Summary and Conclusions: Increasing data of stable response after R withdrawal are now available. In our experience patients who achieved a stable CR or in some cases even a stable PR with plt >50x10^9/L deserve an attempt to discontinue R: an occasional drop of platelet count even after weeks since last R dose seems to be easily managed with re-exposure and didn't affect a possible long term response. If these retrospective observational results were to be confirmed, a personalized patient-tailored R administration could lead to a relevant number of definitive suspension sparing chronic treatment.

THROMBOPOIETIN RECEPTOR AGONISTS IN PRIMARY IMMUNE THROMBOCYTOPENIA: EVALUATION OF EFFICACY (RESPONSE AND SUSTAINED RESPONSE OFF-TREATMENT) AND SAFETY IN A SINGLE CENTER POPULATION

C Santoro[1,*] F De Angelis[1], E Baldacci[1], L Parlanti[1], R Abruzzese[1], F Barone[1], R Bochicchio[1], R Di Mauro[1], R Foà[1], MG Mazzucconi[1]
[1]Cellular Biotechnology and Hematology, Hematology Sapienza University, Rome, Italy

Background: Romiplostim and Eltrombopag are two thrombopoietin receptor agonists (TPO-RAs) which show clinical efficacy in primary immune thrombocytopenia (pITP) and are changing the management of this autoimmune disorder.
Aims: To retrospectively describe the efficacy and safety of TPO-RAs in a pITP population from a single Center.
Methods: All adult pITP patients treated with TPO-RAs are included. Data were captured from the medical records. Response was defined as platelet (plt) count ≥50x10^9/L and at least a 2-fold increase of the baseline value. Complete response was defined as a plt count ≥100x10^9/L. Period in response during TPO-RAs treatment was expressed as the percentage of weeks in response/weeks on treatment. Phases of pITP were defined in relation to diagnosis as follows: acute, within 3 months; persistent, between 3 and 12 months; chronic, more than 12 months.
Results: Since February 2009, 39 pITP patients (25 F, 14 M) resistant to one or more therapy lines, have been treated with TPO-RAs. The median number of therapy lines before the start of TPO-RAs was 2 (1-5): prednisone, dexamethasone, azathioprine, rituximab, splenectomy, interferon. Nine patients had been previously splenectomized. The median age at TPO-RAs start was 63.4 years (19.2-79.3) and the median period between pITP diagnosis and TPO-RAs start 6.9 years (0.1-38.9). Twenty eight patients were treated with Romiplostim and 11 with Eltrombopag. At the start of TPO-RAs, 32 patients were in a chronic phase, 5 in a persistent and 2 in an acute phase. These last 2 patients were severely symptomatic and resistant to high dose steroids and intravenous immunoglobulins. The median plt count at the start of TPO-RAs was 11x10^9/L (2-52). Steroids were a concomitant treatment in 34/39 patients. The median number of weeks on TPO-RAs treatment was 73 (2-262) and the median TPO-RAs dosage was 4 µg/dose (1-10) for Romiplostim and 75 mg/day (25-75) for Eltrombopag. Thirty two/39 patients (82%) obtained a response at least once (26 on concomitant treatment with steroids) after a median period of 3 weeks (1-5). Twenty four/26 maintained the response after steroids discontinuation. Globally, 30/39 (77%) patients obtained a response without concomitant treatment after a median of 8 weeks (2-37). With regard to the entire population, the median percentage of weeks in response/weeks on treatment was 80% (0-100). Twenty/39 patients stopped the first TPO-RA treatment, the reasons being: response to splenectomy in 1, no response in 6, side effects in 5, poor compliance in 1, CR in 7. Among the latter 7 patients, 5 maintained a sustained response at a median follow-up of 2.3 years (0.8-3.4), 1 relapsed after a period of 6 months, 1 developed a splenic lymphoma after 17 months from the last TPO-RA administration. Seven patients switched to the other TPO-RA, obtaining a response in 5 cases (3 without any concomitant treatment). On the whole, 24/39 patients never stopped TPO-RA treatment. We did not observe adverse events possibly related to the study drug. Five patients experienced side effects: osteo arthritic muscle pain in 4, hepatic toxicity in 1.
Summary and Conclusions: We confirm the efficacy and safety of TPO-RAs in pITP patients refractory or resistant to one or more therapy lines. We did not record severe adverse events, but 5 patients experienced side effects which led to stop treatment. We observed 5/39 (13%) persistent responders off treatment, with a median follow-up of 2.3 years. The use of TPO-RAs is progressively increasing and extending to severe patients also in acute or persistent phase, while other therapies are failing or contraindicated.

P607

PREDICTIVE FACTORS ASSOCIATED WITH LONG-TERM EFFECTS OF SPLENECTOMY FOR IDIOPATHIC THROMBOCYTOPENIC PURPURA

M Mitrovic[1,*] S Matic[2,3], M Smiljanic[1], N Suvajdzic[1,3], D Antic[1,3], M Todorovic - Tirnanic[4], I Djunic[1], M Sretenovic[1], D Lekovic[1], D Tomin[1,3], I Elezovic[1,3]
[1]Clinic of Hematology, Clinical Center of Serbia, [2]The First Surgical Clinic, Clinical Center of Serbia, [3]Faculty of Medicine, University of Belgrade, [4]Center for Nuclear Medicine, Clinical Center of Serbia, Belgrade, Serbia

Background: Splenectomy leads to a good response in 60-80% of adult patients with corticosteroid refractory idiopathic thrombocytopenic purpura (ITP). However, data on the long-term efficacy are controversial. Furthermore, it is not clear whether there are pre or post-operative parameters able to predict the therapy failure.
Aims: To evalute long-term efficacy and to determine the preoperative and postoperative factors that predict a successful splenectomy outcome.
Methods: We retrospectively analyzed the data on 93 patients (median age 39 years, range 19-74; 71/22 female/male ratio; median follow-up from diagnosis 86 months, range 6-182; median follow-up from splenectomy 71 months, range 2-148), who underwent splenectomy (laparotomic 55, laparascopic 38) for ITP between 2002 and 2013. Platelet kinetic study with Indium-111 was performed in 33 patients before splenectomy. Patients with platelet count <30×10^9/L or steroid-dependent were splenectomized. Complete response (CR) and partial response (PR) were defined as platelet count >150×10^9/L and 50×10^9/L one month after surgery. Refractoriness was diagnosed when the platelet count remained <30×109/L. Relapse was defined as a drop in the platelet count <150×10^9/L or 50×10^9/L after CR or PR. Refractory or relapsed patients with a platelet count <30×10^9/L or bleeding were treated with steroids, azathioprine, danazol, vinca alkaloids and TPO-agonist.
Results: The median time from diagnosis to splenectomy was 3 months (range 2-132). The median pre-operative platelet count was 67×10^9/L (range 20-

320×10^9/L). Sixty nine of 93 patients (75%) achieved CR and 7/93 (7%) PR. Remaining 15/93 (17%) were refractory. All refractory patients were treated with good response in 8/15 (53%) cases. Fifteen of the 76 (19.7%) responsive patients relapsed with a median time to relapse of 6 months (range 3-20). Eleven of these 15 patients (73%) were treated with a good response in 9/11 (82%) cases. Patients with good response (CR+PR) to splenectomy were previously treated with only one drug (79% *vs.*43% p=0.003) or had lower median an number of pre-splenectomy therapies (1 (range 1-3) *vs.* 2 (range 1-5), p=0.028), had a higher platelet count at the time of splenectomy (91×10^9/L *vs.* 45×10^9/L, p=0.021) and higher platelet count seven days after splenectomy (387×25^9/L *vs.* 25×10^9/L, p=0.0035) than refractory patients. Mixed (the liver and the spleen) platelet destruction site was frequent in refractory patients (4/4 (100%) *vs.* 4/29 (14%) p=0.0003). By multivariate analysis, only the number of former therapies (p=0.045) and higher peak post-splenectomy platelet count (p=0.0089) were predictive of a favorable response to splenectomy. Relapsed patients had significantly lower platelet count seven days (213×10^9/L *vs* 387×10^9/L, p=0.048) and three months (55×10^9/L *vs* 346×10^9/L, p=0.007) after splenectomy. The same parameters retained statistical significance (p=0.076, p=0.0023) by multivariate analysis.

Summary and Conclusions: Splenectomy is effective in approximately two thirds of patients with ITP. Number of pre-splenectomy treatments and the platelet count seven days after surgery were predictive of refractoriness. Platelet count seven days and three months after surgery was predictive of relapse. Further large population based studies for testing a cut-off platelet count that could predict the refractoriness or relapse are needed.

P608

THROMBOPOIETIN RECEPTOR AGONISTS AFFECTS THE LEVELS OF HEPATOCYTE GROWTH FACTOR AND TRANSFORMING GROWTH FACTORS IN IMMUNE THROMBOCYTOPENIA

W Ghanima[1,*] X Feng[2], C Lee[3], J Bussel[3]
[1]Medicine, Østfold Hospital, Fredrikstad, Norway, [2]National Heart, Lung, and Blood Institute, Bethesda, [3]Department of Pediatric Hematology/Oncology, Weill Cornell Medical College, New York, United States

Background: Hepatocyte growth factor (HGF) is a pleotropic cytokine that plays an essential role in differentiation of hematopoietic progenitor cells. It has been shown that the administration of HGF increases platelet counts (PC) and megakaryocytes, probably through enhancement of thrombopoietin (TPO) mRNA expression in hepatocytes. Transgenic mice overexpressing HGF display elevated levels of TPO and develop thrombocytosis. Among other properties, HGF exhibits a potent anti-fibrotic property mediated through the inhibition of α-SMA–positive myofibroblast activation from interstitial fibroblasts, which antagonizes the effect of transforming growth factor B (TGF-B) through inhibition of TGF-B signaling pathway and expression. Romiplostin and eltrombopag are two thrombopoietin receptor agonists (TPO-RA) used in patients with immune thrombocytopenia (ITP) to elevate PC. These agents act by promoting megakaryocyte proliferation and differentiation. The effect of exogenous thrombopoietin (TPO) on the levels of HGF has not been studied previously.
Aims: To determine blood levels of HGF and TGF-B in consecutive samples collected from ITP patients treated with TPO-RA.
Methods: Blood samples from 48 ITP patients receiving treatment with TPO-RA at the Unit of Platelet Disorders at the New York Presbyterian Hospital, New York, USA, were retrospectively retrieved. Pre-treatment (<2 months) with TPO-RA and thereafter sequential on-treatment frozen blood samples were retrieved at 6 months intervals (+/- 1 month), whenever available and up to 24 months. These blood samples were collected during routine hospital visits. Samples were centrifuged at 1400 g for 10 min and aliquoted in appropriate tubes as EDTA plasma and stored at -80°C until assayed. Plasma samples from 16 healthy individuals were analyzed for HGF and TGF-B. These were 9 females/7 males, median age 37 years,(IQR 22-51). TGF-B was analyzed using ELISA and HGF was analyzed by an immuno-bead-based multiplex assay (R&D systems, Minneapolis, MN, USA). The protocol was approved by the Institutional Review Board of the Weill Medical College of Cornell University, NY, USA and consent was obtained from the patients.
Results: Median age of 46 patients was 50 years (IQR 20-69); 28 (58%) females. Median levels (interquartile range) of PC, HGF and TGF-B are shown in the Table 1. PC increased after treatment with TPO-RA and remained elevated over baseline levels in all measurements. Median pre-treatment HGF levels were higher than controls (p=0.0001) and higher than all of the on-treatment levels (p-values at 6, 12, 18, 24 months were 0.07, 0.1, 0.03, 0.002 respectively). Paired pre-treatment values differed significantly from values at 6, 12, 18, and 24 months with p-values of 0.027, 0.005,0.005, and 0.017 respectively. No significant correlations were found between HGF and PC. Median pre-treatment level of TGF-B was significantly lower than in controls (p=0.004), but TGF-B levels increased after initiation of TPO-RA to levels comparable to those of controls. The differences between pre- and on-treatment levels were not significant except at 6 months (p=0.012).
Summary and Conclusions: The study showed that HGF and TGF-B are dysregulated in ITP and that treatment with TPO-RA alters their levels. To our knowledge this is the first study to report on HGF levels in TPO-RA treated ITP patients – a finding that may indicate a regulatory mechanism imposed by low platelet counts to stimulate the production of TPO-RA. Median concentrations of HGF declined after administration of TPO-RA and remained lower than pre-treatment levels. This may indicate a negative regulatory mechanism exerted either by the exogenous TPO or by the platelets and/or the megakaryocytes. However, since there were not significant correlations between HGF and PC, it appears more likely that decreasing levels of HGF are attributable to exogenous TPO. This finding need to be proved and its down stream effects needs to explored using animal models or other relevant methods.

PREOPERATIVE USE OF THROMBOPOIETIN RECEPTOR AGONISTS IN ITP PATIENTS PRIOR TO SPLENECTOMY OR CARDIOVASCULAR SURGERY

E Rossi[1,*] A Ciminello[1], M Cedrone[2], C Santoro[3], F Buccisano[4], L De Padua[5], T Za[1], S Betti[1], B Anaclerico[2], M G Mazzucconi[3], V De Stefano[1]
[1]Institute of Hematology, Catholic University, [2]Hematology, San Giovanni-Addolorata Hospital, [3]Cellular Biotechnology and Hematology, Sapienza University, [4]Hematology, Tor Vergata University, Roma, [5]Hematology, Regina Apostolorum Hospital, Albano Laziale, Italy

Background: Recently, two thrombopoietin (TPO) receptor agonists (TPO-RA) have been introduced in the treatment of immune thrombocytopenia (ITP): eltrombopag (ETP) and romiplostim (RPL). In Europe they are approved for ITP patients as third-line treatment after splenectomy or second-line treatment when surgery is contraindicated.
Aims: To collect data on the preoperative use of TPO-RA before splenectomy or other surgical procedures in ITP patients.
Methods: A retrospective observational study was conducted by five hematology centers on ITP patients who had received TPO-RA as preoperative procedure prior to splenectomy or other elective surgical interventions.
Twelve patients with chronic ITP (M/F 8/12, median age 39 yrs., range 14-75) were identified. All patients had received previous treatments (one line in 2 patients, two in 4 patients, three in 4 patients, >three in 2 patients). The planned surgical intervention was splenectomy in 9 cases, uterine polipectomy in one, endarterectomy in one, and aortic valve and aortic arch prosthetic substitution in one. The median platelet count prior to starting TPO-RA was 9x10^9/L (range 2-36). Eight patients received RPL and four ETP; one of the latter had first received RPL, which was switched to ETP because of lack of response. Seven patients received concomitant treatment with steroids. The final dose of TPO-RA was between 2 and 8 µgr/kg /week for RPL and 50 or 75 mg /day for ETP.
Results: In 9 patients surgery was carried out after median 3 months from starting treatment (range 1-9); in one remaining patient splenectomy was posposed after 4 years on RPL. The platelet count at the time of surgery was >100x10^9/L (range 102-398) in 8 patients, 75x10^9/L in one, and 49x10^9/L in one. In one patient ETP was withdrawn after 7 weeks because of lack of response and splenectomy was successively carried out using steroids and high-dose immunoglobulins (HD-Ig); no other patient received preoperative HD-Ig. Finally, splenectomy was renounced in a 14-y.o. patient who had underwent 3 previous lines of treatment and after RPL achieved a durable response which was maintained after withdrawal of the drug. Splenectomy induced a complete response in 7 patients (median platelet count after 2 weeks from the intervention 550x10^9/L, range 138-747) and had no effect in one (platelet count 49x10^9/L). No bleeding complication was recorded in any patient. TPO-RA were withdrawn after splenectomy and polipectomy; RPL was prolonged as indefinite treatment in the two patients who underwent cardiovascular surgery

and received anti-vitamin K or antiplatelet agents. One 34-y.o. patient had pulmonary embolism after laparoscopic splenectomy carried out after RPL administration. The platelet count at the time of intervention and one and two weeks after was 75x10^9/L, 117x10^9/L, and 653x10^9/L, respectively; no antithrombic prophylaxis had been given.
Summary and Conclusions: The preoperative use of TPO-RA is effective to achieve a safe platelet count before surgery, and is of special value in those patients undergoing cardiovascular surgery with need of long-term antithrombotic treatment. The occurrence of one venous thromboembolic event in this small series is however cause of concern about safety of TPO-RA in this setting.

P610

A SINGLE CENTRE RETROSPECTIVE ANALYSIS OF 57 A SINGLE CENTRE RETROSPECTIVE ANALYSIS OF 57 CONSECUTIVE LAPAROSCOPIC SPLENECTOMIES IN PATIENTS WITH IMMUNE THROMBOCYTOPENIC PURPURA

S Novelli[1,*] E Barranco[1], A Garrido[1], A Esquirol[1], I Garcia[1], R Martino[1], M Granell[1], J Briones[1], C Moreno[1], S Saavedra[1], S Brunet[1], E Targarona[2], J Sierra[1]
[1]Hematology, [2]Surgery, Hospital de la Santa Creu i Sant Pau, Barcelona, Spain

Background: Immune thrombocytopenic purpura (ITP) is a common autoimmune disease characterized by autoantibody destruction of platelets, impaired platelet production and altered cellular immunity. It can be primary if it presents alone or secondary, if it takes place in setting of other conditions (HIV, cancer, other autoimmune disorders, hepatitis viruses).
Systemic corticosteroids remain the first line treatment. After failure or dependence to corticosteroids splenectomy has been the best therapeutic option for many years. With the recent emergence of thrombopoietin analogues the role of splenectomy has been questioned, mainly in fragile patients.
Aims: Our primary aim was to analyze the ITP relapse free survival after splenectomy and to describe the early and late complications in the population of study. A secondary objective was to identify variables associated with a higher risk of ITP relapse.
Methods: We retrospectively identified 57 consecutive laparoscopic splenectomies performed in patients with ITP in our center from 1998 to 2013.
Patient's baseline characteristics are resumed in Table 1.

Table 1.

Corticosteroid dependence was defined as the inability to stop corticosteroids without presenting platelets counts inferior to 30x10^9/L. Corticosteroid resistance was defined as the lack of response in the platelets counts. Descriptive and frequencies analyses were performed. We estimated the probability of staging free of relapse after splenectomy (RFS) using the Kaplan Meier analysis. Clinically relevant variables (age, sex, time to splenectomy, resistance to corticosteroids, and platelet count after splenectomy) were analyzed in a univariate analysis. With those variables which showed statistical significance in the univariate analysis we performed a multivariate analysis using Cox's regression.
Results: The laparoscopic splenectomy was successful in 51 cases (89%). The platelet count performed in the following 12 hours after splenectomy was analyzed in 46 cases; it was less than 100x10^9/L in 17% and greater than or equal to 100x10^9/L in 83% of patients. The post surgical complications during admission were mild bleeding in 3 (43%) patients, abscess in 3 (43%) patients and severe bleeding in one patient, the last one (14%) resulting in death. There were 6 complications after 6 months of surgery: 5 (83%)were infectious (3 community acquired pneumonia, 1 herpes zoster and 1 CMV pneumonitis) and 1 (17%) was related to surgery (chronic abdominal pain). The median time to relapse was 47 months (range 0 - 180). The RFS at 180 months of follow up is 68.4% (IC 95% 57.6 – 79.9). When analyzing the RFS by gender, age (less than 60 years old *vs* more than or equal to 60 years old), platelet count after splenectomy (less than 100x10^9/L *vs* greater than or equal to 100x10^9/L), time to splenectomy, and corticosteroids dependence/resistance we found that only platelet count after splenectomy and age showed statistically significant differences in the univariate analysis. The RFS in patients with less than 100x10^9/L platelets was 46.9% *vs* 68.4% in those with more or equal to 100x10^9/L ($p<0.05$). For those patients older than 60 years the RFS was 53.3% and it was 87.7% in the younger group ($p<0.05$). In the multivariate analysis using Cox regression the variables included were age, platelet count after splenectomy and also median time to splenectomy because there are some reports indicating that it may be relevant. We only found statistical significance in platelet count after splenectomy ($p<0.05$) with a hazard ratio of 0.34 (IC 95% 0.08-1.5).
Summary and Conclusions: Laparoscopic splenectomy provides a long lasting remission time in patients with corticosteroid resistance/dependence ITP and remains an excellent option with low rate of complications. Age should be taken into account before splenectomy. The most predictive data of relapse is the platelet count after surgery. We did not find that the time to splenectomy from diagnosis of ITP had an impact in the outcome.

P611

THE TREATMENT WITH ELTROMBOPAG OF THE REFRACTORY ITP

GD Gaman[1,2,*] MA Gaman[3]
[1]Hematology, University of Medicine and Pharmacy of Craiova, [2]Hematology, Filantropia City Hospital, Craiova, [3]"Carol Davila" University of Medicine and Pharmacy, Bucharest, Bucharest, Romania

Background: Refractory ITPs are the cases in which ITP is initially responsive to first line therapy (Prednisone, Dexamethasone – high dose, IVIG) or second line therapy (splenectomy, Danazol, VKR, CVP treatment) but which decay because of the inefficiency of the former therapies.
Aims: The demonstration of the beneficial effect of Eltrombopag 50 mg/day, administered in due course in 18 cases of refractory ITP, diagnosed in the Clinic of Hematology from Craiova, Romania, in between January 2009 – January 2013 (48 months).
Methods: Of a total number of 156 patients diagnosed with ITP in our Clinic, only 18 fulfilled the criteria for refractory ITP. The median age of the patients was of 42 years and the sex ration M/F was of 5 to 13. All of the cases were treated with the same dose of Eltrombopag (50 mg/day, number of thrombocytes ≥90000/mm^3, without the reduction of this dose in the event of obtaining a favourable or complete response). We did not raise the dose to 75 mg/day in the only non-responder patient from the group, taking into account the former therapies (4-6 type of treatment), the complete remission length (in months), the period of time from the initial diagnosis to the point in which the cases were considered refractory ITP, the interval in which complete remission appeared from the start of treatment with Eltrombopag, the type of response (complete, with the normalisation of the number of thrombocytes, or favourable, with a number of thrombocytes ≥90000/mm^3). Only 50% of the patients relapsed after splenectomy (9 patients) and the other half refused the surgical intervention in fear of the comorbidities. The patients were followed-up monthly, observing their clinical state and eventual side effects, and curves which evaluated the evolution of the number of thrombocytes were drawn.
Results: Of the 18 patients with refractory ITP, 33% previously received four types of therapy, whereas 67% five or six types of treatment. The length of complete remission varied between 11 and 34 months. After 11-34 months, the diagnosis was of refractory ITP and the treatment with Eltrombopag was of 50 mg/day, doses which were not adjusted, nor discontinued. Of the 18 patients, 17 achieved complete responses, with the normalisation of the number of thrombocytes (66% - complete remission, with a number of thrombocytes=156000-225000/mm^3, or efficient responses with a number of thrombocytes=90000-133000/mm^3). The period of time until the complete or efficient response was achieved was between one to 24 months. A single patient was a non-responder to Eltrombopag after the continuation of therapy for six months. None of the patients received Eltrombopag 75 mg/day as specified on their informed consent.
Summary and Conclusions: Although expensive, the treatment with Eltrombopag was extremely efficient in 17 of the 18 cases of refractory ITP and had minimal side effects (dizziness – 3 cases, reversible introversion – 7 cases). After the treatment with Eltrombopag, the patients maintain the initial quality of the response: complete (21-47 months of treatment) or efficient (11-39 months of treatment).

P612

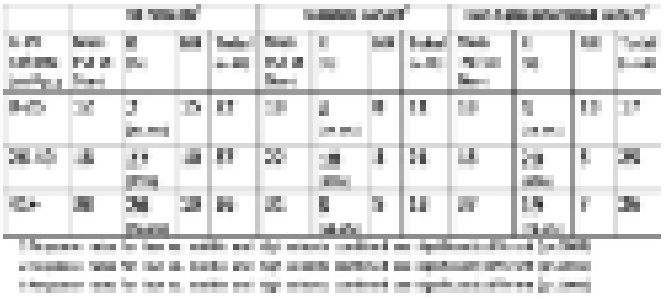
THROMBOPOIETIC AGENTS INCREASE PLATELET COUNTS MORE EFFECTIVELY IN ITP PATIENTS WITH HIGHER PLATELET PRODUCTION PRIOR TO TREATMENT

A Kruse[1,*] P Morrissey[1], C Tchatchouang[1], N Haq[1], M Arfuso[1], J Bussel[1]
[1]Pediatric Hematology Oncology, Weil Cornell Medical College, New York, United States

Background: Thrombopoietin Receptor Agonists (TPO Agents) increase platelet counts in ITP patients by stimulating platelet production. Why the majority but not all patients respond to these agents is unknown. The Immature

Platelet Fraction (IPF), a marker of Reticulated, newly-produced Platelets (RPs), is a good indicator of a patient's platelet production abilities.
Aims: The aim of this study was to explore whether a patient's ability to produce new platelets was associated with his/her platelet response to TPO Agents.
Methods: Ninety-five ITP patients treated with a single TPO-A were retrospectively analyzed: 16 were treated with E5501, 21 with romiplostim and 55 with eltrombopag. Forty-four patients were male and 51 female, with a median age of 22 years (range 2-81) and a median duration of ITP before TPO treatment of 4 years (range 0-38). Absolute IPF (A-IPF) values and platelet counts were measured using a Sysmex XE-2100 machine. Platelet and A-IPF counts were collected and organized by month, and the median count from each month was recorded for each of 7 relevant time periods: Pre-Treatment, 1, 2,3,4,5 and 6 months. Patients were deemed platelet count responders if the average of their platelet counts doubled and was higher than $50x10^9$/L. To distinguish patients by their platelet production capabilities, subjects were stratified into three cohorts based on their A-IPF values prior to treatment: 0-25 (low), 26-40 (middle) and 41+ (high). Fisher's exact tests were used to analyze differences in the distribution of variables among patient subsets.
Results: Response rates for the low, medium, and high A-IPF cohorts were, 7/22 (23.5%), 27/37 (73%) and 26/36 (72.2%), respectively (Table). Response rates between the three A-IPF cohorts were significantly different (p=.003). Patients from the middle A-IPF cohort (p=.0028) and patients from the high A-IPF cohort (p=.0056) each had a significantly higher response rate than did patients from the low cohort. Patients from the high and middle cohorts did not have significantly different response rates (p=.794). Among the 68 non-splenectomized patients, response rates between the three A-IPF cohorts were also significantly different (p=.0006); patients with higher A-IPF's had significantly greater response rates (Table). Response rates for the low, medium, and high cohorts were, 4/17 (23.5%), 20/25 (80%) and 19/26 (73.1%), respectively. Similarly in the 45 pediatric patients, response rates between the three A-IPF cohorts were significantly different (p=.0085); patients with higher A-IPF's had significantly greater response rates (Table). Response rates for the low, medium, and high cohorts were, 3/11 (27.3%), 18/21 (86%) and 8/13(61.5%), respectively (Table 1). Age, sex and splenectomy are not significantly related to TPO response. Response rates were almost identical for pediatric (<21yo) *vs.* adult patients, females *vs.* males, and splenectomized *vs.* non-splenectomized patients. Duration of ITP may predict TPO response. Response rates were significantly different (p=.0396) when stratifying patients into three cohorts: 0-1.5, 1.5-3, and 3+ years. Among these groups there were 9/20 (45%), 18/22 (81.8%), 33/53 (62.3%) responders, respectively. Median A-IPF each cohort was between 36 and 38.

Table 1.



Summary and Conclusions: High A-IPF in ITP, the baseline ability to produce platelets, may be useful in predicting the efficacy of TPO-A on an individual basis. Further study of the mechanism of this phenomenon may reveal novel therapeutic approaches for difficult patients with ITP.

P613

ELTROMBOPAG GIVEN 2 TIMES A WEEK AS MAINTENANCE THERAPY IN RESPONDING PATIENTS AFTER AN INDUCTION STANDARD TREATMENT OF 50 MG ORALLY ONCE DAILY IS EQUALLY EFFECTIVE AND SAFE IN ITP PATIENTS.

F Iuliano[1,*] M Luci[1], E Iuliano[2], A Pomillo[1], A Perricelli[1], G Cervo[1], F Corea[1], M Mazzulla[1,3], MC Aurelio[1]
[1]Internal Medicine, U.O di Onco-Ematologia S.O. "N.Giannettasio" ASP1 Cosenza, Rossano (CS), [2]Internal Medicine, Magna Graecia University, Salvatore Venuta Campus, Catanzaro, [3]Tor Vergata University, Rome, Italy

Background: Eltrombopag is an oral, non-peptide thrombopoietin receptor agonist that has shown efficacy and safety in chronic immune thrombocytopenia (ITP).) patients not responding to previous therapy.However, when eltrombopag is discontinued, platelet counts usually return to baseline within 2 weeks. As reported in different case series only 15% of patients achieve a durable response after treatment discontinuation.
Aims: To evaluate the efficacy and safety of eltrombopag given at a dose of 25 mg every 3 days as maintenance therapy in responding patients after an initial standard dose of 50 mg orally once daily.
Results: A total of 8 consecutive adult patients, female (50%),median (range) age 50 (24-71) years, median (range) baseline platelet count 19 (3-32)$x10^9$/L.,median of 3 (2-4) prior ITP therapies,received eltrombopag with 50 mg once daily starting dose to maintain platelet counts in the target range of 50-150$x10^9$/L.. The median time since ITP diagnosis was 3 years (range, 1-4 years) and none of the patients had undergone a splenectomy. The efficacy of oral eltrombopag was assessed after 6 weeks administration. All patients achieved a platelet count ≥$50x10^9$/L. and 6 out of 8 pts achieved CR (defined as platelet count ≥100 * $10^{\wedge 9}$/L measured on two occasions >7 days apart and the absence of bleeding). In 4 out of 8 patients occurred more dose adjustments and treatment interruptions to maintain platelet counts in the target range Moreover it was not possible, in this subset, to stop the treatment for a relapse within the first three weeks of discontinuation. For all these reasons a maintenance dose of 25 mg every 3 days starting on the ninth month. The median (range) follow-up of this case series was of 7 months (6-20), during which all patients maintained a safe platelet count without the need to increase the dose or frequency of administration. No adverse events were observed.
Summary and Conclusions: Maintenance therapy was manageable and well-tolerated. Maintenance can allow for improved health care resource allocation providing cost savings and potentially improves patients' quality of life by reducing the time required for laboratory tests, medical examinations togheter with a total adhesion to the treatment and may be an effective alternative for patients who can not discontinue the drug

P614

ROMIPLOSTIM: EFFICACY AND SAFETY IN PATIENTS WITH IMMUNE THROMBOCYTOPENIA (ITP). SINGLE CENTRE EXPERIENCE

I Zotova[1,*] K Abdulkadyrov[1]
[1]hematology, Russian Research Institute of hematology, Saint-Petersburg, Russian Federation

Background: Use of thrombopoietin receptor agonists (TPO-RAs) is based on the current knowledge of the ITP pathophysiology. Long-term administration of TPO-RAs results in improved treatment outcomes for patients with chronic ITP (cITP).
Aims: To evaluate efficacy and safety of romiplostim (R) used as a second- and third- line treatment in patients with cITP who are resistant to prior therapy.
Methods: 45 patients (40 female, 5 male) were treated with R. Median age was 48 years (range, 22-74). The mean duration of ITP was 8.5 years (1.5-47). One line of previous therapy (corticosteroids) received 51% patients (23/45), two and more lines of therapy received 49% patients (22/45), 6 of those underwent splenectomy. Second- and subsequent lines of therapy included intravenous immunoglobulin, mycophenolate, rituximab, cyclophosphamide, vincristine and eltrombopag. 14 patients continued to receive concomitant ITP medications at the start of treatment with R. The mean baseline platelet count was 17 ´ 10^9/ L (range,1-48 ´ 10^9/L).The hemorrhagic syndrome mainly presented as cutaneous manifestations with ecchymosis and petechiasis observed in 95% of patients. Additional hemorrhagic events included epistaxis and gingival bleedings (45% of patients),menorrhagia (30%),macrohematuria (2%) and hemoptysis (2%).The initial dose of R was 1 mкg/kg in 34 patients, 2 mkg/kg in 7 and 3 mкg/kg in 4, the maximum dose of R amounting to 10 mкg/kg. The therapy response was defined as platelet count >50 ´ 10^9/L and resolution of hemorrhage.
Results: Mean therapy duration was 47 weeks (range, 5-173).The median dose of R was 4.5 mkg/kg/week. 88% of patients (40/45) achieved sustained response to the therapy. The target platelet count was achieved by 2 week (w2) in 16 (36%) patients, by w3 in 19 (44%) patients, by w4 in 8 (18%) and by w5 in 1 (2%) patient. Five patients did not respond to the therapy despite being administered maximum therapeutic doses of R. One patient was primary refractory (treatment for 10 weeks with no response, dose R 10 mkg/kg was used for 4 weeks of that period). In four patients the achieved response was lost, further escalation dose of R to the maximum dose (its use for 3 weeks) was ineffective and the treatment was discontinued. Concomitant ITP medications could be completely withdrawn in 13/14 of patients. Side effects were minimal and included skin rash, headache and myalgia. A thrombotic complication was seen in one patient 73-year-old female with vascular risk factors experienced a transient ischemic foot attack with local soft tissue necrosis in 59 week of treatment, platelet count was 137 ´ 10^9/L, a dose of R was 7 mкg/kg. The signs of this event were stopped 3 weeks later in the course of conservative therapy with resumption of treatment R 2 mkg/kg for the achievement of the desired clinical benefit (hemostatic effect). Three patients sustain the complete response after discontinue treatment of R without any ITP treatment (24, 5 and 4 months of duration, respectively).
Summary and Conclusions: R is a novel therapeutic option for patients with cITP that was shown to provide long-term control of hemorrhagic syndrome, rapidly increase and effectively sustain platelet counts with acceptable tolerability as well as maitain durable response in some patients after treatment withdrawal.

CORRELATION BETWEEN OXIDATIVE STRESS AND BIOMARKERS OF JOINT DAMAGE IN PATIENTS WITH SEVERE HAEMOPHILIA TREATED BY DIFFERENT PROPHYLAXIS REGIMENS

I Djunic[1,*] V Dopsaj[2], P Miljic[1], N Suvajdzic-Vukovic[1], D Tomin[1], M Virijevic[1], A Novkovic[3], D Tomin[1], I Elezovic[1]
[1]Clinic for Hematology, Clinical Center of Serbia, [2]Institute for Medical Biochemistry, Pharmacy Faculty of Belgrade University, [3]Clinical Hospital Center "Zemun", Belgrade, Serbia

Background: Haemophilic arthropathy is the main cause of morbidity in individuals with severe haemophilia and prevention of joint disease is the primary goal of treatment. Recurrent bleeding into joints causes damage to all joint structures, but the precise mechanism by which this induces haemophilic arthropathy is still unclear. Recently, it was shown that one effect of blood in the joint is degradation of cartilage. Biomarkers of cartilage turnover can be measured in physiological fluids, such as plasma and urine.
Aims: The aims of this study were to detect correlation between a marker of oxidative stress -advanced oxidation protein products (AOPP) and serum/urine concentrations of biomarkers of joint cartilage degradation, as well as to estimate the influence of different prophylaxis regimens for severe haemophilia on this process.
Methods: The study included 20 adult patients with severe haemophilia, manifested by plasma factor (F)VIII/IX <1% of normal, without inhibitor. Five patients with haemophilia A received prophylaxis with FVIII concentrate in the standard dose of 20 IU/kg three times per week, while another five patients with haemophilia A were given an intermediate dose of FVIII concentrate as prophylaxis, 10-15 IU/kg thrice weekly. Seven patients with haemophilia A and three with haemophilia B, received FVIII/IX concentrate only on-demand. The following were measured: a) AOPP - a serum marker of oxidative stress and b) biomarkers of joint cartilage degradation - serum cartilage oligomeric matrix protein (COMP) and urinary C-terminal telopeptide of type II collagen (CTX-II). Blood and urine samples were collected initially, before the start of treatment (labelled AOPP-1, COMP-1 and CTX-II-1) and after 3 months follow-up (labelled AOPP-2, COMP-2 and CTX-II-2).
Results: The mean age of the patients was 32 years (range 19-55). In the group of patients given standard dose prophylaxis, the mean values of AOPP-2 (p=0.018), COMP-2 (p=0.043) and CTX-II-2 (p=0.014) were significantly lower than those for AOPP-1, COMP-1 and CTX-II-2. Likewise, the mean values for AOPP-2 (p=0.047) and CTX-II-2 (p=0.028) in the five patients receiving intermediate dose prophylaxis were also decreased when compared to initial values, but COPM level was not significantly changed. In patients treated on demand the mean values for AOPP, COMP and CTX-II did not alter significantly. The results showed marked positive correlations between AOPP and both COMP and CTX-II. Namely, lower values of AOPP were significantly associated with decreased levels of both biomarkers of cartilage degradation: COMP (p=0.008) and CTX-II (p=0.014).
Summary and Conclusions: The precise mechanism of joint disease in patients with severe haemophilia remains unknown but probably involves blood-induced increase of oxidative stress, which leads to higher joint cartilage turnover. The most important clinical strategy for management of these patients and prevention of severe arthropathy is treatment by continuous prophylaxis with intravenously applied FVIII/IX.

P616

BONE MINERAL DENSITY IN MEN AND CHILDREN WITH HAEMOPHILIA A AND B: A SYSTEMATIC REVIEW AND META-ANALYSIS

SA Paschou[1], P Anagnostis[2,*] SN Karras[1], C Annweiler[3], S Vakalopoulou[2], D Goulis[1], V Garipidou[2]
[1]Unit of Reproductive Endocrinology, First Department of Obstetrics and Gynecology, Medical School, [2]Haemophilia Center of Northern Greece, Aristotle University of Thessaloniki, Thessaloniki, [3]Department Geriatric Medicine, UPRES EA 4638, University Hospital, Angers, France; Robarts Research Institute, Department of Medical Biophysics, Schulich School of Medicine and Dentistry, the University of Western Ontario, London, Ontario, Canada, Angers, Greece

Background: Haemophilia is not considered among the classic causes of secondary osteoporosis.
Aims: The aim of this study was to systematically review the literature for case-control trials that have studied bone mass in males with haemophilia and to meta-analyze the best evidence available.
Methods: Electronic databases MEDLINE, EMBASE and CENTRAL were systematically searched for case-control trials that have studied bone mass in men or boys with haemophilia. Standardized mean difference (SMD) for bone mineral density (BMD) in the lumbar spine was the main study outcome and SMD in femoral neck and total hip BMD the secondary ones. Patient and control characteristics, such as age, body mass index (BMI), level of physical activity and blood-borne infections were recorded as possible predictors of the main outcome.
Results: Thirteen studies were included in the systematic review and 10 in the main outcome meta-analysis. Men with haemophilia demonstrated reduced lumbar spine [random effects SMD [95% confidence interval (CI)] -0.56 (-0.84; -0.28), between-study heterogeneity (I^2)=51%] and femoral neck BMD [random effects SMD (95% CI) -0.82 (-1.21; -0.44), I^2=63%] compared with controls, which indicated a large and clinically significant association. Similar results were obtained for children [random effects SMD (95% CI) -0.92 (-1.77; -0.07), I^2=92%]. No evidence of publication bias was detected. There was no evidence that age, BMI, level of physical activity or presence of blood-borne infections predicted lumbar spine BMD. Using the 'Common Language Effect Size' approach, the probability is about 72% that an individual without haemophilia would have higher lumbar spine BMD than an individual with haemophilia, if both individuals were chosen at random from a population.
Summary and Conclusions: This meta-analysis shows that men with haemophilia present a significant reduction in both lumbar spine and hip BMD, which appears to begin in childhood.

P617

CAN SECONDARY PROPHYLAXIS IN HAEMOPHILIA BE A CAUSE OF ISCHEMIA?

M Sonmez[1,*] H M Ozbas[1], A Mentese[2], D Us Altay[2]
[1]Haematology, [2]Biochemistry, Karadeniz Teknik University Medical Faculty, Trabzon, Turkey

Background: In the treatment of haemophilia, prophylactic factor is used to reduce bleeding frequency, to prevent complications and to improve quality of life. Life expectancy of patients with haemophilia improved with the advent of efficient management of bleeding attacks and widespread use of prophylactic treatment. The incidence of ischemic cardiovascular and cerebrovascular events is known to be lower compared to the general population due to the protective effect of hypocoagulable state associated with factor deficiency in haemophilia patients. The effect of factor administration during bleeding or of prophylactic treatment on ischemia development is not known. SCUBE 1, a new biochemical marker of protein structure, found in endothelial cells and platelets, is stored in α granules of platelets and released when platelets are stimulated. Levels of SCUBE 1 were found elevated in acute coronary syndrome and ischemic cerebrovascular events, making SCUBE 1 an early and potent indicator of ischemia.
Aims: The present study was designed to investigate the effect of factor treatment, SCUBE 1 levels.
Methods: Ten patients with haemophilia A and 3 with haemophilia B receiving prophylactic treatment were included into the study. Bloods samples were collected before and one hour after prophylactic administration. Additionally, during follow-ups, when bleeding episodes were observed blood samples were collected before and one hour after factor administration. In factor-treated cases, blood samples were drawn after administering the first 1000 units. Thirty healthy subjects were used as controls. Sera samples were stored at -80ºC and SCUBE 1 levels were studied using ELISA.
Results: Mean age for the patient and control groups were 35±10 and 34±7 years respectively. SCUBE 1 levels for groups were 235.4±20.3 ng/ml, 258.5±23.4 ng/ml and 235.9±16 in control, patients with bleeding before factor administration and patients before prophylaxis, respectively. SCUBE 1 levels were found to be 233.9±19.6 ng/ml and 280±29.7 ng/ml after factor administration in groups admitting for bleeding and prophylaxis, respectively. Statistically, patients admitting for bleeding had higher SCUBE 1 levels compared to controls, decreasing to that of control after factor administration ($p<0.01$). In prophylaxis group, SCUBE 1 levels of patients before factor administration were found to be comparable to that of controls, increased after factor administration ($p<0.0001$).
Summary and Conclusions: We conclude that, factor administration for prophylaxis may lead to ischemia, while administration in case of bleeding may have anti-ischemic behaviour.

P618

APPLICATION OF THE US NATIONAL INSTITUTE OF HEALTH (NIH) 2008 GUIDELINES FOR VON WILLEBRAND DISEASE IN A NATIONAL PAEDIATRIC COMPREHENSIVE CARE CENTRE.

I E Regan[1,*] A Burke[1], O M Cormack[1], C Fox[1], B Nolan[1]
[1]Coagulation/Haematology, Our Ladys Childrens Hospital, Crumlin, Dublin, Ireland

Background: Von Willebrand's Disease (VWD) is the most common inherited bleeding condition, affecting males and females in approximately equal proportions, and occurring in up to 1% of the world populations. Clinical and laboratory evaluation for VWD is relatively complex and there isno single laboratory test that can screen for the presence of VWD. The 2008 NHLBI/NIH guidelines on "The Diagnosis, Evaluation and Management of von Willebrand Disease" suggest an algorithmic approach to the clinical and laboratory diagnosis of VWD. These guidelines proposed more stringent diagnostic criteria to replace the 1995 and 2004 UKHCDO guidelines.

Aims: The aim of this project was to reclassify the patient cohort at Our Lady's Children's Hospital Crumlin, Dublin, Ireland (OLCHC) for Von Willebrand disease (VWD). OLCHC is the National Paediatric Comprehensive Care Centre.
Methods: Case records of children under 18 years of age with VWD or possible VWD were retrospectively extracted from the Irish National Bleeding Disorder database. These records were then analysed according to the NHLBI/NIH diagnostic criteria. The algorithm applied was; If VWF levels <30 IU/dl on two separate occasions - VWD; If VWF levels 30-50 IU/dl on two separate occasions - 'Low VWF levels'; If VWF not less than 50 IU/dl on two occasions and multiple testing - not VWD. Where insufficient laboratory data were available patients were recalled to a review clinic, tests for FBC, Coagulation screen, and VW screen were performed. Multimer and gene mutation analysis were performed on patients with possible diagnosis of Type 2 and Type 3 VWD. If patients did not meet the NIH guidelines but still had a significant bleeding history, haemostatic investigations such as factor assays and platelet function tests were performed.
Results: 217 children had been historically diagnosed with VWD or possible VWD. Following the review there was a 72% reduction in the number of patients diagnosed with Type 1 VWD. Predictably, no significant change in numbers diagnosed with Type 2 and Type 3 VWD. 78 (36% of total population) is now classified as Low VWF. 37 (17% of total population) were deemed to have no form of VWD and reclassified as normal. Not all patients (36 (17%)) have returned for reclassification so remain as unspecified or possible VWD (Figure 1).

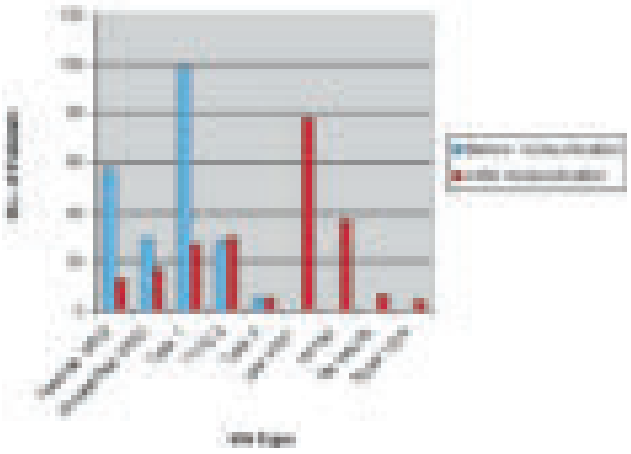

Figure 1. VWD classification.

Summary and Conclusions: Our data strongly suggest overdiagnosis of VWD in this paediatric population using previous guidelines. This review has eliminated possible VWD and unspecified VWD type categories, however a number of patients have not returned for reclassification and remain with the above diagnosis. This has however implications for service resources where newly reclassified patients need to be informed and require counseling. Diagnosis, especially for individuals with mildly decreased VWF (30–50% or IU/dl), requires correlation of clinical assessment (personal and family history of bleeding) and results of laboratory testing. This recommendation does not preclude the diagnosis of VWD in individuals with VWF:RCo of 30–50 IU/dl if there is supporting clinical and/or family evidence for VWD. This recommendation also does not preclude the use of agents to increase VWF levels in those who have VWF:RCo of 30-50 IU/dl and may be at risk for bleeding.

P619

VON WILLEBRAND'S DISEASE AND PLATELET FUNCTION DISORDERS IN WOMEN WITH MENORRHAGIA

S Hacioglu[1], I Sari[1,*] A Keskin[1]
[1]Hematology Department, Pamukkale University, Denizli, Turkey

Background: Menstruation disorders are common clinical problems in fertile women and menorrhagia is most common of them. Von Willebrand disease (VWD) is the most common clinical entity among inherited coagulation disorders causing menorrhagia.
Aims: In this study, our aim was to determine the frequency of platelet function disorders and VWD in women referred to gynecology clinics in our province with menorrhagia and no proved local gynecologic pathology.
Methods: Study was performed with 90 voluntary female patients. Menorrhagia was determined with PBAC scoring method. Patients with 100 or more PBAC scores were included in the study. Complete blood count, peripheral smear for evaluating platelet count and morphology, blood group, PT, APTT, fibrinogen, FVIII and FIX levels, VWF: Ag level, ristocetin cofactor activity and platelet aggregation tests with ADP, collagen, ristocetin and epinephrine had been done in study population.
Results: In 90 patients included in the study with menorrhagia; 13.3% (12/90) VWD, 26.7% (24/90) platelet function disorders and 4.4%(4/90) moderate factor VIII deficiency had been determined. No pathology had been detected in 55.6% (50/90). Amongst platelet function disorders, Glanzmann's thrombasthenia in one (4.1%) patients and Bernard–Soulier disease in one (4.1%) patients. In 22 (91.6%) patients, the platelet function defects could not be classified into specific groups. Impaired aggregation response to ristocetine was the most common disorder 40.9% (9/22) among unclassified platelet disorders, whereas decreased response to both ristocetine and ADP was the second most common with a rate of 22.7% (5/22). In the third place, diminished aggregation response to collagen and epinephrine was determined at a rate of 13.6% (3/22). In addition, impaired aggregation responses had been detected in 2 patients (9%) to ADP, in 1 patient (4.5%) to collagen and ADP, in 1 patient (4.5%) to epinephrine and collagen and in 1 patient (4.5%) to ristocetine and epinephrine. In the comparison of menstrual bleeding characteristics and history of bleeding frequency of patients with a diagnosis of VWD and patients without a bleeding disorder, patients with VWD had significantly increased number of used pads during one menstruation cycle (p=0.006), the frequency of changing pads (p=0.031), and PBAC scores (p<0.001). In the comparison of the laboratory data of patients with VWH and platelet function disorder and those without bleeding disorder, there were no significant differences between the groups in terms of Hb, Htc, MCV, PLT, PT and fibrinogen levels, whereas APTT was significantly longer in the VWH group (p=0,01), and FVIII, FIX and VWF:Ag levels were significantly lower in the VWH (respectively; p=0.024, p=0.028, p=0.03).
Summary and Conclusions: In this study, it was emphasized that unrecognized hereditary bleeding disorders could be found in heavy and / or prolonged menstruation and screening of those disorders was absolutely necessary.

P620

MONITORING OF SUBSTITUTION THERAPY WITH RECOMBINANT FACTOR XIII OF A PATIENT WITH SEVERE FACTOR XIII A SUBUNIT DEFICIENCY

A Kerényi[1,*] A Árokszállási[2], É Katona[3], Á Schlammadinger[2], Z Bereczky[3], Z Boda[2], L Muszbek[3]
[1]Institute of Laboratory Medicine, [2]Institute of Medicine, Division of Haemostasis, [3]Clinical Research Center, University of Debrecen, Debrecen, Hungary

Background: Coagulation factor XIII (FXIII), a tetrameric zymogen (FXIII-A_2B_2), consists of two catalytic A and two inhibitory/carrier B subunits. It is activated by thrombin and Ca^{2+} in the final phase of coagulation cascade. Activated FXIII (FXIIIa) is a transglutaminase which crosslinks peptide chains through ε(γ-glutamyl)lysyl bonds. The main task of FXIIIa is to cross-link fibrin chains and α_2-plasmin inhibitor to fibrin to make fibrin clot more resistant against the shear stress of circulating blood and to provide protection against fibrinolysis. FXIII-A deficiency is a rare (1:1-3 millions) but severe bleeding diathesis and due to the high risk of intracranial bleeding it needs life-long prophylactic substitution, preferably by FXIII concentrate. Beside plasma derived FXIII-A_2B_2 concentrate, most recently recombinant FXIII-A_2 (rFXIII) (Novo Nordisk, Denmark) has also been approved for prophylaxis. rFXIII needs the patient's own FXIII-B to remain in the plasma with a half-life of 8-13 days. A 19-year-old male with long history of bleeding complications was admitted to the clinic with intramuscular hematoma. After diagnosis of FXIII-A deficiency he was administered 35 U/kg rFXIII and later he was put on prophylactic therapy.
Aims: To give a complete laboratory diagnosis of FXIII deficiency and to monitor the changes in FXIII activity, FXIII-A_2B_2, FXIII-A and total plus free FXIII-B antigen in the plasma following the administration of rFXIII. The possible appearance of anti-FXIII-A alloantibody was also investigated.
Methods: FXIII activity was measured by the ammonia release method using blank subtration (REA-Clot FXIII, Reanal-ker, Budapest). FXIII antigens were determined by highly sensitive ELISA methods developed and published by our laboratory. The genetic defect in the FXIII-A gene was detected by fluorescent DNA sequencing. The presence of alloantibody was tested in mixing study.
Results: At admission the patient had normal hemostasis screening tests and platelet count. von Willebrand disease was excluded. FXIII activity was <1%, FXIII-A_2B_2 and FXIII-A antigen were <0.1%. Total FXIII-B was 54%. His platelets were exempt of FXIII activity and FXIII-A antigen. The diagnosis of FXIII-A deficiency was confirmed by genetic testing. The patient was compound heterozygote possessing the missense and nonsense mutations, c.1149G>C, p.Arg382Ser and c.1201C>T, p.Gln400X. One hour following the administration of 35 U/kg rFXIII, FXIII activity, FXIII-A_2B_2 and FXIII-A antigen levels jumped to 70% and did not change significantly in the next 5 hours. In the circulation of our patient the half-life of prophylactic rFXIII was approximately 8 days. After 4 weeks the mean (n=3) pre-dose FXIII activity was 4.5%. FXIII-A_2B_2 and FXIII-A antigen levels were comparable. Free FXIII-B level dropped by 62% one hour after the administration of rFXIII but returned to pre-dose level within three days. Interestingly, total FXIII-B started to raise within one hour after the administration of rFXIII-A and it peaked on days 3-6 and did not decrease to the pretreatment level even on day 28. The patient during 4 months of treatment was exempt of bleeding symptoms in spite of tooth extractions.

Summary and Conclusions: rFXIII treatment resulting in a pre-dose level above 4% provided an efficient safe prophylaxis for a patient with severe FXIII-A deficiency. The patient's own FXIII-B was effectively utilized for complex formation and the administration of rFXIII-A induced the elevation of FXIII-B plasma level.

