ABSTRACT BOOK

ISSN 0390-6078

The abstract book of the 19th Congress of the European Hematology Association is published as a supplement of Haematologica/the Hematology Journal in one volume per year.

All business correspondence and purchase and reprint requests should be addressed either to Haematologica Journal Office, via Giuseppe Belli 4, 27100 Pavia, Italy; phone: +39 0382 27129; fax: +39 0382 394705; e-mail: office@haematologica.org or to the European Hematology Association, Koninginnegracht 12b, 2514 AA The Hague, The Netherlands; phone: +31 (0)70 345 55 63; fax: + 31 (0)70 392 36 63; e-mail: info@ehaweb.org.

The Abstract book is available both at http://www.haematologica.org and http://www.ehaweb.org

Designed to expand your knowledge!

The EHA Learning Center is accessible from your computer and mobile devices. All you need is an internet connection!

The Learning Center is fully linked to the EHA-CME System. Your credit points earned by successfully completing a CME activity, are directly uploaded into your personal CME account.

The EHA Learning Center offers a frame work of tools to deliver a centric learning experience by unifying theory, practice, technology and content.

Over the years, EHA has developed a number of online learning tools to facilitate easier access to knowledge for doctors. As a result, EHA's learning resources expanded into an extensive and user friendly platform.

It provides easy access to different ways of learning. All content on the EHA Learning Center is organized according to the European Hematology Curriculum.

See you soon at the EHA Learning Center!

EUROPEAN
HEMATOLOGY
ASSOCIATION

The European Hematology Association (EHA) promotes excellence in patient care, research and education in hematology.
By organizing an Annual Congress, providing an educational program based on the European Hematology Curriculum, publishing a journal, lobbying for hematology and promoting research, the Association supports hematologists in- and outside Europe to further improve hematology patient care.

Information about all the activities of the Association can be found on the website: ehaweb.org

EUROPEAN
HEMATOLOGY
ASSOCIATION

Raise the voice of European Hematology:

Become a member now!

Reduced fee of € 20 for Junior Members (up to 36 years of age)

Exclusive Membership Benefits are

- Free and unlimited access to EHA Learning Center
- Subscription to Haematologica/The Hematology Journal (impact factor 5.935 – monthly hard copy delivery)
- Eligibility to Career Development Program of EHA
- Eligibility to EHA Congress travel grants
- Discount on EHA Congress registration fee & all other EHA events
- Priority access to webcasts of EHA Congress
- Nomination and voting rights in EHA board member election
- Access to EHA membership directory
- Subscription to EHA newsletter (half-yearly hard copy delivery)
- Subscription to EHA e-bulletin

MILAN
19TH CONGRESS
JUNE 12 - 15 | 2014
European Hematology Association

Word of Welcome

On behalf of the EHA Board and the Scientific Program Committee we are pleased to present the Abstract Book of the 19th Congress of EHA.

The Scientific Program Committee has compiled an exciting and topical program of Simultaneous and Poster Sessions from over 2,300 submitted abstracts. Join our expert moderators for a walk along the (e)posters in your field of interest on Friday and Saturday and attend one of the 40 Simultaneous Sessions on Saturday and Sunday. The six Best Abstracts have been selected for presentation during the Presidential Symposium on Saturday afternoon.

In addition, please find at the end of the book also the late breaking abstracts that were submitted, reviewed and selected in April. The Scientific Program Committee is very excited about the quality of the studies represented in these abstracts and feels that they are a nice addition to the program. The eight selected oral presentations will be presented on Saturday in two Late Breaking Simultaneous Sessions. Furthermore, eleven posters are available for viewing in the Poster Area and will be presented on Saturday as well.

On behalf of the EHA Board, the committees and all the people involved in this years' EHA congress, we thank you for coming to Milan and wish you a good meeting.

Pieter Sonneveld
Chair Scientific Program Committee

haematologica
Journal of the European Hematology Association
Owned & published by the Ferrata Storti Foundation

Information for readers, authors and subscribers

Haematologica/The Hematology Journal (print edition, pISSN 0390-6078, eISSN 1592-8721) publishes peer-reviewed papers on all areas of experimental and clinical hematology. The journal is owned by a non-profit organization, the Ferrata Storti Foundation, and serves the scientific community strictly following the World Association of Medical Editors (WAME) recommendations on publication ethics policies for medical journals (www.wame.org/pubethicrecom. htm).

Haematologica/The Hematology Journal publishes editorials, perspectives, research papers, decision making & problem solving papers, review articles, brief reports and scientific letters. Manuscripts should be prepared according to the Uniform Requirements for Manuscripts Submitted to Biomedical Journals, prepared by the International Committee of Medical Journal Editors (ICMJE) and fully available online (http://www.icmje.org). Additional papers may be considered for the purely online journal (Haematologica/The Hematology Journal on Internet, eISSN 1592-8721). Because there are no space constraints online, Haematologica/The Hematology Journal will publish several items deemed by peer review to be scientifically sound and mainly useful as educational papers. These will include case reports, irreplaceable images, educational material from scientific meetings, meeting abstracts, and letters to the Editor.

Papers should be submitted online at http://www.haematologica.org/.

Conflict of interests. According to the International Committee of Medical Journal Editors (http://www.icmje.org/#conflicts), "Public trust in the peer review process and the credibility of published articles depend in part on how well conflict of interest is handled during writing, peer review, and editorial decision making". The ad hoc journal's policy is reported in detail online (http://www.haematologica.org/misc/about.dtl).

Galley Proofs and Reprints. Galley proofs should be corrected and returned by email, fax or express delivery within 48 hours. Minor corrections or reasonable additions are permitted; however, excessive alterations will require editorial re-evaluation and will be possibly charged to the authors. Papers accepted for publication will be printed without cost. The cost of printing color figures will be communicated upon request. Reprints may be ordered at cost by returning the appropriate form sent by the Publisher.

Transfer of Copyright and Permission to Reproduce Parts of Published Papers. Authors will grant copyright of their articles to the Ferrata Storti Foundation. No formal permission will be required to reproduce parts (tables or illustrations) of published papers, provided the source is quoted appropriately and reproduction has no commercial intent. Reproductions with commercial intent will require written permission and payment of royalties.

Detailed information about subscriptions is available online at URL http://www.haematologica.org. While access to the online journal is free, online access to some additional items available on http://www.haematologica.org may require either institutional or personal subscription.

Rates of the International edition for the year 2014 are as following:

	Institutional	*Personal*
Print edition (including full access to the online CME for personal subscribers)	*Euro 500*	*Euro 150*
Full access to the online CME only		*Euro 75*

To subscribe to the International edition, please visit our web site http://www.haematologica.org/misc/subscribe.dtl or contact: Haematologica Office, via Giuseppe Belli 4, 27100 Pavia, Italy (phone +39.0382.27129, fax +39.0382.394705, E-mail: office@haematologica.org).

Advertisements. Contact the Advertising Manager, Haematologica Office, via Giuseppe Belli 4, 27100 Pavia, Italy (phone +39.0382.27129, fax +39.0382.394705, e-mail: info@haematologica.org).

Disclaimer. Whilst every effort is made by the publishers and the editorial board to see that no inaccurate or misleading data, opinion or statement appears in this journal, they wish to make it clear that the data and opinions appearing in the articles or advertisements herein are the responsibility of the contributor or advisor concerned. Accordingly, the publisher, the editorial board and their respective employees, officers and agents accept no liability whatsoever for the consequences of any inaccurate or misleading data, opinion or statement. Whilst all due care is taken to ensure that drug doses and other quantities are presented accurately, readers are advised that new methods and techniques involving drug usage, and described within this journal, should only be followed in conjunction with the drug manufacturer's own published literature.

Direttore responsabile: Prof. Edoardo Ascari; Autorizzazione del Tribunale di Pavia n. 63 del 5 marzo 1955.

haematologica
the hematology journal

The origin of a name that reflects Europe's cultural roots.

Ancient Greek

αἷμα [haima] = blood
αἵματος [haimatos] = of blood
λόγος [logos]= reasoning

Scientific Latin

haematologicus (adjective) = related to blood

Scientific Latin

haematologica (adjective, plural and neuter, used as a noun) = hematological subjects

Modern English

the hematology journal
2012 JCR® Impact Factor = 5.935

Haematologica/The Hematology Journal, as the official organ of the European Hematology Association (EHA), aims not only to serve the scientific community, but also to promote European cultural identity.

POSTER SESSION I

Acute lymphoblastic leukemia - Biology 1

P100

NOVEL STAT5B MUTATIONS AS DRIVERS OF T-CELL ACUTE LYMPHO BLASTIC LEUKEMIA

Background: T-cell acute lymphoblastic leukemia (T-ALL) is caused by the cooperation of multiple oncogenic lesions. Recent evidence supports that IL-7 and its receptor IL-7R contribute to T-ALL development (Zenatti *et al.*, 2011). The two main pathways induced by IL-7R are JAK/STAT5 and PI3K/AKT/MTOR. Activating mutations to *IL7R*, *JAK1, JAK2* or *JAK3* are estimated to occur in 20-30% of all T-ALL patients (Cools 2013). STAT5 plays an important role in many hematologic malignancies but constitutive STAT5 activation often is a secondary event. Mutations in *STAT5B* (N642H) were recently described in LGL-leukemia in patients with an unusually aggressive and fatal form of the disease (Rajala *et al.*, 2013). Here we report novel activating *STAT5B* mutations as drivers of T-ALL.
Aims: The aim for the study is to determine the prevalence and functional effects of *STAT5B* mutations in T-ALL.
Results: Sequencing of a relapsed T-ALL index patient revealed 3 different somatic missense mutations in *STAT5B* (T648S, N642H, I704L). To investigate the prevalence of these mutations in T-ALL we used targeted next generation sequencing (MiSeq, Illumina) to sequence the SH2 dimerization and the transactivation domains of *STAT5B* from 68 T-ALL patients. In this validation cohort we detected *STAT5B* mutations in 5 additional patients, all of which occurred in the SH2 domain. One patient had a Y665F mutation whereas 4 patients had N642H mutation. Altogether 6 of 68 patients in the cohort had *STAT5B* mutations. To investigate the effect on transcriptional activity and phosphorylation of *STAT5B* mutations identified in the index patient (*i.e.* N642H, T648S, I704L), the mutant and wild type (WT) *STAT5B* constructs were transiently transfected into HeLa cells together with a STAT5 specific luciferase reporter plasmid. Western blot analysis showed that the N642H induced strong constitutive phosphorylation of STAT5B, while the I704L mutation induced phosphorylation to a lesser extent. Compared to WT *STAT5B* the N642H and I704L mutants increased transcriptional activity by 26- and 17-fold, respectively, however the T648S mutation had no effect. Using *ex vivo* drug testing the *STAT5B* mutated blasts were resistant (EC50 >=1 uM) to inhibitors of PI3K (*e.g.* idelalisib, XL147), dual inhibitors of PI3K/MTOR (PF-04691502, dactolisib) and MTOR inhibitors (temsirolimus, everolimus). Furthermore the blasts showed no response to AKT1 inhibitors (MK-2220) or JAK inhibitors (ruxolitinb, tofacitinib). In contrast, the cells were most sensitive to the pan-BCL-2 inhibitor navitoclax (EC50 82 nM). To assess the expression of BCL-2 family members (BCL-2, BCL-XL, BCL-XS and MCL1) in *STAT5B* mutated blasts from the index patient qRT-PCR was performed. RNA from the peripheral blood CD3-positive fraction of a healthy donor and the mononuclear BM fraction from two T-ALL patients with no *STAT5B* mutations served as controls. While BCL-2 and MCL1 expression were similar across all samples, BCL-XL expression was higher in the *STAT5B* mutated blasts compared to controls by 12- and 4-fold in the diagnostic and relapse sample, respectively.
Summary and Conclusions: *STAT5B* mutations are recurrent (8.8%) in T-ALL and their occurrence underlines the significance of the IL7R-JAK-STAT5 pathway in the pathogenesis of T-ALL. These mutations are activating and thus likely oncogenic. Our results suggest that BCL-XL inhibition is cytotoxic to *STAT5B* mutated T-ALL blasts, and therefore therapies targeting specifically BCL-2 may be ineffective.

P101

PHF6 LOSS DRIVES IL7R ONCOGENE ADDICTION IN T-ALL

K Durinck[1,*] P Rondou[1], I Van de Walle[2], C De Bock[3,4], N Van Roy[1], Y Benoît[5], B Poppe[1], T Taghon[2], J Soulier[6], J Cools[3,4], P Van Vlierberghe[1], F Speleman[1]
[1]Center for Medical Genetics, Ghent University, [2]Department of Clinical Chemistry, Microbiology and Immunology, Ghent University Hospital, Ghent, [3]Center for Human Genetics, KU Leuven, [4]Center for the Biology of Disease, VIB Leuven, Leuven, [5]Department of Pediatric Hemato-Oncology, Ghent University Hospital, Ghent, Belgium, [6]APHP Hematology Laboratory, Hôpital Saint Louis, Paris, France

Background: T-cell acute lymphoblastic leukemia (T-ALL) is a genetically heterogeneous disease. Genetic subgroups are marked by overexpression of particular driver oncogenes that disrupt normal thymocyte differentiation, while other lesions occur across different genetic subtypes and impact on proliferation, self-renewal and survival. In this latter group, the *PHF6* gene is frequently targeted by loss-of-function mutations or deletions, with the highest prevalence in *TLX1* or *TLX3* rearranged T-ALLs. Further insights into the tumor suppressor role of PHF6 will contribute to the deciphering of the complex rewiring of the cellular program of normal thymocytes during malignant transformation and will serve as a prelude to a rational design for targeted therapy.
Aims: Gain insight in the role of PHF6 through transcriptome analysis following modulation of *PHF6* expression in precursor T-cells and T-ALL lymphoblasts and functionally validate relevant candidate PHF6 target genes both *in vitro* and *in vivo*.
Methods: Transcriptome wide perturbation effects were measured following PHF6 knock down in the *PHF6* wild-type T-ALL cell lines Jurkat, ALL-SIL and MOHITO (mouse) and will be evaluated upon PHF6 reconstitution in *PHF6* deficient T-ALL cell lines HPB-ALL and DND-41. In parallel, gene expression profiles were established from cord blood $CD34^+$ progenitor T-cells, cultured for short-term on an OP9-DL1 feeder layer, with stable knockdown of PHF6. Murine bone marrow transplant assays were performed to assess the effects of PHF6 deficiency *in vivo*. In addition, a large primary cohort of T-ALL patients was screened for the association between *PHF6* mutations and other genetic defects.
Results: Modulation of *PHF6* expression induced robust transcriptional regulatory effects of PHF6 on *IL7R* expression. *IL7R* encodes a cytokine receptor critically involved in normal T-cell development and acts as a bona fide oncogene in subsets of T-ALLs. Using the IL7-dependent MOHITO mouse T-ALL cell line, we show that IL7 stimulation induced prolonged and enhanced induction of the IL7R downstream mediators (pJAK1, pJAK3 and pSTAT5) in *PHF6* knock down cells as compared to *PHF6* expressing controls, suggesting a functional PHF6-IL7R-JAK-STAT pathway in murine T-ALL. Furthermore, genomic analysis of an extend series of primary T-ALL samples unraveled a significant association between *PHF6* and *JAK3* mutations in T-ALL patients. To further explore the molecular basis for TLX1-PHF6 interaction, we looked into the TLX1 driven transcriptome and observed suppression of *IL7R* expression. In view of these findings, we hypothesize that loss of PHF6 rescues immature TLX1 overexpressing thymocytes from reduced IL7R-dependent survival/proliferative signals, thus providing an essential cooperative event in TLX1 driven leukemogenesis. Given the almost exclusive occurrence of *PHF6* mutations in T-ALL, we assumed a specific function for PHF6 in normal T-cell development. Indeed, stable PHF6 knock down in immature human thymocytes demonstrated strong effects on normal differentiation in the OP9 culture system in keeping with a context dependent regulatory role for PHF6 in T-cell development.
Summary and Conclusions: Our data provide fundamental novel insights into the role of PHF6 in T-cell development and transformation. We demonstrate a crucial role for PHF6-controlled IL7R expression, the latter which is down-regulated in TLX1 overexpressing T-ALLs, thus suggesting an essential cooperative role for PHF6 during TLX1 driven T-ALL development. These novel observations mark the IL7R-JAK-STAT signaling pathway as an important entry point for further therapeutic intervention in TLX1 driven leukemias.

P102

LEAFING THROUGH THE GENOME OF B-LINEAGE ACUTE LYMPHOBLASTIC LEUKEMIA BY NEXT-GENERATION SEQUENCING TECHNOLOGIES

M Messina[1,*] S Chiaretti[1], J Wang[2], V Gianfelici[1], F Brugnoletti[1], AL Fedullo[1], A Piciocchi[3], AD Negulici[1], L Pasqualucci[4], AM Testi[1], A Vitale[1], A Guarini[1], R Rabadan[2], R Foà[1]

[1]Department of Cellular Biotechnologies and Hematology, Sapienza University, Rome, Italy, [2]Department of Systems Biology, Biomedical Informatics and Center for Computational Biology and Bioinformatics, Columbia University, New York, United States, [3]GIMEMA Data Center, Rome, Italy, [4]Institute for Cancer Genetics and the Herbert Irving Comprehensive Cancer Center, Columbia University, New York, United States

Background: The molecular characterization of B-lineage acute lymphoblastic leukemia ALL (B-ALL) currently relies on the identification of recurrent structural rearrangements (*ETV6-RUNX1*, *TCF3-PBX1*, *BCR-ABL1*, *MLL* rearrangements) - with a diverse distribution and impact on outcome between children and adults. However, many of these alterations alone do not induce leukemia in experimental models. Furthermore, a considerable proportion of patients lack recurrent chromosomal alterations, thus suggesting that additional submicroscopic lesions could have a role in leukemogenesis.
Aims: 1) To describe the molecular landscape of "genetically unclassified" B-ALL patients; 2) to evaluate the association between specific alterations, affecting one gene or gene category, and age-cohorts; 3) to assess the "targettability" of the mutated genes and the suitability of genetically-driven therapies.
Methods: The genome of 15 B-ALL patients (and their paired normal DNA, Discovery panel) without any major chromosomal abnormality and belonging to different age cohorts, namely children (2-15 years), adolescents/young adults (AYA, 16-40 years) and adults (>40 years) was analyzed by whole-exome sequencing (WES, Agilent SureSelect Human All Exon 50Mb, Illumina HiSeq 2000). WES was then broadened to 72 additional B-ALL cases (Screening panel 1) and we focused on the genes resulted from the Discovery panel and on known driver genes. We then selected the genes recurrently mutated for a further screening by conventional Sanger sequencing (ABI PRISM 3100 Genetic Analyzer, Applied Biosystems), or targeted amplicon sequencing (Genome Sequencer Junior, 454 Life Sciences, Roche) of the Screening panel 2 (N=66). Overall, 29 children, 72 AYA and 52 adults were included in the study.
Results: WES of the Discovery panel highlighted 139 non-silent mutations (9.3/sample) affecting 135 genes mainly involved in RAS signal transduction, transcription and chromatin remodeling, regulation of cell proliferation, as well as genes encoding for tyrosine kinases. Indeed, Screening 1 and 2 revealed that the RAS pathway is frequently altered in this B-ALL subgroup, with 25% of cases being affected. *FLT3* was mutated in 9% of cases with the mutations being mainly represented by internal tandem duplications (36%) and affecting the tyrosine kinase domain in 28% of cases. More importantly, *FLT3* mutations clustered in adults (13%) and AYA (8%), while only 3% of children displayed *FLT3* mutations. *KRAS* and *NRAS* were mutated in 8.5 and 9% of cases, respectively, with the mutations targeting almost exclusively the G12/G13 hotspot. Moreover, we found a trend to accumulate in childhood. The screening of the genes associated to a high-risk phenotype showed that *JAK2* and *IL7R* are mutated in 4% of cases. Notably, among the B-lineage specific genes, we detected *PAX5* mutations in 13% of patients with an incidence increasing with age. Interestingly, besides the well-known P80R we observed other 2 hotspots: G30 and S55.
Summary and Conclusions: By next-generation sequencing, we have shed light on the genome of "genetically unclassified" B-ALL. This approach showed that this subgroup is characterized by 9 mutations/sample and a considerable heterogeneity of mutations distribution across different age cohorts. This pattern of lesions might sustain a diverse outcome between children and adults, and prompt the development of therapeutic strategies targeted according to the differential recurrence of the above reported alterations.

P103

IMPACT OF VIRUSES ON THE PATHOGENESIS OF SPORADIC CHILDHOOD ACUTE LYMPHOBLASTIC LEUKEMIA: INTEGRATION AND PRESENCE OF 25.525 VIRAL GENOMES TESTED BY NEXT GENERATION SEQUENCING

U Fischer[1,*] C Bartenhagen[2], K Korn[3], M Gombert[1], C Chen[1], V Okpanyi[1], P Husemann[1], C Eckert[4], A Ensser[3], M Dugas[2], A Borkhardt[1]
[1]Department of Pediatric Oncology, Hematology and Clinical Immunology, University Children's Hospital, Medical Faculty, Heinrich Heine University Duesseldorf, Duesseldorf, [2]Institute of Medical Informatics, University of Muenster, Muenster, [3]Institute for Clinical and Molecular Virology, University Hospital, Friedrich Alexander University of Erlangen-Nuremberg, Erlangen, [4]Department of Pediatrics, Division of Oncology and Hematology, Charité Berlin, Berlin, Germany

Background: The incidence of childhood acute lymphoblastic leukemia (ALL) is rising steadily. Accumulating epidemiologic evidence suggests that viral infections early in life account for this increase. The putative infectious agent is still unknown. Theoretically, transforming viruses may integrate into the genome of precursor B-cells, disturbing differentiation and proliferation control. Alternatively, common pathogens may act indirectly, eliciting an abnormal immunological response resulting in autonomous precursor B-cell proliferation.
Aims: Previous attempts to identify a candidate virus by low-throughput techniques were unsuccessful due to detection limits: 95% probability to detect viral genomes >9 kb present in at least one copy per cell was achieved. But the smallest virus genomes are about 3 kb, and many oncogenic viruses are smaller than 9 kb. We aimed at developing a next generation sequencing based, bioinformatics pipeline for the detection of known and novel viruses in childhood ALL.
Methods: Whole-genome sequencing of leukemic and remission bone marrow from 15 children with precursor B cell ALL was performed. Data sets of five healthy probands derived from the 1000 genomes database (www.1000genomes.org) were used as controls. Paired-end sequences were aligned against the human reference genome (GRCh37.55) employing BWA. Aligment was repeated with all unmapped reads with higher sensitivity and mapping concordance ≥85% using Bowtie2. Remaining unmapped reads were aligned against 25,525 viral reference genomes (Genome Information Broker for Viruses database, GIB) allowing multiple matches. Repeat sequences and regions of high homology with the human reference were filtered. Paired-end reads of both human and viral sequence were considered for breakpoint detection of viral integration. Viruses with at least two single-end alignments or one spanning read were chosen for manual inspection and validation.
Results: *In silico* simulations showed that a typical virus genome (≥2 kb) and viral integration sites are detected with >99.9% probability within ≥100 million sequencing reads by the developed bioinformatics pipeline. 442 million sequencing reads were generated per sample on average. About 10% could not be mapped to the human reference and thus potentially encoded viral sequences. Few viruses were detected in healthy controls: Herpesviridae (EBV, n=5, HHV-7, n=3) and Adenoviridae (ADV, n=2). In the patient samples, viral DNA corresponding to common human pathogens (Anelloviridae, Herpesviridae, and Parvoviridae) was detected in 11 cases. No evidence was found for the presence of other human or non-human DNA viruses.
Likely due to contaminated blood transfusions the incidence of the Anelloviridae TTV and TTMDV increased from two cases at diagnosis to six in remission. At diagnosis six patients were positive for at least one other virus. EBV (n=3), VZV (n=1), and HHV-7 (n=3) were detected. In four relapse samples EBV (n=3), HHV-7 (n=3), and HHV-6 (n=1) were identified. None of the patients of whom both diagnosis and relapse samples were available (n=8) showed persistence of a virus.
Most viruses detected at remission were not found in leukemic samples of the same patient: HSV (1/1), VZV (1/1), CMV (2/2), EBV (0/1), HHV-6 (2/2), HHV-7 (2/6), Parvovirus B19 (1/1), TTV (4/5), TTMDV (1/2). EBV was detected in leukemic cells of six out of 15 patients, but only in one corresponding remission sample.
Summary and Conclusions: Our analyses suggest that the sought-after virus(es) could be very common ones provoking an exceptional immunological response of the B-cell compartment in genetically and immunologically susceptible children.

P104

THE FIRST LNCRNA LANDSCAPE OF MAJOR GENETIC T-ALL SUBSETS AND GUILT-BY-ASSOCIATION ANALYSIS FOR ETP-ALL SPECIFIC LNCRNAS

A Wallaert[1,*] K Durinck[1], W Vanloocke[1], PJ Volders[1], I Vandewalle[2], Y Benoit[1], B Poppe[1], P Mestdagh[1], J Vandesompele[1], T Taghon[2], J Soulier[3], J Cools[4], P Rondou[1], P Van Vlierberghe[1], F Speleman[1]
[1]Center for Medical Genetics, [2]Department of Clinical Chemistry, Microbiology and Immunology, Ghent University, Ghent, Belgium, [3]Hôpital Saint Louis, Institut Universitaire d'Hématologie, Paris, France, [4]Center for Human Genetics, KULeuven, Leuven, Belgium

Background: T-cell acute lymphoblastic leukemia (T-ALL) is a hematologic cancer caused by uncontrolled proliferation of immature thymocytes that arrested during differentiation. T-ALL can be classified into molecular genetic subgroups that are defined by overexpression of transcription factor oncogenes including *LYL1*, *TLX1*, *TLX3*, *TAL1*/*LMO2* or *HOXA*. The *LYL1*$^+$ T-ALL subtype characteristically shows an immature immunophenotype and is closely related to the recently identified poor prognostic T-ALL subtypes including early T-cell precursor ALL (ETP-ALL) or early immature T-ALL.
Aims: Long noncoding RNAs are emerging as important players in cancer development. In order to assess the possible role of lncRNAs in T-ALL, we aimed to perform lncRNA expression profiling in primary T-ALL samples, T-ALL cell lines and normal immature thymocytes to define whether a specific lncRNA expression landscape is linked to particular T-ALL subgroups and driver genes.
Methods: We analyzed a clinically and genetically annotated cohort of 64 T-ALL samples (including 15 immature, 17 TLX and 25 TAL-rearranged T-ALL patients), 7 T-ALL cell lines and sorted subsets of immature thymocytes from four healthy donors using an in house developed Agilent platform covering all protein coding genes and 12,000 previously annotated lncRNAs. This dataset was further expanded by RNA-sequencing data from an independent cohort of 31 T-ALLs (Atak *et al.*, PLoS Genetics, 2013).
Results: First, we validated our datasets by demonstrating similar clustering of major genetic subsets based on the expression pattern of protein coding genes. Next, we searched for subgroup specific lncRNA expression signatures in T-ALL. Each of the genetic subgroups was characterized by a distinct subset of differentially expressed lncRNAs, including 461 TLX1-specific, 1494 TAL1-specific and 1448 immature-specific lncRNAs ($p < 0.05$, corrected for

multiple testing). Using the top 50 most differentially expressed lncRNAs for each subgroup, individual patients could be assigned to their appropriate molecular genetic T-ALL subtype (Pearson clustering). Given their proposed association with poor clinical outcome, we further focused on the early immature T-ALL subtype and looked for putative functionally relevant lncRNAs in this genetic subgroup. To this end, a guilt-by-association was performed for the top 10 most differentially expressed known lncRNAs derived from the Agilent platform and an additional top 10 expressed previously unannotated lncRNAs identified through RNA-seq analysis. Of further interest, several immature T-ALL specific lncRNAs were located in the immediate vicinity of important protein coding genes implicated in early haematopoiesis and leukemia such as *MYB*, *RUNX2* and *MEF2C*. Further analyses of selected immature T-ALL associated lncRNAs also showed strong differential expression between $CD34^+CD4^-CD8^-$ *versus* $CD4^+CD8^+$ double positive thymocytes, pointing at important roles for these lncRNAs in normal differentiation. Finally, we selected several top candidate ETP-ALL specific lncRNAs for further functional analyses in order to unravel their exact role in early haematopoiesis and malignant T cell transformation as a prelude for possible lncRNA oriented molecular therapy in immature T-ALL.
Summary and Conclusions: This is the first comprehensive analysis of lncRNA expression in primary T-ALL samples and their normal thymic counterparts. Our finding that lncRNA expression patterns follow the previously established genetic classification is of importance as it marks functional relevance for lncRNAs in T-ALL development.

P105

PTEN MICRO-DELETIONS IN T-CELL ACUTE LYMPHOBLASTIC LEUKEMIA ARE CAUSED BY ILLEGITIMATE RAG-MEDIATED RECOMBINATION EVENTS

R Mendes[1,*] L Sarmento[2], K Canté-Barrett[1], J Buijs-Gladdines[1], V Povoa[2], W Smits[1], A Yunes[3], R Pieters[1,4], J Barata[2], J Meijerink[1]
[1]Department of Pediatric Oncology/Hematology, Erasmus MC Rotterdam-Sophia Children's Hospital, Rotterdam, Netherlands, [2]Instituto de Medicina Molecular, Faculdade de Medicina da Universidade de Lisboa, Lisboa, Portugal, [3]Centro Infantil Boldrini, Sao Paulo, Brazil, [4]Prinses Maxima Center, Utrecht, Netherlands

Background: T-cell acute lymphoblastic leukemia (T-ALL) is characterized by distinct chromosomal abnormalities and mutations. The Phosphatidylinositol 3-kinase (PI3K) signal transduction pathway is often aberrantly activated in various cancers. The main negative regulator of PI3K activity is the phosphatase and tensin homolog (PTEN) tumor suppressor gene. In T-ALL, *PTEN* is inactivated by point-, frameshift insertion/deletion mutations and entire locus deletions. For some seemingly *PTEN* wild-type or monoallelic mutated T-ALL patients that lack total PTEN protein, the mutational mechanisms remain unclear.
Aims: Our goal is therefore to investigate copy-number variations among *PTEN* exons and to detect potential additional *PTEN* deletions.
Results: Here, we show that *PTEN* can be inactivated by micro-deletions spanning introns 1-3 or introns 3-5 in 8% of pediatric T-ALL patients. These micro-deletions were clonal in 5 out of 146 patients, whereas in 8 patients they were present at the sub-clonal level and only detected through PCR techniques. Specific sequences flanking these deletions together with insertion of random nucleotides between the breakpoints pointed to illegitimate RAG-mediated activity. The cryptic RAG recombination signal sequences (cRSS) that flanked the breakpoints drive RAG-dependent recombination in an *in vitro* reporter system as efficiently as established RSSs from TCR gene segments. Similar to other PTEN-inactivating events, *PTEN* micro-deletions are strongly associated with the TALLMO T-ALL cluster, characterized by TAL1 or LMO2 chromosomal rearrangements. As these leukemias frequently display rearranged αβ T-cell receptors at a maturation stage with ongoing RAG activity, our results imply that the TALLMO subgroup has an increased chance of acquiring *PTEN* micro-deletions. Notably, primary and secondary xenotransplants of human *TAL1*-rearranged T-ALL cells in NSG-mice displayed sub-clonal *PTEN* micro-deletions, and we identified equivalent micro-deletions in thymocytes of healthy individuals.
Summary and Conclusions: We propose that *PTEN* micro-deletions result from ongoing RAG activity that is perpetuated during the leukemogenic process, thereby contributing to clonal diversification and disease progression.

P106

CMYC-TRANSLOCATIONS IN T-CELL ACUTE LYMPHOBLASTIC LEUKEMIA

R La Starza[1,*] C Borga[2], G Barba[1], C Schwab[3], V Pierini[1], A Lema Fernandez[1], A Leszl[2], G Sammarelli[4], E Rossetti[4], G Cazzaniga[5], S Chiaretti[6], C Morerio[7], C Matteucci[1], C Harrison[3], G te Kronnie[2], C Mecucci[1]
[1]Hematology and Bone Marrow Transplantation Unit, University of Perugia, Perugia, [2]Oncohematology, Department of Women's and Children's Health, University of Padova, Padova, Italy, [3]Leukaemia Research Cytogenetics Group, Northern Institute for Cancer Research, Newcastle University, Newcastle-upon-Tyne, United Kingdom, [4]Hematology and Bone Marrow Transplantation Unit, University of Parma, Parma, [5]Centro Ricerca Tettamanti, Pediatric Clinic, University of Milano-Bicocca, Monza, [6]Hematology, Department of Cellular Biotechnologies and Hematology, Sapienza University, Roma, [7]Laboratorio di Citogenetica Ematoncologica, Istituto di Ricovero e Cura a Carattere Scientifico Istituto G Gaslini, Genova, Italy

Background: *CMYC* is a transcription factor which regulates critical cell functions such as metabolism, proliferation, and survival. In T-ALL high *CMYC* expression is mainly caused by activation of *NOTCH1* and post-transcriptional mechanisms mediated by *PTEN*.
Aims: To delineate the genetic profile and clinical-hematological features of human T-ALL with *CMYC*-translocations.
Methods: We investigated 62 adults and 132 children belonging to the AIEOP, GIMEMA, and UK clinical trials. *CMYC* was studied by LSI MYC Dual Color, Break Apart Rearrangement Probe (Vysis-Abbott) and homegrown G248P8135G5, RP11-367L7 and RP11-26E5 clones. Affymetrix HU133 Plus 2.0 arrays were used for whole transcriptome profiling (GEP) and Cytoscan HD Platform for SNPa. CI-FISH was performed as described (La Starza R, Leuk Res 2013). *NOTCH1*, *FBW7*, and *PTEN* were analysed by DHPLC (Transgenomic) and sequencing (AB3500 Genetic Analyzer).
Results: CI-FISH and/or predictive analysis by microarray classified 155 cases into 5 distinct molecular subtypes, *i.e. TAL/LMO* (56), *HOXA* (48), *TLX3* (31), *TLX1* (15), and *NKX2-1* (5). *CMYC* reciprocal translocations were detected in 12 cases and involved *TCR* loci in 6 cases while remained undetermined in the other 6. FISH showed that the 8q24 breakpoints clustered at the telomeric region of *CMYC* in all cases with *TCR* translocations, while in 3/6 non-*TC*R translocations breakpoints fell upstream (1 case) or within (2 cases) fosmid G248P8135G5. As type B abnormalities, *CMYC*-translocations occurred in all cases in association with other changes (range: 1-10 additional abnormalities). Association with the TAL/LMO subgroup was significant (Pearson Chi-square, P=0,018). Frequent concurrent rearrangements were *CDKN2A/B* deletions (58,3%) and *PTEN* deletion and/or mutation (41,6%). *NOTCH1* and *FBXW7* mutations were found in a single case. In accordance with their secondary nature, *CMYC*-translocations were found in variable sized subclones (range: 8-62%) in 6 cases, suggesting a contribution to disease progression rather than to disease initiation. Notably, *CMYC*-positive clones appeared to be treatment-resistant. In one case, paired diagnosis/relapse samples showed an increase in size of the CMYC clone from 8% to 100%, whereas other abnormalities $ETV6^{del}$, $BCL1B^{del}$, and $WT1^{del}$ disappeared. In a second case, backtracking to initial diagnosis did not show the *CMYC*-translocation that at relapse was present in 60% of cells. Within the *TAL/LMO* subgroup, 7 translocated *CMYC* specimens with available material for GEP showed high *CMYC* expression in the fourth quartile. Interestingly, in the same quartile, *CMYC* translocated cases showed significantly upregulated *CD44* expression and absence of activated *NOTCH1* signaling compared to cases without these translocations.
Summary and Conclusions: *CMYC*-translocations occurred in about 6% of *NOTCH1* independent T-ALL with marked leukocytosis (>50.000/mmc in 90%; >100.000/mmc in 60% of cases) and a cortical/mature differentiation arrest (60% of cases). *CMYC*-translocations clustered in *TAL/LMO* positive T-ALL with co-occurrence of poor prognostic markers, such as high *CD44* expression and *PTEN* inactivation. Our findings recapitulate murine models in which c-Myc had a crucial role on maintenance and self-renewal of leukemia-initiating cells resulting into resistance to chemotherapy and disease relapse. Early identification (and eradication) of small *CMYC*-positive subclones not only at diagnosis but also during treatment might be helpful to prevent disease progression.

P107

REVEALING EXPRESSION, POST-TRANSLATIONAL MODIFICATIONS AND PROTEOLYSIS IN CHILDHOOD ACUTE LEUKEMIA USING A NOVEL FLOW CYTOMETRY-BASED METHOD OF AFFINITY PROTEOMICS

D Kuzilkova[1,*] V Kanderova[1], J Stuchly[1], K Fiser[1], W Wu[2], A Holm[2], O Hrusak[1], F Lund-Johansen[2], T Kalina[1]
[1]CLIP-Cytometry, Dpt. of Pediatric Haematology and Oncology, 2nd School of Medicine, Charles University and University Hospital Motol, Prague, Czech Republic, [2]Dpt. of Immunology, Rikshospitalet University Hospital, Oslo, Norway

Background: Acute leukemia (AL) is the most common childhood malignancy. It is driven by a number of aberrations detectable at the DNA and mRNA level, but the functional consequences of these alterations at the cellular level are not fully understood. Proteins are the entities that form connection between gene expression and cellular response. Therefore, more effective and sensitive approaches to detect changes in proteome are needed. In the present study we develop and validate new affinity proteomics based tool for analysis of clinical samples.
Aims: Using Size-exclusion Chromatography - Microsphere-based Affinity Proteomics (SEC-MAP) we are able to resolve expression and activation (*e.g.* phosphorylation) of proteins in AL cells.
Methods: SEC-MAP array is a set of 1728 populations of fluorescently-labeled latex microbeads each carrying an antibody against a human protein. We isolate the cellular proteins from membranes, nuclei and cytoplasm using detergents, label them with biotin and separate them using gel chromatography into 24 fractions. These fractions are incubated with SEC-MAP microbeads and the

antibody-protein binding is detected using fluorescently-labeled streptavidin by flow cytometry.
Results: We have compared the data collected by SEC-MAP array in leukemic cell lines (n=11) and healthy peripheral blood B-cells, T-cells and monocytes with classical flow cytometry-based immunophenotyping. Thirty-four markers for leukemia classification correlated qualitatively within both methods. Next, we evaluated leukemia classification markers in bone marrow or peripheral blood from fifty-seven patients with leukemia at diagnosis. We were able to correctly classify all patients' samples to myelo-, B- and T-cell origin using SEC-MAP technology. We have further examined the expression of 499 proteins in 69 diagnostic samples of AL. The analysis was performed using in-house automatic software created in R-project. For the normalization of protein expression we have used loess normalization commonly used in mRNA profiling studies. Due to ability of SEC-MAP to separate proteins according to their size we have not only quantified the expression of proteins but also evaluated proteins' size that could serve as a sign of proteolysis. We have detected signs of proteolysis in twelve samples (based on *e.g.* cleaved PARP1, BLNK and BAD). These samples were therefore excluded from the final analyses. Moreover we have evaluated the sensitivity to proteolysis of four commonly used house-keeping proteins (β-actin, β2-microglobulin, AKT1 and ABL1). ABL1 and AKT1 were cleaved while β-actin and β2-microglobulin were not detected in their cleaved forms in the proteolytically degraded diagnostic samples. Therefore we propose to use ABL1 and AKT1 as house-keeping proteins whenever proteolysis has to be excluded. So far we have identified 44 proteins (*e.g.* SH2D1A, TCF7, GLUD1, TCF3, CD72) differentially expressed in different subtypes of AL and validated their expression with different methods (*e.g.* flow cytometry, western blot, real-time quantitative PCR).
Summary and Conclusions: In summary, SEC-MAP is a high-content method of functional proteomics that combines the capacity of DNA microarray and high-throughput evaluation by flow cytometry. It can detect changes in expression, post-translational modification and subcellular localization of hundreds of proteins in relatively small-size sample (only 10 million cells needed).

RNA-SEQ ANALYSIS TO DISSECT THE BIOLOGY OF EARLY RESPONSE TO TREATMENT IN HIGH RISK *VS.* STANDARD RISK CHILDHOOD BCP-ALL PATIENTS

G Fazio[1,*] M Severgnini[2], I Cifola[2], S Bungaro[1], A Biondi[1], G De Bellis[2], G Cazzaniga[1]
[1]Pediatric Clinic, University of Milan-Bicocca, Tettamanti Research Center, Monza, [2]Institute for Biomedical Technologies (ITB), National Research Council (CNR), Segrate, Italy

Background: Acute Lymphoblastic Leukemia (ALL) is the most frequent type of childhood leukemia. It is a multi-step complex process, characterized by the expansion of a pre-leukemic clone after a variable latency time, accumulating cooperative genetic events required for the full transformation and clinical manifestation. Recently, the technological advances for genome-wide profiling have allowed both a better understanding of the molecular basis and heterogeneity of pediatric ALL, and a more precise definition of risk factors. However, incidence and cure rates differ among children, reflecting a diverse response to drug treatment and defining low-risk and high-risk patients. The comprehension of the leukemia biology, as well as the risk prediction, could be enhanced by investigations that address the individual differences.
Aims: The aim is to apply a whole-transcriptome sequencing approach (RNA-Seq) to characterize and compare low- *versus* high-risk patients to identify new genetic explanations for their different early response to therapy, as reflected by the minimal residual disease (MRD) monitoring; moreover, we focused on the identification of novel pre-leukemic and leukemogenic events.
Methods: Total RNA was extracted from primary leukemic blast samples of 10 pediatric ALL patients, included in the Italian AIEOP-BFM ALL2000 protocol. Genome-wide DNA profiling was performed by Affymetrix whole-genome 2.7M arrays. RNA-Seq experiments were carried out by using an Illumina GAIIx platform. Different strategies, such as RT-PCR and/or FISH analyses, were employed for validation.
Results: We analyzed the transcriptome of 10 childhood ALL cases (4 low- and 6 high-risk patients, according to MRD classification), not carrying any other clinical or genetic risk factor. For each case, we identified the already known and novel transcripts, single-nucleotide variants, alternative splicing events and related expression levels. Priority was given to putative fusion transcripts, which could originate from intra- or inter-chromosomal structural rearrangements. We identified 67 fusion events. Strikingly 60 out of 67 events were identified as intra-chromosomal fusions, and 59/60 were involving two contiguous genes or whose gene loci were even overlapping (the so-called "con-joined genes", CGs). These new fusion transcripts are being validated, in the same patient cohort. Furthermore, among the intra-chromosomal fusions, the NUP214-ABL1 fusion was identified in one high-risk patient. This event is noteworthy, since it was previously known as involved mainly in T-ALL and to be responsive to kinase inhibitors, and was found here in a high risk B-cell phenotype leukemia. Moreover, among the seven putative inter-chromosomal fusions, the novel PAX5-POM121C fusion was identified in one low-risk patient (and confirmed by RT-PCR and Sanger sequencing on an independent primary sample).
Summary and Conclusions: RNA-Seq represents one of the most suitable and comprehensive approaches to identify the genetic alterations harbored by leukemia clones. Our analyses detected highly recurrent novel fusion genes, originated either by classical inter-chromosomal or by intra-chromosomal rearrangements (recently defined as con-joined genes). Further evaluations will address SNPs, mutations, changes in expression profiles and alternative splicing events that could be related to a different associated risk of relapse and the feasibility of a screening of the candidates on a large population of consecutive cases.

P109

DARATUMUMAB TREATMENT ALONE OR IN COMBINATION WITH VINCRISTINE RESULTS IN THE INHIBITION OF TUMOR GROWTH AND LONG TERM SURVIVAL IN PRECLINICAL MODELS OF ACUTE LYMPHOCYTIC LEUKEMIA

P Doshi[1,*] A K Sasser[2], A Axel[2], J Lammerts van Bueren[3]
[1]Oncology Translational Medicine and Early Development, [2]Oncology Biomarkers, Janssen R&D, Spring House, United States, [3]Genmab B.V., Utrecht, Netherlands

Background: Daratumumab is a human antibody that binds to CD38 on the cell surface and induces cell killing by multiple mechanisms including complement mediated cytotoxicity (CDC), antibody-dependent cellular cytotoxicity (ADCC), antibody-dependent cell phagocytosis (ADCP) and apoptosis.
Aims: Efficacy of daratumumab as an anti-tumor therapy was evaluated in 9 ALL tumor cell lines *in vitro* and in *in vivo* tumor models.
Methods: The expression of CD38, CD 46, CD55 and CD59 on tumor cell lines was determined using flow cytometry. ADCC assays were carried out using tumor cell lines as target cells and human PBMC as effector cells in a ratio of 50:1. CDC assays were carried out using human serum at 10%. For *in vivo* model, NALM-6 ALL cells were injected intravenously via the tail vein in SCID mice and the animals were treated with daratumumab alone (10 mg/kg QWx5), vincristine (0.5 mg/kg QWx5) alone or in combination. For patient-derived ALL models, tumor cells were injected intravenously and the dosing was initiated when tumor burden in the peripheral blood was no more than 10%. The animals were treated with daratumumab alone (10 mg/kg QWx3) or a non-specific control antibody. Tumor growth in the blood was monitored as circulating CD45+ cells by flow cytometry.
Results: Evaluation of the expression of CD38 in 9 ALL cell lines suggested that CD38 expression varied among different cell lines but the majority (88%, n=8/9) had >1000 CD38 receptors per cell. Treatment with vincristine did not modulate CD38 expression. Daratumumab induced apoptosis in 5 out of 9 (55%) cell lines in the presence of a cross-linking agent and <20% apoptosis was observed in 4 cell lines with or without cross-linker. Interestingly, in tumor cell killing assays, daratumumab induced minimal ADCC (5-20%) and low levels of (2-5%) CDC mediated cell killing. In addition, no direct correlation was observed between CD38 expression and the extent of ADCC and CDC. The levels of complement inhibitory proteins (CIP) (CD46, CD55 and CD59) were evaluated to determine if these proteins affected CDC in response to daratumumab but no direct correlation was observed between CDC and CIP expression. In patient-derived $CD38^+$/$BCR\text{-}ABL^+$ B-ALL-7015 model, daratumumab treatment resulted in significant tumor growth inhibition $p<0.001$) by day 22 compared to the control antibody. In $CD38^+$/$BCR\text{-}ABL^-$ T-ALL-7473 model, treatment with daratumumab resulted in significant tumor growth inhibition by day 7 ($p<0.05$) but the animals developed disease by day 14 and were sacrificed on day 21. In NALM-6 cell line-based model, treatment with daratumumab either alone or in combination with vincristine showed significant prolongation of survival. The animals in the control group died by day 22 and the animals in vincristine group died by day 43, however, 80-100% of the animals in daratumumab alone or in combination with vincristine survived beyond day 88.
Summary and Conclusions: These data suggest that daratumumab inhibits growth of ALL tumors that express high levels of CD38 and may offer therapeutic benefit in the clinical setting of ALL.

P110

EVALUATION OF TP53 MUTATIONS IN ACUTE LYMPHOBLASTIC LEUKEMIA (ALL): RESULTS FROM IRON (INTERLABORATORY ROBUSTNESS OF NEXT-GENERATION SEQUENCING) II STUDY

Background: Acute lymphoblastic leukemia (ALL) is a heterogeneous disease that affects children and adults, with a different incidence and outcome. While there is a great knowledge of recurrent molecular aberrations (*i.e. BCR/ABL1*, *MLL* rearrangements, *E2A/PBX1*, *ETV6/RUNX1* in B-lineage ALL, *NOTCH1* and *FWB71* in T-lineage ALL), *TP53* mutations have not been widely investigated until recently; even at present, its evaluation was carried out in relatively small cohorts of patients, and in children at recurrence of disease.
Aims: Within the IRON (Interlaboratory RObustness of Next-generation sequencing) II study, 949 ALL samples were evaluated for *TP53* mutations to establish their incidence at diagnosis and relapse in both adults and children, and to correlate their presence with molecular and immunophenotypic subtypes.
Methods: Ten centers worldwide participated to the study. To identify *TP53* mutations, the 454 Life Sciences, a Roche company GS Junior system was used. A custom assay plate was designed to screen exons 4 to 11. This 96-well plate allowed studying eleven samples simultaneously, through the use of Multiplex Identifier (MID) sequences that identify each sample. For analysis, Quality Control (QC) analysis excluded samples with a coverage less than 80 reads in forward and reverse directions. The variant analysis was performed centrally, using Amplicon Variant Analyzer (AVA-Roche 454) and Sequence Pilot (JSI Medical Systems) software. A cut-off ³ 2% was applied to define variants. The *TP53* at ENSG00000141510 was used as reference sequence.
Results: A total of 877 samples were evaluable for variant analysis: 307 were pediatric and 558 adult; for 12 cases age was not available. The pediatric cohort was composed of 44 T-ALL and 263 B-ALL: B-ALL cases included 16 *BCR/ABL1+*, 13 *MLL* rearranged, 13 *E2A/PBX1+*, 43 *ETV6/RUNX1+* and 175 negative for the above aberrations. The adult cohort included 117 T-ALL and 441 B-ALL, the latter group thus subdivided: 126 *BCR/ABL1+*, 43 *MLL* rearranged, 9 *E2A/PBX1+*, 244 negative for recurrent fusion genes. Molecular characterization was not available for a total of 22 cases.
In 95 samples variants were identified, of which 64 were deleterious mutations: 40 missense (42.1%), 3 nonsense and 3 splice variants -all known IARC mutations- and 11 indels plus 7 frameshift (18.9%), not reported in any database; mutations affected mostly exons 5 (26.6%) and 8 (29.7%).
Overall, 664 patients were exclusively analyzed at diagnosis and 144 at relapse; 69 matched copies at diagnosis and relapses were analyzed. *TP53* mutations were observed at similar rate in B- and T-ALL 4.23% and 4.7% respectively.
Focusing on B-ALL subgroups evaluated exclusively at diagnosis, mutations were detected in 0.9% *BCR/ABL1+*, 7.5% *MLL* rearranged, 5.5% *E2A/PBX1+,* 3.3% *ETV6/RUNX1+*, 4.5% in molecularly negative cases; this latter subgroup was further evaluated for hypodiploidy and mutations were detected in 20% of cases. In B-ALL, comparison between diagnosis and relapse showed an increase of *TP53* mutation rate in both children (2.3% *vs* 8.3%, p=0.031) and adults (5.1% *vs* 11.5%, p=0.059). A similar trend was observed in T-ALL.
Summary and Conclusions: *TP53* mutations affect B- and T-ALL and their incidence does not significantly differ between children and adults. Within B-ALL molecular subsets, they were more recurrent in *MLL* rearranged, *E2A/PBX1+* and molecularly negative cases. An association with hypodiploidy is confirmed. Finally, a significantly increased incidence of *TP53* mutations at relapse is observed for both cohorts. Correlation with outcome is warranted.

P111

INVESTIGATION OF PH-LIKE ALL BY GENE SET ENRICHMENT ANALYSIS AND IDENTIFICATION OF THEIR SPECIFIC EXPRESSION GENES

Background: Recently, "Ph-like" or "*BCR-ABL1*-like" acute lymphoblastic leukemia (ALL) has been proposed as a subset of B-cell precursor (BCP-) ALL with unfavorable outcome. Although Ph-like ALL lacks *BCR-ABL1* as well as other well-known fusion transcripts, they exhibit a gene expression profile of *BCR-ABL1*-positive ALL-like signature. Since some of Ph-like ALL possess tyrosine kinase (TK)-related fusion transcript and have sensitivity for tyrosine kinase inhibitor, it is important to distinguish Ph-like ALL from other fusion gene-negative BCP-ALLs. The diagnosis of Ph-like ALL is essentially performed by clustering analysis based on gene expression data of a group of patients using Affymetrix GeneChip®, diagnostic method applicable to individual patient using other microarray system is strongly desired. Therefore, we have developed methods to diagnose Ph-like ALL using Gene Set Enrichment Analysis (GSEA). As we presented previously, GSEA and clustering analysis identified distinct subsets of BCP-ALL with approximately 40% overlapping, whereas GSEA can also detect a group with poor prognosis including tyrosine kinase-related fusion transcript-positive cases (ASH 2013).
Aims: In this study, we intended to Ph-like ALL by GSEA based on gene expression data using different microarray system. Furthermore, we also investigated Ph-like ALL specific expression genes to develop alternative diagnostic method for Ph-like ALL.
Methods: Gene expression of 152 BCP-ALL cases enrolled on Tokyo Children Cancer Study Group (TCCSG) trials, including TCCSG L07-1602 and L09-1603, were analyzed by microarray Agilent Whole Human Genome DNA Microarray 4x44K v2, respectively. Based on these expression data, Ph-like ALL were investigated using GSEA, a computational method that ascertains whether a given gene set is significantly enriched in a list of genes ranked by their correlation with a phenotype of interest. The specific expression genes of Ph-like ALL, as well as Ph1 ALL, were investigated by fold-change analysis using GeneSpring GX software (Agilent).
Results: 10 cases (6.6%) of Ph-like ALL were identified in 152 cases of BCP-ALL by GSEA. They included the cases with Ph-like-related fusion transcripts, such as *P2RY8-CRLF2*, *IGH@-CRLF2*, *SNX2-ABL1*, *EBF1-PDGFRB*, as well as *ATF7IP-PDGFRB*, a novel fusion transcript involving *PDGFRB*. Some of them revealed early relapses. Next, genes specifically expressed in Ph-like and Ph1 ALL were explored. In similar to Ph1-ALL, high expression of *GPR110*, *MUC4*, *SEMA6A*, *GREM1*, *IL2RA* and *BAALC*, and low expression of *RICS*, *SOX11*, *RGS1*, *RGS13*, *BCL2L11*, *NR4A1*, *NR4A3* and *BTG3* were observed in Ph-like ALL. Interestingly, high-expression of *CRLF2* and *LDB3*, and low expression of *ABCC4* and *CCNA1* were observed only in Ph-like ALL cases.
Summary and Conclusions: We presented that GSEA can identify Ph-like ALL cases expressing uncommon TK-related fusion transcripts with poor prognosis. Since GSEA is applicable to identification of Ph-like ALL from individual patient based on the gene expression data using other microarray system than GeneChip®, it should be more practical for clinical use. We also identified specific genes expressed in Ph-like ALL cases and the development of method to distinguish Ph-like ALL from other BCP-ALL based on expression of these genes is now underway.

P112

ROLE OF THE HYSTONE DEACETYLASE INHIBITOR GIVINOSTAT (ITF2357) IN TREATMENT OF CRLF2 REARRANGED ACUTE LYMPHOBLASTIC LEUKEMIA

AM Savino[1,*] C Palmi[1], G Fazio[1], M Bardini[1], F Rizzo[1], V Cazzaniga[1], C Bugarin[1], G Fossati[2], A Biondi[1], G Cazzaniga[1]
[1]Pediatric Department, Tettamanti Research Center, University of Milano-Bicocca, San Gerardo Hospital, Monza, [2]Italfarmaco S.p.a, Cinisello Balsamo (MI), Italy

Background: Novel genomic abnormalities of the *CRLF2* and *JAK2* genes have been recently reported in a subset of childhood ALL patients without known chromosomal aberrations, leading to the deregulation of the CRLF2 cytokine receptor pathway and associated to a poor prognosis. Inhibition of CRLF2/JAK2 signalling has the potential to become a therapeutic intervention for this subgroup of patients. In addition to the use of JAK2 inhibitors, numerous reports indicate that a broader antitumor activity is necessary to effectively treat tumor cells with aberrant JAK2 signalling. Alterations of epigenetic programmes is a common feature of tumor cells and novel therapies involving HDAC inhibition have been employed to treat different kind of neoplasms due to the key involvement of acetylation in the regulation of transcription and a number of signal transduction pathways. Previous studies have shown that the HDAC inhibitor Givinostat/ITF2357 has potent anti-tumor activity against hematological malignancies, including myeloproliferative neoplasms (MPN) carrying the JAK2V617F mutation. Indeed, the molecule is currently being evaluated in a phase1/2 study in patients with polycytemia vera.
Aims: In 10% of pediatric high-risk ALL and about 20% in Down Syndrome ALL patients, *JAK2* mutations are characterized by a specific and frequent R683G mutation. Interestingly R683 and V617, commonly mutated in MPN, are located in the same JAK2 pseudokinase domain. This opens the possibility that givinostat could have an inhibitory activity also on ALL blasts positive for JAK2 mutations and on ALL with disregulation of JAK/STAT pathway independently of JAK2 mutations.
Results: Here we demonstrate that givinostat at low concentrations inhibits proliferation and induces apoptosis in human B cell precursor leukaemia MHH-

CALL4 and MUTZ 5 cell lines positive for JAK2 mutations (R683G and I682F respectively) and *CRLF2* rearrangements. Givinostat inhibited proliferation with IC50 between 0.08-0.17 uM and induced apoptosis with IC50 between 0.17-0.25 uM. We investigated by RQ-PCR the expression of some target genes of the JAK-STAT pathway and B cells development. At 100-200 nM, Givinostat downregulated of the expression of *JAK2*, STAT5A and its target cMyc together with CRLF2 and IL7 receptor genes. Key factors of B cell development (EBF1, PAX5, IKZF1, E2A) were also downmodulated. The phosphorilation of target proteins downstream to CRLF2-mediated JAK-STAT pathway were assayed by phosphoflow analysis. Givinostat inhibited the phoshorilation of Stat5 both at a basal level and after stimulation with the CRLF2 ligand TSLP. These analysis were also performed on blasts from different BCP-ALL patients. Thus, cells from secondary xenograft with wt Jak2 and overexpressing CRLF2 due to P2RY8-CRLF2 fusion, were used. A low concentration (200 nM) of Givinostat inhibited proliferation and induced cell death of blasts at a three-fold greater rate than vehicle. Moreover, Givinostat inhibited Stat5 phosphorylation induced by TSLP stimulation. Downmodulation of basal level of genes of the JAK/STAT pathway was confirmed in these cells.

Summary and Conclusions: Altogheter, our data indicate that Givinostat inhibits the proliferation and induces apoptosis of ALL CRLF2 positive cells bearing or not JAK2 mutations through a specific downmodulation of the genes involved in JAK/STAT pathway and inhibition of their downstream effector molecules. Studies on xenograft models of BCP-ALL leukemia in NOD/SCID mouse are in progress.

TELOMERE DNA CONTENT AND TP53 STATE PROVIDE AN INSIGHT INTO GENOMIC INSTABILITY IN OLDER ADULT PATIENTS WITH ALL

G Zakout[1,*] L Rai-Shetty[1], AV Moorman[2], AK Fielding[1]
[1]Hematology, Cancer Institute, University College London, [2]Leukaemia Research Cytogenetics Group, Northern Institute for Cancer Research, Newcastle University, London, United Kingdom

Background: Genetic abnormalities in acute lymphoblastic leukemia (ALL) are a major contributing factor to age-related inferior outcomes. Unfavorable genetic anomalies - especially low hypodiploid/near triploid and complex karyotypes - rise with increasing age. Telomere shortening is a hallmark of aging. Telomere attrition results from critical telomere shortening, which -in the absence of TP53 - generates end-to-end chromosome fusion, causing genomic instability. Previous studies assessing cancer genome telomere DNA content in epithelial tumors revealed a significant association between cancer genome telomere gain (relative to matched non tumor sample)and frequency of structural variations/mutations characteristic of genomic instability. We hypothesized that older adult patients with ALL would exhibit leukemic telomere changes which could confer genomic instability and may account for poor risk genetics.

Aims: To evaluate the genetic landscape of patients aged ≥60 with *de novo* ALL by assessing cytogenetics, TP53 status and copy number alterations (CNA) of key ALL genes IKZF1, CDKN2A/B, PAX5, EBF1, ETV6, BTG1, RB1 and the PAR1 region (CSF2RA, IL3RA, CRLF2 and P2RY8) at diagnosis. To assess the relationship between genetics and leukemic telomere DNA content.

Methods: Genomic DNA from diagnostic samples of 52 patients aged ≥60 enrolled in the prospective UKALL14, UKALL60+ and MRD feasibility trials was assessed for CNA using Multiplex Ligation Probe Amplification (MLPA) p335-B1 kit. Relative telomere length was quantified using monochrome multiplex quantitative PCR (qPCR) (Cawthon 2009) in diagnostic and matched remission DNA (N=22). Relative Telomere/Single copy gene (β globin) ratio generated for each leukemic DNA sample was compared to that generated for matched remission DNA and expressed as a log2 ratio. Telomere gain was defined as log2 ratio >0 and loss as <0. TP53 was assessed by fluorescent *in situ* hybridization for deletions and direct sequencing of hot spots exons 5-8 for mutations (N=34). Minimal residual disease (MRD) was assessed by immunoglobulin gene/T cell receptor rearrangement or BCR-ABL qPCR.

Results: Patient characteristics are shown in the Table 1. Fourteen of 52 patients (27%) and 12 of 33 (36%) Philadelphia negative patients had ≥4 genetic anomalies by MLPA, significantly higher than the 3% seen in a younger cohort from the UKALLXII/ECOG2993 trial. The median number of CNA was 2 (range 0-7). Ten had TP53 deletions and/or mutations (del±mut). Eight of 22 patients (36%) had telomere gain. Those with telomere gain had significantly more CNA (p<0.01); median 4 (range 2-7) compared to 1 (range 0-2) in those with telomere loss (p<0.01). Of the 22 patients where telomere state was evaluated, cytogenetic data was available in 20. Patients with telomere gain were more likely to have low hypodiploid/near triploid or complex karyotype (5/7) and those with telomere loss were more likely to have t(4;11), t(9;22) or standard risk cytogenetics (12/13); p<0.01. Six of 8 patients with telomere gain had TP53 del±mut *versus* 2 of 12 with loss (p=0.01). There was no association between MRD state post induction and CNA frequency or telomere state. Paired diagnostic/relapse DNA samples were available in two patients. In both cases, relapse DNA showed telomere gain relative to the diagnostic DNA and had new CNA and/or cytogenetic anomalies.

Table 1. Patient characteristics.

Summary and Conclusions: The prevalence of genetic anomalies in our older cohort was strikingly higher than that of a published younger cohort. Of note, the pattern of telomere DNA alteration in the older adult ALL was similar to that reported in solid tumors. There was a significant association between telomere gain and both CNA frequency and nonreciprocal translocations. The prevalence of TP53 del±mut in those with telomere gain supports previous observations that unchecked telomere dysfunction plays a role in genomic instability. This could account for the poor risk genetic abnormalities characteristic of ALL in older adult patients. However leukemic telomere gain could be a response to rather than the cause of a genetic crisis caused by constitutional telomere attrition. A potential causal relationship will be explored in future mechanistic studies.

P114

FUNCTIONAL STUDIES OF IK6 EXPRESSION SHED LIGHT ON THE COOPERATING MECHANISMS UNDERLYING THE GAIN OF MALIGNANCY IN B-CELL ACUTE LYMPHOBLASTIC LEUKAEMIA

N Zareian[1,*] B Patel[1], G Zakout[1], A Dey[1], AZ Castleton[1], L Rai-Shetty[1], A Moorman[2], AK Fielding[1]
[1]Haematology, University College London (UCL), London, [2]Northern Institute of Cancer Research, Newcastle, United Kingdom

Background: Alterations of the transcription factor *IKZF1* gene occur in approximately 70% of *BCR-ABL1* and 29% of *BCR-ABL1*-negative ALLs. Deletion of exons 4-7 is the most common alteration, resulting in the expression of dominant negative cytoplasmic isoform, Ik6. We found *IKZF1*Δ4-7 in 45% of *BCR-ABL1*-negative ALL by a sensitive (10^{-4}) PCR method in 161 consecutive 25-59 year olds enrolled on UKALL14; approximately double the reported incidence. *IKZF1*Δ4-7 was typically subclonal with <0.01% of cells bearing *IKZF1*Δ 4-7 in the subclonal cases, compared to in >90% of cells in cases where *IKZF1* was part of the major clone. Analysis of paired relapse samples from 14 diagnostic cases with *IKZF*1Δ4-7 showed patterns discrepant in both directions, as well as concordant suggesting that the gain of malignancy conferred by *IKZF1* lesions must be context dependent.

Aims: We aimed to study the context and mechanisms by which *IK6* expression contributes to enhanced leukaemogenesis and to determine cooperating lesions.

Methods: Three (two *BCR-ABL1* neg, NALM-6 and REH and one *BCR-ABL1* pos, SD-1) *IKZF1* wild-type pre-B ALL cell lines were evaluated by MLPA (P335-100R). We over-expressed dominant negative isoform, *IK6*, by retroviral transduction with MSCV-IK6-IRES-mRFP (kindly provided by Charles Mullighan). Cells were flow-sorted to >95% purity by monomer-red fluorescent protein expression. mRFP alone vector-transduced cells were the control. We evaluated drug sensitivity to vincristine, daunorubicin and cyatarabine, cell prolifer-

ation kinetics (MTS assay) and DNA double strand break (DSB) repair following exposure to γ irradiation by confocal microscopy for antiphosphorylated H2AX. Data are from 3 independent experiments.
Results: MLPA confirmed the *IKZF1* wild type status of all cell lines prior to manipulation. SD-1 showed no other genetic abnormalities. Nalm-6 (near diploid karyotype) and REH (ETV6-RUNX1 positive) both showed homozygous deletion of *CDKN2A* and *CDKN2B* and duplication of *PAX-5* exon 10. REH also showed deletion of *ETV-6* and *BTG-1*. The doubling time of SD-1/IK6 was significantly greater than that of SD-1/mRFP, 14.5 *vs* 28.3 hrs (p=0.042), whereas there was no significant difference in doubling times in either of the *BCR/ABL1* neg cell line pairs. SD-1/IK6 cells were significantly less sensitive than SD-1/mRFP to all the drugs tested, at all the 3 concentrations tested (p values<0.05). By contrast, there was no difference in drug sensitivity between Nalm-6/IK6 and REH/IK6 and their control counterparts. The Figure 1 shows sensitivity to daunorubicin as an example. SD-1/IK6 showed significantly less DSB repair after γ irradiation than SD-1/mRFP at each of the time-points tested (20min (p=0.031), 3hrs (p=0.043), 5hrs (p=0.042), and 24hrs (p=0.014)). By contrast there was no difference in DSB repair in either of the *BCRABL-1* negative cell line pairs.

Figure 1.

Summary and Conclusions: Our data show that overexpression of *IK6* in a B-precursor ALL cell lines conferred a higher growth rate, drug resistance and compromised DNA DSB repair when *BCRABL1* was present. None of these changes occurred in the two *BCR-ABL1* negative cell lines studied, despite the presence of other potential cooperating lesions. Our data suggest a starting point and a model for further exploration of the link between *IKZF1* mutations and *BCR-ABL1* pos ALL and work is ongoing. By contrast, the poor risk phenotype conferred by IK6 expression in *BCR-ABL1* neg ALL cannot be modeled or elucidated further by this dataset suggesting that alternative co-operations to those revealed by MLPA analysis are in operation.

P115

ETV6-RUNX1 DE-REGULATES THE CYTOSKELETON AND MIGRATION PROPERTIES OF B CELL PROGENITOR CELLS

C Palmi[1,*] G Fazio[1], AM Savino[1], J Procter[2], L Howell[2], G Longinotti[1], I Brunati[1], V Andrè[1], V Cazzaniga[1], P Della Mina[3], A Villa[3], M Greaves[2], A Biondi[1], G D'Amico[1], A Ford[2], G Cazzaniga[1]
[1]Centro Ricerca Tettamanti, Università di Milano-Bicocca, Monza, Italy, [2]Haemato-Oncology Research Unit, Division of Molecular Pathology, The Institute of Cancer Research, Sutton, United Kingdom, [3]Microscopy and Image Analysis Consortium, Università di Milano-Bicocca, Monza, Italy

Background: Although ETV6-RUNX1 fusion is a frequent initiating event in childhood leukemia, its role in leukemogenesis is still unknown. The main impact of the fusion itself is to generate and sustain a clone of clinically silent pre-leukemic B cell progenitor (BCP) cells. Second hits, occurring even several years later, are required for overt disease. The understanding of the features and interactions of ETV6-RUNX1 positive cells during this "latency" period might help explaining how they can persist, and whether they could be prone to additional genetic changes. In particular, the site of localization and interaction with the microenvironment is crucial to sustain the hematopoietic stem cells in quiescence and the survival of both normal and pre-leukemic cells.
Aims: The aim of this work was to investigate whether the ETV6-RUNX1 pre-leukemic clone showed alterations in its adhesive and migratory properties that could provide a rationale for its persistence and proliferation.
Methods: We have employed two different model systems to study the ETV6-RUNX1 pre-leukemic phase. Indeed, this type of study is not feasible in clinical samples at diagnosis of leukemia, where the analysis of the fusion function is confounded by the additional genetic abnormalities. We have therefore used a murine progenitor cell line (Ba/F3), with hormone inducible ETV6-RUNX1 expression and we confirmed our results in pre-BI cells, primary cells derived from a wild-type mouse fetal liver.
Results: We observed that the expression of ETV6-RUNX1 in Ba/F3 cell line resulted in changes in the cellular morphology and phenotype: several molecules involved in cell adhesion were deregulated in expression and we observed an increase in the adhesion of ETV6-RUNX1 positive cells to murine endothelial cell lines. We showed that the expression of the fusion in Ba/F3 cell line caused alteration in the expression of genes regulating cell shape, formation of pseudopodia, cell migration, actin and microtubule organization. In particular, among the most over-expressed genes in ETV6-RUNX1 positive cells, we identified two negative regulators of CDC42. Consistently, we observed a reduction of CDC42 at the transcription and protein level. CDC42 not only has a pivotal role in cell cycle progression, but also in cytoskeleton rearrangement during directional migration. In parallel, we investigated the migration abilities of ETV6-RUNX1 inducible Ba/F3 cells. Interestingly, we found that the fusion gene significantly impaired the chemotactic response to CXCL12, although the cell-surface expression of the receptor CXCR4 was unaffected. Indeed, the CXCL12 chemotaxis defect was not due to a general impairment of movement of ETV6-RUNX1 positive cells, as their spontaneous motility and migration towards a general stimulus was instead increased. We then excluded a possible role in this migration defect of several players of CXCL12/CXCR4 pathway, including CXCR7, FLT3L receptor, CCL2/CCR2 and EGF/EGFR axes. We were able to demonstrate that ETV6-RUNX1 impairs the calcium flux, a very proximal CXCR4 signaling event, and the phosphorylation of ERK kinase, as a downstream event. Importantly, the results observed in the Ba/F3 ETV6-RUNX1 inducible expression system were reproducible in primary pre-BI cells.
Summary and Conclusions: The abnormalities described here could alter the interaction of ETV6-RUNX1 pre-leukemic BCP cells with the microenvironment and contribute to the pathogenesis of the disease, with potential implications to develop strategies for effective eradication of leukemia.

P116

ECTOPIC EXPRESSION OF THE HEDGEHOG PATHWAY LIGANDS SHH AND IHH IN T-CELL ACUTE LYMPHOBLASTIC LEUKEMIA (T-ALL)

A Dagklis[1,2,*] D Pauwels[3], I Lahortiga[1,2], S Degryse[1,2], K Jacobs[1,2], N Mentens[1,2], E Radaelli[2], J Cools[1,2]
[1]Center for Human Genetics, KULeuven, [2]VIB Center for the Biology of Disease, VIB KULeuven Belgium, [3]Thrombogenics, Leuven, Belgium

Background: The hedgehog (HH) pathway plays an important role in the development of normal tissues and mutations in HH pathway genes have been identified in various solid tumors. In addition, ectopic activation of the HH pathway has been reported in hematological malignancies and leads to increased growth, stem cell survival, resistance to therapy and relapse.
Aims: Based on the importance of the HH pathway in solid cancers, hematologic malignancies and in normal T-cell development, we investigated its potential role as an oncogenic factor and a potential target for therapy in T-ALL.
Methods: We analyzed gene expression profiles of human T-ALL samples, and determined the effects of HH ligands IHH or SHH stimulation on T-ALL cell lines. SMO, GLI1, SUFU or control siRNA were transfected by electroporation in the same cell lines. For bone marrow (BM) transplantation assays, retroviral Shh, Ihh, JAK3(M511I) and JAK3(L857Q) constructs, were used to transduce primary BM cells and transfected cells were injected in irradiated recipient mice.
Results: Analysis of gene expression profiles of primary T-ALL samples identified a subset of T-ALL cases with elevated expression of the SHH and IHH ligands, with a clear correlation with increased levels of the main activators of the pathway, SMO and GLI1. In addition, a strong correlation between hedgehog ectopic expression and certain T-ALL genes was observed. Inhibition of the HH pathway caused a decrease of proliferation of various T-ALL cell lines, which was associated with downregulation of GLI1 and BCL2, two well-established HH pathway target genes. Furthermore, knock down of negative regulators of the pathway led to increased cell proliferation. These data indicate that a subset of T-ALL cases have ectopic expression of HH ligands that may activate an autocrine loop. One of the genes that was found to be co-expressed with components of the HH pathway in T-ALL patients was the JAK3 kinase. For this reason we took advantage of a JAK3 mutation driven mouse leukemia model in order to decipher the role of the ectopic HH pathway activation in a leukemic background. Expression of JAK3 M511I or JAK3 L857Q activating mutants in the BM cells of mice led to the development of a fatal transplantable T-ALL disease with a latency of >150 days. The immunophenotype of the leukemic clones were variable and clonal populations could arise at the CD4CD8 double negative, CD4CD8 double positive or CD8 single positive stages. Ectopic expression of the HH ligands in the JAK3 mouse leukemia model did not lead to an acceleration of the disease, but caused a consistent block in differentiation of the leukemia cells at the CD4CD8 double positive and CD8 single positive stage in mice expressing the Ihh and Shh ligand respectively. Also in wild type animals, ectopic expression of Ihh or Shh caused a block of differentiation of CD4CD8 double positive and CD4CD8 double negative thymocytes. As a consequence, the percentage of mature T cells in the blood and spleen was significant reduced. Moreover, all mice expressing the HH ligands showed enlarged lymph nodes with a major lymphocytic infiltration.
Summary and Conclusions: In this report we demonstrate that the HH pathway is activated in a subset of T-ALL patients by ectopic expression of the ligands by the leukemia cells. In addition, HH activation affects T-ALL cells growth *in vitro* and causes a block of differentiation in a JAK3 mutant driven mouse T-ALL model. In conclusion, our data indicate that HH pathway can play a role at least in a fraction of T-ALL patients and therefore considered as a new target for therapy in T-ALL.

Acute lymphoblastic leukemia - Clinical 1

P117

NON-INTENSIVE, BUT NO-INTERRUPTIONS PROTOCOL PROVIDES COMPARABLE RESULTS IN AYA AND OLDER ADULTS WITH PH-NEGATIVE ACUTE LYMPHOBLASTIC LEUKEMIA: THE RUSSIAN ACUTE LYMPHOBLASTIC LEUKEMIA (RALL) STUDY GR

E Parovichnikova[1,*] V Troitskaya[2], S Bondarenko[3], A Sokolov[4], G Kliasova[2], L Kuzmina[1], S Kravchenko[2], O Baranova[5], E Karyakina[5], T Ryltzova[6], L Gavrilova[7], T Konstantinova[8], T Kaporskaya[9], O Samoilova[5], T Zagoskina[10], E Zinina[5], I Kryuchkova[5], I Toropova[9], A Pristupa[11], Z Akhmerzaeva[4], T Obukhova[12], M Rusinov[13], S Kulikov[13], V Savchenko[1]
[1]Bone Marrow Transplant Department, [2]Hematology Research center, Moscow, [3]Bone Marrow Transplant Department, I.P.Pavlov State Medical University, St.Petersburg, [4]Hematology, Hematology Research center, Moscow, [5]OKB, Tula, [6]Hematology, OKB, Tula, [7]Hematology, [8]OKB, Ekaterinburg, [9]OKB, Irkutsk, [10]OKB, Kirov, [11]OKB, Ryazan, [12]Genetic department, [13]Biostatistic department, Hematology Research center, Moscow, Russian Federation

Background: It is now broadly discussed that so called "pediatric approach" applied in adult ALL is more reasonable and effective especially in adolescence and younger adults (AYA), and pediatric schedules are considered to be more aggressive comparing to adults protocols.
Aims: RALL has initiated a pediatric oriented not in intensity but in prolonged non-stop cytostatic drugs application protocol and in 2009 has started a prospective multicenter trial for adult Ph-negative ALL "ALL-2009" based on the following criteria: 1) less intensity but no-interruptions during induction/consolidation/maintenance; 2) prolonged up to the end of treatment L-asparaginase (Σ=590.000 IU) if tolerable; 3) autologous stem cell transplantation with BEAM conditioning for T-cell ALL followed by maintenance. Allo-BMT was an option for high risk patients with sibling donors. The study is registered on the ClinicalTrials.gov public site; NCT01193933.
Methods: From Jan, 2000, till Jan, 2014, 30 centers enrolled 231 pts: median age 28 years (15-55 years), 104f/127m; in 2,6% phenotype was unknown (n=6), B-lineage ALL - 62,8% (n=145), T-lineage ALL - 34,2% (n=79), biphenotypic - 0,4% (n=1). Cytogenetics was available in 50% of patients (n=116) and 47,4% of them (n=55) had normal karyotype (NK). 27,8% of patients (n=55) were in the standard risk (SR) group (WBC <30 for B-lineage, <100 for T-lineage; EGIL BII-III, T-III; LDH <2N; no late CR; t(4;11)-negative), 72,2% (n=143) - in the high risk (HR) group (WBC ≥30 for B-lineage, ≥100 for T-lineage; EGIL BI, T-I-II-IV; LDH >2N; late CR; t(4;11)-positive), 18 patients were not qualified by risk group. The analysis was performed in Jan, 2014.
Results: Blast cell count ≥25% at +8 day leaded to the substitution of prednisolone by dexamethazone in 60% of patients. The portion of non-responders to PRD was 51% in SR and 64% - in HR groups (p=0,06). CR rate in AYA was=97 (93,2%); in older adults ALL=75 (82,4%) with 4 (3,8%) and 13 (14,3%) induction deaths and 3 (2,9%) and 3 (3,3%) resistant leukemia from 104 and 91, respectively. L-asparaginase was stopped due to toxicity in 19% of patients, but it did not influence long-term results. 20 of 65 (31%) CR T-ALL patients underwent autologous BMT after BEAM conditioning and proceeded to the maintenance. No relapses were registered in this group. Allogeneic BMT was performed in 9 patients on our protocol. At 48 mo OS for the whole group constituted - 65,6%, DFS - 69,3%. OS was substantially better (p=0,01) in AYA (72%) than in older adults (57,3%), but DFS did not differ much (p=0,3): 71% *vs* 66,6%, demonstrating high efficacy of the treatment approach in both groups. OS and DFS differed in B-ALL patients with NK in comparison with abnormal karyotype: 80% *vs* 57%,(p=0,01) and 81% *vs* 61%, respectively (p=0,02), but not in T-ALL patients.
Summary and Conclusions: Our data demonstrate that the applied treatment is rather effective in both age cohorts though OS is somewhat worse in older adults. DFS approached to 66,6% in older adults and exceeded 70% in the AYA. Abnormal karyotype for B-ALL is a steady risk factor adversely influencing OS and DFS.

Background: Recently, next-generation tyrosine kinase inhibitors (TKI) that inhibit the BCR-ABL tyrosine kinase more potently than imatinib have been used in the treatment of Ph+ ALL.
Aims: This study evaluated the clinical significance of MRD from the analysis of two sets of prospective data on the treatment outcomes of imatinib and nilotinib plus multiagent combination chemotherapy for newly diagnosed adult Ph+ ALL.
Methods: Patients with newly diagnosed Ph+ ALL and either 15 or 18 years old or over were eligible for each clinical trial when they met the inclusion criteria and gave informed consent. All patients received induction treatment composed of vincristine/prednisolone/daunorubicin (mVPD) plus concomitant imatinib or nilotinib. After achieving hematologic complete remission (HCR), either five cycles of consolidation therapy with concomitant TKI followed by 2 years of TKI maintenance (non-alloHCT) or allogeneic hematopoietic cell transplantation (alloHCT) was performed as post-remission therapy. MRD was evaluated in terms of the ratio between the amount of *BCR-ABL*/*G6PDH* RNA of peripheral blood, and was monitored from the time of HCR and every 3 months thereafter (for alloHCT recipients, just before alloHCT and every 3 months afterward) for 2 years. MRD was monitored with a LightCycler-T® (9;22) Quantification Kit (Roche Diagnotics [Schweiz] AG, Switzerland) with a sensitivity of 1×10^{-6}. In terms of molecular response, MR3 was defined as the achievement of $\leq1\times10^{-3}$, and molecular complete remission (MCR, MR6) was defined as the achievement of $\leq1\times10^{-6}$.
Results: Eighty-seven patients on an imatinib-based protocol (cohort I) and 90 patients on a nilotinib-based protocol (cohort N) were sufficient for MRD analysis. The median age of patients in cohort N was significantly higher than that of cohort I (47 *vs.* 41 years old; p=0.035). The HCR rate of all patients in both cohorts was 92.7% and the MCR rate at the time of HCR was 52.4%, and the cumulative rate of MCR was 93.9% among 164 patients who achieved HCR, which were not significantly different between cohort I and N. When treatment outcomes were compared according to the MRD level at four time points, the proportion of patients achieving MR6 in cohort N was slightly higher than that of cohort I with near statistical significance at 3 time points. After 35.0 months of follow-up for surviving patients, the 3-year hematologic relapse-free survival (HRFS) rate was 59.9%, which was significantly higher in cohort N than in cohort I (73.5% *vs.* 48.5%; p=0.001). The 5-year overall survival (OS) rate was 35.0%, which was higher in cohort N than in cohort I, with marginal statistical significance (57.0% *vs.* 39.2%; p=0.053). The achievement of MR3 at the time of HCR was an important prognostic factor (5-year OS rate, MR3 *vs.* no MR3=33.9% *vs.* 14.3%; p=0.001) and showed a significant difference in outcomes, especially in the non-alloHCT cohort (5-year OS rate, MR3 *vs.* no MR3=32.3% *vs.* 50.0%, p=0.877 in the alloHCT cohort and 25.3% *vs.* 6.9%, p<0.001 in the non-alloHCT cohort). The achievement of MR6 at 3 months after alloHCT was an important prognostic factor in both cohort I and N.
Summary and Conclusions: Combination therapy with nilotinib is superior to that of imatinib in terms of the achievement of deep molecular response, the prevention of hematologic relapse, and the OS. MRD monitoring based on the *BCR-ABL/G6PDH* was a meaningful method for the prediction of outcome, and the achievement of MR3 at 3 months after HCR and MR6 at 3 months after alloHCT were important prognostic indices for predicting OS.

P119

THE POOR PROGNOSTIC VALUE OF IKZF1-DELETION IN CHINESE ADULT COMMON B-CELL ACUTE LYMPHOBLASTIC LEUKEMIA AND THE SUPERIORITY OF STEM CELL TRANSPLANTATION OVER CHEMOTHERAPY FOR IKZF1 DELETED PATIENTS

QM Yao[1], KY Liu[1], LP Xu[1], DH Liu[1], XH Zhang[1], YH Chen[1], Q Jiang[1], H Jiang[1], X Leng[1], N Li[1], LD Li[1], Y Chang[1], JL Li[1], YZ Qin[1], YR Liu[1], B Jiang[1], SS Chen[1], XJ Huang[1], GR Ruan[1,*]
[1]Peking University People's Hospital and Institute of Hematology,Beijing Key Laboratory of Hematopoietic Stem Cell Transplantation, Beijing, China

Background: Early studies suggest that IKZF1 deletions are associated with an adverse prognosis, especially in pediatric B-cell acute lymphoblastic leukemia (B-ALL) patients. Nevertheless, the prognostic role of IKZF1 deletions alone in BCR-ABL-positive or BCR-ABL-negative patients in adult common B cell (Com-B) ALL is not well defined. It remains unclear whether HSCT (hematopoietic stem cell transplantation) is superior to chemotherapy alone as postremission treatment for IKZF1 deleted patients.
Aims: The objectives of the study were designed to evaluate the prognostic role of the deletions of IKZF1 in adult Com-B ALL and to compare the efficacy of HSCT with that of chemotherapy alone as postremission treatment for IKZF1 deleted adult ALL.
Methods: Untreated 190 adult ALL patients were recruited from 2007-2012. Patients received 1-2 cycles of induction therapy and, if in remission, were allowed to select ongoing systemic chemotherapy or HSCT. BCR-ABL positive patients were treated with chemotherapy or HSCT plus tyrosine kinase inhibitors (TKIs). Deletions in the exons 4 to 7, exons 4 to 8, exons 2 to 7, exons 2 to 8 of the IKZF1 gene (types △4-7, △4-8, △2-7, and △2-8) were detected using multiplex RQ-PCR, multiplex fluorescent PCR and sequence analysis. The study's end points of disease-free survival (DFS) and overall survival (OS) were analyzed using the Kaplan-Meier method.
Results: The detection rate of IKZF1-deletion in untreated 190 ALL patients was 33.7%, including 32 (66.7%) with BCR-ABL1-positive ALL, and 32(23.0%) with BCR-ABL1-negative ALL. The 64 positive cases included 4 (18.2%) cases with type progenitor B ALL, 6 (22.2%) cases with precursor B ALL, 54 (45.0%) cases with Com-B ALL, and no one case with T ALL. In the 120 Com-B ALL, patients with IKZF1 wide type (n=66) had a significantly better prognosis than those with IKZF1-deletion (n=54) (OS time: 63.2±2.0 *vs* 34.7±2.3 months, *P*=0.035; DFS time: 40.9±3.5 *vs* 19.8±2.4 months, *P*=0.007; Cumulative incidence of relapse (CIR): 47.8% *versus* 29.7%, *P*=0.027). Patients with IKZF1-deletion but not BCR-ABL rearrangement (n=27) experienced inferior outcome than patients with BCR-ABL rearrangement but not IKZF1-deletion (n=13) (DFS time: 14.4±2.2 *vs* 43.0±5.8 months, *P*=0.005, Figure 1 A; CIR: 52.5% *versus* 15.4%, *P*=0.033) and patients without IKZF1-deletion or BCR-ABL rearrangement (DFS time: 14.4±2.2 *vs* 39.2±4.0 months, *P*=0.004; CIR: 52.5% *versus* 27.5%, *P*=0.037). In Com-B ALL-HSCT group, IKZF1-deleted patients (n=25) had an unfavorable outcome compared to IKZF1 wild-type patients (n=41) (DFS time: 19.8±2.4 *vs* 40.9±3.5 months, *P*=0.017) while in chemotherapy-alone group there was no difference between patients with IKZF1-deletion (n=22) and patients with IKZF1 wild-type (n=23). In IKZF1-deleted group, patients received HSCT acquired longer OS time (39.2±1.8 *vs* 27.7±5.1 months, *P*=0.004, Figure 1 B) and DFS time (23.4±2.8 *vs* 12.7±3.0 months, *P*=0.014, Figure 1 C) than those received chemotherapy only. Independent negative prognosis value of IKZF1 deletions and positive prognosis value of HSCT were confirmed by multivariate analysis.

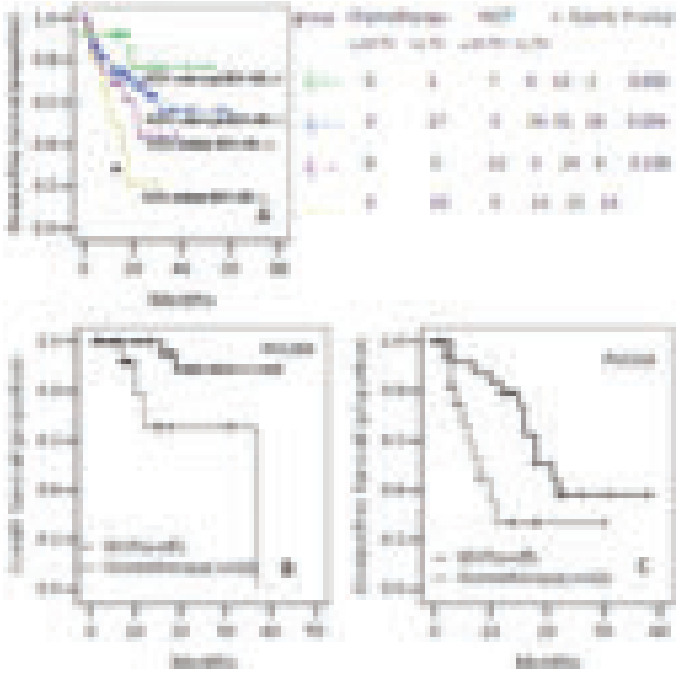

Figure 1. Survival curves of patients with IKZF1-deletion in the Com B ALL. Results from DFS ratios (Figure 1A) indicate that patients with IKZF1-deletion but not BCR-ABL rearrangement experience a poor prognostic outcome. Each subgroup is compared with IKZF1 deleted and BCR-ABL negative subgroup (see asterisk), respectively. Results from both OS (Figure 1B) and DFS (Figure 1C) ratios exhibit that HSCT is superior to chemotherapy alone as postremission treatment for patients with IKZF1-deletion.

Summary and Conclusions: IKZF1 deletions are associated with poor prognosis which is even more obvious than BCR-ABL rearrangement due to the use of TKIs in Chinese adult Com-B ALL. HSCT is superior to chemotherapy alone as postremission treatment for patients with IKZF1-deletion.

P120

PROGNOSTIC IMPACT OF IKZF1 DELETIONS IN PEDIATRIC B-CELL PRECURSOR ACUTE LYMPHOBLASTIC LEUKEMIA TREATED ACCORDING TO NOPHO PROTOCOLS – THE SWEDISH EXPERIENCE

I Ivanov Öfverholm[1,*] L Olsson[2], U Norén-Nyström[3], E Forestier[3], J Nordlund[4], H Sjögren[5], I Golovleva[3], M Heyman[6], V Zachariadis[1], A Nordgren[1], B Johansson[2], G Barbany[1]
[1]Molecular Medicine and Surgery, Karolinska Institutet, Stockholm, [2]Laboratory Medicine, Lund University, Lund, [3]Medical Bioscience, University of Umeå, Umeå, [4]Medical Sciences, Uppsala Universitet, Uppsala, [5]Clinical Chemistry and Transfusion Medicine, University of Gothenburg, Gothenburg, [6]Women's and Children's Health, Karolinska Institutet, Stockholm, Sweden

Background: Recently, *IKZF1* deletions have been shown to be associated not only with the leukemogenic process but also to confer a poor prognosis in all risk groups of B-cell precursor ALL. In a previous study, we used Multiplex Ligation-dependent Probe Amplification (MLPA) to investigate the presence of *IKZF1* deletions in bone marrow DNA from 116 children diagnosed with BCP ALL in a single center and treated according to NOPHO protocols. Deletions were detected in 16% of cases; both event free survival and overall survival were significantly reduced in the *IKZF1*-deleted group compared to the group with intact *IKZF1* (Öfverholm *et al.* Leukemia 2013).
Aims: The aim of our study is to further validate the prognostic impact of *IKZF1* deletions, and to ascertain if they are an independent risk factor when minimal residual disease (MRD) data are taken into account.
Methods: We investigated 362 pediatric BCP ALL cases accrued between 1992 and 2013 and uniformly treated according to the NOPHO-ALL 1992, 2000, and 2008 protocols in Sweden. The *IKZF1* deletion status, based on either SNP array (n=246) or MLPA (n=116) analyses, was known in all cases.
Results: Preliminary analyses indicate that the prognostic significance of *IKZF1* deletions is retained in the larger cohort, with the highest impact on survival being observed in the group lacking risk-stratifying aberrations at diagnosis. Updated survival analyses and the clinical implications of *IKZF1* aberrations will be presented at the conference.
Summary and Conclusions: We conclude that our data support the relevance of *IKZF1* deletion as a prognostic factor for childhood BCP ALL treated according to NOPHO protocols.

P121

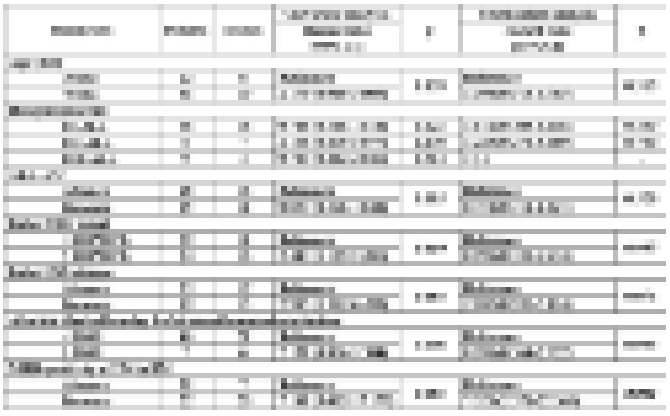
COMPARISON OF BONE MARROW AND PERIPHERAL BLOOD SAMPLES FOR MINIMAL RESIDUAL DISEASE MONITORING IN INFANTS WITH MLL-REARRANGED ACUTE LYMPHOBLASTIC LEUKEMIA TREATED BY MLL-BABY PROTOCOL

G Tsaur[1,*] A Popov[1], T Riger[1], A Solodovnikov[2], T Nasedkina[3], A Kustanovich[4], O Aleinikova[4], E Shorikov[1], O Streneva[1], L Saveliev[2], L Fechina[1]
[1]Regional Children's Hospital, Research Institute of Medical Cell Technologies, [2]Ural State Medical University, Ekaterinburg, [3]Engelgardt Institute of Molecular Biology Russian Academy of Science, Moscow, Russian Federation, [4]Belarusian Research Center for Pediatric Oncology, Hematology and Immunology, Minsk, Belarus

Background: Minimal residual disease (MRD) is powerful tool for prediction of treatment outcome in leukemia patients of various age groups, including infants with acute lymphoblastic leukemia (ALL). In the vast majority of cases only bone marrow (BM) samples are used for MRD detection.
Aims: To estimate prognostic significance of MRD in BM and peripheral blood (PB) by qualitative detection of different *MLL* fusion gene transcripts (FGt) in infants with ALL treated by MLL-Baby protocol.
Methods: Fifty three infants (20 boys and 33 girls) and with defined *MLL* rearrangements were included in the current study. Median age was 5.3 months (range 0.03-11.80). MRD detection was performed from BM and PB samples by real-time quantitative PCR and nested RT-PCR with sensitivity non-less than 1E-04. MRD-negativity was defined as absence of FGt in the both assays. Median of follow-up period in the observed group was 5.2 years. TPs for MRD assessment were as follows: day 15 of remission induction (time point (TP) 1), at the end of remission induction (TP2), after each course of all-trans retinoic acid (ATRA) administration (TP3-TP9). Informed consent was obtained in all cases.
Results: We estimated 142 paired BM/PB samples. 79 samples were double positive, 41 were double negative Thus concordance between MRD results in BM and PB samples achieved 84.5%. Concordance varied between different TPs of MLL-Baby protocol from 79.0% to 100%. The highest concordance rate was at TP4 and TP7 (92.3% and 100% respectively). All discrepant results (22 samples 15.49%) were BM-positive/PB-negative. MRD-positivity at TP4 in BM led to unfavorable outcome. Event-free survival was significantly lower in MRD-positive group in comparison to MRD-negative one (9.9±6.1 *vs* 75.9±8.0, p=0.001). MRD-

positivity at this TP in BM was the only significant factor in the diagnostic model where initial risk factors (age at diagnosis, initial WBC count, immunophenotype, CNS disease, presence of *MLL-AF4*) were combined to response criteria (number of blast cells at day 8 of dexamethasone prophase) (Table 1). We could not find any TP when MRD data obtained from PB samples had prognostic values.

Table 1.



Summary and Conclusions: Despite high qualitative concordance rate between BM and PB samples we could not show prognostic significance of MRD monitoring by FGt detection in PB. Univariate and multivariate analysis revealed that MRD-positivity at TP4 in BM was significant and independent prognostic factor of unfavorable outcome

P122

***IN VIVO* RESPONSE TO REMISSION INDUCTION POLY-CHEMOTHERAPY IN NOD/SCID/HUALL REFLECTS PATIENT RISK AND OUTCOME**

V Münch,[1,*] N Hasan[1], M Schirmer[1], S M Eckhoff[1], KM Debatin[1], L H Meyer[1]
[1]Department of Pediatrics and Adolescent Medicine, Ulm University Medical Center, Ulm, Germany

Background: Acute lymphoblastic leukemia (ALL) is the most frequent malignant disease in children and adolescents. Continuous improvement of therapy regimens increased the 5-year event free survival rate to 80%. Therapy response to initial remission induction treatment, which typically combines vincristine, corticoids, and asparaginase, is an important factor for patient risk stratification. Nevertheless, overall 20% of patients diagnosed with ALL encounter relapse. Thus, novel therapeutics are urgently needed and will most likely be combined with already established treatment regimens. For this reason, we took advantage of our previously established NOD/SCID/huALL xenograft model, which resembles human disease and is a suitable model for evaluating novel substances in a preclinical setting.
Aims: In this study, we aimed to establish a poly-chemotherapy treatment regimen in our NOD/SCID/huALL xenograft model in order to test the therapy effectivity by combining vincristine (V), dexamethasone (D), and asparaginase (A) on different patient-derived xenograft (pdx) ALL samples, which further can be combined with the evaluation of novel compounds.
Methods: Pdx B-cell precursor ALL samples (n=6) were established in the NOD/SCID/huALL model and engraftment efficiency was monitored weekly by the detection of human cells in the recipients' peripheral blood. Multi-agent chemotherapy combining VDA or vehicle-treatment was started upon appearance of 5% human cells and was administered for 2 weeks. Time to leukemia reoccurrence (TTR) was calculated as the time from treatment start to onset of leukemia-related morbidity of mice, which then were sacrificed confirming full-blown leukemia by the detection of high percentages of human cells in spleen, bone marrow, and peripheral blood.
Results: In each mouse receiving VDA of all 6 individual pdx ALL samples, a significant delay of post-treatment leukemia manifestation was observed compared to vehicle-treated recipients (Paired T-test, p=.0021). Interestingly, leukemia manifestation after VDA treatment in one pdx ALL sample did not reoccur within an observation time of 30 weeks suggesting induction of successful long-term remission. Previously, we showed that a short time to leukemia engraftment (TTL^{short}) of diagnostic patient ALL cells in NOD/SCID mice is strongly associated with an early patient relapse, while long time to leukemia engraftment (TTL^{long}) of diagnostic patient ALL cells in our model was shown to have favourable patient outcome. According to TTL^{short}/TTL^{long} phenotypes of pdx ALL samples we also observed clear differences of post-treatment leukemia reoccurrence after VDA remission induction treatment. Interestingly, we observed longer TTR of VDA treated TTL^{long} xenografts compared to significantly shorter TTR of VDA treated TTL^{short} xenografts, which resembles favourable outcome and higher relapse risk, respectively, suggesting that post-treatment leukemia reoccurrence is an intrinsic factor of ALL cells.
Summary and Conclusions: In summary, we successfully established an *in vivo* preclinical setting in our NOD/SCID/huALL xenograft model for analysing novel substances for the treatment of ALL in combination with already applied multi-agent chemotherapy modalities. Most importantly, we observe that our model shows leukemia characteristics of human disease, which is reflected by combination chemotherapy in association of patient relapse probability and time to leukemia reoccurrence after VDA treatment in pdx ALL samples.

P123

USE OF BCR/ABL GENOMIC BREAKPOINT FOR MRD MONITORING IN CHILDHOOD ALL AND ITS COMPARISON WITH OTHER STANDARD METHODS

L Hovorkova[1, 2,*] M Zaliova[1, 2], K Muzikova[1, 2], E Fronkova[1, 2], J Stary[1], J Trka[1,2], J Zuna[1,2]
[1]Department of Paediatric Haematology and Oncology, [2]CLIP Childhood Leukaemia Investigation Prague, Charles University Prague, 2nd Faculty of Medicine and UH Motol, Prague, Czech Republic

Background: Among childhood ALL subtypes, patients harbouring BCR/ABL fusion belong to those with the worst prognosis. The role of minimal residual disease (MRD) in this subgroup is unclear; however, MRD is used in HSCT indication according to the worldwide protocol for the BCR/ABL+ ALL - EsPhALL. In general, the standard method for MRD monitoring in ALL is quantification of Ig/TCR rearrangements. Quantification of the fusion transcript is easier/cheaper technique; however, as we showed previously, the correlation between these two methods in some BCR/ABL+ patients is not satisfactory. We demonstrated presence of BCR/ABL within the non-lymphoid (Ig/TCR-negative) population and worse prognosis of such patients (Zaliova, 2009). Moreover, mRNA quantification might not always correspond to the number of positive cells (possible changes of expression under particular conditions or in various cell types).
Aims: We aimed to establish MRD monitoring based on the detection of the genomic (intronic) BCR/ABL fusion and the BCR/ABL DNA quantification.
Methods: We performed multiplex long distance DNA PCR to find genomic BCR/ABL breakpoint in 15 patients with minor BCR/ABL fusion. The patient-specific fusion sequence was used for MRD quantification by qPCR. Using this approach we measured 149 bone marrow (BM) and 64 peripheral blood (PB) samples from 12 patients. The results were compared with data from Ig/TCR and BCR/ABL transcript quantification. For correlation analysis double negative results were excluded.
Results: We found genomic BCR/ABL breakpoint in 14/15 (93%) patients. Analysis of MRD data in BM samples confirmed poor correlation between Ig/TCR and BCR/ABL mRNA quantification (R^2=0.72; n=89). Moreover, we saw similar difference also when comparing the two DNA methods (Ig/TCR *vs.* BCR/ABL DNA, R^2=0.68; n=92). The correlation between BCR/ABL mRNA and BCR/ABL DNA approach was more satisfactory (R^2=0.83; n=98). Correlation in PB samples was higher (R^2=0.79, 0.80 and 0.89, respectively).
Summary and Conclusions: We believe that the BCR/ABL quantification at genomic level brings the most precise picture of leukaemic burden. Our analysis confirmed poor correlation between BCR/ABL and Ig/TCR data. As we showed previously, at least in some patients this discrepancy is caused by the presence of BCR/ABL in non-lymphoid cells. In our cohort, correlation of the two BCR/ABL based methods was in general good. However, in some patients (4/12) we observed higher genomic BCR/ABL MRD compared to the transcript levels in consecutive samples suggesting either that treatment (possibly by imatinib) can in some patients influence the BCR/ABL expression or that BCR/ABL+ cells might differ in their responsiveness to treatment (cells with low BCR/ABL expression being more resistant). This might be important from the clinical point of view as these data suggest that not only Ig/TCR monitoring, but also BCR/ABL transcript quantification might underestimate the real MRD load. We found better correlation of all methods in PB reflecting probably more uniform cell population released from BM. However, in significant number of paired samples the MRD levels were more than 1 log lower in PB compared to BM (48%, 38% and 27% using BCR/ABL mRNA, Ig/TCR and BCR/ABL DNA quantification, respectively) questioning the use of PB for standard MRD monitoring. The most reliable method for useful and reasonable MRD detection in BCR/ABL+ ALL needs to be discussed within large therapeutic protocol and, importantly, with respect to clinical data.
Support: MH CZ–DRO Univ. Hospital Motol 00064203; UNCE 204012.

P124

NEGATIVE OUTCOME IN PTEN MUTATED ACUTE LYMPHOBLASTIC LEUKEMIA PEDIATRIC PATIENTS COULD BE MODULATED BY THE PRESENCE OF NOTCH1/FBXW7 MUTATIONS

N Vega[1,*] R Malatesta[1], S Rives[2], M Torrebadell[1], T Toll[1], A Català[2], R Berrueco[2], M Camós[1]
[1]Hematology Lab, [2]Hematology and Oncology Department, Hospital Sant Joan de Deu, Barcelona, Spain

Background: Recent advances in the knowledge of biology of acute lymphoblas-

tic leukemia (ALL) and the use of risk-directed therapy have led to a significant improvement in survival of pediatric patients. However, T-cell ALL patients have poorer prognosis than B-cell precursor ALL cases and biomarkers to stratify patients in different risk groups are needed. NOTCH1 activating mutations have been described to confer a better prognosis in several studies, but their effect on outcome is controversial. Recently, a role of PTEN and/or RAS mutations on prognosis of pediatric and adult ALL patients has been suggested.
Aims: To analyze the prognostic effect of clinical and biological variables, including mutations of NOTCH1/FBXW7 and PTEN in a series of homogeneously treated pediatric ALL patients diagnosed in a single center.
Methods: Newly diagnosed ALL patients aged 0-18 years, enrolled in the consecutive SHOP (Spanish Hemato-Oncology Pediatric Society) protocols ALL-SHOP-99 and ALL-SHOP-2005 between 2003 and 2013 were included. Mutations of NOTCH1 (exons 26, 27 & 34), FBXW7 (exons 8-12) and PTEN (exon 7) were screened by PCR and direct sequencing.
Results: A total of 216 patients diagnosed with ALL (B-cell precursor ALL, n=189; T-cell ALL, n=24) were included. T-cell patients (67% males) had a median age of 7.6 years (range 2.2-15.4) and a median WBC count of 44.5 $x10^9$/L (range 1.1-588). Four patients had CNS involvement. Seventeen cases (71%) presented a T-cortical phenotype and 2 patients were diagnosed with early-T cell precursor leukemia. Point mutations in NOTCH1 and/or FBXW7 genes were found in 9 cases (9/15 analyzed, 60%) and indels PTEN mutations were present in 4 patients (4/15, 27%). Minimal residual disease (MRD) at day +14 by flow cytometry was negative (<0.01%) in 7 cases and 11 patients (46%) had MRD levels >0.1%. All cases achieved a morphological complete remission (CR) after induction with negative MRD in 16 patients (67%). After a median follow up of 3.5 years (0.02-9 years), 6 patients had died (5 of disease progression after relapse, 1 toxic death after hematopoietic stem cell transplant). Overall survival (OS) at 5 years of T-cell patients was inferior to B-cell precursor cases (67% *vs* 83%, p=0.06). In the univariate analysis, male patients showed a trend for a worse OS (60% *vs* 100%, p=0.08) and WBC count >200 $x10^9$/L associated significantly with a lower OS (40% *vs* 81%, p=0.035). PTEN mutations also conferred a significant worse prognosis (OS of 33% *vs* 90%, p=0.01). By contrast, NOTCH1/FBXW7 mutations showed a trend for a better outcome, but the low number of cases precluded the finding of statistical significance. When NOTCH1/FBXW7 and PTEN mutations were combined, we observed significant differences in survival, with the worst survival corresponding to PTEN mutated & NOTCH1/FBXW7 wild type cases. Noticeably, the only case with double PTEN& NOTCH1/FBXW7 mutation is still alive in first CR after 2 years of follow-up. Similar results were obtained for event free survival. Further analysis to complete the study in the whole series of patients is currently undergoing.
Summary and Conclusions: We have reproduced the value of clinical variables (gender and hyperleukocytosis >200 $x10^9$/L) as prognostic factors in pediatric T-ALL, and demonstrated the adverse effect of PTEN mutations in our patients. Our observations, in line with previous reports (Trinquand *et al.*, 2013), suggest a modulating effect of NOTCH1/FBXW7 mutations on the worse outcome of PTEN mutated cases, although a larger number of patients is needed to confirm our results.

P125

CORRELATIONS OF EXPOSURE AND RESPONSE FOR INOTUZUMAB OZOGAMICIN IN PATIENTS WITH RELAPSED OR REFRACTORY, CD22-POSITIVE ADULT ACUTE LYMPHOCYTIC LEUKEMIA

K T Luu[1,*] J P Boni[2]
[1]Oncology, Pfizer, Inc., San Diego, [2]Oncology, Pfizer, Inc., Collegeville, United States

Background: Inotuzumab ozogamicin (InO) is an antibody targeting CD22, conjugated with a cytotoxic antitumor antibiotic (calicheamicin), in development for the treatment of acute lymphocytic leukemia (ALL).
Aims: As a follow-on to recent findings[1] we report here interim results of exposure-response analysis for this open-label, phase 1 study of InO in patients with relapsed or refractory CD22-positive ALL.
Methods: InO was administered intravenously on Days 1, 8, and 15 over each 28-day cycle for up to 6 cycles until progressive disease, patient refusal, or intolerable toxicity.
Results: A linear, one-compartment, population-based model described InO concentrations in serum for N=31 patients, yielding clearance of 0.0413 L/hr (SE=0.00463), and central volume of distribution of 5.02 L (SE=0.524); inter-individual variability were 72.1% and 34.0%, respectively. Cumulative area under the serum concentration curve (cAUC; sum over all treatment cycles) and average minimum concentration (Cmin; average across all treatment cycles) were graphically correlated against each patient's response outcome (N=27 subjects). The median cAUC in patients who experienced a complete response (CR; 249.2 hrxµg/mL) was higher than for patients who failed treatment (non-CR; 68.2 hrxµg/mL). Similarly, the median Cmin in patients with CR (40.6 ng/mL) was higher than for patients with non-CR (4.42 ng/mL). The median pre-treatment blast count was lower in patients with CR (0/uL) than in patients with non-CR (553/uL). cAUC across all patients appeared to be negatively trended with higher blast cell count.
Summary and Conclusions: In summary, InO exposure is an important driver of InO response in the treatment of ALL, and this exposure appears to be contemporaneously influenced by the presence of pre-treatment circulating blasts.

P126

REDUCED PENETRANCE OF INHERITED SUSCEPTIBILITY TO PRE B-ALL CAUSED BY GERMLINE TRANSMISSION OF PAX5 C.547G>A

F Auer[1,*] F Rüschendorf[2], M Gombert[1], M Harit[3], M Weintraub[3], OY Weinstein[4], I Lerer[4], P Stepensky[3], A Borkhardt[1], J Hauer[1]
[1]Department of Pediatric Oncology, Hematology and Clinical Immunology, Center for Child and Adolescent Health, Heinrich Heine University, Düsseldorf, [2]Max-Delbrück-Center for Molecular Medicine (MDC), Berlin-Buch, Germany, [3]Department of Pediatric Hematology-Oncology and Bone Marrow Transplantation, Hadassah-Hebrew University Medical Center, [4]Department of Human Genetics & Metabolic Diseases, Hadassah Medical Center, Ein Kerem, Jerusalem, Israel

Background: Although the overall survival rate for children affected with precursor B cell leukemia (pre B-ALL), which is one of the most common childhood malignancies exceeds 80% the overall survival of relapsed ALL is much less and needs improvement.
Aims: Since the development of pre B-ALL is multifactorial and so far the relevance of hereditary alterations is insufficiently understood, the identification of potential susceptibility loci that predispose to leukemia is extremely important in order to develop individual disease based treatments.
Methods: We describe a family from Ashkenazi Jewish origin with three cases of pre B-ALL. We performed SNP array analysis using the Illumina Human660W-Quad-v1 BeadChip and whole exome sequencing on a HiSeq 2000 (Illumina) of germline and leukemic samples.
Results: Applying cytogenetic and SNP array analysis we identified the homozygous loss of a chromosome 9p region involving the CDKN2A/B encoding region in the leukemic samples. Additionally we identified a heterozygous *PAX5* c.547G>A SNP (p.Gly183Ser) located on chromosome 9p downstream of the CDKN2A/B region in the germline of the affected children, as described previously in two families from Puerto Rican and African American ancestries (Shah *et al.*, 2013). The acquired chr. 9p aberration in the leukemic cells subsequently leads to loss of the wt *PAX5* allele and hence to reduced Pax5 activity, due to retention of the *PAX5* allele encoding p.Gly183Ser. In this pedigree, the *PAX5* c.547G>A variant is transmitted from the grandfather to the fathers and subsequently to five out of seven children, three of whom developed pre B-ALL. Hence the inherited predisposition to pre B-ALL follows an autosomal dominant mendelian transmission with reduced penetrance.
Summary and Conclusions: Thus we confirm and extend the recently reported genetic susceptibility to pre B-ALL in families carrying a *PAX5* c.547G>A germline mutation in combination with structural chr, 9p aberrations and subsequent loss of heterozygosity of the wt *PAX5* allele. With respect to the reduced penetrance of pre B-ALL development the selection of additional mutations, which cooperate with inherited *PAX5* c.547G>A, are likely and currently under investigation.

EXPRESSION OF THE IMMUNOGLOBULIN SUPERFAMILY CELL MEMBRANE ADHESION MOLECULE CD146 IN ACUTE LEUKEMIA

F Cavazzini[1,*] D Campioni[1], F Luisa[1], B Buldini[2], M A Bardi[1], B Michielotto[2], M C Lazzari[3], M Ongari[3], M Dabusti[1], G Daghia[1], L Formigaro[1], M Cavallari[1], E Lista[1], O Sofritti[1], G Basso[2], F Lanza[3], A Cuneo[1]
[1]Section of Hematology, University of Ferrara, FERRARA, [2]Dipartimento di Salute della Donna e del Bambino, University of Padua, Padova, [3]Hematology Unit, Azienda Istituti Ospitalieri Cremona, Cremona, Italy

Background: The expression of the immunoglobulin superfamily cell membrane adhesion molecule CD146 has been observed on several human cell types including a subset of T- lymphocytes as well as in a number of solid tumors.
Aims: Aim of this study was to investigate CD146 expression in Acute Leukemia (AL) by a multiparametric flow cytometric approach.
Methods: We studied 162 patients diagnosed with AL (121 AML, 38 B-ALL, 3 T-ALL) and 10 healthy controls admitted to 3 italian centers between 2010 and 2012. The purity of CD146+ leukemic blasts was assessed by flow cytometry and CD146 positivity was considered for an antigen expression of at least 30%. Conventional cytogenetic analysis of Bone Marrow or Peripheral Blood samples was performed in all patients. Fluorescence *In Situ* Hybridization (FISH) was performed using the following probes: 11q23/*MLL*, 14q32/*IGH*, 8q24/*MYC*, *RUNX1-CBFA2*, *CBFB/MYH11*, *ETV6/RUNX1*, *TCF3/PBX1*, *BCR/ABL*. The

cut-off level for break-a-part and translocation probes was set at respectively at 3% and 1.5%. Statistical analysis used Fisher's exact test and Mann-Whitney test for categorical and numerical variables respectively. A ROC analysis on 38 B-ALL was performed to illustrate the overall discriminator potential of CD146 expression for Ph+ B-ALL.

Results: In our series median age was 57 yrs (range 2-87) and Male:Female ratio was 1.1. A CD146 expression >30% was detected in 4/121 cases of AML (3.3%, median age 69, range 28-87 yrs) and 11/41 ALL cases (26.8%, median age 37.5, range 2-80 yrs) (p<0.001). No associations were found for CD146 expression with sex and age. In 10 healthy controls CD146 expression ranged between the 0.5-1% of the total number of the lymphocytes. In CD146+ AML cases the mean percentage of CD146+ blasts on the total number of cells analysed was 15% which was significantly higher than that observed in healthy controls (p<0.01). The four CD146+ AML cases were classified as secondary AML not otherwise specified. No associations were found between karyotype and CD146 expression. Nine out of 38 B-ALL cases were CD146+ (mean value 67.1%, 44 –98%). When comparing CD146+ to CD146- blasts no significant differences were observed in the expression of common diagnostic markers (TdT, CD19, CD22, HLA-DR) while CD10 and CD20 expression resulted higher in the CD146+ cases though without statistical significance (p=0.21). Of 38 B-ALL cases analysed: 42.1% had normal karyotype, 18.4% a t(9;22) translocation, 10.5% a t(12:21), while t(1;19) and t(4;11) were present in 5.3% and 2.6% of cases respectively. The remaining cases presented hyperdiploid karyotype (7.9%) or other aberrations (13.1%). Of the 9 CD146+ B-ALL cases: 7 had a t(9;22) translocation, one had a t(1;19) and the latter hyperdiploid karyotype. CD146 expression strongly associated with the presence of Ph+ abnormality (p<0.001). A ROC analysis was performed to illustrate the discriminatory potential of CD146 expression for Ph+ B-ALL cases with an area under curve (AUC) of 0.98 (95% CI: 0.95, 1,00) and a CD146 cutpoint of 44% (sensitivity 100%, specificity 93.6%: positive likelihood-ratio 15.5, negative likelihood-ratio 0). Three cases of T-lineage ALL cases were investigated also due to their rarity as compared to B-ALL: in 2/3 cases the mean percentage of CD146+ blasts was 95% of the total number of blasts.

Summary and Conclusions: In conclusion, our results showed a higher expression of CD146 in ALL compared to AML. Moreover a strong association between the presence of the t(9;22)/*BCR-ABL* and CD146 positivity in B-ALL was also observed suggesting that CD146 may be considered in the setting of clinical trials as additional marker especially in Acute Lymphoblastic Leukemia patients.

P128

MLL REARRANGEMENT CONFERS THE POOREST PROGNOSIS AS THE SECOND MOST FREQUENT CHROMOSOME ABERRATION IN ADULT ACUTE LYMPHOBLASTIC LEUKEMIA, DATA FROM A SINGLE INSTITUTION IN CHINA

H Zhou[1,*] R Cao[1], H Li[1], L Liao[1], N Xu[1], D Xu[1], Y Wei[1], Y Zhang[1], Z Fan[1], F Huang[1], Z Zheng[1], Z Yi[1], C Yin[1], Q Liu[1], R Feng[1], X Liu[1], J Sun[1], B Xu[1], F Meng[1]
[1]Department of Hematology, Nanfang Hospital, Southern Medical University, Guangzhou, China

Background: Chromosomal rearrangements of mixed-lineage leukemia (MLL) gene are associated with poor prognosis in infant and children acute lymphoblastic leukemia (ALL), but it was relatively marginally addressed in adult ALL. In fact, the prognostic significance of MLL rearrangement might raise up as tyrosine kinase inhibitors (TKIs) have bridged the gap between Ph-positive subset and Ph-negative group.

Aims: Herein we presented 24 MLL-rearranged cases by a single institution-based retrospective analysis among 330 cases of adult ALL to shed light to clinico-pathological features and outcome of this subset among the whole cohort.

Methods: A retrospective study was undertaken to describe the clinical, pathological, immunological features and outcome of MLL-rearranged population among adult ALL from JAN 2006 to JAN 2012 in Nanfang Hospital.

Results: Twenty-four MLL-rearranged patients were identified among 330 adult ALL, being the second (n=24, 7%) most frequent chromosome aberration as following Philadelphia chromosome (n=66, 20%). The MLL-rearranged population included 22 primary patients and 2 cases secondary to breast cancer, a median age of 30-years old (range 16-73). MLL subset had significantly higher white blood count (median=123 G/L) and higher frequency central nervous system involvement (29%) than Ph-positive and Ph/MLL double-negative (DN) group. ProB was the predominant immunophenotype (n=14, 58%) in MLL subset, followed by comB (n=5) and early T-cell precursor (ETP, n=4), while common-B was dominant in both Ph (n=49, 74%) and DN (n=123, 51%) group. Furthermore, proB and ETP subset of the whole cohort were strongly associated with the poorer outcome of 20% and 15% of 5-year overall-survival (OS), respectively, comparing with of 40% in comB (proB *Vs* comB: p=0.001; ETP *Vs* comB: p<0.001) and 45% in non-ETP-T ALL (NET) (proB *Vs* NET: p=0.051; ETP *Vs* NET: p=0.023) group. The 5-year OS of MLL subset was only 11%, significantly lower than 27% of MLL-negative group (p=0.002), respectively. Pediatric-inspired regimen (n=41, 12%) produced significantly superior 5-year OS than adult protocol (60% *versus* 40%, p<0.001). Similarly, allogeneic hematopoietic stem cell transplantation (allo-HSCT, n=129, 39%) yielded 40% of 5-year OS, comparing to 20% in non-HSCT group (p<0.001). Multivariate survival analysis confirmed MLL rearrangement (p=0.019) and immunophenotype (p=0.022) were independent prognostic factors (Figure 1).

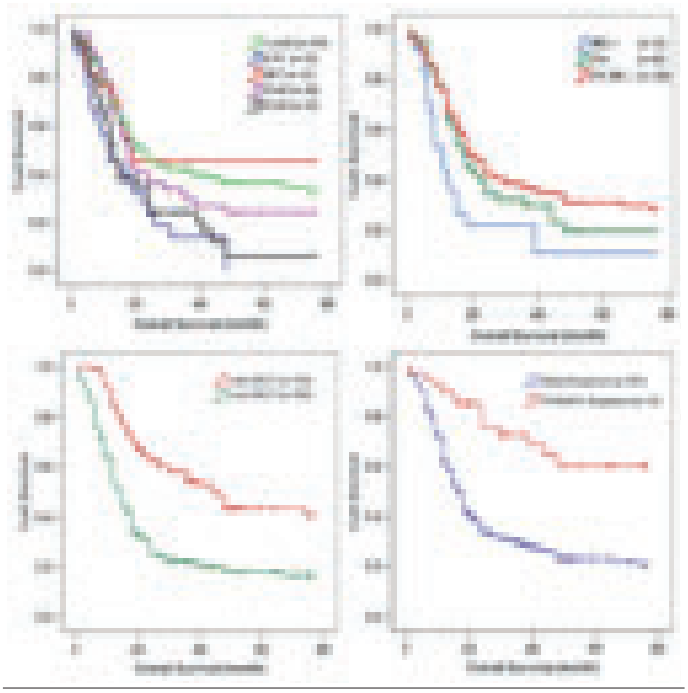

Figure 1.

Summary and Conclusions: Our data showed MLL rearrangement confers the poorest prognosis as the second most frequent chromosome aberration in adult ALL and it deserves more research efforts.

P129

COMBINED TRG AND IGH CLONALITY TESTING ON THE PGM USING LYMPHOTRACK™ REAGENTS & BIOINFORMATICS

NC Adams[1,*] GM Pawlowsky[1], Y Huang[2], K Hutt[2], J Miller[1,2,3], AR Cubbon[1,3]
[1]LabPMM GmbH, Martinsried, Germany, [2]Invivoscribe Technologies, Inc., [3]LabPMM LLC, San Diego, United States

Background: Assays that identify clonal lymphocyte populations by detecting over represented V-J gene rearrangements within the antigen receptor genes of clinical specimens are used on a routine basis to assist in the detection of lymphoproliferative disease. Sensitive detection of tumour-specific DNA sequences, identified in initial samples, can also assist in determining therapeutic efficacy and often provide the first indication of clinical relapse. PCR-based methods run on capillary electrophoresis instruments are the current gold standard for clonality testing. However, these methods often do not provide sufficient sensitivity and, absent separate sequencing steps, are incapable of identifying the specific V-J DNA sequence data required to track clones in follow up testing. The emergence of massively parallel sequencing (MPS) platforms has facilitated development of powerful new approaches for clonality detection and monitoring. Here we report performance of an MPS assay and associated bioinformatics developed for the PGM platform to detect and monitor *IGH* and *TRG* clonality.

Aims: To develop a rapid, easy to use multiplex PCR NGS assay for the combined analysis of TCRG and IGH for clonality detection on the PGM NGS sequencing platform.

Methods: Optimized V and J consensus primers targeted all *IGH* and *TRG* variable (V) and joining (J) region gene segments that are rearranged in lymphoid cells. Separate multiplex PCR master mixes amplified *IGH* and *TRG* gene rearrangements while incorporating sequence indices into products, which allowed simultaneous sequencing and tracking of as many as 12 individual samples for each marker, plus controls, in each run. Amplicons were purified, quantified and pooled for library formation. The harmonized, quantified libraries were loaded onto the OneTouch ES. The enriched emulsion PCR libraries were sequenced using the Ion 316 Chip Kit v2 and Ion PGM Sequencing 400 Kits. Data were analyzed using Invivoscribe proprietary bioinformatics software run on standard Windows platforms.

Results: The PGM platform provided sustainable, rapid turn around times, frequently less than 36 hours from processing of primary sample to result. This assay and bioinformatics package reproducibly identified clonality and DNA sequences for *TRG* and *IGH* V-J gene rearrangements. Automated data out-

puts include frequency distributions and V-J gene usage, as well as complete DNA sequences for up to 1 million sequence reads. DNAs from cell lines serially diluted into polyclonal tonsil DNA, confirmed the linearity and low run-to-run variance of the assay. Good linearity (R^2>0.95) and reproducibility were achieved. Genomic DNA from peripheral blood (PB), tonsil, and bone marrow aspirates were tested for *TRG* and *IGH* gene rearrangements yielding excellent results.

Summary and Conclusions: We have previously developed *IGH* and *TRG* NGS assays for the Illumina MiSeq and HiSeq platforms. Now we demonstrate an adapted workflow for the IonTorrent PGM that is quicker and less costly for laboratories handling small numbers of samples. These assays run on the PGM platform can simultaneously identify both clonal *IGH* and *TRG* V-J rearrangements, associated specimen-specific V-J region DNA sequences, provide frequency distribution of V region and J region segment utilization, and can be used to monitor their presence in subsequent samples. When coupled with the bioinformatics and visualization software this assay provides robust detection and enhanced data-rich outputs.

Acute myeloid leukemia - Biology 1

P130

AML WITH EVI1 REARRANGEMENTS ARE CHARACTERIZED BY FREQUENT SF3B1 AND IKZF1 MUTATIONS

VP Lavallée[1,2,*] I Boivin[1], RN Armstrong[1], S Lemieux[1], J Hébert[1,2], G Sauvageau[1,2]

[1]Institute for Research in Immunology and Cancer, Université de Montréal, [2]Hematology-Oncology Division, Hôpital Maisonneuve-Rosemont, Montréal, Canada

Background: Acute myeloid leukemias with *EVI1* translocations (*EVI1*-t AML) are a rare subtype of AML accounting for less than 3% of patients. The most frequent rearrangement, inv(3)(q21q26.2)/t(3;3)(q21;q26.2);*RPN1-EVI1*, is a distinct genetic entity in the WHO 2008 classification. It is characterized by multilineage dysplasia, atypical megakaryocytes with normal or high platelet counts and a poor outcome.

Aims: Co-occurring gene mutations are unknown in *EVI1*-t AML. We performed a comprehensive genome-wide analysis of mutations in *EVI1*-t leukemias using next-generation sequencing (NGS) to identify recurrent mutations that may provide key insights into the biology of this disease.

Methods: We performed transcriptome analysis of 9 adult *EVI1*-t leukemias, including 5 samples with *RPN1-EVI1* fusion and 4 with other rearrangements. Results were compared to our cohort of 143 sequenced AML with various other cytogenetic anomalies. Libraries were prepared with standard TruSeq protocols and sequencing was performed using HiSeq2000 (Illumina). Non tumoral DNA isolated from buccal swabs or saliva was used to confirm the somatic status of the identified mutations.

Results: Within a set of 35 genes frequently mutated in AML and other myeloid malignancies, *RAS* pathway mutations were the most frequent type in *EVI1*-t AML (6/9), followed by mutations in genes involved in RNA splicing (5/9 samples: 4 *SF3B1* and 1 *U2AF1*). *SF3B1* mutations were exclusive to the *RPN1-EVI1* subgroup and rarely detected (2/143) in non *EVI1*-t leukemias (*EVI1*-t *vs* non *EVI1*-t, p<0.0001). All other mutations identified in *EVI1*-t AML are shown in Figure 1. To identify novel mutations, we analyzed all genes with variants called in ≥2 *EVI1*-t specimens. After removing polymorphisms (dbSNP v.137), 20 genes were selected. Targeted sequencing of non-tumoral DNA revealed non-annotated inherited polymorphisms in 19/20 genes. One gene, *IKZF1*, contained 4 somatic mutations in 3/9 samples which were confirmed by Sanger sequencing of tumor cDNA. No *IKZF1* mutation was found in non *EVI1*-t AML (3/9 *vs* 0/143, p=0.0001). To our knowledge, recurrent *IKZF1* mutations have not been described in AML. In acute lymphoblastic leukemia, *IKZF1* alterations can result in haploinsufficiency or in the expression of a dominant negative isoform. Two samples shared an *IKZF1* N159S mutation. This mutant, located in one of the N-terminal zinc finger (DNA-binding) domain, is expected to have a dominant negative effect similar to the G158S variant previously described. The two additional mutations identified, R213X and p.N270KfsX6, are predicted to result in truncated proteins. *IKZF1* is located on chromosome 7p12.2 and monosomy 7 is the most frequent cytogenetic anomaly associated with *EVI1*-t leukemias. Two samples had a monosomy 7 and *IKZF1* expression was lower in these samples than in those without monosomy 7 (average RPKM: 14 *vs* 36, p=0.06), suggesting that monosomy 7 might result in *IKZF1* haploinsufficiency in *EVI1*-t AML. In null mice, the loss of Ikaros is associated with abnormal red cells, increased megakaryocytes and elevated platelet counts (Lopez *et al.,* PNAS, 2002), a phenotype similar to that described in *EVI1*-t leukemias.

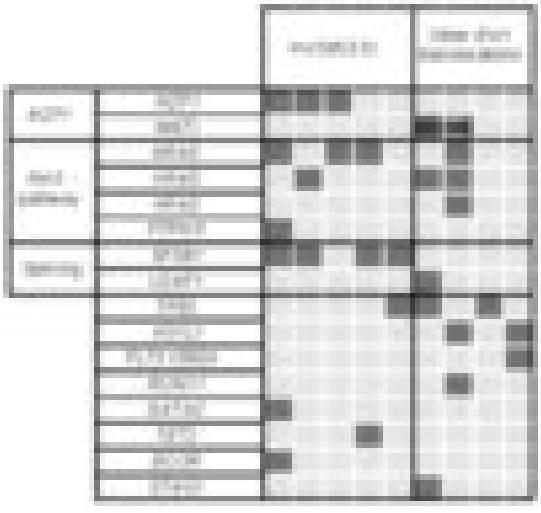

Figure 1. Mutations in *EVI1*-t AML.

Summary and Conclusions: We provide the first genomic characterization of AML with *EVI1* rearrangements by NGS. This study reveals frequent *SF3B1* and novel recurrent *IKZF1* genetic lesions. Although these results need to be confirmed in a larger cohort, we propose that *IKZF1* mutations and deletions might contribute to the distinct phenotype of these leukemias, especially in the *RPN1-EVI1* AML subgroup.

P131

SEQUENTIAL CARBOXY-TERMINAL PHOSPHORYLATION OF EVI1 UPON DNA DAMAGE

DJ White[1], R Paredes[1], M Schneider[1,*] J Muter[1], R Unwin[1], A Pierce[1], AD Whetton[1], S Meyer[1,2,3]
[1]Stem Cell and Leukaemia Proteomics Laboratory, Institute of Cancer Sciences, [2]Department of Paediatric and Adolescent Oncology, University of Manchester, Manchester, [3]Department of Paediatric Oncology, Royal Manchester Children's Hospital, Manchster, United Kingdom

Background: The *EVI1* proto-oncogene is overexpressed in 10% of acute myeloid leukaemia (AML) and is associated with very poor prognosis. *EVI1* overexpression is also a key event in leukaemic transformation in Fanconi Anaemia (FA), an inherited defect in the DNA damage response with extreme predisposition to malignancy. The *EVI1* gene encodes a DNA binding protein with roles in gene expression and epigenetic regulation. Detailed understanding of EVI1 protein regulation is incomplete, however an important role for post-translational modification is emerging. We hypothesised that protein phosphorylation might be govern EVI1 function.
Aims: Identify and characterise EVI1 phosphorylation events plus their downstream effects.
Methods: Endogenous EVI1 from EVI1-overexpressing FA-derived SB1690CB AML cells was analysed after enrichment using mass spectrometry. EVI1 protein was analysed from untreated and irradiated (X-rays; 10 Gy) cells and specific phosphorylation events identified. Phospho-specific antibodies were generated and used to confirm EVI1 phosphorylation on a specific serine residue, assess phosphorylation dynamics and characterise the effect of kinase inhibitors. Phosphorylation site-mutated EVI1 was expressed in bone marrow progenitor cells and the impact on myeloid transformation determined.
Results: In untreated cells we detected an EVI1 phosphorylation site on serine-860 (Ser860). However, after DNA damage EVI1 was phosphorylated on both Ser860 and Ser858. Induction of the doubly phosphorylated form of EVI1 was seen within 15 min of DNA damage and peaked after one hour. In contrast, the cellular pool of EVI1 phosphorylated on S860 alone was reduced, suggesting that Ser858 and 860 phosphorylation is dynamically phosphorylated in response to DNA damage. The Ser858 phosphorylation site matches the ATM kinase motif. Treatment with the ATM inhibitor KU-55933 abrogated the DNA damage-dependent phosphorylation on Ser858. Increase in the proportion of blast cells was detected in serial replating assays with phosphomimetic EVI1 mutants compared with a non-phosphorylatable EVI1, indicating that S858 and S860 phosphorylation modulates EVI1 function.
Summary and Conclusions: DNA damage modulates EVI1 phosphorylation, which may regulate its function in myeloid transformation and self-renewal.

P132

SETBP1 MUTATIONS IN 106 PATIENTS WITH THERAPY-RELATED MYELOID NEOPLASMS

E Fabiani[1,*] G Falconi[1], L Fianchi[1], M Criscuolo[1], CR Spertilli[1], A La Brocca[1], M Picardi[1], G Leone[1], MT Voso[1]
[1]Università Cattolica del Sacro Cuore, Institute of Haematology, Rome, Italy

Background: Therapy-related myeloid neoplasms (t-MN) are myeloid disorders developing in patients treated with radiotherapy and/or chemotherapy for cancer or autoimmune diseases. t-MNs are characterized by high incidence of complex karyotypes and frequent monosomies and/or deletions of chromosomes 7 and/or 5, whereas the recently identified mutations of epigenetic regulators and of the spliceosome machinery are rare, with the exception of SRSF2. Recently, new sequencing technologies have enabled large screening of somatic mutations in myeloid malignancies, leading to the discovery of new hot spot mutations in genes candidate as leukemic transformation drivers. Among these, SET binding protein 1 (SETBP1) mutations, previously associated to Schinzel-Giedion syndrome, were reported in several myeloid neoplasms, in particular in patients with chromosome 7 alterations and SRSF2 mutations.
Aims: Object of our study was to determine the frequency of SETBP1 mutations in a cohort of 106 t-MN patients.
Methods: The study population included 106 patients affected by t-MN. According to the proportion of blasts, there were 53 t-MDS and 53 t-AML. Karyotype was abnormal in 52 of 81 (64.19%) patients in whom the karyotype was available. Chromosome 7 alterations were present in 16/81 (19.75%).
Mononuclear cells (MNCs) were separated from the BM at the time of diagnosis by Ficoll gradient centrifugation. DNA was extracted using a QIAamp DNA Mini Kit (Qiagen). Detection of SETBP1 mutations was performed by Sanger sequencing (Life technologies). t-MN patients were also tested for mutations in DNMT3A, IDH1, IDH2, SRSF2, U2AF1 and SF3B1. Paired T-test was performed to test the association between SETBP1 mutations and other screened genes and patient's karyotype.
Results: We identified three point mutations in the SKI-homologous domain of SETBP1 in our patient cohort (3/106; 2.83%). Two patients had a G870S (COSM1234973) and one a S869R mutation. Two of three SETBP1 mutated patients (both carriers of G870S mutation) also had a SRSF2 mutation at position P95 (P95H and P95R with contextually P96 insertion). No other associations between SETBP1 mutations and spliceosome machinery or epigenetic regulators somatic mutations were found. All three SETBP1-mutated patients had a different primary tumor (Non-Hodgkin lymphoma, breast and thyroid cancer), but interestingly, all patients had developed a t-MDS (one RAEB1 and two RAEB2). None of the t-AML patients resulted mutated. Looking at karyotype associations, the two patients carriers of a G870S mutation had a complex karyotype without chromosome 7 aberration, whereas the S869R mutation carrier had a chromosome 7 deletion. The low number of SETBP1-mutated t-MN patients precluded survival analysis in this cohort.
Summary and Conclusions: We found a low incidence of mutations in the SKI-homologous domain of SETBP1. In our t-MN patients SETBP1 and SRSF2 mutations were frequently associated, whereas there was no association between SETBP1 mutation and chromosome 7 alteration, suggesting a limited role of these mutations in t-MN pathogenesis.

FANCONI ANEMIA AND DNA-REPAIR GENE VARIANTS IN THERAPY-RELATED MYELOID NEOPLASMS

MT Voso[1,*] E Fabiani[1], Z Zang[2], L Fianchi[1], G Falconi[1], M Martini[3], SL Zhang[4], R Santangelo[5], LM Larocca[3], M Criscuolo[1], A La Brocca[1], I Cutcutache[4], S Rozen[4], S Hohaus[1], G Leone[1], P Tan[4], D G Tenen[4]
[1]Università Cattolica del Sacro Cuore, Institute of Haematology, Rome, Italy, [2]National Cancer Centre, Singapore, Singapore, [3]Università Cattolica del Sacro Cuore, Anatomia Patologica, Rome, Italy, [4]Duke-NUS Graduate Medical School, Singapore, Singapore, [5]Università Cattolica del Sacro Cuore, Microbiologia, Rome, Italy

Background: Therapy-related myeloid neoplasms (t-MN) include myelodysplastic syndromes and acute myeloid leukemias occurring as a late effect of chemotherapy and/or radiotherapy for a primary malignancy or for autoimmune diseases. The incidence of this complication has been raising in the last years due to the prolonged survival and the higher number of treated patients. Still, less than 5% of patients exposed to cytotoxic drugs and radiotherapy develop a t-MN, suggesting underlying individual susceptibility. The association of breast and other cancers to myeloid neoplasms is frequent in Fanconi Anemia (FA), a syndrome characterized by chromosomal instability, developmental abnormalities, aplastic anemia and predisposition to cancer. So far, mutations in FANC genes have been rarely described in hematological malignancies outside the syndromic picture of FA.
Aims: We were interested in the prevalence of FANC and other DNA-repair gene variants in t-MN following cytotoxic treatment for breast cancer and lymphoproliferative diseases.
Methods: The test- patient cohort included 37 patients with a t-MN. According to the proportion of blasts, there were 19 t-MDS and 18 t-AML. The primary malignancy was Hodgkin lymphoma (HL) in 7 patients, non-HL in 12 patients and breast cancer in 18 patients. DNA isolated from BM-MNCs at t-MN diagnosis was analyzed using Agilent HaloPlex system and validated with Sanger sequencing and Pyrosequencing. We selected 41 genes, including 14 FANC pathway genes and 27 further DNA repair genes. For the ATM SNV analysis, we included BM samples from further 60 t-MN patients, adding to a total of 97 t-MN patients (48 t-MDS and 49 t-AML). Control samples were obtained from 129 Caucasians with a negative history for previous malignancies and normal PB cell counts. Differences in the distribution of ATM SNV between patients and controls were evaluated using the Fisher's Exact test.
Results: DNA-repair and FANC gene variants were frequent in our t-MN patients, with 21 of 37 patients (57%) carriers of at least one genomic variant. There were no differences in latency from the primary cytotoxic treatment and t-MN in mutated *vs* unmutated patients and the median overall survival after t-MN diagnosis was similar for the two groups. The gene with the highest frequency of variant sequences was TP53 (15 variants in 10 patients). Looking at FANC genes, we found 7 heterozygous variants in 6 patients (16%), including two FANCA (L6F and S90T), three FANCD2 (T1376A, P256S and M1023V), one FANCJ (I364V) and one FANCC (L36F). Six variants were novel, according to the NCBI and Cosmic databases, whereas the FANCA L6F had been previously described (*www.1000genomes.org*). Control tissues confirmed that the variants were germ-line in 5 patients with available material (Table 1). The frequency of FANC variants in our t-MN cohort was higher than that reported in 200 *de novo* AML patients by the Cancer Genome Atlas Research Network.
In the extended study population, the ATM P1054R variant was significantly more frequent in t-MN compared to controls (10.3% *vs* 2.3%, p=0.018). This translates into a 4.8-fold increased t-MN risk.

Table 1. Characteristics of patients with FANC and DNA-repair variants.

Summary and Conclusions: The high incidence of FANC germline variants in our t-MN cohort may be the underlying cause for increased susceptibility to primary cancers and may induce secondary leukemogenesis.
In the same line, the higher prevalence of the ATM P1054R SNV in t-MN may increase sensitivity of hematopoietic progenitor cells to the DNA damaging effect of chemo- and radio-therapy leading to secondary leukemia.

P134

SELECTION OF A PRE-EXISTING TP53 MUTATED CLONE IN THERAPY-RELATED ACUTE MYELOID LEUKEMIA

E Schulz[1,*] K Kashofer[2], KN Mhatre[1], G Höfler[2], H Sill[1]
[1]Department of Internal Medicine, Division of Hematology, [2]Institute of Pathology, Medical University of Graz, Graz, Austria

Background: Therapy-related myeloid neoplasms (t-MNs) are thought to arise due to mutational events in hematopoietic stem and precursor cells induced by cytotoxic treatments for a primary disorder. However, no consistent biomarker has been identified yet that unambiguously classifies a particular neoplasm as "therapy-related". This raises the possibility that other mechanisms may also be operational in their pathogenesis.
Aims: Our aim was to demonstrate that leukemia-specific mutations were pre-existing in some of these patients and we, therefore, focused on the *TP53* gene which is frequently mutated in t-MNs.
Methods: We used Sanger sequencing of paired samples - t-MN and constitutional material - for initial mutation identification and rearrangement-specific PCR for the detection of a *TP53* duplication in pre-leukemic specimens, respectively. Quantitative PCR was performed to semi-quantify the mutated clone and Ion torrent deep sequencing (Life Technologies, Carlsbad, CA) to search for co-operating mutations.
Results: We screened 53 t-MN specimens for *TP53* mutations and identified one patient with a somatic heterozygous 64-base pair duplication (NM_000546.5:c.276_339dup:p.Leu114Profs*31) who developed therapy-related acute myeloid leukemia (t-AML) with complex karyotype (46-50,XY,del(5)(q12q33),?r(7)(p22q11)[cp20]) 13 years after combined modality treatment for Hodgkin's lymphoma. This duplication was particularly amenable for detection by a highly sensitive PCR assay enabling the detection of 0.01% rearranged cells. We could not only unambiguously detect the presence of *TP53* mutated cells in the patient´s pre-treatment bone marrow but also in a lymphadenitis sample obtained seven years before lymphoma diagnosis. Quantitative PCR estimated the amount of affected bone marrow cells as <1% as compared to the t-AML specimen. Analysis of the *FLT3*, *NPM1*, *ASXL*, *TET2*, *IDH1/2*, *HRAS*, *KRAS*, *RUNX1*, *MLL*, *JAK2*, *WT1*, *PTEN* and *PHF6* genes by deep sequencing using bone marrow and leukemia specimens did not show evidence of co-operating mutations.
Summary and Conclusions: The fact that a leukemia-specific *TP53* mutation is already present before any chemo- or radiotherapy has been administered suggests a different mode of therapy-related leukemogenesis than currently assumed. Instead of inducing a leukemia-specific mutation, cytotoxic treatments have facilitated the expansion of a pre-leukemic clone in this patient.

P135

GENOMIC ANALYSIS OF THE CLONAL ORIGIN AND EVOLUTION OF ACUTE PROMYELOCYTIC LEUKEMIA IN A UNIQUE PATIENT WITH A VERY LATE (17 YEARS) RELAPSE

X Zhang[1,*] Q Zhang[2], AN Tran[3], D Xu[1], M Björkholm[1]
[1]Department of Medicine, Karolinska Institutet, Stockholm, Sweden, [2]Qilu Hospital, Shandong University, Jinan, China, [3]Department of Clinical Genetics, Karolinska Institutet, Stockholm, Sweden

Background: Acute promyelocytic leukemia (APL) is a distinct subtype of acute myeloid leukemia characterized by a balanced reciprocal translocation t(15;17)(q22;q12-21). The introduction of all-*trans*-retinoic acid (ATRA) has considerably improved complete remission (CR) rate and survival of APL patients. APL is now a highly curable disease and late relapses beyond 7 years are very rare. Here we describe a female patient with manifestation of APL 17 years after the initial APL diagnosis (Figure 1A).
Aims: To elucidate whether the more recent manifestation of the disease is a very late relapse or a *de novo* APL in this unique patient by genomic analyses.
Methods: Whole genome sequencing (WGS) and array-comparative genomic hybridization (CGH) were performed on genomic DNA from the patient's bone marrow specimens at initial (1994) and second diagnosis (2011), and blood samples during second CR.
Results: The patient was initially treated with ATRA and chemotherapy in 1994 while ATRA and chemotherapy plus arsenic were given in 2011 (Figure 1A). WGS revealed two different *PML/RAR*α gene fusions (Chr17: 38489469-Chr15:74316176 and Chr15:74316160-Chr17:38489139) in APL cells from both samples, with the first fusion being predominant in both (Figure 1B). The fusion genes were further verified by Sanger sequencing (Figure 1B). Although the fusion genes/breakpoints were identical, significant differences in genetic aberrations were observed between the first and second APL samples, as revealed by WGS and array-CGH. Importantly, WGS and the fragment length analysis demonstrated FLT3ITD and FLT3-D835 point mutation in the first and second APL samples, respectively.

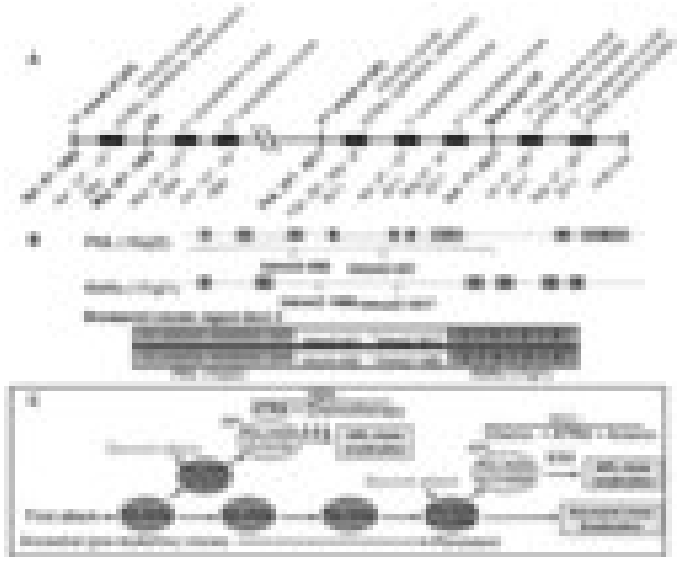

Figure 1.

Summary and Conclusions: We believe that our patient documents the longest interval between diagnosis and relapse of APL described in the literature to date. Genomic analyses show how APL clones evolved between the two manifestations of APL in this patient (Figure 1C). Likely, the patient's hematopoietic cells underwent *PML-RAR*α gene fusion following a genetic attack, leading to the generation of abnormal ancestral or pre-leukemic clones, which is consistent with a recent study. These clones then transformed into APL following acquisition of *FLT3ITD* by another genetic attack. The patient obtained a CR following ATRA treatment plus chemotherapy in 1994. APL blast clones were eradicated after treatment, but the ancestral clones carrying the *PML-RAR*α fusion gene were persistent and acquired a *FLT3-D835* point mutation later. The *PML-RARα/FLT3-D835* clones then contributed to the second onset of APL in 2011. At relapse, the patient was given ATRA and chemotherapy as induction and ATRA/arsenic acid as consolidation therapy. The patient has now remained in a molecular remission for three years, hopefully, indicating that a "non-aggressive" approach was appropriate for this patient. In summary, we here describe an extremely late relapse of APL and the leukemic clonal evolution. Very late relapses in APL, as seen in this unique patient, are more likely caused by a new genetic attack on existing pre-APL clones, which differs from early relapses resulting from the re-growth of original residual APL blasts. Genomic characterization of late relapses may have therapeutic implications.

P136

NOVEL MUTATED GENES IN ACUTE PROMYELOCYTIC LEUKEMIA IDENTIFIED BY WHOLE-EXOME SEQUENCING

M Ibañez[1,*] J Carbonell-Caballero[2], E Such[1], J Jimenez-Almazán[2], E Barragán[1], E Vidal[2], L García-Alonso[2], I Luna[1], I Gómez-Seguí[1], M López-Pavía[1], CM Alonso[1], E Villamón[1], I Martín[1], P Montesinos[1], MA Sanz[1], J Dopazo[2], J Cervera[1]
[1]Hematology Service, Hospital Universitario y Politécnico La Fe, [2]Computation-

al Genomics Department, Centro de Investigación Príncipe Felipe, Valencia, Spain

Background: Acute Promyelocytic Leukemia (APL) is a rare hematologic neoplasm characterized by the fusion gene *PML/RARA*. However, it is known that this abnormality itself is not able to reproduce the whole leukemic phenotype. Preliminary APL whole exome studies have identified a huge number of somatic mutations affecting 135 different genes in a non-recurrent manner, except for *FLT3*, *WT1* and *KRAS*. These findings suggest that APL is a heterogeneous disease with secondary relevant changes not yet defined.
Aims: We performed whole-exome sequencing (WES) of tumor-normal matched samples to identify new gene mutations that might carry prognostic value in APL. Novel candidate-genes, together with other previously described[1,2], were resequenced in an independent cohort of APL patients. The obtained results were further studied by *in silico* analysis to enlarge our understanding of their role in the pathology and entry genetic pathways.
Methods: WES was performed on matched samples from 5 *de novo* APL patients, as our study cohort. Library preparation and exome capture were performed according to the protocol version 2.1 from Baylor College of Medicine for sequencing with SOLID 4 platform as recommended by the manufacturer. WES data were analyzed using and in-house bioinformatic pipeline. Candidate variants were confirmed by Sanger sequencing. We extended the analysis of these variants to a validation APL cohort (n=76). Furthermore, a custom panel of 97 genes (17 genes from in-house results and 80 genes reported to be mutated in at least 1 patient from APL previous studies[1,2]) was performed on a subset of the validation cohort (n=25) using SureDesign Tool (Agilent) for NGS, according to the manufacturer's instructions. Samples were provided by the Hospital La Fe Biobank.
Results: We identified 32 SN*Vs* non-synonymous coding mutations and 18 small indels, with an average of 10 mutations per sample (range 7-14). We confirmed 17 SN*Vs* and 1 indel of the candidate variants (36%) in 17 genes by Sanger sequencing. Among them, no recurrent specific variants were observed through the study and the validation cohorts, with the exception of *FLT3*. Over the 25 patients analysed by the genes panel, we detected a mean of 7,76 mutations per sample (range 1-23). We identified a total of 92 variants affecting 54 different genes, where 33 were mutated in more than one patient. When we focused our research on these genes, we found that 10 mutated genes (2 of them, listed from our WES results) had a higher frequency in our cohort than expected in the 1000g database ($P \leq 0{,}01$). Pathways analysis of the mutated genes are been analyzed and the complete results will be presented in the meeting.
Summary and Conclusions: This study shows a comprehensive analysis of APL combining WES with the frequency assessment of somatic mutations from a custom panel of targeted genes by NGS. We identified recurrent deleterious mutations in 10 genes with a strong potential to be involved in APL pathogenesis. The relevance of the newly defined mutated genes for APL pathogenesis will require functional validation studies.

Background: Disease relapse is a fundamental clinical challenge for Acute Myeloid Leukemia (AML) since most patients have poor clinical outcomes. The biological basis of relapse in AML remains unclear, and a role for epigenetic mechanisms has not been examined in depth. Genetic evolution of the disease after induction treatment is widely believed to underlie the emergence of chemotherapy resistant clones. However, recent reports have identified only a limited number of somatic mutations and copy number abberations upon disease relapse, and in some cases, no relapse-specific events were detected. These findings suggest a role for other mechanisms in relapsed AML. We hypothesize that epigenetic plasticity and dysregulation of biological pathways contribute to the relapsed disease phenotype in AML.
Aims: In this study, we aimed to determine epigenetic patterning (DNA methylation) and its potential functional consequences in relapsed AML.
Results: DNA methylation profiling using Enhanced Reduced Representation Bisulfite Sequencing (ERRBS) of 39-paired diagnosis and relapse AML patient samples was performed. Cells analyzed were enriched for the blast population. We identified thousands of statistically significant changes in cytosine methylation patterns. All patients acquired both hyper- and hypomethylated differentially methylated CpGs (DMC) and regions (DMR) resulting in a range of cytosine methylation patterning upon disease relapse. In spite of the variety of cytosine methylation patterns, the majority of differentially methylated cytosines are located in intergenic regions in all cases. Interestingly, however, a subset of promoters were hypermethylated in almost all patients at relapse. This heterogeneity is not uniformly driven by mutations in epigenetic modifiers known to affect DNA methylation; has been confirmed in two independent patient cohorts (n=71 and n=31 paired diagnosis and relapse AML patient samples); and is reproducible in a xenograft model of relapsed AML treated with cytosine arabinoside (Ara-C). Integrated analysis with ENCODE datasets revealed enrichment for differential cytosine methylation upon disease relapse at distal regulatory elements (including enhancers and insulators) and regions affected by histone marks associated with cell cycle and transcriptional regulation. Pathway enrichment analysis of differentially expressed genes (determined from RNA-seq) and genes affected by differential methylation within their promoters upon disease relapse revealed convergence on commonly affected biological pathways between the patients. In particular, there was a strong overlap between gene promoters differentially methylated in relapsed compared to diagnostic AML in the patients and xenografted sample ($p<0.01$, hypergeometric test), including members of the Wnt signaling pathway.
Summary and Conclusions: We conclude that there are extensive and dynamic changes in DNA methylation patterns between diagnosis and relapse in AML. Preliminary analysis demonstrates convergent epigenetic targeting of specific gene pathways that may contribute to relapsed AML pathogenesis. The genomic distribution of reprogrammed methylation also suggests a role for epigenetic plasticity at distal regulatory elements. These findings suggest that mechanisms regulating cytosine methylation may be altered from *de novo* states after exposure to induction chemotherapy or facilitate survival of minor clones of disease during treatment resulting in widespread epigenetic reprogramming upon disease relapse.

WHOLE EXOME SEQUENCING REVEALS CLONAL EVOLUTION PATTERNS AND DRIVER GENETIC ALTERATIONS OF RELAPSED PEDIATRIC ACUTE MYELOID LEUKEMIA

K Yoshida[1,*] N Shiba[2], A Shimada[3], K Terui[4], M Kato[5, 6], Y Shiraishi[7], Y Okuno[8], Y Nagata[1], A Kon[1], K Kataoka[1], T Yoshizato[1], Y Shiozawa[1], M Matsunawa[1], K Chiba[7], H Tanaka[9], M Sanada[1], S Miyano[7, 9], E Ito[4], Y Hayashi[2], S Ogawa[1]
[1]Department of Pathology and Tumor Biology, Graduate School of Medicine, Kyoto University, Kyoto, [2]Department of Hematology/Oncology, Gunma Children's Medical Center, Shibukawa, [3]Department of Pediatrics, Okayama University Graduate School of Medicine, Okayama, [4]Department of Pediatrics, Hirosaki University Graduate School of Medicine, Hirosaki, [5]Department of Hematology/Oncology, Saitama Children's Medical Center, Saitama, [6]Department of Pediatrics, Graduate school of Medicine, University of Tokyo, [7]Laboratory of DNA Information Analysis, Human Genome Center, Institute of Medical Science, The University of Tokyo, Tokyo, [8]Department of Pediatrics, Nagoya University Graduate School of Medicine, Nagoya, [9]Laboratory of Sequence Analysis, Human Genome Center, Institute of Medical Science, The University of Tokyo, Tokyo, Japan

Background: Pediatric acute myeloid leukemia (AML) comprises ~20% of pediatric leukemia, representing one of the major therapeutic challenges in pediatric oncology. Nearly 40% of patients still suffer from a relapse after first-line therapies and once the relapse occurs, long-term survival rates decrease, ranging from 21% to 34%. The recent development of high-throughput sequencing technologies has provided an unprecedented opportunity to investigate comprehensive genetic alterations that are involved in the tumor recurrence of various cancers including adult AML. However, little is known about the molecular mechanisms of relapsed pediatric AML.
Aims: The purpose of this study is to identify the clonal evolution patterns and the major mutational events in relapsed pediatric AML.

Methods: We performed whole exome sequencing of 6 relapsed AML cases, in which diagnostic, relapsed and complete remission samples were available. Copy number alterations and structural variants including tandem duplications were also analyzed using whole exome sequencing data. Subsequently, deep sequencing of identified mutations was performed to evaluate intra-tumor heterogeneity and the clonal origin of relapsed clones.
Results: Whole exome sequencing of 18 samples from 6 patients with different subtypes of pediatric AML were analyzed with a mean coverage of more than x100, by which 95% of the targeted sequences were analyzed at more than x20 depth on average. The mean number of nonsynonymous mutations was higher at relapsed phase than at the time of diagnosis (14.0/case *vs* 10.5/case). Mutational signature was dominated by C>T transitions at both phases. Clonality assessment using variant allele frequencies of individual mutations revealed the presence of intra-tumor heterogeneity both at the diagnostic and at therelapse phases. In all 6 patients, relapsed AML evolved from one of the subclones that were present at the diagnostic phase. In all cases, relapsed AML was accompanied by many additional mutations that were absent (relapse specific mutations) or existed only with lower allele frequencies (relapse enriched mutations) in the diagnostic samples, indicating a multistep process of leukemia recurrence. Mutations that were specific to or enriched in relapsed specimens were found in several driver genes including *ASXL1*, *NRAS* and *CREBBP*, suggesting these mutations could contribute to tumor recurrence. In some cases, AML relapse may accompany a dynamic clonal change. For example, some *bona fide* driver mutations, such as *KRAS* mutations, that were predominant at the time of diagnosis disappeared in relapsed samples.
Summary and Conclusions: Whole exome sequencing unmasked the clonal structure of primary and relapsed pediatric AML, which helped to understand the underlying mechanism of relapse in pediatric AML. Our results suggested that the intra-tumor heterogeneity was common in pediatric AML both at presentation and at relapse and subclonal mutations involving RAS pathway genes and chromatin modifiers could contribute to the AML relapse.

P139

IDENTIFICATION OF SOMATIC MUTATIONS OR FUSIONS BY RNA-SEQUENCING IN ACUTE MYELOID LEUKEMIA.

I Viganò[1,*] R Piazza[2], A Pirola[2], C Donadoni[2], E Vagge[1], R Spinelli[2], L Borin[3], F Rusconi[1], C Gambacorti-Passerini[2,3]
[1]University of Milano-Bicocca, Monza, Italy, [2]Dept. of Health Sciences, University of Milano-Bicocca, [3]Hematology, San Gerardo Hospital, Monza, Italy

Background: For patients with diagnosis of acute myeloid leukemia (AML) the presence or absence of specific genetic alterations is useful for both prognosis and treatment choice (according to AML classification). However standard techniques, like cytogenetics and PCR, are able to identify only a limited number of alterations.
Aims: We tested RNA-sequencing in AML patients in order to validate this technique as a method to identify fusions and mutations in a clinical setting and obtain information about genetic variations in AML.
Methods: We collected samples from peripheral blood or bone marrow of 13 consecutive patients with new diagnosis AML of any type. RNA-sequencing data were generated using an Illumina Genome Analyzer IIx following standard library-prep protocols. Alignment to the reference GRCh37/hg19 genome was performed using BWA. Alignment data were processed using Samtools. Single nucleotide and small indels detection was performed using in-house software and applied to a predetermined list of 45 genes involved in AML pathogenesis (CEBPA, NPM1, FLT3, RUNX1, MLL, WT1, EZH2, NF1, MECOM(EVI1), KIT, H-RAS, K-RAS, TET2, IDH1, IDH2, DNMT3A, BCOR, BCORL1, NUP98, ASXL1, ABCB5, BAALC, CEP72, DIP2C, ROBO1, KLC1, TP53, IGFBP7, SETBP1, JAK2, NRAS, NOTCH1, CDKN2A, MPL, SF3B1, BRAF, PTPN11, SRSF2, IKZF1, GATA1, MYD88, ATM, CBL, PHF6, BCL2). The presence of fusions was assessed using FusionAnalyser.
Results: We identified a total of 9 fusions and 28 single nucleotide variants with a median number of 2 single nucleotide variants per patient (range 0-6). 5 patients had fusions that were previously detected with standard techniques (1 AML-ETO, 3 PML-RARA and 1 CBFB-MYH11); for all these patients known fusions were confirmed by RNA-sequencing. In 4 patients, previously unreported fusions were detected. Two of them were already known from the literature (ZMYM2-FGFR1 and MLL-MLLT10) and two were new (ETS2-ERG and WDFY3-WAS). The ZMYM2-FGFR1 is particularly interesting, because it is potentially targetable by using Ponatinib. Interestingly, we were able to identify new potential targeted therapies for 7 patients with single-nucleotide mutations: NOTCH1 D622E using NOTCH inhibitors; KIT N511K using Dasatinib; KRAS A155T using RAS inhibitors; MLL G256E, DNMT3A C599G, TET2 L1801R and EZH2 T80S using demethylating agents. Considering both new and already known mutations and fusions, 12 out of 13 patients could have received a patient tailored treatment based on these data (Table 1).
Summary and Conclusions: Our study demonstrates that RNA-sequencing leads to rapid detection of somatic mutations and fusions in AML patients. The possibility of recognizing a subset of genetic variations with potentially therapeutic value could pave the way to a genomic-centered, "personalized" therapy.

IMPROVED COPY NUMBER VARIATION ESTIMATION FROM NEXT GENERATION SEQUENCING DATA REVEALS FOCAL GENETIC LESIONS SUCH AS MLL-PTD IN ACUTE MYELOID LEUKEMIA

M A Sanders[1,2,*] R Hoogenboezem[1], S Gröschel[1], A Zeilemaker[1], WM Geertsma-Kleinekoort[1], R Delwel[1], JJ Goeman[2,3], PJ Valk[1]
[1]Hematology, Erasmus Medical Centre, Rotterdam, [2]Medical Statistics and Bioinformatics, Leiden University Medical Center, Leiden, [3]Health Evidence - Biostatistics, Radboud University Medical Center, Nijmegen, Netherlands

Background: Different next generation sequencing (NGS) platforms generate high-quality data which allows, in addition to the detection of mutations, small deletions or insertions (indels), for the estimation of copy number variations (CNVs). CN*Vs* in combination with concomitant single nucleotide variants (SNVs) or indels, possibly in the same regions, can be utilized for further delineation of the biology of acute myeloid leukemia (AML). Remarkably, AML patients have an exceptionally low number of CNVs, with a mean of 2.38 CN*Vs* per case as previously measured by DNA mapping arrays. The increased resolution of NGS derived high-density sequence data could enable the detection of novel genetic lesions in AML, which could serve as guides towards the identification of novel cancer-related genes.
Aims: The development of an algorithm that mitigates systematic bias from the NGS data in conjunction with the robust detection of novel genetic lesions in AML.
Methods: Whole genome sequencing was performed on 3 primary AML patients, harboring the chromosomal rearrangements inv(3)(q21q26) or t(3;3)(q21;q26), and matched *in vitro* cultured T-cells using the Complete Genomics platform. Whole exome sequencing was performed on 30 primary AML patients, 30 matched relapse samples, and 30 matched *in vitro* cultured T-cells controls using the Illumina HiSeq 2500 platform. The NGS data was analysed with an in-house developed package CNVsvd. In short, we count the number of fragments in consecutive 0.5 kb windows and compare them to the counts derived from a reference set of healthy individuals. Of a selected number of AML patients the CN*Vs* were also determined using Affymetrix 500K DNA mapping arrays.
Results: The whole genome sequencing data revealed an extensive number of small genetic lesions, more than 100 CN*Vs* per AML case, initially missed with the DNA mapping array. Most of these CN*Vs* are concomitantly detected in the matched controls and are therefore deemed to be germline CNVs, which in principal could still play a vital role in leukemogenesis. Importantly, the vast majority of CN*Vs* was corroborated by structural variants present in the NGS data. Surprisingly, on average 7 somatic CN*Vs* (sCNV) were detected per AML case using WGS data in conjunction with the CNVsvd package, while on average 2 sCN*Vs* per AML case were detected with the DNA mapping arrays. Most of these novel sCN*Vs* were small genetic lesions, between 1.5 and 6 kb in size, likely to be missed because of the lower resolution of DNA mapping arrays. Similarly, on average, a substantial lower number of CN*Vs* were detected with the DNA mapping arrays compared to those derived from whole exome sequencing data (2.4 *vs.* 9.5, p=0.0345). The power and resolution of our novel statistical tool was illustrated by the detection of acquired MLL-partial tandem duplication (MLL-PTD) lesions in 7 AML patients, which resurfaced in 4 matched relapse cases, and were not detected in the matched control samples. All MLL-PTD lesions were confirmed by standard PCR methodology.
Summary and Conclusions: Our algorithm enables reliable detection of small genetic lesions from different types of NGS data. The analyses based on NGS data revealed that AML has, on average, more genetic lesions than previously thought based on DNA mapping array data. The discordance can be mainly attributed to the increased resolution of NGS data with respect to DNA mapping arrays and the robust removal of systematic noise by our algorithm. Analysis of CN*Vs* derived from whole exome sequencing data reveals a substantial number of cases with MLL-PTD within diagnostic-relapse AML pairs, previously missed with DNA mapping arrays.

P141

HALOPLEX TARGET DNA ENRICHMENT ALLOWS INVESTIGATION OF COPY NUMBER AND MUTATIONAL STATUS OF KEY GENES IN ACUTE MYELOID LEUKAEMIA WITH NORMAL KARYOTYPE

N Bolli[1,*] N Manes[2], T McKerrel[2], J Chi[3], N Park[2], G Gundem[2], M Quail[2], N Conte[4], I Varela[5], C Grove[2], P Campbell[2], P Costeas[6], G Vassiliou[2]

Background: Acute myeloid leukaemia (AML) is a deadly haematological malignancy for which individualized treatment based on prognostic stratification is essential to maximize chances of survival. Karyotypic abnormalities carry prognostic significance, but are absent in about 50% of patients (NK-AML), and in this subgroup analysis of gene mutations can be used to stratify patients. Recent advances in AML genomics have defined the set of genes which are recurrently mutated in NK-AML, whilst the prognostic impact of many of these has been determined. Therefore, clinical-grade sequencing platforms will be increasingly useful in clinical practice in the next few years, and this highlights the need for reliable methods targeted gene re-sequencing.
Aims: HaloPlex is a novel, rapid approach for targeted DNA enrichment that requires low amounts of input DNA. We evaluated its performance in detecting abnormalities in coding sequence and copy number of genes recurrently mutated in NK-AML, with special focus on reproducibility and on the quantitative value of data.
Methods: Genomic DNA from 43 NK-AML samples from 40 patients was subjected to Haloplex target enrichment for 24 genes. Target-enriched DNA was sequenced on HiSeq2000, and reads were aligned using BWA. Substitutions and indels were called using standard algorithms and mutations called as previously described (Papaemmanuil *et al.*, Blood 2013).
Results: We sequenced 32.26 gigabases (Gb). A mean of 66.13% mapped on-target (62.94%>74.15%). The mean coverage of the target region was 3674.69x and 91.16% of bases were covered at >30X. Read depth showed significant variability, and coverage across consecutive bases could vary by several folds. This variability was expected as HaloPlex target-enrichment employs digestion of genomic DNA and specific capture of variable-length fragments with subsequent PCR amplification. Nevertheless, we found that this variability in coverage was predictable and highly consistent across samples. Consequently, using normalized data we were able to identify an interstitial deletion of BCOR and three MLL partial tandem duplications. We also report an amplification of KRAS, an event with driver potential in solid cancers but not previously described in AML. The quantitative nature if the data was retained when looking at point mutations, as demonstrated by a narrow range of allelic frequency of heterozygous SNPs. We identified likely oncogenic mutations in 38/40 samples with a median of 3 (1-5) per sample. NPM1 mutations were the most frequent (69%), followed by FLT3 (58%), DNMT3A (35%) and TET2 (32%). As described, NPM1 mutations co-occurred with FLT3 and DNMT3A. Both mono- and bi-allelic FLT3-ITDs were reliably identified. The recurrence rates were consistent with previously published data. We estimated allelic frequency of each mutation and reconstructed the phylogeny of mutations in each. In 2 cases with serial samples we studied the dynamics of tumour evolution and described variants lost and gained at relapse, implying that subclonal evolution can be inferred using Haloplex targeted data.
Summary and Conclusions: Haloplex target enrichment followed by massively parallel sequencing is a simple, rapid and robust method for high throughput screening of gene alterations in NK-AML. It may help prognostic stratification, treatment decisions and minimal residual disease assessment in clinical practice. It can reliably call copy number alterations, substitutions and indels. However, the targeting design should be checked carefully to ensure that the inherent variability in coverage will not affect the efficiency of variant calling.

THE CAMP RESPONSE ELEMENT BINDING PROTEIN (CREB) OVEREXPRESSION INDUCES MYELOID TRANSFORMATION IN ZEBRAFISH

C Tregnago[1,*] V Bisio[1], E Manara[2], S Aveic[1], C Borga[1], S Bresolin[1], G Germano[2], G Basso[1], M Pigazzi[2]
[1]Dipartimento di salute della donna e del bambino, Università degli Studi di Padova, [2]Dipartimento di salute della donna e del bambino, IRP, Padova, Italy

Background: Pediatric acute myeloid leukemia (AML), is a heterogeneous disease characterized by multiplicity of genetic or epigenetic events that can lead to transformation. Identifying specific leukemogenic aberrations may guide the development of targeted therapy approaches for selected patient groups. We previously identified and characterized one AML proto-oncogene: the cAMP response element binding protein (CREB). Its overexpression has been found in 66% of pediatric AML patients, and represents a poor prognostic marker in human AML. *In vitro* and *in vivo* studies demonstrated that its overexpression leads to abnormal cell proliferation, cell cycle progression and higher clonogenic potential, through an aberrant transcriptional regulation of its target genes. However the molecular mechanism and the transcriptional networks by which CREB triggers leukemogenesis has never been underpinned.
Aims: The aim of this study is to investigate the effects of CREB overexpression on hematopoiesis using the zebrafish *in vivo* model. Moreover, the identification of the main deregulated CREB targets will be pursued, in order to discover relevant pathways which will be considered for further therapeutic targeting.
Methods: We developed a zebrafish model that overexpressed human CREB in myeloid precursor cells, by injecting a plasmid which expressed CREB under control of *pu.1* promoter into 1-cell stage zebrafish embryos. The plasmid was constructed using the site-specific recombination-based cloning (multisite Gateway technology) Tol2kit system. Gene expression studies were conducted by RQ-PCR and whole mount *in situ* hybridization. Hematopoiesis after CREB enforced expression was investigated by flow cytometry analysis of kidney marrow cells, by immunohistochemistry. RNA extracted from kidney of 5 CREB and 5 control zebrafish were analyzed for gene expression (GeneChip Zebrafish Genome Arrays, Affymetrix, Santa Clara, CA, USA).
Results: Results showed that CREB recognized the cyclic-AMP responsive elements at genes promoter modifying gene expression. We documented the up-regulation of its targets, particularly of *bcl-2* and *jun*. Then, we controlled gene expression of genes involved in myelopoiesis and found increased levels of *pu.1*, *mpo* and *gata1* during the primitive hematopoiesis. Then, we monitored the kidney marrow of zebrafish during growth: 6-8 months old CREB zebrafish showed an impairment of myelopoiesis with a loss of cell precursors and increased myelo-monocytes by flow cytometry analysis. From 9 to 14 months, CREB overexpressing zebrafish developed a fatal myeloproliferative neoplasm (MPN) with 41% mortality rate. A clonal expansion of mature myelo-monocitic cells were present in kidney marrow with an impairment of lymphocyte production. Histological analysis revealed that myeloid cells infiltrated extramedullary organs, such as heart, liver, and abdominal organs, leading to zebrafish death. Immunohistochemistry assays displayed that disseminated blasts expressed human CREB. Microarray analysis identified 92 CREB target genes differentially expressed, belonging to proliferation/differentiation MAPK and cell cycle/DNA repair pathways.
Summary and Conclusions: This represents the first evidence that CREB overexpression triggers myeloid transformation in zebrafish. This model will serve to identify CREB mediated genes/pathways that contribute to the myeloid transformation, with the final aim of identifying novel therapeutic targets.

P144

POTENT COOPERATION BETWEEN THE NUP98-NSD1 FUSION AND THE FLT3-ITD MUTATION IN ACUTE MYELOID LEUKAEMIA INDUCTION

A Thanasopoulou[1,*] A Tzankov[2], J Schwaller[1]
[1]Department of Biomedicine, University Children's Hospital, [2]Institute for Pathology, University Hospital, Basel, Switzerland

Background: The NUP98-NSD1 fusion, resulting from an acute myeloid leukaemia (AML)-associated cytogenetically silent chromosomal translocation, is frequently found in pediatric cytogenetically normal AML and associated with aggressive disease and poor prognosis. Co-existence of a FLT3-ITD activating mutation has been reported in more than 70% of these patients but its functional significance remains unclear.
Aims: In order to address the functional synergism between the two mutations, NUP98-NSD1 and FLT3-ITD, we determined the transforming potential of retrovirally expressed NUP98-NSD1 and FLT3-ITD in murine bone marrow *in vitro* and *in vivo*.

Methods: Lineage marker-negative murine bone marrow cells were transduced with *pMSCV-NUP98-NSD1-neo* or *pMSCV-FLT3-ITD-GFP* retroviral vectors or both. Transduced cells were analyzed for their clonogenic potential by serial plating in growth-factor containing methylcellulose followed by expansion and injection into sublethally irradiated syngeneic recipients.
Results: Expression of NUP98-NSD1 provided aberrant self-renewal potential to bone marrow progenitor cells. Co-expression of FLT3-ITD increased proliferation but impaired self-renewal *in vitro*. Transplantation of cells expressing NUP98-NSD1 and FLT3-ITD into mice resulted in transplantable AML after a short latency. The leukaemic blasts expressed myeloid markers (Mac-1^+/Gr-1^+/FcγRII/III$^+$/c-kit^{lo}/CD34^{lo}). Splinkerette-PCR revealed similar patterns of potential retroviral integration sites of *in vitro* immortalized bone marrow cells before and after expansion *in vivo*. Mice that received cells expressing solely NUP98-NSD1 did not develop AML but showed signs of a myeloid hyperplasia after long latency, characterized by expansion of Mac-1^+/Gr-1^+ cells in the bone marrow and active extramedullary haematopoiesis in the spleen. Interestingly, similar to what has been observed in patients carrying NUP98-NSD1, an increased *Flt3-ITD* to wildtype *Flt3* mRNA expression ratio was found to be associated with a more aggressive disease induced by co-expression of NUP98-NSD1 and FLT3-ITD. Additionally, the shorter latency of AML induction correlated with increased activation of the FLT3-STAT5 signaling axe as shown by increased pFLT3 levels and increased basal and GM-CSF induced pSTAT5 levels, as assessed by flow cytometry. To further underline the importance of FLT3 signaling for NUP98-NSD1 induced AML we treated *ex vivo* immortalized progenitors as well as *in vivo* established leukemic blasts with a small molecule FLT3 inhibitor (PKC-412) and found that proliferation of all cells co-expressing NUP98-NSD1 and FLT3-ITD was significantly impaired by PKC-412.
Summary and Conclusions: Our data revealed a potent cooperation between NUP98-NSD1 and FLT3-ITD for the induction of AML disease *in vivo* and underlined the significance of aberrant FLT3 signaling for maintenance of NUP98-NSD1-positive AML. In addition, we provided the rationale and a mouse model that allows to functionally explore the use of small molecule FLT3 inhibitors for NUP98-NSD1 positive AML.

P145

AN INDUCIBLE MOUSE MODEL FOR MLL-ENL MIXED-LINEAGE LEUKEMIA
V Stavropoulou[1,*] S Juge[1], JF Spetz[2], A Tzankov[3], L Brault[1], M Iacovino[4], M Kyba[4], A H Peters[2], J Schwaller[1]
[1]Dept. of Biomedicine, University Children's Hospital, [2]Friedrich Miescher Institute for Biomedical Research, [3]Institute for Pathology, University Hospital Basel, Basel, Switzerland, [4]Department of Pediatrics, Lillehei Heart Institute, University of Minnesota, Minneapolis, United States

Background: The t(11;19)(q23;p13.3) translocation leading to expression of the MLL-ENL fusion protein is one of the most prevalent MLL gene alterations, mostly associated with mixed lineage or B-cell acute lymphoblastic leukemia. The existing retroviral and knock-in models do not closely recapitulate the human disease, possibly because of a failure to activate MLL-ENL expression in the appropriate hematopoietic compartment.
Aims: To establish an inducible mouse model for MLL-ENL that recapitulates the human disease and thereby facilitates the dissection of the mechanisms underlying MLL-ENL leukemogenesis.
Results: We used the doxycycline (DOX)-induced gene expression system to establish transgenic rtTA;MLL-ENL mice. DOX-induced *ex vivo* expression of MLL-ENL provided bone marrow and hematopoietic stem and progenitor cells with a strong long-term self-renewal capacity, causing the accumulation of immature blast-like cells upon serial replating in methylcellulose cultures. In the presence of factors favoring myelopoiesis, like IL-3, DOX removal resulted in a complete differentiation towards the granulocytic-monocytic, lineages expressing high levels of Mac1/Gr-1, whereas IL-7 favored differentiation towards the B-cell lineage characterized by the expression of high levels of B220. Induction of MLL-ENL expression in newborn or adult mice resulted in 100% of the mice in a leukemic phenotype that phenocopied pre-B- and myeloid mixed lineage leukemia. Diseased mice had excessive splenomegaly, massive lymph node and multi-organ infiltration characterized by the coexistence of at least two types of blasts of various sizes and granularity that expressed intermediate levels of myeloid markers or lymphoid markers. Transplantation of B220^{high}, blasts into sub-lethally irradiated recipients rapidly induced the disease (15.6±0.5 days) whereas transplantation of B220^{low} blasts resulted in significantly longer latency (22.5±1.1 days) suggesting that the B220^{high} population is enriched for leukemia initiating cells. Expression of the fusion gene and disease induction was DOX dosage dependent and fully reversible upon DOX removal. Interestingly, low level MLL-ENL expression resulting from the inherent leakiness of the DOX-inducible system never resulted in any disease. Transplantation of long-term hematopoietic stem cells (LT-HSCs) and granulocyte-monocyte progenitors (GMPs) from naïve rtTA;MLL-ENL mice into lethally irradiated recipients revealed that the LT-HSCs induced the disease in all the recipients whereas GMPs never resulted in any disease, suggesting that MLL-ENL preferentially transforms LT-HSCs rather than committed progenitors.
Summary and Conclusions: We established a novel inducible transgenic mouse model that phenocopies the human MLL-ENL mixed-lineage leukemia. *Ex vivo* and *in vivo* transformation and disease development was always DOX dependent and fully reversible upon MLL-ENL downregulation. Conditional activation of the fusion in different cells of the hematopoietic hierarchy suggested that in contrast to other MLL fusions, MLL-ENL leukemia originates from hematopoietic stem cells or early progenitors rather than more mature lineage-committed progenitor cells.

P146

LATS1 IS A NOVEL PUTATIVE TUMOR SUPPRESSOR IN ACUTE HOX-INDUCED LEUKEMIA
E Schmidt[1,*] J Krosl[2], J Chagraoui[2], N Mayotte[2], N Bäumer[1], M Sauvageau[2], W E Berdel[1], G Sauvageau[2]
[1]Department of Hematology and Oncology, University Hospital Muenster, Muenster, Germany, [2]Institute for Research in Immunology and Cancer, University of Montreal, Montreal, Canada

Background: It is estimated that 50% of human leukemias are induced by the misregulation of Hox genes and their cofactors such as Meis1. A genetic modifier screen in drosophila showed that hth/MEIS directly interacts with YKI, a transcription co-factor and component of the Hippo signaling network. The Hippo signaling network has been proposed to play a tumor suppressive role in carcinoma development but to date its function in hematopoiesis and leukemia remains unknown.
Aims: The aim of our study is to elucidate the function of the Hippo signaling pathway in Hox / Meis induced Leukemia and to characterize its role in the murine hematopoietic system.
Methods: The core components of the Hippo pathway are expressed in the Hoxa9+Meis1-induced leukemia named FLA2 in which approximately 70% of cells represent leukemia initiating cells (LIC) (Wilhelm B *et al.*, 2011). Freshly isolated FLA2 cells were retrovirally transduced with shRNA targeting Hippo signaling network core components (MST1 and 2, LATS1 and 2, YAP and TAZ) and transplanted into recipient mice. The proportions of shRNA transduced (GFP+) cells were determined at the time of transplantation (day 0), and at the time of sacrifice. We then isolated the CD150+CD48- Lin- stem/progenitor cells from murine BM, co-infected them first with Hoxa9 and Meis1 cDNA carrying retroviruses, and then knocked down Yap or Lats1. The latency of leukemia onset after transplantation was compared to the shLuc - control. To test wether normal murine hematopoiesis is affected by the loss of function of core components of the canonical Hippo pathway, HSC-enriched CD150$^+$CD48$^-$Lin$^-$, cells were infected over 5 days by co-culture with retroviral producer cells in an arrayed 96-well format, with one shRNA per well. Directly after infection, the *in vivo* reconstituting potential of ¼ of each well was evaluated through duplicate competitive repopulation assays involving the co-transplantation of 1.5x10^5 congenic BM competitor cells into irradiated recipients. The remaining cell fraction served to asses gene transfer by GFP fluorescence measurements. Blood reconstitution was evaluated at an early (4wks) and late time point (16-20wks), tracking the contribution of the donor CD45.1+ transduced (GFP+) cells to recipient hematopoiesis over time. As baseline references we used shRNA to Luciferase (no effect) and Nup98HoxA10 overexpression (stem cell expansion).
Results: Expression of the core Hippo pathway constituents in different subpopulations of primitive murine hematopoietic cells as well as in FLA2-leukemia could be detected by quantitative RT-PCR. During the time between transplantation of FLA2-leukemia and sacrifice of the mice, the proportions of shTaz (GFP+) cells to the leukemic cell populations decreased to 10-20% of the initial day 0 values. Conversely, the Lats1 knockdown leads to >50% increase over the initial proportion of the GFP+ cells ($p < 0.05$, Mann-Whitney-Test). This effect is not limited to FLA2 leukemia. AML development in mice induced by overexpression of HoxA9 and Meis is accelerated with additional Lats 1 loss of function. The Median survival of transplanted mice is 46 days (range 45-50 days) compared to 53 days of the shLuciferase control (range 52-56 days). Yap loss of function prolongs the latency of leukemia onset significantly ($p < 0.05$, Mantel Cox Test) to >70 days. Consistent with our previous observations we detected a strong impact of LATS1 loss of function on normal HSC-function, resulting in higher long - term reconstitution rates compared the shLuciferase control. Moreover, one third of transplanted mice developed acute leukemia (myeloid and lymphoid).
Summary and Conclusions: Our observations suggest that LATS1 acts as a tumor suppressor in Hox/Meis-induced leukemia and putatively in the hematopoietic system. This indicates a possibility for a specific targeting of the Hox/Meis-activated cellular pathways.

P147

THE MYB-GATA1 FUSION IN THE CONTEXT OF LOW GATA1 EXPRESSION FAVOURS THE BASOPHILIC DIFFERENTIATION OF HUMAN HEMATOPOIETIC STEM/PROGENITOR CELLS
V Prouzet-Mauleon[1], S Ducassou[1], P Brunet de la Grange[2], C Quelen[3], P Brousset[3], F Moreau-Gaudry[1], FX Mahon[1], E Lippert, [1,*]
[1]INSERM U1035-Université de Bordeaux, [2]EFSAL, Bordeaux, [3]Inserm/CNRS/UPS - UMR1037, Toulouse, France

Background: Acute basophilic leukemia with t(X;6) translocations represent a rare specific hematological malignancy encountered in male infants. The t(X;6) translocation has two consequences: i) the fusion of MYB and GATA1, two transcription factors important for the regulation of hematopoiesis and ii) the destruction of the GATA1 gene, resulting in the absence of this protein in the cells of the affected male patients (Quelen *et al.*, Blood, 2011;117(21):5719-5722). We and other have previously shown that murine hematopoietic stem cells expressing MYB-GATA1 and low levels of GATA1 display an increased self renewal and a propensity to develop acute myeloblastic leukemia. However, no evidence of a basophilic phenotype has been observed in this model thus far.
Aims: Since this genetic abnormality correlates with a characteristic basophilic leukemia, we explored whether the expression of MYB-GATA1 in cells expressing a low level of GATA1 would result in a basophilic differentiation.
Methods: Lentiviral vectors encoding MYB-GATA1 along with a TdTomato marker or a shGATA1 with a GFP marker were generated, as well as control vectors (empty vector withTdTomato or irrelevant shRNA with GFP). Normal human CD34+ stem / progenitor cells were isolated from placental blood by immunoselection. They were infected with control or relevant vectors after a 24 hour culture in medium containing IL-3, SCF and TPO. 100 000 cells were then engrafted in immunodeficient (NOD-SCID-γ) mice after myeloablation by busulfan. Twelve weeks later, hematopoiesis was examined for basophilic differentiation by analyzing the expression of CD117, CD203c, FcεRI and CD123 by flow cytometry.
Results: No mouse developed signs of leukemia. There were no anomalies of the various organs studied (spleen, liver, lungs). CD34+ cells were efficiently infected by control vectors (45-65% expressing both the TdTomato and GFP markers) and the MYB-GATA1 and shGATA1 expressing vectors (6-17% double transfectants). Efficiencies of engraftments, appreciated by measuring cells expressing the human CD45 antigen, were similar for control and MYB-GATA1/shGATA1 infected cells. The proportion of persistent CD34+ cells was slightly higher in mice engrafted with MYB-GATA1/shGATA1 (median: 21% *versus* 10%), as was the percentage of myeloid CD33+ cells (59% *vs* 19%), confirming results obtained previously with murine cells. Expression of the basophilic marker CD123 was similar in both groups (7 *vs* 5.5%), but other basophilic / mast cell antigens FcεRI (5.05 *vs* 1.45), CD203c (6.6 *vs* 1.15) and CD117 (20.85 *vs* 1.85) were significantly higher in cells expressing MYB-GATA1 and shGATA1.
Summary and Conclusions: Expression of the chimeric protein MYB-GATA1 in the context of low expression of GATA1 reproduces the conditions observed in leukemic blast cells. These conditions increase the self renewal of CD34 positive cells and favour a myeloid differentiation. They also promote the expression of basophilic and mast-cell markers FcεRI, CD203c and CD117. This validates the importance of MYB-GATA1 fusion and low GATA1 expression in basophilic leukemia, and suggests that additional anomalies are necessary for the full leukemic phenotype.

P148

THE IKAROS 6 ISOFORM COOPERATES WITH BCR-ABL1 TO INDUCE HUMAN ACUTE MYELOID LEUKEMIA IN XENOGRAFTS

A Theocharides[1,2,*] S Dobson[2], E Laurenti[2], F Notta[2], V Voisin[3], PY Cheng[2], CG Mullighan[4], MD Minden[2], E Torlakovic[5], JE Dick[2]
[1]University Hospital Zurich, Division of hematology, Zurich, Switzerland, [2]Princess Margaret Cancer Centre, University Health Network, [3]Pathway and Network Analyses for OICR Cancer Stem Cell Research, University of Toronto, Toronto, Canada, [4]St. Jude Childrens Hospital, Memphis, United States, [5]Department of Laboratory Hematology, TGH, University Health Network, Toronto, Canada

Background: Historically, our understanding of mechanisms underlying human leukemogenesis are inferred from genetically engineered mouse models. Relatively few models that use primary human cells recapitulate the full leukemic transformation as assayed in xenografts and myeloid transformation is infrequent.
Aims: We aimed to determine the functional consequence of combinatorial overexpression of *BCR-ABL1* and a dominant negative isoform of IKAROS, Ik6, in human lineage depleted cord blood (LIN-CB) cells.
Methods: LIN-CB cells were exposed to lentiviruses, and then to retroviral supernatants. Four independent cultures were generated: control, Ik6, *BCR-ABL1* and *BCR-ABL1*-Ik6. Cells were seeded after infection into lympho-myeloid promoting culture conditions. NSG mice were intrafemorally transplanted with transduced LIN-CB and sacrificed at 16-20 weeks post-transplantation or when sick. Engrafted human cells were characterized by flow cytometry and extensive histopathological analysis. Gene expression, gene set enrichment, pathway and network analysis were performed on purified double-transduced cells cultured *in vitro*.
Results: We report a humanized experimental leukemia model where xenografts develop aggressive acute myeloid leukemia (AML) with disseminated myeloid sarcomas within 4 weeks following transplantation of cord blood transduced with vectors expressing *BCR-ABL1* and Ik6. Ik6 induced transcriptional programs in *BCR-ABL1* transduced progenitors that contained repressed B cell progenitor programs, along with strong stemness, proliferation, and granulocyte-monocytic progenitor signatures; a novel combination not induced in control groups.
Summary and Conclusions: Thus, wild type IKAROS restrains stemness properties and has tumor suppressor activity in *BCR-ABL1* initiated leukemia. Although IKAROS mutations/deletions are common in lymphoid transformation, they are found also at low frequency in AML that progress from a prior myeloproliferative neoplasms (MPN) state. Our experimental system provides an excellent model to gain insight into these rare cases of AML transformation and the properties conferred by IKAROS loss of function as a secondary mutation. More generally, our data point to the importance of deregulated stemness/lineage commitment programs in human myeloid leukemogenesis.

SERIAL TRANSPLANTATION AND *IN VIVO* MONITORING OF PATIENT-DERIVED XENOGRAFTS: AN ADVANCED PRECLINICAL MODEL TO STUDY DIVERSE GENETIC AML SUBGROUPS IN MICE

B Vick[1,2,3], M Rothenberg[4], N Sandhoefer[2,3,4,5], M Carlet[1], C Finkenzeller[1], C Krupka[4,6], M Grunert[1], A Trumpp[2,3,7], S Corbacioglu[8], M Ebinger[9], MC André[9,10], W Hiddemann[2,3,4,5], M Subklewe[2,3,4,6], S Schneider[4], K Spiekermann[2,3,4,5], K H Metzeler[2,3,4,5,*] I Jeremias[1,2,3,11]
[1]Group Apoptosis, Department of Gene Vectors, Helmholtz Zentrum München, München, [2]German Cancer Consortium (DKTK), [3]German Cancer Research Center (DKFZ), Heidelberg, [4]Department of Internal Medicine III, Ludwig-Maximilians-Universität, [5]Clinical Cooperation Group Leukemia, [6]Clinical Cooperation Group Immunotherapy, Helmholtz Zentrum München, München, [7]Division of Stem Cells and Cancer, German Cancer Research Center (DKFZ), Heidelberg, [8]Department of Pediatrics, University of Regensburg, Regensburg, [9]Department of Pediatric Hematology/Oncology, Eberhard Karls Universität, Tübingen, Germany, [10]Department of Pediatric Intensive Care Medicine, University Childrens Hospital (UKBB), Basel, Switzerland, [11]Department of Oncology, Dr. von Haunersches Kinderspital, Ludwig-Maximilians-Universität, München, Germany

Background: Despite recent improvements in diagnosis and treatment of acute myeloid leukemia (AML), the majority of patients suffer from a persistently poor prognosis. Preclinical research can improve the understanding of AML biology and help to develop novel therapeutic approaches. In recent years, primary human AML cells have been engrafted successfully in immuno-compromised mice to study stem cell features and to analyze treatment response on AML cells *in vivo*. However, until now, re-engraftment of patient-derived cells has only been analyzed to assess self-renewal capacity.
Aims: We aimed at improving the individualized xenograft mouse models of AML by establishing patient-derived xenografted (Pdx) lines and introducing *in vivo* monitoring. To confirm the validity of this model, we evaluated the consequences of sequential transplantation and transgene expression on genetic and functional characteristics of Pdx cells, and efficiency of *in vivo* bioluminescence imaging (BLI).
Methods: Patient-derived AML cells were injected into NOD/scid IL2 receptor γ chain knockout (NSG) mice. After successful engraftment, human cells were re-transplanted into next generation recipients for up to six passages to establish Pdx lines. Pdx cells and lines were genetically characterized by targeted resequencing of 43 AML-related genes. Furthermore, cells were transduced with lentiviral constructs containing enhanced firefly luciferase to facilitate BLI.
Results: Serial transplantation of Pdx cells was feasible in 6/12 of initially engrafted samples. Growth and sample characteristics like passaging time (indicating time from cell injection until overt disease), percentage of human cells within mouse bone marrow (BM) or peripheral blood (PB), and immunophenotype remained stable in Pdx lines. Targeted resequencing confirmed that clonal and subclonal mutations in patient specimens were preserved in the matched Pdx lines. However, subclones present in the primary sample became a major clone in two of six Pdx samples, and in another two samples, subclones within the patient were not detectable within Pdx cells. Therefore, we conclude that some subclones may have engraftment and/or growth advantages within the mouse. Nevertheless, the genetic characteristics of the primary samples were preserved within Pdx cells to a high extent. Until now, disease monitoring within the individualized xenograft mouse model of AML was challenging. Human cells are secreted into PB only at late disease stages. BM biopsies can be performed only infrequently due to animal welfare. Therefore, most data is determined by post mortem analysis. Here we show that transgenic Pdx (t-Pdx) cells expressing luciferase can be visualized by BLI. BLI was very sensitive, visualizing t-Pdx cells on a 10^{-4}, level of mouse BM cells on day one after cell injection. Additionally, growth of t-Pdx cells could be followed over time in an exponential manner. Furthermore, we performed limiting dilution transplantation assays, and found that the frequency of leukemia initiating cells could be determined within four to six weeks. Importantly, sample characteristics of t-Pdx cells still maintain immunophenotypic and mutational characteristics of the primary patient samples.
Summary and Conclusions: We conclude that Pdx lines faithfully represent the AML sample they originate from. Prospectively, these advancements enable repetitive, clinically relevant studies on AML biology and preclinical treatment trials on genetically defined and heterogeneous subgroups.

LEUKEMIC STEM CELLS OF ACUTE MYELOID LEUKEMIA PATIENTS CARRYING NPM1 MUTATION ARE CANDIDATES FOR TARGETED IMMUNOTHERAPY

V Schneider[1], L Bullinger[1], L Zhang[1, 2], M Rojewski[3], M Wiesneth[3], S Hofmann[1], M Götz[1], H Schrezenmeier[3], U Botzenhardt[1], T F Barth[4], K Döhner[1], H Döhner[1], J Greiner[1,5,*]

[1]Department of Internal Medicine III, University of Ulm, Ulm, Germany, [2]Huazhong University of Science and Technology, Wuhan, China, [3]Institute of Transfusion Medicine, [4]Department of Pathology, University of Ulm, Ulm, [5]Hematology and Oncology, Diakonie Hospital, Stuttgart, Germany

Background: The nucleophosmin 1 (*NPM1*) gene is an interesting candidate for targeted immunotherapy in acute myeloid leukemia (AML). Mutations in *NPM1* are one of the most frequent molecular alterations in AML. Immune responses against the mutated protein of *NPM1* were described and might contribute to the favourable prognosis of AML patients carrying $NPM1^{mut}$. However, underlying mechanisms are still not clear. Leukemic stem cells (LSC) might be the source for leukemic self-renewal and might account to disease relapse after treatment.
Aims: We were interested in expression differences of the LSC enriched cell fraction descendent of $NPM1^{wt}$ and $NPM1^{mut}$ primary AML patients. We suggest that expression differences between the patients groups could be a factor for the better overall survival of $NPM1^{mut}$ patients. In addition we aimed to study new targets on $NPM1^{mut}$ LSC for new therapeutical purposes.
Methods: We enriched the CD34+CD38- fraction of primary AML peripheral blood mononuclear cells (PBMC), by Fluorescence-activated cell sorting (FACS). We sorted 21 AML patient samples; 12 $NPM1^{wt}$ and 9 $NPM1^{mut}$. We also enriched healthy donor samples for HSC purification, in order to compare expression levels. Enriched CD34+CD38- cells in $NPM1^{mut}$ AML samples harbor cytoplasmic NPM1 demonstrated via immunocytochemical staining. Functional assays, confirming the biological importance of these factors have been performed.
Results: We showed that enriched CD34+CD38- cells in $NPM1^{mut}$ AML samples harbor cytoplasmic *NPM1* via immunocytochemical staining, indicating that these cells belong to the leukemic clone. The cell number and RNA quality was sufficient for further Microarray studies in which we analyzed the CD34+CD38- enriched compartments descendent from $NPM1^{mut}$ and $NPM1^{wt}$ patients. Those showed significant differences in gene expression patterns which noticeably are immunologically coined, for example: immunoglobulin superfamily, member 10 (p=0.0003405; fold change: 6.22) and the interleukin 12 receptor, β 1 (p=0.000834, fold change: 1.87). This impression was confirmed by pathway analysis indicating deregulation of pathways like the NO2-dependent IL 12 Pathway in NK cells and the Th1/Th2 Differentiation and the Platelet Amyloid Precursor Protein Pathway. Furthermore we screened our data for new potential therapeutic target structures, specifically on enriched CD34+CD38- cells of $NPM1^{mut}$ patients, comparing the expression level of target genes to $NPM1^{wt}$ CD34+CD38- cells, and the expression level on HSC. Amongst others, our most promising candidates are SERPINA1 (p=0.0062344, fold change: 14.32), OSCAR (p=6.11E-05, fold change: 9.03) and several further interesting genes. These genes could be used in order to target CD34+CD38- cells of $NPM1^{mut}$ patients in a therapeutic manner.
Summary and Conclusions: Taken together, we could demonstrate that leukemic progenitor cells of $NPM1^{mut}$ and $NPM1^{wt}$ AML patients can be effectively separated for array analysis. The frequency of CD34+CD38- enriched LSC population in $NPM1^{mut}$ AML patients is significantly lower. Markedly, genes with immunological functions seem to play an important role in the $NPM1^{mut}$ AML subtype. Besides peptides derived from $NPM1^{mut}$, which were already described as an immunogenic target for specific immunotherapy, further interesting targets have been detected, like the cell surface marker CD96 and *IL12RB1*. Our functional assays suggest that these detected targets might have a therapeutic potential that has to be elucidated in clinical trials.

P151

MESENCHYMAL STEM CELLS (MSCS) OF AML PATIENTS HARBOR CHROMOSOMAL DEFECTS DISTINCT FROM THOSE OF LEUKEMIC CELLS

P Bernasconi[1,*] I Dambruoso[1], M Cervio[2], M Gotti[1], M Boni[1], R Zappatore[1], C Calvello[1], C Delfante[2], G Viarengo[2], C Perotti[2]

[1]Dept. Hematology, Fondazione IRCCS Policlinico San Matteo, [2]Dept. Immuno-Hematology, Fondazione IRCCS Policlinico San Matteo, Pavia, Italy

Background: Various studies have demonstrated that the bone marrow microenvironment (the niche) is involved in leukemia development. As MSCs are key components of the niche, it was questioned whether MSCs from AML patients (pts) carry the same chromosomal defects of leukemic cells.
Aims: Thus, this possibility was tested by the present study which examined leukemic and MSCs from fourteen AML pts with three different technologies, conventional cytogenetics (CC), FISH and aCGH/SNPa.
Methods: At disease onset after informed consent all the fourteen pts were submitted to bone marrow (BM) aspiration. BM cells were submitted to CC and FISH analyses. In addition, MSC were isolated from BM cell suspension (10-15 ml) as previously described. Briefly, mononucleated cells were isolated from BM by density gradient centrifugation using Lympholyte®-H and seeded in 75 cm^2 cell culture flasks at a cell density of 10^6 cells/cm^2. Cells were cultured at 37°C, 5% CO2 in MEM-alpha medium containing 1% Penicillin/Streptomycin, 1% L-Glutamine and 10% fetal bovine serum. After 48-h adhesion, non-adherent cells were removed and culture medium replaced. Growth medium was changed every three days. MSCs were examined after the first passage and their phenotype was evaluated by flow cytometry. Cells were detached from culture using Tripsin-EDTA and after washing stained for ten minutes with the following fluorochrome-conjugated antibodies: anti-CD90-FITC, anti-CD105-PE, anti-CD14-FITC, anti-CD73-PE, anti-CD34-FITC, anti-CD80-PE, anti-CD133-APC, anti-CD31-PE and anti-CD45-APC-Alexa750. Stained cells were acquired with a Beckman Coulter Navios instrument and data analyzed with Kalooza software. The commercial FISH probes used were LSI D7S486/CEP7, LSI AMLE-TO from Abbot Molecular Inc. (Chicago, Il, USA) and ON c-Myc/SE8, SE10(D10Z1) from Kreatech (Amsterdam, NL). Their cut-off values were determined by applying a one-sided 95% confidence interval. aCGH/SNPa was carried out with the SureScan Microarray Scanner G4900DA (Agilent Technologies Inc. Santa Clara, CA).
Results: In leukemic cells CC revealed a chromosomally normal pattern in seven pts, a -7 in two, a del(7)(q31) in one, a +8 and a +10 in one each, a t(8;21)(q24,q22) in one and a complex karyotype in the last pt. All these defects were confirmed by FISH. In order to establish whether leukemic cells and MSCs shared the same pattern, MSCs cultures were tested with FISH. Flow-cytometry revealed that MSCs purity was 50-87%. FISH showed a normal pattern in all the cultures examined. In contrast, aCGH/SNPa revealed an amplification of the entire chromosome 5 in one pt, a LOH of a 3.8 Mb sized region located on 13q31.1 in one, a LOH of a 4.3 Mb region mapped on chromosomes 6 and 18 in two, an amplification of three 71Kb, 322Kb and 47Kb sized regions of chromosomes 5, 18 and 20 in one and an amplification of three 17Kb, 40Kb and 70Kb sized regions of chromosomes 9, 11 and 15 in another pt. In this last an amplification of six genes including *JAK1, ELN, FGFR2* was observed. FISH revealed that chromosome 5 amplification, the only defect tested by this technique, was produced by a true trisomy.
Summary and Conclusions: In conclusion i) MSCs from chromosomally abnormal AML pts may have a normal FISH pattern, but may contain on aCGH/SNPa analysis LOH or amplifications different from those of leukemic cells; ii) usually, these lesions are uncommon in AML; iii) MSCs defects may flag a leukemogenic-induced genomic instability which not only affects the hematopoietic tissue but also the niche; iv) aCGH/SNPa is a powerful technique for identifying clonal markers.

P152

ALTERATIONS IN MESENCHYMAL STROMAL PRECURSOR CELLS FROM THE BONE MARROW OF THE ACUTE MYELOID LEUKEMIA PATIENTS: NEWLY DIAGNOSED, AND BEFORE AND AFTER ALLOGENEIC HEMATOPOIETIC STEM CELL TRANSPLANTATION

I Shipounova[1,*] A Bigildeev[1], N Petinaty[1], N Drize[1], T Sorokina[2], L Kuzmina[2], E Parovichnikova[2], V Savchenko[3]

[1]Physiology of Hematopoiesis laboratory, [2]High Dose Chemotherapy of hemoblastoses, hematopoiesis depressions and Bone Marrow Transplantation Department, [3]Director, National Hematology Research Centre, Moscow, Russian Federation

Background: Stromal microenvironment is essential for normal hematopoiesis, as it forms niches for hematopoietic precursors. Leukemia and high dose chemotherapy affect both hematopoietic and stromal precursor cells. Changes in the hematopoiesis that occur during acute myeloid leukemia (AML) can cause some variations in the composition of the stromal microenvironment.
Aims: The goal of this study was to analyze the alterations in the characteristics of human multipotent mesenchymal stromal cells (MSC) and their more differentiated progeny - fibroblastic colony forming units (CFU-F), derived from the bone marrow (BM) of AML patients.
Methods: Eleven newly diagnosed cases and 20 patients before and during 1 year after allogeneic hematopoietic stem cell transplantation (alloHSCT) were involved in the study after informed consent. BM was aspirated prior to any treatment in the newly diagnosed group and before the conditioning and at 6 time points during 1st year after the alloHSCT in the group of patients with alloHSCT. MSC were cultured in aMEM with 10% fetal calf serum. Cumulative MSC production was counted after 3 passages. CFU-F concentration was analyzed in standard conditions. The relative expression level (REL) of different genes was measured by RT2 Profiler PCR Array (Qiagen) and TaqMan RQ-PCR. As a control MSC and CFU-F from 50 healthy donors of BM for alloHSCT were used.
Results: The CFU-F concentration in the BM of patients at the moment of AML diagnostics was half of the donor's (13.9±8.1 *versus* 32.2±4.3 per 10^6 nucleated cells in donor BM, p=0.06). Most of the patients assigned to alloHSCT were in the remission and at that moment CFU-F concentration in their BM was slightly lower than in donors (26.7±7.2 per 10^6 BM nucleated cells). After the alloHSCT CFU-F concentration in patients' BM decreased 3-9 folds for the next year of observation. The decrease at each time point was highly significant comparing to donors. Similar picture was observed in MSC analysis. Cumulative cell production in MSC of newly diagnosed AML patients was also half of

the donors (3.8±1.1 x10^6 *versus* 7.6±0.8x10^6 for donors' MSC, p=0.02). MSC from the BM of patients before alloHSCT were also slightly and insignificantly lower than from healthy donors (5.9±1 x10^6), and after alloHSCT cumulative MSC production decreased 1.3-5.2 folds for the next year. The decrease at almost each time point was significant comparing to donors. All these effects were reflected in the proliferation rate of studied MSC: time of reaching confluent monolayer at Po of MSC from newly diagnosed patients and the ones after alloHSCT was significantly prolonged comparing to donors. Gene expression analysis revealed that in MSC at the moment of AML diagnosis then REL of FGF2, IL1B, IL6, JAG1, PDGFB, VCAM1, VEGFA decreased more than 2 fold. Prior to alloHSCT the REL of IL6 and IL1B were still very low, following the transplantation the REL of IL6, JAG1, PDGFB increased, while IL1B stayed at the low level at least for 6 months.

Summary and Conclusions: During the AML development leukemic cells alter the stromal precursor cells leading to the decrease in their proliferative ability, in the REL of many regulatory genes and in the number of more differentiated stromal precursor cells in the BM. Chemotherapy used for induction of the remission in these patients did not alter the stromal precursor cells significantly. Conditioning regiments used for the alloHSCT significantly damage both types of studied stromal precursors, and the effect lasted at least for 1 year. So, both AML cells and chemotherapy affect BM hematopoietic microenvironment.

P153

COMPREHENSIVE ASSESSMENT OF BONE MARROW STROMA-DERIVED SOLUBLE FACTORS AND IMPACT ON *EX VIVO* DRUG SENSITIVITIES OF PRIMARY AML CELLS

R Karjalainen[1,*] MM Majumder[1], T Pemovska[1], M Kontro[2,3], BT Gjertsen[4], A Parsons[1], M Suvela[1], B Yadav[1], T Aittokallio[1], K Porkka[2, 3], O Kallioniemi[1], K Wennerberg[1], C Heckman[1]

[1]Institute for Molecular Medicine Finland, FIMM, [2]Hematology Research Unit Helsinki, University of Helsinki, [3]Helsinki University Central Hospital (HUCH), Helsinki, Finland, [4]Department of Clinical Science, University of Bergen, Bergen, Norway

Background: The bone marrow (BM) microenvironment is composed of multiple cell types that via direct cell-to-cell interactions and soluble factors support the survival of leukemic cells and influence their response to therapeutic agents. Thus, survival signals from the BM microenvironment may contribute to the development of drug resistance. However, failure to mimic these interactions *ex vivo* leads to poor translation of results from drug sensitivity testing assays. More reliable prediction of drug sensitivity is needed and recent focus has been directed towards methods that take into account the supporting impact of the tumor microenvironment.

Aims: In these studies we aimed to develop a more predictive high throughput assay mimicking the *in vivo* tumor microenvironment in order to assess drug sensitivities of primary acute myeloid leukemia (AML) cells *ex vivo*.

Methods: Conditioned medium (CM) was collected from the HS-5 human BM stromal cell line (American Type Culture Collection, ATCC) and combined with RPMI medium for drug sensitivity testing. Mononuclear cell medium (MCM, Promocell) was used as the standard medium comparison. Sensitivity of primary AML (n=13) or healthy (n=5) BM mononuclear cells to 306 approved and investigational drugs was measured at five different concentrations covering a 10,000-fold concentration range. Cell viability was measured after 72 h and dose response curves generated for each tested drug. Drug sensitivity scores (DSS) were calculated based on the area under the dose response curve. The same cells were cultured in 25% CM or in MCM and the drug sensitivities compared. Drug sensitivities of matched fresh and vitally frozen biobanked AML cells were also assessed. Growth factors and cytokines present in the CM were detected by an antibody array (RayBioTech).

Results: HS-5 CM supported fresh and biobanked primary AML cells, promoting their overall survival. Freshly isolated AML cells had a mean viability of 128% after 3 days in CM compared to 63% in MCM. The viability of biobanked cells was 85% in CM *vs.* 20% in conventional medium. The supportive effect of the CM was seen with *ex vivo* drug sensitivity testing where sensitivities differed significantly when comparing CM to standard medium results. When cultured in CM, AML cells positive for the FLT-ITD mutation exhibited reduced efficacy to multiple tyrosine kinase inhibitors (TKIs) targeting VEGFR, PDGFR, ABL KIT, as well as FLT3. However the FLT3-ITD AML cells were sensitive to these inhibitors when cultured in the conventional medium. Comprehensive assessment of soluble factors in the HS-5 CM detected several inflammatory cytokines and chemokines, including high levels of IL-6, IL-8, GM-CSF, G-CSF, GRO, and MCP-1 that can activate adaptive survival signals, such as the JAK/STAT pathway. Corresponding to these findings, we observed increased sensitivity of AML cells to the JAK1/2 inhibitor ruxolitinib when cultured in CM (DSS 14 *vs.* 3).

Summary and Conclusions: Our data indicate that conditioned medium from stromal cells supports both fresh and biobanked AML cells, providing soluble factors present in the BM niche necessary for cell survival. Inflammatory cytokines present in the CM reduce the efficacy of multiple TKIs by activating adaptive survival pathways. Taken together, our results suggest that using conditioned medium from a stromal cell line in an *ex vivo* drug sensitivity assay, may better recapitulate the bone marrow microenvironment and the development of resistance to TKIs often observed in leukemia patients. This setting could therefore potentially provide better prediction of the *in vivo* response.

P154

THE CATS (FAM64A) PROTEIN IS IMPORTANT FOR CLONOGENICITY OF THE MONOCITIC LEUKEMIA CELL LINE U937

I Barbutti[1,*] JA Machado-Neto[1], F Traina[1,2], ST O Saad[1], LF Archangelo[1]

[1]Hemocentro, UNICAMP, Campinas, [2]Department of Internal Medicine, USP, Ribeirão Preto, Brazil

Background: The CATS (FAM64A) protein was described as an interacting partner of both CALM and the leukemic fusion protein CALM/AF10. CATS localizes in the nucleus and nucleoli, causing both CALM and CALM/AF10 accumulation in those structures. It has been suggested that CATS could participate in leukemogenesis.

Aims: The aim of this study was to analyze CATS expression during erythroid, megakaryocytic and granulocytic differentiation of leukemia cell lines and to investigate CATS function upon its depletion in the CALM/AF10-containing U937 cell line.

Methods: Leukemia cells differentiated into erythroid (HE-HU+KU812), megakaryocytic (PMA+K562) and granulocytic (ATRA+NB4 or U937) lineages were analyzed for *CATS* expression by qRT-PCR. Lentivirus targeting CATS silencing (Sta Cruz Biotechnologies) was used to transduce the U937 cells. Depletion was confirmed at RNA (qRT-PCR) and protein (Western blotting) levels. CATS depleted (shCATS) and control cells (shControl) underwent functional *in vitro* assays. Cell proliferation was assessed by MTT assay and BrdU incorporation. Apoptosis was accessed by Annexin-V/PI staining of normal cultured, serum starved and UV-irradiated cells. Cell cycle was accessed by FACS analysis of the DNA content using PI. Migration was analyzed in 8µm pore-sized transwell plates, in which cells migrated towards the chemotatic stimulus of 10% FBS or CXCL12-containing medium. To access the clonogenicity cells were cultivated in semi-solid media without growth factors and colonies were counted after 7 days. Proliferation was also assessed *in vivo* using xenotransplant model of tumor growth, in which cells were inoculated subcutaneously into NOD-SCID mice. Tumors were excised after 12 days of growth, measured and weighted. Expression analysis of cell cycle- and migration-related proteins were performed by Western blotting; and of self-renewal-related genes by qRT-PCR.

Results: *CATS* expression decreased by 58% and 43%, during erythroid and megakaryocytic differentiation, respectively. Interestingly, *CATS* transcript levels increased by 2 fold during ATRA induced granulocytic differentiation of NB4 (4 days of differentiation) and U937 cells (2 days of differentiation); in which *CATS* expression decreased after 4 days of differentiation. CATS depletion was about 80% in shCATS cells. Proliferation of these cells was reduced by 20% when compared to control whereas no effect was observed on cell death. Accordingly, a significant decrease of 12% in the percentage of cells in S phase of the cell cycle was observed forCATS. Moreover, CATS silenced cells migrated less towards serum condition (15%) than control, while no difference was observed towards the chemoatractant CXCL12. Most notably, shCATS cells formed significantly less colonies (66%) on semi-solid medium than control cells. No difference in tumor growth was observed by shCATS cells compared to those formed by shControl cells. Finally, CATS silencing downregulated *GLI1* transcript expression (85%) and altered expression of the cell cycle protein CYCLIN E and the expression and stability of the microtubule dynamic-related protein a-TUBULIN.

Summary and Conclusions: *CATS* seems to be responsive to the differentiation inducer retinoic acid. Moreover, CATS seems to play a role in controlling cell proliferation, migration, and most importantly, the clonogenicity of U937 cell line. More studies are needed in order to investigate whether these functions are specific to the CALM/AF10-containing U937 cells or if it is extendable to other cell lines.

P155

LEUKEMOGENIC FLT3-ITD AND KIT D814V DEPEND MORE ON CALM FUNCTION THAN THEIR WILD TYPES TO TRANSMIT GROWTH/SURVIVAL SIGNALS: IDENTIFICATION OF CALM AS A NEW THERAPEUTIC TARGET

S Rai[1,*], H Tanaka[1], Y Taniguchi[1], T Shimada[1], M Suzuki[2], A Tanimura[3], K Matsui[3], T Watanabe[4], Y Kanakura[3], I Matsumura[1]

[1]Department of Hematology and Rheumatology, Kinki University Faculty of Medicine, Osakasayama city, [2]Division of Hematological Malignancy, National Cancer Center Research Institute, chuo Tokyo, [3]Department of Hematology and Oncology, Osaka University Graduate School of Medicine, suita Osaka, [4]Department of Biological Science, Graduate School of Humanities and Sciences, Nara Women's University, nara Nara, Japan

Background: Clathrin Assembly Lymphoid Myeloid leukemia protein (CALM)

is implicated in the formation of clathrin-coated vesicles which mediates endocytosis and intracellular trafficking of growth factor receptors and nutrients. We previously reported that CALM regulates intracellular trafficking of receptor tyrosine kinases (RTKs), such as FLT3 and KIT, thereby regulating the growth and survival of hematopoietic stem/progenitor cells (18th Congress of EHA 2013). Meanwhile, it has been reported that oncogenic RTKs are mislocalized in cytoplasm, where they transmit aberrant signals to downstream molecules. However, the precise mechanisms how they are transported in cytoplasm and transmit their signals are not fully understood. Also, the roles of CALM in this system remain unknown, Among mutated RTKs, FLT3 internal tandem duplications (ITD) and a point mutation of KIT at D816 (corresponding to murine KIT D814) have been shown to be involved in the pathogenesis of acute myeloid leukemia (AML).

Aims: In the present study, we investigated the roles for CALM in their intracellular trafficking and leukemogenic activity of these mutated RTKs.

Results: We introduced murine FLT3 wild-type (WT) and ITD and KIT (WT and D814V) into murine embryonic fibroblasts (MEFs) isolated from CALM$^{-/-}$ and WT mice, respectively, and examined the role of CALM in their intracellular trafficking. In response to each ligand, FLT3 WT and KIT WT were internalized from membrane to cytoplasm and transported from early to late endosomes and consequently to lysosome in WT MEFs. In these processes, the trafficking from early to late endosomes was impaired in CALM$^{-/-}$, MEFs. In contrast, FLT3 ITD and KIT D814V were distributed at close to endoplasmic reticulum (ER) and Golgi in cytoplasm with a punctate pattern irrespective of ligand stimulation in WT MEFs, from where they transmitted the signals. However, in CALM$^{-/-}$ MEFs, these RTK mutants were predominantly localized apart from ER and Golgi with a diffused pattern, indicating that the system retaining mutated RTKs at ER or Golgi is disrupted by CALM deficiency. Next, we knocked down (KD) the expression of CALM by stably transfecting shRNA against CALM into an IL-3-dependent cell line Ba/F3 engineered to express FLT3 (WT and ITD) and KIT (WT and D814V), respectively. Ba/F3 cells transfected with FLT3 WT and KIT WT dose-dependently proliferated in response to each ligand. However, CALM shRNA partially suppressed their growth, while it hardly affected IL-3-dependent growth. Although FLT3 ITD and KIT D814V enabled Ba/F3 cells to grow independently of IL-3, the growth mediated by FLT3 ITD and KIT D814V was severely inhibited by CALM KD. As for this mechanism, we found that tyrosine autophosphorylation of FLT3 ITD and KIT D814V located in cytoplasm was suppressed by CALM KD, while ligand-induced tyrosine phosphorylation of membrane-bounded FLT WT and KIT WT was hardly influenced. These results indicate FLT3 ITD and KIT D814V depends more on CALM function than respective WTs to transmit their signals. In accord with these *in vitro* results, tumorigenic activities of FLT3 ITD and KIT V816V were severely suppressed by CALM KD in mouse transplantation model using these Ba/F3 clones.

Summary and Conclusions: Intracellualr localization and transport of FLT3 ITD and KIT D814V are different from those of WTs, where the roles of CALM were also distinct between these mutants and WTs. In addition, our results indicate that CALM plays a critical role in leukemogenic activity of FLT3 ITD and KIT D814V and would be a promising therapeutic target.

P156

TARGETING THE HOXA CLUSTER IN MLL-FUSION LEUKEMIAS

L Kettyle[1,*] G Dickson[2], J Bijl[3], C Burt[1], K Mills[1], A Thompson[1]
[1]Haematology, Centre for Cancer Research and Cell Biology, Queen's University Belfast, Belfast, [2]Research Department of Haematology, Cancer Institute, University College London, London, United Kingdom, [3]Centre de Recherche de Hôpital Maisonneuve-Rosemont (HMR), HMR, Montreal, Canada

Background: *Hox* genes are highly expressed in normal hematopoietic stem and progenitor cells but rapidly decrease during normal differentiation, however elevated levels are maintained in leukemia. *Hox* expression is epigenetically regulated by polycomb repressor complexes (PRCs) and histone modifiers *e.g.* Mixed Lineage Leukemia (MLL). Translocations involving MLL are frequent in acute leukemia however the role and necessity of HOX-TALE expression in disease maintenance is not fully elucidated.

Aims: To identify the criticality of the HoxA cluster in MLL-fusion leukemia maintenance.

Results: A transgenic mouse line in which the complete HoxA cluster is flanked by loxP sites (HoxA$^{flox/flox}$) has been established and crossed with MxCre mice to generate a MxCre/HoxA$^{flox/flox}$ (MAFF) mouse line. Ectopic overexpression of MLL-fusion oncogenes in sorted primary MAFF bone marrow cells result in increased colony formation and growth in liquid culture. Transformed bone marrow cells were grown in methylcellulose culture to form colonies and serially replated after 5-7 days. Cells were transplanted into irradiated recipient mice from each stage of plating to give rise to primary MLL-fusion leukemias.

Leukemias generated in the MAFF background had one of the HoxA cluster alleles deleted due to background activation of the *Mx1* promoter. Haploinsufficiency of the HoxA cluster was still capable of initiating primary leukemia, with limited compensation from the intact HoxA cluster. Single colonies selected from methylcellulose and expanded in liquid culture demonstrated deletion of the HoxA cluster by PCR, validated by DNA sequencing.

Exposure of the MAFF MLL-fusion leukemias to Interferon-α *in vitro* activated the *Mx1* promoter and resulted in deletion of the HoxA cluster. Preliminary results indicate that loss of HoxA has no anti-proliferative effects in liquid culture and a moderate decrease in colony formation in methylcellulose.

Summary and Conclusions: Studies are ongoing to assess the complete deletion of the HoxA cluster in MLL-fusion leukemias, to determine their necessity in maintaining the leukemic phenotype in pre-established disease.

It is anticipated that models generated will provide a platform to further examine the role of HoxA in MLL-fusion leukemia maintenance and help identify key underlying molecular mechanisms in this disease subtype for future drug discovery.

P157

LOW MST1 HIPPO KINASE EXPRESSION CONTRIBUTES TO DIFFERENTIATION DEFICIENCY IN AML CELLS

J Wampfler[1,*] G Loforese[2], D Stroka[2], MF Fey[3], MP Tschan[1]
[1]Devision of Experimental Pathology, Institute of Pathology University of Bern, [2]Visceral and Transplantation Surgery, Department of Clinical Research, University of Bern, [3]Department of Medical Oncology, Inselspital, Bern University Hospital, Bern, Switzerland

Background: The Hippo pathway represents a signal transduction pathway that is involved in regulation of organ growth, regeneration, differentiation and gene expression control. The Ser/Thr kinases mammalian sterile 20-like kinase 1/2 (MST1/2; Hippo in Drosophila) at the top of the cascade activate the LATS1/2 kinases, which in turn inhibit the transcriptional co-activators YAP and TAZ (Yorkie in Drosophila). Unphosphorylated YAP and TAZ interact with the TEAD transcription factor to drive the expression of mainly growth-promoting and apoptosis-inhibiting genes. Thus, the growth inhibitory activity of the Hippo pathway functions by inhibiting nuclear accumulation of active YAP and activation of growth-promoting genes. In this context, active MST1 is considered a tumor suppressor and its expression is significantly repressed in breast, non-small cell lung and gastric cancer.

Aims: In our study we aimed at quantifying expression levels and testing a possible function of MST1 in the pathology of acute myeloid leukemia (AML), a disease characterized by a block of myeloid differentiation and increased cell survival.

Methods: mRNA expression of MST1 was measured by low density array in clinical AML patient samples (n=98) among FAB subtypes M0 to M4, CD34$^+$ progenitor cells, macrophages and granulocytes of healthy individuals.

Neutrophil differentiation of CD34$^+$ progenitor cells was induced using granulocyte colony stimulating factor (G-CSF) and MST1 mRNA expression was measured at day 3, 6 and 12. The APL cell lines NB4, HT93 and the AML cell line HL-60 were differentiated towards granulocytes by 1μM all-trans retionoic Acid (ATRA) treatment for 6 days. Gene expression of MST1, G-CSF-R was determined by quantitative real-time RT-PCR. Western Blotting was used to measure protein levels of MST1, YAP1 and YAP1-PH. NB4 cells were transduced with a lentiviral vector expressing a small hairpin (sh)RNA targeting MST1 mRNA.

Results: Firstly, we quantified MST1 mRNA expression in clinical AML patient samples (n=98; FAB subtypes M0 to M4). We observed a highly significant ($p<0.001$) about 7-fold downregulation of MST1 in AML blasts, normal CD34$^+$ progenitor cells and macrophages of healthy individuals as compared to mature neutrophils from healthy donors (Figure 1 a). Accordingly, neutrophil differentiation of CD34$^+$ progenitor cells using granulocyte colony stimulating factor (G-CSF) resulted in increased MST1 mRNA expression (Figure 1 b). We next analyzed MST1 mRNA and protein expression during *in vitro* neutrophil differentiation of NB4 and HT93 acute promyelocytic leukemia (APL) cell lines. APL t(15;17) cells express the leukemic fusion protein PML-RARA, which represses genes important for neutrophil differentiation. Pharmacological doses of all-trans retinoic acid (ATRA) can overcome this differentiation block. ATRA-induced neutrophil differentiation of both APL cells resulted in a significant 10-fold induction of MST1 mRNA paralleled by a marked increase in MST1 protein expression (Figure 1 c). Importantly, in ATRA-resistant NB4-R2 MST1 expression was not upregulated indicating that MST1 induction is not due to an unspecific ATRA-response. Increased MST1 expression was also observed during neutrophil differentiation of PML-RARA negative HL60 AML cells. Next, to address the functional involvement of MST1 in neutrophil differentiation, we generated NB4 MST1 knockdown cells using a lentiviral vector expressing small harpin (sh) RNA targeting MST1. Knockdown efficiency as assessed by qPCR and Western blotting was 80%. Inhibition of MST1 resulted in significantly attenuated neutrophil differentiation as shown by significantly reduced CD11b surface (Figure 1 d) and G-CSF-R mRNA expression. Of note, preliminary data show decreased YAP1 phosphorylation in NB4 MST1 knockdown cells supporting functionality of the MST1 knockdown.

Summary and Conclusions: Collectively, our findings suggest that MST1 expression is associated with an immature myeloid phenotype and define a novel regulatory, MST1-mediated (Hippo) pathway required for neutrophil differentiation of APL cells.

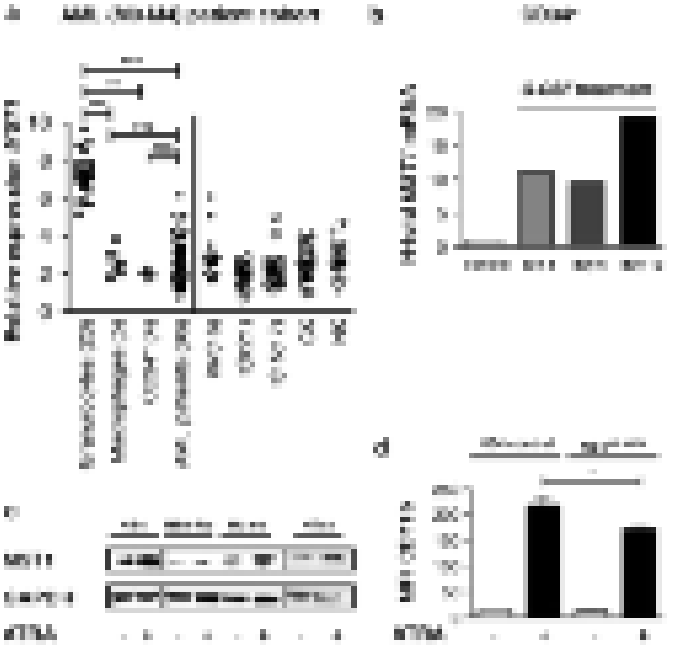

Figure 1.

P158

NOVEL FUNCTION FOR THE RNA BINDING PROTEINS RBM38 AND DND1 IN AML CELL DIFFERENTIATION

J Wampfler[1,*] MF Fey[2], MP Tschan[1]
[1]Devision of Experimental Pathology, Institute of Pathology University of Bern, [2]Department of Medical Oncology, Inselspital, Bern University Hospital, Bern, Switzerland

Background: The RNA binding proteins RBM binding motif protein 38 (RBM38) and DEAD END 1 (DND1) are known to selectively stabilize mRNAs by attenuating RNAse activity or protecting them from miRNA-mediated cleavage (Figure 1 a). Both proteins can cause cell cycle arrest in G1 phase by, for example, stabilizing the mRNA of the cell cycle inhibitor $p21^{CIP1}$. Low expression of these genes may lead to decreased stability of $p21^{CIP1}$ or increased vulnerability to miRNAs.
Aims: In our study we aimed at quantifying expression levels and testing possible functions of RBM38 and DND1 in the molecular pathology of acute myeloid leukemia (AML), a disease characterized by a block of myeloid differentiation and increased cell survival.
Methods: mRNA expression of RBM38 and DND1 was measured by low density array in clinical AML patient samples (n=98) among FAB subtypes M0 to M4, $CD34^+$ progenitor cells, macrophages and granulocytes of healthy individuals. The APL cell line NB4 and its resistant subline NB4-R2 were differentiated towards granulocytes by 1μM all-trans retionoic Acid (ATRA) treatment for 6 days. Successful neutrophil differentiation was evidenced by CD11b FACS analysis or increased of granulocyte colony-stimulating factor receptor (G-CSF-R) mRNA expression. Gene expression of RBM38, DND1, G-CSF-R and $p21^{CIP1}$ was measured by quantitative real-time RT-PCR. Protein expression was assesed by Western Blotting. NB4 cells were transduced with a lentiviral vector expressing a small hairpin (sh)RNA targeting RBM38 and DND1 mRNA. Knock-down efficiency was validated by qPCR and Western blotting. Differences between two groups were assessed using the non-parametric Mann-Whitney-U test. P-values <0.05 were considered to be statistically significant.
Results: In a first attempt to investigate a possible role for RBM38 and DND1 in AML pathology, we quantified their mRNA expression in clinical AML patient samples (n=98). We observed a highly significant down-regulation of RBM38 and DND1 mRNA expression in AML blasts, normal $CD34^+$ progenitor cells, macrophages of healthy individuals as compared to mature neutrophils from healthy donors. These findings clearly indicate that low RBM38 and DND1 mRNA expression is associated with an immature myeloid phenotype. To investigate the function of RBM38 upon differentiation, $CD34^+$ progenitor cells were treated with G-CSF to induce granulocyte differentiation. RBM38 mRNA was 6-fold induced compared to day 0 of differentiation. Next, we analyzed RBM38 and DND1 expression during *in vitro* neutrophil differentiation of NB4 acute promyelocytic leukemia (APL) cells as a model for neutrophil differentiation. The PML-RARA-mediated differentiation block at the promyelocyte stage in APL cells can be overcome by treating them with pharmacological doses of all-trans retinoic acid (ATRA). Neutrophil differentiation of NB4 APL cells resulted in a 12- and 4-fold induction of RBM38 and DND1 mRNA expression, respectively (Figure 1 b). Increased mRNA levels were paralleled by protein expression. NB4-R2 ATRA-resistant cells did not show increased RBM38 and DND1 expression indicating that the activation of gene expression is not due to an unspecific ATRA-response. Next, to address the function of RBM38 and DND1 in neutrophil differentiation, we generated two independent NB4 RBM38 as well as DND1 knock-down cell lines. Generally, RBM38 and DND1 NB4 knock-down cells displayed significantly attenuated neutrophil differentiation compared to control transduced cells as assessed by CD11b (Figure 1 c) and G-CSF-R expression. Of note, inhibiting RBM38 and DND1 also resulted in decreased $p21^{CIP1}$ mRNA (Figure 1 d) and protein expression due the lack of $p21^{CIP1}$ mRNA stabilization in the absence of these proteins.

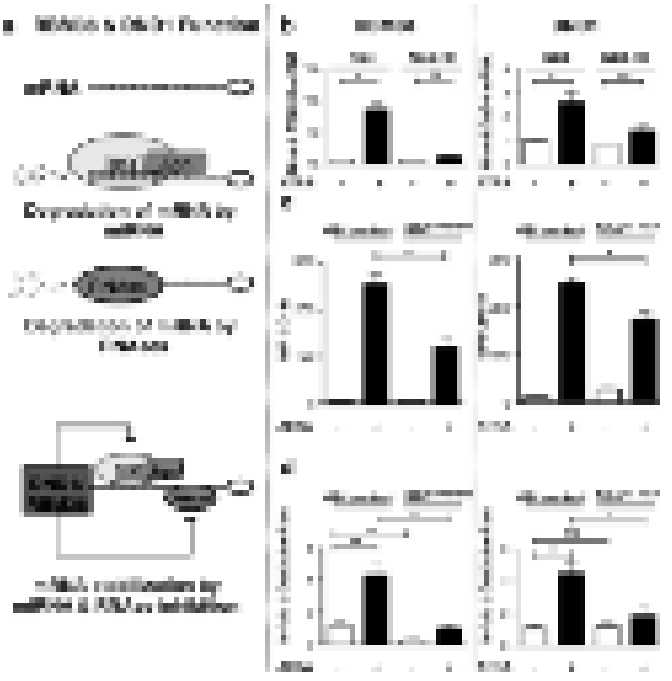

Figure 1.

Summary and Conclusions: Our results clearly indicate that RNA binding proteins RBM38 and DND1 play significant new roles in neutrophil differentiation of leukemic cells, and we propose that low expression levels of these genes contribute to the immature AML phenotype.

Acute myeloid leukemia - Clinical 1

EARLY PERIPHERAL BLAST CELL CLEARANCE ASSESSED BY FLOW CYTOMETRY IN INDUCTION IS A NOVEL POWERFUL PROGNOSTIC INDICATOR IN ACUTE MYELOID LEUKEMIA: A NORTHERN ITALY LEUKEMIA GROUP (NILG) STUDY

Maria Imbaro Chieti, [4]Hematology, Ospedale Molinette, [5]Hematology, Università di Torino, Azienda Ospedaliera S. Giovanni Battista, Torino, [6]Hematology, Ospedale dell'Angelo, Venezia-Mestre, Italy

Background: In acute myeloid leukemia (AML), genetics is the most relevant prognostic factor representing the framework of European Leukemia Net (ELN) risk stratification system. It defines subgroups with high likelihood to achieve complete remission (CR) and long survival (ELN-favorable) and at the opposite a category with poor response to chemotherapy (ELN-adverse). However, in the absence of genetic determinants, ELN system merges patients (pts) with heterogeneous diseases. At any rate, the response to remission induction therapy remains a powerful prognostic parameter, expressing chemosensitivity of AML cells. In responsive pts, minimal residual disease (MRD) is emerging as an accurate tool to refine risk category. Typically MRD is evaluated after one or two consolidation cycles, however an earlier assessment has been shown to correlate with CR achievement and survival.
Aims: To predict the outcome to induction therapy as early as possible, we studied the peripheral blast cell clearance (PBC) after the first 3 days of induction therapy.
Methods: Eligible pts had untreated non-M3 AML according to the World Health Organization criteria and participated into the NILG AML 02/06 clinical trial, in which they were randomized between a standard *versus* an experimental induction therapy. At diagnosis, bone marrow aberrant leukemia-associated immunophenotypes (LAIPs) were identified by flow cytometry. We quantified LAIP cells by single platform before treatment on day 1 and then following the first 3 days of therapy (day 4). PBC of each individual pt was expressed as the ratio between absolute LAIP cell count on days 1 and 4 converted to a logarithmic scale.
Results: Between 2007-2012, 178 pts were enrolled in PBC study, of whom 27 were excluded because of the lack of circulating blasts (n=7, 3.9%), undetectable LAIP (n=17, 9.6%) or less than 100/μL LAIP cells at day 1 (n=3, 1.7%). Thus, 151 pts (84.8%) were assessable. The median value of LAIP cells decreased from 4.198/μL (range 120-148.859) on day 1 to 41.8/μL (0.07-44,802.3) on day 4, for a median PBC index of 1.9 (0.40-4.50). After the first induction course, 108 pts (71.6%) achieved CR, 36 (23.8%) were refractory and 7 (4.6%) died of complications. Although no difference in day 1 LAIP cells was noted between CR and refractory pts, the latter exhibited a significantly higher LAIP cell count at day 4 and a lower PBC index (1.0) compared with CR pts (2.3; p<0.0001). By ROC curves we identified 1.5 log as the most accurate cut-off separating pts with high and low PBC index, respectively (PBC-H, PBC-L), also correlating significantly with the main prognostic factors (Table 1). Among the evaluable pts, 84/92 PBC-H (91.3%) achieved CR after a single course compared to 24/52 PBC-L (46.2%; p<0.0001). In multivariate analysis, PBC index was the only predictive factor for CR (p=0.0004) and a significant predictive factor for event-free survival (p=0.0001).
Summary and Conclusions: PBC is a new very early and powerful outcome predictor in AML. This analysis is simple and minimally invasive, providing a real time quantification of AML burden reduction in the first days of chemotherapy. Along with other prognostic markers, it could allow to customize AML induction treatment.

PROPENSITY SCORE MATCHED COMPARISON OF INTERMEDIATE INTENSITY CHEMOTHERAPY INDUCTION *VERSUS* INTENSIVE CHEMOTHERAPY INDUCTION IN ELDERLY PATIENTS (AGES 60 YEARS OR OLDER) WITH AML

K Takahashi[1,*] H Kantarjian[2], F Ravandi[2], G Garcia-Manero[2], G Borthakur[2], T Kadia[2], C DiNardo[2], E Jabbour[2], M Konopleva[2], M Andreeff[2], J Cortes[2]

[1]Cancer Medicine, [2]Leukemia, UT MD ANDERSON CANCER CENTER, Houston, United States

Background: A majority of patients with acute myeloid leukemia (AML) age ≥60 are unable to tolerate intensive chemotherapy (IC) induction. Front-line therapy with clofarabine plus low dose cytarabine (CLDA) has been used for this subset of patients. We hypothesized that CLDA provides equivalent outcome on elderly patients with AML compared to conventional IC induction with less toxicity.
Aims: To compare treatment related toxicity and outcome of CLDA induction *vs.* conventional IC induction in elderly patients with AML.
Methods: Previously untreated patients with AML, age ≥60, who received front-line therapy between 2002 and 2012 by one of the following regimens were matched by the propensity score to adjust pre-treatment confounding factors: 1) clofarabine and low dose cytarabine (CLDA group: clofarabine 20 or 30 mg/m^2 intravenous daily for 5 days+cytarabine 20 mg/m^2 subcutaneous once or twice daily for 10 to 14 days, N=142) or 2) idarubicin and high dose cytarabine (IA group: idarubicin 12 mg/m^2 intravenous once daily for 3 days and cytarabine 1.5 gram/m^2 intravenous over 24 hours for 3 to 4 days, N=104).
Results: Propensity matching resulted in 66 patients from each group to be matched for their pre-treatment characteristics including age, performance status, organ function, cardiac function, and cytogenetics. Proportion of patients who achieved complete remission (CR) within 2 course of induction were similar between 2 groups (CLDA *vs.* IA, 59% *vs.* 53%, P=0.48). For responders, 95% of the patients in CLDA group achieved CR within 2 cycles of treatment, whereas 100% of patients in IA group achieved CR within 2 cycles of treatment. Proportion of patients who experienced grade 3 or more toxicity during induction was significantly higher in IA group (CLDA *vs.* IA, 48% *vs.* 73%, P=0.004). The median length of hospital stay during the induction was similar between 2 groups (CLDA *vs.* IA, 27 *vs.* 26 days, P=0.85). Mortality at 4 and 8 weeks were similar between 2 groups (CLDA *vs.* IA, 5% *vs.* 11% at 4 weeks and 14% *vs.* 15% at 8 weeks, P=0.32 and 0.80, respectively). Comparable proportion of patients were bridged to stem cell transplant during the first CR (CLDA *vs.* IA, 6% *vs.* 5%, P=1.00). There was no statistical difference in overall survival (OS) between 2 groups (CLDA *vs.* IA, 11.4 months [95% CI: 7.0-15.8] *vs.* 10.4 months [95% CI: 4.9-15.9], P=0.60, Figure 1). In an analysis sub-grouped by clinical characteristics, no difference in OS was observed between 2 groups in any of the subgroups (by age ≥70 *vs.* <70, adverse risk cytogenetics *vs.* favorable or intermediate risk, *FLT3*-ITD *vs.* wild type, performance status ≥3 *vs.* <3, bone marrow blast >30% *vs.* ≤30%, white blood cell count >20x10^3/μL *vs.* ≤20x10^3/μL). Multivariate Cox proportional hazard regression for OS showed that adverse risk cytogenetics, age ≥70, bone marrow blast >30%, and performance status ≥3 adversely affected OS but induction regimen did not affect OS.

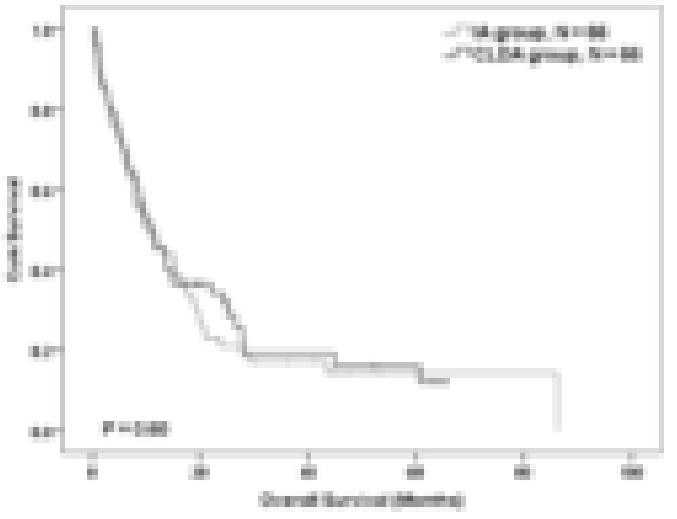

Figure 1.

Summary and Conclusions: In this clinically well matched cohort, induction chemotherapy with CLDA showed equivalent treatment response and survival in patients with AML age ≥60 but was associated with significantly less toxicity compared to conventional IC induction. Intensity of induction therapy in elderly AML patients may be attenuated without compromising outcome. Prospective randomized trial to confirm these findings is warranted.

P161

PROGNOSTIC SIGNIFICANCE OF THE MRC CYTOGENETIC CLASSIFICATION COMPARED WITH THE EUROPEAN LEUKEMIANET GENETIC RISK CLASSIFICATION SYSTEM IN PATIENTS WITH ACUTE MYELOID LEUKEMIA

T Kadia[1,*] H Kantarjian[1], G Garcia-Manero[1], G Borthakur[1], E Jabbour[1], N Daver[1], N Pemmaraju[1], M Brandt[1], S Pierce[1], J Cortes[1], F Ravandi[1]
[1]Leukemia, MD Anderson Cancer Center, Houston, United States

Background: The prognostic relevance of cytogenetic and molecular aberrations in patients with acute myeloid leukemia (AML) is well established. Recent reports by the Medical Research Council (MRC) and by the European LeukemiaNet (ELN) have further established the predictive value of both cytogenetic abnormalities and a number of recurring gene mutations in determining disease free and overall survival of patients.
Aims: We conduct this study to validate the prognostic significance of these classification systems in a cohort of patients treated relatively uniformly at our institution. Patients younger than 65 were treated mainly with induction regimens containing high dose cytarabine and idarubicin and patients over 65 years of age received mainly non intensive regimens.
Methods: Patients with newly diagnosed AML treated at our institution from 1993-2012 were included in this study. Patients with available cytogenetics and molecular data were then classified according to the MRC as well as the ELN criteria and were evaluated for outcome.
Results: 2070 patients with a median age of 60 (range, 12-89) had complete cytogenetic data, of which 1196 (55%) were male and 972 (47%) were <60 years of age. 766 patients (37%) had normal karyotype including 330 (34%) patients <60 years. The remainder had at least 1 cytogenetic abnormality. 27%, 10%, 5%, 3%, and 17% of patients had at 1, 2, 3, 4, or 5+ abnormalities, respectively. In patients <60, the proportions were 31%, 11%, 5%, 2%, and 13%, respectively. The outcome by various cytogenetic abnormalities (including the uncommon karyotypes, but excluding APL) defined by the MRC was as predicted (Figure 1). Among the patients <60, 20%, 48%, and 32% were in the favorable (FAV), intermediate (INT), and adverse (ADV) prognostic categories of the MRC-C, respectively. FLT3 and NPM1 mutation data was available in a subset of 1026 patients (50%), allowing classification by ELN-C; 487 patients (47%) were <60 yrs of age and 539 patients (53%) were ≥60. The proportion of patients in each of the ELN-C categories were: FAV: 26%, INT-1: 18%, INT-2: 24%, and ADV: 32%. Overall survival in the same cohort of patients, for <age 60 (Figure 1A and IC) and ≥age 60 (Figure 1B and 1D) by MRC-C and ELN-C risk groups are shown below.

