Acknowledgements

First and foremost I offer my deepest gratitude to my supervisor, Prof. Luigi Curini, who supported me with his expertise throughout my dissertation. I would like to sincerely thank him for his guidance, carried out with patience and respect. He has always been there to discuss any major concern and to help me solving any trouble I faced during the work. His hints and suggestions leaded me to constantly improve my research. Despite his many commitments, prof. Curini has always found a way to supervise my work with accuracy, even when we were several time zones away from each other. Far from any rhetoric, I have really much appreciated his helpfulness.

I am also grateful to some other people who gave me suggestions about how to improve the present work. In particular, I would like to thank Prof. Paolo Martelli who devoted time to revising one chapter of the present work, giving me useful ideas to clarify some aspects of the dissertation before writing the final handout. In turn, Prof. Fabio Franchino gave me some hints to improve one empirical chapter and he deserves my gratitude for that.

I would like to thank Prof. Gary King, for hosting me at the Institute for Quantitative Social Science (IQSS), Harvard University, and for his advices about how to make my research more interesting, as well as Prof. Stefano Iacus for helping me to join the IQSS. I really appreciated the time spent there, and such experience contributed in several ways to enhance the quality of my work. In this sense, I also thank Professors Stephen Ansolabehere,

Nahomi Ichino, James Snyder and Arthur Spirling for their politeness. They devoted their time to read and discuss with me some points of the present dissertation and indeed the final version of my research benefits from their hints and suggestions.

Along the same vein, I am grateful to the discussant and to the participants at the Research Workshop in Comparative Politics, Harvard University, where I presented an early draft of the present research. All the smart comments that I received there have been precious and I tried to take them all into account, in order to improve my study.

That said, I cannot leave aside my family. My parents, Nicolangela and Vittorio, and my brother, Simone who always supported me and did their best to help me realize my dreams.

I also want to thank my grandfather, who fostered my passion for politics since I was a kid, as well as my father did. They also brought me to a local party congress when I was seventeen and, in a sense, that was the day when the present research began.

To conclude, I want to say thank you to my friends. First of all, my best friend Alessandro, whose *voice* is the only one I usually listen to; my crew, that will never *exit* from my life, no matter where we will be; my ‘group’ that leaded me to discover the importance of *loyalty* while pursuing a common passion. Last, but not least, I want to thank my ‘Bostonian’ friends, i.e., those that hopefully have been reading through these lines: I promise I’ll bring you an hard copy, someday.

Chapter 1

Introduction

1.1 Why Factions?

Many studies in the field of political science rely on the assumption that parties are unitary actors, and focus on them as the unit of analysis. Indeed political parties play a preeminent role in representative democracies. They interact together in the electoral market or in the parliamentary arena, trying to maximise their own rewards through processes of cooperation (e.g., building coalitions) and conflict (even the most cohesive coalition faces internal strife).

In a word, parties matter: they affect government formation, portfolio allocation and policy-making. Although reasonable the unitary actor assumption is just a fictional representation of real world politics. For this reason it is worth to relax such overstated claim, opening the black box of intra-party decision-making to provide new and more realistic models of party politics.

Sometimes parties do behave *as if* they were united, nonetheless they are actually divided into many subgroups. These subgroups, that might have different shapes and attributes, have been identified under the label of party factions.

Factions exist, many parties in many countries are indeed factionalized as

lots of studies had shown. A growing branch of literature on party politics has started to address the topic of party faction. After the 1990s these studies increased providing evidence about the role played by factions in the party system. Factions do matter indirectly, due to their influence on party strategy, and directly, through the impact on the whole party system whenever they decide not to follow the line (splitting during roll call votes or building a new rival party before the electoral campaign). Hence the dynamics of inter-factional bargaining and their consequences are a real world puzzle that could help us to understand the evolution of party system, above and beyond the *anthropomorphic* ‘unitary actor assumption’.

Party’s members are not equal among themselves. They retain non-identical preferences and different perspectives on how party strategy and party platform ought to be. As none of them is able, on its own, to gain control over the party those members who retain the most similar preferences coalesce to gain influence on internal decision-making. Within each group (party) several members cluster together creating rival subgroups (factions) to enhance their stakes. Intra-party politics then is characterized by a twofold process: on one hand these subgroups face the incentive to compete against each other to share the private goods (office, policy and electoral payoffs) while at the same time they need to cooperate in order to preserve party unity, which is the public good that allows to gain access to the payoffs.

Every time a faction’s return is unsatisfactory, the subgroup faces the incentive to leave the party joining another one or competing on its own to produce the good. Every time a faction proves to be useless or damaging for the party itself it will be sent off. In this sense the party is the arena where groups with similar but non-identical preferences bargain to reach an internal equilibrium.

For the sake of preserving unity this equilibrium must take into account the stakes of all factions according to their contribution to the public good.

This factional agreement will be the shield behind which the party achieves its unity to compete in the electoral market and in the parliamentary arena.

This is the reason why the present analyses will focus on intra-party decision making. We will investigate the patterns of conflict and cooperation between factions addressing how parties keep their unity and why do they split. Accordingly, we consider the party as the endogenous product of intra-party, inter-factional competition.

Factional preferences and intra-party dynamics in fact shape the party: they impact on its unity, on the internal equilibrium and on the likelihood of splits. As far as they affect party unity and party fission, factions shape not only the party but the system as a whole. Our research question then deals with the patterns of inter-factional conflict. We will investigate how parties are ruled to find what bargaining dynamics drive them.

Does the party behave following a winner-take-all rule or does it allocate resources in proportion to factions' strength? Does the median faction play a crucial role? Is the party leader allowed to exploit greater payoffs or is she constrained by factions? And if so, under what circumstances and to what extent? Having discussed the reasons why parties should pursue internal unity we will be concerned with the motives of their breakup. Why do parties split? Finally we will provide some contributions to check whether internal division and fission do indeed affect the party system or if, to the contrary, party unity is not at all a source of party strength.

Factions and fissions are the two crucial aspects of the present work. As we will see these two features are common to many political systems. However they are endemic in some countries, like Italy. Hence this country is a theoretically promising context to study the politics of factions and fissions. In addition the high number of parties and factions provides a wide documentation about intra-party politics that allows to extract a huge amount of data

and to conduct large-N analysis. Moreover the broad changes experienced by the Italian political system after 1992 allow to assess the impact of electoral rules on intra-party politics. These reasons explain why the Italian case is well suited for this kind of analysis, even though future researches should investigate patterns of intra-party politics in a comparative perspective.

Within the Italian case study, we will address the questions presented above, focusing on two main elements: *preferences* and *rules*. The present work stresses the importance of policy preferences as determinants of actors' choices, while controlling for the effects carried out by intra-party rules. Party organization in fact provides actors with constraints and opportunities, shaping the field where factional struggles happen. We believe that divergent policy preferences are the basis for factional conflict and cooperation. However we claim that different sets of rules might affect factional bargaining. Hence we want to assess what are the primary sources of party behaviour testing which of these two aspects is prevailing.

Does party structure affect the internal life of parties? Which rules are the most relevant? How do they impact on intra-party politics? Do preferences matter anyway? Do they interact with party organization leading to different outcomes under different rules?

To test these effects we will gather data looking at party congress, that represents the main arena where factions interact and fight against each other. Indeed the congress is the battleground where latent subgroups might exploit public visibility; it is also the place where each faction expresses its view about party line (by means of a congress motions) and where each party member has to make her own choice between one list of delegates or another one. The sum of these individual choices provides a measure of the strength of each faction. Moreover the party congress elects the party body and, directly or indirectly, the party leadership. Finally the congress can ratify or modify

the party statute, which is an all-inclusive set of rules that establishes party organizational structure, sets up prohibitions and provides some arrangements related to inter-factional competition: in a word, it defines the rules of the game.

Exploiting information collected from party congress we are able to analyze both preferences and rules. We will take into account the first aspect, preferences, through a new dataset that, by means of quantitative text analysis, estimates the policy positions of factions analysing the motion presented during the congress. Then, looking at party statutes we will assess the impact of internal rules on the inter-factional bargaining.

Taking into account alternative rules and contrasting and modes of party organization, as well as different levels of internal heterogeneity, we will analyze the nature of intra-party competition. In line with the idea of party as a solution to collective action problems, we will provide a game-theoretic model, based on the ‘exit voice and loyalty’ framework (Hirschman 1970), that help us to conceive intra-party politics as an inter-play between *party factions* and the *party leader*. In addition we will also take into account the role of exogenous elements related to the electoral system and inter-party competition. Starting from the implications derived from our theory and building on the existing literature we will address several facets of intra-party politics, from the degree of factionalism and the dynamics of payoffs allocation up to party split. After having discussed how inter-factional conflict shape the party we will assess its effects on the whole party system.

Summing up, the final aim of the present work is to contribute to ‘a new model of party politics that abandons the unitary actor assumption and sees the decision making “engine” of political parties as being driven by intra-party, inter-factional competition’ (Giannetti and Laver 2009: 166).

1.2 Literature on Intra-party Politics and Party Factions

Factions exist: ‘Factionalism is a fact of life within most political parties’ (Harmel *et al.* 1995: 7). Indeed ‘most parties in the world have wings or tendencies’ (Chambers 2008: 304). It could even be argued that ‘Political parties are driven by the spirit of faction [...]’. [*Hence*] factions are ubiquitous’ (Heller 2008: 2, italic added). Accordingly literature on intra-party politics has shown the presence of factions within several parties, all over the world.

Although the study of party factions started in the 1960s, it was a niche topic until the 1990s while it has undergone a sharply increase in the new millennium. Since then a bunch of case studies took into account intra-party division and the role of factions in real world politics. They covered almost all world’s regions, from Australia to Brazil, from Mexico to Japan, from Germany to Israel and South Africa. Without leaving aside Italy, UK and the US.¹

Obviously the mere existence of factions does not represent, per se, a sufficient condition to make their study useful or desirable. If factions were not ‘thinking actors’ there would be nothing to analyze. Following Descartes’ claim, their existence would be ‘proved’ only if factions *think* and act (more or less) consequently, thus justifying the need to study them. If this was not the case we should revert to an individual level of analysis (i.e., the single member) to understand the decision-making process within the party.

However, as we will show, factions are indeed rational actors. They are

¹We track comparative analysis or single case study for at least 38 countries: Australia, Argentina, Bolivia, Brazil, Chile, Colombia, Costa Rica, Czech Republic, Denmark, France, Estonia, Germany, Greece, Honduras, Hungary, India, Ireland, Israel, Italy, Japan, South Korea, Mexico, Nederland, Norway, Peru, Poland, Portugal, Russia, South Africa, Spain, Sweden, Taiwan, Thailand, Turkey, United Kingdom, United States, Uruguay, Venezuela. Additionally there are studies related to ‘factions’ within the European Parliament.

1.2. LITERATURE ON INTRA-PARTY POLITICS AND PARTY FACTIONS

able to take collective decisions and, likewise parties, often behave *as if* they were a unitary actor. Revising Descartes in a rational choice framework we can state that factions exist, therefore they think: *sunt ergo cogitant*.

Given that individual party members are rational choosers there would be no point in creating or joining factions if these were irrelevant within the party. In this sense the mere existence of a huge number of factionalized parties is a proof of the relevance of factions.

Let us discuss more in depth this point. Although parties are an entity per se they are also a sum of individuals: they are teams composed by a variety of players that coordinate themselves to solve collective action dilemmas and coordination problems (Aldrich 1995; Cox and McCubbins 1993; Kiewit and McCubbins 1991).² Parties aggregate like-minded members that, compared to rivals, retain partially common preferences, interests and beliefs (Aldrich 1995; Aldrich and Bianco 1992).

Extending this reasoning inside the party we observe that, in turn, members who share the most similar views tend to aggregate together (Bernauer and Bräuninger 2009) in order to gain influence on party strategy, and maximize their benefits. Parties are probably something more than a simple sum of individual preferences: they are organization built through institutions that shape and sometimes whip members' desires. In the same vein factions are more than an aggregate of activists. At the inner level (the intra-party arena) factions behave like parties do at the outer level (the party system). They organize and coordinate their members' behaviour (Giannetti and Laver 2009) structuring individual preferences in order to maximize individual payoffs (this is straightforward when thinking about splits on roll call votes or party fission);³ they

²Parties, for instance, coordinate their members to extract greater payoffs in the parliamentary arena (through log-rolling and coordinated voting behavior) and in the electoral market.

³See paragraphs 8.3 and 6.2 respectively.

synchronize their adherents' wills affecting individuals' decisions and party's choices.

Indeed factions do matter. They affect several areas of politics, from party competition to policy-making and cabinet formation. More precisely a number of works managed to show the impact of factions on: coalition and government bargaining (Giannetti and Benoit 2009; Laver and Shepsle 1990a, 1990b, 1996; Luebbert 1986; Maor 1998; Strøm 1994); portfolio allocation (Bouissou 2001; Debus and Bräuninger 2009; Leiserson 1968; Mershon 2001a, 2001b; Ono 2010); government duration, termination and reshuffle (Budge 1985; Boucek 2003a; Druckman 1996; Chambers 2008; Saalfeld 2009); patronage and corruption (Golden and Chang 2001; Kato and Mershon 2006; Zuckerman 1975, 1979); party position-taking and party competition (Budge *et al.* 2010; Cailaud and Tirole 2002; Giannetti and Laver 2009; Levy 2004; McAllister 1991; Morgenstern 2001; Persico *et al.* 2011; Roemer 1999; 2001; Snyder and Ting 2002); policy-making (Depauw and Martin 2009; Giannetti and Laver 2009; Mulé 2001); party cohesion and discipline (Depauw and Martin 2009; Giannetti and Laver 2009; Hix *et al.* 2005, 2007; Kam 2009; Desposato 2006a); party switching (Kweit 1986; Heller and Mershon 2005, 2008; Desposato 2006b); party change (Budge 1985; Duncan 2007; Harmel and Tan 2003); party fission (Giannetti and Laver 2001; Kato 1998; Laver and Sergenti 2010; Park 2010; Reed and Scheiner 2003) and party system as a whole (Kato 1998; Laver and Benoit 2001, 2003; Sartori 1976; Zariski and Welch 1975).

It goes without saying that a plurality of these studies concerns Italy and Japan, countries where the existence of subgroups is so unquestionable that they are somehow integrated in the system. Struggle between factions in two ruling parties like the Italian Christian Democratic Party (DC) or the Liberal Democratic Party (LDP) in Japan are well known and widely analyzed. However factions does not exist only among parties in office: in both countries

1.2. LITERATURE ON INTRA-PARTY POLITICS AND PARTY FACTIONS

the Italian Socialist Party (PSI) and the Japanese Socialist/Social Democratic Party were highly divided, even when out of office. The same is true for Mexico where the former dominant party, the Institutional Revolutionary Party, was divided in many subgroups likewise one main opposition party, the Democratic Revolutionary Party. In turn factionalism is not a feature shared only by one-dominant party systems. Italian and Japanese parties keep a considerable degree of division still now that these two systems are experiencing government alternation.

We find more or less organized and more or less durable factions also in other countries like UK or Germany, whose parties are supposed to be stronger and more cohesive. In the United Kingdom the three main parties, Conservatives, Labour and Liberal Democrats, are composed by *clubs*, factions, wings or tendencies. These clubs fight to take control over the party enhancing their members' career and faction's policy view. In such context factional conflict was the key element that pushed Labour right-wing factions outside the party in 1981, to create the Social Democratic Party, that later merged with the Liberals to form the Liberal Democrats. We observe something similar with respect to Germany where party members are organized in *kreis* (circles) that support their own different stakes. The fractionalisation of the German Social Democratic Party proved its relevance when, in 2005, two splinter groups composed by left-wing activists split and created the Labour and Social Justice – The Electoral Alternative (WASG). This group immediately fused with the Party of Democratic Socialism, which was in turn highly factionalised, to build a new party: The Left (*Die Linke*). Intra-party divisions within German parties also allow to explain the end of Schröder's government and the advent of the Grand Coalition. Similar patterns can be found in other countries too; it is worth to recall, just as an example, that in France the Socialist Party has always been divided in factions that competed to elect the leader and to

establish the line.

The term *faction* was already used in the 18th century by thinkers like Burke, Hume and Madison as a forerunner for the concept of party, to identify competitive groups within the polity. However it acquired the current meaning only later on. In 1949, analysing primaries among the US Southern Democrats, Key (1949) referred to factions as intra-party groups. Notwithstanding this, the term itself and its definition have long been contested in the literature. Beside ‘factions’ (Duverger 1954; Key 1949, 1958) some authors proposed alternative names like ‘tendencies’ (Rose 1964), ‘fractions’ (Sartori 1971, 1976), ‘currents’ (Belloni and Beller 1978) and ‘clusters’ (Reiter 1981) as well as wings, rivalries and nucleus (e.g., Duverger 1951). Some of these terms were only a matter of linguistic tastes while others tried to convey a classification of intra-party groups.

Indeed a bunch of studies had provided definitions and taxonomies of different kinds of party factions according to some properties (Beller and Belloni 1978; Belloni and Beller 1976, 1978; Bettcher 2005, Boucek 2009; Chambers 1963; Hine 1982; Rose 1964; Key 1949, 1958; Nicholas 1965; Panebianco 1988; Reiter 1981; Sartori 1971, 1976; Seyd 1972; Zariski 1960; Zincone 1972). They distinguished factions by size, composition (faction as parliamentary subgroup or as intra-party unit), organization (e.g., factional press and headquarters), pervasiveness (local or national), autonomous linkage with voters and collateral extra-party structures and organizations (i.e., trade unions); autonomous access to resources (membership drive and fundraising); aim (ideology, clientelism, leader support); cohesiveness (agreement or division within the faction); duration (long-term groups or temporary fluid aggregations).

Key (1949: 16) provided a first definition of faction as ‘any combination, clique, or grouping of voters and political leaders who unite at a particular time in support of a candidate’. Zariski (1960: 33) generalized this idea defin-

1.2. LITERATURE ON INTRA-PARTY POLITICS AND PARTY FACTIONS

ing them as ‘any intraparty combination, clique or grouping whose members share a sense of common identity and common purpose and are organized collectively - as a distinct bloc within the party - to achieve their goals’. According to Zariski, factions gathered for different purposes: patronage; pursuit of local or interest groups’ requests; promotion of values; influence on party strategy; control of party’s and government’s policies. Another definition was provided by Nicholas (1965) who looked at them as ‘leader-follower’ groups. He considered factions as personal troops tied to their General, with defined tasks and hierarchy: members give support to the leader in intraparty conflict, and they receive back job, function, and money. Other authors investigated the relationship between factions and leaders. The International Comparative Political Parties survey (ICPP) for instance operationalized factionalism according to party coherence (Janda, 1979, 1980a, 1980b, 1993). These studies highlighted that ideological factions and leadership factions are linked because members mobilize behind a leader (Janda 1993).

Sartori (1971, 1976) defined factions as personalized power groups totally committed to power manipulation. In brief, he distinguished between factions of principles/values (ideologically oriented) and factions of interests/convenience (office-seeking); however he overstressed the role of patronage claiming that factions of principles maintain ideological elements only for instrumental purposes and tend to transform into faction of interests. Bettcher (2005) shared a similar view, while Passigli (1972; Sartori 1973: 48) claimed that, to the contrary, factions of convenience might create or stress the ideological framework when their leader’s power is falling.

Contra Sartori other scholars (Seyd 1972; Rose 1964, 1974) emphasized the role of ideology. Rose (1964) for instance distinguished between faction and tendency. A faction is a group of parliamentary members established to pursue a range of policies through an organized activity, and for a long-time

period. Its main characteristics are ideology, leadership, technical expertise, availability of resources and communication facility; therefore factions are well structured and hold a defined organization chart (a similar point of view was provided by Hine 1982). Conversely, a tendency is defined as a disorganized set, built according to shared attitudes; these attitudes could persist along time, even if the group who supports them is quite unstable and precarious. This subgroup is therefore temporary and could easily disappear or convert into a more stable faction.

Despite the undeniable differences in structure and organization between types of factions, it is possible to provide a definition that encompasses all these intra-party subgroups. Beller and Belloni (1978: 448) argued against the mere categorization: ‘factions in villages if they exist will be village factions; in Communist parties, factions will be Communist party factions’. Accordingly they stressed the need to focus on similarities instead of differences: ‘what is significant about factions ultimately is not their structural properties but their *activity* and its consequences [...] their dynamics and competitive politics’. Hence they provided a general definition of the concept as: ‘any relatively organized group that exists within the context of some other group and which (as a political faction) competes with rivals for power advantages within the larger group of which it is a part’. This approach toward the conceptualization of factions has been retrieved by Boucek (2009: 468) who defined factionalism as ‘the partitioning of a political party (or other organization and group) into subunits which are more or less institutionalized and who engage in collective action in order to achieve their members’ particular objectives’.

Besides looking for a definition many works on party factions analyzed them as a dependent variable to assess where do they come from. Analysing the determinants of factionalism they focused on party system competitiveness (Boucek 2005, 2010, 2011; Golembiewski 1958; Sartori 1971, 1976: 86; Zarisky

1960), on the incentives provided by the institutional factors like the electoral systems (Boucek 2003b; Bowler *et al.* 1999; Carey 2007; Carey e Shugart 1995; Cox and Rosenbluth 1993; Cox *et al.* 1999; Katz 1986a; Shugart 2001, 2005; Strøm and Müller 2009; Zuckerman 1979), on the amount of resources available within the party (Golden and Chang 2001; Zincone 1972; Zuckerman 1979) and on intra-party rules (Rahat and Hazan 2001; Sartori 1971, 1976). Only recently some authors highlighted the relationship between policy preferences and intra-party divisions (Bernauer and Bräuninger 2009; Giannetti and Laver 2009; Spirling and Quinn 2010).

Another branch of literature stressed the impact of competing set of intra-party attributes (related in particular with the level of internal democracy) on intra-party organization and on the relationship between leadership, middle-level activists (roughly factions) and party members (Katz 2001; Katz and Mair 1994; LeDuc 2001; Mair 1994, 1997; Marsh 1993; Pennings and Hazan 2001; Rahat and Hazan 2001; Rahat *et al.* 2008). These studies seem to show that although moderate level of internal democracy might have positive effects, radical levels could harm party unity (Pennings and Hazan 2001) or even end up fostering the leader in face of party members and factions (Rahat *et al.* 2008).

Conversely other works treat factionalism as an independent variable. Instead of analyzing elements that affect party unity they showed the impact of factions on several topics (see above) ranging from coalition government and portfolio allocation (e.g., Giannetti and Benoit 2009) to party position-taking and party fission.

Existing literature highlights some features of intra-party politics. First of all ‘it is difficult to discuss the making or breaking of parties without referring to intra-party factions or groupings of some shape or form’ (Giannetti and Laver 2009: 146). Factions, like any other political actor, care to some extent

about office, policy and votes (Müller and Strøm 1999). They retain divergent preferences; within the intra-party environment they bargain to reach a compromise while competing to maximize their payoffs. This factional strife, which develops under the threat of a party fission, is affected by internal rules and party system dynamics; it shapes the party and, through the party, the whole political system.

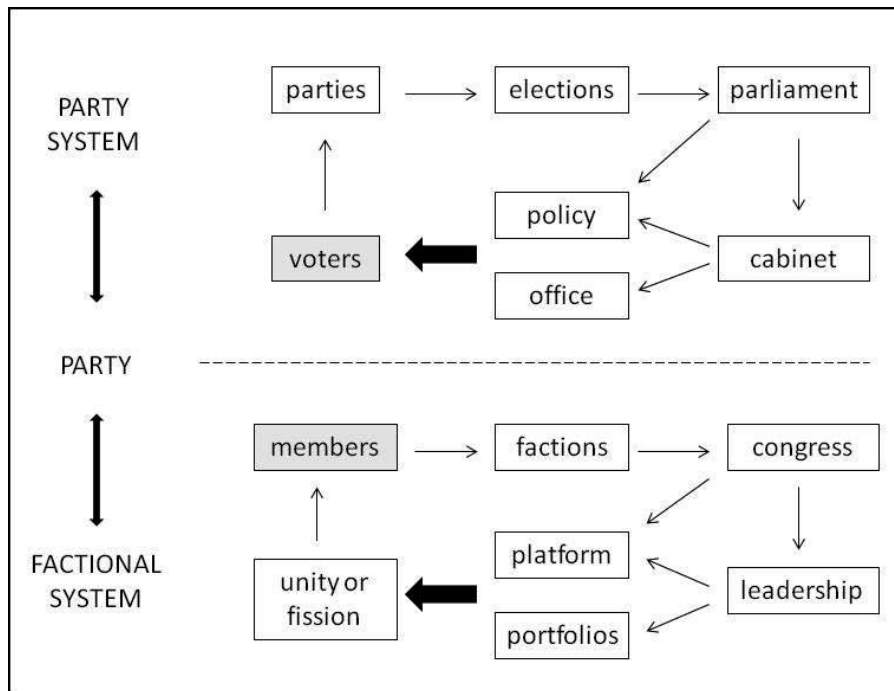

The present work will address all these topics. On one side we will discuss the impact of factional preferences as well as the effect of internal rules. On the other hand we will take into account the reciprocal interaction between the factional system and the party system. On these bases we will investigate all the main topics covered by the literature: the causes of factionalism, intra-party portfolio allocation, party position-taking, the determinants of party fission and finally the effects of intra-party divisions on the political system.

1.3 Intra-party politics and the Party System

The aim of the present work is to explain how inter-factional bargaining takes place and what effects does it produce on the party and the party system. To provide a complete description of internal dynamics we want to observe them step by step, tracking the main phases of party's internal life and matching the main stages of the everyday course of the political system. Figure 1.1 depicts both arenas portraying the structure of representative democracy at the inner level (the factional system) and at the outer level (the party system), beginning with the basic unit of each system: party *members* and *voters*.

The elections are the starting point in the life of a representative democracy. Voters exert the right to choose, among competing sets of candidates, their delegates to the Parliament. Candidates are generally grouped into parties

Figure 1.1: The Party System and the Factional System

that appeal to the electorate presenting their different policy views that can be usually summarized along the ideological left-right scale. After votes have been casted, the electoral system transforms them into seats determining the electoral strength of each parliamentary party group. Group size and its policy ideal point, are the crucial elements that allow parties to bargain in order to form a new government, providing them with a share of cabinet portfolios (office payoffs). The parliament and the cabinet in turn affect the policy-making through bills and ministerial decrees.

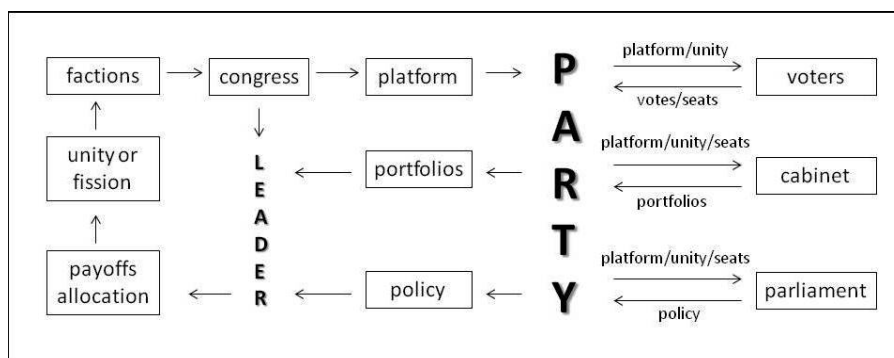

Where is the party? Where are the factions? Likewise citizens in representative democracies, parties usually allow their members to send delegates to party body (the agency in charge of running the party). During the party congress members that retain similar views about how party line ought to be could gather together presenting a motion. In chapter 4 we will describe this process underlining what rules affect the likelihood that competing sub-groups will contest the congress presenting their own motion attached to a

list of candidates to party body. Moreover we will investigate what elements increase the number of competing factions. The congress establishes the internal equilibrium between the rival subgroups, setting the new party line and electing (directly or indirectly) the party leadership with the task of enacting this line and allocating (policy and office) payoffs among factions. Accordingly in chapter 6 we will analyze how parties set their line; we will focus on the role of factions policy preferences in interaction with the power exerted by the party leader, which might vary under different party rules. The party platform in turn is a key element for the party and has an impact on the party system too: it allows parties to appeal for voters' support during general election. Party platform will be more credible as long as the party appears to be unified around it. Presenting a cohesive front to the electorate might in fact improve its electoral performance (this will be tested in paragraph 8.5). The electoral system translates votes into seats defining the strength of each party in the parliamentary arena. Parties' size along with their platforms are decisive elements during negotiations over government formation. In addition party unity and party rules too could be key sources of bargaining power that increases the party's chances to join the new cabinet. Paragraph 8.4 will test this claim. Then, if the party succeed in joining the ruling coalition it will be awarded with a certain number of ministerial posts. These office payoffs have to be shared between the different factions. Likewise during the inter-factional bargaining over the party line, we argue that intra-party portfolio allocation is affected by factional preferences and by party rules. In chapter 5 we analyse these dynamics. After the legislature has began and office payoffs have been distributed the everyday policy-making takes place. In paragraph 8.3 we test whether intra-party divisions exert an effect on it altering the level of party cohesion during roll-call votes.

So far we argued that intra-party politics affects policy, office and votes,

and, through them, alters the party system. This is however a mutual relationship insofar the party system contributes to shape the total amount of payoffs available to each party. In turn policy office and electoral rewards, along with the criteria adopted to allocate them, have an effect on intra-party equilibriums altering the extent of factionalism (as described in chapter 4) and the likelihood of a party fission (this topic will be addressed in chapter 7). Figure 1.2 summarizes the main interactions between the two fields of politics.

Figure 1.2: Interactions between The Party System and the Factional System

In the following paragraphs we will deepen the explanation of our research question introducing a short description of the topics investigated in each related empirical chapter (4 through 8). Then we will sketch a brief outline of the whole dissertation.

1.4 Where Do Factions Come From?

As discussed in paragraph 1.2 many works tried to explain factionalism as a dependent variable. In chapter 4 we will build on the existing literature to answer the question: where do factions come from? We know that the party is not a given entity. Following this reasoning we should be aware that factions are not fixed as well. Instead they are an endogenous output of the intra-party environment and the party system. Along this line we retain that it does not

make sense to treat them as stable. Even organized factions in fact might divide and recombine themselves across subsequent party congresses. Hence it is reasonable to look there in order to map the party's factional structure (see chapter 3 for a detailed discussion). Provided that factions are neither stable nor exogenous we will try to find the grounds of factionalism. Starting from the existing literature and according to our theoretical framework (see chapter 2), we investigate, first of all, whether intra-party rules exert constraints on the expression of internal dissent measuring their impact on the likelihood of holding contested congresses. Then we estimate what attributes increase or decrease the number of factions. Among the others, we will consider policy heterogeneity (micro-founding in a sense the existence of factions within the party), availability of resources and patronage, the impact of the electoral system, as well as competing sets of organizational rules.

1.5 How to Allocate Portfolios among Factions?

Once we acknowledged that factions exist, the question about how payoffs are shared among them flows out naturally. We will address this topic focusing on office and policy payoffs. Starting from the empirical implications of our theoretical model (that will be discussed in paragraph 2.2), chapter 5 will improve on Mershon (2001a, 2001b) work by investigating the patterns of intra-party portfolio allocation. Noticeably whenever a party is in office its leader decide how to assign ministerial posts to party members. However payoffs are not necessarily distributed at leader's discretion because parties are internally divided and factions try to influence such process (Ono 2010). Focusing on portfolios allotment we will observe inter-factional bargaining testing whether a kind of Gamson (1961) law applies to intra-party politics (see later for a description). Conversely we can also control if the party leader is able to

exploit her position to gain a larger share of payoffs. In addition we will assess how formal and informal rules alter the patterns of bargaining. Finally we will also take into account factional preferences to evaluate how they impinge on payoffs allocation.

1.6 Who Sets the Party Line?

Chapter 6 bears a resemblance with the fifth inasmuch as both deal with bargaining dynamics of payoffs allocation. Like the previous one, this chapter develops the arguments presented in the theoretical chapter (number 2). Considering the party platform as a policy payoff that has to be shared among factions, here we try to understand who runs the party and who sets the line. Does the leader rule on her own? Is she constrained by activists and factions? We derive some hypotheses from the literature on party organization (see paragraph 1.2) and from the theoretical model shown in paragraph 2.2. Then we measure the relationship between factional preferences and party platform according to contrasting models of party (mass, catch-all, cartel). We analyse party position as the endogenous output of an inter-factional competition. Although carried in a non-strategic setting, however we build bridges with the dynamic theories of party competition developed after Downs (1957).

1.7 Why Does the Party Break Up?

Party unity can be reached even inside divided parties, as the present dissertation will show. The previous chapters (5 and 6) highlighted how factions bargain to reach a compromise and how the leader acts to preserve party unity. Notwithstanding, sometimes the party breaks up. By definition, factionalism deals with intra-party divisions. Disagreement could materialize in a threefold

behaviour: splits on parliamentary votes, MP's switching between different groups,⁴ and party fission. In chapter 7 we focus on the latter to analyze the determinants of factional breakaways (that are not such a 'rare' event as one might think). Given the existence of strategies to keep the party together we wonder why often the cooperation fails and factional conflict yields party fission. Under what conditions does this happen? To answer this question we will start from the results shown in chapter 5 and 6. Following our game-theoretic model (chapter 2) we will take into account the whole set of payoffs (policy, office, votes) available to the factions along with features related to party and party system that provide constraints (e.g., loyalty, disproportional electoral rules) or incentives (lack of democracy, centralized candidate selection) for the breakaway. In addition we will examine the effect of leader's attitude toward minorities, which is the product of party system competitiveness and leader autonomy.

⁴Switching is the results of an individual MP's choice to abandon its group joining another one during the legislative term. Nonetheless looking at the Italian case until 1994 (namely for three quarters of the time of the present analysis) switches involved legislators moving in clusters due to party mergers and splits (Heller and Mershon 2005; Verzichelli 1996). These changes often concerned factions' breakaway within divided parties: e.g., the breakaway of PSI left-wing in 1963, the fission of the Italian Social Movement (MSI) in 1976, whose moderate factions created National Democracy (DN), or the split of the left-wing faction from the Italian Social Democratic Party (PSDI) in 1989. After the 1994 individual switching grew, however some of them were still related to factional membership. For instance the split within the Italian Popular Party (PPI) in 1995 when the right-wing abandoned the party to create a new parliamentary group, the Unified Christian Democrats (CDU), or the two fissions occurred within the Communist Refoundation Party (PRC) in 1995 and 1998 that witnessed the breakaway of its right-wing parliamentary party factions (*Comunisti Unitari* and *Comunisti Italiani*, respectively). Although weakened the linkage between parliamentary switching and factional affiliation is still there: in 2007 a left-wing subgroup broke away from the Democrats of the Left (DS) when the mainstream endorsed party dissolution to merge with The Daisy – Democracy is Freedom (DL) in order to create the Democratic Party (PD); similarly in 2009 a small splinter group exited from the PD and built the Alliance for Italy (API); along the same vein in 2010 the minority faction within the ruling party, the People of Freedom (PDL), broke away building a new group, Future and Freedom for Italy (FLI).

1.8 Does Intra-party Politics Affect the Party System?

The last empirical chapter (number 8) focuses on the effects of factionalism on the party system. We measure the degree of division existing within each party congress and we analyze its consequences. We know that all political actors care, to some extent, about policy, office, and votes (Müller and Strøm, 1999) Accordingly we will measure the impact intra-party divisions on these three domains of politics. First of all we account for their effect on policy through an analysis of MPs' cohesion during parliamentary roll-call votes. Then we look at the relationship between factionalism and office to assess whether a broader disunity damages the party in the process of government formation, altering the likelihood of being involved in a coalition cabinet and consequently decreasing the whole amount of payoffs available to party factions. Finally we consider the effect of factionalism on votes to establish whether party heterogeneity impinges on its electoral fortunes (positively or negatively).

1.9 Outline of the Dissertation

So far we presented the research question explaining why it is worth to investigate factionalism and its linkage with party fission. We summarized the main features of this work, focusing in particular on the relationship between factional preferences and party rules and on the interaction between intra-party politics and party system. We overviewed the main literature on intra-party politics and we briefly introduced the content of four empirical chapters, showing how they allow to thoroughly describe everyday politics.

In the next chapter (the number 2), we will provide a theory of factional

politics focusing on distributive bargaining and party unity. From our game-theoretic model we will derive some general implications that will be tested in the course of the dissertation through more specific hypotheses. In addition we will better discuss the interplay between party leader and party factions showing how contrasting leader selection procedures might establish different intra-party environments. Later, in chapter 3, we will discuss the suitability of Italy as a case study. We will illustrate the dataset, explaining how it has been built and showing some measures of validity and reliability. As far as we are dealing with a text analysis that encompasses 64 years of Italian history, we will also discuss the changes in the political language across time.

Then we will illustrate the results of our work. First of all, in chapter 4 we take factions as the dependent variable investigating the causes of factionalism; Then we concentrate on intra-party bargaining: in chapter 5 we extend Merston's studies on factional portfolio allocation taking into account all the parties included in our dataset. In chapter 6 we deal with the 'game' of party position-taking, analysing the role played by factions in shaping party position. Having discussed how factions cooperate to maintain party unity, in chapter 7 we investigate the determinants of party fission looking at factional breakaways. Chapter 8 measures the impact of intra-party politics on the party system. We examine the effects of intra-party divisions on policy (MPs cohesion in parliamentary votes), office (the likelihood of being involved in coalition governments), and votes (parties' electoral performance). Finally in chapter 9 we conclude summarizing our main findings, with a focus on the role played by factions' preferences and intra-party rules, and we will carry out a comparison between the theoretical expectations and the empirical findings, as an attempt to validate our theory. Then we conclude building bridges for future researches.

Chapter 2

Factional Politics: A Theory of Party Unity and Party Fission

2.1 Introduction

In the present chapter we describe our theory of party unity and party fission. Taking the cue from distributive bargaining games, like for instance the Ultimatum game, we provide a game-theoretic model to describe the interplay between party leader and party factions. We will focus on the distributive dynamics carried out by the leader in order to preserve party unity and to avoid the breakaway of internal minorities following the ‘exit voice and loyalty’ framework.¹ We assume that contrasting modes of leader selection (see paragraph 2.3) might alter the degree of autonomy retained by the leader in front of party factions, with effects on distributive dynamics and party unity. Accordingly, we will provide alternative models to describe these two different intra-party environments, depending on leader autonomy. Given that party factions and party leadership are insider actors, we argue that they have full

¹The ‘exit voice and loyalty’ game has been proposed by Hirschman (1970). Additional details are discussed in chapter 7.

access to information about payoffs, strategies, moves and nodes of the game.² We also assume common knowledge between the actors. Hence we will represent intra-party dynamics through games of perfect (and complete) information. Then, starting from the theoretical implications derived from the two games, we will raise some expectations about the shape of intra-party politics focusing on the degree of factionalism, on the distribution of (policy and office) payoffs and on party fission. Across the related empirical chapters (4 through 7) we will test these expectation and finally, in chapter 9, we will sum up the empirical results to provide a validation for our theory.

2.2 A Theory of Party Unity and Party Fission

All political actors care, to some extent, about policy, office and votes (Müller and Strøm 1999). Being political actors, factions retain the same desires; they are interested in all the three types of payoffs and they want to maximize their share. Some authors focused on the idea that factions are interested only in patronage. To the contrary we claim that they have a care in policy too. We can easily demonstrate that factions hold different preferences and conflicting views about party platform (Debus and Bräuninger 2009); in the present analysis differences between factions' policy positions within each congress are often statistically significant.³ Other authors already shown that policy matters: preferences shape factional membership (Bernauer and Bräuninger 2009) and voting behaviour (Cowley 2002; Giannetti and Laver 2009; Rosenthal and Voeten 2004; Spirling and Quinn 2010).

²This in addition helps to understand why it is so crucial for factions (i.e., for minority factions) to get represented inside party body and party executive.

³In the 84% of cases (70 congresses out of 83) we have at least two factions whose positions are statistically different. See confidence intervals in Appendix B.

There is general agreement around this idea; even authors that emphasized the role of patronage somehow recognize that factions could be arrayed along the left-right scale and they indeed do so (e.g., Bettcher 2005; Golden and Chang 2001; Zuckerman 1979). As an example, DC factions should be considered like typical actors interested only in patronage, given that DC was always in power sharing office benefits and clientele. Nonetheless scholars unanimously admit that DC factions retained divergent policy positions: Zuckerman (1979: 110), for instance, aligned them along the left-right scale; Golden and Chang (2001: 605) described them as ‘not ideologically distinct *nonetheless* [...] they can be arrayed ideologically’; Bettcher, although stressing the primacy of patronage, implicitly recognized that all factions care (at least partially) to policy; he admits that DC factions shared similarities with factions of principle such that they ‘identified themselves along a left-right spectrum’ (Bettcher 2005: 350). Indeed DC factions reverted to ideology as a glue for their unity and as a source of legitimacy (Calise 2000: 87).

Following Sartori (1976) it could be argued that factions hold ideological positions only for instrumental reasons. However we should remind that it ‘Doesn’t really matter for our purposes whether the public expression of policy preference is sincere or not. What matters is that it is costly to turn back from this. Thus a politician whose private desires deal only with getting into office for its own sake must become inextricably associated with a particular policy position in order to fulfil these objectives’ (Laver and Shepsle 1996: 249). Obviously a faction, exactly like any other actor, ‘may well have an interest in changing its policy position for all sorts of reasons’ (Laver and Shepsle 1996: 249). However to avoid loss of credibility these changes must be rare or limited and, therefore, policy positions should be quiet stable. Factional array within the DC was stable indeed; for instance left-wing subgroups were almost always on the left-wing side (Bettcher 2005: 352). Furthermore this is true for many

factions in many parties (see appendix B). According to this idea, stability in left-right arrangement confirms that even instrumental preferences become actual policy positions with real effects on politics.

We will regard factions as rational actors interested in maximizing their payoffs. Inside each party, factions have to deal with reciprocal interactions. They are involved in a common effort to produce a public good: keeping the party together. Party unity in fact enhances party strength in the electoral arena (e.g., McGann 2002; Snyder and Ting 2002) and during the negotiation over coalition government (e.g., Bäck 2009; Baron 1998), increasing the total amount of payoffs that its members can exploit. On one side then, factions need to cooperate reaching an agreement to foster the party. On the other side they quarrel about how to share the private benefits derived from the public good. In this sense intra-party politics is a matter of conflict and cooperation with factions looking for an equilibrium between the two (Maor 1997). Sometimes these contrasting forces do not balance and the party breaks up. These three aspects of intra-party dynamics that we investigate later correspond to the three faces of factionalism (cooperative, competitive and degenerative) highlighted by Boucek (2009).

We already discussed that parties, although considered unitary actors, are composed by members and subgroups that retain divergent preferences. These preferences are, by their nature, conflicting. Then divisions, compromises and struggles are traits common to almost all parties. However in many of them and most of the time ‘internal disagreements are resolved before party positions are defined formally – as in party manifestos – or behaviorally – as in legislative votes and speeches’ because ‘The incentives for parties to present a unified front in the wider political arena are strong’ (Heller 2008: 2). In this sense ‘the display of party unity does not imply a lack of conflict inside the party; rather it simply shows that party members have agreed to a party position

that they all can support, or at least tolerate. The key question then is not whether parties evince unity, but rather how they choose the positions around which they unify' (Heller 2008: 4).

We will discuss these negotiations focusing on office payoffs and party position-taking. Here we present a theoretical framework that encompasses both aspects. Suppose we have only two factions, i and j . They belong to the same party and have to share the total amount of resources (office, policy) available within their party. Each faction could propose to the other how to share those payoffs. If they make a deal their benefit will be higher. On the contrary if they fail to reach a compromise they will split; each faction will try to affect the party system on its own but the payoffs will be lower. As a consequence they will look for a compromise. The choice about how to share payoffs (e.g., ministers) is not so different from the decision about how to set party position; here we account for them both.

Each faction will be better off if the final agreement coincides with its ideal point (e.g., if all cabinet posts are assigned to its members or if the party position matches faction's preference). This occurrence defines the extremes of the Pareto set of all the achievable agreements: either faction i obtain 100% of the spoils or faction j will do. Among these two extremes there are (in)finite combinations that lead to feasible deals.

Which one will be picked up? Being able to measure their reciprocal strength, the factions will grant to the opponent a quota of payoffs equal to its contribution to the coalition (Gamson 1961; Warwick 2001; Levy 2004). Factional strength is to be measured as the number of congress votes gained by the faction: as far as one member equals one vote and each member is a resource for the party (due to her membership drive and her physical work within the organization) the total number of members that support one of the

factions is the best way to measure the factional contribution to the coalition.⁴ In this sense proportional allocation is a rule of thumb, a kind of focal point of the game recognized by all players as the one which is the most proper and that corresponds to a sense of justice. This is particularly true considering that in a legislative arena each faction would benefit from a split according to the number of seats it retains (Gamson 1961 and on office payoffs; Warwick 2001 on policy payoffs). If this is the case a minority faction will accept only a distribution of payoffs that is proportional to its power within the party. This share equals the benefit of joining another party or contributing to the government on its own. The faction will be indifferent among the two options (to stay or to leave); however it will rather stay, avoiding to incur the cost of leaving the party (this cost for instance is represented by loyalty or by the need to create a new organization, and so on).

In the real world things are slightly complicated. So far we discussed only the bargaining between factions, leaving aside the role of party leader. However, as far as we are dealing with the production of a public good (party unity) we have to cope with the classic collective action dilemma (Olson 1965). Although repeated interaction between factions fosters the emergence of cooperative norms (Boucek 2003a) the party will need to select one actor that organizes the subgroups to carry out the public good (e.g., Cox and McCubbins 1993). This role is played by the party leader who may be in charge of dividing the payoffs among all factions. As far as leader's first desire should be to keep its status she will probably overpay her own faction, to avoid losing its support and to minimize the risk of being dismissed from the office.⁵ Actually

⁴Size matters: talking about the strength of the median DC faction, *Dorotei*, Andreotti noted that they were strong due to their size, 'because size is power' (from "La Repubblica" July 8th, 2010, translation mine).

⁵Leaders face a kind of *Madison's Dilemma*: 'Agents who are placed in a position of leadership [...] can be expected to exploit it – to use the authority they have been granted to advance their own interests' (Kiewit and McCubbins 1991: 47).

this unequal allotment could be reasonable in light of the added value provided by the leader: a strong leader increases the spoils assigned to her party granting more benefits to all factions. If this is the case it would be reasonable to assign to her (i.e., to the faction linked to her) this surplus.⁶ The stronger the leader, the greater her advantage.

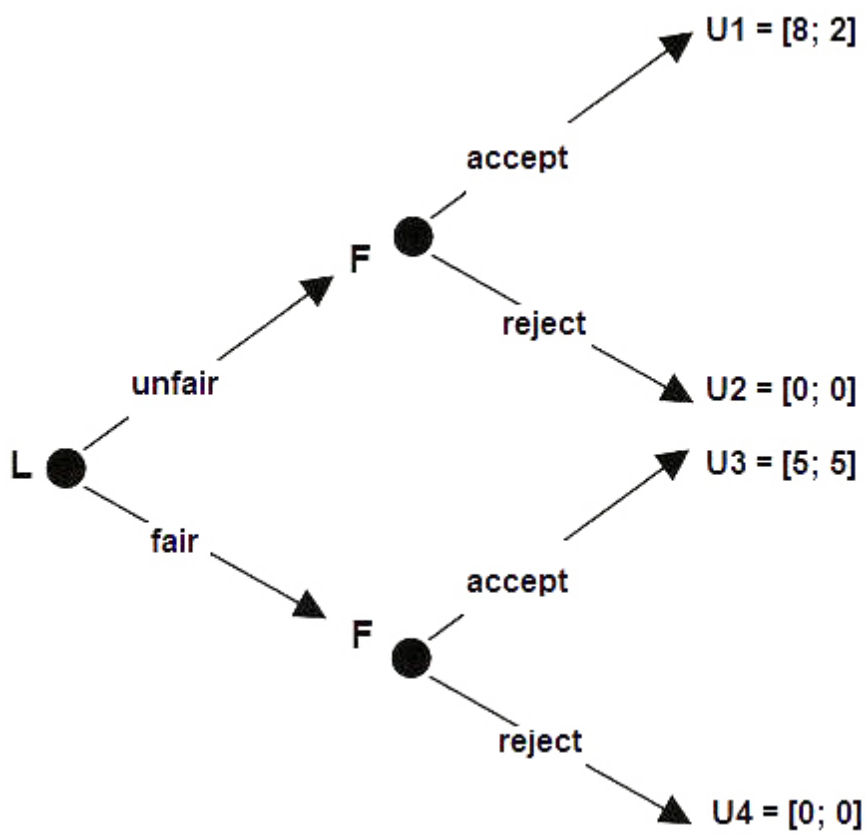

We can model this idea following the classic *ultimatum game*, like in figure 2.1. There are two actors: the party leader, L, tied to the mainstream faction (composed by her followers) and a minority faction, F, that gathers dissenting members.

L has to split a total amount of payoffs equal to 10; she can make a proposal that can be accepted or rejected by the minority group. If the minority refuses the payoffs of both actors shrink to zero, like in upshots 2 (U2) and 4 (U4). To give an idea: the law proposed by the leader is not passed or the party is no longer able to join the coalition government, losing policy and office payoffs. Suppose that the two factions retain approximately 50% of party members each. The leader might offer a fair deal (granting 5 out of 10 to the minority faction) or otherwise she can propose an unfair sharing (retaining a quota of benefits greater than her faction's size). The minority faction may either accept or refuse the proposal. The classic game-theoretic solution is that the leader proposes the unequal distribution and the minority accepts the deal leading to upshot 1 (U1): both actors maximize their payoffs given the credible outcomes of the game.

However empirical evidence from real world politics and experimental economics provided confirmation for the alternative solution (U3) according to

⁶This reasoning is analogous to the principal-agent paradigm: to solve the collective action dilemma party factions should assign to the party leader (i.e., a political entrepreneur) a remuneration that coincides with the surplus produced thanks to her contribution (Alchian and Demsetz 1972).

Figure 2.1: Inter-factional Bargaining as an Ultimatum Game

Note: L = party leader; F = minority faction. Leader moves first. Actors payoffs are indicated in square brackets and kept separated by a semicolon. Leader payoffs are indicated first, followed by faction payoffs.

whom the payoffs will be split evenly (e.g., Güth 1982; Nowak *et al.* 2000). This could be due to many possible reasons. We argue that the degree of leader autonomy, determined mainly by the leader selection procedures could be the key element to explain these contrasting empirical results.

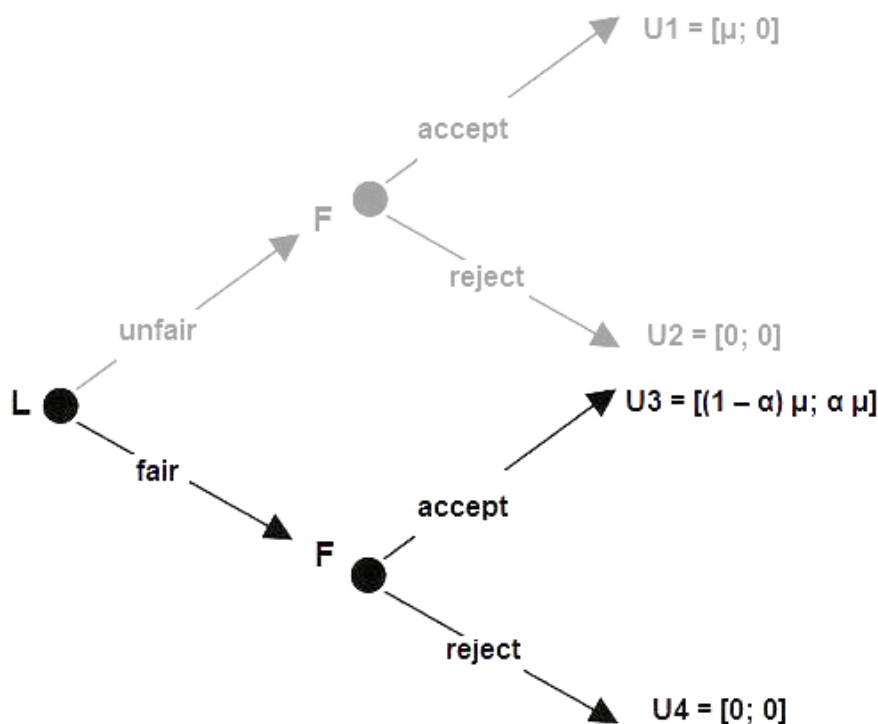

The party leader is responsible for payoffs allocation within factions. We can face two paths: either the leader is voted by the party body or she is directly elected by the rank and file (see figure 2.4 below). In the first case her election might result from inter-factional compromise. This happens, more likely, when the leader is nominated in small committees (smoke-filled rooms) where any single activist can alter the equilibrium by changing her position. In this context each faction retains a stronger veto power and the need for a compromise will be greater. The appointed leader is nothing more than the product of inter-factional arrangements and has to stick to the inter-factional agreement on which her delegation was based on, given that any deviation from the deal will lead to her dismissal. The leader has no autonomy and plays no role, so that party factions will keep on dividing payoffs according to their strength, as discussed before.⁷

Starting from the *ultimatum game* described above, in figure 2.2 we represent the decision-making process inside parties ruled by a bounded leader (BL). We assume that the leader has to decide how to split the total amount of (policy, office and electoral) payoffs that come from party unity, μ . However she has simply no choice (or a very restricted room for manoeuvre). In fact the leader must enact the factional agreement and she can only propose to faction F a *fair* deal. L will grant to the minority a share of payoffs equal (or close) to its size, α (that is the share of congress votes won by that faction). In turn, F will accept the offer, leading the game to the equilibrium U3. Conversely, L

⁷Empirical evidence from Japan underpins this idea: after 1980 the LDP president (who is in charge of allocating office posts) has been elected through factional bargaining; as a consequence the fairness in portfolio allocation increased (Di Virgilio and Kato 2001).

will keep the remaining share of payoffs ($1-\alpha$ times μ) per se (or rather, she will assign it to the mainstream faction, composed by her followers).