P621

OPTIMAL MANAGEMENT OF A RARE COAGULATION DISORDER: FACTOR V DEFICIENCY

M Elshinawy[1,*] A Alrawas[1], I beshlawy[1], W bashir[1], H Nazir[1], S Tony[1], M Zachariah[1], Y Wali[1]
[1]Pediatric Hematology, Sultan Qaboos University Hospital, Muscat, Oman

Background: Congenital factor V deficiency is a very rare coagulation disorder, with an estimated prevalence of 1/1,000,000. In literature, Most of the reported cases are characterized by a mild to moderate bleeding phenotype.
Aims: To describe the initial presentations, clinical course and management of congenital factor V deficiency cases in Oman.
Methods: This is a prospective case series study.
Results: Two infants presented with intracranial hemorrhage at the ages of 4 weeks and 10 days respectively. The first baby was found to have marked prolongation of both prothrombin time (34 seconds) and partial thromboplastin time (175 seconds), correctable with mixing study. Factor assay revealed severe congenital factor V deficiency. Fresh frozen plasma (FFP) was given repeatedly and he underwent neurosurgical evacuation of his parieto-temporal hematoma. Unfortunately, the second baby was misdiagnosed as late hemorrhagic disease of newborn in a peripheral hospital. She sustained recurrent intracranial bleeds which negatively impacted her neurodevelopment. This baby was referred to our hospital at the age of 3 months and diagnosed with severe factor V deficiency. The sibling of the 1st baby was delivered by an elective cesarean section in our centre, screened at day 3 of life and diagnosed with severe factor V deficiency as well. Our fourth patient has moderate factor V deficiency, manifesting with infrequent musculoskeletal bleeds that require on-demand FFP. All data are displayed in Table 1. Despite the lack of internationally-agreed guidelines, the three babies with severe congenital factor V deficiency were started on regular prophylaxis. To reduce the risk of blood borne infections, we opted to use solvent/detergent (S/D)-treated plasma twice weekly; through a port-a-cath.

Table 1. Clinical characteristics and management of factor V deficiency cases.

Summary and Conclusions: Early recognition and optimal management of rare coagulation disorders are major determinants of prognosis. Compared to on-demand therapy, life-long prophylaxis in severe coagulation disorders is the standard of care. However, many difficulties exist including lack of commercially available purified products, risk of viral transmission and difficult venous access. We recommend establishing a national registry of rare coagulation disorders in collaboration with the international registry to identify the prevalence, genotypes, severity, clinical profile and therapeutic options of such rare conditions.

P622

THE CLINICOLABORATORY CHARACTERISTICS AND TREATMENT OUTCOMES OF 10 KOREAN PATIENTS WITH FACTOR V DEFICIENCY

YH Park[1,*] JH Lim[1], HG Yi[1], MH Lee[1], CS Kim[1]
[1]Hematology and Oncology, Inha University Hospital, University of Inha College of Medicine, Incheon, Korea, Republic Of

Background: Factor V (FV) deficiency is a rare bleeding disorder associated with a spectrum of haemorrhagic symptoms, ranging from mucosa and soft tissue bleedings such as epistaxis and hemarthroses to life-threatening haemorrhages. Until now, more than 200 cases of FV deficiency have been described in literature and occurred approximately 10 times more frequently in Western Asia where consanguineous marriage are common.
Aims: We retrospectively analysed the clinicolaboratory features and treatment outcomes of FV deficiency in 10 Korean patients.
Methods: Between January 1987 and December 2012, nine case reports published in Korean journal or presented at Korea Society on Thrombosis and Hemostasis (KSTH) and one medical record in our institution were reviewed.
Results: The median age of all patients at diagnosis, 6 males and 4 females, was 26 years (range, 1 month - 73 years). Based on population size of 45 million, the estimated incidence of FV deficiency in Korea is 0.01 cases per million person years. Seven of 10 patients (70%) are classified as severe FV deficiency characterized by FV levels below 5% and, 1 (10%) as moderate FV deficiency, showing FV levels 5 ~ 10%. Of all patients with median levels of plasma FV of 3.5% (range, 1% to 16%), 80% was diagnosed as inherited FV deficiency, and 30% had a positive family history. One patient had combined FV and factor VIII deficiency, especially. The most frequent clinical features were mucosal tract bleedings (40%) such as epistaxis, oral cavity haemorrhages, and menorrhagia in female. Hemarthroses and postoperative bleeding occurred in 1 and 4 of affected patients, respectively. In 4 of 7 patients with severe FV deficiency, life-threatening bleeding episodes were occurred in peritoneal cavity (2 cases), central nerve system (1 case), and retroperitoneal space (1 case), respectively. No lethal haemorrhages happened to patients with mild or moderate FV deficiency. Majority of bleeding episodes were controlled with local measures, administration of antifibrinolytic drugs, and fresh-frozen plasma (FFP) replacement, and in 2 cases of severe bleeding not controlled with FFP replacement, the immunosuppressive therapy with corticosteroids and/or cyclophosphamide was done. One of them with acquired FV inhibitors confirmed by the Bethesda method died from postoperative bleeding complications.
Summary and Conclusions: Compared with a few countries in Western Asia, this present study shows that similar bleeding manifestations were noted in all patients with FV deficiency in Korea. However, fatal bleeding events had tendency to occur more frequently in Korean patients with severe FV deficiency.

P623

DETECTION OF ANTI-THROMBOPOIETIN AUTOANTIBODY AMONG IMMUNE THROMBOCYTOPENIC PATIENTS

K Miyazaki[1,*] T Satoh[2,3], E Osawa[2], N Modegi[2], A Kita[2], S Kurihara[2], Y Kawasaki[2], N Shimada[2], K Nagane[2], M Higashihara[1], S Takahashi[2,3]
[1]Department Of Hematology, Kitasato University School Of Medicine, [2]Division of Hematology, Kitasato University School of Allied Health Sciences, [3]Division of Molecular Hematology, Kitasato University Graduate School of Medical Sciences, Sagamihara, Japan

Background: Immune thrombocytopenia (ITP) is an autoimmune disorder, manifesting isolated thrombocytopenia, caused by autoantibody-mediated platelet destruction and impaired platelet production. Plasma levels of thrombopoitin (TPO) are normal or slightly elevated in ITP despite the low platelet count. However, it has not been cleared what keeps plasma TPO concentration relatively low in ITP.
Aims: In this study, we verified a hypothesis that anti-TPO antibodies are possibly involved in the pathophysiology of ITP by suppressing TPO level.
Methods: Hundred four ITP patients and 69 healthy individuals were enrolled in this study. Plasama samples were examined to detect anti-TPO antibodies by ELISA. Next we refined IgG from 14 samples (6 cases of anti-TPO (+), 4 cases of anti-TPO (-), and 4 healthy controls). We added each IgG fraction to TPO-dependent human leukemia cell line UT-7/TPO to culture in the presence of human recombinant TPO, and examined the effect on the cell growth.
Results: In eight of 104 ITP patients (7.7%) anti-TPO autoantibody was detected, and the plasma TPO levels (32.2±30.2 *vs* 59.9±67.5 pg/mL) and platelet counts (28±22 *vs* 64±47 x10^9/L) seemed to be relatively lower in anti-TPO(+) patients than the others. Next refined plasma IgG fraction from three of six anti-TPO(+) patients significantly inhibited the growth of UT-7/TPO, which is presumably due to neutralization of TPO by anti-TPO antibodies. In contrast, such an inhibitory effect was never observed among either anti-TPO(-) patients or healthy individuals. Additionally we analyzed the clinical features of ITP patients with anti-TPO antibody. Seven of eight anti-TPO(+) cases (87.5%) were positive for anti-nuclear antibodies (ANAs) in contrast to only 44 of 96 anti-TPO(-) cases (45.8%) (Table 1).

Table 1. Clinical features of anti-TPO antibody (+) ITP patients.

Case	1	2	3	4	5	6	7	8
Age	24	77	51	83	42	20	53	39
Male/Female	M	F	F	M	F	M	M	F
PLT (x10^9/L)	4	36	59	9	120	330	71	262
TPO plasma (pg/mL)	25.4	10.3	5.17	186.7	80.5	6.04	95.6	101.5
ANAs	+	+	+	+	+	+	-	+
aPL	nt	nt	-	+	+	+	nt	+
Growth of UT-7/TPO	N	N	I	N	I	nt	nt	I

ANAs, anti-nuclear antibodies; aPL, anti-phospholipid antibodies; nt, not tested; I, inhibited; N, Not inhibited.

Summary and Conclusions: Although some knowledge has been accumulated about pathophysiology of ITP, the diagnosis is still a process of exclusion,

and the etiology is heterogeneous, which can result in a variety of therapeutic responses. Our results demonstrated that anti-TPO antibodies can be detected in a proportion of ITP patients. Although the number is limited, anti-TPO(+) patients seemed to show relatively lower platelet counts and TPO levels, and to be associated with other autoantibodies, such as ANAs and antiphospholipid antibodies. These suggest that anti-TPO antibody could be involved in the pathophysiology of ITP at least in a certain number of patients, and might affect therapeutic response to TPO receptor agonists. Accumulation of cases is required to elucidate the significance of anti-TPO antibody in pathophysiology and clinical features of ITP.

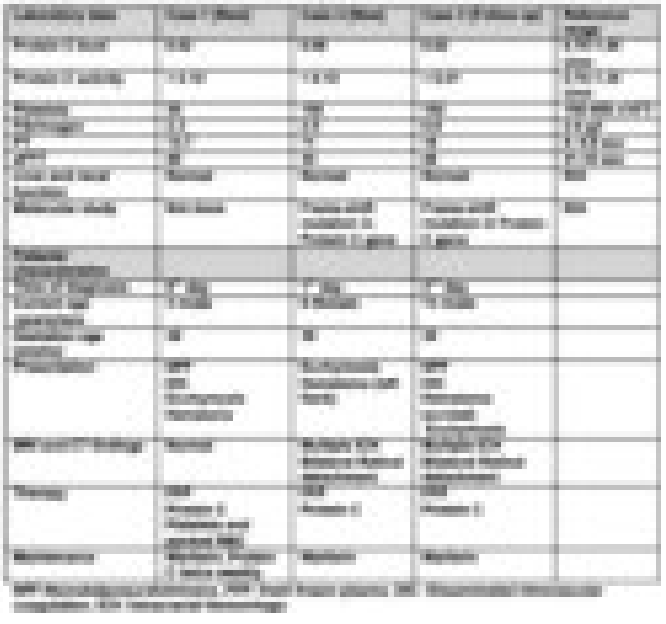
P624

HOMOZYGOUS PROTEIN C DEFICIENCY: A DESCRIPTION OF TWO NEW CASES AND LONG-TERM SURVIVAL OF A THIRD CASE SUCCESSFULLY TREATED WITH ORAL ANTICOAGULANT THERAPY, A REPORT FROM SAUDI ARABIA

G Elyamany[1,2,*]F Al-Batniji[3], H Elfaraidi[3], A Alzahrani[3], F Alabbas[3], O Alsuhaibani[2], B Alharthi[2], K Fadalla[2], Y Elborai[3,4], A Elarja[2], A Al-Abulaaly[2]
[1]Department of Hematology and Blood Bank, Theodor Bilharz Research Institute, Cairo, Egypt, [2]Dept. of Pathology and Laboratory Medicine, [3]Pediatric Hem/Onc and Stem Cell Transplant, Prince Sultan Military Medical City (PSMMC), Riyadh, Saudi Arabia, [4]Pediatric Hem/Onc and Stem Cell Transplant, National Cancer Institute, Cairo University, Cairo, Egypt

Background: Homozygous protein C deficiency is a rare autosomal recessive disorder that usually presents in the neonatal period with purpura fulminans (PF) and severe disseminated intravascular coagulation (DIC), often with concomitant venous thromboembolism. Mutational analysis of symptomatic patients shows a wide range of genetic mutations.
Aims: We report here a quite rare 3 cases of severe homozygous protein C deficiency, two new cases and a Long-term survival of a third case successfully treated with Warfarin therapy.
Methods: Patients: Three cases from 2 families (case 2and 3 are from same family while case 1 from different family), Informed consent was obtained from parents. Protein C levels and activity: Plasma Protein C antigen level was measured by enzyme immunoassay while the protein C activity was measured by using chromogenic assay. PCR and sequencing: DNA was extracted from the patients and parents blood samples. Protein C gene was amplified by PCR and sequencing was carried out on the amplified PCR products and the samples were run on the DNA analyzer and data were analyzed.
Results: The patients and parents characteristics at diagnosis were summarized on Table 1. Case 1: A 3 year-old boy that developed PF and DIC shortly after birth. He was born after an uneventful pregnancy, no family history of thrombosis but positive for consanguinity. The father and the mother have protein C antigenic levels of 0.56 and 0.36 U/ml respectively and protein C activity levels of 0.57, 0.48 U/ml respectively (Figure 1).

Table 1. Patients characteristics and laboratory data.



Case 2: An 8 year-old female, he was a product of full term unremarkable pregnancy who developed ecchymosis and hematoma of left flank shortly after birth. No family history of thrombosis but positive for consanguinity. The father and the mother have protein C antigenic levels of 0.67 and 0.63 U/ml respectively and protein C activity levels of 0.69, 0.66 U/ml respectively. Case 3: A 13 year-old boy (brother of case 2) that developed PF and DIC shortly after birth. He was born after an uneventful pregnancy at 39 week by ventouse extraction due to fetal distress. Case 1 and 2 were treated during the acute phase by FFP at a dose of 15 ml/kg every 12/hours alternating with protein C concentrate, an initial dose of 100 U/kg followed by 50 U/kg every 12 hours, the treatment was continued until all lesions had resolved. Case 3 was treated by FFP at a dose of 15 ml/kg every 12/hours as a replacement therapy as protein C concentrate was not available. Due to repeated thrombotic attaches in case 1, the patient on protein C replacement therapy as a maintenance therapy (50 U/kg twice weekly) with a small dose of warfarin to maintain INR between 1.5 and 2.5. The maintenance therapy for case 2 and 3 consists of warfarin therapy alone; the dose of Warfarin therapy is adjusted to maintain a target INR between 2.5 and 3.5. Molecular analysis of case 2 and 3 and their parents revealed presence of CCTG nucleotide repeats (effective insertion), homozygous in the case 2 and 3 while heterozygous of parents which resulted in a frame-shift causing a premature stop codon at amino acid 383. Currently our cases are doing well with no neurological deficit but case 2 and 3 are blind with long-term survival on Warfarin therapy alone (8 and 13 years respectively).

Figure 1. Case 1 shows typical skin lesion of neonatal purpurafulminans.

Summary and Conclusions: Homozygous protein C deficiency state is usually not compatible with long-term survival and often fatal unless there is early recognition of the clinical symptoms, prompt diagnosis, and urgent therapy is crucial to avoid further damage after delivery.

P625

AN AUDIT TO DETERMINE THE SAFETY OF THE NOVEL ORAL ANTICOAGULANTS, DABIGATRAN AND RIVAROXABAN, FOR PATIENTS INITIATED ON ANTICOAGULANT THERAPY

H Kurunadalingam[1,*] S Patel[2], I Gabriel[3], R Morgan[3], H Yarranton[3], M Vizcaychipi[1]
[1]Anaesthesia, [2]Pharmacy, [3]Medicine, Chelsea and Westminster Hospital, London, United Kingdom

Background: In the UK, dabigatran and rivaroxaban are licensed and approved by National Institute for Health and Care Excellence (NICE) for the prevention of stroke and systemic embolism in patients with non-valvular atrial fibrillation (AF) and rivaroxaban is also licensed for treatment and secondary prevention of deep vein thrombosis (DVT) and pulmonary embolism (PE), approved by NICE in 2012. However, experience amongst clinicians in the UK using novel oral anticoagulants (NOACs) remains fairly limited. Warfarin therapy was considered the first line option for these indications where the experience and knowledge of warfarin use is substantially greater. However, the advantages of these NOAC agents are: no routine monitoring, fixed dosing and no lifestyle/food restrictions. At our hospital, NOACs were prescribed from December 2011 for stroke prevention in AF and VTE treatment where warfarin was not suitable. The aim of this audit is to determine the safety of NOACs in clinical practice, focusing on adverse effects, bleeding outcomes, and management.
Aims: Determine the siginificant risks of using dabigatran and rivaroxaban in clinical practice compared with clinical trial literature and decide whether they are the new safer alternative to warfarin.
Methods: The audit team agreed the aims and standards and reviewed the literature. A pharmacy report identified patients prescribed NOACs from December 2011 to April 2013. Clinical information was accessed using patient medical notes and electronic records. A data template spreadsheet was developed to record audit data.
Results: 165 patients were initiated on NOAC therapy; 33 patients excluded. 132 patients were included in the audit. The majority of patients on rivaroxaban (n=50) were aged 71 to 90years old and on dabigatran (n=43) were aged 61 to 80years old (Table 1).
Summary and Conclusions: The NOACs have many advantages and are generally well tolerated with a good adverse effect profile. However, patients did experience bleeding events and the management is challenging with no specific antidote currently available.

Table 1.

	Rivaroxaban (n=79)	Dabigatran (n=53)
Indication for NOAC		
DVT	23	
PE	15	
DVT and PE	7	
Stroke prevention in AF	34	53
Adverse Effects		
Dyspepsia	1	3
Back Pain	1	0
Chest Pain	2	0
Fatigue	1	0
Diarrhoea	0	1
Arthralgia	1	0
Bleeding Events		
Non-Major Bleeding Event		
Epistaxis	2	0
Haemoptysis	0	1
Haematuria	1	3
Ear	0	0
Skin	1	0
Gastrointestinal related	3	2
Major Bleeding Event		
Decreased in Hamoglobin >4.0 g/dL	1	1
Transfusion of ≥3 units of red blood cells within a 24 hour period	0	0
Requiring intervention e.g. embolisation, superficial vascular repair, nasal packing	0	0
Intraspinal or intramusclar bleed wit compartment syndrome	0	0
Retroperitoneal, pericardial or intraocular bleed	0	0

Management of the major bleeding events involved a seven unit blood transfusion and Novoseven (coagulation factor VIIa recombinant) for a patient on rivaroxaban and a four unit blood transfusion for the patient on dabigatran. Both patients survived.

Quality of life

P626

COMPREHENSIVE SYMPTOM PROFILE IN PATIENTS WITH CHRONIC MYELOID LEUKEMIA: PRACTICABILITY AND SENSITIVITY OF THE NEW SYMPTOM ASSESSMENT TOOL CSP LEUK-CML

T Nikitina[1], T Ionova[1,*] E Usacheva[2], D Fedorenko[3], K Kurbatova[1], G Gorodokin[4], A Novik[1]
[1]Multinational Center for Quality of Life Research, [2]Hematological Center № 1, Saint-Petersburg, [3]National Pirogov Medical Surgical Center, Moscow, Russian Federation, [4]New Jersey Center for Quality of Life and Health Outcomes Research, New Jersey, United States

Background: Symptom profile and severity is one of the important treatment outcomes in patients with chronic myeloid leukemia (CML). Comprehensive symptom assessment before treatment as well as monitoring during treatment and at follow-up is worthwhile. Recently a new tool, Comprehensive Symptom Profile in Chronic Myeloid Leukemia (CSP Leuk-CML), has been developed to assess disease and treatment related symptoms in CML patients.
Aims: We aimed to test practicability and sensitivity of CSP- Leuk-CML in CML patients.
Methods: 75 patients with chronic phase CML resistant or intolerant to imatinib were enrolled in the study: mean age – 51.3 years old, SD 15.4; range – 22-83 years; male/female – 37/38. The patients filled out CSP Leuk-CML and generic quality of life (QoL) questionnaire SF-36 before second-line therapy, at 3 and 6 months after treatment start. Hematologists participating in the study were interviewed regarding the use of PROs in their decision-making. Analysis of symptom severity in different patient groups was performed using t-test.
Results: Practicability of CSP Leuk-CML was shown: patients needed about 15 min to answer it; the proportion of missing values was 0.56% for all questions; all items were easy for the patients to read and understand. Hematologists considered information about changes in symptom profile practical and useful for their decision-making. Of special importance for them was information about patient-reported treatment side effects. Usefulness of the tool to distinguish patients in terms of severity and number of disease- and treatment specific symptoms was demonstrated. The construct validity of CSP Leuk-CML was proven by factor analysis and "known-group" comparison. Factor analysis found five underlining constructs (domains) of the tool (explained 66% of the total variance) with Chronbach alphas varied from 0.72 to 0.94, which were clinically relevant and increased the practicality of the tool. Moderate correlations of five CSP Leuk-CML domains with the grades of QoL worsening were revealed (r=0.43-0.81; p<0.001): the higher symptom severity the more QoL worsening (r=0.43-0.81; p<0.001). A number of CML-specific symptoms were more severe in patients with side effects of treatment than in those without side effects (*fatigue, constant tiredness, decreased work energy, excessive sweat at rest, heat sensation, abdominal pain, diarrhea, edema, anxiety, restless dreams*; p<0,05). Sensitivity of the tool to clinical changes was demonstrated: symptom severity at 3 months after treatment start was reduced (*fatigue, excessive sweat at rest, muscle spasms, dry mouth, diarrhea, palpitation, shortness of breath, edema, numbness, restless dreams;* ES=0.36-0.46).
Summary and Conclusions: The CSP Leuk-CML is an appropriate, practical and sensitive tool to assess symptom profile and severity in CML patients. Further studies are needed before the wide-spread use of the CSP Leuk-CML in clinical practice and in clinical trials. Comprehensive symptom monitoring using patient-reported outcome measures may be recommended to clearly determine treatment outcomes in this patient cohort.

P627

PROGNOSTIC VALUE OF NEUROPSYCHOLOGICAL AND BIOLOGICAL FACTORS IN OLDER PATIENTS WITH HEMATOLOGICAL MALIGNANCIES ADMITTED TO RECEIVE CHEMOTHERAPY

S Dubruille[1,*] Y Libert[1], M Maerevoet[2], M Roos[3], S Vandenbossche[1], N Meuleman[2], D Razavi[1], D Bron[2]
[1]Psycho-Oncology Unit, [2]Hematology Department, [3]Oncogeriatry Unit, Institut Jules Bordet, Brussels, Belgium

Background: A Comprehensive Geriatric Assessment (CGA) is recommended to detect vulnerable cancer patients for whom chemotherapy may lead to severe impairment on functionality, quality of life, or survival. However, little is known about the reliability of G8 screening tool and the prognostic value of neuropsychological and biological factors in older patients with hematological malignancies admitted to receive chemotherapy.
Aims: To assess in "Go- and Slow-Go" patients with malignant hemopathies the reliability of G8 as a screening tool and to identify the predictive value of neuropsychological and biological factors assessed in the CGA in terms of one-year overall survival (OS).
Methods: G8 and CGA were proposed to 107 consecutive patients (65-89 yrs) with hematological malignancies admitted to receive chemotherapy. An initial full-dose or reduced-dose chemotherapy has been administrated to patients according to a multidisciplinary team decision.

Results: Ninety patients were evaluable for both scales, of which 72% and 80%, were defined as "vulnerable" when evaluated with G8 (≤14.5) or CGA (≥2 impairments), respectively. The area under ROC-curve of G8 compared to CGA was 0.749±0.051 (S=79.2% and Sp=55.6%). During the one-year follow-up, 27% (n=21) of older patients treated for hematological malignancies died. The leading cause of death (86%) was the disease progression. Retrospectively, neither the G8 nor the CGA total score had an impact with the initial treatment choice and were not predictive for one-year OS. Regarding the various CGA items, the multivariate Cox proportional hazards model adjusted for potential confounders showed that falls (OR=2.9) and ulcer disease (OR=4.4) were significantly and independently associated with mortality. Accordingly, we have found -using the log-rank test- a significant impact on one-year OS of acute or chronic ulcer disease (p<0.0001) and of ≥1 falls during the last year (p=0.014). Nevertheless, it seems that cognitive impairment (abnormal MoCA) (p=0.024) and renal impairment (p=0.083) may also have an impact on one-year OS.
Summary and Conclusions: Our small series of older patients admitted to receive chemotherapy for hematological malignancies suggests that G8 is a moderate screening tool for identifying patients who should benefit from a CGA and, in contrast with a population of solid tumor, is not predictive of OS. Some specific factors in the CGA (ulcer disease, falls during the last year, cognitive impairment and renal function) have more impact than other on one-year OS. Prospective trials are needed to further determine whether the combination of these specific items could be more adapted to "go- and slow-go" older patients with hematological malignancies.

P628

THE VALUE OF DASATINIB THERAPY IN PATIENTS WITH IMATINIB-RESISTANT OR -INTOLERANT CHRONIC MYELOID LEUKEMIA FROM PHYSICIAN'S AND PATIENT'S PERSPECTIVE: "REAL WORLD" OUTCOMES

T Ionova[1,*] T Nikitina[1], T Gritsenko[2], V Ivanova[3], G Kuchma[4], T Shnaider[5], I Sannikova[6], E Usacheva[7], D Fedorenko[8], K Kurbatova[1]
[1]Multinational Center for Quality of Life Research, Saint-Petersburg, [2]Samara State Medical University, Samara, [3]Botkin Clinical City Hospital, Moscow, [4]Orenburg State Medical Academy, Orenburg, [5]Regional Hospital, Saint-Petersburg, [6]Regional Clinical City Hospital, Voronezh, [7]Hematological Center № 1, Saint-Petersburg, [8]National Pirogov Medical Surgical Center, Moscow, Russian Federation

Background: There is limited published data about the efficacy and safety of the second-line therapy with dasatinib in patients in chronic phase chronic myeloid leukemia (CML-CP) in a "real world" patients setting outside clinical trials. In addition, comprehensive evaluation of benefits and risks of the treatment is worthwhile to better define treatment outcomes in this patients' population.
Aims: We aimed to study clinical and patient-reported outcomes as well as safety of dasatinib treatment in a "real world" setting within the context of its approved indication through the analysis of prospectively collected data in patients with imatinib resistance or intolerance receiving dasatinib as the second-line therapy.
Methods: 75 CML-CP patients resistant or -intolerant to imatinib were enrolled in the prospective, multicenter, non-interventional study (mean age – 51.3 years old, SD 15.4; range – 22–83 years; male/female – 37/38). The median of disease duration was 5.8 years (0.75–17 years). 63 patients had resistance to imatinib; 12 patients were intolerant to imatinib; the median duration of imatinib treatment – 40 months (4–121 months). All the patients received dasatinib as the second-line therapy (100 mg daily). Median follow-up was 12 months. For quality of life (QoL) and symptom assessment patients filled out the SF-36 and Comprehensive Symptom Profile in Chronic Myeloid Leukemia Patients (CSP Leuk-CML), respectively, at base-line, in 1, 3, 6 months after treatment start and every 6 months thereafter. Statistical analysis was made using general linear model (repeated measures)with adjustment for age and gender. Mean symptom severity and percentage of patients with moderate-to-severe (ratings ≥5) symptoms was evaluated.
Results: After 12 months of treatment 79% patients achieved or maintained complete hematologic response and 63% – major cytogenetic response. Six cases of pleural effusion events were registered: they were easily managed in 5 cases; one patient died at 1 month after treatment start due to accompanied infection complication. Severe hematological adverse effects were observed in four cases (grade III-IV neutropenia and thrombocytopenia). Three patients died of disease progression at 6 months of follow-up; one more patient died of sepsis. At median follow-up of 12 months (range 1-24 months) event-free survival rate was 76% (95% CI; 54.7 - 88.4%). At 12 months of dasatinib treatment QoL parameters were stable for 5 out of 8 scales of the SF-36; vitality, social functioning and mental health significantly improved (p<0.001). QoL response in terms of stabilization or improvement was registered in 69% of patients; among them 39% improved, and 30% were stable. While treatment the number of patients with moderate-to-severe symptoms decreased (p<0.05). The majority of symptoms improved or were stable by 12 months of treatment. Positive changes in QoL and symptom severity preserved at 18 and 24 months of dasatinib treatment.
Summary and Conclusions: Thus, our study on "real world" patient data confirms that dasatinib as second-line therapy in CML-CP patients is effective both in terms of clinical outcomes and patient-reported outcomes, as well as exhibits good tolerability. Comprehensive evaluation of the outcomes of the second-line treatment of CML-CP allows to assess the benefits and risks of therapy both from physician's and patient's perspective.

P629

COVARIATION OF PSYCHOLOGICAL AND INFLAMMATORY VARIABLES IN PATIENTS WITH CHRONIC LYMPHOCYTIC LEUKEMIA RECEIVING IBRUTINIB

K Maddocks[1,*] N Godiwala[1], T Westbrook[1], JC Byrd[1], BL Andersen[1], AJ Johnson[1]
[1]The Ohio State University, Columbus, United States

Background: Ibrutinib has been shown to induce durable responses in patients with high risk relapsed/refractory (r/r) chronic lymphocytic leukemia (CLL) (Byrd *et al.*, 2013). Psychological factors, particularly stress, have been shown to covary with immunity and cytokines in solid tumor cancers.
Aims: This pilot study examines temporal changes and covariation in inflammatory/angiogenic markers and psychological variables among r/r CLL patients receiving Ibrutinib. We hypothesized that these variables would improve during treatment and would covary over time.
Methods: Patients enrolled in our single-institution phase-II trial of Ibrutinib with r/r CLL (N=148) provided blood and psychological data on day 1 (of 28) of cycles 1-3. For this pilot, ELISA assays were performed on a subset (N=24; mean age=65; 50% female) of patients representing a distribution of scores (0-33) on a cancer-specific stress measure. Depressive symptoms, mood disturbance, fatigue, and quality of life (QOL) were also assessed. Assays measured IL-6, TNF-alpha, VEGF, CRP, BAFF, CCL3, and IL-16 levels in the patients' plasma. Hierarchical linear modeling examined change over time for all variables and covariation between psychological and inflammatory/angiogenic markers.
Results: Improvements were observed in stress, depressive symptoms, fatigue, and QOL (p-values <0.05). Decreases were observed in IL-16, TNF-alpha, and CCL3 (p-values <0.05). Controlling for age, chromosome 17p deletion, and gender, covariation between the following variables was found: TNF-alpha with stress, depressive symptoms, mood disturbance, and QOL; IL-6 with mood disturbance, fatigue, and QOL; and VEGF with depressive symptoms (all p-values <0.05). That is, changes in inflammatory/angiogenic markers were correlated with changes in psychological variables.
Summary and Conclusions: These pilot data suggest that in addition to providing clinical benefit, Ibrutinib treatment contributes to improvements in psychological functioning and decreases in inflammation.

P630

A MULTINATIONAL OBSERVATIONAL STUDY IN MULTIPLE MYELOMA (PREAMBLE): ASSESSMENT OF DISEASE IMPACT ON WORK PRODUCTIVITY AND ACTIVITY

P Moreau[1,*] R Vij[2], L Annemans[3], H Goldschmidt[4], G Cook[5], A Palumbo[6], B Durie[7], D Cella[8], D Reece[9], JB Bartlett[10], TK Le[10], C Davis[10]
[1]University Hospital of Nantes, Nantes, France, [2]Washington University School of Medicine, St. Louis, MO, United States, [3]Ghent University and Brussels University, Gent, Belgium, [4]Universitätsklinikum Heidelberg, Heidelberg, Germany, [5]St. James University Hospital, Leeds, West Yorkshire, United Kingdom, [6]University of Torino, Torino, Italy, [7]Cedar-Sinai Medical Center/International Myeloma Foundation, West Hollywood, CA, [8]Northwestern University, Evanston, IL, United States, [9]Princess Margaret Hospital, Toronto, Ontario, Canada, [10]Bristol-Myers Squibb Company, Princeton, NJ, United States

Background: Cancer disease burden, treatment burden, and late effects of treatment have a potential impact on work productivity. Patients with multiple myeloma (MM) may experience anemia, renal impairment, and bone disease with associated symptoms of pain and fatigue. While data suggest that MM may impact work productivity, limited evidence currently exists.
Aims: PREAMBLE (Prospective Research Assessment in Multiple Myeloma: an Observational Evaluation) is a multinational, observational cohort study undertaken to prospectively evaluate the real-world effectiveness, healthcare resource utilization, and patient-reported outcomes (including work productivity) associated with the treatment of relapsed and/or refractory (R/R) MM. The aim of this report is to provide data on the initial (baseline) assessment of disease impact on work productivity for patients enrolled in PREAMBLE.
Methods: Patients completed questionnaires for quality of life and physical well-being, including the Work Productivity and Activity Impairment Questionnaire: General Health V2.0 (WPAI:GH). The WPAI:GH is a 6-item, patient-reported assessment of absenteeism, presenteeism (work impairment), and general activity impairment. As of the last data cut-off (November 22, 2013), 156 of 185 treated patients had completed the questionnaire at baseline. All patients had received prior therapy for MM.
Results: The mean time from initiation of current therapy for R/R MM to baseline WPAI:GH completion was 20 days. The majority of patients (94%) report-

ed that their activity level was impaired. Twenty-three of the 156 patients (15%) who completed the questionnaire were gainfully employed. Among the 16 of 23 employed patients who responded, a reported 22% of work time was missed. All 23 patients reported that health affected their work, with a mean impairment of 37%. Results are shown in the Table 1.

Table 1. Baseline WPAI:GH*.

Summary and Conclusions: Patients with R/R MM had already experienced a negative impact on general activity at baseline assessment. While 15% of the patients were employed, all reported impairment of work productivity to some extent. As all patients had prior treatment, it is possible that productivity may not have been impacted by MM alone. Additional follow-up will be needed to determine more fully the impact of both disease and therapy on work productivity.

P631

BONE MARROW ASPIRATION: A RANDOMIZED TRIAL ON THE QUALITY OF THE BONE MARROW SPECIMEN USING SLOW OR RAPID ASPIRATION TECHNIQUES AND ASSESSMENT OF THE PAIN INTENSITY

CF Hasselgren[1], AS L Østergaard[1], AE Bilgrau[2,3], P Johansen[4], J C Korup[1], M Bøgsted[2,3], M Grønkjær[5], P Jensen[1,*]
[1]Department of hematology, [2]Department of hematology, Research Laboratory, Aalborg University Hospital, [3]Department of Mathematical Sciences, Aalborg University, [4]Department of Pathology, [5]Clinical Nursing Research Unit, Aalborg University Hospital, Aalborg, Denmark

Background: In bone marrow aspiration/biopsy (BMA), rapid aspiration technique is often recommended to reduce peripheral blood contamination in order to achieve best possible quality. There is limited evidence on whether speed of aspiration affects the quality of the bone marrow specimen. BMA is associated with pain and discomfort. However, it is not known if the intensity of pain is dependent of the aspiration technique.
Aims: To assess the quality of the bone marrow specimen and the overall pain intensity using slow (S) and rapid (R) aspiration techniques.
Methods: From Nov 2012 to Sep 2013 482 adult patients, among those scheduled for BMA at the Department of Hematology, Aalborg University Hospital, were randomized for either an S-technique (a slow, low differential pressure, uniform pull of a 10ml syringe, aspirating in the same pace as the appearance of the bone marrow for approx. 5 to 15 seconds), when having BMA, or an R-technique (a quick pull creating high differential pressure in a 10ml syringe for approx. 1 second and holding a high differential pressure during aspiration of marrow). The aspiration technique was blinded for the patients and pathologist. Bone marrow cellularity was graded as either no, few, moderate number or many nucleated cell. We defined no or few nucleated cells as inferior quality. The number of marrow particles (0 to >25) was assessed by the pathologist. We defined less than 11 marrow particles as inferior quality. One pathologist examined all samples. Patients assessed the overall pain intensity according to a Visual Analogue Scale (VAS) (0 to 10 where 0 is no pain and 10 is the worst pain imaginable). The BMA was, apart from the difference in aspiration technique, performed according to the standard procedure of the department. The biopsy site was the post. sup. iliac crest. Biopsies and aspirations were performed for all patients. The statistical analyses were carried out using Fisher's exact test for categorical and Wilcoxon's rank sum test for continuous variables, 5% was chosen as significance level, and effect estimates are provided with 95% one-sided confidence intervals. The analysis on cellularity and the number of marrow particles were performed as non-inferiority tests for the null-hypothesis that the number of inferior quality aspirates of the S-technique is no worse than the number of inferior quality aspirates using the R-technique.
Results: Before analysis, 38 patients were excluded for various reasons (hypoplasia/aplasia 5, fibrosis 13, samples lost/destroyed 10, other 10). No significant difference in the two groups. For bone marrow particles, the odds ratio (OR), for having a poor quality aspirate using the S- compared to the R-technique was 2.52 (1.62,∞). For cellularity, the OR was 3.046 (1.93,∞). We also found a statistical significant difference of 1 VAS point (P <0.001) of the median pain intensity in favor of the S-technique. The pathologist assessed whether the specimen as a whole (including information about blood, biopsy, and aspirated marrow) was sufficient to make a diagnosis. For this question there is no statistically significant difference (P=0.175) between the two groups.
Summary and Conclusions: The quality of BMA using the R-technique for aspirating bone marrow is higher than the quality using the S-technique. The pain intensity is statistically higher when using the R-compared to the S-technique. However, the difference in pain intensity is rather small compared to the general variability of the VAS pain score and thus the R-technique is preferred for BMA.

P632

IMPACT OF ANEMIA ON HEALTH-RELATED QUALITY-OF-LIFE AND CARDIAC REMODELING IN PATIENTS WITH LOWER-RISK MYELODYSPLASTIC SYNDROMES (MDS). RESULTS OF GLOBQOL OBSERVATIONAL PROSPECTIVE STUDY.

F Ramos[1,*] C Pedro[2], M Tormo[3], R de Paz[4], P Font[5], E Luño[6], M Caballero[7], F Solano[8], M Almagro[9], B Xicoy[10], M Jiménez[11]
[1]Dept. Haematology, Hospital Universitario de León, León, [2]Dept. Haematology, Hospital del Mar, Barcelona, [3]Dept. Haematology/Oncology, Hospital Clínico, Valencia, [4]Dept. Haematology, Hospital Universitario La Paz, [5]Dept. Haematology, Hospital Universitario Gregorio Marañón, Madrid, [6]Dept. Haematology, Hospital Universitario Central de Asturias, Oviedo, [7]Dept. Haematology, Hospital Insular, Las Palmas de Gran Canaria, [8]Dept. Haematology, Hospital Ntra. Sra. del Prado, Madrid, [9]Dept. Haematology, Hospital Universitario Virgen de las Nieves, Granada, [10]Dept. Haematology, Hospital Universitari Germans Trias i Pujol, Badalona, [11]Novartis Oncology, Barcelona, Spain

Background: Patients with lower-risk myelodysplastic syndromes (LR-MDS) have a diminished health-related quality of life (HRQoL), mainly due to fatigue and other anemia-related symptoms.
Aims: To assess the eventual changes in the HRQoL and cardiac remodeling of patients with LR-MDS during a one-year follow-up, and to analyse their clinico-biological correlations.
Methods: An observational, prospective, multicenter study was performed in 10 Spanish hospitals, including 39 adult patients (9 non-evaluable for not fulfilling selection criteria and/or lack of essential data) with LR-MDS (IPSS score <1.5 or Spanish Scoring System score <2), not receiving disease-modifying therapies. All patients gave informed consent. Socio-demographic, clinical and analytical data were collected at baseline and at 4 follow-up visits, including comorbidity, performance status, Short Physical Performance Battery, echocardiography, hemoglobin, and serum iron parameters. HRQoL was assessed using the SF-36 and EORTC QLQ-C30 questionnaires (at 0, 6 and 12m) and the FACT-An scale (at 3 and 9m), and cardiac remodeling through echocardiography. The perceived need for erythrocyte transfusions (assessed synchronically and independently by both patients and haematologists) was measured using the LASA scale. Seventeen patients (56.7%) were males, median age was 77.6, 18 (60%) were smokers/former smokers and 23 (76.7%) had one or more comorbid conditions (range 0-9, mean 2.4; cardiac disease 26.7%, diabetes mellitus 23.3%, arrhythmia 20.0%, moderate lung disease 20%). Most frequent subtype was Refractory Cytopenia with Multilineage Dysplasia (63.3%), twenty-one (70%) had a low IPSS score and median time since diagnosis was 5 months. Twenty-seven (90%) had an ECOG performance lower than 2, mean hemoglobin concentration was 10.1 g/dL (range 7-12, SD 1.5), 8 (26.7%) were receiving erythroid stimulating agents (ESA) and 4 (13,3%) were transfusion-dependent at study outset.
Results: During follow-up 17 patients (56.7%) initiated ESA therapy and 2 (6.7%) received iron chelating therapy, none of the patients evolved into other MDS subtype or acute myeloid leukemia, 7 (23.3%) developed cardiac failure or atrial fibrillation and 3 (10%) died. Mean hemoglobin concentration, serum ferritin levels, serum transferrin saturation as well as the overall HRQoL and functional parameters remained stable. Nevertheless, we observed statistically significant decrease in the SF-36 physical function and average Fact-An scores (p=0.029 in both cases), as well as a trend towards a lower score in the QLQ-C30 physical role domain (p=0.065). We also observed a statistically significant reduction in gait speed (p=0.038) and a trend towards a higher left ventricular end-diastolic diameter (p=0.081). In addition, patients communicated a non-significant slightly lower (Bland-Altman) perceived transfusion need than their physicians, according to the LASA scale.
Summary and Conclusions: Despite receiving active observation and supportive care as needed that kept stable their mean hemoglobin concentration and iron parameters, lower risk MDS patients suffered from a slight reduction

in their physical performance and showed a trend towards a higher left ventricular end-diastolic diameter during a one-year follow-up. Gate speed may be used to document their physical decline and to identify those patients that may need other disease- and HRQoL-modifying therapies during follow-up. Sequential echocardiography might also be of help for early detection of cardiac consequences of chronic anemia.

P633

THE BURDEN OF RELAPSE ON EUROPEAN HEMATOLOGISTS TREATING MULTIPLE MYELOMA

T Hansen[1,*] M Streetly[2], S Laurenson[3], J Lawrence[4], C Hulin[5]
[1]Department of Oncology and Hematology, University Medical Center Hamburg-Eppendorf, Hamburg, Germany, [2]Department of Hematology, Guys Hospital, London, [3]Adelphi Values, [4]Adelphi Research, Bollington, United Kingdom, [5]Department of Hematology and Internal Medicine, CHU Nancy-Brabois, Vandoeuvre lès Nancy, France

Background: Multiple myeloma (MM) accounts for 1% of all cancers and affects 0.003% of Europeans each year. Due to the incurable and chronic nature of the disease, almost all patients experience successive relapses. Each relapse typically requires a treatment alteration and increased symptom management. We hypothesize that the occurrence of a relapse may place a burden on the patient's physician, in terms of their emotional well-being, workload and stress levels.
Aims: To assess the impact that relapse events have on hematologists, by evaluating their experience of treating relapsed and/or refractory MM patients.
Methods: Thirty interviews were conducted with hematologists in the UK, France, Germany, Italy and Spain (6 per country). Hematologists were included if they had personally treated ≥10 MM patients in the previous month and ≥5 MM patients that had undergone a clinical relapse in the previous year. 'Myeloma UK' (a registered charity) was consulted for input into study design. During in-depth qualitative interviews, hematologists were asked open-ended questions relating to their observations, hopes for their patients, and how relapse affected consultations.
Results: Hematologists reported that consultations with relapsed MM patients often last 2–3 times longer than consultations with non-relapsed patients. This reduces the number of hours available for consultations with other patients, and thereby increases physicians' levels of stress. Information provided to MM patients depends on the physician's preference. Although some physicians felt obliged to provide full details to patients at all times, others reported that in instances where a patient was not yet symptomatic and did not require a treatment change – it was stressful determining whether to inform the patient of their relapse. Hematologists also reported that patients' reactions to the news that they have relapsed can be unpredictable. These factors make it difficult for physicians to prepare for consultations with MM patients who are no longer responding to treatment or who are experiencing a relapse event.
Hematologists reported that their hopes for their patients to remain relapse-free with long periods of remission are seldom realized. This can result in fear, anxiety and disappointment (feelings which are exacerbated by the gradual exhaustion of treatment options). As a result, some physicians described feeling reluctant to engage in emotional conversations with their patients, to minimize the emotional impact that relapse inflicts upon them. The most frequently expressed emotions by hematologists in relation to relapse were "uncertainty", "upset" and "stress". They also considered the wider implications of relapse on the healthcare system; specifically, resource use (*e.g.* the need to involve psychologists and pain specialists at relapse): "The burden of relapse on the healthcare service is a significant one – there is a need for more resources" (including physical, therapeutic and financial resources).
Summary and Conclusions: For hematologists treating MM patients, relapse is associated with failed hopes, difficult consultations and enhanced levels of stress which are collectively very challenging. As a result, relapse may cause hematologists to struggle with the emotional aspects of treatment (*i.e.* interaction with their patients). In order to provide holistic disease management, it is important to assess and evaluate the impact of relapsing patients on their physicians. The subsequent impact on patients (of physicians experiencing increased stress) should also be considered.

P634

A FEASIBILITY STUDY OF VIRTUAL REALITY EXERCISE USING WII FIT AMONG PATIENTS WITH HEMATOLOGIC MALIGNANCIES RECEIVING CHEMOTHERAPY

K Tsuda[1,*] K Sudo[2], G Goto[3], M Takai[4], T Itokawa[1], T Issiki[1], N Takei[1], K Kobayashi[1], T Tanimoto[5], T Komatsu[1]
[1]Division of Hematology, [2]Department of Rehabilitation, Teikyo University Chiba Medical Center, Ichihara, [3]Department of Rehabilitation, Tsukuba Memorial Hospital, Tsukuba, [4]Department of Rehabilitation, Tokyo Metropolitan Rehabilitation Hospital, [5]Navitas Clinic, Tokyo, Japan

Background: Compared with patients with solid tumors, adherence rates of rehabilitation exercise are quite lower in patients with hematologic malignancies (60-85% and 22.5-45.8%, respectively) because of more intensive chemotherapeutic regimens. Virtual reality exercise is available even in the biological clean room and may improve adherence rates in those patients.
Aims: To clarify the feasibility of virtual reality exercise using Wii Fit among patients with hematologic malignancies receiving chemotherapy.
Methods: Sixteen hospitalized patients with hematologic malignancies aged 60 years or older participated in once a day, 5 times a week, 20-minutes exercise program using Nintendo Wii Fit (Nintendo, Kyoto, Japan) from the start of chemotherapy until their hospital discharge. Eight patients had acute myeloid leukemia, 2 had acute lymphoblastic leukemia, 1 had adult T-cell leukemia, 1 had T-cell prolymphocytic leukemia and 4 had non hodgkin lymphoma. Two activities, Hula Hoop and Basic Step, were chosen in patients' preference. Both of these exercises were light to moderate intensity; Hula Hoop was 4 Metabolic Equivalent of Task (METs) and Basic Step was 3 METs. Adherence rates, safety, physical and psychological performances were assesed. Adherence rates are calculated as the ratio of the number of days actually exercised to the number of days scheduled to exercise in advance.
Results: The median age was 66 years (range, 60-76) and 6 patients (38%) were female. Eight patients (50%) received their initial chemotherapy and the rest eight patients (50%) had received chemotherapy previously, ranging 1 to 4 regimens (median 1). The median duration of hospital stay was 26.5 days (range, 12-126). Nine (56.3%) participants completed the virtual reality exercise intervention with 88 sessions, and adherence rates were 61.1%. Four (25%) participants dropped out due to rapid progression of the disease and three (18.8%) dropped out due to patients' refusal after baseline asessment. We observed no intervention-related adverse effects more than grade 2 according to National Cancer Institute Common Terminology Criteria for Adverse Events version 3.0. Table 1 shows changes in physical and psychosocial measures from baseline to post exercise. Compared with before and after exercise intervention, the median score of Barthel index assessing activity of daily life kept 100 (range 85-100). The median grip strength of the right hand slightly decreased from 36 kg (range 18-44) to 32 kg (range 18-42) and that of the left hand increased from 29 kg (range 16-46) to 32 kg (range 18-32). The median one leg standing time of the right leg kept 15.0 seconds during hospitalization and that of the left leg increased from 10 seconds (range 2.0-45.0) to 12.0 seconds (range 3.5-32.0). The median knee extension strength of the right leg increased from 0.79 kg (range 0.16-1.50) to 0.91kg (range 0.57-1.62) and that of the left leg increased from 0.79 kg (range 0.37-1.52) to 1.02 kg (range 0.61-1.41). The median Timed Up and Go Test (TUG) score increased from 8.20 (range 5.90-19.00) to 8.56 (range 8.56-13.00). The median Instrumental Activities of Daily Living score of men decreased from 4 (range 2-5) to 2 (range 2-4) and that of women decreased from 6 (range 5-7) to 2. The median anxiety score accoding to Hospital Anxiety and Depression Scale (HADS) decreased from 6.5 (range 1.0-14.0) to 5.0 (range 1.0-8.0) and the median depression score according to HADS decreased from 7.0 (range 4.0-17.0) to 6.0 (range 1.0-12.0). We observed maintenance of physical fitness and psychosocial performance during hospitalization receiving chemotherapy.

Table 1. Changes in physical and psychosocial measures from baseline to post exercise.

Summary and Conclusions: Virtual reality exercise using Wii Fit is feasible, safe and preliminary efficacious among patients with hematologic malignancies receiving chemotherapy.

P635

A EUROPEAN STUDY OF THE EMOTIONAL AND PHYSICAL IMPACT OF RELAPSE ON PATIENTS WITH MULTIPLE MYELOMA

C Hulin[1,*] T Hansen[2], S Laurenson[3], J Lawrence[4], M Streetly[5]
[1]Department of Hematology and Internal Medicine, CHU Nancy-Brabois, Vandoeuvre lès Nancy, France, [2]Department of Oncology and Hematology, University Medical Center Hamburg-Eppendorf, Hamburg, Germany, [3]Adelphi Values, [4]Adelphi Research, Bollington, [5]Department of Hematology, Guys Hospital, London, United Kingdom

Background: Multiple Myeloma (MM) affects 3/100,000 Europeans each year and remains incurable. Almost all patients (pts) experience successive clinical relapses (defined by calcium elevation, renal insufficiency, anemia and bone abnormalities), which may be accompanied by debilitating symptoms (*e.g.* infections, bone pain and fatigue). This, coupled with the chronic nature of the disease, is likely to impact on pts' emotional and physical well-being. However, there is currently no published evidence supporting this. It is important to understand the impact of relapse to inform clinical practice.
Aims: To provide a better understanding of the impact of relapse in MM patients, and how this changes over time.
Methods: Fifty qualitative interviews were conducted with relapsed and/or refractory MM pts in the UK, France, Germany, Italy and Spain (10 per country). 'Myeloma UK' (a registered charity) was consulted for input into study design. Only pts with ≥1 physician-diagnosed, clinical relapse were included. Pts with biochemical relapse (without symptoms) were excluded. The median number of treatment (Tx) lines for pts was 2 (1–6). To prepare for interviews, pts were asked to draw graphical diagrams illustrating changes in their emotional and physical well-being over time. During the interview discussions, pts were asked open-ended questions about the impact of MM on their lives (*e.g.* daily activities, relationships, quality of life), with a focus on individual relapse events.
Results: Pts reported a substantial decline in their emotional well-being at diagnosis (Dx) (Figure 1). This decline was most pronounced in younger pts who were struggling to accept their disease. Following initial Tx and symptom reduction, pts' emotional well-being improved, but not to pre-Dx levels. Well-being declined at the first relapse (the most emotionally challenging time since Dx); the most frequently expressed emotions were "scared", "depressed", "worried", "confused", "frustrated" and "powerless". Some pts reported that the impact of the second relapse was not as substantial as the first, as they knew what to expect. Others reported that multiple relapses were associated with loss of hope and increasing distress, as they felt that they were exhausting Tx options and "getting closer to the end". Pts also reported reduced physical ability (*e.g.* capacity to carry out daily activities) attributed to MM symptoms, Tx side effects and old age/frailty. As a result, pts reported an increased reliance on immediate family and a decline in social life. For some, attending family events (*e.g.* holidays, weddings and graduation ceremonies) improved emotional well-being. Tx side effects and frequent hospital visits (for monitoring and Tx) had social and practical impacts on pts' lives. The travel associated with hospital visits had financial implications.

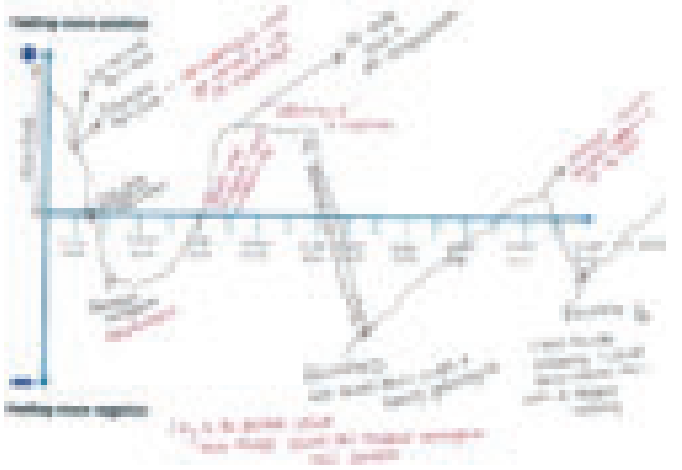


Figure 1.

Summary and Conclusions: Relapse impacts on the emotional and physical well-being of MM pts. The emotional response documented in this research varied according to pts' characters and disease histories, but included shock, anxiety, uncertainty and distress. Notably, pts' emotional well-being did not return to pre-Dx levels, indicating that the fear of relapse is a prominent emotion. Relapse was also associated with increased reliance on family members and reduced social interactions, particularly when there was a decrease in physical abilities. These findings highlight a potential unmet need for additional support, tailored toward individual pt needs. Further investigation is warranted to assess the impact of relapse on carers and family members.

