#### Abstract

Given a Markovian Brownian martingale $Z$, we build a process $X$ which is a martingale in its own filtration and satisfies $X_{1}=Z_{1}$. We call $X$ a dynamic bridge, because its terminal value $Z_{1}$ is not known in advance. We compute its semimartingale decomposition explicitly under both its own filtration $\mathcal{F}^{X}$ and the filtration $\mathcal{F}^{X, Z}$ jointly generated by $X$ and $Z$. Our construction is heavily based on parabolic partial differential equations and filtering techniques. As an application, we explicitly solve an equilibrium model with insider trading that can be viewed as a non-Gaussian generalization of the model of Back and Pedersen (1998) [3], where the insider's additional information evolves over time.

## 1. Introduction

Consider two independent Brownian motions $B$ and $\beta$ over the time interval $[0,1]$, and define a signal process $Z$ as the unique strong solution to

$$
\mathrm{d} Z_{t}=\sigma(t) a\left(V(t), Z_{t}\right) \mathrm{d} \beta_{t}
$$

[^0]where $\sigma:[0,1] \mapsto \mathbb{R}_{+}$is a deterministic function, $V(t):=c+\int_{0}^{t} \sigma^{2}(s) \mathrm{d} s$ for some constant $c>0$, and $a:[0,1] \times \mathbb{R} \mapsto \mathbb{R}$ is regular enough for ensuring the existence of a unique strong solution. Moreover, $\sigma, V$ and $a$ are required to satisfy further regularity conditions, precise statements of which are given in Assumptions 2.1-2.3.

We are interested in the construction of a Markov process $X$ which is a martingale in its own filtration and is such that $X_{1}=Z_{1}$. This construction will be performed adding a well-chosen drift to a suitable Brownian martingale corresponding to $B$. Such a drift will be a nonlinear function of $Z_{t}$ and $X_{t}$. Our goal is to obtain the Doob-Meyer decomposition of $X$ under both filtrations $\mathcal{F}^{X}$ and $\mathcal{F}^{X, Z}$, i.e. that generated by $X$ itself and that generated jointly by $X$ and the signal $Z$. We called such a process a dynamic Markov bridge because it is Markov and especially because its terminal value is not fixed in advance but it is dynamic itself, being the terminal value of the process $Z$. This construction is obtained in Theorem 2.1, which is the main result of the mathematical part of the paper.

This study has a two-fold motivation, probabilistic and financial. First, the purely probabilistic one: in the paper by Föllmer et al. [11], a thorough investigation of this problem has been done in the case $a \equiv \sigma \equiv 1$, where both $Z$ and $X$ are Gaussian processes. More precisely, they studied solutions $X$ of the stochastic differential equations (SDEs) $\mathrm{d} X_{t}=\mathrm{d} B_{t}+\alpha_{t} \mathrm{~d} t$, where $\alpha_{t}$ depends linearly on $X$ and $Z=\beta$. They obtain a characterization of such linear drifts $\alpha_{t}$ making $X$ a Brownian motion in its own filtration in terms of Volterra kernels solutions to some integral equations, which can be reduced in some special case to a Sturm-Liouville equation. Föllmer et al. were in turn motivated by the following natural modification of the classical Brownian bridge dynamics:

$$
\mathrm{d} X_{t}=\mathrm{d} B_{t}+\frac{\beta_{t}-X_{t}}{1-t} \mathrm{~d} t
$$

where in the drift $\beta_{t}$ replaces $\beta_{1}$ as in the classical "static" Brownian bridge. It has been shown in [11] that $X$ is still a bridge in the sense that $X_{1}=\beta_{1}$, but it is not a Brownian motion in its own filtration. They then focused more on general linear drifts preserving the Brownian property. Considering only linear drifts allows them to use the nice and powerful relation between Gaussian processes and Volterra kernels. A few questions naturally arise from that work: What happens if the signal $Z$ is not necessarily Gaussian? Is it still possible to construct a "dynamic" bridge $X$ with the required properties? It turns out that it is still possible, but using completely different techniques. Indeed, $Z$ being no longer Gaussian, one is led to consider nonlinear drifts to build the bridge, which makes the use of Gaussian process theory impossible. However, the Markov nature of the problem allows us to use techniques from parabolic partial differential equation (PDEs) and those from filtering theory in order to carry out our analysis.

The second motivation, which we share with Föllmer et al. [11], is a financial one: The dynamic bridge $X$ is the solution of a Kyle-Back-type equilibrium model of a gradually informed insider trading (see [2] for initial information and [3,22,9] for the dynamic information case). In such a model, the insider observes a signal process (unknown to the market) $Z$ as above with $a \equiv 1$ driven by the Brownian motion $\beta$. The insider applies a well-chosen drift, modeling her strategy, to the Brownian motion $B$ in such a way that (i) the resulting process $X$ ends up in $Z_{1}$ and (ii) the distribution of the process remains unchanged, i.e. $X$ is again a Brownian motion in its own filtration. Condition (i) guarantees that the strategy maximizes the insider's expected gain. On the other hand, condition (ii) means that the strategy of the insider, i.e. the drift, is "inconspicuous", and this corresponds to the notion of equilibrium as defined in [2,3]. The reader is referred once more to the papers $[2,3,22,9]$ for more financial as well as mathematical details.

Our probabilistic construction of the dynamic bridge $X$ leads to an interesting generalization of such a model, in which the signal modeling the insider's dynamic information is not necessarily Gaussian. Even in this more general framework, we are able to give an explicit solution for the equilibrium total demand and the optimal insider's strategy in our main result of the financial part of the paper, Theorem 5.1. Interestingly, the existence of a solution for the insider's maximization problem imposes a very precise structure on the form of the signal volatility $a\left(t, Z_{t}\right)$ (see Section 5), resulting in the insider's signal being a function of a Gaussian process. This seems to indicate that a non-trivial generalization beyond a Gaussian setting is impossible. Nonetheless, we would like to stress the fact that while the financial application forces the signal to be 'almost Gaussian', as explained in Remark 5.5, the construction we perform in Section 2 is much more general, since it includes signals which are not necessarily Gaussian.

The paper is structured as follows. Section 2 contains the motivation and formal definition of such a bridge. A new proof of Gaussian bridge construction is given in Section 3, while in Section 4 the general construction is proved. At the end of this section, we also give an application of our result to build an Ornstein-Uhlenbeck bridge. Finally, in Section 5, we briefly introduce the financial model and we apply the main result contained in Section 2 to find the equilibrium total demand and optimal insider's strategy.

## 2. Formulation of the problem and some auxiliary results

Let $\left(\Omega, \mathcal{G},\left(\mathcal{G}_{t}\right), \mathbb{Q}\right)$ be a filtered probability space satisfying the usual conditions. Note that we do not require $\mathcal{G}_{0}$ to be trivial. Assume that on this probability space there exist two independent standard Brownian motions, $B$ and $\beta$, and a random variable $Z_{0}$ in $\mathcal{G}_{0}$, which implies that $Z_{0}$ is independent from $B$ and $\beta$.

Let $\mathcal{Z}=\left(\Omega, \mathcal{G},\left(\mathcal{G}_{t}\right),\left(Z_{t}\right),\left(P^{z}\right)_{z \in \mathbb{R}}\right)$ be a diffusion process with values in $\mathbb{R}$. Here we are using the formulation of a Markov process as given, for example, in Blumenthal and Getoor [7] or Sharpe [20]. Time varies in the finite interval [0, 1]. We will use the notation $\mathbb{R}_{+}$for $[0, \infty)$ and $\mathcal{F}_{t}^{Y}$ for $\sigma\left(Y_{s} ; s \leq t\right)$ for any (possibly, vector-valued) stochastic process $Y$.

We further assume that $Z$ is the unique strong solution on $\left(\Omega, \mathcal{G},\left(\mathcal{G}_{t}\right), \mathbb{Q}\right)$ of

$$
\begin{equation*}
\mathrm{d} Z_{t}=\sigma(t) a\left(V(t), Z_{t}\right) \mathrm{d} \beta_{t}, \quad t \in(0,1] \tag{2.1}
\end{equation*}
$$

with $Z_{0} \in \mathcal{G}_{0}$ being a random variable with distribution $\mu$, and where $\sigma:[0,1] \mapsto \mathbb{R}_{+}$is a deterministic function, $V(t):=c+\int_{0}^{t} \sigma^{2}(s) \mathrm{d} s$ for some constant $c>0$, and $a:[0,1] \times \mathbb{R} \mapsto \mathbb{R}$ is regular enough for ensuring the existence of a unique strong solution. Moreover, $\sigma, V$ and $a$ are required to satisfy further regularity conditions, precise statements of which are given in Assumptions 2.1-2.3 below.

The rest of this section will be devoted to the construction of a process $X$ and a probability measure $\mu$ on $\mathbb{R}$ satisfying the following three conditions.

C1 For every $T<1, X$ is the unique strong solution of the SDE

$$
X_{t}=\int_{0}^{t} a\left(s, X_{s}\right) \mathrm{d} B_{s}+\int_{0}^{t} \alpha\left(s, X_{s}, Z_{s}\right) \mathrm{d} s, \quad \text { for } t \in(0, T]
$$

for some Borel-measurable real-valued function $\alpha$. Moreover, $(X, Z)$ is a Markov process. More precisely, $\left(\Omega, \mathcal{G},\left(\mathcal{G}_{t}\right),\left(X_{t}, Z_{t}\right),\left(P^{x, z}\right)_{\left.(x, z) \in \mathbb{R}^{2}\right)}\right)$ is a Markov process with values in $\mathbb{R}^{2}$ endowed with its Borel $\sigma$-algebra, with an initial distribution given by $\delta_{0} \otimes \mu$, where $\delta_{0}$ is the Dirac measure at 0 .

C2 $\lim _{t \uparrow 1} X_{t}$ exists $P^{0, z}$-a.s., and $X_{1}:=\lim _{t \uparrow 1} X_{t}=Z_{1}, P^{0, z}$-a.s.
C3 $\left(X_{t}\right)_{t \in[0,1]}$ is a local martingale in its own filtration.
Remark 2.1. In view of Theorem 8.1 in [15], condition C3 implies that $X$, if exists, will be a diffusion process with diffusion coefficient $a$ and no drift in its own filtration. As C 2 is also in place, this diffusion process will be conditioned to hit $Z_{1}$ at time 1 . If we have allowed $X$ to be adapted to the filtration generated by $Z_{1}$ and $B$, such a process can be obtained using the available theory of 'static' Markov bridges (see, e.g., [10] and Proposition 37 in [5]) with a drift $\alpha\left(t, X_{t}, Z_{1}\right)$, since $Z_{1}$ and $B$ are independent. However, condition $C 1$ stipulates that $X$ should be adapted to the filtration generated by the independent processes $Z$ and $B$. This forces us to develop a theory of 'dynamic' Markov bridges, as we will describe in the subsequent sections.

Remark 2.2. The main difficulty with the construction of the process $X$ is that all the conditions $\mathrm{C} 1-\mathrm{C} 3$ have to be met simultaneously. To illustrate this point, consider the simple case $a=$ $\sigma=1$.

If one allows the drift, $\alpha$, in condition C 1 to depend on $Z_{1}$, then

$$
\begin{equation*}
X_{t}=B_{t}+\int_{0}^{t} \frac{Z_{1}-X_{s}}{1-s} \mathrm{~d} s \tag{2.2}
\end{equation*}
$$

has a unique strong solution over $[0,1)$, and its solution can be continuously extended to the full interval $[0,1]$ since, conditioned on $Z_{1}=z$, this is the SDE for a Brownian bridge from 0 to $z$ over the interval $[0,1]$. This is a Markovian bridge conditioned to hit $Z_{1}$ at $t=1$ and, moreover, it is a martingale in its own filtration (see expression (10) and the discussion after it in [11]).

If we replace $Z_{1}$ with $Z_{t}$ in the above formulation, we obtain the SDE

$$
X_{t}=B_{t}+\int_{0}^{t} \frac{Z_{s}-X_{s}}{1-s} \mathrm{~d} s
$$

which has a unique strong solution which satisfies C 1 and C 2 (see Lemma 2.1 in [11]). However, $X$ does not satisfy C3 (see Lemma 2.2 in [11]).

One is also tempted to think that a projection of the solution of (2.2) onto the filtration generated by $X$ and $Z$ could give us the construction that we seek. Note that the solution of (2.2) is adapted to the filtration $\left(\mathcal{F}_{t}^{B, Z}\right)$ enlarged with $Z_{1}$. In this enlarged filtration $Z$ has the decomposition

$$
Z_{t}=\bar{\beta}_{t}+\int_{0}^{t} \frac{Z_{1}-Z_{s}}{1-s} \mathrm{~d} s
$$

where $\bar{\beta}$ is a standard Brownian motion adapted to this filtration (see Theorem 3 in Chapter VI of [18]) and independent of $B$. Comparison of the SDEs for $X$ and $Z$ reveals an inherent symmetry of these two processes. Thus, the semimartingale decomposition of these two processes with respect to $\left(\mathcal{F}_{t}^{X, Z}\right)$ should have a symmetric structure; in particular, if one is a martingale with respect to $\left(\mathcal{F}_{t}^{X, Z}\right)$, then so is the other. However, this is inconsistent with the structural assumptions we have on $X$ and $Z$ which are manifested in C 1 and (2.1).

These examples, in particular the last one, demonstrate that the solution to our problem cannot be obtained via a combination of available enlargement of filtration and nonlinear filtering techniques.

We would like to stress here that the functions $\sigma$ and $V$ that appeared in the dynamics of $Z$ play a crucial role in the existence of the solution of the problem above. Indeed, suppose that $\sigma \equiv 1$
and $V(t)=t$ for each $t \geq 0$, and that $a(t, z)$ is regular enough to ensure the existence of a square integrable non-constant solution to (2.1). Suppose that there exists a solution to the problem defined by conditions $\mathrm{C} 1-\mathrm{C} 3$. Consider the probability measure $\mathbb{P}$ defined on $\left(\Omega, \mathcal{F}_{1}^{X} \vee \mathcal{F}_{1}^{Z}\right)$ by

$$
\mathbb{P}(E)=\int_{\mathbb{R}} P^{0, z}(E) \mu(\mathrm{d} z), \quad \forall E \in \mathcal{F}_{1}^{X} \vee \mathcal{F}_{1}^{Z}
$$

Note that $X_{1}=Z_{1}, P^{0, z}$-a.s., for every $z \in \mathbb{R}$, implies that $X_{1}=Z_{1}, \mathbb{P}$-a.s.; therefore, for any bounded measurable function $f$,

$$
\begin{equation*}
\mathbb{E}\left[f\left(Z_{1}\right)\right]=\mathbb{E}\left[f\left(X_{1}\right)\right], \tag{2.3}
\end{equation*}
$$

where $\mathbb{E}$ is the expectation operator with respect to $\mathbb{P}$. On the one hand,

$$
\mathbb{E}\left[f\left(Z_{1}\right)\right]=\mathbb{E}\left[\mathbb{E}\left[f\left(Z_{1}\right) \mid Z_{0}\right]\right]=\int_{\mathbb{R}} E^{P^{z}}\left[f\left(Z_{1}\right)\right] \mu(\mathrm{d} z)=\int_{\mathbb{R}} \int_{\mathbb{R}} f(y) p(z, y) \mathrm{d} y \mu(\mathrm{~d} z)
$$

where $p(z, y) \mathrm{d} y=P^{z}\left(Z_{1} \in \mathrm{~d} y\right)$. On the other hand, conditions C 1 and C 3 imply that

$$
X_{t}=\int_{0}^{t} a\left(s, X_{s}\right) \mathrm{d} B_{s}^{X}
$$

for some Brownian motion $B^{X}$ adapted to $\mathcal{F}^{X}$. Comparing this to (2.1), we see that the law of $X_{t}$ is that of $Z_{t}$ conditioned on $Z_{0}=0$ for any $t \in[0,1]$. Therefore,

$$
\begin{equation*}
\mathbb{E}\left[f\left(X_{1}\right)\right]=\int_{\mathbb{R}} f(y) p(0, y) \mathrm{d} y . \tag{2.4}
\end{equation*}
$$

Let $f(y)=\mathrm{e}^{\mathrm{i} r y}$. Then, in view of (2.3), we have

$$
\begin{aligned}
\int_{\mathbb{R}} \mathrm{e}^{\mathrm{i} r y} p(0, y) \mathrm{d} y & =\int_{\mathbb{R}} \int_{\mathbb{R}} \mathrm{e}^{\mathrm{i} r y} p(z, y) \mathrm{d} y \mu(\mathrm{~d} z) \\
& =\int_{\mathbb{R}} \mathrm{e}^{\mathrm{i} r y}\left(\int_{\mathbb{R}} p(z, y) \mu(\mathrm{d} z)\right) \mathrm{d} y
\end{aligned}
$$

Note that the interchange of integrals is justified since $\left|\mathrm{e}^{\mathrm{i} r y} p(z, y)\right|<p(z, y)$ and $\int_{\mathbb{R}} \int_{\mathbb{R}}$ $p(z, y) \mathrm{d} y \mu(\mathrm{~d} z)=1$. This implies that the characteristic functions of the measures $p(0, y) \mathrm{d} y$ and $\left(\int_{\mathbb{R}} p(z, y) \mu(\mathrm{d} z)\right) \mathrm{d} y$ are the same. We can assume, without substantial loss of generality, that $p$ is continuous in both parameters. ${ }^{1}$ Therefore, we can invert the Fourier transform to identify $\mu$ as the Dirac measure at 0 and conclude that $X$ and $Z$ have the same law.