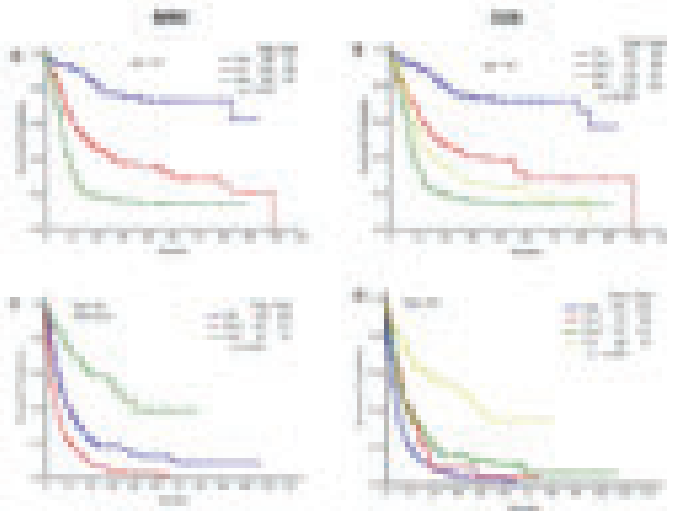

Figure 1.

Summary and Conclusions: The revised MRC-C and the ELN-C were able to distinguish separate prognostic groups for patients with AML based on their genetic abnormalities. Among the patients >60 years, the MRC-C was more predictive of the outcome, particularly for patients with intermediate risk disease where INT-1 and INT-2 were not able to discriminate prognosis.

P162

WT1-ASSOCIATED MISSPLICING IN ACUTE MYELOID LEUKEMIA

AM Mohamed[1,*] M Thénoz[2], D Maucort-Boulch[3], M Cheok[4], H Mortada[5], D Auboeuf[5], M El-Hamri[6], C Koering[7], I Tigaud[8], C Dumontet[6], E Cros[9], C Pinatel[10], O Nibourel[11], C Preudhomme[11], X Thomas[6], F E Nicolini[12], F Solly[13], E Wattel[6], F Mortreux[7]
[1]University Lyon I, CNRS, ENS, Faculté de Médecine Lyon sud, [2]University Lyon 1, CNRS, ENS, Faculté de Médecins Lyon sud, [3]Laboratoire de Biostatistique Santé, Lyon University Hospital, Lyon, [4]Inserm, Lille, [5]Inserm, [6]Hématologie, Lyon University Hospital, [7]Lyon I University, CNRS, ENS, Faculté de Médecine Lyon sud, [8]Cytogénétique, Lyon University Hospital, [9]Lyon I University, [10]Centre Léon Bérard, Lyon, [11]Hématologie, Lille University Hospital, Lille, [12]Hématologie, Lyon I University, Lyon, [13]Hématologie, Saint-Etienne University Hospital, Saint-Etienne, France

Background: While about one third of expressed genes are abnormally spliced in AML, the causes, mechanisms, and consequences of missplicing remain incompletely understood in this disease. WT1 is overexpressed in the majority of AML while it represses the splicing-factor kinase SRPK1 and physically interacts with the splicing factors WTAP, RBM4, and U2AF1/U2AF2.
Aims: To determine whether and how WT1 modifies alternative exon usage (AEU) in AML and to test if these changes have a clinical impact.
Methods: The exon expression profiles of 3 AML cell lines (MOLM13, Kasumi, and KG1) knocked down (KD) or not for WT1 gene expression were examined using Affymetrix HTA2 exon arrays. Four WT1-specific AEUs involving 4 ATP-binding cassette transporter genes (ABC-A2, -A3, -A5, and -C3) were quantified by quantitative exon specific PCR (qESPCR) in fresh AML cells deriving from 132 AML patients of whom 106 have been treated with intensive chemotherapy (median follow-up 27 months). Overall survival (OS) and disease-free survival (DFS) were compared with the log-rank test. Hazard ratio (HR) and 95% confidence interval (CI) were estimated by Cox proportional hazards regression models to determine independent risk factors associated with survival in multivariate analyses. The 25 patients who received allogeneic HSCT were censored on the day of cell infusion.
Results: WT1-KD was confirmed by western blot analysis for the 3 cell lines. Upon WT1-KD, 954 AEUs were identified in 846 genes, of which 337 (40%) were altered at the whole gene expression level. 73/100 array-predicted exon usages were validated by ESPCR. Gene ontology analysis showed a significant gene enrichment in pathways such as hematopoietic cell lineage, calcium signaling, ABC transporters, DNA replication, and pyrimidine and purine metabolism. To test the relationship between WT1 expression and AEUs *in vivo*, 4 WT1-induced AEUs identified in 4 ABC transporters were quantified through qESPCR in 132 AML. A statistically significant correlation linked WT1 expression and the distribution of the 4 ABC transporter isoforms in the 132 AML diagnostic samples ($p<0,01$ for each, Spearman Rank Correlation) but not in control samples. As an additional control experiment, qESPCR was carried out with the 132 AML for 2 AEUs of the TET2 gene mRNA that were not found to be linked with WT1 expression *ex vivo*. In contrast to ABC transporters, no correlation could be evidenced between WT1 expression and the distribution of the 4 TET2 isoforms in fresh AML samples. By univariate analysis, ABC-A3 exons 18-20 expression, *i.e.* exon skipping of exon 19 significantly affected both OS and DFS; higher the level of 18-20 isoform expression, poorer the outcome. Alternatively, an elevated expression level of the alternative ABC-A3 19-20 isoform was associated with statistically significant better OS and DFS. In multivariate analysis, age cytogenetic, and ABC A3 exon 19 skipping were identified to be independent prognostic factors for OS and DFS (Table 1). Age and ABC-A3 exon exclusion were identified to be independent prognostic factor for OS in the 49 patients with normal karyotype.

Table 1. Multivariate analyses of survival outcomes in AML treated with intensive chemotherapy.

Summary and Conclusions: In AML, WT1 affects AEUs of numerous key genes involved in hematologic differentiation, leukemogenesis, and resistance to chemotherapy. 4/4 tested AEUs displayed the same correlation with WT1 expression *in vivo* and *ex vivo*. This correlation was specific because it was not observed in control samples or in AML with 2 TET2 AEUs found WT1-independent *ex vivo*. These results help explain the deregulated pattern of AEUs

observed in AML cells where spliceosome gene mutations represent a rare event. ABC-A3 missplicing possesses a strong prognostic impact indicating that besides whole gene transcription, qESPCR might represent a promising tool for assessing AML aggressiveness at the time of diagnostic in patients with normal or abnormal karyotype.

P163

VALIDATION OF EUROPEAN LEUKEMIA NET (ELN) GUIDELINES FOR CYTOGENETICALLY NORMAL AML IN ASSOCIATION WITH NPM1 AND FLT3-ITD MUTATIONS: FURTHER STRATIFICATION FOCUSING ON WT1 EXPRESSION

JH Yoon[1,*] HJ Kim[1], YW Jeon[1], JH Kim[1], SH Shin[1], SE Lee[1], KS Eom[1], YJ Kim[1], S Lee[1], CK Min[1], SG Cho[1], DW Kim[1], JW Lee[1], WS Min[1], CW Park[1]
[1]Department of Hematology, Catholic BMT Center, Seoul St. Mary's Hospital, Seoul, Korea, Republic Of

Background: According to the risk-stratifications of the karyotypes of adult AML, intermediate-risk group is mostly comprised of cytogenetically-normal (CN)-AML and other undefined karyotypes. According to the European Leukemia Net (ELN) guidelines, CN-AML is divided into four molecular subgroups based on the mutation statuses of *NPM1* and *FLT3-ITD*. Except isolated *NPM1*mut CN-AML, another 3 subgroups belong to the risk-group of 'Intermediate-I', but the guidelines suggest that most of the cases in the 'Intermediate-1' risk-group are associated with poor prognosis.
Aims: We validated the characteristics and identified clinical outcomes of CN-AML patients in a single center in Korea based on the ELN guidelines. We then further modified the stratification using *WT1* expression.
Methods: This single center retrospective study enrolled 223 adult CN-AML patients (median 55 yrs (18-83) from 2007 to 2011. Except 18 untreated patients, 156 were treated with standard chemotherapy and 49 were treated with attenuated chemotherapy. After achieving complete remission (CR), patients with available donor were treated with allogeneic (allo)-HSCT (n=98) and the rest were treated with auto-HSCT (n=13) or chemotherapy alone (n=48). We calculated clinical outcomes after dividing the CN-AML patients into 4 subgroups based on the ELN guidelines; isolated *NPM1*mut CN-AML (n=47), *NPM1*wt/*FLT3-ITD*-neg (n=125), *NPM1*mut/*FLT3-ITD*-pos (n=35), and *NPM1*wt/*FLT3-ITD*-pos (n=16). We then used diagnostic *WT1* expression measured by RQ-PCR (*WT1* ProfileQuant™ kit, Ipsogen, France) method for additional stratification of the 'Intermediate-I' risk-group and also calculated the clinical outcomes. The significant cut-off of *WT1* expression was calculated with ROC curve analysis.

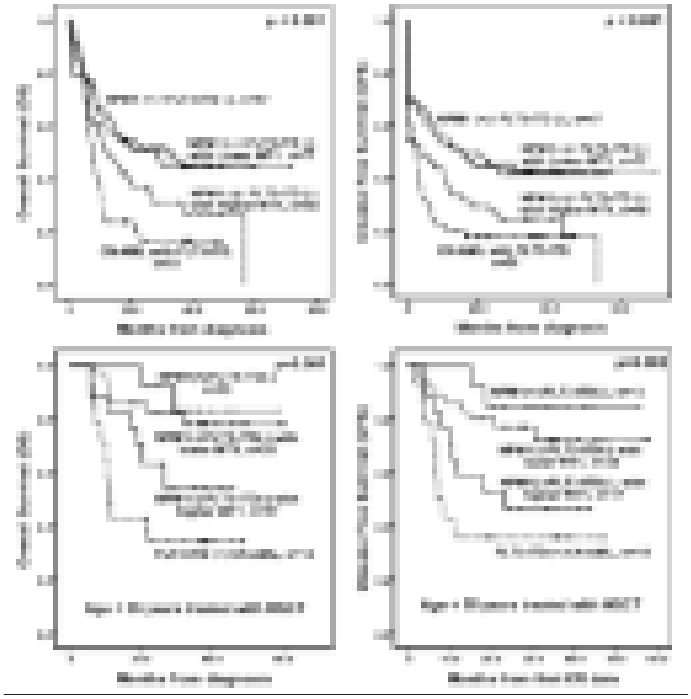

Figure 1.

Results: We identified that *NPM1*mut was 36.8% among CN-AML, and *NPM1*mut CN-AML patients were older (54.4yrs *vs.* 49.8yrs) and showed leukocytosis, higher blast counts and higher *WT1* expression compared to *NPM1*wt CN-AML. Higher proportion of *FLT3-ITD* mutation was also identified in *NPM1*mut CN-AML (42.7% *vs.* 11.3%). Isolated *NPM1*mut CN-AML showed the most favorable outcomes with higher CR rate (80.9% *vs.* 67.5%) and significantly lower refractory cases (4.7% *vs.* 27.5%) compared to the other 3 subgroups. Isolated *NPM1*mut CN-AML also showed significantly superior 4-year OS at 70% especially in the younger patient subgroup. Without regarding *NPM1* mutation, the presence of *FLT3-ITD* showed the worst 4-year OS <20% with higher incidence of relapse. In the intermediate-I risk-group, *NPM1*wt/*FLT3-ITD*-neg CN-AML could be further stratified with diagnostic *WT1* expression. *NPM1*wt/*FLT3-ITD*-neg CN-AML with lower *WT1* (n=77) showed favorable OS (p=0.060) and DFS (p=0.015) than the group with higher *WT1* (n=48), and the superior results were comparable with those of isolated *NPM1*mut CN-AML. We finally suggest that isolated *NPM1*mut or *NPM1*wt/*FLT3-ITD*-neg with lower *WT1* can be considered as a lower-risk group, while *FLT3-ITD*-pos or *NPM1*wt/*FLT3-ITD*-neg with higher *WT1* as a higher-risk group. And we found that survival outcomes of the higher-risk CN-AML could be improved with HSCT, presenting 4-year OS >35% in the younger patients subgroup.
Summary and Conclusions: Our modified stratification using *WT1* expression is considered reasonable for CN-AML and should be validated by larger studies in the future. Based on this study, higher-risk CN-AML should be treated with risk-adapted approach including HSCT.

P164

WT1 MUTATIONS ARE SECONDARY EVENTS IN AML, SHOW VARYING FREQUENCIES WITHIN GENETIC SUBGROUPS AND DIFFERENT IMPACT ON PROGNOSIS

M Krauth[1,*] C Eder[1], T Alpermann[1], F Dicker[1], U Bacher[1], M Ulke[1], A Kohlmann[1], S Kuznia[1], W Kern[1], T Haferlach[1], C Haferlach[1], S Schnittger[1]
[1]MLL Munich Leukemia Laboratory, Munich, Germany

Background: Mutations (mut) in the *WT1* gene belong to the first genetic aberrations described in AML. In contrast to recurrent fusion genes *WT1*mut do not seem to be disease defining. However, the impact of *WT1*mut still is discussed controversially.
Aims: To analyze the frequency and prognostic impact of *WT1*mut in AML patients (pts).
Methods: 3,157 unselected AML pts were analyzed (*de novo*: n=2,699, s-AML: n=234, t-AML: n=224; 1,708 males, 1,449 females). Median age was 67.1 years (y) (range: 17.8-100.4 y; <60 y: n=1,108, ≥60 y: n=2,049). The mutational hot spot regions of *WT1* (exons 7 and 9) were analyzed by direct Sanger sequencing. Karyotype and *WT1* mutation status was available in all pts. Other mutations were assessed in subsets: *ASXL1* (n=1,951), *CEBPA* (n=2,670), *DNMT3A* (n=1,293), *FLT3*-ITD (n=3,149), *FLT3*-TKD (n=3,004), *IDH1*R132 (n=2,431), *IDH2*R140 (n=2,380), *IDH2*R172 (n=2,412), *KRAS* (n=1,409), *NRAS* (n=1,780), *NPM1* (n=3,003), *MLL*-PTD (n=2,961), *RUNX1* (n=2,390), *TET2* (n=1,016) and *TP53* (n=1,215).
Results: 189 *WT1* mutations were detected (exon 7: n=151, exon 9: n=38). Most were disrupting frameshift (n=142) or nonsense (n=14) mutations, whereas 24 were missense (mostly in exon 9: n=19), only 2 indel and 7 splice site mutations. 14 patients had 2 mutations. Thus, the total frequency of *WT1*mut pts was 175/3,157 (5.5%). With regard to genetic subtypes, significantly higher frequencies were detected in biallelic *CEBPA*mut (15/110, 13.6%, p=0.001), followed by t(15;17)/*PML-RARA* (18/164, 11.0%, p=0.004), and *FLT3*-ITD (58/682, 8.5%, p<0.001). Lower frequencies were observed in *DNMT3A*mut (18/412, 4.3%, p=0.014), *ASXL1*mut (6/355, 1.7%, p<0.001), *IDH2*R140 (5/286, 1.7%, p=0.001), and *IDH1*R132 (2/222, 0.9%, p<0.001). *WT1*mut were never detected in pts with complex karyotypes (0/175, p=0.047). *WT1*mut were more frequent in females (95/1,449, 6.6%) than in males (80/1,708, 4.7%) (p=0.014) and in younger pts (<60 y: 102/1,108, 9.2% *vs.* ≥60 y: 73/2,049, 3.6%, p<0.001). Median age of pts with *WT1*mut was 55.5 *vs.* 63.6 y in *WT1*wt (p<0.001). Stability of *WT1*mut was analyzed in 35 paired diagnostic and relapse samples. In 23/35 (65.7%) *WT1*mut was retained at relapse and in 12/35 (34.3%) it was lost. In 5 cases a sample at 2nd relapse was available. 3 of these retained and 2 lost the *WT1*mut. Survival was calculated for intensively treated pts (n=1,936, *WT1*mut: n=132, 6.8%). In the total cohort, *WT1*mut had no impact on prognosis. In pts ≥60 y there was a trend to shorter event free survival (EFS) for *WT1mut* (9.3 *vs.* 12.3 m, p=0.052). In prognostically favorable subgroups with high *WT1*mut incidences (biallelic *CEBPA*mut and *PML-RARA*) no effect on outcome was seen. Restricting to normal karyotype AML (*WT1*mut: n=85, *WT1*wt: n=1,093) *WT1*mut pts had shorter EFS (10.8 *vs.* 17.9 m, p=0.008). This was true for younger (12.2 *vs.* 29.0 m, p=0.007) as well as for older pts (9.3 *vs.* 13.9 m, p=0.016). In multivariate analysis, *WT1*mut had an independent adverse impact on EFS (p=0.002, HR: 1.64) besides *FLT3*-ITD status (p<0.001, HR: 1.71) and age (p<0.001, HR: 1.28), but only in normal karyotype AML.
Summary and Conclusions: *WT1* mutations are more frequent in females and younger patients, t(15;17)/*PML-RARA*, biallelic *CEBPA*mut, and *FLT3*-ITD mutated AML. *WT1* mutations were nearly mutually exclusive of *ASXL1*, *IDH1*, *IDH2* and complex karyotypes. The distribution pattern in different genetic subtypes and the instability during follow-up as shown by paired sample analyses clearly emphasize a secondary character of *WT1*. In normal karyotype AML, an independent adverse impact of *WT1*mut on EFS was shown.

A RAPID BACTERIAL-BASED BIOLUMINESCENT ASSAY FOR IN-VITRO TESTING OF CHEMOTHERAPY SENSITIVITY IN ACUTE MYELOID LEUKAEMIA.

E Anderson[1,*] H Alloush[1], K Page[1], B Rees[1], A Martin[2], M Ruddock[2], C Reid[2], J Lamont[2], M A Smith[3], J G Smith[4], V Salisbury[1], P Mehta[5]
[1]Health and Applied Science, University of the West of England, Bristol, [2]Randox Laboratories Ltd, Belfast, [3]Royal Marsden, NHS Foundation Trust, London, [4]Frimley Park NHS Foundation Trust, Frimley, [5]Bristol Haematology and Oncology Centre, University Hospitals Bristol, NHS Foundation Trust, Bristol, United Kingdom

Background: Patients with Acute Myeloid Leukaemia (AML) are routinely given chemotherapy regimens containing cytosine arabinoside (Ara-C), although up to 30% of intensively treated patients fail to respond/relapse, due to non-uptake of Ara-C or lack of conversion to the active form (Ara-CTP) as a possible cause. Patients aged over 70 years are more commonly being given low-dose Ara-C where remission rates are low (~20%).
Aims: A whole cell bacterial biosensor has been constructed for rapid detection of Ara-CTP within leukaemic cells. The assay incorporating this biosensor enables same-day prediction of patient response to chemotherapy before the start of treatment. Verification and clinical utility of the assay have been assessed herein.
Methods: The assay uses a genetically modified *E. coli,* expressing the human deoxycytidine kinase (dCK) gene responsible for conversion of Ara-C to Ara-CTP, and a *lux*-expression cassette, which enables an increase in bioluminescence in response to Ara-CTP.
Results: For validation, the minimum detection level of Ara-CTP was determined in seven AML cell lines using both the biosensor and HPLC. The limit of detection of Ara-CTP was found to be 25 nM using the biosensor assay (requiring 2 million cells), compared to 50 nM with HPLC (requiring 20 million cells). Results from the two methods of analysis correlated statistically across the seven cell lines (R=0.9722, p=0.0028), indicating that the biosensor is accurately detecting Ara-CTP. An MRC-funded retrospective study is currently evaluating the biosensor in clinical samples to determine the uptake and metabolism of Ara-C by the leukaemic blast cells, and shows promising correlation with outcomes examined to date (n=50).
Summary and Conclusions: This technology is currently being extended to other chemotherapy agents in combination with Ara-C, and could allow provision of an individual chemo-sensitivity profile to augment the clinical information available at the point of treatment for these patients.

P166

MULTICENTER SURVEY ON OUTCOME OF AML REFRACTORY TO FIRST INDUCTION CHEMOTHERAPY IN THE LAST 4 YEARS (2010-2013)

D Lazzarotto[1,*] A Candoni[1], G Nadali[2], L Pavan[3], F Mosna[4], E Simeone[1], M Gottardi[4], F Gherlinzoni[4], G Semenzato[3], G Pizzolo[2], R Fanin[1]
[1]Division of Hematology and SCT, University of Udine, Udine, [2]Division of Hematology, University of Verona, Verona, [3]Division of Hematology, University of Padova, Padova, [4]Division of Hematology, Hospital of Treviso, Treviso, Italy

Background: Despite the development of a variety of new investigational therapies, Acute Myeloid Leukemia (AML) refractory to first induction chemotherapy remains a challenge and there are only few recent epidemiologic data regarding the outcome of this group of patients.
Aims: In this multicenter survey we evaluate the prognosis and outcome of 76 patients (pts) with AML, diagnosed and treated in four Institutions (Udine, Verona, Treviso, Padova), during the last 4 years (between 2010 and 2013).
Results: All 76 AML cases were refractory to first induction course of chemotherapy. Data were updated as of January 2014. There were 43 male and 33 females with a median age 63 years, (range: 19-79); 57% (43/76) of pts were younger than 65 yrs and 39% (30/76) had AML secondary to MDS. At onset 49% of cases presented an adverse karyotype. According to the risk stratification at diagnosis based on cytogenetic/molecular profile (Dohner *et al.*, Blood 2010), 20/76 (26,3%) of pts were classified as a Favorable/Intermediate-I risk group and 45/76 (59,2%) as Intermediate-II/Adverse risk group; in 11/76 (14,5%) cases cytogenetic/molecular profile were not available. After a median follow up of 9 months (range 1-40), 56/76 (74%) of pts had died and only 20/76 (26%) were alive (12/20 with active AML and 8/20 in cytologic Complete Remission-cCR). Twenty-four pts (32%) underwent allogeneic hematopoietic stem cell transplantation (HSCT) and of these 21% (5/24) were alive at last follow up (January 2014). The 12 and 21 months probability of Overall Survival (OS) of the whole population was 48% and 21%, respectively. The probability of OS was significantly improved by HSCT procedure (32% *vs* 6% at 25 months; log-rank, p=0,0007) and was better in those pts with Favourable/Intermediate-I cytogenetic/molecular risk at diagnosis (34% *vs* 17% at 20 months; log-rank, p=0,018). A pre-transplant cCR status was a significant factor (P=0,0007) to predict a favourable outcome after HSCT.
Summary and Conclusions: Treatment options of AML refractory to first induction course are still limited and the prognosis of these pts remains currently extremely poor. This survey shows that these pts are rarely cured without undergoing allogeneic HSCT and confirms the importance of initiating an urgent unrelated donor search in AML pts with no matched sibling donor and without response to first induction chemotherapy. Moreover, the outcome of HSCT procedure is better in patients who achieve HSCT with a good AML debulking. To reach this goal, new and tailored protocols of salvage therapy (with new drugs or new combinations) would need to be developed.

P167

PRETREATMENT RISK SCORE FOR PREDICTION OF EARLY DEATH AFTER INDUCTION THERAPY IN PATIENTS WITH NEWLY DIAGNOSED MYELOID LEUKEMIA

I Djunic[1,2,*] M Virijevic[2], D Tomin[1], A Novkovic[3], N Colovic[1], A Vidovic[1], N Suvajdzic-Vukovic[1]
[1]Clinic for Hematology, Clinical Center of Serbia, [2]Climic for hematology, Clinical Center of Serbia, [3]Clinical Hospital Center "Zemun", Belgrade, Serbia

Background: Outcome in acute myeloid leukemia (AML) worsens with age due to the higher rate of early death (ED) in older patients. Eligibility for intensive AML treatment protocols is therefore typically based on age as the implied principal predictor of ED. However, it was recently shown that other health and disease-related pretreatment factors can affect the outcome of AML patients after induction therapy.
Aims: To elaborate original prognostic score system for prediction of ED after induction therapy in AML patients based on analysis of pretreatment risk factors.
Methods: This single-centre study included 376 adult patients with nonpromyelocytic newly diagnosed AML, aged ≤60 years. All patients were given induction therapy, which consisted of doxorubicin at 60 mg/m2 daily on days 1-3, in combination with cytarabine 200mg/m2 daily as a continuous intravenous infusion for 7 days (3+7 regimen). The following parameters were estimated as risk factors for ED: age, leukocytosis (WBC <30x109/L *vs* ≥30x109/L), PS, cytogenetic risk group, comorbidities, elevated fibrinogen (>4g/L), decreased albumin (<40 g/L), elevated lactate dehydrogenase (LDH) >1.5xupper limit of normal (N), elevated bilirubin (1.5xN), elevated transaminase (1.5xN) and elevated creatinine (>176 µmol/l). Performance status (PS) evaluated by the Eastern Cooperative Oncology Group (ECOG), ranged between 0-4. The cytogenetic risk group was assessed according to the recommendation of the European LeukemiaNet (ELN). Comorbidities were evaluated using the haematopoetic cell transplantation-specific comorbidity index (HCT-CI). ED is defined as death occurring 30 days of initiation of treatment. Integer weights for the risk score were derived from Cox proportional hazards modeling. The prognostic score was validated via 10-fold cross validation.
Results: The mean age of the patients was 52 years (range 18-60). Our results showed that the most significant adverse factors for ED in univariate analysis were: age ≥55 years (p=0.007), ECOG PS ≥2 (p=0.001), leukocytosis (p=0.046), elevated LDH (p <0.001), elevated fibrinogen (p=0.004), elevated bilirubin (p <0.001), transaminase (p <0.001) and creatinine (p <0.001), decreased albumin (p <0.001) and HCT-CI ≥3 (p <0.001). Our prognostic scoring system was developed after analysis of the prognostic risk factors: elevated LDH, bilirubin and transaminase=1 point, elevated creatinine=1.5 points, decreased albumin=2 points and HCT-CI ≥3=3 points. According to this prognostic model, patients were classified into three risk groups for prediction of ED: low risk=0-1.5 points, intermediate risk=2-4 points, and high risk=>4 points. ED between these groups was highly significant (p <0.001).
Summary and Conclusions: The prognostic model developed in this study can distinguish between AML patients in different risk groups for prediction of ED. This model, based on analysis of pretreatment risk factors, indicates a subset of high risk patients not suitable for intensive chemotherapy, despite their eligibility regarding age (≤60 years).

P168

TRAIL AND ITS RECEPTORS EXPRESSION ON LEUKEMIC CELLS OF PATIENTS WITH AML1-ETO POSITIVE ACUTE MYELOID LEUKEMIA

LG Liu[1,*] J Chen[1], PF Yu[1], Y Xie[1]
[1]Hematological department, Shanghai fifth people's hospital, Fudan university, Shanghai, China

Background: TRAIL signaling pathway is an important pathway having broadly biological activities involving cell apoptosis, differentiation and proliferation. There are AML1 consensus bingding sites in the promoter of TRAIL and TRAIL receptor 2 which imply exsiting the relationship between TRAIL signaling pathway and AML1-ETO positive acute myeloid leukemia (AML). However, the expression of TRAIL and its receptors on leukemic cells of AML1-ETO positive acute myeloid leikemia patients is unknown.
Aims: To detect the expression of TRAIL, TRAIL receptor 1(DR4), TRAIL receptor 2 (DR5), TRAIL receptor 3 (Decoy receptor 1, DcR 1) and TRAIL receptor 4 (Decoy receptor 2, DcR2) on leukemic cells of patients with AML1-ETO positive AML and investigate its possible clinical significance.
Methods: The mean fluorescence intensity (MFI) of TRAIL, DR4, DR5, DcR1 and DcR2 expression were analysed by using flow cytometry on bone marrow

CD34+ cells from patient with AML1-ETO positive AML, AML1-ETO negative AML and non-hematological maliganancies (such as iron deficiency, idiopathic neutropenia and thrombocytopenia, the control group). The study was aproved by the hospital ethics committe and the infromed consent were obtained from all the patients.

Results: Comparing with AML1-ETO negative AML group and the control group, the MFIs of bone marrow CD34+ cells from patients with AML1-ETO positive AML were significantly higher ($p<0.01$, respectively). Regarding DR4 expression, the MFIs of both AML1-ETO positive AML and AML1-ETO negative patients were higher than the control group ($p<0.01$), but there were no significantly difference between the AML1-ETO positive and negative AML groups ($p>0.05$). The MFIs of DR5 expression in patients with AML1-ETO posivite AML were significantly higher than the AML1-ETO negative AML group ($p<0.01$) and the control group ($p<0.01$). The MFIs of DcR1 expression in both patients groups with AML1-ETO positive and negative AML were higher than the control group ($p<0.01$), but there was no difference between the two AML groups. The MFIs of DcR2 in AML1-ETO positive AML group was significantly lower than AML1-ETO negative AML group ($p<0.01$) and the control group ($p<0.01$) (Table 1 and Figure 1).

Table 1. The MFIs of TRAIL and its receptors expression on BM CD34+ cells from patients with AML1-ETO positive AML(A), negative AML(B) and the control(C) ($\bar{x}$±SD).

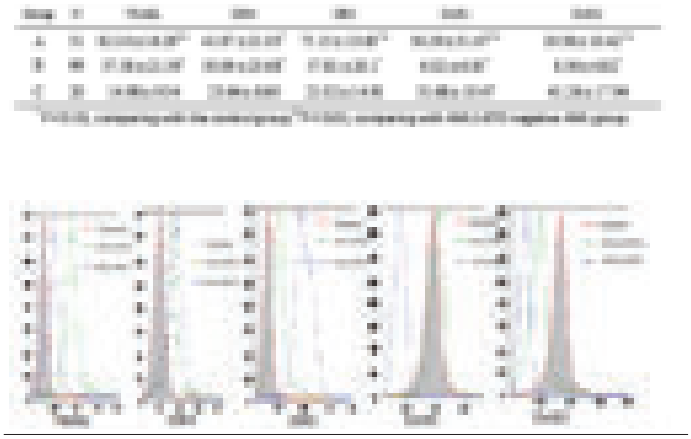

Figure 1. A representive cureve of MFI of TRIAL and its receptors on bone marrow CD34+ cells in three different groups.

Summary and Conclusions: The expression of TRAIL and its receptors in patients with AML1-ETO positve AML are significnatly different from the patients with AML1-ETO negative AML and the non-hematological maligancies patient which imply the TRAIL sigaling pathway involving the pathogensis of AML1-ETO positve AML and need to be further investigated.

P169

TWO-GROUP STUDY OF MEDIAL MICROSCOPY AS A ROBUST TOOL TO HARMONIZE AND STANDARDIZE HAEMATOLOGICAL DIAGNOSIS

G Zini[1,*] O Barbagallo[1], MC Tisi[1], G d'Onofrio[1]
[1]Hematology, Università Cattolica Rome, Rome, Italy

Background: Morphological blood cell evaluation through microscopic examination remains a cornerstone in the integrated diagnostic process in haematology. Many factors contribute to a lack of standardization of this diagnostic tool. According to literature, concordance rate between experienced morphologists from different Institutions is highly variable. The availability of a new technology, the medial microscopy (MM), a robotic scanner microscope capable of digitizing an entire or a selected part of a glass slide, makes available on the web the optical scanning of PB and BM smears and allows a virtual community to be trained and harmonized with the same diagnostic approach of the optical microscope routinely used for the diagnosis, reproducing same facilities of smear navigation and zooming and offering the possibility of field identification (FOVs) through a grid system.

Aims: To evaluate the reproducibility on morphologically critical cell classification through the assessment of the inter-observer agreement using MM.

Methods: A digitized smear was prepared from BM of an untreated patient with AML with monocytic differentiation. Two different selections of three FO*V*s (out of 1500) were submitted for cell identification to 2 different groups of expert morphologists (EM): an Italian (G1) and an International (G2) group composed by 8 and 16 EM respectively. G1 group evaluated 288 cells and G2 group evaluated 110 cells. All EMs were required to separately record in a pre-defined form the number of blasts listed in the subtypes (agranular, granular, monoblasts, promonocytes and unspecified[6]) and of immature/atypical and mature monocytes. Filled forms were evaluated anonymously and data were analyzed with standard statistics.

Results: In the G1 group 86% of the 288 cells were assigned to one of the different subgroups of blast with a consensus agreement ≥90% in 85% of EM and an overall consensus of 79%. In the G2 group the consensus agreement on 110 cells was verified at the 75% and 60% level of EM for all cell types. Agreement on the definition of a cell as "blast" or "non-blast" was 91/110 cells (83%). Agreement on the "blastic" nature of cells of monocytic lineage was also excellent (Figure 1). The Table 1 shows examples of classification for cells of the monocytic lineage with high level (D05, D10, D17) o lack of agreement (D106, D107).

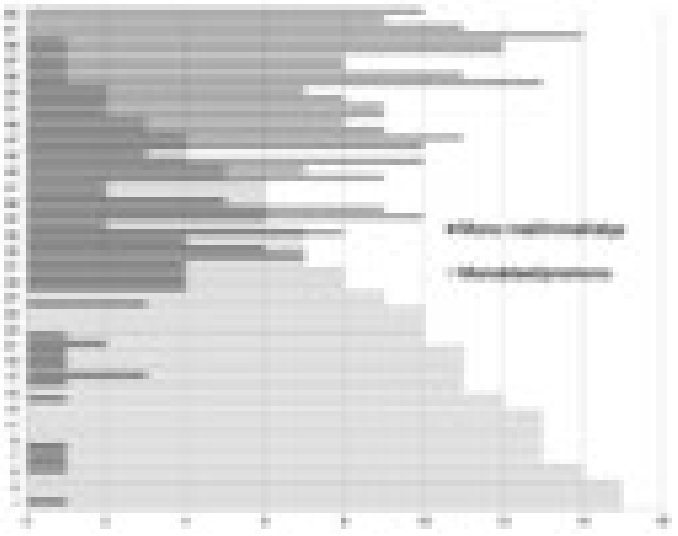

Figure 1. Agreement on the blastic nature of monocytic cells. Cell number (y-axis) *versus* number of participants who have classified each cell as monoblast/promonocyte or atypical-immature monocyte/mature monocytes.

Table 1. Examples of agreement and disagreement in the cytomorphological classification of five cells.

	Number of participants that identified the cell as:					
Cell Number	Mono-blast	Promo-nocyte	Myelo-blast	Atypical monocyte	Mature monocyte	Blast* (any type)
D05	14	1	0	0	0	15/15
D10	5	9	0	1	0	14/15
D17	4	11	0	1	0	15/16
D106	0	6	5	4	1	11/16
D107	0	7	4	4	0	11/16

**blasts=monoblasts+promonocytes+myeloblasts.*

Summary and Conclusions: Agreement on cell classification and definition of blast cells, monoblasts and promonocytes was excellent in both groups: better results in G1 may be explained by cultural homogeneity. In a previous study, first line consensus agreement on similar cell photographs submitted to international EMs was lesser (20-50%) (Zini *et al.* Br J Haematol 2010;151:359-64). One main reason for the excellent results obtained with MM is that cells are evaluated "in the company they keep" on the smear, as it happens in the routine diagnostic process at the microscope. MM does represent a robust method for standardization and harmonization in cytomorphological diagnosis, quality assurance and proficiency testing in haematology.

P170

HIGH EXPRESSION LEVEL OF PRAME GENE IS FAVORABLE PROGNOSTIC FACTOR IN ACUTE PROMYELOCYTIC LEUKEMIA PATIENTS

V Misyurin[1,*] A Misyurin[1,2], L Kesaeva[1,2], Y Finashutina[1,2], I Soldatova[1,2], A Krutov[2], E Misyurina[2], A Lukina[3], I Sannikova[4], M Rotanova[5], V Lapin[5], O Rukavitsyn[6], S Shamanskiy[6], N Huazheva[7], V Ivanova[7], N Arhipova[8], Y Lesnaya[8], O Shitova[8], E Borisenkova[9], T Tolstokoraya[9], E Golubeva[9], N Bychkova[9], N Vopilina[10], I Guschanskaya[11], G Mihaylova[11], A Baryshnikov[1]
[1]Federal State Budgetary Institution "N.N. Blokhin Russian Cancer Research Center" under the Russian Academy of Medical Sciences, [2]«GeneTechnology» LLC, [3]FSBI Hematological Research Center, Moscow, [4]Regional Clinical Hospital №1, Voronezh, [5]Yaroslavl Regional Hospital, Yaroslavl, [6]Academician N.N. Burdenko Main Military Clinical Hospital, [7]S.P. Botkin City Clinical Hospital, [8]City Clinical Hospital № 40, Moscow, [9]Kaluga Regional Clinical Hospital №1, Kaluga, [10]Tambov Regional Hospital, Tambov, [11]Bryansk regional hospital №1, Bryansk, Russian Federation

Background: An appearance of a chimeric oncogene *PML/RAR*α is a cause of acute promyelocytic leukemia (APL) development. This molecular marker is used for diagnosis and minimal residual disease monitoring in patients with APL. *PRAME* gene related to a group of cancer-testis genes is expressed in APL and in a lot of other malignancies.
Aims: We studied the ratio between *PRAME* and isoforms bcr1 and bcr3 of *PML/RAR*α expression levels and compared it with a clinical data of patients with APL.
Methods: We compared mRNA expression levels of gene *PRAME* and *PML/RAR*α isoforms bcr1 and bcr3. All expression levels was confirmed after equation to *ABL* level. As the detection method we used RQ PCR. To create positive control, we cloned the genes sequences into expression vectors. We have observed the condition of patients within 20 months after the confirmation diagnosis. Therapy of all patients carried out according to AIDA protocol. Mann-Whitney test was used for comparison of the genes expression level.
Results: We found out that the gene *PRAME* is expressed in bone marrow of all primary APL patients (n=72, 100%). According our data, we divided the APL patients into two groups: with a high (more then 5%) and low (less then 5%) *PRAME* expression level in relation to *PML/RAR*α isoforms expression level. There were 28 patients (male, n=19; female, n=9; median age 29 y.o.) in first group and 44 patients (male, n=23; female, n=21; median age 28 y.o.) in second group. During 20 months of observation, 11 (15% of the total) patients of the second group developed hematologic relapse of APL. Among them 2 patients had isoform bcr1 and 9 patients had bcr3 isoform of *PML/RAR*α gene. All patients from the first group had not relapse during the observation period.
Summary and Conclusions: Patients with a low *PRAME* expression level compared with *PML/RAR*α gene expression level had a leukemia relapse earlier than patients with the high ratio values (p=0,0023). The most unfavorable prognostic factor is the expression of the isoform bcr3 *PML/RAR*α gene and low expression level of gene *PRAME*. We suggest that the ratio between their expression levels accurately determines a risk of relapse.

P171

ASXL1 MUTATIONS DEFINE A SUBGROUP OF AML PATIENTS WITH DISTINCT GENE EXPRESSION PROFILE AND POOR PROGNOSIS: A META-ANALYSIS OF 3311 ADULT AML PATIENTS

V Shivarov[1,*] M Ivanova[2]
[1]National Hematology Hospital, [2]Medical University, Sofia, Bulgaria

Background: *Addition of sex combs-like 1* (*ASXL1*) is a tumor-suppressor gene recurrently mutated in a broad spectrum of myeloid malignancies. In the last decade the elucidation of prognostic role of different somatic mutations in acute myeloid leukemia (AML) is gaining a growing clinical interest.
Aims: We performed a meta-analysis on published data from 6 independent reports of 3311 adult AML patients, including 385 *ASXL1* mutated cases to provide a robust evidence supporting *ASXL1* mutations testing in clinical setting for AML patients.
Results: Our meta-analysis showed that *ASXL1* mutations were associated with male gender and advanced age and were more frequent in secondary AML. Notably, *ASXL1* mutations were mutually exclusive with *FLT3* and *NPM1* mutations. *ASXL1* mutations appeared to be an independent adverse prognostic factor in all patients (OS (p<0.00001) and EFS (p=0.01)). This was also true for the subgroup of elderly patients over 60 years ((OS (p=0.002)). We also performed a meta-analysis of gene expression profiles of 3 publically available datasets. We were able to identify a signature of 92 genes, which were differentially expressed in *ASXL1* mutated *vs.* unmutated cases.
Summary and Conclusions: In conclusion, our data show that *ASXL1* mutations define a subgroup of AML patients with specific molecular profile and worse prognosis that justifies their testing in clinical settings.
Acknowledgements: This work is supported financially by Project ID_09_157 (Contract 5/16.12.2009) from the National Science Fund, Bulgaria.

P172

INCIDENCE AND PROGNOSTIC IMPACT OF FLT3 AND NPM1 MUTATIONS IN ACUTE MYELOID LEUKEMIA AND CKIT AND NRAS GENE MUTATIONS IN RUNX1/RUNX1T1 AML

E Petrova[1,*] I Martynkevich[1], L Polushkina[1], L Martynenko[1], M Ivanova[1], N Cybakova[1], E Kleina[1], E Shabanova[1], S Gritsaev[1], K Abdulkadyrov[1]
[1]Russian Research Institute of Hematology and Transfusiology, Saint-Petersburg, Saint-Petersburg, Russian Federation

Background: Several genetic alterations such as translocations, gene mutations and deletions play an important role in myeloid leukemogenesis. Activating mutations of *FLT3* receptor and *NPM1* are one of the most common genetic abnormalities reported. However, the prevalence and prognostic significance of this mutations in AML patients is still controversial. Higher complete remission rate and lower incidence of relapse led the researches to consider AML with t(8;21) as a favorable prognostic group. Nevertheless, approximately 30–50% of patients carrying this translocation relapse. The reason may be the presence of the mutations of different genes, that can considerably influence the prognosis.
Aims: The aim of the study was to determine the incidence and prognostic impact of *FLT3* and *NPM1* mutations in AML patients; and *CKIT* and *NRAS* gene mutations in AML with t(8;21).
Methods: Cytogenetic studies were performed on bone marrow samples using standard GTG-method. Polymerase chain reaction with the following restriction or direct sequencing analyses was performed to detect mutational status of *FLT3, NPM1, CKIT* and *NRAS* genes.
Results: 280 patients with *de novo* AML in the age of 18 to 86 years (Me=55) were analyzed. The male/female ratio was 134/146. Mutations in *FLT3* and *NPM1* were detected in 90/280 (32.1%) patients. A total of 107 mutations were revealed in this group: 54 – *FLT3-ITD*, 21 – *FLT3-TKD* and 32 – in *NPM1* gene. 73 (26.1%) patients had single mutations: 41 (14.6%) – *FLT3-ITD*, 15 (5.6%) – *FLT3-TKD* and 17 (6.1%) – in *NPM1*. In 17 patients mutations occurred simultaneously: 11 (3.9%) with *FLT3-ITD* and in *NPM1*, 4 (1.4%) with *FLT3-ITD* and *FLT3-TKD*, 2 (0.7%) with *FLT3-TKD* and in *NPM1*. According to the cytogenetic analyses patients were separated in the next groups: with normal karyotype (NK) – 151 (53.9%), with complex karyotype – 39 (13.9%), with another chromosomal aberrations – 90 (32.2%). We found that mutations with the significantly higher incidence (p=0.02) were observed in the groups of patients with NK (57/151) and the intermediate risk group (28/90), whereas there were only 5/39 patients with mutations in the group with complex karyotype. As the result of overall survival (OS) analyses we revealed the significant unfavourable influence of *FLT3-ITD* mutation on the prognosis (p=0.012).
Mutations of 8, 11 and 17 (D816V) exons of *CKIT* and 12, 13 and 61 codons of *NRAS* were analyzed in 21 patients with *de novo* AML and t(8;21) with the median age of 53 years (range 17–70). Mutation D816V in *CKIT* gene was detected in 3 (14,3%) patients. There were no mutations of 8 or 11 exons of *CKIT* in the investigated group. Mutations G12D, G13D in *NRAS* were found in 2 (9,5%) patients. We detected the significant differences of overall (p=0.041) and relapse-free survival (p=0.009) in patients with and without D816V mutation. Mutations in *NRAS* didn't show the same correlation (p=0.086).
Summary and Conclusions: Mutations in *FLT3* and *NPM1* had a significantly higher incidence in the group of patients with intermediate risk comparing with the group with complex karyotype. *FLT3* mutations showed the adverse prognostic value. The incidence of mutations in *CKIT* and *NRAS* genes in patients with t(8;21) was relatively high. *CKIT* D816V mutation was associated with higher relapse incidence and a worse survival in *RUNX1/RUNX1T1* AML patients, while *NRAS* mutations showed lack of prognostic significance. It could be recommended to further accumulate clinical and molecular-genetic data while choosing therapy regimen in AML with t(8;21) patients, as it showed quite heterogeneity.

THE NUP98 FUSION PROTEINS ARE RECURRENT ABERRANCIES IN ACUTE MYELOID LEUKEMIA: A REPORT FROM THE AIEOP AML-2002 STUDY GROUP.

M Pigazzi[1,*] E Manara[1], V Bisio[1], M Togni[2], R Masetti[3], A Astolfi[3], C Micalizzi[4], N Santoro[5], G Menna[6], M Zecca[7], P Pierani[8], A Biondi[9], L Franco[10], A Pession[11], G Basso[12]

Background: The Nucleoporin 98 (NUP98) is part of a family of proteins that are involved in the nuclear pore complex known to control the trafficking between nucleus and cytoplasm. However, *NUP98* is discovered to play a critical role in gene regulation being involved in several chromosomal translocations in hematopoietic disorders. Thirty different *NUP98* partner genes have been identified among human myelodisplastic syndrome and acute myeloid leukemia (AML). The chimeric NUP98 protein has the N-terminal of NUP98 and the C-terminal of its partner gene. Partners, if belonging to the homeobox genes conserved the DNA-binding domain, if not, they maintain chromatin interaction domains, mediating in any case a transcriptional regulatory function of the chimera, as recently described for *NUP98-NSD1* and *NUP98-JARID1A* fusions.
Aims: Here, we aim to identify the more frequent NUP98 fusions at diagnosis of Italian AML.
Methods: We performed a molecular screening of 8 partner genes of *NUP98*, in particular *NSD1, HOXC11,PHF23, HOXA9, JARID1A, HOXD13, LEDGF, DDX10* in 169 patients affected by AML *de novo* enrolled in the AIEOP LAM 2002/01 protocol. All patients were previously found negative for known recurrent genetic abnormalities involving *MLL*, *CBFB*, and *FLT3* genes.
Results: We found 21 out of the 169 negative patients (14%) harboring one of the *NUP98* chimeric fusion studied, identifying a new AML subgroup. By considering the Italian pediatric AML 2002/01 protocol 21 out of 482 enrolled patients had

a NUP98 rearrangement confirming a final frequency of NUP98 aberrancies of the 4.3% at diagnosis. In particular, 6 out of 169 patients were found positive for t(5;11)(q35;p15.5)*NUP98-NSD1*, 5/169 for t(11;12)(p15;q13)*NUP98-HOXC11*, 3/169 for t(11;17)(p15.5;p13)*NUP98-PHF23*, 2/169 for t(7;11)(p15;p15)*NUP98-HOXA9*, 2/169 for t(5;11)(q35;p15.5)*NUP98-JARID1A*, one patient harbored the t(2;11)(q31;p15)NUP98-HOXD13, one the t(9;11)(p22;p15.5)*NUP98-LEDGF*, and one the inv (11)(p15q22)*NUP98-DDX10*. Same rearrangements were screened in a group of 34 FLT3ITD patients and revealed a strong association (50%) exclusively with the *NUP98-NSD1* translocation as previously described. We then considered the *NUP98* rearrangements for their clinical impact and revealed that NUP98-rearranged patients event free survival (EFS) was significantly dismal (n=21, EFS at 10 years=15.1%, SE 8.8), than the rest of *NUP98*-negative patients (n=148, EFS=51.1%, SE 4.4). These data support the hypothesis that all *NUP98* rearrangements mediated a similar leukemia phenotype by controlling the expression of a series of common genes. In fact, partner genes with DNA binding domains (ie. *HOXA9*, *HOXC11*) are shown to interact with typical loci, such as the *HOX* locus, that are the same affected at the chromatin levels by methylation and acetylation (ie. *JARID1A*, *NSD1*, *PHF23*), or by RNA helicase domains (ie. *DDX10*) of those partner genes. Furthermore, the aberrant transcriptional regulation mediated by *NUP98*-fusions is shown to be enforced by their ability to sequester the wild type *NUP98*, which plays a critical role during normal hematopoiesis.

Summary and Conclusions: Finally, we described that *NUP98* is not rarely involved in somatic translocations causing AML in childhood. Furthermore, *NUP98* rearrangements identify a new subgroup of AML with a similar destiny of very poor prognosis, opening for further consideration in novel biological studies in order to attempt to a future targeting of NUP98 to improve their outcome.

SUPER-SILAC BASED QUANTITATIVE PROTEOMICS IN ACUTE MYELOID LEUKEMIA

E Aasebø[1,*] M Vaudel[1], O Mjaavatten[1], SO Døskeland[1], BT Gjertsen[2,3], Ø Bruserud[3], F S Berven[1], F Selheim[1]

[1]Department of Biomedicine, [2]Department of Clinical Science, University of Bergen, [3]Department of Internal Medicine, Haukeland University Hospital, Bergen, Norway

Background: Acute myeloid leukemia (AML) is an aggressive hematopoietic cancer of the myeloid lineage, where immature myeloblasts accumulate in the bone marrow. The disease is heterogeneous in both biological and clinical aspects. This complicates prognostication for patients receiving conventional intensive chemotherapy, particularly for the intermediate risk group, which lacks risk-stratifying factors. The treatment regime and therapy outcome thus depends on age, cytogenetics, molecular genetic abnormalities, and also previous clinical history. Quantitative mass-spectrometry based proteomics is a powerful analytical technique with potential to improve clinical evaluation in AML, providing complementary information to cytogenetic studies. Here, we applied the super-SILAC approach in which the cell lines used as internal standard are cultured in a modified medium where the endogenous light isotopes (^{12}C and/or ^{14}N) of the amino acids arginine and lysine are exchanged with heavy isotopes (^{13}C and/or ^{15}N, respectively), inducing a controlled mass increase of the amino acids which is measurable by mass spectrometry and allows distinguishing the internal standard from patient samples.

Aims: Using mass-spectrometry based quantitative proteomics, we aimed at gaining deeper clinical and biological insight into the leukemic proteome by comparing the blast cell proteome of 13 AML patients sampled at 1) time of diagnosis and 2) during relapse, after conventional intensive chemotherapy. Proteins with altered expression pattern between these stages of the disease could provide new biomarkers for improved prognostication and risk stratification of patients.

Methods: To obtain accurate protein quantification of AML patient blast cells, and at the same time cover the heterogeneity of the disease, we first generated an internal standard of five AML-derived cell lines, selected based on their diversity in regard to clinical, cytogenetic and molecular risk factors used for prognostication of AML patients. The five metabolically labeled cell lines were combined in order to generate the internal standard, which was spiked into each of the lysates obtained from individual AML patient blast cells in ratio 1:1. Protein separation was obtained with SDS-PAGE, followed by tryptic digestion, peptide separation by liquid chromatography and measurement by tandem mass spectrometry. Based on the acquired spectra, proteins were identified and quantified using MaxQuant coupled to its integrated search engine Andromeda. Statistical analysis was conducted using the Perseus software. Informed consent was obtained from all patients used in this study.

Results: The relative protein abundance was obtained between each patient (light isotope) and the internal standard (heavy isotope), enabling relative quantification of thousands of proteins between the individual samples. Approximately 3000 proteins could be quantified accurately in the AML patient blast cells proteome. Comparing how protein expression changed in 13 patients from time of diagnosis to relapsed leukemia revealed significantly altered expression of several hundred proteins, including proteins previously described as altered during relapse. Proteins involved in *e.g.* transcription and mitochondrial processes were expressed in a significantly higher level at relapsed disease, compared to the primary disease. Oppositely, some protein phosphatases and proteins involved in immune defense processes were higher expressed during primary disease. Interestingly, the significantly regulated proteins allowed us to segregate the relapsed leukemia patients into subgroups, revealing biomarker candidates that could potentially be used for improved risk stratification.

Summary and Conclusions: By using our super-SILAC proteomic approach we were able to quantify thousands of proteins in the leukemic proteome derived from 13 AML patients. By comparing the blast cell proteome from 13 patients sampled 1) at time of diagnosis and 2) relapsed disease, we were able to reveal AML-related proteins and pathways that were significantly regulated before and after conventional chemotherapy. We propose that new risk stratification markers and an improved understanding of chemoresistance mechanisms can be obtained from these data.

P175

EARLY ABSOLUTE LYMPHOCYTE COUNT IS NOT A PREDICTOR OF RELAPSE OR SURVIVAL IN ACUTE MYELOID LEUKEMIA

E Yamazaki[1,*] E Yamamoto[1], E Ogusa[2], S Koyama[1], W Yamamoto[2], Y Nakajima[1], S Ito[3], K Motohashi[4], M Hagihara[4], K Matsumoto[2], M Tanaka[4], H Koharazawa[5], N Tomita[1], J Taguchi[3], K Fujimaki[6], H Fujita[7], S Fujisawa[4], H Kanamori[2], K Ogawa[8], Y Ishigatsubo[1]

[1]Department of Internal Medicine and Clinical Immunology, Yokohama City University Graduate Scool of Medicine, [2]Department of Hematology, Kanagawa Cancer Center, Yokohama, [3]Department of Hematology, Shizuoka Red Cross Hospital, Shizuoka, [4]Department of Hematology, Yokohama City University Medical Center, Yokohama, [5]Department of Hematology, Yamato City Hospital, Yamato, [6]Department of Hematology, Fujisawa City Hospital, Fujisawa, [7]Department of Hematology, Saiseikai Yokohama Nanbu Howpital, Yokohama, [8]Department of Hematology, Yokosuka City Hospital, Yokosuka, Japan

Background: The absolute lymphocyte count (ALC) recovery is an independent predictor for survival in acute myeloid leukemia (AML) post autologous transplantation or in childhood acute lymphoblastic leukemia after induction chemotherapy. However, the role of ALC recovery after induction chemotherapy in adult AML is controversial.

Aims: We examined the ALC recovery after induction chemotherapy to assess survival in adult AML.

Methods: We performed a retrospective study involving 303 adult patients newly diagnosed with AML excepted acute promyelocytic leukemia between 2001 and 2012 who received either daunorubicin or idarubicin in combination with cytarabine as induction therapy. 230 patients (75.9%) obtained complete remission (CR). Data was analyzed for survival in these 230 patients.

Results: The study included 140 males and 90 females, with median age at diagnosis of 48 years (range, 15-77 years). Pretreatment cytogenetics was determined in 228 (99%): 57 (25%) were categorized as favorable (t(8;21) or inv(16)/t(16;16) with or without other abnormalities), 23 (10%) had abnormalities of chromosome 7 and/or complex karyotype defined as ≥3 aberrations (adverse), while the remaining 148 (64%) were categorized as intermediate with other findings, primarily composed of a normal karyotype (45%). 171 patients obtained CR with 1 course of induction chemotherapy, while 46 needed 2 courses, and 13 needed 3 courses. Sixty-eight patients received an allogeneic transplantation in their first CR, with 53 patients receiving it after their first relapse. With a median follow-up of 3.7 years (range, 0.3 - 11.7 years), relapse and death occurred in 105 and 87 patients, respectively. Disease-free survival (DFS) and overall survival (OS) for all patients are 42.4% and 64.1% at 3 years, respectively. The ALC at 28 days after first induction chemotherapy initiation was 705/μl (range 56-3781/μl). We divided ALC at time of day 28 into quartiles and then assessed DFS and OS. Lower quartile was 442.5/μl and upper quartile was 1043/μl in ALC of our cohort. Neither DFS nor OS have significant differences between the top and bottom quartile of ALC at day 28. Survival curves were superimposed in these groups. Same result was shown in the subgroup of patients who obtained CR with 1 cycle of induction therapy. Multivariate analysis showed the recovery of platelet count and hemoglobin level at day 28 and favorable cytogenetic abnormalities were significant predictors for DFS, while favorable cytogenetics and age at diagnosis were significant predictors for OS (Figure 1).

Figure 1. Survival according to ALC at day 28.

Summary and Conclusions: ALC at 28 days from therapy initiation is not predictive of DFS or OS for adult AML.

Acute myeloid leukemia - Clinical 2

P176

TREATMENT WITH RADIATION, CHEMOTHERAPY, OR BOTH DEMONSTRATES SIMILAR OUTCOMES IN PATIENTS WITH ISOLATED MYELOID SARCOMA THAT MAY NOT BE DIFFERENT THAN *DE NOVO* ACUTE MYELOID LEUKEMIA

FM Feller[1,*] S M Devlin[2], E M Stein[1], M S Tallman[1], R K Rampal[1]
[1]Leukemia, [2]Memorial Sloan Kettering Cancer Center, New York, United States

Background: The presentation of acute myeloid leukemia as an isolated extramedullary tumor without bone marrow involvement is an uncommon event but one that poses difficulties in clinical decision-making. Due to its rarity, the treatment of isolated myeloid sarcomas has never been validated in a randomized clinical trial, and treatment paradigms have been developed based largely on case reports and clinician experiences. Various treatment modalities, such as systemic chemotherapy and radiation therapy have been employed in the treatment of this condition, however there is a paucity of data to guide the utilization of these different approaches in the treatment of myeloid sarcoma.
Aims: To determine the impact of chemotherapy, radiation therapy, and the combination of chemotherapy and radiation therapy on the survival and disease response in patients with isolated myeloid sarcoma.
Methods: We performed a retrospective review to compare radiation therapy (RT), chemotherapy (CT) and combination radiation and chemotherapy. A PubMed search was completed that identified seven publications consisting of large case reports or reviews where individual patient characteristics (including treatment course, site of disease, overall survival and time to development of bone marrow involvement) were defined. We included adult patients who had extramedullary myeloid sarcoma without bone marrow involvement at the time of diagnosis and excluded patients with leukemia cutis or lymph nodes as their sole site of disease. Seventy -one patients were included in the analysis and the primary outcome was overall survival.
Results: There was no significant difference in overall survival (p=0.41) whether patients were initially treated with radiation therapy (n=14, 11.2 months, 10- NR), chemotherapy (n=40, 19 months, 13- 36) or the combination of chemotherapy and radiation (n=17, 24 months, 12- NR) (Figure 1). At two years, the cumulative incidence of progression of disease to involve the bone marrow is overall 0.70 (0.56- 0.81) with no difference seen amongst the three treatment groups (RT 0.79; 0.42- 0.93, CT 0.70; 0.48- 0.85, combination 0.66; 0.29- 0.87). In terms of overall survival, the median overall survival of patients presenting with isolated myeloid sarcoma is 16 months (n=71). For comparison, AML patients treated on the ECOG1900 trial who received standard therapy had a median overall survival of 15.7 months, suggesting that the survival of patients with isolated myeloid sarcoma is likely no worse than those with *de novo* AML who undergo standard induction therapy.

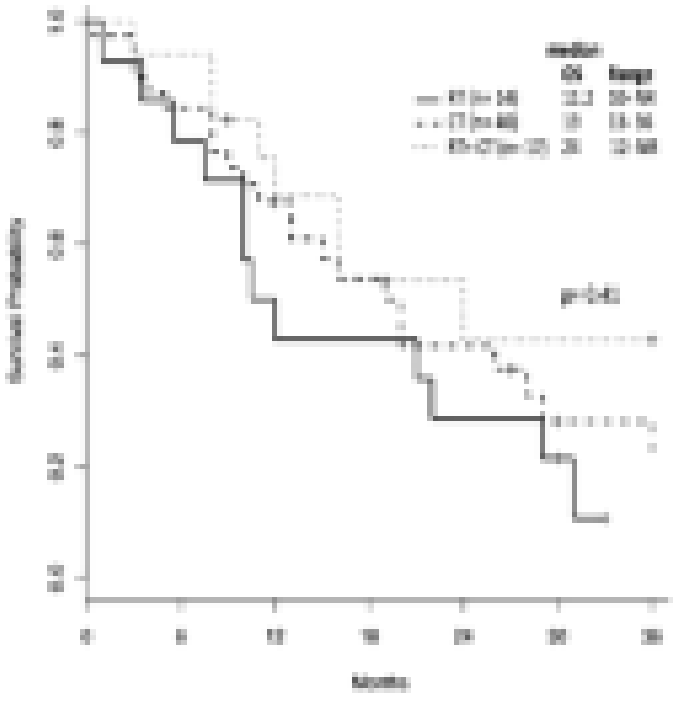

Figure 1.

Summary and Conclusions: In summary, this study is unique in its focus solely on adult isolated myeloid sarcoma as the initial presentation of AML with the exclusion of skin and lymph node sites of disease, acknowledging the relatively small number of patients included in some cohorts. Our data support the use of chemotherapy alone or radiation therapy alone as initial treatment for isolated myeloid sarcoma, and suggest that combined modality therapy would not have an additive effect. Notably, the rate of disease progression to involve the bone marrow was similar in both the chemotherapy and radiation therapy treated patients. This raises questions about possible unique aspects of the biology of myeloid sarcoma, which may allow it to evade the effects of systemic chemotherapy. Further evaluation involving larger numbers of patients and inclusion of primary patient data from Memorial Sloan- Kettering Cancer Center, as well as investigation of the role for allogeneic stem cell transplantation as part of first line therapy are required and currently underway.

U. santiago de Compostela, Santiago de Compostela, [16]Hematology, Germans Trias y Pujol, Badalona, [17]Hematology, H.U. Virgen del Rocio, Sevilla, [18]Hematology, H. G. U. Gregorio Marañon, Madrid, [19]Hematology, C. Asistencial U. Burgos, Burgos, [20]Hematology, H. Virgen del Puerto, Plasencia, Caceres, [21]Hematology, H. U. Politecnic la Fe, Valencia, [22]Hematology, H.U. de Leon, Leon, Spain

Background: Outcome with intensive chemotherapy in AML patients above the age of 70 is disappointing (median OS 4.6 months). The MD Anderson CC has identified as OS risk factors: age >80 yrs, ECOG ≥2, creatinine >1.3mg/dL and adverse cytogenetic (0 as opposed to 4 risk factors OS: 11.3 and 0.5 months respectively*; Kantarjian et al. Blood 2010)*. Azacitidine (AZA) has been explored in bone marrow blast <30% AML patients (median OS 24.5 months; *Fenaux et al. JCO 2010)*. The *ALMA study* has suggested as OS risk factors for first line AZA treated AML patients: ECOG≥2, pretreatment WBC >10.000/µL, bone marrow blast >30% and adverse cytogenetic (*Ramos et al., ASH 2012)*.
Aims: The aim of this study is to analyze the effectiveness and toxicity of AZA in 70 yr and above AML patients and to validate both, *MDACC* and *ALMA* scales.
Methods: We carried out the analysis of the 70 yr old and above patients included in the *ALMA study*, which consisted of AML patients from 22 Spanish sites, treated with AZA as first line. We evaluated effectiveness as *ELN-2010* criteria, toxicity as *CTCAE v3.0 scale*, *OS* and the mortality within the first 8 weeks (*M8wks*).
Results: Eighty eight (65 male/23female) out of 110 pt included in ALMA study were 70 or older, median age 76 (70-89). Risk factors as follows, age ≥80y: 28pt, ECOG≥2: 26pt, Creatinine >1.3 mg/dL: 17pt, adverse cytogenetic: 22pt, pretreatment WBC >10.000/µL: 25pt, BM blast >30%: 55pt. Seventy four patients were evaluated for efficacy, ORR 17% (CR+CRi 11pt, PR2pt). Median follow up 8.5 months (0.5-52), 49pt progressed and 74pt died. The *M8wks* was 9% and median OS 10 months. (1 year OS 40%). In this study age >80, ECOG≥2 and pretreatment WBC >10.000/µL predicted *M8wks* (p 0.05, 0.05, 0.04) and ECOG≥2, adverse cytogenetic, bone marrow blast >30% predicted OS (p<0.01). The *ALMA scale* (0 *versus* 1-2 *versus* 3-4 risk factors) predicted *M8wks* (p<0.01) as well as OS (16.5 *vs* 10 *vs* 3 months; p<0.01), while *MDACC scale* (0 *versus* 1-2 *versus* 3-4 risk factors) predicted OS (15 *vs* 7.7 *vs* 4.5 months; p<0.01) but didn't predicted *M8wks* (p 0.57). We analyzed a total of 540 AZA cycles (median 4, range 1-29) for toxicity, only in 3 cases treatment was discontinued because of toxicity.
Summary and Conclusions: These results suggest AZA as an effective and well-tolerated first line treatments in 70 and above AML patients. The OS seems longer than the previous reported with intensive chemotherapy, even in those patients with no MDACC RF. The *ALMA scale* predicts OS and *M8wks* in these elderly AML pt treated with AZA as first line.

P178

LOW DOSE GEMTUZUMAB OZOGAMICIN PLUS FLAI AS INDUCTION THERAPY IN CD33-POSITIVE AML. DEFINITIVE RESULTS AND LONG TERM OUTCOME OF A PHASE III MULTICENTER PROSPECTIVE CLINICAL TRIAL (NCT.00909168).

A Candoni[1,*] G Martinelli[2], F Gherlinzoni[3], G Visani[4], E Simeone[1], C Papayanidis[2], I Iacobucci[2], M Gottardi[3], A Isidori[4], E Ottaviani[2], M Baccarani[2], R Fanin[1]
[1]Division of Hematology and SCT, University of Udine, Udine, [2]Institute of Hematology and Oncology A. and L. Seragnoli, University of Bologna, Bologna, [3]Division of Hematology, Hospital of Treviso, Treviso, [4]Hematology and HSCT Center, San Salvatore Hospital, Pesaro, Italy

Background: The role and safety of Gemtuzumab-ozogamicin (GO) containing combinations in previously untreated AML patients younger than 65 remains to be defined. Here we report the definitive results from a phase III multicenter clinical trial combining low dose of GO with FLAI (Fludarabine, Cytarabine, Idarubicin) as Induction regimen (eudract: 2007-005248-26; ClinicalTrials.gov NCT00909168).
Aims: Here we report the definitive results from a phase III multicenter clinical trial combining low dose of GO with FLAI (Fludarabine, Cytarabine, Idarubicin) as Induction regimen (eudract: 2007-005248-26; ClinicalTrials.gov NCT00909168).
Methods: Primary endpoints: Feasibility, Efficacy (CR+PR rate) and Toxicity of FLAI+GO; DFS and OS. Secondary endpoints: Evaluation of Minimal Residual Disease by WT1 (and other biologic markers) expression and monitoring. Feasibility and outcome of consolidation with Hematopoietic stem cell transplant (HSCT). One hundred thirty consecutive and untreated AML patients were included. All patients were younger than 65 with a median age of 52 years (range, 18-65) and CD33 expression exceeded 20% in all cases. The M/F ratio was 65/65, and 92/130 (71%) of patients were poor-risk at diagnosis. The induction regimen (GO-FLAI) included fludarabine (30 mg/sqm) and Ara-C (2 g/sqm) on days 1-5, idarubicin (10 mg/sqm) on days 1, 3, and 5 and GO (3 mg/sqm) on day 6. HSCT was planned for all high risk AML patients in first complete remission (CR), after consolidation with intermediate doses of Ara-C and idarubicin (ID-AC and IDA). Cytogenetic, multidrug-resistance phenotype, FLT3 and NPM mutation status, WT1 quantitative expression analyses, were performed at diagnosis in all patients. Quantitative WT1 gene expression (RQ-PCR technique validated by Leukemia Net), cytogenetic (in positive cases) and specific molecular marker analyses were performed after induction to detect and follow Minimal Residual Disease.
Results: Patients were evaluated for response rate, treatment-related adverse events, overall survival (OS) and disease free survival (DFS), feasibility and outcome of intensification with HSCT. After induction with GO-FLAI, CR rate was 83% (104 of 126 evaluable pts); five patients achieved partial remission and 17/130 (13%) were resistant (Overall response rate 87%). There were only 4 cases of death during induction (DDI 3%). The haematological and extra haematological toxicity of GO-FLAI was manageable and will be reported in detail; 45% of patients experienced transient and reversible GO infusion-related adverse events (especially fever and chills), but no cases of veno-occlusive disease occurred during chemotherapy or after allogeneic HSCT. In the setting of patients who achieved a cytological CR after GO-FLAI, the mean of WT1 copies dropped from 8178±10040/10^4ABL (at diagnosis) to 165±227 copies/10^4ABL after induction therapy [P<0.05]. After a median follow-up of 48 months, 67/130 (52%) patients are alive. The probability of 1, 2, 5-year OS was 80%, 63% and 52%. The probability of 1, 2, 5-year DFS was 71%, 54% and 47%. Allogeneic and autologus HSCT was performed in 58 (44%) and 24 (18%) patients, respectively.
Summary and Conclusions: The definitive results of this trial confirm that GO (3 mg/sqm) combined with FLAI is an effective and well tolerated induction regimen for CD33 positive AML patients younger than 65 years, with a high complete response rate, good disease debulking, favourable safety profile and low DDI, allowing consolidation therapy with HSCT early and in a high proportion of cases (82/130, 62%). Moreover, these results support the reassessment of GO-containing combinations as front-line AML therapy.

P179

PHASE IB STUDY OF PF-04449913, A HEDGEHOG (HH) INHIBITOR, IN COMBINATION WITH LOW-DOSE CYTARABINE OR INTENSIVE CHEMOTHERAPY, IN ACUTE MYELOID LEUKEMIA (AML) OR HIGH-RISK MYELODYSPLASTIC SYNDROME (MDS)

J Cortes[1,*] A O'Connell[2], MN Shaik[3], R Cesari[4], A Abbattista[4], A Woolfson[5], D Pollyea[6], M Savona[7]
[1]University of Texas, MD Anderson Cancer Center, Houston, [2]Pfizer Oncology, Collegeville, [3]Pfizer Oncology, La Jolla, United States, [4]Pfizer Oncology, Milan, Italy, [5]Pfizer Oncology, New York, [6]University of Colorado Cancer Center, Aurora, [7]Tennessee Oncology, Nashville, United States

Background: Aberrant activation of the Hh pathway has been mechanistically linked to both hematologic malignancies and solid tumors through direct cell-cycle interactions, cancer stem cell inhibition, indirect stromal interactions, and anti-angiogenic effects. PF-04449913 (PF) is a potent, selective, oral inhibitor of the Hh pathway, which acts through inhibition of Smoothened, with demonstrated activity in pre-clinical models. Single-agent treatment of patients (pts) with hematologic diseases in a phase I study provided preliminary evidence of clinical activity.
Aims: Primary objectives of the phase IB dose-finding portion were to determine the maximum tolerated dose (MTD) and recommended phase 2 dose (RP2D) of PF in combination with low-dose cytarabine (LDAC; Arm A for unfit pts, ie, those not fit for high-dose chemotherapy) or intensive chemotherapy (cytarabine and daunorubicin; Arm C for fit pts) in pts with AML or high-risk MDS.
Methods: The study followed a standard 3+3 design, and the primary endpoint was occurrence of first-cycle dose-limiting toxicities (DLTs). In Arm A pts received oral PF administered continuously once daily (starting dose 100 or 200 mg) in combination with 20 mg LDAC administered subcutaneously twice daily on days 1-10 of each 28-day cycle. In Arm C, pts received PF continuously once daily (starting dose 100 or 200 mg) beginning on day -3, in combination with IV daunorubicin (60 mg/m^2 on days 1-3 of induction) and cytarabine (100 mg/m^2, on days 1-7 of induction) followed by consolidation (2-4 cycles of cytarabine 1 g/m^2 twice daily on days 1, 3, and 5 of each cycle); thereafter, single-agent PF was administered as maintenance therapy in 28-day cycles.
Results: Eighteen unfit pts were enrolled in Arm A (11 males/7 females; 100 mg PF, N=12; 200 mg PF, N=6). Median age was 75 years (data undergoing validation). The most common PF-related adverse events (AEs) included dysgeusia (22%) and nausea (22%). The most frequently reported non-hematologic PF-related ≥G3 AEs included G3 dehydration, hyperuricemia, fatigue, muscle spasms (all 6%) and G4 asthenia (6%). Two on-study deaths were reported, one due to acute respiratory distress syndrome and one to acute myocardial infarction. Twenty-two fit pts were enrolled in Arm C (12 males/10 females; 100 mg PF, N=16; 200 mg PF, N=6). Median age was 59 years (data undergoing validation). The most common PF-related AEs included nausea (64%), diarrhea (32%) and muscle spasms (32%). The most frequently reported non-hematologic PF-related ≥G3 AEs included G3 pyrexia, myalgia, and rash (all 5%). A DLT of G4 polyneuropathy, later attributed to concomitant medication, was reported at the 100-mg dose level; treatment was permanently discontinued. No ≥G3 QTcF prolongation was observed in either arm. A 100-mg daily dose was selected as the RP2D for fit and unfit pts, based on the observed tolerability profile and the increase in PF exposures observed with strong CYP3A4 inhibitors such as azoles. Preliminary efficacy signals were observed, with complete responses reported in both fit and unfit pts.
Summary and Conclusions: Oral administration of PF in combination with LDAC or intensive chemotherapy was clinically manageable and relatively well tolerated in pts with AML or high-risk MDS, and showed favorable pharmacokinetic characteristics. Based on the observed safety profile and increased exposure from drug-drug interactions with strong CYP3A4 inhibitors, the RP2D was established at 100-mg daily for both combinations. The trial is registered at clinicaltrials.gov; NCT01546038.

P180

RESULTS OF A PHASE 1 STUDY OF BMN 673, A POTENT AND SPECIFIC PARP-1/2 INHIBITOR, IN PATIENTS WITH ADVANCED HEMATOLOGICAL MALIGNANCIES

G J Mufti[1,*] E Estey[2], R Popat[3], R Mattison[4], T Menne[5], J Azar[6], A Bloor[7], T Gaymes[1], A Khwaja[3], M Juckett[4], A Lennard[5], C Zhang[8], G JA Gallant[8], AK Gopal[2]
[1]King's College Hospital NHS Foundation Trust, London, United Kingdom, [2]University of Washington/Seattle Cancer Care Alliance, Seattle, WA, United States, [3]University College London Cancer Institute, London, United Kingdom, [4]University of Wisconsin, Madison, WI, United States, [5]The Newcastle Upon Tyne NHS Foundation Trust, Newcastle Upon Tyne, United Kingdom, [6]Indiana University Melvin and Bren Simon Cancer Center, Indianapolis, IN, United States, [7]Christie Hospital NHS Trust, Manchester, United Kingdom, [8]BioMarin Pharmaceutical Inc., Novato, CA, United States

Background: BMN 673 is the most potent inhibitor of poly(ADP-ribose) polymerase (PARP)-1/2 in clinical development (IC50<1nM, *in vitro*), inducing synthetic lethality in tumors deficient in homologous recombination. Non-clinically, hematological malignancies, including Acute Myeloid Leukemia (AML), Myelodysplastic Syndrome (MDS), Chronic Lymphocytic Leukemia (CLL) and Mantle Cell Leukemia (MCL), have exhibited sensitivity to PARP inhibition, as a consequence of defects in DNA repair that could lead to deficient homologous recombination.
Aims: The main objective of this study was to identify the maximum tolerated dose (MTD) independently in the 2 study arms (Arm 1: AML and MDS; Arm 2: CLL and MCL).
Methods: Safety, pharmacokinetics (PK), pharmacodynamics (PD), and preliminary efficacy of BMN 673 were evaluated in a 2-arm study. Oral BMN 673 was administered on a continuous daily schedule (21-day cycle) at escalating dose levels.
Results: 33 pts (Arm 1: 21 AML, 4 MDS; Arm 2: 4 CLL, 4 MCL), 10F/23M, median age 71 (range 22-86), ECOG PS 0-1 were enrolled. Median number of previous regimens was 3 (range 1-7) in Arm 1 and 6 (range 1-13) in Arm 2. BMN 673 dose levels were: 100, 200, 300, 450, 900, 1350 and 2000 µg/day. Dose-limiting toxicities (DLTs) included febrile neutropenia and neu-

tropenic sepsis in 2/4 pts at 2000 µg/day in Arm 1 and severe neutropenia in 2/5 pts at 900 µg/day in Arm 2. Overall, the most frequent drug-related adverse events were fatigue (all grades=27%), neutropenia (27%), nausea (24%), infections (21%), and thrombocytopenia (12%). No alopecia was reported. No responses were seen. Stable disease was seen in 13/25 pts in Arm 1 and 5/8 pts in Arm 2. 1 MDS pt received 24 cycles of BMN 673 (484 days) and became RBC transfusion independent.
Summary and Conclusions: The MTD of BMN 673 appears to be different in pts with AML, MDS, CLL and MCL. As a single-agent, BMN 673 has demonstrated limited activity in an unselected group of pts with advanced hematological malignancies.

P181

PHASE 2, OPEN-LABEL STUDY OF E7070, IDARUBICIN AND CYTARABINE IN PATIENTS WITH RELAPSED OR REFRACTORY ACUTE MYELOID LEUKEMA AND HIGH-RISK MYELODYSPLASTIC SYNDROME

G Borthakur[1,*] J E Cortes[1], T M Kadia[1], N Pemmaraju[1], E Jabbour[1], N Jain[1], N Daver[1], H Kantarjian[1]
[1]Leukemia, University of Texas MD Anderson Cancer Center, Houston, United States

Background: E7070 (Indisulam) is a novel sulfonamide drug that impacts energy metabolism and cell cycle progression. E7070 suppresses cell cycle progression partly by reducing cyclin H expression and thereby inhibiting phosphorylation of Rb protein. One of its potential metabolic targets is malate dehydrogenase. Pre-clinical studies have established synergy of E7070 with nucleoside analogs as well as topoisomerase inhibitors.
Aims: We designed a phase 2 study of E7070 (E) in combination with idarubicin (I) and cytarabine (A) in patients with relapsed-refractory acute myelogenous leukemia (AML) and high-risk myelodysplastic syndromes (MDS).
Methods: In Stage 1 patients receive E7070 at 400 mg/m^2 intravenously on day 1 and day 8 in a 21 day cycle (E). Patients with clinical benefit after single agent E7070 can continue for another 5 cycles. In the absence of benefit with E7070 alone, patients can proceed to stage 2to receive E7070 at the same dose on day 1 and day 8 followed by Idarubicin 8 mg/m^2 IVx3 and Cytarabine 1.0 g/m^2 IV over 24 hours daily on day 9-12 (age <60 years) or days 9-11 (age >60 years) in a 28 day cycle (E+IA). Patients with response can receive up to 2 additional cycles of E+IA. The efficacy of the regimen is assessed according to the Simon's two-stage Minmax design. The investigational therapy will be considered promising if the response rate is 25% or higher. The study will stop if the toxicity is likely to be greater than 33%. The planned accrual is 40 patients. Patients are considered evaluable they received E and achieved response or received at least one treatment with E+IA.
Results: This report is a planned interim analysis for futility. Twenty-one patients with relapsed/refractory AML (N=20) or MDS (N=1) and median age of 65 years (range, 45-76 yrs) have been enrolled. Eight patients have poor risk cytogenetics, median number of prior treatments are 2 (range, 1-4), 13 (62%) received prior cytarabine based regimens (including stem cell transplant =2) and 16 (76%) received hypomethylating agent. No response was seen after stage 1 (E). Of the 15 patients who received at least one cycle of E and E+IA (stage 2) each, 8 (53%) achieved complete remission (CR) or CR with incomplete recovery of counts (CRi). Four of the responders have diploid cytogenetics while it is poor-risk in the other four. All received prior cytarabine based regimen or several cycles of hypomethylating agent. Infectious events were encountered in 16/21 patients and 2 patients had prolonged marrow hypoplasia (>42 days). Grade 3 hyperbilirubinemia has been the only ≥grade 3 non-hematological toxicity.
Summary and Conclusions: Interim analysis shows promising responses with a regimen of E7070 in combination with Idarubicin and cytarabine among patients with relapsed/refractory myeloid malignancies. E7070 appears to lack single agent activity and the treatment cycle with E7070 alone will be omitted in future patients. Based on study design accrual is continuing.

P182

AZACITIDINE AND INTENSIVE CHEMOTHERAPY IN THE TREATMENT OF ELDERLY PATIENTS WITH ACUTE MYELOID LEUKEMIA: A META-ANALYSIS

S Gao[1], L Su[1,*] W Li[1], Y Li[2], P Yu[1]
[1]Cancer center, The First hospital, Jilin University, [2]Department of Hematology, The central Hospital of Changchun, Changchun, China

Background: The prognosis of elderly patients with acute myeloid leukemia (AML) is poor and the optimal therapeutic regimen is still investigated. In recent years, increasing studies focused on azacitidine in the treatment of elderly patients with AML. Azacitidine treatment was linked to lower CR rates, but long-term survival was comparable with intensive chemotherapy. However, there are some controversies. Hence, the attempt on evaluating the efficacy between azacitidine and intensive chemotherapy was performed with a meta-analysis.
Aims: To compare the efficacy and safety of azacitidine and intensive chemotherapy in elderly patients with AML.
Methods: A literature search was undertaken through September 2013 looking for the cohort studies evaluating the efficacy and safety of azacitidine and intensive chemotherapy in the treatment of elderly patients with AML. From 287 full-text articles and 207 meeting abstracts, six were included in this study. Heterogeneity was assessed by using the I^2 index, and quality assessment was performed with the Newcastle-Ottawa Scale.
Results: Compared with intensive chemotherapy, azacitidine treatment was associated with a lower complete remission (CR) rate (OR=0.40; 95% IC=0.19-0.84; *P*=0.02), but a higher partial remission (PR) rate (OR=3.39; 95% IC=1.35-8.49; *P*=0.009). However, early mortality (OR=0.22; 95% IC=0.03-1.99; *P*=0.18), one year (OR=0.93; 95% IC=0.53-1.64; *P*=0.80), and two year (OR=0.51; 95% IC=0.25-1.06; *P*=0.07) survival were not significantly different between patients treatment with azacitidine and intensive chemotherapy.
Summary and Conclusions: Both this and previous studies indicate that azacitidine treatment might be a valuable alternative to intensive chemotherapy in elderly patients with AML.

P183

THE ADDITION OF CLADRIBINE TO THE STANDARD 7+3 (CYTARABINE/DAUNORUBICIN) DID NOT IMPROVE OUTCOMES OF THE FIT SECONDARY ACUTE MYELOID LEUKEMIA TREATMENT – RETROSPECTIVE MULTICENTER PALG STUDY.

S Grosicki[1,*] E Bodzenta[1], S Ilona[1], A Wierzbowska[2], M Kuydowicz[2], M Joks[3], A Czyz[3], E Patkowska[4], K Warzocha[4], M Watek[5], M Pasiarski[5], B Piatkowska-Jakubas[6]
[1]Department of Hematology, SPZOZ ZSM w Chorzowie, Chorzow, [2]Department of Hematology, Medical University, Lodz, [3]Department of Hematology, Medical University, Poznan, [4]Department of Hematology, Institute of Hematology and Transfusiology, Warsaw, [5]Department of Hematology, Swiętokrzyskie Centrum Onkologii, Kielce, [6]Department of Hematology, Jagiellonian University, Cracow, Poland

Background: Recognition of the secondary acute myeloid leukemia (sAML) is increasing because of more effective treatment of cancers in last years. Outcomes in this group of patients' treatment are particularly bad. Previous studies proved that addition of cladribine to the standard 3+7 induction in AML patientsbelow 60 improved complete remission rate (CR) and overall survival (OS) (Holowiecki *et al.* JCO 2012).
Aims: The goal of this retrospective, multicenter PALG study was assessment of the results of intensive chemotherapy of sAML treatment in Poland.
Methods: Forty three patients, 59% female with median of age 56 (21-73) diagnosed on 2004-2013 in 6 PALG centers were entered to the study. Median time from diagnosis of primary neoplasm (do czego do rozpoznania AML?) was 5 years. Median WBC at diagnosis of sAML was 12.35 G/l. Cytogenetic risk was low in 9%, intermediate 37%, high in 22%, not known in 32% of patients. According to FAB classification they were M0 in 9%, M1 in 26%, M2 in 26%, M4 in 27%, M5 in 9%, M6 in 3%. In 80% of cases diagnosis of sAML was preceded by solid cancers (the most frequent was breast cancer in 44%), in 20% hematologic neoplasms. In 76% chemotherapy, in 57% radiotherapy, in 46% both before diagnosis of sAML were given. In 46,5% (n=20) sAML patients DAC induction regimen (daunorubicin 60 mg/m^2/d 1-3, cytarabine 200 mg/m^2/d 1-7, cladribine 5 mg/m^2/d 1-5) was given. Reminders receiving as induction DA 7+3 regimen (the same regimen as DAC without cladribine). In DAC and DA arm after CR assessment allogeneic hematopoietic stem cell transplantation (alloHSCT) was carried out in 6 and 2 cases respectively.
Results: After whole induction CR was obtained in 55% (n=11) *vs.* 52% (n=12) in DAC and DA arm respectively, p=0.90. Toxicity was similar in both groups. Progression free survival (PFS) was 23% *vs.* 41% patients after 4 years in DAC and DA arm respectively, p=0.21. Median OS was 20% *vs.* 26% patients were alive in group DAC *vs.* DA after 4 years respectively, p=0.35.
Summary and Conclusions: Secondary AML remains a challenge because of increasing frequency and poor prognosis. In our study we do not observed improvement of the treatment outcomes of fit sAML by addition of cladribine to standard induction as it was proved in primary AML. This observation requires further prospective studies.

P184

ARTESUNATE, AN ANTIMALARIAL DRUG DISPLAYS PRECLINICAL ACTIVITY IN FLT3 MUTATED LEUKEMIA AND SYNERGISES WITH ARAC

U Mony[1,*] R Hoya-Arias[1], S Ambati[2], B Pera[1], Y Dogan[3], E Peguero[1], JH Shieh[1], M Moore[1]
[1]Cell Biology Program, [2]Department of Pediatrics, [3]Cancer Biology and Genetics program, Memorial Sloan-Kettering Cancer Center, New York, United States

Background: Acute myeloid leukemias (AML) are a group of heterogeneous hematological clonal disorders, marked by an abnormal accumulation of undif-

ferentiated myeloblasts in the peripheral blood and bone marrow and is one of the leading causes of blood cancer related deaths worldwide. Novel targeted agents in combination with standard chemotherapy or combination therapy to target multiple pathogenic signaling pathways are needed to effectively cure or overcome therapy resistance in the disease. Studies have found that bone marrow is hypoxic and leukemia develops in a hypoxic bone marrow environment and hypoxia promotes chemoresistance. Approximately 20-25% of *de-novo* AML patients have mutations in the FLT-3 gene that is associated with poor prognosis. Despite many efforts in the past to develop a therapeutic target for FLT3, none of the agents tested have yet to be FDA approved for clinical use.
Aims: To identify a drug that can selectively target FLT3 mutated leukemia, which is effective under hypoxic conditions as well and will have limited toxicity to patients.
Results: Artesunate, derived from a plant *Artemisia annua* L. is an FDA approved drug for treating malaria and has been reported to have anti-cancer activity. We evaluated the *in vitro* toxicity of Artesunate in a panel of human AML cell lines representative of a number of molecular subtypes, with or without FLT3 mutation. Artesunate induced cytotoxicity in all tested AML cell lines under both normoxic and hypoxic conditions, but cells expressing FLT3/ITD showed greater sensitivity to the cytotoxic effects of Artesunate as compared to other AML cell lines. The anti-proliferative effect of Artesunate in FLT3/ITD expressing cell lines MV4-11 ($IC_{50:}$ 0.05μM) and MOLM-13 ($IC_{50:}$ 0.06μM) was 1100 and 900 fold greater respectively compared to the wild type FLT3 HL-60 cells ($IC_{50:}$56.15μM) under hypoxic conditions. We compared Artesunate with other FLT3 inhibitors that are under investigation, CEP-701 and PKC-412, and found a similar antiproliferative activity with similar $IC_{50.}$ In MV4-11 and MOLM-13 cells, artesunate exposure led to a decrease in S and G2/M phase, down-regulation in the downstream phospho-signaling proteins such as STAT-5, AKT and ERK and also a disruption in the mitochondrial membrane potential. The *in vivo* anti leukemic activity of Artesunate was evaluated using a NOD.Cg-Prkdc^{scid} IL2rg^{tmWjl} /Sz (NSG) mouse bone marrow engraftment model. MV4-11 cells ($2.5x10^4$, cells) transduced with GFP luciferase were injected intravenously into the tail veins of 9 mice. Vehicle (DMSO) or Artesunate (100mg/kg/day once daily) were given intraperitoneally for 14 days, after the engraftment of tumor cells was confirmed using bioluminescent imaging. The control animals had a median survival time of 43 days; whereas the Artesunate treated mice had a median survival of 66 days. After establishing the *in vitro* and *in vivo* cytotoxicity of Artesunate in FLT3/ITD expressing cells, we looked at the combination of Artesunate with AraC, a standard chemotherapeutic agent for AML. We found synergism in our *in vitro* study.
Summary and Conclusions: The encouraging results reported in this study indicate that a clinical study combining Artesunate with AraC in AML patients should be considered.

PHASE I STUDY OF OPB-51602, AN INHIBITOR OF STAT3 PHOSPHORYLATION, IN PATIENTS WITH RELAPSED/REFRACTORY HEMATOLOGICAL MALIGNANCIES

Y Terui[1,*] M Ogura[2], T Uchida[2], F Hayakawa[3], Y Kobayashi[4], M Taniwaki[5], Y Takamatsu[6], T Naoe[7], K Tobinai[4], W Munakata[4], K Kitamura[8], N Usui[9], N Komatsu[10], T Yamauchi[11], A Kageyama[12], K Hatake[1]
[1]Cancer Institute Hospital, JFCR, Tokyo, [2]Nagoya Daini Red Cross Hospital, [3]Nagoya University Hospital, Nagoya, [4]National Cancer Center Hospital, Tokyo, [5]University Hospital, Kyoto Prefectural University of Medicine, Kyoto, [6]Fukuoka University Hospital, Fukuoka, [7]Nagoya Medical Center, Nagoya, [8]University of Tokyo, [9]Jikei University School of Medicine Dai-San Hospital, [10]Juntendo University Juntendo Hospital, Tokyo, [11]Fujii Memorial Research Institute, Otsuka Pharmaceutical Co., Ltd., Otsu, [12]Otsuka Pharmaceutical Co.,Ltd, Tokyo, Japan

Background: STAT3 is constitutively activated in growth signaling pathways of various hematological malignancies, and inhibition of STAT3 in cell lines such as KG-1 and U937 can lead to cell death *in vitro* and *in vivo*. OPB-51602 is an oral STAT3 inhibitor of small molecular compound.
Aims: A multicenter phase I study was conducted to evaluate the safety, pharmacokinetics (PK), pharmacodynamics (PD), and antitumor activity of OPB-51602 in patients (pts) with hematological malignancies.
Methods: OPB-51602 was administered orally once daily, continuously for 4 weeks per cycle until disease progression or unacceptable toxicity to assess the PD effects on STAT3 phosphorylation (pSTAT) in lymph nodes (LNs) and bone marrows (BMs) were conducted. The starting dose was 1 mg/day, and dose escalations to 2, 3, 4, and 6 mg/day were planned. In the first treatment cycle, single and repeated dose PK was assessed on Days 1 to 4 and 28 to 31, respectively. Dose escalation was based on the "3+3" design, maximum tolerated dose (MTD) was defined as the dose with at least 2/6 dose-limiting toxicities (DLTs) in the 1st cycle, and toxicities were graded by NCI-CTC v4.0.
Results: Twenty pts including AML (n=7), FL (n=3), DLBCL (n=5), MM (n=4), and AITL (n=1) were treated at doses of 1 mg/day (n=4), 2 mg/day (n=3), 3 mg/day (n=4), 4 mg/day (n=6), and 6 mg/day (n=3). Median number of treatment cycles for 1, 2, 3, 4, and 6 mg/day was 3.5 (range: 1-8), 2 (1-17), 1 (0-1), 1 (0-7), and 1 (1-2), respectively. Fourteen pts were assessed for pSTAT in LNs and BMs at screening, and 4 pts tested positive for pSTAT. The main toxicities of all grades were nausea (73%), peripheral sensory neuropathy (45%), fatigue/malaise (45%), vomiting (36%) and diarrhea (35%). These toxicities were predominantly of grade 1 or 2. Six mg/day was judged to be the MTD, where DLT of grade 3 lactic acidosis occurred in 1 pts. The recommended dose for OPB-51602 for hematological malignancies was determined to be 4 mg/day. OPB-51602 was rapidly absorbed after both single and repeated doses, with maximum plasma concentrations at a median Tmax between 4.0 and 4.5 hours after the single dosing on Day 1, and between 2.0 and 4.0 hours after repeated dosing. The mean elimination half-lives of repeated doses were between 50.2 and 78.4 hours. AUC24h and Cmax increased dose-dependently following single and multiple dosing across the 1 to 6 mg dose range. No clear response, including pSTAT3 positive pts, was observed, while stable disease was observed in 3 ts.
Summary and Conclusions: The MTD of OPB-51602 was determined to be 6 mg/day. Long-term administration of OPB-51602 at higher doses was difficult with this daily dosing schedule and there was no responder. Therefore, further clinical development of OPB-51602 in hematological malignancies with this schedule was to be terminated.

P186

TREATMENT WITH QUIZARTINIB (AC220) ENABLES A HIGH RATE OF PATIENTS WITH RELAPSED OR REFRACTORY FLT3-ITD(+) ACUTE MYELOID LEUKEMIA TO BE BRIDGED TO HSCT

G Martinelli[1,*] M J Levis[2], A E Perl[3], H Dombret[4], B Steffen[5], P Rousselot[6], E H Estey[7], N P Shah[8], G Gammon[9], D Trone[10], J E Cortes[11]
[1]Seragnoli Institute of Hematology, Bologna University School of Medicine, Bologna, Italy, [2]Department of Oncology, Johns Hopkins University School of Medicine, Baltimore, [3]Division of Hematology/Oncology, University of Pennsylvania, Philadephia, United States, [4]Hematologie Adultes, Hopital Saint-Louis, Paris, France, [5]Dept of Medicine, Hematology/Oncology, Goethe University of Frankfurt, Frankfurt, Germany, [6]Service d'Hematologie et Oncologie, Hopital de Versailles, Le Chesnay, France, [7]Division of Hematology, University of Washington/Fred Hutchinson Cancer Research Center, Seattle, [8]Dept. Medicine, Division of Hematology/Oncology, University of California at San Francisco, San Francisco, [9]Clinical Development, [10]Biostatistics, Ambit Biosciences Corp, San Diego, [11]Department of Leukemia, The University of Texas MD Anderson Cancer Center, Houston, United States

Background: For FLT3-ITD(+) AML patients (pts) who are relapsed or refractory to chemotherapy, allogeneic hematopoietic stem cell transplant (HSCT) offers the best prospect for long-term survival. Pts are unlikely to undergo HSCT unless their blast count can be reduced to an acceptable minimum, ideally below 5% blasts, which defines composite complete response (CRc: CR+CRp+CRi). Quizartinib is an orally active inhibitor of the FLT3 receptor tyrosine kinase being developed for the treatment of AML. We present a new analysis from 212 FLT3-ITD(+) pts who were relapsed or refractory to previous salvage therapy or HSCT and who were then treated with quizartinib across two Phase 2 studies.
Aims: The aims of both studies were to determine the composite complete remission rate (CRc) defined as CR+CRi+CRp and the impact of treatment with quizartinib to enable pts to become eligible for HSCT.
Methods: All pts gave informed consent. In Study A, 136 pts received 90-200 mg/day quizartinib; in Study B, 76 pts were randomized to either 30 mg/day or 60 mg/day. In both studies quizartinib was given orally during continuous 28 day cycles, until relapse, intolerance or proceeding to HSCT.
Results: Median baseline blast count in Study A was 81% and 67% in Study B. Median age in Study A was 50 yrs and 55 yrs in Study B. In Study A, 47 of 136 (35%) pts proceeded to HSCT; of these 26/47 (55%) had achieved a CRc and 18/47 (38%) achieved a PR prior to HSCT. In Study B 28/76 (37%) pts proceeded to HSCT and of these 23/28 (82%) had achieved a CRc and 4/28 (14%) achieved a PR prior to HSCT. In Study A, pts proceeding to HSCT had a median overall survival (OS) of 34.1 weeks and a 1 yr survival rate of 36% compared to an OS of 18.4 weeks and 1 yr survival of 12% for pts not undergoing HSCT. In Study B, pts randomized to 30 mg/day quizartinib and who underwent HSCT had an OS of 31 weeks compared to 19 weeks for pts without HSCT; pts treated with 60 mg/day and who underwent HSCT had an OS of 28.1 weeks compared to 16.3 weeks for pts without HSCT. When both treatment groups in Study B are combined, for all pts who received a HSCT the OS was 28.1 weeks and the OS for pts who did not receive a HSCT the OS was 16.4 weeks. The current follow-up period in Study B is considerably shorter than the follow-up period for Study A and there remain 35 (46%) subjects in Study B alive and censored for overall survival.
Summary and Conclusions: Pts able to receive a HSCT after response to quizartinib have an improved outcome compared to those who did not have a HSCT. The ability of quizartinib to lower the blast count in a high percentage of pts (46% pts in both studies combined achieved a CRc) and bridge these pts to a potentially curative HSCT, together with an acceptable safety profile, represents an important clinical benefit from quizartinib. Updated results with additional follow up from Study B will be available for presentation.

P187

QUIZARTINIB (AC220) IN PATIENTS WITH FLT3-ITD(+) RELAPSED OR REFRACTORY ACUTE MYELOID LEUKEMIA: FINAL RESULTS OF A RANDOMIZED PHASE 2 STUDY

N Russell[1,*] M S Tallman[2], S Goldberg[3], A E Perl[4], JP Marie[5], G Martinelli[6], R A Larson[7], G Schiller[8], D Trone[9], G Gammon[10], M Levis[11], J E Cortes[12]

Seragnoli, University of Bologna, Bologna, Italy, [7]Dept Oncology/Hematology, University of Chicago, Chicago, [8]Dept Hematology/Oncology, UCLA School of Medicine, Los Angeles, [9]Biostatistics, [10]Clinical Development, Ambit Biosciences Corp, San Diego, [11]Sidney Kimmel Cancer Center, Johns Hopkins University, Baltimore, [12]Department of Leukemia, MD Anderson Cancer Center, Houston, United States

Background: The presence of FLT3-internal tandem duplication (ITD) in patients (pts) with acute myeloid leukemia (AML) is associated with early relapse and poor survival. Quizartinib (AC220) is an orally active inhibitor of the FLT3 receptor tyrosine kinase being developed for the treatment of pts with FLT3-ITD(+) AML. A previous Phase 2 study showed a high level of activity at doses of 90 to 200 mg daily. This randomized, open-label, study was conducted to assess the safety and efficacy of two lower doses of quizartinib in FLT3-ITD+ pts, aged 18 years or older, with relapsed or refractory AML after either one-second line therapy or HSCT.
Aims: The aim of the study was to evaluate the composite complete remission rate (CRc) at different doses of quizartinib and the rate of Grade 2 or higher prolongation of QTcF. CRc was defined as CR+CRi+CRp.
Methods: All pts gave informed consent and were randomized to quizartinib 30 mg/day (Group A) or 60 mg/day (Group B) given orally during 28-day continuous treatment cycles, until relapse, intolerance or proceeding to HSCT.
Results: Seventy six pts were randomized equally to the two arms. Demographics and baseline characteristics were balanced between the two arms except for age over 60 years (42% Group A, 26% Group B) and the percentage with secondary AML (8% Group A, 18% Group B). The analysis included a minimum of 8 weeks of follow-up. The median baseline blast count was 67%. The median duration of treatment in Group A was 10.9 weeks (range 2.1 to 24.9+ weeks) and 11.0 weeks (range 2.6 to 26 weeks) in Group B. The CRc (CR+CRp+CRi) rate in both groups was 47% and the overall response rate (CRc+partial response (PR)) was 61% in Group A and 71% in Group B. Median time to CRc was 4.4 weeks (95%CI: 4.1 – 7.7 weeks) in Group A and 4.6 weeks (95% CI: 4.1 – 8.0 weeks) in Group B. The median duration of CRc in Group A was 4.1 weeks with 28% of subjects who achieved a CRc censored for undergoing HSCT and 20.0 weeks in Group B with 50% of subjects who achieved a CRc censored for undergoing HSCT. 32% of pts in Group A and 42% in Group B were able to receive a HSCT, mostly after achieving CRc (82%) or PR (14%). The median overall survival was 20.7 weeks in Group A; and 25.4 weeks in Group B with 35 of the 76 patients alive at last follow-up (range: 7.4 – 40.4+ weeks). Of the 35 (46%) subjects who remain alive, 24 subjects were alive >24 weeks and 2 subjects were alive >36 weeks. Grade 2 or greater QTcF prolongation occurred in 11% Group A pts and in 17% Group B pts; overall, 4% of subjects had Grade 3 QTcF prolongation. The most common treatment related adverse events occurring in 15% or more pts were diarrhea (18%), febrile neutropenia (16%), and QT prolongation (15%).
Summary and Conclusions: Quizartinib in second salvage or post HSCT FLT3-ITD+ AML demonstrated a high degree of efficacy (CRc 47%) with an acceptable safety profile, specifically decreased QTcF prolongation rates compared to higher doses used previously. Further analysis with additional follow-up will be available for presentation.

P188

BUPARLISIB, A PI3K INHIBITOR, DEMONSTRATES ACCEPTABLE TOLERABILITY AND PRELIMINARY ACTIVITY IN A PHASE I/II TRIAL OF PATIENTS WITH ADVANCED LEUKEMIAS

N Daver[1,*] H Kantarjian[1], L DeBose[1], E Jabbour[1], G Borthakur[1], N Pemmaraju[1], G Garcia - Manero[1], S Kornblau[1], W Wierda[1], J Burger[1], C DiNardo[1], F Ravandi[1], J Cortes[1], M Andreeff[1], M Konopleva[1]
[1]Leukemia, The University of Texas MD Anderson Cancer Center, Houston, United States

Background: Phosphatidylinositol-3-kinase (PI3K) signaling plays a crucial role in oncogene-mediated tumor growth and proliferation. In many tumors, the PI3K signaling pathway is constitutively activated. Buparlisib (BKM120) is an oral pan-class I PI3K inhibitor belonging to the 2,6-dimorpholino pyrimidine derivative family.
Aims: This phase I/II study was conducted to determine the dose limiting toxicity (DLT) and maximum tolerated dose (MTD) of buparlisib in patients (pts) with acute leukemias.
Methods: Pts with acute myelogenous leukemia (AML), acute lymphoblastic leukemia (ALL) or mixed phenotype acute leukemia (MPAL); relapsed/refractory to standard chemotherapy or unsuitable for standard chemotherapy were eligible. Pts with ECOG performance, status 0–2 with adequate organ function and no active,, uncontrolled intercurrent illness or infection, received oral buparlisib continuously daily in 28-day cycles. The starting dose was 80 mg/day. Western blot analysis was performed to evaluate the depth of PI3K/Akt/mTOR inhibition.
Results: Eleven pts received at least 1 dose of buparlisib (10 AML, 1 MPAL) and were included in this analysis. The median (med) age was 70 years (range, 32-85). All pts had received prior therapy. The med number of prior therapies was 4 (range 1–6): hypomethylating agents (n=13), fludarabine (n=6), clofarabine (n=5), cladribine (n=2), and allogeneic stem cell transplant (n=2); either alone or in combination. Cytogenetics analysis showed diploid karyotype in 4 (36%), complex cytogenetics including chromosome 5 and/or 7 abnormalities in 3 (27%), and other cytogenetic aberrations in 4 (36%) pts. Molecular analysis showed *IDH 1/2* mutations in 2, *K-RAS, NRAS, DNMT3A, NPM1, KIT* and *FGFR1* mutation in 1 pt each, respectively. Nine pts received buparlisib 80 mg/day; six of these pts were evaluable for toxicity and DLT (Gr 2 confusion) was seen in 1 pt. Per protocol the dose was escalated to 100 mg/day. Two pts received 100 mg/day: both pts experienced DLTs in the form of Gr 2 and Gr 3 confusion, respectively. The MTD was established as 80mg/day. Med number of cycles received was 1 (range 1–3) and the most common cause of discontinuation was progressive disease (n=7). Of the 11 pts treated, 1 had stable disease at the 80mg/day dosage. The response lasted 80 days. Med overall survival was 51 days (range 11–260). Other drug-related toxicities ≥grade 2 included Gr 3 mucositis (n=1), Gr 2 dysphagia (n=1), Gr 2 fatigue (n=2), Gr 2 elevated serum bilirubin (n=1) and Gr 2 nausea (n=1). On Western blot profiling, a decrease in p-pS6K/total pS6K was observed in 5/7 (71%) samples with a mean quantitative inhibition of 65% (range 32–100%). Similarly, a decrease in p-FOXO3/total FOXO3 was observed in 4/6 (67%) samples with a mean quantitative inhibition of 93% (range 89 –100%. The pt with stable disease had decreases in both p-pS6K/total PS6K (45%) and p-FOXO3/total FOXO3 (100%).
Summary and Conclusions: Buparlisib administered at 80 mg/day showed modest efficacy and was tolerable in pts with previously treated acute leukemias. Additional studies of buparlisib; either alone or in combination are warranted.

P189

CHARACTERIZATION OF GLOBAL HYDROXYMETHYLATION LEVELS IN AML

Ll Kroeze[1], M G Aslanyan[1], A van Rooij[2], T N Koorenhof-Scheele[1], M Massop[1], T Carell[3], J B Boezeman[1], JP Marie[4], C J Halkes[5], T de Witte[6], G Huls[7], S Suciu[8], R A Wevers[2], B A van der Reijden[1], J H Jansen[1,*]
[1]Laboratory of Hematology, [2]Laboratory for Genetic, Endocrine and Metabolic Diseases, Radboud university medical center, Nijmegen, Netherlands, [3]Department of Chemistry, CIPSM, Ludwig-Maximilians-University, Munich, Germany, [4]Department Hematology and Tumor Bank, Saint-Antoine Hospital, Paris, France, [5]Department of Hematology, Leiden University Medical Center, Leiden, [6]Department of Tumor Immunology, [7]Department of Hematology, Radboud university medical center, Nijmegen, Netherlands, [8]EORTC Headquarters, Brussels, Belgium

Background: Patients with acute myeloid leukemia (AML) frequently harbor mutations in genes involved in the DNA (hydroxy)methylation pathway, namely *DNMT3A*, *TET2*, *IDH1* and *IDH2*. DNMT3A is responsible for *de novo* DNA methylation, whereas TET proteins are able to initiate DNA demethylation by converting 5-methylcytosine (5mC) into 5-hydroxymethylcytosine (5hmC). One of the essential co-substrates for the TET proteins, α-ketoglutarate, is produced by IDH proteins. Altered DNA methylation is frequently observed in leukemia, however less is known about hydroxymethylation levels.
Aims: Measure global (hydroxy)methylation levels in AML patients, and correlate these levels with mutational status and overall survival.
Methods: DNA samples from 206 clinically and molecularly well-characterized younger adult AML patients (≤60 years) included in the EORTC/GIMEMA AML-12 06991 clinical trial were analyzed for mutations in *DNMT3A*, *TET2*, *IDH1*, *IDH2*, *FLT3* and *NPM1*, and for *CBFB-MYH11*, *BCR-ABL1*, *AML1-ETO* and *MLL* translocations. Global 5-(hydroxy)methylcytosine levels were measured using HPLC-MS/MS.
Results: A wide range of 5hmC levels was detected in AML patients (15 fold difference), whereas 5hmC levels in healthy control cells were confined to a narrow range (1.5 fold difference). In remission, 5hmC values were normalized to levels comparable to healthy bone marrow and peripheral blood, indicating that the aberrant 5hmC levels at diagnosis are intrinsic to the leukemic cells. Patients with mutations in *TET2* or *IDH1/2* had significantly lower levels of 5hmC compared to patients without mutated *TET2* and *IDH1/2* (both $P<.001$), whereas mutations in *DNMT3A* did not influence global 5hmC levels. Interestingly, high 5hmC correlated with poor overall survival (P=.047, HR=1.81). *AML1-ETO* and *MLL* translocations were frequently present in patients with high 5hmC levels.

Summary and Conclusions: High levels of 5hmC independently correlated with inferior overall survival in AML.

P190

FRONTLINE TREATMENT WITH INTENSIVE CHEMOTHERAPY, AZACITIDINE OR BEST SUPPORTIVE CARE IN OLDER PATIENTS WITH ACUTE MYELOID LEUKEMIA: A POPULATION-BASED ANALYSIS FROM A REGIONAL HEALTHCARE NETWORK

P Bories[1,2,*] S Bertoli[1], E Bérard[3], J Laurent[3], E Duchayne[4], A Sarry[1], E Delabesse[4], O Beyne-Rauzy[5], F Huguet[1], C Récher[1]
[1]Hématologie, CHU Toulouse, Toulouse, [2]Hématologie, CHU Strasbourg, Strasbourg, [3]Epidémiologie, [4]Laboratoire d'Hématologie, [5]Service de médecine interne, CHU Toulouse, Toulouse, France

Background: The efficacy of conventional treatments in older patients (pts) with acute myeloid leukemia (AML) remains unsatisfactory, with low remission rates and poor overall survival. Few pts above 60 years (yrs) really benefit from intensive chemotherapy (ICT). Azacitidine (AZA) has been recently approved for AML pts with 20-30% bone marrow (BM) blasts but little is known in pts with more than 30% BM blasts.
Aims: Taking advantage of our regional healthcare network, the first aim of this study was to describe the distribution of treatments, prognostic factors and outcome of all newly diagnosed non-M3 AML pts aged 60 years or older, selected in daily practice for ICT, AZA or best supportive care (BSC) over a 4-year period of time (2007-2010). The second aim was to compare the survival of pts treated with AZA *vs* respectively ICT and BSC using time-dependent analysis (Royston and Parmar model) and propensity score matching.
Results: Among the 385 AML pts aged 60 y or more, diagnosed between 2007 and 2010, 51 were excluded from the analysis because of early death (ED) occurring before therapeutic decision in 20 pts and missing information in 31 pts. Thus, 334 pts were evaluable (86.7%), including 115 pts treated with ICT (34.4%), 95 pts treated with AZA (28.4%), and 124 pts treated with BSC (37.1%). Median follow-up was 35 months. Overall median age was 75 yrs (ICT, 68 yrs; AZA, 76 yrs and BSC, 80.5 yrs; p<0.001). Twenty percent of the entire population had prior history of myelodysplastic syndrome (ICT 6.7%, AZA 29.5%, and BSC 25%; p<0.01 for AZA *vs.* ICT and p=0.017 for AZA *vs.* BSC), median WBC was 4.25 G/L (ICT 9.5 G/L, AZA 2.3 G/L and BSC 5.3 G/L, p<0.001) and cytogenetics (CG) were adverse in 28.4% (ICT 17.4%, AZA 45.3% and BSC 25.8%, p<0.001 for AZA *vs.* ICT and p=1 for AZA *vs.* BSC). ED (occurring within two months after diagnosis) was observed in 92 pts (27.5%) including 18 pts treated with ICT (15.7%), 11 pts in AZA group (11.6%) and 60 pts in BSC group (48.4%) (CTI *vs* AZA p=0,39; AZA *vs* BSC p<0.0001). We identified 56 pts in the AZA arm (59%) requiring hospitalization for infection (median number of hospitalization per patient, 1; range 1 to 7). Overall response (CR+CRi) was documented in 78 pts treated with ICT (67.8%), and in 18 pts treated with AZA (18.9%). Additionaly 6 pts treated with AZA have obtained PR and 24 pts (25.3%) with stable disease were classified as major hematological improvement on at least one lineage according to MDS response criteria. Median overall survival (OS) in ICT, AZA and BSC were of 18.9, 11.3 and 1.8 months, respectively. In pts treated with AZA, OS was negatively impacted in multivariate analysis by higher age (95% Confidence Interval, 1.01-1.10, HR 1.05 for one year increase, p=0.010), adverse CG (95% CI, 1.44-4.49, HR 2.55, p=0.001), lymphocyte count <0.5 G/L at diagnosis (95% CI, 1.19-5.26, HR 2.5, p=0.015) and higher LDH level (95% CI, 1.0002-1.0012, HR 1.0007 for one unit increase, p=0.005). We compared the survival of pts treated by AZA *vs* ICT and BSC using time-dependent analysis and propensity score matching (calculated on age, AML *de novo* or secondary status, BM blasts, platelets count and CG for ICT *vs* AZA and on age and WBC for AZA *vs* BSC comparison). Pts treated by ICT had a better overall survival compared to those treated with AZA from 6 months after diagnosis, whereas pts treated with AZA had a better overall survival compared to those treated with BSC from 1 day after diagnosis.
Summary and Conclusions: This study of "real life" practice shows that there is a room for low intensive therapies such as AZA in selected elderly AML patients.

P191

INCIDENCE AND MANAGEMENT OF VENOUS THROMBOSIS IN ACUTE LEUKEMIA: A MULTICENTER STUDY

M Napolitano[1,*] L Valore[1], G Saccullo[1], A Malato[2], C Vetro[3], ME Mitra[1], A Lucchesi[4], F Fabbiano[2], D Mannina[5], A Casuccio[6], A Candoni[7], F Di Raimondo[3], V De Stefano[8], S Siragusa[1]
[1]Hematology Unit, University of Palermo, [2]Hematology Unit, Ospedale "Cervello", Palermo, [3]Hematology Unit, Univeristy of Catania, Catania, [4]Hematology Unit, Istituto Scientifico Romagnolo per lo studio e la cura dei tumori, Meldola, [5]Hematology Unit, "Papardo" General Hospital, Messina, [6]Epidemiology and Statistics, University of Palermo, Palermo, [7]Hematology Unit, Ospedale " S. Maria della Misericordia ", Udine, [8]Hematology Unit, Università Cattolica, Roma, Italy

Background: Venous thrombosis (VT) frequently complicates the clinical course of cancer. Available data on the incidence and management of VT in Acute Leukemia (AL) are scanty and quite discordant.
Aims: We have performed a multicenter study with the primary objective to evaluate the incidence of venous thrombotic complications in a population of patients with AL. Secondary objective was to evaluate the management of these complications in patients with AL.
Methods: Available clinical records of out and in-patients diagnosed with AL from January 2008 to June 2013 in 7 Regional Reference Hospitals were analyzed. Cases of venous thrombosis (VT), including thrombosis in atypical sites [Retinal occlusion (RO) and Cerebral Sinus Thrombosis (CST)], were reported. Available laboratory tests at diagnosis of VT included complete blood cells count (CBC), basal coagulation tests (PT, aPTT, fibrinogen), Antithrombin, anticoagulant Protein S and C and D-dimer. Instrumental diagnosis of deep vein thrombosis (DVT), pulmonary embolism (PE) and RO and CST was performed according to ACCP guidelines. In the statistical analysis, logistic regression model was applied. Fisher's exact test was used to determine relationships between categorical variables.
Results: Over a population of 1487 patients with AL, 97 cases of VT were recorded: 71 cases were associated with Acute Myeloid Leukemia (AML) and 26 with Acute Lymphoblastic Leukemia (ALL). Fifty-four patients were males and 43 females (4 with AML, 10 with ALL), with a mean age of 52±15,5 years; Twenty-four patients presented at least a concomitant chronic disease,12 were receiving anticoagulant prophylactic treatment with low molecular weight heparin (LMWH). There were 72 cases of DVT of upper arms, 16 cases of proximal DVT of limbs (two complicated with PE), 4 cases of PE, 2 cases of RO, 2 of CST and 1 intracardiac clot. In 76/97 (78,6%) cases of VT, a central venous catheter (CVC) was placed; moreover, 68/72 DVT of upper arms were significantly associated with a CVC insertion (p<0.01).VT occurred during chemotherapy (CHT) in 88/97 (90.7%) cases,9 cases were diagnosed in concomitance with AL. In both subgroups with VT,there was no statistical significant difference between time at diagnosis of VT and time at diagnosis of AL. At CBC, thrombocytopenia was the most frequent abnormality. Severe thrombocytopenia (PLT<30000/mmc) was recorded in 25 cases. Coagulation tests were normal in all cases. Prothrombotic mutations were available only for 19/97 cases, 1 case was heterozygous for Factor V Leiden and 1 was homozygous for Factor II (G20210A) mutation. Most VT (83/97) were treated with LMWH at therapeutic doses for the first month witha dose reduction in the following months, for severe thrombocytopenia after CHT; 1 case was treated with unfractioned heparin, 1 case with warfarin; 6 cases did not receive treatment due to severe thrombocytopenia. No cases of VT–related deaths nor fatal complications during treatment were recorded. Three cases of mild bleeding were reported.Treatments with LMWH lasted from 3 to 6 months. All patients clinically recovered from VT, only 2 late recurrences (PEs) were observed.
Summary and Conclusions: The incidence (6.6%) of VT in the analyzed cohort of patients with AL is almost similar to previous reports.. Atypical sites VT must be suspected to be correctly diagnosed and treated. Anticoagulant treatment schedules and duration in patients with VT and AL seems safe and effective, even if it is influenced by many factors, mainly related to CHT and severe thrombocytopenia. The optimal management of VT in patients with AL requires further, prospective studies

tario Príncipe de Asturias, Madrid, [24]Hematology, Hospital de la Santa Creu i Sant Pau, Barcelona, [25]Universidad de Navarra, Pamplona, [26]Universidad del País Vasco, Bilbao, Spain, [27]Bath Cancer Research, Bath, United Kingdom, [28]Vivia Biotech, Madrid, Spain, [29]Hematology, Vivia Biotech, [30]Medicxact, Madrid, Spain

Background: Complete remission (CR) after induction therapy is the first treatment goal in acute myeloid leukemia (AML) patients.
Aims: To determine the ability of the Vivia's novel *ex vivo* drug sensitivity platform Exvitech to predict the CR rates after induction chemotherapy with cytarabine (Ara-C) and idarubicin (Ida) in 1st line AML.
Methods: This non-interventional and prospective study included samples from adult patients diagnosed with *de novo* AML in Spanish centers from the PETHEMA group. Marrow samples were sent to Vivia laboratories and incubated for 48h in whole samples in well plates containing Ara-C, Ida, or their combination, each at 8 different concentrations. Depletion of leukemic cells was quantified by subtracting live cells in each well with drugs from the control wells without drugs. Pharmacological responses are calculated using pharmacokinetic population models. Induction response was assessed according to the Cheson criteria (2003). Patients attaining a CR/CRi were classified as responders and the remaining as resistant. Patients dying during induction response assessment were non-evaluable. The correlation was modeled using a generalized additive model with a logit link and a binomial distribution for residuals. Kernel density estimates were then used to plot empirical probability density functions for both groups. Their separation was quantified as the area under the ROC curve and a cut point was selected using the Youden's criteria to optimize the classification probabilities (sensitivity, specificity). 95% confidence intervals for sampling errors were calculated for all these quantifiers.
Results: 180 patient samples were used to calculate the dose response (DR) curves for Ara-C alone, Ida alone, and their synergism. For clinical correlation we used 77 patients with a median age of 55 years (range 31 to 73). DR for Ara-C alone are shown in Figure 1A; note that for many samples there is a significant number (>20%) of resistant cells to Ara-C (bracket). This is a strong clinical predictor of resistance because in the patient the drug will never be present at these high doses for 48h. The second variable that is a good predictor of response is the synergism between these 2 drugs. The generalized additive model identified an algebraic combination of these 2 variables that yielded the best marker to separate both groups of patients. The probability density functions had minimal overlap. The area under the corresponding ROC curve was 0.935 (0.872, 0.997), and the classification probabilities for the optimal cut point, were 87% (68% to 95%) and 91% (80% to 96%) for sensitivity and specificity, respectively. Results are shown in Figure 1B; 54 patients (70.1%) achieved CR after Ida+Ara-C, and the remaining 23 (29.9%) were resistant. Correlations of the PM test are shown in Figure 1B. 20 of the 23 (86.9%) patients who fail to achieve CR were predicted as resistance in the *ex vivo* test. 49 of the 54 patients (90.74%) who achieved CR showed good *ex vivo* sensitivity to Ida+Ara-C predicting for CR. When the *ex vivo* test predicted a patient as sensitive it was correct in 49/52 cases (94.23%), and when it predicted resistant it was correct 20/25 cases (80%). Overall, 69/77 patients (89.61%) had an accurate prediction of their response to treatment.

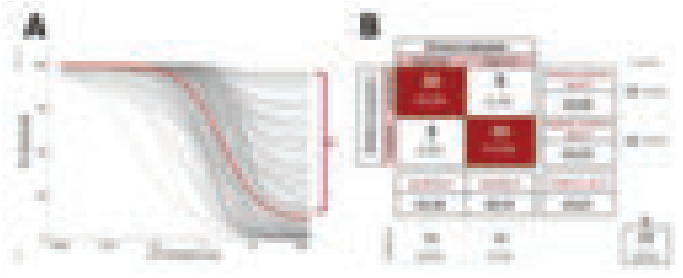

Figure 1. A) Dose response curves for Ara-C on 180 samples from AML patients in terms of the % survival of leukemic cells show the pharmacological profile of this drug. Note the 40% of samples with submaximal efficacy (bracket). B) Correlation with clinical outcome of the *ex vivo* pharmacological profiles in terms of sensitive *vs* resistant patients.

Summary and Conclusions: This study shows that this novel *ex vivo* pharmacological profile test is able to predict the clinical response to Ida+Ara-C induction. We are increasing the number of patients in this ongoing study, and we are planning a PM Test-adapted Clinical Trial.

Chronic lymphocytic leukemia and related disorders - Biology 1

RUXOLITINIB INDUCES APOPTOSIS OF B-CELL RECEPTOR STIMULATED CHRONIC LYMPHOCYTIC LEUKEMIA (CLL) CELLS

U Rozovski[1,*] J Yuan Wu[1], D Harris[1], Z Liu[1], P Li[1], I Hazan-Halevi[1], A Ferrajoli[1], J Burger[1], S O'brien[1], W Wierda[1], M Keating[1], Z Estrov[1]
[1]Leukemia, MD Anderson Cancer Center, Houston, United States

Background: Stimulation of the B-cell receptor (BCR) protects chronic lymphocytic leukemia (CLL) cells from apoptosis and induces their proliferation. It is assumed that when CLL cells reside in the lymph-nodes extracellular signals activates the BCR and provides them with survival advantage. Whether the JAK-2/STAT3 pathway, known to elicit similar effects in various hematological and solid tumors is engaged in this process is unknown.
Aims: 1) Determine whether stimulation of the BCR induces JAK-2/STAT3 mediated tyrosine pSTAT3 and protects CLL cells from apoptosis. 2) Determine whether the JAK1/2 inhibitor ruxolitinib inhibits this pathway in CLL cells
Methods: CLL cells, fractionated from the peripheral blood of 19 previously untreated patients were used in the different experiments performed in this study. Anti-IgM antibodies were used to stimulate the BCR, and stimulated or unstimulated cells were treated with the JAK1/2 inhibitor, ruxolitinib, the bcr-abl/lyn inhibitor, dasatinib or with U0126, a MAPK signaling pathway inhibitor. The protein levels of STAT3 and tyrosine pSTAT3 were assessed by western immunobloting, and for immunopercipitation studies we used JAK2, pJAK2, STAT3 and pSTAT3 antibodies. Nuclear and cytoplasmatic extracts were prepared and the purity was confirmed by the absence of lamin B in the cytoplasmic extract and the absence of ribosomal S6 from the nuclear extracts. Localization of pSTAT3 to the nuclear and cytoplasmic extracts was confirmed by confocal microscopy. Apoptosis was assessed by Annexin V/PI, and levels of STAT3 target genes by real time PCR (RT-PCR) and quantitative reverse-transcription PCR (qRT-PCR).
Results: Tyrosine pSTAT3 was not detected in unstimulated CLL cells. Stimulation of the CLL-BCR using anti-IgM antibodies induced tyrosine phosphorylation of STAT3, which was transient. STAT3 remained phosphorylated for 48 h in the presence of anti-IgM antibodies. However, 2 h after anti-IgM antibodies were washed out of the culture media we could no longer detect tyrosine pSTAT3. When the BCR was stimulated, tyrosine pSTAT3 was found in the cytoplasmic and nuclear extracts. Confocal microscopy confirmed that following BCR stimulation tyrosine pSTAT3 was localized to the nucleus. By RT-PCR and qRT-PCR we show that following stimulation of the BCR and localization of tyrosine pSTAT3 in the nucleus, STAT3-regulated genes are upregulated, suggesting that BCR mediated induction of tyrosine pSTAT3 is biologically active and induce transcription. Immunopercipitation studies revealed that pJAK2 and tyrosine pSTAT3 co-immunopercipitated suggesting that STAT3 phosphorylation occurs through the JAK-2/STAT3 pathway. Because tyrosine pSTAT3 protects CLL from apoptosis we hypothesized that ruxolitinib, a JAK1/2 inhibitor, would prevent phosphorylation of STAT3 and induce apoptosis of BCR-stimulated CLL cells. Ruxolitinib, but not dasatinib or U0126 inhibited tyrosine phosphorylation of STAT3 in a time and dose dependent manner. Likewise, ruxolitinib, but not dasatinib or U0126 induced apoptosis of BCR-stimulated CLL cells.
Summary and Conclusions: Our findings suggest that stimulation of the BCR activates the JAK-2/STAT3 pathway and induces transient phosphorylation of STAT3. Ruxolitinib inhibited the phosphorylation of STAT3 and induced apoptosis of CLL cells. Whether treatment with ruxolitinib would benefit patients with CLL remains to be determined.

VARIABLE REACTIVE OXYGEN SPECIES LEVELS ARE ASSOCIATED WITH ANERGY IN CLL

A Linley[1,*] S Krysov[1], V Coelho[2], F Forconi[1], F Stevenson[1], A Steele[1], G Packham[1]
[1]Cancer Sciences Unit, University of Southampton, Southampton, [2]Cancer Institute, UCL, London, United Kingdom

Background: Reactive oxygen species (ROS) are important regulators of cell signalling, replication and survival, and are essential for normal cell physiology. If uncontrolled however, ROS are associated with cell damage and implicated in therapy resistance. Previous studies have demonstrated that chronic lymphocytic leukaemia (CLL) cells contain variable levels of ROS which are, on average, higher than normal B cells. However, the relationship between ROS levels and disease subsets has not been examined.
Aims: We have sougt to investigate potential associations between ROS levels, *IGHV* mutation status and the extent of B-cell receptor (BCR) anergy, an important determinant of clinical behaviour.
Methods: Examine intracellular ROS levels in primary CLL cells stained with CM-H_2DCFDA using FACS.
Protein expression analysis of pErk-1/2 and p-Akt in cells treated with N-acetyl

cysteine (NAC) or left untreated prior to stimulation with immoblised anti-IgM and IgD. Examine surface expression of the migration molecule CXCR4 using FACS. Transwell migration assays to dertermine effect of NAC on CLL migration to the chemokines CXCL12 and CXCL13. Protein expression analysis of p-Erk-1/2 and p-Akt in cells pre-treated with NAC or left untreated prior to stimulation with CXCL12 or CXCL13.
Results: Flow cytometry analysis of unstimulated primary CLL cells demonstrated that ROS levels differed substantially between samples. Overall, ROS levels were higher in M-CLL compared to U-CLL (*P*=0.003). ROS levels were also higher in samples that had strong features of anergy, including down-modulation of surface IgM (sIgM) expression (*P*=0.003) and signalling capacity (*P*=0.001). Some patients also demonstrated intraclonal variation in ROS production. This was observed in both M-CLL and U-CLL, but somewhat more frequent in U-CLL. Analysis of these 'sub-populations' found that ROS levels were inversely proportional to CXCR4 expression, which is down-modulated in the tissues and therefore marks the most recent emigrees into the blood. Further studies demonstrated that the antioxidant N-acetyl cysteine decreased anti-IgM signalling responses, and CXCL12 or CXCL13-induced migration, implying functional roles for ROS in CLL signal transduction.
Summary and Conclusions: Overall, these results indicate that increased ROS is a consequence of antigen engagement in CLL, potentially linked to the extent of anergy.

P195

HIGH LEVEL OF COBLL1, A NOVEL ROR1 BINDING PARTNER, IDENTIFIES CHRONIC LYMPHOCYTIC LEUKEMIA (CLL) PATIENTS WITH MUTATED IGHV

H Plesingerova[1,2,*] P Janovska[3], A Shaik[3], L Poppova[1,2], A Libra[4], K Plevova[1,2,3], J Machac[5], I Slapak[5], S Pavlova[1,2,3], S Pospisilova[1,2], V Bryja[3,6]
[1]Molecular medicine, Central European Institute of Technology, [2]Centre of Molecular Biology and Gene Therapy, Department of Internal Medicine - Hematology and Oncology, University Hospital Brno, [3]Institute of Experimental Biology, Faculty of Science, Masaryk University, Brno, [4]Generi Biotech, s.r.o., Hradec Kralove, [5]Clinic of Pediatric Ear, Nose and Throat Diseases, University Hospital Brno, Faculty of Medicine, Masaryk University, [6]Department of Cytokinetics, Institute of Biophysics, Academy of Sciences of the Czech Republic, Brno, Czech Republic

Background: Chronic lymphocytic leukemia (CLL) is a disorder with a variable clinical course and up-regulated expression of a transmembrane tyrosine-protein kinase (ROR1), a member of Wnt – planar cell polarity (PCP) pathway. This pathway has an important role in the early embryonic development and controls pathogenesis of CLL via regulation of cell migration and chemotaxis.
Aims: The main aim of the study was (i) to identify ROR1 downstream signalling by the proteomic analysis of ROR1 binding proteins in CLL and (ii) to analyse the role and clinical value of selected binding partners.
Methods: The search for ROR1 binding partners was performed using mass spectrometry. For expression analysis, a cohort of 186 unselected CLL patients was tested. B-lymphocytes were separated from peripheral blood using gradient centrifugation with non-B-cell depletion. mRNA expression was examined by qRT-PCR. The protein expression was further tested using Western Blot. B-cells from healthy tonsills (n=4) were fasc-sorted via IgD and CD38 staining into naïve, germinal centre and memory B-cells, which were tested by qRT-PCR. Expression vectors containing COBLL1 and ROR1 were transfected into HEK293 cells to visualize their localization.
Results: We identified a novel Ror1 binding partner in CLL cells – cordon blue protein like 1 (COBLL1). In HEK293 cells, COBLL1 was localized mainly in cytoplasm but following ROR1 overexpression both proteins were strongly co-localized in the membrane filopodia. In CLL patients COBLL1 showed variable expression with significantly higher expression in the patients with mutated IGHV (n=70) compared to the patients with unmutated IGHV (n=116; p<0.0001, Mann-Whitney U test). Accordingly, the patients with COBLL1 expression above defined threshold had longer treatment-free survival (48 months) compared to the patients with expression bellow this threshold (32 months; p=0.0004, Mantel-Cox test). Also, the expression of COBLL1 decreased with disease severity according to the cytogenetic hierarchical model (del 13q, normal karyotype *vs.* del 17p, del 11q; p<0.03, Mann-Whitney U test). The difference in COBLL1 expression between the patients with mutated and unmutated IGHV was also confirmed at a protein level (n=10). Median expression in the patients with mutated IGHV was similar to the expression in healthy germinal centre B-cells, whereas median expression in the patients with unmutated IGHV corresponded to the expression in healthy naïve and memory B-cells.
Summary and Conclusions: We identified COBLL1 as a novel ROR1 interaction partner. COBLL1 expression in CLL cells correlates with patient's prognosis. Different expression in healthy tonsillar subpopulations suggests its physiological role in germinal centre transition.

Background: The development and progression of Chronic Lymphocytic Leukemia (CLL) is dependent upon a complex microenvironmental network of cellular and molecular signals. As an example, the *in vitro* survival of CLL cells is supported by nurse-like cells, which have been identified as a CLL-specific tumor-associated macrophage (TAM) population. However little is known regarding the role of TAMs in CLL development and progression.
Aims: Aim of this study is to investigate to what extent and through which molecular mechanisms the interaction between CLL cells and TAMs influence the leukemic growth *in vivo* and, finally, to explore this cellular interaction for therapeutic purposes.
Methods: For *in vivo* studies we took advantage of different CLL mouse systems: i) the Eμ-TCL1 mouse model; the xenograft model we developed, based on the engraftment of MEC1 CLL human cell line into Rag2$^{-/-}$γc$^{-/-}$ mice which recapitulates the distribution of aggressive human CLL. To characterize the molecular repertoire of CLL infiltrating TAMs, a whole genome transcriptional profile analysis was performed, by using the Illumina direct hybridization system, directly on TAMs and leukemic cells purified from the bone marrow (BM) of Rag2$^{-/-}$γc$^{-/-}$, xeno-transplanted mice. We exploited a liposome-mediated macrophage killing approach, based on the liposome mediated internalization of clodronate (clodrolip) in macrophages for both *in vivo* and *in vitro* cytotoxicity studies performed in CLL animal systems and primary samples from CLL patients.
Results: We analyzed the whole-genome transcriptome of TAMs and leukemic B cells isolated from the bone marrow of MEC1-bearing mice and found an enrichment of genes involved in inflammation and interaction between TAMs and B cells. To unravel the functional role of TAMs in CLL development and progression, we transplanted Rag2$^{-/-}$γc$^{-/-}$, mice intravenously (i.v.) with MEC1 cells and depleted macrophages by i.v. clodrolip delivery. Macrophage depletion resulted in a drastically reduced accumulation of CLL cells in all tissues. Moreover, when C57BL/6 mice were transplanted with leukemic cells from Eμ-TCL1 transgenic mice and macrophage-depleted, significantly fewer leukemic B cells were detected in the lymphoid tissues analyzed. Interestingly, *in vitro* cytotoxicity studies performed on MEC1 cells as well as on human primary CLL cells proved that clodrolip have no direct toxic effect on leukemic B cells. However when unseparated PBMC of CLL patients were treated with different doses of clodrolip *in vitro*, we observed a marked depletion of both monocytes/macrophages and leukemic cells. Finally, to explore the possibility that manipulating leukemic cell/macrophage interactions might be exploited as a potential novel therapeutic strategy, Rag2$^{-/-}$γc$^{-/-}$ animals transplanted subcutaneously with MEC1 cells and carrying visible leukemic lymph nodes (LN) were injected with clodrolip in the proximity of the LNs. This treatment drastically reduced LN size and favourably impacted on the overall mouse survival.
Summary and Conclusions: In summary all these *in vitro* and *in vivo* observations clearly suggest that the survival and proliferation of CLL cells strongly depend on the support of monocyte/macrophage lineage cells. Our data open up novel therapeutic venues for CLL based on interfering with leukemic cell-macrophage interactions.

HYPOXIA - A CENTRAL MICROENVIRONMENTAL DETERMINANT OF PROLIFERATION AND DRUG-RESISTANCE OF PRIMARY CLL CELLS

M Huelsemann[1], D Baatout[1], L Kintzele[1], H J Becker[1], S Theurich[1], M von Berwelt-Baildon[1], C P Pallasch[1], M Hallek[1], C M Wendtner[1], LP Frenzel, [1,*]

Background: Although common *in vitro* set-ups tried to address the most relevant pro-survival stimuli (*e.g.* CD40L, BCR, IL-4) in CLL in the past, it remains still unknown *e.g.* why ABT-199 eradicates CLL cells from lymph nodes much more efficiently compared to fludarabine. Hypoxia as a general environmental variable is poorly understood so far. It is known that the physiologic oxygen tension in malignant lymph nodes and bone marrow is around 1% O_2. Moreover, we know from solid malignancies that oxygen tension tremendously affect proliferation and drug-response.
Aims: Therefore our aim was to elucidate the impact of hypoxia on physiology and drug-resistance of primary CLL cells.

Methods: We have established an *in vitro* model, which mimics hypoxic conditions in concert with established pro-survival stimuli (CD40L, BCR, CpGs), in order to understand the molecular basis of biology of CLL cells resident in the microenvironment. CLL cells were cultured up to seven days in hypoxia (1% O_2) or normoxia (21% O_2). Hypoxic conditions were validated by overexpression of HIF1α and miRNA-210.
Results: Hypoxia is known to protect malignant cells in solid cancers from chemotherapy. Surprisingly, we made similar observations, since classical DNA-targeting drugs like fludarabine were inefficient to kill CLL cells under hypoxic conditions. However, we identified ABT-737 and ABT-199, which affect mitochondrial integrity, to be even more efficient under hypoxic conditions compared to normoxia. In order to explain this discrepancy we investigated the expression of mitochondrial localized anti-/proapoptotic genes on mRNA and protein level. We show that the de-regulation Mcl-1 under hypoxic conditions is essential for ABT sensitivity. Our data reveal that Mcl-1 is regulated under hypoxic conditions by un-coupled phospho-proteomics. Importantly, genetic and pharmacologic approaches, which target phospho-kinases reverts ABT-sensitivity towards resistance and sensitizes CLL cells towards fludarabine in hypoxia. Moreover, we investigated the impact of hypoxia on proliferation of CLL cells. Surprisingly, our data uncover, that proliferation of primary CLL cells is controlled by BCR signaling, while survival is enhanced by CD40:CD40L interaction under hypoxia.
Summary and Conclusions: Our findings give answers on fundamental clinical observations regarding drug-response, proliferation and survival of CLL cells within the microenvironment. Hypoxic *in vitro* settings seem to reflect existing *in vivo* settings. Further improvement of novel *in vitro* models like ours will help us understand the complex *in vivo* situation.

LENALIDOMIDE INDUCES A PRO-INFLAMMATORY PHENOTYPE IN NURSE-LIKE CELLS DERIVED FROM CHRONIC LYMPHOCYTIC LEUKEMIA

S Fiorcari[1,*] R Maffei[1], S Martinelli[1], J Bulgarelli[1], V Audrito[2], P Zucchini[1], E Zanetti[1], E Colaci[1], L Potenza[1], F Narni[1], S Deaglio[2], M Luppi[1], R Marasca[1]
[1]University of Modena and Reggio Emilia, Modena, [2]University of Turin and HuGef Human Genetics Foundation, Turin, Italy

Background: Lenalidomide is an immunomodulatory agent clinically active in CLL patients. The specific mechanism of action is still undefined, but includes the modulation of microenvironment. In CLL patients, nurse-like cells (NLCs) differentiate from CD14+ mononuclear cells and nurture/protect CLL cells from apoptosis. NLCs resemble M2 macrophages with potent immunosuppressive functions.
Aims: We investigated whether lenalidomide may interfere with the nursing and protective phenotype of NLCs.
Methods: Upon lenalidomide stimulation *in vitro*, actin polymerization, adhesion to HUVEC and migration were evaluated on CD14+ circulating monocytes isolated from CLL patients. NLCs were generated in presence or absence of lenalidomide: cell surface markers, phagocytosis and induction of T cell proliferation were analyzed after 10 days. In some experiments, we used Rho GTPases inhibitors.
Results: CLL-derived CD14+ monocytes showed higher actin polymerization levels after treatment with lenalidomide compared to unstimulated control. F-actin formation increased to 120%, 225% and 268% upon stimulation with lenalidomide 0.5μM, 1μM, 10μM compared to control (100%). The addition of specific GTPases inhibitors (RhoA, Rap1 and Rac1 inhibitors) strongly affected F-actin formation induced by lenalidomide treatment. When CD14+ monocytes were cultured on HUVEC endothelial layer, treatment with lenalidomide strongly stimulated the adhesion from 100% to 238% (±37%) ($p<0.05$). In accordance, lenalidomide increased Akt phosphorylation and ILK (integrin linked kinase) expression in CD14+ monocytes. Lenalidomide-induced adhesion was mediated through Rap1 and Rac1. Moreover, we investigated the ability of CD14+ monocytes to migrate in response to CCL2, CCL3, CXCL12 during stimulation with lenalidomide. Lenalidomide determined a reduction of 24%, 32% and 20% in monocytes migration in response to CCL2, CCL3 and CXCL12 respectively. These impairments were not determined by a reduction in monocytes viability or down-regulation of chemokine receptors, but we found an increased expression of CORO1B and a down-regulation of RhoH ($p<0.05$) as documented by real-time PCR and Western blot. Then, we focused our attention on CLL tissue monocytes, also known as NLCs, which showed a different and particular morphology *in vitro* after treatment with lenalidomide with higher FSC and SSC compared to untreated control. First, treatment with lenalidomide 0.5μM and 1μM increased the number of NLCs to 268% and 309% compared to untreated control respectively ($p<0.05$). At the same time, lenalidomide strongly increased CLL adhesion to NLCs to 227% and 212% with the addition of 0.5μM and 1μM doses (Figure 1A) inducing a strong expression of CD11b and MAC1 on NLCs surface. In this scenario, NLCs did not exert a pro-survival effect on CLL cells, in fact lenalidomide treatment reduced CLL viability in contact with NLCs from 54.2% to 44.5% ($p<0.05$). Of interest, we found that lenalidomide is able to interfere with leukemia-promoting properties of NLCs by increasing their phagocytic activity and improving NLCs-mediated T cell proliferation. In fact stimulation with lenalidomide increased the phagocytic activity of NLCs to 141% and 155% with 0.5μM and 1μM compared to control (100%) ($p<0.05$), and strongly improved theability of T cells to undergo proliferation from 19.5% to 35% (%of dividing cells) ($p<0.05$, Figure.1B).

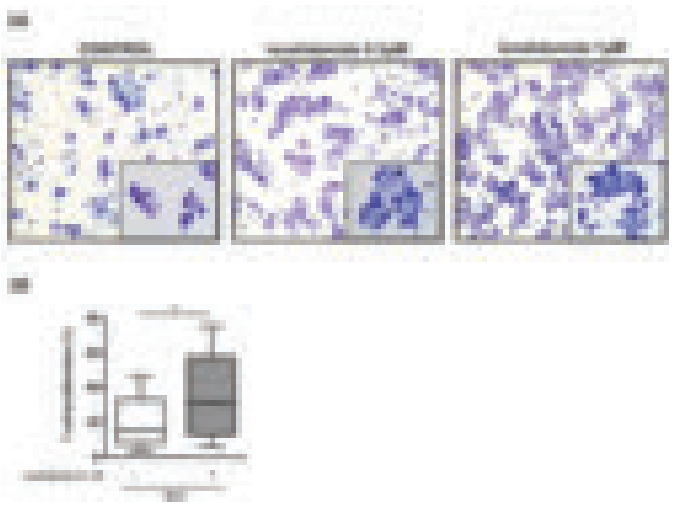

Figure 1.

Summary and Conclusions: Collectively, our data provide new insights into the mechanism of action of lenalidomide that interferes with the supporting and protective microenvironment generated by CLL into tissues.

CLL DERIVED EXOSOMES ENCAPSULATE SPECIFIC MICRORNAS AND INFLUENCE STROMAL CELL BEHAVIOUR

M Farahani[1,*] P Angelillo[1], M Kelly[1], L Liu[2], C Rubbi[1], N Kalakonda[1]
[1]Department of Molecular and Clinical Cancer Medicine, University of liverpool, [2]Department of Plant Sciences, Institute of Integrative Biology, liverpool, United Kingdom

Background: Exosomes, nanometre-sized (40–100 nm) vesicles of endocytic origin, are vehicles of communication between tumour cells and their microenvironment. Exosomes are discrete lipid-bound vesicles that encapsulate cytoplasmic proteins and RNA (including microRNA). Uptake of exosomes results in altered expression of mRNA and proteins in recipient cells. Previous reports have highlighted the importance, and tumour-specific differences in exosomal cargo, in the pathophysiology and behaviour of individual cancers. Given the critical role of microRNAs in Chronic lymphocytic leukemia (CLL), the importance of CLL derived exosomes and their microRNA content in disease biology is not yet established.
Aims: In this study, we investigated secreted exosomes and cells from primary CLL samples for their microRNA content and sought to elucidate their effects on stromal cells.
Results: Having optimised a protocol for purifying exosomes derived from cultured CLL cells and patient plasma, validation of their physical characteristics was performed by Electron microscopy (EM) and Atomic force microscopy (AFM). Verification of the purity and integrity of the exosomes was achieved by flow cytometry and western blotting and further confirmed their derivation from CLL cells. MicroRNA expression profiling was performed on patient cellular RNA and exosomal RNA using Exiqon LNA arrays. qRT-PCR was used to further validate expression of differentially expressed selected microRNAs.. We show that, amongst other microRNAs, miR-202 is specifically enriched in CLL derived exosomes and down regulated in paired CLL cells. Importantly, miR-202 is down regulated in a larger cohort of primary CLL cells, compared to normal B cells, implying a tumour suppressive role. In co-culture experiments, using the normal human stromal cells (HS-5 cell line) and exosomes, and subsequent confocal microscopy we demonstrate uptake and co-localisation of CLL derived exosomes with Lamp-1 (a marker for late endosomes), verifying that the endocytosed exosomes are trafficked to endosomal organelles. Moreover, uptake of CLL exosomes by the stromal cells resulted in increased expression of genes such as c-fos and ATM, while the expression of 'suppressor of fused' (Sufu) (one of the validated targets for miR-202) was decreased. Finally, we show that CLL exosomes derived *in vitro* (culture medium) or *in vivo* (patient plasma) significantly increases cell proliferation in HS-5 compared with exosomes derived from normal plasma.
Summary and Conclusions: Our findings show that CLL derived exosomes indeed harbour unique molecular profiles and are enriched in miR-202. CLL exosomes modulate mRNA and protein expression in recipient stromal cells and alter cellular behaviour. Our study suggests an important role for exo-

somes, and their content, in CLL-microenvironment interactions to influence disease behaviour and outcomes.

DIFFERENT CLL STEREOTYPED SUBSETS, VARYING TELOMERE LENGTHS: A MEASURE OF DISTINCT PROLIFERATIVE HISTORIES LINKED WITH UNIQUE CLINICOBIOLOGICAL FEATURES

T Touloumenidou[1], S Ntoufa[2], L Mansouri[3], N Papakonstantinou, [2,*]LA Sutton[4], M Roumeliotou[5], M Chatzouli[6], A Anagnostopoulos[7], P Panagiotidis[8], C Belessi[6], G Roos[9], R Rosenquist[4], K Stamatopoulos[2]

Papnicolaou Hospital, [2]Institute of Applied Biosciences, CERTH, Thessaloniki, Greece, [3]Department of Immunology, Genetics and Pathology, Science for Life Laboratory, Uppsla University, [4]Department of Immunology, Genetics and Pathology, Science for Life Laboratory, Uppsala University, Uppsala, Sweden, [5]First Propaedeutic Department of Medicine, University of Athens, Athens, [6]Department of Hematology, Nikea General Hospital, Piraeus, [7]Department of Hematology and HCT Unit, G. Papanicolaou Hospital, Thessaloniki, [8]First Department of Propaedeutic Medicine, University of Athens, Athens, Greece, [9]Department of Medical Biosciences, Umea University, Umea, Sweden

Background: Telomeres play a critical role in maintaining genomic integrity and are also implicated in the regulation of cell proliferation and senescence. Indeed, telomere length (TL) reflects the replicative history of individual cells with repetitive rounds of cell division and proliferation leading to telomere erosion at the ends of DNA. In CLL, short telomeres have been associated with unmutated IGHV genes, complex karyotype and inferior outcome, linking extensive replication histories with clinical aggressiveness.
Aims: Given the extreme heterogeneity of CLL, analysis of more homogeneous subgroups would provide an accurate view of TL function and hence its relevance for clonal behavior. Here we investigated TL in a series of 446 patients with CLL, particularly focusing on subsets of cases with stereotyped B-cell receptor immunoglobulins (BcR IG); members of which are increasingly shown to display similarities extending beyond IG sequences to clinicobiological profiles and outcomes.
Methods: TL measurements were performed on DNA isolated from diagnostic peripheral blood samples (>70% $CD19^+$ cells) by quantitative real-time PCR. Overall, TL was found to be highly variable. Using a telomere/single copy gene (T/S) threshold value of 1086 units (cut-off at the median) we divided the cohort into two subgroups based on long or short telomeres.
Results: In keeping with the literature, shorter telomeres were significantly ($p<0.001$) more frequent among cases with Binet stages B-C at diagnosis, unmutated IGHV genes and TP53 aberration (TP53ab) due to del(17p) and/or TP53 mutation. Within our cohort, 129/447 (29%) cases belonged to major stereotyped subsets, including both IGHV-unmutated (U-CLL) subsets #1 (n=49), 6 (n=6), 7 (n=5), 8 (n=8) and IGHV-mutated (M-CLL) subsets #4 (n=30), 16 (n=7), 77 (n=5) as well as subset #2 (IGHV3-21/IGLV3-21) with variable IGHV mutational status (n=19, of whom 14 concerned M-CLL). Overall, significant ($p<0.05$) differences were identified between subsets, however, average TLs for different subsets largely followed the general association with IGHV mutational status. In detail, among M-CLL, subset #16 cases had the longest telomeres (T/S=2464.8) followed by subset #4 (T/S=1858.3) and subset #77 (T/S=1840.6), thus differing from all U-CLL subsets that carried considerably shorter telomeres (T/S values: 718.3, 817.5, 703.9, 901.8, for subsets #1, 6, 7 and 8, respectively). Subset #2 exhibited intermediate TL between M-CLL and U-CLL (average T/S=1044.5), significantly ($p<0.001$) differing from the former. Remarkably, within subset #2, M-CLL cases had significantly shorter telomeres than U-CLL (average T/S values: 947.2 *vs* 1316.2; $p<0.0001$). Concerning possible clinical implications, significantly shorter time-to-first-treatment ($p\leq0.007$) was found for patients with Binet stages B-C, TP53ab, del(11q), U-CLL, subsets #1 and #2, as well as shorter TLs. However, TL did not retain prognostic significance for TTFT on multivariate analysis, where only clinical stage, TP53ab and U-CLL status emerged as independent negative prognostic factors ($p<0.001$).
Summary and Conclusions: In conclusion, we document different TLs for different CLL stereotyped subsets, indicating distinct replication histories shaped by subset-biased profiles of cell activation and apoptosis resistance due to both cell-extrinsic (*i.e.* antigenic activation) and cell intrinsic mechanisms (*i.e.* genetic defects). The finding of short telomeres in subset #2, even in IGHV-mutated cases, strongly alludes to intense proliferation in this highly aggressive CLL subset.

P201

SKEWING OF THE T-CELL RECEPTOR REPERTOIRE IN CHRONIC LYMPHOCYTIC LEUKEMIA: WHAT LIES BENEATH?

A Vardi[1,2], A Agathangelidis, [3,*]E Stalika[2], LA Sutton[4], M Karypidou[1], A Anagnostopoulos[1], A Hadzidimitriou[2], P Ghia[3], R Rosenquist[4], K Stamatopoulos[2]
[1]Hematology Department and HCT Unit, G. Papanicolaou Hospital, [2]Institute of Applied Biosciences, Center for Research and Technology Hellas, Thessaloniki, Greece, [3]Division of Molecular Oncology and Department of Onco-Hematology, Istituto Scientifico San Raffaele e Fondazione Centro San Raffaele, Milan, Italy, [4]Department of Immunology, Genetics and Pathology, Science for Life Laboratory, Uppsala University, Uppsala, Sweden

Background: Chronic lymphocytic leukemia (CLL) is characterized by a remarkably restricted immunoglobulin (IG) gene repertoire, mainly attributable to the existence of subsets of patients with stereotyped B-cell receptor (BcR) IGs, strongly implying clonal selection by a restricted set of antigens. Little information exists regarding the role of antigenic stimulation in the selection and activation of cognate T cells, yet this information would be highly relevant in light of the interactions of the malignant B cells with T cells.
Aims: Our preliminary studies of the T-cell receptor β chain (TRB) gene repertoire in 12 cases from CLL subset #4 revealed TRBV repertoire skewing in all cases and shared T-cell clonotypes among different patients. In the present study, we expanded our sample series so as to include cases belonging to other major subsets as well as cases with heterogeneous (non-stereotyped) BcR IGs.
Methods: In total, we analyzed 71 peripheral blood samples from 56 CLL patients, belonging to subset #1 (n=15 cases), subset #2 (n=15 cases) or to no known subset (n=6 cases), together with 20 subset #4 cases; samples from different time points were analyzed for 6 cases (5 subset #4 and 1 subset #1 case). No case had evidence of infection at sampling. PCR amplicons for TRBV-TRBD-TRBJ gene rearrangements (BIOMED2 protocol) were subcloned by transformation into E. coli/TOP10F bacteria and individual colonies were chosen randomly and subjected to Sanger sequencing. Only productive rearrangements (n=1310, range 5-77 per case) were included in the analysis.
Results: Forty-seven of 56 (84%) cases were found to carry clusters of identical rearrangements (≥2) corresponding to distinct clonotypes; the number of expanded clonotypes/case ranged from 1-15 (median 3). The frequency of the most expanded (immunodominant) clonotype/case ranged from 4-80% (median 17.4%). Collectively, the frequency of all expanded clonotypes/case ranged from 10.7-88.8% (median 43.5%). In 2/6 cases where samples from different time points were analyzed, at least one clonotype was found to persist (both cases belonged to subset #4). The TRBV gene repertoire exhibited remarkable restrictions, with 6 genes (namely TRBV12-3, TRBV19, TRBV20-1, TRBV27, TRBV6-5 and TRBV7-9) accounting for almost half of the cohort (46.5%). The exact same genes dominated the TRBV repertoire of clonotypes (45.6%). Similar results were obtained at the individual subset level since these genes were found among the most frequent within each subset, as well as within heterogeneous rearrangements (only unique rearrangements were included in repertoire analyses). In terms of TRB CDR3 sequence analysis, we identified 4 "public" clonotypes shared by 4 pairs of different patients; interestingly, 2/4 pairs of patients with identical clonotypes did not belong to the same subset. In addition, 4 highly similar clonotypes (>85% sequence identity) were identified between different patients.
Summary and Conclusions: In conclusion, the present study, by far the largest to-date, provides clear molecular evidence of TRBV repertoire skewing in CLL, strongly supporting antigen selection of T cells. The finding of "public" clonotypes together with the similar distribution of TRBV genes among CLL patients, regardless of whether they belong to stereotyped subsets or not, may suggest that the T cell driving antigens could include epitopes implicated in the selection of the malignant B cells and/or CLL-cell (tumor-) derived epitopes. The exact functional role of clonally expanded T-cells remains to be elucidated.

P202

BIOLOGICAL AND CLINICAL RELEVANCE OF MIRNAS INDUCED IN CHRONIC LYMPHOCYTIC LEUKEMIA (CLL) CELLS DURING ADMINISTRATION OF THERAPY *IN VIVO* AND *IN VITRO*

K Cerna[1,2,*] J Oppelt[1], L Radova[1], F Pardy[1], N Tom[1, 2], K Musilova[1,2], J Malcikova[1,2], K Plevova[1,2], B Tichy[1,2], Y Brychtova[2], M Doubek[1,2], M Trbusek[1,2], J Koca[1], R Calogero[3], J Mayer[1,2], S Pospisilova[1,2], M Mraz[1,2]
[1]CEITEC MU, [2]Dept. of Internal Medicine - Hematology and Oncology, University Hospital Brno and Faculty of Medicine, Masaryk University, Brno, Czech Republic, [3]Dept. of Biotechnology and Health Sciences, University of Torino, Torino, Italy

Background: MiRNAs are known to be involved in the pathogenesis of CLL and affect its clinical course. However, their function in the apoptotic pathways in CLL B-cells, and their roles in primary and/or acquired resistance to therapy are unclear.
Aims: The aim of this study was to reveal miRNAs changed with apoptotic response of CLL cells and to test their role in response to FCR treatment *in vivo*.
Results: To screen for DNA damage-regulated miRNAs we used RNAs isolated from patients (pts.) B-cells (purity>95%, CD5+19+) treated *in vitro* with fludarabine dose of ~LC50 (3.5 μg/ml; 48hrs). Five paired samples (n=10) were analyzed for miRNAs expression each using 2 next-generation sequencing (NGS) approaches (SOLiD; HiSeq). Obtained sequences were mapped to miRBase and miRNA changes were analyzed by a pair-wise comparison with edgeR and baySeq packages (Bioconductor). The overlap of 2 NGS sequencing platforms analyzed by the 2 mentioned statistical approaches identified 6 miRNAs significantly changed with DNA damage (FDR<0.1). HiSeq validation on 5 additional independent paired samples (n=10) confirmed changed expression of all 6 miRNAs (3 down-, 3 up-regulated). We further screened the expression of the two most constantly up-regulated miRNAs, namely miR-34a and miR-1246, in a

cohort of pts. (n=40) treated with fludarabine, cyclophosphamide and rituximab (FCR) regimen *in vivo*. We observed significant induction of miR-34a and miR-1246 at 48 hrs post FCR administration (fold induction [FI]=1.8; p<0.001; FI=2.2; p=0.01, respectively). Interestingly, the basal miR-34a levels before the therapeutic intervention were able to distinguish pts. with more aggressive disease. The pts. with low miR-34a expression (lowest quartile) had a shorter time to treatment failure (1.04 yrs. *vs.* 2.16 years; p=0.002; HR=4.3; 95% CI=1.68-10.98) and a remarkably shorter time to relapse after FCR-achieved remission (1.28 yrs. *vs.* not reached; p=0.05; HR=3.07; 95% CI=0.97-9.65). We further screened the expression of miR-34a in 158 CLL pts. using an in-house designed assay for its absolute quantification. We defined a cut-point (copies of miR-34a) that segregates pts. with extremely unfavorable prognosis (overall survival [OS] 1.37 yrs. *vs.* not reached; p=0.0001; HR=3.89; CI=2.05-7.39) and this was independent of other prognostic markers (FISH, IgHV, age, sex) in a multivariate analysis. We have previously described that low miR-34a levels associate with p53 mutations, and low-miR-34a identified such CLL cases with a sensitivity and specificity of 0.75 and 0.91, respectively. In an OS multivariate analysis limited to wt-*TP53* samples (n=116) miR-34a was the strongest predictor of OS (1.29 yrs. *vs.* not reached; p=0.002; HR=9.82; CI=2.30-42.05).

Summary and Conclusions: We have defined that FCR-induced miR-34a can be used as a strong predictive and prognostic marker. We have newly identified other 5 miRNAs involved in DNA damage response in CLL (including miR-1246). The investigation of the biological and prognostic role of miR-1246 and other miRNAs is ongoing. These miRNAs likely have convergent functions since the DNA damage induced miRNAs share >50 predicted targets with miR-34a, and thus could affect therapy response and aggressiveness of CLL. This is currently being investigated using integrated analysis of miRNA and mRNA profiling.

INTRA-PATIENT CLONAL AND SUBCLONAL HETEROGENEITY OF CHRONIC LYMPHOCYTIC LEUKEMIA: EVIDENCES FROM CIRCULATING AND LYMPH NODAL COMPARTMENTS

I Del Giudice[1,*] M Marinelli[1], J Wang[2], M Messina[1], S Bonina[1], S Chiaretti[1], C Ilari[1], L Cafforio[1], S Raponi[1], FR Mauro[1], V Di Maio[1], MS De Propris[1], M Nanni[1], C Ciardullo[3], G Gaidano[3], D Rossi[3], A Guarini[1], R Rabadan[2], R Foà[1]
[1]Department of Cellular Biotechnologies and Hematology, Hematology, Sapienza University, Rome, Italy, [2]Department of Biomedical Informatics, Center for Computational Biology and Bioinformatics, Columbia University, New York, United States, [3]Division of Hematology, Department of Translational Medicine, Amedeo Avogadro University of Eastern Piedmont, Novara, Italy

Background: In lymph nodes (LN), the crosstalk with accessory cells prevents chronic lymphocytic leukemia (CLL) cells from apoptosis and enhances their proliferation. A better knowledge of the biology and trafficking of CLL cells derived from different compartments, *i.e.* peripheral blood (PB) and LN, could help to elucidate the effects of tumor-host interactions *in vivo*, critical for the maintenance and expansion of the neoplastic B-cell clone.

Aims: To evaluate if CLL cells resident in the LN compartment and those simultaneously circulating in the PB show different genomic features according to the site of origin.

Methods: We performed Whole-Exome Sequencing (WES, Agilent SureSelect Human All Exon 50Mb, Illumina HiSeq 2000) and Copy Number Aberration (CNA) detection (CytoScan HD array, Affymetrix) on genomic DNA extracted from paired PB, LN and saliva samples of 9 untreated CLL patients. Cases were selected on the basis of: *i)* availability of CLL cells simultaneously extracted from PB and LN biopsies; *ii)* $CD5^+/CD19^+$ cells in PB and LN >70%; *iii*) absence of Richter syndrome and *iv)* availability of germline material (saliva). Candidate mutations were verified by Sanger sequencing, that was also used to determine their distribution in the two compartments. The Roche GSJ 454 platform was utilized to determine the allele variant frequency (VF) in each compartment for all the identified mutations.

Results: Sanger validation of WES data identified 64 nonsynonymous somatic mutations in 60 genes, with the following distribution: 53 (82.9%) present in both compartments, 4 (6.2%) specific of PB, 7 (10.9%) specific of LN. Six of the 7 mutations specific of the LN compartment (*ZNF215, KIF26B, POLR2A, DAPK1, WLS, SF3B1*) were identified as circulating subclones (VF 0.5-5.3%) in the corresponding PB compartment by an ultra-deep sequencing approach (10,000X coverage); similarly, 2 (*ABCC9, MUC5B)* of the 4 PB specific mutations were found in the corresponding LN (VF 1.3-9.6%). CNAs (82.4% losses and 17.6% gains) consisted of 41 lesions: 27 (65.8%) present in both compartments, 7 (17.1%) specific of PB and 7 (17.1%) specific of LN. An inter-patients and intra-patient heterogeneity in the load and distribution of mutations and CNAs was evident. Two were the most informative cases: case #10 (2 mutations and 4 CNAs specific of LN) and case #100 (2 mutations and 7 CNAs specific of PB; 5 mutations and 1 CNAs specific of LN). They were further characterized in the PB of a subsequent relapse. In case #10, the LN specific *ZNF215* mutation expanded from 3.6% to 27.15%, and the previously LN specific CNAs - del8(p23.3-p11.1), del9(p24.3-p13.1), gain 2(p25.3-p14) - appeared in the PB at disease relapse. In case #100, the LN specific *SF3B1* mutation expanded from 5.93% to 44.46% and the PB specific *ABCC9* and *MUC5B* mutations disappeared in the PB at disease relapse. In addition, del11q was larger (19.4 Mb) than what previously detected in the PB (0.3 Mb, including *ATM*) and included *BIRC3*, similarly to the lesion documented in the LN (36 Mb including both *ATM* and *BIRC3*).

Summary and Conclusions: A subset of untreated CLL patients with LN involvement shows a specific pattern of mutations and CNAs in LN-derived tumor cells compared with the corresponding circulating counterpart, providing evidence of an intra-patient clonal heterogeneity according to the disease compartment. The appearance in the PB at relapse of LN-derived mutations and CNAs supports the notion that the LN microenvironment contributes to CLL cell proliferation and selection of clones carrying unfavorable lesions.

P204

OVERCOMING RESISTANCE TO THE NOVEL BH3-MIMETIC ABT-199 IN A CLL LYMPH NODE MODEL; THE ROLE OF ABL AND BTK

R Thijssen[1,*] CR Geest[1], MF de Rooij[2], N Liu[3], BI Florea[3], K Weller[1], HS Overkleeft[3], MH van Oers[4], M Spaargaren[2], AP Kater[4], E Eldering[1]
[1]Experimental Immunology, [2]Pathology, Academic Medical Center, Amsterdam, [3]Bio-organic Chemistry, Leiden Institute of Chemistry, Leiden, [4]Hematology, Academic Medical Center, Amsterdam, Netherlands

Background: Chronic lymphocytic leukemia (CLL) cells are highly sensitive to the Bcl-2-selective BH3-mimetic ABT-199. In patients, ABT-199 induces clear reductions in peripheral blood lymphocyte counts and lymph nodes (LN) size. Yet in LNs, pro-survival signals can upregulate Bcl-2 members that are not targeted by ABT-199, and this may induce (partial) resistance.

Aims: Here, we analysed sensitivity to ABT-199 in a simplified CLL LN model, using *in* vitro CD40 stimulation.

Results: Prolonged CD40 stimulation resulted in full resistance to 10μM ABT-199, due to strong induction of Bcl-XL, Mcl-1 and Bfl-1. These CD40-mediated effects could blocked by the broad spectrum kinase inhibitor dasatinib. Using interaction proteomics, Abl and Btk were identified as dominant targets of dasatinib in primary CLL. Like dasatinib, the Abl inhibitor imatinib, but not Btk inhibitor ibrutinib, could overcome resistance for BH3-mimetics. Conversely, BCR- and chemokine-controlled adhesion could be abolished by dasatinib and ibrutinib, but not by imatinib.

Summary and Conclusions: Our *in vitro* data suggest that long-term clinical application of ABT-199 in CLL might select for resistant clones at protective niches. This may be overcome by combination treatment with kinase inhibitors that prevent emergence of resistance (Figure 1).

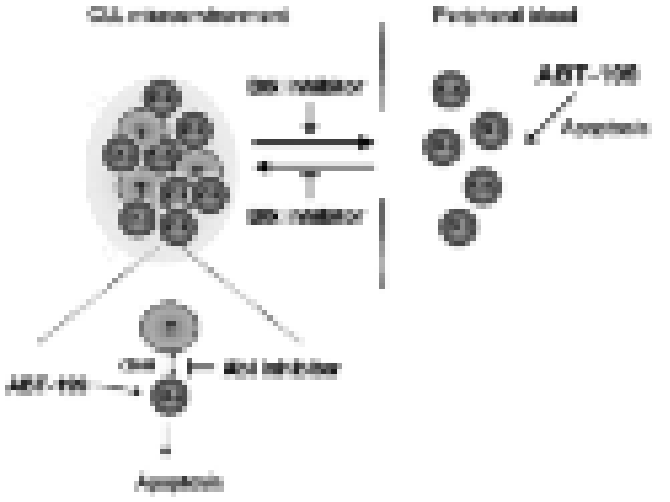

Figure 1.

P205

TARGETING NOTCH2 SIGNALING BY GLIOTOXIN INDUCES APOPTOSIS IN CLL CELLS BY A MECHANISM INVOLVING NOTCH3 AND NR4A1

R Hubmann[1,*] M Hilgarth[1], S Schnabl[1], E Ponath[1], D Demirtas[1], M Reiter[1], U Jäger[1], C Zielinski[1], M Shehata[1]
[1]Comprehensive Cancer Center, Medical University of Vienna, Vienna, Austria

Background: Chronic lymphocytic leukemia (CLL) cells express constitutively activated NOTCH2 in a protein kinase C (PKC) dependent manner linking NOTCH2 to the activated state of the leukemic cells. The transcriptional activity of NOTCH2 is associated with the expression of the B-cell differentiation/acti-

vation marker CD23 and CLL cell viability. Moreover, *NOTCH1* gain of function mutations are found in a subset of CLL cases and have an adverse prognostic impact. We have recently shown that the NOTCH2 transactivation inhibitor gliotoxin (WO 2006/135949) induces apoptosis in CLL cells.
Aims: The aim of this study was to clarify the regulation and possible functions of the individual NOTCH family members (NOTCH1-4) in the apoptotic response of CLL cells to gliotoxin.
Methods: Twenty CLL patients, including all prognostic subtypes and four cases with *NOTCH1* gain of function mutations were enrolled in this study. Dose and time dependent effects of gliotoxin on CLL cell viability and on the induction of apoptosis was determined by MTT-assays and by FACS analysis, respectively. The expression of NOTCH and apoptosis related genes was determined by RT-PCR.
Results: Gliotoxin inhibited cell viability and effectively induced apoptosis (IC_{50} between 0.2μM and 0.5μM) in CLL cells after 3 days of incubation. NOTCH1 mutational status had no significant impact on the sensitivity of CLL cells to gliotoxin. At the molecular level, short term (4 hours) exposure of CLL cells revealed that *NOTCH1* was equally transcribed in unstimulated and in PMA activated CLL cells. *NOTCH2* was upregulated in PMA activated CLL lymphocytes whereas *NOTCH4* was only weakly detectable in unstimulated CLL cells. Gliotoxin treatment resulted in the downregulation of *NOTCH1, NOTCH2* and *NOTCH4* mRNA expression. Interestingly, the inhibition of NOTCH2 activity by gliotoxin was associated with the concomitant induction of NOTCH3 signaling. This was indicated by the induced mRNA expression of *NOTCH3,* the NOTCH ligands *JAG2* (in unstimulated CLL cells) and *DLL1* (in PMA activated CLL cells), and the NOTCH3 preferred target gene *HEY1*. Moreover, the induced transcription of *HEY1* correlated with enhanced *NR4A1* gene activity, a key regulator of activation induced cell death (AICD) in lymphocytes. These data may thus point to a pro-apoptotic role for NOTCH3 mediated *NR4A1* regulation in CLL cells. In line with this hypothesis, the inhibition of all NOTCH receptors with the the γ-secretase inhibitor (GSI) DAPT led to downregulation of *NR4A1* and counteracted the pro-apoptotic effect of gliotoxin.
Summary and Conclusions: In summary, the data suggest that gliotoxin may selectively target the anti-apoptotic arm of NOTCH signaling irrespective of the NOTCH1 mutational status in CLL cells. Therefore, the individual NOTCH receptors may have opposite effects on CLL cell viability which should be considered in therapeutic approaches aimed to target NOTCH signaling in CLL.

IMMUNOHISTOCHEMICAL ANALYSIS OF IL-6, IL-8/CXCR2 AXIS, TYROSINE P-STAT–3 AND SOCS-3 IN CLL LYMPH NODES: CORRELATION WITH MICROVASCULAR CHARACTERISTICS, CLINICAL FEATURES AND PROGNOSIS

G Levidou[1,*] S Sachanas[2], G Pangalis[2], C Kalpadakis[3], X Yiakoumis[2], M Moschogiannis[2], M C Kyrtsonis[4], T Vassilakopoulos[4], P Tsirkinidis[2], F Kontopidou[4], S Kokoris[4], M Angelopoulou[4], M Siakantaris[5], H Papadaki[6], N Kavantzas[7], P Panayiotidis[4], E Patsouris[7], P Korkolopoulou[7]
[1]First Department of Pathology,, University of Athens, [2]Hematology Department, Athens Medical Center, Athens, [3]Hematology Depatrment, University of Crete, Heraklion, [4]Hematology Department, [5]First Department of Internal Medicine, University of Athens, Athens, [6]Hematology Department, University of Crete, Heraklion, [7]First Department of Pathology, University of Athens, Athens, Greece

Background: A number of studies pursued during the last few years have looked into the potential pathophysiological role of angiogenesis in CLL but the results have often been inconsistent.
Aims: To: evaluate simultaneously the immunohistochemical expression of pro-angiogenic factor VEGF, cytokine IL-6, chemokine IL-8 and its receptor CXCR2 along with tyrosine p-STAT–3 and SOCS-3 within and outside the proliferation centres (PCs) of lymph nodes, examine the relationships of these molecules with microvascular characteristics of lymph nodes and determine their prognostic significancy.
Methods: Immunostaining for IL-8, IL-6, CXCR2, SOCS-3, tyrosine p-STAT-3 and VEGF was performed on paraffin-embedded 4μm sections inlymph nodes of 62 CLL patients. The microvascular characteristics were evaluated using CD34. A Histo-score (H-score) based on the percentage of stained neoplastic cells multiplied by staining intensity was calculated.
Results: Microvessel density, major axis length, minor axis length, area, perimeter, shape factor and Total vascular area were higher in the PCs when compared to the non-PC areas.IL-8 and CXCR2 expression were detected only in 5/51 (9.80%) 7/51 (13.21%) of the examined cases respectively, whereas IL-6 expression was detected in 49/51 (96.08%). Tyrosine p-STAT-3 expression was nuclear and was detected in 36/51 (66.67%) of the examined cases. In 21/35 (66.67%) positive cases immunoreactivity was mainly observed in the PCs. SOCS-3 expression was cytoplasmic and was detected in 34/35 (97.1%) of the examined cases. VEGF expression was cytoplasmic and was observed in all the examined cases (41/41, 100%) cases. Further on,VEGF H-score was negatively correlated with MVD and shape factor, whereas VEGF H-score within the PCs was unrelated to the microvessels characteristics in the same area (p>0.10) and it was negatively correlated with Binet stage Tyrosine p-STAT-3 positivity (p=0.0303) and increased VEGF H-score (p=0.0205) were correlated with increased TTP (median TTP for p-STAT-3 positivity 137.766 months *vs* 58.26 and median TTP for increased VEGF H-score 100,3 months *vs* 42,36). The former relationship remained significant in multivariate survival analysis (HR=0.202, p=0,024).
Summary and Conclusions: The present study constitutes the first attempt to elucidate the significance of angiogenesis and proangiogenic cytokines, IL-6, IL-8 and VEGF along with tyrosine p-STAT-3 and SOCS-3 in lymph nodes involved by CLL. Both the extent of microvasculature and microvessel caliber were significantly lower within the PCs as compared to the non-PC area.Tyrosine p-STAT-3 positivity emerged as an independent favourable prognosticator in terms of time to progression.

P207

EXPRESSION AND FUNCTIONAL ACTIVITY OF THE TNFR-SUPERFAMILY MEMBER DEATH RECEPTOR 3 IN CHRONIC LYMPHOCYTIC LEUKEMIA B CELLS ACTIVATED BY THE BCR

C Cavallini[1,*] O Lovato[1], A Bertolaso[2], E Zoratti[1], M Tinelli[3], C Tecchio[3], O Perbellini[3], A Zamò[2], G Pizzolo[3], M T Scupoli[1]

Background: Growing evidences suggest a dynamic balance of B-cell chronic lymphocytic leukemia (B-CLL) cells between the blood and lymphoid tissues, which represent permissive niches for cell proliferation and survival. Within lymphoid tissue sites, molecules of the tumor necrosis factor (TNF) superfamily have been shown to play a supportive role and contribute to the pathogenesis of B-CLL. Thereby, investigating expression and functions of novel TNFR-superfamily members in B-CLL would allow us to gain deeper insights into molecular crosstalk within leukemic microenvironments. Death receptor (DR) 3 is a TNFR-superfamily member expressed in lymphocyte-enriched tissues that binds to the TNF-like ligand 1A (TL1A), a TNF superfamily member. The TL1A/DR3 axis is implicated in regulatory mechanisms of adaptive immune response under physiological and pathological settings. Further evidence for the implication of TL1A in regulatory mechanisms arises from our recent data showing an inhibitory function of TL1A on B-cell proliferation. In leukemia cells, DR3 expression and functions have not been explored so far.
Aims: Our aims were to investigate the expression of DR3 in B cells from B-CLL patients and to explore the possible role of TL1A/DR3 axis in the disease.
Methods: B cells were purified from PBMC of 37 B-CLL patients by negative selection with magnetic beads. DR3 surface expression was measured by flow cytometry at baseline and following stimulation with F(ab')2 anti-human IgM conjugated to latex microspheres. DR3 expression was confirmed by western blot and immunofluorescence analysis on B-CLL lymph nodes. DR3 function was studied by MTT assay and Annexin V assay. TL1A serum levels were measured by ELISA.
Results: Under basal conditions CLL B cells *in vitro* expressed low levels of DR3. Stimulation of the B cell receptor (BCR) with anti-IgM antibodies induced a statistically significant increase of DR3 expression in CLL B cells ($p<0.001$). Induced DR3 expression showed great variability amongst B-CLL cells (variance (σ^2)=6.38). Flow cytometry data were confirmed by Western blot analysis. The relevance of these findings was further confirmed by immuofluorescence analysis of B-CLL lymph-node specimens showing that i*n vivo* high levels of DR3 were expressed by a number of B-CLL cells. To assess whether the anti-IgM-induced DR3 molecule was functionally active in CLL B cells, we examined the ability of DR3 to modulate their metabolic activity. Stimulation of DR3 with TL1A in the presence of BCR engagement showed that TL1A induced an equal or greater than 25% decrease of metabolic activity in 37.5% of B-CLL cell samples. In these samples the modulation is not due to reduced survival, as assessed by Annexin V assay. No change in metabolic activity was observed following TL1A treatment, in the absence of anti-IgM. Higher levels of DR3 expression were significantly associated with early-stage (Rai 0) disease (p=0.019) and higher serum levels of TL1A were significantly associated with early-stage (Rai 0) disease (p=0.023) and absence of CD38 expressions (p=0.035).
Summary and Conclusions: In this study, we describe for the first time that B-CLL cells activated by the BCR stimulation express DR3 and TL1A reduces metabolic activity in some B-CLL cells. Herein, our data show a novel regulatory role for TL1A that, in the presence of antigen stimulation, may modulate leukemic cell metabolism through DR3 in early-stage B-CLL and suggest that homeostatic functions of TL1A may influence the clinical course of B-CLL disease.

P208

VASCULAR ENDOTHELIAL GROWTH FACTOR (VEGF) INCREASES CELL MIGRATION THROUGH INTERACTION WITH THE CXCR4/SDF1 AXIS IN B-CELL CHRONIC LYMPHOCYTIC LEUKEMIA (B-CLL)

S Ballester Garcia[1,*] P Eroles Asensio[1], A Perez Martinez[1,2], E Tormo Martín[1], B Pineda Merlo[1], B Navarro Cubells[1,2], A Teruel Casasús[1,2], C Solano Vercet[1,2], MJ Treol Casterá[1,2]
[1]Hematology-Oncology, INCLIVA Biomedical Research Institute, [2]Hematology-Oncology, Hospital Clínico, VALENCIA, Spain

Background: Vascular endothelial cell growth factor (VEGF) is a multifunction-

al cytokine involved in angiogenesis and development. In B-CLL, it is known that malignant cells possess VEGF receptors and secrete VEGF. Patients with advanced stage have higher levels of VEGF, so it is probably involved in tumor progression. In other cell lines, VEGF is a major stimulating factor for migration, survival and proliferation and its action is mediated through another G-coupled protein system, CXCR4/SDF-1.
Aims: In the present study, we analyzed the role of exogenous VEGF on B-CLL migration as well its relationship with the G-coupled proteins CXCR4, CXCR7 and CD49d.
Methods: We obtained peripheral blood mononuclear cells from 33 patients diagnosed of CLL according to established clinical and laboratory protocols. We also used the CLL cell line Mec-1 and human umbilical vein endothelial cells (HUVEC). B-lymphocytes were purified by Ficoll-Hypaque density gradient centrifugation anti-CD19 conjugated Dynabeads. Then we analysed by flow cytometry the expression of CXCR4, CXCR7 and CD49d before and after exogenous VEGF exposure, VEGF-R2 inhibitor or both. In order to evaluate the role of VEGF in the motility of these cells, we performed an *in vitro* 6h transmigration assay towards a media containing (or not) SDF-1. B-CLL ($5x10^5$ cells) cells were incubated on the upper chamber of transwell filters coated with HUVEC in the presence or absence of VEGF [50 ng/ml] 24h, VEGFR2/KDR inhibitor [70nM] or both simultaneously. Migration ratio was given as mean±SD between B-CLL cells treated with VEGF, VEGF-R2 inhibitor *versus* control. Statistical analysis was performed by non-parametric Wilcoxon test using SPSS statistical software (version 19.0). We also studied the expression CXCR4 and p-CXCR4 using confocal laser scanning microscopy. Mec-1 cells were cultured in the presence of VEGF [50 ng/ml] for 24h or absence. The cells were fixed in 3.7% paraformaldehyde and permeabilized by 0.2% triton X-100. The slides were blocked in 5% serum and incubated with primary antibodies CXCR4 and p-CXCR4 overnight at 4ºC and stained with corresponding secondary antibodies.
Results: Basal CXCR4, CXCR7 and CD49d expression levels of B-CLL cells were highly variable among the 33 patients analyzed. Mean fluorescent intensity (MFI) of CXCR4 expression was significantly higher on cells treated with VEGF *versus* untreated cells (9.64±95, p=0.028). However, we did not detect a significant difference in the percentage of cells expressing this receptor. On the other hand, VEGF treatment did not influence either MFI or the number of CXCR7 and CD49d expressing cells. Exposure to a VEGFR2 inhibitor reduced the percentage of cells expressing CXCR4 and CXCR7, suggesting a potential regulatory role of this receptor in the expression of these chemokines. Concerning cell migration, we observed a significant increase of Mec-1 and B-CLL cells treated with VEGF *versus* the control (27.66±69.97 p=0.03). Furthermore, the treatment with VEGFR2 inhibitor reduced significantly the migration index (-23.18±33.5, p=0.001) and the motility was restored by the addition both, VEGF and R2-inhibitor (36.04±39.33, p=0.001). Finally, we observed and increased fluorescent signals of both, CXCR4 and p-CXCR4 in Mec1 treated with VEGF *versus* controls (Figure 1).

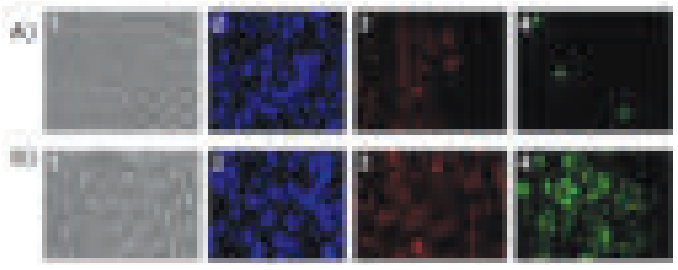

Figure 1. Fluorescent signals from CXCR4- Alexa fluor 647 (3) as well as from Phospho-CXCR4- Fluorescein goat anti rabbit IgGa (4) detected by immunofluorescence were analyzed by confocal microscopy. Nuclei were counter strained with Hoescht 33258 (5mg/100ul). A) Cell line MEC-1 control. B) Cell line MEC-1 treated with VEGF (50 ng/ml) for 24h.

Summary and Conclusions: These preliminary data suggest that VEGF seems to be involved in B-CLL migration through the up-regulation of CXCR4 levels and it also interacts with other g-protein receptor coupled sinaling pathways. New therapeutic strategies focussed on blocking both the SDF1-CXCR4 axis and/or VEGF pathway could have a potential therapeutic role in the treatment of this entity. Detailed molecular mechanisms implicated in this process should be further studied.

ANALYSIS OF IMMUNOGLOBULIN GENE REARRANGEMENTS IN CHINESE AND ITALIAN PATIENTS WITH CHRONIC LYMPHOCYTIC LEUKEMIA
M Marinelli[1,*] Y Xia[2], I Del Giudice[1], C Ilari[1], L Cafforio[1], I Della Starza[1], S Raponi[1], S Bonina[1], Z Yu[3], W Yang[3], L Qiu[3], E Tse[4], J Li[2], W Xu[2], A Guarini[1], R Foà[1]
[1]Department of Cellular Biothecnology and Hematology, Sapienza University, Rome, Italy, [2]Department of Hematology, the First Affiliated Hospital of Nanjing Medical University, Jiangsu Province Hospital, Nanjing, [3]Department of Lymphoma & Myeloma Institute of Hematology, CAMS & PUMC, Tianjin, [4]Department of Medicine, Queen Mary Hospital, Hong Kong University, Hong Kong, China

Background: In Asia, chronic lymphocytic leukemia (CLL) incidence is 5-10 times lower than in the Western world and does not change in Asian residents in the US and in their descendants. The underlying environmental and genetic bases remain obscure. Previous data seem to suggest a different distribution of immunoglobulin heavy chain variable (IGHV) gene families between Asian and Caucasian CLL.
Aims: To characterize IGHV-D-J rearrangements and stereotype of the HCDR3 region of a series of Chinese CLL and compare them to those present in Italian CLL.
Methods: CLL cells from 399 Chinese patients at presentation (319 from China, 80 from Hong Kong) and from two Italian cohorts have been analyzed. IGHV-D-J gene rearrangements were analyzed by the IMGT database (http://imgt.cines.fr). We evaluated: IGHV-D-J gene usage and IGHV mutational status; HCDR3 region by the ClustalW2 software (http://www.ebi.ac.uk). Stereotyped HCDR3s were defined according to published criteria.
Results: Of the 399 Chinese patients, 38.6% were IGHV unmutated (UM) and 61.4% mutated (M). The IGHV family distribution was as follows: VH3 (49.9%), VH4 (27.6%), VH1 (14.3%), VH2 (3%), VH5 (2.2%), VH6 and VH7 (1.5% each). The most representative IGHV genes were: V4-34 (10.5%), V3-23 (9.8%), V3-7 (9.8%), V4-39 (6%), V1-69 (5.3%), V4-59 (5%), V3-30 (4.3%), V3-74 (3.7%), V3-33 (3.2%), V3-48 (3%), V3-21 (3%), V5-51 (2%), V1-2 (1.7%). We compared the Chinese series with two Italian CLL cohorts: i) 579 unselected patients (49.4% UM, 50.6% M), comparable with those reported by Agathangelidis *et al.*, 2012; ii) 329 patients at diagnosis (38% UM, 62% M, similar to the Chinese series). From the first comparison, the frequency of VH1 in Chinese CLL was lower (p=0.0001) and that of VH4 was higher (p=0.01). V1-69 (p=0.0001), V1-2 (p=0.002) and V3-30 (p=0.04) were underrepresented in Chinese CLL, whilst V4-59 (p=0.003), V3-7 (p=0.03) and V4-39 (p=0.06) were more recurrent in Chinese than Italian CLL. Regarding IGHD, in Chinese CLL, the DH3 (40.8%) was the most frequent followed by DH6 (20.3%) and DH2 (13.5%), with a higher representation of DH6 (p=0.0034). D3-3 (p=0.0009) was lower, whilst D6-13 (p=0.0028) and D3-10 (p=0.006) were higher in Chinese CLL. We then examined the 329 Italian CLL at diagnosis, in order to avoid selection biases. VH1 was again lower in Chinese CLL (p=0.01); V1-69 (p=0.003), V1-2 (p=0.01), V3-30 (p=0.05) and D3-3 (p=0.005) were underrepresented in Chinese CLL, whilst V4-39 (p=0.04), DH6 (p=0.01), D6-13 (p=0.003) and D3-10 (p=0.046) were more recurrent in Chinese than Italian CLL. No difference was found in the IGHJ families. The proportion of known stereotyped receptors was significantly lower in Chinese (14.4%) than in Italian CLL (31.4%) (p=0.0001), although a significantly higher frequency of subset #8 was observed in Chinese (10.4% of stereotyped cases) compared to Italian CLL (1.4%) (p=0.0095). Moreover, 6 new paired clusters were identified among Chinese cases.
Summary and Conclusions: Our data show a different IGHV and IGHD gene usage between Chinese and Italian CLL. Of interest is the low frequency of V1-69, V1-2, V3-30, D3-3 and the high frequency of V4-39, DH6, D6-13, D3-10 in the Chinese series. In addition, a low representation of stereotyped receptors was identified among Chinese CLL, although with a high frequency of subset #8. By extending this study to other Chinese collaborators, it will be possible to corroborate these results and identify potential new subsets of Chinese CLL. These data could ultimately translate into pathogenetic hypotheses for Chinese CLL.

P210

BASAL CA2+ SIGNALING IS PARTICULARLY INCREASED IN MUTATED CHRONIC LYMPHOCYTIC LEUKEMIA
AF Muggen[1,*] S Yuvuraj[2], LP Kil[2], MC van Zelm[1], JJ van Dongen[1], RW Hendriks[2], A W Langerak[1]
[1]Immunology, [2]Pulmonary Medicine, Erasmus MC, Rotterdam, Netherlands

Background: Chronic lymphocytic leukemia (CLL) patients can be divided on the basis of the somatic hypermutation (SHM) status of their B-cell antigen receptor (BCR) genes into unmutated CLL (U-CLL) or mutated CLL (M-CLL) subgroups. Furthermore, approximately 30% of CLL patients express a stereotypic BCR, while the other 70% express a heterogeneous receptor. The existence of these stereotyped B cell receptors (BCR) in different CLL patients is interpreted as an indication for specific antigenic stimulation driving CLL pathogenesis. However, it was recently reported that CLL is driven by (higher basal) autonomous signaling based on Ca^{2+}, influx assays instead of antigen-dependent signals. This autonomous signal is induced by the immunoglobulin heavy chain complementarity determining region 3 (HCDR3) of the CLL BCRs, which are supposed to recognize an internal epitope within framework 2 (FR2) of the BCR. We hypothesized that these seemingly contrasting observations may not be mutually exclusive, and that the level of cell-autonomous signaling may differ between CLL subgroups.
Aims: Our aim is to determine whether basal signaling is different between CLL subgroups.

Methods: From our cohort of well-defined CLL samples consisting of cases belonging to specific stereotypic CLL subsets and heterogeneous CLL, we selected representative samples of stereotypic or heterogenous U-CLL and M-CLL cases (n=68). From these MNC samples, CLL B cells were untouched isolated by MACS. As controls we used MNCs from healthy individuals over 50 years of age (n=14). After loading the cells with labeled Ca^{2+} indicators Fluo-3 AM and Fura Red AM, we investigated BCR signaling by use of Ca^{2+}, influx assays on a LSR II flow cytometer.
Results: Our results show variation in basal BCR signaling between B cells of healthy individuals and CLL cells from stereotypic and heterogeneous U-CLL and M-CLL cases. We confirmed that basal Ca^{2+} signaling in CLL cells is higher than in normal B cells, but we also found that basal signaling is particularly high in M-CLL subgroups and to a lesser extent in U-CLL subgroups. The degree of basal signaling was not correlated with BCR characteristics like membrane Ig levels, HCDR3 length, or HCDR3 charge. Furthermore, the expression levels of CD5 (negative BCR-regulator) did not influence basal Ca^{2+} levels. Additionally, within our cohort we could not detect mutations leading to amino acid change within the earlier found FR2 epitope known to induce autonomous BCR signaling in CLL, which could influence our observed variation in basal Ca^{2+} levels.
Summary and Conclusions: Basal Ca^{2+}, signaling in CLL samples is higher compared to healthy controls. The Ca^{2+} levels were not uniformly high in all samples, but correlated to the IGHV SHM status. U-CLL showed marginally increased Ca^{2+} levels, whereas M-CLL samples had the highest basal Ca^{2+} levels. We therefore conclude that the level of basal Ca^{2+} signaling is not uniformly enhanced in CLL B cells, and speculate that this may depend on the degree of anergy of these cells.

P211

SRC INHIBITORS DOWNREGULATE CD20 AND MODULATE THE ACTIVITY OF THE CD20 PROMOTER

M Winiarska[1,*] K Bojarczuk[1], B Pyrzynska[1], N Miazek[1], P Zapala[1], M Bobrowicz[1], M Dwojak[1], M Siernicka[1], J Golab[1]
[1]Department of Immunology, The Medical University of Warsaw, Warsaw, Poland

Background: The monoclonal antibodies against CD20 antigen (rituximab and ofatumumab) have been developed and used in clinic as a therapeutic strategy in B-cell malignancies. These antibodies eliminate B cells by triggering indirect effector mechanisms of the immune system, namely complement-dependent cytotoxicity (CDC), antibody-dependent cellular cytotoxicity (ADCC), or immunophagocytosis. Although for many years CD20 has been described as a stable antigen, accumulating evidence indicates that CD20 can be modulated at both transcriptional and posttranscriptional levels. It seems that down-regulation of CD20 levels is one of the reasons of tumor resistance to rituximab. We have previously discovered that CD20 expression is strictly dependent on the activity of BCR signaling pathways. However, to the best of our knowledge, the role of SRC family kinases (SFKs) in the regulation of CD20 expression has not been studied so far.
Aims: The aim of this study was to explore the molecular mechanisms of SFK-dependent CD20 regulation in B-cell neoplasms.
Methods: CD20 surface level, rituximab-mediated CDC (R-CDC) and ADCC in CD20-positive lymphoma cell lines and primary cells from patients were determined with flow cytometry. Total CD20 protein levels were assayed with Western blotting, the expression of CD20 gene was determined with qRT-PCR. The CD20 promoter activity was measured with reporter *Firefly* luciferase assay.
Results: Initial experiments showed upon treatment with SFKs inhibitors a significantly reduced binding of anti-CD20 mAb to lymphoma cell lines as well as primary cells isolated from patients. All tested SFKs inhibitors, as well as shRNA targeting Lyn, Fyn or Lck kinase impaired CDC and ADCC over a dose range of rituximab concentrations (1-100 ug/ml) in Raji cells. Interestingly, in Raji cells incubated for 48h with dasatinib we also observed a dose-dependent reduction of total CD20 protein levels, when assayed by Western blotting. Moreover, quantitative PCR analysis revealed that the transcriptional regulation is the major mechanism responsible for the reduction of CD20 level upon dasatinib treatment. Consistently, the exogenously expressed CD20 under the control of CMV promoter was not sensitive to dasatinib treatment. To further elucidate the mechanism of transcriptional regulation of CD20 we performed the luciferase assays to estimate the activity of CD20 promoter and its truncated forms. Dasatinib or AKT kinase inhibitor (MK-2206) strongly decreased the activity of CD20 promoter, while the overexpression of CA-AKT partially blocked the inhibition caused by dasatinib. Using the truncated versions of the CD20 promoter we found that lack of the region (-313/-198) made the promoter unsensitive to dasatinib treatment. Since this particular region is known to contain a putative Octamer transcription factor binding site, we introduced mutations in the BAT-box sequence. Although basal promoter activity was indeed decreased, dasatinib was equally effective in reducing the activity of both wild-type and mutated CD20 promoter.
Summary and Conclusions: The most important finding of this study is that SFKs inhibitors strongly down-regulate in the transcriptional mechanism CD20 levels in tumor cells, leading to decreased binding of anti-CD20 mAbs to the surface CD20 and to impaired activation of antitumor effector mechanisms of the immune system. While impaired CDC is a direct result of decreased CD20 levels, inhibition of ADCC is caused by impairment of cytolytic activity of NK cells.

COMPLEX ACTIVATION OF ANGIOGENIC SIGNALING IN CHRONIC LYMPHOCYTIC LEUKEMIA: EVIDENCE FROM CIRCULATING ANGIOGENIC CYTOKINES

L Smolej[1,*] C Andrys[2], V Rezacova[2], M Simkovic[1], M Motyckova[1], D Belada[1], P Zak[1]
[1]4th Department of Internal Medicine - Hematology, [2]Institute of Clinical Immunology and Allergology, University Hospital and Charles University Faculty of Medicine, Hradec Kralove, Czech Republic

Background: Chronic lymphocytic leukemia (CLL) has a remarkably heterogeneous clinical course. Assessment of angiogenesis may potentially improve individual patient´s prognostic stratification.
Aims: To investigate prognostic relevance of circulating basic fibroblast growth factor (FGF-2), vascular endothelial growth factor (VEGF), soluble endoglin (sCD105), endostatin, and angiopoietin-2 (Ang-2) in patients with CLL.
Methods: Plasma levels of angiogenic factors were quantified using enzyme-linked immunosorbent assay in patients with untreated CLL (median age, 63 years [range, 31-88]; males, 69%) (FGF-2, VEGF, n=181; sCD105, n=175; endostatin, n=137; Ang-2, n=130). Eighty healthy donors served as control group.
Results: All circulating cytokines except endostatin were significantly elevated in CLL patients *vs.* controls (FGF-2 and sCD105: p<0.0001; VEGF, p=0.0004; Ang-2: p=0.001). sCD105 progressively increased with advancing Rai stages (Rai low *vs.* intermediate *vs.* high, p=0.024 and p=0.033). Patients with progressive disease had significantly higher levels of sCD105, endostatin and Ang-2 in comparison to patients with stable course (sCD105: p=0.0008; endostatin: p=0.019; Ang-2: p=0.015). Time to treatment was significantly shorter in patients with high sCD105 levels (median 15 months *vs.* not reached, p=0.0045). In patients who achieved at least partial response after fludarabine-based chemo(immuno)therapy, levels of FGF-2, VEGF, and sCD105 decreased significantly (p<0.0001, p=0.0027 and p=0.0098).
Summary and Conclusions: Our results indicate that a complex network of angiogenic signaling is active in CLL and has an impact on clinical course; sCD105 appears to have the best prognostic value among these cytokines. Updated results will be presented. Supported by grant NT/13412-4 from the Internal Grant Agency, Ministry of Health, Czech Republic, by DRO (Univ Hospital Hradec Králové, 00179906) from Ministry of Health, Czech Republic, and by programme PRVOUK P37/08.

CHRONIC LYMPHOCYTIC LEUKEMIA CELL CAPACITY OF EXPRESSING AND RESPONDING TO SURFACE IGM (S-IGM) OR S-IGD PREDICTS DISEASE PROGRESSION AND IS ASSOCIATED WITH SPECIFIC MIRNA/MRNA SIGNATURES

F Morabito[1,*] G Cutrona[2], A G Recchia[1], M Gentile[1], E Vigna[1], S Matis[2], M Colombo[2], C Massucco[3], S Bossio[1], L De Stefano[1], U Consoli[4], I Vincelli[5], C Musolino[6], A Neri[7], C Tripodo[8], M Ferrarini[9]

Martino-National Cancer Institute, Genova, [4]Hematology-Oncology Division, Garibaldi-Nesima Hospital of Catania, Catania, [5]Hematology Division, "Bianchi Melacrino Morelli" Civil Hospital of Reggio Calabria, Reggio Calabria, [6]Hematology Division, University of Messina, Messina, [7]Department of Clinical and Community Science, University of Milan; IRCCS Foundation Cà Granda Policlinical Hospital, Milan, [8]Department of Health Science, Tumour Immunology Unit, Human Pathology Section, University of Palermo School of Medicine, Palermo, [9]Scientific Division, IRCCS AOU San Martino-IST, Genova, Italy

Background: Signaling via BcR is thought to activate proliferation and survival pathways in CLL cells and has also been linked to poor outcome.
Aims: We investigated i) the intensity of sIgM and sIgD expression by flow cytometry, ii) their ability to predict progression free survival (PFS) and iii) specific miRNA and GEP signatures associated with sIgM and sIgG expression.
Methods: 372 newly diagnosed patients were prospectively enrolled from diagnosis (clinicaltrial.gov identifier NCT00917540). The intensity of sIgM and sIgD expression was calculated as Relative Fluorescence Intensity (RFI). Highly-purified B-cells were employed for GEP (GeneChip® Gene 1.0ST Array, Affymetrix Inc.) and miRNA (Agilent's Human V2 platform) analyses.
Results: The mean sIgM density measured as RFI value±sem was 56.9±5.6 in the entire cohort, with a median value of 34 (range 6.7-1430). ROC analysis showed that 10 was the most suitable RFI threshold for sIgM to distinguish those cases operationally defined as sIgM-low group (234/372, 62.9%) from sIgM-high group (AUC=0.629, *P*<0.0001). The PFS of the sIgM-low group was significantly longer than sIgM-high cases (H.R. 2.2, 95%CI 1.4-3.5, *P*<0.0001). Similarly, using a RFI threshold value for sIgD of 12, the 86 cases with sIgD-high had a significantly higher risk to progress (HR=2.4, 95%CI 1.5-3.8, *P*<.0001). Among the 234 sIgM-low cases there was a concordantly low sIgD density in 194 cases, while 46/138 of sIgM-high cases exhibited high sIgD RFI levels (*P*=0.001). Cases were subdivided in 3 groups: sIgM-low sIgD-low (n=194), sIgM or sIgD-high (n=132), and sIgM and sIgD-high (n=46). Differences in clinical outcome were observed between sIgM-low sIgD-low, sIgM-or IgD-high, and sIgM-and sIgD-high cases with 4.5 times higher risk of progression (95%C.I. 2.5-8.1, P<0.0001) for the latter group. A significantly higher number of CD38 and ZAP-70 positive as well as *IGHV*-unmutated (*IGHV*-UM) cases were detected in sIgD- and sIgM-high group, while a significantly higher percentage of patients with trisomy 12, del(11)(q22.3) and del(17)(p13) was noticed. In a Cox multivariate model, CD38-positive [HR=2.2, 95%CI 1.2-3.8, P=.006], *IGHV*-UM [HR=3.0, 95%CI 1.6-5.6, P=.001] and sIgM- and sIgD-high cases [HR=2.1, 95%CI 1.2-4.0, P=.016] maintained an independent association with PFS. A GEP multiclass supervised analyses according to the three sIgD/sIgM density categories identified 23 differently modulated genes, 18 of which showed a prognostic relevance in predicting PFS. Finally, a miRNA multiclass supervised analysis identified 4 differently modulated miRNAs. Specifically, miR-146b-5p showed an up-regulation gradient from sIgDlow/sIgM low to sIgD high/sIgM high groups, while an opposite gradient was documented for miR-575, miR-1225-5p and miR-373*: miR-146b-5p (*P*=.011) was significantly associated with PFS. *In vitro* stimulation of CLL cells by autologous T cells activated and expanded by CD3/CD28 MACSiBead™(Miltenyi) particles and IL2, causes up-regulation of both sIgD and sIgM expression in a subset of B-cells also showing CD38bight, CXCR4dim and CD5bright, indicating that microenvironment signals have a role in BcR regulation.
Summary and Conclusions: A high cell surface density of IgM and IgD correlates with shorter PFS, independently from other known prognostic markers. Moreover, some genes and miRNAs are differently regulated in those cases highly expressing sIgD and sIgM and predict a poor clinical outcome. Finally, we highlight the relevance of sIgD and sIgM regulation in the natural history of early unfavorable CLL patients.

P214

B-CELL RECEPTOR SIGNALLING ENHANCES GLYCOLYSIS IN CHRONIC LYMPHOCYTIC LEUKAEMIA

B Valle Argos[1,*] A Linley[1], S Krysov[1], A J Steele[1], F Forconi[1], F Stevenson[1], G Packham[1]
[1]Cancer Sciences Division, University of Southampton, Southampton, United Kingdom

Background: Signaling via the B-cell receptor (BCR) plays a key role in chronic lymphocytic leukaemia (CLL) and is an effective target for therapeutic attack. We have previously demonstrated that stimulation of surface IgM of CLL cells induces expression of the growth promoting oncoprotein, MYC. In addition to its roles in driving cell division, MYC promotes a switch in metabolism, promoting glycolysis, even in the presence of adequate levels of oxygen. This is called aerobic glycolysis, or the Warburg effect, and is important to provide biosynthetic metabolites.
Aims: Here, we have investigated the effects of BCR stimulation on the expression of glycolytic enzymes in primary CLL samples.
Methods: Analysis of the protein expression of MYC, pERK1/2 and pAKT in CLL samples after stimulation with soluble or immobilised anti-IgM (Western blot), and the change in expression after ibrutinib and tamatinib treatment. Analysis of the gene expression of CLL samples stimulated with sIgM (afimetrix array). Validation by Q-PCR analysis of MYC and metabolic target genes: HK2, LDHA and ODC1, after stimulation of CLL cells with both immobilised anti-IgM and CpG-ODN and the change in expression after ibrutinib and tamatinib treatment.
Results: Analysis of gene expression array data, revealed that anti-IgM stimulation of CLL cells induced expression of a wide range of enzymes involved in glycolysis, as well as glutaminolysis which is also controlled by MYC. Q-PCR analysis confirmed that anti-IgM expression increased expression of hexokinase 2 (HK2), lactate dehydrogenase A (LDHA), as well as ornithine decarboxylase (ODC) which catalyses the rate-limiting step in polyamine biosynthesis. These MYC target genes were more strongly induced in cells stimulated with immobilized anti-IgM, compared to soluble antibody. Anti-IgM-induced expression of MYC, HK2, LDHA and ODC was inhibited by the BTK inhibitor ibrutinib and the SYK inhibitor tamatinib. Similar results were obtained following treatment of CLL cells with the toll-like receptor 9 ligand CpG-ODN.
Summary and Conclusions: These results demonstrate that BCR signaling can enhance growth-promoting glycolysis in CLL cells. Inhibition of glycolysis-promoting signaling may contribute to the therapeutic effects of novel kinase inhibitors targeted towards the BCR in this disease.

P215

NICHEFORMING STROMAL ELEMENTS OF BONE MARROW AND LYMPH NODES IN CLL

N Semenova[1,*] S Bessmeltsev[1], V Rugal[1]
[1]Russian research institute hematology and transfusiology, Saint-Petersburg, Russian Federation

Background: The niche microenvironment of bone marrow controls development HSC and lineage commitent of T and B lymphocytis. Niche lymph nodes regulate development B-precursors that travel from bone marrow. However, the state niche hemopoietic and lymphoid microenvironment when lymphocytis proliferation is impaired continues to be studied insufficiently.
Aims: The aim of the study were investigation of the morphofunctional features of stromal elements of hemopoietic and lymphoid microenvironment that form niche lymphoid precursors in CLL.
Methods: Endosteal cells and microvessels of bone marrow 79 patients with CLL has been studied in trephine biopsies. Follicular dendritic cells and microvessels lymph nodes of 57 patients were studied. Histological, histochemical, morphometric and immunohistochemical methods were used. The statistical significance was considered with p≤0,05 (Student criterion).
Results: Nodular, interstitial and diffuse lymphocytic infiltration of bone marrow are detected. Disorders of microenvironment at all types of infiltration was established. Loose network of reticulin fibers in nodular infiltration. Silver impregnation showed the increase number reticulin fibers endosteal areas bone marrow in interstitial and diffuse types. Density microvessels increase in the progression of bone marrow infiltration. In diffuse infiltration size of vessels increased by almost 2 times in comparison with the control group (17,9±of 4.7% instead of 9.1±1,2%), and, what is especially important, the increase of number of vessels in subendosteal spaces was noted. Analysis of endosteal cells showed an increase of number of cells per unit of area at interstitial (1,8±0,4 against 1.4±0.2 in the control group) and diffuse (2,3±0,7) infiltration. The change of morphology endosteal cell was established too. In lymph node biopsies of CLL patients restructuring of the stroma was noted. Identified destructive changes of reticulin frame. Disintegration of follicular dendritic cells and reduction of their number almost 3 times (to 7.2±1.3% in CLL and 23±3.1% in the control group) was noted. Density microvessels lymph nodes was increased - 12,8±0.3% in CLL (6,5 approximately 0.5% in the control group). Thus, the reduction of the number of follicular dendritic cells and increase of angiogenesis are the key factors of stroma damage lymphoid microenvironment in CLL.
Summary and Conclusions: Changes of stromal nicheforming structures of bone marrow and lymph nodes indicate of their involvement in the genesis of neoplastic transformation of lymphoid precursors and can identify the realignment of the microenvironment function directed on maintenance of leukemic clone.

Departamento de Medicina, Fundación Centro de Investigación del Cáncer. Salamanca, Salamanca, Spain

Background: It is well-known that B-cell chronic lymphocytic leukemia (CLL) patients have an impaired immune function -particularly in advanced disease, which significantly contributes to a higher risk of infections. The introduction of new therapeutic agents, such as the purine analogues *plus* rituximab, has significantly improved the clinical responses in CLL, but so far their impact on the overall immune function in CLL patients after therapy, remains to be fully understood.
Aims: To evaluate the effect of the number of prior treatment lines received on the different normal circulating leucocyte cell populations, including normal B-cell subsets, in advanced-stage CLL patients (B/C Binet stages).
Methods: The distribution of peripheral blood (PB) leukocytes was analyzed in 128 untreated CLL patients, and compared to that of 83 patients who had previously been treated with 1 line of treatment (n=53) or >1 line of treatment (n=30), and who failed to respond. Analysis was performed by 8-color flow cytometry with monoclonal antibodies against CD3, CD4, CD5, CD8, TCRgd, CD19, CD20, CD27, CD38, CD45, CD56, sIgM, sIgA, sIgG, sIgLambda and sIgKappa.
Results: The absolute count of circulating malignant B cells was not significantly different (p>0.05) in the untreated *vs.* previously treated patients who received 1 or >1 treatment lines (83,081±87,956 *vs* 72,533±89,258 *vs* 63,764±85,153 cells/uL; respectively). In contrast, other prognostic parameters (proportion of cases in Binet C stage and degree of thrombocytopenia) were significantly lower in untreated *vs.* 2-lines treated patients. Also, as compared to untreated patients, PB normal B cells were reduced in patients who had received either 1 line or >1 lines of treatment (81±123 *vs* 38±61 and 56±154 cells/uL, p<0.001). When dissecting the normal B-cell subsets, therapy-related decreased B-cell numbers were mostly due to a reduced number of circulating memory B cells (62±86 *vs* 21±41 and 19±29 cells/uL; p<0.001), including all memory isotypes (p≤0.001): IgM (21±29 *vs* 6±12 and 6±10 cells/uL), IgG (23±51 *vs* 10±29 and 8±15 cells/uL) and IgA (17±27 *vs* 5±9 and 5±11 cells/uL). No differences (p>0.1) were found as regards the absolute count of immature (5±10 *vs* 7±24 and 7±20 cells/uL) and naïve B cells (13±46 *vs* 9±30 *vs* 30±120 cells/uL), nor for circulating plasma cells (5±29 *vs* 4±18 and 2±5 cells/uL), regardless of the therapy status. As compared to untreated patients, the absolute count of CD4+ T cells, CD4/CD8 double negative TCRαβ cells and neutrophils were significantly (p≤0.02) lower in patients previously treated with 1 or more lines of treatment (1,801±1,291 *vs* 1,446±1,308 and 1254±1014 CD4+ T cells/ul; 122±145 *vs* 159±649 and 63±94 CD4-CD8- T cells/uL and 5,432±3,337 *vs* 4,362±2,943 and 3,679±3,453 neutrophils/uL). In contrast, therapy did not show a significant impact on the absolute count of PB T CD8+ and TCRgd cells. No statistically significant differences (excluding neutrophils) were observed in the number of PB eosinophils, basophils, monocytes, NK cells and dendritic cells.
Summary and Conclusions: While there are no differences regarding the number of leukemic cells, previously treated patients have significantly reduced counts of total and memory (all isotypes) normal B-cell subsets when compared to untreated patients. Together with this, CD4+ helper and double negative T cells, as well as neutrophils, could also be compromised after treatment. Monitoring of these therapy-related immune defects could contribute to a better management of infectious complications in advanced-stage CLL patients.

P217

THE INFLUENCE OF BENDAMUSTINE USED ALONE OR IN COMBINATION WITH RITUXIMAB ON APOPTOSIS AND THE EXPRESSION OF SOME APOPTOSIS-REGULATING PROTEINS DEPENDING ON THE IGVH MUTATIONAL STATUS OF CLL CELLS

A Korycka-Wolowiec[1,*] E Ziolkowska[1], B Cebula-Obrzut[2], J Z Blonski[1], E Lech-Maranda[3], P Smolewski[2], T Robak[1]

[1]Department of Hematology, [2]Department of Experimental Hematology, Medical University of Lodz, Lodz, [3]Department of Hematology, Institute of Hematology and Transfusion Medicine, Warsaw, Poland

Background: Bendamustine (BENDA) used either alone or in combination with rituximab (RIT) is effective in the treatment of chronic lymphocytic leukemia (CLL). However, the influence of these drugs on the expression of apoptosis-regulating markers depending on IGVH mutational status has not been studied yet.
Aims: The aim of our study was to evaluate the influence of the above mentioned drugs on the expression of apoptosis-involved proteins depending on the IGVH mutational status of CLL cells *in vitro*.
Methods: The study was performed in 26 untreated CLL patients (11F, 15 M), aged 49-80 (mean 65.6) yrs who gave written consent for collection of the peripheral blood. The IGVH gene was mutated (IGVH+) in 13 patients, and unmutated (IGVH-) in 13 patients. Peripheral blood CD19+ cells at the concentration of 1.0x106 cells/ml were incubated in RPMI1640 medium containing 10% fetal calf serum and 10% autologous serum with addition of BENDA (40mg/ml), RIT (10mg/ml) or BENDA (40mg/ml)+RIT (10mg/ml), for 48 hours. Control cultures were incubated without the drugs. The influence of these drugs on the mitochondrial potential decrease ($\Delta\Psi_m^{low}$), the active forms of caspases-3,-9 and -8, the expression of BAX, PUMA, P53, APAF-1, BCL-2 and FADD proteins were evaluated by the flow cytometry.
Results: BENDA used alone and in combination with RIT statistically significantly increased the percentage of $\Delta\Psi_m^{low}$ cells (52.4% and 60.0%; respectively for IGVH+, and 60.7% and 62.8%; respectively for IGVH- group) as compared to the control culture (31.6%). However, an increase of the percentage of $\Delta\Psi_{m-}^{low}$ cells after the incubation with BENDA or BENDA+RIT was similar in both groups. The percentage of cells with expression of the active forms of caspases-3,-9,-8 in both groups was also significantly higher under the influence of BENDA or BENDA+RIT than after incubation with RIT or in the control culture. There were also no significant differences with regard to the mutational status. BENDA used alone and BENDA+RIT significantly increased the percentage of BAX+ cells as compared to the control culture and RIT alone. The percentage of PUMA+ cells increased significantly under the influence BENDA as compared to the control culture in IGVH+ group, whereas an increase of the percentage of these cells in IGVH- group was observed after BENDA+RIT as compared to either control culture or RIT used alone. Expression of P53 increased significantly under the influence of each of the drugs used alone as compared to the control culture, or BENDA and BENDA+RIT as compared to RIT. Additionally, BENDA increased the percentage of APAF-1 positive cells as compared to the control culture, but the differences were insignificant. There was no effect of these drugs on the BCL-2 and FADD expressing cells. There were also no differences in the influence of the drugs on the expression of the above mentioned apoptosis-involved proteins in both IGVH groups.
Summary and Conclusions: We demonstrated that BENDA used either alone or in combination with RIT induces apoptosis as well as expression of the apoptosis-involved proteins, regardless of the IGVH gene mutational status. However, the impact of IGVH mutational status on the BENDA-induced expression of apoptosis-regulating factors deserves further studies.
The work was supported by Mundipharma Research LtD grant.

P218

DECREASED DKK-1 LEVELS IN CHRONIC LYMPHOCYTIC LEUKEMIA AT INITIAL DIAGNOSIS MIGHT BE PREDICTIVE OF A HIGHER MORTALITY

GE Pamuk[1,*] MS Uyanik[1], ON Pamuk[2], U Tapan[3]

[1]Department of Hematology, [2]Department of Rheumatology, Trakya University Medical Faculty, Istanbul, Turkey, [3]Department of Internal Medicine, Tufts University School of Medicine, Steward Carney Hospital, Boston, Massachusetts, United States

Background: In addition to its various physiologic functions, the Wnt pathway also plays a role in tumorigenesis. Dickkopf-1 (DKK-1) binds with high-affinity to the Wnt coreceptor LRP6 domain. The clinical significance of Wnt pathway inhibition with DKK-1 was shown in various cancers; however, there is too few data in chronic lymphocytic leukemia (CLL) and nonHodgkin lymphoma (NHL). It was reported that the Wnt pathway had an antiapoptotic role; and that osteopontin (OPN) gene was directly targeted by Wnt.
Aims: In our study, we determined whether plasma levels of DKK-1 and OPN which have roles in the Wnt pathway were different in CLL and NHL patients than in healthy controls. In addition, we tested whether DKK-1 and OPN levels could be of clinical or prognostic importance in CLL and NHL.
Methods: We included 36 CLL patients (26 males, 10 females, mean age: 60.4±12.5), 24 NHL patients (17 males, 7 females, mean age: 54.3±16.4), and 21 healthy controls (13 males, 8 females, mean age: 55.7±8.3) into our study. Ethical committee approval and consent from all subjects were obtained. Patients' clinical and demographic features, treatment modalities, and response to treatment were obtained from hospital files. Blood was obtained from all patients at the time of initial diagnosis; DKK-1 and OPN levels in plasma were determined with ELISA.
Results: CLL patients (668.9±495.5 pg/mL) had significantly lower DKK-1 levels than NHL (978.9±263.7 pg/mL) and control groups (956.7±283.6) (p levels, respectively, 0.048 and 0.017). NHL and control groups had similar DKK-1 levels. OPN level was significantly higher in NHL group (5.7±9.4 ng/mL) than in CLL (1.37±1.15 ng/mL) and control groups (3.03±5.3 ng/mL) (p values, 0.017 and <0.001). CLL and control groups did not have significant difference in OPN

levels (p>0.05). CLL patients with early and late Rai stages of disease had similar DKK-1 and OPN levels. After a median follow-up of 48 months, 13 CLL patients died. When DKK-1 and OPN levels in initial plasma samples from CLL patients who have died were compared to those who were alive, it was observed that DKK-1 levels were significantly lower in the former group (449.3±365.5 pg/mL *vs.* 819.5±468 pg/mL, p=0.035). Among the NHL group, patients with extranodal involvement had significantly higher OPN levels than those with no involvement (9.1±13.3 ng/mL *vs.* 2.9±1.9 ng/mL, p=0.04).
Summary and Conclusions: Our results demonstrated that the Wnt pathway inhibitor DKK-1 was decreased in CLL; and lower levels were associated with higher mortality in CLL patients. OPN which is another protein related to Wnt pathway was increased in NHL and was associated with extranodal involvement. In order to reveal the pathogenic and clinical role of DKK-1 and OPN in CLL and NHL, larger studies need to be conducted.

P219

MRD ANALYSIS IN BONE MARROW ASPIRATE AT 3 MONTHS AFTER TREATMENT IS THE OPTIMAL RESPONSE ASSESSMENT FOR CLL AND CAN PREDICT SUSTAINED MRD-NEGATIVE REMISSION INDEPENDENT OF ADVERSE PROGNOSTIC MARKERS

A Rawstron[1,*] D Cohen[2], R de Tute[1], D Phillips[2], A Chalmers[2], L McParland[2], A Varghese[3], T Munir[3], P Hillmen[3,4]
[1]HMDS, St. James's Institute of Oncology, [2]Leeds Institute of Clinical Trials Research, University of Leeds, [3]Department of Haematology, St. James's Institute of Oncology, [4]Leeds Institute of Cancer and Pathology, University of Leeds, Leeds, United Kingdom

Background: The level of minimal residual disease (MRD) detected by sensitive quantitative assays is a strong independent predictor of progression-free and overall survival in CLL. Morphological assessment of trephine biopsies is a subjective analysis with significant patient discomfort and low sensitivity for detection of residual disease. There is usually a close correlation between the levels of CLL in the blood and bone marrow, raising the possibility that high sensitivity MRD analysis could be more informative in predicting outcome than morphological assessment of a bone marrow biopsy. However, therapeutic antibodies, including rituximab, preferentially deplete cells in the peripheral blood and are likely to compromise the prognostic value of peripheral blood MRD analysis during and soon after therapy.
Aims: To determine the optimal site and time point for response and residual disease assessment after chemo-immunotherapy.
Methods: Sensitive multi-parameter flow cytometry (1 CLL cell in 10^4 leucocytes) was performed in the peripheral blood (n=280) and bone marrow (n=337) at 3 months after treatment and at 12, 18 and 24 months after randomisation (evaluable in n=222, 190, and 148 respectively) in 415 participants in the UK FCR-based CLL Trials (ADMIRE and ARCTIC). Adverse prognostic features were defined as <2% IGHV mutation or deletion in 17p or 11q identified by FISH. Trephine biopsies were evaluated by two independent pathologists, with immunohistochemistry performed when lymphoid nodules were evident.
Results: Peripheral blood MRD levels at 3 months after treatment were >1% in 16/280 cases, of which 12/13 evaluable showed morphologically evident disease in the trephine biopsy. Blood MRD levels were <0.01% in 212/280 cases, of which 130/190 evaluable (68.4%) also had no detectable disease in the bone marrow by morphology or flow cytometry but disease was detected in the bone marrow in over a quarter of cases (Table 1). Bone marrow aspirate disease levels at 3 months after treatment were >1% in 49 cases of which 38/42 evaluable also showed morphologically evident disease. Aspirate MRD levels were <0.01% in 178/339 of which 147/178 had an assessable trephine biopsy and only 1/147 had morphologically evident disease. Sequential analysis of cases with <0.01% MRD in the bone marrow at 3 months after treatment demonstrated that 96% (132/138), 90% (114/126) and 89% (93/105) maintained <0.01% disease in the peripheral blood at 12, 18, and 24 months after randomisation respectively. Of all evaluable cases with adverse prognostic features, 62% (118/190) had detectable residual disease (>0.01%) within 12 months after randomisation compared to 34% (31/91) without adverse prognostic markers (P<0.0001). However, of the cases with adverse prognostic features who achieved <0.01% residual disease at 12 months after randomisation, CLL levels were persistently depleted (<0.01%) at the 2 year time-point in 85% (46/54) and this was not significantly different to the 91% (43/47) of cases without adverse prognostic markers who maintained <0.01% MRD at both time points (P=0.37).
Summary and Conclusions: The presence of >1% MRD in peripheral blood or bone marrow is equivalent to a partial response and assessment of a trephine biopsy provides little or no additional information. Peripheral blood evaluation within 6 months of treatment is less sensitive than bone marrow aspirate evaluation for the detection of residual disease. Approximately 80% of individuals achieving <0.01% MRD in the bone marrow at 3 months after treatment maintain an MRD-negative remission for the following 18 months, and this remains the most sensitive site and time-point for disease assessment after chemo-immunotherapy. Poor-risk prognostic features predict for a lower probability of achieving <0.01% MRD but the probability of maintaining a prolonged MRD-negative remission is similar in people with good-risk *vs.* adverse prognostic markers. This supports the concept that achieving deep depletion in frontline treatment can overcome adverse biological features.

Background: In CLL, subsets with stereotyped B-cell receptor immunoglobulins (BcR IG) represent a remarkable one-third of all cases. Intriguingly, CLL subset patients expressing certain stereotyped BcR IG have high intra-subset homogeneity regarding biological and clinical features as well as outcome. CLL subset #2, the largest subset overall, carries IGHV3-21/IGLV3-21 IG that virtually always bear somatic hypermutations (SHM), ranging from minimal or borderline (most frequently) to extensive (rarely).
Aims: Among 8593 CLL patients with available IG and clinicobiological information, we identified 254 (3%) cases classified as subset #2 that we characterized in detail.
Methods: Patient characteristics were as follows: 60% males; median age: 64; Binet stages B-C: 53%; SHM status: 61% IGHV-mutated (<98% germline identity, M-CLL), 39% IGHV-unmutated (U-CLL; only 2/254 cases with no SHM); FISH aberrations: isolated del(13q): 56% (47% in M-CLL *vs* 70% in U-CLL,

p=0.02) | trisomy 12: 4.7% | del(11q): 23% (23% in M-CLL *vs* 26% in U-CLL, p=0.8) | del(17p): 4.7%.
Results: No differences in time-to-first-treatment (TTFT) were found between U-CLL *vs* M-CLL subset #2 cases (19 *vs* 23 months, p=0.6). Interestingly, however, among the M-CLL, the presence of del(11q) was associated with significantly shorter TTFT (13 *vs* 29 months, p=0.03); no such differences were seen among U-CLL subset #2 cases, regarding the incidence of del(11q). We next compared subset #2 cases to 183 non-subset #2 IGHV3-21 (non#2/3-21) CLL cases and noted a significantly lower (p=0.002) SHM load with 53% of the non#2/3-21 cases (97/183) being U-CLL. Non#2/3-21 CLL also had significantly longer TTFT compared to subset #2 CLL (60 *vs* 19 months, p=0.001). This difference arose mainly from the superior outcome of non#2/3-21 cases with mutated IGs (median TTFT 153 months) since the TTFT of non#2/3-21 U-CLL, although longer, did not differ significantly from subset #2 (30 *vs* 19 months, p=0.4). No other major differences were found (genomic aberrations included). Within our cohort we also identified a minor group of 19 cases (0.2% of the series), termed subset #169, that express the IGHV3-48/IGLV3-21 gene combination, carry VH CDR3 identical in length and similar in composition to those of subset #2 IG and display an analogous SHM profile. Given the overall high identity (97%) between the IGHV3-21 and IGHV3-48 genes, we explored whether subsets #2 and #169, whose immunogenetic signatures are clearly related, share similar clinicobiological features and outcomes. Indeed, this turned out to be the case, since their FISH genomic profiles were similar, especially with regards to del(11q) (38% in subset #169) and del(17p) (absent in subset #169); as was their median TTFT (p=1). Of note, in an ongoing study from our group, subsets #2 and #169 display an almost identical (~45%) frequency of *SF3B1* mutations.
Summary and Conclusions: Altogether, we demonstrate that IGHV3-21 CLL should not be considered as homogeneous, with subset #2 emerging as uniformly aggressive, thus contasting non#2/3-21 patients whose prognosis clearly depends on SHM status like the rest CLL. We also argue that studying BcR stereotypy is relevant for improved understanding and eventual management of CLL through the identification of subsets with distinct features that can be expected to benefit from the implementation of specific treatments. Finally, we highlight for the first time the biological and clinical links between subsets with related immune signatures, raising the intriguing possibility that a higher-order organization of subsets based on their immunogenetic features will also be highly relevant.

P221

IMMUNOGLOBULIN HEAVY VARIABLE GENES AND ALLELES: NEW ENTITIES, NEW NAMES AND IMPLICATIONS FOR RESEARCH AND PROGNOSTICATION IN CLL

A Xochelli[1,*] A Agathangelidis[2], I Kavakiotis[3], E Minga[1], LA Sutton[4], P Baliakas[4], I Chouvarda[5], V Giudicelli [6]I Vlahavas[3], N Maglaveras[1,5], L Bonello[7], L Trentin[8], M Montillo[9], P Panagiotidis[10], C Geisler[11], AW Langerak[12], S Pospisilova[13], DF Jelinek[14], D Oscier[15], N Chiorazzi[16], N Darzentas[17], F Davi[18], P Ghia[2,19], R Rosenquist[4], A Hadzidimitriou[1,4], C Belessi[20], MP Lefranc[6], K Stamatopoulos[1,4,21]

Papanicolaou Hospital, Thessaloniki, Greece

Background: The development of novel sequencing technologies has led to a far more accurate view of the human genome. Indeed, recent findings have altered our notions regarding the configuration of immunoglobulin (IG) gene loci and the actual number of gene alleles, as described by the International ImMunoGeneTics information system (IMGT), the global reference in Immunogenetics and Immunoinformatics. Overall, 34 changes were incorporated in the latest version (3.3.0 reference directory release: 201408-4) of the IMGT/V-QUEST tool. Twenty of these changes concerned the identification and addition of new germline immunoglobulin heavy variable (IGHV) gene alleles (19 Functional and 1 Open Reading Frame), whereas the remaining 14 were due to the assignment of new allele names to the existing nomenclature system (13/14 Functional, 1 Open Reading Frame).
Aims: In CLL, the mutational status of the clonotypic rearranged IGHV gene is strongly associated with patient outcome. Correct determination of this parameter strictly depends on the comparison of the nucleotide sequence of the clonotypic rearranged IGHV gene with that of the closest germline counterpart. Consequently, changes in the reference directories could, in principle, affect the correct interpretation of the IGHV mutational status in CLL which is the focus of the present study.
Methods: In order to explore this issue, we analyzed 8337 IGHV-IGHD-IGHJ rearrangement sequences from CLL patients from our database with the IMGT/HighV-QUEST tool using two different versions of the IMGT/V-QUEST: version 3.2.32 (2 December 2013) *versus* version: 3.3.0 (20 February 2014) and compared the tool outputs.
Results: Differences due to change of the IGHV gene allele name were identified in 405 sequences (4.8%). In 291/405 (71.9%) of these cases, the germline identity (GI) remained the same, since the difference concerned only the renamed gene allele. In the remaining 114 (28.1%) cases, differences were also identified in% GI since a novel IGHV gene allele was recognized. Focusing on the IGHV mutational status and in keeping with previous reports, we subdivided our sequences into four different subgroups: truly unmutated (100% GI), minimally mutated (99-99.9% GI), borderline mutated (98-98.9% GI) and mutated (<98% GI). Overall, a change in the mutational status category was identified in 50 (0.6%) sequences, though never one that entailed crossing the 98% GI cut-off value used for prognostication in CLL. In more detail, 2 sequences moved from the mutated to the borderline mutated subgroup; 15 from the borderline mutated to either the truly unmutated (4/15) or the minimally mutated (11/15) subgroup; and 33 from the minimally mutated to the truly unmutated subgroup. Understandably, cases that were reported as truly unmutated from the previous IMGT/HighV-QUEST tool version were not affected. All 4 sequences that moved from the borderline mutated to the truly unmutated group were previously assigned to IGHV3-43*01 and are now assigned to the newly reported IGHV3-43D*01.
Summary and Conclusions: In conclusion, the recent addition of new germline IGHV gene alleles led to a number of changes concerning both IGHV gene nomenclature and germline sequence composition affecting the alignment output of the IMGT/HighV-QUEST tool. Given the prognostic value of somatic hypermutation status in CLL, both physicians and researchers should be alerted and re-evaluate sequence data, especially for those IGHV-IGHD-IGHJ gene rearrangements that up to date were considered as borderline mutated, where caution is warranted.

P222

AN ENTITY EVOLVING INTO A COMMUNITY: DEFINING THE COMMON ANCESTOR OF CLL SUBSET #4

LA Sutton[1,*] G Papadopoulos[2], A Hadzidimitriou[1,3], S Papadopoulos[2], E Kostareli[4,5], R Rosenquist[1], D Tzovaras[2], K Stamatopoulos[1,3,6]
[1]Department of Immunology, Genetics & Pathology, Science for Life Laboratory, Uppsala University, Uppsala, Sweden, [2]Information Technologies Institute, CERTH, [3]Institute of Applied Biosciences, CERTH, Thessaloniki, Greece, [4]Department of Otolaryngology, Head and Neck Surgery, University Hospital Heidelberg, [5]German Cancer Research Center (DKFZ), DKFZ-ZMBH Alliance, Heidelberg, Germany, [6]Hematology Department and HCT Unit, G. Papanicolaou Hospital, Thessaloniki, Greece

Background: CLL clones assigned to stereotyped subset #4 are characterized molecularly by B-cell receptor immunoglobulins (BcR IGs) that exhibit a series of distinctive immunogenetic features. More specifically, they are IgG-switched and composed of heavy chains encoded by the IGHV4-34 gene and light chains encoded by the IGKV2-30 gene. This distinctive BcR archetype expressed by subset #4 cases is itself significant owing to its absence from normal individuals or those with other lymphoproliferative disorders. The VH CDR3s of subset #4 BcR IGs are long and enriched in positively charged residues, reminiscent of pathogenic anti-DNA antibodies. Indeed, subset #4 is defined by a (K/R)RYY motif; a motif deemed to be not only 'CLL-biased' but also exclusive to subset #4. In addition, both the VH and VK domains of subset #4 demonstrate a high impact of somatic hypermutation (SHM) and are remarkable for carrying shared 'stereotyped' amino acid changes introduced by SHM. Subset #4 is also outstanding due to intense intraclonal diversification (ID) within the clonotypic BcR IG genes. By conducting a large-scale longitudinal study of subset #4 we previously: (i) established a hierarchical pattern of subclonal evolution, thus revealing which SHMs were negatively or positively selected; (ii) observed distinct clusters of subcloned sequences, with *e.g.* the minor ones often disappearing at later time-points and hence being selected against; and, (iii) noted that despite the high intensity of ID, certain residues remained essentially unaltered.
Aims: We here sought to revisit ID in subset #4 clones as a whole for the first time, and reconstruct their evolutionary history as a community of related clones profiled at different time-points.

Methods: We assessed both heavy and light chains (IGHV-IGHD-IGHJ rearrangements (n=511) and IGKV-IGKJ rearrangements (n=398) derived from 8 subset #4 cases. Sequence data was processed through application of the Damerau–Levenshtein distance, *i.e.* the number of changes required to transform one sequence to the other.
Results: Two important observations stemmed out of this analysis. Firstly, a number of clonal clusters from different patients were found to lie very close to one another due to a high degree of sequence relatedness, forming a core from which clusters that exhibited greater sequence variation stemmed from. This 'branching' could perhaps result from specific selective pressures that occurred in parallel in distinct subclones, thereby fine-tuning their BcR affinities. Secondly, minor clones from individual patients were found to have been mutated to such an extent that they now bore closer resemblance to the sequences of another patient. Viewing the entire subset #4 dataset as a single entity that has branched through diversification, facilitated reconstruction of its evolutionary history and enabled inference of a common ancestral sequence from which all subset #4 cases could have derived: ARGYADTAVVRRYYYGMDV, created by the association of the IGHV4-34 and IGHJ6 genes with the IGHD5-18 gene in reading frame 1. Of note, this task was hitherto unattainable due to the heavy SHM load within the antigen-binding sites, rendering the reliable identification of the IGHD gene particularly difficult if not altogether impossible.
Summary and Conclusions: These results have implications for improved understanding of the ontogeny of CLL subset #4, as well as the design of studies concerning the antigenic specificity of the clonotypic BcR IGs.

P223

MATCHED PATTERN DISCOVERY ACROSS PAIRED IMMUNOGLOBULIN HEAVY AND LIGHT CHAINS IN CLL REVEALS UNIQUE SUBSET-DEFINING AMINO ACID ASSOCIATIONS

LA Sutton[1,*] P Moschonas[2], A Vardi[3,4], V Bikos[5], XJ Yan[6], M Chatzouli[7], A Anagnostopoulos[3], C Belessi[7], N Chiorazzi[6], R Rosenquist[1], D Tzovaras[2], K Stamatopoulos[1,3,4], A Hadzidimitriou[1,4]
[1]Department of Immunology, Genetics and Pathology, Science for Life Laboratory, Uppsala University, Uppsala, Sweden, [2]Information Technologies Institute, CERTH, [3]Hematology Department and HCT Unit, G. Papanicolaou Hospital, [4]Institute of Applied Biosciences, CERTH, Thessaloniki, Greece, [5]CEITEC, Masaryk University, Brno, Czech Republic, [6]The Feinstein Institute for Medical Research, North Shore-Long Island Jewish (LIJ) Health System, Manhasset, New York, United States, [7]Hematology Department, Nikea General Hospital, Piraeus, Greece

Background: Immunogenetic analyses have helped to understand the pathogenesis of CLL and also to define subgroups with strikingly different behavior and outcome on top of unprecedented B-cell receptor (BcR) restriction (stereotypy), cementing the idea that antigenic elements select the leukemic clones. Even though recognition of certain antigenic epitopes may be critically dependent on conformations achieved by the interaction of both the IG heavy chain (HC) and light chain (LC) proteins, the focus to date has been on the IG HC gene, with studies on CLL IG LCs lagging behind. That said, previous studies from our group have demonstrated that CLL LCs can be as important as HCs, and that even very slight sequence alterations in LCs can be selected for and likely confer a functional advantage to the clone.
Aims: We here aimed to gain an even deeper view of CLL IG primary structures by searching for pattern associations between paired HC and LC gene rearrangements of 1331 CLL cases, the largest series to date, focusing on the main antigen-binding sites *i.e.* the HC and LC CDR3s.
Methods: We applied exhaustive amino acid pattern discovery that initially detected patterns within the VH and VK/VL CDR3s before associating these patterns with each other, either within the same chain (intra-association) or across chains (heavy-light inter-association).
Results: Overall, 14,544 patterns were discovered, of which 10,050 concerned the VH CDR3s; the remaining involved the VK (n=2528) or VL (n=1966) CDR3s, respectively. The discovered patterns varied in length from 1 to 22 amino acids. A total of 248,626 patterns were discovered with at least 2 occurrences across VH-VK chains, and 161,940 such patterns across VH-VL chains, being detected in 84.2% and 67.6% of the respective datasets. Starting from VH CDR3 patterns characteristic of stereotyped subsets, we explored whether certain VH/VK or VH/VL associations could be unique to particular subsets. We identified subset-biased and, most interestingly, subset-specific associations, *i.e.*, matched patterns that were restricted to specific subsets. Of note, several of the subset-specific associations concerned dipeptides or even single amino acids within the VH and VK or VL CDR3, respectively. Examples include: (i) Q at VH CDR3 position 4 and S at VK CDR3 position 5 was detected only in subset #1 (clan I IGHV genes/IGKV1(D)-39), being present in 54/55 cases (98.1%); (ii) RY at VH CDR3 positions 12-13 and M at VK CDR3 position 1 was detected only in subset #4 (IGHV4-34/IGKV2-30), being present in all 26 (100%) subset #4 cases; (iii) DV at VH CDR3 positions 8-9 and D/P at VL CDR3 position 8 was detected only in subset #2 (IGHV3-21/IGLV3-21), being present in 48/51 (94%) subset #2 cases.
Summary and Conclusions: In conclusion, we herein demonstrate that CLL stereotyped subsets can now be more accurately defined based on IG gene usage, CDR3 length and pivotal short amino acid patterns or, remarkably, even single residues with a precise offset in both the HC and LC chain CDR3s. This finding draws further molecular analogies between stereotyped BcR IGs and the IGs expressed by mouse B-1 cells, supporting the notion that at least certain CLL clones may be derived from a B cell population intermediary to a true innate immune system and the conventional adaptive B cell immune system and hence functionally similar to what has previously been suggested for mouse B-1 cells.

P224

FCΓRIIB INHIBITS BCR SIGNALING IN HUMAN NORMAL B CELLS BUT IS DISRUPTED IN CLL CELLS

R Bosch[1,*] G Ferrer[2], R Damle[3], S Jansà[2], E Bonvini[4], K Rai[5], E Montserrat[6], J Sierra[1], N Chiorazzi[7], C Moreno[1]
[1]Hematology, Hospital de la Santa Creu i Sant Pau, [2]Laboratory of Translational Hematology, Institute of Hematology and Oncology, Hospital Clínic, IDIBAPS, Barcelona, Spain, [3]Experimental CLL Research and Treatment Program, The Feinstein Institute for Medical Research Manhasset, New YorK, [4]Macrogenics, Inc., Rockville, MD, [5]Hematology/Oncology, Oncology LIJ Medical Center, Lake Success, NY, United States, [6]Hematology, Institute of Hematology and Oncology, Hospital Clínic, IDIBAPS,, Barcelona, Spain, [7]Experimental CLL Research and Treatment Program, The Feinstein Institute for Medical Research, Manhasset, NY, United States

Background: FcγRIIb is a low-affinity receptor that regulates B-cell activation by inhibiting signaling from the B-cell receptor (BCR) in murine normal B cells. BCR signaling is required for the survival and proliferation of human normal B cells and chronic lymphocytic leukemia (CLL) cells, but the role of FcγRIIb in these cells has been poorly studied.
Aims: To evaluate the expression and function of FcγRIIb in CLL and normal B cells.
Methods: We analyzed the expression of FcγRIIb on B cells from 85 patients with CLL and 14 healthy individuals by using a novel Alexa488-conjugated anti-human FcγRIIb mAb from Macrogenics, and evaluated the prognostic relevance of this receptor in patients with CLL. B cells were isolated from 18 CLL patients (9 *IgHV* mutated, 9 *IgHV* unmutated) and 10 healthy donors, co-cultured with HS-5 stromal cells, and stimulated with the following antibodies: $F(ab')_2$ fragments of polyclonal rabbit IgG anti-human IgM to induce BCR signaling, the undigested whole IgG rabbit anti-human IgM molecule to crosslink BCR and FcγRIIb, the unconjugated form of FcγRIIb mAb to stimulate FcγRIIb and two further combinations, FcγRIIb and $F(ab')_2$ and FcγRIIb and whole IgG antibody. Viability, activation and proliferation were analyzed by flow cytometry, and pSHIP and pAKT protein expression by Western Blot.
Results: The expression of FcγRIIb was significantly lower in leukemic cells than in CD19+CD5+ and CD19+CD5- normal cells (MFI 6901 *vs* 10180 and 12120, respectively; *p<0.01*). Patients with higher expression of FcγRIIb showed longer survival than those with lower FcγRIIb levels (7.8 *vs* 3.3 years, respectively; *p<0.01*). In normal B cells the co-ligation of BCR and FcγRIIb with the whole IgG form significantly decreased the activation and proliferation mediated by BCR. This inhibitory effect, however, was not observed when cells were stimulated either with the combination of FcγRIIb and $F(ab')_2$ or FcγRIIb and whole IgG antibody. With regard to CLL cells, the BCR-FcγRIIb coaggregation did not induce changes in cell activation and proliferation. However, this co-ligation was able to rescue the decrease of viability induced by BCR stimulation. We further observed that the effect of crosslinking BCR-FcγRIIb was significantly different in proliferation between unmutated and mutated CLL. A significant increase on proliferation was induced in unmutated cases while no effect was seen in mutated cases. At the molecular level, the co-ligation of BCR-FcγRIIb in normal B cells induced the upregulation of pSHIP and the downregulation of pAKT. Most CLL cells, however, showed high basal expression of pSHIP and no significant changes were observed in this protein after BCR-FcγRIIb co-ligation, although a slightly decrease of pAKT was observed. To date, no significant differences in pSHIP and pAKT expression were observed in mutated *vs.* unmutated cases.
Summary and Conclusions: Our results indicate that CLL cells show significantly lower expression of FcγRIIb than normal B cells. Furthermore, the function of FcγRIIb seems to be different when compared it in both populations. Thus, in normal B cells, FcγRIIb inhibits BCR signalling, an effect that clearly depends on its co-ligation with BCR, which triggers downstream signalling through SHIP and AKT. In contrast, in CLL cells, the co-ligation of FcγRIIb-BCR does not significantly inhibit BCR signalling, and particularly in unmutated CLL has a positive effect with an increase of BCR-mediated proliferation. All these findings support further investigation of FcγRIIb in the physiopathology of CLL.

P225

THE DUAL PI3K/MTOR INHIBITOR PF-04691502 INDUCES SUBSTANTIAL APOPTOSIS IN CHRONIC LYMPHOCYTIC LEUKEMIA CELLS INDEPENDENTLY OF PROGNOSTIC MARKERS

MD Blunt[1,*] M Larrayoz[1], M Aguilar-Hernandez[1], M Reynolds[1], J C Strefford[1], F Stevenson[1], F Forconi[1], G Packham[1], A J Steele[1]
[1]Cancer Sciences, University of Southampton, Southampton, United Kingdom

Background: CLL is currently incurable by chemotherapy alone with drug resistance and treatment relapse a common occurrence. Pharmacological targeting of dysregulated signalling pathways within CLL cells however, offers the potential to provide improved therapeutic options with reduced toxicity. In this regard, the PI3K-mTOR pathway is particularly attractive because it is activated upon ligation of various chemokine and cytokine receptors expressed by CLL cells as well as following B cell receptor engagement. PI3K mediated signalling is known to be overactive in all CLL, although patients with un-mutated IGHV have increased PI3K expression compared to patients with mutated IGHV. The PI3Kδ selective inhibitor Idelalisib (GS-1101) is currently in Phase 3 clinical trials for CLL and in combination with rituximab significantly improved overall survival among patients with relapsed CLL compared to rituximab alone. In addition to PI3Kδ, there are three other PI3K isoforms, PI3Kα PI3Kβ and PI3Kγ, with PI3Kα known to have a role in CLL survival and chemotaxis. It has previously been shown in neutrophils that functional redundancy between PI3K isoforms is evident, with inhibition of any three PI3K isoforms required for maximal apoptosis. In addition, pharmacological inhibition of mTOR is known to induce cell cycle arrest and apoptosis in CLL cells, however prolonged selective inhibition of mTOR results in a positive feedback loop and PI3K\Akt reactivation. To overcome these caveats, pan-PI3K and dual mTOR inhibition may achieve superior toxicity against CLL cells compared to PI3Kδ inhibition alone.
Aims: To investigate the effect of a dual PI3K and mTOR inhibitor, PF-04691502, on CLL cells.
Methods: Twenty six primary CLL samples were treated with PF-04691502 in the presence or absence of stromal cells and apoptosis assessed using propidium iodide/ Annexin V staining and PARP cleavage. The effect of PF-04691502 on B cell receptor and chemokine receptor induced signalling, survival and chemotaxis were assessed by immunoblotting and flow cytometry.
Results: PI3Kδ inhibition using Idelalisib *in vitro* resulted in 20% apoptosis of CLL cells after 24 hours at 10μM concentration, in contrast, PF-04691502 induced 80% apoptosis of CLL cells at 10μM concentration after 24 hours. PF-04691502 had an IC_{50} value of 1μM as assessed by propidium iodide and Annexin V staining, with little toxicity to normal B or T cells evident. Induction of apoptosis by PF-04691502 occurred independently of IGHV mutational status, CD38 expression and ZAP-70 expression. PF-04691502 inhibited both soluble and immobilised anti-IgM induced signalling and overcame anti-IgM stimulated survival signals. PF-04691502 inhibited CXCL12 induced signalling and abrogated CLL migration towards CXCL12 in a Transwell chemotaxis assay. Finally, PF-04691502 was able to overcome protection following co-culture with stroma and induced significant apoptosis of CLL cells when added continuously or in wash out experiments.
Summary and Conclusions: PF-04691502 is a novel dual PI3K/mTOR inhibitor which induces substantial apoptosis of CLL cells independently of prognostic markers and may be of value for the treatment of CLL patients.

