELL TRANSPLANTATION FOR ADULT ACUTE LYMPHOBLASTIC LEUKEMIA

R. Guo [1,*], J. Liu [2]

[1]*Department of Hematology, the First Affiliated Hospital of Zhengzhou University, Zhengzhou,* [2]*Hematopoietic Stem Cell Transplantation Center, Institute of Hematology and Blood Diseases Hospital, Chinese Academy of Medical Sciences and Peking Union Medical College, Tianjin, China*



Background: Post-transplant relapse and graft-versus-host disease (GVHD) remain to be the principal leading causes of failure after allogeneic hematopoietic stem cell transplantation (allo-HSCT) in patients with adult acute lymphoblastic leukemia (ALL), especially relapse. The degree of methylation of tumor suppressor genes is closely related to the subtypes and prognosis of ALL. Decitabine is one of hypomethylating agents inducing leukemic differentiation and re-expression of epigenetically silenced tumor antigens. The aim of this study was to investigate the safety and efficacy of maintenance treatment with low-dose decitabine after allo-HSCT for adult ALL.
Aims: The aim of this study was to investigate the safety and efficacy of maintenance treatment with low-dose decitabine after allo-HSCT for adult ALL.
Methods: We enrolled 34 patients with ALL who underwent allo-HSCT from August 2016 to April 2020 and gave them low-dose decitabine maintenance treatment after transplantation. GVHD, relapse and overall survival (OS) were observed, and the safety of the regimen was evaluated.
Results: Among the 34 patients enrolled, 32 patients (94.1%) developed only grade I-II myelosuppression, 6 patients relapsed and 6 patients died. The 2-year cumulative incidence of relapse rate (CIR), OS and disease-free survival (DFS) were 20.2%, 77.5% and 73.6%, respectively. The 2-year CIR, OS and DFS of 12 patients with T-ALL/Lymphoblastic Lymphoma (LBL) were 8.3%, 90% and 81.5%, respectively. Among the 7 patients with T-ALL, no one relapsed. During maintenance treatment, only 1 patient (2.9%) developed grade IV acute GVHD and 4 (11.8%) patients had severe chronic GVHD.
Summary/Conclusion: Maintenance treatment with low-dose decitabine after transplantation was associated with good tolerance, a low relapse rate without significantly affecting GVHD, and satisfactory survival in patients with ALL, especially patients with T-ALL.

PB1361 BLINATUMOMAB FOR HLA LOSS RELAPSE AFTER HAPLOIDENTICAL HEMATOPOIETIC STEM CELL TRANSPLANTATION

H. Wu [1], Z. Cai [1], J. Shi [1], Y. Luo [1], H. Huang [1,*], Y. Zhao [1]

[1]*The First Affiliated Hospital, Zhejiang University School of Medicine, Hangzhou, China*

Background: Loss of patient-specific HLA after haploidentical hematopoietic stem cell transplantation (haplo-HSCT) is considered as a relapse mechanism for lacking the incompatible molecule to elicit alloreactivity, which extensively diminishing graft versus leukemia (GVL) effects. Blinatumomab, as a CD3/CD19 bispecific antibody, can yield a profound response via redirecting T cells towards malignant lymphoblasts in B-cell acute lymphoblastic leukemia (B-ALL). We aimed to assess whether blinatumomab could result in a considerable response by regenerating immunological engagement in patients with HLA loss relapse after haplo-HSCT.
Aims: As there are no clinical data on blinatumomab for posttransplantation HLA loss relapse, we herein report the preliminary results of blinatumomab in treating B-ALL with HLA loss recurrence after haplo-HSCT.
Methods: We recruited patients with B-ALL at the First Affiliated Hospital of Zhejiang University School of Medicine. Eligible patients were diagnosed with HLA loss relapse after haplo-HSCT. One cycle of blinatumomab treatment lasted for 6 weeks, including a 4-week continuous i.v. infusion period and a 2-week treatment-free interval. During the first induction cycle, an initial dose of 9 μg/day was used for the first 7 days and the dose was increased to 28 μg/day starting on day 8 (week 2) and continuing through day 29 (week 4). The 28 μg/day dose was used for all subsequent cycles. Patients received up to 5 cycles of blinatumomab, with efficacy follow-up at 3, 6, 9, 12, 18, and 24 months after treatment initiation. The primary endpoint was CR/CRh rates in the 2 cycles of blinatumomab treatment.
Results: Between January 2017 and July 2019, 4 eligible patients relapsed HLA loss relapse after haplo-HSCT were enrolled in the study. Four patients achieved a CR/CRh with three MRD-negative response within the first 1 cycle of treatment. Three of the four met a primary endpoint with CR/CRh and MRD-negative response within 2 cycles of treatment. One patient developed new EM sites of skin after the first cycle (Fig 1). Cytokine release syndrome was observed in one patient. Cytopenias, as well as elevated alanine aminotransferase and aspartate aminotransferase, were two common adverse effects during treatment.

Summary/Conclusion: Blinatumomab can induce rapid and robust remission in B-ALL patients undergoing HLA loss relapsed after haplo-HSCT. By *redirecting* lysis of CD19-positive lymphoblast who losing the incompatible HLA, blinatumomab is a potential strategy to eradicate malignant cells via restoring GVL effects. A randomized clinical trial assessing blinatumomab in patients with HLA loss relapse after HSCT is warranted.

PB1362 INCIDENCE OF HEMATOLOGICAL MALIGNANCIES AT THE NATIONAL CANCER INSTITUTE IN PERU. A 19 YEARS' EXPERIENCE.

J. Vasquez [1,*], E. Diaz [2], E. Poquioma [2], T. Vidaurre [1]

[1]*Medical Oncology,* [2]*Epidemiology, Instituto Nacional de Enfermedades Neoplasicas, LIMA, Peru*

Background: Cancer is a public health problem that affects the whole world, is divided into 2 major groups, solid tumors and hematological malignancies (HM). International studies mainly from developed countries report that HM account for 10% of all cancers, being the most frequent lymphoma followed by multiple myeloma (MM). National Cancer Institute (NCI), the leading public institution in Peru treats almost the 20% of cancer patients in the country.
Aims: To determine the incidence of HM by sub-type in the leading cancer center in Peru and its association with sex and age group.
Methods: We reviewed the database at the NCI Epidemiology Department in Peru from 2000 to 2018. The classification was based on the International Classification version 10 (ICD-10) and the ICD for Oncology version 3 (ICD-O 3) and divided into the main subtypes: Acute Lymphoblastic Leukemia (ALL), Acute Myeloid Leukemia (AML), Chronic Lymphocytic Leukemia (CLL), Chronic Myeloid Leukemia (CML), Non-Hodgkin lymphoma (NHL), Hodgkin lymphoma (HL), MM, other leukemias (OtL), and other HM (oHM). Baseline characteristics (BLC) as age, age group, sex and sub-type of HM were collected. The age group was divided as follows: 0-14 years, 15-39 years (Adolescent and Young Adult, AYA), 40-64 years, and >64 years. BLC were compared using Chi-square test. The Stata software version 16 was use for the analysis.
Results: During the study period 12.4% (n= 23,795) were HM. The median age was 43 (range 0-103). 53.7% (n=12,798) were male. The most frequent HM was NHL with 44.1% (n=10,502), followed by ALL with 23.9% (n=5,684) and AML with 12.9% (n=3,072). MM and HL were 5.7% and 5.5% (n=1,351, and n=1,316), respectively. CLL was presented in 0.95% (n=225). The most frequent age group was those 40-64 years old with 32.1% (n=7,642), follow by the AYA group with 24.4% (n=5,812), the less common groups were 0-14 years group with 21.5% (n=5,113) and >64 years with 21.97% (n=5228). In the 0-14 group the most frequent HM was ALL with 63.1% (n=3,226) followed by AML with 13.5% (n=689). In the AYA group the most frequent HM was NHL with 31.5% (n=1,833) followed by ALL with 29.7% (n=1,727). In the 40-64 group the most frequent HM was NHL with 58.5% (n=4,497) followed by AML with 11.6% (n=889) and in the > 64 years group was NHL with 69.5% (n=3,632) followed by MM with 9.8% (n=514). There was a statistically significant difference between the subtypes and age ranges (p<0.001) (see table 1). In the first three age groups the most frequent sex was male, with 58.9%, 56.7% and 51%, respectively. However, in the > 64 years group the predominant sex was female with 50.6%. The difference between sex and age ranges was statistically significant p<0.001.

Table 1: Sub-types of HM according to age ranges.

Types of HM	Total n (%)	0-14 y n (%)	15-39 y n (%)	40-64 y n (%)	>64 y n (%)	p-value
ALL	5,684 (23.9)	3,226 (63.1)	1,727 (29.7)	616 (8.1)	115 (2.2)	<0.001
CLL	225 (0.95)	0	8 (0.14)	92 (1.2)	125 (2.4)	
AML	3,072 (12.9)	689 (13.5)	1,032 (17.8)	889 (11.6)	462 (8.8)	
CML	896 (3.8)	39 (0.8)	417 (7.2)	354 (4.6)	86 (1.6)	
NHL	10,502 (44.1)	540 (10.6)	1,833 (31.5)	4,497 (58.5)	3,632 (69.5)	
HL	1,316 (5.5)	422 (8.3)	515 (8.9)	246 (3.2)	133 (2.5)	
MM	1,351 (5.7)	0	72 (1.2)	765 (10.0)	514 (9.8)	
Other leukemias	673 (2.8)	146 (2.9)	196 (3.4)	173 (2.3)	158 (3.0)	
Other HM	76 (0.3)	51 (1.0)	12 (0.2)	10 (0.1)	3 (0.1)	
Total	23,795 (100)	5,113 (100)	5,812 (100)	7,642 (100)	5,228 (100)	

Summary/Conclusion: HM account for 12% of cancers. Most of patients are male. The most affected group was 40-64 years. The most frequent HM is NHL. Unlike developed countries the second most frequent HM was ALL, being this latter the most frequent HM in the 0-14 years group and the most frequent leukemia in AYA group. AML was the second most frequent HM in 0-14 years group and the most frequent leukemia in ≥ 40 years group. Also, unlike developed countries CLL was rare. MM ranked fifth in incidence. There was a statistically significant difference between the subtype and the age range.

PB1363 OUTCOME OF ADOLESCENTS AND YOUNG ADULTS WITH ACUTE LYMPHOBLASTIC LEUKEMIA TREATED WITH PEDIATRIC PROTOCOL

I. Frikha [1,*], A. Koubaa [1], I. Turki [1], M. mdhaffar [1], I. Ben Amor [1], S. Hdijji [1], M. Charfi [1], L. Khalifa [1], Y. Fakhfakh [1], O. Kassar [1], F. Kallel [1], M. Elloumi [1]

[1]*Department of hematology, Hedi Chaker Hospital, Sfax, Tunisia*

Background: Several retrospective studies have confirmed that adolescents and young adults (AyA) with acute lymphoblastic leukemia (ALL) treated with pediatric protocols have better outcomes than similarly aged patients treated with adult protocols.
Aims: We reported feasibility and results of a pediatric-based protocol (EORTC 58951) in adolescents and young adults.
Methods: From January 2000 to December 2019, 87 patients aged 16 to 30 years with newly diagnosed ALL were treated, in the department of hematology of Hedi Chaker Hospital, according to the pediatric protocol EORTC 58951. Further leukemia characteristics (Sex, White Blood cell count, Blasts phenotype, Cytogenetic results), we studied the protocol results: response to prophase), risk group stratification (average: AR1 and AR2, very high: VHR), remission rate, death rate, relapse rate and survivals (overall OS and event free EFS).
Results: Eighty-seven AyA ALL were treated with the pediatric protocol. The patients were 56 males (64%) and 31 females. WBC counts more than 100 Giga/l was noted for 25 patients (19%). Immunophenotyping was performed in all patients: 44 B-ALL (51%), 43 T-ALL (49%).
Twenty five patients (29%) were corticoresistant. Seventy eight patients (89%) achieved CR. Five patients failed to respond after 2 courses of chemotherapy and died and 4 patients died during induction chemotherapy as a result of infectious complications. Eleven patients (13%) were treated according AR1 arm, 48 patients (55%) according AR2 arm and 28 (32%) according VHR arm. Twenty eight patients (51.7%) with VHR arm protocol were eligible for allogeneic stem-cell transplantation but, only 10 were allograft: 4 were alive in complete remission and 6 died (by GVH for 2 patients and relapse for 4 patients). Relapse was observed in 22 patients (29%), among them 12 during the first year of treatment. The mean follow up was 128 months. The 10 years OS and EFS were respectively 50% and 49%.
Summary/Conclusion: The results of this pediatric-based study show that response to therapy and prognostic in adolescent and young adults were better than those treated with adult protocols and tolerability of chemotherapy is acceptable. However OS and EFS, were better than adult ALL treated by adult protocol (OS and EFS at 5 years = 35%: local study) but were not satisfactory. Our results were less than those described in the literature (OS ~ 80% and EFS ~ 70%). To further improve our results, it is necessary to expand donor sources such as matched unrelated.

PB1364 A SINGLE-ARM, OPEN-LABEL PHASE 2 PILOT STUDY OF VYXEOS (CPX-351) IN ADULTS WITH RELAPSED OR REFRACTORY ACUTE LYMPHOBLASTIC LEUKEMIA.

B. Shah [1,*], N. Rozario [1], E. Turba [1], J. Chavez [1], C. Bello [1], J. Lancet [1]

[1]*Malignant Hematology, Moffitt Cancer Center, Tampa, United States*

Background: Vyxeos is a liposomal formulation employing a 1:5 molar ratio of daunorubicin:cytarabine. Clinical trials in high risk acute myeloid leukemias demonstrated a significant benefit in CR rates and median OS, culminating in FDA approval August 2017. Emerging pediatric data suggest this benefit may extend to acute lymphoblastic leukemia (ALL).
Aims: The following pilot trial was performed to better understand the activity and toxicity profile in adults with relapsed and refractory ALL.
Methods: Adults with ALL or mixed phenotype leukemia were eligible if ≥5% lymphoblasts and/or extramedullary disease >1x1cm. Induction

consisted of Vyxeos 100 units/m^2 on days 1, 3 and 5. Those with clinical benefit could receive up to 3 cycles of consolidation delivered at 65 units/m^2 on days 1 & 3 after recovery of neutrophils (>500 cells/μL) and platelets (>50,000 cells/μL).

Results: Ten patients have been treated to date, with median age of 40y (22-74y), 8 male, and 3 caucasian. Six had B-ALL, including 1 B-myeloid. Three of 4 T-ALL had early t-cell precursor (ETP) phenotype. NGS was available in 9, and include TP53 mutation (n=4), and PH-like changes (n=2). Median prior lines was 3, with 6 showing primary refractory disease. Prior blinatumomab, inotuzumab, CAR-T cell therapy, and allogeneic transplant were noted in 5, 2, 1, and 2 patients.

Pancytopenia was uniform during induction, with febrile neutropenia noted in 8. One passed from pneumonia after moving to comfort measures in lieu of intubation 20 days after Vyxeos, and is non-evaluable for response. A second patient developed grade 3 sepsis. The remainder of infections were grade 1-2. One had grade 3 gastrointestinal bleed, and 3 had grade 1 spontaneous subdural bleeding. One case of veno-occlusive disease was observed in a patient with prior allogeneic transplant and inotuzumab. Median time to ANC recovery was 32 days among 9 evaluable. Two with refractory disease failed to recover platelets; among the remaining 7, median time to platelet recovery was 30 days. Adverse events were uncommon during consolidation, and include foot cellulitis and myopericarditis, each in 1.

Among 9 evaluable patients, 3 achieved CR/CRi, including 2 ETP T-ALL and one B-ALL. Two with TP53 mutation demonstrated >50% blast reduction with hematologic recovery, allowing for prolonged time to subsequent therapy. Three received 1-3 cycles consolidation. One was bridged to donor leukocyte infusion. Responses were noted in only 2 after progression following Vyxeos. Median PFS was 28 days, time to next therapy 76 days, and OS 189 days.

Summary/Conclusion: Vyxeos in high risk refractory adult ALL was overall well tolerated and active, with median OS of approximately 6mo. A second induction course or the addition of novel agents may further improve on remission rates and duration of response.

PB1365 L-ASPARAGINASE HYPERSENSITIVITY AND SURVIVAL RELATIONSHIP IN TURKISH PEDIATRIC ACUTE LYMPHOBLASTIC LEUKEMİA PATIENTS TREATED WITH MODIFIED ST. JUDE TOTAL XV TREATMENT PROTOCOL

H. Yilmaz [1], O. Uysal Soyer [2], B. Sekerel [2], F. Gumruk [3], S. Aytac [3,*]

[1]Department of Pediatrics, [2]2Department of Pediatric Allergy and Immunology, [3]Department of Pediatric Hematology, Hacettepe University, Faculty of Medicine, Ankara, Turkey

Background: Hypersensitivity is the most common side effect of L-Asparaginase (L-Asp), which is used in the treatment of acute lymphoblastic leukemia (ALL), most common malignancy of childhood with a survival rate of up to 90%. The irritating formulation is discontinued and replaced with other formulations, due to allergic reactions. Also, anti-asparaginase antibodies in patients who develop hypersensitivity may lead to decrease in drug efficacy, relapse and survival disadvantage.

Aims: In this study, we aimed to demonstrate the adverse effect of L-Asp hypersensitivity on the survival of children with newly diagnosed ALL by evaluating the survival of patients with and without L-Asp hypersensitivity comparatively.

Methods: 182 newly diagnosed ALL patients whose mean age at diagnosis was 6.7 ± 4.4 years (1-18 years) treated with Modified St. Jude Total XV Therapy between 1 January 2008 and 30 January 2016. The survival of patients who showed a clinical allergic reaction to L-Asparaginase (Group A) and those who did not (Group B) were comparatively evaluatedretrospectively. Besides, in order to evaluate the effectiveness of High Dose Methylprednisolone (HDMP) treatment, patients were randomized consecutively and HDMP (maximum 1000 mg / day) of 20 mg/kg/day (n = 65) and 10 mg/kg/day (n = 90) were administered for 7 days prior to Modified St. Jude Total XV protocol induction therapy. MP at 10 mg/kg/day and 5 mg/kg/day were continued with induction therapy for initial 7 days, respectively. Then, MP at 2 mg/kg/day in both groups during day 8-21 of induction was given and discontinued. In patients with hyperleukocytosis at diagnosis (n=28), MP was started at lower doses (1 mg/kg/day) and gradually increased for 7 days.

Results: Clinical hypersensitivity reactions to L-Asp were observed in 43 (23%) patients (Group A), 40 (93%) during the maintenance and 3 (7%) during the induction, and desensitization was applied to the patients with antihistamine and steroid. The remaining 138 (%76) patients (Group B) did not show any clinical allergic reactions to L-Asp. The age, gender, leukocyte count, immunophenotype and risk group distribution at diagnosis of Group A and Group B were found to be similar (p = 0.553, p = 0.318, p = 0.079, p = 1,000, p = 0.431, respectively). In addition, no statistically significant difference was found between the rates of patients who developed L-Asp allergy in the two groups in which 10 mg/kg/day and 20 mg/kg/day YDMP treatment was initiated (p = 0.127). The 5-year event-free (EFS) and overall survival (OAS) rates of Group A and Group B were similar (p = 0.116 and p = 0.250, respectively). Although premedication was applied for subsequent doses, 21 (49%) of the patients with recurrent allergic reactions continued their treatment with PEG-Asparaginase and 16 (37%) with Erwinia L-Asp.

Table 1. Comparison of Characteristics and Treatment Results of Group A and Group B

	Group A (n=43) n (%)	Group B (n=138) n (%)	*p* value
Age (year) (mean± SD) (min-max)	6,28 ± 4,1 (0,94-15,37)	6,80 ± 4,5 (0,96-18)	0,553
Age (year)			
• 1-9,9	34 (%79)	105 (%76)	0,686
• 10-18	9 (%21)	33 (%24)	
Gender			
• Female	15 (%35)	60 (%43)	0,318
• Male	28 (%65)	78 (%57)	
Leucocyte Count			
• ≥ 50x10^9/L	12 (%28)	22 (%16)	0,079
• < 50x10^9/L	31 (%72)	116 (%84)	
Immunophenotype			
• Precursor B cell ALL	40 (%93)	126 (%91)	1,000
• T cell ALL	3 (%7)	12 (%9)	
Risk Groups			
• Low	18 (%42)	70 (%52)	0,431
• Standart	19 (%44)	53 (%39)	
• High	6 (%14)	25 (%9)	
Event-free Survival (5-year)	%90,7 (%86,3-95,1)	%84,6 (%81,5-87,7)	0,259
Overall Survival (5-year)	%94,7 (%91,0-98,4)	%88,1 (%85,3-90,9)	0,116

Summary/Conclusion: The incidence of allergic reaction, which is the most common side effect of L-Asp, has been reported in the literature in a wide range of 0-76% and mostly in the post-induction period. The rate of clinical allergic reaction to L-Asp found in our study was much lower compared to the St. Jude Total XV protocol (23% vs 40%). The observation of allergy in very few patients during induction can be explained by the suppression of hypersensitivity reaction due to the use of HDMP before and during the induction period. Additionally, no significant difference in the survival rates of patients who developed antibodies or allergies compared to patients who did not was revealed in accordance with our study.

PB1366 FERRITIN AS A MARKER FOR PROGNOSIS OF THYROID PATHOLOGY AND FEATURES OF THE AMINO ACIDS PROFILE IN THE LONG-TERM CARE OF CHILDREN WHO HAVE SUFFERED FOR ALL AFTER CHORNOBYL ACCIDENT

K. Bruslova [1,*], V. Bebeshko [1], N. Tsvietkova [1], L. Lyashenko [1], T. Pushkaryova [1], L. Gonchar [1], S. Iatsemyrskyi [1], A. Zaitseva [1]

[1]State Institution "National Research Center for Radiation Medicine of NAMS of Ukraine", Kyiv, Ukraine

Background: There are few data on metabolic changes in the body of children who have suffered from ALL and have a long-term EFS. The relationship between thyroid status, protein and iron metabolism has not been described under such conditions so far. The contact of described patients group with radiation factor has not been taken into account also.

Aims: To determine the influnce of ferritin on thyroid function and connection with amino acids (AC) profile in the urine of patients affected by the Chornobyl accident and who suffered from ALL in childhood.

Methods: There are 84 children living in radiation-contaminated areas and suffered from ALL in childhood (pro B - 8, common ALL - 66, pre-B - 6, T-ALL - 4) were examined. EFS of the patients ranged from 10 to 15 years. Ionising radiation dose for bone marrow of children were 5.31 ± 1.14 mSv. All children were examined after completing the full course of chemotherapy for ALL. The percentage and morphological characteristics of bone marrow erythroid cells, erythrocytes morphometric parameters, serum iron, serum ferritin (SF) and transferrin

levels, transferrin saturation coefficient, the percentage of bone marrow sideroblasts, urine AC levels: Lyz, Arg, O-Pro (oxyproline), Asp, Tre, Ser, Glu, Pro, Gly, Ala, Cys,Val, Met, Leu, Tyr, Phe; serum thyroid stimulating hormone (TSH) and free thyroxine (FT4) levels were stydied. We used generally accepted statistical methods (t-Student, Spearman's correlation coefficient, U-Test).
Results: In 53 children (63.1%) - SF was 285.4 ± 11.3 ng / ml, in 16 (19%) - 497.6 ± 13.6 ng / ml, in 15 (17.9%) - 783.7 ± 14.2 ng / ml. After 3-5 years of treatment end in 14 children (16.6%) thyroid pathology was detected: in 6 - hypothyroidism (SF 423.5 ± 12.1 ng / ml), in 7 - thyroiditis (SF 851.2 ± 15.5 ng / ml), one child had papillary thyroid cancer (SF - 489.6 ng / ml). A positive correlation between TSH and O-Pro (rs = 0.42) and negative correlation with FT4 (rs = -0.52) was found. In addition, SF was inversely correlated with TSH (rs = -0.46). In patients with serum iron levels higher than 27 µmol / l, the correlation was established between its amount and O-Pro (rs = -0.88) and the precursor O-Pro - Proline (rs = 0.86), which are markers of the collagen condition. The obtained results emphasize metabolic changes in ALL patients with excess iron in the body, which adversely affect the thyroid function in the remote period after chemotherapy.
Summary/Conclusion: Ferrokinetic processes affect the mechanisms of leukemogenesis and metabolic changes in children, which is associated with the development of multiorgan pathology and requires correction at the proper time.

PB1367 ACUTE LEUKEMIA AT ALEXANDRIA UNIVERSITY CHILDREN'S HOSPITAL: A SIX YEARS' EXPERIENCE

S. Abo El Ezz [1], M. Salama [1], H. Hassab [1], Y. El Chazli [1,*]

[1]Pediatrics, Alexandria University, Alexandria, Egypt

Background: Acute leukemia (AL) is the most common form of pediatric cancer. Nowadays, it is curable in the majority of pediatric patients, with 95% achieving long-term remission. The two most common subtypes of AL in children are Acute Lymphoblastic Leukemia (ALL) and Acute Myeloid Leukemia (AML).
Aims: to report the epidemiology and treatment outcome of children with AL in our center.
Methods: This was a retrospective study. The available data were retrieved from medical files of children newly diagnosed with AL during the period from 1st January 2013 to 31st December 2018 at Alexandria University Children's Hospital, a large tertiary care center in northern Egypt. The demographic, initial clinical, and laboratory data were collected, as well as the treatment protocol and outcome of included patients.
Results: A total of 413 patients was identified during the study period, of which 98 have been transferred to a central children's cancer hospital in Cairo, and 315 were treated and further analyzed. The patients' age ranged from 2.0 to 288 months, the majority of patients were from 1-10 years of age, 19 (6%) patients were more than ten years of age, and 13 (4.1%) patients were less than one year of age. One hundred sixty eight (53.3%) patients were males, while the females represented 147 (51.1%) patients. Two hundred fifty seven (81.6%) patients had ALL and 58 (18.4%) patients had AML. At presentation, the median total leucocytic count was 12.0 x10^3/µL, ranging from 0.2 - 989 x10^3/µL; 37 (11.7%) patients had hyperleukocytosis. From 2013 to 2016, ALL patients were treated according to the modified CCG-1991 standard risk protocol and CCG-1961 high-risk protocol, then Total study XV protocol was used starting in 2017. AML patients were treated according to the MRC 12 protocol. Regarding patients' outcome, 128 (49.8%) of ALL patients were in remission after treatment, 56 (21.8%) were on treatment, 57 (22.2%) have died, 9 (3.5%) died after relapse, 6 (2.3%) relapsed on treatment and 1 (0.4%) patient had a therapy-induced AML. Among the AML patients, 21 (36.2%) patients were in remission after end treatment, 3 (5.2%) still on treatment, 27 (46.6%) died, 6 (10.3%) died after relapse, and one (1.7%) patient has been lost to follow up, which significantly worse outcome than ALL patients, (p<0.001*). Only 6.7% of patients relapsed over the study period; hematological relapse was the most common form (71%). Using the Kaplan-Meier survival curve, the 3-years overall survival for all treated patients was 70.4%. Early deaths were more marked among infant leukemia and AML patients, and the most common cause of death among all categories was infectious complications. The 3-years overall survival for ALL patients was 76.4% versus 43.2% in AML patients (p<0.001*). Among ALL patients, B-ALL had a higher 3-year event-free survival (75.3%) compared to T-ALL (58.8%), p = 0.035.
Summary/Conclusion: This study showed the distribution of patients treated in our center, showing high mortality, especially early in the treatment of high-risk categories, identifying the areas where improvement of patient care can lead to improvement of survival rates. The relapse rate was not high but might be underestimated by the follow-up period's relatively short duration.

PB1368 CYTOGENETIC HETEROGENEITY IN PATIENTS WITH ACUTE LYMPHOBLASTIC LEUKEMIA AND TRANSLOCATION T(12;21)(P13;Q22), TEL/AML1 (ETV6-RUNX1)

A. Athanasiadou [1,*], G. Papaioannou [1], M. Gkaitatzi [1], T. Touloumenidou [1], M. Lamprou [2], M. Ioannidou [3], M. Iskas [1], A. Papalexandri [1], V. Andari [2], A. Tragiannidis [3], E. Hatzipantelis [3], E. Papakonstantinou [2], A. Anagnostopoulos [1]

[1]Hematology & HCT Unit, General Hospital "George Papanikolaou", [2]Pediatric Oncology Department, Hippokration General Hospital, [3]Hematology-Oncology Unit, 2nd Department of Pediatrics, School of Medicine, Aristotle University of Thessaloniki, Thessaloniki, Greece

Background: Translocation t(12;21)(p13;q22) and presence of the chimeric gene *ETV6-RUNX1* occurs more frequently (25-30%) in children with acute lymphoblastic leukemia (ALL), however only in 1-4% of adults. This translocation t(12;21)(p13;q22) cannot be detected through conventional cytogenetics, thus can only be diagnosed through FISH and RT-PCR methods and confers a favorable prognosis. However, 20% of the patients may relapse after years.
Aims: To study the frequency, type and long-term clinical impact of additional cytogenetic aberrations detected along with t(12;21)(p13;q22) in ALL patients.
Methods: We studied 41 B-ALL patients, 21 males and 20 females. Median age at diagnosis was 4 (range 2-24) years old. Flow cytometry revealed common ALL in 25 and pre-B ALL in 16 patients. Median WBC count at diagnosis was 6,7 K/µl (0,84-120). *ETV6-RUNX1* transcripts were detected in all patients. Further transcript study was performed in 31 patients. Type I (298 bp zone) and type II (259 bp) transcripts were found in 24 and 7 patients respectively. All patients underwent bone marrow cytogenetic analysis.
Results: Complete cytogenetic analysis was performed in 39/41 patient samples. Karyotype was normal in 12 and abnormal in 27 (69%) patients. Thirteen patients had diploidy, 7 had hyperdiploidy, 3 had hypodiploidy, 2 had hypotriploidy and 2 had hypotetraploidy. Structural chromosomal abnormalities were detected in 10/27 samples, numerical in 2/27 while both type of abnormalities in 15/27. Aberrations of chromosomes 12p or 21 or both (12p/21) were detected in ten, nine and one patient respectively. Deletion of 11q, and aberrations of 6q and 9p were detected in four, six and two patients respectively. Complex karyotype (three or more aberrations) was found in eighteen patients with median number of aberrations 5 (range 3-15). Ten patients had more than 4 aberrations. Clinical data was available for 40/41 patients. They all achieved hematologic remission. In a median follow up of 57.47 months (27-161), 10-year possibility of overall survival (OS) was 94% and 10-year disease free survival DFS was 92%. 10 year DFS was 86% for patients bearing abnormal karyotype and 100% for the normal karyotype group. Thirty-seven patients still remain in first remission, while two have relapsed. One of the relapsed patients died, while the other one is in second remission. One patient died in first remission. At the time of relapse the karyotype was abnormal in two relapsed patients. Clonal evolution with abnormalities as –Y, +21 and add(22)(q11) was detected in the one, whose diagnostic cytogenetic sample was available.
Summary/Conclusion: ALL with t(12;21)(p13;q22) is a disease with favorable prognosis and of wide heterogeneity. Additional aberrations involving chromosome 12, 21, 6, 9 and 11 as well as complex karyotype are frequently detected. Abnormal karyotype and clonal evolution is observed in relapse. Further study is needed in larger cohorts as well as with longer monitoring in order to investigate the biological and prognostic significance of additional chromosomal abnormalities.

PB1369 VALIDATION OF OPTICAL GENOME MAPPING FOR DIAGNOSIS OF ACUTE LEUKAEMIA IN PEDIATRIC PATIENTS

E. G Sánchez [1,*], A. Gómez [2], R. Giménez [1], M. Trandafir [1], C. Patón [1], L. Madero [3], M. Ramírez [3]

[1]Oncohematology, Fundación para la Investigación Biomédica del Hospital Infantil Universitario Niño Jesús (FIB HNJ), [2]Cytogenetics, [3]Oncohematology, Hospital Infantil Universitario Niño Jesús, MADRID, Spain

Background: Cytogenetics has led to the discovery of multiple chromosomal anomalies associated with hemato-oncologic diseases in children and adolescents. From its beginning till now, and with the contribution of the molecular biology, there has been an improvement of the classic cytogenetic that allow cytogenetists to perform a more precise diagnosis. The introduction of next generation sequencing (NGS) has dramatically changed the way clinical molecular laboratories analyze their samples over the past 10 years, but for most clinical cytogenetic analyses a combination of karyotyping (KT), fluorescence in situ hybridization (FISH) and CNV-microarrays are still performed to detect genetic biomarkers of disease. Each of these tests has its own limitations such as maximum banding resolution (KT), knowledge of which loci to test and is limited in throughput (FISH) and lacking the ability to identify balanced chromosomal aberrations, to map gained material or nor are able to detect mosaicism lower than 5-20% (CNV-microarrays). These conventional cytogenetic techniques allow the detection of Structural variants (SV) significantly contributing to the discovery of disease causing genes are part of the routine diagnostic workflow in any tertiary hospital in the national health system. This is especially important in a center such as Hospital Infantil Universitario Niño Jesús, which cares for children and adolescents, populations in which rare genetic-based diseases are added to hemato-oncological pathology, for which genetic diagnosis is essential during the diagnostic phase. Recently, genome-imaging of extremely long linear molecules by optical genome mapping (OGM) to detect SVs and copy number variants (CNVs) has emerged as an efficient technology to replace the conventional cytogenetic diagnostic techniques improving the limitations mentioned above.
Aims: Our main objective was performed a clinical validation study of Acute lymphoblastic and myeloid leukaemia samples by (OGM) using Bionano Saphyr platform previously analysed using karyotyping, FISH and/or CNV-microarrays. Moreover, we proposed to identify new cytogenetic alterations related to paediatric diseases not previously detected by current methodologies.
Methods: Bone marrow aspirates and frozen cell samples at diagnosis of patients with leukaemia were processed for OGM with the Bionano Genomics Saphyr System. In brief, the ultra-high molecular weight (UHMW) gDNA from children and adolescent samples was extracted, labelled and loaded onto Bionano chip to perform a run in Saphyr platform. Then, the data collection was analysed and the results were validated and statistically analysed. Finally, novel findings by OGM were examined.
Results: We obtained not only a full concordance with previously diagnostic results obtained by conventional cytogenetic techniques but also we described novel structural variants missed by the other methods which could play an important role for the outcome of the leukaemia disease.
Summary/Conclusion: The analysis of SV and CNV by OGM emerge as a powerful tool in cytogenetic laboratories improving the pediatric routine diagnosis of Acute Leukemia both in children and adolescents.

PB1370 MANAGEMENT AND MORTALITY OF ACUTE LEUKEMIA DURING COVID-19 PANDEMIC: 8-MONTH FOLLOW-UP AT A SINGLE INSTITUTION IN PERU.

J. Vasquez [1,*], E. Peña [1], T. Vidaurre [1]

[1]*Medical Oncology, Instituto Nacional de Enfermedades Neoplasicas, LIMA, Peru*

Background: The COVID-19 pandemic is a global public health crisis. Most patients were affected on their active treatment, patients with acute leukemia are particularly vulnerable to any change in their curative therapy. It has been almost a year since the first reported case of COVID-19 in Peru. Our country had the highest mortality rates per one million population during the first wave. Since January 2021 we are on the second wave with the total excess deaths higher than the first wave.
Aims: The aim of this study was to report the management and mortality of acute leukemias during the COVID-19 pandemic and its impact in relapse or survival of leukemia patients.
Methods: We included prospectively patients aged 14 years or older with the diagnosis of acute leukemia on active treatment and treated at the National Cancer Institute (NCI) in Peru since March 8th, 2020 to June 20th, 2020. The first result was reported as part of a multicenter study in the ASH 2020 annual meeting, now we are reporting a follow-up after 8 months of the last recorded case. We compared the leukemia status between the first cohort and the last cohort using chi-square test.
Results: 126 patients were evaluated during the first 100 days of started the COVID-19 pandemic in Peru (cut point June 20th 2020), the median age was 32 (range 15-70). 52% were male. 65% of patients had high-risk factors. 53% of patients were Ph negative Acute lymphoblastic leukemia (Ph- ALL), both Ph + ALL and Acute myeloid leukemia (AML) were 18.2% each one of them. Acute promyelocytic leukemia (APL) were 10.3% (n=13). 83.3% were on complete response. 45% of patients were on consolidation, 33% on maintenance, 12.6% on reinduction and 8.7% on induction. Modification of treatment due to COVID-19 was made in 34.9%. The reasons for modification were mainly due to logistic issues (54.5%) followed by medical decision (45.5%). 3.9% of patients had COVID-19 infection, 80% of them were mild-moderate cases. Only 1 patient (25%) died from COVID-19 disease.
On June 2020, 61% of patients were alive in CR and 20.6% were alive with leukemia, (total 103 patients alive). 23 patients (18.2%) died during the study period, 14.3% had leukemia-related death, 3.2% treatment-related death (on CR), and 0.8% COVID-related death.
Up to February 28th, 2021 of the 103 patients alive in the first cohort 63 (61.1%) patients are alive in CR (previous 77 patients) being that 18% of patients relapsed. Of the 26 patients alive with leukemia (1 received intensive treatment and achieved CR). During this second cohort 9 (8.8%) patients died, 8 from leukemia-related death (7.8%) and 1 (0.9%) patient from treatment-related death. It is important to note of the 8 patients with leukemia-related death 6 (75%) were on CR. In the second cohort no COVID-19 infection was reported. From the initial 126 patients only 94 (74.5%) patients are alive. For the total cohort leukemia related death accounts for 20.6% (n=26), treatment-related death in 3.9 (n=5) and COVID-19 in one case. The difference between the leukemia status in both cohorts were compared with a statistically significant difference p<0.001.
Summary/Conclusion: The modification on the treatment due to COVID-19 was mainly because logistic issues followed by medical decision. The mortality of patients with acute leukemia has increased in a short period of time, being that a quarter of them have died mainly due to leukemia-related death, followed by treatment-related death. Both COVID-19 infection and COVID-19 death were rare in our cohort. The difference in deaths and relapsed between both cohorts was statistically significant.

PB1371 THE IMPACT OF RISK STRATIFICATION BY EARLY BONE-MARROW RESPONSE IN CHILDHOOD T- ACUTE LYMPHOBLASTIC LEUKAEMIA (A SINGLE INSTITUTION EXPERIENCE IN AZIZA OTHMANA HOSPITAL, TUNIS, TUNISIA).

B. A. Yosr [1,1,*], K. Yasmine [1], J. Rim [1], C. Ons [1], B. Marwa [1], B. Manel [1], K. Salma [1], A. Mariem [1], B. L. Rayhane [1], M. Balkis [1], A. Lamia [1]

[1]*Clinical Hematology, Aziza Othmana Hospital, Hospital Aziza Othmana, Tunis, Tunisia*

Background: T-cell acute lymphoblastic leukemia (T-ALL) represents approximately 15% of all newly diagnosed ALL cases in pediatric patients. Although historically, outcomes for T-ALL were inferior to those of B lymphoblastic leukemia (B-ALL), the prognosis of T-ALL has been steadily improving in recent years due to increased chemotherapy protocols in particular with the use of high doses of Methotrexate and Asparaginase.
Aims: This study aimed to assess the therapeutic outcomes of children and adolescents with T-ALL treated according to the EORTC 58951 protocol, patients were stratified by age, WBC at diagnosis, immunophenotype, karyotype and steroids response in peripheral smears after 7 days of corticosteroid and one IT dose of MTX. The stratification strategy was extended by additional use of early response to therapy: blast cell count in the bone marrow (BM) was examined on D19 during remission induction, and determination of MRD measured by FCM in the BM at the end of induction (D35). All patients were assigned to a DXM based induction. Patients whose blast cells were ≥ 25% in BM (M3 marrow) at D 19, or whose MRD was positive at the end of induction, had their treatment one step upgraded.
Methods: Between January 2006 and December 2017, 377 children and adolescents with previously untreated ALL were treated according to the EORTC 58951 protocol, 93 (24.6%) have T-ALL. Median age was 13 years (18months to 25 years), the ratio of male to female was 4.1: 1, 7.5% and 2.7% have initial system nervous system and testicular involvement, Median WBC was 61.5 G/l (1.5 – 960 G/l) and 40.9% with a WBC ≥ 100 Giga/l.
Results: All patients received phase IA RM2- VHR according to the EORTC58951 protocol, with a 4-drug induction containing

dexamethasone and an early introduction of Methotrexate high dose on day 8 and Cyclophosphamide on day 9. 42.4% were steroid poor responders at day 8 in in the peripheral blood (pB). On day 19, 18.4% had M3 marrow. The CR was 88,2%, induction failure and induction death rates were 6.5% and 5.3% respectively. MRD results detected by a simplified flow cytometric assay, sensitivity of 0,01%, between 0,01% and 0,1%, between 0,1% and >1% was achieved respectively in 40.3%, 34.7%, 20.8% and 4.2%.
41.4% were assigned to the average 2 risk (AR2) group, 37.9% to the very high risk (VHR) group and 20.7% had received sibling stem cell transplantation in 1st CR.
The 5-year OS, EFS and RFS were 72.9%, 66.4% and 77.7% respectively. In Univariate analyses, WBC< 100 G/l, no M3 bone marrow on day 19 and complete remission at the end of induction have a significantly better OS. The prognostic value of morphological assessment of bone marrow blasts on day 19 during remission induction and the achieving of complete remission at the end of induction were the most prognostic factors for EFS and RFS.The 5-year OS was 90% for patients assigned to AR2 group, 66.4% for VHR and 76.9% for sibling stem cell transplant in CR1 (p: 0.04).
Summary/Conclusion: Early treatment response as assessed by morphological examination has important prognostic significance, and can be performed in a resource poor patient population.

PB1372 L-ASPARAGINASE ASSOCIATED ACUTE PANCREATITIS IN CHILDREN WITH ACUTE LYMPHOBLASTIC LEUKEMIA

Ö. Tüfekçi [1], S. Aytaç [2], Ç. Coşkun [3], D. Karapınar [3], M. Evim [4], S. Güler [4], M. Erdem [5], T. Karapınar [5], Y. Oymak [5], S. Yılmaz [1], H. Ören [1,*], N. Yaralı [6], A. Ayçiçek [7], G. N. Özdemir [7], C. Albayrak [8], E. Ünal [9], A. Özcan [9], B. Adaklı Aksoy [10], A. Meral Güneş [4]

[1]Pediatric Hematology, Dokuz Eylül University Faculty of Medicine, İzmir, [2]Pediatric Hematology, Hacettepe University Faculty of Medicine, Ankara, [3]Pediatric Hematology, Ege University Faculty of Medicine, İzmir, [4]Pediatric Hematology, Uludağ University Faculty of Medicine, Bursa, [5]Pediatric Hematology and Oncology, Dr. Behçet Uz Children's Hospital, İzmir, [6]Pediatric Hematology and Oncology, Ankara City Hospital, Ankara, [7]Pediatric Hematology and Oncology, University of Health Sciences, İstanbul, [8]Ondokuz Mayıs University Faculty of Medicine, Pediatric Hematology, Samsun, [9]Pediatric Hematology and Oncology, Erciyes University Faculty of Medicine, Kayseri, [10]Pediatric Hematology and Oncology, Altınbaş University Faculty of Medicine, İstanbul, Turkey

Background: L-asparaginase (L-ASP) is one of the most important chemotherapy drugs in the treatment of acute lymphoblastic leukemia (ALL). This drug, which has a crucial role in the treatment of ALL induction, has many toxicities like hypersensitivity reactions, pancreatitis, hemostatic disorders, liver function test disorders, and hyperlipidemia. L-ASP-associated pancreatitis is a serious condition with a frequency of 2-10%, with significant morbidity and sometimes death.
Aims: In this study, we aimed to describe the clinical findings and complications of L-ASP-associated acute pancreatitis in children with ALL and also to examine the attitude of the centers in terms of re-administration of L- ASP after development of pancreatitis.
Methods: Patient data form sent to pediatric hematology/oncology clinics with the announcement of Turkish Pediatric Hematology Society for retrospective evaluation of ALL cases with L-ASP associated acute pancreatitis. All patients were treated with ALLIC or BFM based ALL protocols.
Results: Thirty-one ALL patients from 10 centers, who were diagnosed with L-ASP-associated acute pancreatitis between September 2008 and January 2020 were included in the study. The median follow-up time was 59 months (8-139 months). There was a total of 34 acute pancreatitis episodes due to recurrences in two patients. The median age was 70 months (21-213 months) and male to female ratio was 0.9. Twenty-four patients (77%) were newly diagnosed ALL patients and 7 patients (22%) were relapse patients. Of the 24 newly diagnosed ALL patients; 7 patients (29%) were in the standard risk group, 8 patients (33%) were in the medium-risk group, and the remaining 9 patients (38%) were in the high-risk group. Acute pancreatitis occurred during treatment phase of induction in 9 (26%) patients, consolidation in 6 (18%), re-induction in 9 (26%), maintenance in 3 (9%) and relapse in 7 (21%) patients. E. Coli L-asparaginase was the most frequently used (74%) preparation. The most common complaint was abdominal pain (96%); followed by anorexia (68%), nausea/vomiting (56%) and high fever (39%). The median time between the last dose of L-ASP and the diagnosis of acute pancreatitis was 6 days (1-18 days). The median duration of treatment interruption was 16 days (0-240 days). Complications of pancreatitis was death in 3 patients (9.6%), insulin dependent diabetes in 6 patients (19.3%), and pancreatic pseudocyst in 6 patients (19.3%). L-ASP was completely removed from the protocol in 23 patients (74%) after the incidence of acute pancreatitis while it was re-administered in 6 patients (19%). Pancreatitits recurred in 2 (33%) of those 6 patients but none of the repeated episodes resulted in death.
Summary/Conclusion: This retrospective study demonstrated a relatively high complication rate due to L-ASP associated acute pancreatitis. Most centers showed a tendency to permanently discontinue L-ASP treatment after the incidence of pancreatitis. Re-exposure to L-ASP resulted with recurrence in some of the patients. Although there are serious complications resulting in death after L-ASP-associated pancreatitis, it has already been known that event-free survival is negatively affected in patients who can not receive scheduled L-ASP doses. For this reason, large-scaled comprehensive studies are needed to determine the criteria for re-administration of the drug and also to make changes in the general protocol approach when necessary.

PB1373 ACUTE LYMPHOBLASTIC LEUKEMIA IN ADOLESCENTS AND YOUNG ADULTS HEMATOLGY DEPARTMENT EXPERIENCE OF AZIZA OTHMANA HOSPITAL

B. Marwa [1,*], K. yasmine [1], S. kefi [1], E. azza [1], A. lamia [1], B. manel [1], M. raoudha [1], D. jaber [1], E. berred [1], K. rchid [1], B. N. hend [1], B. L. raihane [1], K. kacem [1], M. achour [1], B. meddeb [1], Y. ben abdennebi [1]

[1]HEMATOLOGY, AZIZA OTHMENA HOSPITAL, TUNIS, Tunisia

Background: Acute lymphoblastic leukaemia (ALL) in the adolescent and young adults(AYA) population constitute a different group from acute leukaemia in children: by their incidence, which is lower, their particular epidemiological and biological profiles and finally by their prognosis which is worse.However, since the use of pediatric protocols, various studies have shown improvement in their survival.
Aims: This epidemiological study involved 79 adolescent and young adults aged between 15 and 26 years with acute lymphoblastic leukemia (ALL) and treated according to the pediatric protocol EORTC 58951. We will only report the therapeutic results of Philadelphia-negative ALL.
Methods: This is a retrospective study between January 2006 and December 2017 (12 years) at the department of Hematology at Aziza Othmana Hospital.
Results: Median age was 17 years (15-26 years). Sex ratio was 2.95 (59M / 20F).Forty patients (50%) had a tumor syndrome. Central nervous system involvement was noted in 5 patients (6%)
The mean rate of WBC was 60 G (0.8-407 G). WBC rate > 50 G was noted in 33% of patients and> 100G in 21.5%. ALL T was found in 48% of patient vs. 40% of ALL B. Karyotype was normal in 41%. 33 patients had cytogenetic abnormalities (40.5%) among them 6 (9%) had a translocation t (9, 22). Only patients who are Philadelphia negative will be analyzed.
All patients received RM2-VHR induction. Corticosensitivity was studied by a myelogram on D7 in 63 patients (M1: 6 patients, M2: 8 patients, M3: 33 patients and failure: 16 patients) and by a blood smear on D8 in all patients (17.8% of corticosteroid resistance).
Chemo sensitivity was studied by a myelogram on D19 in 71 patients: 15.5% were chemo-resistant. Three patients (4.1%) died in induction.
The remission rate was 93.1%. Minimal Residual Disease (MRD) was carried out in 65 patients: MRD 10^{-3} in 4 (6%).Thirty-four patients (47.8%) were treated according to the RM2 arm and 37 (52.2%) according to the VHR arm, among which 25 (67.5%) had an indication to transplantation. Allogeneic hematopoietic stem cell transplantation (alloHSCT)was only performed in 8 patients. - One patient died during treatment (1.4%). Fifteen patients relapsed (22%).
At 36 months: Overall Survival (OS), event-free survival (EFS) and relapse free survival (RFS)are respectively 78.4%, 81.2% and 74.1%.
At 5 years: OS, EFS and RFS are respectively 75.1%, 76.1% and 69.3%
Summary/Conclusion:: in our study, we confirm the specific aspects of ALL AYA: presence of tumor syndrome as well as the initial involvement of the central nervous system, high wbc's rate, the predominance of ALL - T, the higher frequency of Phi positive ALL and CorticO-chemoresistance. With leukemia regimens based on pediatric protocols, the survival of AYA group has clearly improved compared to patients treated with adult protocols with acceptable toxicity.

PB1374 L'ASPARAGINASE ALLERGIC REACTIONS IN CHILDREN WITH ACUTE LYMPHOBLASTIC LEUKEMIA

M. Sabrine [1,*], B. A. Yosr [1], B. Marwa [1], A. Emna [1], A. Lamia [1], M. Raoutha [1], K. Selma [1], J. Dorra [1], B. Manel [1], B. N. Hend [1], B. Emna [1], K. Rachid [1], A. Meriem [1], K. Karima [1], B. Raihane [1], M. Balkis [1]

[1]*hematology, Aziza Othmana hospital, Tunis, Tunisia*

Background: L-asparaginase (LASPA) is an important anti-tumoral drug in the treatment of acute lymphoblastic leukemia in children, however, its toxicity, mainly due to severe allergic reactions, limits its use and even leads to its permanent discontinuation.
Aims: Describe the allergic reactions associated with the use of LASPA and their impact on overall survival (OS) and relapse-free survival (RFS).
Methods: Retrospective study conducted over 10 years (from January 2006 to December 2015) involving 316 patients treated in the clinical hematology department of Aziza Othmana Hospital according to the EORTC 58951 protocol and who received E.coli asparaginase.Allergic reactions were graded according to the Common Terminology Criteria for Adverse Events (CTAE) score
Results: All patients received intravenous LASPA.
Out of 316 patients,74 had an allergic reaction to L-asparaginase.
The median age was 6 years (18 months - 26 years) with a sex ratio of 2.36 (52 males and 22 females).
According to the CTAE score, they were grade 1 or 2 in 66% of cases, grade 3 in 24% of cases and grade 4 in 10% of cases. No deaths were noted. The occurrence of allergic reactions were noted essentially, (in 84% of cases), in post induction at the time of reintroduction of LASPA, and after having received an average of 5 doses(1-7).
The severity of the reaction was independent of age (p=0.45) and the total dose of LASPA.
Forty three patients were switched to Erwiniase. An allergic reaction was noted in 25.6% of these patients.
Of the 31 patients (42%) who were not switched to Erwiniase, 17 patients (55%) were permanently discontinued, and 14 patients (45%) were premedicated for E.coli asparaginase and have continued
their treatment with LASPA.
The 5-years OS was significantly different between patients in whom LASPA was permanently discontinued due to a severe allergic reaction and patients who continued LASPA therapy (94% versus 64% with p=0.005).
Similarly, The 5 –years RFS was 85% versus 65% with p=0.034.
Patients who received a total dose of LASPA ≥100 000 IU/m2 had better OS and RFS than those who received a lower dose with p=0.004 and p=0.01, respectively.
However, the switch to Erwiniase had no impact on OS and RFS with p=0.07 and p=0.11, respectively.
Summary/Conclusion: Discontinuation of LASPA treatment due to allergic reactions is quite frequent with important prognostic implication, which encourages to better study these allergic reactions to better manage them and to discuss new therapeutic alternatives more effective and less allergenic than LASPA to optimize the survival rates of LAL.

