#### Abstract

In this paper we introduce the notion of Einstein-type structure on a Riemannian manifold ( $M, g$ ), unifying various particular cases recently studied in the literature, such as gradient Ricci solitons, Yamabe solitons and quasi-Einstein manifolds. We show that these general structures can be locally classified when the Bach tensor is null.

## 1. Introduction and main results

In the last years there has been an increasing interest in the study of Riemannian manifolds endowed with metrics satisfying some structural equations, possibly involving curvature and some globally defined vector fields. These objects naturally arise in several different frameworks; the most important and well studied examples are Ricci solitons, see, e.g., [Hamilton 1988; Perelman 2002; Ni and Wallach 2008; Naber 2010; Cao and Chen 2012; Brendle 2013] and references therein. Other examples are, for instance, Ricci almost solitons [Pigola et al. 2011], Yamabe solitons [Daskalopoulos and Sesum 2013; Cao et al. 2012], Yamabe quasisolitons [Huang and Li 2014; Wang 2013], conformal gradient solitons [Tashiro 1965; Catino et al. 2012], quasi-Einstein manifolds [Kim and Kim 2003; Case et al. 2011; Catino et al. 2013; He et al. 2012], and $\rho$-Einstein solitons [Catino and Mazzieri 2016; Catino et al. 2015].

In this paper we study Riemannian manifolds satisfying a general structural condition that includes all the aforementioned examples as particular cases, in order to hopefully provide a useful compendium that also gives a summary and unification of classification problems thoroughly studied over the past years.

[^0]Towards this aim we consider a smooth, connected Riemannian manifold ( $M, g$ ) of dimension $m \geq 3$, and we denote by Ric and $S$ the corresponding Ricci tensor and scalar curvature, respectively (see the next section for the details). We denote by Hess $(f)$ the Hessian of a function $f \in C^{\infty}(M)$ and by $\mathscr{L}_{X} g$ the Lie derivative of the metric $g$ in the direction of the vector field $X$. We introduce the following:

Definition 1.1. We say that $(M, g)$ is an Einstein-type manifold (or, equivalently, that $(M, g)$ supports an Einstein-type structure) if there exist $X \in \mathfrak{X}(M)$ and $\lambda \in C^{\infty}(M)$ such that

$$
\begin{equation*}
\alpha \operatorname{Ric}+\frac{\beta}{2} \mathscr{L}_{X} g+\mu X^{\mathrm{b}} \otimes X^{\mathrm{b}}=(\rho S+\lambda) g, \tag{1-1}
\end{equation*}
$$

for some constants $\alpha, \beta, \mu, \rho \in \mathbb{R}$, with $(\alpha, \beta, \mu) \neq(0,0,0)$. If $X=\nabla f$ for some $f \in$ $C^{\infty}(M)$, we say that $(M, g)$ is a gradient Einstein-type manifold. Accordingly (1-1) becomes

$$
\begin{equation*}
\alpha \operatorname{Ric}+\beta \operatorname{Hess}(f)+\mu d f \otimes d f=(\rho S+\lambda) g, \tag{1-2}
\end{equation*}
$$

for some $\alpha, \beta, \mu, \rho \in \mathbb{R}$.
Here $\mathfrak{X}(M)$ denotes the set of smooth vector fields on $M$ and $X^{b}$ the 1-form metrically dual to $X$.

We note that, from the definition, the term $\rho S$ could clearly be absorbed into the function $\lambda$. However, we keep them separate in order to explicitly include and highlight the case of $\rho$-Einstein solitons.

In the present paper we focus our analysis on the gradient case.
Leaving aside the case $\beta=0$ that will be addressed separately, see Proposition 5.7, we say that the gradient Einstein-type manifold $(M, g)$ is nondegenerate if $\beta \neq 0$ and $\beta^{2} \neq(m-2) \alpha \mu$; otherwise, that is if $\beta \neq 0$ and $\beta^{2}=(m-2) \alpha \mu$, we have a degenerate gradient Einstein-type manifold. Note that, in this last case, necessarily $\alpha$ and $\mu$ are not null. The above terminology is justified by the next observation:
$(M, g)$ is conformally Einstein

## 企

$(M, g)$ is a degenerate, gradient, Einstein-type manifold, for some $\alpha, \beta, \mu \neq 0$.

For the proof and for the notion of conformally Einstein manifold see Section 2.
In case $f$ is constant we say that the Einstein-type structure is trivial. Note that, since $m \geq 3$, in this case $(M, g)$ is Einstein. However, the converse is generally false; indeed, if $(M, g)$ is Einstein, then for some constant $\Lambda \in \mathbb{R}$ we have Ric $=\Lambda g$ and inserting into (1-2) we obtain

$$
\beta \operatorname{Hess}(f)+\mu d f \otimes d f=(\rho S+\lambda-\Lambda \alpha) g .
$$

Thus, if $\rho \neq 0,(M, g)$ is a Yamabe quasisoliton and $f$ is not necessarily constant (see [Huang and Li 2014; Wang 2013]).

We will also deal with the case $\alpha=0$ separately, see Theorem 1.4. We explicitly remark that, from the definition, $\alpha$ and $\beta$ cannot both be equal to zero.

As we have already noted, the class of manifolds satisfying Definition 1.1 gives rise to the previously quoted examples by specifying, in general not in a unique way, the values of the parameters and possibly the function $\lambda$. In particular we have:
(1) Einstein manifolds: $(\alpha, \beta, \mu, \rho)=(1,0,0,1 / m), \lambda=0$ (or, equivalently for $m \geq 3, \rho=0$ and $\lambda=S / m)$.
(2) Ricci solitons: $(\alpha, \beta, \mu, \rho)=(1,1,0,0), \lambda \in \mathbb{R}$.
(3) Ricci almost solitons: $(\alpha, \beta, \mu, \rho)=(1,1,0,0), \lambda \in C^{\infty}(M)$.
(4) Yamabe solitons: $(\alpha, \beta, \mu, \rho)=(0,1,0,1), \lambda \in \mathbb{R}$.
(5) Yamabe quasisolitons: $(\alpha, \beta, \mu, \rho)=(0,1,-1 / k, 1), k \in \mathbb{R} \backslash\{0\}, \lambda \in \mathbb{R}$.
(6) conformal gradient solitons: $(\alpha, \beta, \mu, \rho)=(0,1,0,0), \lambda \in C^{\infty}(M)$.
(7) quasi-Einstein manifolds: $(\alpha, \beta, \mu, \rho)=(1,1,-1 / k, 0), \lambda \in \mathbb{R}, k \neq 0$.
(8) $\rho$-Einstein solitons: $(\alpha, \beta, \mu, \rho)=(1,1,0, \rho), \rho \neq 0, \lambda \in \mathbb{R}$.

Of course one may wonder about the existence of Einstein-type structures. We know from the literature positive answers to the various examples that we mentioned earlier. For the general case we can consider three different necessary conditions. The first two are the general integrability conditions (4-5) and (4-6) contained in Theorem 4.4 below. The third comes from the simple observation that, in the case $\mu \neq 0$, tracing (1-2) and defining $u=e^{f \mu / \beta}$, the existence of a gradient Einstein-type structure on $(M, g)$ yields the existence of a positive solution of

$$
L u=\Delta u-\frac{\mu}{\beta^{2}}[m \lambda+(m \rho-\alpha) S] u=0
$$

so that, by a well-known spectral result (see, for instance, [Fischer-Colbrie and Schoen 1980; Moss and Piepenbrink 1978]), the operator $L$ is stable, or, in other words, the spectral radius of $L, \lambda_{1}^{L}(M)$, is nonnegative. Here we will not further pursue this direction.

As it appears in Definition 1.1, the fact that $(M, g)$ is an Einstein-type manifold can be interpreted as a prescribed condition on the Ricci tensor of $g$ (see, for instance, the nice survey [Bourguignon 1981]), that is, on the "trace part" of the Riemann tensor. Thus, it is reasonable to expect classification and rigidity results for these structures only assuming further conditions on the traceless part of the Riemann tensor, i.e., on the Weyl tensor. Indeed, most of the aforementioned papers pursue this direction, for instance, assuming that $(M, g)$ is locally conformally flat or has harmonic Weyl tensor. In the spirit of the recent work of H.-D. Cao
and Q. Chen [2013], we study the class of gradient Einstein-type manifolds with vanishing Bach tensor along the integral curves of $f$. We note that this condition is weaker than local conformal flatness (see Section 2).

It turns out that, as in the case of gradient Ricci solitons (see [Cao and Chen 2012; 2013; Cao et al. 2014]), the leading actor is a three tensor, $D$, that plays a fundamental role in relating the Einstein-type structure to the geometry of the underlying manifold. $D$ naturally appears when writing the first two integrability conditions for the structure defining the differential system (1-2). Quite unexpectedly, the constant $\rho$ and the function $\lambda$ have no influence on this relation.

Our main purpose is to give local characterizations of complete, noncompact, nondegenerate gradient Einstein-type manifolds. Denoting with $B$ the Bach tensor of $(M, g)$ (see Section 2), our first result is
Theorem 1.2. Let $(M, g)$ be a complete, noncompact, nondegenerate, gradient, Einstein-type manifold of dimension $m \geq 3$. If $B(\nabla f, \cdot)=0$ and $f$ is a proper function, then, in a neighborhood of every regular level set of $f$, the manifold $(M, g)$ is locally a warped product with $(m-1)$-dimensional Einstein fibers.

In dimension four we improve this result, obtaining
Corollary 1.3. Let $\left(M^{4}, g\right)$ be a complete, noncompact, nondegenerate, gradient, Einstein-type manifold of dimension four. If $B(\nabla f, \cdot)=0$ and $f$ is a proper function, then, in a neighborhood of every regular level set of $f$, the manifold $(M, g)$ is locally a warped product with three-dimensional fibers of constant curvature. In particular, $\left(M^{4}, g\right)$ is locally conformally flat.

As we will show in Section 7, the properness assumption is satisfied by some important subclasses of Einstein-type manifolds, under quite natural geometric assumptions. As a consequence, in the case of gradient Ricci solitons, we recover a local version of the results in [Cao and Chen 2013; Cao et al. 2014], while, in the cases of $\rho$-Einstein solitons and Ricci almost solitons, we prove two new classification theorems (see Theorem 7.1 and 7.2).

