X-ray Single-Crystal Structure Determination.

Crystal data and structure determination results are summarized in Table 1S. X-ray data collection was carried out at 180 K using graphite-monochromated Mo K α radiation ($\lambda = 0.71073 \text{ \AA}$) on a Bruker SMART-APEX II diffractometer equipped with an Oxford Cryosystems N₂ gas blower. A ω -scan at three different ϕ settings and a detector position of -30° in 2θ was performed within the Bragg limits of $1.5 < \theta < 27.7^\circ$. Determination of the integrated intensities and unit cell refinements were performed using SAINT¹. The intensity data were corrected for absorption by using SADABS.¹ No *decay correction* was applied. The structures were solved by direct methods (SIR2014)² and refined by full-matrix least squares on F² (SHELX 2014)³ with the WINGX interface.⁴

All hydrogen atoms were located from the difference Fourier map and refined as “riding” on the adjacent carbon with individual isotropic temperature factor 1.2 or 1.5 (H-methyl group) times the value of the equivalent temperature factor of the parent atom. All non-hydrogen atoms were *refined with full occupancy and anisotropic displacement parameters*. The diagram was drawn using ORTEPIII program.⁵