P226

INDIRECT INDUCTION OF REGULATORY T CELLS ACCOMPANIES IMMUNE RESPONSES DURING VACCINATION OF CHRONIC LYMPHOCYTIC LEUKEMIA PATIENTS WITH SHORT, RHAMM-DERIVED, MHC-I-RESTRICTED PEPTIDE

J Zaleska[1,*] A Karczmarczyk[1], M Zajac[1], K Skorka[1], M Karp[1], M Grzywnowicz[1], W Tomczak[2], P Wlasiuk[1], A Dmoszynska[2], T Stoklosa[3], J Greiner[4,5], M Schmitt[6], K Giannopoulos[1,2]
[1]Experimental Hematooncology Department, [2]Department of Hematooncology and Bone Marrow Transplantation, Medical University of Lublin, Lublin, [3]Department of Immunology, Medical University of Warsaw, Warsaw, Poland, [4]Department of Internal Medicine III, Univeristy of Ulm, Ulm, [5]Hematology and oncology, Diakonie-Klinikum Stuttgart, Stuttgart, [6]Medical Clinic V (Hematology/Oncology/Rheumatology), University Clinic Heidelberg, Heidelberg, Germany

Background: The receptor for hyaluronic acid mediated motility (RHAMM) is a tumor-associated antigen in chronic lymphocytic leukemia (CLL). $CD8^+$ T cells primed with the RHAMM-derived epitope R3, which is restricted by HLA-A2, effectively lyse $RHAMM^+$ CLL cells. In phase I clinical trial of R3 peptide vaccination we proved safety and efficacy of specific induction of antitumor immune response against RHAMM antigen. In patients with clinical responses, we found increased frequencies of R3-specific $CD8^+$ T cells. Intriguingly, vaccination was associated with the induction of regulatory T cells (Treg) in four patients. This phenomena could be either interpreted as the result of effective induction of immune response that is followed by induction of suppressive mechanisms of immune system in an indirect manner or unexpected direct induction of Treg by short MHC I –restricted peptide. Both could result in reduced cytotoxic antitumor response limiting thereby clinical effectiveness of peptide immunotherapy. Recent findings also demonstrated specific Treg reduction after incubation with thalidomide both *in vivo* and *in vitro* providing a rationale to combine peptide vaccination with immunomodulatory drugs.
Aims: Define an influence of short MHC-restricted peptide R3 on Treg induction during vaccination in CLL patients.
Methods: Six HLA-$A2^+$ CLL patients were vaccinated four times at biweekly intervals with the R3 peptide emulsified in incomplete Freund's adjuvant and GM-CSF. Before and after each vaccine dose ELISA experiments were performed to assess IL-2 serum levels of 6 CLL patients and results were correlated with frequencies of Treg. Peripheral blood mononuclear cells were incubated with peptide R3 at concentration of 10 μg/mL and flow cytometry analyses of the frequency of Treg were evaluated after 1, 2 and 3 weeks of cell culture. To analyze suppressive potential of Treg mixed lymphocyte peptide cultures (MLPC) were performed. At day +21 of MLPC, cells were harvested and evaluated for their specific cytotoxicity in ELISpot assays. To characterize possible immunostimulatory effect of thalidomide able to restore immune response in this *in vitro* system, cell cultures were supplemented with thalidomide concentration of 10 μg/mL and specific release of interferon γ was assessed using ELISpot methodology.
Results: The IL-2 serum levels in CLL patients during vaccination strongly correlated with the frequency of Treg (r2=0.970, p<0.001). In *in vitro* experiments we observed no induction of Treg by R3 peptide both in CLL and HV after 7, 14 and 21 days of cell culture. However, we found statistically significant difference between Treg rates before cell culture in CLL patients and HV (13.88 *vs* 5.85, p=0.008). MLPC revealed suppressive Treg effect on R3-specific cytotoxic immune responses in 9 of 12 CLL patients. The addition of thalidomide to the MLPC resulted in the increase of specific immune responses against R3 epitope in only 2 of 8 patients.
Summary and Conclusions: There is no evidence on direct effect of short MHC class I epitopes on Treg induction during peptide vaccination. Increased frequencies of Treg in CLL could effectively inhibit immune responses against $R3^+$ target cells. In our *in vitro* system the addition of thalidomide to cell culture could effectively restore immune responses *in vitro* against $R3^+$ target cells only in limited numbers of patients. The induction of Treg during vaccination might result from activation of suppressive mechanisms of immune response; one of possible inducer could be IL-2 which increased concentrations after vaccination correlated with Treg. Future peptide vaccination schedules should be accompanied by drugs that limit Treg.

ANTI-ROR1 MONOCLONAL ANTIBODIES INDUCED APOPTOSIS OF CLL CELLS AND ALTERED PHOSPHORYLATION OF SRC AND PI3-KINASES

AH Daneshmanesh[1,*] M Hojjat-Farsangi[1], A Moshfegh[1], E Mikaelsson[1], AS Khan[1], A Österborg[2], H Mellstedt[2]
[1]Department of Oncology-Pathology, Cancer Center Karolinska, Karolinska Institute, [2]Department of Oncology (Radiumhemmet) and Hematology, Karolinska Institute and Karolinska University Hospital, Stockholm, Sweden

Background: Phosphoinositide 3-kinases (PI3Ks) are a family of lipid kinases playing an important role in the regulation of survival of cancer cells. In CLL cells, the PI3K pathway is constitutively activated. Activation of PI3Ks in cancer occurs via different mechanisms. Mutation, amplification or overexpression of upstream receptor tyrosine kinases (RTKs) is such a mechanism. The class IA PI3K p110 catalytic subunits are activated upon Src homology 2 domain-mediated binding of the p85 regulatory subunits to tyrosine phosphorylated motifs in RTKs. In CLL and AML the p110-δ subunit (p110δ) is shown to be the predominant isoform of PI3K. Increased p110δ activity has also been seen in colon and bladder cancers, as well as in glioblastomas. Src proteins are activated in various cancers such as colon, liver, lung, breast and pancreas. Phosphorylation of Src proteins induces survival, proliferation and invasion of cancer cells. ROR1 is a type I transmembrane RTK, overexpressed and constitutively phosphorylated in CLL cells. ROR1 mediated Src phosphorylation triggered activation of AKT in lung carcinoma.
Aims: To study the effect of an anti-ROR1 CRD mAb on apoptosis and phosphorylation of Src and PI3Kδ in CLL.
Methods: Cell lysates were prepared from untreated and anti-ROR1 CRD mAb treated CLL samples and subjected to Western blot analysis for identification of total and phosphorylated Src, PI3K p85 isoform and PI3Kδ. Apoptotic effect of anti-ROR1 mAb on CLL cells was assayed by MTT and Annexin, V/PI in 24 h. ROR1 expression was determined by flowcytometry and Western blot. Phosphoproteins were measured before incubation with the mAb and after 20 min-24 h.
Results: The percentage of $ROR1^+$/CLL cells was 77±4% (mean±SEM) (range: 70-89%). The frequency of apoptotic cells induced by the anti-CRD mAb was in the range of 40-62% (mean±SEM: 48±2%). The difference compared to CLL cells with isotype control was highly statistically significant (p<0.0001). Western blot analysis showed that co-culturing of CLL cells with the anti-ROR1 CRD mAb decreased the level of phosphorylated Src. PI3Kδ (p110δ) as well as PI3K p85 isoform but not the p55 isoform, were dephosphorylated in treated as compared to untreated samples
Summary and Conclusions: Incubation of CLL cells with an anti-ROR1 CRD mAb induced apoptosis of primary CLL cells. Apoptosis was preceded by dephosphorylation of Src, PI3K p85 isoform, and PI3Kδ proteins indicating deactivation of these signaling proteins by the anti-ROR1 mAb. p110 (PI3Kδ) phosphorylation is mediated by Src and p85 recruitment increases the catalytic activity of the p110 subunit. Our data may suggest that binding of anti-ROR1 CRD mAb to ROR1 RTK might induce an inhibitory signal, decreasing phosphorylation of the Src protein leading to dephosphorylation of the PI3K p85 isoform thus abrogating p85 recruitment. This might lead to inactivation of the PI3K catalytic subunit (p110) preventing the signal transmission of pathways

downstream of PI3K. Further studies are warranted to better understand the signaling pathways associated with ROR1 and downstream signaling effects of ROR1 targeting drugs.

Background: Prospective identification of patients with chronic lymphocytic leukemia (CLL) destined to progress would greatly facilitate their clinical management. Recently, whole-genome DNA methylation analyses identified three clinico-biological CLL subgroups with an epigenetic signature related to different normal B-cell counterparts.
Aims: To develop a clinically-applicable method to identify these three new subgroups and to study their clinical relevance.
Methods: Using a linear discriminant analysis, we built a prediction model using five epigenetic biomarkers that was able to accurately classify CLL patients into the three subgroups, namely naive B cell-like, intermediate and memory B cell-like CLL. DNA methylation was quantified by highly reproducible bisulfite pyrosequencing (BPS) assays in two independent CLL series.
Results: In the initial series (n=211), the three subgroups showed differential levels of *IGHV* mutation ($P<0.001$) and *VH* usage ($P<0.04$), as well as different clinical features and outcome in terms of time-to-first-treatment (TTT) and overall survival ($P<0.001$). A multivariate Cox model showed that epigenetic classification was the strongest predictor of TTT ($P<0.001$) along with Binet stage ($P<0.001$). These findings were corroborated in a validation series (n=97).
Summary and Conclusions: In this study, we developed a simple and robust method using epigenetic biomarkers to categorize CLLs into three subgroups with different clinico-biological features and outcome.

P229

IDENTIFICATION AND FUNCTIONAL CHARACTERIZATION OF TUMOR SPECIFIC ANTIBODY RESPONSES IN CHRONIC LYMPHOCYTIC LEUKEMIA

V Griggio[1,2,*] G Mandili[2], C Vitale[1], M Capello[2], M Robino[1], M Rigoni[1], M Foglietta[1], B Castella[1], P Sciancalepore[1], ME Canepari[1], F Novelli[2], M Boccadoro[1], M Massaia[1], M Coscia[1]
[1]Division of Hematology, [2]Molecular biotechnology and health sciences - Center for Experimental Research and Medical Studies, University of Torino, Torino, Italy

Background: Chronic lymphocytic leukemia (CLL) is characterized by extreme clinical and biological variability. Several phenomena of immune dysfunction and autoimmunity have been described in CLL but little is known about antibody (Ab) immune responses.
Aims: This study aims at understanding the functional role of humoral responses in CLL and specifically at 1) identifying circulating Ab in CLL pts' sera; 2) characterizing tumor antigens (Ag) recognized by serum Ab and 3) evaluating whether the identified immune responses have a cytotoxic effect toward leukemic cells.
Methods: Proteins from CLL cells were separated to obtain proteomic maps which were blotted with autologous sera to reveal Ab-based reactivity. To verify the CLL-specificity of recognition, 8 pts maps were also probed with sera of 8 healthy donors (HD). Ag spots were identified by Mass Spectrometry (MS). Ag surface expression on viable and apoptotic cells was evaluated by flow cytometry after 4 days of culture. C4 deposit was evaluated by flow cytometry. Complement-dependent cytotoxicity (CDC) was performed incubating CLL cells alone or in presence of alemtuzumab and subsequently with CLL pts' sera for 1h at 37°C. Cell viability was evaluated by Annexin-V/Propidium Iodide assay. Disease progression was evaluated according to IWCLL/NCI-WG 2008 guidelines for CLL. Statistical correlations were performed using t-test, Mann-Withney rank sum test and 2-test.
Results: Sera obtained from 35 untreated CLL pts were individually screened for the presence of IgG-based reactivity against autologous proteins extracted from leukemic cells. As a control, sera obtained from 8 HD were probed on as many CLL maps. Overall, the number of spots produced from the 35 CLL sera was significantly higher than the number produced by the 8 HD sera (145 *vs* 3, respectively; p=.007). MS analysis allowed the identification of 50 proteins that were recurrently recognized by pts sera. The 5 most frequently recognized proteins were ENOA, CAZA1, G3P, ODPB, GDIR2. Sera from 29 out of 35 CLL pts exhibited immunoreactivity. Among these, 69% were polyreactive and recognized up to 20 Ag. Pts with progressive CLL showed a significantly higher number of spots compared to pts with stable disease (p=.031). Sera from 54% of pts exhibited reactivity toward ENOA, whereas none of the HD sera was ENOA-reactive. Flow cytometry revealed that ENOA was not expressed on the surface of CLL B cells at baseline conditions. We observed that ENOA surface expression was significantly increased on the apoptotic fraction of CLL cells (p=.008) but not on viable fraction after 4 days of culture. ENOA Ab-reactivity significantly correlated with higher number of leucocytes, higher lymphocytosis and lower platelet count (always p<0.01). The presence of specific anti ENOA-, G3P-, GDIR2- Ab was significantly correlated with the status of progressive disease (p=.02). We therefore evaluated whether the humoral responses identified by SERPA were capable of trigger CDC. Results from CDC assay demonstrated that there was no deposit of the C4 component on CLL cells surface and that CLL sera had no cytotoxic effect toward leukemic cells.
Summary and Conclusions: In this study we identified tumor Ag capable of eliciting humoral responses in CLL. Circulating Ab identified by SERPA in most pts' sera were not able to induce CDC toward leukemic cells and the Ab-based reactivity correlated with parameters of disease progression. Our results suggest that the immunoreactivity against self-Ag may be the expression of a dysfunctional immune system in CLL.

RAPID DETERMINATION OF SOMATIC HYPERMUTATION STATUS OF IMMUNOGLOBULIN HEAVY CHAIN GENES USING NEXT GENERATION SEQUENCING AND LYMPHOTRACK™ BIOINFORMATICS

Y Huang[1,*] K Hutt[1], R L Ringler[1], J Panganiban[1], JE Miller[1], J Thornes[1], M Klass[1]
[1]Invivoscribe Technologies, Inc., San Diego, United States

Background: During B-cell development, genes encoding the *IGH* molecules are assembled from V, D, and J gene segments to generate V-D-J combinations of unique length and sequence in each cell. Since leukemias and lymphomas originate from the malignant transformation of individual lymphoid cells, they generally share one or more of these cell specific or "clonal" gene rearrangements. After gene rearrangement, normal B cells undergo somatic hypermutation (SHM) in germinal centers in an antigen driven process designed to generate additional diversity within the antigen binding CDR3 regions. The cells then undergo further selection as part of a process termed affinity maturation. The presence of SHM is defined as ≥2% difference from the germline V gene sequence. SHM status provides important prognostic information for patients with chronic lymphocytic leukemia (CLL). Presence of SHM is associated with better prognosis. Sequencing of IGH provides information on variable segment usage, and, in specific instances, clinical outcomes can be further predicted based on V gene usage. Specifically, presence of V3-21 portends a worse prognosis independent of mutation status or other prognostic indicators. The gold standard method used to determine SHM status requires two steps: a PCR/capillary electrophoresis (CE) based method to detect clonality, followed by Sanger sequencing to establish SHM status. This approach is labor intensive and time consuming.
Aims: Develop a sensitive, robust and reliable NGS assay with bioinformatics tools for identifying clonal *IGH* gene rearrangements, specific clonal V-J sequences, and SHM status.
Methods: Invivoscribe's MiSeq formatted SHM Assay employs two master mixes. One amplifies the genomic DNA between the upstream leader (VHL) region and the downstream joining (J) region of the IGH gene. The other amplifies from the framework1 (FR1) to J region. Amplicon products from VHL/J primers span the entire variable (V) region, including the FR1, CDR1, FR2, CDR2, FR3, and CDR3 regions. Amplicon products from FR1/J primers encompass portions of the FR1 region to the downstream J region. Multiplexed PCR is followed by amplicon purification using the AMPureXP PCR system. The purified equimolar amounts of amplicons are pooled to form a library. A portion of the library is loaded onto the MiSeq sequencing system and sequenced using the MiSeq v3 Reagent kit (600 cycles). The MiSeq data is analyzed using Invivoscribe LymphoTrack™ bioinformatics software which generates frequency distributions, identifies V-J DNA sequences, V-J gene usage, and determines the SHM status.
Results: This assay demonstrated excellent linearity ($R^2>0.95$), sensitivity (<1%) and reproducibility using contrived samples. Both the SHM results obtained from this assay, as well as V3-21 status, were concordant with data from traditional methods using gel extraction and Sanger sequencing. CLL samples tested with this assay demonstrated excellent agreement with clinical outcomes.
Summary and Conclusions: A comprehensive NGS assay has been developed for the Illumina MiSeq platform that identifies clonal IGH V-J rearrangements and associated specific V-J region DNA sequences. The assay can be used to determine the SHM status in CLL specimens and provide frequency

distributions of V region and J region segments important in detecting IGH V3-21, an independent determinant of poor prognosis in CLL.

P231

CONCORDANCE IN IGH & TRG CLONALITY TESTING: COMPARISON OF DATA GENERATED USING THE MISEQ & PGM PLATFORMS.

NC Adams[1,*] GM Pawlowsky[1], Y Huang[2], K Hutt[2], AR Cubbon[1,3], M Klass[2], J Miller[1,2,3]
[1]LabPMM GmbH, Martinsried, Germany, [2]Invivoscribe Technologies, Inc., [3]LabPMM LLC, San Diego, United States

Background: Assays that identify clonal lymphocyte populations in clinical specimens are used on a routine basis to assist in the detection of lymphoproliferative disease. Sensitive assays that identify antigen receptor loci-specific V-J gene rearrangement DNA sequences in clinical samples are proving to be powerful tools for evaluating the efficacy of therapeutics, aiding in the detection of initial clonal populations, and identifying sequence information required to track those clones in subsequent samples. PCR-based methods with amplicon detection by capillary electrophoresis have long been the gold standard for clonality testing. However, these methods often do not provide sufficient sensitivity and, without separate sequencing steps, do not provide the data required to identify the specific V-J DNA sequences required to track clones in follow up testing. The emergence of massively parallel sequencing (MPS) platforms has facilitated development of powerful new approaches for detecting and monitoring clonality. Here we present data on the analytical performance of Invivoscribe's LymphoTrack™ assays and associated bioinformatics on two popular MPS platforms.
Aims: To develop NGS assays for T and B cell clonality detection utilizing TRG and IGH gene rearrangements respectively and to further demonstrate the concordance of their results on both the PGM and MiSeq platforms.
Methods: Genomic DNA from peripheral blood, tonsil and bone marrow aspirates were tested for *TRG* and *IGH* gene rearrangements. Optimized V and J consensus primers targeted all *IGH* and *TRG* V and J region gene segments that are rearranged in lymphoid malignancies. Multiplex PCR master mixes were used to amplify *IGH* or *TRG* V-J gene rearrangements separately. On the Illumina platform the libraries for IGH and TRG assays and products were routinely combined and run on the same MiSeq run. For PGM formatted assays separate PCRs were used to generate amplicon for reads in each direction. The amplicon libraries were combined prior to the emulsion PCR step. PGM amplicon products were purified, quantified, pooled and the harmonized libraries were loaded onto the OneTouch 2. The enriched emulsion PCR libraries were sequenced using the Ion 316 Chip Kit v2 and Ion PGM Sequencing 400 Kits. MiSeq libraries were quantified and harmonized then loaded directly onto the MiSeq. Data from both instruments were analyzed using Invivoscribe's LymphoTrack™ bioinformatics software run on a standard Windows computer.
Results: Cell line DNA serially diluted into polyclonal tonsil DNA confirmed the linearity and low run-to-run variance of the assay on both platforms. Both PGM and MiSeq formatted assays analyzed using the LymphoTrack, ^{TM}, bioinformatics software package reproducibly identified clonality and DNA sequences for each *TRG* and *IGH* V-J gene rearrangement. Automated data outputs from paired samples on both platforms were concordant demonstrating equivalent results between platforms, as well as platform-specific intra- and inter-assay reproducibility. When coupled with the LymphoTrack, ^{TM}, bioinformatics and visualization software these assays provide robust detection and enhanced data-rich outputs.
Summary and Conclusions: Data from both platforms are equivalent and can be used to identify clonal lymphocyte populations by their unique DNA sequence, which can be subsequently used to track clones in follow up testing. Having access to both platforms allows laboratories to adapt workflow according to testing needs and throughput.

P232

THE GENE EXPRESSION RESPONSE TO INTERLEUKIN-4 AND ITS DIFFERENTIAL MODULATION BY NFKB CORRELATE WITH ZAP70 IN CHRONIC LYMPHOCYTIC LEUKEMIA

N Ruiz Lafuente[1], MJ Alcaraz Garcia[1], S Sebastian Ruiz[1], J Gomez Espuch[1], C Funes[1], JM Moraleda[1], MDC Garcia Garay[2], N Montes Barqueros[1], A Minguela[1], AM Garcia Alonso[1], MR Alvarez Lopez[1], A Parrado[1,*]
[1]Hospital Clinico Universitario Virgen de la Arrixaca, Murcia, [2]Hospital General Universitario Santa Lucia, Cartagena, Spain

Background: In chronic lymphocytic leukemia (CLL), interactions of the malignant B lymphocytes with microenvironment play a crucial role in disease progression. Interleukin 4 (IL-4), an essential mediator of B cell development, induces signaling cascades that lead to activation of transcription factors STAT6 and NFkB, affecting proliferation, differentiation and survival.
Aims: The aims of this study were to compare the gene expression changes induced by IL-4 in CLL and in normal B cells (NBC), and to determine how these are affected in CLL by inhibitors of the IL-4 pathway.
Methods: The gene expression profiles (GEPs) of the B cells from 23 patients and 13 controls were performed by oligonucleotide microarrays including ~ 40 000 probe sets designed to cover the whole human genome. The basal GEPs, and the GEPs of cells cultured with nothing, were used as references for comparison with the GEPs of cells cultured with IL-4. An one-way ANOVA test with post hoc analysis was used to identify the IL-4 targets, defined as genes significantly up-regulated or down-regulated by IL-4 with respect to the two references ($p<0.05$, 2-fold cut-off). Real time RT-PCR was performed for target validation. The effect of the NF-kB activation inhibitor 6-Amino-4-(4-phenoxyphenylethylamino)quinazoline on specific IL-4 targets was studied in selected patients.
Results: Sets of 232 non-redundant entities in CLL and 146 in NBC (95 common, 283 altogether), of which 189 were well-defined genes in CLL and 123 in NBC (83 common, 229 altogether) were identified as IL-4 targets. To the best of our knowledge, most of them were novel IL-4 targets for CLL (98%), B cells of any source (83%), or any cell type (70%). The intensity of their responses was significantly higher for 54 genes in CLL compared to NBC, and for 11 genes in NBC compared to CLL ($p<0.05$). In CLL, the response of a substantial part of the genes correlated positively or negatively with expression of ZAP70, and these were designated $ZAP70^{Pos}$ genes or $ZAP70^{Neg}$ genes. Wnt signaling, regulation of epithelial to mesenchymal transition, and cell adhesion, were associated to $ZAP70^{Pos}$ genes, whereas oxidative stress regulation, and angiogenesis were associated to $ZAP70^{Neg}$ genes. The response of most $ZAP70^{Pos}$ genes to IL-4 was downregulated by an NFkB activation inhibitor, and the response of most $ZAP70^{Neg}$ genes to IL-4 was upregulated by the inhibitor, suggesting a novel mechanism by which NFkB sinergizes or antagonizes the response of specific genes to IL-4.
Summary and Conclusions: Sets of novel and specific IL-4 targets were identified in CLL and NBC. A relationship between IL-4, ZAP70 expression and NFkB inhibition suggests a novel mechanism for regulating gene expression in CLL. Our study support that strategies directed to the IL-4 pathway may be of therapeutic interest.

Background: Fludarabine, cyclophosphamide and rituximab (FCR) is the gold standard treatment for patients with CLL who require therapy and are considered fit for fludarabine based treatment. FC has been delivered intravenously previously but in the UK the oral route of administration for F and C is standard. Here we report higher rates of complete remission and MRD negativity in 207 patients treated with oral FCR in two parallel phase IIB NCRI trials (ADMIRE and ARCTIC).

Aims: To assess the efficacy of oral FCR control arm of ARCTIC and ADMIRE trial.

Methods: ARCTIC and ADMIRE were two phase IIB randomised controlled trials in the same patient population of untreated CLL conducted between June 2009-September 2012. ADMIRE recruited 215 patients from 29 UK research centres; ARCTIC recruited 200 patients from 35 UK research centres. Both trials had the same FCR control arm (n=207) but different experimental arms. FCR treatment included IV rituximab given on day 1 (375mg/m^2 Cycle 1; 500mg/m^2 Cycles 2-6), oral fludarabine (24mg/m^2/day for 5 days) and oral cyclophosphamide (150mg/m^2/day) for 5 days repeated every 28 days. ADMIRE compared FCR to FCM-R (addition of mitoxantrone to FCR) while ARCTIC compared FCR to FCM-miniR (addition of low dose rituximab to FCM). Patients with neutropenia delaying therapy received G-CSF (lenograstim 263mcg/day; Days 7-13) on all remaining cycles. Prophylaxis with co-trimoxazole and acyclovir was used. For both trials, the primary endpoint was complete response rates (CR/CRi); short-term secondary endpoints included MRD eradication, overall response rates (ORR) and safety.

Results: A total of 207 patients were randomised to the oral FCR control arms in ADMIRE and ARCTIC. The median age was 62 (38-77) and 35.7% were over 65; 72.5% male; 15.9% progressive stage A, 48.3% stage B and 35.7% stage C. 16.4% had a creatinine clearance under 60ml/min. 66.3% (114/172) had unmutated Ig genes; 7.0% (13/186) 17p deletion; and 14.4% (27/187) 11q deletion. 87.4% (181/207) of patients received greater than 3 cycles of treatment with 73.4% (152/207) receiving all 6 cycles. 102 (51.5%) of 198 received G-CSF during treatment. 132 (63.8%) patients experienced a dose modification. Of the assessable 187 patients, 137 (73.3%) achieved CR/CRi and 187/193 (96.9%) achieved at least a PR. MRD by flow cytometry (sensitivity 10^{-4}) was assessed in marrow 3 months post treatment, 58.1% (108/186) of assessable patients had undetectable MRD (108/186).

Summary and Conclusions: The response rates (CR/CRi and MRD eradication) to FCR given orally in 207 patients in ARCTIC and ADMIRE are much higher than previous multicentre studies of intravenous therapy. We report response rates of 73.3% for FCR and 69.7% for the whole cohort of 415 patients. This compares favourably to CR rates of 38% for FC in LRF CLL4 Trial and 44% for FCR in the GCLLSG CLL8 Trial. MRD in the marrow was undetectable in 58.1% of patients receiving FCR in control arm and 53.1% in the whole cohort. The overall response rate was 96.9% (CR/CRi+PR) in FCR control arm and 96.2% in the whole cohort. Explanations that may contribute to this improved efficacy maybe that: the (1) FC chemotherapy is spread over 5 rather than 3 days per cycle; (2) dose intensity and timing was prospectively supported by the use of G-CSF (51.5% patients) which along with appropriate dose modification enabled ¾ of patients (73.4%) to receive 6 cycles of FCR; and (3) patients received prophylaxis with co-trimoxazole and aciclovir. Our results suggest that FCR is more effective when given orally with greater convenience to patients and reduced cost justifying the use of this oral regimen.

DEVELOPMENT AND VALIDATION OF COMPREHENSIVE CLL MUTATION DETECTION PANEL USING ION TORRENT NEXT GENERATION SEQUENCING PLATFORM

A Lozanski[1], I Flinn[2], M Davis[1], J Byrd[1], G Lozanski[3,*]

[1]Internal Medicine, The Ohio State University Comprehensive Cancer Center, Columbus, OH, [2]Sarah Cannon Research Institute, Nashville, TN, [3]Pathology, The Ohio State University Wexner Medical Center, Columbus, OH, United States

Background: Mutations of multiple genes have emerged as important risk stratification and prognostication indicators in chronic lymphocytic leukemia (CLL). These mutations affect a heterogeneous population of genes involved in a wide variety of functions including sensing of DNA damage, DNA repair, signal transduction and spliceosome assembly and function. Several of these mutations show an association with poor response to certain types of therapy in CLL. Moreover, some of these mutations are absent at initial presentation and appear rapidly in a subset of patients who become therapy resistant or show disease progression including those with Richter's transformation. These findings create a need for a rapid, reproducible and sensitive method for mutation identification occurring on a sub clonal level obtained at initial presentation and during therapy allowing for "real time monitoring" of high risk CLL patients involved in clinical trials. Considering the high number of mutations and that some of these mutations show a wide distribution throughout large genes such as ATM, the Sanger sequencing method currently used in most clinical laboratories is not suitable for such rapid analysis.

Aims: To address this method challenge, we developed and validated a comprehensive CLL focused mutation analysis panel using Next Generation Sequencing/Ion Torrent platform.

Methods: A CLL focused mutation panel was developed using the AmpliSeq design site. The following genes were included: ATM, BIRC3, BRAF,BTK, CCND1, CCND2, CRM1, DDX3X, ERK1, ERK2, FBXW7, KLHL6 exon1, KRAS, MDM2 snp309, MYD88, NOTCH1 exon34, TP53, PLCG2,SF3B1, SMARCA2 and ZMYM3 with in silico coverage 98.9% of targeted sequence. Barcoded libraries were prepared in two pools using 15ng of DNA derived from isolated CLL cells from baseline samples of 64 patients with previously untreated CLL treated on a Sarah Cannon Research Institute clinical trial. Following standard processing, samples were analyzed on the Ion Torrent using 316 and 318 chips. Raw data was analyzed by Ion Torrent Server Suite v.3.6.2. Calls were made using variant Caller v3.6.63335 using Somatic Low Stringency setting. Coverage analysis was performed using Coverage Analysis v.3.6.633324. For a subset of specimens, multiple runs were performed to evaluate reproducibility and precision.

Results: With the exception of NOTCH1 exon34 and MDM2 snp309 (that will be reported separately) all 64 samples were successfully analyzed with an average depth of 685 (range 308 to 2123) and average uniformity of 90% (range 65.8 to 95.3). Comparison of in silico and analytical runs showed highly concordant on target coverage of 98.1% (range 96.3-99.4). Detected mutations and SNPs were observed with expected frequencies consistent with those reported in the literature and SNP databases. There was 100% complete agreement between multiple runs of samples analyzed in separate experiments. Complete analysis of 5 samples of DNA performed by a single technologist was reproducibly achieved in 5 working days.

Summary and Conclusions: The Ion Torrent platform based NGS comprehensive CLL mutation detection panel as noted above allows for the rapid, accurate, reproducible and sensitive detection of multiple mutations a in large number of genes. After further validation in a clinical CLIA certified molecular laboratory (ongoing) this approach will offer real time analysis of mutations of multiple genes in high risk CLL patients participating in clinical trials to help guide appropriate initial therapy and modification of therapy during treatment.

P235

PHASE 1 STUDY OF SINGLE AGENT CC-292, A HIGHLY SELECTIVE BRUTON'S TYROSINE KINASE (BTK) INHIBITOR, IN RELAPSED/REFRACTORY CHRONIC LYMPHOCYTIC LEUKEMIA (CLL)

[13]Robert H. Lurie Comprehensive Cancer Center, Feinberg School of Medicine, Northwestern University, Chicago, [14]Celgene Corporation, Summit, [15]Celgene Corporation, Berkeley Heights, [16]University of California, San Diego, Moores Cancer Center, La Jolla, United States

Background: CC-292 is an oral, highly selective small-molecule covalent inhibitor of Btk, which plays an important role in the biology of B-cell malignancies.
Aims: This phase 1 trial investigated the safety, dose limiting toxicities (DLT), and activity of single agent CC-292, administered once (QD) or twice daily (BID) to pts with relapsed or refractory (R/R) CLL and NHL. Here, we focus on the safety and clinical activity in CLL and small lymphocytic lymphoma (SLL) pts.
Methods: Eligible pts with R/R CLL/SLL after ≥1 prior therapy received CC-292 at doses of 125, 250, 400, 625, 750, and 1000mg QD or 375 and 500mg BID. As the maximum tolerable dose was not reached, CLL pts were enrolled in two expansion cohorts at 750mg QD and at 500mg BID. All pts received continuous dosing in 28-day cycles until progressive disease or intolerable toxicity. Clinical activity was investigator assessed per 2008 IwCLL criteria. This analysis reports safety and efficacy on all pts enrolled as of cutoff date 12-31-2013.
Results: A total of 84 CLL/SLL pts were evaluated across all doses for safety, including 29 and 28 CLL pts at 750mg QD and 500mg BID, respectively, in the expansion cohorts. Median age was 66.5 (34–89) and median number of prior therapies was 3 (1–12). 56 (67%) pts had ≥1 high risk factor, including 45 (54%) with unmutated IgHV, 18 (21%) with del11q22, and 20 (24%) with del17p. Median time on therapy was 254 days (16–797). Only one CLL patient at the 500mg BID dose level experienced a DLT (grade 4 thrombocytopenia) during Cycle 1. Otherwise, grade 3/4 adverse events (AEs) occurring in ≥2 pts in the 750mg QD, 1000mg QD, 375mg BID, and 500mg BID dose cohorts included pneumonia (17%), febrile neutropenia (7%), diarrhea (7%), neutropenia (5%), thrombocytopenia (5%), fever (5%), sepsis (4%), anemia (4%), respiratory failure (3%), and confusion (3%). Overall, 67 SAEs were observed in 37 pts; 21 SAEs were deemed possibly related to CC-292. Results are summarized for 70 efficacy-evaluable pts at dose levels 750mg QD, 1000mg QD, 375mg BID, and 500mg BID (29, 7, 6, 28 pts, respectively). The PR rate at the 4 dose levels was 34%, 57%, 67%, and 39%, respectively. In addition, PR with lymphocytosis was achieved by 7 (24%) pts at the 750mg QD dose level and 6 (21%) pts at the 500mg BID dose level. In pts with del11q, del17p, unmutated IgVH, and no high-risk genomic factors, the PR rates were 46% (6/13), 47% (7/15), 61% (20/33), and 27% (6/22), respectively. 87% of pts experienced a ≥25% increase in absolute lymphocyte count (ALC), which usually resolved with continued treatment. Importantly, nodal responses were induced in the majority of pts receiving BID dosing (375mg: 67%; 500mg: 61%) with lymph node size reduction over time from cycle 2 (mean reduction of 42% and 40%, respectively) to cycle 7 (mean reduction of 60% and 60%, respectively). At time of data cut, 41%, 43%, 83%, and 73% of pts were still on study at dose levels 750mg QD, 1000mg QD, 375mg BID, and 500mg BID, respectively.
Summary and Conclusions: CC-292 is well tolerated as an oral daily monotherapy. Single-agent therapy with CC-292 is sufficient to achieve high nodal and partial response rates in R/R CLL pts, including those with high-risk cytogenetic features. These results support continued development of CC-292 for the treatment of pts with CLL/SLL. Two Phase 1b studies of CC-292 in combination with lenalidomide or rituximab, respectively, are ongoing to determine safety and tolerability, evaluate preliminary efficacy, and ascertain whether these combination regimens might improve outcomes in CLL pts.

P236

PRE-TREATMENT WITH IDELALISIB MARKEDLY REDUCES RITUXIMAB INFUSION-RELATED REACTIONS AND INFUSION INTERRUPTIONS IN PATIENTS WITH CLL

P Hillmen[1,*] RR Furman[2], SE Coutre[3], JP Sharman[4], JM Pagel[5], JC Barrientos[6], AD Zelenetz[7], TJ Kipps[8], I Flinn[9], P Ghia[10], HA Eradat[11], N Lamanna[12], B Coiffier[13], A Pettitt[14], W Ye[15], TM Jahn[15], R Dubowy[15], SM O'Brien[16], MJ Hallek[17], BD Cheson[18]

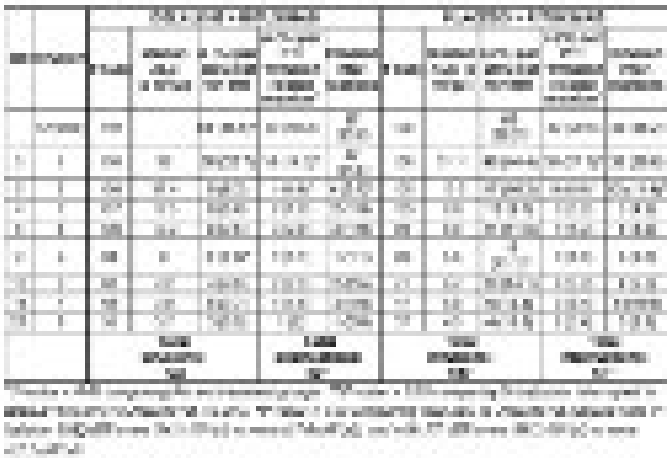
Background: Rituximab (R) and other anti-CD20 antibodies are important agents in the treatment of CLL. However, infusion-related reactions (IRRs) during the first infusion of R in patients with CLL have been reported to occur as frequently as 94% (O'Brien 2001), presenting a significant medical burden. IRRs may be more frequent in patients with high absolute lymphocyte counts (ALCs) (Winkler 1999). The combination of the oral selective inhibitor of PI3Kδ idelalisib with R has been demonstrated to be highly active in heavily pretreated patients with CLL in a Phase 3 trial (Furman, NEJM 2014).
Aims: As PI3Kδ is expressed in various cell types that may be involved in cytokine release and response, we assessed if IDELA has an effect on the frequency of R IRRs.
Methods: A Phase 3 double-blinded study evaluated IDELA+R *vs* placebo+R in pts with relapsed CLL who experienced progression within 24 months since completion of the last therapy and who were considered unfit to receive cytotoxic therapy. R was administered at 375 mg/m^2 (1st dose) and then at 500 mg/m^2, every 2 weeks for the next 4 doses and then every 4 weeks for a total of 8 doses. Infusion premedication as recommended by the protocol included an antipyretic and an antihistamine; local procedures often also included steroids. Per protocol, the 150 mg standard dose of idelalisib/placebo (150 mg BID) was recommended to be administered 30 minutes before the start of each R infusion. IRRs were analyzed in two ways: 1) per MedDRA preferred term (PT) "infusion-related reaction" (PT-IRR), and 2) per any adverse event (AE) starting on the day of infusion and on the list of Standardised MedDRA Queries (SMQ) as related to IRRs (SMQ-IRR). The data presented are from an exploratory analysis based on an interim analysis of the Phase 3 study.
Results: 220 subjects were randomized 1:1 and 218 received at least one dose of rituximab, 110 with IDELA and 108 with placebo. 99.7% of infusions were preceded by premedication. The Table 1 depicts the frequencies of the IRRs, along with the respective median absolute lymphocyte count (ALC). On both arms, IRRs were most common after the 1st and 2nd R infusions. Placebo+R subjects who experienced dose #1 infusion reactions had higher ALCs than those who didn't ($p<0.05$). Subjects on IDELA+R experienced significantly fewer ($p<0.05$) PT-IRRs during the 1st and 2nd infusions despite a 3.5 fold higher median ALC at the 2nd infusion. In addition, when comparing the overall incidence of SMQ-IRR AEs, subjects on IDELA+R experienced significantly fewer ($p<0.05$) events. Fewer infusion interruptions were required in the IDELA+R arm than in the placebo+R arm (5.8% *vs* 11.1%, $p<0.05$). Gr 3 IRR AEs were reported for 3 infusions (in 3 subjects) in those receiving IDELA and for 7 infusions (in 5 subjects) in those receiving placebo.

Table 1.



Summary and Conclusions: In this randomized double-blinded Phase 3 study, IDELA treatment given only 30 minutes before R reduced the frequency of IRRs and infusion interruptions. This protective effect was even more marked with the second R infusion when subjects had been receiving IDELA for 2 weeks, despite a 3.5-fold higher ALC in the IDELA group. This finding is consistent with the known mechanism of action of IDELA, and indicates that IDELA reduces the significant burden of IRRs in patients receiving R, and could potentially do so with newer generation anti-CD20 antibodies.

P237

SEVERE INFECTIONS ARE MORE COMMON IN PHYSICALLY FIT CLL PATIENTS WITH FCR-THERAPY COMPARED TO BR: RESULTS OF THE INTERMIN-ANALYSIS OF THE CLL10 TRIAL OF THE GERMAN CLL STUDY GROUP

P Langerbeins[1,*] R Busch[2], CD Schweighofer[1], C Müller[1], P Cramer[1], AM Fink[1], G Fätkenheuer[1], P Hartmann[1], S Stilgenbauer[3], S Böttcher[4], CM Wendtner[5], M Hallek[1], B Eichhorst[1]
[1]Department I of Internal Medicine, University Hospital Cologne, Köln, [2]Institute of Medical Statistics and Epidemiology, Technical University Munich,

Munich, [3]Department III of Internal Medicine, University Hospital Ulm, Ulm, [4]Second Department of Medicine, University Hospital of Schleswig-Holstein, Campus Kiel, Kiel, [5]Department I of Internal Medicine, Klinikum Schwabing, Munich, Germany

Background: Infections are common complications in CLL patients correlating with immune defects caused by the disease itself as well as treatment-related immunosuppression. Fludarabine, cyclophosphamide and rituximab (FCR) as first-line treatment is associated with a higher risk of infection compared to bendamustine plus rituximab (BR).
Aims: This analysis was performed to prospectively assess frequency, characteristics and risk factors of infections in advanced CLL during and after first-line with FCR *versus* BR in physically fit patients.
Methods: Within the multicenter phase-III CLL10 trial detailed information on the incidence of infections were prospectively evaluated. Except for PCJ-prophylaxis in longer lasting neutropenia the protocol did not recommend routine anti-infective prophylaxis during and after chemoimmuntherapy.
Results: 561 patients were included in the study, 282 (50.3%) were randomised to the FCR and 279 (49.7%) to the BR arm. Median observation time was 27.9 months. 395 (70.4%) of all patients developed an infection. A total of 1050 infections were reported and 26.2% were defined as severe (CTC grade 3-5). When comparing the different treatment arms significantly more patients treated with FCR developed an infection (53.2 *vs.* 46.8%, p=0.034) and infections were more severe (29.8 *vs.* 21.3%, p=0.002). The average number of infections in all affected patients was 2.6. Median time from registration to onset was 4.6 months in the FCR-group compared to 5.0 months in the BR-group. Late infections occurred significantly more in the FCR-treated patients after initial response (23.8 *vs.* 10.7%, p<0.000) and final restaging (19.8 *vs.* 10.8%, p=0.008). The causative pathogen was identified as bacterial in 15.7%, as viral in 14.8%, as fungal in 2%, and as other in 2.3%. The pathogen was unknown in 66.8%. Viral infections were significantly more common in patients treated with FCR (20.8% *vs.* 12.3%, p=0.007). 13.9% of all infections were classified as fever of unknown origin, followed by pneumonia in 8.9%, and bacteremia in 3%. Severe pneumonia was more frequently observed in patients treated with FCR (32 *vs.* 17, p=0.027). Antibiotic treatment was administered in 76.1% of all documented infections, followed by antiviral, and antifungal treatment in 15.3, and 4.6% respectively. G-CSF was administered in 85 (8.3%) cases and was significantly more frequently given with FCR treatment (10.8 *vs.* 4.8%, p=0.001). Inpatient treatment was necessary in 141 and intensive care treatment in 12 patients, there was no significant differences in both treatment arms. Six patients in the BR arm and seven patients in the FCR arm died due to treatment related infectious complications. Pneumonias and sepsis were the reason for death in five patients each; one patient each died because of neutropenic colitis, hepatitis B and progressive multifocal leukencephalopathy.
Summary and Conclusions: Infections are more frequently observed in CLL patients treated with first-line FCR than BR. The causative pathogen is rarely detected and infections occur rather late during the course of treatment. In conclusion we recommend anti-infective prophylaxis in neutropenic patients during first-line chemoimmuntherapy.

P238

LATE ONSET NEUTROPENIA IS A COMMON COMPLICATION OF FLUDARABINE, CYCLOPHOSPHAMIDE AND RITUXIMAB (FCR) THERAPY AND IS ASSOCIATED WITH SUBSTANTIAL MORBIDITY AND HOSPITALIZATION

P Ho[1,*] S Romero[1], TE Lew[2], P Turner[1], J Seymour[3], C Smith[4], D Carney[3], A Grigg[1], C Tam[3]
[1]Clinical Haematology, Austin Health, [2]Faculty of Medicine, Nursing and Health Sciences, Monash University, [3]Clinical Haematology, Peter MacCallum Cancer Centre, [4]Austin Pathology, Austin Health, Melbourne, Australia

Background: Neutropenic complications, including late-onset neutropenia (LON), are known to complicate FCR chemotherapy. However, the incidence, clinical significance and risk factors for LON remain unclear.
Aims: Determine the incidence and risk factors for the development of haematological complications associated with FCR.
Methods: We performed a retrospective analysis of 104 consecutive patients (pts) who received FCR treatment across 2 major cancer centres between 01/2004 and 11/2012, in order to determine the incidence, clinical consequence and risk factor for development of neutropenic complications (a) during therapy, and (b) in the first year after treatment completion. Eight-six pts received follow-up at their primary treatment center, with a minimum of 3 complete blood count over the 12 month study period. LON was defined as grade III-IV neutropenia (G3-4N) developing at least four weeks after cessation of therapy. Severe prolonged cytopenias are defined as grade III-IV cytopenias persisting for >4 weeks post completion of treatment.
Results: DURING THERAPY: the median age of the 104 pts (71M, 33F) was 66 years (range: 40-83). 69 received FCR for CLL; 35 for low-grade non-Hodgkin lymphomas. 44 previously untreated and 60 had prior chemotherapy [median 2 (range 1 – 6) regimens]. The median number of FCR cycles received was 4 (range: 1-6), and 16 pts received maintenance rituximab. G3-4N occurred in (43%), and febrile neutropenia in 20% of pts (5.8% per cycle). ONE YEAR POST THERAPY: Of the 86 pts assessable, LON was documented in 25 (29%) after a median of 95 (range 53-326) days from treatment cessation. The median LON neutrophil count was $0.4x10^9$/L (range: 0.0-0.9). LON was associated with substantial morbidity: 28% of pts were hospitalized for neutropenic complications and 32% were administered antibiotics and G-CSF. There was no significant association between the risk of LON development and age, ECOG, disease subtype, previous therapy, number of FCR cycles, maintenance rituximab, baseline hemoglobin / neutrophil / platelet or baseline creatinine. However, there was a positive association between LON and the occurrence of G3-4N during treatment: of those pts who developed G3-4N during therapy (n=35), LON developed in 15 (43%; p=0.017 compared with 19% in pts without G3-4N, Figure 1); this risk of LON rises to 57% for pts who developed G3-4N and received GCSF support. Among pts who did not develop G3-4N during treatment, female sex emerged as the dominant risk factor for LON (33% risk, *vs* 13% for males, p=0.07). Prolonged severe cytopenias occurred in 20 pts and similarly was more common in women (p<0.001) and those with grade 3-4N during treatment (p-0.005).

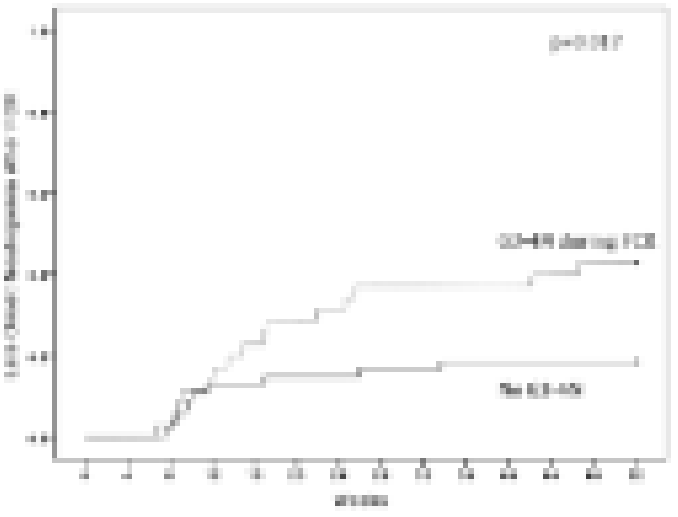


Figure 1.

Summary and Conclusions: Neutropenic complications, particularly LON, is an under-recognized and poorly reported complication of FCR. LON in pts receiving FCR is associated with high morbidity and frequent hospitalization. Pts who develop G3-4N during FCR chemotherapy are at high risk of subsequent LON, particularly if their chemotherapy was supported using GCSF. Our results demonstrate that the onset of G3-4N during FCR chemotherapy identifies pts at high risk for late neutropenic complications, and sound a cautionary note regarding the use of GCSF support during FCR therapy.

P239

EFFECT OF IDELALISIB/RITUXIMAB COMBINATION TREATMENT OF RELAPSED CLL ON THE BCR SIGNALING-RELATED CHEMOKINES CCL3 AND CCL4: DATA FROM A PHASE 3, RANDOMIZED, DOUBLE-BLIND, PLACEBO-CONTROLLED TRIAL

[1]Università Vita-Salute San Raffaele and Istituto Scientifico San Raffaele, Milano, Italy, [2]Stanford Cancer Center, Stanford University School of Medicine, Stanford, [3]Weill Cornell Medical College, New York, [4]Georgetown University Medical Center, Washington, [5]Fred Hutchinson Cancer Research Center, Seattle, United States, [6]The Leeds Teaching Hospitals, St. James Institute of Oncology, Leeds, United Kingdom, [7]Hofstra North Shore-LIJ School of Medicine, Hempstead, [8]Memorial Sloan Kettering Cancer Center, New York, [9]University of California School of Medicine, San Diego, San Diego, [10]Sarah Cannon Research Institute, Nashville, United States, [11]University of Cologne, Cologne, Germany, [12]Lyon Sud University Hospital, Pierre-Bénite, France, [13]University of Texas MD Anderson Cancer Center, Houston, United States, [14]Ulm University, Ulm, Germany, [15]Gilead Sciences, Foster City, [16]Willamette Valley Cancer Institute and Research Center/US Oncology Research, Springfield, United States

Background: Idelalisib (IDELA) is a potent and selective inhibitor of PI3Kδ, which is critical for activation, proliferation and survival of B cells and their homing and retention in lymphoid tissues. Inhibition of PI3Kδ modulates BCR signaling as well as signaling through cytokine and chemokine receptors. Data

generated both *in vitro* and in clinical studies have demonstrated that IDELA reduces the levels of CCL3 and CCL4 (MIP-1α/β) (Hoellenriegel *et al.*, Blood, 2011), two chemokines secreted by CLL cells in response to BCR activation. Importantly, high levels of CCL3 and CCL4 have been associated with shorter PFS in CLL and therefore have been suggested as BCR-related risk factors with cut-off levels for negative prognosis of >10 pg/mL and >60 pg/mL, respectively (Burger *et al.*, Trends in Immunology 2013).

Aims: This report describes the effect of IDELA treatment on CCL3 and CCL4 levels in patients enrolled in a randomized, placebo controlled phase 3 study.

Methods: GS-US-312-0116 is a phase 3, randomized double-blind placebo-controlled study evaluating the efficacy and safety of IDELA in combination with rituximab (R) for previously treated CLL. The plasma levels of CLL3 and CCL4 were assessed at baseline (BL) and at Week 4 (Wk4) of treatment with IDELA+R or placebo+R. CLL3 and CCL4 quantification was performed by EMD Millipore, at St. Charles, MO, USA, using a bead-based enzyme-linked immunosorbent assay.

Results: As shown in the Table 1 below, there was a prominent reduction of CCL3 and CCL4 plasma levels in patients on IDELA+R after 4 weeks of treatment. The reduction in CCL3 and CCL4 levels at Wk4 was superior with IDELA treatment (82.7% mean decrease from BL; median level of 11.9 pg/mL for CCL3 and 63.5% mean decrease from BL; median level of 35.7 pg/mL for CCL4) as compared to placebo (24.3% mean decrease from BL; median level of 53.2 pg/mL for CCL3 and 21.3% mean decrease from BL; median level of 74.0 pg/mL for CCL4). This difference was highly significant (p-value <0.0001). In addition, 37% and 47% of patients with BL levels above the respective negative prognosis cut-offs for CCL3 and CCL4, reached levels below the cut-off at Wk4 of IDELA+R treatment. In comparison, on placebo+R, only 4% and 12% of patients, respectively, achieved such a reduction.

Table 1.

Summary and Conclusions: The results from this prospective, placebo-controlled study confirm that in patients with CLL, treatment with IDELA rapidly and prominently reduces the levels of chemokines related to activated BCR signaling. Moreover, as high levels of CCL3 and CCL4 have been suggested as BCR-related risk factors in CLL, the rapid normalization of their levels may contribute to the strong clinical benefit observed with IDELA and other emerging novel therapies that inhibit BCR signaling.

P240

B2-MICROGLOBULIN IS A DYNAMIC MARKER OF PROGNOSIS DURING TREATMENT OF CLL WITH FCR OR IBRUTINIB-BASED REGIMENS.

PA Thompson[1,*] MJ Keating[1], JA Burger[1], N Jain[1], A Ferrajoli[1], Z Estrov[1], SM O'Brien[1], WG Wierda[1]
[1]Department of Leukemia, UT MD Anderson Cancer Center, Houston, United States

Background: In CLL, free plasma β_2-microglobulin (B2M) correlates with disease stage and tumor burden. Elevated B2M at diagnosis is independently associated with shorter time-to-first therapy and when treatment is required, is independently associated with poorer progression-free and overall survival. While the significance of initial B2M is established, changes in B2M during therapy and associations with patient outcomes have not been explored.

Aims: We analyzed patients (pts) treated on investigational protocols with FCR and ibrutinib-based regimens (Ib) at MDACC from 2008-2013, to determine whether patterns of change in B2M differed according to treatment protocol and would be predictive of outcome.

Methods: Patients treated with FCR or Ib (Ib monotherapy, n=35, Ib+rituximab, n=37 or Ib+bendamustine+rituximab, n=11), between 2008 and 2013 were eligible for inclusion, provided they had ≥3 months of follow-up, a baseline B2M level and at least one other B2M measurement. Follow-up B2M measurements were not mandated in these studies and were performed according to individual physician practice. The following variables were analyzed: B2M at 6 months (where available), lowest level achieved and time to B2M normalization or nadir.

Results: Baseline characteristics were as follows:

Characteristic	Ib-based (n=83), n(%)	FCR (n=198), n(%)	P value
Age (median, range)	65 (35-83)	59 (32-79)	0.02
B2M ≥4.0	47 (57)	82 (41)	0.02
Rai Stage III/IV	47 (57)	80 (40)	0.01
IGHV MS			
Unmutated	58 (75)	106 (54)	<0.001
Mutated	9 (12)	71 (36)	
ZAP70+	48 (71)	119 (65)	0.43
17p-	35 (42)	11 (6)	<0.001

There was no correlation between B2M at baseline, 6 months or nadir and any other baseline characteristic, except Rai stage. B2M fell rapidly during Ib-treatment despite a transient lymphocytosis during this time. Despite a higher median baseline B2M, and higher-risk genetic features, similar rates of normalization of B2M were seen for pts treated with Ib-based regimens and FCR (63.9 *vs.* 67.2). 88% of treatment-naïve Ib-treated pts normalized their B2M (p=0.04 *vs* FCR). When only patients with >1 year of follow-up were analyzed (to avoid bias from shorter follow-up in the Ib patients), median time to normalization or nadir was shorter for Ib than FCR: 335 *vs.* 433 days, p=0.001 for Ib *vs.* FCR). Landmark PFS analysis was performed from the date of B2M nadir; normalization of B2M was associated with superior PFS in both Ib and FCR-treated pts (see Figure 1). This remained significant when stratifying for pts with baseline B2M <4.0 or ≥4.0. Achieving minimal residual disease (MRD) negativity by flow cytometry in FCR-treated pts is associated with superior survival. When only FCR pts achieving MRD-negativity were analyzed (n=112), a trend remained for improved PFS in pts who also normalized of B2M (n=83) *vs.* those who did not (n=29), p=0.08.

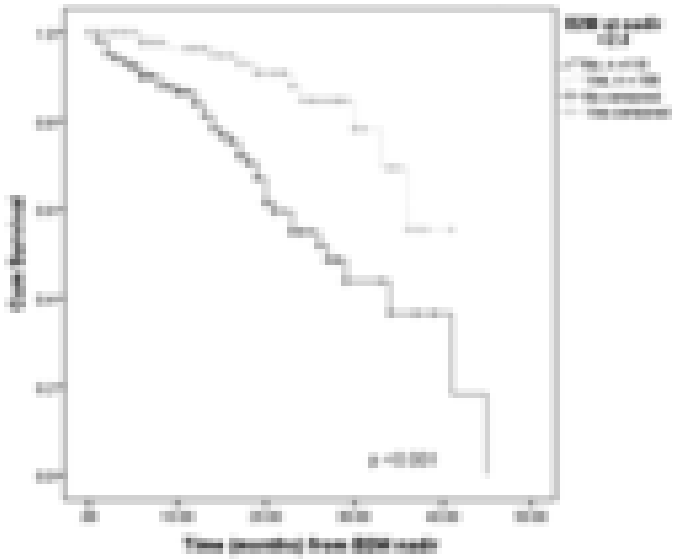

Figure 1. Landmark PFS from B2M nadir in all patients.

Summary and Conclusions: A more rapid and complete normalization of B2M level was observed with Ib treatment than with FCR, the reasons for which are unclear. B2M evaluated during treatment is a robust tumor marker and normalization of B2M was associated with improved PFS in both Ib- and FCR-treated pts. Serial B2M assessment may be particularly useful in Ib-treated patients to identify patients early who are at higher risk of relapse, especially as utility of MRD assessment is limited due to low rates of CR. Its ability to further subdivide patients achieving MRD-negativity after FCR requires further study. We intend to confirm these results in Ib-treated patients prospectively in a 200 patient study of Ib *vs.* Ib+rituximab.

FIRST-LINE TREATMENT STRATEGIES FOR PREVIOUSLY UNTREATED PATIENTS WITH CHRONIC LYMPHOCYTIC LEUKAEMIA: PRELIMINARY RESULTS OF A NETWORK META-ANALYSIS

M Rancea[1], N Skoetz[1], S Trelle[2,3], BR da Costa[2], A Engert[4], K Fischer[4], M Hallek[4], B Eichhorst[4,*]
[1]Department I of Internal Medicine, University Hospital of Cologne, Cochrane Haematological Malignancies Group, Cologne, Germany, [2]Institute of Social and Preventive Medicine, [3]Clinical Trials Unit, University of Bern, Bern, Switzerland, [4]Department I of Internal Medicine, University Hospital of Cologne, Center of Integrated Oncology, Cologne/Bonn, Germany

Background: Chronic lymphocytic leukaemia (CLL) accounts for 25% of cases and is the most common lymphoid malignancy in Western countries. This disease affects predominantly elderly patients with a median age of 72 years at diagnosis. The highly variable course of CLL leads to a variety of therapy options for patients needing treatment. Chlorambucil (Clb) was considered standard first-line therapy for many years, but the implementation of newer treatment options have increased patient-related outcomes in comparison to Clb.
Aims: To assess the efficacy of different first-line therapy regimens and to provide a hierarchy of the best treatment options for previously untreated patients with CLL.
Methods: Sensitive search strategies for CENTRAL, EMBASE, and MEDLINE (1946 to 02.2014) were conducted to identify randomized controlled trials (RCTs). Furthermore, relevant conferences (ASCO, ASH, EHA) were searched up to 2013 and the German CLL Study Group provided unpublished data. RCTs that compared at least one treatment regimen to another regimen or to observation only in previously untreated CLL patients were included. Two authors independently assessed studies for their eligibility, extracted data, and assessed the quality of the trials according to the methodology standards of the Cochrane Collaboration. Overall survival (OS) and progression-free survival (PFS) were regarded as primary endpoints, secondary endpoints included treatment-related mortality and secondary malignancies. A Bayesian random-effects model was used for the network meta-analysis, combining head-to-head trials with indirect evidence. The results are reported relatively to Clb, a hazard ratio (HR) >1 indicating superiority of Clb.
Results: The sensitive search resulted in 6,871 relevant references, of which data from 33 RCTs were included. The final network was constructed from 21 different first-line treatment regimens and comprised a total of 11,638 patients. Overall, the quality of the evidence was judged as moderate. Data from 18 different regimens were available for analysis of OS in comparison to Clb. Seven regimens had a more than 50% probability to be better than Clb. Obinutuzumab (GA101) plus Clb (HR 0.41, 95% credible intervals (Crl) 0.22 to 0.78) showed the highest probability to be better than Clb. Treatment with Clb-rituximab (R) (HR 0.66, 95% Crl 0.33 to 1.32) showed a probability of 88%, bendamustine (B)-R (HR 0.64, 95% 0.30 to 1.44) of 87% and treatment with fludarabine, cyclophosphamide, rituximab (FCR) (HR 0.76, 95% Crl 0.47 to 1.27) reached a probability of 86% to be better than Clb. Regarding PFS, GA101 plus Clb (HR 0.18, 95% Crl 0.05 to 0.67) had a 99% probability to be better than Clb, followed by FCR (HR 0.42, 95% Crl 0.15 to 1.13) with a probability of 96%. Subgroup analysis for patients in Binet stages B/C only showed similar results for OS and PFS. Overall, the between trial heterogeneity was low τ^2=0.016 for OS. Results regarding treatment-related mortality and secondary malignancies will be awaited (Figure 1).

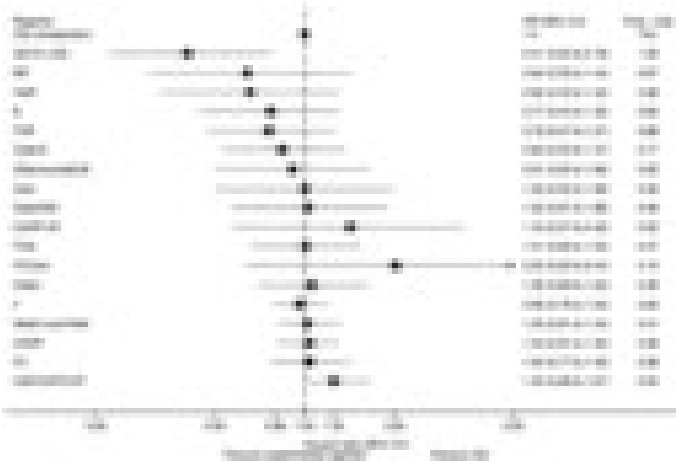

Figure 1.

Summary and Conclusions: This network meta-analysis shows a statistically significant improvement in OS following treatment with GA101 plus Clb for treatment-naïve patients with CLL. Also, FCR, BR and Clb-R shows a high probability to be better than Clb alone regarding OS. These results were similar for PFS. However, patients characteristics of the included trials were heterogeneous (fit *versus* less fit patients). Longer follow-up results of newer recent trials will give further information for patient-related outcomes.
This project was funded by the Federal Ministry of Education and Research, grant number: 01KG1015.

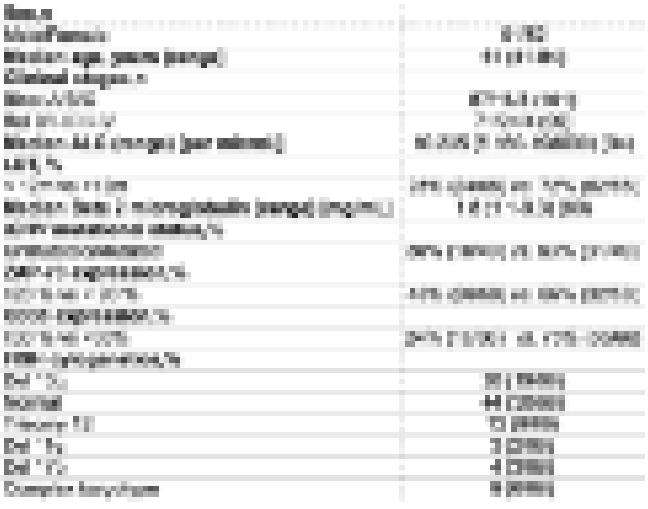
P242

CHRONIC LYMPHOCYTIC LEUKEMIA: A SMALL PROPORTION OF LONG-TERM SURVIVORS COULD ACTUALLY BE CURED

C Moreno[1,*] R Bosch[1], CA del Villar[1], C González[2], N Vilalta[1], M Martinez de Sola[1], M Granell[1], S Novelli[1], S Saavedra[1], S Miqueleiz[1], J Briones[1], S Brunet[1], A Garrido[1], A Esquirol[1], I García[1], A Aventín[3], J Nomdedéu[3], R Martino[1], J Delgado[4], J Sierra[1]
[1]Hematology, [2]Hospital Sant Pau I Santa Creu of Barcelona, Barcelona, Spain, [3]Laboratory of Hematology, Hospital Sant Pau I Santa Creu of Barcelona, [4]Hematology, Hospital Clinic, Barcelona, Spain

Background: Progress in the general management and treatment of patients with CLL has resulted in a longer overall survival. There is little information however on whether such an improvement is due to the favorable characteristics of patients at diagnosis and the indolent clinical course of the disease or to modern treatment approaches. Likewise, whether some patients with sustained response and long survival are actually cured is not known. The analysis of unselected series of patients with a long follow up can contribute to shed light on these issues.
Aims: To analyze the characteristics at diagnosis, over the course of the disease, and at last follow up of patients with CLL surviving more than 10 years from diagnosis.
Methods: One-hundred and three patients (24% of the whole series) from the Sant Pau Hospital from Barcelona with a survival longer than 10 years from the time of diagnosis were analyzed
Results: The main characteristics of the 103 patients are shown in the Table 1. Treatment-free survival at 10 and 20 years was 62% (95% CI, 52-70) and 39% (95% CI, 28-50), respectively. After a median follow-up of 14 years (range, 11-32), 56 patients required therapy. Most of these patients had unmutated IGHV genes and poor cytogenetics at the time of diagnosis. Front-line therapy consisted of alkylating agents (n=32) or fludarabine-based treatments (n=24). Thirty-eight patients (76%) achieved complete remission, 11 patients partial remission (22%), 1 patient (2%) had no response, and 6 were not evaluable. No significant differences in the response rate were observed among different prognostic subgroups. The median duration of response to first therapy was 33 months (range, 2-173). Duration of response was significantly longer in patients with good *vs.* poor cytogenetics and low *vs.* high β-2 microglobulin at treatment. Thirty-two of 56 patients had a second progression and received further treatment, and 21 patients were given ≥3 lines of therapy. Ten patients underwent stem cell transplantation (2 autografts and 8 allografts). Richter's transformation was documented in 3 out of 103 patients, while 8 patients developed a second malignancy and 5 patients developed autoimmune hemolytic anemia during the evolution of the disease. At last follow-up, 7 patients were free of disease (of which 3 had been treated with allogeneic stem cell transplantation, and the remaining with different modalities of therapy) and 80 patients remained alive but with signs of persistent disease.

Table 1. Clinical and biological characteristics at diagnosis (num).



Summary and Conclusions: Not unexpectedly, most patients with CLL enjoying very long survival had good clinical and biological features at diagnosis. Long-term survivors with poor prognostic factors (*i.e.*, unmutated IGHV genes, high expression of ZAP-70, and/or poor cytogenetics) were likely to progress

and require therapy. In patients requiring therapy, poor cytogenetics and high β-2 microglobulin were associated with a shorter duration of response. Further studies are needed to identify those patients in which achieving CR is a necessary condition for prolonging survival, as opposed to those in whom disease control (without aiming for a CR) is a reasonable treatment goal.

P243

RICHTER'S TRANSFORMATION IN PATIENTS WITH CHRONIC LYMPHOCYTIC LEUKEMIA (CLL): ANALYSIS OF BIOLOGICAL AND CLINICAL RISK FACTORS AND OUTCOMES

E Gershom[1,*] S Huang[2], M Suhua Ye[1], M Ahmed[1], TL Gillan[3], AS Gerrie[4], HA Leitch[5], CL Toze[4], KM Ramadan[5]
[1]Division of Hematology, St Paul's Hospital, [2]Leukemia/BMT Program of BC, Vancouver General Hospital, [3]Cytogenetics Laboratory, Vancouver General Hospital and The University of British Columbia, [4]Leukemia/BMT Program of BC, Vancouver General Hospital and The University of British Columbia, [5]St Paul's Hospital and The University of British Columbia, Vancouver, Canada

Background: Among CLL patients (pts), 5-10% develop an aggressive large B-cell lymphoma, Richter's transformation (RT) that results in rapid clinical deterioration with increased lymphadenopathy, splenomegaly and worsening B symptoms. The risk factors for the development of RT are not well defined due to limited data.
Aims: The purpose of this study was to perform actuarial analysis of biological and clinical risk factors and survival outcomes among CLL pts with RT compared to a CLL control group (grp) with no RT. The parameters included were age grp, Rai stage, diagnosis decade, lymphocyte count, lactate dehydrogenase (LDH) level, hemoglobin (Hb), platelet count, prior treatment, immunophenotype and FISH cytogenetics.
Methods: A population based retrospective analysis through an electronic search of pts within the St Paul's Hospital CLL and BC Provincial CLL databases between 1980-2013 was carried out. RT patients were either biopsy confirmed or considered to have RT by treating physician based on clinical presentations such as rapid increase in lymph node size and LDH, unusual disease site such as CNS, Liver. Chi square test was used for comparison of parameters and association with RT using a CLL control grp without RT. Survival analysis was performed by the Kaplan-Meier method.

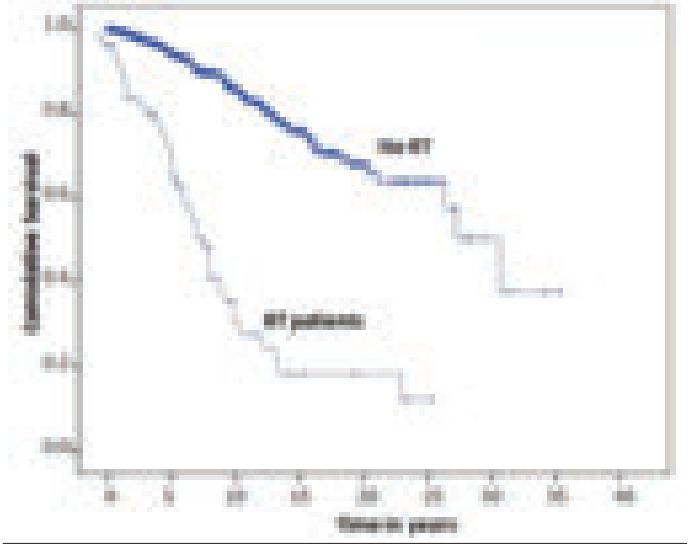


Figure 1. Overall survival of CLL patients with Ritchers Transformation (RT) *versus* control group of CLL patients with No RT.

Results: Among 1631 pts with CLL, 59 (3.6%) developed RT and of these 20 were biopsy confirmed. The median overall survival (OS) from the time of CLL diagnosis for the RT grp is 8.18 years (0-26 yrs) and for the CLL control grp is 30 years (0-35 years (yrs)), p=0.017. The median time from CLL diagnosis to RT was 4.9 years and the median OS post RT was 9 months (0-10.6 yrs). Within the RT grp, the median OS was worse for those with advanced Rai Stage - High: 2.0, Intermediate: 7.7 and low: 10.4 years (p=0.039) and those who had previous treatment for CLL had OS of 7.2 yrs *versus* 10.5 yrs with no previous treatments (p<0.001). However, there was no significant difference in OS for LDH>1.5 upper limit of normal (ULN), decade of CLL diagnosis and type of treatment. LDH>1.5ULN, advanced Rai stage, low Hb and low platelet counts at time of CLL diagnosis were significantly associated with the RT *versus* the CLL control grp (p<0.01). Among pts tested, flow cytometry and FISH at diagnosis showed CD38$^+$, (Odds ratio [OR] 4.76), trisomy 12 (OR 8.55), 11q- (OR 30.49) and 17p- (16.25) were significantly associated with RT (p<0.01 for all comparisons) but not for 13q- (OR 0.90). Within the RT grp, CD38$^+$ alone and flow pattern (typical/atypical) had no effect on OS. RT pts with high-risk FISH abnormalities (17p- or 11q-) had significantly worse OS compared to those without; while the presence of 13q- or +12 had no effect on OS (p<0.01). On multivariate analysis, only advanced Rai stage was significant with a Cox hazard ratio of 4.69 (p=0.01). Finally, using the BC province general population life tables, the 5 year relative survival ratio for the various age groups was 0.75 for the RT grp and 0.93 for the CLL control grp (Figure 1).
Summary and Conclusions: This study of 59 RT pts is the largest to date analyzing biological and clinical risk factors for outcomes. RT significantly shortened OS compared to CLL control grp. Pts with LDH>1.5ULN, advanced Rai stage, CD38$^+$ and >1 FISH abnormalities at diagnosis should be closely monitored for RT. Early treatment of CLL pts correlating to high risk of RT warrants further investigation. Expanding this study provincially and nationwide, along with a more comprehensive analysis of clinical and biological parameters and their combinations would help in better predicting RT among CLL pts leading to improved patient care.

P244

INTERIM RESULTS FROM A PHASE IIA STUDY OF THE ANTI-CXCL12 SPIEGELMER OLAPTESED PEGOL (NOX-A12) IN COMBINATION WITH BENDAMUSTINE/RITUXIMAB IN PATIENTS WITH CHRONIC LYMPHOCYTIC LEUKEMIA

M Steurer[1,*] L Scarfò[2], M Montillo[3], A Janssens[4], S Wildner[1], F Mauro[5], L Trentin[6], J Thaler[7], S Burgstaller[7], A Kruschinski[8], T Dümmler[8], K Riecke[8], P Ghia[2], F Caligaris-Cappio[2], M Gobbi[9]
[1]Division of Hematology and Oncology, Innsbruck Medical University, Innsbruck, Austria, [2]Department of Onco-Hematology, Universita Vita-Salute San Raffaele, [3]Department of Haematology & Oncology, Niguarda Cancer Center, Milan, Italy, [4]Internal Medicine, University Gasthuisberg, Leuven, Belgium, [5]Department of Cellular Biotechnologies and Hematology, Sapienza University, Rome, [6]Department of Medicine, University of Padua, Padua, Italy, [7]Department of Internal Medicine IV, Wels-Grieskirchen Hospital, Wels, Austria, [8]NOXXON Pharma AG, Berlin, Germany, [9]IRCCS AOU S.Martino, IST Genova, Genova, Italy

Background: Olaptesed pegol (NOX-A12) is a novel, potent, L-stereoisomer RNA aptamer that binds and neutralizes CXCL12/SDF-1, a chemokine which attracts and activates immune- and non-immune cells via interaction with the receptors, CXCR4 and CXCR7. The signaling of CXCL12 is pivotal to the interactions of leukemic cells with bone marrow microenvironment. The therapeutic concept of olaptesed is to inhibit such tumor-supporting pathways and thereby mobilizing and sensitizing CLL cells to chemotherapy.
Aims: Here we aim to assess the activity and safety of olaptesed in combination with rituximab and bendamustine in patients with relapsed / refractory CLL.
Methods: This multicenter Phase IIa study investigates olaptesed alone and in combination with BR in relapsed / refractory CLL patients. The study population was split into a pilot and expansion group. Patients were treated using a dose titration design with intravenous (IV) olaptesed at doses increasing from 1 mg/kg to 2 mg/kg and 4 mg/kg at cycles 1, 2 and 3, respectively at 1 hour before rituximab treatment. During cycles 4 to 6, olaptesed was dosed at the highest individually titrated dose. Rituximab was administered IV at doses of 375 mg/m² on day 1 of 1st 28-day cycle and 500 mg/m on day 1 of subsequent cycles. Bendamustine (70 - 100 mg/m²) was given IV on days 2-3 (cycle 1) or days 1-2 (cycles 2-6) of each 28-day cycle following administration of rituximab. To study PK/PD, a pilot dose of 1 to 4 mg/kg olaptesed alone was administered to the initial 10 patients before start of the regular treatment regimen. Clinical response was assessed according to NCI-WG Guidelines (Hallek M *et al.* Blood 111; 2008: 5446-56). To date, 20 patients are evaluable (11 women, 9 men) with a median age of 67 years (range 52 to 79). At screening 4, 7 and 9 patients presented with Binet stage A, B and C, respectively. The median prior treatment line was one. 7 patients presented an unfavorable disease state being relapsed within 24 months after fludarabine or bendamustine treatment (4 patients) or presenting a deletion/mutation of the TP53 gene (3 patients). Most patients (15 of 20) were previously treated with fludarabine or bendamustine.
Results: Flow cytometric analysis of CD19$^+$/CD5^{high} CLL cells showed a rapid mobilization of these cells into the peripheral blood which lasted throughout the observational time of 72h. Reduction of lymphadenopathy by ≥50% occurred in 11 out of 14 evaluable patients by the end of treatment. Concomitantly, rapid reduction of lymphocytosis in peripheral blood with normalization by treatment cycle 2 – 3 was observed. Also, the CLL to leukocyte ratio improved on average from >60% in cycle 1 to <2% at cycle 4. Olaptesed at 1, 2 and 4 mg/kg BW at a single dose and in combination with BR was safe and well tolerated. The maximum tolerated dose was not reached and all patients could have been titrated up to 4 mg/kg. With 4 patients (20%) achieving a complete response and 14 patients (70%) achieving a partial response, the overall response rate was 90%.
Summary and Conclusions: Olaptesed as a single dose and in combination with BR was safe and well tolerated. Compared to historical data, olaptesed shows superiority over baseline therapy with regards to overall response rate and increasing rates of high quality responses. Moreover, the evaluation of the baseline characteristics indicates that "relapsed / refractory patients", a hard-to-treat patient population, were enrolled in the study, which underlines the clinical relevance of the observed effects and warrants further development of this Spiegelmer in CLL.

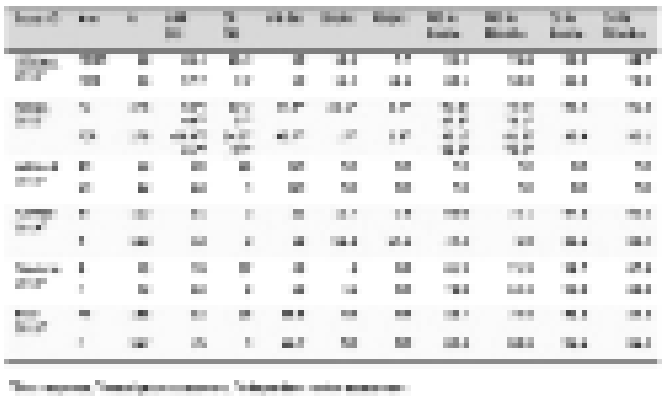
P245

A SYSTEMATIC REVIEW AND EVIDENCE SYNTHESIS OF RANDOMISED CONTROLLED TRIALS (RCT) FOR THE TREATMENT OF RELAPASED OR REFRACTORY CHRONIC LYMPHOCTYIC LEUKEMIA (CLL)

JM Quigley[1,*] J Thompson[1], L Barcena[1], SJ Mealing[1], V Leblond[2]
[1]Health Economics, ICON, Oxford, United Kingdom, [2]Hematology, Hôpital Pitié-Salpêtrière, Paris, France

Background: Patients with relapsed CLL often have limited treatment options due to toxicity or resistance to first-line therapies. Frailty and comorbidities are also important consideration in the elderly population. Idelalisib is a novel oral inhibitor of PK13K δ for the treatment of relapsed or refractory CLL.
Aims: To evaluate the relative efficacy of commonly used treatments for relapsed/ refractory CLL.
Methods: Relevant RCTs were identified via formal searches of the EMBASE, MEDLINE, MEDLINE-in-process and CENTRAL databases. Treatments of interest were idelalisib (I), ibrutinib (Ib), alemtuzumab (A), fludarabine (F), rituximab (R), ofatumumab (O), methylprednisolone (MP), chlorambucil (Cl), cyclophosphamide (C), lenalidomide (L) alone or in combination in adult patients with relapsed/refractory CLL. Conference abstracts from EHA and ASH 2012/2013 were also searched. Screening was carried out independently by two reviewers. Meta-analysis was planned to generate relative efficacy estimates for all endpoints of interest. Response, Overall Survival (OS) and Progression Free Survival (PFS) were outcomes of interest.
Results: 1464 abstracts were review and from this 20 full papers were screened, with five full papers and a conference abstract included in the review. Three studies restricted participants to one previous line of treatment and patients in another had an average of 2.2 previous lines of therapy. Patients receiving I had received, on average, three previous treatments. Eligibility criteria were not reported in the remaining study. Imbalances in del 17p also existed in all identified studies, with ~25% for I, <10% all other treatment options. Evidence networks containing I could not be created for any endpoint of interest and so no formal evidence synthesis was possible. Despite the baseline imbalances, the overall response and stable disease rates for idelalisib were comparable to those observed for other therapies (see Table 1). PFS and OS rates at 6 and 12 months were also comparable with those observed for other therapies (Table 1). The hazard ratios derived for I+R *vs.* R (PFS: 0.15 [0.08, 0.28] OS 0.28 [0.09, 0.86]) were better than those for other pairwise comparisons (PFS range 0.65 [95% CI 0.51, 0.82] to 0.87 [0.6, 1.27]; OS range 0.65 [0.45, 0.94] to 0.83 [0.59, 1.17]).

Table 1. Results of systematic review of RCTs.



Summary and Conclusions: The availability of randomised evidence of treatments for relapsed/ refractory CLL is limited and currently does not support formal evidence synthesis. Overall, despite being used in a harder to treat population, idelalisib appears to have a comparable response profile and PFS and OS rates at 6 and 12 months to other available treatments.

P246

PROSPECTIVE VALIDATION OF A RISK SCORE BASED ON BIOLOGICAL MARKERS FOR PREDICTING PFS IN BINET STAGE A CLL PATIENTS: RESULTS OF THE MULTICENTER O-CLL1-GISL STUDY

Background: The clinical course of chronic lymphocytic leukemia (CLL) patients is characterized by marked variability, with some cases requiring therapy shortly after diagnosis and others living for decades without ever requiring therapy. A risk score based on three biological features (CD38, ZAP-70 and IGHV mutational status) was previously developed to predict progression-free survival (PFS) in untreated Binet A CLL patients. Using this scoring system patients were stratified into 3 risk groups: low-risk (absence of unfavorable markers or score 0), intermediate-risk (score 1, presence of 1 unfavorable marker) and high-risk (score 2-3, presence of 2/3 unfavorable markers). According to this score system the patients had significantly different clinical courses.
Aims: Here we perform a score validation analysis in a prospective and independent cohort of patients.
Methods: Biological markers (CD38, ZAP-70 and IGHV mutational status) and gene expression profiles (GEP) of leukemic cells from CLL patients included in a prospective multicenter observational study (O-CLL1-GISL protocol, clinicaltrial.gov ID:NCT00917549) were used to assess the value and reproducibility of this score. Sub-analyses were also performed in the setting of Rai low-risk and clinical monoclonal B-cell lymphocytosis (cMBL) cases, included in this cohort.
Results: To date, 468 Binet A patients have been enrolled. According to the progression risk score, 237 patients (50.6%) were classified as low-risk, 99 (21.2%) as intermediate-risk, and 132 (28.2%) as high-risk (69 cases had score 2 and 63 score 3). The high-risk group included more numerous patients with unfavorable cytogenetic alterations (1.4% *vs* 4.9% *vs* 20.1%; P<.0001), with higher β2-microglobulin levels (34.1% *vs* 28.4% *vs* 52.9%; P=.002) and with NOTCH1 mutations cases (4.8% *vs* 5.6% *vs* 30.4.%; P<.0001) than the low-risk and intermediate-risk group. The 3-year PFS probability was 91.7%, 82.9% and 57.4% for low-, intermediate- and high-risk (P<.0001) cases, respectively. These values were similar to those found in the original cohort. At Cox multivariate analysis, Rai stage, absolute lymphocyte count, progression risk score and β-2 microglobulin maintained an independent prognostic impact on PFS. This score remained a predictor of progression when analysis was limited to 371 Rai 0 cases (P<.0001). While high-risk cMBL patients (3-year PFS probability 84.3%, HR=7.3, 95% CI 1.9–27.6, P=.003), but not intermediate-risk (3-years PFS probability 89.5%, HR=3.5, 95% CI 0.8-15.9, P=.1), showed a significantly shorter PFS than low-risk (3-year PFS probability 98.6%, HR=1). Gene expression profiling indicated that the risk groups identified here were characterized by specific transcriptional patterns that could distinguish between low- and high-risk groups. Among the genes found to be modulated in multiclass SAM analyses some are known to have prognostic relevance and showed the higher value in score 3 group, *i.e.* ZAP70, CD38, LPL, CRY1 and LDOC1 genes.
Summary and Conclusions: These results confirm the ability of this progression risk score to predict PFS among Binet A patients. The utility of the score was also extended by demonstrating that it retains prognostic value when applied exclusively to Rai 0 patients. Specific transcriptional patterns were significantly associated with risk groups.

P247

SALVAGE TREATMENT WITH BENDAMUSTINE, OFATUMUMAB, HIGH-DOSE METHYLPREDNISOLONE (BOMP) IN HIGH-RISK R/R CLL: INTERIM RESULTS OF THE FRENCH CLL INTERGROUP (GCFLLC/MW - GOELAMS) ICLL01 PHASE 2 TRIAL.

Background: For relapsing or refractory (R/R) CLL patients, combination of bendamustine and rituximab (BR) has previously been evaluated as safe and efficient with an overall response (ORR) and complete response (CR) rates of 59% and 9% respectively in the CLL2M trial (Fischer 2011). Ofatumumab is a recently developed anti-CD20 immunotherapy providing an ORR of 58% in fludarabine/alemtuzumab-R/R CLL patients if used as monotherapy (Wierda JCO 2010). High doses methylprednisolone (HDMP) alone or in combination with rituximab have also been used in poor prognosis patients with bulky nodal involvement or p53 impairment. (Castro 2008, Xu 2010).
Aims: Based on these results, we tested the combination of bendamustine, ofatumumab and HDMP (the BOMP regimen) for the treatment of R/R patients, especially following fludarabine cyclophophamide rituximab (FCR) as previous treatment(s), an increasing challenge of our current practice.
Methods: We report a planned interim analysis of the phase II ICLL01 trial (NCT01612988) evaluating the efficacy and toxicity of the BOMP in fit R/R CLL patients, pretreated with 1 to 3 previous lines. Treatment consisted on a prephase of ofatumumab (300 mg) followed by 6 monthly courses of BOMP including bendamustine (70 mg/m2 d1-2), ofatumumab 1000 mg TD (d1 and d15 on 1st and 2nd courses) and high dose methylprednisolone (1 g/m2 d1-3). Primary endpoint was CR rate at 6 cycles of BOMP according to IWCLL 2008 guidelines.
Results: Data from the first 55 pts (enrolled between july 2012 and may 2013) are available. Median age was 63.8 yrs. Patients had been previously pretreated with a median of 1 (1-3) lines, including FCR-based regimens in 51/55 (93%) and 22/55 (42%) had experienced high-risk relapses within 24 months post-FCR, with 7/55 (13%) being fludarabine-refractory. *IGVH* gene status was unmutated in 90%. Karyotypes were complex (≥3 abnormalities) in 18/46 (39%) successful cases. Using FISH, we found 15/55 (27%) del17p, 6/55 (11%) tri12, 18/55 (33%) del11q, 35/55 (64%) del13q. *TP53* gene mutations were observed in 17/55 (31%). Hence p53 impairment by deletion and/or mutation was found in 19/55 (34%). Patients with either a high-risk relapse (≤2 years post-FCR) and/or p53 impairment accounted for 40/55 (73%). A total of 292 and mean number of 5.3 cycles were administered. Safety analysis available for the first 268 cycles recorded 119 grade 3-4 adverse events (AE) including neutropenia (15.3%), thrombocytopenia (10.1%), infection (7.5%) and anemia (2.2%). Non-hematologic/infectious grade 3-4 toxicity included hyperglycemia (3,4%), digestive AE (nausea, vomiting and/or diarrhea) (1.5%) and cardiovascular AE (1.11%). Overall, 36 out of 55 pts (65.5%) had at least one grade 3-4 AE. Twenty eight severe adverse events were reported in 18 patients. With a median follow-up of 340 (39-558) days following inclusion, we observed 7 deaths, related to disease progression (4), EBV-induced lymphoproliferation (1), progressive multifocal leuco-encephalitis (1) and sepsis (persistant pancytopenia) (1) with 5,5% TRM. We recorded 14 relapses including 4 Richter Syndromes. Following evaluation after 6 BOMP cycles, 5 pts proceeded to allogeneic transplantation. Response was evaluable in 52/55 patients. The ORR was 74.5% with 20% CR (11/55), 54.5% PR (30 pts including 5 nPR, 1 CRi and 4 CRu), 9,1% stable disease (5/55) and 10,9% progressive disease (6/55). Blood and bone marrow 9-color flow MRD analysis as well as statistical analysis on the impact of molecular biomarkers will be available.
Summary and Conclusions: Taking into account the very adverse profile of the treated population, this analysis shows promising results of the BOMP regimen, as compared with the results of both CLL2M (BR) and Gimema (bendamustine plus ofatumumab) trials (Cortelezzi 2013) and constitute an important set of information, for forthcoming comparison with next emerging therapy of CLL.

P248

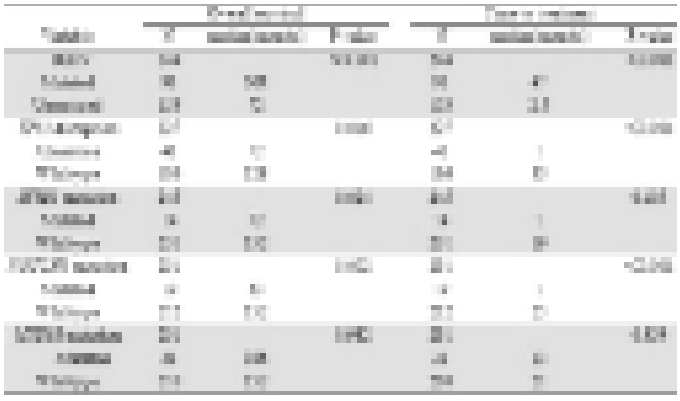
NOVEL GENE MUTATIONS IN CHINESE CHRONIC LYMPHOCYTIC LEUKEMIA PATIENTS

Y Xia[1,*] W Xu[1], L Fan[1], C Qiao[1], WY Shen[1], L Wang[1], J Xu[1], JY Li[1]
[1]Department of Hematology, The First Affiliated Hospital of Nanjing Medical University, Nanjing, China

Background: Chronic lymphocytic leukemia (CLL) is a clinical heterogeneous disease with different molecular and cytogenetic abnormities. Several recurrent gene alterations detected by next-generation sequencing (NGS) have shown promising prognostic value in CLL including *SF3B1*mut and *NOTCH1*mut. However, the precise prognostic value of novel genomic mutations is still under dispute and there is no integrated study of these mutations in Chinese CLL patients.
Aims: The aim of this study is to assess the incidence and prognostic value of *SF3B1*, *NOTCH1* and *MYD88* along with *TP53* mutation in Chinese CLL cohort.
Methods: A total of 247 patients were included in this study. The median age was 61 years old with a male/female ratio of 2.05. The median follow-up was 35 months. Sanger sequencing was performed for exon4-9 of *TP53*, exon14-16 of *SF3B1*, exon 3-5 of *MYD88* and PEST domain of *NOTCH1*.
Results: Significant high incidence of *MYD88*mut (8.3%, 19/229) was observed, while *SF3B1*mut was relatively infrequent (5.3%, 14/245). 8.2% (19/231) and 16.3% (40/245) patients carried *NOTCH1*mut and *TP53*mut respectively. Detailed mutation rates regarding disease course are listed in Table 1. Of 226 patients who were analyzed for all four genes, 66.4% (150/226) patients had no gene alterations. 29.6% (67/226) showed single, 3.1% (7/226) two and 0.8% (2/226) three different mutations. Of note, *MYD88*mut were mutually exclusive of *NOTCH1*mut and *SF3B1*mut in our cohort. No correlation of any mutation with age or gender could be found. *SF3B1*mut, *NOTCH1*mut and *TP53*mut showed significant association with unmutated IGHV status, whereas *MYD88*mut were more frequent in CLL patients harboring mutated IGHV gene. Moreover, *NOTCH1*mut were associated with IGHV4-39 (P=0.012) and IGHV1-69 (P=0.006), while *SF3B1*mut correlated with IGHV4-59 (P<0.001). For the cytogenetic part, *NOTCH1*mut correlated with trisomy 12 (P=0.033), so did *TP53*mut with del(17p13) (P<0.001). *SF3B1*mut and *NOTCH1*mut were associated with shorter OS (overall survival), with median OS of 72 (P=0.024) and 63 (P=0.002) months. For the TP53 disruption patients, we further divided them into 2 groups according to their IGHV mutational status. Those carried unmutated *IGHV* gene showed significant worse prognosis compared to those with mutated IGHV gene (median OS: 71 *vs* 152 months, P=0.014). *MYD88*mut showed no impact on OS (median OS: NR *vs* 152 months, P=0.503). To our surprise, *SF3B1*mut did not affect time to treatment (TTT) in our cohort (P=0.105). Detailed data are listed in Table 2. Multivariate analysis of TTT (Time to treatment) only identified unmutated *IGHV* status (P=0.005) and TP53 disruption (P=0.019) as independent prognostic factors, while *NOTCH1*mut (P=0.088) had no statistical significance.

Table 1. Different frequency of novel gene mutation regarding to disease stage.

Table 2. Overall survival and time to treatment of Chinese CLL cohort.



Summary and Conclusions: Our data suggest remarkable differences of both incidence and prognostic value of novel gene mutations between Chinese and western CLL patients. Of particular interest, *SF3B1*mut were relatively rare even in the relapsed/refractory group and held limited prognostic value of TTT in Chinese CLL cohorts. In contrast, *MYD88*mut seemed to be more common but showed no prognostic impact. The reason of the discrepancy is yet unknown. The application of NGS might help to elucidate the underlying mechanism.

P249

A PHASE II MULTI-CENTER TRIAL OF PENTOSTATIN PLUS CYCLOPHOSPHAMIDE WITH OFATUMUMAB (PCO) IN OLDER PREVIOUSLY UNTREATED CHRONIC LYMPHOCYTIC LEUKEMIA (CLL) PATIENTS

M Montillo[1,*] D Rossi[2], M Motta[3], G Quaresmini[4], M Rossi[5], M Coscia[6], A Anastasia[7], F Rossini[8], A Cortellezzi[9], G Nador[10], L Scarfò[11], R Cairoli[12], AM Frustaci[1], D Dal Ceggio[3], P Picardi[1], L De Paoli[2], E Orlandi[5], A Rambaldi[4], E Morra[1], M Massaia[6], A Tedeschi[1]

Città della Salute e della Scienza di Torino, Torino, [7]Dept. of Haematology, Humanitas Cancer Center, Rozzano, [8]Haematology Unit, Ospedale San Gerardo, Monza, [9]Dept. of Haematology and BMT Unit, University of Milan, Ospedale Maggiore, Milan, [10]Internal Medicine Dept., Hospital of Legnano, Legnano, [11]Dept. of Onco-Haematology, University Vita-Salute San Raffaele, Milan, [12]Dept. of Internal Medicine, Ospedale Valduce, Como, Italy

Background: The addition of anti-CD20 monoclonal antibody [mAb] rituximab to the FC platform (FCR) improved response rates, progression free survival and also overall survival. However, FCR showed considerable hematologic toxicity, particularly among patients over age 70. Pentostatin in CLL demonstrated similar activity with minor myelotoxicity compared to other purine analogues. Moreover, when administered with other myelotoxic agents such as cyclophosphamide resulted in a better toxicity profile. Ofatumumab is a fully human anti-CD20 mAb more effective than rituximab when used as single agent in patients with previously treated CLL being also effective in rituximab-refractory patients.
Aims: Given the reported efficacy of chemo immunotherapy [CIT] in CLL and the activity and toxicity profile of pentostatin combinations, we designed a trial of pentostatin, cyclophosphamide, and Ofatumumab for previously untreated older patients with CLL.
Methods: Patients with CLL requiring therapy (2008 NCI-WG guidelines) aged ≥65 years and ECOG PS of 0-2 were enrolled to receive Pentostatin 2 mg/sqm and Cyclophosphamide 600 mg/sqm both as intravenous infusions at day 1 of each 21 day cycle and Ofatumumab administered as intravenous infusions (Cycle 1: 300 mg day 1 and 1000 mg day 2, subsequent cycles: 1000 mg at day 1). Patients received up to 6 courses of treatment. The primary endpoint was overall response rate (ORR) including detection of minimal residual disease (MRD) and secondary endpoints included, progression-free survival (PFS) overall survival (OS) and safety.
Results: Forty-seven patients from 12 centres from the italians regions of Lombardy and Piedmont were included. Median age was 72.2 years with 60% aged over 70, 31 patients were males (66%). Twelve patients (25%) presented a Binet stage C; 6 patients (13%) had a bulky disease; 10 (21%) showed an unfavorable FISH aberration such as 17p or 11q deletion (respectively in 3 and 7 patients). Unmutated IGHV status was detected in 49%. ORR was 89% with 51% CR (18)/CR with incomplete marrow recovery [CRi] (6). Nor IGHV unmutated status, neither 17p/11q deletion had a unfavorable impact on quality of response. The six intended courses of treatment were administered in 44 (94%) patients, and 93% of these received full-dose treatment. Reasons for discontinuation before treatment completion were: 1 acute renal failure (2 courses completed); 1 septic shock (2 courses); 1 persistent skin rash (5 courses). Main reason for dose reduction was myelosuppression. At least 1 episode of grade ≥3 AEs was experienced by 59,6% of patients, with the most common being neutropenia [grade 3, 10 pts; grade 4, 17 pts]; anemia in 1 case, while thrombocytopenia was detected only as grade 1. Grade 3-4 infusion-related AEs were reported in 4% of patients and included skin rash, dispnoea, lipotimia, chills, glottis edema, hypotension, nausea. Five patients (10,6%) experienced infection episodes with two major events: 1 pneumonia and 1 septic shock leading to death. Median follow up from the beginning of treatment is 17 months.
Summary and Conclusions: Ofatumumab added to Pentostatin and Cyclophosphamide demonstrated clinically important results and is well tolerated in patients with previously untreated CLL. In this preliminary report the efficacy of this ofatumumab-based CIT compares favorably to the historical rituximab-based CIT using the same chemotherapeutic agents with a more manageable side effect profile in this older population. Further data, including MRD detection will be presented at the Meeting.
The project has been realized by Rete Ematologica Lombarda (REL) with the support of Lombardy Region.

P250

TGR-1202, A NOVEL ONCE DAILY PI3K DELTA INHIBITOR, DEMONSTRATES PROMISING CLINICAL ACTIVITY WITH A FAVORABLE SAFETY PROFILE IN PATIENTS WITH RELAPSED OR REFRACTORY HEMATOLOGIC MALIGNANCIES

HA Burris[1, 2,*] M R Patel[1,3], MC Lanasa[4], D Brander[4], OA O'Connor[5], C Deng[5], M Gutierrez[6], S Jones[1], JG Kuhn[7], HP Miskin[8], P Sportelli[8], S Vakkalanka[9], I Flinn[1,2]
[1]Sarah Cannon Research Institute, [2]Tennessee Oncology, Nashville, TN, [3]Florida Cancer Specialists, Sarasota, FL, [4]Duke University Medical Center, Durham, NC, [5]Columbia University Medical Center/New York Presbyterian Hospital, New York, NY, [6]John Theurer Cancer Center, Hackensack University Medical Center, Hackensack, NJ, [7]The University of Texas Health Science Center at San Antonio, San Antonio, TX, [8]TG Therapeutics, Inc., New York, NY, United States, [9]Rhizen Pharmaceuticals S A, La Chaux-de-Fonds, Switzerland

Background: TGR-1202 is a novel, once-daily PI3Kδ inhibitor with unique pharmacologic properties including an extended half-life and structural design which differs significantly from other leading PI3Kδ inhibitors in development. Preliminary data from an ongoing Ph I study of TGR-1202 demonstrated clinical activity in patients with advanced hematologic malignancies with a favorable safety profile.
Aims: Herein we present updated results from this Phase I, first in human study of TGR-1202.
Methods: TGR-1202 is administered orally daily following a 3+3 dose escalation design. Previously treated patients with an ECOG PS <2 and confirmed diagnosis of B-cell non-Hodgkin lymphoma (NHL), chronic lymphocytic leukemia (CLL), Hodgkin's Lymphoma or other lymphoproliferative disorders are eligible. Endpoints include safety, PK/PD, and efficacy.
Results: 27 patients have been enrolled to date across 7 dose levels: 50, 100, 200, 400, 800, 1200, and 1800 mg QD. Informed consent obtained for all patients. 74% male, ECOG 0/1: 33%/67%, median age of 59 years (range: 28-82), median 3 (range: 1-14) prior treatment regimens, and 40% were refractory to prior treatment. Evaluable patients include 7 indolent NHL (iNHL), 11 CLL/SLL, 4 Hodgkin's lymphoma, 2 mantle cell lymphoma (MCL), 1 each of lymphoplasmacytic lymphoma, DLBCL, and atypical hairy cell leukemia. TGR-1202 was well tolerated. Grade ≥3 AE's in >5% of patients were limited to: dyspnea (7%), neutropenia (15%), rash (7%), and thrombocytopenia (7%). Two DLTs were observed: 1 Grade 3 rash at 800 mg (pt rechallenged with no recurrence), and 1 Grade 3 hypokalemia at 1800 mg (patient discontinued due to non-compliance). Notably, no hepatotoxicity has been observed to date. Of the 27 enrolled, 23 were evaluable for efficacy. A significant dose-response relationship was observed. Of the 13 patients treated at <800 mg QD who completed 2 cycles of treatment, 7 achieved stable disease. Of 10 patients treated at ≥800 mg QD: 4/6 CLL patients (67%) achieved a nodal partial response, 1/3 Hodgkin's patients (33%) achieved a partial response. Nodal reductions occurred rapidly in patients with CLL and were accompanied by marked lymphocytosis.
Summary and Conclusions: TGR-1202 is well tolerated in patients with relapsed/refractory hematologic malignancies with no reported hepatic toxicity and promising clinical activity at doses ≥800 mg QD. Long term tolerability has been established with patients having been on TGR-1202 for 12+ months with no safety concerns identified. Enrollment continues in expansion cohorts and at higher dose cohorts. Updated safety, efficacy, PK, and PD data will be presented.

P251

THE ROLE OF ALLOGENEIC STEM-CELL TRANSPLANTATION FOR RICHTER'S SYNDROME - META-ANALYSIS

D Antic[1,*] N Milic[2], V Vukovic[3], M Todorovic[1], J Bila[1], B Andjelic[3], V Djurasinovic[3], A Sretenovic[3], J Jelicic[3], B Mihaljevic[1]
[1]Clinic for hematology, Clinical Center Serbia, Medical faculty, Belgrade, [2]Institute for Medical Statistics and Informatics, Medical Faculty University of Belgrade, [3]Clinic for hematology, Clinical Center Serbia, Belgrade, Serbia

Background: Richter's syndrome (RS) is transformation of chronic lymphocytic leukemia (CLL) into aggressive lymphoma and occurs in 2% to 8% of patients with CLL. Despite use of multiagent immunochemotherapy regimens, median survival has generally not exceeded 1 year. Because of that allo stem cell transplantation (SCT) is of considerable interest having in mind dose intensity delivered by high-dose cytotoxic therapy and graft-*versus*-leukemia activity. Also, important question is about time for alloSCT: as postremission therapy in patients with chemotherapy-sensitive disease and in patients refractory to chemotherapy as salvage therapy?
Aims: There is lack of studies with reasonable sample size about role of allo SCT in patients with RS. Therefore, we decided to obtain meta analysis comparing value of allo SCT in patients with chemotherapy-sensitive disease and in patients refractory to (immune)chemotherapy.
Methods: Literature search: A search strategy was developed to identify publications reporting on allo SCT in patients with RS available through MEDLINE, EMBASE and Cochrane Library databases. Reference lists of articles identified during electronic searches were searched to identify other articles of potential relevance. In addition, hand searching of conference proceedings was conducted. Experts of the field were also contacted. Statistical analysis: The meta-analysis of studies has been developed in accordance with the rules accepted by the Cochrane Collaboration. The odds ratio (OR) of the effect of alloSCT in patients with chemotherapy-sensitive disease relative to alloSCT salvage approach was estimated by pooling individual trial results using the fixed effects method of Mantel-Haenszel. The automatic "zero cell" correction was utilized so that the studies with no events in a given arm would still be included for analysis. Result of evaluated end point (overall survival) have been demonstrated in the form of OR with 95% confidence interval (CI). Patients with complete (CR) or partial remission (PR) considered as chemotherapy-sensitive disease, while patients with stable disease (SD) or disease progression (PD) considered as refractory to chemotherapy.
Results: Three studies with data on alloSCT in CR/PR or salvage alloSCT were identified and all had accomplished 3 years of follow up. Of 49 patients involved, 24 patients received alloSCT in CR/PR and 25 received salvage alloSCT. Patients with chemotherapy-sensitive disease who underwent allogeneic SCT as postremission therapy had longer survival than patients who underwent allogeneicSCT as salvage therapy (p=0,007) (3-years OS 58.3% *vs* 20%, respectively). Meta analysis identified alloSCT derived as postremission therapy as a factor with significant impact on survival of patients with RS (OR=0,16;95%CI 0,04-0,60).
Summary and Conclusions: First meta analysis regarding to role of alloSCT in RS shows that RS patients with alloSCT as postremission therapy had significantly prolonged survival than patients with allo SCT as salvage approach. Therefore, alloSCT absolutely need to be part of therapeutic approach in chemotherapy-sensitive RS patients.

P252

HEALTH-RELATED QUALITY OF LIFE IMPACT OF IDELALISIB (IDELA) IN PATIENTS WITH RELAPSED CHRONIC LYMPHOCYTIC LEUKEMIA (CLL): PHASE 3 RESULTS

HA Eradat[1,*] P Ghia[2], SM O'Brien[3], P Hillmen[4], RR Furman[5], SE Coutre[6], JP Sharman[7], BD Cheson[8], JM Pagel[9], JC Barrientos[10], AD Zelenetz[11], TJ Kipps[12], IW Flinn[13], N Lamanna[14], MJ Hallek[15], B Coiffier[16], A Pettitt[17], Y Kim[18], TM Jahn[18], LI Wagner[19]

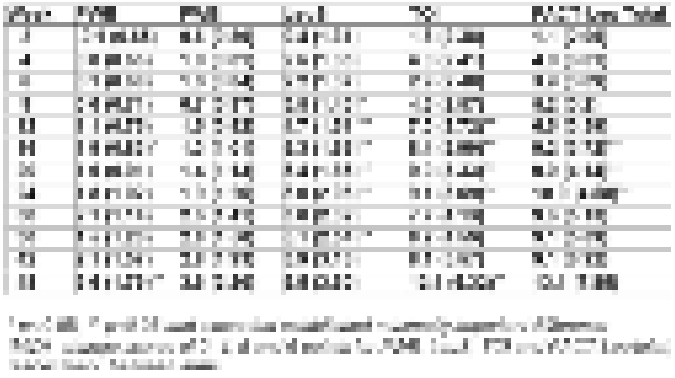
Background: Patient-reported outcomes (PROs), including health-related quality of life (HRQL), from randomized clinical trials may be used to inform clinical decision making and reimbursement decisions. Idelalisib (IDELA), an oral inhibitor of PI3Kδ, is highly active in frail, heavily pretreated patients with CLL as single agent or combined with rituximab (R).
Aims: The aim of this study was to use PROs to evaluate HRQL among patients with relapsed CLL being treated with idelalisib in Study 116, a double-blind, placebo-controlled phase 3 trial (Furman *et al.*, NEJM, 2014).
Methods: Patients were randomized to IDELA+rituximab (R) (n=110) *vs.* placebo+R (n=110). The 44-item Functional Assessment of Cancer Therapy-Leukemia (FACT-Leu) scale was used to measure physical (PWB), functional (FWB), social (SWB) and emotional (EWB) well-being and leukemia-specific concerns (LeuS). The FACT-Leu total score is the sum of subscales; Trial outcome index (TOI) is the sum of PWB, FWB and LeuS. Higher scores reflect better HRQL. Repeated measures mixed-effects models assessed change from baseline within and between arms.
Results: IDELA+R was superior for OS: HR=0.28 (0.09, 0.86), p=0.018. In the mixed-effects model analysis, PWB (p=0.015), FWB (p=0.014), LeuS (p=0.001), TOI (p=0.002), and FACT-Leu total (p=0.006) scores were significantly higher for IDELA+R. EWB/SWB scores did not change significantly over time. Repeated measure mixed-effects model results are shown in the Table 1.

Table 1.



Summary and Conclusions: In this frail CLL population, IDELA+R had superior efficacy, clinically significant improvements in HRQL, and superior symptom control occurring by 8 weeks compared to R+placebo.

P253

BLOOD STREAM INFECTIONS IN CHRONIC LYMPHOCYTIC LEUKEMIA: STABLE DISTRIBUTION BUT WITH INCREASED MORTALITY RATE?

C Kjellander[1,*] M Björkholm[1], O Landgren[2], O Källman[3], CE Weibull[4], T J Löve[5], CC Giske[3], SY Kristinsson[1]

[1]Department of Medicine, Division of Hematology, Karolinska Institutet, Stockholm, Sweden, [2]Medical Oncology Branch, National Institutes of Health (NIH), Bethesda, MD, United States, [3]Department of Clinical Microbiology, Karolinska Institutet – MTC, [4]Department of Medical Epidemiology and Biostatistics, Karolinska Institutet, Stockholm, Sweden, [5]Centre for Rheumatology Research, Landspitali University Hospital, Reykjavik, Iceland

Background: The clinical management of chronic lymphocytic leukemia (CLL) has changed considerably during the last three decades. This has led to an improvement in overall survival in CLL. Infections, mainly due to hypogammaglobulinemia and therapy-related T- and B-cell immunodeficiencies, represent a major cause of morbidity and mortality in CLL.
Aims: The aim of the study was to elucidate potential temporal trends in blood stream infections among CLL patients; association to mortality and introduction of new anti-tumoural treatments.
Methods: The study cohort included 120,038 blood cultures analyzed 1988-2006 at the Clinical Microbiology laboratory Karolinska University Hospital Solna. These individuals were linked to the nationwide Swedish Cancer Registry to identify all persons with CLL (ICD-10 code C91.1) diagnosed before blood cultures analysis. Blood stream infections were divided into three calendar periods (1988-1993, 1994-1999 and 2000-2006) according to year of CLL diagnosis. A positive clinical relevant blood stream infection excluded possible skin contaminants. Survival was analyzed using all-cause mortality with follow-up to December 31, 2009. Cox proportional hazards modeling was used to estimate relative risks, yielding hazard ratios (HR) with 95% confidence intervals (CI).
Results: A total of 215 episodes of blood stream infections in 115 CLL patients were identified. Mean age at first blood culture following diagnosis was 72.9 years, with a male predominance (66%). Dominating pathogens were coagulase-negative staphylococci (for 1988-1993, 1994-1999 and 2000-2006 corresponding numbers were 22 (31%), 23 (22%) and 5 (12%), respectively), *Escherichia coli* (11 (16%), 15 (14%) and 9 (22%)), *Streptococcus pneumoniae* (7 (10%), 13 (12%) and 6 (15%)), *Pseudomonas aeruginosa* (2 (3%), 8 (8%) and 3 (7%)), *Staphylococcus aureus* (1 (1%), 6 (6%) and 6 (15%)) and viridians streptococci (5 (7%), 6 (6%) and 2 (5%)). The number of blood stream infections was stable as well as the relative proportions of Gram-positive and Gram-negative bacteria, over the three calendar periods. There was a significantly increased risk of dying in the last calendar period in CLL patients with a positive clinically relevant blood culture (HR=2.52; 95% CI 1.44-4.41) compared to others (possibly clinically relevant and negative blood cultures), as well as compared to negative blood cultures alone (HR=2.44; 95% CI 1.38-4.30). When analyzing the exposure as time varying, the mortality rates were significantly increased after a positive clinically relevant blood culture compared to before in patients diagnosed 1994-1999 (HR=2.59; 95% CI 1.74-3.85) and 2000-2006 (HR=3.21; 95% CI 1.83-5.62).
Summary and Conclusions: The distribution of blood stream infections in the last decades remained stable despite advances in management of CLL patients. Importantly, in recent years, an increased risk of dying was observed in patients with a positive clinical relevant blood culture. A possible explanation for this finding is that CLL patients, despite improved survival, are more immunocompromised with the expansion of the anti-tumoural armamentarium in the later calendar periods. Treatment-related infections and the role of prophylaxis need to be studied further in CLL.

Background: In chronic myeloid leukemia (CML), resistance against imatinib is a major challenge in clinical practice. In many of these patients, *BCR/ABL* mutations are detected. These patients are candidates for second- or third-generation BCR/ABL tyrosine kinase inhibitors (TKI). However, even when treated with such novel TKI, patients often relapse which is best explained by activation of additional oncogenic pathways in leukemic cells. Therefore, current research is seeking drug combinations involving second- or third-generation TKI and other targeted drugs, with the aim to overcome resistance and to prolong relapse-free surival. Bardoxolone methyl (CDDO-Me) is a novel agent that suppresses survival of leukemic cells by targeting several pro-oncogenic molecules, including Akt, mTOR, and STAT3.
Aims: In the current study, we examined potential cooperative effects of bardoxolone methyl and BCR/ABL TKI. Drug interactions were analyzed at the molecular level (deactivation of critical target-proteins) and in functional assays determining growth and survival (apoptosis) of leukemic cells.
Methods: Primary CML cells were obtained from the blood of 12 CML patients. Four patients had developed resistance against at least two TKI. Furthermore, we examined drug effects in four human CML cell lines, namely KU812, K562, imatinib-resistant K562 cells and imatinib-resistant KCL22, as well as in Ba/F3 cells expressing various BCR/ABL mutants (E255K, H396P, F359V, Y325F, G250E, T315I). Protein expression and phosphorylation was analysed by Western blotting. Cell proliferation was assessed by ^{3}H-thymidine-uptake and apoptosis was determined by flow cytometry.
Results: Bardoxolone methyl was found to inhibit the proliferation and viability of all BCR/ABL+ cell lines (human and Ba/F3) tested and also in primary leukemic cells isolated from pre-treated patients, including those harbouring BCR/ABL T315I. IC_{50}-values ranged between 0.1 and 0.5 µM without a significant difference when comparing imatinib-naïve with imatinib-resistant cells. We next combined bardoxolone methyl with two novel BCR/ABL TKI, dasatinib and ponatinib. Clear synergistic effects were seen with both TKI in all imatinib-sensitive and imatinib-resistant cell lines and in all primary cell samples tested. In Ba/F3 cells harbouring BCR/ABL T315I, the most impressive synergy was seen with bardoxolone methyl and ponatinib. Synergistic effects were accompanied by simultaneous inhibition of multiple signalling molecules, including STAT3 and STAT5. By contrast, exposure to Bardoxolone methyl resulted in deactivation of STAT3 but not deactivation of STAT5 and BCR/ABL; and exposure to the TKI caused deactivation of STAT5 but not STAT3. Bardoxolone methyl is also known to increase expression of heme oxygenase-1 (HO-1), a heat-shock-protein that is associated with drug resistance and abnormal cell survival. Therefore we combined bardoxolone methyl with the HO-1 inhibitor SMA-ZnPP, which also resulted in synergistic growth-inhibitory effects in all primary CML cells and all cell lines tested. Finally, SMA-ZnPP was found to sensitize CML cells against the drug-combination "bardoxolone methyl+TKI". In fact, the combination "bardoxolone methyl+TKI+SMA-ZnPP" produced highly potent anti-proliferative and pro-apoptotic effects in BCR/ABL+ leukemic cells.
Summary and Conclusions: Bardoxolone methyl and SMA-ZnPP enhance TKI effects in CML cells by blocking STAT3 and HO-1 activity. Whether such drug combinations are effective *in vivo* in TKI-resistant CML remains to be elucidated.

CD62L EXPRESSION ON T CELLS IS DECREASED IN PATIENTS WITH EARLY CHRONIC PHASE CHRONIC MYELOGENOUS LEUKEMIA (CML-CP) AND PREDICTS RESPONSE TO THERAPY WITH FRONTLINE NILOTINIB

S Sopper[1,*] S Mustjoki[2], A Loskog[3], B Gjertsen[4], U Mark[5], J Haenig[6], N Jurjonas[7], G Gastl[1], F Giles[8], A Hochhaus[9], G Ossenkoppele[10], K Porkka[2], D Wolf[11]
[1]Hematology and Oncology, Medizinische Universität Innsbruck, Innsbruck, Austria, [2]Biomedica, Helsinki, Finland, [3]Oncology, University Uppsala, Uppsala, Sweden, [4]University Hospital, Bergen, Norway, [5]Novartis, Basel, Switzerland, [6]Novartis, Vienna, Austria, [7]Novartis, Helsinki, Finland, [8]National University, Galway, Ireland, [9]University, Jena, Germany, [10]VU Medical Center, Amsterdam, Netherlands, [11]Internal Medicine III, University Hospital, Bonn, Germany

Background: Imatinib and dasatinib modulate immune responses *in vitro* and *in vivo*. Immunological surveillance in the MRD-situation might be of particular relevance for long-term control or even elimination of CML-repopulating stem cells. Little is known about potential immune-modulatory effects of nilotinib *in vivo*. The ENEST1st study (NCT01061177) is focused on examining the role of first-line nilotinib therapy in CML-CP. A comprehensive immunological monitoring program within this ENEST1st substudy allows characterization of nilotinib-induced immunological changes and their potential correlation with clinical response parameters.
Aims: The identification of immunological changes induced by nilotinib and definition of immunological surrogates for response prediction in newly diagnosed CML-CP patients.
Methods: Peripheral blood was taken prior to treatment initiation and after 6 and12 months (mo) from 50 patients treated on the ENEST1st study. Samples were analyzed by nine colour flow cytometry employing six panels of antibodies to determine various leukocyte populations including T cell subsets. Soluble factors in plasma were measured by ELISA. Changes in immune cell parameters were correlated to clinical endpoints.
Results: 55% of the patients included into this substudy achieved MMR at 6mo, 75% at 12mo and 79% at 12mo of therapy. $MR^{4.5}$ was achieved by 5%, 18%, 24% of patients at 6, 12 and 24 mo of therapy, respectively. The proportion of CD8+ T cells significantly decreased while CD4+ T cells increased during therapy. Expression of the known lymph node homing marker CD62L was very low at baseline (median 5,7%) and the proportion of CD62L-expressing cells among CD4+ and CD8+ T cells negatively correlated with SOKAL score. During treatment, CD62L expression on both T cell subsets significantly increased (median 72,3%) and was restored to normal levels. Moreover, higher expression of CD62L+ cells was negatively associated with lower BCR-ABL mRNA burden at different time points and also predicted the time to reach MMR. More than 60% of patients with CD62L expressing cells above 25% (upper third) but less than 10% of the other patients reached MMR within the first three months ($p \leq 0.001$). As CD62L is a marker for naïve T cells, low expression of CD62L seems to indicate increased proportions of memory cells. However, a detailed characterization of other T cell differentiation marker, such as CD45RA, CD45R0, CD28, CD27 and CD95, did not reveal significant T cell subset alterations. Thus we speculated that low levels CD62L expression levels might be the result of increased shedding. Indeed, levels of metalloproteinases (MMP), mediating proteolytic cleavage of CD62L, were increased in plasma before compared to after treatment initiation. Finally, plasma taken at baseline but not after treatment initiation down modulated CD62L on normal T-cells.
Summary and Conclusions: Here we show decreased expression of CD62L in patients with CML-CP, probably due to cleavage by aberrantly expressed/activated MMP. CD62L is an important adhesion molecule regulating migration and homeostasis of immune cells. This may partly explain why patients with relatively normal CD62L expression are able to rapidly reduce BCR-ABL mRNA burden upon initiation of therapy. Alternatively, other targets of MMP might be causally involved in this process and CD62L expression may just represent a surrogate marker for MMP activity.

P256

LASP1 IS A NOVEL BCR-ABL SUBSTRATE AND A PHOSPHORYLATION-DEPENDENT BINDING PARTNER OF CRKL IN CHRONIC MYELOID LEUKEMIA

JJ Frietsch[1,*] C Kastner[2], TGP Grunewald[3], H Schweigel[4], P Nollau[4], J Ziermann[1], JH Clement[1], P La Rosée[1], A Hochhaus[1], E Butt[2]
[1]Klinik für Innere Medizin II, Abteilung für Hämatologie und Internistische Onkologie, Universitätsklinikum Jena, Jena, [2]Institute for Clinical Biochemistry and Pathobiochemistry, University of Wuerzburg, Wuerzburg, Germany, [3]INSERM Unit 830, Genetics and Biology of Cancers, Institute Curie Research Center, Paris, France, [4]Department of Clinical Chemistry, University Medical Center Hamburg-Eppendorf, Hamburg, Germany

Background: Chronic myeloid leukemia (CML) is characterized by a genomic translocation generating the Philadelphia chromosome with a permanent active BCR-ABL oncogene and yielding a complex pattern of atypically tyrosine-phosphorylated proteins that ultimately drive the malignant phenotype of CML. Recently the LIM and SH3 domain protein 1 (LASP1), a protein involved in cell proliferation and migration, was identified as a component of a six gene signature strongly predictive for disease progression and relapse in CML patients. However, the underlying molecular mechanisms why LASP1 expression correlates with dismal outcome remained unresolved.
Aims: It is thought that leukemia stem cells (LSC) (primitive CML progenitor cells) may not be addicted to BCR-ABL and shift to other pathways when treated with tyrosine kinase inhibitors (TKI) and are the reason for insufficient responses, relapse or progression into advanced phase or blast crisis. The identification and inhibition of pathways implicated in LSC survival, in combination with conventional therapy is the new therapeutic ambition in CML treatment to overcome TKI resistance and eradicate minimal residual disease in CML. In this context, the role of LASP1 in aberrant BCR-ABL signaling and CML progression is elucidated.
Methods: Comprehensive transcriptomic microarray data, immunofluorescence imaging and biochemical analysis like phosphopeptide binding assay, Western blot, immunoprecipitation and protein overlays were used to elucidate the role of LASP1 in CML progression in BCR-ABL positive cell lines and in blood leucocytes from CML patients before and after TKI therapy.

Results: LASP1 as a novel and highly overexpressed direct substrate of BCR-ABL in CML. The protein is specifically phosphorylated by BCR-ABL at tyrosine-171 in CML patients, which is abolished by tyrosine kinase inhibitor therapy. pLASP1-Y171 binds to non-phosphorylated CRKL, another specific BCR-ABL substrate and bona fide biomarker for BCR-ABL activity, at amino acids 36-39 of the SH2 domain of CRKL. Immunofluorescence validated localization of LASP1 and colocalization with CRKL. Accordingly, the BCR-ABL-mediated pathophysiological hyper-phosphorylation of LASP1 in CML disrupts normal regulation of CRKL and LASP1, which likely has implications on downstream BCR-ABL signalling.
Summary and Conclusions: In summary, the results suggest that LASP1 phosphorylation might serve as an additional biomarker for assessment of BCR-ABL activity and point to an important role of LASP1 in aberrant BCR-ABL signaling. Moreover, these data provide a first mechanistic insight in why LASP1 overexpression might contribute to CML progression.

P257

DNA METHYLTRANSFERASE 1-DRIVEN HYPER-METHYLATION OF B CATENIN ANTAGONIST CHIBBY1 IS NOT AN EPIGENETIC MARK OF CHRONIC MYELOID LEUKEMIA RESISTANCE TO IMATINIB

E Leo[1,*] M Mancini[1], F Castagnetti[1], G Gugliotta[1], MA Santucci[1], G Martinelli[1]
[1]Department of Experimental Diagnostic and Specialty Medicine - DIMES, University of Bologna, Bologna, Italy

Background: Chibby1 is an antagonist of β catenin, a central component of chronic myeloid leukemia pathogenesis and progression to blast crisis. Our recently published study proved that Chibby1 down-modulation is a component of β catenin activation associated with the *BCR-ABL1* fusion gene, partly contingent upon transcriptional events and driven by DNA hyper-methylation at promoter-associated CpG islands of the Chibby1-encoding gene *C22orf2*. Moreover, it established that Chibby1 induction in response to imatinib in chronic myeloid leukemia cells proceeds, at least partly, from *C22orf2* promoter demethylation. Indeed, methylator phenotype encompassing genes involved in leukemic cell proliferation and survival is a common event in chronic myeloid leukemia, eventually associated with the disease progression and drug resistance outcome.
Aims: We investigated whether DNA methyltransferase 1 is responsible for epigenetic control on tumor suppressor genes (such as *CBY1* and *BCL2-like11*) in K562 cell line and mononuclear cell fractions from bone marrow samples of chronic myeloid leukemia patients. Moreover we assessed the correlation between DNMT1 activity and imatinib resistance in imatinib-responsive and -resistant chronic myeloid leukemia patients.
Methods: PCR amplification of DNA from chromatin immunoprecipitation products was used to assess the amounts of DNA methyltransferase 1 and 5 methylcytosine at a 205 bp promoter region encompassing nucleotides -85 to +120 of C22*orf*2 promoter and at a 342 bp sequence of the pro-apoptotic *BCL2-like11* (BIM) in *BCR-ABL1+* cell line K562 and mononuclear cell fractions from bone marrow samples of imatinib-responsive and -resistant chronic myeloid leukemia patients.
Results: We found that DNA methyltransferase 1 enhanced recruitment is involved in hyper-methylation of C22*orf*2 promoter, associated with Chibby1 transcript reduction in three out of five imatinib-responsive patients and all three imatinib-resistant patients, supporting that such epigenetic modification is not the cause of overt resistance to imatinib. Further investigation showing that the DNA methyltransferase 1-driven hyper-methylation of the pro-apoptotic *BCL2-like11*, a crucial gene for the prognosis and response of chronic myeloid leukemia to imatinib, is not strictly associated with drug resistance.
Summary and Conclusions: Those findings suggest that DNA methyltransferase 1-driven epigenetic control on *Chibby1* and other tumor suppressor genes such as *BCL2-like11* is not the cause of overt chronic myeloid leukemia resistance to imatinib. Still, the DNMT1-driven hyper-methylation at those critical genes for cell survival and proliferation may contribute to the disease clonal evolution, hence supporting the clinical use of de-methylating agents, in particular, in the disease advanced stages.

MYELOID DERIVED SUPPRESSOR CELLS (MDSCS) AS POTENTIAL IMMUNE ESCAPE MECHANISM IN CML PATIENTS

C Giallongo[1,*] N Parrinello[1], D Tibullo[1], P La Cava[1], A Romano[1], A Chiarenza[1], F Stagno[1], P Vigneri[1], G A Palumbo[1], F Di Raimondo[1]
[1]Clinical and Molecular Biomedicine, section of Hematology, University of Catania, catania, Italy

Background: In some solid tumors it has been demonstrated that a subpopulation of myeloid cells, defined as "myeloid-derived suppressor cells" (MDSCs), plays an important role in inducing T cell tolerance by production of arginase 1 (arg1) that depletes microenvironment of arginine, an essential aminoacid for T cell function. Since chronic myeloid leukemia (CML) patients have high levels of immature myeloid cells it is of interest to investigate if these cells have MDSCs phenotype and activity.
Aims: The aim of this study was to analyze MDSCs and investigate their activity in CML patients.
Methods: MDSCs were analyzed in peripheral blood (PB) of healthy donors (HD; n=20), 30 CML patients at diagnosis, 21 of which collected from diagnosis and followed during imatinib. Granulocytic MDSCs (G-MDSCs) were identified as CD11b+CD33+CD14-HLADR- cells, while the monocytic MDSCs (Mo-MDSCs) as CD14+HLADR by cytofluorimetric analysis. Arg1 expression was assessed using real time PCR and Western Blot and the circulating protein was measured by ELISA.
Results: CML patients showed high levels of Mo- and Gr-MDSCs at diagnosis in comparison to HD (41±8 and 82,5±12,2% respectively in CML *vs* 9±2,1 and 55±5,3% in HD; p<0.001), while after imatinib therapy both subpopulations decreased returning to normal values. Also T-reg (CD4+ $CD25^{high}$ Foxp3+ cells) was significantly increased at diagnosis in respect to HD (from 6,1±0,8% to 9±2%; p<0.001) with a significant correlation with the percentage of Gr-MDSCs (r=0,6254; p<0.001). In order to evaluate if at least in part MDSCs belong to the tumor clone, we analyzed BCR/ABL expression in both CD11b+CD33+CD14-HLADR- and CD14+HLADR- subpopulation cells and all 3 analyzed patients showed the oncoprotein expression in both the two subsets. Either in PB cells and purified Gr-MDSCs, we showed a significant increase in Arg1 expression in CML patients at diagnosis compared to HD (p<0.001) and decreased after therapy. The same data were confirmed by Western Blot analysis. The differences in Arg1 concentration in serum of HD and CML patients at diagnosis was statistically significant (64±37,5 *vs* 260,6±64,3 ng/ml; p<0.0001) and a significant correlation was observed with the percentage of Gr-MDSCs (r=0,61; p<0.05). To verify whether the population of cells with the phenotype of Gr-MDSCs and high levels of Arg1 expression in CML patients could be functionally defined as MDSCs, we determined their ability to inhibit the proliferation of CFSE+ T cells. A significant suppressive function was observed (p<0.001). Since CML patients at diagnosis have high levels of arg1 in serum, subsequent experiments were designed to further understand whether also circulating protein has immunosuppressive activity with CML MDSCs. After 72 h from mitogen stimulation and incubation with HD or CML serum, the percentage of proliferation of CFSE-labeled T cells was significantly inhibited with CML serum compared to positive control (HD T cells plus PHA) (p<0.05) and this inhibitory effect was lost by the addition of Nor.NOHA (p<0.05).
Summary and Conclusions: Our data indicate that CML cells create an immunotolerant environment associated to MDSCs expansion with immunosuppressive capacity mediated by arginase1 (arg1) that could hinder the use of immunotherapy in CML patients. MDSCs should be monitored in imatinib discontinuation trials to understand their importance in relapsing patients.

P259

BIN1 AND RIN1 MODULATION IN CHRONIC MYELOID LEUKEMIA

S Trino[1,*] L De Luca[1], V Simeon[1], I Laurenzana[1], A Morano[1], A Caivano[1], F La Rocca[1], E Bracco[2], E Signorino[2], G Pietrantuono[3], G Bianchino[4], V Grieco[4], G Saglio[2], P Musto[5], D Cilloni[2]
[1]Laboratory of Pre-clinical and Translational Research, IRCCS-CROB, Referral Cancer Center of Basilicata, Rionero in Vulture (Pz), [2]Department of Clinical and Biological Sciences, University of Turin, Turin, [3]Department of Onco-Hematology, [4]Laboratory of Clinical Research and Advanced Diagnostics, [5]Scientific Direction, IRCCS-CROB, Referral Cancer Center of Basilicata, Rionero in Vulture (Pz), Italy

Background: The role of *Bcr-Abl* in the pathogenesis of Chronic Myeloid Leukemia (CML) is well established, however the mechanisms involved in progression remain poorly understood. By making use of *Drosophila Melanogaster* transgenic model for human *Bcr-Abl* gene, we have identified the involvement in CML progression of different genes regulating the recycling and the degradation of tyrosine kinase receptors (RTKs) through the assembly of clathrin coated vesicles. Among them, we focused our attention on Bridging Integrator 1 (Bin1) and its activator Rin1.
Aims: We aimed to identify and characterize a new possible mechanism substaing BCR-ABL pathway acting through a defect in recycling and degradation of RTKs through the assembly of clathrin coated vesicles.
Methods: *Bin1* and *Rin1* expression was measured by quantitative Real Time PCR (qRT-PCR) in 82 samples from CML patients and in 10 healthy control samples. Among CML, 34 samples were collected at diagnosis and 45 during the tyrosine kinase inhibitors (TKIs) treatment, 11 of which in Complete Molecular Response (CMR), 17 in Major Molecular Response (MMR), 17 in <MMR and 3 Imatinib resistant patients. Western Blot (WB) analysis was performed to analyze Bin1 and Rin1 expression in control subjects and CML patients. Bin1 and Rin1 expression was also analyzed by qRT-PCR and WB in K562 and HEK-293 cell lines after treatment with Imatinib at different times (24 and 48 hours).
Results: qRT-PCR data indicated that *Bin1* expression was significantly down-regulated in CML patients at diagnosis compared to healthy subjects (p=0.0001). Overall, during TKIs therapy, the transcript levels of *Bin1* showed an up-regulation trend from <MMR (p=0.0001) to MMR (p=0.0001), to CMR (p=0.0001) compared with diagnosis. Interesting, *Bin1* was also down-regulated in three TKIs resistant patients as observed in diagnosis ones (Figure 1A). These results demonstrated an indirect correlation between *Bin1* and *Bcr-Abl*

transcript expression levels (Figure 1A and 1C). Bin1 is activated by Rin1, a RAS effector protein, to promote the formation of early endosome structures. Besides, Rin1 interacts with Bcr-Abl stabilizing the fusion protein in CML cell lines. To assess if Rin1 was correlated with Bin1 in CML patients, we analyzed *Rin1* transcript levels in the same cohort of subjects. Like *Bin1*, *Rin1* expression was down-regulated in CML patients at diagnosis respect to healthy subjects (p=0.01), and was up-regulated during TKIs therapy from <MMR (p=0.0001) to MMR (p=0.05), to CMR (p=0.001) compared with diagnosis. Moreover, *Rin1* remained down-regulated in resistant patients (Figure 1B). To confirm the qRT-PCR data on CML patients, we analyzed both protein expression by WB analysis and we observed the same trend of transcript levels. To better elucidate the inverse correlation between Bcr-Abl, Bin1 and Rin1, we performed i*n vitro* experiments by Imatinib treatment, in K562 and HEK-293 cells. WB data showed an up-regulation of Bin1 and Rin1 proteins in K562 cell line, after 24 and 48 hours of treatment; we did not observe any variation of their expression in non tumorigenic cell line, HEK-293.

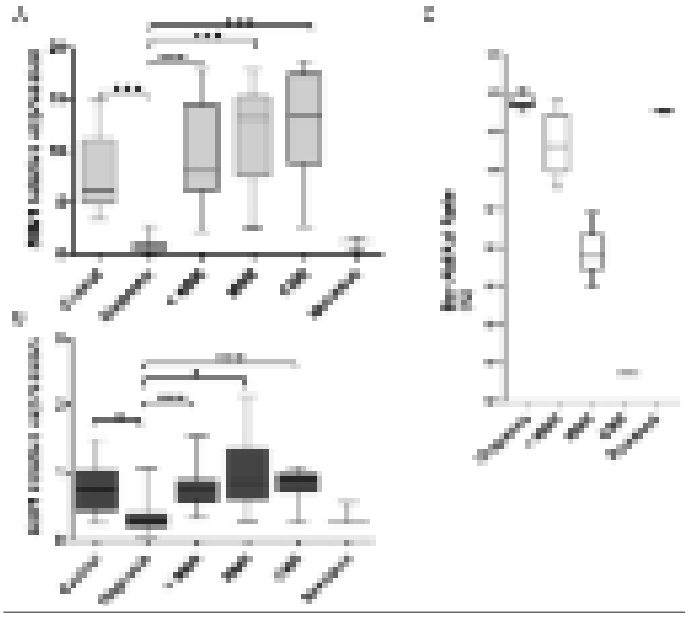

Figure 1. *BIN1* A) and *RIN1* B) expression levels were evaluated by qRT-PCR in control subjects, CML samples at diagnosis, and during TKIs treatment (<MMR, MMR, CMR and resistant patients). C) Numbers of *Bcr-Abl* transcripts were evaluated by qRT-PCR as Bcr-Abl/Abl Ratio (%) in CML saples at diagnosis and during TKIs treatment (<MMR, MMR, CMR and resistant patients).

Summary and Conclusions: Our results show a significant association between *Bin1* and *Rin1* expression and clinical phases of CML, suggesting an indirect correlation with Bcr-Abl levels. This study proposes a new deregulated mechanism in CML indicating Bin1 and Rin1 as possible players in the maintenance of the abnormal signaling in this haematological disease.

P260

PROMOTER METHYLATION OF THE TUMOR SUPPRESSOR GENES ON THE SHORT ARM OF CHROMOSOME 1 IN CHRONIC MYELOGENOUS LEUKEMIA

N Mori[1,*] M Ohwashi[1], H Shimura[1], K Yoshinaga[1], M Shiseki[1], J Tanaka[1]
[1]Hematology, Tokyo Women's Medical University, Tokyo, Japan

Background: Chronic myelogenous leukemia (CML) is a hematological disorder characterized by Philadelphia chromosome and /or *BCR-ABL* fusion gene. We previously reported frequent loss of heterozygosity on the short arm of chromosome 1 (1p) in the progression of CML. Methylation (5-mC) in a promoter CpG of several tumor suppressor genes has been associated with loss or decreased expression in many tumors. Among candidate genes on 1p36, methylation of the *RIZ1, RUNX3,* and *p73* genes has been found, and the *RIZ1* gene was also inactivated by frameshift and missense mutations in solid tumors. We recently reported that RIZ1 methylation was more frequent in myelodysplastic syndrome and secondary leukemia. However, 5-mC was converted to 5-hmC by tet enzyme, and both 5-mC and 5-hmC were detected by conventional methylation specific polymerase chain reaction (MS-PCR).
Aims: To elucidate the relevance of tumor suppressor genes on 1p, we analyzed mutation and promoter methylation on the *RIZ1, RUNX3*, and *p73* genes in CML. To distinguish 5-mC from 5-hmC in promoter region, we performed oxidative MS-PCR.
Methods: Mononuclear cells were isolated from bone marrow or peripheral blood samples after obtaining written informed consent from 61 patients with CML. The 61 CML consisted of 43 chronic phase (CP), 2 accelerated phase (AP), and 16 blast crisis (BC). This study was performed according to ethical criteria of our institute. Genomic DNA was treated with bisulfite, and treated DNA was subject to amplification with HotStarTaq Master Mix Kit (Qiagen, Valencia, CA, USA) for MS-PCR. Bisulfite sequence was performed in both directions. Oxidative MS-PCR analysis was performed using $KRuO_4$ before bisulfite treatment. Samples that showed methylation more than twice were assessed as positive. Mutation was analyzed using PCR-single strand conformation polymorphism (SSCP) analysis. Quantitative real time reverse transcriptase-PCR was performed in 14 patients of which RNA was suitable for analysis. K-562 myeloid leukemia cells were grown in RPMI 1640 in the presence of various concentrations of 5-Aza-dC with or without tricostatin A (TSA). The correlation between the frequency of methylation and type of disease or clinical characteristics was analyzed using the chi-square test or Fisher's exact probability test. Analysis was performed using SPSS Software.
Results: MS-PCR showed methylation of the *RIZ1, RUNX3* and *p73* genes in 24 of the 60 (40%), 21 of the 61 (36%), and 28 of 60 (46%) patients, respectively. Methylation at all the three loci was detected in 19 of 60 patients (32%). Bisulfite sequence analysis revealed that methylation was present at many CpG sites in the *RIZ1, RUNX3,* and *p73* promoter regions in CML. *RIZ1* methylation was detected in 14 of the 43 CML in CP (33%), none of the 2 CML in AP, and ten of 15 CML in BC (67%). Methylation of the *RUNX3* gene was detected in 12 of the 43 samples of CP (30%), 0 of the 2 AP, and nine of the 16 BC (60%). Methylation of the *p73* gene was observed in 16 of the 43 samples of CP (37%), 0 of the 2 AP, and 12 of 15 BC (80%). *RIZ1, RUNX3*, and *p73* methylation was more frequent in BC than in first, CP. Oxidative MS-PCR analysis together with MS-PCR can distinguish 5-mC from 5-hmC: 5-mC in the *RIZ1, RUNX3,* and *p73* genes was detected in 10 of 22 (45%), 16 of 21 (76%), and 16 of 26 (62%) samples with methylation detected by conventional MS-PCR, respectively. PCR- SSCP analysis on the *RIZ1, RUNX3*, and *p73* genes showed mobility shifts in 2 CML patients in exon 3 of the *p73* gene, however sequence analysis reveals one-base deletion in intron 2. Quantitative real time reverse transcriptase-PCR analysis showed decreased expression of the *RIZ1, RUNX3,* and *p73* genes in several patients with or without 5-mC. Treatment of K-562 cells (that have 5-mC in *RIZ1* and *RUNX3*) with 5-Aza-dC and TSA induced growth suppression, demethylation, and reexpression of the genes.
Summary and Conclusions: Multiple tumor suppressor genes on 1p were inactivated in CML in part by methylation. In comparison with CP, higher incidence of the *RIZ1, RUNX3, and p73* methylation was found in BC. Oxidative MS-PCR analysis was useful to detect real 5-mC. Combination treatment of 5-Aza-dC and TSA resulted in reactivation of the repressed genes more efficiently.

Seragnoli", [4]Institute of Haematology "L. e A. Seragnoli", "L. e A. Seragnoli", Bologna, [5]San Luigi Gonzaga Hospital, University of Turin, Orbassano, Italy, [6]HRB Clinical Research Facility, NUIG & TCD, Galway, Ireland, [7]Jena Hospital, Jena University, Jena, Germany

Background: Treatment of patients with CML-CP with tyrosine kinase inhibitors (TKIs) can substantially improve the life expectancy of these patients. However, it is becoming evident that persistant leukemic stem cells, which in their quiescent state are insensitive to TKIs, can lead to a resurgence of CML. The Evaluating Nilotinib Efficacy and Safety in Trial as First-Line Treatment (ENEST1st) is a phase 3b is an open-label study of nilotinib 300 mg twice daily (BID) in adults with newly diagnosed BCR-ABL positive CML-CP.
Aims: The aim of the ENEST1st sub-study N10 is to investigate BM microenvironment markers that regulate leukemic stem cells in the BM niches of nilotinib-treated patients.
Methods: We enrolled 37 patients from 21 Italian ENEST1st centers, from whom written informed consent had been obtained, for participation in substudy N10. Patients were monitored by Real Time RT-PCR (RT-qPCR) for the expression of the fusion BCR-ABL mRNA. Response was based on ELN recommendations (Baccarani M, *et al.* Blood 2013 122:872-884). In an interim analysis, molecular and cytogenetics response by 24 months was assessed.Mononuclear cells were collected from BM and PB samples at the screening visit (V0) and after 3 months of treatment (V4). Total RNA from BM and PB mononuclear cells was purified. RT-qPCR for the expression of 10 genes (ARF, KIT, CXCR4, FLT3, LIF, NANOg, PML, PRAME, SET and TIE), involved in the regulation of the stemness and survival signaling of hematopoietic stem cells was conducted. RT-qPCR results were normalized by the expression of GUS mRNA (Normalized mRNA copy Number: NCN).

Results: Interim molecular analysis of MMR until the 24th month was available for 27 of the 37 patients, showing an optimal response in 20 patients, a warning response in 4 patients and a failure response in 3 patients. We observed a significant correlation in the expression of two genes involved in the regulation of stem cell pluripotency (NANOg) or cytokine signaling (SET) and patient's outcome. Indeed, NANOg and SET mRNA were significantly down-regulated in PB samples at diagnosis of patients with optimal response compared to patients with warning/failure response, (NANOg mRNA: 0.3±0.25 NCN by GUS mRNA *vs* 0.6±0.7 NCN by GUS mRNA, respectively; p=0.05; SET mRNA: 0.2±0.3 NCN by GUS mRNA *vs* 2.3±4.2 NCN, respectively; p=0.03).
Summary and Conclusions: These data suggest that expression analysis of genes involved in cell pluripotency (NANOg) and/or cell signaling (SET) at baseline, may assist in the early prediction of molecular response in patients treated with nilotinib. Further studies are planned to evaluate the role of stroma-secreted cytokines, such as SDF1 and VEGF, in the regulation of TKI-responsiveness in CML patients, since factors that modulate hematopoiesis may also promote leukemogenesis, enhance blast survival and make them resistant to treatment within the BM microenvironment.

EFFECTS OF THE PI3-KINASE/MTOR INHIBITOR BEZ235 ON ONCOGENIC SIGNALING, PROLIFERATION AND SURVIVAL OF LEUKEMIC CELLS IN CML

I Sadovnik[1,*] H Herrmann[1,2], G Stefanzl[1], D Berger[1], G Hoermann[3], K Blatt[1], S Cerny-Reiterer[1,2], W R Sperr[1,2], H Sill[4], P Valent[1,2]
[1]Department of Medicine I, [2]Ludwig Boltzmann Cluster Oncology, [3]Department of Laboratory Medicine, Medical University of Vienna, Vienna, [4]Division of Hematology, Medical University of Graz, Graz, Austria

Background: In Ph+ chronic myeloid leukemia (CML) the BCR/ABL oncoprotein represents a major pro-oncogenic driver responsible for proliferation and accumulation of leukemic cells. The BCR/ABL tyrosine kinase inhibitor (TKI) imatinib produces long-lasting complete molecular remissions (CMR) in a subset of patients with CML. For patients with imatinib-resistant CML, novel second and third generation BCR/ABL TKI, such as nilotinib or ponatinib are available. However, not all patients achieve long-lasting CMR during TKI therapy. Therefore, current research is seeking novel targets in CML cells. The PI3-kinase and the mammalian target of rapamycin (mTOR) are two key downstream-signaling molecules considered responsible for BCR/ABL-induced proliferation of leukemic cells.
Aims: In the present study, we examined the effects of the dual PI3-kinase/mTOR blocker BEZ235 on growth and survival of CML cells.
Methods: A total of 7 patients with CML (chronic phase, n=6; accelerated phase, n=1) were examined. Proliferation of mononuclear CML cells was determined by ^{3}H-thymidine uptake and apoptosis by PI/AnnexinV-staining and staining for active caspase 3.
Results: BEZ235 was found to inhibit the proliferation of primary CML cells in a dose-dependent manner. In addition, BEZ235 suppressed the proliferation of various CML cell lines, including K562 (IC50: 50-100 nM), imatinib-resistant K562 (IC50: 50-100 nM), KU812 (IC50: 20-50 nM) and KCL22 cells (IC50: 10-20 nM). Moreover, BEZ235 induced growth-inhibition in Ba/F3 cells expressing various imatinib-resistant mutants of BCR/ABL, including T315I. Despite these impressive effects, BEZ235 did not induce apoptosis in CML cell lines. In subsequent experiments we found that BEZ235 downregulates the phosphorylation of the 40S ribosomal protein S6, and less effectively also Akt in BCR/ABL+ cells, but even upregulates the expression of activated STAT5 and the STAT5-target gene CD25. Based on these observations, we combined BEZ235 with nilotinib and ponatinib, both of which are known to induce apoptosis, growth inhibition and STAT5-downregulation in CML cells. We found that BEZ235 and nilotinib as well as BEZ235 and ponatinib exert strong cooperative growth-inhibitory effects in CML cells.
Summary and Conclusions: In conclusion, BEZ235 is a potent inhibitor of BCR/ABL-dependent proliferation of CML cells, but exert little if any effects on cell survival. Moreover, our data show that BEZ235 and various BCR/ABL TKIs synergize with each other in counteracting proliferation in CML cells. Whether BEZ235 alone or in combination with nilotinib or ponatnib, can also suppress the proliferation of leukemic cells *in vivo* in patients with CML remains to be determined in clinical trials.

P263

IMPACT OF CLONAL EVOLUTION ON THE OVERALL SURVIVAL OF PATIENTS WITH CML TREATED WITH IMATINIB: EXPERIENCE OF ONE CENTER

A Lukianova[1,*] O Zotova[1], M Valchuk[1], M Simonova[1], Y Karol[1], L Lukavetskyy[1], K Kotlyarchuk[1], V Novak[1]
[1]SI "Institute of Blood Pathology and Transfusion Medicine, NAMS of Ukraine", Lviv, Ukraine

Background: Occurrence of secondary chromosomal aberrations in patients with chronic myeloid leukemia (CML) is one of the factors influencing patient survival. These changes may appear on the background of treatment with tyrosine kinase inhibitors (TKI) both in Ph-positive (Ph+) and Ph-negative cells (Ph-). The influence of these abnormalities developing in the first category of cells was describes by many authors, whereas data concerning Ph-negative cells is limited.
Aims: Purpose of this study was to establish influence of chromosomal abnormalities in Ph+ and Ph- cells on the overall survival of patients with CML treated with imatinib.
Results: Cytogenetic examination was conducted in 101 patients with CML treated with TKI imatinib for median of 82 months (ranging from 9 to 166 months). Overall, median observation time for these patients from the diagnosis of CML was 94 months (from 25 to 296 months). The emergence of secondary cytogenetic abnormalities (clonal evolution) in Ph+ cells was revealed in 23 patients compared to 6 patients developing these changes in Ph–, cells. Spectrum of additional chromosomal aberrations in Ph+ cells was as follows: +der(22)t(9;22), +8, i(17)(q10), ider(22;22)t(9;22), idic der(22;22)t(9;22), -7, +19, +21, -Y and other structural or numerical aberrations. In Ph– cells +8 and del(7q) were revealed. Two peaks when the secondary chromosomal abnormalities were detected most frequently occurred between 12th and 36th month of imatinib therapy and after 60th month of this treatment. Among 23 patients with additional aberrations in Ph+, cells 9 subjects lost partial (PCyR) or complete (CCyR) cytogenetic response during treatment, and other 16 subjects did not reach any cytogenetic response at all. All patients with abnormalities in Ph- cells were diagnosed with these changes exceptionally during PCyR or CCyR. Thereafter all patients with cytogenetic aberrations in Ph– cells lost their cytogenetic response at different time points. Patient survival in two groups significantly differed; in particular, median survival was not reached in patients without clonal evolution, while in patients with clonal evolution it was detected at 100 months from the time of diagnosis (Figure 1).

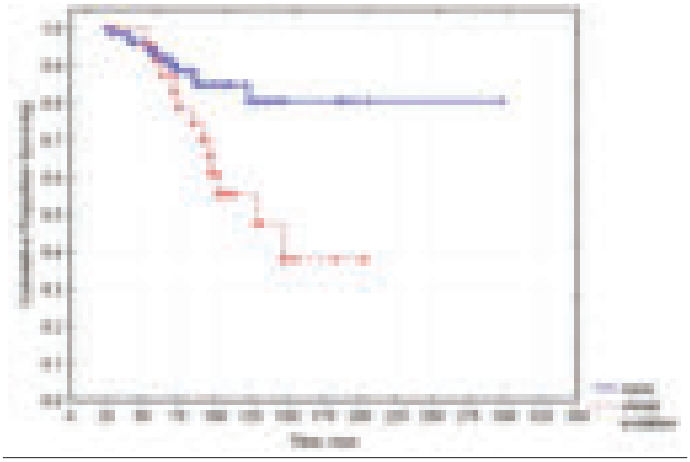

Figure 1. Overall survival of CML patiens with and without clonal evolution.

Summary and Conclusions: Occurrence of secondary changes both in Ph-positive and Ph-negative cells is a sign of unfavorable prognosis concerning treatment response and patient survival. The highest risk of clonal evolution was observed between 12th and 36th months of treatment with imatinib.

A FUNCTIONAL POLYMORPHISM IN THE 3' UNTRANSLATED REGION OF THE ARHGAP26 GENE CONFERS AN INCREASED RISK OF CHRONIC MYELOID LEUKEMIA AND CAUSES ILLEGITIMATE REGULATION BY MICRORNA-18A-3P

A Dzikiewicz-Krawczyk[1,*] E Mały[2], M Fichna[1], E Strauss[1], D Januszkiewicz-Lewandowska[1,3], J Nowak[1]
[1]Institute of Human Genetics, [2]Department of Medical Diagnostics, [3]Department of Oncology, Hematology and Bone Marrow Transplantation, Poznań University of Medical Sciences, Poznań, Poland

Background: MicroRNAs are small regulatory RNAs that control a wide variety of biological processes, such as proliferation, apoptosis and differentiation. MicroRNAs also play a crucial role in normal hematopoiesis by controlling the differentiation of hematopoietic stem cells into different types of mature blood cells, while deregulation of microRNA networks has been linked to hematological malignancies. Polymorphisms in microRNA binding sites (miRSNPs) in target genes may alter the strength of microRNA interaction with target transcripts thereby deregulating protein levels.
Aims: In this study we aimed at identifying miRSNPs associated with the risk of chronic myeloid leukemia and assessing the impact of these miRSNPs on the protein expression.
Methods: We analyzed with specialized algorithms (miRANDA, PITA, Patro-

cles and PolymiRTS) the 3' untranslated regions of 132 leukemia-associated genes and identified 111 putative miRSNPs, of which 10 were chosen for further investigation, based on the concordance of at least two applied algorithms. We genotyped patients with chronic myeloid leukemia (CML, n=140) and healthy controls (n=471). MiRSNPs found to be associated with leukemia risk were analyzed for their impact on the protein levels by luciferase reporter assay.
Results: Here we show that variant alleles of *ARHGAP26*_rs187729 T>C and *IRF8*_ rs10514611 C>T were associated with an increased risk of CML in the recessive model, with adjusted odds ratio (OR) and 95% confidence interval (95% CI)=1.63 (1.08-2.47) and 2.4 (1.12-5.15), respectively. Luciferase reporter assay revealed that the C allele of *ARHGAP26*_rs187729 creates an illegitimate binding site for miR-18a-3p, which leads to a 34% decrease in the protein levels (Figure 1).

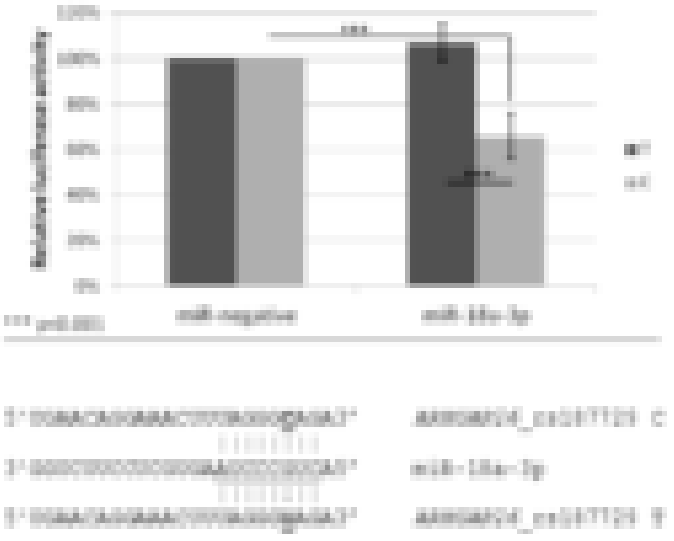

Figure 1. *ARHGAP26*_rs187729.

Summary and Conclusions: Our results demonstrate that the functional polymorphism in the 3'UTR of the tumor suppressor *ARHGAP26* leads to decreased protein levels mediated by miR-18a-3p, which may contribute to an increased risk of CML.

PHARMACOGENETIC DETERMINANTS OF PLASMATIC AND INTRACELLULAR TYROSINE KINASE INHIBITORS
C Fava[1,*] J Cusato[2], A Ariaudo[2], A D'Avolio[2], S De Francia[3], E Giugliano[1], G Rege-Cambrin[1], G Saglio[1]
[1]Division of Haematology and Internal Medicine, University of Turin, San Luigi Hospital, Orbassano, [2]Dept. of Clinical Pharmacology and Pharmacogenetics, University of Turin, Amedeo di Savoia Hospital, Turin, [3]Dept. of Clinical Pharmacology, University of Turin, San Luigi Hospital, Orbassano, Italy

Background: Tyrosine Kinase Inhibitors (TKIs) imatinib (IM), nilotinib (N) and dasatinib (D) are commercially available for the treatment of Ph+ Chronic Myeloid Leukemia. IM has a half-life of 12-20 hours (h), N of 15-17 h whereas D has a half-life of 3-5 h only. IM influx is dependent on hOCT1 protein and on other minor transporters. D and N have cellular uptake by diffusion. IM, D and N efflux is dependent on ABCB1 and ABCG2 transporters. Pharmacokinetic (PK)-related factors affecting exposure to TKIs may be involved in resistance to these drugs. TKI plasma level is correlated with efficacy. However there is a wide interpatient variability in drug exposure and this may be partly due to polymorphisms in transporter genes. Furthermore intracellular TKI accumulation and retention was identified as the underlying mechanism of induction of apoptosis but how this concentration is correlated to plasma concentration was never investigated.
Aims: We evaluated plasma and intracellular concentrations of the 3 drugs and we investigated the correlation between plasmatic and intracellular concentrations of IM, D and N, and genotypes of ABCB1 (3435C>T, 1236 C>T, ABCB1 2677 G>T).
Methods: Samples were collected after steady state was reached. HPLC-UV was used for plasma determination of IM and N; while for D analyses an HPLC-MS was used. For intracellular PK, drugs were extracted from isolated peripheral blood mononuclear cells (PBMC), after sonication. Chromatographic intracellular PK evaluation was performed on an HPLC-MS instrument. The allelic discrimination analysis was performed in PCR real-time (BIORAD, Milano, Italia) using the TaqMan assays (Applied Biosystems, Foster City, CA).
Results: We analyzed 56 patients from our Institution: 27 were treated with IM [8 females (F), 19 males (M)], 15 with D (7 F, 9 M) and 14 with N (7 F, 7 M). The median plasma level was 1116 ng/ml (744-1388) for IM, 2.48 ng/ml (0.78-5.74) for D, 1202 ng/ml (680-1638) for N. The median intracellular concentration was 5676 ng/ml (4474-8233) for IM, 452 ng/ml (133-767) for D, 4821 ng/ml (743-8697) for N. The PBMC/plasma ratio was 5.36 for IM, 167 for D and 4.7 for N. We found a statistically significant correlation between the PBMC/plasma ratio of IM and ABCB11236C>T polymorphism: patients carrying CC wild type (WT) had higher ratios *versus* heterozygotes/mutated patients (p=0.027). Significant correlations between plasma concentrations (p=0.011) and ABCB1 3435C>T SNP was observed, with higher concentrations for the TT group *versus* CC+CT group. Accordingly, the CC+CT group had higher PBMC/plasma ratio as compared with the TT group (p=0.018). No correlation was found either between IM and D intracellular concentrations and transporter polymorphisms, or between drug concentrations and genotypes for N. We are now expanding the number of samples in order to verify these data. Finally we found a positive Spearman correlation between plasmatic and intracellular concentration for the 3 drugs (R=0.6, p=0.001 for IM; R=0.559, p=0.024 for D; R=0.508, p=0.064 for N).
Summary and Conclusions: Drugs, particularly D, accumulate in cells, with a correlation between plasmatic and intracellular concentration. Bcr-Abl kinase activity is inhibited in a concentration-dependent fashion, indicating that the cytotoxicity of high-dose pulse exposure to TKIs correlates with the magnitude of target inhibition, and that high-dose pulse therapy and low-dose continuous therapy confer equivalent cytotoxicity to CML cells. Our experiments on a wider population may contribute to understand these mechanisms.

P266

MUTATED SETBP1 INCREASES THE NUCLEAR LOCALIZATION OF PP2A AND ITS PHOSPHORYLATED FORM
M Mauri[1,*] S Redaelli[1], S Valletta[1], A Parmiani[1], F Guzzi[1], M Parenti[1], R Piazza[1], C Gambacorti Passerini[1, 2]
[1]Dept Health Sciences, University Milano Bicocca, [2]Division of haematology, San Gerardo Hospital, Monza, Italy

Background: Mutations in the SET binding protein 1 (*SETBP1*) gene have been identified in patients with Schinzel-Giedion syndrome, in atypical chronic myeloid leukaemia (aCML) and in other proliferative disorders. These mutations strongly suggest an involvement of SETBP1 in the onset of these diseases. In literature there are evidences suggesting that SETBP1 over-expression leads to an increased proliferation of leukemic cells through its interaction with SET and secondarily to an inhibition of PP2A.
Aims: To analyze whether the presence of SETBP1 mutations alters the localization of PP2A within the cells.
Methods: HEK 293T cells were transiently or stably transfected to express SETBP1 wild type (WT) or G870S. Confocal imaging approach was applied to characterize the molecular mechanisms underlying the modification of PP2A expression and localization exerted by the SETBP1 G870S mutation recurrently identified in patients affected by aCML.

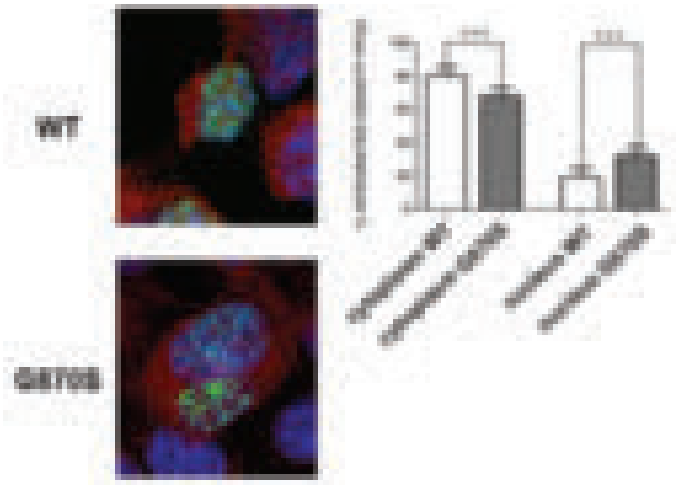

Figure 1. Blue: DAPI; Green: SETBP1; Red: Total PP2A.

Results: In HEK 293T cells transiently transfected with SETBP1 G870S we observed an increased localization of PP2A in the nucleus compared to its distribution in cells expressing SETBP1 WT as shown in Figure 1 (nuclear distribution of PP2A in SETBP1 WT cells *vs* SETBP1 G870S: 20%±5.6% *vs* 32%±5.1%; p<0.001 on three independent experiments). Moreover the antiproliferative effects

exerted by PP2A are reduced by its phosphorylation in Tyr307 (p-Tyr307) leading to a weak interaction with specific cytoplasmatic pathways. The localization analysis of p-Tyr307 PP2A confirmed that the over-expression of SETBP1 G870S predominantly causes retention of this fraction in the nucleus. (% p-Tyr 307 PP2A nuclear distribution in cells expressing SETBP1 WT 48%±4.6% and in cells expressing SETBP1 G870S 61%±4.6%; p<0.01 on three independent experiments). The same impaired localization was observed analyzing the distribution of total as well as phosphorylated PP2A in HEK 293T cells stably expressing SETBP1 WT or G870S (% PP2A nuclear distribution in cells expressing SETBP1 WT *vs* SETBP1 G870S 26%±5.3% *vs* 40%±3.5%; p-Tyr 307 PP2A nuclear distribution in cells expressing SETBP1 WT *vs* SETBP1 G870S 52%±4.7% *vs* 64%±3.9%; p<0.001 on three independent experiments).
Summary and Conclusions: These findings suggest a mechanism of action by witch SETBP1 G870S mutation causes nuclear accumulation of p-Tyr 307 PP2A reducing its effect in the regulation of cell proliferation.

P267

THE COMBINATION OF PANOBINOSTAT AND PONATINIB EXERTS SYNERGISTIC CYTOTOXICITY IN IMATINIB-RESISTANT CHRONIC MYELOID LEUKEMIA CELL LINES INCLUDING BCR-ABL GENE MUTATION WITH T315I

Y Matsuda[1,*] T Yamauchi[1], M Takai[1], H Shigemi[1], K Uzui[1], R Nishi[1], S Kimura[2], T Maekawa[3], T Ueda[1]
[1]Hematology and Oncology, University of Fukui, Fukui, [2]Hematology, Respiratory Medicine and Oncology, Saga University, Saga, [3]Transfusion Medicine and Cell Therapy, Kyoto University Hospital, Kyoto, Japan

Background: Current first-line treatment options for chronic myeloid leukemia (CML) include imatinib (IM), nilotinib and dasatinib. Nevertheless, a small percentage of CML patients are primarily refractory or secondarily resistant to these agents. The major mechanism of drug resistance of CML is the reactivation of ABL kinase either through *BCR-ABL* gene mutation or gene amplification. A novel pan-histone deacetylase (HDAC) inhibitor, panobinostat induces the acetylation of hsp90, and inhibits its chaperone function in association with the client proteins BCR-ABL, leading to the degradation of it. Moreover it increases acetylated histone in treated cells, resulting in induction of apoptosis. A new pan-ABL tyrosine kinase inhibitor, ponatinib is a promising therapeutic option in patients with all kinds of *BCR-ABL* mutation including T315I. Thus new agents that can overcome the reactivation of ABL kinase are needed.
Aims: We hypothesized that the combination of panobinostat and ponatinib exerts synergistic cytotoxicity against IM-resistant cells through different mechanisms of action of each agent.
Results: K562/IM-R1 and Ba/F3/T315I cell lines were evaluated for the cytotoxicity of panobinostat and ponatinib *in vitro*. K562/IM-R1 cells, established in our previous study, showed BCR-ABL overexpression due to *BCR-ABL* gene amplification. Ba/F3/T315I cells showed *BCR-ABL* with a T315I mutation.The XTT proliferation assay revealed that panobinostat inhibited similarly the growth of K562, K562/IM-R1, Ba/F3, and Ba/F3/T315I cells regardless of their IM-resistance, with 50% inhibitory concentration (IC50) values of around 50 nM (40.0 - 51.0 nM). Ponatinib inhibited the growth of both K562/IM-R1 cells (IC50, 3.8 nM) and Ba/F3/T315I cells (IC50, 30 nM) as potently as their parental K562 cells (IC50, 2 nM) and Ba/F3 cells (IC50, 5 nM). Importantly, the combination of 2 agents exhibited enhanced growth inhibition effects on all cell lines. The combination index calculated using their IC50 values was less than 1.0 in all cell lines, which clearly showed synergism. In the estimation of apoptosis, when the cells were treated with panobinostat or ponatinib at 10 nM (only in Ba/F3/T315I, 30 nM) for 48 h alone or in combination, the combination led to greater-than-additive apoptotic cell death than each agent alone, evaluated by annexin V-positivity. Western blotting was used to evaluate the protein expression levels of BCR-ABL and phospho(p)-BCR-ABL and their downstream signal pathways, STAT5, AKT, ERK1/2, and their phosphorylation in all cell lines after treatment as mentioned above. Ponatinib inhibited the autophosphorylation of BCR-ABL and the phosphorylation of STAT5, AKT, ERK1/2 in both K562/IM-R1 and Ba/F3/T315I cell lines. Treatment with panobinostat mildly reduced the BCR-ABL and p-BCR-ABL expression levels in K562/IM-R1 and Ba/F3/T315I cells. Moreover, the combination of the 2 agents augmented the inhibition of the autophosphorylation of BCR-ABL in these cell lines. And especially in K562/IM-R1 and Ba/F3/T315I cell lines, it was observed that the phosphorylation of downstream signals was also more inhibited in combination than each alone. The activity of HDAC, determined using the HDAC assay Kit, was inhibited by panobinostat in all cell lines regardless of IM sensitivity. In comparison, IM did not alter cellular HDAC activity. Upon treatment with panobinostat, the protein expression levels of acetylated histone H3 and H4 were increased, suggesting the consequence of the inhibition of HDAC. Moreover, the protein levels of acetylated H3 were more enhanced in combination than each alone in all cell lines.
Summary and Conclusions: We firstly reported that panobinostat and ponatinib demonstrated synergistic cytotoxicity against IM-resistant cell lines not only due to *BCR-ABL* gene amplification but also *BCR-ABL* T315I mutation.

P268

GENE EXPRESSION PROFILING OF CD34+/LIN- CELLS OF PATIENTS WITH CHRONIC MYELOID LEUKEMIA AT DIAGNOSIS IDENTIFIES NEW GENES RELATED TO THE NUMBER OF CD34+/LIN- CELLS DURING NILOTINIB TREATMENT

A Trojani[1,*] M Lodola[1], B Di Camillo[2], A Capucci[3], L Cavalli[3], A Perego[4], E Pogliani[5], E Orlandi[6], A Iurlo[7], S Malato[8], P Corradini[9], R Cairoli[10], M Bregni[11], S Pauli[12], E Morra[1], E Pungolino[1]
[1]Ospedale Niguarda, Milano, [2]Università di Padova, Padova, [3]Spedali Civili Brescia, Brescia, [4]Ospedale Desio, Desio, [5]S.Gerardo, Monza, [6]Policlinico S.Matteo, Pavia, [7]Ospedale Maggiore Policlinico, Milano, [8]Ospedale San Raffaele, Milano, [9]Istituto dei Tumori, Milano, [10]Ospedale Valduce, Como, [11]A.O. di Circolo di Busto Arstizio, Busto Arstizio, [12]A.O. Ospedale S.Antonio, Gallarate, Italy

Background: Chronic myeloid leukemia (CML) is a disease of stemming from genetic damage to a hematopoietic stem cell. Despite nilotinib being a very effective drug for the treatment of CML, drug resistance can emerge. Over the last few years, gene expression profiling (GEP) provides a powerful tool to predict treatment-specific response by the discovery of new biomarkers and pathways. In the contest of the REL-PhilosoPhi34 study on behalf of the Rete Ematologica Lombarda, we performed an exploratory study regarding the GEP of CD34+/lin- cells of CML patients at diagnosis before nilotinib treatment.
Aims: This study aimed to determine GEP of bone marrow (BM) CD34+/lin- cells of newly diagnosed CML patients before starting nilotinib treatment. Patients were divided into 2 groups based on the number of BM CD34+/lin- cells determined at diagnosis and after 3 and 6 months of treatment with nilotinib in order to identify genes and molecular mechanisms correlated to the nilotinib citotoxicity.
Methods: CD34+/lin- cells were isolated from BM mononuclear cells (MNCs) of 30 CML patients at diagnosis. MNCs as well as CD34+/lin- cell counts of 22 CML patients were measured at diagnosis and after 3 and 6 months of nilotinib, respectively. Microarray of BM CD34+/lin- cells of 22 CML patients at diagnosis was performed using the latest generation Affymetrix GeneChip HTA 2.0. Data were preprocessed and normalized using RMA. Selection and data analysis were performed using t-test.
Results: From the comparison between the BM CD34+/lin- cell counts from each patient at diagnosis and after 3 and 6 months of nilotinib, patients were divided into 2 groups: group 1 (*n*=18) showed highly reduced levels of CD34+/lin- cells while group 2 (*n*=4) demonstrated increasing levels of CD34+/lin- cells after 3 and 6 months of nilotinib, respectively. We identified 56 transcripts that were differently expressed between the 2 groups of CML patients. Among them, *SNORD17, SNORD105B, KIAA1324L* genes were underexpressed while *NFKBIA, SNORD58C, RNU5E-1, RNU6-82, TTN-AS1, MIR3153, HIST1H1A, SCRNA14* genes were overexpressed in group 1 compared to group 2, respectively. Very interestingly, *NFKBIA* is involved in several pathways regulating apoptosis: ERK signaling, MAPK family pathways, NF-KappaB pathways, PDGF pathway, PI3K signaling, TNF signaling. *HIST1H1A* belongs to the ProteinKinase-A signaling pathway that regulates processes as growth, development and metabolism. *RNU5E-1* and *RNU6-82* are involved in the spliceosomal splicing cycle and their functions still need to be discovered. Of note, 31/56 transcripts are located on chromosome 15 suggesting that this region could be crucial for transcriptional regulation of CML correlated to nilotinib response.
Summary and Conclusions: This is the first GEP study of CD34+/lin- cells with Affymetrix Genechip HTA 2.0 of CML patients aimed to examine the mechanisms underlying nilotinib response or resistance. The microarray study of CML patients at diagnosis highlighted 56 transcripts mostly present in chromosome 15 and differently expressed in 2 groups of patients based on the loss of cellularity induced by 3 and 6 months of nilotinib treatment. *NFKBIA* was overexpressed in patients who demonstrated a loss of CD34+/lin- cells after 3 and 6 months of nilotinib suggesting that this gene could be involved in nilotinib-response. Ongoing studies will determine the comparison of GEP of CML patients at diagnosis as well as after treatment with nilotinib to predict response or failure providing new insights into the molecular mechanisms in CML.

P269

EXPRESSION LEVELS OF CERAMIDE-GENERATING AND CLEARANCE GENES IN NEWLY DIAGNOSED AND TYROSINE KINASE INHIBITOR-RESISTANT CHRONIC MYELOID LEUKEMIA PATIENTS: AN ATTEMPT TO FIND NOVEL TARGETS

M Kartal Yandim[1,*] I Kozanoglu[2], H Ozdogu[2], O Piskin[3], M A Ozcan[3], G Saydam[4], F Sahin[4], F Avcu[5], A U Ural[6], Y Baran[1]
[1]Molecular Biology and Genetics, Izmir Institute of Technology, Izmir, [2]Hematology, Baskent University, Adana, [3]Hematology, Dokuz Eylul University, [4]Hematology, Ege University, Izmir, [5]Hematology, Gulhane Military Medical Academy, [6]Hematology, Bayındır Hospital, Ankara, Turkey

Background: Ceramide, generated in response to ionizing radiation, heat stress, oxidative stress, and chemotherapeutics, is the key molecule of sphingolipid family. Increased intracellular levels of ceramide through ceramide syn-

thase genes (CerS1-6) results in growth inhibition, differentiation, apoptosis, alteration of telomerase activity and telomere length, and senescence. On the other hand, increased sphingosine 1-phosphate (S1P) and glucosylceramide (GC) levels through sphingosine kinase-1(SK1) and glucosylceramide synthase (GCS) gene overexpression, respectively, result in the induction of cell proliferation, drug resistance, transformation, angiogenesis, and mobility. In our previous *in vitro* studies, we showed for the first time that bioactive sphingolipids have essential roles in resistance to tyrosine kinase inhibitors (TKIs) and we investigated and published for the first time that targeting bioactive sphingolipids in chronic myeloid leukemia (CML) cells increased sensitivity to TKIs.
Aims: In this study, we aimed to examine the expression levels of of bioactive sphingolipid genes in newly diagnosed, TKI-treated and have demonstrated minimum hematological response or TKI-resistant CML patients.
Methods: Total RNAs were isolated from mononuclear cells obtained from bone marrow samples of CML patients and then converted to cDNA by reverse transcriptase. Expression levels of BCR/ABL, CerS1-6 genes, GCS and SK-1 genes were analyzed by real-time PCR. Forty patients with different disease profiles were involved in this study.
Results: Expression levels of CerS1, CerS2, CerS4, CerS5, and CerS6 genes were increased considerably in CML patients showing minimum hematological response to TKI treatment than newly-diagnosed and drug-resistant CML patients. On the other hand, expression levels of GCS and SK-1 genes were significantly higher in drug-resistant patients than that of the newly-diagnosed CML patients and TKI-treated patients showing minimum hematological response.
Summary and Conclusions: Our previous studies showed that overexpression of CerS1 gene or application of ceramide analogs synergistically increased cytotoxic and apoptotic effects of TKIs in CML cells whereas suppression of GCS and SK-1 resulted in synergistically increased TKI-induced cell death. We also previously showed that SK-1 regulates expression levels and protein stability of BCR/ABL. In conclusion, the results of this study confirmed our *in vitro* studies and showed a significant correlation between the expression levels of bioactive sphingolipid genes and the sensitivity or resistance of CML patients to TKIs. A correlation between expression levels of SK-1 and BCR/ABL was also determined. Taken together, all these results suggest that expression levels of bioactive sphingolipid genes can be novel markers for determination of drug resistance in CML patients. More importantly, they can be used as novel targets for more effective treatment of resistant CML patients.
This study was supported by TUBITAK with the Project number 111S391 to Y.B.

Background: Chronic myeloid leukemia (CML) is a myeloproliferative disorder of hematopoietic stem cells carrying the hallmark of the Philadelphia (Ph) chromosome and an oncogenic BCR-ABL1 fusion gene. Imatinib, a BCR-ABL1 tyrosine kinase inhibitor (TKI) is used as the first line therapy for newly diagnosed CML patients. MicroRNAs (miRNAs) are conserved small non-coding RNAs that negatively regulate gene expression. miRNA profiles are markedly altered in cancers and some of them have a causal role in cancer initiation and progression. Aberrant expression of miRNAs in CML has previously been reported however the role of miRNAs in CML is still poorly understood.
Aims: Here, we compared the miRNA expression profiles of CML cells and healthy cells, we investigated whether TKI treatment could affect the expression of these miRNAs and we focused on miRNA-30e, whose downregulated expression may be crucial in CML.
Methods: miRNA expression was profiled using Agilent miRNA microarrays and verified using Applied Biosystems TaqMan. Bioinformatics and molecular analyses were performed using: Ingenuity systems, miRNA target predictors, real-time PCR, Western blots, luciferase assays and annexin-PI.
Results: We compared the miRNA expression pattern of 2 BCR-ABL–positive CML cell lines (K562 and Meg-01) in reference to a pool of healthy blood. In addition, we looked into the expression profile of K562 cells treated with 2 different types of TKIs; imatinib and dasatinib. With the aid of unsupervised hierarchical clustering we found that healthy blood samples were clustered separately from K562 and Meg-01 cells. Untreated K562 cells were clustered separately from treated ones and imatinib treated K562 cells were clustered closely to those treated with dasatinib. The microarray results were validated by real-time PCR. The expression level of 73 miRNAs in K562 and Meg-01 cells was opposite to their expression in normal blood. Of these miRNAs, the expression of 14 was routed back to near normal levels following exposure to imatinib and/or dasatinib. Seven were downregulated in K562 and upregulated following treatment: miRNA-23b, 30e, 154, 454, 564, 671-5p and 765; and seven were upregulated in K562 and downregulated following treatment: miRNA-9, 193b, 320a, 320b, 500, 132 and 892. The reduced expression of miRNA-30e was one of the most significant changes detected between the CML cell line cells and the healthy cells. In compliance with the CML cell lines, miRNA-30e expression was downregulated in primary CML samples and was restored after imatinib treatment. Since miRNA-30e expression was low in CML we sought to assess the possibility that this miRNA targets BCR-ABL. Indeed, target predictors, TargetScan and PicTar, revealed a conserved target site for miRNA-30e in the 3'-UTR of the ABL1 gene. Overexpression of miRNA-30e led to the downregulation of BCR-ABL1 and ABL1 protein expression. Overexpression of miRNA-30e also led to reduced expression of the phosphorylated form of the BCR-ABL1 target, CrkL, signifying a decline in BCR-ABL1 activity. Additionally, based on luciferase assays, ABL1 was indeed shown to be a target gene regulated by miRNA-30e. Lastly, miRNA-30e significantly enhances imatinib-induced cytotoxicity by promoting a 2-fold induction in imatinib-mediated apoptosis.
Summary and Conclusions: Although further analyses and patient studies are required, these data suggest that miRNA-30e may function as a tumor suppressor miRNA implicated in the pathogenesis of CML and its clinical response to imatinib. Furthermore, the combination of TKI treatment and miRNA-30e present therapeutic potential for CML.

ANTILEUKEMIC EFFECT OF PLK INHIBITOR AND IN COMBINATION WITH ABL TYROSINE KINASE INHIBITORS AGAINST BCR-ABL-POSITIVE CELLS
S Okabe[1,*] T Tauchi[1], Y Tanaka[1], T Kitahara[1], K Ohyashiki[1]
[1]First Department of Internal Medicine, TOKYO MEDICAL UNIVERSITY, Shinjuku-Ku, Japan

Background: ABL tyrosine kinase inhibitor (TKI), imatinib and second-generation ABL TKIs, nilotinib and dasatinib have demonstrated the potency against chronic myeloid leukemia (CML) patients. However, resistance to ABL TKI can develop in CML patients due to BCR-ABL point mutations. Moreover, ABL TKIs do not eliminate the leukemia stem cells (LSCs). These leukemia cells are contained within a niche in the bone marrow and are often impervious to current treatments. Therefore, new approach against BCR-ABL mutant cells and LSCs may improve the outcome of BCR-ABL-positive leukemia patients. Polo-like kinases (PLK) are the family of serine threonine kinases and essential for mitosis. PLK is also critical regulator of cell cycle progression and DNA damage response. One of the PLK and phosphoinositide 3-kinase (PI3K) inhibitor, rigosertib (ON 01910.Na) is a novel synthetic benzyl styryl sulfone that is cytotoxic against a variety of human tumor cell lines.
Aims: We suggested that rigosertib mediated inhibition PLK and PI3K activity and in combination with ABL TKIs may abrogate the proliferation and survival of Ph-positive leukemia cells including T315I mutation and ABL TKI resistant.
Methods: In this study, we investigated the combination therapy with a rigosertib and an ABL TKIs (imatinib, nilotinib and ponatinib) by using the BCR-ABL positive cell line, K562, murine Ba/F3 BCR-ABL cell line with T315I mutant, nilotinib resistant K562 and ponatinib resistant Ba/F3 BCR-ABL cells and primary samples.
Results: 72 h treatment of rigosertib exhibits cell growth inhibition and induced apoptosis against K562 cells. The treatment of imatinib, nilotinib and ponatinib exhibits cell growth inhibition partially against K562 cells in the presence of feeder cell (HS-5) conditioned media. We found that the treatment of rigosertib abrogated the protective effects of HS-5 conditioned media in K562 cells. Phosphorylation of BCR-ABL, Crk-L was reduced and activity of caspase 3, PARP and γH2A.X phosphorylation was increased. Combined treatment of K562 cells or primary samples with imatinib and rigosertib caused significantly more cytotoxicity. Phosphorylation of BCR-ABL, Crk-L was reduced and cleaved PARP and γH2A.X phosphorylation was increased. Anti-apoptotic protein, Mcl-1 was also decreased. We also found the phosphorylation of histone H3 was increased after rigosertib treatment suggested that the cells arrested in G2/M phase. We investigated the rigosertib activity against T315I positive cells. Rigosertib potently induced cell growth inhibition and increased apoptosis. Combined treatment of Ba/F3 T315I cells with ponatinib and rigosertib caused significantly more cytotoxicity than each drug alone. We next investigated by using ponatinib resistant Ba/F3 cells and nilotinib resistant K562 cells. In the ponatinib resistant cell lines, IC50 of ponatinib was up to 200 nM. BCR-ABL triple point mutations (T315I, E255K and Y253H) were detected by direct sequence analysis. The treatment of rigosertib exhibits cell growth inhibition against Ba/F3 ponatinib resistant cells or nilotinib resistant cells and increased apoptosis. We found cleaved PARP, caspase 3 and γH2A.X phosphorylation was increased.
Summary and Conclusions: Our preclinical results indicated that administration of the PLK and PI3K inhibitor, rigosertib may be a powerful strategy against ABL TKI resistant cells and enhance cytotoxic effects of ABL TKI against those Philadelphia chromosome-positive leukemia cells.

CYTOPLASMATYC COMPARTMENTALIZATION OF BETA CATENIN FOLLOWING CHIBBY ENFORCED EXPRESSION ACTIVATES AUTOPHAGY AS PRO-SURVIVAL MECHANISM IN CELLS EXPRESSING THE BCR-ABL1 FUSION GENE

M Mancini[1,*] E Leo[1], V Campi[1], F Castagnetti[1], L Zazzeroni[1], MA Santucci[1], G Martinelli[1]
[1]DIMES, Istituto di Ematologia Seràgnoli, Bologna, Italy

Background: Autophagy is a genetically regulated process of adaptation to metabolic stress. Besides its controversial role in tumor cell survival, it may promote tumor cell survival through events encompassing metabolic reprogramming. The participation of autophagy in CML cell persistence in response to tyrosine kinase inhibitors support that autophagy may be a component of BCR-ABL1 leukemogenic potential. Here we report that catenin nuclear export and inactivation driven by the enforced expression of its antagonist Chibby (Cby) activates autophagy in K562 cell line. B-Catenin translocation from nuclear into cytoplasmatic compartment was associated with a significant increase of different markers of autophagy such as Beclin 1, enhanced conversion of cytosolic-associated protein light chain 3, and presence of autophagosomes, detected by immunofluorescence microscopy. More importantly, autophagic flux activates calpain which, in turn, cleaves b-catenin into a 75 kDa fragment still owning transcriptional activity.
Aims: To identify autophagy role in CML pharmacologic resistance.
Methods: K562 cell line is a human BCR-ABL1 positive cell line. It exhibits low levels of Cby transcript and no Cby protein. A construct containing the whole wt CBY coding sequence was inserted into a commercial plasmid. The construct coding for a 14-3-3-binding defective protein (Cby S20A) has been kindly purchased by K.I. Takemaru. Both wt Cby construct and Cby S20A mutant were transfected in the BCR-ABL1+ cell line K562 by means of electroporation. Stable Cby expression was achieved after two month selection in RPMI additioned with G418. Protein and transcript expression were detected by RT-PCR and western blotting and the proliferation rate by count on a phase contrast microscopy. Autophagy was evaluated using an Autophagy Antibody Sampler Kit purchased by Cell Signaling.
Results: Our results demonstrate that b-catenin cytoplasmic relocation proceeding from Cby enforced expression or elicited by Cby induction in response to IM activates autophagy which promotes survival of K562 cells. Autophagy was neither induced in K562 cells transucing the mutant S20A conctruct not observed in K562 cells where b-catenin was abrogated by siRNA, supporting its dependence upon b-catenin relocation to the cytoplasm. Moreover, autophagy was associated with the activation of calpain, proceeding from the Ca^{2+} release from ER and caspase 12 activation, which, in turn, drives the b-catenin cleavage into a 75 kDa fragment and its nuclear import.
Summary and Conclusions: Here we confirmed the autophagy is a survival pathway likely involved in the disease persistence during therapy with IM or other TK inhibitors. Moreover, we identified a putative autophagy-associated mediator of resistance to BCR-ABL1 TK inhibition, a b-catenin 75 kDa cleaved fragment still owning transcriptional activity. Further investigation is required to elucidate the target genes of such fragment.

TYROSINE KINASE INHIBITORS DO NOT AFFECT EXPRESSION OF DNA METHYLTRANSFERASES AND GLOBAL METHYLATION LEVEL IN CHRONIC MYELOID LEUKEMIA CELLS

J Drzewinska-Chanko[1], K Bajorek[1], E Glodkowska-Mrowka[1], J Barankiewicz[1], M M Machnicki[1], I Seferynska[2], M Wnuk[3], T Stoklosa[1,*]
[1]Immunology, The Medical University of Warsaw, [2]Hematology, Institute of Hematology and Blood Transfusion, Warsaw, [3]Genetics, University of Rzeszow, Rzeszow, Poland

Background: Imatinib, a selective inhibitor of ABL1 kinase activity, revolutionized the treatment of BCR/ABL1-positive leukemias and paved the way for the successful development of a family of tyrosine kinase inhibitors (TKIs). Several TKIs are now approved for the treatment of different human cancers, five of them are used to treat patients with chronic myelogenous leukemia (CML). Unfortunately for a significant number of patients success of TKIs is not fully achieved by the development of resistance to the therapy or toxicities. Recent reports demonstrating serious cardiovascular side effects caused by next-generation TKIs such nilotinib and ponatinib proves that many questions regarding mechanisms of TKI activity remain unclear. Among them is the potential influence of TKI on DNA methylation. Methylation of cytosine residues within DNA is the classical epigenetic mark and is catalyzed by a group of DNA methyltransferases (DNMTs) with major members: DNMT1, DNMT3A and DNMT3B. DNMT1 is responsible for constitutive methylation while the main role of DNMT3A and DNMT3B is *de novo* methylation of unmethylated DNA. There are contradicting reports published on the role of imatinib and selected other TKIs on DNMTs expression (showing both up- an dowregulation), therefore we decided to comprehensively evaluate if, and how all TKI currently used in CML treatment (imatinib, dasatinib, nilotinib, bosutinib and ponatinib) may affect global methylation level and DNA methyltransferases expression.
Aims: Comprehensive analysis of the influence of first and next generation tyrosine kinase inhibitors (TKIs) on the expression of DNA methyltransferases in CML cell lines and in primary CML CD34+ cells from patients at various stages of the disease and on the global methylation level.
Methods: To study the expression of *DNMTs* genes in CML cells upon TKI treatment, qPCR according to MIQE guidelines was employed. Expression was analyzed in human K562 BCR-ABL1-positive cell line (and HL60 as BCR-ABL-negative control) and in CD34+ progenitor cell pool isolated from peripheral blood leukocytes of CML patients at various stages of the disease: chronic phase (CML-CP) and blastic phase (CML-BP). Blood samples were taken after informed consent. Western blotting analysis was also performed to verify the protein levels of DNMTs upon TKI treatment (imatinib, dasatinib, nilotinib, bosutinib and ponatinib) and to confirm shutdown of BCR-ABL1 kinase activity. To determine global level of 5-methylcytosine (mC) and 5-hydroxymethylcytosine, high performance liquid chromatography (HPLC) was used (according to procedure described by Wnuk *et al.*, Age (Dordr); 2014 Feb;36(1):31-48).
Results: Expression of *DNMT1, DNMT3A* and *DNMT3B* was not significantly affected at the mRNA or protein level by any of the TKIs which were used (neither in K562 cells nor in primary CML CD34+ cells from CML-CP and CML-BC patients). Cells were incubated with TKI concentrations ranging from 1nM to 1uM (relevant to concentrations observed in patients for each TKI used in this study), analysis was performed at 24, 48 and 72h timepoints. TKIs concentrations, which were employed, were effective in shutting down BCR-ABL1 kinase activity, while they were not cytotoxic yet at the time of analysis, as verified by Western blotting of phospho-CrkI and viability assays. Finally, as shown in Figure 1, level of global DNA methylation in K562 cells remained unchanged upon treatment with two selected TKIs which was determined by HPLC method. Although imatinib seemed to slightly increase proportion of methylated cytosines, this was not significant and nilotinib did not exert any effects on global methylation level.

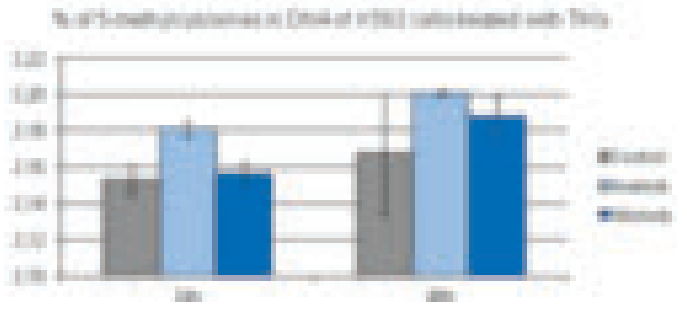

Figure 1. Global levels of methylation in K562 cells incubated for 24h or 48h with imatinib or nilotinib at 100 nM and 10 nM respectively. Global level of methylated cytosines was measured by HPLC.

Summary and Conclusions: Despite recent advances in the field of CML genetics, role of epigenetics in the pathogenesis of CML and the interplay between long-term TKI treatment and epigenetic changes remain to be fully elucidated. Although there are reports demonstrating up- or downregulation of selected *DNMT*s expression upon treatment with imatinib and other TKIs (such as dasatinib and nilotinib), in our opinion this might be caused by high concentrations and long incubation time with TKI. Our observations show that if TKIs affect epigenetic landscape of CML, this is not directly mediated through induction of aberrant DNMTs expression.

Chronic myeloid leukemia - Clinical 1

Medizinische Klinik, Hämatologie und Onkologie, Universitätsmedizin Mannheim, Mannheim, [24]Institute of Medical Information Sciences, Biometry and Epidemiology, Ludwig-Maximilians-Universität München, München, Germany

Background: As there are only few data available about the incidence, the stage of disease at diagnosis, the treatment and the outcome of chronic myeloid leukemia (CML) in Europe the European Treatment and Outcome Study (EUTOS) for CML collected such data in 27 European countries and promotes cooperation between hematologists and scientists.
Aims: The population-based registry was set up inside the infrastructure of the EUTOS to further explore the epidemiology, characteristics, treatment and outcomes of CML in Europe. This work focused on the estimation of incidence of CML in Europe and the single countries participating in the registry.
Methods: The population-based registry aimed to document all newly diagnosed adult patients with Ph^+ and/or BCR-ABL+ CML at any stage of disease in whole countries or specified regions of Europe. The registration period varied between 12 and 60 months in the different countries, from January 2008 to December 2012. Raw incidences were calculated for the countries and regions and adjusted to the registration period. For countries observed in whole population data from the United Nations database were used while the study groups provided the population numbers of the specified regions for countries that were observed partially.
Results: Overall Incidences could be calculated for 20 European countries: Austria, Croatia, Cyprus, Czech Republic, Estonia, Finland, France, Germany, Italy, Latvia, Lithuania, the Netherlands, Poland, Russia, Serbia, Slovakia, Slovenia, Spain, Sweden and the United Kingdom. 2,956 patients were registered.Estimations of raw incidences per 100,000 persons per year ranged from 0.739 in the United Kingdom to 1.964 in Finland. The overall incidence for all countries was 1.029, with 0.907 in females and 1.163 in males. Incidences rose with age group (20-29 years: 0.421, 30-39 years: 0.634, 40-50 years: 0.978, 50-60 years: 1.348, 60-70 years: 1.529, 70-80 years: 1.794, 80 years and up 1.738).
Summary and Conclusions: This is the first report of the first paneuropean prospective study of the incidence of CML in Europe. The study covers 20 countries, for a total of about 80 million adult inhabitants (^{3} 18 years old), over a period of one to five years. While estimation of incidences for small countries or countries that only observed small regions may be subject to large variations due to small patient numbers, the estimation of incidence over all participating regions can serve as a robust estimation for the incidence of CML in Europe. Even though we have to assume that the calculated raw incidence of 1.029 is likely to be an underestimation as it is impossible to exclude that some new cases were not registered, solid estimates of the incidence in males and females, and particularly by age, are provided. In the very young, 18 to 40 years old, the incidence is as low as 0.498, while in people more than 70 years old the incidence is as high as 1.663. It is well known that especially older patients are underrepresented in prospective studies of treatment.

Medizinische Klinik und Poliklinik, Universitätsklinikum Eppendorf, Hamburg, [16]Klinik für Innere Medizin II, Universitätsklinikum, Jena, Germany

Background: Treatment of chronic myeloid leukemia (CML)-blast crisis (BC) has remained unsatisfactory in spite of the success with tyrosine kinase inhibition (TKI) of chronic phase CML. Few prospective studies of BC-treatment in the TKI-era are available.
Aims: We have used the randomized CML-Study IV to analyse treatment of BC and its outcome.
Methods: CML-Study IV is a 5-arm randomized optimization study of imatinib (IM) therapy (IM 400mg *vs.* IM 400mg+IFN *vs.* IM 400mg+AraC *vs.* IM 800mg *vs.* IM after IFN failure). Recruitment was from 7/2002 to 3/2012. Definition of BC was according to ELN criteria. No recommendations were given for the management of BC. Comparison was with 699 BC-patients from the pre-imatinib era (CML-studies I-IIIA).
Results: Median observation time was 7.2 (range:2.1-9.8) years. 78 out of 1551 patients developed BC after a median time of 15 months. 8-year cumulative incidence of BC was 5.6% (95%>confidence interval (CI): 4.5-7.7%). Cumulative incidence was higher in the IM after IFN arm (8-year cumulative incidence: 8.5%, 95%>CI:5-14%), but we did not find statistically significant differences. 21 patients from the IM 400 mg arm, 17 from the IM+IFN arm, 11 from the IM+AraC arm, 11 from the IM after IFN arm and 17 from the IM 800 mg arm developed BC. Median age at BC was 58 years, 59% were male. 23% were high-risk patients according to the EUTOS score. 32% had lymphoid and 45% myeloid BC. 23% had mixed or megakaryoblastic phenotype or no information. Median survival after diagnosis of BC was 8.9 (0.1-118+) months, compared to 4 months in the pre-imatinib era. 65 patients had received BC-specific treatment and were evaluable. Treatment consisted of TKI (group 1, n=18, 11 transplanted), intensive chemotherapy (group 2, n =18, 9 transplanted), or a combination of chemotherapy and TKI successively and / or simultaneously (group 3, n=29, 19 transplanted). 13 patients did not receive specific therapy due to early death (n=8) or other reasons (n=5). TKI comprised dasatinib (n=27), IM (n=19) and nilotinib (n=8). Intensive chemotherapy consisted of acute leukemia-type therapies. Patients with lymphoid BC showed better survival than patients with myeloid BC (median survival: 1.62 (0.01-9.8+) *vs.* 0.74 (0.02-9.6+) years, hazard ratio (HR): 0.69, 95%>CI:0.39-1.20. The differences were not statistically significant., most probably due to small sample size. 40 patients were transplanted after a median of 115 (29-309) days after diagnosis of BC. Besides age, we could not identify any prognostic factors for the success of transplantation. TKI between start of BC and transplantation appeared to have no Survival seemed to be best in patients that had been transplanted. Transplanted patients had a median survival after transplantation of 5.4 (0.05-9.6+) years in group 3, of 5,9 (0.02-9.4+)years in group 2 and of 1.4 (0.25-6.7+) years in group 1. Median survival after BC declined to 7 months after censoring at transplantation. There were hints that survival after BC was better when the patients had been originally treated at a university hospital compared to patients treated at municipal hospitals (HR: 0.44, 95%>CI: [0.23; 0.82]) or by office-based physicians (HR: 0.41, 95%>CI: [0.20; 0.83]).
Summary and Conclusions: In CML patients treated with IM the incidence of BC is comparatively low even after 8 years. BC patients show a considerable variation of survival times and transplantation may offer a superior outcome.

Seràgnoli", University of Bologna, Bologna, Italy

Background: Ten years after the introduction of tyrosine kinase inhibitors (TKIs) in the therapeutic scenario of chronic myeloid leukemia (CML), the assessment of treatment efficacy is based more and more on the early responses. However, the long term outcome remains critical. The phase 3 trials comparing 2nd generation TKIs *versus* imatinib (IM) have not clearly demonstrated an improvement in overall survival (OS) and IM still represents an important treatment option. An analysis of long-term events is extremely relevant to decide on the allocation of resources.
Aims: To assess the long-term outcome of CML patients in early chronic phase (ECP) treated frontline with IM and to analyze the causes of death.
Methods: 559 patients enrolled within 3 multicentric prospective studies conducted by the GIMEMA CML WP (NCT00514488, NCT00510926, observational trial CML023) were analyzed. Information on survival and progression were prospectively collected for all patients, including after treatment discontinuation. Definitions: failure, according to 2013 European LeukemiaNet criteria; progression, transformation to accelerated or blastic phase at any time; death (unspecified), at any time and for any reason; CML-related death, at any time and after progression or in unknown phase. All the analysis were made according to the intention-to-treat principle.

Figure 1. Estimated survival probability.

Results: Baseline demographics characteristics: median age, 52 years (18-84 years); male sex: 60%; high Sokal, high Euro and high EUTOS score: 22%, 7% and 7%; clonal chromosomal abnormalities in Ph+ cells: 4%; e13a2 BCR-ABL transcript: 36%. Median follow-up 76 months (37-99 months). Only 4% of patients were lost to follow-up and ≥95% of patients had at least 5-year observation. The reasons for IM discontinuation were: lack of efficacy (18%), toxicity or death in remission (10%), other reasons (7%). The subsequent treatment was: nilotinib or dasatinib (50%), ≥two 2nd or 3rd generation TKIs (7%), α-interferon (1%), allogeneic SCT (9%), chemotherapy (11%), none (treatment-free remission, 7%), unknown (14%). The 8-year failure-free survival (FFS), progression-free survival (PFS) and OS were 55% (95% CI: 51-60%), 66% (95% CI: 61-70%), 84% (95% CI: 78-89%) and 85% (95% CI: 79-90%), respectively. A higher age (continuous variable), a higher performance status (ECOG ≥1) and a e13a2 transcript type resulted independent poor prognostic factors on OS. Overall, sixty-five patients died. Approximately half of all the observed deaths were CML-related or due to unknown reasons; a relevant number of patients died for other causes: second malignancy (26%), infection (9%), cardiovascular event (8%), hemorrhage (3%), pulmonary embolism after surgery (1%), respiratory failure (1%). The age at death was significantly lower in patients with CML-related death. According to the time from IM start to the occurrence of death, no significant differences were observed between deaths related or unrelated to CML. Considering only CML-related deaths, patients with high Sokal, high Euro and high EUTOS scores had significantly lower survival probability with respect to low and intermediate risk patients (Figure 1).
Summary and Conclusions: In a large cohort of IM-treated CML patients in ECP, enrolled within prospective multicentric independent studies, a favourable long-term outcome was observed, especially in non-high risk patients. The age and the performance status significantly influenced the OS and the survival was almost equally dependent on CML-related or unrelated deaths. Elderly and unfit patients are often excluded from clinical trials: an effort to collect long-term data on severe and unfrequent toxicities and on cause of deaths observed in the daily practice with the different TKIs, outside of clinical trials, is strongly required to optimize medicare spending.

Botkin, Moscow, [5]Astrakhan State Medical Academy, Astrakhan, [6]Orel City Clinical Hospital, Orel, [7]Center for Hematology, Yaroslavl City Clinical Hospital, Yaroslavl, [8]Novosibirsk State University, Novosibirsk, Russian Federation

Background: Chronic myeloid leukemia (CML) is prone to a progression from a chronic phase (CP) to an acceleration phase (AP) and a blast crisis (BC). Molecular mechanisms that underlie CML progression aren't clearly known and continue to be a point of investigation. It has been shown recently that some genes from a cancer-testis (CT) family may be activated and hyperexpressed during malignant tumor progression.
Aims: To analyze a cancer-testis genes (CTG) *GAGE1*, *NY-ESO-1*, *MAGEA1*, *SCP1*, *SEMG1*, *SPANXA1*, *SSX1* and *PRAME* expression profile in peripheral blood (PB) of newly diagnosed CML patients as well as in a PB and a bone marrow (BM) of CML patients, by whom a therapy was carried out, on different CML stages: CP, AP and BC.
Methods: We used RQ PCR to evaluate mRNA expression levels of CTG in a PB (n=22) and a BM (n=9) of primary CML patients; in a PB of a treated CML patients in a CP (n=45), AP (n=50) and BC (n=14), in a BM of treated CML patients in a CP (n=15), AP (n=9) and BC (n=7) and 1 patient, who had a CP after BC. A median age was 50 y.o. There were 47% of men and 53% of women. Imatinib therapy was applied for all patients. CTG expression was counted respectively to Abl expression level. PB samples of healthy donors were as a negative control (n=15).
Results: An expression of a single gene from CT-family (*PRAME*) was observed in CP of CML in 3/22 of primary patients (14%) and 7/45 of treated patients (16%) in PB samples. *PRAME* expression level was comparable in both groups (5,5% and 4,9%, respectively, p=0,004, according to Mann-Whitney test). We haven't detected any CTG expression in BM of primary patients. In BM of treated patients with CP of CML was revealed an expression of *NY-ESO-1* (1/15, 7% of cases), *SCP-1* (1/15, 7%) and *PRAME* (4/15, 27%), at the level 35%, 0,14% and 27%, respectively. A multiple CTG expression was observed in a PB of patients with AP of CML: *GAGE1* (7/50, 14% of cases), *MAGEA1* (1/50, 2%), *SEMG1* (12/50, 24%), *SPANXA1* (2/50, 4%) *SSX1* (7/50, 14%) and *PRAME* (19/50, 38%); median levels were 1,2%, 0,01%, 1,3%, 0,3%, 0,5% and 24%, respectively. In BM of patients with AP CML was observed an expression of *SEMG1* (3/9, 33% of cases), *SSX1* (1/9, 11%) and *PRAME* (7/9, 78%); median levels were 1,4%, 0,3%, and 44%, respectively. In PB of patients with BC CML was observed *GAGE1* (4/14, 29%), *SEMG1* (5/14, 36%), *SPANXA1* (1/14, 7%), *SSX1* (2/14, 14%) and *PRAME* (12/14, 86%) expression; median levels were 1,2%, 3,3%, 1,7%, 0,4% and 22%, respectively. In BM of patients with BC CML was observed an expression of *GAGE1* (1/7, 14%) and PRAME (7/7, 100%); median levels were 0,1%, and 36%, respectively. Neither of analyzed CTG was expressed in a PB of the patient who gets to CP of CML after BC.
Summary and Conclusions: It turned out that an expression activation of these eight CTG is strongly associated with CML progression from CP into AP and BP. These data suggest that at least some of CTG may be involved into evolution of CML towards terminal phases. Expression of CTG may be used as early molecular predictor of CML progression into AP and BC.

P278

PROGNOSIS FOR CML PATIENTS WITH >10% BCR-ABL AFTER 3 MONTHS OF IMATINIB DEPENDS ON THE INITIAL RATE OF BCR-ABL DECLINE

S Branford[1,*] D Yeung[1], W T Parker[1], L Purins[1], J Braley[1], JF Seymour[2], DM Ross[1], ND Roberts[1], TP Hughes[1]
[1]Centre for Cancer Biology, SA Pathology, Adelaide, [2]Peter MacCallum Cancer Centre, Melbourne, Australia

Background: The molecular response to kinase inhibitors at 3 months (mo) has prognostic significance for patients (pt) with CML. BCR-ABL >10% IS (international scale) is consistently associated with significantly inferior long-term outcomes. It has been suggested that measuring BCR-ABL at 3 mo is the only requirement to predict outcome. Nevertheless, the ELN recommend caution before treatment intervention at 3 mo based on a single measurement. Indeed, many pt with values >10% ultimately achieve satisfactory outcomes. Better early discriminators of the poorest risk pt are needed.
Aims: The kinetics of response at relapse is predictive of outcome when assessed by the BCR-ABL doubling time (Lin Blood 1996, Branford Blood 2004 & 2012). We therefore examined the kinetics of molecular response at 3 mo to determine if the poorest risk pt could be identified among those with a BCR-ABL value >10%.
Methods: 528 first line imatinib treated pt were evaluated. The kinetics of response at 3 mo were determined from the number of days over which BCR-ABL halved (halving time). Halving times were calculated from the individual patient baseline BCR-ABL value (median 103%, range 2-1046). The analysis incorporated the number of days from imatinib start to the 3 mo sample collection, which varied from day 70 to 126 (median 86).

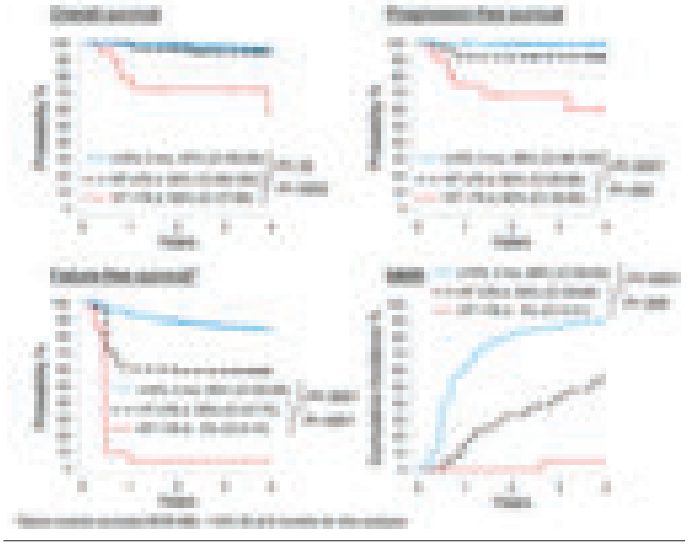

Figure 1. Outcome for patients ≤10% BCR-ABL at 3 mo compared with patients >10% divided by the 3 mo halving time. 410 patients had a BCR-ABL value ≤10% at 3 mo. Of the 97 patients with >10% at 3 mo, 95 had a baseline assessment and halving times were calculated. The results of the patients >10% at 3 mo are divided by their halving times (HT) at 3 mo: ≤76 days (d) n=74, HT >76 days n=21.

Results: 507 pt had a 3 mo assessment. Outcomes by 4 years were significantly superior for those ≤10% (n=410) compared with >10% (n=97): overall survival (OS) 97 v 87% *P*=.0001; progression-free survival (accelerated/blast phase: PFS) 99 v 86% *P*<.0001; failure-free survival (FFS) 85 v 48% *P*<.0001; MMR 88 v 41% *P*<.0001; and $MR^{4.5}$ 41 v 6% *P*<.0001. BCR-ABL halving times at 3 mo were calculated for pt >10% at 3 mo. The gradient from baseline ranged from a shallow to a steep decline, or no change or a rise in some cases, which led to variable halving times. To assess the linearity of our method outside of the IS range and hence the validity of calculating halving times, we examined 485 pt with additional measurements at 1 and 2 mo. The consistency of the logarithmic decline was assessed from the correlation coefficient *r* of the regression lines for the 356/485 pt (73%) with a decline at each measurement. Irrespective of the gradient of the decline or the baseline BCR-ABL value of these patients, BCR-ABL demonstrated a constant logarithmic decline; median *r* -0.98, quartiles -0.99, -0.97. Furthermore, there was no significant difference between these *r* values and those of 73 pt with measurements from mo 1 to 3 where all BCR-ABL values were within the recognized effective IS measurement range (≤10%), *P*=.26, indicating linearity above and below the IS range using our method. Among pt with >10% BCR-ABL at 3 mo, the kinetics were correlated with outcome measures. A halving time of 76 days was the optimal threshold for PFS by ROC analysis. Significantly inferior outcomes occurred for the 21 pt with halving times >76 days for OS, PFS, FFS and MMR, Figure 1. In a Cox proportional hazards model including Sokal, sex, age and assigned dose, the halving time at 3 mo was the only independent predictor of outcome in this poor risk group, ≤76 v >76 days: OS hazard ratio (HR) 6.6 (CI 1.5–30) *P*=.013, PFS HR 5.2 (CI 1.5–18) *P*=.009 and FFS HR 6.8 (CI 3.5–13) *P*<.0001. Only 1/410 pt with BCR-ABL <10% at 3 mo had >76 day halving time.
Summary and Conclusions: Our study has highlighted that the rate of BCR-ABL change from baseline may be a critical prognostic discriminator of the very poor prognosis pt among those who are >10% at 3 mo. This may help to further refine recommendations for treatment decisions at early timepoints.

HIGH BCR-ABL/GUSIS LEVELS AT DIAGNOSIS ARE ASSOCIATED WITH UNFAVORABLE RESPONSES TO IMATINIB

Background: The approval of three tyrosine kinase inhibitors (TKIs) for the first line treatment of Chronic Myeloid Leukemia (CML) has generated a need for molecular parameters predictive of unfavorable responses to Imatinib Mesylate (IM) that may identify patients that would benefit from the first line use of second generation drugs Dasatinib and Nilotinib. Growing evidence suggests that failure to achieve early molecular responses (*i.e.* BCR-ABL/ABL^{IS} levels <10% after 3 months or <1% after 6 months of TKI treatment) results in inferior rates of both overall and progression-free survival.
Aims: We wanted to establish if high *BCR-ABL* transcripts at diagnosis would be associated with unfavorable responses to IM.
Methods: Thus, we correlated quantitative determinations of *BCR-ABL* levels at diagnosis with the outcome of 230 newly diagnosed CML patients that were assigned to receive IM 400 mg/die. *BCR-ABL* transcripts were measured from peripheral blood samples drawn before exposure to any form of treatment. Real-Time Quantitative PCR (RQ-PCR) determinations were subsequently performed in triplicates using *glucuronidase-β* (*GUS*) as the reference gene, since previous evidence has demonstrated that *ABL* is not a reliable control gene in samples collected at diagnosis. Values were then reported on the International Scale employing a conversion factor obtained from the laboratory of the University of Heidelberg in Mannheim, Germany.
Results: Median follow-up of the study population was 50 months. Estimated 5-year cumulative incidences of complete hematologic response, complete cytogenetic response (CCyR) and major molecular response were 97.9%, 89.5% and 64.7%. Five-year probabilities of overall survival (OS), transformation-free survival (TFS: survival without disease transformation to the accelerated phase or blast crisis) and failure-free survival (FFS: survival without IM failure as defined by the 2009 European Leukemia Net recommendations) were 93.8%, 97.8% and 76%. Elevated BCR-ABL/GUS^{IS} correlated with inferior probabilities of optimal response (p<0.001), and lower rates of CCyR after 12 months of IM (p<0.001). Moreover, high BCR-ABL/GUS^{IS} transcripts were associated with lower probabilities of FFS (p<0.001) and TFS (p=0.01). When we employed the 2009 European Leukemia Net criteria to subdivide our patient cohort in optimal responders, suboptimal responders and individuals failing IM, we found that increasingly elevated BCR-ABL/GUS^{IS} transcripts accurately distinguished the three patient groups (optimal *vs* suboptimal p<0.001; optimal *vs* resistant p<0.001; suboptimal *vs* resistant p<0.001). Furthermore, using receiver operating characteristic curves we found that progressively higher BCR-ABL/GUS^{IS} levels at diagnosis defined quantitative transcript thresholds (15.96% for Optimal Response, 16.01% for EFS, 16.09% for FFS, 20.36% for TFS and 22.04% for OS) that separated low risk from high risk patients. Finally, we wanted to determine the concordance rates between BCR-ABL/GUS^{IS} levels at diagnosis and early molecular responses (eMRs) at 3 and 6 months. We therefore employed the 15.96% BCR-ABL/GUS^{IS} threshold to identify subjects with high (<15.96%) or low (>15.96%) probabilities of obtaining an Optimal Response and found that 69% of patients displaying <15.96% BCR-ABL/GUS^{IS} achieved <10% BCR-ABL/ABL^{IS} levels after 3 months of IM (p<0.001). Likewise, 78% of subjects presenting <15.96% BCR-ABL/GUS^{IS} at diagnosis attained <1% BCR-ABL/ABL^{IS} after 6 months of therapy (p<0.001).
Summary and Conclusions: We conclude that high *BCR-ABL* transcripts at diagnosis measured by RQ-PCR employing *GUS* as a reference gene allow the identification of CML patients unlikely to benefit from IM that should receive alternative forms of treatment.

P280

NGS-ASSISTED DNA-BASED DIGITAL QPCR FOR THE DETECTION AND QUANTIFICATION OF RESIDUAL DISEASE IN CML PATIENTS WITH UNDETECTABLE BCR-ABL1 TRANSCRIPTS

M Alikian[1,2,*] P Ellery[2], M Forbes[2], G Gerrard[1, 2], M Mueller[3], A Sosinsky[3], D Kasperaviciute[3], P Takousis[4], A Whale[5], D Milojkovic[2], J Apperley[2], J Huggett[5], L Foroni[1,2], R Alistair[1,2]

[1]Imperial Molecular Pathology, Imperial Healthcare Trust, Hammersmith Hospital, [2]Centre for Haematology, Faculty of Medicine, Imperial College London, [3]Clinical Sciences Centre, Imperial College London, [4]6Department of Genomics of Common Disease, Imperial College London, [5]LGC, Teddington, Middlesex, UK, London, United Kingdom

Background: Recent studies indicate that 40% of CML patients who achieve complete molecular remission (CMR) on imatinib remain disease-free after discontinuation of tyrosine kinase inhibitors therapy, raising the possibility of an "operational cure" at a level that is below the threshold of detection by RT-qPCR (10^{-5}). However, the safe introduction of a TKI withdrawal policy would require a reliable and cost effective method of identifying patients with the lowest likelihood of relapse. Such event is likely to be related to the presence of residual disease, which may include transcriptionally quiescent TKI-resistant leukaemic stem cells.[3] A means of detecting these cells, (not depend on oncogene transcription) may therefore be clinically valuable. Preliminary data suggest that PCR based on genomic DNA amplification of the fusion gene may be more sensitive for the detection of residual disease than one that relies on cDNA and may therefore help to predict outcome post-withdrawal. However, the former method is labour intensive and requires a customised patient-specific assay with the use of up to 250 primers combinations.
Aims: Here we describe a DNA-based method of detecting and quantifying low levels of BCR-ABL1 positive disease that improves on previous methodologies by 1) rapid identification of *BCR-ABL1* fusion junctions using targeted next generation sequencing 2) use of a digital PCR (dPCR) platform, which provides absolute molecular quantification without the need for standard curve.
Methods: The fusion junction was mapped in disease samples from 32 CML patients using Illumina's MiSeq platform. A custom TruSeq DNA target enrichment kit (Illumina) was used to enrich for the BCR and ABL1 genes. The enriching probes were designed via the online tool Design Studio covering both genes plus 50kb upstream and downstream of *BCR* and *ABL1*, respectively. The workflow involved sample quantification, library prep, multiplexed sample pooling, enrichment-probe hybridisation, template preparation, and sequencing. Fusion junctions were predicted via a custom designed bioinformatics algorithm. Breakpoints in all 32 patients were successfully mapped. DNA-dPCR was performed using the Fluidigm BioMark Platform on 36 follow-up samples in MR^4 or better and 9 follow-up samples in MMR or higher, from 6 patients in total. DNA-dPCR was performed with and without preamplification of 14 cycles. We also compared DNA dPCR to other methods of BCR-ABL1 quantification (cDNA-dPCR, DNA-qPCR and RT-qPCR).
Results: DNA-dPCR with preamplification detected BCR-ABL1 DNA in 29/36 (80.5%) MR^4 samples. Positive samples corresponded to 6/6 patients. Without preamplification we found that only 17/36 (47.2%) samples were positive corresponding to 5/6 patients. Compared to cDNA-dPCR, we found that only 7/36 samples (19.4) were positive, corresponding to 3/6 patients. All samples were negative by cDNA-dPCR without preamplification. Compared to DNA-qPCR, 5/36 samples (13.8%) gave a positive result. The five samples corresponded to 3/6 patients. This data shows that all patients have detectable disease level by DNA-dPCR at least in one sample while in MR^4.
Summary and Conclusions: In conclusion, our investigations demonstrate that DNA based dPCR is the most sensitive available technique for detecting low levels of BCR-ABL1-positive disease, and that the introduction a preamplification step of 14 cycles prior to the dPCR amplification further increases the sensitivity of this method. NGS-based DNA-dPCR facilitates the stratification of patients with residual disease below the detection limit of RT-qPCR and may, therefore, prove useful in the in the identification of patients from whom TKI therapy could be safely reduced or withdrawn.

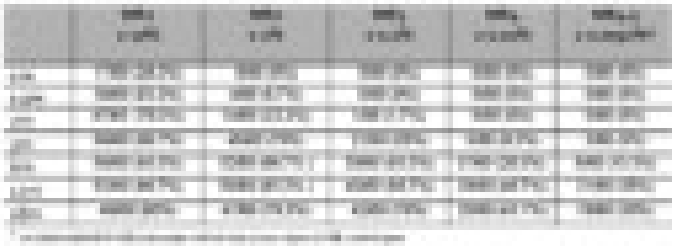
Background: In newly diagnosed CML-CP patients, BCR-ABL ratios during the first trimester of nilotinib treatment, and the kinetic of their descent, could be predictive of deep molecular response thereafter.
Aims: To analyze the molecular response during the first trimester of nilotinib therapy in newly diagnosed CML-CP patients.
Methods: Patients: ENEST1st is a study of nilotinib 300 mg BID in adults with newly diagnosed BCR-ABL+ CML-CP. In this substudy, imatinib pretreatment was not allowed. **Methods:** BCR-ABLIS ratios were measured prior to nilotinib, and subsequently every 2 weeks until the 3rd month (m), and at 6, 12 and 18 m. Sokal, Euro and Eutos scores were calculated with data at diagnosis. Differential count and BCR-ABL values were centrally measured in an ELN-EUTOS certified laboratory. Molecular response classified according to ELN2013 recommendations. Baseline ratios were not included for this analysis. Kinetics of changes were calculated using the ratio of that at a given timepoint compared to that of an earlier timepoint. Logistic regressions and ROC analysis have been used, and positive and negative predictive values (PPV and NPV, respectively) were calculated.
Results: 61 patients. Age: 51,8 y (19-81), M/F: 67%/33%. Risk: Sokal (L,I,H):60%, 28.3%, 11.7%. Euro (L, I, H): 52.5%, 42,4%, 5,1%. Eutos (L,H): 96,7%, 3,3%. 1 patient was excluded because of lack of molecular data (baseline). Ten patients abandoned during the first 18 m because of AE's. They have been classified as non-responders after the time they went off-study. Outcomes: No patient died or had transformation. Optimal responses at 3,6,12 m and 18m were obtained in 97%, 87%, 67%, and 70%, respectively. MR4.5 at 18m has been achieved in 30%. (Table 1). MMR at 12m: In multivariant analysis, only the ratio 3m/d45 was independently associated with MMR at 12m (p=0.015). MMR at 18m: Only sokal, and ratio at 2m were independently associated (p=0.024 and p=0.013, respectively]. $MR4^{\text{at 18 m:}}$ In univariant analysis, spleen size at diagnosis, ratio at 2m, and ratios 3m/d15 and 3m/d45 were associated with MR4 at 18 m. Only spleen size was significant in the multivariant analysis. ROC analysis of the ratio 2m disclosed a cut-point of 1.52. MR4.5 at 18 m: In univariant analysis, spleen size, and ratios at 1m, 1,5m and 2 m, and the ratios 3m/d15 and 3m/d45 were significantly associated with MR4.5 at 18 m. In the multivariant analysis the only independent variable was the BCR-ABL ratio at 2m. The ROC curve disclosed a cut-off of 1.52 (PPV: 90.6% NPV: 59.1%). [OR: 13.96(3.23-60.2) P=0.0004)].

Table 1.



Summary and Conclusions: Our results show that, in newly diagnosed patients, nilotinib resulted in rapid responses, and the proportions of optimal response at 3m (BCR-ABL IS ≤10%), and at 6m (BCR-ABL IS ≤1%) were 97% and 87%, respectively. Nilotinib treatment resulted in MR4 and MR4.5 at 18M in 42% and 30% of patients, respectively. The only diagnostic variable associated with MR4 and MR4.5 at 18 months has been the spleen size. Besides, our study shows the significant association of the molecular response during the first 2 months of therapy and MR4 and MR4.5 at 18 months, as demonstrated by their significant association with ratios at 1m, 1.5 m, and 2 m. The only independent variable associated with MMR, MR4, and MR4.5 at 18m was the ratio at 2m.These results support a prospective analysis of the prognostic value of the very early molecular response (before the third month of therapy) in patients treated with Nilotinib.

P282

THE DECLINE OF BCR-ABL/GUS RATIO IN CML PATIENTS TREATED UPFRONT WITH NILOTINIB SHOWS A RAPID DESCENT DURING THE FIRST TRIMESTER, AND THE RESPONSES ARE SIMILAR TO THOSE ACHIEVED WITH ABL AS CONTROL

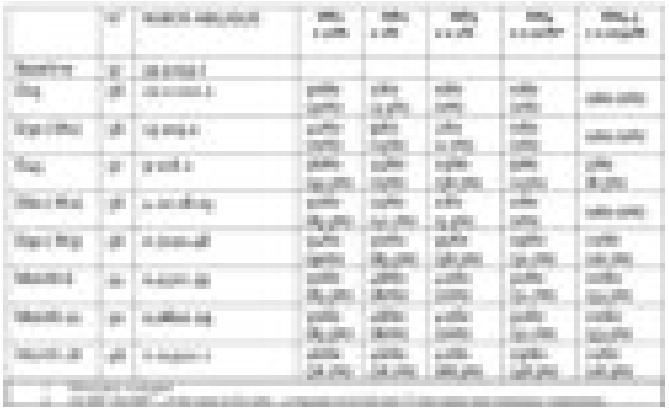
Background: The exact decline of BCR-ABL ratios during the first trimester of therapy has not been previously reported in CML patients treated upfront with Nilotinib.
Aims: To analyze the kinetic of the descent, and the molecular response, using BCR-ABL/GUS ratios during the during the first trimester of therapy, and at 6, 12 and 18 months (m).
Methods: BCR-ABL/GUS ratios were measured prior to nilotinib, and subsequently every 2 weeks until the 3rd month (m), and at 6, 12 and 18 m. Sokal scores were calculated with data at diagnosis. Kinetics of changes were calculated using the slopes of the curves of interest. Molecular response was classified according to ELN2013 recommendations.
Results: 61 patients. Age: 51,8 y (19-81), M/F: 67%/33%. Risk: Sokal (L,I,H):60%, 28.3%, 11.7%. Ten patients abandoned during the first 18 m because of AE's. They have been classified as non-responders after the time they went off-study.
Outcomes: No patient died or had transformation. The kinetic of the descent showed a fast decline of BCR-ABL/GUS ratios during the first trimester. We compared the slopes of the BCR-ABL/GUS ratio in the intervals Baseline-D90 and D90 (3m)-18m. The slopes of the values of Log(BCR-ABL/GUS) before and after the 3rd m were ignificantly different (-0,78±0,34 *vs* -0,1 ±0,11) (p<0,001). (Table 1). The responses were fast. Of note, the proportion of patients having a ratio of 10% or less at 1 month was 70%. The frequencies of optimal responses (ITT method) at 3, 6 and 12 m were 90%, 80% and 70% respectively. The frequencies of MR^4 and $MR^{4.5}$, at 18 m were 48% and 18%, respectively.

Table 1.



Summary and Conclusions: Using frequent measures during the first trimester of Nilotinib therapy, our results show that the curve of descent of BCR-ABL /GUS ratios has a biphasic shape, with a steeper descent during the first 3 months of therapy, and a significant slower decrease thereafter. The frequencies of MMR at 12m, and MR^4 and MR $^{4.5}$, at 18 m (70%, 40%, and 18%, respectively) are equivalent to those reported in the ENEST1st core study, in which ABL was used as control (68%, 36.3% and 19.8%, respectively) (Giles, F. *et al.* Blood 2013 122:4030). In summary, in CML-CP patients treated upfront with NIlotinib, the molecular response using BCR-ABL/GUS shows a rapid decline during the first trimester of therapy, and the frequency of responses are similar to those reported using ABL as gene control.

Background: Imatinib induces complete cytogenetic response (CCyR) in up to 80% of chronic myeloid leukemia (CML) patients (pts) and major molecular response (MMR) in 33-60% of them. These patients enjoy life expectancy similar to the general population. However even undetectable BCR-ABL may not equate to eradication of the disease because the sensitivity of the standard diagnostic method, the Q-RT-PCR, is limited. A new diagnostic method, the digital-PCR (dPCR), able to detect 1 BCR-ABL+ cell out of 10^7 cells, corresponding to a 100 times increased sensitivity as compared to conventional Q-RT-PCR, was developed (Goh HG *et al.*, Leuk Lymphoma 52(5): 896-904. 2011). Therefore dPCR, assessing with more sensitivity the presence of minimal residual disease, could potentially identify pts in whom CML is eradicated.
Aims: The Imatinib Suspension And Validation (ISAV) study is aimed at assessing the capability of dPCR to predict relapses after imatinib discontinuation in CML pts with negative Q-RT-PCR results.
Methods: This study involves 15 sites, 10 in Italy and 5 in each of the following countries: Germany, Spain, The Netherlands, Canada and Israel. In this study CML patients (Chronic Phase or Accelerated Phase) under imatinib therapy since more than 2 years and in complete molecular remission (CMR) were eligible. Patients had to be in CMR for at least 18 months, with a minimum of 3 Q-RT-PCR performed in their own sites. After signing the informed consent, pts were tested for dPCR and discontinued imatinib therapy. They are being monitored by standard Q-RT-PCR for 36 months to assess the maintenance of the molecular remission. The loss of molecular remission is defined as two consecutive positive Q-RT-PCR tests with at least one BCR-ABL/ABL value above 0.1%. Patients losing molecular remission resumed imatinib treatment at the same dosage used before interruption. Patients' quality of life during imatinib discontinuation/resumption is being evaluated through the EORTC – C30 Quality of Life questionnaire.
Results: The enrolment in the ISAV study began in November 2011 and ended in July 2013. The study enrolled 112 pts: Italy 69.6%, Berlin 21.4%, Montreal 5.3%, Zaragoza 2.6% and Tel Hashomer 0.9%. Fifty-nine percent of pts were male and 37.6% were aged 65 or older; median duration of imatinib treatment is 103.2 months with median duration of CMR of 26.94 months before imatinib discontinuation. To date, the median follow-up (FUP) time is 11.27 months [95% CI: 11.04-14.03] and 109 pts out of 112 (97.3%) had at least 1 Q-RT-PCR performed after imatinib discontinuation. All the pts have reached 6 months of FUP. Of these pts, 30 remained Q-RT-PCR negative (27.5%) and 41 pts (37.6%) relapsed and resumed imatinib. Ninety percent of pts relapsed in the first 9 months. A loss of CCyR happened in 8 pts (19.5%); no case of progression of CML was observed. After the resumption of imatinib the median time to either MMR or CMR, whichever came first, was 2.07 [95% CI: 1.15-2.53] months. Finally, 38 pts (34.9%) regained Q-RT-PCR positivity but never lost MMR. The median time to Q-RT-PCR positivity in this group was 3.68 months [95% CI: 3.02-4.99] and the range of duration of Q-RT-PCR positivity (below 0.1%) is between 2 and 19 months. No significant correlation between relapse and previous duration of imatinib treatment, time to CCyR or duration of CMR was present. Instead, an inverse relationship between pt age and risk of relapse was present: 73.9% of pts <=45 years relapsed *vs* 27.9% of >45years, P(Chisq) <0.0001. dPCR results show that 23.4% of pts were positive and 76.6% negative; however 60% (15/25) of dPCR+ and 31.7% (26/82) of dPCR- pts relapsed (see Table 1). To date, the Negative Predictive Value (NPV) of dPCR is 68%, with a significant NPV ratio (dPCR/Q-RT-PCR) of 1.11 [95% CI: 1.02-1.21].

Table 1. dPCR results.

Summary and Conclusions: After 28 months from the beginning of the study with a median follow-up of 11.27 months, 37.6% of pts relapsed; the majority of relapses happened in the first 9 months after imatinib discontinuation. Age inversely correlated with the risk of relapse. dPCR analysis preferentially identified relapsed patients. Funded by Regione Lombardia.

Co., Ltd, Yongin, [13]St. Mary's Hospital, The Catholic University of Korea, Seoul, Korea, Republic Of

Background: Radotinib is an orally active, selective BCR-ABL1 tyrosine kinase inhibitor (TKI), approved for the second-line treatment of CP-CML patients in Korea. Earlier 12 month results of radotinib demonstrated that radotinib is effective and well tolerated in CP-CML patients with resistance and/or intolerance to BCR-ABL1 TKIs.
Aims: We update the latest results of radotinib treatment and evaluate early response to radotinib as a predictor of long-term outcome in failed patients to BCR-ABL 1 TKIs with a minimum follow-up of 24 months.
Methods: Ph+ CP-CML patients who failed prior TKI therapy were enrolled between July 2009 and November 2011. All patients were treated with radotinib 400 mg twice daily. Cytogenetic and molecular assays were performed at baseline, every 3 months, and at treatment failure. Safety parameters were also analyzed. Probabilities of OS and PFS were calculated using Kaplan-Meier method.
Results: A total of 77 CP CML patients (18 years of age or over) were enrolled. This analysis includes data from last enrolled patient who received at least 24 months of radotinib therapy. With a median follow-up of 34.5 months, 35 patients (45.5%) completed 24 months treatment, and 42 patients (54.5%) discontinued the treatment before 24 months. Median duration of radotinib exposure was 19.5 (0.3-48.9) months. Cumulative incidence of CCyR by 24 months was 70.0% and of patients achieving CCyR, 46.2% (18/39) achieved MMR. The drug-related safety profiles were consistent with those previously reported and new safety issues have not been observed after 12 months. Most drug-related AEs have developed within 12 months, and have shown minimal increase compared with rates at 12 months follow up. Estimated OS and PFS at 24 months were 93.3% and 90.9, respectively. In patients with BCR-ABL1 ≤10% at 3 months, higher rates of OS (100% *vs* 88.2%, *P*=0.0668) and PFS (100% *vs* 75.1%, *P*=0.0015) at 24 months were observed, compared with that of the patients with BCR-ABL1 >10%. Also, OS (100% *vs* 85.8%, *P*=0.0153) and PFS (100% *vs* 63.1%, *P*<0.0001) were higher among patients with BCR-ABL1 ≤10% at 6 months compared with those who achieved BCR-ABL1 >10%. In patients with Ph+ <65% at 3 months, higher rates of OS (100% *vs* 83.5%, *P*=0.0258) and PFS (100% *vs* 63.4%, *P*=0.0001) were observed, compared with that of the patients with Ph+ ≥65%. And, OS (100% *vs* 87.6%, *P*=0.0060) and PFS (100% *vs* 71.6%, *P*<0.0001) were higher among patients with Ph+ <35% at 6 months compared with those who achieved Ph+ ≥35% at 6 months.
Summary and Conclusions: In TKI failed CML-CP patients, the minimum 24 months follow up data shows that radotinib maintains the effective response. Furthermore, achievement of early cytogenetic and molecular responses at 3 and 6 months are predictive of long-term outcomes of second-line radotinib therapy.

P285

MR4.5 AT POST-TRANSPLANT 3 MONTHS WAS A PREDICTIVE FACTOR FOR LONG-TERM OUTCOMES IN THE PATIENTS UNDERWENT ALLOGENEIC SCT IN CML CP

SE Lee[1,2,*] SY Choi[2], SH Kim[2], YJ Oh[2], MJ Chae[2], HY Song[2], HL Yoo[2], MY Lee[2], EJ Jang[2], KH Jeong[2], JS Lee[2], DW Kim[1,2]

[1]Department of Hematology, Seoul St. Mary's Hospital, The Catholic University of Korea, [2]Cancer Research Institute, The Catholic University of Korea, Seoul, Korea, Republic Of

Background: Since the first BCR-ABL1 tyrosine kinase inhibitor (TKI), imatinib mesylate (IM), has become a first-line therapy for chronic-phase (CP)chronic myeloid leukemia (CML), more potent second-generation TKIs have used in routine practice. However, allogeneic stem cell transplantation (SCT) remains to be an important treatment of patients in advanced-phase CML at diagnosis, with a T315I mutation or progression to the accelerated phase (AP) or the blast phase (BP) at the time of TKI failure. Previous studies showed the role of TKIs as an option for salvage therapy for relapsed patients, emphasizing the importance of a post-transplant monitoring by qRT-PCR.
Aims: This study is performed to identify a predictor for post-transplant relapse and outcomes in the patients underwent allogeneic SCT in CML CP.
Methods: A total of 110 consecutive patients with CML CP underwent allogeneic SCT at Seoul St. Mary's Hospital between May 2001 and December 2013. As we intended to investigate an early predictor for post-transplant relapse in CML CP, 9 advanced patients (6 in AP and 3 in BC) at the time of transplant were excluded, and 101 CP patients were evaluated. All of the patients received grafts from either a HLA identical sibling or an unrelated donor, and 64 patients received a myeloablative regimen and 37 patients received a reduced intensity conditioning regimen. In addition, to identify a predictive role of the BCR-ABL1transcript levels after SCT, 89 and 85 patients who had available records at, respectively, 1 and 3 months after SCT were analyzed. MMR was defined as a BCR-ABL1 transcript level of 0.1% or lower on the international scale (IS). $MR^{4.5}$ was defined as a reduction in the BCR-ABL1 transcript level by 0.0032% or lower.
Results: A total of 101 patients (60 men, 41 women) with a median age of 32 years (range, 13-54 years) were accessed. Of the 101 patients, 47 were TKI-naïve at the time of transplantation, and 51 received IM as their frontline therapy; the remaining 3 received frontline 2G-TKI. Upon the failure of frontline TKI therapy, 17 patients were given other TKI as a second-line therapy, of whom 9 were administered a third-line TKI. After a median follow-up of 126.4 months, the 4-year overall survival and event-free survival were 80.6% and 57.3%, respectively. Of the 101 patients, 36 relapsed after SCT, including hematological relapse (n=11), cytogenetic relapse (n=19), and molecular relapse (n=6). The overall cumulative incidence of relapse at 4 years was 29.6%. In the analysis evaluating a predictive role of the BCR-ABL1 transcript levels after SCT, the $MR^{4.5}$, at 3 months was associated with a lower relapse rate and higher EFS. Multivariate analyses including the potential variables affecting relapse and EFS, respectively revealed that the $MR^{4.5}$, at 3 months remains a higher EFS [RR (95% CI) 2.73 (1.12-6.68), p=0.028] and had a trend for lower relapse rate [RR (95% CI) 2.46 (0.87-6.95), p=0.089].
Summary and Conclusions: Our data showed the $MR^{4.5}$, at 3 months was associated with a lower relapse rate and higher EFS in the patients underwent allogeneic SCT in CML CP. It may imply that frequent molecular monitoring and intervention are required for patients with no reduction of BCR-ABL1 transcripts to these levels after SCT. However, to evaluate the value of using a TKI in the patients with a higher risk for relapse after SCT, future studies are need.

P286

MOLECULAR MONITORING USING PERIPHERAL BLOOD COMBINED WITH BONE MARROW AT 3 MONTHS OR 6 MONTHS PROVIDES A BETTER PREDICTOR OF OUTCOMES FOR PATIENTS WITH CHRONIC MYELOID LEUKEMIA

Q Jiang[1,*] X Huang[1], Y Qin[1]

[1]Peking University People's Hospital, Peking University Institute of Hematology, Beijing, China

Background: Peripheral blood (PB) was the preferred sample of molecular monitoring by quantitative real-time RT-PCR (Q-PCR) for chronic myeloid leukemia (CML) compared with bone marrow (BM) because of a significant concordance and convenience. Prognostic significance of optimal molecular response according to European leukemiaNet (ELN) recommendations on tyrosine kinase inhibitor (TKI) therapy (Version. 2013) comes primarily from monitoring evidences using PB. However, results from Stock *et al.* and our previous prospective study questioned the concordance between PB and BM assays based on each local laboratory standard.
Aims: A comparative study was performed to determine whether early molecular response in BM had actually the same prognostic importance to that in PB and whether molecular monitoring using PB and BM were comparable based on the international scale (IS).
Methods: Between May 2006 and October 2013, 405 CML patients with Philadelphia chromosome (Ph) positive and p210 BCR-ABL positive who were treated by TKI were enrolled in our study. Among them, 137 newly diagnosed CML patients in chronic phase (CP) who received upfront imatinib or nilotinib and underwent sequential molecular detections every 3 or 6 months from the onset of TKI therapy were followed up for a median of 30 months (range, 6-78 months). All patients provided written informed consent. In total, 1148 simultaneous paired PB and BM samples from 405 CML patients and 506 paired samples from the 137 newly diagnosed CML patients on treatment were analyzed. Q-PCR sensitivity defining undetectable BCR-ABL was at least 4.5 logs below the international standard baseline. Molecular response was assessed according to the ELN recommendations (Version. 2013).
Results: Among the 137 newly diagnosed CML-CP patients on upfront TKI therapy, the median Q-PCR value of BCR-ABL in PB was lower than that in BM at 3 months or 6 months (P<0.001), comparable to that in BM at 12 months (P=0.541) and higher than that in BM 18 months later (P<0.001). There were higher proportions of patients with $BCR\text{-}ABL^{IS}$ ≤10% (82.5% *vs.* 71.5%,

P=0.031) and MR4.5 (5.8% *vs.* 0, P=0.007) at 3 months and a low tendency of patients with MR4 (25.8% *vs.* 36.3%, P=0.074) after 18 months in PB than those in BM. Patients with optimal molecular response in both PB and BM had higher rates of event-free survival (EFS) and transformation-free survival (TFS) at 3 years than those without optimal in both PB and BM at 3 months or 6 months (all P values <0.001). Patients with BCR-ABL^{IS} >10% in PB but ≤10% in BM at 3 months had higher rates of EFS and TFS at 3 years than those with BCR-ABL^{IS} >10% in both PB and BM (85.7% *vs.* 45.5%, P=0.026 and 100% *vs.* 75%, P=0.051), similar to those with BCR-ABL^{IS}, ≤10% both in PB and BM. Patients with BCR-ABL^{IS} ≤1% in PB but >1% in BM at 6 months had lower rates of EFS and TFS at 3 years than those with BCR-ABL^{IS} ≤1% both in PB and BM (75% *vs.* 96%, P<0.001 and 83.3% *vs.* 100%, P<0.001), similar to those with BCR-ABL^{IS}, >1% in PB but ≤1% in BM or BCR-ABL^{IS}, >1% in both PB and BM. Among 1148 simultaneous paired samples from 405 patients, BCR-ABL transcript level in PB was lower than that in BM where BM BCR-ABL^{IS} >1% (P<0.001), comparable with that in BM where BM BCR-ABL^{IS} 0.1% - 1% (P=0.336), and higher than that in BM where BM BCR-ABL^{IS} <0.1% (P<0.001), respectively.

Summary and Conclusions: Molecular monitoring using PB combined with BM at 3 months or 6 months provides a better predictor of long-term outcome. Our study confirmed that Q-PCR monitoring for CML using PB is not as equally effective as monitoring using BM and PB assay provides a high sensitivity than BM assay for patients with MMR or deeper molecular response.