In the special case $\alpha=0$ (which includes Yamabe solitons, Yamabe quasisolitons and conformal gradient solitons) we give a version of Theorem 1.2 in the following local result that provides a very precise description of the metric in this situation. Note that Theorem 1.4 and Corollary 1.5 also apply to the compact case.
Theorem 1.4. Let $(M, g)$ be a complete, gradient, Einstein-type manifold of dimension $m \geq 3$ with $\alpha=0$. Then, in a neighborhood of every regular level set of $f$, the manifold $(M, g)$ is locally a warped product with $(m-1)$-dimensional fibers. More precisely, every regular level set $\Sigma$ of $f$ admits a maximal open neighborhood $U \subset M^{m}$ on which $f$ only depends on the signed distance $r$ to the hypersurface $\Sigma$. In addition, the potential function $f$ can be chosen in such a way that the metric $g$ takes the form on $U$

$$
g=d r \otimes d r+\left(\frac{f^{\prime}(r)}{f^{\prime}(0)} e^{\mu f(r)}\right)^{2} g^{\Sigma}
$$

where $g^{\Sigma}$ is the metric induced by $g$ on $\Sigma$. As a consequence, $f$ has at most two critical points on $M^{m}$ and we have the following cases:
(1) If $f$ has no critical points, then $(M, g)$ is globally conformally equivalent to a direct product $I \times N^{m-1}$ of some interval $I=\left(t_{*}, t^{*}\right) \subseteq \mathbb{R}$ with a (m-1)dimensional complete Riemannian manifold $\left(N^{m-1}, g^{N}\right)$. More precisely, the metric takes the form

$$
g=u^{2}(t)\left(d t^{2}+g^{N}\right)
$$

where $u:\left(t_{*}, t^{*}\right) \rightarrow \mathbb{R}$ is some positive smooth function.
(2) If $f$ has only one critical point $O \in M^{m}$, then $(M, g)$ is globally conformally equivalent to the interior of a Euclidean ball of radius $t^{*} \in(0,+\infty]$. More precisely, on $M^{m} \backslash\{O\}$, the metric takes the form

$$
g=v^{2}(t)\left(d t^{2}+t^{2} g^{\mathbb{S}^{m-1}}\right)
$$

where $v:\left(0, t^{*}\right) \rightarrow \mathbb{R}$ is some positive smooth function and $\mathbb{S}^{m-1}$ denotes the standard unit sphere of dimension $m-1$. In particular $(M, g)$ is complete, noncompact, and rotationally symmetric.
(3) If the function $f$ has two critical points $N, S \in M^{m}$, then $(M, g)$ is globally conformally equivalent to $\mathbb{S}^{m}$. More precisely, on $M^{m} \backslash\{N, S\}$, the metric takes the form

$$
g=w^{2}(t)\left(d t^{2}+\sin ^{2}(t) g^{\mathbb{S}^{m-1}}\right)
$$

where $w:(0, \pi) \rightarrow \mathbb{R}$ is some smooth positive function. In particular $(M, g)$ is compact and rotationally symmetric.

In this case we can obtain a stronger global result just assuming nonnegativity of the Ricci curvature, namely we have the following:

Corollary 1.5. Any nontrivial, complete, gradient, Einstein-type manifold of dimension $m \geq 3$ with $\alpha=0$ and nonnegative Ricci curvature is either rotationally symmetric or it is isometric to a Riemannian product $\mathbb{R} \times N^{m-1}$, where $N^{m-1}$ is an ( $m-1$ )-dimensional Riemannian manifold with nonnegative Ricci curvature.

The proof of Theorem 1.4 follows immediately from [Catino et al. 2012] by substituting $u=e^{\mu f}$ in the equation. This result covers the cases of Yamabe solitons [Cao et al. 2012] and conformal gradient solitons [Catino et al. 2012]. Concerning Yamabe quasisolitons, Corollary 1.5 improves the results in [Huang
and Li 2014]. In particular, this shows that most of the assumptions in [Huang and Li 2014, Theorem 1.1] are not necessary.

The paper is organized as follows. In Section 2 we recall some useful definitions and properties of various geometric tensors and fix our conventions and notation. In Section 3 we collect some useful commutation relations for covariant derivatives of functions and tensors. In Section 4 we prove the two aforementioned integrability conditions that follow directly from the Einstein-type structures. In Section 5 we compute the squared norm of the tensor $D$ in terms of $D$ itself, the Bach tensor $B$ and the potential function $f$. In Section 6 we relate the tensor $D$ to the geometry of the regular level sets of the potential function $f$. Finally, in Section 7 we prove Theorem 1.2 and Corollary 1.3, and we give some geometric applications in the special cases of gradient Ricci solitons, $\rho$-Einstein solitons, and Ricci almost solitons.

## 2. Definitions and notation

In this section we recall some useful definitions and properties of various geometric tensors and fix our conventions and notation.

To perform computations, we freely use the method of the moving frame referring to a local orthonormal coframe of the $m$-dimensional Riemannian manifold $(M, g)$. We fix the index range $1 \leq i, j, \ldots \leq m$ and recall that the Einstein summation convention will be in force throughout.

We denote by $R$ the Riemann curvature tensor (of type $(1,3)$ ) associated to the metric $g$, and by Ric and $S$ the corresponding Ricci tensor and scalar curvature, respectively. The components of the $(0,4)$-versions of the Riemann tensor and of the Weyl tensor $W$ are related by the formula

$$
\begin{align*}
R_{i j k t}=W_{i j k t}+\frac{1}{m-2}\left(R_{i k} \delta_{j t}-R_{i t} \delta_{j k}\right. & \left.+R_{j t} \delta_{i k}-R_{j k} \delta_{i t}\right)  \tag{2-1}\\
& -\frac{S}{(m-1)(m-2)}\left(\delta_{i k} \delta_{j t}-\delta_{i t} \delta_{j k}\right)
\end{align*}
$$

and they satisfy the symmetry relations

$$
\begin{aligned}
R_{i j k t} & =-R_{j i k t}=-R_{i j t k}=R_{k t i j}, \\
W_{i j k t} & =-W_{j i k t}=-W_{i j t k}=W_{k t i j} .
\end{aligned}
$$

A computation shows that the Weyl tensor is also totally trace-free. The Schouten tensor A is defined by

$$
\mathrm{A}=\operatorname{Ric}-\frac{S}{2(m-1)} g .
$$

Tracing we have $\operatorname{tr}(\mathrm{A})=A_{t t}=((m-2)) /(2(m-1)) S$.
Remark 2.1. Some authors adopt a different convention and define the Schouten tensor as $A /(m-2)$.

According to this convention the (components of the) Ricci tensor and the scalar curvature are respectively given by $R_{i j}=R_{i t j t}=R_{t i t j}$ and $S=R_{t t}$. We note that, in terms of the Schouten tensor and of the Weyl tensor, the Riemann curvature tensor can be expressed in the form

$$
R=\mathrm{W}+\frac{1}{m-2} \mathrm{~A} \otimes g,
$$

where $\otimes$ is the Kulkarni-Nomizu product; in components,

$$
R_{i j k t}=W_{i j k t}+\frac{1}{m-2}\left(A_{i k} \delta_{j t}-A_{i t} \delta_{j k}+A_{j t} \delta_{i k}-A_{j k} \delta_{i t}\right)
$$

Next we introduce the Cotton tensor $C$ as the obstruction to the commutativity of the covariant derivative of the Schouten tensor, that is

$$
\begin{equation*}
C_{i j k}=A_{i j, k}-A_{i k, j}=R_{i j, k}-R_{i k, j}-\frac{1}{2(m-1)}\left(S_{k} \delta_{i j}-S_{j} \delta_{i k}\right) . \tag{2-2}
\end{equation*}
$$

We also recall that the Cotton tensor, for $m \geq 4$, can be defined as one of the possible divergences of the Weyl tensor; precisely

$$
\begin{equation*}
C_{i j k}=\left(\frac{m-2}{m-3}\right) W_{t i k j, t}=-\left(\frac{m-2}{m-3}\right) W_{t i j k, t} . \tag{2-3}
\end{equation*}
$$

A computation shows that the two definitions (for $m \geq 4$ ) coincide.
Remark 2.2. It is worthwhile to recall that the Cotton tensor is skew-symmetric in the second and third indices (i.e., $C_{i j k}=-C_{i k j}$ ) and totally trace-free (i.e., $\left.C_{i i k}=C_{i k i}=C_{k i i}=0\right)$.

We are now ready to define the Bach tensor B, originally introduced by Bach [1921] in the study of conformal relativity. Its components are

$$
\begin{equation*}
B_{i j}=\frac{1}{m-2}\left(C_{j i k, k}+R_{k t} W_{i k j t}\right), \tag{2-4}
\end{equation*}
$$

that, in case $m \geq 4$, by (2-3) can be alternatively written as

$$
B_{i j}=\frac{1}{m-3} W_{i k j t, t k}+\frac{1}{m-2} R_{k t} W_{i k j t} .
$$

Note that if ( $M, g$ ) is either locally conformally flat (i.e., $C=0$ if $m=3$ or $W=0$ if $m \geq 4$ ) or Einstein, then $B=0$. A computation shows that the Bach tensor is symmetric (i.e., $B_{i j}=B_{j i}$ ) and evidently trace-free (i.e., $B_{i i}=0$ ). As a consequence we observe that we can write

$$
B_{i j}=\frac{1}{m-2}\left(C_{i j k, k}+R_{k l} W_{i k j l}\right) .
$$

We recall that

Definition 2.3. The manifold ( $M, g$ ) is conformally Einstein if its metric $g$ can be pointwise conformally deformed to an Einstein metric $\tilde{g}$.

We observe that, if $\tilde{g}=e^{2 a \varphi} g$, for some $\varphi \in C^{\infty}(M)$ and some constant $a \in \mathbb{R}$, then its Ricci tensor Ric is related to that of $g$ by the well-known formula (see [Besse 2008])
(2-5) $\widetilde{\operatorname{Ric}}=\operatorname{Ric}-(m-2) a \operatorname{Hess}(\varphi)+(m-2) a^{2} d \varphi \otimes \varphi-\left[(m-2) a^{2}|\nabla \varphi|^{2}+a \Delta \varphi\right] g$.
Here the various operators (for their precise definitions see Section 3) are defined with respect to the metric $g$.