Figure 2.2: Distributive Dynamics with Leader Bounded by Factional Agreement

Note: μ = value of party unity; α = minority size. We assume that $\alpha \in (0, .5)$. L = party leader; F = minority faction. Leader moves first. Actors payoffs are indicated in square brackets and kept separated by a semicolon. Leader payoffs are indicated first, followed by faction payoffs.

The previous game was useful to understand bargaining dynamics enacted by non-autonomous leaders. As discussed so far, under a weak leadership, factions' vetoes exert insurmountable constraints. Their common interest in the benefits coming from party unity enhances a fair distribution of payoffs.

Alternatively the leader could be directly elected by a wide 'selectorate' e.g., the rank and file or the whole assembly of delegates at party congress. The broader turnout decreases factions' veto powers; elements like name recognisability, polls and the front-runner effect (Kenig 2009b) as well as the greater

legitimacy granted by direct election (Michels 1911) foster the new leader in front of middle-level activists (see figure 2.4).⁸ She will be stronger than factions and she will also provide the party with the added value of her personal charisma. In such situation the leader will decide on her own how to assign benefits. As long as she received the mandate from party members through a direct election, the leader benefits of a larger degree of autonomy. She will try to exploit such autonomy to increase her payoffs (and to reward her followers on which her power relies on).

Considering the *ultimatum game* of figure 2.1 we contend that, in the first stage, an autonomous leader (AL) will always try to make an unfair offer, as an attempt to reward her followers and to avoid the risk of being dismissed by the mainstream faction (which is responsible for her election).⁹ However the leader's proposal will not be implemented without factions' consent.

We modify the previous game adding additional stages: after the leader's (*unfair*) proposal the minorities might accept or voice; then the leader might look for a compromise or whip the dissenters and they in turn could decide whether to accept the whip or to leave the party (figure 2.3).

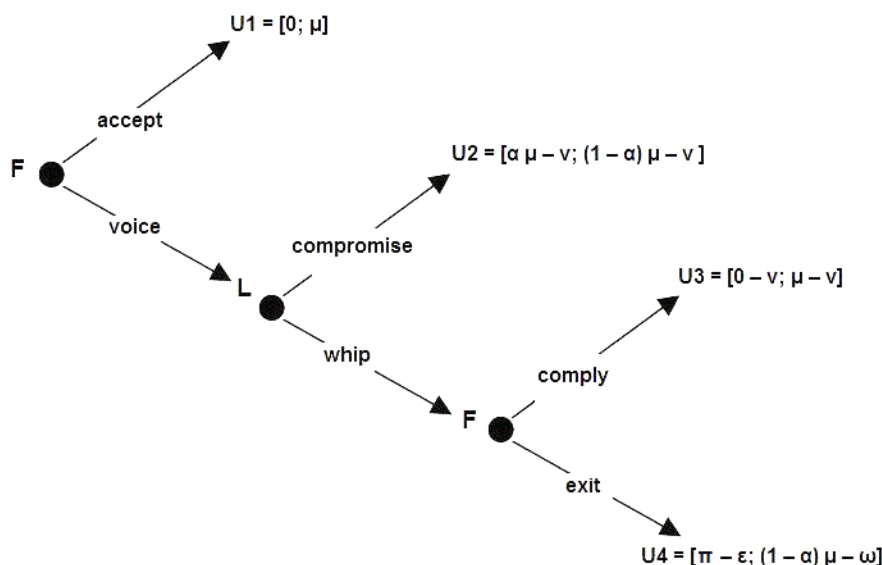

There are still only two actors: the party leader, L, tied to the mainstream faction (composed by her followers) and a minority faction, F, that gathers dissenting members. Minority's size is equal to α , i.e., the share of congress votes won by the faction (a positive value lower than 0.5). There is a total amount of payoffs to be shared; these rewards include office (posts in party body or cabinet spoils), policy (party position) and electoral payoffs (candidacies and parliamentary seats). These returns correspond to μ , that expresses the value

⁸The rationale is that 'the less consistently and intensively involved the participant in the candidate selection process, the more he or she will be swayed by name recognition and the more likely he or she is to take cues from the highly visible central leadership' (Katz 2001: 291).

⁹The mainstream faction could in fact decide to replace her with another leader who, due for instance to her stronger personal charisma, is more able to overpay her supporters

of party unity. The greater this coefficient, the greater the sum of party's payoffs. However to simplify our analysis we assume that the amount of payoffs is fixed so that μ is constant and equal to 1. Furthermore any strategy that undermines party unity or cohesion imposes costs on the actors.¹⁰

Figure 2.3: Party Unity and Party Fission Game

Note: μ = value of party unity; α = minority size; ν = cost of public voice; ε = cost of breakaway; π = difference in minority payoffs after breakaway; ω = cost of party breakup.

We assume that: $\mu = 1$; $\alpha \in (0, .5)$; $\varepsilon \in (0, .5)$; $\omega \in (0, .5)$; $\nu \in (0, .5)$; $\pi < 1$; $\nu < \alpha$. F = minority faction; L = party leader. Actors payoffs are indicated in square brackets and kept separated by a semicolon. Faction payoffs are indicated first, followed by leader payoffs.

The leader proposes to the minorities a deal, trying to exploit her dominant position to keep the whole set of benefits. The minority faction might accept or voice. If the faction complies the gain will be zero (dissenters are excluded

¹⁰We distinguish between ‘*unity*’, when factions stay within the party even though they might openly support different views and strategies, and ‘*cohesion*’, when factions think and act in a cohesive manner that is in agreement with the party line. Party unity refers to the idea of keeping the party together. This could imply cohesion though the latter is not required. We can observe unity with (when all factions agreed on party line) or without cohesion (when several factions express their dissenting voices from within). We observe a lack of unity when intra-party dissent erupts in a party fission. Vice versa we refer to cohesion as the lack of dissent over the party line. Note that a cohesive environment could be built by means of compromise (reaching an agreement) or through enforced (or internalized) discipline and loyalty (see chapter 6). We refer to this concept when factions are cohesive in supporting the party line (or in non opposing it) even if their support is not sincere.

from the allocation of rewards) and conversely leader's payoffs will be equal to μ (U1). Otherwise F can choose to voice; the whole party will pay the cost ν , due to public expression of internal dissent (this cost is greater, for instance, among undemocratic parties that do not tolerate internal dissent).¹¹ Then L can propose a new deal. She can reverse her choice, offering a compromise (each faction will be rewarded on the basis of its strength) or she can stay put, whipping the minority to keep the entire benefit. A compromise will assign μ times α minus the cost ν to the minority faction, leaving to L μ times $(1 - \alpha)$ minus ν (U2). Under the whipping option the game will reach the final stage where the dissenters can either comply or pick up the exit option, leaving the party. If they obey (U3) the payoffs will be very similar to the first stage (when F chose accept) but they are lowered by the value ν for both actors, because the public audience acknowledged the existence of intra-party disagreements (arguably this minus value could be weighted by the extent of the disagreement i.e., the share of dissenters within the party).¹² To the contrary if the minority faction breaks away (U4) its payoffs will be π minus the value ε (i.e., the costs of leaving the party). This upshot takes into account the likelihood of being able to gain seats in the next election (e.g., a function of the disproportionality of the electoral system) along with the price for infringed loyalty and the leverage exerted by the minority. In case of split, L will exploit the whole amount of rewards lowered by the contribution of the

¹¹We could also differentiate the cost of voice for the leader from that paid by the minority faction. The source of such cost might in fact come from alternative sources. However, as we will discuss when talking about the operationalization of this parameter, we assume that these sources are complementary in that the grater the cost of voice suffered by the leader, the higher the price that minority faction will end up paying. In a sense, the extent of this cost is the same for the whole party and for all the actors involved in the game.

¹²Note that heterogeneity could also strengthen the party in the electoral arena allowing it to appeal to a broader public (Katz 1985; McAllister 1991; Morgenstern 2001; Shepsle 1972; but see Alesina and Cukierman 1990). Nonetheless several authors argue that disunity is damaging for party's electoral performance (McGann 2002; Snyder and Ting 2002). Which effect is actually prevailing remains a disputed question (Pasquino 1986). We will better address this topic in paragraph 8.5.

minority faction that now is lacking: μ times $(1 - \alpha)$. Compared to the case of compromise after voice, the leader will not pay any cost for party disunity because the split has canceled the previous disputes providing the party with a clearer and stronger label's value; however L will pay the price ω representing a loss in image due to leader's inability to keep the party together. This price could be higher for a core party that loses its status because of the split or in highly competitive party systems (Boucek 2010), mainly for ruling parties.¹³

According to figure 2.3, table 2.1 summarizes the four possible upshots of the game and reports the payoffs obtained by each actor (F and L) providing a brief description of the moves that led to each outcome.

Table 2.1: Upshots of the Game and Related Actors' Payoffs

Upslot	Description	Faction (F)	Leader (L)
U1	F accepts the unfair deal	0	μ
U2	F voices, L offers a compromise	$\alpha \times \mu - \nu$	$(1 - \alpha) \times \mu - \nu$
U3	L whips F, who complies	$0 - \nu$	$\mu - \nu$
U4	L whips F, who breaks away	$\pi - \varepsilon$	$(1 - \alpha) \times \mu - \omega$

From a backward induction we can draw some observations. In the final stage F faces the choice between *exit* or *accept*; for large values of ε or low π the minority will prefer to accept the whip instead of leaving the party. For value of ω lower than ν the output will be the second best for L that can exploit all the amount of payoffs sustaining the cost ν while F's return is lower than zero. However F knows that it would be better off choosing *accept* at the first stage (because it avoids to suffer the loss due to ν) so that U1 would be the equilibrium. This pattern resembles that of the dictator game where the responder has no choice and can just accept the proposal. Although we claim

¹³This in turn could be proportional to the strength of the splinter group (α) under the idea that the breakaway of a small faction does not damage the party too much. Note however that even a small faction may be very powerful if it retains the power to make or break governments (Boucek 2010). See also chapter 5, paragraph 8.5 and footnote 21, chapter 7, for a deeper discussion on this.

that minority group will have zero payoff, we would expect that (according to economics experimental results) the leader allocates a non-zero share of benefits. Anyway, this share will be considerably lower compared to the case of bounded leaders (figure 2.2). To the contrary when ε is relatively small and π is wide F will choose *exit* at the last stage. In this context, whenever ω is lower than ν the leader will carry the game up to that point, whipping the dissenters in the previous stage and leading the game to U4. Finally, when the costs ω is wide and $\pi - \varepsilon$ is positive L will try to reach a *compromise* at the second stage to avoid the risk of suffering a party fission in the next one, hence the final outcome will be U2. Table 2.2 sums up the upshots related to each possible equilibrium. We distinguish between non credible threat (when faction's payoffs is greater inside the party), credible weak threat (by splitting away the faction can only minimize its loss, compared to the worst option available within),¹⁴ and credible strong threat (the faction would rather break away gaining positive payoffs, unless the leader overpays it with a larger amount of revenues).

Table 2.2: Summary of the Equilibriums and Related Upshots according to the Value of Some Parameters

Leader Focus	Faction Threat to Breakaway		
	Non-Credible ($\varepsilon > \pi$ and $\pi - \varepsilon < 0 - \nu$)	Weak & Credible ($\varepsilon > \pi$ and $\pi - \varepsilon > 0 - \nu$)	Strong & Credible ($\varepsilon < \pi$)
Unity ($\omega > \nu$)	U1 accept	U2 voice; compromise	U2 voice; compromise
Cohesion ($\omega < \nu$)	U1 accept	U1 accept	U4 voice; exit; whip

Starting from the equilibriums described in these two games we can make some points about the shape of intra-party dynamics. The models focus pri-

¹⁴Minimizing the loss could be a rational choice and, accordingly, the threat of split is credible. However the cost of breaking away outweighs the benefit. Factions have to choose between two options that will equally convey negative payoffs. This scenario then is weaker compared to cases where factions gain strictly positive payoffs after the fission.

marily on two facets. One concerns the *distribution of policy and office payoffs*. In chapters 5 and 6 we will examine portfolio allocation and party position-taking accounting for contrasting patterns of inter-factional bargaining. Our aim is to distinguish elements that boost fairness and consensual dynamics (i.e., *compromise*) from those that promote leader’s discretionality and favor minority’s compliance (i.e., *accept*). The second topic that emerges from our theoretical discussion is related to *party fission*. Chapter 7 addresses this question to establish which conditions generate factional breakaways (i.e., *exit*). In addition we can also draw some implications about the *degree of factionalism* (topic discussed in chapter 4) to assess features that favor or inhibit the expression of dissent (i.e., *voice*).

As described in table 2.2, intra-party politics is a two-sided game. On one hand we observe elements that impinge on faction’s choice, while on the other we find those that affect leader’s reply. Each factor that alters the ratio between ω and ν or between π and ε , leads to contrasting outputs increasing or decreasing the expression of dissent, the fairness in payoffs allocation and the likelihood of party fission. In table 2.3 we record the expected effect on the facets of intra-party politics (*voice, compromise, exit*) entailed by an increase of each element ($\omega, \nu, \pi, \varepsilon$), along with an intuition about what each value refers to.

Furthermore, following our general theory, we would expect to observe different outcomes depending on leader selection procedures. We argued that such organizational attribute enables to build distinct party environments that may even correspond to alternative patterns of party (see paragraph 2.3 for a deeper discussion). To take into account such peculiarities in fact we provided two separate games (figure 2.2 and 2.3). Accordingly we will compare, through the chapters, the dynamics among parties ruled by autonomous (AL) or bounded leaders (BL). Our expectations about the effects of BL on intra-

party dynamics are derived from the game in figure 2.2; the impacts of AL, on the contrary, is related to the game shown in figure 2.3. Across the dissertation we will assess similarities and divergences between these two patterns of party. Moreover, we will also focus on the interaction between leader autonomy and party system competitiveness ($AL*\omega$) raising hypotheses accordingly. Table 2.3 resumes all these elements along with their expected effect on the shape of intra-party politics.

Table 2.3: Parameters of the Games and their Expected Effect on the Facets of Intra-party Politics

Parameter	Description	Voice	Compromise	Exit
ε	Exit cost: Loyalty and disproportionality	-	-	-
π	Trade-off: Heterogeneity and minority leverage	+	+	+
ω	Breakup cost: Party system competitiveness	+	+	-
ν	Voice cost: Intra-party democracy and discipline	-	-	+
AL	Autonomous leader	0/-	-	+
$AL*\omega$	Autonomous leader in competitive system	0/-	+	-
BL	Bounded leader	+	+	-

Here we provide some insights about the meaning of each parameter while a more detailed description will be carried out in the empirical part of the dissertation. The value ε expresses the exit cost, which increases for instance when loyalty toward party structure and party symbols is very strong or under political systems with disproportional electoral rules that exert barriers to the entrance of new parties in the electoral market. The parameter π represents the ‘trade-off’, i.e., the net benefit available to minority factions after the split. Due to membership costs (Snyder and Ting 2002), when party heterogeneity is too large each faction would benefit from a split which should increase its gain in terms of policy payoffs. The faction in fact will cease to suffer this membership cost (which is proportional to its distance from the bulk of factions) and it will also profit from the enhanced clearness in party label. In addition we account for the potential expected increase in office payoffs, which

is related to the leverage of each faction: when the split increases the bargaining power of a faction beyond its size, the net benefit of its breakaway raises. However, when factions are already overpaid within their own party the value of such parameter shrinks. The third element, ω , refers to party system competitiveness: in competitive party systems any single split might alter the balance of power between government and opposition (in the parliamentary arena) or between rival parties (in the electoral market) raising the cost of party breakup. Finally, ν , is the cost of voice that should increase when the intra-party level of democracy is lower. When public voice is detrimental for the party, the minority will pay a higher price for expressing dissent (due for instance to whipping and sanctions); conversely the party leadership will suffer for the lack of cohesion due to the public acknowledgement of internal disputes. Here we summarize the general expectations derived from table 2.3 related to the three areas of analysis.

Voice – Factionalism, chapter 4. Elements that increase the exit costs (ε), such as a strong party loyalty, should deter factions from disclosing their dissent decreasing the degree of factionalism. Looking at table 2.2, when ε is larger than π in fact we record voice only in one equilibrium out of four while for small values of ε the minority should always revert to *voice* as a strategy to enhance its welfare. In turn, an increase in π boosts factionalism: the minority tries to exploit its stronger leverage through the *voice* option, to bargain a good deal that might convey larger payoffs. Along the same vein we contend that under competitive party systems (ω), where each subgroup might alter the balance of power between rival parties, the leverage of minorities increases thereby making *voice* more profitable. By definition, we expect that an increase in the cost of voice (ν) will reduce its usage (we observe *voice* in only one equilibrium out of three when ν is large). Finally, in parties whose leaders are bounded by factions we should always observe *voice*. Factional bargaining in fact is

the device adopted to select the leader and to allocate payoffs. Accordingly, each subgroup should try to affect this process by building its own faction. Compared to that case, we should observe slight dissent when leaders are autonomous (*voice* appears in half of the equilibriums) although this difference could be neglected under competitive conditions.

Compromise – Payoffs allocation, chapters 5 and 6. We raise an argument considering policy and office payoffs altogether, insofar as we assume that their allocation follows a common dynamic. When the exit costs (ε) are larger minority has no longer a blackmail power on party leadership. Hence we expect less consensual dynamics (in three out of four equilibriums the final upshot should be to *accept* the unfair allowance) and low *compromise*. For opposite reasons when π is larger than ε factions exploit their wide leverage and there would be more room for a *compromise*. However this is true only inasmuch as party system competitiveness (ω) is strong too. Competitive conditions in fact appear as the primary determinant of factional cooperation and uphold the reaching of a compromise between party factions. Accordingly, we will focus mainly on this aspect in the related empirical chapters. Conversely, the cost of voice (ν) brings minorities to *accept* an unfair deal whenever they know that the leadership is not willing to address their demands, and they are not strong enough to carry their threat up to the breaking point. As a matter of fact under parties ruled by bounded leaders the reach of a *compromise* should be the rule: as discussed before, the leader is selected after an inter-factional negotiation and she has to stick to such deal. Autonomous leaders, on the contrary, try to enhance their own interests. However this is no longer true when party unity is an issue at stake, i.e., under highly competitive political systems when a fission could strongly harm the party.

Exit – Party fission, chapter 7. Noticeably, the cost of exit (ε) is expected to exert a straightforward effect on the occurrence of party fission. All the

elements that boost exit costs contribute to preserve party unity and in fact from table 2.2 we do not observe *exit* when ε is larger than π . Vice versa, larger values of π confirms that the threat of a breakaway is strong and credible and, accordingly, the minority will pick up the *exit* option unless the party leader is prone to heed its requests by overpaying it. This will not happen in low competitive political systems (such as in a dominant party system) where in fact we would expect more *exit*, while an increase in competitiveness (ω) should decrease splits. A growing cost of voice (ν) yields as an effect the lack of room for internal dissent and, on the other side, brings the leader to refuse any compromise, trading unity for cohesion. As a consequence, we should observe more frequent *exit* for large values of ν , when the minority faction possesses a credible and strong threat. To conclude, we contend that, compared to their bounded counterparts, autonomous leaders foster the likelihood of splits. However, when facing competitive conditions, leaders should exploit their greater autonomy to cater to minority factions in order to avoid damaging splits and to preserve party unity.

The intuitions developed from the theoretical framework and described in table 2.3 will be retrieved in chapters 4, 5, 6 and 7, whose subjects are in fact directly affected by the implications that emerged from the game-theoretic models (with respect to factionalism, payoffs allocation and party fission). In each chapter we will raise and test more specific hypotheses, operationalizing the parameters of table 2.3 through variables that are suitable for that specific context, following in many cases the suggestions provided by the existing literature.

As an example, in chapter 4, when dealing with the causes of factionalism, we will pay attention to party organization measuring most of the parameters according to intra-party rules and including some other hypotheses drawn from the literature. In chapter 5 we focus on portfolio allocation and accordingly we

will adopt variables connected, for instance, with cabinet stability or with the literature on the distribution of cabinet posts. In chapter 6, which is related to party platform, we test the impact of our parameters focusing on intra-party competition in the electoral arena, following the literature on party position-taking. Finally, in chapter 7 we will be concerned mainly with intra-party equilibriums, operationalizing the parameters accordingly.

We should note that, depending on their operationalization, the impact of such variables might sometimes encompasses more than one parameter. However, apart from few exceptions that will be discussed more deeply in each chapter, the effects caught by these variables maintain a common direction. For instance, a variable might entail an increase in π and a decrease in ε in the meanwhile. In this sense, whether due to one causal relationship or to both of them, these variables will allow to assess the validity of our theory anyway. Later, in chapter 9, we will resume the results of each chapter to analyze them in the light of our game-theoretic model.

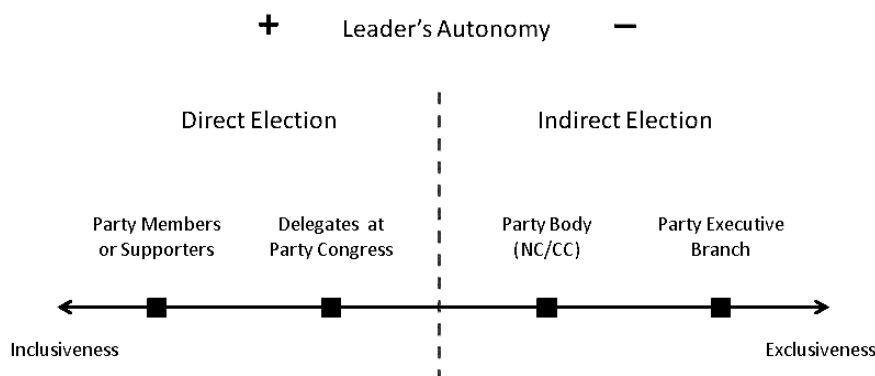

2.3 The Party Leader Selectorate: Autonomy or Dependence

In the previous paragraph we introduced two different games to describe intra-party dynamics under autonomous or bounded leaderships. We argued that the two contrasting leader selection procedures described above give rise to different party environments and even to alternative models of party: on one side the mass party, with its strong linkage to membership, hierarchy and bureaucracy, while on the other side we find a modern party structure, that emphasizes the primacy of party leader and appeals directly to party members or to the whole electorate, bypassing middle-level activists.

Several authors suggested that direct forms of internal democracy might allow party leaders to manipulate the members for their own ends (Katz, 2001; Katz and Mair 1995; Kenig 2009b; Mair, 1994, 1997; Marsh, 1993; Michels 1911; Ostrogorski 1902; Poguntke and Webb, 2005; Rahat *et al.*, 2008). In this vein we retain that, thanks to elements like name recognisability and the front runner effect (Kenig 2009b), the direct election made by a wide and inclusive selectorate paves the way to a ‘Bonapartist’ form of intra-party democracy (Michels 1911) and to a less representative party environment (Rahat *et al.* 2008). As discussed below, we dichotomize the leader’s selection procedure distinguishing between direct election (by members or delegates), which fosters leader’s autonomy, and indirect election (by a small party body committee) that keeps the leader tied to factional vetoes.¹⁵

We conclude the theoretical part of this work drawing figure 2.4 that describes the linkage between the election of party leader and her degree of autonomy. This attribute has been already introduced in the game-theoretic model discussed above and will be retrieved in the course of the dissertation to test some hypotheses and interactions that flow from the game.

Figure 2.4: Leader Selectorate and Leader Autonomy

¹⁵In chapter 6 we will provide additional arguments related with this idea.

2.3. THE PARTY LEADER SELECTORATE: AUTONOMY OR DEPENDENCE

The picture brings together two elements: the party leader in fact might be elected directly by members or activists, or indirectly by a selected committee. The dichotomy direct/indirect election overlaps with the inclusiveness of the selectorate in that when the leader is directly elected, the selectorate is wide and inclusive. On the contrary indirect election is usually carried out by a small committee.

On the left extreme of the continuum we find wide and inclusive selectorates; they correspond to the total number of party members or even encompass party supporters and sympathizers (meaning anyone who is willing to subscribe a declaration of identification with the party while casting the vote to elect the party leader). So far in the Italian political system only the Democratic Party adopted this mechanism to select its leader, twice, in 2007 and 2009.

Alternatively leader's selection could be devoted to the party congress. In this case the leader is directly elected by the whole assembly of party delegates during the congress. Italian parties started to introduce this method at the end of the 1970s and nowadays this is the most common way. The selectorate is quite large given that usually around a thousand of delegates participate to the national congress. In most of the cases the election is just a formality because the leader has already been elected by the party members: often delegates ratify a choice that has already been done elsewhere, resulting from the sum of votes casted at the local level. Sometimes the election is indeed a ritual where the leader is appointed by acclamation (this happens in particular within personal parties, see later). In our sample approximately one out of four leaders has been elected directly during the congress or through 'primary' elections. On the other side of the continuum we find smaller selectorates. The congress usually appoints a smaller selected committee, like the National Council or the Central Committee, which is a kind of internal par-

liament in charge of controlling the leadership. This committee is composed on average by a hundred of members. They might elect the leader on their own or, alternatively, her election could be demanded to the executive branch, which is a tiny group composed by few members (at most a dozen of people). They choose one of them as the new party leader and provide her with the necessary assistance to run the party until the following congress. These two latter procedures were the standard in past years.

The relevance of leader selection mechanisms is underpinned by an in-depth examination of intra-party debates. Reading through the motions presented during party congresses we observe that factions often complained about how the direct election of leader had altered the shape of intra-party dynamics. We report as an example some hints extracted from DC congress held in the 1980s. In 1976 in fact the party started to select its leader by means of direct election through a wider selectorate (composed by congress delegates instead of members of the National Council). During the 1984 congress, Vincenzo Scotti, the runner up party leader candidate (jointly supported by a moderate subgroup, *Impegno Riformista*, and by a left-wing faction, *Forze Nuove*) warned against the risk of transforming the DC into a plebiscitarian party ruled by charismatic leaders, after the introduction of direct election. Later, in the motion presented in 1989, *Forze Nuove* was still complaining against plebiscitarianism, arguing that the direct election had created a personalized leadership that attempts to disempower middle-level activists by appealing directly to the grassroots. Conversely during the same congress another left-wing faction, *Base*, supported this organizational arrangement as a device to overcome the idea of party leader as a *primus inter pares*, constantly bounded by factional veto powers. We should note that factions have long been familiar with this idea of a dualism, between a party ruled through factional agreements or led by a strong leader able to promote the stakes of the mainstream (see on this

point the motion presented in 1967 by *Taviani*, which claimed for more leader autonomy in spite of factional constraints).

The suggestions portrayed by this qualitative inquiry provide us with further good reasons to analyze separately these two intra-party environments. Across the dissertation then we will focus on the impact of *leader autonomy*, conceived as the product of two features: the *direct election* of party leader and the *size of the selectorate*.

Chapter 3

Analyzing Intra-party Politics: The Dataset on the Italian Case

3.1 Factional Politics: The Italian Case

The life of Italian parties has always been characterized by high level of internal factionalism. Almost all the relevant parties during the Italian First Republic (1946-1994) were continuously affected by factional quarrels and compromises. *Dorotei*, *Nuove Cronache*, *Base*, *Forze Nuove* and many others within the DC; *Sinistra Socialista* and *Autonomia* inside the PSI; *Presenza Liberale* and *Libertà Nuova* among those of the Italian Liberal Party (PLI) and then *Rinnovamento*, *Riscossa*, *Iniziativa*, *Democrazia*, *Impegno*, *Unità*. These names, followed by an adjective (socialist, liberal, republican) to identify their party affiliation, were equally spread across parties. Factions have long been crucial for Italian politics. They were steadily mentioned in the everyday political chronicles due to the impact exerted within their parties and in the legislative arena. Many bill proposals were rejected due to the veto of some factions. Many governments resigned for the same reasons while the fate of others was strongly linked to the outcome of party congresses (Curini and

Martelli 2009; Giannetti 2010; Mershon 1994).

Factions were indeed able to promote or to end governments and political formulas; it is not by chance that the rise of the centre-left government coalition in the 1960s had to wait until within the DC and the PSI those factions favourable to start such alliance were strong enough to overcome the vetoes of internal minorities (Curini and Martelli 2009). In fact the Fanfani IV Cabinet was appointed with the decisive support of the socialists (February 1962) only after the DC leader, Moro, won the party congress (January 1962) with a motion favourable to the advent of the centre-left political formula.

Beside the DC, the Italian Socialist Party was factionalized as well. Since its foundation in the 19th century the party was composed by several subgroups (maximalists versus reformists) and it has repeatedly been weakened by the breakaways of its moderate or extreme wings. During the First Republic only the Italian Communist Party appeared to be undivided. This was probably due to strict and undemocratic internal rules. The party was organized according to the principles of democratic centralism, combining strong party discipline in the external behaviour with (theoretically) wide freedom of thought within the party body. Notwithstanding at the end of the 1960s some intra-party groups formed. However, due to party rules, these groups were not allowed to stabilize as organized factions. Only one, *Manifesto*, attempted to do so but was sent off from the party in 1969 while others (i.e., the right-wing *Miglioristi* and the left-wing *Cossuttiani*) survived as latent entities. Regardless of this exception all the other parties (the social-democrats, the liberals, the republicans and even the post-fascist MSI) were composed by organized factions (Lombardo 1972).

After 1994 a set of institutional changes led to the Italian Second Republic, with a renewed political system characterized by high fluidity and party instability (parties die and birth at a crazy rate). In such context factionalism,

although softened, seems to persist. Apart from personal parties (Calise 2010) like Forza Italia (FI), Northern League (LN) or Italy of the Values (IDV), all the main actors that characterize the Second Republic are internally divided.

We provide some examples. Within the far-left PRC several Trotskyists factions fight against the party mainstream. The right-wing National Alliance (AN) was divided in three for it a liberal-democratic faction, strongly linked to the party leader Fini (*Nuova Alleanza*), was challenged by a group loyal to the centre-right coalition leader Berlusconi (*Destra Protagonista*) and by a third faction more attentive to pro-State issues on the economic dimension (*Destra Sociale*). The centre-left DS has been affected, since its birth, by factional struggles promoted by an internal left (*Correntone*) and a right-wing group (*Liberal*); the mainstream faction in turn was not completely cohesive due to quarrels between Veltroni's partisans (*Veltroniani*) and the followers of D'Alema (*Dalemiani*).

Both AN and DS are no longer alive because they merged with other parties to form new rallies. Their subgroups however survived and brought their pre-existing factional conflicts in the new parties. The DS merged with the DL into the PD. Two left-wing factions that opposed this merger decided to break away. Notwithstanding the new party was highly factionalized and the conflict between *Veltroniani* and *Dalemiani* perpetuated inside it. The first PD party leader, Veltroni, appointed in 2007 by a wide margin and with the support of *Dalemiani* too, has been under attack by D'Alema followers since the beginning and was forced to resign quite soon. In 2009 the new party leader, Bersani, belonging to the *Dalemiani* faction *Riformisti E Democratici* (RED), defeated the incumbent Franceschini (supported by Veltroni). After the congress, Franceschini's faction *Area Democratica* re-approached Bersani in order to enhance party unity. Veltroni disappointed by this shift gathered its followers together with other dissatisfied members and built a new

organized faction, *MoDem* (*Movimento Democratico*), that overtly oppose the mainstream group.

Something similar happened to AN. A few months before the fusion between National Alliance and Forza Italia into the PDL, a splinter group (*D-Destra*) broke away from AN.¹ The conflict between Fini's partisans (*Finiani*) and Berlusconi's fans (*Berluscones*) that characterized AN internal life continued within the PDL. After AN 2002 congress factional conflict exacerbated and the party leader, Fini, addressed this concern changing the rules. He decreased the level of democracy (with a formal ban on factional grouping) while building intra-party routines based on compromise (e.g., all the factions retained ministers in the Berlusconi II Cabinet).

Within the PDL, on the contrary, reaching a compromise was harder. The agreement set during the fusion assigned 70% of all spoils (within the party body and the government) to former FI members while ex AN factions had to divide the remaining 30%. Given that FI was a personal party tied to Berlusconi, not familiar with internal dissent (Calise 2010; Poli 2001; Raniolo 2006), inside the PDL there was little room for Fini's followers. They retained around 10% of all charges.² This percentage was not far from being proper if we consider the pre-existing intra-party equilibriums in AN: indeed the three main factions retained roughly 30% each of the 2002 congress votes meaning that they should expect to receive one third of the quota of payoffs assigned to former AN members in the new party.

However AN, contrary to FI, was an heavily organized party, more capable to mobilize members and activists. For these reasons *Finiani* subgroups were

¹This group in turn was born from the split of the right-wing faction *Destra Sociale*.

²They held roughly 8% of posts in party body: around 13 seats out of 172 in the board and 3 out of 36 in the executive branch. In the Senate 10 out of 146 MPs were loyal to Fini while in the House their percentage was slightly higher: at least 34 MPs belonged to *Finiani* (around 12%).

probably able to gain more than 10% of approval within PDL members.³ This is why Lower House Speaker Fini demanded for a new congress where each faction could have been weighted according to its share of members votes. This constituted also a way to counteract the overriding power of the self-enthroned (Kenig 2009a) party leader Berlusconi, who was ruling the party on his own. This factional strife was revealed during a party meeting in April 2010, when Fini claimed for more consensual intra-party dynamics. However the mainstream's reply was to explicitly forbid any intra-party faction.

The conflict worsened in July when it became clear that public dissent was no longer accepted by the leadership (likewise inside parties ruled by means of democratic centralism). The executive party branch lowered the degree of internal democracy stating that minority faction's leader Fini was unfit to be a PDL member, as long as his public statements released on several policy issues (like justice, immigration, devolution, social policy and civil rights) were considered to lay very far away from PDL platform and outside from its ideology. It also imposed sanctions on three of his followers. Such punishments immediately triggered the split of the *Finiani* faction from the party.

This parenthesis on the history of Italian factions confirms how pervasive they are in the Italian political system. Indeed many works discussed the role of factions within Italian parties (Allum 1997; Bettcher 2005; Boucek 2010; Giannetti and Laver 2009; Giannetti and Mulé 2006; Golden and Chang 2001; Katz 1986a; Kato and Mershon 2006; Leonardi 1973, Leonardi and Wertman 1989; Mershon 1994, 2001a, 2001b; Pasquino 1980; Sartori 1973; Zariski 1962, 1965; Zariski and Welch 1975; Zuckerman 1975, 1979). Among these studies

³*Finiani* faction was organized through a net of associations and foundations, linked to and somehow coordinated by Fini's think-tank *FareFuturo*. Some of these subgroups were more radical in their opposition to PDL leadership; among them we recall *Generazione Italia*, led by Fini's heir apparent, Italo Bocchino, and *Libertiamo*. Others were instead moderate like for instance *Area Nazionale* or *Spazio Aperto*, created by Silvano Moffa (who in fact broke away from the PDL in July 2010 but returned in the centre-right fold in December).

it is worth to recall two of them that will be mentioned in the course of the dissertation.

One is related to factions during the First Republic while the other involves divisions in the Second. Mershon (2001a, 2001b) investigated portfolio allocation inside the Christian Democratic Party. She shown that cabinet spoils (ministers and junior ministers) were distributed to each faction proportionally to their share of seats in party body. This pattern held especially when DC was ruling alone; in coalition governments to the contrary there was a slight advantage for the median faction and the same happened when the party leader started to be elected directly by the congress instead of by the National Council. She provided a partial confirmation to Gamson (1961) hypothesis (which attests that office payoffs are distributed to coalition members according to their contribution to the coalition i.e., faction's size); she also highlighted the role of intra-party preferences and rules, given that the median faction, due to its strategic position, could be overpaid depending on the effective internal rules. Another interesting contribution concerns the voting behaviour of MPs belonging to the Democrats of the Left. Analyzing roll calls on foreign policy issues, Giannetti and Laver (2009) shown that factional membership (determined according to the signature on motions presented during party congress) affected MPs' votes in the parliamentary arena.

All these reasons help to illustrate the explicative potential of the Italian context. This case study fits the main topics of intra-party politics discussed in the present dissertation. Italy is indeed a benchmark to study *the politics of faction* (Zuckerman 1979) and it is well suited to analyze party fissions too. Although splits (and factionalism) affect politics all around the world (e.g., Mair 1990) they 'are endemic in certain countries, for example Japan and Italy' (Laver and Kato 2001: 510). Sartori (1976: 81) stated that the Italian party system 'results from a process of 'fission'. The Italian genetics of the case is

that parties came first, and their factionism grew and consolidate itself later'. Along Italian history, party fission affected the political system several times. We already mentioned the iterated waves of fission within the PSI, which generated new rival parties like the Italian Communist Party and the Italian Social Democratic Party, and the split of PDL that altered current Italian politics increasing government instability and contributing to the dissolution of the Berlusconi IV Cabinet.

The Italian context is promising for even more reasons. The huge number of parties that filled its political history (around 10 within each legislature) and the high number of factions (about 3 inside each divided party) allow to collect a number of cases wide enough to carry a large-N statistical analysis. The same holds for the high cabinet instability rate (60 governments in 64 years) that allows us to track reshaping in alliances, party policy positions and allotment of office payoffs almost year by year. In turn the wide number of general elections (17) held since 1946 under four different electoral systems provides much information about electoral payoffs and allows to test the effect of changes in the electoral laws.⁴

All these features will be of use in the course of this work. The key element that has made this research possible however is another one: the availability of a large amount of documents related to the internal life of Italian parties and to party factions. Although several authors pointed out the importance of collecting data about factions' preferences (Budge *et al.* 2010; Giannetti and Benoit 2009; Laver and Benoit 2001) finding information about them is often a difficult task. Intra-party politics takes place in the shadow, it's a sort

⁴The electoral rule has been a pure open list PR from 1946 to 1992 except in 1953 when was added a majority prize (two third of seats) for the coalition able to gain a majority of votes. Elections were held under a mixed system (75% plurality and 25% closed list PR) from 1994 to 2001. Finally in 2006 and 2008 the electoral system was a closed list PR with thresholds and a majority prize for the coalition that won a plurality of votes. For this reason the Italian case is a kind of political laboratory suitable to generate and test hypotheses (Giannetti and Grofman 2011).

of ‘invisible politics’ (Sartori 1976). So far in fact only few works managed to measure factional preferences (Debus and Bräuninger 2009; Giannetti and Laver 2009; Spirling and Quinn 2010) but they do so only for a single party or for a limited lapse of time. The present research tries to fill this gap providing a new dataset that contains information about factions’ policy positions among Italian parties from 1946 to 2010.

For the Italian case, as Sartori (1971: 24) recognized, there is a bunch of documentation available: ‘although dispersed, [...] exists, rather, it is copious. The question is how to detect and to make use of such documentation in order to transform “banal data” into information that enables us to solve the matter’. In the next paragraph we will address this concern explaining how we can exploit such information, to build a dataset that represents a first attempt to systematically gather data on party factions and intra-party struggles. This dataset then will be analyzed to shed light on factional conflict and intra-party bargaining.

3.2 Party Congress Arena: where Factional Bargaining Takes Place

To assess intra-party equilibriums and dynamics we need to gather data about the factional structure of parties. In particular we need to know the number, the strength and, most important, the preferences of each faction. According to Boucek (2009: 467): ‘Depending on available data for any given party, the unit of measurement may be faction parliamentary memberships (the number of MPs affiliated to each faction), the voting strength of individual factions on party decisional bodies such as party congresses (using motion votes as indicators of factional strength) or on party executives (using indi-

vidual factions' seat shares) or in cabinet (based on the number and type of portfolios received by each faction) or in legislatures (based on factions' committee memberships and chairs, etc.)'.

Likewise we can determine policy positions of subgroups looking at party body or analyzing their behavior in the legislative arena. Although some authors shown that it is possible to estimate factional preferences through roll-call votes (Cowley 2002; Rosenthal and Voeten 2004; Spirling and Quinn 2010), it has been argued that 'content analysis on texts drafted by [...] intra-party groups seem to be the best choice to identify their respective preferences, in particular if the research question deals with changes of the positions of political actors over time'. (Benoit *et al.* 2009: 443; Benoit and Laver 2006; Bäck *et al.* 2011). In a congress motion each faction is (almost) completely free to present its view about party platform; in this context the discipline (Laver 1999) only plays a limited role in bounding the expression of factions' preferences so that text analysis should be less influenced, compared to roll call votes (Spirling and McLean 2007). Moreover not all votes are roll-call votes, thus they do not provide a complete picture of voting behaviour. We know that the decision to call a roll-call vote may also be strategic and biased according to the issues or the group that call it (Carrubba *et al.* 2006; Giannetti and Benoit 2009: 233). In addition roll-call analysis is strictly related to voting behaviour, which provides actors with a limited set of options: "yes", "no" or "abstention",⁵ while there could be a variety of preferences behind a similar voting behaviour: actors may say "yes" or "no" for very different (and sometimes opposite) reasons. Text analysis helps scholars to discover and highlight the actual positions of political actors by providing a broader set of information about their preferences. For all these reasons we will analyze factions'

⁵Due to parliamentary rules, in the Italian context the voting behavior includes the absence as a fourth alternative (Curini and Zucchini 2010; Landi and Pelizzo 2006). When strategic, in fact, the absence allows to express a policy position (see paragraph 8.3).

positions through text analysis focusing on party congresses.⁶

Scholars suggest to refer to party congress as a source of data (Boucek 2009, 2010; Giannetti and Benoit 2009; Giannetti and Laver 2009; Mershon 2001a, 2001b; Reiter 2004). Indeed ‘Many gains in understanding intra-party politics may derive from analysis of internal party organisation, such as formal and informal factions’ (Giannetti and Benoit 2009: 235) in particular by examining ‘debates at party congresses between different party factions’ (Giannetti and Benoit 2009: 234). With respect to the Italian context this is even more true. Indeed the only ‘hard data’ about factions are those related to party congresses (Giannetti and Laver 2009; Sartori 1976).

The party congress represents the key moment in party’s internal life, like general elections are the crucial starting point for representative democracy. Indeed ‘For factions, the closest approximation to that sort of competitive arena is internal party elections, since it is there that factions organize teams of candidates and appeal to people enjoying the right to vote for one team or another’ Mershon (2001a: 561). During the party congress those subgroups prone to organize as a faction present a list of candidates to party body. Often this list is attached to a ‘motion’, i.e., an omnibus policy document that aims to shape party strategy and ideology. Motions set out factions’ ‘opposing views on the ideological direction of the party’ (Giannetti and Laver 2009: 154). After a public debate party congress’ delegates vote on the policy principals and establish the new party line that the leadership should pursue. They appoint members in party executives and party body (a committee in charge of running the party); elect (directly or indirectly) the party leader; ratify the party statute; set the new party line and strategy casting a vote on a

⁶It could be argued that talk (and language) is cheap. However Giannetti and Laver (2009) found some relations between politician speeches during party congress and their consequential political behaviour in the parliamentary arena. Therefore, ‘if the politician speaks and behaves in a consistent manner, [...] may well become associated with a particular position on a particular dimensions’ (Laver and Shepsle 1996: 248).

3.2. PARTY CONGRESS ARENA: WHERE FACTIONAL BARGAINING TAKES PLACE

motion that commits the leadership to some general policy statements, until the next congress. In fact ‘party delegates vote on the policy principals in an annual conference whereas the balance of power between faction, that is, the proportion of votes that each faction receives, is translated into policy recommendations’ (Levy 2004: 251).

During the competition for gaining members’ support, the party splits in many subgroups. The party congress however is not only a source of division, it is also the place where the party tries to reach its unity through a compromise among its factions. Either the bargaining is successful or the party will more likely incur in a breakup. Many fissions indeed take place during the congress or soon after.

The party congress is the arena where those who want to distinguish themselves from party mainstream can exploit visibility towards party members and voters, in order to show that they retain a different policy position. For these reasons party congresses can be used systematically to map the factional structure of parties (Giannetti and Laver 2009). Data drawn from congresses provide us with objective criteria to analyze intra-party divisions. Information that flows from official sources is the only way to overcome scholars’ personal beliefs about the actual number of factions inside parties.⁷ In addition these data provide a measure of the strength of each faction, through the number of congress votes gained by each list or the number of members elected in party body (when data on members’ votes are lacking). Finally they allow to assess policy preferences of each faction by means of a content analysis; in fact recent developments in quantitative text analysis can be exploited to estimate factions’ ideal point analyzing congress’ motions.

For these methodological reasons related to data collection, and given the

⁷As an example, Pasquino (1972) counted four factions within the PSI in 1971, Sartori (1971) to the contrary argued that they were five and other scholars enumerated up to seven subgroups.

need to identify intra-party subgroups according to objective criteria, we consider as a faction each party subgroup that contested the congress presenting its own list of candidates attached to a policy motion (following Giannetti and Laver 2009). As far as we are dealing with divided parties we excluded from the analysis actors like ‘personal parties’, where the leader exerts a strong impact on members and activists (e.g., Raniolo 2006). Here we would expect lower or null level of polarization. Even if those parties were internally polarized, such divisions would not emerge as organized factions given that those actors are, by definition, *parties without factions* (Lombardo 1972).⁸ Indeed those parties held congresses very seldom and these meetings are almost never contested. They are nothing else than conventions devoted to celebrate internal unity and party leadership.

Similarly *unitary congresses*, meaning those where there is no competition between lists of factions and the delegates agreed to approve a common motion of intent, are excluded from the analysis. We do not claim that there is a lack of factionalism inside parties whose congresses are unitary. Sometimes minority factions might refuse to present their motion and their list, for whatever reasons; they might agree with the mainstream or they do not feel to be strong enough to defy the leadership. Indeed the previous game-theoretic model proved that the existence of internal dissenters is not a sufficient condition for the emergence of voice (i.e., minority motions).

This does not happen only in the presence of strong and autonomous leader but also when the party is ruled through inter-factional compromise. Such agreements in fact could be reached either after the congress (then we will observe internal conflict) or before. In this latter case we will not be able to measure intra-party division and conflict (even though they exist) because

⁸Hereby we would face atomization of intra-party preferences rather than factionalism; the analysis of such atomization however is behind the scope of this dissertation.

they have been already solved: the unitary congress motion (as well as the division of party body's spoils) expresses a common equilibrium on which all subgroups agreed. We do not investigate this preemptive agreement assuming that it should not follow a different logic from other intra-party bargaining dynamics. Admittedly some groups contest the congress together, presenting a common list and a common motion, but they join forces only to be stronger during the struggle, raising more votes (and sometimes bypassing thresholds established by electoral rules). However we do not investigate the process that led to such alliance between factional subgroups. We measure their common position and their common strength assuming that within the party they will bargain as a unitary actor (this is not completely far from being true if we recall our previous statement about how instrumental preferences might become actual and stable policy positions).⁹

Finally, for analogous reasons, we did not include those (few) congresses where factions competed without presenting motions.¹⁰ We could have reverted to speeches delivered by factional leaders during the party congress to measure policy preferences of each subgroup. However this is unfeasible due to methodological reasons related to the automated tool for textual analysis we adopted. In fact the linguistic features of speeches are different from issued documents, like motions or manifestos.¹¹ Analyzing these two different kinds of document together would produce biased estimates (see Debus e Bräuninger 2009, 131).

We gathered motions from official proceedings related to national con-

⁹This was done also for analytical purposes. To estimate actors' positions we need a policy document like congress motions. Had we considered factional subgroups we simply wouldn't have found data about their policy positions and we would have been forced to treat them as missing cases.

¹⁰Among them: DC 1973, PSI 1976, and PD 2007 congresses.

¹¹Accordingly we excluded from the analysis other congress documents whose linguistic features were divergent (for instance, in 1961, Pertini contested the PSI congress writing a 'letter' to party members using attributes typical of personal correspondence).

gresses edited by parties and from parties' official newspapers or reviews.¹² Motions related to the most recent congresses have been downloaded from the official parties' websites.¹³

We tried to collect data about parties' factional structure analysing the whole population of party congresses held by the Italian parties (approximately 300). However some of them (roughly 50%) should be excluded for the methodological reasons discussed so far. Unfortunately, due to lacks in data sources we were not able to find information on the whole population of contested congresses. After the collapse of the Italian party system, in 1992-1994, many of the existing parties disappeared and their archives disappeared as well; moreover issues of some parties' newspapers are not always available. We have been able to find information on approximately 50% of the total number of contested congresses. Overall we gathered 254 motions related to 83 congresses of 18 parties. Almost two hundreds of them (nested in 64 congresses) concern the First Republic while the remaining data (19 congresses with 56 motions) belong to the Second Republic. On average the number of motions per congress is three. Table 3.1 shows more details about the motions gathered.

For several parties (AN, PD, PDA, PDCI, PS, PSIUP, UDC) we have data concerning only one congress. Conversely the maximum number of congresses analyzed pertains to PSI (12 congresses) and to DC, PLI, PRI (with 11 con-

¹²We referred to the newspaper "L'Avanti" for PSI, "La Giustizia", "L'Umanità" and "Critica Sociale" with respect to PSDI, "L'Unità" for PCI and DS, "La Voce Repubblicana" for PRI and "Il Secolo d'Italia" to gather data on MSI factions.

¹³Information on AN and DS were available respectively on www.alleanzanazionale.it and www.dsonline.it even though we revert to the Internet Archive (www.archive.org) to visualize most of these pages. We found data about the Greens on www.verdi.it; NPSI motions are available on www.socialisti.net; data about PD has been gathered from <http://beta.partitodemocratico.it>; PDCI motions were displayed at www.comunisti-italiani.it; information about PRC congresses was found at www.rifondazione.it; we referred to www.partitosocialista.it for data on PS; finally data on UDC were found on www.udc-italia.it.

3.2. PARTY CONGRESS ARENA: WHERE FACTIONAL BARGAINING TAKES PLACE

Table 3.1: List of Parties, Number of Congresses and Motions Included in the Analysis

Party	Congr. Held	Contested Congr.	Available Data	% on Held	% on Contest.	Missing Cases	N of Motions	Average Motions
AN	3	1	1	33	100	0	4	4
DC	18	13	11	61	85	2	41	3.73
DS	4	4	4	100	100	0	12	3
FV	18	16	2	11	13	14	6	3
MSI	18	7	5	28	71	2	20	4
NPSI	6	2	2	33	100	0	4	2
PCI	16	3	3	19	100	0	8	2.67
PD	3	3	1	33	33	2	3	3
PDA	2	2	1	50	50	1	3	3
PDCI	5	1	1	20	100	0	2	2
PLI	18	11	11	61	100	0	35	3.18
PRC	8	6	6	75	100	0	20	3.33
PRI	22	15	11	50	73	4	25	2.27
PS	2	1	1	50	100	0	3	3
PSDI	24	21	9	38	43	12	25	2.77
PSI	24	12	12	50	100	0	38	3.17
PSIUP	4	1	1	25	100	0	3	3
UDC	3	1	1	33	100	0	2	2
Total	198	120	83	42	69	37	254	3.06

gresses each). We found also 9 PSDI congresses and 6 related to PRC. One of the latter is not actually a congress although it looks like. In 1998 the PRC mainstream split and during a party body meeting four factions competed to take control over the party in order to set the new line; each faction presented a motion voted by members of the party National Political Committee. For this reason we managed to analyze it as if it was a real congress. In general the present database is unbalanced because it contains more information about some parties and only few cases related to others: there are 38 motions nested in 12 PSI congresses but only two motions presented in the unique contested congress held by PDCI and UDC. This feature however does not affect the analysis as we will discuss later.

Column seven provides an estimate about the number of missing congresses, considering only the contested (or presumably contested) congresses that we were not able to account for. Among the parties included in the analysis we have 37 missing cases whereas the number of contested congresses amounts (presumably) to 120. The percentage of missing cases then is around 30%.

With a few exceptions we cover the entire set of contested congresses for a large number of parties. There are multiple missing congresses only for two parties: PSDI and the Greens. The PSDI merged its archive with PSI (after 1966) but some data get lost; the Greens hold a National Assembly approximately once a year and their internal life is particularly tangled so that it was not possible to gather data on past congresses. On the other side we have been able to account for a huge part of internal debates within parties like DC, PLI, PRI and PSI and we collected almost all data about congresses pertaining to DS and PRC. In the next section we will illustrate how these textual documents have been analyzed in order to get factions' policy positions.

3.3 From Words to Fact(ion)s: Measuring Factions' Policy Positions through Wordfish

To extract factions' policy positions from the motions they presented during party congress we need to apply techniques of text analysis. The oldest foremost method of analysis consisted in the hand-coding of textual documents, as carried out for instance by the Manifesto Research Group and the Comparative Manifesto Project (CMP). The CMP analysed electoral manifestos presented by parties through manual coding (see Budge *et al.* 2001 for more details). For each manifesto, human coders divided the text into a number of quasi-sentences and assigned them to one of the 56 pre-determined categories, according to a classification scheme. Noticeably this technique is too much time consuming particularly when the amount of text to analyze is quite large. Given the high number of motions gathered (and their wide length) we could not adopt such procedure to analyze our data.

To cope with this concern scholars started to develop semi-automated and

automated techniques of text analysis. Among the others we find Wordscores (Laver, Benoit and Garry 2003), Rhetorical Ideal Points (Monroe and Maeda 2004) and Wordfish (Slapin and Proksch 2008; Proksch e Slapin 2009a). They provide quicker (but still reliable) means to determine political actors' ideal points. We decided to analyze our data through Wordfish, due to some technical advantages that will be explained soon.

Wordfish is an automated scaling technique, developed to run with the R statistical software, that produces estimates of policy positions comparing several textual documents. This method has already been applied to different text sources (manifestos, speeches, statements and pledges) measuring policy positions of parties and interests groups in Germany, Japan and the European Union (Klüver 2009; Proksch and Slapin 2009b; 2010; Proksch *et al.* 2011).

Wordfish assumes that the words usage provides information about the policy position of each document with respect to others.¹⁴ It further assumes that, for each word, the probability to appear in a document is independent of the presence of other words,¹⁵ therefore it treats each text as a vector of randomly distributed words.¹⁶ Then, looking at the frequencies of words contained in each text, this package allows to determine the differences between alternative documents scaling them on a common latent dimension thereby measuring their relative policy position.