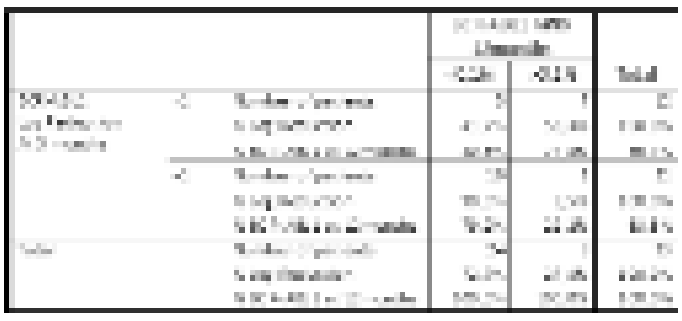
P287

BCR-ABL1 RATIO LOG REDUCTION IS A BETTER PREDICTOR OF MAJOR MOLECULAR RESPONSE (MMR) THAN 10% RATIO CUT-OFF AT 3 MONTHS IN CHRONIC MYELOID LEUKEMIA PATIENTS TREATED WITH TYROSINE KINASE INHIBITORS

R Del Orbe[1,*] A Piñan[1], M Zamora[1], E Landeta[1], I Amarika[1], E Amutio[1], JC Garcia Ruiz[1]
[1]Hematology, University Hospital Cruces, Barakaldo, Spain

Background: Monitoring molecular response to treatment in patients diagnosed with Chronic Myeloid Leukemia (CML) has changed dramatically in recent years. The latest recommendations of the European Leukemia Net, considered an optimal response values below 10% in the ratio of BCR-ABL1 at 3 months of treatment on any Tyrosine Kinase Inhibitors (TKI) and less than 0.1% at 12 months (MMR), since it predicts better long term disease-free survival. In patients with BCR-ABL1 ratio greater than 10% at 3rd month is recommended to monitor more closely and even consider a change of treatment to another TKI. Moreover, a cutoff value of 10% BCR–ABL1 ratio at 3 months has been correlated as a predictor to achieve MMR; however the role of the kinetics of molecular response is still unclear.
Aims: To assess if BCR-ABL1 log reduction at 3rd month from diagnosis (Dx) can predict achieving MMR compared to a level below 10% of BCR–ABL1 ratio.
Methods: BCR-ABL1 levels were measured (LightCycler© 480, Roche) in a subset of 45 TKI-treated patients at Dx, 3 months and 12 months and Log reduction was calculated on basis of results at Dx and 3rd month.
Results: Of forty-five patients, 33 (73.3%) had <10% BCR–ABL1 ratio at 3rd month and 12 patients (26.7%) >10%. 29 patients (64.4%) achieved a MRR at a year. 9/33 (27.3%) of patients who were in optimal response at 3rd month (<10% BCR-ABL1) failed to achieve MMR at 12 months of treatment. BCR-ABL1 Log reduction ≥1 was observed in 19/24 (79.2%) patients who had <10% ratio BCR-ABL1 ratio at 3rd month and achieved MMR at a year; behaving as a better predictor of MMR than ratio <10% at 3rd month (odds ratio [OR] 13.3, CI 2.5-70.5, *P*=0.002). There were not significant differences in relation to age and median follow-up was 36.6 months (Table 1).

Table 1.



Summary and Conclusions: The only interpretation of the 10% BCR-ABL1 ratio at 3rd month cannot identify a subgroup of patients who fail to achieve MMR at a year, making it necessary to consider the kinetics of response, setting a cutoff log reduction ≥1 at 3 months of treatment in monitoring patients with chronic phase CML.

P288

GENEXPERT BCR-ABL1/ABL1 MONITOR TEST (IS) FOR ROUTINE MONITORING OF CHRONIC MYELOID LEUKEMIA PATIENTS

G Balatzenko[1,*] V Hrischev[2], A Lilova[2], M Guenova[3]
[1]Laboratory of Cytogenetics & Molecular Biology, [2]Hematology Clinic, [3]Laboratory of Haematopathology &Immunology, National Hospital for Active Treatment of Hematological Diseases, Sofia, Bulgaria

Background: Molecular monitoring is an important element of therapeutic response evaluation in chronic myeloid leukemia (CML) patients treated with tyrosine-kinase inhibitors. Currently, the routinely used approach for the estimation of *BCR-ABL*1 transcripts level is a quantitative real time reverse transcription polymerase chain reaction (Q-RT-PCR). However, the method includes several steps, it is labor-intensive and time-consuming. The Cepheid's GeneXpert System is a fully automated RT-PCR based system that claims a standardized *BCR-ABL1/ABL1* measurement in less than 2 hours.
Aims: To evaluate the clinical practicability of *BCR-ABL1/ABL1* evaluation for patients' monitoring using GeneXpert BCR-ABL1/ABL1 Monitor Test (IS) in comparison to the results achieved with routine RT-PCR assays.
Methods: A total of 457 peripheral blood samples from BCR-ABL1(+) CML patients at different time points in the course of the follow up were tested using the GeneXpert *BCR-ABL1/ABL1* test including 5 patients with atypical *BCR-ABL1* mRNA (4 with e1a2; 1 with e1a3). The results from 114 samples were compared with the results, obtained by routine Q-RT-PCR testing using BCR-ABL1 Mbcr IS-MMR DX Kit CE (Ipsogen/Qiagen). Additionally, 50% of the *BCR-ABL1*(-) samples were also tested by nested RT-PCR.
Results: The automated *BCR-ABL1* testing was successful in 449 samples (98.2%): 355 samples were BCR-ABL1(+), the highest *BCR-ABL1/ABL1* ratio observed was 26% (IS), and the lowest - 0.00048% (IS), while in the remaining BCR-ABL1(-)cases the sensitivity of the detection varied from 0.011% (IS) to 0.00017% (IS). The testing failed in only 8 samples (1.8%) due to technical problems associated with high leucocytes count (n=4), other technical reasons (n=2) or unsuccessful ABL1 amplification (n=1). Besides, a weak positive reaction (*BCR-ABL1/ABL1* ratio 0.0044%) was observed in one p210(-) /p190(+) patient, who was found negative at the second testing. The comparison of the results obtained by the automated and the routine Q-RT-PCR testing revealed excellent concordance within the range of *BCR-ABL1/ABL1* ratio between 10% - 0.05%. In patients outside these ranges of *BCR-ABL1/ABL1* levels some discrepancies in the results were observed both in regard to the routine quantitative and nested RT-PCR assays, therefore the reproducibility of the results below 0.05% should be interpreted with caution and are subject for further refinement.
Summary and Conclusions: Our results clearly demonstrate that GeneXpert BCR-ABL1/ABL1 Monitor Test (IS) is a fast and convenient alternative to routine Q-RT-PCR testing, particularly in *BCR-ABL1*-positive patients with levels of *BCR-ABL1/ABL1* between 10% - 0.05%. This approach is useful in clinical practice for evaluation of early molecular response and to distinguish patients with major molecular response (MMR).
Acknowledgements: The study was partially supported by National Science Fund and Novartis Oncology Bulgaria.

Background: Imatinib can be discontinued without molecular relapse at least in some CML patients. But little is known about whether the assumption could be exploitable for the second-generation ABL-tyrosine kinase inhibitors.
Aims: We conducted a prospective, multicenter clinical trial to assess whether dasatinib can be discontinued without molecular relapse in CML patients in complete molecular response (CMR).
Methods: 88 CML patients in chronic phase were pre-registered according to

the criteria of our Dasatinib Discontinuation (DADI) trial (UMIN000005130). CMR was defined as "No detectable BCR-ABL transcript determined by international scale (IS)-based RQ-PCR at a single central laboratory. The levels of BCR-ABL transcripts were monitored every 3 months throughout the pre-registration period during the dasatinib treatment. Patients with sustained CMR for one-year duration were then enrolled for this dasatinib-discontinuation stage. After discontinuation, RQ-PCR was performed monthly for the first 6 months. Molecular relapse was defined as positivity of BCR-ABL transcript by RQ-PCR even at one analysis point. Dasatinib was immediately reintroduced in patients who showed molecular relapse. RQ-PCR monitoring was performed 1 month, 3 months, 6 months, and 12 months after the re-introduction of dasatinib. Primary endpoint of this study was "Molecular relapse-free survival (MoRFS) rate at 6 months after discontinuation of dasatinib."

Results: In total, 88 patients were pre-registered at 41 participating institutions in Japan. Among them, a total of 64 patients who maintained stable CMR for one year after pre-registration were enrolled for the dasatinib-discontinuation stage. One of 64 patients was excluded from the study because the patient's CML cells expressed both major and minor bcr-abl and minor bcr-abl was still detected even after the full enrolment. All of these 63 patients (41 male, 22 female) had been treated with imatinib before the start of the dasatinib treatments. Among these 63, 13 were imatinib-resistant, and 36 were imatinib-intolerant. Other previous treatments were; IFN-α (n=12), nilotinib (n=4), IFN-α and nilotinib (n=1). Median age was 59.4 years (range 24-84). Sokal scores were; low 70%, intermediate 15%, and high 15%. In this interim analysis with a data cut-off date of 31 Jan 2014, 62 patients out of 88 pre-registered patients were over the observation period of 6 months after the dasatinib-discontinuation. Among 62, 30 patients achieved 6 months-sustained CMR after dasatinib-discontinuation. The estimated MoRFS at 6 months determined by Kaplan-Meier method was 48.3%. Reintroduction of dasatinib to the relapsed patients showed rapid molecular responses in all of them. Among the 32 patients who lost CMR after dasatinib-discontinuation, 29 patients were available for the evaluation of reintroduction to CMR. 28 out of 29 patients (97%) returned to CMR again within 3 months (11 patients at 1 month, 15 patients at 3 months and 2 patients at 6 month) after the reintroduction, and all these patients have sustained CMR up to now. The remaining one patient out of 29 also showed a marked reduction of the BCR-ABL transcript level at 3 months.

Summary and Conclusions: Dasatinib could be safely discontinued in a proportion of CML patients with stable CMR for at least one year, provided that frequent molecular monitoring is performed. Patients who lost CMR after dasatinib-discontinuation still maintained good sensitivity to the reintroduction of dasatinib.

Background: The recent several reports to assess whether imatinib (IM) can be discontinued in chronic myeloid leukemia (CML) patients have shown that IM discontinuation can be employed based on clinical study in patients who had enough IM therapy and UMRD durations prior to IM discontinuation. However, further validation on precise indications for tyrosine kinase inhibitor (TKI) cessation is needed.

Aims: This study is performed to identify predictor of successful TKI discontinuation for CML patients achieving undetectable molecular residual disease (UMRD) for at least one year.

Methods: A total of 94 patients discontinued IM therapy, including 78 patients enrolled on the Korean Imatinib Discontinuation Study (KIDS) and 16 patients with IM discontinuation due to patient's request (N=15), and drug related adverse event (N=1) after achieving a UMRD. All of patients received only IM before TKI discontinuation with achieving a UMRD for at least 1 year. For the patients enrolled on KIDS, molecular response was monitored using quantitative reverse transcriptase polymerase chain reaction (qRT-PCR) assay every month up to 6 month follow-up, every 2 months up to 12 month follow-up, and every 3 months thereafter, whereas 16 patients who discontinued IM in real practice were monitored qRT-PCR every 3 months. The loss of MMR and UMRD were defined on 2 consecutive assessments, and if loss of MMR occurred, IM treatment was re-introduced.

Results: 49 women and 45 men were included and their median age was 48 years (range, 18-77). The percentages of patients with low, intermediate and high Sokal risk scores were 30%, 29% and 17%, respectively with unknown risk score in 24%. Prior to discontinuation, the median time from TKI therapy to UMRD was 26 months (range, 4.2 - 114.4 months) and the median TKI duration was 80.7 months (range, 32.9 - 141.3 months) including 40.2 months (range, 5.7 - 130.7 months) of sustained UMRD.

After a median follow-up of 11.6 months (range, 1.0 - 114.9), since discontinuation of IM, the 12-month probability of sustained MMR was 65.3%±5.3%.

All of 29 patients who lost MMR were re-treated with IM for a median of 9.5 months (range, 0.1 - 29.2 months). 22 of these patients re-achieved MMR at a median of 2.7 months (range, 0.9 - 14.0 months) after resuming IM therapy and 16 of these patients re-achieved UMRD at a median of 5.6 months (range, 2.8 - 17.8 months). Univariate analysis showed that IM duration and UMRD duration before treatment discontinuation had a higher 12-month probability of sustained MMR.

Summary and Conclusions: Although probability of sustained molecular response is relatively lower than those of our previous KIDS, our data suggested TKI may be discontinued in CML patients with undetectable molecular residual disease for at least 1 year, with utilizing increasingly sensitive PCR technology. To, make more concrete conclusion, further clinical investigation on a large patient population and much longer follow-up are needed.

Background: As the number of studies of imatinib discontinuation have been increasingly conducted, the information on post-discontinuation quality of life (QOL) is becoming of considerable important for patients and health-related personnel.

Aims: The purpose of this study was to investigate whether chronic myeloid leukemia (CML) patients who maintained undetectable molecular residual disease (UMRD) with long-term imatinib therapy show different health-related profiles after cessation of imatinib.

Methods: Forty five patients who maintained UMRD after imatinib cessation were given questionnaire for 2 times (before discontinuation and at 6 month post-discontinuation). The health surveys were modified SF-36+FACT.leu composed of imatinib-related adverse events (22 parameters), physical (parameters) and mental (10 parameters) health parameters.

Results: Among 22 parameters of imatinib-related adverse events, 17 parameters significantly improved or disappeared after imatinib cessation except for weight change, skin color change to red, pruritus, skin rash, and sore throat. Three of 11 parameters of physical health (limited social activity, vulnerable to illness, and suffer from drug adverse events) and only 1 of 10 parameters of mental health (loss hope in the fight against the illness) significantly improved. Some parameters of physical health (enjoy life, well-being sense, healthy as anyone as I know, sleep well, and do for fun) and other parameters of mental health (accept the illness, satisfy to treatment, and satisfaction with family communication) worsen after cessation, but not significantly. Younger patients, female patients, and patients with low Sokal score showed a tendency of remarkable improvements in physical and mental health parameters. Interestingly some patients (approximately 25%) have experienced the aggravation of joint pain and myalgia in early period of imatinib cessation, but not related CPK elevation.

Summary and Conclusions: Regardless of significant improvement of drug related adverse events, physical and mental health related parameters were not significantly improved. In addition, older, male gender, and high Sokal risk patients should be carefully monitored after treatment discontinuation.

DIAGNOSIS AND DISEASE MONITORING OF MDS PATIENTS WITH A DELETION 5Q USING A SIMPLE 4-PARAMETER FLOW CYTOMETRIC TEST

U Oelschlaegel[1,*] B Mohr[1], M Kramer[1], S Parmentier[1], K Sockel[1], C Thiede[1], M Bornhäuser[1], AA van de Loosdrecht[2], G Ehninger[1], U Platzbecker[1], TM Westers[2]
[1]Medical Clinic and Policlinic I, MK1-L06, UNIVERSITY HOSPITAL DRESDEN, Dresden, Germany, [2]VU University Medical Center, Amsterdam, Netherlands

Background: Patients with MDS and a del(5q) abnormality often display characteristic cytomorphologic features in the bone marrow (BM).
Aims: Whether dyspoietic abnormalities detectable by flow cytometry (FCM) differ between cytogenetic MDS subtypes is not known. Therefore, the immunophenotype in BM of MDS patients with (n=60) and without (n=160) del(5q), adding healthy BM (n=50) and non-clonal cytopenias (n=88) as further controls should be compared.
Methods: A standardized 8-color lyse-stain-wash procedure was performed. Samples were measured on a FACS Canto II. Sensitivity and specificity of the developed score were assessed using ROC analysis. Thereby, a logistic regression model allowed for a differential weighting of the single immunophenotypic features.
Results: Remarkably, a unique 4-parameter del(5q) specific immunophenotypic profile including the percentage of myeloid progenitors (myPC>2%), CD45 MFI ratio (lymphocytes and progenitors ≤7.0), sideward scatter (SSC) ratio (granulocytes and lymphocytes <6.0), as well as CD71 expression on granulocytes (≤20%) could be defined. A subsequently developed clinical score additionally including female gender and a differential weighting of all parameters allowed a distinct separation of del(5q) (score ≥15.0; maximum score=18.0) from non-del(5q) MDS by FCM with high sensitivity (95%; mean score=16.5±1.5) and specificity (85%; mean score=11.5±3.5). Notably, karyotype complexity in the context of del(5q) has no significant influence on the proposed del(5q) FCM score, arguing for del(5q) as a rather early cytogenetic abnormality which drives the cell surface protein expression. Interestingly, del(5q) MDS with a non-informative immunophenotype frequently presented with a mutation in the *TP53* gene (9/10). Furthermore, the disappearance of the del(5q) immunophenotypic profile was observed in all patients (n=13) achieving a complete cytogenetic remission during treatment with lenalidomide (median score=13.0; range: 11.5-14.5).
Summary and Conclusions: We demonstrate for the first time a strong association of a cytogenetic abnormality with a simple and reliable cell surface immunophenotypic profile in MDS, which emphasizes the role of FCM as a reliable tool for diagnostics and disease monitoring.

P293

LENALIDOMIDE MODIFIES THE BEHAVIOR OF MESENCHYMAL STROMAL CELLS (MSC) FROM PATIENTS WITH MYELODYSPLASTIC SYNDROMES WITH 5Q- (MDS-5Q-)

S Muntion[1,*] M Diez-Campelo[1], S Rojas[2], C M Santamaria[2], T L Ramos[2], S Preciado[2], JC Caballero[2], A Redondo[2], LI Sanchez-Abarca[2], F Sanchez-Guijo[1], M D Cañizo[1]
[1]Hematologia, Ibsal. Hospital universitario Salamanca, [2]Hematologia, Hospital universitario Salamanca, Salamanca, Spain

Background: Raaijmakers *et al.* (Nature, 2010) have shown that deletion of *Dicer1* in MSC-derived osteoprogenitorsas well as its target gene *SBDS*(Shwachman-Blackfan-Diamond Syndrome gene)resulted in myelodysplasia in a murine model. We have shown that MSC from MDS patients show decreased expression of both DICER1 and SBDS, as well as an altered expression of microRNAs when compared with MSC from healthy donors, and MSC from 5q- syndromes have a different genomic profile compared to other MDS (Lopez Villar, Leukemia 2009 and Santamaría. Haematologica 2010). In the current work we have hypothesized thatlenalidomide, the standard treatment for 5q- syndrome patients, could act not only on hematopoietic progenitors but also on the BM microenvironment.
Aims: To analyze the "*in vitro*" effects of Lenalidomide onBM-MSC from MDS -5q- patients and to evaluate the characteristics of MSC from lenalidomide-treated patients before and after initiating the treatment.
Methods: MSC from BM of 9 healthy donors (HD) and 6 5q-patients were isolated and expanded up to third passage. Cells were treated with 50 mMlenalidomide or its solvent (DMSO) as control. MSC gene expression profile changes was studied with the Affymetrix platform (Human Gene S1.0) in 5q-patients (n=4) and healthy donors HD (n=3).Microarray data were confirmed by RT-PCR forANgpt1, IL32, TNFa. In addition and due to their relevance in the animal model the expression of Dicer1, Drosha, and SBDS was studied by RT-PCR. Subsequently some microRNAs involved in hematopoiesis or immune system regulation were analyzed. In order, to see whether the genetic expression could translate into protein expression,levels SBDS and ANGPT1 were analyzed byWestern Blot (WB). Once we verified the effect oflenalidomide on MSC at the molecular level,functional clonogenic assays were performed to seeif the MSC behavior was modified. For this purpose, MSC from 5q- syndromes patients and HD were pre-treated with lenalidomide, and clonogeneic assays with CD34+ HPC were performed. In addition, MSC from 5 patients before and after treatment included ina clinical trial with lenalidomide were expanded and analyzed for DICER and SBDS expression by RT-PCR and WB.
Results: Array expression analysis confirmed that 306 genesshowed significant different expression changeswhen MSC from patients and HD were compared. By RT-PCR analysis MSC from MDS-5q- showed lower expression of DICER, DROSHA, SBDS andANGPT1 when compared with those from HD. This expression increased when MSC were treated withLenalidomide. Also microRNAs expression of mir-150, mir-181, and mir-222 was increased in MSC from MDS-5q- after lenalidomide treatment. In order to know if the increased expression of molecules such as DICER or SBDS could modify the capacity of MSC for supporting hematopoiesis, MSC from patients were treated with lenalidomide and co-cultured with CD34+ HPC. In all cases the number of colonies was superior when co-culture was done with lenalidomide treated MSC. When MSC fromtreated patients were analyzed before and after therapy, we could confirm that both, gene and protein expression, were increased for SBDS in all cases showing hematological response.
Summary and Conclusions: We can conclude that Lenalidomide not onlymodifies HPC from 5q- patients but also the BMmicroenvironment by increasing the expression of*DICER-1*, *SBDS* and other genes as well as the expression of some microRNAs leading to an improvement of their capacity to support hematopoiesis.

P294

IMPAIRED LINEAGE PRIMING AND PROLIFERATIVE POTENTIAL OF BONE MARROW MESENCHYMAL STEM CELLS IN PATIENTS WITH MYELODYSPLASTIC SYNDROMES ARE ASSOCIATED WITH ABNORMAL WNT SIGNALING PATHWAY

K Pavlaki[1], C Pontikoglou[1,*] A Batsali[1], S Mastrodemou[1], I Mavroudi[1], A Damianaki[1], P Kanellou[1], M Psyllaki[1], S Kyriakaki[1], MC Kastrinaki[1], HA Papadaki[1]
[1]Department of Hematology, University of Crete School of Medicine, Heraklion, Crete, Greece

Background: We and others have previously shown that Bone Marrow (BM) Mesenchymal Stem Cells (MSCs) from patients with Myelodysplastic Syndrome (MDS) display a defective proliferative capacity associated with an impaired colony forming potential and passage recovery in long-term cultures. The underlying mechanisms remain, however, obscure
Aims: Given that WNT-signaling pathways play a key role in MSC differentiation proliferation and self-renewal, we explored the possibility that the defective proliferative potential of patient-derived MSCs might be attributed, at least in part, to deregulated WNT-signaling. Furthermore we assessed lineage priming of undifferentiated cultured MDS-derived MSCs.
Methods: We studied 30 patients with *de novo* MDS and 32 age- and sex-matched healthy individuals. BM MSCs were expanded and re-seeded for a total of 10 passages (P). Undifferentiated P2, P6 and P10 MSCs from patient and control cultures were assessed for the expression of osteogenesis- and adipogenesis -related genes by real-time RT-PCR. The expression of 84 genes related to WNT-mediated signal transduction was assessed using a PCR Array (SABiosciences, Qiagen). The fold change (FC) for each gene between the group of patients and the group of controls was calculated with the ΔΔCt method ($FC=2^{-\Delta\Delta Ct}$). In a separate set of experiments the canonical WNT pathway was pharmacologically activated in P2 patient-derived MSCs using 6-bromo-indirubin-3′-oxime (BIO) (TOCRIS, Bristol, UK)
Results: 23 out of 84 WNT-related genes were differentially expressed between patients and controls. Among the non-canonical WNT pathway signaling molecules, a significant up-regulation was observed in WNT5A (FC 3.17), WNT5B (FC 3.33), WNT9A (FC 4.14) and WNT7A (FC 2.0174). A significant increase was also identified in genes implicated in canonical WNT pathway inhibition namely KREMEN1 (FC 4.21), SENP2 (FC 4.64), AES (FC 3.2), GSK3A (FC 3.98), AXIN1 (FC 2.26), CSNK1A1 (FC 2.43), CSNK2A1 (FC 2.25), SFRP1 (FC 2.8962) and CXXC4 (FC 2.9366). To explore the connection between abnormal WNT signaling and defective proliferative potential we activated canonical WNT-pathway in patient MSCs and evaluated cell proliferation by MTT. Exposure of P2 MSCs for 20 days to 10nM BIO resulted in significantly increased cell numbers (P=.0045). Since undifferentiated MSCs are primed towards the adipogenic and osteogenic lineages among others, we examined the expression of osteogenesis and adipogenesis associated genes in undifferentiated MSC cultures, through passages. The expression of osteogenesis-related genes BSP, DLX5, RUNX2 and OSX through P2-P10 was significantly decreased in patient MSCs (P<.05 for each gene). Similarly, the adipogenesis-related genes CEBPA and PPARG were significantly decreased in P2-P10 patient MSCs (P<.05, for each gene). Activation of canonical WNT has

been shown to prime undifferentiated MSCs towards the osteoblastic lineage. Provided that in patient MSCs the canonical WNT signaling is down-regulated, we investigated whether the reduced osteoblastic lineage priming of MDS-derived MSCs might be attributed, at least partly, to the impaired canonical WNT signaling. Indeed, ttreatment with 2μM BIO for 48h resulted in significant up-regulation in the expression of RUNX2 and DLX5 (P<.05 for each gene)
Summary and Conclusions: Overall our data indicate, for the first time, abnormal WNT signaling in MSCs of MDS patients. This abnormality may be implicated in the defective proliferative potential of patient MSCs and in their reduced lineage priming towards the osteoblastic lineage. Our findings support the concept of a primary MSC defect that might have a contributory effect in MDS natural history

P295

INCREASED EXPRESSION OF INTERFERON RELATED GENES IN THE BONE MARROW MICROENVIRONMENT OF MYELODYSPLASTIC SYNDROMES

M Kim[1,*] S Hwang[2], K Park[2], SY Kim[3], TY Kim[4], TY Kim[4,5], SS Yoon[4,5], EY Song[3], YK Lee[6], DS Lee[3,4]
[1]Department of Laboratory Medicine, Hallym University Sacred Heart Hospital, Anayng, [2]Korean Bioinformation Center, Korea Research Institute of Bioscience and Biotechnology, Daejeon, [3]Department of Laboratory Medicine, [4]Cancer Research Institute, [5]Department of Internal Medicine, Seoul National University College of Medicine, Seoul, [6]Department of Laboratory Medicine, Hallym University College of Medicine, Anayng, Korea, Republic Of

Background: Myelodysplastic syndromes (MDS) are a group of heterogenous diseases characterized by ineffective hematopoiesis and variable degree of the increase in blasts with multiple evolutionary stages. Molecular pathogenesis of MDS has been extensively studied using BM (bone marrow) hematopoietic cells, while the molecular changes of the MDS BM microenvironment are rarely known.
Aims: We analyzed the differential gene expression of BM mesenchymal cells of non-hematopoietic origin in adult MDS patients.
Methods: Primary culture of adherent cell layers (considered as BM mesenchymal cells) derived from BM hematopoietic cells was performed obtained from 7 adult normal controls and 7 MDS patients (3 RCMD, 3 RAEB-1 and 1 RAEB-2). cDNA microarray analysis was performed using humanHT-12 expression v.4 bead array, and data were analyzed using Illumina GenomeStudio v2009.2. Differentially expressed genes (DEGs) were selected by double criteria: Student's t-test p-value <0.01 and fold change >1.5. Functional enrichment analysis with respect to Reactome pathway was performed on KOBAS web server. The significance criteria were gene count ≥3 and p-value <0.01. Functional enrichment analysis with respect to transcription factor targets was performed on TransFind web server with default options.

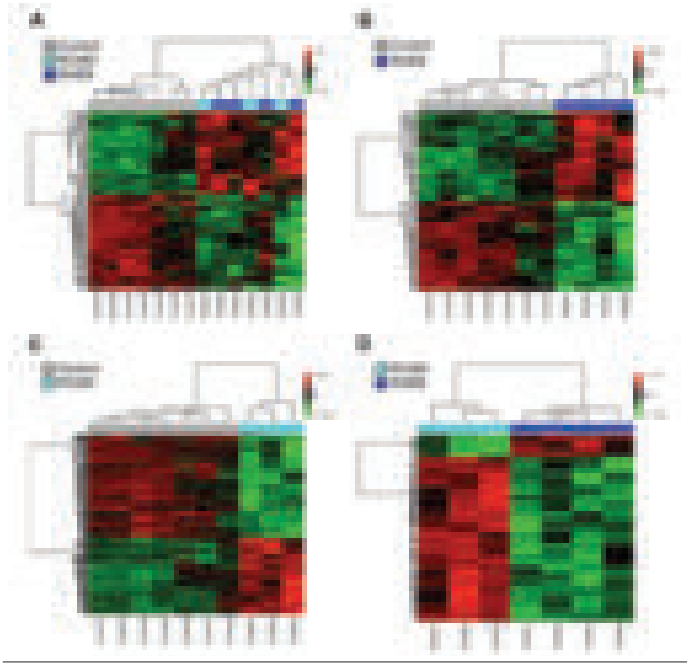

Figure 1.

Results: Differential expression was tested for all possible pairwise comparisons between sample groups, namely, MDS (=RCMD+RAEB) BM mesenchymal cells *vs.* control BM mesenchymal cells, RCMD BM mesenchymal cells *vs.* control BM mesenchymal cells, RAEB BM mesenchymal cells *vs.* control BM mesenchymal cells, and RCMD BM mesenchymal cells *vs.* RAEB BM mesenchymal cells. A total of 452 DEGs were identified: 105, 314, 68 and 51 DEGs, respectively, in each comparison. The similarity of differential expression signatures between RCMD *vs.* control and RAEB *vs.* control was significant, leading to p-value of 0 by assessing with OrderedList program. Hierarchical clustering clearly separated the two groups in every comparison (Figure 1). The functional enrichment analysis showed that both RCMD and RAEB BM mesenchymal cells showed strong up-regulation of interferon alpha/β (IFN-α/β) pathway, compared with control BM mesenchymal cells. In RCMD BM mesenchymal cells, genes involved in IFN-α/β signaling, ISG15 antiviral mechanism, immune system or IFN-γ signaling were overexpressed than in control. In RAEB BM mesenchymal cells, genes involved in IFN-α/β signaling or ISG15 (IFN stimulated genes) antiviral mechanism were overexpressed than in control. In RCMD BM mesenchymal cells, genes involved in RNA polymerase I/RNA polymerase III/mitochondrial transcription or GTP hydrolysis/joining of the 60S ribosomal subunit were overexpressed than in RAEB mesenchymal cells. The analysis for the identification of genes for transcription factor targets, RAEB BM mesenchymal cells showed overexpression of ICSBP (interferon consensus sequence-binding protein, IRF8) and IRF (interferon regulatory factor) related genes than control. RCMD BM mesenchymal cells showed overexpression of ZIC1 (Zic family member 1), STRA13 (stimulated by retinoic acid 13), USF (upstream stimulatory factor), and AhR-HIF (aryl hydrocarbon receptor - hypoxia inducible factor) related genes than RAEB BM mesenchymal cells. No specific transcription factor related genes were identified in the comparison between RCMD BM mesenchymal cells.
Summary and Conclusions: Interferon related genes were overexpressed both in adult RCMD and RAEB BM mesenchymal cells.

P296

IDENTIFICATION OF ACQUIRED MUTATIONS BY WHOLE-GENOME SEQUENCING IN MONOMAC SYNDROME EVOLVING INTO MYELODYSPLASIA AND ACUTE LEUKEMIA

T Fujiwara[1,*] N Fukuhara[2], R Funayama[3], N Nariai[4], M Kamata[2], T Nagashima[3], K Kojima[4], Y Onishi[2], Y Sasahara[5], K Ishizawa[2], M Nagasaki[4], K Nakayama[3], H Harigae[2]
[1]Molecular Hematology/Oncology, [2]Hematology and Rheumatology, [3]Cell Proliferation, Tohoku University Graduate School of Medicine, [4]Biomedical Information Analysis, Tohoku University Graduate School, [5]Pediatrics, Tohoku University Graduate School of Medicine, Sendai, Japan

Background: Heterozygous *GATA-2* germline mutations are associated with overlapping clinical manifestations termed 'GATA-2 deficiency', including i) familial myelodysplastic syndrome (MDS)/acute myeloid leukemia (AML), ii) Emberger syndrome and iii) an immunodeficiency termed monocytopenia characterised by mycobacterium avium complex (MonoMAC)/dendritic cell, monocyte, B- and NK-lymphoid deficiency (DCML) (Dickinson *et al.,* Hsu *et al.,* Ostergaard *et al.,* 2011). The disease is characterized by immunodeficiency and predisposition to MDS and AML. However, there is considerable clinical heterogeneity among patients, and the underlying molecular basis remains unknown.
Aims: We conducted whole-genome sequencing to identify acquired genome alterations attributable to the evolution of germline *GATA-2* haploinsufficiency into MDS/AML.
Methods: DNA samples were obtained from a single patient, from nails, peripheral leukocytes at immunodeficiency (MonoMAC), bone marrow (BM) mononuclear cells for MDS and BM-derived mesenchymal stem cells (BM-MSCs). To establish BM-MSCs, BM mononuclear cells from the patient were cultured in Dulbecco's modified Eagle medium containing 20% fetal bovine serum and 10 ng/mL basic fibroblast growth factor (Peprotech). The genomic DNA samples were amplified using the REPLI-g Midi Kit (QIAGEN), and sequencing libraries were subsequently prepared according to the TruSeq DNA Sample Prep Guide (Illumina). The libraries were sequenced on an Illumina HiSeq 2000. After sequencing, reads were mapped to the human reference genome (GRCh37/hg19) with decoy sequences (hs37d5) using BWA (Li and Durbin, 2009) with the default options. *GATA-2* mRNA was cloned into pBABE-puro retroviral vector, and the mutation was subsequently introduced with site-directed mutagenesis kit (Agilent). Quantitative ChIP analysis was performed using anti-GATA-2 antibody (H-116, Santa Cruz), which recognizes amino acid residues 120 – 235 of human GATA-2.
Results: We investigated a 35-year-old man with MonoMAC syndrome, who had been treated for recurrent mycobacterial and viral infections, and eventually evolved into MDS/AML. Sanger sequencing identified a germline 988 C>T heterozygous mutation. The mutation resulted in the generation of a premature stop codon at Arg330 (Arg330X), located in the N-terminal zinc finger domain. Quantitative ChIP analysis with anti-GATA-2 antibody based on K562 cells, overexpressed with the GATA-2 Arg330X, suggested that the mutation caused a loss-of-function as it was defective in DNA binding. Whole-genome sequencing was conducted with DNA samples from MonoMAC, MDS and BM-MSCs. Data from the nail sample were excluded from analysis due to a low mapping rate of the sequence on the human genome. First, we focused on the MDS-specific genome deletion based on several structural variant callers, including

BreakDancer, Pindel, and CNVnator (Suzuki *et al.,* 2011). However, we did not identify a candidate genomic deletion that may contribute to the evolution into MDS. Our next strategy was to sort the MDS-specific point mutations using the GATK Unified Genotyper (McKenna *et al.,* 2010). A total of 280 MDS-specific nonsynonymous single nucleotide variants were identified, which were subsequently narrowed down based on the single nucleotide polymorphism database, the functional missense database, and NCBI information (http://www.ncbi.nlm.nih.gov). Finally, we identified three candidate mutations, EZH2 (p.E210K), HECW2 (p.V701M) and GATA-1 (p.R293Q). Sanger sequence-based validation analysis, based on nail, MonoMAC, MDS, and BM-MSCs samples, confirmed that all three mutations were observed only in the MDS sample. We are currently performing a molecular analysis to determine how these mutations could contribute to the evolution to MDS/AML.
Summary and Conclusions: The new mutations identified in *EZH2*, *HECW2* and *GATA-1* appear to be important secondary events leading to the development of MDS/AML in the present case. Our data offer a better understanding of the pathophysiology of GATA-2 deficiency syndrome.

P297

CHROMOTHRIPSIS IN BONE MARROW CELLS OF ADULT PATIENTS WITH NEWLY DIAGNOSED MYELODYSPLASTIC SYNDROMES (MDS) WITH COMPLEX KARYOTYPES.

Z Zemanova[1,*] H Lhotska[1], J Brezinova[2], L Lizcova[1], K Svobodova[1], I Sarova[1,2], S Izakova[1], S Ransdorfova[2], Z Krejcik[2], M Dostalova[2], M Siskova[3], A Jonasova[3], R Neuwirtova[3], J Cermak[2], K Michalova[1]
[1]Center of Oncocytogenetics, Institute of Medical Biochemistry and Laboratory Diagnostics, General University Hospital and First Faculty of Medicine, Charles University in Prague, [2]Institute of Hematology and Blood Transfusion, [3]1st Medical Department, General University Hospital and First Faculty of Medicine, Charles University in Prague, Prague, Czech Republic

Background: Approximately 20% of patients with newly diagnosed MDS have complex chromosomal aberrations (CCAs) which are associated with a poor prognosis and high risk of transformation to AML. The mechanisms leading to formation of CCAs in MDS remain poorly understood. It is not clear whether the complex karyotypes arise by a gradual acquisition of genetic changes during the clonal evolution or by extensive chromosome fragmentation and reorganization through a unique cellular crisis (chromothripsis).
Aims: The aim of the study was to perform detailed genome wide analyses of bone marrow cells of newly diagnosed MDS patients with CCAs in order to assess the frequency and clinical significance of chromothripsis in the high risk MDS.
Methods: A comprehensive retrospective molecular cytogenetic analysis was performed of fixed bone-marrow cells from 170 patients with CCAs (³3 aberrations) identified with conventional G-banding technique at the time of diagnosis of MDS (85 men, 85 women; median age 67 years). The CCAs and breakpoints on the affected chromosomes were studied by FISH with Vysis DNA probes (Abbott, Des Plaines, IL) and mFISH/mBAND methods, using the 24*X*Cyte and the *X*Cyte color kits (MetaSystems, Altlussheim, Germany). Genomic imbalances were identified with CytoChip Cancer SNP 180K (BlueGnome, Cambridge, UK) or with Illumina Human CytoSNP-12 arrays (Illumina, San Diego, CA).
Results: The molecular cytogenetic findings in 83 patients of this cohort corresponded to the gradual accumulation of random chromosomal changes during the clonal evolution. In the rest of the patients (87pts; 51%), mFISH/mBAND and microarray assays showed breaks with a large number of chromatin losses and gains, probably as a results of chromothripsis. The fragmentation or shattering of chromosomes into many small pieces was observed as well. Parts of the fragmented chromosomes were often translocated or inserted elsewhere in the genome, leading to the chaotically reassembled chromosomes with the most frequently shattered nos. 5, 7, 17, and 12. Surprisingly, the OS of patients with shattered chromosomes did not significantly differ from that of patients with no evidence of fragmentation (p=0.224; median OS in both groups, four months).
Summary and Conclusions: Signs of chromothripsis were observed in 51% of MDS patients with CCAs. Although initial studies have suggested that patients displaying the chromothripsis have more aggressive tumors and poor outcomes, in this cohort no significant difference in the OS of patients with and without chromothripsis was found. It can be assumed that in MDS, CCAs can occur by either mechanism, *i.e.*, as the result of chromothripsis or with gradual clonal evolution. However, under both circumstances the prognosis is very poor.

NMR-BASED METABOLOMICS DEFINES CHARACTERISTIC METABOLOMIC SIGNATURE FOR MYELODYSPLASTIC SYNDROME (MDS)

MT Shabani-Rad[1,*] J Luider[1], I Auer[1], A Mansoor[1], HR Habibi[2]
[1]DPLM, CLS/University of Calgary, [2]Biological Sciences, University of Calgary, Calgary, Canada

Background: Myelodysplastic syndrome (MDS) is one of the challenging hematological disorder from diagnostic and treatment aspects. This disease usually presents with pancytopenia and it is important to distinguish MDS from other causes of leukopenia. With aging population, the incidence of MDS patients is in a significant uptrend and it is critical to use new technologies like as metabolomics for early and definite diagnosis of this disease. Metabolomics provide a direct functional and interactive readout of overall integrated genomics, proteomics and environmental systems. By application of mass spectrometry, chromatographic techniques or NMR, metabolomics provides highly sophisticated, specific and sensitive data. Application of LC-MS in metabolomics provides major tools to analyze a large number of metabolites simultaneously.
Aims: 1. To define the metabolomic profile of hematopoietic cells of normal, myelodysplastic syndrome and Leukopenic cases. 2. To pursue the hypothesis that borderline MDS cases presenting with leukopenia may show similar metabolomic signature as MDS at early phase of the disease. This may help differentiating these cases from non-MDS leukopenia.
Methods: Hematopoietic bone marrow cells from three categories of normal, Leukopenic and MDS cases were collected and myeloid cells sorted by flow cytometry were stored at -80 C prior to analysis. Then all specimens were analysed by NMR mass spectrometry (NMR-GC-MS) to define the metabolomic profile for different types of metabolites. The data analysis was performed by biostatistical software using PCA and OPLS-DA and outcomes were plotted with no knowledge of categorical information.
Results: Total of 46 specimens were analysed; normal (21), leukopenia with diagnosis of MDS (15) and leukopenia with no history of MDS (10) respectively. Biostatiscal analysis was able to define distinct clusters of normal, Leukopenic-MDS and Leukopenic-Non-MDS cases with significant p value of 0.0001 and higher (1.23e-8). Four cases of borderline MDS were clustered with definite MDS cases on OPLS plot. A panel of metabolites with most significant differences were selected and by application of SUS-Plot (three-dimensional Shared & Unique plots) few metabolites were chosen for future studies. Heaxanic acid was identified as specific metabolite for MDS group (Figure 1).

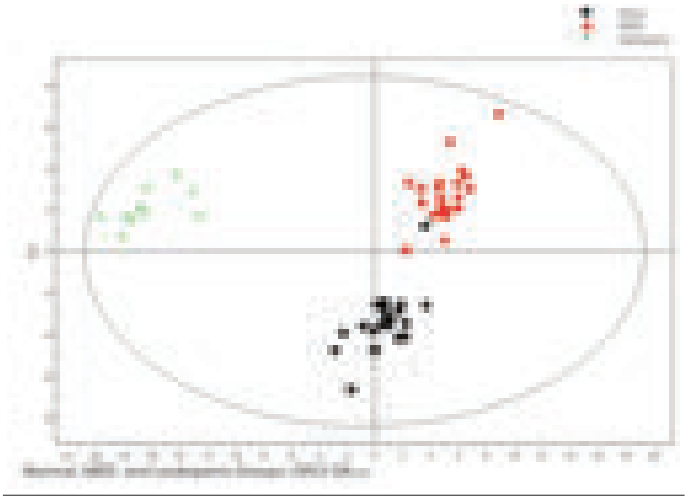

Figure 1.

Summary and Conclusions: This pilot study reveals a characteristic metabolomic signature for MDS. This finding if confirmed by future studies may provide more information for early diagnosis of MDS and distinction of borderline MDS cases form non-MDS leukopenia. In addition, the current metabolomic profile may facilitate future search for new biomarkers for diagnostic or therapeutic purposes.

P299

CIRCULATING SERUM MICRORNA-21 PREDICTS SURVIVAL AND RESPONSE TO HYPOMETHYLATING AGENTS IN PATIENTS WITH MYELODYSPLASTIC SYNDROMES

JY Lee[1,*] SJ Kim[1], Y Kim[1], DY Hwang[1], SY Hyun[1], JE Jang[1], JW Cheong[1], JS Kim[1], YH Min[1]
[1]Internal medicine, Severance hospital, Seoul, Korea, Republic Of

Background: Although hypomethylating agents therapy (HMT) have considerably improved the outcomes of patients with myelodysplastic syndrome (MDS), the discovery of sensitive non-invasive biomarkers that can facilitate prediction of response to HMT and therapeutic outcomes are highly desirable to determine optimized strategies of epigenetic therapy for MDS. Circulating microRNAs have been evaluated as potential biomarkers for cancer diagnosis and prognosis prediction.
Aims: This study was designed to evaluate the significance of serum microRNA (miR)-21 as a biomarker for predicting response in MDS patients treated with HMA.

Methods: Serum miR-21 level was measured by quantitative RT-PCR in a cohort of 58 MDS patient and 14 healthy controls. We analyzed the correlation between serum miR-21 level and clinical characteristics, response to HMA and survival.
Results: Serum miR-192 was an internal control, and diagnostic performance was evaluated according to receiver operating characteristics (ROCs). ROC analysis indicated that serum miR-21 levels differentiated responders from non-responders with an area under the curve of 0.648 (95% confidence, 0.49 to 0.72). The baseline level of serum miR-21 was significantly lower in the responder group than in the non-responder group (*P*=0.041). The overall response rate (ORR) of the high miR-21 group was significantly lower than that of the low miR-21 group (41.2 *vs.* 73.2%, *P*=0.021). Progression-free survival (PFS) was significantly inferior in the high group *versus* the low group (14.0 *vs.* 44.5 months, *P*=0.001). Multivariate analyses revealed that the initial serum miR-21 level (*P*=0.001) and circulating blasts (*P*=0.007) were prognostic factors for PFS.
Summary and Conclusions: In this study, we evaluated the levels of serum miR-21 in patients with MDS, and found that Serum miR-21 level was significantly associated with ORR and PFS in MDS patients treated with HMAs. Although validation with a large prospective study is required, serum miR-21 is a potential biomarker of epigenetic therapy in MDS patients.

ANTI-ERYTHROBLAST AUTOIMMUNITY IN EARLY MYELODYSPLASTIC SYNDROMES: ENHANCEMENT OF EPO/EPO-R SYSTEM AND PRO-APOPTOTIC EFFECT

A Zaninoni[1,*] F G Imperiali[1], A Cattaneo[2], B Fattizzo[1], A Cortelezzi[1,3], L Porretti[2], A Zanella[1], W Barcellini[1]
[1]U.O. Oncoematologia, [2]UO Laboratorio Centrale di Analisi Chimico Cliniche e Microbiologiche, Fondazione IRCCS Ca' Granda Ospedale Maggiore Policlinico, [3]Università degli studi, Milano, Italy

Background: Anti-erythroblast autoimmunity has been preliminary demonstrated in a small group of patients with early myelodysplatic syndromes (MDS), *i.e.* refractory anemia (RA) and RA with ringed sideroblasts (RARS), by mitogen-stimulated-direct antiglobulin test (MS-DAT) performed on marrow samples. This autoantibodies, rather than being cytopathic, were found to induce an hyperplastic and diserythropoietic growth *in vitro* of bone marrow (BM) progenitors.
Aims: To confirm the presence of anti-erythroblast autoantibodies in a larger cohort of patients with early MDS, and further characterise their biologic properties and target BM cell.
Methods: We evaluated 70 consecutive MDS patients (median age 78 years, range 41-93; 27 women and 43 men). Fourty-eight out of 70 patients were classified as RA and 22 as RARS, IPSS index was Low for 55/70 (78%) patients and Int-1 for 15/70 (22%). MS-DAT was performed by stimulating BM with PMA and PHA; antibodies were detected in culture supernatants by competitive solid phase ELISA. To further identify the target population of the autoimmune reaction, BM-MS-DAT positive and negative supernatants were tested on normal bone marrow and cells were labeled with Fab'anti-human IgG FITC, anti-glycophorin-A PE, anti-CD71 PerCP, anti-CD34 PECy7 and anti-CD45 APC antibodies, at 4°C in the dark for cytometric analysis. Acquisition and analysis were performed on a FACSCanto II flow cytometer, using FACSDiva 6.0 software.
Results: Thirty-eight out of 70 patients (54%) showed BM-MS-DAT positive values (cut-off value of 150 ng/mL); gender, MDS type, IPSS index, blood counts and therapy were comparable between the two groups. BM-MS-DAT positive patients showed an absolute number of reticulocytes (68±5.5 *vs* 43±4.2, mean±SE, p=0.018), unconjugated bilirubin and LDH levels higher and haptoglobin levels lower (63±6 *vs* 102.5±16.7, mean±SE, p=0.05) compared with negative patients. Moreover, the total marrow erythroblasts, as well as proerythroblasts, basophilic, polychromatic, and orthochromatic erythroblasts were higher in positive *versus* negative cases (p=0.029). Flowcytometric experiments aimed at further characterize the target BM cell of anti-erythroblast autoimmunity, showed a definite binding (20%) of BM-MS-DAT positive supernatants on $CD45^{dim}Gly\text{-}A^{dim}CD71^{bright}$, cells (erythrocyte precursors at different maturation stage), and no staining on $CD45^{-}Gly^{bright}CD71^{-}$ cells (erythrocytes); moreover we found an intermediate population $CD45^{-}Gly\text{-}A^{dim}CD71^{dim}$, with a lower IgG binding (6%). BM-MS-DAT negative supernatants gave no binding on both populations. EPO levels were reduced (13.8±3.2 *versus* 33.9±7.8 mUI/ml, mean±SE, p=0.033) and EPO-R expression increased (45.6±8.0*versus* 19.6±3.2 pg/ml, p=0.03) in bone marrow culture supernatants from BM-MS-DAT-positive patients compared with negative ones. Finally, the level of the pro-apoptotic protein Bax was higher in BM-MS-DAT positive *versus* negative patients (66.9±14.1 *versus* 21.3±3.3 pg/ml, p=0.03) and, consistently, Bcl2 level was lower in the former (10.9±2.4 *vs* 15±3.2 pg/ml), although not significantly.
Summary and Conclusions: Our results confirm the presence of autoimmunity directed against erythroblast precursors in a larger cohort of RA and RARS patients. We suggest that these autoantibodies may amplify the EPO/EPO-R system leading to a pro-apoptotic rather than a cytopathic effect.

P301

TET2 MUTATION IS FREQUENT AND ASSOCIATED WITH FAVORABLE OUTCOME IN CHRONIC MYELOMONOCYTIC LEUKEMIA

HW Kao[1,*] LY Shih[2, 3], MC Kuo[1], P Dunn[2, 3], PN Wang[1], JH Wu[1], YS Shih[3], CL Lai[1], EH Lee[4], DC Liang[4]
[1]Chang Gung Memorial Hospital, Taoyuan, [2]Chang Gung Memorial Hospital, Taipei, [3]Chang Gung University, Taoyuan, [4]Mackay Memorial Hospital, Taipei, Taiwan, Republic of China

Background: Chronic myelomonocytic leukemia (CMML) is a clonal hematopoietic malignancy with overlap features of both myeloproliferative and myelodysplastic neoplasms and characterized by monocytosis and risk of acute myeloid leukemia transformation (sAML). Several groups have described gene mutations involving DNA methylation in CMML, but their prognostic impact remained to be defined.
Aims: We aimed to determine the frequencies of *TET2, DNMT3A, IDH1* and *IDH2* mutations and their correlation with the clinicohematological features and outcomes in CMML patients.
Methods: Bone marrow samples of 105 CMML patients were analyzed for *TET2*, *DNMT3A, IDH1* and *IDH2* mutations. *DNMT3A* mutations were detected by denaturing high performance liquid chromatography followed by direct sequencing for PCR products of exons 2-23. Mutational analysis of *TET2* gene was performed by PCR followed by direct sequencing for PCR products amplified with primer pairs covering the whole coding sequences. The hot spots of *IDH1* and *IDH2* genes on exon 4 were PCR-amplified from gDNA and subjected to direct sequencing.
Results: There were 63 CMML-1 and 42 CMML-2 patients with a median age of 70.7 (range 30.2-94.9) years. The median follow-up time was 12.0 months. Cytogenetic data was available in 78 patients. Sixty-eight patients had IPSS <2 and 24 patients had IPSS□2. Very low, low, intermediate, high and very high risk categories according to IPSS-R were found in 3, 18, 23, 19, and 15 patients, respectively. None of our patients received demethylating therapy. The overall frequency of gene mutations involving DNA methylation was 52.0%, with a frequency of 40.2% (41/102), 8.7% (9/104), 0% (0/105), and 7.6% (8/105) for *TET2*, *DNMT3A, IDH1* and *IDH2* mutations, respectively. These gene mutations were mutually exclusive except two with co-existence of *TET2* and *DNMT3A* mutations and one with coexistence of *DNMT3A* and *IDH2* mutations. *TET2* mutations were associated with higher levels of hemoglobin and lower percentage of blasts in blood and bone marrow. *DNMT3A* mutations were associated with female sex, lower levels of hemoglobin, higher percentage of blasts in blood and bone marrow, and higher cytogenetic risk. *IDH2* mutations were associated with a lower risk of AML transformation. In univariate analysis, the presence of anemia (Hb<10 g/dL) and thrombocytopenia (Platelet <$100x10^9$/L) were associated with inferior AML-free survival and overall survival, while *TET2* mutation conferred a favorable AML-free survival (median 15.2 *vs* 7.7 months, *P*=0.001) and overall survival (median 26.2 *vs* 11.8 months, *P*=0.001). In multivariate analysis, *TET2* mutations (*P*=0.001) and thrombocytopenia remained the independent prognostic factors for AML-free survival and overall survival.
Summary and Conclusions: *TET2* mutation occurred frequently and conferred a favorable outcome in CMML. The detection of *TET2* mutation is helpful in the prognostic stratification for CMML patients.

P302

ROLE OF REACTIVE OXYGEN SPECIES PRODUCED BY MALIGNANT MONOCYTES IN CHRONIC MYELOMONOCYTIC LEUKEMIA

J Aurelius[1], O Werlenius, [1,*]R Riise[1], A Hallner[1], M Brune[2], L Möllgård[2], K Hellstrand[1], F B Thorén[1]
[1]University of Gothenburg, [2]Sahlgrenska University Hospital, Gothenburg, Sweden

Background: Chronic myelomonocytic leukemia (CMML) is a myelodysplastic/myeloproliferative neoplasm with dismal prognosis and few efficacious treatment options. Immunotherapy with histamine dihydrochloride (HDC) and IL-2 has been shown to decrease the relapse rate in AML with monocytic differentiation by inhibiting NADPH-oxidase-derived immunosuppressive reactive oxygen species (ROS) through interaction with surface-bound histamine type 2-receptors (H_2Rs) on the malignant clone. Since monocytosis is a defining feature of CMML, we hypothesized that ROS-production by malignant monocytes may be a mechanism by which CMML escapes immune surveillance, and that HDC and IL-2 has potential as immunotherapy also in CMML
Aims: To evaluate the pre-clinical rationale of HDC-based immunotherapy in CMML
Methods: After receiving written consent, venous blood samples were collected from patients with CMML under medical surveillance at hospitals in western and southern Sweden. PBMCs were isolated by density gradient centrifugation (Lymphoprep), and subjected to immunophenotyping by flow cytometry. Monocytes were defined as being $CD33^{+}CD14^{+}$, and NK-cells as $CD56^{+}CD3^{-}$. Monocytes and NK cells were isolated by either FACS or immunomagnetic isolation. Extracellular ROS production by monocytes was assessed by isoluminol-enhanced chemiluminescense upon stimulation with fMLF in the presence or absence of the

ROS inhibiting agent HDC. To assess immunosuppressive properties of monocytes, NK cells and monocytes were co-cultures over night in presence or absence of HDC (100uM), NADPH-oxidase inhibitor DPI (3uM), ROS scavenger catalase (200U/ml) or PARP-1 inhibitor PJ34 (0.5uM) at ratios ranging from 1:1 to 16:1. NK cell exerted cytotoxicity and degranulation against malignant monocytes was studied using a FACS-based 4-hour ADCC-assay in presence of IL-2 (500U/ml). In order to achieve potent target recognition the malignant monocytes were coated with a humanized anti-CD33 antibody (SGN-33, Abbvie). Cytotoxicity, with or without ROS inhibitors, was analyzed by FACS after staining with Annexin-V and ToPro, gating on apoptotic and lysed target cells, respectively. Degranulating NK cells were defined as the $CD107a^+$ subset.

Results: We found that the $CD33^+CD14^+$ monocytic population of CMML cells express NADPH-oxidase, as measured by surface-bound $gp91^{phox}$, and H_2R. Moreover, this monocytic population produce high levels of ROS upon stimulation with fMLF. The presence of HDC decreases ROS-production significantly ($p<0.001$). Upon co-culture, malignant monocytes induced high levels of apoptosis in NK cells. This was significantly decreased by both ROS inhibitors and PARP-1 inhibitors, indicating a ROS-mediated immunosuppression. Similar suppression, albeit to a lesser extent, was seen upon co-culture with $CD4^+$ and $CD8^+$ T cells. Moreover, NK mediated cytotoxity and degranulation against ROS-producing target cells was significantly augmented in the presence of HDC.

Summary and Conclusions: Our results show that the monocytic subset of malignant cells in CMML does produce ROS, and that monocyte-derived ROS is highly suppressive to adjacent NK and T cells. Importantly, NK-cells were rescued either by preventing ROS-production via HDC or the NADPH-oxidase inhibitor DPI, or by scavenging ROS by means of catalase. In line with previous studies we show that PARP-1-inhibition rescued NK cells from succumbing to monocyte-induced death, supporting the putative notion that ROS-induced lymphocyte apoptosis is caspase independent. Our results also show that NK cell cytotoxicity can be augmentet by HDC. The results from this study reflect what is seen in monocytic AML, *i.e.* subtypes of AML that respond well to HDC/IL_2 immunotherapy, and are suggestive of a potential role for HDC as immunotherapy in CMML. HDC/IL-2 regimens are well tolerated and safe, and a clinical study of HDC-based immunotherapy in CMML thus seems highly warranted. Also, the impact of immunosuppressive malignant monocytes should be considered in all immunotherapies targeting CMML.

P303

DISTURBANCE OF EPIGENETIC STATUS IN STROMAL CELLS COULD BE INDUCED BY INTERACTION WITH MDS/AML-INITIATING CELLS

M Kobune[1], H Horiguchi[1,2,*] S Kikuchi[1], K Takada[1], S Iyama[1], T Sato[1], A Hashimoto[1], A Tatekoshi[1], T Hayashi[1], K Miyanishi[1], Y Sato[1], R Takimoto[1], J Kato[1]

[1]Medical Oncology and Hematology, Sapporo Medical University School of Medicine, [2]Hematology and Gastroenterology, Higashi Sapporo Hospital, Sapporo, Japan

Background: The failure of normal hematopoiesis in myeloid neoplasm could be induced by a variety of mechanism. Regarding myelodysplastic syndrome (MDS)/acute leukemia (AML), aberrant hematopoietic stem/progenitor cells with exhibiting ineffective hematopoiesis and impaired differentiation ability gradually substitute it for normal hematopoietic stem/progenitor cells during a long term as a consequent of replacement of stem cell niche. Recently, genetic deletion of Dicer gene specifically in stromal cells developing into MDS/AML, suggesting the possibility that stromal disturbance could be involved in pathogenesis of MDS/AML. However, it has not yet been clarified precise mechanism how MDS stem/progenitor cells could replace normal hematopoietic stem/progenitor cells.

Aims: To gain insight into the contribution of stromal function to develop into MDS/AML, we first examined the supporting activity of stromal cell and gene expression in MDS/AML-derived stromal cells as compared with normal stromal cells. Subsequently, underlying mechanisms involved in the pathogenesis of MDS/AML were analyzed particularly in the view of BM microenvironment.

Methods: In an attempt to analyze the supporting activity of bone marrow (BM) stromal cells, we first established the MDS/AML-derived stromal cells and healthy volunteer (HV)-derived-stromal cells. Next, MDS/AML-derived CD34+ cells or normal CD34+ cells were cocultured with established stromal cells using cytokines including stem cell factor, thrombopoietin, flt3-ligand in the presence of notch ligand (for normal CD34+ cells) or IL-3 (for AML/MDS derived cells). Subsequently, we analyzed clonogenic cells after 2 weeks coculture, 5 week cobblestone area-forming cells (CAFC) and repopulating cells in immunedeficient mice (NSG mice). Finally, we established contact and non-contact culture system between MDS/AML-initiating cells and stromal cells to determine the factors involved in the alteration of stromal function.

Results: The support of clonogenic cells after 2 weeks coculture and 5 weeks CAFCs was observed after coculture with normal CD34+ cells and HV-derived stromal cells. Furthermore, these cocultured cells engrafted into immunedeficient mice. Interestingly, the number of colony-forming units (CFU) mixed cells (MIXs) and CAFC derived from CD34+ cells was drastically reduced after coculture with MDS/AML-derived stromal cells. Nevertheless, MDS/AML-derived stromal cells support the proliferation of leukemia-initiating cells (L-ICs) and L-ICs were detected after third relating. These results indicate that MDS/AML-derived stromal cells preferentially support leukemia stem/progenitor cells, but not normal CD34+ cells. We compared the mRNA expression between (HV)-derived-stromal cells, MDS/AML-derived stromal cells and 5-aza-dC-treated stromal cells. The expression of several factors including hedgehog-interacting protein (HHIP) was reduced in MDS/AML-derived stromal cells. Moreover, promoter methylation of HHIP gene was enhanced in MDS/AML-derived stromal cells (Figure 1). 5-aza-dC treatment restored the expression in some of genes and the stromal supporting activity for normal CD34+ cells partially recovered. The contact and non-contact culture system demonstrated that alteration of stromal function could be induced by even non-contact culture, indicating that certain humoral factors may be involved in the alteration of stromal gene expression.

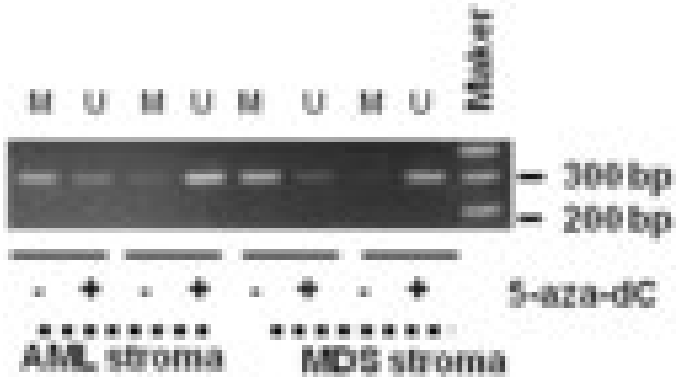

Figure 1.

Summary and Conclusions: These results suggest that reduction of several gene expressions was detected in MDS/AML stromal cells by changes of methylation status. The epigenetic alteration of stromal genome may be involved in the progression of myeloid disorders.

INDEPENDENT MULTICENTRIC STUDY ON THE INTEREST OF OGATA SCORE AND OF CD5, CD7 AND CD56 IN MDS AND MDS/MPS IN REAL LIFE

V Bardet[1], O Wagner Ballon[2], J Guy[3], C Morvan[4], E Benayoun[2], C Rossi[3], N Freynet[2], C Debord[1], F Trimoreau[4], S Mathis[1], N Chapuis[1], MC Béné[5], J Feuillard[4], E Guerin[4,*]

[1]hematology laboratory, CHU Cochin, Paris, [2]hematology laboratory, CHU Mondor, Créteil, [3]hematology laboratory, CHU Dijon, Dijon, [4]hematology laboratory, CHU Limoges/Umr Cnrs 6101, Limoges, [5]hematology laboratory, CHU Nantes, Nantes, France

Background: Even if of interest, flow cytometry (FCM) is perceived by numerous medical biologists as difficult and expensive, requiring high level of expertise.

Aims: We performed a multicentric open real life study to evaluate the interest of the technically simple FCM score described by Ogata *et al.* for diagnosis of myelodysplastic (MDS) and myelodysplastic/myeloproliferative syndromes (MDS/MPS).

Methods: Six hundred fifty two patients were recruited prospectively in four different centers: 346 MDS, 54 MDS/MPS and 253 controls. MDS were separated in proven when there is ring sideroblast, excess of blast or clonal cytogenetic abnormalities (n=235, 12 RA, 53 RCMD, 31 ASIA, 11 $5q^-$ syndromes, 90 RAEB1 and 38 RAEB 2) and not proven low risk MDS (n=111, 38 RA and 76 RCMD). Controls (n=253) were patient with normal bone marrow (n=17) or with cytopenia due mainly to vitamin deficiency (n=45, 19%), idiopathic thrombocytopenia (n=41, 18%), idiopathic or iatrogenic cytopenia (n=38, 16%) and renal insufficiency (n=24, 10%). Markers used to assess the Ogata's FCM score were CD45, CD34, CD10 and CD19. Additional labeling of CD5 and CD7 on myeloblasts and CD56 on monocytes was evaluated on a series of 292 patients: 107 controls and 185 MDS or MDS/SMP patients (72 non proven MDS, 52 low risk proven MDS, 26 RAEB 1, 16 RAEB 2 and 19 MDS/SMP. Labeling, FCM acquisition and analysis was performed in each participating center. As described by Della Porta *et al.*, we analyzed four parameters: (1) the percentage of CD34+ myeloblasts among all acquired cells (normal range (NR) <2%); (2) the percentage B-cell progenitors, here defined as CD34+CD19+ cells, among all CD34+ cells (NR>5%); (3) the lymphocyte/myeloblast ratio (NR=4 - 7.5); (4) the granulocyte/lymphocyte SSC peak chanel ratio (NR>6). One point was given for each abnormal parameter to calculate classical Ogata score. Extended Ogata score was calculated by adding one point when CD5 or CD7 was expressed on myeloblast or when CD56 was expressed on monocytes. A score of 2 or more is considered as positive for both classical and extended Ogata's score.

Results: None of the four parameters was informative enough on its own.

Specificity of classical Ogata's score was 89% and sensitivity was 50%, 56%, 68%, 84% and 72% for not proven MDS, proven low grade MDS, RAEB1, RAEB2 and MDS/MPS respectively. Interestingly, sensitivity increased with the severity of the disease. Specificity of the extended Ogata's score was hardly changed from 87% to 85%. Sensitivity of the extended Ogata's score was increased for all categories of patients, being 63% for low risk MDS (56% for not proven and 74% for proven), 100% for RAEB 1 and 2 and 90% for MDS/MPS. We recalculated an extended Ogata's score with CD56 only (CD56-Ogata's score). Specificity was 87%, and sensitivity was 60% for low risk MDS (56% for not proven and 65% for proven), 100% for RAEB and 84% for MDS/SMP. Thus the CD56-Ogata's is almost as informative as the extended Ogata's score.

Summary and Conclusions: This study shows that Ogata's score was feasible, reproducible and robust in routine real diagnosis life of MDS. But sensitivity was poor, mainly in low risk MDS. Adding labeling of CD56 on monocytes improved the informativity of Ogata's score, being quite efficient in diagnosis MDS/MPS. Thus,CD56-Ogata's FMC score would be helpful to stratify patients with genuine myelodysplastic syndromes.

P305

SELECTIVE EFFECT OF LENALIDOMIDE ON CELL CYCLE AND INOSITIDE-DEPENDENT ERYTHROID SIGNALLING IN DEL(5Q) CELLS AND MYELODYSPLASTIC SYNDROMES (MDS)

MY Follo[1,*] S Mongiorgi[1], C Clissa[2], A Poli[1], A Lonetti[1], M Stanzani[2], A Cappellini[3], AM Billi[1], L Manzoli[1], L Cocco[1], C Finelli[2]
[1]Dept. Biomedical Sciences, University of Bologna, [2]Dept. Hematology, Institute "Seràgnoli", Bologna, [3]Dept. Human Social Sciences and Health, University of Cassino, Cassino, Italy

Background: Lenalidomide is currently used in the treatment of del(5q) low-risk MDS patients, where it may suppress the del(5q) clone and restore a normal erythropoiesis. The exact molecular mechanisms underlying the effect of Lenalidomide in MDS patients are not completely understood, even though it has been demonstrated that in Lenalidomide-sensitive del(5q) cell lines, Akt phosphorylation is inhibited. Interestingly, Akt signalling is activated both in high-risk MDS, where it activates cell proliferation, and in low-risk MDS, where it is associated with response to erythropoietin.
Aims: To detect the specific effect of Lenalidomide on clonal del(5q) and normal (5q+) cells, in low-risk MDS patients and in cell lines, mainly focusing on erythropoiesis, cell cycle and signal transduction pathways involved in cell proliferation and differentiation.
Methods: This study included 6 patients diagnosed with del(5q) MDS (IPSS: Low or Int-1) treated with Lenalidomide. Given the limited number of cells, we quantified the expression of Akt in bone marrow total mononuclear cells by immunocytochemistry only. In particular, we analyzed Akt and RPS14 co-localization, in order to specifically detect the del(5q) clone. Moreover, by Real-Time PCR analyses, we also assessed the expression of Globin genes, to evaluate the effect of the drug on erythropoiesis. To better discriminate between del(5q) and normal (5q+) cells, we studied the effect of Lenalidomide on Namalwa cells, showing a del(5q) karyotype, and in U937 cells, showing a normal 5q chromosome. In both cell lines, we quantified the expression of Globin genes, cell cycle and inositide signalling molecules, by Real-Time PCR, immunocytochemistry, Western blot and flow cytometry.
Results: In our case series, 4/6 del(5q) low-risk MDS patients responded to Lenalidomide, whereas the 2 non responder patients early discontinued Lenalidomide for adverse events, and for these patients neither a clinical assessment of Lenalidomide effect, nor a molecular analysis, were possible. Responder patients showed an activation of erythropoiesis, in that Beta-Globin levels increased, as compared with baseline. Moreover, these subjects displayed a specific phosphorylation of Akt in cells not showing the 5q deletion.
As for cell lines, Lenalidomide specifically induced an accumulation of Namalwa cells in G0/G1 phase, which corresponded to a slight decrease of p-Akt, an increase of p27 and a decreased expression of cyclin B1, cyclin E and cyclin D3. On the contrary, in normal (5q+) cells, Lenalidomide did not affect cell cycle, but induced both p-Akt and Gamma-Globin.
Summary and Conclusions: Our data show that Lenalidomide can induce a selective arrest of cell cycle in G1 phase of del(5q) cells, therefore slowing the proliferation rate of this clonal cell population. On the contrary, cyclins, Akt and Gamma-Globin are specifically activated in normal (5q+) cells, possibly stimulating a normal cell proliferation and erythroid differentiation. Taken together, these findings could lead to a better comprehension of the effect of Lenalidomide in MDS and pave the way to innovative targeted therapies in low-risk MDS patients without del(5q).

P306

POSSIBLE PREVENTIVE ROLE OF CXCR4 AND ACTIVE CASPASE 3 IN LEUKEMIC EVOLUTION OF MYELODYSPLASTIC SYNDROMES

V Nikolova[1,*] V Shivarov[2], S Angelova[3]
[1]Haemato-Oncology, The Royal Marsden NHS Foundation Trust, London, United Kingdom, [2]Lab Haematopathology and Immunology, National Specialized Hospital for Active Treatment of Haematological Diseases, [3] Lab of Cytogenetics and Molecular Biology, National Specialized Hospital for Active Treatment of Haematological Diseases, Sofia, Bulgaria, Sofia, Bulgaria

Background: WHO guideline defines the approach to the myelodysplastic syndromes (MDS) diagnosis. Moreover, IPSS provides patient division into risk categories concerning the probability of acute myeloid leukemia (AML) transformation. Nevertheless, biological mechanisms underlying MDS evolution to AML remain not entirely understood, as well as some protective mechanisms supporting MDS clonal cells to escape from progression. Some chemokines as SDF-1 and its receptor CXCR4 are suggested to be involved in the regulation of survival-apoptosis of hematopoietic progenitor cells (HPC) in MDS.
Aims: To analyze CXCR4 expression on bone marrow myeloblasts (BM Mybl) in MDS, AML and control samples and to compare it to the intracellular levels of apoptotic proteins active Caspase-3 (aC3) and Bcl2.
Methods: Patients with MDS, AML and non-clonal cytopenia (n=89) were enrolled in the study. MDS were divided into 2 groups: MDSI [RA, RARS, RCMD] and MDSII [RAEB1, RAEB2]. CXCR4 (measured as% positive cells and MFI) was analyzed on BM Mybl by flow cytometry (FCM) using 6- or 7-color antibody combinations: CD34, CD133, CD184, CD33, CD117, HLA-DR, CD45. Additionally, the levels of aC3 and Bcl2 were measured by FCM in cell lysates from BM using a CBA method.
Results: CXCR4 showed significant difference between control cases and all MDS:%CXCR4+ Mybl (p=0.0467), CXCR4-MFI on Mybl (p=0.0004) with lower values in MDS. Moreover, both parameters can reliably distinguish reactive BM from the earliest MDS (resp. p=0.0402, p=0.0201). Additionally,%CXCR4+ Mybl revealed specific dynamics within the MDS group: considerable decrease was observed in RAEB1 compared to earlier stages followed by an increase in RAEB2. Regarding apoptotic proteins the analysis showed differences in aC3 and Bcl2 levels (UI/ml) between MDSI and MDSII with a higher increase of aC3 indicating almost 3-fold activation of apoptosis in MDSII. Additionally, Bcl2 showed difference between RAEB1 and RAEB2 (med 771.8 *vs* 1231.4, p=0.0864). Compared to the whole MDS group, the AML apoptosis protein pattern showed significant increase of Bcl2 levels (med 719.2 *vs* 3179.75) in correlation with markedly lower aC3 (med 40.5 *vs* 14.4, p=0.0087)
Summary and Conclusions: The difference in CXCR4 expression in MDS compared to reactive BM cases indicates different communication of clonal HPC in MDS with BM microenvironment (BMME). It is known that SDF-1/CXCR4 plays an important role in retaining the leukemic cells within the BMME, enhancing their survival and decreasing apoptosis. In this context, our finding of a significant decrease of the% CXCR4+ Mybl in RAEB1 preceding its subsequent increase in RAEB2 may be a sign of activated protective mechanisms against leukemic progression. We suggest that the low CXCR4 expression might aim to prevent clonal HPC from hiding in stem cell niches and thus escape apoptosis. Regarding apoptotic parameters compared to MDSI, in MDSII the increased Bcl2 is paralleled by a marked increase of aC3, while in AML further Bcl2 increase is accompanied by aC3 drop. This may indicate that C3 activation (enhanced apoptosis) might attempt to prevent clonal MDS cells from expansion and transformation. The subsequent aC3 decrease as a sign of an exhausted apoptosis and activation of proapoptotic Bcl2 can suggest leukemic evolution. Taken together, the decrease of CXCR4 expression in RAEB1 might be an additional mechanism to counteract the activated anti-apoptotic Bcl2. The pattern of subsequent CXCR4 and Bcl2 increase and aC3 level decrease may signal pending leukemic evolution and should be considered in the future risk assessment of MDS.

P307

NEW GERMLINE TERT GENE MUTATIONS IN APLASTIC ANEMIA / HYPOCELLULAR MYELODYSPLASTIC SYNDROMES

C Matteucci[1,*] T Iannotti[1], V Nofrini[1], L Brandimarte[1], V Pierini[1], G Barba[1], V Di Battista[1], F Arcioni[1], R La Starza[1], F Aversa[2], C Mecucci[1]
[1]Haematology and Bone Marrow Transplantation Unit, University of Perugia, Perugia, [2]Clinical and Experimental Medicine Dept, University of Parma, Parma, Italy

Background: As linear eukaryotic chromosome end-caps telomeres serve to prevent chromosome rearrangements and genomic instability. The telomerase complex, which maintains telomere length, includes *TERT* gene encoding reverse transcriptase and *TERC* gene encoding RNA template. *TERT* and *TERC* mutations underlie diskeratosis congenita (DC) and aplastic anemia (AA) (Savage SA and Bertuch AA, Genet Med 2010). Even in patients without DC, *TERT* gene mutations may be a risk factor for Myelodysplastic syndromes (MDS) and its evolution towards acute myeloid leukemia. (Calado RT, Hematology Am Soc Hematol Educ Program, 2009).
Aims: To investigate *TERT* and *TERC* gene mutations in severe AA or hypocellular MDS (h-MDS).
Methods: 8 patients (4 males, 4 females, mean age 32 years) with AA or h-MDS were recruited. Selection criteria: clinical history, no infectious diseases, no response to immunosuppression. Mutational analysis: DNA was obtained from bone marrow or peripheral blood. *TERT* (16 exons) and *TERC* were investigated by DHPLC (Transgenomic) and Sanger (AB 3500 Genetic Analyzer). PCR:

AmpliTaq Gold Polymerase (Applied Biosystem) or Robust Start Taq KAPA2G (KapaBiosystems). Cloning: RNA extraction (Trizol, Life Technologies); reverse transcription (Thermoscript™, RT-PCR System, Life Technologies); amplification (TERT_2CF (5'-CAGCGCTACTGGCAAATGCG-3' and TERT_2543R (5'-GGCACTGGACGTAGGACTTG-3'). Sub-cloning into pGEM-T easy vector (Promega). Q-FISH: Cy3 linked telomeric (PANAGENE, Korea) and chr 2 centromeric PNA probe, (DAKOCytomation, Denmark). Data were analysed with ISIS software (MetaSystems, Altlussheim, Germany) and expressed as T/C% (Perner S *et al.*, Am J Pathol 2003). For each patient 3 age and sex-matched healthy controls were recruited.

Results: Four new *TERT* coding region mutations were found. Sibling patients nos. 3 and 4 bore the same missense mutation: c. 2093 G>A p. R698Q at exon 5, defined as damaging by *in silico* analysis (SIFT and PolyPhen-2 databases). Clinical effects were significantly different. Patient 3 (female) had severe AA, idiopathic pulmonary fibrosis and liver cirrhosis. She died 41 months after diagnosis. Patient no. 4 (male) had slight macrocytic anemia, mild pulmonary fibrosis and telomere shortening (mean T/C%: 10.9 *vs* 17.7, p<0.05). Patient no.6 with severe AA bore a new missense mutation c. 2020 G>A p. G674S at exon 5 (defined as benign by SIFT and PolyPhen-2), and had significant telomere shortening (T/C%: 18.7 *vs* 25.3, p<0.05). Matched allogeneic transplantation was successful (+20 months). The patient's mother, 1 sister and 1 brother had the same exon 5 mutation without phenotype. Patient no.8 with family background had h-MDS and an acquired 47,XX,+8 karyotype. As compound heterozygous, she bore an exon 2 nonsense mutation (c.1209C>A p.C403*), and an exon 8 missense mutation (c.2455C>T p.R819C). Both were germline, being found in CD3+ T-lymphocytes. Other phenotypes included idiopathic pulmonary fibrosis, skin hyper-pigmentation, osteoarthritis. Telomere length: mean T/C% 9.4 *vs.* 18.1 (p<0.05). Disease is stable at 136 months after diagnosis (Table 1).

Table 1.

Summary and Conclusions: We found 4 new germline *TERT* gene mutations in 8 AA/h-MDS patients. Family history was the major clue to gene mutations. Phenotypes revealed different penetrance.

P308

IS THERE A RELATIONSHIP BETWEEN BONE MARROW CYTOMORPHOLOGY AND FLOW CYTOMETRY IN MYELODYSPLASTIC SYNDROMES?

C Morvan[1,*] E Guerin[1], F Trimoreau[1], MP Gourin[2], JB Woillard[3], P Olombel[1], MJ Couraud[1], A Bourinet[1], J Feuillard[1]
[1]hematology laboratory, CHU Limoges/Umr Cnrs 6101, [2]hematology, [3]pharmacology, CHU Limoges, Limoges, France

Background: A cytomorphology score has been established by the French Group of myelodysplasia to help to morphological diagnosis of myelodysplastic syndromes (MDS). But, in cases of absence of specific markers (excess of blast, cytogenetic abnormalities, ringed sideroblasts) or obvious cytological abnormalities, diagnosis of myelodysplastic syndromes remain challenging. A recent retrospective multicenter study (Della Porta *et al.* 2009) from the European LeukemiaNet (ELN) has validated a previously published flow cytometric (FCM) score for the diagnosis of low-grade myelodysplastic syndromes published by Ogata. Based on four reproducible parameters and a threshold of two, this score has a high (92%) specificity albeit a poor sensitivity (69%), which does not allow to exclude MDS diagnosis when a score of 1 or 0 is observed.

Aims: We compared a cytomorphology score adapted from the French Group of myelodysplasia and Ogata score for FCM.

Methods: In 2011, data from 96 samples were collected. 60 MDS or MDS/MPN (myeloprolferative/myelodysplastic neoplasm) including, 29 low grade MDS, 17 high grade MDS and 14 MDS/MPN were compared to 36 controls (2 healthy subjects, 11 vitamin deficiency, 3 inflammatory, 7 renal failure, 1 excessive alcohol intake, 1 thyroid dysfunction, 4 idiopathic thrombocytopenic, 1 autoimmune cytopenia, 1 haemorrhagia, 8 transient cytopenia, 1 cancer). Bone marrow smears were analysed by two independant cytologists. The 14 discordant cases were reviewed by a third cytologist. The intensity of myelodysplasia was quantified by a cytological score from 0 to 6 for the 3 hematopoietic lineages: 0 point in absence of abnormality, 1 point for dysplasia over to 10% of cells of the lineage, and 2 points for dysplasia over 50%. By FCM, we studied the four parameters of the Ogata score: (1) the percentage of CD34+ myeloblasts among all acquired cells (threshold for normal<2%); (2) the percentage B-cell progenitors, here defined as CD34+CD19+ cells, among all CD34+ cells (threshold for normal>5%); (3) the lymphocyte/myeloblast ratio (normal range: 4- 7.5); (4) the granulocyte/lymphocyte SSC peak chanel ratio (threshold for normal>6). One point was given for each abnormal FCM parameter. Both scoring systems were compared by Cohen's kappa coefficient as well as the Chi-square test.

Results: In this series, sensitivity and specificity of the cytological score were 73% and 75% for diagnosis of MDS and was 61% and 83% for FCM. Cohen's kappa coefficient was 0.204 (cytological score *vs.* Ogata score). According to the classification of Landis and Koch, the agreement between these scores was poor. But, taking cytology as reference, Chi-square test for a cytological score greater than or equal to 2 was significant (p=0.0168). Furthermore, 36%, 50% and 78% of samples had a positive Ogata score when the cytological score was between 0 and 2, equal to 3 or between 4 and 6 respectively.

Summary and Conclusions: Cytology and FCM abnormalities both reflects dysmyelopoiesis but do not allow to assess the diagnosis of MDS on its own, being not absolutely specific. The intensity of cytomorphological dysplasia is somehow related to the number of FCM abnormalities, but the strength of this association is weak and does not reach the significance. Thus, (i) cytological evaluation of dysplasia remains the reference and (ii) further studies are needed to determine whether combination of cytomorphology and FCM would do better to diagnose MDS in case of absence of specific marker.

P309

MOLECULAR CYTOGENETIC CHARACTERIZATION OF T(2;5)(P16.2;Q33.1) LEADING TO PDGFRB/SPTBN1 GENE FUSION IN A CASE OF MDS RESPONSIVE TO IMATINIB MESYLATE

D Koumbi[1,*] M Psyllaki[2], V Pappa[3], S Zachaki[1], A Daraki[1], K Manola[1], A Parcharidou[4], G Pantelias[1], C Sambani[1]
[1]Laboratory of Cytogenetics, NCSR "Demokritos", ATHENS, [2]Department of Hematology, University Hospital of Crete, Crete, [3]Hematology Unit, 2nd Dept. of Internal Medicine, ''Attikon" University Hospital, Athens, Greece, [4]Bedford Hospital NHC, Bedford, United Kingdom

Background: PDGFRB is a member of the tyrosine kinase family and PDGFRB gene rearrangements, already reported in myeloproliferative neoplasms (MPN), lead to its constitutive activation, ultimately affecting cell proliferation and migration. MPN patients with PDGFRB rearrangements have been reported to respond promptly to imatinib mesylate therapeutic regimes. The reciprocal t(2;5)(p16;q33) (PDGFRB/SPTBN1) has been reported only in one case of atypical MPN. The partner gene, SPTBN1 is a cytoskeletal protein with a role in mitotic spindles assembly.

Aims: The aim of the study was to detect the partner genes involved in the rare balanced translocation t(2;5)(p16;q33) encountered for the first time in a patient with MDS.

Methods: A 78-year-old man with a past history of surgically removed thymoma, presented in 2012 for investigation of macrocytic anemia. Bone marrow smear showed mild dysplastic features in the granulocytic and megakaryocytic series. Bone marrow biopsy showed 60% cellularity and 4% CD34+ cells. The findings were consistent with MDS diagnosis. One year later, a new biopsy showed 23% CD34+ cells and dyserythropoiesis. The patient has been recently administrated imatinib mesylate therapeutic regime.

Following karyotypic analysis on unstimulated bone marrow cells, interphase and metaphase Fluorescence *In Situ* Hybridization (FISH) analysis with specific in-house BAC probes (UCSC Genome Bioinformatics, Source Bioscience) was performed in order to refine the chromosome breakpoints and detect the partner genes. For FISH analyses, RP11-100O5/RP11-368O19 BAC probes encompassing the PDGFRB gene at 5q33.1 and RP11-423N19/RP11-1022E1 BAC probes flanking the SPTBN1 gene at 2p16.2, were fluorescently labeled by nick-translation (La Roche, Ltd) and used as dual-color break-apart probes.

Results: Chromosome analysis at diagnosis showed the karyotype: 46,XY,t(2;5)(p16;q33)[20]/46,XY[5]. PDGFRB and SPTBN1 gene rearrangements were detected in 56% of the cells. Metaphase FISH analysis revealed translocation of the 5' region of PDGFRB at 2p16.2 and fusion with the 3' region of SPTBN1 on derivative chromosome 2. Accordingly, the 5' of SPTBN1 gene was translocated at 5q33.1 and fused with the 3' of PDGFRB gene onto derivative chromosome 5. The patient has shown favorable response to imatinib treatment thus far.

Summary and Conclusions: In the current study, complete molecular cyto-

genetic characterization of the rare translocation t(2;5)(p16.2;q33), encountered for the first time in a MDS case, was carried out. FISH analyses, employing in-house developed dual-color, break-apart probes, revealed that the t(2;5)(p16;q33) initially detected in conventional karyotypic analysis, involved disruption of the genes PDGFRB and SPTBN1, located at 5q33.1 and 2p16.2, respectively. The specific chromosomal aberration led to the formation of the 3'PDGFRB/5'SPTBN1 and 5'PDGFRB/3'SPTBN1 fusion genes on derivative chromosomes 2 and 5, respectively. Importantly, based on these results underlying the rearrangement of the tyrosine kinase gene PDGFRB in the t(2;5)(p16.2;q33.1), a targeted signal transduction therapy (imatinib mesylate) has been administrated.

P310

THE INTERPLAY BETWEEN OXIDATIVE STRESS AND EPIGENETIC PROFILE IN MYELOID NEOPLASIAS

AC Gonçalves[1,2,3], R Alves[1,2,3], E Cortesão[3,4,5], I Baldeiras[2,6], JP Carda[4,5], A Barbosa-Ribeiro[1,7], A Borges[8], A Pereira[8], L Ribeiro[3,4], L Mota-Vieira[9], JM Nascimento-Costa[3, 0,11], AB Sarmento-Ribeiro[1,2,3,4,*]
[1]Applied Molecular Biology and University Clinic of Hematology, Faculty of Medicine University of Coimbra, [2]Center for Neuroscience and Cell Biology (CNC), [3]CIMAGO – Center of Investigation on Environment Genetics and Oncobiology, Faculty of Medicine University of Coimbra, [4]Clinical Hematology, Centro Hospitalar e Universitário de Coimbra, [5]University Clinic of Hematology, Faculty of Medicine, University of Coimbra, [6]Faculty of Medicine University of Coimbra, [7]Centro Hospitalar e Universitário de Coimbra, Coimbra, [8]Medicine Service, Hospital Distrital da Figueira da Foz, Figueira da Foz, [9]Molecular Pathology and Genetic Unity, Hospital do Divino Espirito Santo, Ponta Delgada - Açores, [10]Oncology and Paliative Care, Faculty of Medicine University of Coimbra, [11]Medicine Department, Centro Hospitalar e Universitário de Coimbra, Coimbra, Portugal

Background: The pathogenesis of myeloid neoplasias (MN), such as Myelodysplastic Syndrome (MDS) and Myeloproliferative Neoplasias (MPN), is complex and involve multiple genetic and epigenetic events. Oxidative stress (OS), resulting from an imbalance between Reactive Oxygen Species (ROS) production and antioxidant defenses, contributes to cell proliferation and damage, apoptosis and dysfunctional hematopoiesis. Furthermore, aberrant methylation patterns are other mechanisms common in hematopoietic neoplasias. Although the cause of altered patterns of DNA methylation in cancer remains unknown, oxidative stress might influence DNA methylation profile.
Aims: In this context, we evaluate the interplay between oxidative stress and epigenetic profile in MN patients, and analyzed their possible role as a risk factor and prognostic marker in these hematological neoplasias.
Methods: This study enrolled 73 MN patients (60 MDS and 13 MPN) and 20 controls (CTL), after informed consent. The oxidative stress levels were analyzed by the quantifications of erythrocyte activity of glutathione peroxidase (GL-PX) and glutathione redutase (GL-Red), erythrocyte levels of reduced (GSH), oxidized (GSSH) and total glutathione (totalGS), and plasma levels of vitamin A (vitA) and E (vitE), uric acid, total antioxidant status (TAS) and nitrate ($NO3^-$) plus nitrite ($NO2^-$), using standard methods. The oxidative damage was analyzed through malondialdehyde (MDA) levels and 8-hydroxy-2'-deoxyguanosine (8-OHdG) plasma levels by ELISA assays. The promoter methylation profile of cancer related genes, namely *p15, p16, p53, MGMT and DAPK*, were assessed by MS-PCR and global methylation were analyzed by 5-methyl-cytosine (5mC) and 5-hydroxymethyl-cytosine (5hmC) levels and methylation status of LINE1 sequences. The statistical analysis was carried out by variance analysis and c^2 test (p<0.05).
Results: Our results shown a decrease in enzymatic and non-enzymatic antioxidant defenses (TAS: 1,09±0,16 mM MN *vs* 1,22±0,23 mM CTL, p=0,039; totalGS: 10,75±3,53 µmol/gHb MN *vs* 11,86±2,37 µmol/gHb CTL, p=0,047) and an increase in erythrocyte lipid peroxidation (58,05±21,36 nmol/gHb MN *vs* 49,47± 24,61 nmol/gHb CTL, p=0,042) and DNA damage (8-OHdG: 37,67±5,18 pg/mL MN *vs* 31,36±4,03 pg/mL CTL, p=1,45x10^{-5}). Moreover, 81,5% of these patients presented at least one methylated gene and 58% presented two or more methylated genes. Besides that, MN patients show increased levels of 5mC and 5hmC, comparatively to controls (5mC: 8,27±4,23% *vs* 4,34±2,18%, p=0,022; 5hmC: 3,72±2,98% *vs* 1,82±0,47%, p=0,049). Moreover, taken together our results, we observe that MN patient's with the highest oxidative stress levels, namely the high DNA damage levels (8-OHdG), presents elevated levels of 5mC and 5hmC. Since we have observed a decrease in LINE1 methylation and an increased in the frequency of promoter methylation of cancer related genes, these results suggest that oxidative stress influence the methylation status inducing global hypomethylation but also gene specific methylation. Finally, we also observe that methylation status and oxidative stress are MDS subtype dependent and those patients we the high levels of 8-OHdG and with two or more methylated genes seem to have lower survival.
Summary and Conclusions: In summary, oxidative stress and aberrant methylation status may contribute to the development of MN, such as MDS and NMP, and could be a risk factor and prognostic marker in these neoplasias.

Myelodysplastic syndromes - Clinical 1

P311

IMMUNE SURVEILLANCE IMPACTS PROGNOSIS: REGULATORY T CELLS AND PROGENITOR B CELLS ARE INDEPENDENT PREDICTORS OF SURVIVAL IN LOW AND INTERMEDIATE RISK MDS

J Kahn[1,*] M Chamuleau[1], T Westers[1], L van Dreunen[1], M van Spronzen[1], GJ Ossenkoppele[1], A van de Loosdrecht[1]
[1]Hematology, VU University, Amsterdam, Netherlands

Background: Research has provided evidence for active immune surveillance in patients with myelodysplastic syndromes (MDS). Immune surveillance is characterized by an activated, mostly adaptive, immune system. While the presence of active immune surveillance in MDS has been observed, little is known about its prognostic implications.
Aims: To identify the prognostic implications of immune surveillance in patients with low and intermediate risk MDS.
Methods: 47 patients with low and intermediate risk MDS were included in the study. All patients had signed informed consent forms. Patients received standard Epo-G-CSF therapy according to Dutch guidelines. Bone marrow and peripheral blood aspirates were taken and analysed with flow cytometry. Our focus lay on immune cells possibly involved in active immune surveillance, including progenitor B cells ($CD10^+CD34^+$), effector and naïve T cells ($CD8^+CD45RA^{++}CD27^+$, $CD8^+CD45RA^{++}CD27^-$, $CD4^+CD45RA^{++}CD27^+$, $CD4^+CD45RA^{++}CD27^-$), regulatory T cells ($CD4^+CD25^{hi}FoxP3^+$) and NK cells ($CD3^-CD16^+CD56^{dim}$). Overall survival (OS) and progression free survival (PFS) were calculated for all our patients. OS was defined as the time between inclusion in our study and death or date of last follow-us, PFS was defined as time between inclusion in our study until progression to RAEB-2 or AML, death or last follow-up. Statistical analyses were performed using the Cox proportional hazards regression model. The predictive power of our survival model and markers was calculated with Harrold's c-concordance. In all analyses, a p-value <5% was considered statistically significant.
Results: The median OS of our patient group was 35 months [range: 8–62 months] with a similar median PFS of 35 months [range: 22-46 months]. We found the percentage of regulatory T cells to be predictive of PFS and OS, with a hazard ratio of respectively 1.30 (95% CI 1.07 -1.58, p<0.01) and 1.29 (95% CI 1.03 – 1.60, p<0.05). In addition, we found the percentage of progenitor B cells to be a predictor of PFS and OS with a hazard ratio of 0.87 (95% CI 0.80-0.96, p<0.01) and 0.87 (95% CI 0.79 – 0.96, p<0.01). We did not find any of the other markers to be predictors of survival. Based on multivariate analyses, the percentage of regulatory T cells and progenitor B cells impacted survival independently of known prognostic factors, including the newly revised international prognostic scoring system (IPSS-R). Using Harrol's c concordance, we demonstrate an increase in the correct prediction of PFS from 73% to 83% when adding our newly identified prognostic markers to the universally used IPSS-R.
Summary and Conclusions: This study provides evidence for a prognostic impact of immune surveillance in patients with low and intermediate risk MDS. Our data show that an immune regulatory environment, characterized by a high number of regulatory T cells and a low numbers of progenitor B cells, is associated with poorer survival. The number of regulatory T cells and progenitor B cells impacted survival independently from known prognostic factors such as the IPSS-R. They can therefore be considered novel, independent prognostic factors in low- and intermediate risk MDS, underlining the importance of immune surveillance in the prognosis of MDS.

P312

DEFERASIROX CHELATION THERAPY IN TRANSFUSION DEPENDENT MDS PATIENTS. A "REAL WORLD" REPORT FROM TWO REGIONAL ITALIAN REGISTRIES: GRUPPO ROMANO MIELODISPLASIE AND REGISTRO BASILICATA

Background: Deferasirox (DFX) has been approved for iron chelation therapy (ICT) in transfusion dependent MDS patients. Most of the available data

comes from selected MDS patients. Few data are available regarding the use of DFX outside clinical trials.
Aims: to retrospectively evaluate safety, compliance, efficacy and effect on hematopoiesis of DFX in a large "real world" MDS population
Methods: one hundred and eighteen MDS transfusion dependent patients were submitted to DFX in 11 hematological centres (9 from Lazio and 2 from Basilicata). Patients were followed-up for 24 months and data were collected at baseline (soon before starting DFX) and at 3, 6, 12, 24 months from starting ICT. DFX dose was established at discretion of the prescribing clinician. Adverse events (AEs) were defined according to CTCAE.3 (2003) definition. Efficacy of the treatment was measured by monitoring serum ferritin levels at the abovementioned time-points. Hematological improvement (HI) was defined according to International Working Group criteria 2006. Friedman test was performed to evaluate differences in serum ferritin levels over the time.
Results: Median age was 72 yrs (range 35-90) and 61% of the population aged more than 70 yrs. There were 66 males and 52 female. Fifty-five (47%), 41 (35%), 12 (10%) and 3 (2%) patients qualified as low, intermediate-1, intermediate-2 and high IPSS, respectively; IPSS was unknown in 7 (6%). Median time between diagnosis and DFX initiation was 30 months (3–153). Patients have been receiving regular blood transfusions for a median of 14 months (3–156) with a median number of units received of 26 (10–362). Median serum ferritin level was 1773 ng/ml (range 443-7339 ng/ml). Fifty five (47%) patients received DFX at the starting dose of 10 mg/kg and 63 (53%) of 20 mg/kg. Seventy-seven (65%) completed the planned treatment (12 months). Forty-one (35%) discontinued ICT, 21 (19%) due to DFX toxicities: 12 (54%) gastrointestinal, 4 (18%) hepatic, 3 (14%) renal, 2 (9%) cutaneous and 1 (5%) arthralgias. ICT discontinuation was not significantly associated with concomitant treatment (lenalidomide/azacitidine) nor with any clinical feature. Overall, 64 drug related AEs were reported in 56 (47%) distinct patients. AEs were: in 31 (48%) gastrointestinal, in 15 (23%) renal, in 10 (17%) cutaneous, in 4 (6%) hepatic and in 4 (6%) arthralgias. Of these 64 AEs, 27 (42%) were >grade 2. From a median starting value of 1773 ng/ml (range 443-7339) serum ferritin decreased to a median value of 1300 ng/ml (101–4623) and 1180 ng/ml (100-4500), at 12 and 24 months, respectively (P<0.0001). We also evaluated the effect of DFX on hematopoiesis function. Patients who were contemporarily receiving DFX plus azacitidine or lenalidomide were excluded from this analysis; therefore the analyzed cohort accounted for 85 patients. HI was observed in 19 (22%) and the type of improvement was as follows: HI-E in 16 (19%) with 5 converting to transfusion independency, HI-N and HI-P in 7 (8%) and in 4 (5%), respectively. Responses were observed, after at least 6 months of ICT. No clinical feature significantly associated with HI was found.
Summary and Conclusions: 65% of the patients on ICT was able to complete the planned treatment despite the advanced age or the assumption of concomitant medications such as lenalidomide and azacitidine. Discontinuation due to toxicity was observed in a limited number of patients. DFX was effective in reducing serum ferritin levels. HI was associated in some instances with reduced transfusion need or transfusion independency.

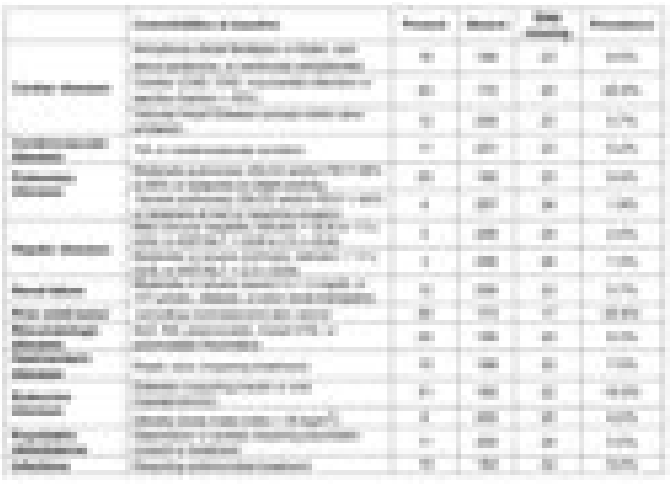
P313

THE INCIDENCE OF COMORBIDITIES AT THE TIME OF DIAGNOSIS IN PATIENTS AFFECTED BY MYELODYSPLASTIC SYNDROMES: OVERVIEW THROUGH THE "REL" ("RETE EMATOLOGICA LOMBARDA") DISEASE REGISTRY

M Riva[1,*] A Molteni[1], M Della Porta[2], L Borin[3], A Freyrie[4], A Pellizzari[5], M Bernardi[6], E Ravano[1], G Quaresmini[7], J Mariotti[8], F Gigli[9], V Speziale[10], C Landoni[11], E Morra[1]
[1]Hematology, AO Niguarda Ca' Granda, Milan, [2]Hematology, Policlinico San Matteo, Pavia, [3]Hematology, Ospedale San Gerardo, Monza, [4]Hematology, Ospedale Maggiore Policlinico, Milan, [5]Hematology, Spedali Civili, Brescia, [6]Hematology, Ospedale San Raffaele, Milan, [7]Hematology, Ospedale Papa Giovanni XXIII, Bergamo, [8]Transfusion and Hematology, AO "Treviglio-Caravaggio", Treviglio, [9]Hematology, Istituto Europeo di Oncologia, Milan, [10]Internal Medicine, AO Legnano, Legnano, [11]Oncology, AO Ospedale di Circolo, Busto Arsizio, Italy

Background: The importance of evaluation of comorbidities in patients (pts) affected by myelodysplastic syndromes (MDS) was recently highlighted, as it may help tailoring treatment strategies and improving the ability of therapeutic decisions. A prognostic score, called MDS-CI, was recently validated to provide information about overall survival and risk of non-leukemic mortality, identifying three groups of risk.
Aims: To assess the incidence of comorbidities at the time of diagnosis in MDS pts in the "REL" Disease Registry.
Methods: The "REL" MDS Disease Registry was consulted after 31 months of activity (July 2011 – February 2014) and the recorded data were analyzed. Comorbidities, according to an adapted "Hematopoietic Cell Transplantation-specific Comorbidity Index" (HCT-CI) were assessed primarily at the time of diagnosis. The MDS-CI was calculated at baseline. Comorbidities subsequently arisen and recorded were then also reported.
Results: The Registry, at time of extraction, contained data of 255 pts from 11 centers in Lombardia region.
Data about the presence of comorbidities were available in 235 cases. Of them: 179 were primary MDS, 24 t-related MDS and 32 MDS/MPN cases. Concerning primary MDS pts: the RCUD were 25, the RCMD were 62, the MDS 5q-associated were 6, the RARS were 27, the AREB-1 were 35, the AREB-2 were 23, the MDS-U was 1. The IPSS was distributed as follow: "low" in 43 cases, "intermediate-1" in 85, "intermediate-2" in 25, "high" in 5, "not valuable" in 21. According to WPSS the pts were stratified in: "very low" risk 35 cases, "low" risk 54, "intermediate" risk 31, "high" risk 30, "very high" risk 7 and "not valuable" 22. The prevalence of comorbidities at baseline, as explicated in the Table 1, was found as follows: cardiac diseases 35.1%, cerebrovascular disease 5.2%, pulmonary diseases 11.3%, hepatic diseases 3.8%, renal failures 5.7%, prior solid tumor 20.6%, rheumatologic diseases 9.3%, gastroenteric diseases 7.0%, endocrine diseases 18.5%, psychiatric disturbances 5.5%, infections 9.4%. The MDS-CI was evaluable in 207 cases. Of them, 131 pts had a "low" risk, 66 an "intermediate" risk and 10 a "high" risk. The comorbidities arisen at least 30 days after the diagnosis time were the following: cardiac disease in 13 more cases, cerebrovascular disease in 2 more cases, pulmonary disease in 3 more cases, hepatic disease in 5 more cases, renal failure in 1 more case, solid tumor in 5 more cases, rheumatologic disease in 2 more cases, gastroenteric diseases in 2 more cases, endocrine disease in 4 more cases, psychiatric disturbance in 1 more case, infections in 9 more cases.

Table 1.



Summary and Conclusions: These data, coming from a Disease Registry, allow to obtain an insight into the real life of the targeted disease. Explicitly, among the comorbidities, cardiac disease, diabetes and prior solid tumor are widely recurrent in MSD pts. Considering the disease specific MDS-CI at baseline, the most patients have a low comorbidity risk.

P314

MYOCARDIAL TISSUE CHARACTERIZATION BY CARDIAC MR IMAGING IN MYELODYSPLASTIC SYNDROMES

A Pepe[1,*] A Meloni[1], G Carulli[2], E N Oliva[3], F Arcioni[4], S Storti[5], E Grassedonio[6], S Renne[7], M Missere[8], V Positano[1], M Rizzo[9]

Background: Magnetic Resonance Imaging (MRI) provides unique insight regarding tissue characterization in the heart.
Aims: We reported the baseline MRI findings at the end of the recruitment in the MIOMED (Myocardial Iron Overload in MyElodysplastic Diseases) study. In particular, we evaluated the distribution of iron overload in the whole left ventricle (LV) and he presence of myocardial fibrosis in patients with myelodysplastic syndromes (MDS); the association with LV function was also investigated. No data are available in the literature about this issue.
Methods: MIOMED is an observational, MRI multicentre study in low and inter-

mediate-1 risk MDS patients who have not received regular iron chelation therapy. Out of the 51 MDS patients enrolled, 48 underwent the baseline MRI exam. Mean age was 71.7±8.5 years and 17 patients were females. MIO was assessed using a multislice multiecho T2* approach. Biventricular function parameters were quantified by cine sequences. Myocardial fibrosis was evaluated by late gadolinium enhancement acquisitions.

Results: We found 27 (56.3%) patients with no MIO (all 16 segmental T2* values >20 ms). The remaining patients showed an heterogeneous MIO (some segments with T2* values >20 ms and other segments with T2* values <20 ms) and of them 2 (9.5%) showed a global T2* value <20 ms, indicating significant MIO. A reduced LV ejection fraction (EF) was found in the 29.5% of cases and a reduced RV EF in the 23.3%. There was not a significant association between heart T2* values and LV EF. Myocardial fibrosis was detected in the 35.9% of the patients. Three patients showed an ischemic pattern and one of them had a transmural fibrosis in the LV apical region. Out of the 3 patients with an ischemic pattern, only one patient had a positive history for a previous myocardial infarction. The majority of the patients had two or more foci of myocardial fibrosis, involving more frequently the septal segments. Patients with myocardial fibrosis were significantly older (75.4±7.9 *vs* 68.9±7.6 yrs; P=0.019). Global heart T2* and LV volumes were not significantly different between patients with and without fibrosis. The LV EF was lower in fibrotic patients but the statistical significance was not reached (58.4±11.7 *vs* 64.8±8.9%; P=0.067).

Summary and Conclusions: Although a significant heart iron was found only in two cases, nearly half the patients had abnormal T2* values in at least one myocardial segment. This finding underlines the importance to use a multislice approach in order to perform an early diagnosis and prevent a more diffuse iron distribution by chelation therapy. This goal could be critical in patients with myocardial fibrosis that seems to be a relative common findings in the old MDS patients. In fact, an underlying heart damage as represented by fibrosis could make the hearts of the old MDS patients more sensitive to lower levels of accumulated iron.

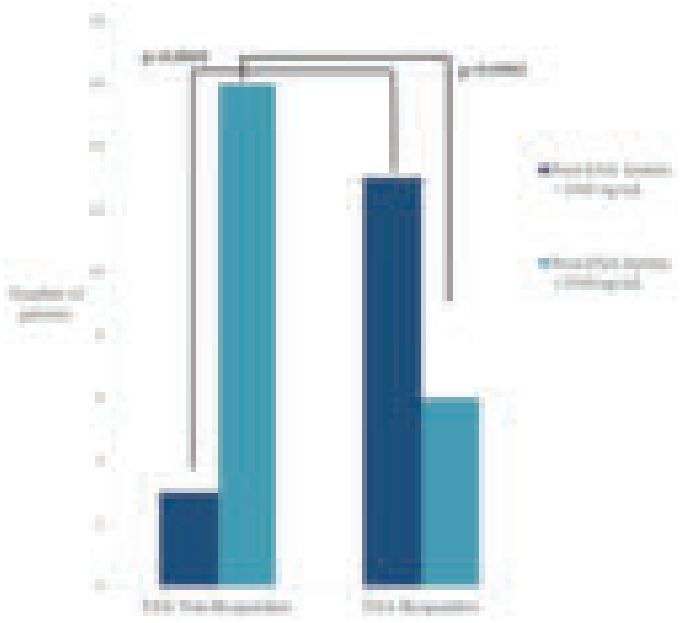

Figure 1. Number of patients with post-ESA ferritin level < or ≥ 1000 ng/mL by response to ESA.

P315

PRE AND POST-TREATMENT SERUM FERRITIN LEVELS IN PATIENTS WITH LOWER RISK MYELODYSPLASTIC SYNDROMES RECEIVING ERYTHROPOIESIS STIMULATING AGENTS

E Tsang[1], H A Leitch[2,*]
[1]Medicine, University of British Columbia, [2]Hematology, St. Paul's Hospital and the University of British Columbia, Vancouver, Canada

Background: Multiple analyses in lower risk MDS document inferior survival in patients with transfusional iron overload (IOL) indicated by increased ferritin levels. Reducing IOL with iron chelation therapy appears to result in clinical benefit in at least some MDS patients. Erythropoiesis stimulating agents (ESA) may reduce red blood cell (RBC) transfusion requirements (TR). Restoration of effective erythropoiesis should reduce IOL by incorporation of excess iron into newly formed RBC, however, few data are available on IOL status with ESA.

Aims: We aimed to examine IOL status in MDS patients receiving ESA.

Methods: We performed an analysis of MDS patients treated with ESA. Patients were identified from the database and charts reviewed. Data extracted included baseline characteristics and ferritin levels prior to (pre-ESA) and following (post-ESA) treatment, and response by IWG 2006 criteria was determined.

Results: Of 349 MDS patients, 49 received an ESA for at least 1.5 months, had ferritin levels available and were not receiving concomitant iron chelation or other MDS therapy. The median age was 70 (range 32-89) years and 26 (53%) were male. MDS diagnosis by FAB or WHO criteria was: RA, n=3; RARS, n=20; RCMD, n=16; other, n=10. IPSS scores were: low, n=23; intermediate (int)-1, n=23; ≤int-1, n=4; and int-2 risk, n=4. Median marrow blast count was 2 (0-7)%. Median erythropoietin (EPO; n=23) level was 50 (18-1459) IU/mL and median pre-ESA ferritin level 509 (76-3285) ng/mL. Median pre-ESA hemoglobin (HGB) was 89 (56-120)G/L and 26 patients were RBC transfusion dependent. Prognostic score for ESA response was: 0, n=13; 1, n=5; and 2, n=2. Baseline characteristics were similar in ESA responders (ER) and ESA non-responders (ENR) as was time from ESA start date to post-ESA ferritin measurement (P=NS for all). 46 patients received EPO and 3 darbopoietin in standard doses and schedules. Dose escalations were given in 12 patients and GCSF added in 5. Median ESA duration was 6.7 (1.5-85.9) months. 21 (43%) patients had an erythroid response: HGB improvement, n=21 (43%); transfusion response, n=4 (8%) with 3 (6%) becoming transfusion independent. The median TR in ER was stable at 4 (2-5) U/8wk (P=NS) but increased in ENR from 4 (1.2-10.6) to 5 (1-16) U/8wk (P=0.0001). Median ferritin level in ER was: pre-ESA, 473 (91-2727); post-ESA, 801 (130-11,164) ng/mL (P=0.01). In ENR median ferritin was: pre-ESA, 672 (76-3285); post-ESA, 1423 (431-6593)ng/mL (P<0.0001). Patients with post-ESA ferritin ≥1000ng/mL were: ER, 6/19 (32%); ENR, 16/19 (84%). Conversely, post-ESA ferritin <1000ng/mL was: ER, 13/19 (68%); ENR, 3/19 (16%; P=0.003; Figure 1). Similarly, though there was no association between pre-ESA HGB level and post-ESA HGB ≥100g/L (P=NS), of patients with post-ESA HGB ≥100g/L, the ferritin was <1000ng/mL in 13/20 (65%) and ≥1000ng/mL in 7/20 (35%). Conversely, with post-ESA HGB <100g/L, ferritin was <1000ng/mL in 1/7 (14%) and ≥1000ng/mL in 6/7 (35%; P=0.03). At a median follow up of 28 (4-226) months, the two year OS for ER and ENR, respectively, was 80% and 86% (P=NS).

Summary and Conclusions: In MDS patients responding to ESA, ferritin levels increased less than in ESA non-responders. Both response to ESA and achieving a post-ESA HGB ≥100g/L were associated with post-ESA ferritin <1000ng/mL (P<0.0001 and P=0.03, respectively). This is to our knowledge the first analysis of serial ferritin levels in patients receiving ESA. Whether iron overload may be significantly reduced by ESA will require analysis of larger numbers of patients with measurement of IOL parameters at regular intervals. An analysis from the Canadian MDS database of iron status in non- transfusion dependent patients with lower risk MDS receiving ESA is in progress.

P316

VALIDATION OF LOW RISK PROGNOSTIC SCORING SYSTEM (LR-PSS) IN 318 PATIENTS WITH LOWER RISK IPSS MYELODYSPLASTIC SYNDROME FROM A SINGLE CENTER.

H Pomares[1,*] R Duarte[1], I Sanchez-Ortega[1], E Alonso[2], A Fernandez de Sevilla[1], M Arnan[1]
[1]Hematology, Catalan Institute of Oncology. Hospital Duran i Reynals, [2]Hematology, Hospital Universitari de Bellvitge, L'Hospitalet de Llobregat. Barcelona, Spain

Background: Myelodysplastic syndrome (MDS) treatment decision is currently based on the International Prognostic Scoring System (IPSS) and IPSS-R (Greenberg *et al.*, 2012), which have been recently validated in our series of patients (P-195. Stockholm. EHA 2013). Nearly 90% of patients from our series were low and intermediated-1 IPSS. Current prognostic models for MDS do not allow the identification of patients with lower risk IPSS disease and poor prognosis. A prognostic scoring system specifically for this cohort of patients (LR-PSS) was developed based on age ≥60 years, hemoglobin <10g/dl, platelet count <50k/uL or 50-200k/uL, bone marrow blast ≥4% and unfavorable cytogenetic (non-del(5q), non–diploid) (Garcia-Manero. *Leukemia* 2008) which divided patients into 3 risk categories.

Aims: The purpose of this study was to validate the prognostic value of Low Risk Prognostic Scoring System (LR-PSS) in our cohort of 318 lower risk IPSS (Low and intermediate-1 IPSS) MDS patients.

Methods: Between 1987 and 2013, 744 patients with MDS were diagnosed at the Catalan Institute of Oncology in Barcelona. Among them, IPSS could be assessed in 360 (48.3%) patients with cytogenetic analysis available. We evaluated in lower IPSS patients the prognostic power of LR-PSS analyzing as endpoints overall survival (OS) and leukemia free survival (LFS).

Results: 318 (88%) of patients with IPSS available, had lower risk MDS. 200 (63%) had low risk disease and 118 (37%) had intermediate-1 risk. Median age at diagnosis was 71 years (range 29-101). 219 (69%) were male. Median follow up was 102 months (range 79-125). WHO 2008 was: 1% CRDU, 9%RA, 43% RCMD, 19% RAEB-1, 2% RAEB-2, 23% CMML, the remaining 3% were MDS-U and isolated 5q deletion. At diagnosis: Median hemoglobin, platelet and bone marrow blast were 11.7 g/dL (5.5-16), 156 x10^9/L (1-1492) and 3% (0-10). 46 (14,5%) patients have unfavorable LR-PSS cytogenetic at diagnosis. At the time of last follow up 137 (43.1%) patients had died and among patients with PFS data available (n=210) 37 (17.6%) had progressed to AML.

Classification of lower risk IPSS MDS patients (n=318) according to LR-PSS were: category 1 (score 0-2), category 2 (score 3-4) and category 3 (score 5-7) in 70 (22%), 211 (66.4%) and 37 (11,6%), respectively. Categories based on the LR-PSS system had different median survival rates: 113 months (95% CI 79-145) in category 1; 78 months (95% CI 63-93) in category 2 and 31 months (95% CI 26-37) in category 3 (p<0.001). Rate of progression to acute myeloid leukemia in category 1 and 2 of LR-PSS was 13% (6/47) and 18% (23/126) respectively while 30% (8/27) of lower risk IPSS patients who were reclassified as category 3 LR-PSS progressed to acute myeloid leukemia (Figure 1).

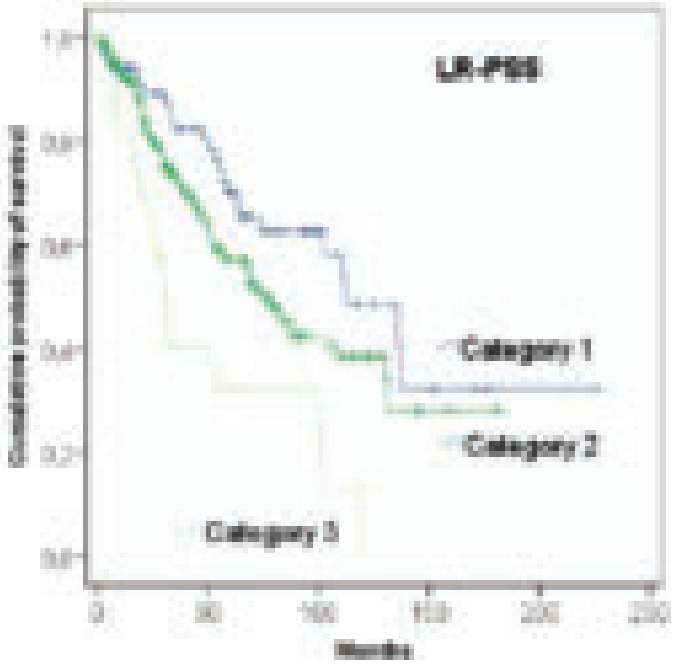

Figure 1. Survival of lower risk IPSS MDS patients based on LR-PSS categories.

Summary and Conclusions: The implementation of LR-PSS in lower IPSS MDS patients could allow us to identify patients with lower risk MDS and poor prognosis who could benefit from an earlier intervention.

P317

MRI SURVEY IN TRANSFUSION-DEPENDENT AND NON-TRANSFUSION-DEPENDENT MDS PATIENTS

A Pepe[1,*] A Meloni[1], G Carulli[2], E N Oliva[3], F Arcioni[4], V Fraticelli[5], P Toia[6], S Renne[7], G Restaino[8], V Positano[1], M Rizzo[9]

Background: Several studies have shown cardiac diseases as causes of death in myelodisplastic (MDS) patients receiving transfusions. So iron overload may be considered an independent negative prognostic factor. There are few and rather contradictory studies using Magnetic Resonance Imaging (MRI) in the evaluation of MDS syndromes.
Aims: We report the baseline MRI findings at the end of the recruitment in the MIOMED (Myocardial Iron Overload in MyElodysplastic Diseases) study. We investigated hepatic, pancreatic and cardiac iron overload and biventricular functional parameters in MDS patients, outlying the differences between transfusion dependent (TD) and non transfusion dependent (non-TD) patients.
Methods: MIOMED is an observational, MRI multicentre study in low and intermediate-1 risk MDS patients who have not received regular iron chelation therapy. Forty-eight patients (71.7±8.5 years, 17 F) underwent the baseline MRI exam. Hepatic T2* values were converted into liver iron concentration (LIC). T2* measurements were performed in pancreatic head, body and tail. Myocardial iron overload (MIO) was assessed using a multislice multiecho T2* approach. Biventricular function parameters were quantified by cine sequences.
Results: The mean LIC was 7.6±8.8 mg/g/dw, the mean global pancreas T2*, assessed in 20 patients, was 24.0±13.46 ms and the mean global heart T2* was 38.7±8.3 ms. Global heart T2* values were not significantly correlated with LIC or serum ferritin levels. Thirty-two (66.6%) patients were non-TD while 16 patients were TD. The two groups were homogeneous for age, sex and hemoglobin levels but TD patients had significantly higher serum ferritin levels (1612±864 *vs* 711±430; P<0.0001). The percentage of patients with detectable hepatic iron (LIC≥3 mg/g/dw) was significantly higher in the TD group (Figure 1, left). Mean LIC was 14.4±11.1 mg/g/dw in the TD group and 4.2±4.6 mg/g/dw in the non-TD group (P<0.0001). The percentage of patients with detectable pancreatic iron (T2*<26 ms) was comparable between the two groups (Figure 1, center). A significant heart iron (T2*<20 ms) was found in two patients; both with an heterogeneous pattern (some segments with T2*>20 ms and others with T2*<20 ms). Out of the two patients with significant heart iron, one patient was not transfused and he did not show significant hepatic iron (LIC=2.12 mg/g/dw) while the other one was regularly transfused and he received sporadically (less than two weeks/month) chelation treatment with deferoxamine in the 2 years before the MRI. Both patients had pancreatic iron overload (T2*=9.79 ms and T2*=2.45 ms, respectively). The global heart T2* (Figure 1, right), the pattern of iron burden and the number of segments with T2*<20 ms were comparable between the two groups. Biventricular volumes and ejection fraction and left ventricular mass index were comparable between the two groups.

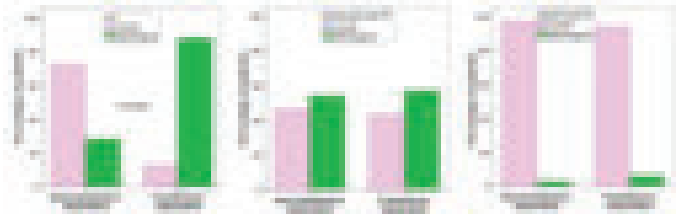

Figure 1.

Summary and Conclusions: As expected, regularly transfused MDS patients showed significantly higher levels of hepatic iron overload, that, however, was present in almost the 30% of non-TD patients, mainly due to increased intestinal iron and augmented erythropoiesis. MIO is not frequent in MDS patients but it can be present also in non-TD patients and in absence of detectable hepatic iron. Conversely, no patients without pancreatic iron overload had cardiac iron overload. Our data remark the importance to check directly for heart iron with a more sensitive segmental approach avoiding to estimate heart iron burden from indirect indicators such as LIC, serum ferritin or transfusion state.

P318

THE IMPACT OF TRANSFUSION DEPENDENCY ON THE OUTCOME OF PATIENTS WITH VERY LOW AND LOW RISK MYELODYSPLASTIC SYNDROME ACCORDING TO THE IPSS-R.

M Arnan[1,*] H Pomares[1], I Sánchez-Ortega[1], E Alonso[2], A Fernández de Sevilla[1], R Duarte[1]
[1]Hospital Duran i Reynals. Institut Català d'Oncologia., [2]Hospital de Bellvitge., L'Hospitalet del Llobregat., Spain

Background: The recent revision of the International Prognostic Scoring System (IPSS-R) (Greenberg P *et al.* Blood 2012) has provided us an updated tool to better define prognosis and life expectancy of patients with myelodysplastic syndrome (MDS). Although transfusion dependency (TD) has been described as an independent prognostic factor for survival n MDS patients (Malcovati L *et al.* JCO 2007), it was not included in IPSS-R analysis mainly due to limited availability of transfusion data on patients used for deriving the IPSS-R.
Aims: We retrospectively analysed the outcome of 744 patients with the novo MDS diagnosed between 1994 and June 2013 at the Catalan Institute of Oncology in Barcelona and we analysed the prognostic value of TD and the impact on survival in IPSS-R subgroups.
Results: A total of 744 patients were included in this analysis. Their median age was 72 years (27-101 years) and 64% patients were male. IPSS-R could be assessed in 360 patients, of whom 267 (74%) were in the Very Low or Low risk groups (determined as 'LOWER RISK'). The median OS of IPSS-R Very Low, Low, Intermediate, High and Very High risk groups was 8.5, 7.3, 4.4, 1.3 and 0.6 years, respectively. (Figure 1. p<0.0001). Among the 360 patients in whom IPSS-R could be assessed, 34% of patients were RBC TD (defined as having at least 1 RBC transfusion every 8 weeks for at least 4 months) and 9% of patients presented IO (defined as serum ferritin ≥1000 ng/ml). TD and IO are more common in the Very High (76%/8%), High (56%/20%) and Intermediate (53%/17%) risk groups as compared to the lower risk IPSS-R groups: Low (29%/8%) and Very Low (20%/5%). In multivariate analysis, RBC-transfusion dependency (HR 3.18; P<0.0001) was associated with poor survival, inde-

pendent of the IPSS-R category, age at diagnosis and IO. The median OS of TD patients (n=116) was significantly lower (4.1 *vs.* 10.7 years; p<0.0001) than that of Non-TD (n=227). (Figure 2. p<0.0001). As TD is more common in the IPSS-R higher risk patients, but the majority of patients of our series were of lower risk, we restricted further analysis to assess the specific impact of TD in IPSS-R lower risk groups. The median OS between Low and Very Low risk group was not significantly different (8.1 *vs* 9.5 years; p=0.4), consequently we grouped both together. The median OS of TD lower risk IPSS-R patients (n=65) was significantly shorter than that of transfusion-independent (n=190) patients (5 *vs* 11 years; p<0.0001).

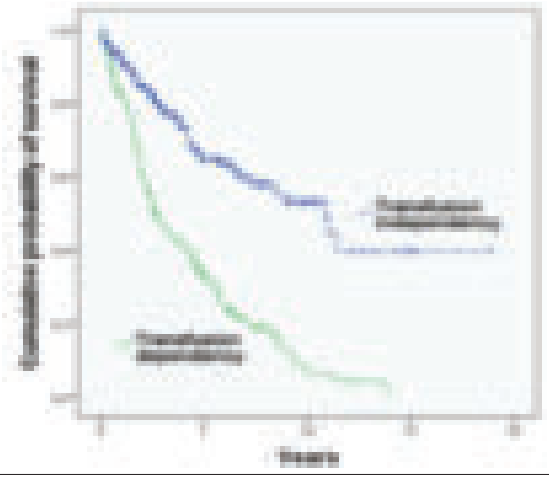

Figure 1. Survival of MDS patients based on development of transfusion requirements.

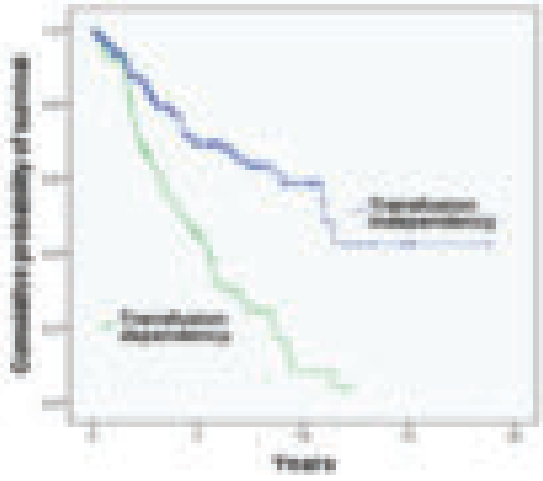

Figure 2. Survival of lower risk IPSS-R MDS patients based on development of transfusion requirements.

Summary and Conclusions: The inclusion of transfusion dependency in risk stratification of patients with lower risk IPSS-R, could allow us to identify a subset of patients with lower risk disease disease and poor prognosis who could benefit from an earlier intervention.

P319

CALRETICULIN MUTATION WAS RARELY DETECTED IN PATIENTS WITH MYELODYSPLASTIC SYNDROME

HA Hou[1,*] YY Kuo[1], WC Chou[1], PH Chen[1], HF Tien[1]
[1]National Taiwan University Hsopital, Taipei, Taiwan, Republic of China

Background: Recently, somatic mutations in exon 9 of *calreticulin* (*CALR*) were detected in patients with myeloproliferative neoplasms (MPN) who had nonmutated *JAK2* and *MPL*. Similar genetic alterations, such as mutations of *ASXL1, IDH,* and *TET2,* etc, have been identified in both myelodysplastic syndrome (MDS) and MPN, raising the possibility that *CALR* mutations may also occur in patients with MDS.
Aims: The study was aimed to investigate the incidence and clinical implication of *CALR* mutations in MDS patients.
Methods: To further characterize *CALR* mutations in MDS, we performed Sanger sequencing of *CALR* exon 9 in 453 patients with *de novo* MDS, according to the WHO classification, as well as 98 patients with CMML and acute myeloid leukemia (AML) with blast percentage of 20% to 30%, that is refractory anemia with excess blasts in transformation (RAEBT) by the FAB classification. Mutational analysis was performed by genomic DNA polymerase chain reaction followed by direct sequencing. The primer sequences were as follows: human *CALR* exon 9 sense primer 5'-GGCAACGAGACGTGGGGCGT-3', and antisense primer 5'-CAGAGACATT ATTTGGCGCGGCC-3'. Abnormal sequencing results were confirmed by at least two repeated analyses.
Results: Totally, two (0.56%) of 355 WHO-defined MDS patients had *CALR* mutations at diagnosis. Patient 1, who had initial presentation of anemia and thrombocytopenia, was diagnosed as having RARS. He had intermediate-1 risk MDS based on the International Prognostic Scoring System (IPSS) and low risk MDS by the revised IPSS (IPSS-R). He also harbored *DNMT3A* and *SF3B1* mutations in addition to *CALR* mutation at diagnosis. He was still alive without disease progression at the time of this study 57 months after diagnosis. Patient 2, diagnosed as having RA, had low risk characteristics according to both the IPSS and the IPSS-R. She remained transfusion dependent during the follow-up period of 27.4 months. We did not find any *CALR* mutation in 98 patients with CMML or RAEBT at diagnosis. Intriguingly, among 107 *CALR*-wild patients who were sequentially studied, one (patient 3) acquired *CALR* mutation 33.5 months after diagnosis when the disease progressed from RAEBT to AML by the FAB classification. A novel *RUNX1* mutation was also acquired at the same time in this patient. The *CALR* of other 106 patients remained in germline during follow-ups. Because direct sequencing might not be sensitive enough to detect low level of *CALR* mutant, we therefore did TA cloning followed by direct sequencing of the three *CALR*-wild samples obtained at diagnosis and subsequent follow-ups from patient 3. We could not find any *CALR* mutation in the 65, 43 and 54 clones analyzed using cloning technique in this patient, respectively. Nevertheless, we could not exclude the possibility that minor population of cells with *CALR* mutant existed initially but escaped the detection of direct sequencing or TA cloning technique.
Summary and Conclusions: We showed that *CALR* mutations were rarely detected in patients with MDS both at diagnosis and disease progression.

P320

THE ROLE OF TP53 MUTATIONS IN LOW-RISK MDS PATIENTS

M Belickova[1,*] J Vesela[1], A Jonasova[2], A Kohlmann[3], E Stara[1], B Planetova[1], J Valka[1], Z Zemanova[2], J Brezinova[1], K Michalova[1,2], J Cermak[1]
[1]Institute of Hematology and Blood Transfusion, [2]General University Hospital, Prague, Czech Republic, [3]Munich Leukemia Laboratory, München, Germany

Background: A negative prognostic impact of *TP53* gene point mutations in the myelodysplastic syndrome (MDS) patients has not been intensively studied yet.
Aims: In this study we performed an analysis of: the incidence of *TP53* gene mutations in low-risk MDS patients, the effect of *TP53* mutations on disease progression, the impact of treatment on mutated clones, the size of mutated clones with regard to the type of cell population and the effect of *TP53* mutations on mRNA levels of *TP53*, *MDM2, MYC,* and *p21* genes.
Methods: *TP53* mutations were analyzed in DNA from CD34+ or CD34- cells isolated from bone marrow of 103 patients included into cohort according to the International Prognostic Scoring System low risk or intermediate-1 risk using primers designed within the IRON-II study research consortium (Roche Applied Science) on the GS Junior system. If mutations were detected, we searched for mutations in the various cell populations (CD34+, CD34-, CD14+, CD3+, granulocytes) and at different time-points of the disease. TaqMan Gene Expression Assays were used to determine relative expression levels of mRNA of *TP53, p21, MYC* and *MDM2* genes in CD34+ cells between patients with and without mutation.
Results: The overall incidence of *TP53* mutations was 11.7% (12/103), 3 patients had two mutated clones. The mutation frequency in low-risk MDS patients with and without del(5q) were 20.4% (11/54) and 2.0% (2/49) respectively. The allele burden of mutation was in the range of 2.1 – 76.8%. Out of the detected mutations were 14 missense and 1 nonsense. We found significant differences in the size of the mutated clone cells between bone marrow and peripheral blood. So far, 9 of 12 (75%) patients carrying mutations showed progression towards acute leukemia. Patients with *TP53* mutation showed 1.6-fold lower mRNA expression of *TP53* (p=0.05) in CD34+ cells than those with wild type *TP53*. Non-significant change of mRNA expression of *p21, MYC* and *MDM2* genes were detected between groups of patients with and without mutation.
Summary and Conclusions: Using sensitive next generation sequencing technology, that is able to detect mutations with low abundance, we confirmed in a large cohort of patients a significantly higher frequency of *TP53* mutations in low-risk MDS patients with del(5q) in comparison to those without del(5q). Furthermore, we found the association between presence of *TP53* mutations and increased risk of leukemic transformation. We were not able to detect a half of identified mutations by Sanger sequencing (<20% mutation burden).
Supported by grant (NT/13899, NT/14377, NT/14539) and the project for conceptual development of research organization (00023736) from the Ministry of Health of the Czech Republic.

P321

IDENTIFICATION OF DYSPLASIA IN PERIPHERAL BLOOD USING FLOW CYTOMETRY

R Schabath[1,*] T Alperman[1], C Haferlach[1], S Schnittger[1], T Haferlach[1], W Kern[1]
[1]MLL, München, Germany

Background: For the diagnostic work-up of patients with suspected myelodysplastic syndrome (MDS) flow cytometry (FC) of bone marrow (BM) is recommended by ELN guidelines.
Aims: Identify dysplastic features by FC in peripheral blood (PB) and assess their significance by follow-up BM analysis.
Methods: From 157 patients (pts) with suspected MDS PB was analyzed by FC applying defined ELN criteria. In addition, samples were analyzed for the presence of CD71-positive erythroid cells. In all pts at least one BM sample was analyzed during follow-up by morphology and cytogenetics to confirm MDS according to WHO 2008 criteria.
Results: BM assessment at follow-up resulted in 1) proven MDS (n=96), 2) no MDS (n=32), and 3) MPN, MDS/MPN, or "MDS possible" (dysplasia by morphology, not sufficient to diagnose MDS) (n=29). Median time to MDS confirmation was 0.9 months (range, 0.1-53.0), median time to last BM assessment without MDS confirmation was 0.8 months (0.2-23.0). All 34 pts with myeloid progenitor cells (MPC) by FC in PB had finally proven MDS. However, in addition 62/94 (66.0%) of those without MPC (p<0.0001) also had proven MDS. 17 of these 34 cases in addition displayed an aberrant antigen expression. Focusing on granulocytes side-scatter (SSC) signals were analyzed as ratio of mean SSC signals granulocytes/lymphocytes (G/L). We found a significantly lower SSC ratio G/L in pts with proven MDS as compared to those without (mean±SD 5.7±1.1 *vs.* 6.3±1.0, p=0.015). A mean SSC ratio G/L of 3.9 was found to most specifically identify pts with MDS: all 6 cases with a ratio <3.9 had MDS. Regarding aberrant antigen expression in granulocytes, MDS was more frequently diagnosed among cases with *vs.* without the following features: aberrant CD11b/CD16 expression pattern (43/46 investigated, 93.5% *vs.* 53/82, 64.6%; p=0.0002), lack of CD10 expression (37/43, 86.0% *vs.* 59/85, 69.4%; p=0.052), CD56 expression (19/21, 90.5% *vs.* 77/107, 72.0%; p=0.098). Cumulating this data, ≥2 aberrantly expressed antigens on granulocytes were found indicative of MDS: 42/45 (93.3%) of investigated pts with aberrant expression of ≥2 antigens had MDS while only 54/83 (65.1%) of those with <2 aberrantly expressed antigen had finally proven MDS (p=0.0003). Regarding aberrant antigen expression in monocytes, pts with the following features more frequently had MDS as compared to those without: reduced expression of HLA-DR, CD13, CD11b, or CD15, aberrant expression of CD2 or CD34 (as single makers all n.s.). Cumulating this data also resulted in a significant relation to a diagnosis of MDS during follow-up: 31/36 (86.1%) of pts with aberrant expression of ≥2 antigens on monocytes were diagnosed MDS *vs.* 65/92 (70.7%) of those without (p=0.052). Regarding erythroid cells, MDS was diagnosed in more cases with CD71-positivity (33/37, 89.2%) than in those without (63/91, 65.5%; p=0.023). Integrating the data for the different cell compartments, pts were separated according to the presence of the following 5 criteria: 1) presence of MPC in PB by FC, 2) aberrant expression of ≥1 antigen in MPC in PB, 3) aberrant expression of ≥2 antigens in granulocytes in PB, 4) aberrant expression of ≥2 antigens in monocytes in PB, and 5) presence of CD71-positive erythroid cells in PB: 44/46 (95.7%) cases with ≥2 of the criteria had MDS which was true for 52/82 (63.4%) of those with ≤1 criterion (p<0.0001). Applying these criteria to the remaining 29 pts with MPN, MDS/MPN, or possible MDS, 11 (37.9%) of them fulfilled ≥2 criteria which was true for 2/32 (6.3%) of pts not diagnosed MDS (p=0.004).
Summary and Conclusions: FC reveals MDS-related features in PB which may be used to identify pts with a high probability of MDS.

P322

DEVELOPMENT OF A HIGH RESOLUTION MELTING CURVE ANALYSIS SCREENING TEST FOR SRSF2 SPLICING FACTOR GENE MUTATIONS

E Garza[1,2,3,*] E Fabiani[4], N Noguera[2,3,5], P Panetta[6], M L Piredda[2,3], L Borgia[2,3], G Catalano[2], M T Voso[4], F Lo Coco[2,3]
[1]Laboratorios Dr. Moreira, Monterrey, Mexico, [2]Department of Biopathology, "Tor Vergata" University, [3]Laboratory of Neuro-Oncoematology, Santa Lucia Foundation, [4]Department of Hematology, Universita' Cattolica Sacro Cuore, Rome, Italy, [5]Hematology Department of Chemical Biochemistry, Rosario National University, Rosario, Argentina, [6]Fondazione Policlinico Tor Vergata, Rome, Italy

Background: Recently, somatic mutations of the spliceosome machinery have been identified in hematological malignancies and solid tumors. SRSF2 (*Serine-Arginine Splicing Factor 2*), is a member of the serine/arginine (S/A) rich family pre-mRNA splicing factors and plays a role in mRNA export from the nucleus and translation. SRSF2 mutations are present in about 12% myelodysplastic syndromes (MDS) without ringed sideroblasts (RS), 5.5% refractory anemia with ringed sideroblasts (RARS)/refractory cytopenia with multilineage dysplasia (RCMD) with RS(n: 73), 28% chronic myelomonocytic leukemia (CMML) (n: 88), 6.5% acute myeloblastic leukemia (AML)/MDS (n: 62), 0.7% in *de novo* AML (n: 151) and 1.9% in myeloproliferative disease (MPN) (n: 53). Subsequent studies have shown similar results regarding the "hot spot" localization in which 95% of the mutations were located at the aminoacid position P95, corresponding to the exon 2 of the SRSF2 gene. In MDS SRSF2 mutations have shown a significant prognostic impact, associated to higher AML transformation rates, shorter overall survival and shorter time to AML progression compared to non mutated cases.
Aims: The aim of this study was the development of a high resolution melting curve analysis (HRM) to screen for SRSF2 "hot spot" mutations in a fast, sensitive and reliable way.
Methods: 42 bone marrow samples were selected from patients who underwent cytogenetic analysis as a part of the laboratory workup to establish the diagnosis of MDS. Positive controls from known mutated cases were included. DNA was obtained using silica columns. All samples analyzed by HRM were confirmed by direct sequencing. HRM was carried out in a 50 µL reaction and the following reagent concentrations were used: high resolution mastermix 2X, $MgCl_2$ 3.5 mM, primers 0.5 µM and DNA 50 ng/µL. PCR protocol was composed by a single hot start cycle with a temperature of 95°C for 10 minutes then 55 cycles of 95°C for 10s, 61°C for 10s and 72°C for 10s. A melting temperature form 65-95°C with a ramp of 0.02°C/s was used. The real time platform and the software used for analysis were operated according to manufacturer's instructions.
Results: HRM gene scanning test was able to identify 4 melting patterns corresponding to a negative (wild type) group, and 3 different mutated groups (Figure 1). Each mutated group was identified accordingly to the positive control used; P95H, P95L and P95R respectively. From the 42 selected patients, 4 samples were identified as mutated (9.5%). Positive and negative results from HRM were compared with direct sequencing results with a concordance of 100%. Sensitivity analysis was performed using a mutated DNA sample subjected to dilutions with a wild type (WT) sample (Figure 1). The test showed detection sensitivity up to 1:9 (mutated:WT) dilutions, indicating high analytical sensitivity. Melting genotype analysis was not included in this study.

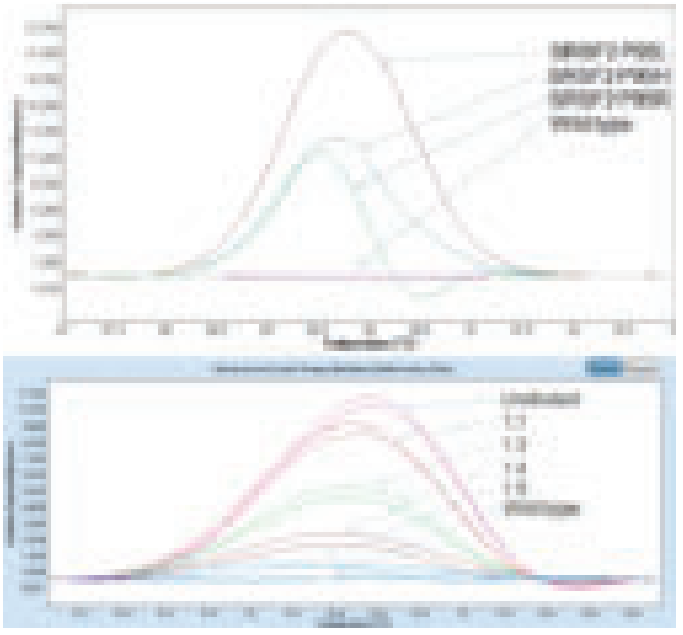

Figure 1. Normalized and Temp-Shifted Difference Plot.

Summary and Conclusions: In the present study, SRSF2 "hot spot" mutations were identified in a fast and reliable fashion using a HRM screening test. This test might be helpful to save and optimize laboratory resources by selecting cases to be confirmed thus, reducing turn-around time. Given the clinical implications of SRSF2 mutations, this rapid screening method may provide useful Information for clinical decision making.

P323

THE USE OF MEDICAL CLAIMS TO ASSESS INCIDENCE, DIAGNOSTIC PROCEDURES AND INITIAL TREATMENT AMONG PATIENTS WITH MYELODYSPLASTIC SYNDROMES IN THE NETHERLANDS

AG Dinmohamed[1,*] Y van Norden[2], O Visser[3], EF Posthuma[4], PC Huijgens[5], P Sonneveld[1], AA van de Loosdrecht[5], M Jongen-Lavrencic[1]
[1]Hematology, [2]Clinical Trial Center, Erasmus MC Cancer Institute, Rotterdam, [3]Registration and Research, Comprehensive Cancer Centre, Utrecht, [4]Internal Medicine, Reinier de Graaf Group, Delft, [5]Hematology, VU University Medical Center, Amsterdam, Netherlands

Background: Recent evidence from a medical claims-based study suggested that elderly patients (≥65 years) with myelodysplastic syndromes (MDS) were underreported in population-based cancer registries from the US (Cogle, *Blood* 2011). This may also hold true for the nationwide population-based Netherlands Cancer Registry (NCR). All residents of the Netherlands are legally obliged to take out a Dutch medical insurance for the standard package. Analyses of Dutch medical claims might therefore complement NCR data on MDS.
Aims: We conducted a nationwide medical claims-based study to assess incidence, diagnostic procedures and initial treatment among adult MDS patients (≥18 years) in the Netherlands from 2008 to 2010.
Methods: We identified 3,681 adult MDS patients (median age 77 years) from the nationwide *Diagnose Behandeling Combinatie* (DBC; Diagnosis Treatment Combination) Information System (DIS) from 2008 to 2010. A DBC medical claim is initiated when a diagnosis is made and a particular treatment is started. We exclusively selected patients with an initial DBC medical claim for MDS to omit prevalent cases for measuring the disease incidence. Age-standardized incidence rates (ASRs) of MDS were calculated per 100,000 person-years. Information regarding diagnostic procedures and initial treatment was available in the DIS for 3,628 patients (99%).
Results: The overall ASR of MDS was 5.4/100,000 in 2008-2010, and was higher in males (7.0/100,000) than in females (3.9/100,000). The age-specific incidence increased in parallel with older age, with the highest incidence among those aged ≥80 years (84.4/100,000). In 45% of the patients no bone marrow (BM) examinations were performed. Patients that did not undergo a BM examination were older compared with those who underwent a BM examination (median age 79 *vs.* 74; *P*<.001). The performance of BM examinations decreased in parallel with older age (Figure 1; *P* for trend <.001). The overall ASR of MDS in the cohort of patients that underwent BM examinations was 3.0/100,000 in 2008-2010. A comparison of the DBC cohort with recent population-based data from the NCR (Dinmohamed, *Eur J Cancer* 2013) revealed that the ASR in the entire DBC cohort was almost 2-fold higher than the NCR (5.4 *vs.* 2.8/100,000 in 2008-2010). However, rates were almost equal if only cases with BM examinations were selected in the DBC cohort (3.0 *vs.* 2.8/100,000 in 2008-2010). Regarding initial treatment in the BM (*n*=1,969) and non-BM (*n*=1,659) cohort, 66% and 66% received no therapy, 22% and 28% received supportive care, 6% and 1% were started on intensive therapy (chemotherapy alone+allogeneic stem cell transplantation), and 6% and 5% received other therapy, respectively.

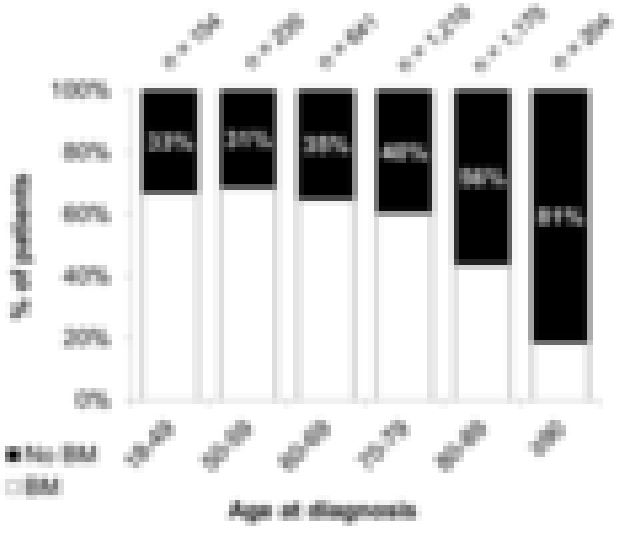

Figure 1. The performance of bone marrow (BM) examinations in MDS patients with initial DBC claims according to age category at diagnosis. Data are shown for 3,628 patients with available data regarding the BM performance status.

Summary and Conclusions: The discrepancy in incidence rates between the population-based NCR and this medical-claims based study is mostly due to the large proportion of diagnoses without BM examinations in the DBC cohort. Incidence rates were comparable with NCR data if cases with only BM examinations were selected in the DBC cohort. We cannot assess whether the non-BM cases in the DBC cohort were truly MDS, though it is unlikely that all non-BM cases reflect true MDS cases. As expected, initial treatment was conservative as MDS is primarily a disorder of the elderly. Elderly MDS patients are by definition not suitable candidates for intensive therapy. BM examination is an essential diagnostic procedure in MDS as MDS might be underdiagnosed or misdiagnosed without BM confirmation. Therefore, guidelines on diagnosis of MDS should be followed more stringently to ensure accurate prognostication and appropriate risk-adapted treatment (Malcovati, *Blood* 2013).

P324

GLUTATHIONE S-TRANSFERASE P1 (GSTP1) PROMOTER HYPERMETHYLATION IN MDS

S Zachaki[1], A Daraki[1], M Kalomoiraki[1], C Stavropoulou[1], D Koumbi[1], KN Manola[1], A Parcharidou[2], P Kollia[3], C Sambani, [1,*]
[1]Laboratory of Cytogenetics, NCSR "Demokritos", Athens, Greece, [2]Bedford Hospital NHC, Bedford, United Kingdom, [3]Department of Genetics & Biotechnology, Faculty of Biology, University of Athens, Athens, Greece

Background: GSTP1 gene expression has been linked with cancer incidence and drug resistance. Recently, there is an ongoing preclinical and clinical platform of drug discovery and development around GSTP1 linked to the activity of GSTP1 inhibitors in stimulating multilineage differentiation of hematopoietic progenitors. It is well-established that gene silencing by epigenetic alterations are common events in carcinogenesis. The GSTP1 gene has been reported to be the target of somatic CpG island promoter hypermethylation in various types of neoplasia, such as prostate, breast and liver cancer.
Aims: The aim of the study was to investigate the possible contribution of epigenetic inactivation of the GSTP1 gene in MDS and AML, through DNA promoter hypermethylation. We also assessed possible associations of GSTP1 methylation pattern with the presence of the $A^{313}G$ GSTP1 inactivating polymorphism and specific chromosomal aberrations.
Methods: Our case-control study enrolled 76 patients [(22 MDS, 29 *de novo* AML and 25 AML cases preceded by MDS (MDS-AML)] and 13 healthy donors. Cytogenetic analysis of bone marrow samples was successfully performed for all patients at diagnosis. Total genomic DNA was extracted from patients' and controls' samples using the QIAamp DNA-extraction midi kit (Qiagen, Hilden, Germany). GSTP1 promoter methylation status was studied by methylation-specific PCR (MSP) using the CpG WIZ® GSTpi Amplification Kit (Chemicon, Canada, USA). $A^{313}G$ GSTP1 genotyping was performed by Real-Time PCR on the Biorad CFX96 (Biorad, California, USA) using GoTaq® qPCR Master Mix (Promega, USA).
Results: Our results showed that GSTP1 promoter was hypermethylated in 32 out of 76 patients (42.1%). All control samples were found to be completely unmethylated. Hypermethylation of GSTP1 promoter was found in 14 out of 22 MDS (63.6%), 6 out of 29 AML (20.7%) and 12 out of 25 MDS-AML cases (48.0%). A significantly increased frequency was observed in MDS ($p<0.001$) and MDS-AML patients ($p<0.001$). The GSTP1 promoter hypermethylation was found not to be associated with the GSTP1 polymorphic gene status. Stratification of patients according to their karyotype revealed an increased frequency of methylated cases in the group of patients showing a normal karyotype, as compared to those with an abnormal karyotype (53.3% *vs* 39.3%, respectively); however, this trend did not reach statistical significance. Moreover, among patients with an abnormal karyotype, the higher frequency of methylated cases was found in cases with -7/del(7q) (60.0%).
Summary and Conclusions: Our results indicate an important role of the GSTP1 epigenetic silencing in MDS pathogenesis, extending the knowledge on epigenetic alterations of the GSTP1 gene in hematological malignancies. Further, these findings might suggest that hypermethylated GSTP1 gene could be a potential epigenetic biomarker for MDS response to treatment, mainly related to administration of GSTP1 inhibitor.

P325

THE IMPORTANCE OF CYTOGENETIC SCORING SYSTEM IN MYELODYSPLASTIC SYNDROME

B Drevojankova[1,*] A Strnkova[2], M Stoklasova[1], L Dostalova[1], A Burdova[1], T Sablaturova[1], J Zmolikova[1], D Klodova[3], J Gumulec[4], D Adamova[5], M Wrobel[3], M Brejcha[3]
[1]Laboratory of Medical Genetic, [2]Laboratory Agel, Novy Jicin, Czech republic, [3]Department of Hematology, Hospital Novy Jicin a.s., Novy Jicin, [4]The Institute of Clinical Haematology, Faculty Hospital Ostrava, Ostrava, [5]Department of Hematology, Hospital Opava, Opava, Czech Republic

Background: The myelodysplastic syndromes (MDS) are a group of hematopoietic disorders characterized by clonal hematopoiesis, impaired differentiation, peripheral-blood cytopenias, and a risk of progression to acute myeloid leukemia. Conventional cytogenetic analysis (CCA) is one of many prognostic factors included in International Prognostic Scoring System (IPSS).
Aims: Compare our data with New Comprehensive Cytogenetic Scoring System defined by Schanz *et al.* 2012.
Methods: We investigated 728 patients (346 men, 382 woman) with primary MDS in years 2003-2013. The CCA was performed on bone marrow samples using short time cultivation (24-48 hours). Interphase FISH (I-FISH) was carried out using DNA probes designed to detect 5q, 7q, 11q, 12p, 17p and 20q deletions, trisomy 8, loss Y (MetaSystems Germany, Abbott Molecular).
Results: We cultivated 94% of samples succesfully. Chromosomal aberrations were detected in 22% of patients analyzed using CCA and I-FISH. CCA revealed chromosomal aberrations in 8% of patients with negative I-FISH results. For statistical analysis of our data we followed The New Comprehensive Cytogenetic Scoring System of chromosomal aberrations in MDS defined by Schanz (Schanz J, *et al.* J Clin Oncol 2012) and we classified chromosomal

abnormalities into five prognostic subgroups: *very good* -20 patients(3%), *good* – 556 patients (81%), *intermediate* -41 patients (6%), *poor* – 22 patients (3%) and *very poor* – 43 patients (6%).
Summary and Conclusions: We compared our data with New Comprehensive Cytogenetic Scoring System defined by Schanz *et al.* 2012 and our results are consistent with it. We were able to classify 686 of our patients into this scoring system. According to our results it is important to combined both cytogenetic methods (CCA and I-FISH) to correct classification of patients into prognostic subgroups and suggest appropriate therapy.

P326

DAPK AND TRAIL RECEPTORS METHYLATION STATUS IN MYELODYSPLASTIC SYNDROMES PATIENTS
E Cortesão[1,2,3,*]J Jorge[4], AC Gonçalves[3,4,5], A Pires[4], R Alves[3,4,5], C Mocho[2], L Rito[1,2], E Magalhães[2], JP Carda[1,6], C Geraldes[1,2,3], AI Espadana[2], A Pereira[3,7], L Ribeiro[2,3], JM Nascimento-Costa[3,8,9], AB Sarmento-Ribeiro[2,3,4,5]
[1]University Clinic of Hematology, Faculty of Medicine, University of Coimbra, [2]Clinical Hematology Service, Centro Hospitalar e Universitário de Coimbra (CHUC), [3]CIMAGO – Center of Investigation on Environment Genetics and Oncobiology, Faculty of Medicine University of Coimbra, [4]Applied Molecular Biology and University Clinic of Hematology, Faculty of Medicine, University of Coimbra, [5]Center for Neuroscience and Cell Biology (CNC), [6]Centro Hospitalar e Universitário de Coimbra (CHUC), Coimbra, [7]Medicine service, Hospital Distrital da Figueira da Foz, Figueira da Foz, [8]Medicine Department, Centro Hospitalar e Universitário de Coimbra (CHUC), [9]Oncology abd Paliative Care, Faculty of Medicine, University of Coimbra, Coimbra, Portugal

Background: MDS are a heterogeneous group of clonal hematopoietic stem-cell disorders characterized by ineffective hematopoiesis, peripheral-blood cytopenias, and increased probability of leukemic transformation. Although MDS pathogenesis is not completely understood, deregulated epigenetic mechanisms are likely involved. DNA methylation is one of the epigenetics processes more frequently studied and several genes have been shown to be transcriptionally silenced in association with promoter methylation. Our previous studies, according with others, show that aberrant methylation of *p15* and *p16* gene promoter region could be associated with MDS initiation and progression. However, the role of methylation status of *DAPK* gene and particularly of *TRAIL-Rs* (TNF Related Apoptotic Induced Ligand, receptors) genes is not yet clarified. Furthermore, methylation profile could be influenced by Vitamin B12 and Folic acid levels as they are co-factors in 1-carbon metabolism enzymes related with SAM (S-Adenosyl Methionine) formation, the major endogenous methyl donor.
Aims: In this context, our aims were to investigate the DNA methylation status of *DAPK, and TRAIL-Rs, TRAIL DcR2* and *TRAIL DR4,* genes in Myelodysplastic Syndrome (MDS) patients at diagnosis, and correlated it with clinical data and vitamin levels.
Methods: The methylation status of *DAPK and TRAIL-Rs (namely, the anti-apoptotic TRAIL DcR2* and *the pro-apoptotic, TRAIL DR4)* genes were analyzed in bone marrow cells of 82 patients with *de novo* MDS, collected at diagnosis and in 14 non-neoplastic patients. Genomic DNA was isolated by standard protocols and modified using sodium bisulfite. The MS-PCR for gene promoter methylation was performed using two sets of primers, one for methylated DNA and other for unmethylated DNA. The MDS patient group median age was 76 years (22-89), gender M/F=40/42, WHO subtypes: 10 RCUD, 5 RA-RS, 41 RCMD, 3 RCMD-RS, 5 RAEB-1, 9 RAEB-2, 8 CMML and 1 5q-. χ^2 and Kruskal-Wallis testes were used to analysed results, that were considered statistically significant when $p<0.05$.
Results: Overall, 81,5% of MDS patients presented at least one methylated gene in BM samples and 58% presented two or more methylated genes. Moreover, about 71% of the MDS patients, presented the *DAPK* gene methylated (distributed according MDS subtype: RCUD:66%; RARS:100%, RCMD:65,8%, RAEB-1:100%, RAEB-2:0%, CMML:100%), 23% presented the TRAIL *DR4* gene methylated (RCUD:33%, RARS:67%,RCDM:23%, RAEB-1:0%, RAEB-2:0, CMML:0%) and 18% presented the TRAIL *DcR2* gene methylated (RCUD:11%, RARS:13,4%, RCMD:13,8%, RAEB-1:33%, RAEB-2:20%, CMML:22%) Moreover, we observed a significant increase in TRAIL DR4 methylation in MDS patients relatively to controls (p=0,041). Besides that, in MDS patients, methylation status seems to be independent of cytogenetic abnormalities, ferritin, erythropoietin and ß-2 microglobulin levels. However, we observed a decrease of DAPK and all TRAIL receptors methylation in patients with high folate levels. We also observed an absence of methylation in TRAIL DcR1 genes in patients with high vitamin B12 levels.
Summary and Conclusions: Our results show that DAPK and TRAIL-DR4 aberrant methylation seems to be a common event in MDS patients and could be related with MDS subtypes and group risk. Moreover, folate and vitamin B12 levels could modulate, at least in part, the methylation gene status in MDS patients.

IDENTIFICATION OF NOVEL ALTERNATIVE SPLICE VARIANTS OF SIRTUINS IN MULTIPLE MYELOMA: A BIOLOGICALLY RELEVANT INDICATOR OF POOR OUTCOME
C Michele[1,2,*]A Cagnetta[1,2], YT Tai[2], D Chauhan[2], A Nencioni[1], F Patrone[1], M Gobbi[1], N Munshi[2], K C Anderson[2]
[1]Medical Oncology, I.R.C.C.S. A.O.U. San Martino -IST, Genoa, Italy, [2]Medical Oncology, Dana Farber Cancer Institute, Boston, United States

Background: Alternative splicing (AS) is a normal epigenetic event with a critical role in the regulation of gene expression. Previous studies showed increased AS in Multiple Myeloma (MM) cells, suggesting the need to assess both expression level of genes and post translational modifications, mediating overall gene function. The NAD-dependent deacetylases Sirtuins (SIRTs), mammalian homologues of the yeast Sir2, modulate various biological processes including metabolism, cell survival, development, chromatin dynamics, or DNA repair. Recent microarray profiling data using newly diagnosed patients with MM, suggests clinical relevance of such deacetylases since their level predicts for both progression free and overall survival. Among SIRTs family members SIRT-5 and SIRT-7 transcript levels positively correlated with disease progression (from MGUS to active MM).
Aims: These studies provide the rationale for further examining the biological processes including epigenetic changes, mutations, or AS events that contribute to aberrant expression of SIRTs in MM.
Methods: Purified RNA from MM cell lines, newly diagnosed MM patient cells, as well as peripheral blood mononuclear cells (PBMCs) from normal healthy donors was subjected to SIRT expression analysis. Specifically, SIRTs-specific primers were developed and optimized using standard RT-PCR conditions. RNA integrity was confirmed using Glyceraldehyde 3-phosphate dehydrogenase (GAPDH) as an endogenous control. Aberrant splicing of SIRT-5 and SIRT-7 was confirmed by cloning and sequencing, followed by analysis of their expression patterns in MM patients *versus* normal PBMCs. High throughput GeneChip Human Exon 1.0 ST Arrays in MM patients (n=170) confirmed the clinical relevance of our findings
Results: We found that SIRTs genes undergo aberrant splicing in MM patients. To our knowledge, this is the first report showing SIRTs miss-splicing event in MM. Through cloning and sequencing analysis we identified novel spliced isoforms of SIRT-5 and SIRT-7; these occurred as a result of aberrant AS within exon-3 and exon-2, respectively. Specifically, exon skipping was noted in SIRT-7 variants, via cryptic 5 prime or 3 prime splice sites on exon 3 and/or through partial retention of an intron (500bp) created SIRT-5 variants. The novel spliced forms were widely expressed in MM cell lines as well as in patients with MM or monoclonal gammopathy of undetermined significance (MGUS), without significance occurrence in normal PBMCs. Preliminary data show that even though these novel isoforms exhibit reduced deacetylase activity *versus* full-length variants, this characteristic may impart distinct functional outcome. Finally, longitudinal analyses suggested that aberrant splicing of SIRT5 and SIRT7 correlated with disease status. Correlation analyses between splice-variants of these genes and clinical features of patients showed an association between SIRT5 splice-variants and overall survival of MM patients
Summary and Conclusions: In the current study, we have identified novel transcript variants of SIRT-5 and SIRT-7 in MM cells. These aberrant isoforms allow for generating transcripts that encode for dysfunctional proteins, which in turn, may contribute to the genetic heterogeneity in MM. Overall, our results suggest that SIRT5 and SIRT7 mis-splicing are a common characteristic of MM and has the potential to generate transcripts encoding proteins with altered function. Thus, splice-variants of these genes might provide disease markers and targets for novel therapeutics in MM.

P328

BONE MARROW CD14+ CELLS SHOW DIFFERENT TRANSCRIPTIONAL PROFILES IN MULTIPLE MYELOMA (MM) AS COMPARED TO SMOLDERING MM AND MGUS: OVEREXPRESSION OF IL-21R AND ITS INVOLVEMENT IN OSTEOCLASTOGENESIS.
M Bolzoni[1], P Storti[1], D Guasco[1], D Ronchetti[2], L Agnelli[2], F Costa[1], S Bonomini[1], B Dalla Palma[1], L Craviotto[1], A Neri[2], F Aversa[1], N Giuliani[1,*]
[1]Clincal and Experimental Medicine, Hematology, University of Parma, Parma, [2]Clinical Sciences and Community Health, University of Milan, Milan, Italy

Background: Bone marrow (BM) microenvironment alterations characterize patients with multiple myeloma (MM), as compared to smoldering MM (SMM) and monoclonal gammopathy of uncertain significance (MGUS). Studies focusing on the presence of potential molecular alterations in the BM microenvironment cells are ongoing.
Aims: This study was aimed at analyzing the transcriptional profile of the BM

CD14+ cells across different types of monoclonal gammopathies, based on their primarily involvement in osteoclastogenesis that is typically increased in MM patients.
Methods: CD14+ monocytes were purified from a total cohort of 36 patients including 21 patients with symptomatic MM, 8 patients with SMM and 7 patients with MGUS. CD14+, cells were isolated from the CD138 negative fraction of BM samples of patients by immunomagnetic method with anti-CD14 monoclonal antibody conjugated with microbeads. The presence of potential hemopoietic and CD138+ contaminating cells was excluded by FACS analysis. Only samples with CD14 purity greater than 95% were profiled on GeneChip® HG-U133Plus 2.0 arrays (Affymetrix®). Selected genes were then validated by Real-Time quantitative PCR.
Results: A multiclass analysis identified 14 differentially expressed genes in MGUS, SMM and symptomatic MM. The comparison of symptomatic MM with both SMM and MGUS samples identified 101 genes differentially expressed in CD14+ (58 up-regulated and 43 down-regulated genes in MM). Interestingly, among the differentially expressed genes we found cytokine receptors (*IL21R* and *IL-15R),* chemokines with pro-osteoclastogenic properties *(CXCL10* and *CXCL11),* interferon-inducible proteins (*IFI27* and *IFI44*) and *SLAM7* that were up-regulated in CD14+ of MM patients as compared to SMM and MGUS.
Because recent data indicate that IL-21 is a growth factor for MM cells and may promote osteoclastogenesis in pathophysiological conditions such as rheumatoid arthritis, we further investigate the potential role of *IL-21R* over-expression in CD14+, cells. Firstly, by western blot analysis we confirmed that IL-21 receptor was up-regulated at protein level in CD14+, of MM patients as compared to both SMM and MGUS; whereas the BM IL-21 levels detected by ELISA in a proprietary larger cohort of 77 newly diagnosed MM, 42 SMM and 41 MGUS patients did not showed any statistically significant difference across the three groups of patients (IL-21 median levels: 34, 30.6, and 33.71 pg/ml, respectively). On the other hand, the treatment with rhIL-21 at the concentration levels detected into the BM (30 pg/ml) stimulated BM CD14+-derived *in vitro* osteoclastogenesis and increased the number and the size of osteoclasts, in the presence of RANKL (20-30 ng/ml), in BM samples of MM patients; conversely, this was not observed in samples obtained from SMM and MGUS. Finally, we showed that rhIL-21 stimulated the expression of the RANKL receptor RANK in CD14+, indicating that IL-21 increased the sensitivity of CD14+ cells to the pro-osteoclastogenic effect of RANKL.
Summary and Conclusions: Overall, our results indicate that a different transcriptional signature may be identified in BM CD14+ cells of patients with MM as compared to those with SMM and MGUS, including the overexpression of *IL-21R.* Consequently the involvement of IL-21/IL-21R axis has been demonstrated in the increased CD14+-derived osteoclastogenesis that characterizes MM patients.

P329

HOW DOES LENALIDOMIDE/DEXAMETHASONE REDUCES RISK OF TRANSFORMATION IN HIGH-RISK SMOLDERING MULTIPLE MYELOMA? LONGITUDINAL IMMUNOPHENOTYPIC PROFILING OF IMMUNE EFFECTOR CELLS FROM THE QUIREDEX TRIAL

B Paiva[1,*] MV Mateos[2], L Lopez-Corral[2], MB Vidriales[2], I Sanchez-Abarca[2], LA Corchete[2], MT Hernandez[3], J Bargay[4], F de Arriba[5], J de la Rubia[6], AI Teruel[7], P Giraldo[8], L Rosiñol[9], F Prosper[1], A Oriol[10], J Hernandez[11], G Esteves[12], F Leal da Costa[13], JA Perez Simon[14], JJ Lahuerta[15], J Blade[9], JF San Miguel[1]
[1]Clinica Universidad de Navarra, Centro de Investigacion Medica Aplicada (CIMA), Pamplona, [2]Hospital Universitario de Salamanca, Instituto de Investigaion Biomedica de Salamanca, IBMCC (USAL-CSIC), Salamanca, [3]Hospital Universitario de Canarias, Tenerife, [4]Hospital Sont Llatzer, Palma de Maiorca, [5]Hospital Morales Messeguer, Murcia, [6]Hospital Universitario La Fe, [7]Hospital Universitario de Valencia, Valencia, [8]Hospital Miguel Servet, Zaragoza, [9]Hospital Clínic, IDIBAPS, Barcelona, [10]Hospital Universitari Germans Trias i Pujol, Badalona, [11]Hospital General de Segovia, Segovia, Spain, [12]Hospital de Santa María, [13]Instituto Portugués de Oncología, Lisboa, Portugal, [14]Hospital Virgen del Rocio, Sevilla, [15]Hospital Universitario 12 de Octubre, Madrid, Spain

Background: Recently reported from the QUIREDEX trial showed a significantly longer time-to progression and overall survival for high-risk smoldering multiple myeloma (SMM) patients receiving the combination of lenalidomide with low-dose dexamethasone (LEN-LoDEX) *versus* observation (Mateos, NEJM 2013). In addition to the anti-myeloma effect of lenalidomide, its immunomodulatory properties over effector T- and NK-cells may also be playing a role delaying tumor progression; however, since lenalidomide was combined with the immunosuppressant dexamethasone, the direct possible *in vivo* synergistic effects of the combination on SMM patients' immune system remains unknown.
Aims: To evaluate the immunophenotypic profiles of T- and NK-cells from high-risk SMM patients treated according to the QUIREDEX trial.
Methods: In this pre-planned exploratory analysis, we evaluated by multiparameter flow cytometry a total of 30 different markers distributed across 4-color MoAb combinations on longitudinally collected peripheral blood (PB) samples, and analyzing the numbers and immunophenotypic profiles of T- and NK-cells from high-risk SMM patients (N=31; 104 samples) treated according to the QUIREDEX trial (NCT 00480363): an induction phase of 9 four-week cycles of LenDex followed by maintenance with lenalidomide until disease progression. 10 healthy adults (HA) aged over 60 years were also studied and used as normal reference.
Results: To evaluate the immune status of T and NK cells of SMM patients, we compared them at baseline *vs* HA. Overall, the absolute number T and NK cells was similar between the two groups, except for γδ T cells which were significantly increased in SMM patients (median of 37 *vs* 27 cells/μL; P=0.02) However, when a detailed immunophenotypic profiling was performed, CD4 and/or CD8 T cells from high-risk SMM patients showed decreased expression of activation markers (CD25, P≤.004; CD54, P<0.001 and CD154, P=0.002), as well as decreased production of the Th1 related cytokines (IFNγ, P=0.03; TNFα, P≤0.003; and IL-2, P=0.02). To assess the combined effect of LEN-LoDEX on T- and NK-cells, we compared baseline samples *vs* those after 3 and 9 cycles of LEN-LoDEX. Accordingly, CD4 and/or CD8 T cells showed up-regulation of Th1 related chemokines (CCR5; p<.001) and cytokine production (IFNγ, P=.03; TNFα, P=.03 and IL-2, P=.02), as well as increased expression of activation markers (CD69, P≤.005; CD25, P<.001; CD28, P≤.04; CD54, P<.001 and HLA-DR, P<.001). Similarly, CD56dim and CD56bright NK cells showed up-regulation of HLA-DR (P<.001), the ADCC associated receptor CD16 (p≤0.005), and the adhesion molecules CD11a (p≤0.001) and CD11b (p≤0.005). Cell cycle analysis unraveled that the percentage of cells in S-phase was significantly increased from baseline *vs.* 3 *vs.* 9 cycles of LEN-LoDEX for T CD4 (0.04 *vs.* 0.13 *vs.* 0.13; p<0.001), CD8 (0.05 *vs* 0.13 *vs* 0.18; p<0.001) and NK cells (0.07 *vs.* 0.16 *vs.* 0.15; p<0.001), suggesting that PB analyses may reflect increased proliferation observed on other sites. To address the question whether dexamethasone antagonizes the immunomodulatory properties of LEN, we compared in 11 patients' T- and NK-cells immunophenotypic profiles at the end of induction *vs* maintenance (LEN alone and at least 3 months after DEX discontinuation). Overall, there were no significant differences in cell numbers nor immunophenotypic expression profiles of all T- and NK- subsets under study, with the exception for CD40L (CD154) which was slightly higher at the end of induction (P=0.048).
Summary and Conclusions: We showed that high-risk SMM patients present increased absolute numbers of γδ T cells but an overall T-cell impaired activation profile. Treatment with LEN-LoDEX induces immune activation and proliferation of T- and NK-cells which may contribute to the clinically observed disease control. Finally, our results show that DEX does not significantly alter the immunomodulatory effects of LEN.

P330

LONG-TERM RESULTS OF THE GIMEMA VEL-03-096 TRIAL IN MULTIPLE MYELOMA PATIENTS RECEIVING VTD CONSOLIDATION AFTER ASCT: IMPACT OF MRD KINETICS ON DURATION OF RESPONSE AND OVERALL SURVIVAL

S Ferrero[1,*] M Ladetto[1], D Drandi[1], F Cavallo[1, 2], E Genuardi[1], M Urbano[1], P Ghione[1], M Grasso[3], F Rossini[4], T Guglielmelli[5], C Cangialosi[6], AM Liberati[7], V Callea[8], T Caravita[9], C Crippa[10], L De Rosa[9], F Pisani[9], AP Falcone[11], P Pregno[2], S Oliva[1,2], R Passera[1], M Boccadoro[1,2], A Palumbo[1,2]
[1]Università di Torino, [2]GIMEMA MM, Torino, [3]GIMEMA MM, Cuneo, [4]GIMEMA MM, Monza, [5]GIMEMA MM, Orbassano, [6]GIMEMA MM, Palermo, [7]GIMEMA MM, Perugia, [8]GIMEMA MM, Reggio Calabria, [9]GIMEMA MM, Roma, [10]GIMEMA MM, Brescia, [11]GIMEMA MM, San Giovanni Rotondo, Italy

Background: New drugs allowed the achievement of remarkable levels of cytoreduction and improved survival rates in multiple myeloma (MM), though relapse is still the rule even in case of optimal response. This led to a growing interest in minimal residual disease (MRD) monitoring for early identification of patients at high relapse risk. Polimerase-chain reaction (PCR)-based approaches proved highly predictive for outcome discrimination, including in autologous (ASCT) transplantation and new drugs settings. Our group reported some MRD responses following a consolidation program with bortezomib, thalidomide and dexamethasone in 39 patients obtaining at least very good partial remission after ASCT: moreover, patients achieving a low post-consolidation tumor burden by Real-time Quantitative (RQ)-PCR had lower relapse risk.[Ladetto JCO2010]
Aims: Based on the long-term (93 months median follow-up, mFU) results of the GIMEMA VEL-03-096 trial (EudraCTN200400053128), our present work addresses additional relevant issues, such as: 1) the long-term outcome of patients achieving MRD responses in the absence of further treatment and particularly the impact on overall survival (OS); 2) the prognostic role of MRD kinetics during post-consolidation phases and in particular the impact of MRD reappearance; 3) the time lag between MRD reappearance and clinical relapse.
Methods: Inclusion criteria and treatment schedule have been already reported. MRD was assessed on bone marrow at diagnosis and at specific timepoints up to clinical relapse using both qualitative nested-PCR and RQ-PCR and employing immunoglobulin heavy chain-derived patient specific primers, as described [Voena *et al.*, Leukemia 1997; Ladetto *et al.*, Biol Bone Marrow Transpl 2000; van der Velden *et al.*, Leukemia 2007]. "Major MRD response" was defined as the occurrence of two consecutive MRD results scoring less than 1.00E-04 by RQ-PCR; "MRD reappearance" as a confirmed positive MRD

conversion by nested-PCR or an increase of MRD levels of at least one log by RQ-PCR; "MRD persistence" as not attaining MRD response at all.
Results: Among the 39 patients 27 serological progressions, 22 clinical relapses and 12 deaths were observed. Median duration of response (DOR) was 38 months and median OS was not reached (nr), OS at mFU was 64%. 270 of the planned samples (86%) were received by our lab. Overall, 26 patients reached major MRD response (67%) at a median time of 19 months (range: 9-42) from therapy start. Major MRD response was strongly associated with better outcome in terms of median DOR (62 *vs* 9 months, p<0.001) and OS (72% *vs* 48% at mFU, p=0.041, Figure 1A-B). Interestingly, patients with ongoing major MRD response, MRD reappearance or MRD persistence showed progressive increase in relapse risk (median DOR nr *vs* 38 *vs* 9 months, Figure 1C). Of the 26 patients obtaining major MRD response 11 (42%) received a retreatment at a median time of 42 months from major MRD response achievement (range: 22-87). Of these 11 clinical relapses, 7 were anticipated by MRD reappearance (64%), occurring at a median time of 9 months before the start of salvage treatment (range: 2-39). The 4 relapses not anticipated by a documented MRD reappearance always occurred in cases with inadequate follow-up sampling. Interestingly, disease kinetics from MRD reappearance was comparable to that of MRD persistence (time to next treatment, TNT 9 *vs* 10 months, p=0.706), indicating that the time spent in MRD response represents the measure of the benefit obtained by achieving a deeper level of cytoreduction.

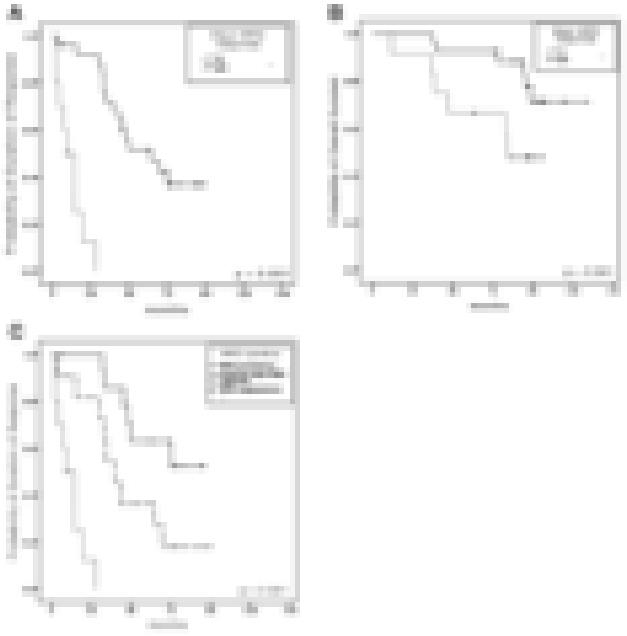

Figure 1. DOR (A) and OS (B) by major MRD response achievement. DOR (C) by MRD kynetics.

Summary and Conclusions: Our long-term data suggest that MM treatment should pursue two main objectives: 1) inducing maximal cytoreduction and possibly MRD response with induction and consolidation treatments; 2) avoiding MRD reappearances, through long-term maintenance or by testing preemptive therapy in the context of future prospective trials. These observations will have increasing relevance considering that high-throughput sequencing will allow MRD monitoring in the vast majority of MM patients.

P331

THE EXPRESSION OF HIGH LEVELS OF CRBN ISOFORM LACKING IMIDS BINDING DOMAIN PREDICTS FOR A LOWER PROBABILITY OF HIGH-QUALITY RESPONSE TO IMID-BASED UPFRONT THERAPY IN NEWLY DIAGNOSED MYELOMA PATIENTS

C Terragna[1,*] AF Dico[1], M Martello[1], E Borsi[1], E Zamagni[1], L Pantani[1], P Tacchetti[1], B Zannetti[1], K Mancuso[1], A Brioli[1], S Rocchi[1], B Santacroce[1], G Martinelli[1], M Cavo[1]
[1]DIMES, University of Bologna, "Seràgnoli" Institute of Hematology, Bologna, Italy

Background: In recent years, the immunomodulator derivatives (IMiDs) have been extensively used for the treatment of multiple myeloma (MM). The protein Cereblon, which is encoded by *CRBN* located on chromosome 3, has been proposed as a primary target of IMiDs. In particular, in several studies the down-regulation of CRBN was linked to IMiDs resistance. More recently, attempts have been done, to validate *CRBN* as a molecular biomarker of response to IMiDs. However, development of a reproducible assay has been hampered by the recognition that splicing events ultimately result in the expression of different CRBN isoforms. Of interest, the loss of exon 10 results in a truncated CRBN isoform, which lack the IMiDs binding domain.
Aims: To set up and validate a consistent Real-time assay for the quantification of *CRBN* isoforms and to explore its role as biomarker for the response to IMiDs-based therapy.
Methods: The study included a cohort of 100 patients with newly diagnosed MM who were homogeneously treated with IMiD-based induction therapy prior to autologous stem cell transplantation. Response to therapy was evaluated according to the International Myeloma Working Group criteria. Gene expression profiling was performed according to standardized procedures (Affymetrix), using the HG-U133 Plus 2.0 array. The study was performed on the enriched CD138+ cell fraction obtained from patients' bone marrow samples collected at diagnosis. A Real-time assay was set up to get an absolute quantification of both the *CRBN* full-length isoform and the truncated one, lacking exons 8 and 10, which code for the IMiDs binding domain. The GAPDH gene was used to normalize expression data and final results were expressed as the percentage of the truncated isoform out of the whole amount of detected isoforms.
Results: The *CRBN*-assay was tested on 100 newly diagnosed MM patients who were clustered in two subgroups according to the percentage of spliced *CRBN (e.g.* exceeding or not the median threshold value of 4.49%). Group A included 34 patients who expressed >4.49% of spliced *CRBN*, while in group B were included 66 patients with a lower percentage of spliced *CRBN*. The two subgroups of patients were homogeneous for baseline clinical characteristics, except for a slightly higher frequency of t(4;14) in group B. After induction therapy, 23/34 (67.6%) patients in group A failed at least a VGPR (very good partial response), whereas the remaining 10 achieved this objective (p<0,01, Fisher exact test). Conversely, in group B patients the frequencies of patients achieving or failing at least VGPR were almost similar (46% and 54%, respectively). The differential expression of 1352 probe sets characterized the transcriptome profile of patients with higher amount of spliced *CRBN*: *IRF4* resulted significantly down regulated in this subgroup of patients (Fold Change, FC=-1,304, p=0,004); the DNA damage control pathway resulted significantly de-regulated, as a consequence of the over-expression of *CHK1* (FC=3,083, p=0,01), *14-3-3* (FC=2,266, p=0,02), *CDC25* (FC=1,531, p=0,01) and the down-regulation of RAD9 (FC=-1,057, p=0,01).
Summary and Conclusions: We set up and validate a consistent Real-time assay for the quantification of actually available *CRBN* isoforms. By applying this assay, we found that a higher expression of spliced *CRBN* predicts for a lower probability to achieve a high-quality response to IMiD-based upfront therapy.

P332

ACTIVATED AND EXPANDED NATURAL KILLER (NKAE) CELLS KILL MULTIPLE MYELOMA (MM) CLONOGENIC PLASMA CELLS THROUGH NKG2D AND NKP30 RECEPTORS AND THEIR LIGANDS

A Leivas[1,*] R M Risueño[2], A Pérez-Martínez[3], L Fernández-Casanova[4], JJ Lahuerta[1], J Martínez-López[1]
[1]Hematology Service, Hospital Universitario 12 de Octubre, Madrid, [2]Leukemia stem cell group, Hematology, Josep Carreras Leukemia Research Institute, Barcelona, [3]Pediatric Onco-Hematology Service, Hospital Universitario La Paz, [4]Clinical Research, Centro Nacional de Investigaciones Oncológicas, Madrid, Spain

Background: MM remains an incurable disease, nowadays most of the available drugs do not destroy clonogenic tumor cell what leads to disease progression. MM precursor display stem cell properties that mediate drug resistance and could be analyzed by side population detection. Natural Killer (NK) cells produce death of MM cells, however they preserve CD34+ hematopoietic progenitor cell. To date NK cell specific activity on MM clonogenic tumor cell is still unknown.
Aims: This study compares cytotoxic activity of autologous NKAE cells on MM clonogenic tumor cells with baseline effect of autologous NK cells. On the other hand, MM clonogenic cells were phenotypically characterized for NK cell ligands to see specific sensibility to NK cell activity.
Methods: We studied NK cells from MM patients' (n=36) or healthy subject's (HS, n=14) peripheral blood. MM patients' NK cells were co-cultured with K562-mb15-41BBL (kindly gave by Baylor College of Medicine, Houston, Texas) cells for NKAEs obtaining. Time resolved fluorescence was employed to detect anti-tumor cytotoxic activity after facing NK/NKAEs cells to MM cells. Flow cytometry analysis was performed to determine NK and MM phenotypic membrane receptor expression profile. For side population studies DyeCycle Violet efflux was detected. NK cell specific activity on clonogenic tumor cells was studied by methylcellulose clonogenic assay. Specific receptor blocking was achieved by NK cells incubation with monoclonal antibodies. Results are presented as mean±SEM.
Results: NK cells from patients (n=20) produce 28,8±2,8% lysis of bulk MM cells, nevertheless NKAEs killed 68±0,4% of bulk MM cells (n=3) at 8:1 ratio. Colony formation showed that NK cells from HS (n=5) decreased MM colony growth in a NK cell dose dependent manner when MM cells are exposed to NK cells, maximum effect was 87,6±3,8% colonies growth inhibition at 32:1 ratio

(NK:MM) compared to autonomous growth of human MM cells (RPMI-8226, NCI-H929 and OPM-2 cell lines). Patients NK cells (n=8) reduced 57,9±12,1% (32:1) colonies generation of MM cells without evidence of NK cell dose relationship. In contrast, patient NKAEs (n=6) reduced 93,6±2,7% (32:1) colonies growth, showing a strong dose-dependent relationship as expected (Figure 1A). At 8:1 ratio MM cell destruction by NK cell was higher on clonogenic MM cells (48,2±6,9% in MM patients and 58,3±4% in HS) than corresponding bulk MM cells (28,8±2,8% in MM patients and 21,1±4,5% in HS). Then NK cell (n=18) and NKAEs (n=5) phenotype were compared. NKAEs showed overexpression of NKG2D and NKp30 receptors. Blocking NKAEs NKp30 receptor (n=2) reduced 38% MM cells lysis, while NKG2D blockade decreased 12% lysis. NKAEs methylcellulose cultures (n=3) showed 15% and 20% increased colonies growth when NKp30 or NKG2D receptors were previously blocked respectively. Flow cytometry analysis of MM cells exhibited that side population have same expression profile of NKG2D ligands (ULBP-1, ULBP-2, ULBP-3, MICA, MICB) when compare to no side population cells in MM cell lines (U-266, RPMI-8226, NCI-H929, OPM-2, L-363, JJN-3, MM.1S), however they have down regulated apoptosis receptors (FAS, TRAIL-DR4, TRAIL-DR5) and DNAM-1 ligands (CD112 and CD155) expression (Figure 1B).

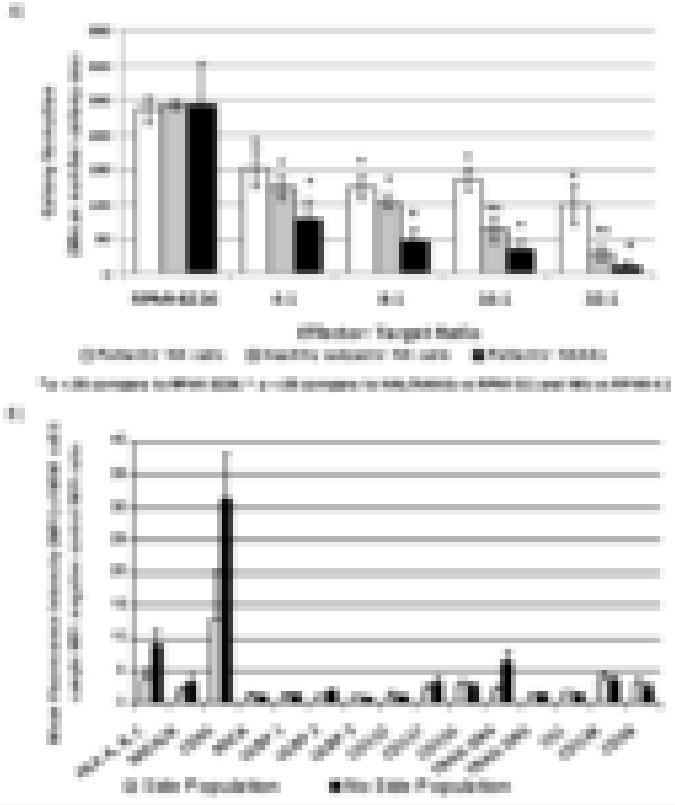

Figure 1. A) Clonogenic assay of MM cell line R PMI-8226 after exposure to MM patients' NK cells, healthy subjects' NK cells and MM patients' N KAEs. B) Membrane receptor expression profile analysis by flow cytometry of side population and no side population from MM cell lines (n=7).

Summary and Conclusions: NK cells are effective against MM clonogenic tumor cell. Patient NK cell stimulation produces NKAEs that have enhanced cytotoxic activity against MM clonogenic tumor cells. Integrity of NKp30 and NKG2D receptors is critical in NK cell activity against MM clonogenic cells. NKG2D ligands of MM side population could be a therapeutic target for MM treatment.

P333

CIRCULATING MIR-34A AND MIR-130A AS BIOMARKERS OF EXTRAMEDULLARY DISEASE

L Kubiczkova[1,*] L Sedlarikova[1], F Kryukov[1,2], J Nekvindova[3], L Radova[4], D Vrabel[1], Z Adam[5], L Pour[5], S Sevcikova[1,6], R Hajek[1,2]
[1]Pathological Physiology, Masaryk University, Faculty of Medicine, Brno, [2]Faculty of Medicine, University of Ostrava, Ostrava, [3]Faculty of Medicine and Dentistry, Palacky University Olomouc, Olomouc, [4]Central European Institute of Technology, Masaryk University, [5]Department of Internal Medicine - Hematooncology, [6]Department of Clinical Hematology, University Hospital Brno, Brno, Czech Republic

Background: MicroRNAs (miRNA), short non-coding regulatory RNAs, are implicated in deregulation of critical pathways involved in multiple myeloma (MM) and extramedullary form of MM (EM). Circulating miRNAs are highly stable and are both detectable and quantifiable in a range of accessible body fluids; thus, they have the potential to be useful diagnostic biomarkers, as was shown in our previous study on MM. Here, we have identified a specific serum miRNA profile in patients with extramedullary disease and correlated it with clinically important parameters.
Aims: The goal of this study was to identify circulating miRNA signature using Taqman Low Density Arrays and assay specific quantitative PCR (qPCR) on a cohort of patients with extramedullary disease, MM patients and healthy controls, and to compare miRNA levels with clinical parameters.
Methods: One hundred serum samples obtained from relapsed EM patients, newly diagnosed MM patients and healthy donors (HD) were evaluated for this study. Screening analysis of 667 miRNAs was performed on 5 EM samples, 5 MM samples and 6 HD samples using TaqMan Low Density Arrays (TLDA). Levels of 4 differentially expressed miRNAs from TLDA (p<0.05) between EM *vs* MM, and EM *vs* HD were confirmed by qPCR using absolute quantification approach on 35 EM, 35 MM and 30 HD serum samples. Receiver Operating Characteristic (ROC) analysis was used to calculate specificity and sensitivity of each miRNA and their combination. Biochemical characteristics were also available for EM and MM patients. P values <0.05 were considered as significant.
Results: MiRNA TLDA profiling revealed 14 deregulated miRNAs (all p<0.05, adjusted p<0.41) between MM patients and EM. Further, 20 miRNAs were on the top of the list of deregulated miRNAs between EM and HD serum samples (all p<0.05, adjusted p<0.40). MiR-222, miR-130a, miR-34a and miR-195 were further verified on a bigger cohort of EM, MM and HD samples. MiR-130a was significantly down-regulated, miR-222 and miR-34a were up-regulated in EM samples when compared with HD (all p<0.005); moreover, miR-130a was down-regulated and miR-34a up-regulated also in EM when compared with MM sera (p<0.06). To discriminate EM from other groups, ROC curve was calculated. To distinguish EM from HD, it revealed highest sensitivity of 74.3%, specificity of 90.0% and area under the curve (AUC)=0.879 for the combination of miR-130a and miR-34a. Further, when EM *vs* MM were compared, this combination of miRNA revealed sensitivity of 54.3% and specificity of 80% with AUC=0.675. In the cohort of EM patients, miR-130a significantly correlated with most of clinically relevant parameters; there was a positive correlation with level of hemoglobin and thrombocytes count (r_s=0.397 and 0.439, all p<0.05) and a negative correlation with levels of monoclonal immunoglobulin, β_2-microglobulin and C-reactive protein (r_s=-0.398, -0.427 and -0.488, all p<0.05). This miRNA was also associated with higher ISS stage (p=0.017). Further, miR-222 correlated positively with lactate dehydrogenase (r_s=0.417, p<0.05); miR-222 and miR-34a were associated positively with percentage of plasma cell infiltration in the bone marrow (r_s=0.435 and 0.562, p<0.05).
Summary and Conclusions: Altogether, our first observations demonstrate that circulating miR-130a and miR-34a may be promising biomarkers for patients with extramedullary disease and prompt further studies in this field.

Background: Our automated flow cytometry-based Exvitech© platform allows the measurement of bortezomib induced depletion of different bone marrow cell populations. We can evaluate in the same myeloma bone marrow sample, the efficacy of bortezomib in depleting myeloma plasma cells as well as the toxic-

ity on myeloid precursors, B-precursors, and mature lymphocytes. Sensitivity is measured by standard pharmacology with 8 concentration dose responses in each of these cell subpopulations.
Aims: To compare bortezomib drug efficacy in the target myeloma population with its expected hematotoxicity from depleting myeloid precursors. This data enables an *ex vivo* therapeutic index for each patient.
Methods: 10 bone marrow (BM) samples from patients diagnosed with MM were sent to Vivia from different hospitals across Spain within 24h. The whole sample in heparin tubes was diluted with 20% SBF retaining the erythrocyte population and serum proteins, and was plated into 96-well assay plates containing 8 concentrations of each drug. The plates were incubated for 12-hours, and then prepared for analysis by our flow cytometry-based Exvitech© platform. A multiple staining (CD45v450/Anexin-FITC/CD117-PE/CD34PerCP/CD38-APC/CD19APC.Cy7) was performed to identify and distinguish the following BM populations: plasma cells ($CD45^{-/+}/CD38^{+}/CD19^{-}$), myeloid precursors ($CD34^{+}/CD45^{-/+}CD117^{+}/CD19^{-}$), B-lymphocyte precursors ($CD34^{+}/CD45^{-/+}CD117^{-}/CD19^{+}$), and normal lymphocytes ($CD45^{+}/SSC^{lo}$). Drug response was evaluated as depletion of each cell population relative to the average of 6 control wells without drug in each plate. All processes have been automated increasing the accuracy of the analysis.
Results: Overall, the effect of bortezomib was clearly higher in the tumor population, since the toxicity to residual BM normal populations was low, demonstrating its selectivity for the pathologic plasma cells. However, there is a high inter-patient variability in the bortezomib's effect inside the plasma cell population and in the healthy cell populations that could correspond to the range of responses seen in the clinical outcome of the patients. Interestingly, we observed the opposite effect as expected in one patient sample, shown in the Figure 1; bortezomib has a non-selective action, with a similar effect in the plasma cells than in all the precursor populations with the exception of the normal residual lymphocytes. We would interpret this data as suggestive that the probability of hematological toxicity in this case could be especially high, and hence the patient may not be a good candidate for bortezomib based therapies.

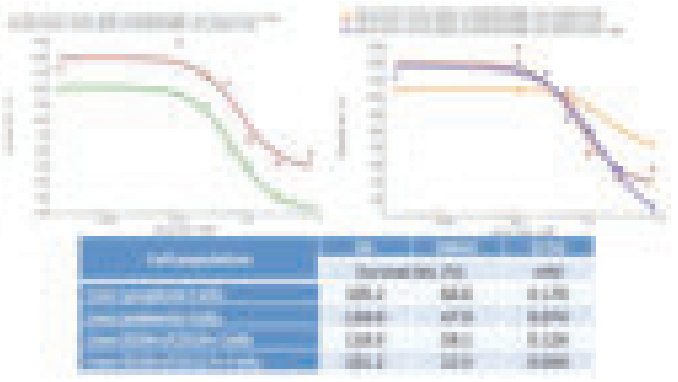

Figure 1.

Summary and Conclusions: These preliminary results show that Vivia Exvitech© platform is able to measure within the same sample the efficacy and toxicity of bortezomib on different BM populations. This platform enables measuring the effect simultaneously in the clonal plasma cells and in a putative stem cell precursor, myeloid precursors or mature lymphocytes. The example shown here for bortezomib is being extended to evaluate full drug combination treatments. This simultaneous analysis for bortezomib based treatments at the different cell levels might be able to predict the clinical response, the clinical follow up and possible hematological toxicities associated with these treatments. We pretend to establish for each individual patient an *ex vivo* hematologic therapeutic index based on the responses of each cell population to a given treatment.

P335

DOES CHARACTERISTIC PHENOTYPE FOR PLASMA CELL LEUKAEMIA EXIST?

L Rihova[1,2,*] R Bezdekova[1,2], P Vsianska[1,2], P Kucerova[1], R Suska[1], M Penka[1], L Pour[2,3], R Hajek[1,2,4]
[1]Department of Clinical Haematology, University Hospital Brno, [2]Babak Myeloma Group by Department of Pathological Physiology, Masaryk University, [3]Department of Internal Medicine - Hematology and Oncology, University Hospital Brno and Faculty of Medicine, Masaryk University, Brno, [4]Department of Haematooncology, University Hospital Ostrava and Faculty of Medicine, Ostrava University, Ostrava, Czech Republic

Background: Plasma cell leukaemia (PCL) is characterized by a presence of circulating plasma cells (PCs) in peripheral blood. Primary PCL (pPCL) occurs in patients with no evidence of multiple myeloma (MM) while secondary PCL (sPCL) is end-stage of relapsed and/or refractory MM. Detection of circulating PCs by flow cytometry is important for diagnosis determination and for discrimination of PCL from reactive plasmacytosis as well. Identification of phenotype profile characteristic for PCL could help in early treatment intervention.
Aims: Analyses of pPCL and sPCL to identify phenotype profile in comparison with MM.
Methods: Total of 86 patients was analysed: 12 patients with pPCL, 10 patients with sPCL and 64 newly diagnosed MM patients. Whole peripheral blood (PB) and/or bone marrow (BM) $CD38^{+}CD138^{+}$ PCs were analysed. Expression of surface antigens (CD19, CD20, CD27, CD28, CD44, CD56, and CD117) together with intracellular nestin was studied by flow cytometry. PCs were considered positive for given marker when its expression exceeds 20%.
Results: There were found similar relative number of PCs in peripheral blood of pPCL (26.7%) and sPCL (26.8%), on the other hand, infiltration of bone marrow was the highest in sPCL (55.6%) when compared to pPCL (39.2%) and MM (5.8%). No presence of $CD19^{+}$ and/or $CD20^{+}$ PCs was found in sPCL, but slightly increased number of positive cases was found in pPCL (16.7% for CD19 and/or CD20 in PB; 18.2% for CD19 and 27.3% for CD20 in BM) when compared to MM (4.7% for CD19 and 11.7% for CD20 in BM). Number of $CD56^{+}$ positive cases was higher in BM of MM (87.5%) then in pPCL (54.5%) and sPCL (66.7%), similar expression was found in PB (58.3% for pPCL and 50.0% for sPCL). Number of CD27 positive cases was the highest in BM of MM (MM 51.6%; pPCL 9.1%; sPCL 28.6%); the same positivity of CD27 was found in PB of both PCLs (25.0%). No big differences were detected in expression of CD28 in BM (30.0% in pPCL, 42.9% in sPCL and 22.6% in MM) and /or PB (16.7% in pPCL *vs.* 28.6% in sPCL). Surprisingly both PCLs expressed CD44 in 100% of BM samples, while MM in 70.7%; PB expression was lower in pPCL (85.7%) then in sPCL (100.0%). CD117 was mostly expressed in BM of sPCL (50.0%) and MM (43.5%) when compared to pPCL (10.0%), similar expression were found in PB of both PCLs (8.3% in pPCL *vs.* 14.3% in sPCL). Nestin, a marker of stem cell, was highly expressed in sPCL (80.0%) and pPCL (75.0%), but decreased in MM (36.1%); PB expression in PCLs was not so different (57.1% in pPCL *vs.* 66.7% in sPCL).
Summary and Conclusions: Phenotype profile of pPCL and sPCL did not differ so much in peripheral blood and/or bone marrow, except for a disappearance of CD19 and CD20 in sPCL and decrease of CD117 in pPCL. Lower expression of CD56, CD27 and overexpression of CD44 with nestin was characteristic for both PCLs when compared to MM.

GENE EXPRESSION PROFILING AND COPY NUMBER ALTERATIONS OF CIRCULATING CLONOTYPIC B CELLS OF MULTIPLE MYELOMA NEWLY DIAGNOSED PATIENTS REVEALS PATHWAYS POTENTIALLY INVOLVED IN THE DISEASE PERSISTENCE

M Martello[1,*] AF Dico[1], E Borsi[1], E Zamagni[1], L Pantani[1], P Tacchetti[1], B Zannetti[1], K Mancuso[1], A Brioli[1], S Rocchi[1], B Santacroce[1], G Martinelli[1], M Cavo[1], C Terragna[1]
[1]DIMES-Department of Experimental Diagnostic and Specialty Medicine, Bologna, Italy

Background: In recent years, increasing efforts have been devoted to adjust the Multiple Myeloma (MM) therapeutic approach, in order to get patients' "real cure", instead of "functional cure". Indeed, even if a significant fraction of MM patients are able to achieve complete responses, nevertheless they ultimately relapse. The persistence of Myeloma Propagating Cells (MPCs) has been supposed to be one of the major causes of MM drug-resistance. However, very little is known about the molecular background of MPCs, even if several studies suggested that they display phenotypic characteristics resembling the memory B cells that reside in the CD138- compartment.
Aims: To evaluate the genomic and genetic background MM CD138-B+ cells, located both in bone marrow (BM) and in peripheral blood (PBL) as compared to the CD138+ neoplastic clone.
Methods: We collected the CD138+ and CD138- cell fractions from 50 newly diagnosed MM patients. We isolated the B cell population and, whenever possible, the memory B cell clone. Clonogenic assays were performed using cell fractions obtained from RPMI-8226 and NCI-H929. For each cell fraction, we performed a sequencing of the IgH VDJ rearrangement. The complete set of genomic aberrations and the gene expression profile were performed according to standardized procedures (Affymetrix), using the SNPs array 6.0 and the HG-U133 Plus 2.0 array.
Results: The clonogenic potential, tested by plating cells in conditioned media, resulted higher for CD138- as compared to CD138+ cells. By VDJ rearrangement analyses, a clonal relationship between the CD138+ clone and the memory B cells clone was confirmed. SNPs arrays showed that both BM and PBL CD138+ cell fractions displayed exactly the same genomic macro-alterations. On the contrary, in the BM and PBL CD138-19+27+ memory B cell fractions any macro-alteration was detected, whereas several micro-alterations were highlighted. These micro-alterations were located out of any genomic variant regions and were presumably associated to MM pathogenesis, since, among others, *KRAS*, *WWOX* and *XIAP* genes are located in the amplified regions. The memory B cells were also characterized by the presence of several LOH

regions, which cover at least 106 tumor suppressor genes (among which are *TP53*, *CDKN2C* and *RASSF1A*), already known to be involved in MM and other hematological malignancies. To get insight into the biology of the clonotypic B cell population, the gene expression profiles of 5 donors B cells and 11 MM B cells samples were compared. Unsupervised analysis, by hierarchical clustering was able discriminate the differential expression of 11480 probes (Fold Change: <-2;>2; FDR: 0,05; p <0,05). An overall de-regulation of pathways involved in self-renewal mechanisms was observed (down-regulation of Hedgehog pathway; over-expression of Notch and Wnt signaling). In addition, the down-regulation of genes related to the unfolded protein response (such as *IRE1*α and *XBP1*: -18.0; -19.96. p<0,05) supports the hypothesis of a phenotypic expression related to proteasome inhibitor resistance.
Summary and Conclusions: Data suggest that the MM CD138+ clone might resume the end of the complex process of tumorigenesis, proven by the presence of numerous macro-alterations, possibly due to an already established genomic instability. In contrast, MM B cells, while lacking macro-alterations, display several micro-alterations and a peculiar transcriptional program, thus supporting the idea that these post germinal center cells might be involved in the transforming event, which originate and sustain the neoplastic clone.

CAN GENOME ARRAY SCREENING REPLACE FISH AS A FRONT-LINE TEST IN MULTIPLE MYELOMA?

K Gancheva[1,*] T Boneva[2], D Brazma[3], J Howard-Reeves[3], J Raynov[2], C Grace[1], E P Nacheva[1]
[1]Haematology, UCL Medical School, London, United Kingdom, [2]Haematology, Military Medical Academy, Sofia, Bulgaria, [3]Haematology, Royal Free NHS Foundation Trust, London, United Kingdom

Background: Multiple myeloma (MM) is a malignant disorder characterized by neoplastic transformation of mature B cells in the bone marrow, accompanied by complex genetic changes. The disease is heterogeneous at both clinical and genomic levels. Molecular genetics and genomic investigations have demonstrated that disease evolution is associated with accumulation of specific aberrations, mostly genome imbalances that not only shed light on the disease pathogenesis but also allow risk assessment and treatment monitoring.
Aims: The aim of our study was to evaluate the role of whole genome profiling in identification of multiple changes in bone marrow samples from MM patients.
Methods: Here we present results of FISH and whole genome screening by array comparative genomic hybridization (aCGH) of CD138(+) cell enriched bone marrow samples from 50 patients with MM.
Results: Genome copy number changes were detected in all samples. One of the two genome imbalances clinically significant for high-risk myeloma, *i.e.* 1q gain and 17p13 loss, as per the guidelines of the International Myeloma Working Group (Chng *et al.*, Leukemia 2013), were detected in 30/50 samples (60%). Six of the samples tested by FISH from this group were also *IGH/FGFR3* fusion carriers. The remaining 20 samples (40%) have complex molecular karyotypes of which 7 cases had 12p13 deletions, also associated with poor overall survival (Avet-Loiseau H *et al.*, JCO 2009). Only one of these 20 samples was found to be positive for *IGH/FGFR3* fusion, which was also harboring the 12p13 loss. These data, albeit limited, indicate that the *IGH/FGFR3* fusion gene appears to be a secondary event in MM genomes.
Summary and Conclusions: Employing array platforms routinely used in constitutional genetic studies we demonstrate the ability of aCGH to detect clonal imbalances to a level well below established clinically significant thresholds. By combining target enrichment and complemented with tests for IGH rearrangements aCGH offers a cost-neutral alternative to multiprobe FISH screening. The application of aCGH as a first tier test in the diagnostic workup of myeloma enables high-risk disease stratification with the added benefit of providing whole genome data to assist in establishing clinically relevant predicative markers.

P338

COMPARATIVE STUDY OF GENE EXPRESSION PROFILING BETWEEN ASYMPTOMATIC AND SYMPTOMATIC WALDENSTRÖM'S MACROGLOBULINEMIA PATIENTS

C Jiménez[1,*] ME Sarasquete[1], C Chillón[1], F Escalante[2], IP Conde[1], M Alcoceba[1], E Sebastián[1], A Bárez[3], JM Hernández[4], A Balanzategui[1], MJ Peñarrubia[5], R Corral[1], L Marín[1], P Giraldo[6], M González[1], R García-Sanz[1]
[1]University Hospital of Salamanca, Salamanca, [2]Virgen Blanca Hospital of León, León, [3]Nuestra Señora de Sonsoles Hospital of Ávila, Ávila, [4]General Hospital of Segovia, Segovia, [5]Clinical Hospital of Valladolid, Valladolid, [6]Miguel Servet Hospital of Zaragoza, Zaragoza, Spain

Background: Waldenström's macroglobulinemia (WM) is a B-cell malignancy characterized by the accumulation in the bone marrow of clonal B lymphocytes with lymphoplasmacytic differentiation. The recently identified somatic mutations in *MYD88* and *CXCR4* genes have provided new insights into the molecular mechanisms that may contribute to the pathogenesis of the disease. However, these genetic alterations do not allow either to differentiate indolent from symptomatic forms, or to predict progression.
Aims: To identify differently expressed genes among asymptomatic and symptomatic WM. To correlate the gene expression pattern with clinical and biological characteristics of the patients in order to establish risk factors and molecular mechanisms associated with progression.
Methods: Gene expression profile (GEP) by quantitative PCR (Taqman probes) was performed in bone marrow CD19+ cells of 19 asymptomatic WM and 18 symptomatic WM. Data were analyzed with ExpressionSuite Software v1.0.3 (Life Technologies software) and statistical analysis was performed with SPSS v15.0 (SPSS Inc., Armonk, New York) using the Mann-Whitney U-test to identify statistically significant differences (p<0.05) between groups.
Results: The comparison between asymptomatic and symptomatic WM CD19+ cells highlighted differently expressed genes; in particular, ADARB1 (alternative splicing) and GPSM2 (G-protein signaling modulator) were upregulated in asymptomatic cases, whereas CD79A (BCR related), MEKK and P38 (MAPKs pathway) and MYD88 were overexpressed in symptomatic WM, thus suggesting perhaps a more intense activity of the signaling pathways responsible for WM cell growth and survival. Regarding the other relevant pathway in the pathogenesis of WM (which involves CXCR4 receptor), our study showed different gene expression profiling signature in patients with CXCR4 mutation (n=10) *versus* unmutated patients (n=27). Interestingly, among these genes are included ARID1A (which was recently found to be mutated in 17% WM), BTK (which is activated by CXCR4), CD79A (also reported to have mutations in 5.5% WM), IRAK4, PI3K and NF-KB3 (activated by MYD88 pathway), MEKK, MAP3K, ERK and JNK (belonging to MAPKs pathway), PAX5 (gene involved in plasma cell differentiation that had already been described as deregulated in WM) and OBF1 (required for the formation of germinal centers). Then, we correlated clinical and biological characteristics of symptomatic WM patients with GEP. We identified some slight differences in patients with poor prognosis features (*i.e.* albumin <3.5g/dl) and concerned oncogenes (SRC), genes involved in cell cycle (cyclin D1 and D2) or genes that define the molecular signature of WM (CXCR4). It is worth pointing out that the different gene expression pattern also affected parameters included in the International prognostic scoring system for WM such as β2-microglobulin, monoclonal component and hemoglobin. However, due to the low number of patients included, further validation is required. Finally, regarding response to treatment, in contrast to asymptomatic WM, GPSM2 was downregulated in patients with complete or partial response.
Summary and Conclusions: We have identified significant differences in GEP among indolent *versus* symptomatic WM patients, concerning genes involved in WM pathogenic mechanisms. Besides, the results suggest that BCR and BTK signaling pathways (together with the already known MYD88 and CXCR4) may play an important role in the biology and pathogenesis of the disease.

P339

TRANSCRIPTIONAL REGULATION OF ALTERNATE SPLICING BY DP1 AND THEIR FUNCTIONAL IMPACT IN MULTIPLE MYELOMA

M Fulciniti[1,*] M Kemal Samur[1], R Bandi[1], M Bashin[1], P shah[1], M Gkotzamanidou[1], A Cagnetta[1], F Magrangeas[2], S Minvielle[2], C Li[1], K Anderson[1], H Avet-loiseau[3], N Munshi[1]
[1]Dana Farber Cancer Institute, Noston, United States, [2]Center for Cancer Research, Nantes, [3]Unité de Génomique du Myélome, Toulouse, France

Background: With cumulative acquisition of new genetic and epigenetic abnormalities there is growing interest in targeting transcription factors (TFs) as they represent common oncogenic regulators in malignant cell growth and survival. Our gene expression profile analysis of 172 uniformly treated MM patients identified significant association of TFDP1 overexpression with shorter overall and event-free survival in MM. DP1 is a binding partners for E2F transcription factors and the heterodimer complex enhances both the DNA binding affinity and the transcriptional activity of the complex.
Aims: We evaluated functional and molecular role of Dp1 in MM and comprehensively characterized its impact on transcriptome and allelic variants in MM.
Methods: Specific shRNA constructs were utilized to evaluate functional and molecular effect of Dp1 silencing in MM. An integrated analysis incorporating ChIP-seq and expression data following gene silencing was performed in MM cell lines in order to identify DP1 response program in MM. Impact of Dp1 on alternate splicing was evaluated by genome-wide analysis of alternate splicing in total RNA from Dp1 silenced MM1S cells using Human Exon1 ST array.
Results: We have observed inhibition of MM growth after DP1 knock-down, independently of the genetic background of myeloma cells. Based on these results suggesting a potential role of DP1 as candidate oncogene in MM, we performed an integrated analysis incorporating genomewide DNA-binding regions and RNA expression following Dp1 and E2F1 gene silencing. Functional annotation of the overlapping target genes derived from both genome-wide studies revealed a strong enrichment for pathways involved in DNA replication, metabolism and repair. Interestingly, the most significant association was observed with ''regulation of RNA metabolic processes'' (40 target genes), ''RNA processing'' (93 target genes) and ''RNA splicing'' (95 genes), suggesting role of Dp1 in RNA splicing. This results prompted us to evaluate the impact of Dp1 on alternate splicing (AS). Splicing profiles showed that Dp1 knock down causes widespread changes in AS. We have identified 1213 alternatively spliced exons that mapped to 818 genes in shDP1 compared to control pLKO.1-transduced MM1S cells,

suggesting impact of Dp1 silencing on alternate splicing through its transcriptional regulation of splicing factor (SF) expression. Further analysis of Dp1 modulated SFs and alternatively spliced genes identified significant interrelation between the two suggesting that Dp1 controls SFs expression which in turn lead to changes in alternate splicing pattern to have subsequent molecular and biological impact. We next evaluated the expression of Dp1-modulated splicing factors in our clinically annotated cohort of MM patients and identified 23 SFs upregulated in MM compared to normal plasma cells. Importantly, the Dp1 was associated with increased expression of the SR protein splicing factor SRSF1 and its high expression was observed to predict poor prognosis in 2 different datasets. Our data for the first time shows that SFs are upregulated in myeloma and link to clinical outcome. Moreover, we have observed significant coexpression of DP1 and SRSF1 in MM patients; and that SRSF1 knockdown reduces DP1-mediated cell proliferation. These results suggest a mechanism for SRSF1 upregulation in tumors with elevated DP1 and identify SRSF1 as a critical DP1 target that contributes to its oncogenic potential by enabling expression of specific protein isoforms through alternative splicing.
Summary and Conclusions: We observed that the DP1/E2F signaling pathway plays a significant role in myeloma by inducing alternate splicing through their transcriptional control of specific splicing factors with potential functional, clinical and therapeutic implications in myeloma.

P340

DOWNREGULATION OF TELOMERASE ACTIVITY IN RESPONSE TO NEW GENERATION OF PROTEASOME INHIBITORS (EPOXOMICIN AND MG132) IN MULTIPLE MYELOMA CELLS

E Muchtar[1,2,*] O Uziel[3], N Shalem[3], E Beery[3], Y Nordenberg[3,4,5], M Bakhanashvili[6], A Gutkin[3], M Lahav[2,7]
[1]Institute of hematology, Rabin Medical Center, Petah Tikva, [2]Sackler School of Medicine, Tel-Aviv University, Ramat-Aviv, [3]Felsenstein Medical Research Center, [4]Endocrinology Laboratory, Rabin Medical Center, Petah Tikva, [5]Dep of Human Molecular Genetics and Biochemistry, Sackler School of Medicine, Tel-Aviv University, Ramat-Aviv, [6]Unit of Infectious Diseases, Sheba Medical Center, Tel-Hashomer Hospital, Ramat Gan, [7]Internal Medicine A, Rabin Medical Center, Petah Tikva, Israel

Background: Proteasome inhibitors are effective drugs against multiple myeloma (MM). The mechanism of action of these pleiotropic agents has not been yet fully elucidated. The importance of telomerase activity (TA) in MM has been repeatedly demonstrated. Previously we showed that the first generation proteasome inhibitor bortezomib (B) inhibits TA in MM cells by both transcriptional and post-translational mechanisms and has a potential clinical significance.
Aims: In the current study we evaluated the anti telomerase activity of the new generation of proteasome inhibitors, epoxomicin (EP) and MG132 (MG) in order to clarify whether telomerase inhibition represents a class effect.
Methods: MM cell lines, ARP-1, CAG, RPMI 8226 and U266 were exposed to EP or MG for 24-48 hours. Viability was assessed by the WST-1 and Trypan Blue exclusion assays, TA by the TRAP assay, hTERT expression by real time PCR, transcription factors (TF) binding by the ChIP assay and post-translational modifications were evaluated by IP and Western blot.
Results: EP and MG differentially downregulated the proliferation and TA in all MM cell lines. The downregulation of TA and hTERT (the gene encoding for telomerase) expression was faster in CAG than ARP-1 cells. EP was more potent than MG and therefore further mechanistic studies were performed on this compound. The inhibition of TA was mainly transcriptionally regulated and the phosphorylation of the enzyme was not changed. The binding of three positive regulator transcription factors (TF): SP1, c-Myc and NFkB to the hTERT promoter was decreased by EP in CAG cells as well as their total cellular concentrations. In ARP-1 cells the SP1 and c-MYC binding and content were similarly affected by EP while NFkB was not affected. Interestingly the transcription factor WT-1 (Wilms' tumor-1) exhibited an increased binding to the hTERT promoter while its total cellular amount remained unchanged.
Summary and Conclusions: Our results demonstrate the effects of EP and MG on TA in MM. These results combined with our previous study of bortezomib define telomerase as a general target for proteasome inhibitors. The inhibitory effect on TA is exerted on several regulatory levels, transcriptional and post translational. SP1, C-Myc and NFkB were involved in mediating these effects. A novel finding of this study is the role of WT-1. WT-1 appears as a negative regulator of hTERT expression. The results of this study may contribute to future development of telomerase inhibition as a therapeutic modality in MM.

P341

HSP90 INHIBITOR-DRUG CONJUGATES (HDC) WITH ANTITUMOR AGENTS TARGETING HEMATOLOGICAL MALIGNANCES

PE Rao[1,*] D Proia[1], J Chu[1], J Sang[1], W Ying[2], D Chimmanamada[2], T Kowalczyk-Przewloka[2], J Jiang[2]
[1]Biology, [2]Chemistry, Synta Pharmaceuticals Inc, Lexington, United States

Background: Chemotherapeutic drugs have been the mainstay of cancer therapy for many decades however their effectiveness is often hampered by systemic toxicities due to off-target effects on normal tissues. Targeted delivery strategies such as Antibody Drug-Conjugates (ADCs) offer a means to overcome this limitation, by delivering cytotoxic payloads directly to tumors. We have developed a novel small molecule-drug conjugate platform technology (Hsp90 Inhibitor-Drug Conjugate; HDC) that exploits the unique properties of Hsp90 (heat shock protein 90), a ubiquitously expressed molecular chaperone protein that regulates the maturation and functional stability of multiple cellular client proteins. Hsp90 is overexpressed in many human cancers and inhibitors of Hsp90 have shown preferential tumor retention in preclinical models, compared to normal tissues.
Aims: HDCs consist of three key components: the Hsp90 inhibitor targeting moiety (ligand), the payload (chemotherapeutic agent), and the linker. We have made conjugates with payloads targeting hematological malignancies including lenalidomide, proteasome inhibitors and DNA alkylating agents.
Results: Using a lenalidomide-containing HDC we have demonstrated preferential uptake and retention in myeloma cell lines compared with normal PBMC *in vitro*. Moreover, robust tumor uptake was observed in xenograft tumors *in vivo*, with retention of both the HDC and the lenalidomide payload for more than 24 hours following a single administration. In contrast, dosing with lenalidomide alone resulted in drug clearance from tumors within 6 hours. HDC-induced extended tumor retention of lenalidomide produced xenograft tumor growth inhibition equivalent to using lenalidomide at 7 times higher dose. At the molecular level, both lenalidomide and the lenalidomide HDC exhibit antitumor effects by down regulating IRF4 and inducing degradation of Ikaros and Aiolos, two transcription factors responsible for production of factors promoting the expansion of normal and malignant B and plasma cell lineages. Like lenalidomide, they also induce phosphorylation of CD28 and increase CD56 expression on NKT cells. Proteasome inhibitors such as bortezomib and carfilzomib have been also been approved for treatment of multiple myeloma. But side effects such as neuropathy have been noted. HDC conjugates carrying bortezomib, carfilzomib and delanzomib with demonstrated proteasome inhibition activity have been produced. Several of the most potently cytotoxic conjugates have both proteasome and Hsp90 inhibitory activity, revealing the feasibility of developing a tunable HDC with various degrees of intrinsic proteasome and Hsp90 inhibitory activity.
Summary and Conclusions: The HDC technology presented here can be applied to other chemotherapeutic payloads in order to improve antitumor activity and work on HDC-alkylating agents is underway. Thus HDC represents a promising platform technology for generating diverse anticancer agents for evaluation in patients with hematological malignances.

P342

TOLL-LIKE RECEPTOR ACTIVATION PROMOTES MULTIPLE MYELOMA CELL GROWTH AND SURVIVAL BY SUPPRESSION OF ENDOPLASMIC RETICULUM STRESS FACTOR CHOP

T Bagratuni[1,*] E Kastritis[1], C Liacos[1], E Eleutherakis-Papaiakovou[1], N Kanellias[1], E Terpos[1], MA Dimopoulos[1]
[1]University of Athens, Athens, Greece

Background: Toll-like receptor family (TLR) of receptors is an essential part of innate immunity. During infection, human immune cells sense the presence of invading pathogens through the TLRs which then activate transcriptional programs that orchestrate adaptive responses and induce the endoplasmic reticulum (ER) unfolded protein response (UPR) to accomodate essential protein translation. If the UPR fails to resolve the protein-folding defect, due to severe and prolonged ER stress, apoptosis is activated. However, the timing sequence of the prolonged ER stress has probably imlications for ER stress-induced apoptosis that might help cells to adapt under these conditions rather than driving them to apoptosis. The prolonged stress, possibly arising from a massive increase in protein synthesis, has shown to suppress CHOP, an apoptosis mediator, in ER-stressed macrophages, while low levels of CHOP expression promote B cell survival.
Aims: The aim of our study was to investigate TLR4 signaling in myeloma cells and to explore possible implications with ER UPR as a potential mechanism of drug resistance.
Results: First we found that TLR-4 mRNA is expressed at increased levels (2-10 fold) both in HMCLs and primary cells. To test the whether TLR-4 signaling may suppress CHOP expression during sustained UPR response, two HMCLs, H929 and U266, were pre-treated with low dose LPS (1 ng/mL) and then subjected to ER stress conditions with tunicamycin (TM).LPS pre-treatment significantly decreased CHOP mRNA expression but did not suppress ATF4 mRNA levels which also were not altered by TM treatment. Furthermore, LPS pre-treatment did not suppress XBP-1 splicing compared to the control ER-stressed cells. To test the specificity of these effects, similar experiments where performed on other cancer tissues such as ovarian cancer cell lines. Although LPS pre-treatment increased TLR-4 mRNA expression in SKOV3 ovarian cell line, CHOP mRNA levels remained unchanged prior and after treatment while TM treatment did not make any difference in CHOP mRNA expression. These results indicate the relevance of this pathway in MM cells which are highly dependent on the UPR as a repair mechanism. Apoptosis of pre-treated LPS myeloma cells which were

exposed to TM was reduced by 30% compared to the TM-stressed only cells as observed with Annexin-PI staining. Thus, downregulation of CHOP by TLR4 ligands may confer resistance to apoptotic stimuli and enhance survival of MM cells. Consequently we evaluated the activity of bortezomib in LPS pre-treated cell lines (U266 and JJN3). LPS pre-treatment partially abrogated the efficacy of bortezomib in these cell lines by decreasing its anti-proliferative effects compared to the non-LPS-pretreated cell lines as tested by the WST1 assay.Additional data on the mechanisms involved in these effects will be presented at the meeting. Then, we examined the impact bortezomib therapy on TLR4 and CHOP mRNA expression in primary tumors cells, collected before and at day 7 after bortezomib-based therapy from 6 myeloma patients. In 5 out of 6 cases TLR-4 expression was significantly up-regulated and was accompanied with a coupled down-regulation of CHOP mRNA expression.

Summary and Conclusions: In conclusion, our data suggest that the TLR-4 signaling pathway might provide a translational control pathway which enables cells to carry out essential protein synthesis and avoid CHOP-induced apoptosis. Further exploration of this pathway is needed to establish its role as a potential mechanism of drug resistance of MM cells.

ENDOPLASMIC RETICULUM STRESS-RELATED GENE EXPRESSION CAN PREDICT RESPONSE TO BORTEZOMIB IN MYELOMA

N Tomoko[1,*] R Masaki[1], M Ayako[1], F Mori[1], I Asahi[1], K Shigeru[1], I Takashi[1], K Hirokazu[1], N Akio[1], I Shinsuke[1]

[1]Department of Medical Oncology and Immunology, Nagoya City University Graduate School of Medical Sciences, Nagoya, Japan

Background: Bortezomib (BTZ), a proteasome inhibitor, is widely used in the treatment of Multiple Myeloma (MM). However, a fraction of MM patients shows poor response to the treatment.

Aims: To explore predictive biomarkers in terms of the efficacy of the BTZ, expression of proteasome and endoplasmic reticulum (ER) stress-related genes was evaluated in primary samples obtained from MM patients who received combination treatment of BTZ and Dexamethasone (BD) after informed consent being obtained in our institute.

Methods: Fifty-seven MM samples were collected prior to BD therapy, and subjected to mRNA analysis using real-time PCR. We then analyzed if their progression free survival (PFS) correlated with specific gene expression profiles. We artificially modulated the specific gene expression in MM cell lines to make sure its role in the sensitivity to BTZ.

Results: Fifty-seven patients were divided into two groups, *i.e.*, short PFS group (PFS=<6mos, n=32) and long PFS group (PFS>6mos, n=25). Among 15 genes analyzed, *ATF3* and *ATF4* expression levels were significantly lower in short responders (p=0.0157 and p=0.0085). When either *ATF3* or *ATF4* expression was silenced in KMS-11 cells, these cells became resistant to BTZ accompanied with lower induction levels of Noxa, CHOP and DR5 (Figure 1).

Figure 1.

Summary and Conclusions: Basal expression levels of *ATF3* and *ATF4* may be used as predictive biomarkers for the efficacy of BTZ in the patients with MM, although large-scale replication studies are still needed.

MODIFYING DNA REPAIR PATHWAYS IN CHEMOTHERAPY BY GENOTOXIC DRUGS – TOWARDS PERSONALIZED MYELOMA THERAPY

M Gkotzamanidou[1,*] M Shammas[1], AM Dimopoulos[2], KC Anderson[1], NC Munshi[1], V L Souliotis[3]

[1]Medical Oncology, Dana-Farber Cancer Institute, Harvard Medical School, Boston, United States, [2]Department of Clinical Therapeutics, University of Athens School of Medicine, [3]Medicinal Chemistry and Biotechnology, National Hellenic Research Foundation, Athens, Greece

Background: Melphalan is an alkylating agent producing N-alkylpurine-monoadducts, transformed in part into DNA interstrand crosslinks (ICL) and considered to be the critical cytotoxic lesions. ICLs are repaired by the coordination of several pathways, including nucleotide excision repair (NER), homologous recombination (HR) and non-homologous end-joining (NHEJ). High-dose melphalan (HDM) followed by autologous stem-cell transplantation (ASCT) has been the gold-standard of treatment for eligible patients with Multiple Myeloma (MM), while the combination with prednisone has been the reference regime for first line treatment of elderly patients for several decades. MM is the second most prevalent hematological malignancy. Despite recent advances in MM treatment, it remains an incurable disease. Hence, there is an urgent need for optimizing melphalan-based MM regimen by improving the patient classification, and identifying the patients who could most benefit.

Aims: In the present study, we focused on the potential involvement of HR and NHEJ pathways in the repair of melphalan-induced DNA damage in MM and on the link between DNA repair efficiency and clinical response to melphalan.

Methods: We examined two human MM cell lines (HMCLs; melphalan-sensitive RPMI-8226 and resistant LR5) and bone marrow plasma cells (BMPCs) from 30 newly diagnosed MM patients (16M/14F; median age 58 years) who consequently received HDM and supported by ASCT. All patients provided written informed consent. Patient response status was assessed according to the IMW Criteria. Primary cells and HMCLs were *ex vivo* treated with melphalan either alone or in combination with inhibitors of HR (RI-1) or NHEJ (SCR7) and the levels of the N-ras-specific monoadducts and ICLs were evaluated by Southern blot analysis, as well as DSBs (intermediates of ICL repair) by immunofluorescence γH2AX staining. The induction of apoptosis by melphalan, using a photometric enzyme-immunoassay, was also studied.

Results: Monoadducts, ICLs and DSBs repair efficiencies in BMPCs were correlated with clinical response of MM patients and categorized them into 2 groups, responders (≥PR, n=18) and non-responders (<PR, n=12) to melphalan therapy, with non-responders exhibiting significantly higher DNA repair efficiencies (all P<0.001). Also, melphalan-induced apoptosis in BMPCs inversely correlated with the repair efficiencies of all lesions examined, with the toxicity being significantly higher in responders than in non-responders (all P<0.01). To note, LR5 cells showed higher repair efficiencies of monoadducts, ICLs and DSBs and lower toxicity than RPMI-8226 cells. Furthermore, we found that the combined treatment of melphalan with the HR or NHEJ inhibitors had no effect on the repair efficiency of both monoadducts and ICLs, while suppressed the removal of DSBs. The γ-H2AX foci formation followed the timing of ICL formation and reached maximal levels within 8h. Thereafter, γ-H2AX foci levels declined rapidly, suggesting the resolution of the intermediate DSBs by downstream pathways (HR, NHEJ). Interestingly, the repair efficiency of DSBs in BMPCs was significantly higher in non-responders ($t_{1/2}$ of damage removal, 9h) than in responders ($t_{1/2}$ 12h) (P<0.02). Finally, the combined treatment of cells with melphalan and DNA repair inhibitors strongly enhanced the cytotoxic activity of melphalan (all P<0.01).

Summary and Conclusions: Our findings provide a mechanistic correlation between the efficiency of HR and NHEJ pathways and response to melphalan therapy. Specific inhibition of these DNA repair pathways might be an effective strategy to enhance sensitivity of cancer cells.

P345

***EX VIVO* HIGH THROUGHPUT DRUG SENSITIVITY AND RESISTANCE TESTING IDENTIFIES ONCOGENIC PATHWAY ADDICTION AND NOVEL TREATMENT OPTIONS FOR MULTIPLE MYELOMA**

MM Majumder[1,*] P Anttila[2], R Silvennoinen[3], R Karjalainen[1], H Kuusanmäki[1], J Lievonen[4], A Parsons[1], M Suvela[1], M Säily[5], K Porkka[4], C Heckman[1]

[1]University of Helsinki, Institute for Molecular Medicine Finland(FIMM), [2]Cancer Center, Helsinki University Central Hospital, Helsinki, [3]Hematology Unit, Kuopio University Hospital, Kuopio, [4]Hematology Unit, Helsinki University Central Hospital, Helsinki, [5]Hematology-Oncology Unit, Oulu University Hospital, Oulu, Finland

Background: Multiple myeloma (MM) is an incurable malignancy characterized by clonal expansion of malignant plasma cells. The introduction of novel therapies including proteasome inhibitors and immunomodulatory drugs has significantly improved overall survival in recent years. However, relapsed disease and drug resistance remain a major challenge.. *Ex vivo* drug testing offers a powerful tool to predict drug sensitivity and guide treatment decisions. This in turn also helps to understand dependency of oncogenic signaling networks based on the response against specific targets.

Aims: In the current study we aimed to identify drug sensitivity patterns, novel therapeutic options and elucidate critical signaling networks in newly diagnosed and relapsed MM patients using a chemical systems biology approach.

Methods: Plasma cells (CD138+) were enriched from fresh bone marrow aspirates derived from 8 diagnosed and 17 relapsed myeloma patients. The cells were screened against 306 oncology drugs (both approved and investigational) representing diverse mechanisms of actions. In order to detect any cytotoxic effects on other bone marrow cell populations, CD138 negative cells from the same sample were screened in parallel for 5 patients. A drug sensitivity score (DSS) and selective drug sensitivity score (sDSS) were calculated based on previously described methods (Pemovska *et al.*, 2013). These were used to compare drug responses across the sample cohort.

Results: Proteasome inhibitors, melphalan, CDK inhibitors and survivin inhibitors were cytotoxic to all cell populations tested in the *ex vivo* assay. Auranofin, an anti-rheumatoid drug targeting IKK showed select cytotoxicity towards

MM cells. In addition, CD138+ cells were selectively sensitive to epigenetic modulators such as the demethylase inhibitor GSK-J4 and the p53 activator PRIMA-1MET. Based on the *ex vivo* drug responses, three major subgroups of patients were identified. One subgroup showed extreme sensitivity to IGF1R, PI3K and ATP competitive mTOR inhibitors. Two subgroups showed varied sensitivity to MEK inhibitors. However, these drugs had no effect on the CD138 negative population, suggesting the CD138+ cell sensitivities were disease specific responses possibly due to the drugs targeting specific underlying molecular aberrations. We also identified a subgroup that was extremely refractory to most targeted drugs tested in our assay. However, this subgroup showed sensitivity to BCL2 inhibitors. In addition, approximately 33% of the MM samples tested responded to glucocorticoids. No clear difference in drug response was observed between MM samples obtained from diagnosed or relapsed patients. Currently we are gathering genomic, transcriptomic and epigenetic data to understand detailed molecular events that help to explain drug responses in each patient subgroup

Summary and Conclusions: Based on an *ex vivo* high throughout chemical biology assay, we identified three subgroups of myeloma patients. The subgroups were defined based on select sensitivity to specific classes of targeted drugs. From the drug sensitivity profiles, PI3K/mTOR, MAPK, IGF1R mediated pathways appeared to be active in malignant plasma cells and likely play important roles in MM pathogenesis. These results suggest that targeting those pathways may be an extremely effective strategy to selectively eradicate MM cells, and argues in favor of individualized treatment design based on *ex vivo* drug response and disease molecular profiles.

D'Annunzio" University, Chieti, [6]Unit of Hematology, IRCCS-Centro di Riferimento Oncologico della Basilicata, Rionero in Vulture, [7]Department of Biomedical Sciences and Human Oncology, University of Bari Medical School, Bari, Italy, [8]Department of Biochemistry and Molecular Biology, Monash University, Melbourne, Australia, [9]Scientific Direction, IRCCS-Centro di Riferimento Oncologico della Basilicata, Rionero in Vulture, [10]Cellule Staminali Post-Natali e Terapia Cellulari, IRCCS- G. Gaslini Institute, Genoa, Italy

Background: Multiple myeloma (MM) remains an incurable malignancy despite important recent advances in treatments. Neo-vascularization entails a crucial aspect of interactions between neoplastic plasma cells (PCs) and their microenvironment. Without it, MM would be unable to grow and progress, and would probably regress to a low-mass steady-state comparable to monoclonal gammopathy of undetermined significance (MGUS). To overcome drug resistance and improve clinical response to novel therapeutic approaches halting both PC growth and the increased bone marrow (BM) microvascular density are needed. In this setting, monoclonal antibodies against MM-specific cell surface antigens represent a promising therapeutic approach, which is, however, hampered by a lack of appropriate membrane target structures expressed across all MM cells. The Eph receptors, a large family of receptor tyrosine kinases, have been implicated in many processes involved in malignancy, including alteration of the tumour microenvironment, and in angiogenesis, in both of which EphA3 likely plays an active role. Interestingly, the over-expression of EphA3 is sufficient to confer tumorigenic potential, although probably further mechanisms can occur to abnormally activate the receptor. A first-in-class engineered IgG1 antibody targeting the EphA3 was developed and it is now under phase I clinical trials in USA and Australia for the treatment of EphA3 over-expressing hematological myeloid malignancies refractory to conventional treatment.

Aims: We investigated the role of EphA3 in MM angiogenesis and the effect of a specific monoclonal antibody to define EphA3 as a new possible therapeutic target in MM.

Methods: EphA3 mRNA and protein were evaluated in endothelial cell (ECs) of 40 patients with active MM (MMECs), 10 with monoclonal gammapathies of undetermined significance (MGECs), and 8 with benign anemia (ECs controls) by absolute real time PCR and by western blot coupled to immunofluorescence and FACS analysis respectively. Immunoistochemistry was also performed on MM BM biopsies. The biological effects of EphA3 targeting were studied *in vitro* silencing (siRNA) the EphA3 mRNA in MMECs and using the anti EphA3 antibody testing them in series of *in vitro* functional assays including viability, apoptosis, adhesion, migration, wound healing and angiogenesis tests.The expession of EphA3 pro-angiogenic targets in silincing MMECs was studied by gene expression profiling. We further examined the inhibitory capacity of anti-EphA3 antibody (Ab) on tumor growth in SCID mice bearing MM tumor cell xenografts. Finally, we assessed morphology, vessel density, and apoptosis of excised xenotransplanted tumors.

Results: Briefly, our data showed that EphA3 mRNA and protein levels were progressively increased from ECs to MGECs, reaching the highest values in MMECs. EphA3 stained intensely and diffusely MM microvessels and PC in MM BM biopsies. The EphA3 targeting by either siRNA or anti EphA3 Ab impaired the MMECs angiogenesis related functions both *in vitro* (Figure 1) and *in vivo*. In particular, tumour masses developed in xenograft mice treated with anti-EphA3 Ab were smaller in size and showed foci of ischemic-hemorrhagic necrosis, in association with a significant ($P < 0.05$) reduction in the number of intact tumor microvessels compared to the mice treated with control isotype antibody. Finally, the transcriptional profiles of EphA3-siRNA MMECs showed a downregulation of the adhesion, migration and angiogenesis molecules such as RYK, JAM2, VEGFA, FLNA, CD148.

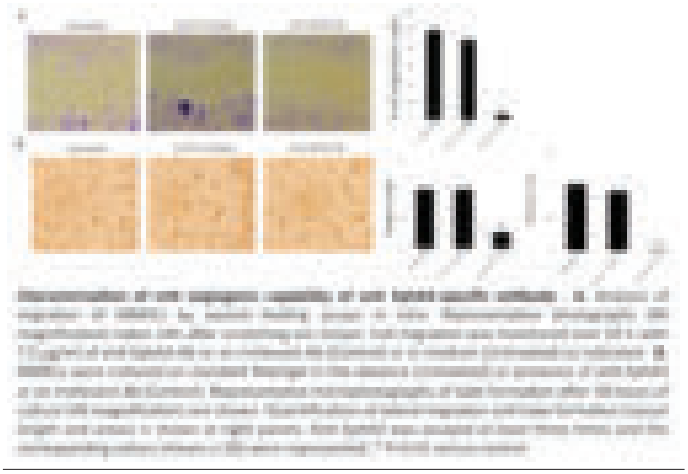

Figure 1.

Summary and Conclusions: EphA3 plays a critical role in MM angiogenesis; the anti EphA3 Ab inhibits this process *in vitro* and *in vivo*. EphA3 targeting could represent a new possible strategy for the treatment of MM patients.

Myeloma and other monoclonal gammopathies - Clinical 1

INITIAL RESULTS FROM A PHASE 2 STUDY OF CARFILZOMIB, LENALIDOMIDE, AND LOW-DOSE DEXAMETHASONE (KRD) PLUS AUTOLOGOUS STEM CELL TRANSPLANTATION (ASCT) IN NEWLY DIAGNOSED MULTIPLE MYELOMA (NDMM)

TM Zimmerman[1,*] K Griffith[2], JK Jasielec[1], CA Rosenbaum[1], K McDonnell[1], J Marin[1], J Bakker[1], JG Berdeja[3], R Vij[4], AJ Jakubowiak[1]
[1]The University of Chicago, Chicago, [2]University of Michigan, Ann Arbor, [3]Sarah Cannon Cancer Center, Nashville, [4]Washington University, St. Louis, United States

Background: In a previous phase 1/2 study, KRd provided a high stringent complete response (sCR) rate of 55% and durable disease control with a 3-year progression-free survival (PFS) of 79% and overall survival (OS) of 96% after extended treatment, with the majority of transplant-eligible patients (pts) deferring ASCT per study design (Jakubowiak *et al.* Blood 2012; Jasielec *et al.* ASH 2013).
Aims: We conducted a phase 2 study (NCT01816971) to assess whether incorporating ASCT into an extended KRd treatment plan can further improve outcomes in transplant-eligible pts with NDMM.
Methods: Pts with symptomatic NDMM per IMWG criteria and transplant candidates were eligible for enrollment. All pts provided written informed consent. For induction (cycles 1–4), pts received 28-day cycles: carfilzomib (CFZ) IV on days 1, 2, 8, 9, 15, and 16 at 20 mg/m^2 days 1 and 2 of cycle 1 and 36 mg/m^2 IV thereafter; daily lenalidomide (LEN) 25 mg PO (d1–21); and weekly dexamethasone (dex) 40 mg IV/PO. After cycle 4, pts proceeded to stem cell collection with G-CSF+plerixafor followed by high-dose melphalan 200 mg/m^2 with ASCT. Post-ASCT (70–90 days), KRd was resumed as consolidation (cycles 5–8) with CFZ at the pre-transplant dose, dex reduced to 20 mg, and LEN reduced to 15 mg for the first consolidation cycle with the option to increase to pre-transplant tolerated doses for the remaining cycles (7+). For extended treatment (Cycles 9–18), KRd was given with a modified CFZ schedule (days 1, 2, 15, 16) followed by single-agent LEN maintenance until progression. The primary endpoint is rate of sCR at the end of cycle 8. Based on a sCR rate of 30% after 8 cycles in the prior study, we estimate that a sCR of 50% with KRd plus ASCT after 8 cycles will support further evaluation.
Results: As of February 24, 2014, 26 pts have been enrolled. Median age was 62y (range 44–76) and 58% of pts were ISS stage I/II. All 26 pts were evaluable for response and toxicity and continue protocol treatment: 13 pts completed induction, 11 pts completed ASCT, 9 started consolidation, and 8 completed consolidation. At a median of 4 KRd cycles (range 1–10), all 26 pts achieved ≥partial response (PR), 62% ≥very good PR (VGPR), and 23% sCR. After ASCT, ≥VGPR was 91% and sCR 27%.The rate of sCR at the end of 8 cycles (primary end-point) was 50%. In patients who completed ASCT and ≥1 cycle of KRd consolidation (range 5–10 total KRd cycles), the sCR rate was 75% and the rate of negative minimal residual disease by 9-color flow cytometry was 66%. After a median follow-up of 7 months (range 1–13), all pts were alive and progression free. There were no new or unexpected toxicities in the induction phase and no unexpected toxicities in the consolidation phase compared with those previously reported. Enrollment is continuing, with a target of 53 pts. Updated results will be reported during the meeting.
Summary and Conclusions: These preliminary data are very encouraging and suggest that pairing KRd with ASCT in NDMM can further increase the depth of response, possibly translating into improved survival outcomes.

P348

THE USE OF SINGLE AGENT ZOLEDRONIC ACID PREVENTS THE DEVELOPMENT OF BONE DISEASE COMPLICATIONS IN MYELOMA PATIENTS WITH ASYMPTOMATIC RELAPSES WITH NO DEMONSTRATED EFFECT ON SYMPTOMS PROGRESSION

R Garcia-Sanz[1,*] A Oriol[2], J De la Rubia[3], L Palomera[4], P Ribas[5], MT Hernández[6], MJ Moreno[7], J Bargay[8], A Ramírez[9], AI Teruel[10], MJ Blanchard[11], M Gironella[12], M Granell[13], JF San Miguel[14]
[1]Hematology, University Hospital of Salamanca, Salamanca, [2]Hematology, Hosptial Germans Trias I Pujol, Barcelona, [3]Hematology, Hospital La Fe, Valencia, [4]Hematology, Hospital Lozano Blesa, Zaragoza, [5]Hematology, Hospital Dr. Pesset, Valencia, [6]Hematology, Hospital Universitario de Canarias, Santa Cruz de Tenerife, [7]Hematology, Hospital Morales Meseguer, Murcia, [8]Hematology, Hospital Son Llázer, Palma de Mallorca, [9]Hematology, Hospital Central de Asturias, Oviedo, [10]Hematology, Hospital Clínico Universitario, Valencia, [11]Hematology, Hospital Ramón y Cajal, Madrid, [12]Hematology, Hospital Vall d'Hebron, [13]Hematology, Hospital Sant Pau, Barcelona, [14]Hematology, Clinica Universitaria de Pamplona, Pamplona, Spain

Background: Zoledronic Acid (ZOL) is presumed to have anti-myeloma effect, although it is small and the real clinical effect remains to be elucidated, especially without chemotherapy. Current therapies induce response in most patients, but virtually all of them relapse, usually with an initial M-component re-growth (biochemical relapse) with no clinical symptoms. In such a case, the usual decision is not to treat the patient at this point, a perfect situation to explore the antitumor benefit of ZOL in the absence of any other cytotoxic therapy.
Aims: To evaluate the potential anti-tumor effect of ZOL treatment in MM patients under asymptomatic biochemical relapse after prior standard therapy. Primary end-point was Symptomatic Progression Free Survival (sPFS). Secondary evaluation variables were response rate, skeletal related events and time to next chemotherapy.
Methods: Patients and methods: Since JUN10 to JUL12, 100 patients were recruited in a randomized, prospective, open label phase IV trial in which a group of patients received ZOL (4 mg iv./4 wk, 12 doses) or no ZOL. All patients were monitorized every 4 wk until AUG13 in which database was closed.
Results: Results: 51 pts were randomized to receive ZOL while 49 received no ZOL. All patients were in Asymptomatic Biochemical Relapse, median age 68yr (40-87) and male/female 53/47. M-component was IgG (72%), IgA (25%) and only light chain (3%). Relapse presented after 1, 2 or ³3 lines of therapy in 67%, 22% and 11% of cases, respectively. Prior treatment included transplant (66%), bortezomib (53%) or IMiDs (36%). 1-2 skeletal related events (SRE) had presented in 32% of cases. Bone marrow plasma cell infiltration by flow cytometry was low 1,65% (0,01%>96%), 44% abnormal (2-100%). FISH/cytogenetics was abnormal in 52% of cases: t(11;14) 19%, Rb deletion (alone) 17%, del(p53) 8%, t(4;14) 4% and t(14;x) 4%. ZOL and no ZOL groups were well balanced for prognostic features, prior response, and time from diagnosis the inclusion in the trial. 40 patients completed the 12 visits programmed in the trial and four terminated before completion due to patient refusal (n=2) and development of other diseases (n=2). The remaining 56 patients stopped the trial due to progression before 12 months (n=55) and osteonecrosis of the jaw development (n=1). Median sPFS since inclusion was of 309 days (10.1 months), being slightly longer for the ZOL group (13 months) *vs.* no ZOL group (9 months), although differences were not statistically significant. The 30-month projected sPFS was 38% *vs.* 19% for ZOL *vs.* no ZOL pts. (p>0,1). The pattern of symptomatic progression varied according to the group of therapy. Thus, in the group of patients not treated with ZOL, 33 progressions were noted: 17 progressed with more advanced bone disease (12 cases of new bone lesions or regrowth of prior lesions, 2 spinal cord compressions, and 3 cases of hypercalcemia), 14 with anemia and 2 with renal dysfunction. By contrast, 28 progressions were seen in the group of patients treated with ZOL: 6 with new or enlarged bone lesions, 19 with anemia, 1 with renal dysfunction, 1 with extramedullary growth and one hyperviscosity (P=0.031). There were 8 SRE that presented only in the group of patients treated without ZOL (p=0.003) (Figure 1).