P636

EDUCATIONAL INTERVENTION IN CANCER PATIENTS: THE IMPACT OF A CANCER SYMPOSIA ON PATIENT KNOWLEDGE

L Padrnos[1,*] Q Wu[1], R Scherber[1], B Robert[2], D Amylou[1], R Mesa[1]
[1]Mayo Clinic Hospital Arizona, Scottsdale, [2]Paradise Valley Community College, Phoenix, United States

Background: Patients diagnosed with cancer experience a significant information need. This knowledge deficit can negatively impact quality of life, contribute to anxiety, and decrease compliance with health care recommendations. Similarly, information provision may improve patient experience, symptom management, and interrelationships. In 2013 we evaluated a patient centered symposia of cancer patients for impact on symptom, quality of life, and knowledge level. 115 patients participated in the pre and post symposia questionnaires. The 2013 conference revealed no change in quality of life but did demonstrate significant knowledge deficits in the broad population of cancer patients that were improved by attendance. This inspired a deeper investigation into patient level of knowledge, information sources, and desired type of information provided in cancer patients.
Aims: The aim of this study is to build on the 2013 symposia data and evaluate the impact of a patient centered cancer symposium on knowledge level, reported symptom burden, and desired information from a broad population of cancer patients.
Methods: Surveys were distributed to the attendees of the third annual Mayo Clinic "Living with Cancer" patient symposium in January 2014. While 700 individuals registered for the event, only individuals with a past or present cancer diagnosis were asked to participate. Surveys included demographic data in addition to a questionnaire evaluating disease comprehension, symptom burden, patient desired information, and desired role in health care decision making process.
Results: 113 patients have completed the pre-intervention survey to date. There was slightly more female participants (60.2%). Disease types included 40% hematologic malignancies, 27% breast cancer, 20% prostate cancer and 13% other. The majority of patients were greater than 3 years from cancer diagnosis (62%). Most respondent reported understanding their disease quite a bit (51%) or very much (31%). Respondents reported the majority of their knowledge regarding their disease came from their oncologist (52%), previous symposiums (27%), or the internet (21%). Most respondents reported "quite a bit" or greater comprehension of screening tests (78%), monitoring disease response to treatment (74%), monitoring disease recurrence (68%), symptoms (74%) and treatment options (67%). There was no consensus among participants regarding understanding or limiting risk factors, symptoms associated with disease relapse, treatment side effects, fatigue and pain management, navigating the health care system, financial considerations, or confidence in their primary care physician's involvement in their cancer or post-cancer care. A large proportion of attendees reported "quite a bit" or greater desire for increased information/understanding regarding their disease (83%), risk factors (83%), nutrition (80%), screening tests (69%), and management of fatigue (69%) and stress (68%).
Summary and Conclusions: Cancer diagnosis, treatment and survivorship require significant health care and personal decisions. Individuals diagnosed with cancer experience a knowledge deficit which can negatively impact quality of life. Patients acquire information to decrease this knowledge deficit through multiple paths, including patient centered symposiums. Individuals, who choose to attend these conferences, seek to improve an already solid knowledge base. Further research regarding timing, focus, mode, and individualization of information provision are current and future needs in cancer care research. Further results of cancer knowledge and the impact of this intervention are being assessed and will be presented.

P637

PATIENTS' EXPERIENCES WITH CHRONIC LYMPHOCYTIC LEUKEMIA: EVIDENCE FROM QUALITATIVE RESEARCH WITH TREATED AND "WATCH AND WAIT" PATIENTS

K McCarrier[1], S Bull[2], K Simacek[3], P Wicks[3], S Fleming[4], R Pierson[4,*] M Wolfe[1], D Cella[5], M Rothman[4]
[1]Health Research Associates, Inc., Seattle, [2]Janssen Research & Development,, Raritan, [3]PatientsLikeMe Inc, Cambridge, [4]Janseen Global Services, LLC, Raritan, [5]Northwestern University, Chicago, United States

Background: We sought to better understand the patient experience with chronic lymphocytic leukemia (CLL) and its treatment using qualitative methods.
Aims: Specifically, we sought to document concerns about starting treatment expressed by "watch and wait" (WW) patients with CLL; and to examine differences in disease symptom reported among treated and WW patients.
Methods: Adults with CLL participating as members of the PatientsLikeMe online patient community were invited to complete a web-based survey about their experiences with the condition. Treatment status, CLL stage, performance status, and demographic variables were collected for descriptive analyses. Open-ended survey questions elicited descriptions of CLL symptoms and impacts; experiences with treatment (treated patients only); and perceptions of treatment (WW patients). Survey responses were coded for qualitative content analysis.
Results: Survey responses from 50 members of the online CLL patient community were coded for content analysis. The mean age of respondents was 60.5 years; 54% were female; 96% were White. When surveyed, 20% of respondents were receiving current treatment, 16% had received previous treatment, and 64% were under (WW) for their CLL. Most patients (78.0%) reported experiencing at least 1 symptom and 17% of patients reported their symptoms

required them to be in bed for up to 50% of their waking day. Among the 50 patients, 369 descriptions of CLL symptoms were coded in qualitative analyses. The five most frequently-expressed disease symptoms were the same across treated and WW patients, but more prevalent among treated patients compared to WW patients. These key symptoms included fatigue[pcyc1] (expressed by 25% of WW and 67% of treated patients), tiredness (34% *vs.* 55%), night sweats (34% *vs.* 44%), swollen lymph nodes (31% *vs.* 33%) and pain (19% *vs.* 33%). Conversely, the most frequently-expressed impact of CLL, worry and fear was more prevalent among WW (69%) than treated (61%) [pcyc2] patients. When asked about their concerns regarding use of CLL treatment, WW patients most-commonly expressed concern about potential treatment side-effects (noted by 63% of the 32 WW patients); becoming a burden to others (37.5% of WW patients), or having a decreased quality of life (31% of WW patients).Among the 18 respondents who had received treatment, ten (56%) reported experiencing difficulties from their treatment such as emotional and physical side-effects (*e.g.* "*It has left my immune system compromised*" and "*After treatment, I began to feel anxiety and depression"*) and disruption in their daily activities ("*Taking treatment makes it where I have to rest more*"). An equal number (56%) of treated patients described beneficial aspects of their treatment, including the elimination of specific symptoms (*e.g. "no more sweats"* and "*I'm not sick as often as I used to be*"); regaining energy (*e.g.* "*I started to feel like my old self*" or "*I have energy for a good portion of the day*") and entering remission (*e.g.* "*It eradicated my disease*").

Summary and Conclusions: Although many WW patients express concern about potential treatment side effects, patients who have received treatment describe positive and negative aspects of the treatment experience with similar frequency. Results identify little difference in the types of CLL symptoms experienced by WW and treated patients, but suggest a higher symptom burden on treated patients. Emotional effects (*e.g.*, worry, fear, depression) were the most frequently-expressed impacts of CLL, and appear to be slightly more relevant to WW patients.

P638

BURDEN OF ILLNESS OF PATIENS WITH CHRONIC LYMPHOCYTIC LEUKEMIA THAT ARE REFRACTORY TO FLUDARABINE AND ALEMTUZUMAB-CONTAINING REGIMENS IN SPAIN: AVERAGE COST ESTIMATION BY MONTECARLO SIMULATION

J Parrondo García[1,*] J Loscertales Pueyo[2], C Roldán Acevedo[1], J Delgado Gonzalez[3]
[1]Market Access & Health Economic, GSK Spain, Tres Cantos, [2]Hematology, Hospital de la Princesa, Madrid, [3]Hematology, Hospital Clinic, Barcelona, Spain

Background: Chronic lymphocytic leukemia (CLL) is the most common adult leukemia in western countries, accounting for more than 30% of total leukemias. Symptomatic CLL significantly impacts on patient's quality of life and is associated with high direct and indirect management costs. Though current CLL treatment has improved in recent years, no cure exists for this disease and a proportion of patients become refractory to both fludarabine- and alemtuzumab-containing regimens or "double refractory" (DRCLL). These patients were estimated from the Spanish Leukemia Registry data (2002 report) to constitute 2.96% of CLL patients in Spain. While there is a perception of high costs related to the management of these patients, there is no Spanish data on the burden of illness.
Aims: The aim of this study was to estimate the average management cost of DRCLL patients from the Spanish National Health System perspective.
Methods: MonteCarlo simulations are commonly used in rare diseases when the reduced number of patient makes it very difficult to obtain enough real-life data to perform statistical analysis. This technique assigns randomly generated values for patient parameters from mathematical distributions that describe real-life distributions. Since the prevalence of DRCLL patients in Spain is small, MonteCarlo simulation technique was deemed appropriate. In order to develop the mathematical distributions that describe life expectancy and resource consumption in these patients, the Spanish subgroup of patients (n=12) from a retrospective medical chart review study conducted in European centres in 2009 was used. Direct health care resource-use was obtained from the study database for patients diagnosed with DRCLL until death or loss of follow-up and classified into the following categories: hospital stay and physician visits, transfusions, laboratory analysis, imaging tests, other tests or medical interventions, drug treatment for cytopenia, chemotherapy and other drug costs. Unit costs were derived from national databases and official government journals and expressed in € 2014 applying the corresponding CPI variation when needed. Gamma distributions were then developed with the daily average cost of the 12 patients for each cost category and an exponential distribution was developed for overall survival with data from the 8 patients that were followed until death. One million simulations were performed.
Results: Mean and median life expectancy from DRCLL diagnosis were 230 and 159 days, respectively (P_{25-75}: 66-319 days). Mean cost per patient was €46,613.32 (P_{25-75}: €9,284.32 - €57,173.67). Hospital stays and physician visits accounted for 47.74% of mean daily cost, 3.42% of cost were attributed to transfusions, 7.79% to laboratory analysis, 5.18% to imaging tests, 11.83% to other tests or interventions, 19.77% to drug therapy for cytopenia, 3.95% to chemotherapy and 0.32% to other drug costs.

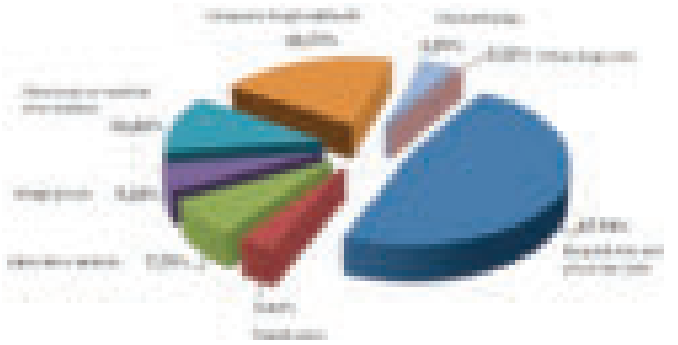

Figure 1.

Summary and Conclusions: DRCLL patients have poor prognosis with a life expectancy of less than a year and their management is associated with substantial direct medical costs. Hospital stays and physician visits were identified as the key drivers of total cost while chemotherapy cost accounted for less than 4% of total costs.

P639

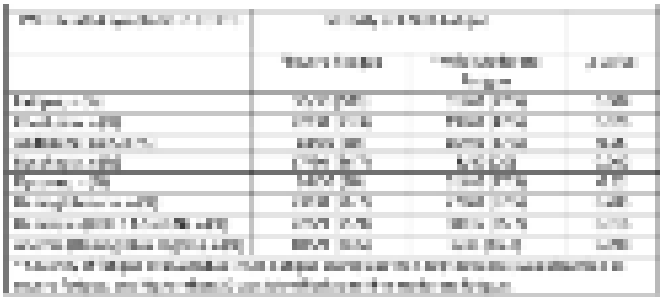
SIGNIFICANT DISEASE BURDEN EVALUATED BY FACIT-FATIGUE AND EORTC QLQ-C30 IN PATIENTS WITH PAROXYSMAL NOCTURNAL HEMOGLOBINURIA FROM A KOREAN PROSPECTIVE PNH REGISTRY

JW Lee[1,*] JH Jang[2], JS Kim[3], JH Lee[4], JS Park[5], JS Chung[6], JH Lee[7], JA Kim[8], DY Jo[9], Y Park[10]
[1]The Catholic University of Korea, [2]Sungkyunkwan University School of Medicine, [3]Yonsei University College of Medicine, [4]University of Ulsan College of Medicine, Seoul, [5]Ajou University School of Medicine, Suwon, [6]Pusan National University Hospital, Pusan, [7]Gachon University Gil Medical Center, Incheon, [8]The Catholic University of Korea, St. Vincent Hospital, Seoul, [9]Chungnan National University Hospital, Daejeon, [10]Korea University School of Medicine, Anam, Seoul, Korea, Republic Of

Background: Paroxysmal nocturnal hemoglobinuria (PNH) is a rare and progressive disease driven by complement-mediated hemolysis leading to thromboembolism (TE), organ function impairment, and death. Beyond these risks, patients with PNH suffer from a poor quality of life, including disabling symptoms of fatigue, abdominal pain, chest pain, dyspnea, and hemoglobinuria.
Aims: To assess patient-reported severity of fatigue and incidence of PNH-associated clinical symptoms among 70 untreated patients enrolled in the Korean prospective PNH Registry.
Methods: Korean patients with a diagnosis of PNH are eligible for inclusion in the prospective registry study designed to identify key symptoms. Patient medical information and study questionnaire data were collected at study enrollment and the last 6 month follow-up, and included data based on the validated Functional Assessment of Chronic Illness Therapy Fatigue subscale version 4 (FACIT-Fatigue) and the European Organization for Research and Treatment of Cancer Quality of Life Questionnaire C30, version 3 (EORTC QLQ-C30). Patients receiving eculizumab treatment or bone marrow transplantation (BMT) were excluded. Severe fatigue was identified as FACIT-Fatigue score of less than 30 (<30 score), and clinical symptoms, including abdominal pain, chest pain, dyspnea, swallowing difficulty, and hemoglobinuria, were based on patients' self-report in EORTC QLQ-C30.
Results: At the time of analysis, completed questionnaires were available for 70 patients. Among the 70 patients, the median FACIT-Fatigue score was 29 at enrollment and 31 at 6 month follow-up; there was no association between two different time points (p=0.102). Mean age was 45 years (range, 19-73; standard deviation, 13.2) and 41 patients (58.6%) were female. At 6 month follow-up time, median lactate dehydrogenase (LDH) was 4.75-fold above the upper limit of normal. Of the 70 patients, the majority of patients reported (EORTC-assessed) fatigue (61; 87.1%), dyspnea (55; 78.6%), hemoglobinuria (50; 71.4%), chest pain (41; 58.6%), abdominal pain (33; 47.1%), and dysphagia (25; 35.7%). Red blood cell transfusion was administered to 31 (44.3%) of the 70 patients during the last 6 month follow-up. Thirty patients (43%) were experiencing severe fatigue and 57% of patients had mild to moderate fatigue (assessed by FACIT-Fatigue). Incidence of selected PNH-related symptoms in those two fatigue groups is presented in Table 1. Regardless of the severity of fatigue, clinical symptoms, hemolysis (LDH≥1.5×ULN), and anemia were commonly experienced by PNH patients (Table 1). However, the prevalence of abdominal pain, chest pain, and dysphagia were significantly higher in the severe fatigue group.
Summary and Conclusions: Overall, results demonstrated that PNH patients commonly experience severe fatigue and this can have a negative impact on patients' quality of life and daily activities. The prevalence of severe fatigue remained constant from baseline through 6 months. These data confirm that

PNH patients with severe fatigue also frequently suffer disabling symptoms such as chest pain, dyspnea, abdominal pain, dysphagia, and hemoglobinuria. Interestingly, symptoms that could be associated with contributing to severe fatigue (ie, dyspnea, anemia, and hemolysis) did not predict the level of fatigue in PNH patients. While abdominal pain, chest pain, and dysphagia were higher with severe fatigue, the high prevalence of these symptoms with mild to moderate fatigue was still meaningful. PNH with moderate/severe fatigue should be evaluated as part of a full, comprehensive clinical workup to assess all PNH-related symptoms and disease burden. Patients' self-reporting questionnaires should be considered for routine use for the management of quality of life in patients with PNH.

Table 1.



P640

PERSPECTIVE OF CHILDREN WITH CANCER ABOUT CANCER RELATED FATIGUE: A SINGLE CENTER EXPERIENCE

M Hesham[1,*] AM EL-Dakhakhny[2], SEA Bassam[2], NR Abdel Fattah[3], RAE Abd Elaziz [4]

[1]Pediatric, Zagazig University- Faculty of Medicine, [2]Pediatric Nursing, Zagazig University- Faculty of Nursing, [3]Psychiatry, Zagzig University - Faculty of Medicine, [4]Pediatric Nursing, Zagazig University - Faculty of Nursing, Zagazig, Egypt

Background: Fatigue is the most common and incapacitating side effect in patients with Cancer. Although most cancer patients report that fatigue is a major obstacle to maintaining normal daily activities and quality of life, it is seldom assessed and treated in clinical practice.
Aims: to evaluate cancer- related fatigue and determine its possible causes according to perspectives of children with cancer.
Methods: This prospective study was conducted on a sample of 125 children with cancer (64 males and 61 females) at Oncology Unit at Zagazig University Children Hospital during a period from October 2011 to June 2013. Their age ranged between 6 -18 years. Five tools were used in this study, **The first** was A questionnaire interview sheet.**The second** was The Multidimensional Fatigue Symptom Inventory-Short Form to assess the principal manifestations of fatigue, **the third** was The cancer fatigue scale to assess physical, affective, and cognitive aspects of fatigue experienced by cancer patient., and the **fourth** was Fatigue assessment scale for assessment of severity of fatigue. **The fifth** was Multidimensional Assessment of fatigue scale which measures four dimensions of fatigue: severity, distress and degree of interference in activities of daily living, as well as timing degree of interference in activities of daily living.
Results: Our data revealed that 76.8% of children mentioned fatigue as a sense of physical tiredness, 75.2% of them mentioned it as not able to do things and 63.2% mentioned persistent tiredness and fatigue with rest. Also, 72% of children mentioned cancer treatment as a cause of fatigue and 91.2% of children mentioned that hospital had role in their fatigue. High score of physical fatigue type was reported by 93.6% of studied children, while 63.2% of them reported higher score of affective fatigue, in addition to 44% of them reported cognitive fatigue type. Moderate fatigue was reported by 71.2% of children; while 19.2% reported severe fatigue. About 93.6% of studied children mentioned high score of fatigue interference on daily activities.The The majority (96.1%) of studied children who did not practice exercise reported high score of total fatigue type with statistical significant relation.
Summary and Conclusions: The children with cancer oriented about definition, causes, and degree, as well as types of fatigue. Moreover, they oriented about multidimensional aspect of fatigue including fatigue effect on daily living activities. So, it could be recommended that an assessment and management of cancer –related Fatigue should be enrolled in daily routine care of cancer children.

Background: Despite therapeutic advancements, patients (pts) with multiple myeloma (MM) relapse or become refractory to frontline therapies, and thus an unmet need remains. Panobinostat (PAN) is a potent pan-deacetylase inhibitor (pan-DACi) that demonstrated synergistic antimyeloma activity when combined with bortezomib (BTZ)+dexamethasone (Dex) in preclinical studies. Results from phase 1 and 2 studies demonstrated durable responses in pts with relapsed (Rel) or relapsed/refractory (Rel/Ref) MM treated with PAN/BTZ/Dex, including pts with BTZ-Ref MM.
Aims: The PANORAMA 1 study was conducted to determine if the addition of PAN to BTZ/Dex increased progression free survival (PFS) compared with placebo (Pbo)/BTZ/Dex in pts with Rel or Rel/Ref MM.
Methods: Eligible pts had Rel or Rel/Ref MM (excluding BTZ- and primary-Ref MM) following 1-3 prior regimens. Pts received oral PAN (20 mg) or Pbo 3 times per week+intravenous BTZ (1.3 mg/m^2; days 1, 4, 8, and 11) during weeks 1-2 with oral Dex (20 mg) on the days of and after BTZ in treatment phase (TP) 1, eight 3-week cycles. Pts demonstrating benefit could proceed to TP2, with PAN dosing maintained and BTZ/Dex less frequent. The primary endpoint was PFS with response assessed by modified European Society for Blood and Marrow Transplantation criteria as per investigator's assessment. Other endpoints included overall survival (OS), overall response rate (ORR), near complete/complete response (nCR/CR) rate, duration of response (DOR), quality of life, pharmacokinetics, and safety.
Results: A total of 768 pts (PAN+BTZ+Dex [n=387]; Pbo+BTZ+Dex [n=381]) were randomized. Median age was 63 years (range, 28-84 years), 55% had Eastern Cooperative Oncology Group performance status 1-2, and 47% had International Staging System stage II/III. Nearly half (48%) received ≥2 prior regimens. Prior therapies included BTZ (43%), thalidomide (51%), and lenalidomide (20%), with 25% receiving prior BTZ+immunomodulatory drugs. The primary endpoint was met: median PFS, 12.0 *vs* 8.1 months (*P* <.0001; hazard ratio [HR], 0.63; 95% CI, 0.52-0.76) for pts treated with PAN/BTZ/Dex *vs* Pbo/BTZ/Dex (Figure 1). ORR was 61% *vs* 55% in the PAN/BTZ/Dex and Pbo/BTZ/Dex arms, respectively, with DOR of 13.1 *vs* 10.9 months. Analysis of the rate of nCR+CR demonstrated a clear benefit for pts on the PAN/BTZ/Dex arm (27.6%; 95% CI, 23.2-32.4) *vs* the Pbo/BTZ/Dex arm (15.7%; 95% CI, 12.2-19.8). Among pts who achieved ≥nCR, median PFS was 19.4 months for the PAN/BTZ/Dex arm *vs* 15.2 months for the Pbo/BTZ/Dex arm (*P*=.00006; HR, 0.56; 95% CI, 0.37-0.86). PFS and ORR were confirmed by an independent review committee. OS data are not yet mature. Common grade 3/4 nonhematologic adverse events (AEs) regardless of study drug relationship in the PAN/BTZ/Dex and Pbo/BTZ/Dex arms, respectively, included diarrhea (26% *vs* 8.0%), asthenia/fatigue (24% *vs* 11.9%), and peripheral neuropathy (18% *vs* 15%). Common grade 3/4 hematologic laboratory abnormalities included thrombocytopenia (67% *vs* 31%) and neutropenia (35% *vs* 11%). In general, these AEs were manageable with dose reduction and supportive care. AEs led to discontinuation in 36% in the PAN/BTZ/Dex arm and 20% in the Pbo/BTZ/Dex arm. AEs leading to discontinuation included diarrhea (4.5%), peripheral neuropa-

thy (3.7%), asthenia and fatigue (2.9% each), and thrombocytopenia (1.6%) in the PAN/BTZ/Dex arm and fatigue (2.9%), pneumonia (2.1%), peripheral neuropathy (1.9%), and diarrhea (1.6%) in the Pbo/BTZ/Dex arm. On-treatment deaths occurred in 8% and 5%, respectively.

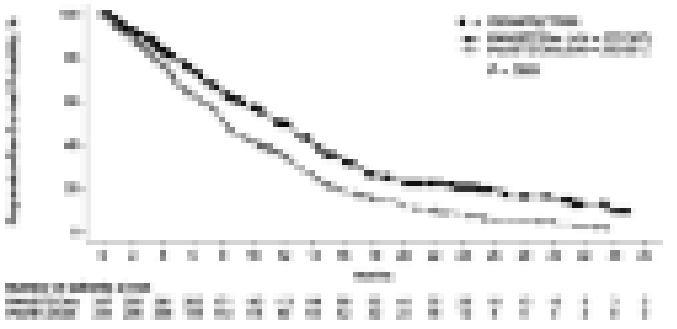

Figure 1.

Summary and Conclusions: The addition of PAN to BTZ/Dex led to a significant and clinically relevant improvement in PFS compared with Pbo/BTZ/Dex in pts with Rel or Rel/Ref MM, with improvement in DOR and nCR+CR rate.

S642

E1A06: A PHASE III TRIAL COMPARING MELPHALAN, PREDNISONE, AND THALIDOMIDE (MPT) *VERSUS* MELPHALAN, PREDNISONE, AND LENALIDOMIDE (MPR) IN NEWLY DIAGNOSED MULTIPLE MYELOMA MM)

AK Stewart[1,*] S Jacobus[2], R Fonseca[1], M Weiss[3], NS Callander[4], AA Chanan-Khan[5], SV Rajkumar[6]

[1]Mayo Clinic, Scottsdale, [2]Dana-Farber Cancer Institute, Boston, [3]Marshfield Clinic, Marshfield, [4]University of Wisconsin, Madison, United States, [5]Mayo Clinic, Jacksonville, United Kingdom, [6]Mayo Clinic, Rochester, United States

Background: Melphalan, prednisone and thalidomide (MPT) is an accepted regimen in newly diagnosed MM. Early studies suggested that lenalidomide (R) might be substituted for thalidomide (T) with equal efficacy and less toxicity. We present E1A06, a randomized, multicenter phase 3 trial comparing MPT *vs.* MPR in pts with untreated, symptomatic, transplant ineligible MM

Aims: The primary objective was PFS differences between pts receiving MPT: M 9 mg/m^2 and P 100 mg p.o. each on days 1-4 with T 100 mg daily *vs.* MPR: M 5 mg/m^{2}and P 100 mg p.o. each on days 1-4 with R 10 mg p.o. on days 1-21. MPT or MPR therapy was continued for twelve 28 day cycles followed by T 100mg or R 10mg daily until relapse. Aspirin prophylaxis was required.

Methods: Pts were stratified by ISS stage (I-II *vs.* III) and age (<65 *vs.* ≥65). Inferiority of MPR was defined as a PFS treatment hazard ratio (HR) of MPT/MPR ≤0.82. Secondary objectives included OS between the arms, toxicities, response rates, depth of response and quality of life (QoL) change.

Results: 306 pts were enrolled. Treatment arms were balanced for age, ISS stage and other major prognostic factors. Median age was 75.7y. The median follow-up was 40.7 months (m). Median time on therapy was 12m, and 23m for the 46% of pts on maintenance therapy, with no differences by arm. Per protocol partial response rate was 62% (MPT) *vs.* 61% (MPR) with no difference in VGPR/CR rates (18.8% *vs.* 23%). Grade ≥3 toxicity was 71.6% (MPT) *vs.* 56.7% (MPR); p=0.008. By ITT, the median PFS was 21m on MPT and 18.7m on MPR; HR 0.84 [95%CI: 0.64, 1.09]. The null hypothesis of inferiority of MPR was not rejected. Three year OS was identical by arm at 63% and median OS was not significantly different; p=0.476. Second primary malignancies were observed in 17 (MPT) *vs.* 14 (MPR) pts with incidence rates of 3.47 and 2.01 (/100 person years). DVT/PE occurred in 8.8% *vs.* 6.7% of pts. QoL analysis favored MPR by induction end; p=0.007.

Summary and Conclusions: This phase III trial compares the efficacy of MPT and MPR in elderly patients with newly diagnosed MM. Response rates, PFS and OS were similar between the two arms; however, there was significantly better QOL at 12m and lower toxicity with MPR.

S643

LENALIDOMIDE+LOW-DOSE DEXAMETHASONE (RD) *VS.* MELPHALAN-PREDNISONE-THALIDOMIDE (MPT) IN NEWLY DIAGNOSED MULTIPLE MYELOMA (NDMM) PATIENTS (PTS): THE FIRST TRIAL

T Facon[1,*] MA Dimopoulos[2], A Dispenzieri[3], JV Catalano[4], A Belch[5], C Hulin[6], M Cavo[7], A Pinto[8], KC Weisel[9], H Ludwig[10], N Bahlis[11], A Banos[12], M Tiab[13], M Delforge[14], J Cavenagh[15], C Geraldes[16], JJ Lee[17], C Chen[18], A Oriol[19], J De La Rubia[20], L Qiu[21], D White[22], D Binder[23], KC Anderson[24], P Moreau[25], M Attal[26], R Knight[27], G Chen[27], J Van Oostendorp[27], CJ Jacques[27], A Ervin-Haynes[27], L Benboubker[28]

Background: The MPT regimen is recognized as a standard therapy (Tx) for stem cell transplantation (SCT)-ineligible NDMM pts, based on a statistically significant advantage in overall survival (OS) and progression-free survival (PFS) *vs.* the combination of melphalan (MEL) and prednisone (PRED) (Facon, Lancet 2007; Fayers, Blood 2011; National Comprehensive Cancer Network, 2013). In the randomized ECOG E4A03 trial Rd increased OS and improved tolerability *vs.* lenalidomide (LEN) and high-dose dexamethasone (DEX) in NDMM pts (Rajkumar, Lancet Oncol 2010).

Aims: The FIRST trial (MM-020/IFM-0701) is a multicenter, open-label, pivotal phase 3 trial comparing the efficacy and safety of continuous Rd *vs.* MPT in SCT-ineligible NDMM pts.

Methods: SCT-ineligible NDMM pts or ≥65 years (yrs) were randomized to 1 of 3 arms: continuous Rd (LEN 25 mg/D, D1–21 and DEX 40 mg/week [wk] in 28-day cycles until disease progression); Rd18 (Rd in 28-day cycles for 72 wks [18 cycles]); or MPT (MEL 0.25 mg/kg/D, D1–4; PRED 2 mg/kg/D, D1–4; and thalidomide 200 mg/D in 42-day cycles for 72 wks [12 cycles]). Response was assessed using IMWG criteria after each cycle. Enrollment of pts with renal impairment was allowed with the exception of pts on dialysis. Thromboprophylaxis was mandatory. Stratification factors included age, International Staging System (ISS), and country. The primary endpoint was PFS (continuous Rd *vs.* MPT). Secondary endpoints included OS, overall response rate (ORR), time to response, duration of response (DOR), time to 2nd antimyeloma Tx, safety, and quality of life; exploratory analyses included PFS2.

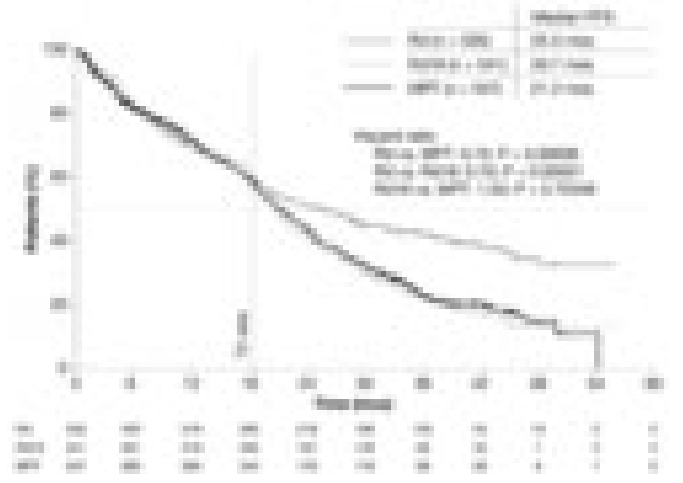

Figure 1. PFS in pts treated with continuous Rd, Rd for 72 wks (Rd18), or MPT for 72 wks.

Results: 1,623 pts were randomized to continuous Rd (535 pts), Rd18 (541 pts), and MPT (547 pts). Median age was 73 yrs, 35% of pts were ≥75 yrs, and 40% had ISS stage 3 disease. With a median follow-up of 37 months (mos), 23% of pts (121 pts) remained on continuous Rd. There was a 28% reduction in risk of PFS events with continuous Rd *vs.* MPT (HR=0.72; *P*=0.00006); there was also a reduction with Rd18 (HR=0.70; *P*=0.00001). Median PFS with continuous Rd, Rd18, and MPT were 25.5, 20.7, and 21.2 mos, respectively (Figure 1). The OS interim analysis showed a 22% reduction in risk of death in favor of continuous

Rd *vs.* MPT (HR=0.78; *P*=0.0168). Secondary endpoints consistently showed improvement with continuous Rd *vs.* MPT, respectively: ORR 75% *vs.* 62% (*P* <0.00001); median DOR 35.0 *vs.* 22.3 mos (HR=0.63; *P* <0.00001); and time to 2nd antimyeloma Tx 39.1 *vs.* 26.7 mos (HR=0.66; *P* <0.00001). Relevant grade 3–4 adverse events with continuous Rd *vs.* MPT, respectively, were neutropenia (28% *vs.* 45%), thrombocytopenia (8% *vs.* 11%), febrile neutropenia (1% *vs.* 3%), infection (29% *vs.* 17%), peripheral sensory neuropathy (1% *vs.* 9%), and deep-vein thrombosis and/or pulmonary embolism (8% *vs.* 5%). The incidence of hematologic second primary malignancies (SPMs) was 0.4% with continuous Rd *vs.* 2.2% with MPT; the incidence of solid tumor SPMs was similar in both Tx arms (2.8%).

Summary and Conclusions: In SCT-ineligible NDMM pts, Tx with the all-oral doublet continuous Rd significantly improved PFS, with an OS benefit at interim analysis, *vs.* the standard triplet MPT and *vs.* Rd18. The safety profile of continuous Rd was manageable with a lower incidence of hematologic SPMs *vs.* MPT. Thus, continuous Rd should be considered a new standard of care for SCT-ineligible NDMM pts.

S644

DO WE STILL NEED THE ALKYLATORS AS PART OF THE UPFRONT-TREATMENT OF ELDERLY NEWLY DIAGNOSED MULTIPLE MYELOMA PATIENTS? UPDATED FOLLOW-UP OF GEM2005MAS65 SPANISH TRIAL COMPARING VMP *VS* VTP AS INDUCTION

Background: Introduction: Melphalan (M) has been the most relevant drug for myeloma treatment for over 30 years and in combination with prednisone (MP) has been the backbone for new combinations development including thalidomide (MPT), lenalidomide (MPR) and bortezomib (MPV).

VMP has shown significantly increase the overall survival (OS) over MP in the VISTA trial. The main issue of VISTA is the toxicity profile and early discontinuations, which have been significantly reduced by the weekly and SQ administration of bortezomib. New alkylator-free schemes, such as lenalidomide plus low-dose dex, are emerging and challenging the role of alkylators in the treatment for elderly patients. The GEM2005 addressed this question in 2010 by comparing VMP with VTP as induction and the initial results, although with a short median follow-up, supported the value of alkylators upfront. In order to consolidate data on this hot topic, we have updated the outcome with very long follow-up (median of 72 months).

Aims: Pts and Methods: Between April 2005, and October 2008, 260 pts were randomized to receive 6 cycles, of VMP *vs* VTP as induction and those who completed the induction therapy were subsequently randomly assigned to maintenance therapy with VT or VP. The details were previously described (Lancet Oncology 2010), but during induction bz was given twice a week during the first cycle followed by five additional cycles in which bz was given weekly. Thalidomide was given at dose of 100 mg and melphalan and prednisone at conventional doses.

Results: Results: The median PFS was 32m and 23m for VMP and VTP arms, respectively (p=0.09). Deaths occurred in 73 pts treated with VMP (56%) and 91 pts (70%) in the VTP arm. VMP significantly prolonged the overall survival as compared with VTP (median of 63m *vs* 43m in VMP and VTP arms, respectively; HR:0,67; (p=0,01)). These results were not influenced by the maintenance received, VT or VP. Subsequent drugs used in first clinical relapse were balanced in both induction groups and included lenalidomide combinations in 40 (43.4%) pts, bz-based therapy in 19 (20.5%) pts, chemotherapy in 27 pts (29.1%) and six (6.5%) pts supportive care. OS from relapse was significantly longer for pts treated with VMP than VTP (17 *vs* 12 m, p=0,05). In multivariate analysis, to receive VMP as induction (HR:1,3), to have standard-risk cytogenetic abnormalities (HR: 1,85) and to achieve CR (HR=2,14) were independent factors associated with significantly longer OS. Pts who achieved CR had a significantly longer OS (median of 78 m) as compared with pts who didn't (median of 60 m) (HR: 2,26; p<0.0001) and this was more evident for pts who received VMP as induction (OS not reached: 53% at 8yrs) as compared with VTP (73m) (p=0,05). Moreover, median OS in the group of pts who achieved immunophenotypic CR has not been reached and 54% remain alive at 8 years while it was 58 months in patient who didn't achieve immunophenotypic CR. This benefit was also more evident for VMP and (median OS not reached: 66% alive at 8yrs) *vs* 73m for VTP (p=0,05).

Summary and Conclusions: Conclusions: Melphalan, in combination with bortezomib, should be maintained as one of the standards of care for treatment of elderly MM patients. VMP followed by maintenance with VT or VP significantly improved OS as compared with VTP. Patients who achieved CR and immunophenotypic response had significantly longer OS than patients who didn't and this benefit is even more evident in the VMP arm.

S645

CHARACTERISTICS AND OUTCOMES OF 714 PATIENTS WITH SYSTEMIC AL AMYLOIDOSIS –ANALYSIS OF A PROSPECTIVE OBSERVATIONAL STUDY (ALCHEMY STUDY)

A Wechalekar[1,*] D Foard[1], L Rannagan[1], T Lane[1], S Sachachtanatham[1], S Mahmood[1], R Sayeed[1], K Patel[1], C Whelan[1], P Hawkins[1], J Gillmore[1]

[1]National Amyloidosis Centre, University College London Medical School, London, United Kingdom

Background: Systemic AL amyloidosis is a challanging condition to treat. Rarity of the disease as well as frailty of patients with advanced end organ damange makes clinical trials challanging and large prospective trials are lacking. We report the outcomes from ALChemy study (*AL Che*motherapy study) - one of the largest prospective observational trials in AL amyloidosis.

Aims: To assess the characteristics and treatent outcomes in a large prospectively followed cohort of patients with sytemic AL amyloidosis

Methods: We report the characteristics and outcomes of 714 patients with systemic AL amyloidosis seen at the UK National Amyloidosis centre from September 2009 to December 2013 who consented for recruitment in the ALChemy study. Treatment data on initial 500 patients is presented here - an update of all 714 will be presented at the meeting. Data on treatment/response/toxicity was collected monthly and with protocolized assessments every six months.

Results: Heart was involved in 68%, kidneys in 67% and liver in 13%. The Mayo disease stage was: stage I – 125 (18%); stage II - 287 (40%); stage III – 301 (42%). Median overall survival (OS) was not reached. The estimated survival at 12, 36 and 48 months was 67%, 56% and 51% respectively. Median OS was 8.8 months for Mayo stage III and 4.7 months for patients with NT-proBNP >8500 ng/L. In a landmark analysis of stage III patients at six months, the median survival was 49 months. Treatments were: thalidomide based 58%, lenalidomide based 3%, MelDex 6% and bortezomib based 25%. There was with no significant difference in survival with either regime but with estimated 75% *vs.* 61% survival at four months for patients with New Mayo stage 4 disease treated with Thalidomide-based/MelDex *vs.* bortezomib based regimes respectively. On an intention to treat basis, 51% achieved a ≥partial haematological response (PR) with a complete response (CR) in 14% and dFLC-VGPR in 24%. The median number of cycles was 4 and 59% experienced ≥grade 3. Fluid overload and infection were the commonest toxicities and cause of serious adverse events. Twenty-five percent patients reported ≥grade 3 toxicity in more than one cycle.

Summary and Conclusions: This large patient cohort confirms the improved survival in AL amyloidosis with median OS over 4 years. There is a significant problem of early deaths in patients with advanced stage disease. However, even patients with advanced systemic AL amyloidosis who surivive the first few months, have excellent longer term outcomes. There is substantial treatment related toxicity. Fluid overload, the commonest toxicity encountered, may be avoided in many cases by simple measures like daily weights and early diuretic adjustment helped by patient/physicial education. This trial confirms the utility of careful observational trials as a very important tool to study rare diseases.

Acute myeloid leukemia - Clinical 1

Background: Based on the WHO-2008 classification more than 70% of all acute myeloid leukemia (AML) patients can be categorized according to their underlying genetic aberrations with AML exhibiting nucleophosmin-1 gene (*NPM1*) mutations representing the largest genetic subgroup. In a biomarker study within a randomized trial of older AML patients, we could demonstrate that patients with mutated *NPM1* in the absence of a *FLT3*-ITD significantly benefit from *all*-trans retinoic acid (ATRA) as adjunct to chemotherapy (Schlenk *et al.* Haematologica 2009;94:54-69).
Aims: To evaluate the impact of ATRA in combination with chemotherapy on outcome, and to assess the *NPM1* mutational status in relation to ATRA as a marker for response in younger adult AML-patients entered in the prospective randomized treatment trial AMLSG 07-04 (ClinicalTrials.gov Identifier: NCT00151242).
Methods: Patients (18 to 60 years of age) were accrued between 2004 and 2009. They were randomized up-front for open-label treatment with ATRA and in the first 372 patients also for valproic acid (VPA). Induction therapy consisted of two cycles of ICE. For consolidation therapy, patients with high-risk AML, defined either by high-risk cytogenetics or induction failure, were assigned to receive allogeneic hematopoietic stem cell transplantation (allo-HSCT) from a matched related (MRD) or unrelated donor. All other patients were assigned to 3 cycles of high-dose cytarabine or, if an MRD was available, an allo-HSCT in intermediate-risk AML. During induction cycles, ATRA was given in a dosage of 45mg/m² from day 6 to 8, and 15mg/m² from day 9 to 21. The primary and secondary end points of the study were event-free survival (EFS) and rate of complete remission (CR) as well as cumulative incidence of relapse (CIR) and overall survival (OS), respectively. The analyses were performed on an intention-to-treat (ITT) and a per-protocol (PP) basis.
Results: A total of 1100 patients were randomized, 556 in the standard arm, and 544 in the ATRA-arm; in both arms n=19 patients received or did not receive ATRA in contrary to their randomization. After a planned interim analysis on the endpoint CR-rate, the randomization for VPA was stopped in 2006 due to ineffectiveness. Median follow-up for survival was 5.1 years. *NPM1* mutational status was available in 1007 patients (92%) and a mutation was identified in 287 (29%) patients. Pretreatment patient characteristics were well balanced between the standard and the ATRA-arm, except for higher white blood counts (WBC) and peripheral blast percentages in the standard arm (p=0.003, each). In multivariable analyses on the endpoint CR, ATRA neither as single factor nor as interaction term with *NPM1* had a significant impact on an ITT basis. In contrast, the same analysis on a PP basis revealed a significant impact of the ATRA-*NPM1* interaction (OR, 2.07; p=0.03) indicating a higher probability for AML-patients with mutated *NPM1* treated with ATRA to achieve a CR. Almost similar results were found for EFS; in the ITT analysis the impact of the ATRA-*NPM1* interaction was not significant, whereas in the PP analysis this interaction had a significant impact (HR, 0.75; p=0.04) indicating a higher probability for AML-patients with mutated *NPM1* treated with ATRA to stay event-free. Explorative analysis in all patients on OS revealed a benefit for ATRA (ITT, p=0.09; PP, p=0.01). This beneficial effect of ATRA could be attributed to patients with ELN-favourable risk including core-binding factor AML, AML with *CEBPA*dm and AML with mutated *NPM1* in the absence of *FLT3*-ITD (p=0.04).
Summary and Conclusions: ATRA as adjunct to chemotherapy improved response to induction therapy and EFS in *NPM1* mutated-AML, as well as OS in patients with ELN favourable risk.

S647

RESULTS OF A RANDOMIZED MULTICENTER PHASE 2 STUDY OF A 5-DAY REGIMEN OF SGI-110, A NOVEL HYPOMETHYLATING AGENT, IN TREATMENT NAÏVE ELDERLY ACUTE MYELOID LEUKEMIA NOT ELIGIBLE FOR INTENSIVE THERAPY

K Yee[1,*] N Daver[2], P Kropf[3], R Tibes[4], C O'Connell[5], G Roboz[6], K Walsh[7], N Pemmaraju[2], T Rosenblat[8], J Berdeja[9], S Lunin[10], W Chung[11], JP Issa[11], S Naim[12], P Taverna[12], Y Hao[12], M Azab[12], H Kantarjian[2]
[1]Princess Margaret Cancer Center, Toronto, Canada, [2]University of Texas, MD Anderson Cancer Center, Houston, [3]Fox Chase Cancer Center, Philadelphia, [4]Mayo Clinic, Scottsdale, [5]USC Keck School of Medicine, University of Southern California, Los Angeles, [6]Weill Cornell Medical College, New York, [7]The Ohio State University, Columbus, [8]New York-Presbyterian/Columbia University Medical Center, New York, [9]Sarah Cannon Research Institute, Nashville, [10]Florida Cancer Specialist, Englewood, [11]Fels Institute, Temple University, Philadelphia, [12]Astex Pharmaceuticals Inc., Dublin, United States

Background: SGI-110 is a second generation Hypomethylating Agent (HMA) given as a small volume subcutaneous (SC) administration. Relative to first generation HMAs, SGI-110 prolongs half-life and extends exposure to the cytidine analog decitabine. In the Phase 1 study, SGI-110 given daily for 5 days (QDx5) produced potent hypomethylation and clinical responses in MDS and AML patients previously treated with first generation HMAs (Kantarjian *et al.* 2012). The Biologically Effective Dose (BED) defined as the smallest dose producing maximum demethylation was 60 mg/m^2 QDx5 while 90 mg/m^2 QDx5 was the highest dose with no Dose Limiting Toxicities.
Aims: To assess efficacy and safety of two doses of SGI-110 given as a 5-day SC regimen every 28 days in elderly AML.
Methods: In a randomized Phase 2 study, treatment naïve elderly (≥65 years) AML patients who were not suitable for intensive induction chemotherapy due to secondary AML, unfavorable cytogenetics, poor Performance Status (PS), or major organ dysfunction were randomized to one of two SC SGI-110 doses – 60 mg/m^2 QDx5 or 90 mg/m^2 QDx5 every 28 days till progression. The primary endpoint was Overall Complete Remission (OCR=CR+CRi+CRp) rate at any time based on International Working Group Criteria (Cheson 2003). Adverse events (AEs) and Long Interspersed Nucleotide Element (LINE-1) DNA methylation pharmacodynamics were also reported.
Results: The study has completed enrolment with 51 patients treated: 24 and 27 patients were randomized to 60 and 90 mg/m^2 doses respectively. Patient characteristics were generally balanced between the 2 dose groups. However there were more patients with poor PS on the 60 mg/m^2 dose and more patients with poor risk cytogenetics in the 90 mg/m^2 dose: Median age (78y; 77y); ECOG PS 2 (46%, 26%), Males (58%, 59%), poor risk cytogenetics (33%, 44%) for the 60 and 90 mg/m^2 dose groups respectively. The primary endpoint of OCR was observed in 12 (8 CR+4CRi) and 12 (9CR+3CRi) patients or 50% and 44% for 60 and 90 mg/m^2 dose groups respectively. OCR for both doses combined was achieved in 24 of 51 patients (17 CR, 7 CRi, no CRp) or 47% (95% CI: 32.9%, 61.5%). LINE-1 DNA methylation data before and after treatment were available in 48 (94.1%) patients. The average maximum LINE-1 demethylation was similar for the 2 dose groups (-18.6% for 60 mg/m^2 and -21.4% for 90 mg/m^2). The 90 mg/m^2 dose showed similar safety profile to 60 mg/m^2 except for neutropenia for which the incidence was higher in the 90 mg/m^2 dose group. The most common adverse events (AEs) ≥Grade 3, regardless of relationship to SGI-110, for the 2 doses combined were febrile neutropenia (43%), thrombocytopenia (39%), neutropenia (33%), anemia (24%), and leukopenia (22%). SGI-110 treatment with the two dose groups combined was associated with relatively low all-cause mortality (compared to intensive chemotherapy) at 30/60 days of 5.9%, and 15.7% respectively.
Summary and Conclusions: Second generation HMA SGI-110 SC QDx5 treatment is well tolerated and clinically active in elderly AML patients with other poor prognostic criteria who are unlikely to benefit from intensive chemotherapy. CR, OCR, safety, and early mortality compare favorably with previous results reported for other HMA treatment and merit confirmation in a larger randomized trial. Efficacy and safety were largely similar for the 2 dose groups. These data support evaluation of the 60 mg/m^2 QDx5 every 28 days dose regimen in a Phase 3 investigation of SGI-110 in elderly AML not eligible for intensive chemotherapy.

S648

A PHASE I DOSE-ESCALATION STUDY OF PRI-724, A CBP/B-CATENIN MODULATOR IN PATIENTS WITH ADVANCED ACUTE MYELOID LEUKEMIA (AML)

J E Cortes[1,*] B Z Carter[2], A Quintas-Cardama[1], T Inada[3], K Morita[3], M Fujimori[3], H Kouji[3], P Y Mak[2], V Ruvolo[2], G Borthakur[1], M Andreeff[1], M Konopleva[1], F Ravandi[1], H Kantarjian[1]

[1]Department of Leukemia, [2]Department of Leukemia-Research, The University of Texas MD Anderson Cancer Center, Houston, United States, [3]Clinical Development, PRISM Pharma Co., Ltd, Yokohama, Japan

Background: PRI-724 is a first-in-class CBP/β-catenin modulator that inhibits the cAMP-response element-binding protein (CREB)-binding protein (CBP) and β-catenin interaction and decreases leukemic stem cell proliferation and survival. In pre-clinical models, PRI-724 and its active metabolite C-82 increase p300/β-catenin binding and promote differentiation of leukemia initiating cells, thereby increasing sensitivity to cytotoxic drugs.
Aims: The aims of this study are to evaluate PRI-724 in patients with AML for safety, toxicity, tolerability, efficacy and PK profile; and to delineate the pharmacodynamic marker of drug-on-target effect with gene expression in peripheral blood (PB) and bone marrow (BM) in patients.
Methods: Relapsed/refractory AML patients age over 18 years old were enrolled. PRI-724 was given as a continuous infusion X 7 days q 2 weeks starting at 640 mg/m^2/day with dose escalation in a 3+3 design up to 1280mg/m^2/day unless a dose limiting toxicity (DLT) occurred. Based on available PK and safety data from solid tumor phase I study, no dose escalation beyond 1280 mg/m^2 was planned. Survivin expression of both PB and BM were measured by RT-PCR and flow cytometory and CD44 by RT-PCR.
Results: Dose-escalation phase was completed with 3 cohorts (640, 920 and 1280 mg/m^2) including 14 pts. Median age was 62 years (range 42-83). 9 of 14 pts (64%) were evaluable for DLT (*i.e.*, completed 28-day observation); 5 other discontinued early for progressive disease without DLT. Evaluable patients completed a median of 3 cycles (range, 2 to 5). The maximum dose was determined to be 1280 mg/m^2/day. There was no DLT and no MTD at the doses evaluated. Of 104 reported AEs, only 4 grade-1 AEs (2 nausea, 1 vomiting and 1 diarrhea) were judged to be related to the study drug. All 16 reported SAEs were considered by the investigators not study drug related. Per protocol, BM blast assessment was done at pre-treatment and at the end of Cycle2. Within the evaluable subjects, 7 of 9 (78%) had samples available for PD evaluation; relative to baseline, 5 of 7 (71%) showed blast decrease at the end of Cycle2 with median decrease of 44% [range 14-78%]. 2 of 7 (29%) showed blast decrease to 10% in the BM; one from baseline of 46% and the other from 18%. Decrease of CD44 expressions in both PB and BM was closely correlated with the decrease of blast counts. BM survivin decrease was also seen. The median Cmax and $AUC_{0\text{-}t}$ for C-82 at 920 mg/m^2/day were 2512 ng/mL and 272912 h*ng/mL. The median elimination T½ was 1.96 h.
Summary and Conclusions: PRI-724 is well tolerated in this study with an acceptable toxicity profile. The down-regulation of CD44 expression in PB and BM and survivin expression in BM serves as a pharmacodynamic marker of drug-on-target effect. Studies combining PRI-724 with standard anti-leukemia chemotherapy are on-going for AML and CML patients.

S649

PHASE I/II STUDY OF VOLASERTIB, AN INTRAVENOUS POLO-LIKE KINASE INHIBITOR (PLK), IN PATIENTS WITH RELAPSED/REFRACTORY ACUTE MYELOID LEUKEMIA (AML): UPDATED PHASE I RESULTS FOR VOLASERTIB MONOTHERAPY

H Döhner[1,*] G Bug[2], C Müller-Tidow[3], A Krämer[4], M Lübbert[5], U Krug[3], RF Schlenk[1], F Voss[6], T Taube[7], D Liu[7], P Garin-Chesa[8], O G Ottmann[2]
[1]Department of Internal Medicine III, University of Ulm, Ulm, [2]Department of Medicine, Hematology/Oncology, Goethe University, Frankfurt/Main, [3]Department of Medicine, Hematology and Oncology, University Hospital Muenster, Muenster, [4]Department of Internal Medicine V, University of Heidelberg, Heidelberg, [5]Department of Hematology and Oncology, University of Freiburg, Freiburg, [6]Boehringer Ingelheim Pharma GmbH & Co. KG, Ingelheim, [7]Boehringer Ingelheim Pharma GmbH & Co. KG, Biberach, Germany, [8]Boehringer Ingelheim RCV GmbH & Co. KG, Vienna, Austria

Background: The prognosis of patients (pts) with relapsed or refractory (rel/ref) AML considered unlikely to benefit from, or tolerate, intensive salvage treatment is unfavorable and novel therapies are needed. Plks are critical in cellular division and mitotic progression. Volasertib (lab code: BI 6727) is a selective and potent cell cycle kinase inhibitor that induces mitotic arrest and apoptosis by targeting Plk. Here we present from the phase I/II study, the updated phase I results of volasertib monotherapy in pts with rel/ref AML considered ineligible for intensive salvage treatment.
Aims: This study aimed to determine the maximum tolerated dose (MTD), safety, and pharmacokinetics (PK) of volasertib monotherapy.
Methods: Pts with rel/ref AML received volasertib as a 1-hr intravenous infusion on Days 1 and 15 Q4W. Dose escalation for MTD determination followed a 3+3 design with de-escalation. Blood samples for PK analyses of volasertib were taken in Cycles 1 and 2, before and at several time points after infusion, up to 2 weeks. Bone marrow samples were collected in Cycle 1.
Results: Increasing volasertib doses (150-200 mg, 350-550 mg) were evaluated in 56 pts including an MTD extension cohort of 15 pts (median age: 70 yrs [range 26-84]; 84% aged ≥65 yrs). All pts had failed prior AML treatment (median of two previous lines of antileukemic therapy [range 1-5]).
Over all cycles, adverse events (AEs) were reported in all 56 pts. Drug-related AEs were reported in 38 pts (68%). Most frequent drug-related AEs (>10%) were anemia (27%), thrombocytopenia and neutropenia (25% each), leukopenia (13%), and alopecia (11%). Grade ≥3 drug-related AEs (occurring in ≥3 pts) included neutropenia and thrombocytopenia (25% each), anemia (21%), leukopenia (13%), mucosal inflammation (7%), and pneumonia (5%). Dose-limiting toxicities (DLTs) in Cycle 1 were: pneumonia (fungal; 150 mg, n=1); mucosal inflammation (400 mg, n=1); pyrexia (450 mg, n=1); thrombocytopenia and epistaxis (500 mg, n=1); gastrointestinal (GI) inflammation and oesophagitis (500 mg, n=1); mucosal inflammation (550 mg, n=1); pneumonia, mucosal inflammation, GI hemorrhage, hemoptysis, lung infiltration and dyspnea (550 mg, n=1). Based on reported DLTs the MTD was determined to be 450 mg.
At higher volasertib doses (≥350 mg), antileukemic activity was observed with 5/43 pts (12%) achieving a complete remission with incomplete blood count recovery (CRi), as best response. Pts achieving CRi stayed on treatment for a median of 3 cycles (range 2-9). Bone marrow samples showed a pattern of nuclear condensation and fragmentation characteristic of apoptosis following prolonged mitotic arrest by Plk inhibition (Polo-arrest). Volasertib is a moderate clearance drug with a volume of distribution >5000 L and a terminal half-life of ~113 hrs. No accumulation was observed between the first two analyzed treatment cycles.
Summary and Conclusions: This study determined the MTD of volasertib to be 450 mg on Days 1 and 15 Q4W. The safety profile of volasertib was clinically manageable in this heavily pretreated pt population at doses above the recommended phase II dose previously determined in solid tumors. Most of the higher grade drug-related AEs were expected from the antimitotic mode of action. These results demonstrate the clinical antileukemic effect of single agent volasertib in pts with rel/ref AML, further supporting Plk as a potential therapeutic target in AML. A phase III trial of low dose cytarabine, with or without volasertib, in older untreated pts with AML ineligible for intensive therapy, is ongoing.