This calculus is worked out by something like an expectation-maximization (EM) algorithm, that is an iterative method that allows to find maximum like-

¹⁴It could be argued that single words are uninformative about policy positions. This is far from being true because words matter. To cite an example, during the 2009 PD congress some critics argued against Bersani (one of the three candidates) claiming that his victory would have transformed the PD into a social-democratic party. The PD president Rosy Bindi (allied with Bersani) addressed these criticisms claiming that 'Bersani's motion does not contain the word "social-democracy".' (from "La Repubblica" August 15th, 2009, translation mine).

¹⁵Although this assumption is false in real world, it has proved to properly perform classifications.

¹⁶The authors proved that Wordfish estimates are robust to its main assumptions (Slapin and Proksch 2008).

likelihood estimates in the presence of latent variables.¹⁷ The algorithm compares the actual frequency of each word with their expected values. The software assumes that words follow a Poisson distribution, in agreement with the main literature on content analyses;¹⁸ being skewed the Poisson is perfectly suited to analyze the distribution of words in textual documents, which is skewed as well. The Poisson is defined by one parameter only, provided that the mean and the variance of the distribution coincide. This allows to simplify the analysis decreasing the computational effort. The distribution then could be summarized as follows:

$$y_{ijt} \sim \text{Poisson}(\lambda_{ijt}) \quad (3.1)$$

Where y_{ijt} measures how often the word j appears in the document related to party (faction) i at time t . The parameter λ , in turn, is described by the following equation:

$$\lambda_{ijt} = \exp(\alpha_{it} + \psi_j + \beta_j \times \omega_{it}) \quad (3.2)$$

These four parameters, measured by the algorithm, represent respectively the document position (ω) at time t , along with its fixed effect (α), the words discriminating parameter (β) and the word's fixed effect (ψ), that is the logged

¹⁷Despite Slapin and Proksch's claim, this is not an actual EM algorithm 'because there is no random variable whose expectation could be taken. The model contains only fixed effects.' (Lowe and Benoit 2011: 11). On the contrary Lowe and Benoit (2011) shown that Wordfish corresponds to a multinomial choice model.

¹⁸For a review: Slapin and Proksch (2008: 708).

3.3. FROM WORDS TO FACT(ION)S: MEASURING FACTIONS' POLICY POSITIONS THROUGH WORDFISH

mean count of each word across all the documents. This latter parameter helps to control the higher or lower usage of certain words across different texts. For instance, common words not associated with any political meaning (i.e., articles, prepositions, etc.) appear frequently but are uniformly spread across documents. Hence they carry a strong fixed effect while their discriminating power will be close to zero. Conversely the fixed effect helps to assure proper estimates of rare words. As a matter of fact words that appear only in one document should carry a theoretically infinite discriminating power because they are sufficient to identify that document. To cope with this issue the software decreases the β values of uncommon words (that appear for instance in one document only). Thanks to this property Wordfish allows to analyze all the words contained in each text without the need to exclude some of them. On the other side, the document's fixed effect discounts the different length of the texts analyzed to make sure that this feature does not alter the results.

Starting from these fixed effects the algorithm evaluates the two parameters of interests: ω and β .¹⁹ The first parameter, ω , represents the policy positions of textual documents (with mean 0 and standard deviation equal to 1). Given that we are dealing with congress motions, the software extracts the estimates of factions' policy positions. Factions' ideal points are scaled along a single latent dimension whose meaning is to be interpreted ex-post according to the political connotation of the texts submitted to the analysis. For instance, if documents are related to a single issue (e.g., environmental policy) this topic will define the policy continuum. To the contrary, when the statements encompass the whole spectrum of policy issues (like in our case) the latent dimension extracted should be interpreted as a more general left-right scale.²⁰

¹⁹In the first step the algorithm estimates the party parameters conditional on the expectation for the word values. In the second step it keeps fixed the former and estimates the new words parameters. Then it repeats this iterative process until the convergence.

²⁰The software can also allow to build multidimensional spaces producing estimates of actors' preferences on different issues. To do so the documents should be divided into

The other parameter, β , is the word discrimination parameter. It measures how much each word is helpful in classifying documents; it also corresponds to the word's placement along the policy scale showing whether the word stands on the left or on the right of the continuum. As we discussed above, words that appear with an high frequency across all documents have a discriminating power close to zero while words that appear only in a few documents are highly helpful to distinguish between documents that are on opposite sides of the scale. These words will retain an higher absolute value of β and will be located on the extremes of the policy dimension. β values are important because they allow to carry a first diagnostic of the results; by comparing the estimated policy position of words with their actual usage in real world political language, scholars can make sure that the software succeeded in understanding the substantial political meaning of such words.

When compared to other techniques of content analysis Wordfish retains some advantages. With respect to hand coding (where for instance the same document analyzed by two different coders might lead to different results) Wordfish assures replicable estimates of parties positions that are more reliable and unaffected by any possible coder's bias.²¹ In addition Wordfish is more suitable than other automated techniques. The main improvement consists in the ability to produce time series estimates, an aspect that is particularly relevant for our purposes. The algorithm assumes that words usage is constant over time.²² Documents related to the same actor at different points in time are considered to be independent with respect to each other. Therefore the

single issue sub-sections (including statements related only to one topic, e.g., foreign policy) running distinct analyses on each.

²¹Curini (2010) shows that expert's surveys could be biased according to the expert's policy preferences. The same logic might as well apply to coders' judgments during hand coding.

²²Wordfish is able to account for changes in word usage when new words enter the political arena or older words disappear from it but not when the meaning of words switches (i.e. from the left side to the right or vice versa).

position of one actor at time t does not affect its placement at time $t+1$. Its position will be similar across time only if its word usage has remained unchanged. To the contrary whenever the content of documents related to the same actor varies over time the program will be able to detect such changes; any modification will produce adjustments in actors' position that are not artefacts of the model. A further element validates the choice of this tool in the present dissertation. Compared to Wordscores, another technique of text analysis based on words usage, Wordfish does not require finding a reference text to anchor the documents in order to define the extremes of the scale. Finding a text that is common to all the documents would be hard, especially in our case given that we are dealing with a wide temporal extent. In addition this software does not require to build dictionaries that define the political meaning of words that are on the extremes. To the contrary it analyzes all the words contained in each document assigning a substantial political meaning to them, without any ex-ante judgement. Finally, Wordfish provides confidence intervals of the estimates through a parametric bootstrap.²³

For all these reasons Wordfish proved to be suitable to carry our analysis. It has been shown that Wordfish's outputs are highly correlated with the results of other methods like expert surveys, hand coding or content analysis software (Klüver 2009; Slapin and Proksch 2008). Furthermore it represents a faster way to estimate time series policy positions of actors that are usually more reliable when compared to other techniques (e.g., Proksch *et al.* 2011).

As we said, Wordfish requires to assume that words usage has remained

²³For large datasets the bootstrap technique is very time consuming and might take several days or even months on a standard computer. Therefore scholars are developing new tools to quickly assess the standard errors of the estimates. For instances, the R package 'Austin' (Lowe 2011) managed to do that. By reverting to a multinomial-Poisson (MP) transformation that connects the Poisson with multinomial regression models, this package allows to easily compute the uncertainty around the estimated parameters. 'Standard errors derived this way tend, empirically, to be very slightly larger than the standard errors provided by a parametric bootstrap according to the procedure recommended by Slapin and Proksch, but effectively instantaneous to compute.' (Lowe and Benoit 2011: 12).

relatively constant over time. Our analysis encompasses a temporal horizon that ranges from 1946 up to 2010. The congresses included in the dataset are spanned from the end of the II World War, through the Cold War, the Protests of 1968, the fall of Berlin Wall and the collapse of communism, until *Tangentopoli* and the advent of the Italian Second Republic. For this reason we want to control for any possible alteration in words usage. To make sure that our research fits the requirement of language stability we split our documents into two datasets choosing the 1989 as the break point.

Far from producing the *end of history* (Fukuyama 1989, 1992) the downfall of communism certainly yielded changes that affected several issues like foreign policy (due to modification in the structure of international system) or the economic dimension (the left extreme of the state-market continuum disappeared from the options available). These changes have reasonably altered the political meaning of some words; this effect could be even more consistent in a political context, like the Italian one, where the Communist Party was quite strong both in the electoral and parliamentary arena and the debate over communism was an issue of the political agenda so that even centre-right parties (like PLI and MSI) usually emphasized their anti-communist positions. This choice became controversial at the end of the 1980s; just to make an example the internal debate within the MSI developed around the need to define the party as something else than a mere barrier against the communism. Furthermore the Fall of Berlin Wall was the first factors that contributed to alter the Italian party system at the beginning of the 1990s, in particular with respect to the renewal of the Italian Communist Party (Giannetti and Mulé 2006). In sum, this event promoted the beginning of the Italian transition (Bufacchi and Burgess 1998; Bull and Rhodes 1997; Pasquino 2000; Tranfaglia 2003); ‘according to many scholars the Italian transition began the day after the fall of the Berlin wall (November 8th, 1989). As long as the Italian

politics was dominated by the cleavage communism/anticommunism and by the belonging to the Western bloc, the end of the international strife led to adjustments in party competition and redefined the protagonist of such competition' (Pasquino 2000: 204, translation mine). In addition the end of western-eastern struggle caused two other events that Pasquino recalls as crucial moments of the transition: the already mentioned transformation of PCI into PDS and the electoral success of the Northern League in 1992, made possible because moderate voters were no longer 'forced' to support the classic anticommunist parties like DC and its allies (Pasquino 2000: 207). After five years of transition (1989-1994) the Italian political language and the dynamics of political communication were changed indeed (Antonelli 2000; Dell'Anna 2010; Gualdo 2004); the transition led to the rise of new styles of language and communication and fostered trends that were already begun in the previous decades (Dell'Anna 2010: 79) as will be shown later. All these reasons then support the choice of 1989 as the break point.

Dividing the sample allows to control for any possible change in language usage, however it decreases the number of documents analyzed altogether and the number of unique words used to estimate positions. This problem might concern centre-right parties, particularly in the second period (after 1988) because there are only few documents that express their positions and the number of words helpful to identify them is lower as well (overall only one third of our data is related to the second period). For this reason we supplemented these documents including in the analysis other texts that retain similar linguistic properties. More explicitly we included few party manifestos of centre-right parties. Excluding these documents anyway leads to very similar results.

We carried two separate analyses using Wordfish to get estimates of factions' positions. In both analyses our documents cover the whole spectrum of the left-right continuum. In the first period (1946-1988) we analyze mo-

tions of factions belonging to the left-wing Italian Socialist Party of Proletarian Unity (PSIUP) as well as documents related to congresses held by the far-right post-fascist Italian Social Movement (MSI). Similarly for the second period (1989-2010) our data include texts belonging to the far-left Communist Refoundation Party, born from a fusion between the left-wing heirs of PSIUP and the left-wing heirs of PCI, and motions of National Alliance (that in turn represents the continuation of the MSI).

Figure 3.3 plots the policy positions of all the factions included in the analysis.²⁴ We labeled them according to the party they belong to and we clustered their parties by the political family they stand for, in order to get a better visual representation. In details, we find post-fascist parties (MSI and AN) located on the far-right (black); the liberal-democratic family (PLI) is placed on the centre-right (blue); Christian democrats (gray) stand mainly in the centre during the first period (DC) while they are more on the centre-right side in the second period (UDC); the family (orange) that gathers together social-democratic and non-Marxist left (PSDI, PDA, PRI, DS, PD, NPSI, Greens) appears located on the centre-left side, although it shifts toward the centre in the 1980s and during the second period; finally, on the left-wing (red) we find socialist and communist parties (PCI, PSI, PSIUP, PRC, PDCI). From this picture we observe that, first of all, the software has been able to distinguish between parties and political families. At a first sight we find a ‘red’ spot on the left, and ‘black’ and ‘blue’ ones on the right. Across the political families the single dots (party factions) rarely overlaps: we hardly ever find socialist factions to the right with respect to Christian-democratic or liberal party subgroups. Accordingly we almost never find Christian-democratic factions more on the left than social-democratic ones. In a sense, this additionally

²⁴We replicated the analysis using the R package ‘Austin’. These results are firmly correlated (0.99) with those shown in figure 3.3.

3.3. FROM WORDS TO FACT(ION)S: MEASURING FACTIONS' POLICY POSITIONS THROUGH WORDFISH

proves that our analysis recognized the latent dimension as a left-right scale. Indeed this scale usually represents a proxy for ideology (Downs 1957; Ieraci 2006) that in turn is the clue to distinguish political family. They appear to be properly located hence we can argue that the latent dimension on which factions are arrayed has been correctly detected.

Figure 3.4 confirms this idea; it shows the weighted mean of all the factions' positions within each party congress (considering only major parties). Like in the previous graph we find socialists and communists on the left, although we observe a moderate shift of the PSI (see later). Once again the DC is located on the centre, the liberals and the post-fascists on the centre-right, the democrats and social-democrats mainly in centre-left positions. This is true for both time periods. This graph also allows to monitor changes in party position over time. We observe, for instance, that DC position is closer to the centre-left in the 1960s, when the centre-left formula was adopted with the entrance of the PSI in the coalition government. We also note that after the 1970s and more deeply during the 1980s many parties followed a rightward drift. This feature affects in particular PSI, PSDI, PLI and PRI (whose positions however are not shown in this picture). This shift is consistent with the changes in the economic policies due to the international crisis burst in 1972-1973 and with the need for a deflationary policy able to drop inflation and to cut government spending in order to stop the growth of public debt. All this features will be discussed more in depth in the next paragraph, where we will assess the validity of the present dataset.

CHAPTER 3. ANALYZING INTRA-PARTY POLITICS: THE DATASET ON THE ITALIAN CASE

Figure 3.1: Factions' Position on the Left-Right Scale in the First and Second Period (Parties Clustered by Political Family)

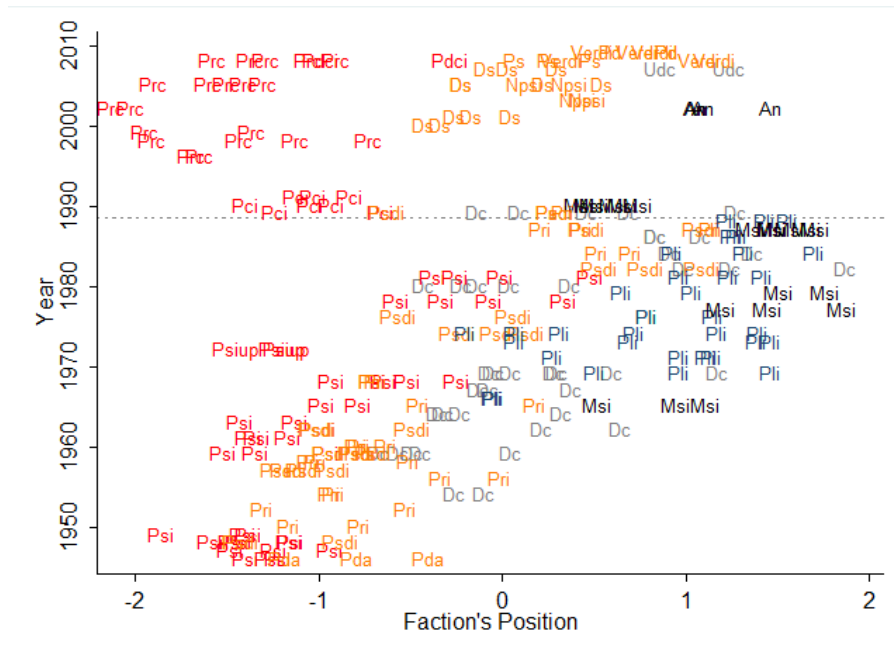

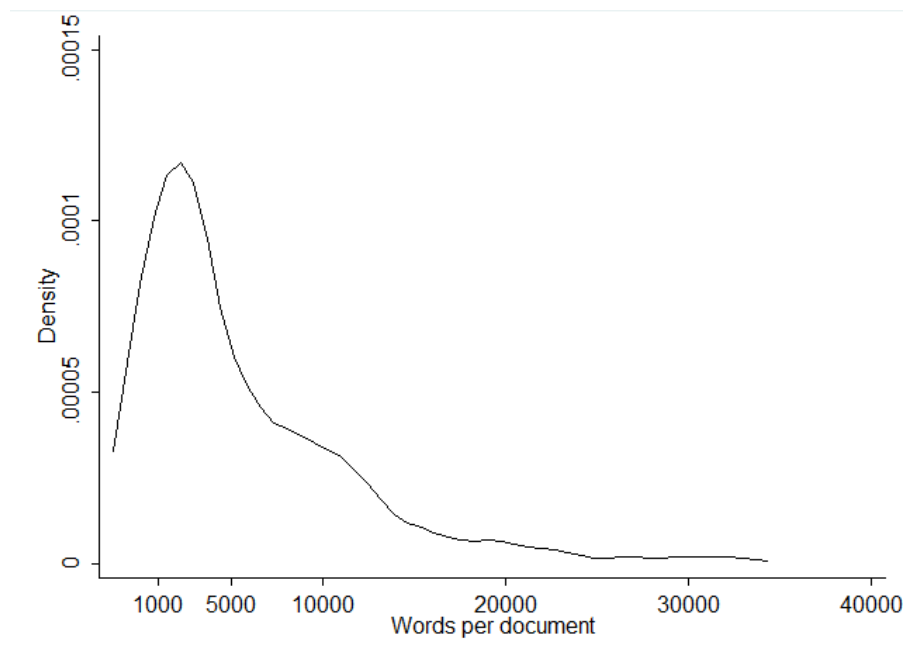

Figure 3.2: Weighted Mean of Factions' Position within each Party Congress in the First and Second Period (Main Parties Only)

3.4 Assessing the Validity and the Reliability of the Estimates

First of all we provide some details about the analysis. Both in the first and in the second period the word count matrix contains approximately 35,000 unique words that help to distinguish between documents. Figure 3.5 reports the kernel density of the number of words per text.

Figure 3.3: Kernel Density of Documents Length

The length of each single text largely differs; on average it is equal to 5,403 words, however it ranges from a minimum of 70, contained in one of the motions presented during the PDA congress in 1946, to a maximum of 32,849 words wrote by the PRC mainstream in 2002. Roughly 50% of documents contain more than 3,400 words while only 37 (14%) are below the threshold of 1,000 words (most of them are related to PRI congresses).²⁵ The number of

²⁵One thousand words is the typical number of ‘scored words’ contained in speeches analysed by Giannetti and Laver (2009) through Wordscores. That software however scores only

words included in each text seems large enough to provide valid estimates of their positions.

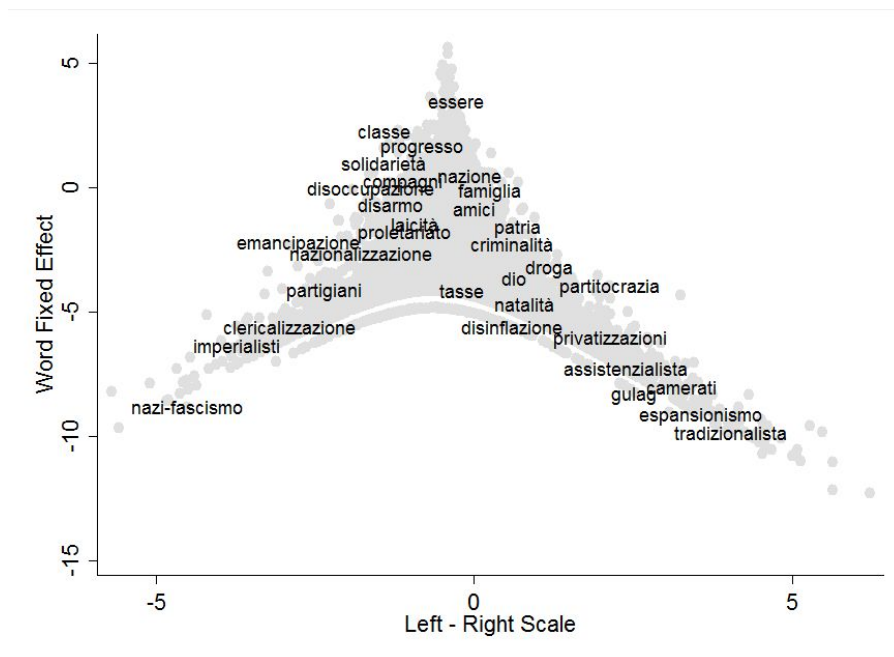

A first analysis to get a diagnostics of our results is done looking at words' β parameters. Figures 3.6 and 3.7 display the parameters of each word separately for the first and second period. We highlighted some words as an example. In the first period we find on the right side words like *god*, *motherland* and *family* (“dio”, “patria” and “famiglia”) that are traditionally associated with conservative values, while on the left we have *class* (“classe”), *solidarity* (“solidarietà”), *nationalization* (“nazionalizzazione”). We can also distinguish words used by party members to refer to each other: *comrades* (“compagni”) used within socialist and communist parties, stands on the left; *friends* (“amici”) used among DC members is located in the centre while *companions* (“camerati”) the epithet adopted by fascist movements appears on the right. In the second period *no-global*, *collective bargaining* (“concertazione”) and *peace* (“pace”) stands on the left while *meritocratic* (“meritocratici”), *soldiers* (“soldati”) and *devolution* (“devoluzione”) are recognized to be right-wing words that help us detecting right-wing parties. On both side of the scale we find words that refer to different issues (e.g., economic, social and foreign policies). For instance concerns about *unemployment* (“disoccupazione”) and *redistribution* (“redistribuzione”) are attributed to left-wing parties while on the right side we find *disinflation* (“disinflazione”) and *privatization* (“privatizzazioni”). When it comes to social policy, the left stresses *laity* (“laicità”) and defends *homosexuality* (“omosessualità”) against any discriminations, while the right criticizes *euthanasia* (“eutanasia”) and emphasizes *birth-rate* (“natalità”), along with many words related to law and order such as *crime* (“criminalità”). The same holds for other issues; considering foreign policy the left

words contained in both ‘virgin’ and ‘reference’ texts. To the contrary Wordfish runs the analysis considering all the words included in a text.

3.4. ASSESSING THE VALIDITY AND THE RELIABILITY OF THE ESTIMATES

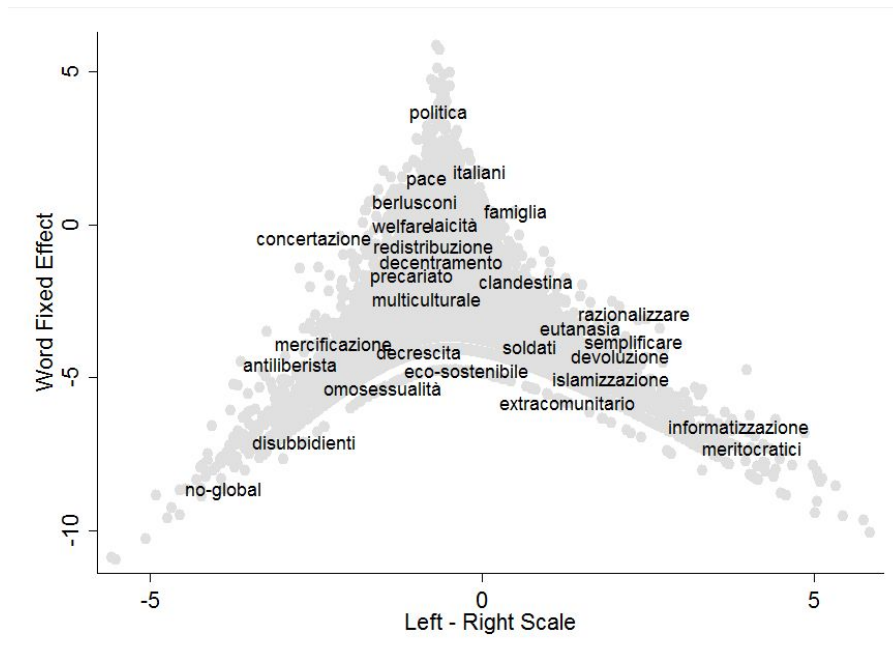

claims for *peace* and *disarmament* (“disarmo”), while the right speaks about *gulag* and want to support the *soldiers* (“soldati”). These examples confirm that β values assigned by Wordfish are coherent with the actual meaning of words in the Italian political language, so that they appear on the proper side of the left-right scale.

Figure 3.4: Beta Coefficients and Diagnostic of Words’ Estimates (First Period)

The following step to assess the validity of our results is to consider the estimates of factions’ positions. We need to check that inside each party left-wing and right-wing factions are properly located. Then we want to make sure that, overall, factions belonging to left-wing parties stand on the left with respect to factions in right-wing parties. First of all within each party congress we arrayed factions from left to right according to the literature (e.g., Giannetti and Laver 2009; Mershon 2001a) and newspaper reports. We compared these expected ordinal positions with factions’ observed rank, measured

Figure 3.5: Beta Coefficients and Diagnostic of Words' Estimates (Second Period)

through Wordfish. The polychoric correlation between two scales is strong and significant (0.68).²⁶

Factions seem to be accurately located along the whole left-right scale too. In both time periods the mean position of factions belonging to the same party is coherent with the party expected placement. Figure 3.8 and 3.9 display, for each party, the mean (along with the 95% confidence interval) of its factions positions separately for the first and the second period (major parties only).

²⁶We also managed to catch adjustments in factions' placement across time. Although factions' location along the internal left-right scale tends to be steady (as discussed in chapter 1), scholars report a couple of exceptions. Within the DC for instance *Nuove Cronache* (tied to Fanfani) moved from left to right while Andreotti's faction (*Primavera*) temporarily shifted from right to left in 1980 and back to the right afterwards (Bettcher 2005; Boucek 2010). Conversely, the left-wing *Forze Nuove* moved to the right in the early 1980s when it firmly opposed the idea of a 'Historic Compromise' (i.e., a coalition deal between DC and PCI) in continuity with the 'National Solidarity' formula, which ruled Italy between 1976 and 1979 through the external support of PCI. *Forze Nuove* was instead more favorable to restore the alliance with the PSI, which in turn opposed any attempt to include the PCI in the ruling coalition during the 1980s (see Curini and Martelli 2009). Our data succeeded in tracking these three shifts (see Appendix B for more details).

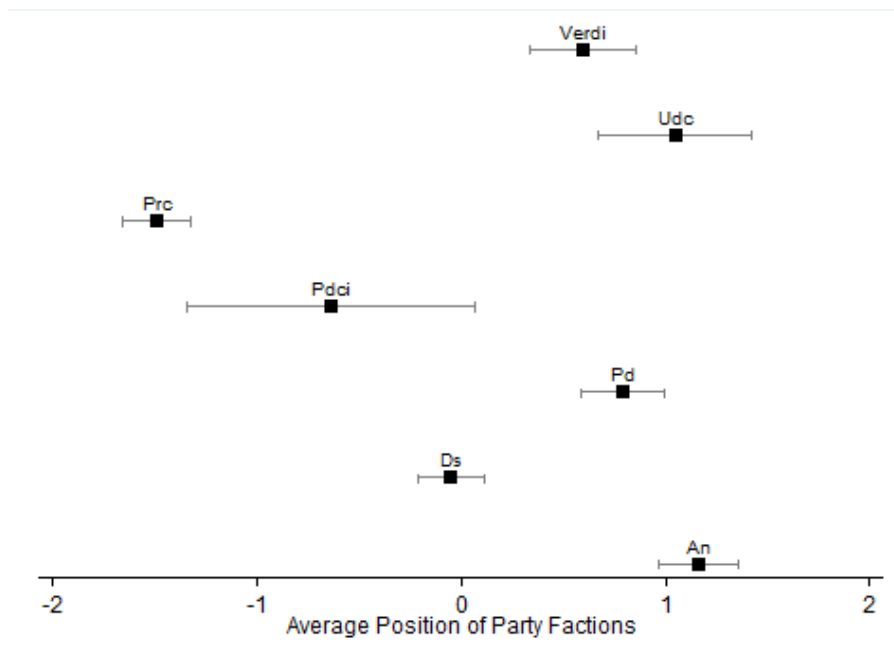

3.4. ASSESSING THE VALIDITY AND THE RELIABILITY OF THE ESTIMATES

Figure 3.6: First Period. Average Position of Factions over Party

Note: 95% Confidence Interval reported. The y-axis is only used for illustration purposes and has no substantial meaning.

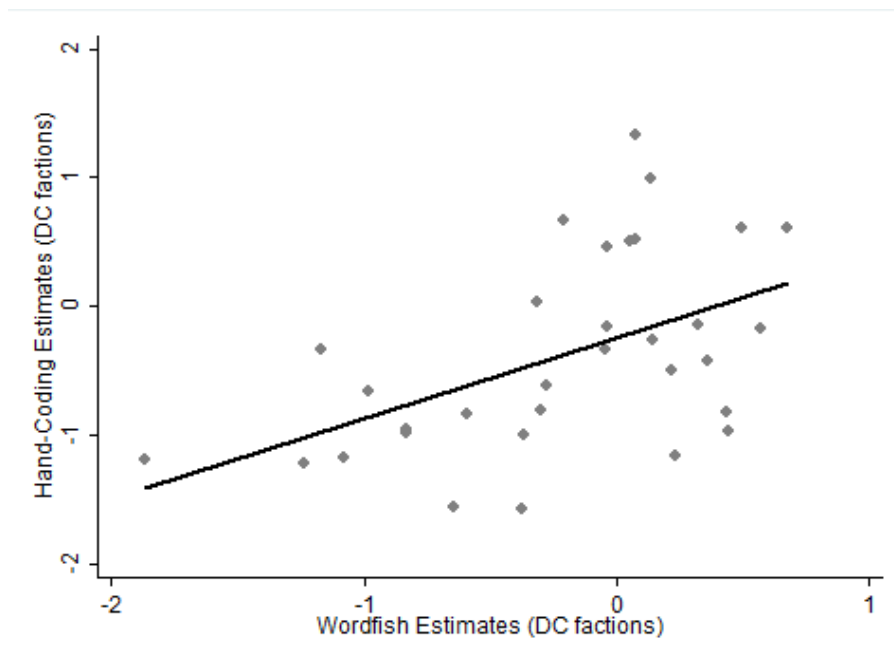

Figure 3.7: Second Period. Average Position of Factions over Party

Note: 95% Confidence Interval reported. Main parties only. The y-axis is only used for illustration purposes and has no substantial meaning.

So far we assessed that overall our estimates are valid. We also tried to check their reliability. To do that we compared DC factions' positions, estimated through Wordfish, with the estimates of a sample of 32 DC motions analyzed by means of hand-coding, following the coding scheme provided by Curini and Martelli (2009, 2010).²⁷ The hand-coding estimates have been measured through the vanilla method (Gabel and Huber 2000) as described in chapter 6. We find a positive correlation (.50) between hand-coding data and Wordfish estimates. Figure 3.10 plots the estimates together with a fitted regression line.²⁸ This result seems to confirm that Wordfish outputs are reliable when compared to alternative techniques of measurement.

Figure 3.8: Comparison between Wordfish and Hand-coding Estimates for a Sample of 32 DC Factions

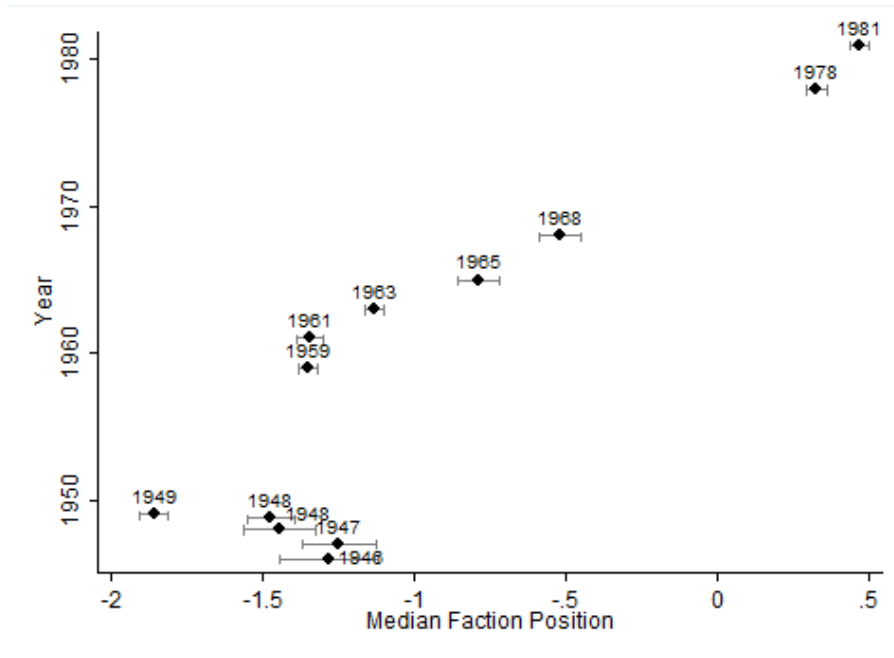

Note: The black line indicates the linear fit.

²⁷To ensure an unbiased estimation the motions have been analyzed by an external trained coder. The coding scheme here adopted is similar to that provided by the Comparative Manifesto Project (CMP). However the number of categories of the CMP dataset has been extended to take into account some peculiarities of the Italian political context (such as positive or negative references made by parties to the Catholic Church). See chapter 6 for a more detailed description, and in particular footnote 15, chapter 6.

²⁸The coefficient of the OLS regression is .629 (standard error: .199).

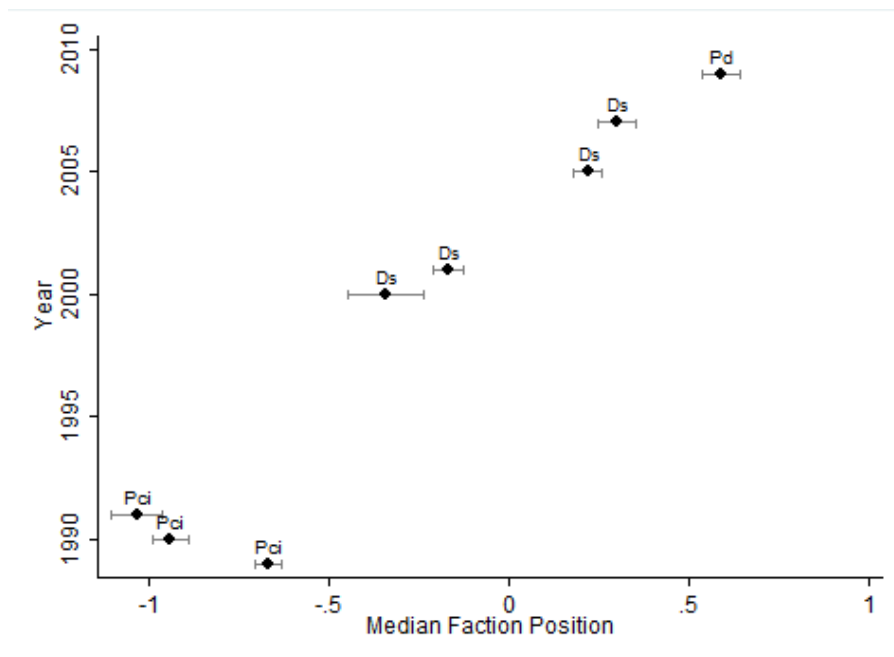

As a final point we will show that the present analysis is also able to track changes in party placement at several point in time, matching the evolution of the party system. In particular we will discuss the trajectories made by the PSI (figure 3.11) and the heirs of PCI (figure 3.12) who chose moderate platforms converging toward the centre in order to gain a more strategic position. To start with, PSI factions shifted from left to the centre according to the evolution of PSI that began in the 1960s and increased during the 1980s (Curini 2011; Curini and Martelli 2009, 2010). Since 1946 the PSI median faction retained a left-wing position. After the party split, in 1947, two social-democratic factions broke away from the party and the median faction moved towards the left, reaching the most extreme position in 1949 when the left took control over the party pushing other moderate factions to leave. After ten years of unitary congresses, held under a regime of democratic centralism, in 1959 three factions battled presenting three alternative motions. The moderate group, *Autonomia*, won the congress and the PSI started to move toward the centre. The shift continued during the 1960s when the PSI was involved for the first time in a centre-left coalition with DC, PSDI and PRI. After the 1963 congress a splinter group left the party to create the PSIUP (that unsurprisingly held a more leftist position). In the next congress the PSI moved again reproaching with the other ruling parties. This movement yielded to a fusion with its twin social-democratic ally, PSDI, in 1968. Finally a deeper change was enacted after the 1978 and 1981 congresses, when Craxi was elected as party leader. Under his leadership the reformist factions continuously moved to the centre and the whole party moved accordingly, in order to gain a strategic policy position (Curini and Martelli 2009: 154) that enables Craxi to be appointed as the first socialist prime minister in the history of the Republic.

Figure 3.9: PSI Shift from Left towards the Centre

Note: Median Faction Position with a 90% Confidence Interval

Figure 3.10: Trajectory from Left to the Centre Made by the Heirs of PCI

Note: Median Faction Position with a 90% Confidence Interval

Something similar happened to the Italian Communist Party and to its heirs. At the beginning of the 1990s the PCI debated over the need to change its name and ideology (Ignazi 1992). It enacted such striking change transforming itself into the Democratic Party of the Left (PDS). The median faction however kept a left-wing position; ‘looking at the part elite level, from 1991 onwards there have been substantial changes in PDS-DS policy positions, with the party moving progressively toward the centre of political spectrum’ (Gianetti and Mulé 2006: 462). Indeed our database is able to catch these changes. In 1998 the party merged with small parties and adjusted its label from PDS to DS, removing any residual linkage with its communist past. Within this new party the median faction retained a more moderate ideal point. This shift goes on and on: in four DS congresses the median group has continuously moderated its stance. In 2007 the DS merged with DL creating the Democratic Party. After that, once again, the median faction moved far away from the left.

3.5 Changes in Political Language and Communication

In this chapter we argued that the beginning of the Italian transition (1989-1994) altered the dynamics of political communication and the use of language (Antonelli 2000; Dell’Anna 2010; Dell’Anna and Gualdo 2004; Gualdo 2004). Several features contributed to these changes: new policy issues entered the political arena filling the agenda with new words; adjustments in the characteristics of the political system altered the nature of the game and its protagonists; the rise of new parties and the processes of ‘presidentialization’, personalization and ‘spectacularization’ of politics modified language, lexicon,

rhetoric and content of political discourse. As long as our database is built through text analysis of written documents we can investigate these changes to assess, from a quantitative point of view, what is really changed and what is not. As we said, the documents included in our analysis cover 64 years of political language and we divided them, before and after 1989, precisely to account for words usage change during the Italian transition. Here we will make sure that language has indeed changed, but we can also take advantage of our data to assess the quality and the magnitude of such changes through a comparison between the use of political language before and after the Italian transition.

We revert to Wordfish's outputs in order to measure adjustments in words usage. In particular we can compare any single word measuring whether its usage across all documents has changed, on average, before and after the 1989. So far, most of the qualitative studies about language has focused on changes in speeches; here to the contrary we focus on written texts. This feature allows us to assess whether the changes in political language have been different or, to the contrary, alteration in written communication is different from the findings pertaining to the oral discourse.

Our dataset does not include all the motions written in the history of Italian party congresses, however the number of words included in the sample is large enough and it includes parties that encompass the whole political spectrum.²⁹ For this reason we can assume that our data allow to properly track the relevant changes. Figures 3.13 through 3.17 provide a comparison between words included in texts related to the first or the second period analyzed. On the y-axis we report the word fixed effect (ψ), which is the logged mean count of each word across all the documents as measured by Wordfish. Words that

²⁹The number of unique words analyzed in the first and second period is very similar: 32,585 against 35,391 respectively.

3.5. CHANGES IN POLITICAL LANGUAGE AND COMMUNICATION

more commonly appear across all documents will retain an higher fixed effect. Words whose fixed effect has increased, when passing from the first to the second period, could be considered as more common and more often used in the new context (and vice versa). In each picture we reported some of them as an example to compare and discuss the nature of changes.

To start with, we claimed that during the transition new policy issues have entered the political agenda (figure 3.13).³⁰ Undeniably one of these topics is related to the ‘Europeanization’ of politics and policies (e.g., Franchino and Radaelli 2004). This change affects political communication too (Della Porta and Caiani 2006). It goes without saying that the enactment of Maastricht treaty in 1992 is one of the crucial events that fostered Europeanization enhancing Europe as a community. This happened in the middle of the Italian transition, fostering the need to bother about Europe as a content of political communication. In fact even when looking at party congresses we observe that the usage of words related to the European Union has dramatically increased in the second period. The fixed effect of all those words that refer to the concept of EU grew. Figure 3.13 shows the change in the usage of the word *Europe* (“Europa”) itself, which became in the second period one of the most widely used across all parties.

Another topic that entered the policy agenda in the 1980s, growing across time, concerns the environmental dimensions. These themes were stressed by the ecologist movements and by the Greens, a single-issue party that formed in the 1980s (although was formally founded in 1990) from a fusion of several Greens’ lists.³¹ This reason in turn contributes to explain why the environmental dimension has emerged and its salience broadened (Curini and Martelli

³⁰Note that this does not affect Wordfish estimates as we highlighted before.

³¹Within some parties there are also subgroups that, acting as single-issue factions, stress the environmental topic above the other. This happened for instance within the DS where the faction *Ecologisti DS* presented its own motion during the 2005 congress.

2009, tab. 1.2). Overall the fixed effect of words related to the environment, like *ecology* (“ecologia”), has expanded in the second period, attesting that parties tend now to include more frequently this issue in their political discourses.

Something similar concerns the devolution of power from the state to the regions. Likewise the Greens’ lists, another single-issue movement born at the end of the 1980s and entered the parliamentary arena gaining a few seats. This movement was focused on devolution and subsidiarity arguing about the need to reform the Italian Constitution and administration in order to build a federal state. Groups belonging to this movement joined together and created the Northern League, which was officially founded in 1989. Although the issue of decentralization was brought inside the agenda by this single-issue movement, later on it overflowed to the whole policy arena so that almost all parties felt the need to address the matter of the federalist reform. Accordingly the mean count of words related to *federalism* (“federalismo”) is higher during the second period. Note that in our database this effect is not due to the presence of the Northern League, because this party is not included in the analysis. This increase reflects the growing relevance that this topic retains in the agenda.

Linked to the federal reform we highlight another issue that emerged during the transition i.e., the debate over the Constitutional reform of the Italian political systems (see Curini and Martelli 2009, tab 1.2). Once again the topic was introduced in the agenda during the 1980s, by the PSI leader Craxi, and developed later on. Although an agreement around a Constitutional reform was never reached, the Italian political system was altered due to the reform of the electoral system, promoted by two referenda held in 1991 and 1993. This change in turn is one of the focal aspects of the Italian transition. Besides the idea of a majoritarian reform of the electoral system other potential reforms

3.5. CHANGES IN POLITICAL LANGUAGE AND COMMUNICATION

were debated in the 1990s to increase the government's powers trying to build a presidential (or semi-presidential) republic. Figure 3.13 confirms that the salience of this topic increased in the second period when the word count of *presidentialism* (“presidenzialismo”) is considerably higher.

Finally one last issue, related to the corruption scandal called *Tangentopoli* (bribesville), gained relevance in the early 1990s and contributed to sustain the transition. In 1992 the opening of the judicial inquiry *Mani Pulite* (clean hands) shed light on the linkage between politics and business discovering that the party system was permeated by political corruption. Actually some scandals related to bribes emerged already in the 1970s and the issue of ethical behavior of politician was introduced by the communist leader Berlinguer, at that time. However the salience of this topic increased only after the 1992 when the post-communist PDS tried to exploit its advantage on this valence issue to seize the power (Curini and Martelli 2009, 2010). Indeed we registered a slight increase in the usage of words like *scandals* (“scandali”) and *corruption* (“corruzione”) during the second period when, after Tangentopoli, the conflict between politicians and the Bench blown up (the leader of the centre-right coalition Berlusconi was often charged of corruption and his governments often passed laws to increase cabinet control on the judicial).

The Italian transition was sustained by changes in the political system that in turn affected shape and content of political discourse. The new mixed electoral system experienced from 1994 to 2001 and the PR with majority prize adopted in 2006 and 2008 changed the structure of party competition and the way electoral campaigns are conducted. The party-centred approach toward electoral competition was replaced by the rise of pre-electoral coalitions and candidate-centred campaigns (from 1994 to 2001 for general elections and during the whole Second Republic for local elections). These changes upheld

Figure 3.11: Logged Mean Count of Words related to New Policy Issues. Differences between First and Second Period

the process of personalization of politics increasing the relevance of charismatic leaders up to the birth of personal parties. Accordingly the centrality of the parliament decreased in favour of a greater level of government agenda power. All these features altered the political communication and are caught by our analysis as we can see from figure 3.14 and 3.15.

Figure 3.15 in particular provides a clearer description of the variation in words usage before and after the transition due to changes in the attributes of the political system. Positive values indicates an increase in the words usage in recent years while negative values illustrate words that were more widespread in the past. Indeed the word *parliament* (“Parlamento”) seems to be less used nowadays while *government* (“governo”) receives more quotations. Correspondingly the word *party* (“partito”) is now less mentioned than it used to be. On one side this is due to the decreasing role of parties which are now

3.5. CHANGES IN POLITICAL LANGUAGE AND COMMUNICATION

Figure 3.12: Logged Mean Count of Words related to Political System Changes. Differences between First and Second Period

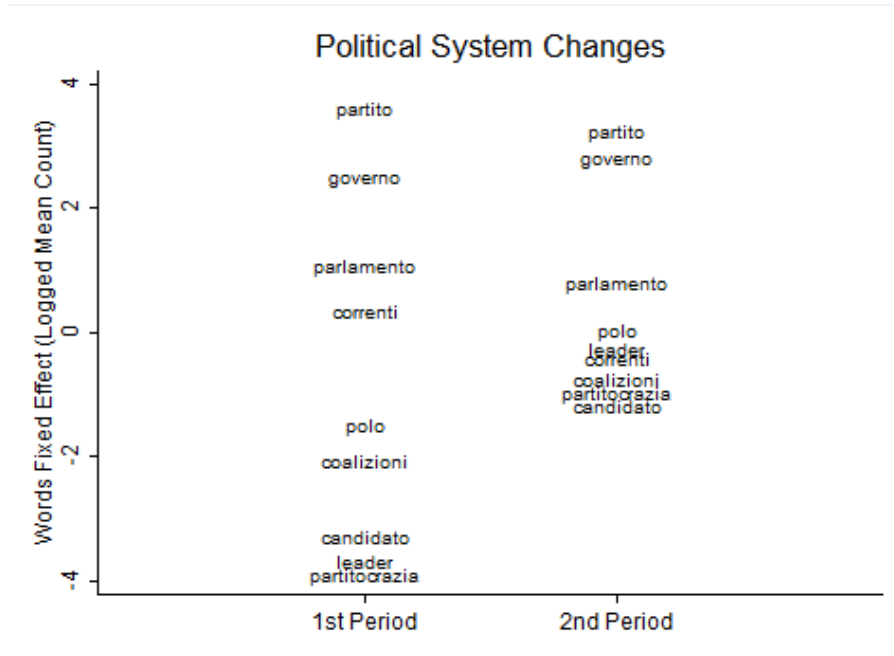

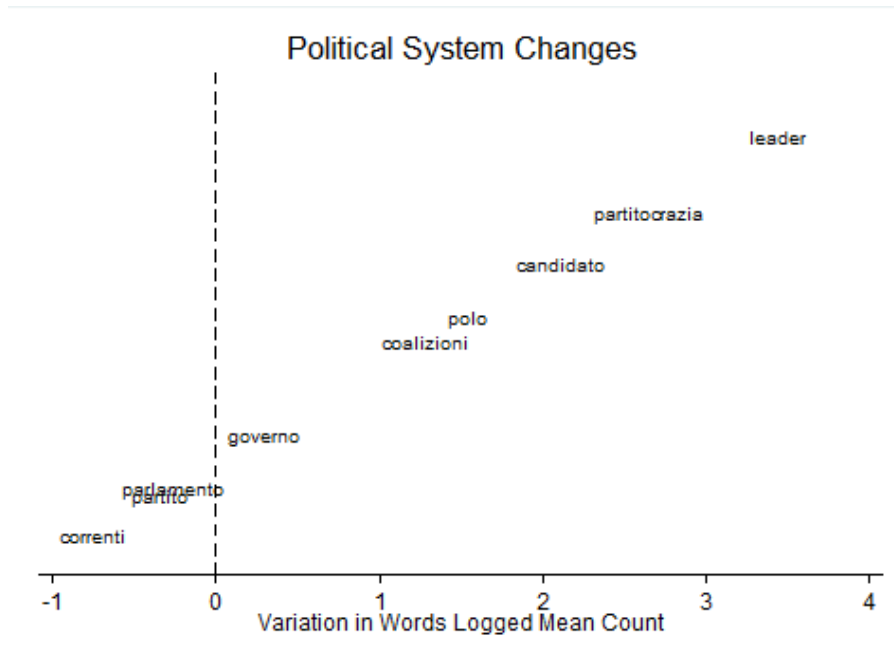

Figure 3.13: Differences in the Logged Mean Count of Words related to Political System Changes

Note: Negative values indicate words that were used more frequently during the first period while positive values assess an increase in word usage in the second period, after the transition

less pervading than during the First Republic. The neologism “partitocrazia” (*partitocracy*) was coined precisely to indicate the overwhelming supremacy of parties over the political life that is one of the features of the First Republic. This word appears to be used more frequently after the transition with the intent of criticizing such ‘old regime’.

Furthermore, to cut any linkage with the partitocracy the new Italian parties ceased to use the label party and refer to themselves through other words like alliance (e.g., National Alliance, Democratic Alliance, Alliance for Italy), movement (Movement for Autonomies, MPA), league (Northern League), pact, federation, union, people (i.e., People of Freedom) or they even use simply a noun or an adjective (Forza Italia, The Daisy, Democrats of the Left and so on). In the Second Republic only few groups still maintain the word *party* inside their labels (the communists PDCI and PRC although they now are fused in the Left Federation, the Democratic Party and the two small heirs of the PSI). All said and done however the word *party* is still there and factions still adopt it in their congress motions. We observe something similar concerning the word *factions* (“correnti”): its usage decreased during the second period even within factionalized parties; nonetheless Italian politics is still dealing with them and this word is still used in the political language.

Conversely the rise of pre-electoral coalitions increased the citation of words that denote the alliance, like *pole* (“polo”) or *coalitions* (“coalizioni”). Finally the trend towards the personalization of politics appears clearly evident: for instance the usage of the word “*leader*” is strikingly increased but also the word *candidate* (“candidato”) is widely used in the second period confirming the shift to a candidate-centred politics. The role of candidates over parties was enhanced by the electoral districts (from 1994 to 2001) and by the elections for majors and ‘governors’ (from 1993 up to date). In addition there is an effect played by the party (or the coalition) leader due to the frontal clash

3.5. CHANGES IN POLITICAL LANGUAGE AND COMMUNICATION

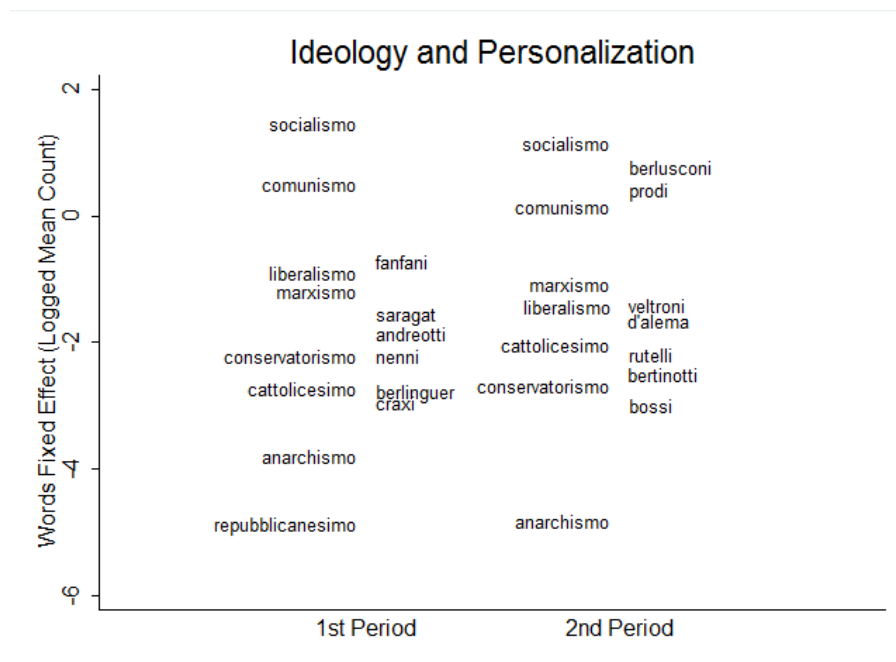

between coalitions that characterized Italian politics after 1993. As an example, under the current electoral system the majority prize assigns relevance to the coalitions and to their leaders, whose name must be indicated before the elections; moreover the name of party leader is often included in the party logo.

Figure 3.16 provides a mixture of the attributes considered so far. We investigate more in depth the changes in the dimensions of electoral competition and in personalization. To simplify the communication with the voters, parties usually summarize the struggle along one dimension represented by the traditional left-right scale. This dimension in turn is generally associated with ideological views. Some scholars claimed that the role of ideology is declining nowadays. If this is true we should observe a reduction of the words associated with it. Looking at figure 3.16 we observe that, with few exceptions, the use of such words (i.e., *socialism*, *communism*, *liberalism* and *conservatism*) is diminished. However ideology is still there and parties keep it alive in their internal debates.

The second aspect that we want to deepen concerns personalization. It has been argued that modern politics emphasizes the role of party leaders; then we would expect to find more citations of their names during the second period compared to the first. Looking at politicians' names we note an overwhelming number of quotes concerning Berlusconi and Prodi. Surprisingly all the other leaders of Second Republic's parties (e.g., Bertinotti, Bossi, D'Alema, Rutelli, Veltroni) are mentioned as much as their counterparts during the First Republic (e.g., Andreotti, Berlinguer, Craxi, Fanfani, Nenni, Saragat). To sum up it seems that ideology is slightly declining, however it is not disappeared at all. As far as leaders are concerned, intra-party debates do not appear to be more focused on them now than in the past; the only exceptions are the two long-standing leaders of the centre-left and centre-right coalitions: Prodi

(from 1996 until 2008) and Berlusconi (from 1994 until 2011). This is in line with the new bipolar party system and seems to indicate that personalization is really increased at the top level of the pre-electoral coalitions, whose leaders attract a large share of the political discourse.