Now we can easily prove statement (1-3); indeed, suppose that $\beta \neq 0$ and $\beta^{2}=(m-2) \alpha \mu$, that is, the Einstein-type structure is degenerate. Tracing (1-2) we obtain

$$
\begin{equation*}
\frac{1}{\alpha}(\rho S+\lambda)=\frac{1}{m}\left(S+\frac{\beta}{\alpha} \Delta f+\frac{\mu}{\alpha}|\nabla f|^{2}\right) . \tag{2-6}
\end{equation*}
$$

Choose $\varphi=f$ and $a=-\beta /((m-2) \alpha)$ in (2-5) to obtain

$$
\begin{equation*}
\widetilde{\mathrm{Ric}}=\frac{1}{\alpha}\left[\frac{\beta^{2}}{(m-2) \alpha}-\mu\right] d f \otimes d f+\frac{1}{\alpha}(\rho S+\lambda) g+\frac{\beta}{(m-2) \alpha}\left(\Delta f-\frac{\beta}{\alpha}|\nabla f|^{2}\right) g . \tag{2-7}
\end{equation*}
$$

Inserting (2-6) into (2-7) and using the fact that the Einstein-type structure is degenerate yields

$$
\widetilde{\operatorname{Ric}}=\frac{1}{\alpha}\left[\frac{\beta^{2}}{(m-2) \alpha}-\mu\right] d f \otimes d f+\frac{1}{m}\left[S+2 \frac{\beta}{\alpha} \frac{m-1}{m-2} \Delta f-\frac{\mu}{\alpha}(m-1)|\nabla f|^{2}\right] g .
$$

Hence, since $\beta^{2}=(m-2) \alpha \mu$,

$$
\widetilde{\mathrm{Ric}}=\frac{1}{m}\left[S+2 \frac{\beta}{\alpha} \frac{m-1}{m-2} \Delta f-\frac{\mu}{\alpha}(m-1)|\nabla f|^{2}\right] g,
$$

that is, $\tilde{g}=e^{-(2 \beta) /((m-2) \alpha) f} g$ is an Einstein metric (this was also obtained in [Besse 2008, Theorem 1.159]).

Conversely suppose that $\tilde{g}=e^{2 a f} g, a \neq 0$, is an Einstein metric, so that $\widetilde{\text { Ric }}=\Lambda \tilde{g}$, for some $\Lambda \in \mathbb{R}$. From (2-5)

$$
\begin{align*}
& \operatorname{Ric}-(m-2) a \operatorname{Hess}(f)+(m-2) a^{2} d f \otimes d f  \tag{2-8}\\
&=\left[\Lambda e^{2 a f}+(m-2) a^{2}|\nabla f|^{2}+a \Delta f\right] g .
\end{align*}
$$

Tracing we get

$$
\frac{S}{m-1}=\left[(m-2) a^{2}|\nabla f|^{2}+a \Delta f\right]+a \Delta f+\frac{m}{m-1} \Lambda e^{2 a f} .
$$

Thus, inserting into (2-8),

$$
\operatorname{Ric}-(m-2) a \operatorname{Hess}(f)+(m-2) a^{2} d f \otimes d f=\left(\frac{S}{m-1}-a \Delta f-\frac{\Lambda}{m-1} e^{2 a f}\right) g .
$$

We choose $\alpha=1, \beta=-(m-2) a, \mu=(m-2) a^{2}, \rho=1 /(m-1)$, and $\lambda(x)=$ $-a \Delta f-\Lambda /(m-1) e^{2 a f}$. We note that $\beta \neq 0$ and

$$
\beta^{2}=(m-2)^{2} a^{2}=(m-2) \alpha \mu,
$$

so this choice of $\alpha, \beta, \mu, \rho$, and $\lambda$ yields a degenerate Einstein-type structure.
To conclude we note that the equivalence of degenerate gradient Ricci solitons and conformally Einstein metrics is well-known in conformal geometry (see [Catino 2012; Jauregui and Wylie 2015]).

## 3. Some basics on moving frames and commutation rules

In this section we collect some useful commutation relations for covariant derivatives of functions and tensors that will be used in the rest of the paper. All of these formulas are well-known to experts.

Let $(M, g)$ be a Riemannian manifold of dimension $m \geq 3$. For the sake of completeness (see [Alías et al. 2016] for details) we recall that having fixed a (local) orthonormal coframe $\left\{\theta^{i}\right\}$, with dual frame $\left\{e_{i}\right\}$, the corresponding Levi-Civita connection forms $\left\{\theta_{j}^{i}\right\}$ are the 1-forms uniquely defined by the requirements

$$
d \theta^{i}=-\theta_{j}^{i} \wedge \theta^{j} \text { (first structure equations), and } \quad \theta_{j}^{i}+\theta_{i}^{j}=0
$$

The curvature forms $\left\{\Theta_{j}^{i}\right\}$ associated to the connection are the 2-forms defined via the second structure equations

$$
d \theta_{j}^{i}=-\theta_{k}^{i} \wedge \theta_{j}^{k}+\Theta_{j}^{i}
$$

They are skew-symmetric (i.e., $\Theta_{j}^{i}+\Theta_{i}^{j}=0$ ) and they can be written as

$$
\Theta_{j}^{i}=\frac{1}{2} R_{j k t}^{i} \theta^{k} \wedge \theta^{t}=\sum_{k<t} R_{j k t}^{i} \theta^{k} \wedge \theta^{t},
$$

where $R_{j k t}^{i}$ are precisely the coefficients of the ((1,3)-version of the) Riemann curvature tensor.

The covariant derivative of a vector field $X \in \mathfrak{X}(M)$ is defined by

$$
\nabla X=\left(d X^{i}+X^{j} \theta_{j}^{i}\right) \otimes e_{i}=X_{k}^{i} \theta^{k} \otimes e_{i}
$$

while the covariant derivative of a 1 -form $\omega$ is defined by

$$
\nabla \omega=\left(d \omega_{i}-w_{j} \theta_{i}^{j}\right) \otimes \theta^{i}=\omega_{i k} \theta^{k} \otimes \theta^{i} .
$$

The divergence of the vector field $X \in \mathfrak{X}(M)$ is the trace of the endomorphism $(\nabla X)^{\sharp}: T M \rightarrow T M$, that is,

$$
\operatorname{div} X=\operatorname{tr}(\nabla X)^{\sharp}=g\left(\nabla_{e_{i}} X, e_{i}\right)=X_{i}^{i} .
$$

For a smooth function $f$ we can write

$$
d f=f_{i} \theta^{i},
$$

for some smooth coefficients $f_{i} \in C^{\infty}(M)$. The Hessian of $f, \operatorname{Hess}(f)$, is the $(0,2)$-tensor defined as

$$
\operatorname{Hess}(f)=\nabla d f=f_{i j} \theta^{j} \otimes \theta^{i}
$$

with

$$
f_{i j} \theta^{j}=d f_{i}-f_{t} \theta_{i}^{t} .
$$

Note that (see Lemma 3.1 below)

$$
f_{i j}=f_{j i} .
$$

The Laplacian of $f, \Delta f$, is the trace of the Hessian, in other words

$$
\Delta f=\operatorname{tr}(\operatorname{Hess}(f))=f_{i i}
$$

The moving frame formalism reveals extremely useful in determining the commutation rules of geometric tensors. Some of them will be essential in our computations.

Lemma 3.1. Let $f \in C^{3}(M)$. The following equalities hold.
(3-1) $\quad f_{i j}=f_{j i}$.
(3-2) $\quad f_{i j k}=f_{j i k}$.
(3-3) $\quad f_{i j k}=f_{i k j}+f_{t} R_{t i j k}$.

$$
\begin{align*}
f_{i j k}=f_{i k j}+f_{t} W_{t i j k}+\frac{1}{m-2}\left(f_{t} R_{t j} \delta_{i k}\right. & \left.-f_{t} R_{t k} \delta_{i j}+f_{j} R_{i k}-f_{k} R_{i j}\right)  \tag{3-4}\\
& -\frac{S}{(m-1)(m-2)}\left(f_{j} \delta_{i k}-f_{k} \delta_{i j}\right)
\end{align*}
$$

$$
\begin{equation*}
f_{i j k}=f_{i k j}+f_{t} W_{t i j k}+\frac{1}{m-2}\left(f_{t} A_{t j} \delta_{i k}-f_{t} A_{t k} \delta_{i j}+f_{j} A_{i k}-f_{k} A_{i j}\right) \tag{3-5}
\end{equation*}
$$

In particular, tracing (3-3), we deduce

$$
\begin{equation*}
f_{i t t}=f_{t t i}+f_{t} R_{t i} . \tag{3-6}
\end{equation*}
$$

For the Riemann curvature tensor we recall the classical Bianchi identities that in our formalism become

$$
\begin{aligned}
R_{i j k t}+R_{i t j k}+R_{i k t j} & =0 \\
R_{i j k t, l}+R_{i j l k, t}+R_{i j t l, k} & =0
\end{aligned} \quad \text { (first Bianchi identity), }, \text { second Bianchi identity). } .
$$

For the derivatives of the curvature we have the well known formulas

## Lemma 3.2.

$$
\begin{aligned}
R_{i j k t, l r}-R_{i j k t, r l} & =R_{s j k t} R_{s i l r}+R_{i s k t} R_{s j l r}+R_{i j s t} R_{s k l r}+R_{i j k s} R_{s t l r}, \\
R_{i j, k}-R_{i k, j} & =-R_{t i j k, t}=R_{t i k j, t}, \\
R_{i j, k t}-R_{i j, t k} & =R_{l i k t} R_{l j}+R_{l j k t} R_{l i} .
\end{aligned}
$$

The first Bianchi identities imply that

$$
\begin{equation*}
C_{i j k}+C_{j k i}+C_{k i j}=0 . \tag{3-7}
\end{equation*}
$$

From the definition of the Cotton tensor we also deduce that

$$
C_{i j k, t}=A_{i j, k t}-A_{i k, j t}=R_{i j, k t}-R_{i k, j t}-\frac{1}{2(m-1)}\left(S_{k t} \delta_{i j}-S_{j t} \delta_{i k}\right) .
$$

On the other hand, by Lemma 3.2 and Schur's identity $S_{i}=\frac{1}{2} R_{i k, k}$,

$$
R_{i k, j k}=R_{i k, k j}+R_{t i j k} R_{t k}+R_{t k j k} R_{t i}=\frac{1}{2} S_{i j}-R_{t k} R_{i t j k}+R_{i t} R_{t j} .
$$

This enables us to obtain the following expression for the divergence of the Cotton tensor:

$$
C_{i j k, k}=R_{i j, k k}-\frac{m-2}{2(m-1)} S_{i j}+R_{t k} R_{i t j k}-R_{i t} R_{t j}-\frac{1}{2(m-1)} \Delta S \delta_{i j} .
$$

The previous relation also shows that

$$
\begin{equation*}
C_{i j k, k}=C_{j i k, k}, \tag{3-8}
\end{equation*}
$$

thus confirming the symmetry of the Bach tensor, see (2-4).
Taking the covariant derivative of (3-7) and using (3-8) we also deduce

$$
C_{k i j, k}=0 .
$$

## 4. The tensor $\boldsymbol{D}$ and the integrability conditions

The main result of this section concerns two natural integrability conditions that follow directly from the Einstein-type structure; as in the case of Ricci solitons and Yamabe (quasi-)solitons, there is a natural tensor that turns out to play a fundamental role in relating the Einstein-type structure to the geometry of the underlying manifold. Quite surprisingly, as it is shown in Theorem 4.4, the presence of the constant $\rho$ and of the function $\lambda$ seems to be completely irrelevant.

