Giuliana Sala; Elena Cornelli; Serena Bezze; Paola Marchisio

Abstract: Microbiological analysis on nasal saline irrigations (NSIs) used in hospitalized children was performed. 24.9% out of 253 collected samples were positive; the number of positive samples significantly ( $p$ -value  $< 0.001$ ) increased over time. *Staphylococcus aureus* was the most frequently detected bacterium (28.6%); none of the 118 patients receiving NSIs developed nasosinusual infection. Colonization by cutaneous and environmental germs is frequent and precocious; the respect of hygienic measure should be advocated in order to reduce contamination.

Milan, May 7nd 2018

Dear Editor,

this paper reports and original research assessing the risk of bacterial contamination of saline solution in hospitalized children daily undergoing nasal saline irrigations by the use of a syringe bulb and saline solution bottle.

We hope it will be considered of interest.

Yours faithfully,

Sara Torretta

## ANSWER RO REVIEWER

Title: BACTERIAL CONTAMINATION OF SALINE NASAL IRRIGATIONS IN CHILDREN: AN ORIGINAL RESEARCH

American Journal of Infection Control

Highlights (mandatory)

Highlights consist of a short collection of bullet points that convey the core findings of the article and should be submitted in a separate file in the online submission system. Please use 'Highlights' in the file name and include 3 to 5 bullet points (maximum 85 characters, including spaces, per bullet point). See the following website for more information

<http://www.elsevier.com/highlights>

*Highlights have been uploaded.*

Reviewers' comments:

This is an interesting study but am not certain it supports the conclusion. I think that it should focus on NSIs being effective treatment and potentially cutting down on other therapies such as antihistamines in young children and improper use of antibiotics both of which are important. It also supports some infection control aspects such as good hand hygiene and single patient use. It also supports the conclusion that there is excessive bacterial flora in hospital settings and that despite instruction, translocation is possible. My concern about the conclusion the way it exists now is that despite not seeing colonization progress to infection we should use new supplies and equipment every day. This could translate into many other practices that have no benefit to preventing infection when it is very unlikely to occur.

This should be revised as a Brief Report of a maximum of 1000 words, a 2-3 sentence unstructured abstract.

Tables and figures should have a full legend since they should be interpretable without referring to the article.

*We thank the Reviewer for these suggestions and the chance to improve our manuscript. The paper has been shortened into a brief report, conclusions have been changed, abstract and legends have been modified accordingly.*

4 **ORIGINAL RESEARCH**

5 **Abstract**

6 Microbiological analysis on nasal saline irrigations (NSIs) used in hospitalized children was  
7 performed.

8 24.9% out of 253 collected samples were positive; the number of positive samples  
9 significantly (p-value < 0.001) increased over time. *Staphylococcus aureus* was the most  
10 frequently detected bacterium (28.6%); none of the 118 patients receiving NSIs developed  
11 nasosinusual infection.

12 Colonization by cutaneous and environmental germs is frequent and precocious; the  
13 respect of hygienic measure should be advocated in order to reduce contamination.

14 | **Key words:** Children; Nasal saline irrigation; Bacterial contamination.

15

16

Formatted

## HIGHLIGHTS

- Nasal saline irrigations are widely used in clinical practice
- Bacterial contamination is frequent and precocious, but not associated with infection
- Non-respiratory bacteria are generally involved
- Bacterial translocation from healthcare professionals may be a source
- Respect of hygienic measures could decrease the risk of bacterial contamination

1 **BACTERIAL CONTAMINATION OF SALINE NASAL IRRIGATIONS IN CHILDREN: AN**  
2 **ORIGINAL RESEARCH**

3

4

5 **BACKGROUND**

6 Nasal saline irrigations (NSIs) are used in patients with upper respiratory tract infections  
7 and allergic rhinitis.<sup>1-4</sup> A national survey documented that the majority of Italian  
8 paediatricians consider them effective and well tolerated.<sup>3</sup> Different devices are actually  
9 available<sup>3</sup> and NSIs performed by repeatedly resampling from a saline solution bottle by  
10 means of a bulb syringe is probably the easiest and most inexpensive approach.

