Comments from the Reviewer #1:**Comments to the Author**

This paper report a point of view regarding the possible role of diet in thyroid cancer influence.

It is interesting and well-structured

Author's response: We are very grateful to the Reviewer for his/her appreciation of our findings and his/her most positive report. We are hopeful that the constructive suggestions and the proposed corrections will improve our exposition in the updated manuscript. All the corrections in the revised manuscript are made in yellow for the Reviewer's convenience.

I suggest to change the word "nutrizionist" in "nutritionist".

Author's response: We are apologize for the typing error. The term "nutrizionist" has been correctly changed to "nutritionist".

I suggest an English revision made by a native-spoken english.

Author's response: We thank the reviewer for the important observations, and we have done a thorough English grammar revision of the manuscript. Therefore, we have changed several lines that have highlighted in red for those deleted words and written in red for those added words for the Reviewer's convenience.

Some repetitions should be avoided. For example, pag 7/44, the first sentence should be deleted.

Author's response: We appreciate the reviewer's suggestion, and we have deleted that sentence. We have highlighted in red the deleted part for the Reviewer's convenience.

Please verify that all acronyms are correctly reported. Example: pag 8/44, line 18 PUFAs should be reported as (PUFAs).

Author's response: We thank the reviewer for that observation, and we have modified the text as suggested. We have verified that all acronyms are correctly reported and modified several lines (Page 9 lines 7, 9) that we have highlighted in yellow the added words and red the deleted ones for the Reviewer's convenience.

Regarding the study EPIC, could the authors specify if it evaluated quantity and/or quality of fish consumption?

1 1 *Author's response: We value the reviewers' significant observation, and we have modified the text*
2
3 2 *reporting detailed information on the quantity and quality of the fish analysed.*

4
5 3
6
7 4 **Pag 6/45, after the description of a meta-analysis (line 43) there is no reference.**

8
9 5 *Author's response: We have added the specific reference.*

10 6
11 7
12 8 **Pag 11/44, line 7: the sentence "In conclusion, the association between hypovitaminosis**
13
14 8 **D and TC is still controversial" should be placed at the end of the section (line 23) as a**
15
16 9 **conclusive remark.**

17 10
18
19 11 *Author's response: We appreciate the reviewer's important observation, and we have modified the*
20
21 12 *text as his/her request. We have highlighted in yellow for the Reviewer's convenience.*

22
23 13
24
25 14 **Pag 14/44, line 16 Wie should be Wie et al.**

26
27 15 *Author's response: We thank the reviewer for that observation, and we have modified the text as*
28
29 16 *his/her request (Page 15 line 16). We have highlighted in yellow for the Reviewer's convenience.*

30
31 17
32
33 18 **When reported "etc" should be removed**

34 19 *Author's response: We thank the reviewer for that observation, and we have modified the text as*
35
36 20 *his/her request (Page 8 lines 14,15, Page 19 line 10). We have highlighted in red the deleted parts for*
37
38 21 *the Reviewer's convenience.*

39
40 22
41
42 23 **Section "Conclusion". On the basis of the evidence described in the text the sentence**
43
44 24 **"Significant associations between single nutrients or food and TC risk have been**
45
46 25 **observed." seems too optimistic. I think that this sentence should be moderate.**

47

Running title: Diet and Thyroid Cancer Risk.

Abstract

The incidence of differentiated thyroid cancer has been increased in the last decades all over the world. Different environmental factors are possible perpetrators of this exponential growth increase. The nutritional factors are among the main environmental factors studied for thyroid cancer in recent years. The review aims of review is to give an overview among of the main dietary factors involved on thyroid cancer risk, providing also specific nutrition recommendations as the point of view of from the endocrinological Nutritionist point of view. Among single food, fish and shellfish are the major primary natural source of iodine in the human diet, and as well as selenium and vitamin D, all. These nutrients are essential for the synthesis of thyroid hormones; however, their consumption is are not consistently related to thyroid cancer risk. The high consumption intake of fruit and vegetables, probably due to their vitamin and antioxidant content, shows a weak inverse association with thyroid cancer risk. No important effect on thyroid cancer risk of Alcohol, meat, or other food-groups/nutrients emerged showed no significant effect on thyroid cancer. In conclusion, to date, no definite an association among dietary factors, specific dietary patterns and thyroid cancer, as well as in and its clinical severity and aggressiveness have been found.

However, it is important essential to underline that in the future, prospective studies should be carried out to specifically precisely evaluate the qualitative and quantitative intake of nutrients by patients, in order to establish with more confidence a potential correlation between food intake and the occurrence and development of thyroid cancer.

TEXT

Introduction

Thyroid cancer (TC) is considered a rare disease since it constitutes <1% of all cancers ¹. However, it represents the most frequent endocrine cancer, affecting 5% of thyroid nodules, which have a prevalence of 20-50% in the general population, increasing due to **the improvement** **improved** **of** diagnostic techniques and early diagnosis ². In particular, Ultrasound (US) and fine-needle aspiration are the most important diagnostic tool for **the evaluation of** **evaluating** thyroid nodules ³⁻⁵.

TC has a greater prevalence in the female sex, with a 3:1 female-to-male ratio in most geographic regions and demographic groups. Although these tumors are **very** rare in children, they affect a younger population than most malignancies, with a maximum incidence between 25 and 60 years ⁶. Survival is very high, exceeding 90% at 5 years in differentiated forms ⁶. Moreover, since the TC prognosis is excellent in most cases and **the** mortality rate remains very low, to date, there is **a lot** **of** **much** interest in the personalized risk-based treatment ⁷.

TC generally originates from follicular cells **and** **are** **is** divided into papillary, follicular, anaplastic and medullary carcinoma ⁸. Papillary carcinoma is the most frequent form of differentiated TC (DTC), comprising about 80% ⁹. It has slow growth and can **give rise to** **cause** loco-regional lymph node metastases. In some patients, the tumor is multifocal and can affect both lobes of the thyroid gland ¹⁰. Follicular carcinoma represents about 15% of **differentiated** DTC and can **give rise to** **produce** distant metastases. Anaplastic carcinoma is a rare type of tumor, <1% of thyroid tumors, but it is particularly aggressive already at diagnosis with **inadequate** **poor** response to conventional therapies ¹¹. Medullary carcinoma originates from parafollicular cells (or C cells), and the diagnosis is based on the basal or stimulated calcitonin dosage ¹². This tumor can occur in familial forms as the manifestation of genetic syndromes, such as multiple neoplastic syndrome type 2.

In the **differentiated** DTC, some recurrent genetic mutations have been found that specifically affect receptors with tyrosine kinase activity and their pathways: in particular BRAF (V600E) mutation, RET/PTC rearrangements RAS and pTERT mutations in papillary carcinoma and PAX8–

1 1 PPAR γ rearrangements or RAS and pTERT mutations in follicular carcinoma^{8,13}. These mutations
2
3 2 also justify the known relationship between exposure to ionizing radiation and increased TC
4
5 3 incidence of TC, since radiation induces double-stranded DNA breaks and genetic rearrangements¹⁴.

7 4 As reported in clinical studies, the thyroid is particularly sensitive to the long-term effects of
8
9
10 5 radiation exposure¹⁵. This association was evaluated in population-based case-control studies both
11
12 6 of adolescents exposed to radiation following the Chernobyl accident and of subjects exposed to the
13
14 7 atomic bombings of Hiroshima and Nagasaki, in which where an increased incidence of TC was
15
16 8 demonstrated¹⁶. The adverse effects of radiation in inducing TC have been reported in atomic bomb
17
18 9 survivors from 62 to 66 years after exposure during their childhood¹⁷. Of interest Remarkably,
19
20 10 Mesrine et al. prospectively analyzed 86,960 women followed-up over 1990-2008, finding
21
22 11 associations between nevi, baseline residential ultraviolet exposure, and thyroid cancer risk¹⁸. Results
23
24 12 such as showed that ultraviolet exposure level and the number of nevi were associated with nodules
25
26
27 13 or histories of dysthyroidism thyroid disturbances, and the number of nevi was positively associated
28
29 14 with TC risk (HR=1.7, 95% CI=1.0, 2.8; p=0.01). This risk was restricted to females with dietary
30
31 15 iodine below the median intake. The authors concluded that TC risk was associated with the number
32
33 16 of nevi and residential ultraviolet exposure¹⁸.

35 17 In addition to ionizing radiation, the main risk factors known for TC are family history,
36
37
38 18 female gender, and obesity^{19,20}. A family history of TC in first-degree relatives is associated with a
39
40 19 10-fold increased risk of non-medullary TC based on a large case-control study²¹. Although the
41
42 20 incidence of this cancer incidence is significantly higher in women, no clear pathophysiological and
43
44 21 hormonal mechanisms have been identified²². Some observational studies have shown an association
45
46 22 between excess weight and increased TC risk of TC, both well-differentiated and anaplastic. In
47
48 23 particular, a meta-analysis of 22 prospective studies showed that a high body mass index (BMI) is
49
50 24 associated with an increased TC risk of TC, and that this association is even stronger in younger
51
52
53 25 subjects than in elderly ones. The presence of obesity would also seem to be associated with TC with
54
55 26 a worse prognosis (PMID: 26756356).

Beyond ionizing radiation, family history of TC, female gender, and obesity, other environmental factors seem to play a potential role in the TC's pathogenesis of TC, such as single foods or dietary patterns, including fish, vegetables, vitamin D, selenium and Mediterranean diet (MD)²⁰. Of interest, it is noteworthy that nutritional and dietary patterns in recent years have gained high interest as possible promoters and modifiable risk factors for TC²⁰, as well as they represent a major significant objective of the dietetic and metabolic multidisciplinary rehabilitation in patients with obesity, aimed to achieve at achieving a weight loss and the improvement of obesity-related cardiovascular and metabolic diseases²³; beyond the drug therapy for obesity^{24, 25}.

In particular, the low dietary iodine intake was negatively associated to with increased TC risk of TC, favoring the development of more aggressive histotypes²⁰. Also in addition, the low dietary intake of selenium and vitamin D were associated with TC. However, but the evidence are scarce very limited, despite their well-known anti-cancer potentials of these nutrients, and the clinical usefulness of their dietary supplementation is still uncertain in this setting. Despite considering that single foods, fish, vegetables, and fruits might exert protective effects on TC risk; but the evidence is limited even in this case, the evidence is scarce and albeit the The relationship between single foods and TC remains difficult to examine. Although no clear link role between dietary factors and TC has been firmly established so far, some dietary patterns, in particular MD are supposed to play a role in thyroid carcinogenesis as well as in its stage and aggressiveness. In fact, diet Unlike the study of individual foods or nutrients, diet because it is a complex interaction of single nutrients, foods and phytonutrients, and numerous individual compounds²⁶. For this reason, the benefits of the dietary pattern are due to is a synergistic and/or accumulative effect of nutrients and foods which together, confer overall benefit²⁶. In this context, in promoting to promote the reduction of TC risk, the focus should be on a healthy dietary pattern, in particularly the MD and not on individual nutrients.