Let $(M, g)$ be gradient Einstein-type manifold of dimension $m \geq 3$. Equation (1-2) in components reads as

$$
\begin{equation*}
\alpha R_{i j}+\beta f_{i j}+\mu f_{i} f_{j}=(\rho S+\lambda) \delta_{i j} \tag{4-1}
\end{equation*}
$$

Tracing the previous relation we immediately deduce that

$$
\begin{equation*}
(\alpha-m \rho) S+\beta \Delta f+\mu|\nabla f|^{2}=m \lambda \tag{4-2}
\end{equation*}
$$

Definition 4.1. We define the tensor $D$ by its components

$$
\begin{align*}
& D_{i j k}=\frac{1}{m-2}\left(f_{k} R_{i j}-f_{j} R_{i k}\right)+\frac{1}{(m-1)(m-2)} f_{t}\left(R_{t k} \delta_{i j}-R_{t j} \delta_{i k}\right)  \tag{4-3}\\
&-\frac{S}{(m-1)(m-2)}\left(f_{k} \delta_{i j}-f_{j} \delta_{i k}\right)
\end{align*}
$$

Note that $D$ is skew-symmetric in the second and third indices (i.e., $D_{i j k}=-D_{i k j}$ ) and totally trace-free (i.e., $D_{i i k}=D_{i k i}=D_{k i i}=0$ ).

Remark 4.2. We explicitly note that our conventions for the Cotton tensor and for the tensor $D$ differ from those in [Cao and Chen 2013].

Lemma 4.3. Let $(M, g)$ be a gradient Einstein-type manifold of dimension $m \geq 3$.
The tensor $D$ can be written as

$$
\begin{align*}
& D_{i j k}=\frac{\beta}{\alpha}\left[\frac{1}{m-2}\left(f_{j} f_{i k}-f_{k} f_{i j}\right)+\frac{1}{(m-1)(m-2)} f_{t}\left(f_{t j} \delta_{i k}-f_{t k} \delta_{i j}\right)\right.  \tag{4-4}\\
&\left.-\frac{\Delta f}{(m-1)(m-2)}\left(f_{j} \delta_{i k}-f_{k} \delta_{i j}\right)\right] .
\end{align*}
$$

The proof is just a simple computation, using the definitions of the tensors involved, (4-1) and (4-2).

The following theorem should be compared with [Cao and Chen 2013, Lemma 3.1 and Equation (4.1)], [Cao et al. 2014, Lemma 2.4 and Equation (2.12)] and [Huang and Li 2014, Proposition 2.2]. This result highlights the geometric relevance of $D$ in this general situation and shows that, even in this more general framework, similar structural equations hold.
Theorem 4.4. Let $(M, g)$ be a gradient Einstein-type manifold with $\beta \neq 0$ of dimension $m \geq 3$. Then the following integrability conditions hold
(4-6) $\alpha B_{i j}=\frac{1}{m-2}\left\{\left[\beta-\frac{(m-2) \alpha \mu}{\beta}\right] D_{i j k, k}+\beta\left(\frac{m-3}{m-2}\right) f_{t} C_{j i t}-\mu f_{t} f_{k} W_{i t j k}\right\}$.
Proof. We begin with the covariant derivative of (4-1) to get

$$
\alpha R_{i j, k}+\beta f_{i j, k}+\mu\left(f_{i k} f_{j}+f_{i} f_{j k}\right)=\left(\rho S_{k}+\lambda_{k}\right) \delta_{i j} .
$$

Skew-symmetrizing with respect to $j$ and $k$ and using (3-3) we obtain

$$
\begin{align*}
\alpha\left(R_{i j, k}-R_{i k, j}\right)+\beta f_{t} R_{t i j k}+\mu\left(f_{i k} f_{j}\right. & \left.-f_{i j} f_{k}\right)  \tag{4-7}\\
& =\rho\left(S_{k} \delta_{i j}-S_{j} \delta_{i k}\right)+\left(\lambda_{k} \delta_{i j}-\lambda_{j} \delta_{i k}\right) .
\end{align*}
$$

To get rid of the two terms on the right-hand side of (4-7) we proceed as follows. First we trace the equation with respect to $i$ and $j$ and we use Schur's identity $S_{k}=2 R_{t k, t}$ to deduce

$$
\begin{equation*}
[\alpha-2 \rho(m-1)] S_{k}=2 \beta f_{t} R_{t k}+2(m-1) \lambda_{k}-2 \mu\left(f_{t} f_{t k}-\Delta f f_{k}\right) \tag{4-8}
\end{equation*}
$$

Second, from equations (4-1) and (4-2) we respectively have

$$
\begin{equation*}
f_{t k}=\frac{1}{\beta}\left[(\rho S+\lambda) \delta_{t k}-\alpha R_{t k}-\mu f_{t} f_{k}\right] b u \tag{4-9}
\end{equation*}
$$

and

$$
\Delta f=\frac{1}{\beta}\left[(m \rho-\alpha) S+m \lambda-\mu|\nabla f|^{2}\right]
$$

Inserting the two previous relations into (4-8) and simplifying we deduce the following important equation

$$
\begin{align*}
& {[\alpha-2 \rho(m-1)] S_{k}=2\left(\beta+\frac{\alpha \mu}{\beta}\right) f_{t} R_{t k}+2(m-1) \lambda_{k}}  \tag{4-10}\\
& \quad-\frac{2 \mu}{\beta}[\alpha-\rho(m-1)] S f_{k}+\frac{2 \mu}{\beta}(m-1) \lambda f_{k}
\end{align*}
$$

From (2-1) and (4-4) we deduce that

$$
\begin{equation*}
f_{t} R_{t i j k}=f_{t} W_{t i j k}-D_{i j k}-\frac{1}{m-1}\left(f_{t} R_{t k} \delta_{i j}-f_{t} R_{t j} \delta_{i k}\right) \tag{4-11}
\end{equation*}
$$

Inserting now (4-11), (2-2), and (4-10) into (4-7) and simplifying we get (4-5).
Taking the divergence of (4-5) we obtain

$$
\alpha C_{i j k, k}-\beta f_{t k} W_{i t j k}-\beta\left(\frac{m-3}{m-2}\right) f_{t} C_{j i t}=\left[\beta-\frac{(m-2) \alpha \mu}{\beta}\right] D_{i j k, k}
$$

Using the definition of the Bach tensor (2-4), (4-9), and the symmetries of $W$ we immediately deduce (4-6).

Remark 4.5. Equation (4-10) is the analogue of the fundamental relation $S_{k}=$ $2 f_{t} R_{t k}$, valid for every gradient Ricci soliton.

Remark 4.6. In the case $\beta=0$ (and thus $\alpha \neq 0$ ), by direct calculations, using (2-2), (4-3), and (4-1), one can show that $D=0$ and equations (4-5) and (4-6) take the form

$$
\begin{aligned}
\alpha C_{i j k} & =-\mu\left(f_{j} f_{i k}-f_{k} f_{i j}\right)-\frac{\mu}{m-1} f_{t}\left(f_{t j} \delta_{i k}-f_{t k} \delta_{i j}\right)+\frac{\mu \Delta f}{m-1}\left(f_{j} \delta_{i k}-f_{k} \delta_{i j}\right) \\
\alpha B_{i j} & =\frac{1}{m-2}\left\{\alpha C_{i j k, k}-\mu f_{t} f_{k} W_{i t j k}\right\}
\end{aligned}
$$

## 5. Vanishing of the tensor $\boldsymbol{D}$

In this section we compute the squared norm of the tensor $D$ in terms of $D$ itself, the Bach tensor $B$, and the potential function $f$. Moreover, under the assumption of Theorem 1.2, we prove the vanishing of $D$. We begin with

Lemma 5.1. Let $(M, g)$ be a nondegenerate gradient Einstein-type manifold of dimension $m \geq 3$. If $\alpha \neq 0$,

$$
\begin{align*}
& \left(\frac{m-2}{2}\right)\left[\beta-\frac{(m-2) \alpha \mu}{\beta}\right]|D|^{2}  \tag{5-1}\\
& \quad=-\beta(m-2) f_{i} f_{j} B_{i j}+\frac{\beta}{\alpha}\left[\beta-\frac{(m-2) \alpha \mu}{\beta}\right]\left(f_{i} f_{j} D_{i j k}\right)_{k}
\end{align*}
$$

while if $\alpha=0$

$$
\begin{equation*}
\left(\frac{m-2}{2}\right)|D|^{2}=-(m-2) f_{i} f_{j} B_{i j}+\left(f_{i} f_{j} C_{i j k}\right)_{k} \tag{5-2}
\end{equation*}
$$

Proof. We observe that, since $D$ is totally trace-free and $D_{i j k}=-D_{i k j}$,

$$
|D|^{2}=D_{i j k} D_{i j k}=\frac{1}{m-2} D_{i j k}\left(f_{k} R_{i j}-f_{j} R_{i k}\right)=\frac{1}{m-2}\left(f_{k} R_{i j} D_{i j k}+f_{j} R_{i k} D_{i k j}\right)
$$

so that

$$
|D|^{2}=\frac{2}{m-2} f_{k} R_{i j} D_{i j k}
$$

The nondegeneracy condition $\beta-(m-2) \alpha \mu / \beta \neq 0$ implies that, using (4-5) and the definition of the Bach tensor, we can write

$$
\begin{aligned}
\left(\frac{m-2}{2}\right)\left[\beta-\frac{(m-2) \alpha \mu}{\beta}\right]|D|^{2} & =f_{k} R_{i j}\left(\alpha C_{i j k}+\beta f_{t} W_{t i j k}\right) \\
& =\alpha f_{k} R_{i j} C_{i j k}-\beta f_{i} f_{j} R_{t k} W_{i t j k} \\
& =\alpha f_{k} R_{i j} C_{i j k}-\beta(m-2) f_{i} f_{j} B_{i j}+\beta f_{i} f_{j} C_{i j k, k}
\end{aligned}
$$