PB1375 ACUTE LYMPHOBLASTIC LEUKEMIA: A DECADE OF MONOCENTRIC EXPERIENCE IN MOROCCO

S. Ahchouch 1,*, E. M. Mahtat 1, S. Jennane 1, M. Ababou 1, H. El maaroufi 1, K. Doghmi 1

[1]*Clinical Hematology, Military Hospital Of Instruction Mohammed V, Rabat, Morocco*

Background: Several factors influence the prognosis of adult patients with novo acute lymphoblastic leukemia (ALL) including the evaluation of the therapeutic response after induction MRD1(by Flow Cytometry or molecular methods). Unfortunately, access to molecular tests in our country is limited and measurement until a few years ago was based only on measurement of cytogenetic remission.
Aims: The purpose of our study was initially describe the characteristics of adult patients treated for de Novo ALL. The secondary aim was to assess the efficacy and tolerance of the treatments received in terms of OS and PFS as well as to define the prognostic factors influencing these parameters.
Methods: We retrospectively collected data from the medical records of all young patients(age>18 years) diagnosed as having de Novo ALL between January 2010 and September 2020 at the clinical hematology service of the military hospital of Instruction Mohammed V in Rabat. All the patients were treated according to several therapeutic protocols: GRAALL-2005 and GRAALL 2014 for young patients(<60 years old) and according to the GRAALL-SA or EWALL-PH-02 protocols for the elderly(>60 years old).The FRALLE 93 and FRALLE 2000 protocols have been used in patients aged between 18 and 20 years.Allo-HCT has been indicated in eligible patients classified as high risk with an HLA-matched donor
Results: Forty-five patients were enrolled in our study.Mean age at diagnosis was 34.37± 16.42 years with a sex ratio of 1.8.13.3% of patients had lymphadenopathy,15.6% hepato-splenomegaly and 33.3% of patients had a bone pain at diagnosis.More than half(66.7%) of all patients had an ALL with B-Phenotype(ALL-B II in 66.7%) and 33.3% LAL-T.33.3% of patients had leukocytosis(WBC>100,000/mm3 in ALL-T and >30,000/mm3 in ALL-B)and 6.7% had initial central nervous system involvement.Fourteen(31.1%) patients had an unfavorable karyotype of which nine were carriers a Philadelphia chromosome.The M-BCR-Abl and m-BCR-Abl transcripts were found in 7(15.5%) and 3(8.9%)patients respectively. Almost half(47.7%) of all patients were treated according to GRAALL-2005 protocol,13.3% based on GRAAL-2014 protocol.Only 8,9% were treated according to the GRAALL-SA and EWALLPH-02 protocols.Imatinib was the most widely used TKI(17.8%).Complete hematologic remission(CR1)after induction was obtained in 84.4% of cases.Thirteen(28.28%)patients underwent an Allo-HCT among then, two were ALL Ph positive.The donors were geno-identical in 22.2% of cases and haplo-identical,-Matched unrelated Donod (MUD)or from umbilical Cord Blood(UCB) in 2.2% of cases.Haematological, infectious, thromboembolic/hemorrhagic toxicities were reported in 91.1%, 8.9% and 8.9%, respectively. Only one patient(2.2%)developed a L-Asparaginase-related toxicity and four(8.9%)patients had grade 1-3 peripheral neuropathy due to vincritine.In our series, multivariate analysis showed CR1 as being the only independent factor influencing both PFS[95% CI, 0,02-0.31](p = 0.00) and OS[95% CI, 0.06-0.58](p = 0.00).After a median follow-up of 27 months, the medians of PFS and OS were 19, 6 months and 37.3 months, respectively, with 24(53.3%) relapses and 18(40%) deaths.
Summary/Conclusion: The epidemiological and clinical profile of our patients is consistent with the findings of the studies. Our survival results are still lower than those reported in clinical trials. This may due to the limited access to Allo-HCT and the measurement of RC1 by molecular technics.It is a more precise reflection of therapeutic efficacy and allows the implementation of an optimized treatment, better adapted to the risks.

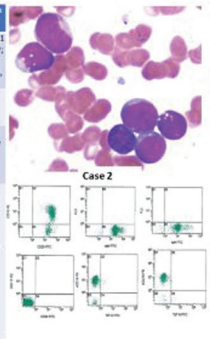
PB1376 SEVERE HAEMOPHILIA A DIAGNOSED IN A CHILD WITH ALL: FIRST REPORT IN GREECE

M. Ioannidou [1,*], M. Palabougiouki [1], E. Thomaidou [1], A. Bangeas [1], A. Tragiannidis [1], T. Papageorgiou [1], M. Economou [2], A. Teli [2], V. Tsavdaridou [3], A. Galli-Tsinopoulou [1], E. Hatzipantelis [1]

[1]*Children & Adolescent Haematology-Oncology Unit, 2nd Department of Pediatrics, School of Medicine, Faculty of Health Sciences, AHEPA University General Hospital of Thessaloniki,* [2]*Bleeding Disorders Centre, 1st Department of Pediatrics,School of Medicine, Faculty of Health Sciences, Hippokration General Hospital,* [3]*Department of Immunology, Microbiology Laboratory, AHEPA University Hospital, Aristotle University of Thessaloniki, Thessaloniki, Greece*

Background: The coincidence of acute lymphoblastic leukaemia (ALL) and hemophilia is extremely rare in pediatric age group.
Aims: We report the 1st case in Greece with severe haemophilia A diagnosed in a child with ALL.
Methods: A 2,5 year old boy admitted to our Unit due to generalized weakness and episodes of severe nose bleeding for the last month. Family history revealed that boy's uncle (mother's brother) suffered from haemophilia A. From physical examination, paleness, petechiaes and ecchymoses were noticed, as well as, organomegaly. Peripheral blood count showed hemoglobin level of 5.6 g%, white cell count of 212 × 109/L (blasts 95%), and platelet count of 16 × 109/L. Activated partial thromboplastin time (APTT) found very high, but prothrombin time (PT) not.
Results: Bone marrow aspiration-immunophenotype confirmed the diagnosis of B-II (common) ALL. RT-PCR for genetic alterations BCR abl, AF-4/MLL and TEL-AML1 found negative. CSF was also negative for blastic cells. Following the placement of central venous catheter prolonged bleeding was noticed. Prolonged APTT and family history led to the possibility of hemophilia which finally diagnosed from laboratory tests (FVIII levels <1%). The patient was placed on induction therapy for ALL, according to ALLIC 2009 protocol, and FVIII replacement. On day 33 of treatment, the patient achieved complete remission. He

finished successfully the first 6 months of treatment and he will hopefully continue on maintenance phase of the protocol.
Summary/Conclusion: The most common haemorrhagic disorder in children with leukaemia is disseminated intravascular coagulation (DIC). The diagnosis of haemophilia A is very rare and there is no clear therapeutic plan in such cases, but timely diagnosis should not be delayed and proper treatment should be based on clinical findings.



PB1377 B-ACUTE LYMPHOBLASTIC LEUKAEMIA/LYMPHOMA WITH ATYPICAL CLINICOPATHOLOGICAL/GENETIC FEATURES

D. S. Soliman [1,2,3,*], A. Amer [1], H. El Omri [4], S. Kohla [1], I. Bilal [5], A.-S. Ahmad [1], I. Ganwo [1], E. McBride [5], S. Elkorashi [4], F. Ibrahim [1]

[1]Department of laboratory medicine and pathology, Hamad medical corporation, [2]Department of laboratory medicine and pathology, Weill Cornell Qatar, [3]Clinical pathology department, National Cancer Institute, [4]Clinical Hematology, Hamad medical corporation, [5]Hematology, Sidra Medical and Research Center, Doha, Qatar

Background: B-acute lymphoblastic leukemia/lymphoblastic lymphoma is a hematologic neoplasm of precursor lymphoid B-cells. The lymphoblasts are almost always positive for the B-cell markers and TdT in most cases, whereas CD20 and CD34 expression is variable. B-ALL/LBL demarcated by expression of at least one surrogate immaturity marker and typically lack features indicating mature phenotype.
Aims: The objective of this review is to recap B-ALL/LBL with unusual clinicopathologic features diagnosed in our center.
Methods: We reviewed patients with B-ALL/LBL diagnosed in Hamad medical corporation according to WHO 2016 diagnostic criteria (2011-2019). We included B-ALL with one or more unusual features including: atypical clinical presentation, rare morphology, unusual cytogenetics, rare immunophenotype and phenotype overlapping with mature B-cell neoplasms. The relevant data correlated with the disease course, and patients' response. The relevant and most recent literature was reviewed.
Results: 15 patients with unusual challenging clinicopathologic features were detected. Rare cases showed lack of expression of immaturity markers in an otherwise typical ALL (three patients), including two patients of pediatric age group, one (# case 2) received ALL BFM 2009 protocol with good response and negative MRD. The second child (case #3), had some features overlapping with high grade B-cell lymphomas a very rare diagnosis in pediatric age group. The patients were treated according to Inter-B-NHL Ritux 2010 IGR 2009 and showed complete remission.
Few B-ALL cases showed asynchronous expression of immaturity marker (TdT) associated with markers indicating mature phenotype (mature B-ALL) (3 patients); including two patients with t(9;22)(q32;q11). Our cohort included three exceptional cases that showed loss/down regulation of pan B-markers CD19 and CD22. A single case showed rare coexistence of IGH and MYC rearrangements in de novo precursor B-ALL (double hit B-ALL). Two cases of B-ALL showed positivity for MPO by IHC in an otherwise typical B-ALL immunophenotype.
Unusual morphologic features detected in B-ALL, included increased fibrosis, BM necrosis, abnormal eosinophilia, lymphoblasts with granulation/ or pseudo Chediak-Higashi globule, Cup-like blasts or increased megakaryocytes (at presentation).

	Case No	Age/sex	Morphology	FCM features	Cytogenetics
B-ALL with negative immaturity markers	Case #1	M/26	PB: Pancytopenia, BM: 65% with stippled nuclear chromatin with vacuolation	CD45+(dim), CD19+, CD10 +(dim). CD34-, TdT-, surface IgM-, cytoplasmic IgM-, surface Kappa-, Lambda light -, CD20-	46,XY,t(8;15;17)(q13;q11.2;q23)[12] MYC-, BCL-2-, BCL-6-
	Case #2	M/9 Mon	PB: Pancytopenia BM: 40% blastoid morphology	CD45+ (negative to dim), CD19+, CD10+, CD20+, cCD79a+, HLA-DR+, cIgM+, sIgM+, TdT-, CD34 & CD117-	46,XY [30]
	Case #3	M/11	Pancytopenia, 4% blasts, stippled nuclear chromatin with vacuolation	68% B-cells with normal CD45+ (in the lymphocyte gate), CD19+, CD10+, CD20+, cBCL2+, sIgM+ with Lambda light chain restriction. CD34-, TdT-, and CD117-. MYC positive, BCL-2 pos	FISH:14q rearrangement, failed KT
B-ALL with down regulation of CD19 (Three cases)	Case #4	M/13 Mon	P.B: No circulating blasts BM: Microblasts	19% blasts (in the blast gate), CD45+(mod), CD10+, TdT+, sIgM+, CD19-, cytoplasmic CD22- and surface Kappa-, Lambda light chain-.	46,XY
	Case #5	F/41	P.B: Pancytopenia (severe anemia), no blasts. BM: Increased fibrosis (MF 2/3 score).	20% blasts, cCD79a+, CD10+, cCD22 (dim), cIgM, CD15+, CD13 (Par) and TdT. CD19 (partial on minority), PAX-5+.	Normal FISH KT:
	Case #6	M/23	Blasts morphology	91% blasts, CD34+, HLA-DR+, cCD79a+, dim CD19 (par), TdT+, CD10 (par) and cCD22 (par, dim).	46,XY

Summary/Conclusion: The complexity and variety of cases presented in this review emphasize the importance of multi-parametric approach and its value in the proper categorization of patients with B-ALL/LBL. Few cases of precursor B-ALL patients show clearly overlapping feature with mature B-cell neoplasms, however, currently no definitive WHO category that can adopt such B- neoplasms and no standard treatment protocols. In similar cases the expression of TdT was given the upper hand over other features. In pediatric age group, cases that lack expression of immaturity markers, were best classified as precursor B-ALL, being the commonest in this age group, and supported by dim CD45 expression, blastoid morphology and/or lack of surface immunoglobulin expression. Pan B-cell markers is rarely lost in denovo B-lymphoid neoplasms. Reporting B-ALL with such peculiar features would probably draw attention to B-ALL unusual/overlapping features and experiences regarding treatment and disease outcome.

PB1378 PH+ ACUTE LYMPHOBLASTIC LEUKEMIA PRESENTED AS CHOLESTATIC JAUNDICE IN A 3-YEAR- OLD BOY

E. Thomaidou [1,*], A. Bangeas [1], M. Ioannidou [1], M. Palabougiouki [1], A. Tragiannidis [1], T. Moudiou [1], T. Papageorgiou [1], V. Tsavdaridou [2], A. Athanasiadou [3], A. Papalexandri [3], A. Galli - Tsinopoulou [1], E. Hatzipantelis [1]

[1]Children & Adolescent Hematology-Oncology Unit, 2nd Department of Pediatrics, School of Medicine, Faculty of Health Sciences, Aristotle University of Thessaloniki, AHEPA University General Hospital of Thessaloniki, [2]Department of Immunology, Microbiology Laboratory, AHEPA University Hospital, Aristotle University of Thessaloniki, [3]Hematology & HCT Unit, General Hospital "George Papanikolaou", Thessaloniki, Greece

Background: Acute lymphoblastic leukemia (ALL) is the most frequent malignancy in pediatric population and it can manifest with uncommon clinical features, including liver disorder.
Aims: We report an unusual case of Ph+ ALL presenting with cholestatic jaundice on initial diagnosis.
Methods: A 3-year-old boy of Asian descent, with a history of congenital hypothyroidism, presented with cholestatic jaundice and transaminasemia. Symptoms started with low grade fever for 3 days and an abdominal pain radiating to his back and he gradually developed clinical jaundice. On admission his peripheral blood count showed leukostasis, with a total white blood count of > 100 K/μl (total blast cells 80%), thrombocytopenia, with a platelet count of 19 K/μL, and anemia, with hemoglobin levels of 7,1 g/dL. Biochemical findings revealed direct hyperbilirubinemia, with total bilirubin levels of 17,3 U/L and conjugated bilirubin levels of 15,5 U/L, and remarkably elevated transaminase levels with alanine aminotransferase (ALT) 1607 U/L and aspartic aminotransferase (AST) 3246 U/L. Gamma glutamyl transferase (GGT) was 115 U/L and lactate dehydrogenase (LDH) was 1256 U/L.
Results: Serology for hepatotropic viruses was negative, as well as antinuclear antibodies and immunoglobulin levels. An abdominal ultrasound showed remarkable gallbladder wall thickening with a small amount of perihepatic free fluid. Bone marrow aspiration – immunophenotype confirmed Common ALL (B-II) diagnosis, while RT-PCR for BCR - ABL was positive. The boy started induction therapy (ALLIC 2009 chemotherapy protocol – prednisolone) with improvement of jaundice and liver function. On day 8 he started treatment with imatinib mesylate, as well as, continuation of standard chemotherapy plan. Bilirubin and transaminases levels gradually raised again. Meanwhile, after asparaginase administration he developed pancreatitis with elevated amylase and lipase levels, leading to a discontinuation of all the hepatotoxic agents and concerns regarding the course of treatment. Apart from the hematologic malignancy, viral causes, autoimmune hepatitis, Wilson's disease, and alpha-1-antitrypsin deficiency that were excluded, other causes of hepatocellular disfunction needed to be examined, such as cystic fibrosis, Dubin – Johnson, Rotor and metabolic syndromes. Up to date a liver biopsy is pending, as well as, the results of the genetic analysis with whole exome sequencing and metabolic screening.
Summary/Conclusion: Acute lymphoblastic leukemia is the most common malignancy in children and a plethora of symptoms can be manifested as a precursor of this type of blood malignancy. In most of the cases cure rate approaches 90%, but at the rare entity of Ph+ ALL prognosis is unfavorable. Challenging and unusual manifestations of ALL, such as direct hyperbilirubinemia and liver dysfunction requires great awareness at diagnosis and individualized treatment.

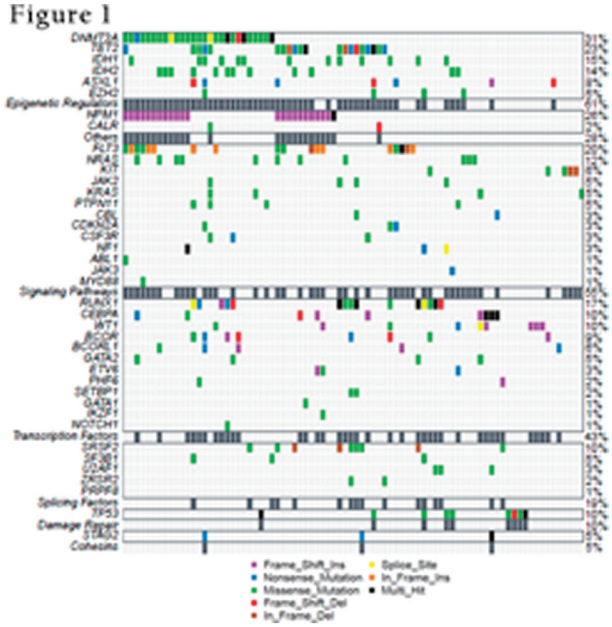
PB1379 BLINATUMOMAB FOR THE TREATMENT OF ADULT RELAPSED/REFRACTORY PHILADELPHIA CHROMOSOME-NEGATIVE B-CELL ACUTE LYMPHOBLASTIC LEUKEMIA: A SINGLE-CENTER REAL-LIFE EXPERIENCE OVER TWO YEARS

A. Ghiaur [1,*], B. Ionescu [1], A. Tatic [1,2], M. Cirstea [1,2], A. Bardas [1,2], M. C. Stancioaica [1], R. Hirjan [1], A. M. Chirila [1], C. Constantin [1], C. Doran [1], D. Coriu [1,2]

[1]Acute Leukemia Department, Center of Hematology and Bone Marrow Transplantation, Fundeni Clinical Institute, [2]Carol Davila University of Medicine and Pharmacy, Bucharest, Romania

Background: Adults with relapsed/refractory B-cell acute lymphoblastic leukemia (R/R B-cell ALL) have a dismal prognosis and a high mortality rate. The advent of new targeted therapies has led to higher rates of complete remission (CR), prolonged the overall survival (OS) and increased the likelihood of proceeding to allogeneic hematopoietic stem cell transplantation (HSCT).
Blinatumomab is a bispecific T cell-engaging antibody that binds CD3-positive T cells to CD19-positive lymphoblasts leading to the lysis of both malignant and normal B cells. The mechanisms of resistance remain unclear, but the occurence of extramedullary relapse, the loss of CD19 expression and a high disease burden are described as potential predictive factors for a poor response.
Aims: To describe patient characteristics, analyze outcomes, including the CR rate, OS and the proportion of patients who subsequently underwent allogeneic HSCT and review the tolerability of the drug.
Methods: This is a retrospective analysis of 10 patients with R/R B-cell ALL, with a median age of 29 (18-50) years, treated with blinatumomab between January 2019 and December 2020 at Fundeni Clinical Institute. Survival rates were calculated using the Kaplan-Meier method, adjusting for key patient demographic and clinical characteristics at baseline.
Results: Four patients (40%) had combined medullary and extramedullary localization – bone/lymph node/spleen. The median tumor burden before treatment was 45% blast cells (0.1 – 80%). The median number of previous salvage therapies was 1.7 (1-3).
The rate of CR was 40% (N=4) after the first cycle of blinatumomab. Among the responders, 50% (N=2) went on to receive allogeneic HSCT, and the remaining two patients relapsed before they could proceed to HSCT. All of the patients with high tumor burden received prephase therapy consisting of dexamethasone and, in selected cases, cyclophosphamide. The response rate was higher in patients with lower tumor burden compared with those with more than 50% blasts. The median OS was 5.2 months, and for those patients who achieved CR, the median RFS was 4.5 months, with a median follow-up of 9.8 months.
The treatment was generally well tolerated. All patients experienced adverse events, the most common being fever (90%, 9 patients). One of the patients developed disseminated intravascular coagulation as well as grade 3 cytokine release syndrome, leading to treatment discontinuation; one patient had grade 2 mandibular pain, which required opiod analgesia and one patient had a prolonged fever that lasted almost 3 weeks.
Summary/Conclusion: The rate of CR and the percentage of patients who underwent allogeneic HSCT following treatment with blinatumomab are similar to those reported previously. The RFS and OS rates are lower than the existing literature data. Along with previous studies, the current work highlights the existence of a subgroup of patients with poor response to blinatumomab monoterapy, which remains a major challenge in clinical practice.

Acute myeloid leukemia - Biology & Translational Research



PB1380 ARGENTINE REAL WORLD DATA EXPERIENCE ON GENE MUTATION PROFILING PANELS IN ACUTE MYELOID LEUKEMIA

M. Lincango-Yupanki [1,*], M. Asinari [2], M. Zeballos [2], F. Jauk [3], M. Rahhal [4], L. Zanella [5,6], I. Giere [7], M. J. Mela Osorio [6,7], M. Zubieta [4], A. Giménez Conca [3,6], E. Agriello [5,6], A. Navickas [4,6], M. B. Castro [2], J. Arbelbide [3], A. L. Basquiera [2], C. Belli [1,6]

[1]Laboratorio de Genética Hematológica, Instituto de Medicina Experimental (IMEX-CONICET)/ Academia Nacional de Medicina, Buenos Aires, Buenos Aires, [2]Hospital Córdoba, Córdoba, [3]Hospital Italiano Buenos Aires, Buenos Aires, [4]Hospital El Cruce, Florencio Varela, [5]Laboratorio de Especialidades Bioquímicas, Bahía Blanca, [6]Grupo Argentino de Leucemias Agudas (GALA), [7]FUNDALEU, Buenos Aires, Argentina

Background: Sequencing data from patients with Acute Myeloid Leukemia (AML) constitute a significant guidance at prognostic and therapeutic stages to support clinical decision making. In Argentina, next generation sequencing (NGS) on hematological diseases is performed in few institutions and the experience is currently based on small cohorts of patients. We have organized a collaborative working group in an effort to interactively increase the knowledge in our media.
Aims: To evaluate NGS real-world data from AML patients in a multicenter Argentine study.
Methods: Sequencing and clinical data of 90 adult AML patients were gathered from five centers performing NGS located across Argentina. Data was analyzed by using R-bioconductor (v4.0.3) and SPSS software. Statistical analyzes included Fisher's exact /Chi2 and Kaplan Meir/Log-rank test. Median values are presented with interquartile ranges, unless otherwise specified. P values <0.05 were considered significant and, when appropriate, a false discovery rate (FDR) <0.05 was calculated.
Results: Sequencing data was obtained from eight different myeloid panels (customized or commercially available kits), targeting a median of 54 (range 30-81) complete or hot-spot gene regions. Our patients showed a median age of 58 (41-68) years and a sex ratio (M/F) of 1.36 (49/36). In this cohort, 44 genes showed at least one alteration, with a total of 291 pathogenic variants. The median of sequence variants per patient was 3 (2-5) with a median variant allele frequency of 0.4 (0.26-0.47). The most compromised genes were DNMT3A, NPM1, TET2, FLT3 and RUNX1 affecting 60% of the cohort (Figure 1). Sequence alterations in FLT3 (P<0.001) and NPM1 (P=0.008) were found differentially enriched in patients with normal karyotype. Secondary-type AML based on Lindsley's 2015 classification (sAML-L) of variants were significantly associated with secondary-type AML (P<0.001). Within this classification, the most affected genes were SRSF2, BCOR and ASXL1 in 70% of the patients, also RUNX1 sequence variants were found significantly enriched (P=0.024, FDR=0.02) and TET2 mutations showed a tendency (P=0.04, FDR=0.23). Meanwhile, non-sAML-L were distinguished by NPM1 mutations (P<0.001; FDR=0.001). In addition, the somatic interaction of mutations was analyzed and, in accordance with the literature, NPM1-FLT3 (P<0.001), RUNX1-BCOR (P=0.003), TET2-SRSF2 (P=0.003), DNMT3A-IDH2 (P=0.006) were co-occurring events, while RUNX1-NPM1 (P=0.008) were mutually exclusive.
The median follow-up of this cohort was 18 (4-19) months with 51 reported deaths. The first-line therapy was 76% standard chemotherapy, 20% hypomethylating agents and 31 patients received hematopoietic stem cell transplantation. This procedure was favorable in terms of overall survival for patients <65 years with adverse molecular findings classified according to the ELN17 (38 vs 3 months, P=0.003) and to the Eisfeld's 2020 proposal (29 vs 3 months, P<0.001), also with sAML-L or TP53 (19 vs 4 months, P=0.009) and for those with DNMT3A-TET2-ASXL1 (DTA) variants (29 vs 12 months, P=0.026).

Figure 1

Summary/Conclusion: Compilation and analysis of real-world NGS data from multiple institutions which are generated in diverse sequencing platforms represents a challenge in a collaborative setting. Nevertheless, our results are comparable to those reported in the literature and offer clinically relevant evidence that may help Argentine hematologists to make treatment decisions.

PB1381 IDENTIFICATION AND VALIDATION OF A SUBSET OF CANDIDATE FDA-APPROVED DRUGS FOR REPURPOSING IN HOXA EXPRESSING AML

K. Butcher [1,*], L. Kettyle [2], M. Grundy [1], C. Seedhouse [1], A. Thompson [1]

[1]Blood Cancer and Stem Cells, University of Nottingham, Nottingham, [2]Centre for Cancer Research and Cell Biology, Queen's University Belfast, Belfast, United Kingdom

Background: Increased HOXA expression is associated with intermediate to poor prognosis in acute myeloid leukaemia (AML) and decreased expression acts as a readout for candidate experimental therapies. Underlying causes of increased HOXA expression range from gross rearrangements involving the Mixed Lineage Leukaemia (MLL) gene to mutations in single genes such as Nucleophosmin. To date, direct targeting of HOXA proteins has not been clinically feasible. In a *Hoxa* cluster-dependency model of MLL-rearranged leukaemia, we recently identified a group of FDA-approved drugs that could potentially target *HOXA* signatures indirectly by disrupting key pathways and processes.
Aims: This study aims to further identify and validate a subset of FDA-approved drugs in HOXA overexpressing AML.
Methods: RNA-sequencing was performed following conditional deletion of the *Hoxa* cluster in a mouse model of MLL-AF9 leukaemia. Bioinformatics tools including QUADrATiC, Ingenuity Pathway Analysis and the LINCS platform were used to identify candidate pathways and FDA-approved drugs. A subset of drugs were validated using cell viability assays in a panel of AML cell lines (including HL60, MOLM-13, MV4-11, OCI-AML3, THP1 and KG1a), and calculated IC50 values were obtained from dose-response curves for a subset of the candidate drugs.
Results: Connectivity mapping of the RNAseq data identified a list of candidate FDA-approved drugs with the potential to mimic *HOXA* deletion. These drugs include: Anisomycin, Butein, Calmidazolium, Digitoxigenin, Strophanthidin, Calcitriol, Emetine, Mefloquine and Trichostatin A. Cell viability assays identified measurable anti-leukaemia effects of some of these drugs at concentrations achievable clinically, most notably Anisomycin (Figure 1). Current and future work will evaluate anti-leukaemia effects of these drugs using colony forming ability, cell cycle and apoptosis analysis which will be presented during the meeting.

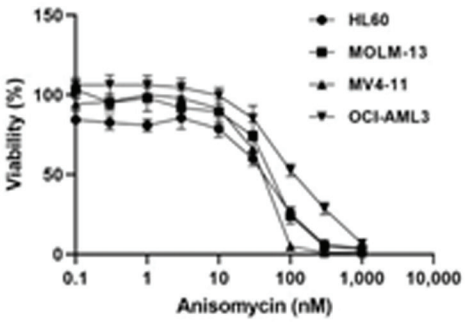


Figure 1: Effect of FDA approved drug Anisomycin on AML cell lines. Dose response of anisomycin on AML cell lines HL60, MOLM-13, MV4-11 and OCI-AML3 treated for 24 hours and subjected to RealTime-Glo™ cell viability assay (n=3).

Summary/Conclusion: Drug repurposing is an attractive and economical approach to identifying new treatment options for AML patients. This study demonstrates anti-leukaemia activity of several drugs currently used for other diseases or disorders. It is anticipated that once fully validated, some of these drugs may be accelerated to clinical application, as the toxicity profiles are already established.
In summary, this study has identified and evaluated the potential of candidate FDA-approved drugs to induce cell death in AML cell lines. Further investigation of these drugs alone and in combination with first-line therapies will provide new and safer treatment options for AML patients.

PB1383 DUAL ROLES FOR PROTEOSTATIC TARGETING IN ACUTE MYELOID LEUKAEMIA

W. Grey [1,*], A. Rio-Machin [2], P. Casado-Izquierdo [2], E. Gronroos [1], S. Ali [1], J. Miettinen [3], F. Copley [2], P. Alun [3], H. Caroline [3], S. Charles [1], C. Pedro [2], G. John [2], F. Jude [2], B. Dominique [1]

[1]The Francis Crick Institute, [2]Bart's Cancer Institute, London, United Kingdom, [3]FINN, Helsinki, Finland

Background: Acute myeloid leukemia (AML) is an aggressive hematological disorder comprising a hierarchy of quiescent leukemic stem cells (LSCs) and proliferating blasts with limited self-renewal ability. AML has a dismal prognosis, with extremely low two-year survival rates in the poorest cytogenetic risk patients, primarily due to the failure of intensive chemotherapy protocols to deplete LSCs, and the significant toxicity towards healthy hematopoietic cells. Whilst much work has been done to identify genetic and epigenetic vulnerabilities in AML LSCs, little is known about protein dynamics and the role of protein degradation in drug resistance and relapse.
Aims: - Delineate the roles of CKS1 in normal and malignant hematopoietic stem cells.
- Develop new strategies to specifcally target AML LSCs.
- Investigate critical roles for CKS1 in LSC intracellular signalling pathways.
Methods:.
Results: Using a highly specific inhibitor of the $SCF^{SKP2\text{-}CKS1}$complex, we present a dual role for CKS1-dependent protein degradation in reducing AML blasts *in vivo*, and importantly depleting LSCs. Whilst many AML LSC targeted therapies show significant toxicity to healthy hematopoiesis, inhibition of CKS1-dependent protein degradation has the opposite effect, protecting normal hematopoietic cells from chemotherapeutic toxicity. Together these findings demonstrate CKS1-dependent proteostasis is key for normal and malignant stem cell biology.
Summary/Conclusion: The inhibition of CKS1-dependent protein degradation holds excellent promise for AML therapy, both as a single agent towards $CKS1B^{high}$AML, and in combination with induction chemotherapy in other AML cases. Reports of *CKS1B* overexpression correlating with outcome in other solid cancer types, novel ways to modulate CKS1, and the development of more clinically ready molecules to target CKS1, indicate that proteostatic targeting, through the CKS1/CKS2 axis, holds much hope for future cancer therapy.

PB1384 MIRNA EXPRESSION IN ADULT ACUTE MYELOID LEUKAEMIA: BIOMARKERS FOR RISK SUBGROUPS?

P. Uysal-Onganer [1], M. Mortoglou [1], E. Brown [2,*], L. Davis [3], K. Orchard [4], S. Caserta [2], K. Mills [3], B.-A. Guinn [2]

[1]School of Life Sciences, University of Westminster, London, [2]Department of Biomedical Sciences, University of Hull, Hull, [3]Patrick G. Johnson Centre for Cancer Research, Queens University Belfast, Belfast, [4]Department of Haematology, University Hospital Southampton NHS Foundation Trust, Southampton, United Kingdom

Background: MicroRNAs (miRNAs) are small, single strands of non-coding nucleotides that are highly conserved and endogenous. MiRNAs regulate gene transcription and translation through their targeting of specific RNAs for silencing or degradation. In recent years their importance as regulators of gene expression in health and disease has been increasingly recognised, providing a new class of readily detectable biomarkers. Acute myeloid leukaemia (AML) is a rare, heterogenous and often-times difficult to treat disease. It affects children, predominantly through single genetic changes that are impactful enough to cause AML or through the accumulation of genetic change over many years in adults. However both age groups show many similarities as well as differences, the former providing new avenues for therapy.
Aims: To better understand these two forms of AML, separated by the age of onset, we have examined the miRNAs that are differentially expressed between risk subgroups in two publicly accessible databases.
Methods: We used the (1) National Cancer Institute's Therapeutically Applicable Research to Generate Effective Treatments (NCI-TARGET) that examined paediatric patients and (2) The Cancer Genome Atlas

(TCGA) that examined adults with AML to identify miRNAs that were differentually expressed between risk subgroups.
Results: Four mIRs (mIR3186, mIR486-1, mIR1915 and mIR4740) were differentially expressed (by more than two-fold levels) when comparing intermediate vs good, and poor vs good, risk subgroups in the TCGA dataset. 21 mIRs were differentially expressed in standard versus low, while only two mIRs were differentially expressed when we compared high versus low, risk subgroups, but these were expressed in both subgroup comparisons. Analysis using the TCGA-LAML dataset showed that four differentially expressed mIRs had elevated expression in the poor risk subgroups compared to intermediate and good risk TCGA subgroups. These were mir486-1 (p=2.011 x 10-12), miR378G (p=0.01594), miR1915 (p=0.01915) and miR8086 (p=0.023). In addition, below median levels of miR486-1 and miR1915 were associated with worse outcomes in adults with AML (p=0.0062 and p=0.021, respectively).
Summary/Conclusion: Future work will include pathway and ROC analysis to determine the utility of these miRs as targets for therapy and biomarkers for survival, respectively.

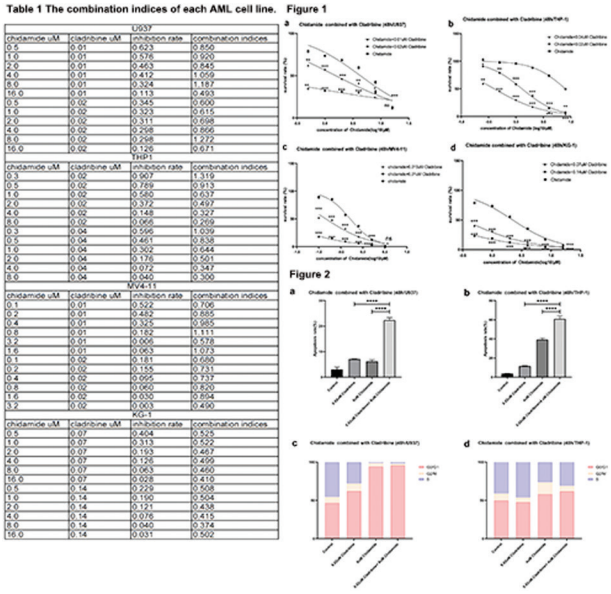
PB1385 NILOTINIB INHIBITS INFLAMMATION IN ACUTE MYELOID LEUKEMIA

J. L. Marin-Rubio [1,*], T. Heunis [1], M. E. Dueñas [1], J. Inns [1], M. Trost [1]

[1]Biosciences Institute, Newcastle University, Newcastle upon Tyne, United Kingdom

Background: Inflammation may be particularly important in the context of monocyte-rich myeloid neoplasms. The discovery of drugs that prevent chronic or acute inflammation is a major goal of the pharmaceutical industry. A proof-of-concept screening showed that the BCR-ABL inhibitor nilotinib, but not the structurally similar imatinib, blocks the pro-inflammatory phenotype by MALDI-TOF.
Aims: Our main aim was to identify the off-targets proteins for nilotinib compared with imatinib in human immortalised monocytes derived from AML. And to study the differences between nilotinib and imatinib in the inflammatory response in acute myeloid leukemia and multiple myeloma cells.
Methods: In order to identify the off-targets for nilotinib, we performed a thermal proteome profiling (TPP) over a range of temperatures and compound concentrations. We validated the effects of these off-targets by western blot, RTqPCR, ELISA and flow cytometry experiments.
Results: We show that nilotinib affects MAPK signalling and, ultimately preventing the transcription of pro-inflammatory genes, cell adhesion markers and innate immunity markers.
Summary/Conclusion: In consequence, nilotinib may have therapeutic potential through the inhibition of MAPK pathway in inflammatory diseases as well as in myeloid malignancies such as myeloid leukemia and multiple myeloma.

PB1386 SYNERGISTIC EFFECTS OF A NOVEL COMBINATION OF CLADRIBINE AND CHIDAMIDE ON CELL PROLIFERATION AND APOPTOSIS OF ACUTE MYELOID LEUKEMIA



S. Gu [1], Z. Ge [1,2,*]

[1]Department of Hematology, Zhongda Hospital, Medical school of Southeast University, Institution of Hematology Southeast University, Nanjing, China, [2]Hershey Medical Center, Pennsylvania State University Medical College, Hershey, United States

Background: Chidamide is a histone deacetylase inhibitor (HDACi), selectively suppresses the activities of histone deacetylases 1, 2, 3, and 10. Cladribine, the deoxyadenosine analog, exerts its cytotoxic effect by being rapidly phosphorylated to the undegradable triphosphate (2-CDATP) by adenosine deaminase. The anti-leukemia effects of the two drugs have been reported. However, the synergistic therapeutic effects of the two drugs are still undetermined in acute myeloid leukemia (AML).
Aims: The relevant research that combine the cladribine with chidamide in AML has not been reported. The present resarch is aim to explore the synergistic therapeutic effects of the two drugs in AML and to provide a novel drug combination for relapse and refractory AML patients.
Methods: Cell Counting Kit-8 (CCK-8) cell proliferation assay, Annexin V apoptosis assay and Propidium Iodide cell cycle assay were performed in AML cell lines U937, THP-1, MV4-11, and KG-1 in presence of chidamide, cladribine, chidamide+ cladribine, and no-treatment control for 48h. Data were expressed as the mean ± standard deviation. T-tests statistical analysis was employed for determining the significant difference between groups. A synergistic effect was determined by the combination indices (CIs) with CompuSyn software.
Results: The 50% inhibiting concentration (IC50) of chidamide is 9.358±1.448μmol/L in U937 cells, 7.918±1.666μmol/L THP-1, 0.517±1.337μmol/L MV4-11, and 2.23±0.6885μmol/L KG-1. The IC50 of cladribine is 0.024±3.071μmol/L, 0.05±0.411μmol/L, 0.021±2.019μmol/L, and 0.14±3.13μmol/L in U937, THP-1, MV4-11, KG-1 cells, respectively. Two doses (IC50 or 1/2 IC50) of cladribine were respectively combined with various doses of chidamide for cell proliferation assay in each cell line. The survival rate decreases significantly in the combo group (chidamide plus cladribine) compared to single drug control in each cell line (Figure 1). The CI analysis showed that 7 combination doses of the two drugs have a significant synergistic effect in U937, and two in 8 in THP1, 8 in MV4-11, and all the tested combination doses (12) in KG-1 (Table 1). The combination of chidamide and cladribine significantly elevated the apoptosis rate of two cell lines, U937 and THP-1, compared with chidamide alone (p <0.0001) and cladribine alone (p <0.0001, Figure 2 a, b). The combo treatment also arrested the cell cycle at the G0/G1 phase in both THP-1 (p <0.0001) and U937 (p <0.0001, figure 2 c, d) cells.

Table 1 The combination indices of each AML cell line.

Summary/Conclusion: Combination of chidamide and cladribine has a synergistic effect on cell proliferation arrest, apoptosis, and cell cycle arrest in acute myeloid leukemia cells. Our data provide experimental evidence for the novel potential combination on AML therapy. The clinical study is goning on.

PB1387 A CASE OF IDH1 MUTATED AML IN AN ADULT PATIENT AFFECTED BY OLLIER DISEASE, BIOLOGICAL SPECULATIONS AND CLINICAL IMPLICATIONS

G. Bertani [1,*], V. Mancini [1], R. Greco [1], E. M. Bertinato [1], G. Magliano [1], S. Veronese [2], F. Ballardini [3], R. Cairoli [1]

[1]Hematology, [2]Pathology, ASST-GOM Niguarda Ca' Granda, [3]Hematology, Università degli Studi, Milan, Italy

Background: Ollier disease (OD) is a rare congenital, non hereditary disorder, characterized by early development of multiple enchondromas and genetically by mutations in isocitrate dehydrogenase (IDH) 1 and 2. Mutations are found in chondromas, but not in other tissues, suggesting that they occur during embryonic development in mesoderm, giving rise to a somatic genetic mosaicism, with the gene being mutated only in tissues of mesodermal origin. Clinically, OD is associated with an increased risk of cancer, including chondrosarcomas and gliomas. Haematopoietic cells precursors (hemangioblasts) embriologically derive from mesoderm and thus bone marrow may be involved in OD manifestations. Furthermore, IDH 1 and 2 are frequently mutated in AML. However, AML cases in OD are anecdotal and reported only in paediatric patients.

Aims: We report the case of a patient affected by OD, who at 35 years developed AML harbouring IDH1, NPM1 and FLT3 TKD mutation and speculate about etiopathogenesis.
Methods: Patient's diagnostic and therapeutic management was performed according to our centre policy as indicated in "Results".
Results: In November 2020 a 35 years old man was admitted to our unit with haemorrhagic symptoms. He had a diagnosis of OD and had underwent surgery at 14 and 22 years to remove enchondromas in the left hand. His blood counts were: WBC 85.470/mm^3, Hb 9,9 g/dl, platelets 11.000/mm^3. A bone marrow evaluation led to a diagnosis of AML, FAB M2, with normal karyotype, NPM1 exon 11 (W288Cfs*12), FLT3 TKD (D835Y and I836del) and IDH1 (R132H) mutation. An induction chemotherapy with "7+3" associated with midostaurin (days 8-21) was administered and complete remission was obtained. Subsequently the patient underwent three consolidation cycles with HD Ara-C and midostaurin (days 8-21). At a molecular level NPM1 and FLT3TKD mutations were not detectable by qualitative nested PCR after induction, while IDH1 mutation was present at all bone marrow evaluations, even after the last consolidation.
Summary/Conclusion: Mutations of the IDH 1 and/or 2 gene are found in about 16% of AMLs. IDH proteins catalyze the conversion of isocitrate to α-ketoglutarate. Mutations lead to gain of function and an enhanced production of 2-hydroxyglutarate, responsible for increased DNA methylation. According to recent AML pathogenetic models, mutations in genes encoding epigenetic modifiers, such as DNMT3A, ASXL1, TET2, IDH1,and IDH2, are acquired early in a founding clone and may be found in the context of a clonal haeatopoiesis (CHIP), even in healthy subjects. Additional mutations, such as those involving NPM1 or signalling molecules (FLT3, RAS), are secondary events occurring later during leukemogenesis. IDH 1 and 2 mutations may persist in a patient treated for AML after therapy and represent, rather than a molecular marker of MRD, a risk factor for disease relapse.
In our patient IDH1 mutation was still detectable in bone marrow after achievement of CR, indicating the persistence of a clone of haematopoietic precursors harbouring a congenital mutation, associated with OD. It is important to note that the patient had remained free from leukaemia during three decades and a half, with AML developing only after acquisition of two other gene mutations (NPM1 and FLT3 TKD). These observations shed light on the paradigm of multiple genetic hits hypothesis of leukemogenesis and, after demonstration of the same IDH1 (R132H) mutation in chondroma tissue, prompt us to monitor the patient rather than candidate him to alloHCT in I CR.

PB1389 PREDICTIVE FACTORS AFFECTING THERAPY RESPONSE IN PATIENTS WITH ACUTE MYELOID LEUKEMIA

M. Kolesnikova [1,*], A. Sen'kova [2], M. Zenkova [2], T. Pospelova [3]

[1]Novosibirsk Hematology Center, [2]Institute of Chemical Biology and Fundamental Medicine, [3]Department for therapy, hematology and transfusiology of Novosibirsk State Medical University, Novosibirsk State Medical University, Novosibirsk, Russian Federation

Background: Actual prognostic factors for predicting therapy response in patients with acute myeloid leukemia (AML) are formed on the basis of detected cytogenetic and molecular genetic abnormalities, as well as initial clinical data, including the patient's age, the number of leukocytes in peripheral blood, and the level of blasts in the bone marrow. However, the therapy response is often influenced by the presence of primary resistance of tumor cells to cytotoxic drugs. Assessment of the combined impact of these factors on the therapy response of leukemia patients can be done by the forming of the multivariate predictive models.
Aims: The aim of this work was to assess the risk of development and progression of drugresistance in patientswith acute myeloidleukemia based on thepatients' age, MDR1 gene expression, sensitivity of tumor cells to cytostatic drugs, cytogenetic and molecular genetic abnormalities detected initially at diagnosis before treatment start.
Methods: The study included 53 patients withAML.Leukemic cells were collected from peripheral blood and bone marrow of patients. Assessment of multidrug resistance in tumor cells of leukemia patients was performed using real-time RT-qPCR) and WST1-test. RT-qPCR was used to evaluate the expression of the MDR1 gene. WST1-test was used to evaluate the sensitivity of tumor cells to chemotherapeutic drugs *in vitro*. The correlation analysis was performed using Spearmen's correlation coefficient (r).All statistical analyses were done with software MS Excel, OriginPro 7.5, Statistica 10.0.
Results: The average age of the patients was 51.2±14.5 years.In the group of AML patients who receivedanthracycline-based therapy, reliable correlations for response to therapy ($p < 0.05$) with the following indicatorswere obtained: age ($r = 0.55$), sensitivity to daunorubicin ($r = 0.72$), karyotype of tumor cells ($r = 0.6$), standard risk stratification by genetics ($r = 0.7$), total sensitivity to cytotoxic drugs ($r = 0.61$), standard prognosis stratification by cytogenetic/molecular markers and clinical characteristics($r = 0.55$). There was also direct correlation between response to therapy and the level of MDR1 gene expression ($r = 1.0$), however, due to the small sample size the differences were statistically insignificant, $p > 0.05$. Based on this data, a new prognostic scale was developed –all patients were divided into 3 prognostic groups: low risk group, intermediate risk group and high risk group.
Summary/Conclusion: Thus, the prognostic factors influencing the therapy response of AML patients were analyzed. The most prognostic values were detected for the following variables: the sensitivity of tumor cells to cytostatic drugs, the level of MDR1 gene expression, the karyotype of tumor cells, the age of patients, and the presence of cytogenetic abnormalities in tumor cells. Our prognostic scale allows to predictthe patient's response to the planned treatment protocol before the therapystart, which enables a personalized approach to the selection of patient management strategy.

Acute myeloid leukemia - Clinical

PB1390 RETROSPECTIVE ASSESSMENT OF TREATMENT PATTERNS AND RESOURCE UTILIZATION FOR PATIENTS NEWLY DIAGNOSED WITH ACUTE MYELOID LEUKEMIA IN CANADA, UK, FRANCE, GERMANY, ITALY, AND SPAIN

M. V. Shah [1,*], A. Ogbonnaya [2], B. K. Schroader [2], C. Seal [2], S. Murty [2], F. Manuguid [3], L. Margotto [4]

[1]Astellas Pharma, Inc., Northbrook, IL, [2]Xcenda LLC, Palm Harbor, FL, United States, [3]IQVIA, London, United Kingdom, [4]IQVIA, Milan, Italy

Background: Few studies have assessed treatment patterns and healthcare resource utilization (HRU) in patients with acute myeloid leukemia (AML) by *FMS*-like tyrosine kinase 3 (*FLT3*) mutation status (ie, *FLT3* gene mutation [*FLT3*$^{mut+}$] vs *FLT3* wild-type [*FLT3*^{wt}]), the most frequently identified molecular mutation in AML. The rapidly evolving treatment landscape and high cost of care in AML widen the persistent gap in detailed real-world evidence for this population.
Aims: To describe and compare baseline characteristics, real-world treatment patterns, and AML-related HRU by *FLT3* mutation status in patients newly diagnosed with AML.
Methods: Retrospective chart-level data were abstracted by hematology/oncology physicians that participate in the IQVIA Oncology Panel Survey in Canada, the UK, France, Germany, Italy, and Spain. Patients newly diagnosed with *FLT3*$^{mut+}$ or *FLT3*^{wt} AML from 01/09/2017-30/06/2019 were selected for inclusion (study period: 01/01/2017-31/03/2020). The index date was defined as the date of first treatment after initial AML diagnosis; follow-up ended at death, end of available data, or end of study. Treatment patterns were assessed from the index date until the end of follow-up; HRU was assessed from the diagnosis date through the end of follow-up.
Results: Data from 525 patients were included (*FLT3*$^{mut+}$, 41.5%; *FLT3*^{wt}, 58.5%; **Table**). In both cohorts, >80% of patients started AML treatment in 2019 and had a median follow-up of 4.4 months. Patients with *FLT3*$^{mut+}$ vs *FLT3*^{wt} AML were significantly younger and more likely to be in the adverse molecular/genetic risk group at diagnosis (both $P<0.0001$). Most patients received only one line of therapy during the follow-up period (*FLT3*$^{mut+}$, 89.4%; *FLT3*^{wt}, 90.6%). A higher proportion of patients with *FLT3*$^{mut+}$ (84.9%, n=185) than *FLT3*^{wt} AML (58.6%, n=180) received first-line high-intensity chemotherapy (HIC). The predominant HIC regimen was 7+3 (7 days cytarabine + 3 days anthracycline) (*FLT3*$^{mut+}$, 89.2%; *FLT3*^{wt}, 81.1%)—most commonly 7+3 with FLT3 inhibitor (predominantly midostaurin) (43.8%) in *FLT3*$^{mut+}$ patients and 7+3 alone (72.0%) in *FLT3*^{wt} patients. Nearly all patients who received low-intensity chemotherapy (LIC) had *FLT3*^{wt} AML; the predominant LIC regimen was a hypomethylating agent with or without venetoclax (*FLT3*$^{mut+}$, 51.5%; *FLT3*^{wt}, 67.7%). Most patients received supportive care during treatment, and transfusion of blood products was common (**Table**). HRU was assessed in 424 patients (80.8%). Patients with *FLT3*$^{mut+}$ vs *FLT3*^{wt} AML had ≥4 times more inpatient admissions

(*P*=0.0045) and higher proportions of intensive care unit admissions (*P*=0.0003) and emergency department visits (*P*=0.0005).

Table. Patient Characteristics, Treatment Patterns, and HRU in Patients Newly Diagnosed With AML by *FLT3* Mutation Status

Outpatient visits, n (%)	150 (88.8)	208 (81.6)	0.0693
Number of visits PPPM, mean (SD)	3.0 (14.2)	1.4 (1.8)	0.0675

[a] Bold formatting indicates values that are statistically significant (*P*<0.05).