The present review summarizes the current epidemiological evidence on TC's nutritional risk factors for TC, with particular attention to MD, and provides the nutrition and dietetics guidance to

1 1 be followed by nutritionists for the reduction of to reduce TC risk, paying particular attention to the
2
3 2 MD.

PEER REVIEW COPY
Panminerva Medica

1 1 Nutrition and Thyroid Cancer Risk

2
3
4 2 As we have seen previously, TC is among common endocrine carcinoma, and it increased
5
6 3 rapidly worldwide during the past three decades²⁷. Beyond genetic predisposition, TC risk is related
7
8 4 to different factors such as radiation, thyroid disorders, hormonal and growth factors, obesity, and
9
10 5 nutritional factor^{27,28,29}.

11
12 6 Environmental carcinogens, probably higher in the last decades, including nutritional factors,
13
14 7 may explain the high incidence of TC³⁰. Previous evidence reported that some nutritional factors
15
16 8 could possibly affect TC risk, but most of these data were inconsistent due to diverse dietary patterns,
17
18 9 eating habits, lifestyles, and other environmental risk factors in the different populations studied. Of
19
20 10 interest, the populations living in iodine sufficient regions with high fish consumption of fish showed
21
22 11 either no relationship or lowered TC risk^{27,31}. Therefore, populations exposed to certain food types
23
24 12 can have an increased or reduced TC risk compared with those who are not²⁷. Most of the studies
25
26 13 conducted who that evaluated the relationship between TC risk and nutrition have focused on single
27
28 14 dietary factors, such as food items (fish, vegetables, etc) or nutrients (vitamin D, selenium, among
29
30 15 others etc)²⁰. In particular, some foods, including fish and other iodine-rich foods^{27,28}, vegetables,
31
32 16 and fruits and other polyphenols-rich foods^{27,28,32-34}, might have potential protective effects on TC
33
34 17 risk. Contrariwise, high intake of meat, in particularly chicken, mutton, lamb³⁵, pork, and poultry³⁴,
35
36 18 ³⁶ were associated with a higher TC risk of TC.

37

The Main evidence for a single food

Fish and shellfish consumption

Fish and shellfish are an essential important source of different nutrients, such as iodine, selenium, and vitamin D, all crucial essential factors for the synthesizing of thyroid hormones ³⁷.

To date, one of the well-established risk-modifying factors for TC is the dietary exposures ^{27, 28, 38}. Among these have been suggested intake of iodine-rich seafood ^{39, 40}, goitrogenic vegetables ^{31, 41}, Poly-Unsaturated Fatty Acids (PUFAs) ⁴², and alcohol ⁴³. Fish and shellfish are considered healthy foods in different dietary patterns, including MD ⁴⁴, because of their content in iodine, selenium, the good fat n-3 Poly Fatty Acids (PUFAs) (eicosapentaenoic acid (EPA) and docosahexaenoic acid (DHA)) and lipid-soluble vitamins, including retinol, vitamin D, and vitamin E ⁴⁵.

In a recent EPIC (European Prospective Investigation into Cancer and Nutrition) study, Zamora-Ros et al. prospectively evaluated the association between quantity and quality of fish consumption and TC risk in a cohort of >500,000 men and women recruited in 10 European countries. In particular, based on quality, the fish was classified as: lean fish with <4 g/100 g of fat (e.g., cod, haddock, and plaice), and fatty fish with fat content between 4 and 14 g/100 g (e.g., salmon, tuna, and trout). While the amount of fish consumed was classified into: shellfish intake (including seafood such as prawn, crab, and mussels), fish and fish product intake (sum of lean and fatty fish and fish products), and total fish and shellfish intake, which was defined as the sum of intakes of fish, fish products, and shellfish. Dietary data were collected with quantitative or semiquantitative food frequency questionnaires that were developed and locally validated in EPIC previously. The results of the study reported no significant association between fish consumption and TC risk; likewise, no significant correlation was reported with the intake of any specific type of fish, fish product, or shellfish ⁴⁶.

This large study's results of this large study are also in agreement with a previous cohort study (24), a systematic review ⁴⁷, a meta-analysis ³⁸, and a pooled analysis of case-control studies

1 from the United States, Europe, Japan, and China ⁴⁰. **In addition** **Besides**, fish is a rich source of n-3
 2
 3 PUFAs (EPA and DHA), that through their impact on prostaglandin synthesis, have anti-
 4
 5 inflammatory properties and have been reported to be a protective factor in TC risk ⁴⁸, in particular,
 6
 7 an inverse association between PUFA intake and TC risk was showed in the EPIC study ⁴².
 8

11 *Vitamin D*

14 7 Vitamin D, in addition to its **main** **central** role in calcium homeostasis, can regulate (directly
 15
 16 or indirectly), multiple signalling pathways involved in cellular proliferation and differentiation,
 17
 18 apoptosis, inflammation, invasion, angiogenesis, and metastasis, with the potential to affect cancer
 19
 20 development and growth ⁴⁹, as well as reduce tumor-induced angiogenesis and invasiveness ⁵⁰. The
 21
 22 most recognized anti-neoplastic effect of vitamin D is its ability to inhibit cell proliferation ⁵¹. Besides
 23
 24 its anti-proliferative effects, vitamin D also regulates inhibiting anti-apoptotic proteins (BCL-2 and
 25
 26 BCL-XL) and inducing the expression of pro-apoptotic proteins (BAX, BAK, and BAD), the key
 27
 28 mediators of apoptosis ⁴⁹. Beyond the importance of vitamin D in inflammatory processes associated
 29
 30 **to** **with** several chronic diseases, including obesity ⁵²⁻⁵⁴, polycystic ovary syndrome ^{55,56}, and psoriasis
 31
 32 ⁵⁷, **the role of** vitamin D's **role** has been determined in autoimmune and malignant thyroid diseases
 33
 34 ⁵⁸. Different preclinical studies have **shown** **growth** arrest of TC after the administration of
 35
 36 pharmacological doses of vitamin D in differentiated TC cell lines ⁵⁹. The main form of vitamin D,
 37
 38 the vitamin D (subscript 3) (or cholecalciferol), is synthesized in the skin by 7-dehydrocholesterol
 39
 40 reductase upon exposure to ultraviolet B (UVB) radiation, and can **also** be **also** obtained from a few
 41
 42 dietary sources (mainly fatty fish) ⁴⁹ and meat ⁶⁰. In addition to the production of vitamin D, the
 43
 44 indices of solar UVB irradiance can be associated with the genesis of some cancers. In particular,
 45
 46 Grant has evaluated the cancer mortality rates for 48 continental Spanish provinces for 1978-1992
 47
 48 **concerning** **respect to** mortality rates for latitude (an index of solar UVB levels), reporting that nine
 49
 50 cancers were significantly correlated with latitude, including TC **thyroid cancer**. **In a** **Additionally**, TC
 51
 52 was associated with non-melanoma skin cancer, highlighting that **the** **TC's** development **of TC** can a
 53
 54
 55

1 1 have different etiology ⁶¹. In this context, an inverse association between UV-B exposure and non-
 2 skin cancer mortality, including TC, has been reported, probably through vitamin D, produced of
 3 exposure to the sun via the skin. Boscoe and Schymura ¹ showed the inverse relationships between
 4 UV-B exposure and TC (only in females), suggesting the **vital important** role in **maintaining** of
 5 adequate vitamin D levels linked to sun exposure ⁶².

6 Beyond TC risk, vitamin D also plays an **indispensable important** role in thyroid
 7 autoimmunity, improving the innate immune response and exerting an inhibitory action on the
 8 adaptive immune system ⁴⁹. Calcitriol, the activated (or hormonal metabolite of) vitamin D, has been
 9 reported to modulate the cytokine milieu to a more tolerogenic immune status ⁶³. Dutta et al.
 10 confirmed that anti-thyroid peroxidase antibody positivity is more prevalent in individuals with
 11 hypovitaminosis D and reported a negative correlation between anti-thyroid peroxidase antibody and
 12 serum 25-hydroxyvitamin D (25(OH)D). However, **in spite of the** large volume of evidence linking
 13 vitamin D with thyroid autoimmunity and cancer, meaningful clinical studies on **the** impact of vitamin
 14 D supplementation **are needed** ⁶⁴.

15 Hashimoto's thyroiditis (HT) and **differentiated** DTC represents **the** most common
 16 autoimmune and malignant thyroid diseases ⁶⁵, and hypovitaminosis D represents a **prevalent joint**
 17 risk factor for HT ⁶⁶ and **differentiated** DTC ⁶⁷.

18 Sirtuins are the histone deacetylases **that are** involved in several metabolic pathways ⁶⁸ and
 19 regulate post-translational modification of cellular regulator proteins on **the** energy status of the cell
 20 ⁶⁹. Recently, Sirtuin 1 has been shown to be regulated by vitamin D by deacetylation of forkhead box
 21 protein O3a (FOXO3a) ⁷⁰. **The latter was** reported as **an** important risk factor for TC ⁷¹, **therefore**
 22 suggesting a potential key role of vitamin D-SIRT1-FOXO3a signaling in immune regulation and
 23 TC. Recently, Roehlen et al. have genotyped the SNP's FOXO3a in 257 subjects with
 24 **DTC differentiated thyroid carcinoma**, 139 individuals with Hashimoto thyroiditis compared to 463
 25 healthy controls ⁶⁵. The **Authors** have found that SNP's of FOXO3a, in particular rs9400239T and
 26 rs4945816C, independent of the vitamin D status, may constitute risk factors for Hashimoto

1 thyroiditis, indicating the implication of FOXO3a in the pathogenesis of autoimmune thyroid
 2 diseases. In addition, The anti-proliferative vitamin D effects on SIRT1 activity, show a keycritical
 3 role of the vitamin D-SIRT1-FOXO3a axis for protective vitamin D effects⁶⁵. In addition, also sSome
 4 alterations of genetic variants that encode crucial enzymes for the synthesis, metabolism and
 5 degradation (DHCR7 rs12785878, CYP2R1 rs2060793, CYP24A1 rs6013897, respectively) of
 6 vitamin D, and they have been associated with serum levels of 25(OH)D and on the susceptibility to
 7 TC⁷². In particular, The case-control study done by Carvalho et al. in a case-control study investigated
 8 the effect of these variants in the vitamin D pathway and susceptibility to TC in 500 patients
 9 with differentiated DTC and 500 controls. The results of this study showed the association between
 10 DHCR7 rs12785878 and TC under, suggesting that DHCR7 polymorphisms due to its effect on
 11 circulating 25(OH)D levels, may be associated with an increased risk of TC⁷².