By the symmetries of the Cotton tensor we also have

$$
\begin{aligned}
f_{i} f_{j} C_{i j k, k} & =f_{i}\left(f_{j} C_{i j k}\right)_{k}-f_{i} f_{j k} C_{i j k} \\
& =\left(f_{i} f_{j} C_{i j k}\right)_{k}-f_{i k} f_{j} C_{i j k} \\
& =\left(f_{i} f_{j} C_{i j k}\right)_{k}+f_{i j} f_{k} C_{i j k}
\end{aligned}
$$

Therefore we obtain

$$
\begin{align*}
\left(\frac{m-2}{2}\right)[\beta & \left.-\frac{(m-2) \alpha \mu}{\beta}\right]|D|^{2}  \tag{5-3}\\
& =\alpha f_{k} R_{i j} C_{i j k}-\beta(m-2) f_{i} f_{j} B_{i j}+\beta\left(f_{i} f_{j} C_{i j k}\right)_{k}+\beta f_{i j} f_{k} C_{i j k}
\end{align*}
$$

If $\alpha=0$, using (4-1) in (5-3) we immediately get

$$
\left(\frac{m-2}{2}\right)|D|^{2}=-(m-2) f_{i} f_{j} B_{i j}+\left(f_{i} f_{j} C_{i j k}\right)_{k},
$$

that is (5-2).
If $\alpha \neq 0$, using equations (4-1) and (4-5) in (5-3) and simplifying we deduce

$$
\begin{align*}
& \left(\frac{m-2}{2}\right)\left[\beta-\frac{(m-2) \alpha \mu}{\beta}\right]|D|^{2}  \tag{5-4}\\
& \quad=-\beta(m-2) f_{i} f_{j} B_{i j}+\frac{\beta}{\alpha}\left[\beta-\frac{(m-2) \alpha \mu}{\beta}\right]\left(f_{i} f_{j} D_{i j k}\right)_{k},
\end{align*}
$$

that is, (5-1).
Remark 5.2. In the case $\alpha \neq 0,(5-1)$ can be obtained in a direct way. One takes the second integrability condition (4-6), multiplies both members by $f_{i} f_{j}$ and simplifies, using the symmetries of the tensors involved and (4-5).

Theorem 5.3. Let $(M, g)$ be a complete nondegenerate gradient Einstein-type manifold of dimension $m \geq 3$. If $B(\nabla f, \cdot)=0$ and $f$ is proper, then $D=0$.

Proof. We define the vector field $Y=Y(\alpha)$ of components

$$
Y_{k}= \begin{cases}(\beta / \alpha) f_{i} f_{j} D_{i j k} & \text { if } \alpha \neq 0  \tag{5-5}\\ f_{i} f_{j} C_{i j k} & \text { if } \alpha=0\end{cases}
$$

By the symmetries of $D$ and $C$ we immediately have

$$
\begin{equation*}
g(Y, \nabla f)=0 . \tag{5-6}
\end{equation*}
$$

If $B(\nabla f, \cdot)=0$ and $\alpha \neq 0$, from (5-1) we obtain

$$
\left(\frac{m-2}{2}\right)|D|^{2}=\frac{\beta}{\alpha}\left(f_{i} f_{j} D_{i j k}\right)_{k},
$$

while if $\alpha=0$ from (5-2) we deduce

$$
\left(\frac{m-2}{2}\right)|D|^{2}=\left(f_{i} f_{j} C_{i j k}\right)_{k} .
$$

In both cases

$$
\begin{equation*}
\left(\frac{m-2}{2}\right)|D|^{2}=\operatorname{div} Y . \tag{5-7}
\end{equation*}
$$

Now let $c$ be a regular value of $f$ and $\Omega_{c}$ and $\Sigma_{c}$ be, respectively, the corresponding sublevel set and level hypersurface, i.e., $\Omega_{c}=\{x \in M: f(x) \leq c\}$ and $\Sigma_{c}=\{x \in M: f(x)=c\}$. Integrating (5-7) on $\Omega_{c}$ and using the divergence theorem we get

$$
\int_{\Omega_{c}}\left(\frac{m-2}{2}\right)|D|^{2}=\int_{\Omega_{c}} \operatorname{div} Y=\int_{\Sigma_{c}} g(Y, v),
$$

where $v$ is the unit normal to $\Sigma_{c}$. Since $v$ is in the direction of $\nabla f$, using (5-6) and letting $c \rightarrow+\infty$ we immediately deduce

$$
\int_{M}\left(\frac{m-2}{2}\right)|D|^{2}=0
$$

which implies $D=0$ on $M$.
Remark 5.4. The validity of Theorem 5.3 is based on that of the divergence theorem in this situation. Thus, instead of using properness of $f$, we can use [Gol'dshtein and Troyanov 1999, Theorem A] to obtain the above conclusion, that is $D \equiv 0$, under the following assumptions; for some $p>1, M$ is $p$-parabolic and the vector field $Y \in L^{q}(M)$, where $q$ is the conjugate exponent of $p$. We note that a sufficient condition for $p$-parabolicity is

$$
\frac{1}{\operatorname{vol}\left(\partial B_{r}\right)^{\frac{1}{p-1}}} \notin L^{1}(+\infty)
$$

(see, e.g., [Troyanov 1999]), and, according to (5-5), $Y \in L^{q}(M)$ if for some pair of conjugate exponents $P, P^{\prime}$ we have

$$
|\nabla f| \in L^{2 P q}(M) \quad \text { and } \quad|D| \in L^{P^{\prime} q}(M) \text { if } \alpha \neq 0
$$

or

$$
|\nabla f| \in L^{2 P q}(M) \quad \text { and } \quad|C| \in L^{P^{\prime} q}(M) \text { if } \alpha=0 .
$$

Remark 5.5. A simple computation using the definition of the tensor $D$ gives

$$
f_{i} D_{i j k}=\frac{1}{m-1}\left(f_{t} f_{k} R_{t j}-f_{t} f_{j} R_{t k}\right),
$$

and then

$$
f_{i} f_{j} D_{i j k}=\frac{1}{m-1}\left(\operatorname{Ric}(\nabla f, \nabla f) f_{k}-|\nabla f|^{2} f_{t} R_{t k}\right) .
$$

This shows that, in the case $\alpha \neq 0$, the vector field $Y$ defined in (5-5) can be expressed in the remarkable form

$$
Y=\frac{\beta}{\alpha(m-1)}\left[\operatorname{Ric}(\nabla f, \nabla f) \nabla f-|\nabla f|^{2}\left(\operatorname{Ric}(\nabla f, \cdot)^{\sharp}\right)\right],
$$

where $\sharp$ denotes the usual musical isomorphism.
Moreover, in the special case of a gradient Ricci soliton ( $M, g, f, \lambda$ ), using the fundamental relation $S_{k}=2 f_{t} R_{t k}$, the vector field $Y$ can also be written in the equivalent form

$$
Y=\frac{1}{2(m-1)}\left[g(\nabla S, \nabla f) \nabla f-|\nabla f|^{2} \nabla S\right] .
$$

We also observe that

$$
g(Y, \nabla f)=0, g(Y, \nabla S)=\frac{1}{2(m-1)}\left[g(\nabla S, \nabla f)^{2}-|\nabla S|^{2}|\nabla f|^{2}\right] \leq 0,
$$

and that

$$
|Y|^{2}=\frac{1}{4(m-1)^{2}}|\nabla f|^{2}\left[|\nabla S|^{2}|\nabla f|^{2}-g(\nabla S, \nabla f)^{2}\right]=-\frac{1}{2(m-1)}|\nabla f|^{2} g(Y, \nabla S) .
$$

Remark 5.6. In case $\beta=0$ and $\mu \neq 0$, using Remark 4.6 and arguing as in Lemma 5.1, one can obtain the following identity

$$
\frac{\alpha}{2 \mu}|C|^{2}=(m-2) f_{i} f_{j} B_{i j}-\left(f_{i} f_{j} C_{i j k}\right)_{k} .
$$

Then, following the proof of Theorem 5.3, we obtain
Proposition 5.7. Let $(M, g)$ be a complete nondegenerate gradient Einstein-type manifold of dimension $m \geq 3$ and with $\beta=0$. If $B(\nabla f, \cdot)=0$ and $f$ is proper, then $C=0$.

## 6. $D$ and the geometry of the level sets of $\boldsymbol{f}$

In this section we relate the tensor $D$ to the geometry of the regular level sets of the potential function $f$. Our first result highlights, in the case $\alpha \neq 0$, the link between the squared norm of the tensor $D$ and the second fundamental form of the level sets of $f$. This should be compared with [Cao and Chen 2013, Proposition 3.1] and [Cao and Chen 2012, Lemma 4.1]. For the case $\alpha=0$ we refer to [Huang and Li 2014, Proposition 2.3].

From now on, we extend our index convention assuming $1 \leq i, j, k, \ldots \leq m$ and $1 \leq a, b, c, \ldots \leq m-1$.

Proposition 6.1. Let $(M, g)$ be a complete, m-dimensional, gradient, Einsteintype manifold with $\alpha, \beta \neq 0$ and $m \geq 3$. Let $c$ be a regular value of $f$ and let $\Sigma_{c}=\{x \in M \mid f(x)=c\}$ be the corresponding level hypersurface. For $p \in \Sigma_{c}$ choose an orthonormal frame such that $\left\{e_{1}, \ldots, e_{m-1}\right\}$ are tangent to $\Sigma_{c}$ and $e_{m}=\nabla f /|\nabla f|$ (i.e., $\left\{e_{1}, \ldots, e_{m-1}, e_{m}\right\}$ is a local first order frame along $f$ ). Then, in $p$, the squared norm of the tensor $D$ can be written as

$$
\begin{equation*}
|D|^{2}=\left(\frac{\beta}{\alpha}\right)^{2} \frac{2|\nabla f|^{4}}{(m-2)^{2}}\left|h_{a b}-h \delta_{a b}\right|^{2}+\frac{2|\nabla f|^{2}}{(m-1)(m-2)} R_{a m} R_{a m}, \tag{6-1}
\end{equation*}
$$

where $h_{a b}$ are the coefficients of the second fundamental tensor and $h$ is the mean curvature of $\Sigma_{c}$.