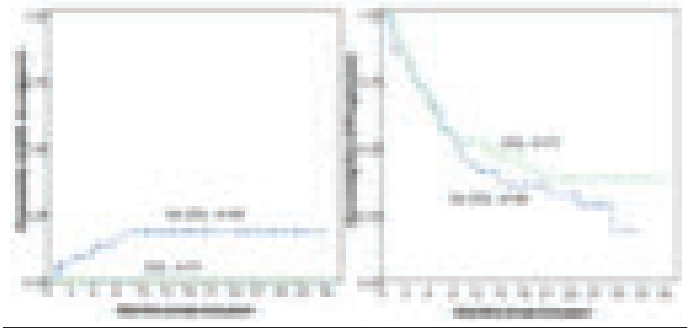

Figure 1.

Summary and Conclusions: Zoledronic Acid single therapy reduces the risk of progression with symptomatic bone disease and SREs in MM with asymptomatic relapse. The possible antitumor effect of Zoledronic Acid alone in biochemical relapses could not be completely demonstrated. These results support the use of Zoledronic acid alone in patients with biochemical relapses or progressions in whom the physician decides not to initiate cytotoxic therapy based on the absence of symptomatic disease.

Background: Rd and MPR showed to be effective and safe in newly diag-

nosed multiple myeloma (MM) patients. Cyclophosphamide is a less toxic alkylating alternative agent. A formal comparison between 2-drug and 3-drug lenalidomide-containing combinations has not yet been performed.
Aims: To compare a not-alkylating regimen (Rd) *vs* two different alkylating-based regimens (MPR or CPR) in a community-based setting of MM pts ≥65 years old or not eligible for autologous stem cell transplantation. The primary endpoint was progression-free survival (PFS).
Methods: 662 patients with newly diagnosed MM were randomized to receive nine 28-day cycles of Rd, MPR or CPR. Upfront dose reductions of dexamethasone, melphalan and cyclophosphamide were performed according to patients age (Rd: lenalidomide 25 mg/day for 21 days; dexamethasone 40 mg on days 1,8,15 and 22 in pts 65-75 years old and 20 mg in those >75 years; MPR: lenalidomide 10 mg/day for 21 days; melphalan orally 0.18 mg/Kg for 4 days in pts 65-75 years old and 0.13 mg/Kg in >75 years pts; prednisone 1.5 mg/Kg for 4 days; CPR: lenalidomide 25 mg/day for 21 days; cyclophosphamide orally 50 mg/day for 21 days in pts 65-75 years old and 50 mg every other day in >75 years pts; prednisone 25 mg every other day). After induction, patients were randomized to receive maintenance with lenalidomide alone (R) or with prednisone (RP), until disease progression.
Results: Patients characteristics were well balanced in all groups. 212 patients in Rd, 210 in MPR and 220 in CPR arm were evaluable for response. After induction, at least partial response (PR) rate was 78%, 73% and 73% in Rd, MPR and CPR arms, respectively (Rd *vs* MPR p=0.138; Rd *vs* CPR p=0.205). After a median follow-up of 26 months, median PFS was 22 months in Rd, 27 months in MPR and 23 months in CPR patients (Rd *vs* MPR p=0.231; Rd *vs* CPR p=0.862). Grade ≥3 hematologic adverse events were 29% in Rd, 67% in MPR and 32% in CPR arms (Rd *vs* MPR p<0.0001; CPR *vs* MPR p<0.0001). No difference was noticed in grade ≥3 non-hematologic adverse events between the treatment groups: 29% with Rd, 31% with MPR, 30% with CPR. 203 patients in the R group and 198 in the RP group started maintenance treatment. After a median follow-up of 18 months, 2-year PFS from the beginning of maintenance treatment was 52% in R and 58% in RP patients (p=0.570). A sub-group analysis according to patient's frailty, as established by ADL, IADL, Charlson scores and age (Larocca A, *et al.* Blood ASH meeting 2013; 122: abstract 687) was conducted. No significant PFS difference was reported among the three arms in fit and frail patients. Grade ≥3 hematologic toxicity was sensibly higher in the MPR arm in both fit and frail patients.
Summary and Conclusions: In a community-based population, triplet alkylating combinations do not offer a significant PFS advantage over doublet therapy without alkylating agents. In a subgroup analysis according patient's frailty, PFS was similar in fit, unfit and frail patients regardless of treatment, yet grade ≥3 hematologic toxicity was higher with MPR. Updated data will be presented at the meeting.

P350

SAFETY AND EFFICACY OF DARATUMUMAB WITH LENALIDOMIDE AND DEXAMETHASONE IN RELAPSED OR RELAPSED, REFRACTORY MULTIPLE MYELOMA.

T Plesner[1,*] HT Arkenau[2], HM Lokhorst[3], P Gimsing[4], J Krejcik[1], C Lemech[2], MC Minnema[3], U Lassen[4], T Ahmadi[5], H Yeh[5], M Guckert[5], N C Brun[6], S Lisby[6], L Basse[6], A Palumbo[7], PG Richardson[8]
[1]Vejle Hospital,, Vejle, Denmark, [2]Sarah Cannon Research Centre, London, United Kingdom, [3]UMC Utrecht, Utrecht, Netherlands, [4]Copenhagen University Hospital, Copenhagen, Denmark, [5]Janssen Research & Development, New Jersey, United States, [6]Genmab A/S, Copenhagen, Denmark, [7]University of Torino, Torino, Italy, [8]Dana-Farber Cancer Institute, Boston, United States

Background: Daratumumab (DARA) (HuMax™-CD38), a human IgG1κ monoclonal antibody effectively mediates destruction of CD38-expressing malignant plasma cells. In the first-in-human dose-escalation study, 42% of heavily pretreated patients with relapsed or relapsed, refractory (RR) multiple myeloma (MM) treated with DARA alone (≥4mg/kg) achieved partial response (PR) and 25% had minimal response (MR) (modified IMWG guidelines). In preclinical studies, DARA+lenalidomide (LEN) enhanced killing of MM cells *in vitro.*
Aims: We evaluated safety, pharmacokinetics (PK) and efficacy of DARA+LEN+dexamethasone (DEX) in patients with relapsed or RR MM.
Methods: In this ongoing phase I/II open-label multicenter dose-escalation (part 1) study, patients (≥18 years old) with life expectancy ≥3 months and ECOG status 0, 1 or 2 received DARA+LEN+DEX: (DARA [2-16 mg/kg] per week [8 wks], twice a month [16 wks], then, once monthly until disease progression, unmanageable toxicity or 24 months in total; LEN [25 mg]; DEX [40 mg] once weekly). Cohort expansion (part 2) study explores testing of maximum DARA dose determined in part 1.
Results: Data from 12 patients (10 men, 2 women), median age 62 years (48-76) are evaluable to date. Median prior therapies: 4 (2-4); median ECOG status: 0.5 (0-1); median DARA infusions: 14.5 (1-23); median infusion time: 6.6 (5.9-7.3) hours. One patient (2 mg/kg dose) withdrew from study due to recurrent grade 1 QT prolongation and hypokalemia. Most frequent (>40% patients) adverse events were neutropenia and diarrhea; 17 were ≥grade 3 with 70% hematological (neutropenia, thrombocytopenia, anemia). MTD was not reached. DARA+LEN+DEX PK-profile was similar to DARA alone suggesting LEN and DEX do not affect the DARA PK-profile. Available preliminary efficacy data from 11 patients demonstrated marked decrease in M-protein in all patients; 8/11 patients achieved PR or better, 5/11 with VGPR, 2/11 with MR. Median time to response was 4.1 weeks (2.1-4.3).
Summary and Conclusions: DARA+LEN+DEX has favorable safety profile with manageable toxicities in relapsed and RR MM. Encouraging early activity is seen with marked reduction in M-protein and 8/11 patients (72%) achieving PR or better. Longer follow up is necessary to estimate overall depth of response.

P351

POMALIDOMIDE, BORTEZOMIB, AND LOW-DOSE DEXAMETHASONE (PVD) IN LENALIDOMIDE-REFRACTORY AND PROTEASOME INHIBITOR-EXPOSED MYELOMA: THE MM-005 TRIAL

P Richardson[1,*] C Hofmeister[2], N Raje[3], D Siegel[4], S Lonial[5], J Laubach[1], Y Efebera[6], DH Vesole[4], AK Nooka[5], J Rosenblatt[7], MH Zaki[8], Y Hua[8], Y Li[8], S Shah[8], J Wang[8], KC Anderson[1]
[1]Jerome Lipper Multiple Myeloma Center, Dana-Farber Cancer Institute, Boston, [2]Division of Hematology, Ohio State University, Columbus, [3]Massachusetts General Hospital, Boston, [4]John Theurer Cancer Center at Hackensack UMC, Hackensack, [5]Winship Cancer Institute, Atlanta, [6]The Ohio State University, Columbus, [7]Beth Israel Deaconess Medical Center, Boston, [8]Celgene Corporation, Summit, United States

Background: The combination of an immunomodulatory drug (lenalidomide [LEN] or pomalidomide [POM]) with the proteasome inhibitor (PI) bortezomib (BORT) and low-dose dexamethasone (LoDEX) has demonstrated activity in multiple myeloma patients (pts; Richardson PG. *Blood.* 2014; Nooka AK. *Leukemia*. 2013). POM has been approved in Europe in combination with LoDEX for the treatment (Tx) of relapsed and refractory multiple myeloma (RRMM) pts who have received ≥2 prior Tx, including LEN and BORT, and have demonstrated progressive disease (PD) on the last therapy.
Aims: MM-005 is a phase 1 study designed to identify the optimal dose of POM, BORT, and LoDEX combination therapy (PVD) for a phase 3 trial (MM-007) comparing PVD *vs.* BORT+LoDEX in RRMM pts.
Methods: Eligible pts received 1-4 prior lines of Tx, including ≥2 consecutive cycles of LEN and a PI. Pts must have been LEN refractory and PI exposed but not BORT refractory. The maximum tolerated dose (MTD) was determined using a 3+3 design. Each cohort received 21-day cycles of POM (1-4 mg/day on days 1-14), intravenous (IV) BORT (1-1.3 mg/m^2 on days 1, 4, 8, and 11), and LoDEX (20 mg/day on days 1, 2, 4, 5, 8, 9, 11, and 12; pts aged >75 years [yrs] received 10 mg/day on days 1, 2, 4, 5, 8, 9, 11, and 12). A 6-pt cohort was added to receive subcutaneous (SC) BORT at the MTD. Tx continued until PD or unacceptable adverse event (AE). MTD was the primary endpoint; additional endpoints included safety, overall response rate (ORR; ≥partial response [PR]), time to response (TTR), duration of response (DoR), pharmacokinetics, and the safety and efficacy of SC BORT.
Results: The trial is fully enrolled (N=28): 22 pts in IV BORT and 6 pts in SC BORT cohorts. Median prior Tx was 2 (range, 1-4). No dose-limiting toxicities (DLTs) were observed. Recommended PVD dose (21-day cycles) was found to be POM 4 mg on days 1-14; BORT 1.3 mg/m^2 on days 1, 4, 8, and 11 for cycles 1-8 and days 1 and 8 for cycle 9+; and LoDEX 20 mg (10 mg for pts >75 yrs) on days 1, 2, 4, 5, 8, 9, 11, and 12 for cycles 1-8 and days 1, 2, 8, and 9 for cycle 9+. The most common grade 3-4 AEs that occurred in the IV cohort included: neutropenia (36%) and thrombocytopenia (27%); for the SC cohort, a total of 7 grade 3 AEs were recorded (1 pt for each); no grade 4 AEs were observed. Peripheral neuropathy (PN) in IV cohorts was 0% grade 3-4, 14% grade 2, and 32% grade 1; 1 pt reported grade 2 PN in the SC cohort. No pt discontinued due to Tx-related AEs. ORR (IV cohorts) was 71% (38% ≥very good PR [VGPR]), median TTR was 1 cycle, and median DoR was 11 cycles. Preliminary ORR (median 5 cycles received) for SC pts was 67% (1 PR, 2 VGPRs, 1 complete response [CR]). Four of 6 pts receiving SC BORT still remain on Tx, 1 of whom has not yet responded. Within these small cohorts, BORT administration route (IV *vs.* SC) did not appear to impact POM exposure, which was within the range previously observed. Additional long-term follow-up data will be presented.
Summary and Conclusions: PVD was well tolerated in LEN-refractory/BORT-exposed pts with no DLTs or discontinuations due to Tx-related AEs. PVD was effective in all cohorts, with an encouraging ORR of approximately 70%, including a high rate of VGPRs and a CR. These results provide further evidence that POM is tolerable and effective as part of combination therapies and support its use as a backbone in Tx strategies for RRMM. The optimal PVD dose identified is under further evaluation in the ongoing MM-007 phase 3 trial (N=782).

P352

THE REVII TRIAL: LENALIDOMIDE AND DEXAMETHASONE AS SECOND LINE TREATMENT IN MYELOMA FOLLOWED BY EXTENDED LENALIDOMID *VS* LEN/DEX

J Lund[1,*] A Gruber[1], B Lauri[2], C Blimark[3], A Swedin[4], M Hansson[4], K Forsberg[5], L Ahlberg[6], C Carlsson[7], A Waage[8], P Gimsing[9], A J Vangsted[10], U Frølund[10], M Hardling[11], UH Mellqvist[3], H Nahi[1]

[1]Department of Hematology, Karolinska University Hospital, Stockholm, [2]Department of Internal Medicine, Sunderby Hospital, Luleå, Luleå, [3]Department of Hematology, Sahlgrenska University Hospital, Gothenburg, [4]Department of Hematology, Skåne University Hospital, Lund, [5]Department of Hematology, Norrland University Hospital, Umeå, [6]Department of Hematology, University Hospital of Linköping, Linköping, [7]Department of Internal Medicine, Hallands Hospital, Halmstad, Sweden, [8]Department of Hematology, Hospital of St Olav, IFK, NTNU, Trondheim, Norway, [9]Department of Hematology, Rigshospitalet, Copenhagen, [10]Department of Hematology, Hospital of Roskilde, Roskilde, Denmark, [11]Department of Hematology, Uddevalla Hospital, Uddevalla, Sweden

Background: The current indication for the use of lenalidomid in Europe is relapsed or refractory multiple myeloma patients and is based upon a subset analysis from two phase III studies (Weber 2007, Dimopoulos 2007), where the benefit of initiating lenalidomide plus betamethasone at first relapse was analyzed (Stadtmauer 2009). The analysis found that patients with only one prior therapy had significantly longer median TTP compared with those treated in later lines (17.1 months *vs.* 10.6 months).
Aims: Here we report outcomes from the REVII trial in 2nd line treatment of MM, a two part study with first an observational part with standard treatment of lenalidomide combined with corticosteroids and then, a randomized part, where patients that had responded in the first part, were randomized to lenalidomide combined with dexamethasone or lenalidomide as a single drug.
Methods: 132 patients with multiple myeloma in first relapse were included in the first, observational part of the study, and treated with up to 9 cycles of lenalidomide combined with betamethasone or dexamethasone according to local routines. Patients that had achieved at least partial response (PR) and had consolidation with at least two additional cycles were offered to take part in the second part of the study. Next where 63 patients were randomized to be treated with either lenalidomide combined with dexamethasone or lenalidomide as a single drug for a maximum of 24 cycles (96 weeks). In the first part the primary endpoint was time to response and the secondary endpoints were quality of life, safety and cytogenetic markers. In the second part primary endpoint was time to progression and secondary was safety. Survival data were calculated from first entry in the observational study. Data cutoff was 31st January 2014, with a median follow-up of 12 months.
Results: A very high proportion of patients achieved PR or better (≥PR 88%). [SP1] Of the patients 5% were primary refractory and progressed without any prior response and 7% got a minor response or stable disease. Very good partial response or better (≥VGPR) was achieved in 44% of the patients. First response was achieved after a median of 7.5 weeks and best response after a median of 10 weeks. The PFS for all patients at 12 and 18 months was 68% and 62%, respectively and the OS was 88% and 81% respectively. After randomizations no differences in responses between the Len and the Len/dex group were found. The PFS at 12 and 18 months was 84%/72% for the Len group and 86%/75% for the Len/Dex group (p=0.64). OS was 100%/86% for the Len group and 100%/92% for the Len/Dex group (p=0.94). Further results will be presented at the conference.
Summary and Conclusions: Len/Dex was associated with a very high response rate at 2nd line treatment of MM. On achieving at least PR, continuing with dexamethasone does not add any benefit for the patients regarding responses, PFS or OS.

P353

PRELIMINARY PRE-RANDOMIZATION RESULTS FROM A PHASE 3 STUDY OF FRONTLINE SUBCUTANEOUS (SC) BORTEZOMIB-BASED INDUCTION AND CONSOLIDATION IN TRANSPLANTATION-ELIGIBLE MULTIPLE MYELOMA (MM) PATIENTS (PTS)

Background: Induction chemotherapy followed by high-dose therapy (HDT) and autologous stem cell transplantation (ASCT) remains standard frontline treatment for eligible MM pts. Post-ASCT consolidation/maintenance may produce deeper/more prolonged responses leading to improved outcomes. Several studies have shown pre- and post-ASCT bortezomib (Btz)-based consolidation/maintenance to be well tolerated, and lead to increased CR and VGPR rates. SC Btz has demonstrated equivalent efficacy and improved tolerability compared to IV Btz in relapsed MM (Moreau *et al.*, Lancet Oncol 2011); however, data on frontline SC Btz are limited.
Aims: The overall study aim is to evaluate if SC Btz-thalidomide-prednisolone (VTP) consolidation after SC Btz-cyclophosphamide-dexamethasone (SC VCD) induction and HDT-ASCT produces an improved CR+VGPR rate compared with thalidomide-prednisolone (TP) consolidation (NCT01539083). This analysis was performed to evaluate the safety/tolerability of SC VCD induction and obtain preliminary response data prior to pt randomization to consolidation.
Methods: Consenting adults with previously untreated MM, ECOG PS 0–2, and who were HDT-ASCT-eligible were included. Pts received 3×21-d cycles of SC VCD induction (Btz 1.3 mg/m² SC d 1, 4, 8, 11; cyclophosphamide 300 mg/m² PO d 1, 8, 15; dexamethasone 20 mg PO d 1, 2, 4, 5, 8, 9, 11, 12), followed by peripheral blood stem cell (PBSC) mobilization, HDT (melphalan 200 mg/m², IV), and ASCT. Pts without evidence of disease progression post-ASCT were then randomized 1:1 to VTP or TP consolidation. Adverse events (AEs) were graded by NCI-CTCAE v4.0. Responses were investigator-assessed by IMWG criteria.
Results: At data cut-off (Nov 30, 2013), 187 pts had been enrolled at centers in Australia (88%), China (3%), and Korea (9%). Median age was 59 yrs (range 32–71), 55% were male, 32%/51%/17% had ISS stage I/II/III MM, and adverse cytogenetics included 7% t(4:14), 6% del 17p, 17% amp 1q, and 3% t(14:16). Pts received a median of 3 cycles of SC VCD (range 1–3); mean Btz dose intensity was 5.12 mg/m²/cycle (98% of planned). 152/162 (94%) pts had proceeded to the PBSC phase and 135/153 (88%) to ASCT. Overall, 31 pts had discontinued treatment (10, 8, and 13 during induction, PBSC phase, and ASCT, respectively), 8 due to AEs. 48 pts were ongoing (25, 9, and 14 in the induction, PBSC, and ASCT phases, respectively). At clinical cut-off for this analysis, 108/139 (78%) pts had proceeded to randomization to consolidation. Most common any-grade (G) treatment-emergent AEs during induction were constipation (35%), nausea (33%), and fatigue (25%). 34% of pts had G ≥3 AEs, including 6% neutropenia. 29% of pts had peripheral neuropathy (1 pt G 3), and 21% had injection site reactions (no G ≥3). Best confirmed response rates (≥PR) were 79% (25% CR+VGPR; 8% CR) post-induction, 83% (32% CR+VGPR; 10% CR) post-PBSC phase, and 87% (35% CR+VGPR; 13% CR) post-HDT-ASCT.
Summary and Conclusions: These data suggest that VCD incorporating SC Btz is a tolerable and active induction therapy in previously untreated MM pts. Rates of neuropathy and discontinuations due to AEs were low, and a substantial proportion of pts proceeded to ASCT. Preliminary response rates appear similar to previous large studies investigating VCD induction (Einsele *et al.*, ASH 2009, Goldschmidt *et al.*, ASH 2013). Randomization to consolidation is ongoing.

P354

GERIATRIC ASSESSMENT PREDICTS SURVIVAL AND RISK OF SERIOUS ADVERSE EVENTS FOR ELDERLY NEWLY DIAGNOSED MULTIPLE MYELOMA PATIENTS.

R Mina[1,*] A Larocca[1], M Offidani[2], S Bringhen[1], A La Fauci[2], R Hajek[3], V Montefusco[2], A Brioli[2], C Musolino[2], A P Falcone[2], A Siniscalchi[2], C Pautasso[1], T Guglielmelli[2], ID Vincelli[2], AM Liberati[2], VE Muccio[1], P Caraffa[2], G Benevolo[2], F Gentilini[2], S Pulini[2], L Pour[4], P Musto[2], M T Petrucci[2], P Sonneveld[5], M Boccadoro[1], A Palumbo[1]
[1]Myeloma Unit, Division of Hematology, University of Torino, Torino, [2]Italian Multiple Myeloma Network, GIMEMA, Italy, [3]University Hospital Brno and Faculty of Medicine OU, Ostrava, [4]University Hospital Brno and Faculty of Medicine MU, Brno, Czech Republic, [5]Erasmus University Medical Center, Rotterdam, Netherlands

Background: Multiple myeloma is a neoplastic disease typical of elderly patients and aging is associated with worse survival. Elderly patients are highly heterogeneous. Aging and frailty have a negative impact on treatment tolerance and outcome of cancer patients. A geriatric assessment can better define patient status and help physicians tailor treatment.
Aims: The primary endpoint was to define a frailty score and assess its impact on outcome and toxicity. The secondary endpoint was to assess its value in subgroup of patients defined at high risk by International Staging System (ISS) and Fluorescence *In Situ* Hybridization (FISH).
Methods: Newly diagnosed multiple myeloma (NDMM) patients enrolled in 3 prospective trials including lenalidomide, bortezomib or carfilzomib were retrospectively analyzed. At diagnosis, a geriatric assessment was performed to assess co-morbidities (Charlson index), cognitive and functional conditions [Activity of Daily Living (ADL) and Instrumental Activity of Daily living (IADL) scores].
Results: We assessed 869 NDMM elderly patients. The prognostic role of age (‹75, 75-80, ›80 years), Charlson (≤1, ≥2), ADL (›4,≤4) and IADL (›5, ≤5) indices on overall survival (OS) was investigated using the Cox proportional hazard

model. An additive frailty score was calculated (range 0-5) and three groups of patients were identified: fit (score=0, 39%); unfit (score=1, 31%), and frail (score ≥2, 30%). Progression-free survival (HR=1.68, CI 1.31-2.15, p<0.001) and OS (HR=3.57, CI 2.37-5.39, p<0.001) were significantly shorter for frail patients compared with fit patients. In a Cox's model including ISS, FISH risk group and type of therapy (lenalidomide *versus* no lenalidomide), frail patients showed a higher risk of disease progression (HR 1.48, CI 1.15-1.92, p=0.003) and death (HR 2.88, CI 1.88-4.40, p<0.001). The risks of grade 3 or higher non-hematologic adverse events (HR 1.57, CI 1.12-2.19, p=0.008) and drug discontinuation (HR 2.21, CI 1.57-3.09, p<0.001) were higher for frail patients. The cumulative incidence of non-hematologic grade 3 or higher adverse events was higher for frail patients, and 4-month rate was 7.4% in fit and 19.2% in frail patients. The combination of the frailty score with ISS staging significantly improved risk assessment (Figure 1).

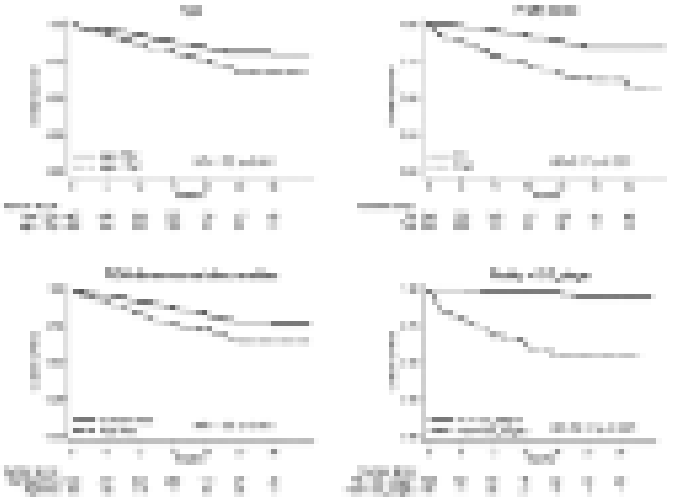

Figure 1.

Summary and Conclusions: This simple score system based on age and geriatric assessment is able to identify frail patients at higher risk of toxicities and with a poor outcome. This approach should be used in the clinical practice to improve patient outcome and quality of life, reducing adverse events and health-care related costs.

ORAL INVESTIGATIONAL PROTEASOME INHIBITOR IXAZOMIB CITRATE (MLN9708) PLUS LENALIDOMIDE-DEXAMETHASONE IN ELDERLY PATIENTS (PTS) WITH PREVIOUSLY UNTREATED MULTIPLE MYELOMA

PG Richardson[1,*] CA Rosenbaum[2], CC Hofmeister[3], M Htut[4], DH Vesole[5], JG Berdeja[6], M Liedtke[7], A Chari[8], SD Smith[9], D Lebovic[10], D Berg[11], E Liao[11], B Tejura[11], AM Hui[11], R Baz[12]

[1]Dana-Farber Cancer Institute, Boston, MA, [2]Hematology/Oncology, University of Chicago, Chicago, IL, [3]The Ohio State University, Columbus, OH, [4]Hematology and Stem Cell Transplant, City of Hope National Medical, Duarte, CA, [5]John Theurer Cancer Center at Hackensack University Medical Center, Hackensack, NJ, [6]Sarah Cannon Research Institute, Nashville, TN, [7]Stanford Cancer Institute, Stanford, CA, [8]Mount Sinai School of Medicine, New York, NY, [9]Oregon Health & Science University/now University of Washington, Fred Hutchinson Cancer Research Center, Seattle, WA, [10]University of Michigan, Ann Arbor, MI, [11]Takeda Pharmaceuticals International Co., Cambridge, MA, [12]Malignant Hematology, H. Lee Moffitt Cancer Center, Tampa, FL, United States

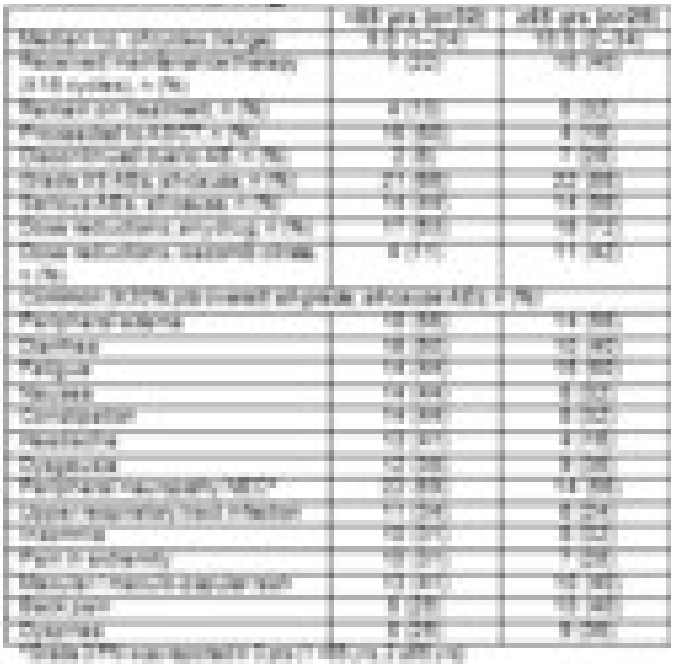
Background: Safe and effective novel long-term combination regimens are required for elderly multiple myeloma (MM) pts ineligible for autologous stem cell transplant (ASCT). Ixazomib citrate is the first oral proteasome inhibitor with reported clinical activity in MM. This phase 1/2 study investigated twice-weekly oral ixazomib citrate plus lenalidomide-dexamethasone in ASCT-eligible and -ineligible pts with previously untreated MM (NCT01383928). This subanalysis evaluates efficacy and safety in elderly *vs* younger pts.

Aims: Phase 1 objectives included evaluation of safety, tolerability, maximum tolerated dose (MTD), and recommended phase 2 dose (RP2D). Phase 2 objectives included assessment of CR+VGPR rate and overall response rate (ORR). This subanalysis evaluated efficacy and safety in elderly (≥65 yrs) *vs* younger (<65 yrs) pts, and includes data up to Jan 9, 2014 (median treatment duration, 6.9 months).

Methods: Pts received oral ixazomib citrate on days 1, 4, 8, and 11, lenalidomide 25 mg on days 1-14, and dexamethasone 20 mg on days 1, 2, 4, 5, 8, 9, 11, and 12 (reduced to 10 mg in cycles 9–16) in 21-day cycles. After 16 cycles, pts received only ixazomib citrate, on the same dose and twice-weekly schedule (maintenance therapy) until progression or unacceptable toxicity. Transplant-eligible pts could undergo stem cell collection after 3 cycles and ASCT after 6 cycles. In the phase 1 study, two fixed doses of ixazomib citrate were investigated: 3.0 and 3.7 mg. No AEs met the DLT criteria in cycle 1 at either dose of ixazomib citrate. The RP2D was selected as 3.0 mg.

Results: 64 pts (14 phase 1, 50 phase 2) were analyzed, including 38 aged <65 yrs and 26 aged ≥65 yrs (of whom six were aged ≥75 yrs); 32 and 25 pts, respectively, were treated at the RP2D. Disease characteristics were similar between the two age groups, though there was a trend for a higher ISS stage in older patients (39% and 58% stage II/III MM in pts aged <65 and ≥65 yrs, respectively). The CR+VGPR rate in pts aged <65 and ≥65 yrs was 67% and 65%, respectively (including 33% and 23% CR, and 33% and 42% VGPR), and ORR was 92% and 96%, respectively. At the time of data cut-off, 8 patients, all <65 yrs, had disease progression. Data on treatment exposure, disposition, and common AEs at the RP2D are shown in the Table 1. The types of treatment-emergent AEs were similar between the age groups, although the frequency could be different; for example, the incidences of diarrhea, nausea, and PN were higher in the <65 yrs group, whereas the incidence of fatigue was higher in the ≥65 yrs group, and the incidence of rash was similar in the two groups. Patients aged ≥65 yrs experienced more Grade ≥3 and serious AEs and required more dose reductions, but also stayed on the study drug longer. There was one on-study death at cycle 4, due to cardiorespiratory arrest (likely PE) in a pt aged 82 yrs (considered related to lenalidomide by the investigator). There was no evidence of cumulative toxicities.

Table 1. Treatment exposure, disposition, and common AEs at the RP2 ofixazomib citrate (3.0 mg).



Summary and Conclusions: These data suggest that the oral triplet combination of ixazomib citrate plus lenalidomide-dexamethasone is associated with encouraging antitumor activity across the age groups analyzed, with CR+VGPR rates of 65-67% and CR rates of 23-33%. Reversible and manageable toxicities, with limited grade 3 PN, were seen regardless of age. The data support further studies using weekly dosing, including ongoing phase 3 trials.

Background: Pts with RR MM received DARA for 9 wks in doses of 0.005-24mg/kg in the GEN501 dose-escalation part[1].

Aims: The purpose of the GEN501 expansion part was to evaluate safety and efficacy of 2 doses of DARA for up to 24 mths using alternate dose schedules.
Methods: Pts ≥18 yrs, RR to at least 2 prior lines of therapy, incl. IMiDs and proteasome inhibitors, and ineligible for salvage ASCT were enrolled at 2 dose levels: A) 8mg/kg +/- pre-dose (10mg) wkly for the first 8 infusions; B) 16mg/kg without pre-dose with a 3-wk washout period between the first 2 doses followed by 7 wkly doses. All pts were then dosed every 2nd wk for 16 wks followed by dosing every 4th wk until disease progression, toxicity or for max 24 mths.
Results: Data from 30 pts in the 8mg/kg cohort and 15 pts in the 16mg/kg cohort recruited into the GEN501 expansion part are presented. Median age was 58.2 (35.1-76.9) and 64.1 (50.5-75.0) years, prior treatment lines were 5 (3-11), and 4 (2-8) and time since diagnosis was 5.5 (2.1-15.2) and 7.1 (0.4-13.3) years, respectively. Median number of DARA infusions was 10.5 *vs* 7.0, reflecting the more recent initiation of the 16mg/kg cohort. Mean infusion times were 3.5 *vs* 3.4 hours in the 8 and 16mg/kg groups, respectively (Table 1).

Table 1. Response.

	PD	SD	MR	PR	VGPR	ORR[A]
8 mg/kg n=30	9	14	5	2	0	7%
16 mg/kg n=13[B]	3	3	1	3	3	46%

[A]PR or better.
[B]2 pts had 1st dose at data cut-off.

Safety. No dose-related increase in adverse events (AEs) was observed. Most common AEs reported (in ≥20% of all pts) were pyrexia, allergic rhinitis, fatigue, upper respiratory tract infection, diarrhea, dyspnea and cough. Only mild (Gr 1 & 2) infusion-related reactions (IRRs) were reported with 20% in the 8mg/kg group *vs.* 27% in the 16mg/kg group. Six patients had thrombocytopenia; one was considered related to DARA. One SAE of lymphocytopenia observed was considered related to DARA. One pt was withdrawn after first full dose due to decreased platelet count Gr 4. This patient received the first full infusion when the platelets were Gr 3. Omission of the pre-dose increased neither the incidence nor the severity of IRRs.
Summary and Conclusions: DARA monotherapy in RR MM pts resulted in high single agent activity when administered at 16 mg/kg (46% ORR). Toxicities proved manageable, with an overall favorable safety profile. Full response data will be presented at the meeting including bone marrow assessments.

P357

EFFICACY AND SAFETY OF THREE SUBCUTANEOUS BORTEZOMIB COMBINATIONS IN ELDERLY, NEWLY DIAGNOSED MULTIPLE MYELOMA PATIENTS

C Cerrato[1,*] S Oliva[1], MT Petrucci[2], P Caraffa[2], C Nozzoli[2], P Finsinger[2], A Larocca[1], L De Rosa[2], L De Paoli[2], V Montefusco[2], E Saraci[1], O Villani[2], AM Carella[2], G Benevolo[2], F Morabito[2], AM Liberati[2], D Derudas[2], M Boccadoro[1], P Sonneveld[3], A Palumbo[1]
[1]Myeloma Unit, Division of Hematology, University of Torino, Torino, [2]Italian Multiple Myeloma Network, GIMEMA, Italy, [3]Erasmus University Medical Center, Rotterdam, Netherlands

Background: Multiple myeloma is primarily a disease of the elderly. Frail elderly patients are more susceptible to adverse events (AEs) and drug discontinuation, thus suggesting the need for an adapted-reduced dose strategy. Weekly and subcutaneous (sc) bortezomib administration was associated with a significant reduction in AEs, particularly peripheral neuropathy (PN), without affecting efficacy. (Moreau P, *et al. Lancet Oncol*. 2011;12(5):431-40)
Aims: To assess efficacy and safety of 3 reduced-dose intensity sc bortezomib-based treatments in elderly, newly diagnosed multiple myeloma (NDMM) patients.
Methods: Patients with NDMM ≥75 years, or younger with comorbidities, were enrolled. Induction phase consisted of nine 28-day cycles with sc bortezomib 1.3 mg/m^2 on days 1, 8, 15, 22, plus oral prednisone 50 mg every other day (VP) or VP plus oral cyclophosphamide 50 mg every other day (VCP) or oral melphalan 2 mg every other day (VMP), followed by maintenance with sc bortezomib every 2 weeks until progression. A geriatric assessment was performed at baseline and included Charlson comorbidity index, Activity of Daily Living score (ADL) and Instrumental Activity of Daily Living score (IADL).
Results: Overall, 152 patients were enrolled: 51 patients in the VP, 51 in the VCP and 50 in the VMP groups. Median age was 78 years and 30% of patients were older than 80 years. By combining the geriatric assessment with age, patients were classified as fit (18%), unfit (28%) or frail (54%). International Staging System III and High-Risk Interphase Fluorescence *In Situ* Hybridization profile [presence of del17 and/or t(4;14) and/or t(14,16)] were well balanced in the three groups. The overall response rate (ORR) was 67% in the VP, 67% in the VCP, and 80% in the VMP groups. After a median follow-up of 21 months, the median PFS was 15, 15 and 22 months (p=not significant) and 2-year OS estimates were 62%, 76% and 81% (p=not significant) in the VP, VCP and VMP group, respectively. Grade ≥3 hematological AEs occurred in less than 10% in all the three groups during induction. Grade ≥3 non-hematologic AEs were mainly infections (12%) and cardiovascular events (8%), and they were particularly higher in patients receiving melphalan (22% of infections and 14% of cardiac events). Grade ≥3 peripheral neuropathy (PN) was 6% in all groups. From start of maintenance, the median follow-up was 9 months and the median PFS was 6 months, no significant differences between the cohorts were noticed. Maintenance was well tolerated and grade ≥3 AEs were less than 4%. The median PFS 14 months in patients <75 years, 15 months in patients 75-80 years and 16 months in patients >80 years (p=not significant) and the respective 2-year OS was 67%, 76%, 74%, respectively; p=not significant). A slight increase in discontinuation rate for toxicities or death associated with age was detected (16%, 20%, 25%, respectively). The 2-year OS was 88% in fit, 79% in unfit and 64% in frail patients (p=0.019 for frail *vs* fit), the respective grade ≥3 AEs were 30%, 39% and 44%. Discontinuation rate due to toxicity or death was 11% in fit, 21% in unfit and 26% in frail patients.
Summary and Conclusions: The combinations VP, VCP and VMP with subcutaneous bortezomib showed similar efficacy in elderly NDMM patients, whereas a worse safety profile was observed in patients receiving 3 drugs, particularly when melphalan was used. Geriatric assessment is essential to identify at baseline fit, unfit and frail patients and should be routinely performed.

P358

RICOLINOSTAT (ACY-1215), THE FIRST SELECTIVE HISTONE DEACETYLASE 6 INHIBITOR, IS ACTIVE AND WELL TOLDERATED IN COMBINATION WITH LENALIDOMIDE OR BORTEZOMIB IN PATIENTS WITH REFRACTORY MYELOMA

N Raje[1,*] D Vogl[2], W Bensinger[3], P Voorhees[4], P Hari[5], J Berdeja[6], S Jagannath[7], S Jones[8], C Wheeler[8], J Supko[1], R Orlowski[9], P Richardson[10], S Lonial[11]
[1]Massachusetts General Hospital, Boston, [2]University of Pennsylvania, Philadelphia, [3]Fred Hutchinson Cancer Research Center, Seattle, [4]University of North Carolina, Chapel Hill, [5]Medical College of Wisconsin, Milwaukee, [6]Sarah Cannon Research Institute, Nashville, [7]Mt Sinai Hospital, New York City, [8]Acetylon Pharmaceuticals Inc., Boston, [9]MD Anderson Cancer Institute, Houston, [10]Dana Farber Cancer Institute, Boston, [11]Winship Cancer Institute, Emory University School of Medicine, Atlanta, United States

Background: Ricolinostat, an oral selective HDAC6 inhibitor, is well tolerated in the clinic as monotherapy and demonstrates potent synergistic activity with bortezomib (BORT) (Raje Blood, V20(210):4061) and with lenalidomide (LEN) in preclinical models. Ricolinostat is being developed as a combination agent in relapsed or refractory (R/R) multiple myeloma (MM).
Methods: Two parallel open label single arm phase I/II trials study ricolinostat with BORT (ACY-100), and LEN (ACE-MM-101) with dose escalation in a 3+3 design in R/R MM patients (pts). In ACY-100, R/R pts who received at least two lines of therapy (tx) including a proteasome inhibitor and an immunomodulatory agent, ineligible for or refused autologous stem cell transplant (ASCT), had adequate marrow reserve and hepatic function with creatinine clearance (CrCl)>30mg/mL, were eligible for the phase 1b study. BORT 1.0-1.3 mg/m^2 on days 1, 4, 8 and 11 and Dex 80 mg/week were combined with escalating doses of ricolinostat up to 160 mg bid days 1-5, 8-12 on a 21 day schedule. ACE-MM-101 included R/R pts who received at least one prior tx and have CrCl>50 mg/mL and other entry criteria as above. LEN 25 mg is given daily on 21 days of a 28 day schedule, with ricolinostat on a schedule of up to 160 mg bid days 1-5, 8-12 and 15-19 or continuous 21 day dosing if tolerated. Peripheral blood samples were obtained for PK and PD assessment of acetylated tubulin and acetylated histones in both trials.
Results: As of Jan 31, 2014 25 heavily pretreated pts enrolled in ACY-100. 72% were refractory to the most recent tx. Treatment emergent AEs were mostly grade 1-2 and not attributed to study drug. AEs ≥grade 3 were hematologic abnormalities (8), elevated amylase (2), other asymptomatic laboratory abnormalities (3), and one pt with stomach cramps, diarrhea, and fatigue. One pt with cardiac history had a fatal pulmonary embolism after 3 cycles of tx. 17/25 pts were evaluable for response; the overall response rate was 47% in evaluable pts, or 33% of the ITT population. Eleven pts refractory to BORT were evaluable for response. One pt had CR, one had PR and 9 had SD with median time on study 4 (2-18) cycles. 21 pts have been enrolled in the ACE-MM-101 trial and completed a median of 6 (1-17) cycles. 9 pts received ≥3 prior txs, and 8 pts were refractory to the most recent tx. Treatment emergent AEs were mostly low grade and not considered related to ricolinostat and included diarrhea, fatigue, headache, muscle spasms, neutropenia, rash and upper respiratory infection. Two grade 3 neutropenia events were considered possibly related to ricolinostat. All pts had ≥SD as the best response. 66.6% had ≥PR, including 1 CR, 4 VGPR, 9 PR, 3 MR, seventeen pts had prior LEN tx. Seven patients were refractory to either full dose or maintenance LEN. One pt had VGPR, one PR, one MR and four SD. PK and PD: There were no drug-drug interactions with ricolinostat and LEN or BORT. PK was dose proportional up to 160 mg with

C_{max} 1-2 μM. PD showed increased acetylated tubulin, a marker of HDAC6 inhibition, in all pts ≥160 mg and showed increased acetylated histone, a Class 1 HDAC marker, at 240 mg.
Summary and Conclusions: Ricolinostat (qd and bid) can be safely combined with full doses of BORT or LEN. Durable responses have been observed in pts previously refractory to the combination partner and phase 2 studies are planned.

P359

A PHASE 2 STUDY OF CIRCULARLY PERMUTED TRAIL (CPT) PLUS THALIDOMIDE AND DEXAMETHASONE *VERSUS* THALIDOMIDE AND DEXAMETHASON IN PATIENTS WITH RELAPSED OR REFRACTORY MULTIPLE MYELOMA

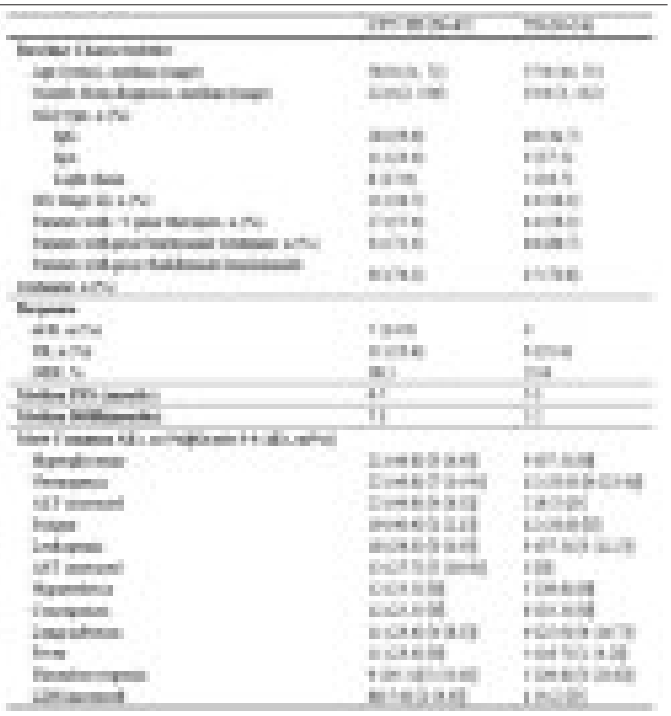
Ltd., Beijing, [15]Hematology, Ruijin Hospital, Shanghai Jiao Tong University School of Medicine, Shanghai, [16]State Key Lab. of Experimental Hematology, Institute of Hematology and Blood Diseases Hospital, CAMS & PUMC, Tianjin, [17]Beijing Hospital of the Ministry of Health, Beijing, [18]Hematology, The First Affiliated Hospital of Nanjing Medical University, Nanjing, [19]Hematology, The Third Xiangya Hospital of Central South University, Changsha, China

Background: CPT is a recombinant mutant of human Apo2L/TRAIL developed by Beijing Sunbio Biotech Co. Ltd. as a targeted therapy for multiple myeloma (MM) and other hematologic malignancies. CPT is a dual pro-apoptotic receptor agonist that directly activates both pro-apoptotic receptors TRAIL-R1 (DR4) and TRAIL-R2 (DR5). CPT selectively induces apoptosis in a variety of cancer cells, while sparing most normal cells in preclinical models. CPT as a mono-therapy has shown definitive activities for patients with relapsed or refractory multiple myeloma (RRMM) in phase 1 and 2 studies.
Aims: This multi-center, open-label phase 2 study was designed to compare the efficacy and safety of CPT plus thalidomide and dexamethason (CPT+TD) *versus* thalidomide and dexamethason (TD) in RRMM patients.
Methods: Eligible RRMM patients were randomized (2:1) to receive CPT+TD or TD. Each cycle was 28-days: CPT IV 10mg/kg on days 1-5, thalidomide PO 150mg daily, and dexamethason PO 40mg on days 1-4. Treatment was continued until having finished 4 cycles or disease progression or unacceptable toxicity. Treatment beyond 4 cycles was permitted at physician's discretion, yet with the treatment cycle adjusted to 6 weeks. The primary endpoint was overall response rate (ORR, defined as ≥partial response [PR]) based on EBMT criteria. Secondary endpoints included progression free survival (PFS), duration of response (DOR) and safety. Safety was assessed according to NCI-CTCAE 3.0. All patients provided written informed consent.
Results: A total of 71 RRMM patients were enrolled, and 47 patients were randomized to CPT+TD group and 24 patients to TD group. Baseline demographics and disease characteristics were well balanced between CPT+TD and TD (Table 1), including the median age (58.0 years *vs.* 57.0 years), the proportion of patients with ≥3 prior anti-myeloma therapies (57.4% *vs.* 58.3%), with prior bortezomib treatment (72.3% *vs.* 66.7%) or with prior thalidomide or lenalidomide (74.5% *vs.* 70.8%), and ISS (Stage III: 44.7% *vs.* 58.3%), etc. With CPT+TD and TD treatments□no complete response (CR) was observed, near CR was 14.9% *vs.* 0, PR was 23.4% *vs.* 25.0%, and ORR was 38.3% *vs.* 25.0% (Table 1). The ORR difference, however, was not significant owing to the small sample size (P =0.08). The median PFS was 6.7 months in CPT+TD *vs.* 3.1 months in TD (P=0.16), and the median DOR in response patients was 7.1 months *vs.* 3.2 months (P=0.49). The addition of CPT to TD treatment significantly improved the ORR and the median PFS in patients with refractory disease (P=0.02, P=0.03, respectively), the median PFS in patients received ≥3 prior therapies (P=0.01), and the median PFS in those with IgG type MM (P=0.01). In both groups, the ORR, the median PFS and the median DOR seemed superior in patients never treated with bortezomib or immunomodulatory drugs (thalidomide or lenalidomide), but no statistical significance obtained possibly due to the small sample of the trial.
The majority of most common adverse events (AEs) were similar for both treatments except that the occurrences of ALT and AST elevation were more frequent in CPT+TD (P=0.001, P=0.003, respectively) (Table 1). Common grade 3-4 AEs for CPT+TD and TD included neutropenia (14.9% *vs.* 25.0%), thrombocytopenia (10.6% *vs.* 20.8%), increased AST (10.6% *vs.* 0), etc. Treatment-related dose reductions and/or interruptions in CPT+TD and TD group were 38.3% and 29.2%, respectively. In CPT+TD group, dose reductions and/or interruptions due to CPT-related AEs occurred in 8.5% (4/47) of patients.

Table 1. Baseline characteristics, efficacy and safety profile of patients treated with CPT+TD or TD.



Summary and Conclusions: This study showed that the combination of CPT with TD regimen was effective and well tolerated for patients with RRMM. The addition of CPT to TD improved the clinical responses and the PFS. Although a CPT-related liver toxicity was observed, most AEs were mild to moderate and controllable. Further confirmatory study is indicated.

P360

PRELIMINARY SAFETY AND EFFICACY OF TH-302, AN INVESTIGATIONAL HYPOXIA-TARGETED DRUG, AND DEXAMETHASONE (DEX) IN PATIENTS (PTS) WITH RELAPSED/REFRACTORY MULTIPLE MYELOMA (RR MM)

J P Laubach[1,*] N Raje[2], P Armand[1], R L Schlossman[1], J Rosenblatt[3], JV Matous[4], J Hedlund[5,6], M Martin[6,7], C Reynolds[6,8], KH Shain[9], I Zackon[6,10], L Stampleman[6,11], EN Boswell[1], S Chuma[1], R Liguori[1,6], DR Handisides[12], S Kroll[12], KC Anderson[1], PG Richardson[1], IM Ghobrial[1,6]
[1]Jerome Lipper Multiple Myeloma Center, Department of Medical Oncology, Dana-Farber Cancer Institute, Harvard Medical School, [2]Massachusetts General Hospital, [3]Beth Israel Deaconess, Boston, MA, [4]Colorado Blood Cancer Institute, Denver, CO, [5]Maine Center For Cancer Medicine, Scarborough, ME, [6]Blood Cancer Research Partnership, Boston, MA, [7]The West Clinic, Memphis, TN, [8]Ocala Oncology Center, Ocala, FL, [9]Moffit Cancer Center, Tampa, FL, [10]New York Oncology, Hematology, Albany, NY, [11]Pacific Cancer Care, Salina, CA, [12]Threshold Pharmaceutical, Inc., South San Francisco, CA, United States

Background: While alkylators, IMiDs and proteasome inhibitors are current standard treatment for patients (pts) with multiple myeloma (MM), the presence of hypoxia in the diseased bone marrow (Colla *et al.*, *Leukemia* 2010) presents a new therapeutic target for MM. TH-302 is a novel 2-nitroimidazole prodrug of the DNA alkylator bromo-isophosphoramide mustard that is selectively activated under hypoxic conditions. Synergistic induction of apoptosis in MM cells by TH-302 and bortezomib was shown in MM models *in vivo* and *in vitro* (Hu *et al.*, *Mol Cancer Ther* 2013). This current Phase 1/2 study investigates TH-302 with dex in pts with relapsed/refractory multiple myeloma (RR MM). In the dose-escalation stage of the study, the maximum tolerated dose (MTD) of biweekly TH-302 was established at 340 mg/m^2 and preliminary activity has been reported based on modified IMWG criteria (Ghobrial *et al.*, ASH 2013). The 340 mg/m^2 plus dex expansion arm is ongoing.
Aims: Preliminary assessment of safety and efficacy of TH-302 at the MTD (340 mg/m^2) plus dex in pts with RR MM.
Methods: This Phase 1/2 open-label multicenter study is evaluating IV TH-302 (240-480 mg/m^2) plus PO dex (40 mg) on Days 1, 4, 8 and 11 of a 21-day cycle

in heavily pretreated RR MM pts. At the MTD, a Simon two-stage mini-max design was implemented to pursue a regimen with ≥25% response rate or discontinue if ≤5% (90% power, 10% alpha).
Results: Sixteen pts (11 male, 5 female) were enrolled through completion of the initial stage of the Simon design, including 9 at the MTD. Median number of lines of prior therapy were 6 (3-11) and median age was 60 years (53 – 86). All pts had previously received both bortezomib and lenalidomide/thalidomide containing regimens and an alkylating agent. The most common ≥Gr 3 AEs included thrombocytopenia (44%) and leukopenia (38%). Dose limiting Gr 3 stomatitis was reported in the 480 mg/m^2 cohort but not seen at lower doses. Seven pts had SAEs, 6 of which were related to TH-302, including 3 pts with pneumonia. Pre-specified target for response for the initial 9-pt Simon stage at the MTD was achieved with 1 PR, 2 MRs, 4 SDs, 1 PD and 1 NE (ORR 33%). To date, 15 of 24 pts have been enrolled to evaluate safety and efficacy of TH-302 at the MTD (340 mg/m^2) plus dex.
Summary and Conclusions: TH-302 can be administered at 340 mg/m^2, biweekly with dex. Encouraging preliminary clinical activity has been noted in pts with heavily pre-treated RR MM. Data from pts in the Simon two-stage treated at the MTD will be updated and presented at the meeting.

Background: Multiple myeloma with del(17p) and/or t(4;14) is characterized with short survival related to early relapse rates (median TTP <4 months) and rapid development of resistance mechanisms to multiple agents. IMiDs® imunomodulatory agents and proteasome inhibitors (bortezomib) also display a shortened median survival of approximately 9 months in RRMM. We and others have shown that pomalidomide plus low-dose dexamethasone has prolonged time to progression (TTP) in RRMM who have progressed after multiple treatment options. However, the median TTP appeared shorter <4 months for patients with del17p and/or t(4;14).
Aims: We have designed a phase 2 multicenter, open-label study aimed to determine the efficacy and safety profile of pomalidomide in RRMM patients with del(17p) and/or t(4;14).
Methods: This study enrolled patients with progressive RRMM that were relapsing to lenalidomide (minimum two cycles). Del(17p) and/or t(4;14) was identified centrally using FISH on bone marrow plasma cells. The response was evaluated centrally according to IMWG criteria. The primary objective was to evaluate TTP. Pomalidomide was given orally at 4 mg daily on days 1–21 of each 28-days and dexamethasone orally at 40 mg daily on days 1, 8, 15 and 22 of each cycle. Venous thrombotic event (VTE) prophylaxis was mandatory. The primary analysis was conducted on the ITT population. An interim analysis is reported.
Results: 50 patients (gender ratio 1.5) were enrolled, the median age was 59 yrs (range, 30-80). The median time from diagnosis to enrolment was 3 years (IQ 2-4), 40% had ISS 3, and 60% high β2m. All patients had loss of 17p (46%) and/or t(4;14) (64%). The median number of prior lines of therapy was 3 (1-10). 84% were refractory to lenalidomide, 54% to proteasome inhibitor, 36% were refractory to an alkylating agent, and 76% were refractory to the last line of therapy prior to study entry. The overall response rate (ORR) was 20%, 27% in del(17p) and 16% in t(4;14));54% had stable disease. The median duration of response was not reached. With a median follow-up of 5 months (IQ 3-11), 66% have stopped treatment including 76% due to progression of MM, and 38% had died. The median TTP (range) for the cohort as a whole is approaching 3 months (2-5), with a clear difference in favour for del(17p), 8 months (3;nr) *versus* 3 months (2;4) for t(4;14). The median OS for the cohort as a whole is 12 months (CI95% 5;nr), with a 8-months event-free survival rate of 59%. Interestingly, del(17p) patients benefited more from pomalidomide plus low-dose dexamethasone as median OS was not reached, with 63% survival at 8-month, while for t(4;14) patients median OS was 9 months (4.5;16). However, it appears that t(4;14) patients were able to be rescued in some extent by investigators following pomalidomide therapy. Toxicity was manageable in these fragile RRMM patients with 40% of serious adverse events (SAEs) reported related to the studied treatment.
Summary and Conclusions: Pomalidomide plus low dose dexamethasone is active and well tolerated in this RRMM population characterized with high and rapid development of a refractoriness state. This study provides further evidence that pomalidomide is active in patients with adverse FISH cytogenetic and that ongoing triplet-based combination should demonstrate improved response rates and survival in future studies.

Background: The phase 3 GIMEMA-MMY-3006 study comparing bortezomib-thalidomide-dexamethasone (VTD) *vs.* thalidomide-dexamethasone (TD) as induction therapy before, and consolidation after, double autologous stem-cell transplantation (ASCT) provided demonstration of superior CR/nCR rates after induction (the primary study endpoint) and across all subsequent treatment phases, a gain which translated into significantly longer PFS for patients randomized to the VTD arm (Cavo, Lancet 2010; Blood 2012).
Aims: We herein report an updated analysis of the study with a focus on long term outcomes, including PFS2, time to second anti-myeloma therapy, treatment-free interval and post-relapse OS.
Methods: Overall, 474 patients were included in the trial. After a median follow up of 65 months, 251 patients (53%) have progressed and of these 221 (88%) had available data on salvage therapy after relapse.
Results: On an intention-to-treat basis, median PFS was 57 months for patients randomized to the VTD arm as compared to 42 months for those assigned in the TD arm (HR 0.67; p=0.001). Overall, randomization to VTD was associated with a 34% reduction in the risk of relapse or progression (median TTP, 61 *vs* 45 months for patients in the TD arm; p=0.001). No statistically significant difference in 5-years estimates of OS was observed between VTD and TD groups (80% *vs* 73%). PFS2, defined as the time from initial randomization to second objective disease progression or death from any cause, was significantly longer for patients randomised to VTD than for those in the TD group (76% *vs.* 63% at 5 years, respectively; HR 0.64, p=0.009). Globally, 73% and 83% of patients in the VTD and TD arms required the start of salvage therapy due to symptomatic relapse. Median time to subsequent anti-myeloma therapy (defined as the interval between start of induction treatment and the first dose of second-line therapy) was significantly longer for patients assigned to VTD than for those who experienced relapse in the TD cohort (40 *vs* 31 months, p=0.014). Similarly, median treatment-free interval (defined as the time between last administration of front-line therapy and start of salvage treatment) was 26 months in VTD group *vs* 16 months in TD arm (p=0.016). Most of the patients received a novel agent-containing salvage therapy, while 18% was treated with conventional chemotherapy. As expected, a greater percentage of patients in the TD arm were treated with second-line bortezomib-based combinations in comparison with those relapsing in the VTD arm (72% *vs* 46%, respectively, p=0.001). Within the VTD group, no difference in PFS2 was seen regarding the use of bortezomib or an IMiD as (part of) second-line therapy (64 *vs* 62 months, respectively). Clinical benefit from primary randomization to VTD *vs* TD was also observed in terms of second PFS (defined as the interval between first and second progression) (HR 0.61, p=0.032). The median OS after relapse was 36 months for both TD and VTD groups. No differences in post relapse OS were observed for patients primarily assigned to VTD or TD who received a subsequent bortezomib-based salvage therapy.
Summary and Conclusions: With an extended follow-up of approximately 5 years, VTD was superior to TD in terms of extended PFS, TTP, time to subsequent anti-MM therapy and treatment-free interval. PFS2, which has been recently proposed as a surrogate for OS, was significantly longer for patients randomized to VTD, with no difference regardless of the use of bortezomib or an IMiD as part of second-line therapy. This finding, along with similar post-relapse OS values across the two groups, suggest that short-term exposure to VTD did not select the emergence of more resistant, or bortezomib- resistant, clones at the time of relapse.

ISCIII, Zaragoza, Spain, [12]Seoul National University Hospital, Seoul, Korea, Republic Of, [13]Instituto Português de Oncologia Porto, Porto, Portugal, [14]Hopital J Monod Rhumato Nord, Le Havre, [15]Centre Hospitalier Regional Universitaire Hôpital de Pontchaillou, Rennes Cedex, France, [16]CHUM- Hôpital Notre-Dame, [17]Evidera, Montreal, Canada, [18]Celgene Corporation, Summit, United States, [19]Centre Hospitalier Regional Universitaire-Hopital Claude Huriez, Lille, France

Background: In the pivotal phase 3 FIRST trial, transplant-ineligible NDMM pts treated continuously with lenalidomide and low-dose dexamethasone (Rd) showed improved progression-free survival (PFS) and overall survival (OS) compared with either Rd treatment (Tx) given for a fixed duration (Rd18) or melphalan-prednisone-thalidomide (MPT) (Dimopoulos, Blood 2013). The assessment of QOL is of particular importance in elderly pts.
Aims: Evaluate changes in HRQOL during Tx with Rd, Rd18, and MPT in NDMM pts from the FIRST trial.
Methods: Transplant-ineligible NDMM pts were randomized to continuous Rd until disease progression (n=535), Rd for 18 cycles (Rd18; 72 weeks [wks]; n=541), or MPT (12 cycles; 72 wks; n=547). HRQOL was assessed using three validated questionnaires, the EORTC QLQ-C30, QLQ-MY20, and EQ-5D which were completed at: baseline (beginning Cycle 1); at the end of Cycle 1; after 3, 6, 12, and 18 months (mos) of Tx; and at study discontinuation. Cross-sectional and longitudinal analyses were performed. Changes from baseline at each time point were estimated with a focus on 7 pre-selected clinically-relevant domains: 1) Global QOL, 2) Physical Functioning, 3) Pain, 4) Fatigue, 5) Disease Symptoms, 6) Side Effects of Treatment, and 7) Health Utility (EQ-5D). A sub-analysis based on age ≤75 *versus* (*vs.*) >75 of QOL was performed.
Results: Across Tx arms, questionnaire compliance was high (≥84%) at the end of Cycle 1 and after 3 and 6 mos. Compliance rates were lower in the MPT arm than both the Rd arms at 12 mos (81% *vs.* 91%; $P \leq 0.002$) and 18 mos (67% *vs.* 89%; $P \leq 0.002$). In all Tx arms, scores for Global QOL, Physical Functioning, Pain, Fatigue, Disease Symptoms, and Health Utility improved significantly ($P \leq 0.05$) from baseline at most time points. For the Side Effects of Treatment domain, Tx with MPT was associated with a consistent and significant worsening from baseline at all time points. Side Effects of Treatment scores in the MPT arm showed significantly greater deterioration *vs.* the continuous Rd arm at Cycle 1 and after 3 and 12 mos of Tx ($P \leq 0.05$). Disease progression was associated with a worsening in HRQOL scores for all domains, across all 3 Tx groups ($P < 0.001$). The analysis performed, stratifying groups by age, showed that in pts >75, treatment does not impair HRQOL with regards to the domains of interest. In particular this subset analysis demonstrated a trend in pain reduction from baseline for pts >75.
Summary and Conclusions: The improvement in PFS and OS observed with continuous Rd Tx in the FIRST trial were accompanied with benefit observed in clinically relevant HRQOL measurements. Disease progression was associated with worsening HRQOL scores across all Tx groups. Side Effects of Treatment scores were significantly worse in the MPT arm than the continuous Rd arm.

Background: Once patients (pts) become refractory or intolerant to treatment (Tx) with novel agents, survival is significantly shortened (median overall survival [OS] of only 9 mos) (Kumar SK, *Leukemia.* 2012). Depth of response to Tx has been shown to be a predictor of favorable outcomes (Harousseau J-L. *Haematologica.* 2010). Pomalidomide (POM) has been approved for pts with relapsed/refractory multiple myeloma (RRMM) who have received ≥2 prior Tx, including lenalidomide (LEN) and bortezomib (BORT), and demonstrated disease progression on their last line of Tx. MM-003, a randomized pivotal phase 3 trial, compared the efficacy and safety of POM+low-dose dexamethasone (LoDEX) *vs.* high-dose dexamethasone (HiDEX) in RRMM pts. Trial results demonstrated significantly longer progression-free survival (PFS) and OS for POM+LoDEX, with acceptable tolerability (San Miguel J. *Lancet Oncol.* 2013).
Aims: To analyze the impact of the previous Tx and depth of response on response rate and/or survival from the MM-003 trial.
Methods: Pts must have been refractory to the last prior Tx (progressive disease [PD] during Tx or within 60 days) and must have exhausted LEN and BORT after ≥2 consecutive cycles of each agent (alone or in combination). Pts were randomized 2:1 to receive 28-day (D) cycles of POM 4 mg D1-21/28 days+LoDEX 40 mg (20 mg for pts >75 yrs) weekly or HiDEX 40 mg (20 mg for pts >75 yrs) D1-4, D9-12, and D17-20. Tx continued until PD or unacceptable toxicity. PFS was the primary endpoint; secondary endpoints included OS, overall response rate (ORR; ≥partial response [PR]), time to progression (TTP), and safety. This analysis examined pt outcomes by prior Tx history and depth of response, with a median follow-up of 15.4 mos.
Results: 455 pts were randomized: 302 pts received POM+LoDEX and 153 pts received HiDEX. Pt characteristics were well balanced between arms. Median number of prior Tx was 5 (range, 2-17). Most pts (75%) were double refractory to LEN and BORT. POM+LoDEX significantly prolonged PFS *vs.* HiDEX regardless of number or type of prior Tx (Figure 1A), with favorable OS outcomes as well (Figure 1B). Significant PFS and OS benefits were observed even in pts who were refractory to LEN as the last prior Tx. The ORR was significantly higher for pts receiving POM+LoDEX *vs.* HiDEX (32% *vs.* 11%; $P < .001$), with similar response rates regardless of prior Tx. An exploratory analysis found that TTP for pts treated with POM+LoDEX in this trial was similar to that observed with their last prior line of Tx (4.6 mos *vs.* 4.4 mos; $P = .32$), whereas it was significantly shorter in pts who received HiDEX *vs.* the last prior line of Tx (2.1 mos *vs.* 4.3 mos; $P < .001$). When examining outcomes by depth of response, median PFS was longer for pts with M-protein reductions ≥50% (8.4 mos) or ≥25% (7.4 mos) *vs.* 0% to 25% (2.3 mos). Additionally, median OS was longer for pts with M-protein reductions ≥50% (19.9 mos) or ≥25% (17.2 mos) *vs.* 0% to 25% (7.5 mos).

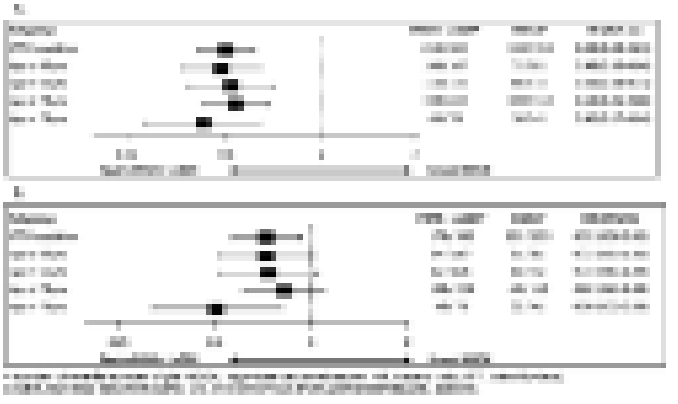

Figure 1.

Summary and Conclusions: In heavily pretreated RRMM pts, POM+LoDEX provided consistent efficacy regardless of number or type of prior Tx. Importantly, LEN as the last prior Tx did not impact response, PFS, or OS *vs.* the overall intent-to-treat population. Pts achieving responses ≥minimal response attained a significant survival benefit, which was higher in pts achieving PR. Taken together, POM+LoDEX should be considered a standard Tx option in RRMM pts, regardless of last prior Tx.

Myeloma and other monoclonal gammopathies - Clinical 2

P365

ACTIVITY OF MV-NIS IN A PHASE I TRIAL FOR PATIENTS WITH RELAPSED, REFRACTORY MULTIPLE MYELOMA (MM)

A Dispenzieri[1,*] MQ Lacy[2], KM Laumann[3], B LaPlant[3], D Dingli[1], MA Gertz[1], F Buadi[1], V Lowe[4], M O'Connor[4], N Leung[1], SV Rajkumar[1], SK Kumar[1], C Tong[5], A Birgin[1], KW Peng[5], MJ Federspiel[5], SJ Russell[5]
[1]Division of Hematology, [2]Mayo Clinic, Rochester, United States, [3]Division of Biostatistics, [4]Department of Radiology, [5]Molecular Medicine, Mayo Clinic, Rochester, United States

Background: MV-NIS is an Edmonston-lineage measles virus that expresses the human sodium-iodide symporter (hNIS). The virus is oncolytic to primary myeloma cells and cell lines, and its activity can be monitored by noninvasive imaging of radioiodine uptake by hNIS. CD46, the receptor for MV, is overexpressed in myeloma cells.
Aims: To conducted a Phase I study to determine the safety and efficacy of MV-NIS in patients with relapsed, refractory MM.
Methods: The trial is a standard 3+3 dose escalation design but with two patient cohorts. Cohort 1 included single agent intravenous MV-NIS administered at TCID50 titers of: 10^6, 10^7, 10^8, 10^9, 10^{10}, and 10^{11}. Cohort 2 patients started treatment with cyclophosphamide 10 mg/kg 2 days prior to MV-NIS at MTD/100. Antibody response to measles was tested pre and post therapy. Bone marrow myeloma (CD138+) and non-myeloma cells (CD138-) were tested for CD46 expression and MV infectivity. PK and biodistribution were followed, respectively, by MV-N by Q-RT-PCR in blood, urine, and gargle samples and by serial nuclear imaging. Eligible patients had adequate bone marrow and organ reserve and had explored all other myeloma treatment options.
Results: Thirty-one patients have been treated. Two patients were replaced for lack of protocol completion. Cohort I initially enrolled 13 patients receiving one dose 10^6, 10^7 10^8 or 10^9 TCID50 of MV-NIS. Since no DLT was observed, per protocol Cohort 2 began accrual, recruiting 8 patients. At trial conception, manufacturing allowed doses only up to 10^9, but technology improvements subsequently allowed for two higher dose levels (10^{10} and 10^{11}). Therefore, Cohort 2 accrual was suspended, and Cohort 1 accrual was resumed to test these 2 higher levels (11 additional patients). Grade 3-4 AEs deemed at least possibly related to protocol therapy in both cohorts at all dose levels were: neutropenia (n=8); thrombocytopenia (n=4); anemia (n=3); and lymphopenia (n=1). One patient treated in cohort 2, dose level 3 (*e.g.* CTX and TCID50 $9x10^7$) had a grade 3 left ventricular failure possibly related to therapy. In Cohort 1, MTD has not been reached, and TCID50 10^{11}, will be the dose used in an upcoming Phase II trial of single agent MV-NIS. Grade 1-2 AEs seen in at least 5 patients were: nausea (n=11); chills (n=9); fever (n=6); and rash, neutropenia, thrombocytopenia, and vomiting (each n=5). Most patients had low baseline anti-IgG MV titers which boosted by six weeks post MV-NIS treatment. MV-N RNA sequences were amplified from gargle specimens, blood and urine. The most dramatically positive ^{123}I scan was seen in 1 patient at the 10^{11} demonstrating proof of principle of NIS. One patient treated at TCID50 10^{11}, achieved a CR that persists for more than 8 months. Transient drops in serum FLCs were seen in other patients.
Summary and Conclusions: Intravenous administration of MV-NIS is feasible and produced a CR in one patient at top dose level. The virus is capable of replicating before being cleared by the immune system. The Phase II trial will open in a month using the 10^{11}, dose. Oncolytic viruses offer a promising new modality for the targeted infection and destruction of disseminated cancer.
This work was supported by funds from the NIH/NCI (R01CA125614, R01CA168719), Al and Mary Agnes McQuinn, the Richard M Schulze Family Foundation. The NCI (RAID Program) supported cGMP virus manufacture and toxicology/pharmacology studies.

P366

OUTCOMES OF PRIMARY SYSTEMIC LIGHT CHAIN (AL) AMYLOIDOSIS IN PATIENTS TREATED UPFRONT WITH BORTEZOMIB OR LENALIDOMIDE AND THE IMPORTANCE OF RISK ADAPTED STRATEGIES

E Kastritis[1,*] M Roussou[1], M Gavriatopoulou[1], M Migkou[2], C Pamboucas[1], E Kaldara[3], A Ntalianis[3], E Psimenou[4], S Toumanidis[1], E Terpos[1], MA Dimopoulos[1]
[1]Department of Clinical Therapeutics, National and Kapodistrian University of Athens, [2]Department of Clinical Therapeutics, National and Kapodistrian University of Athens,, [3]National and Kapodistrian University of Athens, School of Medicine, [4]Nephrology Unit, Alexandra Hospital, Athens, Greece

Background: Bortezomib and lenalidomide are increasingly used in patients with AL amyloidosis, but long-term data of their use as first line therapy in AL amyloidosis are lacking. Furthermore, despite the use of these effective therapies early death remains a significant complication of AL and new startegies are neede in order to reduce early mortality
Aims: We report our experience after long follow up of the outcomes of patients who received bortezomib or lenalidomide as a primary therapy for AL amyloidosis. Furthermore, in order to reduce early mortality and retain the rapid activity of bortezomib, three years ago we implemented a risk-adapted approach for bortezomib dose and schedule, based on cardiobiomarkers, age and systolic blood pressure.
Methods: We analyzed the outcomes of 85 consecutive patients, who received primary therapy with bortezomib (N=49) or lenalidomide (N=36)(maximum 12 cycles – no maintenance). Standard bortezomib/dexamethasone was given in 26 patients and risk-adapted bortezomib in 23 patients (of which N=11 received full dose/schedule bortezomib/dexamethasone and N=12 weekly (attenuated) bortezomib/ dexamethasone), based on cardiac biomarkers, systolic blood pressure, presence of neuropathy and age.
Results: On intent to treat, 67% of patients achieved a hematologic response (24% hemCRs and 8% VGPRs) and 34% an organ response; both were more frequent with bortezomib *vs* lenalidomide. Onset of hematologic remission was significantly more rapid with bortezomib. Median survival is 47 months. An early death occurred in 20%: in 36% of patients treated with standard bortezomib, in 22% of lenalidomide-treated patients (p=0.940); but only in 4.5% of patients treated with the risk-adapted bortezomib approach. Activity, in terms of hemPR/hemCR and NTproBNP response, was similar for bortezomib regimens. In patients with a minimal follow up of 3 years, 19% of patients with Mayo stage-3 disease remain alive, the survival of patients with stage-2 disease is 28 months and has not been reached for patients with Mayo stage-1 disease (the 3-year survival is 88%) but is similar for patients treated with bortezomib or lenalidomide.
Summary and Conclusions: long term follow up indicates that remissions obtained with lenalidomide or bortezomib may be durable. There was no difference in the survival of patients treated with bortezomib *vs* lenalidomide, although bortezomib acts faster and induces deeper responses. A risk-adapted treatment strategy based on bortezomib may reduce early mortality and preserve activity but longer follow up is needed in order to evaluate whether this strategy improves other outcomes.

P367

BORTEZOMIB COMBINATION THERAPY, AND SUBSEQUENT BORTEZOMIB RE-TREATMENT, IS A USEFUL TREATMENT STRATEGY FOR MULTIPLE MYELOMA PATIENTS WITH RAS MUTATIONS

D Smith[1,*] L Percy[1], M Kumar[2], E Armenteros[2], A Lach[3], G Herledan[3], M Stubbs[1], J Downward[2], K Yong[1]
[1]Haematology, University College Hospital, London, [2]London Research Institute, [3]University College London, London, United Kingdom

Background: Mutations of the RAS gene family are prevalent in MM. A synthetic lethality screen in RAS mutant cells identified genes encoding for proteasome subunits, suggesting that MM tumours bearing RAS mutations may be particularly sensitive to bortezomib.
Aims: To investigate if MM disease response to bortezomib is linked to NRAS/KRAS mutational status.
Methods: 70 patients treated at a single centre with bortezomib for relapsed disease were analysed for RAS mutation status to correlate with clinical outcomes.
Results: Patients were mainly relapsed/refractory (92.8%), had received a median of 4 prior lines of therapy and 97% were bortezomib naïve. Pre-treatment bone marrow samples were obtained with informed consent and RAS mutation analysis performed on RNA extracted from CD138 selected cells. RAS mutations were detected in 31 patients (44.3%). 22 patients (31.4%) had mutations in NRAS and 10 patients (14.3%) in KRAS (1 patient had mutations in both). NRAS mutations were found in codons 61 (n=12), 13 (n=5), 12 (n=4) and 64 (n=1). KRAS mutations were detected in codons 61 (n=6), 12 (n=3) and 117 (n=1). There was no association between RAS mutation and high risk FISH.[KY1] All patients were treated with bortezomib regimens: single agent bortezomib (4 patients), bortezomib/dexamethasone (23), bortezomib/dexamethasone/cyclophosphamide (31), bortezomib/dexamethasone/doxorubicin (9) and bortezomib/dexamethasone/thalidomide (3), with an even split between patient groups. 86.7% of patients with RAS mutations responded to treatment compared to 72.2% with WT RAS. No difference in PFS was observed between the two groups (8.0 months WT *vs* 8.0 RAS). OS was shorter in patients with RAS mutations (27.0 months *vs* 40.7, NS). Analysis of NRAS and KRAS mutations separately showed response rates (≥PR) were similar (85.7% NRAS *vs* 88.9% KRAS). Patients with KRAS mutations had a trend to shorter OS (24.8 KRAS *vs* 28.2 NRAS *vs* 40.7 WT). At relapse post initial exposure to bortezomib a similar percentage of patients in each group received further therapy (6/8 KRAS, 16/19 NRAS, 31/33 WT). Median OS from date of relapse was shorter in patients with RAS mutations (11.7 months KRAS *vs* 22.1 NRAS *VS* 33.8 WT, p=0.04 for KRAS *vs* WT). Patients with RAS mutations had similar PFS and OS whether treated with repeat bortezomib or lenalidomide (PFS 8.5 months bortezomib *vs* 7.0 lenalidomide, OS 28.67 *vs* 33.67). In contrast in patients with WT RAS PFS was significantly shorter with bortezomib re-treatment compared to lenalidomide (5.67 months *vs* 10.5, p=0.015), as was OS (25.6 months with bortezomib *vs* 46.6 with lenalidomide, NS).
Summary and Conclusions: Although RAS mutation status had no impact on the outcome of initial bortezomib therapy, at disease progression patients with KRAS mutations fared worse. This may reflect the association of KRAS mutations with advanced disease, but also suggests tumours with mutant KRAS are

relatively more sensitive to bortezomib combination therapy than other subsequent therapy. In contrast to a recent report on the resistance of NRAS mutant tumours to single agent bortezomib, we found no impact of NRAS mutations on sensitivity to combination bortezomib regimens. Patients with WT RAS fared worse when retreated with bortezomib than if they received lenalidomide but those with RAS mutations had similar outcomes with either therapy, suggesting RAS mutation status may confer added bortezomib sensitivity. Although our findings await confirmation in a larger patient cohort they suggest that bortezomib combination therapy, and bortezomib re-treatment, is a useful strategy for MM patients with RAS mutations.

P368

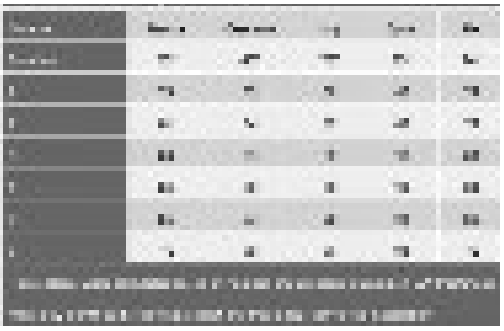
EUROPEAN POST-APPROVAL SAFETY STUDY (PASS) OF RELAPSE/REFRACTORY MULTIPLE MYELOMA (RRMM): PATTERNS OF ANTITHROMBOTIC PROPHYLAXIS IN A LARGE COHORT OF MM PATIENTS TREATED WITH LENALIDOMIDE

B Gamberi[1,*] J Caers[2], J Parreira[3], M Haenel[4], GM Bos[5], F Escalante[6], P Bacon[7], B Rosettani[7], E Kueenburg[7], M Ramos Rodriguez[7], N Brandenburg[8], N Minton[8], B Andreasson[9]

[1]Arcispdedale S. Maria Nuova, Reggio Emilia, Italy, [2]CHU, Liege, Belgium, [3]Instituto Português de Oncologia Francisco Gentil de Lisboa, Lisboa, Portugal, [4]Klinikum Chemnitz, Chemnitz, Germany, [5]UMC Maastricht, Maastricht, Netherlands, [6]Hospital de León, Leon, Spain, [7]Celgene International, Boudry, Switzerland, [8]Celgene Corporation, Summit, United States, [9]Uddevalla Sjukhus, Uddevalla, Sweden

Background: EU PASS is an observational, non-interventional post-authorization study designed to investigate the safety of lenalidomide (LEN) and other agents in the treatment of RRMM patients (pts) in a real-world setting. Venous thromboembolic events (VTE) are common among cancer pts (7%) and recognized as a possible adverse event (AE) associated with the administration of LEN+dexamethasone (DEX) therapy (Tx). Among RRMM pts treated with LEN and high-dose DEX, grade (Gr) 3–4 VTE was experienced by 11-14% of pts (Dimopoulos, NEJM 2007; Weber, NEJM 2007). Recommendations for thromboprophylactic Tx based on the number of VTE risk factors have been published. Larocca (Blood 2012) reported that the incidence of VTE was similar in NDMM pts treated with LEN+low dose DEX, who were randomized to receive either acetylsalicylic acid (ASA) 100 mg/day (2%) or low-molecular-weight-heparin (LMWH) enoxaparin 40 mg/day (1%).
Aims: To investigate the frequency and patterns of thromboprophylactic medication used in LEN-treated pts, and describe the proportion of pts who experienced a VTE while receiving RRMM Tx.
Methods: RRMM pts who had received ≥1 prior Tx were enrolled at the investigator's discretion into a LEN- or background cohort (other regimens). This analysis will focus only on pts who were treated within the LEN cohort. Thromboprophylactic medication was administered as per local standard practice. AEs were graded according to NCI-CTCAE (v3). Patterns of thromboprophylactic usage were examined using descriptive statistics.
Results: As of November 2013, a total of 3,520 pts across 269 institutions in 17 European countries were enrolled; of those, 62% received LEN (n=2,166). Pts in the LEN cohort had a median age of 68 years (range 25–95) and 54% were male. Median number of prior RRMM Tx was 2 (range 0–6); 18% had 1 prior, 57% had 2 prior, and 24% had ≥3 prior Tx; 12% of pts had a history of prior VTE. A total of 71% (n=1527) of pts were receiving thromboprophylactic Tx prior to starting LEN; 81% (n=1558) received Tx on commencing LEN and this number increased to 84% (n=871) for those remaining on LEN by month 6. On commencing LEN, thromboprophylaxis included 42% (n=800) ASA, 31% (n=589) LMWH, 5% (n=90) warfarin, and 8% (n=149) other agents. The proportion of pts receiving prophylaxis at 6 months was 91-93% in Italy and Spain, 75–76% in UK and France, and 60% in Germany (Table 1). A total of 5% (n=117) out of the 2,166 pts in the LEN cohort developed VTE while on Tx; among these 59% (n=69) occurred within the first 6 months. The occurrence of VTE Gr 3-4 was 3% (n=56).

Table 1. Percent of patients receiving any form of thromboprophylaxis in the first 6 months of LEN treatment by country and by month.



Summary and Conclusions: Patterns of thromboprophylactic medication in the big 5 EU countries were comparable and highest in Italy and Spain, intermediate in the UK and France and lowest in Germany. ASA was the most frequently prescribed Tx. In RRMM pts treated with LEN, there was sustained compliance to thromboprophylaxis during the first 6 months. The incidence of VTE during LEN Tx was 5%. Further analyses will examine the incidence by type of prophylaxis used as well as other risk factors.

P369

RANDOMIZED PHASE 2 STUDY OF BORTEZOMIB, THALIDOMIDE, AND DEXAMETHASONE WITH OR WITHOUT CYCLOPHOSPHAMIDE AS INDUCTION THERAPY IN PREVIOUSLY UNTREATED MULTIPLE MYELOMA (MM): LONG-TERM FOLLOW-UP RESULTS

Background: Bortezomib in combination with thalidomide and dexamethasone (VTD) is an effective regimen in patients (pts) with previously untreated MM. We conducted an open-label phase 2 study to evaluate the efficacy and safety of VTD and VTD plus cyclophosphamide (VTDC) as induction therapy prior to high-dose therapy plus stem cell transplant (HDT/SCT) (NCT00531453). Primary results showed that both VTD and VTDC are active induction regimens resulting in bone marrow confirmed complete response (CR) rates of 29% and 31% post-induction, and 57% and 61% post-HDT/SCT, respectively (Ludwig *et al. JCO* 2012). There were no significant differences in efficacy between the 2 regimens, indicating no benefit from the addition of cyclophosphamide.
Aims: To assess any differences in long-term outcomes between the 2 regimens, this long-term extension follow-up phase of the study evaluated final time-to-event data: updated post-treatment results are reported.
Methods: Adult pts were randomized (1:1) to receive i.v. bortezomib (1.3 mg/m^2), thalidomide (100 mg), and dexamethasone (40 mg), with or without cyclophosphamide 400 mg/m^2 for 4x21-day cycles, followed by HDT/SCT. This long-term extension study assessed time-to-event endpoints, including time-to-next therapy (TTNT), progression-free survival (PFS) and overall survival (OS).
Results: 98 pts (49 VTD, 49 VTDC) were included in the intent-to-treat and safety populations. At the final analysis, median duration of follow-up was 64.8 months (65.3 months VTD, 64.7 months VTDC). Median TTNT was 51.8 months (95% CI 31.9, NE) and 47.9 months (95% CI 28.7, NE) in the VTD and VTDC treatment groups, respectively. The type of subsequent therapy was similar in both treatment groups; dexamethasone (41.8%), lenalidomide (33.7%), bortezomib (31.6%) and thalidomide (17.3%) were the most commonly used agents. In a sensitivity analysis (10 pts starting subsequent therapy after 'relapse from CR' or 'clinical relapse' but without IMWG criteria-based progression were considered to have progressed), PFS and TTP were similar in the VTD and VTDC groups: median PFS was 34.1 months (95% CI 23.5, NE) and 34.2 months (95% CI 23.5, 48.2), and median TTP was 34.7 months (95% CI 23.9, NE) and 34.5 months (95% CI 23.5, 50.6), respectively. The 3-year and 5-year OS rates were similar for both treatment groups: 79.6% (95% CI 65.4, 88.5) *vs* 83.7% (95% CI 70.0, 91.5) at 3 years, and 69.1% (95% CI 54.1, 80.1) *vs* 65.3% (95% CI 50.1, 76.8) at 5 years for the VTD and VTDC treatment groups, respectively (Figure 1A). Of pts with bone-marrow-confirmed CR available for MRD analysis, 34 were MRD-negative and 8 MRD-positive by multiparameter flow cytometry. When analyzed by MRD status, OS was longer in MRD-negative *vs* MRD-positive pts (hazard ratio [HR] 3.66, p=0.0318) (Figure 1B). Although not significant, a similar trend was seen for PFS (HR 2.29, p=0.0849). During this follow-up period, no new adverse events and no second primary malignancies were reported.
Summary and Conclusions: The VTD induction regimen followed by HDT/SCT provides long-term disease control (median TTNT 51.8 months, 5-year OS 69.1%). Consistent with the primary analysis results, there was no significant difference in long-term outcomes between the VTD and VDTC groups.

Analysis of OS and PFS by MRD status confirms the importance of achieving an immunophenotypic CR after treatment.

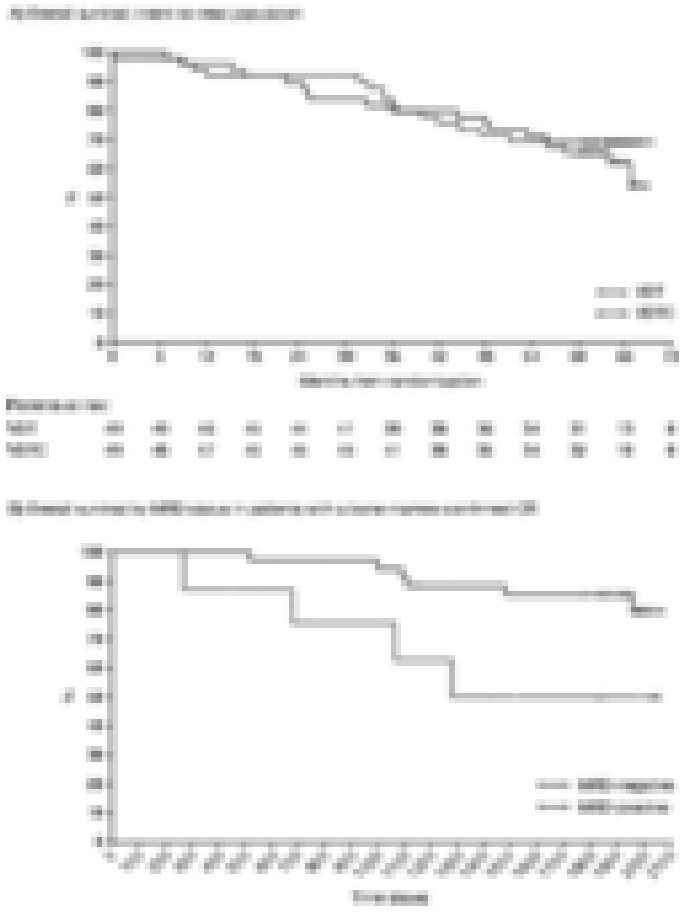

Figure 1.

P370

A PHASE 1 STUDY OF FILANESIB (ARRY-520) WITH BORTEZOMIB (BTZ) AND DEXAMETHASONE (DEX) IN RELAPSED OR REFRACTORY MULTIPLE MYELOMA (RRMM)

A Chari[1,*] M Htut[2], J Zonder[3], J Fay[4], A Jakubowiak[5], B Harrison[6], K Lau[1], S Burt[3], B Hilder[7], AM Ptaszynski[8], S Rush[7], J Kaufman[9]
[1]Hem/Onc, Mt Sinai, New York, [2]City of Hope National Medical Center, Duarte, [3]Karmanos Cancer Inst, Detroit, [4]Baylor Medical Center, Dallas, [5]University of Chicago Medical Centre, Chicago, [6]MMRC, Norwalk, [7]Array BioPharma, Raleigh, [8]Array BioPharma, Boulder, [9]Emory University School of Medicine, Atlanta, United States

Background: Filanesib is a novel KSP inhibitor with encouraging activity in patients (pts) with RRMM. In preclinical models, the activity of filanesib is synergistic with BTZ, providing a rationale to combine these drugs in the clinic.
Aims: ARRAY-520-111 is a Phase 1 study to identify the maximum tolerated dose of filanesib, BTZ and dex.
Methods: Eligible pts have RRMM with ≥2 prior lines of therapy, including a proteasome inhibitor (PI) and an IMiD. Filanesib is administered intravenously (IV) on days (D) 1, 2, 15, 16 (Schedule 1) or on D1, 15 (Schedule 2); BTZ is administered IV or subcutaneously weekly on D1, 8, 15; and 40 mg oral dex, if given, is taken on D 1, 8, 15 in a 28D cycle. G-CSF is given for 5-7D starting D3 or 4 and again D17 or 18. The safety of filanesib+BTZ in the early portion of dose escalation has been reported previously. This abstract will focus on the safety and activity of higher doses of filanesib in this dose escalation study (≥1.25 mg/m^2/D filanesib+1.3 mg/m^2/D BTZ).
Results: In Schedule 1, 19 pts have been treated at filanesib doses of 1.25 and 1.5 mg/m^2/D with 1.3 mg/m^2/D BTZ, without and with dex. Pts received a median of 5 prior therapies and 42% were BTZ refractory. The maximum planned dose in this schedule has been established as 1.5 mg/m^2/D filanesib and 1.3 mg/m^2/D BTZ+40 mg dex. In Schedule 2, 10 pts have been treated at doses of 2.25 and 3.0 mg/m^2/D filanesib with 1.3 mg/m^2/D BTZ+dex. Pts had received a median of 4 prior therapies. The recommended Phase 2 dose (RP2D) in this schedule has been established as 3.0 mg/m^2/D filanesib and 1.3 mg/m^2/D BTZ+40 mg dex. Both schedules have shown acceptable tolerability, with the most common adverse events (AEs) being transient, non-cumulative myelosuppression: based on laboratory data, Grade (Gr) 3-4 neutropenia was observed in 38% of pts and Gr3-4 thrombocytopenia in 27% of pts. A low overall rate of non-hematological toxicity was observed: no Gr3-4 non-hematologic AEs were observed in more than 9% of patients. Among all 29 pts treated at doses of ≥1.25 mg/m^2/D filanesib+1.3 mg/m^2/D BTZ, treatment-emergent neuropathy (Gr2) was observed in only 1 pt. In the 19 pts in Schedule 1 who received ≥1.25 mg/m^2/D filanesib+1.3 mg/m^2/D BTZ, the overall response rate (ORR, ≥PR) was 42% (8/19) and the clinical benefit rate (CBR, ≥MR) was 58%. In the subset of pts with BTZ-sensitive disease, an ORR of 56% (5/9) and a CBR of 89% was observed. In pts with PI-refractory disease, an ORR of 30% (3/10) was observed. The median time on treatment in Schedule 1 has been 12 months (range 1, 14.3+). The observed duration of response to-date ranged from 3.1+ to 11.4+ months. The 10 pts in Schedule 2 had received a median of 1 cycle of treatment at the time of data cutoff and 8 pts remained on study with 2 MR observed to date. High pre-dose levels of alpha 1-acid glycoprotein (AAG) are a potential marker of lack of response to filanesib. To date in PI-refractory pts, responses occurred only in pts with low AAG levels.
Summary and Conclusions: Filanesib combined with weekly BTZ, dex, and prophylactic G-CSF appears well tolerated with manageable AEs in heavily pretreated pts. This combination has shown promising activity both in BTZ-sensitive (ORR=56%; CBR=89%) and in PI-refractory MM (ORR=30%). In addition, a more convenient schedule of filanesib on D1, 15+weekly BTZ, is feasible. Expansion cohorts of 21 pts of both schedules are ongoing in pts with BTZ-sensitive disease who received 1-3 prior therapies. These data will be updated at time of presentation and will include pts in the expansion cohorts.

P371

A COMPARISON BETWEEN NEXT-GENERATION SEQUENCING AND ASO-QPCR FOR MINIMAL RESIDUAL DISEASE DETECTION IN MULTIPLE MYELOMA: THE CLINICAL VALUE IN ASCT SETTING

H Takamatsu[1], R Murata[2], S Ito[3], J Zheng[4], M Moorhead[4], Y Terasaki[5], T Yoshida[6], M Faham, [4,*]S Nakao[1]
[1]Kanazawa University, [2]NTT West Kanazawa Hospital, Kanazawa, [3]Iwate Medical University School of Medicine, Morioka, Japan, [4]Sequenta, Inc., South San Francisco, United States, [5]Toyama City Hospital, Toyama, [6]Shizuoka City Shimizu Hospital, Shizuoka, Japan

Background: Although molecular complete remission (mCR) in multiple myeloma (MM) can be assessed by allele-specific oligonucleotide (ASO)-PCR, this technique requires preparation of clonotype-specific primers for each individual which is laborious and time-consuming. We utilized a sequencing method, termed the LymphoSIGHT™ platform, which employs consensus primers and high-throughput sequencing to amplify and sequence all rearranged immunoglobulin gene segments present in a myeloma clone.
Aims: We compared the LymphoSIGHT™ method with ASO-qPCR for MRD detection in autografts in the autologous peripheral blood stem cell transplantation (ASCT) setting.
Methods: Forty-four Japanese patients with newly diagnosed MM who received various induction regimens prior to ASCT were retrospectively analyzed. All patients had achieved a partial response (PR) or complete response (CR) after ASCT. BM slides from 29 MM patients and fresh BM cells from 15 MM patients at diagnosis as well as autografts were obtained for DNA extraction. IGH-based ASO-qPCR was performed as described previously (van der Velden *et al.*, Methods Mol Biol 2009). We performed next-generation sequencing (NGS) using the LymphoSIGHT method (Faham *et al.*, Blood 2012). Using universal primer sets, we amplified IGH variable (V), diversity (D), and joining (J) gene segments, IGH-DJ, and IGK from genomic DNA. Amplified products were subjected to deep sequencing using NGS. Reads were analyzed using standardized algorithms for clonotype determination. Myeloma-specific clonotypes were identified for each patient based on their high frequency in BM samples. The presence of the myeloma clonotype was then assessed in follow-up samples.
Results: MRD in autografts could be assessed in 44 of 44 patients (100%) by NGS and 36 of 44 patients (82%) by ASO-qPCR. MRD in autografts was detected in 35 of 44 (80%) by NGS and 16 of 36 (44%) by ASO-qPCR. Two cases where MRD was not detected by NGS (MRD^{NGS}(-)) and 19 MRD^{NGS}(+) cases received post-ASCT therapy using novel agents such as bortezomib/lenalidomide/thalidomide while 7 MRD^{NGS}(-) cases and 16 MRD^{NGS}(+) cases were followed without post-ASCT therapy. The MRD^{NGS}(-) cases without post-ASCT therapy showed a significantly better PFS than those MRD NGS(+) cases without post-ASCT therapy (P=0.025) although overall survival rates were comparable among the three groups (Figure 1A). To investigate the value of sensitive detection by NGS, we compared PFS in 7 MRD^{NGS}(-) cases (Group 1) with the 6 MRD^{NGS}(+) cases where MRD was not detected by ASO-qPCR (MRD^{ASO}(-)) (Group 2). The patients in both groups did not receive any post-ASCT therapy. Group 1 tended to show a better PFS than Group 2 (P=0.091) (Figure 1B). Additional patients and samples are being analyzed and results will be presented.
Summary and Conclusions: Detection of MRD in the post-ASCT setting is a significant predictor of PFS, and MRD-negativity in autografts revealed by NGS

may be more closely associated with durable remission of MM than that revealed by ASO-qPCR.

Figure 1. Comparison between NGS and ASO-qPCR for MRD detection in MM. PFS according to MRD in autograft by NGS (A), and PFS comparison between NGS and ASO-qPCR in cases without post-ASCT Tx.

P372

VORINOSTAT (V) IN COMBINATION WITH BORTEZOMIB (B), DOXORUBICIN (D) AND DEXAMETHASONE (D) (VBDD) IN PATIENTS WITH REFRACTORY OR RELAPSED MULTIPLE MYELOMA (RRMM): AN INTERIM PHASE I/II ANALYSIS

M Kleber[1,*] D Wider[1], K Keller[2], B Groß[1], H Reinhard[1], D Jakobs[1], M Burbeck[1], M Pantic[1], A May[3], J Duyster[1], M Jung[2], R Waesch[1], M Engelhardt[1]
[1]Department of Hematology, Oncology and Stem Cell Transplantation, University of Freiburg Medical Center, [2]Institute of Pharmaceutical Sciences, Albert-Ludwigs-University Freiburg, [3]Institute of Pathology, University Medical Center, Albert-Ludwigs-University, Freiburg, Germany

Background: The combination of bortezomib, doxorubicin and dexamethasone (BDD) is well tolerated and induces a high overall response rate (ORR). Preclinical studies have demonstrated that vorinostat, a histone deacetylase inhibitor, is synergistic with bortezomib and doxorubicin.
Aims: The aim of this phase I/II study was to determine the tolerability and activity of the combination of BDD with vorinostat (VBDD) in RRMM.
Methods: Patients received escalated vorinostat-doses (provided by MSD) at 100mg (dose level [DL] 0), 200mg (DL +1) and 300mg (DL +2) on days 1-4, 8-11, 15-18, combined with bortezomib 1.3mg/m^2 day 1,8,15 (provided by Janssen-Cilag GmbH), dexamethasone 40mg day 1,8,15,22 and doxorubicin on 9mg/m^2 day 1+8 (Figure 1A). The primary objective was the maximum tolerated dose (MTD; 3+3 dose escalation design). Secondary objectives were safety, response assessed by EBMT and IMWG criteria, progression-free survival and overall survival. ORR (>PR) was assessed every 4 weeks and at discontinuation or end of treatment (EOT). Correlative endpoints include prognostic MM-parameters, organ function, QoL-, comorbidity-assessments and translational studies (*e.g.* HDAC-activity decrease in PB MNCs, global acetylation and gene expression analysis). Dose limiting toxicities (DLTs) were defined as any possibly drug related adverse events (AEs) ≥grade 3 (CTCAE) within the 1st cycle. After completion of 6 cycles, patients could continue with bortezomib maintenance or proceed to (most often 2nd) ASCT.
Results: To date, 26/30 patients have been enrolled (median age: 63 years [range 54-78], 58% males). Median prior therapy lines were substantial with 3 (range 1-8): bortezomib, thalidomide or lenalidomide had been given in 81%, 23% and 31%, respectively; 84% of patients had undergone prior SCTs. Cytogenetic abnormalities included del(17p) (n=4), t(4;14) (n=2), gain(1q) (n=4), t(11;14) (n=4) and hyperdiploidy (n=7). The median Karnofsky Performance Status was 90% (range 70-100%). No DLTs have been observed to date; with 3 patients each being included in DL 0 and DL +1, the following patients safely proceeded to DL +2 (Figure 1B). Nine SAEs occurred in 7/26 patients (27%): bacteraemia (n=1) and herpes zoster reactivation (n=1) were suspected to be related to all VBDD-drugs. No causal relationship to study drugs was suspected for pneumonia (2), syncope (1), pathological fracture (1), respiratory infection (1) and 2 death due to PD with persisting plasma cell leukemia (PCL) or refractory disease. Best response and response at EOT defined by ORR was 60% and 45%, and the clinical benefit rate (CR, PR, SD) 92% and 90%, respectively (Figure 1C). At a median follow-up of 12 months (range 1-28), there have been only 2 patients with PD (1 with RRMM and 1 with PCL). The analysis of HDAC activity (before cycle 1, d1 and under VBDD treatment, cycle 2, d8) after VBDD initiation demonstrated HDAC-downregulation in 7/10 (70%) patients (Figure 1D). Further analyses will determine whether HDAC activity and treatment response may correlate and whether this HDAC downregulation may precede and/or indicate depth of response.
Summary and Conclusions: VBDD is a well tolerated and effective regimen in heavily pretreated RRMM patients. There have been no observed DLT and the MTD of vorinostat was set at 300mg, with all reported SAEs being in line with the known safety profile of the investigated drugs. Our alternative vorinostat-schedule (dosing of 4 days on and 4 days off) induced excellent tolerability and seems to enhance the antimyeloma response, warranting completion of this study.

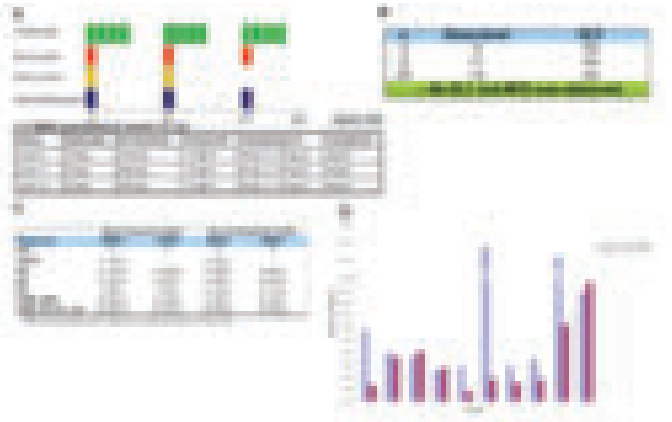

Figure 1. A)VBDD-treatment schedule; B) DLT in dose levels 0,+1 and +2; C) best response (n=25) and EOT (n=20) according to IMWG and EBMT criteria and D) HDAC activity (before cycle 1, d1 and under VBDD treatment, cycle 2, d8) after VBDD initiation demonstrated HDAC-downregulation in 7/10 (70%) patients.

P373

A PHASE IB DOSE ESCALATION TRIAL OF SAR650984 (ANTI-CD-38 MAB) IN COMBINATION WITH LENALIDOMIDE AND DEXAMETHASONE IN RELAPSED/REFRACTORY MULTIPLE MYELOMA

T Martin[1,*] R Baz[2], D Benson[3], N Lendvai[4], R Vij[5], E Charpentier[6], K Hsu[6]
[1]Hematology, University of California San Francisco, San Francisco, [2]Hematology, Moffitt cancer center, Tampa, [3]Hematology, Ohio state university medical center, columbus, [4]Hematology, Memorial Sloan-Kettering Cancer Center, New York, [5]Hematology, Washington University Medical School, St Louis, [6]Sanofi Oncology, Sanofi, Cambridge, United States

Background: SAR650984 (SAR) is a humanized IgG1 monoclonal antibody that binds selectively to a unique epitope on human CD38 receptor. SAR kills tumor cells via antibody-dependent cellular-mediated cytotoxicity, complement-dependent cytotoxicity, direct apoptosis induction without secondary crosslinking and allosteric inhibition on CD38 enzymatic activity. We present data on the dose escalation phase of the study (NCT01749969)
Aims: To determine the safety profile of SAR650984 in combination with Lenolidomide and dexamethasone in heavily pretreated patients with refractory and relapsing multiple myeloma
Methods: Three dose levels (DL) of SAR 3, 5 and 10 mg/kg were evaluated in combination with lenalidomide (LEN) and dexamethasone (Dex). LEN 25 mg was given on days (d) 1 – 21 and D 40 mg on d 1, 8, 15 and 22 every 28 d's. SAR was given IV on d 1 and 15 and escalated using the classic 3+3 design. All patients signed an IRB approved informed consent.
Results: 13 patients (pts) with RRMM were treated; median age 61 yrs (48 - 73); median prior treatment regimens 6 (2 - 12), 100% had received prior LEN (23% prior pomalidomide) and 92.3% previously received bortezomib (38.5% prior carfilzomib). The median time from diagnosis to first SAR dosing was 4.5 yrs (3 - 11). The maximum tolerated dose was not reached. The most frequent adverse events included nausea, cough (n=6 each); fatigue, muscle spasm, infection (n=5 each); vomiting, diarrhea, dehydration and insomnia (n=4 each). Grade (G) ≥3 hematologic abnormalities were neutropenia (n=4) and thrombocytopenia (n=3). One pt discontinued therapy (cycle 1, d 1) due to an infusion reaction (bronchospasm G 3). The ORR (≥PR), according to IMWG criteria, among 12 evaluable pts was 58%. Responses occurred at each DL of 3mg/kg (1PR), 5mg/kg (1PR, 1 VGPR) and 10 mg/kg (1PR, 3 VGPR). Clinical benefit response (≥MR) was 67% with 1 MR at 3 mg/kg. Median time on treatment was 20.6 weeks (0 - 35) and 7 pts remain on therapy. PK showed non linearity at select dose levels, SAR plasma trough levels were above target for tumor eradication from preclinical data.
Summary and Conclusions: The combination of SAR with LEN/Dex was tolerated and no DLT's were reported at any DL. SAR+LEN/Dex demonstrated encouraging efficacy in pts with heavily pretreated RRMM. An expansion cohort of 18 pts recently enrolled on the trial and the results will be reported at the meeting.

P374

IDENTIFICATION OF REVERSIBLE RENAL DAMAGE AND EARLY MARKERS OF RESPONSE TO CHEMOTHERAPY IN AL AMYLOIDOSIS: A STUDY ON 732 PATIENTS

G Palladini[1,*] U Hegenbart[2], P Milani[1], C Kimmich[2], A Foli[1], A Ho[2], M Vidus Rosin[1], R Albertini[3], R Moratti[4], G Merlini[1], S Schönland[2]
[1]Department of Molecular Medicine, University of Pavia, Pavia, Italy, [2]Department of Internal Medicine V, Division of Hematology / Oncology / Rheumatology, Uni-

versity of Heidelberg, Heidelberg, Germany, [3]Clinical Chemistry Laboratory, [4]Scientific Direction, Fondazione IRCCS Policlinico San Matteo, Pavia, Italy

Background: The kidney is involved in 70% of patients with AL amyloidosis, but little is known on factors affecting progression and potential reversibility of renal damage, and the criteria for renal response have never been validated.
Aims: To identify prognostic factors, response and progression criteria for renal involvement in AL amyloidosis.
Methods: We systematically searched the databases of the Pavia and Heidelberg amyloidosis canters for previously untreated patients with renal AL amyloidosis diagnosed between 2004 and 2012. Italian patients (n=461) were used as testing cohort and German patients (n=271) as validation cohort. All the patients gave written informed consent. The study endpoint was time from diagnosis to dialysis initiation (renal survival). Patients who died off-dialysis were censored.
Results: Seventy-one (15%) patients required dialysis in the Italian group and 84 (31%) in the German series after a median time of 85 and 69 months, respectively. Baseline proteinuria >5 g/24 hours and estimated glomerular filtration rate (eGFR) <50 mL/min per 1.73 m^2 were associated with poorer renal survival. Patients with proteinuria below and eGFR above the thresholds were at low-risk of dialysis (0 and 4% at three years in the testing and validation cohorts, respectively), whereas subjects with both high proteinuria and low eGFR were at high-risk (60% at three years in the Italian and 85% in the German series). Patients with either proteinuria above the cutoff or eGFR below the threshold were at intermediate-risk of progression (18% and 31% at three years in the testing and validation cohorts, respectively). The difference in renal survival between the three stages was significant (P<0.001 in both groups). Response and progression were assessed at three and six months. A decrease in eGFR by ≥25% was associated with poor renal survival in both cohorts and was adopted as the criterion for renal progression. A decrease in proteinuria by ≥30% or below 0.5 g/24 hours in the absence of renal progression was the criterion for renal response, being associated with longer renal survival in both series. Hematologic very good partial or complete remission improved renal outcome.
Summary and Conclusions: We identified and validated a staging system for renal involvement and criteria for early assessment of renal response and progression in AL amyloidosis which should be used in routine clinical practice and clinical trial design.

P375

MONOCLONAL GAMMOPATHY OF UNDETERMINED SIGNIFICANCE (MGUS) IS ASSOCIATED WITH A 30% INCREASED RISK OF DYING AT 8 YEARS OF FOLLOW-UP: RESULTS FROM A SCREENED CROSS-SECTIONAL POPULATION-BASED STUDY

EK Lindqvist[1,*] SH Lund[2], R Costello[3], D Burton[3], N Korde[3], S Mailankody[3], M Björkholm[1], V Gudnason[2], [4], G Eiriksdottir[4], LJ Launer[5], TB Harris[5], M Hultcrantz[1], O Landgren[1], [3], SY Kristinsson[1], [2]
[1]Department of Medicine, Division of Hematology, Karolinska University Hospital and Karolinska Institutet, Stockholm, Sweden, [2]Faculty of Medicine, University of Iceland, Reykjavik, Iceland, [3]Center for Cancer Research, National Cancer Institute (NCI), National Institutes of Health (NIH), Bethesda, United States, [4]Icelandic Heart Association, Kopavogur, Iceland, [5]National Institute on Ageing, National Institutes of Health (NIH), Bethesda, United States

Background: Multiple myeloma (MM) is a hematological malignancy where abnormal plasma cells proliferate and accumulate in the bone marrow. All cases of MM are preceded by the asymptomatic condition monoclonal gammopathy of undetermined significance (MGUS), where an M-protein is present in the blood but there are no other signs of hematologic malignancy. The prevalence of MGUS increases with age, and has been estimated to be 3-4% in a population aged 65 years or above. However, since MGUS by its nature is asymptomatic and likely to remain undiscovered, there is there is limited information on prevalence and survival in MGUS.
Aims: This study aims to determine the prevalence of MGUS in a screened, elderly population, and to evaluate the effect of MGUS on survival.
Methods: The cohort under study was the longitudinal AGES-Reykjavik Study. The participants were men and women born 1907-1934 in Iceland, who were examined up to six times by the Icelandic Heart Association. Blood samples from all participants, collected in 2002-2006, were screened for M-protein using serum protein electrophoresis (SPEP) as well as free light chain (FLC) analysis. Information on outcome was supplemented by matching hospital, nursing home, and mortality records to the cohort. The survival of individuals with MGUS *versus* those without was compared by calculating hazard ratios (HRs) and confidence intervals (CIs), based on a Cox proportional hazard model adjusting for age and gender, and by using Kaplan Meier analysis.
Results: Out of 5,784 participants, 313 participants (5.4%) had 1, 2 or 3 M-protein bands on SPEP. A total of 464 participants (8.0%) had a pathological FLC ratio (reference interval 0.26-1.65), but normal SPEP. Due to missing information, 36 observations were excluded from the analyses, and 2 were excluded because of conflicting results on SPEP and FLC. The median age at inclusion in the cohort was 77 years (range 66-98). Individuals with MGUS and with FLC-MGUS were older (78.5 years) than individuals without MGUS (76.8 years). Among individuals with MGUS, 53.7% were male, compared to 50.2% of individuals with FLC-MGUS and 40.9% of individuals with no MGUS. Of visible M-protein bands on SPEP, IgG was the most common isotype (56.5%), followed by IgM (30.7%), IgA (10.5%), free kappa/lambda only (1.9%) and IgD (0.3%). After a median follow-up time of 8 years, we found that individuals with MGUS had a significantly higher risk of death (HR=1.3, 95% CI 1.1-1.5) than individuals with no MGUS, whereas individuals with FLC-MGUS did not (HR=1.1, 95% CI 0.9-1.2) (Figure 1).

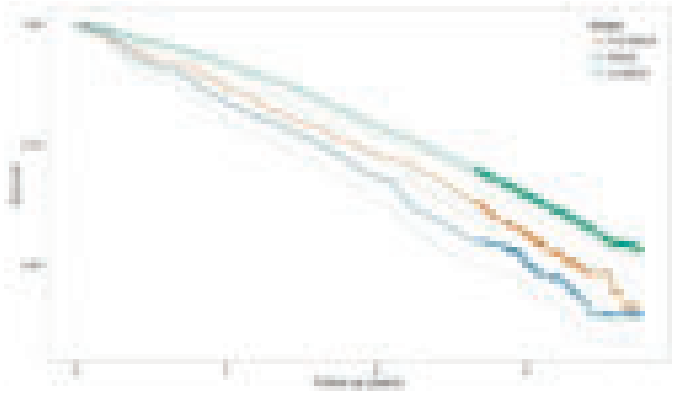

Figure 1.

Summary and Conclusions: In this large, population-based cohort screening study, we found that compared to individuals without MGUS, individuals with MGUS have a 30% increased risk of dying at a median of 8 years of follow-up. This is in contrast to previous, hospital-based studies. Our findings also suggest that MGUS is perhaps even more common than previously assumed. Attention should be directed towards characterizing causes of death as well as finding the underlying reasons for inferior survival in MGUS.

Medizinische Abteilung Zentrum für Onkologie, Hämatologie und Palliativmedizin, Wilhelminenspital, Vienna, Austria, [9]NOXXON Pharma AG, Berlin, [10]Internal Medicine I, Oncology and Hematology, University of Freiburg, Freiburg, Germany

Background: Olaptesed pegol (NOX-A12) is a novel L-stereoisomer RNA aptamer (Spiegelmer®) that binds and neutralizes the chemokine CXCL12 with high affinity. CXCL12, through interaction with the chemokine receptors CXCR4 and CXCR7, is responsible for homing and trafficking of healthy and malignant blood cells to the bone marrow (BM) stroma. Preclinical studies have shown synergistic activity of CXCL12-targeting and anti-myeloma agents, specifically bortezomib, suggesting that targeting of the myeloma niche may enhance treatment efficacy.
Aims: Here we aim to assess the activity and safety of olaptesed in combination with bortezomib and dexamethasone in patients with relapsed/refractory multiple myeloma (MM).
Methods: Twenty-nine patients with relapsed or refractory MM were enrolled. At this time, data from 20 patients (10 males and 10 females) are evaluable. Median (range) age was 65 years (48-79). Patients had received 2 (1-6) prior treatment lines. Pre-treatment consisted of dexamethasone in 19, lenalidomide in 15, bortezomib in 10 and carfilzomib in 1 patient. Seven patients underwent stem cell transplantation. Four patients presented with ISS stage I, 8 with stage 2 and 8 with stage III. Twelve patients had IgG, 2 presented with IgA and 6 with light chain myeloma. Thirteen patients had "high-risk" cytogenetic aberrations, defined by the presence of t(4;14) or del17p. Six patients were refractory to their last prior treatment, 10 were progressing during or shortly after maintenance therapy, mostly lenalidomide-dexamethasone. Patients were treated using a dose titration design with intravenous olaptesed at doses increasing from 1

mg/kg to 2 mg/kg and 4 mg/kg at cycles 1, 2 and 3, respectively, at 1 hour prior to bortezomib administration. During cycles 4 to 8, olaptesed was dosed at the highest individually titrated dose. Bortezomib (1.3 mg/m^2) was given on days 1, 4, 8 and 11 as intravenous injection. Oral dexamethasone (20 mg) was added on the day of and the day after bortezomib administration. Response was evaluated based on the uniform response criteria of the IMWG (Rajkumar SV et. al. Blood 2011; 117: 4691-5). To study PK/PD, a pilot dose of 1 to 4 mg/kg olaptesed alone was administered to the initial 10 patients before the start of the regular treatment regimen.

Results: The median number of completed cycles was 7.5 (0-8). The overall response rate was 70% with 6 patients achieving VGPR and 8 PR. Minimal response was noted in 1 patient, and 3 patients had progressive disease. Levels of circulating CD138$^+$/CD38$^+$, plasma cells were studied for 72 hours in the pilot phase and for 24 hours at cycles 1 and 4. A 2-fold increase of plasma cells compared to baseline was noted already after one hour and an increased mobilization persisted throughout the observation period (Figure 1). Treatment with olaptesed in combination with VD was safe and well tolerated without a significant increase in adverse events compared to VD-treated MM patients. The dose of olaptesed was titrated up to 4 mg/kg in all 15 patients treated beyond cycle 3.

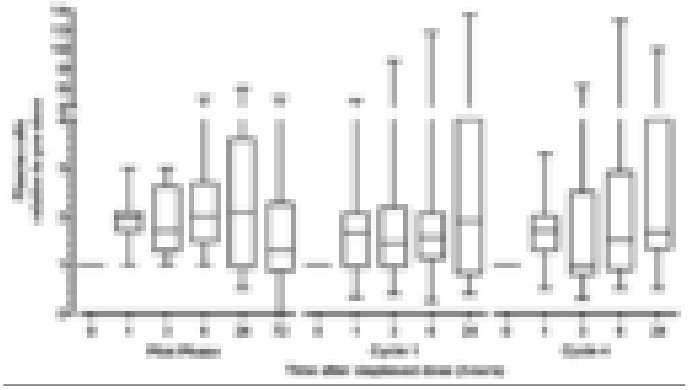

Figure 1.

Summary and Conclusions: The analysis of 20 evaluable patients documented an ORR of 70%, which is comparable to published data of the VD regimen. Considering that the study population included patients retreated with bortezomib and a marked proportion of patients with unfavorable cytogenetics, these results support the further development of olaptesed pegol in MM.

P377

IDENTIFICATION OF MYELOMA-SPECIFIC CLONOTYPES IN DIAGNOSTIC SAMPLES FROM PATIENTS WITH MULTIPLE MYELOMA USING NEXT-GENERATION SEQUENCING METHOD

S Maheo[1], M Klinger[2], M Faham[2], H Avet-Loiseau[3,*]
[1]University Hospital Toulouse, Toulouse, France, [2]Sequenta, Inc., South San Francisco, United States, [3]University Hospital Toulouse, Toulouse, France

Background: Recent reports support the prognostic importance of minimal residual disease (MRD) levels in multiple myeloma (MM) patients and suggest that novel methods for MRD assessment can play a role in the evolving MM treatment paradigm. The application of next-generation sequencing-based MRD assessment has been previously demonstrated in multiple lymphoid malignancies (Faham *et al.* Blood 2012, Ladetto *et al.* Leukemia 2013). This quantitative method, termed the LymphoSIGHT™ platform, relies on amplification and sequencing of immunoglobulin gene segments using consensus primers, with a demonstrated applicability higher than 90% in MM patients (Vij *et al.*, Clin Lymphoma Myeloma Leukemia 2013).

Aims: This technical study is aimed at assessing optimal sample type and preparation techniques. Previous experience suggested that myeloma cells may be diminished in a PBMC preparation. In this study, we evaluated this hypothesis by comparing the myeloma level in PBMC preparations and samples following RBC lysis. In addition, we evaluated the effectiveness of identifying myeloma clonotypes using DNA obtained from Bone Marrow Aspirate (BMA) slides.

Methods: Baseline samples were collected from 23 patients with MM. The following samples were provided at baseline: BMA slides, BMA cell preparations using a Ficoll protocol, and BMA cell preparations using an RBC lysis protocol. The Ficoll BMA cell preparations were divided into the mononuclear cell fraction and the lower Ficoll fraction which is typically comprised of granulocytes and erythrocytes. Identification of myeloma cells was performed using Sequenta's LymphoSIGHT™ platform. Briefly, using universal primer sets, we amplified immunoglobulin heavy chain (IGH) and light chain (IGK) variable, diversity, and joining gene segments from genomic DNA. Amplified products were sequenced and analyzed using standardized algorithms for clonotype determination. Tumor-specific clonotypes were identified for each patient based on their high-frequency (>5%) within the B-cell repertoire. Following identification of the myeloma-specific clonotypes, we assessed each of the cell preparations for the presence of the myeloma clonotype(s).

Results: The sequencing assay detected the presence of a myeloma-specific clonal gene rearrangement in 22 of 23 (96%) of patients with MM. Applicability rates were 17/18 (94%) in BMA slides and 18/19 (95%) in RBC lysis cell preparations. These applicability rates are consistent with previous reports of sequencing applicability in MM patients. In thirteen patients, we investigated the potential loss of myeloma-specific clonotypes due to Ficoll cell preparation. The variation in myeloma cell loss was typically low but ranged from essentially no loss to the loss of more than 90% of the myeloma cells in the PBMC of one patient compared to the RBC lysis preparation. The myeloma cells were detected in the typically discarded lower layer of the Ficoll preparation which explained the loss.

Summary and Conclusions: These results suggest that sequencing based MRD analysis is applicable in >95% of patients with MM. Further evaluation and optimization of sample processing methods is ongoing to enable application of the sequencing method for clinical MRD assessment in MM patients.

P378

MULTIPLE MYELOMA PATIENTS THAT DEVELOP SECOND PRIMARY MALIGNANCY HAVE A WORSE PROGNOSIS THAN MULTIPLE MYELOMA PATIENTS TREATED BEFORE THE INTRODUCTION OF NOVEL AGENTS: A POPULATION BASED-STUDY

G Jónsdóttir[1,*] SH Lund[1], O Landgren[2,3], M Björkholm[2], I Turesson[4], A Wahlin[5], C Blimark[6], M Hultcrantz[2], A Porwit[7], S Y Kristinsson[1,2]
[1]Faculty of Medicine, University of Iceland, Reykjavik, Iceland, [2]Department of Medicine, Division of Hematology, Karolinska University Hospital and Karolinska Institutet, Stockholm, Sweden, [3]Center for Cancer Research, NCI, NIH, Bethesda, United States, [4]Department of Hematology and Coagulation Disorders, Skåne University Hospital, Malmö, [5]Department of Radiation Sciences, University of Umeå, Umeå, [6]Department of Medicine, Section of Hematology and Coagulation, Sahlgrenska University Hospital, Gothenburg, Sweden, [7]University Health Network, Department of Laboratory Medicine and Pathobiology, Toronto General Hospital, Toronto, Canada

Background: The survival of patients with multiple myeloma (MM) has significantly improved over the last decades due to increasingly effective therapies. With this improvement the incidence of second primary malignancies (SPM), including acute myeloid leukemia (AML) and myelodysplastic syndromes (MDS), has become a concern. In a recent meta-analysis, exposure to lenalidomide plus melphalan significantly increased hematological SPM. However, the effect of SPM on survival in patients with MM has not been established.

Aims: The aim of this population-based study was to assess the effect of SPM on survival in patients with MM.

Methods: All MM patients diagnosed in Sweden 1958-2011 were identified from the Swedish Cancer Registry. We identified information on all subsequent SPM diagnoses among patients in the MM cohort. For each MM patient with SPM, two controls without SPM from the MM cohort were selected and matched by year of birth, sex, and date of MM diagnosis. Survival was estimated from SPM diagnosis (and corresponding date for controls) until death, with follow-up to 2012. Cox regression was used to calculate hazard ratios (HR) and 95% confidence intervals (CIs), adjusting for gender, age at MM diagnosis, and calendar period.

Results: Among 26,627 patients diagnosed with MM in Sweden 1958-2011, a total of 1,812 developed SPM and 5,132 MM patients were matched controls. Median age at MM diagnosis was 70 years and 74 years at SPM diagnosis. Of the 1,812 patients that developed SPM, 25% were gastrointestinal, 12% hematological, 13% non-melanoma skin cancer, 3% malignant melanoma, 5% respiratory, 3% nervous system tumors, 15% male reproductive system, 6% breast, 3% female reproductive system, 8% kidney and urinary tract, and 6% unspecified. Overall patients with SPM had a statistically significant 1.8-fold (95% CI 1.7-1.9) increased risk of death in comparison to control MM group. Median survival was 0.9 years after SPM diagnosis and 2.5 years after corresponding date for controls. MM patients with SPM diagnosed 2001-2011 had a significant 1.2-fold (1.01-1.42) increased risk of death in comparison to MM patients without SPM diagnosed 1958-2000 (Figure). MM patients with SPM 1958-2000 had a significant 1.6-fold (1.4-1.9) increased risk of death in comparison to MM patients with SPM 2001-2011. There was a statistically significant increased risk of death in MM patients with the following cancer groups (compared to without): gastrointestinal (HR=2.3; 2.1-2.5), hematological (2.9; 2.5-3.3), non-melanoma skin cancer (1.2; 1.0-1.3), respiratory (3.7; 3.0-4.5), nervous system tumors (3.9; 3.0-5.1), male reproductive system (1.3; 1.2-1.6), female reproductive system (2.0; 1.5-2.7), kidney and urinary tract (1.9; 1.6-2.3), and unspecified tumors (2.5; 2.1-3.1). There was no significant effect on survival in patients with malignant melanoma (1.1; 0.8-1.5) and breast cancer (1.3; 1.0-1.6) (Figure 1).

Summary and Conclusions: In this large population-based study including more than 25,000 MM patients, we found that despite the improvement in MM

survival in recent years, patients diagnosed with SPM in the last decade have an increased risk of death compared to MM patients without SPM before the introduction of the novel agents. Although MM patients in general benefit from the new therapies, the prognosis in patients with SPM is a concern. Clearly, there is need to clarify the underlying biological mechanisms and risk factors for SPM in the clinical setting to be able to provide effective MM treatment without increasing SPM.

BORTEZOMIB OR THALIDOMIDE INCORPORATED INTO AUTOLOGOUS STEM CELL TRANSPLANTATION *VERSUS* NOVEL AGENT-BASED TREATMENTS FOR ELDERLY PATIENTS WITH NEWLY DIAGNOSED MULTIPLE MYELOMA: A CASE-MATCH COMPARISON

P Tacchetti[1,*] S Bringhen[2], E Zamagni[1], L Pantani[1], A Pezzi[1], B Zannetti[1], P Tosi[3], A Larocca[2], A Brioli[1], K Mancuso[1], F Patriarca[4], S Rocchi[1], N Testoni[1], V Montefusco[5], B Gamberi[6], G Marzocchi[1], C Terragna[1], A Palumbo[2], M Cavo[1]
[1]Bologna University School of Medicine, Seràgnoli Institute of Hematology, Bologna, [2]Torino University, Hematology Unit, Department of Oncology and Hematology San Giovanni Battista, Torino, [3]Rimini Hospital, Hematology Unit, Rimini, [4]Udine University, Hematologic Clinic, Department of Experimental and Clinical Medical Sciences, Udine, [5]Fondazione IRCCS Istituto Nazionale dei Tumori, Division of Hematology, Milano, [6]Azienda Ospedaliera ASMN, IRCCS, Hematology Unit, Department of Oncology, Reggio Emilia, Italy

Background: In the novel agent era, the role of autologous stem cell transplantation (ASCT) for newly diagnosed multiple myeloma (MM) patients (pts) over 65 years of age still remains an open issue.
Aims: We aimed at exploring the role of novel agents incorporated into ASCT in comparison with novel agents alone in elderly MM pts.
Methods: We retrospectively analyzed 63 pts with a median age of 68 years (range 66-72) who were considered eligible to receive up-front novel agents plus ASCT, and we performed a case-match comparison with a series of pts who were enrolled in two GIMEMA trials for elderly pts and were treated with melphalan-prednisone plus thalidomide (MPT) (78 pts) or bortezomib (MPV) (111 pts).
Results: At diagnosis, 50% of ASCT-eligible pts had ISS stage 2-3 and 24% had renal impairment. Cytogenetic abnormalities were evaluable in half of the pts: t(4;14) was detected in 19% of them and 17p deletion in 15%. Induction therapies were bortezomib-based (37 pts) or thalidomide-based (26 pts) (median number of cycles received: 4) and affected at least a VGPR in 57% and 36% of the pts, respectively. A median of $7.2x10^6$ CD34+ cells/kg (IQR 5.8-10.9) was collected following cyclophosphamide plus G-CSF (58 pts) or G-CSF alone (5 pts). Melphalan dose prior to ASCT was 200 mg/m^2, in 39/63 pts, and 140 mg/m^2 in the remaining pts due to impaired renal function; 16 pts received a tandem ASCT. Hematologic recovery occurred at day 12 both for platelets and neutrophils (range 7-16 and 10-15). No transplant-related mortality was observed at 100 days. Two pts experienced grade 4 mucositis, and 13 pts (20%) presented grade 3 toxicities, mainly mucositis and infections. Overall, 98% of the pts achieved at least PR, including 79% at least VGPR and 51% CR. With a median follow up of 48 months, 4-years OS was 77%, median TTP and PFS were 42 and 43.4 months, respectively. Case matching was performed with a 1:3 ratio, with respect to age (+/-2 years), ISS stage and year of treatment; ASCT-eligible pts who had received bortezomib-based induction therapy were matched with pts treated with MPV, whereas pts who had received thalidomide-based induction were matched with pts treated with MPT. Baseline characteristics were similar between pts who received or not ASCT. The median number of MPT or MPV cycles actually received was 6. Novel agent-based ASCT significantly increased the probability to achieve CR as a best response (51% *vs* 29%, P=0.002), and extended TTP (43 *vs* 25 months, P=0.0013), PFS (43 *vs* 24 months, P=0.0007) and time to next treatment (33 *vs* 23 months, P=0.0077), in comparison to the control group. OS was similar between the two groups (66% at 48 months), as well post relapse OS (41% at 48 months in both groups). We performed a multivariate Cox regression analysis, that included different therapies, along with baseline and treatment-related features as prognostic factors. Variables significantly related to extended TTP and PFS included novel agent-based ASCT (P=0.006 and P=0.003), ISS 1 *vs* 2 and 3 (P=0.03 and P=0.01) and receiving a bortezomib-based therapy followed or not by ASCT (P=0.02 and P=0.03). Prolonged OS was significantly related to attainment of CR as a best response and ISS 1 (P=0.005 for both).
Summary and Conclusions: This analysis suggests that ASCT is feasible and well tolerated in selected MM pts aged >65. With the limitations of a retrospective case-match analysis and different treatments, novel agents incorporated into ASCT seem to offer better outcomes in comparison with novel agent-based treatments alone and should be considered a valid option for fit elderly pts.

P380

CAN 24-HOUR URINE COLLECTION BE REPLACED BY AN EARLY MORNING SAMPLE FOR BENCE JONES PROTEIN DETECTION AND QUANTIFICATION?

P Milani[1,*] G Palladini[1], C Klersy[2], V Valentini[1], F Lavatelli[1], M Nuvolone[1], L Zanolla[3], G Righetti[4], V Meneghini[5], MS Graziani[4], G Merlini[1]
[1]Department of Molecular Medicine, University of Pavia, [2]Scientific Direction, Fondazione IRCCS Policlinico San Matteo, Pavia, [3]Cardiology Department, [4]Clinical Chemistry Laboratory, [5]Hematology Department, Ospedale Civile Maggiore, Verona, Italy

Background: Detection and quantification of Bence Jones protein (BJP) is necessary in multiple myeloma, AL amyloidosis, and other monoclonal gammopathies. For BJP quantification a 24h urine collection is required; however, this can be inconvenient and subject to errors, particularly in the outpatient setting. Total protein excretion can be measured in an early morning void (EMV) and expressed as protein-to-creatinine ratio.
Aims: In the present study we tested if an EMV sample could be used to detect and quantify BJP in 337 outpatients from two hematology Clinics.
Methods: Two-hundred four had AL amyloidosis, 56 MGUS, 51 MM, 17 SMM, 9 WM. All the patients gave written informed consent. Patients were asked to provide the 24h urine collection and the early morning void (EMV) obtained at the end of the collection. The BJP was detected by agarose gel immunofixation. The BJP quantification was performed by densitometric scanning of the electrophoretic monoclonal peak.
Results: In 132 patients BJP was detected in both samples, in 13 only in the EMV, and in 1 only in the 24h sample (agreement 96%, Kappa-statistic 0.91 in the overall population). When the BJP was visible at electrophoresis (68 pairs of samples) it was quantified by densitometric scanning of the peak and expressed in mg/24h or mg/g-creatinine. There was very good agreement between BJP expressed as mg/24h and mg/g-creatinine in the 24h samples (Lin's correlation coefficient [cc] 0.95), mg/g-creatinine in the 24h and EMV samples (cc 0.95), and mg/24h in the 24h sample and mg/g-creatinine in the EMV (cc 0.91). In 25 patients with ≥2 measurements, agreement between changes in BJP expressed in mg/24h in the 24h sample and in mg/g-creatinine in the EMV was suboptimal (cc 0.72). However, agreement between BJP changes expressed in mg/g-creatinine in the 24h sample and in the EMV was better (cc 0.85).
Summary and Conclusions: An EMV can be used for BJP detection and measurement. The better agreement in BJP changes between the 24h and EMV samples when BJP is expressed in mg/g-creatinine probably reflects patients' errors in timed urine collection.

P381

PHASE II TRIAL OF LENALIDOMIDE, DEXAMETHASONE AND CYCLOPHOSPHAMIDE (LENDEXAL) FOR PREVIOUSLY UNTREATED PATIENTS WITH LIGHT-CHAIN AMYLOIDOSIS

MT Cibeira[1,*] A Oriol[2], JJ Lahuerta[3], M V Mateos[4], J de la Rubia[5], M Hernández[6], M Granell[7], C Fernández de Larrea[8], JF San Miguel[4], J Bladé[8]
[1]Hematology, Hospital Clinic of Barcelona, [2]Hospital Universitari Germans Trias i Pujol, Barcelona, [3]Hospital Universitario Doce de Octubre, Madrid, [4]Hospital Universitario de Salamanca, Salamanca, [5]Hospital Universitario La Fe, Valencia, [6]Hospital Universitario de Canarias, Canarias, [7]Hospital de la Santa Creu i Sant Pau, [8]Hospital Clinic of Barcelona, Barcelona, Spain

Background: Oral melphalan and dexamethasone is the standard treatment for newly diagnosed patients with immunoglobulin light chain (AL) amyloidosis not eligible for high-dose melphalan and stem cell transplantation (HDM/SCT). However, new treatment options are still needed for this patient population.
Aims: Based on the activity of IMiDs® (immunolodulatory drugs) in relapsed/refractory AL amyloidosis, we designed a prospective and multicenter phase II trial with lenalidomide, dexamethasone and cyclophosphamide for newly diagnosed patients not eligible for autologous transplant (clinicaltrials.gov identifier: NCT01194791).
Methods: The main inclusion criteria were newly diagnosed AL amyloidosis confirmed by biopsy, significant organ involvement, cardiac ejection fraction

over 50%, serum creatinine below 3 mg/dL, and not being eligible for autologous transplant. Treatment schedule consisted of 6 cycles of lenalidomide at 15 mg orally (po) on days 1 to 21, dexamethasone at 20 mg po on days 1 to 4 and 9 to 12, and cyclophosphamide at 300 mg/m^2 intravenously (iv) on days 1 and 8 every 28 days, followed by 6 more cycles of lenalidomide at the same dose, dexamethasone at 20 mg po on days 1 to 4 and cyclophosphamide 300 mg/m^2 iv on day 1. After these 12 cycles, maintenance with lenalidomide (10 mg po on days 1 to 21) and dexamethasone (20 mg po on days 1 to 4) was planned until discontinuation due to intolerance or disease progression. All patients received prophylaxis of thromboembolic events with oral aspirin (100 mg) or subcutaneous low-molecular-weight heparin. The primary end-point was hematologic response.
Results: From September 2010 to December 2012, 28 patients were included in the study. Twenty-three patients had cardiac involvement, with cardiac stage 3 in 13 of them. The overall hematologic response rate was 46%, including 14% complete responses. The organ response rate was 32%. In 5 patients lenalidomide was reduced or discontinued due to toxicity. A therapy-related serious adverse event was reported in 7 patients. So far, 11 patients remain on the study and 17 have been discontinuated mostly due to death secondary to AL-related cardiac or renal events (8 patients), progression or lack of response (4), and toxicity (3).
Summary and Conclusions: In agreement with previous reports, our results support the efficacy and tolerability of the combination lenalidomide/dexamethasone/cyclophosphamide in this poor prognostic population of patients with AL amyloidosis.

P382

THE ADDITION OF BORTEZOMIB TO STANDARD MELPHALAN/DEXAMETHASONE IMPROVES THE QUALITY OF RESPONSE BUT DOES NOT REDUCE THE RATE OF EARLY DEATHS IN AL AMYLOIDOSIS: A MATCHED CASE CONTROL COMPARISON

G Palladini[1,*] P Milani[1], M Vidus Rosin[1], M Basset[1], F Lavatelli[1], A Foli[1], G Merlini[1]
[1]Department of Molecular Medicine, University of Pavia, Pavia, Italy

Background: Oral melphalan and dexamethasone (MDex) is standard treatment in patients with AL amyloidosis who are not eligible for stem cell transplantation. Following encouraging reports on the activity of bortezomib combined with alkylators and dexamethasone, these combinations are being moved to frontline therapy.
Aims: We compared the outcome of 87 patients treated with bortezomib plus MDex (BMDex) with that of 87 controls treated with MDex.
Methods: Patients and controls were matched for all known prognostic factors, including age, cardiac and renal function and clonal burden. All the patients gave written informed consent.
Results: There was no significant difference in the rate of severe adverse events (17% in the MDex cohort and 22% in the BMDex group, P=0.444). Most common were fluid retention and cytopenia (9% and 7% in both cohorts, respectively). Peripheral neuropathy was observed only in BMDex patients (5%). A higher rate of complete responses was observed with BMDex (42% *vs.* 19%, P=0.002), but this did not result in a survival improvement. However, when patients with class III or IV heart failure and N-terminal pro-natriuretic peptide type-B >8500 ng/mL where excluded, a significant survival advantage for BMDex appeared (median survival 61 months *vs.* not reached, P=0.014). Patients treated with full-dose dexamethasone (40 mg) had similar response rates and survival whether they received bortezomib or not.
Summary and Conclusions: The addition of bortezomib to MDex does not overcome the poor prognosis of advanced cardiac amyloidosis. Intermediate-risk patients, who are not deemed eligible for high-dose dexamethasone, are likely to take the greatest advantage from combinations of bortezomib, alkylators and dexamethasone.

P383

THE PERCENTAGE OF CLONAL PLASMA CELLS IN BONE MARROW BY CIG-FISH: COMPARISON AMONG LIGHT CHAIN CARDIAC AMYLOIDOSIS, MONOCLONAL GAMMOPATHY OF UNDERMINED SIGNIFICANCE AND MULTIPLE MYELOMA

SY Kim[1,*] K Im[2], SN Park[2], J Kwon[2], JA Kim[1], Q Choi[1], SM Hwang[3], SS Yoon[4], DS Lee[1]
[1]Department of Laboratory Medicine, [2]Cancer Research Institute, Seoul National University College of Medicine, [3]Department of Laboratory Medicine, Seoul National University Bundang Hospital, [4]Department of Internal Medicine, Seoul National University College of Medicine, Seoul, Korea, Republic Of

Background: Amyloid light chain (AL) amyloidosis is a disease of clonal plasma cells synthesizing structurally abnormal light chain. Since infiltration of plasma cells in in bone marrow (BM) is minimal in amyloidosis and mature plasma cells have low proliferative activity, classic cytogenetic analysis is hampered. Thereon, we performed immunofluorescence detection of cytoplasmic light-chain (clg FISH) in AL amyloidosis, monoclonal gammopathy of undetermined significance (MGUS) and multiple myeloma (MM).
Aims: The aim of this stud is to investigate the characteristics of cytogenetic abnormaliteis found in AL amyloidosis as compared with other plasma cell neoplasms, and to determine the significance of proportions of abnormal clones measured by the clg FISH method.
Methods: A total of 230 patients was enrolled; 25 cardiac AL, 25 MUGS, and 180 MM patients. Plasma cell Sorting was performed by clg-FISH targeting IGH, RB1, TP53, 1p25/1q32, CEP 9/p16.
Results: Of 25 amyloidosis patients, 16 (61.5%) presented at least one cytogenetic abnormalities. IGH rearrangement was most frequent in 13 (50%; 13/16, 81.3%) patients, followed by RB1 deletions in 3. Eleven AL amyloidosis patients with ≤30% BM plasma cells showed only IGH rearrangements without other cytogenetic abnormalities and% of clonal cells with IGH among among total plasma cells in BM ranged from 16% to 100%. In 5 patients with >30% BM plasma cells showed multiple abnormalities. In these patients, clg-FISH revealed abnormalities in >90% of plasma cells. The 6-month mortality rate of AL amyloidosis patients with single IGH rearrangements were 27.3% (3/11), which higher than those of amyloidosis patients with multiple abnormalities (0/5). Among 25 MGUS patients, 8 (32%) patients showed cytogenetic abnormalities. Of note, the most frequent abnormality was trisomy 9, which was found in 7 (28%; 7/8, 87.5%) patients. Five MGUS patients presented trisomy 9 as single abnormality and the% clonal plasma cells ranged from 55% to 90%. Among 180 MM patients, 150 (83.3%) presented ≥2 cytogenetic abnormalities, 110 (61.1%) patients presented IGH rearrangements, 91 (50.6%) had trisomies or tetrasomies of chromosome 9, and 37 (20.6%) patients presented both abnormalities. The% clonal plasma cells ranged from 12-100%. The difference in% clonal plasma cells in BM was not significantly between AL amyloidosis and MGUS (mean, 63.8% *vs* 71.9%, P=0.971), and higher in MM (mean, 91%; P <0.001).
Summary and Conclusions: AL amyloidosis patients presented IGH rearrangement as a most frequent single cytogenetic abnormality. The percentage of clonal plasma cells in BM by Ig-FISH was not significantly different among AL amyloidosis and MGUS. The clinical presentation of cardiac amyloidosis was not dependent of the plasma cell burden or the clone size harboring cytogenetic abnormalities.

PLATELET MICROPARTICLE PROCOAGULANT AND PROANGIOGENIC FEATURES IN ESSENTIAL THROMBOCYTHEMIA (ET)

S Gamba[1,*] M Marchetti[1], A Vignoli[1], L Russo[1], C J Tartari[1], G Finazzi[2], A Rambaldi[2], A Falanga[1]
[1]Div. Immunohematology and Transfusion Medicine, [2]Div. Hematology, Hospital Papa Giovanni XXIII, Bergamo, Italy

Background: Circulating microparticles (MP) are altered in number and composition in various diseases associated to a high thrombotic risk, including ET. In addition to their role in the process of thrombus formation, MP are also important in tumor progression, particularly in the neoangiogenesis process. Platelets, which circulate in an activated status in ET, represent the main source of MP in these patients.
Aims: To characterize the procoagulant and proangiogenic properties of MP released *in vitro* by platelets isolated from patients with ET.
Methods: A total of 23 ET (11M/12F) and 16 healthy (CTR: 9M/7F) subjects were included into the study after informed consent. Platelets were isolated from venous blood samples collected in sodium citrate (3.2%) according to a standardized procedure, and re-suspended in Hepes Tyrode buffer at the concentration of $1x10^9$ platelets/ml and left unstirred for 20 min at 37 C° for the releasing of MP. At the end of incubation, platelet MP (PMP) were isolated by two serial high speed centrifugations (4,000 rpm for 20 min and 14,000 rpm for 60 min) and re-suspended in a fixed volume of the appropriate buffers for the different analyses. PMP were quantified by flow cytometry (Accuri C6, Becton Dickinson) as CD41 positive events. The calibrated automated thrombography (CAT assay by Stago) was used to measure the PMP thrombin generation (TG) potential, while the P-PPL/1 assay (Stago) to evaluate phospholipid-dependent procoagulant activity (PCA). The capillary-like tube formation assay in Matrigel was employed to characterize the PMP proangiogenic potential. Finally, VEGF levels in PMP lysates were measured by ELISA.
Results: Significantly higher PMP levels were found in plasma of ET patients compared to controls (3,359±345 *vs* 1,562± 134/uL; p<0.05). After correction for the respective *in vivo* platelet counts, we observed that ET patients displayed significantly lower rate of circulating PMP per platelets compared to controls (6.5 *vs* 11.4 PMP/plt, p<0.05). The *in vitro* study, showed that platelets from ET patients released **s**ignificantly (p<0.05) lower quantity of PMP compared to controls (1.85±1.0 *vs* 6.04±1.34 $x10^6$/ml). Concerning the TG assay, PMP obtained by platelets from ET patients showed a lower TG activity compared to controls (p<0.05), as demonstrated by longer lag-time (23±0.9 *vs* 21.8±1.9 min) and lower peak of thrombin (91.6±11.8 *vs* 183.5±17.9 nM FIIa). Likewise, PMP from ET patients induced significantly lower phospholipid-dependent PCA compared to controls (54.8±5.53 *vs* 34.9±2.56 sec; p<0.05). After normalization of the PMP count, the procoagulant potential of PMP from ET patients remained lower than that of controls. Finally, in the capillary like tube formation assay, the PMP from ET patients were less proangiogenic compared to control PMP (At $5x10^6$, MP/ml: 560±36 *vs* 713±48 mm/cm²; p<0.05), although VEGF levels were higher in PMP from ET than controls (68±43 *vs* 33±22 pg/ml; p=n.s).
Summary and Conclusions: Our data show that platelets isolated from ET patients generate *in vitro* less PMP than controls, when resuspended at the same concentration. This finding is in agreement with the observation that *in vivo* the rate of PMP per platelets is significantly lower in ET than in controls. Moreover, PMP released *in vitro* from ET patients show a lower procoagulant and proangiogenic potential. Therefore, the demonstrated higher PCA of MP *in vivo* might be mainly due to the presence of elevated number of MP in plasma but not to an intrinsic increased procoagulant potential.

P385

ACTIVATING MUTATIONS IN TRANSCRIPTION FACTOR NF-E2 ALTER PROTEIN-PROTEIN INTERACTIONS

T Basu[1,*] A Gründer[1], W Wang[1], MA Sanders[2], PJ Valk[2], HL Pahl[1]
[1]Section of Molecular Hematology, Department of Hematology / Oncology, Universtity Hospital Freiburg, Freiburg, Germany, [2]Department of Hematology, Erasmus University Medical Center, Rotterdam, Netherlands

Background: We have recently described indel mutations in the gene encoding the transcription factor NF-E2 in patients with myeloproliferative neoplasms (MPN). These alterations lead to the formation of truncated proteins, which, despite having lost the ability to bind DNA, nonetheless increase the activity of wild type NF-E2. To date, the mechanism of action by which truncated NF-E2 augments the transactivating potential of its wild type counterpart remains unclear.
Aims: We hypothesized that truncation of NF-E2 alters the range of protein-protein interactions exerted and that these aberrant interactions confer the activating phenotype.
Methods: Using co-transfection and co-immunoprecipitation assays, we investigated protein-protein interactions of wild type NF-E2 and its truncation mutants.
Results: Here we demonstrate for the first time that NF-E2, which is known to form heterodimers with small Maf proteins, can alternatively form homodimers. The truncated mutants, in contrast, have lost both the ability to interact with Maf proteins as well as the ability to homodimerize.
The E3-ubiquitin ligase ITCH has previously been reported to bind wild type NF-E2, thereby sequestering and stabilizing the protein in the cytoplasm. We have recently demonstrated mislocalization of NF-E2 in patients with PMF (primary myelofibrosis). Compared to either healthy controls or patients with ET (essential thrombocythemia), PMF patients display nuclear NF-E2 in a significantly higher number of early erythroblasts, an observation that can be exploited diagnostically to identify early, pre-fibrotic PMF patients.
We hypothesized that altered NF-E2 / ITCH interactions may underlie the observed protein mislocalization in PMF patients. However, even the shortest truncation mutant, which is comprised of only 79 amino acids of the NF-E2 N-terminus, retains the ability to interact with ITCH. Co-expression of ITCH increases the amount of truncated NF-E2 protein detectable, suggesting that the interaction stabilizes the mutant protein, just as it does wild type NF-E2.
Summary and Conclusions: Consequently, we propose that mutant NF-E2 occupies the available ITCH protein, thereby preventing it from sequestering the wild type transcription factor in the cytoplasm. This leads to the observed increase in nuclear NF-E2 in PMF patients with the concomitant increase in NF-E2 transcriptional activity observed in the presence of mutant NF-E2. While only a subset of PMF patients carries NF-E2 mutations, the vast majority of MPN patients express significantly elevated NF-E2 levels. An excess of wild type NF-E2 may likewise prevent ITCH from effectively sequestering the transcription factor. The mechanism causing increased nuclear NF-E2 activity by decreasing cytoplasmic sequestration, elucidated here, may thus be active in the majority of MPN patients and constitute a paradigm for explaining the elevated NF-E2 activity observed in MPN.

MORGANA IS A NEW ONCOSUPPRESSOR IN CHRONIC MYELOID LEUKEMIA

A Di Savino[1], C Panuzzo[1], S Rocca[2], U Familiari[3], R Ferretti[2], F Fusella[2], R Piazza[4], C Gambacorti Passerini[4], E Giuliano[1], S Crivellaro[1], G Carrà[1], A Camporeale[2], B Miniscalco[5], JC Cutrin[2], E Turco[2], L Silengo[2], E Hirsch[2], M Papotti[3], PP Pandolfi[6], G Saglio[1], G Tarone[2], A Morotti[1,*] M Brancaccio[2]
[1]clinical and biological sciences, San Luigi Hospital, University Of Turin, orbassano, [2]Dept. Biotechnology and Health Sciences, university turin, turin, [3]Division of Pathology, San Luigi Hospital, University Of Turin, orbassano, [4]dipartimento di scienze della salute, università milano bicocca, monza, [5]Department of Veterinary Sciences, university turin, turin, Italy, [6]Beth Israel Deaconess Medical Center, Harvard University, Boston, United States

Background: We recently described morgana as an essential protein able to regulate centrosome duplication and genomic stability, by inhibiting ROCK. We have previously generated a morgana null murine model which is characterized by an embryonic lethal phenotype. From 12 months of age onwards, *morgana* +/- mice showed clear pathological signs, such as rapid weight loss, hunched posture and severe hypokinesia and died as a result.
Aims: First, we aimed to identify the cause of death of morgana +/- mice and then we assessed whether morgana could play a role in a corresponding human pathology.
Methods: Peripheral and bone marrow samples from Morgana +/- mice have been studied using conventional methods, including flow cytometry, colony formation assay, cytogenetics and bone marrow transplantation assays. Human samples have been collected from informed patients upon ethical committee approval. Bone marrow samples have been used to assess the expression levels of morgana using both western immunoblot, immunofluorescence, quantitative PCR and immunohystochemistry. Furthermore primary cells have been treated with different ROCK inhibitors to assess apoptosis induction.
Results: Here we show that morgana +/- mice spontaneously develop a lethal myeloproliferative disease resembling human atypical chronic myeloid leukemia (aCML), preceded by ROCK hyperactivation centrosome amplification and cytogenetic abnormalities in the bone marrow (BM). Moreover, we found that morgana is often underexpressed in the BM of patients affected by aCML, a rare disorder characterized by non-recurrent cytogenetic abnormalities, whose molecular basis is poorly understood. Morgana is also underexpressed in the BM of a portion of patients affected by Philadelphia positive CML (Ph+ CML) caused by the BCR-ABL oncogene. Notably, we found that morgana underexpression predicts a worse response to Imatinib, the Ph+ CML standard treatment.
Summary and Conclusions: Morgana can act as an oncosuppressor in CML with different modalities: morgana underexpression induces centrosome amplification and cytogenetic abnormalities and in Ph+ CML, it synergizes with BCR-ABL signaling, therefore reducing the efficacy of Imatinib treatment. Importantly, ROCK inhibition in the BM of patients underexpressing morgana restored the efficacy of Imatinib to induce apoptosis, suggesting that ROCK inhibitors, in combination with Imatinib treatment, can overcome suboptimal responses in patients in which morgana is underexpressed.

P387

CD4+ T CELL FUNCTIONS ARE POTENTLY SUPPRESSED BY THE JANUS KINASE 1/2 (JAK1/JAK2) INHIBITOR RUXOLITINIB

S Parampalli Yajnanarayana[1,*] T Stuebig[2], I Cornez[1], H Alchalby[2], C Wolschke[2], A Heine[1], P Brossart[1], N Kröger[2], D Wolf[1]
[1]Department of Internal Medicine III,, Oncology, Hematology and Rheumatology, University Hospital of Bonn, Bonn, [2]Department for Stem cell Transplantation, University Medical Center Hamburg-Eppendorf, Center of Oncology, Hamburg, Germany

Background: Recent discoveries of activating JAK mutations in patients with myeloproliferative diseases (MPNs) coupled with the so far known biology of JAKs in cytokine signalling provided the rationale for targeting these kinases in MPNs. Ruxolitinib (INCB018424) is the first JAK1/JAK2 inhibitor approved for treatment of patients with myelofibrosis (MF). Although ruxolitinib shows limited anti-clonal activity, a profound improvement of quality of life and splenomegaly in MF patients is observed and linked to a substantial reduction of MF-associated circulating pro-inflammatory and pro-angiogenic factors. JAK/STAT-signalling is known to be involved in the regulation of various immune cells including $CD4^+$ T cells, which critically orchestrate inflammatory responses. To better understand how ruxolitinib is modulating $CD4^+$ T cell response, we here provide an in depth analysis of $CD4^+$ T cell function upon ruxolitinib exposure.
Aims: We aim to characterise in detail the JAK1/2 inhibition on CD4+ T cells by phenotypic and functional assays.
Methods: Highly purified $CD4^+$, T cells isolated from healthy human PBMCs were stimulated with i) plate bound anti-CD3, ii) plate bound anti-CD3 and soluble anti-CD28 antibodies, iii) IL-2 in the presence of increasing concentrations of ruxolitinib (0.1μM–10μM) or the respective vehicle control (DMSO). Cytokine production was quantified by flow-based bead assays (Human Th1/Th2 FlowCytomix Multiplex). Proliferation was detected by CFSE dilution analysis. Differentiation was analyzed by using $CD4^+CD62L^+$ T cells isolated from C57BL/6 mice exposed to TH1, TH17 or iTreg differentiation cocktails in combination with anti-CD3 and anti-CD28 stimulation. For analysis of apoptosis/necrosis induction, annexin/propidium iodide staining was applied. Signalling events were analyzed by using phospho-flow technology to evaluate ruxolitinib-mediated changes of TCR- and/or cytokine-induced signalling cascades (using pS6, pSTAT5, pERK, pAKT, pP38, pcFos, pcJun and pCD3Z antibodies). Additionally we analysed patients treated with ruxolitinib (n=9) for changes in their T-cell compartment. Therefore, cells were collected prior to and during ruxolitinib therapy in weekly intervals. T-cells were analyzed according to their expression of CD3 and CD4 and further characterized as activated (HLA-DR+), Treg (CD25hi/CD127low) or TH1 (IFNg+) and Th17 (IL17+) cells.
Results: $CD4^+$ T cell proliferation is dose-dependently suppressed by ruxolitinib when T cells were activated by each of the three conditions tested. In line with previous studies, production of pro-inflammatory cytokines such as IL-1β, IL-5, IL-6 and TNF-α was dose-dependently inhibited in ruxolitinib, whereas expression of the pro-inflammatory IL-8 was increased in a dose-dependent manner. Interestingly, despite the complete proliferation block, we also observed an increase in IL-2 particularly at the lower ruxolitinib concentrations (0.1μM) followed by a dose dependent reduction at higher dose-levels (10μM). After short-term activation of ruxolitinib-exposed $CD4^+$ T cells by anti-CD3 and anti-CD28, proximal TCR signaling events were not affected, whereas a clear down-regulation of IL-2 induced STAT5 phosphorylation could be detected. After wash-out, ruxolitinib-induced inhibitory effects on $CD4^+$ T cell function were fully reversible, as shown by re-induction of the T cell activation markers CD25 and CD69 upon stimulation. Finally, we could provide clear evidence that the differentiation capacity of naïve $CD4^+$ T cells into TH1, TH17 and iTreg was markedly reduced. Finally, we could prove tha *in vivo* significance of our *in vitro* findings, as patients treated with ruxolitinib showed reduced numbers of activated T cells as well as reduced numbers in pro-inflammatory TH1 and TH17 cells. Similarly and in line with our *in vitro* results, Treg were clearly reduced in patients during ruxolitinib therapy.
Summary and Conclusions: We could show that ruxolitinib potently affects $CD4^+$ T cell biology. These data provide a rationale for testing JAK inhibitors in diseases triggered by hyperactive $CD4^+$, T cells, such as autoimmune diseases. In addition, they also provide an explanation for the increased infection rates (*i.e.* viral reactivation and urinary tract infection) seen in ruxolitinib-treated patients.

INTRACELLULAR CALCIUM DEPOSITS AND STORE OPERATED CALCIUM ENTRY IN CD34+ CELLS FROM PATIENTS WITH MYELOFIBROSIS CARRYING A CALR MUTATION

V Poletto[1,*] I Canobbio[2], D Pietra[3], S Dragoni[2], E Bonetti[1], R Campanelli[1], M Massa[1], G Fois[1], P Catarsi[1], L Villani[1], M Torti[2], F Tanzi[2], M Cazzola[3], F Moccia[2], G Barosi[1], V Rosti[1]
[1]Centro per lo Studio e la Cura della Mielofibrosi, LSR Area Biotecnologie, Fondazione IRCCS Policlinico San Matteo, [2]Dipartimento di Biologia e Biotecnologie, Universita' di Pavia, [3]Dipartimento di Ematologia-Oncologia, Fondazione IRCCS Policlinico San Matteo, Pavia, Italy

Background: Mutations at exon 9 of the calreticulin gene (*CALR*) have been recently identified in about 70% of patients with primary myelofibrosis (PMF) or essential thrombocythemia (ET), who were wild type for *JAK-2* and/or *MPL* mutations. *CALR* gene product is an endoplasmic reticulum (ER) Ca^{2+} binding chaperone, which is involved also in the regulation of glycoprotein folding. In patients with PMF or ET, *CALR* mutations, which occur in a multipotent hematopoietic progenitor cell, are mainly represented by either a 52-bp deletion or a 5 bp insertion, resulting in a novel C-terminal peptide sequence. This is the domain responsible for the Ca^{2+}-binding activity of the protein and this mutation is predicted to lower Ca^{2+} storage capacity in the ER. ER-Ca^{2+} content is tightly coupled to a well known mechanism of Ca^{2+} influx in hematopoietic cells, namely, store-operated Ca^{2+} entry (SOCE), which is activated upon a fall in ER Ca^{2+} content to refill ER and activates specific Ca^{2+}-dependent signaling pathways. The interaction between ER-dependent Ca^{2+} release and SOCE is involved in the regulation of gene expression, apoptosis, cell migration, and cell proliferation/differentiation. The mechanisms by which *CALR* mutations produce a myeloproliferative phenotype are unknown.
Aims: Based on the role that *CALR* plays in regulating Ca^{2+} homeostasis, we have studied intracellular Ca^{2+} deposit and SOCE in CD34+ cells obtained from the peripheral blood of 3 patients with PMF carrying the 52-bp deletion of CALR gene, 3 patients with PMF carrying a JAK2V617F mutation, and 1 healthy subject.
Methods: CD34+ cells were loaded with 4 mcM fura-2 acetoxymethyl ester for 1 hour at room temperature. Depletion of intracellular Ca^{2+} stores was obtained by the addition of 10 mcM cyclopiazonic acid (CPA) to a 0 Ca^{2+} bathing medium. Subsequent replenishment of Ca^{2+} (1.5 mM) to the extracellular solution elicited a rise in $[Ca^{2+}]_i$ due to Ca^{2+} influx through open store-operated Ca^{2+} channels. The amplitude of the peak Ca^{2+} response to CPA was measured as the difference between the ratio at the peak and the mean ratio of 1 min baseline before the peak. SOCE amplitude was measured as the difference between the peak and the mean ratio of 1 min baseline recorded before Ca^{2+} readdition. Data are expressed as mean +/- SE.
Results: Resting Ca^{2+} levels in CD34+ cells from *CALR*-mutated patients were slightly lower as compared to V617F*JAK2* mutated patients (68.7±24.0 nM *vs* 82.2±13.2 nM), but considerably higher than the healthy donor (33.5 nM). CD34+ cells from CALR-mutated patients release more Ca^{2+} from ER stores as compared to V617F*JAK2* mutated patients (52.8 nM±28.6 *vs* 37.7 nM±19.1, respectively) and compared to the healthy donor (30 nM). SOCE of CD34+ cells of *CALR* mutated patients (228.5 nM±26.1) was slightly reduced compared to *JAK2*-mutated patients (370.2±174.6) and lower than SOCE of a healthy subject (130 nM).
Summary and Conclusions: Our results suggest that *CALR* mutation in CD34+ cells of patients with PMF is associated with i) a reduction in basal Ca^{2+} levels compared to *JAK2* mutated cells, but an increase compared to healthy CD34+ cells; ii) an increased amount of free Ca^{2+} in the ER compared to *JAK2*-mutated and healthy CD34+ cells and, iii) a decreased SOCE compared to healthy CD34+ cells and, at a lower extent, compared to *JAK2*-mutated CD34+ cells. Taken together, these results seem to suggest that *CALR* mutation could be implicated in the myeloproliferative phenotype that characterizes PMF patients carrying CALR mutations by interfering with the signaling role of Ca^{2+}.

P389

VEGF-INDUCED CA2+ SIGNALS ARE DERANGED IN ENDOTHELIAL PROGENITOR CELLS FROM PATIENTS WITH MYELOFIBROSIS CARRYING JAK2 MUTATIONS

S Dragoni[1], V Poletto[2,*] F A Ruffinatti[3], G Barosi[2], F Tanzi[1], V Rosti[2], F Moccia[1]
[1]Department of Biology and Biotechnology, University of Pavia, [2]Foundation IRCCS Policlinico San Matteo, Pavia, [3]University of Turin, Turin, Italy

Background: Recent studies have unveiled that calreticulin mutations may occur in patients with myelofibrosis who are wild type for Janus kinase 2 gene (JAK2). This phenotype might have an impact on intracellular Ca^{2+} signalling, which serves as a versatile messenger system in virtually all cell types. However, parallel work from our group has demonstrated that circulating endothelial progenitor cells (EPCs) from JAK2-mutated patients undergo a dramatic remodelling of the Ca^{2+} toolkit (Dragoni *et al.*, PloS One, in press). There is a significantly higher amount of free Ca^{2+} in the endoplasmic reticulum of these cells, whereas both inositol-1,4,5-trisphosphate receptors ($InsP_3Rs$) and store-operated Ca^{2+} entry (SOCE) are up-regulated. SOCE is the most important pathway for Ca^{2+} inflow in healthy EPCs, controlling VEGF-induced proliferation, tubulogenesis and NF-kB-dependent gene expression. However, the pharmacological inhibition of this pathway did not interfere with proliferation of EPCs isolated from JAK2-mutated patients and seeded in the presence of an expansion medium containing VEGF, bFGF and EGF.
Aims: The present investigation aimed at assessing whether VEGF evokes intracellular Ca^{2+} oscillations in EPCs derived from patients carrying JAK2 mutation and whether they are remodelled as compared to control cells.
Methods: Epifluorescence microscopy was employed to monitor and record intracellular Ca^{2+} signals in EPCs loaded with the Ca^{2+}-sensitive fluorochrome Fura-2/AM (2 μM; 30 min). VEGF was applied at 10 ng/ml.
Results: VEGF-induced asynchronous oscillations in $[Ca^{2+}]_i$ in EPCs of JAK2-mutated patients; this pattern of signalling is similar to that displayed by con-

trol cells. The amplitude of VEGF-evoked Ca^{2+} transients remained constant throughout the stimulation; however, their amplitude was significantly ($p<0.05$) reduced as compared to healthy cells. Subsequent wavelet analysis revealed that the oscillatory activity in EPCs from JAK2-mutated patients was significantly ($p<0.05$) less robust relative to control cells. The pharmacological inhibition of phospholipase Cg (PLCg)/$InsP_3Rs$ pathway abolished the onset of the Ca^{2+} response. The same result was obtained by removing external Ca^{2+}, thereby indicating that Ca^{2+} inflow is essential to trigger the signal. This finding is strikingly different from healthy cells, which require Ca^{2+} influx only to maintain, not to initiate, the Ca^{2+} train. SOCE blockade with BTP-2 reduced the number of VEGF-induced Ca^{2+} oscillations in EPCs from JAK2-mutated patients, but did not prevent them. La^{3+} and Gd^{3+}, in turn, suppressed the onset of the Ca^{2+} train; this suggested that the Ca^{2+} entry pathway triggering the Ca^{2+} response to VEGF is sensitive to these trivalent cations, but not to BTP-2. This pathway could be gated by 1-Oleoyl-2-acetyl-glycerol, a membrane permeable DAG analogue, that activates an influx of Ca^{2+} blocked by Gd^{3+} and La^{3+}, but unaffected by BTP-2, in EPCs from JAK2-mutated cells, but not in healthy cells.
Summary and Conclusions: The Ca^{2+} machinery shaping the Ca^{2+} response to VEGF is remodelled in EPCs from patients carrying JAK2 mutation. The oscillatory activity is less robust as compared to control cells despite for the higher expression of $InsP_3Rs$ and SOCE. The oscillatory signal is initiated by an OAG-mediated influx of Ca^{2+}, which in turns elicits the interplay between $InsP_3$-mediated Ca^{2+} release and SOCE. Future studies will have to assess why this mode of Ca^{2+} signal is not able to deliver a pro-angiogenic stimulus to these cells.

P390

INTEGRATED GENOMIC ANALYSIS ILLUSTRATES THE CENTRAL ROLE OF JAK-STAT PATHWAY ACTIVATION IN MYELOPROLIFERATIVE NEOPLASM PATHOGENESIS

R Rampal[1,*] F Al-Shahrour[2], O Abdel-Wahab[1], J Patel[1], JP Brunel[2], C Mermel[3], A Bass[2], J Pretz[2], J Ahn[1], T Hricik[1], O Kilpivaara[4], M Wadleigh[2], L Busque[5], DG Gililand[6], T Golub[3], B Ebert[2], R Levine[1]
[1]Memorial Sloan-Kettering Cancer Center, New York, [2]Dana Farber Cancer Institute, [3]Broad Institute of Harvard University and MIT, Boston, United States, [4]University of Helsinki, Helsinki, Finland, [5]Maisonneuve-Rosemont Hosptial, Montreal, Canada, [6]Perelman School of Medicine, University of Pennsylvania, Pennsylvania, United States

Background: The Philadelphia chromosome-negative myeloproliferative neoplasm (MPNs) are clonal hematopoietic disorders consisting of polycythemia vera (PV), essential thrombocythemia (ET), and primary myelofibrosis (PMF). To date, genomic studies have identified somatic alterations in the majority of MPN patients, including *JAK2* mutations in the majority of MPN patients and *CALR* mutations in *JAK2* mutant-negative MPN patients. However, the role of JAK-STAT pathway activation in different MPNs, particularly in patients without *JAK2* mutations, has not been definitively delineated. Further, the impact of *JAK2V617F* allele burden as well as the impact of different somatic alterations, including mutations in epigenetic regulators, such as *TET2* or *ASXL1*, on transcriptional output has not been extensively evaluated. Given the relative genetic heterogeneity of the MPNs, evaluation of the transcriptional output found in the MPNs could have broad therapeutic and biologic implications.
Aims: To characterize the transcriptional output of patients with MPNs with and without *JAK2* mutations.
Methods: We performed gene expression profiling using Affymetrix oligonucleotide microarrays in granulocytes from normal individuals and a cohort of well-characterized patients with chronic MPNs and integrated this data with detailed molecular characterization in order to understand how transcriptional output in MPN cells relates to the clinical phenotype and molecular genotype of MPN patients.
Results: We observed that a transcriptional signature consistent with activated *JAK2* signaling is seen in all MPN patients regardless of clinical phenotype or mutational status (Figure 1). In addition, the activated *JAK2* signature was present in patients with somatic *CALR* mutations. Conversely, GSEA revealed significant enrichment of the *CALR*-mutant MPN gene signature in *JAK2*V617F-mutant MPN patients relative to normal individuals consistent with a shared mechanism of transformation by *JAK2* and *CALR* mutations. In terms of patients with *JAK2*V617F mutations, patients with homozygous *JAK2*V617F mutations were characterized by a distinctive transcriptional profile compared to patients with heterozygous *JAK2* mutations. The genes most highly differentially expressed in MPN patients with homozygous *JAK2*V617F mutation included *JAK2* itself as well as *CD177*/*PRV1*. We also identified a distinct transcriptional signature of *TET2* mutations in MPN patent samples consisting of of 61 significantly differentially expressed genes in *TET2* mutant *versus* wildtype MPN patients (FDR<0.05).
Summary and Conclusions: Our data indicate that MPN patients, regardless of diagnosis or *JAK2* mutational status are characterized by a distinct gene expression signature with upregulation of JAK-STAT target genes, demonstrating the central importance of the JAK-STAT pathway in MPN pathogenesis. These findings imply that therapeutic interventions aimed at the JAK-STAT pathway may have efficacy regardless of the observed genotype and are likely to continue to represent an important therapeutic strategy in MPNs. As well, other genomic alterations, such as changes in the *JAK2*V617F allele burden as well as the presence of other mutational events such as *TET2* mutations, can alter the gene expression signature, and potentially phenotype, of the MPNs. As such, the wide array of genomic alterations that co-occur with *JAK2*/*MPL*/*CALR* mutations. likely play a role in the phenotypic heterogeneity observed across the MPNs. Further analysis of these alterations using human samples and animal models is required.

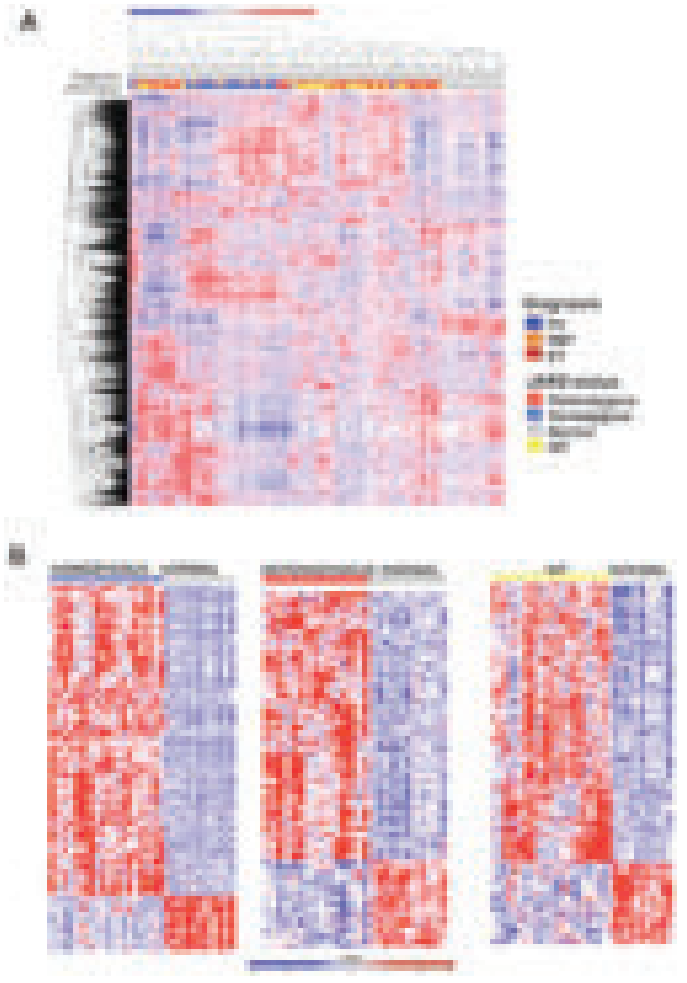

Figure 1.

Background: Refractory Anaemia with Ring Sideroblasts (RARS) and marked Thrombocytosis (RARS-T) is a myeloproliferative (MPN)/myelodysplastic (MDS) neoplasm with the *JAK2*^{V617F} mutation present in half of all and *MPL*^{W515} in few RARS-T cases. Recently somatic mutations in the Calreticulin (CALR) gene have been reported in a high proportion of *JAK2*- and *MPL*-non mutated MPN cases
Aims: The purpose of our study was to analyse the frequency of *CALR* mutations on a large RARS-T and RARS cohort and understand whether *CALR* mutations may also be responsible for thrombocytosis in this disease.
Methods: One hundred and twenty four samples including 95 RARS-T and 29 RARS from seven European centres in three European countries were collected and tested

Results: A total of 124 cases with MDS-RS (95 RARS-T and 29 RARS including 62 males and 62 females) were recorded in the study, which is, to our best knowledge, the largest series of MDS-RS studied for *CALR* mutations. Median age at diagnosis was 74 and 73 years for the RARS-T and RARS cohort, respectively. *SF3B1* mutation was noted in 24 (82.7%) RARS and 83 (88.3%) RARS-T, confirming that this mutation is highly represented in MDS-RS.A *JAK2*^{V617F} mutation was noted in 47 of the 95 RARS-T patients (49.4%) but none in RARS patients. A *CALR* mutation was noted in only one (1%) RARS-T and one (3.4%) RARS patient, each. The *CALR* mutation found in the RARS-T patient was a 10 bp (1129-1138) deletion located in the exon 9 which is not the most frequent reported *CARL* mutation. Surprisingly, this patient presented also a *JAK2*^{V617F} mutation with a low allele burden (4%) and a *SF3B1* mutation. The mutational status of this patient has been confirmed in two independent laboratories. He patient has been treated with Hydroxyurea since 2010 with a good tolerance. The latest full blood count showed haemoglobin 104 g/L, platelet count 584 G/L and leucocytes 4.3 G/L.Among the 29 RARS, we also identified a single case with *CALR* mutation. This unique *CALR*-positive RARS case was a 70-year old man who did not have elevated platelet count but rather a thrombocytopenia, and carried a *SF3B1* mutation. No *JAK2*^{V617F}, *MPL* or cytogenetic abnormality was noted in this patient.
Summary and Conclusions: *CALR* mutations are rare in MDS with RS and do not explain the myeloproliferation in the *JAK2*^{V617F}- and *MPL*-negative RARS-T cases. In addition, we report the first case of coexisting *CALR* and *JAK2*^{V617F} mutations in RARS-T.

P392

GATA1 IS OVEREXPRESSED IN PATIENTS WITH ESSENTIAL THROMBOCYTHEMIA AND IT IS NORMALIZED BY ANAGRELIDE TREATMENT.

C Rinaldi[1,*] C Graham[1], L Brown[1]
[1]University of Lincoln, Lincoln, United Kingdom

Background: GATA1 is the founding member of the GATA transcription factor family and is essential for cell maturation and differentiation within the erythroid and megakaryocytic lineages. GATA1 is a pleotropic transcription factor, whose expression is essential in these lineages; its function depends upon its ability to bind to both DNA and protein partners. Disturbance of either of these functions causes severe hematopoietic dysfunction and can result in blood disorders, such as thrombocytopenia, anaemia and even leukaemia. Ectopic expression of GATA1 in the murine myeloid cell line M1 induces c-Mpl appearance and megakaryocyte (MK) differentiation. The same phenomenon has been showed to occur in hematopoietic stem cells; in that forced increased expression of GATA1 blocked self-renewal and induced the exclusive generation of MegE lineages. Several studies, have suggested a connection between GATA1 and myeloproliferative neoplasia (MPN). We previously reported, high GATA1 transcript levels are found in the bone marrow of patients with ET and PV, independent of the JAK2 V617F mutation. However, over expression of GATA1 is not seen in other MPN. Anagrelide (ANA) has been proven to be an effective drug in reducing platelet count and thrombotic risk in management of ET and PMF patients. However, the mechanisms by which this drug induces this effect is still unclear. Recently Erusalimsky and colleges have reported that ANA results in down-modulation of GATA1 and its co-factor FOG1 in MK during *in vitro* differentiation.
Aims: In this study, we analysed the expression of GATA1 in peripheral blood (PB) samples from 30 patients with ET and compared the levels of expression before and after treatment with common cytoreductive agents such as hydroxyurea (HU) and ANA.
Results: We confirmed the data obtained in BM, with a significant up-regulation of GATA1 in ET compared to controls. When we measured the expression of GATA1 before and during treatment with ANA, there was a significant reduction of the GATA1 expression at 3 and 6 months of therapy, concomitantly with a reduction in platelets (PLT) counts. Interestingly, this was not equally observed in patients treated with HU, where despite reduction in PLT counts, the GATA1 levels rose. Furthermore, when we analysed patients on combination treatment ANA+HU, GATA1 expression reduced only when patients were taking ANA. When ANA treatment was stopped and the patient continued only on HU, GATA1 levels rose again.
Summary and Conclusions: This data suggests a direct effect of ANA on GATA1 expression. GATA1 may represent a generic molecular marker in ET and a possible additional diagnostic criteria in thrombocytosis. GATA1 overexpression is independent from JAK2 mutations, and responds specifically to ANA therapy suggesting a role in monitoring therapy response.

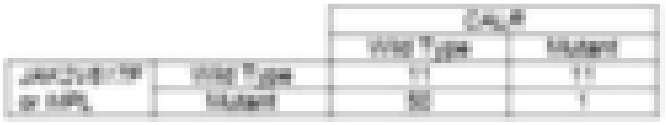
IMPORTANCE OF CALR MUTATIONS IN THE DIAGNOSIS OF PRIMARY MYELOFIBROSIS

L Zamora[1,*] M Cabezón[1], O Garcia[2], P Velez[3], N Estrada[2], S Marcé[1], C Boqué[3], B Xicoy[2], C Fernandez[4], D Dominguez[1], M Xandri[1], E Casanovas[3], A Fernandez de Sevilla[3], D Gallardo[4], JM Ribera[2], E Feliu[1], F Millá[1]
[1]Laboratori Hematologia, [2]Hematologia Clínica, ICO-Hospital Germans Trias i Pujol. IJC, Badalona, [3]Hematologia Clínica, ICO-Hospital Duran i Reynals, Barcelona, [4]Hematologia Clínica, ICO-Hospital Josep Trueta, Girona, Spain

Background: In the last World Health Organization (WHO) classification, somatic mutations had been incorporated into diagnostic criteria for primary myelofibrosis (PMF). *JAK2V617F* and *MPL* mutations have been reported in 50-70% of patients with PMF, being 30-50% of patients the ones who didn't have any of these molecular markers. Recently it has been discovered mutations in calreticulin (*CALR*) gene which occur in 80-88% of PMF patients not having *JAK2V617F* or *MPL* mutations.
Aims: The aim of this study was to analyze the incidence and prognostic relevance of *CALR* mutational status in serial diagnosed patients with PMF who had not received previous treatment.
Methods: A total of 73 consecutive PMF patients were included (median age 69; 45 males) with fulfilling the WHO criteria valid at the moment of their diagnosis. This study was conducted in accordance with the Declaration of Helsinki. Genomic DNA was extracted from bone marrow or peripheral blood samples using the QIAamp DNA Blood mini kit (Qiagen). All samples were coded and assayed blindly for the *JAK2V617F, MPL* and *CALR* mutations. To detect the presence or absence of *JAK2V617F* mutation, an Allele-Specific PCR using TaqMan allelic discrimination was used. We used Sanger sequencing to detect MPL exon 10 mutations. And we screen for insertion and deletion mutations in *CALR* with 6-FAM labeled primers spanning exon 9. We confirm and describe *CALR* mutations type with Sanger sequencing. Laboratory parameters (red blood cell indexes, leukocyte and platelet counts) and clinical data (constitutional symptoms, complications and progression) were collected. **Results:** A total of 46/73 (63%) patients were *JAK2V617F* positive and from the 27 *JAK2V617F* negative, 5 had *MPL* mutations (18.5%). Twelve patients out of 73 (16.5%) had a *CALR* mutation (8 Type1, 1 Type2 and 3 which weren't any of the 36 described ones). One patient harbors both *JAK2V617F* and *CALR* mutation, the other eleven patients were *JAK2V617F* and *MPL* negative (50% of double negative patients) (Table 1). In global, 85% of patients carried a *JAK2V617F, MPL* or *CALR* mutation.
CALR mutation did not correlate with the presence of constitutional symptoms, complications (thrombosis, hemorrhage, transformation) or overall survival.

Table 1. *JAK2V617F, MPL* or *CALR* mutation distribution in a cohort of 73 PMF.



Summary and Conclusions: The study of *JAK2V617F, MPL* and *CALR* mutations demonstrate a clonal maker in 85% of PMF patients. Even it is described that CALR mutations are mutually exclusive with *JAK2V617F* or *MPL* mutations, we have found one patient who harbor both mutations. We will need more patients with PMF to corroborate if there is any clinical difference between those patients who have CALR mutations and the wild-type ones.

P394

THE SOMATIC MUTATION RATE IS INCREASED IN PATIENTS WITH CLASSICAL MYELOPROLIFERATIVE NEOPLASMS WHO HAVE A SECOND PRIMARY TUMOR

M Berardi[1,*] T Rondelli[1], MC Susini[2], A Pellecchia[1], R Fjerza[2], L Boni[3], M Sica[1], P Guglielmelli[2], L Luzzatto[4, 5], AM Vannucchi[2], R Notaro[1]
[1]Core Research Laboratory - ITT, Istituto Toscano Tumori - AOU Careggi, [2]Hematology, University of Florence, [3]Clinical Trials Coordinating Center, Core Research Laboratory - ITT, Istituto Toscano Tumori - AOU Careggi, [4]Scientific Direction, Istituto Toscano Tumori, [5]University of Florence, Firenze, Italy

Background: Classical chronic myeloproliferative neoplasms (MPNs) are associated with one of a set of specific somatic mutations, the most common of which is in the *JAK2* gene. Patients with MPN have an increased risk to develop acute myeloid leukemia (AML): whether they have also an increased risk to develop non-hematological malignancies is still controversial. Since MPNs are relatively rare, it has been suggested that an increased rate of somatic mutation may underlie the *JAK2* mutation as well as evolution to AML.
Aims: To investigate the role of the somatic mutation rate (μ) in classical MPNs.
Methods: Since measuring μ is rather labor-intensive, in this study we have measured instead the frequency of peripheral blood granulocytes carrying inactivating mutations in the X-linked gene *PIG-A,* whose product is required for glycosyl-phosphatidylinositol-anchored (GPI) proteins to become surface bound. We have shown previously that *PIG-A* is a good sentinel gene for this purpose, and that the frequency (*f*) of *PIG-A* mutant cells may be a good surrogate of μ (Rondelli *et al*. *PlosOne*. *2013*, 8:e54046). Five million granulocytes isolated from each patient were stained with a mixture of moAbs that recognize 3 different GPI-linked proteins (CD59, CD55, CD24), plus one pan-leukocyte marker (anti CD45-APC) and one granulocyte marker (anti-CD11b-FITC). *f* values were determined by flow cytometry.

Results: We have measured *f* in 102 patients with MPN, including 36 with polycythemia vera (PV), 23 with essential thrombocythemia (ET), 25 with primary myelofibrosis (PMF), 18 with post-PV/post-ET MF. Overall the proportion of those with a JAK2(V617F) mutation was 88%. The median value of *f* in these patients was not different from that of healthy controls ($5.5x10^{-6}$ *vs*. $4.9x10^{-6}$). We found no correlation between the value of *f* and the allele burden of *JAK2*(V617F) (R^2=0.0002). However, *f* was higher than $14.5x10^{-6}$ (the value that defines the 90th percentile in healthy controls) in 24.5% of patients with MPN, a proportion significantly higher than in controls (*P*<0.006). Moreover, in a subset of 18 patients who in addition to MPN had at least one primary tumor (2 had lymphomas and 16 had one of several types of epithelial tumors), the median value of *f* was 13.8 $x10^{-6}$: *i.e.,* significantly higher than in healthy controls (Mann Whitney test, *P*<0.005) (Figure 1).

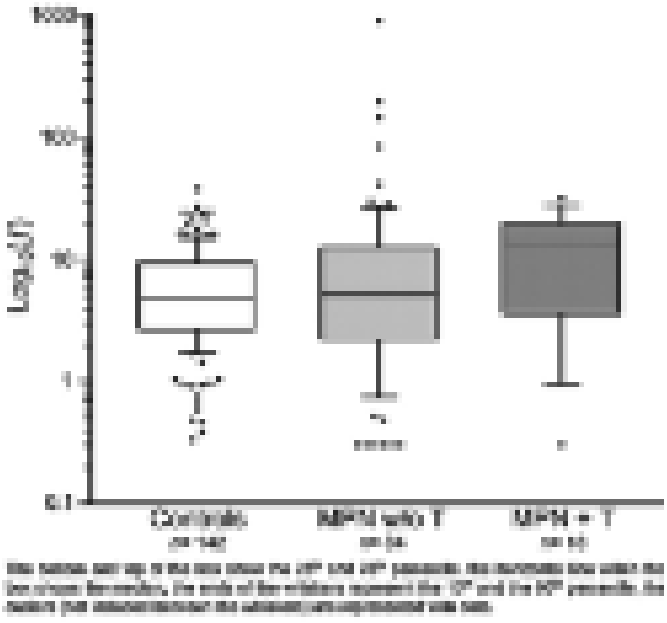


Figure 1. Box and whisker plot of mutant frequency (f) in controls, in patients affected by MPNs (MPN+T) and without (MPN w/o T) a second tumor.

Summary and Conclusions: 1) Although we cannot automatically extrapolate from our sentinel gene *PIG-A* to all other genes, we find no evidence that the *JAK2*(V617F) mutation In MPNs arises through genetic instability. 2) There was no significant difference in *f* values between MPN patients with or without a *JAK2* mutation, and no correlation between *f* and *JAK2*(V617F) allele burden: thus, *JAK2* mutation does not cause genetic instability. 3) Patients who have MPN and another malignancy are examples of multiple primary tumors. To the best of our knowledge, for the first time these data provide direct evidence that an intrinsically higher rate of somatic mutation plays a role in causing multiple primary tumors in subjects who did not otherwise appear to be 'cancer-prone'.

P395

MOUSE LEUKEMIC TRANSFORMATION IN PMF XENOGRAFT MODEL REVEALS PARACRINE REGULATION IN DISEASE PROGRESSION

I Triviai[1,2,*] M Ziegler[2], U Bergholtz[2], A Oler[3], T Stuebig[1], V Prassolov[4], B Fehse[1], C Kozak[5], N Kroeger[1], C Stocking[2]
[1]Clinic for Stem Cell Transplantation, UKE, [2]Viral Pathogenesis, HPI, Hamburg, Germany, [3]3Computational Biology Section, National Institute of Allergy and Infectious Diseases, Bethesda, United States, [4]Engelhardt Institute of Molecular Biology, Engelhardt Institute of Molecular Biology, Moscow, Russian Federation, [5]Laboratory of Molecular Microbiology, National Institute of Allergy and Infectious Diseases, Bethesda, United States

Background: Primary Myelofibrosis (PMF) is a myeloproliferating neoplasm characterized by profound bone marrow microenvironment disruption that subsequently leads to fibrosis and AML transition. Despite the identification of abnormal myeloid types during disease development, the complex cellular interactions supporting their expansion in the context of chronic myeloproliferation and disease evolution remains elusive.
Aims: In our studies to identify the PMF neoplastic stem cells in a xenotransplantation mouse model, we observed the peculiar emergence of mouse origin myeloid leukemia.
Results: Analysis of murine leukemic clones revealed multiple clonal integrations of ecotropic endogenous retrovirus (eERV). In addition to the single eERV provirus located on chromosome 11 (*Emv30*) in the NOD genome, up to five *de novo* germline eERV integrations were observed in mice from four independent NSG mouse colonies. Analysis of the *Emv30* provirus and the replicating eERV demonstrated that neither mutations nor recombination events were necessary for virus replication or AML induction. However, acquired pathogenicity could be attributed to PMF-mediated paracrine stimulation of the myeloid compartment, observed in spleen and bone marrow of xenografted mice. These proliferating cells serve as targets for retroviral transformation, as evidenced by integration in the *Evi1* locus – a hotspot for retroviral-induced myeloid leukemia.
Summary and Conclusions: In conclusion, this study corroborates a critical role of paracrine stimulation in PMF disease progression, underlines the importance of target cell numbers in ERV pathogenicity, and mandates awareness of ERV-replication in interpreting results from severely immunodeficient NOD mice.

P396

CYTOGENETIC INVESTIGATION OF G-CSF-STIMULATED PERIPHERAL BLOOD IN PATIENTS WITH PRIMARY MYELOFIBROSIS

R Lozynskyy[1,*] M Lozynska[2], Y Vyhovska[1], V Novak[3]
[1]Hematological, Institute of Blood Pathology and Transfusion Medicine of National Academy of Medical Scienses of Ukraine, [2]Diagnostics of Hereditary Pathology, Institute of Hereditary Pathology of National Academy of Medical Sciences of Ukraine, [3]Transfusion Medicine, Institute of Blood Pathology and Transfusion Medicine of National Academy of Medical Scienses of Ukraine, Lviv, Ukraine

Background: The role of karyotyping in primary myelofibrosis (PMF) is not so well established, comparing with chronic myeloid leukemia, due to technical difficulties in obtaining of sufficient amount of bone marrow (BM) aspirate for cytogenetic investigation in many patients. The unfavorable cytogenetic changes in BM for PMF include complex karyotype or sole or two abnormalities that include +8, -7/7q-, i(17q), inv(3), -5/5q-, 12p-, or 11q23. However, the pathological process in PMF is not limited to BM. Some immature hemopoetic progenitor and stem cells affected with the disease relocate into the peripheral blood. Further improvements of the suitable diagnostic approaches are needed for better understanding of the PMF development and progression.
Aims: The **aim** of the study was to investigate the karyotype of the peripheral blood cells from myeloid strain of hematopoesis in patients with PMF.
Methods: The cytogenetic study was carried out for the peripheral blood from 18 patients with symptomatic PMF. In the group were 9 males and 9 females. Six patients weren't treated previously, the others received hydroxyurea. The cytostatic agent was stopped for 72 h before the sample collection. The peripheral blood cells were cultivated for 24h with recombinant human granulocyte-colony stimulating factor (G-CSF). Cytogenetic analysis was performed using G-method of differential staining. 15-20 metaphases were analyzed for every sample.
Results: The mitotic activity in the investigated samples in the presence of G-CSF was high enough to produce adequate number of metaphases for routine cytogenetic analysis in PMF patients, even if the bone marrow aspiration was unsuccessful. Chromosomal abnormalities were revealed in the blood of 8 (44.4%) patients (4 males and 4 females). Other patients had normal karyotype. All patients with cytogenetical abnormalities had mosaic karyotype with 2 or more clones. The spectrum of karyotypic changes included trisomy of chromosome 8, structural rearrangements of chromosome 1, deletions of 5q and 20q, and monosomies, especially of chromosomes 5, 7, 19 and 21. The rearranged chromosome 1 appeared in extra copies in one sample. The hypodiploid karyotypes were notable findings. In 2 patients tetraploid clones were revealed.
Summary and Conclusions: The profile of the abnormalities is partially comparable with data obtained from BM in other studies. A wide spectrum of cytogenetic abnormalities and mosaicism may indicate a significant contribution of pathological myeloid precursors and stem cells to the evolution of the disease and to the development of therapy resistance. The abnormal polyploid clones revealed in the peripheral blood of PMF patients could be probably produced by the blast cells (like polyploid cancer cells in solid tumors), because the polyploid megakaryocytes in endomitosis were unlikely to appear in the peripheral blood. The further studies are needed to establish the role of karyotyping of the peripheral blood and the exact cytogenetical abnormalities relevant in the diagnostics and monitoring of PMF.

P397

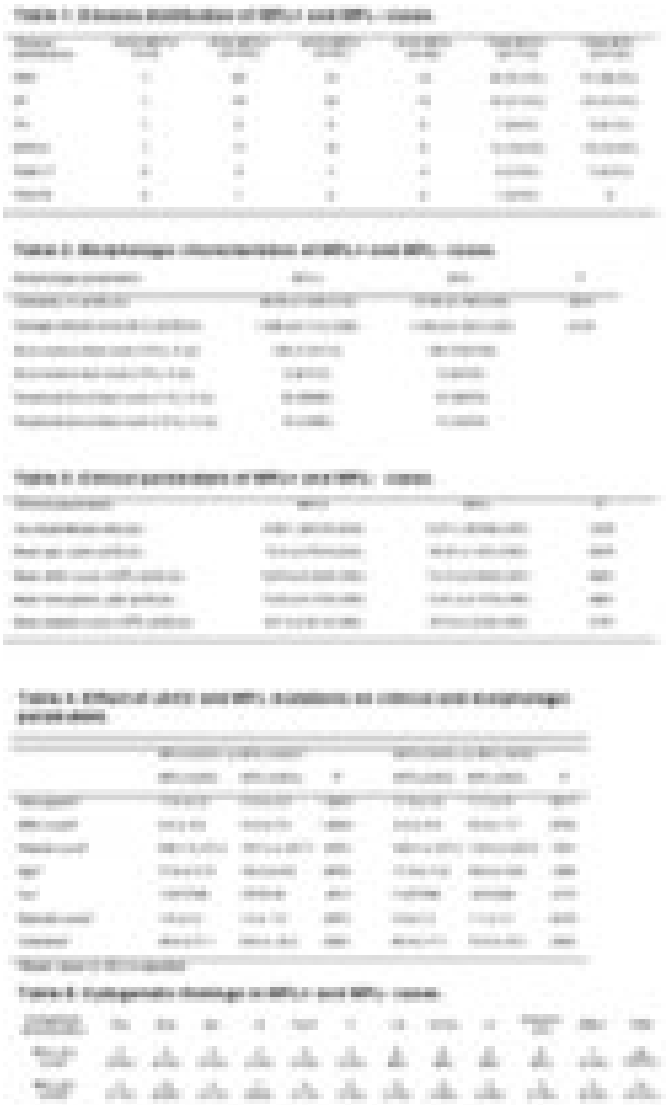
CHARACTERIZATION OF MPL-MUTATED MYELOID NEOPLASMS: A REVIEW OF 224 MPL+ CASES

K Lin[1,*] G Xu[1], Z Wu[1], M Imai[1], P Paterson[1], K Janatpour[1], B Dabbas[1]
[1]Hematopathology, genoptix/Norvatis. Inc, Carlsbad, United States

Background: Mutations within the myeloproliferative leukemia virus (*MPL*) gene have been identified in some myeloid neoplasms; however, MPL+ myeloid neoplasms have not been well characterized.
Aims: This study investigated the disease distribution, morphology, cytogenetic abnormalities, and select clinical features of MPL+ myeloid neoplasms in select cases.
Methods: 224 MPL+ myeloid neoplasms in blood or bone marrow from our case files from January 2008 to February 2012 and randomly selected 300

MPL-, BCR/ABL- myeloid neoplasms were retrived. Disease distribution, morphology, cytogenetic abnormalities, and select clinical features of MPL+ myeloid neoplasms were compared among select MPL+/JAK2-, MPL-/JAK2+, and JAK2-/MPL- cases.

Results: Results showed that MPL mutations occur in myeloid neoplasms including primary myelofibrosis; essential thrombocytosis; myeloproliferative neoplasm (MPN), unclassifiable; polycythemia vera (PV); refractory anemia with ring sideroblasts and marked thrombocytosis (RARS-T); and myeloid neoplasms associated with *PDGFB* rearrangement. Compared to MPL-, MPL+ cases are associated with lower hemoglobin, lower WBC counts, older age, higher reticulin scores, and lower bone marrow cellularity. Compared to MPL-/JAK2+, MPL+/JAK2- cases are associated with lower hemoglobin, lower WBC counts, lower bone marrow cellularity, but no significant differences in reticulin scores or patient age. Compared to MPL-/JAK2-, MPL+/JAK2- cases show significantly higher reticulin scores, but no statistical differences in hemoglobin, WBC counts, patient age, or bone marrow cellularity. MPL and JAK2 V617F mutations can coexist (7.9%); however, MPL mutations and BCR/ABL appear mutually exclusive. Overall incidence of cytogenetic abnormalities was not significantly different in cases with or without MPL mutations.



Summary and Conclusions: In this study, MPL positivity alone does not appear to result in a distinct entity.

P398

DEREGULATION OF MICRORNA146B-1 IS ASSOCIATED WITH MYELOFIBROSIS IN MYELOPROLIFERATIVE NEOPLASMS

JS Ha[1,*] Y Do[2], H Jung[3], S Park[1], K Kim[1], J Lee[1], W Lee[1], N Ryoo[1], D Jeon[1], J Kim[1], K Kwon[2], I Jung[4]

[1]Laboratory Medicine, [2]Internal Medicine, division of HematoOncology, [3]Pathology, [4]Preventive medicine, division of Occupational and Environmental medicine, Keimyung University School of Medicine, Daegu, Korea, Republic Of

Background: The myeloproliferative neoplasm (MPN) is a clonal hematopoietic disorder, which is characterized by extensive proliferation of multilineage blood cells and variable fibrosis. MicroRNAs (miRNAs) function as gene repressors by binding to the target messenger RNAs and which deregulation has been suggested to contribute to myeloproliferative neoplasm pathogenesis. Through miRNA profiling studies about MPN, some of miRNAs showed deregulated expression patterns associated with specific MPN subtypes or clinical presentations.

Aims: Our goal was to evaluate the expression of selected miRNAs previously described to be associated with primary myelofibrosis (PMF), in order to establish those miRNAs as potential markers for differentiating MPN subtypes or as fibrosis-associated markers.

Methods: Total 39 bone marrow samples of MPNs, 15 polycythemia vera (PV), 22 essential thrombocythemia (ET) and 5 PMF, and 15 normal controls which are not presenting fibrosis were included. Using stem loop-primed reverse transcription and quantitative real-time polymerase chain reaction, the expression of miRNAs (miR150-1, miR146b-1, miR31-1, miR95-2 and miR28-1) was evaluated from paraffin-embedded bone marrow biopsy. RNU6-2_11 was used as endogenous control for relative quantification. Information for *JAK2* V617F mutation, hematologic indexes and fibrosis grade was collected from medical records.

Results: Among miR150-1, miR146b-1, miR31-1, miR95-2 and miR28-1, the expression of miR146b-1 and miR150-1 were higher in MPNs compared to normal controls (*P*=0.022, 0.003, respectively). However, no significant differences were found among MPN subtypes. The expression of miR146b-1 was significantly associated with fibrosis grade. MPNs with severe fibrosis showed significantly higher expression of miR146b-1 than MPNs with moderate or mild fibrosis (*P*=0.015). There was no association between expression of miRNAs and J*AK2* V617F mutation or hematologic indexes such as WBC, platelet count, hemoglobin level or frequencies of complications.

Summary and Conclusions: We suggest that miR14b-1 and miR150-1 are upregulated in MPN patients and especially miR146b-1 is a potential fibrosis-associated factor. For evaluation of the contribution of miR146b-1 deregulation to fibrosis pathogenesis, study for larger number of patients is needed.

P399

HIGH THROUGHPUT SCREENING ON PERIFPERHAL BLOOD CD34 CELLS WITH A FLOW CYTOMETRY AUTOMATED PLATFORM (EXVITECH), TO IDENTIFY SENSITIVITY TO RUXOLITINIB IN MYELOFIBROSIS PATIENTS

A Arenas[1], J Gorrochategui[2], A Robles[2], P Hernandez-Campo[2], S Barrio[1], R Ayala[1], J Ballesteros[2], J Martínez-López, [1,*]

[1]Hematology, Hospital Universitario 12 de Octubre, Madrid, [2]Vivia Biotech, Tres Cantos, Madrid, Spain

Background: Ruxolitinib is a potent JAK1/JAK2 inhibitor that has demonstrated improved survival, rapid decreased of splenomegaly in myelofibrosis (MF) patients; however, some of them do not have an adequate response, and identifying patients with a good response would enable personalizing its treatment.

Aims: To design an ex-vivo model, based on flow cytometry, to identify sensitivity to Ruxolutinib of CD34+ cells from peripheral blood and correlate it to their clinical evolution.

Methods: We have studied secondary or primary MF patients (n=12), and then we have compared three ex-vivo models to test Ruxolitinib sensitivity in patient samples from peripheral blood. Briefly, in the first model, mononuclear cells isolated from peripheral blood were cultured in Methocult TM GF_H4535 with 20 ng/ml IL-3, and 50 ng/ml SCF. After 2 weeks incubation, cells were plated at 15.000 per well in 96-well plates in increasing concentrations of Ruxolitinib. After incubation, at either 24-48-72 hours, cells were labelled with Annexin V and CD13, and analysed by the automated multiparametric flow cytometry platform ExviTech. In the second model, peripheral blood was treated directly with increasing concentration of Ruxolitinib. After 48-72 hr incubation, cells were analysed using Annexin V and CD34 to monitoring the sensitivity of CD34+ cells. In the third model we used the classic method; mononucleated cells were cultured in methylcellulose directly with increasing concentrations of Ruxolitinib for 12 to 14 days.

Results: In 9 out of 10 patient samples we could identify a population of 1.5±1.5% CD34+ cells in peripheral blood enough to study sensitivity to Ruxolitinib with the ExviTech platform. Freshly isolated CD34+ cells directly incubated with drug (model 2) were more sensitive to Ruxolitinib than cells treated after methylcellulose culture. Using this novel model 2, we identified 4 patients out of 7 with a high sensitivity to Ruxolutinib (Emax=92.5±10.7 *vs* Emax=23.8±11.8). However, in the model 1 using differentiated cells after 15 days of culture only 2 out of 8 samples were moderately sensitive to Ruxolitinib (Emax=49.39± 15.49). Nevertheless, in the third model, all samples were quite sensitive to Ruxolitinib, appearing very similar without appropriate stratification; they had an Emax=9.9±17.2. The correlation between the first and third models using 15 day of culture was not significant (p>0.5), but it showed a trend (Figure 1A). Model 2, incubating the drug in the freshly extracted cells, labelling CD34+ cells, seems to correlate with clinical response (decrease spleen size) of patient treated with Ruxolitinib efficacy (Emax), which measures the% cells left alive after incubation with the drug (Figure 1B). The more effi-

cacious Ruxolitinib is in depleting CD34+ cells in the patient samples, the more that the spleen volume decreases. Interestingly, mutated CALR CD34+ cells appear to be less sensitive (Emax=89.54±27.45) to Ruxolitinib than mutated JAK2V617F (Emax=29.7±38.0) (Figure 1C).

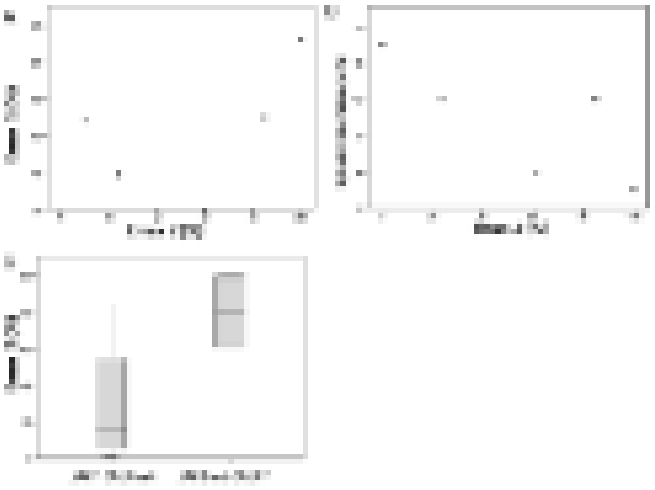


Figure 1. Comparison between model 1 Emax (Emax1) (Ruxolitinib treatment after 15 days in methylcellulose culture) and model 2 Emax (Emax2) Ruxolitinib treatment of fresh blood and CD34+ cell analysis). B) Clinical correlation between spleen decrease after 3 month of Ruxolitinib patient treatment, with model 2 Emax. C) Correlation between Emax2 and presence of mutated JAK2 (JAK2*) or mutated CALR (CALR*).

Summary and Conclusions: Study of the sensitivity to Ruxolitinib in CD34+ cells from peripheral Blood is feasible in MF patients; results are obtained in less than 72h and hence potentially prior to treatment. The best *ex vivo* model is the direct assay on freshly extracted CD34+ cells with minimal manipulation. It correlates better with Ruxolitinib clinical response in terms of spleen volume, and with the presence of JAK2 and CALR mutations. It seems that CD34+ cells are more sensitive to Ruxolitinib than the method of isolating and culturing cells for 15 days to differentiate.

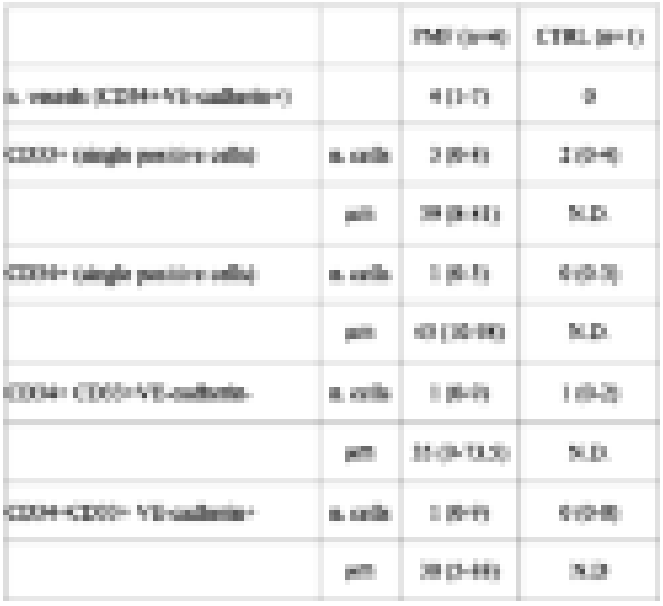
P400

HEMATOPOIETIC PROGENITOR CELLS EXPRESSING VE-CADHERIN ARE DETECTABLE IN THE SPLEEN OF PATIENTS WITH MYELOFIBROSIS AND ARE IN CLOSE CONTACT WITH MICROVESSELS

R Campanelli[1,*] G Fois[1], B G Erba[2], V Poletto[1], E Bonetti[1], L Cobianchi[3], D Ingo[3], L Villani[1], P Catarsi[1], M Massa[1], V Rosti[1], E Dejana[2], G Barosi[1]
[1]Centro per lo Studio e la Cura della Mielofibrosi - L.S.R. Area Biotecnologie, Fondazione IRCCS Policlinico San Matteo, Pavia, [2]Istituto di Oncologia Molecolare, IFOM-IEO, Milano, [3]Chirurgia Generale, Fondazione IRCCS Policlinico San Matteo, Pavia, Italy

Background: Increased microvessel density contributes to abnormal bone marrow and spleen microenvironment in myelofibrosis (MF). In a previous work, we provided evidence that endothelial cells from either the spleen or the splenic vein of patients with MF frequently share the same genetic abnormality with the hematopoietic malignant cells: the *JAK2*V617F mutation (Rosti *et al.* Blood 2013). The existence of a common progenitor to endothelial and hematopoietic cells in which the V617F mutation occurs could explain the involvement of V617F-endothelial cells in the process of endotheliopoiesis and endothelium renewal. An alternative hypothesis for explaining the presence of the mutation in splenic endothelial cells and splenic vein is that the MF stem cell represents the cell giving rise to mutated endothelia. This event, which has been described in glioblastoma (Soda Y *et al.*, PNAS 2011) and in neuroblastoma (Pezzolo A *et al.*, J Clin Oncol 2007), would assimilate the spleen of patients with MF to a solid tumor and would justify the extension of the phenomenon to the microvessels and to the large vessels of the spleen.
Aims: To investigate the presence of transitional cells expressing both myeloid and endothelial cell markers in the spleen of patients with MF.
Methods: Spleens were collected from 4 patients with MF, who received splenectomy for transfusion-dependent anemia and/or relieve symptoms of massive splenomegaly, and a healthy subject who underwent spleen surgery after traumatic damage (CTRL). Fresh spleen samples were embedded in OCT, snap-frozen, and stored in liquid nitrogen. Spleen sections (4 µm) were stained with antibodies directed towards CD33 (myeloid lineage cells marker), CD34 (hematopoietic and endothelial progenitor cells marker), and VE-cadherin (endothelial marker). The images were obtained by confocal laser scanning microscopy (Olympus Fluoview FV10i, 60x objective) and processed by IMAGE J software. We evaluated 10 fields for each spleen section, measured the number of different cell subsets and their distance from the nearest vessel (in µm) (median/ten fields/patient). The results are shown as median/mean.
Results: The number of CD33+, CD34+, and CD34+CD33+ cells was higher in MF patients than in CTRLs. When we investigated the presence of cells expressing both hematopoietic and endothelial surface markers (CD34+CD33+VE-cadherin+), we found these cells in the spleen of all 4 MF patients (Table 1) and they were most likely to be found 40-50 µm from the nearest vessel structure. Besides, approximately 36% of the CD34+CD33+VE-cadherin+ cells were found within 20 µm of a vessel structure in MF spleens. On the contrary, CD34+CD33+VE-cadherin+ were never observed in the CTRL spleen.

Table 1.



Summary and Conclusions: Cells co-expressing both myeloid and endothelial markers can be identified in the spleen of patients with MF but not in a spleen from a normal subject. These "transitional cells", expressing the CD34, CD33 and VE-cadherin antigens, are located at a lower distance from vessels with respect to other cellular populations, supporting the hypothesis that they could contribute, through a transdifferentiation mechanism, to the formation of mutated endothelium.

P401

EVALUATION OF THE ASSOCIATION BETWEEN JAK2 46/1 HAPLOTYPE AND MYELOPROLIFERATIVE NEOPLASMS

JS Ha[1,*] S Park[1], K Kim[1], J Lee[1], W Lee[1], N Ryoo[1], D Jeon[1], J Kim[1], Y Do[2], K Kwon[2], H Jung[3], I Chung[4]
[1]Laboratory Medicine, [2]Internal medicine, division of HematoOncology, [3]Pathology, [4]Preventive Medicine, Division of occupational and evironmental medicine, Keimyung University School of Medicine, Daegu, Korea, Republic Of

Background: Myeloproliferative neoplasm (MPN) is a hematologic malignancy characterized by chronic excessive production of one or more lineage of blood cells, and increased risk of secondary leukemic transformation. Recently, the G allele on *JAK2* rs10974944 which is part of the *JAK2* 46/1 haplotype has been suggested as a susceptibility factor of MPN development.
Aims: Our aim was to verify the relationship of *JAK2* 46/1 haplotype with development of MPNs in Korean population. Additionally, we evaluated the association between several clinicohematologic features and *JAK2* 46/1 haplotype to know how it works in MPN.
Methods: We selected 151 patients who had been diagnosed MPNs, including polycythaemia vera (PV, 35 patients), essential thrombocythaemia (ET, 108 patients), and primary myelofibrosis (PMF, 8 patients). Fifty healthy individuals were selected as normal control. The genotype of rs10974944 was analysed by direct sequencing.
Results: We found that the frequency of G allele was significantly higher in MPN patients (OR, 2.213; 95% CI 1.152~4.250, P<0.05) than in controls. The *JAK2* V617F mutation was higher in the G homo allele than in others (OR, 5.018; 95% CI 1.112~22.650, P<0.05) in studied population. In PV, patients which contain G allele (GG and GC) had higher WBC than those contain CC allele. ET patients contain GG/GC allele showed lower platelet count than those with CC allele. In *JAK2* V617F (+) ET patients, G allele was associated with more frequent organomegaly.

Summary and Conclusions: In aggrement with previous reports, the presence G allele of *JAK2* rs10974944 SNP is a possible oncogenic predisposing factor in MPN development. Moreover, at least partially, G allele has clinicohematologic effects in PV and ET.

P402

THE MULTIKINASE INHIBITOR R763/AS703569 BLOCKS STAT5 ACTIVITY AND INDUCES APOPTOSIS IN NEOPLASTIC HUMAN MAST CELLS

B Peter[1, 2,*]K Blatt[2], H Herrmann[1], G Stefanzl[2], K V Gleixner[1, 2], E Hadzijusufovic[1, 2], W R Sperr[1, 2], J Schwaab[3], M Willmann[4], A Reiter[3], P Valent[1, 2]
[1]Ludwig Boltzmann Cluster Oncology, Medical University of Vienna, [2]Department of Internal Medicine I, Medical University of Vienna, Vienna, Austria, [3]Medical Department, Division of Hematology and Oncology, Medical University of Mannheim, Mannheim, Germany, [4]Department/Clinic for Companion Animals and Horses, University of Veterinary Medicine, Vienna, Austria

Background: Systemic mastocytosis (SM) is a myeloid neoplasm defined by excessive proliferation and accumulation of neoplastic mast cells (MC) in one or more internal organs. Most patients with SM express a D816V-mutated variant of *KIT*, which confers resistance against several tyrosine kinase inhibitors (TKI) including imatinib. Apart from KIT, a number of additional kinase targets and signal transduction molecules, like Akt, Btk or STAT5, play a major role in growth and expansion of neoplastic MC in advanced SM. R763/AS703569 is a multi-targeted drug known to interact with a number of important signalling molecules such as Aurora kinase-A and -B, KIT or Btk.
Aims: We tested the effects of R763/AS703569 on growth, cell cycle-progression and survival of the human MC leukemia cell lines HMC-1.1 (lacking *KIT* D816V) and HMC-1.2 (expressing *KIT* D816V) as well as the canine mastocytoma cell lines C2 (harbouring a *KIT* ITD in exon 11) and NI-1 (exhibiting a duplication in exon 8 and a deletion in exon 10 of *KIT*).
Results: R763/AS703569 was found to counteract proliferation of both HMC-1 subclones with higher IC_{50} values obtained in HMC-1.1 cells (5-50 nM) than in HMC-1.2 cells (1-10 nM). We were also able to show that R763/AS703569 induces growth arrest in primary neoplastic MC in most (11/15) patients, with IC_{50} values ranging between 0.001 and 0.5 μM. In addition, R763/AS703569 was also able to inhibit growth of C2 cells (IC_{50}: 1-5 nM) and NI-1 cells (IC_{50}: 50-100 nM) in a dose-dependent manner. Furthermore R763/AS703569 induced a strong G2/M arrest in all cell lines tested. The R763/AS703569-induced growth inhibition was accompanied by apoptosis as evidenced by TUNEL assay, light microscopy and detection of cleaved caspase 3. As assessed by Western blotting, R763/AS703569 was found to inhibit the phosphorylation of several key kinase targets, including KIT, Btk, Akt and Aurora kinase-A in HMC-1 cells. In addition, R763/AS703569 was found to block the activation of STAT5 in both HMC-1 subclones. Interestingly, R763/AS703569-induced deactivation of STAT5 was seen within a few minutes and it occurred at very low drug concentrations (<10 nM), whereas the R763/AS703569-induced deactivation of KIT, Btk, Akt and Aurora kinase-A occurred between 100 and 1,000 nM. Based on the unique target spectrum and major drug-effects observed, we asked whether R763/AS703569 and other targeted drugs would exert synergistic anti-neoplastic effects. In order to address this question, drug combination experiments were performed. We found that R763/AS703569 cooperates with the multikinase inhibitors PKC412 (midostaurin) and dasatinib in producing growth inhibition and apoptosis in neoplastic MC.
Summary and Conclusions: Together, R763/AS703569 is a novel promising multi-kinase- and STAT5 blocker that overrides drug resistance in KIT D816V-transformed neoplastic MC. Whether R763/AS703569 is also able to block neoplastic cell growth *in vivo* in patients with advanced SM remains to be determined in clinical trials.

Myeloproliferative neoplasms - Clinical 1

P403

RESULTS FROM A 3.5-YEAR UPDATE OF COMFORT-II, A PHASE 3 STUDY COMPARING RUXOLITINIB (RUX) WITH BEST AVAILABLE THERAPY (BAT) FOR THE TREATMENT OF MYELOFIBROSIS

C Harrison[1,*] D Niederwieser[2], A Vannucchi[3], JJ Kiladjian[4], T Barbui[5], H Gisslinger[6], F Passamonti[7], F Cervantes[8], HK Al-Ali[2], D Cilloni[9], P Zachee[10], L Descamps[11], V Stalbovskaya[12], P Gopalakrishna[12], L Knoops[13], G Barosi[14]
[1]Guy's and St Thomas' NHS Foundation Trust, London, United Kingdom, [2]University of Leipzig, Leipzig, Germany, [3]University of Florence, Florence, Italy, [4]Hôpital Saint-Louis et Université Paris Diderot, Paris, France, [5]A.O. Ospedali Riuniti di Bergamo, Bergamo, Italy, [6]Medical University of Vienna, Vienna, Austria, [7]Ospedale di Circolo e Fondazione Macchi, Varese, Italy, [8]Hospital Clínic, IDIBAPS, Barcelona, Spain, [9]University of Turin, Turin, Italy, [10]ZNA Stuivenberg, Antwerp, Belgium, [11]Novartis Pharma S.A.S, Rueil-Malmaison, France, [12]Novartis Pharma AG, Basel, Switzerland, [13]Cliniques Universitaires Saint-Luc and de Duve Institute, Université catholique de Louvain, Brussels, Belgium, [14]IRCCS Policlinico San Matteo Foundation, Pavia, Italy

Background: Ruxolitinib (RUX), a potent JAK1/JAK2 inhibitor, has shown rapid and durable improvements in MF-related splenomegaly, symptoms, and quality of life measures in the phase 3 COMFORT studies. RUX therapy remains well tolerated and has been associated with a significant survival advantage at 2 and 3 years of follow-up in COMFORT-II.
Aims: This 3.5-year analysis of COMFORT-II presents updated efficacy and safety findings and longer-term survival data, including results from some patients (pts) for whom survival information was not previously collected.
Methods: COMFORT-II is a randomized (2:1), open-label study comparing RUX (15 or 20 mg bid based on baseline (BL) platelet count [100-200 or >200 × 10^9/L, respectively]) *vs* best available therapy (BAT) in pts with MF (N=219). Study findings are based on an intention-to-treat (ITT) analysis. An increase in spleen volume >25% over on-study nadir that was no longer a ≥35% reduction from BL was considered a loss of response. The original informed consent and case report form did not include follow-up of pts for survival after they had discontinued from the study, and only on amending was this information collected. Overall, 41 pts did not have follow-up information; 28 pts prior to the amendment. The Kaplan-Meier method was used to estimate overall survival (OS); analysis of OS has been updated with longer follow-up and to include additional survival information for 15 of 41 pts who previously lacked follow-up information (RUX, n=5; BAT, n=10).
Results: The median duration of RUX treatment in pts originally randomized to RUX (N=146) was 2.6 years. In the 73 pts originally randomized to BAT, 62% of pts (45/73) crossed over to RUX after a median of 66 weeks, with 40% (18/45) still ongoing in the extension phase. These pts have 1.2 years median duration of RUX treatment. Discontinuations were reported in 63% of RUX pts (92/146) primarily because of adverse events (AEs; 20%) and disease progression (18%). All BAT pts discontinued from the BAT arm. Of those who crossed over to receive RUX, 60% (27/45) discontinued; 18% (8/45) discontinued due to AEs. In total, 52% of RUX pts achieved a ≥35% reduction from BL spleen volume at least once during treatment with loss of response noted in 45% (34 pts) to date. No new or unexpected AEs were observed with longer follow-up. Since prior analysis (Cervantes *Blood* 2013), new grade 3/4 AEs included anemia (RUX, n=1), thrombocytopenia (RUX and RUX+extension phase, 1 pt each), pneumonia (RUX crossover, n=1), and acute renal failure (RUX, n=1). Overall AEs after treatment discontinuation were not different than AEs on treatment and no new patterns of AEs emerged. Overall, 27% (n=40) and 40% (n=30) of pts in the RUX and BAT arms, respectively, died during the study. Deaths that occurred on treatment or within 28 days after discontinuation were reported in 10% (n=14) of RUX pts and 8% (n=6) of BAT pts (2 deaths after RUX crossover). In the ITT analysis, RUX was associated with a 42% reduction in the risk of death compared with BAT (HR=0.58, 95% CI 0.36-0.93); the median OS has not yet been reached. The probability of survival at 3.5 years was 71% and 54% in the RUX and BAT arm, respectively (log-rank *P*=.02; Figure 1).

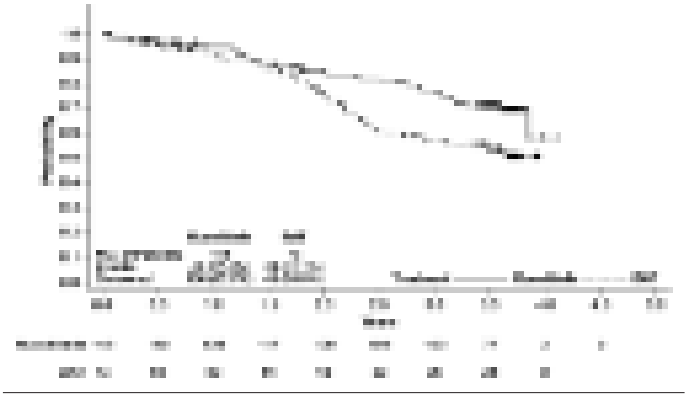


Figure 1. Overall survival in COMFORT-II (3.5 years).

Summary and Conclusions: RUX treatment continues to provide a survival advantage consistent with that observed in previous analyses. Inclusion of pts initially lost to follow-up results in separation of survival curves sooner than previously reported (78 *vs* 96 wk). The survival advantage is suggested to reflect improvements of outcomes in RUX pts and worsening of BAT pts. Because of the large number of pts who crossed over from the BAT arm to receive RUX, this OS analysis remains a conservative estimate of the effect of ruxolitinib treatment on survival.

P404

OUTCOME OF JAK2/MPL/CALR TRIPLE NEGATIVE PATIENTS WITH MYELOFIBROSIS AFTER ALLOGENEIC STEM CELL TRANSPLANTATION

V Panagiota[1,*] F Thol[1], B Markus[2], B Fehse[3], H Alchalby[3], A Badbaran[3], U Lehmann[4], C Koenecke[1], R Shahswar[1], A Chaturvedi[1], M Stadler[1], M Eder[1], G Göhring[5], M Koenigsmann[6], A Kloos[1], A Trummer[1], B Schlegelberger[4], HH Kreipe[4], A Ganser[1], N Kröger[3], M Heuser[1]

[1]Department of Hematology, Hemostasis, Oncology and Stem Cell Transplantation, Medical Hannover School, Hannover, [2]Department of Cardiology, University Hospital Marburg, Marburg, [3]Department of Stem Cell Transplantation, University Medical Center Hamburg-Eppendorf, Hamburg, [4]Institute of Pathology, [5]Institute of Cell and Molecular Pathology, Medical Hannover School, [6]Outpatient Oncology Center Hannover, Hannover, Germany

Background: Calreticulin (CALR) mutations have been identified in JAK2 and MPL wildtype patients with essential thrombocythemia and myelofibrosis, leaving a small proportion of patients without one of the three canonical mutations (triple negative patients). Triple negative patients with myelofibrosis not undergoing alloHSCT have been associated with poor outcome (Tefferi *et al.* 2014).
Aims: To evaluate clinical characteristics and outcome of myelofibrosis patients with or without *CALR*, *JAK2* or *MPL* mutations who underwent allogeneic hematopoietic stem cell transplantation (alloHSCT).
Methods: 133 patients with WHO defined primary myelofibrosis (n=97, 73%) or post-ET/post-PV myelofibrosis (n=36, 27%) underwent alloHSCT. Bone marrow or peripheral blood samples were obtained before transplantation. *JAK2, MPL*, and *CALR* were amplified by PCR and were directly sequenced. Mutations were confirmed in an independent experiment.
Results: Median age at transplant was 57 years (range 18-75). The majority of patients (n=90, 67%) were transplanted with a matched donor (29 from related and 61 from unrelated donors). Fourty-three patients (32%) received a mismatched unrelated allograft. The conditioning regimen was of reduced intensity in all but one patient. Fourty-five patients died by the time of last follow-up (34%). Median follow-up was 4.04 years after transplantation. Twenty nine patients (22%) were triple negative, 71 (53%) had JAK2 mutations, 28 (21%) had CALR and 5 (4%) had MPL mutations. Comparing triple negative patients with JAK2/CALR/MPL mutated patients there were no significant differences for patient, disease or transplant characteristics except a higher frequency of male patients in the group of triple negative patients (72% *vs* 50%, P=.03). Univariate analysis disclosed significant overall survival differences between triple negative, JAK2/MPL-mutated or CALR mutated patients (4-year OS 48.3% *vs* 65.8% *vs* 85.7%, respectively, P=.015, Figure 1). Cumulative incidence of relapse (CIR) was not significantly different in triple negative patients compared to JAK2/MPL or CALR mutated patients (4-year CIR 32% *vs* 23% *vs* 12% respectively, P=.70), while NRM was significantly higher in the triple negative patients compared to JAK2/MPL or CALR mutated patients (4-year NRM 50% *vs* 30% *vs* 8% respectively, P=.013). In multivariate analysis triple negative patients had significantly shorter OS and higher NRM compared to patients with any of the three CALR, JAK2, or MPL mutations (HR 2.1, 95%CI 1.12-4.02, P=.02; NRM: HR 2.2, 95%CI 1.10-4.71 P=.026). Of all other patient, disease and transplant characteristics only age above the median age and female donor sex predicted shorter OS after alloHSCT in multivariate analysis. Age above the median age remained as independent predictor of a higher risk for NRM. Stage III/IV acute GvHD was found in 20.4% and 15.4% of triple negative and patients with any mutation, respectively. Extensive chronic GvHD was found in 21.7% and 10.8% of triple negative and patients with any mutation, respectively.

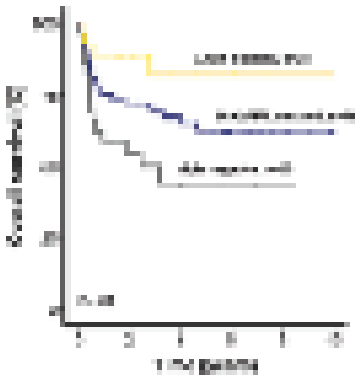

Figure 1.

Summary and Conclusions: Triple negative patients have a shorter overall survival after alloHSCT and a higher rate of NRM in comparison to patients carrying CALR, JAK2, or MPL mutations, possibly related to higher rates of more severe GvHD. However, alloHSCT can still induce long-term remissions in a significant proportion of triple negative patients. CALR mutation testing should be included in the work up of myelofibrosis patients undergoing alloHSCT as it can separate patients with favorable and less favorable prognosis.

P405

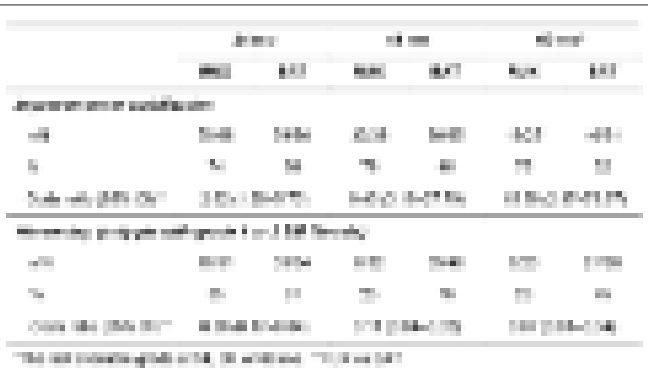
CHANGES IN BONE MARROW MORPHOLOGY IN PATIENTS WITH MYELOFIBROSIS TREATED FOR UP TO 5 YEARS WITH EITHER RUXOLITINIB OR BEST AVAILABLE THERAPY

HM Kvasnicka[1,*] J Thiele[2], CE Bueso-Ramos[3], W Sun[4], J Cortes[3], HM Kantarjian[3], S Verstovsek[3]

[1]Senckenberg Institute of Pathology, University of Frankfurt, Frankfurt, [2]University of Cologne, Cologne, Germany, [3]The University of Texas, MD Anderson Cancer Center, Houston, [4]Incyte Corporation, Wilmington, United States

Background: Myelofibrosis (MF) is a life-shortening MPN characterized by progressive bone marrow (BM) fibrosis, extramedullary hematopoiesis, and debilitating symptoms. Conventional therapy for MF, even if prolonged, does not improve BM fibrosis.
Aims: This analysis evaluated the effects of up to 5 years therapy with ruxolitinib (RUX), a JAK1/JAK2 inhibitor, on BM fibrosis in a cohort of pts with MF from a phase 1/2 study (NCT00509899) and compared them with data from a cohort treated with best available therapy (BAT).
Methods: RUX-treated pts had primary MF (PMF), post-PV MF, or post-ET MF and were studied at the MD Anderson Cancer Center. BM biopsies were obtained at baseline (BL) and at 24 months (mo) (68 pts), 48 mo (38 pts), 54 mo (23 pts), 60 mo (10 pts), or 66 mo (4 pts) of RUX. For the BAT cohort, BM biopsies were prospectively collected from 192 pts with PMF treated with BAT (45% hydroxyurea, 8% interferon-α, 25% assorted therapies, 22% supportive-only therapy) for 24 mo (98 pts), 48 mo (65 pts), 54 mo (16 pts), 60 mo (9 pts), or 66 mo (6 pts). Samples from the BAT cohort were matched to those from the RUX cohort for BL BM morphology. Grades of reticulin fibrosis (WHO), collagen deposition, and osteosclerosis based on the ELN criteria were determined by consensus after independent blinded review by 3 pathologists (HMK/JT/CBR). Samples were categorized as showing improvement, stabilization, or worsening from BL in BM fibrosis grade. Odds ratios were determined by logistic regression. Separate analyses were conducted to explore associations of changes in (a) BM fibrosis grade or (b) the abundance of megakaryocytes (MEG) and select stromal cell populations (plasma cells, macrophages) and MEG dysplasia with changes in hemoglobin (Hb), platelet count, WBC count, and palpable spleen length (SPL) at 24 mo. Due to sample size limitations, these analyses were descriptive in nature.
Results: Compared with the RUX cohort, pts in the BAT cohort overall had lower IPSS risk (high-risk: RUX, 59%; BAT, 15%) and less splenomegaly (mean SPL: RUX, 18.8 cm; BAT, 3.6 cm) at BL. There were no statistically significant differences in percentage distribution of BM fibrosis grade (*P*=0.3298, Cochran-Mantel-Haenszel test). In the RUX cohort, at BL, 60% of pts had ≥90% hematopoietic cellularity; 22%, 53%, and 25% had BM fibrosis grade 1, 2, and 3, respectively; collagen accumulation and osteosclerosis was seen in 47% (18% grade 2/3) and 50% (19% grade 2/3) of pts, respectively. The odds of improved or stabilized BM fibrosis after 24, 48, and 60 mo were greater with RUX than BAT, whereas the odds of worsening were reduced with RUX *vs* BAT (Table 1). Improvement or stabilization of BM fibrosis with RUX was concordant with the direction of changes in both collagen deposition and osteosclerosis. A reduction in BM fibrosis grade at 24 mo coincided with mild reduction in Hb and WBC median values at 24 mo, with the latter being known JAK2 inhibition effects. Pts with an increased frequency of BM macrophages exhibited a higher median Hb, while a decreased number of stromal plasma cells was associated with an increase in Hb (both at 24 mo). Additional correlations between morphology changes with biomarker alterations are ongoing.

Table 1.



Summary and Conclusions: These results show that long-term RUX therapy, unlike BAT, may forestall or reverse BM fibrosis. Complex relationships between changes in fibrosis and clinicolaboratory parameters are possibly consistent with a JAK-mediated effect. Interrelationships of BM cell population alterations with clinicolaboratory changes denote a possible RUX effect on BM stroma biology. Collectively, these data suggest that sustained JAK inhibition may be disease-modifying in MF.

P406

SURVIVAL IN PATIENTS WITH FAMILIAL AND SPORADIC MYELOPROLIFERATIVE NEOPLASMS

M Hultcrantz[1,*] SH Lund[2], O Landgren[3], J Samuelsson[4], L Goldin[5], A Oddson[6], M Björkholm[1], SY Kristinsson[1, 2]
[1]Department of Medicine, Division of Hematology, Karolinska University Hospital and Karolinska Institutet, Stockholm, Sweden, [2]Faculty of Medicine and Department of Hematology, University of Iceland and Landspitali National University Hospital, Reykjavik, Iceland, [3]National Cancer Institute, National Institutes of Health, Bethesda, United States, [4]Department of Medicine, Division of Hematology, South Hospital, Stockholm, Sweden, [5]Division of Cancer Epidemiology and Genetics, National Institutes of Health, Bethesda, United States, [6]deCODE Genetics, Reykjavik, Iceland

Background: Myeloproliferative neoplasms (MPNs) are chronic hematological malignancies associated with an elevated risk of thromboembolic events, transformation to acute myeloid leukemia, and a shortened life expectancy compared to the general population. MPNs show a familial clustering with a 5- to 7-fold elevated risk of MPNs among first-degree relatives of MPN patients compared to relatives of matched controls. There are however no studies comparing survival in patients with familial *versus* sporadic MPN.
Aims: To elucidate possible differences in survival in familial compared to sporadic MPN patients in a large population-based study.
Methods: Patients diagnosed with MPNs between 1958 and 2005 were identified through the Swedish Cancer Register and our national MPN network consisting of all hematology and oncology centers in Sweden. Time of death was obtained from the Cause of Death Register with follow-up to December 31, 2007. MPN patients who had at least one linkable first-degree relative with any MPN in the Swedish Multigenerational Register were included in the study. Cox regression was used to estimate hazard ratios (HRs) with 95% confidence intervals (CIs) of death from any cause in familial compared to sporadic MPN patients. Survival was estimated by the Kaplan-Meier method.
Results: A total of 8,122 MPN patients with a linkable first-degree relative were included. Ninety-two (1.1%) MPN patients had a first-degree relative with any MPN. We found no differences in overall survival in patients with familial MPN compared to sporadic MPN, HR=1.1 (95% CI 0.9-1.5; p=0.39; Figure 1). In stratified analyses, there were no significant differences in outcome between male MPN patients (HR=1.2, 95% CI 0.7-1.9), female MPN patients (HR=1.1, 95% CI 0.7-1.8) or between MPN patients aged <70 year (HR=0.8 95% CI 0.5-1.2) and ≥70 years (HR=1.2, 95% 0.7-2.1) when familial MPN patients were compared to the corresponding sporadic MPN patients groups. In addition, in stratified analyses of patients with different MPN subtypes (polycythemia vera (PV), essential thrombocythemia (ET), primary myelofibrosis (PMF) and MPN unclassifiable (MPN-U)), there was no difference in survival in patients with or without a family history of MPN. The HRs in familial MPN patients with PV, ET, MPN, MPN-U were HR=1.2 (95% CI 0.8-1.9), HR=1.0 (95% CI 0.4-2.4), HR=0.4 (95% CI 0.03-5.1), and HR=1.3 (95% CI 0.43-5.1), respectively when compared to sporadic MPN patients of the corresponding subtype.

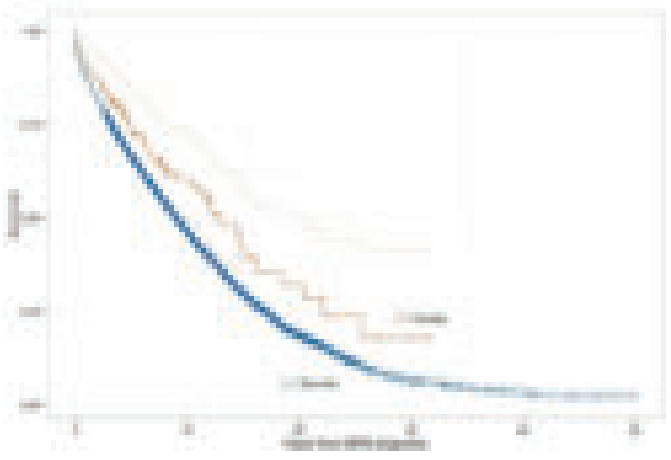


Figure 1. Kaplan-Meier curve of overall survival over time in familial and sporadic MPN patients with 95% confidence intervals.

Summary and Conclusions: In this large population-based on more than 8,000 patients, we found survival to be similar in patients with familial and sporadic MPNs. Our findings do not suggest a more aggressive disease course in familial MPNs. We recommend that family history of MPN should be incorporated in the clinical work-up of MPN patients. However until we gain more insight regarding the potential differences in genetic background and in rate of complications, clinical management should not differ between familial and sporadic MPN patients.

P407

SPLANCNIC VEIN THROMBOSIS ASSOCIATED WITH MYELOPROLIFERATIVE NEOPLASMS. A STUDY OF THE IWG-MRT IN 494 SUBJECTS.

Matteo Foundation, Pavia, Italy, [5]University of Barcelona, Barcelona, Spain, [6]Hematology Institute and Blood Bank, Kfar Saba, Israel, [7]University of Birmingham, Birmingham, United Kingdom, [8]A.O. Papa Giovanni XXIII, Bergamo, [9]Catholic University, Roma, Italy, [10]Guy's Hospital, London, United Kingdom, [11]University of Bari, Bari, Italy, [12]Medical University of Vienna, Vienna, Austria, [13]St Orsola-Malpighi Hospital, Bologna, [14]San Bortolo Hospital, Vicenza, Italy, [15]Laboratoire d'Hématologie CHU, Dijon, France, [16]Mayo Clinic, Rochester, United States

Background: Philadelphia-negative Myeloproliferative Neoplasms (MPN) include Polycythemia Vera (PV), Essential Thrombocythemia (ET), Myelofibrosis both Primary (PMF) and secondary to PV and ET (PPV-, PET-MF) as well as unclassified MPN (U-MPN). An increased risk of venous thrombosis in unusual sites, ie splanchnic vessels (SVT), is particularly associated with MPN. SVT can lead to complications such as portal hypertension, esophageal and gastric varices, ascites and hepatic failure. A recent meta-analysis reported that a MPN is the underlying cause of portal vein thrombosis in 31.5% and of Budd Chiari syndrome in 40.9% of cases (Smalberg, 2012); however analysis of disease characteristics and outcome has been hampered by heterogeneity of available patients' cohorts comprising relatively small number of cases.
Aims: We conducted a retrospective multicenter study collecting clinical and biological data of patients (pts) with SVT associated with WHO2008-diagnosed MPN, with the aim to describe patients' characteristics, trends and prognostic factors that may have implications for clinical practice.
Methods: Data were collected from 16 international hematologic centers in the framework of IWG-MRT.
Results: A total of 494 cases of portal, splenic or mesenteric vein thrombosis (75.2%) or Budd Chiari syndrome (24.8%) associated with MPN were collected. Current analysis refers to 475/494 cases, and final data will be presented at EHA meeting. Frequency of MPN associated subtype was 38.1% ET (n=181), 34.9% PV (n=166), 16.2% MF (n=77), 10.8% U-MPN (n=51). Median follow-up 87.9 mo (range 0.5-430); female 61.3% (n=292; P<0.0001 *vs* male); median age at MPN diagnosis (dg) 44.4 y (range 12-90), significantly younger than non-SVT associated MPN. In 229 cases (48%) MPN and SVT dg were coincident, while in 104 (22%) SVT occurred before MPN dg (median 40 mo, range 5-335) and in 129 (27%) during MPN follow up (median 79 mo, range 5-394). Biological featured included JAK2V617F mutation present in 99% PV, 84.7% ET, 88.1% PMF and 92.9% U-MPN pts, while erythropoietin-independent colonies (EEC) were present at diagnosis in 80/110 evaluated cases (72.7%), 38/47 PV (84.4%), 32/45 ET (71.1%), 8/11 PMF (72.7%) and 2/7 U-MPN (28.6%). A concurrent thrombophilic status was found in 38.9% of cases. Therapy after SVT included anticoagulation in 77% of pts, antiaggregant therapy in 23.5% and both in 1.5%; 68.8% of pts received cytotoxic drugs, 11.4% were treated with trans jugular portosystemic shunt. No differences in survival were noted with these approaches. Beta blockers was used in 48.5% of pts and correlated with improved survival (p=0.041). At last follow up 70/473 pts (14.8%) died; causes of death are evolution to AL (16.4%), other cancers (14.5%), disease progression without AL (12.7%), SVT (10.9%), hepatic failure and venous thrombosis other than SVT (9.1% each), heart failure and arterial thrombosis (7.3% each), hemorrhage (5.5%), renal failure and infection (3.6% each). After 10 y follow up 8/166 PV (5%), 14/181 ET (8%), 14/77 PMF (18%) and 1/51 U-MPN (1.96%) pts died (p<0.01). Survival was significantly affected by occurrence of thrombosis other than SVT (p<0.0001), that occurred in 35.8% of pts but not by recurrence in splanchnic vessels (p=0.068).
Summary and Conclusions: This large study describes characteristics, therapeutic options and outcome of SVT associated with MPN, pointing to an overall good prognosis compared with non-SVT associated MPN and identified thrombosis in districts other than splancnic district as the leading cause of death, suggesting the need to potentiate antithrombotic therapy.