Figure 3.14: Logged Mean Count of Words related to Ideology and Personalization. Differences between First and Second Period

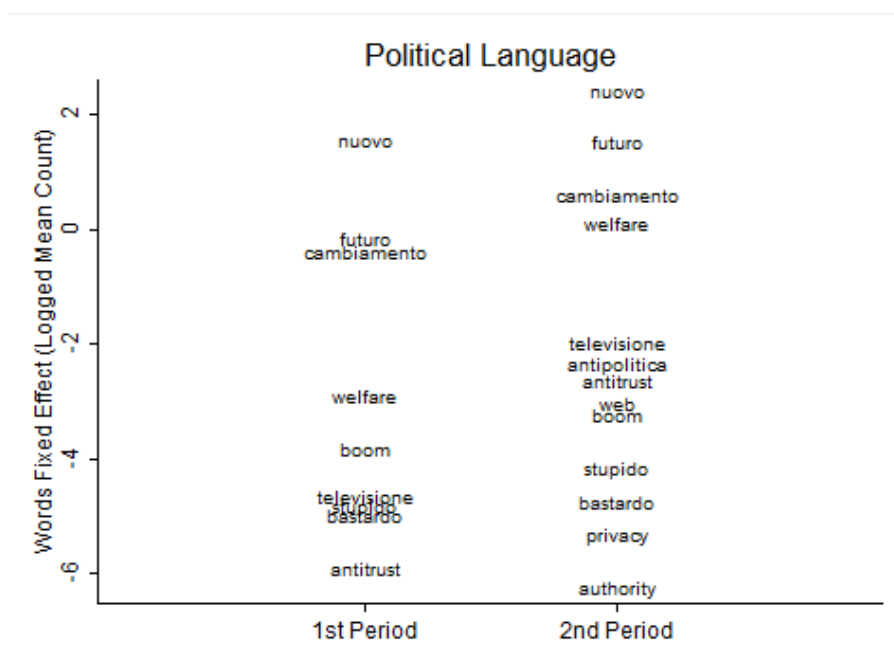

Finally one last comparison between the pre- and post-1989 communication concerns the use of language. From figure 3.17 we note first of all a strong growth of English terms. For instance references to “*welfare*” strongly increased attesting that what has long been called ‘*stato sociale*’ is now being referred to with its English translation. Similarly words like “*antitrust*” or “*boom*” are more common now than in the past. Other English words appeared for the first time only in the second period, among them “*privacy*” and “*authority*”. This pattern somehow contrasts with the idea of a political language closer to the common citizen. Some scholars argued that politicians try to simplify the language (Antonelli 2000) even through the use of dialects. To

3.5. CHANGES IN POLITICAL LANGUAGE AND COMMUNICATION

the contrary in congress motions we do find an extensive use of foreign terms whose understanding should be theoretically harder for the broad public. Anyway it must be noted that motions are usually addressed to party members and activists whose knowledge of technical terms imported from other languages should be greater compared to wider (but less skilled) audiences. As far as the use of bad language is concerned we did not find many examples; its usage is in fact more typical in the oral language while we are dealing with written texts. Anyway the words *stupid* (“stupido”) and *bastard* (“bastardo”), likewise other minor offences, are more mentioned now. It goes without saying that in recent years the use of mass media has sharply increased altering the content of political discourse and, accordingly, references to media like *television* (“televisione”) or new media (i.e., internet) are now often included in the motions presented during the congress.

Finally a last feature highlighted by Dell’Anna (2010: 81) refers to the dynamic old-new. Since the collapse of the First Republic, politicians try to ride the wave of political scepticism, “*antipolitica*”, (which is indeed a word that characterizes the Second Republic) setting them apart from the old regime. This implies the vast use of words related to the concepts of *new* (“nuovo”), *change* (“cambiamento”) and *future* (“futuro”). Parties want to ride the change, presenting themselves as something else, something new, a modern entity oriented towards the future, up to the point that one of the newcomers in the Italian party system has included this word in the label, calling itself Future and Freedom for Italy.

Figure 3.15: Logged Mean Count of Words related to the Use of Political Language. Differences between First and Second Period

Chapter 4

Where Do Factions Come From? The Determinants of Factionalism

4.1 Introduction

In this chapter we investigate the determinants of factionalism. We will present some hypotheses drawn from the existing literature and connected to our theoretical framework to attest what elements contribute to increase or reduce the number of factions inside parties. However we know that our definition of ‘faction’ is somehow endogenous to the observed intra-party dynamics. In fact, as discussed before, the only objective criterion to assess the number of faction is to count how many subgroups contested the congress presenting a motion. Noticeably this is possible only if the congress is contested while we do not observe a measurable value when intra-party dynamics lead to hold a unitary debate. Consequently our dependent variable, the number of factions, is observed only when the congress is contested. We must be aware of this potential selection bias in order to properly handle it. Depending on its

causes and its magnitude, such bias could theoretically affect our results and the validity of our claims. Here we will detect the occurrence of this selection bias. Stressing the effect of party's rules and organization we will investigate what elements impacts on the likelihood of observing unitary or contested congresses. Then, focusing on the latter, we will examine the variables that affect the number of factions that present a motion. Being aware of this sample selection, in the rest of our dissertation we will be dealing with contested congresses only, generalizing our results only to that extent.

4.2 The Role of Rules: Party Organization and Intra-party Representativeness

In the previous chapter we mapped intra-party divergent policy positions showing that factions do not retain exactly the same preferences. As a matter of fact, they also retain distinct internal rules. Contrasting organizational structures end up building party environments that grant different degrees of representativeness to intra-party minorities. As long as we are dealing with fractionalization, in the present chapter we will focus mainly on the effect of party rules and organization.

Here we provide a summary to describe the attributes of different party statutes. We detail information related to four intra-party rules: disproportional internal electoral system, democratic centralism, direct election of party leader (leader autonomy) and factional ban. We distinguish them according to the degree of representativeness they allow. For instance, we assign a low (L) degree of representativeness to statutes that enact highly disproportional rules, strong ban on factions, direct election of party leader or organize the party through democratic centralism. Conversely an high (H) representative-

4.2. THE ROLE OF RULES: PARTY ORGANIZATION AND INTRA-PARTY REPRESENTATIVENESS

ness is assured by the lack of such attributes, while for two attributes (internal electoral system and factional ban) we might also find medium (M) levels of representativeness when the enactment is not so strict. The lower the degree of representation granted to internal minorities, the greater the advantage retained by party mainstream.¹ Table 4.1 reports the percentage of contested congresses held under each rule (among those included in the dataset, whose total number is 83).

Table 4.1: Intra-party Rules and their Level of Representativeness (Percentage of Congresses Held under Each Rule)

Rule	Representativeness		
	Low	Medium	High
Disproportional Internal Rule	14	22	64
Factions Ban	41	7	52
Democratic Centralism	2	n.a.	98
Direct Election (Leader Autonomy)	27	n.a.	73

Table 4.2 details, per each party, the percentage of congresses held under the different rules. They vary by party, but also across time within the same party. For instance, the DC switched from a majoritarian system to proportional representation in the 1970s, and then step back introducing thresholds and majority prize; in those years they changed also the mode of leader's election. After having abolished democratic centralism, the PCI modified its statute again during the last congresses, to promote internal debate. Other parties too repeatedly adjusted the statute to alter the level of representativeness.

These variables will be resumed in the course of dissertation to assess their impact on several domains of intra-party politics. For the sake of establishing

¹We consider the direct election of party leader as a rule that favors the mainstream in spite of internal minority. See Rahat *et al.* (2008) for a similar point of view about how an inclusive selectorate might decrease the representativeness.

Table 4.2: Details about Internal Rules per Party (Percentage of Congresses Held under Each Rule)

Party	Representativeness									
	Disproportional Internal Rule			Factions Ban			Democratic Centralism		Direct Election	
	L	M	H	L	M	H	L	H	L	H
AN			100	100				100		100
DC	55		45	55		45		100	45	55

PSIUP			100			100		100		100
UDC			100			100		100		100

which element, between preferences or rules, is the best predictor of intra-party dynamics, at the end of this work we will retrieve this information to compare the effects of intra-party representativeness, granted by the rules, and intra-party division, conveyed by factions' preferences (see paragraph 9.1).

4.3 The Determinants of Factionalism: Literature and Hypotheses

Literature on intra-party politics investigated the causes of factionalism. Many studies addressed the topic analyzing the role played by rules and attributes of the party and the party system. No studies however accounted for a comprehensive explanation of the phenomenon. This lack concerns, in particular, the effect of policy preferences as a source of intra-party division. Although recent studies confirms the existence of divergent policy views, they do not investigate how such differences affect the degree of factionalism within

the party. Beside summarizing the hypotheses proposed by the existing literature we will also provide other arguments about the elements that might affect the likelihood of a contested congress testing the existence of a selection bias and its determinants. We will provide a comprehensive explanation of the causes of factionalism; a first group of hypotheses deals with the number of factions while another group (indicated by the letter 'b') focuses on the likelihood that the congress is contested. This latter set of variables is related exclusively to internal rules, to assess whether the modes of party organization lead to different patterns of bargaining (i.e., uncontested congresses) and to the emergence of a selection bias in our sample.

The debate on the sources of factionalism was opened by Sartori who focused on the impact of internal electoral rules on the number of factions. Sartori (1971; 1976: 86) applied Duverger's Laws to intra-party politics claiming that proportional representation (PR) is a sufficient (but not unique) condition for the growth of intra-party fragmentation: PR 'does become a sufficient cause of the multiplication of fractions'. Under disproportional intra-party electoral rules (like majoritarian systems, PR with high thresholds and rules that establish a majority prize for the first ranked group) factions should face the incentive to merge together in order to take advantage of the electoral system increasing their weight (and consequentially their strength) inside party body. Accordingly we would expect a greater number of factions within parties whose electoral rules are purely proportional.

Hypothesis 4.1: Disproportional internal electoral rules decrease the number of factions

Additionally, because of disproportionality, minority factions will find it harder to get represented inside party body. Hence dissenting members could

refuse to openly defy the party mainstream, avoiding to contest the congress, with the hope that unitary intra-party dynamics will leave them with a decent share of seats in party body.

Hypothesis 4.1b: Disproportional internal electoral rules decrease the likelihood that the congress will be contested

We can also assume that parties enact disproportional rules when the cost of ν outweighs ω . In line with this idea, discussed in chapter 2, we should observe low or no voice, as suggested in H 4.1 (a and b).

Besides rules Sartori (1976, 79) accounted for the impact of intra-party preferences. He hypothesized that inside polarized parties the number of subgroups should be greater. To overcome the lack of data and tools useful to measure factions' ideal points and party polarization, he suggested using the effective number of parties as a proxy for it. He anticipated the idea that 'Shared preferences are important bases of political parties' (Aldrich 1995: 29) claiming that the greater the number of parties, the greater the number of options available; therefore any potential party member might find a party that is relatively close to her (up to the extreme case where each voter builds her own party). As a consequence the need to cultivate intra-party fragmentation decreases and each party will be barely polarized. Other scholars hypothesised that the heterogeneity of party's rank and file might increase the number of factions (Bogaards and Boucek 2010; Reiter 2004).

Thanks to our database we are able to directly test this hypothesis, measuring intra-party preferences without the need to rely on the proxy variable suggested by Sartori. We will contend that an increase in internal polarization leads to a growth in factionalism. In addition we should remind that polarization, due to the cost of membership (see paragraph 2.2 and chapter 7), impacts

on the ratio between π and *varepsilon* thereby encouraging factions to pick up the voice option in order to extract a wider amount of payoffs.

Hypothesis 4.2: Intra-party polarization increases the number of factions

In addition the literature investigated other possible causes of intra-party fractionalization. One of these features is related to the resources available within the party (Golden and Chang 2001; Zincone 1972; Zuckerman 1979) meaning in particular money, clientele and patronage. Zincone (1972) highlighted the importance of an autonomous access to resources that is crucial to build, organize and maintain alive a faction. Factions that have their own headquarters, collect membership drive and issue their own newspapers and magazines will be able to survive and to grow.

Indeed many Italian party factions printed magazines to promote themselves, to express their views and to inform members about party's and faction's meetings and decisions. Factional magazines were so important that one strategy to decrease factionalism was precisely to forbid printing them. Often faction and magazine's name coincided. The first DC faction, *Cronache Sociali*, was named after the homonym review; the DC left-wing faction *Base* published a periodical called exactly 'rank and file'; within the MSI the left-wing faction linked to Rauti changed its name from *Linea Futura* to *Spazio Nuovo* and modified its magazine accordingly. In turn the PCI group *Manifesto* took its name from the monthly issued in 1969. Nowadays some factions still retained their own press like 'Aprile', review that was linked to the DS faction *Correntone* or 'Area' that expressed the views of the 'social right', *Destra Sociale*, within AN. The web of course decreases the cost of publishing periodicals so that Aprile became soon issued only via internet, being called

‘Aprile on-line’; similarly the *Finiani* faction published on-line its review *‘Fare Futuro Web Megazine’*.

Nevertheless, it is not easy to find measures of the financial autonomy of factions. Anyway we argued that parties divide resources between activists (and factions). Thus we can reasonably assume that inside parties whose monetary capabilities are greater factions might exploit a larger amount of resources. There is room for more subgroups and they will be able to persist. We can hypothesise that, the greater the party revenues the higher the number of factions within it. The same logic concerns the number of party members; they have to pay a quota for their membership, thus parties with a greater number of members will have more financial resources and will end up being more divided.

To measure party resources we can also adopt its size, measured through the number of votes gained in the last elections, as a proxy. According to Pasquino (1972) ‘The elections represent, at any level, [...] a crucial opportunity to boost the faction, as long as gaining seats constitutes a mechanism to multiply the resources available to the faction itself’ (Sartori 1973: 87, translation mine).

The bigger the party, the greater the number of factions.² Additionally, the internal structure of big parties will be more complex, leading to an increase in factionalism (Reiter 2004; König 2006). Intuitively large parties attract a wider number of members. Hence, despite they coalesce on the basis of policy preferences (Aldrich 1995; Krehbiel 1993; Snyder and Ting 2002), their internal polarization should be greater.

*Hypothesis 4.3: The number of factions increases along with party size
and with the availability of resources within the party*

²A number of studies shown that large dominant parties are highly factionalized (e.g., Bogaards and Boucek 2010).

Furthermore several authors discussed the impact of the electoral system on factionalism. This effect has been tested with respect to the Japanese case, where the changes in the electoral system altered the factional structure (Cox and Rosenbluth 1993; Cox *et al.* 1999). According to the Italian case scholars focused on the role played by preference voting (Katz 1986a; Katz and Bardi 1980; Pasquino 1972; Wildgen 1985) arguing that it fosters intra-party competition. By providing factions with the access to parliamentary seats (and to the resources they supply), preference voting grants them a place where to grow and replicate increasing party heterogeneity. In addition, preference voting decrease the price of ν and, as a consequence, should boost the adoption of voice in intra-party dynamics.

Our dataset allows to test this aspect comparing Italy before and after the electoral reforms experienced since the 1990s. These changes allow to perform a comparison between systems based on open list PR, before 1994, and those adopted afterwards (Carey and Shugart 1995). Since 1994 Italy experienced two different electoral rules: a mixed systems (1994-2001) with a 25% closed list PR quota and the remaining 75% of seats assigned via ‘first-past-the-post’, and a closed list PR with thresholds and majority prize (in 2006 and 2008). Furthermore between 1994 and 2001 the selection of candidates elected under plurality districts has been centralized being transferred from the regional to the national level (Di Virgilio 1998; Di Virgilio and Kato 2001). Both these systems have in common a closed list PR (at least for a proportion of seats) and shared the idea of a centralized representation.

Intuitively, open list PR boosts the dispersion of authority and multiplies the power structures within the party. When district magnitude is very high, like during the First Republic, intra-party competition for preference votes fosters the incentive to break the monolithic party structure (Carey and Shugart 1995; Shugart 2001; 2005) so that candidates try to exploit their factional link-

age in order to get elected. To the contrary under closed list systems, or when the candidate selection procedure is highly centralized, party elites retain a greater control over candidacies, decreasing the relevance and the number of factions (Pasquino 1972; Cox *et al.* 1999; Carey 2007)

Hypothesis 4.4: Closed list PR and centralized candidate selection decrease the number of factions

Following Sartori categorization between factions of interests and factions of principles it could be argued that the former growth only inside parties in office, to exploit the payoffs coming from cabinet membership. Then inside parties in office we should observe a wider number of factions because, beside factions of principles, other subgroups will originate solely to take advantage of office payoffs available within the party.

Hypothesis 4.5: The number of factions is greater within parties in office

Finally we want to check the role of intra-party rules (other than the internal electoral system). We focus on party statutes to detect features related to party organization. According to Sartori (1976: 85) ‘party statutes contain, roughly, three major elements: a set of prohibitions, the organisational structure, and the electoral arrangements’. We will evaluate whether each element affects the degree of factionalism or the likelihood of observing contested congresses.

First of all statutes might prescribe an explicit ban on the existence of organized factions. We argue that such explicit prohibition should increase the cost of voice decreasing the number of subgroups that contest the congress

and even leading to a unitary congress. We also contend that such ban could be adopted inside parties whose leaders are focused on enhancing cohesion (ν is greater than ω) thereby reducing factionalism.

Hypothesis 4.6: An explicit ban on factions should decrease their number

Hypothesis 4.6b: An explicit ban on factions should decrease the likelihood that the congress will be contested

A second element deals directly with party organization. Some parties, especially those based on Marxist ideology, are organized according to the principles of ‘democratic centralism’. This is something different from the mere absence of organized factions. Under democratic centralism party members are theoretically free to discuss and support different views about party strategy and ideology. However the dissent must be expressed only inside the party. Once the party body sets the line, its choice must be enacted even by dissenting members. In the Italian context the PCI has been adopting this rule for almost all the extent of its life (actually its statute was modified only at the end of the 1980s precisely to leave room for inter-factional competition). The PSI adopted the same rule from 1949 until 1957, under the orthodox leadership of Morandi. During the Second Republic only one party, the communist PDCI, retains a similar organization although the People of Freedom and the Northern League portray a similar structure. In congresses held under this rule we would expect a lower level of factionalization or even a complete absence of dissent due to the large value of ν . The public expression of dissent jeopardizes the idea of a cohesive party (granted by democratic centralism) weakening the leader who in turn will be likely to impose cohesion through discipline, which raises the

voice cost for dissenters too.

*Hypothesis 4.7b: In parties organized through ‘democratic centralism’
the likelihood that the congress will be contested is lower*

The third and last element we will account for concerns the strength and the autonomy of party leader. When the leader is elected directly by a wide selectorate (e.g., party members) she can improve her autonomy to unify the whole party behind her. To the contrary, leaders appointed in smoke-filled rooms will end up being hostage of party factions. In a small committee in fact the vote of any single activist might be decisive to appoint one or another leader. Hence even small subgroups of activists might want to exploit such incentives by gathering together. We would expect a lower number of factions and contested congresses within parties whose leader are stronger and more autonomous.

*Hypothesis 4.8: Leader autonomy (fostered by direct election and wide
selectorates) should decrease the number of factions*

*Hypothesis 4.8b: Leader autonomy (fostered by direct election and wide
selectorates) should decrease the likelihood of a contested congress*

When leader autonomy reaches the extreme i.e., inside personal parties, we should not find any observable disagreement. Charismatic leaders in fact boost party loyalty, which increases the exit costs (ε) thereby making the voice option pointless. Hence, despite the existence of heterogeneity, the party congress will probably be unchallenged.

Hypothesis 4.9b: Within ‘personal parties’ the likelihood that the congress will be contested is lower

4.4 Data and Methodology

In the previous chapter we presented the details of the motions collected showing that, among the parties included in the dataset, the medium number of motions presented during each congresses is equal to three. There are no differences between the First and the Second Republic; whenever the congress is contested we observe, on average, three factions competing together. Similarly, for any decade analyzed we registered a mean of three motions per congress. Differences between parties are tiny. We observe a number of factions closer to four within DC and MSI-AN while there are only two factions inside UDC, PDCI and NPSI and approximately two factions within the PRI, whose internal life has been often characterized by a dualism between the mainstream and a minority group. This is coherent with Sartori’s claim about the maximum number of ideological faction, which should be three. According to Sartori (1971, 1976) a party may have at most one pivotal mainstream faction, one left-wing and one right-wing. It is not straightforward clear why it should be so, given that in multiparty systems we hardly find only three parties located on the left, right or at the centre of the policy space. However, let us take this statement for true. The mean number of factions in our data is indeed three.³ Figure 4.1 confirms that this value represents the mean, the mode and the median. However, the picture indicates that some variation exists. Un-

³Our factions could be defined as ‘factions of principles’ because we retain only factions that contested the congress presenting a motion. Nonetheless, as already discussed, all factions care to some extent about policy. Although we include factions that Sartori would label as ‘factions of interests’, these are in turn ‘factions of principles’, at least in part. In other words, our dataset refers to factions *tout court* and their average number equals three.

der different conditions the number of factions that contest a congress might increase or decrease.

Figure 4.1: Number of Factions (Motions) per Congress

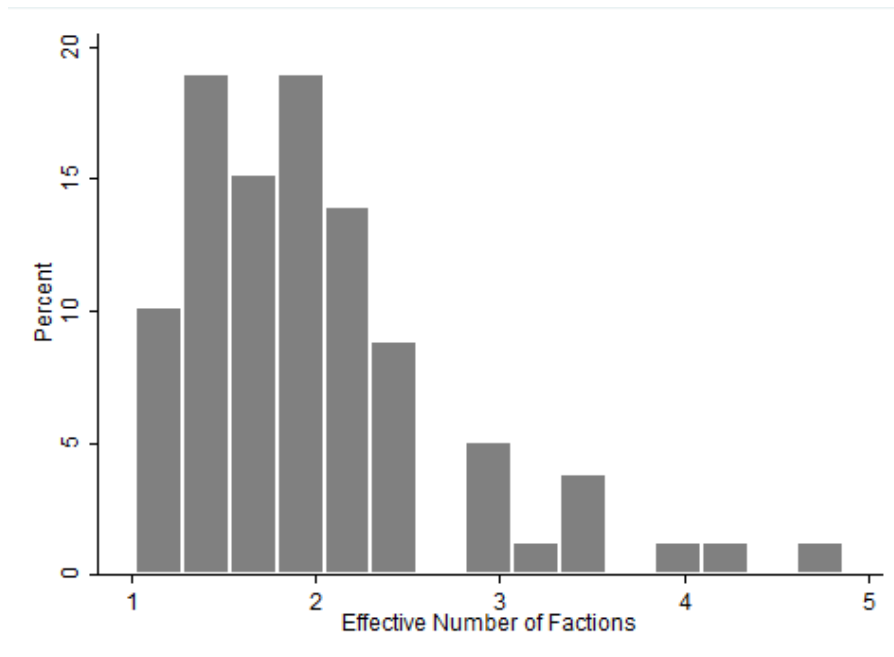

In figure 4.2 we provide the effective number of factions (ENF) within each congress. The ENF has been calculated using the Laasko and Taagepera (1979) formula to measure the effective number of parties, as suggested by Boucek (2009). The two measures of intra-party fractionalization, NOF and ENF, are strongly and positively correlated (.80).

In two third of cases the ENF ranges between one and two (which is the mean value of ENF). This path seems to underline that it is unlikely to find parties divided into many factions that retain approximately the same strength. Conversely even when the majority faction is quite strong we often find a considerable minority group that holds around 20% of congress votes.

To test what elements affect the number of factions we built a dataset that includes all the contested congresses of parties listed in table 3.1 for which we

Figure 4.2: Effective Number of Factions per Congress

were able to find data; this total amounts to 83 cases. The dependent variable (y) is NUMBER OF FACTIONS (NOF), which corresponds to the number of motions presented by factions during the congress. We will test the previous hypotheses by means of an OLS. As far as we have multiple observations nested within each party across time they might not be independent. To cope with this issue we clustered observations by party estimating standard errors on clusters. Clustered standard errors in fact are heteroskedastic and autocorrelation consistent (Rogers 1993).

However the results of such OLS analysis would be biased if there exists a problem with sample selection. To assure unbiased estimates then we need to run an Heckman (1979) model. To do so, we retrieved the parties listed in table 3.1 and for each of them we pooled together all the congresses held during its entire life. We built a database that contains information about both contested and uncontested congresses whose total number of cases is 198 (as shown in table 3.1).

On this dataset we apply the Heckman model that estimates the parameters through two stages. In the first stage the model assesses the effect of some variables on a dichotomous variable (z). The variable z is a dummy that determines whether our dependent variable y is observed or not; it takes value 1 when the outcome is observed and zero when it is not. Then the second stage estimates the impact of another set of variables on the expected value of y , conditional on it being observed. Whenever the error terms of the two analyses (the first one on z and the second run on y) are correlated ($\rho \neq 0$) there exists a selection bias that would confirm the need to revert the Heckman model.

In our analysis the first stage estimates the impact of some variables on the likelihood that the congress will be contested. The z variable is CONTESTED CONGRESS, a dummy that takes value 1 when the congress is contested and value 0 when it is unitary. Within this dataset there are 120 contested congresses (60% of the total). At this stage we include four independent variables to assess whether they affect the probability to observe y . These variables are the following. DISPROPORTIONAL RULE (H 4.1b) a categorical variable that takes value 0 when the party congress electoral rule is a pure PR; it takes value 1 when the voting rule is a PR with majority prize and a low threshold (5%); it assumes value 2 when the congress is held under a majoritarian system or under a PR with majority prize and high threshold of representation (20%).⁴ FACTIONS BAN (H 4.6b) that equals 1 when the statute enacts an explicit ban on the existence of organized factions, it takes values 2 when even temporary tendencies are banned while it assumes value 0 when there is no explicit ban; DEMOCRATIC CENTRALISM (H 4.7b) takes value 1 when party organization follows this guideline and 0 when not; LEADER AUTONOMY (H 4.8b) is equal to 1 when the party leader is elected during the party

⁴Such partition has been chosen following Sartori (1976: 89).

congress directly by party delegates or party members while it takes value 0 when the leader is appointed by a small committee.

Then the second stage estimates the impact on the dependent variable NOF testing the hypotheses discussed before. At this stage we add a few new variables to some of the previous ones.⁵ We test the impact of: DISPROPORTIONAL RULE (H 4.1); INTERNAL POLARIZATION (H 4.2), measured as the absolute value of the distance between the two opposite extreme factions within each party congress; PARTY SIZE (H 4.3), the percentage of votes gained by the party in the last election before the congress (which accounts for the amount of resources available within the party); OPEN LIST (H 4.4), a dummy variable that measures the impact of the preference voting; it takes value 1 when the electoral system is an open list PR (from 1946 to 1992) and value 0 when the electoral law includes a closed list PR (for the whole amount of seats like in 2006 and 2008 or limited to the 25% quota assigned through PR from 1994 to 2001). Our dataset however includes parties that are out of parliament; thus to assess the impact of this latter rule on parties that hold parliamentary seats we add a control variable, EXTRAPARLIAMENTARY, that equals 1 when the party is out of parliament and 0 otherwise. The remaining variables are: PARTY IN OFFICE (H 4.5), a dummy that assess whether the party is involved in the government (value 1) or not (value 0); FACTIONS BAN (H 4.6) and LEADER AUTONOMY (H 4.7).

So far we analyzed almost 200 congresses (120 of whom are contested). However we know that the total number of congresses held by Italian parties after 1946 is around 300 units (as discussed in chapter 3). For some of them

⁵To reach a convergence the Heckman model usually requires inclusion of at least one variable that affects z without affecting y . At the first stage of our analysis we focused only on the role of intra-party rules, then variables like PARTY SIZE, OPEN LIST and INTERNAL POLARIZATION (that can be measured only when y is observed) have been excluded. Among the four variables included at the first stage we discarded DEMOCRATIC CENTRALISM at the second stage, assuming that its main impact involves the nature of the congress itself. There are in fact only 2 contested congresses held under this rule.

we were not able to find any information at all while for others we managed to assess some details. In particular we gathered information from party statutes (measuring those variables tested in the first stage of the Heckman model) and we were able to attest whether the congress was contested or unchallenged. Therefore we are able to extend our dataset increasing the number of cases beyond the range of parties shown in table 3.1, providing a more comprehensive description of the effects of party statutes on the likelihood to observe unitary or contested congresses.

This larger sample contains information about 221 cases. It includes parties that played an important role during the Second Republic. Among them we find the post-communist PDS; the Italian Popular Party, heir of DC, and its successor, DL, as well as some personal parties like IDV, LN or FI and its heir PDL (Calise 2010; Raniolo 2006). Insofar as almost none of them has ever hold a contested congress we are not able to consider them in the course of the dissertation and those parties would not even enter the second stage of the Heckman analysis.⁶ However, given that some of them are personal parties, we are now able to test the impact of H 4.9 through the dummy variable PERSONAL PARTY that equals 1 when the party is firmly loyal to its leader; we consider as personal parties Forza Italia, the People of Freedom, the Northern League and Italy of the Values.⁷

⁶Only the PPI held a contested congress but we were not able to find motions about it. Hence we could not measure the degree of internal divisions.

⁷All the other variables remain the same as before, except DEMOCRATIC CENTRALISM. On this variable we assign an intermediate value of 0.5 to LN and PDL as far as their party structure, although not officially organized according to this dictate (value 0), bears many resemblances with this type of party (value 1), for instance through the ban on any public expression of dissent.

4.5 Analysis and Results

Table 4.3 reports the results of our analysis. Column one shows the coefficients of the OLS regression on the selected dataset (model 1); column two presents the results of the Heckman model on the whole dataset (model 2); column three estimates Heckman model on the larger dataset (model 3). The Heckman model has been estimated through Maximum Likelihood; observations have been clustered by party and standard errors are estimated on cluster to cope with the issue of the independence of observations (repeated congresses within the same party).

To start with we comment the results of the Heckman model on the selection equation. The rho is statistically different from zero meaning that there is a matter of sample selection and the coefficients of the OLS could be biased.

The first stage tells us that, among the parties analyzed in the dissertation, only one variable seems to alter the likelihood of observing the outcome (i.e., a contested congress): DEMOCRATIC CENTRALISM in fact decreases such likelihood, while impact of the other variables is not significant.

When including other parties into the dataset we find statistically significant coefficients for three variables: DISPROPORTIONAL RULE, likewise DEMOCRATIC CENTRALISM, decreases the likelihood of a contested congress. PERSONAL PARTY too shows the same effect as none of the personal parties has actually held a contested congress. LEADER AUTONOMY does not appear to be significant after controlling for PERSONAL PARTY; finally FACTIONS BAN does not have any effect on the nature of the congress.

We turn now to comment the results of the outcome equation. Model 2 and 3 report almost identical results. DISPROPORTIONAL RULE is significant and decreases the number of factions. On the contrary INTERNAL

POLARIZATION has a positive effect on NOF: the greater the range of policy views within the party, the greater the number of factions that will contest the congress. Resources play a role as well: the coefficient of PARTY SIZE is positive and significant, meaning that parties whose amount of resources is greater face higher factionalism. OPEN LIST too contributes to increase NOF, breaking the monolithic party structure, while being an EXTRAPARLIAMENTARY party has no effect on internal divisiveness. Surprisingly PARTY IN OFFICE is negative and significant; among ruling parties the number of factions is lower, denying the idea that a larger share of spoils leads to a growing factionalism. Finally the role of party rules like FACTIONS BAN and LEADER AUTONOMY does not seem to yield significant effects on the number of factions.

When comparing these results with those of the OLS we note that two more variables (OPEN LIST and PARTY IN OFFICE) became significant while overall the coefficients are not much affected by the selection bias. To provide a proper interpretation of the coefficients, table 4.4 shows, according to model 2, the effect of each variable for the predicted value of NOF (conditional on y being observed), as well as the effect on the predicted probability of y being observed. We report the elasticities, measured as the ratio of the incremental change of the dependent variable with respect to a proportional incremental change of each independent variable.

4.6 The Determinants of Factionalism: Findings

In this chapter we focused and the causes of factionalism to determine what elements increase or decrease the number of factions within a party during

contested congresses. Through an Heckman model we handled any possible bias due to sample selection. We tested whether intra-party rules make the difference, assessing the impact of a set of party organizational attributes on the likelihood that the congress will be contested or unitary. Our results reveal that some rule do indeed play a role while others do not affect the expression or the degree of dissent within the party.

First of all DEMOCRATIC CENTRALISM (H 4.7b) has a clear effect on intra-party dynamics. Such undemocratic party rule acts like a deterrent for contested congresses. This come as no surprise given that democratic centralism, by definition, forbids any public expression of dissent. For instance, the PCI had to change the statute at the end of the 1980s when it decided to hold contested congresses in order to involve minorities in the decision making around structural changes of party ideology. The statute however was changed only to grant equal opportunities to all the competitors for it democratic centralism allows (theoretically) intra-party struggles (unless they lead to factionism). In fact a party that adopts democratic centralism may hold a contested congress (like PDCI in 2008 and PSI in 1949) however this is simply less likely.

On the contrary an explicit ban over the existence of organized factions has no impact on factionalism. FACTIONS BAN does not yield unitary congresses (H 4.6) nor does it decrease the number of factions (H 4.6b). This result is far from being unexpected. First of all factions took advantage from the unclear definition of their concept to survive the ban. Actually even the most heavily organized factions often do not call themselves ‘faction’.⁸ They usually prefer to adopt other names like ‘association’, ‘foundation’, ‘area’ and so on (Venditti

⁸In 2008, when Veltroni was the PD leader, his main opponent, D’Alema, created the association *Riformisti E Democratici*, and claimed that RED was not a faction but a resource for the party. One year later Pierluigi Bersani, member of RED, was appointed as the new party leader. In October 2011, during a meeting of the PD minority faction *MoDem*, Veltroni, the head of this new subgroup, stated that the *MoDem* was not a faction as well.

1981). Hence it is not easy to accuse a group of factionalism. Within the party, lawmakers and receivers coincide (Zincone 1972), then party members might decide which rule to enact and which not. It is more difficult to skip a stricter rule, like democratic centralism, than other directives related to faint concepts as for instance the ban on factions. Indeed the ban does not assure that factions do not arise and organize inside the party and such prohibition was often ignored: DC factions persisted despite the ban and the same happened within other parties. To quote an Italian saying, “*capons do not celebrate Christmas*”; factions often agreed on banning themselves in order to promote internal cohesion but, following a prisoners’ dilemma logic, none of them was the first to demobilize, and such rule was hardly ever applied.

The LEADER AUTONOMY too does not affect factionalism (H 4.8; H 4.8b). Even though a directly elected leader could be autonomous from party factions, this does not imply that her opponents will not challenge her leadership demanding for a contested congress. Only when the leader has completely prevailed over internal dissent the likelihood of contested congresses will decrease, as the variable PERSONAL PARTY showed (H 4.9).

Inside personal parties the direct election of the leader is carried to an extreme so that she is not even formally voted by delegates but just elected by acclamation. Indeed personal parties are so strongly tied and loyal to their leaders that it is often difficult to express dissent and organize to contest the congress challenging the leadership. They are not only less likely to hold contested congresses but often they do not celebrate congresses at all. For instance the Northern League, that for ages has been firmly loyal to its leader Bossi, has not been holding a national congress since 2002; Forza Italia (Berlusconi’s party) celebrated only two (uncontested) congresses in 15 years; Italy of the Values, a party created by the former attorney Di Pietro (famous after *Tangentopoli* scandal), held its first congress in 2010, 12 years after its birth; despite

the existence of some forms of internal dissent its minority faction (called *La Base – Idv*, that means, ‘rank-and-file’ – Idv) failed to present its own motion and the congress has gone uncontested. These examples confirm that when leaders are stronger factions remain latent and leaders’ power results in unitary intra-party dynamics (at least on façade).⁹

Beside elements contained in party statutes we tested the impact of another rule related to the party congress electoral system (H 4.1; H 4.1b). DISPROPORTIONAL RULE seems to decrease the likelihood of a contested congress. Minorities knows that their strength will be disempowered by the internal electoral system. Hence they would find lower incentives to defy party mainstream. They will try instead to reach an agreement with the majority faction well before the congress so that the distribution of payoffs will not be demanded to factional competition during the congress but will be the result of an ex-ante bargaining between the mainstream and the minority faction. However this result is quite ambiguous because this effect does not hold among parties in-

⁹Actually we can observe divisions even though these might remain latent so that politicians claims that their parties are not factionalized. Within the Northern League a new tendency, *Maroniani*, arose in 2011 gathering the followers of Roberto Maroni, who was the Minister of the Interior at that time. This faction contested many local LN congresses presenting its own candidates in opposition to the party mainstream led by the founding father Bossi and informally labeled *Cerchio Magico* (Magic Circle). At the peak of such factional strife, in January 2012, *Maroniani* requested to the leadership to call a new national congress (that would be the first in 10 years). Despite the absence of organized factions, there are some division inside the PDL too. We already discussed the breakaway of the *Finiani* and the formal ban on internal factionalism enacted in 2010. Notwithstanding in 2011 the followers of the former Minister of Economic Development, Claudio Scajola, organized and built the *Cristoforo Colombo Foundation* that represents a kind of faction composed mainly by former DC politicians. In order to force the Prime Minister Berlusconi to resign, a few MPs belonging to this faction switched off from the PDL in autumn 2011 and created a small parliamentary group affiliated with the new Italian Liberal Party. Inside the PDL there are also other associations and foundations like *Riformismo E Libertà* that includes former PSI politicians, the conservative *Magna Carta Foundation*, the network *Rete Italia* (tied to the Catholic group *Comunione e Liberazione*), the right-wings *Destra-PDL* and *Nuova Italia Foundation*, as well as many others. However these ‘factions’ do not publicly manifest themselves during a national congress, so far. This is in line with the findings discussed in the present chapter about the likelihood to observe contested congresses within personal parties. Moreover, for the methodological reasons discussed in chapter 3, these cases are excluded from the present analysis. Nonetheless in chapter 9 we will address this point building bridges for future researches that might enable to investigate intra-party dynamics even in absence of contested congresses.

cluded in our original dataset (model 2). Conversely the effect of the internal electoral system on the number of factions is more straightforward. Disproportional rules result in a lower chance for small factions to get represented inside party body. Therefore they will face the incentive to merge in order to contest the congress together, enhancing the opportunity to overcome the threshold or to win the majority prize. Arguably factions might feel free to divide soon after the congress (and in some cases this happened indeed). Anyway, once they contested the congress together signing a common motion, they are perceived as a unitary actor so that breaking the factional alliance will not be costless (e.g., in term of credibility).

The role of electoral rules, confirmed by our results, is strongly emphasized when looking at real world politics. For instance left-wing factions within the DC have always battled to get proportional representation for the election of congress' delegates (Boucek 2010; Venditti 1981: 40; Zincone 1972). In 1954 the left subgroup *Forze Sociali* proposed a motion to introduce the PR; this motion however was defeated by a small margin and the PR system was enacted only ten years later in 1964. At the end of the 1970s, when the system was modified to include a threshold and a majority prize, left-wing factions complained and fought once again to re-introduce a pure PR (Venditti 1981), which allowed them to exert a stronger influence over party mainstream.

Apart from formal rules other features contribute to the growth of factionalism. First of all the heterogeneity of policy preferences matters (H 4.2). INTERNAL POLARIZATION increases the number of factions. When the congress is contested broader levels of divisiveness lead to an higher number of factions that decide to run in the internal elections. Policy heterogeneity is always a source of factionalism. If we include in model 2 the interaction between INTERNAL POLARIZATION and PARTY IN OFFICE, this coefficient will not be significant, meaning that there is no conditional effect. The impact

of policy motivation remains the same even within parties in office, contrary to the idea of ruling parties composed mainly by factions of interests, which should not care about policy payoffs.

The availability of resources (H 4.3) is another element that boosts factionalism. We measured this variable through PARTY SIZE (the share of party votes). We could have measured party resources using two other variables: the number of party members or the financial budget (i.e., the party revenues). We gathered these data even though it is difficult to find information about (there are in fact many missing values). Anyway the correlation between PARTY SIZE, members and revenues is strong and statistically significant. In the dataset with 198 congresses PARTY SIZE is correlated with membership (.85) and revenues (.90). This data confirms that PARTY SIZE is a suitable proxy for the amount of financial resources.

When it comes to our H 4.5 we found that, contrary to our expectation, being a cabinet member decreases NOF. After controlling for rules, preferences and size we observe that the total number of subgroups within PARTY IN OFFICE is lower. This effect might be related to the results shown in paragraphs 8.3 and 8.4, and in footnote 33 (chapter 7). Party unity is a source of bargaining power that increases the party's appeal as a partner of a coalition government. Then less divided parties are more likely to get in office (Warwick 1996). Once in office they will face even more incentives to keep their unity in order to exploit patronage and to improve government effectiveness (Katz 1986b). In addition the cost of division increases because the life of ruling parties is more under public scrutiny compared to opposition parties. Accordingly, and in line with our theoretical model, we could expect an increase in the cost of voice (ν) among ruling parties, which yields as a consequence a decrease in factionalism (minorities will be less prone to resort to the voice option). These elements seem to explain why, within our data, parties in office

appear to be less factionalized.

Finally the data confirm that the electoral system (H 4.4) provides incentives for factionalism: open list PR grants to a wider number of factions the opportunity to gain parliamentary seats allowing them to perpetuate.

In sum we found confirmation for the role of policy preferences as a source of factionalism. In addition the availability of resources within the party contributes to feed factions, although there seems to be no added value from cabinet participation and, conversely, parties in office are less factionalized due to the growing incentives for unity and cohesion. The electoral system has an effect: when changing from closed list to open list PR the number of factions increases. Finally the impact of intra-party rules seems less clear. Formal rules play a role, especially when they are strictly enacted, although sometimes party might decide to escape them. With the exception of the internal electoral system, that seems to work according to Duverger's laws, the rules related to party organization seem to affect more the shape of intra-party conflict than its extent.

Overall undemocratic party rules (like democratic centralism) or undemocratic party structures (like those of personal parties), do indeed exert constraints on the expression of internal dissent. Actually we cannot say nothing about the degree of factionalism within those parties simply because we are not able to observe it. Although there might exist heterogeneity of preferences, the way these parties are organized is effective in decreasing the probability to observe internal struggles. Within these parties the conflict could probably be observed only when it erupts producing visible consequences like party splits.

This chapter shown that, if a bias exists, it is limited to undemocratic party structures characterized by DEMOCRATIC CENTRALISM or to PERSONAL PARTY. Accordingly we will proceed with caution when generalizing the results of the empirical chapters to these parties, whose internal dynamics

4.6. THE DETERMINANTS OF FACTIONALISM: FINDINGS

might not follow the classic form of factional competition through congress motions. Instead, we will focus more on intra-party conflict and bargaining within factionalized parties.

Chapter 5

Portfolio Allocation among Italian Factions

5.1 Introduction

The topic of portfolio allocation dynamics has been widely studied. Gamson (1961) seminal work opened the debate on how government coalitions distribute office payoffs to their members. He hypothesised that payoffs are distributed proportionally to the amount of resources provided by each member of the coalition (Gamson 1961: 376). That is: in multiparty governments, cabinet portfolios (y) are allocated to parties proportionally to their share of seats, measured as percentage (x) of the total seats held by parties that support the governing coalition. Later studies found empirical support for this idea (among them: Browne and Franklin 1973; Browne and Frendreis 1980; Druckman and Roberts 2003; Laver and Schofield 1998; Schofield and Laver 1985; Warwick and Druckman 2001, 2006). The empirical evidence led scholars to refer to such hypothesis as Gamson's Law. Indeed Laver (1998: 7) pointed out that Gamson's Law boasts 'one of the highest non-trivial R-squared figures in political science'. Notwithstanding, another branch of the literature raised an

alternative hypothesis built on bargaining theories (Ansolabehere *et al.* 2005; Baron and Ferejohn 1989; Fréchet *et al.* 2005; Morelli 1999; Snyder *et al.* 2005). These scholars argue that the formateur party i.e., the first party in charge of building a coalition, can exploit its strategic role ‘to pivot between alternative minimal-winning coalitions’ (Carroll and Cox 2007: 300) in order to obtain a share of posts greater than its share of seats. Despite these theories, recent empirical studies confirm, overall, the results of Gamson’s Law (Carroll and Cox 2007; Laver *et al.* 2010; Warwick and Druckman 2006). So far we summarized the literature on portfolio allocation between parties. Conversely we will focus on the intra-party dynamics to assess how cabinet posts are assigned within the party.

5.2 Intra-party Bargaining over Office Payoffs: Literature and Hypotheses

Most of the quarrel between Gamson’s Law and bargaining models is carried out looking at the inter-party level of analysis while the intra-party facet of portfolio allocation has received less attention. There are few, though important, studies related to distribution of office payoffs between factions. These works usually concern Italy and Japan and investigate the patterns of portfolio allocation within two dominant parties: the Italian Christian Democratic Party (Mershon 2001a, 2001b) and the Japanese Liberal Democratic Party (Adachi and Watanabe 2007; Bouissou 2001; Kohno 1997; Leiserson 1968; Ono 2010; Sato and Matsuzaky 1986; Wada and Schofield 1996), or both of them (Kato and Mershon 2006).

We will consider the party as a coalition of factions that have to split the whole amount of party payoffs (Leiserson 1968; Panebianco 1988). To

keep unity and soften the opposition of rival factions the party leader should allocate portfolios among all party factions. In this sense we would expect that Gamson's Law holds, ruling inter-factional bargaining within the party.

Most of the critics of Gamson's Law pointed out that this is just an empirical regularity with a huge need for theoretical foundation (Warwick and Druckman 2006: 660). Carroll and Cox (2007) started to fill this lack, developing a theoretical model that underpins the adoption of a proportionality criterion in portfolio allocation among members of pre-electoral coalition. The party, like a pre-electoral coalition, has an incentive to keep its unity (which is the public good) and to coordinate the behaviour of its members during the negotiation over cabinet formation. By establishing an internal rule of thumb that assigns proportional payoffs to each faction, the party pushes all its subgroups to work together maximizing party's strength and bargaining power, like pre-electoral coalitions do. For instance 'By agreeing *ex ante* to a more Gamsonian division of office spoils *ex post*, the coalition can motivate its members to campaign harder, thus conferring external benefits on all.' (Carroll and Cox 2007: 301). With respect to factions this might concern both the electoral campaign (particularly when factions compete for preference voting) and the everyday life of parties that involves also fund-raising and membership drive, which are directly linked to factional power and party strength. If this is the case we would observe that, overall, office payoffs are distributed proportionally to each faction size.

Hypothesis 5.1: The faction share of portfolios should correspond with its share of seats in party body

Mershon (2001a, 2001b) tested this hypothesis with respect to the Italian Christian Democratic Party. Her work confirms that, overall, cabinet posts

are awarded in proportion to faction size. Analyzing data on 145 DC factions she found that a unitary increase in the share of seats held in DC National Council raised the faction's share of ministers by 0.78; this path seemed even stronger when considering data on junior ministers: for 74 factions analysed she found a perfect proportionality, meaning that one point increase in the share of seats yielded a 1.05 gain in the faction's quota of undersecretaries.

Nevertheless, apart from confirming Gamson hypothesis her analysis also revealed the existence of 'variations across groups of governments [*i.e., observations*] and across types of factions that are masked by the overall pattern' (Mershon 2001a, 573, *italic added*). These deviations were related to changes in party rule (among them the shift to PR in party congress elections and the direct election of party leader), strategic faction's position (being the median faction or one of the wings) and party system features (number and nature of DC allies). Here we will expand Mershon work to include these and other possible explanations.

First of all we provide alternative hypotheses related to the bargaining theories. As long as we are dealing with a unidimensional space we can argue that within each party the median faction might exploit its strategic bargaining position to increase its share of office payoffs well above its actual size (Bouissou 2001, 584). Indeed Mershon (2001a, 2001b) already observed that the median faction within the DC was overpaid. Similarly we can adapt the concept of *formateur party* drawn by bargaining theories to the factional context. We assume that the party leader is the agent who has the power to allocate payoffs. Like in a setter game she can propose to the factions one among several possible distributions of payoffs that they might accept or reject. Obviously the party leader wants first of all to keep her status, but also to recompense her followers and to enhance their strength within the party. Moving first, the leader can propose to other factions an almost right deal (close to perfect proportionality)

that is hard to be rejected, even though she can exploit its discretionality to grant to her factions a more than proportional reward. Thus the faction to whom the leader belongs to can theoretically take advantage of its linkage with the leader and we will consider it as a kind of *'formateur faction'*. If this suggestion holds true, we would observe an increase in its share of cabinet posts above the gamsonian prediction.¹

Hypothesis 5.2a: The median faction should gain a share of portfolios that is more than proportional to its seats share

Hypothesis 5.2b: The party leader's faction should gain a share of portfolios that is more than proportional to its seats share

This idea of a setter game is related to what discussed in chapter 2. Retrieving those concepts we would expect that the formateur faction's gain will be greater when the leader is more autonomous from factional constraints (i.e., when there is a direct election). This point was already raised by Mershon (2001a, 2001b) who showed that the direct election of party leader decreased the degree of proportionality in portfolio allocation within the DC.² Such concept is also related to the idea that autonomous leaders are less likely to be challenged or removed from their charge. This is particularly true for leaders that are popular among voters and whose factions are stronger within the

¹Boucek (2010: 127) highlighted that majoritarian arrangements within the LDP pushed intra-party politics toward a bipolarized model of competition. In such context, even if minority groups were not excluded from payoffs allotment, the mainstream factions (those who supported the winning party leader) won the lion's share of portfolios (Boucek 2010; Di Virgilio and Kato 2001).

²Kato and Mershon (2006) pointed out that contrasting modes of leadership selection lead to different patterns of allocation. In the Japanese LDP the party leader was elected, until the 1980s, by the congress and under such context portfolio allocation followed 'winner-take-all dynamics'. Afterwards, LDP internal rules changed and the leader was chosen through factional negotiation. These dynamics forced the leader to comply with the factional deal, thereby increasing the fairness in portfolio allocation (Di Virgilio and Kato 2001).

party: they can exploit a huge degree of discretionality in assigning office pay-offs (Ono 2010). We can test the effect of this party rule in interaction with hypothesis 5.1 and 5.2b as follow:

Hypothesis 5.3a: The degree of proportionality in portfolio allocation should be lower among parties whose leaders are more autonomous

Hypothesis 5.3b: The party leader's faction should gain a share of portfolios that is more than proportional to its seats share when the party leader is more autonomous

Another intra-party attribute might affect this outcome. Mershon investigated the impact of the party congress electoral rule; overall her results indicate that proportionality was greater under PR internal electoral systems. However those results were controversial as she highlighted that direct election of party leader seems to matter more. Here we can double check this hypothesis to make sure whether non-proportional rules foster a 'winner-takes-all' allocation of payoffs. An highly disproportional internal electoral system might allow one faction to gain a full majority within the party body, so that it can exclude the minorities from the distribution of cabinet spoils. In fact, as we argued in the previous chapters, disproportional internal rule might increase the cost of voice (ν) thereby denying room for the achievement of compromise.

Hypothesis 5.4: The degree of proportionality in portfolio allocation should be higher when the party body electoral rule is strictly proportional

As we have just suggested, cooperative norms can foster proportional al-

location of payoffs despite the internal electoral rule. Repeated interactions between factions might lead them to discover the advantages of cooperation, fostering proportional distributive dynamics (Boucek 2003a). Indeed some scholars underlined how LDP factions developed proportionality norms as time went (Bouissou 2001; Sato and Matsuzaki 1986).

Hypothesis 5.5: The degree of proportionality in portfolio allocation should be higher among older parties where cooperative norms are established

In addition we want to control any alteration in bargaining dynamics due to factions' blackmail power. Intra-party minorities might increase their bargaining power threatening to defect, leaving the party. Indeed Wada and Schofield (1996) argued that the shift towards proportional allocation within LDP factions has been fostered by factional leaders' threat of exiting from the party. The mainstream faction then should cater to the minority as much as possible in order to avoid a fission that could damage the party (Boucek 2003a, 2010; Hirschman 1970). Similarly, Mutlu (2011) highlights how party leaders use pork-barrel politics as a strategy to keep their party united. In this sense we can hypothesise that minority factions will be overpaid; their share of posts will be greater than their size.

This will happen however only under two conditions: the threat to defect must be credible and harmful for the party. To be harmful the threat must involve at least a medium sized minority faction. To be credible that faction should gain only a limited amount of policy payoffs from party membership (larger policy payoffs in fact reduce the trade-off and therefore credibility of a split).

We know that party members (and factions) incur a cost for joining a

party (Snyder and Ting 2002). This cost increases along with the distance between faction's and party's positions. In this vein we can hypothesise that the greater the distance, the higher this cost and, similarly, the higher the net benefit of a breakaway (π). Therefore the probability of a breakaway grows as the distance enlarges (see chapter 7 on this point). Accordingly, factions whose ideal point is far from the bulk of party members must be overpaid in the allotment of cabinet posts to balance their lower policy returns (at least when the leader wants to prevent them from breaking away). Warwick (1998) suggested a similar reasoning for coalition governments: a greater distance between one party and the cabinet's ideal point requires an higher attribution of cabinet posts to bring the party inside the coalition. Following this logic we would expect that medium sized factions whose preferences diverge from party mainstream will be overpaid while smaller factions will be underpaid because their threat is not harmful (although could be credible when they are located far away from the median faction).

Hypothesis 5.6: Minority factions' share of portfolios should increase along with their size and their distance from the median faction (i.e., the likelihood of their breakaway)

To conclude, we will take into account the impact of party system competitiveness on allocation dynamics. We contend that in a low competitive parliamentary arena, where the ruling coalition retains a safe margin on the opposition parties (ω is low), leaders will not fear the risk of losing office due to potential defections of minority factions. Accordingly, they will try to overpay their followers

Hypothesis 5.7: The party leader faction should be overpaid when the cabinet retains a safe parliamentary support

5.3 Data and Methodology

The analysis carried out in the present chapter closely resembles what already done by Mershon on portfolio allocation within the DC. The database here used is built following most of the criteria she adopted in her work. Like Mershon (2001b: 285–286) we disaggregate data as follow: for each party congress our unit of analysis is the faction share of portfolios within any single government that was in power until the following party congress. This allows to increase the number of observations and makes this analysis comparable with other studies in the field of portfolio allotment. Following Mershon, we ascribed factional affiliation to party ministers referring to the official proceeding issued by the party after the congress, checking whether a minister had signed one of the motions presented by party factions (see Giannetti and Laver 2009 for a similar approach). In a few cases factional affiliation has been inferred looking at newspaper reports, ministers' biography or sources of data provided by the literature (e.g., Venditti 1981).