[b] Molecular/genetic risk stratification at diagnosis were provider-reported and captured from patients' medical charts.

Abbreviations: AML, acute myeloid leukemia; *FLT3*$^{mut+}$, *FMS*-like tyrosine kinase 3 mutation; *FLT3*^{wt}, *FMS*-like tyrosine kinase 3 wild-type; HRU, healthcare resource utilization; ICU, intensive care unit; LOS, length of stay; PPPM, per patient per month; SD, standard deviation.

Summary/Conclusion: These real-world data illustrate the differences in demographic and clinical characteristics, first-line treatment patterns, and HRU between *FLT3*$^{mut+}$ and *FLT3*^{wt} AML patient populations in Canada, the UK, France, Germany, Italy, and Spain. Age and *FLT3* mutation status appeared to influence the type of induction regimen used; although most patients received HIC, *FLT3*$^{mut+}$ vs *FLT3*^{wt} patients were significantly younger and a higher percentage received HIC. Nearly half of *FLT3*$^{mut+}$ patients receiving HIC also received a FLT3 inhibitor. The high use of supportive care and inpatient and outpatient HRU highlight the significant morbidity and economic burden associated with managing AML, the importance of knowing patients' *FLT3* mutation status, and the need to further understand how patients with *FLT3*$^{mut+}$ AML may differ from other patients with AML.

PB1391 A PHASE 1A/B DOSE ESCALATION STUDY OF THE MUTATION AGNOSTIC FLT3/BTK INHIBITOR LUXEPTINIB (CG-806) IN PATIENTS WITH RELAPSED OR REFRACTORY ACUTE MYELOID LEUKEMIA

A. Goldberg [1], P. Koller [2], B. Tomlinson [3], M. Cherry [4], H. Zhang [5], N. Rastgoo [5], K. Benbatoul [5], Y. Jin [5], M. Thayer [5], J. Marango [5], S. Howell [6], W. Rice [5], R. Bejar [5,6,*]

[1]Department of Medicine, Leukemia Service, Memorial Sloan-Kettering Cancer Center, New York, [2]Department of Hematology/HCT, City of Hope, Duarte, [3]University Hospital of Cleveland, Cleveland, [4]Morristown Medical Center, Morristown, [5]Aptose Biosciences, Inc, [6]Moores Cancer Center, University of California San Diego Health, San Diego, United States

Background: Luxeptinib (CG-806) is a potent oral small molecule inhibitor of the wild type and all mutant forms of the FLT3 kinase, including ITD, D835Y, and F691L. Luxeptinib simultaneously suppresses additional signaling pathways in AML cells (CSF1R, PDGFRα, TRK, SYK, BTK, LYN, AKT, ERK, MAPK), kills primary AML cells insensitive to other FLT3 inhibitors at pM and low nM concentrations, and shows enhanced activity in combination with venetoclax. Patient-derived AML cells retain sensitivity to luxeptinib even when harboring mutations of *NPM1*, *IDH1*, *ASXL1*, or *TP53*. Luxeptinib is being evaluated in a Phase 1a/b trial in patients with relapsed or refractory (R/R) AML (NCT04477291).
Aims: The primary objectives are to assess the safety and tolerability of luxeptinib and to determine the recommended Phase 2 dose for future clinical trials in patients with R/R AML. Key secondary objectives include elucidation of the pharmacokinetic (PK) and pharmacodynamic (PD) characteristics, and evidence of antitumor activity.
Methods: The study is enrolling patients with relapsed or refractory *de novo* AML, secondary AML, or therapy-related AML. Luxeptinib is administered continuously as oral capsules BID in 28-day cycles, in ascending cohorts of 3 or 4 patients. Treatment emergent adverse events (TEAEs) and tumor responses are evaluated using CTCEA and International Working Group criteria respectively.
Results: As of December 10, 2020, a total of 4 patients (mean age 67.0 ± 20.9 years, 2 FLT3-ITD, 1 FLT3-ITD/TKD, and 1 FLT3-WT) with a median of 3 prior treatments (range, 2 - 8) have been treated with luxeptinib at the starting dose level of 450 mg BID. Observed possibly drug related TEAEs included nausea in 2 (50%; Gr 1), prolonged activated partial thromboplastin time in 1 (25%; Gr 1), increased blood alkaline phosphatase in 1 (25%; Gr 1), headache in 1 (25%; Gr 1), pericardial effusion in 1 (25%; Gr 3), photophobia in 1 (25%; Gr 1), and pleural effusion in 1 (25%; Gr 2). The steady-state (C_{min}) plasma levels of luxeptinib in AML patients treated with 450 mg Q12 hours were generally in the 1μM range by the end of Cycle 1. PD analysis demonstrated luxeptinib in the plasma of patients significantly reduced phosphorylated FLT3, ERK, SYK and PDGFRα in EOL-1 reporter cells in a plasma inhibitor activity (PIA) assay. One heavily pretreated patient with relapsed AML with mutated *NPM1*, *DNMT3A*, and *FLT3*-ITD who had previously progressed after chemotherapy, alloSCT, and two FLT3 inhibitors (gilteritinib, crenolanib) demonstrated clinical anti-leukemic activity with a decrease in peripheral blood blasts from 93% to 10% during Cycle 1.
Summary/Conclusion: Luxeptinib has been well tolerated at the starting dose level of 450mg Q12 hours. Pharmacodynamic studies documented inhibition of FLT3 signaling pathway, and anti-leukemic activity has been observed in the setting of AML relapsed following therapy with multiple prior FLT3 inhibitors. Enrollment of patients with R/R AML continues and updated clinical data from this dose escalation study will be presented at the meeting.

PB1392 PROGNOSTIC IMPACT OF MOLECULAR MARKERS IN ELDERLY PATIENTS AFFECTED BY NEWLY DIAGNOSED ACUTE MYELOID LEUKEMIA: MONOCENTRIC EXPERIENCE

D. De Novellis [1,*], F. Grimaldi [2], F. P. Tambaro [1], O. Finizio [3], F. Ferrara [3]

[1]Pediatric Onco-Hematology, AORN Santobono-Pausilipon, [2]Dipartimento di Medicina Clinica e Chirurgia, AOU Federico II, [3]Hematology division, AORN Cardarelli Hospital, Naples, Italy

Background: Acute Myeloid Leukemia (AML) is a bone marrow clonal disorder characterized by the proliferation of myeloid blasts. The European LeukemiaNet (ELN) 2017 risk stratification is a consolidated prognostic system focused on AML genetic features which is able to predict the probability of AML response and relapse following an intensive chemotherapeutic approach.
However, chemosensitivity and risk of disease relapse is age-dependent and limited for patient aged up to 60 years.
Aims: We investigated the predictability of this risk stratification in AML patients aged ≥ 60 years who underwent intensive chemotherapy.
Methods: We retrospectively revised data of 79 patients with new diagnosis of AML since 01/01/2015, followed at AORN Cardarelli Hospital, Naples. The inclusion criteria were age ≥60 years, Eastern Cooperative Oncology Group (ECOG) score ≤2, intensive chemotherapy as frontline approach. Patients were risk stratified according to ELN 2017 recommendations.
Results: Patients and disease characteristics are summarized in Table1. The median age of the entire population was 66 years (60-77). Mutations in NPM1 and FLT3-ITD were detected in 24/75 (32%) and 19/75 (25%) cases. Patients were classified, according to ELN 2017 stratification, as follows: 17/75 (23%) favourable, 40/75 (53%) intermediate and 18/75 (24%) adverse risk. A hematologic al complete response (CR) after induction treatment was achieved by 32/75 (43%) patients and was significantly associated with favourable ELN 2017 risk (p=0.03).The median Overall Survival (mOS) of the entire population was 6 months (0-59)(CI:4.82-7.10). The ELN2017 stratified mOS was 9 (0-59) for favourable, 5 (0-56) for intermediate and 4 months (0-43) for adverse risk AML (p=0.1).

Particularly, the difference in mOS resulted significant in comparing the favourable to intermediate+adverse risk AML (9 vs 5 months; p=0.038). No significant differences in terms of mOS were observed between NPM1 mutated vs unmutated (7 vs 6 months; p=0.806) or FLT3-ITD mutated vs unmutated AML (2 vs 6 months; p=0.119), respectively.
In multivariate analysis, the only conditions significantly related to longer OS were the allogenic hematopoietic stem cell transplantation (HSCT)(median OS not reached;HR:15.19;CI:3.34-69.05;p<0.005) and a CR after induction therapy (median OS 11months;HR:2.55;CI:1.30-5.00;p=0.006), while belonging to ELN 2017 favourable risk compared to intermediate+adverse risk AML was not significant (median OS 9 months; HR:0.58;CI:0.25-1.35; p=0.201).
The median Disease-Free Survival (mDFS) of the entire population was 8 months (1-58)(CI:3,92-12,07). No significant differences were found among the ELN2017 groups in mDFS. In multivariate analysis no variables resulted significantly associated with longer DSF.

	Global population	Favorable risk	Intermediate risk	Adverse risk
Patients (n)	75	17	40	18
Median age (range), years	66 (60-77)	64 (60-73)	65 (60-73)	69 (60-77)
ECOG score n (%)				
0	64 (85)	16 (94)	36 (90)	12 (66)
1	7 (9)	1 (6)	3 (7)	3 (17)
2	4 (6)	0	1 (3)	3 (17)
Gender n (%)				
M	50 (67)	15 (88)	26 (65)	9 (50)
F	25 (33)	2 (12)	14 (35)	9 (50)
Mutations or karyotype abnormalities n (%)				
NPM1	24 (32)	14 (82)	10 (25)	0
FLT3-ITD	19 (25)	3* (18)	9 (22)	7 (39)
FLT3-TKD	5 (7)	3 (18)	2 (5)	0
T(8;21)	0	0	0	0
INV(16) o t(16;16)	3 (4)	3 (18)	0	0
INV (3)	1 (1)	0	0	1 (6)
1st line chemotherapy n (%)				
FLA	51 (68)	8 (47)	28 (70)	15 (82)
FLAI	8 (11)	3 (18)	5 (13)	0
3+7	4 (5)	1 (6)	2 (5)	1 (6)
3+7 + Midostaurin	8 (11)	4 (24)	3 (7)	1 (6)
CPX 351	3 (4)	0	2 (5)	1 (6)
ICE	1 (1)	1 (6)	0	0
Hematological CR n (%)	32 (43)	13 (77)	10 (25)	9 (50)
Relapse n (%)	18 (56)	8 (61)	5 (50)	5 (56)
Allogenic HSCT n (%)	11 (15)	2 (12)	7 [18)	2 (11)
Median OS (range),months	6 (0-59)	9 (0-59)	5 (0-56)	4 (0-43)
Median DFS (range),months	8 (1-58)	8 (1-58)	5 (2-55)	11 (2-27)

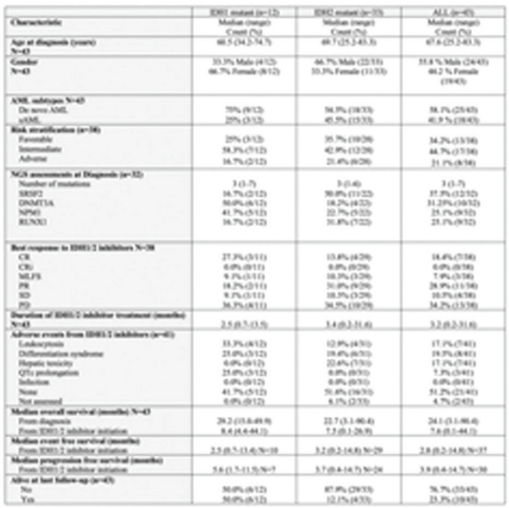
Summary/Conclusion: Our study demonstrated only the ELN2017 favourable risk had a significant benefit in terms of CR rate and mOS but not mDFS in patients aged ≥60 years with AML diagnosis who underwent intensive chemotherapy as frontline approach. The outcome of ELN2017 intermediate and adverse risk AML was very poor, without any difference between the two risk classes. Interestingly, NPM1 or FLT3-ITD mutations added no significant variation in terms of mOS or mDFS, while a significant impact of HSCT still remained.
Our results finally showed how prognostic significance of genetic abnormalities in AML might be influenced by age, and that a new risk stratification integrating performance status, age, presence of targetable mutations by tyrosine kinase inhibitors and transplant eligibility should be considered in setting of elderly patients.

PB1393 FAVOURABLE OUTCOMES WITH ATRA AND ARSENIC VERSUS ATRA AND CHEMOTHERAPY IN NEWLY DIAGNOSED ACUTE PROMYELOCYTIC LEUKEMIA IN WESTERN AUSTRALIA-A POPULATION-BASED STUDY.

A. Martin [1,*], T. S. Copeland [2], D. Purtill [2], R. de Kraa [2], M. Leahy [1], J. Cooney [2]

[1]Hematology, Royal Perth Hospital, [2]Hematology, Fiona Stanley Hospital, Perth, Australia

Background: Outcomes of Acute Promyelocytic Leukemia (APML) have improved considerably with the use of targeted therapies in trials.
Aims: We aimed to study the outcomes of APML in real-word WA patients.
Methods: Retrospective, multicentre analysis of survival outcomes of patients with APML presenting to public tertiary hospitals from 2005-2019 was undertaken, median follow-up of 46months (mo). Kaplan Meir survival analysis with log-rank Mantel Cox test, Cox proportional hazard was used, p<0.05 was considered significant.
Results: De-novo APML (n=89) patients had overall survival (OS) of 110.25 mo (95% CI 97.8-122.5) and early mortality rate of 10.1%. Of the treated patients (n=88), patients received ATRA-IDA (n=21), ATRA-IDA-ATO (n=30), ATRA-ATO (n=35), 7+3 Idarubicin/Cytarabine/ATRA (n=2). Event free survival, OS of patients on ATRA-IDA, ATRA-IDA-ATO, ATRA-ATO was 57.2%, 86.6 % and 88.5 % (p=0.0154); 80.3 (95% CI 55.5-105.1), 123 (95%CI 107-138.9) and 80.6 (95% CI 71.3-89.9) mo (p=0.041) respectively. Secondary malignancy occurred in 4.7%, 10%, 0% patients on ATRA-IDA, ATRA-IDA-ATO, ATRA-ATO respectively. Using Cox regression, age at diagnosis significantly influenced overall survival outcomes (p=0.01, HR 1.051 (95% CI 1.011-1.093).
Summary/Conclusion: Population-based outcomes of APML have shown an improvement in EFS and OS with ATRA-ATO which may be attributed to reduction in relapse-related mortality and secondary malignancies.



PB1394 SURVIVAL OUTCOMES AND ADVERSE EVENTS OF IDH1/2 MUTANT AML PATIENTS TREATED WITH IDH1/2 INHIBITORS: A SINGLE INSTITUTIONAL EXPERIENCE

C. N. Logothetis [1,*], C. Talati [2], G. Calon [3], N. P. Horvat [3], V. O. Volpe [2], N. Vincelette [2], A. T. Kuykendall [2], O. Chan [2], D. A. Sallman [2], E. Padron [2], K. Sweet [2], R. S. Komrokji [2], L. Zhang [4], J. E. Lancet [2], S. Yun [2]

[1]Department of Internal Medicine, University of South Florida, [2]Malignant Hematology Department, H. Lee Moffitt Cancer Cancer Center and Research Institute, [3]Morsani College of Medicine, University of South Florida, [4]Hematopathology and Laboratory Medicine Department, H. Lee Moffitt Cancer Cancer Center and Research Institute, Tampa, United States

Background: Recent genomic studies showed that IDH1/2 are frequently mutated in AML at about 20% and pre-clinical studies demonstrated that aberrant 2-HG elevation driven by the mutant IDH1/2 proteins plays a pivotal role in AML development by suppressing 5mC-to-5hmC conversion. Subsequent clinical trials of IDH1/2 inhibitors demonstrated promising outcomes in *IDH1/2*^{mut} AML patients.
Aims: In this single institutional retrospective study, we explored the efficacy and safety outcomes of *IDH1/2*^{mut} AML patients treated with Ivosidenib or Enasidenib.
Methods: We retrospectively identified AML patients who had *IDH1/2* somatic mutations based on NGS assessments. Clinical and demographic data were extracted from the medical records. Statistical analyses were performed using GraphPad Prism (v.7.03) and SPSS (v.24.0).
Results: A total of 43 (*IDH1*^{mut}, n=12; *IDH2*^{mut}, n=33; both *IDH1/2*^{mut}, n=2) patients were included in the study. Median age at AML diagnosis was 67.6 (24.2-83.3) years and 24 (55.8%) patients were male. Eighteen (42%) patients had secondary AML and 13 (34.2%), 17 (44.7%), and 8 (21.1%) patients had favorable, intermediate, and adverse risk, respectively. A total of 23 (53.5%) and 9 (20.9%) patients received intensive chemotherapy and hypomethylating agents as their 1st line therapy. One patient received Enasidenib as the 1st line therapy and the rest of the patients had relapsed/refractory disease prior to IDH1/2 inhibitor therapy. Median number of treatment prior to IDH1/2 inhibitors was 4 (0-8). The median duration of IDH1/2 inhibitor treatment was 3.2 (0.2-31.6) months (*IDH1*^{mut}, 2.5 [0.7-13.5]; *IDH2*^{mut}, 3.4 [0.2-31.6]). Treatment response was assessed in 38 patients and 18 had overall response (CR, n=7 [18.4%]; PR, n=11 [28.9%]). Of note, among 33 (76.7%) patients who had NGS assessments prior to IDH1/2 inhibitor initiation, a total of 13 patients had concurrent somatic mutations in the survival pathway that include *FLT3, KRAS, NRAS,* and *PTPN11*. The overall response rate in these patients was not statistically different compared to patients who did not have survival pathway mutations (38.5% vs. 40%, p>0.05). The median PFS was 3.9 (0.4-14.7) months (*IDH1*^{mut}, 5.6 [1.7-11.5] vs. *IDH2*^{mut}, 3.7 [0.4-14.7], p>0.05) and median OS was 7.6 (0.4-44.1) months. The most common reason for IDH1/2 inhibitor discontinuation was disease progression (n=21) followed by adverse events (n=3) and allogeneic transplant (n=2). The adverse events were assessed in 41 patients and the most common adverse events were differentiation syndrome (*IDH1*^{mut}, n=3; *IDH2*^{mut}, n=5) and leukocytosis (*IDH1*^{mut}, n=4; *IDH2*^{mut}, n=4) followed by hepatic toxicity (*IDH2*^{mut} n=7), and QTc prolongation (*IDH1*^{mut}, n=3).

Table 1. Characteristics of the study cohort

Summary/Conclusion: Our study indicates that IDH1/2 inhibitors remain a viable option for the refractory/relapsed *IDH1/2*^{mut} AML. However, significant number of patients failed to show any response and many of the patients who showed initial response had short response duration. These findings warrant further studies to identify underlying resistance mechanisms of IDH1/2 inhibitors and the optimal combination therapeutic strategies.

PB1395 SYSTEMATIC LITERATURE REVIEW OF THE EFFICACY AND SAFETY OF MAINTENANCE THERAPIES FOR ADULTS WITH ACUTE MYELOID LEUKEMIA IN COMPLETE REMISSION WHO ARE INELIGIBLE FOR HEMATOPOIETIC STEM CELL TRANSPLANT

B. Suero [1,*], H. Cameron [1], G. Thompson [2], M. Ahmed [1], C. Chen [3]

[1]Eversana, Burlington, Canada, [2]Bristol Myers Squibb, London, United Kingdom, [3]Bristol Myers Squibb, Princeton, United States

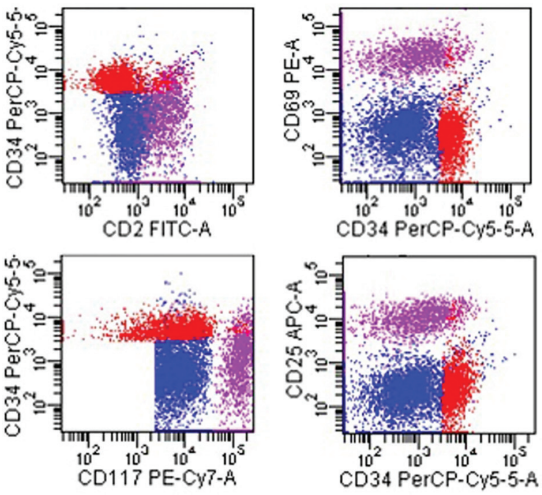
Background: Intensive induction therapy in patients (pts) with acute myeloid leukemia (AML) can induce complete remission (CR) and is often followed by consolidation chemotherapy and/or allogeneic hematopoietic stem cell transplant (HSCT) in eligible patients. However, in elderly pts with AML who are HSCT-ineligible, relapse rates are relatively high, overall survival (OS) rates are low, and pts have limited treatment options. Maintenance/post-remission therapy intends to prolong the duration of remission and survival in pts with AML; however, additional studies are required to evaluate maintenance options for HSCT-ineligible pts.
Aims: Identify clinical studies from a systematic literature review (SLR) of randomized controlled trials (RCTs) to assess the efficacy and safety of maintenance therapy in HSCT-ineligible adult pts ≥18 y with newly diagnosed AML who have achieved CR or CR with incomplete platelet recovery (CRi) after intensive chemotherapy induction, with or without consolidation.
Methods: An SLR of RCTs reporting efficacy (OS, relapse/disease/event-free survival [RFS/DFS/EFS], and time to relapse), time to discontinuation, and safety of maintenance therapy was performed to identify relevant studies from 2005–2020 indexed in MEDLINE®, Embase, and EBM Reviews databases (Cochrane Database of Systematic Reviews, Cochrane Central Register of Controlled Trials, Database of Abstracts of Reviews of Effects and Health Technology Assessment Database) using controlled vocabulary and keywords. A supplementary search of clinicaltrials.gov, the FDA database, and abstracts from selected hematology conferences (2018–2019) was also conducted. Two independent reviewers determined eligibility and quality of all studies for inclusion using the Population, Intervention, Comparator, Outcomes, Study Design, and Time framework.
Results: The SLR identified 6701 citations through database searches and 1 from a supplementary search; of these, 25 publications were included in the review representing 22 distinct RCTs. All 22 studies included a maintenance phase with treatments across 3 broad classes of drugs (hypomethylating agents [n=8], immunotherapies [n=7], and anthracyclines [n=4]) and 3 other therapies, although variability in study design was significant. Of the 16 trials with pts randomized to maintenance therapy, 13 trials were designed to assess the efficacy of different maintenance therapies with the baseline population comprising pts randomized to maintenance therapy and outcomes reported by maintenance arm. The remaining trials were designed to assess the efficacy of induction (n=7) and consolidation therapies (n=2). All 13 trials with the primary analysis of maintenance therapy reported RFS/DFS/EFS by maintenance treatment arm, and 11 studies reported OS. Although time zero definitions for RFS/DFS/EFS and OS differed across trials, median RFS/DFS/EFS and median OS ranged from 5–16 and 10–39 mo, respectively. Only the QUAZAR trial of oral azacitidine demonstrated significant improvements in both RFS and OS with maintenance therapy (**Table**). A total of 17 studies reported safety outcomes related to maintenance therapy, with infection being the most commonly reported adverse event (n=10).

Median RFS and OS with oral azacitidine maintenance in the QUAZAR trial

	Median RFS, months (95% CI)	Median OS, months (95% CI)
Oral azacitidine maintenance	10 (8–13)	25 (19–31)
No maintenance	5 (5–6)	15 (12–18)

CI, confidence interval; OS, overall survival; RFS, relapse-free survival

Wei AH et al. *Blood* 2019;134(suppl 2):LBA-3



Summary/Conclusion: This SLR identified 22 RCTs reporting efficacy and safety data on maintenance therapies in the treatment of AML in adult pts who achieved CR/CRi and were ineligible for HSCT. Study design varied significantly. Few RCTs eligible for review were adequately designed to assess the efficacy of maintenance therapies and only 1 study demonstrated a significant survival benefit with maintenance therapy.

PB1396 KIT D816 MUTATED T(8;21)(Q22;Q22.1) ACUTE MYELOID LEUKEMIA WITH CONCURRENT SYSTEMIC MASTOCYTOSIS SHOWS POOR RESPONSE TO COMMON CHEMOTHERAPY AND TRANSPLANTATION

W. Zhang [1,*], X. Cao [1], D. Liu [1], Z. Wei [1], M. Xiong [1], J. Zhou [1]

[1]Department of Transplantation, Hebei Yanda Ludaopei Hospital, Langfang City, China

Background: Acute myeloid leukemia with t(8;21)(q22;q22.1) translocation was classified as favorable risk group in NCCN guidelines, whereas KIT D816mutations is a poor prognostic factor. Such patients with concurrent systemic mastocytosis are extremely rare, their clinical features and prognosis are still unclear.
Aims: To explore the clinical features and prognosis of t(8;21)AML bearing KIT D816 mutation associated with SM.
Methods: The clinical data, outcomes of chemotherapy and allo-HSCT of 5 patients with t(8;21) AML bearing KIT D816 mutation associated with SM admitted to Hebei Yanda Ludaopei Hospital from July 3, 2019 to February 1, 2021 were retrospectively analyzed. The median follow-up time was 323 (112-580) days.
Results: Among the 5 patients, 4 were males and 1 female, with a median age of 9 (3-16) years old. The median ratio of bone marrow blasts at onset was 64 (46-78.5)%; the chromosome was t(8;21)(q22;q22.1), and the RUNX1-RUNX1T1 fusion gene was positive. After 2 courses of chemotherapy, 3 patients achieved complete morphological remission, and 2 patients were in NR status. Flow cytometry shows malignant myeloblasts in 3 patients, in addition abnormal mast cells were found in 4 patients. A less than 3log reduction of RUNX1/RUNX1T1 transcript in bone marrow was seen in all of 5 patients. The flow sorting of 2 patients showed that the RUNX1-RUNX1T1 fusion gene mainly been expressed by abnormal mast cell. 4 patients underwent allo-HSCT, all haplotype 5/10 compatible, adopting Bu/Cy-based myeloablative intensified conditioning regimen. After transplantation, all 4 patients had hematopoietic engraftment. The bone marrow findings at +30 days all showed CR status, no malignant myeloblasts were found in bone marrow flow cytometry, yet abnormal phenotypic mast cells were found. RUNX1-RUNX1T1 transcripts did not turn negative. All 5 patients met the diagnostic criteria for SM: ① KIT D816 mutation was detected (3 cases of D816V mutation, 3 cases of D816Y mutation, 1 case of D816F mutation; 1 patient had the above 3 mutations); ②>25% of mast cells found in bone marrow cytology of all patients were immature or atypical mast cells; ③mast cells all expressed CD25, with or without CD2. Subsequently 1 patients was treated with midostaurin, RUNX1-RUNX1T1 and mast cells became negative after 63 days of treatment. The other 3 patients were treated with dasatinib and/or interferon. The fusion genes and abnormal mast cells did not turn negative. Patient who did not undergo transplantation continued to detect abnormal mast cells and transcripts of RUNX1-RUNX1T1.

Summary/Conclusion: t(8;21)AML bearing KIT D816 mutation associated with SM shows poor response to common chemotherapy and allo-HSCT, neither can eliminate clonal mast cells, hence this type of disease requires targeted therapy intervention.

PB1397 COVID-19 IN PATIENTS WITH ACUTE LEUKEMIA: THE EXPERIENCE OF A HEMATOLOGICAL CENTER

A. Malato [1,*], A. Mulè [1], V. Calafiore [1], F. Di Bassiano [1], R. Mauro [1], C. Cangialosi [1], U. Biondo [1], C. Patti [1]

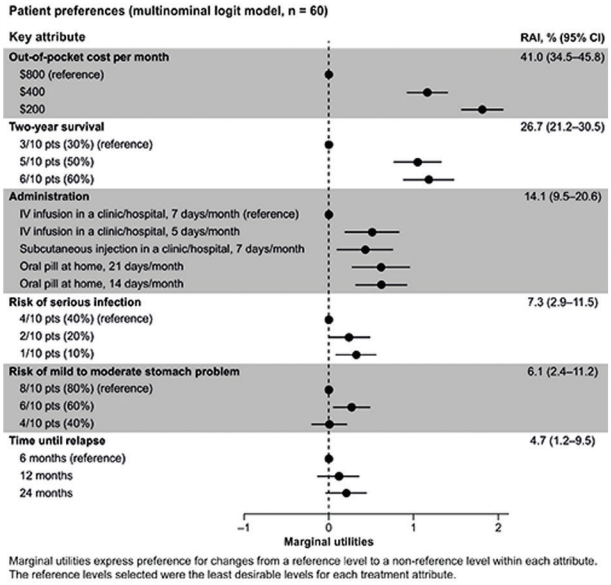
[1]UOC di Oncoematologia, Ospedali Riuniti Villa Sofia-Cervello, Palermo, Italy, palermo, Italy

Background: Patients with hematologic malignancies appear to have a greater risk of SARS-CoV-2 infection and severe disease due to myelosuppression; furthermore, delays in treatment of patients with hematologic malignancies, especially those with acute leukemia planned for chemotherapy or transplantation, are associated with a risk of disease progression. To date, some societies recommend that chemotherapy should generally not be started until COVID-19 symptoms have completely resolved and viral testing becomes negative. However, implications of the aforementioned recommendations remain uncertain in routine clinical practice, and data on COVID-19 in patients with hematologic malignancies are still limited.
Aims: We carried out a single-center analysis of acute leukemia inpatients who developed COVID-19 during the last year.
Methods: Since February 2020 to February 2021, a total of 310 Hospitalizations, 163 adult patients were admitted in our Center for treatment of hematologic malignancies. The indication for admission was acute myeloid leukemia (AML) in 50 (30%) patients, acute lymphoblastic leukemia (ALL) in 14 (8%), lymphoma in 54 (33%), myeloma in 14 (8%), other 31 (19%). Diagnosis of SARS-CoV-2 infection was based on virus detection by real-time polymerase chain reaction (SARS-CoV-2 E-gene RT-PCR) in respiratory tract specimens. Standard preventive measures for SARS-CoV-2 infection control were applied to all patients care, accordance with National disease control and prevention guidelines.
Results: Ten (6%) patients tested positive for SARS-CoV-2 via PCR in a unique Covid-19 outbreak during hospitalization stay, and they were immediately transferred to Covid Infectious Unit. All these patients, were affected by Acute Leukemia (8 pts AML, 2 pts ALL ph negative), the majority of them was in peak of cytopenia at the Covid-19 infection time. Nine patients had been treated with intensive chemotherapy before SARS-CoV-2 confirmation. At SARS-CoV-2 diagnosis, only one patient had untreated, newly diagnosed AML; 3 patients had refractory/relapsed AML. One patient was in complete remission with incomplete hematologic recovery (CRi). Deep vein thrombosis complicated by pulmonary embolism and interstitial pneumonia was observed in a patients despite anticoagulation and in thrombocytopenia. After SARS-CoV-2 infection, no leukemia-specific treatment was adjusted. Three patients (30%) died due to severe acute respiratory distress syndrome (ARDS) despite extracorporeal membrane oxygenation (ECMO) in deep aplasia, all of them was in refractory disease. Seven patients delayed in chemotherapy treatment for a media of 34 days; chemotherapy started until COVID-19 symptoms have completely resolved and two viral testing becomes negative. However, these patients are still alive and maintained their complete remission, remaining for long-time negative for SARS-CoV-2. One patient underwent to bone marrow transplantation

ID	Age	Sex	Diagnosis	Time of Covid-19 infection	Covid-19 complications	Change or delay in the Hematological Treatment	Days delay	Deaths owing to Covid-19	Remission status after current therapy
1	82	M	AML	No yet treated	progressive respiratory failure	No treatment	Na	died owing to progressive respiratory failure before treatment could be started	Na
2	56	F	AML	in peak cytopenia post I consolidation	None	delay	60	no	RC
3	62	M	AML	Relapsed post I induction	progressive respiratory failure	Na	Na	died owing to progressive respiratory failure	Na
4	64	M	AML	in peak cytopenia post	Interstitial pneumonia	delay	30	no	RC
5	53	M	AML	in peak cytopenia post I induction	None	delay	10	no	In peak cytopenia after allo-BMT
6	67	F	AML	Relapsed post I induction	DVT-EP; Interstitial pneumonia	delay	30	no	RC;scheduled to allo-BMT
7	62	F	AML	in peak cytopenia post I consolidation	Interstitial pneumonia	delay	40	No	RC
8	66	M	ALL Ph-	in peak cytopenia post I consolidation	Interstitial pneumonia	delay	50	No	RC
9	21	M	ALL Ph-	RC post II consolidation	None	delay	20	No	RC
10	59	M	AML	Refractory to I induction	progressive respiratory failure	Na	Na	died owing to progressive respiratory failure	Na

AML: Acute myeloid Leukemia; ALL Ph-: acute lymphoblastic Leukemia Philadelphia negative. RC: Complete Remission, allo-BMT: allogeneic bone marrow transplant. DVT-EP: Deep vein Thrombosis-Embolism Pulmonary; Na: not applicable

Summary/Conclusion: Our findings support the vulnerability of patients with hematologic malignancies in the COVID-19 pandemic, and we reported a high COVID-19 infection mortality of 30%, in accordance with other hematological case series. However, deaths owing to Covid-19 were observed in patients in disease leukemia progression; furthermore, our recovered COVID-19 leukemia patients remained negative for SARS-CoV-2 after delivery of chemotherapy, and underwent to their following chemotherapy and allo-BMT program without any other complications.



PB1398 PATIENT PREFERENCES FOR MAINTENANCE THERAPY OF ACUTE MYELOID LEUKEMIA: A DISCRETE CHOICE EXPERIMENT SUBANALYSIS OF PATIENTS IN GERMANY AND ITALY

K. Cutts [1,*], T. Tervonen [2,3], J. Seo [1], S. Abi Nehme [4], I. La Torre [4], C. Chen [4], C. Beach [4], J. Wang [4]

[1]Evidera, Bethesda, United States, [2]Evidera, London, United Kingdom, [3]University of Groningen, University Medical Center Groningen, Department of Epidemiology, Groningen, Netherlands, [4]Bristol Myers Squibb, Princeton, United States

Background: In older patients (pts) with acute myeloid leukemia (AML), intensive chemotherapy can induce complete remission, but responses are often short and overall survival (OS) is poor after relapse. Azacitadine (AZA) maintenance therapies (MT) may improve disease-free survival in pts aged ≥60 years, but have not been shown to improve OS (Oliva EN, et al. ASH 2019; Huls G, et al. *Blood* 2019). In addition, AZA is given subcutaneously or intravenously (IV), resulting in a high administration burden and potential for infusion reactions. In the phase 3 QUAZAR AML-001 study, a novel oral formulation of AZA was the first MT to show a significant and clinically meaningful improvement in both OS and relapse-free survival (Wei AH, et al. *N Engl J Med* 2020). While oral AZA offers an effective MT option, little is known about the treatment preferences of pts with AML. We conducted a discrete choice experiment (DCE) survey of pts aged ≥55 years with AML in the USA, Canada, Germany, and Italy to assess the relative importance of key attributes of MT options (Tervonen T, et al. ASH 2020). Globally, pts placed the highest importance on survival probability at 2 years and were willing to accept reduced efficacy for the convenience of oral administration; this subgroup analysis explored the importance that pts in Germany and Italy placed on key factors.
Aims: To examine the relative importance of key attributes of MT among a subgroup of pts aged ≥55 years with AML from Germany and Italy.
Methods: An online DCE was conducted in the USA, Canada, Germany, and Italy between November 2019 and April 2020 to identify preferences for MT attributes among pts aged ≥55 years with AML. DCE data were analyzed using a multinomial logit (MNL) model. The MNL model estimated marginal utilities, which describe the relative value of changing from a reference to a non-reference level. The derived marginal utilities were used to calculate relative attribute importance (RAI), where higher values indicated larger effects on preferences. The 95% confidence intervals (CI) were estimated using a bootstrap algorithm over one thousand iterations.
Results: The survey was completed by 170 pts, including 30 from Germany and 30 from Italy. Among pts from Germany and Italy, mean age was 62.9 years and 67% were male. In all, 67% of pts had achieved remission at some point, 70% were diagnosed with AML >6 months

before survey completion, and 75% experienced ≥1 relapse event. The estimated MNL models revealed that pts most valued decreasing out-of-pocket cost from $800 to $400 or $200 (RAI = 41.0%, 95% CI 34.5–45.8) and increasing 2-year survival from 30% to 50% or 60% (RAI = 26.7%, 95% CI 21.2–30.5; Figure). Pts preferred therapies with oral administration once daily for 14 or 21 days per month, followed by IV administration 5 days per month, and subcutaneous injection 7 days per month, compared with IV administration in a hospital or clinic 7 days per month (RAI = 14.1%, 95% CI 9.5–20.6). Pt were least concerned about the treatment risks of serious infection, mild-to-moderate stomach problems, and unlike in the global population, time until relapse.

Marginal utilities express preference for changes from a reference level to a non-reference level within each attribute. The reference levels selected were the least desirable levels for each treatment attribute.

Summary/Conclusion: Consistent with findings from the global population, results from this subanalysis of pts from Germany and Italy aged ≥55 years with AML indicated that the most important clinical attribute of MT is improved 2-year survival. Lower out-of-pocket costs and the convenience of an oral pill were also valued. As there is no standard approach to treating AML after intensive chemotherapy, pt preferences should inform decision-making when selecting an MT.

PB1399 ACUTE PROMYELOCYTIC LEUKEMIA WITH PML-RARA: 10 YEARS EXPERIENCE OF A PORTUGUESE SINGLE CENTER.

M. Dias [1,*], R. Peixeiro [1], L. Regadas [1], R. Cabral [1], J. Coutinho [1]

[1]*Hematologia Clínica, Centro Hospitalar Universitário do Porto, Porto, Portugal*

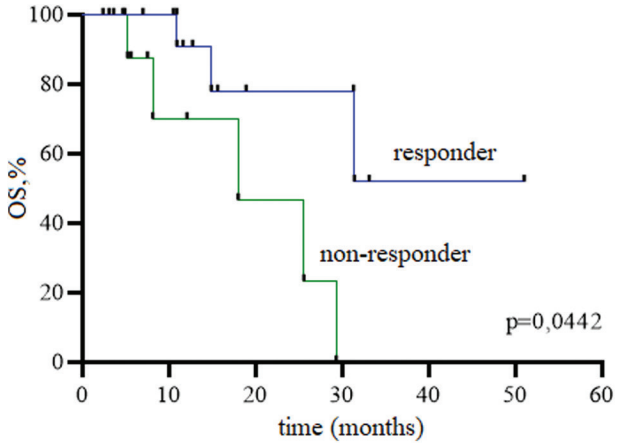
Background: Acute promyelocytic leukemia with PML-RARa (APL) is a subgroup of acute myeloid leukemia with a favorable prognosis after the advent of differentiation agents. The present standard of care for non-high risk APL is the chemo-free combination therapy of trans retinoic acid (ATRA) plus arsenic trioxide (ATO). These therapies comprise a specific toxicity profile.
Aims: Description of one center therapy experience. Comparison of outcomes and toxicities between two different treatment regimens.
Methods: A retrospective single-center study including all patients (pts) diagnosed with de novo APL between June/2010 and June/2020. Low and intermediate risk groups (low/int), according to the Sanz Risk Score, were analyzed together. Prior to 2017, the PETHEMA APL 2005 protocol (and 2012 update) was in use to all patients; from 2017 onwards, pts were progressively switched to the AML17 protocol. Early and late death refer to events occurring during the 30 days after diagnosis or later, respectively.
Results: We identified 32 pts with a median age at diagnosis of 46y (range 22-80y) and female predominance (n=20, 62.5%). The majority presented with bleeding (n=26, 81.3%) and had low/int risk criteria (n= 26, 81.2%).
High-risk group: 5 pts completed induction with ATRA+Idarrubicin (AIDA), 1 pt with ATRA in monotherapy. Low/int-risk group: until 2017, 11 pts (42.3%) completed induction with AIDA; after 2017, 10 pts (38.5%) were treated with ATRA+ATO; the remaining 5 pts (received only ATRA or ATO in monotherapy (and 1 pt wasn't treated) due to early complications.
All pts evaluated at the end of the induction cycle (n=27) met complete hematologic response criteria (CHR). Pts received consolidation and maintenance therapy according to the established protocols with the exception of 7 pts due to complications during treatment (n=5 AIDA, n=2 ATRA+ATO).
The main toxicities observed in our sample and their management are reported in Table 1.
With a median follow-up time of 35 months (52.4 and 19.8 months in AIDA and ATRA+ATO, respectively), the median overall survival was 32 months (51.5 and 22 months in AIDA and ATRA+ATO, respectively) and the overall mortality rate was 25% (n=8). Four of the above pts were undertreated (3 early deaths and 1 late death) and the remaining 4 pts were treated according to the AIDA protocol (1 early death and 3 late deaths; n=3 int/low and n=1 high risk). Five pts relapsed (4 in the AIDA group and 1 in the ATRA+ATO), with a median time to relapse of 13 months. Four of these pts were rescued (n=2 ATRA+ATO; n=1 ATO monotherapy; n=1 AIDA) and consolidated with autologous stem cell transplantation and remain in molecular response.

Table 1: Treatment Related Toxicities

	Total	AIDA	ATRA+ATO	ATO	ATRA
Number	31	16 (51,6%)	10 (32,3%)	2 (6,4%)	3 (9,7%)
Treatment related toxicities - Description and Management					
Infections	18 (58,1%)	14 (87,5%)	0	1 (50%)	3 (100%)
Transitory Withdrawal	2/18 (11,1%)	2/14 (14,3%)		0	0
Permanent Withdrawal	4/18 (22,2%)	4/14 (28,6%)		0	0
Death	5/18 (27,7%)	2/14 (14,3%)		0	3/3 (100%)
Differentiation Syndrome	13 (41,9%)	8 (50%)	2 (20%)	1 (50%)	2 (66,7%)
Transitory Withdrawal	5/13 (38,5%)	2/8 (25%)	0	1/1 (100%)	2/2 (100%)
Hepatotoxicity	5 (16,1%)	0	3 (30%)	1 (50%)	0
Transitory Withdrawal	2/5 (40%)		1/3 (33,3%)	1/1 (100%)	
QTc interval extension	2 (6,4%)	0	2 (20%)	0	0
Transitory Withdrawal	1/2 (50%)		1/2 (50%)		
Permanent Withdrawal	1/2 (50%)		1/2 (50%)		
Pericarditis	1 (3,2%)	0	1 (10%)	0	0
Permanent Withdrawal	1/1 (100%)		1/1 (100%)		
Dermatotoxicity	3 (9,6%)	1 (6,3%)	1 (10%)	1 (50%)	0
Transitory Withdrawal	2/3 (67,7%)	1/1 (100%)		1/1 (100%)	

ATRA: All-Trans Retinoic Acid; ATO: Arsenic Trioxide; AIDA: ATRA + Idarrubicin

Summary/Conclusion: We present the real-life experience of one small center in the management of APL across a long and changing period. We underline the inclusion of undertreated pts due to comorbidities and early life-threatening complications. We confirmed the differences in toxicity profiles of chemotherapy-based and -free regimens, with infections in almost all pts in the AIDA group and hepatotoxicity and cardiac complications in a substantial part of the ATRA+ATO treated pts. Both regimens induced CHR in all pts post-induction, but we observed a trend for higher relapse risk in the AIDA group, at least partially explained by the short follow-up and low number of pts in the ATRA+ATO group.



PB1402 EFFICACY AND SAFETY OF GEMTUZUMAB IN RELAPSED AND REFRACTORY AML IN REAL WORLD PRACTICE

I. Budaeva [1,*], D. Zaitsev [1], A. Shatilova [1], D. Motorin [1], V. Ivanov [1], K. Bogdanov [1], Y. Mirolyubova [1], T. Nikulina [1], E. Goryunova [1], A. Petrov [1], R. Vabishchevich [1], R. Badaev [1], D. Zammoeva [1], Y. Alexeeva [1], A. Zaritskey [1], L. Girshova [1]

[1]*Almazov National Medical Research Centre, St. Petersburg, Russian Federation*

Background: ALFA group and some others have shown gemtuzumab (GO) to be effective in low risk acute myeloid leukemia (AML). However, limited data on GO efficacy are available in relapse/refractory (R/R) setting outside clinical trials.
Aims: To assess the efficacy and safety of GO in combination with chemotherapy "FLAG+/-Ida" and azacitidine in patients with R/R AML in real clinical practice.
Methods: The study included 32 patients (16 male, 16 female patients, median age–44 years (23-83 y.o.)). 46,8% (15/32) with refractory and 53,2% (17/32) with relapsed AML. 46,8% (15/32) patients received "GO-FLAG+/-Ida", 53,2% patients (17/32) received "GO-azacitidine". "GO-azacitidine" was given to patients unfit for intensive chemotherapy (advanced age, low somatic status, relapse or refractoriness to high-dose chemotherapy). 19 (59,3%) patients underwent the BMT subsequently.
Results: ORR (CR, CR_{MRD-}; CRi, MFLS) was 59,4% (19/32). Early mortality was 9,4 % (3/32). OR rate was not associated with expression of CD33 (p=0,452), gender (p=0,6), age (p=0,145), prognostic risk group (p=0,646), number of previous lines (p=0,482), number of relapses

(p=0,489). 80% patients, refractory to FLAG, achieved a response after "GO-azacitidine" with subsequent BMT. Non-eligible for high-dose chemotherapy patients obtained "GO-azacitidine" regimen. 66,6% of them improved their somatic status and subsequently undergone BMT. 1 of 2 patients with a relapse after high-dose chemotherapy achieved a response, BMT was performed in 2 patients. The rate of toxicity was not significantly different between the groups. No cases of VOD were reported. The rate of infusion-related complications was 46,7% (7/15) (40%>grade 1-2, 6,7%>grade 3) in the "GO-FLAG+/-Ida" group and 35,3% patients (6/17) (29,4%>grade 1-2, 5,9%>grade 4) in the "GO-azacitidine" group. SAEs were reported in 33,3% patients in the "GO- FLAG+/-Ida" group, with 100% having sepsis, and 35,3% in the "GO-azacitidine" group (66,6%>sepsis, 16,7%>acute cardiovascular failure, 16,7%>acute respiratory). No significant difference was observed in grade 3-4 neutropenia between the groups. The duration of thrombocytopenia was higher in patients who received GO in combination with "FLAG+/-Ida", however, no significant differences were observed. The median of OS was 31,4 months, the median of RFS was 13,3 months. The median of OS was 31,4 months, the median of RFS was 13,3 months. OS was higher in the group of patients responded to therapy than in non-responder to therapy (median not achieved versus 17,97 months, respectively, p=0,044) (Fig. 1).

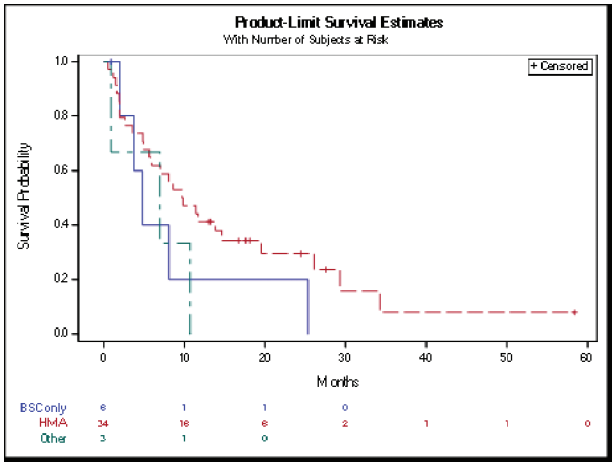
Summary/Conclusion: The combinations GO with FLAG/FLAG-Ida and azacitidine have shown to be effective regimen in patients with relapsed and refractory AML. The remission rate did not depend on the risk group, gender, age, CD33 expression, number of previous lines of therapy, number of relapses. "GO-azacitidine" demonstrated efficacy and tolerability in patients, refractory to high dose chemotherapy and in patients with poor performance status, enabling some patients to proceed to the BMT. The rate of toxicity, the duration of blood levels recovery was not statistically different between the groups, however, there was a higher duration of thrombocytopenia in "GO-FLAG+/-Ida" group. There was a higher OS in the GO responders in contrast to non-responders.

PB1403 EVALUATION OF MYELODYSPLASTIC SYNDROME AND ACUTE MYELOID LEUKEMIA PATIENTS TREATED WITH HYPOMETHYLATING AGENTS: A REAL WORLD EXPERIENCE

T. Avci [1], E. Gunduz [2,*], B. Aras [3], C. Bal [4], S. Isiksoy [5]

[1]Internal Medicine, [2]Hematology, [3]Medical Genetics, [4]Biostatistics, [5]Pathology, Osmangazi University School of Medicine, Eskisehir, Turkey

Background: Hypomethylating agents (HMAs), azacitidine and decitabine, are a standard of care in high risk myelodysplastic syndromes (MDS) and in acute myeloid leukemia (AML) patients ineligible for intensive therapy. The clinical activity of HMAs in myeloid neoplasms has been firmly established now, but still remains limited in the real world especially in terms of using after failure of the first HMA.
Aims: In this study, it was aimed to evaluate the clinical and laboratory characteristics of patients with MDS and AML who were treated with HMAs, as well as their treatment responses and factors affecting prognosis.
Methods: A hundred and twenty patients, over the age of 18 who were diagnosed AML or MDS according to WHO 2008 diagnostic criteria between August 2010 and February 2020 and received at least 4 cycles of HMA were included in the study. The data was collected retrospectively.
Results: Seventy four (61.7%) of patients were male and 46 (38.3%) were female. The diagnosis was MDS in 63 (52.5%) and AML in 57 (47.5%) of patients. The mean age at the time of diagnosis was 69.9 ± 12 years. Sixty four (53.3%) of the patients received only azacitidine, 8 (6.7%) only decitabine, and 48 (40%) azacitidine and decitabine consecutively. When we compared the laboratory findings before and after HMA treatment, there was an improvement in hemoglobin level, white blood cell, neutrophil, platelet and blast counts (p<0.05). The need for red blood cell and platelet suspensions during HMA treatment was significantly higher than the pre-treatment period (p <0.001). While febrile neutropenia (FN) developed in 96 (80%) of the patients totally, FN developed in 75 (66.9%) of 112 patients who received azacitidine and in 49 (87.5%) of 56 patients who received decitabine. Complete response, partial response or hematological recovery was detected in 63 (52.5%) of the patients. Relapse or progression developed in 81 (67.5%) patients. Response rates were similar in patients with AML and MDS (p=0.48). FN and relapse or progression were significantly higher in AML patients (p = 0.007 and p = 0.03). Survival in MDS was longer than AML patients (17.2±9 vs 12±6.7 months, p = 0.003).
Single cox-regression analysis revealed that mortality risk was 2.2 times higher in AML patients compared to MDS (HR=0.45, p=0.01, 95% CI 0.28–0.73). High blast ratio in flow cytometry before treatment, presence of poor risk cytogenetic before treatment, high blast ratio in flow cytometry after treatment, high blast ratio in post-treatment bone marrow biopsy, poor risk cytogenetic after treatment, increased number of platelet suspensions before treatment, presence of FN, length of hospitalization, no response to treatment and presence of relapse / progression were poor prognostic in terms of survival.
Multiple cox-regression analysis revealed that the mortality risk in AML patients was 2.39 times higher than MDS patients (p = 0.03, 95% CI 1.04--5.5). Those with a higher pre-treatment platelet suspension replacement and those who had FN had a higher risk. The mortality decreased as the number of azacitidine cycles increased (HR = 0.9, p = 0.002 (95% CR 0.84-0.96).
Summary/Conclusion: In conclusion, response rates are similar in AML and MDS treated with HMAs. Although FN and relapse/progression are higher, and survival is shorter in AML, HMAs are effective in MDS and AML patients witha response rate of 52.5%.