However, under the assumption that $\mu=\delta_{0}$, Remark 5.2(i) in [11] shows that such a construction is not possible. Indeed, Remark 5.2(i) in [11] contains the following statement: Given filtration $\mathcal{F}_{t}$ and a square integrable $\mathcal{F}_{t}$-adapted processes $X$ and $M$ with the same second moments such that (i) $X$ is a local martingale in its own filtration, (ii) $M$ is an $\mathcal{F}_{t}$-martingale, and (iii) $M_{1}=X_{1}$, then $M_{t}=X_{t}$ for all $t \in[0,1]$. Applying this result to our setting, we get $X_{t}=Z_{t}$ for all $t \in[0,1]$ and, thus,

$$
\int_{0}^{t} a\left(s, Z_{s}\right) \mathrm{d} \beta_{s}=Z_{t}=X_{t}=\int_{0}^{t} a\left(s, Z_{s}\right) \mathrm{d} B_{s}+\int_{0}^{t} \alpha\left(s, Z_{s}, Z_{s}\right) \mathrm{d} s
$$

[^1]This implies that $\int_{0}^{t} \alpha\left(s, Z_{s}, Z_{s}\right) \mathrm{d} s$ is a continuous martingale with finite variation, and therefore it is identically 0 . Thus,

$$
\int_{0}^{t} a\left(s, Z_{s}\right) \mathrm{d} \beta_{s}=Z_{t}=X_{t}=\int_{0}^{t} a\left(s, X_{s}\right) \mathrm{d} B_{s} .
$$

Since $B$ and $\beta$ are independent, this yields that $[Z, X] \equiv 0$. However, as $Z=X$, we have $[Z, Z] \equiv 0$, which implies that $X=Z \equiv 0$, which is a contradiction.

This example highlights that the relationship between $V(t)$ and $t$ is very important for the existence of a solution to the problem we aim to solve. The following assumption formalizes this relationship along with imposing some regularity conditions. In particular, Assumption 2.1.1 rules out the above pathology, Assumption 2.1.2 controls the speed of convergence of $V(t)-t$ to 0 as $t \rightarrow 1$ (for an earlier use of this assumption see [9]), and Assumptions 2.1.3-2.1.5 ensure sufficient regularity for the problem.

Assumption 2.1. Fix a real number $c \in(0,1] . \sigma:[0,1] \mapsto \mathbb{R}_{+}$and $a:[0,1] \times \mathbb{R} \mapsto \mathbb{R}_{+}$are two measurable functions such that

1. $V(t):=c+\int_{0}^{t} \sigma^{2}(u) \mathrm{d} u>t$ for every $t \in[0,1)$, and $V(1)=1$;
2. $\lim _{t \uparrow 1} \lambda^{2}(t) \Lambda(t) \log (\Lambda(t))=0$, where $\lambda(t)=\exp \left\{-\int_{0}^{t} \frac{1}{V(s)-s} \mathrm{~d} s\right\}$ and $\Lambda(t)=\int_{0}^{t} \frac{1+\sigma^{2}(s)}{\lambda^{2}(s)} \mathrm{d} s$;
3. $\sigma^{2}(t)$ is bounded on $[0,1]$;
4. $a(t, z)$ is uniformly bounded away from zero, i.e. there exists a constant $\epsilon>0$ such that $a(t, z) \geq \epsilon$ for all $t \in[0,1]$ and $z \in \mathbb{R}$;
5. $a(\cdot, \cdot) \in C^{1,2}$ and has enough regularity in order for (2.1) to have a unique strong solution. ${ }^{2}$

Remark 2.3. Notice that Assumption 2.1.2 is, in fact, an assumption on $\Lambda(t)$, since we always have that $\lim _{t \uparrow 1} \lambda(t)=0$. Indeed, since $V(t)$ is increasing and $V(1)=1$, we have that $V(t) \leq 1$ for $t \in[0,1]$, and therefore

$$
\begin{equation*}
\lambda(t) \leq 1-t, \tag{2.5}
\end{equation*}
$$

which leads to conclusion that $\lim _{t \uparrow 1} \lambda(t)=0$. For another use of this assumption, and further discussion, see [9].

Although Assumption 2.1.2 seems to be involved, it is satisfied in many cases. The following remark states a sufficient condition for this assumption to be satisfied.

Remark 2.4. Note that, when $\lim _{t \uparrow 1} \Lambda(t)<\infty$, the condition is automatically satisfied due to the preceding remark. Next, suppose that $\lim _{t \uparrow 1} \Lambda(t)=\infty, \sigma$ is continuous in a vicinity of 1 and $\sigma(1) \neq 1$. Then, an application of L'Hôpital's rule yields

$$
0 \leq \lim _{t \uparrow 1} \frac{\Lambda(t) \log (\Lambda(t))}{\lambda^{-2}(t)}=\frac{1+\sigma^{2}(1)}{2} \lim _{t \uparrow 1} \frac{\log (\Lambda(t))}{(V(t)-t)^{-1}}
$$

Then note that, since $\lim _{t \uparrow 1} \lambda^{2}(t) \Lambda(t)=0, \Lambda(t) \leq \lambda^{-2}(t)$ for $t$ close to 1 . Thus,

$$
\begin{aligned}
0 & \leq \lim _{t \uparrow 1} \frac{\Lambda(t) \log (\Lambda(t))}{\lambda_{t}^{-2}} \leq \frac{1+\sigma^{2}(1)}{2} \lim _{t \uparrow 1} \frac{\log \left(\lambda^{-2}(t)\right)}{(V(t)-t)^{-1}} \\
& =\left(1+\sigma^{2}(1)\right) \lim _{t \uparrow 1} \frac{\int_{0}^{t} \frac{1}{V(s)-s} \mathrm{~d} s}{(V(t)-t)^{-1}}=0,
\end{aligned}
$$

[^2]after another application of L'Hôpital's rule, since $\sigma^{2}(1) \neq 1$. This in particular shows that Assumption 2.1.2 is satisfied when $\sigma$ is a constant.

Before we present our main result, we shall collect some preliminary results on the transition density of the diffusion

$$
\mathrm{d} \xi_{t}=a\left(t, \xi_{t}\right) \mathrm{d} \beta_{t}
$$

We are in particular interested in the existence and smoothness of this transition density. The natural way to obtain these results is to use the link between the transition density and the fundamental solution of

$$
\begin{equation*}
w_{u}(u, z)=\frac{1}{2}\left(a^{2}(u, z) w(u, z)\right)_{z z} \tag{2.6}
\end{equation*}
$$

established in Corollary 3.2.2 in [21]. However, as we do not assume $a$ to be bounded, this theorem is not applicable. On the other hand, since $a$ is bounded away from 0 , the function

$$
\begin{equation*}
A(t, x):=\int_{0}^{x} \frac{1}{a(t, y)} \mathrm{d} y \tag{2.7}
\end{equation*}
$$

is well defined, and the transformation defined by $\zeta_{t}:=A\left(t, \xi_{t}\right)$ will yield, via Itô's formula,

$$
\begin{equation*}
\mathrm{d} \zeta_{t}=\mathrm{d} \beta_{t}+b\left(t, \zeta_{t}\right) \mathrm{d} t \tag{2.8}
\end{equation*}
$$

where

$$
\begin{equation*}
b(t, x):=A_{t}\left(t, A^{-1}(t, x)\right)-\frac{1}{2} a_{z}\left(t, A^{-1}(t, x)\right), \tag{2.9}
\end{equation*}
$$

and $A^{-1}$, the inverse of $A$, is taken with respect to the space variable. This transformation along with the next assumption is going to provide a uniformly elliptic operator which via Theorem 10 in Chapter I of [12] and Theorem 3.2.1 of [21] would imply the existence and smoothness of the transition density of $\xi$.

Assumption 2.2. $b$ and $b_{x}$ are uniformly bounded on $[0,1] \times \mathbb{R}$ and $b_{x}$ is Lipschitz continuous uniformly in $t$.

Due to this assumption, Corollary 3.2.2 of [21] implies that the transition density of $\zeta$ is the fundamental solution of

$$
\begin{equation*}
w_{u}(u, z)=\frac{1}{2} w_{z z}(u, z)-(b(u, z) w(u, z))_{z} . \tag{2.10}
\end{equation*}
$$

For the reader's convenience, we recall the definition (p. 3 of [12]) of the fundamental solution, $\Gamma(t, x ; u, z)$, of (2.10) as the function satisfying the following.

1. For fixed $(t, x), \Gamma(t, x ; u, z)$ satisfies (2.10) for all $u>t$.
2. For every continuous and bounded $f: \mathbb{R} \mapsto \mathbb{R}$,

$$
\begin{equation*}
\lim _{u \downarrow t} \int_{\mathbb{R}} \Gamma(t, x ; u, z) f(x) \mathrm{d} x=f(z) \tag{2.11}
\end{equation*}
$$

The following proposition provides the existence of the transition density of $\xi$ and formalizes the smoothness requirement on the transition density together with some properties that we will use later.

Proposition 2.1. Under Assumptions 2.1 and 2.2, there exists a fundamental solution, $\Gamma \in$ $C^{1,2,1,2}$, to (2.10) which also solves the adjoint equation

$$
\begin{equation*}
v_{t}(t, x)+b(t, x) v_{x}(t, x)+\frac{1}{2} v_{x x}(t, x)=0 \tag{2.12}
\end{equation*}
$$

Moreover, the function $G(t, x ; u, z)$, defined by

$$
\begin{equation*}
G(t, x ; u, z):=\Gamma(t, A(t, x) ; u, A(u, z)) \frac{1}{a(u, z)} \tag{2.13}
\end{equation*}
$$

satisfies (2.6) for fixed $(t, x)$, and it is the transition density of $\xi$, i.e.

$$
G(t, x ; u, z) \mathrm{d} z=P\left(\xi_{u} \in \mathrm{~d} z \mid \xi_{t}=x\right) \quad \text { for } u \geq t
$$

Furthermore, $G_{x}(t, x ; u, z)$ exists, and satisfies

$$
\begin{equation*}
\int_{\mathbb{R}} G_{x}(t, x ; u, z) \mathrm{d} z=0=\int_{\mathbb{R}} \Gamma_{x}(t, x ; u, z) \mathrm{d} z \tag{2.14}
\end{equation*}
$$

Proof. Since $b$ and $b_{x}$ are bounded and Hölder continuous under the assumptions of the proposition, it follows from Theorem 10 in Chapter I of [12] that the fundamental solution, $\Gamma(t, x ; u, z)$, to (2.10) exists, and is also the fundamental solution of (2.12) by Theorem 15 in Chapter I of [12]. In particular, $\Gamma \in C^{1,2,1,2}$. Moreover, Assumption 2.2 also implies, due to Corollary 3.2.2 in [21], that $\Gamma$ is the transition density of $\zeta$.

Define $G(t, x ; u, z)$ by (2.13), and observe that $G(t, x ; u, z)$ for fixed $(t, x)$ solves (2.6). Since, by definition, $\zeta_{t}=A\left(t, \xi_{t}\right)$, and $A$ is strictly increasing,

$$
\begin{aligned}
G(t, x ; u, z) \mathrm{d} z & =\Gamma(t, A(t, x) ; u, A(u, z)) \frac{1}{a(u, z)} \mathrm{d} z \\
& =\Gamma(t, A(t, x) ; u, A(u, z)) \mathrm{d} A(u, z) \\
& =P\left(\zeta_{u} \in \mathrm{~d} A(u, z) \mid \zeta_{t}=A(t, x)\right) \\
& =P\left(A\left(u, \xi_{u}\right) \in \mathrm{d} A(u, z) \mid A\left(t, \xi_{t}\right)=A(t, x)\right) \\
& =P\left(\xi_{u} \in \mathrm{~d} z \mid \xi_{t}=x\right)
\end{aligned}
$$

which establishes that $G$ is the transition density of $\xi$.
Moreover, Equations (6.12) and (6.13) following Theorem 11 in Chapter I of [12] give the following estimates:

$$
\begin{align*}
& \Gamma(t, x ; u, z) \leq C \frac{1}{\sqrt{u-t}} \exp \left(-c \frac{(x-z)^{2}}{2(u-t)}\right), \quad \text { and }  \tag{2.15}\\
& \left|\Gamma_{x}(t, x ; u, z)\right| \leq C \frac{1}{u-t} \exp \left(-c \frac{(x-z)^{2}}{2(u-t)}\right) \tag{2.16}
\end{align*}
$$

for some positive $C$, depending on $c$, and any $c<1$. Note that $\int_{\mathbb{R}} G(t, x ; u, z) \mathrm{d} z=1=$ $\int_{\mathbb{R}} \Gamma(t, x ; u, z) \mathrm{d} z$, since both $G$ and $\Gamma$ are transition densities. Thus, (2.14) will hold if one can interchange the derivative and the integral. This is justified since, due to (2.16), $\left|\Gamma_{x}\right| \leq$
$K \exp \left(-c_{1} z^{2}\right)$ when $x$ is restricted to a bounded interval and where the constants $K$ and $c_{1}$ do not depend on $x$ and might depend on $u$ and $t$. The result then follows from an application of the Dominated Convergence Theorem.

In order to motivate our main result, let us first consider the special case of $\sigma \equiv 0$ so that $Z_{1}=Z_{0}$. In terms of the insider trading models that we have in mind, this corresponds to the case when the insider has the complete information at time 0 regarding the value of the traded asset at time 1 , as in [2]. If $\mu(\mathrm{d} z)=G(0,0 ; 1, z) \mathrm{d} z$, then there exists a unique strong solution to

$$
\mathrm{d} X_{t}=a\left(t, X_{t}\right) \mathrm{d} B_{t}+a^{2}\left(t, X_{t}\right) \frac{G_{x}\left(t, X_{t}, 1, Z_{0}\right)}{G\left(t, X_{t} ; 1, Z_{0}\right)} \mathrm{d} t
$$

with the initial condition $X_{0}=0$, which satisfies all the properties stated in C1-C3. (See Proposition 37 in [5] for a proof of this and other related results. Observe that this result does not require uniform ellipticity of $a$, and thus the extension to the time-inhomogeneous case is immediate.)

The specific form of the drift term in the SDE above thus gives us a hint on how to formulate the solution of the original problem stated at the beginning of this section. Before we state our main result, we introduce one last assumption.

Assumption 2.3. $b(t, x)$ is absolutely continuous with respect to $t$ for each $x$, i.e. there exists a measurable function $b_{t}:[0,1] \times \mathbb{R} \mapsto \mathbb{R}$ such that

$$
b(t, x)=b(0, x)+\int_{0}^{t} b_{t}(s, x) \mathrm{d} s
$$

for each $x \in \mathbb{R}$. Moreover, $b_{t}$ is uniformly bounded.
Theorem 2.1. Suppose that $\mu(\mathrm{d} z)=G(0,0 ; c, z) \mathrm{d} z$, where $c \in(0,1)$ is the real number fixed in Assumption 2.1 and $G$ is given by (2.13). Let, for $t<1$,

$$
\begin{equation*}
\mathrm{d} X_{t}=a\left(t, X_{t}\right) \mathrm{d} B_{t}+a^{2}\left(t, X_{t}\right) \frac{\rho_{x}\left(t, X_{t}, Z_{t}\right)}{\rho\left(t, X_{t}, Z_{t}\right)} \mathrm{d} t \tag{2.17}
\end{equation*}
$$

where

$$
\begin{equation*}
\rho(t, x, z):=G(t, x ; V(t), z) \tag{2.18}
\end{equation*}
$$

Under Assumptions 2.1-2.3, on every interval $[0, T]$ with $T<1$, there exists a unique strong solution to the above SDE with the initial condition $X_{0}=0$. Moreover, the conditions $\mathrm{C} 1-\mathrm{C} 3$ are satisfied.

We will give a proof of this result in the special case $a \equiv 1$ in Section 3, and a proof of the general result will be given in Section 4. However, we shall now state and prove two lemmata to show how the choice of the drift term in (2.17) would imply condition C3, i.e. $X$ as defined in (2.17) is a local martingale in its own filtration. Before we can formulate them, we need to introduce the following notation.

Let $\mathcal{F}:=\sigma\left(X_{t}, Z_{t} ; t<1\right)$, and define the probability measure $\mathbb{P}$ on $(\Omega, \mathcal{F})$ by

$$
\begin{equation*}
\mathbb{P}(E)=\int_{\mathbb{R}} P^{0, z}(E) \mu(\mathrm{d} z) \tag{2.19}
\end{equation*}
$$

for any $E \in \mathcal{F}$. Of course, in order for this construction to make sense, we need the existence of a solution to (2.17). This will be proved in Section 4 in Corollary 4.1; thus, the above probability
space exists, and is well defined. Under $\mathbb{P},\left(X_{t}, Z_{t}\right)_{t<1}$ would still be a strong Markov process (see Corollary 4.1). Let $\mathcal{N}$ be the null sets of $\mathbb{P}$. Proposition 2.7 .7 in [13] shows that the filtration $\left(\mathcal{N} \vee \mathcal{F}_{t}^{X, Z}\right)_{t<1}$ is right continuous. With an abuse of notation, we shall still denote the $\sigma$-algebra generated by $\mathcal{F}$ 구 $Y$. Next, let $\widetilde{\mathcal{F}}_{t}^{X}:=\cap_{1>u>t} \mathcal{F}_{u}^{X}$. We shall see in Remark 4.1 later that $\mathcal{F}^{X}$ is right continuous, i.e. $\mathcal{F}_{t}^{X}=\widetilde{\mathcal{F}}_{t}^{X}$. We say that $g_{t}: \Omega \times \mathbb{R} \mapsto \mathbb{R}$ is the conditional density of $Z_{t}$ given $\mathcal{F}_{t}^{X}$, if $g_{t}$ is measurable with respect to the product $\sigma$-algebra, $\mathcal{F}_{t}^{X} \times \mathcal{B}$, where $\mathcal{B}$ is the Borel $\sigma$-algebra of $\mathbb{R}$, and for any bounded measurable function $f$

$$
\mathbb{E}\left[f\left(Z_{t}\right) \mid \mathcal{F}_{t}^{X}\right]=\int_{\mathbb{R}} f(z) g_{t}(\omega, z) \mathrm{d} z
$$

where $\mathbb{E}$ is the expectation operator under $\mathbb{P}$. Note that, due to the Markov property of $(X, Z)$, $\mathbb{E}^{\mathbb{Q}}\left[f\left(Z_{1}\right) \mid \mathcal{F}_{t}^{X}\right]=\mathbb{E}\left[f\left(Z_{1}\right) \mid \mathcal{F}_{t}^{X}\right]$, but we will keep the above notation for clarity of the exposition. We will often write $\mathbb{P}\left[Z_{t} \in \mathrm{~d} z \mid \mathcal{F}_{t}^{X}\right]=g_{t}(\omega, z) \mathrm{d} z$ in order to refer to the conditional density property described above. Now, we are ready to state and prove the following lemma.