The present work however presents some non trivial changes and improvements. First of all, Mershon analysis relied on one party only while here we investigate the patterns of portfolio allocation considering a wide number of parties. With respect to those listed in table 3.1, we analyze only parties that have been involved in at least one cabinet after the congress. Hence the number of parties included in this dataset is equal to nine: we track almost all parties that held ministerial posts during the First Republic (DC, PLI, PRI, PSDI, PSI) as well as a few factionalized parties that have been in office dur-

ing the Second Republic (AN, DS, NPSI, PRC). Mershon’s analysis covered at most 20 governments and 163 cases (factions); our dataset instead includes information on 331 factions spread along 49 Italian governments, whereas the total number of governments in office from 1946 to 2010 is 61.

With respect to Mershon there is only one difference concerning the method of data gathering for it we do not consider factions as given. We use data drawn from party congresses with a twofold purpose: to detect the factions and to assess the ministers who belong to each of them. Mershon indeed referred to data from party congresses only for the second purpose while she counted DC factions as given. This is why the number of DC factions in our dataset is slightly lower (151 versus 163) although we analysed DC intra-party equilibriums in a broader number of congresses (11 against 6) and governments (32 instead of 20). All these features clearly highlight that our dataset is much more complete and tracks the patterns of intra-party bargaining over office payoffs in a widely comprehensive perspective (see table 5.1 for more details).

Table 5.1: Details on the Data Analyzed: Number of Observations per Party

Party	Governments	Cases
AN	3	10
DC	32	151
DS	3	10
NPSI	1	2
PLI	9	30
PRC	1	5
PRI	13	28
PSDI	18	44
PSI	14	51
Total	49	331

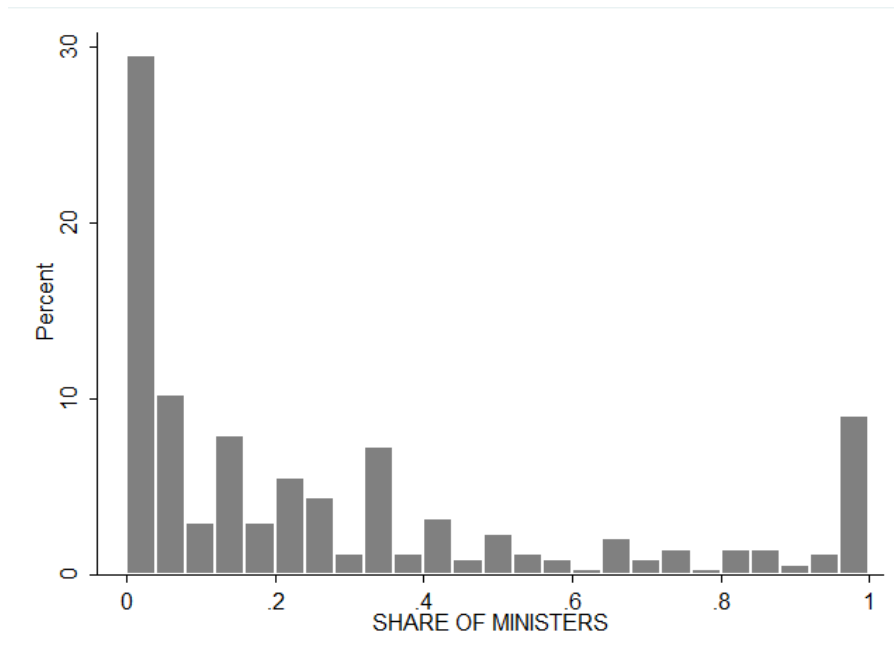

There are also further improvements provided by this research. Mershon investigated the impact of intra-party policy preferences according to strategic factional placement on the internal left-right scale. She evaluated the different distributions of payoffs considering whether the faction was the median or it was located on the wings. However she measured the median faction only

looking at the traditional qualitative ordinal array of DC subgroups. Here we can improve this point evaluating the impact of policy preferences on office payoffs. First of all we will determine the median faction using the quantitative estimates of factions' positions presented in chapter 3. Moreover we can account for the role of preferences considering, for each subgroup, the distance between its ideal point and the median faction. Then we can assess whether this distance affects the intra-party bargaining or not.

Finally one last difference concerns model estimation. As far as our dependent variable (y) is a proportion (the share of ministers assigned to each faction) using the ordinary least squares regression (as done by Mershon) may not produce accurate estimates. This happens because the values of y are bounded between 0 (the faction does not hold any minister) and 1 (the whole share of party ministers is assigned to one faction only). In such situations the assumptions required by the OLS might not hold as we could have heteroskedasticity or the errors might be not normal distributed (see Wooldridge 2002). Moreover the predicted values might fall outside the unit interval. Then we should adopt other models like the beta maximum likelihood estimation (Paolino 2001) or the fractional logit (Papke and Wooldridge 1996, 2008). Ono (2010) for instance analyzed portfolio allocation among LDP factions using a beta-binomial model. This model however does not allow the dependent variable to assume values that are exactly equals to 0 or 1. In our case this could be an issue because approximately 40% of our factions retain a share of payoffs that is either 0 or 1, as shown in figure 5.1 (Papke and Wooldridge 1996: 620).

Consequently we will analyze our data by means of a fractional logit. Moreover, as long as we have repeated observations nested within each party congress, we clustered them accordingly, providing standard errors on congress.

Figure 5.1: Distribution of the Share of Minister per Faction

Our dependent variable is SHARE OF MINISTERS, the percentage of ministers belonging to faction i over the total number of portfolios assigned to party j within government k . The independent variables are the following.

SHARE OF SEATS: the percentage of seats retained in party body (i.e., the National Council or the Central Committee); sometimes we compensate for unavailable data using the percentage of votes gained in party congress. MEDIAN FACTION: a dummy variable that identifies the median faction (value 1) within each party congress. PARTY LEADER FACTION: a dummy variable that identifies the faction to whom the party leader belongs to (value 1); in one case (PSI 1946 congress) we did not assign value 1 to any faction because the party appointed an independent leader with the task to appease the subgroups. LEADER AUTONOMY: measures the party leader's degree of autonomy; it equals 1 when the party leader is elected during the party congress directly by party delegates or party members while it takes value 0 when the leader is appointed by a small committee. DISPROPORTIONAL

RULE: accounts for the party congress electoral rule; it takes value 0 when the rule is a pure PR; value 1 when the voting rule is a PR with majority prize and a low threshold (5%); value 2 when the congress is held under a majoritarian system or under a PR with majority prize and high threshold of representation (20%). PARTY AGE: years elapsed from party birth until each government took the office. DISTANCE: corresponds to the squared distance between faction i and the median faction within the party congress. PARLIAMENTARY SUPPORT: the share of seats retained by the ruling coalition.

To investigate the effect of each variable on portfolio allocation we included also some interaction terms. We focused in particular on the interactions between SHARE OF SEATS and the other variables (LEADER AUTONOMY, DISPROPORTIONAL RULE, PARTY AGE, DISTANCE) to attest whether, under particular conditions, the impact of faction size changes. In this way we can better assess if the Gamson's Law actually shapes intra-party bargaining. Finally we provide also the interaction term between LEADER AUTONOMY and PARTY LEADER FACTION to verify whether the effect of each variable is conditional upon the other.

5.4 Analysis and Results

Table 5.2 provides the results of the analysis. We presented several nested models in order to account for all the hypotheses raised above. Model 1 is our baseline model; we include only one independent variable, SHARE OF SEATS. We want to test H 5.1: if a Gamson's Law exists we will observe a significant coefficient for this variable; additionally the conditional marginal effect of SHARE OF SEATS (when this variable is fixed at the mean) should be equal to one, attesting that there is, overall, a perfect proportionality between faction's size and the percentage of ministers assigned to it.

In model 2 we investigate H 6.2a and H 6.2b; we add the two variables related to the bargaining theories of portfolio allocation: MEDIAN FACTION and PARTY LEADER FACTION, which represents a kind of formateur faction. We include them simultaneously even if they are strongly correlated.³ However the post estimation diagnostic does not underline any strong problem with collinearity. Moreover testing the two variables in separate models leads to equal results.

In model 3 we take into consideration the impact of formal rules through the variables LEADER AUTONOMY and DISPROPORTIONAL RULE. We introduce also two interaction terms between these variables and SHARE OF SEATS to check whether the pattern of proportionality changes according to variations in intra-party rules. Model 3 compares H 5.3a and H 5.4 controlling if one of these two sets of rules retains a wider impact.

In model 4 we test H 5.5, related to intra-party informal rules, through an interaction term to assess whether the impact of SHARE OF SEATS is more or less proportional as PARTY AGE increases hereby fostering internal cooperative norms.

Model 5 evaluates the effect of factions' policy preferences on intra-party bargaining (H 5.6). The interaction between the variable DISTANCE and SHARE OF SEATS tracks changes in the pattern of proportionality according to deviations in faction's preferences (we can compare differences between factions that are marginal or pivotal with respect to the bulk of party members). We can also detect adjustments in the bargaining power of these factions according to variations in their size: do strong internal minorities exert a blackmail power despite their extreme policy preferences?

Finally in model 6 we replicate model 5 adding the interaction between

³Apart from few exceptions, we observe that party leaders tend to be selected choosing inside the median faction. This allow to minimize potential agency losses that could be higher when leaders's preferences are extreme (Kiewiet and McCubbins 1991).

LEADER AUTONOMY and PARTY LEADER FACTION (as suggested in H 5.3b) to provide a whole depiction of the intra-party balance of power between party leader and minority factions, while in model 7 we test the interaction between PARTY LEADER FACTION and PARLIAMENTARY SUPPORT (H 5.7).

To start with we comment the general results while later we will provide additional remarks on each model. First of all, SHARE OF SEATS is always significant confirming that size does matter. Larger factions are able to extract a greater amount of office payoffs. However (except in model 6) the coefficient of PARTY LEADER FACTION is always significant and positive as well, even controlling for SHARE OF SEATS. This indicates that, at least in part, bargaining theories apply to intra-party politics as long as the party leader is able to exploit her strategic role to assign to her faction a share of payoffs larger than the actual faction size. When looking at the other variables (and at their interaction terms) we note that only few are significant. Moving from model 1 to 5 we remove after each step those variables that retain no effect on SHARE OF MINISTERS (i.e., MEDIAN FACTION, DISPROPORTIONAL RULE, PARTY AGE). We find statistically significant effects only for three other variables, LEADER AUTONOMY and DISTANCE, as well as for their interaction with SHARE OF SEATS, and for PARLIAMENTARY SUPPORT in interaction with PARTY LEADER FACTION.

To provide a more substantive interpretation of the present analysis we turn now to comment each model. In the baseline model SHARE OF SEATS is significant; when the faction size is set at its mean (29% of seats) the conditional marginal effect on the dependent variable is equal to 1.14. This seems to point out that, overall, portfolio allocation is proportional to faction size and figure 5.2 seems to confirm this idea.

CHAPTER 5. PORTFOLIO ALLOCATION AMONG ITALIAN FACTIONS

Figure 5.2: Faction Share of Ministers as its Seats Share Changes

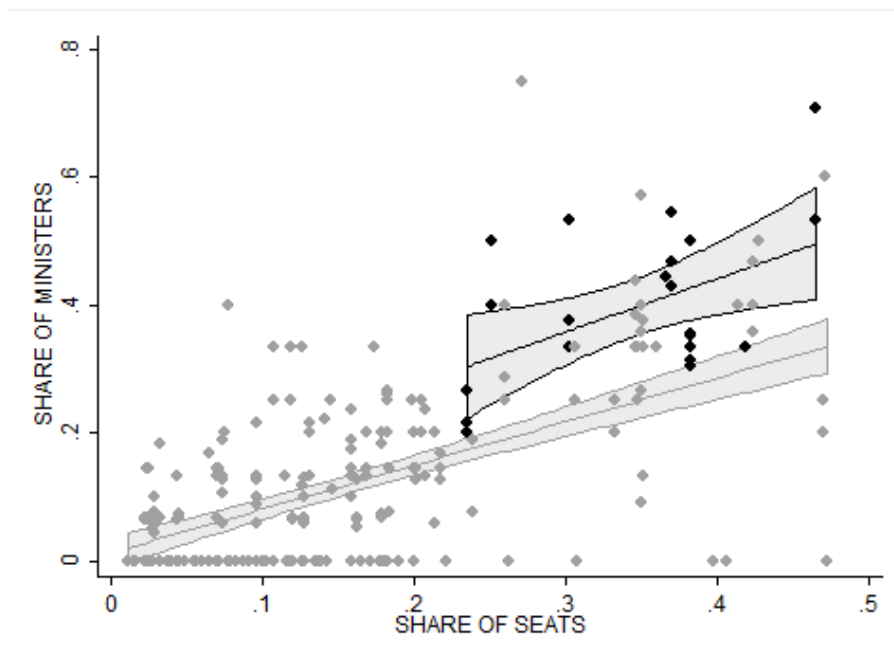

Note: The light gray area indicates the linear fit with a 95% Confidence Interval

Model 2 however finds more confirmation for the bargaining theories. PARTY LEADER FACTION is significant even after controlling for the share of seats. No matter its size, the faction the leader belongs to is always able to gain an higher number of portfolios when compared to the others. The conditional marginal effect (when all the variables are fixed at their mean) highlights a 10% increase in its share of ministers. Correspondingly the degree of proportionality is higher among party leader factions (mainstream); overall they are overpaid as the marginal impact of SHARE OF SEATS is 1.19 while this effect falls below the value of 1 for factions not linked to the leader (0.89). Figure 5.3 illustrates that among minority factions (whose share of seats stands underneath 50%) party leader followers (black dots) are able to extract a greater amount of office payoffs, no matter their size.⁴ Finally the model tells us that being the median faction does not impact on the share of ministers gained,

⁴We provide the best linear fit only related to minority subgroups to compare the two types of factions (mainstream and non-mainstream). While the party leader might belong to a minority group, there are no majority factions that are not linked to it.

unless the median coincides with the party mainstream. This is in agreement with the idea of a setter game where only the party leader can take advantage of her role to decide what factions to reward and what to punish.

Figure 5.3: Faction Share of Ministers as its Seats Share Changes. Difference between Mainstream (Black) and Non-Mainstream Factions (Gray)

Note: The two areas indicate the linear fit with a 95% Confidence Interval for mainstream (black frame) and non-mainstream factions (gray frame)

Model 3 compares the impact of two sets of intra-party rules. The effect of the internal electoral system is not significant. Majoritarian party rules do not foster ‘winner-take-all’ dynamics: the minorities are still involved in portfolio allotment. The electoral system plays a role only by transforming votes (won by factions during the congress) into seats (inside party body), but the magnitude of this effect does not enlarge beyond the mechanical level of disproportionality. Conversely the direct election of party leader, by fostering her autonomy, increases the ability to allocate payoffs according to her wishes, thereby reducing the level of proportionality in portfolio allotment. We find confirmation for Merston’s claim (2001a: 573): ‘Once direct elections for the

DC secretary general were instituted [...] the norm of proportionality exerted a rather weak influence on the distribution of ministerial posts among DC factions. In this sense, the institutional reform with the strongest impact on inter-factional portfolio allocation was not the shift to PR but the decision to hold direct elections for the secretary general.⁷ Indeed the marginal impact of SHARE OF SEATS drops from 1.03 to 0.89 when leaders are more autonomous. However the party leader faction does not automatically gain from this shift. The marginal effect of PARTY LEADER FACTION increases barely by 1% when leaders are directly elected. The question then is who does benefit from such discretionality in portfolio allocation.

Models 5, 6 and 7 try to provide an answer. By including the variable DISTANCE and its interaction with SHARE OF SEATS we investigate how policy preferences affect the inter-factional bargaining. They are both significant, controlling for PARTY LEADER FACTION. According to H 5.6 the interaction between the size of a minority faction and its distance from the bulk of party members should catch the blackmail power of internal minorities.

Figure 5.4 reports the marginal impact of SHARE OF SEATS as DISTANCE increases, along with a 90% confidence interval, for minority factions not linked to the party leader. We highlight how this effect varies according to the size of the minority group, drawing as an example three different lines. The dotted one sketches the degree of proportionality for a small subgroup (that retains 10% of party body seats); the dashed line shows the effect for a medium sized minority (30%) and the solid one illustrates the impact on a very strong non-mainstream faction (i.e., a group that retains 50% of seats but did not prevail during the election for party leader). We observe that the smaller faction is strongly underpaid: a 10% increase in size is rewarded by only an additional 4% of the share of ministers. On the contrary the medium sized group receives a proportional return in office payoffs for any increase in

its strength. Moreover, as the distance between this subgroup and the median faction increases the degree of proportionality increases as well up to the point that this group will be overpaid when its ideal point is far away from the core of party preferences. Something similar happens to the largest minority faction: this powerful group is strongly overpaid; its reward is more than proportional and grows when faction's policy position diverges from that of the median faction.⁵

Figure 5.4: Marginal Effect of Share of Seats on Share of Ministers as Distance Increases

Note: Impact among non-mainstream factions. The graph reports the marginal effect, with a 95% Confidence Interval, for three differently sized minorities (that retain respectively 10%, 30% and 50% of seats in party body)

Here we focused on minority factions to whom the party leader does not belong. We assume that a growing distance between the ideal point of each minority group and the median faction raises the cost of party membership for the minority (Snyder and Ting 2002). Ceteris paribus its total amount of

⁵We observe the same effect for factions that hold an intermediate percentage of seats, between 30% and 50%.

payoffs will be lower and the faction will face increasing incentives to break away (this reasoning is sustained by the empirical evidence that will be shown in chapter 7). Minority factions can try to increase their amount of payoffs threatening to split from the party (Boucek 2003a; Hirschman 1970). This blackmail strategy however could be successful only if the threat is credible and harmful. The party leader in turn will address minority factions requests only in such situations. The present analysis seems to confirm this pattern. To keep party unity, the leader caters to minority factions with a share of seats greater than their actual size. However this happens only when the size of the minority groups is already medium or large, while smaller factions do not carry any real blackmail power and therefore their stakes remain completely ignored. When the likelihood of their breakaway increases, powerful minorities receive a growing amount of cabinet posts as an incentive to stay within the party. In sum, through portfolio allocation the party leader compensates to those minority factions whose threat of exit is credible and harmful for the party. In order to provide them with a reason to stay within the party, their lower amount of policy payoffs is balanced by means of a more than proportional share of office payoffs (Warwick 1998).

Model 5, likewise models 3 and 4, reports an advantage for the party leader faction and a decrease in proportionality (that means a more discretionary distribution of payoffs) when the leader is directly elected. However in model 6, after including the interaction between PARTY LEADER FACTION and LEADER AUTONOMY, these variables are no longer significant. Overall the PARTY LEADER FACTION does not seem to gain from its status and the deviations from a gamsonian pattern seem to be caused mainly by the blackmail power of the minorities. Notwithstanding, the marginal effect of being the PARTY LEADER FACTION is significant (and positive) only when the leader relies on a greater autonomy thanks to its direct election, as shown

in table 5.3.⁶

Table 5.3: Marginal Effect of Being the Party Leader Faction Conditional on Leader Autonomy

Marginal Effect on SHARE OF MINISTERS when:	
LEADER AUTONOMY = 0	0.110 (0.101)
LEADER AUTONOMY = 1	0.107*** (0.030)

Based on model 6 from Table 5.2
 All other variables set at their means
 Clustered standard errors in parentheses
 * $p < 0.1$, ** $p < 0.05$, *** $p < 0.01$

As a final point, we look at the interaction included in model 7, which involves PARLIAMENTARY SUPPORT and PARTY LEADER FACTION, to assess under what conditions the mainstream faction turns out to be over-paid. Figure 5.5 illustrates the advantage exploited by the party leader faction, conditional on the balance of power between government and opposition. We distinguish between autonomous (black) and bounded leaders (gray). Overall the mainstream is able to take advantage of its link with the party leader only when the cabinet retains a safe majority. The wider the margin of the ruling coalition, the lower the degree of competitiveness and, as a consequence, the higher the benefit extracted by the mainstream faction in terms of office payoffs.⁷ We did not find significant differences when comparing contrasting leaderships, even though under autonomous leaders there is more variation in the size of mainstream's surplus so that the PARTY LEADER FACTION

⁶It could be argued that these results are inflated by the presence of parties with a low number of cabinet posts. Here the minister(s) would be more likely assigned to the mainstream faction at the expense of minority. However, when excluding from the sample parties that retain only few ministers (for instance, one or two) the results of the analyses hold and the advantage of the mainstream faction seems even strengthened.

⁷This result holds when considering the size of all the parties that sustain the cabinet (even only through external support) instead of the percentage of seats retained by parties in office.

could hope to receive a slight larger bonus.⁸

Figure 5.5: Marginal Impact of being the Party Leader Faction on the Share of Ministers as the Margin of Parliamentary Support Retained by Government Parties Growths. Differences between Autonomous (Black) or Bounded Leaders (Gray)

Note: The graph reports the marginal effect when LEADER AUTONOMY = 0 (gray line) and when LEADER AUTONOMY = 1 (black line), along with the 95% Confidence Interval (light-gray and black areas, respectively)

5.5 Intra-party Portfolio Allocation: Findings

Empirical evidence drawn from Italian factions does not allow to reject the idea of proportionality in intra-party portfolio allocation. Overall, faction size matters and the distribution of office payoffs is often in line with what suggested by the Gamson's hypothesis. However despite what shown in figure

⁸When testing the interaction between SHARE OF VOTES and PARLIAMENTARY SUPPORT we observe that the degree of proportionality is constant across different level of PARLIAMENTARY SUPPORT when the leader is bounded by factional constraints and has to stick to the inter-factional deal. On the contrary, under autonomous leaders the proportional effect of SHARE OF SEATS on SHARE OF MINISTERS decreases when the size of PARLIAMENTARY SUPPORT retained by the cabinet grows.

5.2 there are important deviations from a perfect one to one correspondence between size and payoffs.

In this chapter we tried to go further explaining such deviations. First of all we observed a significant advantage exploited by the party leader faction. Even controlling for faction's size this effect still holds; acting as the proposer in a setter game, the party leader is able to reward her followers with an amount of payoffs greater than their strength in party body. This evidence is in line with the bargaining theories that predict larger payoffs for the formateur in spite of proportional allocation.

We deepened this analysis looking at the effects played by formal and informal rules. Transforming party congress votes in party body seats, the electoral system plays a role but its impact is confined only to that extent. Factions that receive a share of seats lower than their congress votes or do not pass the threshold will gain lower office payoffs accordingly. Conversely if they win representation in party body they will be rewarded on the basis of their strength within that arena: there are no 'winner-take-all' dynamics beyond this point.

Contrary to empirical evidence from Japanese LDP factions we do not find any increase in proportionality across time. Perhaps cooperative norms that emerge within older parties could be counterbalanced by an increase in loyalty: cooperation should lead to a more proportional allocation while the increased loyalty, which raises the cost of the exit option (ε), could force minority factions to stay within and to accept an unfair distribution of payoffs, as suggested from our theory (see chapter 7 for a more detailed discussion on loyalty). Due to this countervailing mechanism, the overall effect on portfolio allocation is not significant.

The direct election of party leader seems to play a more direct effect, decreasing the degree of proportionality in portfolio allocation. To provide the public good (party unity and party strength), she identifies and provides se-

lective incentives that ensure the mobilization of all factions. When the leader is more autonomous she can exploit her role to reward her followers or to keep party unity by heeding the requests posed by internal minorities.

However our findings suggest that this second effect is prevailing. Besides rewarding her supporters, the party leader addresses the requests of minority (whose leverage is wide) in order to solve all the credible threats to party unity. In this sense portfolio allocation becomes a strategy to ward off potential harmful threats and to balance the total amount of returns for those factions whose policy payoffs are lower, thus contributing to keep the party together.

This aspect is even more relevant inside competitive parliamentary arenas, where the margin of ruling parties is lower and any single split might alter the balance of power between government and opposition. On the contrary, when the cabinet retains a wide parliamentary support party leaders will be able to exert a larger degree of discretionality in portfolio allocation, being able to enhance their own stakes and the payoffs of the mainstream faction.

Chapter 6

Bounded Oligarchy: Factional Bargaining over Party Position-taking

6.1 Introduction

In the previous chapter we addressed factional bargaining over office payoffs. Here we will investigate intra-party dynamics related to party position-taking, to assess how factions bargain over policy payoffs. The process of party position-taking can be analysed as the distribution of policy payoffs within the party.¹ The party position corresponds to the amount of payoffs to be shared and each faction will try to affect this process minimizing the distance between the party platform and its ideal point. In this chapter we will retrieve many aspects that have been analyzed before (concerning the dynamics of factional negotiations) assuming that factions bargain over party position. We will investigate whether a kind of Gamson's law applies to the allocation of policy

¹Warwick proposed a similar idea arguing that the ideal point of a coalition government is like a policy payoff that has to be shared by the members of the coalition (Warwick 2001).

payoffs or whether some actors, like the median faction, can extract larger revenues. We will try to assess whether factions have an impact on party position (Aldrich 1983; Aldrich and McGinnis 1989; McGann 2002; Strøm 1990; Ware 1992) or if, alternatively, parties try to get rid of factional preferences in order to assume vote-maximizing positions (Downs 1957). By modelling party placement as the result of inter-factional competition, we will highlight how and under what circumstances factions shape the party, bounding the leader in the choice of the platform. Furthermore, we will assess how party organization affects this outcome analysing whether different internal rules alter the equilibrium between factions and leaders. In this way we will provide new insights about the linkage between party leaders, members, and activists.

6.2 Who Sets the Party Position: Literature and Hypotheses

The literature on party position-taking is vast, and it focuses mainly on two aspects. One is to analyse the interactive moving of actors involved in party competition to find the existence of equilibrium. Downs' (1957) spatial theory shows that in a two-party system such equilibrium consists in a centripetal convergence of actors toward the median voter. This result, however, relies upon lots of assumptions about the motivations and individual features of political actors. Starting from this conclusion, scholars have tried to relax those assumptions. New models account for some aspects of 'real world politics', providing more realistic results that better fit empirical evidence. Among these models we focus on those concerning multiparty systems, given that our hypotheses will be tested looking at the Italian case. For instance, the 'unified theory of party competition' (Adams *et al.* 2005) provides some arguments to

support the idea of centrifugal equilibrium. According to this model parties are pushed away from the centre, in the direction of those voters who feel identified with them. Although parties maintain a link with their partisans' preferences, this model predicts that parties maximize votes, adopting a slight moderate position with respect to their followers.²

Another branch of the literature looks at the process of position-taking not as the product of exogenous strategic interactions between parties in the system, but as the endogenous result of an inward competition within the party (Budge *et al.* 2010; Levy 2004). Starting from the idea that parties are somehow bounded by intra-party structure, scholars investigate the effect of organization and internal rules, on one side, and divergent intra-party preferences on the other. Both elements affect party position and its changes across time.

The present work is more centred on this second branch of studies, but will provide hypotheses and results that take both into account. In particular, we will raise and test hypotheses dealing with factional preferences, intra-party organization, and the pressure for a (partial) convergence due to party competition.

Parties are clearly not unitary actors (e.g., Laver 1999; Laver and Benoit 2003; Laver and Schofield 1990; Strøm 1994). They are composed by members that retain similar but non-identical preferences. Those members that share the most similar policy view gather together organizing factions. Despite the existence of some common traits shared by all the members (Aldrich 1995; Krehbiel 1993; Snyder and Ting 2002), in fact the policy positions of internal factions are not exactly the same (Bernauer and Bräuninger 2009; Giannetti and Laver 2009). Each faction will try to enhance its preferred policy position

²Other models predict similar results (e.g., McGann 2002). See Budge *et al.* (2010) for a review.

in order to affect the party platform. Our dataset will help to map these divergent preferences to analyse their impact on the process of position-taking.

It has been argued that the party's ideal point depends on how internal organizational structure aggregates the preferences of members. Among divided parties the internal equilibrium is the result of a factional strife (Giannetti and Mulé 2006: 462; Levy 2004). Factions bargain to influence party strategy according to their power (Laver and Shepsle 1990b: 504). Depending on the party decision-making process, this strife might follow different paths leading to different potential outcomes (new party platforms). The decision-making process in turn is affected by intra-party rules and organization, and by the model of party that we take into account.

We might hypothesize that parties are (wholly or partially) bounded by their factions, or alternatively, they are absolutely free to set their platform. In the first case party position should lie somewhere inside the Pareto set of factions' positions. According to Levy (2004: 251): 'parties can offer to voters any policy in the Pareto set of their members. Parties cannot commit to offer any policy outside the Pareto set but the party members can find mechanisms (such as bargaining) that allow them to choose policies within the Pareto set' (then this agreement will be enforceable). A stable agreement could be reached only inside it.³ If this is the case any point inside this range should be related with the actual party position.

However, the actual location of party along the continuum depends on the bargaining power of each faction. This varies according to factions' size, measured as the share of votes gained during the congress (or the share of seats inside party body). As Budge *et al.* (2010: 793) point out: 'The stronger one faction is relative to the others the more it overcomes resistance and carries

³Moreover, both voters and rival parties believe that only positions inside the Pareto set can be stable.

its preferred policy further’.

Among the points inside the Pareto set, two carry a theoretically substantial meaning that depends on the structure of intra-party dynamics. For the sake of preserving unity, inter-factional competition may build a consensual environment where all faction’s preferences are somehow taken into account (Budge *et al.* 2010; Giannetti and Laver 2009). At the level of legislative party group Heller and Mershon (2009b) hypothesized that the party ideal point should be close to the average ideal point of legislative members. Extending this idea to party body, we observe that ‘Indeed the mechanisms in which Western European parties reach internal compromise do mimic some form of a weighted average of the ideal policies of their factions’ (Levy 2004: 251). Hence, we would expect that party platform is set with a strong degree of proportionality. This idea refers to a kind of Gamson (1961) rule in the distribution of internal policy payoffs (i.e., party position).⁴ As far as each faction is able to affect party position according to its strength in party body (due to the results of party congress/convention) we would expect that a factional agreement could be reached considering the weighted mean of the factions’ ideal points. Then such equilibrium will be the best predictor of party position and will bound the leader in the choice of platform and strategy.

Hypothesis 6.1a: The factions’ preferences affect party position so that a ‘Gamsonian agreement’ position is strongly related to the party’s ideal point

It has been argued that when the electoral system provides incentives for

⁴As discussed in the previous chapter, the Gamson (1961) hypothesis is essentially a proportionality rule stating that office payoffs are allocated to each member proportionally to its contribution to the coalition. Warwick (2001) extended this reasoning to policy payoffs showing that ‘coalition policy corresponds with the weighted mean position of the parties in government, with the parties’ seat share constituting the weights’ (Warwick 2001: 1215).

inter-factional competition, the common interests in partisan unity are insufficient to prevent internal dissension so that factions divide during the electoral campaign (Morgenstern 2001). To the contrary we claim that, to keep their unity, parties cater to all factions according to the latter's share of votes in the congress body. We stress the importance of party unity, which is a key source for party strength, particularly in the electoral arena. We hypothesize that the cost of a breakup (ω) lifts as general elections approach, increasing the importance of preserving party unity to avoid an electoral debacle, insofar as disunity means defeat (Schattschneider 1942). A fission in fact yields negative effects on party performance (see paragraph 8.5 and footnotes 21 and 24, chapter 7). Accordingly, many scholars have stated that party manifestos take into consideration the concerns of both mainstream and minority factions precisely to boost party unity (and credibility) before elections (e.g., Levy 2004). If this is the case, the impact of factional agreement on party position should increase as the legislative term comes to an end.

Hypothesis 6.1b: As time passes and the new general elections approach, the effect of the 'Gamsonian agreement' on party position should be greater

Alternatively, inter-factional conflict may assume the traits of a winner-take-all competition, with the median faction (mainstream) free to set its ideal point as the overall party position.⁵ Although occasionally the median faction could suddenly change party platform for strategic or contingent reasons, we expect that on average the party will be located inside the Pareto set, closer to the mainstream's ideal point.

This is true for several reasons: the median faction still has a commitment

⁵It is worth remembering that the median is not a 'dictator' because its peculiar position depends on the preferences of all other factions (Black 1958).

with party members, due to the result of the party congress; strong deviations of its position from the ideological position of the bulk of party members could result in a loss of internal consensus (for the mainstream) and in a change of the dominant faction in the following party congress; minority factions could feel dissatisfied if the party is ruled only according to the will of the mainstream, and hence could exploit their bargaining power by threatening to defect and to leave the party (Boucek 2003a).⁶

Finally, as far as we deal with a unidimensional policy space, the median voter theorem applies and the median faction's position emerges as the party position. This path actually bears a resemblance to the previous one. The median faction is not a 'dictator'; it competes during the party congress for members' votes. Hence, its position emerges as a kind of consensual equilibrium of all members' preference. Therefore, compared with the previous hypothesis, we just want to check whether party position is pushed away from that point in the direction of the median faction.

Hypothesis 6.2: Party position is biased towards the ideal point of the median faction

We will measure the influence of the median faction above and beyond its contribution to the *Gamsonian agreement* through a variable that records the deviation of the median faction from the weighted mean.⁷ If our second hypothesis is true we would expect a positive significant value of the coefficient of such variable.

A third possible pattern assumes that parties are bounded only in a limited

⁶Their bargaining power will be higher if the threat is credible and could harm the party (resulting in a loss of votes, seats, or strategic position).

⁷This makes it possible to overcome any possible problem of correlation between the median and the *Gamsonian agreement*. Indeed these two positions are highly correlated (.99). See Warwick (2001: 1223) for an analogous argument.

way by factions. The increasing personalization of politics in modern democracies (Poguntke and Webb 2005) boosts the party leaders' power in spite of the strength of factions. Whether the party leader, due to her charisma or her 'dominant position' within the party, is able to set the new platform we would expect a deviation from the factional agreement in the direction of her interests. However, party leaders are democratically elected; hence, the rank-and-file retain an influence over party position (Heller and Mershon 2009b). The leader's first purpose is to remain in charge; in addition, as the agent delegated by party members, she will have more discretion in setting party position, and she will exploit this feature provided she can keep the members' approval.

When dealing with party leadership, however, we have to take into account different intra-party rules and organizational patterns that affect internal dynamics, providing the leader with greater or lower power. This in turn affects the leadership's ability to deviate from the inter-factional agreement in the direction of its preferred party position. According to the cartel party model (Katz and Mair 1995), leaders want more autonomy from activists' factions in order to be free to pursue the building of a cross-party cartel (Katz 2001; Mair 1997). Their purpose is to lower members' stakes, pushing the party to a moderate position and thereby increasing both party votes and the likelihood of being involved in government coalitions (Mair 1994; Marsh 1993). One strategy to enhance the leader's autonomy is to empower the ordinary party members (or supporters), thus increasing the nominal level of intra-party democracy (the rationale has been also discussed in paragraph 2.3).

Recent trends attest to an increase in the inclusiveness of party leader selection mechanisms, and these trends are particularly evident among Italian parties. Historically based on a small committee (National Council or Central Committee), the selection procedure was extended to the whole audience of

delegates at party congress, and, recently, the selectorate has tended to include all party members (and sometimes even unregistered supporters) through direct election of the leader (by means of closed or open ‘primaries’).⁸

Italian mass parties started to enlarge the selectorate at the end of the 1970s.⁹ In 1976 the election of the DC leader was demanded of congress delegates instead of members of the National Council; the PSI set the same rule in 1981, strengthening Craxi’s personalized leadership.¹⁰

Although some authors claimed that intra-party democracy increases members’ influence over the party leadership (Pennings and Hazan 2001, Scarrow 1999, 2005) here we raise an alternative argument. Noticeably, the expanded inclusiveness of the leader’s selectorate does not necessarily increase the rank-and-file’s control over the leadership but paradoxically can be a leader’s strategy to defang the base (Katz 2001; Mair 1994, 1997; Marsh 1993; Michels 1911; Ostrogorski 1902; Poguntke and Webb 2005; Rahat *et al.* 2008).¹¹

Inclusiveness produced less tight contests and a decrease in competitiveness

⁸Open primaries have been adopted so far only by the PD to select the party leader. Recently other parties, like Left Ecology and Freedom (SEL) or the PDL, seem willing to adopt the same device to appoint the leader.

⁹See Fabbrini (1994) and Calise (2005) on the link between the personalized power of Italian leaders and their direct election by party delegates. Moreover, Mershon (2001) shows the impact of such rule on portfolio allocation among DC factions: after direct election ministerial payoffs were no longer shared proportionally by all party subgroups. Refer to chapter 5 of the present dissertation for an analogous argument.

¹⁰While inside the PSI Craxi was strengthened by such rule, factions within the DC still maintained some influence. Notwithstanding this, in 1976 the direct election was crucial to select Zaccagnini as party leader. Zaccagnini was somehow autonomous from factional membership and factional ties; he tried to end intra-party fragmentation but he failed to reach this purpose. Later on De Mita was elected leader in 1982 through direct election. Likewise Zaccagnini, once appointed De Mita tried to cut out factional disputes. Contrary to Craxi however he did not succeed in getting rid of subgroups. Nonetheless his direct election granted him a certain degree of autonomy up to the point that he was the first DC leader able to cumulate his party leadership with the role of prime minister, in 1988. See Curini and Martelli (2009, pp. 142-144) for a comparison between Craxi’s and De Mita’s attempts to unify their parties.

¹¹Inclusiveness and democratization do not necessarily go hand in hand (Lundell 2004; Rahat and Hazan 2001). Even a supporter of intra-party democracy like Scarrow (2005: 6) recognizes that inclusiveness ‘may also centralize the decision process by minimizing the power of organizational subunits within the party [...] In fact, in some cases national leaders may advocate intra-party democratization because they see it as a way of weakening regional party leaders’.

(Kenig 2009b), complicating the task of removing an unwanted leader.¹² In addition, a directly elected party leader retains a higher legitimacy (Michels 1911); thus, she can cut out middle-level activists, getting rid of party factions' ties. As long as the leader autonomy increases, the party should be less bounded by factions and will converge toward the centre of the policy space.

Hypothesis 6.3: When intra-party rules increase the inclusiveness of the leader's selectorate the 'Gamsonian agreement' should be less (if at all) useful to predict party position, which instead will be attracted by the centre of policy space

Finally, if parties behave as catch-all actors (Kirchheimer 1966) we should observe a decline in factional constraints on party platform. Parties will appeal to a broader public, seeking the support of groups that lie outside the traditional party organization. If this holds we would expect parties to converge towards the centre, to gain more votes and more resources, independently of intra-party preferences and of the effect of party rules.

Hypothesis 6.4: Party position is independent from factions' position and, overall, will be attracted by the centre of policy space no matter the shape of intra-party rules

H 6.1 (a and b), H 6.3, and H 6.4 represent three different models of party: mass, cartel, and catch-all. In some sense they express a fulfilment or a response to the others (see Katz 2001). We will compare them to assess under what condition each one prevails. In our analysis H 6.1a and H 6.4 are the two true alternative hypotheses: we want to assess whether, overall, factions

¹²With regard to candidate selection, inclusiveness also produces lower levels of representation (Rahat *et al.* 2008).

bound the leader or if instead the party is free to move. H 6.3 lies somewhere in the middle: we will test whether the rise of the cartel party (conditional on changes in party rules) actually impacts on H 6.1a building a new party that bears a resemblance to H 6.4, but only with strict conditions.¹³

6.3 Data and Methodology

To test the hypotheses raised before we want to compare the factions' preferences, as shown in chapter 3, with a measure of parties' positions. This confrontation is made possible thanks to a recently built dataset, the Italian Legislative Speeches dataset (ILS), which provides information about the party positions of Italian parties from 1946 to 2010 (Curini 2011; Curini and Martelli 2009, 2010).¹⁴

Those data are based on a codification of all the investiture debates of the Italian governments.¹⁵ Compared with Comparative Manifesto Project (CMP) data, ILS retains some advantages. First of all, CMP does not distinguish between positions of parties that run together in the election as an electoral cartel but split afterwards; second, it does not assess the positions of new parties that form during the legislative term (i.e., due to party fission); finally,

¹³Contrary to the mass and the catch-all models, the cartel party 'whether understood as a synthesis/thesis in a dialectic process or as the next stage in a cyclical process [...] does not represent a steady state' (Katz 2001: 282).

¹⁴The dataset is available at: <http://www.socpol.unimi.it/docenti/curini>

¹⁵For each debate, the authors selected and codified the speech released by the party leader (or by a relevant MP) plus the Prime Minister's programmatic speech. The method adopted to codify speeches is similar to that employed by the well-known Comparative Manifesto Project in order to analyze the contents of party electoral programs (see Budge *et al.* 2001 for a detailed description). In each legislative speech the authors identified the number of quasi-sentences and assigned each of them to a number of pre-established categories that form the classification scheme. To take account of the Italian political context the original 56 categories of the CMP dataset have been increased to 68. The dataset contains the percentage of the total text of legislative speech that deals with these categories. The dataset was constantly updated until December 2010 and includes information about a few additional debates over crucial votes of confidence (i.e., the debate related to Prodi I vote of no-confidence and two debates on confidence votes faced in September and December 2010 by Berlusconi IV cabinet).

CMP provides only one value per legislature while ILS, given the high level of Italian governments' instability, tracks parties' positions almost year by year, increasing the number of cases included in our analysis. In fact, we can compare factions' positions with the first known value of party position expressed after the congress (that for the same reasons discussed before is temporally connected to the congress). Furthermore, thanks to ILS, we can compare the factional equilibrium reached during congress at time t with all the values of policy positions held by the party until the new congress at time $t+1$. This allows us to model changes in intra-party dynamics and bargaining over time: for instance, we can model the effect of party fissions (happened not immediately after the congress) over party position, and we can assess whether bargaining dynamics vary as time passes.¹⁶

Using ILS we estimated party positions following the 'vanilla method' (Gabel and Huber 2000). We ran a factor analysis on the percentage of quasi-sentences, and we extracted the first component; the standardized values of party positions have been located on the latent dimension that emerged from the analysis.¹⁷ Vanilla estimates are strongly correlated with the traditional RILE scale measured on ILS and with the results of the vanilla method applied to CMP data.¹⁸

In the next section we will compare these two datasets. Despite differ-

¹⁶When one or more factions leave the party during the period between one congress and the next, we rearranged the result of factional agreement measuring the new balance of power among the remaining subgroups. We excluded those cases where, due to party fissions, there is only one faction left; however, had we included these data the main results would not have changed.

¹⁷Given that we divided motions in two time periods before running Wordfish, we did the same when dealing with factor analysis. We divided ILS in two subsamples and ran two separate analyses. The results of these two factor analyses are highly correlated (0.87), with parties' positions as they emerge from the analysis run on the whole dataset.

¹⁸The correlation between vanilla method estimates and the RILE scale measured on ILS is strong and significant ($r = 0.85$). Overall estimates of parties' positions, determined by applying the vanilla method to ILS and CMP, are positively correlated (0.57); among data included in our analysis this coefficient increases to 0.61. Although we use ILS to test our hypothesis we assess their reliability using CMP data; this does not alter our main results.

ences, these data share some traits. Both are related to Italy from 1946 to 2010 (though they have been divided in two time periods, before and after 1989, in order to estimate positions). Both are built through content analysis. Wordfish algorithm and factor analysis produce normalized estimates of positions extracted along a seemingly common latent dimension.¹⁹ The parties' and factions' positions are aligned along the left-right scale, and these data cover the entire length of the continuum.²⁰

They come, however, from two completely different sources: factions' positions are extracted from debates that took place in party body, while the data about parties are related to speeches delivered in the legislative arena. This can be an advantage because the two measures are independent and exogenous with respect to each other. One possible problem, however, is related to the idea that the legislative party branch might retain a different position compared with the party body. Anyway, given the strong control usually exerted by Italian party bodies over their elected representatives, we can reasonably retain that the position of the legislative party group will correspond to the actual party position.

Having information on party positions within each cabinet as well as factional preferences within each party congress we can merge these data together to build two datasets. In the first one we assess the impact of factions preferences comparing them with the first known estimate of the party position,

¹⁹It could be argued that intra-party politics involves more than one dimension. We know, however, that parties function as logrollers reducing complex issues into a low-dimensional space (Levy 2004; Poole and Rosenthal 1997). If parties reduce the complexity on a single dimensional space they need to compromise on that. In addition, both processes used to estimate positions (Wordfish and factor analysis) follow a similar logic that reduces many issues onto a single latent dimension.

²⁰More precisely, according to factor analysis in the first period the two most extreme parties are the PSIUP and the MSI. In factions' dataset we have documents about PSIUP factions' and about MSI, and they are on the extremes as well. Similarly, in the second period the two most radical parties are PRC and MSI-AN; indeed the dataset on factions contains information about subgroups belonging to these two parties and they are located on the wings. Hence, the whole left-right dimension is covered by data. However, the range of the scales is different; then we divided all the values for the length of each continuum.

measured after that the party congress has been held; here the number of cases amounts to 65. In the second dataset we enlarge the number of cases comparing factions' ideal points with all the estimates of party position measured between the end of the party congress until the following one; the number of observations enlarges up to 172.

6.4 Analysis and Results

We can turn now to the analysis testing the five hypotheses presented in section two. Table 6.1 gives some details about their operationalization, along with an explanation of how to assess their effect.

Our dependent variable is PARTY POSITION (PP) estimated through vanilla method applied to ILS. Right-wing parties retain positive values while PP is negative for parties located on the extreme left of the scale. Here we describe the independent variables. GAMSONIAN AGREEMENT POSITION (GAP) is the mean of the factions' positions weighted by their share of seats in party body, measured within each party congress; positive values indicate that the factions' average is on the right and vice versa. The greater this values is, the greater PP should be (the more GAP is on the right the more we expect PP to be there). YEARS BEFORE ELECTIONS (YBE) is the number of years remaining before the next general elections. We analyse its interaction with GAP: as YBE shrinks, the marginal effect of GAP on PP should increase (and vice versa). DISTANCE MEDIAN – GAP, measured as the distance between the median faction and the factional agreement position, records the influence of the median faction above and beyond its contribution to GAP. The ability to attract PP towards its ideal point is caught by a positive significant value of this variable. LEADER AUTONOMY is a dummy variable that

Table 6.1: Party Position-Taking: Hypotheses and Operationalization

Hypothesis and Context	Variable	Operationalization	Expected Effect
Dependent Variable	PARTY POSITION (PP)	Vanilla estimate of party position based on ILS	n.a.
5.1a: Mass party ruled by consensual dynamics	GAMSONIAN AGREEMENT POSITION (GAP)	Mean of factions' positions weighted by their share of seats in party body	(+) GAP affects PP (e.g., the more GAP stands on the right the more the party should be there)
5.1b: Mass party ruled by consensual dynamics: proportionality increases as new elections approach	GAP*YEARS BEFORE ELECTIONS (YBE)	Interaction between the GAP and the number of years remaining before the next general elections	(-) GAP marginal effect on PP increases when the YBE shrinks, and vice versa
5.2: Mass party ruled by winner-take-all dynamics	DISTANCE MEDIAN - GAP	Distance between the median faction's position and GAP	(+) A positive coefficient highlights a deviation from GAP towards the median faction
5.3: Cartel party	GAP*LEADER AUTONOMY PARLIAMENTARY CENTRE OF GRAVITY	Interaction between GAP and a dummy variable that assumes value 1 when the party leader is elected directly by delegates (or through primaries) and 0 when she is elected by a small committee Mean of parties' positions weighted by their share of seats in Parliament (proxy for the centre of policy space)	(- / 0) Among parties whose leader is elected by a wide selectorate the marginal effect of GAP should be lower (or not significant at all) (+) Among parties whose leader is elected by a wide selectorate the policy centre should affect PP
5.4: Catch-all party	GAP PARLIAMENTARY CENTRE OF GRAVITY	Mean of factions' positions weighted by their share of seats in party body Mean of parties' positions weighted by their share of seats in Parliament (proxy for the centre of policy space)	(0) GAP effect on PP should never be significant (+) The centre of policy space should always affect PP

accounts for the personalization of politics and for the party leader's strength; it assumes the value 1 when the leader is directly elected (by delegates during party congress or by party members or supporters through 'primary election'), and the value 0 when the party leader is nominated by a less inclusive electorate (i.e., a small committee like the party's National Council or Central Committee).²¹ We analyse the interaction between GAP and this variable, and we expect that GAP's effect on PP should be lower or not statistically different from zero when leader autonomy is greater. Finally, PARLIAMEN-TARY CENTRE OF GRAVITY is the mean of the parties' positions weighted by their share of seats in Parliament, used as a proxy for the centre of political space. The higher this value, the greater the value of PP (if the political centre attracts the parties we will find a positive significant value of this variable).

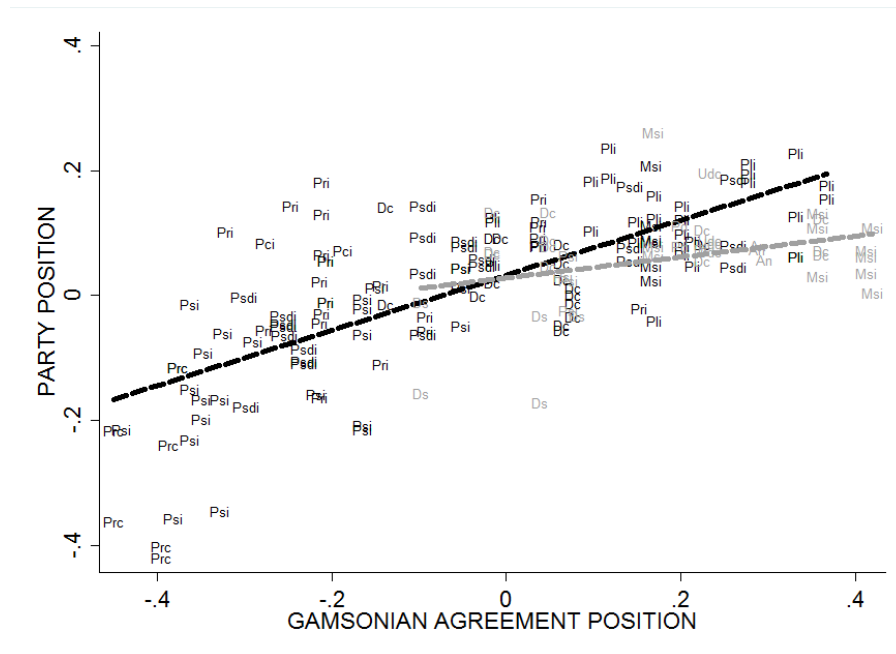

Figure 6.1 provides a first visual analysis of our main hypotheses. For each party congress we show the GAP value along with all the PP values measured before the next congress. We distinguished between parties whose leader is autonomous (grey) or not (black). Accordingly, we plotted two dashed lines with the fitted value of the regression for the two contexts.

This first enquiry tells us that factions do matter: there is a positive relationship between GAP and PP, attesting that the parties' ideal point is not independent from the factions' preferences. However, we observe differences between parties whose leaders are stronger or weaker. The black line is steeper while the grey is smoother, indicating that when leaders retain direct legitimacy they gain autonomy and are able to get rid of the factions' influence.

Now we investigate more in depth the contribution provided by our co-

²¹We do not distinguish between leaders elected by delegates or through closed/open primaries because the latter context concerns only one congress among those included in the dataset (PD 2009, with the adoption of open primaries). In addition, even when leaders are elected by delegates, party members often know which leader is attached to each factional motion they vote for, so that this procedure resembles that of closed primaries.

Figure 6.1: Party Position and Weighted Mean of Factions

Note: The dashed lines express the fitted value for autonomous (grey) or bounded (black) party leaders

variates to the dependent variable by testing several models. In model 1, our baseline model, we regress PARTY POSITION (taking the first known value after the congress) on the factional agreements (GAP). In model 2 we add, as control variables, the DISTANCE MEDIAN - GAP and the PARLIAMENTARY CENTRE OF GRAVITY. In model 3 we include two interactions: between GAP and LEADER AUTONOMY and between GAP and YBE. In the fourth model we replicate the third model on the larger dataset.

We test these models by means of an OLS regression. Given that our observations are nested within parties they might not be independent. To assure unbiased results of our analysis we cluster observations by party, providing standard errors on cluster.²² Table 6.2 reports the results.

The GAP coefficient is always significant: factions exert an effect on their

²²In model 4 we have repeated observations within each congress. Therefore, we change the cluster variable providing standard errors by congress. Clustered standard errors are heteroskedastic and autocorrelation consistent (Rogers 1993).

Table 6.2: OLS Regression of PARTY POSITION

	(1)	(2)	(3)	(4)
GAMSONIAN AGREEMENT POSITION	0.392*** (0.106)	0.410*** (0.128)	0.678*** (0.134)	0.544*** (0.0916)
DISTANCE MEDIAN – GAP		-0.191 (0.310)	-0.131 (0.293)	-0.257 (0.176)

parties' placement, and this is confirmed after including some control variables. To the contrary, DISTANCE MEDIAN – GAP is never significant; we did not register any disproportionate effect of the median faction. Within each party the median, like any other faction, affects the platform only to the extent of its strength in party body. The political centre seems to have no effect. PARLIAMENTARY CENTRE OF GRAVITY is not significant in model 2 and 3, while it appears to have an impact on party position only in model 4.²³

Both interactions are significant and retain the expected sign. According to our hypothesis and to the theoretical framework described in chapter 2, LEADER AUTONOMY decreases the effect of GAP on PP, and this effect is quite strong. For instance, according to model 4, the impact of GAP ceased to be significant among parties that elect their leader through a wide selectorate.²⁴

²³Adding to model 4 an interaction between this variable and LEADER AUTONOMY we found that this effect is significant only when the latter variable retains value 1.