PB1404 REAL-WORLD TREATMENT PATTERNS AND CLINICAL OUTCOMES IN UNFIT PATIENTS WITH AML RECEIVING FIRST LINE SYSTEMIC TREATMENT OR BEST SUPPORTIVE CARE (CURRENT): A BELGIAN SUBANALYSIS

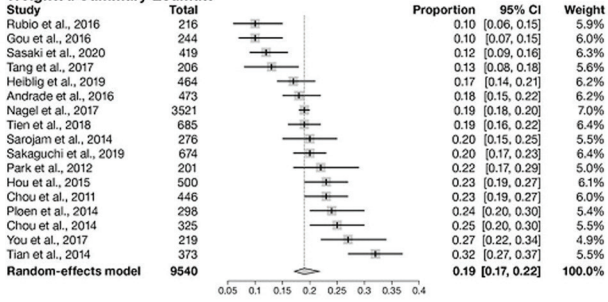
V. Havelange [1], L. Stas [2,*], M. Van den Enden [2], J. Maertens [3]

[1]Department of hematology, Cliniques Saint-Luc, Université Catholique de Louvain, Brussels, [2]AbbVie, Wavre, [3]Department of Hematology, University Hospitals Leuven, Leuven, Belgium

Background: Acute myeloid leukemia (AML) is a disease affecting older patients with a median age of 67 years. Because of age, comorbidities and unfavorable cytogenetics, older patients are frequently not eligible to the standard 7+3 induction chemotherapy combining aracytine and an anthracycline. Their survival remains poor.There is a growing need to better understand the current treatment patterns and their associated outcomes since the field of AML is evolving with the emergence of newer agents.
Aims: To describe treatment patterns and clinical outcomes including survival and remission rates, clinic-pathological characteristics and healthcare resource utilization of AML patients who are unfit to receive intensive chemotherapy in the Belgian real world clinical practice.
Methods: This retrospective chart review was conducted in 6 centers across Belgium. Adult patients who were deemed ineligible for intensive chemotherapy and that have started a systemic treatment or best supportive care between 1st of January 2015 and 31th of December 2018 in the first line setting were included. Patients were followed until death or last recorded contact, whichever came first at time of data collection. Primary objective was to evaluate the overall survival of these patients in the real-world setting. Secondary objectives included but were not limited to progression free survival, time to treatment failure and healthcare resource utilization.
Results: In this Belgian sub analysis, 43 patients were included (65% male, 35% female and 65% >75 years old) of whom 37 (86%) received systemic treatments (29,7% azacitidine, 62,2% decitabine and 8,1% other systemic treatment) and 6 (14%) received Best supportive care including transfusions, pain relief and infection management. Median OS in the overall population was 8,5 months (respectively 9,76 months, 6,74 months and 4,77 months in patients who were treated with hypomethylating agents, other systemic treatment, or best supportive care). A CR/CRI was achieved in 29% of the patients who received systemic treatment, median time to best response was 129,5 days, median duration of the complete response was 458,5 days. During the first

course of systemic treatment 34/37 patients were hospitalized due to treatment administration-related (45,5%) and infections (38,1%).

Summary/Conclusion: This Belgian sub analysis of the real-world study shows that OS and CR/CRi rates reported are consistent with previous clinical trials but that outcomes for this patient population remain poor. Future combination therapies with HMA or new agents will hopefully improve their outcome.



PB1405 FREQUENCY OF FLT3-ITD AND FLT3-TKD MUTATIONS IN PATIENTS WITH ACUTE MYELOID LEUKEMIA: A SYSTEMATIC LITERATURE REVIEW AND META-ANALYSIS

J. Lewis [1,*], N. J. Robinson [2], B. Pandya [1], M. Shah [1], L. Sullivan [1], N. Daver [3], J. Sierra [4]

[1]Astellas Pharma, Inc., Northbrook, IL, United States, [2]Astellas Pharma Europe B.V., Leiden, Netherlands, [3]The University of Texas MD Anderson Cancer Center, Houston, TX, United States, [4]Hospital Santa Creu i Sant Pau and José Carreras Leukemia Research Institute, Barcelona, Spain

Background: There is a range of estimates for the frequency of *FMS*-like tyrosine kinase 3 (*FLT3*) mutations in patients with acute myeloid leukemia (AML) in the literature, but no available systematic review on this topic.
Aims: To provide a comprehensive review of the *FLT3* mutation frequency in unselected populations of patients with AML.
Methods: We conducted systematic literature searches of the Medline/PubMed and Embase databases through 31/08/2020. Search terms were "acute myeloid leukemia," "AML," "fms like tyrosine kinase 3," and "FLT3" combined with "epidemiology," "incidence," "prevalence," "frequency," "presentation," and "occurrence." There were no limits on publication year. Full-text English-language papers of studies with ≥200 total patients were selected. Only studies reporting data for both the *FLT3*–internal tandem duplication (*FLT3*-ITD) mutation and *FLT3*–tyrosine kinase domain *(FLT3*-TKD) point mutation, study location (country), population source (eg, hospital or medical center), data collection dates, age range, sex distribution, and a description of *FLT3* mutation test methodology were included. Animal studies, in vitro studies, case reports, commentaries, reviews, and clinical trials were excluded. Using meta-analysis methods, weighted summary estimates and confidence intervals (CIs) were generated for each *FLT3* mutation from untransformed data.
Results: Of 1,618 records identified, 17 studies were included (16 hospital or medical center cohort studies, one cross-sectional study). Studies were conducted in Asia, Europe, South America, or North America with data collection dates ranging from 1994 through 2018. Sample sizes for the 16 cohort studies ranged from 201 to 685 total patients; the cross-sectional study included 3,521 patients. Across studies, 46.8% to 60.0% of participants were male. One study included only children (aged 0-17.9 years [Rubio 2016]), two studies included children and adults (aged 1-84 years [You 2017]; 0-21 years [median: 7 years] [Andrade 2016]), and 14 studies included patients aged ≥15 years. All studies reported using a polymerase chain reaction (PCR)–based test to identify the mutations; some studies reported also using additional methods (gene sequencing, fluorescence fragment analysis). Across the 17 studies, the frequency of FLT3-ITD mutation ranged from 10.2% to 31.6% (Figure), and the frequency of FLT3-TKD mutation ranged from 1.9% to 8.8% (not shown). These ranges were unchanged when the three studies with patients aged

Figure. Proportion of AML Patients With the *FLT3*-ITD Mutation Across 17 Studies, Weighted Summary Estimate

Abbreviations: AML, acute myeloid leukemia; CI, confidence interval; *FLT3*-ITD, *FMS*-like tyrosine kinase 3 gene internal tandem duplication.

Summary/Conclusion: We conducted a comprehensive systematic review of the frequency of the *FLT3* mutation in unselected populations of patients with AML. The results suggest a population frequency of around 19% for a *FLT3*-ITD mutation and 5% for a *FLT3*-TKD mutation. Further research is needed to help explain the heterogeneity in the frequency of the *FLT3* mutation across populations, and to put these results into context (including comparison with selected populations, such as in clinical trials).

PB1406 EUROPEAN GUIDELINES AND REAL-WORLD EVIDENCE OF MAINTENANCE TREATMENTS FOR ADULTS WITH ACUTE MYELOID LEUKEMIA IN FIRST COMPLETE REMISSION

M. Ahmed [1,*], G. Thompson [2], C. Martin [1], H. Cameron [1], C. Chen [3]

[1]Eversana, Burlington, Canada, [2]Bristol Myers Squibb, London, United Kingdom, [3]Bristol Myers Squibb, Princeton, United States

Background: Standard treatment with chemotherapy of patients with acute myeloid leukemia (AML) can induce remission; however, despite previous evaluation in clinical trials, maintenance/post-remission therapy is currently not a standard approach in the treatment of AML. Variation in therapy approval, reimbursement, and clinical practice may influence regional differences across Europe. Currently, recommendations from European organizations on maintenance therapy lack consistency, and the use of maintenance in the real-world setting in Europe is poorly understood.
Aims: Identify European guideline recommendations and real-world evidence on the use of maintenance/post-remission therapy for adult patients with AML who had achieved complete remission after intensive chemotherapy induction.
Methods: Two targeted literature reviews were conducted by an information specialist via database searches of MEDLINE® and EMBASE using controlled vocabulary (eg, "leukemia, myeloid, acute") and keywords (eg, "observational study" and "retrospective"); search results were not limited by language, region, or publication year. Additionally, literature searches of region-specific hematology conferences were conducted to identify unpublished treatment guidelines and real-world studies. Webpages of European health ministries were also searched for treatment guidelines. Identified records were reviewed at the title/abstract and full-text levels, with relevant information from included studies extracted.
Results: In total, for treatment guidelines, 116 records were identified from database searches and 13 from supplementary searches. For real-world studies, 482 records were identified from database searches. After screening, 14 records were included in the review of guidelines (3 pan-European, 11 region-specific) and 5 studies were included in the review of real-world studies (all limited to conference abstracts in 2010–2019, with no full publications identified; locations: 2 in Spain, 1 each in Russia, the UK, and Italy). Guidelines regarding induction and consolidation with chemotherapy were consistent, but recommendations for maintenance therapy varied (recommended [n = 7], not recommended [n = 5], and no guidance [n = 2]). In the guidelines that recommended maintenance therapy, the most common therapy was midostaurin (n = 4). Other therapies included azacitidine (n = 1) and histamine dihydrochloride (n = 1); notably, 2 guidelines recommended use of post-remission maintenance therapy, but the therapy was not specified. For the real-world studies, all 5 studies evaluated the efficacy of maintenance with injectable azacitidine (**Table**). Overall, the design of studies was heterogenous with limited sample size (range: n = 3–24), with only one study providing a direct comparison of treatment effects between maintenance options (injectable azacitidine maintenance vs no maintenance). Reported outcomes varied across studies, with survival at study follow-up and relapse rates being the most frequently reported. In the largest study (n = 24), the

relapse rate (at 10 months) with azacitidine maintenance was 17% (n = 2/12) vs 67% (n = 8/12) with no maintenance.

Summary of real-world studies evaluating maintenance with injectable azacitidine

Patient population (N)	Maintenance therapy details	Outcomes
Girshova L, et al. *Clin Lymphoma Myeloma Leuk* 2019;19(suppl 1):S204		
• AZA maintenance (n = 12) or no maintenance (n = 12)	• AZA, subcutaneous, 75 mg/m^2	• Median RFS (AZA vs non-AZA): NR vs 8.7 mo • Relapse rate (at 10 mo; AZA vs non-AZA): 2/12 vs 8/12
Shah V, et al. *Haematologica* 2014;99:619		
• AZA maintenance (n = 2)	• "5-day AZA regimen", RoA unspecified	• Discontinuation from maintenance: 100%
De La Fuente A, et al. *Haematologica* 2011;96:479		
• AZA maintenance (n = 5)	• AZA, RoA and dose unspecified	• Mean OS of 2 patients that died: 22.9 mo
Loseto G, et al. *Haematologica* 2011;96:195		
• AZA maintenance (n = 3)	• AZA, 75 mg/m^2/d, RoA unspecified	• CR maintained for all 3 patients (4–12 cycles) • AEs: Gr 3 hematologic toxicity (n = 2); gr 4 neutropenia (n = 1)
Hernandez Vazquez H, et al. *Haematologica* 2010;95:564-565		
• AZA maintenance (n = 6)	• AZA, 75 mg/m^2/d, RoA unspecified	• Alive and transfusion-independent at 9 mo: 66%

AE, adverse event; AZA, azacitidine; CR, complete remission; d, day; mo, month; gr, grade; NR, not reported; RFS, relapse-free survival; RoA, route of administration

Summary/Conclusion: There is a lack of consistency in recommendations for maintenance therapy across European guidelines, and very limited evidence exists in the published literature on the use of maintenance after first complete remission in the real-world setting, thereby highlighting an unmet need in the treatment of AML.

PB1407 PEVOLAM: TRIAL DESIGN FOR A RANDOMIZED PHASE 3 MULTICENTER STUDY COMPARING AZACITIDINE PLUS PEVONEDISTAT VS AZACITIDINE IN OLDER OR UNFIT PATIENTS WITH NEWLY DIAGNOSED ACUTE MYELOID LEUKEMIA

J. Bergua [1,*], R. Rodríguez Veiga [2], A. Contento Gonzalo [3], J. Serrano Lopez [4], J. Labrador [5], J. Lorenzo Algarra [6], R. Coll Jorda [7], M. Arnan [8], S. Vives Polo [9,10], C. Background: Despite recently approved treatment options, outcomes remain poor in patients (pts) with acute myeloid leukemia (AML) who are older or unfit for intensive chemotherapy. Pevonedistat (PEVO) is a first-in-class small-molecule inhibitor of the neural-precursor-cell-expressed developmentally down-regulated protein 8 (NEDD8)-activating enzyme (NAE), an enzyme that targets critical regulatory proteins for degradation. NAE inhibition interferes with protein homeostasis, leading to cancer-cell death. The combination of PEVO+AZA has shown synergistic antitumor activity in some AML cell lines *in vitro*. PEVO has also shown encouraging clinical efficacy in combination with AZA with a similar safety profile to that of AZA alone with no added myelosuppression. In a randomized, phase 2 trial (NCT02610777), median OS trended longer with PEVO+AZA compared with AZA alone (23.6 versus 16.0 months, respectively; P = 0.081) in pts with low-blast AML (N = 36).
Aims: The primary objective of this trial (NCT04090736) will be to evaluate if PEVO+AZA improves OS compared with AZA alone in treatment-naive pts with AML who are ineligible for standard induction chemotherapy. Key secondary objectives will be event-free survival (EFS) and the proportion of pts achieving composite complete remission when treated with PEVO+AZA (arm A) versus AZA alone (arm B). Pt reported outcomes and centralized minimal residual disease will be analyzed.
Methods: This phase 3, prospective, randomized (1:1), open-label study conducted at 62 sites in Spain will compare PEVO+AZA versus AZA alone. The planned sample size of 466 pts (233 pts in each treatment arm) is estimated to be enrolled within 24 months. An additional follow-up of 22 months after the accrual will be needed to obtain a total of 386 OS events. This will provide 80% power to detect a statistically significant difference in OS between the two treatment arms under the assumption of a hazard ratio of 0.75. An interim analysis of OS will be performed after 75% of death events have occurred. Pts in arm A will receive PEVO 20 mg/m^2 intravenously on days 1, 3 and 5 plus AZA 75 mg/m^2 subcutaneously on the 5-on/2-off (weekend)/2-on schedule in a 28-day cycle. Pts in Arm B will receive AZA 75 mg/m^2 on the 5-on/2-off (weekend)/2-on schedule in a 28-day cycle. Eligible pts include adults with newly diagnosed AML who have an Eastern Cooperative Oncology Group Performance Status (ECOG PS) score of ≤ 3 and are not eligible for intensive chemotherapy (≥ 75 years of age, or ≥ 18 years of age with comorbidities that preclude intensive chemotherapy [e.g., renal, cardiac, or hepatic dysfunction, or ECOG PS of 2 or 3]). Pts with secondary AML are also eligible for inclusion. Exclusion criteria include white blood cell count ≥ 25 × 10^9/L, previous treatment for myelodysplastic syndrome or chronic myelomonocytic leukemia or myeloproliferative neoplasm, with chemotherapy or other antineoplastic agents including up to two cycles of hypomethylating agents. An independent data monitoring committee will review safety and efficacy data.
Results: N/A
Summary/Conclusion: Since September 2019 and throughout the coronavirus pandemic, 187 pts were recruited; recruitment is ongoing. Given its novel mechanism of action and non-myelosuppressive safety profile, data from this trial may support the use of PEVO as an additional combination therapy partner for pts with AML to improve survival outcomes while preserving QoL.

PB1408 PHASE 1/2 FIRST IN HUMAN STUDY OF THE MENIN-KMT2A (MLL) INHIBITOR KO-539 IN PATIENTS WITH RELAPSED OR REFRACTORY ACUTE MYELOID LEUKEMIA

E. Wang [1,*], J. Altman [2], G. Issa [3], K. Pettit [4], S. DeBotton [5], S. DeBotton [5], R. Walter [6], P. Fenaux [7], L. Ades [7], F. Burrows [8], B. Tomkinson [9], B. Martell [9], A. Fathi [10]

[1]Roswell Park Comprehensive Cancer Center, Buffalo, [2]Northwestern Medical Faculty Foundation, Chicago, [3]The University of Texas MD Anderson Cancer Center, Houston, [4]University of Michigan, Ann Arbor, United States, [5]Institut Gustave Roussy Service d'Hématologie Clinique, Villejuif, France, [6]Fred Hutchinson Cancer Research Center, Seattle, United States, [7]Hospital Saint Louis, Paris, France, [8]Kura Oncology, San Diego, [9]Kura Oncology, [10]Massachusetts General Hospital, Harvard Medical School, Boston, United States

Background: The histone-lysine-*N*-methyltransferase 2A (*KMT2A*) gene (formerly known as mixed-lineage leukemia (*MLL*)) plays an essential role in regulating gene expression including that of *MEIS1* and the homeobox gene family, which are known to be important for maintenance of leukemia when dysregulated. In 5-10% of acute myeloid leukemia (AML) cases, specific *KMT2A* gene perturbations can occur which result in an aggressive and poor prognosis. The Menin-KMT2A complex also appears to play a central role in the epigenetic dysregulation in AMLs with co-mutations in genes such as *NPM1*, *IDH1/2*, *FLT3*, *EZH2*, and *DNMT3A*, with *NPM1* mutation accounting for 25-30%. Therefore, there is strong rationale for targeting these AML subsets, which may be exquisitely sensitive to the menin-KMT2A complex inhibition.
Aims: The objectives of the Phase (Ph) 1 dose escalation are to assess safety and tolerability, characterize the pharmacokinetics (PK), determine a recommended Ph2 dose (RP2D), and investigate early signs of anti-leukemic activity. The Ph1 expansion cohorts will assess anti-leukemic activity, PK, safety and tolerability in AML pts with *NPM1* mutation or *KMT2A* rearrangement at doses that have already met the safety threshold to help determine a minimally safe and biologically effective dose. Once a RP2D has been determined, Ph2 expansion cohorts including AML pts with *NPM1* mutation or *KMT2A* rearrangements will be conducted to assess safety, tolerability and efficacy at the RP2D.
Methods: KO-539 is a novel, once daily, oral investigational drug candidate targeting the menin-KMT2A protein-protein interaction.

KOMET-001 (NCT04067336) is an ongoing Ph1/2 open-label study evaluating KO-539 in adult patients (pts) with relapsed or refractory (R/R) AML. Key inclusion criteria include: R/R AML defined as the appearance of > 5% blasts in the bone marrow and who have failed or are ineligible for any approved standard of care therapies, including transplant, ECOG performance status of 0 to 2, and adequate organ function. Key exclusion criteria include: pts with acute promyelocytic leukemia or chronic myelogenous leukemia in blast crisis, clinically active central nervous system leukemia, pts who have undergone transplant and have not had adequate hematologic recovery or with Grade >2 active graft-versus-host disease issues, or pts on concomitant drugs that are strong inhibitors or inducers of CYP3A4 except for antibiotics, antifungals, and antivirals. All pts are being followed for safety during treatment and up to approximately 28 days after treatment discontinuation, or until immediately before the initiation of another anticancer therapy, whichever occurs first. Anticipated efficacy assessment will include assessment of: complete remission (CR) plus complete remission with partial hematologic recovery (CRh) composite; CR with and without minimal residual disease (MRD), and duration of remission (DOR) as key secondary endpoints. Additional anticipated assessments in the expansion cohorts will include transfusion independence, relapse-free survival (RFS), and overall survival.
Exploratory biomarkers will be examined in bone marrow biopsies/aspirate as well as peripheral blood collected serially from all pts pre- and post-treatment.
KOMET-001 is continuing to enroll pts in dose escalation and, in parallel, will be enrolling Ph1 expansion cohorts in genetically defined populations to better inform the RP2D. This will be followed by the Ph2 expansion portion in genetically defined populations once a RP2D is determined.
Results: N/A (trial in progress)
Summary/Conclusion: N/A (trial in progress)

PB1409 CPX-351 IN THERAPHY RELATED ACUTE MYELOID LEUKEMIA AND ACUTE MYELOID LEUKEMIA WITH MYELODYSPLASIA-RELATED CHANGES: A MULTICENTER REAL-LIFE EXPERIENCE IN YOUNG PATIENTS (<60 YEARS OLD)

B. Garibaldi [1,*], L. Brunetti [2], E. Mauro [3], C. Maugeri [3], M. S. Parisi [3], P. F. Fiumara [3], A. Duminuco [1], G. A. Palumbo 1 4, F. Di Raimondo [3,5], C. Vetro [3]

[1]Postgraduate School of Hematology, University of Catania, Catania, [2]Division of Haematology, A.O.S. Maria della Misericordia, Perugia, [3]Division of Haematology, A.O.U. Policlinico "G.Rodolico" - S.Marco, [4]Department of Scienze Mediche Chirurgiche e Tecnologie Avanzate "G.F. Ingrassia", [5]Department of Chirurgia Generale e Specialità Medico-Chirurgiche, University of Catania, Catania, Italy

Background: Therapy-related acute myeloid leukemia (t-AML) and AML with myelodysplasia-related changes (AML-MRC) are two AML subtypes with very poor prognosis. The CLTR0310-301 study showed survival advantages in favour of CPX-351 compared to "7+3" in newly diagnosed t-AML or AML-MRC, 60-75 years old.
Aims: To explore the efficacy of CPX-351 in younger patients in a real-life setting.
Methods: Since September 2019 we treated 9 patients with CPX-351, with a median age of 51 (range 32-59) and ECOG range 0-2. Our cohort consisted in 6 patients with MRC-AML, 2 patients with t-AML and 1 patient with t-AML after a therapy-related myelodysplastic syndrome (t-MDS). 2 patients (both with AML-MRC) harboured *FLT3*-ITD (Allelic Ratio 0.1), 1 patient *IDH1* and 1 patient *TP53* mutation. 4 patients had a complex karyotype and 2 patients had received prior treatment with hypomethylating agents (HMA).
Results: All patients underwent induction therapy with intravenous administration of CPX-351 at day 1, 3 and 5 except 1 patient who received just two doses due to pneumonia outbreak. One patient developed a right upper limb lesion, initially with phlebitic appearance and then with necrotic evolution. He eventually died due to severe pneumonia. Eight out of 9 patients were evaluable at the end of treatment. Disease re-evaluation was performed on average 42 days since induction therapy start. Four patients reached a complete remission (CR) and 1 patient a CR with incomplete haematological recovery (CRi), with 63% overall response rate (ORR). One patient showed a partial remission (PR), while 2 patients were refractory. Median days of severe neutropenia (defined as neutrophils lower than 500/uL) were 31. Median days of severe thrombocytopenia (defined as platelets lower than 20.000/uL) were 25. The patient in PR, who was *FLT3* mutated, underwent reinduction, with administration of CPX-351 in day 1 and 3, obtaining a CR. Three patients completed both consolidation cycles and underwent bone marrow transplantation. One patient, who was *IDH1* mutated, received just one consolidation cycle before transplant and 1 patient was transplanted immediately after induction. A 46 years old patient in CR after induction relapsed after 5 months being off therapy due to a fungal infection whose treatment required a long period of hospitalization to carry out targeted antifungal therapy. Given the CR achieved and the high infectious risk highlighted during induction, the patient did not carry out any consolidation cycle while waiting for transplant. The 2 refractory patients, who both showed complex karyotype and one of them was *TP53* mutated, were switched to other regimens.
Summary/Conclusion: We found that CPX-351 is active in young patients with t-AML and AML-MRC with a rate of ORR higher than that reported in the pivotal study (63% vs 47%). This improvement be explained by the fact that younger patients better tolerate chemotherapy and its complications. Complex karyotype and *TP53* mutation confirmed their role as negative prognostic factors, while better prognosis was observed for *FLT3* and *IDHs* mutated patients although numbers are too small to drive full conclusions. With this therapy we were able to bridge 5 out of 8 (62%) evaluable candidate patients to HSCT. Regarding the safety profile, the most frequent complication was febrile neutropenia (60%), successfully managed with supportive therapy. In conclusion, our results are in line with those reported by other institution real-life data in patients <60 years.

PB1410 IDENTIFYING LEUKEMIA-ASSOCIATED IMMUNOPHENOTYPES IN ACUTE MYELOID LEUKEMIA PATIENTS USING MULTIPARAMETER FLOW CYTOMETRY

H. Rasheed [1,*], H. Donia [1], E. Nadwan [2], Z. Mourad [1], N. Farahat [1]

[1]Clinical and Chemical Pathology, [2]Internal Medicine Department, Faculty of Medicine, Alexandria University, Alexandria, Egypt

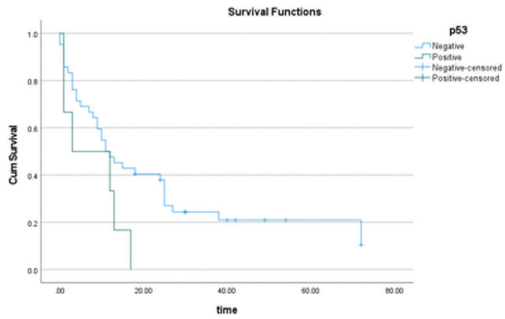
Background: Acute myeloid leukemia is nowadays considered the most common acute leukemia in adults and the most common cause of leukemia-associated mortality in adults. Being a heterogeneous disease, patients can achieve complete hematological remission with bone marrow blasts <5% by intensive chemotherapy, but will eventually relapse due to the persistence of leukemic cells after chemotherapy unidentified by routine morphologic evaluation which is known as minimal residual disease.
Aims: To identify leukemia-associated immunophenotypes in sixty acute myeloid leukemia patients at diagnosis using an eight color multiparameter flow cytometry panel and to detect if they showed any alteration in relapse/refractory cases.
Methods: Eight color multiparameter flow cytometry panel with CD45/SSC log gating strategy was used for analysis of leukemia-associated immunophenotypes in bone marrow samples obtained from sixty consecutive, unselected acute myeloid leukemia patients presenting to Alexandria University Hospitals at diagnosis, relapse and refractory cases. Twenty bone marrow samples from patients performing bone marrow aspirate for non-malignant hematological indications and twenty regenerative bone marrow samples from acute lymphoblastic leukemia patients on chemotherapy in follow up of matched age and sex were included as controls.
Results: Leukemia-associated immunophenotypes were observed in 53 cases (88.3%). Only one aberrant immunophenotype was identified in five cases (8.3%), while two to twelve aberrant immunophenotypes were found in the other 48 cases (80%). *Strong leukemia-associated immunophenotypes* were obtained by the combination of CD2, CD4, CD56 with either CD34 or CD117, in contrast to CD19 which has to be combined with CD117. Refractory cases showed the presence of same leukemia-associated immunophenotypes at both initial diagnosis and persistent disease, while one of the relapsed cases showed acquisition of new leukemia-associated immunophenotypes after relapse.
Summary/Conclusion: The good choice of leukemia-associated immunophenotypes depends on their specificity rather than their frequency. The results of this study can help in increasing the sensitivity of leukemia-associated immunophenotypes strategy in minimal residual disease using multiparameter flowcytometry in acute myeloid leukemia patients which is considered an important post-diagnosis parameter associated with prognosis and clinical outcome.

PB1411 JUVENILE MYELOMONOCYTIC LEUKEMIA IN A PATIENT WITH NOONAN SYNDROME AND FAMILIAL MEDITERRANEAN SYNDROME

D. Babikyan [1,2,*], A. Zakharyan [2]

[1]Center of Medical Genetics and Primary Health Care, [2]Yerevan State Medical University, Yerevan, Armenia

Background: We report a female patient of Armenian origin initially suspected with myelodysplastic syndrome of unknown origin at the age of 8 y.o based on initial analysis of the bone marrow described also with abnormal hemoglobin, anemia and neutropenia. However, the clinical picture was also characterized with periodic fevers accompanied with joint and thoracic pains starting from the age 5 y.o. Later, the patient was described with splenomegaly and hepatomegaly. No familial case was reported. Further, she developed a swelling of the feet with pain, exudative pneumonia, general weakness and loss of weight.
Aims: The lack of clinical diagnosis for treatment required performance of the differential complex examinations, including the cellular immunophenotyping, cytogenetic, and whole genome analyses.
Methods: The analysis of human cluster of differentiation (CD) antigens the patient's bone marrow was analyzed by flow cytometry analysis capturing 30 human CDs. Molecular cytogenetic analysis was performed by FISH method on the patient's bone marrow cells for the detection of the major seven cytogenetic aberrations related to leukemias. Whole Exome Sequencing (WES) of the patient's DNA extracted from the peripheric leukocytes on a MiSeq platform.
Results: Immunophenotyping analysis detected less than 7% of blast cells in the bone marrow which antigen spectrum (CD7, CD11a, CD11c, CD13, CD33, CD34, CD45, CD64, CD117, CD123, and HLA-DR) confirmed its relation to acute myeloid leukemia. Molecular cytogenetic analysis did not find any cytogenetic aberration in the bone marrow. However, the WES detected two pathogenic variants in two genes: a heterozygous variant c.214G>A (p.Ala-72Thr) in the PTPN11 gene which is associated with developmental and lymphatic dysplasia and a heterozygous variant c.2080A>G (p.Met694Val) in the MEFV gene which is associated to hereditary autoinflammatory syndromes. De novo status of the detected PTPN11 variant was confirmed by parental testing. Detection of the heterozygous state of the PTPN11 variant with frequency of 40% is compatible with both germline and mosaic states.
Summary/Conclusion: The WES result was compatible with a genetic diagnosis of the autosomal-dominant Noonan syndrome type 1 and/or the predisposition to juvenile myelomonocytic leukemia caused by somatic PTPN11 variants. Further physical examination of the patient did describe several features characteristic to the Noonan syndrome, including the short stature, chest abnormality, hypertelorism, as well as facial and developmental features of variable degree. Pathogenic somatic variants in the PTPN11 gene are associated with juvenile myelomonocytic leukemia. Leukemias occurring in the absence of any other finding of Noonan syndrome could harbor somatic PTPN11 variants, particularly in children with myelodysplastic syndrome. The latter is indeed more specific in case of excess of blast cells in acute myeloid leukemia with poor prognosis. Therefore, more detailed physical and phenotypic characterization of the patient at the initial state of the disease could support to the suspicion of the rare genetic syndrome of DNA reparation system associated with oncological features. The heterozygous MEFV pathogenic variant common in the Armenian population is the strongest pathogenic variant in patients with Familial Mediterranean Fever (FMF). Despite FMF is an autosomal recessive disorder, less than 10% of cases are described with only one MEFV mutation. Thus, several clinical features of the patient not specific to the myelomonocytic leukemia are explained with accompanied autoinflammatory condition.



PB1412 IMPACT OF P53 AND BCL2 EXPRESSION ON PROGNOSIS IN PATIENTS WITH ACUTE MYELOID LEUKAEMIA: A TEN YEAR SINGLE CENTRE STUDY

L. Mcdonald [1,*], B. Hennessy [1], S. Kumar [1], D. Walsh [1], L. Sutton [2], M. Nur [2], C. Schilling [2], E. Elhassadi [1]

[1]Haematology, [2]Pathology, University Hospital Waterford, Waterford, Ireland

Background: Acute myeloid leukaemia (AML) is a heterogenous disorder that arises from clonal expansion of malignant haematopoetic precursor cells. Somatic mutations of the tumour suppressor p53 gene have been reported in 5-10% of all patients with AML, although the incidence is higher in therapy-related disease and elderly patients. Alteration or loss of the p53 gene is one of the most powerful independent indicators of poor outcome. Overexpression of the *BCL2* proto-oncogene in AML is less well described in the literature and its impact on prognosis is uncertain.
Aims: This is a single-centre, retrospective analysis of AML patients treated over a ten year period (2006-2016).
Methods: Patients were identified through our pathology database. p53 expression was analysed as a surrogate marker for TP53 mutation, as was BCL2 expression, by immunohistochemical analysis of marrow trephine biopsies. We analysed presentation, management and overall survival (OS) of AML patients, and correlated these with p53 mutational status and with BCL2 expression.
Results: We identified 48 patients with AML; the majority were male (60%) and the median age at diagnosis was 68.5 years (range 37-85). Thirty-four patients (71%) had *denovo* presentation of AML. p53 overexpression was identified in 6 patients (12.5%), of whom 3 had secondary AML, and 3 had *denovo* presentations. *BCL2*expression analysis showed a median value of 60% (range 5-100%). *BCL2* positivity was seen in 39 patients (81.2%).

Figure 1: Overall survival comparison of patients with *TP53* positive disease vs *TP53* negative disease

Thirty-nine patients (83%) received active treatment; the remainder received only supportive care due either to frailty or patient choice. Nineteen patients (49%) of patients subsequently had relapsed/refractory disease. Five patients (13.5%) with *BCL2* overexpression at diagnosis received Venetoclax as single agent, either as 2nd or 3rd line therapy. Median OS was 11.5 months (range 0-72); at time of follow-up, 39 patients (81%) had died. Twenty-six patients died from disease progression (79%) and 7 (19%) of sepsis; in 2% the cause of death was unknown. OS in those with wild-type p53 was 11.5 months, which compared favourably to 7.5 months in those with p53 overexpression. *BCL2* overexpression also conferred a poorer prognosis; median OS was 10 months compared to 17 months in *BCL2* negative disease.
Summary/Conclusion: This study reflects real-life practice in treating AML patients outside of a clinical trial context. It demonstrates a slightly higher prevalence of p53 mutation in the elderly, and confirmed the previously reported poor prognosis of p53 alterations in AML (OS 7.5 months). It also demonstrates poorer OS in disease with *BCL2*overexpression. Further studies are needed to identify treatment strategies to overcome both p53 and *BCL2* disruption in AML.

PB1413 REAL WORLD DATA ON THE USE OF BCL2 INHIBITION IN ACUTE MYELOID LEUKAEMIA; THE IRISH EXPERIENCE

L. Mcdonald [1,*], P. Murphy [2], V. Mykytiv [3], A. Hayat [4], M. R. Cahill [3], G. Crotty [5], K. Perera [5], H. Enright [6], L. Smyth [7], J. Krawczyk [4], R. O'Doherty [8], S. Maung [8], A. Fortune [8], D. O'Keeffe [9], S. Kumar [1], B. Hennessy [1], E. Elhassadi [1]

[1]Haematology, University Hospital Waterford, Waterford, [2]Haematology, Beaumont Hospital, Dublin, [3]Haematology, Cork University Hospital, Cork, [4]Haematology, University Hospital Galway, Galway, [5]Haematology, Midland Regional Hospital, Tullamore, [6]Haematology, Tallaght University Hospital, [7]Haematology, St. Vincent's University Hospital, [8]Haematology, Mater Misericordiae University Hospital, Dublin, [9]Haematology, University Hospital Limerick, Limerick, Ireland

Background: The BCL2 gene is a regulator of apoptosis, playing a key role in leukaemogenesis. BCL2 positivity in Acute Myeloid Leukaemia (AML) and its impact on prognosis is unclear. Recently, BCL2 inhibitors (Venetoclax) have shown promise in AML when used in combination with other agents. Treatment of relapsed/refractory AML is an unmet need and often has a dismal prognosis, especially in patients unsuitable for intensive chemotherapy.
Aims: Venetoclax was, until recently, made available in Ireland on a named-patient basis for use in AML. The aim of this multicentre, retrospective study was to analyse its use in this context.
Methods: Data was collected from 9 centers in Ireland. Patient and disease characteristics, prior treatment and outcomes were analysed. Real world data was also gathered regarding tolerability of Venetoclax and adverse events.
Results: Data were collected for 26 AML patients treated with Venetoclax. Most had *de novo* AML (n=19; 73%). Cytogenetic and molecular analyses are outlined in Table 1. Indications for initiating Venetoclax therapy were refractory disease (n=15, 58%) and relapsed disease (35%). One patient had not tolerated Azacitadine. Venetoclax was used as a single agent in 13 patients (50%) and in combination in 11 patients (42%). Other agents used were Azacitadine (n=8, 61.5%), Decitabine (n=2, 15%), and induction chemotherapy (n=1).
When initially investigated for treatment of CLL, the main risk with initiating Venetoclax was Tumour Lysis Syndrome (TLS). This is less well characterised for patients with AML, and therefore a more rapid dose escalation regimen has been advocated. The majority (n=18, 72%) were admitted to hospital for initiation of therapy. Most patients (69%) received TLS prophylaxis with Allopurinol alone. Seven patients (27%) received Rasburicase, and one patient received intravenous fluid alone. TLS was reported in only one patient who had received Rasburicase.
Venetoclax was mostly well-tolerated. Ten patients (40%) had adverse events or side effects. Myelosuppression was the most commonly reported adverse event (n=9, 36%) and treatment was temporarily interrupted due to cytopenia in 4 of these. GCSF support was commonly used. Infections were reported in 5 patients (20%), and recurrent febrile neutropenia led to treatment discontinuation in one. Overall, seven patients required hospital admission due to Venetoclax toxicity (28%).
The median duration of treatment was 2 months (range 0.5-12). Treatment response was assessed clinically (peripheral blood counts) in 17 patients (71%) and by bone marrow aspirate and trephine biopsies in seven patients (29%). Response to treatment was variable; the majority (n=11, 46%) had progressive disease, 8 patients (33%) had stable disease, 4 patients achieved Partial Response (17%) and only one patient had a Complete Response. There was no significant difference between response rates and survival in patients treated with Venetoclax as a single agent compared to in combination (median survival from commencing Venetoclax was 2 months vs. 3 months respectively). At time of data collection, 19 patients had died (76%).
Summary/Conclusion: Venetoclax is not yet a standardised treatment for AML, and in Ireland was available only on a Compassionate Access Scheme and this has now closed. This study of real-world data indicates that Venetoclax is well-tolerated with a low risk of serious adverse events. However, OS was not as prolonged as has been reported in the literature. Based on our experience, Venetoclax may be more effective when commenced earlier in patients with relapsed/refractory disease.

PB1414 FREQUENCY OF AN HP196–197 INSERTION (6BP) IN C/EBPA TAD2 REGION IN RUSSIAN POPULATION OF AML PATIENTS COMPARING TO CONTROL COHORTS.

Y. Kozhevnikova [1,*], N. Risinskaya [2], I. Fevraleva [2], A. Sudarikov [2]

[1]Lomonosov Moscow State University, School of Medicine, [2]National Research Center for Hematology, Moscow, Russian Federation

Background: CCAAT/enhancer-binding protein-α (C/EBPα) is a transcription factor encoded by the CEBPA gene and involved in the control of proliferation and differentiation of myeloid progenitors. C/EBPα consists of C-terminal DNA-binding basic leucine zipper (bZIP) domain and two transactivation domains TAD 1 and TAD 2 in the NH2 terminus. Mutations in CEBPA are found in 5% to 14% of acute myeloid leukemia (AML). AML patients with biallelic mutations of CEBPA are included in "favorable" group, which determines treatment strategy. It has been shown that HP196–197 insertion (6bp) in TAD2 domain is a common inherited mutation spread in normal population; however, there has been no studies on the occurrence of this insertion in the Russian population.
Aims: To compare the frequency of 6bp insertion in TAD2 domain of CEBPA gene in AML patients with healthy and no-myeloid leukemia (CLL) control cohorts.

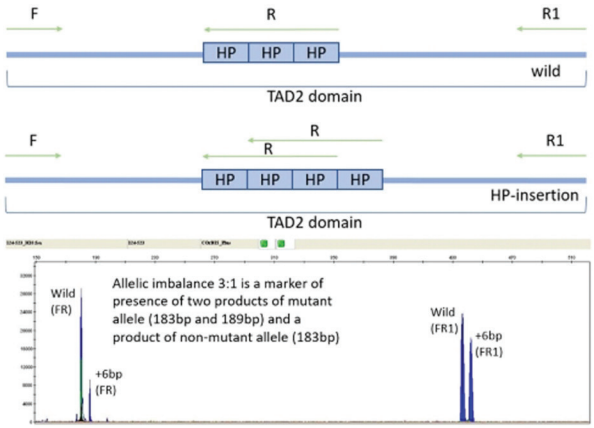
Methods: The study included 120 healthy controls, 117 de-novo AML patients, and 100 chronic lymphocytic leukemia (CLL) patients undergoing treatment at the National Research Center for Hematology (Moscow, Russia). Genomic DNA was isolated from bone marrow/peripheral blood samples taken at the time of diagnosis. For AML patients we also analyzed bone marrow/peripheral blood samples taken after treatment. Detection of 6bp insertion was performed on genomic DNA by PCR and fragment analysis. To amplify the region, we used a fluorescently labeled forward (F) primer FAM-5′-CCGGCTACCTGGACGGCAGG-3′ and a reverse (R1) primer 5′-CGTTGCTGTTCTTGTCCACCGACTTCTT-3′ [T Benthaus et al, 2008]. The fragment analysis was performed on ABI3130 Genetic Analyzer (Thermofisher Scientific, USA). Comparisons between patient characteristics were performed using the Pearson χ^2 test for binary variables.
Samples with detected 6bp insertion in TAD2 domain were further analyzed to confirm that 6bp insertion was located in a region that accounts for a His–Pro duplication (HP196–197ins). Samples were amplified using fluorescently labeled forward (F) primer FAM-5′-CCGGCTACCTGGACGGCAGG-3′ [T Benthaus et al, 2008] and reversed (R) primer 5′-TGCGGGTGCGGGTGCGGGT-3′ [in house design] with subsequent fragment analysis (see figure 1).
Results: 6bp insertion in TAD2 domain of CEBPA gene was detected in 7 of 117 (6%) AML patients, in 9 of 120 (7,5%) healthy controls, and in 10 of 100 (10%) CLL patients; differences between these groups were not statistically significant (χ^2=1.234, df=2, p=0.540). It was confirmed that 6bp insertion was HP196–197ins in all cases. In all AML patients with 6bp insertion in TAD2 domain in samples taken before treatment, this insertion was also detected after treatment as well.
Summary/Conclusion: Expected occurrence of 6bp insertion in TAD2 domain of CEBPA gene (HP196–197ins) is equal in AML patients, healthy controls, and patients with non-myeloid leukemia. Moreover, this insertion in AML patients persists after treatment, which suggests its hereditary nature. Therefore, this insertion should not be taken into account when determining the risk group and treatment strategy.



PB1415 A PHASE 1 STUDY OF NKX101, AN ALLOGENEIC CAR NATURAL KILLER (NK) CELL THERAPY, IN SUBJECTS WITH RELAPSED/REFRACTORY (R/R) ACUTE MYELOID LEUKEMIA (AML) OR HIGHER RISK MYELODYSPLASTIC SYNDROME (MDS)

C. Bachier [1,*], G. Borthakur [2], C. Hosing [3], W. Blum [4], M. Rotta [5], P. Ojeras [6], M. Hiremath [6], K. Rajangam [6], N. Majhail [7], S. Nikiforow [8]

[1]Sarah Cannon Center for Blood Cancer, Sarah Cannon Blood Caner Network, Nashville, TN, [2]Dept. of Leukemia, [3]Dept. of Stem Cell Transplantation and Cellular Therapy, University of Texas MD Anderson Cancer Center, Houston, TX, [4]Winship Cancer Institute, Emory University, Atlanta, GA, [5]Colorado Blood Cancer Institute, Sarah Cannon Blood Cancer Network, Denver, CO, [6]Nkarta Therapeutics, South San Francisco, CA, [7]Cleveland Clinic, Taussig Cancer Institute, Cleveland, OH, [8]Dana-Farber Cancer Institute, Boston, MA, United States

Background: Patients with R/R AML, or R/R higher risk MDS have a poor prognosis with a 5-year survival of <10%, or median overall survival of 0.8-3.0 years, respectively. Novel chimeric antigen receptor (CAR) T cell products

have had limited clinical success in patients with myeloid disorders due to absence of clear targets and a hostile microenvironment. Complete remission with or without hematologic recovery was achieved in 20%>50% of patients treated with non-engineered, allogeneic, haplo-matched NK cells after lymphodepletion; and minimal cytokine release syndrome and neurotoxicity were observed. The cytolytic activity of NK cells is due to the balance of activating and inhibitory signaling; key among the activating receptors is NKG2D, which recognizes multiple ligands upregulated in tumor tissues. NKX101 is composed of CAR NK cells engineered to express a chimeric receptor that fuses the extracellular ligand-binding domain of NKG2D to co-stimulatory (OX40) and signaling (CD3ζ) domains, to enhance its intrinsic antitumor activity. NKX101 also expresses a membrane-bound form of interleukin-15 that serves as an autocrine growth factor to increase NK cell persistence. Preclinical characterization has demonstrated that NKX101 achieves a 4- to 8-fold greater cytotoxicity, superior intrinsic longevity, and enhanced antitumor activity in AML xenograft models relative to nonengineered NK cells.
Aims: A Phase 1 study to investigate NKX101 in subjects with R/R AML or higher risk MDS.

Methods: This multicenter, open-label, Phase 1 study of NKX101 will be conducted in 2 parts: Part 1 to determine the recommended Phase 2 dose (RP2D) of NKX101 utilizing a modified "3+3" enrollment schema. The study will enroll subjects with either R/R primary or secondary AML or R/R higher risk (intermediate-, high-, and very high-risk) MDS. Building on existing clinical data with nonengineered haplomatched NK cells (referenced above), NKX101 manufactured from NK cells obtained from haplomatched, related donors (H) will be used in Part 1. Part 2 (dose expansion) will evaluate safety, tolerability, pharmacokinetics (PK), immunogenicity, pharmacodynamics (PDn), and antitumor activity of NKX101 from unrelated, HLA-mismatched donors with separate expansion cohorts for patients with AML or MDS. The starting dose of NKX101 is 1×10^8 CAR NK cells where NKX101 will be administered on Days 0, 7, and 14 of a 28-day cycle following standard fludarabine/cyclophosphamide lymphodepletion. Three dose levels are planned. Additional dosing schedules may be considered in the future. The primary endpoint is incidence of adverse events, dose-limiting toxicities, clinically significant laboratory abnormalities, and determination of the RP2D. Secondary endpoints include evaluation of standard cellular PK parameters, PDn, immunogenicity, and antitumor responses. AML patients will be assessed for efficacy using updated ELN criteria including measurable residual disease assessment, and MDS using modified IWG criteria. Exploratory endpoints are correlation of various degrees of HLA and KIR ligand match/mismatch between donor and recipient with primary and secondary safety, PK, and efficacy measures.
Results: The trial is in progress.
Summary/Conclusion: NKX101 is a novel fourth generation allogeneic CAR NK being evaluated in a Phase 1 trial with R/R AML or higher risk MDS patients at multiple centers (NCT04623944).

PB1416 MUTATION SPECTRUM OF FLT3-ITD POSITIVE ACUTE MYELOID LEUKEMIA AND ITS PROGNOSTIC INDICATIONS IN A CHINESE PATIENT COHORT

X. Shi [1], L. Su [1], C. Wang [1], H. Fan [1], Y. Yang [1], X. Liang [1], R. Hu [1], Y. Tan [1], S. Gao [1,*]

[1]*Department of Hematology, The First Hospital of Jilin University, Changchun, China*

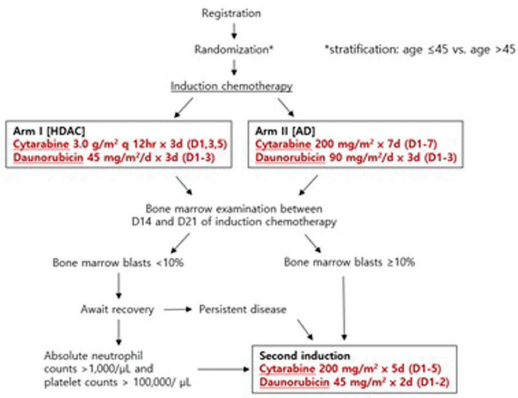
Background: FMS-like tyrosine kinase 3 gene (FLT3) internal tandem duplication (ITD) mutation is one of the most frequent genetic mutations in patients with acute myeloid leukemia (AML). Although patients with FLT3-ITD mutations have an unfavorable outcome, variant allelic frequency (VAF), insertion site (IS), insertion length all may potentially impact the prognostic significance of FLT3-ITD mutations.
Aims: The aim of this study is to explore the mutation spectrum of FLT3-ITD positive AML and potential markers, including VAF, IS, insertion length, co-occurring mutations, which may influence the prognoses of this subset of patients.
Methods: Illumina MiSeq™Dx next generation sequencing (NGS) was performed to screen genetic mutations in 145 *de novo* patients with FLT3-ITD positive AML (excluding acute promyelocytic leukemia). VAF was defined as the fraction of mutant alleles as a percentage of all FLT3 alleles (FLT3-ITD/FLT3-WT + FLT3-ITD).
Results: The median VAF was 36.4% (range 1-81.8%), and median insert length was 45 bp (range 7-186 bp). Patients with FLT3-ITD VAF ≥33% was associated with a higher percentage of bone marrow blasts (0.7959±0.17333 versus 0.7306±0.20225, P=0.038) compared with those with VAF <33%. Forty-one types of other molecular mutations were detected in these patients, and the top three mutated genes were NPM1 (n = 79) (54.5%), DNMT3A (n = 62) (42.8%), and WT1 (n = 25) (17.2%). FLT3-ITD VAF ≥33% was associated with a higher NPM1 mutation ratio (P < 0.05) as compared to the VAF <33%. Based on Cancer Genome Atlas Research Network, the distributions of patient subsets consist of DNA-methylation-related genes (63.4%), the gene encoding nucleophosmin (NPM1) (54.5%), signaling genes (28.3%), myeloid transcription-factor genes (23.4%), tumor suppressor genes (22.8%), cohesin-complex genes (6.2%), and spliceosome-complex genes (6.2%), and chromatin-modifying genes (5.5%).
The CR, ORR, and early mortality rates were 65.3% (64/98), 79.6% (78/98), and 2.7% (3/113), respectively. Finally, 63 cases who achieved CR entered long-term follow-up (including 20 cases who received allo-HSCT). The follow-up time ranged from 3.17 to 60.1 months (median 15.97 months). In total, 42 patients relapsed, and 35 patients died. Our studies showed that longer insertion length (≥45bp) indicated a better RFS (P=0.02) and OS (P=0.016) compared with shorter insert length (<45bp) in patients with normal karyotype who consolidated with chemotherapy only. DNMT3A mutant patients had an inferior RFS and OS (p=0.003 and p=0.011), while NPM1, WT1 mutations had no significant influence on outcomes of patients in this study.
Summary/Conclusion: High FLT3-ITD VAF was associated with high levels of blasts in the bone marrow and NPM1 mutations. DNMT3A might be a poor prognostic factor in FLT3-ITD positive AML patients. The impact of insertion length is still unclear, and further investigation is needed to verify this conclusion.