12 Of interest Remarkably, vitamin D has proven useful also as a prognostic tool for TC, as
 13 examined in 334 patients in a study of Sulibhavi et al.⁷³. In this study, 25(OH)D levels showed no
 14 significant association to cancer stage, but subjects with hypovitaminosis D were more likely to have
 15 advanced disease. The results of this study suggests that hypovitaminosis D may have value as a
 16 negative prognostic indicator in papillary TC⁷³.

17 Although some studies have shown that higher 25(OH)D levels might protect against TC,
 18 other studies do not confirm this association, or have even indicated the opposite to be the case⁷⁴.
 19 Very recently, in a meta-analysis of 14 articles, Zhao et al. investigated the association between deficit
 20 of vitamin D deficiency and TC. These metanalysis results of this metanalysis have shown that
 21 25(OH)D levels were lower in patients with TC preoperatively compared to than controls, concluding
 22 that lower 25(OH)D levels were associated with increased risk for TC and that hypovitaminosis D
 23 may act as a risk factor for TC⁷⁴. In conclusion, the association between hypovitaminosis D and TC
 24 is still controversial.

25
 26 *Fruits and vegetables consumption*

1 The fruits and vegetables consumption intake have been associated with a reduced risk of
 2 several tumors in case-control studies, but these relationships become weak or even null in cohorts
 3 studies^{75, 76}. Nevertheless, the question of what is the optimal amount and type of fruit and vegetable
 4 consumption to reduce the cancer risk of cancer is still unanswered⁷⁵. This issue is reflected by the
 5 fact that recommendations for dietary consumption vary globally. A weak one association between
 6 fruit and vegetable consumption or specific subtypes of fruits and vegetables and cancer risk cannot
 7 yet be excluded⁷⁶, but the current evidence is scarce⁷⁵. Some studies reported inverse associations
 8⁷⁵⁻⁷⁷, whereas other studies found no clear association^{75, 78, 79}. However, some of these may have had
 9 statistical power too low to detect a modest association.

10 Fruit and vegetables contain a variety of various nutrients and phytochemicals, such as
 11 vitamins, antioxidants, flavonoids, and other unidentified compounds. All these nutrients could act
 12 alone or in synergy with each other through several biological mechanisms to reduce risk of the cancer
 13 risk⁸⁰. In particular, the mechanisms by which fruits and vegetables could reduce the cancer risk are
 14 different: neutralization of reactive oxygen species (ROS) and reduce DNA damage through their
 15 antioxidants in fruit and vegetables⁸¹; detoxifying enzymes action by glucosinolates in cruciferous
 16 vegetables⁸², among others.

17 Of interest, fruits and vegetables consumption through its fiber content content of fibre, may
 18 modulate the production of short-chain fatty acids (SCFAs) in the gut with a beneficial effect on gut
 19 microbiota^{83, 84} and steroid hormone concentrations and hormone metabolism⁸¹.

20 Currently, little is known about the association with between fruit and vegetables consumption
 21 and TC risk, particularly in prospective studies. Very recently, Zamora-Ros et al., in the EPIC study,
 22 evaluated the fruit and vegetable consumption and TC risk in over half a million participants,
 23 recruited between 1991 and 2000 with a mean follow-up period of 14 years. The results of this large
 24 study did not report a significant association between fruit and vegetable consumption and TC risk
 25⁴¹. Interestingly, the cruciferous vegetables have been studied more closely due to containing
 26 glucosinolates, a diet source of thiocyanates and isothiocyanates that act as goitrogens⁸⁵ promoting

thyroid tumor growth in rats^{86,87}. Nevertheless, in two recent meta-analyses of retrospective studies, either no relationship or a positive association between cruciferous vegetables consumption and TC risk were evident^{38, 88}.

Alcohol consumption

The alcohol consumption is another important dietary factor on TC risk. In particular, evidence from several prospective⁸⁹⁻⁹³ and case-control studies^{94, 95} has reported a protective association between current moderate alcohol consumption and TC risk.

In a recent large study within the EPIC study, Sen et al. investigated baseline and lifetime alcohol consumption and risk of TC among 477,263 subjects (70% women), and 556 (90% women). The authors of this study observed that moderate alcohol consumption at recruitment was associated with a statistically significant lower risk of TC⁴³. The potential mechanisms explaining the link between alcohol intake and TC risk are not well known and are complex. The direct toxic effect of alcohol on the thyroid has been suggested by some studies^{96, 97}.

Nevertheless, the potential effects of alcohol intake on the thyroid function should be considered speculative as there are much less studied. The free radicals generated by alcohol metabolism lead to oxidative stress in tissues poorly metabolizing alcohol, including thyroid, and leading to hypothalamus-pituitary-thyroid axis dysfunction and reduction of peripheral thyroid hormone concentrations⁹⁸.

Impact of resveratrol

There is an increasing interest in Phytochemical and TC treatment and other types of cancer since there are still limitations for this TC treatment, such as drug resistance or the unfavorable side effects from some treatment options, there is increasing interest on Phytochemical and TC treatment and other types of cancer⁹⁹. The important anti-inflammation, anti-oxidation, and anti-cancer effects found in the Phytochemical (chemical substances produced by plants) have allowed

1 1 them to impact **deeply** **profoundly** in decreasing cell proliferation, angiogenesis, and invasiveness ¹⁰⁰.
 2
 3 2 Resveratrol (3,5,4'-trihydroxy-trans-stilbene) is a phytochemical and a natural stilbenoid **that has** **with**
 4
 5 3 two aromatic rings with **a** methylene bridge. It can be found in grapes, blueberries, raspberries, **and**
 6
 7 4 red wines, **and in** peanuts, pomegranates, and **soybeans** ^{101, 102}. **Resveratrol has shown to be helpful in**
 8
 9 **radioiodine therapy.**

10 5
 11 6
 12 6 Additionally, it has shown to be helpful in radioiodine therapy ^{103, 104} **due to its capacity to**
 13
 14 7 protect normal cells from **reactive oxygen species (ROS)** induced cytotoxicity by reducing them
 15
 16 8 through the hydroxyl groups in the resveratrol's chemical structure. **As it was reported by** **Two**
 17
 18 9 publications **where it was** highlighted the use of resveratrol as co-treatment with radioactive iodine
 19
 20 10 therapy ^{105, 106}. Moreover, **to its ROS scavenging effect,** resveratrol has anti-thyroid cancer activities
 21
 22 11 by regulating TC-specific signaling pathways **to its ROS scavenging effect.** Zheng et al. demonstrated
 23
 24 12 that intragastric and intraperitoneal **resveratrol** administration **of resveratrol** efficiently reduced the
 25
 26 13 frequency and severity of TC-related lesions such as hyperplasia and adenomas ¹⁰⁷. Resveratrol also
 27
 28 14 influences thyroid function by enhancing iodide trapping and **by** increasing thyroid-stimulating
 29
 30 15 hormone (TSH) secretion via activation of sirtuins and the phosphatidylinositol- 4-phosphate 5 kinase
 31
 32 16 γ (PIP5K γ) pathway, positively affects metabolism ¹⁰⁸. These results imply that resveratrol improves
 33
 34 17 retinoic acid sensitivity, enhances **the radiotherapy's efficacy** **of radiotherapy,** induces apoptosis or re-
 35
 36 18 differentiation, and induces cancer stem cells differentiation ⁹⁹.
 37
 38 19
 39
 40 20
 41

42 20 *White meat and Red meat*

43
 44 21 While cooking red meat at a high temperature, carcinogenic compounds such as heterocyclic
 45
 46 22 amines (HCA), polycyclic aromatic hydrocarbons (PAH), N-nitroso compounds, or heme iron are
 47
 48 23 formed ¹⁰⁹.
 49

50
 51 24 From **Wie et al.**'s study done among 26,815 participants in cancer screening examinations
 52
 53 25 from September 2004 to December 2008, **there were selected** 8,024 subjects who completed a self-
 54
 55 26 administered questionnaire **were selected.** In September 2013, **387 cancer cases were classified** from

the National Cancer Registry System, 387 cancer cases were classified, and the remaining individuals were included in the control group. From this study it was concluded that red meat consumption, Na intake and obesity ($BMI \geq 25 \text{ kg/m}^2$) were positively associated with overall cancer incidence in men (HR 1.41, 95% CI 1.02, 1.94; $P= 0.04$), gastric cancer (HR 2.34, 95% CI 1.06, 5.19; $P= 0.0365$) and TC (HR 1.56, 95% CI 1.05, 2.31; $P= 0.0270$), respectively ¹¹⁰. Also, an increased risk of TC associated with nitrate intake was reported in a cohort study of older women in Iowa. This study was a large prospective cohort of 490,194 men and women, ages 50-71 years, in 1995-1996. A 124-item food frequency questionnaire was used to determine the dietary intakes. During an average of 7 years of follow-up, they identified 370 incident TC cases (170 men, 200 women) with complete dietary information. Among men, increasing nitrate intake was positively associated with TC risk (relative risk [RR] for the highest quintile versus lowest quintile $RR = 2.28$, 95% CI: 1.29-4.04; p -trend <0.001). However, no trend with intake among women was observed (p -trend = 0.61). Nitrite intake was not associated with TC risk of TC for either men or women ¹¹¹. A systematic review and meta-analysis published in 2015 concluded that no significant association was observed between nitrate exposure and the TC risk of TC, hyper- and/or hypothyroidism. Additional research is needed to clarify the association between nitrate/nitrite exposures and both thyroid function and cancer ¹¹². On the other hand, high consumption of fresh fish seemed to have a protective effect against TC (OR=0.6; 95% CI: 0.3–1.0; P -trend <0.05). But Nevertheless, when fish products were processed, canned, or frozen, there was a strong positive association with TC (OR=3.0; 95% CI: 1.6–5.3; P -trend <0.01). Among other types of meat, high consumption of chicken (OR=3.0; 95% CI: 1.3–6.8; P -trend <0.01) as well as mutton and lamb (OR=1.8; 95% CI: 1.1–2.8; P -trend <0.01) showed a positive association with TC ³⁵. These studies suggests that several components like red meat, canned or frozen fish, high consumption of chicken, and processed meats like sausages, may influence TC risk.