S650

FIRST-IN-CLASS NAE INHIBITOR MLN4924 IN COMBINATION WITH AZACITIDINE FOR ACUTE MYELOID LEUKEMIA (AML) PATIENTS CONSIDERED UNFIT FOR CONVENTIONAL CHEMOTHERAPY: RESULTS FROM THE C15009 TRIAL

RT Swords[1,*] MR Savona[2], MB Maris[3], HP Erba[4], Z Hua[5], H Faessel[6], SJ Blakemore[7], F Sedarati[8], BJ Dezube[8], BC Medeiros[9]
[1]Sylvester Comprehensive Cancer Center, University of Miami Hospitals and Clinics, Miami, [2]Tennessee Oncology, Nashville, [3]Blood and Marrow Transplant, Colorado Blood Cancer Institute, Denver, [4]Division of Hematology & Oncology, University of Alabama, Birmingham, [5]Biostatistics, [6]Clinical Pharmacology, [7]Translational Medicine, [8]Oncology Clinical Research, Takeda Pharmaceuticals International Co., Cambridge, [9]Division of Hematology, Stanford University School of Medicine, Stanford, United States

Background: The management of AML in older patients considered unfit for standard chemotherapy is challenging. Hypomethylating agents are commonly used alternatives in this group of patients. In the case of azacitidine, complete (CR) and partial remission (PR) rates are generally limited and responses are typically seen after 4-6 cycles. MLN4924 is an investigational NEDD8-activating enzyme (NAE) inhibitor. Preclinical studies in AML cell lines and xenograft models are suggestive of synergistic activity with combined treatment (Smith *et al.*, ASH 2011, abstract #578).
Aims: The primary objectives of this phase 1 dose-escalation study were to define dose-limiting toxicities (DLTs), the maximum tolerated dose (MTD), and the safety and tolerability of MLN4924 in combination with azacitidine. Secondary objectives included assessments of pharmacokinetics (PK) and disease response.
Methods: Previously untreated AML patients aged ≥60 years who were considered unfit for or unlikely to benefit from standard induction chemotherapy received MLN4924 by IV infusion over 1 hour on days 1, 3, and 5. Azacitidine 75 mg/m^2 (IV, n=11, or SC, n=3 [SC only included after dose-escalation phase]) was given on days 1-5 and days 8-9. Cycles were repeated every 28 days. Adverse events (AEs) were evaluated per NCI-CTCAE v4.03. Response was assessed per revised International Working Group recommendations. Blood samples for PK analysis were collected on dosing days 1 and 5 of cycle 1 only.
Results: At data cut-off (Jan 6, 2014), 14 patients had received MLN4924 at 20 mg/m^2 (n=11) and 30 mg/m^2 (n=3). Median age was 76.5 years (63-85), 7/7 were male/female, 8 had *de novo* AML, 6 had MDS/AML, and 4 had adverse and 7 intermediate-risk cytogenetics (3 undetermined). Patients' baseline AML mutation profile will be presented. One patient each had grade 3 AST elevation and grade 2 increased blood bilirubin at MLN4924 30 mg/m^2 that was dose-limiting (Table); liver enzymes returned to normal following discontinuation of MLN4924. None of the 11 patients treated at the MTD (MLN4924 20 mg/m^2 plus IV/SC azacitidine 75 mg/m^2) experienced further DLTs. Ten patients remain on treatment. The most common AEs (Table) included anemia, constipation, and thrombocytopenia (each n=4); 8 patients had drug-related AEs, and 5 had drug-related grade ≥3 AEs, with only anemia and thrombocytopenia (each n=2) seen in >1 patient. The safety profile of azacitidine is well established and no new toxicities were observed with the addition of MLN4924. MLN4924 PK has been previously described in single-agent studies and remained unchanged in com-

bination with IV azacitidine (based on preliminary data: individual PK profiles from 8 patients on days 1 and 5). In the 10 patients evaluable for response, the CR/PR rate was 60%, including 4 CRs and 2 PRs as best response; for five of the six patients reporting a response, the first evidence of response was documented within the first two cycles of therapy (Table 1).

Table 1.

Summary and Conclusions: These data suggest that azacitidine plus MLN4924 20 mg/m^2 is generally well tolerated in older patients with AML who are unfit for standard chemotherapy. A randomized phase 3 trial is currently being planned.

POST-INDUCTION THERAPY FDG-PET IS PROGNOSTIC FOR PROGRESSION-FREE SURVIVAL IN RELAPSED FOLLICULAR LYMPHOMA: A PRELIMINARY ANALYSIS OF THE GAUSS STUDY

L Kostakoglu[1,*] A Goy[2], G Martinelli[3], D Caballero[4], M Crump[5], G Gaidano[6], T Baetz[7], R Buckstein[8], G Fine[9], G Fingerle-Rowson[10], C Berge[10], D Sahin[10], O Press[11], L Sehn[12]

[1]Dept. of Radiology, The Mount Sinai Hospital, New York, [2]John Theurer Cancer Center HUMC, Hackensack, United States, [3]Department of Haematology-Oncology, IEO Istituto Europeo di Oncologia, Milano, Italy, [4]Hematology Department, University Hospital of Salamanca, Salamanca, Spain, [5]Princess Margaret Hospital, University of Toronto, Ontario, Canada, [6]Division of Hematology, Amedeo Avogadro University of Eastern Piedmont, Novara, Italy, [7]Division of Medical Oncology, Kingston General Hospital, Queen's University, Kingston, Ontario, [8]Sunnybrook Health Sciences Center, Toronto, Ontario, Canada, [9]Genentech Inc., South San Francisco, CA, United States, [10]F. Hoffmann-La Roche, Basel, Switzerland, [11]Fred Hutchinson Cancer Research Center, Seattle, United States, [12]Centre for Lymphoid Cancer, British Columbia Cancer Agency, Vancouver, Canada

Background: Use of fluorodeoxyglucose positron emission tomography (FDG-PET) as a prognostic tool after post-induction therapy (post-IT) in follicular lymphoma (FL) has not been fully investigated, particularly following immunotherapy alone, in patients (pts) with relapsed indolent NHL and in regimens that include maintenance. The three evaluation criteria; International Harmonization Project (IHP), Deauville 5-point scale (D5-PS) and European Organisation for Research and Treatment of Cancer criteria (EORTC-c) have not been validated for indolent NHL after induction treatment.

Aims: To determine whether post-IT FDG-PET based response assessment using IHP, D5-PS and EORTC criteria is a suitable prognostic endpoint for PFS in pts with relapsed FL treated with obinutuzumab (GA101) or rituximab monotherapy.

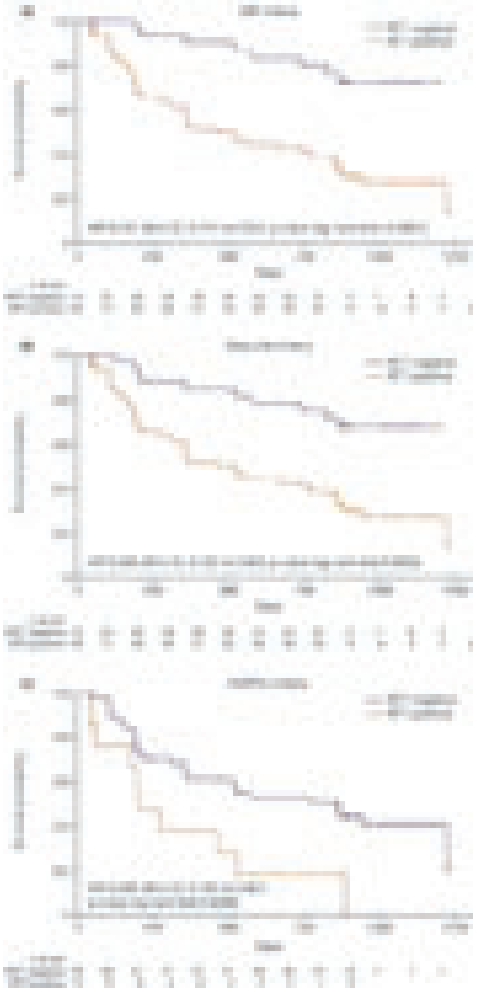

Figure 1.

Methods: In the phase II GAUSS trial (BO21003; NCT00576758), pts with FL were randomized to treatment with obinutuzumab or rituximab monotherapy. FDG-PET was performed at baseline and 4-6 weeks post-IT and was interpreted using IHP as the primary reading criteria, with D5-PS and EORTC-c as secondary reading criteria. The reduction in standardized uptake values (ΔSUV_{max}) between baseline and post-IT was assessed in only those tumours with the highest FDG uptake. Receiver-operating characteristics (ROC) analysis was used to determine an optimal cut-off for ΔSUV_{max} in predicting disease progression or death. Multivariate Cox analyses were performed to assess various factors (post-IT PET result, conventional response and three baseline factors; β2-microglobulin, Follicular Lymphoma International Prognostic Index and bulky disease) as prognostic indicators for PFS.
Results: The clinical results of this study have been presented elsewhere (ASH 2011: Sehn *et al.* Blood 2011;118: Abstract #269). Of 147 evaluable pts, 132 (median age=62 years) were analysed at baseline and 118 at post-IT, using IHP as the primary reading criteria. After a median follow up of 32.1 months, 44.6% of pts in the obinutuzumab arm and 56.1% in the rituximab arm had died or progressed. The post-IT PET results significantly correlated with response by all criteria (IHP, p=0.0002; D5-PS, p=0.0003; EORTC, p=0.0012). Using IHP criteria, the median PFS was 517 days for PET+ pts *versus* 'not reached' for PET- pts (95% confidence interval [CI], 309-772). The risk of disease progression was reduced in PET- compared with PET+ pts using IHP (hazard ratio [HR], 0.25; 95% CI, 0.117-0.5220.117-0.522; p<0.0001), D5-PS (HR 0.31; 95% CI, 0.155-0.6030.155-0.603; p=0.0003) and EORTC criteria (HR 0.39; 95% CI,0.191-0.8070.191-0.807; p=0.0083; Figures 1A-C). Post-IT PET results (p=0.0041) and conventional response (overall p=0.0442) were significant prognostic factors for PFS. The ROC analysis yielded an optimal ΔSUVmax cut-off of 49% in predicting disease progression or death (HR 0.31; 95% CI, 0.161-0.6080.161-0.608; p=0.0003).
Summary and Conclusions: Overall, post-IT PET status was a strong predictor of PFS regardless of the assessment criteria used in this pre-treated FL cohort. The optimal ΔSUVmax cut-off in predicting PFS was around 50%. Further evaluation using quantitative parameters is underway. These data provide further proof that post-IT PET may be used in risk-adapted clinical trials as a surrogate for PFS.

Hoffmann-La Roche Ltd, Basel, Switzerland, [8]Clinical Pharmacology, Roche Products Ltd, Welwyn Garden City, United Kingdom, [9]QEII Health Sciences Centre, Halifax, Nova Scotia, Canada

Background: Rituximab (R) plus chemotherapy induction followed by R maintenance is the backbone therapy for follicular lymphoma (FL). Intravenous R (R^{IV}) administration time and patient convenience could be improved by the development of a subcutaneous formulation (R^{SC}).
Aims: Pharmacokinetic non-inferiority was demonstrated in Stage 1 of the study with a $C_{trough,SC}$:$C_{trough,IV}$ ratio of 1.62 (90% confidence interval [CI]: 1.36-1.94) and provisional efficacy was comparable between R^{SC} and R^{IV} based on 127 randomised patients (pts; Davies *et al.* Lancet Oncol 2014). An additional 283 pts were randomised in Stage 2 to assess efficacy and safety of R^{SC} in a larger patient population.
Methods: SABRINA (BO22334; NCT01200758) is a two-stage phase III study of R^{SC} 1400mg or R^{IV} 375mg/m^2 plus chemotherapy (≤8 cycles CHOP [cyclophosphamide, doxorubicin, vincristine, prednisone] or 8 cycles CVP [cyclophosphamide, vincristine, prednisone]) every 3 weeks during induction (first cycle R^{IV} on both arms) followed by R^{SC} or R^{IV} maintenance every 8 weeks in pts with FL. The primary objective of stage 2 was to provide additional efficacy data and estimate the overall response rate (confirmed [CR] and unconfirmed [CRu] complete response, and partial response) at the end of induction treatment. Here we report pooled efficacy and safety analyses from Stage 1 (127 pts) and Stage 2 (283 pts).
Results: Pts with previously untreated confirmed CD20-positive grade 1, 2, or 3a FL (n=410) were randomised to R^{SC} (n=205) or R^{IV} (n=205). Pts were stratified by Follicular Lymphoma International Prognostic Index score, chemotherapy, and region. In each arm, approximately 64% pts received CHOP and 36% received CVP chemotherapy. Investigator-assessed overall response rates (ORR) at the end of induction were 83.4% (95% CI: 77.6%, 88.2%) in R^{SC} pts and 84.4% (95% CI: 78.7%, 89.1%) in R^{IV} pts. CR/CRu rates were 32.7% (67/205 pts) for R^{SC}, and 31.7% (65/205 pts) for R^{IV}. After a median follow-up of approximately 14.4 months, similar rates of adverse events (AEs; 184/197 [93%] SC; 194/210 [92%] IV) were reported in each arm. The majority of AEs were grade ≤2 in severity (1469/1651 AEs [90%] in the R^{SC} arm; 1225/1386 AEs [88%] in the R^{IV} arm). The incidence of pts with at least one grade ≥3 AE was similar between R^{SC} (96/197, 49%) and R^{IV} (99/210, 47%). Serious AEs (SAEs) were reported in 57 pts (29%) R^{SC} and 55 pts (26%) R^{IV}, respectively. Infections were the most frequently reported SAEs (20/197 [10%] SC; 16/210 [8%] IV) followed by febrile neutropenia (11/197 [6%] SC; 9/210 [4%] IV). Other common haematological AEs were neutropenia and anaemia (both ≤5% of pts in each group). Administration-related reactions occurred in 93 (47%) R^{SC} pts and 70 (33%) R^{IV}, pts and were predominantly grade 1 or 2. The difference was mainly due to grade 1 injection site erythema (10% *vs* 0%) which was anticipated following the change in route of administration.
Summary and Conclusions: R^{SC} demonstrated comparable ORR and CR rates with R^{IV}. The safety profile of R^{SC} and R^{IV} was similar and there were no new safety concerns with the SC formulation. Availability of R^{SC} administration over approximately 5 minutes is expected to have a positive impact on pt convenience and health care resource savings without compromising the anti-lymphoma activity of rituximab.

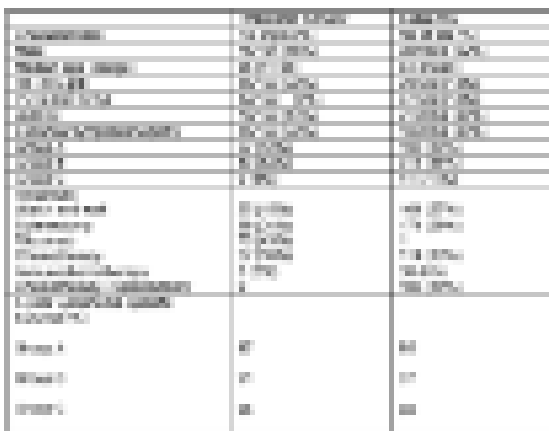
S653

RISK STRATIFICATION IN SMZL PATIENTS: VALIDATION OF THE SIMPLIFIED PROGNOSTIC SCORE FOR SPLENIC MARGINAL ZONE LYMPHOMA OF THE SPLENIC MARGINAL ZONE LYMPHOMA WORKING GROUP

C Kalpadakis[1,*] G A Pangalis[2], T Vassilakopoulos[3], S Sachanas[2], F Kontopidou[4], M Moschogiannis[2], M Ximeri[1], P Tsirkinidis[2], X Yiakoumis[2], H Papadaki[1], MK Angelopoulou[3], C Thieblemont[5]
[1]Haematology, University of Crete, Heraklion, [2]Haematology, Athens Medical Center-Psychikon branch, [3]Haematology, University of Athens, [4]Haematology, Ippokrateion General Hospital, Athens, Greece, [5]Haematology, Hopital Saint-Louis, Paris, France

Background: splenic marginal zone lymphoma (SMZL) is generally characterized by an indolent clinical behavior. However a substantial proportion of patients presents with a more aggressive clinical course and short survival. Several prognostic factors have been proposed. Recently, a new simplified prognostic score has been proposed by the SMZLWG.
Aims: In this collaborative study we evaluate the reproducibility of the simplified risk stratification score in a larger series of SMZL patients.
Methods: The prognostic index was based on the combination of 4 factors: haemoglobin level<9.5 g/dL, platelet counts<80×10^9/L, elevated LDH and the presence of extrahilar lymphadenopathy. All variables were assigned the same value of one point each. Three risk groups were identified: low (A) 0 points, intermediate (B) 1-2 points and a high risk group (C) 3-4 points. Kaplan-Meier method was used to estimate survival and the log-rank test to compare survival curves.
Results: Among 164 SMZL patients, 159 had complete data for all variables and were included in this analysis (Table 1). The median age was 65 years (range, 41-95) with a slight female predominance (89/164 or 54%). Anemia and thrombocytopenia were present in 35/159 (22%) and 12/159 (8%), respectively. Serum lactate dehydrogenase was elevated in 44% (70/159) while 35/159 (22%) of SMZL patients had extrahilar lymphadenopathy at diagnosis. The stratification of our patients in the three risk groups were as follows: 67/159 (42%) were stratified into group A, 83/159 (52%) into group B and 9/159 (6%) into group C. Treatment differed among the three risk groups. The 5- and 10-year LSS was 97% & 93% for group A, 91% & 66% for group B and 65% at 5 years (but not applicable at 10 years due to shorter follow-up) for group C (p=0.0001). The 5- and 10-year OS was 93% & 89% for group A, 81% & 57% for group B and 49% at 5 years (but not applicable at 10 years) for group C (p=0.0001).

Table 1. Comparison of the clinical characteristics between the present study and the SMZLWG pts.



Summary and Conclusions: Our results confirm the applicability of the recently proposed simplified prognostic system of SMZLWG in an independent series of 159 SMZL patients.

S654

A PHASE II STUDY OF RITUXIMAB PLUS LENALIDOMIDE IN PATIENTS WITH EXTRANODAL MARGINAL ZONE B-CELL LYMPHOMA OF THE MUCOSA-ASSOCIATED LYMPHOID TISSUE (MALT LYMPHOMA)

M Raderer[1,*] B Kiesewetter[1], W Willenbacher[2], P Neumeister[3], M Fridrik[4], R Greil[5]
[1]Oncology, Medical University Vienna, Vienna, [2]Internal Medicine, University innsbruck, Innsbruck, [3]Hematology, University Graz, Graz, [4]Internal Medicine, AKH Linz, Linz, [5]Internal Medicine, Paracelsus Universität, Salzburg, Austria

Background: Extranodal marginal zone B-cell lymphoma of the mucosa-associated lymphoid tissue (MALT lymphoma) is a distinct entity thought to arise from marginal zone B-cells related to plasma cells. MALT lymphoma shares some clinical features with multiple myeloma (*e.g.* immunoglobulin production by lymphoma cells and plasmacytic differentiation) and a recent study with lenalidomide (LEN) monotherapy reported activity in MALT lymphoma.
Aims: To further improve the activity of LEN in MALT lymphoma, we initiated a phase II study of rituximab (RIT) plus LEN in pts with MALT lymphoma. Patients (pts) with histologically verified gastric or extragastric MALT lymphoma received RIT 375 mg/m² i.v. day 1 and oral LEN at a dose of 20 mg daily given on days 1 - 21. In gastric MALT lymphoma with evidence of *Helicobacter pylori* (HP) infection, pts had to be refractory to, or relapsing after successful HP-eradication; pts without evidence of HP were directly eligible. Treatment was repeated every 28 days with restaging after 3 and 6 cycles. Patients with stable disease or better after 3 cycles were given another 3 cycles. If remaining lymphoma was detected after 6 cycles another 2 cycles were given for a maximum of 8 cycles. Patients with evidence of progressive disease were taken off study. All pts received prophylactic ASA (100 mg daily) for the duration of treatment, and allopurinol (300 mg daily) for the first 4 weeks of therapy. The primary endpoint of the study was objective response rate and the secondary endpoint was safety and tolerability.
Results:: To date, 43 patients have been enrolled (28 female, 15 male); 30 are evaluable for efficacy, having undergone at least 1 restaging investigation (3 after 8, 20 after 6, and 5 after 3 courses of therapy, and 1 pt after withdrawal following the first course of therapy). The most common primary localizations were the ocular adnexa (13 pts), stomach (10 pts), and lung (5 pts); the remaining pts had MALT lymphoma of the parotid, colon, small intestine, liver, and subcutaneous tissue, respectively. Nine pts were pretreated; 2 pts having relapsed after CR from LEN monotherapy[AM1]. At the time of enrollment 13 pts had localized disease, while the remaining 30 had disseminated disease. The overall response rate was 26/30 (87%), with 14 complete (47%, including the 2 patients pretreated with LEN) and 12 partial remissions (40%). Three pts had stable disease, and 1 pt progressed during therapy and was given salvage therapy. All 43 pts were evaluable for safety. Toxicities were mostly non-haematologic and of grade I/II with exanthema gr I/II in 15 patients being the most common event. Two pts had diarrhea, nausea and joint-pain III, 7 pts presented with exanthema/pruritus III, 1 pt had vertigo III, and 2 pts had infections necessitating hospitalization. Haematologic side effects included leucopenia (10 pts; 1 pt grade III), thrombocytopenia (5 pts; I/II), and anemia (6 pts; 2 grade III). Dose reductions were performed in 10 pts (8 to 15 mg and 2 to 10 mg), while 4 pts discontinued treatment early due to toxicity.
Summary and Conclusions: This is the first study on efficacy of LEN plus RIT in pts with MALT lymphoma. The promising interim analysis CR rate (currently 47%) response rate of 87% is likely to increase in terms of with continued therapy in pts who had not undergone the full scheduled courses. As expected, the response rate is higher than the activity reported with LEN monotherapy in a pilot study in MALT lymphoma (RR 61%), and toxicities appear manageable and mostly non-haematological.

Universitaria S.M. Misericordia, Udine, [7]Dept. of Haematology, Università di Pisa, PIsa, [8]Dept. of Haematology, Ospedali Riuniti Ancona, Ancona, [9]Dept. of Haematology, Fondazione IRCS, Policlinico, Università degli Studi, Milano, [10]Dept. of Haematology, Ospedale S. Bortolo, Vicenza, [11]Dept. of Haematology, Ospedale Umberto I, Nocera Inferiore, Italy

Background: Rituximab (R) plus chemotherapy is a standard of care in pts with indolent lymphoprolipherative disorders. In the Stil trail the combination Bendamustine (B) plus R demonstrated a PFS benefit and improved tolerability comapred with CHOP-R when administered in first line treatment in Waldenstrom's Macroglobulinemia (WM). Limited data are evaluable on the setting of pretreated patients.
Aims: To define the efficacy and tolerability of BR combination as salvage regimen in symptomatic WM patients.
Methods: We retrospectively analyzed the outcome of symptomatic WM patients treated with BR in 11 Italian centers. All patients receiving at least one day of treatment were included in the study. Treatment consisted of: R 375 mg/sqm iv day 1 and B either at the dosage of 90 or 70 mg/sqm iv days 1,2. Therapy was administered every 4 weeks up to 6 courses.
Results: Fifty-four patients are included in the study. At treatment, median age was 70 years (49-86), sex ratio M/F 33/21. Median number of prior regimens was 2 (range 1-6), being median time from WM diagnosis and from last treatment to BR administration of 85 and 15 months respectively. Eighteen patients (33%) presented with refractory disease The 89% of patients had previously received rituximab based immunochemotherapy, in 32% previous treatment included Fludarabine. In the majority of patients (63%) reason for starting treatment was anemia, 17% of patients presented with hyperviscosity syndrome. Median IgM level at treatment was 3995 mg/dL (range 1028-8040). Lymphadenopathy and splenomegaly were present in 31% and 18% patients respectively. Fifteen patients (28%) received B at the lower dosage of 70 mg/sqm. Overall 282 courses of BR treatment were administered, median number 6 (range 2-6). Sixteen patients (29,6%) received fewer than 6 cycles, cytopenia was the major cause of discontinuation 5/16 (31%). No difference in terms of treatment discontinuation was observed according to B dosage administered and patients age. Overall response rate (ORR) was 83.4%, including 5.6% complete remissions CR), 18.5% very good partial remissions (VGPR) and 59.3% partial remissions (PR), 13% of patients remained in stable disease while disease progression rate was 1.9%. One death (1.9%) due to infection was recorded. An amelioration of response was observed in 4 cases: 1 PR converted in VGPR and 3 SD reached a PR, leading to a final ORR of 88.8%. None of the clinical and biological characteristics considered (age, sex, disease status, previous lines of treatment, previous fludarabine, bulky dissease, Hb and IgM level, β 2 microglobulin, B dosage, had an impact in quality of response achievement (CR plus VGPR *versus* PR). A trend, even if not significative (*P=0.05*), of higher ORR achievement was observed among patients treated with the higher dosage of B. Considering that most of the patients received prophylactic growth factors, grade 3-4 neutropenia developed in only 13% of courses, 38% of patients. Dose modification or delayed treatment administration was necessary in 5 and 10% of courses respectively. Twelve episodes of FUO and 3 major infections, leading death in one case, were recorded during treatment. Seven (14.5%) of the 48 responding patients showed a disease progression after a median of 12 m. After a median follow up of 15 monts none of the patients developed secondary myelodisplastic syndrome, acute leukemia or diffuse large B-cell lymphoma. In 2 cases a solid cancer was observed.
Summary and Conclusions: BR combination showed to be as effective as more intensive salvage regimens in pretreated WM patients effective. Treatment showed to be well tolerated even in elderly patients with limited episodes of myelosuppression and infections when compared to purine analogues including regimens.

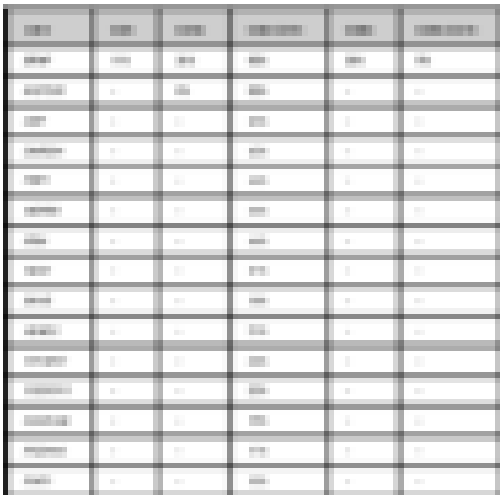
[1]INSERM U985, Villejuif, France, [2]Hematology, Oncology and Tumor Immunology, Charité- University Hospital Berlin, Berlin, Germany, [3]INSERM U872, Paris, France, [4]Graduate School of Medicine, The University of Tokyo, Tokyo, [5]Medicine and Biosystemic Science, Kyushu University Graduate School of Medical Sciences, Fukuoka, Japan, [6]Hôpital Saint-Louis, Paris, [7]Service d'Hématologie Clinique, Centre Hospitalier Victor Dupouy, Argenteuil, [8]INSERM U1009, Villejuif, France

Background: Chronic lymphocytic leukemia (CLL) is a clonal accumulation of mature B-lymphocytes and is the most frequent adult leukemia in western countries. The cell of origin of this incurable disease is still elusive.
Aims: In the present study we aimed to investigate the repartition of acquired mutations in the hematopoietic differentiation tree of CLL patients using a combination of whole-exome and targeted deep resequencing.
Methods: Diagnostic pretreatment blood samples of 24 CLL patients (17 *IGHV*-unmutated and 7 *IGHV*-mutated) were flow-sorted for $CD3^+$ T-lymphocytes, $CD5^+CD19^+$ tumor cells, $CD14^+$ monocytes, and $CD34^+CD19^-$, progenitors. Acquired mutations were identified by comparison of exome sequences of tumor cells and T-lymphocytes. Subsequently we used targeted deep resequencing to simultaneously validate and quantify the mutation burden of candidate mutations in DNA from all sorted cell fractions. In order to establish multipotent progenitor involvement, we genotyped colonies from single $CD34^+CD19^-$, cells from 18 of the investigated patients, grown *in vitro* in myeloid conditions.
Results: Whole-exome sequencing identified a total of 415 somatic mutations predicted to result in protein-coding changes of 361 different genes with a median of 17 mutations/ patient. Among the 24 patients analyzed, only 3 did not exhibit detectable mutations in the $CD34^+$ progenitor or the $CD14^+$ monocyte fractions, all of which exhibiting mutated *IGHV* rearrangements in their CLL cells. In all other 21 patients, at least one mutation was detectable in the $CD14^+$ or in the $CD34^+$ fractions (see Table 1). Genotyping of $CD34^+CD19^-$–derived myeloid colonies confirmed the presence of CLL mutations in myeloid cells in 13 patients. These mutations included classical CLL mutations, such as *SF3B1* or *NOTCH1*, but also *EGR2* and *NFKBIE*, an inhibitor of NFKB.
Recurrence analyses in a cohort of 168 advanced stage patients treated within a French multicentric trial (www.clinicaltrials.gov: NCT00931645), confirmed the recurrent nature of mutations in *EGR2* and in NFKBIE observed in 8.3% and 10.7% of patients, respectively. Missense mutations in *EGR2* associated with shorter time to treatment (median: 15.4 *vs* 1.2; p=0.0006) and a shorter 5-year overall survival (56.2 *vs* 80.4 months; p=0.04). The impact of *EGR2* mutations was confirmed by over expression studies in hematopoietic cell lines. RNA-seq data from CLL patients showed that *EGR2* mutated patients showed a signature of *EGR2* activity that overlap with BCR activation signatures.

Table 1. Representative example of the mutation repartition in a CLL patient.



Summary and Conclusions: Our findings establish the presence of acquired mutations in multipotent haematopoietic progenitors of CLL patients. Early mutations were observed in genes that belong to the most frequent mutated ones in CLL (*NOTCH1, SF3B1, TP53,* and *XPO1)* and in genes that have been reported to be recurrent in other cancers (*e.g. FUBP1, MED12* or *PEG3)*. Together with the previous report of differentiation bias of CLL progenitor cells in xenograft experiments (Kikushige *et al.* Cancer Cell 2011), our results suggest that abnormalities in hematopoietic progenitors and early B-cell differentiation is an early step during CLL pathogenesis. They also support the hypothesis that early CLL mutations, despite their diversity, commonly affect B-cell differentiation, through deregulation of pre-BCR signaling.

S657

SF3B1 MUTATIONS INDUCE COMMON AND LINEAGE SPECIFIC ABERRANT MESSENGER RNA SPLICING IN MALIGNANCIES INCLUDING CHRONIC LYMPHOCYTIC LEUKEMIA AND CONFER SENSITIVITY TO SPLICEOSOME INHIBITION

[1]H3 Biomedicine, Cambridge, [2]Weill Cornell Medical College, New York, [3]Eisai Pharmaceuticals, Andover, United States

Background: Recurrent heterozygous mutations of the spliceosome protein SF3B1 have been identified in chronic lymphocytic leukemia (CLL), myelodysplastic syndromes, and solid tumors. In CLL, SF3B1 mutations are associated with poor prognosis and are enriched in fludarabine-refractory CLL. In MDS, SF3B1 mutations are enriched in subtypes with ringed sideroblasts. SF3B1 is part of the U2 snRNP complex which binds to the pre-mRNA branch point site and is involved in recognition and stabilization of the spliceosome at the 3' splice site.
Aims: Here, we sought to determine the impact of SF3B1 mutations and explore opportunities for therapeutic intervention in SF3B1 mutated cancers.
Results: A comparison of RNAseq data from tumor samples with SF3B1 hotspot mutations ($SF3B1^{MUT}$) or wild-type SF3B1 ($SF3B1^{WT}$) in CLL, melanoma and breast cancer revealed significant increases in the usage of alternative 3' splice sites generating known and new alternative splice junctions in $SF3B1^{MUT}$, samples. These events induce expression of alternative mRNAs that are translated into novel proteins or aberrant mRNAs that are decayed by cells. We identified a common set of aberrantly spliced mRNAs (*e.g.* ZDHHC16 and COASY) across different hotspot mutations and lineages; however, unique alternative splicing profiles were also observed suggesting lineage specific effects. In particular, in CLL we identified multiple aberrantly spliced genes in the NF-KB pathway, FOS/JUN transcriptional network and BCR signaling pathway. RNAseq analysis of several cell lines with endogenous SF3B1 hotspot mutations confirmed the presence of the same spliced isoforms as observed in tumor samples. To prove that $SF3B1^{MUT}$ were inducing alternative splicing, transient transfection of several SF3B1 hotspot mutations in 293FT cells induced the expression of the common alternatively spliced genes suggesting functional similarity. Selective shRNA depletion of mutant SF3B1 allele in $SF3B1^{MUT}$ cells resulted in downregulation of the same splice isoforms. Furthermore, isogenic B-cell lines (NALM-6) expressing the most frequent SF3B1 mutation (K700E) were generated and profiled by RNAseq. As expected, similar alternatively spliced genes were observed only in NALM-6 $SF3B1^{K700E}$, cells. To investigate the role of nonsense-mediated mRNA decay (NMD) in eliminating certain aberrant mRNAs induced by $SF3B1^{MUT}$, we treated NALM-6 $SF3B1^{K700E}$ cells with the NMD inhibitor cylcoheximide. In the treated samples we uncovered expression of several aberrant mRNAs, some of which were shown to be downregulated in patient samples. $SF3B1^{MUT}$, CLL samples displayed evidence of impaired NMD pathway activity since many aberrantly spliced genes that are subject to NMD pathway degradation could be detected in the absence of cycloheximide treatment. Taken together, these results confirm the association between different SF3B1 hotspot mutations, the presence of novel splice isoforms and lineage specific pathway defects. To evaluate therapeutic approaches to the treatment of malignancies with SF3B1 mutations we evaluated a potent and selective inhibitor of SF3B1, E7107. We demonstrated that E7107 binds and inhibits both wild-type and mutant SF3B1 protein. Furthermore, E7107 represses the expression of several common aberrant splice mRNA products in $SF3B1^{MUT}$, cells *in vitro* and *in vivo*. When tested in a NALM-6 mouse model, E7107 induced tumor regressions and increased the overall survival of animals implanted with NALM-6 $SF3B1^{K700E}$, cells.
Summary and Conclusions: These data suggest splicing inhibitors as a promising therapeutic approach for malignancies with SF3B1 mutations, including CLL and MDS.

Background: The complex biology underlying how the CLL cell is influenced by the surrounding immunological and stromal environment is an area of active investigation. IL23R is a heterodimeric construct consisting of the common IL12Rβ1 chain and a unique IL23Rα subunit.
Aims: We investigated i) the expression pattern of the IL23R subunit and its correlation with progression free survival (PFS); ii) the role of the microenvironment in controlling the IL23R complex subunits; iii) the epigenetic regulation of IL23R expression and turn-over; iii) the down-stream signalling induced by IL23R engagement in CLL clones.
Methods: CLL patients were prospectively enrolled from diagnosis (O-CLL1 protocol, clinicaltrial.gov identifier NCT00917540). MiRNA analysis was performed by Agilent's Human V2 platform and by quantitative PCR. The heterodimeric construct of IL23R, consisting of IL23Rα and of IL12Rβ1 sidechains was determined by flow-cytometry using the anti-human IL23R-PE mAb and anti-Human IL-12Rβ1 FITC monoclonal antibodies (R&D Systems). MirVANA microRNA mimics and inhibitors used in this study were purchased from Ambion, Inc. For 3'UTR luciferase reporter experiments, miRNA target reporter vectors were purchased from Origene.
Results: A totale of 233 CLL cases were defined according to a median IL23Rα cut-off value. The 3-year PFS probability of IL23Rα-low patients was 91% as compared to 75% of IL23Rα-high cases [χ2 9.1, P=.003; HR=3.2, 95%CI (1.4-7.1)]. The IL23Rα-high group was enriched in *IGVH* unmutated cases and showed preferential usage of VH1-69 and VH4-34 sequences. In a multivariate model, IL23Rα expression still remained significant in predicting PFS together with CD38 expression and *IGHV* mutational status, while ZAP-70 and FISH lost their significance. IL12Rβ1, was not expressed in circulating B-cells, however *in situ* analyses revealed its expression in association with IL23Rα, within CLL tissue infiltrates, suggesting that regulation of IL12Rβ1 expression in CLL cells occurred according to microenvironment-derived signals, whose prototype is the CD40/CD40L axis. Accordingly, a significant increase of both IL23Rα and IL12Rβ1 expression was documented after co-culturing CLL B-cells in the presence of CD40L-expressing NIH-3T3 cell line. Similar results were obtained by stimulating CLL cells with autologous T cells activated by CD3/CD28 MACSiBead™ (Miltenyi) particles and IL2. CLL cells concomitantly expressed higher levels of CD38, lower levels of CXCR4 and CD5dim or bright, thus indicating that the IL23R complex is expressed by the activated and dividing B-cells. The expression of both chains of the IL23R complex was observed in the spleen of a xenografted mouse (NSG) in the context of proliferating Ki67 positive CLL cells. Global miRNA expression analysis identified miRNAs that inversely correlated with IL12Rβ1 or IL23Rα expression. These miRNAs were tested in a dual luciferase reporter system, in which miR-324-5p and miR-146b-5p were found to target the 3'UTR region of IL23Rα and IL12Rβ1, respectively. Down-regulation of the IL23Rα side chain protein could be achieved in CLL B-cells by the transfection of miR-324-3p mimic, while up-regulation of the IL12Rβ1 subunit was observed through inhibition of miR-146b-5p expression. Finally, the engagement of IL23R complex induced phosphorylation of Stat-3.
Summary and Conclusions: These findings underscore a novel paradigm in the epigenetic regulation of pro-inflammatory cytokine sensing by CLL clones with biological and prognostic relevance.

S659

ISOTYPE MATTERS: FUNCTIONAL DIFFERENCES AFTER SIGM *VERSUS* SIGD TRIGGERING OF THE BCR IN CHRONIC LYMPHOCYTIC LEUKEMIA (CLL)

E ten Hacken[1,*] C Scielzo[2], S O'Brien[1], W G Wierda[1], M J Keating[1], P Ghia[2], F Caligaris-Cappio[2], JA Burger[1]
[1]Department of Leukemia, University of Texas MD Anderson Cancer Center, Houston, United States, [2]Universita' Vita-Salute San Raffaele, Milano, Italy

Background: B-cell receptor (BCR) signaling plays an important role in CLL pathogenesis. CLL cells carrying *IGHV*-unmutated BCRs (U-CLL) are more responsive to surface IgM (sIgM) stimulation in terms of intracellular signaling activation, while cells with *IGHV*-mutated receptors (M-CLL) are usually more anergic. In contrast, previous studies demonstrated that a vast majority of CLL clones are responsive to sIgD stimulation, irrespective of the mutational status.
Aims: The aim of the present study is to characterize functional differences of BCR signaling after surface IgM and IgD triggering in CLL cells.
Methods: Purified CLL cells were stimulated with anti-IgM and anti-IgD or the combination of both anti-IgM and anti-IgD; phosphorylation levels of the BCR-related molecule HS1 (tyrosine^{Y397}) was analyzed in serial samples after 2, 5, 15, 30, and 60 minutes of stimulation by Western Blot and flow cytometry; BCR surface receptor expression and 48-hour cell viability were analyzed by flow cytometry; CCL3 and CCL4 secretion by CLL cells was measured by ELISA after 24-hour stimulation.
Results: HS1 is an early BCR signaling and cytoskeletal molecule, whose phosphorylation correlates with the clinical outcome of CLL patients. We observed that HS1 activation peaked after 2-5 minutes following stimulation, and then returned to baseline at later time points with different patterns. We noted robust and protracted HS1 phosphorylation after anti-IgM stimulation in most samples (19/22; 86%). In contrast, protracted HS1 phosphorylation after anti-IgD stimulation was seen only in 8/22 samples (36%), while 14/22 samples showed only transient HS1 activation that rapidly returned to baseline. The transient nature of IgD signaling may, at least in part, be explained by the rapid receptor internalization following stimulation, as compared to sIgM molecules, as analyzed in 10 CLL samples. The analysis of HS1 activation kinetics in U-CLL and M-CLL samples showed greater responsiveness of U-CLL cells (n=8) to both IgM and IgD stimulation as compared to M-CLL cases (n=6). In line with this finding, the surface expression of IgM (P=0.0004) and IgD (P=0.0042) molecules was detected to be higher in U-CLL (n=22) as compared to M-CLL (n=16) samples. IgM stimulation protected CLL cells from *in vitro* apoptosis to a greater extent than IgD stimulation, as demonstrated in 20 patients following 48 hours of *in vitro* culture. Interestingly, IgD stimulation did not induce secretion of CCL3 or CCL4 chemokines by the CLL cells, whereas IgM induced robust release of these chemokines into CLL cell supernatants (see Figure 1), based on analyses of 10 different patients' samples after 24-hour stimulation with anti-IgM and anti-IgD. sIgM-induced protection from *in vitro* apoptosis and chemokine production were greater in U-CLL as compared to M-CLL cases. Treatment with the combination of both anti-IgM and anti-IgD increased signaling activation, but did not have a significant impact on cell viability and chemokine production, with respect to anti-IgM stimulation alone.

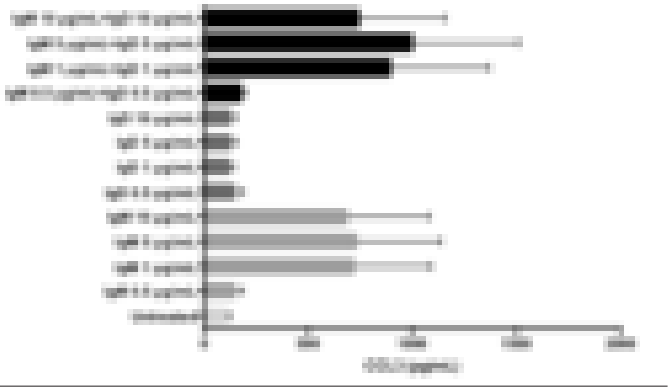

Figure 1.

Summary and Conclusions: sIgM stimulation induces protracted signaling activation, protection from *in vitro* apoptosis and CCL3 and CCL4 production to a greater extent than sIgD stimulation, particularly in U-CLL cells. Taken together, these observations suggest differential functional relevance of sIgM and sIgD triggering in CLL, which is further modulated by BCR signaling differences in patient subsets. Deeper insight into the fine-tuning of BCR signaling in CLL will help understanding and guide us towards pathophysiology-based use of BCR signaling inhibitors.

S660

CLL INDUCES SEVERE SKEWING IN THE MYELOID COMPARTMENT IN PATIENTS AND IN THE TCL1 MOUSE MODEL

B Hanna[1,*] F McClanahan[1, 2], N Zaborsky[3], C Dürr[1], V Gschwend[1], S Stilgenbauer[4], A Egle[3], J Gribben[2], P Lichter[1], M Seiffert[1]
[1]Molecular Genetics, German Cancer Research Center (DKFZ), Heidelberg, Germany, [2]Centre for Haemato-Oncology, Barts Cancer Institute, London, United Kingdom, [3]Laboratory For Immunological And Molecular Cancer Research, Paracelsus Medical University, Salzburg, Austria, [4]Internal Medicine III, University of Ulm, Ulm, Germany

Background: Previous *in vitro* studies have demonstrated that myeloid cells play an important role in providing Chronic Lymphocytic Leukaemia (CLL) cells with survival stimuli. When cultured with CLL cells, blood monocytes can differentiate into adherent Nurse-Like Cells (NLCs) which protect leukaemic cells from undergoing spontaneous apoptosis.
Aims: In the current study, we investigated the changes induced by CLL cells in myeloid cells and their role in disease progression *in vivo*.
Methods: For *in vitro* experiments, human blood monocytes were cultured for 2 days with either CLL cells or normal B cells. Cells were then harvested and

analyzed by flow cytometry. For *in vivo* experiments, we used the well-established transgenic Eμ-TCL1 mouse model of CLL. In addition, we injected young wild-type (WT) C57Bl/6 recipients with CLL cells from spleens from leukaemic mice, and sacrificed them when they exhibited symptoms of progressive CLL. Using an 8-color flow cytometry panel, we performed in depth phenotypic analyses of myeloid cells in spleen, blood and peritoneal cavity. More than 140 serum cytokines from leukemic mice and clinically well-annotated CLL patients were screened with antibody arrays.

Results: Compared to healthy WT mice, mice with CLL exhibited fundamental changes in the composition of myeloid cells with skewing towards subsets with documented immunosuppressive functions. This corresponded with an increased production of pro-inflammatory and immunosuppressive cytokines. In addition, multiple chemo-attractants for myeloid cells, such as MCP-5 were upregulated. This resulted in the recruitment of myeloid cells to tissue sites where they were enriched in the proximity to tumor vasculature. Accordingly, several matrix-remodelling proteins and angiogenic factors including MMP-9 and osteopontin were highly enriched in serum, indicating that CLL might be associated with an induction of tumour angiogenesis. Of interest, conventional dendritic cells were drastically reduced in leukemic mice. This was accompanied by deregulation of key cytokines such as GM-CSF and FLT3-L. Furthermore, similar to many other tumours, peritoneal cavity macrophages harboured a M2-like phenotype. A direct induction of M2 macrophage differentiation by CLL cells was confirmed in co-cultures of human cells with monocytes from healthy donors. Functionally, the described alterations in the myeloid compartment were accompanied by failure to stimulate anti-tumor immune responses. Ongoing work focuses on the molecular characterization of dysregulated cell subsets, and the manipulation of the myeloid compartment *in vivo*.

Summary and Conclusions: Our *in vivo* data suggests that the myeloid compartment contributes as a key player in the pathogenesis of CLL. Skewing of these cells to immunosuppressive subtypes along with their potential role in tumor angiogenesis makes them attractive targets for immunotherapy complementing current standard chemo-immunotherapy approaches.

DEFERASIROX-DEFEROXAMINE COMBINATION THERAPY REDUCES CARDIAC IRON WITH RAPID LIVER IRON REMOVAL AFTER 24 MONTHS IN PATIENTS WITH SEVERE TRANSFUSIONAL IRON OVERLOAD (HYPERION)

Y Ayidinok[1,*] A Kattamis[2], MD Cappellini[3], AE Beshlawy[4], R Origa[5], M Elalfy[6], Y Kilinc[7], S Perrotta[8], Z Karakas[9], V Viprakasit[10], K Musallam[11], N Constantinovici[11], J Shen[12], J B Porter, on behalf of the HYPERION investigators[13]

[1]Ege University Hospital, Izmir, Turkey, [2]First Department of Pediatrics, University of Athens, Athens, Greece, [3]Universitá di Milano, Ca Granda Foundation IRCCS, Milan, Italy, [4]Cairo University, Cairo, Egypt, [5]Ospedale Regionale per le Microcitemie, Cagliari, Italy, [6]Ain Shams University, Cairo, Egypt, [7]Cukurova University, Medical Facility, Adana, Turkey, [8]I°Policlinico II°Università di Napoli, Naples, Italy, [9]Department of Pediatric Hematology, Istanbul University, Istanbul Medical Faculty, Istanbul, Turkey, [10]Department of Pediatrics and Thalassemia Center, Siriraj Hospital, Mahidol University, Bangkok, Thailand, [11]Novartis Pharma AG, Basel, Switzerland, [12]Novartis Pharmaceuticals, East Hanover, New Jersey, United States, [13]University College London, London, United Kingdom

Background: The prospective, Phase II, multinational HYPERION study evaluated the efficacy and safety of deferasirox-deferoxamine (DFX–DFO) in combination followed by DFX monotherapy in patients with severe transfusional cardiac siderosis. During the first 12 months (mo), improvement in cardiac T2* and reduction in liver iron concentration (LIC) were observed in patients with severe liver and cardiac iron overload (IO) while the safety profile was consistent with established monotherapy (Aydinok, *Blood* 2013;122(21) Abst 2257).

Aims: The aim of this HYPERION analysis is to evaluate the efficacy and safety of combination treatment followed by DFX monotherapy for up to 24 mo.

Methods: Study design/inclusion-exclusion criteria have been described (Aydinok, *Blood* 2013;122(21) Abst 2257). Patients aged ≥10 years with CMR-measured cardiac T2* 5–<10 ms, left ventricular ejection fraction (LVEF) ≥56%, and R2-MRI LIC ≥7 mg Fe/g dw were enrolled. Patients achieving cardiac T2* ≥10 ms accompanied by a relative T2* increase of ≥10% from baseline (BL) after 6 mo were switched to DFX monotherapy, but switched back to combination therapy if cardiac T2* fell to <10 ms with a relative decrease of ≥10%. At 24 mo, geometric mean (GM) cardiac T2* ratio (GM_{24}/GM_{BL}), is presented with a 95% CI. Proportion (%) of patients and time to achieving T2* ≥10 ms with ≥10% increase from BL was evaluated. Efficacy was analyzed for all evaluable patients in the full analysis set (FAS) who received ≥1 dose of study drug and had a BL and a post-BL assessment within each visit window.

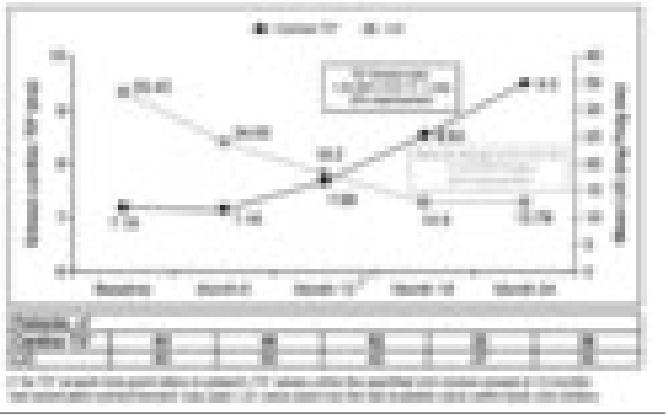

Figure 1. Geometric mean cardiac T2* and mean LIC in patients treated with DFX-DFO in combination followed by DFX monotherapy over 24 months (Full analysis set).

Results: Results are presented for the cumulative 24 mo study. Of the 60 patients enrolled, 34 (56.7%) completed 24 mo. Discontinuations were due to consent withdrawal (6), lost to follow up (6), adverse event (AE) (5), abnormal test procedure ((5), 2 consecutive T2* values were <5 ms), administrative (2), protocol deviation (1), and death (1); majority occurred during the first 12 mo. Mean dose (mg/kg/d) was DFX, 30.5±7.13, 7 d/wk, and DFO, 36.3±6.66, 5 d/wk. Median (range) duration of exposure was DFX, 719.0 (21.0–737.0) and DFO, 407.5 (29.0–737.0) days. Serum ferritin levels decreased by 44% (Median: BL, 5551; 24 mo, 2491 ng/mL). Cardiac T2* increased by 30% (GM: BL, 7.19; 24 mo, 9.5 ms), and LIC decreased by 52% (Mean (SD): BL, 33.43 (14.55); 24 mo, 12.79 (11.72) mg Fe/g dw) (Figure 1). Patients with BL LIC <30 and ≥30 mg Fe/g dw, cardiac T2* improvement was 35% (8.04 to 10.59 ms, n=15) and 26% (6.83 to 8.78 ms, n=21), respectively. Overall, 12.5% (n=6), 19.2% (n=10), 33.3% (n=11) and 47.2% (n=17) of patients achieved T2* ≥10 ms and ≥10% relative increase from BL at Months 6, 12, 18 and 24, respec-

tively. Median time to T2* ≥10 ms and ≥10% relative increase from BL was 722.0 days. 11 patients transitioned to DFX monotherapy. LVEF remained stable during the study. AEs with suspected relationship to either drugs or combination (≥5%) included: abdominal pain, increased urine protein/creatinine ratio (each 8.3%); increased serum creatinine (SCr), diarrhea, and nausea (each 6.7%); 2 patients had increased SCr >33% from BL and >upper limit of normal at 2 consecutive visits; 1 death reported in a patient with pyrexia and altered state of consciousness (suspected DFO). Majority of AEs, including the death, were reported during the first 12 mo.
Summary and Conclusions: In this large clinical trial of DFX–DFO combination therapy, continued improvement in T2* with a clinically significant decrease in LIC was demonstrated in patients with severe liver and cardiac IO. Liver iron removal was rapid and cardiac iron removal was steady with nearly 50% of patients who remained on study achieving T2* ≥10 ms and ≥10% relative increase from BL. LVEF remained stable and there were no new episodes of arrhythmias or cardiac failure, despite severe cardiac IO at BL in all cases (cardiac T2* 5–<10 ms). Safety of the combination therapy was consistent with established monotherapy profiles with no unexpected findings.