Lemma 2.1. Suppose that there exists a unique strong solution of (2.17). If $\rho\left(t, X_{t}, \cdot\right)$ given by (2.18) is the conditional density of $Z_{t}$ given $\mathcal{F}_{t}^{X}$ for every $t \in[0,1)$, then $\left(X_{t}\right)_{t \in[0,1)}$ is a local martingale in its own filtration.

Proof. It follows from standard filtering theory (e.g. Theorem 8.1 in [15]) that

$$
\mathrm{d} X_{t}=a\left(t, X_{t}\right) \mathrm{d} B_{t}^{X}+a^{2}\left(t, X_{t}\right) \mathbb{E}\left[\left.\frac{\rho_{x}\left(t, X_{t}, Z_{t}\right)}{\rho\left(t, X_{t}, Z_{t}\right)} \right\rvert\, \mathcal{F}_{t}^{X}\right] \mathrm{d} t
$$

where $B^{X}$ is an $\mathcal{F}^{X}$-Brownian motion. However, if $\rho\left(t, X_{t}, \cdot\right)$ is the conditional density of $Z_{t}$,

$$
\mathbb{E}\left[\left.\frac{\rho_{x}\left(t, X_{t}, Z_{t}\right)}{\rho\left(t, X_{t}, Z_{t}\right)} \right\rvert\, \mathcal{F}_{t}^{X}\right]=\int_{\mathbb{R}} G_{x}\left(t, X_{t} ; V(t), z\right) \mathrm{d} z=0
$$

due to Proposition 2.1, so

$$
\mathrm{d} X_{t}=a\left(t, X_{t}\right) \mathrm{d} B_{t}^{X}
$$

and, thus, $X$ is a local martingale, since $a$ is continuous.
In view of this lemma, we show in Section 4 that $\rho\left(t, X_{t}, \cdot\right)$ is indeed the conditional density of $Z_{t}$ given $\mathcal{F}_{t}^{X}$ for every $t \in[0,1)$. The following lemma will be key in proving this result.

Lemma 2.2. Suppose that there exists a unique strong solution of (2.17). Let $U_{t}:=A\left(V(t), Z_{t}\right)$ and $R_{t}:=A\left(t, X_{t}\right)$, where $A$ is defined by (2.7). Define

$$
\begin{equation*}
p(t, x, z):=\rho\left(t, A^{-1}(t, x), A^{-1}(V(t), z)\right) a\left(V(t), A^{-1}(V(t), z)\right) \tag{2.20}
\end{equation*}
$$

where $\rho$ is given by (2.18). Then,

1. $p\left(t, R_{t}, \cdot\right)$ is the conditional density of $U_{t}$ given $\mathcal{F}_{t}^{R}$ iff $\rho\left(t, X_{t}, \cdot\right)$ is the conditional density of $Z_{t}$ given $\mathcal{F}_{t}^{X}$;
2. $\left(p\left(t, R_{t}, \cdot\right)\right)_{t \in[0,1)}$ is a weak solution to the following stochastic PDE:

$$
\begin{align*}
g_{t}(z)= & \Gamma(0,0 ; c, z)+\int_{0}^{t} \sigma^{2}(s)\left\{-\left(b(V(s), z) g_{s}(z)\right)_{z}+\frac{1}{2}\left(g_{s}(z)\right)_{z z}\right\} \mathrm{d} s \\
& +\int_{0}^{t} g_{s}(z)\left(\frac{p_{x}\left(s, R_{s}, z\right)}{p\left(s, R_{s}, z\right)}-\int_{\mathbb{R}} g_{s}(z) \frac{p_{x}\left(s, R_{s}, z\right)}{p\left(s, R_{s}, z\right)} \mathrm{d} z\right) \mathrm{d} I_{s}^{g} \tag{2.21}
\end{align*}
$$

where

$$
\mathrm{d} I_{s}^{g}=\mathrm{d} R_{s}-\left(\int_{\mathbb{R}}\left[\frac{p_{x}}{p}\left(s, R_{s}, z\right)+b\left(s, R_{s}\right)\right] g_{s}(z) \mathrm{d} z\right) \mathrm{d} s
$$

Proof. Notice that, since $A(t, \cdot)$ is strictly increasing, $\mathcal{F}_{t}^{R}=\mathcal{F}_{t}^{X}$ for every $t \in[0,1)$, and there is a one-to-one correspondence between the conditional density of $Z$ and that of $U$. More precisely,

$$
\mathbb{P}\left[Z_{t} \in \mathrm{~d} z \mid \mathcal{F}_{t}^{X}\right]=\mathbb{P}\left[U_{t} \in \mathrm{~d} A(V(t), z) \mid \mathcal{F}_{t}^{R}\right]
$$

Thus, if $\mathbb{P}\left[Z_{t} \in \mathrm{~d} z \mid \mathcal{F}_{t}^{X}\right]=\rho\left(t, X_{t}, z\right) \mathrm{d} z$, then

$$
\begin{aligned}
\mathbb{P}\left[U_{t} \in \mathrm{~d} z \mid \mathcal{F}_{t}^{R}\right] & =\mathbb{P}\left[Z_{t} \in \mathrm{~d} A^{-1}(V(t), z) \mid \mathcal{F}_{t}^{X}\right] \\
& =\rho\left(t, X_{t}, A^{-1}(V(t), z)\right) \mathrm{d} A^{-1}(V(t), z) \\
& =\rho\left(t, X_{t}, A^{-1}(V(t), z)\right) a\left(V(t), A^{-1}(V(t), z)\right) \mathrm{d} z \\
& =\rho\left(t, A^{-1}\left(t, R_{t}\right), A^{-1}(V(t), z)\right) a\left(V(t), A^{-1}(V(t), z)\right) \mathrm{d} z \\
& =p\left(t, R_{t}, z\right) \mathrm{d} z
\end{aligned}
$$

by (2.20). The reverse implication can be proved similarly.
In order to prove the second assertion, observe that, due to (2.13) and (2.20), we have

$$
\begin{equation*}
p(t, x, z)=\Gamma(t, x ; V(t), z) \tag{2.22}
\end{equation*}
$$

We have seen in Proposition 2.1 that $\Gamma(t, x ; u, z)$ solves (2.10) for fixed $(t, x)$, and it also solves (2.12) for fixed $(u, z)$. Combining these two facts yields that $p$ satisfies

$$
\begin{align*}
& p_{t}(t, x, z)+b(t, x) p_{x}(t, x, z)+\frac{1}{2} p_{x x}(t, x, z) \\
& \quad=-\sigma^{2}(t)(b(V(t), z) p(t, x, z))_{z}+\frac{1}{2} \sigma^{2}(t) p_{z z}(t, x, z) \tag{2.23}
\end{align*}
$$

Using Itô's formula and (2.23), we get

$$
\begin{aligned}
p\left(t, R_{t}, z\right)= & \Gamma(0,0 ; c, z) \\
& +\int_{0}^{t} \sigma^{2}(s)\left\{-\left(b(V(s), z) p\left(s, R_{s}, z\right)\right)_{z}+\frac{1}{2}\left(p\left(s, R_{s}, z\right)\right)_{z z}\right\} \mathrm{d} s \\
& +\int_{0}^{t} p_{x}\left(s, R_{s}, z\right)\left[\mathrm{d} R_{s}-b\left(s, R_{S}\right) \mathrm{d} s\right]
\end{aligned}
$$

Due to (2.14), $\mathrm{d} I_{s}^{g}=\mathrm{d} R_{s}-b\left(s, R_{s}\right) \mathrm{d} s$ when $g_{t}(z)=p\left(t, R_{t}, z\right)$. By repeating this argument, we arrive at the desired conclusion.

Before we give a proof of Theorem 2.1, we will first investigate the Gaussian case, i.e. $a \equiv 1$.

## 3. Gaussian case

Under the assumption that $a \equiv 1, Z$ becomes a Gaussian martingale, and its transition density is given by $G(t, x ; u, z)=\frac{1}{\sqrt{2 \pi(u-t)}} \exp \left(-\frac{(x-z)^{2}}{2(u-t)}\right)$ since it is a time-changed Brownian motion where the time change is deterministic. In this case, Eq. (2.17) reduces to

$$
\begin{equation*}
\mathrm{d} X_{t}=\mathrm{d} B_{t}+\frac{Z_{t}-X_{t}}{V(t)-t} \mathrm{~d} t \tag{3.24}
\end{equation*}
$$

This equation, together with various properties of its solution, is discussed in Danilova [9], Föllmer, et al. [11] and Wu [22].

Theorem 3.1. Suppose that $a \equiv 1$ and that $\rho$ is given by (2.18). Then, Theorem 2.1 holds.
The proof of the above theorem will be done in several steps, the first of which being the following proposition.

Proposition 3.1. There exists a unique strong solution to (3.24) over [0, 1). Moreover, $\left(\left(X_{t}, Z_{t}\right)\right)_{t \in[0,1)}$ is strong Markov.

Proof. Since $\frac{z-x}{V(t)-t}$ is Lipschitz over any $[0, T]$ for $T<1$, there exists a unique strong solution to the above equation with $X_{0}=0$ by Theorem 38 of Chapter V in [18]. Moreover, Theorem 5.4.20 in [13] yields that ( $X, Z$ ) has a strong Markov property.

The above proposition shows that condition C 1 of the bridge construction is satisfied. We next show that the solution to (3.24) satisfies condition C 2 , and then conclude this section with a proof of Theorem 3.1.

Lemma 3.1. Let Assumption 2.1 hold. Let $\lambda(t)=\exp \left\{-\int_{0}^{t} \frac{1}{V(s)-s} \mathrm{~d} s\right\}$ and $\Lambda(t)=\int_{0}^{t} \frac{1+\sigma^{2}(s)}{\lambda^{2}(s)} \mathrm{d} s$ be as in Assumption 2.1, and let $\ell>0$ be the associated constant in Assumption 2.1. Define

$$
\begin{equation*}
\varphi(t, x, z)=\frac{1}{\sqrt{2(\Lambda(t)+\ell)}} \mathrm{e}^{\frac{(x-z)^{2}}{2 \lambda^{2}(t)(\Lambda(t)+\ell)}} \tag{3.25}
\end{equation*}
$$

Then, $\left(\varphi\left(t, X_{t}, Z_{t}\right)\right)_{t \in[0,1)}$ is a positive supermartingale, and

$$
\begin{equation*}
\lim _{t \uparrow 1} \varphi(t, x, z)=+\infty, \quad x \neq z \tag{3.26}
\end{equation*}
$$

Proof. Direct calculations give

$$
\begin{equation*}
\varphi_{t}(t, x, z)+\frac{z-x}{V(t)-t} \varphi_{x}(t, x, z)+\frac{1}{2} \varphi_{x x}(t, x, z)+\frac{\sigma^{2}(t)}{2} \varphi_{z z}(t, x, z)=0 \tag{3.27}
\end{equation*}
$$

Thus, it follows from Itô's formula that $\varphi\left(t, X_{t}, Z_{t}\right)$ is a local martingale. Since it is obviously positive, it is a supermartingale.

In order to prove convergence when $x \neq z$, consider two cases.

- Case 1: $\lim _{t \uparrow 1} \Lambda(t)<+\infty$. Then, since due to Remark 2.3 we have that $\lim _{t \uparrow 1} \lambda(t)=0$, we obtain that

$$
\begin{equation*}
\lim _{t \uparrow 1} \varphi(t, x, z)=\lim _{t \uparrow 1} \frac{1}{\sqrt{2(\Lambda(t)+\ell)}} \mathrm{e}^{\frac{(x-z)^{2}}{2 \lambda^{2}(t)(\Lambda(t)+\ell)}}=+\infty \tag{3.28}
\end{equation*}
$$

- Case 2: $\lim _{t \uparrow 1} \Lambda(t)=+\infty$. In this case, we will have

$$
\begin{aligned}
\lim _{t \uparrow 1} \log \varphi(t, x, z) & =\lim _{t \uparrow 1} \log (2(\Lambda(t)+\ell))\left[\frac{(x-z)^{2}}{2 \lambda^{2}(t)(\Lambda(t)+\ell) \log (2(\Lambda(t)+\ell))}-\frac{1}{2}\right] \\
& =+\infty
\end{aligned}
$$

where the last equality is due to Assumption 2.1.2. Indeed, the condition yields that

$$
\lim _{t \uparrow 1} \lambda^{2}(t) 2(\Lambda(t)+\ell) \log (2(\Lambda(t)+\ell))=0
$$

since, when $\lim _{t \uparrow 1} \Lambda(t)=\infty, \lim _{t \uparrow 1} \frac{\log (2(\Lambda(t)+\ell))}{\log (\Lambda(t))}=1$ and $\lim _{t \uparrow 1} \lambda^{2}(t) \Lambda(t)=0$. Therefore, we have $\lim _{t \uparrow 1} \varphi(t, x, z)=+\infty$.
The proof is now complete.
Proposition 3.2. $P^{0, z}\left(\lim _{t \uparrow 1} X_{t}=Z_{1}\right)=1$, where $X$ is the unique strong solution to (3.24).
Proof. Let $M_{t}:=\varphi\left(t, X_{t}, Z_{t}\right)$. Then, $M=\left(M_{t}\right)_{t \in[0,1)}$ is a positive supermartingale by the previous lemma. Using the supermartingale convergence theorem, there exists an $M_{1} \geq 0$ such that $\lim _{t \uparrow 1} M_{t}=M_{1}, P^{0, z}$-a.s. Using Fatou's lemma and the fact that $M$ is a supermartingale, we have

$$
M_{0} \geq \liminf _{t \uparrow 1} E^{0, z}\left[M_{t}\right] \geq E^{0, z}\left[M_{1}\right]=E^{0, z}\left[\lim _{t \uparrow 1} \varphi\left(t, X_{t}, Z_{t}\right)\right]
$$

where $E^{0, z}$ is the expectation operator with respect to $P^{0, z}$. Since $M_{0}$ is finite, one has that $\lim _{t \uparrow 1} \varphi\left(t, X_{t}, Z_{t}\right)$ is finite $P^{0, z}$-a.s. Therefore, $P^{0, z}\left(\lim _{t \uparrow 1} X_{t} \neq Z_{1}\right)=0$ in view of (3.26).

Proposition 3.3. Let $a \equiv 1$ and $\mu(\mathrm{d} z)=G(0,0 ; c, z) \mathrm{d} z$, where $c \in(0,1)$ is the real number fixed in Assumption 2.1 and $G$ is given by (2.13). Then,

$$
\mathbb{P}\left[Z_{t} \in \mathrm{~d} z \mid \mathcal{F}_{t}^{X}\right]=G\left(t, X_{t} ; V(t), z\right) \mathrm{d} z
$$

Proof. As $(X, Z)$ is jointly Gaussian, the conditional distribution of $Z_{t}$ given $\mathcal{F}_{1}^{X}$ is also Gaussian (see Theorem 11.1 in [15]). Thus, it suffices to find the conditional mean $\bar{Z}_{t}$ and the variance $\gamma_{t}$ in order to characterize the distribution completely. Theorem 10.3 in [15] yields

$$
\begin{equation*}
\mathrm{d} \widehat{Z}_{t}=\frac{\gamma_{t}}{V(t)-t}\left\{\mathrm{~d} X_{t}-\frac{\widehat{Z}_{t}-X_{t}}{V(t)-t} \mathrm{~d} t\right\} \tag{3.29}
\end{equation*}
$$

and

$$
\begin{equation*}
\frac{\mathrm{d} \gamma_{t}}{\mathrm{~d} t}=\sigma^{2}(t)-\frac{\gamma_{t}}{V(t)-t} \tag{3.30}
\end{equation*}
$$

with the initial conditions that $\widehat{Z_{0}}=\mathbb{E}\left[Z_{0}\right]=0$ and $\gamma_{0}=c$ due to the choice of $\mu$. In particular, $\gamma_{t}$ is deterministic. One can verify directly that $\gamma_{t}=V(t)-t$ satisfies (3.30) and the initial condition since $V(0)=c$ by Assumption 2.1. Thus, (3.29) becomes

$$
\mathrm{d} \widehat{Z}_{t}=\mathrm{d} X_{t}-\frac{\widehat{Z}_{t}-X_{t}}{V(t)-t} \mathrm{~d} t
$$

i.e. $\widehat{Z}$ is a solution to the following SDE:

$$
\begin{equation*}
\mathrm{d} Y_{t}=\mathrm{d} X_{t}-\frac{Y_{t}-X_{t}}{V(t)-t} \mathrm{~d} t \tag{3.31}
\end{equation*}
$$

Clearly, choosing $Y_{t}=X_{t}$ will solve this SDE. Moreover, as the function $\frac{y-x}{V(t)-t}$ is Lipschitz on [ $0, T$ ] for any $T<1$, it follows from Theorem 7 in Chapter V of [18] that (3.31) has a unique solution. Thus, $\widehat{Z}_{t}=X_{t}$, which in turn yields that the conditional distribution of $Z_{t}$ is Gaussian with mean $X_{t}$ and variance $V(t)-t$. Note that the density associated to this distribution is given by $G\left(t, X_{t} ; V(t), \cdot\right)$ when $a \equiv 1$.