Coffee and tea and other drinks

1 1 Coffee and tea are beverages consumed on a daily basis worldwide in adults. Both of them
2
3 2 are rich sources of flavonoids and phenolic acids ¹¹³. Polyphenols may play a role in cancer
4
5 3 prevention, including TC, through the modulation of enzyme activities and signal transduction
6
7 4 pathways related to cellular proliferation, differentiation, apoptosis, inflammation, angiogenesis, and
8
9 5 metastasis (DOI: 10.23736/S1120-4826.19.02522-9) ¹¹⁴. However, there is much a lot of
10
11 6 controversy for the caffeine and theophylline because of their negative and positive effects in
12
13 7 carcinogenesis ¹¹⁵.

14 8 In the report by Alicandro et al., where they reviewed available evidence on coffee drinking
15
16 9 and the risk of all cancers updated to May 2016, they concluded that coffee consumption is not
17
18 10 associated with overall cancer risk ¹¹⁶. The EPIC cohort, which included 476,108 adult men and
19
20 11 women, coffee and tea intakes were assessed through validated country-specific dietary
21
22 12 questionnaires, and during a mean follow-up of 14 years, 748 first incident differentiated DTC cases
23
24 13 were identified. Coffee consumption (per 100 mL/day) was not correlated either with total
25
26 14 differentiated DTC risk (HR: 1.00, 95% CI 0.97-1.04) or with the risk of TC subtypes. Tea
27
28 15 consumption (per 100 mL/day) was not associated with the risk of total differentiated DTC (HR: 0.98,
29
30 16 95% CI 0.95-1.02). An inverse association was found with follicular tumor risk (HR: 0.90, 95% CI
31
32 17 0.81–0.99), but this association was based on a sub-analysis with a small number of cancer cases. In
33
34 18 conclusion, in this large prospective study, coffee and tea consumption were not associated with TC
35
36 19 risk (PMID: 30535794) ¹¹⁴. Hashibe et al. observed in the PLCO trial a decreased risk of endometrial
37
38 20 cancer for coffee intake (RR=0.69, 95% CI=0.52-0.91 for ≥ 2 cups per day), and a decreased risk of
39
40 21 cancer overall with tea intake (RR=0.95, 95% CI=0.94-0.96 for 1+ cups per day vs. <1 cup per
41
42 22 day). This trial started in 1992 and ended enrollment in 2001. Approximately 155,000 women and
43
44 23 men between the ages of 55 and 74 participate in this randomized study ¹¹⁷. Michikawa et al. analyzed
45
46 24 data from a prospective cohort of 100,507 persons, where green tea and coffee consumption were
47
48 25 assessed via a self-administered questionnaire. During a mean 14.2-year follow-up, they documented
49
50 26 159 TC cases. They inferred that high green tea consumption could be associated with premenopausal

1 TC risk, but inversely correlated associated with postmenopausal TC risk¹¹⁸. Finally, Riza et al., in
2
3 their study, they concluded that drinking herbal teas, especially chamomile ($P < 0.001$), protects from
4
5 TC as well as other benign thyroid diseases. From these studies, it can be suggested to drink tea,
6
7 especially chamomile, to prevent TC¹¹⁹.
8

9 10 11 12 *Soy Foods*

13
14 Soy foods They have been considered as excellent replacements for dairy products,
15
16 considered recognized as sources of high-quality protein and healthful fat and uniquely-rich sources
17
18 of isoflavones (classified as phytoestrogens and selective estrogen receptor modulators). Soy foods
19
20 were widely accepted because of the potential effects on health, such as the effectiveness in
21
22 cardiovascular risk reduction, antioxidative effect of flavonoids may protect from cancer^{120, 121},
23
24 preventive roles in hypertension, hypercholesterolemia¹²², body weight loss¹²³. Nonetheless, there
25
26 are reports of possible disruption of thyroid function and sexual hormones. A cross-sectional study
27
28 of 11,688 women aged 30–50 years of North American Adventist church showed that high intake of
29
30 isoflavones was related to increased risk of nulliparity and nulligravida null gravity¹²⁴. There are also
31
32 reports of soy products in infant diet before 4 months of age and a 25% higher risk of menarche
33
34 before 12 years of age¹²⁵. About the thyroid gland disturbance, more long-term epidemiological
35
36 studies are needed to verify soy-thyroid interaction in real conditions since in clinical trials; isolated
37
38 isoflavones are used with a wide range of concentrations and heterogenic conditions¹²⁶. In the
39
40 multiethnic population-based case-control study of thyroid cancer conducted from the San Francisco
41
42 Bay Area with 817 cases diagnosed between 1995 and 1998, 608 (74%) were examined.
43
44 Phytoestrogen consumption was determined via a food-frequency questionnaire and a newly
45
46 developed nutrient database. They reported that the consumption of traditional and nontraditional
47
48 soy-based foods and alfalfa sprouts were associated with a reduced TC risk of TC¹²⁷. In a recent
49
50 study by Xiao et al., the association between dietary flavonoid intake and TC risk in 491,840
51
52 participants was investigated. It was reported that TC risk was not associated with the dietary intake
53
54
55

1 1 of isoflavones ¹²⁸. After analyzing **carefully** the results from these few studies **carefully**, it remains
2
3 2 inconclusive the potential influence of isoflavones on TC risk.

Panminerva Medica

1 1 Mediterranean diet

2
3
4 2 This dietary pattern is commonly used by the people living **on** the Mediterranean coasts ¹²⁹.

5
6 3 It is characterized by **a** higher intake of **the** majority of plant-derived foods, including vegetable and
7
8 4 fruits, legumes, whole-grains, and extra virgin olive oil as **the** only source of fat, moderate alcohol
9
10 5 consumption (especially red wine), moderate intake of animal protein (most represented by fish and
11
12 6 dairy products), and **very limited** **minimal** consumption of meat and highly processed foods ¹²⁹.

13
14 7 Additionally, it is low in saturated fatty acids and provides high amounts of monounsaturated fatty
15
16 8 acids and n-3 PUFAs, mainly derived from olive oil as alpha-linolenic acid and long-chain PUFAs

17
18
19 9 **from** fish ¹³⁰. The foods and beverages of plant origins are widely rich in polyphenols, **in particularly**
20
21 10 fruits, vegetables, spices, nuts. **etc** ^{131, 132}. The MD's beneficial effects **of the MD** are the high

22
23 11 content in antioxidants and anti-inflammatory compounds, including polyphenols, to play a role in

24
25 12 **the preventing of** cancer ^{129, 133} and other diseases such as cardio-metabolic, neurodegenerative
26
27 13 disorders¹²⁹, among others. **There are several** papers showing **the** antitumor effects of natural

28
29 14 polyphenols ¹³², including anthocyanins from blueberries, epigallocatechin gallate from green tea,

30
31
32 15 and resveratrol from red wine. **All these** functions are associated with cell survival, proliferation,
33
34 16 differentiation, migration, angiogenesis, hormone activities, detoxification enzymes, and immune

35
36 17 responses ¹³². **In spite of** **Despite** all the existing robust evidence regarding the MD and its advantages,

37
38 18 more studies are needed to show a direct causal relationship **of between** this diet and the reduction **of**

39
40 19 TC risk. As **it was** reported by the EPIC cohort, which included 476,108 men and women from 10

41
42 20 European countries, no associations between dietary polyphenol consumption and TC risk **were as**

43
44
45 21 demonstrated ¹³⁴.

46
47 22 The MD was associated with **a** lower risk of breast cancer ^{135, 136}, gastroenteropancreatic
48
49 23 neuroendocrine tumors aggressiveness ¹³⁷⁻¹³⁹, and other cancers ^{140, 141}. Nonetheless, **there are** only **a**

50
51 24 few studies **that** link dietary patterns to TC ^{29, 34, 142}. In a case-control study of 113 subjects, Markaki

1 et al.³⁴ found that dietary patterns of fruits, raw vegetables, and mixed raw vegetables and fruits were
2
3 negatively associated with TC (ORs 0.68, 0.71, 0.73, respectively).
4

5 Another study did not report any difference between traditional Polynesian diet (characterized by
6
7 high consumption of fish, seafood, and fruits) and Western diet (characterized by high consumption
8
9 of meat and starchy food), in 229 cases of differentiated DTC diagnosed, and 371 controls¹⁴². Very
10
11 recently, Sangsefidi ZS et al., in a case-control study among 309 clinic-based participants in the
12
13 northeast of Iran, evaluated the role of major dietary patterns on differentiated DTC. The only
14
15 association reported in this study was that the western diet had 2.85 times more chance for
16
17 differentiated DTC (OR=2.85, 95% CI=1.15-7.06)²⁹.

Dietary indications as Medical Prescription in the Reduction of Thyroid Cancer Risk: The Point of View of the Endocrinological Nutritionist

The current state of the dietary recommendations for the prevention of TC are lacking remains controversial, as the clinical studies' results of the clinical studies are inconsistent. However, based on current scientific evidence, we can give some dietary indications as a medical prescription to reduce in the reduction of TC risk, considering that the choice of food must be made by analyzing considering the presence of beneficial nutrients²⁰. The principal dietary indications are summarized as follows:

1. Iodine intake and fish: Correction of iodine deficiency has shifted thyroid cancer subtypes toward less aggressive forms, without affecting the cancer's overall risk for cancer. High iodine intake seems to exert a protective effect against cancer;
2. Fruits and vegetables: They may provide a protective role for combining the combination of bioactive components with antioxidant activity, such as selenium and vitamin D, micronutrients, and phytochemicals. Eat 2 servings of fruits and at least 7.5 servings *per day* (600 g/d) of green-yellow and cruciferous vegetables (salads) *per day*;
3. Selenium, vitamin D: Despite the well-known anti-cancer activities and potentials, there is limited evidence on the association between either selenium or vitamin D deficiency and TC, as well as on the clinical usefulness of their supplementation in these patients;
4. **Bodyweight**: Obesity is associated with the incidence of various tumors, including differentiated DTC. An association between excessive weight and TC risk of TC, with more aggressive behavior, emerges from most of the studies.
5. Alcohol, red meat and dairy: To limit excess consumption of alcohol, meat, and dairy food even if no clear associations were found among the consumption of these foods on TC risk;
6. Don't consume processed food;

1 1 7. Don't consume frozen or canned fish or seafood;

2
3 2 8. Drink daily chamomile tea and herbal tea to prevent TC;

4
5 3 9. Adopt healthy lifestyle habits: Exercise 30 minutes daily or 1 hour every 2 days.