S662

INTERIM RESULTS FROM A PHASE 2A, OPEN-LABEL, DOSE-FINDING STUDY TO DETERMINE THE SAFETY, EFFICACY, AND TOLERABILITY OF SOTATERCEPT (ACE-011) IN ADULTS WITH BETA-THALASSEMIA

J Porter[1,*] MD Cappellini[2], R Origa[3], GL Forni[4], A Laadem[5], F Galacteros[6], E Voskaridou[7], D Miteva[5], V Sung[5], R Chopra[5], JB Arlet[8], JA Ribeil[8], K Klesczewski[5], K Attie[9], M Garbowski[1], G Graziadei[2], M Balocco[4], O Hermine[8]
[1]University College London, London, United Kingdom, [2]Ca' Granda Foundation IRCCS, University of Milan, Milan, [3]Università degli Studi di Cagliari, Ospedale Regionale per le Microcitemie, Cagliari, [4]Ente Ospedaliero Ospedali Galliera, Genoa, Italy, [5]Celgene Corporation, Summit, United States, [6]Groupe Hospitalier Henri Mondor, Créteil, France, [7]Laiko General Hospital, Athens, Greece, [8]Hôpital Necker-Enfants Malades, Institut Imagine, Paris, France, [9]Acceleron Pharma, Cambridge, United States

Background: β-thalassemias are characterized by ineffective erythropoiesis leading to anemia, erythroid hyperplasia, iron overload, and organ failure. Sotatercept (ACE-011), a novel and first-in-class activin type IIA receptor fusion protein, acts on late-stage erythropoiesis to increase release of mature erythrocytes into circulation (Carrancio S, *et al.* Br J Haematol 2014; in press). In healthy volunteers, sotatercept therapy was associated with increased red blood cell (RBC) parameters, including hemoglobin (Hb) level (Sherman ML, *et al.* J Clin Pharmacol 2013;53:1121-30). RAP-011, a murine version of sotatercept, was effective in a β-thalassemia mouse model, supporting clinical development of sotatercept (Dussiot M, *et al.* Nat Med 2014; in press).
Aims: To determine a safe, tolerable, and effective dose of sotatercept in β-thalassemia major (TM) patients (pts) with transfusion-dependent thalassemia (TDT), or β-thalassemia intermedia (TI) pts with TDT or non-transfusion-dependent thalassemia (NTDT).
Methods: In this ongoing phase 2a, multicenter, open-label dose-finding study, pts received sotatercept subcutaneously (SC) once every 3 weeks; dose escalation to 0.75 mg/kg is ongoing. Efficacy is assessed by Hb increase from baseline (BL) for NTDT pts and RBC transfusion burden reduction for TDT pts. Safety is assessed by NCI-CTCAE v4.0. All pts provided informed consent.
Results: Of the 25 pts in the sotatercept 0.1, 0.3, and 0.5 mg/kg dose groups, 18 (72%) had NTDT (17 TI, 1 Hb-E/β-thalassemia) and 7 (28%) had TDT (5 TM, 2 TI). Six NTDT pts were treated in each dose group. Median BL Hb for NTDT pts was 8.7 g/dL (range 6.1–10.7), 8.3 g/dL (range 6.0–9.5), and 8.2 g/dL (range 6.4–9.3) in the 0.1, 0.3, and 0.5 mg/kg dose groups, respectively. In the first 3 cycles, one or more Hb increases of ≥1.0 g/dL were seen in 0 (0%), 5 (83%), and 5 (83%) NTDT pts in the 0.1, 0.3, and 0.5 mg/kg groups, respectively. Hb increases of ≥2.0 g/dL were seen in 0 (0%), 1 (17%), and 2 (33%) NTDT pts, respectively. Area under the curve and peak concentration of sotatercept increased proportional to dose. Increased exposure was associated with higher Hb increases in the first 3 cycles for NTDT pts (n=17; r=0.77, P<0.001). No appreciable reduction in transfusion burden was seen for TDT pts in the 0.1 and 0.3 mg/kg groups. Treatment of the 0.5 mg/kg group is ongoing. Sotatercept was well tolerated; 19 (76%) pts remain on treatment. Three grade ≥2 treatment-related adverse events leading to discontinuation were seen: worsening grade 3 bone pain in 1 TDT pt with history of severe osteoporosis and grade 2 phlebitis in 1 NTDT pt with underlying high D-dimer at BL, both in the 0.1 mg/kg group, and grade 3 ventricular extrasystoles in a pt with history of ventricular extrasystoles at BL in the 0.5 mg/kg group. Three pts discontinued due to lack of efficacy: 2 and 1 in the 0.1 and 0.3 mg/kg groups, respectively.
Summary and Conclusions: These preliminary data suggest sotatercept given SC once every 3 weeks increases serum Hb, improving anemia. Sotatercept may provide clinical benefit to β-thalassemia pts with a favorable safety profile, addressing a significant unmet need. These data suggest a dose-dependent effect for sotatercept, supporting further study of the exposure–effect relationship in β-thalassemia pts. Updated safety and efficacy data will be presented.
JP, MDC, and OH contributed equally to this abstract.

A PHASE 1 DOSE-ESCALATION TRIAL OF TOPICAL SODIUM NITRITE IN PATIENTS WITH SICKLE CELL ANEMIA AND LEG ULCERS: EVIDENCE OF IN HUMAN EFFECT ON BLOOD FLOW

C Minniti[1,*] GJ Kato[2], A Gorbach[3], C Hon[4], KM H Delaney[5], M Siedel[6], S Yoon[7], D Xu[1], N Malik[8], M Peters Lawrence[1], C Cantilena[1], J Nichols[1], L Mendelsohn[1], G Grimes[4]
[1]Hematology, National Institutes of health, Bethesda, [2]Hematology, University Of Pittsburg, Pittsburg, [3]Infrared Imaging and Thermometry, | National Institute of Biomedical Imaging and Bioengineering, [4]Pharmacy, [5]Cardiovascular and Pulmonary, [6]Biomdcl Engnrg & Physl Scnc Shared Resource Prgm, [7]National Institute of Biomedical Imaging and Bioengineering, [8]Biomedical Engnrg & Physl Scnc Shared Resource Prgm, National Institutes of Health, Bethesda, United States

Background: Chronic leg ulcers are a debilitating complication of sickle cell disease (SCD). There is a need for well-tolerated, effective therapies. Sodium nitrite functions as a reservoir of nitric oxide, whose vasodilating, angiogenic, antiplatelet and anti-microbicidal activities make it an attractive investigational therapy for wound healing.
Aims: We assessed safety and tolerability of escalating doses of a novel preparation of topical sodium nitrite and examined changes in microcirculation to investigate mechanism of action.
Methods: A phase 1, dose-escalation study of topical sodium nitrite (ClinicalTrials.gov NCT01316796) was conducted in adults with SCD and chronic leg ulcers. Sodium nitrite was applied twice a week for 4 weeks to one ulcer per patient in five cohorts of escalating concentrations. Safety, tolerability and pharmacokinetic of nitrite and nitrate were obtained. Laser speckle blood flow images and infrared (IR) thermal images of the ulcer peri-wound area were obtained before and after application. Ulcer size and pain were measured at each visit. A brief pain inventory (BPI) was administered before and after the trial.
Results: 18 subjects enrolled and completed the trial. Tolerability was excellent, with no serious adverse events. In five subjects diastolic blood pressure decreased transiently below 50mmHg. Methemoglobin did not exceed safety thresholds. There appeared minimal systemic absorption after cream application; increases in whole blood nitrite concentration were attributable to the oral administration of hydroxyurea. We observed a dose-dependent decrease in leg ulcer size (p<0.0001) and pain (p<0.0001). Wound size decreased by: 30% for cohort 1, 4% for cohort 2, 38% for cohort 3, 68.5% for cohort 3a (one healed) and 88% for cohort 4, (two healed). BPI improved significantly in pain severity (p<0.005) and interference (p<0.001) and overall opioid use decreased. The Visual Analogue Scale (VAS) mean score was 3.7±3.4 cm at enrollment, decreasing to 1.2+1.4 cm (p<0.0003). In the 9 patients that had more than one ulcer, VAS scores for non-treated ulcers did not change significantly, mean of 2.7± 2.6 cm *vs.* 2 ±2.4 cm (p=0.8) at the end. There was a statistically significant decrease in total WBC, from 9.9±4.5K/ul to 8.7±3.1K/ul, p=0.001. Significant increases in peri-wound temperature (p<0.01) and blood flow (p=0.00016) were observed after nitrite application.
Summary and Conclusions: On the basis of these safety, pharmacokinetic and tolerability data, and promising efficacy results, topical sodium nitrite warrants further clinical evaluation in patients with sickle cell disease and/or other types of leg ulcers

S664

ACE-536 INCREASES HEMOGLOBIN LEVELS IN ADULTS WITH BETA-THALASSEMIA: PRELIMINARY RESULTS FROM A PHASE 2 STUDY

A Piga[1,*] A Melpignano[2], S Perrotta[3], C Borgna-Pignatti[4], V Caruso[5], E Voskaridou[6], A Filosa[7], Y Aydinok[8], C Condon[9], D Wilson[9], M Sherman[9], K Attie[9]
[1]A.O.U. San Luigi Gonzaga, Turin, [2]Ospedale "A. Perrino", Brindisi, [3]Second University of Naples, Naples, [4]University of Ferrara, Ferrara, [5]Garibaldi Hospital, Catania, Italy, [6]Laiko General Hospital, Athens, Greece, [7]AORN "A. Cardarelli", Naples, Italy, [8]Ege University Children's Hospital, Izmir, Turkey, [9]Acceleron Pharma, Cambridge, MA, United States

Background: ACE-536 is a recombinant fusion protein containing modified activin receptor type IIB, being developed for the treatment of anemias due to ineffective erythropoiesis (IE), such as β-thalassemia (β-thal). In β-thal, IE is due to intracellular α-globin aggregates causing premature death of late-stage erythroid precursors. Patients with β-thal often have elevated levels of EPO and are unresponsive to erythropoiesis-stimulating agents (ESAs). ACE-536 binds to ligands in the TGF-β superfamily and promotes late-stage erythroid differentiation via a mechanism distinct from ESAs. In a healthy volunteer study, ACE-536 was well-tolerated and increased hemoglobin (Hgb) levels (Attie K *et al.*, Am J Hematol 2014). Murine ACE-536 (RAP-536) increased Hgb levels and decreased RBC inclusion bodies and hemolysis in a mouse model of β-thal (Suragani R *et al.*, Blood 2012;120:248).
Aims: This is an ongoing, phase 2, multicenter, open-label, dose-finding study to evaluate the effects of ACE-536 in adults with transfusion-dependent (TD) or non-transfusion dependent (NTD) β-thalassemia. Study outcomes include erythroid response (either Hgb increase in NTD patients or reduced RBC trans-

fusion burden in TD patients), safety, tolerability, PK, and pharmacodynamic biomarkers.

Methods: Inclusion criteria included age ≥18 yr and anemia defined as either Hgb <10.0 g/dL (NTD, defined as <4 units RBCs/8 wks prior to baseline) or requiring ≥4 units RBCs/8 weeks prior to baseline (TD). ACE-536 was administered in sequential cohorts (n=6) at dose levels of 0.2, 0.4, 0.6, 0.8 mg/kg by subcutaneous (SC) injection once every 3 weeks for up to 5 doses with a 2-month follow-up. Further dose escalation cohorts and an expansion cohort (n=30) are planned, contingent on periodic safety data review.

Results: Preliminary baseline data were available for the 24 patients (12M/12F, 20 NTD/4TD) enrolled in the first 4 cohorts as of 07Feb2014. Median age was 34.5 yr (range: 20-57 yr); 79% had prior splenectomy. Genetic analysis and disease history were consistent with β-thal intermedia for all patients enrolled to date, including 5 with α-globin triplication/quadruplication. Median (range) baseline Hgb (over 28 days prior to treatment) for the NTD patients was 8.4 (6.5-9.6) g/dL. Preliminary efficacy data were evaluated for the NTD patients in the first 3 cohorts and demonstrated a mean (SD) Hgb increase after 3 cycles (~9 weeks) of 0.0 (0.8), 0.9 (0.4), and 1.4 (0.4) g/dL in the 0.2 (n=6), 0.4 (n=5), and 0.6 (n=5) mg/kg groups, respectively (see Figure 1). Preliminary efficacy data were available for the 4 TD patients enrolled to date (1 pt at 0.6 and 3 pts at 0.8 mg/kg) and demonstrated reductions in transfusion requirement. ACE-536 was generally well tolerated. No related serious adverse events (AEs) have been reported to date. One patient discontinued treatment early due to a related AE (ankle pain in the 0.8 mg/kg cohort). No notable changes in mean platelets or WBC were observed.

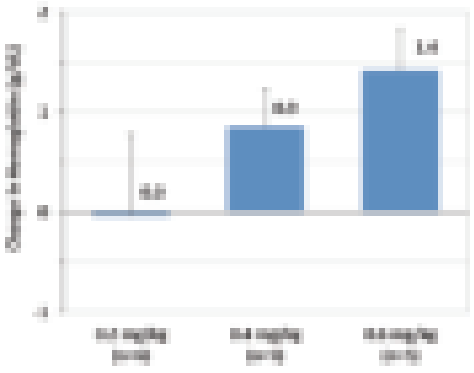

Figure 1. Mean (± SD) change in hemoglobin after 3 cycles non-transfusion dependent patients.

Summary and Conclusions: Based on preliminary data, ACE-536 administered SC every 3 weeks increased Hgb levels in NTD patients and decreased transfusion requirement in TD patients with β-thalassemia via a novel mechanism of action with a favorable safety profile. These data strongly support further evaluation of ACE-536 in patients with β-thalassemia.

S665

CLINICAL AND MOLECULAR HETEROGENEITY OF 47 PATIENTS AFFECTED BY CONGENITAL DYSERYTHROPOIETIC ANEMIA TYPE II (CDAII)

P Bianchi[1,*] E Fermo[1], C Vercellati[1], A P Marcello[1], A Zaninoni[1], R van Wijk[2], E Lazarova[3], A Zanella[1], W Barcellini[1]

[1]Oncohematology Unit, Physiopathology of Anemia Unit, Foundation IRCCS Cà Granda Policlinico Milan, Milan, Italy, [2]Department of Clinical Chemistry and Haematology, University Medical Center Utrecht, Utrecht, Netherlands, [3]Clinical biology, Transfusion, Red blood cell pathology laboratory, Erasme Hospital, Brussels, Belgium

Background: CDAII, the most frequent type of congenital dyserythropoietic anaemia, is an autosomal recessive disease characterized by ineffective erythropoiesis, peripheral hemolysis, erythroblast morphological abnormalities and hypoglycosylation of some RBC membrane proteins. SEC23B gene, encoding the COPII coat component involved in protein trafficking from the endoplasmic reticulum to the Golgi apparatus, has been identified as the causative gene for CDAII; approximately 60 different mutations have been reported.

Aims: To describe the phenotype and genotype features of 47 CDAII patients (22 females, 25 males) from 42 unrelated families, diagnosed over a period of 30 years.

Methods: The diagnosis was made by presence of congenital anaemia/jaundice, ineffective erythropoiesis, typical morphologic appearance of bone marrow erythroblasts, hypoglycosylation of band 3 in SDS-PAGE and presence of mutations in *SEC23B* gene.

Results: The age at diagnosis (median 5 yrs, range birth-49 yrs) drastically decreased in patients born in the last decade, likely due to the availability of SDS-PAGE analysis and molecular testing. About 2/3 of patients had more than one misdiagnosis, in particular HS (15 cases). Clinical presentation was mild in 11 patients, moderate in 28, and severe in 8. Median Hb and reticulocytes levels were 10.3 g/dL (range 3.1-12.4) and 79 $x10^9$/L (range 3-369) respectively. Two cases presented with hydrops foetalis: one died at 11 yrs, and the other underwent BM transplantation. Eight were transfusion-dependent and 10 needed occasional support only. Fourteen had been splenectomised (mean age at splenectomy 20 yrs, range 7-39) and 13 patients underwent iron chelation (maximum ferritin levels: median 504, range 32-4000). The patients were characterized at molecular level by direct sequencing: 29 different mutations (15 disruptive and 14 missense) were identified among the 94 mutated alleles, 8 were new (Glu10X, Arg18Cys, delLeu245, delAsp377Phe fs, Arg550X, Asp600Asn, His757Pro, Ser617Pro). Missense mutations affect highly conserved residues in multiple domains of SEC23B. Taken together the two most frequent mutations, c.325G>A (Glu109Lys) and c.40C>T (Arg14Trp) account in our series for the 56% of mutant alleles. Out of the 47 patients, 15 were homozygous (14 carrying c.325G>A), 10 compound heterozygous for two different missense mutations and 18 for one missense and one drastic mutation; 2 unrelated subjects showed only one mutation at heterozygous level. Interestingly, two unrelated patients with mild/moderate clinical presentation were compound heterozygous for one stop and the splicing mutation c.221+31a>g, in spite of the commonly reported opinion that combination of two drastic mutation could be lethal. The 14 cases with homozygous Glu109Lys mutation (12 unrelated) displayed median Hb levels of 9.2 g/dL (range 7-11.2) and maximum ferritin levels: 701 mg/ml, (range 110-1740); 5 patients need occasional blood transfusion, and 4 had been splenectomised for a previous diagnosis of HS.

Summary and Conclusions: The analysis of this large series of patients confirms the clinical and molecular heterogeneity of this disease and underlines the usefulness of molecular testing to avoid misdiagnosis.

THE OCCURRENCE AND IMPACT OF JOINT BLEEDS IN VON WILLEBRAND DISEASE

KP van Galen[1,*] YV Sanders[2], U Vojinovic[2], J Eikenboom[3], MH Cnossen[4], S Zweegman[5], RE Schutgens[1], AG van der Bom[6], K Fijnvandraat[7], B Laros-van Gorkom[8], K Meijer[9], MR Nijziel[10], F Leebeek[2], EP Mauser-Bunschoten[1]

Background: Von Willebrand disease (VWD) is a heterogeneous inherited bleeding disorder that affects up to 1% of the population. Joint bleeds are not predominant, but have been reported to occur in 8-45% of patients with VWD, especially in those with a more severe phenotype. Joint bleeds can lead to structural joint damage. The most severe type 3 VWD patients develop similar rates of joint range of motion limitation over time as moderate hemophilia A patients. However, the severity, onset and impact of joint bleeds and its complications in VWD patients are largely unknown.
Aims: The aim of this study is to assess the incidence, onset and treatment of joint bleeds and its impact on quality of life and joint integrity in moderate and severe VWD.
Methods: In the Willebrand in the Netherlands (WIN) study 804 moderate and severe VWD patients (VWF activity ≤30U/dL) completed a comprehensive questionnaire after giving informed consent. We quantified joint bleed occurrence as reported in the questionnaires and examined the medical files for documentation on joint bleeds and joint problems from all patients who had reported treatment for joint bleeds with desmopressin or clotting factor concentrate (CFC) and from as many patients without joint bleeds for comparison, matched for gender, age, FVIII and VWF activity.
Results: Twenty three percent of the patients (184/804) self-reported joint bleeds in the questionnaire, mostly in the knee, followed by the ankle and elbow. These patients had more severe VWD (type 3 VWD 12% *vs.* 4%, p<0.01, OR 3.4, 95%CI 1.8-6.2; FVIII level ≤10 IU/dL in 9% *vs.* 3%, p<0.01, OR 3.8, 95%CI 1.9-7.8), reported more joint damage (54% *vs* 18%, p<0.01) and large joint surgery more often (25% *vs* 11%, p<0.01) compared to the patients not reporting joint bleeds. Also, patients with joint bleeds reported lower quality of life (SF36 mental component summary ß -2.78, 95%CI -4.74 to -0.83, p<0.01 and physical component summary ß -4.03, 95%CI -6.92 to -1.14, p<0.01), still significant after correction for age, comorbidity, epistaxis and menorrhagia in women. In the medical files, we found documentation of joint bleed treatment with CFC or desmopressin in 55 of the 79 patients (70%) who had self-reported treatment for joint bleeds. Of these 55 patients 38% had type 3, 40% type 2 and 22% type 1 VWD. The first joint bleed occurred in childhood in most cases (65% before age 16, median age 12 years, range 3-69). More than 10 joint bleeds were documented in the medical files of 9/55 (18%) patients. Compared to 55 matched control VWD patients without joint bleeds, patients with joint bleeds used CFC prophylaxis more often (29% *vs.* 2%, p<0.01). The frequency of joint bleeds decreased >50% in 14/16 VWD patients with joint bleeds who started CFC prophylaxis. We found documented X-ray joint damage in 44% of the patients with joint bleeds compared to 11% of the controls (p<0.01). Orthopedic joint surgery, performed in 14 patients and 6 controls (26% *vs.* 11%, p=0.03), was performed because of arthropathy due to joint bleeds in 10 of the 20 joint bleed patients undergoing joint surgery. Impaired mobility occurred in 7 cases and 1 control patient (p=0.08). We found notes on joint pain in 24 cases and 10 controls (p<0.01), but pain medication prescriptions in only 6 cases and 3 controls (p=0.49).
Summary and Conclusions: Joint bleeds in VWD mostly occur at young age, in all three VWD types, are associated with more severe VWD, lower quality of life and significantly more radiologic and self-reported joint damage. Radiologic joint damage also occurs in 11% of moderate and severe VWD patients without clear clinical joint bleeds. The relatively low proportion of VWD patients with joint bleeds using CFC prophylaxis and pain medication suggests that treatment of VWD patients with joint bleeds can be improved.

S667

BIOCHEMICAL MARKERS OF JOINT DAMAGE ARE INCREASED AFTER A JOINT BLEED; AN EXPLORATIVE HUMAN AND CANINE *IN VIVO* STUDY

L Van Vulpen[1,2,*] M van Meegeren[1,2], N Jansen[1,2], G Roosendaal[1], S Mastbergen[2], F Lafeber[2], R Schutgens[1]
[1]Van Creveldkliniek, [2]Rheumatology & Clinical Immunology, UMC Utrecht, Utrecht, Netherlands

Background: Haemophilic arthropathy is one of the major causes of morbidity amongst haemophilia patients. At the moment, the only way to evaluate joint damage is by radiologic examination. Detection of early and small changes due to a joint bleed, for instance by the use of biomarkers, would be favourable to monitor joint disease progression, adapt treatment, and evaluate its efficacy in haemophilia patients. It is previously shown that a panel of four biomarkers for cartilage degradation (uCTX-II, sCOMP, sC1,C2, sCS846) is associated with overall radiographic joint damage (Jansen *et al.*, Arthritis Rheum 2009).
Aims: The purpose of this study is to investigate whether those biochemical markers are sensitive to changes in joint tissue turnover induced by a joint bleed.
Methods: Blood and urine samples were collected from 10 haemophilia patients after they reported a joint bleed: within two days, after 3-5 days, 12-14 days and 90 days (last time point considered baseline). Commercially available assays for serum and urine biomarkers were performed: urinary C-terminal telopeptide of type II collagen (uCTX-II), serum cartilage oligomeric matrix protein (sCOMP), serum cartilage cleavage product C1,2C, and serum chondroitin sulfate (sCS846). The same panel of biomarkers was explored in dogs (n=7) after induction of a joint bleed by intra-articular blood injections. Biomaterials were collected at baseline, day two, one and two weeks later.
Results: In haemophilia patients, levels of uCTX-II and sCS846 increased five days after the bleed when compared to baseline (uCTX-II +52%; p=0.021; sCS846 +14%; p=0.011; see Figure 1).
In dogs, uCTX-II increased statistically significant from day two to day seven (from 75% to 154% of baseline; p=0.018), and sCOMP from baseline to day two (+46%; p=0.028).

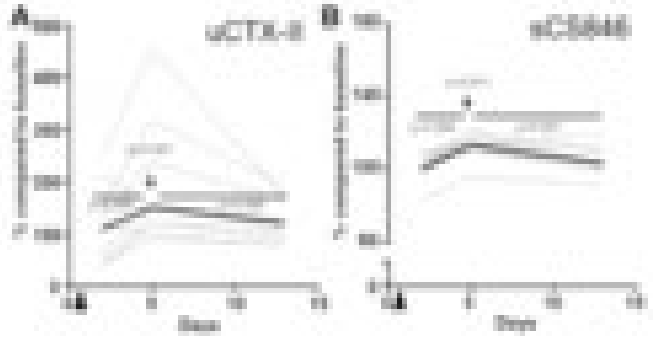

Figure 1. Biomarkers of joint demage increase after an acute joint bleed in haemophilia patients.

Summary and Conclusions: This study demonstrates that biochemical markers of joint tissue damage increase already after a single joint bleed, both in a clinical and an experimental setting. This might be useful in monitoring the impact of a joint bleed and in evaluation of treatment in haemophilia patients.

THROMBOPOIETIN RECEPTOR AGONISTS SHIFTS THE BALANCE OF FCGAMMA RECEPTORS TOWARDS THE INHIBITORY FCGAMMA RECEPTOR IIB ON MONOCYTES IN IMMUNE THROMBOCYTOPENIA

J Peng[1,*] S Liu[1], XG Liu[1], Q Feng[1], H Zhou[1], M Hou[1]
[1]Department of Hematology, Qilu Hospital, Shandong University, jinan, China

Background: The human FcγR receptor (FcγR) system comprises the activating FcγRs (FcγRI, FcγRIIa and FcγRIII) and the inhibitory FcγR (FcγRIIb), the balance of which determines the magnitude of inflammatory response. Impaired homeostasis in FcγR expression has been implicated in the pathogenesis of primary immune thrombocytopenia (ITP). Clinical studies using thrombopoietin (TPO) receptor agonists to stimulate platelet production have yielded favorable outcomes in ITP patients.
Aims: The study is aimed to investigate the effects of thrombopoietic agents on modulation of FcγRs on monocytes in ITP patients and murine models.
Results: In the present study, expression of FcγRs on monocytes was determined in 17 corticosteroid-resistant/relapsed chronioc ITP patients before and after eltrombopag treatment. Eltrombopag was given orally with an initial dose of 25 mg/d, and adjusted between 25 and 75 mg/d to maintain platelet counts ≥50 000/μL. Results showed that 6 weeks after the initiation of eltrombopag administration, mRNA and protein expression levels of FcγRIIb were significantly elevated. Concurrently, levels of FcγRI and IIa were decreased remarkably, whereas FcγRIII expression remained unchanged. *In vitro* phagocytosis assay of IgG-opsonized platelets indicated that the shift of FcγR balance towards the inhibitory FcγRIIb on monocytes of ITP patients was accompanied by a considerable decrease in monocyte phagocytic capacity after eltrombopag treatment. Modulation of monocyte FcγR balance by TPO receptor agonists was

also found in a murine model of ITP in which splenocytes from CD61 knockout mice immmunized against CD61+ platelets were transferred into C57BL/6 severe combined immunodeficient (SCID) (CD61+) mouse recipients, and their platelet counts and phenotypes were observed. When thrombocytopenia was induced in the SCID mouse recipients, romiplostim was injected subcutaneously at a dose of 100 μg/kg every 3 days. After 2 weeks of romiplostim administration, platelet counts in SCID mice elevated remarkably, and a significant increase in the inhibitory FcγRII expression together with a decrease in expression of activating FcγRI were observed.

Summary and Conclusions: These findings suggested that the recovery of platelet counts after TPO receptor agonist treatment in ITP is accompanied by a change in the FcγR balance toward the inhibitory FcγRIIb on monocytes, and the thrombopoietic agents have profound effects on immune modulation in ITP.

THE IMPACT OF BLEEDING COMPLICATIONS IN PATIENTS RECEIVING NOVEL ORAL ANTICOAGULANTS: A SYSTEMATIC REVIEW AND META-ANALYSIS

C Chai-Adisaksopha[1,2,*] T Isayama[3], W Lim[1], M Crowther[1]
[1]St. Joseph Healthcare, McMaster University, Hamilton, Canada, [2]Chiang Mai University, Chiang Mai, Thailand, [3]Sunnybrook Health Sciences Center, University of Toronto, Toronto, Canada

Background: Vitamin K antagonists (VKAs) have been the standard of care for treatment of thromboembolic diseases including venous thromboembolism and stroke prevention from atrial fibrillation. Novel oral anticoagulants (NOACs) have been developed and found to be at least non-inferior to VKAs with regards to efficacy. However the risk of bleeding with NOACs remains controversial. We therefore performed a systematic review and meta-analysis of phase III randomized controlled trials (RCTs) evaluating on NOACs compare with VKAs for VTE and stroke prevention from atrial fibrillation.
Aims: We aimed to assess the bleeding side effects of NOACs compared with warfarin (target INR 2.0 to 3.0) in the patients with VTE and atrial fibrillation.
Methods: We searched MEDLINE, EMBASE, CENTRAL, conferences abstracts and www.clinicaltrials.gov up to the last week of January 2014 with no language restriction. Two reviewers independently performed study selection, data extraction and study quality assessment. Selected outcomes were major bleeding, clinically relevant non-major bleeding, gastrointestinal hemorrhage and intracranial hemorrhage. We analyzed the pooled relative risk (RR) and corresponding 95% confidence internal [CI] for major bleeding and other secondary outcomes using the Mantel-Hanszel random effect model.
Results: A total of 13 RCTs (4 evaluating dabigatran, 4 rivaroxaban, 3 apixaban and 2 edoxaban) involving 102,638 patients were retreived. NOACs significantly reduced the risk of overall major bleeding (4.01% *versus* 4.62%, RR 0.73; 95% confidence interval [CI] 0.63-0.85, number needed to harm (NNH)=164), clinically relevant non-major bleeding (10.20% *versus* 11.04%, RR 0.78; 95% CI 0.68-0.89, NNH=122) and intracranial bleeding (0.52% *versus* 1.12%, RR 0.43; 95% CI 0.37-0.49, NNH=166). There was no significant difference in gastrointestinal hemorrage between NOACs and VKAs (2.27% *versus* 1.89%, RR 1.09; 95% CI 0.88-1.34) (Table 1).

Table 1.

Summary and Conclusions: When compared to VKAs administered to a target INR of 2.0 to 3.0, NOACs cause less major bleeding, clinically relevant non-major bleeding and intracranial hemorrhage. Additionally, NOACs do not increase the risk of gastrointestinal hemorrhage.

S670

HEMORRHAGIC RISK IN HEMODIALYSIS PATIENTS WITH ATRIAL FIBRILLATION TAKING ORAL ANTICOAGULATION THERAPY: RESULTS FROM A MULTICENTER ITALIAN STUDY

M Carpenedo[1,*] E Rossi[2], MC Luise[2], H Riva[2], A Stella[3], EM Pogliani[1], A Santoro[4], MG Valsecchi[5], S Genovesi[2]
[1]Hematology and Transplantation Unit, A.O San Gerardo di Monza and University of Milan Bicocca, [2]Department of Health Science, University of Milan Bicocca, [3]Nefrology Unit, A.O San Gerardo di Monza, Monza, [4]Nefrology Unit, S.Orsola-Malpighi, Bologna, [5]Department of Health Science, Medical Statistic Unit, University of Milan Bicocca, Monza, Italy

Background: The prevalence of atrial fibrillation (AF) in patients with end-stage renal disease (ESRD) on hemodialysis (HD) is high, estimated to be between thirteen and 27%. Oral anticoagulation therapy (OAT) is the recommended treatment for thromboembolism prevention in patients with AF. Traditional OAT with dicumarolic drugs such as warfarin is the most widespread choice, however its use is controversial in HD population in which the risk of bleeding is dramatically increased: HD patients taking OAT indeed, show major bleeding episode rates twice as high as HD patients without OAT treatment ongoing.
Aims: Safety of dicumarolic OAT was studied in a population of patients with AF managed in 10 Italian HD centers.
Methods: A Cox model was used to relate OAT to bleeding events, adjusted for possible confounders such as antiplatelet therapy, age, dialytic duration, comorbidities, percentage time in therapeutic INR range (TTR) according to the linear prediction method of Rosendaal(1) and INR variability (variance growth rate or VGR) according to Fihn method (2). VGR method takes both INR variability and the TTR into consideration, as it shows the degree of variation from the target INR over a period of time.
Results: All alive patients under observation in the centers at 31/10/2010, with paroxysmal, persistent or permanent documented AF, were recruited and followed up for two years. At recruitment, 134 patients over 290 were taking OAT. The overall median TTR was 54% (IQR: 42 to 67%). The median of INR variability (VGR) was equal to 0.34 (IQR: 0.16 to 0.87). Table 1 shows HAS-BLED score values according to hemorrhagic episodes. During follow-up 42 patients experienced hemorrhagic events for a total of 77 events, 3 of which were hemorrhagic strokes. After adjustment for possible confounders, OAT at recruitment resulted to be associated to an increased risk of bleeding episodes (HR 5.79, p=0.010). Having experienced hemorrhagic events before recruitment was related to a higher risk of a new bleeding episode (HR 2.39, p=0.015). In patients taking OAT the higher was the TTR, the lower was the risk of bleeding (HR 0.10, p=0.046), while higher VGR values were associated to a higher rate of bleeding during follow-up (HR=1.41, p=0.027).

Tablel 1.

Summary and Conclusions: In HD patients with AF, dicumarolic therapy greatly increases the incidence of bleeding, however hemorrhagic risk is reduced in subjects in whom INR is strictly kept within the therapeutic range and managed with low INR variability. Moreover patients with previous hemorrhagic episodes have a risk of bleeding more than doubled. Our data show that both TTR and VGR values are useful indicators of OAT management also in this setting of HD population. Large randomized controlled studied are needed in order to establish if HD patients, like people without severe renal impairment, could really benefit from OAT introduction.

Background: The combined analysis of the genome and transcriptome in cancer may illuminate the impact of recurrent molecular abnormalities on gene expression, thus affording a better understanding of the causes of the observed variability in the transcriptome, disease pathogenesis and outcome.
Aims: We aimed to determine the impact of the common mutations on the transcriptome in myelodysplastic syndromes (MDS).
Methods: We have recently performed a large mutation screen of 111 cancer genes (including *SF3B1, SRSF2, TET2, ASXL1* and many others) in 738 MDS patients. In this current study, we have linked this genomic data with gene expression microarray data on bone marrow CD34+ cells of 124 MDS patients and 17 controls. We used linear models to deconvolute the expression of genes into contributions stemming from genetic and cytogenetic abnormalities, providing deep insights into how driver mutations affect the transcriptome.
Results: To obtain an overview of the main patterns of gene expression changes, we performed a principal components analysis. The expression changes associated with the first component PC1 are dominated by genes related to hematopoietic differentiation; for example the stem cell factors *KIT*, *CD34* and also *FLT3* have positive values in PC1 while members of the α and β globin gene clusters have negative values. The second component PC2 has low levels of multiple chemokines and high levels of eosinophil- and neutrophil-related genes as well as the hematopoietic transcription factor *KLF1*. When overlaying the status of 12 recurrent genetic and 4 cytogenetic alterations, we found that PC1 can be largely attributed to the antagonistic occurrence of *SF3B1* and *SRSF2* mutations (having low and high values in PC1 respectively). These data suggest that the mutational status shapes the gene expression landscape. To investigate the association of gene expression and mutation data, we fitted a linear model to each gene using the 16 genetic and cytogenetic variables, gender and age as covariates. The MDS transcriptome was globally perturbed by genetic and cytogenetic driver alterations, with approximately 20% of genes showing differential expression due to any mutation. *SF3B1* mutations had the largest number of differentially expressed genes (n=605). Patterns of mutational co-occurrence were reflected by the overlap of associated expression changes: correlated mutations show greater overlap of their expression targets and mutually exclusive abnormalities tend to have different target sets. Distinct differentially expressed genes were associated with the most common splicing gene mutations (*SF3B1, SRSF2, U2AF1* and *ZRSR2*) in MDS, suggesting that different phenotypes associated with these mutations may be driven by different effects on gene expression and that the target genes are different. Most genes deregulated by *EZH2* and *ASXL1* mutations had higher expression compared to non-target genes. Data from the NIH roadmap epigenome consortium show an enrichment of repressive H3K27me3 signal for these genes in normal CD34+ cells. This provides additional evidence that *EZH2* and *ASXL1* mutations lead to derepression of certain Polycomb group target loci. We modelled the influence of mutations, cytogenetics, gene expression and blood/bone marrow counts on MDS patient survival. The transcriptome was the most powerful predictor of outcome, suggesting that the incorporation of gene expression data into existing MDS prognostic scoring systems should be considered.
Summary and Conclusions: This study provides important insights into the impact of the common gene mutations and cytogenetic alterations on the transcriptome in MDS.

S672

MULTIPLE CONCOMITANT MUTATIONS TARGETING RAS-PATHWAY IN JUVENILE MYELOMONOCYTIC LEUKEMIA (JMML) SUGGEST A DOSE-RELATED EFFECT OF RAS ONCOGENESIS

A Caye[1,2,*] M Strullu[1,2], B Cassinat[2,3], J Lachenaud[1,2], O Fenneteau[4], E Verger[2,3], M Tartaglia[5], R Ahmadian[6], F Méchinaud[7], JH Dalle[8], Y Bertrand[9], A Baruchel[8], C Chomienne[2,3], H Cavé[1,2]
[1]Molecular Genetics, Hôpital Robert Debré, Assistance-Publique Hôpitaux de Paris, [2]U1131, Inserm, [3]cellular biology, Hôpital Saint-Louis, Assistance Publique Hôpitaux de Paris, [4]Biologic Hematology, Hôpital Robert Debré, Assistance-Publique Hôpitaux de Paris, Paris, France, [5]Dipartimento di Ematologia, Oncologia e Medicina Molecolare, Istituto Superiore di Sanità, Rome, Italy, [6]Institut für Biochemie und Molekularbiologie II, Medizinische Fakultat der Heinrich-Heine-Universität, Dusseldorf, Germany, [7]Paediatric hematology, CHU de Nantes, Nantes, [8]Paediatric Hematology, Hôpital Robert Debré, Assistance-Publique Hôpitaux de Paris, Paris, [9]Paediatric Hematology, Hopital de Lyon, Lyon, France

Background: JMML is a rare myeloproliferative/myelodysplastic syndrome of early childhood. It is initiated by mutations, classically described as mutually exclusive, in RAS (NRAS, KRAS) or regulators of the RAS pathway (PTPN11, NF1 or CBL) leading to the hyperactivation of the RAS signaling pathway. In most cases, JMML is a severe disease and the only curative treatment is bone marrow transplantation. Nevertheless, clinical presentation and evolution of JMML are highly heterogeneous since transformation to AML occur in one third of patients while some patients exhibit an indolent disease or even experiment spontaneous remission. This heterogeneity is only partially related to the initiating mutation and could be explained by the presence of additional mutations.
Aims: Additional genetic events were analyzed in the whole french cohort of JMML in order to evaluate their frequency, their repartition in the different JMML genetic subtypes and their potential impact on JMML evolution.
Methods: Paired tumoral and germline DNA from the 120 patients of the JMML french cohort was analyzed by SNP array (N=70) and/or whole exome sequencing (N=10) and/or high-throughput targeted sequencing (N=87). The order of appearance of these mutations was investigated by sequencing isolated colonies obtained by culturing myeloid progenitors on methylcellulose.
Results: The screening for additional mutations in 120 JMML, of which the initiating mutation had been previously identified, could uncover additional molecular abnormalities (mutations, deletions or acquired uniparental disomy) in 26 JMML cases (21%). When including karyotype abnormalities, 48/120 (40%) JMML presented at least 1 additional clonal abnormality. Unexpectedly, in 13 JMML, at least one of these additional events consisted in a second RAS-pathway activating event. Various combinations, involving up to 3 such mutations, were observed. Clonal analysis demonstrated the coexistence of these mutations in myeloid progenitors. The most frequent association was a secondary somatic inactivation of NF1 in 6/33 (18%) of JMML with PTPN11 mutation. Interestingly, 11/19 (58%) JMML with NRAS initiating mutation had at least 1 clonal additional abnormality. The additionalmutation directly impacted the RAS pathway in 3 cases, including a mutation of RRAS in two. These 3 later patients developed a particularly aggressive disease with blast excess at diagnosis and rapid transformation to AML with myelodysplasia. On the other hand, none of the NRAS patients who survived without bone marrow transplantation ("long survivors") had additional genetic events. Moreover, NRAS mutated patients who displayed no additional mutation had none of the following markers of severity: death, post-transplantation relapse, medullar blast excess (>10%) at diagnosis or blast crisis. On the contrary, all patients with one or more additional abnormality had at least one of these severity criteria.
Summary and Conclusions: The finding in sporadic JMML of multiple concomitant genetic events targeting the RAS-pathway challenges the dogma that these mutations are mutually exclusive and seems to mark very aggressive and rapidly progressing JMML. These observations suggest a dose effect of RAS-pathway activation, especially in a NRAS-mutated context. They also provide a clinical confirmation for RAS-mutated conditional expression studies in mice which first demonstrated the dose-related effect of RAS oncogenesis. The use of RAS inhibitors could be of particular therapeutic interest in this sub-group of very aggressive JMML.

S673

SF3B1 PLAYS AN IMPORTANT ROLE IN THE REGULATION OF HEMATOPOIETIC STEMS CELLS, BUT HAPLOINSUFFICIENCY OF SF3B1 MAY NOT BE SOLELY RESPONSIBLE FOR MYELODYSPLASIA

M Matsunawa[1,*] R Yamamoto[2], M Sanada[1], A Kon[1], A Sato-Otsubo[1], Y Shiozawa[1], K Yoshida[1], Y Nagata[1], T Yoshizato[1], M Otsu[2], K Isono[3], H Koseki[3], H Nakauchi[2], S Ogawa[1]
[1]Departments of Pathology and Tumor Biology, Graduate School of Medicine, Kyoto University, Kyoto, [2]Division of Stem Cell Therapy, Center for Stem Cell Biology and Medicine, Institute of Medical Science, University of Tokyo, Tokyo, [3]Laboratory for Developmental Genetics, RIKEN Research Center for Integrative Medical Sciences, Yokohama, Japan

Background: SF3B1 is a core component of the mRNA splicing machinery and is frequently mutated in MDS, particularly characterized by the presence of increased ring sideroblasts (RS). Most of *SF3B1* mutations reported in MDS are clustered in 5 hot-spot amino-acid positions. However, the molecular mechanism by which the *SF3B1* mutation leads to myelodysplasia and promotes the formation of RS is unknown. Previously we reported hematological phenotype of *Sf3b1*$^{+/-}$ mice aged 3 months. In this study, we additionally performed more detail analysis with *Sf3b1*$^{+/-}$ mice older than 6 months of age.
Aims: To clarify the role of *SF3B1* in hematopoiesis and to obtain insights into how the deregulation of *SF3B1* leads to the development of MDS phenotypes,

we investigated the hematological phenotype of *Sf3b1*$^{+/-}$ mice.
Methods: Analysis of peripheral blood (PB) count and RS were performed 3–13-month-old mice. Examinations of hematopoietic stem cells (HSCs)/progenitor cells, and splenic B cells were performed in 3- and 8-month-old mice. *In vitro* colony assays and competitive transplantation assays were conducted using 3-months-old mice.
Results: There was no significant change in complete PB counts between *Sf3b1*$^{+/+}$ and *Sf3b1*$^{+/-}$ mice at any time points up to 13 months. Total bone marrow (BM) cellularity, lineage composition and spleen weights of *Sf3b1*$^{+/-}$ mice were examined at 3 months and 8 months, and no obvious differences were detected between *Sf3b1*$^{+/+}$ and *Sf3b1*$^{+/-}$ mice. Morphologic abnormalities in PB and BM cells were not recognized. In contrast to a previous report describing increased formation of RS in the same *Sf3b1*$^{+/-}$ mouse strain, we observed very few sideroblasts and no RS formation until 13 months of age. To further assess the hematopoietic system in the BM, we evaluated HSCs and progenitor cells by flow cytometric analyses. The frequency and the absolute number of HSCs, defined as CD34^{-}KSL cells, were significantly decreased in *Sf3b1*$^{+/-}$ mice aged 3 months. Whereas, there were no significant differences in the number of progenitor cells including HPC fraction (CD34^{+}KSL cells), MEPs, CMPs, and GMPs between *Sf3b1*$^{+/+}$ and *Sf3b1*$^{+/-}$ mice. *SF3B1* mutations were also seen in a subset of CLL cases, but no obvious changes in a CLPs population as well as in splenic B cell populations were observed in *Sf3b1*$^{+/-}$ mice. Similar results were obtained from 8-month-old mice. Consistent with the reduction in the HSC fraction, *in vitro* colony assays indicated the significantly lower number of hematopoietic colonies in *Sf3b1*$^{+/-}$ mice BM cells than that in *Sf3b1*$^{+/+}$ mice. Subsequently, we assessed the reconstitution capacity of whole BM cells, using competitive repopulation assays. The chimerism of *Sf3b1*$^{+/-}$-derived cells was significantly lower than that of *Sf3b1*$^{+/+}$-derived cells. To confirm this finding further, we performed competitive repopulation assays using purified HSCs (CD34^{-}KSL cells). Similarly, the chimerism of donor-derived cells was also reduced in mice transplanted with *Sf3b1*$^{+/-}$ mice-derived HSCs. These findings were confirmed by competitive repopulation assays using enriched long-term HSCs (CD150^{+}CD34^{-}KSL cells). Furthermore, we performed serial transplantation experiments of whole BM and HSCs to assess the long-term reconstitution capacity of *Sf3b1*$^{+/-}$ HSCs more precisely. *Sf3b1*$^{+/-}$ mice showed reduced chimerism of donor-derived cells in the primary transplantations, and the reduced chimerism was even more pronounced after secondary transplantations.
Summary and Conclusions: HSCs from *Sf3b1*$^{+/-}$ mice showed a reduction in their number and compromised repopulation capacity of hematopoiesis. *Sf3b1*$^{+/-}$ mice aged older than 6 months exhibited similar hematological phenotype to 3-month-old *Sf3b1*$^{+/-}$ mice. There was no increase in RS or evidence of myeloid dysplasia in *Sf3b1*$^{+/-}$ mice, at least until 13 months of age. These results that indicate haploinsufficiency of *Sf3b1* leads to compromised stem cell function but not to myelodysplasia, were compatible with the fact that most of *SF3B1* mutations in MDS are suggested to be a gain-of-function.

Background: Myelodysplastic syndromes (MDS) are a heterogeneous group of chronic myeloid neoplasms characterized by varying degrees of cytopenias and a high propensity to acute myeloid leukemia. Diagnosis and prognostication of MDS may be improved by High-throughput mutation/copy number profiling, which also provide a new insight into their pathogenesis.
Aims: The purpose of this study is to investigate the role of gene mutations in the pathogenesis/clonal evolution of MDS and their impact on prognostication in MDS.
Methods: A total of 944 patients with various MDS subtypes were screened for gene mutations and deletions in 104 known/putative genes relevant to MDS using targeted deep-sequencing and/or array-based genomic hybridization. Somatic mutations were identified through in-house pipeline, correlations of different gene mutations and their clonal architecture were investigated. Impact of genetic lesions on overall survival (OS) was investigated by univariate analysis and a conventional Cox regression to build a new prognostic model based on gene mutations.
Results: After excluding sequencing/mapping errors and known or possible polymorphisms, a total of 2,764 single nucleotide variants and insertions/deletions were detected in 96 genes as high-probability somatic changes. A total of 47 genes were considered as statistically significantly mutated (q<0.01), of which only 6 genes (*TET2*, *SF3B1*, *ASXL1*, *SRSF2*, *DNMT3A*, and *RUNX1)* were mutated in >10% of the cases. Significant correlations were observed for different gene mutations, particular combinations of gene mutations occurred more frequently than expected, suggesting the presence of functional interactions between these mutations. Intratumor heterogeneity was evident in as many as 456 cases (48.3%), even though the small number of gene mutations available for evaluation was thought substantially to underestimate the real frequency. The number of observed intratumoral subpopulations tended to correlate with the number of detected mutations and therefore, advanced WHO subtypes and risk groups with poorer prognosis. Mean variant allele frequencies (VAFs) showed significant variations among major gene targets and VAF values were significantly biased for some combinations of genes, suggesting the presence of chronogenic hierarchy among these common mutations during clonal evolution in MDS. The impact of these genetic lesions on clinical outcomes was initially investigated in 875 patients. In univariate analysis, 25 out of 48 genes tested significantly affected overall survival (P <0.05), and only *SF3B1* mutations were associated with a better clinical outcome. Importantly, the impact on survival was observed even for subclonal mutations. Finally, to evaluate the combined effect of these multiple gene mutations/deletions, together with common clinical/cytogenetic variables used for IPSS-R, OS was modeled by a Cox regression. We found that when combined with traditional prognostic valuables, such as age, white cell counts, hemoglobin, platelet counts, cytogenetic score in IPSS-R, the mutation/deletion status of a set of genes could be used to build a prognostic system more accurately predict the survival of patients.
Summary and Conclusions: Large-scale genetic and molecular profiling using deep sequencing not only provided novel insights into the pathogenesis and clonal evolution of MDS, but also enabled to build a more robust prognostic model based on both gene mutations and other clinical variables that could potentially outperform the conventional prognostic systems.

Background: Juvenile myelomonocytic leukemia (JMML) is an aggressive clonal myeloid neoplasm of early childhood associated with mutations in Ras pathway genes (*PTPN11*, *KRAS*, *NRAS*, *CBL* and *NF1*). Elevated fetal hemoglobin (HbF) levels and monosomy 7 are frequently observed. Stem cell transplantation is the only available curative treatment option but only provides an event-free survival of about 50%.
Aims: Gain insight in the molecular networks involved in JMML pathogenesis based on mRNA, microRNA and long non-coding RNA transcriptome analysis of JMML samples.
Methods: Expression of 27958 mRNA probes and 23042 lncRNA probes was assessed in diagnostic bone marrow or peripheral blood mononuclear cells of 63 JMML patients and 5 healthy donors, using a custom designed Agilent array. In addition, cDNA of 768 microRNAs was pre-amplified and quantified using miRNA specific Taqman probes.
Results: Unsupervised clustering of an initial cohort of 14 patients generated two subgroups with *let-7e* and RNA-binding protein *LIN28B* amongst the most significantly differentially expressed genes. In the final cohort, relative higher *LIN28B* expression was observed in 35 of 63 cases (55.6%) and was defined as the average of the healthy donors plus three standard deviations. Univariable Cox regression showed that logarithmic *LIN28B* expression as a dichotomous variable can predict overall survival (p=0.035, exp(B)=4.227, CI(95%)=1.108-16.125). Patients with higher *LIN28B* mRNA levels experience a significant worse overall survival (Kaplan-Meier plot, p=0.022). HbF and platelet count were also significant prognostic factors, as described previously (p=0.023 and 0.027 respectively). There was no association between *LIN28B* expression and Ras pathway mutation status. We observed the strongest miRNA anti-correlation between *LIN28B* and five *let-7* family members (d, b, g, e and a), and the second highest positive mRNA correlation between *LIN28B* and

HMGA2. Recently, it was shown that the *LIN28B – let-7 – HMGA2* axis determines higher self-renewal of fetal hematopoietic stem cells (Copley, 2013). This indicates that *LIN28B* confers augmented self-renewal to leukemic hematopoietic stem cells in JMML and – since this is an early childhood disease – this is potentially already initiated during embryogenesis.
JMML patients frequently show elevated HbF levels at diagnosis. A positive correlation was found between *LIN28B* expression and HbF levels (r_s=0.64, p<0.001, N=41). Interestingly, our gene expression profiling data showed that both probes corresponding to *HBG1* (encoding the human γ globin chain) and *HBBP1* (encoding a lncRNA-affiliated hemoglobin β pseudogene) were strongly correlated with *LIN28B* expression in our patient series. This emphasizes the central role for *LIN28B* in the fetal (leukemic) hematopoietic stem cell system. Strikingly, patients with monosomy 7 (n=7/56) never displayed increased *LIN28B* expression (Chi-square p=0.0017), suggesting the presence of a *LIN28B* activating transcription factor on chromosome 7. We identified *MNX1* (*HLXB9*) as a possible activator of *LIN28B* based on a very strong correlation and siRNA knockdown (Figure 1).

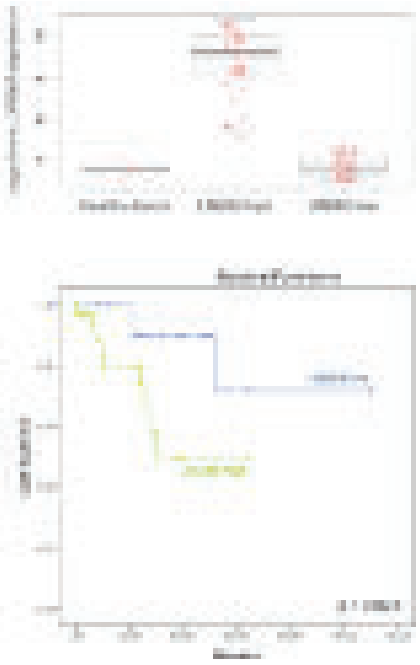

Figure 1.