Remark 6.2. Note that $\left|h_{a b}-h \delta_{a b}\right|^{2}$ is the squared norm of the traceless second fundamental tensor $\Phi$ of components $\Phi_{a b}=h_{a b}-h \delta_{a b}$.

Proof. First of all, we observe that in the chosen frame we have

$$
d f=f_{a} \theta^{a}+f_{m} \theta^{m}=|\nabla f| \theta^{m},
$$

since $f_{a}=0, a=1, \ldots, m-1$.
The second fundamental tensor $I I$ of the immersion $\Sigma_{c} \hookrightarrow M$ is

$$
I I=h_{a b} \theta^{b} \otimes \theta^{a} \otimes v,
$$

where the coefficients $h_{a b}=h_{b a}$ are defined as

$$
\nabla e_{m}=\nabla v=\theta_{m}^{a} \otimes e_{a}=-\theta_{a}^{m} \otimes e_{a}=-h_{a b} \theta^{b} \otimes e_{a}
$$

(see also [Alías et al. 2016]), so that

$$
h_{a b}=g\left(I I\left(e_{a}, e_{b}\right), v\right)=-g\left(\nabla_{e_{a}} v, e_{b}\right)=-(\nabla v)^{b}\left(e_{a}, e_{b}\right) .
$$

In the present setting we have

$$
\nabla v=\frac{1}{|\nabla f|} \nabla(\nabla f)+\nabla\left(\frac{1}{|\nabla f|}\right) \otimes \nabla f
$$

and

$$
(\nabla v)^{b}=\frac{1}{|\nabla f|} \operatorname{Hess}(f)+d\left(\frac{1}{|\nabla f|}\right) \otimes d f .
$$

Thus, using (4-1), we deduce

$$
\begin{equation*}
h_{a b}=-\frac{1}{|\nabla f|} f_{a b}=\frac{1}{\beta|\nabla f|}\left[\alpha R_{a b}-(\rho S+\lambda) \delta_{a b}\right] . \tag{6-2}
\end{equation*}
$$

The mean curvature $h$ is defined as $h=h_{a a} /(m-1)$. Tracing (6-2) we get

$$
\begin{equation*}
h=\frac{1}{\beta|\nabla f|}\left[\left(\frac{\alpha}{m-1}-\rho\right) S-\frac{\alpha}{m-1} R_{m m}-\lambda\right] . \tag{6-3}
\end{equation*}
$$

Now we compute the squared norm of the traceless second fundamental tensor $\Phi$.

$$
\begin{align*}
\left|h_{a b}-h \delta_{a b}\right|^{2}= & \left|h_{a b}\right|^{2}-2 h h_{a a}+(m-1) h^{2}=\left|h_{a b}\right|^{2}-(m-1) h^{2}  \tag{6-4}\\
= & \frac{1}{\beta^{2}|\nabla f|^{2}}\left\{\left[\alpha R_{a b}-(\rho S+\lambda) \delta_{a b}\right]^{2}\right. \\
& \left.\quad-(m-1)\left[\left(\frac{\alpha}{m-1}-\rho\right) S-\frac{\alpha}{m-1} R_{m m}-\lambda\right]^{2}\right\} \\
= & \frac{\alpha^{2}}{\beta^{2}|\nabla f|^{2}}\left\{\mid \text { Ric }\left.\right|^{2}-2 R_{a m} R_{a m}-\left(R_{m m}\right)^{2}\right. \\
& \left.\quad-\frac{1}{m-1}\left[S^{2}-2 S R_{m m}+\left(R_{m m}\right)^{2}\right]\right\} \\
= & \frac{\alpha^{2}}{\beta^{2}|\nabla f|^{2}}\left[\mid \text { Ric }\left.\right|^{2}-2 R_{a m} R_{a m}-\frac{m}{m-1}\left(R_{m m}\right)^{2}\right. \\
& \left.\quad-\frac{1}{m-1} S^{2}+\frac{2}{m-1} S R_{m m}\right] .
\end{align*}
$$

On the other hand, from the definition of $D$ we have

$$
\begin{align*}
& |D|^{2}=\frac{\left(f_{k} R_{i j}-f_{j} R_{i k}\right)^{2}}{(m-2)^{2}}  \tag{6-5}\\
& +\frac{\left(f_{t} R_{t k} \delta_{i j}-f_{t} R_{t j} \delta_{i k}\right)^{2}}{(m-1)^{2}(m-2)^{2}}+\frac{S^{2}}{(m-1)^{2}(m-2)^{2}}\left(f_{k} \delta_{i j}-f_{j} \delta_{i k}\right)^{2} \\
& +\frac{2}{(m-1)(m-2)^{2}}\left(f_{k} R_{i j}-f_{j} R_{i k}\right)\left(f_{t} R_{t k} \delta_{i j}-f_{t} R_{t j}\right) \\
& -\frac{2 S}{(m-1)(m-2)^{2}}\left(f_{k} R_{i j}-f_{j} R_{i k}\right)\left(f_{k} \delta_{i j}-f_{j} \delta_{i k}\right) \\
& -\frac{2 S}{(m-1)^{2}(m-2)^{2}}\left(f_{t} R_{t k} \delta_{i j}-f_{t} R_{t j} \delta_{i k}\right)\left(f_{k} \delta_{i j}-f_{j} \delta_{i k}\right) \\
& =\frac{2|\nabla f|^{2}}{(m-2)^{2}}\left(|\mathrm{Ric}|^{2}-R_{a m} R_{a m}-R_{m m} R_{m m}\right) \\
& +\frac{2|\nabla f|^{2}}{(m-1)(m-2)^{2}}\left(R_{a m} R_{a m}+R_{m m} R_{m m}\right) \\
& +\frac{2 S^{2}}{(m-1)(m-2)^{2}}|\nabla f|^{2} \\
& +\frac{4|\nabla f|^{2}}{(m-1)(m-2)^{2}}\left(S R_{m m}-\left(R_{m m}\right)^{2}-R_{a m} R_{a m}\right) \\
& -\frac{4 S|\nabla f|^{2}}{(m-1)(m-2)^{2}}\left(S-R_{m m}\right)-\frac{4 S|\nabla f|^{2}}{(m-1)(m-2)^{2}} R_{m m} .
\end{align*}
$$

Simplifying, rearranging, and comparing (6-4) and (6-5) we arrive at

$$
\frac{(m-2)^{2}}{2|\nabla f|^{2}}|D|^{2}=\left(\frac{\beta}{\alpha}\right)^{2}|\nabla f|^{2}\left|h_{a b}-h \delta_{a b}\right|^{2}+\left(\frac{m-2}{m-1}\right) R_{a m} R_{a m},
$$

which easily implies (6-1).
Proposition 6.1 is one of the key ingredients in the proof of the following theorem, which generalizes [Cao and Chen 2013, Proposition 3.2 ] (compare also with [Huang and Li 2014, Proposition 2.4]). Our proof is similar to those in [Cao and Chen 2013; Huang and Li 2014], but the presence of $\mu$ and the nonconstancy of $\lambda$ require extra care, in particular in showing that $S$ is constant on $\Sigma_{c}$.

Theorem 6.3. Let $(M, g)$ be a complete, $m$-dimensional ( $m \geq 3$ ), gradient, Einsteintype manifold with $\alpha, \beta \neq 0$ and tensor $D \equiv 0$. Let c be a regular value of $f$ and let $\Sigma_{c}=\{x \in M \mid f(x)=c\}$ be the corresponding level hypersurface. Choose any local orthonormal frame such that $\left\{e_{1}, \ldots, e_{m-1}\right\}$ are tangent to $\Sigma_{c}$ and $e_{m}=\nabla f /|\nabla f|$ (i.e., $\left\{e_{1}, \ldots, e_{m-1}, e_{m}\right\}$ is a first order frame along $f$ ). Then
(1) $|\nabla f|^{2}$ is constant on $\Sigma_{c}$;
(2) $R_{a m}=R_{m a}=0$ for every $a=1, \ldots, m-1$ and $e_{m}$ is an eigenvector of Ric;
(3) $\Sigma_{c}$ is totally umbilical;
(4) the mean curvature $h$ is constant on $\Sigma_{c}$;
(5) the scalar curvature $S$ and $\lambda$ are constant on $\Sigma_{c}$;
(6) $\Sigma_{c}$ is Einstein with respect to the induced metric;
(7) on $\Sigma_{c}$ the (components of the) Ricci tensor of $M$ can be written as $R_{a b}=$ $\left(S-\Lambda_{1}\right) /(m-1) \delta_{a b}$, where $\Lambda_{1} \in \mathbb{R}$ is an eigenvalue of multiplicity 1 or $m$ (and in this latter case $S=m \Lambda_{1}$ ); in either case $e_{m}$ is an eigenvector associated to $\Lambda_{1}$.