PB1417 A PROSPECTIVE RANDOMIZED COMPARISON OF HIGH-DOSE CYTARABINE AND HIGH-DOSE DAUNORUBICIN IN THE INDUCTION CHEMOTHERAPY FOR ACUTE MYELOID LEUKEMIA

E.-J. Choi [1,*], J.-H. Park [1], H.-S. Park [1], J.-H. Lee [1], K.-H. Lee [1], Y.-S. Lee [1], Y.-A. Kang [1], M. Jeon [1], J. M. Woo [1], H. Kang [1], J.-H. Lee [1]

[1]*Department of Hematology, Asan Medical Center, University of Ulsan College of Medicine, Seoul, Korea, Republic Of*

Background: Over the past four decades, induction chemotherapy for acute myeloid leukemia (AML) has been standardized as so-called 7+3 regimen comprising 7 days of cytarabine and 3 days of anthracycline. To improve the treatment outcomes of AML patients, several prospective trials had been conducted with regards to the dosing schedule of induction chemotherapies. The E1900 trial showed improved complete remission (CR) rate and survival with high-dose daunorubicin (90 mg/m^2/d for 3 days) than standard-dose daunorubicin (45 mg/m^2/d for 3 days). During the similar period, our group also conducted a randomized study comparing high-dose and standard-dose daunorubicin (90 vs. 45 mg/m^2/d for 3 days) and confirmed superior CR rate and survival of high-dose daunorubicin. A randomized trial of Australian group comparing standard dose cytarabine (100 mg/m^2/d for 7 days) and high-dose cytarabine (3 g/m^2 q12hr for 4 days) showed improved duration of response, disease-free survival and overall survival (OS) after CR of high-dose cytarabine. Later, another randomized trial also revealed that high-dose cytarabine was associated with higher CR rate and longer survival than standard-dose cytarabine.
Aims: To optimize the induction treatment of AML, we designed a randomized study comparing high-dose cytarabine and high-dose daunorubicin for newly diagnosed AML patients.



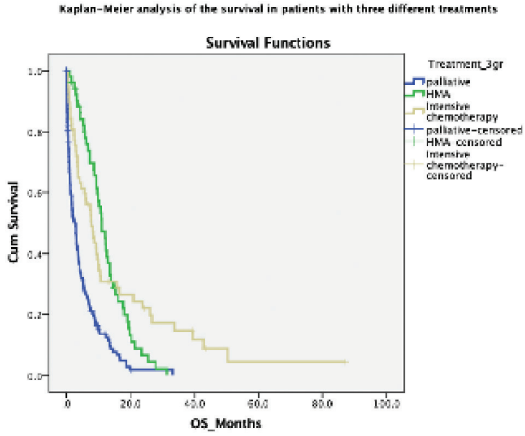
Methods: The patients with previously untreated AML who are ≤60 years old and eligible for intensive induction chemotherapy have been recruited in the study. Patients are randomized to one of the two induction treatment arms; high-dose cytarabine plus daunorubicin ([HDAC], cytarabine 3.0 g/m^2 q12hr on days 1, 3, 5 plus daunorubicin 45 mg/m^2/day on day 1-3) or cytarabine plus high-dose daunorubicin arm ([AD], cytarabine 200 mg/m^2/day on day 1-7 plus daunorubicin 90 mg/m^2/day on day 1-3). Patients who achieve CR receive consolidation chemotherapy or can proceed with hematopoietic cell transplantation (HCT) based on their genetic risk. The study was designed as a single-center, non-blind, two-arm randomized prospective controlled trial and plans to expand into a multicenter study. The primary endpoint is event-free survival, and the secondary endpoints include CR rate, cumulative incidence of relapse, regimen-related toxicities, and OS.
Results: Between March 2018 and December 2020, 103 patients were enrolled in the study; 48 in HDAC and 46 in AD arm. The median age was 49 (range, 16-60) and 61 patients were male (59.2%). Of 103 patients, 51 (49.5%) were classified into favorable genetic risk, 19 (18.4%) into intermediate risk, and 32 (31.1%) into adverse risk according to the European Leukemia Net risk stratification. *FMS-like tyrosine kinase 3*-internal tandem duplication and nucleophosmin mutations were detected in 18 and 29 patients, respectively. Overall, 75 and 2 patients achieved CR and CR with incomplete hematologic recovery, and 47 and 2 patients proceeded with allogeneic and autologous HCT, respectively. Eighteen patients died, and 2 died within 30 days from randomization.
Summary/Conclusion: We are currently conducting a randomized controlled trial for newly diagnosed AML patients comparing two induction chemotherapeutic regimens; high-dose cytarabine and high-dose daunorubicin. We expect to get insights from this study into optimal induction chemotherapy for AML patients and to reveal the relationship between genetic risk based on the mutational study and the benefits of each induction regimen.

PB1418 LIPOSOMAL ANNAMYCIN FOR R/R AML

R. Shepard [1,*], R. SHEPARD [2]

[1]*HEMATOLOGY, POZNAN UNIVERSITY OF MEDICAL SCIENCES, POZNAN, Poland,* [2]*CLINICAL RESEARCH, Moleculin Biotech, MIAMI BEACH, United States*

Background: Despite progress in the treatment of AML, most patients will relapse and die from refractory disease (R/R AML). De novo and acquired MDR is a critical mechanism of resistance and limits the efficacy of anthracyclines. Liposomal Annamycin is a novel anthracycline that has been shown to overcome MDR in vitro and in vivo. In addition it has been shown both preclinically and clinically to have no cardiotoxicity.
Aims: The aims this phase I/II trial is to determine the MTD or RP2D for the phase II component to evaluate efficacy. In addition, confirmation of no cardiotoxicity is an aim.
Methods: The clinical trial is a standard 3 + 3 first proving safety with an expansion phase at the MTD to determine efficacy. The cohorts started at a dose of 120 mg/m2 and is now up to 240 mg/m2 with no significant toxicity. All patients have very sensitive testing for any cardiotoxocity including strain echocardiography performed in the Duke cardio-oncology lab with review in cardio-oncology at the Cleveland Clinic. Sensitive biomarkers are also done for all patients.
Results: To date, no significant toxicity has been seen. All cardiotoxicity testing including strain echocardiography and biomarkers have remained completely normal.



Summary/Conclusion: This ongoing phase I/II clinical trial is being done in Europe to confirm the previous clinical trials done in the US showing no cardiotoxicity and the ability to overcome MDR. From the previous studies, Liposomal Annamycin was shown to overcome MDR and have no cardiotoxicity.

PB1419 REAL-LIFE EFFICACY OF FIXED-DOSE HYPOMETHYLATING AGENTS IN OLDER PATIENTS WITH ACUTE MYELOID LEUKEMIA: A SINGLE CENTER EXPERIENCE

T. Rungjirajittranon [1,*], S. Kungwankiatichai [1], C. Kunacheewa [1], W. Owatthanapanich [1]

[1]*Division of Hematology, Department of Medicine, Faculty of Medicine Siriraj Hospital, Mahidol University, Bangkok 10700, Thailand*

Background: Prognosis of elderly patients with acute myeloid leukemia (AML) is dismal. Hypomethylating agents(HMAs) are recommended treatments for these patients due to their acceptable toxicity profiles and favorable efficacy. However, their high cost precludes their general use, especially in developing countries. Therefore, the fixed-dose HMAs approach was adopted in Thailand in order to reduce the expense.
Aims: This study aimed to investigate the clinical outcome of various treatment protocols including intensive chemotherapy, fixed-dose HMAs, and palliative treatment in Thai AML patients aged over 60 years. Fixed-dose HMAs included 5-azacitidine given at 100 mg per day for 7 days and decitabine given at 20 mg per day for 5 days.
Methods: We conducted a 10-year retrospective, single-center study in elderly AML patients diagnosed between January 1, 2010, and December 31, 2020. The inclusion criteria were (1) patients aged above 60 years; and (2) patients with newly diagnosed AML. The exclusion criteria were acute promyelocytic leukemia with *PML-RARA*.
Results: A total of 243 elderly AML patients were enrolled, with a mean age of 71± 8 years. Most of which (70%) had de novo AML. Poor risk cytogenetics was observed in the majority of cases (32.9%). The overall mortality rate was 90.9%. Median overall survival (OS) was 5 months (95% CI 3.6-6.4). Comparing a 3-group of treatment regimens (intensive chemotherapies fixed-dose HMAs and palliative treatment), the proportions of patients in each category accounted for 23.5%, 21.3%, and 55.1%, respectively. Median OS in each therapeutic option was 7.7, 11, and 2.5 months, respectively. From a multivariate analysis, palliative treatment had significantly inferior OS when compared to intensive treatment and fixed-dose HMAs (HR 0.41: 95% CI 0.28-0.61 and HR 0.42: 95% CI 0.29-0.60, respectively). Nevertheless, the OS outcome in patients with fixed-dose HMAs was comparable to those with intensive treatment (HR 0.89: 95% CI 0.57-1.38).

Summary/Conclusion: Our study confirms the poor outcome of AML in elderly patients, especially in patients receiving palliative strategy. The fixed-dose regimen of HMAs is the treatment of choice for these patients which is non-inferiority to intensive therapy.

PB1420 CORE-BINDING FACTOR ACUTE MYELOID LEUKEMIA: RESULTS OF A TUNISIAN EXPERIENCE

H. Ben Neji [1,*], R. Jaidi [1], M. Bchir [1], R. Kharrat [1], W. Ayed [2], A. Amouri [2], B. Meddeb [1]

[1]Hematology, Aziza Othmana Hospital, [2]Department of Genetics, Institut Pasteur, Tunis, Tunisia

Background: Core-binding factor acute myeloid leukemia (CBF-AML) belong to the cytogenetic favourable risk group. Although the prognosis of CBF-AML is better than other cytogenetic groups, 30 to 40% of patients will experience relapse and require stem cell transplantation.
Aims: In this study we aimed to assess treatment outcome of CBF- AML treated in in our hospital.
Methods: We retrospectively evaluated outcomes of CBF-AML treated at the hematology department of Aziza Othmana hospital between 2010 and 2019. All patients had cytogenetic at diagnosis. Only few patients had fusion genes study.
For all patients, induction consisted of idarubicine 12mg/m^2 per day on days 1 to 3 and cytarabine 200mg/m^2 per day over 7 days. Patients in complete remission had 3 consolidations consisting of high dose cytarabine.
Results: Five hundred and twenty-one AML adult patients were treated during the period of study. 32 patients had CBF-AML (6.1%). Median age was 34.5 years (range 20 to 56 y). Median WBC at diagnosis was 16.9 G/L (range 0.3 to 86.4 G/L). 78.1% of patients had inv 16 (p13;q22) and 21.9% had t(8;21) (q22;q22). 11 patients had additional cytogenetic abnormalities.
One patient died during induction. Complete remission was achieved in 90% of CBF-AML. Relapse occurred in 9 patients (31%) at a median of 12.9 months (range 5.4 to 48.5 months). A second remission was obtained in 77.7% of patients. Allogeneic stem cell transplantation was performed in only 3 patients. Median overall survival (OS) and relapse free survival (RFS) at 5 years were 60%.
Summary/Conclusion: In our study, Complete remission was achieved in 90 % of the CBF-AML patients. It is consistent with published results. Long term survival in our series compared favourably with results reported by cooperative groups.
In our study very few CBF-AML patients in relapse had stem cell transplantation. In fact, in our country allogeneic stem cell transplantation is performed in only one center receiving patients from all the country and is limited to young patients having an HLA-matched sibling donor. Our results could be improved using autologous system cell transplantation which can be considered as a part of post remission therapy in CBF-AML offering superior RFS an OS in favourable risk AML in first remission compared to chemotherapy.

PB1421 T(6;9)(P22;Q34)/DEK-NUP214-POSITIVE ACUTE MYELOID LEUKEMIA IN ADULTS IS A RARE POOR PROGNOSIS SUBTYPE AFFECTING YOUNGER PATIENTS: THE BULGARIAN EXPERIENCE

G. Balatzenko [1,*], S. Angelova [1], I. Ivanova [1], M. Romanova [1], Y. Davidkova [2], M. Yagurinoski [2], B. Spassov [3], M. Stoychov-Yaguronoska [3], M. Donchev [3], G. Arnaudov [3], E. Hadjiev [4], G. Tsvetkova [4], M. Guenova [2]

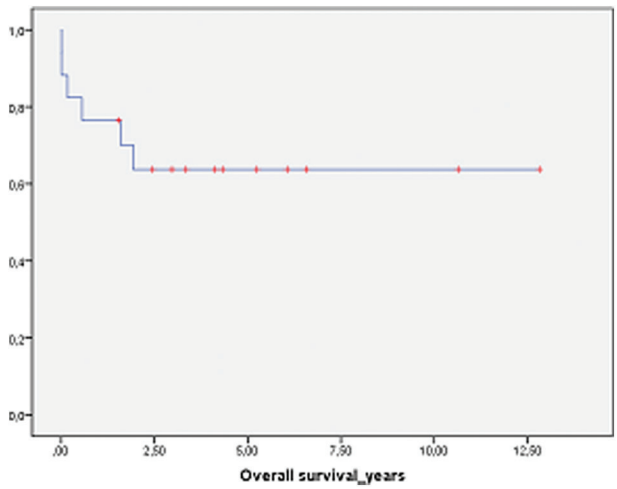
[1]Laboratory of Medical Genetics, [2]Laboratory of Clinical Immunology, [3]Hematology Clinic, National Specialised Hospital for Active Treatment of Hematological Diseases, [4]Clinical Hematology Department, University Hospital Alexandrovska, Sofia, Bulgaria

Background: Translocation t(6;9)(p22;q34) is a recurrent rare genetic abnormality which defines an unique acute myeloid leukemia (AML) subtype characterized by poor prognosis. At molecular level, t(6;9) results in *DEK-NUP214* fusion gene formation which has a key role in the pathogenesis of the disease. The translocation accounts for only 0.5-2% of AML cases and therefore information concerning the clinical and laboratory features of t(6;9)/*DEK-NUP214*-positive patients (pts) is relatively limited. No data concerning the incidence and characteristics of AML with this abnormality in Bulgarian patients have been published so far.
Aims: To determine the incidence and the main characteristics of Bulgarian patients with t(6;9)/*DEK-NUP214*-positive AML.
Methods: Bone marrow aspirates of 945 consecutive adult pts with confirmed diagnosis AML were tested centrally in the Laboratory of Cytogenetics and Molecular Biology of the National Specialized Hospital for Active Treatment of Hematological Diseases – Sofia. Successful karyotypes were obtained in 812 of the cases. In all pts with cytogenetically detected t(6;9), the presence of the *DEK-NUP214* fusion transcripts was confirmed by reverse transcription polymerase chain reaction (RT-PCR). AML diagnosis and subclassification were performed according to the WHO Classification criteria (2016).
Results: Overall, t(6;9)/*DEK-NUP214* was detected in 6 (0.74%) pts, including 4 males and 2 females, with a mean age of 40±7.4 years (range 33 – 53 years). The median white blood cell (WBC) count in positive pts was 86x10^9/L (range 21-106x10^9/L), the median platelet count - 29x10^9/L (range 14-97x10^9/L), and the median hemoglobin level - 78.5 g/L (range 55-96 g/L). All pts were with de novo AML. The average bone marrow blast cell infiltration was 62.7%±29.5%. In 5/6 pts morphology revealed a monocytic component and AML was classified as AML-M4 according to FAB criteria. However, basophilia wasn't encountered in any of the cases. In 5 patients, t(6;9) was the sole chromosome abnormality, while in 1 patient, in addition, trisomy 13 was observed in all metaphases. *FLT3*-ITD was found in 3/6 of the *DEK-NUP214*-positive pts, and interestingly, a certain number of "cup-like" blasts was seen in all of them. Immunophenotyping revealed CD34 and/or CD117 positivity and aberrant myelomonocytic phenotypes in all pts, with an aberrant expression of CD56 in 2 of them. In two pts early dead occurred. In the remaining 4 pts, a standard 7+3 induction protocol ± midostaurin was initiated, but without significant reduction of blast population. Complete remission (CR) was achieved in 2 pts after a second high-dose induction course, followed by allogenic stem cell transplantation in 1 of them who is still alive 30 months after the diagnosis. The other was lost of follow up. The remaining patients were refractory and died within 2-13 months.
Summary/Conclusion: The present study confirmed the low incidence of t(6;9)/*DEK-NUP214* in Bulgarian pts with AML. Despite of the heterogeneous clinical and laboratory features, our series was characterized by relatively younger age, high WBC counts, myelomonocytic morphology, absence of additional chromosomal aberrations in most of the cases, presence of *FLT3-ITD* in half of the pts and poor outcome with conventional chemotherapy.

PB1422 OUTCOME OF TREATING PEDIATRIC LANGERHANS HISTIOCYTOSIS WITH LCH III IN TERTIARY CENTER, SAUDI ARABIA.

A. AlMohammadi [1,*], A. Baothman [2], K. A. Abdullah [2], M. Shahda [2]

[1]KAMC-PEDIATRIC, Jeddah, Saudi Arabia, [2]KAMC-PEDIATRIC, KAMC-PEDIATRIC, Jeddah, Saudi Arabia



Background: *Background:* Langerhans cell histiocytosis (LCH) is a rare disease affects any age and any organ; its presentations and outcome vary from self-healing lesions to life-threatening disseminated disease.
Aims: This study evaluated the outcome of treating children diagnosed with Langerhans cell histiocytosis (LCH) at Oncology Center, Saudi Arabia.
Methods: Through a retrospective study design, the researchers reviewed the medical records and electronic files of all children (aged from 0-≤ 14 years) who had been diagnosed and treated for LCH at Princess Norah Oncology Center (PNOC), King Abdelaziz Medical City, Saudi Arabia, in the period from January 2000 to December 2019 (n=33).
Results: Males constituted (66.7%), with remarkable dominance of Saudis (93.9%). The median age at diagnosis was 28 months (IQR=49 months); (42.4%) were diagnosed before reaching their second birthday. Fourteen patients (42.4%) had multisystem (MS-LCH) involvement, of which 13 patients with risk organ (RO) (+) and one patient without risk organ (RO) (-). Most of the patients received LCH III protocols. Reactivation occurred in 11 patients (33.3%), and two deaths (6.1%) occurred in cases with MS (RO) (+) progressive disease. The overall survival was 93.9%; with no statistically significant difference in event free survival observed between patients with multisystem compared to single system involvement.
Summary/Conclusion: Excellent outcome of LCH is associated with single system involvement and worse outcome (reactivations, or morality) is determined by multi-organ involvement especially at younger age less than 24 months. Better understanding of pathophysiology and genetic molecular background could lead to a striking transformation to novel therapy that warrants a prospective clinical trial.[u1] A high mortality in patients with progressive disease demands an earlier aggressive salvage in such group. Prospective clinical trials are required for improved treatment strategies in these subgroups.

PB1423 CHILDREN ACUTE PROMYELOCYTIC LEUKEMIA: HEMATOLOGY DEPARTMENT EXPERIENCE AT AZIZA OTHMANA HOSPITAL

R. Jaidi [1,*], M. Bahri [1], O. Charef [1], E. Azza [1], L. Aissaoui [1], D. Jabr [1], R. Mansouri [1], H. Ben Neji [1], M. Bechir [1], E. Berred [1], M. achour [1], R. Kharrat [1], K. kacem [1], R. Benlakhel [1], B. Meddeb [1], Y. Benabdennebi [1]

[1]Hematology, aziza othmana Hospital, Tunis, Tunisia

Background: Acute promyelocytic leukemia (APL) is a rare subtype of AML which represents < or = 10% of childhood acute myelogenous leukemia.
Aims: We conducted a retrospective analysis diagnosed between January 2008 to December 2016 and actively followed. The hematologic complete remission (CR) rate and overall survival (OS) rate were evaluated. Prognostic factors and complications were investigated
Methods: We studied the outcomes of children, up to 18 years of age, with APL treated by acute promyelocytic leukemia (APL) 2005 protocol, in Hematology Departement of Aziza Othmana Hospital.
We conducted a retrospective analysis diagnosed between January 2008 to December 2016 and actively followed. The hematologic complete remission (CR) rate and overall survival (OS) rate were evaluated. Prognostic factors and complications were investigated
Results: A total of 13 patients with a median age of 9 years (range, 2-18 years) were included. We had 9 boys vs 8 girls, sex ratio 1.1.
76.5 % patients had hemorrhagic findings at admission. Severe bleeding manifested as intracranial haemorrhage was present in one patient. Disseminated intravascular coagulation (DIC) was diagnosted in 11 patients (65%). We stratified APL patients into three risk subgroups using Sanz score: low risk (1 patient), intermediate risk (6 patients) and high risk (10 patients).
All patients were treated with AIDA 2005 protocol. Induction death rate was 6%. Nine patients showed side effects of ATRA such as differentiation syndrome (7 patients), pseudotumor cerebri (one patient) and Sweet syndrome (one patient).
The median overall survival of the live patients was 8.4 years. The 5-year overall survival was estimated at 64%. On univariate analysis of overall survival, age, number of leukocytes, Prothrombin Time, risk classification and blast marrow infiltration were associated with overall survival. Sex, and DIC were not significant predictors of overall survival.

Summary/Conclusion: Life-threatening bleeding was the primary problem in APL. Urgent treatment with ATRA is a critical factor to reduce early losses.

PB1424 ALL-TRANS RETINOIC ACID INDUCED MYOCARDITIS AS PART OF DIFFERENTIATION SYNDROME: A CASE REPORT AND LITERATURE REVIEW

N. Kim [1,*], K. Y. Kim [1], D. Verghese [1], S. H. Eshan [1], M. Ayaz Ahmed [1]

[1]Amita Health St Joseph Hospital Chicago, Chicago, United States

Background: Acute promyelocytic leukemia (APL) is a distinct subtype of acute myeloid leukemia defined by the translocation t(15;17)(q22;21). All-trans retinoic acid (ATRA) is a cornerstone of treatment for APL. However, ATRA use is associated with a spectrum of severe complications known as differentiation syndrome (DS). With the exception of pericardial effusion, cardiac involvement is extremely rare after ATRA exposure.
Aims: We present a patient who developed myocarditis as an unusual complication after ATRA treatment.
Methods: A 23-year-old female presented with one week history of generalized headache, emesis, and ecchymosis. Lab findings revealed leukocytosis (44.5 x 109/mm^3), normocytic anemia (11.3 g/dL), thrombocytopenia (38 000/mm^3), hypofibrinogenemia (fibrinogen 64 mg/dL), elevated d-dimer (48 293 ng/mL), and coagulopathy (prothrombin time international normalized ratio 2.0) consistent with disseminated intravascular coagulation. Peripheral blood smear demonstrated 82% blasts with Auer rods, consistent with acute promyelocytic anemia (APL) and later confirmed on bone marrow aspirate and biopsy. PCR for PML-RARA fusion gene was positive. Karyotype was 46,XX,del(9)(q13q22),t(15;17)(q24;q21). On confirmation of the diagnosis, the patient was initiated on ATRA and idarubicin. One day following the first administration of ATRA, the patient began to complain of dyspnea on exertion and chest pain. She developed transient hypoxia (SpO2 90%) and sinus tachycardia.
Results: Troponin I was elevated to 2849 pg/mL, but there were no electrocardiographic changes suggestive of ischemia. Computerized tomography of the chest demonstrated new bilateral interstitial infiltrates and small pleural effusions. Blood and bronchoalveolar lavage microbiology cultures were negative. Echocardiogram was negative for any valvular dysfunction, systolic dysfunction, or wall motion abnormalities. However, cardiac magnetic resonance imaging (MRI) demonstrated delayed focal subepicardial enhancement suggestive of myocarditis. The patient was immediately started on intravenous dexamethasone 10 mg every 12 hours for treatment of both DS and myocarditis, and demonstrated resolution of symptoms as well as normalization of cardiac enzymes. She was advised to continue a prolonged prednisone tapering regimen after completion of dexamethasone for 14 days. Three months after her diagnosis, follow-up echocardiogram demonstrated normal function with a complete resolution of symptoms.
Summary/Conclusion: DS is a heterogeneous condition whose pathogenesis and diagnostic criteria remain yet to be clearly defined. This patient meets criteria for possible differentiation syndrome given the presence of dyspnea with interstitial pulmonary infiltrates, as well as a small pericardial effusion, after ATRA induction. Review of existing literature identified 11 other cases of ATRA-induced myocarditis, of which only 2 reported concurrent DS-defining symptoms. All cases demonstrated onset of symptoms within 1 month of ATRA induction. Due to the scarcity of available reports, cardiac complications are an under-recognized sequelae of ATRA use. We postulate that myocarditis although rare, is likely to be a constituent of the amalgam of pathologies involved in DS. Cardiac MRI may be a more accurate non-invasive diagnostic test to confirm myopericarditis after ATRA induction.

PB1425 THERAPY-RELATED MYELOID NEOPLASMS: A DESCRIPTIVE ANALYSIS AT A SINGLE INSTITUTION

B. Merchán Muñoz [1,*], M. I. Nuevo López [1], M. Mora Argumánez [1], A. Gil Perez [1], H. Guillen Garcia [1], A. Vazquez Ramo [1], A. B. Santos Montero [1], N. Golbano López [1], S. Herrero Martin [1], J. Arbeteta Juanis [1], D. Morales Sanz [1], M. Diaz Morfa [1], D. Subira Perez [1], D. De Miguel Llorente [1]

[1]Hematology, Hospital Universitario Guadalajara, Guadalajara, Spain

Background: Over the years, the incidence of therapy-related myeloid neoplasm (t-MN) has increased as a consequence of the increased survival rate of cancer due to constant improvement of treatments. t-MN represents 10-20% of all myeloid neoplasms and its prognosis is relatively poor.
Aims: The aim of this study was to analyze the characteristics and the outcome of patients with t-MN.
Methods: The present retrospective study comprises a series of 23 patients with t-MN diagnosed at Hospital Universitario Guadalajara between 2009 and 2020. Electronic medical records from the database were reviewed in order to identify all cases of t-MN. The data collected included: age, sex, cytogenetics, primary malignancy type or autoimmune disease and treatment received.
Results: The median age of the patients was 72 years (range, 56 to 85 years) and 52% of them were male. Fourteen patients (61%) had preceding solid tumors (the most frequent was lung cancer), 3 patients (13%) had hematologic malignancies and 6 patients (26%) had autoimmune conditions. The median interval between primary malignant disease and t-MN diagnosis was 6.9 years (range, 0.3 to 22.5). Immunosuppressant drugs were administered to 6 patients (26%), 7 patients (30%) were treated with chemotherapy alone and 10 patients (43%) received radiation associated with chemotherapy. The type of chemotherapy received was alkylating agents alone or different

combinations of alkylating, targeting topoisomerase II, alkaloids and antimetabolites agents. Patients treated with immunosuppressant drugs took longer to develop t-MN (median 10 years) and they had a better survival rate.
Unbalanced aberrations of chromosomes 5 and 7 and/or a complex karyotype were described in 7 patients (30%); all these patients had received alkylating agents and/or radiotherapy. Six (26%) patients exhibited TP53 mutation, 5 of them (83%) developed t-AML and all these 5 patients deceased due to progression of the condition, despite the treatment received (intensive anthracycline and cytarabine based chemotherapy, daunorubicin and cytarabine liposome or hypomethylating agents). The median overall survival after t-AML diagnosis was 8 months.
Summary/Conclusion: Development of t-MN is a serious complication with poor prognosis. Predictive markers should be identified in patients with cancer in order to prevent the risk of developing t-MN.

PB1426 TAGRAXOFUSP AS FIRST-LINE TREATMENT OF BLASTIC PLASMACYTOID DENDRITIC CELL NEOPLASM (BPDCN). A CASE REPORT

C. Navajas Laguna [1,*], M. Á. Domínguez Muñoz [1], I. Simón Pilo [1], V. Calama Ruiz-Mateos [1], M. Yebenes Ramírez [1], M. Vahí Sánchez de Medina [1], C. Couto Caro [1]

[1]HOSPITAL VIRGEN DE VALME, SEVILLA, Spain

Background: Blastic plasmacytoid dendritic cell neoplasm (BPDCN) is a rare myeloid malignancy, for which conventional chemotherapy has poor outcomes. Tagraxofusp (SL-401) is a CD123-directed cytotoxin consisting of human interleukin-3 fused to truncated diphtheria toxin which has recently been approved by EMA.
Aims: To describe our positive experience with Tagraxofusp and to present our diagnosis process and observed adverse events.
Methods: We present the case of a 38-year-old female, who presented with pancytopenia, polyadenopathy and skin lesions and was diagnosed with blastic plasmacytoid dendritic cell neoplasia with complex karyotype, PTPN11 mutation by NGS Expression. Infiltration of bone marrow, skin, lymph nodes and CNS was noted.
We administered Tagroxofusp according to the dose of the technical data with 12 mcg/kg by intravenous infusion over 15 minutes, once a day, on days 1-5 of a 21-day cycle considering that this administration could be extended with delays until day 10 of the cycle. Prior to preparing each dose vital signs, albumin, transaminases, creatinine, body weight, sistolic blood pressure and heart rate was made.Treatment was administered as a bridge therapy to allogeneic hematopoietic stem cell transplantation (HSCT)
Results: Until the availability of the drug; 4 doses of intrathecal treatment were administered. Two weeks after diagnosis, treatment with tagraxofusp was started. During this time the patient maintained a good general condition. After the second dose of tagraxofusp a grade 2 capillary release syndrome (CLS) emerged. Other adverse events were shaking chills, rash, weight gain, and hepatotoxicity. After resolution of these problems, the next dose of treatment was administered after 21 days with a total of 3 cycles with excellent tolerance in a total of 5 days and without observing adverse events. Evaluation of the disease showed complete remission (medullary, skin, peripheral, CNS, and lymph node) with positive MRD (0.09). The 4th cycle remains pending prior to HSCT.
Summary/Conclusion: The use of tagraxofusp specially as a front-line therapy has shown in this patient promising clinical activity, with a high overall response rate and prolonged responses and acceptable toxicity. CLS grade 2 was observed only in cycle 1, therefore can be good therapeutic option for this hematological disease. Nevertheless future work will define its place in treating relapse or refractory disease as well as its role as a first line therapy or bridge to transplantation.

PB1427 TWO CASE REPORT: CONCURRENT CROHN'S DISEASE AND MYELODYSPLASTIC SYNDROME OR ACUTE LEUKEMIA

Z. Mlayah [1,*], B. Sara [1], L. Mohamed Adnene [1]

[1]Hematology, CHU Fattouma Bourguiba Monastir, monastir, Tunisia

Background: Many cases of simultaneous development of inflammatory bowl diseases and myelodysplastic syndrome or acute myeloid leukemia have been reported since 1980. Until today there are 70 cases including ours published in reference sites in the majority of these cases the acute leukemia was associated with the ulcerative colitis while the Crohn's disease was associated with the myelodysplastic syndrome (MDS).
Aims: The objective is to insist on the association between inflammatory bowel disease and myelodysplasia or acute leukemia and to analyze the propses explanations for the mechanism leading to this association
Methods: We report two cases,followed up in our clinical hematology service in Monastir-TUNISIA,of crohn's disease associated with hematological malignancies: the first is about a patient who had myelodysplasia progressed to an acute myeloid leukemia (AML) in whom Crohn's disease was diagnosed few months later. The second is a about a simultaneous discovery of crohn's disease and acute myeloid Leukemia: this patient was followed up by gastrologists for crohn's disease and some months later (before the onset of the treatment) a myeloid leukemia was diagnosed.
Results: Many studies reported patients with myelodysplastic syndrome or myeloid leukemia associated with Crohn's disease have received treatment for crohn's disease or radiological examinations before the onset of the hematologic malignancy. However other studies have found that there's no connection between radiation, Crohn's disease treatment and the onset of MDS or leukemia. Our cases confirmed these studies because the MDS or the AML were discovered before the onset of the Crohn's disease treatment.
The other propositions include a common chromosome abnormality. However, many cases have been reported to have normal karyotype. In our cases the karyotype was abnormal witch can support this suggestion but the fact that many cases present a normal karyotype still against.
The most attractive proposition still: a common immune dysfunction: admitting that inflammatory bowel disease and MDS are autoimmune diseases. In the MDS there is T-cell clonal proliferation, tumor necrosis factor secretion and excessive interleukin 1 and 6 which can lead to the development of the IBD.
Summary/Conclusion: Crohn's disease can precede the MDS or acute leukemia or inversely, so a patient followed up by hematologists for a hematological malignancy can develop an inflammatory bowel disease and a patient followed up by gastrologists for IBD can develop a MDS or AML.
Many explanations were supposed to the possible common mechanism leading to this association but the causal relationship has yet to be determined.

Aggressive Non-Hodgkin lymphoma - Clinical

PB1428 THE CORRELATION BETWEEN SKIN RESPONSE AND BLOOD INVOLVEMENT WITH MOGAMULIZUMAB

P. Quaglino [1,*], L. Iversen [2], R. Dummer [3], A. Musiek [4], J.-P. Rosen [5]

[1]University of Turin, Turin, Italy, [2]Department of Dermatology, Aarhus University Hospital, Aarhus, Denmark, [3]Universitäts Spital Zürich, Zürich, Switzerland, [4]Division of Dermatology, Washington University in Saint Louis, St Louis, United States, [5]Kyowa Kirin International, Buckinghamshire, United Kingdom

Background: Cutaneous T-cell lymphomas (CTCL) are non-Hodgkin lymphomas with a variety of subtypes. Mycosis fungoides (MF) and Sézary syndrome (SS) together account for up to two-thirds of CTCL cases. Disease staging in CTCL was first comprised of tumour, lymph node and metastasis (TNM) assessments, with blood being added in 2007 due to establishment of blood tumour burden as a negative prognostic factor. Overall survival (OS) and disease-specific survival (DSS) are negatively impacted by increased blood tumour burden and risk of disease progression (RDP) is increased (Agar 2010, Am Soc J Clin Oncol). However, there is still further validation to be done for confirmation.
Aims: This post hoc analysis of MAVORIC trial data looked at the correlation between patients' levels of blood involvement and response in the skin following treatment with either mogamulizumab or vorinostat.
Methods: MAVORIC (NCT01728805) was an open-label, phase 3 study comparing mogamulizumab and vorinostat. Patients were randomised 1:1 to each treatment arm and received either intravenous mogamulizumab 1.0 mg/kg weekly for the first 28-day cycle, then on days 1 and 15 of subsequent cycles, or oral vorinostat 400 mg once daily. Vorinostat treated patients who experienced disease toxicity or intolerable toxicity following at least one cycle could cross over to the mogamulizumab treatment arm. The Modified Severity Weighted Assessment Tool (mSWAT), was used to measure skin response in both mogamulizumab and vorinostat patients and data was stratified by blood classification. The median mSWAT percentage change per treatment cycle and best overall response by percentage change in mSWAT were examined.

Results: Mogamulizumab patients with B1 and B2 blood classifications experienced a greater median percentage change in mSWAT compared to patients with B0, and B2 patients experienced the greatest improvement of -86.0% by Cycle 12 (Figure 1**a**). The majority of patients experienced improvement in mSWAT, with the greatest degree of responses generally experienced by B1 and B2 patients.
Vorinostat patients saw an improvement in median percentage change in mSWAT, although to a lesser degree compared to mogamulizumab patients, with B2 patients showing the lowest response in skin, -22.1% by Cycle 12, compared to other blood classes (Figure 1**b**). Best overall mSWAT response by patient show that vorinostat patients overall experienced less improvement compared to mogamulizumab patients, with little-to-no correlation with blood class.
Summary/Conclusion: MOGA is effective in patients with blood involvement (B1 and B2), including patients with MF. Drug safety is similar between patients irrespective of level of blood involvement.

PB1430 CAR-T CELL THERAPY FOR PEOPLE WITH RELAPSED OR REFRACTORY DIFFUSE LARGE B-CELL LYMPHOMA: A COCHRANE SYSTEMATIC REVIEW

M. Ernst [1,*], M. Goldkuhle [1], M. Abd El Aziz [2], A. Oeser [1], B. Besiroglu [1], J. Caro-Valenzuela [1], L. Estcourt [3], I. Monsef [1], P. Borchmann [4], N. Skoetz [5]

[1]Cochrane Haematology, Department I of Internal Medicine, Center for Integrated Oncology Aachen Bonn Cologne Duesseldorf, Faculty of Medicine and University Hospital, University of Cologne, Cologne, Germany, [2]Department of Surgery, Mayo Clinic, Rochester, MN, United States, [3]Haematology/Transfusion Medicine, NHS Blood and Transplant, Oxford, United Kingdom, [4]Department I of Internal Medicine, [5]Cochrane Cancer, Department I of Internal Medicine, Center for Integrated Oncology Aachen Bonn Cologne Duesseldorf, Faculty of Medicine and University Hospital, University of Cologne, Cologne, Germany

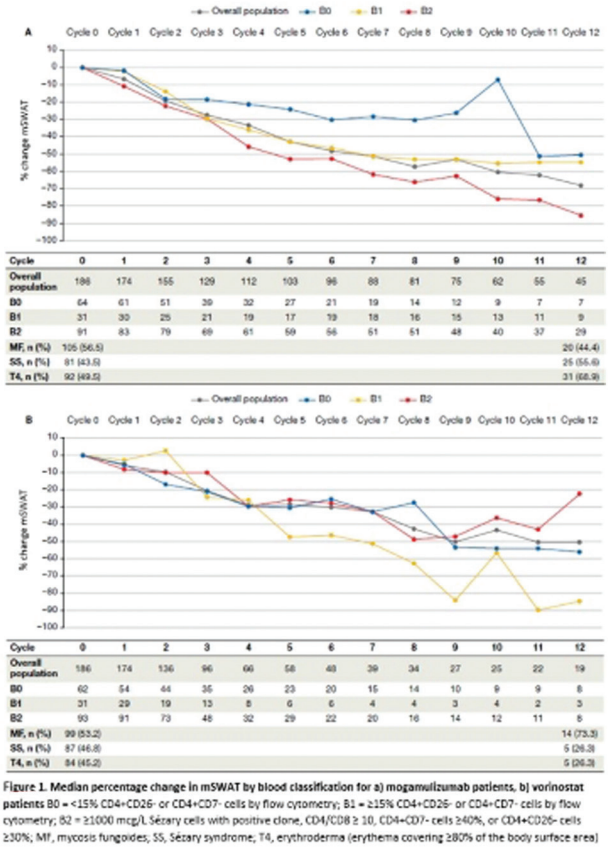


Figure 1. Median percentage change in mSWAT by blood classification for a) mogamulizumab patients, b) vorinostat patients B0 = <15% CD4+CD26- or CD4+CD7- cells by flow cytometry; B1 = ≥15% CD4+CD26- or CD4+CD7- cells by flow cytometry; B2 = ≥1000 mcg/L Sézary cells with positive clone, CD4/CD8 ≥ 10, CD4+CD7- cells ≥40%, or CD4+CD26- cells ≥30%; MF, mycosis fungoides; SS, Sézary syndrome; T4, erythroderma (erythema covering ≥80% of the body surface area)

Background: A substantial proportion of people with diffuse large B-cell lymphoma (DLBCL) experience relapse or are refractory to therapy (r/r). With a median overall survival below 6-12 months, the prognosis of those who relapse or are refractory to advanced lines of treatment or those who are ineligible for autologous stem cell transplantation is very poor. For these individuals, chimeric antigen receptor (CAR)-T cell therapy provides a promising treatment option.
Aims: To assess the benefits and harms of CAR-T cell therapy for people with r/r DLBCL.
Methods: In accordance with a published Cochrane protocol, we systematically searched CENTRAL, MEDLINE, Embase, conference proceedings, trial registries and databases for prospectively planned trials – beginning with randomised controlled trials (RCTs) – evaluating CAR-T cells for people with r/r DLBCL until September 2020. We excluded trials with less than 10 participants with r/r DLBCL and trials with less than 70% of participants with r/r DLBCL, unless respective data were reported separately. Two review authors extracted data and assessed potential risk of bias independently. As we did not identify any controlled trials, we did not meta-analyse data. We used the GRADE approach to assess the certainty of the evidence for prioritised outcomes.
Results: We included 13 uncontrolled trials and identified 38 ongoing trials, three of which are RCTs to be completed between 2022 and 2025. We judged all included trials to be at high risk of bias. Primarily due to the lack of a control group, study limitations and restricted applicability, our certainty in the evidence was very low for all outcomes.
Overall survival (OS) was reported by eight studies with substantial variation in sample size, duration of follow-up and proportion of people with DLBCL. Four studies reported 12-month survival rates of 48-59%, and one study reported an OS rate of 50.5% at 24 months (very low-certainty evidence). Two studies described improvements of **quality of life** over time (very low-certainty evidence). Five studies reported that a vast majority of participants experienced **adverse events** (AEs) (99-100% any grade, 68-98% grade ≥3; very low-certainty evidence). According to three studies, 56-68% of participants had **serious AEs**, while in one study, no serious AEs occurred (very low-certainty evidence). Various criteria were used by 11 studies to report **Cytokine release syndrome** (CRS). In five studies, 42-100% of participants had CRS according to criteria described by Lee 2014 (very low-certainty evidence). Nine studies reported **progression-free survival** (PFS), disease-free survival or relapse-free survival at any time of follow-up. Twelve-month PFS rates between 44-75% were reported by four studies. In one study, relapse-free survival rates remained at 64% at both 12, and 18 months (very low-certainty evidence). All 13 studies provided data on **complete response** (CR). Three studies reported 6-month CR rates between 40-45% (very low-certainty evidence).
Summary/Conclusion: The available evidence on the benefits and harms of CAR-T cell therapy for people with r/r DLBCL is limited, especially due to the absence of comparative clinical trials. Given the uncertainty in the current evidence, the risk of substantial and potentially life-threatening complications that require supplementary treatment and the large number of ongoing investigations, it is critical to continue evaluating how the evidence on this novel therapy will evolve.

PB1431 RELATIONSHIP BETWEEN GENETIC ABERRATIONS IN THE 17P13/TP53 LOCUS AND IMMUNOHISTOCHEMICAL PROTEIN P53 EXPRESSION IN TUMOR CELLS OF DIFFUSE LARGE B-CELL LYMPHOMA

M. Sarpova [1,*], E. Vaneeva [1], D. Diakonov [1], V. Rosin [1], S. Samarina [1]

[1]The Federal State-Financed Scientific Institution Kirov Research Institute of Hematology and Blood Transfusion under the Federal Medical Biological Agence, Kirov, Russian Federation

Background: Diffuse large B-cell lymphoma (DLBCL) is one of the most common, aggressive, clinically and biologically heterogeneous B-cell neoplasms. Impaired cell differentiation, maturation, and proliferation of B lymphoid elements are the main components of the disease pathogenesis. Protein p53 encoded by the *TP53* gene is the key tumor suppressor that holds the cell cycle, enables DNA reparation and apoptosis. Disruption of the structure and functions of this transcription factor in DLBCL patients is caused by various mechanisms, including mutations in *TP53* exons, deletions of chromosome 17p13 locus, abnormal p53 promoter methylation, etc. Inactivation of certain pro-apoptotic genes or hyperactivation of anti-apoptotic mechanisms can also affect p53 functions. Many researchers agree that *TP53* mutations and immunohistochemical (IHC) protein p53 expression in tumor cells are important factors that have an impact on the prognosis of DLBCL. However, studies investigating their relationship are few and contradicting, which confirms the relevance of this study.

Aims: To evaluate the relationship between genetic aberrations in the 17p13/*TP53* locus and IHC protein p53 expression in tumor cells in patients with DLBCL.
Methods: The study included a total of 75 patients aged from 30 to 82 years (median age: 58 years) with newly diagnosed DLBCL who received treatment at the clinic of the Institute. All patients received R-CHOP as a first-line treatment. The deletion of the 17p13/*TP53* locus was determined by fluorescence *in situ* hybridization (FISH) in biopsy specimens of tumor tissue using the Kreatech *TP53* (17p13) / SE 17 FISH probes. The relative number of p53-expressing tumor cells was calculated by IHC and morphometry. The threshold value of IHC p53 expression was evaluated by ROC analysis. The association between 17p13/*TP53* deletion and protein p53 expression in tumor cells was evaluated using Fisher's exact test (F). The correlation was evaluated using Cramer's rule (V).
Results: Deletions of the 17p13/*TP53* locus were detected in 8 (11%) of 75 DLBCL patients. ROC analysis showed that the threshold value of IHC expression of p53-positive cells was 43%. This value was used to determine marker hyperexpression (≥ 43% of tumor cells) in 33 (44%) of subjects. The percentage of expressive cells in the remaining patients was lower than the threshold value. The incidence of 17p13 deletions was significantly higher in patients with p53 hyperexpression than in patients with protein p53 levels below the threshold value: 87.5% vs. 12.5%, respectively (p=0.018; OR=11.04). A correlation between 17p13/*TP53* deletion and protein p53 expression in tumor cells (p=0.018; V=0.3) was established.
Summary/Conclusion: 17p13/*TP53* deletions in DLBCL patients are associated with suprathreshold IHC protein p53 expression in tumor cells. A direct moderate correlation has been established between these laboratory values.

PB1432 RELATIONSHIP BETWEEN PAKT1, PSYK PROTEINS CO-EXPRESSION AND SURVIVAL IN DIFFUSE LARGE B-CELL LYMPHOMA

E. Vaneeva [1,*], V. Rosin [2], D. Diakonov [2], M. Minaev [2]

[1]Лаборатория патоморфологии, KRIHBT, Киров, [2]Laboratory of pathomorphology, KRIHBT, Kirov, Russian Federation

Background: Diffuse large B-cell lymphoma (DLBCL) is the most common type of non-Hodgkin's lymphoma. Currently, a number of clinical stratification systems (international prognostic indexes, staging, and others) are used to determine the prognosis of the disease. However, they do not accurately assess the individual risk of therapy failure. In this regard, it is of interest to search for additional biological criteria that determine the prognosis of the disease.
Dysregulation of key molecules (pAKT1, pSyk) of the PI3K / AKT / mTOR and BCR signaling pathways affects the biological characteristic of tumor cells and may determine the prognosis of DLBCL. It is known that monotypic overexpression of pAKT1 and pSyk is associated with low overall (OS) and progression-free survival (PFS) in DLBCL patients; however, the combined expression of these proteins in this pathology has not been studied, which emphasizes the relevance of the study.
Aims: To assess the association of the co-expression of the pAKT1 and pSyk proteins in tumor cells with OS and PFS in DLBCL patients.
Methods: As a material for the study, FFPE samples of lymph nodes and other organs and tissues were used, obtained from 100 patients with a newly diagnosed DLBCL who were treated at the clinic of the KRIHBT in the period from 2012 to 2018. All patients received standard first-line immunochemotherapy according to the R-CHOP regimen. The determination of the relative number of tumor cells expressing pAKT1, pSyk was carried out using immunohistochemical and morphometric methods. OS and PFS were calculated by the Kaplan-Meier method using the log-rank test. The cutoff for expression of these proteins was calculated using the ROC analysis: for pAKT1 was set at 70% of positive tumor cells, for pSyk - 28%. According to the established thresholds, all subjects were divided into groups with high [≥70% (+) for pAKT1; ≥28% (+) for pSyk] and low [<70% (-) for pAKT1; <28% (-) for pSyk] by expression of the indicated proteins. The interrelation between different variants of pAKT1 and pSyk co-expression with the course of DLBCL was analyzed.
Results: The highest OS (90.2%) was recorded in the group of patients (n=41) with low coexpression of markers (pAKT1-/pSyk -). In the presence of coexpressions of pAKT1+/pSyk- and pAKT1-/pSyk+, it was 52% (n=29) and 60% (n=15), respectively. The lowest values of OS (26.7%) were observed in patients (n=15) with the combination of pAKT1+/pSyk+, which significantly differed from other variants of co-expression of markers (p<0.001; HR=5.2; 95% CI=2.49-10.9).
A similar pattern was established in the analysis of PFS. The proportion of patients without disease progression with the variant of co-expression of pAKT1 - / pSyk- was 78.1% (n=41), and in the presence of combinations of rACT1+/pSyk - and rACT1-/pSyk+ - 55% (n=29) and 53% (n=15), respectively. The lowest level of PFS (40%) was registered in patients with simultaneous overexpression of markers (n=15; p=0.002; HR=3.3; 95% CI=1.54-7.30).
Summary/Conclusion: Conclusion. Combined overexpression of the pAKT1 and pSyk biomarkers is associated with a more unfavorable prognosis of DLBCL compared to other variants of their coexpression.

PB1433 ABNORMAL AND COMPLEX KARYOTYPE IS FREQUENT ON ROUTINE KARYOTYPING ON PRIMARY TISSUE IN PATIENTS WITH DIFFUSE LARGE B-CELL AND TRANSFORMED LYMPHOMA BUT DOES NOT INFLUENCE CLINICAL OUTCOMES

R. M. Koo [1,2,*], M. Armstrong [3], C. Coombes [2], J. Lim [1,2], D. Talaulikar [1,2,3,4]

[1]Department of Haematology, ACT Pathology, [2]Haematology Translational Research Unit, Canberra Hospital and Health Services, [3]Department of Human Genomics, ACT Pathology, [4]Australian National University, Canberra, Australia

Background: Diffuse large B-cell lymphoma (DLBCL) has significant clinico-histological and molecular heterogeneity but the frequency and prognostic significance of cytogenetic abnormalities on primary tissue has not been fully established.
Aims: To describe the the cytogenic and clinical data of DLBCL patients with nodal tissue subjected to conventional karyotyping and describe the effects of chromosomal abnormalities on survival outcomes.
Methods: All cases with cytogenetic studies performed on extramedullary tissue with a histopathological diagnosis of DLBCL made between 2003 and 2017 at ACT Pathology, Australian Capital Territory were included in this study. Histological diagnosis was made in accordance with the World Health Organisation classification criteria, and the lymphoma subtype and cell of origin using Han's algorithm was recorded. Relevant clinical data was extracted from electronical medical records. Chromosome analysis was performed on fresh extramedullary tissue, whereby G-banding metaphases were analysed after a minimum of 24 hours of unstimulated culture. The karyotype was reported in accordance with the International System for Cytogenetic Nomenclature.
Results: In 78 patients identified, an abnormal karyotype (AK) was identified in 50 (64.1%) patients [39 patients (50%) with complex karyotype (CK) and 11 patients (14.1%) with 1-2 chromosomal abnormalities] and more frequent in transformed lymphoma (77.8%, with 55.6% having CK). AK was not associated with an inferior overall survival (OS) and progression-free survival (PFS) when compared to normal karyotype (5-year OS 78% vs 78.2%, p = 0.854 and 5-year PFS 72% vs 71.4%, p = 0.840). In univariate and multivariate analysis, AK, CK and frequent cytogenetic abnormalities were not found to be significant predictors of survival.
Summary/Conclusion: Chromosomal abnormalities in DLBCL detected on routine karyotyping are frequent but do not improve risk-stratification or alter treatment outcomes.