Summary and Conclusions: *LIN28B* is overexpressed in more than half of JMML patients and significantly predicts poor outcome. Strong correlation with HbF levels, *HBG1* and *HMGA2* gene expression suggests that *LIN28B* regulates a leukemic hematopoietic stem cell network. Moreover, patients with monosomy 7 seem to be protected against *LIN28B* overexpression due to the absence of the putative activator *MNX1*. All together, *LIN28B* has a link with most characteristics of the disease and plays a central role in regulatory networks in JMML.

Chronic myeloid leukemia - Clinical 1

S676

EFFICACY AND SAFETY OF IMATINIB IN CML OVER A PERIOD OF 10 YEARS: DATA FROM THE RANDOMIZED CML-STUDY IV

Background: Tyrosine kinase inhibitors (TKI) have changed the natural course of CML. With the advent of 2nd generation TKI and the now available choice of drugs, safety issues have gained interest.
Aims: We have used 1551 patients of the randomized CML-Study IV for a long-term safety and efficacy evaluation of imatinib (IM) and to comparatively analyze adverse drug reactions (ADR) for IM 400 mg, IM 800 mg and IM 400 mg+interferon (IFN).
Methods: ADR were reported at each follow-up visit, coded and graded according to the WHO CTC AE list. Molecular analyses for residual BCR-ABL transcripts were adjusted by the international scale. Efficacy was evaluated by intention to treat. ADR were analyzed as treated. For the general safety analyses, patients were only counted as long as they solely received imatinib. For the treatment comparisons, patients were kept within their randomized groups but only counted as long as they received the randomized treatment. Because of practicality, it was not possible to consider different imatinib doses.
Results: 1501 patients have received imatinib alone or in combination and were evaluable. Median age at diagnosis was 53 years, 88% were EUTOS low risk. At the last evaluation (11.4.2013), 1003 patients still received imatinib, 164 had died, 275 had been switched to a 2nd generation TKI, 106 had been transplanted (numbers in part overlapping). The longest observation time was 11.5 years, the median observation time 6.5 years. Efficacy: 10-year progression-free and overall survival probabilities were 81% and 84%, respectively. 10-year cumulative response rates reached 89% for MMR, 81% for MR^4, 74% for MR$^{4.5}$, and 63% for MR^5. Safety: 1375 patients received imatinib alone, at least for a certain time. In 1018 (74%), non-hematologic ADR were reported during imatinib treatment, in 199 grade 3/4 ADR (14%). 8-year probabilities, all grades, with 95% confidence intervals (CI) were: fluid overload or edema 41 (36-46)%, gastrointestinal 38 (34-43)%, myalgia or arthralgia 25 (21-29)%, rash 20 (17-24)%, muscoloskeletal 17 (13-22)%, fatigue 17 (13-20)%, neurological 11 (8-13)%, and flu-like 10 (8-13)%. By treatment, 8-year probabilities of any non-hematologic ADR, all grades, with 95% CI were 72 (65-78)% for IM 400mg, ≥83 (77-87)% for IM 800mg (last value at around 7 years) and 87 (76-94)% for IM 400mg+IFN and for grade 3/4 ADR, 16 (12-21)% for IM 400mg, ≥34 (24-44)% for IM 800mg and 35 (24-47)% for IM 400mg+IFN. These numbers represent minimum values, since some results were not evaluable and ADR might have been present. Probabilities over time were calculated for each ADR. In 5 patients, peripheral arterial occlusive disease of grade 2 or 3 was reported, but none could be clearly assigned to imatinib. A definite association between any ADR and death was not found. Most patients had their first ADR during their first three years of treatment with decreasing frequencies later on. ADR could be well managed by dose reduction, interruption, symptomatic medication or permanent discontinuation.
Summary and Conclusions: Given that no imatinib-related death was recorded and that grade 3/4 ADR could typically be symptomatically managed we consider imatinib a safe, comparably well tolerated TKI even after prolonged treatment, also at 800 mg and in combination with IFN. After 10 years, imatinib continues to be an excellent choice for most patients with CML.

S677

ENESTND 5-YEAR FOLLOW-UP: CONTINUED BENEFIT OF FRONTLINE NILOTINIB (NIL) COMPARED WITH IMATINIB (IM) IN PATIENTS (PTS) WITH CHRONIC MYELOID LEUKEMIA IN CHRONIC PHASE (CML-CP)

TP Hughes[1,*] PD le Coutre[2], S Jootar[3], J Reiffers[4], AG Turkina[5], G Saglio[6], A Hochhaus[7], HM Kantarjian[8], C Kemp[9], W Deng[9], HD Menssen[10], RA Larson[11]

D. Anderson Cancer Center, Houston, [9]Novartis Pharmaceuticals Corporation, East Hanover, United States, [10]Novartis Pharma AG, Basel, Switzerland, [11]University of Chicago, Chicago, United States

Background: The ongoing Evaluating Nilotinib Efficacy and Safety in Clinical Trials–Newly Diagnosed Pts (ENESTnd) study has continually demonstrated superior efficacy of frontline NIL over IM, with higher rates of major molecular response (MMR; BCR-ABL^{IS} ≤0.1%) and MR$^{4.5}$, (BCR-ABL^{IS} ≤0.0032%), more likely achievement of early molecular milestones (BCR-ABL^{IS} ≤10% at 3 months), lower rates of progression to accelerated phase (AP)/blast crisis (BC) and fewer new BCR-ABL mutations on treatment, in pts with newly diagnosed CML-CP.
Aims: This analysis aims to demonstrate long-term efficacy and safety of NIL compared with IM in ENESTnd, with a minimum follow-up of 5 calendar y (≈ 4.5 months longer than any follow-up previously presented).
Methods: In this phase 3, open-label, multicenter study, 846 adult pts with newly diagnosed CML-CP were stratified according to Sokal risk score and randomized to receive NIL 300 mg twice daily (BID; n=282), NIL 400 mg BID (n=281), or IM 400 mg once daily (n=283). Efficacy analyses were based on all randomized pts. Molecular response assessments were collected during study treatment. Data on progression to AP/BC and overall survival (OS) were prospectively collected during study follow-up and after treatment discontinuation.
Results: After a minimum follow-up of 5 calendar y, over 80% of pts remained on study in all arms (Table 1). Rates of MMR and MR$^{4.5}$, continued to be significantly higher in the NIL arms *vs* the IM arm, with more than half of NIL-treated pts achieving MR$^{4.5}$, by 5 y. For pts achieving MR$^{4.5}$, Kaplan-Meier estimates of remaining in MR$^{4.5}$, for 24 mo were similar across treatment arms (72.0%, 77.8%, 75.5% for NIL 300 mg BID, NIL 400 mg BID, and IM, respectively). No pts had treatment-emergent BCR-ABL mutations since the 4-y analysis or progressed to AP/BC on core treatment since the 2-y analysis. When including progression events occurring after core treatment discontinuation, estimated rates of freedom from progression to AP/BC on study remained higher in NIL-treated pts (Table 1). Overall, fewer deaths occurred on study in the NIL arms *vs* the IM arm. When considering only deaths in advanced CML (ie, the principle cause of death was either "study indication" or "unknown" or not reported but occurred subsequent to a documented progression to AP/BC), estimated rates of survival were higher in the NIL arms *vs* the IM arm. Reasons for death in pts without advanced CML were similar between arms. Safety data after 5 y of follow-up was similar to the known safety profiles of the drugs. The frequency of adverse events (AEs) leading to discontinuation was lowest in the NIL 300 mg BID arm (12.2%), followed by the IM arm (13.9%) and the NIL 400 mg BID arm (19.9%). Newly occurring or worsening total cholesterol abnormalities (all grades) were seen in 27.6%, 26.7% and 3.9% of pts in the NIL 300 mg BID, NIL 400 mg BID, and IM arms, respectively. Cardiovascular events are shown in the Table; rates of these AEs were higher in the NIL 400 mg BID arm than in the NIL 300 mg BID arm.

Table 1.

Summary and Conclusions: The 5-y data confirm the sustained efficacy of frontline NIL over IM in pts with newly diagnosed CML-CP, including achievement of earlier and deeper molecular responses and increased freedom from progression to AP/BC. When considering both safety and efficacy, NIL 300 mg BID continues to be a standard-of-care frontline therapy option in pts with newly diagnosed CML-CP.

S678

DASATINIB DAILY DOSE OPTIMIZATION BASED ON RESIDUAL DRUG LEVELS RESULTED IN REDUCED RISK OF PLEURAL EFFUSIONS AND HIGH MOLECULAR RESPONSE RATES: FINAL RESULTS OF THE RANDOMIZED OPTIM DASATINIB TRIAL.

Background: Dasatinib first line (Sprycel®, Bristol-Myers Squibb) induces higher levels of cytogenetic and molecular responses as compared to imatinib in chronic phase chronic myelogenous leukemia (CP-CML) patients (pts). However, dasatinib is associated with the occurrence of pleural effusions (PE). Cumulative incidence of all grades PE (CI-PE) in the Dasision trial (median age 47y) was reported to be 19% by 36 months with an overall discontinuation rate of 29%. (Jabbour *et al.,* Blood 2014).
Aims: The aim of the Optim dasatinib trial was to validate a dose optimization strategy driven by dasatinib residual plasmatic level (Cmin) in terms of CI-PE and molecular response. (EudraCT 2008-006854-17).
Methods: 289 newly diagnosed CP-CML pts from french and canadian CML centers were assigned to dasatinib 100 mg/d. Dasatinib Cmin levels were assessed 24+/-2h after intake by tandem mass spectrometry at day 15. Pts with high Cmin values (Cmin ≥3 nM) (n=82) were randomized between a dose adaptation arm (A1, 20 mg decrement every 15 days in order to obtain a Cmin value <3nM, minimal dose level 40 mg/d) or no dose modification (A2). Patients with Cmin values <3nM were followed in arm B (n=207). All patients were treated according to the ELN 2009 recommendations. The CI-PE observed in each arm was compared. Intent to treat analysis was used to determine molecular outcomes in each treatment arm.
Results: Patients were recruited between May 2009 and December 2012. Database was locked in January 2014. Median follow-up was 32 months (14-57). Sokal scores were high for 21%, intermediate for 34% and low for 45% of pts. The median age was 53 years (18-86). Median dasatinib Cmin value was 2.1nM (0.1-18.7) with higher Cmin values in pts aged over 50y as compared to younger pts (2.5 *versus* 1.6, p<0.001). Accordingly, median age was higher in arms A1 and A2 as compared to arm B (54 *vs* 42, p=0.0032). After dose optimization in arm A1, median Cmin value was reduced from 5.1nM at randomization to 2.1nM at 12 months. Corresponding median Cmin values were 4.6nM and 4nM in arm A2 and 1.6nM and 1.9nM in arm B respectively. Dose intensity in arm A1 was 57 mg/d and mean daily dose after optimization was 51 mg. Higher dose intensity was observed in arm A2 (96 mg/d) resulting in high discontinuation rate (27%) as compared to arm A1 (13%). The overall CI-PE by 36 months was 16.2% (95%CI: 7.3-28.3). CI-PE was 10.7% (95%CI: 2-27.9) in pts with low Cmin values (arm B), as compared to 29.6% (95%CI: 13.8-47.3) in pts with high Cmin values (arms A1 and A2) (p=0.0002). A dramatic reduction in CI-PE was observed in pts randomized to the optimization strategy (arm A1, 11.3%; 95%CI 0.4-44.2) as compared to pts allocated to a standard follow-up (arm A2, 48.9%; 95%CI 26.4-68.1) (p=0.008). Age and Cmin were independent determinants of PE but the effect of age was overcome by dose optimization. Remarkably high cumulative molecular response rates by 24 months were observed in arms A1, A2 and B for MMR (88%, 82% and 83%), MR4 (69%, 67% and 67%) and CMR4.5 (39%, 32% and 34%), despite a significant dose reduction in arm A1. Of note, emerging adverse events were recorded in this trial such as pulmonary hypertension (2 cases, 0.6%), Raynaud syndrome (2 cases, 0.6%) and follicular hyperplasia (7 cases, 2.4%).
Summary and Conclusions: Dasatinib dose optimization is an efficient strategy to overcome the risk of pleural effusion in high risk patients (defined by a Cmin value ≥3nM) and to reduce the discontinuation rate. The proportion of

patients eligible to dasatinib dose optimization is increasing with age (up to 43% over 60y) reflecting the CP-CML population. Our results suggest that personalized dasatinib dose schedule in this high risk population may be close to 50 mg/d and remains associated with high levels of deep molecular responses.

Background: Ponatinib is a potent oral tyrosine kinase inhibitor active against native and mutated forms of BCR-ABL, including T315I. The phase 2 PACE study demonstrated that ponatinib is highly active in heavily pretreated Philadelphia chromosome–positive (Ph+) leukemia pts.
Aims: The efficacy and safety of ponatinib were evaluated in newly diagnosed CP-CML pts in the EPIC (Evaluation of Ponatinib *vs* Imatinib in CML) trial.
Methods: EPIC was an international, phase 3 trial of ponatinib (45 mg QD) *vs* imatinib (400 mg QD) in newly diagnosed CP-CML pts, with randomization stratified by Sokal risk score. The primary endpoint was major molecular response (MMR) rate at 1 yr. On 18 Oct 2013, EPIC was terminated due to accumulating vascular events in long-term follow-up of the PACE trial. Data as of 7 Oct 2013 are presented; median (range) follow-up was 3 (0.03-12) months. NCT01650805.
Results: At the time of analysis, 306 pts were randomized and gave informed consent. Baseline characteristics were balanced for ponatinib *vs* imatinib: 55 *vs* 52 yrs median age, 17% *vs* 16% high Sokal risk score, 62% *vs* 66% received prior hydroxyurea. Data were available on 267 treated pts (133 ponatinib, 134 imatinib). At analysis, 77% ponatinib and 84% imatinib pts were ongoing; 14 ponatinib and 6 imatinib pts discontinued (discontinuation due to adverse events [AEs]: 9 ponatinib pts [most common: thrombocytopenia and rash]; 1 imatinib pt). Response rates are shown in the Table 1 (evaluable pts defined as pts assessed at 3, 6, 9 months). Most common (≥25%) all-grade treatment-emergent AEs in the ponatinib arm were rash (36%), abdominal pain (32%), headache (31%), lipase increased (26%), and myalgia (26%); in the imatinib arm, nausea (32%) and muscle spasms (31%). 11% ponatinib and 2% imatinib pts had grade 3/4 thrombocytopenia; 3% ponatinib and 8% imatinib pts had grade 3/4 neutropenia. Serious treatment-emergent AEs (SAEs) occurring in ≥3 ponatinib pts were pancreatitis (5 pts), atrial fibrillation (3), and thrombocytopenia (3); no individual SAEs occurred in ≥3 imatinib pts. 9 (7%) ponatinib and 5 (4%) imatinib pts experienced vascular occlusive events (SAEs: 6 ponatinib, 1 imatinib). Updated data will be presented.
Summary and Conclusions: While ponatinib demonstrated early activity in frontline CP-CML, EPIC was terminated because its objectives could not be met, since ponatinib dose reductions were implemented mid-trial due to safety observations in PACE. Further investigation of ponatinib safety is warranted. Ponatinib remains an important treatment option for pretreated CML and Ph+ acute lymphoblastic leukemia pts for whom the need and benefit outweigh the potential risks.

Table 1.

	At 3 months		At 6 months		At 9 months	
	Ponatinib	Imatinib	Ponatinib	Imatinib	Ponatinib	Imatinib
MMR	29% (28/95)	0% (0/98)	66% (27/41)	21% (9/42)	83% (10/12)	44% (7/16)
MR4.5	4% (4/95)	0% (0/98)	10% (4/41)	0% (0/42)	25% (3/12)	0% (0/16)

Background: Most of the knowledge about treatments and outcome of CML patients originates from clinical studies. To get new and unbiased insights in the epidemiology, treatment and outcome of CML, the EUTOS population-based registry of newly diagnosed CML patients was established, - as part of the European Treatment and Outcome Study (EUTOS) for CML.
Aims: The aim was to collect the data of all adults with newly diagnosed CML, irrespective of treatment and of enrolment in studies.
Methods: The EUTOS population-based registry collected data of newly diagnosed CML patients, 18 years or older, over a specified period of time from 2008 till 2012 living in defined regions. The data were collected by 22 study groups in 20 European countries. Data were gathered via a web-based CRF-system.
Results: Till 31.12.2013 2983 patients were registered. Treatment data are currently available for 1948 patients. 94.2% of the patients were diagnosed in chronic phase (CP), 3.6% in accelerated phase (AP), and 2.2% in blastic phase (BP). 54% of the patients were male. The median age at diagnosis was 57 (range: 18-99) years, varying from 50 yrs. in Russia to 62 in Sweden. Stratified by decades, 0.6% patients were 18 or 19 years old, 6.8% 20-29 years, 11.6% 30-39 years, 16.8% 40-49 years, 22.1% 50-59 years, 19.2% 60-69 years, 16.0% 70-79 years, 6.4% 80-89 years, and 0.5% more than 90 years old. According to the WHO PS score, in CP 57.4% of patients were asymptomatic, 36.6% were symptomatic but completely ambulatory, 4.2% were symptomatic but less than 50% in bed during the day, 1.2% were symptomatic with more than 50% in bed during the day, and 0.6% were bedbound. For patients in AP or BP at onset, the corresponding Figures were 31.9%, 41.3%, 18.1%, 7.2%, and 1.4%. For 55.4% of the patients comorbidities were recorded. 18.4% of patients were current smokers, while 16.6% were former smokers, and 65.0% were non-smokers. For the calculation of the prognostic scores 432 patients had to be excluded as they had already been treated before measuring the hematologic values. By EUTOS Score (Hasford *et al.*, 2011) 88.7% of CP patients were low risk, and 11.3% were high risk. By Euro Score 37.8% were low, 51.4% intermediate and 10.9% high. By Sokal Score 34.5% were low, 40.8% intermediate, and 24.8% high. CP patient distribution by spleen volume, blood cell count, and differential are shown in Table 1. 83.3% of the patients received imatinib firstline, 10.9% nilotinib and 3.8% dasatinib. During the first year after diagnosis, 9.4% of patients received nilotinib and 6.0% dasatinib second-line.

Table 1.

Summary and Conclusions: This is the first report of the demographic and baseline characteristics of an unselected, population-based, series of patients with newly diagnosed Ph+, BCR-ABL+ CML. The age distribution and some baseline characteristics are different from many prospective studies. This should be taken in due consideration before extrapolating the results of treatment studies to the overall population. With further follow-up, this registry will provide a population-based insight on treatment, survival, and causes of death.

Acute lymphoblastic leukemia - Biology 1

S681

THE INCIDENCE OF THE HIGH-RISK PH-LIKE ALL SUBTYPE MAY ACCOUNT FOR THE MAJORITY OF NON BCR-ABL1+ B ALL CASES IN ADULTS

E Nievergall[1,2,3], S Heatley[1,2,3], C Kok[1,2], P Dang[1], A Frede[1], S Moore[4], K Roberts[5], D Yeung[6], T Hughes[1,6], C Mullighan[1,7], D White[1,2,8,*]

Background: Adult patients with Acute Lymphoblastic Leukaemia (ALL) have a universally poor outcome, particularly those with *BCR-ABL1+* ALL, though the addition of tyrosine kinase inhibitor (TKI) therapy to the upfront regimen has improved outcomes. In contrast, contemporary therapy for childhood ALL results in 80% event free, and 90% overall 5 year survival. Despite this, relapsed ALL remains the major cause of non-traumatic death in children. Recent genomic profiling of childhood ALL has identified a novel subtype of B-ALL with a gene expression profile similar to *BCR-ABL1+* ALL, but harbouring novel kinase activating rearrangements (Ph-like ALL). Importantly, *in vitro* studies and anecdotal cases suggest that Ph-like ALL, a high-risk subtype, may respond to current TKIs. The frequency of Ph-like ALL rises with increasing age[1], but the frequency and spectrum of lesions in adults is unknown.
Aims: To identify the frequency of Ph-like disease in AYA and adults, and determine *in vitro* sensitivity to kinase inhibitors.
Methods: Ph-like ALL cases were identified by Taqman Low Density Arrays (TLDA) using 20 genes selected from prior paediatric reports. Bioinformatic modelling was used to derive a 9-gene signature. Phospho-flow cytometry (p-Flow) was used to detect pathway activation, resulting in phosphorylation of known kinase targets (ie: CrkI and STAT5) and to assess responsiveness to kinase inhibitors. CRLF2 surface expression was detected by flow cytometry. Candidate RT-PCR for previously identified fusions, sequencing and FISH were used for identification.
Results: Sixty-one AYA/adult *BCR-ABL1* neg ALL diagnosis samples were analysed using TLDA; 27 were AYA (16-39y) and 34 adults (40+y). 15/61 (25%) patients; 3 AYA (11%) and 12 adult (35%) demonstrated a Ph-like signature by TLDA. In 2/3 AYA cases this was accompanied by expression of pSTAT5 and CRLF2. *In vitro* treatment with JAK inhibitors resulted in attenuation of p-STAT5, and candidate PCR identified CRLF2 fusion partners {IGH and P2RY8}. Sequencing revealed a JAK mutation in the IGH-CRLF2 case. In the remaining Ph-like AYA case expression of p-CrkI was attenuated by TKIs and candidate PCR revealed an EBF1-PDGFRB fusion, confirmed by sequencing. In the adult cohort 15/34 patients demonstrated indicative Ph-like positivity by TLDA alone (n=5); by p-Flow (and CRLF2 expression), but not TLDA (n=3); or by both (n=7). Of this latter cohort 5/7 have confirmed fusions, and identification of fusions in the remaining patients are in progress. In all cases CRLF2 cell surface expression by flow correlated with increased mRNA expression and the presence of a *CRLF2* rearrangement. In 4/6 patients with CRLF2 rearrangement non-synonymous (n=2) and synonymous JAK2 mutations (n=2: T875N and R683S) were detected. The presence of JAK alterations has been associated with sensitivity to JAK inhibition detected by reduction in p-STAT5. Where the genetic alteration has been identified the concordance between TLDA and p-Flow was 100% in the AYA cohort and 80% in the adult (Table 1).

Table 1. Summary of the screening of 61 AYA and adult ALL patients for Ph-like disease.

Summary and Conclusions: These preliminary data demonstrate a significantly increased frequency of Ph-like cases in patients aged over 40. This rise is concurrent with the rise in *BCR-ABL1+* ALL, and may suggest in adults, these

two groups constitute the majority of the B cell ALL cohort. Both TLDA and p-Flow analysis enable rapid detection of these cases, and candidate drug sensitivity can be determined using p-Flow. Importantly, this may guide intervention with targeted therapies matched to the identified causative genetic lesion in this high-risk cohort.

BCR-ABL1-LIKE ACUTE LYMPHOBLASTIC LEUKEMIA: A NOVEL SUBTYPE IN ADULTS CHARACTERIZED BY HIGH RELAPSE RATE AND NON-RESPONSE TO TREATMENT

JM Boer[1], B van der Holt[2], C Exalto[3], M A Sanders[3], JJ Cornelissen[3], R Pieters[1], PJ Valk[3], ML den Boer[1], AW Rijneveld[3,*]
[1]Pediatric Oncology/Hematology, Erasmus MC, [2]HOVON Data Center, Erasmus MC Cancer Institute, [3]Department of Hematology, Erasmus MC, Rotterdam, Netherlands

Background: In pediatric patients with precursor B-cell acute lymphoblastic leukemia (BCP-ALL), the *BCR-ABL1*-like expression signature and *IKZF1* deletion were identified as unfavorable prognostic markers (Den Boer *et al.*, Lancet Oncol 2009; van der Veer *et al.*, Blood 2013). *BCR-ABL1*-like BCP-ALL is identified based on a gene expression signature, which is similar to that of *BCR-ABL1* positive ALL, although these cases do not harbor the *BCR-ABL1* translocation. Approximately 40% of pediatric *BCR-ABL1*-like ALL cases have deletions in the B-cell development gene *IKZF1*.
Aims: We investigated whether a *BCR-ABL1*-like group would be present in adolescent and adult BCP-ALL, and its association with *IKZF1* deletion and prognosis.
Methods: Adolescent and adult patients with newly diagnosed BCP-ALL (127 cases, median age 36 years, range 16-71) were included in four consecutive clinical trials of the Dutch-Belgium HOVON study group between 1993 and 2008 (102 cases), or treated according to similar protocols between 1987 and 2009 (25 cases). *BCR-ABL1*-like BCP-ALL cases were identified using hierarchical clustering with 110 probe sets (Den Boer *et al.*, Lancet Oncol 2009) in Affymetrix U133Plus2 expression data. *IKZF1* deletions were detected using the SALSA P202 *IKZF1* Multiplex Ligation-dependent Probe Amplification assay. Frequencies were compared between groups of samples using Fisher's Exact test. We compared the complete response rate, cumulative incidence of relapse, and event-free survival between *BCR-ABL1*-like, *BCR-ABL1*-positive, *MLL*-rearranged, and remaining BCP-ALL cases.
Results: We identified 21 *BCR-ABL1*-like adult BCP-ALL cases (17%, median age 25 years, range 16-59). The complete response rates were statistically different between the four groups, with lower response rates in the *BCR-ABL1*-positive and *BCR-ABL1*-like BCP-ALL subgroups of about 70%, *versus* more than 90% in the other BCP-ALL groups (p<0.001). Event-free survival showed a trend towards a lower probability compared with the remaining cases for *BCR-ABL1*-like BCP-ALL (HR 1.7, p=0.06), similar to the cytogenetically high-risk *BCR-ABL1*-positive BCP-ALL (HR 1.7, p=0.08). The cumulative incidence of relapse was highest in the *BCR-ABL1*-like BCP-ALL (5-year CIR 67%), compared with *BCR-ABL1*-positive (5-year CIR 32%), *MLL*-rearranged (5-year CIR 29%), and remaining BCP-ALL (5-year CIR 47%). *IKZF1* deletions were detected in 56/122 evaluated BCP-ALL cases (46%). Deletion of *IKZF1* was found in a high percentage of *BCR-ABL1*-positive BCP-ALL patients (74%), but was not increased in *BCR-ABL1*-like BCP-ALL patients (35%) compared with the remaining BCP-ALL cases (37%), and showed a trend towards lower event-free survival in *IKZF1*-deleted cases (p=0.1).
Summary and Conclusions: Our findings suggest that *BCR-ABL1*-like BCP-ALL is a new subgroup comprising 17% of adult BCP-ALL, similar to the frequency in pediatric BCP-ALL. This group was characterized by poor treatment response and high relapse rate, compared with *BCR-ABL1*-positive BCP-ALL and remaining BCP-ALL. *IKZF1* deletions in adults were equally common in *BCR-ABL1*-like BCP-ALL cases compared to the remaining BCP-ALL cases. Further research is needed to study outcome in a larger number of patients and to identify possible genomic lesions underlying the *BCR-ABL1*-like BCP-ALL subtype in adults that may provide a rationale for targeted or intensified treatment.

S683

IDENTIFYING THE DEVELOPMENTAL LEVEL OF LEUKEMIA INITIATION IN ETV6-RUNX1+ ACUTE LYMPHOBLASTIC LEUKEMIA BY STUDYING MONOZYGOTIC TWINS

D Alpar[1,*] D Wren[1], MB Mansur[1], NE Potter[1], FW van Delft[2], CM Bateman[1], L Kearney[1], T Szczepanski[3], D Gonzalez de Castro[1], AM Ford[1], M Greaves[1]
[1]Institute of Cancer Research, London, Sutton, [2]Northern Institute for Cancer Research, Newcastle upon Tyne, United Kingdom, [3]Department of Pediatric Hematology and Oncology, Medical University of Silesia, Katowice, Poland

Background: Investigating monozygotic twins with concordant leukemia provides a unique opportunity to analyze the early genetic steps of leukemogenesis. We previously revealed that identical *ETV6-RUNX1* gene fusion is present in both siblings confirming its early (*in utero*) occurrence and implicating its role in the pathogenesis.
Aims: Identification of the fetal cell type which is transformed by *ETV6-RUNX1*.
Methods: Diagnostic bone marrow samples from five monozygotic twin pairs concordant for pediatric *ETV6-RUNX1*$^+$ precursor B-cell ALL were screened for all varieties of immunoglobulin (*IG*) and T-cell receptor (*TCR*) gene rearrangements which are hallmarks of various stages of lymphoid cell development. Identical rearrangements shared by the siblings and indicative of the *IG/TCR* status of the cells giving rise to pre-leukemic clones were identified. The study was conducted in accordance with the Declaration of Helsinki.
Results: Clonal rearrangements were detected in *IGH*, *IGK*, *IGL*, *TCRD*, *TCRG* and *TCRB* genes in 10, 8, 4, 4, 6 and 2 patients, respectively. At least two affected genes were found in each child. In total, 65 rearrangements were identified in the five twin pairs. Five identical junctions (including N bases) shared by the siblings were observed with the following distribution: twins 1A/B *TCRD* VD2-DD3; 2A/B *IGH* V(D)J; 3A/B *IGH* DJ and *IGK* VKde; 5A/B *IGH* DJ. All these rearrangements must have occurred in the single pre-leukemic clone formed *in utero*. The vast majority of clonal markers proved to be patient-specific and are likely to have arisen post-natally in twin-specific sub-clones. Oligoclonality was observed by analyzing the *IGH*, *IGK* and *TCRD* genes and the combined in-depth analysis of these rearrangements with those shared by the twins revealed the long-term (if not permanent) accessibility of both B-lineage specific and cross-lineage loci during the whole period of pre-diagnostic oncogenesis. Siblings in one twin pair (2A/B) reported a significant difference in age at diagnosis (42 *vs* 58 months) and more mature immunogenotype was detected in the older child, supporting the hypothesis that the longevity of the pre-leukemic phase influences immunogenotype maturity, probably due to the ongoing recombinatorial activity.
Summary and Conclusions: To date, some individual twin pairs have been reported with very limited screening for *IG/TCR* rearrangements. We have carried out a comprehensive screen for these rearrangements in a cohort of twin pairs. Our data suggests that the pre-leukemic clone spawned *in utero*, and shared by the twins, has the *IG* and *TCR* feature of a pro- or pre-B cells in 4 out of 5 twin pairs. In the fifth pair, the lack of any shared *IG/TCR* sequences is uninformative and could reflect either an origin in a cell prior to RAG1/2 expression or a pro-B/pre-B origin obscured by ongoing VDJH replacements. The most parsimonious interpretation of these results, also considering previous studies, is that *ETV6-RUNX1* fusion arises in a fetal progenitor or stem cell that lies upstream of B lineage-restricted RAG1/2 active precursors but is either permissive only for B-lineage differentiation or only has a proliferative fitness impact on early B cells. The pre-leukemic clone therefore arises and expands preferentially in the pro- or pre-B lineage compartment, initially in one twin and undergoes DJH and VDJH rearrangements. Clonally descendent cells with self-renewal stem cell activity are sustained in both twins after birth as independent targets for secondary genetic hits essential for clinical development of ALL.

S684

MER TYROSINE KINASE PROMOTES SURVIVAL OF T(1;19) POSITIVE ACUTE LYMPHOBLASTIC LEUKEMIA (ALL) IN THE CENTRAL NERVOUS SYSTEM (CNS) NICHE

S Krause[1,*] C Pfeiffer[1], S Strube[1], A Alsadeq[1], C Vokuhl[2], S Loges[3], J Waizenegger[3], G Cario[1], A Möricke[1], M Stanulla[4], M Schrappe[1], D Schewe[1]
[1]Pediatrics, [2]Pathology, Universitätsklinikum Schleswig-Holstein, Kiel, [3]II. Medical Clinic and Institute of Tumor Biology, Universitätsklinikum Eppendorf, Hamburg, [4]Pediatrics, Medizinische Hochschule, Hannover, Germany

Background: TAM-receptors (Tyro3/Axl/Mer) have been investigated as therapeutic targets in human cancers as they mediate interactions with the microenvironment and play a role in tumor cell proliferation and survival. ALL cells with t(1;19) translocation upregulate Mer and patients with this disease are prone to late CNS relapses.
Aims: To examine the functional role of Mer in the CNS niche in preclinical models and to examine its clinical relevance in a cohort of pediatric ALL patients with t(1;19) translocation.
Methods: 4 ALL (697, UoCB6, REH, SUP-B15) and 1 AML cell line (HL-60) were analyzed for Mer protein expression. Next, they were subjected to coculture with U343 human glioma cells. We examined cell cycle profiles, performed chemosensitivity assays and analyzed Mer regulation in ALL cells subjected to glioma coculture. Furthermore, we established an *in vivo* model in NSG-mice to analyse meningeal infiltration by ALL primary cells. 10 patient samples were grouped as Mer^{high} or Mer^{low} and their ability to infiltrate the murine CNS was assessed. Mice xenografted with a Mer^{high} patient sample were treated with the Mer-specific inhibitor UNC569 in order to prevent CNS infiltration. Finally, a cohort of 64 pediatric ALL patients with the t(1;19) translocation and a control cohort of 95 patients negative for t(1;19) were analyzed for Mer mRNA expression by qRT-PCR. Correlations with clinical parameters were performed.
Results: 697 cells were Mer^{high}, UoCB6 and REH cells Mer^{intermediate}, SUP-B15 cells Mer^{low} and HL-60 Mer^{negative}. Glioma coculture caused a quiescent phenotype in ALL cells, in a manner dependent on their Mer expression levels. A Mer^{high} phenotype correlated with a profound growth arrest in G0/G1, a 7-fold drop in S-Phase and chemotherapy resistance in the presence of glioma

cells. These responses could not be observed in Mer^{low} and Mer^{negative} cells. Glioma coculture upregulated Mer surface expression in Mer^{intermediate} cells but not in Mer^{high}, Mer^{low} and Mer^{negative} cells. *In vivo* experiments with primary cells from 10 ALL patients revealed that systemic disease was established in all xenografts. High xenograft CNS involvement was observed in 4/6 Mer^{high} and 0/4 Mer^{low} patients. Primary cells from Mer^{high} xenografts also showed increased *in vitro* survival in coculture with glioma cells. Mice xenografted with a Mer^{high} patient sample were treated with UNC569 which delayed leukemia onset and remarkably reduced CNS infiltration. Screening of patients for Mer expression by qRT-PCR revealed that Mer was upregulated in all 64 patients in the t(1;19) cohort. All control patients, regardless of lineage (B- or T-ALL) and cytogenetics, were Mer negative. We identified 33 Mer^{high} and 31 Mer^{low} patients in our t(1;19) cohort. We observed a significant correlation between high Mer expression and older age and a trend towards high Mer and a higher WBC count at presentation. Most importantly, high Mer expression was correlated with a positive CNS status at initial diagnosis.
Summary and Conclusions: Our data provide evidence that Mer is a survival marker for t(1;19) positive ALL cells in the CNS niche. Mer expressing ALL cells are growth-arrested and chemo-resistant in the presence of glioma cells. This suggests that dormancy of leukemic cells may be a reason for late relapses in the CNS. Targeting Mer can delay leukemic onset and diminish CNS infiltration. Altogether, our data indicate a potential role for Mer as a diagnostic marker and a therapeutic target to treat and prevent CNS disease in t(1;19) positive ALL.

S685

SMAC MIMETIC TREATMENT IS HIGHLY EFFECTIVE IN A PRECLINICAL PRIMOGRAFT MODEL OF HIGH-RISK ALL *IN VIVO*

M Schirmer[1,*] M Queudeville[1], L Trentin[1], S M Eckhoff[1], L H Meyer[1], KM Debatin[1]
[1]Department of Pediatrics and Adolescent Medicine, University Medical Center Ulm, Ulm, Germany

Background: In childhood acute lymphoblastic leukemia (ALL) major improvements in therapy have led to increased survival rates, however 20% of patients relapse. Because treatment failure is, at least in part, due to defects in apoptosis programs, novel therapeutic strategies that counter apoptosis resistance are required. Since "Inhibitor of Apoptosis" (IAP) proteins are expressed at high levels in acute leukemia and block apoptosis at a central point of the apoptotic machinery, molecules antagonizing these apoptosis inhibitors, so called SMAC mimetics, provide a promising strategy to overcome apoptosis deficiency and effectively treat high-risk ALL. Recently, we reported that B cell precursor- (BCP-) ALL cell lines show a heterogeneous sensitivity towards SMAC mimetics, which induce a TNF-alpha feed forward loop in sensitive cells.
Aims: In this study, we aimed to investigate the effect of the small molecule SMAC mimetic BV6 in a series of 42 primary BCP-ALL samples and in a preclinical primograft model of high-risk ALL *in vivo*. BV6 was kindly provided by Genentech.
Results: Intriguingly, upon treatment with nanomolar concentrations of BV6, induction of cell death was observed in 70% of all individual patient-derived leukemias. Interestingly, SMAC mimetic induced cell death in primary ALL samples was inhibited by the soluble TNF-alpha receptor Etanercept indicating the induction of a TNF-alpha feed forward loop in primary ALL. We previously described that deficient apoptosis signaling in ALL cells is an independent risk factor and indicative for early patient relapse. Importantly, also high-risk ALL with constitutive deficient apoptosis signaling showed increased cell death upon treatment with the SMAC mimetic BV6 and activation of the apoptosis pathway, demonstrating that SMAC mimetics enable intact apoptosis signaling in former apoptosis resistant primary ALL cells. Based on these findings, we further evaluated the *in vivo* efficacy of BV6 on high-risk ALL using our NOD/SCID/huALL primograft model in a preclinical setting. ALL bearing recipients were treated with either multiagent chemotherapy, the SMAC mimetic BV6 or the combination of both for a given time of two weeks. Most importantly, a profound reduction of tumor load and a significant delay of post-treatment leukemia reoccurrence were observed upon BV6 treatment alone, which was as effective as the multiagent chemotherapy regimen. The combination of BV6 with multiagent chemotherapy was even more effective in tumor load-reduction resulting in remission-induction and significantly prolonged survival of animals. Interestingly, concomitant *in vivo* therapy with Etanercept revoked the cell death inducing effect of BV6, indicating that BV6 induced cell death involves signaling via TNF-alpha *in vivo* and thereby provides a potential biomarker for the identification of patients who would benefit from SMAC mimetic treatment. The sensitizing effect of BV6 to multiagent chemotherapy *in vivo* however was dependent on TNF-alpha to a lower extent, demonstrating that sensitization to drug induced cell death by SMAC mimetics is mediated additionally via prevention of caspase inhibition thereby enabling efficient apoptosis signaling.
Summary and Conclusions: Taken together, we show that the small molecule SMAC mimetic BV6 induces cell death via a TNF-alpha loop *ex vivo* and *in vivo* in primary patient-derived ALL. Moreover, BV6 is able to overcome apoptosis deficiency of high- risk ALL leading to prolonged *in vivo* survival in a preclinical therapy model of patient-derived ALL primografts. Thus, induction of cell death by new generation small molecule SMAC mimetics provides a promising novel strategy for targeted therapy of high-risk acute lymphoblastic leukemia.

Hematopoiesis, stem cells and microenvironment

RECONSTITUTION OF THE HUMAN HEMATOPOIETIC STEM CELL NICHE BY *IN VIVO* IMPLANTATION OF CARTILAGE PELLETS DIFFERENTIATED FROM HUMAN BONE MARROW- AND CORD BLOOD- DERIVED MESENCHYMAL STEM CELLS (MSCS)

M Serafini[1,2,*] A S Pievani[1,2], B Sacchetti[3], I Azario[1,2], R Benedetta[2], A Biondi[4], M Riminucci[3], P Bianco[3]
[1]Dulbecco Telethon Institute at Tettamanti Research Center, [2]Tettamanti Research Center, Pediatric Department, University of Milano-Bicocca, MONZA (MI), [3]Department of Molecular Medicine, Sapienza University, Roma, [4]Pediatric Department, University of Milano-Bicocca, Fondazione MBBM/San Gerado Hospital, MONZA (MI), Italy

Background: The bone/bone marrow microenvironment that maintains the hematopoietic stem cell (HSC) state by controlling stem cell self-renewal and differentiation has been defined as the stem cell niche.
Aims: We conceived a novel model in which *in vitro* differentiated cartilage pellets from MSCs generated complete ossicles upon heterotopic implantation in the absence of exogenous scaffolds, reproducing the human HSC niche *in vivo*.
Methods: Human bone marrow (BM) and cord blood (CB) derived MSCs were cultured as micromasses for 21 days in the presence of TGFβ1 to differentiate into cartilage pellets. The generated pellets were implanted in the subcutaneous tissue of SCID-beige mice and harvested at 8 weeks to assess bone and bone marrow formation through histology and FACS analysis.
Results: Heterotopic ossicles, featuring human bone and bone marrow stroma, were regularly observed at 8 weeks. Of note, a near-perfect architecture of a miniature bone organ, including cortical bone, marrow cavity, donor-derived marrow stroma, host-derived sinusoidal circulation, and host-derived hematopoietic tissue developed in a timed fashion. Hematopoietic tissue within the ossicles included erythroid, myeloid and megakaryocytic lineages, as well as hematopoietic progenitor cells, which gave rise to CFU-M, CFU-G, CFU-GM, BFU-E, CFU-GEMM in a methylcellulose-based assay. BM-ossicles contained fewer LSK cells (Lin$^-$Sca-1$^+$c-kit$^+$) than those of BM (0.096±0.007% *vs.* 0.201±0.034%, N=3). Instead, the frequency of LSK in CB-ossicles was similar to that of BM (0.128±0.048%, N=3). Interestingly, the frequency of putative long-term HSC (LSK$^+$CD34$^-$Flk2$^-$), short-term HSC (LSK$^+$CD34$^+$Flk2$^-$) and multipotent progenitors (LSK$^+$CD34$^+$Flk2$^+$) displayed a comparable distribution as found in BM. Similarly, no major differences were observed in megakaryocyte-erythroid (MEP, LSK$^-$FcγR$^-$CD34$^-$), common myeloid (CMP, LSK$^-$FcγR$^-$CD34$^+$), and common granulocyte-macrophage progenitors (GMP, LSK$^-$FcγR$^+$CD34$^+$). Finally, we investigated whether human hematopoietic cells could stably engraft into the generated human niche. CD34+ cells isolated from human CB were injected into sublethally irradiated mice previously implanted with cartilage pellets. Human cell engraftment was in similar proportion in the ossicle marrow generated from both sources and in the BM of the ossicle-bearing mice. Also the multilineage reconstitution was similar in ossicle marrow and control BM, showing the presence of more than 90% of human CD19$^+$ B lymphocytes, with a small percentage of CD3$^+$ T cells, CD56$^+$ NK cells and CD33$^+$ myeloid cells. The majority of human B cells were CD10^{hi}/CD20$^-$ immature, with a small proportion of mature CD20$^+$ showing polyclonal expression of immunoglobulin kappa and lambda light chains on their surface.
Summary and Conclusions: We have shown that heterotopic ossicles that reproduce a functional bone/bone marrow microenvironment can be established, in the absence of any exogenous scaffolds, by human cartilage pellets generated *in vitro* from MSCs of different sources. In this system, blood borne HSCs are retained and seed the development of functional hematopoiesis. Following transplantation of human CB cells, the heterotopic niche is able to support human hematopoiesis, demonstrating that CD34+ HSCs can engraft and generate lineage-committed hematopoietic cells in the ossicles, similarly to BM.

P19INK4D CONTROLS HEMATOPOIETIC STEM CELLS THROUGH MICROENVIRONMENT AT BASAL STATE AND THROUGH APOPTOSIS AT HEMATOPOIETIC STRESS

M Hilpert[1,*] C Legrand[1], D Bluteau[2], N Balayn[1], A Betems[1], O Bluteau[1], JL Villeval[1], F Louache[1], I Plo[1], W Vainchenker[1], L Gilles[1], H Raslova[1]
[1]U1009, INSTITUT GUSTAVE ROUSSY, villejuif, [2]Ecole pratique des Hautes Etudes, Paris, France

Background: Hematopoietic stem cells (HSC) are characterized by self-renewal capacity and the ability to reconstitute the entire hematopoiesis. In the bone marrow (BM) the majority of HSC remains in quiescence. When a stress occurs, HSC rapidly enter the cell cycle to replenish the hematopoietic system. The maintenance of adult HSC in quiescence is mediated either by intrinsic or extrinsic factors. It has been previously shown that thrombopoietin, the main regulator of megakaryocyte (MK) differentiation, has been shown to be required for

the maintenance of adult HSC quiescence through induction of two cyclin-dependent kinase inhibitors (CDKI) $p57^{Kip2}$ and $p19^{INK4d}$, CDKI are divided into two groups, the INK4 ($p19^{INK4d}$, $p18^{INK4c}$, $p16^{INK4a}$, and $p15^{INK4b}$), and the Cip/Kip ($p21^{Cip1}$, $p27^{Kip1}$ and $p57^{Kip2}$) family. p57, p18 and p21 where described to regulate HSC in basal or stress conditions. p19 is expressed in diverse tissues were it plays an important role in cell differentiation, cell cycle, DNA repair and resistance to apoptosis in response to genotoxic stress. We also demonstrated the implication of p19 in megakaryopoiesis and its direct regulation by RUNX1, which negatively regulates the HSC number.

Aims: Although number of studies suggests implication of p19 in HSC biology, its precise role remains to be fully elucidated. Here we used a p19, KO mouse model to study its role in basal and stressed hematopoiesis.

Results: Our studies revealed that p19 KO mice displayed a slight decrease in absolute number of HSC, an enhanced progression from G0 to G1 phase without any increase in S/G2-M phase. Our *in vivo* study of HSC proliferation showed an increased apoptosis in absence of p19. The induction of replicative (5-FU) or genotoxic (5-FU, menadione) stress to quiescent HSC leads to an enhanced mortality of p19, KO mice associated with a marked increase in the exit of HSC from quiescence. Together with an increase in DNA-double strand breaks (DNA-DSB) and a massive apoptosis in S/G2-M phase, these results establish that $p19^{INK4d}$ is crucial to protect HSC from apoptosis especially under stress. Aging HSC is characterized by an amplification of myeloid-biased HSC and an accumulation of DNA damages probably at the origin of some malignant myeloid hemopathies in elder persons. In p19 KO mice, this amplification was not detected. Moreover, the p19 loss enhances accumulation of DNA-DSB during aging at basal state. Surprisingly WT HSC when transplanted in p19 KO, recipients exhibited a defect in their survival protective effect after 5-FU injection. In competitive transplantation assays in WT recipients, p19 KO, HSC display competitive advantage compare to control HSC. This strongly suggests that the HSC microenvironment is also defective in p19 KO, mice. By investigating the MK lineage, we detected an increase in progenitor and mature MK numbers in BM and spleen and a hyperproliferation of 2N/4N MK in BM of p19 KO, mice during aging. This phenotype is accompanied by an increased synthesis of TGFb1 in the extra fluids of BM and spleen of p19 KO mice. All these defects lead to a splenomegaly and a fibrosis in the BM and in the spleen at a higher extent.

Summary and Conclusions: In conclusion, we report here for a first time how a fibrosis could be induced by impairing a protein playing a crucial role in direct regulation of MK cell cycle. The present results also underscore the protective role of $p19^{INK4d}$ during a genotoxic stress and demonstrate that p19, plays an important role in hematopoiesis including during aging. It opens new avenues of research for delineating its precise function in HSC and their niche.

S688

HUMAN STEM CELL MODEL OF RUNX1 ALTERATIONS IN FAMILIAL PLATELET DISORDER WITH PREDISPOSITION TO ACUTE MYELOGENOUS LEUKEMIA (FPD/AML) DISEASE

V Manchev[1,*] I Antony-Debré[1], N Balayn[1], D Bluteau[1], C Legrand[1], T Langlois[1], L Tosca[2], G Tachdjian[2], JA Mills[3], DL French[4], MJ Weiss[3], E Solary[1], R Favier[1], W Vainchenker[1], H Raslova[1]

[1]Inserm U1009, Villejuif, [2]Inserm U935, Clamart, France, [3]Department of Pathology and Laboratory Medicine, [4]Division of Hematology, The Children's Hospital of Philadelphia, Philadelphia, United States

Background: FPD/AML is a constitutional disorder characterized by germline abnormalities in the hematopoietic transcription factor RUNX1, also called AML1. Mouse models have revealed the essential role of Runx1 during the first steps of hematopoiesis with a complete absence of definitive hematopoiesis in *runx1*$^{-/-}$ mouse. The discovery of induced pluripotent stem cells (iPSC) offers a new opportunity to precisely decipher the mechanisms of human pathologies *in vitro*.

Aims: We derived iPSC from FPD/AML patients to explore the disease pathogenesis and to study the first events at the origin of thrombocytopenia and/or leukemia occurring *in utero* due to constitutive abnormalities of *RUNX1*. Our model also aims to explain a long standing observation that certain constitutive mutations of RUNX1 are associated with increased risk to develop leukemia while others lead only to a mild thrombocytopenia.

Methods: iPSC lines were obtained from fibroblasts of 2 FPD/AML pedigrees (2 patients with missense R174Q mutation, and 1 patient with *RUNX1* monoallelic deletion) and from 3 controls. We used a lentivirus, carrying a cassette encoding for the four reprogramming factors, and excisable by Cre-recombinase. To strengthen our model we also knocked down (KD) *RUNX1* in human embryonic stem cells (hESC) using a shRNA. To confirm that the phenotype we observed is due to the *RUNX1* mutation, we introduced a wild type (WT) copy of the gene by homologous recombination. This was achieved using zing finger nucleases specific for the AAVS1 genomic locus with the WT *RUNX1* under the control of the promoter of the pan-hematopoietic gene CD43. Hematopoiesis was induced by coculture on OP9 stromal cells in presence of VEGF, SCF, IL-3, TPO, and EPO.

Results: After genotypic and phenotypic characterization of iPSC lines, hematopoiesis was explored. Hematopoietic progenitors ($CD34^+CD43^+$) were studied in semi-solid and liquid cultures. Methylcellulose colony-forming assays revealed an increased production of granulo-monocytic progenitors by only R174Q FPD/AML patients and a profound decrease in generation of megakaryocytic and primitive erythroid progenitors in both FPD/AML pedigrees compared to controls. Accordingly, in liquid medium, a deep defect in production of erythroblasts and megakaryocytes was observed in both pedigrees and increased production of macrophages and granulocytes in the pedigree with the R174Q mutation. The decrease in RUNX1 level by 80% by using shRNA in the hESC led to the hematopoietic defects similar to those obtained with iPSC carrying the R174Q mutation. The proplatelet formation was affected in both pedigrees in a similar manner, while increased genetic instability was detected only in the presence of R174Q mutation. Finally, we investigated the expression of RUNX1 target genes and confirmed a diminution of *p19INK4D*, *NR4A3* and *GADD45A* expression in hematopoietic progenitors, and of *MYH9*, *MYL9*,and of *p19INK4D*, in megakaryocytes. The reintroduction of the WT *RUNX1* reverted the observed phenotype in the lines with both types of mutations.

Summary and Conclusions: In conclusion, the hematopoietic defects linked to the RUNX1 alterations in adults occur probably already during embryogenesis. The fact that the KD of RUNX1 in hESC recapitulates the phenotype of the R174Q mutant and that this phenotype is reversible by the reintroduction of WT RUNX1 suggests that the leukemia development risk is dependent on the gene dosage of WT RUNX1 in the cells. In summary, these results demonstrate that FPD/AML iPSC represent a valid model for studying this disorder, successfully reproducing the phenotype observed in patients. Moreover, it allows to explain the differences observed with different *RUNX1* mutations.

EVI2B, A NOVEL C/EBPA TARGET GENE, IS REQUIRED FOR MURINE NEUTROPHILIC DIFFERENTIATION AND CONTROLS HEMATOPOIETIC STEM CELL MAINTANENCE

P Zjablovskaja[1,*] M Kardosova[1], T Benoukraf[2], T Brdicka[1], M Balastik[1], R Delwel[3], D Tenen[2], V Horejsi[1], M Alberich-Jorda[1]

[1]Institute of Molecular Genetics of the ASCR, Prague, Czech Republic, [2]Cancer Science Institute, National University of Singapore, Singapore, Singapore, [3]Erasmus University Medical Center, Rotterdam, Netherlands

Background: *Evi2b* encodes a type I transmembrane protein, which is ubiquitously expressed in hematopoietic cells. *Evi2b* was originally identified as a common virus integration site in murine retrovirally-induced leukemias, suggesting that *Evi2b* might be a tumor suppressor gene or a proto-oncogene. Interestingly, we recently identified *EVI2B* as one of the genes belonging to the C/EBPα signature, suggesting it plays a role in granulocytic development. Nevertheless, little is known about the role of Evi2b in hematopoiesis and leukemic transformation.

Aims: To define the function of Evi2b in hematopoiesis. In particular, we aimed to determine the role of Evi2b in granulocytic differentiation and hematopoietic stem cell (HSC) maintenance.

Methods: K562 cells stably transfected with an inducible C/EBPα-ER fusion protein and 32D/G-CSF-R myeloid progenitor cells were used as a model for human or murine granulocytic differentiation, respectively. Distinct murine bone marrow populations were sorted according to expression of cell surface markers (LKS: $lineage^-$ $ckit^+$ $sca1^+$, short-term (ST)-HSC: LKS $CD48^+$ $CD150^-$, long-term (LT)-HSC: LKS $CD48^-$, $CD150^+$). Gene expression was measured by quantitative RT-PCR. Binding of C/EBPα to human *EVI2B* promoter and transactivation were determined by ChIP-seq analysis and luciferase assays, respectively. Murine *Evi2b* silencing was mediated by 2 distinct lentiviral shRNA constructs. Colony cultures were performed using semi-solid Methocult medium. Bone marrow transplantation experiments were performed using C57Bl/NCrl congenic mice strains. LT-HSC proliferation was evaluated by single cell sorting into Terasaki plates with subsequent counting of divided cells. Cell cycle analysis was performed by Pyronin Y and Hoechst 33342 staining. Human *EVI2B* levels were determined using the expression data of 525 AML patient samples (GSE14468).