P408

CLINICAL CHARACTERISTICS IN MYELOPROLIFERATIVE NEOPLASM WITH CALRETICULIN MUTATIONS

T Krähling[1,*] A Tordai[1], G Halm[2], A Bors[1], A Batai[2], J Dolgos[2], I Bodo[2], J Csomor[2], M Egyed[3], A Sipos[2], M Koszarska[1], P Remenyi[2], T Masszi[2], H Andrikovics[1]
[1]Hungarian National Blood Transfusion Service, [2]St. Istvan and St. Laszlo Hospital, Budapest, [3]Kaposi Mor Hospital, Kaposvar, Hungary

Background: Somatic insertions/deletions in the calreticulin (CALR) gene were recently identified in the background of JAK2 V617F negative myeloproliferative neoplasm (MPN).
Aims: The aim of our study was to investigate the frequency and clinical characteristics of CALR mutation-positive MPN in a cohort of Hungarian patients.
Methods: A combination of allele-specific PCR (JAK2-V617F, MPL), quantitative TaqMan-assay (JAK2-V617F), high resolution melting (MPL), fragment-sizing (CALR) and Sanger-sequencing (CALR, MPL) was applied to identify the driver mutation in 215 polycythemia vera (PV), 289 essential thrombocytosis (ET) and 99 primary myelofibrosis (PMF) patients.
Results: PV patients all carried the JAK2 V617F mutation. In the ET cohort, the frequency of V617Fmut was 53.3% (n=154), CALRmut 33.2% (n=96), MPLmut 3.1% (n=9), while 30 patients (10.4%) were JAK2-CALR-MPL mutation negative. Similar distribution of the above mentioned somatic mutations was observed in PMF patients [56.6% V617Fmut (n=56), 25.3% CALRmut (n=25), 7.0% MPLmut (n=7), and 11.1% triple-negative (n=11)]. Comparing CALRmut ET-patients to V617Fmut ET patients, younger age at disease onset (53 *vs.* 61 years, p=0.03), higher platelet count (981 *vs.* 778 G/L; p<0.001), lower hemoglobin (131 *vs.* 147 g/L; p<0.001) and lower white blood cell count (9 *vs.* 10 G/L; p=0.034) was observed. Venous thrombosis (7.1 *vs.*17.6%, p=0.03), arterial thrombosis (9.4 *vs.* 14.4%, p=0.3) or hemorrhage (4.7 *vs.* 9.2%, p=0.3) occurred less frequently in CALRmut compared to V617Fmut ET patients, resulting in lower risk for vascular complications (17.6 *vs.* 35.9%, p=0.003). On the other hand, post-ET myelofibrosis was more frequent in CALRmut patients compared to V617Fmut ET patients (14.9 *vs.* 5.9%, p=0.03), while leukemic-transformation occurred with the same frequency (3.4 *vs.* 2.6%). The type of driver mutation did not influence overall survival in the ET cohort. Among MF patients, younger age at disease onset (55 *vs.* 69 years, p=0.002) and higher platelet count (535 *vs.* 250 G/L; p=0.001) were observed in the CALRmut subgroup compared to JAK2mut patients. Leukemic-transformation was more frequent among the triple negative cases (36.4%; 4/11) compared to V617Fmut (9.3%; 5/54, p=0.038) or CALRmut cases (13.6%; 3/22, p=0.2). CALRmut PMF-patients showed better overall survival compared to JAK2mut PMF-patients (p=0.04) and to triple-negative PMF-cases (p=0.01). In multivariate analyzes, carriership of CALRmut was characterized by HR=0.13, (0.012-0.739, p=0.021) compared to triple negatives. The ratio of type 2 to type 1 CALR mutation was smaller in PMF compared to ET (p=0.05). In ET, CALR mutation load was higher than JAK2 mutation load (p<0.001). CALR mutation load rarely exceeded 50%, but gradually increased in advanced MPN-stages.
Summary and Conclusions: In the present study, we confirmed in an independent cohort that, CALRmut MPN associated with distinct clinical characteristics and extended the available observations to relationships between CALR mutation type, load and clinical outcome.

P409

JAK2 V617F ALLELE BURDEN AND VASCULAR COMPLICATION OCCURRENCE RISK IN PATIENTS WITH PHILADELPHIA-NEGATIVE MYELOPROLIFERATIVE NEOPLASMS

M Borowczyk[1,*] K Lewandowski[1], M Wojtaszewska[1], L Gil[1], M Lewandowska[1], A Lehmann-Kopydłowska[1], R Kroll-Balcerzak[1], A Balcerzak[1], M Iwoła[1], M Michalak[2], M Komarnicki[1]
[1]Department of Hematology and Bone Marrow Transplantation, [2]Department of Computer Science and Statistics, Poznań University of Medical Sciences, Poznań, Poland

Background: Patients with Philadelphia-negative myeloproliferative neoplasms (Ph^-, MPNs) are at increased risk of thromboembolic and hemorrhagic complications. Although the presence of *JAK2* V617F mutation is deemed an important diagnostic criterion for MPNs and is considered as a new thrombosis risk factor beside commonly recognized: age over 60 years and previous history of thrombosis, it remains ambiguous and conflicting in the few previous studies, whether its quantity influences the occurrence of vascular complications in MPNs patients.
Aims: The aim of the study was to establish the influence of *JAK2* V617F presence and allele burden on the risk of vascular complications in MPNs patients and assess its possible application in the risk stratification for vascular complications in patients with Ph^-, MPN.
Methods: Analysis was performed in a cohort of 186 patients diagnosed with polycythemia vera (53), essential thrombocythemia (114), primary myelofibrosis (11) and unclassified MPN (8). Assessment of *JAK2* V617F-positivity was conducted with amplification-refractory mutation system polymerase chain reaction (ARMS-PCR). The type and prevalence of any vascular complications clinically proven and/or confirmed by diagnostic imaging in the studied group over a median follow-up of 29.5 months (range: 0-306), based on a retrospective analysis of patients medical files. The risk of vascular complications in 126 *JAK2* V617F-positive patients was analyzed with respect to allele burden, defined as the ratio of mutated *JAK2* V617F to both *JAK2* V617F and wild-type *JAK2* V617F, assessed with allele-specific 'real-time' quantitative polymerase chain reaction (AS RQ-PCR).
Results: Overall prevalence of any vascular complications was 42.5%. Arterial thrombosis occurred in 22%, venous thromboembolism (VTE) in 11.8%, bleeding episodes in 23.7% of patients. Individuals harboring *JAK2* V617F mutation, regardless of MPN type, were at higher risk of venous thromboembolism (OR=5.5, 95% CI: 1.2-24.5, P=0.006). *JAK2* allele burden higher than 25% identified patients with 7.4-fold increased risk of VTE (95% CI: 1.6-34.7, P=0.004). Nevertheless, no significant increase in the risk of bleeding complications was found in this group in comparison with V617F-negative population OR=0.8, 95% CI: 0.3-2.1, P=0.8. The number of venous thromboembolic events progressively increased in patients along with the increase in *JAK2* V617F allele burden (P=0.0014 using Chi-squared test for trend). Patients with the result >75% of mutant allele burden were also at 4.5-fold higher risk for arterial thrombosis (95%CI: 1.4-13.8, P=0.01). The prognostic value of the mutant allele burden for predicting VTE was confirmed by ROC curve analysis. The best proposed cut-off value for the increase of venous thromboembolism risk was 27% of mutant allele burden with sensitivity of 60% and specificity of 57.5% (Figure 1).

Figure 1. Effects of the *JAK2* V617F mutant allele burden on the risk of vascular complications in patients with Ph MPNs.

Summary and Conclusions: The group of patients with allele burden higher than 25%, as they are at increased risk of VTE and at no increased risk of bleeding, may benefit the most from vigilant monitoring and appropriate prophylaxis against vascular events. Patients with a *JAK2* V617F allele burden higher than 75% require additional management to prevent arterial thrombosis. The inclusion of *JAK2* V617F mutant allele burden in new risk stratifications seems to be justified and requires controlled prospective trials.

P410

RUXOLITINIB PLUS PANOBINOSTAT IN PATIENTS WITH PRIMARY MYELOFIBROSIS, POST–POLYCYTHEMIA VERA MYELOFIBROSIS OR POST–ESSENTIAL THROMBOCYTHEMIA MYELOFIBROSIS: A PHASE 1B DOSE-FINDING STUDY

A M Vannucchi[1,*] F H Heidel[2], V Ribrag[3], JJ Kiladjian[4], F Passamonti[5], A Hayat[6], E Conneally[7], T Kindler[8], B Martino[9], DB Lipka[10], S Acharyya[11], P Gopalakrishna[12], S Loechner[11], S Mu[11], CN Harrison[13]

Background: Myelofibrosis (MF) is a clonal myeloproliferative neoplasm characterized by dysregulation of the Janus kinase (JAK) pathway, resulting in bone marrow fibrosis, splenomegaly, and debilitating constitutional symptoms. Ruxolitinib (RUX), a potent JAK1/JAK2 inhibitor, demonstrated superiority in spleen volume reduction, symptom improvement, and survival compared with the control arm in the phase 3 COMFORT-I and COMFORT-II studies. Panobinostat (PAN) is a potent pan-deacetylase inhibitor (pan-DACi) that inhibits JAK signaling through disruption of the JAK2 protein chaperone heat shock protein 90. The combination of RUX and PAN demonstrated synergistic anti-MF activity in preclinical studies. In phase 1/2 studies, PAN has shown splenomegaly reduction and improvement of marrow fibrosis. The updated results of a phase 1b study of the combination of RUX and PAN in patients (pts) with MF are presented here.

Aims: The primary objective was determination of the recommended phase 2 dose (RP2D) and/or maximum tolerated dose. Secondary objectives included safety, efficacy, and pharmacokinetics.
Methods: Eligible pts had intermediate-1–, -2–, or high-risk MF by International Prognostic Scoring System criteria, with palpable splenomegaly (≥5 cm below the costal margin). The treatment schedule was RUX (5-15 mg) twice daily (bid) every day and PAN (10-25 mg) once daily 3 times per week (tiw; days 2, 4, and 6) every other week (qow) in a 28-day cycle. The primary objective was determination of the recommended phase 2 dose (RP2D) and/or maximum tolerated dose. Dose escalation was guided by a Bayesian logistic regression model with overdose control based on cycle 1 dose-limiting toxicities (DLTs) and additional safety findings. Following identification of the RP2D, additional pts were enrolled and treated at this dose.
Results: Preliminary data presented here are based on a cutoff date of July 31, 2013. A total of 48 pts were enrolled (38 escalation phase and 10 expansion phase). Three DLTs were observed in the escalation phase (grade 4 thrombocytopenia [n=2], grade 3 nausea [n=1]). Preliminary RP2D was identified at RUX 15 mg bid every day and PAN 25 mg tiw qow. In the escalation phase, grade 3/4 adverse events (AEs) regardless of causality included anemia (42%), thrombocytopenia (21%), abdominal pain (8%), and diarrhea (8%), and AEs led to discontinuation in 21% of pts. Anemia (8%) was the most common serious AE in the escalation phase. Grade 3/4 AEs in the expansion phase included anemia (20%) and asthenia (10%). Preliminary activity in the dose-escalation phase was demonstrated by ≥50% decrease in palpable spleen length at any time in 76% of pts, with 50% of pts demonstrating 100% (nonpalpable spleen) response (Figure 1). In the expansion phase, all 4 evaluable pts demonstrated a best spleen response of 100% (nonpalpable spleen).

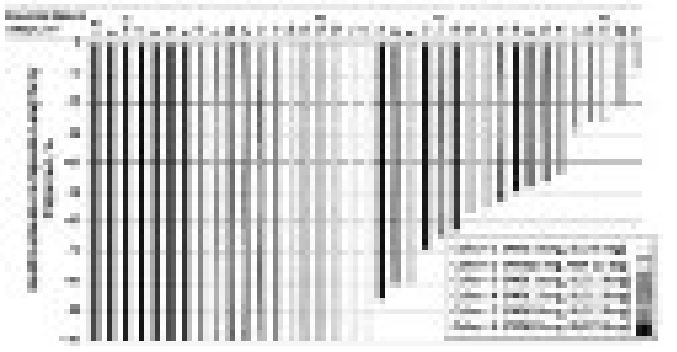

Figure 1.

Summary and Conclusions: The combination of the JAK1/JAK2 inhibitor RUX and the pan-DACi PAN demonstrated a tolerable safety profile with encouraging efficacy as demonstrated by spleen responses in patients with intermediate- and high-risk MF. Patients are currently being treated in the expansion phase at the RP2D. Updated safety and efficacy data from the expansion phase will be presented.

P411

UTILITY OF BONE MARROW HISTOLOGY AND IMMUNOHISTOCHEMISTRY IN THE DIAGNOSTIC WORK-UP OF EOSINOPHILIA OF UNKNOWN SIGNIFICANCE

G Metzgeroth[1,*] J Schwaab[1], A Schmitt-Graeff[2], HP Horny[3], M Jawhar[1], NC Cross[4, 5], WK Hofmann[1], A Reiter[1]
[1]III. Medizinische Klinik, Hämatologie und Onkologie, Universitätsmedizin Mannheim, Mannheim, [2]Institut für Pathologie, Universitätsklinikum Freiburg, Freiburg, [3]Pathologisches Institut, Ludwig-Maximilians-Universität München, München, Germany, [4]Wessex Regional Genetics Laboratory, Salisbury, [5]Human Genetics Division, University of Southampton School of Medicine, Southampton, United Kingdom

Background: Clonal eosinophilia is associated with disparate myeloid neoplasms and the presence of tyrosine kinase fusion genes of which *FIP1L1-PDGFRA* is by far the most frequent. In contrast, sustained non-clonal eosinophilia with organ involvement is associated with autoimmune disorders (reactive hypereosinophilia, HE_R), *e.g.* eosinophilic granulomatosis with polyangiitis (Churg-Strauss syndrome) or as a diagnosis of exclusion, hypereosinophilic syndrome (HES). Irrespective of the final diagnosis, the majority (>80%) of patients with non-clonal eosinophilia achieve durable complete remissions on corticosteroid-based immunosuppression. In cases without a clear diagnosis, a rapid response to corticosteroids is therefore considered as useful marker for almost definite exclusion of clonal eosinophilia. Bone marrow (BM) histology is considered an essential tool in the diagnostic work-up of hypereosinophilia of unknown significance (HE_{US}) and the subsequent differentiation between clonal or non-clonal origin.
Aims: Within the "German Registry on Disorders of Eosinophils and Mast Cells", we therefore retrospectively analysed initially and routinely evaluated histopathological und immunohistochemical BM characteristics of 116 patients who were subsequently identified as *FIP1L1-PDGFRA* positive (n=56) or corticosteroid-responsive HE_R/HES (n=60). The latter group was chosen to maximally exclude the possibility of hidden clonality.
Results: Useful pointers towards a diagnosis of *FIP1L1-PDGFRA* positive disorders were BM hypercellularity (45/56, 80% *vs.* 23/53, 43%; p<0.05) and increased numbers of (CD34-positive) blasts (11/56, 20% *vs.* 2/60, 3%; p<0.05) whereas relative numbers of eosinophils (43%, range 5-80 *vs.* 26%, range 5-30; n.s.) were not informative. Additional features of *FIP1L1-PDGFRA* positivity were significant fibrosis (25/35, 71% *vs.* 1/23, 4%; p<0.05), increased numbers of loosely scattered mast cells (23/33, 70% *vs.* 7/23, 30%; tryptase/CD117 positive, 17/17, 100% *vs.* 4/12, 33%; p<0.05) and aberrant expression of CD25 on mast cells (11/18, 61% *vs.* 2/13, 15%; p<0.05). However, these stainings were in fact only performed in ≤50% of patients (fibrosis 58/116, 50%; tryptase/CD117 29/116, 25%; CD25 31/116, 27%). In *FIP1L1-PDGFRA* positive disease, clonal eosinophilia was suggested in 36/56 (64%) and non-clonal eosinophilia in 13/56 (23%) of cases, while no final diagnosis was made in 7/56 (13%) cases. Preliminary diagnoses towards clonal eosinophilia included chronic eosinophilic leukemia (CEL, n=15), systemic mastocytosis (SM, n=6), chronic myeloid leukemia (CML, n=5) and myeloid neoplasm unclassified in chronic or blast phase (MPN_u, n=10). In HE_R/HES, non-clonal eosinophilia was suggested in 43/60 (72%) and clonal eosinophilia in 7/60 (12%) of cases, while no final diagnosis was made in 10/60 (16%) patients. The overall sensitivity for reliable diagnosis of clonal or non-clonal eosinophilia was 68% (79/116).
Summary and Conclusions: We therefore conclude that 1) numbers of eosinophils in BM are not useful to differentiate between clonal and non-clonal eosinophilia, 2) the most informative stains that fit in with standard work-flows include CD34 for blast cells, tryptase/CD117/CD25 for mast cells and Gomori´s stain for fibrosis, 3) a broad range of myeloid neoplasms (*e.g.* CEL, SM, MPN_u) are associated with suspected clonal eosinophilia, and 4) appropriate use of available and potentially new markers in combination with reference pathology in experienced centers should allow to improve the currently limited diagnostic value of routine BM examinations in the diagnostic work-up of HE_{US}.

P412

INFLUENCE OF IL-28B AND IL-6 GENETIC POLYMORPHISM ON IFN-ALFA TREATMENT OUTCOME IN PATIENTS WITH POLYCYTHEMIA VERA AND ESSENTIAL TROMBOCYTHEMIA

M Lindgren[1,*] J Samuelsson[2], L Nilsson[3], H Knutsen[4], W Ghanima[5], M Åström[6], E Ejerblad[7], A Hugosson[8], J Westin[9], L Palmqvist[10], B Andréasson[11,12]
[1]Department of Internal Medicine, Section of Hematology, Kalmar County Hospital, Kalmar, [2]Department of Internal Medicine, Stockholm South Hospital, Stockholm, [3]Department of Hematology, Skåne University Hospital, Lund, Sweden, [4]Department of Hematology, Ullevål University Hospital, Oslo, [5]Department of Medicine, Östfold Hospital Trust, Fredrikstad, Norway, [6]Department of Hematology, Örebro University Hospital, Örebro, [7]Department of Hematology, Uppsala University Hospital, Uppsala, [8]Department of Medicine, Skaraborg Hospital, Lidköping, [9]Department of Infectious Diseases, [10]Department of Clinical Chemistry, Sahlgrenska University Hospital, Gothenburg, [11]Department of Internal Medicine, Section of Hematology, NU Hospital Group, Uddevalla, [12]Department of Hematology and Coagulation, Sahlgrenska University Hospital, Gothenburg, Sweden

Background: In Polycythemia Vera (PV) and Essential Trombocythemia (ET), Interferon-α (IFN-α) is a therapeutic option with a potential of inducing hematological and molecular response. However, the treatment may be limited due to a lack of efficacy and a multitude of adverse side effects. Genetic polymorphism in the region of the Interleukin-28B (*IL-28B)* gene on chromosome 19 was recently found to be strongly predictive of the responsiveness to dual therapy with Peg-IFN-α and Ribavirin in Hepatitis C virus (HCV) genotype 1 patients. Using genome-wide association studies (GWAS), favorable single nucleotide polymorphisms (SNP) was identified, in particular the rs12979860 CC, rs8099917 TT and rs12980275 AA genotypes (gt), showing increased sustained virological response (SVR) rates with IFN-α treatment. Interleukin-6 (*IL-6*) is a proinflammatory cytokine with a documented role in disease progression of several neoplasms. The G-174C polymorphism of the *IL-6* gene controls serum levels of *IL-6*, with the G allele found to have a higher transcriptional level than the variant C allele and the presence of the C allele resulting in lower *IL-6* levels.
Aims: The outcome of IFN-α treatment may be related to inborn variations in genes involved in inflammation. We address whether polymorphism in the genes of *IL-28B* and *IL-6* influence the outcome of IFN-α treatment in PV and ET.
Methods: In total, 90 patients with PV (n=47) or ET (n=43), currently or previously treated with IFN-α, were included. Prior to IFN-α, 28 patients had been treated with hydroxyurea. Hematological response was evaluated using the European Leukemia Net (ELN) criteria from 2008. Written informed consent was obtained from all patiens. DNA was extracted from whole blood, and genotyping of the four SNPs, rs12979860, rs8099917, rs12980275 in the *IL-28B* gene locus and G-174C in the *IL-6* gene locus was performed by Taqman analysis.

Results: Complete response (CR) was achieved in 28 patients with PV and 30 patients with ET. Partial (PR) or no response (NR) was noted in 19 patients with PV and in 13 patients with ET. The median lenght of IFN-α treatment was 35 months. In the group of PV patients presenting with the favorable *IL-28B* rs12979860 CC gt, 78% responded with CR compared to 46% in the group with CT+TT (p=0,018). A similar response was seen in the combined group of PV and ET with 79% responding with CR in comparison to 54% (p=0,016). The results with regard to *IL28B* rs12980275 AA/AG+GG were similar to the above reported of rs12979860 CC/CT+TT, supposedly due to a well described linkage disequilibrium. The *IL-28B* rs8099917 gt TT/TG+GG did not show a significant association in any group. The combined group of carriers of the CC gt of *IL-6* G-174C had an inferior outcome with CR in 41% compared to carriers of CG or GG gt with CR in 69% (p=0,048). In subgroup analyses, the result for PV (p=0,047) was significant, but not the result for ET (p=0,426) (Table 1).

Table 1. Hematological response (ELN-criteria 2008) during INF-α treatment with regard to IL-28B and IL-6 genotypes.

Summary and Conclusions: Patients with the CC gt of *IL-28B* rs12979860, the AA gt of *IL-28B* rs12980275 and the non-CC gt of *IL-6* G-174C achieve CR more frequently compared to patients carrying the variant alleles. These differences were statistically significant in PV and in the PV+ET group, but not for ET alone. Thus, despite the heterogeneity of the patient cohort, we found evidence suggesting that inborn variations in *IL-28B* and *IL-6* gt influences the hematological response to IFN-α treatment.

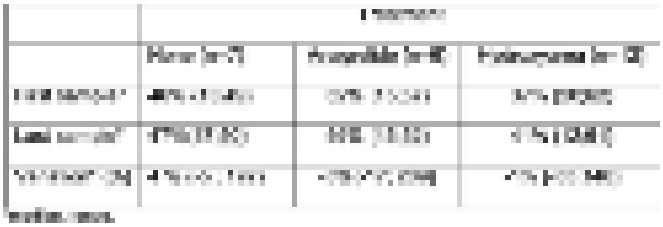
P413

DYNAMICS OF CALR MUTANT ALLELE BURDEN IN ESSENTIAL THROMBOCYTHEMIA PATIENTS

B Bellosillo[1,2,3,*] R Longaron[1,2], S Pairet[1,2], A Alvarez-Larrán[4], L Martinez-Aviles[1,2,5], L Camacho[2], C Fernandez-Rodriguez[2], A Angona[2], A Ancochea[4], S Serrano[1,5], C Besses[2,4]
[1]Pathology, [2]Grup de Recerca Clínica Aplicada en Neoplàsies Hematològiques, Hospital del Mar-IMIM, [3]CEXS, Universitat Pompeu Fabra, [4]Hematology, Hospital del Mar-IMIM, [5]Universitat Autonoma de Barcelona, Barcelona, Spain

Background: Mutations in the calreticulin gene (*CALR*) have been recently described in around 49-84% essential thrombocythemia (ET) and 67-88% primary myelofibrosis (PMF) patients, which lack *JAK2* and *MPL* mutations. However, there is limited information regarding the dynamics of *CALR* mutant allele burden over time in the absence or presence of cytoreductive treatment.
Aims: To analyze the dynamics of *CALR* mutant allele burden over time in a cohort of ET patients.
Methods: From a whole cohort of 220 ET patients diagnosed in a single institution, we analyzed the presence of *CALR* mutations in 74 patients lacking mutations in the *JAK2* (p.V617F) and the *MPL* (exon 10) genes. The mutational analysis of exon 9 of the *CALR* gene was performed in DNA extracted from purified granulocytes by PCR, using a 6-carboxyfluorescein labeled reverse primer, followed by fragment analysis in a Genetic Analyzer 3500DX (Applied Biosystems). The *CALR* mutated allele burden was calculated as the percentage of the peak area of the mutated allele/peak area of the total (wild type+mutated) *CALR*. Variation in the *CALR* mutated allele burden was calculated as follows: (*CALR* mutant in last sample- *CALR* mutant in first sample)/ *CALR* mutant in first samplex100.
Results: *CALR* mutations were detected in 33/74 (45%) patients negative for *JAK2* p.V617F and *MPL* mutations. The cohort of *CALR* positive patients comprised 10 males and 23 females with a median age of 59 years (range 23-93). The mutations detected were: del 52bp (type 1 mutation) in 14/33 cases (42.4%), insertion of 5bp (type 2 mutation) in 12/33 patients (36.4%) and the remaining 7 were other types of mutations (21.2%), including 3 cases in which an insertion or deletion of 1 bp was detected. The median value of *CALR* mutant allele burden in the first sample available was 44.28% (range 13-62%). In 25 patients sequential samples could be analyzed, 7 cases received no treatment, 6 cases received anagrelide and 12 received hydroxyurea (HU) (Table 1). The median time between the first and last sample was 8 years (range 1-12 years). No significant differences were observed among *CALR* mutant allele burden in untreated and treated patients or between anagrelide or HU treatment. Nevertheless, in 2 untreated patients an increase higher than 10% in the *CALR* allelic ratio was observed during follow-up, and in 5/12 patients receiving HU a decrease higher than 15% was observed over time.

Table 1.



Summary and Conclusions: *CALR* mutant allele burden remains stable over time in untreated and cytoreductive-treated ET patients, although in some individual cases a significant variation can be observed.

Background: Ruxolitinib, a small molecule inhibitor of Janus Kinase 1 and 2 (JAK1/2), down-regulates the JAK/STAT pathway which is overactive in myelofibrosis (MF). MF is characterized by bone marrow fibrosis, splenomegaly and reduced health-related quality of life (HRQoL). Ruxolitinib demonstrated a statistically significant reduction in splenomegaly compared with placebo or best available treatment in phase 3 trials (COMFORT-1 and -2, respectively) in patients with intermediate-2 and high-risk disease, according to the International Prognostic Scoring System (IPSS).
Aims: ROBUST, a UK single-arm, open-label phase 2 trial aimed to assess response to ruxolitinib in patients with MF (including patients with intermediate-1 disease plus splenomegaly) using a novel composite endpoint, treatment success, defined as a spleen and/or symptom response and to assess the impact of treatment on HRQoL using the EQ-5D.
Methods: Adults with primary MF, post-polycythemia vera MF and post-essential thrombocythemia MF (World Health Organization criteria) were enrolled in this open-label, multicentre UK study. Patients had intermediate-1, intermediate-2 and high-risk disease (according to the IPSS) with or without prior treatment (excluding JAK2 inhibitors). Patients initiated treatment with ruxolitinib 15 or 20mg twice daily according to baseline platelet levels and the dose could be increased in patients with inadequate responses. Treatment was continued until progression, unacceptable toxicity, death or withdrawal. Spleen length (assessed by palpation), total symptom score (TSS, assessed with the MF Symptom Assessment Form out of 100, MF-SAF) and HRQoL (assessed with the EQ-5D; 1.00 as best health) were measured at baseline and weeks 4, 8 (spleen length only), 12, 24 and 48. The primary composite endpoint, treatment success, was defined as the proportion of patients achieving a 50% reduction in spleen length and/or 50% decrease in TSS at 48 weeks. This final analysis presents data at 48 weeks.
Results: A total of 48 patients (intermediate-1:n=14; intermediate-2:n=13; high:n=21) were included. Mean±SD age was 69.1±10.4 years and 43.8% of patients were female. At baseline, patients had Eastern Cooperative Oncology Group (ECOG) scores of 0 (52.1%), 1 (35.4%) or 2 (12.5%), mean±SD spleen length was 13.5±7.3cm, mean±SD TSS was 16.3±11.9 and mean±SE EQ-5D was 0.72±0.03. Reductions in spleen length and improvements in symptoms scores from baseline to week 48 were seen in all IPSS groups (Table 1). At week 48, 35 and 18 of 48 patients were evaluable for spleen length and TSS, respectively. From baseline, mean spleen length decreased by 5.8±7.0cm and mean TSS improved by 7.8±10.0. In the total population at week 48, 39.6% of patients had a ≥50% decrease in spleen length, 20.8% had a ≥50% reduction in TSS and treat-

ment success was seen in 50.0% of patients. Changes from baseline in splenomegaly outcomes and treatment success were similar in all IPSS groups. Mean platelets levels decreased by approximately 40% from baseline to week 4 and then stabilized. Mean hemoglobin levels decreased from baseline by 10% to week 12, attenuating to 5% by week 48. Adverse events and 48 week EQ-5D data will be available for presentation at the meeting.

Table 1. Summary of efficacy endpoints at 48 weeks.

Summary and Conclusions: Our results demonstrate that MF is associated with a significant symptom burden and adversely affects HRQoL. Ruxolitinib was shown to reduce symptoms and splenomegaly. In our study, treatment success, a composite endpoint combining objective and subjective measures, was seen in all IPSS groups including in over half of patients with intermediate-1 disease.

P415

TREATMENT OF PATIENTS WITH PHILADELPHIA-NEGATIVE MYELOPROLIFERATIVE NEOPLASMS WITH PEGYLATED INTERFERON ALPHA-2A: A PROSPECTIVE MONOCENTER COHORT STUDY.

S Betti[1,*] E Rossi[1], T Za[1], A Ciminello[1], DG De Ritis[1], S Genovese[1], F Annunziata[1], S Marietti[1], P Chiusolo[1], V De Stefano[1]
[1]Institute of Hematology, Catholic University, Roma, Italy

Background: In patients with myeloproliferative neoplasms (MPN), pegylated interferon alpha-2a (PegIFN2a) has been reported to be effective and better tolerated than non-pegylated interferon alpha-2b (IFN2b), and able to induce a reduction of the JAK2 V617F allelic burden up to a complete molecular response. Moreover, the absence of leukemogenic potential renders PegIFN2a a preferential agent in young patients. However, published experience is limited (Kiladjian JJ *et al.*, Blood 2008; Quintas-Cardama A *et al.*, JCO 2009; Gowin K *et al.*, Haematologica 2012).
Aims: To assess in patients with MPN the safety of PegIFN2a and the hematological and molecular response.
Methods: Fifty-four pts. (M/F 22/32, median age 56 yrs, range 35-84) with polycythemia vera (PV, n=22), essential thrombocythemia (ET, n=31), myelofibrosis (MF, n=1) treated with PegIFN2a were prospectively evaluated from July, 2010 to January, 2014. JAK2 V617F-positive patients were preferentially recruited, so that all patients but one with ET had the mutation. Hematological response was assessed according to the ELN criteria (Barosi G *et al.*, Blood 2009). The JAK2 V617F allelic burden was tested before starting treatment and then every 3 months; patients were evaluable for molecular response if quantitated on at least two different occasions.
Results: Twenty-two pts. (median age 50.5, range 35-67) received PegIFN2a as a first line treatment, and 32 after discontinuation of previous treatment because of no response (n=3), hydroxyurea [HU]-related mucocutaneous toxicity (n=12) or fever (n=1), IFN2b-related adverse effects (n=4), concern of leukemogenic potential of HU or pipobroman in younger patients (n=12). The median dosage was initially 90 mcg/ week (range 67-180), and after adjustement for adverse effects and response 90 mcg/week (range 22-270). The median duration of treatment was 37 weeks (range 4-188) in PV, and 28 weeks (range 4-32) in ET; 20 pts. (37%, PV=9, ET=11) were treated >1 year. Hematological response was complete in 13 pts. (24%, PV=5, ET=8) and partial in 26 (48%, PV=8, ET=18); 14 (26%, (PV=9, ET=5)) had no response. Sixteen pts. had splenomegaly, and 5 had a median reduction of 4 cm (range 2-6). The baseline median JAK2 V617F allelic burden was 75.5% in 18 evaluable PV pts. (range 16-100) and decreased to 57.5% (median 3-100) after median 48 weeks (range 20-188) of treatment; 6 pts. (33%) had a decrease >50%, but none achieved a complete molecular response. In 21 evaluable ET pts. the median JAK2 V617F allelic burden was unmodified (27%, range 7-100) in respect to the baseline (27%, range 6-98). Adverse events occurred in 31 pts. (57%), mainly flu-like symptoms (n=17, 31%), thyroiditis (n=8, 15%), itching (n=8, 15%), elevated liver enzymes (n=3, 5%), diarrhea (n=1, 2%), and 20 (37%) had to discontinue treatment. In our cohort 31 pts. had a previous thrombosis (57%); during treatment 5 pts. (9%) had a recurrence (mesenteric vein thrombosis n=1, deep venous thrombosis n=1, TIA n=1, ischemic stroke n=1) or a first event (myocardial infarction n=1), in spite of adequate primary or secondary antithrombotic prophylaxis.
Summary and Conclusions: PegIFN2a was confirmed to be effective in inducing hematological response in MPN patients. A partial molecular response was observed in at least one-third of PV patients, but not in ET patients. However, the rate of discontinuation due to severe adverse effects was higher than previously reported. Finally, cytoreduction obtained with PegIFN2a showed limited efficacy in preventing thrombosis.

P416

SPECIFIC DETECTION OF CALR-MUTATED MYELOPROLIFERATIVE NEOPLASMS BY IMMUNOSTAINING

G Rotunno[1,*] N Bartalucci[1], P Guglielmelli[1], L Calabresi[1], G Raugei[2], V Carrai[2], M Balliu[1], C Mannarelli[1], A Pacilli[1], R Fjerza[1], L Pieri[1], A Bosi[2], R Manfredini[3], A M Vannucchi[1]
[1]Department of Experimental and Clinical Medicine, University of Florence, [2]Hematology Unit, Azienda Ospedaliera Universitaria Careggi, florence, [3]Centre for Regenerative Medicine "Stefano Ferrari", University of Modena and Reggio Emilia, Modena, Italy

Background: Mutations of *CALR*, the gene encoding the endoplasmic reticulum Ca2+ binding chaperon calreticulin, were recently discovered in *JAK2* and *MPL* wild type (wt) patients with essential thrombocythemia (ET) and primary myelofibrosis (PMF); thus identifying *CALR* mutations is important for diagnosing these diseases. *CALR* mutations are heterogeneous and involve the whole exon 9, but all lead to a novel common protein C-terminus.
Aims: We sought to develop a diagnostic tool for identifying *CALR* mutated patients based on the recognition of the novel C-terminus sequence of the protein.
Methods: To this end, we developed a polyclonal antibody directed against a common 17-mer C-terminal peptide from the mutated calreticulin. Purified antibody was used to perform immunostaining on bone marrow (BM) biopsies of PV, ET and PMF patients who provided an informed written consent. Calreticulin expression levels were measured by gene expression array analysis in CD34-positive cells, isolated from BM of healthy donors, induced to erythroid, myeloid and megakaryocytic unilineage differentiation. Genotyping for *JAK2* and *MPL* was performed by Real Time quantitative PCR and mutations in *CALR* were assessed by bidirectional Sanger sequencing.
Results: The antibody specificity was supported by results of western blotting in granulocytes of *CALR* mutated patients. By immunolabelling we show that the antibody specifically labelled patients harboring different types of *CALR* mutations with no staining in subjects with non-hematologic disorders, *JAK2* and *MPL* MPN mutated patients and triple negative ET and PMF. The staining was localized mainly in the megakaryocytes (mk) with a comparable mean percentage of labelling depending on *CALR* mutation type, respectively 91% (range 74-98%) for *CALR*del52, 92% (range 88-98%) for *CALR*ins5 and 87%/98% for the 2 *CALR*indel mutated patients. Conversely myeloid and erythroid cells showed a faint staining suggesting a preferential overexpression of calreticulin in mk lineage. This was indeed supported by finding that calreticulin mRNA level in normal hematopoietic cells was significantly upregulated in megakaryocyte differentiation (fold change 3.4) compared with erythroid and granulocyte (fold change respectively 0.3, 0.6). Using an antibody agaist wt calreticulin, a similar preferential staining of megakaryoyctes was observed in control BM sections.
Summary and Conclusions: Taking advantage of the unique common novel protein due to *CALR* mutations, we developed a polyclonal antibody specifically directed against the mutated protein that selectively labelled cells in BM of *CALR* mutated patients, unlike in normal subject and ET and PMF patients harboring *JAK2* and *MPL* mutations. Therefore, immunostaining using mutated *CALR*-antibody represents a specific, cost-effective and easy diagnostic tool for molecular classification of ET and PMF patients, eventually suitable for small hematology units where sequencing is not available. The almost exclusive staining of the mk lineage, with 80-100% of the cells being labelled, suggests a prevalence of mutated clone over normal megakaryocytopoiesis in *CALR* mutated patients. We also show for the first time that calreticulin is preferentially expressed in cells belonging to the mk lineage, making the case for the specific association of CALR mutations with disorders characterized by extensive involvement of Mk.

THE ROLE OF POLYCOMB PROTEINS IN NON-HODGKIN B CELL LYMPHOMA: FROM PRECLINICAL MODELS TO TARGET THERAPY

S Casola[1,*] M Caganova[2], F Alberghini[1], V Petrocelli[3], G Varano[1], C Carrisi[1], F Zanardi[1], M Rahmat[1], F Mainoldi[1], J Jin[4], M Ponzoni[5], G Pruneri[6]
[1]IFOM Foundation, FIRC Institute of Molecular Oncology, [2]Italian Institute of Technology, [3]IFOM Foundation, Milano, Italy, [4]University of North Carolina, Chapel Hill, United States, [5]Ospedale San Raffaele Scientific Institute, [6]Division of Pathology and Laboratory Medicine, European Institute of Oncology,, Milano, Italy

Background: Polycomb group (PcG) proteins are recruited within two main Polycomb Repressive Complexes (PRC), PRC1 and PRC2, to promote transcriptional repression of target genes. Within PRC2, EZH2 is responsible for histone H3 lysine-27 trimethylation. EZH2 is highly expressed in B cells recruited into the germinal center (GC) reaction during a T-cell dependent immune response. Importantly, *EZH2* gain-of-function mutations are frequently selected in Diffuse Large B-cell lymphomas and Follicular Lymphomas arising from GC B cells, suggesting a possible contribution of the mutant PcG protein to lymphomagenesis. PRC2 has been proposed to act in concert with PRC1, which is responsible through the E3 ligases Ring1a/Ring1b proteins to catalyze lysine-119 monoubiquitylation on Histone H2A. The contribution of EZH2 and the Ring1 proteins to GC B cell responses and B cell lymphomagenesis has remained, till recently, largely unexplored.
Aims: Our work aimed to dissect the *in vivo* function of PRC1/PRC2 in GC B cell biology. Moreover, we investigated the mechanisms through which the Polycomb axis could possibly contribute to the establishment and maintenance of the B cell malignant phenotype in different types of Non-Hodgkin lymphoma (NHL).
Methods: We combined mouse conditional gene targeting studies to high throughput genomic analyses to reveal the molecular targets and mechanism of action of the Polycomb axis in GC B cells. Moreover, conditional gene inactivation studies and highly specific small molecule inhibitors were employed to establish the role and mechanism of action of Polycomb proteins Ezh2 and Ezh1 in the maintenance of different types of NHL.
Results: Inactivation of PRC1 and PRC2 function in GC B cells resulted in marked apoptosis, poor antibody responses and significantly fewer high-affinity memory B cells. Ezh2 sustained the survival of GC B cells protecting cells against genotoxic damage induced by Activation Induced cytidine Deaminase (AID). Genome wide identification of Polycomb targets in GC B cells revealed a significant enrichment for genes whose repression is necessary to sustain GC B cell function and prevent terminal differentiation. Data, to be presented, will reveal the molecular pathways underlying the contribution of PRC1/PRC2 to GC B cell responses and to the maintenance of the malignant B cell phenotype in NHL.
Summary and Conclusions: Our results reveal that key components of Polycomb repressive complexes represent central regulators of GC B cell function. Moreover, using a combination of gene and pharmacological inactivation of Polycomb proteins in NHL, we unravel possible molecular pathways through which the Polycomb axis sustains the transformed B cell phenotype. Finally, we report the identification of genetic mutations that predict response *versus* resistance of NHL cells to EZH2 small molecule inhibitors.

MICROARRAY ANALYSIS OF CHROMOSOME 11Q IN A GROUP OF AGGRESSIVE LYMPHOMA: THE PARTIAL DUPLICATION OF 11Q AS A CYTOGENETIC MARKER OF SUBSET OF THE GREY ZONE BETWEEN BURKITT'S (BL) AND DIFFUSE LARGE B-C

B Grygalewicz[1,*] R Woroniecka[1], G Rymkiewicz[1], J Rygier[1], K Borkowska[1], B Pieńkowska-Grela[1]
[1]Oncology Center and Institute, Warsaw, Poland

Background: Aggressive B-cell lymphomas are clinically and pathologically diverse and reflect multiple pathways of transformation. Most of BL and DLBCL lymphomas can be accurately classified on the basis on clinical data, morphology, immunophenotype and cytogenetic changes. Translocations involving *MYC* oncogene are the molecular hallmark of BL. Most cases involve the *IGH* gene on chromosome 14. Less commonly, the light-chain genes on chromosomes 2 and 22 are involved in the translocation. Generally BL karyotypes are simple with secondary aberrations being singular events. In DLBCL karyotypes are more complex. Chromosomal translocations affecting the band 3q27 with *BCL6* gene are the most common. Other frequent genetic changes include presence of *BCL2* or *MYC* rearrangements. Diagnostically difficult are aggressive B-cell lymphomas with intermediate features between BL and DLBCL. These unclassifiable cases do not form a separate or uniform entity. Here we present a subset of intermediate BL/DLBCL which contains cases with BL morphology but atypical immunophenotype and specific genetic features: presence of chromosomal marker dup11q, lack of *MYC* rearrangement (6 from 7 cases), as well as *BCL2* and *BCL6* rearrangements (all cases).
Aims: The aim of study was detailed description of the marker dup(11q) in a subset of *MYC* negative BL/DLBCL.
Methods: Haematological Cancer+SNP Array (8x60K) CytoSure, classical cytogenetic and FISH with *BCL2, BCL6, MYC, IGH, CEP11,CCND1, ATM, MLL* probes.
Results:
All patients showed simple karyotypes with dup(11). Duplicated region was variable in size and ranged from 71,72Mb to 11,91Mb in chromosomal localization from dup(11)(q24 q12) to dup(11)(q22.2q23.3), respectively. In 5 from 7 patients additional multiplication inside duplicated region (11q23.3) was detected. This multiplication was also various in size from 2,99Mb to 14,2 Mb. In all cases in the minimal region of 11q duplication the *MLL* gene was located. FISH with CEP11 and MLL, ATM and CCND1 probes confirmed duplication and multiplication regions. Additionally, relative position of FISH probe signals revealed inversion of the 11q duplicated region in 5/7 cases. In 6 of 7 cases terminal deletion del(11)(q24.1) was revealed. In one case deletion of 11q24.3 was biallelic. The size of this small region was 774,52Kb and covered five genes: *ETS1, FLI1, KCNJ1, KCNJ5, TP53AIP1.*
Summary and Conclusions: A subgroup of the *MYC* negative intermediate BL/DLBCL showed specific chromosomal marker dup11q. Marker is characterized by repetitively occurring: inversion of the duplicated material, selective amplification of the region 11q23.3 and the simultaneous loss (mono-or biallelic) of a small, telomeric segment with 11q24.1 breakpoint. Further detailed characterization of changes in the marker 11q will be aimed at pre-define genes that potentially involved in the pathogenesis of the group of lymphoma.

P419

THE B CELL ANTIGEN RECEPTOR IS CRITICAL FOR BURKITT LYMPHOMA GROWTH VIA GSK3B REGULATION

G Varano[1,*] S Raffel[2], F Zanardi[1], K Rajewsky [3]S Casola[1]
[1]IFOM - FIRC Institute of Molecular Oncology, Milano, Italy, [2]German Cancer Research Center (DKFZ), Heidelberg, [3]MDC - Max Delbrück Center for Molecular Medicine, Berlin, Germany

Background: Mature B-lymphocytes depend on expression of a functional B cell antigen-receptor (BCR) for survival. It has been proposed that development and maintenance of Burkitt lymphoma (BL), an aggressive malignancy originating from mature B cells, depends on signaling competence of the BCR. Circumstantial evidences support this hypothesis: 1) Ig/MYC translocations preserve Ig loci carrying functional rearrangements; 2) exome sequencing data identified recurrent mutations in genes regulating BCR function. Nevertheless, to date, a conclusive genetic proof supporting the role of the BCR in BL maintenance is still missing.
Aims: We assessed the effect(s) of genetic ablation of the BCR on an aggressive form of c-MYC driven mature B cell malignancy resembling human BL.
Methods: To elucidate the contribution of the BCR in BL maintenance, we used the l-MYC mouse tumor model in which acute ablation of the BCR was induced in tumor B cells via Cre/loxP technology. We employed both *in vitro* and *in vivo* approaches to study the effects of BCR inactivation on tumor growth. Biochemical studies where coupled to whole transcriptome analyses and use of small molecule inhibitors to functionally dissect the molecular pathways controlled by the BCR in c-MYC driven B lymphoma cells.
Results: Acute ablation of the BCR in primary B lymphoma cells isolated from the l-MYC tumor led to the rapid disappearance of tumor cells both *in vitro* and *in vivo* after transplantation into immunoproficient recipients. Importantly, these effects were observed when BCR-deficient lymphoma cells were under competition with their BCR^+ counterparts. We identify GSK3b as a critical modulator of the response of tumor cells to tonic BCR signaling. BCR expression was essential to support PI3 kinase activity and protected tumor cells from mTOR inhibition. Tonic BCR signaling controlled over 400 genes in c-MYC driven B lymphoma cells, mostly through GSK3b modulation. Data to be presented will summarize the major gene categories controlled by the BCR in lymphoma cells. Importantly, we identified lymphomas that had acquired resistance to BCR inactivation, thus becoming BCR-independent. Comparative genome hybridization analysis allowed us to identify a limited set of secondary genetic aberrations that were selectively associated with acquired resistance to BCR loss. Experiments to be presented have addressed the role of specific genetic determinants in enabling lymphoma cells to overcome BCR dependency.
Summary and Conclusions: Our study provides genetic proof that tonic BCR signaling is essential for survival and proliferation of c-MYC transformed aggressive B cell lymphomas. BCR exerts its function primarily through the modulation of GSK3b activity. Our data indicate that BCR-negative tumors succumb in the presence of their BCR^+ counterparts. Therefore, current therapies aimed to interfere with BCR signaling in lymphomas risk to favor the outgrowth of BCR-negative tumors. The identification of genes that render c-MYC driven lymphomas resistant to BCR loss provides the framework for future studies aimed to test their role as novel therapeutic targets.

P420

CONCOMITANT INHIBITION OF EZH1 AND EZH2 IMPAIRS GROWTH OF C-MYC DRIVEN B CELL LYMPHOMAS

V Petrocelli[1,*] G Varano[1], C Carrisi[1], M Rahmat[1], F Zanardi[1], J Jin[2], S Casola[1]
[1]IFOM Foundation, FIRC Institute of Molecular Oncology, Milan, Italy, [2]University of North Carolina, Chapel Hill, United States

Background: Non-Hodgkin B-cell lymphomas (NHL) originate in most cases from B cells recruited into the germinal center (GC) reaction during a T cell dependent immune response. Enhancer of Zeste Homolog 2 (EZH2) is a Polycomb group (PcG) protein that catalyzes Histone H3 lysine-27 trimethylation (H3K27me3) within Polycomb Repressive Complex 2 (PRC2), leading to transcriptional repression of target genes. EZH2 is highly expressed in GC B cells and frequently deregulated in NHL of GC origin, including Burkitt lymphoma (BL). The role of EZH2 in maintenance and progression of c-MYC driven B cell lymphomas is largely unknown. This question is of clinical relevance as highly-specific small molecule inhibitors against EZH2 have been proposed as novel NHL therapeutics.
Aims: Our work investigated the role of EZH2 in the growth of primary c-MYC driven B cell lymphomas.
Methods: We engineered the l-MYC Burkitt lymphoma (BL) mouse model to enable conditional inactivation of the *Ezh2* gene through the Cre/loxP recombination system. We performed *in vitro* and *in vivo* analysis to study the effects of acute inactivation of EZH2 methyltransferase activity on growth of primary lymphomas. Genome wide H3K27me3 and EZH2 profiling combined with transcriptome analysis were employed to identify direct and indirect targets of EZH2 in lymphoma B cells and to reveal the transcriptional changes occurring in PcG mutant tumors following *Ezh2* inactivation. These analysis were complemented by a series of studies aimed to investigate the therapeutic efficacy of a recently described EZH1 and EZH2 double inhibitor, Unc1999 in the treatment of aggressive l-MYC primary lymphomas and human BLs.
Results: Genetic *Ezh2* inactivation was induced in primary B cell lymphomas isolated from l-MYC transgenic mice. Ezh2 inhibition led to global reduction of H3K27me3 levels. Surprisingly, loss of EZH2 function showed minor effects on tumor growth. To test whether the close EZH2 paralog EZH1, had replaced EZH2 catalytic function in PcG mutant lymphomas, we treated l-MYC primary lymphomas with the EZH1/2 small molecule inhibitor UNC1999. Strikingly, concomitant inhibition of EZH1/2, led to a significant impairment in lymphoma growth. Gene expression and H3K27me3 ChIP-seq analyses allowed the elucidation of the possible molecular pathways through which the Ezh proteins sustain the growth of aggressive c-MYC driven B cell lymphomas.
Summary and Conclusions: Our results identify EZH1 and EZH2 as important epigenetic regulators of the growth of c-MYC driven mature B cell lymphomas. The necessity to interfere with both EZH1 and EZH2 function to counteract lymphoma growth highlights the need for further preclinical studies to define the therapeutic efficacy of EZH2-only inhibitors in the cure of Diffuse Large B cell lymphomas and Follicular lymphoma. Finally, our data provide experimental evidence that PRC2 small molecule inhibitors may represent a valid therapeutic approach also for NHL subtypes including BL, which lack *EZH2* gain-of-function mutations.

P421

CLONAL EVOLUTION IN BURKITT LYMPHOMA/LEUKEMIA

SM Aukema[1,*] L Theil[1], M Rohde[2], B Burkhardt[3], W Klapper[4], P M Kluin[5], I Nagel[1], R Siebert[1], EM Murga Penas[1]
[1]Institute of Human Genetics, University Hospital Schleswig-Holstein Campus Kiel/Christian-Albrechts University, Kiel, [2]Department of Pediatric Hematology and Oncology, Justus Liebig University, Giessen, [3]Department of Pediatric Hematology and Oncology, Universitätsklinikum Muenster, Muenster, [4]Institute of Hematopathology, University Hospital Schleswig-Holstein Campus Kiel/Christian-Albrechts University, Kiel, Germany, [5]Department of Pathology & Medical Biology, University of Groningen / University Medical Center Groningen, Groningen, Netherlands

Background: Typical (pediatric) Burkitt lymphoma/leukemia (BL/leukemia) is, in contrast to other *MYC*-translocation positive lymphomas, characterized by an overall low genomic complexity and favorable prognosis with only few relapses. However, the patients who do show relapse or disease progression have a very dismal prognosis. As sequential cytogenetic studies are rarely performed still little is known about the underlying genetics of disease progression and relapse in BL/leukemia.
Aims: (i) To characterize the karyotype complexity, (ii) analyze the cytogenetic evolution and (iii) investigate the secondary cytogenetic changes (SCCs) in BL/leukemia in which sequential cytogenetic studies have been performed.
Methods: From all BL/leukemia samples retrieved at our institution from 1997 to 2013, karyotypes assessed by R-banding and fluorescence *in situ* hybridization (FISH) of six samples of BL/leukemia with sequential cytogenetic data were available. In addition, the published cytogenetic literature was explored using the Mitelman database as comprehensive cytogenetic resource. For each karyotype a complexity score (CS) was calculated by counting the number of numerical and structural chromosomal aberrations. Karyotypes were considered complex (complex karyotype, CK) if showing ≥3 aberrations (including *IG-MYC*). For evaluation of numerical and structural chromosome abnormalities karyotypes were converted with the Cydas software package.
Results: The six cases of BL/L with sequential cytogenetic data available included five pairs of initial diagnosis and sequential samples (one sequential sample n=4; two sequential samples n=1) and another patient was studied at time of first relapse, blast crisis and secondary relapse. A search of the Mitelman database and the literature yielded additionally 18 pairs, including two patients with more than one follow up sample. All samples were positive for the *IG-MYC* translocation and consisted of a t(8;14)(q24;q32)/*IGH-MYC* in 20/24 cases (83%) and *IGK/L-MYC* in 4/24 (17%). The initial diagnostic samples showed a complexity score of 2 (which is similar to other primary BL cases). Secondary investigations had a complexity score of 5 and third investigations a complexity score of 9. In fact, for the four patients with multiple follow-up samples available a mostly linear increase of karyotype complexity could be observed. Complex karyotypes were more frequently observed in sequential samples than in primary samples. Furthermore, we found strong evidence for clonal evolution since 19/24 of the sequential samples contained abnormalities already present at diagnosis with new acquired aberrations. Frequently observed SCCs at diagnosis and sequential samples included (partial) gains of chromosome 1q and 7q as well as (partial) losses of 13q, all being more frequent in the latter group. In contrast, loss of 17p and trisomy 21 were exclusively present in secondary cytogenetic samples, pointing to a role in disease progression. Interestingly, two cases acquired additional *IG*-translocations (involving other genes than *MYC*) during clonal evolution, hereby posing the question whether or not these cases should be considered double-hit lymphomas.
Summary and Conclusions: By analyzing paired BL/Leukemia samples, we found increasing karyotype complexity, specific SCCs, and clonal evolution that might reflect the underlying mechanism of disease progression or relapse and the poor outcome of such cases.
Supported in the framework of MMML-MYC-SYS by the German Ministry of Health (grant 0316166).

P422

ACTIVATED SUMOYLATION MACHINERY IS A HALLMARK OF BURKITT LYMPHOMA WITH NEW THERAPEUTIC IMPLICATIONS

A Höllein[1,*] M Fallahi[2], S Steidle[1], S Schöffmann[1], M Rudelius[3], C Peschel[1], J Cleveland[2], U Keller[1]
[1]3rd Medical Department, Technische Universität München, München, Germany, [2]Department of Cancer Biology, The Scripps Research Institute, Jupiter, United States, [3]Department of Pathology, Universität Würzburg, Würzburg, Germany

Background: Myc oncoproteins (c-Myc, N-Myc and L-Myc) are transcription factors that regulate cell growth, cell division and metabolism under physiologic conditions. Myc overexpression is a hallmark of cancer, present in most advanced tumors, and associated with poor prognosis. We have previously shown that Myc overexpression results in specific cancer cell liabilities, *e.g.* during cell cycle progression, that constitute therapeutic targets for synthetic lethality approaches. Small Ubiquitin-like Modifier (SUMO) proteins covalently bind to other proteins to modify their function. SUMOylation is involved in various cellular processes including transcription and cell cycle progression.
Aims: To assess the role of SUMOylation in Myc induced lymphoma and other cancer and to identify potential new treatment strategies.
Methods: Transcriptome and protein analysis for expression of components and regulators of the SUMOylation machinery in human Burkitt lymphoma, murine Myc-induced lymphomas and control cells was applied. Lymphoma cells were treated with inhibitors of SUMOylation and the effects were validated with stable knock down of essential SUMOylation components.
Results: Hierarchical cluster analysis comparing RNA expression data in murine normal control, pre-malignant and lymphoma Eμ-*Myc* B cells identified a Myc-induced SUMOylation-related gene expression signature. This signature was present in pre-malignant and Eμ-*Myc* lymphoma cells and involved the upregulation of various critical components of the SUMOylation machinery, including the E1 ligases SAE1 and SAE2, the E2 ligase Ube2i and the E3 ligases Ranbp2 and PIAS2. Moreover this translated into elevated protein expression of the whole SUMOylation pathway and ubiquitous hyper-SUMOylation of proteins in Eμ-*Myc* lymphoma cells. For cross-species validation we analyzed human gene expression data and found that the Myc-induced regulation of SUMOylation-associated genes was also present in human *IG/MYC* Burkitt lymphomas, in contrast to Non-*IG/MYC* B-cell lymphomas. Interestingly immunhistochemical staining for SUMO2/3 revealed hyper-SUMOylation in patient samples of Burkitt lymphoma compared to DLBCL, MCL, and FL. What is more analysis of ChIP-on-chip experiments showed direct binding of Myc to regulatory genomic regions of almost all SUMOylation regulators (SUMO2, SUMO3 and E1, E2 and E3 ligases). The characteristic of cancer cells to depend on certain intact physiologic mechanisms is known as non-oncogene addiction. Since SUMOylation of proteins is involved in essential metabolic, survival and proliferation pathways we reasoned that intact SUMOylation is a non oncogenic pathway that Myc-driven cells rely upon. We thus hypothesized that Myc-dependent cells could be specifically susceptible when interfering with SUMOylation by pharmacological means. Eμ-*Myc* lymphoma cells were highly sensitive to the SUMOylation inhibitors ginkolic acid and anarcardic acid and a second generation SUMOylation inhibitor 2-D08. In particular, inhibition of SUMOylation lead to cell cycle arrest, polyploidy, and subsequent cell death. When validating these effects with specific knock down constructs for SAE1 and SAE2, crucial mediators of SUMOylation, the identical phenotype was

observed. This therapeutic effect was Myc-specific as shown by use of genetically defined cell lines and conditional Myc-overexpression systems. Specifically human Burkitt lymphoma cell lines were strikingly more sensitive to inhibition of SUMOylation than non-Myc-transformed lymphoma samples.
Summary and Conclusions: Taken together, we provide correlative and experimental evidence that the Myc-associated expression of genes involved in SUMOylation is a hallmark of Burkitt's lymphoma and constitutes a non oncogenic pathway which is therapeutically exploitable in lymphoma and other Myc-driven cancers.

CD19-TARGETING LIPOSOMES CONTAINING RAPAMYCIN INDUCE AUTOPHAGIC CELL DEATH IN BURKITT'S LYMPHOMA CELLS

T Sato[1], K Ono[1], S Iyama[1], A Tatekoshi[1], A Hashimoto[1], Y Kamihara[1], H Horiguchi[1], K Takada[1], T Hayashi[1], K Miyanishi[1], Y Sato[1], R Takimoto[1], M Kobune[1], J Kato[1,*]
[1]Medical Oncology and Hematology, Sapporo Medical University, School of Medicine, Sapporo, Japan

Background: Patients with Burkitt's lymphoma often have poor outcomes in spite of intensive chemotherapy. The conventional chemotherapeutic agents induce apoptotic and/or necrotic cell death in lymphoma cells. When lymphoma cells are resistant to apoptotic and/or necrotic cell death signaling, induction of different type of cell death, autophagy will be another choice of treatment. An inhibitor of mammalian target of rapamaycin (mTOR), rapamycin has been a representative autophagy-inducing agent, which recent clinical studies have proven to be efficacious against mantle cell lymphoma. On the other hand, CD19-targeting liposomal delivery is an attractive strategy to raise the efficacy of chemotherapeutic agents against B-cell lymphoma as previously demonstrated using doxorubicin.
Aims: In the present study, we first investigated the susceptibility of Burkitt's lymphoma cells against mTOR inhibitors. Second, the effectiveness of CD19-targeting delivery of rapamycin to Burkitt's lymphoma cells was examined.
Methods: Rapamycin was encapsulated by anionic liposome, GLYCOLIPO and conjugated with anti-CD19 antibody (CD19-GL-Rap) or anti-CD2 antibody (CD2-GL-Rap) as control. A fluorescent probe Cy5.5 was also liposomized in the same way (CD19 or CD2-GL-Cy5.5). A Burkitt's lymphoma cell line, SKW6.4 was cultured for over 70-passages with low concentration of doxorubicin, which named SKW-DOX, a doxorubicin-resistant subline. CD19 positive cells were collected using magnetic beads from peripheral blood in leukemic phase or malignant pleural effusion of patients with Burkitt's lymphoma.
Results: Burkitt's lymphoma cell lines, SKW6.4, Raji and Namalwa were all susceptible to rapamycin *in vitro*. The most susceptible cell line, SKW6.4 was selected for further examination. The other mTOR inhibitors, temsirolimus and everolimus had also enough cytotoxic activity against SKW6.4 cells. Then, the CD19-targeting delivery was investigated using CD19 or CD2-GL-Cy5.5. We confirmed beforehand that SKW6.4 cells highly expressed CD19 and had no CD2 on their surface. CD19-GL-Cy5.5 was more effectively uptaken into SKW6.4 cells than CD2-GL-Cy5.5, examined by both flow cytometry and fluorescence microscopy *in vitro*. Even when the cells were inoculated subcutaneously into immunodeficient non-obese diabetic (NOD) severe combined immune-deficient (scid) mice, intravenously administered CD19-GL-Cy5.5 has made subcutaneous tumor fluorescent brighter than CD2-GL-Cy5.5, detected by IVIS system. We next examined the efficacy of CD19 or CD2-GL-Rap. CD19-GL-Rap had a greater cytocidal effect than CD2-GL-Rap *in vitro*. The specific toxicity of CD19-GL-Rap was cancelled by the pretreatment of the cells with neutralizing anti-CD19 antibody. A molecular marker of autophagy, LC3-II was detected by Western blotting in CD19-GL-Rap-treated cells. The cytotoxic activity of CD19-GL-Rap was not reduced by a pan-caspse inhibitor, Z-VAD-FMK or antioxidant, N-atetyl L-cysteine. Not only Burkitt's lymphoma cells collected from our patients but also doxorubicin-resistant SKW6.4 subline, SKW-DOX cells were also susceptible to CD19-GL-Rap. The survival period of mice treated with intravenous CD19-GL-Rap was longer than those with CD2-GL-Rap after the intraperitoneal inoculation of SKW6.4 cells.
Summary and Conclusions: CD19-targeting liposomes containing rapamycin could be a promising treatment inducing autophagic cell death against Burkitt's lymphoma.

TARGETING THE TYROSINE KINASE RECEPTORS ROR1 AND AXL (RTKS) IN BURKITT'S LYMPHOMA

M Hojjat-Farsangi[1,*] AH Daneshmanesh[1], AS Khan[1], A Moshfegh[1], J Wagberg[2], S Byström[2], J Schultz[2], T Olin[2], A Österborg[3], H Mellstedt[1]
[1]Oncology-Pathology, Karolinska Institute, [2]Kancera AB, Karolinska Institutet Science Park, [3]Hematology, Karolinska University Hospital Solna, Stockholm, Sweden

Background: Burkitt's lymphoma (BL) is an aggressive malignancy of B-cell origin and classified into 3 subtypes including endemic, sporadic and immunodeficiency-associated variants. The main transforming event is translocation of the MYC oncogene to one of the immunoglobulin (Ig) heavy or light chain loci. There is a great need to develop novel drug for targeted therapy of cancers, including BL. ROR1 and AXL receptor tyrosine kinases (RTKs) have emerged as interesting molecules for targeted cancer therapy. Both these RTKs have important roles during embryogenesis and are down-regulated in adult human tissues. Both RTKs have been shown to be overexpressed in hematological malignancies and solid tumors. SiRNA targeting these RTKs in CLL cells induced apoptosis.
Aims: To investigate the expression of ROR1 and AXL RTKs in the BL cell lines (LUKAS, NAMALVA and RAMOS). The cytotoxic activity of two novel small-molecule tyrosine kinase inhibitors (TKI) targeting ROR1 and AXL tyrosine kinase domain and the effects on downstream signaling molecules were studied.
Methods: ROR1 and AXL expression were determined by flowcytometry and Western blot (WB). TKI KAN439365 (Kancera AB, Stockholm, Sweden) targeting ROR1 and a commercially available AXL RTK inhibitor (Selleckchem, Houston, TX, USA) were used to treat the BL cell lines. Cytotoxic effects were determined by MTT and Annexin-V/PI assays. PARP and caspase 3 cleavage as well as total and phosphorylated ROR1, Src, PI3K, AKT, mTOR and CREB were analysed by WB.
Results: LUKAS and NAMALVA cells expressed ROR1 as determined by flowcytometry and WB. However, RAMOS cells did not show surface expression of ROR1, but ROR1 was detectable by WB (indicating expression of the cytoplasmic TK domain). ROR1 was phosphorylated in all cell lines. All cell lines but not LUKAS expressed AXL both by flowcytometry and WB. After 18 h of incubation with 1, 5 and 10 μM of the inhibitors, 40-90% of cells were dead. Cell death was preceeded by ROR1 and AXL TKIs induced dephosphorylation of ROR1 and AXL respectively (<2h) as well as of SRC, PI3K, AKT, mTOR, and CREB. ROR1 TKI did not dephosphorylate AXL and AXL TKI did not dephosphorylate ROR1.
Summary and Conclusions: ROR1 and AXL RTKs are overexpressed in Burkitt's lymphoma and are of importance for the survival. Although AXL RTK was not expressed in LUKAS cells, the AXL inhibitor induced apoptosis suggesting other mechanisms of cell killing than mediated by the AXL receptor. ROR1 activation through PI3K/AKT/mTOR pathway might provide a survival signal for BL cells. This is the first report of two novel classes of drugs targeting ROR1 and AXL (ROR1 and AXL-TKI) in BL malignancy. Further characterization of ROR1 and AXL TKI in other primary hematological cells and cell lines should be of interest to establish their potential therapeutic value.

P425

HIGH EXPRESSION OF MIRNA-199A_1 AND MIRNA-497_1 IS ASSOCIATED WITH BETTER OVERALL SURVIVAL IN AGGRESSIVE NON-HODGKIN´S LYMPHOMA

K Troppan[1,*] K Wenzl[1], A Deutsch[1], M Pichler[2], M Graupp[3], C Beham-Schmid[4], P Neumeister[1]
[1]Hematology, [2]Oncology, [3]ENT, [4]Pathology, Medical University Graz, Graz, Austria

Background: Micro-RNAs (miRNAs) are short non-coding single-strand RNA molecules that regulate gene expression at the post-transcriptional level. They are involved in cell development, differentiation, apoptosis, and proliferation. They can either function as tumor suppressor genes or oncogenes in various important pathways. The expression of specific micro RNAs has been identified to correlate with tumor prognosis.
Aims: Since the role of microRNAs in aggressive lymphomas is not precisely elucidated, we aimed to investigate the expression of various microRNAs and evaluate their impact on overall survival of aggressive Non-Hodgkin lymphoma (NHL) patients.
Methods: For microRNA expression analysis we performed real-time PCR on 78 samples, including 42 diffuse large B-cell lymphoma (15 germinal center B, 20 non germinal center B, 7 unclassified), 21 follicular lymphoma grade III, and 15 controls, including 7 peripheral B-cells, 4 germinal-center B-cells, and 4 lymphoma cell lines (Raji, SUDHL4, Karpas, Ly8). Expression levels of 11 microRNAs, including miR15b-2, miR16-1*, miR16-2, miR16-2*, miR27a, miR27a*, miR98-1, miR103a, miR185, miR199a-1, and miR497-1 were measured and correlated with clinical data. Preliminary data showed that these microRNAs may play an important role in lymphoma genesis.
Results: Mir16-1*, miR16-2*, miR27a, miR103a miR185, miR199a-1, and miR497-1 were at least 6 fold differentially expressed in lymphoma samples and controls ($p<0.01$). Highest overexpression was found in miR27a (30 fold overexpression), miR199a-1 (200 fold overexpression) and miR497-1 (80 fold overexpression). An additional Kaplan Meier analysis revealed that a higher expression level of miR497-1 and miR199a-1 is significantly associated with better overall survival in patients with aggressive lymphomas ($p=0.042$, $p=0.007$).
Summary and Conclusions: Our data indicate that various microRNAs are overexpressed in aggressive NHL and may contribute to lymphoma genesis. Furthermore we could demonstrate that high expression levels of miR497-1 and miR199a-1 are associated with better overall survival. To detect possible target genes of these microRNAs further functional characterization is warranted.

LOSS OF BCL2L12 PROTEIN EXPRESSION PREDICTS RELAPSE IN PATIENTS WITH DIFFUSE LARGE B-CELL LYMPHOMA TREATED WITH RITUXIMAB PLUS CONVENTIONAL CHEMOTHERAPY (CYCLOPHOSPHAMIDE, DOXORUBICIN, VINCRISTINE, AN

S Papageorgiou[1,*] CK Kontos[2], P Foukas[3], E Panopoulou[3], P Economopoulou[1], M Kefala[3], ED Ioannidou[1], D Vasilatou[1], E Mpazani[1], I Panayiotides[3], A Scorilas[2], V Pappa[1]
[1]Second Department of Internal Medicine, Propaedeutic, Hematology Unit, University General Hospital "Attikon", Haidari, [2]Department of Biochemistry and Molecular Biology, Faculty of Biology, University of Athens, Athens, [3]Second Department of Pathology, School of Medicine, University of Athens, Attikon University Hospital, Haidari, Greece

Background: Diffuse large B-cell lymphoma (DLBCL) is the most common histological subtype of non-Hodgkin lymphoma (NHL) corresponding to 30-40% of cases in adults. Although classified as a single entity by the World Health Organization (WHO), DLBCL is characterized by significant heterogeneity with variation in molecular pathogenesis, clinical behavior, response to therapy and long term survival. BCL2 family of proteins is the hallmark of apoptosis regulation. Recently, new members of BCL2 family were discovered and found differentially expressed in many types of cancer, including hematologic malignancies. BCL2L12 is a recently identified gene belonging to the BCL2 family. The expression status of BCL2L12 in patients with DLBCL has not been examined yet.
Aims: The aim of the present study was the investigation of protein expression levels of BCL2L12 by immunohistochemistry in patients with DLBCL and its relation to established prognostic factors and survival.
Results: We studied 130 DLBCL patients treated with R-CHOP (68 males and 62 females), with a median age of 67 years (range: 20–95) at the time of diagnosis. High BCL2L12 protein expression was associated with Ki-67 immunopositivity (P=0.009), while low BCL2L12 protein index was related to absence of B-symptoms (P=0.028). Kaplan-Meier survival analysis revealed that low *BCL2L12* protein index predicts short-term relapse in DLBCL patients treated with R-CHOP (P=0.039). In addition, high BCL2L12 protein expression is a favorable biomarker in DLBCL, predicting prolonged overall survival (P=0.041). Most importantly, its prognostic potential regarding overall survival of R-CHOP–treated DLBCL patients was found to be independent of IPI risk and cell-of-origin classification (P=0.048), as shown by multivariate Cox regression analysis.
Summary and Conclusions: Expression of the apoptosis-related protein BCL2L12 is associated with presence of B-symptoms in DLBCL patients treated with R-CHOP and appears as a favorable molecular biomarker in this disease.

NR4A3-MEDIATED APOPTOSIS SUPPRESSES LYMPHOMAGENESIS IN A XENOGRAFT MOUSE MODEL

A Deutsch[1,*] B Rinner[2], K Wenzl[1], K Troppan[1], C Beham-Schmid[3], P Neumeister[1]
[1]Hematology, [2]Centre for Medical Research, [3]Pathology, Graz, Austria

Background: Recently, we described a significant down-regulation of NR4A1 (Nur77) and NR4A3 (Nor-1) -two members of the orphan nuclear receptors acting together as critical tumor suppressor genes in acute myeloid leukemia- in aggressive lymphoma (Deutsch *et al.,* Blood 2014). NR4A1 over-expression proved its pro-apoptotic function in aggressive lymphoma cells and its lymphoma suppressive properties *in vivo* was demonstrated in a xenograft mouse model.
Aims: Since the role of down-regulated NR4A3 in aggressive lymphomas is unknown, we aimed to investigate the function of NR4A3 in lymphoid malignancies.
Methods: For functional characterization NR4A3 was over-expressed in a SuDHL4 lymphoma cell line by using an inducible lentiviral construct followed by various apoptotic assays and followed by a xenograft mouse experiment.
Results: Induction of NR4A3 expression led to a significantly higher proportion of induced SuDHL4 cells undergoing apoptosis as demonstrated by DNA cleavage, Annexin V staining and increased caspase 3-7 activity suggesting a functional redundancy to NR4A1 in aggressive lymphoma. To test the tumor suppressor function of NR4A3 *in vivo*, the stably transduced SuDHL4 lymphoma cell line was further investigated in the NOD scid γ (NSG) mouse model. Induction of NR4A3 in SuDHL4 abrogated tumor growth in the NSG mice, in contrast to vector control- and uninduced SuDHL4 cells, which formed massive tumors.
Summary and Conclusions: Our data suggest that NR4A3 has a pro-apoptotic function in aggressive lymphoma and define that NR4A3 together with NR4A1 function as novel tumor supressor involved in aggressive lymphoma development.

PHENOTYPIC AND FUNCTIONAL LONG-TERM DYNAMICS OF PERIPHERAL BLOOD NATURAL KILLER CELL COMPARTMENT IN DIFFUSE-LARGE-B-CELL LYMPHOMA PATIENTS BEFORE AND AFTER R-CHOP-BASED IMMUNOCHEMOTHERAPY

MC Cox[1,*] S Battella[2], S Pelliccia[3], R La Scaleia[2], A Di Napoli[4], E Alma[3], A Porzia[2], F Mainiero[2], L Ruco[4], A Tafuri[3], A Santoni[5], G Palmieri[2]
[1]Hematology Unit, AO Sant'Andrea, Sapienza University, [2]Experimental Medicine, Sapienza University, [3]Clinical and Molecular Medicine, Hematology Unit, AO Sant'Andrea, Sapienza University, [4]Clinical and Molecular Medicine, Pathology Unit, AO S'Andrea, Sapienza University, [5]Molecular Medicine, Sapienza University, Rome, Italy

Background: Natural Killer (NK) cells represent an important component of tumor immune surveillance, and play a key role in rituximab-dependent killing of lymphoma cells through an antibody-dependent cellular cytotoxicity (ADCC) mechanism. Since NK functions might significantly contribute to the success of rituximab-based therapies, we focused our work on monitoring changes of NK subsets *in vivo*, during immunochemotherapy.
Aims: To assess the phenotypic and functional asset of peripheral blood NK cell subsets in newly diagnosed Diffuse-large-B-cell-lymphoma (DLBCL) patients, and to evaluate its acute and long-term modifications upon R-CHOP regimen.
Methods: PBMC from 32 DLBCL patients and 27 healthy, age- and sex-matched controls were analyzed for: 1) the percentage (over PBMC) of $CD56^{dim}$, $CD56^{bright}$, and CD16+ NK cell subsets, measured by multi-parameter flow cytometric (FACS) analysis; 2) the functional capability of NK cell subsets: *i.e.* the frequency of IFN γ-expressing cells and cytotoxic granule-containing (granzyme B+, GrzB+) cells, evaluated by intracellular staining and FACS analysis; and 3) "natural" and CD16-dependent NK cytotoxic functions, quantified by ^{51}Cr release assay. Patients' PBMC were analyzed at diagnosis, at mid-therapy, and at different time points up to 12 months after the end of R-CHOP therapy. All subjects gave informed consent; the study was approved by the institutional Ethical Committee.
Results: The NK cell compartment of DLBCL patients at diagnosis was phenotypically and functionally altered, in comparison to healthy controls: 1) patients' PBMC showed an absolute NK cell count not different from controls, while the percentage of $CD56^{dim}$ and CD16+ NK cell subsets (over lymphocytes) were higher than controls; 2) the frequency of GrzB+ cells was markedly increased in $CD56^{dim}$, $CD56^{bright}$, and CD16+ NK cell subsets; 3) "natural" and CD16-dependent NK cytotoxic activities, as well as the percentage of IFN γ-producing NK cells upon *in vitro* stimulation were not different compared to healthy subjects. At mid-treatment, 1) the frequency of CD16+ NK cells (over lymphocytes), 2) the percentage of NKG2D+ cells in CD16+ and $CD56^{dim}$ NK subsets, and 3) "natural" and CD16-dependent NK cytotoxic activities were significantly reduced. These impairments persisted up to 1 month after R-CHOP, and recovered stably by 3 months after the end of treatment (last analysis: 12 months after R-CHOP). At odds with the above results, 1) the percentage of GrzB+ cells remained elevated in $CD56^{dim}$, $CD56^{bright}$, and CD16+ NK subsets till 3 months after therapy, and returned to normal by 6 months after therapy, and 2) the frequency of IFN γ+ NK cells did not show any significant variation, at any time point.
Summary and Conclusions: 1) The systemic NK compartment at disease onset showed a phenotypic and functional disturbance, resembling a chronic activation state; 2) The marked therapy-induced reduction of "natural" and CD16-dependent NK cytotoxic activities was accompanied by the down modulation of CD16 and NKG2D activating receptors, and was not associated with a gross impairment of NK cell lytic potential and IFN γ production. This suggests that the therapy-driven continuous stimulation through CD16 receptor could be involved in a prolonged NK cell functional impairment *in vivo*. Since impaired NK cytotoxic functions during immunochemotherapy might affect NK cell-mediated, rituximab-dependent ADCC, our observations may be relevant for the improvement of therapeutic strategies.
M.C. Cox and S. Battella equally contributed to the study.

P429

CONSTITUTIVE ACTIVATION OF THE DNA DAMAGE RESPONSE PATHWAY IS A NOVEL THERAPEUTIC TARGET IN DIFFUSE LARGE B-CELL LYMPHOMA

E Derenzini[1,*] C Agostinelli[2], E Imbrogno[3], I Iacobucci[3], B Casadei[3], E Brighenti[3], S Righi[2], F Fuligni[2], A Ghelli Luserna Di Rorà, [3]A Ferrari[3], G Martinelli[3], S Pileri[2], PL Zinzani[3]
[1]Department of Experimental, Diagnostic and Specialty Medicine - DIMES, University of Bologna, Institute of Hematology and Medical Oncology L.A. Seragnoli, [2]Department of Experimental, Diagnostic and Specialty Medicine - DIMES, University of Bologna, Haematopathology Unit, [3]Department of Experimental, Diagnostic and Specialty Medicine - DIMES, University of Bologna, Institute of Hematology and Medical Oncology L.A. Seragnoli, Bologna, Italy

Background: Diffuse large B-cell lymphoma (DLBCL) frequently shows large numbers of genomic aberrations, G1/S checkpoint dysfunction, which are features of instable genomes, and c-MYC overexpression.
Aims: The recent finding that MYC driven cancers such as Burkitt lymphoma (BL) are sensitive to inhibition of the DNA damage response (DDR) pathway, prompted us to investigate the role of DDR pathway as therapeutic target in DLBCL.
Methods: We analysed by immunohistochemistry the expression levels of active DDR pathway components in 99 consecutive DLBCL patients treated at our insti-

tution, with available complete clinical data. 44 Hodgkin lymphoma (HL) cases, 22 BL, 46 indolent B-cell lymphoma cases and 3 normal tonsils were analysed as a control. The cutoff for positivity was set at 30% of cells expressing the protein of interest. The checkpoint kinase (CHK1/2) inhibitor PF-0477736 was used as a tool to evaluate the role of aberrant DDR signalling in DLBCL pathogenesis and the efficacy of DDR inhibition in DLBCL cell lines and primary cells.
Results: We show that the DDR pathway is aberrantly active in aggressive lymphoma cell lines and primary tissues (DLBCL and BL), whereas indolent B-cell lymphoma subtypes show very low expression of active DDR components. In fact constitutive CHK1 and CDC25c phosphorylation were detected in 38 and 40% of DLBCL cases respectively, and about half (47%) of DLBCL cases displayed constitutive expression of histone H2AX phosphorylated at serine 139 (γH2AX), a marker of DNA damage and genomic instability. Less than 15% of indolent lymphomas showed significant pCHK1, pCDC25 or γH2AX expression. γH2AX expression was found to be an independent negative prognostic predictor in DLBCL patients treated with chemoimmunotherapy, being able to identify patients with poor prognosis even in the low-intermediate international prognostic index (IPI 0-2) subgroup. 5-year survival was 41% for γH2AX positive *vs* 70% for γH2AX negative patients. We observed a significant association between γH2AX expression, DDR activation (defined as constitutive CHK1/CHK2 phosphorylation), c-MYC expression levels, and p53 overexpression, suggesting an intimate relationship between genomic instability, DDR activation, G1/S checkpoint dysfunction and c-MYC expression in DLBCL: triple positive cases (n=17) for c-MYC, γH2AX and DDR activation (pCHK1/2+) were characterized by a significantly higher expression of p53, (cutoff of 50%, which is an accepted marker of *TP53* mutations), compared to triple negative cases (n=25) (53% *vs* 20% respectively, p=0.04). We also demonstrate that both activated B-cell (ABC) and germinal center B-cell (GCB)-derived DLBCL cell lines (SUDHL-4, SUDHL-6, BJAB, HBL-1, TMD8, U2932) are very sensitive to the CHK1/2 inhibitor PF-0477736, with IC50s ranging from 9 to 220 nM at 48 hours. Accordingly PF-0477736 induced cell death at nanomolar concentrations in DLBCL primary cells. PF-0477736 determined inhibition of the phosphorylation of downstream target CDC25c coupled with a rapid increase in γH2AX phosphorylation, consistent with DNA damage accumulation, followed by apoptosis (Annexin V/PI staining). PARP cleavage was detected by western blot as soon as after 24 hours of incubation in all cell lines (Figure 1).

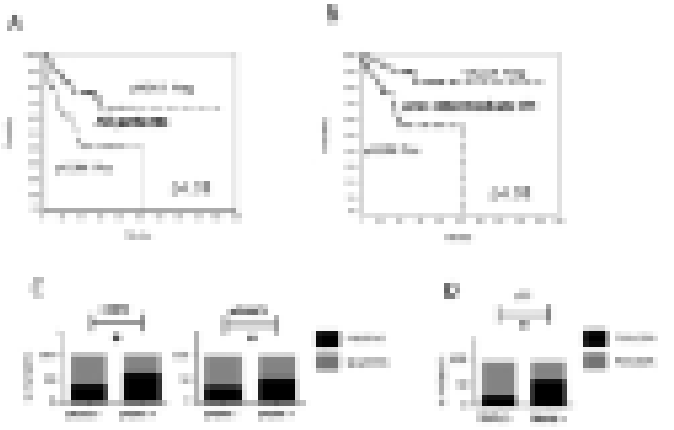

Figure 1.

Summary and Conclusions: These data demonstrate that the DDR pathway is aberrantly active in about half of DLBCL cases and may be involved in resistance to DNA damaging agents, as constitutive γH2AX expression correlates with poor prognosis following conventional chemoimmunotherapy. Pharmacologic inhibition of DDR activation through targeting of CHK kinases may represent a new promising therapeutic strategy in γH2AX positive DLBCL.

P430

FOXO1 TRANSCRIPTION FACTOR MEDIATES TOXICITY OF SYK INHIBITION IN DLBCL.

P Kiliszek[1,*] M Szydlowski[1], T Sewastianik[1], E Bialopiotrowicz[1], E Jablonska[1], A Polak[1], W Prusisz[1], S Markowicz[2], E Nowak[2], M A Grygorowicz[2], K Bojarczuk[3], M Winiarska[3], J Golab[3], P Juszczynski[1]
[1]Dept. of Diagnostic Hematology, Institute of Hematology and Transfusion Medicine, [2]Dept. of Immunology, Maria Sklodowska-Curie Memorial Cancer Center, Institute of Oncology, [3]Dept. of Immunology, Center of Biostructure Research, Medical University of Warsaw, Warsaw, Poland

Background: In normal B lymphocytes, B-cell receptor (BCR)-induced activation of PI3K-AKT kinases and subsequent phosphorylation of FOXO1 is a critical effector of pro-survival signalling mediated by the BCR. In murine models, conditional deletion of FOXO1 protected quiescent peripheral B cells from apoptosis mediated by inducible loss of the BCR, demonstrating that PI3K-AKT-FOXO1 axis plays a central role in B-cell homeostasis. Disruption of the BCR signal also leads to the apoptosis of BCR-dependent diffuse large B-cell lymphoma cells (DLBCL), the effect at least in part mediated by decreased AKT activity.
Aims: Since decreased AKT activity leads to decrease in FOXO1 phosphorylation and its subsequent activation, we hypothesized that FOXO1 might be an important effector of BCR inhibitor-mediated toxicity in human BCR-dependent lymphomas. For this reason, we examined the role of FOXO1 in BCR-dependent DLBCL cells treated with SYK inhibitor.
Methods: BCR-dependent DLBCL cell lines (DHL4, DHL6, Ly1, Ly7) were incubated with SYK inhibitor R406 (4 uM) and AKT phosphorylation, FOXO1 activation and transcriptional activity were assessed by phospho-specific flow cytometry, Western Blot and RT-PCR. FOXO1 activity was also assessed in DLBCL cells transduced with a constitutively active AKT mutant. Toxicity of active FOXO1 was assessed by transducing DLBCL cells with a constitutively nuclear FOXO1 mutant. Cellular proliferation, cell cycle changes and apoptosis were assessed by MTS proliferation assay, DNA content-based flow cytometry and Annexin V-PI staining, respectively. To investigate the role of FOXO1 for the activity of SYK inhibitor in DLBCLs, FOXO1 was silenced with shRNA and cellular proliferation and apoptosis were assessed by MTS assay and Annexin V-PI staining.
Results: In all tested cell lines, AKT and FOXO1 phosphorylations were sensitive to SYK inhibition and decreased after incubation with SYK inhibitor. Diminished FOXO1 phosphorylation resulted in its nuclear relocalization and induction of FOXO1-dependent expression of p27, BIM, TRAIL and GADD45A. In DHL4, DHL6 and Ly7 cells transduced with a constitutively active form of AKT, SYK inhibitor did not modulate FOXO1 phosphorylation and exhibited dramatically decreased toxicity. To assess whether the increased activity of FOXO1 is sufficient to induce apoptosis of DLBCL cells, we transduced DHL4 cells with a constitutively nuclear and transcriptionally active FOXO1-3A mutant. The mutant induced G1/S cell cycle arrest and triggered apoptosis, whereas wild-type FOXO1 did not change proliferation or cellular viability, demonstrating that FOXO1 activation is sufficient to induce apoptosis of DLBCL cells. Finally, we assessed the toxicity of SYK inhibitor in cells lacking FOXO1. DHL4 and Ly7 cells were stably transfected with FOXO1-targeting shRNA, decreasing FOXO1 protein level up to 91%. Compared to non-targeting control, cells with silenced FOXO1 exhibited 70% lower sensitivity to SYK inhibitor, as measured with proliferation and apoptosis assays (p<.0001). Importantly, the alteration in FOXO1 levels did not change the phosphorylation levels of SYK and AKT.
Summary and Conclusions: Taken together, our results demonstrate that in BCR-dependent cell lines, inhibition of SYK leads to decreased FOXO1 phosphorylation and induces expression of pro-apoptotic FOXO1 target genes. FOXO1 silencing decreases the sensitivity of DLBCL cell lines to SYK inhibitor, indicating that FOXO1 is an important effector of SYK inhibition in DLBCL.

P431

KINOME REPROGRAMMING IN DLBCL BY THE BTK-SPECIFIC INHIBITOR ONO-4059 HIGHLIGHTS SYNERGISTIC COMBINATIONS FOR CLINICAL APPLICATION

R Kozaki[1,*] C Hutchinson[1], J Sandrine[2], M JS Dyer[1,2,3]
[1]Cancer Studies & Molecular Medicine, [2]The Ernest Waudby and Helen Scott Haematological Research Institute, [3]Biochemistry, University of Leicester, Leicester, United Kingdom

Background: Although most patients with DLBCL are cured with chemoimmunotherapy, clinical outcomes remain poor for patients with relapsed/refractory (R/R) disease and new therapeutic approaches are needed. We and others have previously shown that BTK inhibitors (BTKi) including Ibrutinib (Imbruvica) and the specific BTKi ONO-4059 can have considerable single agent activity in R/R DLBCL of the Activated B-cell (ABC) phenotype (de Vos *et al.* EHA 2013, Rule *et al.* ASH, 2013). Nevertheless, most R/R DLBCL patients progress on single agent BTK therapy, suggesting the rapid development of resistance. Studies in other malignancies have shown unexpectedly rapid adaptive "reprogramming" of the kinome in response to specific inhibitors (Duncan *et al.*, 2012; Kampen *et al.*, 2013) but kinome reprogramming in DLBCL has not been reported.
Aims: We have sought to determine mechanisms of resistance in the BTKi sensitive ABC-DLBCL cell line TMD-8, in the hope that this might reveal interacting kinase pathways that potentially could be targeted concurrently to enhance efficacy.
Methods: TMD-8 is an ABC-DLBCL cell line, which undergoes rapid, classical apoptosis at nanomolar concentrations of ONO-4059 (EC50 9.5nM). We have previously shown that ONO-4059 synergises with BCL2 inhibitors in TMD-8 *via* upregulation of BIM, following dephosphorylation of ERK (Kozaki *et al.*, EHA 2013). To investigate mechanisms of resistance to BTKi in ABC-DLBCL and to identify interacting kinase pathways, we studied the effects of both short and long-term exposure of ONO-4059 on TMD-8. Secondly, we developed a ONO-4059 resistant TMD-8 cell line (TMD-8R, apoptosis EC50 >3000nM) by prolonged exposure to ONO-4059 over nine months and investigated kinome reprogramming by immunoblot and phosphokinase antibody arrays.

Results: ONO-4059 induced partial down-regulation of both pAKT and pERK1/2 within 4hrs treatment in the parental cell line TMD-8, but then with prolonged drug exposure (>24hrs) hyperactivation of both pAKT and pERK1/2 was observed in surviving cells. In contrast, pSTAT1 and pSTAT3 were down-regulated in both short and long-term exposures. Interestingly, TMD-8R showed comparable inhibition of pBTK on exposure to ONO-4059 but did not undergo apoptosis. TMD-8R showed no up-regulation of BIM and consequently the synergy between BTKi and BCL2 inhibitors was lost. Furthermore, similar hyperactivation of pAKT and pERK after ONO-4059 was observed in the TMD-8R. Activation of both pathways was confirmed functionally by the demonstration of strong synergy between PI3K inhibitors with BTKi in both TMD-8 and TMD-8R.
Summary and Conclusions: These data show that like other malignancies ABC-DLBCL may undergo rapid adaptive kinome reprogramming following exposure to BTKi. The mechanisms underlying this process are being investigated. Practically, activation of the PI3K/AKT pathway in response to BTK inhibition leads to the development of resistance to BTKi. Collectively, these data indicate that the combination of ONO-4059 with PI3K and perhaps BCL2 inhibitors would have maximal efficacy in this difficult to treat patient group.

P432

PRECLINICAL EVALUATION OF A NOVEL, HIGHLY POTENT AND SELECTIVE PI3K-DELTA INHIBITOR, CPL-302-201, FOR THE TREATMENT OF HEMATOLOGIC MALIGNANCIES

B Dymek[1], D Zdzalik[1], M Zagozda[1], M Dziachan[1], M Malczyk[1], A Bujak[1,2], P Grygielewicz[1,2], P Gunerka[1,3], O Musielak[1], M Skupinska[1], J Huczkalitowska[1], K Dubiel[1], M Lamparska-Przybysz[1], M Wieczorek[1], A Stanczak[1,*]
[1]Innovative Drugs R&D Department, Celon Pharma S.A., Kielpin Lomianki, [2]Postgraduate School of Molecular Medicine, Warsaw Medical University, Warsaw, [3]Department of Medical Biotechnology, Medical University of Lodz, Lodz, Poland

Background: PI3Ks belong to the family of lipid kinases that play pivotal role in numerous intracellular signaling pathways. PI3Kα and PI3Kβ are ubiquitously expressed, while PI3Kδ and PI3Kγ are predominantly expressed in hematopoietic cells, although PI3Kγ can also be detected in endothelium, heart and brain. PI3Kδ is the key enzyme involved in BCR and chemokine receptors signaling critical for B cell activation, differentiation and migration. In B cell-derived hematologic malignancies PI3Kδ signaling pathway is engaged in the proliferation and survival of cancer cells. Thus, inhibition of PI3Kδ has been proposed as a new anti-neoplastic therapy in chronic lymphocytic leukemia (CLL) and non-Hodgkin lymphomas. Recent clinical trials showed clinical benefit of Idelalisib (PI3Kδ inhibitor) for CLL patients, however some adverse events were reported. Therefore, there is an urgent need to develop more selective PI3Kδ inhibitors.
Aims: The aim of the study was to investigate the therapeutic potential of a novel PI3Kδ inhibitor CPL-302-201 in hematologic malignancies.
Methods: A novel PI3Kδ inhibitor, CPL-302-201, was developed using knowledge-based drug design approach. To determine the activity and the selectivity of the compound among class I of PI3K lipid kinases and selected protein kinases, ATP-based enzymatic assay was used. Additionally, its biological potency and selectivity was evaluated in a number of cell-based models by Western blot and cell viability assay, ATPlite®.
Results: Obtained results indicate that CPL-302-201 inhibits PI3Kδ kinase activity at low nanomolar concentrations (IC_{50}=6,6 nM) comparable to Idelalisib (IC_{50}=4,1 nM). However, CPL-302-201 exhibits outstanding selectivity over α, β and γ isoforms of PI3K (1890, 830 and 9000-fold, respectively) in comparison to Idelalisib (178, 100 and 27-fold, respectively). Moreover, CPL-302-201 does not inhibit protein kinases from the selectivity panel at the concentration of 1 μM. In cell-based viability assays CPL-302-201 inhibits non-Hodgkin lymphoma cell lines. Western blot analysis has shown that CPL-302-201 significantly inhibits phosphorylation of Akt in Raji cell line after anti-IgM stimulation (IC_{50}<50 nM). Additionally, cellular selectivity of the compound against PI3Kγ has been confirmed by showing no effect on Akt phosphorylation in RAW 264.7 cell line after C5a stimulation up to the concentration of 5μM. Currently, the pharmacokinetic properties of CPL-302-201 are being evaluated.
Summary and Conclusions: We have designed CPL-302-201 – a novel PI3Kδ inhibitor with high potency and outstanding selectivity in comparison to Idelalisib, both in the kinase- and cell-based assays. Preclinical data from non-Hodgkin lymphoma cell lines indicate the therapeutic potential of CPL-302-201 in hematologic malignancies. The activity and unique selectivity of CPL-302-201 qualifies it for the consideration as a drug with a wide therapeutic window and limited side effects in clinical use.

P433

NOVEL HISTONE DEACETYLASE INHIBITOR ST7612AA1 EXHIBITS EFFICACY IN PRE-CLINICAL MODELS OF MATURE B-CELL LYMPHOMAS

E Bernasconi[1,*] I Kwee[1], A Rinaldi[1], M Ponzoni[2], L Cascione[1], L Vesci[3], G Giannini[3], A Stathis[4], E Zucca[4], E Gaudio[1], F Bertoni[1,4]
[1]Lymphoma & Genomics Research Program, IOR Institute of Oncology Research, Bellinzona, Switzerland, [2]Pathology Unit and Unit of Lymphoid Malignancies, San Raffaele H Scientific Institute, Milan, [3]Sigma-Tau Industrie Farmaceutiche Riunite S.p.A, Pomezia, Italy, [4]IOSI Oncology Institute of Southern Switzerland, Bellinzona, Switzerland

Background: Treatment of patients with lymphomas that are resistant/refractory to standard chemotherapy is challenging and urgent. Recently, the important role of epigenetic pathways in the pathogenesis of lymphomas has been highlighted by the observations that several genes encoding epigenetic modifiers are selectively and prominently targeted by mutations and genomic aberrations. Histone deacetylase inhibitors (HDACi) are a class of molecules that have shown clinical efficacy in hematological malignancies.
Aims: Here, we have assessed the *in vitro* and *in vivo* activity of the γ-lactamamide thiol-derivative ST7612AA1 (Sigma Tau, Pomezia, IT), a novel HDACi, in lymphoma cell lines.
Methods: The used cell lines were derived from: diffuse large B-cell lymphoma (DLBCL, n=10), mantle cell lymphoma (n=4), splenic marginal zone lymphoma (n=3). Cells were exposed to increasing concentrations of ST7612AA1 and the MTT assay was performed after 72 hours to determine its effect on proliferation. Apoptosis was assessed by Annexin-V/7-AAD staining. Gene expression profiling (GEP) was done, in triplicate, with the Illumina HumanHT-12 Expression BeadChips on one activated B-cell (ABC) DLBCL (TMD8) and one germinal center B-cell (GCB) DLBCL (DOHH2) cell line treated with ST7612AA1 or DMSO for 8 hrs. Differential expression analysis was performed with LIMMA, GSEA and Metacore. DOHH2 cells were injected s.c. in NOD-SCID mice, then treated with ST7612AA1 (40mg/Kg, p.o.) or its vehicle control.
Results: The median IC50 was 394 nM (range, 46-2664) for all the cell lines without significant differences among histological subtypes or between GCB- and ABC-DLBCL: DLBCL-ABC 257 nM (101-805); DLBCL-GCB 636 nM (46-2664); MCL 433 nM (248-553); SMZL 119 nM (102-257). ST7612AA1 induced apoptosis in 3/6 DLBCL cell lines tested. ST7612AA1 presented both nuclear and cytoplasmic anti-deacetylase activity as demonstrated by Western blotting analysis showing increased levels of both acetylated histone H3 and acetyl-a-tubulin. GEP showed that ST7612AA1 affected important oncogenes and tumor suppressor genes. Among the most down-regulated genes there were TNFRSF17 (BCMA), MYC, IRAK1, MYD88, CCND2, BLK, CDK4, IKZF1, BID, while the up-regulated transcripts comprised CDKN2C (p18), CDKN1A (p21), CDKN2D (p19), HLA, CD69, and genes coding histones, MHC-I, MHC-II and metallothioneins. The down-regulated genes were enriched of MYC and E2F targets and members of the TLR/MYD88 pathway. The gene expression signature also revealed significant overlap with genes affected by other HDAC-i and the MTOR-inhibitor rapamycin. Finally, *in vivo* experiments demonstrated that ST7612AA1 determined a significant delay in tumor progression (P=0.0449).
Summary and Conclusions: ST7612AA1 showed promising activity in preclinical models of mature lymphomas and represent a new HDACi worth of further evaluation as single agents and in combination with other agents.

P434

DARATUMUMAB TREATMENT IN COMBINATION WITH CHOP OR R-CHOP RESULTS IN THE INHIBITION OR REGRESSION OF TUMORS IN PRECLINICAL MODELS OF NON-HODGKINS LYMPHOMA

P Doshi[1,*] AK Sasser[2], A Axel[2], M Sharp[2], J Alvarez[2], J Park[2], J Lammerts van Bueren[3]
[1]Oncology Translational Medicine and Early Development, [2]Oncology Biomarkers, Janssen R&D, Spring House, United States, [3]Genmab B.V., Utrecht, Netherlands

Background: Daratumumab is a human antibody that binds to CD38 on the cell surface and induces cell killing by multiple mechanisms including complement mediated cytotoxicity (CDC), antibody-dependent cellular cytotoxicity (ADCC), antibody-dependent cell phagocytosis (ADCP) and apoptosis. Daratumumab is currently being tested in clinical trials to treat multiple myeloma.
Aims: To explore other hematological malignancies where daratumumab could be efficacious as an anti-tumor therapy, the activity of daratumumab was evaluated *in vitro* and *in vivo* utilizing Non-Hodgkin's Lymphoma (NHL) tumor cell lines and human primary samples.
Methods: The expression of CD38, CD 46, CD55 and CD59 on tumor cell lines was determined using flow cytometry. ADCC assays were carried out using tumor cell lines as target cells and human PBMC as effector cells in a ratio of 50:1. CDC assays were carried out using human serum at 10%. Primary tumor specimens were evaluated by immunohistochemistry (IHC) for CD38 expression. For *in vivo* models, a Burkitt's lymphoma (NAMALWA) or a Diffuse Large B-Cell Lymphoma (DLBCL) (SU-DHL-6) cells were injected subcutaneously in SCID mice and tumors were allowed to grow to about 150-200 mm^3. The animals were treated with daratumumab (10 mg/kg QWx3) or CHOP (QDx5) alone or in combination. For patient-derived DLBCL model, tumor fragments were grafted subcutaneously and the dosing was initiated when tumors reach 125-250 mm^3. The animals were treated with daratumumab alone (20 mg/kg QWx3), CHOP (QDx1), R-CHOP (QDx1) alone or a combination of daratumumab with CHOP or R-CHOP.
Results: Evaluation of 16 NHL cell lines for CD38 expression suggested that

CD38 expression levels varied among cell lines, but the majority (81%, n=13/16) had >1000 CD38 receptors per cell. Daratumumab induced >20% apoptosis in 11 out of 16 cell lines in the presence of a cross-linking agent. In tumor cell killing assays, daratumumab induced >25% ADCC in 7 out of 16 cell lines and >30% CDC in 6 out of 16 cell lines. While no linear correlation was observed between CD38 expression and the extent of ADCC and CDC, tumor cell lysis >10% was observed only in cell lines with >50,000 CD38 receptors/cell. The levels of complement inhibitory proteins (CIP) (CD46, CD55 and CD59) were evaluated to determine of these proteins affected CDC in response to daratumumab but no direct correlation was observed between CDC and CIP expression in these cell lines. In NAMALWA *in vivo* model, daratumumab in combination with CHOP showed significant tumor growth inhibition (47%, p <0.001) compared to the control group on day 26. In SU-DHL-6 model, daratumumab either alone or in combination with CHOP showed significant tumor growth inhibition (55% and 63%, respectively, p<0.01) by day 32. In a patient-derived DLBCL model with high (3+) CD38 expression in 80% of tumor cells by IHC, daratumumab in combination with CHOP or R-CHOP showed tumor regression and the tumors did not regrow when the treatment with daratumumab was stopped after 3 doses. The animals were tumor free at the end of the study (day 60) and showed long-term survival compared to daratumumab alone, CHOP alone or R-CHOP alone.
Summary and Conclusions: These data suggest that daratumumab inhibits growth of NHL tumors that express CD38 and may offer therapeutic benefit in the clinical setting of NHL.

P435

DIGITAL IMAGE ANALYSIS OF KI-67 FOR RISK STRATIFICATION OF PATIENTS WITH MANTLE CELL LYMPHOMA

YN Blaker[1,2,*] M Brodtkorb[1,2,3], J Maddison[4], TS Hveem[2,4,5], JA Nesheim[2,4], HM Mohn[4], K Liestøl[5], J Delabie[6], H Holte[2,3], E B Smeland[1,2], A Kolstad[3], HE Danielsen[2,4,5,7]
[1]Department Of Immunology, Institute for Cancer Research, Oslo University Hospital, [2]Centre for Cancer Biomedicine, Faculty of Medicine, University of Oslo, [3]Department of Oncology, Division of Cancer Medicine, Surgery and Transplantation, [4]Institute for Cancer Genetics and Informatics, Oslo University Hospital, [5]Department of Informatics, University of Oslo, [6]Department of Pathology, Oslo University Hospital, Oslo, Norway, [7]Nuffield Division of Clinical Laboratory Sciences, University of Oxford, Oxford, United Kingdom

Background: Mantle cell lymphoma (MCL) accounts for 4-5% of non-Hodgkin lymphomas in Western countries and is incurable following conventional chemotherapy. MCL is molecularly characterized by the translocation t(11;14)(q13;q32) which leads to overexpression of the cell cycle regulator cyclin D1. The major predictive factor for survival from MCL is proliferation. Counting the fraction of Ki-67-positive cells (Ki-67 index) in 1000 tumor cells in immunostained sections is considered the "gold standard" to predict prognosis. The use of Ki-67-immunostaining for outcome prediction in routine diagnostics has been hampered by interobserver variability due to the lack of a standardized staining technique as well as to the semi-quantitative nature of the scoring performed in routine practice. In this study we applied digital image analysis (DIA) software to determine the proliferation rate in two cohorts of MCL patients and compared the results to manual counting of Ki-67-positive cells as well as to semi-quantitative scoring.
Aims: To develop a standardized software application for fast and objective scoring of Ki-67 in MCL for prognostic stratification in routine diagnostics.
Methods: Two patient cohorts were included in the analysis. In the first cohort, 62 patients included in two Nordic multicenter prospective phase-II studies-MCL2 (Geisler, CH. *et al.* Blood; 2008) and MCL3 (Kolstad, A. *et al.* Submitted), were used to train the software tool (Immunopath) for analysis of the Ki-67 index in each case. Semi-quantitative scores were available from the two studies. In the second cohort, 29 patients included in the LLMPP-study (Rosenwald, A. *et al.* Cancer Cell; 2003) were used to validate the scoring protocol established in the first patient cohort. Representative areas were marked on digital images for DIA and manual counting. In the first patient cohort, the Ki-67 index was counted manually (gold standard) and by DIA on identical digital images on minimum 1000 tumor cells, in addition to DIA of the whole representative tumor area in each case. In the second cohort, the Ki-67 index was counted manually (gold standard) in identical images by two independent observers, in addition to DIA of the whole representative tumor area in each case.
Results: When performing manual counting of Ki-67 index by two independent observers on digital images, the interobserver variability is reduced to a minimum (Spearman's rho=0.978, p <0.001). There was a strong correlation between manual counting and DIA on identical images (Spearman's rho=0.959, p <0.001) (Fig 1). When using Ki-67 index as a continuous parameter in a Cox regression analysis, Ki-67 index showed a statistically significant relevance for OS with both manual counting and DIA in both patient cohorts. There was a less convincing correlation between semi-quantitative scores and manual counts (Spearman's rho=0.807, p <0.001) and semi-quantitative scores were not significant for OS. The DIA showed a trend towards higher estimates of Ki-67 positive cells compared to the manual count (Figure 1).
Summary and Conclusions: Manual quantification of Ki-67 on digital images of immunostained slides practically eliminates interobserver variability. We obtained excellent correlation between manually and digitally quantified Ki-67 index. The Ki-67 index quantified by manual count as well as by DIA is associated with outcome in MCL. However, manual counting is time-consuming and thus not applicable to routine diagnostics. DIA on the other hand can easily be introduced in a routine diagnostic setting and improve risk stratification for MCL.

P436

DETECTION OF SOX11 PROTEIN BY FLOW CYTOMETRY

M Lord[1,*] A Wasik[1], V Priebe[1], Å Jeppsson-Ahlberg[2], B Christensson[1], B Sander[1]
[1]Laboratory Medicine, Karolinska Institutet, [2]Pathology, Karolinska University Hospital, Stockholm, Sweden

Background: Mantle cell lymphoma (MCL) is a rare, but distinct, B cell derived non-Hodgkin lymphoma (NHL), that accounts for 8% of all malignant lymphomas. It is CD20 and CD5 positive with variable expression of CD23. Thus, by flow cytometry a certain phenotypic overlap with B-cell chronic lymphocytic lymphoma (B-CLL) exist. However, MCL, in contrast to B-CLL, overexpress cyclin D1 by the t(11;14)(q13;32) translocation, juxtaposing the CCND1 gene to the IgH enhancer. This translocation is regarded as primary event in the evolution of MCL. Further, the neuronal transcription factor Sry-related high-mobility-group box 11 (SOX11) is found to be highly upregulated in MCL, independent of cyclin D1-status. Here, we investigated if SOX11 expression could be a flow cytometry marker to discriminate MCL from B-CLL.
Aims: The aim of this study was to verify the utility and feasibility of the new monoclonal antibody anti-SOX11 (MRQ-58) for flow cytometric analysis of primary MCL samples.
Methods: Basal protein expression of SOX11 was verified by western blot and flow cytometry using the commercially available mouse monoclonal anti-SOX11 antibody MRQ-58 in six MCL cell lines: Granta519, Rec1, JeKo1, Mino, Z138 and JVM2. Antibody specificity was verified by transient knockdown of SOX11 in Granta519 and Z138 cell lines and immunoreactivity in the nucleus was confirmed by confocal microscopy. SOX11 expression was investigated in 11 tumor samples of primary cyclin D1-positive MCL from 10 patients and 10 tumor samples of B-CLL by multicolor flow cytometry. In all samples SOX11 mRNA levels were also determined by qPCR.
Results: Immunoblotting for SOX11 showed that the antibody used detected a single band at the predicted size for SOX11 protein in SOX11 positive MCL cell lines, but did not bind to any protein in the SOX11 negative MCL cell line, JVM2. Similar results were obtained using flow cytometry: five SOX11 positive cell lines showed higher SOX11 fluorescence intensity compared to isotype control, whereas for JVM2 the SOX11 fluorescence intensity overlapped with the isotype control. Multicolor flow cytometry showed that all primary MCL tested were SOX11 positive with median fluorescence intensity (MFI), after subtraction to isotype control, in the range 12.63 to 87.26 SOX11 was not detected in any of the B-CLL cases by flow cytometry (MFI range -2.25 to 1.24). We correlated MFI to the Ct values obtained from the qPCR results (mean of triplicates). Since we did not relate SOX11 protein levels to any other protein but to the isotype control, we used equal amounts of cDNA within the samples set (the higher Ct the lower mRNA expression). We found that those two parameters correlated, Spearman correlation coefficient -0.69 (p=0.002).
Summary and Conclusions: We showed that SOX11 protein consistently could be detected and quantified by flow cytometry. Implementing detection of SOX11 in the routine diagnostic flow cytometry would be beneficial for accurate and reliable diagnosis of MCL, especially for rare atypical cases of MCL negative for CD5 or cyclin D1. SOX11 expression also helps distinguish MCL from other malignancies with similar phenotype, like B-CLL. Different from immunohistochemistry, analyzing SOX11 by flow cytometry will generate quantitative answers. Possibility of using SOX11 in a multi-color panel with other markers is an additional advantage. Although flow cytometry would not be able distinguish SOX11 nuclear positivity, it could improve diagnosis, as a complement to IHC.

Indolent Non-Hodgkin lymphoma - Clinical

ABSOLUTE MONOCYTE AND LYMPHOCYTE COUNT IN FOLLICULAR LYMPHOMA: PROGNOSTIC ROLE IN SURVIVAL OUTCOME EVALUATION

S Sacchi[1,*] L Marcheselli[1], A Bari[1], S Pozzi[1], G Rossi[2], U Vitolo[3], L Rigacci[4], AM Carella[5], F Merli[6], F Di Raimondo[7], U Consoli[8], MR Federico[1]
[1]Department of Diagnostic, Clinical and Public Health Medicine, University of Modena and Reggio Emilia, MODENA, [2]Department of Hematology, Spedali Civili, BRESCIA, [3]Hematology, Città della Salute e della Scienza Hospital, TORINO, [4]Department of Hematology, Ospedale Careggi, FIRENZE, [5]U.O. Ematologia 1, IRCCS AOU San Martino-IST, GENOVA, [6]Haematology Unit, Arcispedale Santa Maria Nuova, IRCCS, REGGIO EMILIA, [7]Division of Hematology, Oncology, and Clinical Pathology and Department of Clinical and Molecular Biomedicine, University of Catania, [8]U.O.S. di Emato-Oncologia, Ospedale Garibaldi-Nesima, CATANIA, Italy

Background: The Follicular Lymphoma International Prognostic Index (FLIPI) still remains the most used model for risk stratification of patients with follicular lymphoma (FL).After rituximab introduction there was a meaningful improvement in progression free survival (PFS) and overall survival (OS) of FL, and a new prognostic score was considered necessary (FLIPI2). Furthermore several papers were published on prognostic value of lymphopenia and monocytosis in lymphomas, showing that these parameters are able to identify high risk cases. Absolute monocyte count (AMC) and absolute lymphocyte count (ALC) could be considered as surrogate markers: AMC for microenvironment supporting tumor growth and ALC as expression of immune status.
Aims: We performed an ancillary study from FOLL05 clinical trial with the aim to analyze, in patients treated for FL with regimens containing rituximab, the prognostic role of AMC and ALC in terms of PFS and OS. The FOLL05 study was a large prospective, randomized, multicenter protocol of Fondazione Italiana Linfomi, which enrolled from 2006 to 2010 a total of 531 eligible patients; last update was in December 2013. It was approved by ethics committees and required each patient to provide written informed consent.
Methods: Since the cut-offs for AMC and ALC reported in literature were mostly related to aggressive lymphomas, we assessed their reproducibility in FL, modeling AMC and ALC as continuous covariates with a Cox PH restricted cubic spline regression, adjusted by FLIPI and stratified by chemotherapy. The AMC or ALC value who cross the log(HR)=0 was chosen as cut-off. These methods confirm that the cut-offs of AMC >630/mm3 and ALC≤1000/mm3 are applicable also in FL selecting worst groups, as already observed in previous analysis on aggressive lymphomas. We assessed the importance of AMC and ALC predictor over 1000 bootstrap inclusion fraction (BIF) in Cox PH model.
Results: 431 out of 531 patients had complete data for AMC and ALC; median age at diagnosis was 56 years. With a median follow-up of 57 months the 5-years PFS was 57% (95%CI 52-62) and 5-years OS 90% (95%CI 87-93). One hundred seven (25%) patients had AMC >630/mm3. Monocytosis correlated with FLIPI score (P=0.012) while it was not associated with FLIPI2 and any type of chemotherapy. The 5-years PFS was 61% and 44% for AMC ≤630 and >630/mm3, respectively (P=0.0009, Figure 1a). Adjusted by FLIPI and stratified by chemotherapy the HR was 1.66 (95%CI 1.21-2.27) defining AMC >630/mm3 as a strong predictor since the BIF over 1000 bootstrap resamples was 84.8%. The 5-years OS was 93% and 81% for AMC ≤630 and >630/mm3, respectively (P=0.003, Figure 1b). Ninety one (21%) patients had ALC ≤1000/mm3, that was not correlated with FLIPI and chemotherapy, while it was associated with FLIPI2 (P=0.014). The 5-years PFS was 58% and 51% for ALC >1000 and ALC ≤1000/mm3, respectively (P=0.129, Figure 1c). Adjusted by FLIPI and stratified by chemotherapy the HR was 1.22 (95%CI 0.86-1.71) showing ALC ≤1000/mm3 as a very weak predictor since the BIF over 1000 bootstrap resamples was 21%.The 5-years OS was 90% and 93% for ALC >1000and ≤1000/mm3, respectively (P=0.957, Figure 1d).

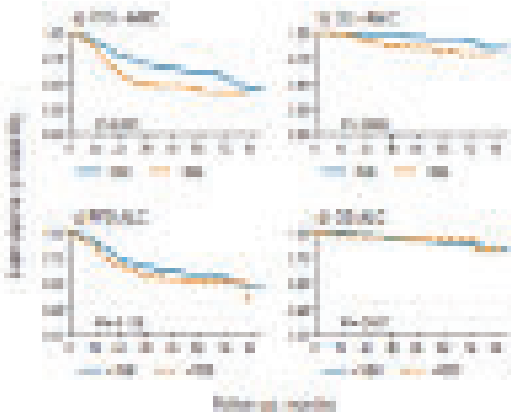

Figure 1. PFS and OS by AMC (a, b) and ALC (c, d) adjusted by FLIPI and stratified by chemotherapy.

Summary and Conclusions: Our large study, with data collected prospectively, showed that monocytosis is a strong negative predictive factor for survival outcome, in particular for PFS, while lymphopenia ≤1000/mm3 showed a weak predictive role.

P438

BRIEF RITUXIMAB, BENDAMUSTINE, MITOXANTRONE (R-BM) INDUCTION PLUS RITUXIMAB CONSOLIDATION IN ELDERLY *DE NOVO* ADVANCED STAGE FOLLICULAR LYMPHOMA: FINAL RESULTS OF A STUDY BY FONDAZIONE ITALIANA LINFOMI

C Boccomini[1,*] M Ladetto[2], L Rigacci[2], M Ceccarelli[2], S Rattotti[2], S Ferrero[2], S Volpetti[2], B Botto[2], A Chiarenza[2], R Freilone[2], P Corradini[2], S Franceschetti[2], C Rusconi[2], C Stelitano[2], C Pecoraro[2], B Puccini[2], M Balzarotti[2], A Tucci[2], S Bolis[2], M Spina[2], L Baldini[2], U Vitolo[1]
[1]SC Hematology, AO Città della Salute e della Scienza di Torino, [2]On the behalf of Fondazione Italiana Linfomi, Turin, Italy

Background: a previous FIL trial (Vitolo *et al.*, JCO 2013) showed that a brief R-FND (Fludarabine, Mitoxantrone, Dexamethasone) induction chemoimmunotherapy followed by rituximab consolidation achieved high CR and PFS rates in elderly Follicular Lymphoma (FL) patients (pts); bendamustine is a well-tolerated and effective drug (Rummel *et al.*, Lancet 2013) but data on its use in combination with other cytotoxic agents are scant.
Aims: to evaluate overall response rate (ORR) of a brief chemoimmunotherapy with R-Bendamustine in combination with Mitoxantrone in elderly pts, reducing toxicity compared to the previous study.
Methods: 76 elderly *de novo* FL pts (age 65-80) were enrolled (Sept 2009-Nov 2011). Inclusion criteria were: grade I, II and IIIa; advanced (stage III/IV) or stage II disease requiring treatment; "FIT" pts according to comprehensive geriatric assessment (ADL, I-ADL, CIRS). Treatment plan was: 4 monthly courses of R-BM (375 mg/m^2 Rituximab day 1, 90 mg/m^2 Bendamustine days 1-2, 8 mg/m^2 Mitoxantrone day 1) followed by 4 weekly Rituximab infusions as consolidation; Rituximab maintenance was not planned because not licensed at that time in Italy. Polymerase chain reaction (PCR) for BCL2/IgH rearrangement was performed on bone marrow samples at diagnosis, after R-BM and at the end of consolidation.
Results: Median age was 71 years (range 65-79); 29 males, 47 females; WHO grading was as follows: I 18%, II 54% and IIIa 28%; 15% had advanced stage II disease, 30% stage III and 55% stage IV; 47% had BM involvement, 20% B symptoms and 7% leukemic dissemination; 59% patients had no comorbidity, 20% one and 21% ≥2 comorbidities. According to FLIPI pts were: low (L) 8%, intermediate (I) 32% and high (H) risk 60%. PCR analysis for BCL2/IgH rearrangement was carried out in 75 pts at diagnosis: 39 (51%) were Bcl-2 positive. Seventy (92%) pts completed the planned treatment: 50/70 (72%) in the planned time. Six pts did not complete the treatment: 1 for progressive disease, 4 for adverse events (2 haematological toxicities with prolonged neutropenia; 1 CMV colitis and 1 for infection and concomitant worsening of pre-existing oral pemfigo) and 1 patient for worsening of performance status. ORR to treatment was 94% with 59 (78%) complete remissions (CR) and 12 (16%) partial remissions (PR). Response to induction R-BM was as follow: 32 (42%) CR, 40 (53%) PR and 4 (5%) stable (SD) or progressive disease (PD); 28 (70%) of the 40 pts in PR after R-BM converted to CR following further Rituximab consolidation. At the end of treatment 25/39 (64%) of pts were PCR negative and most of them, 21/25 (84%), were also in CR. At a median follow-up of 31 months, 2-yrs OS rate was 95% and 2-yrs PFS rate was 88% (no difference in PFS according to FLIPI L+I *vs* H risk: 90% *vs* 87%). Overall, 5 deaths were recorded, one due to progressive disease. A total of 577 courses of R-BM and Rituximab were given and overall the regimen was well-tolerated in an outpatient setting. The most frequent severe toxicity (CTC grade 3-4) was neutropenia reported in 18% of the cycles, but only 6 cases of severe infection and 8 cases of neutropenic fever occurred; 68% of the pts received G-CSF support during treatment (Figure 1).

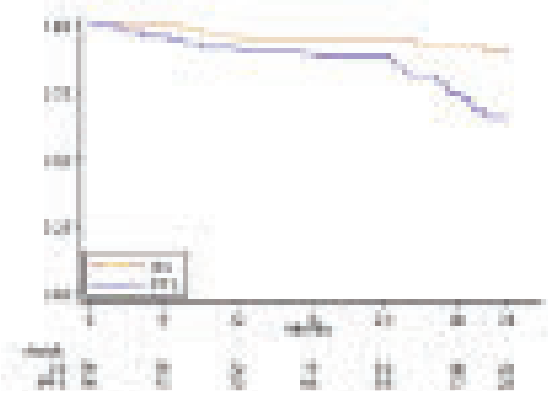

Figure 1.

Summary and Conclusions: the reduction of the amount of chemoimmunotherapy with a brief R-Bendamustine combined with Mitoxantrone regimen is an effective and safe treatment strategy in elderly FL pts with high CR and molecular remission rates and prolonged PFS.

P439

BENDAMUSTINE IS NOT ASSOCIATED WITH AN INCREASE IN INFECTIONS – SYSTEMATIC REVIEW AND META-ANALYSIS OF RANDOMIZED CONTROLLED TRIALS

A Gafter-Gvili[1,*] R Gurion[1], P Raanani[1], O Shpilberg[1], L Vidal[1]
[1]Institute of Hematology, Rabin Medical Center, Petah-Tikva, Israel

Background: Bendamustine is a chemotherapeutic drug with structural similarities to both alkylating agents (nitrogen mustard derivative) and purine analogues (benzimidazole ring). Theoretically, due to its nucleoside-like properties it might be associated with more infections.Data in the literature are lacking regarding the infection-related adverse events of bendamustine-containing regimens.
Aims: We aimed to assess the risk of infections associated with bendamustine.
Methods: Systematic review and meta-analysis of all randomized controlled trials comparing bendamustine containing regimens (alone or combined with other chemotherapeutic agents and/or rituximab) to any other regimens. Trials evaluating bendamustine for any lymphoproliferative disorder or plasma cell dyscrasia were included. A comprehensive search of The Cochrane Library, MEDLINE, conference proceedings and references was conducted until February 2014. Two reviewers appraised the quality of trials and extracted data. Outcomes assessed were: any infections, grade 3-4 infections, fatal infections, grade 3-4 neutropenia and grade 3-4 lymphopenia. For dichotomous data, relative risks (RR) with 95% confidence intervals (CIs) were estimated and pooled. We used fixed effect model to pool data, unless there was significant heterogeneity, in which case we used the random effects model.
Results: Eight trials conducted between the years 2006 and 2013 and randomizing 2022 patients were included. We included 4 trials of patients with non-Hodgkin lymphoma (Rummel 2013, Rummel 2010, Herold 2006 and the Bright study 2013), 3 trials of CLL (Knauf 2009, Niederle 2013, LeBlond 2013), 1 trial of patients with multiple myeloma (Ponish 2006). The bendamustine arm included: bendamustine alone (2 trials), bendamustine-rituximab (BR) (4 trials), bendamustine, vincristine, prednisone (BOP) (1 trial), and bendamustine, prednisone (BP) (1 trial). The comparator arms in 6 of the trials included other alkylating agents: chlorambucil, R-chlorambucil, R -CHOP (in 2 trials), R-COP, COP, and melphalan-prednisone (MP). In 2 trials the comparator arm included fludarabine (alone or with rituximab). There was no statistically significant effect for bendamustine on the rate of any type of infection (RR 1.06 [95% CI 0.83, 1.34], 6 trials). There was no increase in the rate of grade 3-4 infections (RR 1.3 [95% CI 0.73, 2.3], 6 trials) or fatal infections (RR 0.69 [95% CI 0.30, 1.58], 3 trials). There was no difference in the rate of infections between trials that administered bendamustine as first line and trials that administered it for relapse. Data were too scarce to analyze by specific types of infections separately. There was no increase in the rate of grade 3-4 neutropenia in the bendamustine arm (RR 0.9 [95% CI 0.58, 1.42], 6 trials). This was true when the comparator was alkylating agent containing regimens (RR 0.87 [95% CI 0.52, 1.48], 4 trials) as well as fludarabine containing regimens (RR 1.02 [95% CI 0.54, 1.91], 2 trials). There was a significant increase in grade 3-4 lymphopenia in the bendamustine arm compared to the alkylating agent containing regimens arm (RR 1.95[95% CI 1.54, 2.47).
Summary and Conclusions: Our systematic review demonstrates no effect of bendamustine on the rate of infections when compared to either alkylating agents or fludarabine, despite an increase in lymphopenia. Thus, bendamustine remains a safe therapeutic option. The main drawback of this meta-analysis is the heterogeneity between malignancies and treatments.

P440

EXPRESSION OF CD200 AND CD148 IN LEUKEMIC B-CELL CHRONIC LYMPHOPROLIFERATIVE DISORDERS

L Fan[1,*] Y Miao[1], L Wang[1], Y Wu[1], W Xu[1], J Li[1]
[1]Hematology, the First Affiliated Hospital of Nanjing Medical University, Jiangsu Province Hospital, Nanjing, China

Background: B-cell chronic lymphoproliferative disorder (B-CLPD) is comprised of a wide range of B-cell derived malignancies. Characteristic morphology and immunohistochemistry studies are fundamental to the diagnosis of B-CLPD. Compared to traditional histopathological analysis, flow cytometric evaluation of tumor cell immunophenotyping is more reproducible and less time demanding. Although there are some established Immunophenotypic score systems, for example, Matutes score system for the diagnosis of chronic lymphocytic leukemia (CLL), differential diagnosis between these B-CLPD remains difficult in some cases. Thus, new reliable and sensitive biomarkers are urgently needed. Recently, CD200 and CD148 were found expressed in different stages during B cell development, which indicated possible discrimination value.
Aims: To access definite expression patterns of CD200 and CD148 in B-CLPD and its potential diagnostic value.
Methods: Flow cytometric analysis was performed on fresh PB/BM specimen. Specific antibodies conjugated with fluorescein were used with murine isotype control applied with each sample to set negative gate.
Results: We have evaluated the expression patterns of CD200 and CD148 in 376 cases of B-CLPD by flow cytometry. Our results shows that CD200 and CD148 expression patterns distinguishes different B-CLPD, and may have potential differential diagnostic value in B-CLPD, especially in CD5 positive B-CLPD, CLL, mantle cell lymphoma (MCL) and other CD5+ B-CLPD. CLL exhibited relatively uniform cell surface phenotypes of CD200 and CD148 with high positivity and mean fluorescence intensity (MFI) of CD200 and relatively low CD148 MFI; In contrast, MCL showed significantly different expression patterns of low CD200 and strong CD148 expression compared to CLL. There were significant differences of CD200 positivity (P<0.0001), CD200 MFI (P<0.0001), and CD148 MFI (P<0.0001) between CLL and MCL. And other B-CLPD have also showed diverse expression patterns of CD200 and CD148 (Figure 1). ROC and AUC analyses suggested that CD200 MFI yielded an AUC of 0.97 and CD148 MFI yielded an AUC of 0.90 in discriminating CLL from MCL. Furthermore, CD148MFI/CD200MFI >4.8 produced a sensitivity of 94.5% and a specificity of 100% in establishing the diagnosis of MCL when differential diagnosis between MCL and CLL is needed.

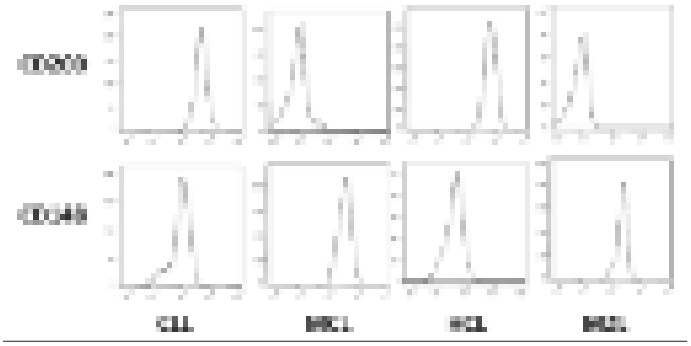

Figure 1.

Summary and Conclusions: We have therefore concluded that CD200 and CD148 expression patterns are totally different among B-CLPD, and the combination of CD200 and CD148 may have potential differential diagnostic value in leukemic B-CLPD, especially in CLL and MCL, and the introduction of CD200 and CD148 could be a powerful tool in B-CLPD diagnostic panel.

P441

ABEXINOSTAT (S78454) A HISTONE DEACETYLASE INHIBITOR, IN PATIENTS WITH REFRACTORY OR RELAPSED HODGKIN'S LYMPHOMA, NON-HODGKIN LYMPHOMA AND CHRONIC LYMPHOCYTIC LEUKAEMIA: PRELIMINARY PHASE II RESULTS

F Broussais-Guillaumot[1,*] F Morschhauser[2], L Terriou[3], WS Kim[4], ST Lim[5], M Egyed[6], B Coiffier[7], E Bachy[7], MJ Dyer[8], A Illes[9], A Rosta[10], B Lemieux[11], KL Wu[12], SS Yoon[13], S Kim[14], Z Gasztonyi[15], J Jakucs[16], F Offner[17], E Van Den Neste[18], L Ysebaert[19], CM Wendtner[20], I Kloos[21], AL Sarry[21], S Malasse[21], V Ribrag[22]

Gent, Gent, [18]hematology, Cliniques Universitaires St. Luc, Bruxelles, Belgium, [19]CHU Hôp. de Purpan, Toulouse, France, [20]Klinikum Schwabing, Muenchen, Germany, [21]Institut de Recherches Internationales Servier, Suresnes, [22]Institut Gustave Roussy, Villejuif, France

Background: Histone deacetylase inhibitors (HDACi) have emerged as promising new anticancer agents with potent and specific activity in hematological malignancies. Abexinostat is a new hydroxymate-based pan-HDACi of class I and II. A phase I/II international, multicentre, open-label, non-randomized, non-comparative dose-escalation study determined the recommended dose (RP2D) with oral abexinostat: 80 mg BID (14 days on, 7 days off). Phase I results have shown that abexinostat has an acceptable safety profile and demonstrated activity on indolent lymphomas and Hodgkin's lymphoma, with 3 complete

responses (CR), 6 partial responses (PR) and 9 stable diseases (SD) in 29 patients treated and with baseline and post-baseline tumor evaluation: 62% had a clinical benefit.
Aims: The aim in this phase II part was to further evaluate the efficacy of abexinostat as a single-agent in patients with relapsed or refractory non-Hodgkin lymphoma (NHL) or chronic lymphocytic leukaemia (CLL) at the RP2D.
Methods: Five cohorts were open in parallel: follicular lymphoma (FL), mantle cell lymphoma (MCL), diffuse large B-cell lymphoma (DLBCL), marginal zone B-cell lymphoma (MZL) or Waldenström macroglobulinaemia (WM)/lymphoplasmatic lymphoma and CLL/lymphocytic lymphoma. The primary endpoint was objective response rate (ORR: CR and PR). The responses were evaluated respectively with Cheson (2007), Hallek (2008) and Kimby (2006) criteria for NHL, CLL and WM. Safety, overall survival (OS) and progression-free survival (PFS) were secondary endpoints.
Results: Until the 1st of July 2013, 53 of 55 patients were treated and evaluable for tumor response: 13 FL, 8 CLL, 5 MZL/2 WM, 10 MCL and 15 DLBCL. Median age was 65 years [range 32-85] and 57% were male. At inclusion, median duration of disease was 4 years [range 0-16] and median treatment free interval was 3.9 months [range 1-89]. 43% of patients were refractory to their last treatment. 70% had received more than 3 previous lines of treatment. 60% of FL, MZL, DLBCL and MCL patients were Ann Arbor Stage III/IV, and 25% of CLL patients were Binet Stage C. ORR was 30% (investigator's assessment) with 3 CR and 13 PR. ORR for the 13 FL patients was 46% with 1 CR and 5 PR, 5 patients had SD. In the 8 CLL patients, 1 achieved PR and 7 had SD. Of the 7 MZL/WM patients, 2 achieved PR and 5 a SD. Of the 10 MCL patients, 1 had a CR, 1 a PR and 5 a SD. Of the 15 DLBCL patients, 1 had a CR, 4 a PR and 5 a SD. OS was not mature (68% of patients alive). Only the median of PFS for MCL and DLBCL were mature: 8 weeks [95% CI 4.8-25] for MCL and 12.2 weeks [95% CI 6.2-16.2] for DLBCL. On the 11 FL patients still alive, 6 were on-going without record of PD including 1 CR [5.5 months of follow-up (FU)], 2 PR [3.4 and 9.2 months of FU] and 3 SD [2.8, 4.4 and 7.1 months of FU] and for MZL/WM patients, 1 was still on-going without record of PD with SD [5.7 months of FU]. Grade 3 and 4 drug-related emergent adverse events (EAEs) were experienced by 82% of patients. The most common were grade 3 and 4 thrombocytopenia (78%), neutropenia (29%) and anemia (9%). Three patients experienced grade 4 febrile neutropenia. The most common non-hematological drug-related EAEs were grade 1 and 2 asthenia, diarrhea and nausea. Only few patients experienced grade 3 asthenia (5.5%), diarrhea (1.8%) and nausea (3.6%). No grade 4 was reported for these for the latter.
Summary and Conclusions: The ORR of 30% is encouraging in this patient population, especially in FL (ORR: 46%). Safety profile of abexinostat is manageable with a safety profile expected in this class of drug. Recruitment is still on-going.

P442

HIGH-DOSE CLARITHROMYCIN IS A FEASIBLE AND ACTIVE MONOTHERAPY FOR PATIENTS WITH RELAPSED/REFRACTORY EXTRANODAL MARGINAL ZONE LYMPHOMA [EMZL]: RESULTS FROM THE "HD-K" PHASE II TRIAL

AJ Ferreri[1,2,*] M Sassone[2], B Kiesewetter[3], S Govi[2], L Scarfò[2], G Donadoni[2], M Raderer[3]
[1]Università Vita e Salute, [2]Unit of Lymphoid Malignancies, Division of Onco-Hematological Medicine, San Raffaele Scientific Institute, Milano, Italy, [3]Clinical Division of Oncology, Dept. of Internal Medicine I, Medical University of Vienna, Vienna, Austria

Background: The antibiotic clarithromycin displays immunomodulatory properties, partially mediated by the suppression of inflammatory cytokines. This macrolide can directly induce TNF-mediated apoptosis in mouse lymphoma cells, with a DNA fragmentation degree similar to that seen in cells treated with chemotherapeutic agents. The combination clarithromycin-lenalidomide-dexamethasone has been associated with high tumour regression rates in patients (pts) with failed multiple myeloma and Waldenstrom's macroglobulinemia. As single agent, conventional-dose clarithromycin has been associated with an overall response rate (ORR) of 38% and a 3-year PFS of 58% in pts with relapsed/refractory EMZL [Govi *et al.* BJH 2010]. A dose-dependent antineoplastic effect was hypothesized, and a phase II trial addressing high-dose clarithromycin (HD-K) in patients with relapsed/refractory EMZL was conducted (clinicaltrials.gov NCT01516606). Herein, we report tolerability and activity results.
Aims: to address tolerability and activity of high dose clarithromycin in pts with repapsed/refractory extranodal marginal zone lymphoma.
Methods: HIV-negative adults (age ≥18 ys; ECOG-PS ≤3) with relapsed/refractory EMZL and at least one measurable/parametrable lesion were registered and treated with four courses of oral clarithromycin 2 g/day, days 1-14, every 21 days. Activity, in terms of ORR (complete and partial responses), was the primary endpoint; following a two-step Simon minimax, with an ORR of 40% (P0) [Govi *et al.* BJH 2010] and an alternative hypothesis of ORR ≥70% (P1), 21 pts were needed (type-I error 5%, power 80%, two-sided). HD-K would be considered active if ≥12 objective response were obtained.
Results: Twenty-three pts were registered (median age 70 ys, range 47-88; M:F ratio: 0.3). HD-K was the salvage therapy at first relapse in 13 pts, and the 3rd-5th line of treatment in the others. Seventeen pts had local disease at the time of treatment, six pts had multiorgan disease. Ocular adnexae (13), stomach (n=4) and lung were the most commonly involved extranodal organs. No pt had increased LDH serum levels; only one pt had B symptoms. Four pts had concomitant HBV/HCV infections. *H. pylori* and *C. psittaci* infections were successfully eradicated with specific antibiotics as part of first-line treatment, with a median time from bacterial eradication to clarithomycin treatment of 24 (10-90) months. This excludes that a potential clarithomycin antitumor activity could be due to antimicrobial effect. The treatment was completed in 19 pts; it was interrupted in 4 pts due to nausea (1) or progressive disease (PD; 3). Eighty (87%) of 92 planned courses were actually delivered. Tolerability was excellent-good; grade 1-2 nausea was the commonest side effect, but it was manageable and did not require dose reduction, only two pts had G3 nausea. No biochemical abnormalities were detected during or after HD-K. Six pts achieved a complete remission and six pts achieved a partial response (ORR=52%; 95%CI=32-72%); 4 pts had stable disease (4+, 7+, 15+, 18+), 7 pts experienced PD (within 6 months). The number of previous lines of treatment did not influence response. After a median follow-up of 12 months, no pt with responsive or stable disease experienced relapse, with a one-year PFS of 68%. All pts are alive, with a median OS of 45 months (8-214).
Summary and Conclusions: HD-K is a safe and active salvage treatment in EMZL pts; it appears more active than conventional-dose clarithromycin. This antibiotic deserves to be further investigated in EMZL and other lymphoma categories, perhaps in combination with immunomodulators.

P443

EPIDEMIOLOGY OF NON-HODGKIN LYMPHOMA IN THE US: DISTRIBUTION BY SUBTYPES, DEMOGRAPHICS, AND TRENDS FROM 1998-2011

R Go[1,*] M Al-Hamadani[2]
[1]HEMATOLOGY, MAYO CLINIC, ROCHESTER, [2]Medical Research, Gundersen Medical Foundation, La Crosse, United States

Background: Over 15 years have passed since the publication of the International Lymphoma Study Group's classification of non-Hodgkin lymphoma (NHL; *Blood* 1997).
Aims: The objectives of our study are to provide a more contemporary description of the epidemiology of NHL in the US derived from population-based data and to determine whether there is disparity in NHL subtype distribution according to racial groups.
Methods: Patients with all types of NHL diagnosed from 1998 to 2011 were identified from the US National Cancer Data Base (NCDB). We obtained patient level data pertaining to demographics and histology. The NCDB is a nationwide oncology outcomes database for more than 1,500 cancer programs and represents 70% of all newly diagnosed cases of cancer in the US.
Results: There were 515,206 patients diagnosed with NHL. The median age at diagnosis was 67.0 years and 52.5% were males. In 2011, the NHL distribution by cell type were B (82.9%), T/NK (4.7%), and not otherwise specified (NOS; 12.4%). The top 10 distinct histologic subtypes were diffuse large cell (39.2%), follicular (19.9%), marginal zone (10.0%), mantle cell (4.8%), small lymphocytic (5.3%), peripheral T-cell NOS (2.0%), Burkitt (1.9%), lymphoplasmacytic (1.4%), anaplastic large cell (1.1%), and angioimmunoblastic T-cell (0.8%). Over the 14-year study period, significant increasing trends were noted in the male predominance (from 51.6% in 1998 to 53.8% in 2011) and proportion of patients with several subtypes of T-cell NHL (angioimmunoblastic, enteropathy-type, hepatosplenic, peripheral NOS) as well as marginal zone lymphoma. Significant disparities exist based on proportions of histologic subtypes seen according to race. In particular, compared to Blacks and Asians, Whites and Native Americans were nearly twice as likely to develop follicular (12.3%/14.1% *vs* 21.5%/20.2%) and mantle cell (2.3%/2.6% *vs* 4.4%/4.0%) lymphomas. Hepatosplenic T-cell lymphoma was least common among Whites (0.03% *vs* 0.10-0.14%) while enteropathy-type T-cell (0.19% *vs* 0.0-0.09%) and small lymphocytic (7.6% *vs* 2.5-6.7%) lymphomas were more common among Asians. Primary effusion lymphoma was more common among Blacks and Native Americans (0.10% *vs* 0.01-0.03%).
Summary and Conclusions: We provide a contemporary epidemiologic description of NHL in the US population. Certain histologic subtypes are more common among racial subgroups and some appear to be increasing in proportion over time relative to others.

P444

UBLITUXIMAB (TG-1101), A NOVEL ANTI-CD20 MONOCLONAL FOR RITUXIMAB RELAPSED/REFRACTORY B-CELL MALIGNANCIES

OA O'Connor[1,*] MT Schreeder[2], C Deng[1], JE Amengual[1], R Boccia[3], MY Khalil[4], D Mahadevan[5], P Nikolinakos[6], M Patterson[1], EK Pauli[2], K Cutter[2], M Mackenzie[7], C DiSilvestre[3], A Moon[4], M Brotherton[5], P Sportelli[8], HP Miskin[8], CM Farber[7]
[1]Columbia University Medical Center, New York, NY, [2]Clearview Cancer Institute, Huntsville, AL, [3]Center for Cancer and Blood Disorders, Bethesda, MD, [4]Clopton Clinic, Jonesboro, AR, [5]West Clinic, Memphis, TN, [6]University Can-

cer and Blood Center, Athens, GA, [7]Carol G. Simon Cancer Center, Morristown, NJ, [8]TG Therapeutics, Inc., New York, NY, United States

Background: The introduction of anti-CD20 therapy has resulted in significant improvement in clinical outcomes for patients with B-cell malignancies. Despite these advances, patients continue to relapse from, or become refractory to, rituximab (RTX) based regimens. Ublituximab (UTX) a novel mAb targeting a unique epitope on the CD20 antigen, has been glycoengineered to enhance affinity for all variants of FcγRIIIa receptors and demonstrates significantly greater ADCC than RTX (Le Garff-Tavernier, 2011). A Phase I trial with single-agent UTX in patients with relapsed/refractory CLL reported an ORR of 45% (EHA 2013).
Aims: Herein we report on two Phase I dose-escalation studies of UTX in patients with RTX relapsed/refractory B-cell malignancies: TG-1101-101, a single-agent dose-escalation study of UTX; and TG-1101-102, a dose-escalation study of UTX in combination with lenalidomide (LEN), an immunomodulatory agent that has displayed single-agent activity in NHL and CLL, and has been shown to synergize with anti-CD20 mAbs.
Methods: Eligible patients for both studies were relapsed/refractory to a prior anti-CD20 regimen; had evaluable disease with confirmed CLL/SLL or NHL diagnosis, no active Hep B/C, and provided informed consent to participate. For TG-1101-101 (single agent UTX), the Phase I dose-escalation used a sequential 3+3 design in dose cohorts of 450, 600, 900, and 1200mg. Expansion cohorts were opened at select doses. UTX was administered weeklyx4 doses in Cycle 1 for NHL and on days 1, 8, 15 in Cycles 1 & 2 for CLL patients (cycle=28 days), with maintenance (monthly cycles 3 - 6 followed by quarterly infusions after cycle 6) for all patients. In TG-1101-102 (UTX+LEN), the dose escalation was a sequential 3+3 design with 4 cohorts of escalating UTX, with LEN started at a fixed dose of 10mg and titrated up to 15mg for CLL and up to 20mg for NHL patients per tolerability. UTX was administered days 1, 8, 15 of Cycles 1 & 2 (Cycle=28 days) with maintenance while LEN was started Cycle 1/Day 9 and continued daily (NHL patients, up to a 7 day rest period (days 21-28) was permitted in any cycle). In both studies, safety and efficacy were primary and secondary endpoints, respectively. PK and correlative PD data were collected in both studies.
Results: In TG-1101-101, 32 patients have been enrolled. Median age 68; 17/15 (M/F); median prior therapies=3 (range 1-9). RTX refractory=41%. UTX was well tolerated with no DLT's observed. The most frequent AE for single agent UTX has been Cycle 1/Day 1 infusion related reactions in CLL patients. 29/32 patients (11 FL, 6 MZL, 6 CLL, 5 MCL, and 1 DLBCL) were evaluable for efficacy: 3 CRs (1 FL and 2 MZL); 9 PR's (4 CLL, 2 MZL, 2 FL, and 1 DLBCL); 13 SD (6 FL, 3 MCL, 2 MZL and 2 CLL) and 4 PD (2 FL, 2 MCL) for an ORR of 41%. 86% of patients remained in SD or better for >12 weeks and median PFS for all patients was 34 weeks (95% CI: 19, NA) with no observed progression in 16/29 patients. In TG-1101-102, 10 patients have been enrolled (5 CLL/SLL, 3 MCL, 1 FL and 1 Burkitt's). Median age 66; 7/3 (M/F); median prior therapies=3 (range 3 – 6). Patients were heavily pretreated with 90% refractory to prior treatment and 70% RTX refractory, including two patients previously refractory to a BTK inhibitor and one patient refractory to a PI3Kδ inhibitor. Adverse events with the combination at a LEN dose of 10mg with dose reductions as needed, were manageable, with no DLTs observed. Gr 3/4 AE's included: neutropenia, thrombocytopenia, leukopenia and dyspnea. Lymphocyte depletion in CLL patients has been rapid and profound. 2 patients (1 MCL patient who had previously progressed on idelalisib, and 1 FL patient) achieved a PR.
Summary and Conclusions: UTX has been well tolerated in both Phase I studies with promising clinical activity for single-agent UTX in patients with RTX-relapsed or refractory disease. The safety profile of UTX supports combination therapy, and the combination of UTX and LEN warrants further exploration. Additional combination studies are ongoing with UTX in combination with novel targeted agents (BTK and PI3Kδ inhibitors).

P445

PATIENT-REPORTED OUTCOMES DATA FROM A PHASE 2 STUDY OF IDELALISIB IN PATIENTS WITH REFRACTORY INDOLENT B-CELL NON-HODGKIN LYMPHOMA (INHL)

G Salles[1,*] ND Wagner-Johnston[2], BS Kahl[3], S De Vos[4], SJ Schuster[5], W Jurczak[6], IW Flinn[7], C Flowers[8], P Martin[9], A Viardot[10], KA Blum[11], AJ Davies[12], PL Zinzani[13], MH Dreyling[14], LI Wagner[15], D Li[16], WR Godfrey[16], AK Gopal[17]
[1]Lyon Sud University Hospital, Pierre-Bénite, France, [2]Washington University School of Medicine in St. Louis, St. Louis, [3]University of Wisconsin Carbone Cancer Center, Madison, [4]University of California, Los Angeles Medical Center, Los Angeles, [5]Abramson Cancer Center at the University of Pennsylvania, Philadelphia, United States, [6]Jagiellonian University, Krakow, Poland, [7]Sarah Cannon Research Institute, Nashville, [8]Emory University, Atlanta, [9]Weill Cornell Medical College, New York, United States, [10]University Hospital Ulm, Ulm, Germany, [11]The Ohio State University, Columbus, United States, [12]University of Southampton, Southampton, United Kingdom, [13]University of Bologna, Bologna, Italy, [14]University Hospital Grosshadern, Munich, Germany, [15]Feinberg School of Medicine, Northwestern University, Chicago, [16]Gilead Sciences, Foster City, [17]University of Washington, Seattle, United States

Background: Idelalisib, a selective oral inhibitor of PI3Kδ, demonstrated considerable anti-tumor activity in patients with relapsed/refractory iNHL in a phase 2 trial (Gopal, 2014).
Aims: The purpose of this analysis was to evaluate patient-reported outcomes (PRO) data to determine whether drug treatment was associated with a change in health-related quality of life (HRQL).
Methods: Eligible iNHL patients (pts) were refractory to both rituximab and an alkylating agent. Idelalisib 150 mg PO BID was administered continuously until disease progression. HRQL was measured by the 42-item Functional Assessment of Cancer Therapy-Lymphoma (FACT-Lym), comprising FACT-G subscales: Physical Well-being (PWB), Social/Family Well-being (SWB), Emotional Well-being (EWB), Functional Well-being (FWB), and the Lymphoma Subscale (LymS). Trial Outcome Index (TOI) is PWB+FWB+LymS. Higher scores reflect better HRQL. Minimally important differences (MID) on the FACT-G ranged 3-7 points (2-5 points for subscales). The FACT-Lym was administered every 4 weeks (0-24), then every 6 weeks (30-48), and at week 60. Change from baseline in FACT-Lym was analyzed.
Results: Enrolled pts (N=125) had a median age of 64 years [range 33-87] and were 64% male. With a median follow up 9.4 months, overall response rate (ORR) is 57% (95% CI=47.6, 65.6) and median DOR is 12.5 months. Median PFS for all pts is 11.0 months. Improvements were noted in the FACT-G, FACT-Lym, and TOI scores during the study, progressively increasing with time. In FACT-G subscales, improvements were noted by 4 weeks for EWB scores. The median best changes from baseline for the FACT-G, FACT-Lym, and TOI total scores were 5.0, 8.3, and 6.0, respectively. LymS change scores exceeded the MID for ≥90% of pts indicating a clinically significant improvement in lymphoma-related concerns at some point in the study. The median best change from baseline for the LymS was 5.0 and median time to improvement was 1.9 months.
Summary and Conclusions: PRO data indicate that clinically significant improvements in HRQL, including lymphoma-related concerns, were noted for most patients.

P446

DROPLET PCR: A NEW SENSITIVE METHOD FOR DETECTING BRAFV600E MUTATION IN HAIRY CELL LEUKEMIA

S Galimberti[1,*] F Guerrini[1], V Mannocci[1], E Ciabatti[1,2], S Grassi[1], MR Metelli[3], M Del Re[4], M Petrini[1]
[1]clinical and experimental medicine, hematology, pisa, [2]GenOMEC, University of Siena, Siena, [3]AOUP, hematology, [4]clinical and experimental medicine, clinical pharmacology, pisa, Italy

Background: Hairy cell leukemia (HCL), that represents approximately 2% of all leukemias, is an indolent lymphoproliferative disease with complete response (CR) rates higher than 80% and long-term survival accounting more than 70% of patients receving rituximab plus 2CdA. In the last recent years, the application of the deep sequencing thechniques allowed to detect the BRAFV600E mutation in up to 100% of the HCL patients, indicating a constitutive activation of the RAF-MEK-ERK pathway. This mutation is also useful for the differentiating HCL cases from other indolent lymphomas, including the splenic marginal-zone or unclassifiable splenic lymphomas or leukemias, that are BRAF unmutated. Different authors described several available molecular techniques for detection of the BRAF mutation: a) the Sanger sequencing, with a sensitivity of 1-5%% (Arcaini L); b) the pyrosequencing, which has a sensitivity of 5% (Laurini JA, Verma S); c) a specific quantitative real-time PCR, with a sensitivity of $2x10^{-4}$ (Schnittger S, Tiacci E).
Aims: The aim of the study was to compare different molecular techniques (real-time PCR and droplet PCR) and their sensitivity/specificity in a series of 40 patients affected by splenic merginal lymphoma and HCL.
Methods: In this study, we assessed 20 untreated cases with splenic marginal lymphoma and further 20 HCL patients by a specific real-time PCR for the BRAFV600E mutation (qBiomarker Somatic Mutation PCR assays BRAF_476, SABiosciences), and by a newer PCR technique: the droplet PCR (PrimePCR™ ddPCR™ Mutation Assay: JAK2 WT for p.V617F, Human- Biorad).
Results: Our HCL patients received R-2CdA, achieved 75% of CR, being the CR the best response for 83% of patients. The 5-year overall survival was 87%, and PFS 66%. All patients, except one HCL case, showed the IgH clonality; as reported even by our group, the sensitivity of this method ranges from $1x10^{-3}$ to $1x10^{-4}$, and this rearrangement was useful for confirming the infiltration of the assessed bone marrow samples. When the same samples were tested for the BRAF mutation by the real-time PCR, all marginal cases resulted wild-type, whereas the mutation was detected in 15 cases (75%) of the HCL patients. The negative case by the IgH resulted mutated by the droplet PCR. Sensitivity tests have been performed for both techniques, diluting a mutated DNA with a pool of wild-type DNAs, from 1x10 to $5x10^{-4}$. The sensitivity of the real-time PCR was $1x10^{-4}$, whereas that of the droplet PCR was $5x10^{-5}$, thus proving that the droplet PCR has got a sensitivity higher than half log. Moreover, the real advantage of the droplet PCR was the possibility of the absolute quantitation of the mutated alleles without necessity of a reference curve, that, at the contrary, is fundamental in the real-time PCR. Twelve HCL cases have been then monitored during the follow-up. At the end of therapy, the droplet PCR showed that the molecular tumor burden reduced of about 2 logs in the whole series; in all cas-

es achieving the CR, the mutation burden reduced, both by real-time and by droplet PCR; in 2 relapsed patients, the RAF mutated allele burden increased; nevertheless, we were not able to predict the relapses, because samples were harvested in concomitance of relapse.
Summary and Conclusions: In conclusion, we demonstrated that the droplet PCR could represent a valid tool either for differential diagnosis of HCL, or for monitoring HCL patients after treatment, including vemurafenib. It is also to consider that costs of this technique are comparable to those of the real-time PCR and that both methods are rapid and exportable in the routinary diagnostic activity.

P447

MINIMAL RESIDUAL DISEASE ANALYSIS BY NEXT-GENERATION SEQUENCING IN BLOOD SERUM FOLLOWING IDIOTYPIC VACCINATION IN PATIENTS WITH RELAPSED FOLLICULAR LYMPHOMA

M Bendandi[1,*] N Langford[2], V Carlton[3], L Weng[3], D Tuse[4], V Klimyuk[5], M Faham[3], JB Ransohoff[6], N Ku[2]
[1]Ross University School of Medicine, Portsmouth, Dominica, [2]DAVA Oncology, Dallas, [3]Sequenta, Inc., South San Francisco, [4]DT Consulting, Sacramento, United States, [5]ICON Genetics GmbH, Halle, [6]Bayer Innovation GmbH, Leverkusen, Germany

Background: A clinical trial was conducted to assess the safety of a plant-based idiotype vaccine in patients with relapsed follicular lymphoma (FL).
Aims: In a correlative analysis, serum samples from patients vaccinated in this study were subjected to minimal residual disease (MRD) assessment using a next-generation sequencing method, termed the LymphoSIGHT™ platform, to evaluate correlations with disease progression.
Methods: The 11 patient cohort was comprised of pretreated, relapsed patients who had not received rituximab in the 4 months prior to enrollment. Enrolled patients underwent lymph node biopsy to manufacture vaccine and received 4-6 months bendamustine-based salvage therapy without antiCD20 antibody followed by 4 months of observation off all therapy to allow for immune recovery. In patients remaining in CR, vaccinations were given monthlyx8 then bimonthlyx4. Serum samples were obtained at the end of observation prior to start of vaccine and collected prior to each vaccination through vaccine 6. MRD assessment was performed using Sequenta's LymphoSIGHT™ platform. Briefly, using universal primer sets, we amplified immunoglobulin heavy chain (IGH) and light chain (IGK) variable, diversity, and joining gene segments from genomic DNA. Amplified products were sequenced and analyzed using standardized algorithms for clonotype determination. Tumor-specific clonotypes were identified for each patient based on their high-frequency within the B-cell repertoire in the lymph node biopsy sample. The presence of the tumor-specific clonotype was then quantitated in serum samples obtained at specified post-vaccination time points. A quantitative and standardized measure of clone level per million leukocytes in each follow-up sample was determined using internal reference DNA.

Table 1. Summary of MRD assessment.

Key: +=positive response; -=negative response; ND=not determined.

Results: Of 11 lymph node biopsy samples screened, we detected a high-frequency clonal rearrangement in 10/11 (91%). Of these patients, the clonotype was also detected in the serum compartment in 4 of 10 (40%) patients at any post-vaccination time point (Table 1). Three patients progressed (T008, T010, T021) prior to completion of all 12 vaccinations; two of whom had positive MRD in the serum at 7 (T008) and 8 (T021) months prior to progression. Patients U001, T003, T006, U011, U016, U017 and T022 completed all 12 vaccinations and were clinically in remission for the 16 month duration of vaccination, suggesting that MRD should have remained negative for all of these patients. However MRD was detected in patients U001 and T006. Further follow-up will determine whether MRD positivity in these patients is indicative of early detection of relapse.
Summary and Conclusions: These proof of concept results demonstrate the application of sequence-based MRD analysis using cell-free samples in FL patients. MRD detection by sequencing is a promising method for assessment of disease status in FL patients, and ultimately, this method may be used as a substitute for repetitive imaging modalities. Future studies will define the optimal use of MRD analysis in prognosis and therapy of FL, as well as the potential role of vaccination strategies in disease control.

Baranov, Petrozavodsk, Russian Federation, [11]HCG Bangalore Institute of Oncology, [12]Narayana Hrudayalaya Hospitals, Bangalore, [13]Basavatarakam IndoAmerican Cancer Hospital & Research Institute, Hyderabad, [14]Ruby Hall Clinic, Maharashtra, [15]Omega Hospitals, Hyderabad, [16]The Karnatak Cancer Therapy and Research Institute, Karnataka, India, [17]Khmelnytskiy Regional Clinical Hospital, Khmelnytskiy, [18]State Cancer Institute, Kyiv, [19]State Institution Institute of Blood Pathology and Transfusion Medicine, Lviv, Ukraine, [20]CJSC BIOCAD, Moscow region, Russian Federation

Background: Approval of the first monoclonal antibody against CD20-antigen, rituximab, heralded the new era of targeted therapy in hematology. Today there are many companies all over the world which have rituximab biosimilar at different stages of development. BIORIX is among the first clinical studies to demonstrate clinical comparability of rituximab biosimilar to innovator rituximab in patients with indolent non-Hodgkin's lymphoma.
Aims: Evaluation of pharmacokinetics, pharmacodynamics, safety and efficacy of BCD-020 (rituximab biosimilar, BIOCAD, Russia) used as monotherapy in patients with indolent B-cell non-Hodgkin's lymphoma in comparison with the parameters of innovator rituximab (RTX).
Methods: 92 patients (aged 18 years and older with diagnosed CD20-positive follicular non-Hodgkin's lymphoma, stage II-IV by Ann Arbor, 1-2 histologic grade, or marginal zone lymphoma) were enrolled into the study. Patients were randomised in 1:1 ratio to receive 375 mg/sq.m of BCD-020 or RTX on days 1, 8, 15 and 22. The primary efficacy endpoint was overall response rate (ORR) at day 50±5. The secondary endpoints included proportion of patients with CR, PR, SD or PD, serum concentration of rituximab, absolute counts of CD20 and CD19-positive cells, as well as safety and immunogenicity.
Results: 72 patients with fNHL were included into the study (35 patients in BCD-020 arm, 37 – in RTX arm) as well as 20 patients with SMZL (11 patients and 9 patients, respectively). ORR on day 50±5 in both arms was equivalent: 39.52% in BCD-020 arm and 36.57% of patients in RTX arm (p=0.8250). The lower limit of 95% CI for difference in proportion of ORR between arms was -17.81% which exceeded predefined non-inferiority margin (-20%). CR was registered in 11.62% of the patients treated with BCD-020 and in none of patients from the reference arm (p=0.0555), CRu – in 2.32% and 2.43% (p=1.00), PR – 25.58% and 34.14% (p=0.4763), SD – in 51.16% and 48.78% (p=1.00), PD – 9.30% and 14.60% of patients respectively (p=0.5151). Within the first week after a single infusion of BCD-020 or RTX, the level of CD19 and CD20-positive cells rapidly decreased to almost undetectable values without any obvious recovery by day 50±5 (upon intergroup comparison p>0.05 at all specified time points). 90% CI for the geometric mean of a BCD-020/RTX AUC_{0-t} ratio fell within standard bioequivalence range 80-125% (80.1-118.2% for the ratio of AUC_{0-168} after a single dose and 81.2-124.8% for the ratio of AUC_{0-1176} after 4 doses). There were equal number of AEs in two arms; 78 AEs in BCD-020 arm and 73 AEs in RTX arm. Adverse events of any grade (by CTCAE v.4.03), which were associated with use of BCD-020 or RTX, were reported in 11 (23.91%) patients in BCD-020 arm and in 8 (17.39%) patients in RTX arm (p=0.6073). There were 4 cases of grade 3-4 AEs in each arm. Throughout the clinical study there were 2 SAEs in total, both in RTX arm (4.35%). In BCD-020 arm, there was one case of premature withdrawal due to AE (grade 4 neutropenia); in RTX arm there were two such cases, one of which was due to a SAE (death). Immunogenicity assessment did not detect the appearance of neutralizing antibodies to rituximab in BCD-020 arm as well as in RTX arm.

Summary and Conclusions: BCD-020 is non-inferior to RTX in terms of efficacy on day 50±5, with equivalent PK and PD profile and immunogenicity. BCD-020 was well tolerated, with the safety profile comparable with RTX parameters. CLINICALTRIALS.GOV IDENTIFIER: NCT01701232.

P449

OCCURRENCE OF CHRONIC THERAPY-RELATED HYPOGAMMAGLOBULINAEMIA IN INDOLENT NON HODGKIN LYMPHOMA: SINGLE CENTRE EXPERIENCE.

F De Angelis[1,*] ME Tosti[2], G Annechini[1], S Capria[1], GM D'Elia[1], P D'Urso[1], S Tricarico[1], A Pulsoni[1]
[1]Cellular Biotechnology and Hematology, Hematology "Sapienza" University Rome, [2]Centro Nazionale di Epidemiologia, Sorveglianza e Promozione della Salute, stituto Superiore di Sanità, rome, Italy

Background: The occurrence of Secondary Hypogammaglobulinaemia (SH) after immune and chemotherapic treatments represents a risk factor for infections in patients affected by indolent Non Hodgkin Lymphomas (NHLs). Although concerns have been expressed about the role of Rituximab, few data are available in literature about the insurgence of SH in patients who receive polichemiotherapy and immunotherapic regimens.
Aims: to investigate risk factors for SH development in patients with NHLs and normal Serum Immunoglobulin (SIg) level at baseline treated with chemotherapies with or without the addition of Rituximab.
Methods: We analyzed 266 patients (126 males, 140 female, median age 66.5 years) with diagnosis of indolent Non Hodgkin lymphomas (138 Follicular lymphoma, 36 Marginal Zone Lymphoma, 56 Small Lymphocytes lymphoma, 4 Mucosa Associated Marginal Lymphoma, 7 Mantle Cell Lymphoma with indolent course, 25 Non Hodgkin Lymphoma non other specified) at first diagnosis or with refractory-relapsed disease, treated with different chemotherapic schedules in our institute from 1993 to 2011. Stage of disease at diagnosis was III-IV in 243 (91.3%) and I-II in 23 (8.7%). One hundred and ten patients received CHOP (Cyclophosphamide, Doxorubicin, Vincristine, Prednisone) +\-Rituximab (R), 34 with CVP (Cyclophosphamide, Vincristine, Prednisone) +\- R, 105 with Fludarabine Based Schedules (Fbs) (Fludarabine-Cyclophosphamide, Fludarabine-Mitoxantrone, Fludarabine-Idarubicine-Cyclophosphamide)+\- R; 16 patients were treated with single agent therapies (Chlorambucil, oral Cyclophosphamide). R was added to CHOP or CVP in 75/144 cases and to Fbs in 64/105 cases. Seventy nine patients received both Fbs+/-R and CHOP/CVP +/-R during their clinical history for relapsed or refractory disease; Sixteen patients with early relapsed or refractory disease underwent to high dose chemotherapy followed by Autologous stem cells transplantation (ASCT).
Results: During a median follow up of 84 months (6-219), 45/266 (16.9%) patients developed a SH after a median time of 12 months (1-86) from treatment administration. Exposure to Fbs+\-R is associated with an Odds Ratio (OR) for SH development of 7.55 (CI:3.39-17-95,p <0.001); exposure to CHOP+\-R is not associated with SSH development, with OR of 0.83 (CI 0.40-1.69,p 0.59,). Similar value has been found for CVP+\-R, with a OR of 0.27 (CI0.3-1.15,p 0.066,). We found a significant higher risk of SH insurgence for ASCT procedure, with a OR of 4.33 (CI 1.28-13.9,p:0.09). Rituximab effect was evaluated comparing patients treated with CHOP-CVP without Rituximab *versus* R-CHOP/CVP and with Fbs alone *versus* R-Fbs, respectively: the addition of Rituximab was not associated with an increased risk of SH development both in CHOP/CVP *versus* R-CHOP/R-CVP (OR 0.43 [CI:0.12-1.43], p:0.12,) and Fbs *versus* R-Fbs group (OR 1.86 [CI 0.41- 11.54], p: 0.37). Median reduction of SIg concentration was of 52% (range 11-83); in 33/45 (73%) sIg dosage shows a mild impairment (SIg between 600 mg/dL and 400 mg/dL), while in 12/45 cases (27%) sIg value was inferior to 400 mg/dL. Recurrent non neutropenic infections were observed in 21/45 cases (46%).
Summary and Conclusions: Our experience underlines that therapy-related SH should be a potential side effect not yet well described; although risk-benefit ratio for Fbs is favourable in indolent NHL, we recommend an intensive SIg monitoring in patients exposed in order to early identify SH and reduce the incidence of infection episodes.

P450

PERIPHERAL BLOOD LYMPHOCYTE/MONOCYTE RATIO (LMR) >2 IS ASSOCIATED WITH BETTER OUTCOME IN FOLLICULAR LYMPHOMA (FL): A SINGLE CENTRE EXPERIENCE

A Belotti[1,*] E Doni[1], S Bolis[2], F Rossini[2], I Casaroli[3], S Pezzatti[2], L Verga[2], P Pioltelli[2], E Pogliani[2]
[1]Division of Hematology, [2]Ospedale San Gerardo – Università degli Studi Milano Bicocca, [3]Division of Hematology, Università degli Studi Milano Bicocca, Monza, Italy

Background: Whatch & wait (W&W) strategy is still an option even in the rituximab era for follicular lymphoma (FL). FLIPI2 risk criteria and GELF criteria are useful tools to identify candidate patients with low tumor burden for this approach. From a pathogenetic perspective the number and type of lymphocytes and monocytes/macrophages detectable in the peripheral blood and in the lymph nodes of patients with Hodgkin's and non-Hodgkin's lymphomas have been extensively studied and interesting results indicate they may possibly affect the pathogenesis and prognosis of these diseases. Moreover, peripheral blood lymphocyte to monocyte ratio (LMR) have been recently investigated as a new prognostic parameter in diffuse large B cell Lymphoma (DLBCL); the role of this ratio in FL in the rituximab era is unknown.
Aims: We wanted to investigate the prognostic impact of LMR in FL patients at diagnosis.
Methods: We retrospectively evaluated 132 FL patients (70 females, 62 males, median age 63 years) referred to our division from 2001 to February 2014. Ann-Arbor stages I/II and III/IV were, respectively, 31 patients and 101 patients. FLIPI2 risk classes were: low 50 patients (37%), intermediate 28 patients (6.8%), high 54 patients (41%). At diagnosis, W&W approach was performed on 42 patients (17 patients treated with radiotherapy to symptomatic nodes were included in this group, according to previous studies). Patients requiring chemotherapy were treated with rituximab-containing therapy (RCHOP, RCVP, RBM). Wilcoxon test applied to Kaplan-Meyer method was employed to estimate time to treatment start (TTTS), progression free survival (PFS) and overall survival (OS) of patients with different LMR at diagnosis.
Results: we analyzed different LMR cut-off values and we found that the most discriminative LMR was 2. LMR>2 was found in 97 patients, LMR<2 in 35 patients. Patients with LMR>2 had a longer TTTS, respect to patients with LMR<2 (medians 32 months *vs* 2 months, p=0.0096; see Figure 1). 92 patients were treated with Rituximab-chemotherapy (4 pts still on treatment), with an ORR of 97% (CR 75%, PR 22%). Outcome was superior in the LMR>2 group, compared to the LMR<2 group (2 years PFS 85% and 63%, respectively). No difference in OS were found between the two LMR groups.

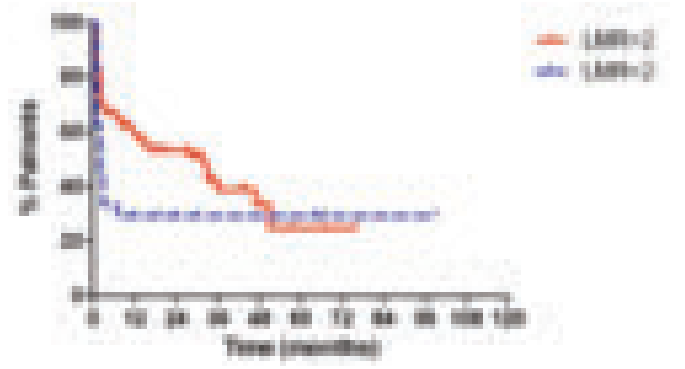

Figure 1. TTTS: time to treatment start.

Summary and Conclusions: LMR at diagnosis can be clinically relevant in patients with follicular lymphoma. In our experience, the majority of patients with LMR<2 required systemic Rituximab-chemotherapy in the first year from diagnosis, with a lower duration of response respect to patients presented with LMR>2 at diagnosis. As recently described in DLBC, this kind of surrogate biomarker of the immune microenvironment may have a prognostic role also in FL and data from perspective studies may help to better explore the exact clinical relevance of LMR. This ratio, easily derivable from WBC count may contribute at diagnosis in the definition of an appropriate follow-up timing for asymptomatic FL patients with low tumor burden. Considering the longer TTTS for patients with LMR>2, the use of this tool may better define selection of ideal candidates for W&W strategy, helping the clinician in transmitting notions to patients about W&W approach.

P451

THERAPEUTIC CONCEPTS AND OUTCOME OF MUCOSA-ASSOCIATED LYMPHOID TISSUE (MALT) LYMPHOMA OF THE OCULAR ADNEXA: A SINGLE-CENTRE EXPERIENCE

B Kiesewetter[1,*] J Lukas[2], A Kuchar[2], ME Mayerhoefer[3], B Streubel[4], H Lagler[5], L Muellauer[4], S Wöhrer[6], J Fischbach[1], M Raderer[1]
[1]Department of Internal Medicine I / Division of Oncology, [2]Department of Ophtalmology, [3]Department of Radiology, [4]Department of Pathology, [5]Department of Internal Medicine I / Division of Infectious Diseases and Tropical Medicine, [6]Department of Internal Medicine I / Division of Bone Marrow Transplantation, Medical University Vienna, Vienna, Austria

Background: Although several histological subtypes may occur, orbital marginal zone B-cell lymphoma (OAML) constitutes for the most frequent diagnosis in orbital lymphoma. Relatively little data, however, have been reported in larger cohorts of patients staged in a uniform way, and no randomised trials exist to put the currently data on local and systemic therapy into perspective.
Aims: In view of this, we have retrospectively analysed patients with OAML diagnosed and treated at our tertiary referral centre to assess clinical characteristics and treatment outcome of this relatively large cohort of Austrian patients.

Methods: We report our experience of 60 patients (33 female, 27 male) with OAML managed 1999-2012. Median age at diagnosis was 64 years (IQR 51–75) and follow-up time 43 months (IQR 16–92). All patients had undergone uniform extensive staging and histological diagnosis was made by a reference pathologist according to the WHO classification. This analysis had been approved by the Ethical Board of the Medical University Vienna.
Results: The majority presented with local disease *i.e.* stage IE according to Ann Arbor (n=40/60, 67%), one patient had stage IIE (2%), two patients stage IIIE (3%) and the remaining 17 (28%) stage IVE disease. Seven patients with stage IVE presented with bilateral orbital disease whereas the others showed involvement of further organs. Only one patient had bone marrow involvement. Treatment data were available in 58 patients. Local treatment with either radiotherapy (24%, 14/58) or surgical resection (5%, 3/58) resulted in complete or partial response (CR or PR) in 82% of patients (CR n=13, PR n=1). One patient had stable disease (SD), one progressive disease (PD) and one was lost to follow-up. However, a total of 8 patients needed consecutive further therapy. Median time to progression (mTTP) in this group was 38 months (IQR 24-53). The majority of patients (45%, 26/58) received first line systemic treatment with immuno-/chemotherapy regimens or therapy with CD20+ antibody rituximab and response rate was identical at 85% (CR n=16, PR n=6, SD n=2, PD n=1, no data n=1). Ten patients warranted further therapy after a mTTP of 16 months (IQR 9-31). Nine patients received antibiotics (doxycycline or clarithromycin) as initial therapy. Two patients achieved CR now ongoing for 6 and 83 months; response rate was 38% (PR n=1, SD n=3, PD n=2, no data n=1). Five patients needed further therapy after 1, 2, 4, 15 and 18 months respectively. Watchful waiting was the initial approach in 6/58 patients (10%), and 4 received systemic therapy after 17, 31, 22 and 86 months. The remaining two were lost to follow up. In total 28/58 patients (48%) progressed and were given at least one further line of therapy. Median TTP in this cohort was 20 months (IQR 9-39). No patient died during first line therapy. Kaplan Meier curve for progression free survival according to first line therapy was estimated but no significant difference in TTP after first line therapy was found (p=0.14, see Figure 1). Elevated β-2-microglobulin, plasmacytic differentiation, presence of autoimmune disorder and site of lymphoma were not associated with a higher risk for progress.

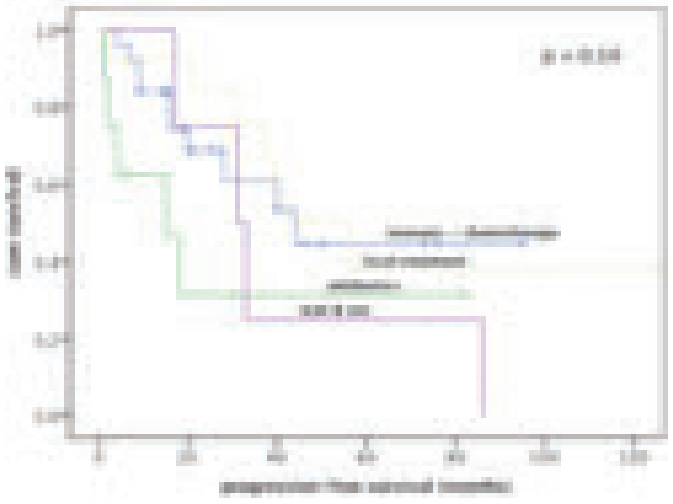

Figure 1.

Summary and Conclusions: Our data underscore the excellent prognosis of OAML irrespective of initial therapy, as there was no significant difference in time to progression and response between local or systemic therapy. In the absence of randomised trials, the least toxic individual approach should be chosen in patients with OAML.

P452

MANAGEMENT OF RELAPSED OR REFRACTORY FOLLICULAR LYMPHOMA PATIENTS IN DAILY PRACTICE: FINAL RESULTS OF THE OLYMPE FRENCH NON INTERVENTIONAL STUDY (ML20248)

P Brice[1,*] M Maynadié[2], P Franchi-Rezgui[1], M Hacini[3], G Laurent[4], E Suc[5], O Fitoussi[6], P Solal-Céligny[7], G Damaj[8], C Haioun[9], F Lazreg[10], D Pau[10], GA Salles[11], P Feugier[12]
[1]Hôpital Saint-Louis, Paris, [2]Hôpital du Bocage, Dijon, [3]Centre hospitalier de Chambéry, Chambéry, [4]Hôpital Purpan, Toulouse, [5]Clinique du Pont de Chaume, Montauban, [6]Polyclinique Bordeaux Nord, Bordeaux, [7]Institut de Cancérologie de l'Ouest, Nantes, [8]Groupe hospitalier Sud, Amiens, [9]Hôpital Henri Mondor, Créteil, [10]Medical Affairs, Roche France, Boulogne-Billancourt, [11]Hospices Civils de Lyon, Pierre Bénite, [12]CHU de Nancy, Nancy, France

Background: There are several unanswered questions on the management of relapsed or refractory (R/R) follicular lymphoma (FL) in the rituximab era. Optimal use of treatments (ttt) such as immunochemotherapy, stem cell transplantation, radioimmunotherapy or rituximab (R) maintenance remains to be clarified.
Aims: The Olympe study was set up to describe, in routine clinical practice, treatment modalities and response rates of R/R FL pt in a French cohort.
Methods: This prospective, multicenter, longitudal, non-interventional study was conducted in patients (pt) with histologically confirmed CD20+ relapsed FL (Grade 1 to 3a) eligible for ttt, regardless of what they had previously received. The primary endpoint was to describe ttt modalities in real life setting in pt treated for R/R FL. Main secondary endpoints included efficacy and safety. Analysis was performed on the total population and on subgroups according to the initiation or not of R maintenance therapy. Data on demographics were collected at inclusion visit while new ttt, efficacy and side effects were prospectively collected.
Results: From January 2007 to April 2013, 260 relapsed FL pt were registered and 241 were analyzed. Nineteen pt were excluded due to either inclusion criteria violation or missing data. At study entry, the median age was 61 years [30-87] and 54% of the pt were men, with Ann Arbor stage I/II (16%) or stage III/IV (84%). Most pt were in 1st relapse (n=143, 59%), and 24.5% of pt were R naive (33.6% in first relapse and 12.2% in 2nd and further relapse). Ttt at time of relapse consisted mainly in R with or without chemotherapy (respectively 74% and 21%), 5% of pt received a ttt without R (chemotherapy or radiotherapy). The median duration of this line of therapy was 3.4 months (mo) [0 – 19] and overall response rate was 52.4% for the whole cohort *(EHA 2010 – Feugier et al.).* Pt were followed-up for a median time of 4.1 years [0.2 – 6.0].
Forty pt did not enter the follow-up phase (31 for disease progression and 9 for premature withdrawal during induction period). Among the remaining 201 pt, 63% (127) received a maintenance ttt with R monotherapy for a median duration of 20 mo [0 – 29]. Disease progression occurred in 106 (44%) pt. Median PFS was 44 mo; it was 64 mo in pt in 1st relapse and 30 mo in pt in ≥2nd relapse (p<0.0001), it was 38 mo in pt without R maintenance and 63 mo in pt with R maintenance. Median OS was not reached and survival estimate at 6 years was 75% (80% in pt in 1st relapse and 67% in pt in ≥2nd relapse). Histologic transformation of FL was reported in only 5% (n=13) of the pt and 2% (n=4) died due to this transformation. A total of 58 (23%) pt died including 30 after the 1st progression: 38 deaths were not related to ttt (disease progression (26 pt), another neoplasy (11 pt), both disease progression and another neoplasy (1 pt), 6 were related to the ttt (all were infections: 2 septic shocks, 1 progressive multifocal leukoencephalopathy, 2 aspergillosis and 1 lung infection), and 14 pt died of causes that did not appear related to ttt or disease. Safety data showed that 166 (68%) pt had an adverse event, the most frequent were infections 47% (n=115) mainly: bronchitis (19%), lung infection (10%), herpes zoster (7%) and pyrexia (22%).
Summary and Conclusions: In France, R/R FL pt receive mainly induction ttt with immunochemotherapy. In the study population, 63% of responder pt received maintenance ttt with R monotherapy. In this difficult-to-treat population, median PFS was 44 mo. These results confirm EORTC 20981 study data in terms of PFS benefit. Safety data are consistent with the known safety profile of immunochemotherapy and R monotherapy, no new safety signal was discovered in this non interventional study.

P453

THE SECOND PRIMARY CANCER RISK AFTER NON HODGKIN LYMPHOMA IS NOT INFLUENCED BY THE SUBTYPE: DATA FROM THE FRENCH CANCER REGISTRIES NETWORK (FRANCIM)

C Rossi[1], J Jégu[2], M Mounier[3,*] M Dandoit[3], O Casasnovas[1], M Velten[2], X Troussard[4], A Monnereau[5], M Maynadié[3]
[1]Hematology, CHU Bocage Dijon, France, Dijon Cedex, [2]Epidemiology, Université de Strasbourg, Strasbourg, [3]Epidemiology, Université de Bourgogne, Dijon Cedex, [4]Epidemiology, Registre des hémopathies malignes de Basse-Normandie, Unité Fonctionnelle Hospitalo-Universitaire n° 0350, Centre Hospitalier Universitaire, Caen, [5]Epidemiology, Institut Bergonié, Bordeaux, France

Background: Non Hodgkin lymphoma (NHL) are known to be a greater risk of second primary cancer (SPC). However, little attention has been focused on SPC risk assessment according to NHL subtypes.
Aims: To determine the risk of second cancer in different NHL subtypes.
Methods: Data from 10 french population-based cancer registries were used to establish a cohort of patients with a first diagnosis of NHL between 1989 and 2004. Seven subtypes of NHL were analysed of NHL were analysed: diffuse large B cell lymphoma (DLBCL), follicular lymphoma (FL), lymphomaplasmocytic lymphoma (LPL), marginal zone lymphoma (MZL), mantle cell lymphoma (MCL), hairy cell leukemia (HCL), T-cell lymphoma. Standardized incidences ratios (SIRs) of metachronous SPC were estimated.
Results: Among the 7,546 patients diagnosed with a NHL, the overall SPC risk was 25% higher compared to the reference population (SIR=1.25; 95% CI 1.15-1.36). The SPC risk differed substantially by lymphoma subtype and was spread from SIR at 1.60 (95%CI 1.20-2.10) for MZL to a non-increased risk for HCL (SIR=0.92; 95% CI 0.61-1.34). Among 580 reported cases of SPC, 89%

were solid tumors and 11% were hematological malignancies. Interestingly, multivariate analysis showed that SPC risk did not differ significantly across NHL subtypes after adjustement on the other covariates (p=0.786).
Summary and Conclusions: NHL patients have an increased risk of SPC that is not influenced by the histological NHL subtype. The differences observed in univariate analysis across NHL subtypes may be due to differences in patients'characteristics.

P454

HEAVY/LIGHT CHAIN CHARACTERISTICS OF PATIENTS WITH INDOLENT AND AGGRESSIVE LYMPHOMAS

GE Pratt[1], O Berlanga[2], A Lokare[3], K Randall[3], S Lee[4], S Harding[2,*]
[1]School of Cancer Sciences, University of Birmingham, [2]The Binding Site Group Ltd, Birmingham, [3]University Hospitals Coventry and Warwickshire NHS Trust, Coventry, [4]University Hospitals Birmingham NHS Trust, Birmingham, United Kingdom

Background: Novel nephelometric immunoassays specific for heavy/light chain (HLC) have become available which allow accurate measurement of HLC subsets (IgGk, IgGl, IgAk, IgAl, IgMk and IgMl). The assays improve detection of serum monoclonal immunoglobulins (M-Ig) in plasma cell proliferative disorders. There are limited data on serum HLC in lymphoma patients.
Aims: To assess the use of HLC immunoassays to detect serum monoclonal component in patients with indolent and aggressive lymphomas.
Methods: The study included 145 patients assessed at Heartlands Hospital, Birmingham, UK. 91 patients had indolent lymphoma (41 follicular, 36 marginal, 10 Waldenstrom's macroglobulinemia (WM), 4 hairy) and 54 had aggressive lymphoma (45 diffuse large B-cell (DLBC), 9 mantle). HLC measurements using polyclonal antibody based immunoassays (The Binding Site, Birmingham, UK) were compared to published normal ranges (IgGk:4.03-9.78g/L; IgGl:1.97-5.71g/L; IgGk/IgGl:0.98-2.75; IgAk:0.48-2.82g/L; IgAl:0.36-1.98g/L; IgAk/IgAl:0.80-2.04; IgMk:0.29-1.82g/L; IgMl:0.17-0.94g/L; IgMk/IgMl:0.96-2.30) and to historic serum immunofixation (IFE), protein electrophoresis (SPEP) and free light chain (FLC) results.
Results: Overall 64/145(44%) patients had an abnormal HLC ratio (24 IgGk, 1 IgGl, 3 IgAk, 11 IgAl, 25 IgMk, 16 IgMl; 16 patients had more than one Ig class abnormal and in 2 patients all three Ig classes had an abnormal HLC ratio). By contrast, 45/145 (31%) patients were IFE positive and 38/145 (26%) were SPEP positive. 29/145 (20%) patients had an abnormal FLC ratio (28 FLCk, 1FLCl). Among the indolent lymphoma types, abnormal HLC ratios were observed in 17/41 follicular lymphoma patients (42%: 12 IgGk, 1 IgGl, 1 IgAl, 6 IgMk and 2 IgMl; 4(10%) patients had more than 1 Ig class abnormal); 16/36 marginal (44%: 3 IgGk, 4 IgAl, 4 IgMk, 9 IgMl; 5(14%) patients had more than 1 Ig class abnormal); 10/10 WM (100%: 4IgGk, 1 IgAk, 1IgAl, 6 IgMk, 4 IgMl; 5(50%) patients had more than 1 Ig class abnormal); and 0/4 patients with hairy lymphoma. By contrast IFE identified a M-Ig in 10/41 (24%) follicular, 12/36 (36%) marginal, 10/10 (100%) WM and 0/4 hairy lymphoma patients. Among the aggressive lymphoma types, abnormal HLC ratios were observed in 20/45 DLBC lymphoma patients (44%: 6 IgGk, 2 IgAk, 5 IgAl, 9 IgMk, 3 IgMl; 4(9%) patients has more than 1 Ig class abnormal) and in 1/9 patients with mantle cell lymphoma (11%: IgMl). IFE was positive in 11/45 (24%) DLBC and 2/9 (22%) mantle cell lymphoma patients. Indolent lymphoma patients with abnormal IgMk/l ratios displayed more frequently adverse disease characteristics including low haemoglobin (p=0.009), elevated B2-microglobulin (p=0.08) and bone marrow involvement (p=0.05). No correlation was found between age, LDH levels, stage of disease and HLC ratios.
Summary and Conclusions: HLC ratios are abnormal in a significant percentage of lymphoma patients, particularly those with indolent types; the M-Ig by HLC is predominantly IgM kappa. HLC may provide a useful means of detecting and monitoring M-Ig in lymphoma patients.

P455

R-CHOP THERAPY ALONE FOR LIMITED-STAGE FOLLICULAR LYMPHOMA: A RETROSPECTIVE STUDY

N Tomita[1,*] T Suzuki[2], Y Ishiyama[3], K Miyashita[4], H Takahashi[5], A Numata[6], S Ito[2], K Motohashi[6], T Tachibana[1], H Takasaki[5], R Kawasaki[4], M Hagihara[6], C Hashimoto[7], E Yamazaki[1], J Taguchi[2], K Fujimaki[4], R Sakai[5], S Fujisawa[6], S Motomura[5], Y Ishigatsubo[1]
[1]Internal Medicine and Clinical Immunology, Yokohama City University Graduate School of Medicine, Yokohama, [2]Hematology, Shizuoka Red Cross Hospital, Shizuoka, [3]Hematology, Yokosuka City Hospital, Yokosuka, [4]Hematology/Immunology, Fujisawa City Hospital, Fujisawa, [5]Medical Oncology, Kanagawa Cancer Center, [6]Hematology, Yokohama City University Medical Center, Yokohama, [7]Hematology/Oncology, Yamato Municipal Hospital, Yamato, Japan

Background: Limited-stage follicular lymphoma (FL) accounts for 10-30% of all FL cases. Irradiation therapy alone is a standard strategy for limited-stage FL, leading to a 10-year progression-free survival (PFS) rate of 30-50%. However, since 2001, as a primary policy, we have been administering irradiation therapy alone to patients with clinical stage (CS) 1 FL and R-CHOP therapy alone to patients with CS 2 FL.
Aims: To evaluate the treatment efficacy of R-CHOP therapy alone in limited-stage FL.
Methods: A total of 35 patients with newly diagnosed FL received R-CHOP therapy with curative intent between 2002 and 2009 in Yokohama City University Hematology Group. Where possible, patients who achieved partial response (PR) after the completion of the R-CHOP therapy received additional irradiation for any residual lesions. Maintenance therapy was not administered.
Results: The median age of the 35 patients (male, 14: female, 21) was 61 years (range, 25-89 years); 7 patients had in CS 1 FL, and 28 patients, CS 2 FL. The pathological grading of FL among the patients was as follows: FL grade 1 in 11 patients, grade 2 in 12, and grade 3 in 12. FL international prognostic indices were low in 30 patients, intermediate in 4, and high in 1. The median number of R-CHOP cycles was 6. On completion of the R-CHOP therapy, 33 patients achieved complete response (CR) and 1 showed PR. The patient showing PR after the completion of R-CHOP was administered additional irradiation. The remaining 1 patient was not evaluated because of discontinuation of hospital visit. The median follow-up period in the survival cases was 61 months. Four patients died: 2 died from lymphoma and the other 2 from pneumonia in the status of CR of lymphoma. In all the 35 patients, the 5-year PFS rate was 70%, and the 5-year overall survival rate was 92%. In the 15 patients with a PFS >5 years, only 1 patient showed disease progression. The 5-year PFS rates in patients with grade 1 or grade 2 FL and grade 3 FL were 84% and 47%, respectively (*P*=0.03). The 5-year PFS rate in patients with CS 1 and CS 2 FL were 80% and 67%, respectively (*P*=0.32) (Figure 1).

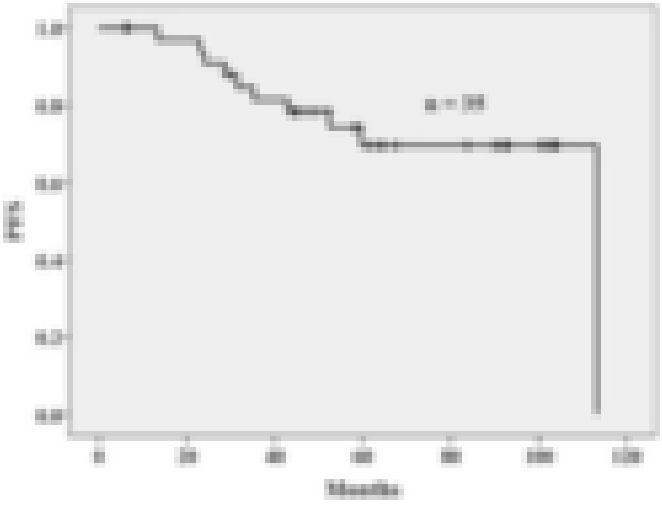

Figure 1.

Summary and Conclusions: The outcome of R-CHOP therapy alone in patients with limited-stage FL was at least equivalent to the reported outcome of irradiation therapy alone. The PFS curve almost plateaued after 5 years. Therefore, R-CHOP therapy could be an alternative to irradiation therapy in patients with limited-stage FL.

P456

PROGRESSION-FREE SURVIVAL AS A SURROGATE ENDPOINT FOR OVERALL SURVIVAL IN RELAPSED-REFRACTORY MANTLE CELL LYMPHOMA

A Amin[1,*] R Taylor[2], A Alonso[3], C Schwenke[4], M Gaudig[5], S Gaugris[6], H Welten[7], W Erhardt[8], G Roberts[1], M O'Leary[1], M Wasserman[9]
[1]Double Helix Consulting, London, [2]University of Exeter Medical School, Exeter, United Kingdom, [3]Maastricht University, Maastricht, Netherlands, [4]SCO:SSiS, Berlin, [5]EMEA Health Economics and Market Access, Janssen, Neuss, Germany, [6]Outcomes Research, Janssen, High Wycombe, United Kingdom, [7]Health Economics and Market Access, Janssen-Cilag BV, Tilburg, Netherlands, [8]Health Economics and Market Access, Janssen-Cilag GmbH, Neuss, Germany, [9]Double Helix Consulting, Singapore, Singapore

Background: Overall survival (OS) is becoming increasingly challenging to establish in clinical trials due to advancements in treatment regimens. As a result the use of other endpoints is becoming more important in making regulatory and funding decisions, specifically for oncology products.
Aims: The purpose of this research is to evaluate the potential for median progression-free survival (PFS) as a surrogate endpoint predicting median OS in relapsed and/or refractory (R/R) mantle cell lymphoma (MCL).
Methods: A systematic literature review was undertaken using MEDLINE and EMBASE, evaluating all clinical trials investigating treatments in adult R/R MCL.

Trials included in the analysis had to report median OS and median PFS. To minimise the risk of attrition bias, studies with substantial loss to follow up (*i.e.* >30%) were excluded. The level of surrogacy was quantified using Pearson and Spearman rank correlation statistics, and weighted least squares (WLS) regression using sample size weights. Correlation statistics were also evaluated within different patient subgroups.
Results: A total of 9 studies were identified in R/R MCL corresponding to 12 independent trial arms. Correlation statistics found a strong association between median PFS and median OS (Spearman=0.873; Pearson=0.660; 95% CI 0.100 to 0.903). WLS regression found a statistically significant relationship between median OS and median PFS (coef.=1.413; 95% CI: 0.271 to 2.555), however the low R^2, value (R^2=0.466) is likely due to a small sample size. Correlations within patient subgroups were tested, however, given the sample size no discernable conclusion can be drawn from statistics.
Summary and Conclusions: Median PFS seems to be an acceptable surrogate endpoint at the individual level, exhibiting a strong correlation with OS in this population of patients. Additional data may help to establish the statistical significance of these findings and further research is needed to assess the validity of PFS at the trial level as well, *i.e.*, to evaluate if the treatment effect on PFS can predict the effect of the treatment on OS.

Aggressive Non-Hodgkin lymphoma - Clinical 1

P457

FREQUENCY OF SURVEILLANCE COMPUTED TOMOGRAPHY IN NON-HODGKIN LYMPHOMA AND THE RISK OF SECONDARY PRIMARY MALIGNANCIES

SH Chien[1,*] CJ Liu[1], JP Gau[1], YW Hu[2], TJ Chiou[1], CH Tzeng[1]
[1]Division of Hematology and Oncology, Department of Medicine, [2]Cancer center, Taipei Veterans General Hospital, Taipei, Taiwan, Republic of China

Background: There is a worldwide growing concern about cancer risk of radiation exposure in medical imaging. With increasing usage of computed tomography (CT) for lymphoma patients with curative-intent treatment, development of secondary primary malignancy related to radiation from CT scans becomes an emerging issue in these long-term survivors.
Aims: To explore the risk of secondary primary malignancy (SPM) related to radiation exposure from CT scans in non-Hodgkin's lymphoma (NHL) patients under curative therapy.
Methods: We conducted a nationwide population-based study analyzing NHL receiving curative-intent treatment between January, 1997 and December, 2010. Dividing patient population into receiving more and fewer CT scans surveillance group according to the medium number of CT scans performed within one year after lymphoma diagnosis, we used the Kaplan-Meier method to compare the cumulative incidence of SPM in these two groups. Propensity score matching was applied to eliminate potential confounders. Group stratification and multivariate analysis under competing risk event was performed to identify independent predictors of SPM.
Results: A total of 4874 patients were enrolled and the medium number of CT scans is eight. Patients receiving **>**8 CT scans had a significantly 2-folds risk of developing SPM (hazard ratio [HR] 2.23, 95% confidence interval [CI] 1.60–3.11; p<0.001) than those with ≤8 and this significant difference was remained even after corrected by propensity scores. Figure 1 revealed the cumulative incidence of patients with more CT scans was higher than those with few significantly (P<0.001). Among 180 SPM identified, those receiving more CT scans had significantly higher SPM incidence in cancers of breast (HR 11.22, 95% CI 1.47–85.64; p=0.02), stomach (HR 5.22, 95% CI 1.17–23.23; p <0.03), and liver and biliary tract (HR 2.18, 95% CI 1.00–4.73; p=0.049) in comparison of those with fewer scans. The risk of SPM would increases 3% per one more CT scans performed.

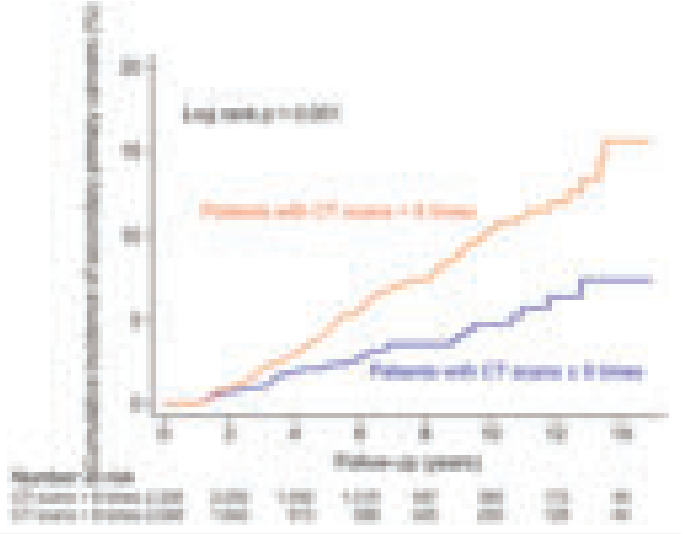

Figure 1.

Summary and Conclusions: Our study demonstrates NHL patients with curative-intent treatment receiving more frequently CT scans surveillance would increase risk of SPM compared to those with few. The incidence of secondary cancer origin from breast, stomach and liver is higher in patients with more CT scans. These sites are usually located at interface or overlapping area and receive double dose of radiation from two CT scans procedures. Physicians should assess the timing of CT scan more carefully and avoid over CT scans, especially in those with complete remission and high curable population.

Abstract withdrawn

P459

MYD88 (L265P) MUTATION IS AN INDEPENDENT PROGNOSTIC FACTOR IN PATIENTS WITH DIFFUSE LARGE B-CELL LYMPHOMA

C Fernández[1,*] M García[2], B Sánchez[3], MC Vela[2], S Pairet[1], L Camacho[1], E Gimeno[3], A Senín[3], C Besses[3], S Serrano[2], A Salar[3], B Bellosillo[2]
[1]Grup de Recerca Clínica Aplicada en Neoplàsies Hematològiques, [2]Pathology Department, [3]Hematology Department, Hospital del Mar-IMIM, Barcelona, Spain

Background: Somatic mutations in the myeloid differentiation primary response gene 88 (*MYD88)* have been described in B cell lymphomas. The leucine to proline exchange at position 265 (L265P) is the most recurrent and biologically potent *MYD88* variation, being found in about 30% of ABC-DLBCL, whereas is uncommon in GCB-DLBCL.
Aims: To study the occurrence of *MYD88* L265P mutation in adult patients with DLBCL and its relation to clinical and biological characteristics and patients' outcome.
Methods: A series of 175 patients with DLBCL diagnosed at our institution between 2000 and 2013 where included. Inclusion criteria where: full clinical data available, treatment with remission intention, enough material for DNA extraction and absence of HIV infection. The presence of *MYD88* L265P mutation was assessed by allele-specific oligonucleotides (ASO)-PCR in DNA samples extracted from FFPE tissue. Overall survival (OS) and progression-free survival (PFS) were calculated since the time from first treatment and according to standard definitions. Multivariate Cox regression was used to determine whether mutation remained independently predictive of PFS and OS after adjusting for clinical variables.
Results: *MYD88* L265P mutation was found in 17 out of 175 cases (10%) and occurred more frequently in males (*P*=.019), cases without B symptoms (*P*=.006) and those with primary extranodal disease (*P*=.02) such as central nervous system (50%), skin (33%) and testes (78%). Univariate analysis showed that *MYD88* L265P mutation (*P*=.001) and intermediate-high or high IPI (*P*=.001) where significantly associated to poor outcome and inferior OS (Figure 1), independently on the primary extranodal origin and the ABC phenotype through Hans' algorithm. For the whole cohort, the median follow-up time was 41 months (range, 2-171 months), with OS at 4 years of 69% and PFS at 4 years of 57%. A total number of 129 patients (74%) received rituximab plus CHOP or CHOP-like schedules, while the remaining cases received other treatments depending on their clinical requirements. We further analysed PFS in those cases treated with rituximab plus CHOP or CHOP-like. The resulting factors associated with high risk of progression were age ≥60 years (*P*=.026), advanced stage (*P*=.001), ECOG 2-4 (*P*=.002), high LDH (*P*=.001), albumin <30 g/L (*P*=.030), IPI intermediate-high or high (*P*<.0001) and *MYD88* L265P mutation (*P*=.011). Only IPI stage and *MYD88* mutation remained significantly associated with a higher risk of progression in the multivariate analysis (*P*<.0001 and *P*=.023, respectively) (Figure 1).

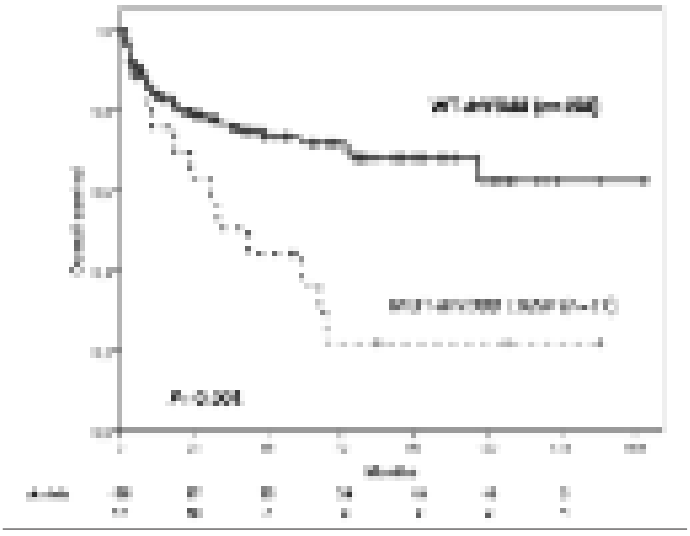

Figure 1.

Summary and Conclusions: Our study shows that *MYD88* L265P is associated with poor prognosis and, although these findings require further validation in prospective studies, suggests that detection of *MYD88* mutation might be useful to identify DLBCL patients at high risk of progression and death with independence of other well-known clinical prognostic factors.

P460

THE ADDITION OF RITUXIMAB TO CODOX-M/IVAC CHEMOTHERAPY IN THE TREATMENT OF BURKITT LYMPHOMA IS SAFE AND IS ASSOCIATED WITH INCREASED EFFICACY IN THE HIV POSITIVE POPULATION

F Alwan[1,*] A He[2], S Montoto[3], S Kassam[4], M Mee[5], F Burns[6, 7], S Edwards[8], A Wilson[3], M Tenant-Flowers[9], R Marcus[4], K M Ardeshna[5], M Bower[10], K Cwynarski[1]
[1]Department of Haematology, Royal Free Hospital, [2]Imperial College School of Medicine, [3]Department of Haemato-Oncology, St Bartholomew's Hospital, Barts Health NHS Trust, [4]Department of Haematological Medicine, King's College Hospital, [5]Department of Haematology, University College Hospital, [6]Department of HIV Medicine, Royal Free Hospital, [7]Research Department of Infection & Population Health, University College London, [8]Mortimer Market Centre, Central & North West London Foundation Trust, [9]Department of HIV and Sexual Health Medicine, King's College Hospital, [10]National Centre for HIV Malignancy, Chelsea & Westminster Hospital, London, United Kingdom

Background: Burkitt lymphoma (BL) is a rare, aggressive non-Hodgkin lymphoma (NHL), more prevalent in people living with HIV (PLWH) and an AIDS-defining illness. Treatment consists of intensive, short duration chemotherapy regimens such as CODOX-M/IVAC. In the HIV negative (HIV-) population the addition of rituximab improves survival. However, fears of increased toxicity have prevented its routine use in BL in PLWH despite toxicity not being seen in people who do not have HIV infection. Rituximab use in PWLH and other types of NHL results in increased overall survival (OS) but there are few well-populated studies looking specifically at HIV-related BL.
Aims: This retrospective study evaluated the effect of adding rituximab to CODOX-M/IVAC chemotherapy on treatment-related toxicity and efficacy in PLWH.
Methods: 91 patients (74 male) with HIV-related BL, treated in five London treatment centers (Chelsea & Westminster, St Bartholomew's, University College, Royal Free & Kings College Hospitals) between 2003 and 2013, were identified from local databases. Toxicity was assessed according to the EORTC Common Toxicity Criteria version 2.0.

Table 1. Frequency of toxic events during each cycle of chemotherapy.

Figure 1. Kaplan-Meier estimator for overall survival when comparing treatment.

Results: 49 patients received CODOX-M/IVAC and 42 R-CODOX-M/R-IVAC with a median of six doses of rituximab. There was no significant difference in baseline characteristics between groups. All patients received opportunistic infection prophylaxis and combination antiretroviral therapy (cART) during lymphoma treatment. The median follow up is 41 months (3-109). At BL diagnosis the median CD4 count was 244 cells/µl (0-864), 35% were established on cART and 2% had undetectable plasma HIV viral loads. Toxicity Whilst infections were common with all but three patients receiving IV antibiotics at some stage, opportunistic infections were infrequent. There were two confirmed and one suspected fungal chest infections, all in patients receiving R-CODOX-M/R-IVAC. There were five cases of CMV reactivation requiring treatment in three patients receiving R-CODOX-M/R-IVAC and 2 receiving CODOX-M/IVAC. The addition

of rituximab did not confer any significant increase in grade 3/4 toxicity such as infections, mucositis, diarrhea, renal impairment and tumor lysis syndrome. There was also no significant increase in bone marrow suppression with a similar length of neutropenia and GCSF use in both groups. Comparative measurements of HIV viral load, CD4 count, hemoglobin, platelet and white cell counts during and after treatment were not significantly different. There was no significant increase in inpatient hospital stay (94 *vs.* 103 days, p=0.58). Survival Sixty patients were alive at last follow-up. The two-year overall survival is 68%. The overall survival is greater for patients receiving rituximab (2 year OS 72% (95%CI: 0.22-0.92, hazard ratio 0.46) *vs.* 55% (95%CI: 1.1-4.5, hazard ratio 2.2) (logrank p=0.04). Of the 31 deaths, six were due to sepsis during chemotherapy (x4 CODOX-M/IVAC, x2 R-CODOX-M/R-IVAC), 15 from progressive disease, four from disease relapse and two were HIV-related. Four deaths were unrelated to treatment of which two occurred while the patients were in complete remission. There was no significant difference in toxic deaths or disease relapse between groups (p =0.137) (Table 1 and Figure 1).
Summary and Conclusions: This study suggests that HIV-related BL should be treated with the same chemotherapeutic approach as people who do not have HIV infection. The addition of Rituximab is safe, does not increase toxicity and confers a significant survival benefit when compared to CODOX-M/IVAC chemotherapy alone.

P461

PHASE 2 STUDY OF IBRUTINIB IN RELAPSED OR REFRACTORY MANTLE CELL LYMPHOMA: UPDATED SAFETY ANALYSIS ON PREVALENCE OF INFECTION, DIARRHEA, AND BLEEDING OVER TIME

S Rule[1,*] ML Wang[2], P Martin[3], R Auer[4], BS Kahl[5], W Jurczak[6], RH Advani[7], J Romaguera[1], M Williams[8], JC Barrientos[9], E Chmielowska[10], JA Radford[11], S Stilgenbauer[12], V Truong[13], M Chang[13], DM Beaupre[13], A Goy[14], KA Blum[15]
[1]Department of Haematology, Derriford Hospital, Plymouth, United Kingdom, [2]Department of Lymphoma/Myeloma, The University of Texas MD Anderson Cancer Center, Houston, [3]Division of Hematology-Oncology, Weill Cornell Medical College, New York, United States, [4]Department Haemato-oncology, Barts Health NHS Trust, London, United Kingdom, [5]Department of Medicine-Hematology/Oncology, University of Wisconsin, Madison, United States, [6]Department of Haematology, Jagiellonian University, Krakow, Poland, [7]Department of Medicine, Division of Oncology, Stanford University Medical Center, Stanford, [8]University of Virginia School of Medicine, Charlottesville, [9]CLL Research and Treatment Program, Division of Hematology and Medical Oncology, Department of Medicine, Hofstra North Shore-LIJ School of Medicine, Hempstead, United States, [10]Oddzial Kliniczny Onkologii, Centrum Onkologii, Bydgoszcz, Poland, [11]The University of Manchester and the Christie NHS Foundation Trust, Manchester, United Kingdom, [12]Universitatsklinikum Ulm, Klinik fur Innere Medizin II, Ulm, Germany, [13]Pharmacyclics, Inc., Sunnyvale, [14]John Theurer Cancer Center at Hackensack University Medical Center, Hackensack, [15]The Ohio State University, Columbus, United States

Background: Bruton's tyrosine kinase (BTK) is a central mediator of B-cell receptor (BCR) signaling essential for B-cell development and function. Ibrutinib, a first-in-class oral BTK inhibitor, induces apoptosis and inhibits migration and adhesion of malignant B-cells. The phase 2 PCYC-1104 trial showed that ibrutinib was active in relapsed/refractory mantle cell lymphoma (MCL) with an overall response rate of 68% (21% complete response [CR]), durable responses, and a favorable safety profile with a low (8%) rate of discontinuation due to adverse events (Wang *et al.*, *N Engl J Med.* 2013). Since responding patients may receive continuous ibrutinib treatment for prolonged periods, further safety analysis was performed to characterize the pattern of adverse events (AEs) with longer term therapy.
Aims: To evaluate changes in prevalence and severity of infection, diarrhea, and bleeding events over time in the PCYC-1104 study population.
Methods: Patients had relapsed or refractory MCL with measurable disease, and provided written informed consent. Ibrutinib 560 mg PO QD was administered continuously until disease progression or unacceptable toxicity. Safety assessments included monitoring and recording of AEs including serious AEs (SAEs), and measurements of protocol-specified laboratory parameters. AEs were characterized by preferred terms using MedDRA version 16.1, and were evaluated over 6-month time intervals (1–6, 7–12, 13–18, 19–24, >24 months). Prevalence was based on the number of patients with an AE occurring during a given interval (either a new episode or an ongoing episode from the prior 6-month period continuing into the current interval).
Results: Safety data are reported for 111 treated patients. Median time on study was 27 months and median treatment duration was 8 months; 46% of patients were treated for >12 months and 26% continue on treatment. Prevalence rates for all grade infection were 69% for the first 6 months and gradually declined thereafter. One SAE of infection occurred beyond 24 months in the current analysis. Overall, patients achieving CR had a lower incidence rate of grade ≥3 infection than non-CR cases. No substantial changes in serum immunoglobulin (Ig) levels (IgA, IgG, IgM) were observed over time. Median times to onset and resolution of diarrhea, one of the more commonly reported AEs with ibrutinib, were 8 and 5 days, respectively. Prevalence rates for diarrhea were highest in the first 6 months (44% all grade; 4.5% grade ≥3; 1% SAE) and decreased thereafter. No SAE of diarrhea occurred after 6 months of therapy. There were no reported cases of colitis. Overall, bleeding events including bruising of any grade occurred in 51% of patients. Prevalence rates for all-grade bleeding were highest (41%) during the first 6-month time interval, decreasing thereafter (14% at more than 24 months). Major bleeding (protocol specified) occurred with a prevalence of less than or equal to 5% during each interval.
Summary and Conclusions: Analysis of longer term safety data related to infection, diarrhea, and bleeding demonstrates that the prevalence rates of these AEs did not increase with continuous ibrutinib therapy. Prevalence of infection and diarrhea generally decreased over time, and prevalence of bleeding events remained stable throughout the course of the study, with the major bleeding rate ≤5%. These results further elucidate the safety profile of ibrutinib in patients with relapsed/refractory MCL.

P462

THE BRUTON'S TYROSINE KINASE (BTK) INHIBITOR ONO-4059: PROMISING SINGLE AGENT ACTIVITY IN PATIENTS WITH RELAPSED AND REFRACTORY NHL

F Morschhauser[1,*] L Terriou[1], M Dyer[2], C Hutchinson[2], S Rule[3], N Shah[3], G Salles[4], L Karlin[4], C Fegan[5], J Bagshawe[5], G Cartron[6], H Honda[7], A Nishimura[7], J Sharpe[7], T Ohno[7], T Yoshizawa[8], T Yasuhiro[8], J Birkett[7]
[1]CHRU-Hôpital Claude Huriez, Lille, France, [2]Leicester Royal Infirmary, Leicester, [3]Derriford Hospital, Plymouth, United Kingdom, [4]Centre Hospitalier Lyon Sud, Pierre Benite, France, [5]University Hospital of Wales, Cardiff, United Kingdom, [6]CHU - St Eloi, Montpellier, France, [7]ONO Pharma UK Ltd, London, United Kingdom, [8]ONO Pharmaceutical CO.,LTD, Osaka, Japan

Background: Bruton's tyrosine kinase (BTK) is a critical kinase involved in B-cell receptor signal transduction. ONO-4059, a highly potent and selective oral BTK inhibitor has demonstrated anti-tumour activity in pre-clinical models (Yasuhiro *et al.*, AACR2013) and in the clinic in both NHL and CLL patients (Salles *et al.*, ASH 2013; Rule *et al.*, ASH 2013). Here, we present data from NHL patients enrolled in the ongoing Phase I study ONO-4059POE001.
Aims: Thirty three (33) patients with relapsed (n=16) or refractory (n=17) NHL were administered ONO-4059 as monotherapy, given once daily (QD) at doses ranging from 20-480mg (6 Cohorts), to determine safety, pharmacokinetics and pharmacodynamics, as well as any preliminary efficacy. Patients can receive ONO-4059 for up to a maximum of 2 years and upon completion of the first 6 months of treatment, intra-patient dose escalation is permitted. Patients had a median age of 63 yrs [range 28-88], median of 4 prior therapies [2-10], a median baseline tumour burden of 3,236mm^2 [619-19,509mm^2], with 31/33 patients (94%) having prior exposure to a rituximab-containing regimen and 11/33 patients (33%) who had prior ASCT.
Results: Thirty three (33) patients were evaluable for safety and 31 patients for efficacy. ONO-4059 was found to be well tolerated with a total of sixty eight (68) ONO-4059-related G1-2 adverse events (CTCAE-V4.0) reported in 19 patients. Eight ONO-4059-related G3 events were reported in 6 patients (thrombocytopenia and anaemia in 1 patient [20 mg], proteinuria and hematuria in 1 patient [320 mg], lymphopenia [160 mg], neutropenia and anaemia [320 mg], and adverse drug reaction (maculopapular rash etc.) [480 mg]. One ONO-4059-related G4 event was reported (allergic reaction [320 mg]). The events of allergic reaction (320mg) and maculopapular rash (480mg) were reported as SAEs. Responses occurred from doses of 40mg upwards. Thirty one (31) eligible patients show a best overall response rate of 42% (13/31) with 13 PR (median reduction of lymph nodes was 84.4% [52.4 - 96.1%]), which include 4 refractory patients (3 ABC-DLBCL and 1 MCL), 7 SD and 11 PD. Of note, in a sub-set of 12 ABC-DLBCL patients (all WT for CD79b), 7 have achieved PR (of which 3 were refractory) resulting in a best ORR of 58% (median reduction of lymph nodes was 80.2% [52.4%-96.1%]) Of the 8 evaluable MCL patients, 4 have achieved PR (of which 1 was refractory) resulting in a best ORR of 50% (median reduction of lymph nodes was 86.1% [84.4%-92.4%]). The pharmacokinetics of ONO-4059 reflects a half-life of ~5-7 hours with sustained inhibition of BTK observed in PBMCs up to 24 hours from first dose.
Summary and Conclusions: ONO-4059 showed a very favorable safety profile along with promising preliminary efficacy in this difficult-to-treat patient population, most notably encouraging responses observed in ABC-DLBCL and MCL patients. The study is ongoing with additional dose escalation cohorts underway.

P463

APOPTOTIC POLYMORPHISMS ARE INVOLVED IN AGGRESSIVENESS AND PROGNOSIS OF DIFFUSE LARGE B-CELL LYMPHOMA

A Borsarelli Carvalho Brito[1,*] C Oliveira[1], MT Delamain[2], EC Miranda[2], CA de Souza[2], J Vassallo[3], CSP Lima[1]
[1]Department of Internal Medicine, [2]Haematology and Haemotherapy Centre, [3]Laboratory of Molecular and Investigative Pathology, Faculty of Medical Sciences, University of Campinas, Campinas, Brazil

Background: Apoptosis plays a key role in non-Hodgkin lymphoma (NHL)

development. BCL-2 family members are crucial regulators of apoptosis, and include the anti-apoptotic *BCL-2* gene and the pro-apoptotic *BAX* gene. The ability to induce apoptosis of damage cells is variable in humans, since several proteins enrolled in process are encode by genes with single nucleotide polymorphisms (SNPs). The variant A allele of the *BCL2* C(-717)A SNP was related to higher expression of the encoded protein compared to the C wild allele. The G wild allele of the *BAX* G(-248)A SNP was associated with higher protein level in some studies but with lower transcriptional activity in others, when compared with the variant A allele. However, their roles in diffuse large B cell lymphoma (DLBCL) are still not clear.

Aims: This study aimed to evaluate whether the SNPs *BCL2* C(-717)A and *BAX* G(-238)A influence the risk, clinical manifestation and outcome of DLBCL patients.

Methods: Our prospective analysis included 135 consecutive DLBCL patients at diagnosis seen at the Haematology and Haemotherapy Centre, from December 2007 to February 2014 and 240 healthy subjects matched to patients by age, gender and race. Median age of patients was 57 years old (range: 17-89); 95 patients (70.4%) had B symptoms, 26 patients (19.2%) had bone marrow involvement (BMI), 61 patients had higher lactate dehydrogenase (LDH) values (45.2%), 15 (11.1%) patients had high risk disease (IPI 4 and 5), and 50 (37.0%) patients had stage IV tumors. Patients received 6 cycles of R-CHOP as treatment. Genomic DNA from peripheral blood of all patients and controls was analyzed by polymerase chain reaction followed by enzymatic digestion for discrimination of distinct SNPs genotypes. Multivariate analysis using the logistic regression model served to obtain age, gender and ethnic origin adjusted odds ratios (ORs) with 95% confidence intervals (95% CIs), and to assess the associations between genotypes and DLBCL. Overall survival (OS) was calculated using the Kaplan-Meier estimate probabilities, and differences between survival curves were analysed by the log-rank test.

Results: The frequencies of *BAX* GG and *BCL-2* CA+AA genotypes were higher in patients than controls (83.7% *versus* 77.9% and 77.8% *versus* 70.0%), respectively. However, only a tendency for statistical significance of differences could be found in study (P=0.06 and P=0.05), reflecting a trend increased risk of 1.81 and 1.63 for DLBCL in individuals with the respective genotypes. When only patients were analyzed, an excess of the *BAX* GG genotype was seen in patients with stage IV tumors compared with those with tumors of I+II+III stages (94% *versus* 80%, P=0.04). The median time of observation of patients enrolled in the study was 20 months (range: 1-68). On univariate analysis, presence of B symptoms (68% *versus* 86%, P=0.04) and BMI (52% *versus* 78%, P=0.004), high levels of LDH (69% *versus* 80%, P=0.02), disease of high risk (52% *versus* 87%, P=0.003), and stage IV (64% *versus* 83% P=0.01) were predictive of worse outcome of DLBCL patients at 24 months of follow up. In addition, patients with *BCL2* -717 CA+AA genotype (68% *versus* 88%, P=0.04) had worse outcome at 24 months of follow up.

Summary and Conclusions: The data present, for the first time, preliminary evidence that inherited abnormality in intrinsic pathway of apoptosis, related to the *BCL2* C(-717)A and *BAX* G(-238)A SNPs, influence the aggressiveness and outcome of DLBCL patients treated with conventional chemotherapy regimen.

Background: Virtually all aggressive lymphomas are 2-deoxy-2-(^{18}F)fluoro-D-glucose positron emission tomography (^{18}FDG-PET) positive. It has been firmly established that negative midtreatment and end-of-treatment ^{18}FDG-PET scans after chemotherapy with or without Rituximab confer an excellent long term prognosis. A favourable prognostic value of a negative pretreatment ^{18}FDG-PET scan is generally assumed, but not substantiated by a large background of data. The Positron Emission Tomography Guided Therapy of Aggressive Non-Hodgkin's Lymphomas (PETAL) trial was initiated to resolve the question whether a change in treatment protocol may improve the outcome of patients with a positive midtreatment ^{18}FDG-PET scan (EudraCT-Nr.: 2006-001641-33). In the PETAL trial, patients with a negative pretreatment ^{18}FDG-PET scan were registered but treated off-protocol according to the physician's discretion.

Aims: This companion study to the PETAL trial aimed at establishing the frequency of negative pretreatment ^{18}FDG-PET scans within a large aggressive lymphoma cohort, encompassing the base line patient's characteristics in pretreatment ^{18}FDG-PET negative and positive patients, recording treatment practice in pretreatment ^{18}FDG-PET negative individuals and gathering information about the long term outcome of these patients.

Methods: Patients with a negative pretreatment ^{18}FDG-PET scan were identified in the PETAL database. The protocol for this study was approved by the German Federal Institute for Drugs and Medical Devices and institutional review boards. Participants provided signed informed consent before enrollment. Information about patient's baseline characteristics, treatment provided and survival status were retrieved and analysed with the SAS software data suite. This analysis of the pretreatment ^{18}FDG-PET negative patients is an explorative additional analysis.

Results: 1075 patients were registered in the PETAL-trial, 80 of whom had a negative pretreatment ^{18}FDG-PET scan (7,4%). More males than females were found in the pretreatment ^{18}FDG-PET negative group (56 *vs.* 24, p=0.03, Fisher's exact test). 11 (13,8%) were diagnosed with aggressive T- cell lymphomas, 69 (86,2%) with diffuse large B-cell-lymphoma or follicular lymphoma grade 3 a/b (^{18}FDG-PET positive patients: 99 (9,7%) aggressive T-cell lymphomas, 928 (90,3%) diffuse large B-cell-lymphomas or follicular lymphomas grade 3 a/b). For pretreatment ^{18}FDG-PET negative and positive patients median age was 60,7 and 57,8 years, respectively (p=0,45, Wilcoxon-test). A favourable International Prognostic Index (IPI) category of 0, 1 or 2 was observed in the majority of pretreatment ^{18}FDG-PET negative patients (69), two patients had an unfavorable IPI of 3 (data pending for nine patients). Eight patients received less than six cycles of Cyclophosphamide, Doxorubicin, Vincristin, Prednisone (CHOP) or Rituximab (R)-CHOP. One Patient received three cycles of R-Bendamustine and, at relapse, six cycles of R-CHOP. At a median follow up of 530 days, overall survival was 93.8% (75/80). Three patients died from lymphoma relapse. Two patients died following a cardiovascular or cerebrovascular event. The three relapsed patients received less than six cycles of R-CHOP as first line therapy.

Summary and Conclusions: Patients with aggressive lymphomas and a negative pretreatment ^{18}FDG-PET scan appear to have an excellent prognosis and a low rate of disease recurrence. Relapse and subsequent death from lymphoma occurred only in patients treated with less than six cycles of R-CHOP. Thus, treatment de-escalation in pretreatment ^{18}FDG-PET scan negative patients is not recommended outside a clinical trial.

BRENTUXIMAB VEDOTIN IN REFRACTORY OR RELAPSED PERIPHERAL T-CELL LYMPHOMA: THE FRENCH NAME PATIENT PROGRAM EXPERIENCE IN 65 PATIENTS

L Mathilde[1,*] A Contejean[2], C Bossard[3], M Parrens[4], M Fournier[5], S Pallardy[5], F Morschhauser[6], R Bouabdallah[7], G Salles[8], H Tilly[9], P Brice[2], R Delarue[10], C Haioun[11], P Gaulard[12]

[1]Hematology, Institut Imagine, [2]Hematology, Hôpital Saint-Louis, Paris, [3]Anatomopathology, Centre Hospitalier Universitaire de Nantes, Nantes, [4]Anatomopathology, Hôpital Haut-Leveque, Pessac, [5]LYSARC, LYON, [6]Hematology, Centre Hospitalier Régional Universitaire de Lille, Lille, [7]Hematology, Institut Paoli Calmettes, Marseille, [8]Hematology, Hospices Civils de Lyon, Lyon, [9]Centre Henri Becquerel, Rouen, [10]Hematology, Hôpital Necker, Paris, [11]Hematology, [12]Anatomopathology, Hôpital Henri Mondor, Créteil, France

Background: Outcome of patients with peripheral T-cell Lymphoma (PTCL) in first relapse or refractory is poor with an overall survival of 6.7 months (Mak V, JCO 2013). Brentuximab Vedotin (BV) is an antibody drug conjugate directed against CD30. Its efficacy was demonstrated in a phase 2 study in patients with relapsed or refractory systemic anaplastic large cell lymphoma (ALCL), with an

overall response rate of 86% and a complete response rate of 57% (Pro B, JCO 2012). ALCL is characterized by a strong and uniform CD30 expression, but little is known about the efficacy of BV in other T-cell lymphoma subtypes with different CD30 expression levels.

Aims: The aim of the study was to investigate the efficacy of BV in patients with relapsed or refractory PTCL.

Methods: Before drug approval, from March 2011 to January 2014, 74 patients were treated in France in a compassionate patient program for recurrent T-cell lymphoma. Diagnosis was confirmed for 65 patients after histopathologic review, according to the 2008 WHO classification. Central review and CD30 immunostaining (with monoclonal mouse anti-Human CD30, Clone Ber-H2, Dako) were performed.

Results: Characteristics of the 65 patients with histological review, before BV treatment, are summarized in Table 1. The median follow-up was 13.4 months [range 0.4-28.9]. Patients were treated for: ALCL (n=24): ALCL ALK- (n=14) and ALCL ALK+ (n=10); systemic PTCL (n=22): PTCL NOS (n=12), adult T-cell leukemia/lymphoma (n=4), enteropathy-associated T-cell lymphoma (n=4), and angioimmunoblastic T-cell lymphoma (n=2); and primary cutaneous lymphoma (n=19): Mycosis Fungoides/Sézary syndrome (n=11) and cutaneous CD30+ T-cell lymphoproliferative disorders (n=8). CD30 was scored as >75%, 10-70% and undetectable (<5%) in respectively 48.8%, 30.2% and 21% of the tested cases. At the time of initiation of BV, 36 patients were refractory to their last line of treatment and 25 were in relapse. Patients underwent a median number of 5 cycles of BV [range 1-16]. Eleven patients received chemotherapy in association with BV. Forty-two patients achieved response during treatment with 32 patients (49.2%) achieving complete response (CR) and 10 (15.4%) partial response (PR) with a median of 4 cycles before best response [range 1-12]. BV was discontinued in 58 patients (89.2%) because of progression (n=18), high-dose consolidative therapy followed by transplantation (n=18), optimal response (n=9), death (n=8), and toxicity (n=5). At the end of the treatment, 29 patients (45.3%) were in CR, and 7 (10.9%) in PR. The median duration of overall response was 8 months [95% CI 4.4; NR]. Median disease-free survival and progression-free survival were 15.5 months [95% CI 5.0; NR] and 6.8 months [95% CI 5.1; 9.4], respectively. The most common adverse events of any grade, regardless of relationship to BV were: neuropathy (n=23), hematological toxicities (anemia (n=22), neutropenia (n=19), thrombocytopenia (n=17)) and infection (n=13), for which 8 patients required a dose reduction. Nineteen patients received after BV a consolidative autologous (n=9) or allogeneic (n=9) stem cell transplantation or radiotherapy (n=1). Median survival was 25.9 months [95% CI 11.9; NR].

Table 1.

Patients characteristics before BV	N= 65
Age at diagnosis (Years) ; Median [Range]	51.5 [18;81]
ECOG: <2/>2/Not evaluated	40/18/7
Ann Arbor stage : I-II/ III-IV/Not evaluated	8/52/5
Number of prior chemotherapy regimens; Median [Range]	3 [1;8]
Prior autologous/ allogenic Steam Cell Transplantation	9/4

Summary and Conclusions: BV has already been proved effective in ALCL and seems also promising in other PTCL. Further analysis will attempt to determine if the response to BV is correlated with histological subgroups or CD30 expression level.

P466

THE ORAL SELECTIVE INHIBITOR OF NUCLEAR EXPORT (SINE) SELINEXOR (KPT-330) ACTIVITY IN DOUBLE HIT DIFFUSE LARGE B CELL LYMPHOMAS (DLBCL) IN PRECLINICAL MODELS & CLINICAL ACTIVITY IN PATIENTS WITH DLBCL

[1]Princess Margaret Cancer Center, Toronto, Canada, [2]Wiel Cornell Medical College, Cornell University, New York; New York, [3]School of Medicine, Washington University, St. Louis; Missouri, [4]Dana Farber Cancer Institute, Boston; Massachusetts, United States, [5]Department of Oncology, [6]Department of Hematology, Rigshospitalet, Copenhagen, Denmark, [7]H. Lee Moffitt Cancer Center & Research Institute, Tampa; Florida, [8]James Cancer Hospital, The Ohio State University, Columbus; Ohio, [9]Tennessee Oncology, Sarah Cannon Research Institute, Nashville; Tennessee, [10]Hackensack University Medical Center, Hackensack; New Jersey, [11]Karyopharm Therapeutics, Natick; Massachusetts, United States, [12]Ozmosis Research, Toronto, Canada

Background: Amongst the ~60,000 cases of DLBCL diagnosed each year in EU/US, ~5% are "double-hit lymphomas" (DH-DLBCL) which overexpress MYC and BCL2/BCL6. DH-DLBCL is relatively resistant to available therapeutic agents including combination chemo-immunotherapy. Selinexor (KPT-330) is a SINE that forms a slowly reversible covalent bond with exportin 1 (XPO1). Inhibition of XPO1 forces the nuclear retention and activation of >10 tumor suppressor proteins (TSP) and is also associated with reduction in protein levels of c-myc and BCL family members. Selinexor showed anti-lymphoma activity in murine models of DLBCL and in spontaneous canine aggressive lymphomas that are similar to human DLBCL.

Aims: Here we investigate the effect of selinexor on XPO1 protein levels *in-vitro* as well as present updated results of selinexor in patients (pts) with DLBCL.

Methods: XPO1 protein levels were assessed by IHC in 62 human DLBCL specimens and compared with levels in normal human tonsils. Cytotoxicity at 48h was evaluated in 9 DLBCL cell lines, including several DH-DLBCL lines. MYC, BLC2 and BLC6 mRNA levels were determined in the nucleus and cytoplasm of the cells. Oral selinexor was given at 8-10 doses / 28-day cycle. XPO1 inhibition leads to rapid elevations in XPO1 mRNA, representing a pharmacodynamic (PDn) marker for selinexor. Tumor biopsies were performed. Response evaluation was done in cycles 1, 2, and every 2 cycles. All pts had heavily pretreated DLBCL with objectively progressive disease (PD) on study entry.

Results: XPO1 levels were overexpressed relative to normal tonsils in 49 of 62 (79%) human DLBCL samples. Selinexor showed potent cytotoxicity against all DLBCL cell lines (IC_{50s} 9.5 - >1000 nM) independent of MYC or BCL2/6 protein levels. Selinexor (10nM) lead to significant reductions in cytoplasmic to nuclear ratios of MYC, BCL2 and BCL6 mRNA levels in in OCI-Ly7 DLBCL cells. Nineteen pts (10 M, 9 F; median age 60 yrs; ECOG PS 0/1: 6/13; median prior regimens: 3.8 range 1-8) received selinexor across 7 dose levels (3 to 45 mg/m^2). Dosing at 60 mg/m^2 twice weekly (BIW) is ongoing and MTD has not been reached. Cycle 1 (DLT period) Grade 3/4 events include neutropenia (2pts) and thrombocytopenia (3pts). The most common Grade 1/2 AEs in Cycle 1: nausea (58%), vomiting (47%), anorexia (37%), & fatigue (32%). Supportive care with appetite stimulants and anti-emetics improved constitutional symptoms. Eighteen pts with progressive disease on study entry were evaluable for efficacy. Best responses included 4 Partial Responses (22%), 8 Stable Disease (44%), and 6 Progressive Disease (33%). Reductions in target lesions of 4 - 93% were observed in 9 pts (Figure 1). 4/19 pts have remained on therapy for >4 months (>4-18) months without clinically significant toxicities. Two pts with DH-DLBLC achieved 20% and 74% reductions in tumors in cycle 1 and continue on study (30+ and 180+ days).

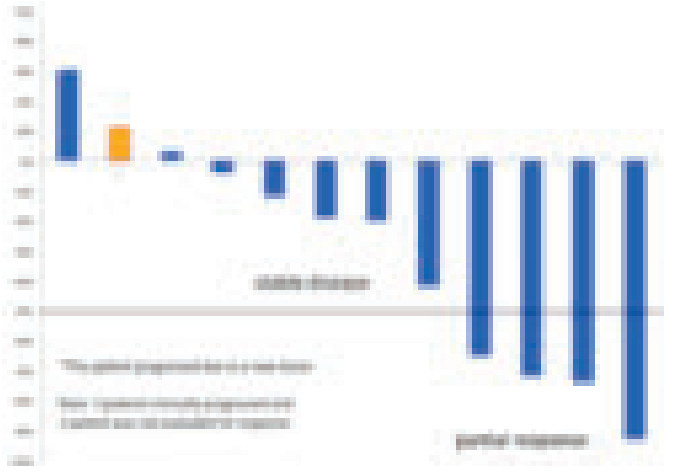

Figure 1. Waterfall Plot: Target Lesions Maximal Percent Change DLBCL Patients

Summary and Conclusions: Most human DLBCL overexpress XPO1 and are highly sensitive to XPO1 inhibition. In addition to forcing the nuclear localization of TSPs, selinexor reduces the relative levels of MYC, BLC2 and BCL6 cytoplasmic mRNAs leading to reduced translation to protein. Oral selinexor is generally well tolerated and can be administered over prolonged periods. Durable single agent activity was observed in heavily pretreated DLBCL pts, including those with DH-DLBCL. Phase 2 studies in DLBCL are planned.

P467

PATIENT PREFERENCE FOR SUBCUTANEOUS OR INTRAVENOUS ADMINISTRATION OF RITUXIMAB IN PREVIOUSLY UNTREATED CD20+ NON-HODGKIN LYMPHOMA: INTERIM DATA FROM THE PREFMAB STUDY

M Rummel[1,*] TM Kim[2], C Plenteda[3], E Capochiani[4], M Mendoza[5], R Smith[5], S Osborne[5], A Grigg[6]

[1]Department of Internal Medicine IV, University Hospital Giessen and Marburg, Giessen, Germany, [2]Seoul National University Hospital, Seoul, Korea, Republic Of, [3]Universita Degli Studi Parma, Parma, [4]Dipartimento di Oncologia, Centro Aziendale di Ematologia, Livorno, Italy, [5]F. Hoffmann-La Roche Ltd., Basel, Switzerland, [6]Austin Hospital, Heidelberg, Victoria, Australia

Background: Rituximab is a mainstay of treatment for follicular lymphoma (FL) and diffuse large B-cell lymphoma (DLBCL). A subcutaneous (SC) rituximab formulation has been developed to improve patient convenience and reduce healthcare resource burden without sacrificing clinical activity for patients receiving rituximab for B-cell hematologic malignancies.
Aims: PrefMab (NCT01724021) is an ongoing, randomised, open-label multicentre study to evaluate preference for rituximab intrvenous (IV) or rituximab SC during immunochemotherapy for non-Hodgkin lymphoma.
Methods: Patients with untreated CD20+ Grade 1–3a DLBCL or FL received 8 cycles of rituximab in combination with 6–8 cycles of CHOP, CVP or bendamustine, per standard local practice. Patients randomised to Arm A received 1 cycle of rituximab IV (375 mg/m^2) then 3 cycles of rituximab SC (1400 mg) followed by 4 cycles of rituximab IV (375 mg/m^2) after interim staging. Those randomised to Arm B received 4 cycles of rituximab IV (375 mg/m^2), then 4 cycles of rituximab SC (1400 mg) after interim staging. Dosing route preference was assessed via a Patient Preference Questionnaire (PPQ; preference recorded as SC, IV or 'no preference') post-therapy in cycles 6 and 8. Chemotherapy Treatment Satisfaction Questionnaires (CTSQ) and Rituximab Administration Satisfaction Questionnaires (RASQ) were completed at cycles 4 and 8. Questionnaire responses were compared using descriptive statistics. Adverse events (AEs) were monitored throughout the study. All patients provided written informed consent.
Results: At November 8th 2013, 433 patients had received treatment (Arm A: n=215; Arm B: n=218); baseline characteristics were well balanced with a mean age of 59 years. Most patients had DLBCL (62%) and 38% had FL. At the data cut-off, 69 patients (16%) had completed treatment; 34 (8%) discontinued study treatment prior to cycle 8, mainly due to AEs (n=13; 11 after IV doses [8 in cycle 1] and 2 after SC doses), disease progression (n=5), stable disease at interim staging (n=4) and withdrawn consent (n=4). The intent-to-treat (ITT) population included 445 patients (Arm A: n=221; Arm B: n=224). In 190 completed PPQs at cycle 6 (see Table 1), rituximab SC was preferred by 157 patients (83%; 95% confidence interval [CI]: 76–88; Arm A: n=76 [82%]; Arm B: n=81 [84%]), and rituximab IV by 15 patients (8%; 95% CI: 4–13; Arm A: n=10 [11%]; Arm B: n=5 [5%]). A similar preference was apparent in 125 completed PPQs for cycle 8: 108 patients (86%; 95% CI: 79–92; Arm A: n=50; Arm B: n=58) preferred rituximab SC, 45% with a 'very strong' and 35% a 'fairly strong' preference. Eleven patients (9%; 95% CI: 4–15) preferred rituximab IV (Arm A: n=7; Arm B: n=4). Reasons for administration route preference were the same as those given at cycle 6 (see Table 1). Data from the RASQ and CTSQ supported patients' preference for SC over IV administration. The occurrence of AEs was similar in both arms, and no new safety issues were detected. There were 7 deaths on-study (4 in Arm A, 3 in Arm B), with one (febrile neutropenia) considered probably rituximab-related.

Table 1. Responses to PPQ in cycle 6.

Summary and Conclusions: These data demonstrate patients' preference for SC *vs* IV rituximab administration during immunochemotherapy for FL and DLBCL. 'Less time in the clinic' was cited by patients as the primary reason for preferring SC administration, followed by 'less emotional distress', and 'more comfortable administration'.

P468

CLINICAL IMPACT OF INCLUSION AND TIMING OF RADIOTHERAPY IN THE TREATMENT OF LIMITED-STAGE NK/T-CELL LYMPHOMA

BH Lee[1,*] JA Kim[1], HY Yhim[2], JY Kwak[2], YR Do[3], Y Park[4], MK Song[5], JS Chung[5], JJ Lee[6], DH Yang[6]

[1]Division of Hematology, Department of Internal Medicine, St. Vincent's hospital, The Catholic University of Korea, Suwon, [2]Division of Hematology/Oncology, Chonbuk National University Medical School, Jeonju, [3]Hemato-oncology, Dongsan Medical Center, Keimyung University School of Medicine, Daegu, [4]Division of Hematology/Oncology, Korea University College of Medicine, Seoul, [5]Division of Hematology-Oncology, Department of Internal Medicine, School of Medicine, Medical Research Institute, Pusan National University Hospital, Pusan, [6]Hematology-oncology, Chonnam National University Hwasun Hospital, Hwasun, Korea, Republic Of

Background: For the treatment of limited-stage (stage I or II stage) natural killer (NK)/T-cell lymphoma, combined treatment modality including radiotherapy (RT) is widely recommend. However, the best standard has not been clearly determined.
Aims: In this study, we analyzed the role and the optimal timing of RT, and the difference of clinical outcome among patients with limited-stage NK/T-cell lymphoma.
Methods: We retrospectively analyzed patients with limited-stage NK/T-cell lymphoma, diagnosed between January, 2004 and April, 2013 from six Korean institutes.These patients were categorized into 3 groups, *i.e.*, 1) anthracycline or non-anthracycline-based chemotherapy followed by radiotherapy (CTx/RT), 2) concurrent chemoradiotherapy (CCRT) followed by non-anthracycline-based chemotherapy (CCRT/CTx), and 3) CTx alone group according to therapeutic modalities.
Results: In total 104 patients with limited-stage NK/T cell lymphoma, the median age was 52 years (range 28~85) and 70 (67.3%) patients were male. Seventy-three (70.2%) patients had RT as initial treatment protocol. According to therapeutic modalities, 29 (27.9%) and 44 (42.3%) patients were treated by CTx/RT and CCRT/CTx, respectively, and the remaining 31 (29.8%) patients were managed by CTx alone as initial therapy. Overall response (OR) rate was 80.8% including complete response (CR) rate 70.2% after initial therapy. Patients who had CTx/RT or CCRT/CTx achieved markedly high CR rate (76.7%) comparing to those had CTx only group with 54.8% (p=0.009). With median follow up of 47.6 months, the 5-year progression free survival (PFS) was 44.2% and overall survival was 75.1%. The 5-year PFS of patients with RT containing protocol and those with CTx only group were 52.1% and 25.8%, respectively (p=0.003). Among patients treated with RT containing protocol, the 5-year PFS was superior in CTx/RT group as 60.6% than CCRT/CTx group as 48.8% (p=0.001). Note that, among CCRT/CTx group, there were 7 patients who could not proceed to the planned following chemotherapy. The causes were disease progression just after CCRT (n=4), and decreased performance status during CCRT (n=3).However, all patients treated with CTx/RT could finish the planned protocol. The site of relapse within RT containing protocol did not have different pattern (Figure 1).

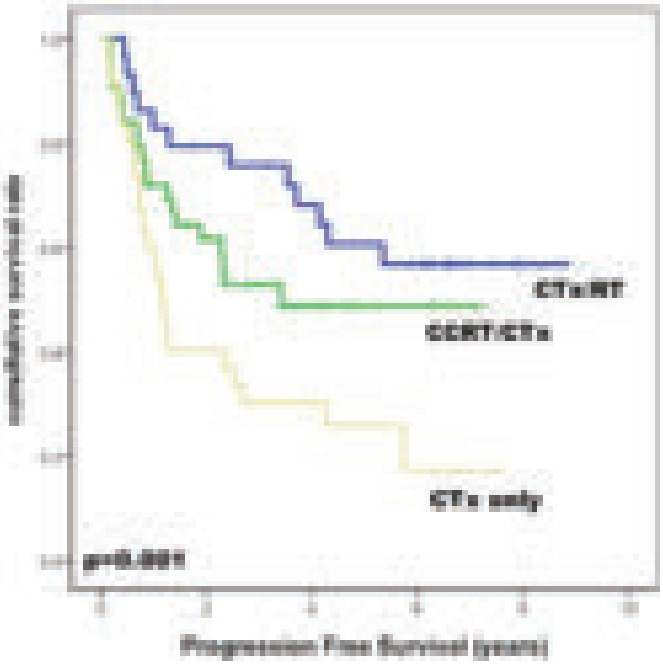

Figure 1.

Summary and Conclusions: Based on this analysis, we were able to emphasize the role of RT for treating limited-stage NK/T cell lymphoma, again. However, the optimal timing of RT in the disease course should be determined carefully in order to complete of planned treatment and prevent disease progression during localized RT. Moreover, RT at upper aerodigestive tract could decrease the therapeutic compliance of next following chemotherapy.