6
7 4 Most of these suggestions are potentially useful also for patients with thyroid cancer (Table 1)

Panminerva Medica

Conclusion

Interesting Significant associations between single nutrients or food and TC risk have been described observed. Understanding the bidirectional relationships between dietary patterns and TC risk is also essential for delineating the risk profile from obesity (Figure 1). Adopting a healthy lifestyle and the education regarding modifiable environmental factors (diet, nutrition, and physical activity) could have beneficial effects *per se* on reducing of TC risk. For achieving dietary-related goals, the skilled Endocrinological Nutritionist should play a central role during the endocrinological examination assessment considering dietary recommendations as like a real one medical prescription for the prevention of TC risk. On the basis of Based on its beneficial antioxidants and anti-inflammatory components, the MD could also presents health benefits also in TC's the prevention of TC. The advantageous beneficial effects of nutritional interventions promoting the Mediterranean food pattern could be extended to patients at risk of developing TC. Future well-designed dietary intervention trials on larger population samples are needed to define specific dietary guidelines for prevention of reducing TC risk.

Table 1: Dietary suggestions for a correct lifestyle in thyroid cancer patients

✓ Iodine intake and fish	<ul style="list-style-type: none"> - A correct intake of iodine with the diet plays a protective role in the development of nodules and, therefore, potentially also thyroid carcinomas - High iodine intake seems to exert a protective effect against cancer
✓ Fruits and vegetables	<ul style="list-style-type: none"> - They may provide a protective role for the combination of bioactive components with antioxidant activity - Eat 2 servings of fruits and at least 7.5 servings per day (600 g/d) of green-yellow and cruciferous vegetables (salads) per day
✓ Selenium, vitamin D	<ul style="list-style-type: none"> - There are limited evidences on the association between either selenium or vitamin D deficiency and TC
✓ Obesity	<ul style="list-style-type: none"> - Obesity is associated with the incidence of various tumors, including differentiated DTC - Weight loss is therefore recommended for patients with thyroid cancer
✓ Alcohol, red meat, and dairy	<ul style="list-style-type: none"> - No clear associations were found among the consumption of these foods on TC risk - In any case, it is advisable not to exceed with these foods in order to reduce the risk of obesity.
✓ Adopt healthy lifestyle habits	<ul style="list-style-type: none"> - It is recommended to perform physical exercise 30 minutes daily or 1 hour every 2 days
✓ Nutritional status in patients treated with Tyrosine Kinase Inhibitors (TKI)	<ul style="list-style-type: none"> - A close monitoring and management of weight loss is crucial to avoid withdrawal and to limit the need for dose reduction - Expert nutritionist interventions are needed in patients affected with advanced TC treated with TKI

Abstract

The incidence of differentiated thyroid cancer has increased in the last decades all over the world. Different environmental factors are possible perpetrators of this exponential growth. Nutritional factors are among the main environmental factors studied for thyroid cancer in recent years. This review aims to overview the main dietary factors involved in thyroid cancer risk, providing specific nutrition recommendations from the endocrinological Nutritionist point of view. Among the single food, fish and shellfish are the primary natural source of iodine, selenium and vitamin D in the human diet. These nutrients are essential for the synthesis of thyroid hormones; however, their consumption is not consistently related to thyroid cancer risk. The high intake of fruit and vegetables, probably due to their vitamin and antioxidant content, shows a weak inverse association with thyroid cancer risk. Alcohol, meat, or other food groups/nutrients showed no significant effect on thyroid cancer. In conclusion, to date, no definite association among dietary factors, specific dietary patterns, and thyroid cancer, and its clinical severity and aggressiveness have been found. However, it is essential to underline that in the future, prospective studies should be carried out to precisely evaluate the qualitative and quantitative intake of nutrients by patients to establish with more confidence a potential correlation between food intake and the occurrence and development of thyroid cancer.

TEXT

Introduction

Thyroid cancer (TC) is considered a rare disease since it constitutes <1% of all cancer ¹. However, it represents the most frequent endocrine cancer, affecting 5% of thyroid nodules, which have a prevalence of 20-50% in the general population, increasing due to improved diagnostic techniques and early diagnosis ². In particular, ultrasound and fine-needle aspiration are the most important diagnostic tools for evaluating thyroid nodules ³⁻⁵.

TC has a greater prevalence in the female sex, with a 3:1 female-to-male ratio in most geographic regions and demographic groups. Although these tumors are rare in children, they affect a younger population than most malignancies, with a maximum incidence between 25 and 60 years ⁶. Survival is very high, exceeding 90% at 5 years in differentiated form ⁶. Moreover, since the TC prognosis is excellent in most cases and the mortality rate remains very low, to date, there is much interest in the personalized risk-based treatment ⁷.

TC generally originates from follicular cells and is divided into papillary, follicular, anaplastic, and medullary carcinoma ⁸. Papillary carcinoma is the most frequent form of differentiated TC (DTC), comprising about 80% ⁹. It has slow growth and can cause loco-regional lymph node metastases. In some patients, the tumor is multifocal and can affect both lobes of the thyroid gland ¹⁰. Follicular carcinoma represents about 15% of DTC and can produce distant metastases. Anaplastic carcinoma is a rare type of tumor, <1% of TC, but it is particularly aggressive already at diagnosis with inadequate response to conventional therapies ¹¹. Medullary carcinoma originates from parafollicular cells (or C cells), and the diagnosis is based on the basal or stimulated calcitonin dosage ¹². This tumor can occur in familial forms as the manifestation of genetic syndromes, such as multiple neoplastic syndrome type 2.

In DTC some recurrent genetic mutations have been found that specifically affect receptors with tyrosine kinase activity and their pathways, such as BRAF (V600E) mutation, RET/PTC rearrangements RAS and pTERT mutations in papillary carcinoma and PAX8-PPAR γ

1 rearrangements or RAS and pTERT mutations in follicular carcinoma ^{8,13}. These mutations also
2
3 justify the known relationship between exposure to ionizing radiation and increased TC incidence
4
5 since radiation induces double-stranded DNA breaks and genetic rearrangement ¹⁴.
6

7
8 As reported in clinical studies, the thyroid is particularly sensitive to the long-term effects of
9
10 radiation exposure ¹⁵. This association was evaluated in population-based case-control studies of
11
12 adolescents exposed to radiation following the Chernobyl accident and subjects exposed to the atomic
13
14 bombings of Hiroshima and Nagasaki, where an increased incidence of TC was demonstrated ¹⁶. The
15
16 adverse effects of radiation in inducing TC have been reported in atomic bomb survivors from 62 to
17
18 66 years after exposure during their childhood ¹⁷. Remarkably, Mesrine et al. prospectively analyzed
19
20 86,960 women followed up over 1990-2008, finding associations between nevi, baseline residential
21
22 ultraviolet exposure, and TC risk ¹⁸. Results showed that ultraviolet exposure level and the number
23
24 of nevi were associated with thyroid nodules or history of thyroid disturbances, and the number of
25
26 nevi was positively associated with TC risk (HR=1.7, 95% CI=1.0, 2.8; $p=0.01$). This risk was
27
28 restricted to females with dietary iodine below the median intake. The authors concluded that TC risk
29
30 was associated with the number of nevi and residential ultraviolet exposure ¹⁸.
31
32

33
34 In addition to ionizing radiation, the main risk factors known for TC are family history,
35
36 female gender, and obesity ¹⁹. A family history of TC in first-degree relatives is associated with a 10-
37
38 fold increased risk of non-medullary TC based on a large case-control study ²⁰. Although this cancer
39
40 incidence is significantly higher in women, no clear pathophysiological and hormonal mechanisms
41
42 have been identified²¹. Some observational studies have shown an association between excess weight
43
44 and increased TC risk, both well-differentiated and anaplastic. In particular, a meta-analysis of 22
45
46 prospective studies showed that a high body mass index (BMI) is associated with an increased TC
47
48 risk, and that this association is even stronger in younger subjects than in elderly ones. The presence
49
50 of obesity would also seem to be associated with TC with a worse prognosis ²².
51

52
53 Beyond ionizing radiation, family history of TC, female gender, and obesity, other
54
55 environmental factors seem to play a potential role in the pathogenesis of TC, such as single foods or

1 dietary patterns, including fish, vegetables, vitamin D, selenium and adherence to the Mediterranean
2 diet (MD)¹⁹. It is noteworthy that nutritional and dietary patterns have recently gained high interest
3 as possible promoters and modifiable risk factors for TC¹⁹. They represent a significant objective of
4 the dietetic and metabolic multidisciplinary rehabilitation in patients with obesity, aiming to achieve
5 a weight loss and the improvement of obesity-related cardiovascular and metabolic diseases²³,
6 beyond the drug therapy for obesity^{24,25}.

7
8
9
10
11
12
13
14 In particular, the low dietary iodine intake was negatively associated with increased TC risk,
15 favoring the development of more aggressive histotype¹⁹. Moreover, the low dietary intake of
16 selenium and vitamin D was associated with TC. However, the evidence is scarce, despite their well-
17 known anticancer potential of these nutrients, and the clinical usefulness of their dietary
18 supplementation is still uncertain in this setting. The relationship between single foods and TC
19 remains difficult to examine. Although no clear link between dietary factors and TC has been firmly
20 established so far, some dietary patterns, in particular, adherence to the MD are supposed to play a
21 role in thyroid carcinogenesis as well as in its stage and aggressiveness. Unlike the study of individual
22 foods or nutrients, diet is a complex interaction of single nutrients, foods and phytonutrients, and
23 numerous individual compounds²⁶. For this reason, the benefit of the dietary pattern is a synergistic
24 and/or accumulative effect of nutrients and foods²⁶. In this context, to promote the reduction of TC
25 risk, the focus should be on a healthy dietary pattern, particularly the adherence to the MD and not,
26 on individual nutrients.

Nutrition and TC risk

As previously reported, TC is among the common endocrine carcinoma, and it increased rapidly worldwide during the past three decades²⁷. Beyond genetic predisposition, TC risk is related to different factors such as radiation, thyroid disorders, hormonal and growth factors, obesity, and nutritional factors²⁸.