²⁴The marginal effect of GAP on PP is equal to .406 (.061) and statistically significant at

Finally, when general elections come closer, increasing the cost of a breakup, inter-factional bargaining becomes more consensual and indeed the impact of GAP on PP increases. However, we can better discuss the effect of these interactions by looking at figures 6.2 and 6.3 (based on model 4). They draw the marginal effect of GAP on PP as the new general elections approach.

Figure 6.2: Marginal Impact of GAP on PARTY POSITION as YBE Changes when Leaders are Autonomous

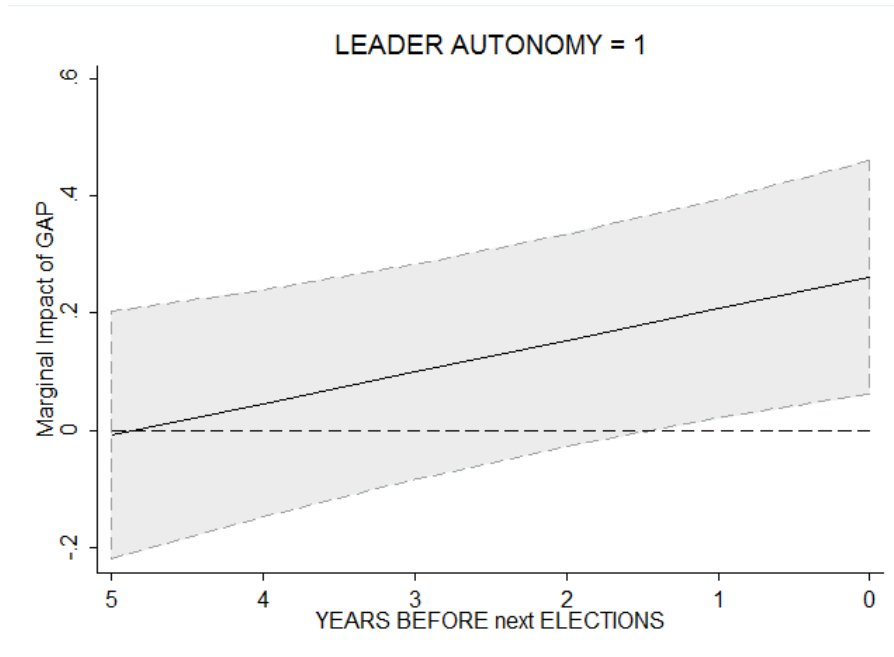

Note: The light gray area represents the 95% Confidence Interval of the estimate

When leaders are selected by party committees (figure 6.2) they are more bounded by the will of factions; factional preferences increasingly shape party position as new elections approach. To the contrary, when intra-party rules grant more autonomy to the leader (figure 6.3) the effect of GAP on PP is no longer significant, unless looming elections increase the need for party unity (high ω), pushing the leader to partially heed factions' requests in order to achieve a compromise (in line with the expectations discussed in chapter 2).

the 99% level when LEADER AUTONOMY equals 0, while this effect is no longer significant when it equals 1: .124 (.093). Clustered standard errors in brackets.

Figure 6.3: Marginal Impact of GAP on PARTY POSITION as YBE Changes when Leaders are Bounded

Note: The light gray area represents the 95% Confidence Interval of the estimate

We turn now to interpret these results in the light of our hypotheses. We can reject H 6.4: as long as GAP is always significant we reject the idea that party positions are independent from factional preferences. Similarly, we can discard H 6.2; from the present analysis does not emerge any disproportionate advantage retained by the median faction above and beyond its share of votes. H 6.1a finds partial confirmation; the hypothesis that parties are shaped by a consensual agreement seems true, but this feature interacts with intra-party rules and with the party system. In line with H 6.1b we observe that as new elections come closer, parties tend to set their platform with an increasing degree of proportionality.²⁵ Finally, we find some evidence for H 6.3, confirming the ‘cartel party’ theory.

²⁵This holds true no matter the changes in the electoral rule. We do not find differences between open list PR, used until 1992, and the systems adopted afterwards (which included a closed list PR, at least in part). Even when factions compete for preference votes (like during the First Republic) the appeal of party unity as a resource for inter-party competition holds and parties seek to foster internal cohesion when setting their positions before the campaign.

Overall, factions do exert constraints on their parties. However, when internal organization promotes the leader's autonomy the party is no longer bounded by activists and the leader retains more discretion in setting the platform. Comparing these results with the literature on party competition, we found that in a multiparty system with parties tied by activists there is no convergence towards the centre, in accordance with recent theories. The political centre exerts an attraction only when party leaders are free enough from factional blackmail to be able to set party position on their own. This aspect, in turn, is in line with the cartel party theory and stresses the ability of autonomous leadership to partially adopt moderate stakes, moving the party towards more convenient positions. This further explains why, in current politics, strong leaders are able to increase party votes, building their electoral (and political) fortunes.

6.5 Leader, Factions, and Party Position-taking: Findings

The present chapter investigated the process of position-taking within the party. We tried to assess whether the party is run as an oligarchy whose leader is completely in control of party's choices, as suggested by Michels (1911).

Our results indicate that, overall, we should reject the idea of parties totally free to move in the policy space in order to maximise their votes. On the contrary we find that party positions are tied to factions' stakes so that the party seems to work as a bounded oligarchy where the leader's wills are somehow limited by factional preferences. The impact of factional constraints is greater when the need for party unity is higher likewise when new general elections approach. In those contexts the electoral payoff of party unity enhances the

need to pursue a compromise among all party subgroups.

This path however is partially different when intra-party rules increase leaders' autonomy. The direct election of party leader by a wide selectorate, like the entire corpus of party members or delegates at party congress, boosts her autonomy in spite of factions' desires.²⁶ In line with the cartel party theory the leader can exploit such autonomy to set a more moderate position that enables the party to build cartels increasing its chances to get office payoffs.²⁷

Despite some authors (Pennings and Hazan 2001; Scarrow 1999, 2005; Scarrow and Gezgor 2010) claim that more intra-party democracy enhances rank-and-file ability to influence the party decision-making, this chapter provides evidence for a converse argument. Our results revive Michels' idea that an increasing direct democracy lead the party towards a kind of 'Bonapartism'. The leaders are able to exploit their strategic and privileged position to preserve and perpetuate themselves up to the point that they are often able to co-opt their heirs (Michels 1911). Their overwhelming supremacy over party members produces high levels of leadership stability. Indeed party leaders remain in charge for decades and a change in the dominant faction is an even more rare event. In such a context the leader might appeal to party members in order to get rid of factions and activists, overcoming any resistance promoted by the internal opposition (Michels 1991).

Thus direct democracy might produce the counterintuitive output of making the party slip towards a 'Bonapartist' oligarchy (recall for instance the debate opened within the DC around this point, as described in paragraph 2.3). In this sense, the direct election of party leaders (e.g., through 'pri-

²⁶For a similar view see McGann (2002).

²⁷In this latter situation we registered indeed a partial convergence towards the centre, even though factional preferences still matter when new elections are behind the corner. Although carried out in a non-strategic setting, this result seems to confirm the most recent developments of Downsian theories (e.g., Adams *et al.* 2005) that predict a centrifugal equilibrium with (only) partial convergence.

maries') might simply be a mean to defang the activists. To sum up, instead of promoting members' control of party elites and the emergence of a widely shared platform, intra-party democracy seems to support leaders' autonomy, leading the party to behave as a real oligarchy and revitalizing Michels' claims once again.

Chapter 7

The Politics of Fission: Determinants of Faction Breakaway

7.1 Introduction

Many scholars analyze politics under the assumption that parties are unitary actors, while we just saw that this is not true. Additionally many works rely on the idea that parties are exogenous elements in the political system, and treat them as given. On the contrary we consider parties as the output of inter-factional bargaining (Giannetti and Laver 2009); far from being fixed and stable entities they are often upset by fusions and fissions (Laver and Benoit 2001, 2003). These changes are affected by the attributes of the party system and in turn they impact on it changing the number of parties, the level of polarization or parliamentary and electoral equilibriums. Although fissions are a kind of rare event they happen more often than one might think; splits affect different parties and political systems but are endemic in some countries, like Italy. In such context fissions are an always existing threat (see later) and

an opportunity to reshape payoffs.¹ ‘If political parties are endogenous, then members of party factions may be seen to belong for as long as it is rational to do so’ (Laver and Kato 2001: 510); day by day, factions are in a dilemma between to stay or to leave the party, breaking away.

In this chapter we will analyze incentives and constraints that affect this choice altering the likelihood of their breakaway. We analyze this outcome as the result of a rational choice made considering policy, office, and electoral payoffs altogether. We retrieve elements analyzed in previous chapters like the impact of portfolio allocation (office payoffs, chapter 5) or party platform (policy payoffs, chapter 6). We will also investigate the constraints posed by intra-party rules or by the party system. This analysis will shed light on how parties try to keep their unity and on why factions decide to leave.

7.2 Factions and Fissions

So far, the literature on party splits has focused more on an individual level of analysis, inquiring about the reasons why a single legislator might want to leave her party and switch to another one (Heller and Mershon 2008). This approach presents some limitations. First of all, in considering parliamentary switching, we implicitly exclude parties that retain no seats in Parliament, while fissions often concern small parties that are out of Parliament (Mair 1990). Moreover, as Giannetti and Laver (2009) stated, ‘In the real political world [...] it is often difficult to discuss the making and breaking of parties without referring to factions or groupings of some shape and form’. In addition,

¹Party fissions however are important sources of party system change in many other countries. Apart from the cases discussed in chapter 1, concerning fissions in Germany and UK, we record analyses related to several political systems like France (Evans 2003), Japan (Cox and Rosenbluth 1995; Kato 1998, Reed and Scheiner 2003), Spain (Gillespie *et al.* 1995), Korea (Park 2010) as well as new Eastern European democracies (e.g., Kreuzer and Pettai 2003).

the literature often measures policy positions using roll call votes while it has been argued that content analyses on ‘texts drafted by [...] intra-party groups seem to be the best choice to identify their respective preferences, in particular if the research question deals with changes of the positions of political actors over time’ (Benoit *et al.* 2009: 443; Benoit and Laver 2006). By adopting party factions as units of analysis we allow to overcome these lacks.

In this chapter we observe fissions at the factional level, analyzing all those situations where a group of members and activists behave as a unique actor. We already know, for instance, that factions coordinate their members’ activities. This is true for voting behaviour (e.g., Giannetti and Laver 2009) but also for breakaways. Party fissions require indeed a coordinated behaviour (Kreuzer and Pettai 2009), therefore we model them following a classic coordination game.

Party members belonging to the same faction might retain different opinions about the strategy to pursue in order to maximise their payoffs (within or without the party). For instance, in a faction composed by only two members one of them might believe that the best method to affect the party is to voice from within, while the other could claim that there is no way to gain satisfactory payoffs staying inside and would rather exit. However they could gain positive payoffs only through coordinated moves. If only one of them leaves the party this effect would be close to zero: there would not be any loss in party votes (except for the splinter member itself) and the leaving member will hardly ever be able to pull the party closer to her position. Conversely if only one member remains within, the faction dissolves (we would require at least two members to call it a faction) and its bargaining power shrinks virtually to zero (or at most will be cut by half).

Figure 7.1 provides the details of the game. Given that member A prefers to leave while member B would rather stay there are two Nash equilibriums.

They will exploit positive payoffs only if both decide to stay within or to break away: factional members need to coordinate.

Figure 7.1: Fission as a Coordination Game. Exit (Go) or Voice (Stay) Payoffs for Two Factional Members.

		Player B	
		<i>Stay</i>	<i>Go</i>
Player A	<i>Stay</i>	1, 2	0, 0
	<i>Go</i>	0, 0	2, 1

Let us extend this example to the more realistic situation where the faction is composed by many members. Two concepts help us to identify the final equilibrium: focal point and strategic move.

Activists will decide to leave whenever they recognize this strategy as the focal point of the game. Imagine that the party takes a position which is recognized by faction members to lay beyond the level of tolerability. For instance, the party could propose a bill or release a favourable declaration on an issue that is strongly opposed by the faction, or take a strategic decision thwarted by the subgroup (i.e., allying or merging with another party or joining a coalition government), or alternatively it could impose sanctions on some factions' activists such that all the other members, even those not directly punished, feel that this act is unacceptable and decide to break away altogether.

Another example of focal point emerges when during a factional assembly the majority of its members decide to pick up the exit option. In these contexts all the faction adherents should recognize the choice to leave as the focal point of the game: the faction coordinates its members, pushing them away from the party as far as they acknowledge that this coordinated strategy maximizes their individual payoffs (see table 7.1).

On the other hand a strategic move can wield the same effect. If the

faction's leader resigns from the party most of her followers will do the same. Noticeably this strategic move could not be done by any activist but only by a prominent member who retains a key role within the party or the faction. There is no need to have temporal contiguity between the leader's and its followers' choice. To the contrary in this case the leader might decide to leave alone precisely to signal to the supporters that they can reach another equilibrium choosing to leave as well.

Something similar happened with the API breakaway from the PD. Rutelli, a well-known top politician, was the first to resign from the PD.² Within a few days other MPs (identified as being part of a common subgroup) followed the leader. A similar dynamic occurred during the split of the faction *Socialisti ed Europei* from the DS. The factional leader, Gavino Angius, announced the decision to break away on its own while after few days many activists belonging to this subgroup made the same choice.

Conversely we provide up-to-date examples concerning the idea of focal point as a mean to reach the equilibrium. When the PDL party body approved measures against three members of a minority faction, MPs belonging to this subgroup (properly coordinated by the faction's head, Fini) commonly agreed on leaving the party to create a new parliamentary group (that eventually became a party). On the other hand after the Greens 2009 congress, when the new party leadership decided to stop the alliance with other left-wing parties, members of the defeated faction favourable to such alliance met together and during an assembly decided to break away.

In the remaining of the chapter we will focus on splits in party body, defining a breakaway as the choice to leave the party made by a faction who contested the congress presenting its own motion. For the reasons discussed

²Rutelli is the former leader of the centre-left coalition and the party leader within the DL. He became later the leader of the splinter group API.

above we count as fissions all those cases where the whole faction, or the majority of its members, or the leader on her own leave the party. Then we will investigate the elements that increase the likelihood of a breakaway to find what features preserve or harm party unity.

7.3 Party Unity and Party Fission: Literature and Hypothesis

Parties are voluntary associations composed by like-minded individuals (Aldrich 1995) that join together to solve collective action dilemmas and coordination problems (Cox and McCubbins 1993; Kiewiet and McCubbins 1991). Parties lead their members to discover the advantages of cooperation. In fact party members and party factions may exploit greater payoffs both in the parliamentary arena (through log-rolling and coordinated voting behavior) and in the electoral market, where enforced cohesion strengthens the value of party label (e.g., Snyder and Ting 2002) and the likelihood of MP's reelection, but also during the negotiations over coalition governments (Bäck and Vernby 2003).

Notwithstanding the incentives to stay together, parties are often internally divided and sometimes such division leads to party breakup. Within the party those members who retain the most similar views gather together (for reasons comparable to that of party formation) and build party factions (Bernauer and Bräuninger 2009). Accordingly we analyze the party as a coalition of factions (Leiserson 1968; Panebianco 1988) that compete against each other to take control over the party and to maximize their share of payoffs, while at the same time they need to cooperate in order to produce the public good, party unity, which the leader is in charge to preserve (Kiewiet and McCubbins 1991). In this sense intra-party politics is a matter of conflict and cooperation under

the shadow of a party fission.

From the theory described in chapter 2 we contend that three basic elements affect the faction's decision about whether to stay or to leave the party: payoffs, intra-party rules and attributes of the political system. Factions evaluate first of all their amount of payoffs. Inside the party they compete to allocate (scarce) resources like cabinet spoils (office payoffs), party line (policy payoffs), and candidacies (electoral payoffs). Although evidence from Italy suggests that rewards are distributed according to the strength of each faction, we observed also some important deviations from a pattern of perfect proportionality.³ Moreover the factional strife happened during the congress creates winners and losers, so that some subgroups could be dissatisfied by the new equilibrium.

Minority factions that lose in the congress struggle face three alternatives: toe the party line ('loyalty'), express dissent from within trying to alter the balance of power ('voice'), or leave the party ('exit').⁴ The choice to stay or to leave depends, first of all, on their share of benefits. Factions compare the rewards available within the party and the payoffs that they will be likely to obtain by splitting away. In this sense fair and consensual intra-party dynamics should promote party unity: when the leader grants to factions a quota of returns proportional to their strength the probability to improve such utility in another way will be lower, and potential defectors will have to cope with fewer temptations. Conversely when payoffs are unsatisfactory (for instance, the party position lies too far from the faction's ideal point or the subgroup is

³Chapters 5 and 6 of the present dissertation provide empirical evidence about the linkage between factions' size and their share of payoffs but they also highlight some degrees of variation.

⁴Our theoretical framework takes the cue from the 'exit voice and loyalty' game, developed by Hirschman (1970) to analyze the behavior of a party member facing the choice between to stay or to leave the party (as well as several other topics). This framework has been retrieved by Kato (1998) and Gehlbach (2006) with specific applications to party fission.

undervalued in terms of cabinet spoils or candidacies) the likelihood of a party breakup rises.

Besides the benefits however, factions have to weigh also the costs of their choice. The decision to break away in fact is subject to constraints provided by intra-party rules (democracy and leader's autonomy) and by the party system (electoral rules and competitiveness), which may increase (or decrease) the exit cost and, consequently the utility and likelihood of a split. Under undemocratic party rules, dissatisfied factions do not have any chance to improve their condition by voicing from within. The voice option in fact could be denied, due to party rules, or the cost could outweigh the benefit. When 'voice' is not a credible alternative, the only option opens to dissenters is the 'exit' (Hirschman 1970). Electoral rules too impinge on this process. When the electoral system provides high barriers to entry (due to disproportionality, district magnitude, thresholds of representation and so on) the breakaways are no longer rewarding and party breakup should become less likely.

Nevertheless, party fission does not only involve splinter groups. On the other side in fact party leaders want to preserve party unity. As discussed in chapter 2, leaders are in charge of sharing benefits among party factions. They can choose either to follow a logic of fairness, or to reward their supporters, or alternatively to allocate payoffs in order to preserve party unity heeding the claims of powerful potential splinter groups. Here the rule adopted to select the party leader matters as well: directly elected leaders may exploit their autonomy to favor their followers by promoting unfair intra-party dynamics that increase the risk of party fission.

As shown in chapters 5 and 6, the leaders' degree of autonomy impinges on their choice concerning the distribution of rewards. In addition, this rule could interact with party system attributes: competitive electoral conditions raise the need for party unity, decreasing the discretionality of autonomous leaders,

and the likelihood of a breakaway. Overall, for the sake of preserving unity, leaders will cater to the minority factions in order to decrease the likelihood of their breakaway as long as they perceive that a fission will damage the whole party. When, on the contrary, they feel that a split will not hurt the party because the splinter group is too small or the fission may produce more clarity about the party label, they will ignore the issues raised by minorities, leaving them dissatisfied and inclined toward a breakaway (Heller and Mershon 2009b).⁵

Factions leave when they are dissatisfied, and they are dissatisfied when party leaders pay no attention to their preferences. Hence we try to shed light on party fission focusing on factional preferences (to find the causes of dissatisfaction) while controlling for the constraints imposed by the rules.

To start with, we focus on elements that alter the structure of incentives (Sartori 1976) available to potential splinter groups. Factions care about policy payoffs. Shared policy preferences tend to structure both party membership (Aldrich 1995; Snyder and Ting 2002) and factional affiliation (Bernauer and Bräuninger 2009; Giannetti and Laver 2009). As far as policy shapes the making of a party, so must it also shape its breaking. According to Boucek (2009: 473) in fact ‘divergent factional preferences [...] create splitting pressure’.⁶ We know that members (and factions) incur a cost from party membership (Snyder and Ting 2002). Factions whose ideal point is close to that of the bulk of party members will face lower costs and will extract an higher amount

⁵In turn, these factions will leave only if they can improve their condition after the split.

⁶Some authors tried to test such idea by looking at party switching (Desposato 2006b; Heller and Mershon 2008; McElroy 2009; McElroy and Benoit 2009). Overall their findings seem to confirm this point even though some results were ambiguous. Desposato (2006b) proved that policy preferences indeed affect switches in Brazil. Heller and Mershon (2008) analyzed switches in the Italian Low Chamber finding a significant effect of policy motivations in three out of four legislatures but not in the pooled sample. Even inside the European Parliament individual MPs seem motivated by policy concern (McElroy and Benoit 2009) even though the impact of policy preferences is not always statistically significant throughout different models (McElroy 2009).

of policy payoffs.

Conversely the cost of membership is higher among factions whose ideal point lies far away. Accordingly they would be more prone to break apart to avoid suffering this huge cost (while, conversely, the price of ε would be lower). After the split in fact they will set a more suitable party platform that provides them with larger benefits in terms of policy payoffs (larger π and, overall, wider ratio between the trade-off, π , and the exit cost, ε). Assuming that party position corresponds with the weighted mean of all factions (Levy 2004), we raise the following claim.⁷

Hypothesis 7.1: The greater the distance between faction i and the weighted mean of all factions, the higher the policy reward attached to faction's breakaway and, consequently, the higher the likelihood of party split

On the other hand, factions are also interested in office payoffs and (factional) career rewards. Hence, they may decide to toe the party line even if their preferences are divergent (Boucek 2003a): in fact the ratio between π and ε decreases when factions can exploit the benefits yielded by office payoffs. We will test the impact of office through three hypotheses. To start with, we argue that political power is in fact a glue for party unity, if this is the case factions should be less willing to leave.

⁷Warwick (2001) showed the existence of a one-to-one correspondence between cabinet position and the weighted mean of government coalition members. Following this idea, discussed in chapter 6, we consider the party as a coalition of actors (factions) who bargain over the party platform according to their strength in the party convention (Levy 2004). For this reason, we take the weighted mean of their ideal points to measure party position. However, using the position of the median faction (Debus and Bräuninger 2009) as a proxy for party position does not alter the results.

Hypothesis 7.2a: The likelihood of a breakaway is lower among parties in office

Nonetheless, politicians sometimes leave ruling parties (Reed and Scheiner 2003). In this regard, scholars have argued that breakups can be prevented only when minority factions hold a share of spoils greater than zero (Caillaud and Tirole 2002).

Hypothesis 7.2b: The likelihood of a breakaway is lower when the faction is in office

Along the same vein we suggested that factions compare their share of payoffs within the party and their potential gain under the alternative option (the breakaway). Accordingly, overpaid factions, whose share of office payoffs is greater than their size in party body, should be less willing to break apart (low π). This is consistent with what discussed in chapter 5, where we argued that, to avoid the exit of powerful minority factions, the party leader might cater to them with a share of portfolios greater than their size (Boucek 2003a; Hirschman 1970).⁸ If this is the case being overpaid reduces the probability of its own breakaway. Conversely underpaid factions that can reasonably expect to gain larger payoffs by splitting away (large π) will be even more dissatisfied and inclined to split (Giannetti and Laver 2001; Laver and Kato 2001; Wada and Schofield 1996).

⁸Minority factions could be overpaid when their threat is credible and harmful and the party leader has a care in preserving unity in spite of cohesion.

Hypothesis 7.2c: The greater the difference between faction's share of office payoffs and size, the lower the chances to extract larger amounts of office rewards after the split and, consequently, the lower the likelihood of its breakaway

Although we claimed that factions care about office, policy, and votes, some scholars have argued that, overall, factions are interested mainly in patronage (Bettcher 2005; Persico et. al 2011; Sartori 1976; Zuckerman 1975, 1979). Nonetheless, they recognize that some factions might care about policy.

Sartori (1976), for instance, distinguished between factions of interests (office-seeking) and factions of principles (ideologically oriented). Similarly, Roemer (2001) argued that there are three types of factions within each party: opportunists (concerned solely with votes and office), militants (policy-seeking), and reformers (a mix of the two).

As Mershon (1996) pointed out, in the Italian context the main reward for cabinet participation is linked to office payoffs. Thus, office-seeking subgroups (factions of interests) will try to get involved, and more likely will be involved, in governments. Following this idea, we can test whether the impact of policy motivations on party splits changes among factions in office.

Hypothesis 7.3: Among factions of interests (those that more likely will try to get access to the spoils), the impact of policy motivations on the likelihood of a faction breakaway should be lower

Besides policy and office, factions also care about electoral payoffs and their members make forecasts about the chances of reelection. We argue that candidacies are part of the total amount of payoffs that party factions have to

divide. Then, candidate selection procedure (i.e., the way MPs are selected) impinges on party unity too.

When evaluating costs and benefits of a split, potential splinter groups take into account their chance to gain seats staying within the party. Under closed list PR and centralized candidate selection procedures the party leader retains control over candidacies (Cox *et al.* 1999; Carey 2007), therefore she is able to deny room for dissenting factions. Having defied the leadership by exerting the voice option, minority factions might fear to be excluded from party list in retaliation. Accordingly, the limited room available to dissenters raises the cost of voice ν , which encourage to revert to exit. On the contrary, through preference voting, open list PR lowers ν and provides factions with open access to parliamentary seats (Katz 1986a; see also chapter 4 of the present dissertation) thereby institutionalizing factionalism (Boucek 2010) and decreasing the likelihood of splits.⁹

With respect to the Italian case we can test this hypothesis by performing a comparison between an electoral system based on open list PR, enacted until 1993, and those adopted afterwards whose selection mechanisms were strongly centralized (Carey and Shugart 1995).¹⁰

Hypothesis 7.4: Closed list PR and centralized candidate selection increase the likelihood of a breakaway

Along the same line factions anticipate the number of parliamentary seats they will be able to win in future elections. Notably, disproportional electoral rules freeze the party system acting as barriers for the entrance of new parties. In this regard, the electoral system raises the exit costs (ε) for dissidents as a

⁹ Accordingly, when candidate selection is devoted to primary elections we should expect similar effects (Hortala-Vallve and Mueller 2011).

¹⁰ Refer to chapter 4 for a detailed description of changes occurred to the Italian electoral system.

function of its disproportionality.¹¹ In addition, it alters the expected electoral payoffs of potential splinter groups with negative effects on their ability to extract additional amounts of policy and office payoffs in the long-run (lowering π). These effects should be greater under single-member plurality systems (Boucek 2010), but can hold even under proportional representation.

Hypothesis 7.5: The higher the disproportionality of the electoral system, the lower the likelihood of a breakaway

Intra-party rules impact on the trade-off between costs and net benefits of a breakaway providing incentives or constraints. Loyalty, taken as an informal internal rule, act as a barrier to exit. The partisan tie to party symbols like logo and label (Kertzer 1996), and the ‘logic of appropriateness’ (Andeweg and Thomassen 2010; Crowe 1983, 1986; Kam 2009) internalized during a long standing militancy might dissuade members from choosing the exit option (Gehlbach 2006; Hirschman 1970; Kato 1998). This effect should be higher among older parties where the importance and the utility of party loyalty is well established thereby increasing the cost of breaking away (ε).¹² It is not by chance that within older parties fissions are often bathed in tears, while among younger ones they are bathed in blood.¹³

¹¹The splinter group will face high start-up costs to create a new party and enter the system as a relevant actor.

¹²Political parties are solutions to collective action problems (Aldrich 1995; Cox and McCubbins 1993; Kiewiet and McCubbins 1991). Although party membership might prove to be costly in the near term, members should be aware of the advantages of cooperation in the long-run once they have experienced them. Intra-party interactions in fact are repeated games where cooperative norms emerge, enhancing party unity over time (Boucek 2003). Therefore even if short-term payoffs might leave factions dissatisfied and inclined to break apart, they can recognize the utility of loyalty and decide to toe the party line in order to gain a greater share of payoffs in the future. However, by controlling for the share of office payoffs we will be able to assess the net impact of loyalty untied to convenience (see later).

¹³A long standing militancy makes members feel like brothers. In this sense we can compare the teary eyes of the members that broke away from the PCI in 1991 (after a long lasting common party militancy) with the riots that happened during congresses held by younger parties (e.g., the NPSI 2005 congress or the Greens 2009 assembly).

Hypothesis 7.6: Among older parties the loyalty effect decreases the likelihood of a breakaway

Sometimes party elites enforce strong transformations in the party structure, changing its symbols (name and logo) or merging the party with others. Such changes are peculiar events and reflect transformations that may not be expected to affect the party position:¹⁴ as Heller and Mershon (2009b: 190) noted, in 1991 many party members left the PCI when it was dissolved to create the PDS ‘even though the main position of that party lay relatively close to their own ideals.’¹⁵ When a party changes its label or its logo the loyalty effect (and the value of ε) should theoretically shrink to zero; similarly when it merges with others all the informal rules established within the former party break down. For these reasons party loyalty may be no longer sufficient to exert barriers to exit.¹⁶

Hypothesis 7.7: When a party changes its symbols or merge with others, the loyalty effect shrinks to zero, fostering the likelihood of faction breakaways

The impact of intra-party formal rules could be tested as well. In democratic parties minority groups can express their dissent from within. In less democratic parties such opportunity usually is not available and factions face the choice between accept the leadership proposal or exit from the party (see for instance the results of chapter 4). This is typical in parties organized

¹⁴Even so, we control for the impact of policy motives through the variable suggested in H 7.1.

¹⁵This aspect finds confirmation in our dataset.

¹⁶We track four changes in party logo and label occurred during a congress: the fusion of the PSIUP into the PCI in 1972, the adjustment of PSI logo in 1978, the evolution of the PCI into PDS in 1991, and the dissolution of the DS to form the PD in 2007.

according to the principles of ‘democratic centralism’ (e.g., Marxist parties). Under democratic centralism, party members are theoretically free to discuss and support different views about party strategy and ideology, but dissent must be expressed only inside the party. Once the party body has set the line, its choice must be enacted even by dissenting members. The public expression of dissent hurts the monolithic structure of these parties weakening them in the eyes of their voters. In such contexts the party leader pays a wide price for ν and would rather prefer to whip the minority (to enhance internal cohesion) instead of bargaining for a compromise. In fact undemocratic parties tend to rely on strong discipline, which increases the propensity for splits (Heller and Mershon 2008; Laver and Schofield 1990) and raises the cost ν for dissenters too, with negative effects on party unity (ν increases the probability of splits).¹⁷ Voice (when tolerated) cannot contribute to reach a compromise and therefore it is not an alternative to exit (Kato 1998): after that minority factions have publicly expressed their dissent it is almost impossible for them to step back and the only realistic choice is to leave the party (Hirschman 1970).¹⁸

¹⁷This is true unless the cost of exit (due to party loyalty) is very high. This pattern is not unusual for instance among communist parties where, despite undemocratic internal rules, the strong loyalty to the party as a machine to implement the Marxist ideals contributed to preserve its unity.

¹⁸Note that, apart from favoring the breakaway of dissenters, leaders may also directly send them off the party. Expulsions are a peculiar trait of undemocratic parties. A few members were ejected from the Italian Communist Party in 1951; after the expulsion they created the Movement of Italian Workers (that later merged with others to form the USI, Independent Socialist Union). In 1969 the PCI sent off the left-wing faction *textitil Manifesto*, charged of factionalism; this episode remains the most well-known case of expulsion in recent years. We observe expulsions also within other parties, like the PDCI; in 2009 a minority group was ejected due to the violation of democratic centralism and factional ban; its members then created a small extreme left party called *Communists – Popular Left*. It is less straightforward the categorization of other splits like the fission of PSI in 1981 (when dissenters grouped into the *Socialists’ League* were sent off after that they had publicly criticized the leadership of Craxi and the lack of internal democracy) or the split of *textitFiniani*, forced to leave the PDL in 2010 (remember that the PDL structure is located halfway between a full democratic party and one organized through democratic centralism, as discussed in chapter 4). According to our theory however, breakaways and expulsions are two products of the same underlying process and the distinction between these two concepts is blurred, in fact ‘since politicians can be assumed to exercise some degree of foresight, it

Hypothesis 7.8: The likelihood of a breakaway increases in parties ruled through ‘democratic centralism’ where the cost of voice thwarts the reach of a compromise

To conclude, following the suggestion of table 2.3, we want to check the effect of leadership autonomy. Overall, compared to their constrained counterparts, autonomous leaders should foster the likelihood of splits.

Hypothesis 7.9: The likelihood of a breakaway increases when leaders are autonomous

However this should happen only in dominant party systems, whereas under growing competitive conditions autonomous leaders will be focused on keeping unity by exploiting their greater autonomy to cater to potential splinter groups. Competitive electoral markets affect the leader’s reply to minority’s requests. In fact they foster the need for party unity raising the cost of breakup (ω), which is instead lower when the competition is less tight (Boucek 2010). Along this line, we claim that the effect of leader autonomy is conditional on competitiveness.

Hypothesis 7.10a: Leader autonomy increases the likelihood of a breakaway when party system competitiveness shrinks

On the other side however, party system competitiveness also provides opportunities or constraints that favor or inhibit party fission. Competitive conditions might alter the balance of power between rival parties. Potential

is reasonable to view expulsions as in essence stemming from voluntary choice’ (Heller and Mershon 2009a: 10).

splinter groups then feel the incentive to defect insofar as, after the split, they can reasonably expect to exploit a share of payoffs larger than their size, due to their growing bargaining power (Giannetti and Laver 2001; Laver and Kato 2001). Conversely, low competitive systems reduce π decreasing their leverage. Nevertheless, we contend that competitiveness interacts with leader autonomy, as hypothesized also in H 7.10a. In fact as party system dominance enlarges (low ω), autonomous leaders will trade unity for cohesion. Beside they will exploit the lack of competition to reward their followers, forgetting about internal minorities: splinter groups will be underpaid (high π) and willing to break away. To the contrary, constrained leaders tend to stick to the coalition deal, no matter the extent of party competition. Accordingly a decrease in competitiveness yields as a unique effect a reduction in minority leverage when parties are ruled by bounded leaders.

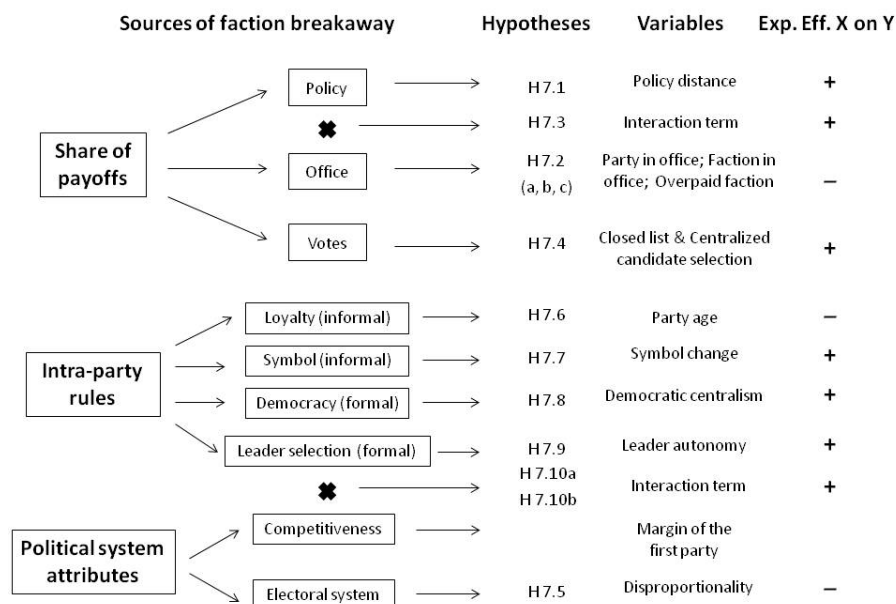

Hypothesis 7.10b: When party leaders are autonomous, a decline in party system competitiveness raises the likelihood of a breakaway

Figure 7.2 summarizes the hypotheses presented above. We report the sources of breakaway, the variables adopted to test them and the expected effect of each variable on the outcome.

7.4 Data and Methodology

In this chapter we evaluate the elements that affect a rare event like party fission. An article by Mair (1990) counted 34 major party fissions occurred between 1945 and 1987 in 14 Western European countries, with a mean close to

Figure 7.2: Determinants of Faction Breakaway. Hypotheses and Operationalization

one per year across Europe.¹⁹ Within his sample, only three fissions (roughly 9%) occurred inside Italian parties. However, he reported only the major fissions, excluding those cases that coincided with fusions. He also excluded cases where parties were not separately catalogued within the electoral data and did not consider small parties or parties that retained no seats in Parliament.²⁰

In contrast, we include even such cases because all of them contribute to alter the system, by changing the equilibrium between parties in Parliament or their electoral performances.²¹ In this new dataset, we consider up to 29

¹⁹Due to the methodological reasons adopted by Mair however the actual number of party fissions across Europe is probably larger than this. A more detailed discussion on this point will be provided below with respect to the Italian case.

²⁰Mair, for instance, did not consider some important fissions, such as the breakaways of two PSI right-wing factions that left the party in 1947 and created the PSDI, as well as the split of a moderate faction within the MSI in 1976.

²¹We record some examples. The split of PSI in 1947 contributed to the dissolution of the ruling coalition, composed by PCI, PSI and DC, and to the emergence of the DC as a *core party* (Curini and Martelli 2009). The breakaways of *Democrazia Nazionale* and *Destra Popolare* from the MSI in 1977 were crucial to sustain the Andreotti III Cabinet, likewise the split of *Cossuttiani* from PRC in 1998, which created PDCI, was of help to keep the centre-left coalition in office until 2001 (jointly with the support of UDEUR, Union of Democrats for Europe, formed after the breakaway of a centrist party). The breakaway of two small

faction breakaways in Italy over a period of 64 years, an approximate mean of one fission every two years.²² This clearly highlights how often party fissions happened: viewed in such context, faction breakaways are not a rare event. They are, instead, an ever-present opportunity to reshape payoffs (Giannetti and Laver 2001; Laver and Kato 2001) and an everyday threat exerted by minority factions on the party mainstream.

Table 7.1 lists some details about the fissions included in the dataset providing the year of the split, the party affected by the fission, the name of the splinter group and the outcome of the breakaway that clarifies whether the faction decided to create its own party or joined an existing one.²³ Just shy of half left to join, soon or later, another party while the others built their own one.

Most of these cases are related to fissions within left or centre-left parties like PSI, PSDI or PRC. However there are also some splits related to centre-right parties like AN, MSI, UDC. Overall it is hard to find a party that has never been affected by a breakaway. A part from those mentioned, during

factions from the PRC in 2006 and 2007 contributed to the fiasco of the electoral alliance The Left – The Rainbow (SA) in the 2008 general elections. These splinter groups, Critical Left (SC) and the Communist Workers Party (PCL), won respectively 0.46% and 0.57% of votes, thwarting SA chances to pass the 4% threshold. In fact SA gained only 3.08% of votes and, for the first time since a century, parties belonging to the socialist and communist political families failed to elect MPs. This, in turn, yields effects on policy-making, party system polarization and fractionalization, as well as on government bargaining and coalition building.

²²The breakaways amount to the 11% of the number of factions considered.

²³One of the cases listed in table 7.1 is not an actual breakaway. It concerns the expulsion of left-wing faction *Sinistra per l'Alternativa* from the PSI in 1981. This sanction was enacted by the PSI leadership after the publication of a letter, wrote by members of the splinter faction, who complained against party leadership because of the lack of internal democracy. They decided to openly manifest their dissent by means of public voice, claiming that there was no room for the expression of dissent inside the party body. The letter is available in “La Repubblica”, October 4th, 1981, or on the web: <http://www.bassanini.eu/public/Appello.1981.pdf>. Following what discussed in footnote 18 (this chapter), we argue that splinter members know whether their action will lead to the expulsion or not (Heller and Mershon 2009a). Accordingly, we treat this case as a breakaway although excluding it from the analysis does not alter the results.

Table 7.1: List of Fissions Included in the Dataset

Year	Party	Splinter Faction	Outcome
1946	PDA	Democrazia Repubblicana	Creates CD (later joins PRI)
1947	PSI	Iniziativa Socialista	Creates PSLI (later becomes PSDI)
1947	PSI	Concentrazione Socialista	Creates PSLI (later becomes PSDI)
1948	PSI	Autonomisti	Creates US (later joins PSLI)
1948	PSLI	Sinistra	Later joins PSU
1949	PSI	Per il Socialismo	Creates PSU (later merges with PSLI)
1957	PSDI	Unità Socialista	Creates MUIS (later joins PSI)
1957	PSDI	Autonomisti	Creates MUIS (later joins PSI)
1964	PSI	Sinistra	Creates PSIUP
1969	PSI	Rinnovamento Socialista	Creates PSU (later renamed PSDI)
1972	PSIUP	Confluenza PSI	Joins PSI
1972	PSIUP	Continuità e Rinnovamento	Creates Nuovo PSIUP
1977	MSI	Destra Popolare	Joins DN
1981	PSI	Sinistra per l'Alternativa	Creates LDS (later joins PCI)
1989	PSDI	Prospettiva Socialista Democratica	Creates UDS (later joins PSI)
1991	PCI	Per la Rifondazione Comunista	Creates PRC
1998	PRC	Cossuttiani	Creates PDCI
1998	PRC	Pontieri	Creates PDCI
2003	NPSI	Socialismo e Libertà	Joins SDI
2005	NPSI	Unità e Rinnovamento	Creates SU-PSI (later creates PS)
2006	AN	D-Destra	Creates La Destra
2006	PRC	Sinistra Critica	Creates SC
2007	PRC	Progetto Comunista	Creates PCL
2007	DS	Correntone	Creates SD (later creates SEL)
2007	DS	Democratici e Socialisti	Creates SD (later joins PS)
2008	UDC	Popolari Liberali	Joins PDL
2008	PDCI	Unire la Sinistra	Merges with other parties to create SEL
2009	PRC	Rifondazione per la Sinistra	Merges with other parties to create SEL
2009	FV	Associazione Ecologisti	Merges with other parties to create SEL

the First Republic all the major parties experienced a split: the PLI (with the breakaway of the Radical Party in 1955), the PRI (its right-wing faction left in 1963 when the PRI supported the first centre-left coalition government) and even the DC, though only when the regime was collapsing: in 1991 and in 1993 two small left-wing faction (*La Rete* and *Cristiano Sociali*) broke away. In addition before the 1953 general elections all the DC allies (PLI, PRI, PSDI) faced the split of dissenters who disagreed with the new electoral law that introduced a majority prize for the coalition of parties that won more than 50% of votes (indeed those splits succeeded in the purpose of preventing the attribution of the majority prize to the DC coalition).²⁴ Similarly during the Second Republic other parties, besides those listed above, were damaged by fissions. For instance the heirs of DC divided and merged several times. The more relevant splits were those of the Christian Democratic Centre (CCD) from the PPI in 1994, the breakaway of the Christian Democrats for the Republic (CDR) from the CCD in 1998, or the several splinter groups that left the UDC.²⁵ In addition, as discussed before, API break apart from the PD in 2009 and the PDL too faced the breakaway of FLI in 2010 (which in turn was damaged by the split of its moderate members in 2011).²⁶ Unfortunately most of those fissions did not happen during the congress hence, due to the

²⁴The DC coalition, which included PSDI, PLI, PRI and two regional parties (SVP, South Tyrolean People's Party and PSDA, Sardinian Action Party), was able to obtain 49.8% of votes, that means 0.2% below the threshold required to gain the majority prize. Three parties composed by factions that broke away from the coalition were responsible for such failure. More in detail: the already cited USI (joined by former PSDI members) gained 0.83% of votes; Popular Unity (UP), composed by factions that split from PSDI and PRI, won 0.63%; National Democratic Alliance (ADN), created by former PLI members, obtained 0.45% of votes.

²⁵For instance the MPA born as a fission of the UDC in 2005 (and in turn suffered the split of We the South, NS, in 2010), likewise the Populars of Italy Tomorrow (PID) that split from UDC in 2010.

²⁶This moderate faction, *FareItalia*, switched off from FLI with its own parliamentary representation. The PDL faced two additional splits, one in October 2010, when members tied to the southern party leader Gianfranco Micciché broke away and created Force of the South, and another one in November 2011 when few members of the *Cristoforo Colombo Foundation* switched off and created their own group (Liberals for Italy) triggering Berlusconi's resignation (see paragraph 8.3).

methodological reasons discussed in chapter 3, we were not able to include these cases in the dataset.

With respect to table 7.1, figure 7.3 sketches the frequency of fissions across time. There are two peaks, one immediately after the beginning of the First Italian Republic and the second one after the transition to the Second Republic. We observe some splits after the fall of Berlin's Wall, when the Italian transition began. However the number of fissions markedly increased during 2006 and 2008 general elections when the electoral rule was changed again, promoting a renewal of the Italian party system. This graph tells that when the party system is particularly fluid, parties tend to divide and merge so that we can easily observe splits. However there are some fissions even between the 1960s and the 1980s when the Italian party system was considered to be highly stable. Hence, apart from the fluidity of the party system, other reasons help that explain why a faction leaves its party, as we will discuss in the next paragraph.

Figure 7.3: Number of Fissions over Time

We will test the hypotheses presented before through a logit regression. The dependent variable is *FISSION*, which has a binary outcome and takes the value 1 when faction i leaves the party during the period between one congress and the following; it takes the value 0 otherwise. We count as a breakaway each case where a faction, its leader, or the majority of its members leave the party (after having presented a motion during the party congress).

However not all the fissions included in the dataset occurred during the congress. Sometimes what the changes occurred between one congress and the following could have an impact on party unity as well. This is particularly true for the share of office payoffs. As we argued, to preserve unity the party leader might cater to minority factions with a share of portfolio larger than their actual size. Such compensation usually happens *ex-post* meaning that during the congress one faction could still be underpaid and, to receive its rewards, it has to wait until the next government is formed. Despite its lower share of payoffs the promise of being overpaid in the next government might prevent the faction from exiting.

To assess this causal relationship we multiply our cases (254 factions) by the number of governments that alternated between one congress and the next one. The total number of cases is 769. In this way we sketch variations in intra-party environment almost year by year to establish what set of intra-party attributes had actually caused the split. With respect to the share of payoffs we can test whether being overpaid or underpaid in portfolio allocation during the lapse of time subsequent to the congress has an impact on the likelihood of a fission.

Within this dataset the number of breakaways amounts to 29. Although fissions are not so rare as one could think, we observe a breakaway only in the 3.8% of cases. To cope with the low variance in the dependent variable we could have used a rare events logistic regression (Tomz *et al.* 2003), which cor-

rects the estimates for the bias that occurs when the observed events are rare. However, using a ‘relogit’ model does not alter the substantive results. Figure 7.2 summarized the independent variables adopted to test our hypotheses. Here we provide a more detailed description.

DISTANCE (H 7.1), measured as the squared Euclidean distance between faction i policy position and the weighted mean of all factions, takes into account the role of policy payoffs. For faction i in party j , office payoff effects are tested through three variables. PARTY IN OFFICE (H 7.2a) and FACTION IN OFFICE (H 7.2b), two dummy variables that each take the value 1 when party j or faction i , respectively, retain cabinet posts; OVERPAID (H 7.2c), a continuous variable that expresses the difference between faction i share of ministers and its share of seats within the party body: positive values suggest that the faction is overpaid, having a percentage of portfolios greater than its size, while it is underpaid when OVERPAID is negative. We assigned the value 0 when the party is not in office. Additionally we test whether policy and office payoffs interact through the interaction term DISTANCE*FACTION IN OFFICE (H 7.3).

Two variables measure the impact of electoral motives and rules: CLOSED LIST (H 7.4), a dummy variable equal to 1 when the electoral system is a closed list PR or a plurality with centralized candidate selection and equal to 0 under open list PR; DISPROPORTIONALITY (H 7.5), measured through the Gallagher index.²⁷

The net effect of loyalty has been assessed through PARTY AGE (H 7.6) that measures the years elapsed from party birth, and controlled through the dummy variable SYMBOL CHANGE (H 7.7), which takes the value 1 when the party changes its symbols (label or logo), during the congress, even in

²⁷We used data provided by Gallagher and Mitchell (2008: appendix B) according to the index outlined by Gallagher (1991).

consequence of a merger.

Turning to intra-party rules, DEMOCRATIC CENTRALISM (H 7.8), a dummy variable equal to 1 when the party structure is organized according to the principles of ‘democratic centralism’, accounts for the level of internal democracy, while LEADER AUTONOMY (H 7.10a), a dichotomic variable equal to 1 when the leader is directly elected (by party members or delegates) and 0 when the leader is indirectly elected (by a small committee), measures the leader’s degree of autonomy.

MARGIN OF VOTES (H 7.9a), is a measure of political system competitiveness. This variable records the difference between the share of votes won by the two main competitors (i.e., the parties that ranked respectively first and second in general elections).²⁸ The higher the gap, the lower the degree of party system dominance.²⁹ Finally we include the interaction term LEADER AUTONOMY*MARGIN OF VOTES (H 7.9b and 6.10b) to assess the conditional effect of these two latter variables.

²⁸We measured the gap between DC (first-ranked) and PSI (second-ranked) in 1946, DC and Popular Democratic Front (FDP) in 1948, DC and PCI from 1953 until 1987, DC and PDS in 1992, PDS and FI in 1996, FI and DS in 2001, ULIVO (PD) and FI in 2006, PDL and PD in 2008. A somehow similar operationalization could be found in Curini and Martelli (2010). Refer to Laver and Benoit (2001) for a theoretically grounded discussion about the relevance of a comparison between the largest two parties as a measure for party system competitiveness/dominance, even in multi-party systems.

²⁹A narrow margin implies greater uncertainty about the outcome, whereas we would observe wider gaps in dominant party systems. The Italian party system was considered as dominated by the DC throughout the whole First Republic (1946-1992). Some authors claimed that the DC was a ‘*core party*’, i.e., a party whose ideal point cannot be defeated in a majority vote (Laver and Schofield 1990, Schofield 1993, 1995; Schofield and Sened 2006). Notably the existence of such party is strongly associated with party system dominance and implies a lower degree of competitiveness within the political system (Bogaards and Boucek 2010). However the DC degree of dominance varied across years. In fact, contrary to what reported in Schofield (1995), recent works proved that the DC was not always a core party (Curini 2011; Curini and Martelli 2009). We compared the variable MARGIN OF VOTES with DOMINANT PARTY SYSTEM, a dummy that witnesses the existence of a core party in the political system, and we found a positive and significant correlation between the two. The polyserial correlation is .60. Note also that a condition to become a core party is to get the highest share of votes. Then the margin of the first party can be considered as a good proxy for party system dominance.

7.5 Analysis and Results

Table 7.2 presents the results of the analysis. The data are encoded by government. To avoid any possible bias due to independence, observations have been clustered by government, within each congress, and standard errors have been estimated on clusters.³⁰

Five models have been provided.³¹ The first four test the role of office payoffs separately while the fifth assesses the conditional effect of leadership autonomy. Model 1 checks how the likelihood of a breakaway varies when party j is or is not in office. Model 2 assesses the differences when faction i retains at least one minister. Model 3 replicates model 2, adding an interaction term between office and policy payoffs. Model 4 investigates whether being overpaid or underpaid in term of office payoffs has an effect on the decision to break away.

Finally model 5 replicates model 4 adding the interaction term between the mode of leader's election and party system competitiveness, to validate our hypotheses about their conditional effect.³²

Across the models, almost all the variables are significant and retain the expected sign. DISTANCE increases the likelihood of fission. Factions do care about party policy position, and they are more likely to leave the party as

³⁰Clustered standard errors are heteroskedastic and autocorrelation consistent (Rogers, 1993). Controlling for temporal dependence through temporal dummies or random effects does not alter the results.

³¹Given that we are dealing with a rare event, to assess the goodness of fit we report the percentage of correctly predicted outcomes and sensitivity (percentage of correctly predicted positive outcomes) measured according to a .05 cut-off point, which is close to the outcome rate (.04). The goodness of fit is similar across the models.

³²In this latter model we omit the variable CLOSED LIST as far as the post-estimation diagnostic highlights some problems due to collinearity. This dummy variable also distinguishes between the First and the Second Republic; however such distinction overlaps with the different levels of political system competitiveness, in that Italy was more close to a dominant party system during the First Republic. The polyserial correlation between the two variables is in fact significant (-.51). Notwithstanding this, keeping the variable inside does not alter the substantive results of the analysis.

CHAPTER 7. THE POLITICS OF FISSION: DETERMINANTS OF
FACTION BREAKAWAY

Table 7.2: Logit Regression of Faction Breakaway (FISSION)

	(1)	(2)	(3)	(4)	(5)
DISTANCE	1.536** (0.739)	1.432** (0.724)	1.359* (0.815)	1.553** (0.738)	1.340* (0.718)

the distance from the bulk of the party factions increases. On the other hand, office payoffs positively affect party unity although belonging to a ruling party is not a sufficient condition to preserve unity. In fact, PARTY IN OFFICE does not affect the likelihood of splits, and its effect is not statistically different from zero.³³ On the contrary, FACTION IN OFFICE decreases the likelihood of breakaway. Party unity is enhanced only when factions receive a quota of payoffs are greater than zero (Caillaud and Tirole 2002) i.e., when they directly targeted with ministerial posts.

The interaction term DISTANCE*FACTION IN OFFICE is not significant: the impact of policy payoffs on FISSIONS is similar between factions in and out of office.³⁴ Moreover, given that in the Italian context the main reward for cabinet participation is linked to office payoffs (Mershon 1996), we tested the impact of policy motivation within a narrower subsample that includes parties in office only the coefficient of DISTANCE is still significant and maintains its sign and magnitude.³⁵ This result provides a further confirmation for the idea that even potential ‘office seeking’ groups are also concerned with policy motivations. OVERPAID is significant and negative as we expected: factions whose share of office payoffs is greater than their size leave with a lower probability meaning that assigning more ministers to one subgroup might prevent

³³We must recall, from chapter 4, that the cost of voice, ν , should be greater among ruling parties inasmuch as their life is more under public scrutiny compared to the opposition. Accordingly, and bearing in mind the portray of table 2.2, we can further hypothesize that among ruling party the likelihood of fission should be greater (due to ν), although only when the cost of ω decreases. We tested this idea adding to model 1 an interaction term between PARTY IN OFFICE and PARLIAMENTARY SUPPORT, i.e., the share of seats retained by the ruling coalition (which is a good proxy for the value of party breakup with respect to members of the ruling coalition that have much to lose in the parliamentary arena). We found indeed a significant coefficient of the interaction, proving that the likelihood of fissions increases among ruling parties though only when PARLIAMENTARY SUPPORT is wide enough (equal or above the 60%). Below that threshold, the increased price of ν is balanced by the high cost of ω . Note also that this result provides an argument for the idea of parties as minimum winning coalitions (Leiserson 1968).