11 Despite they are generally considered safe, bacterial contamination of the device may  
12 occur, as saline bottle bacterial contamination has been described.<sup>5-20</sup>

13 The aim of this study was to evaluate bacterial colonization of saline solution in children  
14 daily undergoing NSIs by the use of a syringe bulb and saline solution bottle.

15 **METHODS**

16 *Materials*

17 Samples of saline solution taken from the bottles used for NSIs in children admitted to our  
18 hospital for lower respiratory tract infections and candidates to daily NSIs.

19 Exclusion criteria were: acute nasosinusal infection; severe systemic diseases (cystic  
20 fibrosis, Kartagener syndrome); neuromuscular, immunological, syndromic or genetic  
21 abnormalities, parents refusal.

22 *Interventions*

23 Before the first use, the syringe needle was used to pierce the rubber bottle cap by the  
24 paediatric nurse, then the needle was removed and the syringe bulb was placed and left  
25 inside the pierced rubber bottle cap. Care givers were instructed about the modality to  
26 perform NSIs as it follows: after washing his\her hands before each use, the syringe  
27 should be filled up with saline solution and used for irrigation. Then it should be placed  
28 inside the pierced rubber bottle cap. NSIs were performed by the children's parents, or by  
29 the healthcare professionals.

30 Paediatric nurses were instructed to periodically pick up 5 ml samples of saline solution  
31 from the bottle by means of the syringe used for NSI (after hands washing and putting  
32 disposable gloves on) just after the bottle opening (day 0), and then the day after (day 1,  
33 within 24 hours), and two (day 2, 48 hours after the bottle opening), three (day 3, 72  
34 hours), four (day 4, 96-120 hours), five (day 5, 120-144 hours), and six (day 6, 140-168  
35 hours) days later. The samples were moved into sterile phials and delivered to the  
36 Microbiological Laboratory to be analysed within two hours.

37 *Microbiological evaluation*

38 Each specimen was immediately vortexed and cultured on Mueller Hinton agar,  
39 MacConkey agar, Mannitol Salt Agar (Difco) under aerobic condition and on Columbia  
40 blood agar (Difco) in a 5%CO<sub>2</sub> atmosphere at 37°C. The plates were firstly examined after

41 18-24 hours of incubation and furtherly checked for the presence of bacterial colonies after  
42 48 hours in order to detect the slow-growing microorganisms. The Microbial identification  
43 was performed at genus and species level according to their typical colony morphology,  
44 Gram stain, standard rapid tests and finally confirmed by biochemical tests (API -  
45 BioMérieux).

#### 46 *Statistical analysis*

47 Descriptive statistics was used to report the main results (given as absolute numbers and  
48 percentages, or as arithmetical mean values  $\pm$  standard deviation).

49 The dichotomous outcomes were analysed using contingency table analysis by means of  
50 Fisher's exact test; time-series regression analysis was used to evaluate the statistical  
51 trend of the percentage of positive samples over time. The characteristic of NSIs performer  
52 were tested as possible confounders.

53

54 **RESULTS**

55 The final analysis was based on 253 samples collected from bottles used for administering  
56 NSIs to 118 children (66, 55.9% males; mean age  $17.0 \pm 15.9$  months).

57 The mean samples for each patient was  $2.1 \pm 2.8$  (Figure 1), and NSIs were performed by  
58 respectively the healthcare professionals and the children's parents in 43.5% and 56.5% of  
59 cases.

60 24.9% of samples were positive at microbiological assessment. Bacterial contamination in  
61 at least one sample was detected in 22.0% of patients, and no significantly difference in  
62 the number of patients with at least one positive sample was found when NSIs performers  
63 were separately considered (healthcare professionals= 21.5% vs. children's parents=  
64 21.5%). Bacterial contamination occurred significantly ( $p$ -value= 0.003) earlier when NSIs  
65 were administered by the healthcare professionals compared to the parents, as 59.2% of  
66 positive samples among those collected by healthcare professionals were taken within 24  
67 hours after the bottle opening, while only 17.4% of positive samples among those collected  
68 by the children's parents were taken within 24 hours after the bottle opening.

69 The number of positive samples at microbiological assessment significantly ( $p$ -value <  
70 0.001) increased over time, with a mean 14.3% (standard error= 0.1;  $p$ -value < 0.001)  
71 daily increase (Figure 2).