Environmental carcinogens, probably higher in the last decades, including nutritional factors, may explain the recent increase in TC incidence²⁹. Previous evidence reported that some nutritional factors could affect TC risk, but most of these data were inconsistent due to diverse dietary patterns, eating habits, lifestyles, and other environmental risk factors in the different populations. Of interest, the populations living in iodine sufficient regions with high fish consumption showed either no relationship or lowered TC risk^{27,30}. Therefore, populations exposed to certain food types can have an increased or reduced TC risk compared with those who are not²⁷. Most of the studies conducted that evaluated the relationship between TC risk and nutrition have focused on single dietary factors, such as food items (fish, vegetables) or nutrients (vitamin D, selenium, among others)¹⁹. In particular, some foods, including fish and other iodine-rich foods²⁷, vegetables, and fruits and other polyphenol-rich foods^{27,31-33}, might have potential protective effects on TC risk. Contrariwise, high intake of meat, particularly chicken, mutton, lamb³⁴, pork, and poultry^{33,35}, were associated with a higher TC risk.

The main evidence for a single food

Fish and shellfish consumption

Fish and shellfish are an essential source of different nutrients, such as iodine, selenium, and vitamin D, all crucial factors for the synthesis of thyroid hormones ³⁶.

One of the well-established risk-modifying factors for TC is the dietary exposures ^{27, 37}. Among these have been suggested intake of iodine-rich seafood ³⁸, goitrogenic vegetables ^{30, 39}, polyunsaturated fatty acids (PUFAs) ⁴⁰, and alcohol ⁴¹. Fish and shellfish are considered healthy foods in different dietary patterns, including MD ⁴², because of their content in iodine, selenium, healthy fat omega-3 PUFAs (eicosapentaenoic acid (EPA) and docosahexaenoic acid (DHA)) and lipid-soluble vitamins, including retinol, vitamin D, and vitamin E ⁴³.

In a recent European Prospective Investigation into Cancer and Nutrition (EPIC) study, Zamora-Ros et al. prospectively evaluated the association between quantity and quality of fish consumption and TC risk in a cohort of >500,000 men and women recruited in 10 European countries. In particular, based on quality, the fish was classified as: lean fish with <4 g/100 g of fat (e.g., cod, haddock, and plaice), and fatty fish with fat content between 4 and 14 g/100 g (e.g., salmon, tuna, and trout). While the amount of fish consumed was classified into: shellfish intake (including seafood such as prawns, crab, and mussels), fish and fish product intake (sum of lean and fatty fish and fish products), and total fish and shellfish intake, which was defined as the sum of intakes of fish, fish products, and shellfish. Dietary data were collected with quantitative or semiquantitative food frequency questionnaires that were developed and locally validated in EPIC. This study reported no significant association between fish consumption and TC risk; likewise, no significant correlation was reported with the intake of any specific type of fish, fish product, or shellfish ⁴⁴.

This large study's results are also in agreement with a previous cohort study ⁴⁵, a systematic review ⁴⁶, and meta-analysis ³⁷. Besides, fish is a rich source of omega-3 PUFAs (EPA and DHA), that, through their impact on prostaglandin synthesis, have anti-inflammatory properties and have

1 been reported to be a protective factor in TC risk⁴⁷. In particular, an inverse association between
2
3 PUFA intake and TC risk was showed in the EPIC study⁴⁰.
4
5

7 *Vitamin D*

9
10 Vitamin D, in addition to its central role in calcium homeostasis, can regulate (directly or
11 indirectly), multiple signaling pathways involved in cellular proliferation and differentiation,
12 apoptosis, inflammation, invasion, angiogenesis, and metastasis, with the potential to affect cancer
13 proliferation⁴⁸ and invasiveness⁴⁹. The most recognized antineoplastic effect of vitamin D is its
14 ability to inhibit cell proliferation⁵⁰. Besides its antiproliferative effects, vitamin D also regulates
15 inhibiting antiapoptotic proteins (BCL-2 and BCL-XL) and inducing the expression of proapoptotic
16 proteins (BAX, BAK, and BAD), the key mediators of apoptosis⁴⁸. Beyond the importance of vitamin
17 D in inflammatory processes associated with several chronic diseases, including obesity⁵¹⁻⁵³,
18 polycystic ovary syndrome^{54, 55}, and psoriasis⁵⁶, vitamin D's role has been determined in
19 autoimmune and malignant thyroid diseases⁵⁷. Different preclinical studies have shown growth arrest
20 of TC after the administration of pharmacological doses of vitamin D in differentiated TC cell lines

1 in females), suggesting a vital role in maintaining adequate vitamin D levels linked to sun exposure
2
3 61.
4

5 Beyond TC risk, vitamin D also plays an indispensable role in thyroid autoimmunity,
6
7 improving the innate immune response and exerting an inhibitory action on the adaptive immune
8
9 system ⁴⁸. Calcitriol, the activated (or hormonal metabolite of) vitamin D, has been reported to
10
11 modulate the cytokine milieu to a more tolerogenic immune status ⁶². Dutta et al. confirmed that anti-
12
13 thyroid peroxidase antibody positivity is more prevalent in individuals with hypovitaminosis D and
14
15 reported a negative correlation between anti-thyroid peroxidase antibody and serum 25-
16
17 hydroxyvitamin D (25(OH)D). However, despite the large volume of evidence linking vitamin D with
18
19 thyroid autoimmunity and cancer, meaningful clinical studies on the impact of vitamin D
20
21 supplementation are needed ⁶³.
22
23

24 Hashimoto's thyroiditis (HT) and DTC represent the most common autoimmune and
25
26 malignant thyroid disease ⁶⁴, and hypovitaminosis D represents a prevalent risk factor for HT ⁶⁵ and
27
28 DTC ⁶⁶.
29
30

31 Sirtuins are histone deacetylases involved in several metabolic pathways ⁶⁷ and regulate
32
33 posttranslational modification of cellular regulator proteins on the energy status of cell ⁶⁸. Recently,
34
35 Sirtuin 1 has been shown to be regulated by vitamin D by deacetylation of forkhead box protein O3a
36
37 (FOXO3a) ⁶⁹. The latter was reported as an important risk factor for TC ⁷⁰, suggesting a potential key
38
39 role of vitamin D-SIRT1-FOXO3a signaling in immune regulation and TC. Recently, Roehlen et al.
40
41 have genotyped the SNP's FOXO3a in 257 subjects with DTC, 139 individuals with HT compared to
42
43 463 healthy controls ⁶⁴. The authors have found that SNP's of FOXO3a, in particular rs9400239T and
44
45 rs4945816C, independent of vitamin D status, may constitute risk factors for HT, indicating the
46
47 implication of FOXO3a in the pathogenesis of autoimmune thyroid diseases. The study authors
48
49 conclude that, both rs4945816C and FOXO3a rs9400239T may constitute risk factors for TC,
50
51 independent of the vitamin D levels. This underlines the role of FOXO3a in pathogenesis of
52
53 autoimmune thyroid diseases. In addition, these evidence suggest that SIRT1 to be a crucial mediator
54
55

1 of anti-proliferative action and immune regulatory indicating that SIRT-FOXO3a is a downstream
2 targets of vitamin D effects. Of interest, a combination of SIRT1 activators and vitamin D, could be
3 a promising approach for novel anti-proliferative therapies also in TC⁶⁴. Some alterations of genetic
4 variants encode crucial enzymes for the synthesis, metabolism, and degradation (DHCR7
5 rs12785878, CYP2R1 rs2060793, CYP24A1 rs6013897, respectively) of vitamin D, and they have
6 been associated with serum levels of 25(OH)D and on the susceptibility to TC⁷¹. The case-control
7 study done by Carvalho et al. investigated the effect of these variants in the vitamin D pathway and
8 susceptibility to TC in 500 patients with DTC and 500 controls. This study showed the association
9 between DHCR7 rs12785878 and TC, suggesting that DHCR7 polymorphisms due to its effect on
10 circulating 25(OH)D levels, may be associated with an increased risk of TC⁷¹.

11 Remarkably, vitamin D has proven useful also as a prognostic tool for TC, as examined in
12 334 patients the study of Sulibhavi et al.⁷². In this study, 25(OH)D levels showed no significant
13 association with cancer stage, but subjects with hypovitaminosis D were more likely to have advanced
14 disease. This study suggests that hypovitaminosis D may have value as a negative prognostic indicator
15 in papillary TC⁷².

16 Although some studies have shown that higher 25(OH)D levels might protect against TC,
17 other studies do not confirm this association or have even indicated the opposite to be case⁷³. Very
18 recently, in a meta-analysis of 14 articles, Zhao et al. investigated the association between vitamin D
19 deficiency and TC. These metanalysis results have shown that 25(OH)D levels were lower in patients
20 with TC preoperatively than controls, concluding that lower 25(OH)D levels were associated with an
21 increased risk for TC and that hypovitaminosis D may act as a risk factor for TC⁷³. In conclusion,
22 the association between hypovitaminosis D and TC is still controversial.

23 *Fruits and vegetables consumption*

24 Fruits and vegetables intake have been associated with a reduced risk of several tumors in
25 case-control studies, but these relationships become weak or even null in cohort studies^{74, 75}.

1 Nevertheless, the question of the optimal amount and type of fruit and vegetable consumption to
2 reduce cancer risk is still unanswered ⁷⁴. This issue is reflected by the fact that recommendations for
3 dietary consumption vary globally. A weak association between fruit and vegetable consumption or
4 specific subtypes of fruits and vegetables and cancer risk cannot yet be excluded ⁷⁵, but the current
5 evidence is scarce ⁷⁴. Some studies reported inverse associations ⁷⁴⁻⁷⁶, whereas other studies found no
6 clear association ^{74, 77, 78}. However, some of these may have had statistical power too low to detect a
7 modest association.

8
9
10
11
12
13
14
15
16 Fruit and vegetables contain various nutrients and phytochemicals, such as vitamins,
17 antioxidants, flavonoids, and other unidentified compounds. All these nutrients could act alone or in
18 synergy through several biological mechanisms to reduce the cancer risk⁷⁹. In particular, the
19 mechanisms by which fruits and vegetables could reduce the cancer risk are different: neutralization
20 of reactive oxygen species (ROS) and reduce DNA damage through their antioxidants ⁸⁰; detoxifying
21 enzyme action by glucosinolates in cruciferous vegetables ⁸⁴, among others.

22
23
24
25
26
27
28
29 Of interest, fruits and vegetables consumption through its fiber content may modulate the
30 production of short-chain fatty acids (SCFAs) in the gut with a beneficial effect on gut microbiota ⁸²,
31 ⁸³ and steroid hormone concentrations and hormone metabolism ⁸⁰.