Proof of Theorem 3.1. Propositions 3.1 and 3.2 establish that conditions C1 and C2 are satisfied. Finally, C3 is satisfied as well due to Proposition 3.3 in view of Lemma 2.1.

## 4. The general case

We now go back to proving Theorem 2.1. The proof is structured in several steps in the following way. We first show that there exists a strong solution, which is also Markov, to the system of SDEs given by (2.1) and (2.17) on the time interval [0,1). Then we show that $\lim _{t \uparrow 1} X_{t}$ exists and equals $Z_{1}, P^{0, z}$-a.s., implying that there is no explosion until time 1 so that the solution can be continuously extended to the whole interval $[0,1]$ and satisfies the bridge condition. Then we characterize the conditional distribution of $Z_{t}$ given $\mathcal{F}_{t}^{X}$ and identify it with $\rho\left(t, X_{t}, \cdot\right)$, which will in turn imply that $X$ is a local martingale in its own filtration via Lemma 2.1. Finally, we provide an application of our method to the construction of Ornstein-Uhlenbeck bridges.

### 4.1. Existence of a strong solution on the time interval $[0,1)$ and the bridge property

Recall from Lemma 2.2 that $U_{t}=A\left(V(t), Z_{t}\right), R_{t}=A\left(t, X_{t}\right)$, where $A$ is defined in (2.7) and $\rho$ is related to $p$ via (2.20). Since $A$ is strictly increasing, the existence of a strong solution with a Markov property to the system of SDEs given by (2.1) and (2.17) and the convergence of $X_{t}$ to $Z_{1}$ is equivalent to the existence of a strong solution with a Markov property of the following system, which can be obtained by an application of Itô's formula,

$$
\begin{align*}
& \mathrm{d} U_{t}=\sigma(t) \mathrm{d} \beta_{t}+\sigma^{2}(t) b\left(t, U_{t}\right) \mathrm{d} t \\
& \mathrm{~d} R_{t}=\mathrm{d} B_{t}+\left\{\frac{p_{x}\left(t, R_{t}, U_{t}\right)}{p\left(t, R_{t}, U_{t}\right)}+b\left(t, R_{t}\right)\right\} \mathrm{d} t, \tag{4.32}
\end{align*}
$$

and convergence of $R_{t}$ to $U_{1}$.
First observe that, due to (2.22), we have $\frac{p_{x}(t, x, z)}{p(t, x, z)}+b(t, x)=\frac{\Gamma_{x}(t, x ; V(t), z)}{\Gamma(t, x ; V(t), z)}+b(t, x)$. Thus, due to Lemma A. 1 and Assumption 2.2, $\frac{p_{x}(t, x, z)}{p(t, x, z)}+b(t, x)$ is locally Lipschitz for $t \in[0, T]$ for any $T<1,{ }^{3}$ and therefore $R$ is the unique strong solution to the corresponding stochastic differential equation on $[0,1)$ up to an explosion time (see Theorem 38 of Chapter V in [18]). Moreover, the solution will have a strong Markov property for any stopping time strictly less than the explosion time by Theorem 5.4.20 in [13]. We shall now see that there will not be any explosion until time 1 and, indeed, that $R_{t}$ converges to $U_{1}$.

Proposition 4.1. Suppose that Assumptions 2.1-2.3 are satisfied. Then

$$
P^{0, z}\left(\lim _{t \uparrow 1} R_{t}=U_{1}\right)=1
$$

Proof. As observed before, there exists a strong solution to (4.32) up to an explosion time. Let us denote this explosion time with $\tau$. We will first argue that $P^{0, z}(\tau<1)=0$. Recall that $p(t, x, z)=\Gamma(t, x ; V(t), z)$ (see (2.22)), and define

$$
\begin{equation*}
h(t, x ; u, z):=\frac{\Gamma(t, x ; u, z)}{q(u-t, x, z)}, \tag{4.33}
\end{equation*}
$$

[^3]where $q$ is the transition density of a standard Brownian motion. This yields that
$$
\frac{p_{x}(t, x, z)}{p(t, x, z)}=\frac{z-x}{V(t)-t}+\frac{h_{x}(t, x ; V(t), z)}{h(t, x ; V(t), z)} .
$$

Proposition A. 1 in the Appendix states that $\frac{h_{x}(t, x ; V(t), z)}{h(t, x ; V(t), z)}$ is uniformly bounded on $[0,1] \times \mathbb{R} \times$ $[0,1] \times \mathbb{R}$; thus we can define an equivalent probability measure $\bar{P}^{0, z}$ on $\mathcal{G}_{1}$ (recall that all the stochastic processes have been defined on $\left(\Omega, \mathcal{G},\left(\mathcal{G}_{t}\right)\right)$, which is introduced at the beginning of Section 2) by the following:

$$
\frac{\mathrm{d} \bar{P}^{0, z}}{\mathrm{~d} P^{0, z}}:=\mathcal{E}\left(\int_{0}^{.} \sigma(s) b\left(s, U_{s}\right) \mathrm{d} \beta_{s}\right)_{1} \mathcal{E}\left(\int_{0}^{.}\left\{b\left(s, R_{s}^{\tau}\right)+\frac{h_{x}\left(s, R_{s}^{\tau} ; V(s), Z_{s}\right)}{h\left(s, R_{s}^{\tau} ; V(s), Z_{s}\right)}\right\} \mathrm{d} B_{s}\right)_{1},
$$

where $R^{\tau}$ is the process $R$ stopped at $\tau$ and $\mathcal{E}(\cdot)_{t}$ denotes the Doléans-Dade stochastic exponential taken at time $t$. Recall that $\sigma$ and $b$ are bounded by Assumptions 2.1 and 2.2. Under this new measure, $\bar{P}^{0, z}$, (4.32) becomes

$$
\begin{align*}
& \mathrm{d} U_{t}=\sigma(t) \mathrm{d} \bar{\beta}_{t} \\
& \mathrm{~d} R_{t}^{\tau}=\mathrm{d} \bar{B}_{t}+\frac{p_{x}\left(t, R_{t}^{\tau}, U_{t}\right)}{p\left(t, R_{t}^{\tau}, U_{t}\right)} \mathrm{d} t=\mathrm{d} \bar{B}_{t}+\frac{U_{t}-R_{t}^{\tau}}{V(t)-t} \mathrm{~d} t \tag{4.34}
\end{align*}
$$

where $\bar{\beta}$ and $\bar{B}$ are two $\left(\mathcal{G}_{t}\right)$-Brownian motions under $\bar{P}^{0, z}$. First, observe that, if $P^{0, z}(\tau<$ $1)>0$, then so is $\bar{P}^{0, z}(\tau<1)$. However, we have shown in Proposition 3.1 that (4.34) has a non-exploding solution over $[0,1)$. This contradiction implies that $P^{0, z}(\tau<1)=0$. Moreover, Proposition 3.2 shows that $\bar{P}^{0, z}\left(\lim _{t \uparrow 1} R_{t}=U_{1}\right)=1$. This yields $P^{0, z}\left(\lim _{t \uparrow 1} R_{t}=U_{1}\right)=1$ due to the equivalence of the measures.

The next proposition and its corollary sum up what we have achieved so far in this section.

Proposition 4.2. Under Assumptions 2.1-2.3, there exists a unique strong solution to the SDE

$$
\mathrm{d} R_{t}=\mathrm{d} B_{t}+\left\{\frac{p_{x}\left(t, R_{t}, U_{t}\right)}{p\left(t, R_{t}, U_{t}\right)}+b\left(t, R_{t}\right)\right\} \mathrm{d} t
$$

with $R_{0}=0$ such that ( $R, U$ ) has a strong Markov property over the interval $[0,1)$. Moreover, $P^{0, z}\left(\lim _{t \uparrow 1} R_{t}=U_{1}\right)=1$.

Proof. Propositions 4.1 and A. 1 imply that $P^{0, z}\left(\lim _{t \uparrow 1} R_{t}=U_{1}\right)=1$, which in turn yields that there is no explosion until time 1. Thus, Theorem 38 of Chapter V in [18] gives that $R$ is indeed the strong solution of the SDE over the time interval [0, 1). Moreover, due to Theorem 5.4.20 in [13], $(R, U)$ has a strong Markov property.

The following corollary is immediate due to the one-to-one relationship, via the strictly monotone transformation $A$, between $(R, U)$ and $(X, Z)$.

Corollary 4.1. Under Assumptions 2.1-2.3, there exists a unique strong solution to (2.17) on $[0,1]$ such that $(X, Z)$ has a strong Markov property. Moreover, $\lim _{t \uparrow 1} X_{t}$ exists $P^{0, z}$-a.s., and $X_{1}:=\lim _{t \uparrow 1} X_{t}=Z_{1}, P^{0, z}$-a.s.

### 4.2. Conditional distribution of $Z$

We now turn to proving that $\rho\left(t, X_{t}, \cdot\right)$ is the conditional density of $Z_{t}$ given $\mathcal{F}_{t}^{X}$, which will in turn imply that the solution of (2.17) is a local martingale in its own filtration via Lemma 2.1. In order to find the conditional density of $Z$, we will first find the conditional density of $U$ given $\left(\mathcal{F}_{t}^{R}\right)$ and then use Lemma 2.2. The reader is asked to review the notation introduced after the statement of Theorem 2.1 at this point. Recall that $U_{t}=A\left(V(t), Z_{t}\right)$ and $R_{t}=A\left(t, X_{t}\right)$, where $A$ is the function defined by (2.7). Under this transformation, $U_{0}$ has a probability density given by $\mathbb{P}\left(U_{0} \in \mathrm{~d} z\right)=\Gamma(0,0 ; c, z) \mathrm{d} z$, where the measure $\mathbb{P}$ is defined by (2.19).

Next, fix a $T<1$ and let $\mathbb{P}_{T}:=\mathbb{P}_{\mathcal{F}_{T}^{X, Z}}$ be the restriction of $\mathbb{P}$ to $\mathcal{F}_{T}^{X, Z}$. The reason for this restriction is due to the fact that the drift term in (4.32) is not defined at $t=1$, and this will lead to inapplicability of the results of [14] that we cite later in this subsection. Note that $\mathbb{P}\left[U_{t} \in \mathrm{~d} z \mid \mathcal{F}_{t}^{R}\right]=\mathbb{P}_{T}\left[U_{t} \in \mathrm{~d} z \mid \mathcal{F}_{t}^{R}\right]$ for $t \in[0, T]$ and, since $T$ is arbitrary, this identity will allow us to obtain all the conditional distributions of $Z_{t}$ for $t<1$.

The remainder of this subsection is devoted to the proof that

$$
\mathbb{P}_{T}\left[U_{t} \in \mathrm{~d} z \mid \mathcal{F}_{t}^{R}\right]=p\left(t, R_{t}, z\right) \mathrm{d} z
$$

where $p$ is defined by (2.20). In order to achieve this goal, we will use the characterization of the conditional distributions obtained by Kurtz and Ocone [14]. We refer the reader to [14] for all unexplained details and terminology.

Remark 4.1. Let $\overline{\mathbb{P}}_{T}$ be the absolutely continuous measure on the same space defined by the Radon-Nikodým derivative

$$
\begin{aligned}
\exp \{ & -\frac{1}{2} \int_{0}^{T}\left(\frac{p_{x}\left(s, R_{s}, U_{s}\right)}{p\left(s, R_{s}, U_{s}\right)}+b\left(s, R_{s}\right)\right)^{2} \mathrm{~d} s \\
& \left.-\int_{0}^{T}\left(\frac{p_{x}\left(s, R_{s}, U_{s}\right)}{p\left(s, R_{s}, U_{s}\right)}+b\left(s, R_{s}\right)\right) \mathrm{d} B_{s}\right\}
\end{aligned}
$$

Note that, under $\overline{\mathbb{P}}_{T}, R$ is a Brownian motion independent of $U$. Moreover, as we have just seen, there is no explosion before time 1 for the system of $\operatorname{SDEs}$ for $(U, R)$. Thus, it follows from the no-explosion criterion (see Exercise 2.10 in Chapter IX of [19]) that $\overline{\mathbb{P}}_{T}$ is a probability measure equivalent to $\mathbb{P}_{T}$. As the natural filtration of a Brownian motion is right continuous, this in turn implies that $\left(\mathcal{F}_{t}^{X}\right)_{t \in[0, T]}$ is right continuous, too.

Let $\mathcal{P}$ be the set of probability measures on the Borel sets of $\mathbb{R}$ topologized by weak convergence. Given $m \in \mathcal{P}$ and $m$-integrable $f$, we write $m f:=\int_{\mathbb{R}} f(z) m(\mathrm{~d} z)$. The next result is Lemma 1.1 in [14].

Lemma 4.1. There is a $\mathcal{P}$-valued $\mathcal{F}^{X}$-optional process $\pi_{t}(\omega, \mathrm{~d} x)$ such that

$$
\pi_{t} f=\mathbb{E}\left[f\left(U_{t}\right) \mid \mathcal{F}_{t}^{R}\right]
$$

for all bounded measurable $f$. Moreover, $\pi_{t}$ has a right-continuous version.
Let us recall the innovation process

$$
I_{t}=R_{t}-\int_{0}^{t} \pi_{s} \kappa_{s} \mathrm{~d} s
$$

where $\kappa_{s}(z):=\frac{p_{x}\left(s, R_{s}, z\right)}{p\left(s, R_{s}, z\right)}+b\left(s, R_{s}\right)$. The next lemma will show that $R$ is an integrable process and, thus, $\pi_{s} \kappa_{s}$ exists for all $s<1$ since $Z$ is integrable and $\frac{p_{x}(s, x, z)}{p(s, x, z)}=\frac{z-x}{V(s)-s}+$ is a bounded function, due to Proposition A.1.

Lemma 4.2. Let $R$ be the unique strong solution of (4.32) under Assumptions 2.1-2.3. Then, for every $T<1$,

$$
\mathbb{E}\left[R_{t}^{2}\right] \leq C\left(1+v_{T}^{-2}\right) \mathrm{e}^{C v_{T}^{-2} t}
$$

for every $t \leq T$, where $C$ is a constant and $\nu_{T}:=\inf _{t \leq T}(V(t)-t)$.
Proof. Note that

$$
\begin{aligned}
\mathbb{E}\left[R_{t}^{2}\right] & \leq C\left(t+\int_{0}^{t} \mathbb{E}\left(\frac{p_{x}\left(s, R_{s}, U_{s}\right)}{p\left(s, R_{s}, U_{s}\right)}+b\left(s, R_{s}\right)\right)^{2} \mathrm{~d} s\right) \\
& \leq C\left(1+v_{T}^{-2}+v_{T}^{-2} \int_{0}^{t} \mathbb{E}\left[R_{s}^{2}\right] \mathrm{d} s\right) \\
& \leq C\left(1+v_{T}^{-2}\right)+C v_{T}^{-2} \int_{0}^{t} \mathbb{E}\left[R_{s}^{2}\right] \mathrm{d} s,
\end{aligned}
$$

where $C$ is a generic constant. The result then follows from Gronwall's inequality.
In order to be able to use the results of [14], we first need to establish the KushnerStratonovich equation satisfied by $\left(\pi_{t}\right)_{t \in[0, T]}$. To this end, let $B\left(\mathbb{R}^{2}\right)$ denote the set of bounded Borel-measurable real-valued functions on $\mathbb{R}^{2}$, and consider the operator $\mathcal{A}_{0}: B\left(\mathbb{R}_{+} \times \mathbb{R}\right) \mapsto$ $B\left(\mathbb{R}^{2}\right)$ defined by

$$
\mathcal{A}_{0} \phi(t, x)=\frac{\partial \phi}{\partial t}(t, x)+\frac{1}{2} \sigma^{2}(t) \frac{\partial^{2} \phi}{\partial x^{2}}(t, x)+\sigma^{2}(t) b(t, x) \frac{\partial \phi}{\partial x}(t, x),
$$

with the domain $\mathcal{D}\left(\mathcal{A}_{0}\right)=C_{c}^{\infty}\left(\mathbb{R}_{+} \times \mathbb{R}\right)$, where $C_{c}^{\infty}$ is the class of infinitely differentiable functions with compact support. Due to Assumptions 2.1-2.3 imposed on $\sigma$ and $b$, it is well known (see e.g. Remark 5.4.17 in [13]) that the martingale problem for $\mathcal{A}_{0}$ is well posed, and its unique solution is given by $\left(t, U_{t}\right)$. Moreover, the Kushner-Stratonovich equation for the conditional distribution of $U$ is given by the following:

$$
\begin{equation*}
\pi_{t} f=\pi_{0} f+\int_{0}^{t} \pi_{s}\left(\mathcal{A}_{0} f\right) \mathrm{d} s+\int_{0}^{t}\left[\pi_{s}\left(\kappa_{s} f\right)-\pi_{s} \kappa_{s} \pi_{s} f\right] \mathrm{d} I_{s} \tag{4.35}
\end{equation*}
$$

for all $f \in C_{c}^{\infty}(\mathbb{R})$ (see Theorem 4.3.1 in [6]). Note that $f$ can be easily made an element of $\mathcal{D}\left(\mathcal{A}_{0}\right)$ by redefining it as $f \mathbf{n}$, where $\mathbf{n} \in C_{c}^{\infty}\left(\mathbb{R}_{+}\right)$is such that $\mathbf{n}(t)=1$ for all $t \in[0,1]$. Thus, the above expression is rigorous. The following theorem is a corollary to Theorem 4.1 in [14].