P469

EFFICALY OF M-NHL-BFM-90 TREATMENT PROTOCOL FOR PATIENTS WITH PRIMARY MEDIASTINAL LARGE B-CELL LYMPHOMA

Y Mangasarova[1,*] E Baryakh[1], V Voroviev[1], A Magomedova[1], S Kravchenko[1]
[1]National Research Center for Hematology, Moscow, Russian Federation

Background: Primary mediastinal large B-cell lymphoma (PMBCL) is an aggressive diffuse large B-cell lymphoma entity. It represents less than 3% of all non-Hodgkin lymphoma cases,, but is over-represented in the young adult population.
Aims: To evaluate the efficacy of modified NHL-BFM-90 (m-NHL-BFM-90) protocol in the treatment for adult PMBCL patients.
Methods: 71 patients (26 men, 45 women) were eligible for our study; median age was 30 years (18 - 70). PMBCL staging criteria developed by Ann Arbor were used to stage the patients. All patients were diagnosed with II stage, in 8 (11%) cases had breast and/or soft tissues involvement. Bulky mediastinal disease was found in 65 (91.5%) patients with PMBCL. Serum lactate dehydrogenase level was increased in 64 (90%) patients. aa-IPI 1 was established in 14 patient (20%), 2 – in 57 (80%), 0 and 3 – in 0. 71 newly diagnosed, previously untreated patients participated in the study performed in the National Research Center for Hematology between November 2004 and February 2014. The treatment is based on the modified NHL-BFM protocol (the dose of methotrexate was reduced to 1500mg/m^2 (12 h) in course A, B and C, doxorubicin (50mg/m^2) was included in the course A). A number of courses (4 or 6) were determined depending on achieving the remission. The patients with residual tumor in mediastinum underwent radiotherapy as consolidating treatment in total dose of 36 Gray.
Results: The 5-year disease-free survival (DFS) and overall survival (OS) were 83% and 89% with PMBCL, during an average follow-up of 38 months. The 5-year DFS and OS were 29% and 57% of patients with soft tissues and/or muscles tumor involving. Serum lactate dehydrogenase level and bulky mediastinal disease didn't impact on DFS and OS. One of the patients has died from chemotherapy complications. Eight patients turned out to be primary-resistant.
Summary and Conclusions: The modified NHL-BFM-90 is a highly effective protocol. The 5-year DFS and OS were 83% and 89% with PMBCL. Soft tissues and/or breast involvement were adverse prognostic factor in patients with PMBCL.

P470

BISPECIFIC T-CELL ENGAGER (BITE®) ANTIBODY BLINATUMOMAB IN PATIENTS (PTS) WITH RELAPSED/REFRACTORY DIFFUSE LARGE B-CELL LYMPHOMA (DLBCL): AN OPEN-LABEL PHASE 2 STUDY

A Viardot[1,*] M Goebeler[2], M Pfreundschuh[3], N Adrian[3], M Libicher[4], G Hess[5], F Zettl[6], S Neumann[7], E Degenhard[8], J Stieglmaier[8], A Zhang[9], D Nagorsen[9], R C Bargou[2]
[1]Department of Internal Medicine III, University Ulm, Ulm, [2]Comprehensive Cancer Center Mainfranken (CCCMF), Department of Internal Medicine II, University Würzburg, Würzburg, [3]Department of Clinical Immunology and Rheumatology, Universitätsklinikum des Saarlandes, Homburg, [4]Department of Radiology, Diakoniekrankenhaus Schwäbisch-Hall, Schwäbisch-Hall, [5]University Hospital, Mainz, [6]University Hospital, Göttingen, [7]Department of Internal Medicine II, University Hospital Schleswig-Holstein Campus Kiel, Kiel, [8]Amgen Research (Munich) GmbH, Munich, Germany, [9]Amgen Inc., Thousand Oaks, CA, United States

Background: The bispecific T-cell engager (BiTE®) antibody, blinatumomab, redirects cytotoxic T cells to CD19$^+$ B-lineage cells, resulting in serial lysis of the target cells. In a phase 1 study in pts with relapsed/refractory non-Hodgkin lymphoma, blinatumomab exhibited anticancer activity and acceptable toxicity. In a subset of pts with DLBCL, stepwise dose escalation with blinatumomab resulted in an overall response rate (ORR) of 55% in evaluable patients (Goebeler *et al. Hematol Oncol* 2013;31[suppl 1]:197).
Aims: The objective of this open-label phase 2 study is to investigate the efficacy and tolerability of blinatumomab in pts with relapsed/refractory DLBCL, comparing stepwise dose escalation with constant target dosing.
Methods: Eligible pts were ≥18 years of age, had relapsed/refractory DLBCL and an ECOG performance status ≤2. Pts received blinatumomab by continuous intravenous infusion for up to 8 weeks. In part 1, a target dose of 112 µg/d was achieved using a double-step escalation dosing regimen (cohort I: 9, 28, and 112 µg/d during weeks 1, 2, and thereafter, respectively) or a flat dose regimen (cohort II: 112 µg/d throughout). Based on the overall benefit/risk assessment for part 1, the dose administered in cohort I was selected for further evaluation in part 2 (cohort III). Pts achieving an objective response could receive a 4-week consolidation cycle, following a 4 week treatment-free period. All pts received prophylactic dexamethasone. The primary endpoint was ORR by Cheson (2007) revised response criteria for malignant lymphomas per independent radiologic assessment. Secondary endpoints included rates of complete response (CR) and partial response (PR), and incidence of adverse events (AE).
Results: 19 pts have been enrolled and treated: 9, 2, and 8 in cohorts I, II, and III, respectively. All pts provided informed consent. Median age was 66 years (range, 39–85); 47% of pts were women. Blinatumomab was given as third-line (median) systemic treatment (range of prior treatments, 1–7). Eight (42%) pts had received previous radiotherapy; 6 (32%) had received autologous hematopoietic stem cell transplantation. At the time of this analysis, 16 pts were evaluable for response (cohort I, n=8; cohort II, n=1; cohort III, n=7). Per independent radiologic assessment, ORR was 44% (cohort I: CR=2, PR=2; cohort II: PR=1; cohort III: CR=1; PR=1). Three pts had stable disease (1 in cohort I and 2 in cohort II). Six pts had progressive disease (3 each in cohorts I and III). Three pts were not evaluable for ORR per protocol definition (1 each in cohorts I, II and III). Further enrollment in cohort II was terminated due to AEs. The most common AEs in cohorts I and III, regardless of causality, were pyrexia (47%), tremor (41%), fatigue (29%), and edema (24%). Fifteen of 17 pts in cohorts I and III had ≥1 grade 3 AE, regardless of causality. Thirteen of the 17 pts in cohorts I and III had CNS AEs, mostly tremor (41%) and speech disorders (18%). Four pts from cohorts I and III had grade 3 CNS AEs; there were no grade 4 or 5 CNS AEs.
Summary and Conclusions: In this ongoing phase 2 study in heavily pretreated adult pts with relapsed/refractory DLBCL, blinatumomab showed antitumor activity. Part 1 of the study established stepwise dosing (9, 28, 112 µg/d) as the recommended blinatumomab dose for this pt population. Evaluation of pts in cohort III is ongoing.

P471

NON PEGILATED LIPOSOMAL DOXORUBICIN IS SAFE AND EFFECTIVE AS PART OF R-COMP IN PATIENTS WITH DIFFUSE LARGE B-CELL LYMPHOMA AND MODERATE/SEVERE HEART DISEASE. RESULTS OF HEART01 TRIAL BY THE FONDAZIONE

M Spina[1,*] S Luminari[2], AJM Ferreri[3], F Zaja[4], M Balzarotti[5], F Salvi[6], M Micheletti[7], G Musuraca[8], E Viel[1], EA Pesce[2], M Federico[2], P Zinzani[9]
[1]Medical Oncology, National Cancer Institute, Aviano, [2]Department of Diagnostic and Clinical Medicine, and Public Health, University of Modena and Reggio Emilia, Modena, [3]Unit of Lymphoid Malignancies, Department of Onco-Hematology,, San Raffaele Scientific Institute, Milan, [4]clinica ematologica, AOUD S. M. Misericordia, Udine, [5]hematology, Humanitas Cancer Center, Rozzano, [6]Hematology, AO SS Antonio e Biagio e C. Arrigo, Alessandria, [7]hematology, Spedali civili, Brescia, [8]hematology, istituto oncologico romagnolo, meldola, [9]hematology, University of Bologna, Bologna, Italy

Background: R-CHOP is the standard treatment for Diffuse Large B-Cell Lymphoma (DLBCL) but is usually contraindicated in patients with concomitant heart disease due to the unsafe cardiac profile of doxorubicin. The encapsulation of doxorubicin into liposomes modifies its pharmacokinetic reducing its concentration in the heart.
Aims: We conducted a multicenter phase II trial investigating activity and safety of R-COMP regimen where conventional doxorubicin was substituted with non-pegilated liposomal doxorubicin (TLC-D99; Myocet ™) in patients with DLBCL presenting with moderate/severe concomitant heart disease.
Methods: Main inclusion criteria were: age >18 years, diagnosis of DLBCL, cardiac disorder defined by at least one of the following: left ventricular ejection fraction (LVEF) <50%, left ventricular hypertrophy, uncontrolled moderate/severe arterial hypertension, history of ischemic cardiopathy, clinically significant ventricular arrhythmia, atrial fibrillation (AF), pulmonary hypertension, moderate/severe mitral valvular disorder, moderate aortic valvular disorder. Enrolled patients received 6 courses of 3-weekly R-COMP (rituximab 375 mg/m^2, cyclophosphamide 750, mg/m^2, vincristine 1.4 mg/m^2, TLC-D99 50 mg/m^2, prednisone 40 mg/m^2/day day 1-5).
Results: Between 2009 and 2011, 51 patients were enrolled. Median age was 77 years (range 53 - 90 years), 34 (68%), were male and 32 (64%) had stage III-IV disease. Sixty-two cardiac disorders were identified at baseline; the most frequent was ischemic cardiopathy (n=20), followed by AF (n=9), baseline LVEF <50% and left ventricular hypertrophy (n=8); 2 and 3 concomitant cardiac disorders were described in 3 e 4 patients respectively. Treatment was completed in 39 (78%) of patients with a median dose intensity for TLC-D99 of 99%. R-COMP was interrupted prematurely due to lack of response (n=1), CEs (n=5), severe infection (n=2), deep venous thrombosis (n=1), renal failure (n=1), other toxicity (n=1), and patient's decision (n=1). As requested by the sequential Bayesian model, the CR rate and the rate of CE never fell outside activity and safety boundaries. In fact, 27 patients achieved a CR (54%; 95%CI=42-72%) and 6 CE were observed, which included significant LVEF reduction (2 patients), clinically significant s-troponine increase (2), hearth failure (1), and cardiac arrest (1). Median LVEF after cycle 3 and at the end of treatment was 59% (range 25-72%) and 57% (30-69%), without significant modifications from baseline values. With a median follow-up of 30 months (range 1-44) 11 patients had lymphoma progression, 8 experienced relapse and 8 died without signs of lymphoma relapse/progression. Overall, 19 patients died due to lymphoma (9), severe infection (2), second cancer (1), hemorrhage (1), myocardial infarction (2), renal insufficiency (1), respiratory insufficiency (1), and unknown cause (2). The 3-year OS and PFS were 54% (95%CI: 34-70%) and 40% (95%CI: 25-54%), respectively. Median LVEF was 55%(n=16, range 30-69%), 56% (n=15, range 30-65%), 58% (n=12%, range 52-66%) and 60% (n=8, range 53-76) at 6, 12, 18 and 24 months respectively. In 8 patients a decrease in LVEF ≥20%

compared with baseline value has occurred, 3 cases after 3 cycles, 1 at the end of the treatment, 1 at 6, 2 at 12 and 1 at 18 months after the end of treatment.
Summary and Conclusions: The substitution of conventional doxorubicin with non pegilated liposomal doxorubicin (TLCD99-Myocet™) in the R-CHOP regimen is a safe and active option for patients with DLBCL presenting with concomitant moderate/severe cardiac disorders.

P472

HIGH DOSES OF ANTIMETABOLITES FOLLOWED BY HIGH-DOSE SEQUENTIAL CHEMOIMMUNOTHERAPY AND AUTOLOGOUS STEM CELL TRANSPLANT IN SYSTEMIC B-CELL LYMPHOMAS WITH CNS INVOLVEMENT: A MULTICENTER PHASE II TRIAL

AJ Ferreri[1,2,*] G Donadoni[1], MG Cabras[3], C Patti[4], M Milan[5], R Zambello[6], C Tarella[7], M Di Nicola[8], AM D' Arco[9], G Doa[10], M Bruno Ventre[11], M Foppoli[1], A Fanni[3], A Mulè[4], G Pinotti[12], F Caligaris-Cappio[1,2], F Ciceri[11]

Cervello", Palermo, [5]Hematology and Bone Marrow Transplantation Unit, Azienda Ospedaliera Bolzano, Bolzano, [6]Division of Hematology, Azienda Ospedaliera di Padua, University of Padua, [7]Universitaria Ematologia e Terapie Cellulari, Azienda Ospedaliera Ordine Mauriziano-Umberto I, University of Turín, Turín, [8]Division of Medical Oncology, Istituto Nazionale dei Tumori, Milano, [9]Division of Oncohematology, Ospedale Umberto I, Nocera Inferiore, [10]Division of Hematology, Azienda Ospedaliera di Nuoro, Nuoro, [11]Hematology and BMT Unit, Department of Onco-Hematology, San Raffaele Scientific Institute, Milano, [12]Division of Medical Oncology, Ospedale di Circolo, Varese, Italy

Background: We report results of a multicentre phase II trial (ClinicalTrials.gov NCT00801216) addressing feasibility and efficacy of a new chemoimmunotherapy combination in patients (pts) with B-cell lymphomas (BCL) and CNS involvement. Experimental treatment is based on the encouraging experiences with high doses of antimetabolites in pts with primary CNS lymphoma (Ferreri *et al.* Lancet 2009) and with high-dose sequential chemoimmunotherapy (R-HDS) supported by autologous stem cell transplant (ASCT) in pts with relapsed BCL (Tarella *et al.* JCO 2008).
Aims: to address tolerability and efficacy of a new intensified chemoimmunotherapy regimen supported by ASCT in pts with secondary CNS lymphoma.
Methods: HIV-negative pts (18-70 ys; ECOG PS ≤3) with systemic BCL and CNS disease at diagnosis or relapse were enrolled. Experimental treatment consisted of 2 c. of methotrexate 3.5 g/m^2 d1 and cytarabine 2 g/m^2 x2/d d2-3, followed by R-HDS with cyclophosphamide 7 g/m^2 d1, cytarabine 2 g/m^2 x2/d d22-25 and etoposide 2 g/m^2, d43, and BCNU-thiotepa conditioning and ASCT. Treatment included 8 doses of rituximab and 4 doses of intrathecal liposomal cytarabine 50 mg. Two-year PFS was the primary endpoint; the planned accrual was 38 pts.
Results: 40 pts were registered (median age 59ys, range 32-70 ys; M/F ratio 1.5): 34 had DLBCL, 3 had blastoid variant of MCL and 3 had FL. CNS disease was detected at presentation in 17 pts (all pts had concomitant extra-CNS disease) and at relapse in 23 (8 had extra-CNS disease), and consisted of brain parenchyma (n=23), meninges (6) or spinal cord (2) lesions, or involvement of multiple CNS organs (9). Response was complete in 23 pts (58%) and partial in 1 (ORR=60%; 95%CI=45-75%), 1 pt had SD, 11 experienced PD (CNS in all pts; extra-CNS in 4), and 4 died of toxicity (sepsis 2, stroke). G4 neutropenia, thrombocytopenia and anemia were recorded in 90%, 76% and 8% of courses. Febrile neutropenia was recorded in 26% of courses; opportunistic infections (CMV in 6 pts, aspergillosis in 1) were successfully managed. Transient increase of transaminases levels (2) and intestinal perforation (1) were the only G4 non-hematological toxicities. ASC collection was successful in 23 (92%) of the 25 referred pts (median 9.5x10^6/kg; range 5.8-18.9); 20 pts eventually received ASCT. At a median follow-up of 3 ys, 16 pts remain relapse-free, with a 2-yr PFS of 40±8%. Seventeen pts are alive and NED, with a 2-yr OS of 41±8%; 2-yr OS of transplanted pts was 64±11%. Age, extra-CNS disease and/or meningeal dissemination did not affect survival.
Summary and Conclusions: This intensified treatment is feasible and effective in pts ≤70 ys with systemic BCL and CNS involvement. Toxicity is almost exclusively haematological and manageable. Survival benefit is also attained in pts with extra-CNS and/or meningeal disease. Since randomized trials are unrealistic in this context, authors recommend this combination as first choice in routine practice.

P473

R-ESHAP-LENALIDOMIDE AS SALVAGE THERAPY IN PATIENTS WITH RELAPSED OR REFRACTORY DIFFUSE LARGE B-CELL LYMPHOMA CANDIDATES TO STEM-CELL TRANSPLANTATION: UPDATED RESULTS OF A PHASE IB GELTAMO STUDY

A Martín[1,2,*] AM Redondo[2], A López-Guillermo[3], A Salar[4], E González-Barca[5], M Canales[6], D Caballero[1,2]
[1]IBSAL, [2]Hospital Universitario de Salamanca, Salamanca, [3]Hospital Clinic, [4]Hospital del Mar, [5]ICO, Barcelona, [6]Hospital La Paz, Madrid, Spain

Background: Diffuse large B-cell lymphoma (DLBCL) patients with relapsed or refractory disease after rituximab-containing first-line therapy have a poor outcome with the current salvage regimens. Consequently, new drugs designed to increase the response rate of salvage regimens should be explored.
Aims: We conducted a phase Ib trial to establish safety, and to determine the maximum-tolerated dose (MTD) of lenalidomide in combination with R-ESHAP (LR-ESHAP) in patients with relapsed or refractory DLBCL. Efficacy data were also collected as secondary objective. EUDRACT number: 2010-018463-41.
Methods: Eligible patients must have refractory or relapsed disease following first-line treatment with rituximab and anthracycline-containing regimens, and be eligible for autologous stem-cell transplantation (ASCT). Subjects received three cycles of lenalidomide (5, 10 or 15 mg) given on days 1 to 14 of every 21-day cycle, in combination with R-ESHAP salvage chemotherapy at standard doses (rituximab 375 mg/m^2 day 1, etoposide 40 mg/m^2 days 1-4, cisplatine 25 mg/m^2 days 1-4; citarabine 2000 mg/m^2 day 5, and methilprednisolone 500 mg days 1-5). Responding patients received BEAM followed by ASCT.
Results: During the escalating phase, 3 patients had dose-limiting toxicity in the 15 mg cohort: 1 grade 3 angioedema, and 2 mobilization failures. The MTD was therefore established at 10 mg of lenalidomide and this cohort was expanded to further explore the safety and efficacy of LR-ESHAP. A total of 20 patients (3, 13, and 4 in the 5, 10, and 15 mg cohorts) were enrolled. 1 patient (10 mg cohort) was excluded due to a major deviation protocol in exclusion criteria (severe hepatic disease not due to lymphoma), so 19 patients were evaluable (17 with DLBCL-NOS, and 2 with Burkitt-like lymphoma). Median age was 58 (23–70) years (60% male). First-line treatment consisted of R-CHOP or similar in 17 patients and Burkitt's lymphoma protocols in 2. Disease status at LR-ESHAP was: primary refractory disease in 13 patients, and relapsed disease in 6 (3 early and 3 late relapses). IPI was 0-1 in 37%, 2-3 in 40%, and 4-5 in 25%. To date, 17 serious adverse events have been reported: 6 episodes of febrile neutropenia, 3 pneumonia, 2 sepsis, 1 ionic imbalance, 1 renal toxicity, 1 facial angioedema, 2 thrombosis (associated to central venous catheter), and 1 graft failure after ASCT, all of them recovered except the graft failure. There were no treatment-related deaths. 17 patients (90%) completed the planned three cycles (3 without lenalidomide in the third cycle due to significant toxicity during the second) and 1 patient two cycles (due to persistent neutropenia and thrombocytopenia after the second cycle). One patient discontinued treatment during the first cycle due to grade 3 facial angioedema. The overall response rate to LR-ESHAP was 74% (42% complete remission). All 18 patients who received at least 2 cycles were successfully mobilized after one (13 patients) or two (5 patients) mobilization procedures, and 14 patients (74% of the overall series) underwent ASCT according to protocol. Reasons for not performing the ASCT were: early progression (n=4), and clinical trial discontinuation due to toxicity (n=1). At the time of this analysis, 9 patients had disease progression and 7 of them have died. With a median follow-up of 11.9 (5.9 to 30) months, the estimated 1-year progression-free survival and overall survival were 61% and 63%, respectively.
Summary and Conclusions: The MTD of lenalidomide in combination with R-ESHAP is 10 mg. LR-ESHAP shows an acceptable safety profile and encouraging activity in rituximab-pretreated relapsed or refractory DLBCL patients. Further investigation with this regimen is warranted.

P474

NCCN-INTERNATIONAL PROGNOSTIC INDEX (NCCN-IPI) IS A POTENTIAL PROGNOSTIC MODEL IN PATIENTS WITH PERIPHERAL T-CELL LYMPHOMA

P Xu[1,*] W Qin[2], L Wang[1], B Chen[2], Y Shen[1], X Xu[2], W Zhao[1]
[1]State Key Laboratory of Medical Genomics, Shanghai Institute of Hematology, Shanghai Rui Jin Hospital, Shanghai Jiao Tong University School of Medicine, [2]Department of Hematology, Hua Shan Hospital, Shanghai Medical College, Fudan University, Shanghai, China

Background: Peripheral T-cell lymphomas (PTCLs) represent the most prevalent subtype among T-cell neoplasms and constitute a heterogeneous group of disorders. Prognostic characterization of patients is an essential prerequisite for risk-adapted therapies in PTCL. Initially designed for aggressive B-cell lymphoma, the International Prognostic Index (IPI) is the most commonly used prognostic scoring system in PTCL. The National Comprehensive Cancer Network (NCCN)-IPI has recently been proposed and demonstrated better discrimination of risk subgroups than IPI in diffuse large B-cell lymphoma. Thus prognostic significance of NCCN-IPI in PTCL remains great interest.
Aims: To validate the prognostic significance of NCCN-IPI in PTCL patients.
Methods: We conducted a retrospective analysis in 252 PTCL patients treated with CHOP (cyclophosphamide, doxorubicin, vincristine and prednisone)-based chemotherapy (eight cases received subsequently high-dose chemotherapy and autologous stem cell transplantation). Informed consent was obtained from all patients, in accordance with the regulations of the Shanghai Rui Jin Hospital and Shanghai Hua Shan Hospital Review Boards.
NCCN-IPI used a maximum of 8 scoring points for categorized age >40-60 (1 pt.), >60-75 (2 pts.) and >75 years (3 pts.), LDH ratio >1-3 (1 pt.) and ≥3 (2 pts.) upper limit of normal in addition to extranodal disease in major organs (either bone marrow, CNS, liver/GI tract or lung), Ann Arbor stage III/IV and ECOG

PS≥2, each having a score of 1. Four risk groups were formed: low (0-1), low-intermediate (2-3), high-intermediate (4-5) and high (6-8).
Results: The estimated 5-year progression free survival (PFS) and overall survival (OS) rate were 21.1% and 36.5%, with median PFS and OS at 12.6 and 30.8 months, respectively. The prognosis of the patients varied from histological subtypes, but in agreement with previous cohort (Figure 1A). NCCN-IPI owned lower Akaike information criterion value (PFS: 1496.267 *vs* 1502.117, OS: 1161.130 *vs* 1172.765) and higher concordance probability index (PFS: 0.72 *vs* 0.69, OS: 0.78 *vs* 0.75) than IPI, which indicated better model fitting and discrimination. Meanwhile, when controlling for NCCN-IPI, histological subtype was no longer a significant predictor of survival (PFS: P=0.232, OS: P=0.132). In the multivariate analysis including the five factors of NCCN-IPI, all the enhancements in NCCN-IPI as the categorization of age, LDH and specific extranodal sites were independent prognostic factors of PFS (P=0.022; P=0.044; P=0.013) and OS (P=0.006; P=0.001; P=0.011), further supporting the predictive efficacy of NCCN-IPI. According to risk subgroups, the survival rate of low-risk patients was remarkably higher in NCCN-IPI than in IPI (5-yr OS 88.9% *vs* 67.6%, 5-yr PFS 48.7% *vs* 38.3%, Figure 1B-E). The identification of these 'ultra' low-risk patients by NCCN-IPI is of paramount importance, since they may benefit from conservative chemotherapy like CHOP regimen to achieve optimal prognosis. Regarding high-risk patients, NCCN-IPI and IPI are both efficient for predicting poor disease outcome (2-yr OS 14.8% *vs* 19.1%, 2-yr PFS 10.0% *vs* 16.3%). These patients should thus receive intensive treatment with stem cell transplant and/or novel targeted agents.

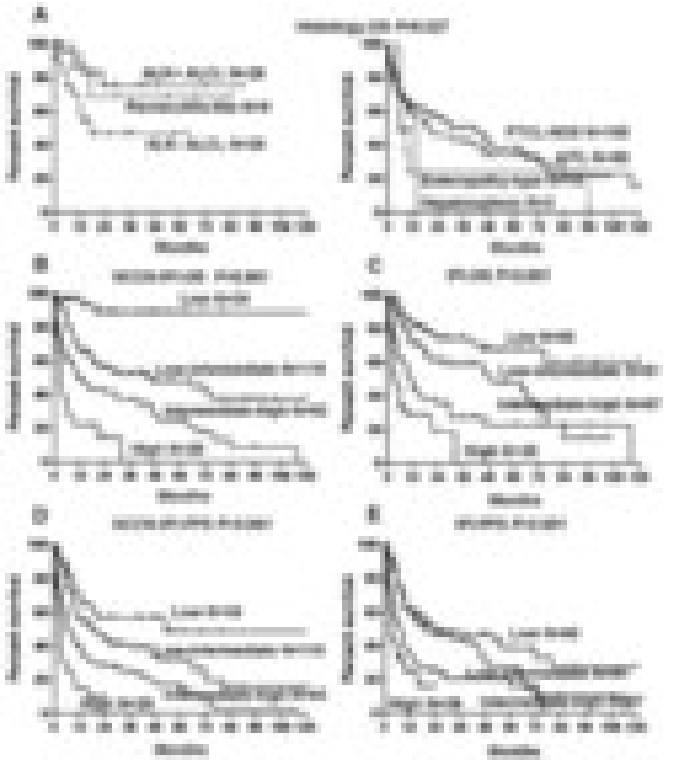

Figure 1. Survival curves of patients with peripheral T-cell lymphoma. (A) Overall survival (OS) according to histological subtypes of PTCL. (B-E) OS (B and C) and progression-free survival (PFS, D and E) according to NCCN-IPI and IPI (Xu *et al.*).

Summary and Conclusions: Similar to B-cell lymphoma, NCCN-IPI is also more powerful than IPI for risk prognostication in PTCL.

RITUXIMAB-CHOP PLUS INTRATHECAL METHOTREXATE AND CONTRALATERAL TESTIS IRRADIATION IN UNTREATED PRIMARY TESTICULAR DIFFUSE LARGE B-CELL LYMPHOMA: LONG-TERM RESULTS OF THE IELSG-10 TRIAL

U Vitolo[1,*] A Chiappella[1], M Martelli[1], AJ Ferreri[1], I Baldi[1], M Balzarotti[1], C Bottelli[1], A Conconi[1], P De Masi[1], H Gomez[1], A Lopez-Guillermo[1], G Martinelli[1], F Merli[1], O Bairey[1], L Orsucci[1], V Pavone[1], U Ricardi[1], S Storti[1], MK Gospodarowicz[1], F Cavalli[1], AH Sarris[1], E Zucca[1]
[1]On behalf of International Extranodal Lymphoma Study Group (IELSG) and Fondazione Italiana Linfomi (FIL), Hematology, Città della Salute e della Scienza Hospital and University, Torino, Italy

Background: Primary testicular lymphoma (PTL) has poor prognosis with an high risk of failures in central nervous system (CNS) and contralateral testis. The IELSG-10 international trial showed the efficacy of conventional Rituximab-CHOP21 (R-CHOP21) associated with CNS intrathecal prophylaxis and contralateral testis irradiation (Vitolo, J Clin Oncol 2011).
Aims: Aim of the current analysis is to evaluate long term outcome and incidence of CNS and contralateral testis relapses.
Methods: From 2001 to 2006, 53 patients were enrolled. Inclusion criteria were: untreated stage I or II diffuse large B-cell lymphoma PTL. After diagnostic orchiectomy, patients were planned to receive 6 or 8 courses of R-CHOP21 followed by prophylactic irradiation (IF-RT) to the contralateral testis at 25 to 30 Gy for all patients. During chemotherapy, intrathecal methotrexate (IT-MTX) was administered as CNS prophylaxis (12 mg, 4 times).
Results: Fifty-three patients were enrolled. Clinical characteristics were: median age 64 years (range 22-79); stage I in 40 patients (75%) and stage II in 13 (25%); bilateral testis involvement in 4 (8%). No patients have CNS involvement at diagnosis. With a median follow-up of 65 months, we previously reported 5-years progression free survival (PFS), overall survival (OS), cumulative incidence of lymphoma progression or death as a result of lymphoma (TTP) and cumulative incidence of CNS relapse were: 74%, 85%, 18% and 6%, respectively. With an extension of follow-up time to a median of 9 years, PFS is 67% (95% CI: 52-78%): one patient failed during treatment and died; 6 died due to causes not related to lymphoma and 10 patients relapsed. Relapses involved lymph node alone in 3 patients, extranodal organs (pleura, skin, CNS) with or without lymph nodes in 7 patients. Four patients experienced CNS relapses: two of them had isolated relapses (one meningeal and one brain parenchymal), one had a concurrent meningeal and lymph nodal relapse and the fourth one had a parenchymal CNS relapse while in second remission after nodal relapse. At 9 years the cumulative incidence of CNS relapse, taking into account the competitive risk of death, remains 6% (95% CI, 0-12%). Contralateral testis relapses continue to be absent. 9- year TTP is 27% (95% CI: 15-39%) and 9-year OS is 75% (95% CI: 60-84%); 14 patients died, 8 of progressive disease, one of gastric cancer after 9 months off therapy, one of heart failure after 17 months, two of acute myelogenous leukemia after 21 and 60 months, one of hepatocarcinoma after 63 months and one of metastatic melanoma after 84 months. (Figure 1).

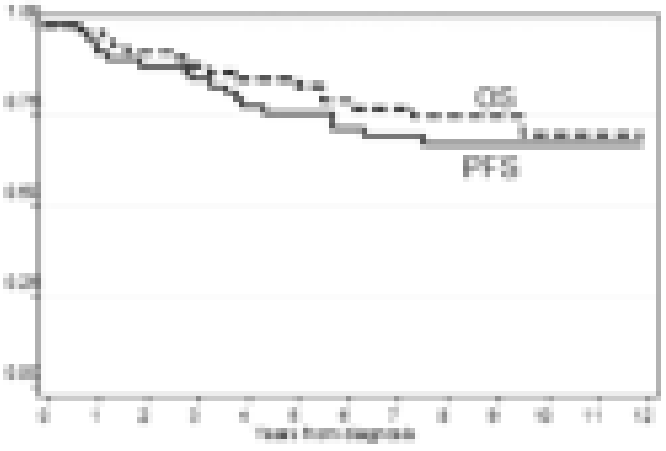

Figure 1. Kaplan-Meier estimates of progression free and overall survival.

Summary and Conclusions: This update of IELG10 study, with a prolonged follow-up, shows a long-term benefit of the R-CHOP21 treatment associated with intrathecal methotrexate and testicular radiotherapy in PTL. To further improve the outcome and reduce CNS relapse, FIL and IESLG planned the ongoing international trial, IELSG30, to test the use of an intensified CNS prophylaxis such as intrathecal liposomal citarabine and systemic intermediate-dose methotrexate.

P476

THE NOVEL ROLE OF BONE MARROW INVOLVEMENT DETECTED BY BOTH STAGING AND INTERIM FDG PET-CT IN DIFFUSE LARGE B-CELL LYMPHOMAS

JH Liang[1], L Wang[1], R Wang[1], L Fan[1], J Xu[1], JY Li[1], W Xu[1,*]
[1]Department of Hematology, the First Affiliated Hospital of Nanjing Medical University, Jiangsu Province Hospital, Nanjing, China

Background: Bone marrow involvement (BMI) detected by either bone marrow biopsy (BMB) or PET-CT at the initial staging (PET(0)-CT) may have an important value in newly diagnosed diffuse large B-cell lymphoma (DLBCL).

Aims: The aim of our study was to confirm the diagnostic and prognostic value of BMI assessed by PET(0)-CT (PET(0)-BMI), evaluate the impact of PET(0)-BMI on the classical International Prognostic Index (IPI) and the significance of BMI detected by PET(inter)-CT (2-4 cycles of standard R-chemotherapy) (PET(inter)-BMI).
Methods: One hundred thirty-five patients with DLBCL were retrospectively enrolled in our study, for whom underwent both a PET(0)-CT and staging BMB. The presence of BMI in patients was determined by BMB and PET(0)-CT results.
Results: BMI was detected by PET(0)-CT in 35 (25.9%) and by BMB in 18 (13.3%) cases with the total number of BMI in 38 (28.2%) according to our criteria. By multivariate analysis, only IPI□2 (P=0.007) and PET(0)-BMI(+) (P=0.005) remained independent predictive factors of progression-free survival (PFS). Patients with PET(0)-BMI(+) had worse PFS than patients with PET-BMI(−), P<0.0001. The same pattern was observed for BMB (P=0.032). Among the 60 patients with IPI of inter-risk, the patients with PET(0)-BMI(+) had significantly inferior PFS than patients with PET(0)-BMI(−) (P=0.005). Among the 35 patients with PET(0)-BMI(+), patients with PET(inter)-BMI(−) had superior PFS than patients with PET(inter)-BMI(+) (P=0.009), the same pattern was observed for ΔSUVmax (P=0.052).
Summary and Conclusions: PET(0)-BMI demonstrates a better diagnostic and prognostic performance. The patients with IPI of inter-risk meanwhile with PET(0)-BMI(+) should be treated as IPI score of high-risk. Furthermore, PET(inter)-BMI(−) appears vital in particular in patients with PET(0)-BMI(+).

Stem cell transplantation - Experimental

MIR-155 IS ASSOCIATED WITH THE LEUKEMOGENIC POTENTIAL OF CLASS IV G-CSFR IN CD34+ PROGENITOR CELLS

H Zhang[1,*] L Goudeva[1], C Gras[1], R Blasczyk[1], C Figueiredo[1]
[1]Institute for Transfusion Medicine, Hannover Medical school, Hannover, Germany

Background: Granulocyte-colony stimulating factor (G-CSF) is a major regulator of granulopoiesis via the G-CSF Receptor (G-CSFR). The class IV G-CSFR (G-CSFRIV) lacks 3 tyrosine residues and the dileucine internalization motif present in the class I G-CSFR (G-CSFRI), and demonstrated to be differentiation defective. Recently, an oncogenic role of G-CSFRIV in human myeloid leukemia has been suggested. MicroRNAs (miRNAs) have been implicated in various pathologies including hematologic malignancies. Whether miRNAs especially miR-155 are related to the leukemogenic potential of G-CSFRIV was not evaluated yet.
Aims: To investigate the leukemogenic mechanism associated with the high expression levels of G-CSFRIV in human CD34+ progenitor cells.
Methods: G-CSFRI or IV overexpressing cells were stimulated with 10-400 ng/ml G-CSF for 1-3 days. Proliferative potential of G-CSFRI and G-CSFRIV overexpressing (G-CSFRI+ and G-CSFRIV+) progenitor cells were analyzed by BrdU incorporation and colony forming unit (CFU) assays. Ki67 and PI cell staining was used to analyse the cell cycle. Annexin V/PI staining was used to detect apoptosis. Signaling pathways were analyzed using phosphflow technology. Levels of miR-155 and its candidate target genes were quantified by real time-PCR. Inhibition assays were performed by using a STAT5 inhibitor and by RNA interference.
Results: Higher proliferation rates were observed in G-CSFRIV+ progenitor cells in comparison to G-CSFRI+ progenitor cells as indicated by enhanced BrdU incorporation (15.8%, p=0.0142 at 100ng/ml and 14.1%, p=0.0022 at 400ng/ml) upon G-CSF stimulation. G-CSFRIV+ progenitor cells generated higher colony numbers (52.0±20.2 *vs.*102.3±6.7, p=0.0087) in the CFU assay, but the cells expressed significantly lower levels of maturity markers. Cell cycle analysis demonstrated an increase in the number of G-CSFRIV+ CD34+ cells in S phase and G2-phase. Accordingly, an increase of Ki67 staining (169.0±47.44 *vs.* 231.7±31.79, p=0.0316) in G-CSFRIV+ progenitor cells was observed. Significantly less apoptosis was observed in G-CSFRIV+ progenitor cells cultured with G-CSF. Furthermore, G-CSF induced sustained Stat5 activity in G-CSFRIV+ progenitor cells. Interestingly, an induction of miR-155 was observed in G-CSFRIV+ progenitor cells in presence of G-CSF (RQ: 0.70±0.11 *vs.* 1.41±0.36, p=0.0040). Moreover, significantly reduced levels of miR-155 target gene transcripts including PU.1, Gfi-1 and TP53INP1 were observed in G-CSFRIV+ progenitor cells. Importantly, a Stat5 inhibitor prevented G-CSF-induced upregulation of miR-155 levels in G-CSFRIV+ progenitor cells (RQ: 1.76±0.36 *vs.* 1.05±0.08 for with and without Stat5 inhibitor respectively, p=0.0112) and the subsequent inhibition of its target genes. Furthermore, the hyperproliferation of G-CSFRIV+ progenitor cells was significantly decreased by the Stat5 inhibitor (p=0.0157) or the shRNA targeting miR-155.
Summary and Conclusions: This study shows that G-CSFRIV mediates a prolonged activation of Stat5 which causes an increase in miR-155 levels and consequently a decrease in the expression of its targets. Moreover, the Stat5/miR-155/miR-155 targets pathway promotes proliferation and survival of progenitor cells indicating of leukemic transformation. We identify that the leukemogenic potential of G-CSFRIV is associated with a Stat5-dependent dysregulation of miR-155 and its target genes. In consideration of the wide applications of G-CSF in the clinic, it is highly recommended to prescreen for G-CSFRIV expression levels in patients and stem cell donors before G-CSF administration. Moreover, our data suggests that Stat5 or miRNA-155 inhibitors strongly contribute to the abrogation of the leukemogenic potential of G-CSFRIV. This may represent a novel therapeutic approach to decrease the risk of leukemia or relapse in patients showing an elevated G-CSFRIV/G-CSFRI ratio.

THE ROLE OF EPITHELIAL TO MESENCHYMAL TRANSITION IN THE REMODELING OF LUNG INJURY INDUCED BY ACUTE GRAFT-*VERSUS*-HOST DISEASE

M Wu[1], C Liu[2], K Zhao[1], X Wu[3], Y Zhang[1], Z Fan[1], Q Fan[1], C Yin[1], Z Zheng[1], Z Yi[1], Q Liu[1,*]
[1]Department of Hematology, Nanfang Hospital, Southern Medical University, Guangzhou, [2]Department of Hematology and oncology, Hunan Provincial Peoples Hospital, Changsha, [3]Institute of Hematology, Medical College, Jinan University, Guangzhou, China

Background: Noninfectious lung injury caused by graft-*versus*-graft disease (GVHD) is a life-threatening complication after allogeneic hematopoietic stem cell transplant (allo-HSCT). Epithelial injury is a central event in the pathogen-

esis of noninfectious lung injury. Recent studies have shown that alveolar epithelial cells are able to self-renew and reestablish a functional alveolar epithelium. In the inflammatory and fibrotic lung diseases, differentiated epithelia also can acquire a myofibroblast phenotype in the process termed epithelial to mesenchymal transition (EMT), which contributes to aberrant healing and fibrosis. Many factors such as inflammatory cytokine TGF-β have been suggested to induce EMT. However, the role of EMT in the remodeling of acute GVHD (aGVHD) induced lung injury is unclear.
Aims: To clarify whether EMT is involved in airway remodeling in an animal model of aGVHD induced lung injury.
Methods: BALB/c mice were lethally irradiated and transplanted T cell-deleted (TCD) bone marrow plus whole spleen cells from C57BL/6 mice as aGVHD group, and only transplanted TCD bone marrow cells as control group. Alveolar epithelial cells were isolated from mice of two groups and Ep-CAM expression was measured by flow cytometry. The mRNA expression of cytokines including IFN-γ and TGF-β was detected by RT-PCR. The mRNA and protein expressions of specific markers, including E-cadherin, vimentin, Snail and surfactant proteins (SP)-C in lung tissue, were detected by RT-PCR and western blot.
Results: All mice in the aGVHD group showed diffuse periluminal infiltrates and parenchymal pneumonitis by histopathology, while the mice in the control group did not show any lung injury evidence. TGF-β mRNA expressions were markedly up-regulated but IFN-γ expressions were down-regulated in the lung injury group as compared to the control group (*P*=0.025 and *P*=0.045). Alveolar epithelial cells of injured lung expressed higher Ep-CAM (*P*=0.017) and lower SP-C (*P*=0.023). RT-PCR and western blot analyses revealed a significant decrease in epithelial marker E-cadherin (*P*=0.029) and increase in mesenchymal marker vimentin (*P*=0.026) in the GVHD damaged lung. Snail, a key EMT related transcription factor, was significantly elevated at mRNA and protein level in comparison to control group (*P*=0.015).
Summary and Conclusions: EMT is involving in the remodeling of lung injury induced by aGVHD. The effects and mechanisms of IFN-γ and TGF-β imbalance in aGVHD induced lung injury are deserved to be further explored.

COMPARISON OF UMBILICAL CORD BLOOD AND HAPLOIDENTICAL DONOR GRAFTS IN ADULTS WITH HIGH RISK HEMATOLOGIC DISEASES AFTER FLUDARABINE CYCLOPHOSPHAMIDE AND TBI 2 GY BASED REDUCED-INTENSITY CONDITIONING RE

J El Cheikh[1,*] R Crocchiolo[2], A Vai[2], S Fürst[1], S Bramanti[2], B Sarina[2], A Granata[1], P Ladaique[1], C Faucher[1], B Mohty[1], S Harbi[1], R Bouabdallah[3], N Vey[3], A Santoro[2], C Chabannon[1], L Castagna[2], D Blaise[1]
[1]Unité de Greffe, Institut Paoli-Calmettes, Marseille, France, [2]Hematology, Humanitas, Milan, Italy, [3]Hématologie, Institut Paoli-Calmettes, Marseille, France

Background: For patients without a suitable matched related donor, Alternative donors such as mismatched unrelated, cord blood and mismatched family donors could be searched. The aim of this retrospective study was to compare the results of graft source on outcome of patients after haploidentical related donor (Haplo), and the unrelated umbilical cord blood (UCB) transplantation in the setting of Non myeloabalative conditioning regimen (NMA). We retrospectively analyzed outcomes in 150 adult patients with high risk hematologic diseases who received Allo-SCT from alternative donors from two centers (Institut Paoli-Calmettes at Marseille France and Humanitas cancer center at Rozzano, Italy): These two centres have been applying common transplant approaches and procedures during the study period. Sixty nine patients received Haplo and 81 patients received UCB. The NMA regimen consisted of fludarabine (Flu), cyclophosphamide (Cy) and low dose TBI (2 Gy) combination in the two groups. The GVHD prophylaxis consisted of Cyclosporine A (CsA) and MMF in all patients in the two groups. In the Haplo group all patients received also 50 mg/kg Cy at day 3 and 4 post transplant. Of note, supportive care was the same during the whole study period. All supportive care measures included red blood cell, and platelet transfusions were significantly increased in cord blood transplantation group. The cumulative incidence of transplant related mortality (TRM) at one year was 23% in the UCB group *versus* 17% in the Haplo group (P=0.39). Grade 2-4 acute graft-*vs.*-host disease (GVHD) and extensive chronic GVHD incidences were 52% *versus* 29% (P=0.05), and 12% *versus* 6% (P<0.0001), in the UCB group *versus* the Haplo group, respectively. The overall survival at 2 years was 45% (95%CI, 34-56%) in the UCB group *versus* 69% (95%CI, 58-80%) in the Haplo group, (P=0.10). The estimate of progression-free survival at 2 years was 36% (95%CI, 25-47%) in the UCB group *versus* 65% (95% CI, 53-77%) in the Haplo group (P=0.01).
Aims: The main difference between the 2 groups was the significantly higher incidence of acute and chronic GVHD in the UCB group. In this study, relapse and PFS was lower in Haplo group than in UCB transplants.
Results: Our results suggest that haploidentical transplants are a good and promising alternative option for patients with high risk hematological diseases who lack an HLA-matched donor (sibling or unrelated donor). This should be now investigated in prospective comparative studies.
Summary and Conclusions: The main difference between the 2 groups was the significantly higher incidence of acute and chronic GVHD in the UCB group. In this study, relapse and PFS was lower in Haplo group than in UCB transplants. Our results suggest that haploidentical transplants are a good and promising alternative option for patients with high risk hematological diseases who lack an HLA-matched donor (sibling or unrelated donor). This should be now investigated in prospective comparative studies.

IMMUNOREGULATORY MECHANISMS OF BLOCKING IL-21 SIGNALING IN ACUTE GVHD MODEL: DUAL REGULATION OF T AND B CELL HOMEOSTASIS

SG Cho[1,2,*]JY Lim[2], KI Im[2], MJ Park[3], N Kim[2], YS Nam[2], ML Cho[3], JH Yoon[1], JW Park[1]
[1]Hematology, [2]Laboratory of Immune Regulation, Convergent Research Consortium for Immunologic Disease, [3]Rheumatism Research Center, Seoul St. Mary's Hospital, The Catholic University of Korea College of Medicine, Seoul, Korea, Republic Of

Background: Interleukin (IL)-21 is a pro-inflammatory cytokine produced by T helper cell (Th) 17 that affects a broad range of cells and is a critical regulator of Th17 development. Several autoimmune diseases accompanied by high levels of IL-21 suggest that blocking the IL-21 signal might ameliorate autoimmune symptoms. Increased IL-21 leads to progression of B cell-mediated autoimmune diseases with rapidly induced cell proliferation, plasma cell differentiation and immunoglobulin production during the response to antigens and cognate helper T cells. Thus, IL-21 plays a key role as a cytokine modulator between T- and B cell for immune homeostasis. Recent reports have also showed that inhibiting IL-21 also decreases disease severity in murine models of acute graft-*versus*-host disease (GVHD). Specifically, disruption of IL-21 signaling, either genetically or via neutralizing mAbs, reduces transplant-related weight loss, tissue pathology, and mortality. Although murine models have indicated that IL-21 blockade is an attractive strategy to reduce GVHD-associated injuries, these studies have not elucidated the molecular mechanisms affecting both T and B cell responses.
Aims: Interleukin (IL)-21 plays a key role in the development of acute graft-*versus*-host diseases (GVHD) after allogeneic bone marrow transplantation (allo-BMT). Therapeutic manipulation of IL-21 activity may improve acute GVHD in early-post-transplant period. We investigated the mechanisms regulating T- and B cells during IL-21 blockade in acute GVHD.
Methods: Recipient mice (BALB/C, H-2K^d) were irradiated with 800 cGy and injected i.v 5x10^6 BM and 5x10^6 spleen cells from donor IL-21$^{-/-}$ and WT mice (C57BL/6, H-2K^b). Survival after BMT was monitored daily, and the degree of clinical GVHD was assessed weekly using a scoring system. Post-transplant immunologic changes were evaluated by serum level of proinflammatory cytokines, real-time PCR of transcriptional factors, immunophenotyping using FACS and confocal examination and Western Blotting.
Results: IL-21 blockade enhanced Treg and Th2 cell differentiation, while inhibiting Th1- and Th17-derived transcription factors and cytokines as a modulator of activated T cells. IL-21$^{-/-}$ cell recipients had increased mature B, marginal zone B and decreased memory B, germinal center formation and plasma cells that did not lead to immunoglobulin production. B cell activating factor (BAFF) and a proliferation-inducing ligand (APRIL) are involved in the induction and maintenance of T- and B-cell responses. We observed decreased levels of only BAFF during acute GVHD and confirmed that this regulation was through BAFF-receptor (BAFF-R) as mammalian target of rapamycin complex 1 (mTORC1) in IL-21 blockade.
Summary and Conclusions: Therefore, this study suggested that IL-21 blockade effects modulate activated T cell as well as B cell homeostasis via BAFF pathway-mediated inhibition in acute GVHD following murine allo-BMT.

P481

IDENTIFYING NOVEL REGULATORS HEMATOPOIETIC STEM CELL EXPANSION *EX VIVO*

J Manesia[1,*] E Van Den Bosch[1], M Franch[2], RN Cadenas[2], DT Madrid[2], AP Montano[2], S khurana[1], C Verfaillie[1]
[1]Stem cell institute, KU leuven, leuven, Belgium, [2]Functional Bioinformatics Group, National Center for Biotechnology-CSIC, madrid, Spain

Background: Maintenance of hematopoietic stem cell (HSC) self-renewal *ex vivo* remains a major challenge in order to exploit sources with limited numbers of HSCs, such as umbilical cord blood, clinically. Self-renewal is a unique attribute of stem cells to maintain the pool of stem cells during cell division. During asymmetrical divisions, one cell retains multi(pluri)potency, while expansion of the stem cell pool is the result of symmetrical divisions. Both intrinsic and extrinsic factors can influence the self-renewal capability of HSC. During embryogenesis, in particular in the fetal liver, HSCs not only give rise to mature progeny but also symmetrically expand (self-renewal) their number in order to create an adequate pool of HSC be adequate for post-natal life. Fetal liver is the organ where expansion of definitive hematopoietic stem cell pool occurs.

Aims: Considering the importance of hematopoietic stem cells from a clinical standpoint, understanding the biology of HSCs and their microenvironment, during early developmental stages would enable us to find out novel intrinsic and extrinsic regulators in the process of migration, homing and expansion (self-renewal).
Results: Here, we performed genome-wide transciptome analysis of murine fetal liver and postnatal bone marrow derived HSC and the murine fetal liver niche (at e12.5-16.5) to identify novel factors involved in symmetrical divisions and hence expansion of HSC using RNA-Seq. Transcriptional regulators were shortlisted after comparing HSC isolated from e14 fetal liver and adult bone marrow. The role of these intrinsic regulators in hematopoiesis is being screened by morpholino knockdown studies, and subsequent RT-PCR using Gata-1(dsred)/Flk(GFP) transgenic Zebrafish lines. Cell extrinsic factors identified by RNAseq from laser-captured microdissection cells that surround Lin-/CD11b+/Sca1+ cells (expressed in e14 fetal liver but not either in e12.5 or e16.5 fetal liver) for which receptors were found on HSC were also shortlisted. The extrinsic regulators are being screened for their role in maintenance of HSC self-renewal using an *ex vivo* culture system wherein the identified secreted molecules are added.
Summary and Conclusions: The ongoing functional validation of transcriptional regulators in HSC and fetal liver HSC niche extrinsic factors will provide novel insights in mechanisms that support symmetrical selfrenewal of HSCs, which may be of great interest for clinical HSC transplantation, gene therapy, or creation of mature blood cells from stem cells.

RECIPIENT BATF3 DEPENDENT DENDRITIC CELLS SUPPRESS ACUTE GRAFT-*VERSUS*-HOST DISEASE AFTER EXPERIMENTAL ALLOGENEIC BONE MARROW TRANSPLANTATION

M Radsak[1,*] M Weber[2], B Rudolph[3], P Stein[4], A Waisman[5], M Bosmann[1,4], H Schild[2]
[1]Hematology / Oncology, [2]Institute of Immunology, [3]Dermatology, [4]Center for Thrombosis and Hemostasis, University Medical Center, [5]Institute of Molecular Medicine, University Medical Center Mainz, Mainz, Germany

Background: Graft-*versus*-host disease (GVHD) is a frequent life-threatening complication following allogeneic haematopoietic stem cell transplantation (HSCT) and induced by donor derived T cells that become activated by host antigen presenting cells.
Aims: The aim of our study was to assess the relevance of host dendritic cell (DC) populations in the initiation of acute GVHD.
Methods: We used three transgenic mouse strains deficient of $CD11c^+$ DC populations in a mouse model of acute GVHD where bone marrow and T cells from BALB/c donors are transplanted into C57BL/6 or CD11c-DTA, CD11c-iDTR or *Batf3* deficient (*Batf3*$^{-/-}$) hosts. DC phenotypes post HSCT were characterized by flow cytometry and *in vivo* cytokine production by quantitative real-time PCR. ^{3}H-thymidin uptake was used to assess T-cell proliferation in allogeneic MLR.
Results: Surprisingly a strong increase in GVHD related mortality was observed in the absence of $CD11c^+$ cells. Likewise *Batf3*$^{-/-}$ mice that lack $CD8\alpha^+$ DCs also displayed a strongly increased GVHD related mortality. In the absence of $CD8\alpha^+$ DCs, we detected an increased activation of the remaining DCs post HSCT, leading to an enhanced priming of allogeneic T cells. Importantly, this was associated with reduced numbers of regulatory T (Treg) cells and TGF-β levels indicating a failure of peripheral tolerance mechanisms after HSCT in the absence of $CD8\alpha^+$ DCs.
Summary and Conclusions: Our results indicate for a critical role of $CD8\alpha^+$ DCs as important inducers of Treg mediated tolerance to control DC activation and T-cell priming in the initiation phase of GVHD.

P483

DISRUPTED TOLL-LIKE RECEPTOR SIGNALING OF INTESTINAL EPITHELIUM IN INTESTINAL GRAFT-*VERSUS*-HOST DISEASE

C Liu[1], M Wu[2], K Zhao[2], X Wu[3], Y Zhang[2], Z Fan[2], Q Fan[2], C Yin[2], Z Zheng[2], Z Yi[2], Q Liu[2,*]
[1]Department of Hematology and oncology, Hunan Provincial Peoples Hospital, Changsha, [2]Department of Hematology, Nanfang Hospital, Southern Medical University, [3]Institute of Hematology, Medical College, Jinan University, Guangzhou, China

Background: The intestine is preferentially damaged in acute graft-*versus*-graft disease (aGVHD). Patients with intestinal GVHD are usually associated with drug-resistant diarrhea and microflora disturbance. Recent studies suggest that toll-like receptor (TLR) signaling can protect the intestinal epithelial barrier and confer commensal tolerance in health. But less is known about how functional *versus* dysfunctional TLR pathway opposes or favours the intestinal GVHD.
Aims: To identify the role of TLR signaling played in the intestinal GVHD.
Methods: In the current study, BALB/c mice were transplanted whole spleen and T cell deleted (TCD) bone marrow cells from C57BL/6 mice as GVHD group, and transplanted TCD bone marrow cells as control group. The jejunum, ileum, colon and rectum epithelium were harvested and total RNA were extracted in two groups. The mRNA expression of classical TLR pathway TLRx/MYD88/IRAK4 signaling molecules (TLR2, TLR4, MYD88, IRAK4 and Tollip) and cytokines (IFN-γ, TNF-α and TGF-β) were detected by RT-PCR.
Results: The intestine of aGVHD recipients showed severe mucosal edema and erythema with histologic changes of apoptotic epithelial cells and crypt cell dropout, while the intestine of recipients in the control group did not show any intestinal GVHD evidence. TLR2 expression was markedly down-regulated and little TLR4 expression was observed in GVHD intestinal epithelium in comparison to control group. MYD88 and IRAK4 expression were lower in the entire GVHD damaged intestine but only significant in colon and rectum between the two groups. Tollip, a TLR signaling inhibitor by interfering IRAK, was found much higher in the GVHD group. For cytokines, both of IFN-γ and TNF-α expression were markedly up-regulated from proximal to distal intestine in GVHD group as compared to control group. There was no difference in TGF-β expression between the two groups.
Summary and Conclusions: We propose TLR signaling in the intestinal epithelium, especially in colon and rectum, presents disruption in intestinal graft-*versus*-host disease. IFN-γ and TNF-α might contribute to accelerate TLR pathway alteration.

P484

CYCLOSPORIN A DOES NOT IMPAIR EARLY GRANULOCYTE EFFECTOR FUNCTION

Background: Severe infections with A*spergillus fumigatus* play a relevant role in immunodeficient patients after myelo-affecting chemotherapy or under long-term immunosuppressive medication, *e.g.* in allogeneic hematopoietic stem cell or solid organ transplantation. In these patients prolonged neutropenia is a major risk factor for fungal infections indicating an essential role of innate immune system in antifungal defense. Data from previous studies suggest that NFAT is a key player in signaling pathways of innate immunity e. g. in polymorphonuclear neutrophils (PMN) and that it can be modulated by commonly used agents like cyclosporin A (CsA).
Aims: The aim of our work is to elucidate the relevance of NFAT-dependent activation signals in PMN whether PMN effector functions are influenced by calcineurin/NFAT inhibitors and if NFAT-dependent signals are essential in immune responses against *Aspergillus fumigatus*.
Methods: To address the above mentioned questions we firstly performed *in vitro* experiments using human (healthy donors) PMN after purification and from whole blood regarding their effector functions in absence or presence of CsA in titrated doses appropriate to therapeutic levels. Phagocytosis and activation-induced shedding of CD62L was measured by flow cytometry using polychromatic microspheres and appropriate surface markers (CD11b-PB, CD62L-APC, CD66b-FITC). Generation of reactive oxygen species was analyzed by dichlorofluorescein assay (DCF) and activation-induced synthesis of IL-8 by enzyme-linked immunosorbent assay (ELISA) and intracellular flow cytometry. Secondly, we applied a murine *Aspergillus fumigatus* pneumonia model to study the antifungal innate immune response *in vivo* with or without intraperitoneal administration of CsA (18mg/kg, appropriate to a serum level of 600ng/ml). Here, PMN recruitment to the lungs, pulmonary clearance of *Aspergillus fumigatus* and survival of infected mice was examined. PMN-depleted mice using an murine Gr1-antibody served as controls.
Results: Administration of CsA had no significant influence on human granulocyte expression of activation markers and shedding of CD62L. Moreover, additional functional testing indicated also no substantial influence on generation of reactive oxygen species (5245 RFU +/- 354 *vs.* 5763 +/- 520 (control) after stimulation with LPS, mean +/- SEM) compared to controls. Likewise the activation-induced synthesis of IL-8 was not reduced in presence of CsA *in vitro* (519pg/ml +/- 81 *vs.* 463 +/- 131 (control) after stimulation with LPS). In contrast, phagocytosis was rather enhanced in presence of CsA (83.5% +/- 1.7 *vs.* 71.0 +/- 1.5 (control) after stimulation with LPS). Regarding survival of *Aspergillus fumigatus* infected mice, successful granulocyte-dependent clearance of fungal infection was not impaired in relevant degree through CsA medication.
Summary and Conclusions: Early granulocyte-based innate immune function is not inhibited by CsA, suggesting that NFAT may play a more crucial role in granulocyte differentiation under steady state conditions. Therefore, we are planning *in vivo* experiments with long-term CsA-pretreated mice and also *ex vivo* analysis of patient blood samples under continuous CsA medication. Finally, we expect our results to lead to a deeper understanding of innate immune response after fungal infection and will therefore contribute to improved therapeutic options for immunodeficient patients.

P485

RECONSTITUTION OF GPI-ANCHOR-NEGATIVE NK CELL POPULATIONS AFTER ALLOGENEIC STEM CELL TRANSPLANTATION FOLLOWING ALEMTUZUMAB-BASED CONDITIONING

A N Lay[1,*] D Wolff[1], M Theobald[1], E Ullrich[2], R G Meyer[1], E M Wagner[1]
[1]Hematology, Oncology and Pneumology, University Medical Center Mainz, Mainz, [2]Childrens Hospital, Hematology & Oncology, Cellular Immunology, Goethe University Frankfurt, Frankfurt, Germany

Background: The anti CD52-antibody Alemtuzumab is used for T cell depletion (TCD) in the context of allogeneic hematopoietic stem cell transplantation (HSCT). We already showed long-term persistence of CD52-/Glykosylphosphatidyl-Inositol (GPI)-negative T cells with impaired antiviral function in patients after HSCT. In addition, we observed a correlation between the persistence of GPI^{neg} regulatory T cells with impaired immunosuppressive capacity and severe acute GvHD.
Aims: Since NK cells influence antitumor reactivity, antiviral defense and GvHD, in this study, we analyzed GPI expression on natural killer (NK) cells of patients undergoing HSCT.
Methods: We examined peripheral blood samples of 12 patients after HSCT following reduced intensity conditioning including Alemtuzmab. By using multicolor FACS-analysis, we phenotypically distinguished the NK cell subpopulations $CD56^{bright}CD16^{dim}$, $CD56^{dim}CD16^{bright}$, $CD56^{dim}CD16^{int}$ and $CD56^{dim}CD16^{neg}$ at d+60 and d+365 after HSCT. GPI^{neg} NK cell subsets were characterized regarding their expression of specific surface antigens involved in cytotoxicity (NKp44, NKp46, NKG2A and NKG2D), maturation and activation (CD62L, CD69). CMV-reactivity was investigated by IFNγ ELISPOT-assay in two patients.
Results: Early after HSCT, we found $CD56^{dim}CD16^{int}$, to be the major NK cell population, at d+356 $CD56^{dim}CD16^{bright}$, becomes, the most prominent population. At d+60, $CD56^{dim}CD16^{bright}$, and $CD56^{bright}CD16^{dim}$ showed 70-90% of GPI^{neg} cells, which decreased over time. $CD56^{dim}CD16^{neg}$ and $CD56^{dim}CD16^{int}$ NK cells were mostly GPI^{pos}. Independent from GPI expression NKp46 was positive in the $CD56^{dim}CD16^{bright}$, / $CD56^{bright}CD16^{dim}$ populations. In contrast, $CD56^{dim}CD16^{neg}$ and $CD56^{dim}CD16^{int}$, NK cells remained, NKp46 negative at d+60. Early after HSCT, all NK cell subsets lacked NKG2D, whereas NKG2A expression remained stable over time. Interestingly, NKp44 was only observed on GPI^{pos} NK cells, and its expression increased late after HSCT, especially in $CD56^{dim}CD16^{int}$, NK cell populations. The activation marker CD69 was mainly expressed on $CD56^{dim}CD16^{neg}$ and $CD56^{dim}CD16^{int}$. CD62L was prominent in $CD56^{dim}CD16^{neg}$ and $CD56^{dim}CD16^{int}$ early after HSCT,, but increased in the $CD56^{dim}CD16^{bright}$/$CD56^{bright}CD16^{dim}$ NK cell population at d+365. Remarkably, we observed the highest frequency of CMV-specific IFN-γ production by NK cells early after transplantation in the absence of T cells.
Summary and Conclusions: We previously showed the reconstitution of functionally impaired GPI^{neg} T cells which may be partly responsible for some of the viral complications after Alemtuzumab-based conditioning. In this context, NK cells play a major role especially early after HSCT. Here we provide for the first time data on a relevant percentage of GPI^{neg} NK cells and their specific subset distribution over time. We observed many NK cells with $CD56^{dim}CD16^{int}$ phenotype early after HSCT, whereas later $CD56^{dim}CD16^{bright}$, NK cells were dominant comparable to the natural NK distribution in healthy donors. Depended on the time after HSCT, the expression of GPI-anchors and natural cytotoxicity receptors, maturation- and activation markers varied. These alterations may impact the capacity of NK cell mediated immune responses depending on the GPI-anchors itself. Further investigations on different NK subsets and their specific function will help to identify patients with a need for specific cellular therapies such as NK cell based DLI.

P486

INDUCTION OF MIXED CHIMERISM USING COMBINATORY CELL-BASED IMMUNE MODULATION WITH MESENCHYMAL STEM CELLS (MSCS) AND REGULATORY T CELLS (TREGS) FOR SOLID ORGAN TRANSPLANTAION

SG Cho[1,2,*] KI Im[2], MJ Park[3], JY Lim[2], N Kim[2], YS Nam[2], EJ Kim[2], ML Cho[3], JH Yoon[1], JW Park[1]
[1]Hematology, [2]Laboratory of Immune Regulation, Convergent Research Consortium for Immunologic Disease, [3]Rheumatism Research Center, Seoul St. Mary's Hospital, The Catholic University of Korea College of Medicine, Seoul, Korea, Republic Of

Background: Establishment of mixed chimerism is an ideal approach to induce donor-specific tolerance expanding its potential in various clinical settings. Despite the developments in partial conditioning regimens, improvements are still needed in reducing toxicity and BMT related complications. Recently, cell-based therapies including mesenchymal stem cells (MSCs) have been incorporated in establishing noncytoreductive mixed chimerism protocols; however, its efficacy is only partial and show reversed immunosuppressive properties.
Aims: We hypothesize that the interaction between MSCs and Tregs may lead to greater inhibition of host immune responses. We investigated the effects of cell-based immune modulation (CCIM) of MSCs and Tregs with a low-intensity conditioning regimen and achieved persistent mixed chimerism and tolerance in an MHC-mismatched transplantation mouse model.
Methods: Recipient mice underwent total-body irradiation (TBI) at a dose of 150 cGy 3 days before BMT, followed by intravenous infusion of 3×10E7 donor BM cells on day -2 and cyclophosphamide (CY, 100 mg/kg) on day -1. On the day of BMT, recipient mice received TCD BM cells or total BM cells. On days +1 and +3 following BMT, they received combinatory cell-based immune modulation of Tregs (2×10E6) and MSCs (2×10E6). To establish GVHD, recipients were lethally irradiated with 750 cGy 1 day before injected 2×10E7 donor BM cells on day 0. On days +1, +10, +16 and +23, recipient mice received MSC alone or combination of MSC and Treg. To assess immune function *in vivo*, full-thickness skin grafts were transplanted from allogeneic mice and syngeneic mice to the dorsa of the recipient mice. All animals were monitored for clinical signs, histopathologic changes, post-transplant immunologic changes, the degree of mixed chimerism, and donor-specific tolerance.
Results: Compared to single cell therapy, CCIM induced a higher engraftment rate and robust donor-specific tolerance to skin allografts across full MHC barriers. These regulatory effects were associated with inhibition of NK cell cytotoxic activity, CD4+IL-17+ cells, memory B cells, plasma cells and immunoglobulin production levels with increased frequencies of CD4+Foxp3+ cells, IL-10-producing mature B cells and myeloid-derived suppressor cells (MDSC). Furthermore, CCIM was able to regulate mortality in a GVHD model through reciprocal regulation of Treg/Th17.
Summary and Conclusions: Taken together, we suggest combinatory cell-based immune modulation (CCIM) of MSCs and regulatory T cells (Tregs) as a clinically applicable strategy for facilitating the induction of mixed chimerism and permanent tolerance for solid organ transplantation.

P487

ACTIVATED MONOCYTE-PHAGOCYTES PROBABLY INITIATE THE ONSET OF PRE-ENGRAFTMENT SYNDROME (PES) FOLLOWING UMBILICAL CORD BLOOD TRANSPLANTATION

J Wang[1,*] Z Sun[1], M Guan[1], H Liu[1], C Zheng[1], J Tong[1]
[1]Department of Hematology, Anhui Provincial Hospital, Hefei, China

Background: Cord blood transplantation (CBT) is being increasingly used for treatment of hematological malignancies and showed many advantages. The immaturity of T cell contained in the graft and the T cell reconstitution is later than bone marrow transplantation (BMT) or peripheral blood stem cell transplantation (PBSCT), but the relapse rate after CBT to be comparable to that BMT or PBSCT. Our clinical analysis revealed the outcome of CBT for high risk acute leukemia relapse after HLA-mismatched CBT was lower than that BMT or PBSCT, but the incidence of graft-*versus* host disease (GVHD) was similar. Pre-engraftment syndrome seems to be a distinct clinical syndrome from engraftment syndrome, which developed usually after cord blood transplantation. PES was defined as unexplained fever >38.3C not associated with infection and unresponsive to antimicrobials, and/or diarrhea, jaundice, and weight gain which occurred before neutrophil recovery. If only the PES patients have simple fever and rash, just the right amount of methyl prednisolone treatment can make the symptoms disappear, but some patients is not sensitive to hormone therapy can accentuate illness. Because when PES occurs the white blood cell number of transplantation patient is extremely low, so they can easy get high fever with the serious complications such as hemorrhage, which may threaten transplant patients life and UCBT success rate. The pathogenesis of PES is not clear. It has been speculated that cytokines induced by the initial immune/inflammation reaction are the primary cause of PES, but no data are available to confirm this supposition. Proteomic patterns have been studied in the fields of transplantation, but no specific marker has been identified also. Our prior studies suggest monocyte-phagocytes from the donor initiate the cause of PES.
Aims: To explore the main effective cells and the pathogenesis of pre-engraftment syndrome (PES) in patients with hematological malignancies after umbilical cord blood transplantation
Methods: We selected 26 patients with PES and 6 patients without PES as control; they were all treated with umbilical cord blood transplantation after myeloablative conditioning regimens. We collected the serum samples before transplantation, PES and after PES been controlled and detected the cytokines related to monocyte-macrophages, T cells and NK cells by multicolor flow cytometry or /and ELISA. The miRNA sequencing was performed on Illumine HiSeq 2000 using TruSeq Rapid SBS Kits. The target genes may be predicted according to the differentially expressed miRNA then analyze GO and pathway by comparing the database of mirbase, miranda, targetscan. Data are summarized as mean±SD. Student t test was used to determine whether there was a statistically significant difference between samples, with two-tailed P values less than 0.05 indicating a significant difference.
Results: 1) The cytokines of IL-1B, IL-6,IL-18 and MCP-1 that related to monocyte-macrophages increased significantly in the 26 CBT patients with PES

compared to before transplantation or the same period of six patients without PES($p<0.01$). Those cytokines declined to the level prior to the occurrence of the PES when the symptom controlled, but neither the cytokines of Th1/Th2/Th17 nor NK had no significant difference. The levels of IL-1b, IL-6, TNF-a and IL-17 in stool of two patients with PES were significantly higher than the peripheral blood. 2) There were no significant difference between PES and the control groups in the levels of serum complement C3a, C4a, C5a ($p>0.05$).3) There were no significant difference between PES and the control groups in the proportion of peripheral blood T or NK cells and the expression of CD11b, CD27, CD57 on NK cells($p>0.05$) on 14 days. 4) We collected nine serum samples for miRNA sequencing in three patients who treated by single umbilical cord blood transplantation at the time of before, occurrence and symptom of PES controlled. The results showed 39 differentially expressed miRNA such as hsa-let-7i-5p, hsa-mir-98-5p, hsa-mir-152-3p, hsa-mir-223-3p and so on. It could be deduced three signaling pathways related to active the monocyte-phagocytes such as TOLL,NOD and RIG-I-like receptor by predicting the target genes +GO+Pathway analysis when development of PES.

Summary and Conclusions: Our preliminary finding confirmed that the monocyte-phagocytes are the effective cells of PES. They are activated by Toll, NOD or RIG-I-like receptor signaling pathway and produce immunological functions. This will provide a reliable experimental basis for the further research of pathogenesis of PES.

P488

INFLUENCE OF HLA-G POLYMORPHISM ON VIRAL REACTIVATION AND OVERALL SURVIVAL AFTER HEMATOPOIETIC STEM CELL TRANSPLANTATION

E Metafuni[1,*] S Bellesi[1], S Giammarco[1], M Stignani[2], O Baricordi[2], R Rizzo[2], S Sica[3], V De Stefano[1], P Chiusolo[1]

[1]Hematology, Università Cattolica del Sacro Cuore, Rome, [2]Experimental and Diagnostic medicine, Università degli studi di Ferrara, [3]Hematology, Università Cattolica del Sacro Cuore, Ferrara, Italy

Background: Human leukocyte antigen-G (HLA-G) is a non-classical class Ib HLA molecule characterized by tolerogenic role widely studied *in vitro*: inhibition of T CD4+ alloproliferative response, inhibition and apoptosis of NK and CD8+ T cells, inhibition of APC, induction of immunosuppressive cells.

The HLA-G expression is regulated by a deletion(del)/insertion(ins) polymorphism of 14 base pair (bp) at the 3' untranslated region of exon 8. The 14bp-insertion is associated with a decreased mRNA stability and a lower HLA-G protein expression.

Aims: We analyzed the possible role of HLA-G polymorphism in the setting of stem cell transplantation (SCT), in terms of Graft-*versus*-host disease (GvHD), viral reactivation, OS and DFS.

Methods: We studied retrospectively 78 patients (pts) (Table 1), 44M/34F, with a median age of 45 years (range 10-65) underwent SCT. The underlying diseases were: 2 Aplastic anemia, 1 HL, 19 ALL, 1 CLL, 46 AML, 2 CML, 2 NHL, 3 IMF, 2 MDS. A myeloablative SCT was performed in 56 pts, while 22 pts received a reduced intensity conditioning. GvHD prophylaxis was obtained with Cyclosporine A and short course of methotrexate. Stem cell source was BM in 5 pts, CB in 4 pts and PB in 69 pts, with a median dose of CD34+ of $6.83*10^6$/Kg (range 1.2-19.7). Donor was sibling in 46 cases and MUD in the other 32 cases. HLA-G polymorphism was determined on genomic DNA extracted by donor and recipient samples before transplant, amplified by standard PCR and visualized on agarose gel electrophoresis. Data were analysed using IBM SPSS Statistics 20 Core System.

Results: No correlation was found between HLA-G and GvHD or DFS. Surprisingly, HLA-G polymorphism showed a relationship with viral reactivation after SCT. After SCT, 14 pts showed a CMV reactivation, 11 pts an EBV reactivation and 21 pts revealed both them. In the setting of CMV reactivation, viral replication achieve a maximum load of 2.200.000 copies/ml, while EBV reactivation reached a maximum of 1.136.000 genome copies/ml. Furthermore, two pts developed EBV-related post-transplant lymphoproliferative disease without circulating viremia. In pts receiving SCT from ins/ins donor, EBV reactivation was detected after a median of 41 days (range 10-102) compared to 64 days (range 16-532) in pts transplanted by ins/del or del/del donor ($p=0.034$). Moreover in the setting of CMV reactivation after SCT, the maximum viral copies number reached by pts receiving stem cells from del/del donor was lower than viral copies titer detected in pts transplanted by ins/del and ins/ins donor, 4140 genome copies/ml (range 1040-2200000) and 10.000 copies/ml (range 6000-331180) respectively ($p=0.0366$). Donor and recipient del/del polymorphism was also associated with a prolonged OS both in terms of TRM (toxicity, MOF, GvHD, infections) and relapse mortality. Median OS was 18 months for del/del pts, 10 months for ins/del pts and 6 months for ins/ins pts ($p=0.023$), while it was 22 months for del/del donor, 9 months for ins/del donor and 6 months for ins/ins donor ($p=0.011$).

Summary and Conclusions: These data highlight that tolerogenic power of HLA-G might play a role in viral infection control after SCT. Particularly, ins/ins donor polymorphism associated with a decreased level of soluble HLA-G molecule, allows earlier viral reactivation (EBV) and a broad viral replication (CMV) after SCT.

Table 1. Patients characteristics.

MYELOID DERIVED SUPPRESSOR CELLS ARE MOBILIZED BY G-CSF IN MICE AND MEN

K Wetzko[1,*] M Schmitz[2], R Wehner[2], K Hölig[1], U Schuler[1], R Ordemann[1], T Chavakis[3], Y Mitroulis[4], G Ehninger[1], M Bornhäuser[1], M von Bonin[1]

[1]Department of Internal Medicine I, University Hospital TU Dresden, [2]Institute of Immunology, Medical Faculty TU Dresden, [3]Department of Internal Medicine III, Division of Vascular Inflammation, Diabetes and Kidney, [4]Institute for Clinical Chemistry and Laboratory Medicine, University Hospital TU Dresden, Dresden, Germany

Background: In solid cancers, the frequency of Myeloid derived suppressor cells (MDSCs) correlates with tumor stage. Progressive disease has been associated with MDSC function as MDSCs are believed to mediate tumor escape from T-cell–mediated immunosurveillance. The relevance of this population in the context of allogeneic hematopoietic stem cell transplantation (HSCT), Graft-*versus*-Host Disease (GvHD), and Graft-*versus*-Leukemia effect (GvL) is largely unknown.

Aims: Therefore, we determined the frequency of MDSC in bone marrow (BM) and leukapheresis products (LPHs) collected for HSCT.

Methods: MDSCs were defined as monocyte-like cells with a lack or low expression of HLA-DR ($CD14^+HLA\text{-}DR^{low/-}$). We quantified MDSCs in the peripheral blood (PB), LPH and BM of healthy volunteer donors by multi-color flow cytometry. For routine diagnostic purposes, we compared leukocyte isolation by density gradient centrifugation (DGC) and red blood cell lysis (RBC-lysis). PB was drawn before (PB) and after receiving G-CSF at 7.5µg/kg/day for 5 days (PB+G-CSF). LPH and BM samples were obtained at the day of donation. All samples were prepared and stained with a panel of antibodies within 24 hours after donation. In C57BL/6J mice, monocytic (CD11b/Ly6C) MDSCs frequency in PB was analyzed before and after subcutaneous application of GCSF (250µg/kg for 6 consecutive days). Functionality of MDSCs was examined using an in-vitro proliferation suppression assay of autologous T-cells.

Results: The frequency of MDSCs in PB of human donors was lower than in BM, but we observed a significant increase of MDSCs in PB upon G-CSF treatment (PB: 29±16%; BM: 41±16%; PB+G-CSF: 44±18%; LPH: 52±14% of CD14+), while relative CD14+HLA-DR+ and CD14+ cell counts remained unchanged. However, the largest number of MDSCs was found in LPHs (PB *vs.* PB+GCSF $p<0.05$; PB *vs.* LPH $p<0.001$; Figure 1). Consistently, G-CSF stimulation in mice resulted in a significant increase of the MDSC frequency in PB (monocytic MDSC: 3.7±0.9% of total leucocytes). In contrast to MDSCs isolated from PB, PB+G-CSF and LPH, MDSCs from BM did not inhibit the proliferation of stimulated autologous T-cells. RBC-lysis shows comparable MDSC frequencies to DGC in PB, PB+G-CSF, LPH and BM, respectively. As RBC-lysis allows a faster processing of samples, this method might represent a more useful technique in routine diagnostics.

Summary and Conclusions: In healthy volunteers, the frequency of phenotypically defined MDSCs was higher in BM compared to PB, but G-CSF treat-

ment led to a significant increase in MDSCs in PB, which was reproduced in the murine system. Finally, the leukapheresis procedure led to a further enrichment of MDSCs in the grafts. However, phenotype did not necessarily predict functionality, as MDSCs isolated from BM did not show any suppressive capacity in an in-vitro proliferation assay. The consequences of these findings on engraftment, GvHD and GvL after allogeneic HSCT remain to be elucidated.

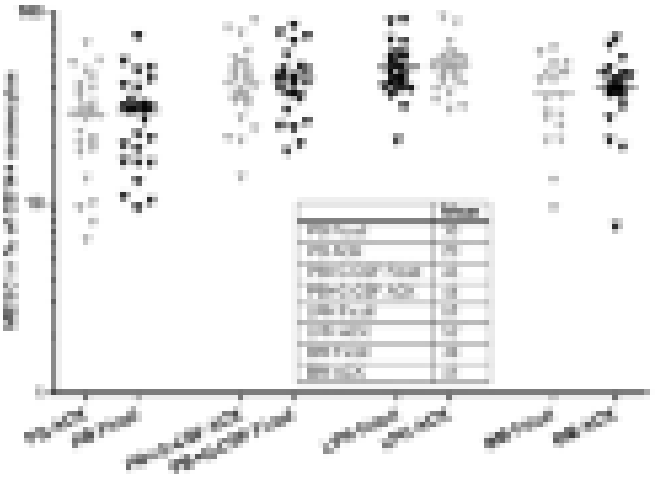

Figure 1.

P490

GRANULOCYTE COLONY-STIMULATING FACTOR MOBILIZATION AFFECTS THE EXPRESSION OF TH1/TH2 CHEMOKINES AND THEIR RECEPTORS

L Xuan[1], X Wu[2], Z Jin[2], X Wang[2], M Dai[1], Y Zhang[1], Y Li[2], Q Liu[1,*]
[1]Nanfang Hospital, Southern Medical University, [2]Institute of Hematology, Medical College, Jinan University, Guangzhou, China

Background: Granulocyte colony-stimulating factor (G-CSF) mobilized peripheral blood stem cell (PBSC) has been used more frequently than bone marrow as the source of stem cells in allogeneic hematopoietic stem cell transplantation (allo-HSCT). Although it contains more mature T cells, neither the incidence nor the severity of acute graft-*versus*-host disease (aGVHD) is higher compared with bone marrow transplantation. This might be due to the immunoregulatory effects of G-CSF on adaptive immunity, including that G-CSF directly modulated via its receptor on T cells or indirectly modulated T cell immune responses via effector cells and cytokines. However, these mechanisms are not fully understood, and whether G-CSF could influence the expression of Th1/Th2 chemokines and their receptors remains unknown.
Aims: To investigate the effect of G-CSF mobilization on the expression of Th1/Th2 chemokines and their receptors.
Methods: The expression levels of Th1 chemokines (CXCL9, CXCL10, and CXCL11), Th2 chemokines (CCL17, CCL22) and their receptors CXCR3 and CCR4 were analyzed in peripheral blood mononuclear cells (PBMCs) from 25 donors before and after G-CSF mobilization, using real-time RT-PCR with SYBR Green-staining. The β_2-microglobulin gene (β_2-MG) was used as an endogenous reference, and the relative mRNA expression level of each gene was evaluated by the $2^{-\Delta C}$, ^{t}×100% method.
Results: The median expression level of CXCR3 was similar before and after G-CSF mobilization (0.1426% and 0.1109%) (P=0.278), while the expression level of CCR4 after G-CSF mobilization (0.0985%) was significantly lower than that before mobilization (0.1415%) (P=0.039). The median expression levels of CXCL9, CXCL10, and CXCL11 genes before mobilization (0.0048%, 0.0576% and 0.0079%) were not significantly different from that after G-CSF mobilization (0.0143%, 0.0666% and 0.0088%)(P=0.086, P=0.535 and P=0.680). The median expression levels of CCL17 and CCL22 were also similar before and after G-CSF mobilization (P=0.155, P=0.476). The expression pattern of three Th1 chemokines before mobilization was CXCL10>CXCL11>CXCL9, whereas it changed to CXCL10>CXCL9>CXCL11 after mobilization. The expression pattern of two Th2 chemokines before mobilization was CCL17>CCL22, whereas it changed to CCL22>CCL17 after mobilization. The relative expression levels of CXCL10 and CXCL11 genes before mobilization both showed a positive correlation to that after mobilization (P<0.001, r=0.760; P=0.024, r=0.470). Before mobilization, significant positive correlation was observed between the expression levels of CXCL9 and CXCL10, CXCL11 and CXCR3, CXCL11 and CCL22, CXCR3 and CCL22 (P<0.001, r=0.902; P=0.003, r=0.584; P=0.022, r=0.473; P<0.001, r=0.674, respectively). After G-CSF mobilization, significant positive correlation was observed between the expression levels of CXCL9 and CCL22, CXCL10 and CXCL11, CXCR3 and CCR4, CXCR3 and CCL22, CXCR3 and CCL17, CCL22 and CCL17 (P=0.001, r=0.653; P=0.001, r=0.665; P=0.002, r=0.602; P=0.028, r=0.458; P<0.001, r=0.738; P=0.044, r=0.424, respectively).
Summary and Conclusions: G-CSF mobilization might mainly influence the expression level of CCR4 genes in Th1/Th2 chemokines and their receptors. The expression patterns of Th1 chemokines and Th2 chemokines might both change after G-CSF mobilization.

P491

GRANULOCYTE COLONY-STIMULATING FACTOR MOBILIZATION AFFECTS THE EXPRESSION OF REGULATORY GAMMA DELTA T CELLS

L Xuan[1], X Wu[2], S Yu[1], Z Yi[1], M Dai[1], Y Li[2], Q Liu[1,*]
[1]Nanfang Hospital, Southern Medical University, [2]Institute of Hematology, Medical College, Jinan University, Guangzhou, China

Background: The immune modulatory effect of granulocyte colony-stimulating factor (G-CSF) on T cells resulted in an unexpected low incidence of graft-*versus*-host disease (GVHD) in allogeneic peripheral blood stem cell transplantation. Our previous studies demonstrated that G-CSF mobilization influenced the distribution and clonality of TRGV and TRDV repertoire (T cell receptors of γδ, T cells), and significant positive correlation was observed between the invariable clonality of TRDV1 gene repertoire after G-CSF mobilization and low incidence of GVHD in recipients (P=0.015, OR=0.047) (Li Xuan *et al.* Journal of Translational Medicine 2011). Regulatory γδ T cells (γδ Tregs), which express Foxp3 and primarily belong to $CD27^{+}CD25^{high}$, phenotype, are a novel subset of cells with immunosuppressive function (Xiaoyan Li *et al.* Journal of Immunology 2012). However, whether G-CSF could influence the expression of γδ Tregs remains unknown.
Aims: To investigate the effect of G-CSF mobilization on the expression of γδ Tregs.
Methods: The immunophenotyping of γδ Tregs was analyzed in peripheral blood mononuclear cells (PBMCs) from 20 donors before and after G-CSF mobilization, using flow cytometry.
Results: Compared with that before mobilization, the Vδ1 proportion was significantly increased (*P*=0.001), whereas the proportions of total γδ T cells and Vδ2 subsets were significantly decreased after G-CSF mobilization (*P*=0.011, *P*=0.005). The proportions of $CD25^{+}$ and $CD27^{+}$ subsets were also significantly increased after mobilization (*P*=0.006, *P*=0.015), and the proportion of $Foxp3^{+}$ subset was similar between the two groups (*P*=0.768). In addition, there was a significant increase in the proportions of $Foxp3^{+}$Vδ1, $CD27^{+}$Vδ1, $CD25^{+}Foxp3^{+}$, and $CD25^{+}CD27^{+}$, subsets (*P*=0.008, *P*=0.007, *P*=0.011, *P*=0.014), and a significant decrease in the proportions of $CD27^{+}$Vδ2 and $CD25^{+}$Vδ2 subsets after mobilization (*P*=0.021, *P*=0.007). We then compared the Foxp3, CD27 and CD25 phenotypes in total γδ T cells, Vδ1 and Vδ2 subsets. We observed a significant increase in the proportions of $CD27^{+}Foxp3^{+}$, Vδ1, $CD25^{+}Foxp3^{+}$, Vδ1 and $CD25^{+}CD27^{+}$Vδ1 subsets after G-CSF mobilization (*P*=0.005, *P*=0.024, *P*=0.040, respectively).
Summary and Conclusions: G-CSF mobilization significantly increased the proportions of Vδ1 subsets, including $Foxp3^{+}$Vδ1, $CD27^{+}Foxp3^{+}$, Vδ1 and $CD25^{+}Foxp3^{+}$, Vδ1 subsets, whereas decreased the Vδ2 proportion.

P492

USE OF UNRELATED DONORS IN ELDERLY PATIENTS (AGE >60 YEARS) UNDERGOING REDUCED-INTENSITY CONDITIONING HEMATOPOIETIC STEM CELL TRANSPLANTATION FOR HEMATOLOGIC MALIGNANCIES

J El Cheikh[1,*] R Devillier[1], S Fürst[1], R Crocchiolo[2], A Granata[1], C Faucher[1], B Mohty[1], S Harbi[1], R Bouabdallah[3], N Vey[3], L Castagna[2], C Chabannon[1], D Blaise[4]
[1]Unité de Transplantation et de Thérapie Cellulaire, Institut Paoli-Calmettes, Marseille, France, [2]Hematology, Humanitas, Milan, Italy, [3]Département d'Onco-Hématologie, [4]Untié de Transplantation et de Thérapie Cellulaire, Institut Paoli-Calmettes, Marseille, France

Background: We retrospectively analyzed outcomes in 62 consecutive hematologic malignancy patients aged >or =60 years (median, 62 years; range: 60-70 years) undergoing reduced intensity conditioning regimens (RIC) from URD. In this study, URD was used only when a MRD was not available.
Then we compared the outcome of 17 elderly patients (age >65 years) with 44 younger patients aged between 60 and 65 years.
Aims: The lower morbidity and mortality of reduced-intensity conditioning (RIC) regimens have allowed allogeneic hematopoietic cell transplantation (HCT) in older patients. However, there are only limited data on the feasibility and outcomes of URD HCT in elderly patients.The aim of the study was to compare the outcome in OS and PFS for patients transplanted using unrelated donor (URD) in patients age 60 or older.
Results: No patients experienced graft rejection. The median HCT comorbidity index score was 2 (range, 0 to 6). With a median follow up of 36 months (range, 5-74), the cumulative incidence of grades II to IV acute GVHD was 28% and of grades III to IV acute GVHD, 13%. At 2 years, the cumulative incidence of chronic GVHD was 27%, progression-free survival (PFS) was 62%, overall

survival (OS) was 63%, and relapse was 14%. Non relapse mortality (NRM) was 24% at 2 years.
The cumulative incidence of grade II–IV Acute GVHD was 43% for the younger group and 17% for the older group (P=0.056). The cumulative incidence of chronic GVHD was not different between the two groups (23% *vs.* 45% (p=0.3), respectively). Two-year OS and PFS was 57% *versus* 86% (P=0.059) and 55% *versus* 86% (P=0.03), in the younger and the older group respectively. The 2-year NRM and relapse was 26% *versus* 14% (P=0.4) and 19% *versus* 0% (P=0.04), in the younger and older group respectively.
Summary and Conclusions: This retrospective study suggest that RIC HCT from URD is a safe and effective option for patients aged >or =60 years or older, and in the absence of suitable related donors, well-matched URD may offer a very reasonable alternative, and that does not appear to be associated with a detrimental outcome. However these results are encouraging showing once again that with an adequate selection, age is not a definitive limitation.

P493

MICAFUNGIN *VERSUS* FLUCONAZOLE OR ITRACONAZOLE FOR PROPHYLAXIS AGAINST INVASIVE FUNGAL INFECTIONS DURING NEUTROPENIA IN PATIENTS UNDERGOING HAPLO-IDENTICAL HEMATOPOIETIC STEM CELL TRANSPLANTATION

J El Cheikh[1,*], R Crocchiolo[2], S Furst[1], S Bramanti[2], B Sarina[2], A Granata[1], C Faucher[1], B Mohty[1], S Harbi[1], R Bouabdallah[1], N Vey[3], C Chabannon[4], A Santoro[2], D Blaise[1], L Castagna[2]
[1]Unité de Greffe, Institut Paoli-Calmettes, Marseille, France, [2]Hematology, Humanitas, Milan, Italy, [3]Hematology, [4]Therapie Cellulaire, Institut Paoli-Calmettes, Marseille, France

Background: Over the past decade, invasive fungal infections (IFI) have remained an important problem in patients undergoing hematopoietic stem cell transplantation (HSCT). The optimal approach for prophylactic antifungal therapy has yet to be determined.
Aims: we conducted a retrospective, bi-institutional comparative clinical study, (Institut Paoli-Calmettes at Marseille France and Humanitas cancer center at Rozzano, Italy), and we compared the efficacy and safety of Micafungin 50mg/day (iv) with those of fluconazole (400mg/day) or itraconazole 200mg/day (iv) as prophylaxis for adult patients with various haematological diseases receiving haplo-identical allogeneic stem cell transplantation (haplo-SCT). Patients received prophylaxis with the beginning of the transplant conditioning regimen until the hospital discharge, or until occurrence of an IFI. We compared the incidence of proven or probable IFI (the primary end point) between the micafungin and fluconazole or itraconazole groups; death from any cause and time to death was secondary end points. Patients were followed for 100 days after haplo-SCT and for 30 days after the last dose of the prophylaxis drug administrated.
Results: From January 2009 to May 2013, a total of 99 patients were identified; 30 patients received micafungin, and 69 patients received fluconazole or itraconazole. 81 patients (82%) received a non myeloabaltive conditioning regimen (NMA), with Fludarabine, Cyclophosphamide and Total body irradiation (TBI) 2 Gy based, or Fludarabine, Busulfan, and Cyclophosphamide based (3%) or other (9%), while five patients (5%) received a thiotepa-based conditioning regimen. The patients and transplant details are shown in the Table 1. Proven or probable invasive fungal infections were reported in 2 patients (7%) in the micafungin group and 8 patients (12%) in the fluconazole or itraconazole group (absolute reduction in the micafungin group, −5%; 95% confidence interval, 0.0565-3.1395, P=0.72). Fewer patients in the micafungin group had invasive aspergillosis (1 [3%] *vs.* 5 [7%], P=0.6). A total of 4 (13%) patients in the micafungin group and 23 (33%) patients in the fluconazole or itraconazole group received empirical antifungal therapy (P=0.14). No serious adverse events related to treatment were reported by patients and there was no treatment discontinuation because of drug related adverse event in both groups. Overall Survival and disease free survival were similar among the two groups (P=0.97). 6 patients (20%) in the micafungin group died within 100 days, as did 10 patients (14%) in the fluconazole or itraconazole group (P=0.57). Interestingly the transplant related mortality (TRM) at 100 days was 0% in the micafungin group *vs* 13% in the second group [CI 95% (0-22)] (p=0,06), whereas the relapse or progression rate at 100 days was 27% *vs.* 8% respectively [CI 95% (14-44)] (p=0,14).
Summary and Conclusions: In patients undergoing to haplo-SCT, antifungal prophylaxis with micafungin is well tolerated and effective to prevent IFI. Furthermore, the incidence of IFI and invasive aspergillosis seems lower even if this did not attend statistical power, probably due to low number of patients.

P494

EFFECT OF UPREGULATED TLR2 EXPRESSION FROM G-CSF-MOBILIZED DONOR GRAFT ON ACUTE GRAFT-*VERSUS*-HOST DISEASE IN MICE

YD Joo[1,*] WS Lee[2], SK Seo[3]
[1]Hematology, Haeundae Paik Hospital, College of Medicine, Inje University,, [2]Hematology, Pusan Paik Hospital, College of Medicine, Inje University,, [3]Microbiology and Immunology, Inje University, Busan, Korea, Republic Of

Background: Our previous study demonstrated that TLR2 expression was increased on donor graft mainly myeloid cell types by G-CSF treatment, which contributed rapid engraftment after allogeneic hematopoietic stem cell transplantation (HSCT) in mice (Cytokine 54:36-42; Immunol Lett. 143: 177-183).
Aims: In current study, we investigated the effects of upregulated TLR2 expression in G-CSF-mobilized donor graft on acute graft-*versus*-host disease (GVHD).
Methods: B6 donor mice were subcutaneous injected with recombinant human G-CSF (10 mg) daily for 5 days. The expression of TLR2 was analyzed on CD11b+, Gr-1+, CD3+, and CD19+ from splenocytes by flow cytometry**.** To evaluate the effect of TLR2 on acute GVHD, lethally irradiated (950 cGy) B6D2F1 mice were transplanted with splenocytes ($2x10^7$) from G-CSF-injected WT B6 or TLR2 KO B6 mice plus WT B6 TCD-BMs ($5x10^6$). Another experimental setting, using blocking antibody, recipients given splenocytes from G-CSF-injected B6 plus TCD-BMs were administrated with 0.2 mg of anti-TLR2 (T2.5) mAb on day 0, 2, and 5 after transplantation. Survival and clinical GVHD scores were monitored every 2 days.
Results: We found that TLR2 was highly expressed on myeloid cell population (CD11b+Gr-1+) but not T and B cells of splenocytes from G-CSF-treated donor mice. Mortality and severity of recipients were not significantly different between G-CSF-treated WT and TLR2 KO donor graft. Moreover, there was no difference on GVHD between anti-TLR2 mAb and control IgG.
Summary and Conclusions: Our results demonstrate that upregulated TLR2 expression in G-CSF-mobilized donor graft affects little on acute GVHD. Our study suggests that TLR2 is valuable target for increasing allo-HSCT efficiency to enhance engraft without acute GVHD enhancement.

P495

ALDEHYDE DEHYDROGENASE-BRIGHT CELLS CORRELATED WITH THE COLONY FORMING UNIT-GRANULOCYTE/MACROPHAGE ASSAY OF THAWED CORD BLOOD UNITS

HR Lee[1,*] S Shin[2, 3, 4], JH Yoon[2, 3, 4], EY Roh[2, 3, 4], BJ Kim[5], EY Song[2]
[1]Department of Laboratory Medicine, Gyeongsang National University Hospital, Jinju, [2]Department of Laboratory Medicine, Seoul National University College of Medicine, [3]Department of Laboratory Medicine, Boramae Hospital, [4]Seoul Metropolitan Government Public Cord Blood Bank (Allcord), [5]Department of Obstetrics and Gynecology, Boramae Hospital, Seoul, Korea, Republic Of

Background: Together with total nucleated cells (TNC) and CD34+ cells, the colony-forming unit-granulocyte/macrophage (CFU-GM) has been regarded as a marker predicting transplantation outcome in hematopoietic stem cell transplantation, because the CFU-GM represents the clonogeneic and proliferative potentials of hematopoietic stem cells. However, CFU assay takes 14 days; therefore, there are some difficulties in application as routine examination. Recently, the number of cells with high aldehyde dehydrogenase (ALDH) activity, namely, ALDH-bright ($ALDH^{br}$) cells, has been suggested as a viable marker of hematopoietic stem cell function.
Aims: We evaluated the suitability of $ALDH^{br}$ cell analysis in the quality assessment of post-thaw cord blood (CB) units.
Methods: We used the 245 CB units rejected from the Seoul Metropolitan Government Public Cord Blood Bank inventory due to inappropriate test results after conventional processing. After thawing of cryopreserved CB units, the numbers of TNC, CD34+ cells, $ALDH^{br}$ cells among CD34+ cells (CD34+$ALDH^{br}$ cells), $ALDH^{br}$ cells, CD34+ cells among $ALDH^{br}$ cells ($ALDH^{br}$CD34+ cells), CFU-GM, and CFU-granulocyte/erythrocyte/macrophage/megakaryocyte (GEMM) were examined. We could extract the numbers of TNC and CD34+ cells before cryopreservation from inventory database. Simple linear regression analysis was performed to assess the correlation among the parameters: the number of TNC (pre-cryopreservation and post-thaw), the number of CD34+ cells (pre-cryopreservation and post-thaw), the numbers of post-thaw CD34+$ALDH^{br}$ cells, $ALDH^{br}$ cells, $ALDH^{br}$CD34+ cells, CFU-GEMM, and CFU-GM.
Results: CD34+ cells were found to represent 0.14%±0.10% of all TNC, and 74.5%±13.8% of CD34+ cells were found to express high ALDH activity (*i.e.*, CD34+$ALDH^{br}$ cells). $ALDH^{br}$ cells were found to represent 0.16%±0.10% of all TNC, and 69.9%±15.5% of $ALDH^{br}$ cells were found to express CD34 (*i.e.*, $ALDH^{br}$CD34+ cells). CFU-GEMM was significantly correlated with the numbers of TNC and CD34+ cells before and after cryopreservation (TNC, r=0.251 and r=0.250, respectively; CD34+ cells, r=0.391 and r=0.347, respectively) and the numbers of CD34+$ALDH^{br}$ cells, $ALDH^{br}$ cells, and $ALDH^{br}$CD34+ cells (r=0.297, r=0.297, and r=0.252, respectively). Although CFU-GM was not correlated with the numbers of TNC before and after cryopreservation, CFU-GM was significantly correlated with the number of CD34+ cells before and after cryopreservation (r=0.418 and r=0.359, respectively) and the numbers of CD34+$ALDH^{br}$ cells, $ALDH^{br}$ cells, and $ALDH^{br}$CD34+ cells (r=0.426, r=0.455, and r=0.469, respectively). CFU-GM showed higher correlation coefficient with the number of CD34+$ALDH^{br}$ cells, $ALDH^{br}$ cells, and $ALDH^{br}$CD34+ cells than with the number of CD34+ cells before and after cryopreservation.
Summary and Conclusions: The high correlation found between the numbers of CD34+$ALDH^{br}$ cells, $ALDH^{br}$ cells, and $ALDH^{br}$CD34+ cells and CFU-GM number supports the suitability of ALDH analysis in the quality assessment of post-thaw CB units.

Stem cell transplantation - Clinical 1

Background: Allo-HSCT has been shown to increase survival and improve cure in acute leukemia (AL). However, this procedure is accompanied by high rates of morbidity and mortality. Several risk scores based on conventional statistical methods may aid HSCT risk assessment, but these methods carry inherent limitations, which might lead to sub-optimal candidate selection. Machine learning (ML) is a field in computer science stemming from artificial intelligence and is part of the data mining approach for data analysis. ML algorithms are commonly applied in technological and commercial settings. They allow for coping with complex data scenarios, thus are potentially suitable for outcome prediction in HSCT. With this background, and using a ML algorithm - the alternating decision tree (ADT), we developed an interpretable prediction model for allo-HSCT outcomes in AL patients.
Aims: The primary endpoint was prediction of NRM 100 days post allo-HSCT. Secondary outcomes were prediction of NRM, leukemia free survival (LFS) and overall survival (OS) at 2 years according to the primary model.
Methods: A cohort of 28,236 adult allo-HSCT recipients from the acute leukemia working party registry of the European Group for Blood and Marrow Transplantation (EBMT) was used to construct the model. Twenty variables were analyzed, including year of transplant (range, 2000-2011), diagnosis (Acute Myeloid Leukemia and Acute Lymphoblastic Leukemia), disease stage (CR1, CR2, advanced/ refractory disease), conditioning regimen (myeloablative or reduced-intensity conditioning), graft type (peripheral blood or bone marrow), donor type (HLA matched related or unrelated), etc. For model development and validation, the dataset was randomly divided into a training set (n=19,765) and a validation set (n=8,707). ADT model includes a graphical tree like structure, detailing variable assigned score, dependence and predictive influence. Patients evaluated are plotted on the tree and gather a cumulative score correlating with the endpoint. For model calibration and risk stratification, the score was transformed into probabilities using logistic regression. Discrimination was assessed using the area under the receiver operating characteristics curve (AUC) and compared for the primary endpoint with the EBMT score.
Results: For prediction of 100 days NRM ten variables were selected by the ADT model, with varying dependence and predictive influence. Patients were stratified into ten risk groups, reflecting ten score intervals with increasing probabilities for the primary outcome (Figure 1). Calibration was excellent. The ADT Model discrimination for day 100 NRM, as assessed by the AUC, was 0.69 and 0.68 on the training and validation sets respectively, performing better than the EBMT score (AUC of 0.62 for both data sets, p-value<0.0001). Two years outcomes (NRM, LFS, OS), correlated with score intervals generated for the primary outcome. For instance, the highest and lowest score intervals corresponded with NRM of 38% and 10% at two years respectively.
Summary and Conclusions: We present a novel prediction model for NRM at day 100 post allo-HSCT, potentially extending to two years. The model enables risk assessment, in a stratified manner, prior to transplantation. Data from approximately 30,000 patients was used for model development, assuring robustness and validity. Incorporation of our model with conventional risk scores, such as the Hematopoietic Cell Transplant-Co-morbidity Index, may further improve predictive performance.

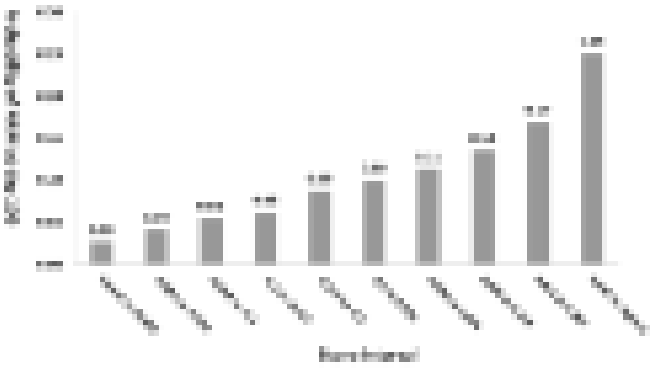

Figure 1.

P497

CONTRASTING EFFECT OF MISSING SELF MODEL AND ACTIVATING DONOR KIR GENES WITH RELEVANT HLA LIGAND IN RECIPIENTS ON PREVENTING RELAPSE AFTER T-CELL-REPLETE HAPLOIDENTICAL TRANSPLANTATION IN CML

XY Zhao[1,*] Y Chang[1], LP Xu[1], X Zhang[1], K Liu[1], D Li[1], X Huang[1]
[1]Beijing Key Laboratory of Hematopoietic Stem Cell Transplantation, Peking University People's Hospital & Peking University Institute of Hematology, Beijing, China

Background: The effect of NK alloreactivity in HLA haploidentical SCT is still under debate. This might be a result of patient heterogeneity and the involvement of activating KIR genes besides the effect of different haploidentcial transplant protocols.
Aims: We prospectively analyzed the HLA typing of donor-recipients pairs as well as the KIR typing of the donor in the relatively purified CML disease aim to further address the predictive roles of NK cells on relapse undergoing T-cells-replete haploidentical transplantation.
Methods: We studied the HLA genotype of 97 donor-recipient pairs and their donor KIR genotype, who underwent T-cells-replete haploidentical transplantation during 2003-2009 in our center.
Results: Among the 97 pairs of donor-recipients, there were 74 donor-recipients pairs with missing self and 23 without missing self. There was a trend towards increased molecular and hematologic relapse rate in patients with missing self between donor and recipients compared to those without missing self (P=0.003 and P=0.015). We found a significantly reduced risk of molecular relapse (P=0.009) and hematologic relapse (P=0.009) in patients with HLA-C1C2 or C2C2 accepting donors with KIR 2DS1 positive or patients with HLA-Bw4 accepting donors with KIR3DS1 positive ("recipient with relevant KIR ligand for donor activating KIR", n=25) compared with "other" (n=72). Meanwhile, among 74 patients absent KIR ligand for donor inhibitory KIR genes, there were 13 patients in "recipient with relevant KIR ligand for donor activating KIR" group and 61 patients in "others" group. The molecular relapse and hematologic relapse in patients of "recipient with relevant KIR ligand for donor activating KIR" group were significantly lower than patients of "others" group (P=0.04 and P=0.03) among patients with missing self between donor and recipients. Multivariate analysis confirmed that recipient with relevant KIR ligand for donor activating KIR were independent factors for preventing relapse.
Summary and Conclusions: we demonstrated that donor-derived "alloreactive" NK cells could be predicted *in vitro* using donor activating KIR gene (KIR2DS1 or KIR3DS1) with their relevant KIR ligand in recipients. Contrasting roles of missing self between donor and recipients on relapse in this T-cells-repleted haploidentical transplantation suggested NK cells alloreactivity might be altered by the process of NK functional education *in vivo*.

P498

IMPACT OF SMOKING ON THE NON-RELAPSE MORTALITY, THE OVERALL SURVIVAL, AND THE INCIDENCE OF SECOND CANCERS AFTER REDUCED INTENSITY ALLOGENEIC STEM CELL TRANSPLANTATION FOR HEMATOLOGIC MALIGNANCIES

F Spina[1,*] C De Philippis[1, 2], L Farina[1], V Montefusco[1], A Dodero[1], P Corradini[1,2]
[1]Hematology, Fondazione IRCCS Istituto Nazionale dei Tumori, [2]Chair of Hematology, Università degli Studi di Milano, Milan, Italy

Background: The impact of smoking on health has been extensively studied in epidemiology, yet the effect of smoking on the allogeneic stem cell transplantation (alloSCT) outcomes has not been determined yet.
Aims: This retrospective monocentric study aimed at understanding whether

smoking affects the survival outcomes of hematologic patients undergoing reduced intensity conditioning (RIC) alloSCT.
Methods: We searched for information on the smoking history (packs-year and duration of exposure) of 301 patients who received RIC alloSCT between 2001 and 2012 in our division, reviewing the clinical charts and by telephone interviews. We analyzed the impact of smoking on non-relapse mortality (NRM) by Cumulative Incidence method, on overall survival (OS) and progression free survival (PFS) by log-rank method. We ran a Cox multivariate analysis for NRM, OS and PFS using pre-transplant disease status, donor type, and smoking as covariates.
Results: We had complete data of 202 patients. All the patients received RIC alloSCT for lymphoma (60%), multiple myeloma (21%), acute myeloid leukemia (AML) or myelodysplastic syndrome (MDS) (17%), or myeloproliferative diseases (MPD, 2%). The median age at alloSCT was 49 years (range, 18-69). Donors were HLA-identical siblings (43%), mismatched siblings (2%), unrelated (43%), or haploidentical (12%). At alloSCT, 50% of patients were in complete response (CR), 36% in partial response (PR), 3% of patients were stable (SD) and 11% were in progression (PD). Forty-nine percent of patients were former smokers, 28% were hard smokers (defined as smokers of >=1 pack per day). Nine percent of patients were still smokers at admission of alloSCT. The exposure to smoking was a median of 1 pack per day (range, 0.1-3) for a median of 15 years (range, 1-40), and smokers had quit smoking by a median interval of 5 years before transplant (range, 0-41). The median follow-up after alloSCT was 4.9 years (range, 0.2-11.9). The NRM at 100 days was 5%, at 1 year 9%, at 3 years 11%. Three-year OS and PFS were 77% and 55%. In univariate analysis, smoking increased NRM (p=0.008), and reduced the OS (p=0.006). The multivariate analysis showed that smoking increased the NRM by a factor of 5.4 (p=0.001). Having a haploidentical donor also impacted NRM (p<0.001). Smoking significantly impacted OS increasing the risk of death by a factor of 2.8 (p=0.001). Overall survival was also impacted by haploidentical donor (p=0.001) and pre-transplant disease in PR (p=0.01) or PD (p<0.001). Smoking did not affect PFS, which was impacted by active disease before alloSCT (p<0.001 for PR, SD and PD). Ten patients had a second cancer after alloSCT (5%). Three cancers occurred in non-smokers (skin carcinoma, breast, and bladder carcinoma), 7 cancers occurred in smokers (bladder carcinoma - 2 patients, skin carcinoma, oropharingeal carcinoma, AML, MDS and MPD). The crude incidence of second cancers was 3% in non-smokers and 7% in smokers. In hard smokers, the incidence of second cancers after alloSCT was 9%. Smokers had a 2.5 risk increase of developing a second cancer compared to non-smokers. Three deaths were caused by a second cancer, and all occurred in smokers.
Summary and Conclusions: Smoking is a significant independent factor that impacts NRM and OS in patients undergoing a RIC alloSCT, and it may increase the incidence of second tumors. Smoking should be considered a comorbid condition before alloSCT. Aggressive anti-smoking campaigns should be undertaken to decrease this avoidable risk.

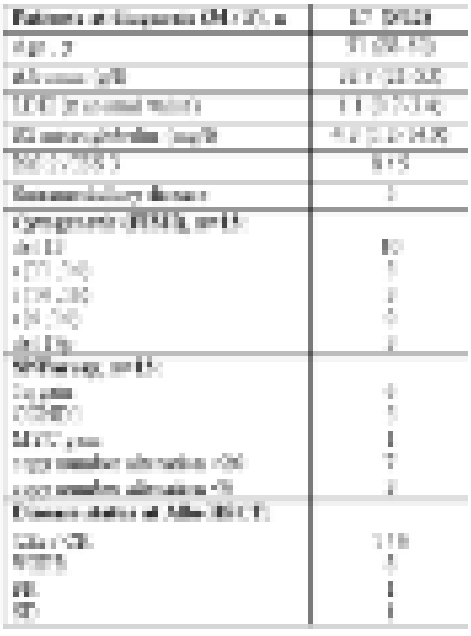
Background: pPCL is a rare plasma cell malignancy with very poor outcome. Novel therapeutic strategies including transplantation (Auto or Allo-HSCT) may improve survival but the prognosis remains poor. Only retrospective studies incorporating up-front Allo-HSCT for pPCL patients have been published.
Aims: We conducted a prospective study incorporating tandem Auto/Allo-HSCT after an induction with doxorubicin-bortezomib-cyclophosphamide and dexamethasone for pPCL patients less than 66-year old.
Methods: After the induction 17 patients (Female 12/Male 5) underwent Allo-HSCT: 1 syngenic, 1 after a reduced intensity conditioning (RIC)-Allo-HSCT and 15 after a tandem Auto/RIC-Allo-HSCT. At diagnosis median age was 51 year [28-60], 8 patients presented an ISS2, 5 ISS3 and 5 an extramedullary disease. The majority of patients had high-risk cytogenetic assessed by FISH or SNParray (Table 1). Patients have been allotransplanted at a median time of 7.4 months [7-18] from diagnosis, in sCR (n=1), CR (n=6), VGPR (n=8), PR (n=1) and in SD (n=1). The conditioning regimen used were: fludarabin-busulfan- antithymoglobulin (n=13), fludarabin-melphalan (n=1), bortezomib-fludarabin-melphalan (n=2) and high-dose melphalan for the syngenic transplantation (n=1). All patients were grafted with peripheral blood stem cells except one who received bone marrow and one cord blood unit, from related (n=9) or HLA-matched unrelated donors (n=8). The median infused CD34 cells number was 6.8 10^6/kg [3-8.5]. All patients received ciclosporine +/- methotrexate as GvHD prophylaxis.
Results: All patients achieved engraftment. The median time for neutrophil (≥1 10^9/l) and platelet (≥25 10^9/l) engraftment was 19 [7-31] and 11 days [10-43] respectively and the median duration of hospitalisation 28 days [1-77]. Six patients developed an acute GvHD which responded to steroid in 5 cases and 1 was steroid-resistant and responded secondary to anti-IL2Rα antibody. At day 100, 16 patients were evaluable: 12 (76%) achieved a VGPR or better (3 in sCR, 4 in CR and 5 in VGPR), 2 (12%) PR and 2 patients (12%) died from EBV reactivation. Three patients received, 3 months after Allo-HSCT as immunomodulation, donor lymphocyte infusions plus Lenalidomide-Cyclophosphamid-Fludarabin (n=1), Bortezomib (n=1) and Lenalidomide (n=1): one patient in PR (transplanted in SD) achieved CR and the two others in VGPR maintained their response. The median follow-up was 22 months [7-41] from diagnosis and 14 months [1-32] from Allo-HSCT: 6/17 (35%) patients relapsed and 5/17 (29%) died. At analysis, median progression-free survival (PFS) and overall survival (OS) were not reached. One year post-diagnosis OS was 87% and post-Allo-HSCT 68%, PFS 86% and 65% respectively. Five patients experienced chronic GvHD: mild (n=4) and extensive (n=1).

Table 1.



Summary and Conclusions: This is the first large prospective trial for pPCL patients including Allo-HSCT. Tandem Auto/RIC-Allo-HSCT or RIC-Allo-HSCT is feasible, inducing a high response rate and allowing a prolong survival. In addition immunomodulation after transplantation may be proposed to patients.

P500

IMPACT OF GRAFT SOURCE ON OUTCOMES OF ALLOGENEIC HEMATOPOIETIC CELL TRANSPLANTATION IN ADULTS WITH PHILADELPHIA CHROMOSOME-NEGATIVE ACUTE LYMPHOBLASTIC LEUKEMIA

Y Nakajima[1,*] T Tachibana[1], K Matsumoto[2], S Koyama[1], E Ogusa[2], W Yamamoto[2], S Ito[3], M Hagihara[4], M Tanaka[4], E Yamazaki[1], J Taguchi[3], N Tomita[1], S Fujisawa[4], H Kanamori[2], Y Ishigatsubo[1]
[1]Department of Internal Medicine and Clinical Immunology, Yokohama City University Graduate School of Medicine, [2]Department of Hematology, Kanagawa Cancer Center, Yokohama, [3]Department of Hematology, Shizuoka Red Cross Hospital,, Shizuoka, [4]Department of Hematology, Yokohama City University Medical Center, Yokohama, Japan

Background: Allogeneic hematopoietic cell transplantation (allo-HCT) remains a curative option for adults with Philadelphia chromosome-negative acute lymphoblastic leukemia (Ph-negative ALL). An unrelated bone marrow (uBM) donor or an umbilical cord blood (CB) donor becomes an alternative source when a suitable related donor is not available.
Aims: To assess the impact of donor source on outcomes of allo-HCT in adults with Ph-negative ALL.
Methods: We analyzed the data from 96 patients with Ph-negative ALL who

underwent allo-HCT between 2000 and 2012 at 4 institutes of the Yokohama City University Hematology Group. We assessed the impact of donor sources on outcomes using univariate and multivariate analyses.

Results: The cohort included 53 men and 43 women with a median age of 32 years (range, 15-62 years). The stem cell source was a related bone marrow (rBM) donor in 25 patients, an uBM donor in 43, a related peripheral blood (rPB) donor in 10, and a donor of a single unit of unrelated umbilical CB in 18. At the time of allo-HCT, 19 patients (76%) in the rBM group, 20 (47%) in the uBM group, 4 (40%) in the rPB group, and 14 (77.8%) in the CB group were in complete remission (CR). Eighty-nine patients received a myeloablative conditioning regimen with cyclophosphamide (CY) plus a total body irradiation based-regimen or CY plus busulfan, while only 7 patients received a reduced intensity conditioning regimen with a fludarabine and melphalan based therapy. The median observation period for the surviving patients was 45 months (range, 3-178 months). The 3-year overall survival (OS), 3-year leukemia-free survival (LFS), and relapse rates at 3 years of all the 96 patients were 45%, 40%, and 34%, respectively. The patients with a CB source had better 3-year OS (72%) and 3-year LFS (69%) than those with a rBM source (61%, and 41%, respectively), an uBM source (38%, and 27%, respectively), or a rPB source (50%, and 44%, respectively; *P*=0.013, and *P*=0.028, respectively). The relapse rates at 3 years were lower in the CB group (13%) than in the other groups (rBM, 33%; uBM, 41%; rPB, 50%; *P*=0.049). No statistically significant difference in non-relapse mortality (NRM) at 3 years or in cumulative incidence of acute graft-*versus*-host disease (aGVHD) was observed between the 4 groups. In the multivariate analysis, the following 3 independent factors were significantly associated with inferior OS and LFS: uBM source (HR, 3.29; 95% CI, 1.2-8.8; *P*=0.02, and HR, 3.3; 95% CI, 1.2-8.8; *P*=0.02, respectively), having no CR at the time of allo-HCT (HR, 3.3; 95% CI, 1.6-6.9; *P*=0.001, and HR, 3.1; 95% CI, 1.5-6.3; *P*=0.003, respectively), and performance status >2 at the time of allo-HCT (HR, 29.7; 95% CI, 4.6-191.5; *P* <0.001, and HR, 14.5; 95% CI, 2.5-84.4; *P*=0.003, respectively). The multivariate analysis demonstrated also that use of a rPB source (HR, 13.9; 95% CI, 2.6-75; *P*=0.002) and having no CR at the time of allo-HCT (HR, 4.4; 95% CI, 1.6-11; *P*=0.003) were significantly associated with a higher risk for relapse. For NRM, only grade 2-4 aGVHD was a significant adverse prognostic factor (HR, 3.3; 95% CI, 1.2-9.1; *P*=0.02) (Figure 1).

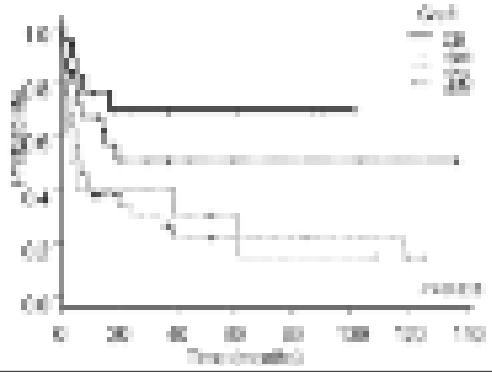


Figure 1. Kaplan-Meier curves for overall survival according to graft sources.

Summary and Conclusions: In our study, allo-HCT using CB resulted in better outcomes with higher OS and LFS rates than that using other sources. With the results of the multivariate analysis, CB source was not associated with poor outcomes, while uBM and rPB were independent adverse prognostic factors. CB could be a good alternative donor source for patients with Ph-negative ALL in CR when a related donor is not available.

P501

A POTENTIAL BENEFIT OF INHIBITORY KIR-MISMATCHED UNMANIPULATED HAPLOIDENTICAL STEM CELL TRANSPLANTATION FOLLOWING TBI-BASED CONDITIONING IN ADULT PATIENTS WITH AML

SA Yahng[1,*] JH Kim[2], YW Jeon[2], JH Yoon[2], SH Shin[2], SE Sung-Eun[2], BS Cho[2], KS Eom[2], YJ Kim[2], S Lee[2], CK Min[2], SG Cho[2], DW Kim[2], JW Lee[2], WS Min[2], CW Park[2], HJ Kim[2]

[1]Hematology, Incheon St. Mary's Hospital, the Catholic University of Korea, Incheon, [2]Hematology, Catholic Blood and Marrow Transplantation Center, Seoul St. Mary's Hospital, The Catholic University of Korea, Seoul, Korea, Republic Of

Background: Donor natural killer (NK) cells, regulated by killer Ig-like receptors (KIR), are known to recognize specific groups of HLA class I alleles for inducing alloreactivity. Effectiveness of donor NK cell alloreactivity determined by inhibitory KIR (iKIR)-ligand incompatibility model in graft-*versus*-host (GVH) vector had been shown in patients with acute myeloid leukemia (AML) receiving haploidentical stem cell transplantation (haplo-SCT) in T cell-deplete (TCD) setting. However, extensive TCD transplant is relatively discouraged due to infectious complications and conflicting impact of NK alloreactivity on transplantation outcome from different haplo-HSCT settings were reported.

Aims: We aimed to evaluate a potential NK cell alloreactivity on transplant outcome after unmanipulated haplo-SCT with total body irradiation (TBI)-based conditioning regimen in adult Korean population with AML.

Methods: A total of 89 consecutive patients with AML received peripheral blood stem cell haplo-SCT at first complete remission (CR1, n=49), second CR (CR2, n=16), or relapsed/refractory (n=9) status between 2008 and 2013. The median age was 41 years (range, 16-69) and identical conditioning regimen (fractionated 800 cGy TBI, reduced doses of fludarabine and busulfan, and anti-thymocyte globulin) was used in all patients. NK cell alloreactivity in GVH vector was predicted when the donor expresses but the recipient lacks an iKIR-ligand (C1, C2, Bw4 or A3/A11) and that in host-*versus*-graft (HVG) vector was determined when the recipient expresses but the donor lacks the ligand. The frequency of iKIR-ligand assessed by high-resolution HLA typing showed that the majority of donors and recipients were C1/C1 homogygous (71%) and Bw4/Bw6 heterozygous (62%), while only 26% had A3/A11 ligand.

Results: All patients achieved neutrophil recovery (median, 11 days) without delayed engraftment failure. After a median follow-up of 24 months, 25 patients died after relapse (n=14) or due to non-relapse mortality (n=11). Two-year relapse-free survival (RFS) from transplant was 62% in all patients and was significantly different between CR1 (76%) *versus* ≥CR2 (33%, p=<0.0001). Patients were then classified according to iKIR-ligand incompatibility model: 28 donor/patient pairs were iKIR-ligand mismatched in GVH vector only (31%; Group 1), 25 pairs mismatched in HVG vector only (28%; Group 2), 32 pairs ligand-compatible in both vectors (36%; Group 3): 4 pairs with iKIR-ligand incompatible in both vectors were excluded from further analysis due to the small number. Two-year RFS was 72%, 51%, and 50%, respectively (p=0.497). However, in patients with CR1, 2-year RFS was 92%, 67%, and 53%, respectively (p=0.043), and cumulative incidence of relapse (CIR) was 8%, 0%, and 41%, respectively (p=0.003) (Figure 1), while significant difference was not found in patients transplanted at ≥CR2. Significantly more number of group 1 patients (n=10, 36%) had advanced status at transplant compared to group 3 (n=3, 12%; p=0.051). By adjusting disease status and donor age (n=85), patients with iKIR-ligand mismatched in HVG vector only (Group 3) showed significantly worse posttransplantation outcome compared to patients in group 1: 2-year RFS (HR 4.03, p=0.013) and CIR (HR 9.40, p=0.007).

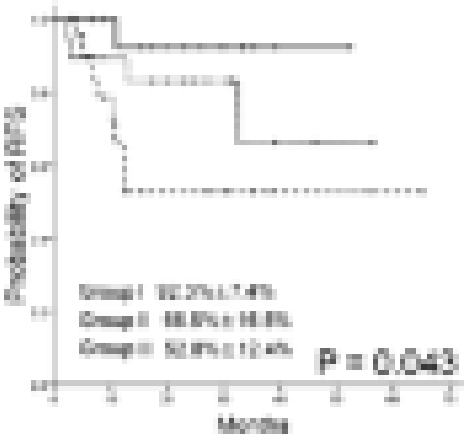

Figure 1.

Summary and Conclusions: Although limited by small number of patients and short duration of follow-up, our study results of posttransplantation outcome after T-cell replete haplo-SCT in adult patients with AML may suggest the beneficial effect of iKIR-ligand incompatible in GVH vector and compatible in HVG vector, showing low CIR leading to better RFS, while transplantation of iKIR-ligand compatible in GVH vector and incompatible in HVG vector may be expected with worse outcome. Further studies using KIR genotyping should be pursued. Meanwhile, donor/patient iKIR-ligand compatibility assessed by HLA genotyping seems to be useful in choosing adequate donor among multiple haploidentical donors.

P502

HIGH BURDEN OF CD34+/CD38-CELLS PREDICTS WORSE OUTCOME IN ACUTE MYELOID LEUKEMIA (AML) PATIENTS AFTER ALLOGENEIC STEM CELL TRANSPLANTATION (HCT) WITH REDUCED INTENSITY CONDITIONING (RIC)

M Jentzsch[1,*] M Bill[1], S Leiblein[1], H Weidner[1], K Wildenberger[1], M Cross[1], M Pless[1], U Bergmann[1], C Nehring-Vucinic[1], N Jäkel[1], R Krahl[1], W Pönisch[1], G N Franke[1], V Vucinic[1], G Behre[1], D Niederwieser[1], S Schwind[1]

[1]Hämatologie, int. Onkologie und Hämostaseologie, Universitätsklinikum Leipzig, Leipzig, Germany

Background: Most patients (pts) with acute myeloid leukemia (AML) achieve complete remission (CR), but the majority subsequently relapses and dies of the disease. In AML, leukemia initiating cells (LICs) are enriched within the CD34+/CD38- cell compartment. LICs are assumed to be less chemotherapy sensitive, enriched in minimal residual disease cell populations and responsible for relapse. Furthermore, they are described to be less immunogenic. The therapeutic approach of RIC-HCT is mainly based on an immunological graft-*versus*-leukemia (GvL) effect. The prognostic impact of the CD34+/CD38-burden at diagnosis remains unknown.
Aims: To analyze the prognostic impact of the CD34+/CD38-burden at diagnosis in AML pts receiving RIC-HCT.
Methods: We analyzed 120 AML pts (median age 65 years [y]; range 47-75y) who received RIC (Fludarabin 30mg/m^2 at day-4 to -2 & 2Gy total body irradiation day 0)-HCT, with pretreatment bone marrow material (BM) available. At HCT all pts were in CR. 99 pts (82.5%) were in first & 21 (17.5%) were in second CR. Donors were human leucocyte antigene (HLA)-matched related (n=17, 14.2%) or HLA-matched (n=69, 57.5%) or mismatched (>=1 antigen; n=34, 28.3%) unrelated. 35 (32.7%) developed acute graft-*versus*-host disease (GvHD; >=grade 2) & 62 (64.6%) chronic GvHD (cGvHD). Median follow-up was 3.8 y for pts alive. Pts were characterized for *NPM1*, *FLT3*-ITD, *FLT3*-TKD & *CEBPA* mutations at diagnosis. Percentage of BM CD34+/CD38- mononuclear cells at diagnosis was measured using flow cytometry.
Results: A cutpoint of 5% defined a high burden of BM CD34+/CD38-cells. In multivariate analysis, the negative prognostic impact of a high CD34+/CD38-burden on OS could be confirmed (Hazard Ratio 2.00, [1.32-3.04, 95%CI], *P*=.001). Pts with a high CD34+/CD38-cell burden were more likely to have *de novo* disease (*P*=.055) & to be *CEBPA* wild-type (*P*=.11) by trend. None of the pts with high CD34+/CD38- burden were *CEBPA* mutated. A high diagnostic CD34+/CD38- burden associated with higher cumulative incidence of relapse (CIR, *P*<.001, Figure 1A) & shorter overall survival (OS, *P*=.018, Figure 1B).

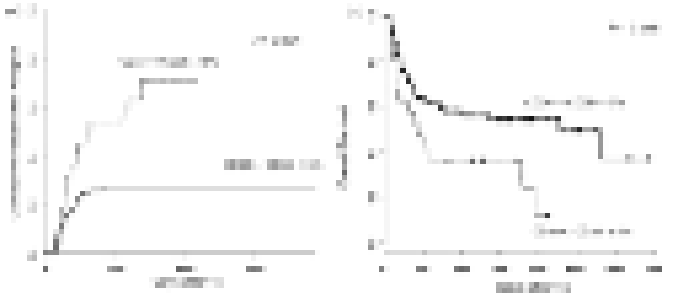

Figure 1. CIR (A) and OS (B) in RIC-HCT treated AML pts according to CD34+/38- burden at diagnosis.

Summary and Conclusions: A high CD34+/CD38-cell burden at diagnosis associated with increased relapse rates & shorter OS in RIC-HCT treated AML pts. The observed worse outcome is likely mediated by LICs within the CD34+/CD38-population, escaping the GvL effect of RIC-HCT. When confirmed an easy cutoff of 5% CD34+/CD38-BM mononuclear cells may help to identify pts at high risk of relapse & may enable studies for LIC targeting therapies in these pts.

P503

PROGNOSTIC SIGNIFICANCE OF IDH MUTATIONS IN ACUTE MYELOID LEUKEMIA (AML) PATIENTS UNDERGOING HEMATOPIETIC STEMCELL TRANSPLANTATION (HCT) AFTER REDUCED INTENSITY CONDITIONING (RIC)

M Bill[1,*] L Schmalbrock[1], M Jentzsch[1], K Schubert[1], K Wildenberger[1], H Weidner[1], W Pönisch[1], V Vucinic[1], G N Franke[1], M Cross[1], G Behre[1], D Niederwieser[1], S Schwind[1]
[1]Hematology, University of Leipzig, Leipzig, Germany

Background: Mutations in the Isocitrat-Dehydrogenase (*IDH*) 1 and 2 genes impact outcome in some AML subgroups. The prognostic significance in AML patients (pts) undergoing RIC-HCT, a post-remission therapy that is mainly based on an immunological graft-*versus*-leukemia effect and offers a potential cure for AML pts, who are ineligible for conventional conditioning, is still unknown.
Aims: To analyze the impact of *IDH* mutations in pts undergoing RIC-HCT.
Methods: We analyzed 143 AML pts (median age, 64 years [y]; range 33–75y) who received RIC (Fludarabine 30mg/m^2 at day -4 to -2 & 2 Gy total body irradiation day 0 [n=137]; Fludarabine 30mg/m^2, Cytarabine 2g/m^2, and Amsakrine 100mg/m^2 at day -12 to -9, Cyclophosphamide 40mg/kg at day -4 to -3, ATG/TG day -3 to -1 & 4 Gy total body irradiation day - 5 [n=4]; 2 Gy total body irradiation day 0 [n=2])-HCT at the University of Leipzig between May 2000 and August 2012, with pretreatment bone marrow or peripheral blood material available. Donors were human leukocyte antigen (HLA)-matched related (n=23; 16.1%) or HLA-matched (n=83; 58.0%) or mismatched (>=1 antigen; n=37; 25.9%) unrelated. The median follow-up for pts alive was 4.4y. 22.3% (n=32) developed acute graft-*versus*-host disease (GvHD; >=grade 2) and 55.8% (n=63) (17.7% (n=20) limited; 38.1% (n=43) extensive) chronic GvHD. Medical research council (MRC) genetic classification was: favorable (n=3; 2.2%) intermediate (n=99; 72.3%) or adverse (adv, n=35; 24.5%). All pts were characterized for *CEBPA* (n=18; 13.0%) and *NPM1* (n=32; 22.9%) mutations, *FLT3*-ITD (n=23; 16.7%) and *FLT3*-TKD (n=12; 9.0%) at diagnosis.
Results: We found an *IDH* mutation (*IDH1* or *IDH2* mutation) in 36 pts (25.2%). 15 pts (10.5%) had an *IDH1* mutation, 9 pts (6.3%) had the most frequently R132C mutation. 21 pts (14.7%) were found *IDH2* mutated, 14 pts (9.8%) had R140Q and 7 pts (4.9%) R172K mutations. The *IDH1*-SNP (rs11554137) was found in 25 pts (17.5%). The presence of *IDH* mutations associated significantly with higher age (*P*=.02) and by trend with higher hemoglobin (Hb) levels at diagnosis (*P*=.15). A mutation in the *IDH1* gene was associated by trend with higher age (*P*=.09) and *FLT*-TKD (*P*=.12) and significantly with lower white blood cell count (*P*=.04). Pts with an *IDH2* R140Q mutation associated with *NPM1* mutations (*P*=.04). The presence of the *IDH1*-SNP associated by trend with *CEBPA* mutations (*P*=.08) and with lower Hb (*P*=.07). Interestingly, none of the pts with the SNP had a *FLT3*-ITD (*P*=.013). In our cohort neither the presence of *IDH1* mutation nor the *IDH1*-SNP associated with overall survival (OS) or event-free survival (EFS). However, the presence of *IDH2* mutations were associated with longer EFS (*P*=.13) by trend. Analyzing subgroups we found a stronger impact of *IDH* mutations on outcome in pts with adverse karyotype. In this subgroup the presence of either *IDH1* or *IDH2* mutations were significantly associated with longer EFS (*P*=.02) and OS (*P*=.03) (Figure 1).

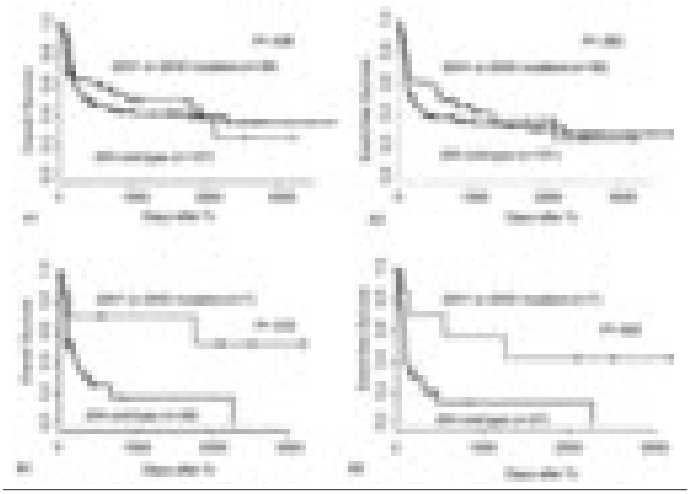

Figure 1. Overall survival (A1) and Event-free survival (A2) in RIC-HCT treated AML patients according to *IDH* mutation status. Figures B: overall survival (B1) and Event-free survival (B2) in RIC-HCT treated AML patients with an adverse karyotype according to *IDH* mutation status.

Summary and Conclusions: In the complete set of AML pts receiving RIC-HCT the presence of *IDH1* mutations did not impact survival, the presence of *IDH2* mutations associated with longer EFS by trend. We observed a stronger effect of *IDH* mutations in pts with adverse karyotype. Here the presence of either *IDH1* or *IDH2* mutations was significantly associated with longer survival. Thus especially pts with adverse cytogenetics harboring *IDH* mutations might benefit from RIC-HCT.

P504

IMPACT OF DOSE INTENSITY OF CONDITIONING ON THE OUTCOMES OF ALLOGENEIC HEMATOPOIETIC STEM CELL TRANSPLANTATION FOR SEVERE APLASTIC ANEMIA FROM AN HLA-IDENTICAL SIBLING

T Mori[1,*] H Koh[2], Y Onishi[3], S Kako[4], M Onizuka[5], H Kanamori[6], K Miyamura[7], N Uchida[8], C Kato[9], H Iida[10], R Suzuki[11], T Ichinohe[12], Y Atsuta[13], S Nakao[14], H Yamazaki[14]
[1]Keio University School of Medicine, Tokyo, [2]Graduate School of Medicine, Osaka City University, Osaka, [3]Tohoku University Hospital, Sendai, [4]Saitama Medical Center, Jichi Medical University, Saitama, [5]Tokai University School of Medicine, [6]Kanagawa Cancer Center, Kanagawa, [7]Japanese Red Cross Nagoya First Hospital, Nagoya, [8]Toranomon Hospital, Tokyo, [9]Meitetsu Hospital, [10]National Hospital Organization Nagoya Medical Center, [11]Nagoya University Graduate School of Medicine, Nagoya, [12]Hiroshima University Hospital, Hiroshima, [13]Japanese Data Center for Hematopoietic Cell Transplantation, Nagoya, [14]Kanazawa University Graduate School of Medical Science, Kanazawa, Japan

Background: The established standard conditioning regimen of allogeneic hematopoietic stem cell transplantation (allo-HSCT) for severe aplastic anemia (SAA) from an HLA-identical sibling is high-dose cyclophosphamide (CY; 200 mg/kg) with or without anti-thymocyte globulin (ATG). Since this regimen is

often associated with serious toxicities such as cardiotoxicity, the safety and efficacy of various less toxic conditioning regimens by reducing the dose of CY have recently been evaluated. However, because of the variation of those conditioning regimens, an optimal regimen has yet to be established.
Aims: The aim of this study is to evaluate the impact of the dose of CY on the outcomes of allo-HSCT for SAA from an HLA-identical sibling in order to explore an optimal conditioning regimen.
Methods: We retrospectively analyzed patients with SAA aged 16 year or older who underwent the first allo-HSCT from an HLA-identical sibling between 1989 and 2010 by using the data from the registry database of Japan Society for Hematopoietic Cell Transplantation. After excluding patients whose essential data of conditioning regimen were missing and patients who received myeloablative conditioning regimens such as those including TBI 8 Gy or greater, 204 patients (median age, 25.5 years (range 16-65)) were evaluable. Conditionings were defined as 1) high-dose CY (200 mg/kg or greater)-based regimen (n=118); 2) reduced-dose CY (100 mg/kg or greater but less than 200 mg//kg)-based (n=38); 3) low-dose CY-based (less than 100 mg/kg)-based (n=48). TBI (less than 8Gy) or local field irradiation were delivered in 106 (52%) patients, and ATG was given to 105 (51%) patients. The proportions of patients who received TBI or local field irradiation were not different among the 3 regimens. In contrast, the proportions of patients who received additional fludarabine were significantly higher in reduced-dose and low-dose CY regimens (26 (68%) of 38 and 47 (98%)) than in high-dose CY (1 (0.8%) of 118; P<0.01).
Results: Median follow-up period of 173 survivors was 49.7 months (range, 2.5-234.2). Five-year overall survival (OS) of all patients was 85.8% (95%CI, 80.5-91.0%). Major causes of death were graft failure in 7 patients, infection in 7, cardiotoxicity in 4, hemorrhage in 4, organ failure in 4, and graft-*versus*-host disease (GVHD) in 3. Although 5-year OS in patients receiving low-dose CY-based regimens (93.0% (95%CI, 85.1-100.0)) tended to be higher than that receiving high-dose CY-based (84.2% (95%CI, 77.1-91.3)) or reduced-dose CY-based regimens (83.8% (95%CI, 71.8-95.8)), the difference was not significant (P=0.214). Among other variables, age of 40 years or older at transplant was identified as the only factor affecting OS. Fatal cardiotoxicity occurred in four patients: 3 with high-dose CY, 1 with reduced-dose CY, but none with low-dose CY.
Summary and Conclusions: These results suggest that the dose of CY of the conditioning could be safely reduced by adding fludarabine in allo-HSCT for SAA from an HLA-identical sibling, leading to the comparable survival rate to that obtained by conventional CY dose and to a reduction of serious toxicities.

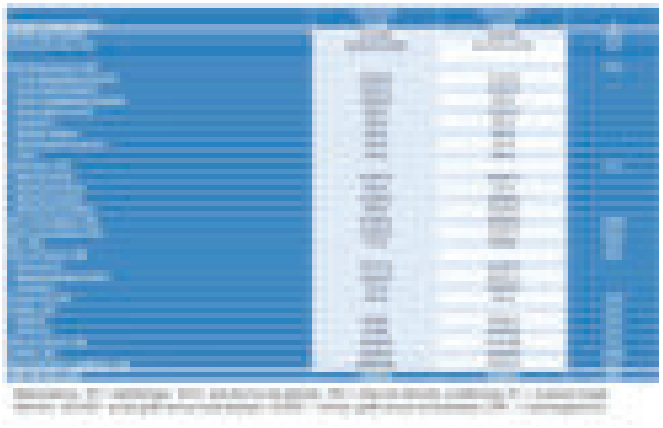
P506

DECREASE OF INVASIVE FUNGAL DISEASE IN OUR CENTER WITH THE USE OF VORICONAZOLE AS ANTIFUNGAL PROPHYLAXIS IN PATIENTS UNDERGOING ALLOGENEIC STEM CELL TRANSPLANTATION

MJ Llamas Poyato[1], C Chic Acevedo[1,*] E García[1], D Buenasmañanas[1], J Serrano[1], JR Molina[1], C Martín[1], R Rojas[1]
[1]Hematology, Hospital Universitario Reina Sofia, Cordoba, Spain

Background: Invasive fungal disease (IFD) causes significant morbidity and mortality in patients undergoing allogeneic hematopoietic stem cell transplantation (allo-HSCT). For decades, the most commonly antifungal used for prophylaxis of IFD was Fluconazole. But this agent is not effective against filamentous fungi. For this reason, some new triazole-drugs with anti-filamentous activity (as Voriconazole) have being used during the last years as antifungal prophylaxis for high-risk patients.
Aims: The aim of our study was to compare retrospectively the incidence of IFD in patients undergoing allo-HSCT in our institution using Fluconazole *vs* Voriconazole as prophylactic treatment.
Methods: In this retrospective study, we analyse 196 allo-HSCT consecutive patients (paediatrics and adults) submitted to this procedure in our institution. Patients were recruited from March 2001 to April 2008. A total of 98 patients received antifungal prophylaxis with Fluconazole and 98 with Voriconazole. Antifungal prophylaxis consisted on Voriconazole 200 mg/12 hours (5mg/kg/12h in children) or Fluconazole 200 mg/12 hours (5mg/kg/day in children) from day -1 or +1 until day +75 or +120 (depending on children or adults respectively). The temporary suspension was applied in those patients with toxicity, without reaching criteria for withdrawal, being able to continue the study drug if the suspected toxicity resolved in 7 days. AGA detection was done twice weekly from year 2004. It was considered positive when the index OD was ≥0.5 in 2 consecutive measurements or ≥0.8 on a single determination. When IFD was suspected a new determination of additional AGA and a high resolution TAC were done as well as a bronchoalveolar lavage. IFDs were classified like possible, probable or proven according to the revised criteria of the EORTC/MSG 2008. The criteria used to evaluate the toxicity were the latest version of the National Cancer Institute Common Terminology Criteria for Adverse Events.
Results: The baseline characteristics of these patients are shown in Table 1. We found differences in terms of: type of graft, regimen and type of conditioning and presence of cGVHD between both groups. The incidence of IFD was 16.3% in the Fluconazole group (n=16) *vs* 7.1% (n=7) in Voriconazole group (*P*=0.046). The median of FFS was 24.5 days and 106 days (*P*=0.003). According to the EORTC/MSG criteria, taking into account only patients who developed IFD, the percentage of possible IFD in the first group was 50% *vs* 14.8% in the second group. Probable: 37.5% *vs.* 71.4%; Proven: 12.5% *vs.* 14.28%. FFS at 180 days post allo-HSCT was 52.9% *vs* 75% (*P*=0.037); We also found significant statistical differences at 360 days post HSCT (83.7% *vs* 92.9%; *P*=0. 034). Deaths caused by IFD were 10.1% in Fluconazole (n=10) and 3.1% in Voriconazole (n=3) (*P*=0. 027). The median follow-up was 34 months. There was no significant difference in overall survival: 52.1% *vs* 52.6% (*P*=0.95). There were no differences in causes of death (*P*=0. 326). A total of 11 patients (11.22%) presented adverse effects in the first group *vs* 18 patients (18.36%) in the second one (*P*=0.065). The most frequent adverse effect for both groups was hepatic toxicity.

Table 1. Characteristics of the patients.



Summary and Conclusions: This study confirms that the use of Voriconazole as antifungal prophylactic treatment in patients undergoing allo-HSCT decreases the incidence of IFD and increases FFS *versus* Fluconazole. In spite of a greater toxicity in Voriconazole group, this toxicity was non severe and rapidly recovered with the withdrawal of the drug.

P507

LONG-TERM SURVIVAL IN PATIENTS RECEIVING RHEPO FOLLOWING ALLOGENEIC HEMATOPOIETIC CELL TRANSPLANTATION

A Jaspers[1], F Baron[1], E Willems[1,*] L Seidel[1], K Hafraoui[1], C Bonnet[1], Y Beguin[1]
[1]Chu of Liège, Liège, Belgium

Background: We recently reported the efficacy of erythropoietin therapy following allogeneic hematopoietic cell transplantation (allo-HCT) on erythroid reconstitution and transfusion requirements.
Aims: As some meta-analyzes suggest increased mortality in patients with cancer receiving erythropoiesis-stimulating agents (ESA) particularly when no concomitant chemotherapy is administered, we assessed long-term follow-up of patients included in the study.
Methods: In this trial, 131 patients given myeloablative or non-myeloablative allo-HCT were randomized 1:1 between two arms: the control arm (no erythropoietic therapy) *vs* the EPO arm (erythropoietin β 500 U/kg/week). Patients were also stratified in 3 cohorts: 42 patients underwent myeloablative HCT (cohort A), while patients in the cohorts B (n=39) and C (n=50) were given non-myeloablative conditioning. RhEPO was administered once a week, from day 28 in cohorts A and B, whereas patients in cohort C received rhEPO from day 0. Treatment duration was initially planned for 16 weeks but there were rules for decreasing or withholding rhEPO according to the Hb level.
Results: The total number of injections of rhEPO until day 126 was 12.6±4.6. After day 126, 19 patients received maintenance therapy with the lowest possible dose of rhEPO. Median times to reach Hb ≥13 g/dL, ≥12 g/dL or +2 g/dL were shorter in the EPO arm and this resulted in a reduction of transfusion requirements in the EPO arm. After a median follow-up of 489 days, we did not observe any fatal TE or CV event and 1 patient in each arm died of an unknown cause. Indeed, 1-year and 5-year OS were 58% and 36% in the control arm and 63% and 40% in the EPO arm (p=0.30). Progression-free survival (PFS) was also similar in the two arms: 1-year and 5-year PFS were 47% and 32% in the control arm and 56% and 32% in the EPO arm (p=0.68). We also observed comparable relapse/progression rate: 31% in both arms at 1 year and 41% in the control arm *vs* 38% in the EPO arm at 5 years. Multivariate analyses with EPO use, conditioning, EBMT risk score and disease risk index were performed for OS and relapse/progression and only the disease risk index was significantly associated with a worsened survival, and with a trend to more relapse.

Summary and Conclusions: In conclusion, rhEPO following allo-HCT did not have an impact on survival in long-term analyses.

P508

SEQUENTIAL THIRD-PARTY MESENCHYMAL STROMAL CELL THERAPY FOR REFRACTORY ACUTE GRAFT-*VERSUS*-HOST DISEASE

F Sanchez-Guijo[1,*] T Caballero-Velazquez[2], O Lopez-Villar[1], A Redondo[1], R Parody[2], C Martinez[3], E Olavarria[4], E Andreu[5], M Diez-Campelo[1], C Regidor[6], E Villaron[1], L Lopez-Corral[1], MC del Cañizo[1], JA Perez-Simon[2]
[1]Servicio de Hematologia, IBSAL-Hospital Universitario de Salamanca, Salamanca, [2]Servicio de Hematologia, IBIS-Hospital Universitario Virgen del Rocio, Sevilla, [3]Servicio de Hematología, Hospital Clinic, Barcelona, [4]Servicio de Hematologia, Hospital de Navarra, [5]Area de Terapia Celular, Clinica Universidad de Navarra, Pamplona, [6]Servicio de Hematologia, Hospital Universitario Puerta de Hierro, Majadahonda (Madrid), Spain

Background: Refractory acute graft-*versus*-host disease (aGVHD) remains the main therapeutic challenge of allogeneic stem cell transplantation (allo-SCT), and although several therapeutic approaches have been assessed, the outcome for steroid-resistant patients remains poor. Mesenchymal stromal cells (MSC) are multipotent progenitors that can be isolated and expanded from bone marrow (BM) and other sources and have shown *in vitro* and *in vivo* immunomodulatory properties. Based on this fact, MSC therapy is being explored in a number of immune-based diseases, including GVHD. Prior data from our group (Perez-Simon *et al.* Haematologica 2011) indicate that BM-MSC from third party donors is a feasible approach and a number of patients needed several doses to achieve a response and the latter was higher when MSC therapy was started early.
Aims: To evaluate the feasibility and efficacy of four sequential doses of cryopreserved third-party BM derived MSC for refractory aGHVD.
Methods: We have treated 28 patients with steroid-refractory aGVHD with cryopreserved third-party BM-derived MSC. Fifteen patients were treated in a multicenter open label phase II trial (EudraCT: 2010-020947-11) and the experience was further expanded using the same criteria in a compassionate use program at the Hospital Universitario de Salamanca. Inform Consent was obtained from all patients and donors and the studies (both the trial and the compassionate use) were approved by the local Ethics Committees and the Spanish Medicines Agency (AEMPS) and GMP cell production fulfilled all the legal requirements. MSC were isolated and expanded from 50 mL of BM following the same IMDP protocol (06-076) in two GMP facilities, and further cryopreserved. Patients received a median dose of 1.1x10e6 MSC/Kg of recipient body weight on days 1, +4, +11, and +18. The response of aGVHD to MSC therapy was evaluated according to standard criteria.
Results: All patients (n=28) received at least 2 doses, whereas 24 received 3 and 21 received the initially scheduled 4 doses on days 1, 4, 11 and 18. There were no adverse events related to the MSC infusion in the 101 procedures performed, with the exception of a cardiac ischemic event in a patient with high cardiovascular risk and comorbidities (prior ischemic cardiac disease, diabetic, with concomitant renal failure and gastrointestinal hemorrhage).
Response of aGVHD at 60 days after the first MSC dose was evaluable in 26 patients. Of them, 18 patients (69.2%) responded to MSC administration and 8 did not. Of the responding patients, 11 achieved a complete response and 7 a partial response. Median time to response was 28 days (range 9-58 days) in the responding patients. We did not find association of MSC response to any clinical or laboratory parameter evaluated (age, sex, disease status at transplantation, conditioning regimen, GVHD prophylaxis, ECOG, absolute lymphocyte counts, among others).
Regarding infectious diseases, in the 60 days after the first MSC administration, 10 patients (35.7%) experienced *de novo* CMV reactivation, 3 patients (10%) were diagnosed of invasive aspergillosis and bacterial infections were reported in 9 patients (32.1%)
Summary and Conclusions: The use of sequential doses of cryopreserved BM-derived MSC on days 1, 4, 11 and 18 in steroid-refractory aGVHD patients is a safe procedure and may offer a higher rate of complete responses.

P509

PLASMA PROHNPS ARE SPECIFIC EARLY MARKERS OF NEUTROPHIL ENGRAFTMENT IN PATIENTS UNDERGOING HIGH-DOSE CHEMOTHERAPY, AUTOLOGOUS OR ALLOGENEIC STEM CELL TRANSPLANTATION

A Glenthøj[1,*] F Emmertsen[1], J Sønderskov[1], P Kampmann[1], H Sengeløv[1], N Borregaard[1]
[1]Department of Hematology, Rigshospitalet, Copenhagen, Denmark

Background: Neutropenia is invariably a consequence of myeloablative conditioning before hematopoietic stem cell transplantation (SCT) as well as high-dose chemotherapy. The risk of life-threatening infections correlates with the length of neutropenia. Several plasma proteins such as lysozyme have been investigated as early markers of bone marrow recovery, but these lack specificity which renders them clinically less useful.
Human neutrophil peptides (HNPs) are abundant antimicrobial peptides exclusively synthesized by late promyelocytes and myelocytes. HNPs are synthesized as 10kD proforms with a common propeptide. These are cleaved off during the promyelocytic stage of differentiation and the mature peptides, HNPs, are stored in azurophil granules. Myelocytes are the main produces of proHNPs, but lack the ability to process to mature HNPs and instead secrete proHNPs unprocessed to the bone marrow plasma, and from here to blood.
Aims: We hypothesized that proHNPs may serve as early and specific markers of granulopoiesis in patients undergoing hematopoietic SCT or high-dose chemotherapy.
Methods: Plasma samples were obtained daily from patients undergoing allogeneic SCT (n=11), autologous SCT (n=16), or high-dose chemotherapy (n=14). Furthermore, plasma samples were taken from patients with AML prior to chemotherapy (n=19) and healthy controls (n=39). ProHNPs, MPO, neutrophil gelatinase-associated lipocalin (NGAL), and lysozyme were measured by ELISA.
Results: In accordance with their short life span, neutrophils disappeared rapidly from circulation after myeloablative conditioning or high-dose chemotherapy. In all patients, plasma levels of proHNPs, MPO, NGAL, and lysozyme declined with the neutrophils counts. Of the investigated proteins, only proHNPs consistently disappeared from circulation along with neutrophils. In general, the plasma content of all proteins investigated started to rise before neutrophils could be detected in circulation. However, only proHNPs invariably preceded the rise in neutrophils. In patients undergoing allogeneic SCT, proHNPs rose five to six days before neutrophil counts. One patient developed septic shock during neutropenia. This was reflected in rising plasma levels of lysozyme and NGAL (Figure 1), which are expressed in non-myeloid tissues. In contrast, proHNPs and MPO followed neutrophil engraftment. Patients undergoing autologous SCT were treated with G-CSF to speed up neutrophil recovery and in these, proHNPs rose approximately two days before neutrophils were detected. As for patients receiving induction or consolidation chemotherapy, proHNPs predated neutrophils by two to four days. Patients with acute myeloid leukemia had significantly lower levels of plasma proHNPs than healthy controls, indicating that proHNPs in contrast to MPO are not produced by leukemic blasts.

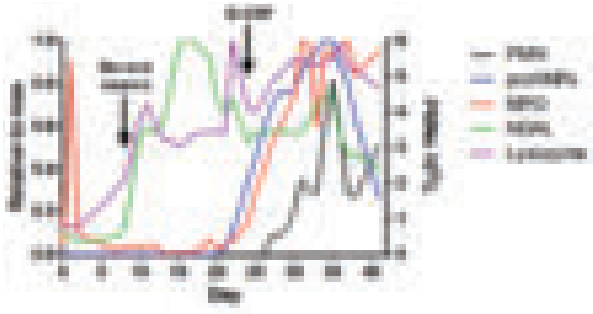


Figure 1.

Summary and Conclusions: ProHNPs are secreted exclusively by promyelocytes and myelocytes, *i.e.* myeloid cells not part of a leukemic clone in AML and ALL and can thus be taken as markers of normal hematopoiesis. In coherence with this, only proHNPs completely disappeared from circulation after myeloablative conditioning or high-dose chemotherapy and consistently returned along with normal granulopoiesis. Detection of proHNPs in plasma after chemotherapy induced bone marrow aplasia can thus been seen as an unequivocal indicator of reemerging granulopoiesis. Clinically, plasma proHNP could be an important tool to distinguish late take from primary graft failure in hematopoietic SCT patients, since measurement of proHNPs in plasma allows early detection of donor cell engraftment.

P510

POOR PROGNOSIS OF PATIENTS WITH SEVERE SINUSOIDAL OBSTRUCTION SYNDROME AFTER ALLOGENEIC HEMATOPOIETIC STEM CELL TRANSPLANTATION IN JAPANESE POPULATION:ON BEHALF OF COMPLICATIONS WORKING GROUP OF JSHCT

K Yakushijin[1,*] Y Atsuta[2], N Doki[3], A Yokota[4], H Kanamori[5], T Miyamoto[6], H Yabe[7], Y Morishima[8], K Kato[9], R Suzuki[2], T Fukuda[10]
[1]Division of Medical Oncology/Hematology, Department of Medicine, Kobe University Graduate School of Medicine, Kobe, [2]Department of HSCT Data Management and Biostatistics, Nagoya University Graduate School of Medicine, Nagoya, [3]Division of Hematology, Tokyo Metropolitan Cancer and Infectious diseases Center Komagome Hospital, Tokyo, [4]Department of Hematology, Chiba Aoba Municipal Hospital, Chiba, [5]Department of Hematology, Kanagawa Cancer Center, Kanagawa, [6]Department of Hematology and Oncology, Kyushu University Hospital, Fukuoka, [7]Department of Cell Transplantation and Regenerative Medicine, Tokai University School of Medicine, Kanagawa, [8]Division of Epidemiology and Prevention, Aichi Cancer Center Research, [9]Department of Hematology and Oncology, Children's Medical Center, Japanese Red Cross Nagoya First Hospital, Nagoya, [10]Stem Cell Transplantation Division, National Cancer Center Hospital, Tokyo, Japan

Background: Sinusoidal obstruction syndrome (SOS) is recognized as one of lethal complications after hematopoietic stem cell transplantation (HSCT). We previously showed that the incidence of SOS after allogeneic HSCT was 11.0% by using the Japan Society for Hematopoietic Cell Transplantation (JSHCT) database and the Seattle criteria (ASH meeting 2013, abstract #2051).
Aims: Herein, we focused on the clinical outcomes of severe SOS patients in order to clarify the prognosis of those patients.
Methods: From 117 transplant centers of the JSHCT 618 patients were diagnosed with SOS between 1999 and 2010. Additional data on the diagnosis and clinical presentation were collected, and survival information was updated. For 462 patients the diagnosis of SOS was confirmed based on the Seattle criteria (presence before day 30 after HSCT, of at least two of the following features: (1) jaundice (2) hepatomegaly and right upper quadrant pain and (3) ascites and/or unexplained weight gain (≥2%)). The Baltimore criteria (hyperbilirubinemia ≥2 mg/dl before day 21 after HSCT and at least, two of the following features: (1) hepatomegaly (2) ascites and (3) weight gain (≥5%)) was used for further risk assessment. Severe SOS was defined as SOS with renal failure (serum creatinine of ≥3xULN or dialysis dependent) and/or respiratory failure (oxygen saturation <90% on room air, oxygen supplement required, or ventilator dependent) at diagnosis. Complete response for SOS (CR) was defined as resolution of all the signs and symptoms of SOS diagnostic criteria.
Results: A total of 107 out of 462 patients met the Baltimore criteria. One hundred and sixty-eight patients were diagnosed as having severe SOS. The median time from the day of transplant to diagnosis of severe SOS was 12 days (range, 0-28). The signs and symptoms at diagnosis were weight gain (90%), jaundice (78%), hepatomegaly (63%), right upper abdominal pain (57%), ascites (56%), respiratory failure (68%), and renal failure (64%). CR rate was only 22% in severe SOS patients (28% and 10% in patients with SOS diagnosed by the Seattle but did not fulfill the Baltimore criteria and in patients who fulfilled the Baltimore criteria, respectively (P=0.01, Fisher's exact test)). The main causes of death for severe SOS patients were SOS-related mortality (61%), disease progression (12%), and others (27%). Probabilities of overall survival calculated by using Kaplan-Meier method with SOS treated as time-dependent variable at day 100 and 2 years after HSCT were 22% and 10% in patients with severe SOS and 50% and 32% in SOS patients without organ failure, respectively (27% and 12% in patients with severe SOS diagnosed by the Seattle but did not fulfill the Baltimore criteria and 14% and 5% in patients who fulfilled the Baltimore criteria, respectively, P <0.001, logrank test).
Summary and Conclusions: This retrospective survey showed that patients with severe SOS had extremely poor prognosis even if the Seattle criteria was applied. We should establish risk classification of SOS, strategies for SOS prevention and treatment for those patients in order to improve overall survival.

P511

HIGH-DOSE PREPARATION WITH THIOTEPA/ETOPOSIDE/ARA-C/MELPHALAN (TEAM) *VS* BEAM FOR AUTOLOGOUS HEMATOPOIETIC STEM CELL TRANSPLANTATION (AUTOHSCT) IN LYMPHOMA: A RETROSPECTIVE STUDY FROM THE EBMT

P Dreger[1,*] A Boumendil[1], H Finel[1], I Majolino[1], H Sayer[1], C Thieblemont[1], R Scime[1], D Blaise[1], J Finke[1], G Salles[1], I Yacoub-Agha[1], E Faber[1], E Nicolas-Virezelier[1], F Merli[1], D Vallisa[1], E Zuffa[1], M Vespignani[1], A Sureda[1]
[1]Lymphoma Working Party, EBMT, Paris, France

Background: Thiotepa is an alkylating agent approved for high-dose therapy for autoHSCT. Because of its excellent capacity to cross the blood-brain barrier, it is regularly used for autoHSCT for primary CNS lymphoma (PCNSL). However, although thiotepa-based myeloablation might have benefits over traditional BEAM preparation because of better brain availability and less pulmonary toxicity, clinical level information about thiotepa-based autoHSCT outside of the PCNSL field is sparse.
Aims: AIM of the present retrospective study was to provide information on the potential risks and benefits of high-dose regimens using thiotepa instead of BCNU together with etoposid, ara-C, and melphalan (TEAM) in autoSCT for distinct subtypes of lymphoma outside of the PCNSL setting.
Methods: PRIMARY OBJECTIVE was to compare the outcome of TEAM-based autoHSCT (TEAM) with that of BEAM autoHSCT (BEAM) separately for diffuse large B-cell lymphoma (DLBCL; excluding PCNSL), follicular lymphoma (FL), and Hodgkin's lymphoma (HL). PRIMARY ENDPOINT was progression-free survival (PFS), secondary endpoints were overall survival (OS), non-relapse mortality (NRM), incidence of relapse (IR), engraftment, and early toxicity. ELIGIBLE were patients >18 years who were registered with the EBMT and had received TEAM or BEAM for a first autoHSCT between 2003-2011 for FL, DLBCL, or HL. Baseline patient, disease, and transplant data were collected from MED-A forms. Centers with potentially eligible patients were contacted to provide additional treatment and follow-up information. STATISTICAL ANALYSIS was based on a 1:2 matched pair comparison using stratified Cox and Fine & Gray regression models for comparison. Matching factors were age (+/- 10 years), sex, lymphoma subtype, time from diagnosis to autoHSCT, remission status at autoHSCT, performance status (PS), and year of autoHSCT.
Results: 309 patients could be matched (TEAM 110, BEAM 199); 7 BEAM patients were used several times as match. Additional information was provided for 174 of these 302 eligible patients. After data retrieval, a total of 42 TEAM could be compared to 72 BEAM matches. Median age of TEAM was 47 years, and 57% were male. 44% had HL, 40% DLBCL, and 16% FL. With a median time from diagnosis of 18 months, remission status at autoHSCT was CR/PR1 in 36%, CR/PR >1 in 50%, more advanced disease in 14%. 14% of the patients had a reduced PS (Karnofsky <90%) at autoHCST. There was no difference with their BEAM matches. There was one non-relapse death in the TEAM group and none in the BEAM group. 3-year PFS, OS, and IR for TEAM *vs* BEAM were 64% *vs* 60%, 82% *vs* 80%, and 33% *vs* 40% without any significant differences. Tolerability of both regimens (TEAM *vs* BEAM) was comparable with nausea (64% *vs* 73%), mucositis (57% *vs* 62%), and infections (55% *vs* 63%) as predominant toxicities. Pneumonia/pneumonitis was reported in 2.3% and 8.3% of TEAM and BEAM patients (p not significant). Other non-infectious complications were rare (10% and 18% in the TEAM and BEAM groups; p not significant) and were mainly attributed to gastro-intestinal and skin events.
Summary and Conclusions: TEAM is a valuable alternative to BEAM in autoHSCT for HL, DLBCL, or FL with no significant differences in terms of safety and efficacy.
Supported by a restricted grant from Riemser AG, Greifswald, Germany.

P512

CO-TRANSPLANTATION OF HAPLOIDENTICAL TRANSPLANTATION AND UMBILICAL CORD BLOOD UNIT PROVIDE SIGNIFICANT SURVIVAL BENEFIT FOR PATIENTS WITH LEUKEMIA

A Sun, [1,*]J Wang[1], S Yang[1], H Zhou[1], H Qiu[1], X Tang[1], Z Jin[1], Y Han[1], C Fu[1], G He[1], X Ma[1], D Wu[1]
[1]the First Affiliated Hospital of Soochow University, Suzhou, China

Background: In the absence of a HLA-matched sibling donor, a HLA-mismatched/haploidentical transplantation can be considered an alternative for allogeneic stem cell transplantation (SCT), although its application is associated with the increased risk of severe acute graft-*versus*- host-disease (aGVHD), prolonged length of hospital stay, and poor overall survival(OS).
Aims: We conducted a HLA-mismatched/haploidentical transplantation combined with a third party single umbilical cord blood (UCB), known as co-transplantation, and compared to the haploidentical transplantation without UCB.
Methods: The co-transplantation group included 95 patients who received HLA-mismatched donor cell combined with third-party single cord blood cell and the control group included 63 patients who received haploidentical sibling donor cell alone.
Results: Neutrophil reconstruction duration of the co-transplantation group was 13d, platelet reconstruction duration was 15d, which have no significant difference compared to the control group (P >0.05). Recurrence rate were 22.4% and 26.2% respectively and with no statistical difference in the two groups (P >0.05). However, the cumulative incidence of aGVHD III-IV in the control group was significantly higher than that of co-transplantation group (36.4%vs19.5%, P<0.05). In the co-transplantation group, 3-year OS, disease free survival (DFS) and treatment related mortality (TRM) were 67.3%, 61.7% and 19.2% respectively and the results were significantly better than that of the control group (OS 42.9%, DFS 35.2% and TRM 38.3%, P <0.05).
Summary and Conclusions: In our experience the co-transplantation of haploidentical transplantation and unrelated cord blood unit offers significant survival benefit for patients with hematologic malignancies.

P513

IMPACT OF CD3/T REGS RATIO IN DONOR GRAFT ON SURVIVAL RATES IN ALLOGENEIC PERIPHERAL BLOOD STEM CELL TRANSPLANTATION

M Delia[1,*] D Pastore[1], A Mestice[1], P Carluccio[1], T Perrone[1], F Gaudio[1], P Curci[1], C Pasciolla[1], C Germano[1], G Nardelli[1], P Pinto[1], G Specchia[1]
[1]Hematology - University of Bari, Bari, Italy

Background: The therapeutic efficacy of allogeneic stem cell transplantation (alloSCT) for hematological malignancies relies largely on the graft *versus* leukemia (GvL) effect exerted by the donor CD3 cells, but an uncontrolled graft-*versus*-host-disease (GvHD) bears a risk of complications. On the other hand, T regs cells (CD4+CD25high Foxp3+) are believed to maintain tolerance and to inhibit GvHD after alloSCT; also, the Foxp3 gene encodes a transcription factor that is a key for thymic development, so T regs cells could preserve an optimal microenviroment for the reconstitution of functional immunity after alloSCT. Moreover, when looking at post allotransplant patients' outcomes, there is no evidence that donor graft CD3/T regs ratio may determine an effect in terms of OS, NRM and relapse free survival rates so far.
Aims: In this study we analyzed the graft CD3+/Tregs ratio (gCD3/Tregs R) and determined its impact on acute GVHD (aGVHD) and survival rates (OS, NRM and Relapse) after myeloablative alloPBSCT.
Methods: We analyzed 102 consecutive patients (median age 39 yy) transplanted with unmanipulated peripheral blood stem cells from an HLA identical related donor (n=78) or an HLA identical unrelated donor (n=32); diagnoses were acute myeloid leukaemia (n=82), acute lymphoblastic leukaemia (n=20).
Results: The median CD3+ and Tregs dose administered was 240 (range (r):

67-550) and 13x10^6/Kg (r: 2-21), respectively; the median gCD3/Tregs R was 22 (r: 8-250). Patients were subdivided into a high gCD3/Tregs R(>36) group(n=46) and a low gCD3/Tregs R(<36) group (n=56). The incidence of aGVHD (grade II-IV) in the low gCD3/Tregs R (LR) group was lower than in the high gCD3/Tregs R (HR) group (10/56 or 18% *vs* 35/46 or 77%, p<.001). The OS, NRM and relapse rate at 3 years was 54, 29 and 34%, respectively. Comparing LR with HR group a statistically significant difference is demonstrated for OS and NRM rates at 3 years (65 *vs* 31%,p<.004; 3 *vs* 71%, p<.001, Table 1), respectively, but not for the R one (35 *vs* 30%, p=ns). Comparing aGVHD+ with aGVHD- group OS, NRM and relapse were always statistically significant different at 3 years (39 *vs* 65%,p<.005; 61 *vs* 7%,p<.001; 9 *vs* 53%,p<.002).
Summary and Conclusions: Taken together, our data may suggest that Tregs content is able to mediate protective effects against aGVHD, while preserving GvL effects as demonstrated by relapse rate comparison between H and LR groups. However, larger studies are needed to understand the real contribution of gCD3/Tregs R on survival rates.

P514

THE IMPACT OF PRETRANSPLANT IRON CHELATING THERAPY WITH DEFERASIROX ON THE OUTCOME IN PATIENTS WITH SEVERE APASTIC ANEMIA UNDERGOING ALLOGENEIC STEM CELL TRANSPLANTATION

JW Lee[1,*] SE Lee[1], JH Kim[1], YW Jeon[1], JH Yoon[1], SH Shin[1], KS Eom[1], YJ Kim[1], HJ Kim[1], S Lee[1], CK Min[1], SG Cho[1], DW Kim[1], WS Min[1], CW Park[1]
[1]Seoul St. Mary's Hospital, The Catholic University of Korea, Seoul, Korea, Republic Of

Background: Pretransplant iron overload have shown the association with a higher risk of transplant-related mortality (TRM) and other complications including fungal infections, hepatic dysfunction after allogeneic stem cell transplantation (SCT). Although these negative impacts of iron overload on the transplant outcomes have been evaluated in the patients with various hematologic disorders including thalassemia, myelodysplastic syndrome, and acute leukemia, it has yet to be analyzed completely for the patients with severe apastic anemia (SAA) undergoing allogeneic SCT. Especially, the impact of pretransplant iron chelating therapy (ICT) on the transplant outcomes was uncertain.
Aims: The aim of this study was to evaluate the impact of pretransplant ICT with deferasirox on the survival outcome and infection rate in patients with SAA undergoing allogeneic SCT.
Methods: we retrospectively analyzed 159 adult patients with SAA who underwent allogeneic SCT from Mar. 2002 to Dec. 2012. They had available pretransplant serum ferritin data. Among them, 50 patients were received pretransplant ICT with deferasorox, when their serum ferritin was more than 1000 μg/L, whereas 59 patients had more than 1000 μg/L of serum ferritin but did not received ICT. Another 50 patients had less than 1000 μg/L of serum ferritin at transplant.
Results: Sixty-nine men and 90 women were assessed. Their median age was 34 years (range, 13-59 years). Primary engraftment was achieved in all, but 11 patients developed secondary graft failure. After a median follow-up of 47.1 (range, 6.1-124.9) months for survivors, the patients with more than 1000 μg/L of pretransplant serum ferritin have significantly increased risk of TRM (15.3% *vs* 3.5%. P=0.039), and lower overall survival (OS) (84.8% *vs* 96.6%, P=0.036) than those with the patients who had less than 1000 μg/L of serum ferritin. For 50 patients receiving pretransplant ICT with deferasirox, median serum ferritin levels decreased from 1995 μg/L at the initiation of ICT to 1240 μg/L before SCT, including 10 patients to less than 1000 μg/L. Median duration of ICT before SCT was 3.6 months, and median MDD (mean daily dose) was 14.8 mg/kg per day. In the comparison between iron overload patients with ICT and those without ICT, pretransplant ICT group showed a lower infection rate after SCT (34% *vs.* 59%, P=0.008). In terms of OS, the possible survival benefit of pretransplant ICT was observed in unrelated transplant setting (93.5% *vs.* 78.3%, P=0.090).
Summary and Conclusions: These results indicate that higher serum ferritin was associated with a negative impact on outcome after SCT in SAA. Pre-SCT ICT can reduce the incidence of infection after SCT. The possible survival benefit of Pre-SCT ICT was present especially in unrelated donor SCT.

P515

IMPACT OF MONOSOMAL KARYOTYPE ON THE OUTCOMES OF ALLOGENEIC HEMATOPOIETIC TRANSPLANTATION FOR OLDER PATIENTS (>60 YEARS OF AGE) WITH AML/MDS

J Leis[1,*] N Khera[1], V Fauble[1], L Sproat[1], C Reeder[1], J Betcher[2], P Noel[1], J Slack[1]
[1]Medicine, Blood and Marrow Transplant Program, [2]Pharmacy, Blood and Marrow Transplant Program, Mayo Clinic Arizona, Phoenix, United States

Background: Karyotype at diagnosis has emerged as the most significant prognostic factor in adult patients (pts) with myeloid malignancies. Recently a distinct group of cytogenetic abnormalities, referred to as monosomal karyotype (MK) have been shown to have particularly poor prognosis. MK was defined (Breems, 2008) as a karyotype with at least two autosomal monosomies or a single autosomal monosomy in combination with at least one structural abnormality. A slight benefit for allogeneic hematopoietic cell transplantation (allo-HCT) compared to chemotherapy or autologous HCT has been demonstrated in young AML (≤60) pts with MK (Cornelissen, 2012). However, the curative potential of allo-HCT in older (≥60) pts AML/MDS with MK is not known.
Aims: 1. Evaluate the impact of cytogenetic abnormalities on the progression-free survival (PFS) of older patients (>60 years) with AML or MDS who underwent an allo-HCT at Mayo Clinic Arizona between 2003-2013.
2. Determine the cumulative incidence of relapse and non-relapse mortality (NRM) in different cytogenetic risk groups.
3. Evaluate other factors that impact PFS outcome in older patients who undergo allo-HCT for AML/MDS.
Methods: In this retrospective review, we analyzed outcomes for 75 AML (n=53) or MDS (n=22) pts ≥60 years old who underwent allo-HCT at Mayo Clinic Arizona between 2005 and 2013, based on cytogenetic grouping as follows: cytogenetically normal (CN, n=26), cytogenetically abnormal but not MK (CA, n=32), and MK (n=17). Univariate and multivariate statistical analyses were performed to evaluate the impact of these 3 cytogenetic groupings on outcome (primary endpoint progression-free survival). The median age for all pts was 66 (60-76), and median follow-up for surviving pts was 26 months (range 90 days – 7.4 years). Forty-one pts had high-risk disease (MDS >5% blasts or AML not in CR), while 34 were considered standard risk (MDS <5% blasts or AML in CR). The majority of pts had good performance status (KPS ≥90% in 70), but 36 pts (48%) had an HCT-CI score of ≥3. Conditioning was myeloablative (Bu-Cy) in 4, reduced toxicity FBM (Fludarabine, BCNU, Melphalan) in 41, and RIC/NMA (fludarabine/busulfan 6.2mg/kg or fludarabine/TBI200cGy) in 30. Donors were matched related in 20, matched unrelated in 38, and mismatched unrelated in 17. GVHD prophylaxis included tacrolimus in all pts combined with mycophenolate mofetil (37) or methotrexate (38); 53 pts received in-vivo T-cell depletion with rabbit anti-thymocyte globulin (rATG, Thymoglobulin, Genzyme, Cambridge, MA).
Results: The Kaplan-Meier estimate of PFS at 2 yrs was 50% (CN), 38% (CA), and 3% (MK); *P*=0.004 (Figure 1). The cumulative incidence of relapse at 1 yrs (with death without relapse as a competing risk) was 26% (CN), 19% (CA), and 68% (MK); *P*=0.01. Relapse was the major cause of death in all cytogenetic groups but accounted for a higher percentage of deaths in pts with MK (50%). In addition NRM at 1 year was significantly higher in MK pts primarily due to GVHD and other causes (13% (CN), 32% (CA), and 58% (MK)). In a Cox proportional hazards analysis adjusted for age (≤66 *vs.* >66), risk status (standard *vs.* high), conditioning (myeloablative [Bu-Cy+FBM] *vs.* RIC/NMA), use of ATG (yes/no), donor type (unrelated *vs.* related), and HCT-CI (0-2 *vs.* ≥3), the only factor predictive for inferior PFS was cytogenetic status (MK *vs.* CN, HR 3.6 [95% CI, 1.52 – 8.72]; P=0.004); (MK *vs.* CA, HR 2.56 [95% CI 1.19 – 5.48]; P=.017).

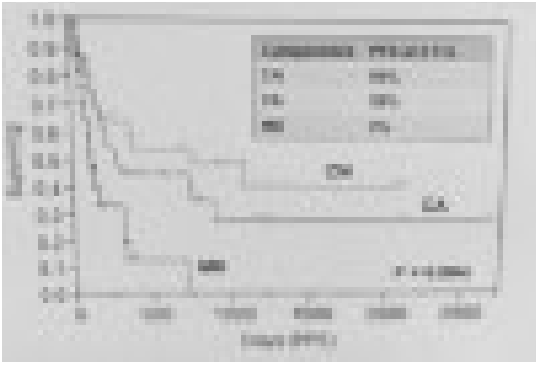

Figure 1.

Summary and Conclusions: Unlike younger patients ≤60 years(Cornelissen, 2012), older patients ≥60years with myeloid malignancies with MK who undergo Allo-HCT have very poor outcomes and limited curative potential. This is primarily due to high rates of relapse and NRM. Although larger studies will be required to confirm our results, novel transplant approaches or post-transplant strategies to prevent relapse should be a focus of future studies in this incurable pt population.

Hematopoiesis, stem cells and microenvironment

THE RUNX-PU.1 PATHWAY PRESERVES NORMAL AND AML/ETO9A LEUKEMIC STEM CELLS

P Staber[1,*] P Zhang[2], M Ye[2], R Welner[2], E Levantini[2], A Di Ruscio[2], A Ebralidze[2], C Bach[2], H Zhang[2], J Zhang[2], G Huang[3], D Tenen[4]
[1]Division of Hematology, Medical University Vienna, Vienna, Austria, [2]BIDMC, Boston, [3]Cincinnati Children's Hospital Medical Center, Cincinnati, United States, [4]Cancer Science Institute, National University of Singapore, Singapore, Singapore

Background: Runx transcription factors contribute to hematopoiesis and are frequently implicated in hematologic malignancies. All three Runx isoforms are expressed at the earliest stages of hematopoiesis; however their function in hematopoietic stem cells (HSCs) and leukemic stem cells is not elucidated.
Aims: Here, we aimed to investigate the functional effects of Runx factors on driving the expression of the hematopoietic transcription factor PU.1 in normal HSCs and leukemic stem cells.
Results: Mechanistically, using a knock-in mouse model in which all three Runx binding sites in the -14kb enhancer of PU.1 are disrupted we observed failure to form chromosomal interactions between the PU.1 enhancer and its proximal promoter. Consequently, decreased PU.1 levels resulted in diminished long-term HSC function through HSC-exhaustion, which could be rescued by reintroducing a PU.1 transgene. Similarly, in a mouse model of AML/ETO9a leukemia, disrupting the Runx binding sites resulted in decreased PU.1 levels. Surprisingly, leukemia onset was delayed and limiting dilution transplantation experiments demonstrated functional loss of leukemia initiating cells.
Summary and Conclusions: Our data demonstrate that Runx-dependent PU.1 chromatin interaction and transcription of PU.1 are essential for both normal and leukemia stem cells. Although low PU.1 levels have been considered as hallmark of leukemia, reducing PU.1 might also target the leukemic stem cell.

THE TISSUE INHIBITOR OF METALLOPROTEINASES-1 (TIMP-1) MODULATES HUMAN HSPC FUNCTIONS THROUGH CD63/PI3K/AKT SIGNALING

L Rossi[1,*] D Forte[1], G Migliardi[2], M Buzzi[3], L Catani[4], RM Lemoli[5], A Curti[1]
[1]Dept. of Diagnostic, Experimental, and Specialty Medicine, Ist. of Hematology "Seragnoli", University of Bologna, Bologna, [2]Institute for Cancer Research and Treatment, Turin, [3]Immunohaematology and Transfusion Medicine Service - S.Orsola-Malpighi Hospital, University of Bologna, [4]Dept. of Diagnostic, Experimental, and Specialty Medicine, Ist. of Hematology "Seragnoli",University of Bologna, Bologna, [5]University of Genoa, Genoa, Italy

Background: Hematopoietic Stem and Progenitors Cells (HSPCs) reside within the Bone Marrow (BM) stem cell niche, a nurturing environment believed to protect HSPCs from external insults. However, recent findings showed that HSPCs actively sense pro-inflammatory factors. Here, we investigate the role of Tissue Inhibitor of Metalloproteinases-1 (TIMP-1) within the BM microenvironment. First described as an inhibitor of Metalloproteinases (MMPs), TIMP-1. also displays cytokine-like functions. We recently found that TIMP-1$^{-/-}$ mice have decreased BM cellularity and that the engraftment capability of TIMP-1$^{-/-}$ HSCs is impaired, due to cell-cycle dysregulation. Strikingly, TIMP-1 is a key member of the inflammatory network and its expression is increased in response to pro-inflammatory cytokines: as such, TIMP-1 may play a key role in regulating emergency hematopoiesis under inflammatory stimuli.
Aims: As a contribution in dissecting the molecular pathways underlying the cross-talk between inflammatory factors and hematopoiesis, our study aims are: 1) to characterize the role of TIMP-1 in HSPCs proliferation and survival within the hematopoietic microenvironment; 2) to uncover TIMP-1's membrane receptor partner in HSPCs and elucidate the downstream signaling pathway ignited by TIMP-1 binding.
Methods: Human CD34$^+$ HSPCs were isolated from different sources, including BM, mobilized peripheral blood (mPB), and cord blood (CB). Investigations were performed at two levels: *1) TIMP-1 functional effect*: CD34$^+$ HSPC proliferation in the presence of different doses of TIMP-1 was tested *in vitro* by CFU-C and Long-Term Cultures (LTCs). TIMP-1 effects on cell proliferation and survival were assessed by PI staining and AnnexinV/PI staining, respectively. Primitive HSC potential was assessed by transplantation of TIMP-1-treated CD34$^+$ cells into immonodeficient mice (NOD/Shi-scid/IL-2Rγ*null* mice). In order to confirm the cytokinic nature of TIMP-1's effects, similar tests were performed in the presence of GM-6001, a synthetic MMP inhibitor. *2) TIMP-1 signalling pathway*: The expression of the tetraspannin receptor CD63 was assessed by flow cytometry, whereas its functional role was assayed by nucleofection of CD63-specific siRNAs in HSPCs. Downstream molecular targets of TIMP-1 (such as pAkt, CycD1, p27) were also confirmed by qPCR and flow cytometry.
Results: Our results suggest that rhTIMP-1 promotes CD34$^+$ cell survival and stimulates (in a dose-dependent manner) HSPC expansion (Figure 1A), without compromising their engraftment potential when transplanted into immunodeficient mice. In addition, clonogenic assays performed in the presence of GM-6001 confirmed that TIMP-1 effects are independent on MMP-inhibition (Figure 1B). The dissection of TIMP-1 signaling pathway indicated that the tetraspanin CD63 receptor is required for TIMP-1's cytokine functions in HSPCs and further investigation indicated that TIMP-1 stimulation induces PI3K recruitment and phopshorylation of AKT (Figure 1C), key modulators of survival/proliferation pathways in HSCs. Downstream targets of pAKT are also modulated, including the proliferation marker CycD1 (Figure 1D), which levels are increased upon exposure to TIMP-1.

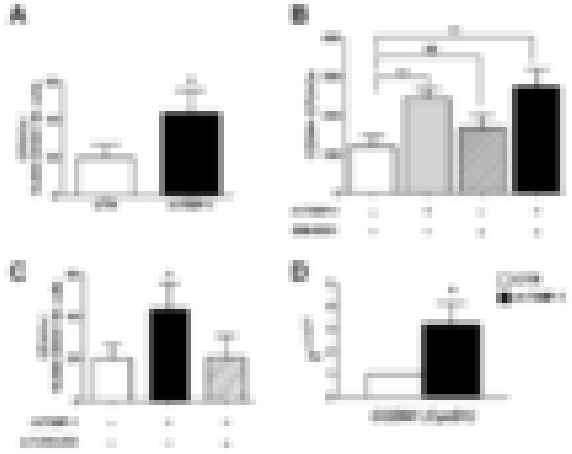

Figure 1.

Summary and Conclusions: These findings indicate that TIMP-1 promotes HSPC expansion and survival in human HSPCs via the activation of CD63/PI3K/pAKT signaling pathway. As such, TIMP-1 might be a key player in the modulating emergency hematopoiesis under inflammatory conditions.
RML and AC equally contributed.

LACK OF GLUCOCORTICOID-INDUCED LEUCINE ZIPPER (GILZ) RESULTS IN B CELL LYMPHOPROLIFERATIVE DISORDER IN MICE

O Bereshchenko[1,*] S Bruscoli[1], M Biagioli[1], T Frammartino[1], D Sorcini[1], M Cimino[1], C Fiorucci[1], C Riccardi[1]
[1]Medicine, Section of Pharmacology, University of Perugia, Perugia, Italy

Background: Glucocorticoids (GC) are widely used as immunosuppressive drugs and antitumor agents in some acute leukemias and multiple myeloma. Therapeutic doses of GC induce growth suppressive and cytotoxic effects on various leukocyte types including B cells. Molecular mechanisms of GC action include induction of GC target genes. Glucocorticoid-induced leucine zipper (GILZ) is a gene rapidly, potently and invariably up-regulated by GC treatment. It mediates a number of GCs effects, such as control of cell proliferation, apoptosis and differentiation. GILZ suppresses Ras/MAPK/Erk and NFkB pathways (Ayroldi *et al.*, Blood 2001; Bruscoli *et al.*, JBC 2012) and promotes TGF-b signaling in T cells (Bereshchenko *et al.*, Cell Reports, in press). It belongs to TSC22d family, members of which were recently found mutated in diffuse large B cell lymphoma patients (Pasqualucci *et al.*, NatGen 2011).
Aims: Here we address the physiologic role of GILZ in normal hematopoiesis, and evaluate its role in mediation of GC effects on various blood cells, using genetic approach.
Methods: Mice deleted for *gilz* gene were recently generated. We have monitored white blood cell counts in wild type (wt) and in gilz knock-out (KO) mice overtime. Development of lymphoid and myeloid lineages was evaluated both by peripheral blood (PB) cell counts (Hematocrit), and by flow cytometry analysis of bone marrow (BM), spleen and PB using Mac-1, B220, CD43, IgM and IgD staining. To test whether the effect of *gilz* gene deletion on hematopoiesis is self-intrinsic, we analysed hematopoiesis in BM chimeras generated by transplanting wt or gilz KO BM cells into lethally irradiated hosts.
Results: Young *gilz* KO mice showed normal body and lymphoid tissues weights and cell counts in PB, thymus, spleen, peripheral lymph nodes and BM. However, overtime *gilz* KO mice showed a 1.5-2 fold increase in white blood cell counts in PB. Increase in lymphocyte counts was due to accumulation of B220$^+$ cells, while the number of Mac-1$^+$ cells did not differ between wt and *gilz* KO mice. Flow cytometry analyis of B220$^+$ cell compartment in BM revealed an increase in the frequency and number of pre-B cells (IgM^{lo}IgD^{lo}), immature (IgM^{hi}IgD^{lo}) and recirculating B cells (IgM^{lo}IgD^{hi}) already in 8-week old mice. Frequency of Mac-1$^+$ cells was decreased in BM of *gilz* KO mice, although their

absolute number did not significantly differ between wt and *gilz* KO mice. Specific expansion of donor-derived B220$^+$ cells was also observed in BM of radiation chimeras, demonstrating the effect of GILZ deletion on B cells is self-intrinsic to hematopoietic cells. Preliminary data suggest that the defect start sas early as at common-lymphoid progenitor (CLP) stage. Treatment of purified B220+ cell with GC *in vitro* resulted in similar degree of apoptosis in wt and gilz KO cells, suggesting that the increase in B cells *in vivo* does not result from decreased sensitivity to the death induced by endogenous GC.
Summary and Conclusions: Our results show that lack of GILZ results in specific defect in B cell development, leading to the expansion of B220$^+$ cells compartment, associated with the expansion of early B cell progenitor cells and suggest that degerulation of GILZ expression may contribute to proliferation or differentiation of early B cells and pathologies of B cell lineage.

P519

TRUNCATION OF GM-CSF AND IL-3 BY DIPEPTIDYLPEPTIDASE 4 (DPP4) ALTERS THEIR RECEPTOR BINDING, SIGNALING AND FUNCTIONAL ACTIVITY IN NORMAL AND MALIGNANT HEMATOPOIETIC CELLS.
H O'Leary[1,*] C Mantel[1], MR Lee[1], X Lai[2], S Cooper[1], HS Boswell[3], HE Broxmeyer[1]
[1]Microbiology and Immunology, [2] Biochemistry and Molecular Biology/Proteomics Facility, [3]Medicine, Indiana University School of Medicine, Indianapolis, United States

Background: Dipeptidylpeptidase 4 (DPP4) is a serine protease that enzymatically cleaves select penultimate amino acids of proteins, resulting in functional alterations. Functional roles of full length (FL) *versus* Truncated (T) cytokines, as well as the mechanisms by which they may impart differing signaling and effects, have not been comprehensively elucidated. Importantly, the signaling alterations between full length and DPP4 truncated proteins, including the ability of the truncated protein to induce signaling that the full length factor can not, has not been investigated. We recently published that the number of cytokines, chemokines and growth factors that have putative DPP4 truncations sites has been dramatically underestimated and may have yet unappreciated clinical application.
Aims: 1) To determine the ability of DPP4 truncated GM-CSF (TGM) and IL-3 (T3) to reciprocally alter the receptor binding, signaling and functional activity of both the full length GM-CSF (FLGM) and IL-3 (FL3).
2) To investigate the signaling induced by FLGM and FL3 *vs* TGM and T3.
Results: We utilized the human, factor-dependent TF-1 cell line, as well as primary human cord blood (CB) cells and primary cells from patients with Acute Myeloid Leukemia (AML) to observe that DPP4 truncation of GM-CSF and IL-3 results in decreased colony stimulating factor (CSF) activity and in significant blocking of the functional ability of the full length CSF in normal and malignant hematopoietic progenitor cells (HPC) at less than a 1:1 ratio of the truncated protein to the full length. Receptor binding studies confirmed our hypothesis that DPP4 truncated GM-CSF (TGM) and IL-3 (T3) have enhanced receptor affinity and can compete to blunt the binding of their full length forms. *In vivo* studies demonstrated that both exogenously added TGM and T3 suppressed the effect of exogenously added full length GM-CSF (FLGM) or IL-3 (FL3) on progenitor cell numbers per femur and diminished HPC cycling. Mechanistic signaling studies show that the signaling induced by the full length *vs* DPP4 truncated proteins is altered with respect to miRNA expression, global protein quantitation, phosphorylation, acetylation, and reactive oxygen species (ROS) induction. Interestingly, miRNA, phosphorylation and global protein analysis showed that DPP4 truncated proteins were able to induce unique signaling that the full length counterparts did not induce, as well as signaling that overlapped with their full length counterparts, revealing the complexity of the signaling interactions and heretofore unknown activities of DPP4 truncated proteins.
Summary and Conclusions: These data show for the first time the ability of DPP4 trucanted proteins (TGM and T3) to reciprocally cross compete for receptor binding, and blunt the functional activity, of FLGM and FL3 on normal and malignant HPC, as well as induce differential signaling compared to that of their full length counterparts.

P520

GATA2 REGULATES DIFFERENTIATION OF BONE MARROW-DERIVED MESENCHYMAL STEM CELLS
M Kamata[1,*] Y Okitsu[1], T Fujiwara[2], S Nakajima[1], T Takahashi[1], A Inoue[1], N Fukuhara[1], Y Onishi[1], K Ishizawa[1], R Shimizu[3], M Yamamoto[4], H Harigae[1]
[1]Hematology and Rheumatology, [2]Molecular Hematology/Oncology, [3]Molecular Hematology, [4]Medical Biochemistry, Tohoku University Graduate School of Medicine, Sendai, Japan

Background: The bone marrow microenvironment comprises multiple cell niches derived from bone marrow mesenchymal stem cells (BM-MSCs). However, the molecular mechanism of BM-MSC differentiation is poorly understood. Transcription factor GATA2 is indispensable in hematopoietic stem cells (HSCs) as well as other hematopoietic lineages, suggesting that it may maintain BM-MSCs in the immature state and contribute to their differentiation.
Aims: We assessed the role of GATA2 in BM-MSC differentiation.
Methods: Murine BM-MSCs were established from *Gata2* conditional knockout mice (Charles *et al.* 2006), with MesenCult MSC Basal Medium (Stem Cell Technology). For GATA2 deletion, the BM-MSCs were infected with retroviruses expressing iCre (Goyama *et al.* 2008). Human BM-MSCs were established from BM mononuclear cells from healthy volunteers, with Dulbecco's modified Eagle medium containing 20% fetal bovine serum, and 10 ng/mL basic fibroblast growth factor (Peprotech). GATA2 loss- and gain-of-function analysis was conducted with specific siRNA and MSCV retrovirus vector, respectively. For transcription profiling, the Human Genome U133 Plus 2.0 Array (Affymetrix) was used. Gene Ontology (GO) analysis was based on DAVID software. A colony-forming assay was conducted with semisolid culture (Stem Cell Technology). Adipocyte differentiation was assessed by Oil Red O staining.
Results: Immunophenotypic analyses confirmed that established BM-MSCs expressed typical surface markers (CD29$^+$CD44$^+$Sca-1$^+$CD11b$^-$CD34$^-$CD45$^-$ and CD29$^+$CD44$^+$CD90$^+$CD105$^+$CD14$^-$CD34$^-$CD45$^-$ for murine and human BM-MSCs, respectively). Differentiation of murine GATA2-deficient BM-MSCs into adipocytes accelerated oil-drop formation and increased adipocyte-specific gene expression, including *Cebpb, Pparg,* and *Fabp4*. Further, GATA2 loss- and gain-of-function analyses in human BM-MSCs confirmed that decreased and increased GATA2 expression accelerated and suppressed, respectively, BM-MSCs differentiation into adipocytes and was accompanied by significant changes in the expression of representative adipocyte-related genes such as *CEBPA*, *CEBPB*, *PPARG*, and *FABP4*. Next, microarray analysis was conducted to characterize the GATA2 target gene ensemble in human BM-MSCs. An average of 2 independent analyses demonstrated that 90 and 189 genes were upregulated or downregulated by a factor of 2, respectively, with GATA2 knockdown. GO analysis identified significant enrichment of genes involved in cell cycle regulation. Concomitantly, flow cytometric analysis based on propidium iodide staining demonstrated that the number of G1/G0 cells increased after GATA2 knockdown. To test whether the ability of BM-MSCs to support HSCs was compromised by reduced GATA2 expression, GATA2 knockdowned BM-MSCs were cocultured with cord blood-derived CD34$^+$, cells, demonstrating that HSC frequency and colony formation were significantly decreased. Finally, because GATA2 expression is decreased in both HSCs and BM-MSCs in patients with aplastic anemia (Fujimaki *et al.* 2001, Xu *et al.* 2009), we evaluated whether the addition of various cytokines influences adipocyte differentiation. Among the cytokines, BMP4 suppressed adipocyte differentiation and significantly induced GATA2.
Summary and Conclusions: Decreased GATA2 expression induced BM-MSC differentiation, particularly into adipocytes, leading to a decreased hematopoietic supporting capacity. Further efforts to identify the regulatory mechanism of GATA2 in HSCs and BM-MSCs may lead to the development of novel therapeutic approaches for bone marrow failure syndrome.

P521

ISOLATION OF A CD34+CD38-CD45+CD117HI POPULATION HIGHLY ENRICHED IN HEMATOPOIETIC STEM CELLS (HSC) IN HUMAN EMBRYONIC AND FETAL LIVER: A MODEL TO HIGHLIGHT KEY REGULATORS OF *EX VIVO* HSC EXPANSION?
S Sanfilippo[1,*] L Petit-Cocault[1], H Fohrer-Ting[2], B Mennesson[3], AL Delezoide[4], ML Brival[5], T Jaffredo[1], M Souyri[1]
[1]CNRS UMR 7622 Biologie du développement, [2]Plateforme d'imagerie Cellulaire et de Cytométrie (CICC), Centre de Recherche des Cordeliers, UMR S 872, Université Pierre et Marie Curie, Paris, [3]Service de Gynécologie-Obstétrique, CH Pontoise, Pontoise, [4]Service de Biologie du développement, CHU Robert Debré, Paris, [5]Service de Gynécologie-Obstétrique, Maternité des Lilas, Les Lilas, France

Background: HSCs are characterized by their ability to both self-renew and differentiate to give rise to the different hematopoietic cell lineages. *Ex vivo* expansion of HSCs without alteration of self-renewal, homing in the bone marrow, and pluripotentiality represents a major therapeutic challenge, especially for treatment of malignant hemopathies, immune deficits or severe anemia. Unlike adult HSCs, which are quiescent, embryonic and fetal HSCs proliferate actively, especially in the fetal liver that is the major site of HSC amplification during embryonic development. Knowledge of the factors and mechanisms which are involved in the regulation of HSC amplification during their development in fetal liver should then provide clues allowing a better control of *ex vivo* expansion of these cells for therapeutic applications.
Aims: Undertake a functional and molecular characterization of populations enriched in HSCs in human embryonic and fetal liver (7 to 26 weeks of gestation - WG).
Methods: On the basis of the CD34$^+$CD38$^-$CD45$^+$, population, we tested: CD110 (Mpl receptor), CD93 (AA4.1) and CD117 (c-kit) as surface markers that could enrich this population in HSCs.
Results: Our results indicate that while CD110 and CD93 do not allow any HSC enrichment during embryonic stages, the CD34$^+$CD38$^-$CD45$^+$CD117^{hi} population presents remarkable potentialities as soon as 7 to 8 WG, which persist during fetal liver development. *In vitro*, long-term culture – initiating cell (LTC-IC) frequency on MS5 support is very high (1/4 to 1/2), and significantly superior to that observed for the CD34$^+$CD38$^-$CD45$^+$CD117$^-$ and CD34$^+$CD38$^-$

CD45+ control populations (1/3330 and 1/50, respectively). In addition, extended LTC-IC (e-LTC-IC) showed that not only CD34+CD38-CD45+CD117hi cells could be maintained in culture for more than 200 days (*versus* 33 days for CD34+CD38-CD45+CD117- cells) with a 8000 fold amplification of hematopoietic cells, but that a significant fraction of immature cells was maintained during passages. *In vivo* NSG engraftment is under investigation.
Summary and Conclusions: All together, our results highlight a very immature CD34+CD38-CD45+CD117hi population present early in the embryonic liver, highly enriched in HSPCs, endowed with high amplification potential *in vitro*, and which persists during development in the liver, in the bone marrow, and in the cord blood. Genome wide transcriptomic analysis of this population should reveal key regulators of HSC amplification that will provide a better context to expand HSC for cell therapy purpose.

P522

A ROLE OF C/EBP-ALPHA IN DEVELOPMENT OF PLASMACYTOID DENDRITIC CELLS IN THE THYMUS
A Wölfler[1,*] A Rosenberger[1], O Wolf[1], A Zebisch[1], I P Touw[2], H Sill[1]
[1]Division of Hematology, Medical University of Graz, Graz, Austria, [2]Department of Hematology, Erasmus Medical Center, Rotterdam, Netherlands

Background: While there is convincing evidence that conventional dendritic cells (cDCs) are derived from myeloid progenitors, the origin of plasmacytoid dendritic cells (pDCs) is less clear.
Aims: The aim of this project was therefore to determine the ancestry of pDCs under steady-state conditions *in vivo* by using a myeloid-specific reporter mouse model and to elucidate regulatory mechanisms involving the myeloid transcription factor C/EBPα in their early development.
Methods: The number of pDCs and their EYFP expression was determined by FACS analysis in spleen, thymus and lymph nodes of both, Cebpa^{Cre} EYFP as well as Mx1^{Cre} Cebpa$^{F/F}$ mice. The first model allows tracing of C/EBPα-positive myeloid progenitors and their progeny by EYFP expression, the latter results in a bone marrow specific knock-out (ko) of C/EBPα and a consecutive loss of all mature myeloid cells. DC formation was modelled *in vitro* by incubation of lineage negative bone marrow (BM) progenitors with FLT3L for 8 days. Apoptosis was detected by annexin V/propidium iodide staining and gene expression profiling was performed using Affymetrix GeneChip Mouse Gene 1.0 ST arrays.
Results: In Cebpa^{Cre} EYFP mice the percentage of EYFP-positive pDCs was increased in the thymus as compared to spleen and lymphnodes (21% *vs.* 13% and 12%; p<0.01) suggesting that a higher number of thymic pDCs is derived from Cebpa-positive myeloid progenitors. Accordingly, bone marrow-specific lack of Cebpa resulted in reduced numbers of thymic pDCs (0.12% in Cebpa wt *vs.* 0.04% in Cebpa ko mice; p<0.01), while the numbers of pDCs in spleen and lymph nodes were not affected. Analysis of pDC-specific surface molecules did not show any difference between myeloid-derived thymic pDCs and their EYFP-negative counterparts. Modelling dendritic cell formation *in vitro* by incubating BM progenitor cells with FLT3L revealed a critical role of C/EBPα in early DC development: while BM progenitors isolated from wt mice proliferated and differentiated into cDCs and pDCs, Cebpa ko BM progenitors displayed increased apoptosis and DC formation was almost absent. Gene expression analysis of FLT3L-stimulated BM progenitors showed not only C/EBPα-dependent upregulation of DC-specific genes, but also upregulation of TNFα and NF-κB-dependent genes including the anti-apoptotic factor Bcl2A1. Addition of TNFα to FLT3L during *in vitro* incubation reduced the percentage of apoptotic cells and partially restored DC formation of Cebpa ko BM progenitors.
Summary and Conclusions: C/EBPα significantly contributes to formation of pDCs in the thymus. Upregulation of Bcl2A1 expression via TNFα and NF-κB-signalling may be among crucial mechanisms of C/EBPα in early DC development.

P523

RECOMBINANT HUMAN IL-12 BUT NOT FILGRASTIM DECREASE ALL-CAUSE MORTALITY IN A PRIMATE MODEL OF ACUTE RADIATION SYNDROME: RESULTS FROM BLINDED VEHICLE-CONTROLLED GLP STUDY
Z Gluzman-Poltorak[1], V Vainstein[1,*] L Basile[1]
[1]Neumedicines, Inc, Pasadena, United States

Background: Hematopoietic Syndrome of Acute Radiation Syndrome (HSARS) is life-threatening illness caused by rapid bone marrow ablation.
The Radiation Injury Treatment Network (RITN) recommends off-label use of leukocyte growth factors. A single published, randomized controlled study (Farese *et al.* Radiat Res. 2013) in non-human primates (NHP) showed that addition of 18 daily filgrastim injections (rHuG-CSF) to intensive, trigger-based medical management (antibiotics, blood products, intravenous fluids) improved survival by 38%. Significant delays in the initiation and potential shortages of full supportive care treatment can be expected in the mass casualty radiation disaster scenarios emphasizing importance of the development of countermeasures that can be effective as single agents without intensive medical management. Recombinant human interleukin-12 (rHuIL-12, HemaMax™) is being developed for mitigation of HSARS under the FDA Animal Rule using a NHP model of HSARS. Our previous randomized, blinded, placebo-controlled GLP study in the NHP model of HSARS showed that a single subcutaneous injection of rHuIL-12 (50ng/kg-500 ng/kg) 24-25 hours after lethal total body irradiation (700cGy; $LD_{90/60}$ significantly improved overall survival without the use of antibiotics, fluids or blood transfusions (log rank test p<0.05). rHuIL-12 also reduced incidence of severe neutropenia and thrombocytopenia, systemic infection and internal organ hemorrhage. Phase 1 randomized double-blind placebo controlled safety studies in 92 healthy human volunteers demonstrated that rHuIL-12 is safe and well-tolerated at unit dose levels up to 12µg (170ng/kg for a 70 kg adult).
Aims: Here we report the results from our second GLP randomized blinded vehicle-controlled NHP study that was designed to confirm to compare rHuIL-12 to rHuG-CSF for treatment of HSARS.
Methods: Rhesus macaques were irradiated (700 cGy) and treated with a single subcutaneous injection of vehicle or rHuIL-12 175ng/kg 24-25 hours after irradiation, daily subcutaneous injections of rHuG-CSF at 10µg/kg/d for 18 days starting 24-25 hours after irradiation, or combination of a single rHuIL-12 and 18 rHuG-CSF injections (26-36 animals/group; male:female=1:1) without antibiotics, intravenous fluids or any blood products.
Results: As shown in Figure 1, single injection of rHuIL-12 increased survival compared to rHuG-CSF (56% *vs* 31%, Logrank test p<0.05) while rHuG-CSF did not provide any survival benefit over the control group (36%). Combination of rHuIL-12 and rHuG-CSF was similar to the rHuIL-12 monotherapy group (58% survival). rHuIL-12 significantly decreased incidence of severe neutropenia (<100 cells/µl) and thrombocytopenia (<10,000 cells/µl) compared to vehicle and to rHuG-CSF. Combination of rHuIL-12 with rHuG-CSF resulted in further improvement of neutrophil and platelet counts. rHuIL-12 also decreased incidence of severe infections, while rHuG-CSF increased incidence of infections and mucositis. During the highest mortality period (Days 10-18) rHuIL-12 improved neutrophils, platelets, lymphocytes, red blood cells, and reticulocytes counts. rHuG-CSF increased neutrophil and platelet counts starting from day 14 only, had no effect on reticulocytes, and negative impact on lymphocytes and red blood cell.

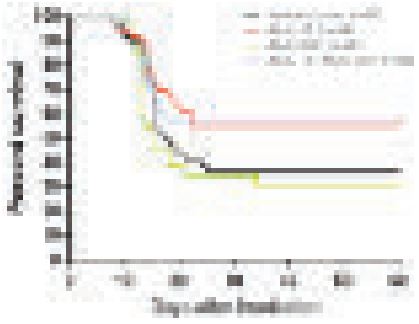

Figure 1. Survival of rhesus monkeys following lethal radiation and treated 24 hours post radiation with either vehicle, rHuIL-12, filgrastim (rHuG-CSF), or combination.

Summary and Conclusions: In conclusion, single subcutaneous injection of rHuIL-12 alone reproducibly improves survival in the NHP model of HSARS at dose levels shown to be safe in healthy human volunteers, while rHuG-CSF has no survival benefit in this model. These results support further development of rHuIL-12 as a medical countermeasure for HSARS.

P524

HISTONE DEACETYLACE INHIBITOR VORINOSTAT REDUCES KIT EXPRESSION BY DEREGULATION OF THE TRANSCRIPTIONAL COMPLEX AND INDUCTION OF HETEROCHROMATIN
H Abdulkadir[1,*]
[1]HERM, Karolinska Institutet, Stockholm, Sweden

Background: Mast cell development and survival requires the binding of stem cell factor (SCF) to its receptor KIT. Mastocytosis is a disease defined by the abnormal increase in mast cell numbers due to a point mutation that render the KIT receptor ligand independent. Today there is no cure for mastocytosis which is lethal in its aggressive form. Vorinostat was the first histone deacetylase inhibitor to be approved for use in cancer therapy. The aim of this study is to investigate the effect of Vorinostat on KIT mutated mast cells and to define a mechanism for the effect obtained.
Aims: The aim of this study is to investigate the effect of Vorinostat on KIT mutated mast cells and to define a mechanism for the effect obtained.
Results: We found that Vorinostat induced apoptosis, dose and time dependently, in KIT D816V mutated mast cells. Vorinostat caused an efficient down-regulation of the KIT receptor, both on mRNA and protein levels as well as of the activity of pathways downstream of KIT. Analysis of transcription factors known to regulate KIT transcription showed that GATA1/2, Myb, ETS2, LOM2

and Sp1 all were downregulated after Vorinostat treatment. However, inhibiting the expression of these genes by RNAi failed to inhibit KIT expression to the same degree as Vorinostat treatment. When analyzing the histone modifications of the c-kit locus, using ChIP in a D816V mutated cell line, Vorinostat treatment induced repressive chromatin mark H3K9 while active chromatin mark H3K18 acetylation was reduced, indicating that the chromatin region had been closed from transcription. To investigate the clinical relevance, primary mast cells from three patients with mild to aggressive systemic mastocytosis was isolated by MACS separation and treated *ex vivo* with 5μM Vorinostat for 24h, whereby the mast cell population entirely vanished.
Summary and Conclusions: In this study we demonstrate that Vorinostat downregulates D816V mutated KIT, by mechanism of heterochromatin formation at the c-kit locus. These results can be translated into the clinic as we show that primary mastocytosis patient cells are sensitive to Vorinostat

P525

ASSOCIATION OF AN IMPAIRED BONE MARROW VASCULAR MICROENVIRONMENT WITH PRIMARY FAILURE OF PLATELET ENGRAFTMENT AFTER ALLOGENEIC HEMATOPOIETIC STEM CELL TRANSPLANTATION
Y Kong[1,*] Y Hu[1], XH Zhang[1], YZ Wang[1], XD Mo[1], YY Zhang[1], Y Wang[1], W Han[1], LP Xu[1], YJ Chang[1], XJ Huang[1]
[1]Peking University People's Hospital, Beijing, China

Background: Primary failure of platelet engraftment (PFPE), defined as the engraftment of all peripheral blood cell lines aside from prolonged thrombocytopenia (platelet≤20×10^9/L or dependence on platelet transfusions) for more than 90 days after allogeneic hematopoietic stem cell transplantation (allo-HSCT), is a serious complication following allo-HSCT. Nevertheless, its underlying mechanisms remain to be elucidated. We previously reported that prolonged thrombocytopenia after allo-HSCT may be related to a reduction in ploidy and an immaturation of megakaryocytes(MKs) (Zhang X, *et al.* **Biol Blood Marrow Transplant**. 2011; 17:274-280). Recently, we have established a reliable assay for detecting the equivalents of the murine bone marrow (BM) microenvironment elements anatomically and phenotypically in human. Moreover, we found that the impaired BM microenvironment may contribute to the occurrence of secondary poor graft function post-HSCT(Kong Y *et al.* **Biol Blood Marrow Transplant**. 2013; 19: 1465-1473). In mice, the cross-talk between MKs and BM endothelial cells(BMECs) in vascular microenvironment regulate the MKs maturation and thrombopoiesis. We therefore hypothesized that the impaired BM microenvironment may hamper the MKs maturation, possibly translating to the occurrence of PFPE post-HSCT.
Aims: To evaluate whether abnormalities of the BM microenvironment are involved in the pathogenesis of PFPE after allo-HSCT.
Methods: In the present prospective nested case-control study, 20 patients with PFPE, 40 matched patients with good graft function (GGF) after allo-HSCT and 16 healthy donors (HDs) were enrolled. The cellular elements of the BM microenvironment, including the BMECs, perivascular cells and endosteal cells, were analyzed by flow cytometry as well as hematoxylin-eosin and immunohistochemical staining in BM trephine biopsies (BMB). Additionally, megakaryocytic-active chemokines, including stromal-derived factor-1(SDF-1) and vascular endothelial growth factor (VEGF) were detected in plasma of BM by enzyme-linked immunesorbent assay. The study was approved by the Ethics Committee of Peking University People's Hospital and written informed consent was obtained from all subjects.
Results: Although no significant different $CD34^+$ cells (0.25% *vs.* 0.26% *vs.* 0.28%, *P*>.05) and endosteal cells (15 per high-power field [hpf] *vs.* 16 per hpf *vs.* 20 per hpf, *P*>.05) were demonstrated among the PFPE,GGF patients and HDs. PFPE patients showed a remarkable decrease in the cellular elements of vascular microenvironment including BMECs (0.01% *vs.* 0.18% *vs.* 0.20%, *P*<.0001) and perivascular cells (0.01% *vs.* 0.12% *vs.* 0.13%, *P*<.0001) in comparison to GGF allo-HSCT recipients and HDs, respectively. Moreover, significant lower levels of SDF-1(3163pg/ml *vs.* 3928pg/ml, *P*=.0002) and VEGF (56pg/ml *vs.* 123pg/ml, *P*<.0001) were demonstrated in BM plasma of PFPE patients than that in GGF patients. Multivariate analyses revealed that BMECs (OR=171.57, *P*=.002) and the cytomegalovirus infection (OR=4.35, *P*=.009) were independent risk factors for PFPE.
Summary and Conclusions: Our results suggest that the impaired BM vascular microenvironment and its associated megakaryocytic-active chemokines may contribute to the occurrence of PFPE after allo-HSCT.

REGULATION OF B LYMPHOPOIESIS BY SIGNAL-TRANSDUCING ADAPTOR PROTEIN-2, STAP-2
M Ichii[1,*] K Oritani[1], N Fujita[1], N Saitoh[1], Y Sekine[2], R Muromoto[2], S Kon[2], K Saitoh[2], T Matsuda[2], Y Kanakura[1]
[1]Hematology and Oncology, Osaka University Graduate School of Medicine, Suita, [2]Immunology, Hokkaido University, Sapporo, Japan

Background: Hematopoiesis is changed in response to various types of stress, including infections and aging. Recent studies have shown that hematopoietic stem and progenitor cells (HSPC) in bone marrow (BM) are affected by pathogens and inflammatory cytokines. These cells express Toll-like receptors (TLRs) and B lymphopoiesis is arrested after exposure to TLR ligands such as LPS. Previously, we cloned signal-transducing adaptor protein-2 (STAP-2) as a c-fms/M-CSFR interacting protein. Like other adapter proteins, STAP-2 interacts with a variety of signaling or transcriptional molecules, and modifies their functions. We reported that STAP-2 combines with MyD88 and IκB kinase (IKK) to activate NF-κB and enhances the production of IL-6 and TNFα in macrophages *in vitro*. The disruption of STAP-2 attenuates dextran sodium sulfate-induced colitis via inhibition of macrophage recruitment. Although these findings suggest that STAP-2 is related to inflammatory and/or immune responses, little has been known about the role in B cell development in BM.
Aims: To evaluate the effects of STAP-2 on lymphopoiesis using gene-modified mice.
Methods: We generated transgenic mice (Tg) that overexpress STAP-2 under the control of the Eμ enhancer. The promoter could drive expression of the inserted cDNA in B lineage cells from pre-pro-B stage. All experimental procedures were conducted under specific pathogen-free conditions, according to protocols approved by Institutional Animal Care and Use Committees of Osaka University. Human BM samples were collected after informed consent, using protocols approved by the Investigational Review Board of Osaka University Hospital.
Results: With quantitative PCR, we first evaluated the expression level of STAP-2 in human BM. Although STAP-2 mRNA was ubiquitously observed, $CD34^+$ HSPC and $CD19^+$ B progenitors expressed the gene much higher than myeloid lineage cells. To study whether STAP-2 could regulate early lymphopoiesis in BM, several subsets of B progenitors in Tg and the deficient mice were analyzed with flow cytometry. As a result, the numbers of pre-pro-B and immature B cells were suppressed with statistical significance in Tg mice, while there were no differences between control and knock-out mice. In colony-forming unit (CFU) assays, we found that STAP-2 expression decreased the ability to generate CFU pre-B colonies. When HSPC (Lin^- $Sca1^+$ $cKit^{hi}$ cells or Lin^- $Sca1^+$ $cKit^{low}$ common lymphoid progenitors (CLP)) derived from Tg were cultured with OP9 stromal cells under B cell condition (1 ng/ml IL-7, 50 ng/ml Flt3-ligand and 20 ng/ml SCF), the production of $B220^+$ B cells were significantly suppressed (CLP cultures; 94.7±0.12% in WT *vs* 42.6± 9.66% in Tg). Moreover, in stromal-cell free cultures, HSPC from Tg arrested the development of B cells at the early stages before starting CD19 expression.
Summary and Conclusions: In this study, we show that the level of STAP-2 influences the early development of B cells at several stages, from pre-pro-B to immature B cells. STAP-2 was highly expressed in HSPC and B progenitors compared to myeloid lineage cells. STAP-2, which function is generally recognized under inflammatory condition, is speculated to interact with key molecules during B lymphopoiesis. Our findings indicate that STAP-2 involves the pathophysiology of B lymphocyte-related disorders caused by acute/chronic inflammation and aging. Further study would clarify the precise molecular mechanisms to suppress B cell generation in BM.

P527

IMPACT OF COLD SHOCK PROTEIN YBX1 ON HEMATOPOIETIC STEM CELL DEVELOPMENT AND FUNCTION
N Mashamba[1,*] D Wolleschak[1], VR Thangapandi[1], S Frey[1], TM Schnoeder[1], T Fischer[1], F Heidel[1]
[1]Hematology and Oncology, Otto-von-Guericke University Magdeburg, Magdeburg, Germany

Background: Y-box binding protein 1 (Ybx1) is an evolutionarily conserved DNA- and RNA- binding protein that is classified as a member of the cold shock proteins. Recent reports have highlighted its importance in regulation of early erythropoiesis and its interaction with evolutionary conserved signaling pathways such as Notch. This role in early hematopoietic development and the interaction with self-renewal associated signaling pathways suggests a requirement for Ybx1 in hematopoietic stem- and progenitor-cell (HSPC) development and function.
Aims: We aimed to assess for the impact of Ybx1 on HSPC development and function.
Methods: Expression levels of Ybx1 were analyzed by qPCR and intracellular flow cytometry on immunophenotypically defined murine bone marrow stem- and progenitor-cell populations. To characterize the requirement of Ybx1 on a functional level, we used a previously published conventional (straight) knockout mouse model (Lu *et al.*, Mol Cell Biol, 2005). In this model, homozygous inactivation of Ybx1 results in embryonic lethality around day E15, mostly due to malformation of the central nervous system while heterozygous animals ($Ybx1^{+/-}$) are born without any significant defects. Self-renewal and differentiation capacity were analyzed by plating fetal liver cells (FLC) or adult hematopoietic stem cells from the respective knockout mice in methylcellulose *in vitro* and by spleen colony formation (CFU-S12) and long-term reconstitution in lethally irradiated recipients *in vivo*.
Results: Ybx1 expression was massively up-regulated during differentiation

with highest levels detectable in multipotent progenitors (MPP) and committed myeloid progenitors (CMP, GMP and MEP). To assess for the role of Ybx1 in hematopoietic development we harvested FLC at day E13.5. FLC numbers were significantly decreased in Ybx1$^{-/-}$ fetuses compared to Ybx1$^{+/+}$ littermate controls. Immunophenotypically, Ybx1$^{-/-}$ showed a lower number of LT-HSC (CD34-LSK) but a higher amount of ST-HSC/MPP (CD34+LSK). Consistently, when injected into lethally irradiated recipient mice, an increased number of spleen colony forming units was detectable on day 12. When transplanted competitively for long-term reconstitution, Ybx1$^{-/-}$, FLC produced a significantly decreased chimerism, which is explained by the decreased number of LT-HSC. Even heterozygous (Ybx1$^{+/-}$) animals showed a slight trend towards a decreased repopulation capacity. To investigate whether this trend could be recapitulated in adult hematopoiesis, we performed immunophenotyping of adult stem- and progenitor-cell populations and functional experiments on adult HSC derived from Ybx1$^{+/+}$ or Ybx1$^{+/-}$ animals. Immunophenotyping of young (<8 weeks) and aged animals revealed no significant quantitative differences in HSPC populations. However, plating of Ybx1$^{+/+}$ or Ybx1$^{+/-}$, HSC in methylcellulose revealed increased differentiation for the heterozygous state after one week and consecutive reduction of colony formation in the second round of plating. Of note, TER119+ cells appeared to be significantly reduced in these platings, which is in line with the previously published requirement of Ybx1 for erythroid development. When injected into lethally irradiated hosts, Ybx1$^{+/-}$, cells produced slightly higher numbers of spleen colonies but a comparable chimerism during long-term reconstitution.
Summary and Conclusions: Taken together, our data provide first evidence for a role of cold shock protein Ybx1 in hematopoietic development, self-renewal and differentiation of hematopoietic stem- and progenitor cells.

P528

IMPACT OF COMMENSAL MICROBIOTA ON HEMATOPOIETIC STEM AND PROGENITOR CELL HOMEOSTASIS

Y Saito, [1,*]L Kovtonyuk[1], H Takizawa[1], M G Manz[1]
[1]Division of Hematology, University Hospital Zurich, Zurich, Switzerland

Background: Most of hematopoietic stem and progenitor cells (HSPCs) reside in the adult hematopoietic bone marrow (BM). However, at any given time, about 1% of HSPCs leave the BM, enter systemic circulation, perambulate peripheral tissues, and some re-home to the BM. It has been suggested that invading pathogens in peripheral tissues induce migration arrest of HSPCs and promote HSPC proliferation and differentiation to ensure local supply of myeloid effector cells. Besides pathogens, commensal microbiota is also known to control quantity and quality of the immune cell pool of peripheral tissues in steady-state. However, it remains unclear if commensal microbiota controls BM HSPC pools and their migration to peripheral tissues.
Aims: We characterize the size and function of HSPCs in the BM, blood, and peripheral organ (spleen) of germ-free (GF) mice in order to address the above issue.
Methods: We use C57BL/6 GF mice that are bread and housed in sterile isolators and recolonized C57BL/6 GF mice are used as controls. Sex- and age-matched mice are used in the studies. The number of colony-forming units in the peripheral blood, BM, and spleen are analyzed after 12-14 days of culture.
Results: We observe that the size as well as the function of HSPCs is similar in the BM of germ-free (GF) and conventional environment control mice. In contrast, lineage$^-$cKit$^+$Sca-1$^+$ (LSK) cells that contain HSPCs are significantly increased in circulation whereas numbers of LSK cells are reduced in the spleen of GF mice compared to controls. Accordingly, the number of immature hematopoietic progenitor cells that generate CFU-GEMM is significantly increased in the peripheral blood and significantly decreased in the spleen whereas it is similar in the BM of GF *versus* control mice.
Summary and Conclusions: These data suggest that commensal microbiota regulate egress from and/or homing of HSPCs to circulation and peripheral tissues in steady-state.

IMMUNOMODULATION EFFECTS OF MESENCHYMAL STEM CELLS IN THE TREATMENT OF REFRACTORY ACUTE GRAFT-*VERSUS*-HOST DISEASE

Q Liu[1,*] K Zhao[1], C Liu[1], M Wu[1], Y Zhang[1], F Huang[1], Z Fan[1], M Dai[1], J Sun[1]
[1]Department of Hematology, Nanfang Hospital, Southern Medical University, Guangzhou, China

Background: Mesenchymal stem cells (MSCs) have been considered as a promising strategy for the prevention and treatment of acute graft-*versus*-host disease (aGVHD), but the mechanism of MSCs ameliorating GVHD is still not fully understood. A few studies suggested that MSCs ameliorated GVHD via protecting and repairing the function of thymus.
Aims: This study explored immunomodulation effects of MSCs in the treatment of refractory aGVHD.
Methods: Twenty refractory aGVHD patients receiving MSCs treatment were enrolled in this study, and twenty grade II to IV aGVHD patients treated without MSCs were matched as non-MSCs group. MSCs were given at a median dose of 1×10^6, cells/kg once weekly until aGVHD got complete response (CR) or MSCs were infused for a total of 8 doses. Lymphocyte subsets of T-cell, B-cell, and NK-cell in peripheral blood were analyzed by flow cytometry before and 30, 60, 90, 180 and 360 days after the MSC infusion in MSC group and the corresponding period in the control group.
Results: A total of the 33 patients who survived more than 30 days after the study treatments were evaluated for the alterations in cellular immune compartment and cGVHD, including 15 cases in MSCs group and 18 in non-MSCs group. In MSCs group, patients had a significantly higher CD4$^+$/CD8$^+$ T-cell ratio at 60, 90 and 180 day after MSCs treatments, which subsequently equalized at 360 day compared with non-MSCs group. The MSC group presented higher percentages of CD4$^+$CD25$^+$ regulatory T cells (Treg) comparing with non-MSCs group, especially at 90 and 180 day, and approached at 360 day. The proportion of CD4$^+$CD45RO$^+$ and CD4$^+$CD45RA$^+$ naïve T-cells in MSC group were also higher than those in non-MSCs group at 60, 90 and 180 day, but not different at 360 day. The proportion of CD19$^+$ and CD16$^+$CD56$^+$ was not detected striking difference between the two groups. Four patients (26.7%) experienced cGVHD in MSCs group, compared with twelve (66.7%) in non-MSCs group (p=0.02).
Summary and Conclusions: In conclusion, our data indicate that MSCs might ameliorate aGVHD and induce longer-lasting immune tolerance by altering cellular immune compartments in peripheral blood. The alteration of the cellular immune compartments is associated with the protecting and repairing role of MSCs to thymus.

P530

ROLE OF STROMAL CELL-MEDIATED NOTCH SIGNALING IN HEMATOLOGICAL MALIGNANCIES

G Bassi[1], P T Kamga[1], A N Kamdje[2], R Stradoni[1], G Malpeli[1], E Amati[1], I Nichele[1], R Carusone[1], J Zanoncello[1], G Pizzolo[1], M Krampera[1,*]
[1]University of Verona, Verona, Italy, [2]University of British Columbia, Vancouver, Canada

Background: Stromal cells are essential components of the bone marrow (BM) microenvironment regulating and supporting the survival of different tumors, including B-cell acute and chronic lymphocytic leukemia (B-ALL and CLL), and acute myeloid leukemia (AML).
Aims: In this study, we investigated the role of Notch signalling in human BM-mesenchymal stromal cell (hBM-MSC)-promoted ALL, CLL and AML survival and chemoresistance.
Results: The block of Notch signalling through γ-secretase inhibitor (GSI) XII reverted the protective effect mediated by co-culture with BM-MSC. The treatment with combinations of anti-Notch neutralizing Abs resulted in the decrease of B-ALL cell survival, either cultured alone or cocultured in presence of BM-MSC from normal donors and B-ALL patients. The inhibition of Notch-3 and -4 or Jagged-1/-2 and DLL-1 resulted in a dramatic increase of apoptotic B-ALL cells by 3 days, similar to what is obtained by blocking all Notch signaling with the GSI XII. The same Notch receptors are involved in CLL survival except for Notch-1 that, in CLL, mediates a synergistic effect with other Notch receptors in inducing the anti-apoptotic phenotype. Some preliminary data showed that Notch system is involved in survival and chemoresistance of acute myeloid leukemia blasts.
Summary and Conclusions: Overall, our findings show that stromal cell-mediated Notch signaling has a role in promoting ALL, CLL and AML survival and resistance to chemotherapy. Therefore, the target of Notch pathway activation may represent a useful strategy to overcome drug resistance and improve the efficacy of conventional treatments.

P531

MUTATIONAL ANALYSIS OF BONE MARROW MESENCHIMAL STROMAL CELLS IN MYELOID MALIGNANCIES

E Fabiani[1,*] G Falconi[1], L Fianchi[1], F Guidi[1], S Bellesi[1], MT Voso[1], G Leone[1], F D'Alò[1]
[1]Università Cattolica del Sacro Cuore, Institute of Haematology, Rome, Italy

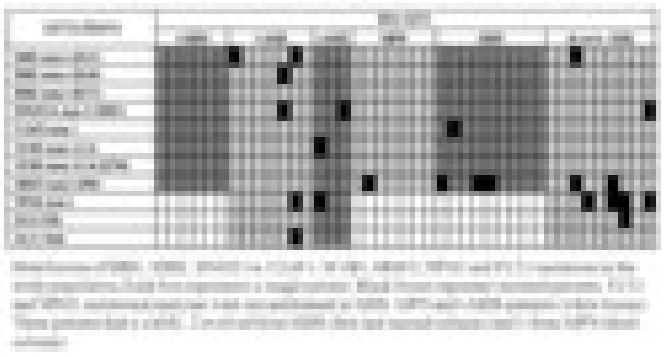
Background: Growing evidence suggest the involvement of the microenvironment in the pathophysiology of hematopoietic malignancies. Mesenchimal stromal cells (MSC) support hematopoiesis through the production and secretion of cytokines, cell-cell interactions and immunomodulating properties. Anomalies of multiple MSC features have been described in MDS and AML. These include significantly reduced growth, proliferative and differentiating capacities, premature replicative senescence, abnormal expression of surface molecules and chemokines, and reduced ability to support hematopoietic stem and progenitor cell growth in long-term culture assays.
Aims: Deep sequencing approaches have identified new recurrent mutations of genes involved in epigenetic and spliceosome machineries in AML and MDS. So far, the prevalence of somatic mutations of epigenetic and spliceosomal

genes in MSC compartment in patients with myeloid malignancies is not known. In this line, we investigated the frequency of recurrent mutations of epigenetic and spliceosomal genes, of FLT3 and NMP1 genes in BM-MNC cells and MSC isolated from 41 patients with myeloid malignancies.

Methods: The study population included 41 patients with myeloid malignancies, 9 *de novo* AML, 9 MDS, 7 MPN, 3 secondary AML (sAML, 2 evolved from MDS, 1 from MPN), and 13 t-MN (7 t-AML and 6 t-MDS). BM-MNCs were isolated from patients at the time of diagnosis. MSCs were expanded using Mesencult medium (Voden) in plastic-adherent cultures up to the second passage. Flow cytometry analysis confirmed the standard MSC phenotype (CD45-, CD73+, CD90+ and CD105+) in more than 99% of MSC population. DNA was extracted from BM-MNC and MSC using QIAamp DNA Mini Kit (Qiagen). The following hotspot mutations were studied on gDNA by Sanger sequencing (Life technologies): IDH1 R132, IDH2 R140 and R172, DNMT3A R882, U2AF1 S34 and R35, SF3B1 exons 13–16, and SRSF2 exon 1. FLT3 mutations (ITD and TKD) were studied by RT-PCR and RFLP RT-PCR, respectively, whereas NPM1 exon 12 mutations were detected by HRM, followed by Sanger sequencing of positive cases, in patients with *de novo* and *therapy-related* AML.

Results: In BM-MNC, FLT3 ITD and FLT3 TKD mutations were found in 2 patients (1 *de novo* AML and 1 t-AML respectively), while NPM1 exon 12 mutations were present in 6 AML (4 *de novo,* 3 COSM158604 and 1 COSM1319219; 1 sAML, COSM158604; 1 t-AML, COSM28937). IDH1 R132 mutations were found in one patient with *de novo* AML (R132C) and in two with t-AML (R132H and R132L). One t-AML patient presented an IDH2 R140Q mutation, while no mutations were detected at the codon R172. Three DNMT3A R882 mutations were found in one *de novo* AML (R882H), one t-AML (R882H) and one sAML post Polycythemia Vera (R882C). One U2AF1 S34Y mutation was found in a MDS, while a SF3B1 K666N mutation was detected in one AML following a primary MDS. Six SRFS2 P95 mutations were found in two *de novo* AML (P95L and P95R), three MDS (P95L, P95H and P95 frameshift mutation) and one MPN (P95H), Table 1. We found no mutations for any of the studied genes in the MSC compartment, both in carriers of mutations in the hematopoietic compartment and in wild-type patients.

Table 1.



Summary and Conclusions: In our cohort of patients, common mutations of genes involved in epigenetic regulation and spliceosome machinery are absent in the mesenchimal compartment of leukemic bone marrows and are restricted only to the malignant hematopoietic clone. Further investigation is required to ascertain the role of methylation and missplicing in the microenvironment dysfunction observed in myeloid malignancies.

P532

ADDITION OF PLERIXAFOR TO G-CSF IMPROVES THE GRAFT CONTENT IN SIDE POPULATION (SP) WITH IMMATURE PHENOTYPE IN PATIENTS THAT FAILED TO RESPOND WELL TO G-CSF ALONE.

F Bijou[1,*] P Brunet de la Grange[2], L Rodriguez[2], A Schmitt[1], D Adiko[3], R Bouzgarrou[2], N Milpied[4], K Bouabdallah[4], A Lascaux[4], B Dazey[2], C Lettelier[2], P Duchez[2], M Vlaski[2], JM Boiron[2], Z Ivanovic[2]

[1]Hematology Oncology, Institut Bergonié, [2]Etablissement Français du Sang, Aquitaine-Limousin, Bordeaux, [3]Hematology Department, Centre Hospitalier de Libourne, Libourne, [4]Hématologie clinique et thérapie cellulaire, Hôpital Haut-Lévêque, Bordeaux, France

Background: Plerixafor the bicyclam compound that inhibits the binding of stromal cell derived factor-1α to its cognate receptor CXCR4 has been used worldwide since its approval. Plerixafor induces rapid release of $CD34^+$ cells into circulation following hematopoietic stem and progenitor cells mobilization (HSPC) and is particularly useful to optimize HSPC mobilization in poor mobilizer patients (PM). Best demonstration of Plerixafor efficacy in terms of collection of cells with great potential to hasten hematological recovery following myelo-suppressive chemotherapy has been shown initially in model of xenotransplantation (Broxmeyer *et al.* J Exp Med 2005 and Hess *et al.* Biol Blood Marrow Transplant 2007). Another convincing example is provided by clinical allogeneic transplantation setting resulting in sustained donor derived hematopoiesis using Plerixafor mobilized HSPC (Devine *et al.* Blood 2008).

Aims: We describe in the present study the phenotype of cells subsets among mobilized HSPC grafts.

Methods: We analyzed apheresis product (AP) derived from graft samples following mobilization of healthy donor (n=1) and patients (n=9). Patients were diagnosed with hematologic malignancies [Myeloma (n=4), Non Hodgkin Lymphoma (n=4), Hodgkin Lymphoma (n=1)]. Patients and donor characteristics are summarized in Table 1. Four patients were mobilized with G-CSF+Plerixafor, among them 2 served as internal control (AP with G-CSF alone on D1 of apheresis and following addition of Plerixafor on Day 2). Two patients and the healthy donor received G-CSF alone while 3 other received Pegylated G-CSF formulation. Phenotypic study of AP was performed by flow cytometry based on CD34, CD38, CD133, CD90 membrane antigens expression and on the proportion of cells with Side Population (SP) activity in order to assess quality of the graft in terms of immature cells content including cells with long term hematopoietic potential (ongoing study).

Results: The percentage of cells with SP phenotype is similar in each arm. However, the phenotypic distribution of these cells seems to be different depending on the patients status [good mobilizer (GM) *versus* PM] and on the type of mobilizing agent used (Table 1). In GM patients, SP cells are mostly present in $CD34^+$, cells population and express immature phenotype ($CD34^+CD38^{low}$, >50%) with parallel expression of CD90 and CD133 markers. In PM patients who required Plerixafor use, SP cells are also present in $CD34^-$ cells fraction (data not shown) and less than 10% of SP cells from the $CD34^+$ fraction display the $CD34^+CD38^{low}$ phenotype (n=2 Pts) comparatively to G-CSF or Pegylated+G-CSF AP counterparts. Interestingly, Plerixafor in one of 2 Pts controls appears to overcome the cells subsets proportion observed with G-CSF alone while leading to increased immature phenotype of the cells present in the grafts (Table 1).

Table 1. This table summarizes donor and patients characteristics. Immature phenotype of $CD34^+$ cells subsets content in graft collected after G-CSF alone, G-GSF+Plerixafor or Pegylated G-CSF injection is detailed.

Summary and Conclusions: The original description of substantial primitive cells subsets with SP phenotype reported by our group brings promising data in the knowledge of functional and phenotypic characterization of G-CSF+Plerixafor mobilized autologous cells in transplantation setting. Thus, this preliminary observation highlights the role of this agent in collection of cells with sustained hematopoiesis potential as suggested in previous clinical study and will probably be confirmed by ongoing more complete evaluation set up in our laboratory.

THE IRON CHELATOR DEFERASIROX AFFECTS REDOX SIGNALING IN HEALTHY HEMATOPOIETIC STEM CELLS

T Tataranni[1], F Agriesti[1], C Mazzoccoli[1], V Ruggieri[1], I Laurenzana[1], F D'Auria[1], F Falzetti[2], M Di Ianni[3], N Capitanio[4], P Musto[5], C Piccoli[6,*]

[1]Laboratory of Pre-Clinical and Translational Research, Centro di Riferimento Oncologico della Basilicata, Rionero in Vulture-PZ, [2]Hematology and Clinical Immunology Section, University of Perugia, Foggia, [3]Department of Internal Medicine and Public Health, University of L'Aquila, L'Aquila, [4]Clinical and Experimental Medicine, University of Foggia, Foggia, [5]Scientific Direction, Centro di Riferimento Oncologico della Basilicata, Rionero in Vulture-PZ, [6]Dept of Clinical and Experimental Medicine, University of Foggia, Foggia, Italy

Background: Hematopoietic stem cells (HSCs) constitute a reservoir of undifferentiated cells that can be committed, upon appropriate stimuli, in the haematic lineages. Although residing in a bone-marrow hypoxic microenvironment (niche) and mainly relying on anaerobic glycolysis, HSCs are endowed with mitochondria. Recently, specific interest has been focused on HSCs mitochondria and on their role as reactive oxygen species (ROS) generators during the early phases of commitment. The iron chelator deferasirox (DFX), but not defer-

oxamine (DFO), both used to treat complications related to transfusional iron overload in myelodisplastic syndrome patients (MDS), is able to induce hematological responses in a consistent percentage of patients but signalling pathways responsible of such a feature are still poorly understood. Consolidated evidences highlight the importance of redox signalling in the homeostasis of fundamental processes in cell adaptive biology and particularly in controlling the balance between self-renewal and differentiation of stem cells. In this setting, reactive species of oxygen (ROS) would act as secondary messengers, modulating the expression of master transcription factors and regulatory proteins leading or (pre)conditioning stem cells towards differentiation.
Aims: In the present study we investigated the effect of DFX and DFO on ROS production in HSCs in order to identify a molecular mechanism explaining the differential effect of iron chelators in rescuing altered hematopoiesis.
Methods: Human HSCs, isolated upon informed consent from peripheral blood of G-CSF-treated healthy donors by immuno-selection against the specific markers CD133 and CD34, were treated with 100 μM DFX or DFO for 24 hours.To completely abrogate ROS production, cells were co-incubated with diphenil iodide (DPI) 100μM, a known inhibitor of the main sources of ROS: the flavo-oxidases of the respiratory chain and the NADPH oxidases. Cell viability was determined by trypan blue staining. ROS levels were analyzed by laser scanning confocal microscopy (LSCM) and flow cytometry after the incubation at 37°C for 15 minutes with the intracellular H_2O_2 specific probe dichlorodihyrofluorescein-diacetate (H_2DCFDA)10μM. Oct4, sox2 and sox17 transcript levels were measured by real time PCR. β-catenin and BMI1 protein levels were assessed by western blotting. Data were presented as mean±s.e.m. and were compared by unpaired Student T-Test; a $p<0.05$ was considered significant.
Results: DFX treatment of HSCs resulted in a significant up-regulation of ROS level whereas no significant change was observed following by DFO treatment and this was observed in HSCs but also in other cell types, thus suggesting a not specific effect on blood cells. This effect seemingly is independent on the DFX iron-chelating property but pertains to additional pharmacological properties that warren further investigation. Moreover, the increase of ROS production in turn led to the activation of oct4, sox2 and sox17 gene expression and the reduction of β-catenin and BMI1 regulatory proteins. These molecular events triggered by DFX were accompanied by an up-regulation of CD71, marker of erythroid progenitors; moreover, an increase of mitochondrial mass, inversely proportional to CD34 expression, was also observed.
Summary and Conclusions: Our data would suggest a novel mechanism by which DFX treatment, through ROS signalling activation, influences key factors involved in self-renewal/differentiation of HSCs. In this scenario, the modulation of ROS, because of their ability to restore the hematopoietic function, could be taken in account as potential further pharmacological target in MDS treatment.

P534

INTERACTIONS BETWEEN MULTIPOTENT MESENCHYMAL STROMAL CELLS AND HEMATOPOIETIC PROGENITOR CELLS ALTER AFTER INTERLEUKIN 1 BETA ADMINISTRATION

A Bigildeev[1,*] E Zezina[2], I Shipounova[1], D Kostyushev[1], N Drize[1]
[1]Lab. Physiology of Hematopoiesis, National Research Hematological Center, [2]Faculty of Biology, Molecular immunology unit, Moscow State University, Moscow, Russian Federation

Background: The stromal microenvironment regulates the maintenance, proliferation and maturation of hematopoietic stem cells (HSCs) and hematopoietic progenitor cells (HPCs). Multipotent mesenchymal stromal cells (MMSCs) have been shown to produce mature stromal cells and maintain HPCs. Based on this property, MMSCs can be used as a model to study the cross-talk between stromal cells and HPCs. The functions of interleukin-1 β (IL-1 β) – proinflammatory cytokine - and its effects on cells of non-hematopoietic origin are poorly understood. It was demonstrated that IL-1 β stimulates growth of the stromal microenvironment *in vivo* and MMSCs *in vitro*.
Aims: The aim of this study was to investigate the effect of IL-1 β on the ability of MMSCs to support HPCs *in vitro*.
Methods: MMSCs were isolated from the bone marrow of 26 donors (13 males and 13 females) ranging in age from 18 to 56 years (median: 32). The samples were collected in the Department of Bone Marrow Transplantation of Hematological Scientific Centre after informed consent and during aspiration of hematopoietic stem cells for allogeneic transplantation. MMSCs were cultivated in standard conditions in α MEM supplemented with 10% fetal bovine serum without or with 4 pg/ml IL-1 β, and the maintenance of HPCs on MMSC layers was estimated using cobblestone area forming cell (CAFC 1-2wk) and long-term culture initiating cell (LTC-IC) assays. The proliferative potential of the MMSCs was assessed by determining the total cell production and clonal efficiency. The relative expression level of various genes in the MMSCs was analyzed using RT[2] Profiler PCR Array (Qiagen) and RQ-PCR.
Results: The total MMSCs production increased 1.3–2 fold after addition of IL-1 β to the culture medium. The clonal efficiency was increased (1.5–2 fold) in populations of MMSCs cultivated with IL-1 β that could be related to the increased frequency of proliferating cells in the MMSC population. Treatment of MMSCs with IL-1 β resulted in enhanced ability of these cells to maintain HPCs, as detected using CAFC and LTC-IC assays. The frequency of CAFC 1-2wk increased in 1.57±0.13 fold (p=0.0004) and LTC-IC in 1.34±0.35 (insignificantly). Gene expression analysis in MMSCs treated with IL-1 β revealed that the relative expression level of ICAM1 was up-regulated (3.08±0.84, p=0.01), while ANXA2 (0.72±0.05, p=0.01) and JAG1 (0.74±0.4, p=0.03) were down-regulated. No differences were detected in the expression of ANG1, VCAM1, and PTHR, which play roles in the adhesion of HSCs. The expression level examination of chemokines and growth factors demonstrated that SDF1 was down-regulated (0.75±0.1, p=0.05) and FGF2 was up-regulated, although not statistically significant (1.3±0.2, p=0.47), but no differences were detected in the expression of thrombopoietin (THPO) or insulin-like growth-factor 1 (IGF).
Summary and Conclusions: The results revealed the participation of IL-1 β in the regulation of hematopoietic stromal niches. IL-1 β enchances the ability of MMSCs to maintain hematopoietic progenitors *in vitro*, and this effect could be explained by increased proliferative potential and cumulative cell production as well as by modulation of the expression of genes participating in the interaction between HPCs and the stromal microenvironment, *e.g.*, adhesion molecules (ICAM1) and growth factors (FGF2 and SDF1).