PB1434 ESCALADE: ACALABRUTINIB + RITUXIMAB, CYCLOPHOSPHAMIDE, DOXORUBICIN, VINCRISTINE, AND PREDNISONE (R-CHOP) IN UNTREATED NON-GERMINAL CENTER B-CELL–LIKE (NON-GCB) DIFFUSE LARGE B-CELL LYMPHOMA (DLBCL)

L. H. Sehn [1,*], B. Kahl [2], M. Matasar [3], G. Lenz [4], K. Izutsu [5], W. Zhao [6], L. Tao [7], R. Calvo [8], P. L. Zinzani [9]

[1]BC Cancer Centre for Lymphoid Cancer, Vancouver, Canada, [2]Washington University in St. Louis, St. Louis, [3]Memorial Sloan Kettering Cancer Center, New York, United States, [4]University Hospital Münster, Münster, Germany, [5]National Cancer Center Hospital, Tokyo, Japan, [6]Shanghai Institute of Haemato-oncology, Shanghai, China, [7]AstraZeneca, South San Francisco, [8]AstraZeneca, Gaithersburg, United States, [9]Institute of Hematology "Seràgnoli" University of Bologna, Bologna, Italy

Background: R-CHOP remains the standard of care for DLBCL. Although most patients can be cured, 35–40% will experience relapsed/refractory disease, leading to poor outcomes in the majority of patients. Covalent irreversible Bruton tyrosine kinase inhibitors (BTKi) have shown higher responses in patients with non-GCB DLBCL than with GCB DLBCL. In untreated non-GCB DLBCL patients, the phase 3 PHOENIX study (Younes et al. *J Clin Oncol*. 2019;37:1285-95) showed that addition of the BTKi ibrutinib to R-CHOP (R-CHOP-I) did not improve outcomes in the intent-to-treat population. However, patients age <60y treated with R-CHOP-I had significantly improved progression-free survival (PFS) and overall survival (OS) compared with those receiving R-CHOP alone. Acalabrutinib is a second-generation BTKi with enhanced kinase selectivity and potential for better efficacy and tolerability than first-generation BTKis. There is a strong rationale for combining acalabrutinib with R-CHOP in patients with untreated DLBCL, and safety of acalabrutinib + R-CHOP has been shown in a phase 1b/2 study (Davies et al. ASH 2020).
Aims: To determine if the addition of acalabrutinib to R-CHOP leads to improved PFS in patients age ≤65y with untreated non-GCB DLBCL.
Methods: ESCALADE (ACE-LY-312; NCT04529772) is a phase 3, randomized, global, double-blind study of acalabrutinib vs placebo in combination with R-CHOP for treatment of newly diagnosed non-GCB DLBCL. The study is recruiting adults ≥18y and ≤65y with previously untreated DLBCL stage II–IV disease with a Revised International Prognostic Index (R-IPI) score of 2–5. Prior to randomization, all patients will receive an initial R-CHOP cycle (cycle 1) as standard-of-care treatment to prevent delays in therapy initiation. Based on central Gene Expression Profile (GEP) testing performed after enrollment, patients with non-GCB DLBCL (activated B-cell like or unclassified) will be randomized into 2 arms to receive acalabrutinib 100 mg twice daily plus R-CHOP or placebo plus R-CHOP from cycle 2 to cycle 6 followed by 2 additional cycles of rituximab + acalabrutinib or placebo (cycles 7 and 8). All patients will receive primary prophylaxis with granulocyte colony-stimulating factors accompanying all R-CHOP cycles. The study aims to randomize 600 patients (~300 per arm). The primary objective is to evaluate whether the addition of acalabrutinib to R-CHOP will prolong PFS. Secondary endpoints include event-free survival, complete response rate, OS, pharmacokinetics, and safety. Key exclusion criteria are central nervous system involvement, primary mediastinal lymphoma, high-grade B-cell lymphoma, diagnosis or treatment of malignancy other than DLBCL, and history of indolent lymphoma. Approximately 250 sites globally will enroll patients. Enrollment began in Q3 of 2020.
Results: Trial in progress.
Summary/Conclusion: Study is currently recruiting.

PB1435 BENDAMUSTINE IS A FAVORABLE LYMPHODEPLETING CHEMOTHERAPY REGIMEN PRIOR TO CAR T CELLS IMMUNOTHERAPY AS FLUDARABINE

P. Zheng [1,*], H. Shi [1], K. Hu [1], X. Ke [1]

[1]*Beijing Boren Hospital, Beijing, China*

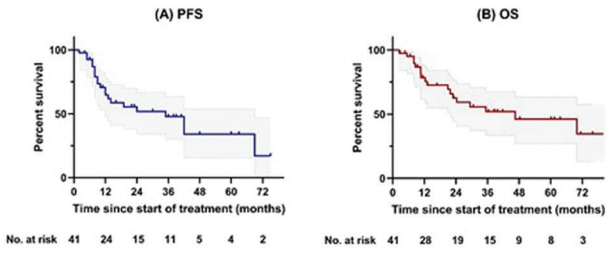
Background: In the process of chimeric antigen receptor (CAR) T cells therapy, it is necessary to carry out pretreatment chemotherapy to reduce lymphocytes called lymphodepleting chemotherapy before infusion of CAR T cells, which makes CAR T cells continuously expanding in *vivo*, plays an anti-tumor effect as well. For the patients of relapsed and refractory B-cell lymphoma (R&R BCL) treated with CAR T, the preferred lymphodepleting chemotherapy should have the dual effect of clearing lymphocytes and reducing tumor load. Bendamustine was reported to treat some R&R BCL, as well acting on lymphocyte clearing.
Aims: To investicate the clinical application of bendamustine as the pretreatment prior to CAR T cells infusion, and to examine its safety and therapeutic effect.
Methods: Twenty-one patients in our cohort were enrolled in this study. All of them were refractory and relapsed patients with poor response to several second-line chemotherapy. The mean age of these 21 patients was 50 years old. Twelve patients were male and 9 patients were female. Nineteen patients were defuse large B cell lymphoma (12 patients were non-GCB and 7 patients were GCB), One patient was follicular lymphoma, and one was Burkitt Lymphoma. About 85.7% patients (18/21) were in stage III-IV, 71.4% patients (15/21) were ECOG≥2. Bendamustine (90 mg/m^2) were used to deplete lymphocytes on days -4~-3 before infusion of CAR T cells (day 0). The CAR T cells for treatment were CD19 or CD20 or CD22 specific chimeric antigen receptor T cells. Average dose of CAR T cells infusion was 2.25×106/kg. CAR T cells in the PB were measured on day 0, 7, 11, 15 and 30, or as necessary by Flow cytometry.
Results: In the bendamustine group, the average peak number of CAR T cells expansion in *vivo* was 1.97×10$^{8/L}$. There were few serious adverse reactions except nausea and vomiting during chemotherapy. The occurrence rate of CRS above grade 2 was 33.3% (7/21) and ICANS above grade 3 was 9.5% (2/21). Three months after CAR T cells infusion, 38.1% patients (8/21) achieved CR, 47.6% patients (10/21) with PR. So the ORR was 85.7%.
Among the 21 patients, 5 patients were treated with CAR T cells twice within 6 months. Fudalabine combined with cyclophosphamide (FC) was chosen for the first lymphodepleting regimen and bendamustine for the second. Bendamustine reduced the number of lymphocytes by 82.3%, while it was 88.6% for FC (P >0.05). Overall the bendamustine regimen was inferior to FC in term of the CAR T cell proliferation rate. There was no significantly difference between these two groups about the occurrence rate of CRS. Regarding CR rate, bendamustine is considered to be superior to FC group.
Summary/Conclusion: Bendamustine can be used as a favorable lymphodepleting chemotherapy drug prior to CAR T.
Key words: Bendamustine, Fludarabine, CAR T, lymphodepleting chemotherapy.

PB1436 DISPARITIES IN LYMPHOMA SURVIVORSHIP ACCORDING TO SOCIO-DEMOGRAPHIC FACTORS; SINGLE CENTER RETROSPECTIVE STUDY IN A COHORT OF 253 DLBCL PATIENTS TREATED WITH RCHOP

M. Symeonidou [1], S. Intzes [1], K. Zagoridis [1], Z. Bezirgiannidou [1], A. Pentidou [1], C. Misidou [1], G. Vrachiolias [1], M. Papoutselis [1], K. Liapis [1], I. Kotsianidis [1], E. Spanoudakis [1,*]

[1]*Hematology, Democritus University of Thrace, Alexandroupolis, Greece*

Background: Diffuse large B cell Lymphoma (DLBCL) is an aggressive histology lymphoma with heterogeneous outcome in the RCHOP immunotherapy era. Although, R-IPI is a useful tool cannot predict accurately outcome for all patients and especially in the real world setting, evidences suggest that sociodemographoc factors are determinants of lymphoma survivorship.
Aims: Our aim was to compare survival in our cohort according to socio-demographic factors.
Methods: In this single center retrospective study we included 253 nodal or extranodal DLBCL patients diagnosed after 2000 and treated with RCHOP. We excluded DLBCL patients with histology of PMBCL n=19, Primary CNS lymphoma n=9, Double hit Lymphoma n=2, Plasmablastic Lymphoma n=1, Lymphoma of the testis n=5 and other than RCHOP first line treatments n=12.
Results: Median age was 67 (16-89 yrs), men to women ratio was 148/92 and among patients in our cohort 186 pts were of Greek origin and 64 were Greek Muslims. Disease characteristics (IPI, Bulky, cell of origin according to Hans Index, stage III-IV) were not different according to ethnic origin except for the presence of ≥ 2 extranodal sites that occurred more frequently in the Greek Muslims cohort (33,5% vs 16,3%% for Greeks, p=0,007, chi-square). Overall survival (OS) according to ethnicity/race was statistically indifferent; median OS for Greeks 96 (61.2-130,8) months vs 63 (49-77,7) months for Greek Muslims (Log Rank p=0,084, Figure 1). Percentage of PET/CT complete metabolic response (CMR) after treatment completion was equal 78,8% vs 81% Greeks vs Greek Muslims (p=0,831, table 1).
The Modified Kuppuswamy scale slightly modified was used for SES assessment and according to this model 100 pts in our cohort were considered low SES and 148 high SES. Disease characteristics were similar between low and high SES cohorts except percentage of 1 extranodal sites (low SES 53,5% vs 42,3 for high SES pts, p=0,004) and ≥ 2 extranodal sites (low SES 27,5% vs 16,8% for high SES pts, p=0,004). Low SES patients had more often B-symptoms (62% vs 47,3% for high SES pts, p=0,023). Overall survival (OS) according to SES was statistically indifferent; median OS for low SES 51 (13,7-88,2) months vs 96 (52-140) months for high SES pts (Log Rank p=0,15, Figure 2). Percentage of PET/CT complete metabolic response (CMR) after treatment completion was equal 87% vs 76,6% for low and high SES respectively (p=0,291).
The Cumulative Illness Rating Scale-Geriatric (CIRS-G) was calculated for all patients and OS according to CIRS-G <3, ≥3 CIRS-G ≤7, and CIRS-G>7 were calculated. Median OS was inferior for DLBCL patients with CIRS-G more or equal to 3; median OS for CIRSG<3 126,5 (103,7-149) months for



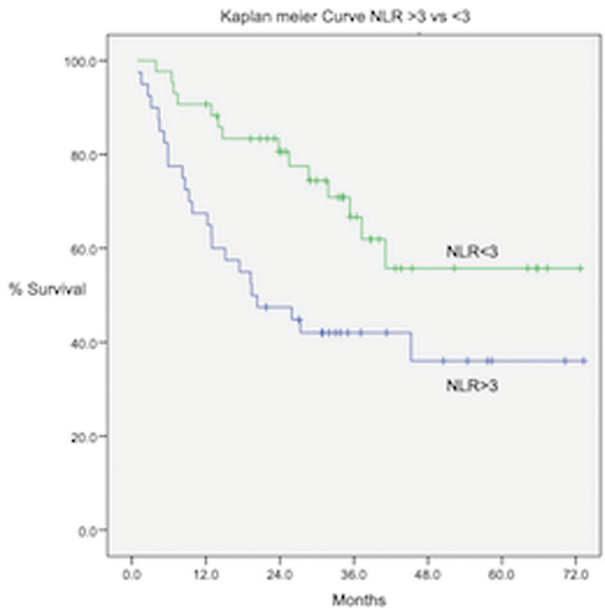
CIRSG 3-7 62,4 (52,1-73,6) months and for CIRSG>7 49,9 (35,2-64,7) months (Log Rank p=0,05, Figure 3).
Summary/Conclusion: In conclusion, lymphoma characteristics, CMR achievement and overall survival, except for percentage of patients with extranodal sites that occurred more often in low SES and Greek Muslims DLBCL patients, were not different according to SES and ethnicity/race. The only factor that is adversely related with overall survival is CIRS-G index more or equal to 3.

PB1437 OUTCOME OF PATIENTS WITH NEWLY DIAGNOSED PRIMARY CNS LYMPHOMA AFTER HIGH-DOSE METHOTREXATE FOLLOWED BY CONSOLIDATION WHOLE-BRAIN RADIOTHERAPY AND CYTARABINE: AN 8-YEAR COHORT STUDY

P. Piriyakhuntorn [1,*], T. Rattanathammethee [1], S. Hantrakool [1], C. Chai-Adisaksopha [1], E. Rattarittamrong [1], A. Tantiworawit [1], L. Norasetthada [1]

[1]Division of Hematology, Department of Internal Medicine, Faculty of Medicine, Chiang Mai University, Chiang Mai, Thailand

Background: Current treatment of primary CNS lymphoma (PCNSL) is a high-dose methotrexate (HD-MTX)-based polychemotherapy. The addition of cytarabine to HD-MTX-based chemotherapy improves clinical outcomes, however the combination therapy increases toxicity. Sequential chemotherapy may decrease toxicity without altering efficacy.
Aims: To analyze efficacy and safety of sequential chemotherapy and cranial radiation for newly diagnosed PCNSL patients.
Methods: This was a single center, retrospective cohort study of consecutive newly diagnosed immunocompetent PCNSL patients treated with HD-MTX (5 cycles of 3 g/m^2 every 2 weeks) followed by consolidation WBRT (total 46 Gy) and cytarabine (2 cycles of 3 g/m^2/d for 2 days every 3 weeks) from January 2013 to December 2020. Initial WBRT before HD-MTX was allowed in patients with Karnofsky performance status less than 70%. Primary outcome was progression-free survival (PFS). Key secondary outcomes were response rate, treatment-related toxicity, and overall survival (OS).
Results: Of 41 patients, 25 patients had complete response (CR) and 10 patients had partial response, which inferred to an overall response rate (ORR) of 85.4% and a CR rate of 60.9%. More than 90% of patients were able to tolerate and complete HD-MTX. Twenty-one patients (51.2%) received initial WBRT before chemotherapy. The incidence of ≥ grade 3 hematologic and non-hematologic toxicities were 4.8% and 17.1%, respectively. Treatment-related mortality rate was 2.4%. There was no difference in toxicity between patients with age < 60 and ≥ 60 years. At the median follow-up duration of 39.8 months, median PFS was 35.2 months (95%CI 12.4 – 69.3) and median OS was 46.5 months (95%CI 21.8 – NR).



Summary/Conclusion: High-dose methotrexate followed by consolidation whole-brain radiotherapy and cytarabine has acceptable efficacy, great tolerability, and low toxicity in newly diagnosed PCNSL patients.

PB1438 NEUTROPHIL/LYMPHOCYTE RATIO (NLR) ITS A WORSE PROGNOSIS FACTOR IN OVERALL SURVIVAL IN LARGE B CELL LYMPHOMA (DLBCL). EXPERIENCE IN HEMATOLOGY CENTER IN NORTHEAST OF MEXICO

G. Sotomayor Duque [1], M. R. Rios Rodelo [1,*], S. Baltazar Arrellano [1], M. P. Pequeño Luevano [1], W. Nava [1], A. Mecott [1], R. Hernandez Valdes [2], R. E. De Leon Cantu [3], L. G. Avila Contreras [1], I. Borjon [1], D. Cruz Contreras [1], M. L. Guajardo [1], J. A. Carrizales Villarreal [1], H. P. Sorkee [1], J. L. Cedillo de la Cerda [1]

[1]Hematology, [2]Chief Hematology Oncology Division, [3]Chief Hematology, IMSS, Monterrey, Mexico

Background: Diffuse Large Cell Lymphoma B (DLBCL) accounts for up to 62% of all Non-Hodgkin Lymphomas. The prognosis of DLBCL is established by considering patient and tumor factors. Neoplasm cells develop immune escape mechanisms in addition to an inflammatory response associated with Cancer. Tumor cells recruit Tumor Associated Neutrophils (NAT) that exert pro-carcinogenic effects such as inhibition of tumor cell apoptosis, angiogenesis, and suppression of the adaptive immune system.
Aims: To assess the impact on Overall survival of NLR in patients with a diagnosis of DLBCL
Methods: We aimed an observational, retrospective, cross-sectional and analytical study. Patients with Diffuse Large B-Cell Lymphoma, diagnosed between January 2014 and December 2018 were included. The qualitative variables were analyzed with the chi-square test and the quantitative variables with the student's t test. The relative risk was measured with a 95% CI, with a p value <0.05% being significant. A survival analysis was performed with Kaplan-Meier curves.
Results: 83 patients were included, 51 (61.4%) were men and 32 (38.5%) were women, with a median age of 61 (range 26-85) years and a median follow-up of 27 (range 0.9-73.2) months. Patients with NLR >3 was associated with lower response to chemo immunotherapy (p=0.001), higher relapse/refractive disease (P=0.003) and more than two lines of treatment (p=0.016). NLR >3 was associated with lower survival with HR 2.36(p=0.011). The Overall Survival at 6 years of patients with NLR> was 36% compared to those with NLR <3 was 56% (p = 0.009).

Summary/Conclusion: The NLR >3 is a predictor of a lower response to immunochemotherapy and more agresive course in addition to being associated with a lower overall survival in patients with DLBCL.

PB1439 HEALTH-RELATED QUALITY OF LIFE EFFECT OF MOGAMULIZUMAB BY PATIENT BLOOD INVOLVEMENT

P. L. Zinzani [1], P. Oztiz-Romero [2,*], M. Lima [3,4], A. O. Huen [5]

[1]Institute of Hematology "Seràgnoli", University of Bologna, Bologna, Italy, [2]Department of Dermatology,, University Complutense, Hospital 12 de Octubre, Medical School, Institute i+12, Madrid, Spain, [3]Unidade Multidisciplinar de Investigação Biomédica, Instituto de Ciências Biomédicas, Universidade do Porto (UMIB/ICBAS/UP), [4]Consulta Multidisciplinar de Linfomas Cutâneos (CMLC) e Unidade de Diagnóstico Hematológico, Serviço de Hematologia Clínica, Centro Hospitalar Universitário do Porto (CHUP), Porto, Portugal, [5]The University of Texas MD Anderson Cancer Center, Houston, United States

Background: Cutaneous T-cell lymphomas (CTCL) are a rare group of non-Hodgkin lymphomas that present in skin and progress to involve extracutaneous sites in a subset of patients. The most studied subtypes, mycosis fungoides (MF) and Sézary syndrome (SS), together represent around two-thirds of all cases. Disease staging of MF/SS is multi-compartmental and utilises a modified disease specific TNMB classification. Leukemic involvement, present by definition in SS and in a proportion of MF patients, has previously been found to be an independent prognostic factor affecting overall survival, disease-specific survival and increasing the risk of disease progression (Agar 2010, Am Soc J Clin Oncol), although further research is ongoing.
As a chronic and generally incurable disease associated with disfiguring skin lesions, intractable itching, sleep disturbance, and psychosocial problems, CTCL has a serious negative effect on patient quality of life (QoL). Therefore treatment goals include reducing the burden of disease, delaying progression, and improving or preserving QoL.
Aims: This post hoc analysis of MAVORIC trial data sought to determine whether baseline blood tumour burden affected treatment effect on patient QoL, where patients classified as B0 are considered to have no blood involvement and patients classified as B1 and B2 are considered to have blood involvement.
Methods: The Phase 3 MAVORIC trial (NCT01728805) was an open-label study that compared mogamulizumab to vorinostat, with patients randomised 1:1 to each treatment arm. Mogamulizumab patients received intravenous treatment, 1.0 mg/kg weekly for the first 28-day cycle then on days 1 and 15 of subsequent cycles. Vorinostat patients received 400mg daily PO. Patient reported outcome (PRO) assessments of health-related QoL (HRQoL) were assessed using the validated Skindex-29, and FACT-G (Functional Assessment of Cancer Therapy - General) instruments. Pruritus was assessed using ItchyQoL and Pruritus Likert Scale. All PROs were administered at baseline and Skindex-29, and FACT-G were then administered at every other treatment visit (Cycle 1, 3, 5, …), and ItchyQoL and Pruritus Likert Scale were administered every 4 weeks at each cycle. Only results taken up to treatment Cycle 12 were analysed as beyond this point, patient numbers were too low to give meaningful data.
Results: Overall, no statistically significant differences were seen between mogamulizumab and vorinostat for patients with no blood involvement. Statistically significant differences were seen for patients with blood involvement, with mogamulizumab patients seeing statistically significant improvement in Skindex-29 for treatment Cycles 3–11 in all domains (Emotional, Functional, Symptoms); and in the Functional Domain of ItchyQoL at most timepoints. In mogamulizumab-treated patients with blood involvement, the Pruritus Likert Scale Score showed a reduction in itch from Cycle 1 and a trend to reducing levels of itch over 12 cycles. The FACT-G Total Score showed greatest improvement from baseline for mogamulizumab patients with blood involvement compared to those without and all vorinostat patients (Figure 1).

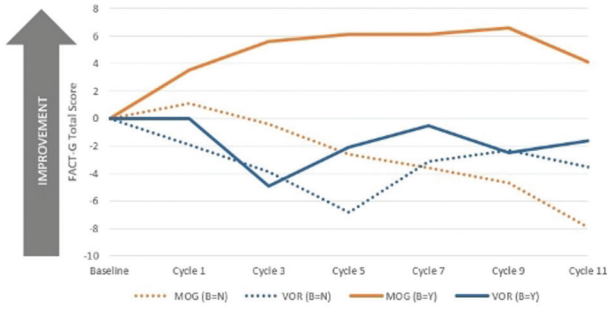


Figure 1. The change from baseline for the FACT-G Total Score by treatment cycle.
B, blood involvement; FACT-G, Functional Assessment of Cancer Therapy-General; MOG, mogamulizumab; N, no blood involvement; VOR, vorinostat; Y, confirmed blood involvement

Summary/Conclusion: Overall, mogamulizumab patients with blood involvement saw greater HRQoL improvement than those without blood involvement. Mogamulizumab offers QoL benefit, assessed across a number of PROs, especially to patients with blood involvement (B1 or B2).

PB1440 PHASE 3 RANDOMIZED STUDY OF LONCASTUXIMAB TESIRINE PLUS RITUXIMAB VERSUS IMMUNOCHEMOTHERAPY IN PATIENTS WITH RELAPSED/REFRACTORY (R/R) DIFFUSE LARGE B-CELL LYMPHOMA (DLBCL) - LOTIS-5

C. Carlo-Stella [1,*], Y. Linhares [2], M. D. Gandhi [3], M. Chung [4], H. Adamis [5], D. Ungar [6], M. Hamadani [7]

[1]Department of Oncology and Hematology, Humanitas Clinical and Research Center - IRCCS and Humanitas University, Rozzano, Milano, Italy, [2]Medical Onology, Miami Cancer Institute, Baptist Health, Miami, FL, [3]Medical Oncology, Virginia Cancer Specialists, Gainesville, VA, [4]Hematology/Oncology, The Oncology Institute of Hope and Innovation, Downey, CA, United States, [5]Clinical Development, ADC Therapeutics SA, Epalinges, Switzerland, [6]Clinical Development, ADC Therapeutics America, Inc., Murray Hill, NJ, [7]Division of Hematology and Oncology, Medical College of Wisconsin, Milwaukee, WI, United States

Background: Patients (pts) with DLBCL for whom frontline therapy is unsuccessful and who are ineligible for autologous stem cell transplantation have poor outcomes with salvage therapy. Single-agent loncastuximab tesirine (Lonca), an antibody-drug conjugate comprising a humanized anti-CD19 monoclonal antibody conjugated to a pyrrolobenzodiazepine dimer toxin, showed antitumor activity and manageable toxicity in pts with R/R B-cell non-Hodgkin lymphoma in a Phase 1 trial (Hamadani *et al*. Blood 2020; blood.2020007512) and in pts with R/R DLBCL in a Phase 2 trial (Caimi *et al*. Blood 2020; 136(Suppl 1):35–37).
Rituximab (R) is part of standard immunochemotherapy for DLBCL, both as frontline therapy and in subsequent treatments.
Aims: LOTIS-5 aims to evaluate Lonca + R (Lonca-R) versus (vs) standard immunochemotherapy of R + gemcitabine + oxaliplatin (R-GemOx) in pts with R/R DLBCL.
Methods: This is a Phase 3 randomized, open-label, 2-part, 2-arm, multicenter study (NCT04384484). A non-randomized safety run-in (Part 1) will compare the safety of Lonca-R with previous safety data for Lonca after the first 20 pts have completed Cycle 1. Part 2 will be started if no significant increase in toxicity occurs; ~330 pts will be randomized 1:1 to receive Lonca-R or R-GemOx.
The primary objective of the study is to evaluate the efficacy of Lonca-R vs R-GemOx. The primary endpoint is progression-free survival by independent review. Secondary endpoints include overall survival; objective response rate; complete response rate; duration of response; frequency and severity of adverse events; changes from baseline in safety laboratory and clinical variables; concentration and pharmacokinetic parameters of Lonca (conjugated and total antibody, and unconjugated warhead); immunogenicity; and changes in patient-reported outcomes. Time-to-event endpoints will be assessed for the intent-to-treat population using a stratified log rank test. The dosing regimen of Lonca-R in both parts of the study will be 150 µg/kg Lonca + 375 mg/m^2 R every 3 weeks (Q3W) for 2 cycles and then 75 µg/kg Lonca + 375 mg/m^2 R for 6 cycles. The dose regimen of R-GemOx in Part 2 will be 375 mg/m^2 R, 1000 mg/m^2 Gem, and 100 mg/m^2 Ox Q2W for 8 cycles.
Key inclusion criteria include age ≥18 years; pathologic diagnosis of DLBCL (including pts with DLBCL transformed from indolent lymphoma) or high-grade B-cell lymphoma with MYC and BCL2 and/or BCL6 rearrangements; ≥1 line of prior systemic therapy; not a candidate for stem cell transplantation; and measurable disease per 2014 Lugano Classification.
The study opened in September 2020 and enrollment is ongoing.
The trial design was presented at 62nd American Society of Hematology Annual Meeting and Exposition, December 5–8, 2020.
This study is sponsored by ADC Therapeutics SA.

PB1441 BRENTUXIMAB VEDOTIN IN COMBINATION WITH LENALIDOMIDE AND RITUXIMAB IN SUBJECTS WITH RELAPSED OR REFRACTORY DIFFUSE LARGE B-CELL LYMPHOMA (DLBCL) (TRIAL IN PROGRESS)

N. L. Bartlett [1,*], C. A. Yasenchak [2], K. K. Ashraf [3], W. N. Harwin [4], R. B. Sims [5], G. S. Nowakowski [6]

[1]Division of Oncology, Washington University School of Medicine, St. Louis, MO, [2]Willamette Valley Cancer Institute and Research Center/US Oncology Research, Springfield, OR, [3]Hematology and Oncology Associates of Alabama, Birmingham, AL, [4]Sarah Cannon Research Institute, Fort Meyers, FL, [5]Seagen Inc., Bothell, WA, [6]Division of Hematology, Mayo Clinic, Rochester, MN, United States

Background: The majority of patients (pts) with relapsed/refractory (R/R) diffuse large B-cell lymphoma (DLBCL) who relapse after HSCT or CAR-T, or who are not candidates for HSCT or CAR-T have poor outcomes and are in need of novel therapies. Brentuximab vedotin (BV) is a CD30-directed ADC and preclinical data provide a strong rationale for combining BV, lenalidomide, and rituximab in the treatment of R/R DLBCL. In addition, in a phase 1 trial in which 37 pts with R/R DLBCL were treated with BV + lenalidomide, the ORR was 56.7% (73.3% in CD30+ pts; manuscript in preparation). The median duration of remission was 13.2 months in pts with a CR or PR and 11.7 months in pts with CR, PR, or stable disease >6 months. The PFS and median OS were 11.2 months and 14.3 months, respectively and results were similar in the CD30+ and CD30 <1% groups. The clinical activity and manageable safety profiles of BV, lenalidomide, and rituximab as single agents, make the combination a potentially viable option in multiply relapsed and heavily pretreated pts.
Aims: To describe the study design and rationale for investigation of the combination of brentuximab vedotin, rituximab, and lenalidomide in a Phase 3 randomized study in R/R DLBCL.
Methods: This is a randomized, double-blind, placebo-controlled, active-comparator, multicenter phase 3 study designed to evaluate the efficacy of BV vs placebo, in combination with lenalidomide + rituximab, in subjects with R/R DLBCL (EudraCT: 2020-002686-33). Prior to randomization, there will be a safety and PK run-in period where 6 pts will receive BV, lenalidomide + rituximab, and safety and PK will be evaluated after the first cycle of treatment; 6/6 subjects have been enrolled.
Key eligibility criteria include: pts aged ≥18 with R/R DLBCL with an eligible subtype; ≥2 prior lines of therapy and have relapsed, declined, or are ineligible for stem cell transplant, or chimeric antigen receptor T-cell (CAR-T) therapy; ECOG 0 to 2; fluorodeoxyglucose-avid disease by PET and bidimensional measurable disease of at least 1.5 cm by CT.
Patients (n=400) will be randomized 1:1 to receive either BV or placebo in combination with lenalidomide + rituximab and will be stratified by CD30 expression (positive [≥1%] versus <1%), prior allogeneic or autologous stem cell transplant therapy (received or not), prior CAR-T therapy (received or not), and cell of origin (GCB or non-GCB).
The primary endpoints are PFS per BICR in the ITT and CD30+ populations. Key secondary endpoints are OS in the ITT and CD30+ populations, and ORR per BICR. Other secondary endpoints include CR rate, duration of response, and safety and tolerability of the combination. Disease response will be assessed by BICR and the investigator according to the Lugano Classification Revised Staging System. Radiographic disease evaluations, including contrast-enhanced CT scans and PET, will be assessed at baseline, then every 6 weeks from randomization until Week 48, then every 12 weeks. PET is not required after CR is achieved. The trial is currently enrolling and will be open in 16 countries.

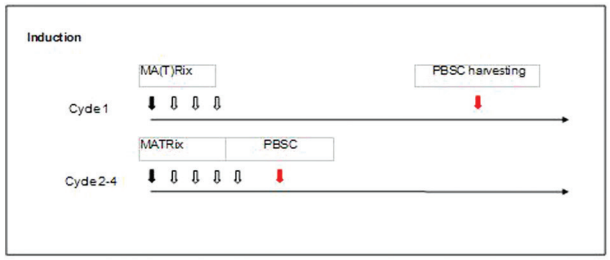
Summary/Conclusion: N/A



PB1442 SAFETY AND FEASIBILITY OF HIGH DOSE CHEMOTHERAPY WITH PBSC RESCUE AND ASCT CONSOLIDATION IN PCNSL: A SINGLE CENTER EXPERIENCE

E. Ravano [1,*], C. Muzi [1], L. Leuzzi [1], M. L. Pioltelli [1], V. R. Zilioli [1], E. Ravelli [1], E. Meli [1], L. Pezzetti [1], G. Grillo [1], R. Cairoli [1]

[1]Hematology, Niguarda GOM, Milan, Italy

Background: Primary diffuse B-cell lymphoma of central nervous system (PCNSL) is a rare and aggressive non Hodgkin Lymphoma (2-3% of NHL). Currently, the standard of care for young and fit patients (pts), is MATRix regimen (Rituximab, HD-Metotrexate, Cytarabine and Thiothepa) and consolidation therapy with autologous stem cell transplantation (ASCT). The mortality reported in literature is 4-6%.
Aims: To study the safety and tolerability of MATRix regimen with sequential autologous peripheral blood stem cell (PBSC) infusion in young and fit pts with PCNSL.
Methods: We report 10 sequential cases of young (< 70 years old) and fit pts with a PCNSL, treated at Niguarda Hospital with the first cycle of MA(T)Rix followed by PBSC harvesting and 3 MATRix with PBSC rescue. Consolidation with ASCT (thiothepa and BCNU conditioning regimen) was performed in all the population in CR/PR.
Results: Ten pts with new diagnosis of PCNSL were treated between October 2014 and March 2019. The population was composed of 8 women and 2 men, median age at diagnosis was 56 years old. Consolidation therapy with high-dose chemotherapy (HDT) and ASCT was performed in 9/10 pts. One received only radiotherapy for progressive disease (PD).
After the first cycle of chemotherapy all pts had a successful stem cell mobilization and adequate harvesting of hematopoietic progenitor cells (median 33.4 x10^6 CD34/Kg). All the following 3 cycles of MATRix had received a rescue of stem cells (median of PBSC infusion at each cycle: 5.3 x10^6 CD34/Kg) on day + 2.
The median rise of neutrophil count (N >1000/mcl) was 13 days after second cycle and 14 days after third and fourth cycles.
Regarding toxicity the major complication were infections. 10/19 (52%) of all the infections occurred during the first cycle. According to NCCN Guidelines ® we observed 15 (79%) grade 1 and 2 infections and 4 (21%) grade 3 or 4.
Neither TRM nor ICU transferral were observed. No patient experienced cardiac or thromboembolic complication. Despite the higher frequency of complication of the first cycle no dose adjustment were made on the following cycles.
With a median of follow up of 16.1 months 50% of pts are in CR, the median OS is 13.6 months and the median PFS is 9 months.

Figure 1.

Treatment schedule:
Induction:
- Cyde 1: Rituximab 375 mg/sqm, Methotrexate 3.5 g/sqm on day 1, Cytarabine 2 g/sqm on day 2 and 3.
- Cyde 2-4: Rituximab 375 mg/sqm, Methotrexate 3.5 g/sqm on day 1, Cytarabine 2 g/sqm on day 2 and 3, Thiotepa 30 mg/sqm on day 4. PBSC rescue on day +2.

Summary/Conclusion: With the limitation of a small series of cases, MATRix regimen with sequential infusion of PBSC and ASCT consolidation is feasible and safe.

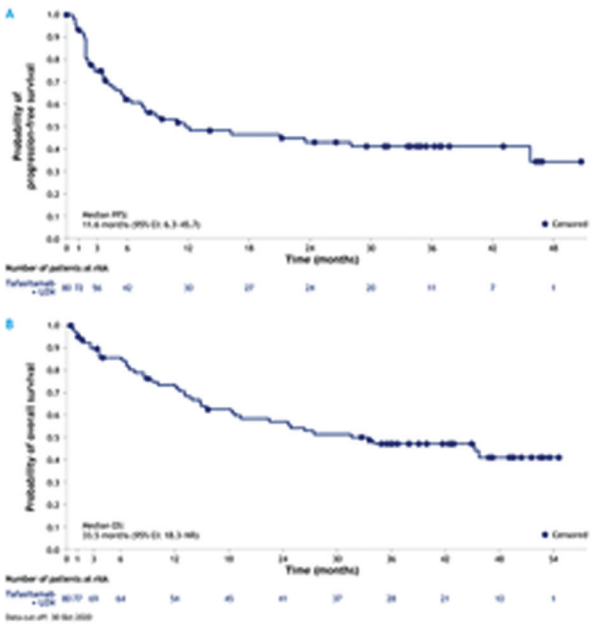
PB1443 ACUTE TOXICITY OF R-CHOP PROTOCOL IN THE TREATMENT OF NON-HODGKIN'S LYMPHOMA: ABOUT 551 CYCLES

E. I. Saidi [1,*], H. Ghedira [1], H. Stambouli [1], R. Jaidi [1], S. Zriba [1], F. M'sadek [1]

[1]Clinical Hematology, Military Hospital of Tunis, Tunis, Tunisia

Background: The R-CHOP chemotherapy protocol is the gold standard for the treatment of non-Hodgkin's B lymphomas due to its efficiency in terms of therapeutic response and survival. However, this therapeutic combination can cause a significant toxicity.

Aims: The aim of this work is to study the incidence and severity of acute toxicity after R-CHOP, to study predictive factors of hematological or extra-hematological complications after R-CHOP, and to estimate the overall survival and mortality rate associated with this protocol.
Methods: This is a sixteen-year retrospective study at the Clinical Hematology Department of the Military Hospital of Tunis. The clinical and biological data of 89 patients were collected and the study of the side effects of 551 R-CHOP type chemotherapy cycles were detailed. The total number was divided into 407 R-CHOP$_{21}$ and 144 R-CHOP$_{14}$ cycles.
Results: Hematological toxicity was observed in 92% of the cycles, with predominantly grade 1 anemia, thrombocytopenia and lymphopenia. Among the 63 (11.4%) cases of grade 4 neutropenia, 34 (6%) progressed to febrile neutropenia (FN) with only 3 during RCHOP$_{14}$. Among the 65 patients who received RCHOP$_{21}$, 15 had primary prophylaxis with granulocyte colony-stimulating factors (G-CSF), and among these patients, only 3 episodes of FN were described, while the total number of FN episodes during RCHOP$_{21}$ was 31 (7.6% of the total cycles of RCHOP$_{21}$). In univariate analysis, it was found that the presence of more than two comorbidities, a positive Charlson score, hypoalbuminemia, hemoglobin lower than 12 g/dl and neutrophil count less than 1500/mm^3 at the pre-treatment assessment, lymphopenia less than 600/mm^3, thrombocytopenia less than 100 000/mm^3, lack of G-CSF prophylaxis, as well as the type of treatment received (RCHOP$_{21}$), were predictive factors for the occurrence of febrile neutropenia. In multivariate analysis, significant risk factors for FN were hypoalbuminemia (p=0.01), neutrophil count less than 1500/mm^3 on pre-chemotherapy workup (p=0.013), lymphopenia and thrombocytopenia ($p < 0.0001$ respectively). Neurological toxicity was seen predominantly (42.8%) at the end of the 5th cycle. An age over 60 was found to be an independent risk factor for neurological toxicity (p=0.005). Pulmonary, hepatic and renal toxicities were not significant. As for cardiac toxicity, it was observed in 4 patients, and resulted in a deadly heart failure in one case. Fifteen deaths were recorded in our study, including three toxic deaths. The overall survival was influenced by the absence of primary G-CSF prophylaxis (p=0.002), the presence of initial liver damage (p=0.001), and the occurrence of FN during the first cycle (p=0.013). The event-free survival was also correlated with the absence of primary G-CSF prophylaxis (p=0.005), the occurrence of FN during cycle 1 (p=0.039), and the presence of initial liver damage (p=0.001).
Summary/Conclusion: Our results confirms the efficiency of the R-CHOP protocol in terms of therapeutic response. However, an acute toxicity, essentially hematological and cardiac, was noted. Systematic G-CSF prophylaxis and close cardiac monitoring would therefore help reduce these adverse effects.



PB1444 LONG-TERM ANALYSES FROM L-MIND, A PHASE II STUDY OF TAFASITAMAB (MOR208) COMBINED WITH LENALIDOMIDE IN PATIENTS WITH RELAPSED OR REFRACTORY DIFFUSE LARGE B-CELL LYMPHOMA (R/R DLBCL)

Background: Tafasitamab is a humanized, Fc-modified anti-CD19 monoclonal antibody that enhances antibody-dependent cellular cytotoxicity and phagocytosis. It is FDA-approved in combination with lenalidomide for adult patients with relapsed/refractory (R/R) diffuse large B-cell lymphoma (DLBCL) not otherwise specified (NOS), including arising from low-grade lymphoma, who are ineligible for autologous stem cell transplant (ASCT).
Aims: L-MIND (NCT02399085) is an ongoing, open-label, single-arm, Phase II study to characterize the safety and efficacy of tafasitamab + lenalidomide in ASCT-ineligible patients with R/R DLBCL. Primary analyses and 2-year efficacy results were previously presented: we report an updated efficacy analysis with ≥35 months follow up (Data cut-off: October 30, 2020).
Methods: Patients were aged ≥18 years with ASCT-ineligible R/R DLBCL, had 1–3 prior systemic therapies (including ≥1 CD20-targeting regimen), with an Eastern Cooperative Oncology Group (ECOG) performance status of 0–2. Patients received 28-day cycles of tafasitamab (12 mg/kg IV), once weekly during cycles 1–3, with a loading dose on Day 4 of cycle 1, then every two weeks (Q2W) during cycles 4–12. Lenalidomide (25 mg PO) was administered on Days 1–21 of cycles 1–12. After cycle 12, progression-free patients received tafasitamab Q2W until disease progression. The primary endpoint was objective response rate (ORR), assessed by IRC. Secondary endpoints included duration of response (DoR), progression-free survival (PFS) and overall survival (OS).
Results: Eighty of 81 enrolled patients received tafasitamab + lenalidomide and were included in the full analysis set. At data cut-off, the overall ORR was 57.5% (n=46/80), including a complete response (CR) in 40% of patients (n=32/80) and a partial response (PR) in 17.5% of patients (n=14/80). Median estimated DoR was 43.9 months (95% confidence interval (CI): 26.1–not reached [NR]), and was NR in patients who achieved a CR (95% CI: 43.9–NR). Median estimated PFS was 11.6 months (95% CI: 6.3–45.7), with a median follow-up of 33.9 months (Fig.); estimated 36-month PFS was 41.1% (95% CI: 29.1–52.7). Median estimated OS was 33.5 months (95% CI: 18.3–NR), with a median follow-up of 42.7 months.
In patients who had received 1 vs ≥2 prior lines of therapy, ORR was 67.5% (n=27/40; CR rate: 47.5%; PR rate: 20.0%) vs 47.5% (n=19/40; CR rate: 32.5%; PR rate: 15.0%). Median estimated DoR was 43.9 months (95% CI 9.1–NR) in patients with 1 prior treatment and not reached (95% CI 15.0–NR) in those receiving ≥2 prior treatments. Median estimated PFS and estimated 36-month PFS were 23.5 months (95% CI 7.4–NR) and 47.8% (95% CI: 30.2–63.4) in patients with 1 prior treatment vs 7.6 months (95% CI 2.7–NR) and 34.3% (95% CI: 18.6–50.7) in those receiving ≥2 prior treatments. Median estimated OS was 45.7 months (95% CI 24.6–NR) in patients with 1 prior treatment compared with 15.5 months (95% CI 8.6–NR) in those receiving ≥2 prior treatments.
There were no unexpected toxicities or new safety signals.

Kaplan-Meier plot of (A) PFS and (B) OS after 35 months follow-up

Summary/Conclusion: Combination therapy with tafasitamab + lenalidomide followed by tafasitamab monotherapy provided durable responses, achieving a median DoR of 43.9 months in patients with R/R DLBCL not eligible for ASCT, with a manageable safety profile. These long-term data indicate that this chemotherapy-free regimen can achieve prolonged remission and survival benefit in this patient population, especially at first relapse, with a median estimated DoR of 43.9 months and median estimated OS of 45.7 months at second-line.

PB1445 MANUFACTURING COMMERCIAL AXICABTAGENE CILOLEUCEL FOR EUROPEAN PATIENTS: A 2-YEAR RETROSPECTIVE ANALYSIS

L. van de Wiel [1,*], D. Hallard [1], S. Ensari [2], D. Rangel [3], A. Dumont [4], E. Granados [5], D. Tonelli [5]

[1]Kite, a Gilead Company, Hoofddorp, Netherlands, [2]Kite, a Gilead Company, Santa Monica, CA, [3]Kite, a Gilead Company, El Segundo, CA, United States, [4]Kite, a Gilead Company, Boulogne-Billancourt, France, [5]Kite, a Gilead Company, Stockley Park, England, United Kingdom

Background: Axicabtagene ciloleucel (axi-cel), an autologous anti-CD19 chimeric antigen receptor T-cell therapy, was granted marketing authorization by the European Commission on August 28, 2018 for use in adults with relapsed/refractory diffuse large B-cell lymphoma and primary mediastinal large B-cell lymphoma after ≥2 prior lines of systemic therapy.
Aims: To describe 2 years of post–marketing authorization experience in manufacturing from a United States site and supplying commercial axi-cel lots in European countries and Israel.
Methods: From apheresis material collected at a qualified treatment center, peripheral blood mononuclear cells (PBMCs) were manufactured and cryopreserved in The Netherlands and then shipped to the United States (El Segundo, CA) to continue manufacturing. If additional apheresis was needed, the first apheresis was considered for each patient, and is subsequently referred to as that patient's lot. The finished product lot was shipped back to The Netherlands for European Qualified Person (QP) release and then sent to the hospital for administration to the patient.
Results: From first apheresis after marketing authorization, September 6, 2018, until September 5, 2020, 1074 patients were included on the Kite Konnect® website and provided apheresis material for axi-cel manufacturing. The median and mean turnaround times from apheresis to QP release were 25 days and 26.2 days, respectively. The median and mean times from apheresis to shipment were 29 days and 31.5 days, respectively. Despite the transatlantic air travel disruption due to the COVID-19 pandemic, the median turnaround time from apheresis to QP release from March 2020 to August 2020 was not affected (25 days).
For those 1074 patients for whom manufacturing was started, 1040 commercial axi-cel lots (97%) were released, and 1000 (93%) were delivered, including 19 lots (1.8%) that were out of specification. Out of specification commercial axi-cel lots were released exceptionally and on physician's request based on a risk/benefit assessment according to the European Union Advanced Therapy Medicinal Product guidelines.
To obtain this level of manufacturing success, a remanufacturing step was required either from frozen PBMC bags in 19 cases (1.8%) or from new apheresis in 19 cases (1.8%). In addition, 18 patients (1.7%) had batches rejected; 7 patients (0.7%) had production terminated, and 9 patients (0.8%) had orders cancelled.
In June 2020, a new facility in Hoofddorp, The Netherlands opened to engineer cell therapies for European patients with the objective of substantially reducing time from apheresis to QP release and to avoid transatlantic transport.
Summary/Conclusion: In conclusion, the initial 2-year experience in manufacturing commercial axi-cel for European countries shows high manufacturing success, with a reliable time from apheresis to QP release (median, 25 days) and a very low percentage (1.8%) of out of specification lots released on physician's request.

PB1446 RELATIONSHIP BETWEEN PAKT1, PSYK PROTEINS CO-EXPRESSION AND SURVIVAL IN DIFFUSE LARGE B-CELL LYMPHOMA

E. Vaneeva [1,*], V. Rosin [1], D. Diakonov [1], M. Minaev [1], S. Samarina [2]

[1]Laboratory of pathomorphology, [2]The Federal State-Financed Scientific Institution Kirov Research Institute of Hematology and Blood Transfusion under the Federal Medical Biological Agency, Kirov, Russian Federation

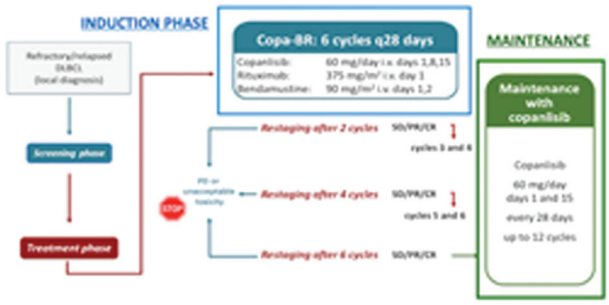
Background: Diffuse large B-cell lymphoma (DLBCL) is the most common type of non-Hodgkin's lymphoma. The clinical criteria characterized by the International Prognostic Index (IPI) provide a standard model for risk stratification. However, there is variability in outcomes in IPI risk groups, which indicating the biological and clinical heterogeneity of the DLBCL and does not allow to accurately assess the individual risk of therapy failure. Development of the additional biological prognostic criteria of disease could allow to lower unfavorable outcome cases. Dysregulation of key molecules (pAKT1, pSyk) of the PI3K/AKT/mTOR and BCR signaling pathways involves the biological behavior of tumor cells and may affect on the course of DLBCL. It worth noting that monotypic overexpression of pAKT1 and pSyk is associated with low overall (OS) and progression-free (PFS) survival in DLBCL patients. Nevertheless, the combined expression of these proteins still has not yet been studied, thus indicates the relevance of the research.
Aims: Assesment of relationship between co-expression pAKT1, pSyk proteins in tumor cells with OS and PFS in DLBCL.
Methods: Formalin fixed, paraffin-embedded lymph node and other organ and tissue samples of 100 patients with newly diagnosed DLBCL were used. All the patients were treated in the clinic of institute from 2012 to 2018 using standard R-CHOP regimen. Determination of the relative number of pAKT1-, pSyk-positive tumor cells was performed by immunohistochemical and morphometric methods. OS and PFS were calculated by the Kaplan-Meier method using the log-rank test. Threshold values for the expression of these proteins were calculated using ROC-analysis: pAKT1-positive tumor cells - 70%; pSyk-positive tumor cells - 28%. According to the established thresholds, all subjects were divided into groups with high [≥70% (+) for pAKT1; ≥28% (+) for pSyk] and low [<70% (-) for pAKT1; <28% (-) for pSyk] protein expression. The interrelation of different variants of pAKT1 and pSyk co-expression with the course of DLBCL was analyzed.
Results: The highest OS (90.2%) was recorded in the group of patients (n=41) with simultaneously low expression of markers (pAKT1-/pSyk-). In the presence of co-expression of pAKT1+/pSyk- and pAKT1-/pSyk+, it was 52% (n=29) and 60% (n=15), respectively. The lowest OS values (26.7%) were observed in patients (n=15) with a combination of pAKT1+/pSyk+, which significantly differed from other variants of co-expression of markers (p<0.001; HR=5.2; 95% CI=2.49-10.9). A similar pattern was found in the analysis of PFS. The proportion of patients without disease progression with the option of co-expression of pAKT1-/pSyk- was 78.1% (n=41), and in the presence of combinations of pAKT1+/pSyk- and pAKT1-/pSyk+ - 55% (n=29) and 53% (n=15), respectively. The lowest PFS (40%) was recorded in patients with simultaneous overexpression of biomarkers (n=15; p=0.002; HR=3.3; 95% CI = 1.54-7.30).
Summary/Conclusion: Combined overexpression of pAKT1/pSyk proteins is associated with a poorer prognosis of DLBCL compared with other variants of their co-expression.