Theorem 4.1. Suppose that the conditions in Assumptions 2.1-2.3 hold. Let $\left(m_{t}\right)$ be an $\mathcal{F}^{X}$-adapted càdlàg $\mathcal{P}$-valued process such that

$$
\begin{equation*}
m_{t} f=\pi_{0} f+\int_{0}^{t} m_{s}\left(\mathcal{A}_{0} f\right) \mathrm{d} s+\int_{0}^{t}\left[m_{s}\left(\kappa_{s} f\right)-m_{s} \kappa_{s} m_{s} f\right] \mathrm{d} I_{s}^{m} \tag{4.36}
\end{equation*}
$$

for all $f \in C_{c}^{\infty}(\mathbb{R})$, where $I_{t}^{m}=R_{t}-\int_{0}^{t} m_{s} \kappa_{s} \mathrm{~d}$. Then, $m_{t}=\pi_{t}$ for all $t<T$, a.s.
Proof. The proof follows along the same lines as the proof of Theorem 4.1 in [14], even though, in contrast to [14], we allow the drift of $R$ to depend on $t$ and $R_{t}$, too. This is due to
the fact that [14] used the assumption that the drift depends only on the signal process, $U$, in order to ensure that the joint martingale problem $(R, U)$ is well posed, i.e. the conditions of Proposition 2.2 in [14] are satisfied. Note that the relevant martingale problem is well posed in our case, since the system of SDEs in (4.32) has a unique strong solution and the drift and dispersion coefficients are bounded on compact domains over the interval [ $0, T$ ] (see Proposition 5.3.20 and Remark 5.4.17 in [13] in this regard).

Now, we can state and prove the following corollary.
Corollary 4.2. Suppose that the conditions in Assumptions 2.1-2.3 hold. Then,

$$
\pi_{t} f=\int_{\mathbb{R}} f(z) p\left(t, R_{t}, z\right) \mathrm{d} z
$$

for any bounded measurable $f$. Therefore,

$$
\mathbb{E}\left[f\left(Z_{t}\right) \mid \mathcal{F}_{t}^{X}\right]=\int_{\mathbb{R}} f(z) \rho\left(t, X_{t}, z\right) \mathrm{d} z
$$

Proof. We have seen in Lemma 2.2 that $p\left(t, R_{t}, \cdot\right)$ satisfies (2.21), i.e. $m_{t}(\mathrm{~d} z):=p\left(t, R_{t}, z\right) \mathrm{d} z$ solves (4.36). Then, it follows from Theorem 4.1 that $p\left(t, R_{t}, \cdot\right)$ is the conditional density of $U_{t}$, which gives the first assertion. The second assertion follows from the explicit relationship between $p$ and $\rho$, as described in Lemma 2.2.

### 4.3. Proof of the main result and application to Ornstein-Uhlenbeck bridges

Now we have all the results necessary to prove Theorem 2.1.
Proof of Theorem 2.1. The strong solution, the Markov property and the fact that $P^{0, z}\left(\lim _{t \uparrow 1} X_{t}=Z_{1}\right)=1$ follow from Corollary 4.1. Moreover, it follows from Corollary 4.2 that $\rho\left(t, X_{t}, z\right)$ is the conditional density of $Z_{t}$ given $\mathcal{F}_{t}^{X}$. Thus, $X$ is a local martingale in its own filtration by Lemma 2.1.

Note that, using the methods employed in this section, one can prove the following theorem as well.

Theorem 4.2. Let $Z$ be the unique strong solution on $\left(\Omega, \mathcal{G},\left(\mathcal{G}_{t}\right), \mathbb{Q}\right)$ to

$$
Z_{t}=Z_{0}+\int_{0}^{t} \sigma(s) \mathrm{d} \beta_{s}+\int_{0}^{t} \sigma^{2}(s) b\left(s, Z_{s}\right) \mathrm{d} s
$$

where $b \in C_{b}^{1,2}$ with bounded derivatives and $\sigma$ is as before. Suppose that $P\left(Z_{0} \in \mathrm{~d} z\right)=$ $\Gamma(0,0 ; c, z) \mathrm{d} z$ for some $c \in(0,1)$. Let $\rho(t, x, z):=\Gamma(t, x ; V(t), z)$, where $V$ is as defined earlier and $\Gamma(t, x ; u, z)$ is the fundamental solution of (2.10). Define $X$ by

$$
\mathrm{d} X_{t}=\mathrm{d} B_{t}+\left\{b\left(s, X_{s}\right)+\frac{\rho_{x}\left(t, X_{t}, Z_{t}\right)}{\rho\left(t, X_{t}, Z_{t}\right)}\right\} \mathrm{d} t
$$

for $t \in(0,1)$ with $X_{0}=0$. Then,

1. in the filtration generated by $X$,

$$
X_{t}-\int_{0}^{t} b\left(s, X_{s}\right) \mathrm{d} s
$$

defines a standard Brownian motion;
2. $X_{1}=Z_{1}, P^{0, z}$-a.s., where $P^{0, z}$ is the law of $(X, Z)$ with $Z_{0}=z$ and $X_{0}=0$.

The following example show that boundedness of $b$ in the above theorem is not a necessary condition for the result to hold as long as $b$ depends linearly on $x$.

Example 4.1. Suppose that $Z$ is an Ornstein-Uhlenbeck type process, i.e.

$$
\mathrm{d} Z_{t}=\sigma(t) \mathrm{d} \beta_{t}-k \sigma^{2}(t) Z_{t} \mathrm{~d} t,
$$

where $k>0$ is a constant. Note that in this case the fundamental solution of (2.10) is given by

$$
\Gamma(s, x ; t, z)=q\left(\left(1-\mathrm{e}^{-2 k(t-s)}\right) / 2 k, x \mathrm{e}^{-k(t-s)}, z\right) .
$$

Let $X$ be defined by $X_{0}=0$ and

$$
\mathrm{d} X_{t}=\mathrm{d} B_{t}+\left\{2 k \frac{Z_{t}-X_{t} \mathrm{e}^{-k(V(t)-t)}}{\mathrm{e}^{k(V(t)-t)}-\mathrm{e}^{-k(V(t)-t)}}-k X_{t}\right\} \mathrm{d} t,
$$

for $t \in(0,1)$. Then, we claim that, if $Z_{0}$ has a probability density given by $\Gamma(0,0 ; c, \cdot)$, then $X$ is an Ornstein-Uhlenbeck process in its own filtration and $X_{1}=Z_{1}, P^{0, z}$-a.s., under an appropriate modification of Assumption 2.1.2, which we will state later. Using the method employed in the proof of Proposition 3.3, we have that $\Gamma(t, x ; V(t), z)$ is the conditional density of $Z_{t}$ given $\mathcal{F}_{t}^{X}$ for $t<1$. Thus, it remains to show that $X_{1}=Z_{1}, P^{0, z}$-a.s.

Note that the above convergence will be obtained if one can find a continuous function $b(t)$ with $b(1)=1$ such that $X_{t}-b(t) Z_{t}$ converges to 0 as $t \uparrow 1$. We will choose this new function so that $Y_{t}:=X_{t}-b(t) Z_{t}$ defines a Markov process. It can be checked directly that, if $b$ satisfies the following ordinary differential equation,

$$
\begin{equation*}
b^{\prime}(t)+\gamma(t) b(t)=\theta(t), \tag{4.37}
\end{equation*}
$$

where

$$
\begin{aligned}
& \gamma(t)=\frac{\mathrm{e}^{-c(V(t)-t)}+\mathrm{e}^{c(V(t)-t)}}{\mathrm{e}^{c(V(t)-t)}-\mathrm{e}^{-c(V(t)-t)}}+c \sigma^{2}(t), \quad \text { and } \\
& \theta(t)=\frac{2 c}{\mathrm{e}^{c(V(t)-t)}-\mathrm{e}^{-c(V(t)-t)}}
\end{aligned}
$$

then $Y$ satisfies the following SDE:

$$
\begin{equation*}
\mathrm{d} Y_{t}=\mathrm{d} B_{t}-b(t) \sigma(t) \mathrm{d} \beta_{t}-c \frac{\mathrm{e}^{-c(V(t)-t)}+\mathrm{e}^{c(V(t)-t)}}{\mathrm{e}^{c(V(t)-t)}-\mathrm{e}^{-c(V(t)-t)}} Y_{t} \mathrm{~d} t \tag{4.38}
\end{equation*}
$$

The solution to (4.37) with the boundary condition $b(1)=1$ is given by

$$
b(t)=\frac{\int_{0}^{t} \mathrm{e}^{s} \int_{0}^{s} \gamma(r) \mathrm{d} r}{\mathrm{e}^{\int_{0}^{t} \gamma(r) \mathrm{d} r}} .
$$

In order to show that $Y_{t}$ converges to 0 as $t \uparrow 1$, consider the function $\varphi$ defined by

$$
\varphi(t, y):=\frac{1}{\sqrt{2(\Lambda(t)+\ell)}} \mathrm{e}^{\frac{y^{2}}{2 \lambda^{2}(t)(\Lambda(t)+\ell)}}
$$

where

$$
\lambda(t):=\exp \left(-c \int_{0}^{t} \frac{\mathrm{e}^{-c(V(s)-s)}+\mathrm{e}^{c(V(s)-s)}}{\mathrm{e}^{c(V(s)-s)}-\mathrm{e}^{-c(V(s)-s)}} \mathrm{d} s\right), \quad \text { and }
$$

$$
\Lambda(t):=\int_{0}^{t} \frac{1+b^{2}(s) \sigma^{2}(s)}{\lambda^{2}(s)} \mathrm{d} s
$$

A direct application of Itô's formula gives that $\varphi\left(t, Y_{t}\right)$ is a positive local martingale, and hence a supermartingale. If Assumption 2.1 holds with $\lambda$ and $\Lambda$ defined above, then we can imitate the proof of Proposition 3.2 using $\varphi(t, y)$ defined above to conclude that $Y_{t}$ converges to 0 as $t \uparrow 1$.

## 5. Application to finance: A generalization of the Back-Pedersen equilibrium model

We will use the previous bridge construction to solve an equilibrium model with information asymmetry that can be viewed as a non-Gaussian generalization of Back and Pedersen's model [3]. We keep the notation of the previous sections; in particular, all the stochastic processes will be defined on $\left(\Omega, \mathcal{G},\left(\mathcal{G}_{t}\right), \mathbb{Q}\right)$.

Consider a stock issued by a company with fundamental value given by the diffusion process $\mathcal{Z}=\left(\Omega, \mathcal{G},\left(\mathcal{G}_{t}\right),\left(Z_{t}\right),\left(P^{z}\right)_{z \in \mathbb{R}}\right)$ with values in $\mathbb{R}$, and satisfying

$$
\begin{equation*}
Z_{t}=Z_{0}+\int_{0}^{t} \sigma(s) a\left(V(s), Z_{s}\right) \mathrm{d} \beta_{s} \tag{5.39}
\end{equation*}
$$

where $\beta$ is a standard Brownian motion adapted to $\left(\mathcal{G}_{t}\right), a$ and $\sigma$ are deterministic functions, $V(t)=c+\int_{0}^{t} \sigma^{2}(s) \mathrm{d} s$, for some constant $c$, and the probability density of $Z_{0}$ is $G(0,0 ; c, \cdot)$ with $G$ given by (2.13). We will require $a$ and $\sigma$ to satisfy some further assumptions which are made precise in Assumption 5.2 below.

Then, if the firm value is observable, the fair stock price should be a function of $Z_{t}$ and $t$. However, the assumption of the company value being discernible by the whole market in continuous time is counterfactual, and it will be more realistic to assume that this information is revealed to the market only at given time intervals (such as dividend payment times or when balance sheets are publicized).

In this model, we therefore assume, without loss of generality, that the time of the next information release is $t=1$, and that the market terminates after that. Hence, in this setting, the stock can be viewed as a European option on the firm value with maturity $T=1$ and payoff $f\left(Z_{1}\right)$. In addition to this risky asset, there is a riskless asset that yields an interest rate normalized to zero for simplicity of exposition.

The microstructure of the market, and the interaction of market participants, are modeled as a generalization of [3]. There are three types of agent: noisy/liquidity traders, an informed trader (insider), and a market maker, all of whom are risk neutral. The agents differ in their information sets, and objectives, as follows.

- Noisy/liquidity traders trade for liquidity reasons, and their total demand at time $t$ is given by a standard $\left(\mathcal{G}_{t}\right)$-Brownian motion $B$, independent of $\beta$ and $Z_{0}$.
- A market maker observes only the total market order process $Y_{t}=\theta_{t}+B_{t}$, where $\theta_{t}$ is the total order of the insider at time $t$, which is an absolutely continuous process, and therefore $Y$ is a continuous semimartingale on $\left(\Omega, \mathcal{G},\left(\mathcal{G}_{t}\right), \mathbb{Q}\right)$. This in particular implies that the market maker's filtration is $\mathcal{F}_{t}^{Y}$. Similar to [8], we assume that the market maker sets the price as a function of weighted total order process at time $t$, i.e. we consider pricing functionals $S\left(Y_{[0, t]}, t\right)$ of the following form:

$$
\begin{equation*}
S\left(Y_{[0, t]}, t\right)=H\left(t, X_{t}\right), \quad \forall t \in[0,1) \tag{5.40}
\end{equation*}
$$

where $X$ is the unique strong solution of

$$
\begin{equation*}
\mathrm{d} X_{t}=w\left(t, X_{t}\right) \mathrm{d} Y_{t}, \quad \forall t \in[0,1), X_{0}=0 \tag{5.41}
\end{equation*}
$$

on $\left(\Omega, \mathcal{G},\left(\mathcal{G}_{t}\right), \mathbb{Q}\right)$ for some deterministic function $w(s, x)$ chosen by the market maker. Moreover, a pricing rule $(H, w)$ has to be admissible in the sense of Definition 5.1. In particular, $H \in C^{1,2}$ and, therefore, $S$ is a semimartingale on $\left(\Omega, \mathcal{G},\left(\mathcal{G}_{t}\right), \mathbb{Q}\right)$ on $[0,1)$.

- The informed investor observes the price process $S_{t}=H\left(t, X_{t}\right)$, where $X$ is given by (5.41), and the true firm value $Z_{t}$, i.e. her filtration is given by $\left(\mathcal{F}_{t}^{Z, S}\right)$. Since she is risk neutral, her objective is to maximize the expected final wealth, i.e.

$$
\begin{equation*}
\sup _{\theta \in \mathcal{A}(H, w)} E^{0, z}\left[W_{1}^{\theta}\right]=\sup _{\theta \in \mathcal{A}(H, w)} E^{0, z}\left[\left(f\left(Z_{1}\right)-S_{1-}\right) \theta_{1}+\int_{0}^{1-} \theta_{s} \mathrm{~d} S_{s}\right], \tag{5.42}
\end{equation*}
$$

where $E^{0, z}$ is the expectation with respect to the probability measure $P^{0, z}$, which is the law of ( $X, Z$ ) with $X_{0}=0$ and $Z_{0}=z$, and $\mathcal{A}(H, w)$ is the set of admissible trading strategies for the given pricing rule $(H, w)$, which will be defined in Definition 5.2. That is, the insider maximizes the expected value of her final wealth $W_{1}^{\theta}$, where the first term on the righthand side of Eq. (5.42) is the contribution to the final wealth due to a potential differential between price and fundamental at the time of information release, and the second term is the contribution to final wealth coming from the trading activity.

Remark 5.1. Note that, by setting $\sigma \equiv 0$ and $c=1$, we obtain the "static information market" considered by [2]. Moreover, setting $a \equiv 1$ results in the model studied by [3].

In both cases, $V(t)-t$ was a measure of the uncertainty of the market about the value of $Z_{t}$, which is equivalent to the informational advantage of the insider in comparison with the market maker (see the discussion at the beginning of p. 393 of [3]). As we will see later in Remark 5.8, this observation remains valid in our generalized case.

Remark 5.2. We stress the fact that the total demand $Y=Y^{\theta}$ depends on the insider's strategy $\theta$, so that the market maker's filtration $\mathcal{F}^{Y}=\mathcal{F}^{Y^{\theta}}$ depends also on $\theta$ (through $Y$ ). To avoid heavy notation, we will drop the superscript $\theta$ from the total demand. So will simply write $Y$ and $\mathcal{F}^{Y}$ instead of $Y^{\theta}$ and $\mathcal{F}^{Y^{\theta}}$, respectively.

Note also that the above market structure implies that the insider's optimal trading strategy takes into account the feedback effect, i.e. that prices react to the insider's trading strategy according to (5.40) and (5.41). Our goal is to find the rational expectations equilibrium of this market, i.e. a pair consisting of an admissible pricing rule and an admissible trading strategy such that (a) given the pricing rule the trading strategy is optimal, and (b) given the trading strategy, there exists a unique strong solution, $X_{t}$, of (5.41) over the time interval $[0,1$ ), and the pricing rule is rational in the following sense:

$$
\begin{equation*}
H\left(t, X_{t}\right)=S_{t}=\mathbb{E}^{\mathbb{Q}}\left[f\left(Z_{1}\right) \mid \mathcal{F}_{t}^{Y}\right] \tag{5.43}
\end{equation*}
$$

with $S_{1}=f\left(Z_{1}\right)$. To formalize this definition of equilibrium, we first need to define the sets of admissible pricing rules and trading strategies.