MODIFIED ACTRIIB-FC FUSION PROTEIN (ACE-536) AMELIORATES ANEMIA IN A MODEL OF SICKLE CELL DISEASE

RN Suragani, [1,*]R Li[1], R Castonguay[2], RS Pearsall[1], R Kumar[3]
[1]Pre clinical Pharmacology, [2]Molecular Biology and Protein Biochemistry, [3]Biology, Acceleron Pharma Inc, Cambridge, United States

Background: Sickle cell disease (SCD) is a hereditary disorder caused by a single point mutation in the β-globin gene resulting in the production of sickle hemoglobin variant (HbSS). In the deoxygenated state, HbS is labile and can undergo auto-oxidation to form hemichromes and polymerize to generate rigid and misshaped erythrocytes. The combination of hemichrome formation and HbS polymerization leads to membrane damage that alters membrane structure and contributes to the very short half-life of sickle erythrocytes. The membrane damage manifest in a redistribution of membrane lipids leading to expression of phosphatidylserine on the outer leaflet of the erythrocyte membrane. Externalized phosphatidylserine promotes adhesion to both macrophages and activated endothelial cells, contributing to both reduced HbS cell lifespan and vascular occlusion. In an attempt to correct the anemia mediated by the short half-life of the red cells there is a tremendous increase in eryrthrocytosis resulting in an increase in peripheral reticulocytes from about 2% to 50% of total red cells.
Aims: An effective treatment for SCD would decrease the anemia and limit the generation of a hypoxic environment thereby reducing the generation of sickled erythrocytes. Additionally, reducing the propensity of the erythrocyte to adhere to the vasculature and macrophages would be expected to reduce the obstruction of blood vessels, ischemic events and pain crises.
Previously, we have shown that RAP-536 (murine ortholog of ACE-536) increases the production of red cells in both normal and thalassemic mice. Importantly, in β-thalassemia mice RAP-536 has been shown to reduce hemichromes on erythrocyte membranes, decrease reactive oxygen species, reduce hemolysis and improve red cell half-life.
In the present study, we extended the evaluation of RAP-536 in the murine model of sickle cell disease (β^S/β^S).
Methods: SCD mice were dosed subcutaneously with RAP-536 (1 mg/kg, twice weekly) or TBS vehicle (VEH) control (N=5/group). Non-symptomatic compound heterozygote (β/β^S) littermates were dosed similarly (N=5/group) and used as controls.
Results: At study baseline, SCD mice had reduced RBC number (-28%, P<0.01) and hemoglobin (-14.5%, P<0.05) and increased reticulocytes (+50%, P<0.001) compared to compound heterozygote mice. Following one month of treatment, RAP-536 significantly increased RBC number (+15.2%, p<0.01), hemoglobin (+9.28%, p<0.05) compared to VEH treatment in SCD mice. Importantly the increased RBC occurred while reticulocytes (-13.5%, p<0.05) decreased, which is potentially consistent with an increase in red cell half-life. RAP-536 treatment of SCD mice for 6-weeks resulted in a substantial decrease in phosphatidylserine (PS) exposure in peripheral blood cells as determined by scramblase enzyme assay (-14%, p=0.08) and annexin-V assay (-18.75%, N.S) suggesting a trend towards improved membrane phospholipid asymmetry compared to vehicle treatment.
Summary and Conclusions: In summary, RAP-536 reduces the anemia and red blood cell pathology in a murine model of SCD. ACE-536 is currently being tested in Phase 2 clinical trials in MDS and β-thalassemia patients, and merits evaluation as a therapy for SCD.

P536

MACROPHAGE MIGRATION INHIBITORY FACTOR INHIBITS OVEREXPANSION OF IMMATURE ERYTHROID CELLS IN THE SPLEEN DURING CHRONIC PSYCHOLOGICAL STRESS

M Budeč[1,*] S Vignjevic[1], D Markovic[1], O Mitrovic[1], S Mojsilovic[1], S Stosic Grujicic[2], V Cokic[1], G Jovcic[1]
[1]Institute for Medical Research, University of Belgrade, [2]Institute for Biological Research "Siniša Stanković", University of Belgrade, Belgrade, Serbia,, Belgrade, Serbia

Background: Psychological stress is a part of modern style of life and stress response can affect multiple organs. Recently, we have reported that chronic psychological stress stimulates extramedullary erythropoiesis. Because inappropriate activation of stress erythropoiesis may predispose to leukemia transformation, the balance between stimulatory and inhibitory regulators of this process is critical at any time. Considering that macrophage migration inhibitory factor (MIF) is secreted in response to stress as well that this cytokine inhibits erythroid differentiation, we assumed that MIF has a role in the control of stress-induced erythropoiesis.
Aims: This study was undertaken to determine whether MIF is involved in the regulation of erythropoiesis during chronic psychological stress using MIF-knockout (MIF-KO) mouse model.
Methods: Adult male C57BL/6 wild type (WT) and MIF-KO mice were subjected to 2 h daily restraint stress for 7 or 14 consecutive days. The number of spleen erythroid progenitors *burst forming units-erythroid (*BFU-E) and colony-forming unit-erythroid (CFU-E) was determined using colony assays whereas analysis of CD71/Ter119 profile of spleen erythroid progenitors was performed by flow cytometry. In WT mice, the spleen expression of MIF was assessed by Western blot and immunohistochemistry.
Results: Chronic restraint stress significantly increased the number of BFU-E and CFU-E cells in the spleen of WT mice. The effect of stress on CFU-E- derived colonies was more prominent in MIF-KO mice suggesting inhibitory role of MIF in these progenitors. Furthermore, analysis of erythroid precursors revealed that both 7 and 14 days of repeated stress elicited a marked increase in the percentage of CD71+Ter119- and CD71+Ter119+ cells, while 14 days of restraint in addition increased the percentage of CD71-Ter119+ cells in WT animals. However, following 14 days of stress exposure, MIF-KO mice demonstrated a significant increase in the percentage of CD71+Ter119+ cells accompanied with a decrease in the percentage of CD71-Ter119+ cells. In addition, according to forward scatter and CD71 expression, total Ter119+ cells were divided into three subpopulations: more immature (E1), less immature (E2) and mature (E3) cells. The results showed that 7 and 14 days of restraint stress increased the percentage of E1 and E2 in WT animals. The same, but significantly profound effect of stress on E1 and E2 cells was observed in MIF-KO mice, with decreased percentage of E3 following 14 days of stress. To further confirm a role of MIF in regulation of stress-induced erythropoiesis, we evaluated expression of this cytokine in the spleen of WT mice. Western blot revealed enhanced MIF expression in the animals restrained for 7 or 14 days. Also, numerous MIF-immunoreactive cells were detected within the red pulp of stressed mice.
Summary and Conclusions: Taken together, obtained results demonstrate for the first time that MIF functions as a negative regulator of extramedullary erythropoieis induced by chronic psychological stress. These findings are important in a view of the fact that chronic psychological stress may be involved in the pathogenesis of hematological malignancies.

P537

PATHOPHYSIOLOGY OF ANEMIA IN THE VK*MYC MOUSE MODEL OF MULTIPLE MYELOMA

A Campanella[1,*] J Bordini[1], S Bertilaccio[2], I Fermo[3], M Ponzoni[4], C Camaschella[1,5]
[1]Division of Genetics and Cell Biology, [2]Division of Molecular Oncology, [3]Division of Immunology, Transplantation and Infectious Diseases, [4]Pathology Unit, San Raffaele Scientific Institute, [5]Vita-Salute San Raffaele University, Milan, Italy

Background: Multiple myeloma (MM) is a disorder characterized by proliferation of plasma cells (PC) in the bone marrow (BM) and by overproduction of monoclonal immunoglobulin detectable as a serum spike (M-spike). Anemia is a common complication of MM and the underlying pathophysiological mechanisms are not completely elucidated. Previous studies suggested both a direct cytotoxic effect of MM PC that leads to apoptosis of erythroid precursors and the functional impairment of their migratory and proliferation capacity induced by bone marrow microenvironment perturbation. Other studies in patients strengthened the importance of inflammatory cytokines that, released by MM PC and monocytes-macrophages, promote the production of the liver hormone hepcidin. Hepcidin targets and degrades the iron exporter ferroportin (Fpn), favoring iron retention in macrophages and thereby iron-restricted anemia, as occurs in all forms of anemia of chronic inflammatory diseases.
Aims: To address the pathophysiology of anemia in the Vk*myc mouse, which spontaneously develops a myeloma-like disease (Chesi M *et al.* 2008).
Methods: We followed disease progression by evaluating the M-spike incidence and size from 35 to 85 weeks of age and by BM histological examination. We measured the hematological and iron parameters, serum erythropoietin and liver hepcidin expression. In BM and spleen we evaluated cellular sub-populations by flow cytometry using different markers combination: CD138 and B220 for B cells, CD11b and F4/80 for monocyte/macrophages, CD44, TER119 and CD71 for erythroid precursors. We determined the iron phenotype by measuring the iron importer transferrin receptor (CD71) and the iron exporter Fpn.
Results: Vk*myc mice slowly develop the disease with M-spike evident by 35 weeks of age. Both the percentage of affected mice and the size of the monoclonal component progress overtime. At 80 weeks, disease indexes mean values are: M-spike size 15%; BM PC expansion 5%, as evaluated by flow cytometry (CD138+B220-) and 25%, as evaluated by histology and no significant PC increase in the spleen. MM PC show increased expression of CD71 and no reduction of Fpn as compared to non malignant PC. Starting from 50 weeks Vk*myc mice show reduction of hemoglobin (Hgb) levels and of red blood cells (RBC) count as compared with wt counterparts. With exception of few cases, anemia of Vk*myc is mild. Both Hgb levels and RBC count indirectly correlate with M spike and PC expansion in BM. Both mild and severe anemias are not the consequence of defective erythropoietin concentration or of abnormal iron metabolism. Hepcidin levels are not statistically different between wt and Vk*myc animals and are not correlated with Hgb or M-spike. With exception of pro-erythroblasts, all the erythroid precursors are statistically reduced in Vk*myc BM with respect of wt counterparts. In parallel the same population is increased in the spleen.
Summary and Conclusions: Vk*myc model is characterized by a limited MM cells expansion and mild anemia. In this condition, which likely reproduces the

initial stages of the human disease, we excluded a role of inflammation and hepcidin in the pathogenesis of anemia. The reduction of BM erythroid precursors may explain reduced Hgb levels and RBC count, while spleen erythropoiesis likely mitigates anemia. Loss of erythroid precursors could result from BM microenvironment perturbation, which is under investigation. Iron sequestration by MM PC high CD71 might contribute to erythropoiesis restriction.

THE SPECTRUM OF ADULT'S PARVOVIRUS B19 INFECTION IN HOSPITAL ACCORDING TO THE CLINICAL BACKGROUND: REPORT OF A SINGLE CENTER EXPERIENCE AND PROPOSALS FOR THE CLINICAL PRACTICE.

A Wolfromm[1,*] C Rodriguez[2], M Michel[3], A Habibi[4], V Audard[5], E Benayoun[1], O Rogier[2], D Challine[2], O Chosidow[6], C Haioun[7], C Pautas[8], X Chevalier[9], JD Lelièvre[10], M Imbert[1], JM Pawlotsky[2], O Wagner-Ballon[1]
[1]Département d'Hématologie et d'Immunologie Biologiques, [2]Département de Bactériologie-Virologie, [3]Service de Médecine interne, [4]Unité des Maladies Génétiques du Globule Rouge, [5]Service de Néphrologie, [6]Service de Dermatologie, [7]Unité fonctionnelle d'Hématologie lymphoïde, [8]Service d'Hématologie clinique, [9]Service de Rhumatologie, [10]Service d'Immunologie Clinique, Hôpital Henri Mondor, APHP, Créteil, France

Background: Parvovirus B19 (PVB19) infection which is usually asymptomatic in healthy adults can lead to a wide spectrum of clinical and biological manifestations depending mainly on the underlying status of the patient, such as chronic hereditary hemolytic anemia or immunodeficiency.
Aims: So far, there is no gold standard for the diagnosis of PVB19 infection and physicians use indifferently either sero-diagnosis, molecular methods or both.
Methods: All cases of PVB19 infection, based indifferently on a positive serological test (positive IgM) and/or by a positive PCR in the peripheral blood and/or the bone marrow, registered from September 2007 to September 2013 in our tertiary referral university hospital were included. When available, frozen stored sera were retrospectively tested to allow complementary PVB19 serology or PCR according to the initial test performed. Demographic characteristics, clinical data, complete blood count (CBC) and reticulocytes count at the time of PVB19 infection diagnosis were collected retrospectively for each patient. All bone marrow smears were retrospectively examined blindly by an expert in order to assess the presence or not of pure red cell aplasia (PRCA) and especially the presence of typical giant pronormoblasts.
Results: Eighty-three PVB19-infected patients at least on one positive criteria, namely IgM antibodies, positive blood PCR and/or positive bone marrow PCR, were included. These patients were dispatched homogeneously in three equilibrated groups statistically independent: 29 patients had no underlying predisposing condition, 25 patients had an underlying hereditary hemolytic anemia (mainly sickle cell disease) and 29 were immunocompromised patients (solid-organ transplant or hematopoietic stem cell transplant, treatment with immunosuppressors, HIV positive patients…). Classical PVB19-related symptoms, namely arthromyalgia and non-specific cutaneous manifestations (macular erythema and/or edema), were less frequent in immunocompromised patients than in patients with no underlying predisposition condition ($p<0.01$) but couldn't be assessed in patients with an underlying hereditary hemolytic anemia due to some confounding factors. All the patients with chronic hemolysis or immunodeficiency displayed anemia compared to only 41.4% of patients with no underlying predisposing condition. As expected, the median reticulocyte count was low (18.5×10^9/l) yet with a large range (0-323). Bicytopenias were displayed by patients belonging to all the three groups and pancytopenias were noticed mainly in the immunocompromised patient group. The classical PRCA was observed in only 9 out of the 28 bone marrow smears that were performed. Interestingly, the presumably pathognomonic feature of PRCA, namely red inclusion in the nucleus of giant pronormoblasts, was found in a single case. Positive IgM were found in 93% of patients with no underlying predisposing condition whereas only 58% of blood PCR were positive in this subgroup. Conversely, both serology and PCR were positive in almost every patient with hereditary hemolytic anemia. In the group of immunocompromised patients, bone marrow PCR analysis, mostly performed by physicians, allowed a positive diagnosis in 91% of cases.
Summary and Conclusions: We report here for the very first time the various characteristics of documented PVB19 infection cases observed in 3 distinct adult populations. The extensive analysis of hematological and clinical features at time of PVB19 infection matched with the available virological parameters lead us to propose some recommendations for the diagnosis of the PVB19 infection according to the clinical background that may be helpful to hematologists in their clinical practice.

CONTINUOUS ERYTHROPOIETIC ACTIVITY OF EPOETIN BETA PEGOL IN A GENE-MODIFIED MOUSE MODEL FOR ERYTHROPOIETIN-DEFICIENCY ANAEMIA

N Suzuki[1,*] Y Sasaki[2], S Yamazaki[1], K Fujita[1], K Kato[1], M Kurasawa[2], K Yorozu[2], Y Shimonaka[2], M Yamamoto[3]
[1]Division of Interdisciplinary Medical Science, Tohoku University Graduate School of Medicine, Sendai, [2]Product Research Department, Chugai Pharmaceutical Co., Ltd., Kamakura, [3]Department of Medical Biochemistry, Tohoku University Graduate School of Medicine, Sendai, Japan

Background: The erythroid growth factor erythropoietin (EPO) is secreted from renal EPO-producing cells (REPs) locating in peritubular interstitial spaces of kidneys under hypoxic/anaemic conditions. Therefore, damage in REPs by kidney diseases often causes aneamia. To treat the renal anaemia, erythropoiesis-stimulating agents (ESAs) have been widely used since more than 20 years ago. Recently, long-acting ESAs were developed in order to avoid frequent administration of ESAs. Epoetin β pegol (C.E.R.A.) is a methoxy polyethylene glycol-conjugated recombinant EPO (rHuEPO), and possesses the longest half-life among currently available ESAs.
Aims: /Methods: The continuous effects of C.E.R.A. on *in vivo* erythropoiesis were investigated by using inherited super-anaemic mice (ISAM), which exhibit adult-onset chronic anaemia due to insufficient expression of the *EPO* gene in REPs.
Results: ISAM showed the phenotype of pure red-cell aplasia associated with high concentrations of iron in the liver, spleen and serum. The iron concentrations were decreased to the normal range 3 days after a single subcutaneous injection of C.E.R.A. or rHuEPO (3 μg/kg for each). As well, elevated concentrations of serum hepcidin, which negatively regulates iron utilization for haemoglobin synthesis, were reduced greater than 75%. Haemoglobin levels in the C.E.R.A.-injected group reached around 9 g/dL at 7 days after administration, and the improved level was maintained at least a week. In contrast, the haemoglobin concentration of rHuEPO group remained low (approximately 3 g/dL). Interestingly, the cardiac hypertrophy, which was caused by the chronic anaemia of ISAM, was significantly improved by C.E.R.A. administration along with correction of anaemia.
Summary and Conclusions: The erythropoietic activity of ESAs is enhanced-by improved retentivity in blood. Additionally we propose that ISAM provide a useful model system for assessment of ESAs.

P540

CATION LEAK ANALYSIS OF ABCB6 MUTANTS IN FAMILIAL PSEUDOHYPERKALEMIA

I Andolfo[1,*] C Auriemma[1], F Vallefuoco[1], R Russo[1], C Langella[1], S L Alper[2], L De Franceschi[3], A Iolascon[1]
[1]Dept. of Molecular Medicine and Medical Biotechnologies, University Federico II of Naples, Ceinge, biotecnologie avanzate, Naples, [2]Division of Nephrology, Beth Israel Deaconess Medical Center, Department of Medicine, Harvard Medical School, Boston, MA 02215, USA, Boston, [3]Department of Medicine, University of Verona, Verona, Italy

Background: Isolated Familial Pseudohyperkalemia (FP) is a dominant red cell trait characterized by cold-induced slow 'passive leak' of red cell K+ into plasma, first described in a large Scottish family from Edinburgh (Stewart GW, *et al.*, 1979). Although in freshly obtained blood samples plasma [K+] was normal, it was increased when measured in blood stored at or below room temperature. This trait was unaccompanied by clinical symptoms or signs except for mild abnormalities of red cell shape. FP Lille was later described in a large Flemish kindred with morphologically normal red cells (Dagher G, *et al.*, 1989; Vantyghem MC, *et al.*, 1991). In this family, red cell K+ efflux measured in the presence of ouabain and bumetanide was normal at 37°C, but greatly increased at 22°C and 9°C. FP Lille mapped to 2q35-q36 (Carella M, *et al.*, 2004). Subsequently, FP Chiswick and FP Falkirk cases with remarkable increased MCV were reported (Haines PG, *et al.*, 2001).
Functional gene mapping and sequencing analysis of the candidate genes within the 2q35-q36 critical interval in three multigenerational FP families with 20 affected individuals identified two novel heterozygous missense mutations in the ABCB6 gene that cosegregated with disease phenotype (Andolfo I. *et al.*, 2013). The two genomic substitutions altered two adjacent nucleotides within codon 375 of ABCB6, a porphyrin transporter that in erythrocyte membranes bears the Langereis blood group antigen system (Krishnamurthy PC, *et al.*, 2006; Helias V, *et al.*, 2012).
Aims: We want to understand the pathogenetic mechanism of cation leak in FP by functional studies of ionic flux of ABCB6 mutants.
Methods: cDNAs encoding full-length wildtype ABCB6 were cloned in pcDNA3.1 vector. The point mutations c.1123C>T (p.R375Q) and c.1123C>T (p.R375W) were introduced into pcDNA3.1-ABCB6 by site-directed mutagenesis. pcDNA3.1-ABCB6-WT, pcDNA3.1-ABCB6-R375Q and pcDNA3.1-ABCB6-R375W were transfected into HEK-293 cells for 72h. The cells were maintained at 37°C and 30°C to evaluate the effects of the temperature. HEK-293 cells contents of Na+ and K+, at 72 hours after transfection, were determined by atomic absorption spectrometry as previously described (De Franceschi L. *et al.*, 2007). Furthermore, 72 hours after transfection, the cells were incubated in a medium containing Rubidium, oubain and bumetanide at 37°C and 30°C. Rubidium was determined in cell lysate and K+ was determined in the supernatant by atomic absorption spectrometry.
Results: ABCB6 mutants R375Q and R375W, expressed in human cell line

HEK-293, lead to less net accumulation of Na+, and to greater loss of cell K+ than produced by overexpression of wildtype ABCB6. The ionic flux alterations are more evident at 30°C. In particular, the mutation R375W shows more significant K+ content alterations in respect with mutation R375Q.
Summary and Conclusions: Here, we performed the first functional study to understand the pathogenetic mechanism of FP. Our findings demonstrate that missense mutations in ABCB6 lead to cellular K+ efflux as exhibited in erythroid cells of patients with FP. Moreover, this method will be used as tool to demonstrate the causative role of variations found in FP patients.

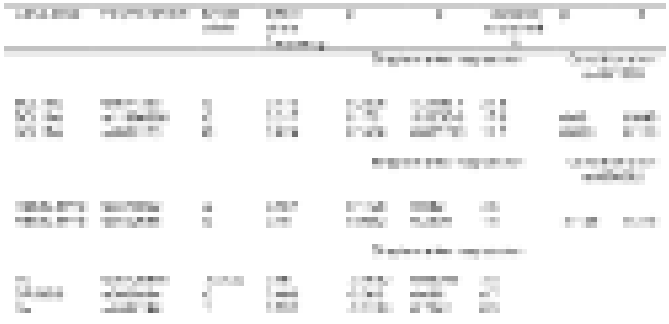
P541

GENETIC MARKERS AND FETAL HEMOGLOBIN (HBF) PRODUCTION: ASSOCIATION STUDY IN DELTABETA THALASSEMIA

JM Nieto[1,*] F De La Fuente Gonzalo[1], L Vinuesa[1], F A Gonzalez[1], A Villegas[1], J Diaz-Mediavilla[1], P Ropero[1]
[1]Hematology, Hospital Clínico San Carlos, Madrid, Spain

Background: HbF is a strong and heritable modifier of disease severity for individuals with β-like thalassemias. Several loci have been described carrying polymorphisms that modulate HbF levels. BCL11A seems to be the most important locus outside the β-globin cluster. It codifies for an HbF silencer that binds to several locations in the β-globin cluster, but most of the studies dealing with BCL11A function focus on a binding region located 1Kb upstream of the δ gene. It has been previously described that HbF production in carriers of the *(δβ)º Spanish* deletion is almost entirely done by the (δβ)º chromosome. Since this deletion eliminates the former BCL11A binding region, an HbF association study in these carriers could be very informative, in order to better understand the role of BCL11A and other HbF modifiers.
Aims: To characterize associations with fetal hemoglobin levels at the BCL11A, HBS1L-MYB, CSNK2A1 and β-globin loci, in a population of 111 *(δβ)º Spanish* deletion carriers.
Methods: We recruited DNA and hematological data from 111 carriers (>5 years old) of the *(δβ)º spanish* deletion. Six of them showed different α^+ thalassemic mutations. We genotyped polymorphisms at the BCL11A, HBS1L-MYB, CSNK2A1, OR51B6, γ and ψβ loci. All DNA genotyping was performed using TaqMan Assays, except for the γ promoter variants which were detected by sequencing (-158 xmnI at γ^G and -AGCA deletion at γ^A). 8 out of 14 polymorphisms passed all the quality controls and were analyzed in a linear regression framework. HbF (g/dl) was $\log_{10}$ transformed and used as a quantitative trait. Statistical analyses were carried out with PLINK (single marker regression, conditional analysis and LD calculations) and SPSS (stepwise linear regression). All analysis tested additive inheritance models and included α-globin locus status as covariate.
Results: Results for single marker regression are shown in Table 1. The most significant SNP at the BCL11A locus was rs4671393 (p=4.219E-7). In the HBS1L-MYB region, only rs9376092 was associated with HbF levels (p=0.049). Surprisingly, none of the markers in the HBB locus showed a significant statistical association, but the AGCA deletion was close to reaching a significant p-value. In addition, conditional analysis on rs4671393 revealed a marginal independent association of other SNP at the BCL11A locus (rs11886868). We performed a stepwise analysis to further understand if rs11886868 and the AGCA deletion had a significant and independent effect on HbF levels when multiple loci are taken into account. This model explained 31.5% of the phenotypic variation in HbF levels with just 2 SNPs (20.7% by rs4671393 and 10.8% by rs9376092). None of the "borderline" alleles (rs11886868 and the AGCA deletion) reach enough significance to be included in the final model.

Table 1. Single marker regression and conditional analysis.



Summary and Conclusions: This is the first HbF association study at different loci performed in δβ thalassemia patients. All cases have the same thalassemic determinant, avoiding possible confounding factors (like influence of the type of mutation on HbF levels).
In our cases, most of the HbF is produced by the chromosome carrying the deletion. This may help to explain why we did not find an association between HbF and -158 xmnI. An observable effect could exist just if this SNP is located in the chromosome that produces HbF, but currently we do not have any way to detect if -158 xmnI is in CIS with the *(δβ)º Spanish* deletion.
Finally, our results suggest that, in our patients, BCL11A should exert most of its effect on the β-globin locus through a different binding point that the one previously mentioned (1Kb upstream of the δ gene).

P542

MITOGEN-STIMULATED DIRECT ANTIGLOBULIN TEST IN PATIENTS WITH HEREDITARY SPHEROCYTOSIS

A Zaninoni[1,*] C Vercellati[1], F G Inperiali[1], A P Marcello[1], E Fermo[1], P Bianchi[1], B Fattizzo[1], A Zanella[1], W Barcellini[1]
[1]U.O. Oncoematologia, Fondazione IRCCS Ca' Granda Ospedale Maggiore Policlinico, Milano, Italy

Background: Hereditary spherocytosis (HS) is an hemolytic anemia due to defects in the red cell membrane proteins (band 3, spectrin, ankyrin, or protein 4.2) that cause loss of membrane surface area, reduced deformability, trapping and destruction of RBCs in the spleen. Naturally occurring autoantibodies (NAbs) against band 3 are thought to be involved in the removal of senescent and damaged erythrocytes. Mitogen-stimulated direct antiglobulin test (MS-DAT) is a functional and quantitative method for the detection of anti-RBC antibodies in mitogen-stimulated whole blood cultures, found positive in some DAT-negative autoimmune Hemolytic anemia (AIHA), and in a fraction (about 40-50%) of patients with chronic lymphocytic leukemia and myelofibrosis.
Aims: To investigate the occurrence of anti-erythrocyte antibodies by MS-DAT in HS, and to relate their presence with the degree of hemolysis and with the type of membrane defect.
Methods: Ninety-one consecutive HS patients (51 male and 40 female, median age 38 yrs, range 2-87 yrs) were investigated; 13 patients had been splenectomized at the moment of the study. Diagnosis was made on the basis of clinical history, physical examination and the results of laboratory tests: complete blood counts, blood smear examination, reticulocyte counts, hemolytic parameters, eosin-5′-maleimide (EMA)-binding test, and red blood cell osmotic fragility tests. All patients underwent SDS-PAGE analysis of the red cell membrane proteins. MS-DAT was performed, by competitive solid phase ELISA, stimulating whole blood with mitogens (PHA, PMA and PWM). Two-hundred and ten healthy blood donors were studied as control group and 43 patients with AIHA were included as positive controls for MS-DAT.
Results: We found that 61% of HS cases were MS-DAT positive: 29 (53%) with band 3 deficiency, 17 (30%) spectrin deficiency, and 9 (17%) with no detectable defect (Figure 1, open symbols for splenectomized cases). The amount of RBC-bound IgG was clearly greater in HS compared to controls (P<0.0001), albeit lower than that observed in AIHA patients (P<0.0001); there was no difference in IgG bound among various HS groups. Since almost all (42/43) AIHA patients showed RBC-bound IgG values higher than 250 ng/mL, 26 HS patients (13 band 3 and 8 spectrin deficiency, and 5 no detectable defect) with values above this threshold were considered separately in the analysis. These cases displayed a significantly higher number of spherocytes (11%) than patients with RBC bound-IgG 150-250 (6.5%, P=0.04) and MS-DAT negative cases (5%, P<0.01); they showed also a more evident hemolytic pattern and a significantly greater number of reticulocytes compared with MS-DAT negative cases ($230x10^3$/mmc *vs* $125x10^3$/mmc, median value, P<0.01).

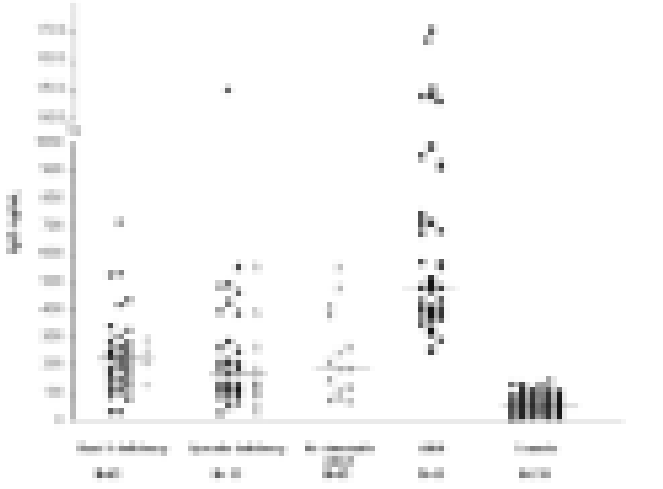


Figure 1.

Summary and Conclusions: These findings suggest that in 60% of patients with HS, mitogen-stimulation is able to induce the production of auto-antibodies which might be responsible for immune-mediated destruction of erythro-

cytes, independently of the membrane structural alteration. These auto-antibodies may be naturally occurring anti-band 3 antibodies, as suggested by their low concentration compared with that found in AIHA, and their pathogenic role in enhancing the hemolytic process in HS.

P543

TWO NOVEL MISSENSE MUTATIONS IN PIEZO1 IN SIX PATIENTS WITH DEHYDRATED HEREDITARY STOMATOCYTOSIS

P Koralkova[1,2,*] J Wegman[3], W Rensma[4], F J Smiers[5], R van Wijk[1]
[1]Department of Clinical Chemistry and Haematology, University Medical Center Utrecht, Utrecht, Netherlands, [2]Department of Biology, Faculty of Medicine and Dentistry, Palacky University, Olomouc, Czech Republic, [3]Department of Hematology, Deventer Ziekenhuis, Deventer, [4]Department of Internal Medicine, St. Elisabeth Hospital, Tilburg, [5]Department of Pediatric Hematology Oncology, Leiden University Medical Center, Leiden, Netherlands

Background: Hereditary stomatocytosis is a rare cause of hereditary hemolytic anemia. It concerns a heterogeneous group of disorders characterized by altered cellular hydration state. Dehydrated hereditary stomatocytosis (DHSt), also known as hereditary xerocytosis, is among this group of so called channelopathies of the red blood cells. It is an autosomal dominant disorder and recently mutations in *PIEZO1* have been linked to this disease. *PIEZO1* encodes a mechanosensitive ion channel protein. As result of mutation DHSt red blood cells exhibit impaired potassium and sodium balance leading to their dehydration. DHSt is characterized by mild to moderate hemolytic anemia and may present with pseudohyperkalemia and perinatal edema.
Aims: We performed DNA sequence analysis of *PIEZO1* in six DHSt patients from three unrelated families. The diagnosis DHSt was established using osmotic gradient ektacytometry by Laser-assisted Optical Rotational Cell Analyzer (LoRRca, Mechatronics, Hoorn, The Netherlands) showing a characteristic left shift of the curve.

Results: DNA analysis revealed four different mutations in *PIEZO1*, two of which were novel (Table 1, novel mutations in bold).

Table 1. *PIEZO1* genotypes of the six DHSt patients.

	Family 1			Family 2		Family 3
PIEZ01	**Patient 1**	**Patient 2**	**Patient 3**	**Patient 4**	**Patient 5**	**Patient 6**
Allele 1	c.6262C>G p.Arg2088Gly	c.6262C>G p.Arg2088Gly	c.6262C>G p.Arg2088Gly	c.1276C>T p.Cys426Arg	c.1276C>T p.Cys426Arg	c.7367G>A p.Arg2456His
Allele 2	normal	c.6495-6508delAGA p.2166-2169delLysl	normal	normal	normal	norma

The two novel mutations c.6262C>G and c.1276C>T both segregated with disease in the respective families. Furthermore, both Arg2088 and Cys426 concern residues that are highly conserved in PIEZO1 (http://genome.ucsc.edu/). Moreover, *in silico* analysis by Polyphen and SIFT predict that substitution with, respectively, glycine and arginine is not tolerated. Interestingly, the p.(Cys426Arg) mutation is the most N-terminal mutation identified so far in PIEZO1.
In addition to the p.Arg2088Gly mutation, a second mutation was identified in patient 2 from family 1. This mutation predicts the deletion of one out of four lysine residues between amino acids 2166-2169 and was previously reported in association with DHSt. The mutation was inherited from the patient's mother who was completely asymptomatic and hematologically normal. Notably, the clinical phenotype of patient 1 was more severe when compared to that of his brother (patient 3) and father (patient 1).
Summary and Conclusions: Molecular characterization of six DHSt patients from three unrelated families revealed four mutations in *PIEZO1*. Two of these mutations have not been previously reported: p.(Arg2088Gly) and p.(Cys426Arg). Our findings further establish the correlation between mutations in PIEZO1 and DHSt, a rare channel disorder of the red blood cell.

P544

THE REDUCTION OF PEROXIREDOXINS ACTIVITY ARE CORELATED WITH THE INCREASE OF REACTIVE OXYGEN SPECIES (ROS) AND CELL HEMOLYSIS OBSERVED IN PATIENTS WITH HEMOLITIC ANEMIAS

KS Romanello[1], K Kirschner Lopes[1], MAC Bezerra[2], BLD Hatzlhofer[2], IDF Domingos[2], A Araujo[3], MAD Oliveira[4], LES Netto[5], FF Costa[6], I Malavazi[1], AFD Cunha[1,*]
[1]Departamento de Genética e Evolução, Universidade Federal de São Carlos, São Carlos, [2]Universidade Federal de Pernambuco, [3]Hemocentro de Pernambuco, Recife, [4]UNESP São Vicente, São Vicente, [5]USP, São Paulo, [6]UNICAMP, Campinas, Brazil

Background: Oxidative stress modulation is tightly related with the physiopathology of various hematologic diseases, especially with hemolytic anemias, such as sickle cell disease (SS), glucose 6-phosphate dehydrogenase (G6PD) deficiency and β thalassemia. In these diseases, the cellular environment is extremely pro-oxidant, which results in oxidative damages and consequently in cell hemolysis that promotes the formation of more reactive oxygen species in other cells. In this context, the efficiency of the cellular anti-oxidant system is vitally important. Among the enzyme able to decompose peroxides (Catalase, Glutathione and Peroxiredoxins), the Peroxiredoxins (PRDX) draw attention for their abundance and great reactivity with their substrates. In the red blood cells, the PRDX2 is the third most abundant protein and probably one of the main protectants of the cell.
Aims: This study evaluated the ROS levels and the gene and protein expression of Peroxiredoxins in reticulocytes and erythrocytes in patients with hemoglobin SC disease, sickle cell disease, β thalassemia and glucose 6-phosphate dehydrogenase (G6PD) deficiency and compared the results with the ones found in healthy volunteers.
Methods: Peroxiredoxin gene and protein expression was evaluated in G6PD deficiency (n=8) hemoglobin SC disease (n=18), sickle cell disease (n=17) and β thalassemia (n=12) patients, and 15 healthy volunteers were included in this study. The ROS levels were measured by flow cytometry using the DCFH-DA reagent. The gene expression and protein production were evaluated using quantitative real time PCR and Western Blotting, respectively. The statistical method used was Mann Whitney an p value<0,05 was considered with statistical significance.
Results: Our results showed a significant increase of ROS in patients with β thalassemia, hemoglobin SC disease and sickle cell disease. The results also showed that the gene and protein expression of PRDX1 were raised in β thalassemia and reduced in patients with sickle cell disease. The *PRDX2* analysis did not show significant differences in the diseases, however the western blotting analysis showed a decrease of this protein in SS patients, suggesting a post-transcriptional mechanism in this disease. *PRDX5* did not show differences in any diseases. The gene and protein expression of PRDX6 was reduced in β-thalassemia and sickle cell disease. In hemoglobin SC disease and G6PD deficiency, protein and transcription analysis of PRDX1, 2 and 6 did not exhibit any significant difference. However, PRDX 1 and 2 was found as a dimer in the patients when compared with controls individuals, where these proteins are found in their active (reduced) state. Futhermore, we found a presence of a high molecular weight structure, indicating a decamer formation only in the patients.
Summary and Conclusions: Our results showed an interesting correlation among oxidative stress in hemolytic anemia patients with the production of peroxiredoxins enzymes. The decrease of expression of these enzymes could be an important event in the increase of hemolysis observed in these patients. Moreover the presence of a dimer and decamer structure observed only in the patients, could indicate that the activity of these proteins were reduced and that the decamer formation could be associated with the chaperone activity observed in these proteins in high levels of oxidative stress. The modulation of these proteins could be used as potential therapeutic targets for the attenuation of the damage caused by the oxidative stress, consequently improving the patients prognostic. This study is supported by CAPES and FAPESP.

P545

HYPERTHERMIA INDUCES ERYPTOSIS IN HEREDITARY SPHEROCYTOSIS

R Crisp[1,2,3,*]D Vota[2], H Donato[1,4], D Vittori[2], E García[5], M C Rapetti[4], A Nesse[2]
[1]Hematología Infantil, Consultorios de Hematología Infantil, [2]Química Biológica, Facultad de Ciencias Exactas y Naturales, UBA, [3]Hematología Clínica, Hospital Nacional Alejandro Posadas, Buenos Aires, [4]Hematología/Oncología, Hospital del Niño de San Justo, San Justo, Buenos Aires, [5]Oncohematología Pediátrica, Hospital Nacional Alejandro Posadas, Buenos Aires, Argentina

Background: In patients with hereditary spherocytosis (HS) anemia frequently gets worse throughout the course of febrile infectious diseases, due to hemolytic crisis. Actually, the incidence of this complication is 67.2% in our series of HS patients. This observation and usual clinical practice suggest a potential harmful action of temperature on erythrocytes, which would affect their survival. Circulating erythrocytes can undergo premature self-destruction through a mechanism known as eryptosis. A variety of clinical disorders are associated with excessive eryptosis. This process can be triggered by the increase of intracellular calcium or high oxidative stress and can be accelerated by different environmental factors.
Aims: To evaluate whether the temperature increment on erythrocytes may be one factor responsible for anemia worsening during febrile processes.
Methods: Erythrocytes from 9 HS patients and 11 normal controls (NC) were incubated at different temperatures, mimicking either the physiologic body temperature (36.5ºC) or a febrile state (38.5ºC). Flow cytometry was used to analyze signs of eryptosis, such as cell shrinkage (forward scatter) and phosphatidylserine (PS) translocation. Intracellular calcium content, as well as reactive oxygen species (ROS) and reduced glutathione levels (GSH), were also determined by flow cytometry.
Results: In NC, percentages of eryptotic cells and PS exposure either at 36.5

or 38.5°C showed no significant difference, while HS erythrocytes showed a significant increase in eryptotic cells (23.3±4.4% *vs.* 40.4±7.0%, for 36.5 and 38.5°C, respectively; n=9; p <0.01) and PS exposure (6.0±1.0% *vs.* 13.5±2,2%; n=9; p <0.01). Temperature increase did not trigger significant changes in ROS or the GSH levels either in HS or in NC erythrocytes. Erythrocytes from HS patients showed significantly higher intracellular calcium content than NC after incubation at 38.5ºC (p <0.05): mean fluorescence intensity was 56.1±6.5 *vs.* 60.4±1.1 in NC (n=3) and 77.3±7.4 *vs.* 143.7±44.4 in HS (n=6), after incubation at 36.5 and 38.5ºC, respectively. Calcium sequestration in the environment significantly decreased the programmed cell death induced by temperature in HS erythrocytes, since the increment of eryptotic cells and PS externalization were significantly lower in free calcium assays.

Summary and Conclusions: Our results showed that high temperature of incubation induced eryptosis of HS erythrocytes, which resulted more sensitive to temperature changes than red blood cells from controls. An increase in intracellular calcium content seems to be an important factor responsible for the eryptosis induced by high temperature, and could explain the worsening of anemia during hyperthermia in these patients. To our knowledge, this is the first report showing a direct harmful effect of hyperthermia on erythrocytes of HS patients.

P546

HAMP GENE MUTATION ASSOCIATED WITH JUVENILE HEMOCHROMATOSIS IN BRAZILIAN FAMILY

P Santos[1,*] R Cançado[2], E Correia[3], M Uellendhal[4,5], P Fonseca[1]
[1]University of Sao Paulo, [2]Santa Casa Medical School of Sao Paulo, [3]Institute of Cardiology Dante Pazzanese, [4]Federal University of Sao Paulo, [5]DASA Diagnostics, Sao Paulo, Brazil

Background: Juvenile hemochromatosis (JH) is a rare form of iron overload that frequently causes cardiomyopathy, hypogonadotrophic hypogonadism and endocrine dysfunctions before the age of 30. JH types 2A and 2B are caused by mutations in *HJV* (OMIM 602390) and *HAMP* (OMIM 606464), respectively. *HJV* mutations are more frequent than *HAMP* mutations.

Aims: to identify the causal mutation of the JH phenotype in a Brazilian family.

Methods: Bidirectional sequencing for each *HFE*, *HJV* (hemojuvelin), *HAMP* (hepcidin), *TFR2* (transferrin receptor 2) and *SLC40A1* (ferroportin) exons and intron-exon regions was performed in three members of a Brazilian family. Nuclear magnetic resonance (NMR) using T2* evaluation was made.

Results: The index case was a 43-year-old Brazilian female who had previous secondary amenorrhea at age 29, osteoporosis, rheumatoid arthritis, osteoarthritis of knees, modification of skin color, and heart failure 8 months ago (left ventricular ejection fraction - LVEF by MRI of 42.8% - NV 56-78%). Her laboratory tests were: hemoblogin (Hb) 11.7 g/dL, transferrin saturation (TS) 100%, serum ferritin (SF) 7,350 ng/mL and MRI using T2* evaluation showed liver iron concentration (LIC) of 30.67 mg Fe/g dry (NV<3.0 mg/g) and myocardium iron concentration (MIC) of 3.40 mg/g (NV<1.1 mg/g).Her sister, a 40-year-old, had articular pain, hearing impairment, skin hyperpigmentation, and secondary amenorrhea (Hb 12.0 g/dL,TS 98.0%, SF 4,880 ng/mL, LIC=39.57 mg/g; MIC=2.96 mg/g and LVEF by MRI of 36%). Her brother, a 33-year-old, had skin hyperpigmentation, and sexual impotence (Hb 14.6 g/dL, SF 4,800 ng/mL, TS 96%, LIC=39.57 mg/g; MIC=4.95mg/g and LVEF by MRI of 42.8%). Secondary causes of iron overload were excluded and, in the family investigation, healthy parents had a history of consanguinity. In the 3 patients, *HAMP* sequencing revealed a substitution in homozygosis G >A at position +14 of the 5'-UTR region (g.47G>A) creating a new AUG codon, which leads to a shift of the reading frame. No other mutation was identified, except heterozygous genotype for the *HFE* p.H63D alteration in the three patients.

Summary and Conclusions: This *HAMP* mutation on 5'-UTR region, firstly found in a Portuguese family (Matthes T, 2004, Blood) and now identified in a Brazilian family, can be an important region during molecular investigation for patients with JH phenotype.

P547

HB CERVANTES, HB MARAÑÓN, HB LA MANCHA AND HB GOYA: DESCRIPTION OF FOUR NEW HEMOGLOBINOPHATIES

F De La Fuente Gonzalo[1,*] JM Nieto[1], FA Gonzalez[1], L Vinuesa[1], P Ricard[2], C Garrido[3], R Martinez[4], A Cervera[5], A Villegas[1], J Diaz-Mediavilla[1], P Ropero[1]
[1]Hematology, Hospital Clínico San Carlos, [2]Hematology, Hospital Universitario Fundación Alcorcón, [3]Pediatría, Hospital Universitario Gregorio Marañón, Madrid, [4]Analisis Clinicos, Complejo Hospitalario de Albacete, Albacete, [5]Pediatría, Hospital Universitario de Mostoles, Madrid, Spain

Background: Thalassemias are the most common monogenic disorders worldwide and represent a serious health problem in areas where their incidence is higher. The α-thalassemias are due to a deficiency or absence of synthesis in the α-chain of hemoglobin (Hb). The defects in the post-translational modifications produce hyper-unstable Hbs that are not detected by most of electrophoretic or chromatographic methods available so far. Structural hemoglobinopathies are due to mutations that cause the change of the amino acid sequence of the protein chain. Some of these variants have altered electrophoretic mobility. They do not have a clinical impact but can cause interference in the analytical determination of some parameters such as the glycosylated hemoglobin in diabetic patients.

Aims: We shown 4 new α-chain Hb variants. Two variants are hyper-unstable and the other 2 are structural variants that have an altered electrophoretic mobility.

Methods: The first 2 families were studied by presenting microcytosis and hypochromia with normal Hb A2 and Hb F without iron deficiency. The other 2 families were studied by presenting a peak of abnormal Hb during routine analytical assays. Haematological data were obtained on a haematology analyzer (Coulter LH750). HbA2 and F quantification and the separation of abnormal Hb were performed by ion-exchange HPLC (VARIANT). The abnormal Hb also was separated by capillary electrophoresis (Sebia). The study of the globin chains was performed by reversed-phase HPLC. The most frequent mutations were ruled out by α-*globin StripAssay* (ViennaLab). The molecular characterization was performed by specific sequencing in an ABI PRISM 3100 Genetic Analyzer.

Results: The haematological parameters and the genotype of the studied subjects are summarized in Table 1. The electrophoretic and chromatographic studies are recruited in Figure 1.

Table 1. Hematological parameters and genotype of the studied subjects. M=Male; F=Female; α^{C}=Cervantes; α^{M}=Marañón; α^{LM}=La Mancha; α^{G}=Goya.

Family	Age (Years)	Sex	Subject	Hb (g/dL)	MCV (fL)	MCH (pg)	HbA2 (%)	Hb F (%)	Hb X (%, by HPLC-Variant)	Genotype
A	54	M	I1	16.5	78.7	24.9	2.7	1.3	--	$\alpha^{C}\alpha/\alpha\alpha$
	25	F	II1	13.8	77.2	24.8	3	0.6	--	$\alpha^{C}\alpha/\alpha\alpha$
	21	M	II2	15.9	81	26.3	2.7	0.4	--	$\alpha^{C}\alpha/\alpha\alpha$
B	14	F	I1	13.9	65.9	21.2	2.6	0.3	--	$\alpha^{M}\alpha/-\alpha^{3,7}$
C	52	M	I1	15.6	93.8	31.1	1.8	0.3	21.9	$\alpha^{LM}\alpha/\alpha\alpha$
D	2	M	I1	12.6	85.4	27.6	2.4	1.8	13.5	$\alpha^{G}\alpha/\alpha\alpha$

Figure 1. Electrophoretic and chromatographic studies.

Summary and Conclusions: In the Hb Cervantes, a residue that interacts with the Alpha-Hemoglobin-Stabilizing Protein (AHSP) that maintains the stability of entire globin chain is affected. For Hb Cervantes, its hyper-instability is due probably to its lower affinity for the AHSP. In the case of the Hb Marañón, a residue that generates an adequate hydrophobic environment for the distal union with the heme group and the α chain, is unstable causing an α-thalassemia phenotype. In our patient, Hb Marañón is also associated with α+-thalassemia deletion which causes a severe phenotype with significant microcytosis and hypochromia. The Hb La Mancha has the same mobility as Hb D, so it could be confused with other variants that do have a clinical expression. Then, it is needed a molecular level characterization by sequencing to study this variant. Finally, Hb Goya has the same mobility as Hb J. A lower percentage of the variant was obtained due to possible instability component, though the patient did not show features of anemia. In the Hb Goya, the helix E is affected. All these variants reveal the complexity and variety of disorders that can be found in the genes encoding Hb. Some variants, such as Hb Cervantes and Hb Marañón, with a significant clinical impact if associated with other forms of α-thalassemia may lead to more severe forms of this set of conditions, as the Hb H disease. Other as Hb Goya and Hb La Mancha, although clinically silent may interfere with various routine analytical assays as the quantification of glycated Hb. In any case, given the variety of alterations already described in Hb genes, we should be aware to this type of emerging diseases.

P548

PDGF, PDGFR AND TGF GENE EXPRESSION PROFILE IN PATIENTS WITH BETA-THALASSEMIA AND SICKLE CELL DISEASE WITH AND WITHOUT PULMONARY HYPERTENSION

K Polonifi[1], G Kapellos[1], D Farmakis[1], A Aessopos[1], A Polizos[1], M Mantzourani[1,*]
[1]University of Athens, athens, Greece

Background: Pulmonary hypertension (PH) is one of the major complications in patients with hemoglobinopathies. Platelet-derived growth factor (PDGF) and transforming growth factor (TGF-β) pathways are among those involved in the development of PH. The expression of PDGF-A, PDGF-B, PDGFR-A, PDGFR-B and TGF-β genes in peripheral blood have not been investigated in relation to PH in patients with inherited hemolytic anemia.
Aims: We sought to quantify the expression of study of PDGF-A, PDGF-B, PDGFR-A, PDGFR-B and TGF-β genes in peripheral blood sample in hemoglobinopathies patients with and without PH in comparison with healthy individuals.
Methods: We enrolled 55 consecutive patients with hemoglobinopathies, including 11 with thalassemia major (TM), 22 with thalassemia intermedia (TI) and 12 with sickle cell disease (SCD). A group of 16 healthy individuals served as controls. PH was defined as a peak tricuspid regurgitation velocity (TRV) >2.9m/s by trans-thoracic echocardiography. Real-time PCR was used to quantify mRNA gene expression of PDGF-A, PDGF-B, PDGFR-A, PDGFR-B and TGF-β by mean of SYBR green detection (CFX96, Biorad). Results were compared to healthy individuals and analyzed by using t-test. There are expressed as: mean value±SEM (p<0,05).
Results: Expression of all studied genes except PDGF-A was significantly higher in TM patients than controls (*PDGFR*-A, 1,2±0,1 *vs* 0,07±0,007, *PDGFR-B*, 0,3±0,03 *vs* 0,23±0,05, *PDGF-B*, 10,3±1,3 *vs* 7,5±0,5 and *TGF*-β, 62,6±15,3 *vs* 59,6±4,7). Moreover, SCD patients expressed higher levels of *PDGFR*-A (1,85±0,2 *vs* 0,07±0,007) and *PDGF-B* (15,6±2,2 *vs* 7,5±0,5) and lower levels of *PDGFR*-B (0,08±0,007 *vs* 0,23±0,05) compared to controls. No statistical significant difference was revealed for *PDGF-A* and *TGF*-β. Interestingly, TI patients with PH presented a significant lower expression of *PDGFR*-A and *PDGFR*-B (0,0003±2,4E-5;0,03±0,002 vs0,07±0,004; 0,23±0,05), *PDGF*-A (0,3±0,002 *vs* 0,4±0,002) and TGF-β (7,9±0,8 *vs* 59,6±4,7) compared to controls. No statistical significant difference was revealed for *PDGFR-B*. TI patients independent the present of PH demonstrated lower expression levels of *PDGFR*-A (0,0003±2,4E-5 *vs* 1,9±0,02) and *TGF* β (7,9±0,8 *vs* 85,4±2,3) compared to total patients with hemoglobinopathies.
Summary and Conclusions: Patients with thalassemia intermedia and PH expressed statistical significant lower levels of PDGF-A, PDGFR-A, PDGFR-B and TGF-β genes in peripheral blood compared to control group. Moreover thalassemia major patients over-expressed PDGF-B, PDGFR-A, PDGFR-B and TGF-β genes compared to control group.

P549

INFLUENCE OF HBG2 XMNI POLYMORPHISM ON HBF LEVELS IN PORTUGUESE BETA-THALASSEMIA CARRIERS

L Manco[1,*] C Pereira[1], L Relvas[2], C Bento[2], A Abade[1], ML Ribeiro[2]
[1]Department of Life Sciences, University of Coimbra, [2]CHUC-Centro Hospitalar e Universitario de Coimbra, Coimbra, Portugal

Background: Increased levels of Hb F can ameliorate the clinical manifestations and severity of sickle cell disease and β-thalassemia (β-thal) hemoglobinopathies. The identification of modulators that are responsible for the reactivation and/or maintenance of Hb F levels in adults have been extensively studied because an understanding of these modulations is important for the development of new therapies. Recent genetic association studies found three major loci involved in HbF variance, including the -158C/T SNP (XmnI, rs7482144) located 5' upstream of *HBG2 (*chr. 11p15), and several SNPs within *BCL11A* intron-2 (chr. 2p16) and in the *HBS1L-MYB* (HMIP) intergenic region (chr. 6p23). Some of these polymorphisms, including *BCL11A* rs766432, *HMIP* rs9399137 and *HBG2* rs7482144, have been associated with the HbF levels in β-thal carriers of different populations.
Aims: To evaluate whether genetic variability of SNPs *BCL11A* rs766432, HMIP rs9399137 and *HBG2* rs7482144 are associated with HbF levels in β-thal carriers of Portuguese descent.
Methods: Sixty seven subjects of Portuguese origin with β-thal *minor*, aged 2-77 years, with HbF levels ranging from 0.2% to 9.5% and heterozygous for one of the following mutations in *HBB* gene [c.118C>T (p.Glu40term); c.48G>A (p.Trp16term); c.92+6T>C; c.126_129 delCTTT; c.92+1G>A], were recruited. HbF and HbA2 levels were determined by HPLC (Variant 2 Bio-Rad Laboratories, Hercules, CA, USA). SNPs rs766432 and rs9399137 were genotyped by allelic discrimination assays using TaqMan probes (Applied Biosystems, Foster City, USA), and rs7482144 by PCR-RFLP with XmnI endonuclease. HbF level was log-transformed to normalize the distribution and statistical analyses were performed by using the PLINK software (http://pngu.mgh.harvard.edu/purcell/plink/). Informed consent was provided by all the participants.
Results: The minor allele frequencies observed for the three polymorphisms in the total sample were: 0.139 for *BCL11A* rs766432-C, 0.25 for HMIP rs9399137-C, and 0.152 for *HBG2* rs7482144-T. Genotype distributions were in agreement with the Hardy-Weinberg equilibrium (p>0.05). The distribution of log transformed HbF values (mean) according to SNP genotypes showed lower values in homozygotes for the major ancestral allele *versus* genotypes with the derived allele (*BCL11A* rs766432: 0.024 *vs.* 0.258; HMIP rs9399137: 0.009 *vs.* 0.186; HBG rs7482144: -0.073 *vs.* 0.499). Linear regression under an additive genetic model to test the association between SNPs and HbF levels showed statistical significance for SNPs *BCL11A* rs766432 (β=0.29; p=0.009), HMIP rs9399137 (β=0.18; p=0.043) and *HBG2* (XmnI) rs7482144 (β=0.49; $p=1.12 \times 10^{-7}$), after adjustment for age and sex. However, conditional analysis demonstrated that after conditioning on the most highly associated SNP rs7482144 (XmnI), no significant interaction with HbF levels was observed for *BCL11A* rs766432 (p=0.11) or HMIP rs9399137 (p=0.27).
Summary and Conclusions: Our results suggest that the increase of HbF levels in Portuguese β-thal carriers is highly associated with the *HBG2* (XmnI) polymorphism. However, our data do not replicate previous findings showing statistically significant associations between the HbF trait and *BCL11A* rs766432 or HMIP rs9399137 polymorphisms.

P550

MOLECULAR CHARACTERIZATION OF THE MUTATIONS CAUSING G6PD DEFICIENCY AMONG EGYPTIAN CHILDREN WITH GENOTYPE - PHENOTYPE CORRELATION

M Elalfy[1], N Soliman[1], A Adly[1,*] T Kamal[1], M El Deeb[1], L Duca[2]
[1]Ain Shams University, Cairo, Egypt, [2]Medicina Interna 1[A] Laboratoria, Italy

Background: Glucose-6-phosphate dehydrogenase (G6PD) deficiency is the most common human enzyme defect. It is considered a health problem, especially in Asia, Middle East and Mediterranean countries with many biochemical and clinical phenotypes. The effective management of G6PD deficiency is to prevent haemolysis by avoiding oxidative stress with fava beans is the commonest. No data is available about the effect of non-fava beans diet in those patients. Molecular characterization of G6PD deficiency variants is essential, since the biochemical characterization has lost its significance due to the individual variability
Aims: was designed to determine the frequency of the common mutations causing G6PD deficiency in Egyptian children, as well as making genotype-phenotype correlation for the identified mutations affecting G6PD gene on Xq28.Also to investigate the challenge of non-fava beans diet on occurrence of hemolysis.
Methods: Quantitative analyses for enzymatic activity, G6PD electrophoresis and molecular typing were performed on 108 G6PD-deficient children. A polymerase chain reaction-amplification refractory mutation system (PCR-ARMS) technique was used to detect the G6PD enzyme mutation with polymerase chain reaction-restriction fragment length polymorphism (PCR-RFLP). Patient's medical records were reviewed as regard age at diagnosis, demographic data, the offending agent which precipitated the first attack, history of blood transfusion and G6PD level at diagnosis. Challenging of patients with haemoglobin level ≥12 gm/dl with intake of non- fava beans diet with monitoring of those patients by complete blood count, reticulocytic count markers of hemolysis.
Results: The G6PD Genotypes detected were; *Mediterranean variant mutation* in 53% (from which 54.7% had G6PD 1311T silent polymorphism), Cairo mutation in 13% and African mutation in 16% of cases. Chatham mutation in 4%, Santmaria in 1% and Asahi mutation in 1% of cases and these 3 molecular defects were first to be described in Egyptian G6PD deficiency. Of the studied patients 83% were symptomatic; 64% demonstrated acute haemolytic crisis with necessity of blood transfusion induced mainly by ingestion of fava beans and 61% had history of neonatal jaundice. Acute haemolytic anemia was found in 79% of Mediterranean variant, 56% of African variant, 61.5% of cairo variant, 50% of Chatham variant, although none of the patients with santmaria and Asahi variants had developed haemolytic crisis.The G6PD enzyme level was significantly lowered in Mediterranean and African mutation compared to other mutations and was not correlated with disease severity. With prospective follow up of patients after ingestion of legumes rather than fava beans taken in small amount (5-20 gm) per day for 3 successive days no attacks of hemolysis were developed as indicated by colour of urine, CBC, reticulocytic count and markers of hemolysis (indirect bilirubin, LDH).
Summary and Conclusions: G6PD deficiency *Mediterranean* mutation is the most common mutation among Egyptian children with G6PD deficiency followed by African and Cairo mutation. This is the first report of G6PD Santamaria, chatham and Asahi among our Egyptian population. Ingestion of small amount of legumes rather than fava beans was not associated with haemolysis in G6PD deficient children.

Thalassemia and sickle cell disease

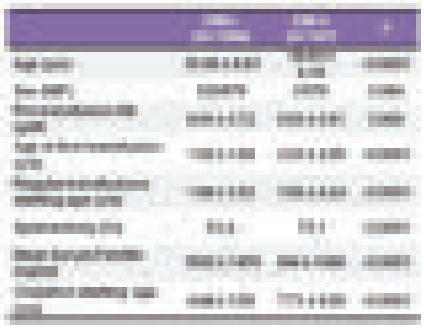
P551

EXTRAMEDULLARY HEMATOPOIESIS (EMH) IS ASSOCIATED WITH A THALASSAEMIA INTERMEDIA-LIKE PATTERN OF MYOCARDIAL AND LIVER IRON LOADING IN REGULARLY POLYTRANSFUSED THALASSAEMIA PATIENTS

P Ricchi[1,*] A Meloni[2], F Terrazzino[3], A Spasiano[1], A Filosa[1], MP Smacchia[4], E Facchini[5], G Restaino[6], R Maria Chiara[7], A Pepe[2]
[1]UOSD Centro per le Microcitemie, AORN Cardarelli, Napoli, [2]Cardiovascular MR Unit, Fondazione G. Monasterio CNR-Regione Toscana, Pisa, Italy, Pisa, [3]U.O.C. Radiologia, Ospedale Civico, Palermo, [4]DAI PEDIATRIA – UOC Oncoematologia, Policlinico Umberto 1, Roma, [5]U.O. Pediatria - Pession, M.O. Oncologia ed Ematologia Pediatrica "Lalla Seràgnoli", Policlinico Universitario S. Orsola-Malpighi, Bologna, [6]Dipartimento di Radiologia, Centro di Ricerca e Formazione ad Alta Tecnologia "G. Paolo II", Campobasso, [7]Struttura Complessa di Radiologia, OSP. SS. Annunziata ASL Taranto, Taranto, Italy

Background: Extramedullary hematopoiesis (EMH) is an incidental finding in regularly and historically polytransfused thalassaemia patients but no study has evaluated if it is a marker of a peculiar pattern of iron loading.
Aims: We studied the relationship between EMH and Magnetic Resonance Imaging (MRI) findings.
Methods: 1266 thalassemia patients (pts) regularly transfused (655 F; 31.25±8.86 years) consecutively enrolled in the Myocardial Iron in Thalassemia (MIOT) Network were considered. MRI was used to assess the presence of EMH by SPGR sequences, to quantify cardiac and hepatic iron overload by a multiecho T2* approach, and to assess cardiac function, volumes and pulmonary diameter by SSFP sequences. Myocardial fibrosis was evaluated by LGE technique.
Results: EMH was detected in 167 pts (13.2%). The Table 1 shows demographic and haematological comparisons between EMH- and EMH+ pts. No significant differences were found in the chelation regimens between the two groups. EMH+ pts had significant less cardiac iron overload than EMH- pts (13.2 *vs* 28.3% of pts with global heart T2* <20 ms; P=0.003). Biventricular volumes, cardiac index, ejection fractions, atrial areas and presence of myocardial fibrosis were comparable between the two groups. EMH+ patients had a significantly higher LV mass index (62.3±13.2 *vs* 58.63±13.19; P=0.001) and a significantly higher pulmonary artery diameter (24.7±4.2 *vs* 23.6±3.8; P=0.002). The MRI LIC was significantly lower in the EMH+ patients than EMH- pts (6.23±8.13 *vs* 9.23±11.71 mg/g/dw; P=<0.0001). Considering the 482 (38.1%) patients with MRI LIC≥7 mg/g dw, the EMH+ group had a significant lower frequency of global heart T2*<20 ms (18.4% *vs* 40.8% p=0.007).

Table 1.



Summary and Conclusions: In this large cohort of regularly transfused thalassemia patients, EMH was not rarely observed and was associated to a heart thalassemia intermedia like pattern (reducedcardiac and liver iron loading and stigmata of high cardiac output state) despite the transfusional regimen.

P552

MAGNETIC RESONANCE IMAGING T2 AND R2* TECHNIQUES REFLECT RENAL HEMOSIDEROSIS IN PATIENTS WITH THALASSEMIA AND SICKLE-CELL DISEASE; CORRELATIONS WITH SERUM FERRITIN AND MARKERS OF HEMOLYSIS

E Voskaridou[1,*] D Christoulas[2], M Douskou[3], V Komninaka[1], E Terpos[4]
[1]Thalassemia Center, Laikon General Hospital, [2]Department of Hematology, 251 General AirForce Hospital, [3]Bioiatriki Medical Center, [4]Department of Clinical Therapeutics, National and Kapodistrian University of Athens, School of Medicine, Athens, Greece

Background: Iron overload is a significant problem in hemoglobinopathies. Recently, magnetic resonance imaging (MRI) gradient echo (T2*), the reciprocal of T2* (known as R2*) and spin echo (T2) techniques have been developed to quantify tissue iron in the liver and the heart. Patients with thalassemia or sickle-cell disease (SCD) may develop kidney insufficiency. The significance of iron overload in the kidneys of these patients is poorly understood.
Aims: To evaluate kidney R2* and T2 MRI as surrogates for kidney iron of patients with different hemoglobinopathies.
Methods: We prospectively studied 158 patients: 85 had thalassemia major (TM), 27 thalassemia intermedia (TI), 37 SCD and 9 double heterozygous SC/β-thalassemia (HbS/β-thal). All patients had MR examinations of the kidneys, liver and heart. For T2* mapping a gradient echo, multi echo FSPGR sequence was used, while for T2 mapping a T2-prepared single shot SSFP technique with multi echoes was performed. The normal reference values of T2 in our lab was <80 msec, while for R2* normal range we used the one previously described by Schein *et al.* (J Magn Reson Imaging 2008;28:698-704), which was 21.3±5.8 Hz with a 95% confidence upper limit of 33.7 Hz. Regarding renal function, patients were divided in the 5 chronic kidney disease (CKD) stages of the KDIGO classification, according to eGFR evaluated by the CKD-EPI formula.
Results: Kidney T2 values were (mean±SD) 100.9±11.7, 99.4±13.7, 99.1±13.4 and 105.9±14.9 msec and for patients with TM, TI, SCD, and HbS/β-thal, respectively; 7/85(8.2%) TM, 2/37(5.4%) SCD, 1/27(3.7%) TI patients and none with HbS/β-thal had T2 values lower than the normal limit of <80 msec. Kidney R2* values were 17.5±11.4, 22.0±19.7, 18.1±14.7 and 22.2±18.8 Hz respectively. Compared to historic controls, 3/85 (3.5%) TM, 4/27 (14.8%) TI, 2/37 (5.4%) SCD and 1/9 (11.1%) HbS/β-thal patients had R2* >upper normal limit of 33.7 Hz. There was no difference between the different groups regarding T2 or R2* values. eGFR values were 107±19, 117±10, 100±33 and 105±27 ml/min/1.73m^2, respectively. Patients with TI had higher eGFR than SCD and TM patients (p=0.014 and p=0.001, respectively). The number of TM, SCD, HbS/β-thal and TI patients with CKD stage 3-5 was 4 (4.7%), 4 (10.8%), 1 (11.1%) and 0, respectively. There was no correlation between T2 or R2* values and eGFR or serum creatinine in all patients groups. This may be due to the different T2 or R2* values between the two kidneys of the same patient (p=0.004 and p=0.08, for T2 and R2*, respectively). Patients with low T2 values (<80 msec) had higher serum ferritin and lower Hb (p=0.009 and p=0.046, respectively). Patients with high R2* values (>33.7 Hz) had higher serum LDH and reticulocyte counts (p=0.022 and p=0.033, respectively). Renal R2* (r=-0.256, p=0.001) but not T2 values correlated also with liver T2* values. In TM patients there was a negative correlation of T2 values with ferritin (r=-0.290, p=0.009) and LDH (r=-0.331, p=0.003), a positive correlation of R2* with ferritin (r=0.402, p=0.001) and LDH (r=0.361, p=0.001) and a negative correlation with Hb (r=-0.240, p=0.03).
Summary and Conclusions: Our study provides evidence that T2 and R2* reflects kidney iron deposition in 3-14% of patients with different hemoglobinopathies. More interestingly, in TM patients both MRI techniques correlated with serum ferritin and LDH. Further studies, possibly with the performance of renal biopsies, will reveal the best MRI technique for detecting iron overload in the kidneys of patients with hemoglobinopathies.

P553

HEPATIC FIBROSIS AND CIRRHOSIS IN PATIENTS WITH THALASSAEMIA MAJOR IS ASSOCIATED WITH PRESENT AND HISTORICAL IRON OVERLOAD, AGE, AND ACTIVE HEPATITIS C INFECTION

SR Pasricha[1,2,*]E Shelton[3], CP Chong[4], L Shochet[4], J Cheong[5], SY Ong[5], A Hodge[5], K Cheng[6], A Dev[5]
[1]MRC Human Immunology Unit, Weatherall Institute of Molecular Medicine, Oxford, United Kingdom, [2]Medical Therapy Unit, [3]Gastroenterology, [4]Haematology, [5]Monash Health, Melbourne, Australia, [6]Radiology, Monash Health, Melbourne, Australia

Background: Patients with transfusion-dependent thalassaemia are at risk of cirrhosis, which can result in liver failure and hepatocellular carcinoma. Standard clinical methods for identifying hepatic pathology (ultrasound, biochemistry) are insensitive to fibrosis. Liver biopsy is invasive and unsuitable for screening. Lack of suitable screening tests has hampered estimates of the prevalence of and risk factors for hepatic fibrosis among patients with thalassaemia. Transient Elastography (TE) enables reliable non-invasive evaluation of liver stiffness and hence, risk of cirrhosis. The Enhanced Liver Fibrosis (ELF) Score comprises a set of extracellular matrix markers and has excellent correlations with liver fibrosis.
Aims: To estimate the prevalence and risk factors for fibrosis, we used TE and ELF to prospectively screen chronically transfused, chelator-treated patients with thalassaemia without previous diagnosis of cirrhosis.
Methods: Adults with transfusion dependent thalassaemia without known cirrhosis were invited to undergo TE and ELF measurements. Concurrent/ historical ferritin and HCV viral load, and recent (<1year) liver ultrasound and T2* MRI data were collected. Prevalence of cirrhosis and fibrosis defined by TE and/or ELF score was calculated, and risk factors for fibrosis evaluated.
Results: We screened 63 patients (mean age 43y, 46% male, 89.9% presently using deferasirox) for liver fibrosis by TE, of whom 61 also had ELF scores measured. Mean concurrent (2013) ferritin was 776.5ng/uL; mean ferritin in 1998, 2003 and 2008 was 734.5ng/uL, 1041.9ng/uL and 1091.1ng/uL respec-

tively; a significant increase was seen between 1998-2003, and a significant reduction from 2008-2013, coinciding with the introduction of deferasirox. Prevalence of HCV Ab was 54%, including 27% with detectable viral load. TE and ELF score were correlated (r=0.47, p=0.0001). By TE, 18/63 (29%) had fibrosis, including 7 (11%) with cirrhosis. By ELF score, 96.7% of patients had evidence of fibrosis, including 34.4% with severe fibrosis. Interestingly, concurrent liver T2* was not correlated with fibrosis risk by either measure. Controlling for confounders by multiple linear regression, TE score was associated with age (p=0.002), presence of detectable HCV virus (p=0.002), and both current (p<0.012) and historic (1998) ferritin (p=0.012) concentrations (R^2=0.457). By multiple regression, ELF score was associated with age (p=0.005) and historic (1998) ferritin levels (p<0.001).

Summary and Conclusions: Hepatic fibrosis and cirrhosis are prevalent in adults with transfusion dependent thalassaemia. Although concurrent ferritin is important, historic iron overload and active hepatitis C viral infection also mediate fibrosis risk. Chronically transfused patients with a history of prior iron loading and/or untreated hepatitis C virus should undergo specific screening for cirrhosis, even if ferritin levels are presently controlled.

P554

FIBROSCAN FOR THE DETECTION OF LIVER FIBROSIS IN HAEMOGLOBINOPATHY PATIENTS REQUIRING CHRONIC TRANSFUSION THERAPY

R Gasiorowski[1,2], S Strasser[3], C Waite[1], S Matthews[1], B Hsu[1], N Subhaharan[3], PJ Ho[1,*]
[1]Institute of Haematology, Royal Prince Alfred Hospital, [2]ANZAC Research Institute, University of Sydney, [3]AW Morrow Gastroenterology and Liver Centre, Royal Prince Alfred Hospital, Sydney, Australia

Background: Iron overload from chronic transfusion therapy is a major risk factor for the development of hepatic fibrosis in haemoglobinopathy patients. Whilst liver biopsy remains the gold standard for assessment of hepatic fibrosis, this test is invasive and subject to sampling variation. Transient elastography (FibroScan) is a novel, rapid, non-invasive test which uses liver stiffness measurements (LSM) to assess hepatic fibrosis. To date few studies have examined the utility of FibroScan in patients with transfusional siderosis.
Aims: This study aimed to examine the relationship between LSM and liver iron concentration (LIC) as measured by MRI in a cohort of haemoglobinopathy patients receiving regular transfusion therapy.
Methods: 27 patients who receive monthly blood transfusion for their haemoglobinopathies had LSM using FibroScan. Scans were deemed successful if at least 10 valid LSM were obtained and the interquartile range/median was <30%. These results were correlated with liver iron concentration measured by MRI in the same patients as part of the ongoing TIMES study - an epidemiological study to assess the prevalence of iron overload using MRI in patients with transfusional siderosis.
Results: Of 27 patients evaluated 23 have thalassaemia major and 4 have sickle cell disease. Four have hepatitis C. The mean age was 33 (range 18-56), the mean ferritin was 1844µg/l (range 344-8036) and the mean LIC was 8.7mg/g (range 0.5->43.0). All patients are currently on iron chelation therapy. The majority of patients (n=22) had no/minimal fibrosis (LSM<7.5kPa) with a mean LIC in this group of 8.0mg/g. However 4 patients had scans consistent with advanced fibrosis/cirrhosis (all with LSM >10.5kPa). Two of these patients have hepatitis C whilst another had a markedly elevated LIC (>43mg/g). However one patient, with sickle cell disease, had elevated liver stiffness despite a low LIC and no other clear risk factors for liver disease. There was no correlation between liver iron content as assessed by MRI and LSM (Figure 1).

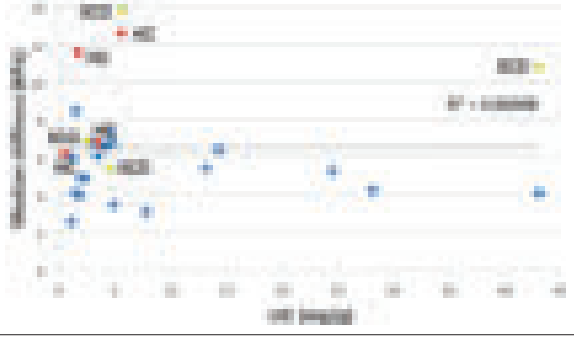


Figure 1. LSM *vs* LIC. Patients with hepatitis C are shown as HC; those with sickle cell disease are shown as SCD.

Summary and Conclusions: FibroScan is likely to prove useful for monitoring for the development of fibrosis in patients with iron overload from chronic transfusion therapy, particularly in those with additional risk factors such as hepatitis C. LSM appear to be independent from LIC. Significant liver fibrosis may be detected in patients without current evidence of high iron load, perhaps due to previous inadequate iron chelation. In one patient with sickle cell disease in our cohort, the elevated LSM may be unrelated to iron, a possible cause being the effect of sinusoidal obstruction incurred during previous sickling crises. Further studies are needed to confirm the utility of FibroScan in patients with transfusional iron overload.

P555

EFFECT OF SPLENECTOMY ON CARDIAC IRON AND FUNCTION IN DIFFERENT TRANSFUSION-DEPENDENT PATIENTS

A Meloni[1], A Carollo[2], S Pulini[3], C Fidone[4], S Campisi[5], V Positano[1], G Valeri[6], M Missere[7], P Keilberg[1], A Pepe[1,*]
[1]Cardiovascular MR Unit, Fondazione G. Monasterio CNR-Regione Toscana, Pisa, [2]Servizio Talassemia-U.O. Pediatria Talassemia, Az. Osp. "Sant'Antonio abate", Trapani, [3]U.O. Ematologia Clinica, Osped. Civile "Spirito Santo", Pescara, [4]U.O.S. di Microcitemia, Az. Osp. Civile, O.M.P.A. di Ragusa, Ragusa, [5]U.O.S. Talassemia, A.O. Umberto I, Siracusa, [6]Dipartimento di Radiologia, Azienda Ospedaliero-Universitaria Ospedali Riuniti "Umberto I-Lancisi-Salesi", Ancona, [7]Dipartimento di radiologia, Centro di Ricerca e Formazione ad Alta Tecnologia nelle Scienze Biomediche, Campobasso, Italy

Background: The main therapeutic rationale for splenectomy in transfusion-dependent patients with hemoglobinopathies is to decrease blood consumption and transfusion requirement. However, since the spleen is a large physiologic iron depot, splenectomy may have a possible role of in determining extrahepatic iron overload.
Aims: This study aims to observe retrospectively the effect of splenectomy on cardiac iron and function in different groups of transfusion-dependent patients.
Methods: 1735 transfusion-dependent patients enrolled in the Myocardial Iron Overload in Thalassemia (MIOT) Network were considered. 14 patients had sickle-thalassemia, 23 patients had sickle-cell disease (SCD), 179 had thalassemia intermedia (TI) and 1519 had thalassemia major (TM). Cardiac iron was assessed using a multislice multiecho T2* approach. Left ventricular ejection fraction (LV EF) was quantified by cine sequences.
Results: The frequency of splenectomy was: 21.4% in sickle-thalassemia, 65.2% in SCD, 84.9% in TI and 55.1% in TM (P<0.0001).
Splenectomized TM patients were older than non-splenectomized patients (34.3±7.9 yrs *vs* 27.2±7.8 yrs; P<0.0001). In each hemoglobinopathy, cardiac T2* and LV EF were comparable between splenectomised and non-splenectomized patients (Figure 1).

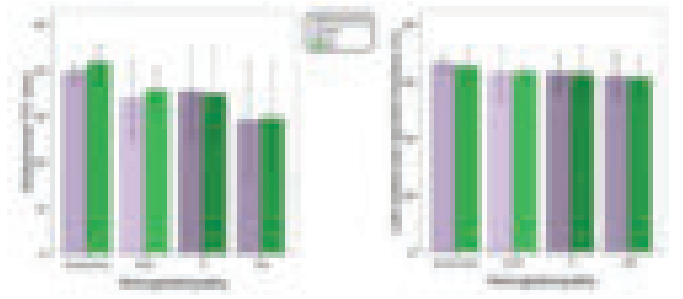

Figure 1.

Summary and Conclusions: Regardless by the type of hemoglobinopathy, in regularly transfused patients splenectomy was not associated with increased cardiac iron and reduced cardiac function.

P556

CORTISOL RESPONSE TO LOW DOSE *VERSUS* STANDARD DOSE ACTH STIMULATION TESTS IN CHILDREN AND YOUNG ADULTS WITH THALASSEMIA MAJOR

M Yassin[1,*] A T soliman[2], V Desantis[3]
[1]Hematology /BMT, National Centre for Cancer Care and Research Hamad Medical Corporation, [2]pediatric endocrinology, Hamad Medical Corporation, Doha, Qatar, [3]pediatric endocrinology, quissana, Ferrara, Italy

Background: Beta Thalassemia major patients with repeated blood transfusion have high prevalence of endocrinopathies due to iron overload
Aims: To evaluate Cortisol response to low dose *versus* standard dose ACTH tests in children and young adults with thalassemia major
Methods: We examined the adrenocortical function in 23 thalassemic patients (10 children and 13 young adults) aged 8-26 years. Serum cortisol and (DHEA-S) concentrations were determined in each subject before blood transfusion both in basal condition and after low dose (LD) (1 mcg), followed by standard dose (SD) (250 mcg, respectively) with synthetic corticotrophin β 1-24 ACTH (Synacthen)
Results: Using a peak total cortisol cutoff level of 550 nmol/L and increments

of 200 mcg above basal cortisol, adrenal insuffi ciency (AI) was demonstrated in 8 patients (34.7%) after the LD ACTH and in 2 patients (8.7%) after SD cosyntropin (ACTH) test, but none of the controls. Using a peak total cortisol cutoff level of 420 nmol/L and increments of 200 mcg above basal cortisol, AI was demonstrated in 5 patients (21.7%) after the LD ACTH and in 2 patients after SD ACTH test (8.7%), but none of controls

Summary and Conclusions: The use of LD ACTH test diagnoses more adrenal abnormalities *versus* SD ACTH in thalassemic patients. The relatively high prevalence of AI in thalassemic adolescents and young adults necessitates that these patients have to be investigated for AI before major surgery and those with impaired cortisol secretion should receive stress doses of corticosteroids during the stressful event.

P557

VENOUS THROMBOEMBOLISM IN SICKLE CELL DISEASE: PREVALENCE AND PATIENT CHARACTERISTICS.

V Van Hamel Parsons[1,*] K Gardner[1,2], R Patel[3], SL Thein[1,2]
[1]King's College Hospital, [2]Molecular Haematology, King's College London, [3]King's Thrombosis Centre, King's College Hospital, London, United Kingdom

Background: Although sickle cell disease (SCD) is recognised to be a hypercoagulable state, there is a dearth of data evaluating the prevalence of venous thromboembolism (VTE) in patients with this condition. The characteristics of SCD patients presenting with deep vein thrombosis (DVT) or pulmonary embolism (PE) are poorly defined, and nature of VTE and clinical outcomes are largely unknown.

Aims: To describe the prevalence, risk factors and presentation of VTE in a large cohort of SCD patients.

Methods: Medical records of all 855 adult SCD patients (all of African descent) regularly attending clinic at King's College Hospital, London, were retrospectively reviewed to identify cases of VTE. Records were reviewed from the earliest date of attendance to the last patient record or death. Within the cases a subset of young adult patients was identified, defined as those ≤25 years old. Patients were excluded if there was no accessible documentation regarding their first VTE as this precluded confirmation of the event.

Results: Amongst the 855 patients, 40 cases of VTE were identified; 30 patients were included. Of 223 patients below 25 years old, 10 young adults with VTE were identified, and 9 included as a subset. The prevalence of VTE in the total cohort was found to be 3.5%, and 4.0% in the young adult subset. The mean length of follow up was 8.1 years (range 3 months – 15.1 years). The mean age at first VTE in the young adult subset was 19 years (range 16-25 years), and 31.9 years (range 16-50 years) for the group as a whole. Regarding the site of the first VTE, 56.7% suffered a PE (of which 76.5% were isolated and 23.5% were associated with symptomatic DVT), 23.3% presented with proximal DVT without PE and 16.7% with distal DVT alone. One patient was found to have an inferior vena cava thrombus on echocardiogram. Overall 43.3% of VTEs were unprovoked (44.4% in the young adult subgroup). 23.3% of patients had recurrent VTE events. 17 patients underwent thrombophilia testing of which 5 were positive. 8 patients also had raised Factor VIII levels (range 201-369 IU/dL, mean 324.4 IU/dL). Conventional VTE risk factors were present in 80.0% of patients; SCD-specific risk factors (including history of chronic leg ulcers, avascular necrosis, splenectomy, HbSC genotype or pulmonary hypertension) were present in 56.7%.

Summary and Conclusions: These data demonstrate that the prevalence of VTE in this SCD population is much greater than that of the non-SCD black population. Strikingly, the prevalence of VTE in young adults with SCD is almost a hundred-fold greater than might be expected for this age group when compared to the non-SCD black population. Epidemiological studies have stated the rates of DVT in the general population to be 2-3 times greater than that of PE; in this SCD population PE was more common than DVT. However, the proportion of unprovoked and provoked VTE remains comparable to a non-SCD population. 26.7% of patients were found to have raised Factor VIII levels; this has previously been identified as an important risk factor in black patients and in this study was also associated with recurrent VTE.

This study indicates that SCD represents a major risk factor for VTE, particularly in young adults. This may have significant implications for both prophylaxis and the management of VTE in these patients.

P558

SICKLE CELL DISEASE IN AN URBAN ENVIRONMENT IN THE UNITED KINGDOM: DESCRIPTION OF AN ADULT COHORT

E Drasar[1,2], A Hearn[1,*] K Gardner[1,2], SL Thein[1,2]
[1]Haematological Medicine, King's College Hospital, [2]Molecular Haematology, King's College, London, United Kingdom

Background: Sickle cell disease (SCD) is the fastest growing serious genetic disease in the UK and Europe with an estimated 12500 affected individuals in the UK. Due to improved comprehensive care, an affected newborn in the UK can now expect to live to adulthood, but an increased lifespan has led to an increased burden of end-organ damage in adults.

Aims: To describe the prevalence and incidence of, and associations between, end-organ complications in an adult SCD cohort in an urban setting in the UK.

Methods: Data were gathered from electronic hospital records captured during steady-state clinic visits of patients from 01/01/2001 to 31/12/2012. End-organ complications were defined using local guidelines and criteria outlined in Ballas *et al.* 2010.

Results: 796 patients have been registered for the 13 year study period. These patients were followed up for a total of 5341 patient years, with a mean follow-up per patient of 6.7 years (range 1-13). Despite the transitory nature of our cohort, patient numbers have increased over the study period from 225 in 2000 to 515 in 2012. The proportions of the different genotypes have remained stable (HbSS 57–65%, HbSC 27–36%, HbSβ^+ 4-5%, and HbSβ^0 1%). Mean age increased from 32 (in 2000) to 36 (in 2012) years (range 16-83), the proportions of the more severe sickle genotypes decreasing with increasing age. 34 patients were identified who had died during the study period, of these 26 had HbSS, 6 HbSC and 2 HbSβ^+. Mean age of death was 41.3 (median 42, range 20 – 79) years. End-organ complications assessed included avascular necrosis, osteomyelitis, acute chest syndrome, tricuspid regurgitant jet velocity ≥2.5 ms, sickle cell lung disease, stroke, retinopathy, gallstones, leg ulcers, priapism, renal impairment (albumin:creatinine ratio ≥4.5 and creatinine clearance <60ml/min). The total number of end-organ complications per patient was calculated using the date last seen as the end point of data collection. Analysis was limited to patients with HbSS and HbSβ^0 (analysed together as sickle cell anaemia, SCA) and HbSC. 48% of patients had no evidence of sickle-related end organ complications at the end of the study period, 26% had 1 complication; 16%, 2 complications; 6%, 3 complications; 3%, 4 complications, and 1% ≥5 complications. The prevalence and incidence of all complications was higher in SCA compared to HbSC, except for sickle retinopathy (prevalence 18% in SCA *vs* 50% in HbSC). Patients with SCA had significantly more complications than patients with HbSC ($p<0.0001$); this persisted when corrected for age ($\beta=0.58$ $p<0.0001$). The number of patients without end-organ complications reduces with increasing age for both sub-groups. However within SCA, patients in their 6th and 7th decades appear to have fewer complications, forming a sub-group with a milder phenotype (see Figure 1). 51% of patients with SCA have at least 1 complication by the end of their 4th decade.

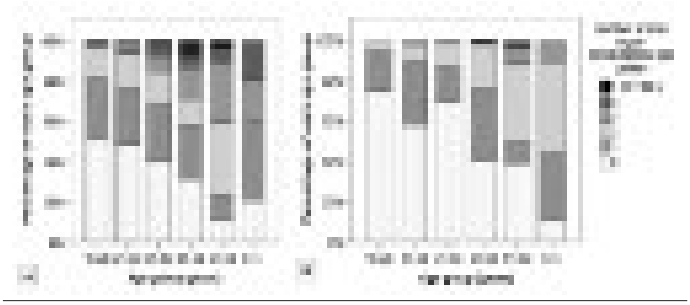

Figure 1.

Summary and Conclusions: The patterns of morbidity and mortality in this UK urban adult sickle cohort are comparable to that previously described in an US cohort. However, the increasing usage of interventions such as hydroxyurea and blood transfusion may alter these patterns of disease presentation and progression.

P559

OPHTHALMOLOGIC COMPLICATIONS IN A SICKLE CELL DISEASE COHORT WITH IN NORTH LEBANON

A Inati[1,*]
[1]Pediatrics-Hematology/Oncology, Rafic Hariri University Hospital, Beirut, Lebanon

Background: Sickle cell disease (SCD) is a hereditary hemoglobinopathy characterized by vaso-occlusion, hemolytic anemia, recurrent infections and end organ failure. Recurrent vaso-occlusion potentially affects the vascular beds of all organs including those of the eye. Previous studies have shown that ophthalmological findings in SCD are often detected before patients report any visual symptoms, underscoring the importance of early screening. To date, no data on the epidemiology and the prevalence of eye complications in the Lebanese SCD population has been reported.

Aims: The primary objectives of this study are to prospectively determine the prevalence of ophthalmological complications in a SCD cohort and the importance of early screening in the detection of asymptomatic eye findings. The secondary objectives are to delineate possible risk factors for ophthalmic complications in the above group.

Methods: A SCD cohort followed in a single comprehensive hemoglobinopathy center in North Lebanon will undergo a detailed ophthalmological exam

including best-corrected visual acuity (BCVA) measurement, slit-lamp examination, direct and indirect ophthalmoscopy and retinal photographs. Fluorescein angiography (FA) will be performed on patients with reduced BCVA or retinal photograph abnormalities. Frequencies of events will be calculated, and Pearson's test used for correlation analysis.
Results: 104 eyes for 52 patients, 86.5% with sickle cell anemia (HbSS) and 13.5% with sickle β thalassemia (S/βT), 52% males and 48% females, mean age at time of testing 13.8 years (age range, 3-44 years) were examined. 88.5% of the patients had history of at least one blood transfusion, and 26.9% and 69% were on iron chelation therapy and hydroxyurea, respectively. BCVA of the right eye was <20/100, 20/100-20/50, and >20/50 in 2.3%, 4.7% and 93% of cases respectively, whereas BCVA of the left eye was <20/100, 20/100-20/50 and >20/50 in 0%, 2.3% and 97.7%, respectively. Among the 44.2% of patients with conjunctival involvement, comma shaped vessels were found in 56.5% of cases, pallor was found in 56.5% of cases and hyperemia in 4.3% of cases. Only 1 patient had evident stage 1 hyphema. Among the 52% of patients with posterior segment manifestations, salmon patch hemorrhages were found in 11.5%, black sunbursts in 38.4%, hairpain loops in 30.7% and seafans in 3.8% of cases. 4/50 patients (8%) had proliferative sickle retinopathy (PSR); 3 (75%) aged 3-9 years had stage 1 and 1 (25%) aged 34 years had stage 4 PSR. Enlarged fovea was seen only in 3 (6%) patients.
Summary and Conclusions: Ophthalmologic findings are quite frequent among Lebanese patients with SCD and proliferative sickle retinopathy is seen at a very young age. This study underscores the importance of early screening and therapeutic intervention for ophthalmologic complications in improving patients' outcome in SCD.

P560

SOLUBLE FMS-LIKE TYROSINE KINASE-1 IN YOUNG PATIENTS WITH SICKLE CELL DISEASE: RELATION TO HEMOLYSIS-ASSOCIATED COMPLICATIONS

AA Tantawy[1,*] AA Adly[1], E Ismail[2], M Zeidan[1]
[1]Pediatrics Department, [2]Clinical Pathology Department, Faculty of Medicine, Ain Shams University, Cairo, Egypt

Background: Many mechanisms contribute to the complex pathophysiology of sickle cell disease (SCD), with dysfunction of the vascular endothelium as a major underlying pathology. Soluble fms-like tyrosine kinase-1 (sFLT-1) is a member of the vascular endothelial growth factor receptor (VEGFR) family. By adhering to and inhibiting VEGF and placenta growth factor, it induces endothelial dysfunction suggesting a possible role in the pathogenesis of SCD-associated vasculopathy and pulmonary hypertension.
Aims: To determine the levels of sFLT-I in young SCD patients compared with age- and sex-matched healthy controls and evaluate its role as potential marker for hemolysis associated complications.
Methods: Thirty-five children and adolescents aged 3.2-18 years (median 12.1 years) with SCD in the steady state were studied stressing on the frequency/severity of sickling crises, transfusion history, hydroxyurea therapy, hematological profile and serum ferritin, and echocardiography assessment of pulmonary hypertension. sFLT-I was measured by enzyme linked immunosorbent assay (ELISA).They were compared to 35 age and sex matched healthy controls.
Results: sFLT-1 was significantly higher in SCD patients in the steady state (median 130pg/ml) compared to controls (median 70 pg/ml), p<0.001. Levels of sFLT-1 were significantly higher in patients with history of manifest or silent stroke (p=0.007) and in the presence of pulmonary hypertension (p<0.001). SCD patients who experienced sickling crisis during the study period had higher sFLT-1 levels than patients in steady state (p<0.001). Hydroxyurea-treated patients had lower sFLT-1 levels than untreated patients (p=0.005). Significant positive correlations were observed between sFLT-1 and transfusion index(r=0.431, p=0.01), WBC count (r=00639, p<0.001), serum indirect bilirubin(r=0.513, p=0.002) and LDH (r=0.335, p=0.049) and serum ferritin (r=0.412, p=0.014) while sFLT-1 was negatively correlated to hemoglobin (r=-0.599, p<0.001) and HbF (r=-0.476, p=0.004). Multiple regression analysis revealed that sickling crisis (p<0.001), pulmonary hypertension (p<0.001), HbF (p=0.03) and indirect bilirubin (p=0.046) were independently related to sFLT-1. ROC curve analysis revealed that the cutoff value of sFLT-1 at 132.5 pg/mL could predict the occurrence of sickling crisis with 100% sensitivity and specificity of 100% [AUC 1.0, p <0.001] and sFLT-1 cutoff value at 127.5 pg/mL could differentiate patients with and without pulmonary hypertension with a sensitivity of 100% and specificity of 74%[AUC 0.958, p <0.001]
Summary and Conclusions: sFLT-1 may be considered a potential biological marker for vascular dysfunction and disease severity in SCD. sFLT-1 levels may contribute to the pathogenesis of SCD-associated pulmonary hypertension and would help in early crisis prediction as well as monitoring the response to hydroxyurea therapy.Further longitudinal studies with large number of patients are needed to verify these preliminary results.

P561

GROWTH DIFFERENTIATION FACTOR-15 IN CHILDREN AND ADOLESCENTS WITH SICKLE CELL DISEASE: RELATION TO HEMOLYSIS, IRON OVERLOAD AND VASCULAR COMPLICATIONS

A Tantawy[1,*] A Adly[1], E Ismail[2], Y Darwish[2], M Zeidan[1]
[1]Pediatrics Department, [2]Clinical Pathology Department, Faculty of Medicine, Ain Shams University, Cairo, Egypt

Background: Growth differentiation factor-15 (GDF-15) is a member of the transforming growth factor-β superfamily, it is strongly expressed in the placenta and during erythroblast maturation.However, GDF-15 is expressed in various tissues and is highly inducible during macrophage activation in response to several inflammatory cytokines and after tissue injury. GDF-15 expression at the high levels contributes to pathological iron overloading through a mechanism of incomplete hepcidin suppression. Sickle cell syndromes are characterized by increased levels of erythropoiesis, although the primary defect in sickle cell involves destruction of mature erythrocytes.
Aims: To determine the serum levels of GDF-15 in children and adolescents with SCD and assess its relation to markers of hemolysis, iron overload and vascular complications.
Methods: GDF-15 levels were measured by enzyme linked immunosorbent assay (ELISA) in 35 SCD patients aged 3.2-18 years (median12.1years) in the steady state and were compared to 35 healthy age and sex matched controls. The results were correlated to clinical and laboratory variables including age,sex, frequency and severity of sickling crises, previous cerebral stroke,transfusion history, hydroxyurea therapy, hematological profile and serum ferritin and echocardiography assessment of pulmonary hypertension.
Results: The median (IQR) of GDF-15 level in SCD was 2750 (1200) pg/ml compared to 90(120) pg/ml in controls, (p<0.001). GDF-15 levels were significantly higher in patients who had serum ferritin ≥2500 µg/L (p<0.001), in patients with previous manifest or silent cerebral stroke(p=0.022), and with splenectomy (p=0.018). GDF-15 level were not significantly related to age,sex,frequency of sickling crises,pulmonary hypertension,or hydroxyurea therapy. GDF-15 levels were positively correlated with transfusion index (r=0.874, p<0.001), LDH (r=0.773, p<0.001), serum indirect bilirubin (r=0.432,p=0.009) and serum ferritin (r=0.790,p<0.001), while GDF-15 levels were negatively correlated to hemoglobin (r=-0.621,p<0.001) and HbF% (r=-0.837,p<0.001). Multiple regression analysis revealed that transfusion index (p=0.001), LDH (p=0.042) and serum ferritin (p=0.006) were independently related to GDF-15 levels in SCD patients.
Summary and Conclusions: Increased GDF-15 in SCD reflects the importance of ineffective erythropoiesis in the pathophysiology and clinical severity of anemia in SCD. GDF-15 levels are significantly related to markers of hemolysis and iron overload in SCD and may provide utility for identifying patients who are at increased risk of thrombotic events. Further longitudinal studies including larger number of patients are needed to verify the practical utility of GDF-15 measurement and its potential to predict the clinical severity and outcome in SCD patients.

P562

PITUITARY ABNORMALITIES IN SHORT ADOLESCENTS AND YOUNG ADULTS WITH SICKLE-CELL DISEASE (SCD) AND RECURRENT VASO-OCCLUSIVE CRISIS

A Soliman[1,*] M yassin [2]V DeSanctis[3]
[1]Pediatric Endocrinology, [2]Hematology, Hamad Medical Center, Doha, Qatar, [3]Pediatric Endocrinology, Quisisana Hospital, Ferrara, Italy

Background: Growth failure is the most frequent endocrine abnormality observed in patients with SCD. Decreased synthesis of IGF-I might be secondary to a disturbed GH-IGF-I axis and defective GH secretion has been reported in some patients. Infarction, atrophy, and hemorrhage may occur in the pituitary gland in SCD during or following the vaso-occlusive crisis.
Aims: To define the possible abnormalities of pituitary gland in sickle-cell disease (SCD) we measured the circulating concentrations of insulin-like Growth factor –I (IGF-I) and studied the Magnetic Resonance Imaging (MRI) of the pituitary gland in 7 adolescents and young adults with SCD with short stature (HtSDS <-2) and history of recurrent painful crisis.
Methods: Seven patients with SCD (age: 24.2 +/- 4.5 years) and short stature (HtSDS=2.5 +/- 0.4) and history of severe and recurrent vaso-occlusive crisis (at least 3 in the past 3 years) were studied. All were transfusion – dependent, with full pubertal development (Tanner's stage 5) (euogonadal). They were regularly transfused since early childhood and underwent chelation therapy using desferrioxamine which was replaced by deferasirox for the last 4 -5 years.
Results: In the 7 patients with SCD circulating IGF-I were decreased (IGF-I SDS=-2.1+/-0.5) compared to adults standards. Pituitary MR imaging showed abnormalities in 4/7 of these patients in the form of heterogeneous appearance of the anterior pituitary, presence of single or multiple hypointense foci due to hemosiderin deposition in the pituitary (4/7) and significantly decreased (2/7) or increased volume (1/7). These lesions can be explained by hemosiderosis of the gland and/or ischemia during the vaso-occlusive crisis (Figure 1).

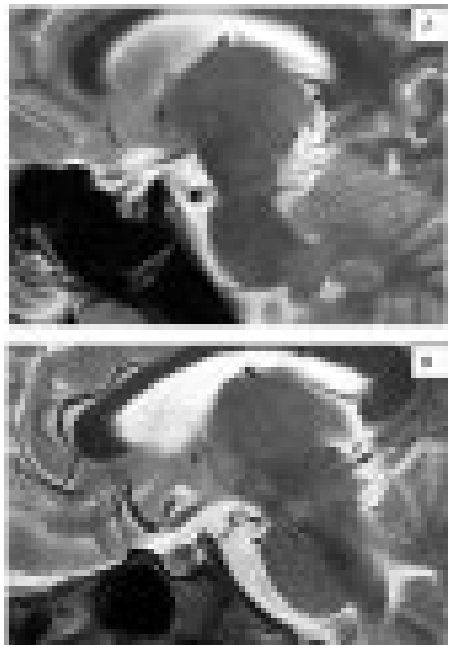

Figure 1. Two pituitary MR images showing deposits of hemosidrin: A) one hypointense lesion; B) many spots.

Summary and Conclusions: Pituitary MR imaging showed significant abnormalities of the anterior pituitary gland in SCD patients with short stature and significant history of vaso-occlusive crisis. This study demonstrated the value of MRI imaging of the pituitary to support investigating of the GH-IGF-I axis in these patients.

A.S, Istanbul, [18]Child Health and Disease, Erciyes University, Medical Faculty, Kayseri, Turkey

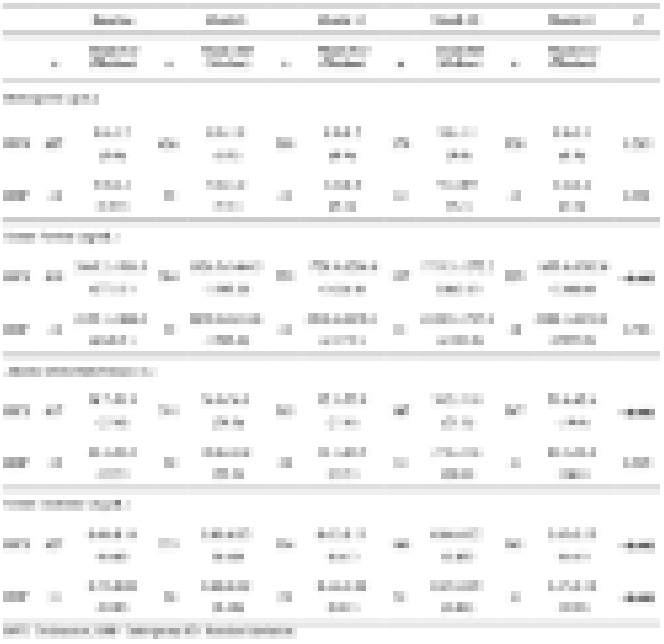
Background: Optimal management of transfusional iron overload (TIO) is still an important indicator of success in treatment of hemoglobinopathies. Outcomes of chelation therapy may directly affected by efficacy, tolerability, and safety of chelators.

Aims: This study aimed to evaluate outcomes of children with hemoglobinopathy receiving oral iron chelators (OIC) for treatment of TIO in Turkey.

Methods: This is a nation-wide, prospective, multi-center, non-interventional study in Turkey which is still ongoing (planned follow-up time: 3 years). Patients aged 2-18 years with β-thalassemia major (bTM) or sickle cell anemia (SCA) who were suffering from TIO and under OIC treatment were included. All patients and/or their parents provided informed consent. Patients' data including clinical and demographic characteristics, laboratory and imaging results related to TIO, and serious adverse events were recorded. Herein, 24-month follow-up results of the study are presented.

Results: Patients (n=474) from 30 centers representing the profiles of Turkish patients were enrolled, of whom 450 (50.7% female; mean age, 9.5±3.8 years) had a primary diagnosis of bTM and 24 (33.3% female; mean age, 10.1±4.2 years) had a primary diagnosis of SCA. Results of some laboratory parameters on the 24-month follow-up are summarized in Table 1. Of the patients, 391 (82.5%) completed 24-month follow-up. There were 209 (53.5%) patients with a hemoglobin level of ≤9 g/dL on month 24. Serum ferritin levels were significantly decreased with DFX therapy; however, no significant change was observed with DFP therapy. The rate of patients treated with DFX and serum ferritin levels of <1000 ng/mL was increased from baseline to month 24 (18.7% *vs.* 38%). Additionally, the mean DFX dose was increased from 26.3±14.1 to 29.0±9.0 mg/kg/day on month 24. The mean level of alanine aminotransferase (ALT) was significantly decreased in patients receiving DFX, whereas no significant change was observed in those receiving DFP; only 18 patients (17 patients receiving DFX and 1 patient receiving DFP) experienced an increase in ALT level of 3 times the upper limit of normal (ULN). Most of these patients had also relatively higher ALT level at baseline. The mean creatinine level was increased both with DFX and DFP therapies. However, no patient had a creatinine level of over ULN.

Table 1. Results of selected laboratory parameters.



Summary and Conclusions: This study comprises the overall prospective largest pediatric cohort including bTM and SCA patients suffering from TIO and under OIC treatment. More than half of the patients had a hemoglobin level of ≤9 g/dL after 24-month follow-up, revealing that such patients still do not receive optimal transfusion regimens according to current guidelines. 24 months follow up results revealed that DFX therapy reduced serum ferritin significantly but DFP therapy did not. There was no clinically significant change in liver or kidney function in this growing population of patients receiving DFX or DFP. In the majority of patients, serum ferritin level remained above the current guideline recommendations and hence optimization of OIC treatment is needed through active dose adjustments and proper monitoring.

P564

NON-TRANSFERRIN BOUND IRON REVISITED: NOW THAT ITS POTENTIAL TOXICITY IS ESTABLISHED, HOW CAN ITS MEASUREMENT HELP TO GUIDE CHELATION

V Berdoukas[1,*] K Farmaki[2], G Chouliaras[2], C Pappa[2], J Tzoumari[2], O Papageorgiou[3], I Cabantchik[4]

[1]Hematology/Oncology and Bone and Marrow Transplantation, CHLA, USC Keck School of Medicine, Los Angeles, United States, [2]Thalassaemia Unit, General Hospital of Corinth, Corinth, [3]Thalassaemia Unit, Karamandaniou Hospital, Patra, Greece, [4]Life Sciences, Hebrew University of Jerusalem, Jerusalem, Israel

Background: It is now possible to measure plasma non-transferrin bound iron (NTBI) readily, reproducibly and at reasonable cost, particularly its labile (chelatable) plasma iron (LPI) component that can infiltrate cells and raise labile cell iron (LCI) and thereby promote formation of noxious radicals.

Aims: Can those measurements provide indications for chelation efficacy/adequacy in maintaining LPI at sub-toxic levels?

Methods: 90 Thalassemia major patients (48 female/42male) from two centres (49 from Corinth and 41 from Patras) receiving chelation therapy, either as monotherapy, or in different combinations were evaluated. The Corinth patients were studied twice one year apart. Compliance was evaluated by history and pharmacy records. Blood samples were drawn after a 24 hour hold of chelator and then at 2 hours after an observed dose. LPI was determined in plasma with the FeROS™ assay (Aferrix, Tel Aviv).
Results: Baseline LPI compared to Compliance showed an R squared of 0.12. The p value was 0.001 indicating that poorer compliance is associated with higher baseline LPI. 60% (56/90) had normal trough LPI (<0.45μM) and of the remaining 34, 50% (17/34) normalized within 2 h of chelation. In 35 (24 on DFP+DFO, 11 on DFX+DFP) that were internally compared, LPI in the DFP+DFO group was significantly lower ($p<0.05$) than in the DFP+DFX group. Detailed regression analysis indicated that DFP+DFO achieved 0.15 μM lower LPI compared to DFP+DFX (adjusted for baseline LPI). DFP+DFO was 9 times more likely to reduce their baseline LPI levels compared to DFP+DFX and 10 times more likely to normalize their baseline LPI levels.
Summary and Conclusions: LPI provides a convenient and immediate measure of chelation efficacy. It is feasible to monitor adequacy of treatment and patient compliance similar to the use of HbA1C in diabetes management. Repeating such measurements every 3 months should be useful as preventive/corrective guidance in patient management.

P565

CHARACTERIZATION OF RARE ALPHA-GLOBIN GENE MUTATIONS IN THAILAND

N Uaprasert[1,*] R Settapiboon[1], S Amornsiriwat[1], P Sutcharitchan[1], P Rojnuckarin[1]
[1]Medicine, Chulalongkorn University, Bangkok, Thailand

Background: Hemoglobin Constant Spring is the commonest α-globin variant worldwide. Other α-globin variants are very rare. Amplification and direct sequencing of the α-globin genes are much more problematic than those of the β-globin gene as the sequences of α1-globin and α2-globin genes are almost identical.
Aims: We developed a simple protocol using a common forward primer and gene-specific reverse primers to separately amplify α1-globin and α2-globin genes followed by direct DNA sequencing to characterize genetic determinants of α-globin variants in Thailand.
Methods: We performed hemoglobin analysis using isoelectric focusing (IEF) and high performance liquid chromatography (HPLC) during 2012-2013. Cases showing unidentified hemoglobin variants were subject to molecular analysis. Direct sequencing on α1-globin and α2-globin gene was performed when α-globin variants were suspected or β-globin gene analysis yielded negative results. Hematological and hemoglobin analysis profiles of α-globin variants in this cohort were compared to those of our uncommon β-globin variants previously published (Int J Hematol 2009;89:568-71) to determine the phenotypes suggestive of α-globin mutations.
Results: In 41 unrelated individuals, 11 types of mutations of the α-globin genes were identified. Mutations on α1-globin gene are much more common (87.8% of cases) than those on α2-globin gene: 24 Hb Hekinan [α1 27(B8) Glu>Asp], 5 Hb Q-Thailand [α1 74(EF3) Asp>His], 2 Hb Lansing [α1 87(F8) His>Gln], 2 Hb Owari [α1 121(H4) Val>Met], 2 Hb G-Georgia [α2 95(G2) Pro>Leu], 1 Hb Port Phillip [α1 91(FG3) Leu>Pro], 1 Hb Westmead [α2 122(H5) His>Gln], 1 Hbl [α2 16(A14) Lys>Glu], 1 Hb J-Singapore [α2 78(EF7) Asn>Asp], 1 IVS-I-117 (G>A) on α1-globin gene, and 1 insertion of 21 bp on α1-globin gene causing a duplication of amino acid residues 93-99. When iron deficiency anemia was excluded, these heterozygous α-globin variants demonstrated normal or α^+-thalassemia phenotypes. This is the first report of Hb Lansing, Hb Owari, Hb G-Georgia, Hb Port Phillip, Hb Westmead, Hbl, Hb J-Singapore and IVS-1-117 mutation in Thai population. All cases with Hb Hekinan, Hb Owari, Hb G-Georgia and Hb Westmead were clearly seen on IEF, while they were undetectable on HPLC, except for 2 compound heterozygosities for HbHekinan and Southeast Asian deletional α^0-thalassemia. Unknown variants of HbA_2 were able to be found in Hb Hekinan, Hb Q-Thailand, Hb G-Georgia and Hb Port Phillip. When compared with uncommon β-globin variants, the presence of unknown variants of HbA_2 (sensitivity 30%, specificity 100%), the presence of HbBart's or HbH (sensitivity 5%, specificity 100%), unknown variants identified only on IEF (sensitivity 70%, specificity 75%), and unknown Hb variant levels of ≤30% on both IEF and HPLC (sensitivity 73%, specificity 100%) were phenotypes suggestive of heterozygous α-globin variants. Using combined characteristics as criteria for α-globin variant testing yielded sensitivity of 90.2% and specificity of 75%. Hb Lansing mutation was previously reported on α2-globin gene, but it was found on α1-globin gene in our study. Interestingly, cases of Hb Lansing on α1-globin gene had Hb Lansing levels of <10% on HPLC and normal oxygen saturation on pulse oximetry, while carriers of Hb Lansing on α2-globin gene in the previous report had HbLansing levels of ≥10% on HPLC and falsely low oxygen saturation.
Summary and Conclusions: This is the largest series of rare α-globin mutations. The majority of them were missed on HPLC. HbHekinan is the most common α-globin variant in Thais accounting for 58.5% of cases. Some distinct hemoglobin analysis characteristics are suggestive of α-globin over b-globin variants. The percentages of Hb variants, as well as their phenotypes, were also determined by the presence of mutations on either α1 or α2 gene and co-inherited α gene deletions.

P566

DETECTION OF B THALASSEMIA CARRIERS BY RED CELL PARAMETERS OBTAINED FROM THE H2 AUTOMATIC COUNTER USING MATHEMATICAL FORMULAS.

A Koren[1,2,*] I Lachover Roth[1], C Levin[1,2], L Zalman[3], H Palmor[3], B Lachover[1], G Koren[1]
[1]Pediatric Hematology, Emek Medical Center, Afula, [2]Faculty of Medicine, The Ruth and Bruce Rapaport, Haifa, [3]Hematology Laboratory, Emek Medical Center, Afula, Israel

Background: β thalassemia is considered the most widespread genetic mutation. According to the World Health Organization (WHO) between 1.5-7% of the world population carried this disease and 60,000 to 400,000 new patients are born every year. In Israel, the incidence of carriers for β thalassemia is around 20% among Jews from Kurdish origin and between 5 to 10% among the Arab population. The treatment of β thalassemia requires medical and financial significant resources. Therefore the implementation of a prevention program for identifying β thalassemia carriers is an important goal. β thalassemia carriers show low MCV and MCH. Those parameters and others like the hemoglobin level, RDW and the total number of RBC are easily measured by the automatized blood cell counters. Most of those findings are similar in β thalassemia carriers and patients with iron deficiency anemia, but some of them like the RBC and the RDW are normal in β thalassemia carriers. Automatic detection of β thalassemia carriers can improve significantly the recognition of couples at risk for having an affected offspring and then further genetic counseling can be provided.
Aims: In the past, several researchers, using different formulas, tried to determine cutoff points for the diagnosis of β thalassemia carriers compared to patients with Iron deficiency or to normal individuals, but none of those formulas are currently used in daily practice.
Methods: The hematological laboratory in the Emek Medical Center collect blood samples from all pregnant women in the north of Israel since 1987 for blood count and HPLC. We had 39,483 samples, 22,872 samples had all parameters, 19,763 were healthy or iron deficiency women according to HPLC, another 3109 were identified as β thalassemia carriers. We applied the blood count parameters from this large number of samples to the formulas previously published, and also used the proposed a new algorithm SVM (support vector machine) to find a reliable formula that can differentiate blood count parameters between those groups.
Summary and Conclusions: Only one of the previous described formulas (Shine & Lai) was reliable enough to detect between β thalassemia carriers and healthy people. Our new formula, found by SVM algorithm also had statistical significance ($p<0.05$), but also had only 31 false negative results and shows a negative predictive value of 99.81%, and sensitivity of 98.93, results similar to Shine's formula and better to all the other formulas. This suggested formula can be incorporated to any automatic blood counter and issued as an advice to the physician when suspected carriers are detected, even without having specific previous request for clinical suspicion. In those individuals a further simple HPLC analysis should be done in order to confirm the diagnosis. This formula is for now just validated among women at fertility age.

THE IMPACT OF IMPLEMENTING MATCHING MICHIGAN AND EPIC3 RECOMMENDATIONS TO REAL LIFE HAEMATO-ONCOLOGY PATIENTS: RESULTS FROM A PROSPECTIVE UK BASED STUDY

S Francis[1,*] M Cooper[2], A Jacob[1], H Jones[2], A MacWhannell[1], S Basu[1]
[1]Department of Haematology, [2]Department of Microbiology, Royal Wolverhampton NHS Trust, Wolverhampton, United Kingdom

Background: Central venous catheters are commonly used in haematology/oncology departments to deliver chemotherapy safely. Large retrospective studies report 1.4-2.2 infections per 1000 catheter days for subcutaneous tunnelled lines (1). Catheter related blood stream infections (CRBSI) are associated with a 25% increase in mortality (2). The Michigan Keystone project implemented specific technical and cultural practices to reduce infections. In England this led to a national patient safety initiative known as Matching Michigan, to minimise CRBSI (3). EPIC3 is a national evidenced based practical guideline published in England to prevent Healthcare associated infections in hospitals (4).
Aims: The aim of this study is to determine whether Matching Michigan and EPIC3 recommendations reduce CRBSI in haematology/oncology patients.
Methods: Prospective data on the insertion and removal dates of central venous catheter devices were collected from January 2013 –December 2013 at New Cross Hospital, Wolverhampton using electronic records and case notes. The ECOG score, comorbidities, episodes and duration of neutropenia and type of line inserted were recorded. Central venous catheter (CVC) tunnelled lines were inserted under radiological guidance. The Visual Infusion Phlebitis (VIP) score was recorded to determine its utility in predicting CRBSI.
Results: 137 patients (average age of 57.7 years; 75 were male) were included in the study. 52 patients had haematological malignancies and 85 patients had oncology cancers. Of the 137 lines inserted, 117 were CVC tunnelled lines (15,101 catheter days) and 20 PICC lines (1,390 catheter days). There were a total of 16491 catheter days with 8 proven CRBSI, giving a CRBSI rate of 0.49 infections per 1000 catheter device days. All 8 infections occurred in the CVC tunnelled lines. Catheter related infections were not related to age >65 (p=0.48), ECOG >1 score (p=0.18), diabetes (p=0.21), inpatient chemotherapy regimens (p=0.16) or neutropenia (p=0.14). The duration of neutropenia >10 days was a significant risk factor (p=0.01). The VIP score was documented in 56 out of 137 patients. The VIP score was positive in 7 patients. Of the 6 patients who had confirmed CRBSI, all 6 had negative VIP scores.
Summary and Conclusions: Duration of neutropenia (>10 days) was the only significant factor to influence line infections. The VIP score has a low sensitivity and does not predict CRBSI. Education of staff, reducing the number of operators inserting CVC lines and having a dedicated line team improves outcomes significantly. Prospectively implementing the measures from EPIC3 and Michigan Keystone project can reduce CRBSI significantly as evidenced by our study in cancer patients.

VARICELLA-ZOSTER VIRUS INFECTIONS IN IMMUNOCOMPROMISED PATIENTS; COMPARISON OF HEMATOLOGY – ONCOLOGY PATIENTS AND OTHER CHRONIC DISEASES

A Yoruk[1,*] O Yasa[2], M Erguven[2], G Ersoy[2], C Timur[1], A Ayhan[1]
[1]Department of Pediatric Hematology and Oncology, [2]Department of Pediatrics, Ministry of Health, Istanbul Medeniyet University Goztepe Research and Training Hospital, Istanbul, Turkey

Background: Varicella is one of the most common childhood infectious diseases. Acute varicella zoster virus (VZV) infection causes varicella and reactivation of a latent infection of VZV seropositive patients causes zoster. Varicella infections are potentially life threatening in immunocompromised patients especially in those whose immune system has been suppressed by diseases such as acute lymphoblastic leukemia (ALL) or by multiagent chemotherapy and corticosteroid treatment. In pediatric hematology - oncology patients varicella-zoster infections are one of the most important cause of mortality and morbidity. Antiviral treatment with acyclovir and varicella zoster immune globulin decreased the mortality rate of varicella infections in children with immune suppression from 7–55% to <1%.
Aims: In this study, we aimed to determine clinical features of varicella and zona zoster infections in our hematology – oncology patients and to compare complication rates, length of hospital stay and acyclovir use in patients with other underlying conditions such as immunosupression and chronic diseases.
Methods: The medical charts of 144 immunocompromised pediatric patients 0 – 18 years of age who were treated in the Department of Pediatric Infectious Diseases between February 2007 – July 2013 were reviewed.
Details on gender, age, underlying conditions, admission symptoms, nature and type of any varicella-associated complications, were noted. Data indicating the length of hospital stay, intensive care unit stay, administration of acyclovir administration of intravenous immunoglobulin antibiotic therapy, and hospitalization outcome (need for intensiv care unit, or death) were collected.
Results: Out of 144 immunocompromised patients 63 (44%) were hematology – oncology patients (Group A) and 81 (56%) had chronic illnesses (Group B). The median age was 5 years 2 months in group A and 3 years in group B. Boys /Girls ratio was 1,6 in the entire study group, 1,1 in group A and 2,1 in group B. Varicella zoster/Zona zoster ratio was 2.5 in group A and 15,2 in group B. In group A leukemia was the major underlying disease (57%, 30 ALL and 6 AML) followed by solid tumors (24%). In group B neurological diseases were the major underlying disease (37%) followed by nephrological diseases (21%). The most common complication was secondary bacterial infection in Group A (n=26, 41%) and group B (n=24, 30%). Neurological complications were observed in 4 children in group B. In group A, 61 patients (96%) and in group B, 64 patients (79%) were treated with intravenous acyclovir. In the entire group median length of hospital stay was 8 days, in group A 8 days and in group B 7 days. The median length of hospital stay was longer in hematology – oncology patients (p<0,001). One children required treatment in intensive care unit. The patient was in group B. Acyclovir treatment rates and duration of acyclovir treatment was higher in hematology – oncology patients (p<0.001).
Summary and Conclusions: In pediatric oncology patients varicella-zoster infections are one of the important causes of mortality and morbidity. With respect to patients with underlying other chronic diseases, oncology patients need longer treatment period. Early diagnosis and treatment of VZV infections in all chronically ill children would reduce morbidity and mortality rates.

P569

CHANGING OF PLATELET DERIVED MICROPARTICLES, SCUBE-1 AND IL-1B IN CHILDREN WITH DENGUE INFECTION

D Sosothikul[1,*] S Lauhasurayotin[1], P Seksarn[1]
[1]Department of Pediatrics, Chulalongkorn University, Bangkok, Thailand

Background: Dengue infection is one of the most important acquired platelet disorders in tropical countries. Platelet activation can lead to platelet dysfunction in various medical conditions such as cancers and thrombosis. The role of platelet activation in the pathogenesis of platelet disorder in dengue infection is not well studied yet.
Aims: To evaluate the role of platelet activation in dengue infection using novel molecular markers such as platelet derived microparticles (PDMP), signal peptide-CUB-EGF domain-containing protein 1(SCUBE-1) and interleukin 1 β (IL-1β) and to correlate these markers with severity of disease.
Methods: Prospective cohort study.
Twenty children (age 5-15 years) who had serological confirmation of dengue infection from June 1st to November 30th, 2013 were recruited in this study. Eight patients were diagnosed with dengue fever (DF) and twelve patients were diagnosed with dengue hemorrhagic fever (DHF). Mean age was 10.45±3.94 years. Blood samples were collected during three stages of disease: febrile stage, toxic stage and recovery stage. Then PDMP, SCUBE-1 and IL-1β levels were measured from patient's plasma by enzyme-linked immunoadsorbent assay. Forty healthy age-matched children served as the control group.
Results: The plasma levels of SCUBE-1 and IL-1β were significantly higher in all stages of dengue infection compared to control group (p<0.001). PDMP levels were significantly increased compare to control group (p=0.007) only in toxic stage of dengue infection. However, levels of PDMP, IL-1β and SCUBE-1 were not significant different between DF and DHF group in any stages.
Summary and Conclusions: Platelet activation can be one of the mechanisms that lead to platelet disorder in patients with dengue viral infection which include thrombocytopenia and platelet dysfunction. However, the novel molecular markers associated with platelet activation may not be useful as a biological marker for dengue disease severity.

P570

PURE RED CELL APLASIA IN PAEDIATRIC HIV

R Thejpal[1,*]
[1]Paediatrics, University of KwaZuluNatal, Durban, South Africa

Background: Anaemia is common in the progression of HIV infection. Vertical-

ly acquired HIV infection impairs immunity in the infant and young child. Co-infection with Parvovirus B19 is an important cause of pure red cell aplasia (PRCA) in this cohort of children and must be managed differently from other causes of PRCA.
Aims: The aim was to describe the frequency and characteristics of PRCA in HIV infected children with anaemia.
Methods: A chart review was conducted of 240 paediatric patients with HIV infection investigated for one or more cytopenias in our unit. Fifty seven patients with red cell hypoplasia (7) or aplasia (50) were identified. The aetiology and response to treatment was evaluated.
Results: There were 20 female patients and 37 males. The median age of presentation was 7 years (2months to 13 years). Parvovirus was identified as the aetiology in 40 patients. In the early part of the study the presence of the typical red cell inclusions and/or the presence of parvovirus IgM was used but since 2003 the parvovirus PCR was used. The remaining patients with PRCA were drug related (lamivudine 5, zidovudine 2) or associated with another co-infection like tuberculosis (5), CMV (2), CMV and EBV (1). In 4 patients the parvovirus studies were not done and no cause could be assigned. The presenting Hb was very low in most patients and the diagnosis often only first considered after the need for multiple transfusions. The Hb was <2g/dl in 13 patients and 2<3g/dl in 23 patients. Treatment with parvovirus PRCA was with transfusions, intra-venous immunoglobulin(IvIg) and starting anti-retroviral therapy. In most instances repeated doses of IvIg were necessary. Drug related PRCA warranted a change in the regimen and erythropoeitin was indicated in these patients with a delayed or inadequate response. Patients with tuberculosis have a variety of changes in the bone marrow which respond to appropriate treatment. Bone marrows have been useful in identfying MOTTs and resistant tuberculosis.
Summary and Conclusions: Response in children with parvovirus related PRCA is similar to that described in adults. The large number of patients we have managed reflects the burden of paediatric HIV disease in the province as well as the cumulative exposure to parvovirus in childhood. Severe and life-threatening anaemia is common and needs transfusion support. Erythropoeitin is indcated in the drug related PRCA and was not usually needed when causative infections were treated. Lamivudine is an important cause at our centre.

P571

ROLE OF PROPHYLAXIS WITH LAMIVUDINE IN MAINTENANCE TREATMENT WITH RITUXIMAB IN NON HODGKIN LYMPHOMA CD20+
C Cerchione[1,*] M Masarone[2], M Persico[2], G Beneduce[1], C Cimmino[1], R Della Pepa[1], S Luponio[1], I Peluso[1], N Pugliese[1], E Seneca[1], M Notarangelo[1], C Mainolfi[3], M Picardi[1], F Pane[1], A De Renzo[1]
[1]Hematology, AOU "Federico II", [2]Hepatology, II University of Naples, [3]Nuclear Medicine - Radiology, AOU "Federico II", Napoli, Italy

Background: In literature, sporadic Hepatitis B Virus (HBV) reactivation cases are reported not only in patients treated with Rituximab-based regimens but also in patient after maintenance with Rituximab single treatment. The aim of this work is to evaluate how many HBV reactivation occurred among patients with positivity of Hepatitis B core antigen (HBcAB +) and Hepatitis B surface antigen negative (HBsAg-) who underwent to maintenance treatment with Rituximab as single agent.
Aims: We analyzed retrospectively the prevalence of HBV reactivation among patients with diagnosis of Non Hodgkin Lymphoma CD20+ HBcAb +/HBsAg– who underwent to maintenance treatment with Rituximab after standard Rituximab-based chemoterapy schedule.
Methods: From January 2007 to December 2013, in our Unit, 92 patients with diagnosis of Non Hodgkin Lymphoma CD20+ underwent, after standard chemoterapy schedule Rituximab-based, to maintenance treatment with Rituximab as single agent (schedule: 375 mg/mq every 3 months for 2 years). Patients were previously treated with different chemotherapy treatments: 42% (39/92) with R-CHOP; 50% (46/92) with R-FN; 3% (3/92) with R-F; 4% (4/92) with R-Chlorambucil. None of these patients received prophylactic treatment with lamivudine during induction or maintenance. All the patients were given blood tests for HBV (HBsAg; HBsAb; HBeAg; HBeAb; HBcAb) before starting maintenance treatment and liver function tests before each administration of Rituximab.
Results: 19% of the patients (18/92) were HBcAb positive. 65% of the patients (60/92) completed the maintenance treatment and 28% of them were HBcAb positive (7/25): only in one of these patients occurred the HBV reactivation (median follow up: 24 months). 28% of the patients (26/92) are still in therapy with Rituximab and 11% of them are HBcAb positive (3/26): all these patients are at risk for HBV reactivation too.
Summary and Conclusions: In patients HBcAb +/ HBsAg– in maintenance with Rituximab as single agent, is suggested prophylaxis with lamivudine. In our retrospective study, HBcAb +/ HBsAg- patients didn't receive any prophylactic treatment with lamivudine during the maintenance treatment with Rituximab and the HBV reactivation occurred only in one patient HBcAb+/HBsAg-, three months after the end of the maintenance therapy. More ambitious prospective studies are required to establish the clinical utility of prophylactic treatment with lamivudine during Rituximab-based-maintenance.

P572

THE IMPACT OF HEPATITIS B VIRUS (HBV) INFECTION ON PROGNOSIS OF PATIENTS WITH DIFFUSE LARGE B-CELL LYMPHOMA AND THE OCCURRENCE OF HEPATITIS FLARES AFTER WITHDRAWAL OF PROPHYLACTIC ANTIVIRAL TREATMENT
MF Law[1,*] HN Chan[2], HK Lai[2], CY Ha[2], C Ng[2], YM Yeung[2], SF Yip[2]
[1]Department of Medicine, Prince of Wales Hospital, Shatin, [2]Department of Medicine, Tuen Mun Hospital, Tuen Mun, Hong Kong

Background: Hepatitis B virus (HBV) infection is a worldwide health problem. It is important to understand its impact on outcomes and prognosis among patients with lymphoma receiving treatment. There is also no consensus on the duration of prophylactic antiviral treatment after cessation of chemotherapy.
Aims: We performed a retrospective study to analyze the characteristics and clinical outcomes of diffuse large B-cell lymphoma (DLBCL) patients with hepatitis B virus (HBV) infection and compare with those without HBV infection. We also assessed the occurrence of hepatitis flares after withdrawal of prophylactic antiviral treatment on completion of chemotherapy.
Methods: Patient records were reviewed retrospectively from all patients aged 18 or above, with untreated DLBCL who had received chemotherapy between January 1996 and December 2010 in Tuen Mun Hospital, Hong Kong. Patients with newly diagnosed DLBCL were treated with curative intent. The hepatitis B surface antigen (HBsAg) positive patients were given prophylactic lamivudine until 6 months after finishing chemotherapy. After chemotherapy and withdrawal of antiviral therapy, patients were followed up regularly to examine for hepatitis flare.
Results: 81 patients were recruited with 16 in the HBsAg positive group and 65 in the HBsAg negative group. The prevalence of hepatitis B among DLBCL patients was 20% in our cohort. The clinical characteristics were similar in both groups of patients. There was no significant difference in terms of marrow involvement, lactate dehydrogenase (LDH) levels, extranodal involvement, proportion of patients receiving rituximab (R) and incidence of advanced stage diseases in the two groups. The median follow-up time for the patients was 47.8 (range 1.1 - 188) months. There was no significant difference in complete remission rate between the two groups (63% in HBsAg positive group *versus* 54% in HBsAg negative group, p=0.59). There was also no statistically significant difference in overall survival between the two groups (p=0.23).
Four of the sixteen HBsAg positive patients (25%) had hepatitis after cessation of chemotherapy and prophylactic lamivudine. One patient was given CHOP (cyclophosphamide, doxorubicin, vincristine and prednisolone) therapy and the other three were given R-CHOP treatment previously. Hepatitis A and hepatitis C virus infection were excluded as causes of the hepatitis flare. The onset of hepatitis ranged from 2 to 4 months (mean 3 months) after stopping lamivudine. These four patients had normal ALT levels before chemotherapy and stopped lamivudine 6 months after completion of chemotherapy. Lamivudine was resumed in these four patients and one patient required addition of adefovir because of the presence of the tyrosine-methionine-aspartate-aspartate (YMDD) mutant. The liver enzymes gradually normalized in all these patients. The patients were all alive after treatment of the hepatitis flares.
Summary and Conclusions: HBV infection did not appear to affect the clinical outcomes and prognosis of DLBCL patients given prophylactic antiviral treatment. Patients should be monitored closely for hepatitis flare after cessation of antiviral agent on completion of chemotherapy. A significant number of hepatitis flares occurred after 6 months of antiviral prophylaxis upon finishing chemotherapy. It is reasonable to consider prophylactic antiviral therapy to extend to at least one year on completion of chemotherapy.

P573

PREVALENCE, CHARACTERISTICS AND MANAGEMENT OF OCCULT HEPATITIS B VIRUS INFECTION (OBI) IN CHRONIC LYMPHOCYTIC LEUKEMIA (CLL) PATIENTS. MONOCENTRIC EXPERIENCE.
I Innocenti[1,*] F Autore[1], B Vannata[1], N Piccirillo[1], P Chiusolo[1], F Sora[1], S Giammarco[1], D Speziale[2], M Pompili[3], D Efremov[4], S Sica[1], L Laurenti[1]
[1]Hematology, [2]Microbiology, [3]Internal Medicine, Catholic University, Pol. A. Gemelli, Rome, [4]Molecolar Hematology, International Centre for Genetic Engineering & Biotechnology, Monterotondo Scalo, Italy

Background: Several reports have emphasized the risk of Hepatitis B virus (HBV) reactivation in patients with lymphoproliferative disorders undergoing cytotoxic treatment. This risk is relevant also in patients with previous HBV infection and serum HBsAg loss or occult B infection (OBI) affected by CLL, especially if they receive treatment with monoclonal antibodies. OBI is defined by the HBV-DNA in the liver with detectable (<200 IU/ml) or undetectable HBV-DNA in the serum and HBsAg negative. OBI may be distinguished as seropositive-OBI (anti-HBc and/or anti-HBs positive) or seronegative-OBI (anti-HBc and anti-HBs negative) on the basis of the HBV antibody profile. The treatment of active HBV in CLL patients requiring chemo and/or immuno-therapy has been well established, while the management of occult B hepatitis infection (OBI) is still debated.
Aims: We report the prevalence and the management of OBI in CLL population.

Methods: We selected, from our CLL database consisting of 510 patients in the care of our Department from January 1997 to December 2011 and followed until December 2013, all patients studied for CLL and HBV serum markers to detect OBI in this population. All the HBsAg-negative patients found to be positive for anti-HBc were enrolled in the study, independently from the anti-HBs status. All patients undergone immunosuppressive therapy were checked at 3-month interval during treatment and for 18 months thereafter for complete HBV serum markers, including anti-HBc IgM and HBV-DNA serum level. In case of HBs-Ag seroreversion (reappearance of serum HBsAg) with detectable HBV-DNA level, we started antiviral therapy with nucleoside/nucleotide analogues. This strategy was followed until June 2010. After this date all OBI patients who underwent chemo-immunotherapy received universal prophylaxis (UP) during treatment and for 12 months after. All patients provided written informed consent. This study was approved by an internal Ethics Committee.
Results: Here we reported 397 CLL patients assessed at diagnosis for HBV serology. At the time of enrolment all patients were checked for co-infection with hepatitis C virus (HCV) and human immunodeficiency virus (HIV) and routine laboratory parameters assessing liver and kidney function. We observed OBI in 34/397 patients, of whom 24 were HBcAb and HBsAb positive and 10 were HBcAb positive and HBsAb negative. When comparing OBI/CLL with B-CLL patients, we did not find any statistical difference among clinical-biological parameters (sex, age, stage of disease, IgVH, FISH, CD38, Zap-70,) and time dependent end-points (PFS/TTT/OS), the only parameter that showed statistical differences was the lower peripheral blood lymphocyte count in OBI/CLL group (median Lymphocyte count 8.033 *vs* 10.500/mmc; p=0.036). Up to 2010 a careful follow-up and TP were adopted: 2 out of 10 patients (20%) with OBI/CLL receiving chemo-immunotherapy showed seroreversion. They were successfully treated with lamivudine without the development of drug-resistance or any kind of toxicity for 37 and 42 months. Thereafter, we adopted UP during and 12 months after immunosuppressive treatment in all CLL patients with OBI: anyone showed evidence of seroreversion.
Summary and Conclusions: In conclusion in all CLL patients with OBI we recommend UP with lamivudine during and 12 months after the chemo and or immunotherapy in order to avoid HBV seroreversion because these patients had high risk of reactivation due to the loss of immunological control over infection.

P574

SAFE RITUXIMAB ADMINISTRATION TO NHL PATIENTS WITH CONCOMITANT HBV ACTIVE INFECTION: THE RISK OF HBV REACTIVATION SHOULD NOT PREVENT US TO DELIVER OPTIMAL TREATMENT

V R Zilioli[1,*] C Rusconi[1], A Esposito[2], M Torretta[1], A Greco[1], P Minga[1], M Zancanella[1], L Paris[1], E Meli[1], G Venturelli[2], M Vinci[3], E Morra[1]
[1]Hematology, [2]Pharmacy, [3]Hepatology, Niguarda Hospital, Milan, Italy

Background: HBV reactivation can occur during treatment (tx) of NHL patients (pts). The standard of care for B-NHL pts is Rituximab(R)- based tx, but R administration is associated with an increased risk of HBV reactivation not only in classical HBsAg+ pts, but also in pts who had resolved HBV infection (HBsAg -/anti HBc+). In HBsAg+ NHL pts undergoing chemotherapy (CT), an antiviral prophylaxis strongly reduces the incidence of HBV hepatitis. High baseline HBVDNA levels are a recognized risk factor for HBV reactivation.
Aims: In November 2013 an Italian Regulatory Agency (AIFA) note prohibited the inclusion of R in the tx of NHL pts with active HBV infection. Since the addition of R to classical CT is associated with superior outcomes, the decision to avoid immunotherapy should be strongly justified even in this small cohort of pts. Here we report our experience of R-tx in NHL pts with active HBV infection.
Methods: From January 2008 until November 2013, 675 NHL pts requiring anti-lymphoma tx referred to our Center and were screened at baseline for HBV parameters. Those pts with signs of active HBV infection (HBsAg+and/or HBVDNA+) were selected for this analysis. Retrospective analysis included: date of diagnosis; HBV parameters and ALT/AST values at baseline, during and after antiviral tx; type and duration of the antiviral tx; HBV reactivations occurrence and timing. HBsAg+ and/or HBVDNA+ pts received Entecavir or Tenofovir. HBsAg and HBVDNA levels were determined at baseline, every 15 days until negativity, and then every 3 months; ALT/AST were tested monthly.
Results: Ten pts were HBsAg+ with active HBVDNA replication (mean 72420327 U/ml, range 10 – 981349498), 3 pts had low HBVDNA level with HBsAg-, and 1 pt tested negative for both HBVDNA and HBsAg, but a previous spontaneously resolved HBV reactivation was documented out of any antiNHL tx. Globally those 14 pts (2,1%) were considered with active HBV infection and an antiviral tx was started. 4 out of 10 HBsAg+ pts had clinical hepatitis (ALT median values 300 U/L, range 87-586) at the time of diagnosis. Seven pts were started on Entecavir, 3 received Tenofovir and 4 (3 HBsAg- and 1 HBsAg+ with very low HBVDNA level) received Lamivudine. Pts with low HBVDNA level could receive the planned antiNHL tx immediately. For pts with high HBVDNA level antiNHL R-tx was started when DNA levels dropped to less than 1000 U/ml, while CT, if required, was administered independently from HBVDNA levels and presence of clinical hepatitis. All pts could receive the planned antiNHL tx, including R administration (median interval from antiviral tx to 1st R dose 1 month, range 0-49). During and after R-tx HBVDNA levels were persistently below 100 U/ml and no HBV reactivation was observed. Three pts died of progressive disease, 3 pts could stop antiviral tx with no need for further antiNHL tx, 6 pts still receive antiviral tx (including 1 pt allotransplanted in June 2011) The mean time of antiviral tx was 25.6 months (range 6-70).
Summary and Conclusions: Our experience suggests that NHL pts with active HBV infection can safely receive R in addiction to chemotherapy, provided that close clinical monitoring and appropriate antiviral tx are ensured. The risk of HBV reactivation should not justify R withdrawal, considering the well established efficacy of the drug in this setting. Prospective trials, especially in endemic areas, could confirm this preliminary data and define optimal antiviral tx characteristics.

P575

A RETROSPECTIVE ANALYSIS OF CYTOMEGALOVIRUS DISEASE IN PATIENTS WITH MALIGNANT LYMPHOMAS WHO HAVE NOT RECEIVED HEMATOPOIETIC STEM CELL TRANSPLANTATION

K Sato[1,*] S Ito[1], T Hosoki[1]
[1]Department of Hematology/Oncology, Asahikawa Kosei Hospital, Asahikawa, Japan

Background: With the widespread use of immunosuppressive treatments, such as rituximab, for elderly patients with malignant lymphoma (ML), fatal cases of cytomegalovirus disease (CMVD) have recently been reported even in ML patients who have not received hematopoietic stem cell transplantation (HSCT). It is well known that HSCT is a risk factor (RF) for the development of CMVD in patients with ML. However, the clinical aspects, such as the incidence or risk RFs for CMVD in ML who have not received HSCT have not been fully clarified.
Aims: To access the clinical background and RFs of the CMVD in patients with ML not receiving HSCT, we performed a retrospective clinical analysis.
Methods: We reviewed all of the ML patients treated in our department from April 2005 to March 2013, and recorded 236 patients (B-cell ML: T/NK-cell ML: Hodgkin's lymphoma=195: 25: 16) who did not receive HSCT, and analyzed the patients with CMVD for their clinical characteristics, overall survival (OS), and RFs for CMVD. CMVD was defined as evidence of CMV by CMV antigenemia or in tissue specimens, associated with clinical symptoms and signs. The OS was estimated using the Kaplan-Meier method and the data were compared by a log-rank test. The RFs for CMVD were evaluated either in a univariate analysis by the chi-squared test, or in a multivariate analysis by the Cox proportional hazards model.
Results: CMVD developed in 5.5% (13/236) of all the ML patients, which included eight males and five females with a median age of 64 years (range, 42–85). The patients included seven cases of B-cell ML and five of T-cell ML. About half (54%; 7/13) of the patients received a steroid pretreatment before the primary treatment (PT) for ML, 62% (8/13) received more than two therapeutic regimens for ML. Twelve (92%) of the patients received anti-CMV treatments. The majority (92%; 12/13 cases) of the patients with CMVD were died. The OS curve in patients with CMVD was significantly worse than that of the patients without CMVD (three-year-OS: 10% *versus* 76%, p<0.0001 by logrank test). The RFs associated with CMVD identified by the univariate analysis were the presence of B-symptoms (p=0.0015), a poor performance status (p=0.0228), a high CRP level (p=0.0001), serum albumin <3.5g/dl (p=0.0003), steroid pretreatment before the PT for ML (p<0.0001), more than two therapeutic regimens for ML (p=0.0070), a diagnosis of T-cell lymphoma (p=0.0008), non-complete remission (p=0.0155). The use of rituximab was not a significant RF for CMVD. In the multivariate analysis, two independent RFs for CMVD, steroid pretreatment before PT for ML (hazard ratio; HR=4.801, p=0.0440), and more than two therapeutic regimens for ML (HR=9.957, p=0.0016), were identified.
Summary and Conclusions: The prognosis of the patients with ML not receiving HSCT who developed CMVD was poor. Attention should be paid to the development of CMVD for the ML patients who have not received HSCT pretreated with steroids or with multiple therapeutic regimens.

P576

TANDEM AUTOLOGOUS STEM CELL TRANSPLANTATION DOESN'T INCREASE THE RISK OF SYMPTOMATIC CYTOMEGALOVIRUS REACTIVATION IN MYELOMA PATIENTS IN THE ERA OF NOVEL AGENTS: A SINGLE INSTITUTION STUDY

F Marchesi[1,*] F Pimpinelli[2], M L Dessanti[1], S Gumenyuk[1], F Palombi[1], F Pisani[1], A Romano[1], A Spadea[1], M Marchio[3], F Ensoli[2], A Mengarelli[1]
[1]Hematology And Stem Cell Transplantation, Regina Elena National Cancer Institute, [2]Molecular Virology, Pathology And Microbiology Laboratory, San Gallicano Dermatological Institute, [3]Regina Elena National Cancer Institute, Rome, Italy

Background: The introduction of proteasome inhibitors and/or immunomodulators in the treatment of myeloma patients has led up to an increase of viral infections by Herpesviridae family. However, few data about the risk of Cytomegalovirus (CMV) reactivation after autologous stem cell transplantation (ASCT) in the era of novel chemotherapeutics are so far published, and it is doubtful whether receipt of tandem transplantation correlates with higher rates of reactivation.

Aims: To address these questions we performed a retrospective chart review single-center study on 78 consecutive multiple myeloma (MM) patients who underwent a tandem non CD34+-selected ASCT.
Methods: From January 2003 to December 2013, a total of 78 consecutive adult patients with a diagnosis of MM (median age at diagnosis 56 years, range 37-69) underwent a non CD34+-selected tandem ASCT following a conditioning regimen Melphalan alone-based at Hematology and Stem Cell Transplantation Unit of Regina Elena National Cancer Institute of Rome. Out of these 78 patients, 42 underwent a tandem ASCT after induction treatment with conventional VAD (Vincristine, Doxorubicin and Dexamethasone; from January 2003 to December 2008), whereas the remaining 36 after treatment with novel agents (Bortezomib-based regimes, n=28, Immunomodulators plus Dexamethasone, n=8; from January 2008 to December 2013). Therefore, a total of 156 procedures of ASCT in 78 myeloma adult patients were included in this analysis. CMV DNAemia by PCR was only tested on clinical suspicion of reactivation and no routine monitoring was adopted. CMV symptomatic infection and end-organ disease were defined according to published criteria.
Results: Overall, we observed 13 episodes of symptomatic reactivation (13/156, 8.3%), in 12 patients (12/78, 15.4%), all successfully treated. No case of end-organ disease or primary infection was documented. Eight patients experienced a CMV reactivation after first ASCT (8/78, 10.2%), of which only one resulted symptomatic also after second transplant. On the other hand, we found a CMV reactivation after second transplant in 4 out of 70 patients (5.7%) who didn't experienced a reactivation after first ASCT. No statistically significant difference was observed between first and second ASCT (8/78, 10.2% *vs.* 5/78, 6.4%; P=0.767). Univariate analysis showed that a pre-transplant treatment with novel agents was the only baseline factor significantly associated with the occurrence of post-ASCT CMV symptomatic reactivation after first [Odds Ratio: 9.897 (95%CI: 1.154-84.840); P=0.021] but not second transplant [Odds Ratio: 5.125 (95%CI: 0.546-48.119); P=0.115].
Summary and Conclusions: Our data suggest that second transplantation doesn't increase the risk of CMV reactivation when compared with the first one and confirm the role of a pre-transplant treatment with novel agents as risk factor for CMV symptomatic reactivation.

P577

IMPACT OF NOSOCOMIAL VIRAL INFECTION IN CHILDREN UNDERGOING INTENSIVE CHEMOTHERAPY OR STEM CELL TRANSPLANTATION FOR HEMATOLOGIC OR MALIGNANT DISEASE
E Nishikawa[1,*] H Yagasaki[1], M Hirai[1], K Shimozawa[1], S Takahashi[1]
[1]Pediatrics, Nihon University, Tokyo, Japan

Background: Community-acquired virus infections by pathogens including influenza virus, parainfluenza virus (PIV), respiratory syncytial virus (RSV), human metapneumovirus (hMPV), norovirus, and rotavirus are self-limiting in nature. These viruses can be transmitted to children receiving treatment by their parents, careworkers, or medical staff. Outbreaks of respiratory and intestinal viral infections were recently reported among patients undergoing chemotherapy or stem cell transplantation (SCT). The incidence of such infections should differ among institutions, but no such data are currently available in Japan.
Aims: To clarify the clinical outcomes and risk factors for the progression to a severe disease in children with nosocomial infection of a community-acquired virus while undergoing chemotherapy or SCT.
Methods: A total of 126 patients (age, 1 day –17 years) who underwent chemotherapy (n=80) or SCT (n=46) between October 2008 and September 2013 were included in this study. Underlying diseases were hematologic malignancy (n=72) and solid tumor (n=54). A direct immunochromatography assay was used to screen influenza, RSV, hMPV, norovirus, and rotavirus antigens, and the shell vial assay was used to screen the PIV antigen. Severe disease in cases of respiratory viral infection was defined as lower respiratory tract infection or disease duration >14 days, while that of intestinal viral infection was defined as dehydration >10% body weight or disease duration >10 days. Supportive care was provided to all patients. Neuraminidase inhibitors were administered to all patients with influenza infection and ribabirin to 8 of 13 patients with RSV infection.
Results: In total, 37 patients were diagnosed with respiratory viral infection (influenza virus, n=13; RSV, n=13; PIV, n=8; and hMPV, n=3). In 12 of these patients, infection progressed to severe disease, including 4 serious complications after RSV or PIV infection; fungal pneumonia (n=3) and multiorgan failure (n=1). In addition, 31 patients were diagnosed with intestinal viral infection (rotavirus, n=10; norovirus, n=21). In 14 of these patients, infection progressed to severe disease, including a fatal complication; sinusoidal obstruction syndrome. Among patients with respiratory viral infection, median age at the time of severe disease (1.5 years) was significantly lower than that at the time of non-severe disease (3 years) (p=0.05). However, duration of neutropenia (absolute neutrophil count <500/uL) and lymphocytopenia (absolute lymphocyte count <200/uL) were not associated with disease severity. In patients with intestinal viral infection, neither age nor duration of neutropenia or lymphocytopenia was associated with disease severity.
Summary and Conclusions: This case series showed that RSV and PIV infections are likely to progress to severe disease in children undergoing intensive chemotherapy or SCT. A significant risk factor for progression with respiratory viral infection was younger age, but not the duration of lymphocytopenia. Because the symptoms of viral enterocolitis mimic those of acute graft-*versus*-host disease (GVHD), the grade of acute GVHD is likely to be overestimated. Therefore, rapid diagnosis and control of nosocomial infection is more important in cases of high-risk transplantation.

P578

CLINICAL CHARACTERISTICS AND OUTCOMES OF RESPIRATORY SYNCYTIAL VIRUS INFECTION IN RECIPIENTS OF ALLOGENEIC STEM CELL TRANSPLANTS
D Gijima[1,*] WJ Hogan[2], MR Litzow[2], DA Gastineau[2], S K Hashmi[2], MM Patnaik[2]
[1]Mayo Medical School, [2]Division of Hematology, Mayo Clinic, Rochester, United States

Background: Respiratory syncytial virus (RSV) is a common cause of respiratory tract infections in pediatric and immunocompromised patients. RSV infections result in significant morbidity and mortality in patients that have undergone allogeneic stem cell transplantation (allo-SCT). In these patients manifestations include; upper and lower respiratory tract infections (URI/LRI), hyperreactive airway disease, acute lung injury (ALI), acute respiratory distress syndrome (ARDS) and in severe cases obliterative bronchiolitis (OB) and chronic oxygen dependancy.
Aims: We carried out this study to document the clinical characteristics, subsequent events and outcomes associated with RSV infections in patients that have undergone allo-SCT.
Methods: After IRB approval, from the years 2006-2013 we identified 47 allo-SCT recipients at the Mayo Clinic, Minnesota that had been diagnosed to have a RSV infection. All demographic, clinical and transplant related data were retrospectively abstracted. RSV infections were diagnosed based on PCR testing of nasopharyngeal swabs. Both pulmonary and transplant related outcomes were analyzed.
Results: Of the 47 study patients, 23 (49%) were male and the median age was 55 years (range, 15-75 years). The median duration between transplant and RSV infection was 230 days (range, 2-1443 days), with 21 (45%) patients being infected at <6 months, 7 (15%) between 6-12 months and 19 (40%) at >12 months after allo-SCT. Seventeen (36%) patients presented with an URI, 16 (34%) with a LRI and 14 (30%) with acute respiratory failure (ALI/ARDS). Three (6%) patients had recurrence of RSV infection and 1 patient had concurrent influenza A infection. Six (13%) patients had experienced influenza A infection at variable time points before their current RSV infection. Of the 47 patients, 28 (60%) required hospitalization and 15 (32%) of these required ICU level care. The median length of hospitalization was 7.5 days (range, 3-46 days). Five (11%) patients did not receive treatment, 20 (43%) were treated with ribavirin only and 21 (45%) received both ribavirin and IVIG. 9 (19%) patients received steroids or an augmentation in their baseline steroid dosage to prevent RSV related sequelae. 17 (36%) patients required some form of respiratory support (7 nasal cannula, 2 BIPAP, 1 CPAP and 7 intubation with mechanical ventilation). DLCO and FEV1 measurements available from pretransplant testing, or at least 4 weeks before RSV infection were compared to values measured at least 4 weeks after resolution of infection. The median change in DLCO was -8% (range, -34 to 14%). The median change in FEV1 was -8% (range, -49 to 12%). 13 patients had no reduction in DLCO, 13 had a reduction of >5% and 3 a reduction of >25%. Ten patients had no reduction in FEV1, 16 a reduction of >5% and 4 a reduction of >25%. Of those with at least a 5% drop in FEV1, 40% were clinically attributed to the development of OB. Ten (21%) patients were diagnosed to have OB, with 7 of these also having concurrent systemic GVHD. At last follow up, 26 (55%) patients had developed chronic GVHD (8 mild, 9 moderate and 9 severe) and 11 (24%) patients had relapsed at some point after transplant. At last follow up, 13 (28%) patients had died.
Summary and Conclusions: RSV infections in allo-SCT recipients are associated with significant morbidity and mortality. In our single center study, approximately a third of patients experienced a chronic drop in FEV1/DLCO after infection and 20% developed obliterative bronchiolitis resulting in chronic oxygen dependancy. Preventive strategies, including the development of a RSV vaccine, are an absolute need.

P579

THE CLINICAL SPECTRUM AND OUTCOMES OF HUMAN HERPESVIRUS 6-RELATED INFECTIONS AFTER ALLOGENEIC HEMATOPOIETIC STEM CELL TRANSPLANTATION
L Hegerova[1,*] M Patnaik[1], W Hogan[1], M Litzow[1], S Hashmi[1]
[1]Hematology, Mayo Clinic, Rochester, United States

Background: Human herpesvirus-6 (HHV-6) infection/reactivation is an important cause of morbidity and mortality, in patients that have undergone allogeneic hematopoietic stem cell transplantation (HSCT). HHV-6 infection can be associated with fevers, engraftment failure, bone marrow suppression, skin rashes, focal and diffuse neurological manifestations. The interpretation of HHV-6 viremia and its association with disease remains problematic as most

adults are latently infected with the virus. Thus, detection of HHV-6, can represent asymptomatic reactivation, chromosomal integration or a true infection. Latency is usually characterized by a very low copy number only detected by high-sensitivity PCR, while viral loads in chromosomally integrated HHV-6 are usually >1 million copies per mL.
Aims: We carried out this study, to define the incidence, morbidity, mortality and transplant related outcomes associated with HHV-6 infection/reactivation in patients that have undergone allogeneic HSCT.
Methods: After due IRB approval, we retrospectively identified 119 allogeneic HSCT patients that had HHV-6 testing (Q-PCR) done at the Mayo Clinic, Minnesota, from 2008-2013. Data collected included baseline demographics, clinical, radiologic and pathologic features and related outcomes.
Results: Of 750 allogeneic HSCT performed, 13 (2%) patients were detected to have HHV-6 viremia.. Median age at time of transplant was 54 years (range, 25 to 65 yr) and 7 (54%) were male.The most common indications for HHV-6 testing were cytopenias (27%), neurological alterations (22%), and neutropenic fevers (17%). In these patients, median time to first detection of HHV-6 was 24 days (range, 11 to 433 days) post-transplant and plasma or cerebrospinal fluid (CSF) levels ranged from <500 to 147,000 copies/mL. One patient had suspected chromosomal integration given copy number >2 million. HHV-6 disease included 5 patients with encephalitis (38%) [Table 1], 5 with neutropenic fevers (38%), and 1 with delayed engraftment (8%).. Four of the 5 patients with encephalitis had detectable HHV-6 DNA in the CSF. Eight (62%) patients had concurrent grade 2-4 acute GVHD, while 6 (46%) had concurrent CMV reactivation. All patients had regression of clinical symptoms or decrease in viral load after antiviral therapy (6 with ganciclovir and 1 with foscarnet). The median duration of therapy was 20 days (range, 14 to 46 days). 46% of patients recieved ganciclovir while 8% recieved foscarnet as first line treatment. The median survival post-allogeneic HSCT in patients with HHV-6 viremia was 12 months (range, 2 to 30) compared to 55 months in those that tested negative (range, 1 to 124, log rank test p=0.02).

Table 1.

Summary and Conclusions: The present study further elucidates the natural history of HHV-6 infection after allogeneic HSCT. Neurological manifestations, especially encephalitis, neutropenic fevers and unexplained cytopenias are common manifestations. Ganciclovir and Foscarnet are relatively effective therapies for symptomatic patients.

P580

ANALYSIS OF PNEUMONIA IN ACUTE LEUKEMIA: A PROSPECTIVE STUDY BY THE "RETE EMATOLOGICA LOMBARDA" (REL)

V Mancini[1,*] C Cattaneo[2], L Verga[3], P Zappasodi[4], C Annaloro[5], T Elisabetta[6], F Pavesi[7], V Saccà[8], A Ferrario[9], G Rossi[10], A Nosari[11]

Niguarda Cà Granda, Milano, Italy

Background: Pneumonia is a major cause of morbidity and mortality among patients (pts) with hematological malignancies who receive cytotoxic chemotherapy.
Aims: In order to develop a rationale policy for the prevention and management of this significant complication, we analyzed characteristics of pneumonia in acute leukaemia (AL) pts referring to 9 haematological institutions participating to REL.
Methods: We prospectively recorded 515 febrile/infectious episodes encountered during hospitalization of 299 adult AL pts, median age 56 years (18-89 y), admitted in 9 haematological centres of Lombardia (period Dec. 2012 – Jan. 2014). We analyzed etiology, microbiologic spectrum, clinical characteristics and outcome in pts with reported pulmonary infection.
Results: Clinical/radiological findings of pneumonia were found in 128/515(24%) febrile cases: 21(16%) in acute lymphoblastic leukemia and 107(84%) in acute myeloid leukemia pts, mainly with active disease (58 *de novo*/33 resistant AL); in 27 cases pneumonia occurred during the consolidation phase. The majority of pts (107) were neutropenic (median duration 22 days range 2-170): a prophylaxis regimen with fluoroquinolone and antifungals was adopted, in 55/128(42%) and 84/128(65%) of cases respectively. In 70/128(54%) episodes of pneumonia, one/more identifiable microbiological agents were detected, isolated from different sites (62 blood, 20 lung, 5 nasal secretion), by cultures, histology or serological methods. Isolates were mainly bacterial (70/88), while a fungal etiology was microbiologically established in 13/88 cases, so divided: 40 gram+ve (45%), 30 gram-ve (34%), 13 moulds (15%>12 Aspergillus, 1 Fusarium); viral agents were 5 (6%); 23 episodes were polymicrobic (8 cases of fungal and bacterial infection together). Coagulase-negative Staphylococci were the most frequent gram+ve (17/40); S. aureus, Streptococci and Enterococci accounted for 4/40, 5/40, 9/40; Pneumococcus was isolated in 2/40 episodes; methicillin-resistant strains accounted for 14/21 of all staphylococci; vancomicin-resistant for 1/9 of Enterococci. Among gram-ve, 15/30 were Enterobacteriaceae (2 ESBL+ strains, 1 multi-resistance Klebsiella); 10/30 were Xanthomonadales and Pseudomonadales (4 multiresistant strains). According to EORTC guidelines pulmonary infiltrates were classified as specific (42%) *vs* aspecific (88/128,68%), depending on the presence of radiological evidence of fungal infections (IFI). We documented 36 possible/14 probable/2 proven IFI. Thirty-day overall mortality was 19/128 (15%) of cases: deaths were more frequent in patients with pneumonia and microbiological documentation of infection (14/19) but, at univariate analysis, etiology (fungal *vs* bacterial) did not retain a prognostic significance. Anyway in the entire population a febrile episode concomitant with pneumonia significantly correlates with the risk of death (OR 8.85 p<0.00001). Among IFI, deaths were more frequent if "probable" (6/19 - p 0.02); at multivariate analisys resistant leukaemia is the only variable that correlates with the risk of death (OR 3.6, p 0.018).
Summary and Conclusions: Pneumonia remains an important determinant of in AL pts, mainly in those with active disease. Up-to-date check of epidemiology and antibacterial resistance patterns in each institution are needed in order to treat these lifethreatening complications effectively.

P581

INFECTIONS IN ACUTE MYELOID LEUKEMIA AND MYELODYSPLASTIC SYNDROME ON TREATMENT WITH AZACYTIDINE: EXPERIENCE OF A SINGLE CENTER

C de Bonis[1], S Lakhwani[1,*] A Martín[1], B González[1], S Iraheta[1], MT Hernández[1], L Hernández-Nieto[1], JM Raya[1]
[1]Hematology, Hospital Universitario de Canarias, Santa Cruz de Tenerife, Spain

Background: Infection is an important cause of morbidity and mortality in patients with acute myeloid leukemia (AML) and myelodysplastic syndrome (MDS). In recent years, the hypomethilating agents (HMA) have become the main therapeutic alternative to intensive chemotherapy (IC) in these patients, even in those with relapsed or refractory disease. The characteristics of infection when HMA are used have not been widely described.
Aims: To describe the incidence and pattern of infectious episodes (IE) and analyze what features of the patient or the disease may be associated with a higher incidence of infections in AML and MDS patients treated with HMA.
Methods: We retrospectively studied 50 patients with MDS or AML who have received at least 2 cycles of 5-azacytidine (AZA) at our institution. Disease, treatment and IE characteristics were recorded and subsequently we analyzed which variables may be associated with them.
Results: We studied 50 patients (mean age 69-years old, range 29-84, male 52%) of which 19 patients (38%) were affected of AML and 31 (62%) of MDS (23 high-risk MDS and 8 low-risk MDS). Average Sorror comorbidity index (SCI) score was 2.8 and 13 patient (12 AML and one high-risk MDS) had previously received IC. Severe neutropenia (<500/mm^3) was present in 43 patients (86%) before or during AZA treatment and 31 of these patients (72%) received antimicrobial prophylaxis during the period of neutropenia. We recorded a total of 85 IE in 36 patients (72%) and the main features of this group were as follows: 1) IE mainly occurred during the first 4 courses of AZA (51%, n=43), being less frequent after them (see Figure 1); 2) Hospitalization was necessary in 34 patients (94%) for one or more episodes; 3) They had received a median of 9 cycles of AZA, and suffered an average of one IE every four courses of AZA; 4) Microbiological isolation was achieved in 45% of IE, involving 25 patients, and in most cases by blood culture; and 5) Severe IE (associated with respiratory failure or hemodynamic instability) were observed in 19 patients (53%). Of the total 50 patients analyzed, 35 were deceased at the time of closing this study, and 18 of them (51%) have died from infectious causes. In our statistical analysis we have found that the risk of infection is associated with a higher score for SCI (p=0,023), and the risk of severe infection with higher scores for SCI (p=0,029), IPSS (p=0,039) and IPSS-R (p=0,034). Both IPSS and IPSS-R are also associated with active infection at the time of dying (p=0,042 and p=0,047 respectively). Severe neutropenia, age or previous IC, were not associated with the risk of infection. Antimicrobial prophylaxis in neutropenic patients is significantly associated with less number of IE (p=0,036), but not with the severity of the episode or death of infectious origin. Finally, we have found that patients who develop severe IE have shorter overall survival (p=0,024).

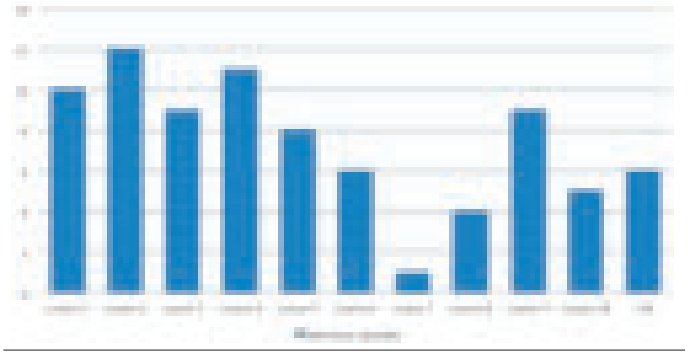

Figure 1. Incidence of infectious episodes on each course of AZA.

Summary and Conclusions: In patients receiving AZA, severe infections (those with respiratory failure or hemodynamic instability) are associated with shorter overall survival. Greater comorbidity and a worse prognostic index were also associated with a higher risk of severe infection. Although antimicrobial prophylaxis seems to decrease the number of total IE, it has not effect on either the severity or the possibility of dying. Studies including a larger number of patients, preferably prospective, are needed to confirm these findings.

P582

ASSESSMENT OF INFECTION EVENTS IN AZACITIDINE (AZA) TREATMENT FOR MYELODYSPLASTIC SYNDROME (MDS) AND ACUTE MYELOID LEUKEMIA (AML). A SINGLE CENTRE EXPERIENCE.

P Romero[1,*] J B Borras[1], F Serra[1], M Nigorra[2], R Del Campo[1], A Cladera[1], I Vazquez[1], M Mascaro[1], E Gonzalez[1], JM Guerra[1], D Gomez[1], J Bargay[1]
[1]Hematology, [2]Pharmacy, Hospital Son Llàtzer, Palma de Mallorca, Spain

Background: Infection is a major source of morbidity and mortality in patients with hematological diagnosis of myelodysplastic syndrome (MDS) and acute myeloid leukemia (AML). 5-azacytidine (AZA), is an alternative treatment in patients not candidates for intensive chemotherapy. Clinical and microbiological features of infections in patients AZA treated are not well known.
Aims: To investigate the impact and features of infective episodes on patients who received AZA in a daily clinical practice at our institution.
Methods: We conducted this analysis on patients who received AZA (75mg/m^{2}x7days subcutaneous/ intravenous/28days as induction and 75mg/m^{2}x5days/28days as maintenance) between January 2007 and December 2013 at our institution for MDS or AML. We used SPSS v.19 © statistics for descriptive statistical analysis(c^{2}test to determine statistical relationships between main variables) and Kaplan-Meier for survival analysis. Patients were included if they had received at least one cycle of AZA.

Table 1.

		Infectious event		
		1st(N= 34)	2nd (N= 19)	3rd (N= 12)
Neutrophils median (x10^9/L)*		0.400 (0-46.9)	0.200 (0-14.0)	0.55 (0-4.6)
Hospital admission	Yes	29 (85.3%)	18 (90%)	9 (75%)
	No	5 (14.7%)	2 (10%)	3 (25%)
Hospitalization, median	(days)	8 (1-97)	7 (4-97)	10 (4-97)
Death by infection		4 (11.8%)	2 (10%)	3 (27.3%)
Disease status		1 DP,3 NA	1 DP, 1 NA	1R, 1 DP, 1 NA
Infectious source	Sepsis	2 (5.9%)	4 (20%)	3 (25%)
	Pneumonia	12 (35.3%)	7 (35%)	3 (25%)
	Urinary	3 (8.8%)	2 (10%)	2 (16.7%)
	Gastrointestinal	1 (2.9%)	1 (5%)	1 (8.3%)
	Febrile syndrome	16 (47.1%)	6 (30%)	3 (25%)
Infectious type	Bacterial	10 (30.3%)	9 (45%)	7 (58.3%)
	Viral	2 (6.1%)	2 (10%)	1 (8.3%)
	Fungal	2 (6.1%)	-	-
	Not document	19 (57.6%)	9 (45%)	4 (33.3%)
Disease status at infection time	CR	3 (9.4%)	2 (10.5%)	1 (9.1%)
	PR	1 (3.1%)	3 (15.8%)	1 (9.1%)
	SD	1 (3.1%)	3 (15.8%)	2 (18.2%)
	NA	23 (71.9%)	5 (26.3)	1 (9.1%)
	R	1 (3.1%)	1 (5.3%)	3 (27.3%)
	DP	3 (9.4%)	5 (26.3)	3 (27.3%)

**Neutrophil baseline median value: 0,9 (0.0-47);Complete response (CR);Partial response (PR);Stable Disease (SD);Not available (NA);Relapse (R);Disease progression (DP).*

Results: We studied 59 patients with a median age of 73 years (33-86 y); 36 were male (61%) and 23 female (39%). 24 MDS (39%) and 35 AML (61%);IPSS:1 low risk (1.7%),6 intermediate-1(10.2%),7 intermediate-2(11.9%) and 10 high risk(16.9%). SORROR (HCT-CI): 44 <3 (76.4%), 15 ≥3 (25.4%). Total AZA cycles were 537 (1-34. Median: 6 cycles).At the time of analysis, 49 (83.1%) patients were dead. Overall Survival (OS) was 17.1 months (IC95%: 12.58-21.62) with a median follow up of 14.5 months. Patient with infectious events were 34 (57.6%) and total infections events 73 (13 patients had 1 infection; 8 patients had 2 infections; 8 patients 3 infections; 5 patients ≥4 infections). Among patients with 3 infectious events, 51(80.95%) infections took place before cycle 6 and 14(19.05%) after cycle 6. Time to the first infection was 50.5 days.Infections were found in 12 MDS patients (35.3%) and 22 AML patients (64.7%). OS no Infection *vs.* infection was 19.47 months (IC 95%: 9.17-29.77) *vs.* 15.78 months(IC 95%:5.95-25.62)(p=0.148);The infection rate per 1000 AZA cycles was 135.94‰ and death rate due to infection per 1000 AZA cycles was 13.03 ‰. There was heterogeneity of isolated microorganisms at infection (1 catheter infection by *Enterobacter faecalis)* (Table 1).
Summary and Conclusions: Results show a high infectious rate, probably related to baseline neutropenia more than related to AZA treatment because there are no statistical differences in terms of OS(p=0.148). None of the patients who died by infection were at CR, PR or SD. Most patients were infected during the first 6 cycles of AZA regardless hematologic disease (*p=0.499*).

P583

PREDICTORS OF G-CSF PROPHYLAXIS IN THE FIRST CYCLE OF CHEMOTHERAPY FOR FEBRILE NEUTROPENIA IN PATIENTS WITH NON-HODGKIN'S LYMPHOMA

P Lugtenburg[1], J Asubonteng[2], L DeCosta[3], Z Szabo[4], J H Page[5], S Wetten[3,*]
[1]Erasmus Mc Cancer Institute, Rotterdam, Netherlands, [2]University of Pittsburgh, Pittsburgh, United States, [3]Amgen Ltd., London, United Kingdom, [4]Amgen, Zug, Switzerland, [5]Amgen, Thousand Oaks, United States

Background: International guidelines recommend primary prophylaxis with granulocyte-colony stimulating factors (G-CSFs) for patients who are assessed to be at high (≥20%) risk of experiencing febrile neutropenia (FN), to support treatment with myelosuppressive chemotherapy. However, G-CSF use varies widely in clinical practice even in high risk patients. There have been several publications investigating predictors of FN but limited study of predictors of G-CSF prophylaxis.
Aims: The main objective of this analysis was to identify predictors of G-CSF prophylaxis in the first cycle of chemotherapy in order to improve our understanding of the relationship between G-CSF use and FN in Non-Hodgkin's Lymphoma (NHL) patients.
Methods: This is a post-hoc analysis of data from IMPACT NHL, an observational, cohort study. The analysis was performed on the subset of prospectively enrolled adults with any histological type of NHL treated with (R)-CHOP. The relationship between baseline patient characteristics and G-CSF prophylaxis in the first cycle of chemotherapy was examined using bivariable and multivariable logistic regression models. The multivariable models were adjusted for age, gender, country, performance status, histology and regimen type.
Results: A total of 1187 patients were included in the analysis, of whom 49% received G-CSF prophylaxis in the first cycle. In bivariable regression, factors significantly associated with G-CSF prophylaxis included older age, country, no bone marrow involvement, dose-dense regimen, investigator assessed high FN risk, DLBCL histology, poor ECOG performance status, higher number of planned cycles and chemotherapy dose, lower serum albumin, lower haemoglobin and lower glucose, higher AST, higher CRP and higher LDH. In adjusted multivariable regression, investigator-assessed high FN risk (OR 2.9, 95% CI 2.14-3.96), lower glucose (<8.8mmol/L) (OR 1.7, 95%CI 1.02-2.75), lower ANC (<3x10^9/L) (OR 1.3, 95%CI 1.10-1.99), and increased LDH (>400 U/L) (OR 1.4, 95% CI 1.01-1.91) were associated with use of G-CSF prophylaxis.
Summary and Conclusions: In addition to well known risk factors for FN, the analysis provides evidence for less considered factors such as country, glucose and LDH to be associated with G-CSF prophylaxis in the first cycle of NHL patients receiving (R)-CHOP. These factors should be considered for future studies and when interpreting studies of G-CSF prophylaxis and patient selection in clinical practice.

P584

ADMISSION OF PATIENTS WITH HEMATOLOGIC MALIGNANCES TO INTENSIVE CARE UNITS

M Badior[1,*] I Carvalhais[1], A Carneiro[1], F Príncipe[1], T Honrado[2], JE Guimarães[1]
[1]Hematology, [2]Intensive Care Unit, Centro Hospitalar de São João, Porto, Portugal

Background: Over the past years, improvements in supportive care measures, as well as new diagnostic and therapeutic tools, have improved the survival of patients with hematologic malignancies. Despite all improvements, this group of

patients is at a high risk of becoming critically ill during chemotherapy treatment and may need admission in an Intensive Care Unit (ICU). It is nowadays clear that these patients will benefit from ICU admission, however there is still some discussion about which are the patients that will really benefit from this admission.
Aims: To evaluate the outcome of critically ill patients with hematologic malignancies admitted to ICU and try to correlate prognostic factors with survival.
Methods: Retrospective analysis of all critically ill patients with hematologic malignancies admitted to ICU between 01 of July 2009 to 30 of June 2012. We then evaluated clinical and demographic data and tried to identify clinically useful prognostic factors.
Results: We evaluated 65 admissions in ICU. 43.1% were males with a median age of 56 years (22-78). The most frequent hematologic diagnosis was AML/high risk MDS in 63.1%, indolent lymphoma in 13.8%, aggressive lymphoma in 10.8%, multiple myeloma in 7.7% and chronic leukemia in 4.6%. At the time of admission in ICU, 55.4% were at their first approach to the hematologic disease, 35.4% were with progressive disease or relapse, 4.6% in complete remission and 4.6% after autologous stem cell transplant. The most frequent reason for ICU admission was acute respiratory failure (61.5%), septic shock with multiple organ failure (23.1%) and neurologic dysfunction (15.4%). 16.9% were admitted directly to ICU from the Emergency Department; 49.2% were neutropenic at time of admission to ICU. Only 57.4% of the patients that were referred from an hematologic unit had microbiology isolations; 91% were receiving broad spectrum antibiotics and 24% antifungal therapy. At ICU 84.6% needed invasive mechanical ventilation, 76.9% vasoactive support and 36.9% renal replacement therapy. The median number of days in ICU was 9. The survival to ICU was 41.5% and from these, 81.5% were discharged from the hospital. In univariate analysis only the need for invasive mechanical ventilation and vasoactive support had a negative influence in survival, and this keeps statistically significance in multivariate analysis. In our cohort, the days of neutropenia, the hematologic diagnosis and the state of the disease at ICU admission have not influenced the outcome of the patients.
Summary and Conclusions: In our cohort of patients we could not find any variable related to the disease with influence in the outcome, but only variables related to the severity of the acute episode. There was no clinical feature or combination of features that could reliably predict a better outcome or even treatment futility. We were lead to assume that the most important strategy to try to improve the outcome of these patients is early admission to ICU in a stage in which organ failure is still minimal or restricted.

Background: There has been to no nationwide survey on chemotherapy-induced nausea and vomiting (CINV) and validation of the guideline made after introduction of NK-1 receptor antagonist to the Japanese market.
Aims: The aim of the study is to investigate occurrence of CINV in hematologic malignancy patients(pts) who are to receive chemotherapy for the first time, and primary care medical staff's perception on CINV for their pts.
Methods: A nationwide survey on CINV was conducted by the CINV Study Group of Japan. Sixteen institutions participated in the study which was approved by the review board. The written consent was obtained from the pts. A 7-day diary for CINV was provided to the patient prior to moderately emetic chemotherapy (MEC) and highly emetic chemotherapy (HEC) to record daily occurrence and severity of CINV and an amount of food intake. Acute and delayed CINV was defined as nausea and vomiting which developed within or after 24 hours after the start of chemotherapy, respectively. The medical staff's also filled out questionnaires of estimating their pts' CINV.
Results: A total of 203 pts were registered from May 2011 to November 2012. The number of patient's diary paired with their staff's report was 196 after pts received HEC or MEC. Underlying diseases were leukemia (38pts), multiple myeloma (11pts), Hodgkin's lymphoma (8pts), and Non Hodgkin's lymphoma(139pts). There were 108 males with a median age of 61 (range: 22-87) and 88 females with a median age of 62.5 (range: 22-87). MEC was given to 19 pts, HEC was given to 177 pts. Acute vomiting was noted in 0 pts (0.0%) with MEC as was in 8 pts (4.5%) with HEC, while delayed vomiting was experienced in 2 pts (10.5%) with MEC and 16 pts (9.0%) with HEC, respectively. Acute nausea was noted in 2 pts (10.5%) with MEC and in 34 pts (19.2%) with HEC, while delayed nausea was experienced in 4 pts (21.1%) with MEC and in 70 pts (39.5%) with HEC, respectively.
The staff estimations' positive predictive value were 14.3% in acute CINV, 25.0% in delayed CINV, respectively. Their negative predictive value were 19.9% in acute CINV, 19.4% in delayed CINV, respectively. Risk factors for acute nausea, acute vomiting, delayed nausea, and delayed vomiting were assessed separately. In acute nausea, multivariate analysis showed risk factors as female gender (Odds ratio 3.178; 95%CI 1.410-7.164; p=0.0053), younger age (Odds ratio 0.6244 (every ten years); 95%CI 0.4737-0.8339; p=0.0013), and increased concentration of hemoglobin (Odds ratio 1.226 (every 1.0 g/dl); 95%CI 1.005-1.496; p=0.0449). In delayed nausea, multivariate analysis showed a risk factor as female gender (Odds ratio 2.209; 95%CI 1.222-3.991; p=0.0087). A combination of 3 anti-emetics (5HT3 receptor antagonist, steroid (prednisolone or dexamethasone), and NK-1 receptor antagonist) was given along the guideline to 26.3% of the pts with MEC and 22.6% of those with HEC. However, 147 pts were received an intermediate- or high-dose steroid for 5 days or more. Two anti-emetics (5HT3 receptor antagonist and steroid) was not risk factor *versus* 3 anti-emetics in multivariate analysis (Table 1).

Table 1.

Summary and Conclusions: Antiemetic use by the Japanese hematologists for hematologic malignancies was not in accordance with the Japanese guideline. It appears that nausea was not still well under control, although vomiting was rarely experienced even in HEC. Further study is especially needed to prevent delayed nausea. It is of interest that Japanese medical staff has overestimated the incidence of CINV.

P586

PROPHYLAXIS WITH FEBUXOSTAT IN COMPARISON TO ALLOPURINOL REDUCES EXPOSURE TO URIC ACID IN PATIENTS AT INTERMEDIATE TO HIGH RISK OF TUMOR LYSIS SYNDROME: RESULTS OF THE FLORENCE STUDY

Background: The risk of tumor lysis syndrome (TLS) and renal events increases by 1.75 and 2.21 fold respectively for every mg/dl increase of serum uric acid (sUA)[1], thus a better control of sUA exposure during chemotherapy (CT) is beneficial for patients.

Aims: To compare Febuxostat with Allopurinol in terms of sUA exposure control and renal function impairment prevention in patients undergoing CT for hematologic malignancies at intermediate to high risk of TLS (as per TLS expert panel risk stratification[2])
Methods: This was a double-blind randomized controlled trial. 346 patients providing written informed consent were stratified according to TLS risk (intermediate *vs* high) and sUA level (≤7.5 mg/dl *vs* >7.5 mg/dl) and randomized in a 1:1 ratio to receive either Febuxostat or Allopurinol for 7-9 days starting from 2 days prior CT. Dose level was upon investigator's choice among low, standard and high containing either Allopurinol 200, 300 and 600 mg daily or fixed Febuxostat 120 mg daily. Primary endpoints were sUA area under the curve (AUC sUA_{1-8}) and change in serum creatinine level from baseline to Day 8. Secondary endpoints were response rate (sUA ≤7.5 mg/dL from the start of CT to Day 8), incidence of laboratory and clinical TLS and safety. The study was performed in 79 sites in Europe and Brazil (NCT01724528).
Results: Baseline demography was similar in both groups. In Febuxostat arm there was a slightly higher number of acute leukemias (n=34 *vs* 25) and lymphomas (n=59 *vs* 54) and a slightly lower number of chronic lymphoid leukemias (n=80 *vs* 94). The majority of patients were at intermediate risk of TLS (82.1%, n=284), had a baseline sUA ≤7.5 mg/dl (87.6%, n=303) and received standard dose therapy (82.7%, n=286). Mean AUC sUA_{1-8} was significantly lower in the Febuxostat arm (514.0±225.71 mgxh/dl *vs* 708.0±234.42 mgxh/dl, p <.0001). There were no significant differences between the Febuxostat and Allopurinol arms in mean change in serum creatinine (-0.83±26.98% *vs* -4.92±16.70%, p=0.0903) nor in secondary efficacy endpoints. Incidence of all adverse events (AEs) and related AEs was 67.6% and 6.4% *vs* 64.7% and 6.4% in the Febuxostat and Allopurinol arms respectively.
Summary and Conclusions: This is the largest trial every performed comparing different TLS prevention methods. Febuxostat showed a significant 28% higher reduction of exposure to sUA during CT over Allopurinol with comparable renal function impairment prevention and safety profile. These results suggest that prophylaxis with Febuxostat may further reduce the risk of TLS development in patients with hematological malignancies at intermediate to high risk of TLS in comparison to Allopurinol.

BUFFY COAT POOLED PLATELETS CRYOPRESERVED IN DIMETHYL-SULPHOXIDE WITH A NEW SYSTEM PRESERVE THEIR *IN VITRO* FUNCTION UP TO 9 MONTHS

M Napolitano[1,*] PS Arfò[2], L Lo Coco[3], G Saccullo[1], G De Francisci[4], A Reina[5], D Allegro[5], R Fadda[6], D Di Liberto[7], S Mancuso[1], R Agliastro[4], F Dieli[7], S Siragusa[1]
[1]Hematology Unit, [2]Research Laboratory, [3]Central Laboratory, university of palermo, [4]Immunohematology and Transfusion Medicine Unit, Ospedale Civico, [5]Promedical Company, [6]CLADIBIOR, university of palermo, [7]CLADIBIOR, palermo, Italy

Background: Cryopreservation of platelets (PLTs) represents a clinical useful method for avoiding platelet shortage.Many studies have tried to define, *in vitro* and *in vivo*, the entity and weight of storage-related PLTs lesions with discordant results related to different methods.
Aims: We have performed an *in vitro* prospective study to evaluate PLTs count, viability and function of buffy coat derived pooled platelet concentrates (BC-PLTs) treated with dimethyl-sulphoxide (DMSO) and cryopreserved at -80°C up to 9 months with an innovative patented system that avoids external manipulations.
Methods: Each BC-PLTs was obtained from 5 buffy coats and pooled according to standard procedures. The final PLTs concentrates were leukoreduced by filtration and transferred to a 650 mL cryopreservation kit (Promedical ®) which allowed mixing with DMSO 25% in a closed system and following removal of supernatant without further manipulations. BC-PLTs were washed prior freezing with removal of at least 84% supernatant solution, suspended in homologous plasma from 1 of the 5 donors to a final concentration of 200 mL and frozen at –80°. BC-PLTs were analyzed immediately pre-freezing (T0) and 3, 6 and 9 months after cryopreservation (CRY BC-PLTs).The following parameters were assayed: PLTs count (PC), mean platelet volume (MPV), pH, flow cytometry (FACS) expression (%) of CD41a, CD42b, CD61a, CD62p, PAC-1, Annexin V PLTs surface antigens and thromboelastography (TEG). CRY BC-PLTs samples were thawed in a bath at 37°C for 5 minutes and evaluated promptly. All the tests were performed according to current European recommendations. PLTs swirl was furthermore visually assessed. Results were expressed as mean +/- standard deviation (SD). Results obtained at T0 and at 3, 6 and 9 months after cryopreservation respectively were analyzed with "Two factor study repeated measure analysis of variance" (ANOVA).
Results: *In vitro* cell parameters were measured on 49 BC-PLTs, 49 CRY BC-PLTs at 3 (T3) and 6 (T6) months and 34 CRY BC-PLT at 9 (T9) months. All the analyzed parameters showed stable values during the cryopreservation period. There were no differences between the groups in PC (1427 +/- 150x109/L at T0 *vs* 1400+/- 170 at T9),CD41a (98.5 +/- 1.94 at T0 *vs* 98.1 +/- 3.07 at T3,98.3 +/- 1.24 at T6 and 97.96 +/- 3.1 at T9), CD62p (59.0 +/- 11.02 at T0,71.1 +/- 14.6 at T3,76.89 +/- 8.65 at T6 and 70.9 +/- 7.4 at T9) and Annexin V expression while a significant reduction in CD 42b (92.7 +/- 4.29 at TO *vs* 23.6 +/- 27.5 at T3, 16.38+/- 12.54 at T6 and 17.3 +/- 9.6 at T9), PAC-1(1.9 +/- 1.34 at T0 *vs* 0.62 +/- 0.4 at T3, 0.63 +/- 0.83 at T6, 0.49 +/- 0.48 at T9) for CRY BC-PLTs was observed after cryoprserevation. TEG parameters were all significantly reduced in CRY BC-PLTs samples(TEG R: 8.3 +/- 2.55 min at T0 *vs* 10.85 +/- 1.6 at T3,11.03+/- 2.69 at T6 and 9.5+/- 1.89 at T9; TEG K:1.6 +/- 0.3 min at T0 *vs* 2.96+/- 1.04 at T3,2.9 +/- 1.3 at T6 and 2.8 +/- 0.6 at T9;TEGα:71.9 +/- 10.7 deg at T0 *vs* 53.4+/- 9.5 at T3,52.11 +/- 13.9 at T6 and 57.6 +/- 11.0 at T9; TEG-MA:70.61 +/- 10 mm at T0 *vs* 62.3+/- 8.79 at T3,62.4 +/- 7.86 at T6 and 60.9 +/- 7.71 at T9) without affecting hemostasis.
Summary and Conclusions: The results of our investigation confirm the potential of a new system to overcome limits to PLTs storage. This method allows cryopreservation of PLTs up to 9 months, as shown by stable *in vitro* function during this period, and avoids apoptosis. Adequate hemostasis achieved at TEG supports the hypothesis that *in vitro* PLTs activation/deterioration doesn't necessarily mirror an impaired hemostatic *in vivo* function of CRY BC-PLTs. The next step of current study will be to evaluate CRY BC- PLTs efficay, recovery and survival *in vivo.*

P588

HEMOSTATIC FUNCTION AND BIOMARKERS OF ENDOTHELIAL DAMAGE BEFORE AND AFTER PLATELET TRANSFUSION IN PATIENTS WITH ACUTE MYELOID LEUKEMIA

AM Larsen[1,*] E B Leinoe[2], P Johansson[3], H Birgens[1], S R Ostrowski[3]
[1]Dep. of Hematology, Copenhagen University Hospital Herlev, Herlev, [2]Dep. of Hematology, [3]Dep. of Immunology, Copenhagen University Hospital Rigshospitalet, Copenhagen, Denmark

Background: Platelet transfusion is a cornerstone of the care in hematologic patients. Though the beneficial effect of platelet transfusion on hemostasis is

well established, there is emerging evidence that platelet transfusion induces an inflammatory response in vascular endothelial cells.
Aims: To investigate functional whole blood hemostasis and circulating levels of endothelial biomarkers before and after platelet transfusion in patients with acute myeloid leukemia (AML), hypothesizing that platelet transfusion would improve hemostasis but also cause a measurable change in endothelial and inflammatory biomarkers.
Methods: Blood were sampled from AML patients immediately before and 1- and 24 hours after platelet transfusion. Remnant samples from the transfused platelet products were also collected. Blood samples from 31 healthy blood donors served as controls. Primary and secondary hemostasis was evaluated by whole blood impedance aggregometry (Multiplate) and thromboelastography (TEG). Samples were analyzed for biomarkers of endothelial activation (sICAM-1), damage (syndecan-1, sThrombomodulin (sTM)) and integrity (sVE-Cadherin) and of platelet activation (sCD40L, TGF-β) by ELISA. Blood counts, standard coagulation tests and HsCRP were measured as routine. Bleeding symptoms on the day of study inclusion were assessed according to the WHO bleeding score (grade 1-4).
Results: 21 patients with AML and 1 patient with high-risk-MDS were included in the study. Median age was 55 years. Pre-transfusion median platelet count increased from 10 10^9/L to 33 and 26 10^9/L, 1 and 24 hours after transfusion, respectively. Despite continued low platelet counts, platelet transfusion normalized the median values of all investigated TEG parameters. Platelet aggregation before and after transfusion also improved, but did not normalize (all $p<0.05$). Considering circulating biomarkers, sVE-Cadherin, reflecting endothelial junction function, was reduced (2214 *vs.* 2049 ng/mL) whereas the platelet activation marker sCD40L was 3-fold increased 1 hour after transfusion (33 *vs.* 91 pg/mL) (both $p<0.05$). Compared to healthy individuals, AML patients had higher sTM, sICAM-1 and HsCRP and lower sCD40L pre-transfusion levels. The change in platelet count (1h δ-value) correlated negatively with the corresponding change in sVE-Cadherin (Figure 1A), indicating that higher platelet count was associated with decreased sVE-Cadherin shedding *i.e.* improved endothelial junction function. The change in platelet count correlated positively with that of sCD40L (Figure 1B), indicating that higher platelet count was associated with increased sCD40L (both $p<0.05$). Interestingly, the 1h sCD40L level correlated positively with Syndecan-1 (24h δ value) and sTM (1h δ value), biomarkers of endothelial glycocalyx and cell damage, indicating that high sCD40L levels disrupted the endothelium (Figure 1C and D). Six patients (27%) were transfused because of bleeding symptoms (all WHO grade 1) and the level of TGF-β was significantly higher in patients with bleeding both before and 1 hour after transfusion compared to patients with no bleeding (n=16). The level of TGF-β in the transfusion products correlated to the post-transfusion change in the biomarker.

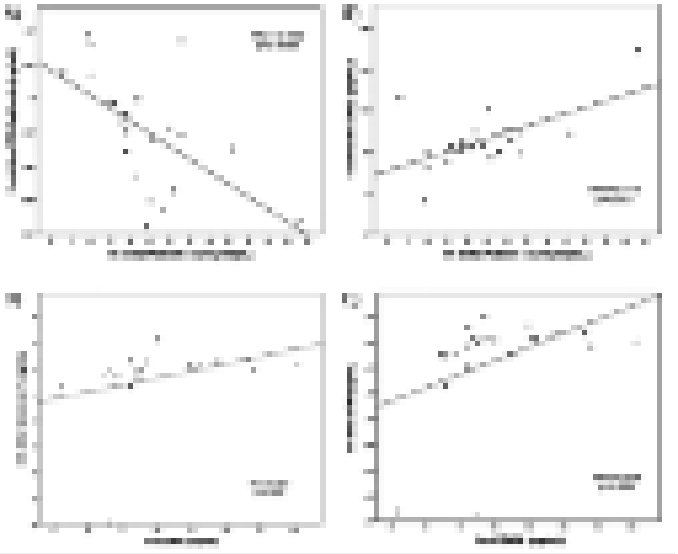

Figure 1.

Summary and Conclusions: Platelet transfusion and the increase in platelet count improved hemostatic function and vascular integrity, the latter assessed by lower sVE-Cadherin. In contrast, the post-transfusion level of sCD40L correlated with biomarkers of endothelial damage. These findings indicate that transfused platelets and platelet-derived pro-inflammatory mediators have opposite directed effects on the endothelium.

ASSESSING RISK OF BLEEDING IN THROMBOCYTOPENIC PATIENTS REQUIRING PLATELET TRANSFUSION PRIOR TO INVASIVE PROCEDURES

M Al Zaabi[1,*] S Clark[1], K Gomez[1], M Sekhar[1]
[1]Royal Free Hospital, London, United Kingdom

Background: Prophylactic platelet transfusion is widely used in thrombocytopenic patients undergoing surgical procedures. Threshold for transfusion in this setting is not well defined and the common practice of maintaining platelet count above $50x10^9$/L is based only on expert opinion and observational studies. Moreover, transfusion outside recommended indications continues to represent a substantial challenge and leads to inappropriate use of blood products and unnecessary transfusions.
Aims: The objective of this study was to assess potential predictors of bleeding in thrombocytopenic patients receiving platelet transfusion prior to invasive procedures.
Methods: We prospectively identified and followed up a total of 58 consecutive thrombocytopenic patients from various medical and surgical units requiring prophylactic preprocedural platelet transfusion. Computer charts and clinical notes were reviewed and patients were interviewed and examined when necessary. Several clinical and laboratory parameters including age, past history of bleeding, raised body temperature, splenomegaly, heparin administration, platelet counts, haematocrit, PT, aPTT and hepatic and renal functions were evaluated. Significant haemorrhage (WHO bleeding grades 2, 3 and 4) during postoperative period was considered as our primary endpoint.
Results: We found out of 58 procedures performed, 17 patients (29%) developed bleeding of WHO grade 2, 3 or 4. Eighty two percent (14/17) of bleeding episodes occurred within the first 72 hours postoperatively. Among factors assessed using multivariate regression analysis, only pretransfusion platelet count and prolonged baseline clotting times were found to significantly influence risk of bleeding. Patients with a pretransfusion platelet count of less than $20x10^9$/ L had more bleeding episodes [P=0.031, 95% confidence interval (CI) 0.03 to 0.67] and a shorter time for the first bleeding event (P=0.035, 95% CI 0.11 to 3.10). A prolongation of PT or aPTT of more than 1.5 times normal value was associated with a shorter time for the first bleeding episode (P=0.017, 95% CI 0.28 to 2.89). However, its correlation with incidence of bleeding was statistically insignificant (P=0.057).
Summary and Conclusions: Our study suggests that thrombocytopenic patients receiving preprocedural platelet transfusion have significant risk of bleeding if their pretransfusion platelet count is lower than $20x10^9$/L or their clotting times are more than 1.5 times normal. Larger randomized controlled trials are required to confirm these findings.

P591

RED CELL BLOOD GROUP GENOTYPING IN A COHORT OF BLOOD DONORS: FOCUS ON THE DUFFY ANTIGEN SYSTEM

A Colpo[1,*] MP Albergoni[1], GE Lunardon[1], R Favero[1], C Vio[1], M Vicarioto[1], G De Silvestro[1]
[1]Department of Transfusion Medicine, Padova University Hospital, Padova, Italy

Background: The Department of Transfusion Medicine of Padua Province supplies nearly 55.000 allogeneic blood units to 12.000 patients. A phenotype matching to AB0, RhD, RhCE and Kell is routinely performed. Nevertheless, the risk of alloimmunization to minor red blood cell (RBC) group antigens is associated with chronic transfusion therapy. In case of alloimmunization there may be long delays in identifying adequate units of RBCs, contributing to the morbidity of diseases. Recently, in our Department, high-throughput molecular techniques of RBC typing have been implemented, in order to obtain mass scale typing of blood donors. Among minor RBC blood group, the Duffy system is clinically significant because implicated in alloimmunization and severe hemolytic transfusion reactions. It is also involved in hemolytic disease of newborn. The FY gene encodes the Duffy antigens. FY has two major codominant alleles, FYA and FYB, that result from a single nucleotide polymorphism (SNP, 125G→A) in exon 2, and the corresponding Fy^a and Fy^b antigens differ by a single aminoacid. Anti-Fy^a and anti-Fy^b, antibodies define 4 main Duffy phenotypes: Fy(a+b-), Fy(a+b+), Fy(a-b+), Fy(a-b-). The rare Fy(a-b-) phenotype in Caucasian population results from a SNP in the promoter region of FY gene (FYGATA) that introduces a premature stop codon into the coding sequence, avoiding Duffy antigen expression on cell surface. Another polymorphism, FYX, is determined by a SNP in the coding sequence of FYB (265C→T). Consequently, the aminoacidic substitution determines instability in the translocation process and reduced amount of Fy^b antigen on cell surface. FYX has been reported in 3.5% of Caucasian donors.
Aims: The aim of this work is to describe the prevalence of FYX and FYGATA in a cohort of blood donors typed in our Department.
Methods: From August 2013 to January 2014 we performed genotyping on DNA samples of 95 blood donors. RBC genotyping was performed with

BLOODchip® (IDCore+, Progenika Grifols, Derio, Spain) using xMAP Luminex® technology. The BloodChip® allows the study of 33 SNPs of 9 erythrocyte system and the deduction of the corresponding phenotype. DNA was extracted from whole blood with automated (EZ1, DNA Blood Kit Qiagen) or manual processing (QIAamp DNA Mini Kit, Qiagen). The medium concentration of DNA was 27,7 ng/uL (optimal range for method 10-80), the medium OD260/OD280 range was 1.9 (optimal range 1.60-1,95). 48/95 donor samples were also typed with serological methods (agglutination on micro-column, Biorad-Diamed).
Results: The genotype was FYA/FYA in 15 donors (16% of total), FYA/FYB in 44 (46%), FYB/FYB in 36 (38%). The genotype FYX has been detected in 8 donors (8.5%). In 4 of them the genotype was FYA/FYB and, in the remaining 4 donors, the genotype was FYB/FYB. 4 of FYX samples have been typed with serological method: in 2 samples the phenotype was Fy(a+b-) (FYA/FYB genotype), in the other 2 samples the phenotype was Fy(a-b+), with FYB/FYB genotype. FYGATA polymorphism has been detected in one donor with FYA/FYB genotype and Fy(a+b-) phenotype.
Summary and Conclusions: It is well known that antibodies used for serological typing cause an "antigen-dose-dependent" agglutination. In case of FYX polymorphism, especially in FYA/FYB genotype, serological methods are not able to identify Fy^b antigen due to Fy^b low-dose on cell surface. The high frequency of FYX polymorphism in our donor cohort and the possible risk of alloimmunization, even with a low dose of antigen, highlight the relevance of RCB group genotyping and the importance of the genotype-phenotype correlation.

P592

A NEW BLOOD PRODUCT SUPPORT PROTOCOL HAS SIGNIFICANTLY REDUCED MASSIVE BLOOD LOSS IN PATIENTS UNDERGOING SURGERY FOR PSEUDOMYXOMA PERITONEI.

N Sargant[1,*] A Roy[1], S Simpson[1], K Chandrakumaran[2], B Moran[2], T Cecil[2], F Mohamed[2], J Bell[3], J Coakes[3], P Wilson[3], S Alves[2]
[1]Haematology department, [2]Surgical department, [3]Anaesthetic department, Hampshire Hospital NHS Trust, Basingstoke, United Kingdom

Background: Hampshire Hospitals NHS Foundation Trust (HHFT) is one of only two hospitals in the United Kingdom that performs complete cytoreductive surgery (CRS) with hyperthermic intraperitoneal chemotherapy (HIPEC) for pseudomyxoma peritonei (PMP), also called the Sugarbaker technique. Currently our center has the largest case series of patients undergoing PMP surgery in the world. PMP surgery is notorious for being synonymous with massive surgical blood loss due to the complexity of the surgery. This includes extensive surgery to remove the tumour throughout the abdomen with instillation of heated chemotherapy into the abdominal cavity. Historical observations & audits within the haematology department have shown that patients often have a rapid & dramatic decrease in their fibrinogen levels with severe derangement of their coagulation parameters. These abnormalities have repeatedly been shown not to improve with the early aggressive use of fresh frozen plasma (FFP) & have only improved with the additional use of cryoprecipitate. Until recently our surgical protocol for blood product use has continued to follow other international centres that perform this surgery with the early & aggressive transfusion of FFP.
Aims: We introduced a new protocol for blood product support in 2013. The aim was to maintain the fibrinogen level as close to 2 g/l throughout the surgery using cryoprecipitate. Based on previous observation we expected to see a reduction in the use of red cells during surgery.
Methods: We compared blood product use on consecutive patients undergoing PMP surgery following the new protocol & compared it to the retrospective requirements using the old protocol.
Results: The implementation of the current protocol resulted in a dramatic fall in the number of red cells & FFP transfused perioperatively. There was also an increase in the number of patients that did not require any red cell transfusions during PMP surgery.
Summary and Conclusions: Our findings support the earlier observation that the most important clotting factor to maintain during PMP surgery is the fibrinogen. Maintaining a fibrinogen level close to 2 g/l resulted in a significant reduction in red cells & FFP required during the surgery. With the extended role of CRS with HIPEC to surgery involving other peritoneal malignancies we feel that cryoprecipitate has a key role to play in preventing the rapid fall of the fibrinogen & hence blood loss during surgery. This finding raises a further question as to the role of FFP in the early treatment of massive surgical blood loss. We believe that these findings may have important implications in other clinical scenarios.

P593

RED BLOOD CELL ALLOIMMUNIZATION IN 18-50 YEAR OLD TRANSFUSED WOMEN A 3 YEAR STUDY

P Moncharmont[1,*] G Barday[2], F Meyer[2]
[1]Immunology, [2]Hemovigilance, EFS Rhone Alpes Site de Lyon Gerland, Lyon, France

Background: Following a red blood cell (RBC) transfusion, delayed adverse transfusion reactions (AR), such as RBC alloimmunization, may occur. The risks for the 18-50 year old female patient population may be severe. Therefore a strict transfusion policy is applied for that category of patients with the objective of preventing complications during pregnancy and delivery such as the risk for haemolytic disease of the foetus and newborn. According to French regulations, RBC concentrates in the Rhesus and Kell systems (C, E, c, e and K antigens) must be matched to these recipients.
Aims: In order to evaluate the incidence of delayed RBC alloimmunization in these female transfused patients, all AR reports collected during a period of three years were studied.
Methods: The study focused on RBC alloimmunization in female patients between 18 and 50 years of age cared for in all hospitals of the Rhone-Alpes area. Each AR had been included in the national haemovigilance database. The specificity of the RBC antibody (Ab), the blood product involved and the imputability were notified.
Results: From January 1st 2010 to December 31st 2012, 8,953 female patients (18-50 year old women) were transfused. Thirty one delayed RBC alloimmunization reports were notified in 30 female patients. Among them, three (10.0%) had sickle cell disease and 2 (6.7%) had thalassemia. Sixteen women (53.3%) had had at least one prior gestation, 18 (60.0%) had been previously transfused and 6 (20.0%) were already RBC alloimmunized at the time of the transfusion. The blood components involved were RBC concentrates in 28 cases (90.3%), apheresis platelet concentrate in one case and pooled platelets concentrates in 2 cases. In 30 reports, the new acquired RBC Ab had one specificity and in one, two specificities (anti-K and anti-Jka). In the 30 new alloimmunizations with only one specificity, anti-S was observed in 7 cases, anti-Kpa in 7, anti-Fya in 4 and anti-Jka in 4. Nevertheless, despite matching between RBC concentrates and recipients in the Rhesus and Kell systems regulations, two alloimmunizations were detected after transfusion in 2 patients, anti-c (one case) and anti-K (one case); the anti-c alloimmunized woman had been transfused with c-positive RBC concentrates because of a life-threatening pathology (severe anaemia due to bleeding in an ectopic pregnancy). Imputability of the blood component was certain in 13 cases (42.0%), probable in 17 cases (54.8%) and possible in one case (3.2%).
Summary and Conclusions: During the 3 year study, among all AR indicating a delayed RBC alloimmunization in a 18-50 year old transfused women population, only five had haemoglobinopathy. The anti-S and anti-Kpa specificities were the most frequently observed and RBC concentrate was the most involved blood component.

P594

RED BLOOD CELLS ALLOIMMUNIZATION IN POLYTRANSFUSED PATIENTS

I Lucea[1,*] I Gonzalez-Gascon y Marin[1], MA Foncillas[1], MS Infante[1], C Heras[1], C Muñoz[1], JA Hernandez[1]
[1]Hematology, Hospital Universitario Infanta Leonor, Madrid, Madrid, Spain

Background: Polytransfused patients were considered if they received more than 20 packed red blood cells (RBC) for a period of over 150 days.
Aims: To know the frequency of alloimmunization in polytransfused patients at a recently opened centre in 2008 with 350 beds.
Methods: Demographic data, as well as total number of RBC received, alloimmunization incidence, alloantibody specificity and system, number of RBC transfused before the first alloantibody and incidence of posterior alloimmunizations, from polytransfused patients were retrospectively analysed.
Results: We found that 121 patients with a median age of 75 years (41-93) had been polytransfused between 28/02/2008 and 31/12/2013. 73 were male (60.3%) and 48 female (39.7%). The median of transfused RBC was 32 (12-203). The frequency of alloimmunization was 14.9% with a median of RBC received before the appearance of the first alloantibody of 9.5 (0-51). 22 antibodies were detected in 18 patients (11 female and 7 male; p=0,079) and its distribution according to specificity was: E (4), C (4), K (4), Kpa (4), D (1), Cw (1) and autoantibodies (4). Interestingly, over half showed Rhesus (Rh) specificity (55.5%) and the rest Kell specificity. In 4 patients an autoantibody was detected with the first alloantibody. 3/18 patients (16.7%) developed a second alloantibody was detected with a median of 23 RBC received (16-32). Among the group of alloimmunized patients, the distribution according to their diagnosis was: hematologic disease 44.6% (5 patients with myelodysplastic syndrome [MDS], 2 patients with acute myeloid leukaemia and 1 patient with Non-Hodgkin's lymphoma), solid neoplasms 22.4%, multifactorial anaemia (renal failure, liver disease, surgery, etc,) 27.4% and HIV 5.6%.
Summary and Conclusions: In our centre, alloimmunization incidence in polytransfused patients was 14.9%. A greater tendency was observed in women than in men. Usually, the alloantibodies discovered were clinically significant which entailed problems in pre-transfusion tests and a great effort was required in the selection of the blood components. In our series, Rh and Kell specificity represented 100% of the alloantibodies system. In view to our data, and in order to prevent alloimmunization in polytransfused patients, we suggest to consider the transfusion of phenotypically identical units for Rh and Kell for patients who are expected to receive high transfusion requirements.

P595

IDENTIFICATION OF ABCB6 GENETIC VARIANTS WITH LOW OR ABSENT PROTEIN EXPRESSION AS THE GENETIC BASIS OF HIGH FREQUENCY BLOOD GROUP ANTIGEN LANGEREIS

M Koszarska[1,*] A Bors[2], H Andrikovics[1], A Tordai[1], K Kiss[3], G Varady[4], E Szabo[4], A Nemeth[4], N Kucsma[3], B Sarkadi[5], G Szakacs[3]
[1]Laboratory of Molecular Diagnostics, Hungarian National Blood Transfusion Service, [2]Laboratory of Molecular Diagnostics, Hungarian National Blood Transfusion Cervice, [3]Institute of Molecular Pharmacology and Institute of Enzymology, Research Center for Natural Sciences, HAS, [4]Institute of Molecular Pharmacology, Research Centre for Natural Sciences, Hungarian Academy of Sciences, [5]Molecular Biophysics Research Group of the Hungarian Academy of Sciences, Semmelweis University, Budapest, Hungary

Background: Blood group antigen variants may trigger severe diseases during pregnancy and blood transfusion, such as hemolytic disease of the fetus and newborn (HDFN) or adverse hemolytic transfusion reactions. Human erythrocytes express about 350 different integral membrane proteins, including transporters, receptors, which may serve as blood group antigens. The molecular basis of the high frequency red-blood-cell (RBC) blood group antigen Langereis (Lan) has recently been ascribed to the *ABCB6* gene. The frequency of Lan-negative blood type is believed to be extremely low (0.02%).
Aims: To identify the genetic background of low RBC ABCB6 protein expression level in healthy individuals.
Methods: 239 healthy volunteers (235 unrelated individuals and 4 family members of one proband selected from the volunteers with low ABCB6 transporter expression) and 2 Lan-negative sisters were enrolled. RBC ABCB6 protein expression level was measured in 51/239 volunteers by flow cytometry (FACS) using anticoagulated blood sample, stained with OSK43 monoclonal antibody specifically recognizing an intracellular epitope of the ABCB6 protein. Screening for *ABCB6* mutations was performed by direct sequencing of all exons and flanking intronic regions. *ABCB6* SNPs R192Q (rs150221689) and G588S (rs145526996) were genotyped by RFLP and LightCycler allelic discrimination system.
Results: Sequencing of two Lan-negative sisters without detectable ABCB6 protein expression revealed a previously described mutation in homozygous form (ABCB6 R192W, rs149202834). FACS analysis of 51 healthy volunteers identified 4 individuals with significantly lower RBC ABCB6 protein expression levels, as they were below 10th percentile of the average ABCB6 expression level in this group and there was a clear cut-off between these 4 individuals and the rest of the group, observed on a histogram set up according to the expression values. Sequencing of the *ABCB6* gene of these 4 individuals revealed three heterozygous mutations: R192Q (affecting the same codon as R192W); IVS9+1G>A (a putative splice variant at the boundary of exon 9); and G588S, present in two unrelated individuals. Analysis of the family members of the individual in whom we originally detected the R192Q missense mutation revealed that low ABCB6 expression segregated with the R192Q mutation. Genotyping of 235 unrelated volunteers for R192Q and G599S variants, identified no further R192Q carriers (allele frequency: 0.2±0.4%). For G588S, 3 additional heterozygous individuals were identified (5/235), resulting in allele frequency of 1.1±0.9% for this variant.
Summary and Conclusions: By screening healthy individuals we identified a new mutation causing the Lan- phenotype. We found significant differences between the expression levels of the wild-type ABCB6 protein and the R192W, R192Q, IVS9+1G>A and G588S polymorphic variants. Our results suggest that the ABCB6 genetic variants linked to lower or absent expression of Langereis may be more common than previously thought.

P596

ANALYSIS OF ADVERSE REACTIONS IN VOLUNTARY WHOLE BLOOD DONORS: EXPERIENCE FROM A GREEK BLOOD CENTRE

A Konstantinidou[1], V Bakaloudi[1], F Girtovitis[1], E Ntinopoulou[1], M Pape[1], V Konstantinou[1], M Chatzikyrkou[1], A Tzioura[1], A Markotsani[1], D Kakalou[1], M Kosmidou[1], H Hassapopoulou-Matamis[1,*]
[1]BLOOD CENTER, AHEPA HOSPITAL, THESSALONIKI, Greece

Background: Adverse reactions (ARs) occasionally occur during or after blood donation and may discourage the donors from further donating.
Aims: The aim of the present study was to assess the frequency, type and cause of ARs and suggest additional preventive measures.
Methods: The study involved all donations (25.774) throughout the year 2012. Each AR, occurring during or after a donation, was recorded by the staff on a new specifically designed individual report form. ARs were classified as local or general. Local ARs include haematoma (due to difficult venous access, vein injury or arterial puncture), delayed bleeding, nerve irritation or injury, local thrombophlebitis, tendon injury, allergy to the needle metal or disinfectant. Systemic ARs are classified as mild, moderate or severe and diagnosed as vasovagal, hypocalcemic, or "other". We registered donors' age, donation status (first time or repeat donor), the time from last meal, insufficient sleep, known postural hypotension, fatigue, fear of the needle stick and/or the sight of blood, seeing someone else fainting, etc.
Results: 91 ARs were recorded (overall incidence 0,35%): 87 general and 4 local. 65 occurred in male donors (71,42%) and 26 in females (28.58%). Vasovagal reactions (87/91) –immediate or delayed- were characterized by discomfort, weakness, pallor, sweating, dizziness, nausea, hypotension, bradycardia. In one case, tetany due to hyperpnoea developed after recovery from a vasovagal reaction. The majority of the vasovagal reactions (57/87) were mild (subjective symptoms only) while 26/87 were moderate (28,57%). In 4 (4,39%). loss of consciousness occurred along with convulsions and incontinence(1), fall causing injury of the donor(1), fall without injury(1). The local ARs included: haematoma (2), local pain (1), possible trauma of the nerve (1). Predisposing factors identified: insufficient sleep in 14(16,09%), fatigue in 11(12,64%), fear of the needle in 11(12,64%), postural hypotension in 10(11,49%), fear of the sight of blood in 8 (9,19%), omission of breakfast or long interval in 4(4,59%), donation too soon after last meal in 3(3,44%), seeing another donor fainting in 3(3,44%), anxiety in 1(1,15%). No risk factor was identified in 17 (19.54%). First time donors were implicated in 25 ARs (28,73%), repeat donors without reactions in the past in 51 (58.62%) and repeat donors with a history of previous ARs in 11 (12,64%). Most ARs (79/87) occurred early (during or immediately after the donation (86,81%). Delayed ARs appeared in 12 donors (13,18%) after leaving the site. In most ARs (78/91) donors <40 years of age were involved (85,72%).
Summary and Conclusions: Our results show insufficient sleep as the commonest risk factor, followed by fatigue and fear of the needle, postural hypotension, fear of the sight of blood, omission of breakfast or lunch. ARs predominated in repeat donors possibly due to less attention by the staff to repeat donors and/or these donors overestimating their physical status and omitting to report predisposing factors. Good interview practices and consistent auditing and reporting ARs help to identify predisposing factors and adopt preventive strategies. Staff should be experienced and adequate at all times for efficient surveillance of the donors.

P597

LEUKOREDUCTION FILTER OBSTRUCTION - THE OPPORTUNITY TO DETECT BLOOD DONORS WITH SICKLE CELL TRAIT

M Pape[1,*] V Bakaloudi[1], E Chrysoulidou[1], F Girtovitis[1], P Chalkia[1], E Ntinopoulou[1], D Pantelidou[1], A Konstantinidou[1], M Xatzikyrkou[1], V Konstantinou[1], A Tzioura[1], C Mpikou[1], E Moumtsaki[1], A Nikolaidou[2], L Skoura[2], H Hassapopoulou-Matamis[1]
[1]Blood Center, [2]Laboratory Department, Ahepa Hospital, Thessaloniki, Greece

Background: The prevalence of hemoglobinopathies in Greece is important. Sickle cell trait (SCT) affects 1% of the general population. It is not widely known that blood from SCT donors usually leads to obstruction of leukoreduction filters or to inefficient leukoreduction. Factors that cause hemoglobin S polymerization and ultimately filter obstruction, include: the relative insolubility of deoxygenated hemoglobin S (HbS), decreased deformability of red blood cells (RBCs), the type of anticoagulant and preservative, the temperature and length of storage, pH changes during storage, the material of the filter itself. RBCs from SCT donors should not be transfused, especially to newborns, patients undergoing general anesthesia or having hypoxemia or increased oxygen demands.
Aims: In this study, we planned to examine the blood donor for sickle cell trait (SCT), each time complete or partial obstruction of a post storage leukoreduction filter occurred, in order to exclude donors with SCT from further blood donation.
Methods: According to our protocol, each time very slow flow and eventual obstruction of a poststorage leukoreduction filter occurs during filtration of packed RBCs, a blood sample from the bag has to be examined for hemoglobin fractions by HPLC (High-performance liquid chromatography). In contrast to traditional liquid chromatography which relies on gravity forces, HPLC relies on pumps to pass a pressurized liquid solvent containing the sample through a column filled with a solid adsorbent material. The components are separated because each component in the sample interacts slightly differently with the adsorbent material and flows out the column at a different flow rate. In case of SCT, the hemoglobin fractions include HB S (less than 45%), while normal blood contains only the A (more than 95%), A2 (less than 4,2%) and F (around 1%) hemoglobin fractions.
Results: During one year (2013), complete or partial obstruction of post storage leukoreduction filters was observed 30 times during filtration of units of RBCs. From the 30 blood samples examined, 5 (16,6%) showed HbS fractions (34,3%>37.4% of total hemoglobin) thus identifying donors with SCT. None of them was aware of having SCT. Two had donated in the past in blood services that do not filter blood units. Although, the remaining blood donors had several donations in our Center, filter obstruction was previously reported only once. The donors were notified and asked to refrain from further donating blood.
Summary and Conclusions: Donors with SCT should be identified and excluded from further donation. Our data underestimate the incidence of SCT among blood donors because not all units of RBCs are leukodepleted with poststorage filters. More blood donors with SCT would be identified if clinical departments also reported all cases of obstruction of bedside filters.

P598

ADMINISTRATION OF FIBRINOGEN CONCENTRATE IN TRAUMA PATIENTS IS ASSOCIATED WITH IMPROVED SURVIVAL AT 6 HOURS BUT NOT AT DISCHARGE

T Papakitsou[1], G Papakitsos[2,*] A Kapsali[3], A Roimba[4]
[1]Haematology, General Hospital Mesologi, Mesologi, [2]Anaesthetic, General

Hospital Arta, [3]Private Clinic, Arta, [4]St Paul General Hospital Thessaloniki, Thessaloniki, Greece

Background: Despite poor evidence and high costs, fibrinogen concentrate (FC) represents one of the most frequently used haemostatic agents in trauma.
Aims: The aim was to assess, whether the administration of FC in severely injured patients was associated with improved outcomes.
Methods: Patients (Injury Severity Score [ISS] ≥14) had received FC during initial care between emergency department (ED) arrival and intensive care unit admission or operation room (FC+) were matched with patients who had not received FC (FC-).
Results: The matched-pairs analysis yielded two comparable cohorts (n=14 in each group) with a mean ISS of 34.6±13.6 (FC+) and 34.1±13.2 (FC-) (p=0.73); the mean age was 46±17 *versus* 46±18 (p=0.72), respectively. Patients were predominantly male (73.1% in both groups, p=1.0). On emergency department arrival, hypotension (systolic blood pressure, ≤85 mm Hg) occurred in 52,3% (FC+) and 47,1% (FC-) (p=0.41) and base excess was -7.35±5.1 mmol/L for FC+ and was -7.45±6.3 mmol/L for FC- (p=0.96). Patients were administered 12.7±13.3 (FC+) *versus* 10.7±11.1(FC-) packed red blood cell units (p=0.20). Thromboembolism occurred in 5.9%(FC+) *versus* 3.5% (FC-) (p=0.06) and multiple organ failure occurred in 62.3% *versus* 48.1% (p=0.003), respectively. Whereas 6-hour mortality was 11.6% for FC+, *versus* 15.5% for FC- (p=0.03), the mean time to death was 6.5±13.4 days, *versus* 5.6±7.9 days (p=0.006). The overall hospital mortality rate was 29.5%, *versus* 24.6% (p=0.40), respectively.
Summary and Conclusions: This study investigates the effect of FC administration in bleeding trauma. In our population of severely injured patients, the early use of FC was associated with a significantly lower 6-hour mortality and an increased time to death, but also an increased rate of multiple organ failure. A reduction of overall hospital mortality was not observed in patients receiving FC.

P599

EVALUATION OF BILIARY INJURY IN NEWBORNS WITH ABO INCOMPATIBILITY

HA Awad[1,*] R El-Farrash[1], EA Ismail[2], AS Aly[1]
[1]Pediatrics Department, [2]Clinical Pathology Department, Faculty of Medicine-Ain Shams University, Cairo, Egypt

Background: The ABO blood group related antigens are known to be expressed not only on the surface of erythrocytes, but also on a variety of cells in the human body. In normal liver, these blood groups related antigens are expressed mainly in the epithelial cells of large bile ducts and virtually absent in hepatocytes. Biliary injury mediated by alloimmune responses to major ABH antigens was described in, liver transplantation using ABO incompatible graft.
Aims: To test the validity of a hypothesis linking IgG antibody-mediated hemolysis of fetal erythrocyte and a similar mechanism for biliary injury, we investigated the structural integrity of the biliary tract in ABO hemolytic disease of the newborn (ABO HDN) through measurement of sensitive biliary enzymes.
Methods: Eighty term and near term newborns were studied; 40 newborns with ABO incompatibility and 40 controls (30 of them were healthy of blood group compatible with their mothers and 10 newborns with Rh incompatibility as a hemolytic control). All neonates were studied stressing on blood grouping and markers of hemolysis; indirect bilirubin and lactate dehydrogenase (LDH). Gamma-glutamyltransferase (GGT) and alkaline phosphatase (ALP) were measured before and after therapy (phototherapy and/or exchange transfusion). Investigations were done to exclude other causes of neonatal hemolytic disease. Patients with ABO HDN were further subdivided according to the age-specific total serum bilirubin nomogram and disease severity into 3 subgroups; mild (n=22), moderate (n=12) and severe (n=6) HDN
Results: Pre-therapy GGT and ALP levels were significantly elevated in all neonates with hemolysis compared with healthy controls (p<0.001). The highest GGT levels observed in ABO-HDN group; however, ALP was consistent among neonates with ABO HDN and Rh HDN. In ABO HDN, pre-therapy GGT and ALP levels were significantly elevated in severe disease compared to mild and moderate disease. GGT and ALP levels were also significantly higher among neonates with ABO HDN with positive direct or indirect antiglobulin test compared to those with negative test (p<0.001). Pre-therapy GGT levels were significantly higher in all ABO HDN subgroups (p<0.05) compared to Rh HDN. However, ALP was significantly higher only in severe hyperbilirubinemia compared to Rh-HDN group. As regards the effect of therapy, both GGT and ALP were significantly decreased post-exchange transfusion among neonates with ABO HDN compared to their baseline levels (p<0.001) while no significant difference was found in Rh HDN group. Moreover, both markers were significantly lower post-exchange transfusion when compared to post-phototherapy (p<0.05). Both pre-therapy GGT and ALP levels were positively correlated in patients with ABO HDN (p=<0.001). Significant positive correlations were found between pre-therapy GGT as well as ALP and each of reticulocyte count, normoblasts, LDH, total and direct bilirubin while GGT and ALP were inversely correlated with hemoglobin among ABO-HDN neonates. Multi regression linear analysis revealed that both LDH and GGT were independently related to ALP levels.
Summary and Conclusions: In ABO-HDN, we assume that binding of anti-A and anti-B antibodies with their corresponding antigens located over the epithelium of the biliary tract resulted in its injury reflected by increased direct bilirubin and both GGT and ALP levels. Early implementation of therapeutic modalities could result in at least partial protection of the biliary structural integrity.

P600

SENSITIVITY OF INDIVIDUAL AND MINI-POOL NUCLEIC ACID TESTING ASSESSED BY DILUTION OF HEPATITIS B NAT YIELD SAMPLES

N Agarwal[1,*] K chatterjee[1]
[1]Transfusion Medicine, All India Institute of Medical Sciences, New Delhi, India

Background: For Nucleic Acid testing (NAT) of blood donations, either the blood samples can be pooled together in a batch of 6 or 8 prior to testing to screen a large number of donations with few tests (MP-NAT), or the tests can be run on every individual sample (ID-NAT). It has been debated in various studies whether pooling of samples results in decreased sensitivity of detection as the volume of individual samples gets lesser in a pool.
Aims: Objective of this study was to investigate the effect of dilution on the sensitivity of tests with low viral load, serology negative, Individual Donor Nucleic Acid Testing (ID-NAT) HBV reactive samples.
Methods: The study was performed on 9 plasma samples which were exclusive Procleix Ultrio Plus HBV yields *i.e.* NAT Ultrio Plus Assay reactive but Serology and Procleix Ultrio non reactive during a Procleix Ultrio Plus pilot study conducted on blood donors for a period of one year, from September 2011 to September 2012, at All India institute of Medical Sciences, New Delhi India. These 9 exclusive Ultrio Plus ID-NAT yield samples were diluted in 1:2, 1:4. 1:6 and 1:8 dilutions using previously tested negative plasma and each dilution of every sample along with archived undiluted sample were retested in three replicates with Procleix Ultrio Plus Assay.
Results: Among NAT yield samples, 88.88% of the samples were detected when retested in ID-NAT in undiluted format.. Samples with higher viral load (sample 5 and 6) were detected by all dilutions. samples with viral load below 20 IU/ml or were not detected by PCR (5 out of 9,55%) when tested in dilutions of 1:6 or 1:8, only 9 out of 27 replicates (33.33%) were detected. This means that more than 76% low viral load samples were missed by MP-NAT of 1:6 or 1:8 dilution out of total NAT yield samples (Figure 1).

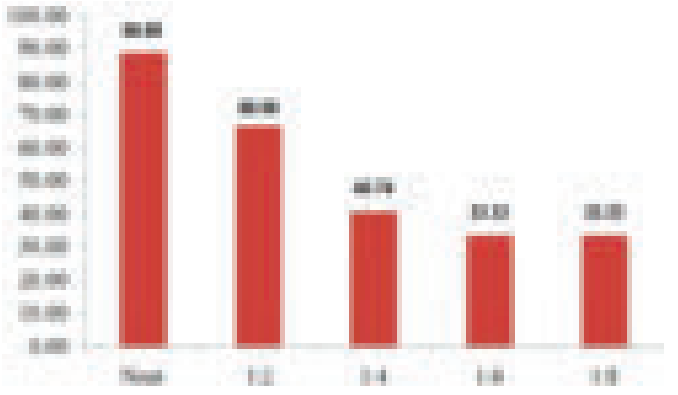

Figure 1.

Summary and Conclusions: Individual Donor NAT is ideal methodology for NAT as dilution due to pooling may miss samples with low viral load as evident in this study.

Immuno-thrombocytopenia

P601

UPDATED RESULTS FROM A LARGE, OBSERVATIONAL STUDY OF PATIENTS (PTS) WITH PRIMARY IMMUNE THROMBOCYTOPENIA (ITP) RECEIVING ROMIPLOSTIM IN EUROPEAN CLINICAL PRACTICE

H Papadaki[1,*] A Janssens[2], G Kaiafa[3], T Kozak[4], D Selleslag[5], M Steurer[6], P Quittet[7], JF Viallard[8], H Wadenvik[9], L Belton[10], G Kreuzbauer[11]
[1]Department of Hematology, University of Crete School of Medicine, University Hospital of Heraklion, Crete, Greece, [2]Department of Hematology, University Hospitals Leuven, Leuven, Belgium, [3]Medical Propedeutic Department of Internal Medicine, Aristotle University of Thessaloniki, AHEPA University General Hospital, Thessaloniki, Greece, [4]3rd Medical Faculty, Charles University, Praha, Czech Republic, [5]Department of Hematology, A-Z Sint-Jan, Bruges-Oostende, Belgium, [6]Division of Hematology and Oncology, Innsbruck Medical University, Innsbruck, Austria, [7]Hematology Department, Hôpital Saint Eloi, Montpellier, [8]Hôpital du Haut Lévèque, University of Bordeaux, Pessac, France, [9]Section of Hematology, Sahlgrenska University Hospital, Gothenburg, Sweden, [10]Biostatistics, LB Biostatistics, London, United Kingdom, [11]International Medical Development and Research, Amgen (Europe) GmbH, Zug, Switzerland

Background: ITP is characterized by low platelet counts and increased risk of bleeding. Severe bleeding episodes are uncommon but may be life-threatening and require hospitalization. Romiplostim is a thrombopoietin-mimetic peptibody approved in Europe for second line treatment in splenectomised and non-splenectomised pts where surgery is contraindicated.
Aims: To describe romiplostim use in European clinical practice, and to describe the demographics, clinical outcomes, and resource utilization in romiplostim-treated pts. Results from a planned interim analysis are reported.
Methods: Eligible pts were adults with primary ITP who had received romiplostim and who had provided informed consent. The observation period was for up to 2 years after romiplostim initiation. Data were collected retrospectively on ITP-related hospitalizations for up to 2 years before romiplostim initiation and on bleeding events for up to 6 months before romiplostim initiation.
Results: An interim analysis was conducted in September 2013. In total, 356 pts had enrolled and 339 were included in the Full Analysis Set. The mean (±SD) duration of romiplostim treatment was 21 (±5) months; 25% of pts remained on study, 11% discontinued, and 65% completed the 2-year observation period. Adverse drug reactions (ADRs) led to early romiplostim discontinuation in 5% of pts. At romiplostim initiation, the median age was 62 years (range 18–91) and median duration of ITP was 3 years (range 0–56), with one-third of pts having ITP for less than 1 year. Most pts (55%) had received ≥3 prior ITP therapies and 34% had undergone splenectomy. The median average weekly dose of romiplostim was 2.8 mcg/kg (Q1-Q3: 1.5–4.4) and most pts (70%) started romiplostim at a 1 mcg/kg dose. Some intermittent dosing with romiplostim was observed: 41% of pts had a >3 week period where doses were withheld or missing. Romiplostim was self-administered by 37% of pts. The median baseline platelet count was $20x10^9$/L (Q1-Q3: 9-35), which rose to $69x10^9$/L (Q1-Q3: 28-139) after 2 weeks of romiplostim treatment and remained >$50x10^9$/L thereafter. Thirty pts (9%) ended romiplostim treatment due to achieving a haemostatic platelet count range, with median platelet counts of $172x10^9$/L (Q1-Q3: 90-261). After romiplostim initiation, there was a decrease in rates of grade ≥3 bleeding events (from 12 to 2 per 100 pt-years) and ITP-related hospitalizations (from 87 to 35 per 100 pt-years). There were some differences in baseline demographics between splenectomised and nonsplenectomised pts, but romiplostim doses and bleeding and hospitalization rates were similar between the two groups (Table 1). Thirteen pts reported a serious ADR. Seven pts experienced 8 thrombotic ADRs (2 each of deep vein thrombosis and pulmonary embolism; 1 each of embolism, myocardial infarction, retinal vein thrombosis, and transient ischaemic attack). Bone marrow fibrosis ADRs occurred in two pts as reported in previous interim analyses (myelofibrosis in pts who were subsequently found to have a diagnosis inconsistent with ITP [MDS and metastases to bone marrow]). No fatal ADRs were reported.

Table 1.

Summary and Conclusions: The dosing, effectiveness, and safety of romiplostim in a real-world ITP pt population appeared comparable with that observed in clinical studies (*e.g.* Kuter BrJH 2013). Hospitalization and bleeding were lower after romiplostim treatment, and outcomes were similar between splenectomised and nonsplenectomised pts.

P602

FEASIBILITY OF ROMIPLOSTIM DISCONTINUATION IN ADULT TPO-MIMETIC RESPONSIVE PATIENT WITH PRIMARY IMMUNE THROMBOCYTOPENIA (ITP): AN OBSERVATIONAL RETROSPECTIVE REPORT IN REAL LIFE CLINICAL PRACTICE

M Carpenedo[1,*] S Cantoni[2], V Coccini[1], M Fedele[1], EM Pogliani[1], E Morra[2]
[1]Hematology and Transplantation Unit, A.O San Gerardo di Monza and University of Milan Bicocca, Monza, [2]Hematology and Oncology Department, A.O Ospedale Niguarda Cà Granda, MIlano, Italy

Background: Thrombopoietin mimetic agents (TPO mimetics) improve platelet (plt) counts in ITP patients (pts) acting on megakariocyte survival and production of plt. They were thought to be a life-long therapy. However, clinical evidence is accumulating showing that this may not be the case
Aims: We report on ITP pts unresponsive to previous therapies who were treated with romiplostim (R) and who were able to discontinue it after achieving response, without relapsing at follow-up
Methods: 30 pts (11 M;mean age at R treatment 50.7 yrs, range 18-82) were treated between Sept 2009-Feb 2014. ITP disease status at R administration: 7 newly, 8 persistent, 15 chronic disease. Lines of previous therapies: mean 2.8, range 2-5. Time between start of any treatment and R: mean 52.7 mos, range 1-264 mos. All pts are enrolled in a local Italian registry (REL-ITP registry), and gave informed consent to demographic and clinical data use at enrollment
Results: 27/30 pts (90%) responded to R according to International Working Party criteria (1).Of the 27 responders: 1 pt discontinued R due to acute myocardial infarction (AMI); 1 pt was lost to follow-up; 5/27 pts R used as bridge to splenectomy; 4/27 pts lost response (12, 6, 11, and 12 mos); in 3/27 pts R administration is ongoing (52, 8 and 7 mos); 13/27 achieved stable, safe plt counts and were able to stop R (Table 1). Pts discontinued R after a mean of 42 weeks (range 12-122) with sustained response maintained at a mean of 26 mos (range 9-51). Mean R dose was 2.43 µg/kg/week (range 0.5-3.8 µg/kg/week). Mean plt count at the time of R discontinuation was $168x10^9$/L (range 48-$500x10^9$/L); mean nadir and peak plt counts off therapy were $128x10^9$/L (range 52-$243x10^9$/L) and $279x10^9$/L (range 120-$411x10^9$/L) respectively. No bleeding events occurred during the observational period; 2 thrombotic events (lower limb superficial phlebitis; AMI) were recorded.

Table 1. Characteristics of patients with sustained response to Romiplostim.

Summary and Conclusions: Sporadic pts have been reported as being able to discontinue treatment with R [2-6] without relapsing off-therapy, however prevalence of long-term remission is currently unknown. In our experience, the percentage of pts able to discontinue R is 48%, if we consider R responders (13/27 responders) and 65% if we consider only pts who received long-term treatment (13/20 pts; *i.e.* not considering pts receiving R as bridge to splenectomy, lost to follow-up, or who discontinued R because of SAE). In 7/13 pts R seemed to be the only treatment responsible for sustained response. In the remaining pts, response might have been either spontaneous (3 newly diagnosed pts) or secondary to rituximab/splenectomy. Nevertheless, use of R may be a treatment option awaiting for plt recovery. No specific pattern of early response (*e.g.*: dose requirements, time to response) seemed to predict for long-term response. However, it seems that pts achieving safe plt counts at lower dosages are probably worth a try of therapy tapering and discontinuation. Manufacturer dose adjustment rules allow R to be discontinued when appropriate and clinical judgment was used to manage pts. If our preliminary retrospective observations were to be confirmed, the proposal of using R as "bridge to recovery" rather than long-term treatment would have relevant clinical impli-

cations: long-term sides effects (*e.g.* marrow fibrosis, thrombotic risk) and treatment costs would be less of an issue.

TREATMENT OF ADULTS WITH PRIMARY IMMUNE THROMBOCYTOPENIA (ITP) WITH ROMIPLOSTIM IN ROUTINE CLINICAL PRACTICE IN GERMANY-INTERIM RESULTS FROM AN OBSERVATIONAL STUDY (PLATEAU)

M Welslau[1,*] M Reiser[2], T Illmer[3], K Josten[4], H Dietzfelbinger[5], A Seitz[6]
[1]Gemeinschaftspraxis Dr. Klausmann / Dr. Welslau, Aschaffenburg, [2]Praxis Internistische Onkologie und Hämatologie (PIOH), Köln, [3]Gemeinschaftspraxis Hämatologie , Dresden, [4]Praxis für Hämatologie und Onkologie, Wiesbaden, [5]Hämatologisch-onkologische Schwerpunktpraxis, Herrsching, [6]Amgen GmbH, München, Germany

Background: In the EU, the thrombopoietin-receptor agonist romiplostim (Nplate®) is recommended for second-line treatment of ITP in adult patients who failed splenectomy or are ineligible for splenectomy to achieve sustained increases in platelet counts (Provan *et al.*, 2010).
Aims: The aim of this ongoing study is to assess the use of romiplostim in clinical practice in Germany.
Methods: This multicentre, prospective and retrospective observational study (data collected before and after initiation of romiplostim) is enrolling ITP patients ≥18 years who received at least one dose of romiplostim in routine clinical practice, with an observation period of 2 years following romiplostim initiation. Endpoints included patient demographics, romiplostim use, platelet counts, adverse drug reactions (ADRs), and other clinically relevant parameters. We report data from an interim analysis conducted in 6/2013.
Results: 125 patients (pts) were enrolled (50% male; median [range] age: 63 [18-89] years). Of these, 122 had received romiplostim, 53 (42%) had completed the 2 year observational period and 21 (17%) had withdrawn (n=3 AE, n=4 death, n=14 other reasons). Median (range) time from ITP diagnosis to romiplostim initiation was 25 (0-436) months.111 pts (92% of 121 evaluable) had received prior ITP therapies (median [range] therapies: 2 [1-20]), 102 pts (83%) were non-splenectomized. 45 pts (37%) had experienced bleeding events within 6 months before romiplostim initiation (grade III/IV: n=3 (2.5%)). Median (range) platelet count at initial romiplostim injection was 26 (2-801) x10^9/L and increased during therapy (Figure 1). Over the observation period, romiplostim was injected at a median (range) dose of 3 (1-10) µg/kg/week. Patients received a median [range] of 39 (1-104) injections over a median (range) observation period of 62 (1-104) wks. The most common reported ADRs (≥5%) were fatigue (8 pts [10%], dizziness (7 pts [9%], nausea (7 pts [9%], vomiting (5 pts [6%]) and diarrhea (4 pts [5%]). One patient reported a vascular access related thromboembolic event. There was no increase in bone marrow reticulin. 6 serious ADRs were reported. Exposure-adjusted bleeding rate (grade 3 or 4) before romiplostim initiation was 6.1 per 100 patient-years *vs.* 3.7 per 100 patient-years after romiplostim initiation. Exposure-adjusted ITP related hospitalization rate before romiplostim initiation was 24 per 100 patient-years *vs.* 14.9 per 100 patient-years after romiplostim initiation.

Figure 1.

Summary and Conclusions: These interim data show that platelet counts in patients treated with romiplostim was increased and maintained at the desired range of 50-250x10^9/L and generally well tolerated in unselected ITP patients treated in routine clinical practice in Germany. Bleeding events and ITP related hospitalization rates were decreased after receiving romiplostim.

[1]Department of Hematology, Nanfang Hospital, Southern Medical University, [2]Department of Hematology, Guangzhou General Hospital of Guangzhou Military Command, [3]Oncology-Hematology Center, he 1st Affiliated Hospital of Guangzhou Medical University, [4]Department of Hematology, Third Affiliated Hospital, Sun Yat-Sen University, [5]Department of Hematology, Guangdong General Hospital, Guangzhou, [6]Department of Hematology, Zhongshan People Hospital, Zhongshan, [7]Department of Hematology, Guangdong No.2 Provincial People's Hospital, [8]Department of Hematology, First Affiliated Hospital, Sun Yat-Sen University, [9]Department of Hematology, Guangzhou Overseas Chinese Hospital, [10]Department of Hematology, Zhujiang Hospital of Southern Medical University, Guangzhou, China

Background: Delayed platelet recovery is a significant complication after allogeneic hematopoietic stem cell transplantation (allo-HSCT) and a significant independent risk factor for increased transplantation-related mortality (TRM) and poorer overall survival (OS). But until now, effective treatment for delayed platelet recovery is limited
Aims: This study was designed to assess the efficacy and safety of recombinant human thrombopoietin (rHuTPO) on platelet recovery after allo-HSCT.
Methods: A prospective, multicenter, non-randomized, open-label study (NCT01379391) was conducted in China. The protocol was approved by ethics committee of Nanfang hospital of southern medical university and informed consent was obtained from each subject. The patient whose platelet counts below 20x10*9/L on +14days after transplantation was enrolled and assigned into TPO arm or TPO-free arm, according to protocol TPO-HSCT-2011.
Results: From JUN 2011 to NOV 2013, a total of 58 patients were enrolled in this study in 10 clinical centers, 57 of them were evaluable. Among them, 30 cases were enrolled into TPO arm and 27 cases in TPO-free arm. TPO arm consisted of 16 patients with precursor cell lymphoblastic leukemia/lymphoma (LBL/ALL, 6 of 15 were refractory or relapsed), 9 patients with acute myeloid leukemia (AML), 2 patients relapsed peripheral T-Cell non-Hodgkin's lymphoma (PTCL-NHL), 2 patients with myelodysplastic syndromes (MDS), 1 patient with severe aplastic anemia (SAA). Among TPO arm, 16 patients with LBL/ALL received intensified HDE-ALL-2011 (NCT01457040) as conditioning regimen, 9 high-risk AML received BU/CY2, 2 received GIAC and 2 received BU/FLU, 1 SAA patient received ATG/CTX/FLU. Eleven of 30 cases in TPO arm underwent HLA-matched sibling HSCT, 9 received haploidentical HSCT, 8 received matched-unrelated donor HSCT, and 2 received mismatched HSCT. The median ANC and CD34+ cells infused in TPO arm was 8.0x10*8/kg (range 2.7-11.9), 3.5 x10*6/kg (range 1.1-10.6), respectively. TPO-free arm consisted of 14 LBL/ALL cases, 5 AML cases, 5 cases of CML and 3 cases of SAA. Among TPO-free arm, 11 patients underwent HDE-ALL-2011 as conditioning regimen, 4 patients with BU/CY2, 3 cases with TBI/CY2 and 3 cases with ATG/CTX/FLU. Ten out of 27 cases in TPO-free arm received HLA-matched sibling donor HSCT, 9 cases received mismatched HSCT, 4 cases with MUD HSCT and 4 with haploidentical HSCT. The median ANC and CD34+ cells infused in TPO-free arm was 7.0x10*8/kg (range 3.5-11.1), 3.8 x10*6/kg (range 2.8-9.7), respectively. No NCI-CTCAE grade III/IV TPO-related adverse events were observed in TPO arm. Incidence of CMV/EBV viremia in TPO, TPO-free arm was 43.3% *vs* 59.3%. The median platelet count significantly increased from 14.5x10*9/L to 44.0x10*9/L in TPO arm after 14 days' TPO treatment, compared to 15.0x10*9/L to 32.0x10*9/L in TPO-free arm. The median time (days) of platelet count above 20x10*9/L, 50x10*9/L, 100x10*9/L in TPO and TPO-free arm were 18.0 *vs* 21.0 (p>0.05), 28.5 *vs* 31.0 (p>0.05) and 36.0 *vs* 46.0 (p<0.05). CFU-MK and flow analysis for megakaryocytic progenitor cells were performed at +14d (prior to TPO), +28d (completion of TPO) after transplantation in 10 cases in TPO arm. CFU-MK assay demonstrated significant increase from 10 to 29 colonies (p<0.01). Flow analysis also showed significant growth of CD34+CD41+ and increasing tendency of CD34+CD61+ population, but not CD41+CD61+ subsets. After a median of 12 months of follow-up, TRMs in TPO and TPO-free arm were 13.3% *vs* 33.3% (p<0.01). Estimated 2-year OS in TPO and TPO-free arm were 70.0% *vs* 33.3% (p<0.01).
Summary and Conclusions: TPO administration could promote platelet engraftment, reduce TRM and improve OS for high-risk delayed platelet recovery after allo-HSCT.

P605

SHORT TERM RE-EXPOSURE TO ROMIPLOSTIM IN PREVIOUSLY TPO-MIMETIC RESPONSIVE ITP PATIENTS ALLOWS RECOVERY OF PLATELET COUNT AND LONG TERM SUSTAINED REMISSION: AN OBSERVATIONAL RETROSPECTIVE CASE-SERIES

M Carpenedo[1,*] S Cantoni[2], V Coccini[1], M Fedele[1], EM Pogliani[1], E Morra[2]
[1]Hematology and Transplantation Unit, A.O San Gerardo di Monza and Uni-

versity of Milan Bicocca, Italy, Monza, [2]Oncology and Hematology Department, A.O Ospedale Niguarda Cà Granda, Milano, Italy

Background: Thrombopoietin mimetic agents such as Romiplostim (R) improve platelet (plt)count in patients (pts) with Primary Immune Thrombocytopenia (ITP) during its use, but most patients (nearly 90% in phase III studies [1,2]) lose response after last dose if drug is discontinued. Efficacy of re-exposure to R in previously responsive patients after a decrease of plt count has not yet been described in real life clinical practice.
Aims: We report on ITP patients who achieved a complete response during R treatment and who were able to discontinue the drug. During follow up some of them experienced an abrupt decrease of plt but a short term re-exposure to R has resulted to a complete long-term response
Methods: 30 pts (11 M; mean age at R treatment 50.7 yrs, range 18-82) were treated with R (ITP disease status at R start: 7 newly diagnosed, 8 persistent, 15 chronic disease) because of unresponsive disease (lines of previous therapies: mean 2.8, range 2-5). All pts are enrolled in a local Italian registry (REL-ITP registry), and gave informed consent to clinical data use
Results: 27/30 pts (90%) responded to R according to International Working Party criteria[3]. 13/27 pts discontinued R after a mean of 42 weeks (range 12-122) because of a complete response (CR) with plt >100x10^9/L (7/13) or response (PR) with plt>50x10^9/L (6/13 pts). 6/13 pts showed stability of plt count after last dose of R (5 pts achieved CR, 1 PR) and didn't require any further treatment (mean time off therapy 28 months, range 11-51). 7/13 pts (2 with previous CR) after last R dose showed a decrease of plt count (mean nadir 45 x10^9/L, range 12-75 x10^9/L) and were re- exposed to R after a mean of 5.7 weeks (range 3-12) since last R dose: one pt needed one single re-exposure after 10 weeks since last R dose to obtain again a stable RC (time off therapy since then 28 months); one pt was treated after 4 weeks since last dose with 10 weekly R doses (now off therapy since 15 months); in five pts a single R shot was given "on demand" for 2 times (3 patients) or 3 times (in 2 patiens) at variable number of weeks since the previous shot (mean 5.6 weeks, range 3-12) and were off therapy since a mean of 25 months (range 11-40). 12 out of 13 pts achieved a CR after the re-exposure, one pt achieved a stable PR and none of them has ever received any treatment. No bleeding events were observed (Table 1).

Table 1.