³⁴In model 3 the marginal effect of DISTANCE on FISSION is .032 (.016) when the faction is in office and .048 (.028) when it is not. Clustered standard error in brackets.

³⁵Among the subsample covering parties in office DISTANCE has a significant positive effect on FISSION: 2.029 (.995). Clustered standard error in brackets.

it from breaking apart while, conversely, underpaid factions are more likely to split.³⁶

Besides policy and office, electoral motives matter as well (Reed and Scheiner 2003). CLOSED LIST is always significant and negative: when the selection of candidatures is centralized the likelihood of split increases, whereas preference voting contributes to preserve unity inside factionalized parties. The variable DISPROPORTIONALITY, in turn, has a significant impact.³⁷ It raises the exit costs and decreases the expected electoral payoffs of splinter groups, lowering the likelihood of a fission. Dissenters would rather stay within the party if the electoral system does not guarantee their reelection outside of it.

Apart from that, formal and informal intra-party rules are sources of break-aways too. Loyalty restrains minorities from breaking away. Having controlled for OVERPAID, which also captures the impact of patterns of cooperation that might emerge over time, the coefficient of PARTY AGE is always significant and in line with our hypothesis.³⁸ This result expresses the positive effect of loyalty on unity due to the ‘logic of appropriateness’ developed during party militancy, net of the ‘logic of consequentiality’ (March and Olsen 1989). This effect is confirmed by SYMBOL CHANGE.³⁹ Having controlled for policy DISTANCE, this latter variable tracks the net effect of changes in party symbols that are untied to deviations in party platform. Its positive coefficient attests

³⁶Overpaying one factions implies underpaying another one. It is up to the leader to decide which group to reward and at the expense of who. Overall, to preserve unity the leader should try to underpay those whose threat of breakaway is non-credible (as suggested in chapter 5).

³⁷Note that although DISPROPORTIONALITY and CLOSED LIST are strongly correlated (.86) the post-estimation diagnostic does not record any trouble with collinearity.

³⁸PARTY AGE could be associated also with members’ chances of reelection related to the electoral value of party label, under the idea that among older parties the label is well established and conveys electoral benefits (see Synder and Ting 2002). Nevertheless, we already controlled for this aspect through DISPROPORTIONALITY and CLOSED LIST, which evaluate the role of electoral motives comparing the expected electoral payoffs that factions would be able to gain inside or outside the party.

³⁹Conversely, when excluding this variable the impact of PARTY AGE on FISSION does not change.

that an adjustment in party logo or label decreases the loyalty of factions rising the probability of a split.

DEMOCRATIC CENTRALISM strongly increases the occurrence of a split. Among undemocratic parties that do not tolerate dissent, the cost of voice is quite large. This is true both for the leadership (voice infringes the monolithic party structure damaging its cohesion) and for the minority (leaders will revert to discipline to impose cohesion after the majority has set the line, hence the dissenters will face the choice between compliance or breakaway).

The coefficient of LEADER AUTONOMY is never statistically different from zero: contrary to H 7.9, autonomous leader does not boost the risk of a split, on the whole. MARGIN OF VOTES is negative and significant however, having included in model 5 the interaction between LEADER AUTONOMY and MARGIN OF VOTES, we want to observe the impact of each variable, conditional on the other (as suggested in H 7.10a and H 7.10b).

In table 7.4 we report the conditional marginal effect of MARGIN OF VOTES. In line with H 7.10b, a wide margin (low competitive systems) increases the likelihood of splits among parties are ruled by autonomous leaders, which take advantage of the lack of competitiveness to maximize their followers' rewards leading to more splits. Conversely, the minor incentives for breaking apart exert a negative impact on FISSION when in sub-competitive party systems when leaders are constrained. In such context, splinter groups have nothing to gain, provided that within the party they already receive a fair share of payoffs distributed by non-autonomous leaders that have to stick to the inter-factional agreement.

Accordingly, from figure 7.3 we observe that greater LEADER AUTONOMY increases the likelihood of a breakaway when party system competitiveness declines (i.e., when MARGIN OF VOTES enlarges), in line with H 7.10a.

Table 7.3: Marginal Effect of Party System Competitiveness Conditional on Leader Autonomy

Marginal Effect on FISSION when:		
LEADER AUTONOMY	= 0	-0.005** (0.002)
LEADER AUTONOMY	= 1	0.019* (0.010)

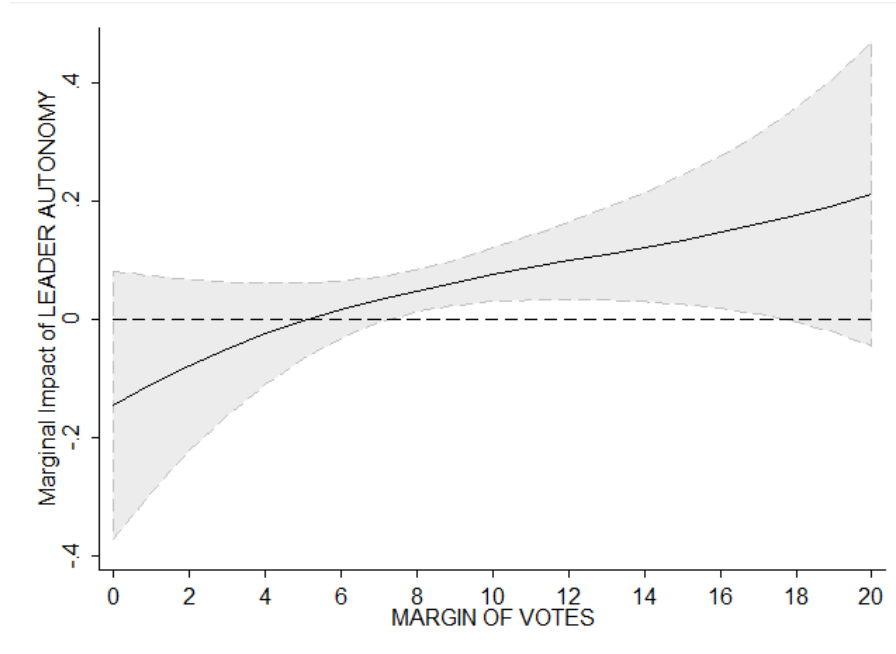

Based on model V from Table 7.2
 Clustered standard errors in parentheses
 * $p < 0.1$, ** $p < 0.05$, *** $p < 0.01$

When the distance between the two main competitors is 7.5% or below this effect is not significant: when party system competitiveness is strong any single vote matters, boosting the need to preserve unity. Therefore we do not observe differences between parties ruled by autonomous or constrained leaders because for both of them the main purpose will be to keep the party together. Conversely, when the margin of the first party grows the competitiveness decreases; then the cost of party breakup shrinks and consequently autonomous leader will not pay too much attention to the requests of internal minorities, leaving them unsatisfied and inclined to break apart. In fact, for values of MARGIN OF VOTES between 7.5% and 17.5%, LEADER AUTONOMY increases the likelihood of splits.

Finally, when the margin is very wide and the system tends to one-party dominance this effect remains positive but no longer significant. This could be due to some reasons. When a single party dominates the political system the cost of a breakup is lower but the incentives for a breakaway are lower as well and, more important, the cost of voice shrinks too (along with the ability of internal minorities to affect policy-making or to hurt the party from within). Dominant parties may want to adopt inclusive strategies, tolerating broader levels of division and dissent in order to preserve their dominance (Laver and Benoit 2003; Boucek 2010). However this latter idea might deserve deeper

investigation.⁴⁰

Figure 7.4: Marginal Effect of LEADER AUTONOMY on FISSION as MARGIN OF VOTES Increases

Note: The light gray area represents the 90% Confidence Interval of the estimate

⁴⁰We tested the impact of party system competitiveness through other variables finding somehow similar results. When using the ENP, Effective Number of Parties (Laasko and Taagepera 1979), as a proxy for competitiveness we found a positive significant effect of LEADER AUTONOMY for medium level of ENP, in line with our hypothesis. The effect is not significant when ENP is very low (single party dominance) or too high (due to uncertainty about the outcome, see Coppedge 1998); refer to Schleiter and Voznaya (2011) for a similar discussion about ENP as a proxy for competitiveness. Using PARLIAMENTARY SUPPORT we find a significant positive effect of LEADER AUTONOMY only among parties in office and we obtain a similar outcome modifying MARGIN OF VOTES to measure the gap between electoral coalitions (when in place). One possible explanation is that among ruling parties, whose life is more under public scrutiny compared to the opposition, the cost of internal voice (ν) is larger and may outweigh the cost of a breakup (ω) when the ruling coalition retains a safe margin (see also footnote 33, this chapter). Under such conditions, for the sake of improving government effectiveness (Katz 1986b), autonomous leaders will trade unity for cohesion, increasing the propensity for splits (see table 2.2). Autonomous leader could better overpay their supporter when they are in office due to the larger availability of office and policy payoffs to be shared. Vice versa, autonomous leader in opposition parties have little to distribute so that unfair dynamics do not hurt minority factions too much. These two latter results, although non identical to the suggestion proposed in H 7.10a, still provide a confirmation for that general idea. However, the specific differences in intra-party dynamics between ruling and opposition parties, along with factional politics inside dominant parties (Bogaards and Boucek 2010; Boucek 2012), are topics that deserve further investigation, although this deeper enquiry lies beyond the scope of the present dissertation (see paragraph 9.3 below).

To conclude, we show more substantively the effects of the variables considered in model 4. Table 7.4 provides the difference in probability to illustrate the deviation in the predicted probability of FISSION due to a change in each parameter (the values of all the other variables are set at their mean). We increase continuous variables by one standard deviation from the mean (which is the default) while dummy variables vary from 0 to 1.

Table 7.4: FISSION. Difference in Probability

Parameter	Default	Increase	Diff. in Probability
DISTANCE	0.103	+0.194	0.004** (0.003)
OVERPAID	0.004	+0.118	-0.006** (0.003)

7.6 The Determinants of Factional Breakaways: Findings

The results of the present analysis shed some light on the reasons why a party breaks up, altering the structure of the party system. We analyzed three

key elements that affect faction's decision to break away finding results that are in line with our main hypotheses. We proved that the amount of payoffs available within or without the party is crucial to explain faction breakaways. However intra-party rules, the electoral system and other attributes of the political system like the level of competitiveness affect the structure of payoffs and, directly and indirectly the likelihood of party breakup. Moreover party leader's attitude to compromise with internal minorities is another important factor that explains party unity and party fission.

First of all, we observe that factions care about office, policy, and electoral payoffs, and that all these three aspects influence their decision to stay or leave the party. Policy motives seem to drive the breaking (and making) of parties; subgroups that share common preferences are more likely to join together (Aldrich 1995) and, accordingly, they are more likely to split when intra-party heterogeneity increases. The bigger the distance between the faction and the party mainstream, the greater the likelihood of a breakaway.⁴¹ Although some scholars have claimed that factions are interested mainly in patronage, our results show that, on the contrary, factions are driven by policy motivations, too. Even among subgroups that are in office (which should be labelled 'factions of interests') policy payoffs impinges on the likelihood of a breakaway, regardless of the risk of losing the office.

Positive office payoffs, in turn, provide incentives to stay within the party. In addition being overpaid decreases the likelihood of a breakaway; conversely

⁴¹Note that another logic, apart from that underlined in H 7.1, may yield the same output. Marginal located minority factions pay a huge cost from membership. This price however is paid also by the party leadership when internal polarization (attached to heterogeneous party membership) increases. When divergent preferences coexist, the blurriness of label growths (Snyder and Ting 2002) and the party could suffer problems of credible commitment towards voters and allies. This effect will be greater, the larger the distance between each faction and the bulk of party members. The leader then will be unwilling to heed the requests of minority factions whose position is strongly marginal and she would rather pursue internal cohesion in spite of unity. A split, in fact, may increase the clearness of party label wielding positive effects on the whole party.

factions whose share of spoils is lower than their strength in party body are more likely to leave, trying to gain greater payoffs from outside the party. This result confirms that portfolio allocation could be a strategy to keep party unity, preventing the threat of a breakaway (in agreement with the findings discussed in chapter 5): the party leader might grant a larger share of payoffs to factions whose breakaway could damage the party.

Electoral payoffs matter as well. Factions evaluate the chances of reelection within or without the party. Notwithstanding their unsatisfactory quota of payoffs, dissenters might prefer to stay within the party if the electoral system does not guarantee their persistence. Accordingly, disproportional rules act as barriers to exit disempowering the strength of splinter groups in future elections and even thwarting their chances to get represented after the breakaway.

Conversely closed list PR and centralized procedures for candidate selection enable party leaders to select candidates and MPs. Hence the leader can punish dissenters leaving minority factions outside the party list or reducing the percentage of candidates assigned to them. In turn, undemocratic party rules that forbid internal dissent exert a similar effect, pushing leaders to whip minority in order to enhance cohesion. Deprived of the voice option (see chapter 4) dissenters will be more inclined to exit. In this sense preference voting, by decreasing the cost of voice, could be a source of party unity in systems characterized by divided parties (along with democratic intra-party rules). In fact it provides factions with open access to parliamentary seats thereby institutionalizing factionalism and sustaining unity. In this sense open list PR is a valid alternative to the adoption of primary elections (Hortala-Vallve and Mueller 2011).

Party loyalty act as a constraint to exit. The partisan tie to symbols and the logic of appropriateness developed during the militancy restrain members from breaking away. In this sense, discipline might help to preserve unity when it

has been endogenously internalized in the rational calculus made by dissenting factions. On the contrary, when discipline is imposed as an exogenous element, like inside divided undemocratic parties, the result will be an increase in the likelihood of splits. Discipline cannot be effective when the ‘exit’ remains an option (Kiewiet and McCubbins 1991). In turn this may help to explain why undemocratic parties are sometimes long lasting without suffering from this lack of democracy: the strong discipline could be balanced by huge levels of loyalty, which raise the exit costs defusing the credibility of such option.⁴²

The loyalty effect however ceases to wield effects when the party transforms its structure changing its symbols or merging with other parties so that the logic of appropriateness is no longer able to avoid splits. This aspect impinges on elites’ attempts to alter the political system in order to reduce party fragmentation. When party merger is only a ‘cold fusion’ process, that comes from an instrumental and strategic calculus untied to any policy basis, the internal wings will be more likely to break apart, thwarting the elites’ effort to simplify the political supply. The lack of loyalty toward the new party in fact does not help to restrain averse members from splitting away.

This path bears a resemblance with changes in the Italian political system occurred since 2008. Political elites pushed for a reduction of fragmentation and two new parties (PD and PDL) arose from the merger between already existing groups (DS and DL created PD, while AN and FI formed the PDL). However the two fusions were followed by several waves of fissions within each

⁴²We registered only episodic moments of conflict within the PCI despite it was ruled through democratic centralism since its birth. This trade-off between discipline and loyalty could be of use also to explain the factional strife that erupted within the LN in January 2012: the LN party mainstream imposed a whip on the internal minority forbidding its leader, Maroni, from taking part in public debates. Despite this strong sanction (closely linked to the idea of democratic centralism, large ν) the head of *Maroniani* faction was willing to remain within the LN. In fact, he confirmed his loyalty and claimed that he would never had left the party after 25 years of militancy (wide ϵ). Nevertheless, after that a broad number of local party branches (large ω) expressed their support for Maroni, deciding to defy the whip, the party mainstream stepped back, withdrawing the ban in order to avoid the risk of a damaging breakaway.

party. Within the PD, the Democratic Left (SD) exited from the party in 2007 and API broke away later on in 2009. In 2007, few months before the birth of PDL, the right-wing faction within AN (one of the founding parties) split creating a new party, *La Destra* (The Right), with the purpose to hinder this merger. Subsequently in 2010 another breakaway involved the PDL, when its minority factions broke apart building the FLI, and two additional splits occurred until 2011. After an initial decrease in the effective number of parties and parliamentary groups (fostered by the formation of PD and PDL) the breakups countervailed this process so that fragmentation started to grow once again.⁴³

Whether regarded in terms of breakaways or expulsions, party fissions involve two sides: the splinter group and the party leader who is in charge of preserving unity. We argue that factions leave the party when they are dissatisfied, and they are dissatisfied when the party leader do not cater to them with a fair share of benefits. In turn the leader will not cater to internal minorities when she is focused on keeping cohesion (homogeneity) in spite of unity.⁴⁴ This happens when a party fission will not harm the party, that means, when party unity is not an issue at stake, like for instance under low competitive

⁴³The ENP, measured according to the number of seats, has grown from 3.08 in May 2008 to 3.40 in December 2010 and 3.99 in December 2011 (Ceron 2011).

⁴⁴The search for more cohesion along with the firm rejection of any internal dissent are indeed two elements that contribute to explain the fission of PDL in 2010 and the breakaway of FLI. Remember, from chapter 3, that PDL openly declared its firm refusal of any public expression of dissent (likewise in parties ruled through democratic centralism). In addition the policy declarations released by Lower House Speaker Fini (head of the minority faction) and by other members of *FareFuturo* and *Generazione Italia* (*Finiani* subgroups) were considered by PDL leadership as laying too far away from the PDL policy platform and ideology. In addition the wide margin of seats retained by the centre-right ruling coalition at the beginning of the XVI Legislature, along with the strong voters' support kept by PDL and LN according to the poll surveys and to the results of local elections, contributed to lower the degree of competitiveness. This allowed PDL leadership to trade unity for cohesion. In search for a tight cohesiveness they decided to push *Finiani* faction outside the party, in order to secure a community of intent that could enhance government effectiveness. In fact the expression of dissent within the PDL was starting to damage party's image and government's efficacy and could have eventually eroded voters' support. However it seems that PDL leadership has underestimated the damaging effect of a split, at least in the long-run.

conditions where the cost of a breakup shrinks.⁴⁵

From our theory then we derive that party fission is an interplay between splinter factions and the leader (tied to the party mainstream), where leader's attitude toward party unity and the shape of payoffs allocation dynamics exert a crucial role in interaction with leader autonomy and with the condition of the electoral market measured in terms of party system competitiveness/dominance.⁴⁶

⁴⁵The lack of competitiveness might also contribute to explain the fractionalization of one-dominant party system as well as the end of party system dominance (Boucek 2010). In this sense, the adoption of fair intra-party dynamics of payoffs allocation in dominant parties allow to preserve them from disruptive factionalism, hereby perpetuating party dominance (consider for instance the Italian DC or the Japanese LDP). However, according to what discussed above (see footnote 40), this topic stands on its own and deserves further and deeper investigation.

⁴⁶Some works provided preliminary insights on how leader's attitude to internal dissent affects party unity and cohesion (Boucek 2010; Ceron 2011).

Chapter 8

Factions, Fissions, and Their Effects on the Party System

8.1 Introduction

So far we highlighted that parties are not unitary actors but are instead divided in many subgroups. We detected their internal subgroups estimating factional preferences and investigating what rules shape intra-party politics; we scrutinized how factions bargain to preserve party unity and why sometimes the party breaks up. Our results depicted the sources of factionalism and proved their impact on intra-party equilibriums. However if intra-party divergences do not yield effects on party politics and the party system, studying factions and fission would be less relevant, if not worthless at all. Some of our findings confirm that the party system affects intra-party politics, for instance through portfolio allocation or providing incentives and constraints to the growth of factions and the likelihood of splits. In this chapter we will go one step forward to assess whether factionalism and party fissions have an impact on real world politics and on the party system as a whole. We will provide a measure of intra-party polarization and we will analyze the impact of divi-

sion on several aspects of politics, focusing on policy, office, and votes. First of all we analyze whether intra-party divergences reflect in different rates of cohesion during parliamentary votes. Then we assess whether greater internal polarization affects the likelihood of being involved in a coalition government. Finally we control if intra-party division alters the electoral performance of a party.

8.2 A Measure of Intra-party Division

To evaluate the impact of factionalism we need a measure of the degree of polarization within the party. However taking into account only the range of preferences existing inside parties would be insufficient. We should better take into account both the preferences and the strength of each faction.

An example helps to explain why. Suppose we have two parties, A and B. A is composed by a strong majority faction that retains 99% of members' support and by a minority faction whose strength is limited (only 1% of seats in party body); the ideal point of the minority lies far far away from the mainstream. On the contrary B is composed by two factions of equal strength whose policy views diverge to a lower extent compared to party A. We can easily argue that party A would be perceived as less divided even if the distance between its two factions is greater than in party B. In party A in fact the overwhelming strength of the mainstream faction with respect to the minority contributes to clarify the party line, assuring that its policy position would be easily identified. On the contrary, despite factions in party B are closer, their equal strength makes it harder to identify where the party is actually located and who sets its line and strategy. Hence the uncertainty around the actual preferences of party B could be greater.

This higher uncertainty might produce some effects. For instance, it may

decrease the likelihood that the party will be involved in a coalition, as we argue later. Additionally its party label appears less clear, the voters then will face difficulties in understanding its actual position on several policy issues and whenever the party expresses a common position the voters would not believe to such commitment because of the broad division existing inside it. Finally, the risible strength of the minority faction in party A would decrease the likelihood that its parliamentary group will split on key votes: if dissenters decide to rebel they face the risk of a punishment without being sure that their defection will really alter the outcome of the vote. In party B to the contrary factions are large enough to believe they are able to alter the result. Moreover, despite their preferences are not much divergent, it could be difficult to find a compromise when the options are just “yes” or “no” (and “abstain”), therefore the party could more easily split.

To provide a measure of polarization that takes into account the bargaining-complexity within the party we retrieve the ‘*ideological standard deviation*’, an indicator used by Warwick (1994) to assess the polarization of a party system, and we adapt it to fit the intra-party environment, given that we consider the party as a ‘factional system’. Therefore we take into account faction’s size and policy position to assess the degree of INTRA-PARTY DIVISION (IPD) within each party congress, through the following formula:

$$IPD = \sqrt{\sum_{i=1}^n s_i (f_i - GAP)^2} \quad (8.1)$$

where s_i is faction i ’s share of seats in party body, f_i is its policy position, and GAP is the GAMSONIAN AGREEMENT POSITION (the weighted mean of factions’ positions measured as described in chapter 6); the summa-

tions are over the number of factions within each congress (n).¹ Figure 8.1 illustrates the distribution of INTRA-PARTY DIVISION within the 83 congresses included in the database. IPD assumes, on average, the value of 0.17. IPD is positively correlated ($r = .84$) with the range of INTERNAL POLARIZATION, shown in chapter 4, and with two measures of internal fragmentation described in the same chapter: NOF ($r = .31$) and ENF ($r = .21$).

As shown in figure 8.2, the mean value of IPD is quite similar for all parties: with few exceptions it ranges from 0.1 to 0.2; NPSI and PCI retain slightly lower values while within the Greens IPD is on average greater than 0.2 (likewise in the unique observation concerning PDA and PDCI). The broader internal division within the Greens comes as no surprise given that this single issue party included subgroups whose ideology differs widely (apart from a common and strong interests in environmental policy). Overall however the variation of IPD across time (within the same party) seems to be larger than the difference across parties. At different points in time parties like DC or PLI experienced very different levels of intra-party division while these levels are more similar within parties like DS or PSDI.

8.3 Policy: Does Factionalism Affect Policy-Making?

To start with we want to test whether intra-party division shapes policy. In chapter 6 we have already shown that party position is affected by the wills of all factions, hence divergent preferences lead to differences in terms of policies. Here we try to go further to determine their impact on parliamentary

¹Note that this formula leads to the same results of the Polarization Index provided by Dalton (2008) to calculate party system polarization.

8.3. POLICY: DOES FACTIONALISM AFFECT POLICY-MAKING?

Figure 8.1: Distribution of Intra-party Division within Party Congresses

Figure 8.2: Intra-party Division per Party

policy-making. We claim that, apart from altering party ideology and position on several issues, the effect of intra-party differences should be observable, resulting in lower degrees of cohesion in parliamentary votes. This in turn could affect the outcome of a vote, changing the content of legislation that will be enacted.

Analysing the roll call votes on divisive foreign policy issues, Giannetti and Laver (2009: 166) found ‘a clear relationship between the factional structure [...] and indicators of party cohesion’ within the Italian Democrats of the Left. Their work sustained the idea of a linkage between factional preferences and voting behaviour.²

Noticeably a party whose factions retain exactly the same preferences should consistently vote in a very cohesive manner. Conversely in a party that is internally polarized, factions could more easily split on parliamentary votes. However this is just a necessary (but not sufficient) condition for a split vote as long as voting behaviour does not depend only on preferences but could be induced through party discipline (Kam 2009; Krehbiel 2000; Laver 1999). A split is more likely to occur when the number of rebels is large enough so that the outcome of the vote could be affected. Otherwise the rebels would face the consequence of their betrayal being punished by the party leader without gaining the benefit coming from a policy change.³ Accordingly we claim that:

²Though Giannetti and Laver’s work is only a case study, we contend that this framework applies to many other contexts. A classical example related to the Italian history concerns the election of Giovanni Gronchi as Head of State in 1955; he was appointed by an heterogeneous majority composed by left-wing and right-wing parties with the decisive contribution provided by both DC left-wing and right-wing factions that voted against the wishes of DC leadership. Beside this example, the Italian politics is studded by cabinets defeated (Boucek 2010; Giannetti 2010; Mershon 1994) and laws rejected due to the defections of MPs belonging to a party faction (note, moreover, that until 1988 the secret ballot provided a safe shield for dissenters).

³Hardly ever a single MP is able to affect the output of a parliamentary vote on her own. This is not unrealistic but it is certainly a rare occurrence. When a single member decides to defy the party line, she faces the risk of punishment (by the party leader) without being sure about the effect of her vote on the final policy output. To the contrary whenever all the members of a faction that shared common policy views on a bill proposal decide to rebel they increased the likelihood of being able to affect legislation. The higher their number the

Hypothesis 8.1: The greater the extent of intra-party division, the lower the cohesion in parliamentary voting

To test this idea we use the main indicator of MPs voting behavior that is roll-call votes and we compare party cohesion in parliamentary votes with IPD, the measure of intra-party division displayed above, which accounts not only for the level of divergence but also for the internal bargaining-complexity.

We know that roll-call votes are not a perfect measure of parliamentary behavior. Not all votes are roll-calls, thus they do not provide a complete picture of voting behavior. The decision to call a roll-call vote may also be strategic and biased according to the issues or the group that call it; this is true for the European Parliament (Carrubba *et al.* 2006; McElroy 2009: 214-215) but also in many other contexts (Giannetti and Benoit 2009: 233). Party groups might call roll-call votes for many different reasons and this strategic behavior could bias the MPs' voting behavior in such votes compared to others, 'however, regardless of the strategic reasons for calling roll-call votes, it is reasonable to assume that roll-call votes are used for the more important decisions' (Hix *et al.* 2005: 215).

Roll-call votes casted in the Italian parliament are accessible only since 1988, after the removal of the secret ballot. Data on roll-call, covering the years from 1988 until 2008, have been collected and made available thanks to Curini and Zucchini (2010). To assess the extent of intra-party cohesion several

greater the potential effect of their defection. Moreover as the percentage of rebels increases the leader will be less able to revert to discipline in order to impose her line without damaging the party: when the entire parliamentary group, but the leader, decides to dissent from the party line it would be theoretically impossible to impose discipline to constrain the MPs and, in case, the party leader will be dismissed. Something similar happened indeed in 1976, when the moderate faction within the MSI supported the formation of Andreotti III Cabinet against the will of the party mainstream, and in 1998 when PRC mainstream group split in two separate factions and a majority of MPs voted against a motion of no confidence on Prodi I Cabinet, presented by their own party. In both cases the parliamentary groups dissolved after the split.

different measures have been calculated. The first one is the well-known Rice (1924, 1928) index:

$$Rice_j = \frac{1}{m} \sum_{i=1}^m \frac{|Yes_{ij} - No_{ij}|}{Yes_{ij} + No_{ij}} s_i (f_i - GAP)^2 \quad (8.2)$$

Noticeably the Rice index of voting likeness considers only “Yes” and “No”. However the voting behavior encompasses other two alternatives i.e., “Abstain” or “Home” where the latter stands for ‘stay home’, i.e., be absent. The rules in the Italian Lower House take all the four options into consideration. In particular, those who abstain are counted for the quorum but not for the calculus of the majority of votes required to pass the bill.⁴ The absences too allow often to express a policy position, when some MPs boycott the vote trying to avoid the achievement of the quorum or when a parliamentary group publicly expresses its firm refusal on a highly divisive bill (Curini and Zucchini 2010).

In this sense abstention and absence are almost never trivial nor neutral. On the contrary they are often a strategic voting behavior intended to signal a third position beyond approval or rejection. Indeed these additional options played often a crucial role during parliamentary votes, even in key votes like cabinet’s investiture. There is evidence suggesting that party factions adopted such strategies during key votes, to halt unwanted bills or pieces of legislation and to defeat governments hereby fostering a cabinet reshuffle that alters the distribution of ministers among party factions (Giannetti 2010).

Being sources of a (potential) tactical voting, abstention and absence require coordination and discipline between MPs belonging to the same group

⁴For instance if a plurality of MPs is in favor of the bill abstentions, by allowing to reach the quorum required to validate the vote, contribute to pass the bill. The opposite holds when a plurality of MPs oppose the project.

(or subgroup). Therefore the logic behind these two options is not much different from the group’s decision to vote in favor or against a bill.⁵ Moreover, these alternative voting options allow factions to express their dissent without the need to cast a vote that is completely in contrast with the party line, while signaling however that their position lies in between. This linkage between factional disagreement and unconventional voting options conveys a further reason to consider them in our analysis of party unity.

To measure parties’ voting cohesion considering all these alternatives we revert to other indexes. The first one is the Agreement Index (AI), applied by Hix *et al.* (2005) in a work on the cohesion of groups in the European Parliament. The index considers separately the three different voting options, “Yes”, “No”, and “Abstain”, creating a count of each choice for each vote.

$$AI_j = \frac{1}{m} \sum_{i=1}^m \frac{\max Y_{ij}, N_{ij}, A_{ij} - \frac{1}{2}(Y_{ij} + N_{ij} + A_{ij} - \max Y_{ij}, N_{ij}, A_{ij})}{Y_{ij} + N_{ij} + A_{ij}} \quad (8.3)$$

where Y_{ij} , N_{ij} and A_{ij} denote respectively the choice to vote “Yes”, “No”, or “Abstain”. Perfect cohesion is indicated by AI equals to one, meaning that all MPs of a party cast the same vote (or do not cast a vote all together). Conversely when AI is zero the MPs are equally divided between the three options, reporting an absolute lack of cohesion. Other authors (Landi and Pelizzo 2006) proposed a modified version of AI adding a fourth category to identify the absents, who chose to stay home (though excluding MPs absent due to parliamentary duty). The Modified Agreement Index (MAI) is measured through the following formula:

⁵Carey (2009) too suggests considering non-voting in addition to cross-voting to analyze party unity.

$$MAI_j = \frac{1}{m} \sum_{i=1}^m \frac{\max(Y_{ij}, N_{ij}, A_{ij}, H_{ij}) - \frac{1}{3}(Y_{ij} + N_{ij} + A_{ij} + H_{ij})}{Y_{ij} + N_{ij} + A_{ij} + H_{ij}} \quad (8.4)$$

where H_{ij} indicates the choice to stay “Home”. Alternatively, Curini and Zucchini (2010) argued that, in line with the rules of the Italian Lower House, abstentions could be likened to favorable votes. Within their dataset almost all the bills submitted to a roll call vote were approved; in those situations indeed the abstentions contributed to match the quorum, validating the vote. In this sense they actually carried a positive effect. Accordingly we provide another alternative measure of AI focused on the actual effect played by the voting behavior. This version, called Actual Agreement Index (AAI), takes into account the absence as a third choice beyond “Yes” and “No” (like in the previous case). However, contrary to MAI, we sum up “Yes” and abstentions due to their common effect on policy-making. We measured the AAI as follows:

$$AAI_j = \frac{1}{m} \sum_{i=1}^m \frac{\max(Y_{ij} + A_{ij}, N_{ij}, H_{ij}) - \frac{1}{2}[(Y_{ij} + A_{ij}) + N_{ij} + H_{ij}]}{(Y_{ij} + A_{ij}) + N_{ij} + H_{ij}} \quad (8.5)$$

The difference between the Rice index and the several types of Agreement indexes are greater when parties tend to abstain, or to stay home, as a block (Hix *et al.* 2005).⁶ However when looking at the correlation between the four measures we observe that the main difference seems to concern the impact of strategic absences, as it emerges from table 8.1.

Among those displayed above, only two correlations appear statistically

⁶For instance, if one party splits between 10 “Yes”, 10 “No” and 100 “Abstain”, it would be completely divided (0.000) according to the Rice index, while the AI would show that the party is relatively cohesive in its choice (0.750); see Hix *et al.* (2005: 216).

8.3. POLICY: DOES FACTIONALISM AFFECT POLICY-MAKING?

Table 8.1: Correlation between Alternative Measures of Party Cohesion in Roll Call votes

Variables	Rice	AI	MAI	AAI
Rice	1.000			
AI	0.642	1.000		
MAI	0.099	0.222	1.000	
AAI	0.003	0.171	0.955	1.000

significant (both at the 99% level): one is between the Rice index and the Agreement Index and the other involves MAI and AAI. This clearly highlights two patterns marked by the choice to consider the absence as a third option beyond “Yes” and “No”. In fact MAI and AAI are firmly correlated with each other while they diverge from AI and Rice, which do not count the absentees.

We will analyze the impact of IPD on party cohesion referring to these four dependent variables. We adopted the Rice index (RICE) and the three different versions of the Hix Agreement Index: AI, MAI and AAI. Data on roll calls are available only for a limited number of cases ($n = 30$) and not for the whole sample of congresses (that is 83). Due to the huge relevance of party switching within the Italian Parliament (Giannetti and Laver 2001; Heller and Mershon 2005, 2008) the indexes have been measured considering only MPs belonging to each parliamentary group at the end of the legislature.

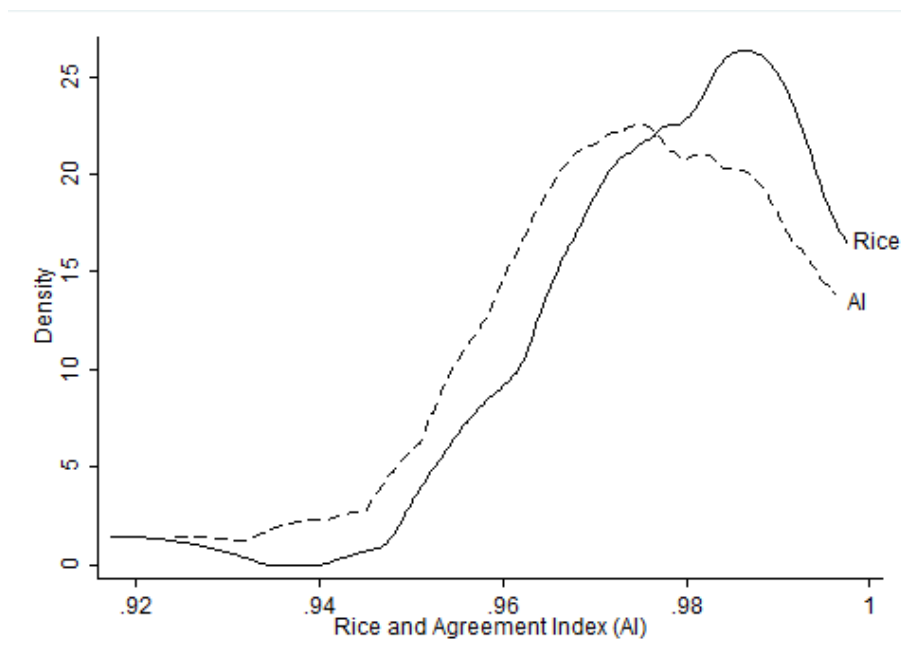

We modified INTRA-PARTY DIVISION accordingly, excluding from the count factions that broke away by the end of the term. When after the fission there is only one faction left we assigned to IPD the value of 0 to indicate the absence of divisions because the sources of polarization i.e., the other splinter factions, were no longer inside the party. When only one group remains inside we would not expect to observe divergent preferences and voting behavior.⁷

We additionally include two control variables. The first one, GROUP SIZE, is the number of MPs belonging to each group. Several authors (Carey 2002; Dion 1997; Sieberer 2006) suggest to control for this aspect as far as roll-call

⁷However considering those situations as missing cases does not alter the results.

indexes of cohesion are artificially inflated for small parties (Desposato 2005). The second variable is RULING PARTY, a dummy variable that takes value 1 when the party belongs to the coalition that supports the government (even if just through an external support); this variable allows to control the differences in cohesion between ruling and opposition parties as long as some authors claimed that parties in office tend to be more unified (Becher and Sieberer 2008; Carey 2002, 2007; Diermeier and Feddersen 1998; Katz 1986b; Saalfeld 1995) while others support the reverse hypothesis (Rahat 2007; Sieberer 2006). Figure 8.3 and 8.4 show that the values of our dependent variables are bounded between 0 (lack of cohesion) and 1 (perfect cohesion).

Figure 8.3: Kernel Density of Rice Index and Agreement Index (AI)

As discussed in chapter 5, in those cases the OLS assumptions might no longer hold and we could find heteroskedasticity or not normally distributed errors (Wooldridge 2002). We need to estimate our parameters through another model like the beta-binomial model (Paolino 2001) or the fractional logit

Figure 8.4: Kernel Density of Actual (AAI) and Modified (MAI) Agreement Index

(Papke and Wooldridge 1996, 2008). Contrary to the fractional logit, the beta-binomial model requires that the dependent variable does not assume values on the extremes of the interval (0 or 1). RICE varies from .94 to .99 and AI similarly assumes values between .92 and .99 (figure 8.3). On the other side MAI ranges from .55 to .85 and the AAI between .53 and .83 (figure 8.4). Hence we can analyze data through beta maximum likelihood estimation, although using a fractional logit does not alter the results. We cluster observations on party to deal with the issue of independence. The results of the analysis are displayed in table 8.2.

The coefficient of IPD retains a significant effect only in two out of four analyses. In line with our hypothesis it has a negative and significant impact, though only when party cohesion is measured through MAI and AAI, the two indexes that interpret strategic abstention as an additional voting option. When roll calls are analyzed through Rice and AI, on the contrary, the effect

Table 8.2: Beta Maximum Likelihood Estimation of Party Cohesion

	(1)	(2)	(3)	(4)
	RICE	AI	MAI	AAI
INTRA-PARTY DIVISION	0.638 (0.875)	1.024 (1.063)	-0.704** (0.285)	-0.860*** (0.296)
GROUP SIZE	0.003* (0.002)	0.006*** (0.002)	0.000 (0.001)	0.000 (0.001)
RULING PARTY	0.325 (0.312)	0.097 (0.177)	0.311** (0.149)	0.245 (0.168)
Constant	3.419*** (0.182)	3.035*** (0.241)	0.488*** (0.114)	0.422*** (0.095)
Observations	30	30	30	30
Log pseudo-likelihood	92.056	91.059	38.342	38.126

Clustered standard errors in parentheses
 * $p < 0.05$, ** $p < 0.01$, *** $p < 0.001$

of IPD is no longer statistically different from zero.

In line with other recent contributions (Depauw and Martin 2009; Sieberer 2006) we found that GROUP SIZE is significant but only when looking at the Rice index or at AI. This effect holds even when adopting the adjusted version of Rice index proposed by Desposato (2005); hence this feature does not seem linked to that kind of bias.⁸

Finally the effect of RULING PARTY is controversial. Members of the ruling coalition report higher levels of cohesion in parliamentary votes (e.g., Carey 2007) although this effect is significant only when analyzing the Modified Agreement Index. If this was the case there would be a resemblance with the findings shown in chapter 4 when we registered a decrease in fractionalization among parties in office. The cost of division could be higher among ruling parties that face incentives to strengthen their cohesion in order to ameliorate government effectiveness (Katz 1986b). However when looking at the other indexes this result loses its significance so that the actual impact of party government on MPs cohesion needs further investigation.

⁸See Sieberer (2006) for an analogous outcome.

8.3. POLICY: DOES FACTIONALISM AFFECT POLICY-MAKING?

Despite the limited number of observations these preliminary results show that, after controlling for party's size and status, factions' behavior seems consistent with their preferences. However the methodological assessment of absentees seems crucial to understand the impact of intra-party politics on parliamentary votes.

The role of coordinated absences as a device to express an alternative position is rooted in the parliamentary split known under the name of "*Aventino* Secession". In 1924, to complain against the disappearance (and the murder) of Giacomo Matteotti (an anti-fascist MP), the representatives belonging to anti-fascist opposition parties withdrawn from the parliament to signal, with their absence, the lack of legitimacy of the oncoming fascist dictatorship. After the advent of the Republic, this parliamentary tactic has been adopted from time to time to signal a firm refusal on several topics. Recently, in October 2011, the whole opposition reverted to such strategy as a mean to defeat the Berlusconi IV Cabinet in a vote of confidence. However the lack of cohesion within the main opposition party led to the failure of this device.⁹ A very similar strategy was adopted one month later, during a crucial (though ordinary) vote on the cabinet's balance sheet. All the opposition parties (including MPs switched off from the PDL few days before) agreed on a common tactic to force the Prime Minister to resign. The opposition was cohesive in refusing to cast a vote, so that the balance sheet was approved but only with 308 votes out of 630 MPs. In consequence of this debacle, which highlighted the lack of a majority, Berlusconi decided to resign.

Overall the absences exert strong effects on the policy-making. An enquiry

⁹MPs belonging to the Radical Party, who were members of the PD parliamentary group, refused to adopt such tactic and participated in the vote, forcing all the other opposition parties to give up with the '*Aventino*'. As a consequence of such behavior the Radicals have been temporarily suspended from the PD group. Something similar already happened a few weeks before when, conversely, the Radicals deserted the room during the vote of no confidence on a cabinet minister.

highlighted that in the XVI Legislature the absence of MPs belonging to the opposition was crucial to sustain the majority in roughly the 35% of parliamentary votes.¹⁰ Some of these votes were non-trivial. For instance many PD representatives were absent during the vote on ‘tax amnesty’, in October 2009; among them Paola Binetti, the leader of a conservative catholic PD faction named *Teodem*. Due to their unjustified absence Binetti and other MPs received a formal warning by party body.¹¹

Indeed strategic absence could be a way used by minority factions to signal their divergent position from party mainstream on specific bills. Another example helps to shed light on the linkage between absences and factionalism. In July 2011, several catholic PD deputies expressed their view on the ‘living will’ by staying home during the vote on that bill, in dissent from the party line. Going back to H 8.1 it seems that, overall, broader levels of intra-party divergence yield lower cohesion in parliamentary voting, in line with the result discussed by Giannetti and Laver (2009).

8.4 Intra-party Politics and Government Formation

The second aspect we want to investigate is the impact of factionalism on office. In chapter 5 we investigated this effect within the party, focusing on portfolio allocation among factions. Here, going one step forward, we want to test whether intra-party politics affects coalition formation.

Groennings (1970) was the first to investigate this topic. He stated that parties weakened by factional disputes face disadvantages in coalition bargain-

¹⁰The enquiry is available on <http://maggioranzasalva.openpolis.it>.

¹¹Binetti complained about this warning. A few months later she switched off the party, together with other MPs belonging to her faction.

ing. Similarly other authors emphasised the positive effect of party unity on office payoffs (Baron 1998; Diermeier and Stevenson 1999). In the same vein, Warwick (2000) said that parties have policy horizons that define the bounds of compromise; narrow horizons, providing more constraints, decrease the likelihood of being involved in the process of coalition formation. Focusing on intra-party organization Strøm (1990) claimed that decentralized intra-party decision-making increases the role of party activists, which are notably more policy-oriented (May 1973) and then, less willing to compromise, hereby decreasing policy flexibility. Hence decentralization complicates negotiations. Accordingly some scholars claim that more democratic parties suffer during bargaining over government formation (Bäck 2009; Müller and Strøm 2000; Pedersen 2010; Warwick 1996). Recently Pedersen (2010) proved that parties with unconstrained negotiators tend to be more often involved in government formation than parties with a strong organization. Bäck (2009: 64) shown that ‘factionalization and intra-party democracy have negative effects on a party’s chances of getting into government’.

Nonetheless other authors argued that factions can provide strategic advantages in coalition bargaining, by increasing party flexibility (Laver and Shepsle 1996, 1999; Maor 1998; Meyer 2012). In addition Maor (1995, 1998) claimed that inside centralized parties the conflict manifests itself in public voice or exit from the party, and these public disputes, more than internal conflict, damage the bargaining power of parties.

Following this literature we focus on how intra-party division and party organization affect the likelihood of being involved in a coalition government, raising two main hypotheses. First of all, a party divided into many factions that retain diverging policy positions will face more troubles in reaching an agreement with other parties to form a coalition. Intra-party divisions make a party less attractive to its potential allies. The uncertainty about internal

equilibrium yields doubts about party's commitment to a coalition deal (Bäck and Vernby 2003). In fact any agreement reached between the party and its allies could be reneged whenever intra-party equilibriums are altered by factional competition. Even so factions might disagree around the choice of coalition partners complicating the task of finding an arrangement.

Hypothesis 8.2: The greater the extent of intra-party division, the lower the likelihood of being involved in coalition governments

Another aspect of intra-party politics that affects government formation concerns party organization: meaning the level of internal democracy and centralization. According to contrasting changes in the internal structure, party leaders could be completely free to negotiate a deal or alternatively constrained by members, activists and factions (Müller and Strøm 1999; Strøm 1994; Warwick 1996: 475). As discussed above unconstrained negotiators should be more easily able to pivot between potential alternatives in order to get involved in a government coalition.

Hypothesis 8.3: The greater the centralization of party decision-making, the higher the likelihood of being involved in coalition governments

We can additionally hypothesise that these two attributes interact so that the effect of intra-party division varies according to party organization. Then we test this claim through an interaction term between intra-party heterogeneity and leader's autonomy. Groennings (1970) claimed that when intra-party disputes happen, centralized parties permit to bypass the conflict allowing the party to remain in the coalition (Bäck 2009). Conversely Maor (1995: 66) argued that organizational decentralization helps to manage internal struggles,

enhancing party's chances to enter the cabinet. We can assess which of these claims is more reasonable testing the following dashing hypotheses.

Hypothesis 8.4a: The negative effect of intra-party division on the likelihood of being involved in coalition governments is lowered among centralized parties

Hypothesis 8.4b: The negative effect of intra-party division on the likelihood of being involved in coalition governments is lowered among decentralized parties

We will test these hypotheses focusing on the likelihood that a party will be involved in a coalition government. The dependent variable is CABINET MEMBERSHIP, a dummy variable that takes value 1 if the party is member of the coalition government in the first cabinet appointed after the end of each party congress. To test H 8.2 we use the variable INTRA-PARTY DIVISION described above. We correct the value of this variable to account for fissions occurred before the bargaining that led to the formation of the new cabinet. Hypothesis 8.3 will be tested through LEADER AUTONOMY, a dummy variable that accounts for the degree of decision-making centralization; it assumes the value 1 when the leader is directly elected by party members or delegates, and the value 0 when the party leader is nominated by a less inclusive electorate. Direct election makes leader more autonomous and able to centralize the decision-making process: the direct legitimacy grants her more power and discretionality during coalition bargaining. Our last claim (H 8.4a versus H 8.4b) will be assessed through an interaction term that encompasses these two variables: INTRA-PARTY DIVISION*LEADER AUTONOMY.

Moreover we add some control variables commonly used in the literature

to check whether our hypotheses hold. Scholars distinguish between internal and external bargaining resources. The former are related to the intra-party attributes discussed so far; the latter concern elements like parties' strength in Parliament and their policy positions. Many authors recognize that party's size could impact on the likelihood of being involved in coalition governments (e.g., Laver and Shepsle 1996); larger parties need a lower number of partners to form a majority, hence they usually face minor difficulties during coalition bargaining as long as they can negotiate with a lower number of potential allies or with smaller groups. To control for this aspect we include the variable `PARTY SIZE` that expresses the percentage of seats retained by party i .

Besides size, party policy views matter as well. Applying the Black (1958) theorem to coalition bargaining we would expect that the median party (i.e., the party to whom the median legislator belongs) is able to exploit its strategic position during negotiations (Bäck 2009; Laver and Schofield 1990: 11). In addition parties try to build connected coalitions that minimize their reciprocal distance (e.g., Axelrod 1970); hence parties whose distance from the government ideal point is lower should have more probability of taking part in the bargaining (Pedersen 2010). Using data from ILS (Curini and Martelli 2009) and applying the 'vanilla method' (Gabel and Huber 2000) to estimate parties' and governments' policy positions on a single dimension (as described in chapter 6) we are able to account for the impact of policy views. We identify the median party within each parliamentary debate by looking at parties' size and policy positions on the left-right scale. Then we create the variable `MEDIAN PARTY`, a dummy that takes value 1 when party i contains the median legislator, and 0 otherwise.

In addition we build the variable `POLICY DISTANCE` that measures the divergence between party i 's and government j 's ideal points. Given that ILS data are measured after the bargaining, when the government has already

been formed, it could be argued that the policy positions expressed during the debate are the endogenous outcome of that negotiation process. To cope with this matter we measure the Euclidean distance between government position at time t (the first government empowered after the congress) and party position at time $t - 1$ (the position expressed during the confidence vote on the previous government, the last one who took office before the end of the party congress).¹²

As a final point, recent contributions to the literature on coalition formation concern the idea that incumbent coalitions are advantaged during bargaining. Incumbent represents ‘the reversal point in the event the other parties fail to agree on an alternative’ (Strøm *et al.* 1994). Furthermore transaction costs ‘increase when parties change coalition partners, which implies that parties that had governed together will prefer to continue this cooperation’, exploiting the established routines and the reciprocal (almost) complete information (Bäck 2009: 54). To sum up, incumbent cabinets will more likely form again (Bäck 2003; Bäck and Dumont 2007; Pedersen 2010; Warwick 1996). The dummy variable INCUMBENT helps to consider this feature; it takes value 1 if the party was member of the government at time $t - 1$, and 0 if not.¹³

We test our hypotheses by means of a logistic regression.¹⁴ The number of cases should be equal to the number of congresses (83), however due to a

¹²However using the distance between party i and government j measured at time t does not alter the main results.

¹³We should also take into account the role of pre-electoral coalitions that are a feature of Italian politics during the Second Republic and seldom during the First one (a coalition composed by DC, PLI, PRI, PSDI, and the regional parties SVP and PSDA, contested the 1953 general elections; see footnote 24, chapter 7). Including a dummy variable to identify parties that are members of a winning pre-electoral coalition (or, conversely, members of a losing coalition) does not alter the substantive results. Moreover such variable would be omitted (and some observations would be dropped) because it predicts perfectly the outcome.

¹⁴Including a lagged dependent variable in a logit regression requires assuming that the parameters relating the independent variables to Y are the same regardless of whether lagged Y is 0 or 1. This is what Beck *et al.* (2002) called ‘restricted transition model’. It also makes sense to include a lagged dependent variable when the lag has an effect per se on Y . Notwithstanding this, testing temporal dependence on the present dataset through random effects or following discrete time duration models (Beck *et al.* 1998) does not alter the results.

few missing cases this value drops to 66. Observations have been clustered by party; we provided standard errors on clusters to deal with the nested structure of data, thereby avoiding any possible bias due to independence. Table 8.3 displays the results of the analysis. We provide two different models in order to test H 8.2 and H 8.3 separately (model 1), or in interaction (model 2) according to H 8.4 (a and b).

Table 8.3: Logistic Regression of CABINET MEMBERSHIP

	(1)	(2)
INTRA-PARTY DIVISION	-5.469* (3.050)	-6.808** (3.385)
LEADER AUTONOMY	-0.850 (0.581)	-1.857* (1.054)
INTRA-PARTY DIVISION* LEADER AUTONOMY		6.987* (3.720)
PARTY SIZE	0.085** (0.041)	0.075* (0.041)
MEDIAN PARTY	-1.319 (1.181)	-1.198 (1.166)
POLICY DISTANCE	-0.164** (0.066)	-0.170** (0.066)
INCUMBENT	3.571*** (0.832)	3.580*** (0.855)
CONSTANT	-1.146* (0.630)	-0.847 (0.627)
Observations	66	66
Log Pseudo-likelihood	-23.583	-23.165
Correctly Predicted	87.88	86.36
Area under the Roc Curve (AUC)	.918	.920

Clustered standard errors in parentheses
 * $p < 0.1$, ** $p < 0.05$, *** $p < 0.01$

In the first model IPD is significant: INTRA-PARTY DIVISION reduces the likelihood of being in office, in line with H 8.2. However contrary to our hypothesis 8.3 the impact of intra-party rules does not seem influential; the coefficient of LEADER AUTONOMY is not significant meaning that autonomous leaders do not necessarily take advantage of their autonomy during coalition bargaining.

8.4. INTRA-PARTY POLITICS AND GOVERNMENT FORMATION

Almost all the control variables are significant, as we expected. PARTY SIZE increases the likelihood of being in office; similarly being member of the former cabinet strongly increases the probability to participate in the new government. Conversely POLICY DISTANCE is negative and significant meaning that such probability decreases as the distance between party policy position (at time $t - 1$) edges away from government position (measured at time t). To conclude with, MEDIAN PARTY does not show a significant coefficient after controlling for size and policy views. The effects of these control variables are confirmed by model 2. The coefficients keep their sign and their level of significance.

We revert to table 8.4 and figure 8.5 to assess the impact of the internal bargaining resources after including the interaction term between INTRA-PARTY DIVISION and LEADER AUTONOMY. The interaction is positive and significant. The marginal effect of INTRA-PARTY DIVISION is significant only when leaders are not autonomous: the greater the level of division the lower the likelihood of participating in the cabinet. On the contrary among parties whose leader are more autonomous (due to direct legitimacy) intra-party division ceases to play any effect.