The definition of admissible pricing rules is a generalization of the one in [2,3]. This generalization allows the market maker to re-weight his past information with a weighting function $w$, as stated in (5.41).

Definition 5.1. For a given semimartingale $Y$ on $\left(\Omega, \mathcal{G},\left(\mathcal{G}_{t}\right), \mathbb{Q}\right)$, an admissible pricing rule is any pair ( $H, w$ ) fulfilling the following conditions.

1. $w:[0,1] \times \mathbb{R} \mapsto \mathbb{R}_{+}$is a function in $C^{1,2}([0,1] \times \mathbb{R})$ bounded away from 0 .
2. There exists a unique strong solution of

$$
\begin{equation*}
\mathrm{d} X_{t}=w\left(t, X_{t}\right) \mathrm{d} Y_{t}, \quad X_{0}=0 \tag{5.44}
\end{equation*}
$$

over the time interval $[0,1)$ on $\left(\Omega, \mathcal{G},\left(\mathcal{F}_{t}^{Y}\right), \mathbb{Q}\right)$.
3. $H \in C^{1,2}([0,1] \times \mathbb{R})$.
4. $x \mapsto H(t, x)$ is strictly increasing for every $t \in[0,1]$.

Moreover, given $\theta \in \mathcal{A}(H, w)$, a pricing rule $(H, w)$ is said to be rational if it satisfies (5.43).
Remark 5.3. The strict monotonicity of $H$ in the space variable implies that $H$ is invertible; thus, the filtration of the insider is generated by $X$ and $Z$. Moreover, since $w$ is bounded away from 0 , the filtrations generated by $X$ and $Y$ are the same. This in turn implies that $\left(\mathcal{F}_{t}^{S, Z}\right)=\left(\mathcal{F}_{t}^{B, Z}\right)$, i.e. the insider has full information about the market.

It is standard (see, e.g., [3,8] or [22]) in the insider trading literature to limit the set of admissible strategies to absolutely continuous ones motivated by the result in Back [2], and we do so. The formal definition of the set of admissible trading strategies is summarized in the following definition.

Definition 5.2. An $\mathcal{F}^{B, Z}$-adapted $\theta$ is said to be an admissible trading strategy for a given pair ( $H, w$ ) if

1. it is absolutely continuous with respect to the Lebesgue measure, i.e. $\theta_{t}=\int_{0}^{t} \alpha_{s} \mathrm{~d} s$;
2. there exists a unique strong solution, $X$, to the $\operatorname{SDE}^{4}(5.44)$ on $\left(\Omega, \mathcal{G},\left(\mathcal{F}_{t}^{B, Z}\right), \mathbb{Q}\right)$ over the interval $[0,1)$;
3. $(X, Z)$ is a Markov process adapted to $\left(\mathcal{G}_{t}\right)$ with law $P^{0, z}$; and
4. no doubling strategies are allowed, i.e.

$$
\begin{equation*}
E^{0, z}\left[\int_{0}^{1} H^{2}\left(t, X_{t}\right) \mathrm{d} t\right]<\infty \tag{5.45}
\end{equation*}
$$

The set of admissible trading strategies for the given pair $(H, w)$ is denoted with $\mathcal{A}(H, w)$.
Given these definitions of admissible pricing rules and trading strategies, it is now possible to formally define the market equilibrium as follows.

Definition 5.3. A triplet $\left(H^{*}, w^{*}, \theta^{*}\right)$ is said to form an equilibrium if $\left(H^{*}, w^{*}\right)$ is an admissible pricing rule for the semimartingale $Y^{*}=B+\theta^{*}, \theta^{*} \in \mathcal{A}\left(H^{*}, w^{*}\right)$, and the following conditions are satisfied.

1. Market efficiency condition: given $\theta^{*},\left(H^{*}, w^{*}\right)$ is a rational pricing rule.
2. Insider optimality condition: given $\left(H^{*}, w^{*}\right), \theta^{*}$ solves the insider optimization problem:

$$
E^{0, z}\left[W_{1}^{\theta^{*}}\right]=\sup _{\theta \in \mathcal{A}\left(H^{*}, w^{*}\right)} E^{0, z}\left[W_{1}^{\theta}\right] .
$$

[^4]Additionally, to define a well-behaved problem, we impose the following technical conditions on the model parameters.

Assumption 5.1. $f: \mathbb{R} \mapsto \mathbb{R}$ is a strictly increasing function belonging to $C^{1}$ such that

$$
|f(z)| \leq k_{1} \exp \left(k_{2} A(1, z)\right), \quad \forall z \in \mathbb{R}
$$

for some constants $k_{1}$ and $k_{2}$, where $A$ is given by (2.7).
Remark 5.4. The assumption that $f$ is strictly increasing implies that the larger the signal $Z$ the larger the value of the risky asset for the insider. This assumption will also play a role in order to prove that the proposed equilibrium pricing rule satisfies condition 4 in Definition 5.1.

Assumption 5.2. We assume that the parameters of the model satisfy the following assumptions.

1. Both $a(t, z)$ and $\sigma(t)$ satisfy Assumption 2.1.
2. $a(t, z)$ also satisfies a nonlinear PDE:

$$
\begin{equation*}
a_{t}(t, z)+\frac{a^{2}(t, z)}{2} a_{z z}(t, z)=0 . \tag{5.46}
\end{equation*}
$$

Remark 5.5. Due to the definition of $b$ given in (2.9), we have

$$
\begin{aligned}
b(t, x) & =A_{t}\left(t, A^{-1}(t, x)\right)-\frac{1}{2} a_{z}\left(t, A^{-1}(t, x)\right) \\
& =-\int_{0}^{A^{-1}(t, x)} \frac{a_{t}(t, y)}{a^{2}(t, y)} \mathrm{d} y-\frac{1}{2} a_{z}\left(t, A^{-1}(t, x)\right) \\
& =\frac{1}{2} \int_{0}^{A^{-1}(t, x)} a_{z z}(t, y) \mathrm{d} y-\frac{1}{2} a_{z}\left(t, A^{-1}(t, x)\right) \\
& =-\frac{1}{2} a_{z}(t, 0),
\end{aligned}
$$

where the second equality is due to the definition of $A$ (see (2.7)) and the third equality follows from Assumption 5.2.2. Therefore, $b$ is continuous and depends only on $t$. Moreover, Assumptions 2.2 and 2.3 are automatically satisfied, since $a \in C^{1,2}$ and $t \in[0,1]$. In this case, $U_{t}=A\left(V(t), Z_{t}\right)$, where $A$ is defined in (2.7), is a Gaussian process. Moreover, in the next subsection, we will give some heuristics indicating that $a(t, z)$ being a solution to (5.46) is a necessary condition for the existence of an equilibrium. This suggests the conclusion that the only possible form for the signal $Z$, for which an equilibrium in the sense of Definition 5.3 exists, is $Z_{t}=\Phi\left(t, U_{t}\right)$, where $U$ is a Gaussian process and $\Phi$ is a deterministic function.

### 5.1. Equilibrium

First, we shall provide some heuristics in order to motivate the PDE (5.46) we imposed on $a(t, z)$.

Let $(H, w)$ be any rational pricing rule. First, notice that a standard application of integration-by-parts formula applied to $W_{1}^{\theta}$ for any $\theta \in \mathcal{A}(H, w)$ gives

$$
\begin{equation*}
W_{1}^{\theta}=\int_{0}^{1}\left(f\left(Z_{1}\right)-S_{s}\right) \alpha_{s} \mathrm{~d} s \tag{5.47}
\end{equation*}
$$

Furthermore,

$$
\begin{equation*}
E^{0, z}\left[\int_{0}^{1}\left(f\left(Z_{1}\right)-S_{s}\right) \alpha_{s} \mathrm{~d} s\right]=E^{0, z}\left[\int_{0}^{1}\left(E^{0, z}\left[f\left(Z_{1}\right) \mid \mathcal{F}_{s}^{B, Z}\right]-S_{s}\right) \alpha_{s} \mathrm{~d} s\right] \tag{5.48}
\end{equation*}
$$

Define the value, $P$, of the stock for the insider by

$$
\begin{equation*}
P_{t}:=E^{0, z}\left[f\left(Z_{1}\right) \mid \mathcal{F}_{t}^{B, Z}\right]=E^{0, z}\left[f\left(Z_{1}\right) \mid \mathcal{F}_{t}^{Z}\right]=F\left(t, Z_{t}\right), \tag{5.49}
\end{equation*}
$$

for some measurable function $F:[0,1] \times \mathbb{R} \mapsto \mathbb{R}$ (due to independence between $Z$ and $B$ and the Markov property of $Z$ ). Note that this expectation is well defined since, due to Assumption 5.1, $\left|f\left(Z_{1}\right)\right| \leq k_{1} \exp \left(k_{2} U_{1}\right)$, where $U_{1}$ is a Gaussian random variable. Moreover, $P_{1}=f\left(Z_{1}\right), P^{0, z_{-}}$ a.s., for every $z \in \mathbb{R}$, and the function $F$ is given by

$$
\begin{equation*}
F(t, z)=\int_{\mathbb{R}} f(y) G(V(t), z ; 1, y) \mathrm{d} y \tag{5.50}
\end{equation*}
$$

where $G$ is the function defined in Proposition 2.1. Due to Assumption 5.1 on $f$, it follows from Theorem 12 in Chapter I of [12] that $F \in C^{1,2}([0,1] \times \mathbb{R})$ and it satisfies

$$
\begin{equation*}
F_{t}(t, z)+\frac{1}{2} \sigma^{2}(t) a^{2}(V(t), z) F_{z z}(t, z)=0 \tag{5.51}
\end{equation*}
$$

In view of (5.47) and (5.48), the insider's optimization problem becomes

$$
\begin{equation*}
\sup _{\theta \in \mathcal{A}(H, w)} E^{0, z}\left[W_{1}^{\theta}\right]=\sup _{\theta \in \mathcal{A}(H, w)} E^{0, z}\left[\int_{0}^{1}\left(F\left(s, Z_{s}\right)-H\left(s, X_{s}\right)\right) \alpha_{s} \mathrm{~d} s\right] . \tag{5.52}
\end{equation*}
$$

Recall that the signal $Z_{t}$ follows

$$
\mathrm{d} Z_{t}=\sigma(t) a\left(V(t), Z_{t}\right) \mathrm{d} \beta_{t} .
$$

Suppose that $\theta_{t}=\int_{0}^{t} \alpha\left(s, X_{s}, Z_{s}\right) \mathrm{d} s$ is a solution of problem (5.52). Then the market price is given by $H\left(t, X_{t}\right)$, with

$$
\mathrm{d} X_{t}=w\left(t, X_{t}\right) \alpha\left(t, X_{t}, Z_{t}\right) \mathrm{d} t+w\left(t, X_{t}\right) \mathrm{d} B_{t} .
$$

Let

$$
\begin{aligned}
J(t, x, z):= & \operatorname{ess} \sup _{\theta \in \mathcal{A}(H, w)} E^{0, z}\left[\int_{t}^{1}\left(F\left(s, Z_{s}\right)-H\left(s, X_{s}\right)\right) \mathrm{d} \theta_{s} \mid X_{t}=x, Z_{t}=z\right], \\
& t \in[0,1]
\end{aligned}
$$

be the associated value function of the insider's problem. Applying the dynamic programming principle formally, we get the following HJB equation:

$$
\begin{align*}
0= & \sup _{\alpha}\left(\left[w(t, x) J_{x}+F(t, z)-H(t, x)\right] \alpha\right)+J_{t}+\frac{1}{2} w^{2}(t, x) J_{x x} \\
& +\frac{1}{2} \sigma^{2}(t) a^{2}(V(t), z) J_{z z} . \tag{5.53}
\end{align*}
$$

Thus, for the existence of an optimal $\alpha$, we need

$$
\begin{equation*}
w(t, x) J_{x}+F(t, z)-H(t, x)=0 \tag{5.54}
\end{equation*}
$$

$$
\begin{equation*}
J_{t}+\frac{1}{2} w^{2}(t, x) J_{x x}+\frac{1}{2} \sigma^{2}(t) a^{2}(V(t), z) J_{z z}=0 . \tag{5.55}
\end{equation*}
$$

Differentiating (5.54) with respect to $x$, and since from (5.54) it follows that $J_{x}=\frac{H(t, x)-F(t, z)}{w(t, x)}$, we get

$$
\begin{equation*}
w^{2}(t, x) J_{x x}=H_{x}(t, x) w(t, x)+(F(t, z)-H(t, x)) w_{x}(t, x) . \tag{5.56}
\end{equation*}
$$

Plugging (5.56) into (5.55) yields

$$
\begin{align*}
J_{t}+ & \frac{1}{2}\left(H_{x}(t, x) w(t, x)+(F(t, z)-H(t, x)) w_{x}(t, x)\right) \\
& +\frac{1}{2} \sigma^{2}(t) a^{2}(V(t), z) J_{z z}=0 \tag{5.57}
\end{align*}
$$

Differentiating (5.54) with respect to $z$ gives $J_{x z}=-\frac{F_{z}(t, z)}{w(t, x)}$, and therefore $J_{z z x}=-\frac{F_{z z}(t, z)}{w(t, x)}$. Thus, after differentiating (5.57) with respect to $x$, we obtain

$$
\begin{align*}
J_{t x} & +\frac{1}{2}\left(H_{x x}(t, x) w(t, x)+(F(t, z)-H(t, x)) w_{x x}(t, x)\right) \\
& -\sigma^{2}(t) \frac{a^{2}(V(t), z)}{2 w(t, x)} F_{z z}(t, z)=0 . \tag{5.58}
\end{align*}
$$

Since differentiating (5.54) with respect to $t$ gives

$$
J_{x t}=\frac{w_{t}(t, x)}{w^{2}(t, x)}(F(t, z)-H(t, x))-\frac{1}{w(t, x)}\left(F_{t}(t, z)-H_{t}(t, x)\right),
$$

(5.58), in view of (5.51), implies that

$$
\begin{align*}
& (H(t, x)-F(t, z))\left\{w_{t}(t, x)+\frac{w^{2}(t, x)}{2} w_{x x}(t, x)\right\} \\
& \quad=w(t, x)\left(H_{t}(t, x)+\frac{1}{2} w^{2}(t, x) H_{x x}(t, x)\right) \tag{5.59}
\end{align*}
$$

Since the right-hand side of (5.59) is not a function of $z$, we must have

$$
\begin{align*}
& w_{t}(t, x)+\frac{w^{2}(t, x)}{2} w_{x x}(t, x)=0  \tag{5.60}\\
& H_{t}(t, x)+\frac{1}{2} w^{2}(t, x) H_{x x}(t, x)=0 \tag{5.61}
\end{align*}
$$

Remark 5.6. In Proposition 5.1, we show that if the system of PDEs given by (5.60) and (5.61) is satisfied, then there exists an optimal strategy for the insider. Under further assumptions, one can show that the requirement on $(H, w)$ posed by the PDEs (5.60) and (5.61) is in fact a necessary condition for the existence of an optimal solution for the insider. Indeed, if $f$ is bounded, and therefore, $F$ and $H$ are bounded, and there exists an optimal strategy for the insider such that the value function is in $C^{1,2,2}$, then Theorem 4.3.1 in [16] gives that $J$ has to satisfy (5.54) and (5.55) simultaneously. Thus, $w$ satisfying the nonlinear PDE above is a necessary condition in order to have a smooth value function $J$.

An examination of (5.61) suggests that $X$ associated with the optimal strategy is a martingale in its own filtration. In view of these observations, recalling the bridge construction in the previous section with certain properties, it is easily seen that $a(t, x)$ is a natural candidate for the equilibrium weight function $w^{*}(t, x)$. That is the reason why we need to assume that $a$ satisfies PDE (5.46).

Remark 5.7. PDE (5.46) admits many explicit solutions satisfying the properties listed in Assumption 2.1. Here are a few examples taken from [17], sections from 1.1.9.10 to 1.1.9.13 and from 1.1.9.18 to 1.1.9.20.
(i) $a(t, z)=a_{0}$ for some constant $a_{0}>0$, which is the case already studied by Back and Pedersen [3].
(ii) $a(t, z)=\sqrt{k_{1}\left(z+k_{2}\right)^{2}+k_{3} \mathrm{e}^{-k_{1} t}}$, where $k_{1}, k_{2}, k_{3}$ are positive constants. Indeed, since $t$ varies on [0, 1], $\inf _{z} a(t, z) \geq \sqrt{k_{3}} \mathrm{e}^{-2 k_{1}}$, so that $a(t, z)$ is uniformly bounded away from zero.
(iii) $a(t, z)=\frac{g(z)}{\sqrt{k_{1} t+k_{2}}}$, where $g$ is solution to $\frac{k_{1}}{g}=g^{\prime \prime}$ and is bounded away from zero.
(iv) (Self-similar solution) $a(t, z)=y(z / \sqrt{t})$, where $y(x)$ satisfies $y^{2} y_{x x}-y_{x} x=0$ and is bounded away from 0 .
(v) (Generalized self-similar solution) $a(t, z)=\mathrm{e}^{-2 k_{1} t} y\left(z \mathrm{e}^{2 k_{1} t}\right)$, where $y(x)$ satisfies

$$
-\frac{1}{2} y^{2} y_{x x}=2 k_{1} x y_{x}-2 k_{1} y
$$

and is bounded away from 0 .
The next proposition describes the optimal insider's strategy in terms of the behavior of the resulting optimal demand at maturity.