32
33
34
35
36 Currently, little is known about the association between fruit and vegetables consumption and
37 TC risk, particularly in prospective studies. Very recently, Zamora-Ros et al., in the EPIC study,
38 evaluated the fruit and vegetable consumption and TC risk in over half a million participants,
39 recruited between 1991 and 2000 with a mean follow-up period of 14 years. This large study did not
40 report a significant association between fruit and vegetable consumption and TC risk ³⁹. Interestingly,
41 the cruciferous vegetables have been studied more closely due to containing glucosinolates, a diet
42 source of thiocyanates and isothiocyanates that act as goitrogens ⁸⁴ promoting TC growth in rats ⁸⁵.
43 Nevertheless, in two recent meta-analyses of retrospective studies, either no relationship or a positive
44 association between cruciferous vegetables consumption and TC risk were evident ^{37, 86}.

Alcohol consumption

Alcohol is another important dietary factor for TC risk. In particular, evidence from several prospective⁸⁷⁻⁸⁹ and case-control studies^{90,91} has reported a protective association between current moderate alcohol consumption and TC risk.

In a recent large study within the EPIC study, Sen et al. investigated baseline and lifetime alcohol consumption and risk of TC among 477,263 subjects (70% women), and 556 (90% women). They observed that moderate alcohol consumption at recruitment was associated with a statistically significant lower risk of TC⁴¹. In particular, compared with participants consuming 15 or more grams (approximately 1-1.5 drinks), subjects consuming 0.1-4.9 g of alcohol per day at recruitment, had a 23% lower risk of TC (HR=0.77; 95% CI=0.60-0.98)⁴¹. In addition, at recruitment non-consumers of alcohol were a similar risk for TC (HR=0.97; 95% CI=0.76-1.25) compared with consumers of 0.1-4.9 g per day. Among consumers for every 10 g of alcohol consumed per day, the risk of TC was lowered by 9% (HR=0.91; 95% CI=0.84-0.98)⁴¹. The potential mechanisms explaining the link between alcohol intake and TC risk are not well known. However, have been proposed different potential explanations for the effect for consumption of alcohol on decreased risk of TC. First, light-to-moderate alcohol intake is correlated with enhanced insulin sensitivity and reduced type 2 diabetes, a known risk factor for increased TC^{92,93}. Second, alcohol consumption is correlated with reduced prevalence of solitary thyroid nodules and goitre⁹⁴, two important risk factors for TC⁹⁵. Third, alcohol consumption have an effect on thyroid volume, thyroid function and the responsiveness of hypothalamic-pituitary-thyroid axis⁹⁵, which consequently lead to the modification of peripheral thyroid hormone concentrations. Of interest, alcohol decreases the thyroid-stimulating hormone (TSH) level since it acts reducing the responsiveness of the hypo-thalamic pituitary-thyroid axis to central stimulation. Nevertheless, the influence is elusive with regarding to the peripheral thyroid hormone concentrations on TC⁹⁵. Fourth, alcohol intake could also potentially influence TC risk by altering sex steroid hormone levels⁹⁵.

1 Nevertheless, the potential effects of alcohol intake on thyroid function should be considered
2
3 speculative as there are many less studied.
4
5

6 7 *Impact of resveratrol* 8

9
10 There is an increasing interest in phytochemical and TC treatment and other types of cancer
11 since there are still limitations for this treatment, such as drug resistance or the unfavourable side
12 effects from some treatment options ⁹⁶. The important anti-inflammatory, anti-oxidative, and anti-
13 proliferative effects found in the phytochemical (chemical substances produced by plants) have
14 allowed them to impact profoundly in decreasing cell proliferation, angiogenesis, and invasiveness
15 ⁹⁷. Resveratrol (3,5,4'-trihydroxy-trans-stilbene) is a phytochemical and a natural stilbenoid with two
16 aromatic rings with a methylene bridge. It can be found in grapes, blueberries, raspberries, red wines,
17 peanuts, pomegranates, and soybeans ^{98,99}.
18
19

20
21 Additionally, it has been shown to be helpful in radioiodine therapy ¹⁰⁰ due to its capacity to
22 protect normal cells from ROS induced cytotoxicity by reducing them through the hydroxyl groups
23 in resveratrol's chemical structure. Two publications highlighted the use of resveratrol as co-
24 treatment with radioactive iodine therapy ¹⁰¹. Moreover, resveratrol has anti-TC activities by
25 regulating TC-specific signaling pathways due to its ROS scavenging effect. Zheng et al.
26 demonstrated that intragastric and intraperitoneal resveratrol administration efficiently reduced the
27 frequency and severity of TC through inhibiting proliferation and suppressing NF-κB mediated
28 inflammatory reaction. ¹⁰².
29
30

31
32 Resveratrol also influences thyroid function by enhancing iodide trapping and increasing TSH
33 secretion via activation of sirtuins and the phosphatidylinositol- 4-phosphate 5 kinase γ (PIP5K γ)
34 pathway, which positively affecting metabolism ¹⁰³. In this context, resveratrol would be favorable in
35 the prevention of TC as it would improve retinoic acid sensitivity, enhance the radiotherapy's
36 efficacy, would induce apoptosis, re-differentiation, and cancer stem cell differentiation. ⁹⁶.

White meat and Red meat

While cooking red meat at a high temperature, carcinogenic compounds such as heterocyclic amines (HCA), polycyclic aromatic hydrocarbons (PAH), N-nitroso compounds, or heme iron are formed¹⁰⁴.

In Wie et al.'s study done among 26,815 participants in cancer screening examinations from September 2004 to December 2008, there were selected 8,024 subjects who completed a self-administered questionnaire. In September 2013, from the National Cancer Registry System, 387 cancer cases were classified, and the remaining individuals were included in the control group. From this study, it was concluded that red meat consumption, sodium intake, and obesity (BMI \geq 25 kg/m²) were positively associated with overall cancer incidence in men (HR 1.41, 95% CI 1.02, 1.94; P= 0.04), gastric cancer (HR 2.34, 95% CI 1.06, 5.19; P= 0.0365) and TC (HR 1.56, 95% CI 1.05, 2.31; P= 0.0270), respectively¹⁰⁵. An increased risk of TC associated with nitrate intake was reported in a cohort study of older women in Iowa. This study was a large prospective cohort of 490,194 men and women, aged 50-71 years, in 1995-1996. A 124-item food frequency questionnaire was used to determine the dietary intakes. During an average of 7 years of follow-up, they identified 370 TC cases (170 men, 200 women) with complete dietary information. Among men, increased nitrate intake was positively associated with TC risk (relative risk [RR] for the highest quintile versus lowest quintile RR = 2.28, 95% CI: 1.29-4.04; p-trend <0.001). However, no trend with intake among women was observed (p-trend = 0.61). Nitrite intake was not associated with TC risk for either men or women¹⁰⁶. A systematic review and meta-analysis published in 2015 concluded that no significant association was observed between nitrate exposure and TC risk, hyper or hypothyroidism. Additional research is needed to clarify the association between nitrate/nitrite exposures and thyroid function and cancer¹⁰⁷. On the other hand, high consumption of fresh fish seemed to have a protective effect against TC (OR=0.6; 95% CI: 0.3–1.0; P-trend <0.05). Nevertheless, when fish products were processed, canned, or frozen, there was a strong positive association with TC (OR=3.0; 95% CI: 1.6–5.3; P-trend <0.01). Among other types of meat, high consumption of chicken (OR=3.0; 95% CI:

1 1.3–6.8; P -trend <0.01) as well as mutton and lamb (OR=1.8; 95% CI: 1.1–2.8; P -trend <0.01)
2
3 showed a positive association with TC³⁴. These studies suggest that several components like red
4
5 meat, canned or frozen fish, high consumption of chicken, and processed meats like sausages, may
6
7 influence TC risk.
8

9 10 11 *Coffee and tea and other drinks*

12
13
14 Coffee and tea are beverages consumed daily worldwide in adults. Both of them are rich
15
16 sources of flavonoids and phenolic acids¹⁰⁸. Polyphenols may play a role in cancer prevention,
17
18 including TC, through the modulation of enzyme activities and signal transduction pathways related
19
20 to cellular proliferation, differentiation, apoptosis, inflammation, angiogenesis, and metastasis^{109,110}.
21
22 There is much for caffeine and theophylline because of their negative and positive effects in
23
24 carcinogenesis¹¹¹.
25

26
27 In the report by Alicandro et al., where they reviewed available evidence on coffee drinking
28
29 and the risk of all cancers updated to May 2016, they concluded that coffee consumption is not
30
31 associated with overall cancer risk¹¹². The EPIC cohort, which included 476,108 adult men and
32
33 women, coffee and tea intakes were assessed through validated country-specific dietary
34
35 questionnaires, and during a mean follow-up of 14 years, 748 DTC cases were identified. Coffee
36
37 consumption (*per* 100 mL/day) was not correlated either with total DTC risk (HR: 1.00, 95% CI 0.97-
38
39 1.04) or with the risk of TC subtypes. Tea consumption (*per* 100 mL/day) was not associated with
40
41 the risk of total DTC (HR: 0.98, 95% CI 0.95-1.02). An inverse association was found with follicular
42
43 tumor risk (HR: 0.90, 95% CI 0.81–0.99), but this association was based on a sub-analysis with a
44
45 small number of cancer cases. In conclusion, in this large prospective study, coffee and tea
46
47 consumption were not associated with TC risk¹¹⁰. Hashibe et al. observed in the PLCO trial a
48
49 decreased risk of endometrial cancer for coffee intake (RR=0.69, 95% CI=0.52-0.91 for ≥ 2 cups *per*
50
51 day), and a decreased risk of cancer overall with tea intake (RR=0.95, 95% CI=0.94-0.96 for 1+ cups
52
53 *per* day vs. <1 cup *per* day). This trial started in 1992 and ended enrollment in 2001. Approximately
54
55

1 155,000 women and men between the ages of 55 and 74 participated in this randomized study ¹¹³.
2
3 Michikawa et al. analyzed data from a prospective cohort of 100,507 individuals, where green tea
4 and coffee consumption were assessed *via* a self-administered questionnaire. During a mean 14.2-
5 year follow-up, they documented 159 TC cases. They inferred that high green tea consumption could
6
7 be associated with premenopausal TC risk but inversely correlated with postmenopausal TC risk ¹¹⁴.
8
9 Finally, Riza et al. reported that drinking herbal teas, especially chamomile ($p<0.001$), protects from
10
11 TC as well as other benign thyroid diseases ¹¹⁵.
12
13
14
15
16
17