PB1447 THE PROGNOSTIC ROLE OF PD-L1 PROTEIN EXPRESSION IN A COMBINED MODEL FOR PREDICTION OF THE SURVIVAL OF DIFFUSE LARGE B CELL LYMPHOMA PATIENTS

S. Samarina [1,*], N. Semenova [2], D. Diakonov [1], V. Rosin [1], E. Vaneeva [1], S. Gritsaev [2]

[1]Federal State Budgetary Institution of Science "Kirov Scientific Re-search Institute of Hematology a, Federal State Budgetary Institution of Science "Kirov Scientific Re-search Institute of Hematology a, Kirov, [2]Federal State Budget Institution Russian Research Institution of Hematology and Transfusiology of Federal Medical Biological Agency, Federal State Budget Institution Russian Research Institution of Hematology and Transfusiology of Federal Medical Biological Agency, St Peterburg, Russian Federation

Background: Diffuse large B-cell lymphoma (DLBCL) is characterized by molecular biological heterogeneity and variability of the clinical course, which casts doubt on the use of a single standard of patient care and promotes the search for risk-adapted approaches in the first line of therapy for patients with DLBCL. The search for new predictors of effectiveness of induction therapy and survival are of significant scientific and practical importance
Aims: The research is aimed at the assessment of prognostic value of PD-L1 protein expression in a combined model for predicting the course of DLBCL in patients receiving induction therapy according to the RCHOP therapy



Methods: A retrospective analysis of the data of 85 DLBCL patients who were treated at the Kirov Scientific Re-search Institute of Hematology and Blood Transfusion was carried out. The median age was 59 (18-80) years. All the patients received no less than 4-6 courses of RCHOP chemotherapy. The median follow-up was 17 (1-168) months. The optimal cut-off threshold for assessing the proportion of cells expressing the PD-L1 protein was determined using the CART (Classification and Regression Tree) machine learning method
Results: The patients were divided into three groups according to the immunohistochemical subtype and IPI risk. In group 1 with GCB type tumors and any risk except high 21 (84%) and 4 (16%) patients, respectively, showed low or higher PD-L1 expression. Low level of PDL1 provided two-year PFS in 76% of all the cases, while higher level of PDL1 – in 100% (p=0,628). Two-year OS was 100% in both groups.
In Group 2 with nonGCB subtype and any risk except high 27 (67,5%) and 13 (32,5%) patients had low and high PD-L1 expression, respectively. Two-year PFS didn't differ much: 46% - in high PDL1 expression level and 49% - in low PD-L1 expression level. At the same time the patients with high PD-L1 expression had shorter OS than those with low expression: 52% and 87%, respectively (p=0,049).
In Group 3 with high IPI risk 9 (45%) and 11 (55%) patients had high and low PD-L1 expression level, respectively. In cases of high PD-L1 two-year OS was 0%, with 46% in cases of low PD-L1 (p=0,002). Two-year OS was 66% in the patients with low PD-L1 expression level (p=0,008).
Summary/Conclusion: High PD-L1 expression level in combination with high IPI and non-GCB tumor subtype is associated with low OS and PFS in DLBCL patients. This is probably due to the low efficacy of induction therapy according to the RCHOP regimen in patients with high IPI risk. This allows us to consider the assessment of the proportion of PD-L1 expressing cells as an additional criterion for stratification of patients into risk groups for predicting the response to treatment and a differentiated approach to the choice of therapeutic tactics at the onset of the pathological process

PB1448 COPANLISIB IN COMBINATION WITH RITUXIMAB-BENDAMUSTINE IN PATIENTS WITH RELAPSED-REFRACTORY DIFFUSE LARGE B-CELL LYMPHOMA: A MULTICENTRIC PHASE II TRIAL OF THE FONDAZIONE ITALIANA LINFOMI (FIL_COPA-RB)

M. Novo [1,*], A. Castellino [2], A. Chiappella [3], G. Ciccone [4], M. Balzarotti [5], A. Di Rocco [6], M. Spina [7], U. Vitolo [1]

[1]Multidisciplinary Oncology Outpatient Clinic, Candiolo Cancer Institute, FPO-IRCCS, Candiolo, [2]Hematology Unit, Santa Croce e Carle Hospital, Cuneo, [3]Division of Hematology and Stem Cell Transplantation, Fondazione IRCCS Istituto Nazionale dei Tumori di Milano, Milano, [4]Unit of Clinical Epidemiology and CPO, Azienda Ospedaliero-Universitaria Città della Salute e della Scienza di Torino, Torino, [5]Hematology Unit, Humanitas Clinical and Researdh Hospital IRCCS, Rozzano (Milano), [6]Department of Translational and Precision Medicine, Università La Sapienza, Roma, [7]Division of Medical Oncology, National Cancer Institute, Aviano, Italy

Background: Diffuse large B cell lymphoma (DLBCL) are curable in 50-60% of cases with frontline immunochemotherapy. Salvage therapy for relapsed/refractory (R/R) DLBCL is able to cure roughly 40-50% of patients, and includes high dose-chemotherapy plus autologous stem cell transplant (ASCT) in chemosensitive fit patients, and chimeric antigen receptor T-cells (CAR-T), permitted only after ≥2 prior systemic regimes in patients with no major comorbidities. Therefore, there is an urgent need to investigate new salvage treatments for R/R DLBCL unresponsive or ineligible to ASCT or CAR-T. Rituximab plus bendamustine (RB) is active in R/R DLBCL with an overall response rate (ORR) ranged from 40 to 60% but usually of short duration. Copanlisib is an intravenous pan-class I PI3K inhibitor with predominant activity against PI3K-α and -δ isoforms, active as single agent in indolent lymphomas and DLBCL with ORR of 59% and 25%, respectively (NCT01660451) (NCT02391116). Most frequent treatment-emergent adverse events are transient hyperglycemia and transient hypertension. The association of copanlisib plus RB (Copa-RB) has been showed a safe treatment in R/R indolent lymphomas (NCT02626455).
Aims: To assess the efficacy and safety of Copa-RB followed by copanlisib maintenance in R/R DLBCL not eligible or relapsed after ASCT or CAR-T
Methods: FIL Copa-RB is a multicentric open-label single arm, single stage, phase II trial. An estimated 81 patients will be enrolled, from 30 centers in Italy. Inclusion criteria are: patients aged 18 or older with histologically confirmed DLBCL (including de-novo DLBCL, DLBCL transformed by indolent lymphomas and high-grade lymphoma) R/R after 1 to 3 previous lines of therapy, considered not candidate or R/R to ASCT or CART, ECOG PS ≤ 2. Exclusion criteria include primary mediastinal B cell lymphoma histology, significant organ dysfunction, uncontrolled hypertension and hyperglycemia (HbA1c> 8.5%). Treatment consists of an induction phase with six 28-day cycles of copa-RB (copanlisib 60 mg intravenously on day (D) 1, D8 and D15, rituximab 375 mg/m2 on D1, bendamustine 90 mg/m2 on D1-D2) followed by a maintenance phase of twelve 28-day cycles of copanlisib 60 mg given on D1 and D15 (Fig.). The primary endpoint is progression free survival (PFS) defined as the time between the date of enrolment and the date of disease progression, relapse or death from any cause, whichever occurs earlier, with an expected improvement of 12-month PFS from 20% to 35%. Secondary endpoints include overall survival, ORR, complete response (CR) rate, duration of response and rate of response improvement during maintenance. Exploratory analysis will include correlation between outcome and cell of origin, MYC, BCL2 and BCL6 overexpression and rearrangements, and mutational analysis of selected genes possibly involved in predicting response to copanlisib. The expected study duration from first patient's first visit to last patient's last visit is approximately 4 years.
Results: The recruitment started in November 2020; at March 1st, 8/81 patients have been enrolled. Results for this study are not yet available.

Summary/Conclusion: The treatment of R/R DLBCL ineligible or unresponsive to ASCT or CAR-T is still an unmet clinical need and new treatment options are warranted. Copanlisib as single agent has been already shown a moderate activity in DLBCL and the association Copa-RB plus copanlisib maintenance could be a new strategy to improve the outcome of these patients. Biomarkers studies would further elucidate patients who are more likely to respond to this treatment.

PB1449 RADIOTHERAPY FOR SYSTEMIC B-CELL LYMPHOMA WITH CUTANEOUS INFILTRATION: IS IT WORTHY?

A. Silva Martins [1,*], M. Sanches [2], R. Cruz [3], D. Alves [1], E. Espada [1], A. Alho [1], J. Melo [1], R. Moreno [1], B. Polo [1], C. Lopes [1], M. J. Costa [1], C. Martins [1], C. Ferreira [3], L. Soares Almeida [2], J. Raposo [1]

[1]Hematology and Bone Marrow Transplantation, [2]Dermatology, [3]Pathology, Centro Hospitalar Universitário Lisboa Norte, Lisboa, Portugal

Background: Cutaneous infiltration by systemic B-cell lymphoma is rare and frequently associated with advanced-stage disease. Radiotherapy is recommended as consolidation therapy in some extranodal B-cell lymphomas and as front-line treatment in primary cutaneous B-cell lymphoma. Studies that address the role of radiotherapy in the treatment of cutaneous infiltration by systemic B-cell lymphoma are lacking.
Aims: 1) to compare response to treatment in patients treated with and without radiotherapy;
2) to analyse disease-free survival (DFS) and relapse location after cutaneous infiltration in systemic B-cell lymphoma.
Methods: Retrospective unicentric cohort study including patients with systemic B-cell lymphoma with cutaneous infiltration treated on a tertiary hospital from 2010 to 2021. Patients were divided in 3 groups according to type of treatment after cutaneous infiltration: chemotherapy (CHEMO), radiotherapy (RT) and chemotherapy followed

by consolidation radiotherapy (CHEMO+RT). Primary outcome was response to treatment and secondary outcomes were DFS and relapse location after cutaneous infiltration. We used Fisher's exact test for group comparisons and survival analysis for DFS calculation. Data was collected by clinical records consultation and SPSS was used for statistical analysis.

Results: Twenty one patients were included in the analysis, 12 were female and median age at diagnosis was 67 years [Q1-Q3 58.5-75.0]. Median follow-up was 22 months [Q1-Q3 12.5-109.0]. Cutaneous infiltration was present at diagnosis in 15 patients (71%); in the 6 patients without infiltration at diagnosis, the median number of treatment lines was 1.5 [Q1-Q3 0.75-3.25]. The most frequent type of lymphoma was diffuse large B cell (DLBCL) (n=13), followed by follicular (n=3) and lymphocytic lymphoma (n=2). Eighty percent of patients had advanced-stage disease at diagnosis (AA stage IV); 2 patients were HIV positive. The head & neck region was the most frequently involved (n=11) and the most frequent types of lesion were nodules (n=8) and tumours (n=8). 6 patients had extensive/distant cutaneous disease. First line of treatment after cutaneous infiltration was CHEMO in 15 patients (R-CHOP in10, R-CVP in 4, GEMOX followed by autologous bone marrow transplant in 1 patient), CHEMO+RT in 3 patients (R-CHOP in 2 and Rituximab in 1; RT dose 25-36 Gy) and RT in 3 patients (12-40 Gy). There were no differences between the groups regarding age at presentation, gender, staging or DLBCL predominance. Complete response (CR) rate was higher in the CHEMO group (80%) than in the RT group (0%) *(p=0.025)*; no difference in CR rate was found between the CHEMO and CHEMO+RT group (67%)(*p=1.00)*. Of the 14 patients that achieved CR, 5 relapsed in the skin and 1 in the skin and nodes. Two of these patients were in the CHEMO+RT group and 4 were in the CHEMO group. All the cutaneous relapses occurred in the site of initial cutaneous infiltration. There were no differences in median DFS between CHEMO and CHEMO+RT (*p=0.638*).

Summary/Conclusion: Radiotherapy as consolidation treatment and as single treatment is not associated with better CR rates or more prolonged DFS than isolated chemotherapy. Relapse after CR in these patients is frequently located in the same cutaneous territory of the initial infiltration. These findings raise the question of the utility of skin radiotherapy in systemic B-cell lymphoma with cutaneous involvement, although more studies with larger sample sizes are needed to confirm our conclusions.

PB1450 DOSE-ADJUSTED EDOCH-RITUXIMAB IN ELDERLY PATIENTS WITH HIGH GRADE DIFFUSE LARGE B-CELL LYMPHOMA

B. Merchán Muñoz [1,*], A. Vazquez Ramo [1], M. I. Nuevo López [1], M. Mora Argumánez [1], A. Gil Perez [1], H. Guillen Garcia [1], A. B. Santos Montero [1], N. Golbano López [1], S. Herrero Martin [1], J. Arbeteta Juanis [1], D. Morales Sanz [1], M. Diaz Morfa [1], D. Subira Perez [1], D. De Miguel Llorente [1]

[1]*Hematology, Hospital Universitario Guadalajara, Guadalajara, Spain*

Background: The standard first-line therapy for diffuse large B-cell lymphoma (DLBCL) is CHOP-R. Many studies have shown the efficacy of EDOCH-R (etoposide, dexamethasone, vincristine, cyclophosphamide, doxorubicin and rituximab) regimen in this pathology with an acceptable toxicity. However, there is few evidence supporting the efficacy and safety in elder patients.

Aims: The aim of this study is to analyze the results of EDOCH-R as first line therapy in patients over 60 years old with de novo DLBCL diagnosis at Hospital Universitario de Guadalajara (HUG).

Methods: The medical records of all the patients with DLBCL over the age of 60, treated with EDOCH-R as first-line therapy at HUG from 01/01/2014 to 31/12/2020 were review, identifying 25 patients in total. Baseline data was collected at diagnosis, including patient demographics, Eastern Cooperative Oncology Group (ECOG), staging, IPI, PET-TC and histologic subtypes. Germinal center B-cell (GCB) and non-GCB DLBCL subtypes were classified based on the algorithm proposed by Hans et al. EDOCH-R administration was planned every 21 days for 6 cycles. None of the patients received radiotherapy. Pegfilgrastim was administered at day 6 of therapy. Adverse events were reported according to the National Cancer Institute reviewed criteria. Statistical analysis was carried out with SPSS software. Overall survival (OS), progression-free survival (PFS) and response rate were the primary end points of this study. The secondary clinical objective included patient safety.

Results: The diagnostic parameters obtained for all the patients are recorded in Table 1. All the patients exhibited a high Ki-67 expression (≥ 80%). Two patients (8%) patients were classified as double expressor (DE) and another 2 (8%) individuals resulted double-hit lymphomas (DHL).

All the patients received EDOCH-R regimen as first-line chemotherapy with a median of 6 cycles. Complete remission (CR) was achieved in 79% of the patients that completed the 6 cycles, and partial remission was achieved in 10% of the patients. One patient (5%) exhibited progressive disease after 4 cycles of therapy. With a median follow-up of 36 months the OS was 65% and PFS was 52%. OS was lower in the group of patients older than 70 years and in those with an IPI greater than 3, although a significant difference was not encountered.

The major side effect of the EDOCH-R regimen was hematologic toxicity. Grade 4 neutropenia, anemia and thrombocytopenia were observed in 76%, 36% and 24% of the patients, respectively. Neutropenic fever developed in 76% of the patients. One patient exhibited a decrease in the cardiac ejection fraction, which led to change the treatment. Three patients (12%) over 70-years-old died of progressive lymphoma, and 2 patients (8%) had to end therapy due to comorbidity factors.

Summary/Conclusion: EDOCH-R is an effective therapy for DLBCL in elderly patients, although it has shown a high hematological toxicity.

PB1451 FRONT-MIND: A PHASE III, RANDOMIZED, DOUBLE-BLIND, PLACEBO-CONTROLLED STUDY COMPARING EFFICACY AND SAFETY OF R-CHOP + TAFASITAMAB + LENALIDOMIDE VS R-CHOP ALONE FOR NEWLY-DIAGNOSED HIGH-RISK DLBCL

U. Vitolo [1,*], G. S. Nowakowski [2], J. M. Burke [3], C. P. Fox [4], M. Trneny [5], A. Chiappella [6], S. Tillmanns [7], A. Sporchia [7], W. Brugger [7], G. Lenz [8]

[1]Candiolo Cancer Institute, FPO-IRCCS, Candiolo (Torino), Italy, [2]Division of Hematology, Mayo Clinic, Rochester, MN, [3]US Oncology Research and Rocky Mountain Cancer Centers, Aurora, CO, United States, [4]Nottingham University Hospitals NHS, Nottingham, United Kingdom, [5]1st Department of Medicine, First Medical Faculty, Charles University and General University Hospital, Prague, Czech Republic, [6]Fondazione IRCCS, Istituto Nazionale dei Tumori, Milano, Italy, [7]MorphoSys AG, Planegg, [8]Department of Medicine A – Haematology and Oncology, University Hospital Münster, Münster, Germany

Background: Tafasitamab is an Fc-modified, humanized monoclonal antibody targeting CD19+ tumor cells, which enhances *in vitro* antibody-dependent cell-mediated cytotoxicity (ADCC) and phagocytosis. Lenalidomide (LEN) has anti-proliferative and anti-angiogenic activities. Tafasitamab + LEN is indicated in adult patients (pts) with relapsed/refractory (R/R) diffuse large B-cell lymphoma (DLBCL) not otherwise specified, including arising from low-grade lymphoma, who are ineligible for autologous stem cell transplantation. The L-MIND study (NCT02399085) showed that tafasitamab + LEN is well tolerated, with an ORR of 57.5% at ≥35 months f/up (reported at this meeting) in pts with R/R DLBCL. R-CHOP is the current standard of care for pts with newly-diagnosed DLBCL. In preclinical studies, tafasitamab + rituximab and tafasitamab + LEN were shown to increase anti-tumor activity compared to either single agent alone. Data from FIRST-MIND (NCT04134936), a Phase Ib, open-label, randomized study of tafasitamab + R-CHOP or tafasitamab + LEN + R-CHOP in pts with newly-diagnosed DLBCL, are reported elsewhere at this congress.
Aims: The Front-MIND study aims to assess the efficacy and safety of tafasitamab + LEN + R-CHOP vs R-CHOP alone in previously untreated, high-intermediate and high-risk pts.
Methods: Front-MIND is a Phase III, multicenter, randomized, double-blind, placebo-controlled study (Fig.). An estimated 880 pts will be enrolled, from 350 centers in America, Europe and Asia-Pacific. Eligible pts are aged 18 to 80 yrs with previously untreated (diagnosis to start of treatment ≤28 days [D]) local biopsy-proven, CD20-positive DLBCL (International Prognostic Index [IPI] ≥3 if >60 yrs/age-adjusted IPI 2–3 if ≤60 yrs), and ECOG PS 0–2. Pts with transformed lymphoma are excluded. Pts will be randomized 1:1 based on stratification factors: IPI intermediate-high vs high risk and geographic region. The experimental arm will comprise six 21-D cycles of tafasitamab (12 mg/kg intravenous D 1, 8 and 15) + LEN (25 mg orally, D1–10) + R-CHOP. The control arm will comprise six 21-D cycles of tafasitamab placebo (0.9% saline solution IV, D1, 8 and 15) + LEN placebo (D1–10) + R-CHOP. Pre-planned Central Nervous System prophylaxis with intravenous high-dose methotrexate is allowed after response assessment at end of treatment. The primary endpoint is investigator-assessed progression-free survival. Secondary endpoints include investigator-assessed event-free survival and overall survival. A large set of translational studies is planned, analyzing the relationship between potential biomarkers and efficacy. Pts will be followed up from their end-of-treatment visit until the end of the study, including clinical evaluation every 3–6 months and imaging every 3–12 months up to 60 months. The expected study duration from first pt's first visit to last pt's last visit is approximately 5 years. The study is conducted with the scientific support of the Fondazione Italiana Linfomi and the German Lymphoma Alliance.
Results: Results for this study are not yet available.

Summary/Conclusion: There remains a high unmet need to improve treatment options for newly diagnosed pts with high-risk DLBCL. The combination of tafasitamab, LEN and R-CHOP may have synergistic potential. Preliminary data from the First-MIND study suggest that tafasitamab ± LEN + R-CHOP is tolerable in pts with treatment-naïve DLBCL. The Phase III Front-MIND study will provide further evaluation of clinical benefits and safety in a high-intermediate and high-risk population of pts with newly diagnosed DLBCL.

PB1452 PRIMARY GASTRIC LARGE B CELL LYMPHOMA:EXPERIENCE OF THE HEMATOLOGY DEPARTMENT OF SFAX

M. Charfi [1,*], G. abichou [1], Y. fakhfakh [1], O. kassar [1], I. saguem [2], W. feki [3], M. elloumi [1]

[1]hematology, Hedi Chaker Hospital, [2]anathomopathology, hbib bourguiba hospital, [3]radiology, Hedi Chaker Hospital, Sfax, Tunisia

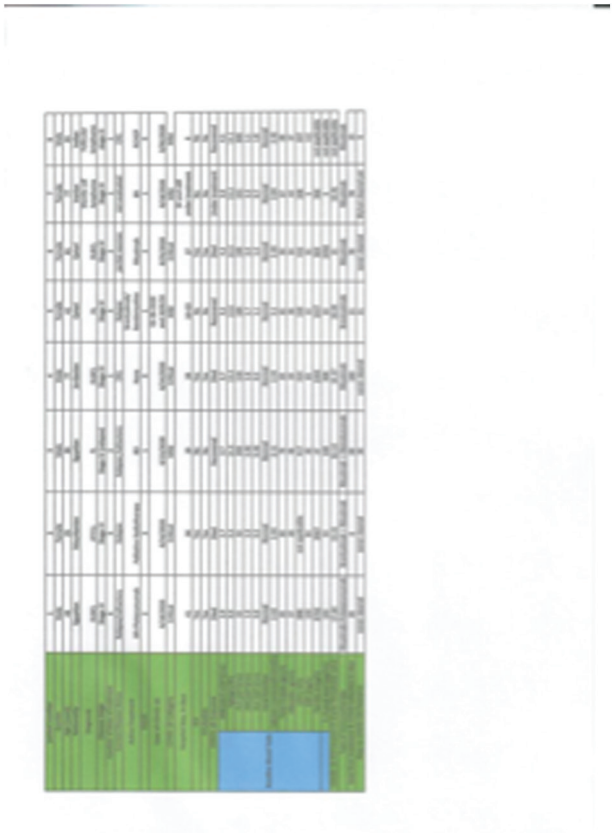
Background: Primary gastric lymphoma (PGL) is a rare disease. It is, however, the most common extra nodal non-Hodgkin lymphoma (NHL). Diffuse large B cell lymphoma (DLBCL) is the common aggressive subtype of gastric NHL.
Aims: The purpose of our study is to analyze its epidemiological aspects, clinical features, endoscopic aspects, therapeutic methods and prognostic factors in our center.
Methods: This retrospective study involved untreated patients with primary gastric large B cell lymphoma diagnosed between January 2006 and December 2019 in the hematology department of Sfax in Tunisia. The Musshoff-modified Ann Arbor System was used for clinical staging. We used the Revised International Prognostic index (R-IPI) score to evaluate prognosis.Patients were treated with chemotherapy (CHOP+/-R, ACVBP+/- R or mini CEOP/CHOP +/- R) alone or followed by radiation or autologous stem cell transplantation. The International Working Group Response Criteria for NHL 1999 was used to evaluate the response. To confirm complete remission, gastric lesions were evaluated by Endoscopy combined to Biopsy. Kaplan-Meier method was used to estimate overall survival (OS) and event free survival (EFS).
Results: A total of 24 eligible patients were identified. Sex ratio was 1.2.Median age was 59 years (17-82). The mean consultation delay was 9 months (1-48 months). Epigastric abdominal pain was the most common revealing symptom (83% of patients), it was associated to B symptoms in 75% of the cases. Performance Status of 2 or greater was noted in eight patients (33%). In Endoscopy, lesions were found more in gastric body and antrum (25%), there were 1 patient who had multiple located lesions and 1 who had diffuse gastric lesions. One patient had stenosis. Nasopharyngeal biopsy was performed on 10 patients and was positive in one case. Elevated LDH level were observed in 5 patients (21 %). 63% of the patients had localized disease (IE or IIE). Half of the patients were screened for Helicobacter Pylori Infection, it was present in 7 patients (58%). A quarter of gastric DLBCL were associated to low-grade mucosa associated lymphoid tissue (MALT) lymphoma. R-IPI was high in 12% of the cases, intermediate in 71% and low in 17%. The Median follow up was 120 months. One patient died of hemorrhagic shock before treatment and 4 patients died while undergoing chemotherapy. The treatment

response was determined in 18 patients, among them:71% achieved complete remission, 24% were evaluated partial response and 5% were in progression. Five Years OS and EFS rates were respectively 61% and 57%.
Summary/Conclusion: The rarity of PGL has left many aspects of this neoplasm to remain unknown. In our study, the initial presentation was with nonspecific symptoms, which often leads to misdiagnose and delay of treatment similarly to data from literature. The most frequent site of lesions in our patients was the antrum of the stomach (29%) which is similar to literature data. The majority of the cases had localized disease (63%) which remains lower than the other reported series (75-84%). Complete remission rates (71%) and five years OS rates (61%) were lower than the values reported in other series in literature and which were respectively 80% and 70-75%. Early diagnosis, availability of Rituximab and autologous stem cell transplant in high risk forms may help to improve our results.

PB1453 FRONTLINE BRENTUXIMAB VEDOTIN AND CHP (A+CHP) IN PATIENTS WITH PERIPHERAL T-CELL LYMPHOMA WITH LESS THAN 10% CD30 EXPRESSION (SGN35-032, TRIAL IN PROGRESS)

D. Jagadeesh [1,*], S. Knowles [2,3], S. Horwitz [4]

[1]Cleveland Clinic Taussig Cancer Institute and Case Comprehensive Cancer Center, Cleveland, OH, [2]Seagen Inc., Bothell, WA, [3]University of Washington, Seattle, WA, [4]Lymphoma Service, Memorial Sloan Kettering Cancer Center, New York, NY, United States



Background: In the ECHELON-2 phase 3 clinical trial, brentuximab vedotin, a CD30-directed antibody-drug conjugate, combined with cyclophosphamide, doxorubicin, and prednisone (A+CHP) showed efficacy in patients (pts) with peripheral T-cell lymphoma (PTCL) across a range of CD30 expression levels, including the lowest eligible level of 10% by IHC.
It is expected that A+CHP will demonstrate efficacy in PTCL with <10% CD30 expression because: i) clinical responses to brentuximab vedotin occurred in pts with low and undetectable CD30 expression (Jagadeesh 2019); and ii) the activity of CHP chemotherapy in PTCL is unrelated to CD30 expression. This study will include subjects with PTCL subtypes other than systemic anaplastic large cell lymphoma (sALCL).
Aims: To describe the rationale and study design of SGN35-032 (EudraCT 2020-002336-74), a study of brentuximab vedotin in combination with cyclophosphamide, doxorubicin, and prednisone (A+CHP) for patients with previously untreated PTCL with <10% CD30 expression.
Methods: This is a dual-cohort, open-label, multicenter, phase 2 clinical trial (EudraCT 2020-002336-74) designed to evaluate the efficacy and safety of A+CHP in subjects with non-sALCL PTCL and CD30 expression <10% on tumor cells. Up to approximately 40 subjects will be enrolled in each of the CD30 negative (expression <1%) and the CD30 positive (expression ≥1% to <10%) cohorts. Only subjects with CD30 expression <10% per central confirmation will be analyzed for the primary and secondary endpoints. Subjects will receive 21-day cycles of A+CHP for a target of 6-8 cycles.
The primary endpoint of this trial is objective response rate (ORR) per blinded independent central review (BICR) using the Revised Response Criteria for Malignant Lymphoma (Cheson 2007). Key secondary endpoints include complete remission (CR) and progression-free survival (PFS) per BICR and overall survival.
Key inclusion criteria include adults with newly diagnosed PTCL, excluding sALCL, per the WHO 2016 classification; CD30 expression <10% by local assessment; and FDG-avid disease by PET and measurable disease of at least 1.5 cm by CT, as assessed by the site radiologist.
Lymphoma response and progression will be assessed by BICR per Cheson 2007 and modified Lugano criteria (Cheson 2014). A PET scan is required at baseline, after Cycle 4, and after the completion of study treatment. Follow-up restaging CT scans will be performed over the next two years.
Efficacy and safety endpoints will be summarized with descriptive statistics by cohort, for both the CD30 negative and the CD30 positive cohorts. Time-to-event endpoints, such as PFS, will be estimated using Kaplan-Meier methodology and Kaplan-Meier plots will be presented. Medians for time-to-event analyses (eg, median PFS),will be presented and two-sided 95% confidence intervals will be calculated using the log-log transformation method.
The trial currently is open at sites in the US. Sites in Europe are expected to open in early 2021.
Results: N/A
Summary/Conclusion: N/A

PB1454 IMPLICATIONS OF IMMUNOMODULATORY MEDICATIONS IN COVID-19 INFECTED HEMATOLOGICAL MALIGNANCY PATIENTS IN QATAR

A. Al Battah [1,*], M. Aldapt [1], A. Ahmad [1], M. Osman [2], H. Elsabah [1], K. Al Aboudi [1], H. El Omri [1], R. Taha [1]

[1]Clinical Hematology, NCCCR/HMC, [2]Internal Medicine, HGH/HMC, Doha, Qatar

Background: Immunomodulatory medications including monoclonal antibodies are widely used in the treatment of many hematological malignancies, however their use during the COVID-10 pandemic was associated with worse outcome for some patients.
Aims: To evaluate the immune & hematologic characteristics of patient demographics, time from last chemo-immunotherapy, cancer status at time of infection, severity of COVID-19 infection, COVID-19 CT value, time of clearance, Immunoglobulin levels & IL-6 levels
Methods: To evaluate the immune & hematologic characteristics of patient demographics, time from last chemo-immunotherapy, cancer status at time of infection, severity of COVID-19 infection, COVID-19 CT value, time of clearance, Immunoglobulin levels & IL-6 levels
Results: during the study period we reviewed 50 patients with hematological malignancy who were diagnosed with confirmed COVID-19 since March 2020, 8 patients fit the inclusion criteria, all of them were having advanced stage lymphoma at some point.
4 patients died, 75% of them had ECOG ≥2 & all of them never cleared the COVID-19 virus, 3 patients recovered, 1 is still recovering but still has reactive COVID PCR test, remains in very stable condition.
the other 4 patents who recovered, 2 cleared their infection within 14 days, 1 patient had reinfection within 3 months & 1 still has positive COVID PCR after 30 days of infection, all of them were in complete remission at time of COVID-19 infection & all of them has mild infection

Summary/Conclusion: Treatment with monoclonal antibodies including regimens during COVID-19 pandemic should be used with caution in regards of its outstanding benefits vs risk of severe & fatal COVID-19 infection in this critical point of time. It was noticed that achieving hematologocal remission is an important factor in patient survival & recovery from COVID-19 infection, patient who died had lower COVID-19 PCR CT values than the patients who survived & never cleared the virus, however survivors mostly had delayed viral clearance than general population in general

PB1455 TREATMENT PATTERN AND PROGNOSIS ANALYSIS OF NEWLY DIAGNOSED T / NK CELL LYMPHOMA PATIENTS

N. Takahashi [1,*], K. Tsukasaki [1], K. Tanae [1], M. Kohri [1], C. Asou [1], D. Okamura [1], M. Ishikawa [1], T. Maeda [1], N. Kawai [1], A. Matsuda [1], N. Asou [1]

[1]Hematology, Saitama Medical University International Medical Center, Hidaka City, Japan

Background: Mature T / NK cell lymphoma account for 10 to 20% of all malignant lymphomas, and their treatment results are poor compared to B-cell lymphomas. The standard treatment is CHOP therapy, but the therapeutic effect is not sufficient. Here, we examined the treatment results of mature T / NK cell lymphoma in our institution.
Aims: To characterize treatment patterns and outcome for newly diagnosed mature T / NK cell lymphoma patients.
Methods: We retrospectively analyzed 123 cases of mature T / NK cell lymphoma who visited our institution from April 2007 to December 2017 based on medical records.
Results: 81 men and 42 women, with median age 68, range 31-90 years. Diagnosis was PTCL-NOS 34 (27.6%), AILT 24 (19.5%), ENKL 23 (18.7%), ALCL 15 (12.2%), ATL 17 (13.8%), MEITL 6 (4.9%) and others 4 (3.3%). Clinical stage I-II 39 (31.7%), extranodal involvement 93 (75.3%), B symptoms 21 (17.7%), bone marrow infiltration 21 (17.1%). Chemotherapy was performed in 109 (88.6%), CHOP 52 (47.7%), CyclOBEAP 17 (15.6%), and 2/3 DeVIC + radiotherapy 14 (12.8%). 9 (7.3%) received only palliative care. The median observation period was 17 months, and the 3-year OS and PFS were 51.6% and 40.2%, and the 3-year PFS of chemotherapy patients was 46.8%. By histological subtype, ALCL ALK+ 100%, ALCL ALK- 66.7%, ENKL 46.5%, AILT 39.7%, PTCL 34.2%, ATL 22.5%, MEITL 0%. By multivariate analysis, PIT, response to initial therapy and MEITL were associated with PFS(P=0.011, P<0.001, P=0.006). PIT, response to initial therapy and Age was associated with OS (P=0.011, P<0.001,P=0.009).
Summary/Conclusion: Mature T / NK cell lymphoma generally have a poorer prognosis than DLBCL, but the prognosis differs depending on the histological subtype, and it is important to determine a stratified treatment policy in the future.

PB1456 SUCCESSFUL TREATMENT BRENTUXIMAB VEDOTIN OF CD30-NEGATIVE ANGIOIMMUNOBLASTIC T-CELL LYMPHOMA: CASE REPORT

E. Lepik [1,*], E. Kondakova [1], V. Baykov [1], N. Mikhaylova [1], A. Kulagin [1]

[1]Pavlov University, Saint Petersburg, Russian Federation

Background: Angioimmunoblastic T-cell lymphoma (AITCL) is one of the aggressive histological variants of peripheral T-cell lymphomas. About 70% of patients receiving first-line treatment develop a relapse or a refractory course. There are currently no treatment standards for relapsed/refractory (r/r) AITCL. A number of new therapeutic approaches aime to improve the results in patients with r/r AITCL, including immunotherapy with an effect not only on tumor cells, but also on cells of the microenvironment.
Aims: We want to demonstrate a case of successful treatment Brentuximab vedotin of CD30-negative angioimmunoblastic T-cell lymphoma.
Methods: A 55-year-old woman was diagnosed with angioimmunoblastic T-cell lymphoma who presented with IVB stage of disease with involvement of the cervical, supraclavicular lymph nodes, palatine tonsils, intrathoracic, axillary lymph nodes, intra-abdominal, retroperitoneal lymph nodes, iliac, inguinal lymph nodes, spleen, skin and bone marrow. The patient underwent several lines of chemotherapy and immunotherapy without achieving an effect (CHOP, GDP, CsA, 5-Azacytidine). After treatment, the therapeutic effects were evaluated by PET-CT. The tumor cells did not have CD30 expression, but due to the presence of CD30 expression on healthy cells of the microenvironment, it was decided to use Brentuximab vedotin (Bv) as a salvage-therapy.
Results: On Bv therapy, a partial response was achieved with an improvement in the quality of life (13 injections were performed in total - 4 in combination with Bendamustine and 3 with Rituximab). Therapy was continued with lenalidomide, resulting in a complete response.
Summary/Conclusion: This clinical case demonstrates that complete response was achieved by the effect of drugs on microenvironment but not on tumor cells, which emphasizes the immune dependence of this histological variant of PTCL.

PB1457 DIFFUSE LARGE B-CELL LYMPHOMA AND HIGH-GRADE B-CELL LYMPHOMA: THERAPEUTIC RESPONSE - UNICENTRIC RETROSPECTIVE DESCRIPTIVE ANALYSIS

B. Castro [1,*], C. Pedrosa [1], R. Peixeiro [1], R. Coutinho [1], P. Seabra [1], R. Cabral [1], L. Regadas [1], C. Casais [1], A. Mota [1], C. Gonçalves [1], L. Xavier [1], J. Coutinho [1]

[1]Serviço de Hematologia Clínica, Centro Hospitalar Universitário do Porto, Porto, Portugal

Background: Relapse/refractoriness (R/R) in diffuse large cell B lymphomas (DLBCL) and high grade (HG- DLBCL) affects more than 1/3 of patients and the existence of a poor prognosis poor prognosis and therapeutic challenge is well known.
Aims: This unicentric retrospective analysis aims to describe the response to 1st-line treatment and relapse of patients with DLBCL and HG- DLBCL.
Methods: Retrospective analysis of DLBCL or HG- DLBCL patients diagnosed and treated at a center between 2015 and 2019. We identified 125 with the diagnosis of DLBCL or HG- DLBCL between 2015-2019. Among this group, 58 did not undergo in curative chemoimmunotherapy (CIT). We report the results of a statistic analysis.
Results: The DLBCL group comprised 47 patients (81%), 13% G-DLBCL (13%) and 6% PTLD; 9% with involvement of extranodal sites. 55% were men; median age of 61 years (52% >60 years); 10% with ECOG ≥2. 10% were HIV+. The International Prognostic Index (IPI) was calculated: low: 26%; low intermediate: 30%; high intermediate: 33%; high: 7%.
The CIT schemes were R-CHOP (n=44), R-CNOP (n=10), R-mini-CHOP (n=8), others (n=5). The dose/replacement adjustment of anthracycline was made in patients aged > 60 years, high ECOG and/or comorbidities. 25% were treated with radiotherapy alone. 67% achieved complete response (CR).
R/R was 44.8% (recurrence n=10; refractoriness n=20). The median time to relapse was 10.5 months. At diagnosis these patients had IPI ≥2 in 87%, mass >7cm in 50% and 73% were CD5+. The activated B Cell subtype was identified in 1/3 of the cases. Five were double/triple-expressor and two double-hit.
Twenty-four patients underwent in second-line therapies. Only 29% (n=7) achieved CR (R-ICE n=3; R-DHAP n=2; R-Bendamustine n=1; CVP n=1). Four patients underwent autotransplantation. Eight performed ≥3 therapeutic lines.
The median follow-up was 19.3 months. The mortality rate was 36%. 71% died from disease progression. The median overall survival of patients undergoing 1st CIT was 39 months.
Summary/Conclusion: By advanced age, commorbidities and/or high ECOG, only 54% of patients with DLBCL or HG- DLBCL were elected to curative CIT. Of the remaining, only 9 are alive with follow-up time ≥ 18 months. The patients studied presented characteristics, risk factors and unsatisfactory responses to CIT in R/R, as described in the literature. Thus, we emphasize the need for therapeutic strategies adapted to improve prognosis.

PB1458 MYD88 EXPRESSION IN PRIMARY AND SECONDARY CNS LYMPHOMAS

B. Balık Aydın [1,*], Y. G. Mutlu [1], A. Çakır [2], Ö. G. Sevindik [1]

[1]Department of hematology, [2]Department of pathology, Istanbul medipol university, Istanbul, Turkey

Background: Myeloid differentiation primary response 88 (MYD88) is a common adaptor protein that is responsible for signaling from several receptors; is encoded by the *MYD88* gene. [1].

Aims: Aim: We aimed to document the level of MYD88 expression, and their associations with clinicopathological parameters in CNS Lymphomas.
Methods: Methods: A total of 9 patients were included in the study. MYD88 protein expression was evaluated by immunohistochemistry (IHC) using two different scoring systems. All samples were diagnosed and selected by a hematopathologist. Tissue samples were collected from all patients before treatment.
MYD88 cytoplasmic expression was classified as four categories according to the staining intensity on a scale from 0 to 3 as follows: 0, no reaction; 1, weak reaction; 2, moderate reaction; and 3, strong reaction. This classification was called the first classification model. In the second classification model, the extent of staining scored as 0 (0% of tumor area stained), 1 (< 10%), 2 (10–50%), or 3 (> 50%) [2]. Staining intensity and the percentage of tumor cell positivity were evaluated and recorded by a hematopathologist.
Results: A majority of the patients in our CNSL cohort had an ABC-like immunophenotype, as has been previously reported [3]. MYD88 protein expression was seen in 8/9 cases (88,8%) and varied widely by intensity and density of expression. Five patients (55,5%) showed high-level MYD88 expression.1 patient didn't show protein expression. 3 of patient (patient 2,3and 9) dead after the diagnose who shows low expression of MYD 88.

Patient	MYD 88 first cl.	MYD 88 second cl.	pathology	localization	Lymphoma type
1	3+	90% (3)	Dlbcl-abc	Temporal lobe	Primary cns
2	1+	20% (2)	Extranodal marginal zone lymphoma	Spinal mass	Patient was lost before evoluation
3	1+	30% (2)	Dlbcl-abc	cerebellum	Primary cns
4	-	-	Dlbcl-abc	Foramen luschka mass	Primary cns
5	2+	100% (3)	Follicular lymphoma -3a	Epidural mass	Secondery cns
6	3+	95% (3)	Dlbcl-abc	Parietal lobe	Primary cns
7	1+	100% (3)	Dlbcl-abc	Temporal lobe	Secondery cns
8	3+	100% (3)	Dlbcl-abc	cerebellum	Secondery cns
9	1+	40% (2)	Dlbcl-abc	Occipital lobe	Primary cns

Summary/Conclusion: Conclusion: MYD 88 protein expression was found both of primary and secondary CNS lymphomas regardless of lymphoma subtype. Further studies are needed for its relationship with prognosis.

PB1459 SUCCESSFUL MANAGEMENT OF EARLY CENTRAL NERVOUS SYSTEM RELAPSE IN A PATIENT WITH PRIMARY MEDIASTINAL LARGE B-CELL LYMPHOMA

R. Lozynskyy [1,2,*], Y. Vyhovska [3,4], I. Bogdan [5], O. Leshchuk [6], Z. Maslyak [3]

[1]Medical Center "Delta Med", [2]Private Clinic "Doctor Smart", [3]Hematology, Institute of Blood Pathology and Transfusion Medicine, [4]Hematology, Danylo Halytskyi Lviv National Medical University, [5]Neurosurgical, Military Medical Center of the Western Region, [6]Medical Center "Salutas", Lviv, Ukraine

Background: Secondary central nervous system involvement as a relapse of primary mediastinal large B-cell lymphoma (PMLBCL) is an infrequent complication that drastically diminishes survival of the affected patients. Whole-brain radiotherapy and high-dose methotrexate (HD-MTX) were reported to improve the disease outcome, nevertheless, the median overall survival varies from 2 to 19 months, according to different authors. Here we present a case of complete cure of this condition.
Aims: The aim of the study was to outline the features of the disease course and management that could lead to long-term survival in case of primary mediastinal large B-cell lymphoma with secondary central nervous system involvement.
Methods: The 19-years-old male patient developed dyspnea and pain in the shoulder in June 2011. There were palpable subclavicular and left axillar lymph nodes revealed, and CT showed conglomerate in the mediastinum sized 160x135x190 mm together with contrast accumulation in both lungs and pleural effusion. Histological and immunohistochemical findings supported the diagnosis of PMLBCL. IPI was considered as low-intermediate. Initially patient received 2 CHOP-Bleo followed by 6 R-CHOP cycles, resulting in CR. Initially patient had received 2 CHOP-Bleo cycles of chemotherapy, followed by 6 R-CHOP cycles resulting in CR. One month later, however, intensive headaches developed. MRI revealed 71x62mm tumor in the right hemisphere (see picture). Right craniotomy with subtotal tumor resection had been performed, followed by 50 Gy ^{60}Co γ-therapy that was used locally on the bed of the removed tumor with subsequent 42 Gy total brain irradiation. After resolution of cytopenia, 2 cycles of HD-MTX 3.5g/m^2 and rituximab 0.375g/m^2 were initiated with 3-week interval between cycles. Immunochemotherapy had been stopped due to the acquisition of acute viral hepatis B, and therapy with peg-interferon-α-2b (peg-IFN) 0.12g weekly was started and lasted 6 months.
Results: The decision to perform subtotal CNS tumor resection instead of biopsy was made intraoperatively by the surgeon, as the result of the macroscopical resemblance of the tumor to glioblastoma. Nevertheless, histology confirmed extranodal PMLBCL in the resected tissue. In the post-operative period, the patient developed secondary epilepsy, successfully controlled with carbamazepine. HD-MTX caused neutropenia with mild infectious complications. The switch from peg-IFN to tenofovir in the treatment of hepatitis B resulted in improvement of the symptoms of epilepsy. Residual dysmorphic changes in the right hemisphere have diminished spontaneously on the further MRI examinations. Body PET-CT after the stop of peg-IFN showed metabolically negative residual tumor mass in the mediastinum, sized 37x24x36mm. Biopsy revealed no bone marrow infiltration with PMLBCL. On the last PET-CT, performed 5 years after the CNS relapse, mediastinal residual tissue was slightly decreased to the maximal size of 29 mm. After the combined therapy the patient remains disease-free for 97 months. He has healthy biological son, born 3 years after the last cycle of HD-MTX.

Summary/Conclusion: Combination therapy including both surgical subtotal resection of localized CNS tumor instead of biopsy and subsequent local and whole brain irradiation followed by HD-MTX-containing regimens, can lead to the long-term remission and could possibly be curative for CNS relapse in some patients with PMLBCL. Further studies are needed to confirm the feasibility of this strategy.

PB1460 BELINOSTAT IS WELL TOLERATED AND EFFICACIOUS IN A PATIENT WITH EARLY RELAPSED PERIPHERAL T-CELL LYMPHOMA: A CASE REPORT.

M. Cimminiello [1,*], R. Chiacchio [2], A. Fé [3], S. P. Pascale [1], N. Filardi [1], A. Amendola [1], I. Chitarrelli [1], A. Matturro [1], D. Vertone [1], F. Centore [4], A. Di Fazio [5], G. Vita [6], M. Pizzuti [1]

[1]UOC di Ematologia con TMO, AOR San Carlo di Potenza, [2]SIC di Anatomia Patologica e Citodiagnostica, AOR San Carlo, [3]UOC di Medicina NUcleare, [4]UOC di Farmacia, [5]SIC di Medicina Legale, AOR San Carlo di Potenza, [6]SIC di Anatomia Patologica e Citodiagnostica, I.R.C.C.-C.R.O.B. Rionero in Vulture, Potenza, Italy

Background: Background: Peripheral T-cell lymphomas (PTCLs) are an aggressive and heterogeneous group of lymphomas with a T-cell origin. They are a rare entities, accounting for 10-15% of Non- Hodgkin lymphomas. The disease is generally incurable if refractory in the absence of transplantation and treatment is aimed at prolonging life and reducing disease-related symptoms. Belinostat is a histone deacetylate inhibitor that was granted accelerated approval by the US Food and Drug Administration on July 3, 2014, for the treatment of patients with relapsed or refractory PTCLs. Continued approval for this indication may be contingent upon verification and description of clinical benefit in the confirmatory trial.
Aims: Case report.

Methods: Case Summary: 60 year old male patient with PTCL not otherwise specified (PTCL-NOS), Ann Arbor stage IVE B, was being treated with four cycles of chemotherapy with CHOEP-21; he achieved a partial remission and a complete remission of disease after completing six cycles CHOEP-21. About 7 months after the end of treatment, he achivied a first relapse. The patient was treated with three courses of GemOX obtained a stable disease. A third line chemotherapy regimen with three cycles of DHAP protocol did not result in lymphoma remission. Subsequent treatment with Belinostat. After three cycles of belinostat, the patient achieved a partial response. After 6 months of belinostat therapy (8 cycles), the patient has maintained a PR. Belinostat therapy was well tolerated for all eight cycles with mild hematological and no hematological toxicities without any toxicity more than CTC grade 2. Belinostat therapy the patient in PR refused to continue the treatment. Two months later we observed a progression of disease and died.
Results: Monotherapy with belinostat has efficacy in Peripheral T-cell lymphomas.
Summary/Conclusion: Discussion: monotherapy with belinostat has comparable efficacy to other agents used in this setting and it is well tolerated in regard to hematologic events, but there is limited data on patient-reported outcomes, reduction in disease-related symptoms, or quality of life.

PB1461 INCIDENTAL DIAGNOSIS OF BURKITT LYMPHOMA ON CECAL APPENDIX: CASE REPORT AND LITERATURE REVIEW

S. Mallano [1,*], C. Buquicchio [1], V. Carluccio [1], G. De Santis [1], C. R. Germano [1], M. Leo [1], G. Lerario [1], R. Miccolis [1], T. M. Santeramo [1], S. Maria Serafina Anna [1], G. Tarantini [1]

[1]*Hematology, p.o. dimiccoli barletta, barletta, Italy*

Background: Primary lymphoid organs are bone marrow and thymus. The secondary lymphoid organs are spleen,lymphonodes and lymphoid tissue associated to mucous membranes.Cecal appendix,therefore,can be site of NHL such as Burkitt lymphoma.BL is an aggressive NHL characterized by translocation and deregulation of the MYC gene on chromosome 8 and the heavy chain gene on chromosome 14.The t(8;14) is the most common translocation in BL occurring in 70-80% of cases.BL is derived from germinal center B cells and hystologicaly is characterized by a monomorphic population of matur lymphocytes with basophilic cytoplasm and prominent vacuoles.The result is a "starry sky" apparence due to macrophages containing cellular debris.The malignant cells express B-cell markers including CD19-CD20-CD79A-PAX5 and for germinal center markers CD10 and bcl6 but are negative for bcl2.There are only 30 cases of appendiceal Burkitt lymphoma in literature.In this cohort,the patients are predominantly male with an average age of 20 years.The majority of cases clinically presented as classical acute appendicitis,the remainder of cases presented atypical clinic but radiological signs of appendicitis.
Aims: In february 2020,a 44-years old man underwent appendicectomy for the diagnosis of acute appendicitis.Intraoperatively,a significant inflamed,edematous appendix without perforation was identified.Biopsy histology demonstrated marked expansion by lymphoid infiltrate composed by monomorphic intermediate-sized and the characteristic starry sky appaerance.In immunochemistry,the cells are CD20+ CD10+ BCL6+ BCL2- cMyc + with Ki67 proliferative index equal to 90%.The translocation t(8;14) in FISH confirms the diagnosis of Burkitt lymphoma.The patient had no B syntoms and was subjected to bone marrow biopsy without marrow infiltration by Burkitt Lymphoma.Total body CT and whole body PET did not demonstrate evidence of residual disease at any nodal or extranodal side.CSF was negative for neoplastic cells.LDH was normal.The Ann Arbor staging classification corresponde to stage IE, low risk.
Methods: The patient was started on a multiagent steroid and chemotherapy regimen(R-CODOX-M-IVAC)and medicated lumbar punctures.Our therapeutic program is to subject the patient to other cycles of therapy and to peripheral stem cells collection according to NCCN guidelines.
Results: Ours is one of the rare cases of appendiceal BL.This case allows us to underline the importance of hystology after appendicectomy to discover incidental diagnosis of NHL and other pathology with poor prognosis if not treated.
Summary/Conclusion: Approximately 1% of appendicetomies have an incidental finding of an appendiceal neoplasm.A primary appendiceal lymphoma is extremely rare. The predominant PAL histological subtype was DLBCL followed by Burkitt lymphoma.Treatment for Burkitt Lymphoma is stratified on patient age and stage.In adult,current recomandations include multiagent regimens with intensive chemotherapy and immunotherapy with anti CD20.Newer anti-CD20,anti-CD19,CD22 monoclonal antibody are under investigation.Follow up is carried out in the basis of the disease responce according to the Lugano criteria.

Bleeding disorders (congenital and acquired)

PB1462 INHIBITORS IN MILD HAEMOPHILIA A: EXPERIENCE OF A SINGLE SPANISH CENTER

M. Lopez [1,*], E. Lopez Ansoar [1], A. Nieto Vazquez [1], O. Dominguez Muñiz [1], C. Albo Lopez [1]

[1]*Hematology Department, Hospital Alvaro Cunqueiro, Vigo, Spain*

Background: In mild hemophilia A (HA) (F8: C> 5%), Desmopressin (DDAVP) is the 1st therapeutic option. When DDAVP fails (40-50%) FVIII Concentrates (CF8) are of choice with the risk of development of "inhibitors" against F8. Previously, the incidence of inhibitors in non-severe (NS) HA was estimated between 3% and 13%. Recently, certain F8 genotypes eas associated with higher rates of inhibitors (even for some the incidence close to that of severe HA). On the other hand, there are limited data on the optimal therapeutic approach to eradicate inhibitors in these patients
Aims: To report the incidence of inhibitors -as well as their management- in a population of patients with mild HA, attended in a 3rd level center in the last year (2020/1 /1- 2020/31/12) in relation to surgical procedures
Methods: 15 Surgical procedures performed on 10 patients with mild HA (F8: C> 5%), all on demand treatment, and the replacement treatments were recorded. The interventions were 5 tooth extractions (2 multiple), 3 major surgeries, 3 minor surgeries and 4 minor procedures. Only 2 patients had a genetic study. The age, type of surgery, number of previous days of exposure (ED) and duration of treatment are recorded (Table 1).The inhibitor is dislodged 15 days and 2 months after the end of treatment.
Results: Two patients (40% of those who received CF8) developed an inhibitor antiF8; In both cases, it was detected in the 2nd control: patient **4** presented it with maximum titer of 2.56 uBT (N <0.6) and patient 7 reached 12.8 uBT, both *type 1* kinetics. Both patients lost response to DDAVP. In **patient 4**, a "watch and wait" strategy was chosen, with progressive clearance until negative titer at day (d) + 57, without bleeding symptons. For **patient 7**, an immunosuppression (IS) strategy was made (Prednisone 1 mg / Kg / day (5 weeks) and descent to suspension + AntiCD20 375 mg / m2 / weekly, 4 weeks) with progressive decrease in inhibitor titer (1st negative control to d + 51); suffered a retroperitoneal hematoma (treatment: Novoseven®, 7 d). At d+162 we certified the success of IS (Response to DDAVP, Inhibitor <0.4 uBT, F8: C 17%, Pharmacokinetic F8 (35 IU/Kg pdF8): recovery 2.25 and terminal half-life 8.75 h-WAPPS Hemo®)

Summary/Conclusion: The incidence of inhibitors in NS-HA increases progressively with the cumulative number of ED to CF8, apparently without reaching a plateau, unlike that observed in severe HA with estimated risk after 20, 50 and 100 SD at 3.5% (95% confidence interval (CI) 2.1–4.9), 6.7% (CI 4.5–8.9) and 13.3% (CI 9.6–17.0), respectively. The development of inhibitors in NS- HA is a relevant problem being important to establish strategies to reduce the risk: knowing the responsible mutation in order to estimate the risk, maximizing the use of DDAVP and antifibrinolytics,.. among other measures. Furthermore,

it is imperative to know more about the treatment regimens aimed at the eradication of inhibitors in NS-HA. IS seems a valid option, as reported by Kempton in a cohort of 32 patients. The "wait and watch" strategy allows confirming the clearance of the inhibitor, but the confirmation of eradication is also influenced by clinical behavior, since, as we are reminded in the INSIGHT Study, many patients are not re-exposed to CF8. Therefore, it is necessary to deepen the registration and modeling of simple and effective therapeutic strategies to manage this problem, in addition to the invaluable contribution of Emicizumab for the management of these patients, specially in cases in which suppression success is not achieved.