Proposition 5.1. Assume that ( $H, w$ ) satisfies

$$
\begin{equation*}
H_{t}(t, x)+\frac{w(t, x)^{2}}{2} H_{x x}(t, x)=0 \tag{5.62}
\end{equation*}
$$

and

$$
\begin{equation*}
w_{t}(t, x)+\frac{w(t, x)^{2}}{2} w_{x x}(t, x)=0 \tag{5.63}
\end{equation*}
$$

If $\theta^{*} \in \mathcal{A}(H, w)$ satisfies $S_{1}:=H\left(1, X_{1}^{*}\right)=F\left(1, Z_{1}\right), P^{0, z}$-a.s., for every $z \in \mathbb{R}$, where $X^{*}$ is the solution to $X_{t}=\int_{0}^{t} w\left(s, X_{s}\right) \mathrm{d} Y_{s}^{*}$ with $Y^{*}=B+\theta^{*}$, and $(H, w)$ is admissible for $Y^{*}$, then $\theta^{*}$ is an optimal strategy, i.e.

$$
E^{0, z}\left[W_{1}^{\theta^{*}}\right] \geq E^{0, z}\left[W_{1}^{\theta}\right]
$$

a.s., for all $\theta \in \mathcal{A}(H, w)$.

Proof. We will adapt Wu's proof of his Lemma 4.2 in [22]. Consider the function

$$
\begin{equation*}
\Psi^{a}(t, x):=\int_{\xi(t, a)}^{x} \frac{H(t, u)-a}{w(t, u)} \mathrm{d} u+\frac{1}{2} \int_{t}^{1} H_{x}(s, \xi(s, a)) w(s, \xi(s, a)) \mathrm{d} s \tag{5.64}
\end{equation*}
$$

where $\xi(t, a)$ is the unique solution of $H(t, \xi(t, a))=a$. Direct differentiation with respect to $x$ gives that

$$
\begin{equation*}
\Psi_{x}^{a}(t, x) w(t, x)=H(t, x)-a . \tag{5.65}
\end{equation*}
$$

Differentiating above with respect to $x$ gives

$$
\begin{equation*}
\Psi_{x x}^{a}(t, x) w^{2}(t, x)=w(t, x) H_{x}(t, x)-(H(t, x)-a) w_{x}(t, x) \tag{5.66}
\end{equation*}
$$

Direct differentiation of $\Psi^{a}(t, x)$ with respect to $t$ gives

$$
\begin{align*}
\Psi_{t}^{a}(t, x)= & \int_{\xi(t, a)}^{x} \frac{H_{t}(t, u)}{w(t, u)} \mathrm{d} u-\int_{\xi(t, a)}^{x} \frac{(H(t, u)-a) w_{t}(t, u)}{w^{2}(t, u)} \mathrm{d} u \\
& -\frac{1}{2} H_{x}(t, \xi(t, a)) w(t, \xi(t, a)) \\
= & \int_{\xi(t, a)}^{x} \frac{H_{t}(t, u)}{w(t, u)} \mathrm{d} u+\frac{1}{2} \int_{\xi(t, a)}^{x}(H(t, u)-a) \mathrm{d} w_{x}(t, u) \\
& -\frac{1}{2} H_{x}(t, \xi(t, a)) w(t, \xi(t, a)) \\
= & \frac{1}{2}\left((H(t, x)-a) w_{x}(t, x)-H_{x}(t, x) w(t, x)\right), \tag{5.67}
\end{align*}
$$

where in order to obtain the last equality we used (5.62) and integration by parts twice on the second integral. Combining (5.66) and (5.67) gives

$$
\begin{equation*}
\Psi_{t}^{a}+\frac{1}{2} w(t, x)^{2} \Psi_{x x}^{a}=0 \tag{5.68}
\end{equation*}
$$

Therefore, from (5.65) and Itô's formula, it follows that

$$
\begin{equation*}
\Psi^{a}\left(1, X_{1}\right)-\Psi^{a}\left(0, X_{0}\right)=\int_{0}^{1} \frac{H\left(t, X_{t}\right)-a}{w\left(t, X_{t}\right)} \mathrm{d} X_{t} \tag{5.69}
\end{equation*}
$$

and, in particular, when $a=F\left(1, Z_{1}\right)$,

$$
\begin{equation*}
\Psi^{F\left(1, Z_{1}\right)}\left(1, X_{1}\right)-\Psi^{F\left(1, Z_{1}\right)}\left(0, X_{0}\right)=\int_{0}^{1} \frac{H\left(t, X_{t}\right)-F\left(1, Z_{1}\right)}{w\left(t, X_{t}\right)} \mathrm{d} X_{t} \tag{5.70}
\end{equation*}
$$

Using (5.47) and (5.70) and admissibility properties of $\theta$, in particular that $\mathrm{d} \theta_{t}=\alpha_{t} \mathrm{~d} t$, the insider optimization problem becomes

$$
\begin{align*}
\sup _{\theta \in \mathcal{A}(H, w)} E^{0, z}\left[W_{1}^{\theta}\right] & =\sup _{\theta \in \mathcal{A}(H, w)} E^{0, z}\left[\int_{0}^{1}\left(F\left(1, Z_{1}\right)-H\left(t, X_{t}\right)\right) \mathrm{d} \theta_{t}\right]  \tag{5.71}\\
& =E^{0, z}\left[\Psi^{F\left(1, Z_{1}\right)}\left(0, X_{0}\right)\right]-\inf _{\theta \in \mathcal{A}(H, w)} E^{0, z}\left[\Psi^{F\left(1, Z_{1}\right)}\left(1, X_{1}\right)\right], \tag{5.72}
\end{align*}
$$

where the last equality is due to (5.45) in Definition 5.2, and

$$
E^{0, z}\left[\left(\int_{0}^{1} F\left(1, Z_{1}\right) \mathrm{d} B_{t}\right)^{2}\right]=E^{0, z}\left[F\left(1, Z_{1}\right)^{2}\right] E^{0}\left[B_{1}^{2}\right]<\infty,
$$

since $Z$ and $B$ are independent.
The conclusion follows from the fact that $\Psi^{F\left(1, Z_{1}\right)}\left(1, X_{1}\right)=\int_{\xi\left(1, F\left(1, Z_{1}\right)\right)}^{X_{1}} \frac{H(1, u)-F\left(1, Z_{1}\right)}{w(t, u)} \mathrm{d} u$, which, due to the fact that $H(t, x)$ is increasing and $w(t, u)$ is positive, is positive unless $X_{1}=\xi\left(1, F\left(1, Z_{1}\right)\right)$, that is, $H\left(1, X_{1}\right)=F\left(1, Z_{1}\right)$. Therefore, an insider trading strategy which gives $H\left(1, X_{1}\right)=F\left(1, Z_{1}\right)$ is optimal.

We have the following sufficient condition for a triplet $\left(H^{*}, w^{*}, \theta^{*}\right)$ to be an equilibrium.
Lemma 5.1. A triplet $\left(H^{*}, w^{*}, \theta^{*}\right)$, where $\left(H^{*}, w^{*}\right)$ is an admissible pricing rule for the semimartingale $Y^{*}=B+\theta^{*}$, and $\theta^{*} \in \mathcal{A}\left(H^{*}, w^{*}\right)$, is an equilibrium if it fulfills the following four conditions.

1. $H^{*}(t, x)$ satisfies the PDE $H_{t}^{*}(t, x)+\frac{1}{2} w^{*}(t, x)^{2} H_{x x}^{*}(t, x)=0$ for any $(t, x) \in[0,1) \times \mathbb{R}$.
2. Weighting function satisfies $w_{t}^{*}(t, x)+\frac{w^{*}(t, x)^{2}}{2} w_{x x}^{*}(t, x)=0$.
3. $Y_{t}^{*}=B_{t}+\theta_{t}^{*}$ is a standard $B M$ in its own filtration.
4. $H^{*}\left(1, X_{1}^{*}\right)=f\left(Z_{1}\right), P^{0, z}$-a.s., for every $z \in \mathbb{R}$, where $X^{*}$ is the solution to $X_{t}=\int_{0}^{t} w\left(s, X_{s}\right) \mathrm{d} Y_{s}^{*}$ with $Y^{*}=B+\theta^{*}$.
5. $\left(H^{*}\left(t, X_{t}^{*}\right)\right)_{t \in[0,1]}$ is an $\left(\mathcal{F}_{t}^{Y^{*}}\right)$-martingale with respect to $\mathbb{Q}$.

Proof. Let $\left(H^{*}, w^{*}, \theta^{*}\right)$ be a triplet satisfying conditions 1 to 4 above. By Proposition 5.1, conditions 1,2 and 4 imply that $\theta^{*}$ is optimal. On the other hand, conditions $1,3,4$ and 5 imply that the pricing rule $\left(H^{*}, w^{*}\right)$ is rational.

Combining Proposition 5.1 and the bridge construction given in the previous section, we can finally state and prove the main result of this section. We recall from Proposition 2.1 that the function $G=G(t, x ; u, y)$ is the transition density of

$$
\begin{equation*}
\mathrm{d} \xi_{t}=a\left(t, \xi_{t}\right) \mathrm{d} \beta_{t} \tag{5.73}
\end{equation*}
$$

and from Theorem 2.1 that there exists a unique strong solution under $\mathcal{F}^{B, Z}$ of the following SDE:

$$
\mathrm{d} X_{t}=a\left(t, X_{t}\right) \mathrm{d} B_{t}+a^{2}\left(t, X_{t}\right) \frac{\rho_{x}\left(t, X_{t}, Z_{t}\right)}{\rho\left(t, X_{t}, Z_{t}\right)} \mathrm{d} t, \quad X_{0}=0
$$

Theorem 5.1. Under Assumptions 5.1 and 5.2, there exists an equilibrium ( $H^{*}, w^{*}, \theta^{*}$ ), where
(i) $H^{*}(t, x)=F\left(V^{-1}(t), x\right)$ where $F$ is given by (5.50) and $w^{*}(t, x)=a(t, x)$ for all $(t, x) \in[0,1] \times \mathbb{R}$;
(ii) $\theta_{t}^{*}=\int_{0}^{t} \alpha_{s}^{*} \mathrm{~d} s$, where $\alpha_{s}^{*}=a\left(s, X_{s}\right) \frac{\rho_{x}\left(s, X_{s}, Z_{s}\right)}{\rho\left(s, X_{s}, Z_{s}\right)}$ with $\rho(t, x, z)=G(t, x ; V(t), z)$ and the process $X^{*}$ is the unique strong solution under $\mathcal{F}^{B, Z}$ of the following SDE:

$$
\mathrm{d} X_{t}=a\left(t, X_{t}\right) \mathrm{d} B_{t}+a^{2}\left(t, X_{t}\right) \frac{\rho_{x}\left(t, X_{t}, Z_{t}\right)}{\rho\left(t, X_{t}, Z_{t}\right)} \mathrm{d} t, \quad X_{0}=0
$$

Proof. We will first show that $\left(H^{*}, w^{*}\right)$ is admissible in the sense of Definition 5.1. Note that, since $F \in C^{1,2}$, so is $H^{*} \in C^{1,2}([0,1] \times \mathbb{R})$, and $w^{*}$ is bounded away from 0 since $a(t, z)$ is assumed to be bounded away from 0 in Assumption 5.2. We also have that $X^{*}$ is the unique strong solution to

$$
X_{t}=\int_{0}^{t} w^{*}\left(s, X_{s}\right) \mathrm{d} Y_{s}^{*}
$$

on $\left(\Omega, \mathcal{G},\left(\mathcal{F}_{t}^{Y^{*}}\right), \mathbb{Q}\right)$, by condition (ii) of the theorem, and that $\mathrm{d} X_{t}=a\left(t, X_{t}\right) \mathrm{d} Y_{t}^{*}=$ $w^{*}\left(t, X_{t}\right) \mathrm{d} Y_{t}^{*}$. In order to complete the proof of admissibility, we next show that $x \mapsto H^{*}(t, x)$
is strictly increasing for every $t \in[0,1]$. Observe that this is equivalent to the analogous property for $F$. First, using (5.50) and (2.13), we obtain

$$
\begin{aligned}
F(t, z) & =\int_{\mathbb{R}} f(y) \Gamma(V(t), A(V(t), z) ; 1, A(1, y)) \mathrm{d} A(1, y) \\
& =\int_{A(1,-\infty)}^{A(1, \infty)} f\left(A^{-1}(1, y)\right) \Gamma(V(t), A(V(t), z) ; 1, y) \mathrm{d} y \\
& =\int_{A(1,-\infty)}^{A(1, \infty)} f\left(A^{-1}(1, y)\right) q(1-V(t), A(V(t), z)+c(t), y) \mathrm{d} y
\end{aligned}
$$

where the last line follows from Lemma A. 3 and $q$ is the transition density of standard Brownian motion given by

$$
q(t, x, y)=\frac{1}{\sqrt{2 \pi t}} \exp \left(-\frac{(x-y)^{2}}{2 t}\right)
$$

and $c(t)=\int_{V(t)}^{1} b(s) \mathrm{d} s$. Due to the bounds on $f$, we can differentiate inside the integral to get that

$$
\begin{aligned}
F_{z}(t, z)= & \int_{A(1,-\infty)}^{A(1, \infty)} f\left(A^{-1}(1, y)\right) q_{x}(1-V(t), A(V(t), z)+c(t), y) \frac{1}{a(V(t), z)} \mathrm{d} y \\
= & -\int_{A(1,-\infty)}^{A(1, \infty)} f\left(A^{-1}(1, y)\right) q_{y}(1-V(t), A(V(t), z)+c(t), y) \frac{1}{a(V(t), z)} \mathrm{d} y \\
= & \int_{A(1,-\infty)}^{A(1, \infty)} f^{\prime}\left(A^{-1}(1, y)\right) \frac{a\left(1, A^{-1}(1, y)\right)}{a(V(t), z)} q \\
& \times(1-V(t), A(V(t), z)+c(t), y) \mathrm{d} y>0
\end{aligned}
$$

where the third equality follows from integration by parts, which is valid due to Assumption 5.1. The final strict inequality is due to the fact that $f$ is strictly increasing and $a$ is strictly positive. Therefore, $\left(H^{*}, w^{*}\right)$ is admissible for the semimartingale $Y^{*}=B+\theta^{*}$.

Next, we turn to verifying that $\theta^{*} \in \mathcal{A}\left(H^{*}, w^{*}\right)$. By construction, $\theta^{*}$ is absolutely continuous. Moreover, conditions 2 and 3 of Definition 5.2 follow from Theorem 2.1. Finally, condition 4 follows from Lemma A.3.

To finish the proof, let us verify that the triplet $\left(H^{*}, w^{*}, \theta^{*}\right)$ given in the statement satisfies the five conditions of Lemma 5.1. First, $H^{*}$ as defined satisfies condition 1 in Lemma 5.1 due to (5.51). The second condition is trivially satisfied due to Assumption 5.2. For the third condition, observe that $X^{*}$ is a local martingale in its own filtration due to Theorem 2.1. However, since $a(t, z)$ is uniformly bounded away from 0 , it follows that the natural filtrations of $X^{*}$ and $Y^{*}$ coincide. The conclusion that $Y^{*}$ is a Brownian motion in its own filtration follows as soon as one observes that $\mathrm{d} Y_{t}^{*}=\frac{1}{a\left(t, X_{t}^{*}\right)} \mathrm{d} X_{t}^{*}$, i.e. $Y^{*}$ is a local martingale with $\left[Y^{*}, Y^{*}\right]_{t}=t$.

In order to verify the fourth condition, observe that $H^{*}(1, x)=F(1, x)=f(x)$. Since, by Theorem 2.1, we have $X_{1}^{*}=Z_{1}, P^{0, z}$-a.s., the condition holds.

Finally, to demonstrate the martingale property of $H^{*}\left(t, X_{t}^{*}\right)$, observe that the transition density of $X^{*}$ is given by $G(t, x ; u, z)$, since in its own filtration

$$
\mathrm{d} X_{t}^{*}=a\left(t, X_{t}^{*}\right) \mathrm{d} Y_{t}^{*}
$$

and $Y^{*}$ is a Brownian motion, so that $X^{*}$ satisfies the same $\operatorname{SDE}(5.73)$ as the process $\xi$. Therefore,

$$
\begin{aligned}
\mathbb{E}^{\mathbb{Q}}\left[f\left(Z_{1}\right) \mid \mathcal{F}_{t}^{X^{*}}\right] & =\mathbb{E}^{\mathbb{Q}}\left[f\left(X_{1}^{*}\right) \mid \mathcal{F}_{t}^{X^{*}}\right] \\
& =\int_{\mathbb{R}} f(y) G\left(t, X_{t}^{*} ; 1, y\right) \mathrm{d} y \\
& =F\left(V^{-1}(t), X_{t}^{*}\right) \\
& =H\left(t, X_{t}^{*}\right),
\end{aligned}
$$

where one to the last equality is due to (5.50).
Remark 5.8. Note that it follows from Corollary 4.2 that the conditional density of $Z_{t}$ given $\mathcal{F}_{t}^{X^{*}}$ is $G\left(t, X_{t}^{*} ; V(t), z\right)$. Note that $G(t, x ; u, z)$ converges to the delta function as $t$ converges to $u$. Therefore, the closer $V(t)$ is to $t$, the smaller is the uncertainty of the market maker about the value of $Z_{t}$. Hence, in our case, as in [3], $V(t)-t$ is a good measurement of the informational advantage of the insider.