Results: We demonstrated that C/EBPα binds to and transactivates *EVI2B* promoter in a dose-dependent manner, and that activation of C/EBPα upregulates *EVI2B* expression. In line with these results, we observed that *EVI2B* expression is downregulated in acute myeloid leukemias characterized by *C/EBP*α promoter hypermethylation. Next, we showed that *Evi2b* expression positively correlates with C/EBPα upregulation during granulocytic differentiation, and that downregulation of Evi2b leads to a block of neutrophilic differentiation in 32D/G-CSF-R cells. Since we observed that *Evi2b* is also abundantly expressed in ST- and LT-HSC, we investigated the role of Evi2b in HSC maintenance. Downregulation of Evi2b in murine LKS cells impairs the ability of this population to form colonies in semi-solid cultures. Further, we showed that Evi2b-silenced LKS cells present reduced ST- and LT-HSC engraftment into lethally irradiated mice. We demonstrated reduced LT-HSC cell proliferation after Evi2b silencing, and accordingly, we showed that Evi2b knockdown in the LKS population increases the percentage of cells in the G_0 quiescent cell cycle phase.

Summary and Conclusions: We have identified *Evi2b* as a target gene of C/EBPα, a crucial transcription factor in granulocytic differentiation. We demonstrated that Evi2b is required for proper granulocytic differentiation in 32D/G-CSF-R cells, and that Evi2b plays a critical role in HSC regulation. Altogether, our data demonstrates that Evi2b is an essential regulator of granulocytic differentiation and HSC maintenance.

TOLL-LIKE RECEPTOR 2 MARKS THE EMERGENCE OF EMBRYONIC HEMATOPOIETIC PRECURSORS

J Balounova[1,*] M Benesova[1], T Vavrochova[1], A Jurisicova[2], HK Sung[2], M Alberich-Jorda[3], D Filipp[1]
[1]Laboratory of Immunobiology, Institute of Molecular Genetics, AS CR, Prague, Czech Republic, [2]Samuel Lunenfeld Research Institute, Mount Sinai Hospital, Toronto, Canada, [3]Laboratory of Molecular Immunology, Institute of Molecular Genetics, AS CR, Prague, Czech Republic

Background: Toll like receptors (*Tlrs*) are critically important in the pathogen recognition and regulation of innate and adaptive immune responses. In addition, direct pathogen sensing of adult bone marrow hematopoietic stem cells and hematopoietic progenitors via *Tlrs* seem to play a crucial role in directing the hematopoietic cell fates towards enhanced myelopoiesis under inflammatory conditions. So far, the expression of *Tlrs* during early stages of embryonic development at the onset of hematopoiesis has not been addressed.
Aims: The aim of this study was to determine the lineage potential of *Tlr2* expressing embryonic hematopoietic progenitors.
Methods: Mouse embryos at different stages of development were dissected from time pregnant females, enzymatically dissociated by Dispase (1 mg/ml) and upon antibody staining analyzed by flow cytometry. For qRT-PCR analyses and *in vitro* assays distinct cellular populations were sorted using Influx cell sorter. Sorted lineage$^-$ CD45$^{+/-}$, c-kit$^{+/-}$, TLR2$^{+/-}$, cells were grown on OP-9 stroma along with myeloid cytokines (SCF, IL-3, M-CSF, GM-CSF) or TLR2 agonist Pam3CSK4. Alternatively, sorted cells were plated directly to semisolid media supplemented with erythroid and myeloid differentiation promoting cytokines (Methocult M3434). Day 3 colonies grown in semisolid media were subjected to single colony qRT-PCR to detect the presence of embryonic hemoglobin. For microscopic analyses embryonic day 7.5 (E7.5) embryos were fixed, stained with TLR2 antibody and visualized by Zeiss LSM 780 microscope equipped with two photon, argon and helium–neon lasers.
Results: Using a transgenic model to trace cells of embryonic origin we showed that *Tlrs* are expressed on embryonic myeloid cells as well as hematopoietic precursors. Together with the prototypic marker of hematopoietic progenitors, c-kit, TLR2 is specifically expressed on the surface of hematopoietic precursors in early gastrulation embryos. Our qRT-PCR analyses showed that E8.5 CD45$^-$, c-kit$^+$, TLR2$^+$, cells express markers of hematopoietic progenitors as well as endothelial cells and myeloid cells. E7.5-E8.5 TLR2$^+$ c-kit$^+$ cells express CD45 mRNA and gradually differentiate through an intermediate c-kit$^+$, CD45$^+$ stage to c-kit$^-$, CD45$^+$ myeloid cells. Upon TLR2 triggering, E8.5 TLR2$^+$ c-kit$^+$ cells proliferate and differentiate to CD45$^+$, CD11b$^+$ myeloid cells in a *MyD88* dependent manner. Pre-circulation E7.5 CD45$^-$, c-kit$^+$, TLR2$^+$, cells as well as E6.5 CD45$^-$, TLR2$^+$, cells differentiate to myeloid cells when cultured on OP-9 stroma with myeloid cytokine supplements. In addition E7.5 CD45$^-$, c-kit$^+$, TLR2$^+$, cells give rise not only to myeloid but also to primitive erythroid colonies when cultured in semisolid media supplemented with erythroid and myeloid differentiation promoting cytokines. Using flow cytometry and whole mount fluorescence microscopy we show that E7.5 TLR2$^+$ progenitors are predominantly detected in the yolk sac (YS) region. Nevertheless scarce TLR2$^+$ c-kit$^+$ cells with a distinct surface expression profile can be also found in the embryo proper (EP). This opens the question whether the emergence of hematopoietic precursors in EP is dependent or not on YS primitive hematopoiesis.
Summary and Conclusions: Our results indicate that the expression of TLR2 marks the emergence of a common embryonic hematopoietic progenitor of early erythro-myeloid lineage and endows embryonic hematopoietic progenitors with the capacity to boost the production of myeloid cells. These data suggest a functional link between embryonic hematopoiesis and pattern recognition receptors under inflammatory conditions.

A SINGLE ONCOGENIC ENHANCER-REARRANGEMENT CAUSES CONCOMITANT EVI1 AND GATA2 DEREGULATION IN LEUKEMIA

S Gröschel[1,*] MA Sanders[1], R Hoogenboezem[1], E de Wit[2], BA Britta[2], C Erpelinck[1], VH van der Velden[3], M Havermans[1], R Avellino[1], K van Lom[1], EJ Rombouts[1], M van Duin[1], K Döhner[4], HB Beverloo[5], JE Bradner[6], H Döhner[4], B Löwenberg[1], PJ Valk[1], EM Bindels[1], W de Laat[2], R Delwel[1]
[1]Department of Hematology, Erasmus Medical Center, Rotterdam, [2]Hubrecht Institute-KNAW & University Medical Center Utrecht, Utrecht, [3]Department of Immunology, Erasmus Medical Center, Rotterdam, Netherlands, [4]Innere Medizin III, Uniklinik Ulm, Ulm, Germany, [5]Department of Clinical Genetics, Erasmus Medical Center, Rotterdam, Netherlands, [6]Department of Medical Oncology, Dana-Farber Cancer Institute, Boston, United States

Background: Acute myeloid leukemia (AML) with chromosomal rearrangements inv(3) or t(3;3) is characterized by overexpression of the proto-oncogene *EVI1* and clinically by an extremely poor response to chemotherapy. The molecular basis of *EVI1* deregulation of this distinct AML subtype is not understood. In the current World Health Organization classification of myeloid malignancies it is speculated that regulatory elements of the housekeeping gene *RPN1* at 3q21 are juxtaposed to the *EVI1* locus at 3q26.2 [inv(3)/t(3;3); *RPN1-EVI1*]. However, this hypothesis has not been experimentally validated.
Aims: To identify regulatory elements involved in the chromosomal 3q21q26 rearrangements driving *EVI1* expression, and to uncover the genomic origin of candidate ectopic *EVI1* enhancers.
Methods: Targeted next generation sequencing of the entire 3q21q26 regions (3q-seq) and transcriptional profiling by RNA-seq were performed in 41 primary AML patient and cell line samples harboring inv(3)/t(3;3). Candidate enhancer elements were identified by combining ChIP-seq with chromosome conformation capture sequencing (4C-seq) and further characterized using *in vitro* reporter assays. Functional validation of the candidate enhancer was carried out by genome-editing experiments, using CRISPR/Cas9 nucleases, followed by qPCR, cytology, proliferation and apoptosis assays.
Results: High-resolution mapping of chromosomal breakpoints by 3q-seq revealed a breakpoint-free segment of 18 kb size downstream of *RPN1*, relocating to the *EVI1* locus in all analyzed cases. Thus, we hypothesized the existence of candidate *EVI1* enhancer elements in this minimal region of rearrangement. 4C-seq was carried out to scan the three-dimensional chromatin environment of the *EVI1* promoter for loop interactions with the 18 kb segment. A contact hotspot of 9 kb within this commonly rearranged segment was identified. ChIP-seq analysis for enhancer-associated histone modifications, as well as BRD4- and p300-binding confirmed exceptionally broad deposition of H3K27ac and BRD4 occupancy in the entire 18 kb segment, with a p300 binding peak in the center of the 9kb *EVI1*-interacting chromatin segment. This 1 kb enhancer element showed significant *EVI1*-promoter driven reporter-gene induction in luciferase assays. Surprisingly, analysis of control samples without 3q rearrangements and of the remaining normal allele in inv(3)/t(3;3) AML revealed that the identified enhancer element was a constituent of the *GATA2* regulatory domain located at 3q21, instead of *RPN1*. RNA-seq and qPCR analysis confirmed reduced and monoallelic *GATA2* expression only from the remaining normal chromosome 3 allele in inv(3)/t(3;3) AMLs (n=69) compared to controls (n=213 unselected AML cases). Genomic excision of the ectopic enhancer element in an inv(3) cell line model (MUTZ-3) abrogated *EVI1* transcription and led to a profound reduction in cell viability, higher rates of apoptosis, along with increased maturation of the AML cells toward a monocyte/macrophage phenotype. Furthermore, we demonstrate that pharmacologic BRD4-inhibition can partly block activity of the ectopic *EVI1* enhancer owing to unique disease-specific enhancer features characterized by BRD4-superloading of the rearranged *EVI1* enhancer.
Summary and Conclusions: Rewiring of a single enhancer deregulates two unrelated disease genes. Using genome-editing tools, we show that targeting the enhancer activity relieves the maturation block of inv(3) leukemia cells. The ectopic enhancer is targetable by BET-inhibitors, which may represent an adjunct to current therapies for this incurable disease.

S692

EFFICACY OF THALIDOMIDE IN THE TREATMENT OF SEVERE RECURRENT EPISTAXIS IN HEREDITARY HEMORRHAGIC TELANGIECTASIA: RESULTS OF A PROSPECTIVE PHASE II CLINICAL TRIAL

R Invernizzi[1,*] F Quaglia[1], F Bellistri[1], F Pagella[1], F Chu[1], E Matti[1], G Spinozzi[1], F Ornati[1], C Canzonieri[1], C Olivieri[1], R Bastia[1], C Danesino[1], M Benazzo[1], CL Balduini[1]
[1]IRCCS Policlinico San Matteo Foundation, University of Pavia, Pavia, Italy

Background: Hereditary hemorrhagic telangiectasia (HHT) is a genetic disease that leads to multiregional angiodysplasia. Severe recurrent epistaxis is the most common presentation, frequently leading to severe anemia. Multiple therapeutic approaches have been tried, but they are largely palliative. Since angiogenesis is involved in the pathogenesis of HHT, anti-angiogenic agents may be effective in its treatment.
Aims: The aims of our open label, phase II, prospective, non-randomized, single-centre study (EudratCT 2011-004096-36, ClinicalTrials.gov Identifier: NCT01485224) were to assess the effectiveness of thalidomide (Thal) in reducing epistaxis and to identify the lowest effective dose in patients with HHT refractory to standard therapy; to evaluate specific biological and clinical parameters predictable for patients response and side effects profile; to assess the efficacy of Thal retreatment in relapsing patients.
Methods: HHT patients with at least one episode of overt bleeding/week requiring at least one blood transfusion during the last three months and refractory to mini-invasive surgical procedures were enrolled. Thal was administered at a starting dose of 50 mg/day orally (off-label use). In the event of no response, Thal dosage was increased by 50 mg/day every 4 weeks until complete or partial response to a maximum dose of 200 mg/day. After response achievement, patients were treated for 16 additional weeks. Monthly follow-up was based on the epistaxis severity score and transfusion need, with adverse events being reported. Response to treatment and side effects profile were correlated with the mutations responsible for HHT and the genetic polymorphisms of *CYP2C19*. Patients relapsing within 52 weeks of ending Thal could be treated again for 8 weeks at the same maximum dose employed during the induction. Thal courses could be repeated at most three times.
Results: Twenty-eight patients for whom informed consent was obtained, 17 M and 11 F, aged 44-84 years (median 64), with mutations in either *ACVRL1* (23 cases) or *ENG* gene (5 cases), were enrolled (median follow-up 62 weeks, range 3-117). Treatment was effective in all 26 evaluable patients. Sixteen cases (62%) responded within 4 weeks of starting the drug: cessation of nose bleeding was observed in 4 cases, and reduction in the severity of epistaxis in 12 cases. Ten patients (38%) achieved partial response after 8 weeks of treatment. Thal significantly increased hemoglobin levels (P=0.04), decreased the transfusion need and improved the quality of life. Slight changes of skin telangiectasias were recorded. Only nonserious, drug-related adverse effects were observed, including constipation and drowsiness. Twenty patients completed the treatment: with a median follow-up of 51 weeks, range 5-97, after the end of therapy, 9 cases remained stable without the loss of response, whereas 11 relapsed (median time to relapse 43 weeks). No correlation was found between genetic or clinical features and time to response or response duration. Four relapsed patients were retreated with Thal with favorable response and without noticeable side effects. The improvement was persistent at 8-30 weeks follow-up.
Summary and Conclusions: Low-dose Thal is safe and very effective for the therapy of epistaxis in HHT patients who did not benefit from other modalities of treatment, allowing for a rapid, often durable clinical improvement. However, the effect of Thal is not permanent and maintenance therapy might be required.

Background: Treatment options for CLL/SLL patients (pts) who fail chemotherapy are limited. Novel targeted therapies, such as ibrutinib (ibr), a first in class covalent inhibitor of Bruton's tyrosine kinase (BTK), may provide an effective therapy in such patients. We report interim results from a phase III randomized study of ibr compared with the anti-CD20 antibody ofatumumab (ofa) in pts with relapsed/refractory (R/R) CLL/SLL (PCYC-1112: RESONATE™). The independent Data Monitoring Committee recommended the interim analysis be considered final because the primary endpoint and a key secondary endpoint were met.
Aims: To evaluate the efficacy and safety of ibrutinib compared with ofatumumab in patients with R/R CLL/SLL.
Methods: Patients with R/R CLL/SLL who failed ≥1 therapy were randomized 1:1 to receive 420 mg oral ibrutinib once daily until progression or IV ofatumumab 300/2000 mg for 12 doses. The primary endpoint was progression-free survival (PFS) assessed by an independent review committee (IRC). Secondary endpoints included overall survival (OS), IRC-assessed overall response rate (ORR), and safety.
Results: Of 391 pts enrolled (median age 67 years; 40% ≥70 years), 195 were randomized to ibr and 196 to ofa. Overall, 53% of pts had Binet Stage C disease, and 32% of those ≥65 years had a cumulative illness rating score >6. Approximately 32% had del17p, 31% del11q, 97% received prior cytotoxic chemotherapy and 45% had disease refractory to purine analogs. Patients in the ibr arm reported a median of 3 prior therapies compared with 2 for ofa. Median time on study was 9.4 months. Ibrutinib significantly lengthened PFS compared with ofa (median not reached *vs* 8.1 months; HR 0.215, CI 0.146–0.317, p<0.0001), representing a 78.5% reduction in risk of progressive disease or death. Ibrutinib significantly improved OS compared with ofa (median not reached for both arms; HR 0.434, CI 0.238–0.789, p=0.0049), representing a 56.6% reduction in the risk of death. ORR was significantly higher with ibrutinib (42.6% *vs* 4.1%, respectively; p<0.0001) and ORR+PR with lymphocytosis was 62.6% *vs* 4.1% for ibr compared with ofa. ORR by investigator assessment similarly favored ibr, and was generally higher than that reported by the IRC at 69.7% and 21.4% for ibr *vs*. ofa, respectively. Analysis of PFS, OS, and ORR in pts with del17p or those with disease refractory to purine analogs similarly favored ibr. The most frequently reported adverse events (AE) for ibr *vs* ofa were diarrhea (47.7% *vs* 17.8%), fatigue (27.7% *vs* 29.8%), and nausea (26.2% *vs* 18.3%). Atrial fibrillation was more frequent with ibr (5.1% *vs* 0.5%). Bleeding events, including petechiae (13.8%) and contusions (10.8%), occurred more frequently with ibr, whereas major hemorrhages were reported at a similar frequency in both treatment arms (1.0% ibr *vs* 1.6% ofa). Two pts in each arm had confirmed Richter's transformation. Rate of AE as the primary reason for study drug discontinuation was similar in the ibr and ofa groups: 4.1% and 3.6%, respectively. At the time of analysis, 86.2% of ibrutinib pts were continuing treatment, and 57 pts randomized to ofa with confirmed progressive disease had initiated ibr in cross-over.
Summary and Conclusions: Compared with ofatumumab, ibrutinib significantly improved PFS, OS and ORR in patients with relapsed/refractory CLL/SLL. The safety profile was comparable to that previously reported (Byrd NEJM 2013). These results support ibrutinib as a beneficial therapy for R/R CLL/SLL patients irrespective of del17p or purine analog refractory disease.

Background: Next generation sequencing has revealed that the coding genome of splenic marginal zone lymphoma (SMZL) is characterized by mutations of genes involved in the physiological differentiation of marginal zone (MZ) B-cells.
Aims: To identify additional molecular mechanisms responsible of the patho-

genesis of SMZL, we applied a candidate gene approach to genes that are well established regulators of MZ B-cells differentiation, but did not emerge from previous genomic studies.
Methods: Seventeen genes were investigated by mutational analysis. Copy number abnormalities were assessed by SNP array (Affymetrix 6.0) and/or FISH. Expression was assessed by biochemical assays and immunohistochemistry. Wild type and mutants were conditionally expresses in HEK-293T, Jurkat, OCI-Ly8 and VL51 cells.
Results: The zinc finger transcription factor *KLF2* was somatically mutated in 20% (19/96) SMZL, thus representing one of the most frequently altered genes in this lymphoma, along with *NOTCH2* (20%) and *MLL2* (15%). Beside mutations, *KLF2* was deleted in 11% (11/96) SMZL, including one focal loss of 174 kb encompassing the sole KLF2 locus. By combining mutations and deletions, 30% (30/96) SMZL harbored *KLF2* lesions. To investigate the full complement of *KLF2* mutations in the spectrum of lymphoid neoplasia, we extended the analysis to 547 mature B-cell tumors. In addition to SMZL, *KLF2* was selectively mutated in post-GC neoplasia, including 16% (4/24) hairy cell leukemia, 15% (12/77) non-germinal center (GC) diffuse large B-cell lymphoma (DLBCL), 9% (5/56) nodal marginal zone lymphoma and 8% (5/61) extranodal marginal zone lymphoma. Conversely, *KLF2* mutations were rare or absent in GCB-DLBCL, follicular lymphoma, Burkitt lymphoma, mantle cell lymphoma, chronic lymphocytic leukemia, and multiple myeloma. The somatic origin of mutations was confirmed by analysis of paired normal DNA. Most (62%) of *KLF2* mutations disrupted its nuclear localization signal (NLS) and/or affected codons required for the interaction between KLF2 and DNA. In normal MZ B-cells of the spleen, KLF2 was expressed with a preferential pattern of nuclear localization. In cell lines and primary tumor cells harboring mutations that truncated or changed the amino acid composition of the NLS, KLF2 was aberrantly displaced into the cytoplasm. Consistently, transient transfection of HEK-293T and OCI-Ly8 cells showed a predominantly nuclear localization of the wild type KLF2, while NLS mutants were dislocated into the cytoplasm. The *CDKN1A* promoter, a known KLF2 direct target, was strongly induced by the wild type KLF2 in luciferase assays. In contrast, KLF2 mutants failed to efficiently up-regulate the reporter. To further investigate the consequences of these mutations, we overexpressed the wild type and mutant KLF2 alleles in lymphoid cell lines. Trunsduction of wild-type KLF2 upregulated the expression of the endogenous CDKN1A mRNA and protein, activated the apoptotic cascade, and enhanced cell death. On the contrary, cells infected with vectors expressing transactivation defective mutants were unable to induce the expression of the endogenous CDKN1A and did not show apoptotic activation.
Summary and Conclusions: These data indicate that: i) *KLF2* is a putative novel tumor-suppressor gene recurrently disrupted in 30% SMZL and, to a lesser extent, in other tumors originating from post-GC B-cells; and ii) *KLF2* mutations promote cell survival by causing the cytoplasmic delocalization of KLF2 and the impairment of its transcriptional function.

Background: The regulation of TCR rearrangements, particularly *TCR*δ and *TCR*β, plays a decisive role in lymphoid differentiation and oncogenic transformation. Unlike *TCR*γ and *TCR*α, the *TCR*δ and *TCR*β loci contain D segments. Productive recombination at the *TCR*β locus is tightly ordered (D-J before V-DJ), with c-Fos acting as a recombinase co-factor. The early stages of *TCR*δ recombination are poorly described and it is generally considered that they are not ordered in mice, whereas it has been suggested that they could be in humans.
Aims: To characterize the control of V(D)J recombination at the human *TCR*δ locus.
Methods: (i) chromatin immunoprecipitation (ChIP), (ii) protein co-immunoprecipitation (Co-IP), (iii) Proximity Ligation Assay (PLA), (iv) testing of RAG enzymatic activity against extrachromosomal substrates and (v) *in vitro* T-cell differentiation of human CD34+ cord blood cells on an OP9-DL1 stromal support, with or without shRNA-mediated inactivation of RUNX1 by lentiviral transduction.
Results: We show that the rearrangements of *TCR*δ are strictly ordered in humans. Within the human *TCR*α/δ locus, the first rearrangement (Dd2-Dd3) occurs at a very immature thymic ETP (Early T-cell Precursor) $CD34^{+}/CD1a^{-}CD7^{+dim}$ stage and systematically precedes Dd2(Dd3)-Jd1 rearrangement. *In silico* analysis identified a full consensus binding site for the RUNX1 transcription factor spanning the human *Dδ2-23RSS* heptamer and *Dδ2* coding sequence. This site is bound directly by RUNX1 in human $CD34^{+}/CD3^{-}$ thymocytes. The RUNX1 binding site is not conserved in the mouse *Dδ1* (which is homologous to human *Dδ2*), and as expected, RUNX1 binding to *Dδ1-23RSS* was not observed in mouse DN RAG2-/- thymocytes. The RUNX1 protein interacts with RAG1, and specifically increases the binding of RAG1 to the *Dδ2-23RSS*. Inactivation of RUNX1 abolished *TCR*δ rearrangements in human CD34+ cord blood cells, thereby inhibiting further T-cell differentiation. Conversely, stable transfection of RUNX1 in a non-lymphoid cell line (BOSC23) that lacked *TCR*δ rearrangement specifically induced Dd2-Dd3 recombination.
Summary and Conclusions: With respect to physiological lymphoid development, the minor population of TCRγδ expressing T-cells (γδ T-cells) has been conserved throughout vertebrate evolution. Our data show that RUNX1 imposes the use of two Dδ gene segments in all rearranged *TCR*δ chains during human, but not murine, *TCR*δ locus recombination. This is an evolutionary advantage for human TCRγδ lymphocytes, which have potentially longer and more diversified TCRδ CDR3 segments than those seen in mice. From an oncological point of view, the majority of *TCR*δ translocations occur during Dδ2-Dδ3 recombination, suggesting a potential role for RUNX1 in their pathogenesis. RUNX1 loss of function or dominant negative fusion proteins could induce maturation arrest due to a failure to initiate *TCR*δ rearrangement. This could, for example, explain the very immature maturation arrest observed in AML FAB M0 or ETP T-ALL with RUNX1 somatic mutations. Furthermore, our results suggest that RUNX1 mediates distinct roles in early lymphoid differentiation in humans and mice, with obvious consequences for extrapolation of murine models to human hematopoiesis. We have identified a novel function of RUNX1 as a cofactor of V(D)J recombination, providing novel insight into its role in normal lymphopoiesis and lymphoid oncogenesis.

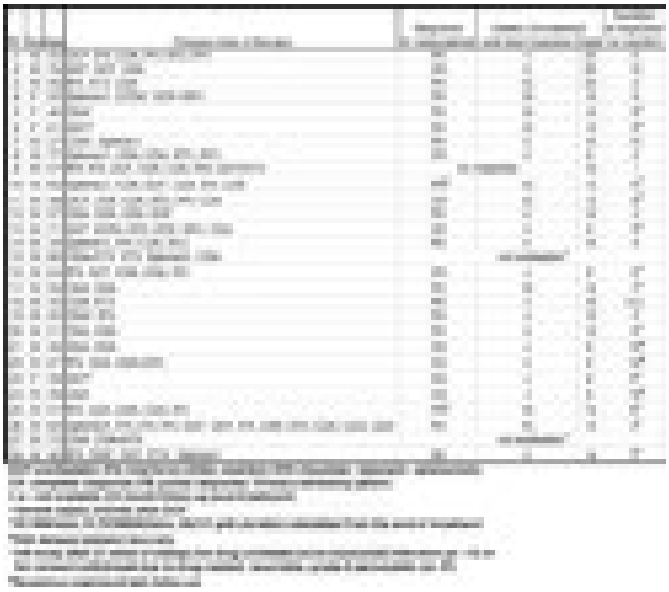
Orsola-Malpighi Hospital and Bologna University School of Medicine, Bologna, Italy

Background: Purine analogs (PAs) are highly effective in hairy cell leukemia (HCL), but ~40% of patients relapse and become less responsive to PAs, which are also myelotoxic and immune-suppressive. We recently discovered BRAF-V600E as the mutation underlying HCL (Tiacci *et al.*, NEJM 2011;364:2305), just at the same time when the oral BRAF inhibitor Vemurafenib proved effective in BRAF-mutated metastatic melanoma. Thus, we designed the first clinical trial to test the concept of BRAF inhibition in refractory/relapsed HCL.
Aims: To assess the efficacy and safety of Vemurafenib in HCL patients refractory to or relapsed after PAs by an academic, phase-2, single-arm, italian, multi-center (n=8) clinical trial (HCL-PG01; EudraCT 2011-005487-13).
Methods: Vemurafenib (960 mg bid) was given for a median of 16 weeks on an outpatient basis to 28 BRAF-V600E+ HCL patients requiring therapy because of cytopenia(s), including (see Table 1): **i)** 6 patients primary refractory to a PA; **ii)** 21 patients who relapsed early and/or repeatedly after PAs and had undergone a median of 4 previous therapies, with 5/21 (24%) and 9/21 (43%) patients not responding to the last PA and last therapy, respectively; in the remaining 16/21 and 12/21 patients, the median response duration was 27 and 26 months after the last PA and last therapy, respectively; **iii)** a 81-year old patient with severe myelotoxicicity after a PA that precluded its further use. Therapies other than PAs included interferon, rituximab and splenectomy in 12, 14 and 8 patients, respectively. Enrollment was completed in 11 months. Complete response (CR) required normal blood counts (N≥1500/mmc, PLT≥100000/mmc, Hb≥11 g/dl), morphological absence of hairy cells in the bone marrow biopsy and blood smear, and no splenomegaly. Partial response (PR) required normal blood counts, and a ≥50% reduction of splenomegaly and of marrow and blood HCL involvement by immunophenotyping. Two patients, who went off-study after ≤1 week of treatment, were not evaluable (see Table 1).

Results: Vemurafenib was well tolerated: drug-related adverse events (mainly arthralgias, various types of skin toxicity, pancreatitis) occurred in all patients, but were always reversible and mostly grade 1-2, with only 6 (23%) patients having grade 3 events and none grade 4. Notably, no myelosuppression was recorded. No keratoacanthomas nor cutaneous squamous cell carcinomas (as reported in melanoma patients) developed, but we observed two basaliomas and one superficial melanoma (all treated with a simple excision) in 3 patients. Strikingly, overall responses (CRs+PRs) were 96% (25/26 patients), with 9/26 (34.6%) CRs and 16/26 (61.4%) PRs and with a median time to response of 8 and 9 weeks, respectively. CR and PR patients included 1 and 5 primary refractory ones, respectively. In all CR patients immunohistochemistry documented minimal residual disease (≤10%) at the end of treatment. Seven of 9 (78%) CR patients still maintain normal blood counts at a median of 9 (range 6-12) months post-treatment. In the other 2 CR patients (pts. 2 and 9), a mild neutropenia (N~1000/mmc) developed 12 and 5 months post-treatment, respectively. Pt. 2 still does not require therapy 15 months post-treatment; pt. 8 required therapy 9 months post-treatment due to a worsening neutropenia. Among the 15/16 PR patients with >1 month follow-up, 8 (53%) maintain normal blood counts at a median of 6 (range 3-9) months post-treatment. The other 7 (47%) patients developed cytopenia(s) at a median of 5 (range 2-10) months post-treatment.

Table 1.



Summary and Conclusions: A brief, oral monotherapy with Vemurafenib proved safe and highly active in heavily pre-treated HCL patients poorly responsive to all conventional therapies. Strategies to further increase CRs and response duration include: combining a BRAF inhibitor with a MEK inhibitor or a B-cell targeting antibody or a kinase inhibitor of the pathways downstream of the B-cell receptor; and/or maintenance therapy with lower, pulsed Vemurafenib doses.

HDAC8 INHIBITS MYELOMA CELLULAR GROWTH THROUGH REGULATION OF HOMOLOGOUS RECOMBINATION AND CYTOSKELETON INTEGRITY

M Gkotzamanidou[1,*] M Shammas[1], M Kemal Samur[2], V L Souliotis[3], M Fulciniti[1], S Minvielle[4], F Magrangeas[4], H Avet-Loiseau[4], K C Anderson[1], N C Munshi[1]
[1]Medical Oncology, [2]Department of Biostatistics and Computational Biology, Dana-Farber Cancer Institute, Harvard Medical School, Boston, United States, [3]Institute of Biology, Medicinal Chemistry and Biotechnology, National Hellenic Research Foundation, Athens, Greece, [4]Center for Cancer Research Nantes-Angers, University of Nantes, Nantes, France

Background: To date, both clinical and preclinical studies have confirmed that MM is vulnerable to epigenetic intervention, with histone deacetylase enzymes (HDAC) emerging as the most promising epigenetic targets. However, little is known about the role of HDAC8, a member of Class I HDAC isoenzymes in MM.
Aims: To investigate the function of HDAC8 in MM biology and to evaluate its potency as therapeutic target.
Methods: Lentiviral-shRNA delivery system was used for knockdown of HDAC8 in OPM2 and U266 cells. The HDAC8 inhibitor PCI-34051 was used as chemical inhibitor. A panel of 15 antibodies (HDAC8, γH2Ax, H2Ax, pATM, pATR, pBRCA1, pBRCA2, pCHK2, pCHK1, ku70, RPA70, 53BP1, DNA-PKs, pP53, Rad51) and nucleolin, GAPDH, were used in immunoblot analysis. Immunofluorescence staining was performed with HDAC8, actin, p53 and Smc1 and Smc3 antibodies and the images were analyzed with confocal microscopy. Singe cell electrophoresis under neutral conditions (comet-assay) was performed in OPM2-HDAC8 knockdown cells with or without exposure to γ irradiation (IR), and in OPM2 and U266 treated and untreated with HDAC8 inhibitor in combination with IR. Co-immunoprecipitation assay was performed for investigation of interactions of HDAC8 after induction of DNA damage. DNA Double-Strand Break (DSB) repair occurring via homologous recombination (HR) pathway was assessed using a transient direct repeat DsRED-GFP/I-SceI plasmid-based system. Expression of DNA damage and repair pathway (DDR) genes was evaluted using a high-throughput PCR assay. Cellular senescence was assessed with SA-β-Galactosidase staining.
Results: We evaluated the expression of HDAC8 in 172 newly-diagnosed MM patients from the IFM myeloma dataset and observed HDAC8 overexpression as well as its significant correlation with poor survival outcome ($p<0.0015$). We further evaluated the expression of HDAC8 in HMCLs (probe ID_223909-s_at, 223345_at) and confirmed the high expression and its cytoplasm and nuclear localization in all six MM cells lines studied (MM1S, OPM2, RPMI8226, U266, MOLP8 and NCI-H929). The HDAC8 depletion in two MM cells lines (OPM2 and U266) resulted in significant inhibition of proliferation of MM cells at 1 week as measured by 3[H]-thymidine assay, and decrease in colony formation as evaluated after 3 weeks post transfection ($p<.001$). Interestingly, the combination of HDAC8 inhibitor with melphalan or bendamustine enhanced the anti-MM effects of the genotoxic agents (all<0.01) and was confirmed to be synergistic using Calcusyn software. Interstingly, U266 cells with HDAC8 depletion exhibited increased levels of markers of DNA damage including γH2Ax, H2Ax, pATR, pBRCA2, pCHK1, RPA70, 53BP1, DNA-PKs, Rad51 and pP53. Moreover, in consistence with this observation HDAC8 knock down led to decreased HR activity as measured by a plasmid based assay and decreased repair of DSBs after IR measured by Singe cell electrophoresis under neutral conditions with or without exposure to γ irradiation (IR). Similar observation were also confirmed following treatment of the cells with HDAC8 inhibitor. The HDAC8 protein co-localized and co-immunoprecipitated with p53 after IR, and with Scm3, member of cohesin. Finally, the depletion of HDAC8 resulted in the higher prevalence of senescence associated with β-Gal-positive cells 3 weeks post transduction.
Summary and Conclusions: Our results demonstrate a mechanistic connection of HDAC8 and DNA damage repair pathway, and provide insights into the effect of HDAC8 on cytoskeleton, that may have therapeutic implications in MM.

S698

ADDITIONAL PROGNOSTIC VALUE OF MULTIPARAMETER FLOW CYTOMETRY (MFC) MINIMAL RESIDUAL DISEASE (MRD) MONITORING OVER COMPLETE RESPONSE (CR) ACROSS THE CLINICAL COURSE OF MULTIPLE MYELOMA (MM) PATIENTS

B Paiva[1,*] M Chandia[2], MB Vidriales[3], JJ Perez[2], N Puig[2], L Lopez-Corral[2], A Melon[2], EM Ocio[2], R Garcia-Sanz[2], NC Gutierrez[2], MV Mateos[2], JF San Miguel[1]
[1]Clinica Universidad de Navarra, Centro de Investigacion Medica Aplicada (CIMA), Pamplona, [2]Hospital Universitario de Salamanca, Instituto de Investi-

gaion Biomedica de Salamanca, IBMCC (USAL-CSIC), [3]HospitaHospital Universitario de Salamanca, Instituto de Investigaion Biomedica de Salamanca, IBMCC (USAL-CSIC), Salamanca, Spain

Background: The continuously increasing rates of CR as well as therapeutic options in MM brought the debate on whether the CR criteria could be refined to further improve prediction of outcome, and particularly to identify patients in CR with shorter TTP and OS. Consequently, the role of MRD monitoring is now under evaluation and published data based on different clinical trials has shown positive results. Interestingly though, it is perhaps outside of clinical trials (thereby without planned regimens) where MRD monitoring may be more valuable to improve prediction of outcomes and help on therapeutic decisions.

Aims: To specifically address the clinical relevance of MRD investigations among patients in CR throughout the whole spectrum of MM patients' clinical course.

Methods: A total of 113 patients in CR as defined by the IMWG criteria were prospectively screened for MRD levels at the University Hospital of Salamanca, between 2000 and 2013 and outside the setting of a specific clinical trial. Elderly (>65y) patients (n=30) were studied after induction therapy (50% being treated without novel agents), whereas transplant-eligible cases (n=51) were monitored after HDT/ASCT (70% receiving previous induction without novel agents). In 22/51 transplant-eligible patients, MRD monitoring was also performed in stem cell harvests. Follow-up MRD studies were performed on 31 patients in CR after up-front treatment (both elderly and transplant-eligible). A total of 43 patients in CR after salvage therapy were also screened for MRD (11 of them overlapping with up-front studies). Overall, a total of 155 bone marrow samples and 22 harvests were analyzed by 4-color MFC, and flow-CR was defined as <0.01% phenotypically aberrant clonal plasma cells. Median follow-up was 6, 5 and 1.5 years for elderly, transplant-eligible and relapsed patients. TTP and OS were measured from the moment of MRD assessment.

Results: Among the 30 elderly patients in CR after induction, 19 (63%) also attained flow-CR, which translated into significantly superior TTP (medians of 39 *vs* 19 months; P=.02) and OS (63m *vs* 24m; P=.03). Similarly, among the 51 patients in CR after HDT/ASCT, 33 (65%) were in flow-CR and again the absence of detectable MRD resulted in significantly prolonged TTP (85m *vs* 13m; P<.001) and a trend for OS (98m *vs* 52m; P=.18). Noteworthy, 73% and 94% of elderly and transplant-eligible patients in CR, but with persistent MRD, had relapsed when the study was closed for analysis. Another interesting finding was the prognostic information derived from MRD investigations on stem cell harvests; MRD was detected in 6 of 22 (27%) harvests (from patients in CR after HDT/ASCT), which translated into significantly shorter TTP (median of 10m *vs.* 85m; P=.001). Regarding those cases in CR after salvage therapy (63% after auto or allo SCT), it was surprising to see that also in the relapse setting approximately half of the patients (46%) could achieve flow-CR, which doubled TTP as compared to cases MRD-positive (25m *vs.* 13m; P=.035), without significant differences for OS (NR *vs* 38m; P=.22). Finally, we took advantage of available longitudinal MRD monitoring after up-front treatment to investigate if MRD recurrence predicted clinical relapse. For this purpose, we focused on 31 patients in conventional plus flow-CR (either after induction or HDT/ASCT), and observed that those cases turning into MRD-positive (42%) had a significantly higher probability of relapse compared to cases with undetectable MRD during follow-up analysis (85% *vs.* 39%; P=.011).

Summary and Conclusions: We specifically showed among patients in conventional CR, that MRD monitoring by MFC is a powerful prognostic biomarker that consistently identifies those patients at higher risk of unsustained CR, and could potentially help on therapeutic decisions throughout MM patients' clinical course.

S699

INHIBITION OF THE STK4 KINASE RESTORES THE HIPPO CO-FACTOR YAP1 AND INDUCES DNA-DAMAGE MEDIATED APOPTOSIS IN MULTIPLE MYELOMA CELLS

F Cottini[1,*] T Hideshima[1], C Xu[1], M Ponzoni[2], P Richardson[1], F Caligaris Cappio[3], K Anderson[1], G Tonon[3]

[1]Medical Oncology, Dana Farber Cancer Institute, Boston, United States, [2]Pathology Unit, [3]Division of Molecular Oncology, San Raffaele Scientific Institute, Milan, Italy

Background: Multiple myeloma (MM) is a clonal proliferation of malignant plasma cells characterized by complex genomic abnormalities. We and others have shown that MM cells have ongoing DNA damage and DNA damage response (DDR), in contrast to normal plasma cells (NPCs) and peripheral blood mononuclear cells (PBMCs) (Walters, Leukemia, 2011).

Aims: Normally ongoing DNA damage leads to elimination of aberrant cells. We investigated the mechanisms which prevent DNA-damage mediated apoptosis in MM, and how we could modulate these pathways to provide novel therapeutic options.

Methods: MM cells were cultured in supplemented RPMI-1640. Lentiviral delivery systems or AMAXA electroporation were used for expression and knockdown of YAP1 and STK4 in MM cells. MM samples and PBMCs were obtained after informed consent and subjected to Ficoll-Paque density sedimentation, followed by CD138-positive selection for MM cells.

Results: MM patient cells and cell lines have ongoing DNA damage, which triggers ATM-mediated DDR but surprisingly no apoptosis. In normal cells, ATM can cause apoptosis not only by activating P53, but also by promoting re-localization of the kinase ABL1 into the nucleus where it phosphorylates YAP1, thereby promoting stabilization of the tumor suppressor p73 and activation of pro-apoptotic p73-target genes. Remarkably, ABL1 has consistent nuclear localization in the majority of MM cells and patient samples tested. Its cellular localization is modulated by DNA damage: ATM inhibitors re-localize ABL1 to the cytosol, while doxorubicin increases ABL1 nuclear localization, promoting apoptosis in MM cells. Conversely, ABL1 is not basally present in the nucleus in normal PBMCs, nor does it shuttle to the nucleus or cause apoptosis upon treatment with similar doses of doxorubicin. A known target of ABL1 is YAP1, a modulator of the Hippo pathway. aCGH data show that YAP1 genomic locus (chr. 11q22) is deleted, alongside with BIRC2 and BIRC3, in up to 11% of MM patients and in two MM cell lines (KMS-18 and KMS-20). Moreover, while PBMCs show variable YAP1 expression levels, the majority of MM patients and cell lines have low levels of YAP1, suggesting a tight regulation of YAP1 levels in these tumor cells. To define the relevance of YAP1 silencing in MM cells, we re-expressed YAP1 in MM cell lines with either YAP1 deletion or low YAP1 expression. These experiments revealed reduced growth and increased apoptosis in cells in which YAP1 had been re-expressed, whereas enhanced growth was observed upon YAP1 silencing in UTMC-2 cells. We showed that YAP1 stabilizes p73 protein in MM cells, thereby promoting transcription of p73-target genes (BAX, PUMA and p21) and apoptosis. ABL1 is crucial to YAP1 apoptotic phenotype, since imatinib treatment precludes cell death by blocking YAP1 phosphorylation and preventing YAP1/p73 complex formation. Moreover, no growth inhibitory effects were identified when a mutant lacking the WW-p73 interaction domains (dWW-YAP1) was re-expressed in MM cells devoid of YAP1. Importantly, STK4 silencing increases YAP1 levels associated with inhibition of MM growth in both *in vitro* and *in vivo* MM models; no similar effects are noted in YAP1-MM deleted cell lines.

Summary and Conclusions: MM cells with ongoing DNA damage avoid cell death due to reduced YAP1 levels. STK4 kinase controls YAP1 levels and cellular localization, and indeed STK4 and YAP1 levels inversely correlate in MM patients. Functional inhibition of STK4 promotes YAP1 upregulation and related MM growth inhibition and cytotoxicity. STK4 kinase inhibitors therefore represent a potential novel therapeutic approach in MM.

S700

IN VIVO TARGETING OF STROMAL-DERIVED FACTOR-1 AS A STRATEGY TO PREVENT MYELOMA CELL BONE TO BONE DISSEMINATION

A Roccaro[1,*] A Sacco[1], M Moschetta[1], Y Mishima[1], P Maiso[1], S Lonardi[2], D Zboralski[3], A Krushinski[3], G Rossi[4], I Ghobrial[1]

[1]Dana-Farber Cancer Institute, Boston, United States, [2]Pathology, Spedali Civili di Brescia, Brescia, Italy, [3]NOXXON Pharma AG, Berlin, Germany, [4]Hematology, Spedali Civili di Brescia, Brescia, Italy

Background: Multiple myeloma (MM) patients present with multiple lytic lesions at diagnosis, indicating the presence of continuous dissemination of MM cells from the primary site of tumor development to multiple distant bone marrow (BM) niches. We hypothesized that stromal-derived factor-1 (SDF1) may represent a target for preventing transition from MGUS (micrometastatic-stage) to active-MM (macrometastatic-stage). We therefore evaluated SDF1 expression in the BM of patients with MGUS, MM, compared to healthy individuals; and tested the effect of SDF1 neutralization withing the bone marrow niches as a strategu to precent MM cell homing and disease progression. AIMS. 1) To evaluated to level of SDF-1 in bone marrow niches colonized by MM cells 2) To evaluate the effect of neutralizing SDF-1 in modulating the bone marrow niches and its effect in preventing MM cell colonization and growth.

Aims: 1) To evaluate the level of SDF-1 in MM cell-colonized bone marrow niches. 2) To evaluate the effect of SDF-1 neutralization on modulating the bone marrow niches and its effect on preventing MM cell colonization and growth.

Methods: SDF1 levels were evaluated by immunohistochemistry on BM specimens of patients with MGUS, active-MM, or healthy individuals; and confirmed by ELISA, using conditioned-medium of BM-mesenchymal stromal cells (BM-MSCs) from MGUS, active-MM and healthy individuals. BM metastatic lesions from primary epithelial tumors were also evaluated, including medullary thyroid-, gastric-, renal-carcinoma, lung adenocarcinoma. Co-localization of SDF1 with MM cell (MM.1S-GFP+)-enriched BM niches was evaluated using *in vivo* confocal microscopy. Effect of NOX-A12 on modulating MM cell dissemination was tested *in vivo*, by using an *in vivo* MM metastasis model. *In vivo* homing and *in vivo* tumor growth of MM cells (MM.1S-GFP+/luc+) was assessed by using *in vivo* confocal microscopy and bioluminescence, in mice treated with 1) vehicle; 2) NOX-A12; 3) bortezomib; 4) NOX-A12+bortezomib. Effects of drug combination on dissemination of MM cells to distant BM niches was evaluated *ex vivo* by immunofluorescence on explanted femurs. DNA synthesis and adhesion of MM cells in the context of NOX-A12 treated primary MM BM-MSCs in presence or absence of bortezomib were tested by thymidine uptake and adhesion *in vitro* assay. Synergism was calculated by using CalcuSyn software.

Results: Patients with active-MM present with higher BM SDF1 expression *vs* MGUS patients and healthy individuals. Similarly, BM presenting with metas-

tasis from epithelial primary tumors had higher SDF1 levels compared to healthy subjects, thus suggesting the importance of SDF1 in favoring tumor cell metastasis to BM niches. SDF1 co-localized at BM level with MM tumor cells *in vivo*. I*n vitro,* NOX-A12 induced a dose-dependent de-adhesion of MM cells from the BMSCs supported by inhibition of BM-MSC-mediated phosphorylation of ERK1/2 and cofilin. Importantly, NOX-A12 induced MM cell mobilization from the BM to the peripheral blood (PB) as shown *ex vivo* by reduction of MM cells in the BM and increased number of MM cells within the PB compared to control mice (P<0.05). This was supported by inhibited homing and dissemination of MM cells to the BM of those mice pre-treated with NOX-A12. Similarly, NOX-A12-pre-treatred mice presented with inhibited dissemination of MM cells from bone to bone, as shown by using an *in vivo* model of MM metastasis (P<0.05). NOX-A12 enhanced MM cell sensitivity to bortezomib, *in vivo*: tumor burden was similar between NOX-A12- and control mice whereas bortezomib-treated mice showed significant reduction in tumor growth *vs.* control (P<0.05); importantly, significant reduction of tumor burden in those mice treated with sequential administration of NOX-A12 and bortezomib was observed, compared to bortezomib-treated mice (P <0.05). Similarly, NOX-A12+bortezomib combination induced significant inhibition of MM cell homing, as shown by *in vivo* confocal microscopy. *In vitro* studies confirmed synergism between NOX-A12 and bortezomib in modulating MM cell survival and adhesion to BM-MSCs.
Summary and Conclusions: SDF-1 represents a valid target for inhibiting MM cell dissemination to distant BM niches, thus providing the rationale for using the SDF1 inhibiting spiegelmer NOX-A12 to target MM cells at the stage of micrometastasis (MGUS), thus preventing development of macrometastatic MM.

S701

CROSS-TALK BETWEEN SPHINGOSINE 1-PHOSPHATE (S1P) AND CXCR4/CXCL12 REGULATES VIABILITY, SUPPORTS CXCR4-DEPENDENT CELL MOTILITY AND DEFINES THE SENSITIVITY TO FTY720 IN MULTIPLE MYELOMA

K Beider[1,*] E Rosenberg[1], H Bitner[1], M Leiba[1], M Koren-Michowitz[1], M Abraham[2], S Klein[2], H Wald[2], A Shimoni[1], A Peled[2], A Nagler[1]
[1]Hematology Division, Bone Marrow Transplantation, The Guy Weinshtock Multiple Myeloma Foundation, Sheba Medical Center, Ramat-Gan, [2]Gene Therpay Institute, Hadassah and Hebrew University Hospital, Jerusalem, Israel

Background: Multiple myeloma (MM) is a malignancy of plasma cells that home and accumulate in bone marrow (BM) microenvironment. CXCR4/CXCL12 chemokine axis has been implicated in MM trafficking and retention in BM. Sphingosine 1-phosphate (S1P) and S1P receptors (S1P1-S1P5) control lymphocyte and plasma cell egress from lymph nodes and support CXCR4-dependent migration and BM homing of hematopoietic stem cells. Sphingosine kinase (SPHK) is a key enzyme in the sphingolipid pathway that produces S1P.
Aims: We therefore asked whether crosstalk between the S1P and CXCR4 pathways is important for MM cell survival and motility *in vitro* using MM cell lines and human MM samples and in xenograft mice MM tumor model *in vivo*.
Results: Expression profile of S1P(1-5) receptors and SPHK1 in MM cell lines and primary MM samples was evaluated by RT-PCR. S1P1, S1P2, S1P4 and SPHK1 were found to be expressed by different MM cell lines (n=7). In addition, primary samples from BM of MM patients (n=24) were analyzed for S1P(1-3) receptors and SPHK1 expression. S1P1 receptor and SPHK1 were found to be was co-expressed in 12 human MM samples. Next, to evaluate the effect of S1P axis modulation on MM viability, cells were treated *in vitro* with FTY720, S1P analogue, which binds to four out of five S1P receptors, and with the SKI-II, SPHK1 inhibitor. FTY720, but not SKI-II, treatment induced cell death of MM cell lines and primary human CD138+ MM cells in a dose-dependent manner (IC50 2-3.5 μM). FTY720-triggered cell death by inducing apoptosis manifested by an increase in Annexin V staining, caspase 3 cleavage and cytochrome C release. FTY720-induced MM cell death was accompanied by reduction in BCL-XL, but not in MCL-1 levels, indicating that FTY720-promoted mitochondrial destabilization with BCL-XL involvement. In addition, treatment of MM cells in the presence of protective bone marrow stromal cells (BMSCs) with FTY720 sensitized the MM cells to the cytotoxic effect of lenalidomide. Exogenous CXCL12 treatment and co-incubation with BMSCs partially protected the MM cells from the FTY720-induced apoptosis, indicating the involvement of CXCR4/CXCL12 pathway in S1P signaling. However, higher doses of FTY720 effectively overcame this protective effect. Oppositely, FTY720 treatment completely abrogated CXCR4-dependent migration of MM cells in response to elevated concentrations of CXCL12 (p<0.001). Mechanistically, pre-treatment with FTY720, but not with SKI-II, fully blocked CXCL12-induced phosphorylation of AKT and Erk1/2 kinases in MM cells. Of note, enforced expression of CXCR4 in MM cells promoted resistance to FTY720-induced apoptosis, whereas silencing of endogenous CXCL12 in MM cells resulted in significantly increased sensitivity to FTY720 treatment (p<0.01). Finally, in xenograft model of systemic MM with BM involvement *in vivo* FTY720 effectively reduced tumor burden in 4 out of 6 treated mice, decreasing the number of MM cells in BM and levels of M protein in blood.
Summary and Conclusions: Taken together, our novel findings demonstrate the activating interaction between S1P and CXCR4/CXCL12 signaling pathways that may be important for MM cell survival and localization of the MM cells in CXCL12-expressing protective niches. Furthermore, S1P targeting with FTY720 limits tumor-promoting activities of S1P and CXCR4/CXCL12 axes and thus may serve a therapeutic target in MM.