72 *Staphylococcus aureus* was the most frequently detected one (28.6%) (Table 1).

73 Polymicrobial contamination was found in 2.4% (6/253) samples.

74 None of the patients developed signs of acute nasosinusual infection.

75

76 **DISCUSSION**

77 Bacterial contamination of saline solution bottles used for NSIs in children is not a rare  
78 event, as it occurred in about 25% of samples. Although no comparable studies have been  
79 previously performed in the paediatric age, our findings lines with literature, as a recent  
80 review of contamination in sinus irrigation device used after functional nasosinusual surgery  
81 documented that the overall prevalence of positive samples ranged between 25-100%,<sup>7</sup>  
82 with *S. aureus* being detected as the main pathogen.

83 We documented a progressive significant increase in the number of contaminated samples  
84 over time, as a not negligible percentage of samples was found to be positive within 24  
85 hours from bottle opening, suggesting that bacterial contamination occurs very  
86 precociously, and confirming a previous report.<sup>10</sup>

87 No bacteria involved in upper airway infections have been isolated, as only germs  
88 generally located at the cutaneous or enviromental surfaces have been discovered, with *S.*  
89 *aureus* and *Neisseria* spp. being the most frequently detected ones.

90 The absence of any sign suggestive for the development of acute nasal or nasosinusual  
91 infections in this cohort of patients seems to suggest that lack of a direct link between  
92 saline solution contamination and the occurrence of any infectious process.

93 Microbiological results make us reflect about the importance of strictly respecting hygienic  
94 measures including accurate hand-washing before NSIs administration in order to reduce  
95 the rate of bacterial contamination resulting from germs spreading from the caregivers'  
96 hands and the surrounding environment. This derives from the observation that positive  
97 cultures were found significantly earlier when NSIs were administered by the healthcare  
98 professionals compared to the parents.

99

100

101 **CONCLUSIONS**

102 This study confirms the safety of NSIs in children, and advocate their use as preventive  
103 and therapeutic means in patients with upper airway disease, as they could possibly cut  
104 down on other therapies such as antihistamines and improper antibiotics.

105 Moreover, our results document the presence of excessive bacterial flora in hospital  
106 settings, and the possibility of bacterial translocation from caregivers and healthcare  
107 professionals, therefore advocating the importance of infection control aspects including  
108 good hand hygiene and single patient use in order to reduce the rate of bacterial  
109 contamination.

110 ~~This is the first study documenting that colonization of nasal saline solution by cutaneous  
111 and environmental but not respiratory germs is possible, frequent, and precocious in  
112 children undergoing NSIs by means of repeated aspiration of sterile saline solution with a  
113 bulb syringe from an irrigation bottle, but there is no evidence that this condition would  
114 facilitate the development of any nasosinusal infection. The respect of hygienic measure,  
115 correct patients education, and daily bottle changing should be advocated in order to  
116 reduce the rate of bacterial contamination, and improved the safety of nasal irrigations.~~

118

119 **Funding:** This research did not receive any specific grant from funding agencies in the  
120 public, commercial, or not-for-profit sectors.

121 **Conflict of interest statement:** Nothing to declare.

## TABLE

**Table I: Number and rate of samples with isolated bacterial ~~Bacteria~~ strains.**

<b>Bacterial strain</b>	<b>№. Number of samples (%)</b>
<i>Staphylococcus aureus</i>	18/63 (28.6%)
Neisseriae spp.	11/63 (17.5%)
<i>Klebsiella pneumoniae</i>	9/63 (14.3%)
<i>Stenotrophomonas maltophilia</i>	9/63 (14.3%)
<i>Alcaligenes xylosoxidans</i>	5/63 (7.9%)
<i>Staphylococcus xylosus</i>	3/63 (4.8%)
<i>Escherichia coli</i>	1/63 (1.6%)
<i>Acinetobacter Iwoffii</i>	1/63 (1.6%)
Aeromonas	1/63 (1.6%)
Forme differoidi	1/63 (1.6%)
<i>Ochromobactum anthropi</i>	1/63 (1.6%)
<i>Pseudomonas aeruginosa</i>	1/63 (1.6%)
<i>Serratia liquefaciens</i>	1/63 (1.6%)
<i>Staphylococcus warneri</i>	1/63 (1.6%)