## Appendix

Proposition A.1. Suppose that Assumptions 2.1-2.3 are satisfied. Then, $\frac{h_{x}}{h}:[0,1] \times \mathbb{R} \times[0,1] \times$ $\mathbb{R} \mapsto \mathbb{R}$ as defined in (4.33) is (uniformly) bounded.

In order to prove the proposition above, we need a few preliminary results. The first one is the following classical result due to [1].

Lemma A.1. There exist positive constants, $\alpha_{1}, \alpha_{2}, M_{1}$ and $M_{2}$ such that

$$
M_{1} q\left(\alpha_{1}(u-t), x, z\right) \leq \Gamma(t, x ; u, z) \leq M_{2} q\left(\alpha_{2}(u-t), x, z\right),
$$

for all $(x, z) \in \mathbb{R}^{2}$ and $u>t$.
Next, we need to obtain estimates on the function $h_{x} / h$. This will be done by following the approach employed in [4]. For this purpose, define the martingale $L$ by

$$
\mathrm{d} L_{u}=-L_{u} b\left(u, \zeta_{u}\right) \mathrm{d} \beta_{u}, \quad u \geq t
$$

with $L_{t}=1$, and let

$$
I(u, z):=\int_{0}^{z} b(u, y) \mathrm{d} y \quad N_{u}:=\int_{t}^{u}\left\{I_{t}\left(s, \zeta_{s}\right)+\frac{1}{2} b_{x}\left(s, \zeta_{s}\right)+\frac{1}{2} b^{2}\left(s, \zeta_{s}\right)\right\} \mathrm{d} s .
$$

Recall that $\zeta_{s}=A\left(s, \xi_{s}\right)$ and $\mathrm{d} \zeta_{s}=\mathrm{d} \beta_{s}+b\left(s, \zeta_{s}\right) \mathrm{d} s$, where the function $b$ has been defined in (2.9).

Remark A.1. Notice that Assumptions 2.2 and 2.3 ensure that the above formulation makes sense.

Then,

$$
L_{u}^{-1}=\exp \left\{I\left(u, \zeta_{u}\right)-I\left(t, \zeta_{t}\right)-N_{u}\right\}
$$

and a straightforward application of Girsanov's theorem yields

$$
\Gamma(t, x ; u, z)=\exp (I(u, z)-I(t, x)) E_{t}^{x, q}\left[\exp \left(-N_{u}\right) \mid \zeta_{u}=z\right] q(u-t, x, z)
$$

where $E_{t}^{x, q}$ is the expectation operator with respect to the law of standard Brownian motion starting at $x$ at time $t$. Therefore, (4.33) becomes

$$
h(t, x ; u, z)=\exp (I(u, z)-I(t, x)) E_{t}^{x, q}\left[\exp \left(-N_{u}\right) \mid \zeta_{u}=z\right]
$$

Observe that $\frac{\partial I(t, x)}{\partial x}=b(t, x)$, which is bounded. Therefore, in order to establish the uniform boundedness of $h_{x} / h$, we need estimates on

$$
\frac{\frac{\partial}{\partial x} E_{t}^{x, q}\left[\exp \left(-N_{u}\right) \mid \zeta_{u}=z\right]}{E_{t}^{x, q}\left[\exp \left(-N_{u}\right) \mid \zeta_{u}=z\right]}
$$

The next lemma is going to give us an alternative representation of the numerator in the above expression which allows us to obtain a uniform bound on $h_{x} / h$.

Lemma A.2. Suppose that Assumptions 2.2 and 2.3 are satisfied and that $\zeta_{t}=x$. Then, we have

$$
\frac{\partial N_{u}}{\partial x}=\int_{t}^{u}\left\{b_{t}\left(s, \zeta_{s}\right)+\frac{1}{2} b_{y y}\left(s, \zeta_{s}\right)+b\left(s, \zeta_{s}\right) b_{y}\left(s, \zeta_{s}\right)\right\} \mathrm{d} s
$$

Moreover,

$$
\frac{\partial}{\partial x} E_{t}^{x, q}\left[\exp \left(-N_{u}\right) \mid \zeta_{u}=z\right]=-E_{t}^{x, q}\left[\left.\exp \left(-N_{u}\right) \frac{\partial N_{u}}{\partial x} \right\rvert\, \zeta_{u}=z\right]
$$

Proof. In order to prove the first statement, note that $\zeta_{u}=x+W_{u}$ for some Brownian motion with $W_{t}=0$. Since the integrands are differentiable functions with bounded derivatives, this allows us to differentiate under the integral sign. Although derivative exists only almost everywhere, this is no problem, since the law of Brownian motion is absolutely continuous with respect to the Lebesgue measure. For the second assertion, take an infinitely differentiable $f: \mathbb{R} \mapsto \mathbb{R}$ with a compact support. Therefore, if differentiation inside the expectation is justified,

$$
\begin{aligned}
\frac{\partial}{\partial x} E_{t}^{x, q}\left[\exp \left(-N_{u}\right) f\left(\zeta_{u}\right)\right] & =E_{t}^{x, q}\left[\frac{\partial}{\partial x}\left\{\exp \left(-N_{u}\right) f\left(\zeta_{u}\right)\right\}\right] \\
& =-E_{t}^{x, q}\left[\frac{\partial N_{u}}{\partial x} \exp \left(-N_{u}\right) f\left(\zeta_{u}\right)\right]+E_{t}^{x, q}\left[\exp \left(-N_{u}\right) f^{\prime}\left(\zeta_{u}\right)\right]
\end{aligned}
$$

As $\frac{\partial N_{u}}{\partial x}, f$ and $f^{\prime}$ are bounded, we only need to show that $\exp \left(-N_{u}\right)$ is bounded by an integrable function in order to justify the differentiation. Indeed, using Assumptions 2.2 and 2.3 on the boundedness of function $b$ and its first derivatives, together with the definition of $N_{u}$, one can easily prove that $N_{u} \geq K\left(m_{u}+x-k\right) \geq K\left(m_{1}+x-k\right)$ for some positive constants $k, K$, where $m_{u}=\min _{t \leq s \leq u} W_{s}$. Thus, $\exp \left(-N_{u}\right)$ is bounded above by the random variable $C \mathrm{e}^{-m_{1}}$ for a positive constant $C$, which may depend on $x$ in a continuous fashion. It follows from the reflection principle for Brownian motion that $-m_{1}$ has the same law as $\left|W_{1}\right|$. Moreover, the random variable $\exp \left(\left|W_{1}\right|\right)$ being integrable, we have that $\exp \left(-N_{u}\right)$ is bounded, uniformly in $u$, by an integrable function which does not depend on $x$ when $x$ is restricted to a compact domain. This justifies the differentiation inside the expectation.

On the other hand,

$$
\begin{aligned}
E_{t}^{x, q}\left[\frac{\partial}{\partial x} E_{t}^{x, q}\left[\exp \left(-N_{u}\right) \mid \zeta_{u}\right] f\left(\zeta_{u}\right)\right]= & E_{t}^{x, q}\left[\frac{\partial}{\partial x}\left\{E_{t}^{x, q}\left[\exp \left(-N_{u}\right) \mid \zeta_{u}\right] f\left(\zeta_{u}\right)\right\}\right] \\
& -E_{t}^{x, q}\left[E_{t}^{x, q}\left[\exp \left(-N_{u}\right) \mid \zeta_{u}\right] f^{\prime}\left(\zeta_{u}\right)\right]
\end{aligned}
$$

thus, we will be done as soon as we have that

$$
\frac{\partial}{\partial x} E_{t}^{x, q}\left[\exp \left(-N_{u}\right) f\left(\zeta_{u}\right)\right]=E_{t}^{x, q}\left[\frac{\partial}{\partial x}\left\{E_{t}^{x, q}\left[\exp \left(-N_{u}\right) \mid \zeta_{u}\right] f\left(\zeta_{u}\right)\right\}\right] .
$$

Since $E_{t}^{x, q}\left[\exp \left(-N_{u}\right) \mid \zeta_{u}\right]$ is bounded and away from zero whenever $\left(x, \zeta_{u}\right)$ belongs to a bounded domain, ${ }^{5}$ and $f$ has a compact support, this will follow if $\frac{\partial}{\partial x} E_{t}^{x, q}\left[\exp \left(-N_{u}\right) \mid \zeta_{u}\right]$ is bounded for fixed $u>t$ whenever $\left(x, \zeta_{u}\right)$ belongs to a bounded domain in $\mathbb{R}^{2}$. To see this, note that

$$
\begin{aligned}
& (u-t) \frac{\partial}{\partial x} \log \Gamma(t, x, u, z)=(u-t) \frac{\partial}{\partial x} \log h(t, x, u, z)+z-x \\
& \quad=-(u-t) b(t, x)+(u-t) \frac{\frac{\partial}{\partial x} E_{t}^{x, q}\left[\exp \left(-N_{u}\right) \mid \zeta_{u}=z\right]}{E_{t}^{x, q}\left[\exp \left(-N_{u}\right) \mid \zeta_{u}=z\right]}+z-x .
\end{aligned}
$$

The claim follows from the boundedness of $b,(2.16)$ and Lemma A.1. Thus,

$$
\frac{\partial}{\partial x} E_{t}^{x, q}\left[\exp \left(-N_{u}\right) \mid \zeta_{u}=z\right]=-E_{t}^{x, q}\left[\left.\exp \left(-N_{u}\right) \frac{\partial N_{u}}{\partial x} \right\rvert\, \zeta_{u}=z\right] .
$$

Proof of Proposition A.1. First, note that, in view of Lemma A.2,

$$
\frac{h_{x}(t, x ; u, z)}{h(t, x ; u, z)}=-\left(b(t, x)+\frac{E_{t}^{x, q}\left[\left.\exp \left(-N_{u}\right) \frac{\partial}{\partial x} N_{u} \right\rvert\, \zeta_{u}=z\right]}{E_{t}^{x, q}\left[\exp \left(-N_{u}\right) \mid \zeta_{u}=z\right]}\right)
$$

As $\frac{\partial}{\partial x} N_{u}$ is uniformly bounded, in $u$ and $x$, we have

$$
\left|\frac{h_{x}(t, x ; u, z)}{h(t, x ; u, z)}\right| \leq|b(t, x)|+\sup _{x}\left\{\operatorname{ess} \sup \left|\frac{\partial}{\partial x} N_{u}\right|\right\}
$$

by Jensen's inequality. However, $\sup _{x}\left\{\right.$ ess sup $\left.\left|\frac{\partial}{\partial x} N_{u}\right|\right\}$ is finite under our assumptions. Finally, since $b$ is also bounded under our assumptions, the result follows.

Lemma A.3. Suppose that $a(t, z)$ and $\sigma(t)$ satisfy Assumption 5.2. Let $Z$ satisfy (2.1), and let $X$ be the process defined in Theorem 5.1. Then,

1. $b(t, z)=b(t)$, where $b$ is defined by (2.9);
2. the fundamental solution of

$$
w_{u}(u, z)=\frac{1}{2} w_{z z}(u, z)-(b(u, z) w(u, z))_{z}
$$

is $\Gamma(t, x ; u, z)=q\left(u-t, x+\int_{t}^{u} b(s) \mathrm{d} s, z\right)$, where $q$ is the transition density of standard Brownian motion;

[^5]3. for every $z \in \mathbb{R}$,
$$
E^{0, z}\left[\int_{0}^{1} H^{2}\left(t, X_{t}\right) \mathrm{d} t\right]<\infty
$$
where $H(t, x)=F\left(V^{-1}(t), x\right)$ with $F$ given by (5.50).
Proof. 1. This follows from Remark 5.5.
2. Recall that $\Gamma$ is the transition density of
$$
\mathrm{d} \zeta_{t}=\mathrm{d} \beta_{t}+b(t) \mathrm{d} t
$$

Thus, $\zeta_{u}-\zeta_{t}$ has a Gaussian distribution with mean $\int_{t}^{u} b(s) \mathrm{d} s$ and variance $u-t$.
3. Under the assumptions of the lemma, the processes $U$ and $R$ as defined in Lemma 2.2 satisfy

$$
\begin{aligned}
& \mathrm{d} U_{t}=\sigma(t) \mathrm{d} \beta_{t}+\sigma^{2}(t) b(t) \mathrm{d} t \\
& \mathrm{~d} R_{t}=\mathrm{d} B_{t}+\left\{\frac{p_{x}\left(t, R_{t}, U_{t}\right)}{p\left(t, R_{t}, U_{t}\right)}+b(t)\right\} \mathrm{d} t
\end{aligned}
$$

where $p(t, x, z)=\Gamma(t, x ; V(t), z)$. Therefore,

$$
\mathrm{d} R_{t}=\mathrm{d} B_{t}+\left\{\frac{U_{t}-R_{t}-\int_{t}^{V(t)} b(s) \mathrm{d} s}{V(t)-t}+b(t)\right\} \mathrm{d} t
$$

The solution of the above SDE is given by

$$
\begin{align*}
R_{t}= & U_{0}+\int_{0}^{t} b(s) \sigma^{2}(s) \mathrm{d} s-\left(U_{0}-R_{0}\right) \exp \left(-\int_{0}^{t} \frac{1}{V(s)-s} \mathrm{~d} s\right) \\
& -\int_{0}^{t} \exp \left(-\int_{s}^{t} \frac{1}{V(u)-u} \mathrm{~d} u\right)\left(b(s) \sigma^{2}(s)-b(s)+\frac{\int_{s}^{V(s)} b(u) \mathrm{d} u}{V(s)-s}\right) \mathrm{d} s \\
& +\int_{0}^{t} \sigma(s)\left(1-\exp \left(-\int_{s}^{t} \frac{1}{V(u)-u} \mathrm{~d} u\right)\right) \mathrm{d} \beta_{s} \\
& +\int_{0}^{t} \exp \left(-\int_{s}^{t} \frac{1}{V(u)-u} \mathrm{~d} u\right) \mathrm{d} B_{s} . \tag{A.74}
\end{align*}
$$

Therefore, $R_{t}$ is a normal variable with bounded (uniformly in $t$ ) mean and variance. Indeed, due to Remark 2.3, $\sup _{s, t} \exp \left(-\int_{s}^{t} \frac{1}{V(u)-u} \mathrm{~d} u\right)<\infty$. Moreover, $b$ and $\sigma$ are bounded by assumption. Therefore, the moment-generating function of $R_{t}$ is a bounded function of time in $[0,1]$. Next, observe that

$$
\begin{aligned}
F(t, z) & =E\left[f\left(Z_{1}\right) \mid Z_{t}=z\right]=E\left[f\left(A^{-1}\left(1, U_{1}\right)\right) \mid U_{t}=A(V(t), z)\right] \\
& \leq k_{1} E\left[\exp \left(k_{2} U_{1}\right) \mid U_{t}=A(V(t), z)\right] \\
& =k_{1} \exp \left(k_{2} \int_{t}^{1} b(s) \mathrm{d} s+k_{2} A(V(t), z)+\frac{1}{2} k_{2}^{2}(1-V(t))\right) \\
& \leq K \exp \left(k_{2} A(V(t), z)\right)
\end{aligned}
$$

due to Assumption 5.1 on $f$; the third line is due to the form of the moment-generating function of the Gaussian random variable $U_{1}-U_{t}$. This in particular implies that

$$
\begin{aligned}
E^{0, z}\left[H^{2}\left(t, X_{t}\right)\right] & =E^{0, z}\left[F^{2}\left(V^{-1}(t), X_{t}\right)\right] \\
& \leq K^{2} E^{0, z}\left[\exp \left(2 k_{2} A\left(t, X_{t}\right)\right)\right] \\
& =K^{2} E^{0, z}\left[\exp \left(2 k_{2} R_{t}\right)\right] .
\end{aligned}
$$

Note that $\sup _{t \in[0,1]} E^{0, z}\left[\exp \left(2 k_{2} R_{t}\right)\right]<\infty$, since the moment-generating function of $R$ is bounded. Hence, the claim follows.

[^0]:    ${ }^{*}$ This research benefited from the support of the "Chair Les Particuliers Face aux Risques", Fondation du Risque (Groupama-ENSAE-Dauphine), and the GIP-ANR "Croyances" project as well as from the "Chaire Risque de crédit", Fédération Bancaire Française, of the Europlace Institute of Finance. Part of this research was done when the second author was visiting Evry University in September 2008.

[^1]:    ${ }^{1}$ This can be achieved by standard regularity assumptions on $a$ which will ensure that $p$ is a continuous solution of a Kolmogorov equation (see Theorem 3.2.1 in [21]).

[^2]:    ${ }^{2}$ A sufficient condition ensuring a strong solution is given in Assumption 2.2.

[^3]:    ${ }^{3}$ Lemma A. 1 gives a lower bound for $p$. This implies that $\frac{p_{x}}{p}(t, x, z)$ has locally bounded derivatives with respect to $x$ and $z$ since $\Gamma$ has continuous second derivatives. Moreover, $b$ is Lipschitz by assumption; thus the claim holds. Note that we require $T<1$ so that $V(t)-t$ is bounded away from 0 for $t \in[0, T]$.

[^4]:    ${ }^{4}$ Note that this SDE is well defined on $\left(\Omega, \mathcal{G},\left(\mathcal{G}_{t}\right), \mathbb{Q}\right)$ since, due to absolute continuity of $\theta, Y=B+\theta$ is a semimartingale on it.

[^5]:    ${ }^{5}$ These can be proven by similar arguments that are used in showing $\exp \left(-N_{u}\right)$ is bounded by an integrable function.