Proof. If $D=0$, from Proposition 6.1 we immediately deduce that

$$
\begin{equation*}
h_{a b}-h \delta_{a b}=0 \tag{6-6}
\end{equation*}
$$

that is, property (3), and

$$
R_{a m}=0, \quad(a=1, \ldots, m-1)
$$

From (6-6) a simple computation using (6-2) and (6-3) shows that

$$
\begin{equation*}
R_{a b}=\frac{S-R_{m m}}{m-1} \delta_{a b} \tag{6-7}
\end{equation*}
$$

which also implies

$$
\operatorname{Ric}(v, v)=\frac{R_{i j} f_{i} f_{j}}{|\nabla f|^{2}}=R_{m m}=R_{m m}|v|^{2}
$$

This complete the proof of (2). To prove (1) we take the covariant derivative of $\beta|\nabla f|^{2}$ and use (4-1).

$$
\begin{aligned}
\beta\left(|\nabla f|^{2}\right)_{k} & =2 \beta f_{i} f_{i k} \\
& =2\left[\left(\rho S+\lambda-\mu|\nabla f|^{2}\right) f_{k}-\alpha f_{t} R_{t k}\right] \\
& =2\left[\left(\rho S+\lambda-\mu|\nabla f|^{2}\right) f_{k}-\alpha f_{c} R_{c k}-\alpha|\nabla f| R_{m k}\right]
\end{aligned}
$$

Evaluating the previous relation at $k=a$ and using property (2) we immediately get

$$
\left(|\nabla f|^{2}\right)_{a}=0
$$

that is (1). To prove (4) we start from the Codazzi equations, that in our setting read

$$
-R_{m a b c}=h_{a b, c}-h_{a c, b}
$$

Tracing with respect to $a$ and $c$ we get

$$
-R_{m a b a}=-R_{m k b k}+R_{m m b m}=h_{a b, a}-h_{a a, b}
$$

that is, using (2),

$$
\begin{equation*}
0=-R_{m b}=h_{a b, a}-h_{a a, b} \tag{6-8}
\end{equation*}
$$

On the other hand, from (3) we have

$$
h_{a b, a}=h_{b} \quad \text { and } \quad h_{a a, b}=(m-1) h_{b},
$$

so that (6-8) immediately implies

$$
0=(m-2) h_{b}, \quad \text { for } \quad b=1, \ldots, m-1 \text {, }
$$

that is (4). To show the validity of (5) we first observe that, evaluating (4-10) at $k=a$ and using (2), we deduce

$$
[\alpha-2 \rho(m-1)] S_{a}-2(m-1) \lambda_{a}=0,
$$

which implies

$$
\begin{equation*}
[\alpha-2 \rho(m-1)] S-2(m-1) \lambda \quad \text { is constant on } \Sigma_{c} . \tag{6-9}
\end{equation*}
$$

From (6-3), the constancy of $h$ and of $|\nabla f|$ on $\Sigma_{c}$ also give that

$$
\begin{equation*}
[\alpha-\rho(m-1)] S-\alpha R_{m m}-(m-1) \lambda \quad \text { is constant on } \Sigma_{c} . \tag{6-10}
\end{equation*}
$$

Combining (6-9) and (6-10) we arrive at

$$
\begin{equation*}
S-2 R_{m m} \quad \text { is constant on } \Sigma_{c} . \tag{6-11}
\end{equation*}
$$

Now we evaluate (4-10) at $k=m$, we use (2) and rearrange to deduce

$$
\begin{aligned}
& {[\alpha-2 \rho(m-1)] S_{m}} \\
& \quad=2\left(\beta+\frac{\alpha \mu}{\beta}\right)|\nabla f| R_{m m}+2(m-1) \lambda_{m}-\frac{2 \mu|\nabla f|}{\beta}\{[\alpha-\rho(m-1)] S-(m-1) \lambda\} \\
& \quad=2 \beta|\nabla f| R_{m m}+2(m-1) \lambda_{m}-\frac{2 \mu|\nabla f|}{\beta}\left\{[\alpha-\rho(m-1)] S-\alpha R_{m m}-(m-1) \lambda\right\} .
\end{aligned}
$$

Since by (1) and (6-10) the quantity $(2 \mu|\nabla f|) / \beta\left\{[\alpha-\rho(m-1)] S-\alpha R_{m m}-(m-1) \lambda\right\}$ is constant on $\Sigma_{c}$ we infer that
(6-12) $\quad[\alpha-2 \rho(m-1)] S_{m}-2 \beta|\nabla f| R_{m m}-2(m-1) \lambda_{m} \quad$ is constant on $\Sigma_{c}$. Now we take the covariant derivative of $(6-12)$ and evaluate at $k=a$ to obtain (6-13) $\quad[\alpha-2 \rho(m-1)] S_{m a}-2 \beta|\nabla f| R_{m m, a}-2(m-1) \lambda_{m a}=0 \quad$ on $\Sigma_{c}$. But $S_{m a}=S_{a m}$ and $\lambda_{m a}=\lambda_{a m}$, thus (6-13) can be written as

$$
\{[\alpha-2 \rho(m-1)] S-2(m-1) \lambda\}_{a m}=2 \beta|\nabla f| R_{m m, a} \quad \text { on } \Sigma_{c},
$$

which implies, by (6-9), that

$$
R_{m m} \text { is constant on } \Sigma_{c} .
$$

The previous relation, (6-11), and (6-9) show that $S$ and $\lambda$ are constant on $\Sigma_{c}$, that is (5). To prove (6) we start from the Gauss equations

$$
{ }^{\Sigma_{c}} R_{a b c d}=R_{a b c d}+h_{a c} h_{b d}-h_{a d} h_{b c},
$$

which, by property (3), can be rewritten as

$$
\begin{equation*}
{ }^{\Sigma_{c}} R_{a b c d}=R_{a b c d}+h^{2}\left(\delta_{a c} \delta_{b d}-\delta_{a d} \delta_{b c}\right) . \tag{6-14}
\end{equation*}
$$

Tracing (6-14) with respect to $b$ and $d$ gives

$$
\begin{equation*}
{ }^{{ }^{c}} R_{a c}=R_{a c}-R_{a m c m}+(m-2) h^{2} \delta_{a c} . \tag{6-15}
\end{equation*}
$$

Tracing again we deduce that

$$
\begin{equation*}
\Sigma_{c} S=S-2 R_{m m}+(m-1)(m-2) h^{2} \quad \text { is constant on } \Sigma_{c} . \tag{6-16}
\end{equation*}
$$

Now a simple computation using decomposition (2-1) of the Riemann tensor, (6-7) and the fact that $W_{a m c m}=0$ (see Proposition 6.4) shows that

$$
\begin{equation*}
R_{a m c m}=\frac{1}{m-1} R_{m m} \delta_{a c} . \tag{6-17}
\end{equation*}
$$

Next, inserting (6-7) and (6-17) into (6-15), we get

$$
{ }^{\Sigma_{c}} R_{a c}=\left[\frac{S-2 R_{m m}}{m-1}+(m-2) h^{2}\right] \delta_{a c},
$$

which shows the validity of (6). Now (7) is an easy consequence of the other properties.

The next two results are analogues of, respectively, Lemmas 4.2 and 4.3 of [Cao and Chen 2013].

Proposition 6.4. Let $(M, g)$ be a complete, noncompact, $m$-dimensional ( $m \geq 3$ ), nondegenerate, Einstein-type manifold with $\alpha \neq 0$. If $D=0$ then $C=0$, unless $f$ is locally constant.

Proof. First of all, by analyticity, it is sufficient to prove the result where $\{\nabla f \neq 0\}$. We choose a local first order frame along $f$ (so that $f_{a}=0, a=1, \ldots, m-1$ and $\left.f_{m}=|\nabla f|\right)$. The vanishing of $D$ implies, by the first integrability condition (4-5), that

$$
\alpha C_{i j k}+\beta f_{t} W_{t i j k}=0,
$$

which implies, since $\alpha \neq 0$,

$$
\begin{equation*}
C_{i j k}=-\frac{\beta}{\alpha} f_{t} W_{t i j k} \tag{6-18}
\end{equation*}
$$

and consequently

$$
f_{i} C_{i j k}=f_{m} C_{m j k}=|\nabla f| C_{m j k}=0, \quad(j, k=1, \ldots, m) .
$$

Thus

$$
C_{m j k}=0
$$

at all points where $|\nabla f| \neq 0$. Using (3) and (4) of Theorem 6.3 we have

$$
h_{a b, c}=0
$$

and from the Codazzi equations we get

$$
-R_{m a b c}=h_{a b, c}-h_{a c, b}=0
$$

Since $R_{a m}=0$ by (2) of Theorem 6.3, from the decomposition (2-1) we easily deduce

$$
W_{a m b c}=0,
$$

which implies by (6-18) that

$$
C_{a b c}=0
$$

By the symmetries of $C$, to conclude it only remains to show that $C_{a b m}=0=C_{a m b}$. First we observe that $R_{a m}=0$ implies, by the definition of covariant derivative,

$$
\begin{aligned}
0 & =d R_{a m} \\
& =R_{k m} \theta_{a}^{k}+R_{a k} \theta_{m}^{k}+R_{a m, k} \theta^{k} \\
& =R_{b m} \theta_{a}^{b}+R_{m m} \theta_{a}^{m}+R_{a b} \theta_{m}^{b}+R_{a m} \theta_{m}^{m}+R_{a m, k} \theta^{k} \\
& =R_{m m} \theta_{a}^{m}+R_{a b} \theta_{m}^{b}+R_{a m, k} \theta^{k},
\end{aligned}
$$

so that, using (6-7),

$$
\begin{align*}
R_{a m, k} \theta^{k}=R_{a m, b} \theta^{b}+R_{a m, m} \theta^{m} & =R_{a b} \theta_{b}^{m}-R_{m m} \theta_{a}^{m}  \tag{6-19}\\
& =\left(\frac{S-R_{m m}}{m-1} \delta_{a b}\right) \theta_{b}^{m}-R_{m m} \theta_{a}^{m} \\
& =\left(\frac{S-m R_{m m}}{m-1}\right) \theta_{a}^{m}
\end{align*}
$$

Now we want to show that $R_{a m, m}=0$. To see that we first evaluate (4-1) for $i=a$ and $j=m$, obtaining $f_{a m}=0$; then we take the covariant derivative of the same equation

$$
\alpha R_{i j, k}+\beta f_{i j k}+\mu\left(f_{i k} f_{j}+f_{i} f_{j k}\right)=\left(\rho S_{k}+\lambda_{k}\right) \delta_{i j}
$$

which for $i=k=m$ and $j=a$ gives (using $f_{a m}=0$ )

$$
\alpha R_{a m, m}=-\beta f_{m a m}
$$

but

$$
f_{m a m}=f_{m m a}+f_{i} R_{i m a m}=f_{m m a},
$$

while (4-2) and Theorem 6.3 tell us that the (globally defined) quantity $\Delta f$ is constant on $\Sigma_{c}$, so that

$$
(\Delta f)_{a}=0
$$

On the other hand, from (4-1) and (6-7) we deduce

$$
\begin{equation*}
\beta f_{a b}=-\frac{1}{m-1}\left\{[\alpha-\rho(m-1)] S-\alpha R_{m m}-(m-1) \lambda\right\} \delta_{a b} \tag{6-20}
\end{equation*}
$$

which implies, by tracing, that

$$
\beta\left(\Delta f-f_{m m}\right) \quad \text { is constant on } \Sigma_{c} .
$$

In particular

$$
f_{\text {mam }}=f_{\text {mma }}=(\Delta f)_{a}=0,
$$

and thus

$$
R_{a m, m}=0 .
$$

Getting back to (6-19) we now have

$$
R_{a m, b} \theta^{b}=\left(\frac{S-m R_{m m}}{m-1}\right) \theta_{a}^{m},
$$

and thus

$$
\begin{align*}
R_{a m, b} & =\left(\frac{S-m R_{m m}}{m-1}\right) \theta_{a}^{m}\left(e_{b}\right)  \tag{6-21}\\
& =\frac{1}{|\nabla f|}\left(\frac{m R_{m m}-S}{m-1}\right) f_{a b} .
\end{align*}
$$