18 *Soy Foods*

19
20 They have been considered excellent replacements for dairy products, recognized as sources
21 of high-quality protein and healthful fat and uniquely-rich sources of isoflavones (classified as
22 phytoestrogens and selective estrogen receptor modulators). Soy foods were widely accepted because
23 of the potential effects on health, such as the effectiveness in cardiovascular risk reduction,
24 antioxidative effect of flavonoids may protect from cancer ¹¹⁶, preventive roles in hypertension,
25 hypercholesterolemia ¹¹⁷, body weight loss ¹¹⁸. Nonetheless, there are reports of possible disruption
26 of thyroid function and sexual hormones. A cross-sectional study of 11,688 women aged 30–50 years
27 of North American Adventist church showed that high intake of isoflavones was related to increased
28 risk of nulliparity and null gravity ¹¹⁹. There are also reports of soy products in infant diet before 4
29 months of age and a 25% higher risk of menarche before 12 years of age ¹²⁰. About the thyroid gland
30 disturbance, more long-term epidemiological studies are needed to verify soy-thyroid interaction in
31 real conditions since in clinical trials; isolated isoflavones are used with a wide range of
32 concentrations and heterogenic conditions ¹²¹. In the multiethnic population-based case-control study
33 of TC conducted from the San Francisco Bay Area with 817 cases diagnosed between 1995 and 1998,
34 608 (74%) were examined. Phytoestrogen consumption was determined *via* a food-frequency
35 questionnaire and a newly developed nutrient database. They reported that the consumption of
36 traditional and nontraditional soy-based foods and alfalfa sprouts were associated with a reduced TC

1 risk ¹²². In a recent study by Xiao et al., the association between dietary flavonoid intake and TC risk
2
3 in 491,840 participants was investigated. It was reported that TC risk was not associated with the
4
5 dietary intake of isoflavones ¹²³. After analyzing the results from these few studies carefully, it
6
7 remains inconclusive the potential influence of isoflavones on TC risk.

Mediterranean diet

This dietary pattern is commonly used by people living on the Mediterranean coast¹²⁴. It is characterized by a higher intake of the majority of plant-derived foods, including vegetable and fruits, legumes, whole-grains, and extra virgin olive oil as the only source of fat, moderate alcohol consumption (especially red wine), moderate intake of animal protein (most represented by fish and dairy products), and minimal consumption of meat and highly processed foods¹²⁴. Additionally, it is low in saturated fatty acids and provides high amounts of monounsaturated fatty acids and omega-3 PUFAs, mainly derived from olive oil as alpha-linolenic acid and long-chain PUFAs fish¹²⁵. The foods and beverages of plant origins are widely rich in polyphenols, particularly fruits, vegetables, spices, nuts¹²⁶. The MD's beneficial effects are the high content in antioxidants and anti-inflammatory compounds, including polyphenols, to play a role in preventing cancer^{124, 127} and other diseases such as cardio-metabolic, neurodegenerative disorders¹²⁴, among others. Several evidence show the antitumor effects of natural polyphenols, including anthocyanins from blueberries, epigallocatechin gallate from green tea, and resveratrol from red wine. These functions are associated with cell survival, proliferation, differentiation, migration, angiogenesis, hormone activities, detoxification enzymes, and immune responses. Despite all the existing robust evidence regarding the MD and its advantages, more studies are needed to show a direct causal relationship between this diet and the reduction of TC risk. As reported by the EPIC cohort, which included 476,108 men and women from 10 European countries, no associations between dietary polyphenol consumption and TC risk were demonstrated¹²⁸.

The MD was associated with a lower risk of breast cancer^{129, 130}, gastroenteropancreatic neuroendocrine tumors aggressiveness¹³¹, and other cancers¹³². Nonetheless, only a few studies link dietary patterns to TC^{28, 33, 133}. In a case-control study of 113 subjects, Markaki et al.³³ found that dietary patterns of fruits, raw vegetables, and mixed raw vegetables and fruits were negatively associated with TC (OR=0.68, 0.71, 0.73, respectively).

1 Another study did not report any difference between traditional Polynesian diet (characterized by
2 high consumption of fish, seafood, and fruits) and Western diet (characterized by high consumption
3 of meat and starchy food), in 229 cases of DTC diagnosed, and 371 controls ¹³³. Very recently,
4 Sangsefidi ZS et al., in a case-control study among 309 clinic-based participants in the northeast of
5 Iran, evaluated the role of major dietary patterns on DTC. The only association reported in this study
6 was that the western diet had 2.85 times more chance for DTC (OR=2.85, 95% CI=1.15-7.06) ²⁸.

Dietary indications as medical prescription in the reduction of TC Risk: the point of view of the endocrinological nutritionist

The current state of the dietary recommendations for the prevention of TC remains controversial, as the clinical studies' results are inconsistent. However, based on current scientific evidence, we can give some dietary indications as a medical prescription to reduce TC risk, considering that the choice of food must be made by analysing the presence of beneficial nutrients¹⁹. The principal dietary indications are summarized as follows:

1. Iodine intake and fish: Correction of iodine deficiency has shifted TC subtypes toward less aggressive forms without affecting cancer's overall risk. High iodine intake seems to exert a protective effect against cancer;
2. Fruits and vegetables: They may provide a protective role for combining bioactive components with antioxidant activity, such as selenium and vitamin D, micronutrients, and phytochemicals. Eating 2 servings of fruits and at least 7.5 servings *per day* (600 g/d) of green-yellow and cruciferous vegetables (salads) *per day*;
3. Selenium, vitamin D: Despite the well-known anti-cancer activities and potentials, there is limited evidence on the association between either selenium or vitamin D deficiency and TC, as well as on the clinical usefulness of their supplementation in these patients;
4. Body weight: Obesity is associated with the incidence of various tumors, including DTC. An association between excessive weight and TC risk, with more aggressive behavior, emerges from most of the studies.
5. Alcohol, red meat and dairy: To limit excess consumption of alcohol, meat, and dairy food even if no clear associations were found among the consumption of these foods on TC risk;
6. Don't consume processed food;
7. Don't consume frozen or canned fish or seafood;

1 8. Drink daily chamomile tea and herbal tea to prevent TC;
2

3 9. Adopt healthy lifestyle habits: Exercise 30 minutes daily or 1 hour every 2 days.
4

5 Most of these suggestions are potentially useful also for patients with TC (Table 1)

Conclusion

1
2
3
4
5
6 Interesting associations between single nutrients or food and TC risk have been described.
7
8 Understanding the bidirectional relationships between dietary patterns and TC risk is also essential
9
10 for delineating the risk profile from obesity (**Figure 1**). Adopting a healthy lifestyle and education
11
12 regarding modifiable environmental factors (diet, nutrition, and physical activity) could have
13
14 beneficial effects *per se* on reducing TC risk. For achieving dietary-related goals, the skilled
15
16 Endocrinological Nutritionist should play a central role during the assessment considering dietary
17
18 recommendations as a real medical prescription for the prevention of TC risk. Based on its beneficial
19
20 antioxidants and anti-inflammatories components, the MD could also present health benefits in TC's
21
22 prevention. The advantageous effects of nutritional interventions promoting the Mediterranean food
23
24 pattern could be extended to patients at risk of developing TC. Future well-designed dietary
25
26 intervention trials on larger population samples are needed to define specific dietary guidelines for
27
28 reducing TC risk.

Conflicts of interest. The authors certify that there is no conflict of interest with any financial organization regarding the material discussed in the manuscript.

Funding. This research received no specific grant from any funding agency, commercial or not-for-profit sectors.

Authors' contributions. The authors' responsibilities were as follows: LB and GM: were responsible for the concept of this paper and drafted the manuscript; GP, DR, EFT, DL, WG, AC, and SS: provided a critical review of the paper. All authors contributed to and agreed on the final version of the manuscript.

Acknowledgements. The scientific support from the Panta Rei Impresa Sociale srl (<https://www.panta-rei.eu/pantarei/>) is acknowledged.

Disclosure statement: The authors have nothing to disclose.

Abbreviations.

Abbreviations: Thyroid cancer (**TC**); differentiated thyroid cancer (**DTC**); body mass index (**BMI**); Mediterranean diet (**MD**); Poly-Unsaturated Fatty Acids (**PUFAs**); eicosapentaenoic acid (**EPA**); docosahexaenoic acid (**DHA**); European Prospective Investigation into Cancer and Nutrition (**EPIC**); ultraviolet B (**UVB**); 25-hydroxyvitamin D (**25(OH)D**); Hashimoto's thyroiditis (**HT**); forkhead box protein O3a (**FOXO3a**); reactive oxygen species (**ROS**); short-chain fatty acids (**SCFAs**); thyroid-stimulating hormone (**TSH**); phosphatidylinositol-4-phosphate 5 kinase γ (**PIP5K γ**); heterocyclic amines (**HCA**); polycyclic aromatic hydrocarbons (**PAH**), relative risk (**RR**).

Table 1: Dietary suggestions for a correct lifestyle in thyroid cancer patients

✓ Iodine intake and fish	<ul style="list-style-type: none"> – A correct intake of iodine with the diet plays a protective role in the development of nodules and, therefore, potentially also thyroid carcinomas – High iodine intake seems to exert a protective effect against cancer
✓ Fruits and vegetables	<ul style="list-style-type: none"> – They may provide a protective role for the combination of bioactive components with antioxidant activity – Eat 2 servings of fruits and at least 7.5 servings per day (600 g/d) of green-yellow and cruciferous vegetables (salads) <i>per</i> day
✓ Selenium, vitamin D	<ul style="list-style-type: none"> – There is limited evidence on the association between either selenium or vitamin D deficiency and TC
✓ Obesity	<ul style="list-style-type: none"> – Obesity is associated with the incidence of various tumors, including DTC – Weight loss is recommended for patients with thyroid cancer
✓ Alcohol, red meat, and dairy	<ul style="list-style-type: none"> – No clear associations were found among the consumption of these foods on TC risk – In any case, it is advisable not to exceed with these foods to reduce the risk of obesity.
✓ Adopt healthy lifestyle habits	<ul style="list-style-type: none"> – It is recommended to perform physical exercise 30 minutes daily or 1 hour every 2 days
✓ Nutritional status in patients treated with Tyrosine Kinase Inhibitors (TKI)	<ul style="list-style-type: none"> – A close monitoring and management of weight loss is crucial to avoid withdrawal and to limit the need for dose reduction – Expert nutritionist interventions are needed in patients affected with advanced TC treated with TKI