This idea seems coherent with Groennings' (1970) argument (summarized in H 8.4a): factionalized parties are less likely to be in office the higher the level of decentralization of intra-party decision-making. An autonomous party leader is more able to handle growing internal disputes (as shown for example in chapter 5) so that these are no longer harmful for party's chances to get in office. Conversely the marginal effect of LEADER AUTONOMY decreases the likelihood of joining the government only when the level of intra-party division approaches zero (figure 8.5).¹⁵ This effect is not significant when internal

¹⁵In our data IPD equals zero when, after a fission, only one faction remains inside the party.

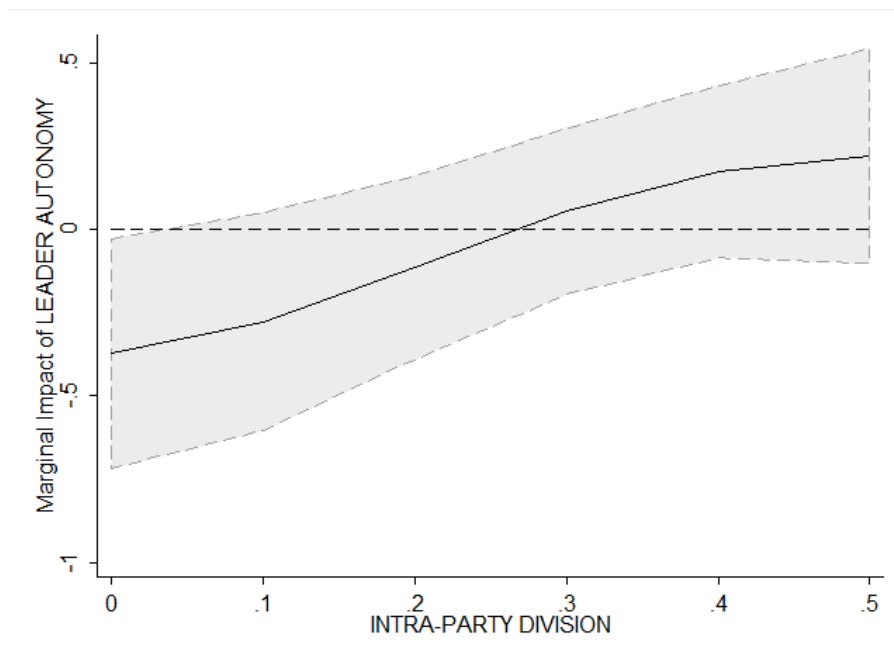

division growths.

Table 8.4: Marginal effect of Intra-party Division Conditional on Leader Autonomy

Figure 8.5: Marginal Effect of LEADER AUTONOMY on CABINET MEMBERSHIP as IPD Increases

Note: The light gray area represents the 95% Confidence Interval of the estimate

Whether this concerns portfolio allocation or the programme of the coalition government, strong leaders have the means to solve these quarrels keeping the party together. By granting more than proportional shares of posts to unsatisfied factions, the leaders can prevail upon minorities managing to

subscribe the coalition deal. In addition, autonomous leaders ensure that the whole party will be credibly committed to such deal. Furthermore, provided that we are dealing with divided parties, the higher degree of independence expressed by a solo head decreases the complexity of bargaining.

Along this line we can additionally hypothesize that, by reconciling divergent preferences, autonomous leaders are also able to decrease the time-span of such negotiation, as suggested by Mershon (1994). However we leave this statement opens for future researches.

On the other hand, autonomous leaders can enhance the chances to get in office even through their impact on intra-party decision making. In chapter 6 in fact we proved that autonomous leaders are free to set party position according to their wills, in particular when the new general elections are far-off. This means that when the coalition bargaining takes place in between two elections, leaders are completely unbounded and can choose a platform that enables them to build cartels and get in office.¹⁶ They also tend to adopt moderate positions (see footnote 23, chapter 6) closer to those of governments, thus decreasing the POLICY DISTANCE and enhancing the probability to get access to the ruling coalition.

To conclude, in table 8.5 we provide a more substantive interpretation of

¹⁶Remember that, due to the high instability rate of Italian cabinets, often coalition bargaining occurred far from the elections. This is true across the whole history of the First Republic but also during the Second Republic where, despite the existence of pre-electoral coalitions, several times the deal was reneged and renegotiated after the elections, leading to appoint governments supported by partners different from those who ran the election together (the so called *ribaltone*, majority reversal). For instance, after the 1994 elections, Berlusconi I Cabinet was replaced by Dini, supported by former opposition parties with the consent of LN (already in office during the previous government); between 1996 and 2001 Prodi I was dismissed and followed by three centre-left cabinets that included two parties previously out of office (the left-wing PDCI and the moderate UDEUR). Similarly, moving from Berlusconi II to Berlusconi III (between 2001 and 2006) two parties (NPSI and PRI) upgraded their status obtaining one minister each. Finally, after the 2008 elections Berlusconi IV Cabinet changed its majority (in 2010) and members belonging to the new coalition partners were appointed as junior ministers; in 2011 the government resigned and it has been replaced by the Monti Cabinet, supported also by some parties defeated during the 2008 elections.

CHAPTER 8. FACTIONS, FISSIONS, AND THEIR EFFECTS ON THE PARTY SYSTEM

the coefficients displayed in model 1 of table 8.3. We report the difference in probability to illustrate the deviation in the predicted probability of CABINET MEMBERSHIP due to a variation in each parameter (the values of all the other variables are set at their mean). We increase continuous variables by one standard deviation from the mean (which is the default) while we report the effect of a change from 0 to 1 for dummies. More polarized parties face a decrease in the probability of joining the government by 15%; being an incumbent party increases such probability by roughly 70%. Policy matters: when the party position lies far from the government ideal point the party is 12% less likely to be involved in the cabinet. Finally size matters as well: when its share of seats passes from 12% to 38% the party's chance to be in office rises by 23%.

Table 8.5: CABINET MEMBERSHIP. Difference in Probability

	Default	Increase	Diff. in Probability
INTRA-PARTY DIVISION	0.12	+0.17	-0.152* (0.081)
LEADER AUTONOMY	0	+1	-0.193 (0.131)

8.5 The Impact of Factions and Fissions on the Electoral Performance

The last element we are concerned with is related to the electoral performance of factionalism. So far we shown that intra-party division produces effects on policy-making and government formation. Here we want to assess if intra-party politics affects the electoral competition altering parties' share of votes. We will analyse two distinct effects: on one side the impact of internal division per se and, on the other hand, the whole effect of disunity that encompass the occurrence of party fissions.

Literature on party factions analysed their impact on the electoral arena raising two contrasting ideas. McAllister (1991: 218) retrieved this electoral hypothesis claiming that 'factions enable the party to present a broader policy appeal to voters at elections while still retaining a common party label'.¹⁷ This idea refers to the concept of catch-all parties (Kirchheimer 1966), that appeal to a wider electorate going beyond their traditional area of support. Growing intra-party differences allow factions to represent a broader extent of political opinions and this could be a way to maximise party's votes (McAllister 1991). However he found little support for this hypothesis and claimed that 'factions and tendencies do not help the party to present a broader appeal to the electorate' (McAllister 1991: 219).

Morgenstern (2001) go further supporting the idea that parties face a diminished likelihood of winning the election due to internal divisiveness. However he also recognize that some attributes of the electoral system might encourage an enlargement of the party ideological spectrum (through growing factionalism) to attract more votes.

Similarly it could be argued that higher levels of internal division allow

¹⁷For a similar view: Shepsle 1972. But see Alesina and Cukierman 1990.

the party to obtain nationwide benefits through votes of exchange (Katz 1985) or because of local intra-party competition due to preference voting (Wildgen 1985). On the other side, we claimed that party unity underpins the electoral value of party label thereby producing positive effects on its share of votes (Boucek 2003a; Laver 1999; McGann 2002; Snyder and Ting 2002). It is not by chance that, when establishing its platform, the party usually takes into account the stakes of all factions in order to present itself as a unified front in the eyes of the voters (Levy 2004), as shown in chapter 6: ‘Major parties [...] are complex structures held together by the fact that disunity means defeat’ (Schattschneider 1942).

We can assess which of these two claims holds true, testing whether intra-party division hurts the party in the electoral arena or, to the contrary, factionalism allows to appeal to a broader set of voters improving party’s electoral performance.

Hypothesis 8.5a: The greater the extent of intra-party division, the lower the share of votes gained by the party

Hypothesis 8.5b: The greater the extent of intra-party heterogeneity, the higher the share of votes won by the party

As far as internal polarization increases the likelihood of breakaways, we want to explore the net effect of division controlling for the occurrence of party fission.¹⁸ We carry out this analysis focusing on changes in party’s votes. Our dependent variables are ABSOLUTE CHANGE, the difference between party’s votes a time t (the first general election held after the congress) minus its votes

¹⁸Although in some cases a breakup might increase the clarity of the party label bearing a positive effect on its share of votes, we retain that, overall, fissions damage the party’s electoral strength entailing a loss of votes.

at time $t - 1$ (the last election held before it), and RELATIVE CHANGE that records the change in party's votes between time t and time $t - 1$, over party size measured at time $t - 1$.¹⁹

The total number of observations is 49, which is lower than the number of congresses (83) because of some missing data. When the party celebrates more than one congress between two subsequent elections we measure the impact of INTRA-PARTY DIVISION only within the last congress. Conversely when between one congress and the next the party contested more than one election we measure as dependent variables all its performances. When two (or more) parties contest one election together as an electoral cartel we compare their performance with the sum of votes gained by each of them in the previous (or in the following) election. For instance, after the merger between PSI and PSDI into PSU, in 1966, we compare PSU share of votes in 1968 with the sum of votes gained by PSI and PSDI in 1963.

The independent variables are: INTRA-PARTY DIVISION (IPD); FISSION, a dummy variable that takes value 1 if the party suffers a breakaway between one election and the next one; SPLINTER GROUP SIZE, a variable that measures the size of the splinter group, summing up the share of congress votes won by factions that leave the party before the next elections (we assigned the value zero when there are no breakaways); TIME IN OFFICE, the percentage of time the party spent in office during the Legislature until the elections.²⁰

¹⁹We are interested in the relative change too. For instance if a small party that retains 7% of votes shrinks by 2%, this loss could prevent it from passing a 5% threshold so that even a small absolute loss will be harmful for the party. On the contrary although a large party (40%) could be damaged by a 2% loss, it maintains a huge share of the electorate. Likewise, when measuring the impact of fissions we retain that a small party could be damaged by the breakaway of a faction representing roughly one third of its members (even though the splinter group's value in general elections equals 2%). On the contrary, in the same vein, a big party should be less (if not at all) concerned by the split of a minority faction whose contribution during general elections is estimated around 2% because this splinter group represents only 5 party voters out of 100.

²⁰The results do not change when counting the percentage of governments the party

We test our hypotheses by means of an OLS. We clustered observations by party, providing standard errors accordingly to deal with the issue of independence. The results are shown in table 8.6.

Table 8.6: OLS Regression of Change in Party Votes

	(1) ABSOLUTE CHANGE	(2) RELATIVE CHANGE	(3) RELATIVE CHANGE	(4) RELATIVE CHANGE
INTRA-PARTY DIVISION	-2.507 (4.473)	-0.379 (0.313)	-0.295 (0.311)	-0.300 (0.326)
FISSION	-2.882* (1.205)	-0.266** (0.079)		
SPLINTER GROUP SIZE			-0.835* (0.296)	-0.819* (0.279)
TIME IN OFFICE				0.062 (0.043)
CONSTANT	0.032 (0.648)	0.065 (0.061)	0.030 (0.063)	-0.004 (0.070)
Observations	49	49	49	49
R^2	0.212	0.175	0.116	0.126

Clustered standard errors in parentheses
 * $p < 0.1$, ** $p < 0.05$, *** $p < 0.01$

Although the coefficient of IPD is negative it does not appear to be significant. This result could mean that division entails contrasting effects none of whom is prevailing. On the contrary FISSION is negative and significant in both analyses. Parties hit by a breakaway suffer a relative decrease in their votes by 27% meaning that on average one voter out of four abandons the party after a fission. This effect is in part directly related to the breakaway, as long as supporters of the splinter group will probably abandon the party in the next elections. However there could be also an additional effect: the fission signals to the public the existence of a strong and potentially damaging divisiveness within the party. This might convey a decrease in voters' trust toward the party wielding additional losses of votes.

participated to (during the Legislature) or using a dummy variable to identify parties that were involved in the last government appointed before the elections.

The average size of splinter groups included in this analysis is equal to 21% whereas the average loss due to FISSION (according to model 2) was 27%. These two values are not statistically different, then we want to control this aspect by means of another variable, SPLINTER GROUP SIZE, that records whether the impact of a fission extends beyond the size of the splinter groups. From model 3 we note the existence of an almost one to one correspondence between the size of the splinter factions and the loss of votes suffered by the party.²¹ The coefficient tells us that any 10% increase in the share of votes of the splinter factions conveys a loss of 8.35% in party's votes. This seems to be the general trend, although there might be some deviations from this path.

Figure 8.6 plots the variation in party votes (RELATIVE CHANGE) along with SPLINTER GROUP SIZE for those parties that suffered a fission between the congress and the elections (we labelled observations using the party label and the year of the congress where the fission happened). We also report the linear fit between the expected values predicted from model 3 and SPLINTER GROUP SIZE (with a 95% confidence interval).

These results do not highlight any significant direct effect of intra-party division on the electoral performance of parties, even though they confirm that fissions matter. Any breakaway can potentially alter the electoral fortunes of a party in agreement with the idea (already discussed in chapters 5 and 7) that fissions are an always existing threat that could harm the party entailing a loss of votes. This is the reason why the mainstream should care about splinter groups' stakes. However as long as the (electoral) loss due to party breakup seems proportional to the strength of the splinter group (within the party body) party leaders might actually disregard the threat of small sized

²¹This holds when controlling for ruling parties, under the idea that a retrospective judgment over the incumbent government might have an impact on vote.

Figure 8.6: Comparison between Loss in Party's Votes and Size of the Splinter Group

Note: The light gray area represents the 95% Confidence Interval of the estimate

splinter groups (see chapter 5).

Note that this empirical correspondence between losses in party body and in the electoral arena could be an argument in favour of the resemblance between party activists and voters, contrary to what generally argued (e.g., May 1973). Either the voters withdraw their consent because of their linkage with the splinter groups (and if so, activists seem to be a good depiction of voters) or the party loses support because of the lack of credibility after the split. The former explanation seems more plausible given the data, although this topic deserves further investigation.

To conclude, as far as intra-party polarization increases the likelihood of a split (as shown in chapter 7), intra-party divisions might exert an indirect effect on party's electoral strength through their impact on party fission. Accordingly, we can argue that a lack of internal cohesion damages the value of party label; to avoid such loss the leadership will be more willing to whip

internal dissenters forcing them to break away (leaders can even send them off the party). In this sense the effect of intra-party division on votes could be considered much more straightforward.

8.6 Factions, Fissions, and the Party System: Findings

This chapter proved that it is worthwhile to study intra-party politics. Factional preferences and their reciprocal strength exert an effect on the party, and through the party on the system as a whole. In addition they play a role in many aspects of political life, like policy-making, government formation and electoral competition, altering the outputs of everyday politics.

First of all intra-party politics affects policies. There is an indirect effect: in chapter 6 we shown that factional preferences shape the intra-party equilibrium by altering the party platform. Besides there is also a direct effect: divided parties tend to be less cohesive during parliamentary votes (even if this result needs further investigation). Despite discipline, there seems to be a linkage between factional preferences and voting behaviour (Giannetti and Laver 2009). Hence in the legislative arena divergent factional preferences might affect the outcome of policy-making and the extent of policy change (note in fact that changing levels of party cohesion might help oversized coalitions to avoid the risk of gridlocks, see König 2006).

Intra-party politics affects office too. From chapter 5 we know that factionalism has an effect on internal portfolio allocation and that the threat of a party fission contributes to alter the share of payoffs providing an advantage to potential splinter groups. On the other side a large branch of literature underlined the role played by factions and fissions in government formation and

termination (e.g., with respect to the Italian case: Giannetti 2010; Giannetti and Laver 2001; Mershon 1994). The present chapter confirmed that growing intra-party struggles exert a direct effect on government formation, jeopardising party's chances of getting in office. This in turn will affect the whole party system altering its features and the potential outcomes (i.e., changing the members of the ruling coalition, the alliances, and presumably the legislation enforced by the cabinet). However our results seem to indicate that party organization attributes interact with factional preferences so that centralized parties with autonomous leader are more able to handle intra-party conflicts and protect party's chances of participating in the government.

Finally intra-party politics affects even votes, in a sense. Factionalism however seems to play only an indirect effect by increasing the likelihood of fissions, which are proved to be damaging for party's electoral fortunes.

Chapter 9

Conclusion

9.1 Preferences and Rules. What Matters Most?

Throughout the chapters we scrutinized several domains of intra-party politics to investigate the shape of internal dynamics. Our research question dealt with the impact of factional struggle on the party and the party system. We were interested in understanding how factions compete against each other and how they bargain to reach a compromise. We additionally investigated the failures of factional bargaining that lead to party break-up. Despite this work addressed disparate topics, ranging from position-taking to government formation, we kept some attributes constant throughout the chapters in order to investigate their effect across the whole dissertation. In particular we focused thoroughly on factional preferences and intra-party rules, to assess which one matters more. Here we report the main findings.

With respect to preferences, in chapter 3 we described the heterogeneity of factions' positions, then in chapter 8 we depicted a measure of intra-party division (IPD). As far as rules are concerned we provided in chapter 4 some descriptive statistics related to party statutes. Following the data presented in table 4.2 here we create an index that expresses, per each party, the average

level of internal representativeness (AIR), among the congresses included in the dataset.

This index could be considered as a proxy for the level of intra-party democracy. It has been measured as the weighted mean of representativeness granted by party statutes within each congress (see table 4.2). The weights correspond to the percentage of congresses held under a particular rule; more precisely we assigned value 1 to rules that provide a high level of representativeness (H), 0.5 to rules that express a medium level (M) and 0 when the representativeness is low (L). Therefore the maximum level of AIR is equal to 1 when the rules guarantee the highest degree of representativeness to the minorities (within all the congresses considered). In table 9.1 we report the mean value of AIR and IPD (over party) to describe the relation existing between statutes' rules and intra-party heterogeneity.

Table 9.1: Details about Internal Rules and Preferences: Mean Value of AIR and IPD within each Party

Party	AIR	IPD
AN	.50	.11
DC	.61	.20
DS	.75	.11
FV	.75	.26
MSI	.80	.16
NPSI	.75	.06
PCI	.83	.09
PD	.75	.15
PDA	.75	.29
PDCI	.50	.24
PLI	.61	.23
PRC	.88	.13
PRI	.66	.12
PS	.75	.16
PSDI	.92	.20
PSI	.90	.18
PSIUP	1.00	.12
UDC	.75	.13

Unsurprisingly the maximum level of AIR is reached by socialist parties like PSIUP, PSDI and PSI whose index ranges from .9 to 1.¹ Those parties

¹Within the Greens (FV) the AIR score is lower compared to our expectation, given that

considered internal democracy as one of the distinguishing traits of their political action.² This is particularly true for the PSDI that characterized itself for a great tolerance of internal dissent; indeed after the split from PSI in 1947 this party enacted the highest level of internal democracy, in contrast with PCI and PSI that were ruled through democratic centralism at the time (Curini and Martelli 2009, pp. 60-61). Similarly after PCI dissolution in 1991 the splinter group that created PRC enacted an high level of democracy as a strategy to differentiate from the PDS whose internal rules were more constraining (Giannetti and Mulé 2006).

On the other side of the continuum the two least representative parties within our sample are AN and PDCI: AN set apart from the democratic organization typical of its ancestor (MSI); the PDCI contrary to its ‘twin’ party, the PRC (who was instead familiar with the deliberative democracy promoted by the extra parliamentary left), supported a more orthodox left-wing position and organized itself according to the ‘democratic centralism’.

In figure 9.1 we compare statutes’ rules and factional preferences. For each congress, we plot the values of AIR and IPD along with the linear fit between the two variables.

This graph highlights that these two features of intra-party politics are truly

their internal life has usually been extremely democratic. Indeed from 1990 to 1993 the Greens did not elect any leader being ruled collectively by all members; since 1993 until 2000 they did not elect not a real leader but only a formal speaker; afterwards the speaker chair was turned into a typical party leader figure, directly elected, precisely to cope with the excessive decentralization of the party decision-making process. The two congresses included in our dataset are subsequent to 2000, hence the poor level of AIR registered in our data is due to the direct election of party leader and it is in line with the actual evolution of dynamics within this party.

²The PSI constitutes a partial exception in that it was sincerely democratic only between the 1960s (when the democratic centralism was completely removed) and the 1980s, when the Craxi personalized leadership restrained the room available for dissenters up to the point that one minority faction was sent off the party in 1981 (see footnotes 18 and 23, chapter 7). Noticeably (due to the methodological reasons explained in chapter 3) our data exclude almost all PSI congresses held in a less democratic environment.

Figure 9.1: Rules and Preferences as Two Independent Features

Note: Distribution of Intra-party Division (IPD) according to different levels of internal representativeness (AIR). The black line indicates the linear fit between the two variables

independent with respect to each other. Indeed their correlation is nearly null (-.05) and not statistically significant. In this sense we can turn to summarize the results of our analyses to assess which of these two attributes is the best predictor of party's behaviour and what is the most powerful factor that explains intra-party dynamics.

We will discuss the relevance of each element together with the impact of their interaction, across the various domains investigated in the empirical chapters. We distinguish between: intra-party formal rules (those reported in table 4.1); intra-party informal rules (i.e., PARTY AGE as long as loyalty is higher among older parties due to the logic of appropriateness, although repeated interactions may foster the emergence of cooperative norms);³ factional preferences (we sum up INTERNAL POLARIZATION, IPD and other related variables, like GAP and DISTANCE). We also pay specific attention

³See chapters 5 and 7 for a deeper discussion around this idea.

to the effects of the interaction between preferences and rules. In addition we account for other features, related to the party or the party system, which are widespread across the dissertation: party strength (PARTY SIZE), party status (whether or not in office, e.g., PARTY IN OFFICE), electoral system (caught by OPEN LIST and DISPROPORTIONALITY) and party competition (PARLIAMENTARY SUPPORT, YBE, PARLIAMENTARY CENTRE OF GRAVITY and MARGIN OF VOTES), even in interaction with LEADER AUTONOMY.

We sketch the effect of these variables across the 8 analyses carried out in the 5 empirical chapters (4 through 8). These analyses inspect the following domains of politics: CONTESTED CONGRESS (chapter 4); fractionalization (NOF, chapter 4); portfolio allocation (SHARE OF MINISTERS, chapter 5); party position-taking (PARTY POSITION, chapter 6); party fission and faction breakaway (FISSION chapter 7); party MPs cohesion in parliamentary voting behaviour (RICE, AI, MAI and AAI, paragraph 8.3); government formation (CABINET MEMBERSHIP paragraph 8.4); electoral performance (ABSOLUTE CHANGE and RELATIVE CHANGE, paragraph 8.5).

In table 9.2 we show whether each attribute has an impact on a specific field, no matter the direction and the magnitude of such effect. As an example, we do not care whether INTERNAL POLARIZATION increases or decreases fractionalization. We just want to record if the variable significantly impacts on the party or the party system. We draw any statistically significant effect (either positive or negative) through the sign “√” while attributes that are not statistically significant are marked by a “×”.

When comparing preferences and rules (as in table 9.2) we observe that the former seem to matter more while the effect of the latter is more contrasting. Indeed factional preferences affect almost all the domains of politics.

CHAPTER 9. CONCLUSION

Table 9.2: Impact of some Attributes on several Domains of Intra-party Politics

CHAPTER	4 Contest. Congr.	4 NOF	5 Portfolio Allocation	6 Position Taking	7 Fission	8.3 MPs Cohesion	8.4 Cabinet Formation	8.5 Party Votes
Formal Intra-party Rules								
Disproportional Rule	√/×	√	×

Democratic Centralism	√				√			
Direct Election	×	×	√	√	√/×		√/×	
Informal Intra-party Rules			×		√			
Factional Preferences		√	√	√	√	√/×	√	√/×
Preferences* Rules				√			√	
Party Size		√				√/×	√	
Ruling Party		√			√/×	√	√	×
Electoral System		√			√			
Competition			√	√/×				
Competition* Leader Autonomy			√/×	√	√			

Divergent intra-party preferences increase the number of factions, constrain the leader in the process of party position-taking and increase the likelihood of fissions. In addition they are taken into account in the process of portfolio allocation: powerful factions whose position lies far away from the bulk of party members tend to be strategically overpaid by the party leader in terms of office payoffs (to counterbalance their lower gain in policy payoffs). Beside shaping the party, factional preferences contribute to alter the party system too. Heterogeneous parties in fact have lower chances to get involved in coalition governments. Those parties seem to be also more divided during roll call votes, even though this effect is less clear and deserves further investigation. On the contrary heterogeneous preferences do not show any direct effect on party's electoral performance, even though they could damage party's share of votes by increasing the likelihood of fissions.

Factional policy preferences are indeed relevant in explaining intra-party politics. Although some scholars claimed that factions are interested mainly in office payoffs (Bettcher 2005; Golden and Chang 2001; Sartori 1976; Zuckerman 1975, 1979) we shown that factions care about policy too. Furthermore among ruling parties, where we should find 'factions of interests' concerned only with patronage, we observed that policy motivations still matter: heterogeneous preferences help to explain factionalism (chapter 4) and breakaways (chapter 7).

Rules seem to play a role as well. To start with, we ascertained the impact of the electoral system on intra-party fractionalization: open list and decentralized candidate selection increase the number of factions. They also affect party unity: disproportional systems act as disincentives for breakaways while preference voting enables to institutionalize factions decreasing the likelihood of splits. On the other hand, the impact of intra-party rules (both formal and informal ones) seems more indefinite. Only some of them do really affect

politics and sometimes these effects are unclear.

To start with we test the impact of informal rules. Due to repeated interactions in fact we would expect a greater degree of cooperation as time passes. When testing this claim we find contrasting results. Looking at portfolio allotment we did not find any increase in proportionality, contrary to what suggested by the cooperative argument. Our suggestion is that the effect of cooperative dynamics is counterbalanced by an increase in loyalty observed within older parties. Accordingly, after controlling for consensual portfolio allocation, we observe that the likelihood of fission is lower inside older parties. This effect, net of the logic of consequentiality related to cooperative dynamics or to the electoral value of party label, expresses the value attached to loyalty due to the logic of appropriateness developed during the militancy and strengthened by the partisans tie to symbols and party structure.

We turn now to consider the impact of rules prescribed by party statutes. First of all, disproportional internal electoral rules exert, within the party, the restrictive effect suggested by the Duverger's Laws about the party system. In fact they allow to halt party fractionalization decreasing the number of factions and the likelihood to observe contested congresses (even if this latter effect is less certain). However we do not register any further impact. In fact disproportional party environments do not alter the dynamics of portfolio allocation. Their effect within this domain is limited to adjustments in factions' size by transforming congress votes into party body seats. This could strengthen the mainstream decreasing the size of internal minorities, however there are no additional 'winner-take-all' dynamics beyond this point.

Other two elements related to party organization show an opposite degree of efficacy. The formal prohibition over the existence of factions does not retain significant effects on factionalism. Often this blurry rule was adopted but not really enforced. Parties in fact are voluntary associations (Rahat *et al.* 2008)

that set up their own rules and, in a sense, they are free to decide which ones to enact (Zincone 1972). Furthermore factional ban puts in place a prisoners' dilemma paradox: even if all subgroups agreed on dissolving themselves, none of them would be the first to demobilize. Although they acknowledge that the whole party could be better off without factions,⁴ each one also knows that its best strategy is to defect deciding to do not demobilize. In fact whenever its opponent was the first to dissolve the faction would benefit from an increase in its share of payoffs being able to exploit its growing bargaining power. We can consider portfolio allocation as an example. When one faction disappears, all the others increase their share of seats in party body, which in turn allow them to augment their relative share of ministers (as shown in chapter 5).⁵ As this feature is common knowledge, each faction will defect instead of complying and will not follow the rule.

On the other side, democratic centralism proved to be relevant in halting factionalism both ex-ante and ex-post: denying room for internal dissent, such undemocratic attribute decreases the likelihood of observing a contested congress so that dissent (if exists) remains latent. Democratic centralism in fact confines dissent only inside the party body. Once the conflict has materialized it is hard to keep it within tolerable levels. Whenever dissidents decide to challenge the mainstream during the congress the party is more likely to break-up; the minority group will be whipped, increasing the probability of a breakaway (or that of an expulsion). When internal disputes are brought on the outside, to the broad public, the minority faction will have no options other than exiting from the party.

⁴As described in paragraph 8.4, for instance, internal heterogeneity decreases the likelihood of being involved in coalition governments reducing the whole amount of office payoffs available to the party in the long run.

⁵Note that an organized faction, being able to mobilize its members and supporters, would probably gain more votes during the congress than an ad-hoc tendency that was born only few weeks before the internal election.

The last attribute provided by party statutes concerns the role of party leader. We investigated whether her direct election, which increases leader's degree of autonomy establishing a different intra-party environment. Overall leader autonomy seems to matter, and its effects are very relevant in shaping the party. In some cases however these upshots are not directly yielded by this rule. The method for selecting the leader proved to be important in interact with other elements and in particular with factional preferences. To begin with there is an impact on the patterns of portfolio allocation. Our findings demonstrate that the direct legitimacy allows leaders to distribute payoffs on their own, decreasing the degree of proportionality in portfolio allocation. They are able to reward their followers increasing the share of ministers assigned to their faction, even if we found only limited support for this claim. Conversely there is clear evidence for the interaction between leader autonomy and factions' policy positions. Independent leaders can revert to office allotment as a strategy to preserve party unity, preventing (credible) breakaways carried out by strong minorities. Indeed powerful minority factions are overpaid when office payoffs are distributed by autonomous leaders.

This feature interacts with preferences. As the distance between one faction and the party's ideal point enlarges, the likelihood of its breakaway increases. The leaders face this credible threat by catering potential splinter groups with greater amounts of office rewards to compensate their lower share of policy payoffs.

Leader's autonomy and factional preferences interacts indeed. Beside portfolio allocation, this interaction involves also the process of party positioning, as we discussed in chapter 6, where we proved that leaders are able to exploit their direct legitimacy to get rid of factional constraints. In fact the impact of factional ties is no longer significant among parties whose leaders are directly elected, unless looming elections boost the need for party unity,

bringing them to partially heed minorities' stakes. In general however leaders are less bounded in choosing the party line so that they can set more moderate positions that prove useful to build 'cartels', enhancing leaders' chances to get in office.

Actually we did not find a direct positive impact of leader's autonomy on the likelihood to be involved in a coalition government, however several results proved the existence of an indirect impact. First of all autonomous leader are indeed able to set moderate positions that increase the probability to get in office (see for instance model 4 in table 6.2 and footnote 23, chapter 6). Moreover greater autonomy allows leaders to halt the negative impact of intra-party heterogeneity on cabinet membership. Although internal divergent preferences harm the party's chances to get involved in a coalition government, this effect ceased to be significant among parties ruled by autonomous leaders. Indeed strong leaders solve the problem of credible commitment generated by heterogeneous factional preferences. Being more autonomous they can enact strategies to solve internal disputes, for instance through a strategic allocation of portfolios that erases any potential dissatisfaction bringing all the factions to strike the coalition deal. In this way fractionalization does no longer reduce party's probability to reach an agreement to enter the cabinet.

We did not register any direct impact on fractionalization. The only effect concerns the decrease in divisiveness observed within personal parties. Here leader's autonomy reaches its peak and the whole party shows a stronger degree of cohesion and loyalty toward leader's choices.

To conclude, direct election per se does not play a role in preserving party unity while its effect is conditional on party system competitiveness.⁶ Overall

⁶Low competitive conditions decrease the likelihood of splits among parties ruled by constrained leader, while they promote breakups when leader autonomy enlarges. The party systems and party competition retain also other effects on factionalism. Apart from pushing autonomous leaders to adopt moderate vote maximizing positions, as discussed above, we observed that looming elections strengthen the need for party unity, increasing the incentive

we did not find differences between autonomous and constrained leaders. However when controlling for competitiveness we observe that autonomous leaders raise the likelihood of breakaways under low competitive systems, where the need for unity is lower and leaders are more concerned with enhancing cohesion or rewarding their followers to remain in power. Conversely, when unity is an issue at stake leaders may take advantage of their autonomy to reward potential splinter groups thus contributing to keep the party together,⁷ like leaders bounded by inter-factional ties do.

Table 9.3 helps to summarize these findings focusing on the interaction between preferences and rules. It describes, in brief, the different intra-party dynamics existing in parties ruled by autonomous or constrained leaders.

Table 9.3: Differences in Intra-party Dynamics. Comparison between Parties Ruled by Autonomous or Bounded Leaders

Party Leader	Portfolio Allocation	Position-taking	Fission	Government Formation
Bounded	Proportionality Overpay followers in low competitive party systems	Tied to factional preferences	Preserve unity (through consensual dynamics)	Lower chances to get in office due to intra-party division
Autonomous	Lower Proportionality (particularly in low competitive party systems) Overpay potential splinter groups (as a strategy to avoid breakaways) Overpay followers	Factional preferences matter only when elections approach Free to set moderate positions (to build cartels)	Boost breakaways in low competitive party systems Prevent splits through portfolio allocation (under high competitive conditions)	Solve factional divergences preserving party's chances to join the coalition Enforce commitment Simplify the bargaining

to set a platform on which all party factions may agreed. This incentive however seems larger among leaders bounded by factional constraints, as discussed in chapter 6. Moreover, low competitive conditions increase leader's discretionality in portfolio allocation providing advantages for the mainstream faction (chapter 5). See paragraph 9.2 for a summary of the interactions between party system competitiveness and leader autonomy.

⁷They actually try to do it (see chapters 5 and 6) and their attempts are successful (as shown in chapter 7).

This summary explains that, overall, constrained leaderships tend to be more associated with a sense of justice, in that all the payoffs are distributed to each faction according to its strength although, when feasible, even bounded leaders try to exploit a degree of discretionality. Consensual dynamics however does not necessarily provide advantages to the party insofar as internal divisions seem to decrease the likelihood to get in office, lowering the total amount of payoffs available to party factions.

Autonomous leaderships, on the contrary, tend to be more effective in ruling the party; although we might find less proportional intra-party dynamics that increase the splits in low competitive party systems, independent leaders can easily allocate payoffs strategically, preventing harmful fissions and reducing the disadvantages faced by divided parties during coalition bargaining. Moreover, they are able to take advantage of their position using discretionality to reward their followers and to build cartels, boosting the probability to participate in the ruling coalition.

9.2 Findings and Implications

Going back to the game-theoretic model discussed in chapter 2, here we resume the expectations generated by our theory to compare them with the empirical findings of the analyses. By doing this, we can try to validate or deny the general claims and we can make some final statements about the implications of the present dissertation. Retrieving the parameters connected with our theoretical framework sketched in table 2.3, table 9.4 compares their expected and observed impact on three areas of intra-party politics. We try to assess if, and to what extent, our theory helps to understand the actual inter-factional dynamics on factionalism (*voice*, chapter 4), payoffs allocation (*compromise*, chapters 5 and 6) and party fission (*exit*, chapter 7).

Table 9.4: Validation of Theory

Parameter	Description	Voice		Compromise		Exit	
		Exp.	Obs.	Exp.	Obs.	Exp.	Obs.
ε	Exit cost	-	-	-	-	0	-
π	Trade-off	+	+	+	+	+	+
ω	Breakup cost	+	n.a.	+	+	-	-
ν	Voice cost	-	-	-	0/-	+	+
AL	Autonomous leader	0/-	0/-	-	-	+	0
AL* ω	- in competitive system	0/-	n.a.	+	+	-	-
BL	Bounded leader	+	0	+	+	-	-

Impact of the parameters derived from the game-theoretic model (chapter 2)
Comparison between expected (Exp.) and observed effects (Obs.)

Voice – Factionalism, chapter 4. The ‘party unity and party fission’ game and the theoretical framework developed around the degree of leader autonomy have been conceived mainly to explore distributive dynamics that prevent splits, thus contributing to keep the party together. However the model produces implications also about the expression of internal dissent and the related degree of factionalism. On this point the model yields expectations that have been partially confirmed by the empirical test of hypotheses carried out in chapter 4.

First of all, growing exit costs (ε) due to a strong party loyalty lessen factionalism. This happens for instance among personal parties, whose members are so firmly tied to their leader’s thoughts that nobody tries to contest the congress (minorities avoid to issue a challenge because they have no realistic option apart from compliance). Larger values of π raise the level of division. Inside polarized parties a broader number of factions will be dissatisfied with the status quo. Polarization in fact increases the cost of membership and decrease the value of party label. Internal subgroups will be more likely to revert to voice as a device to enhance their own policy views and as an attempt to bargain more favorable conditions by threatening to defect. In line with the theory an increase in ν lowers voice. This happens for instance due to disproportional internal rules or to centralized (closed list) and undemocratic

structures (such as democratic centralism). Conversely preference voting provides opportunities for the persistence and propagation of factions.

While a branch of literature conceive factions as ‘power subgroups’ that proliferate inside ruling parties to exploit the benefits of patronage, our theoretical model contends that, for the sake of preserving cohesion and government effectiveness, parties in office tend to be less factionalized. The empirical results outlined in chapter 4 seem to confirm this argument as long as the number of factions is lower among ruling parties.

Contrary to our assumptions, the ban on factions does not help to decrease their number. This rule could be too faint to be enacted. Moreover even if members agreed on dissolving factions none of them would be the first to demobilize, in accordance with a prisoners’ dilemma logic.

To conclude, although we claimed that direct election of party leader should decrease voice we did not find any effect of leader autonomy on the number of factions (apart from that related to personal parties). As far as direct election fosters leader’s strength in front of middle-level activists, one possible explanation is that a larger number of potential challengers will contest the leadership, to take advantage of the larger autonomy, while other factions will gather together to increase the chances of winning the nomination, so that the overall effect is null.

Compromise – Payoffs allocation, chapters 5 and 6. As far as portfolio allocation is concerned, with a couple of exceptions all the other suggestions provided by our model seem validated.

The literature on this topic argues that repeated dynamics foster the emergence of intra-party cooperative norms, leading toward a more proportional allotment of cabinet posts. Contrary to this general idea we assert that, as time passes, the price for infringed loyalty (ε) grows thus defusing the blackmail power of minorities and reducing the room for compromise. In chapter

5 we observe that the effect of time on distribution dynamics is null and we claimed that none of these two stimuli is prevailing. Although this upshot is not in line with our expectation we contend that the impact of exit costs on portfolio allocation is still there, as the effect of loyalty counterbalances that of cooperation. Accordingly, this result does not utterly contradict our theory (in chapter 7 we also provided additional arguments sustaining this idea).

Along the same vein, chapter 5 indicates that an increase in ν (due to disproportional rules enacted within parties whose leadership wants to promote cohesion) has no effect on fairness. However, disproportional intra-party rules exert ‘per se’ mechanical (and probably psychological) unfair effects, reducing the size of minority factions with respect to party mainstream. In this sense they already convey a decrease in proportional dynamics. Beyond this point however any additional ‘winner-take-all’ effect should be countervailed by an increase in π , as long as minority factions are underrepresented and could credibly threaten to break apart. This will foster their leverage leading to an overall null effect on allocation dynamics.

The relevance of π on this point finds additional confirmation in the analysis: medium-sized minority factions, whose distance from party mainstream is wide, are overpaid in terms of ministers. Their lower amount of policy payoffs (which boosts π and provides them with a credible exit threat) is balanced by an increase in their share of office payoffs, though only when their size is large enough to pose a threat to party strength (raising ω).

In accordance with that, the analysis proves that large values of ω enhance proportionality in portfolio allocation whereas in low competitive parliamentary arenas (low ω) the party leader tends to reward the mainstream faction with a more than proportional quota of ministers.

The impact of leader autonomy too is in line with the suggestion proposed by the theory: the degree of proportionality is lower among parties ruled by

autonomous leaders who try to overpay their own faction more than bounded leaders are able to do. However this is no longer true when party system competitiveness boosts the need for party unity. In such context autonomous leaders step back to a fair allocation of portfolios or take advantage of their autonomy to overpay those factions whose threat of breakaway is credible and harmful.

These two latter findings, related to leader autonomy and party system competitiveness, are confirmed by the results displayed in chapter 6. In the process of position-taking, constrained leaders have to consider the policy views of all factions while autonomous leaders are free to set party position on their own (and in fact tend to adopt platforms closer to the centre of the policy space, increasing the possibility to build cartels to take part in coalition governments). On the other side, when new general elections approaches the need for party unity (ω) sharply increases. In view of that, the leadership sets party platform taking into account the wills of all factions with a stronger degree of consensualism.

Furthermore, in line with the propositions drawn from chapter 2, we observe that these two features interact: although autonomous leader are free to get rid of factional preferences, looming elections force them to bargain with internal minorities to reach a compromise over party platform, in order to appeal to the votes presenting a unified front.

These empirical results confirm the idea suggested by our theory: the need for party unity, enhanced by competitive party systems (wide ω), is indeed the primary source of factional cooperation and promotes the achievement of a compromise between party factions.

Exit – Party fission, chapter 7. With respect to the determinants of factional breakaways, almost all the hypotheses formulated from the model presented in chapter 2 have been successfully tested. To start with, when ν

growths we would expect more splits. Indeed centralized candidate selection procedures (such as closed list PR) and severe party discipline (i.e., democratic centralism) push dissenters outside the party.

Noticeably those elements that raise the cost of exit (ε) lower the probability of a fission. We found support for the effect exerted by disproportional electoral systems, which act as barriers to exit. In addition party loyalty plays a role: the partisan tie to symbols and party structure restraints members from breaking away. When ε is larger than π dissenting members would rather stay within the party even if their share of payoffs is unsatisfactory.

Conversely large values of π favor the occurrence of party splits. Factions that are strongly underpaid can reasonably expect to increase their rewards by leaving the party (net of the price of ε). In chapters 7 we proved that this is true for office as well as for policy payoffs. In addition, the level of party system competitiveness impinges on the rate of π : overall, low competitive conditions cut the incentive to leave the party.

However this last attribute interacts with leader autonomy and with leader attitude towards unity or cohesion, which in turn is influenced by the cost ω . Autonomous leaders in fact take advantage of non-competitive party systems (small ω , small π) to get rid of internal minorities and overpay their supporters. As a result they boost the leverage of minorities (increase in π) while ω is fixed at low levels, raising the probability of a split (this is no longer true inside parties ruled by bounded leaders that have to stick to a coalition deal, see footnote 8, chapter 5).

Contrary to our claim we do not find an effect of leader autonomy ‘per se’, however its impact is conditional on the features of party system: autonomy favors an increase in exit when party system competitiveness decreases. Under such environments in fact party leaders trade unity for cohesion. This seems particularly true among parties in office; for the sake of promoting government

effectiveness, ruling parties tend to get rid of dissenters enhancing cohesion at the expense of party unity (see footnotes 33, 40 and 44, chapter 7). This result in turn seems to revitalize the idea of party conceived as a minimum winning coalition of factions (Leiserson 1968).

Overall almost all the hypotheses generated from the model find confirmation. Among the 21 propositions that can be derived from table 2.3 we were able to test 19 of them. Looking at table 9.4 we found a full confirmation of our claims in no less than 15 cases. In other two (the impact of loyalty and disproportional internal rules on payoffs allocation) we observed an indirect support while in two cases only we report no effect, contrary to what hypothesised (bounded leaderships do not appear to boost factionalism and autonomous leaders, ‘per se’, do not encourage breakaways). Then, this empirical test carried out across the chapters seem to provide a first validation for the theory discussed in chapter 2.

The present work also shed light on the interaction between intra-party politics and party system. From the empirical results discussed in chapter 8 we observe that factional politics affects several areas of political life, from policy-making to government formation and electoral competition. Apart from the indirect effect exerted by factions on party platform and payoffs allocation, intra-party heterogeneity seems to yield more direct effects on the party system. In particular, it affects party cohesion during roll call votes and jeopardizes party’s chances to get in office (unless a centralized leadership nullifies the negative effects of internal polarization). In addition, intra-party division may also damage the party in the electoral market when the internal strife erupts in a party fission (which in turn alters party system fragmentation, polarization and competitiveness). To sum up, intra-party politics impacts on policy change, political stability and government effectiveness.

Far from any prescriptive intent, the results of this work drawn some impli-

cations that involve real world politics. A deeper knowledge about intra-party divergent preferences and the effects of internal rules in fact might lead to a better understand of factional bargaining and intra-party dynamics. Though future researches should shed more light on our findings, we can fix some points (summarized in table 9.5) that should be taken into account by political engineers.

Table 9.5: Pros and Cons of Political Institutions Reforms

Feature	Pros	Cons
Preference Voting	– Fragmentation – Fission	+ Factionalism – Cohesion
Disproportional Electoral System	– Fragmentation – Fission – Blackmail	– Accountability
Discipline and Whip	– Factionalism + Cohesion	+ Fragmentation + Fission – Accountability
Leader Direct Election	– Blackmail + Effectiveness	+ Bonapartism

Italy has long been dealing with political instability. The country faces an astonishing fractionalization insofar as to the high number of parties corresponds an equally deeper degree of intra-party divisions. Nonetheless, any attempt to reduce the number of parties has to deal with the peril of a growing factionalism. As discussed in chapter 7, such efforts could be even neutralised when party fusions are followed (or anticipated) by fissions.

On the other side, merging together groups that retain conflicting preferences might enhance rivalries between an increased number of factions (chapter 4), boosting instability in government negotiations and in the parliamentary arena (paragraphs 8.3 and 8.4) or even leading to splits that cancel out the initial decrease in party fragmentation. In this sense any attempt of reform should include adjustments in rules that enable to keep factionalism under control while preserving party unity.

Electoral systems based on preference voting end up undermining the monolithic party structure, fostering factionalism and internal competition (chapter 4). Conversely, PR based on closed list along with centralized selection of candidates and party lists could contain the proliferation of factions but will dramatically amplify the probability of party splits raising the number of parties and increasing the instability in parliamentary arena. Disproportional electoral rules instead prove to be effective in decreasing party fragmentation while taking factionalism under control by avoiding the risk of degenerative intra-party conflicts.

Altering intra-party statutes in turn could be another way to promote changes in the political system, even though the impact of some rules is negligible. Far from playing a direct effect on factionalism some attributes may contribute to foster loyalty, discipline and cohesion while avoiding the risk of splits.

One of such features is the direct election of party leader, which proved to be successful in keeping factions on a leash (chapter 6 and paragraph 8.4) without any negative effect on party unity (at least in competitive party systems). This reform emerges as a unifying factor providing the same effect played by the introduction of primaries for candidate selection, though for opposite mechanisms.

While primaries seem to mitigate the discontent of minorities leading to more consensual dynamics (Hortala-Vallve and Mueller 2011) the direct election of leaders strengthens their autonomy in spite of dissenters. This might bring to cooperative dynamics whenever minorities are strong enough to threaten party unity (chapter 5). However an autonomous and charismatic leader might also exploit her privileged status (Michels 1911) to get rid of internal opposition, as described in chapter 6, transforming the party in her personal property (Calise 2010).

Along the same vein, institutional reforms must not restore forms of party system dominance, preserving high levels of party system competitiveness. Besides several positive effects (for instance on corruption, e.g., Schleiter and Voznaya 2011) competitiveness, by fostering the need for party unity, brings autonomous leaders to engage in consensual and fair intra-party dynamics, looking for a compromise that takes into account the stakes of all the party members.

In this sense the need for a more stable political system should not be detached from the demands for more democracy, accountability and representativeness in intra-party politics. Nonetheless intra-party democracy in some cases turns out to be only a strategy to defang the activists (by formally empowering party members) instead of granting a real representativeness to members' stakes.

That said, it does not matter whether democracy should exist even within the parties or not, or whether system stability should be a priority in spite of members' representativeness. The question is how to find the better trade-off. To achieve it politicians must take into account the relevance of internal preferences and the potential impact of intra-party rules.

9.3 Direction for Future Research

Reading all the way through the chapters we note that the present analysis provides an exhaustive and detailed discussion of intra-party dynamics covering several domains of politics (as described in paragraph 1.3). Nevertheless we left aside some topics that are linked to our work, even though their analysis might lie beyond the scope of this dissertation. We will briefly recall some of them in order to build bridges for future researches.

First of all, the whole analysis is carried out considering only a single di-

mension. Although this idea seems plausible as we already argued in chapter 6 (e.g., Budge *et al.* 2010), it would be profitable to account for factional bargaining in a multidimensional policy space. This would be relevant to map the conflict inside highly heterogeneous parties, like the PD, or to understand the cooperation among factions that shared the same preferences on a unique or several policy dimensions. For instance the attitude towards social policy existing within the DC, related to the common linkage with the Catholic Church, could have been a source of party unity that counterbalanced contrasting views on other dimensions. Something similar might concern single issue parties like the Greens or the Northern League.

In this regard it would be of use to map policy heterogeneity and subgroups' membership even within parties that usually hold unitary congresses or do not hold congresses at all. In this way we can compare internal dynamics to check whether divergent preferences, although non publicly expressed, contribute to shape the party or if, to the contrary, minority's claims are not taken into account at all.

On the same vein, starting from the analysis of intra-party dynamics, future works might contribute to the literature on intra-party democracy. Deepening our examination of party statutes new studies might improve on, building an index that measures the internal degree of democracy that takes into account all the attributes provided by party rules (including candidate selection procedure). This index in turn could prove useful to analyze political accountability comparing different party systems and to explain the level of citizens' satisfaction within each of them.

As far as intra-party democracy is concerned future researches should improve the study of leadership developing valid measures of leader's strength; this will allow to analyze intra-party politics as an interplay between party leader, factions and grassroots, where the leader can be challenged by internal

rivals (on this point the analysis of intra-party negative campaigning would be of interest).

Along the same line, party primaries deserve more attention. Assuming that leaders face challengers, we might want to evaluate whether intra-party politics follows the logic of the selectorate theory (Bueno de Mesquita *et al.* 2003; see also Clark *et al.* 2011). In this sense, as far as factional politics might require small winning coalition, we contend that an increase in the size of the selectorate (from small committees to party members) conveys unfair allocation of private goods (payoffs) and we found empirical evidence sustaining this idea. Accordingly, when moving from leaders elected in small committees (where each member could pivot between alternative potential leaders in order to claim a fair share of payoffs) to leaders selected by party members (even through closed primaries) we would expect to find more autonomy and a lower amount of public good (party unity).

Our results are indeed in line with this theory. Accordingly we claimed that, as far as intra-party politics is concerned, a small selectorate could be more promising in terms of accountability and fairness than a large selectorate and direct democracy (unless party system competitiveness, i.e., challengers coming from outside the party, makes autonomous leaders compromise-oriented too).

Although we claim that party primaries have a negative impact on intra-party representativeness, our data do not allow to control for potential differences between closed and open primaries. By appealing to a widespread target and increasing the heterogeneity of the whole ‘population’, open primaries could also enlarge the size of the winning coalition (while closed primaries do not). This might strengthen party unity (the public good, Hortalá-Vallve and Mueller 2011) and enhance fairness in payoffs allocation (the private goods) wielding positive effects in term of intra-party competitiveness and responsiveness (but see Katz 2001). Hence we strongly recommend to extend the research

carried out by this work investigating the actual impact of open primaries on intra-party equilibriums.

Across the chapters, a couple of results were quite ambiguous. One concerns the impact of factionalism on MPs voting behavior, which deserves further investigation to better understand the role of factions as veto players, and to assess which one among preferences and discipline is the key explanatory element for factional voting behavior. In this sense matching text analysis and roll-call data might lead to a better estimation of actors' policy positions. Roll-calls could be even more useful to map preferences in parties whose congresses are uncontested.

In turn the effect of party system competitiveness and dominance deserves should be deeper investigated in a dynamic setting. Moreover the effect of heterogeneous preference on voters' choice and the linkage between activists and voters during party fissions need additional examination.

In the present work we left aside a few additional analyses. The work on government formation could be deepened considering for instances how factional disputes delay the duration of bargaining (Mershon 1994) and how they affect budget policies and the distribution of outlays. Similarly it would be interesting to deepen the studies on factional politics, linking preferences and internal rules with pork barrel, patronage and corruption (e.g., Golden and Chang 2001). In the same way we should take into account factionalism and internal dynamics within a *core* party (Bogaards and Boucek 2010; Boucek 2012). Finally, factionalism could be analyzed to explain party formation and termination.

Although the present dissertation is related to a single country, the findings of our analysis and the empirical implications of our theoretical model provide novel insights that allow to better understand intra-party dynamics in countries where factional politics matters. Among them we find Japan, France and

many other political systems, but also, to a certain extent, Germany and the UK (as discussed in chapter 1). However, in order to generalize our claims, the present work could be developed and extended to other single case studies. Furthermore, future researches should be carried out in a comparative perspective that investigates the shapes of factionalism and intra-party dynamics within different parties and party systems.

Appendix A

List of Italian Parties with Acronyms and Abbreviations

Label	English Name	Original Name
ADN	National Democratic Alliance	Alleanza Democratica Nazionale
AN	National Alliance	Alleanza Nazionale
API	Alliance for Italy	Alleanza per l'Italia
CCD	Christian Democratic Centre	Centro Cristiano Democratico
CD	Democratic Rally	Concentrazione Democratica
CDR	Christian Democrats for the Republic	Cristiani Democratici per la Repubblica
CDU	Unified Christian Democrats	Cristiani Democratici Uniti
DC	Christian Democratic Party	Democrazia Cristiana
DL	Democracy is Freedom – The Daisy	Democrazia è Libertà – La Margherita
DN	National Democracy	Democrazia Nazionale
DS	Democrats of the Left	Democratici di Sinistra
FI	Forward Italy	Forza Italia
FDP	Popular Democratic Front	Fronte Democratico Popolare
FDS	Force of the South	Forza del Sud
FLI	Future and Freedom for Italy	Futuro e Libertà per l'Italia
FV	Federation of the Greens	Federazione dei Verdi
IDV	Italy of Values	Italia dei Valori
LDS	Socialists' League	Lega dei Socialisti
LN	Northern League	Lega Nord