Schur's identity implies

$$
\begin{equation*}
S_{m}=2 R_{i m, i}=2 R_{a m, a}+2 R_{m m, m} . \tag{6-22}
\end{equation*}
$$

From the definition of $C$ we have, using (6-7) and (6-21),

$$
\begin{align*}
C_{a b m} & =R_{a b, m}-R_{a m, b}-\frac{1}{2(m-1)} S_{m} \delta_{a b}  \tag{6-23}\\
& =\frac{S_{m}-R_{m m, m}}{m-1} \delta_{a b}+\frac{1}{|\nabla f|}\left(\frac{s-m R_{m m}}{m-1}\right) f_{a b}-\frac{1}{2(m-1)} S_{m} \delta_{a b} \\
& =\frac{1}{2(m-1)} S_{m} \delta_{a b}-\frac{1}{m-1} R_{m m, m} \delta_{a b}+\frac{1}{|\nabla f|}\left(\frac{S-m R_{m m}}{m-1}\right) f_{a b} .
\end{align*}
$$

Using (6-22), (6-21), and (6-20) in (6-23) we arrive at

$$
\begin{aligned}
C_{a b m} & =\frac{1}{m-1} R_{c m, c} \delta_{a b}+\frac{1}{|\nabla f|}\left(\frac{S-m R_{m m}}{m-1}\right) f_{a b} \\
& =-\frac{1}{m-1} \frac{1}{|\nabla f|}\left(S-m R_{m m, m}\right) f_{a b}+\frac{1}{|\nabla f|}\left(\frac{S-m R_{m m}}{m-1}\right) f_{a b} \\
& =0,
\end{aligned}
$$

concluding the proof.
In dimension four, we can prove the following:
Corollary 6.5. Let $\left(M^{4}, g\right)$ be a complete, noncompact, nondegenerate, Einsteintype manifold of dimension four with $\alpha \neq 0$. If $D=0$ then $W=0$, unless $f$ is locally constant.

Proof. From Proposition 6.4, we know that $C_{i j k}=0$. Hence, from (4-5), we deduce $f_{t} W_{t i j k}=0$ for any $i, j, k=1, \ldots, 4$. For any $p \in M^{4}$ such that $\nabla f(p) \neq 0$, we choose an orthonormal frame $\left\{e_{1}, \ldots, e_{4}\right\}$ such that $e_{4}=\nabla f /|\nabla f|$, thus we have

$$
W_{4 i j k}(p)=0, \quad \text { for } i, j, k=1, \ldots 4 .
$$

It remains to show that $W_{a b c d}(p)=0$ for any $a, b, c, d=1,2,3$. This follows from the symmetries and the traceless property of the Weyl tensor (see, for instance, [Cao and Chen 2013, Lemma 4.3]).

## 7. Proof of the main theorems and some geometric applications

In this last section we first prove Theorem 1.2 and Corollary 1.3. Then, we give some geometric applications in the special cases of gradient Ricci solitons, $\rho$-Einstein solitons, and Ricci almost solitons. We begin with

Proof of Theorem 1.2 and Corollary 1.3. From Theorem 5.3 we know that the tensor $D$ has to vanish on $M$. Let $\Sigma$ be a regular level set of the function $f: M^{m} \rightarrow \mathbb{R}$, i.e., $|\nabla f| \neq 0$ on $\Sigma$, which exists by Sard's Theorem and the fact that $f$ is nontrivial. By Theorem 6.3 (1) we have that $|\nabla f|$ must be constant on $\Sigma$. Thus, in a neighborhood $U$ of $\Sigma$ which does not contain any critical point of $f$, the potential function $f$ only depends on the signed distance $r$ to the hypersurface $\Sigma$. Hence, by a suitable change of variable, we can express the metric $g_{i j}$ as

$$
d s^{2}=d r^{2}+g_{a b}(r, \theta) d \theta^{a} \otimes d \theta^{b} \quad\left(r_{*}<r<r^{*}\right)
$$

for some maximal $r_{*} \in[-\infty, 0)$ and $r^{*} \in(0, \infty]$, where $\left(\theta^{2}, \ldots, \theta^{m}\right)$ is any local coordinates system on the level surface $\Sigma$. Moreover, by Theorem 6.3 (3)-(4), we have

$$
\frac{\partial}{\partial r} g_{a b}=-2 h_{a b}=\phi(r) g_{a b},
$$

where $\phi(r)=-2 h(r)$. Thus, it follows easily that

$$
g_{a b}(r, \theta)=e^{\Phi(r)} g_{a b}(0, \theta), \quad \text { where } \quad \Phi(r)=\int_{0}^{r} \phi(r) d r .
$$

This proves that on $U$ the metric $g$ takes the form of a warped product metric

$$
d s^{2}=d r^{2}+w(r)^{2} g^{E}, \quad r \in\left(r_{*}, r^{*}\right),
$$

where $w$ is some positive smooth function on $U$, and $g^{E}=g^{\Sigma}$ is the metric defined on the level surface $\Sigma$, which is Einstein, by Theorem 6.3 (6). This concludes the proof of Theorem 1.2.

The proof of Corollary 1.3 follows from the previous considerations combined with Corollary 6.5 .

Next we show that the properness assumption on the potential function $f$ in Theorem 1.2 is automatically satisfied by some classes of Einstein-type manifolds.

First of all, let $(M, g)$ be a complete, noncompact, gradient Ricci soliton with potential function $f$. Then, it is well known that $f$ is always proper, provided that the soliton is either shrinking [Cao and Zhou 2010, Theorem 1.1], or steady with positive Ricci curvature and scalar curvature attaining its maximum at some point [Cao and Chen 2012, Proposition 2.3], or expanding with nonnegative Ricci curvature [Cao et al. 2014, Lemma 5.5]. Hence, in these cases, Theorem 1.2 provides a local version of the classification results obtained in [Cao and Chen 2013; Cao et al. 2014].

Secondly, if $(M, g)$ is a complete, noncompact, gradient shrinking $\rho$-Einstein soliton with $\rho>0$ and bounded scalar curvature, then it follows by [Catino et al. 2015, Lemma 3.2] that the potential function $f$ is proper. Hence, Theorem 1.2 implies the following
Theorem 7.1. Let $(M, g)$ be a complete, noncompact, gradient shrinking $\rho$-Einstein soliton of dimension $m \geq 3$ with bounded scalar curvature and $\rho>0$. If $B(\nabla f, \cdot)=0$, then around any regular point of $f$ the manifold $(M, g)$ is locally a warped product with ( $m-1$ )-dimensional Einstein fibers.

Finally, we want to show the following result concerning gradient Ricci almost solitons which are "strongly" shrinking.
Theorem 7.2. Let $(M, g)$ be a complete, noncompact, gradient Ricci almost soliton of dimension $m \geq 3$ with bounded Ricci curvature and with $\lambda \geq \underline{\lambda}>0$, for some $\underline{\lambda}$. If $B(\nabla f, \cdot)=0$, then around any regular point of $f$ the manifold $(M, g)$ is locally a warped product with ( $m-1$ )-dimensional Einstein fibers.

Proof. By Theorem 1.2 it is sufficient to show that under these assumptions the potential function is proper. To do this we will apply a second variation argument as in [Cao and Zhou 2010, Theorem 1.1]. Let $r(x)=\operatorname{dist}(x, o)$, for some fixed origin $o \in M$. We will show that, for $r(x) \gg 1$,

$$
f(x) \geq \frac{1}{2} \lambda(r(x)-c)^{2},
$$

for some positive constant $c>0$ depending only on $m$ and on the geometry of $g$ on the unit ball $B_{o}(1)$. Let $\gamma(s), 0 \leq s \leq s_{0}$ for some $s_{0}>0$, be any minimizing unit speed geodesic starting from $o=\gamma(0)$ and let $\dot{\gamma}(s)$ be the unit tangent vector of $\gamma$. Then by the second variation of the arc length, we have

$$
\int_{0}^{s_{0}} \phi^{2}(s) \operatorname{Ric}(\dot{\gamma}, \dot{\gamma}) d s \leq(m-1) \int_{0}^{s_{0}}|\dot{\phi}(s)|^{2} d s
$$

for every nonnegative function $\phi:\left[0, s_{0}\right] \rightarrow \mathbb{R}$. We choose $\phi(s)=s$ on $[0,1]$, $\phi(s)=1$ on $\left[1, s_{0}-1\right]$, and $\phi(s)=s_{0}-s$ on $\left[s_{0}-1, s_{0}\right]$. Then, since the solitons
has bounded Ricci curvature, one has

$$
\int_{0}^{s_{0}} \operatorname{Ric}(\dot{\gamma}, \dot{\gamma}) d s \leq 2(m-1)+\max _{B_{1}(o)}|\operatorname{Ric}|+\max _{B_{1}\left(\gamma\left(s_{0}\right)\right)}|\operatorname{Ric}| \leq C,
$$

for some positive constant $C$ independent of $s_{0}$. On the other hand, from the soliton equation, we have

$$
\nabla_{\dot{\gamma}} \nabla_{\dot{\gamma}} f=\lambda-\operatorname{Ric}(\dot{\gamma}, \dot{\gamma}) .
$$

Integrating along $\gamma$, we get

$$
\dot{f}\left(\gamma\left(s_{0}\right)\right)-\dot{f}(\gamma(0))=\int_{0}^{s_{0}} \lambda d s-\int_{0}^{s_{0}} \operatorname{Ric}(\dot{\gamma}, \dot{\gamma}) d s \geq \underline{\lambda} s_{0}-C .
$$

Integrating again, we obtain the desired estimate

$$
f\left(\gamma\left(s_{0}\right)\right) \geq \frac{1}{2} \lambda\left(s_{0}-c\right)^{2},
$$

for some constant $c$. This concludes the proof of the theorem.
Remark 7.3. From the above proof, if $\underline{\lambda}=\underline{\lambda}(r)$ is such that $1 / \underline{\lambda}(r)=o\left(1 / r^{2}\right)$ as $r \rightarrow+\infty$ we have $f(r) \rightarrow+\infty$ as $r \rightarrow+\infty$. This suffices to prove Theorem 7.2.

To conclude, we note that Ricci almost solitons which are warped products were constructed in [Pigola et al. 2011, Remark 2.6].