PB1463 ANALYSIS OF SURVIVAL IN PATIENTS WITH ACID SPHINGOMYELINASE DEFICIENCY TYPE B USING A LARGE, DEIDENTIFIED US ELECTRONIC HEALTH RECORD DATABASE

A. Wilson [1,*], G. Miles [2], K. Patel [2], M. Aguiar [1], R. Jacob [3]

[1]Sanofi Genzyme, Cambridge, MA, [2]Aetion Inc., NY, United States, [3]Sanofi Genzyme, Reading, United Kingdom

Background: Acid sphingomyelinase deficiency (ASMD, historically known as Neimann Pick disease types A and B) is a rare metabolic disease characterized by the accumulation of sphingomyelin in cells and tissues. ASMD is divided into subtypes A, A/B and B. Type B (also known as chronic visceral ASMD) is characterized by onset in childhood or adulthood, hepatosplenomegaly, interstitial lung disease, liver dysfunction, thrombocytopenia, and bone disease, whereas type A has onset in infancy, prominent CNS involvement, and death before age 3. ASMD is sometimes confused with Nieman Pick disease type C (NPC), which shares some clinical features but is separate and biochemically distinct. The most common causes of morbidity and mortality in ASMD type B are respiratory and liver failure. Hematologists are often instrumental in the recognition of this underdiagnosed and often life-threatening disease.
Aims: To describe overall survival (OS) in ASMD type B patients in a real-world setting using data from electronic health records (EHRs).
Methods: Patients with ≥ 2 records of of ICD-10 diagnosis codes for ASMD (E75.241 [Type B],E75.248 [Other], or E75.249 [Unknown]) were identified in Optum's deidentified Market Clarity database between January 1, 2007 and December 31, 2019. Patients were excluded if there was any record of an ICD-10 code for NPC or ASMD type A; any evidence of neurological symptoms prior to age 40 years (typical of NPC & ASMD type A/B), or death prior to age 3 (typical of ASMD type A). Additional cohorts with varying inclusion/exclusion criteria were used for sensitivity analyses. The first ASMD diagnosis was the index date. Follow-up period was from the index date until death, end of patient record, or December 31st, 2019. OS was estimated by Kaplan-Meier time to event analyses and a standardized mortality ratio (SMR) - the ratio of the observed number of deaths in the study population divided by the number of expected deaths based on the age- and-sex-specific mortality in a general population.
Results: We identified 46 patients who met the study criteria. Median age was 35 years, 65.2% were female, and median follow-up was 2.3 years. During follow-up, the most common disease manifestations were respiratory disease (60.9%), headache (50%), cardiovascular events (28.3%) and cirrhosis (23.9%). Six patients died during follow-up. The SMR was 17.69 (95% CI: 3.54, 31.84) when compared to a 2007 general population in the database. When compared to a 2017 general population, which more closely approximates the average follow-up time of the ASMD cohort, the SMR was 57.35 (95% CI: 1.15, 113.55). These data suggest that although survival varied widely, ASMD type B patients are substantially more likely to die compared to the general population.
Summary/Conclusion: This study extends our knowledge of survival in ASMD type B patients. Although limited by the small sample size and the lack of a validated algorithm for identifying ASMD type B in an EHR database, results were consistent with known characteristics of the disease. SMRs could be considered as an alternative approach for OS in rare diseases, when sample sizes are small, and the amount of censoring is large. Our data suggest a high risk of premature death in ASMD type B. Additional studies are needed to confirm these findings and investigate factors associated with mortality in this population and explore methods for addressing limitations in time-to-event statistics in rare diseases.

PB1464 TRANSTHORACIC AORTIC VALVE IMPLANTATION (TAVI) IN HEMOPHILIA

M. Lopez [1,*], E. Lopez Ansoar [1], A. Nieto Vazquez [1], O. Dominguez Muñiz [1], C. Albo Lopez [1]

[1]Hematology Department, Hospital Alvaro Cunqueiro, Vigo, Spain

Background: The increase in life expectancy of hemophiliac patients leads to the appearance of health problems whose proper managment is not clearly defined. Cardiac Surgery presents a major hemostatic challenge for a multitude of reasons, particularly in patients suffering from congenital or acquired hemostatic disorders. Acknowledging that, evidence from the literature suggests that cardiac surgery can be performed safely in this patient population
Aims: We reported the first TAVI performed in our hospital in hemophiliac patient, the management during and after hospital discharge
Methods: Male, 74 years, mild hemophilia A (F8:C 9%, F8 chromogenic 5,4%) without inibitor AntiF8(< 0.6 Bethesda Units, uBT). We not know the responsible mutation. In the past, he received treatment with different Concentrates of F8 (the last, ReFacto AF®). Previous surgeries: Total Hip Prostesis. CV Risk Factors: Arterial Hypertension (Medical treatment), Obesity, Diet-controlled hyperglycemia. He has a chronic liver disease due Virus C.
He had an Severe Aortic stenosis who needed surgical replacement and the chosen option was TAVI to reduce the surgical risks, among which bleeding
Results: 30 minutes before the procedure, ReFacto AF® 50 IU / kg was administered; A 29 mm Corevalve Evolut® R prosthesis was implanted, for which access was required through both femoral and right jugular veins to place a temporary pacemaker, a procedure that required the use of Unfractionated Heparin (5000 IU) without complications. At 3 hours, a 2nd dose of ReFacto AF® of approx. 10 IU / Kg was administered and the plasma levels of F8 were monitored using the chromogenic technique (level 110%). 8 hours after the 1st administration, ReFacto AF® started every 8 hours to maintain a trough level of approx 80% for first 48 hours, then adjusted every 12 hours (trough level of 50%) up to 7 days, then 30% (Desmopressin and ReFacto AF, alternate days) until completing 12 days of treatment. Simultaneously, antithrombotic prophylaxis was started with Enoxaparin® 40 mg (from day +1 to discharge) and simple antiplatelet therapy (ASA 100 mg / day), which he currently maintains. Hospital dischage was at day +14.
The inhibitor was removed 15 days and 2 months after the procedure - according to the protocol of our service - resulting negative. The patient reports an improvement of his quality of life, compared with the previous one, with disappearance of associated symptoms and progressive increase of physical activity, more according to his age and general condition
Summary/Conclusion: We present a succesfully case of TAVI in mild haemophiliac patient. TAVI is a safe and effective option versus open heart surgery in high-risk patients as haemophiliac patients. A search in PuBmed® database, crossing 2 topics: Aortic Stenosis and Haemophilia, showed 5 citations, 1 for Haemophilia B and 4 Haemophilia A; just case reports, so we consider it interesting to communicate our experience in order to generate scientific evidence so as not only to recomend this therapeutic option as of choice in these patients but also to guide the performance of the procedure, in close collaboration with cardiologists and anesthetists

PB1465 EVALUATION OF THE EFFICACY OF MOROCTOCOG ALPHA DURING THE PREVENTIVE TREATMENT OF PATIENTS WITH HEMOPHILIA A

V. Voitsekhovsky [1,*], T. Zabolotskikh [1], C. Mansvetova [2], I. Shestopalova [2], I. Sayapina [1], O. Prikhodko [1], I. Menshikova [1]

[1]Amur State Medical Academy, Blagoveshchensk, [2]Regional Clinical Hospital, Khabarovsk, Russian Federation

Background: The emergence of modern concentrates of coagulation factor VIII (FVIII) has changed the management tactics and improved the quality of life of patients with hemophilia A, compared to the period before 2005, when such patients in Russia received therapy with cryoprecipitate and fresh frozen plasma (FFP).
Aims: The objective of the observational study was a retrospective analysis (2017 - 2019) of the efficacy of using a recombinant

antihemophilic factor (coagulation factor VIII drug with a deleted B domain) - Moroctocog alpha for the prophylactic treatment of patients with severe and moderate forms of hemophilia A living in the Amur Region and in the Khabarovsk Territory of the Far Eastern Federal District of Russia.
Methods: Patients with hemophilia A over the age of 20 were divided into 2 groups. In group 1 - 21 patients received substitution therapy with Moroctocog alpha; age composition: 40-50 years old (n = 10), 30-39 years old (n = 6), 20-29 years old (n = 5). All patients were diagnosed with hemophilic arthropathy: deforming arthrosis of the knee (n = 21), ankle (n = 12), elbow (n = 16) joints. Group 2 included 21 patients who received plasma FVIII and octocog alpha at the age of 40-50 years (n = 8), 30-39 years (n = 8), 20-29 years (n = 5). All patients were diagnosed with hemophilic arthropathy: deforming arthrosis of the knee (n = 21), ankle (n = 13), elbow (n = 17) joints. In both groups, there were 13 patients with severe and 8 with moderate forms of hemophilia A. In both groups, FVIII concentrates at a dose of 20-40 IU / kg of body weight were injected every 2-3 days (2-3 times a week).
Results: Until 2005, when patients of both groups received therapy with cryoprecipitate or FFP "on demand", all of them had frequent hemorrhagic complications from 52 to 6 episodes per year, bleeding and hemorrhage were of all severity, including life-threatening; patients with a severe form were hospitalized 8-10, and with a moderate form - 4 times a year. During the study period, against the background of prophylactic use of the Moroctocog alpha drug and other FVIII drugs no more than 2 episodes of bleeding (spontaneous and post-traumatic) of mild and moderate severity were noted in 7 patients of the first group and 6 patients of the second group. Spontaneous bleeding was diagnosed only in patients with low adherence to treatment, which was stopped by the administration of the drug in therapeutic doses, mainly on an outpatient basis, and rarely required hospitalization. The desired indicators of clinical control were achieved - no more than 2 cases of spontaneous hemarthrosis or other bleedings per year. In both groups, it was possible to achieve a 98% reduction in the number of bleedings compared to the period before 2005, when these patients received treatment with cryoprecipitate and FFP "on demand". When using Moroctocog alpha there were no adverse reactions in patients.
Summary/Conclusion: It was concluded that Moroctocog alpha is not inferior to plasma concentrates FVIII and Octocog alpha in terms of efficacy and safety, and can be effectively used for the preventive treatment of bleeding in hemophilia A.

PB1466 COVID INFECTION REVEALING FACTOR XI DEFICIENCY IN ELDERLY PATIENT

K. Hajar [1,*], B. ghita [1], C. wyssal [1], J. nissrine [1], A. wafae [1], M. mouna [1], H. hicham [1], T.-M. zoubida [1], A. mohammed [1]

[1]internal medecine and clinical hematology, university hospital centre IBN SINA, faculty of medecine and pharmacy of RABAT, university Mohammed V of Rabat, rabat, Morocco

Background: Factor XI deficiency, acquired or constitutional, constitutes a pathology
moderate hemostasis
The hemorrhagic symptomatology of factor XI deficiency varies between patients and
even in the same patient, and requires a triggering factor.
Coagulation disturbances are commonly seen in patients with COVID19. If thrombosis is a clinical feature
predominantly of COVID 19 contributing to visceral failures, events bleeding is infrequent and is probably related to vascular coagulation disseminated.
Aims: We report the case of an 84-year-old subject in whom a covid 19 would have
allowed the late revelation of a constitutional factor XI deficiency.
Methods: We report the case of an 84-year-old subject in whom a covid 19 would have
allowed the late revelation of a constitutional factor XI deficiency.
Results: An 84-year-old patient was admitted to an intensive care unit for the management of acute respiratory distress. He does not report any history of hemorrhage and no similar case in the family.
The clinical examination on admission found signs
respiratory struggle, 90% saturation in ambient air, a syndrome mucocutaneous hemorrhagic disease consisting of clot hematuria, epistaxis and a
extensive hematoma of the rectus abdominis muscles measuring 14 cm / 6 cm, the chest scanner suggested pneumonia COVID type classified CORADS 5 extended over 50-75% of lung surface associated with right proximal pulmonary embolism. an isolated prolongation of the activated partial thromboplastin time at 1.38 without thrombocytopenia, elevation of dimers or consumption of fibrinogen. Wilbrand factor antigen and activity were normales. The exploration of coagulation factors of the endogenous pathway has objectified
a factor XI deficiency estimated at 36%. The hypothesis of a constitutional factor XI deficiency
decompensated by SARS cov 2 infection was therefore raised
The treatment was based on
symptomatic treatment with oxygen therapy and replacement with fresh plasma
frozen. The evolution was marked, after regression of the SARS cov 2 pneumonia,
by the control and the absence of recurrence of hemorrhagic manifestations.
Summary/Conclusion: Constitutional factor XI deficiency is a rare deficiency in coagulation but its incidence
remains underestimated, as it is rarely responsible for a hemorrhagic syndrome and requires a triggering factor for the hemorrhagic syndrome. In our patient, infection with Covid 19 was the viral infection responsible for triggering hemmoragic syndrome secondary to factor XI deficiency.

Bone marrow failure syndromes incl. PNH - Biology & Translational Research

PB1467 APLASTIC ANEMIA PATIENTS COULD BE DIVIDED INTO TWO SUBGROUPS BASED ON THE GENE EXPRESSION IN THEIR BONE MARROW MULTIPOTENT MESENCHYMAL STROMAL CELLS

A. Dorofeeva [1,*], I. Shipounova [1], A. Luchkin [2], Z. Fidarova [2], E. Mikhailova [2], S. Valery [3]

[1]Physiology of hematopoiesis Lab, [2]Department of chemotherapy of hemoblastosis and depression of hematopoiesis with a day hospital, [3]General Director, National Research Center for Hematology, Moscow, Russian Federation

Background: Aplastic anemia (AA) is caused by hematopoietic stem cells (HSC) damage resulting in a bone marrow (BM) failure. An autoimmune attack is the most frequent but probably not the only origin of it.
Aims: The aim of the study was to analyze stromal microenvironment in BM of untreated AA patients through the multipotent mesenchymal stromal cells (MMSC).
Methods: The study included 21 AA (8 with severe AA (SAA) and 13 with non-severe AA (NAA)) patients in the debut. In all patients BM was aspirated after informed consent at diagnostic punctures. MMSC were isolated and cultivated by the standard method. RNA was extracted on passage 1 by the standard protocol. Gene expression was analyzed with Taqman modification of RT-PCR. As a control BM samples of 19 healthy donors of according age were used.
Results: Comparison of gene expression in MMSC from SAA and NAA patients revealed the significant decrease in the expression of *FGF2*, *SDF1*, and *IL1R* in SAA patients. The expression of *FGFR2*, *PTGES*, and *ANGPT1* was significantly decreased in SAA patients compared to donors. MMSCs from NAA patients, on the contrary, revealed increased expression of *FGFR1*, *TGFB2*, and *CFH* in comparison with donors. Thus, stromal precursors in NAA and SAA are altered differently. Probably, it reflects initial differences in the pathogenesis of these forms of AA.
In MMSC of 6 AA patients (3 with NAA and 3 with SAA) there was no expression of *TGFB1*, *ANGPT1*, *IDO1*, and *PTGES*. Moreover most of the other studied genes were dramatically down-regulated in these MMSC (Table). In 5 out of 6 patients these changes were detected even after 6 months of immunosuppressive therapy, while all these patients had responded to the treatment and reached partial remission or hematological improvement within 6 months. So the disrupted expression of these genes may be permanent. Despite of the absence of expression *TGFB1* and *ANGPT1*, which are factor crucial for the hematopoiesis,

the hematopoiesis was partly restored. Both TGFB1 and ANGPT1 regulate quiescence of HSC. Therefore, the lack of these factors could induce HSC activation. The determination of these factors expression in long-term observation may explain mechanisms of HSC survival in such patients. What factors are responsible for the maintenance of hematopoiesis in these patients is the subject of ongoing study.

Table. Relative gene expression level in MMSC from AA patients, subdivided on the absence or presence of *TGFB1* expression

	donors(n=19)	No TGFB1 expression (n=6)	TGFB1 expression is detected (n=15)
FGF2	1.76±0.35	1.03±0.19	4.96±1.37* **
FGFR1	0.07±0.02	0.49±0.06*	0.18±0.07 **
FGFR2	0.24±0.06	0.04±0.02*	0.76±0.44
CFH	0.69±0.14	0.25±0.06*	1.65±0.32 **
TGFB1	0.91±0.12	0±0	1.19±0.12 **
TGFB2	1.64±0.3	0.002±0.001*	6.26±1.19* **
HGF	0.41±0.08	0.07±0.03*	1.65±0.32* **
PDGFRA	0.05±0.03	0.36±0.17	1.26±0.38* **
PDGFRB	0.62±0.1	0.02±0.01	0.16±0.08
PTGES	0.17±0.03	0±0	0.2±0.05 **
IDO1	0.002±0.001	0±0	0.02±0.01
JAG1	1.08±0.47	0.004±0.002*	2.77±1.1 **
IL1R	1.29±0.69	0.0002±0.0002*	1.27±0.3 **
SDF1	2.84±0.42	0.001±0.001	1.04±0.26 **
ANG1	0.68±0.19	0±0	2.18±0.71 **

* - significant differences from donors, ** - significant differences from the subgroup without *TGFB1* expression

Summary/Conclusion: Stromal precursors in BM of untreated NAA and SAA patients are impaired differently. This effect could reflect the different causes of these forms of AA or be the consequence of compensatory reaction of stromal microenvironment to the various levels of hematopoiesis failure. Two subgroups of AA patients had been revealed, which dramatically differ in the pattern of gene expression in MMSCs.

PB1468 IDENTIFICATION OF A NOVEL DELETION IN THE RPS26 GENE IN A GREEK CHILD WITH THE DIAGNOSIS OF BLACKFAN-DIAMOND ANEMIA

I. Pelagiadis [1,*], N. Katzilakis [1], C. Sofocleous [2], M. Stratigaki [1], E. Athanasopoulos [1], E. Stiakaki [1]

[1]Pediatric Hematology-Oncology, School of Medicine, University of Crete, University Hospital of Heraklion, Heraklion, [2]Medical Genetics, School of Medicine, University of Athens, «Aghia Sophia» Childrens' Hospital, Athens, Greece

Background: Blackfan-Diamond Anemia (BDA) is a rare congenital bone marrow failure (BMF) syndrome characterized by selective aplasia of the erythroid progenitor lineage. Typically BDA is diagnosed within the first year of life, with the presentation of normochromic, microcytic anemia accompanied by reticulocytopenia. BDA is caused by inherited or de novo mutations in ribosomal proteins and is recognised as the first known human ribosomopathy. Symptoms are heterogenous, even between affected family members carrying the same mutations. Most often the genes involved are RPS19, RPS24, RPS 17, RPL35A and RPS 26. RPS 26 is responsible for 2.5-6% of DBA patients and to date 30-disease causing variants have been reported. Many of the patients affected present with clinical malformations, and there seems to be a correlation between the phenotype and genotype.
Aims: We describe a case of DBA presenting with heart failure secondary to a serious severe anemia.
Methods: A 3 month old male infant, due to poor feeding and marked paleness undertook a full blood count which revealed remarkable anemia (Hb 1.8 g/dL). The infant was born at 35w gestation age and admitted in NICU due to low birth weight and jaundice though phototherapy was not applied. In the newborn period the infant was feeding well and presented no respiratory distress. Prenatal history was unremarkable and there was no history of anemia. Physical examination revealed no dysmorphic features and normal appearing with no evident anomalies.
The infant was immediately transfused, however, due to deterioration of its clinical condition with gasping and cardiac failure accompanied by bradycardia, was transferred to PICU and eventually intubated. The infant presented kidney failure, with reduced diuresis and hypertension and received anti-hypertensive treatment. The reticulocyte index upon admission was 3.4 percent and all other hematologic parameters and bilirubin levels were normal. A peripheral smear showed the presence of all white blood cell lineages with normal morphology; platelets were increased and displayed variable size (small to large). Red blood cells were decreased and schistocytes, elliptocytes, spherocytes, and Heinz bodies were not present.
The infant had no signs of hemolysis and the presence of infectious etiologies or structural abnormalities was excluded-negative studies for HIV, parvovirus, toxoplasmosis, and cytomegalovirus infection. Since there was no compensatory reticulocytosis, a congenital anemia associated with BMF, such as Diamond Blackfan anemia, was suspected.
Results: Morphologic review of the bone marrow aspirate exhibited complete absence of the erythroid lineage with the presence of hemophagocytic islets. Taking under consideration the bone marrow morphology in conjunction with the low reticulocyte count, a Blackfan-Diamond analysis was performed for the RPS19, RPL11, RPL5 which was negative. Due to the high index of suspicion, whole exome sequencing was performed which revealed a nucleic substitution of c181+1del IG of the RPS26 gene. The mutation was in heterozygosis with a possible formation of a non functional proteic molecule and not described in literature. Upon confirmation of diagnosis, due to the age (<12m), the infant was commenced on regular transfusions in order to avoid side effects from the use of the corticosteroid treatment. The infant has moderate transfusional needs (approx. once every 3 months).
Summary/Conclusion: As the WES/NGS testing becomes more accessible, novel mutations can be identified providing the possibility of the gene therapy in the future.

Bone marrow failure syndromes incl. PNH - Clinical

PB1469 PROFILE OF HEMOPHAGOCYTIC LYMPOHISTIOCYTOSIS (HLH) – PROSPECTIVE OBSERVATIONAL STUDY

S. Siddaiahgari [1,*], A. Rauthan [1], R. K. CS [2], J. Chakrabartty [3], A. Aribandi [2]

[1]Haematology & Bmt, Rainbow children's Hospital, [2]Haematology & Bmt, American Oncology Institute, Hyderabad, [3]Haematology & Bmt, HCG, Kolkata, India

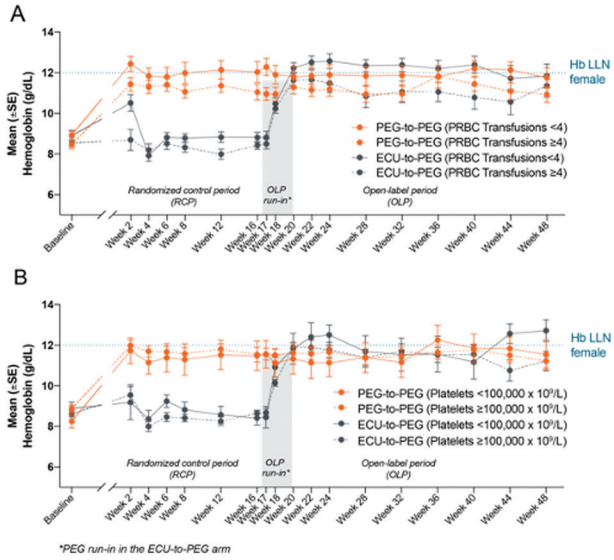
Background: Hemophagocytic Lymphohistioctosis(HLH) is characterised by fever, splenomegaly, cytopenias,hepatitis, altered mental status and neurological involvement. There is marked increase of Histiocytes in bone marrow.
Aims: To study epidemiology, clinical features, laboratory findings & diagnosis of underlying disease associated with HLH and also to assess their response to the treatment
Methods: We enrolled 53 consecutive patients diagnosed with HLH from January 2012 to march 2015 who satisfied the HLH 2009 diagnostic criteria and were between the age of 1 month and 15 years
Results: Most children belonged to age group 31 days -12 months (47.16%). Mean age was 35 months, male (54.71%) children were slightly more affected than female (45.29%) children. The most common presenting symptom in our series was fever (96.2%) and most common sign was pallor (100%). Bone marrow hemophagocytes were demonstrated in 92.15%. Raised S.Ferritin levels >500ng/ml was seen in 98.11% with mean ferritin levels of 4146ng/ml. Transaminitis was seen in 84.9%.Bicytopenia was noticed in 62.26% and pancytopenia in 35.84%. With respect to etiology, Infection was the most common, noticed in 75% of cases. Dengue was found in 14 patients (26.1%). Primary HLH was seen in 5 (9.5%) of children. Out of 53 children enrolled in the study only 47 children received some form of therapy, with prephase steroid alone therapy (n=31) (65.9%) had a improvement in clinical parameter, however on follow up 3 (9.6%) children died and 1 left against medical advice. Among 16 children who had no improvement with steroids were advised complete HLH protocol, but only 12 (25.5%) children parents gave the consent, during course of therapy 7 children died (14.8% in 47) (58.3% in 12 who completed protocol), 3children discharged against medical advice (6.3%) at the time of completion of protocol only 2 (4.2% in 47) (16.6%) in 12 who completed protocol.
Summary/Conclusion: Infection associated HLH has better outcome with early diagnosis and prompt treatment. Primary HLH should be suspected and genetic analysis should be sent for patients <3 yrs, with history of consanguinity and sibling death due to similar condition, those presenting with CNS signs and symptoms & patients who deteriorated rapidly on treatment with Dexamethasone alone

PB1471 LONG-TERM EFFECTS IN SUBGROUPS OF PATIENTS WITH PAROXYSMAL NOCTURNAL HEMOGLOBINURIA TREATED WITH PEGCETACOPLAN VERSUS ECULIZUMAB: 48-WEEK ANALYSIS OF PEGASUS PHASE 3 TRIAL

R. Peffault de Latour [1,*], C. M. de Castro [2], J. Szer [3], K. Usuki [4], P. Hillmen [5], M. Griffin [5], M. Al-Adhami [6], C. Chen [6], H. Nishimori [7], I. C. Weitz [8]

[1]French Reference Center for Aplastic Anemia and Paroxysmal Nocturnal Hemoglobinuria, Assistance Publique – Hôpitaux de Paris, Université de Paris, Paris, France, [2]Duke University School of Medicine, Durham, NC, United States, [3]Department of Clinical Haemotology, Peter MacCallum Cancer Centre & Royal Melbourne Hospital, Melbourne, VIC, Australia, [4]Department of Hematology, NTT Medical Center Tokyo, Tokyo, Japan, [5]Department of Haemotology, St James University Hospital, Leeds, United Kingdom, [6]Apellis Pharmaceuticals, Inc, Waltham, MA, United States, [7]Department of Hematology and Oncology, Okayama University Hospital, Okayama, Japan, [8]Jane Anne Nohl Division of Hematology, Keck-USC School of Medicine, Los Angeles, CA, United States

Background: Pegcetacoplan (PEG), a PEGylated peptide targeting proximal complement protein C3, can control both intravascular and extravascular hemolysis. In the PEGASUS trial (NCT03500549), a phase 3, randomized, open-label, active-comparator controlled study, PEG was shown to be superior to eculizumab (ECU) after 16 weeks in improving hemoglobin (Hb) levels and clinical outcomes in patients with PNH *(Hillmen P et al, EHA 2020)*.



Aims: To identify if the prespecified strata (transfusion history and platelet count) of PEGASUS patients showed additional benefit from PEG vs ECU at 48 weeks.

Methods: Eighty PNH patients (≥18 years) with Hb levels <10.5 g/dL and ECU treatment (≥3 months) were enrolled. Patients entered a 4-week run-in period (RIP) with ECU+PEG (1080 mg subcutaneously 2x/week), then were stratified based on baseline platelet count and prior transfusion requirements, and randomized 1:1 to PEG or ECU monotherapy. The primary endpoint was change in Hb level from baseline to Week 16. Patients could continue to an open label period (OLP) of PEG monotherapy, which included a 4-week RIP (ECU+PEG) for ECU patients (ECU-to-PEG) but not for patients continuing PEG (PEG-to-PEG). Key secondary endpoints were transfusion avoidance and adverse events (AEs). Here, primary and key secondary endpoints were analyzed by subgroups (<4 vs ≥4 packed red blood cell transfusions within 12 months prior to baseline; platelet count at screening [<100,000x10^9/L vs ≥100,000x10^9/L]).

Results: PEG treatment was associated with significantly greater increases in Hb levels from baseline than ECU at Week 16, which were maintained in the PEG-to-PEG arm through Week 48 regardless of baseline subgroup. The ECU-to-PEG arm demonstrated increased Hb levels regardless of prior transfusions (Figure A) or baseline platelet count (Figure B). At Week 48, Hb levels were similar in the <4 (mean [SD]; PEG-to-PEG: 11.8 [1.9] g/dL; ECU-to-PEG: 11.8 [2.2] g/dL) and ≥4 transfusion strata (PEG-to-PEG: 10.9 [1.6] g/dL; ECU-to-PEG: 11.4 [2.2] g/dL). Similar Hb levels were also seen for the <100,000x10^9/L (PEG-to-PEG: 11.5 [2.2] g/dL; ECU-to-PEG: 12.7 [1.4] g/dL) and ≥100,000x10^9/L platelet strata (PEG-to-PEG: 11.2 [1.6] g/dL; ECU-to-PEG: 11.2 [2.3] g/dL).

At Week 48, on PEG monotherapy, both arms had similar proportions of transfusion free patients during the OLP in the <4 (PEG-to-PEG: 80%; ECU-to-PEG: 88%) and ≥4 transfusion strata (PEG-to-PEG: 67%; ECU-to-PEG: 61%). Similar trends were seen in the <100,000x10^9/L (PEG-to-PEG: 75%; ECU-to-PEG: 78%) and ≥100,000x10^9/L platelet strata (PEG-to-PEG: 72%; ECU-to-PEG: 70%).

The most common AEs by physician reported preferred term throughout the study for all patients who received PEG were injection site reactions (36%), hemolysis (24%), and diarrhea (21%). Of all study patients, 30% experienced serious AEs, 6% possibly related to PEG. No cases of meningitis were reported. One COVID-19 death was reported, unrelated to study treatment. Six patients discontinued due to hemolytic events: 5 classified by the treating physician as "hemolysis" and 1 as "hemolytic anemia." Overall, 12 patients (15%) discontinued PEG: 3 in RCP, 8 in OLP due to TEAEs (6 in ECU-to-PEG, 2 in PEG-to-PEG), and one during follow-up; one patient withdrew due to physician decision.

Summary/Conclusion: In the prespecified stratified analysis of PEGASUS, PEG showed treatment effect durability in Hb level with transfusion avoidance in most PNH patients regardless of prior transfusions or baseline platelet count during the OLP through Week 48. The safety profile of PEG was consistent with previously reported data.

PB1472 RHTPO IMPROVES THE OVERALL SURVIVAL OF PATIENTS WITH APLASTIC ANEMIA IN CHINA: RETROSPECTIVE ANALYSIS OF A SINGLE-INSTITUTION

R. Fu [1,*], T. Wang [1], L. Zeng [1]

[1]Tianjin Medical University General Hospital, Tianjin Medical University General Hospital, Tianjin, China

Background: Hematopoietic stimulation therapy is one of the most important dimensions for the treatment of aplastic anemia. The recovery of platelets is the plight of AA recovery.

Aims: To analyze the total effect of rhTPO and(or) rhIL-11 combined with immunosuppressive therapy (IST) for AA patients and compare the effects between them.

Methods: we enrolled 131 AA patients who were divided into 4 groups: the IST group (36 cases), the rhIL-11+IST group (14 cases), the rhTPO+IST group (42 cases), and the rhIL-11+rhTPO+IST group(39 cases). Survival time as well as bone marrow hematopoiesis, peripheral blood cells, immune cell subsets of patients in each group at the 3, 6, and 9 months after ATG/ALG treatment were collected and analyzed.

Results: Patients who were applied IST coupled with rhTPO (including rhTPO+IST group and rhIL-11+rhTPO+IST group) performed much better than without rhTPO group in terms of ORR, improvement of bone marrow hematopoietic, megakaryocyte recovery and overall survival (OS). rhTPO collaborated by rhIL-11 could influence mDC number and help humoral immune reconstitution. Among all the parameters, bone marrow cellularity at 3 months is the only multivariate that affects OS.

Summary/Conclusion: rhTPO is a powerful supplement to IST in treatment of AA, patients could benefit from several aspects, including elevating ORR, shortening bone marrow hematopoietic and magekarocyte recovery time, helping humoral immune reconstitution, and prolonging OS. IL-11 and TPO have a synergistic effect on the mechanism, the combination of these drugs may be the "icing on the cake" for IST treatment of AA.

PB1473 MUTATION ANALYSIS OF CHINESE SPORADIC DIAMOND-BLACKFAN ANEMIA BY NEXT GENERATION SEQUENCING

J. Li [1,*], L. Chen [1], Y. Lin [1], K. Ru [1]

[1]Sino-US Diagnostics Co., Ltd., Tianjin, China

Background: Diamond-Blackfan anemia (DBA) is the second most common congenital bone marrow failure syndrome, after Fanconi anemia, characterized by erythroid aplasia. The estimated prevalence was 5~7 cases per 1000,000 live births in European population and 12 per 1000,000 live births in Japanese population in one year. It is typically occured during infancy and associated with physical abnormalities, such as short stature, craniofacial, upper limb, heart and genitourinary defects. DBA patients also have the tendency of tumor susceptibility, the incidence of which is lower than that in Fanconi anemia or dyskeratosis congenita patients. DBA is commonly diagnosed based on a positive family history, age of onset less than one year old and laboratory findings such as macrocytic anemia, reticulocytopenia, myeloproliferative activity with erythroid precursor cell reduction, elevated erythrocyte adenosine deaminase activity (eADA), and persistence of hemoglobin F (HbF), as well as associated congenital malformations. The phenotypic expression of DBA varies greatly, even in the same family.
Aims: We aimed to expand DBA-related gene mutations library and investigate the relationship between clinical phenotype and genotype in DBA.
Methods: Genomic DNA of 14 clinically suspected congenital DBA patients was selected to detect 71 known genes closely related to congenital bone marrow failure by next-generation sequencing (NGS). The relationship between clinical phenotype and genotype in DBA was analyzed.
Results: We have identified 13 pathogenic variants of 7 genes (RPL11, RPL5, RPS19, RPS26, RPL35A, RPS27, and TSR2) in 14 clinically suspected DBA patients. The ratio of male to female is 1:1. We have identified RPS19 mutations in six patients, and RPL11 and RPS26 mutations in two patients respectively. Among the mutations identified, five were previously reported, and eight variants were novel. Particularly, we have identified one stop-gain mutations, one splicing mutation, four frameshift variants, six missense variants, as well as one start-loss mutation. Except for two adult patients, the other patients were infants, and the median age of onset was one year old. There was no significant difference in gender and age. Among the cases, female patients are more prone to congenital dysplasia or tumor susceptibility. Compared with the European and American patients, the Asian patients with RPS19 and RPL5 gene mutations have a higher rate of congenital dysplasia.
Summary/Conclusion: Our study further fills genetic disease mutation database and enriches the corresponding clinical manifestations. Our results suggested that genetic diagnosis by NGS is a fast, economic and accurate way to detect and identify pathogenic alterations of inherited diseases like Diamond-Blackfan anemia.

PB1474 IDIOPATHIC APLASTIC ANEMIA – ARE THERE OTHER PROGNOSTIC FACTORS?

C. Sol Reis [1,*], R. Pinto [1], M. Sobrinho Simões [1,2,3], F. Trigo [1]

[1]Clinical Hematology, Centro Hospitalar e Universitário São João, [2]Faculdade de Medicina da Universidade do Porto, [3]i3S - Instituto de Investigação e Inovação em Saúde, Porto, Portugal

Background: Idiopathic aplastic anemia (AA) is a rare entity characterized by reduced bone marrow cellularity and consequent pancytopenia due to an immune destruction of the hematopoietic stem cells. Currently there are no defined prognostic scores and therapeutic decision is based on disease severity [according to Camitta's criteria (CC)] and patient's fitness.
Aims: Assessment of prognostic factors in AA.
Methods: Unicentric retrospective analysis of patients (pts) diagnosed with AA between 2008 and 2019. Cox proportional hazard regression analysis was used to analyze factors affecting overall survival (OS) and overall response rate (ORR). OS obtained using the Kaplan-Meyer method was compared by the log-rank test. P<0,05 were considered statistically significant.
Results: 41 pts diagnosed – 37% male, median age at diagnosis 59 years (18-83 years). No cytogenetic abnormalities were identified and 11 pts had a concomitant paroxysmal nocturnal hemoglobinuria clone [PNH – expression defect >0,1% in ≥2 markers (CD55, CD59, CD16, CD24, CD14) in 2 distinct hematopoietic cell lines]. According to CC, 22 % were classified as moderate AA, 42% severe and 36% very severe.
Six pts under 40 years had a matched sibling donor and underwent allogeneic stem cell transplantation as first line treatment - all of then achieved a complete remission (CR).
Twenty-two pts were treated with immunosuppressive therapy [16 antithymocyte globulin (ATG) + cyclosporine (CsA) and 6 CsA], 3 eltrombopag monotherapy and 8 supportive care only. Two pts did not require therapeutic intervention. ORR in non-transplanted pts was 60%. Although ORR was not statistically different between groups, it appears to be superior with ATG+CsA (75% vs 33% CsA vs 33% eltrombopag; p=NS), with inferior outcomes in pts ≥60 years (33% vs 54%; p=0,047; HR 3,22). Regarding ATG source, ORR was superior with horse vs rabbit origin (89% vs 57%; p=0,017; HR 7,07). In non-transplanted pts, only 3 achieved CR, all treated with ATG+CsA. Macrocytosis (MCV>97fL, excluding vitamin deficit) was associated with superior ORR (40% vs 88%; p=0,042; HR 7,07). Also normal LDH at diagnosis was associated with superior ORR (p=0,019; HR 5,52).
Treatment response is one of the main factors influencing OS - pts with ORR had a superior OS (p<0,001). Median OS of pts with treatment response was 70 months vs 4 months in pts without response vs 1,5 months in pts on supportive care only. There were also differences on OS between pts without treatment response and pts only on supportive care (p=0,023). The presence of PNH clone is also associated with superior OS (p=0,049). Age ≥60 years had a negative impact on OS (p<0,001).
Regarding the CC, only absolute neutrophil count (ANC) <0,5x10^9/L had a significant impact on OS in both univariate (p=0,009; HR 3,92) and multivariate analysis (p=0,018; HR 4,02), with a negative impact.
Currently, 53,7% of pts are alive. The main cause of death was infection (63%).
No other variable significantly affected prognosis.
Summary/Conclusion: Age ≥60 years and ANC <0.5x10^9/L negatively affected OS. Since ANC was the only statistically significant component of CC to have an impact on OS (pts with low ANC might have a high rate of infection), raises questions regarding the statistical power of the different CC, that maybe should be reviewed.
Treatment response is associated with favorable OS, with macrocytosis and normal LDH appearing associated with a superior ORR. Also the presence of PNH clone is associated with a superior OS.
More robust studies are needed to validate these prognostic factors.

PB1475 INJECTION-SITE REACTIONS AT WEEK 48 IN THE RANDOMIZED PHASE 3 PEGASUS TRIAL OF PEGCETACOPLAN COMPARED WITH ECULIZUMAB FOR INDIVIDUALS WITH PAROXYSMAL NOCTURNAL HEMOGLOBINURIA

V. Sharma [1,*], I. Weitz [2], J. Koprivnikar [3], B. Conliffe [1], K. Drago [4], C. Chen [4], A. Bachelor [4]

[1]University of Louisville, Louisville, KY, [2]Jane Anne Nohl Division of Hematology, Keck-USC School of Medicine, Los Angeles, CA, [3]John Theurer Cancer Center, Hackensack University Medical Center, Hackensack, NJ, [4]Apellis Pharmaceuticals, Inc, Waltham, MA, United States

Background: Pegcetacoplan (PEG), a PEGylated peptide targeting proximal complement protein C3, can control both intravascular and extravascular hemolysis in paroxysmal nocturnal hemoglobinuria (PNH). In the PEGASUS trial (NCT03500549), a phase 3, randomized, open-label, active-comparator controlled study, PEG was shown to be superior to eculizumab (ECU) after 16 weeks in improving hemoglobin (Hb) levels and clinical outcomes in patients with PNH *(Hillmen P et al, EHA 2020)*. PEG is self-administered twice weekly via two 10-mL subcutaneous injections at two distinct sites, which may lead to injection-site reactions (ISRs).
Aims: Our aim was to compare ISR safety outcomes from the PEGASUS trial to ISR incidences from similarly administered treatments based on published literature.
Methods: PEGASUS subjects received twice-weekly subcutaneous injections of 1080 mg PEG plus their current intravenous ECU dose in an initial 4-week run-in period (RIP), followed by a 16-week 1:1 randomized controlled period (RCP) where participants received PEG (n=41) or ECU monotherapy (n=39). Patients receiving ECU during the RCP entered another 4-week RIP (ECU+PEG), followed by an Open Label Period (OLP), in which all patients received PEG monotherapy.
The primary endpoint was the mean change from baseline in Hb levels at Week 16. Safety was a secondary endpoint and included monitoring incidence of ISRs, adverse events (AE), and treatment-emergent AEs (TEAEs). Therapies comparable to PEG were identified in order to establish a context for PEG-associated ISRs. Inclusion criteria were subcutaneously administered drugs with similar injection volumes (≥10 mL) or PEGylation (with ≥0.5-mL injections). ISR incidences and management strategies reported with identified drugs were evaluated from the prescribing information and published literature.

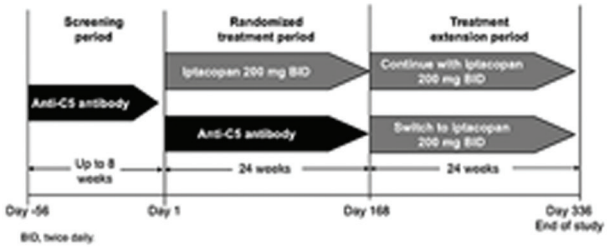
Results: Total reported TEAEs were as follows: i) RIP and open-label RIP (71 subjects, 89%); ii) RCP (PEG arm: 36 subjects [88%]; ECU arm: 36 subjects [92%]); iii) OLP (71 subjects [92%]). Most ISRs occurred during treatment initiation, as 59% of PEG patients experienced ISRs during the initial RIP compared to 37% in the RCP and 26% in the OLP. 2.6% of ECU patients experienced ISRs. In the total cohort, most ISRs were mild; there were a few moderate ISRs (4 in RIP, 3 in RCP+OLP PEG group; minimal intervention indicated) and no ISRs that were severe or led to study drug discontinuation.
Five drugs with comparable mode of delivery to PEG were identified and evaluated for ISR data (see Table). The percent of patients who experienced ISRs for evaluated drugs varied from 5–67% but were generally mild, resolved quickly, and were less likely to occur with subsequent treatments, according to published studies. Prevention or management strategies for ISRs included ice packs, injection-site rotation, and empowering patients to gain confidence in self-administration through training and other initiatives.

Table. Comparative Analysis of ISRs

Drug name	Drug type	Volume per site (mL)	Delivery	Frequency	Most frequent ISRs[a]	ISR incidence[b]
Pegcetacoplan	PEGylated peptide	~10	20-40 min over 2 sites	Twice weekly	Erythema, pruritus, bruising, induration, reaction, swelling[c]	36%[c]
Immunoglobulin with hyaluronidase	Immunoglobulin	≤600	~1-2 mL/min over 2 sites	Monthly	Discomfort, pain, erythema, swelling, itching	38-65%
Deferoxamine	Small molecule	10-20	Continuous pump over 8-24 hours	Daily	Pain, swelling, reddening, itching, blistering, burning	45%
Daratumumab and hyaluronidase[d]	Monoclonal antibody	15	Injected over 3-5 min	Weekly to monthly	Erythema, itching, swelling, bruising	11-67%
Certolizumab pegol	PEGylated antibody fragment	~1	Short injections at up to 2 sites	Monthly	Erythema, bruising, discoloration, pain, swelling	5%
Pegfilgrastim	PEGylated growth factor	0.6	Single injection at 1 site	Once per Chemo-therapy cycle	Pain, redness	8%

[a]Per prescribing information
[b]From published literature
[c]From PEGASUS randomized controlled period + open-label period
[d]Administered by healthcare provider only, whereas all others could be self-administered or administered by healthcare provider
ISR, injection-site reaction

Summary/Conclusion: PEGASUS trial ISRs observed with PEG treatment were more frequent in the initial treatment period and decreased over time, potentially because patients became more experienced with self-injection. ISRs were often mild or manageable and PEG patients on average reported better quality of life than ECU-treated patients at Week 16, indicating these events are likely not a barrier to treatment. Comparable trends for reported ISRs have been observed with other drugs delivered similarly to PEG; management strategies for ISRs with these drugs may potentially be useful for reactions observed with PEG.



PB1476 PH3 STUDY OF EFFICACY AND SAFETY OF IPTACOPAN (LNP023), AN ORAL COMPLEMENT FACTOR B INHIBITOR, IN PTS WITH PAROXYSMAL NOCTURNAL HEMOGLOBINURIA AND RESIDUAL ANEMIA DESPITE ANTI-C5 ANTIBODY TREATMENT

A. M. Risitano [1,2,*], A. Kulasekararaj [3,4], C. M. De Castro [5], S. Nakao [6], P. Scheinberg [7], R. Levitch [8], G. Bermann [8], M. Dahlke [8], R. Peffault de Latour [9]

[1]University of Naples Federico II, Naples, [2]AORN Moscati, Avellino, Italy, [3]National Institute of Health Research/Wellcome King's Clinical Research Facility, King's College Hospital, [4]King's College London, London, United Kingdom, [5]Duke University School of Medicine, Durham, United States, [6]Kanazawa University, Kanazawa, Japan, [7]Hospital A Beneficência Portuguesa, São Paulo, Brazil, [8]Novartis Pharma AG, Basel, Switzerland, [9]Saint-Louis Hospital, Paris, France

Background: The standard of care in PNH is anti-C5 monoclonal antibody (MAb) treatment (tx) with eculizumab (ECU) or ravulizumab (RAV) but hematological responses can be heterogenous. Iptacopan (LNP023) is a first-in-class, oral, small-molecule, selective and reversible complement factor B inhibitor that inhibits both intra- and extravascular hemolysis. In an ongoing Ph2 study (NCT03439839), iptacopan add-on tx has demonstrated improvements in hematological response and biomarkers of disease activity in adult patients (pts) with PNH with active hemolysis despite ECU tx.
Aims: The Ph3 APPLY-PNH study (NCT04558918) will assess the efficacy and safety of iptacopan monotherapy in adult pts with PNH with residual anemia despite prior anti-C5 MAb tx by evaluating its superiority to anti-C5 MAb tx.
Methods: The study comprises an ≤8-wk screening period; a 24-wk, randomized, open-label, active-controlled, parallel-group tx period; and a 24-wk tx extension period (Fig. 1). Pts (N≈91) will be randomized (8:5) to iptacopan monotherapy 200mg orally BID (seamless switch from prior tx) or intravenous ECU/RAV (continue prior tx). Pts will be stratified based on prior anti-C5 tx and transfusion history. On completion of the Wk 24 visit, pts may enter the 24-wk iptacopan tx extension period. Eligible pts must have a confirmed diagnosis of PNH (red blood cells [RBCs] and white blood cells [granulocyte/monocyte] clone size ≥10%) and residual anemia (mean Hb <10g/dL) despite receiving a stable regimen of ECU/RAV in the 6 months preceding randomization. Key exclusion criteria include ECU dosing interval ≤11 days; known or suspected hereditary complement deficiency; hematopoietic stem cell transplantation; laboratory evidence of bone marrow failure; active, systemic infection ≤14 days preceding study drug tx; and history of recurrent, invasive infections caused by encapsulated microorganisms. Primary endpoints are the proportion of pts achieving 1) a sustained increase in Hb levels from baseline (BL) of ≥2g/dL (between D126 and D168) in the absence of RBC transfusions (between D14 and D168); and 2) a sustained increase in Hb levels to ≥12g/dL (between D126 and D168), in the absence of RBC transfusions (between D14 and D168). Potential superiority of iptacopan vs ECU/RAV in the analysis of the primary endpoints will be determined using an odds ratio and tested using a conditional logistic regression model, accounting for stratification factors used at randomization and adjusted for age, sex, and BL Hb. The study α will be split equally between the two endpoints and will determine rejection of each based on the permutation distribution of the *P*-values. Secondary endpoints include RBC transfusion-avoidance between D14 and D168 (except D1-14); and changes from BL in Hb levels, FACIT-Fatigue score, and reticulocytes (per weighted testing approach). The primary and secondary endpoints will be tested using a graphical multiplicity adjustment, where α weights are assigned to the different tests. If all of the above hypotheses (including both primary endpoints) are rejected, the following will be tested at full study α, also in a weighted fashion: % change from BL in lactate dehydrogenase, occurrence of breakthrough hemolysis, and occurrence of major adverse vascular events (including thrombosis). Additional endpoints include safety assessments, PNH clone size, C3d deposition on RBCs, and PROs (PGI-S, EORTC QLQ-C30, EQ-5D-5L).
Results: NA

Figure 1: APPLY-PNH design

Summary/Conclusion: This study will be the first head-to-head comparison of iptacopan vs an anti-C5 MAb in patients with PNH.

PB1477 CATEGORIZED HEMATOLOGIC RESPONSE TO PEGCETACOPLAN VERSUS ECULIZUMAB IN PATIENTS WITH PAROXYSMAL NOCTURNAL HEMOGLOBINURIA: POST HOC ANALYSIS OF PEGASUS PHASE 3 RANDOMIZED TRIAL DATA

A. Risitano [1,2,*], I. C. Weitz [3], C. M. de Castro [4], J.-J. Kiladjian [5,6], M. Griffin [7], H. Nishimori [8], M. Al-Adhami [9], C. Chen [9], S. Baver [9], R. Peffault de Latour [10]

Background: Pegcetacoplan (PEG), a PEGylated peptide targeting proximal complement protein C3, can control both intravascular and extravascular hemolysis. In the PEGASUS trial (NCT03500549), a phase 3, randomized, open-label, active-comparator controlled study, PEG was shown to be superior to eculizumab (ECU) after 16 weeks in improving hemoglobin (Hb) levels and clinical outcomes in patients with paroxysmal nocturnal hemoglobinuria (PNH) *(Hillmen P et al, EHA 2020)*.
Aims: This post-hoc analysis categorized the hematologic response to PEG versus ECU treatment in PEGASUS patients with PNH up to Week 48.
Methods: Hematologic response to PEG or ECU in PEGASUS patients (≥18 years) with PNH and Hb <10.5 g/dL (despite stable ECU treatment for ≥3 months) was categorized as complete, major, good, partial, minor, or no response at baseline, Week 16, and Week 48 using the number of packed red blood cell transfusions required, Hb level, lactate dehydrogenase (LDH) level, and absolute reticulocyte count assessed in the last 6 months of treatment (ARC; categorization criteria per Risitano AM, et al. *Front Immunol*. 2019;10:1157). Hematologic response criteria are as follows: Complete response, no transfusions required, stable Hb (normal range), and no evidence of hemolysis (LDH≤1.5×upper limit of normal [ULN] U/L, ARC≤150,000/μL); Major response: no transfusion, normal Hb, but with evidence of hemolysis (LDH>1.5×ULN U/L and/or ARC>150,000/μL); Good response: no transfusions, but with chronic mild anemia or evidence of hemolysis; Partial response: chronic moderate anemia and/or occasional transfusions (<3 units/6 months); Minor response: regular transfusions required (3-6 units/6 months); No response: regular and frequent transfusions required (>6 units/6 months). Statistical tests were performed to determine significance for patient responses of 'Good,' 'Major,' or 'Complete', collectively (McNemar's test within arms; Chi-squared between arms).