ABT-199 (GDC-0199) IN RELAPSED/REFRACTORY CHRONIC LYMPHOCYTIC LEUKEMIA AND SMALL LYMPHOCYTIC LYMPHOMA: HIGH RESPONSE RATES AMONG PATIENTS WITH HIGH RISK DISEASE FEATURES INCLUDING UNMUTATED IGHV

JF Seymour[1,*] MS Davids[2], JM Pagel[3], BS Kahl[4], WG Wierda[5], S Puvvada[6], JF Gerecitano[7], TJ Kipps[8], MA Anderson[9], DC Huang[10], NK Rudersdorf[11], LA Gressick[11], NP Montalvo[11], J Yang[11], M Zhu[11], M Dunbar[11], E Cerri[11], SH Enschede[11], RA Humerickhouse[11], AW Roberts[9]
[1]Peter MacCullum Cancer Center, Melbourne, Australia, [2]Dana Farber Cancer Institute, Boston, [3]University of Washington, Seattle, [4]University of Wisconsin, Madison, [5]University of Texas, Houston, [6]The University of Arizona, Tucson, [7]Memorial Sloan-Kettering Cancer Center, New York, [8]The University of California San Diego, San Diego, United States, [9]Royal Melbourne Hospital and Walter and Eliza Hall Institute of Medical Research, [10]Walter and Eliza Hall Institute of Medical Research, Melbourne, Australia, [11]AbbVie, North Chicago, United States

Background: Overexpression of BCL-2 in relapsed/refractory (R/R) Chronic Lymphocytic Leukemia (CLL) and Small Lymphocytic Lymphoma (SLL) is associated with resistance to both chemotherapy and apoptosis. ABT-199 is an orally bioavailable, selective BCL-2 inhibitor that triggers apoptosis of CLL cells *in vitro* and *in vivo*, independent of TP53 functional status, making it a promising agent for the treatment of patients (pts) with CLL/SLL, including those with high-risk disease features.
Aims: The primary objectives of this phase I study were to evaluate the safety and pharmacokinetics (PK) and to determine the maximum tolerated dose and a recommended phase 2 dose (RP2D) of ABT-199 monotherapy. A secondary objective was to assess preliminary efficacy.
Methods: Pts received daily oral ABT-199 until progressive disease (PD), intolerance or withdrawal. Following events of tumor lysis syndrome (TLS) early in the trial, a schedule with weekly dose increases to the target cohort dose (150-1200 mg) was implemented. Pts are now being enrolled in the safety expansion (SE) cohort incorporating a weekly ramp-up period from 20, 50, 100, 200 mg to the final RP2D of 400 mg.
Results: As of January 17, 2014, 93 pts (37 in the SE) were enrolled with a median time on study of 6.1 (range, 0 - 27) months. Twenty-three (24%) pts had del(17p), 55 (59%) had fludarabine (F)-refractory CLL, 32 of the 42 pts with available status have unmutated *IGHV*. The median number of prior therapies was 4 (range 1-11). The most common treatment-emergent AEs (>25% pts) of any grade were neutropenia (39%), diarrhea (36%), nausea (35%), upper respiratory tract infection (31%), and fatigue (27%). Grade 3/4 AEs (>5% pts) were neutropenia (36%), anemia (10%), TLS (8%, including 1 Gr5), thrombocytopenia (7%), hyperglycemia (7%), and febrile neutropenia and hypokalemia (6% each). Thirty-one pts discontinued treatment: 20 for progressive disease, 9 for AEs, and 2 for other reasons. Preliminary efficacy results are detailed in the Table 1.

Table 1.

	Total N=93	*IGHV* Unmutated n=32 (42 assessed)	Del (17p) n=23	F-Refractory n=55
Gender M/F	68/25	22/10	18/5	40/14
Age (median)	66	64	66	66
Median Baseline Lymphocyte Count (x 10^9/L)	5.9	5.9	7.0	5.9
Responses				
Total Evaluable*	70	23	21	39
CR/CRi, n (%)	14 (20)	4 (17)	3 (14)	6 (15)
PR, n (%)	39 (56)	13 (57)	12 (57)	23 (59)
SD, n (%)	11 (16)	4 (17)	4 (19)	8 (21)
PD, n (%)	2 (3)	1 (4)	1 (5)	1 (3)
D/C, n (%)	4 (6)	1 (4)	1 (5)	1 (3)
Response Rate (ORR, CR+PR)	76%	74%	71%	74%

**Evaluable pts exclude those with unconfirmed PR and those not yet evaluable. D/C: Discontinued prior to week 6 assessment. The median duration of response (DOR) was 20.5 months [95% CI; 13.8, -] for the 53 responding pts. At 12 months, 91% of CR and 67% of PR pts remain progression-free. Of the 14 CR/CRi pts, 9 were evaluated in local labs by flow cytometry for minimal residual disease (MRD); 5 were MRD negative and of these, 2 were IGHV unmutated, 4 were F-refractory, and 1 had del(17p). Summary and Conclusions: ABT-199 induces a high rate of response in pts with R/R CLL, including those with unmutated IGHV, del(17p), and F-refractory disease. Responses appear to be durable, especially in the 21% who achieved CR/CRi. Several of these high-risk pts achieved MRD negativity. Enrollment continues in the safety expansion cohort to further define safety and efficacy.*

S703

ABT-199 (GDC-0199) COMBINED WITH RITUXIMAB (R) IN PATIENTS (PTS) WITH RELAPSED / REFRACTORY (R/R) CHRONIC LYMPHOCYTIC LEUKEMIA (CLL): INTERIM RESULTS OF A PHASE 1B STUDY

AW Roberts[1,*] S Ma[2], T Kipps[3], JC Barrientos[4], MS Davids[5], MA Anderson[1], C Tam[6], T Mason-Bright[7], NK Rudersdorf[7], J Yang[7], W Munasinghe[7], M Zhu[7], E Cerri[7], SH Enschede[7], RA Humerickhouse[7], JF Seymour[6]
[1]Royal Melbourne Hospital and Walter and Eliza Hall Institute of Medical Research, Melbourne, Australia, [2]Northwestern University, Chicago, [3]University of California San Diego, San Diego, [4]Hofstra North Shore-LIJ School of Medicine, New Hide Park, [5]Dana Farber Cancer Institute, Boston, United States, [6]Peter MacCullum Cancer Center, Melbourne, Australia, [7]AbbVie, North Chicago, United States

Background: ABT-199 is a selective, orally bioavailable BCL-2 antagonist that induces rapid apoptosis of CLL cells and an approximately 80% response rate as monotherapy in pts with R/R CLL. As with DNA damaging chemotherapy, R synergizes with ABT-199 in preclinical models of CD20+ lymphoid cancers.
Aims: Objectives were to evaluate the safety, pharmacokinetics (PK), preliminary efficacy and to determine a maximum tolerated dose (MTD) / recommended phase 2 dose (RPTD) for ABT-199+R.
Methods: Pts began daily ABT-199 at 50 mg (modified to 20 mg) with weekly increases to a final cohort dose (200-600mg). R was then administered at a starting dose of 375 mg/m^2 then 500mg/m^2 monthly for total of 6 doses (cohort 1-2 had 2 additional weekly doses in month 1) with continuation of daily ABT-199 until progressive disease (PD). The MTD/RPTD for the combination will be determined by the Bayesian Continual Reassessment Method. Pts were assessed by CT scan at month 3 (followed by confirmation CT for responders per IWCLL 2008) and by CT scan and bone marrow (BM) biopsy after the end of combination therapy.
Results: As of Jan 17, 2014, 37 pts were enrolled in 5 cohorts (median age 68, 14/23 F/M) with a median time on study: 4.8 (range 0 - 15.2) months, median number of prior therapies: 2 (range 1 - 5); 9 pts were fludarabine-refractory, 9 R-refractory, and 9 had del(17p). Six pts discontinued: 4 due to PD (3 Richter's transformation, 1 progressive CLL), 1 withdrew consent, 1 due to fatal hyperkalemia in the setting of tumor lysis syndrome (TLS) at 1st dose (50 mg) prior to dose modification. The most common treatment-emergent adverse events (AEs, >25% pts) were neutropenia (43%), nausea (38%), diarrhea (30%). The most common grade (G) 3/4 AEs were neutropenia (43%), thrombocytopenia (16%), and anemia (11%). Nine pts had G4 AEs with 14 events (9 neutropenia, 4 thrombocytopenia, 1 hemophagocytic syndrome), of these, 6 pts had interruptions or reductions. All but 1, maintained at a reduced dose of 200 mg, resumed treatment at the final cohort dose. Two G4 events were dose limiting toxicities occurring on combination therapy (in cohort 2): thrombocytopenia (300mg/375mg/m^2) and hemophagocytic syndrome (300mg/500mg/m^2). Preliminary PK data suggest a negligible effect of R on ABT-199 exposure. Of 18 pts who have completed combination therapy or discontinued prior to completion, 7 (39%) achieved complete remission (CR/CRi) and 7 (39%) partial remission (PR). Minimal residual disease (MRD) was quantified by local laboratory in 6/7 CR pts: 4 pts are MRD negative in BM (3 at 10^{-4} and 1 at 10^{-3} sensitivity) and 1 in peripheral blood (10^{-3} sensitivity). Additional results are included in the Table 1 below:

Table 1.

Cohort	Dose	N	Months on Study (median)	Assessment	Responses
Pts evaluable for CR (≥6 mo or PD)					
1	200	6	14	CT & BM	2 CR/CRi, 4 PR
2	300	10	10	CT & BM	5 CR/CRi, 3 PR, 2 PD
3	400	1	-	-	
1 DC					
Pts not yet evaluable for CR (<6 mo)					
3	400	7	5	CT	2 PR, 4 uPR, 1 DC
4	500	6	3	CT	2 PR, 4 uPR

**uPR: unconfirmed partial remission; DC: discontinued*

Summary and Conclusions: To date, the RPTD of R+ABT-199 has not been determined and dose escalation continues. No additional toxicities have been identified when compared to ABT-199 monotherapy. The combination is active in R/R CLL, with a number of patients achieving CR with MRD negativity. A fatal episode of TLS occurred during the ABT-199 lead-in period (prior to R). Following dosing and monitoring modifications, no further TLS events were reported.

S704

SECOND INTERIM ANALYSIS OF A PHASE 3 STUDY EVALUATING IDELALISIB AND RITUXIMAB FOR RELAPSED CLL

SE Coutre[1,*] RR Furman[2], JP Sharman[3], BD Cheson[4], JM Pagel[5], P Hillmen[6], JC Barrientos[7], AD Zelenetz[8], TJ Kipps[9], IW Flinn[10], P Ghia[11], HA Eradat[12], N Lamanna[13], B Coiffier[14], A Pettitt[15], X Li[16], TM Jahn[16], SM O'Brien[17], MJ Hallek[18]

[1]Stanford Cancer Center, Stanford University School of Medicine, Stanford, [2]Weill Cornell Medical College, New York, [3]Willamette Valley Cancer Institute and Research Center/US Oncology Research, Springfield, [4]Georgetown University Medical Center, Washington, [5]Fred Hutchinson Cancer Research Center, Seattle, United States, [6]The Leeds Teaching Hospitals, St. James Institute of Oncology, Leeds, United Kingdom, [7]Hofstra North Shore-LIJ School of Medicine, Hampstead, [8]Memorial Sloan Kettering Cancer Center, New York, [9]University of California School of Medicine, San Diego, [10]Sarah Cannon Research Institute, Nashville, United States, [11]Università Vita-Salute San Raffaele and Istituto Scientifico San Raffaele, Milano, Italy, [12]David Geffen School of Medicine at University of California, Los Angeles, Los Angeles, [13]Memorial Sloan-Kettering Cancer Center, New York, United States, [14]Lyon Sud University Hospital, Pierre-Bénite, France, [15]University of Liverpool, Liverpool, United Kingdom, [16]Gilead Sciences, Foster City, [17]University of Texas MD Anderson Cancer Center, Houston, United States, [18]University of Cologne, Cologne, Germany

Background: Idelalisib (IDELA), an oral inhibitor of PI3Kδ, is highly active in heavily pretreated patients with CLL as a single agent or combined with rituximab (R) as demonstrated in Phase 1 trials.
Aims: This report presents the results from the second interim analysis of a Phase 3, randomized, double-blind, placebo-controlled study of IDELA+R *vs.* placebo (PBO)+R.
Methods: Patients with CLL requiring therapy after progression <24 mos since completion of last therapy and considered unfit to receive cytotoxic therapy were enrolled. Primary endpoint PFS was assessed by IRC and standard criteria (Hallek 2008, Hallek 2012, Cheson 2012). After progression, patients could enroll into a blinded extension study to receive IDELA at 150 mg BID (prior PBO+R) or 300 mg BID (prior IDELA+R). The first interim analysis (Furman *et al.*, NEJM 2014) led to the decision of early termination due to overwhelming efficacy.
Results: A total of 220 patients (110 patients on each arm) with a median age of 71 yrs (78% ≥65 yrs), a median time since diagnosis of 8.5 yrs, and a median number of 3 prior therapies (range: 1-12) were randomized. 44% of patients had del(17p)/*TP53* mutation, 84% had unmutated *IGHV*. The Table 1 summarizes efficacy and safety.

Table 1.

Summary and Conclusions: Similar to the first interim analysis, IDELA+R demonstrated significant improvement in progression-free survival, overall response rate, and lymph node response rate, compared to control, with acceptable safety. The overall survival of patients on IDELA+R remained superior, including patients that crossed over into the extension study.

S705

A PHASE I STUDY OF THE ORAL BTK INHIBITOR ONO-4059 IN PATIENTS WITH RELAPSED/REFRACTORY AND HIGH RISK CHRONIC LYMPHOCYTIC LEUKAEMIA (CLL)

C Fegan[1,*] J Bagshawe[1], G Salles[2], L Karlin[2], S Rule[3], N Shah[3], F Morschhauser[4], L Terriou[4], M Dyer[5], C Hutchinson[5], G Cartron[6], H Honda[7], J Sharpe[7], H Tani[7], T Yoshizawa[8], T Yasuhiro[8], J Birkett[7]

[1]University Hospital of Wales, Cardiff, United Kingdom, [2]Centre Hospitalier Lyon Sud, Pierre-Benite, France, [3]Derriford Hospital, Plymouth, United Kingdom, [4]CHRU - Hôpital Claude Huriez, Lille, France, [5]Leicester Royal Infirmary, Leicester, United Kingdom, [6]CHU - St Eloi, Montpellier, France, [7]Ono Pharma UK Ltd, London, United Kingdom, [8]Ono Pharmaceutical Co., LTD., Osaka, Japan

Background: Bruton's tyrosine kinase (BTK) is a critical kinase involved in B-cell receptor signal transduction. ONO-4059, a highly potent and selective oral BTK inhibitor has demonstrated anti-tumour activity in pre-clinical models (Yasuhiro *et al.*, AACR2013) and in the clinic in both NHL and CLL patients (Salles *et al.*, ASH 2013; Rule *et al.*, ASH 2013). Here, we present data from CLL patients enrolled in the ongoing Phase I study ONO-4059POE001.
Aims: Twenty five CLL patients were administered ONO-4059 as monotherapy, given once daily (QD) to determine safety, pharmacokinetics and pharmacodynamics, and preliminary efficacy. Patients can receive ONO-4059 for up to a maximum of 2 years and upon completion of the first 6 months of treatment, intra-patient dose escalation is permitted. Here, we present data for 25 evaluable patients treated with ONO-4059 at doses ranging from 20-600mg (8 cohorts). Patients had a median age 67 yrs [range 40-79], median baseline tumour burden 5,125 mm^2 [461-19,750 mm^2], median of 4 prior therapies [2-8], including fludarabine (23/25) and rituximab-containing therapy (22/25). Baseline median haematology parameters included hemoglobin 11.1 g/dL [8.5-15.2], WBC 41.2x10^9/L [2.1-394.8], platelets 97x10^9/L [23-185], lymphocytes 37.4x10^9/L [0.5-391], neutrophils 2.39x10^9/L [0.5-11.1]. 8/22 patients were 17p deleted [36%] and 6/22 had the 11q deletion [27%], 19/22 were IgVH unmutated status [86%], with 12/22 [55%] displaying TP53 mutation.
Results: ONO-4059 was found to be well tolerated. A total of 44 ONO-4059-related Grade 1 (27) and 2 (17) adverse events were reported in 18 out of 25 patients. Eleven ONO-4059-related G3 or G4 haematological toxicities were reported in 6 patients and were infrequent and independent of dose; with neutropenia in 5 patients, [G3 x5, G4 x3]), febrile neutropenia in 1 patient [G3] and leucopenia in 2 patients [G3 x2]. Only 3 Grade 3 ONO-4059-related non-haematological events were reported (pyrexiax2, back painx1). Seven ONO-4059-related SAEs were reported in 4 patients (febrile neutropenia [G3] and pyrexia [G3 x2] at 20 mg; rash [G2] at 80 mg, neutropenia [G4] at 320 mg, purpura [G2] and back pain [G3] at 400 mg). All patients experienced rapid reductions in lymphadenopathy observed early in treatment, between D1-D28 of the first cycle, accompanied by an increase in absolute lymphocyte count in some (67%), but not all patients. Best overall response rate according to IWCLL criteria (including modified PR with lymphocytosis) was 90% [based on CT-scan and P/E for 21/25 evaluable patients with 14 PR, 5 PR with lymphocytosis (for 19 responding patients, median reduction of lymph nodes was 79% [Range 52-100]), 1 SD and 1 PD]. Improvements in hemoglobin and platelets were observed from 3 months onwards. To date, 22 of 25 patients remain on treatment with a median duration of treatment of 270 days [Range 1-540].
Summary and Conclusions: In conclusion, ONO-4059 is a highly potent and selective oral Btk inhibitor with a favourable safety profile along with promising efficacy in this heavily pre-treated population, with responses observed in relapsed, refractory and 17p deleted patients and/or TP53 mutated patients.

S706

THE ADDITION OF CD20 MONOCLONAL ANTIBODY TO LENALIDOMIDE IMPROVES RESPONSE RATE AND SURVIVAL IN RELAPSED/REFRACTORY PATIENTS WITH CHRONIC LYMPHOCYTIC LEUKEMIA

PA Thompson[1,*] MJ Keating[1], WG Wierda[1], L Falchi[1], SM O'Brien[1], A Ferrajoli[1]
[1]Department of Leukemia, UT MD Anderson Cancer Center, Houston, United States

Background: Lenalidomide is an immunomodulatory drug active in CLL. The benefit of combination therapy with CD20 mAb compared to Lenalidomide monotherapy (Len) in patients (pts) with CLL is unknown.
Aims: Compare the experience with Len and Len+CD20 mAb in relapsed/refractory (R/R) pts with CLL.
Methods: We studied 139 R/R pts treated with Len *vs.* Len+CD20 mAb at MDACC from 2005-2011; 44 received Len, 59 Len+rituximab (LR) and 36 Len+ofatumumab (LO). We analyzed baseline characteristics associated with response, time-to-treatment failure (TTF), overall survival (OS) and toxicity requiring study cessation.
Results: Groups were similar (Table 1); Len pts were more heavily pre-treated. The following were associated with higher ORR: treatment with Len+CD20 mAb, mutated *IGHV* gene, 73% *vs.* 50%, p=0.03 and B2M <4.0 mg/l, 64% *vs.* 46%, p=0.04. On multivariable analysis (MVA), receiving Len+CD20 mAb was the only independent characteristic associated with higher ORR, [OR 3.8 (1.6-8.4), p=0.002]. Median time to CR was 12mo (3-31), without significant difference between groups. Median TTF was 35 *vs* 28 *vs* 17mo for CR *vs.* nPR *vs* PR, p=0.001. Achieving a response correlated with OS; median OS was 17mo in non-responders *vs.* not reached (NR) at a median follow-up of 43mo in responders, p=0.008. Baseline characteristics associated with shorter OS were: unmutated *IGHV* (37mo *vs.* NR, p=0.01), B2M ≥4.0 (23 *vs.* 71mo, p<0.001), del17p (25 *vs.* 62mo, p=0.005) and fludarabine-refractory CLL (17 *vs.* 62mo, p=0.004). In MVA, the following were independently associated with OS: treat-

ment with Len+CD20 mAb [HR 0.46 (0.27-0.80), p=0.005]. B2M ≥4.0 [HR 2.64 (1.56-4.50), p<0.001], unmutated *IGHV* [HR 2.68 (1.11-6.45), p=0.01], del17p [HR 1.61 (1.0-2.57), p=0.001] and fludarabine-refractory disease [HR 1.91 (1.11-3.29), p=0.02]. Treatment was discontinued due to toxicity in 11 pts (9 in LO and 2 in LR); most common reasons for discontinuation were prolonged cytopenia in 4 cases and infection in 2. One case of tumor flare reaction requiring treatment cessation was seen in the LO group. Age >70 was associated with more frequent cessation for toxicity (22 *vs*. 5%), p=0.007 (Figure 1).

Table 1.

Characteristic	Len (n=44), n(%)	LR (n=59), n(%)	LO (n=34), n(%)	P value
Age (median, range)	63 (49-86)	62 (42-83)	63 (34-82)	0.29
IGHV Unmutated	35 (80)	43 (73)	23 (64)	0.177
N. prior therapies (Median, range)	4 (1-15)	2 (1-9)	2 (1-8)	0.001
B2M ≥4.0 (mg/l)	24 (60)	24 (40)	21 (62)	0.14
17p-	8/42 (19)	15/57 (26)	9/28 (32)	0.45
Fludarabine-refractory	13 (30)	13 (22)	7 (21)	0.58
Rai III/IV	23 (52)	28 (47)	21 (62)	0.52
ORR	14 (32)	39 (66)	23 (68)	0.001
CRR	9	12	9 (26.5)	0.07
TTF in responding pts (mo)	17	25	23	0.26
OS (mo), median	20	NR at 50mo	NR at 39mo	0.008

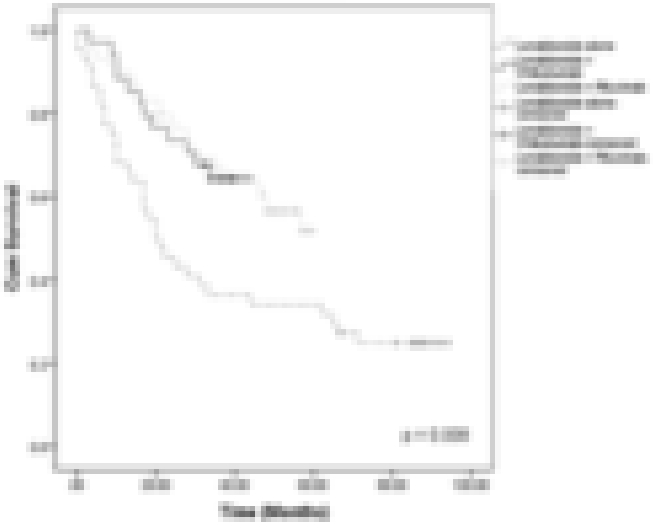

Figure 1. Overall survival according to treatment group.

Summary and Conclusions: Within the limitations of comparing outcomes across studies, addition of CD20 mAb to Len in R/R pts appears to improve response and survival. Achieving CR was associated with longer response duration. B2M ≥4.0, unmutated *IGHV* gene, del17p and fludarabine-refractory disease are all independently associated with worse outcomes, including OS. Prospective confirmation of these findings is warranted.

S707

RECURRENT ETNK1 KINASE DOMAIN MUTATIONS IN SYSTEMIC MASTOCYTOSIS WITH ASSOCIATED EOSINOPHILIA

T Lasho[1], C Finke[1], D Zblewski[1], R Abdelrahman[1], M Patnaik[1], R Knudson[2], K Reichard[3], R Ketterling[2], C Hanson[3], A Tefferi[1], A Pardanani[1,*]
[1]Hematology, [2]Cytogenetics, [3]Hematopathology, MAYO CLINIC, Rochester, United States

Background: While systemic mastocytosis (SM) in adult patients is virtually universally characterized by the *KIT*D816V mutation, there is considerable clinical heterogeneity, suggesting additional genetic or epigenetic events. Studying somatic genetic changes in mast cells is challenging due to their relative inaccessibility in peripheral blood (PB) and bone marrow samples. Up to 30% of SM patients exhibit PB eosinophilia (Lim *et al.* Blood 2009). Further, eosinophils are relatively easily isolated (≥97% purity) and represent the neoplastic clone in such patients (Pardanani *et al.* Leuk Res 2003).
Aims: To identify somatic genetic changes in purified eosinophils from a patient with SM with eosinophilia, using whole exome sequencing.
Methods: The study was approved by our institutional review board. Eosinophils (tumor) were isolated as CD16- cells from the PB granulocyte fraction and T-lymphocytes (non-tumor) were isolated from the PB mononuclear cell fraction by CD3-antibody labeled magnetic-bead separation. Matched genomic libraries were prepared and submitted for exome sequencing. Data were analyzed using the GeneSifter® Software (Perkin Elmer). Post-processed alignments from eosinophils were compared to alignments from the T-lymphocytes to make calls for somatic variants. We initially focused on identifying exonic non-synonymous single nucleotide variants (SNVs). Candidate mutations were validated by Sanger sequencing.
Results: Our experimental design was validated by the observation that heterozygous *KIT*D816V was present in eosinophils (69 reads, 46.4% mutant), but not in T-lymphocytes. Other somatic mutations of interest were: *EZH2*H694R, chr7 position 148506431 (32 reads, 100% mutant), *STAT5*αV707E, chr17 position 40461400 (9 reads, 67% mutant) and *ETNK1*N244S, chr12 position 22811995 (37 reads, 49% mutant). All 3 mutations were validated by targeted resequencing. We conducted targeted sequencing of *STAT5*α and *ETNK1* in 50 patients with SM (23 with eosinophilia), and 25 patients each with myelofibrosis, primary eosinophilia and chronic myelomonocytic leukemia (CMML). No *STAT5*α mutations were identified; however, 9 additional patients carried *ETNK1* mutations (10 total), all within the evolutionarily conserved choline kinase domain. *ETNK1* mutation prevalence was 10% in SM (22% and 0% with and without eosinophilia, respectively; N244S=3, G245A=2), 16% in CMML (all without eosinophilia; N244S=2, N244K/T=1 each), and 4% in primary eosinophilia (N244S=1). *ETNK1* (ethanolamine kinase 1; *EKI1*) catalyzes the rate-controlling step in phosphatidylethanolamine biosynthesis. Ethanolamine is a major membrane phospholipid, in the form of glycerophosphoethanolamine and is also a component of the glycosylphosphatidylinositol (GPI) anchor, which is necessary for cell-surface protein attachment. Computational tools for predicting the functional consequence of non-synonymous SN*Vs* suggested that the aforementioned *ETNK1* mutations were functionally deleterious (http://snps.biofold.org/ phd-snp/phd-snp.html; http://genetics.bwh.harvard.edu/pph2/index.shtml).
Summary and Conclusions: We identified recurrent somatic mutations targeting the kinase domain of *ETNK1*. The mutations appeared to cluster in patients with SM with eosinophilia or CMML. The COSMIC database lists only 2 missense *ETNK1* mutations in hematologic malignancies (one case each with H243Y in atypical chronic myeloid leukemia and N244S in myelodysplastic syndrome). These data suggest that *ETNK1* mutations have pathogenetic significance in myeloid malignancies, particularly SM with eosinophilia. We have cloned full length wild type and mutant *ETNK1* into expression vectors and are pursuing functional studies for confirmation.

S708

DOWN-REGULATION OF THE RIBOSOMAL PROTEIN S14 PATHWAY CONTRIBUTES TO IMPAIRED MEGAKARYOPOIESIS IN PRIMARY MYELOFIBROSIS

L Gendre-Gilles[1,*] T Lasho[2], A Tefferi[2], J Crispino[1]
[1]Hematology/Oncology, Northwestern University, Chicago, [2]Department of Medicine, Mayo Clinic, Rochester, United States

Background: Primary myelofibrosis (PMF) is a clonal hematologic malignancy resulting from the transformation of a pluripotent hematopoietic progenitor cell. A major consequence of this transformation is increased hematopoiesis and an overproduction of abnormal blood cells. PMF is associated with bone marrow fibrosis, extramedullary hematopoiesis, increased numbers of circulating $CD34^+$ cells, splenomegaly, and a propensity to evolve to AML. Patients also display anemia and thrombocytopenia and harbor abnormal, immature megakaryocytes (Mks) in their bone marrow and spleen. PMF patients can present well known mutations including JAK2V617F (65%), MPL (10%), TET2 (17%), CBL (6%), IDH

(4%,), which are not specific to the disease. Recently it has been revealed that most of patients not mutated for JAK2 carry a CALR mutation.
Aims: We hypothesize that the genetic events associated with PMF contribute to defects in Mk maturation, but that additional changes are needed to explain the striking abnormalities seen in PMF relative to the other myeloproliferative diseases. We chose to examine the changes that occur in gene expression of Mks as a way to better understand their abnormal differentiation and to determine their contribution to the disease.
Methods: Primary $CD34^+$ cells from PMF patients and healthy donors were cultivated for 9 days in media without serum and supplemented with thrombopoeitin. Cells were then analysed for their phenotype and their gene expression.
Results: Primary $CD34^+$ cells from PMF patients and healthy donors were cultivated for 9 days. We found that PMF specimens gave rise to a lower percentage of mature ($CD41^+CD42^+$) Mks as compared to healthy donors associated with a lower ploidy level and a greater proliferation. These observations are consistent with the clinical observations that PMF bone marrow is characterized by an increased number of immature, dysplastic Mks. $CD41^+CD42^+$ mature MKs derived from healthy and PMF $CD34^+$ were sorted by flow cytometry. Then, RNA was extracted and whole genome microarray analysis was performed with Illumina Human HT12-v4 arrays. In PMF samples, myeloid transcription factors including CEBP, GFI1, and SPI1 (PU.1), are strikingly and significantly overexpressed. Moreover, c-myb, which regulates the erythroid/Mk cell fate decision, FOG-1 and AML1, are also overexpressed in PMF Mks. This aberrant myeloid gene expression program in PMF Mks is reminiscent of a similar defect we observed in Mks with reduced expression of GATA-1 and GATA-2. Gene Set Enrichment Analysis (GSEA) analysis revealed down-regulation of the RPS14 (Ribosomal protein S14) pathway, which was first described in myelodysplastic syndrome 5q- where this protein is absent. Using two different shRNAs directed against *RPS14*, we show that its down-regulation in primary $CD34^+$ leads to a strong reduction of Mk differentiation, reproducing the phenotype observed with patient samples. Conversely, over-expression of RPS14 in PMF $CD34^+$ cells partially restores their differentiation. As expected, down-regulation of the RPS14 pathway is accompanied with p53 pathway activation. Moreover in wild-type megakaryocytes, down-regulation of RPS14 leads to a reduction of GATA-1 protein level. As GATA-1 has previously been shown to be reduced in PMF Mks, we over-expressed GATA-1 in primary culture of PMF $CD34^+$ with a lentivirus and followed their differentiation. In this condition we observed a greater percentage of $CD41^+CD42^+$ cells and a higher ploidy.
Summary and Conclusions: In conclusion, we show here for the first time the implication of ribosomal pathway in PMF pathogenesis. Since the over-expression of RPS14 or GATA1 partially restore Mk differentiation of PMF patients, these novel findings open new avenue for therapeutic options in PMF.

S709

GENETIC STUDIES REVEAL JAK2 IS NOT ESSENTIAL FOR PLATELET PRODUCTION

SC Meyer[1,*] M D Keller[1], B A Woods[1,2], L M LaFave[1,2], L Bastian[1], M Kleppe[1], N Bhagwat[1], S Marubayashi[1], R L Levine[1,3]
[1]Human Oncology and Pathogenesis Program, Memorial Sloan Kettering Cancer Center, [2]Gerstner Sloan Kettering School of Biomedical Sciences, [3]Leukemia Service, Department of Medicine, Memorial Sloan Kettering Cancer Center, New York, United States

Background: The intensity of JAK kinase inhibitor treatment has been limited by cytopenias, which are thought to be due to on-target JAK2 inhibition. However, the role of JAK2 signaling in megakaryopoiesis has not been evaluated.
Aims: We studied the significance of JAK2 for platelet formation.
Methods: We conditionally deleted *Jak2* in thrombopoiesis through Cre-recombinase-mediated deletion under the control of the Pf4 promoter. We evaluated the impact of *Jak2* deletion in platelets on blood counts, stem/progenitor frequencies, and Jak-Stat signaling.
Results: Pf4-Cre-mediated *Jak2* deletion resulted in abrogation of Jak2 mRNA expression in platelets and in a modest, but significant reduction in megakaryocyte progenitors (MkP, mean reduction 33%, p=0.029). Jak2 mRNA expression was unaffected in Pf4+ $Jak2^{f/f}$ meg-erythroid progenitors (Pre-MegE, p=0.618) and $Lin^-Sca1^+Kit^+$, cells (LSK, p=0.802). Pf4-Cre mediated *Jak2* deletion abolished Jak2 protein expression in Pf4+ $Jak2^{f/f}$ platelets while platelet expression of the thrombopoietin receptor Mpl was not significantly affected. In response to thrombopoietin (Tpo) stimulation, Jak2, Tyk2, Stat3 and Stat5 were not phosphorylated in Pf4+ $Jak2^{f/f}$ platelets in contrast to littermate controls with intact Jak2. Platelet-specific *Jak2* deletion *in vivo* did not result in any reduction of platelet counts, but in significant and progressive thrombocytosis. Average platelet counts in Pf4+ $Jak2^{f/f}$ mice were 4720 G/l (3436-6460 G/l, p<0.0001 *vs.* controls) at 2 months, 3965 G/l (2820-4920 G/l, p<0.0001) at 3 months, 6966 G/l (5008-7884 G/l, p<0.0001) at 4 months and 5966 G/l (3204-7892 G/l, p<0.0001) at 5 months of age. Pf4+ $Jak2^{f/f}$ mice also showed moderate leukocytosis with a mean white blood cell count of 23.7 G/l (compared to 11.9 G/l in controls, p=0.005) suggesting cell non-autonomous effects of Jak2 loss in platelets on megakaryocyte progenitors and hematopoietic stem/progenitor cells with intact Jak2. Pre-MegE were 2-fold (p<0.0001) and MkP 9-fold (p=0.0001) expanded in Pf4+ $Jak2^{f/f}$ mice consistent with expansion of non-*Jak2* deleted progenitors. We observed increased megakaryocyte formation from Pf4+ $Jak2^{f/f}$ bone marrow or from sorted Pf4+ $Jak2^{f/f}$ Pre-MegE or MkP. Platelet-specific Jak2 loss affected hematopoietic stem/progenitor cells *in vivo* with 5- to 6-fold expansion of LSK cells (p<0.0001) which formed higher numbers of megakaryocytic colonies on a per-cell basis than LSK from controls. The proportion of $c\text{-}Kit^{hi}Lin^-Sca1^+Kit^+CD150^+CD48^-$, hematopoietic stem cells in Pf4+ $Jak2^{f/f}$ mice was increased, suggesting LSK expansion was due in part to expansion of megakaryocyte-biased $c\text{-}Kit^{hi}$ stem cells. Serum Tpo levels remained elevated in Pf4+ $Jak2^{f/f}$, mice at a 6.9-fold higher level (Tpo 2524 +/- 230 pg/ml, p<0.0001) as compared to MPL W515L mice with similarly increased platelet counts but markedly reduced serum Tpo levels as compared to control mice (Tpo 230 +/- 37 pg/ml in MPL W515L *vs.* 2787 +/- 204 pg/ml in controls, p<0.0001) Surface expression of Mpl in Pf4+ $Jak2^{f/f}$ platelets was modestly decreased consistent with reduced thrombopoietin internalization/turnover by Jak2-deficient platelets.
Summary and Conclusions: These data demonstrate that JAK2 is dispensable for the production of platelets. Jak2 loss in platelets leads to altered regulation of serum thrombopoietin and cell non-autonomous expansion of stem/progenitor cells. These data suggest the effects of JAK inhibitors on platelet counts are not due to JAK2 inhibition in platelets, but likely due to inhibition of other targets or as a consequence of JAK2 kinase inhibition in stem/progenitor cells.

S710

THE COMBINATION OF JAK INHIBITOR RUXOLITINIB, PAN-PIM INHIBITOR LGH447, AND CDK4/6 INHIBITOR LEE011 IN A PRECLINICAL MOUSE MODEL OF MYELOPROLIFERATIVE NEOPLASIA

M Pinzon-Ortiz[1], X Rong[1], A Saci[1], G Vanasse[1], R Schlegel[1], G Caponigro[1], ZA Cao, [1,*]
[1]Novartis Institutes for BioMedical Research, Cambridge, United States

Background: The JAK/STAT axis is a critical component downstream of multiple cytokine and growth factor receptor signaling pathways. The genetic aberration of *JAK2* V617F and the associated activation of STAT in myeloproliferative neoplasia (MPN) is one example of the involvement of this pathway in human cancer. Activated JAKs phosphorylate STAT proteins, which then upregulate the transcription of STAT target genes, such as *PIM1*. Pim kinases are involved in the regulation of the cell-cycle and proliferation. The inhibition of JAK1/2 by the JAK inhibitor ruxolitinib results in suppression of the JAK/STAT pathway and promotes significant clinical benefit in patients with myelofibrosis. Our previous preclinical studies in a Ba/F3-*JAK2* V617F–driven MPN model demonstrate that the combination of ruxolitinib and the pan-PIM inhibitor LGH447 exhibits greater inhibition of spleen weight increase and some reduction of *JAK2* V617F allele burden compared with ruxolitinib monotherapy. Mutant *JAK2* V617F has been shown to increase CDC25A transcription through activated STAT5. It also regulates p27 at both the gene expression and phosphorylation levels. The activation of CDC25A and modulation of p27 have been postulated to trigger the activation of cyclin-dependent kinases (CDK), such as CDK4, to initiate cell-cycle progression. Additionally, activated STATs and Pims have been shown to activate D cyclins that are upstream of CDK4/6.
Aims: Here, we explored the hypothesis that CDK4/6 inhibition, in conjunction with JAK and PIM inhibition, would enhance therapeutic efficacy against MPN.
Results: LEE011 is a potent and selective inhibitor of CDK4/6. The combination of ruxolitinib and LEE011 was tested in an MPN model with Ba/F3 cells harboring EPOR-*JAK2* V617F. While ruxolitinib monotherapy reduced spleen weight and total tumor burden by more than 50%, it had a marginal effect on *JAK2* V617F allele burden in this model. The combination of ruxolitinib and LEE011 resulted in an additional 2- to 3-fold reduction in spleen weight and total tumor burden. Yet no clear modulation of *JAK2* V617F allele burden was observed. To further enhance the antitumor activity, we tested the triple combination of ruxolitinib, LGH447, and LEE011 in this MPN model. This triple combination resulted in a >99% reduction in total tumor burden and an ≈ 96% reduction in spleen weight. Furthermore, the triple combination of ruxolitinib, LGH447, and LEE011 significantly downmodulated *JAK2* V617F allele burden by >80%.
Summary and Conclusions: Our preclinical data indicate that the triple combination of ruxolitinib, CDK4/6 inhibitor LEE011, and pan-PIM inhibitor LGH447 may preferentially impact the *JAK2* V617F–mutant MPN clones. This combination also achieved greater reductions in tumor burden and spleen weight in our preclinical MPN model. Therefore, potentially greater therapeutic benefit in subgroups of MPN patients may be achieved with the triple combination of ruxolitinib, LGH447, and LEE011.
Note: M Pinzon-Ortiz and X Rong contributed equally to this abstract.

S711

THE HISTONE METHYLTRANSFERASES MLL2 AND MLL4 CONSTITUTE NOVEL NF-E2 TARGET GENES

C Köllerer[1,*] L Pahl[1], J Wehrle[1]
[1]Section of Molecular Hematology, Department of Hematology/Oncology, University Medical Center Freiburg, Center for Clinical Research, Freiburg, Germany

Background: Expression of the transcription factor and epigenetic modulator "nuclear factor erythroid-2" (NF-E2) is aberrantly elevated in patients with Myeloproliferative Neoplasms (MPN). We have shown that NF-E2 overexpression in a murine model causes a phenotype similar to MPN in humans. This includes thrombocytosis, leukocytosis, expansion of the stem- and progenitor cell compartments as well as spontaneous transformation to acute leukemia. Recently, we have identified in-del mutations in the NF-E2 gene in MPN patients. These alterations lead to the formation of truncated proteins, which, despite having lost the ability to bind DNA, nonetheless increase the activity of wild type NF-E2. However, as few target genes of NF-E2 are known, the downstream pathways by which this augmented transcription factor activity exerts its effects remain unknown.
Aims: We therefore sought to identify novel NF-E2 target genes in order to both understand how increased NF-E2 activity contributes to MPN pathophysiology as well as to identify novel drug targets in these etiologies.
Methods: We used lentivirally driven NF-E2 overexpression as well as RNAi mediated NF-E2 silencing in CD34-positive cells to identify novel NF-E2 targets.
Results: Here, we report that the histone methyltransferases MLL2 and MLL4 constitute novel NF-E2 target genes. *In silico* analysis revealed NF-E2 binding to distinct sites in both the MLL2 and MLL4 genes *in vivo* by chromatin immunoprecipitation sequence analysis (ChIP-seq). We confirmed these *in silico* data by ChIP analysis. In HEL cells, NF-E2 binds a site located at bp -1000 in the MLL2 promoter as well as three distinct sites located at -500bp, -20kb and -46kb of the MLL4 promoter. In reporter gene assays, co-transfection of NF-E2 and its obligate heterodimer, MafG, significantly increased MLL2 driven luciferase activity, demonstrating that NF-E2 transactivates transcription of this gene. Most importantly, quantitative RT-PCR showed an increase in MLL2 and MLL4 mRNA in patients with polycythemia vera (PV) compared to healthy controls. Hence, the expression of these epigenetically active enzymes is augmented in PV patients. The MLL4 protein (in the literature also referred to as MLL2) has been previously shown to interact with NF-E2. NF-E2 is required for recruitment of MLL2 to the β-globin locus and for chromatin remodeling and establishment of H3K4me3 and H3K79me3 histone marks at these sites. Our data establish a novel interaction network where NF-E2 both regulates the expression levels of MLL4 while at the same time modulating its epigenetic activity at NF-E2 target genes.
Summary and Conclusions: We therefore conclude that the histone methyltransferases MLL2 and MLL4 are novel NF-E2 target genes and propose that elevated NF-E2 levels in MPN patients contribute to disease pathophysiology in part by affecting histone methylation. These data provide a molecular basis for pre-clinical investigation into the effects of histone methyltransferase inhibitors on MPN cell biology.

Allogeneic stem cell transplantation

S712

HAPLOIDENTICAL STEM CELL TRANSPLANTATION OUTCOME IS NOT INFERIOR TO MATCHED RELATED AND UNRELATED DONOR TRANSPLANTATION: AN INTENTION-TO-TREAT ANALYSIS OF 611 PATIENTS

F Ciceri[1,*], MT Lupo Stanghellini[1], F Giglio[1], R Greco[1], M Bernardi[1], C Bonini[1], M Marcatti[1], A Assanelli[1], C Bordignon[2], J Peccatori[1]
[1]Hematology and BMT Unit, San Raffaele Scientific Institute, [2]Hematology, Vita e Salute University San Raffaele, Milano, Italy

Background: Allogeneic transplantation of haemopoietic stem cells (HCT) from an HLA-matched related (MRD) or unrelated donor (MUD) is a curative option for patients (pts) affected by high-risk hematological diseases. Recently, protocols of HCT from family haploidentical donors based on unmanipulated graft have potentially extended to 100% of candidate patients the access to HCT as the best chance of cure.
Aims: We offered a haploidentical HCT to adult pts lacking a matched donor in the appropriate time according to clinical indications (www.leukemianet.org, www.ebmt.org) as part of tratment algorithm for primary disease.
Methods: Here we are reporting the intention-to-treat (ITT) analysis of HCT in all consecutive HRHD pts referred to our Institution between January 2004 and June 2012.
Results: Indication to HCT was given to 611 pts (median age 49 y, range 10-76; male 394), 120 pts (20%) received a transplant from a MRD; 187 pts (30%) activated a MUD search; 118 pts (19% of total pts, 63% of MUD searching) received a MUD transplant; 12 pts (2%) received a umbilical cord blood unit. Overall, 237 pts received a haplo-HCT (49%). The median time from indication to HCT was 87 days. The median time from indication to activation was 12 days and the median time from activation to HCT was 114 days (range 22-824). Lack of donor was not a limiting factor. Age was not a limiting variable to HCT execution: 107 patients (out of 487 SCT – 22%) were in the 60-69 range of age. The overall survival (OS) analysis in ITT for the entire population was 43% at 2 years, with a median time of survival of 767 days. The 2yOS in pts transplanted in CR was 60%, in pts transplanted in PD is 25% (p <0.001). The OS according to donor source (MRD *vs* MUD *vs* haplo-HCT) was comparable (p=ns) in pts transplanted in CR. The 2-year OS in pts affected by acute myeloid leukemia was 66%, 60% and 13% for patients transplanted in CR1, >CR1 and PD, respectively. The outcome analysis (OS, relapse incidence, transplant related mortality) per donor source was comparable (p=ns) within CR setting.
Summary and Conclusions: For many pts with HRHD, HCT from a MRD provides the best chance for long-term survival. However, only approximately 30% of individuals have a MRD. In our experience, haplo-HCT offers a concrete option of cure to HRHD pts: outcome results are superimposable to MRD and MUD in pts in CR at HCT. In ITT analysis, 80% of candidate pts received an HCT as a potential immunotherapy. All patients affected by HRHD, for whom an HCT is part of their therapeutic program, should proceed with a well-timed HCT whatever the stem cell source, and in the absence of a fully HLA-compatible donor the option of a haploidentical donor should be simultaneously considered.

S713

SUPERIOR SURVIVAL OF UNMANIPULATED HAPLOIDENTICAL HSCT COMPARED WITH CHEMOTHERAPY ALONE USED AS POST-REMISSION THERAPY IN ADULT STANDARD-RISK ACUTE LYMPHOBLASTIC LEUKEMIA IN FIRST COMPLETE REMISSION

CH Yan[1,*] Q Jiang[2], J Wang[2], LP Xu[2], DH Liu[2], H Jiang[2], H Chen[2], XH Zhang[2], KY Liu[2], XJ Huang[2]
[1]Institute of Hematology, [2]Peking University People's Hospital, Peking University Institute of Hematology, Beijing, China

Background: 40% - 50% adult patients with standard-risk ALL in CR1 still develope relapse. And, once relapse, overall survival (OS) at 5 years after relapse is only 15 - 25%. Studies have also shown that the outcome of adult standard-risk ALL in CR1 treated with HLA-identical sibling HSCT is better than treated with chemotherapy alone. However, lack of HLA-identical sibling has restricted the application of allo-HSCT in adult ALL patients. During last decade, the efficacy and safety of haploidentical HSCT have been confirmed to be comparable with HLA-identical sibling HSCT.
Aims: This study was performed to compare the efficacy of haploidentical HSCT with chemotherapy alone used as post-remission treatment of adult standard-risk ALL in CR1
Methods: Consecutive 163 adult patients with standard-risk ALL in CR1 in Peking University Institute of Hematology from January 1, 2000 to May 30, 2013 were retrospectively investigated. Out of these patients, 75 received chemotherapy alone (Group A) and 88 received unmanipulated haploidentical HSCT (Group B).
Results: Cumulative incidence of relapse at 5-year in Group A was significantly higher than those in Group B (68.8% *vs.* 26.7%, P<0.0001). The incidence of treatment-related mortality (TRM) at 5-year was 12.2% in Group A and 19.2%

in Group B (P=0.055). Besides, the OS and DFS in Group A were also significantly inferior to those in Group B (P<0.0001 and P<0.0001). Besides, multivariate analysis demonstrated that CNS leukemia (P=0.039, HR=4.832), T-cell immunophenotype (P=0.017, HR=5.493), expression of E2A-PBX1 (P=0.048, HR=10.312) and minimal residual disease (MRD)-positive before 2nd cycle of consolidation chemotherapy (P=0.008, HR=5.412) were significantly correlated with relapse. Based these risk factors, patients with one of four risk factors were assigned to high-risk group. Otherwise, patients without risk factors were assigned to low-risk group. In low-risk patients, even though the incidence of relapse at 5-year was higher in chemotherapy group than HSCT group (35.9% *vs.* 19.7%, P=0.026), the TRM at 5-year in chemotherapy group was lower than HSCT group (4.8% *vs.* 24.0%, P=0.123).Therefore, finally there were no differences in the OS and DFS between chemotherapy and HSCT (OS: 74.7% *vs.* 69.4%, P=0.861 and DFS: 59.3% *vs.* 56.3%, P=0.421). However, in high-risk patients, the incidence of relapse in chemotherapy group were statistically higher than HSCT group (81.0% *vs.* 34.8%, P<0.0001). And the OS and DFS at 3-year in chemotherapy group were only 5.8% and 5.0%; but the OS and DFS at 5-year in HSCT group were 66.5% and 51.7% (P<0.0001 and P<0.0001). In addition, the incidence of relapse, TRM, OS and DFS at 5-year in patients receiving HSCT in high-risk group were all comparable with patients receiving chemotherapy in low-risk group (relapse: 34.8% *vs.* 39.0%, P=0.351; TRM: 13.5% *vs.* 4.8%, P=0.413; OS: 66.5% *vs.* 74.7%, P=0.964; DFS: 51.7% *vs.* 59.3%, P=0.630). Figure 1. Relapse, treatment-related mortality, overall survival (OS) and disease-free survival (DFS) in all patients (n=163). (A) Cumulative incidence of relapse. (B) Cumulative incidence of treatment-related mortality. (C) OS. (D) DFS. One hundred and sixty three patients were finally enrolled in this study. Out of them, 75 patients received chemotherapy alone (Group A) and other 88 patients received haploidentical HSCT (Group B).

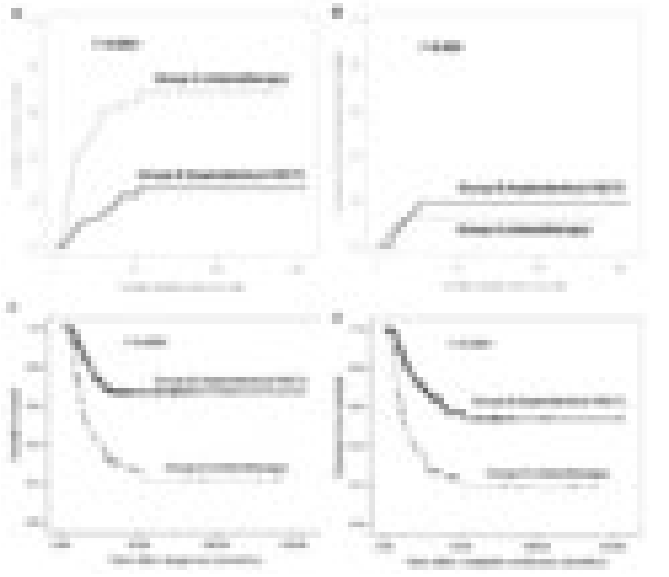

Figure 1.

Summary and Conclusions: This study is the first one to demonstrate the compared with chemotherapy alone, haploidentical HSCT is a better post-remission therapy in adult standard-risk ALL in CR1. Besides, based on the four risk factors, the establishment of risk-stratification could identify the subgroup of patients with higher risk of relapse in adult standard-risk ALL in CR1. Furthermore, risk-stratification directed post-remission therapies using haploidentical HSCT or chemotherapy alone not only reduce relapse rate, but also avoid unnecessary TRM, and finally improve survival.

S714

TREATMENT OF STEROID RESISTANT GRADE II TO IV ACUTE GVHD BY INFUSION OF MESENCHYMAL

L Van Der Wagen[1,2], L te Boome[2], C Mansilla[1], C Lindemans[3], M Cuijpers[2], K Westinga[4], E Petersen[2], E Spierings[1], M Bierings[3], JJ Boelens[1,3], N Wulffraat[1], I Slaper-Cortenbach[4], J Kuball[1,2,*]
[1]Immunology, [2]Hematology, [3]Pediatrics, BMT-Unit, [4]Cell Therapy Facility, Department of Clinical Pharmacy, UMC UTRECHT, Utrecht, Netherlands

Background: Despite major improvements in the last decade in the field of HSCT, acute graft *versus* host disease (aGVHD) remains a life-threatening complication and substantially reduces efficacy of HSCT. In particular, the outcome of patients with severe steroid-resistant aGVHD continues to be poor. Therefore, the search for new therapeutic strategies for the treatment of aGVHD remains of vital importance.

Aims: To test whether treatment of steroid refractory aGVHD patients with Mesenchymal Stromal Cells (MSC) is safe and feasible.
Methods: We expanded MSC using platelet lysate (PL) and infused them in patients with steroidrefractory GVHD. Furthermore immunological changes after infusion of MSC were characterized *in vitro*. Anti-viral and antileukemia responses of reactive T-cells were tested and phenotypical changes in immune cells were followed up as were cytokines implicated in GVHD. MSC from bone marrow of third party healthy volunteers were isolated via plastic adherence using the CellStack system of Macopharma, expanded with PL for up to three passages (P3), harvested using TripLE and stored. In an open-label, non-randomized prospective phase I/II study patients with steroid-refractory GVHD grade II to IV were treated with hPPL-MSC. 50 patients were included and received up to four infusions. Response rates, TRM and other adverse events were assessed for up to 12 months. In addition, a comprehensive phenotypical and functional analysis was performed with PBMCs and serum isolated from all patients before, during, and after infusion of MSC.
Results: The production of MSC using PL in CellStacks takes±22 days to expand from bone marrow to P3, resulting in a mean number of $59x10^5$ MSC per double layer CellStack. All batches fulfilled the release criteria. Between January 2009 and July 2012, 48 out of the 50 patients included were eligible for analysis, 7 children and 41 adults. Mean age was 44,9 years (range 1,3-68,9). Organs involved in aGVHD were the skin (52%), the GI tract (88%) and the liver (35%). Overall GVHD grade was II for 12 (25%), III for 33 (69%), and IV for 3 (6%) patients. Mean number of infusions were 3 (1–4). No severe side effects were observed upon infusions. Median follow up was 5,0 months (range 0,3-46,5). Complete overall response of aGVHD was observed in 24 patients (50%) after a median of 53 days (range 3–116 days). Overall survival was significantly improved in responders when compared to non-responders (p <0.001). Patients who relapsed with GVHD of the gut were again sensitive to steroids, except one patient who then responded well to a second cycle of MSC. Immunological monitoring shows that anti-viral and anti-leukemia reactive T-cells are well preserved in all patients who responded to MSC treatment. In addition, we identified a combination of biomarkers that already 2 weeks after initiation of treatment predicts a complete resolution of GVHD, whilst this usually only became clinically apparent after months.
Summary and Conclusions: Generation and infusion of MSC in patients suffering from steroid-resistant aGVHD grade II- IV is feasible, safe and appears to be effective. Infusion of MSC did not impair anti-virus or anti-leukemia reactive T-cells. Identified biomarkers predict early a usually late clinical resolution of GVHD and thus might be useful to early guide clinical decision making.

S715

USE OF HIGH-THROUGHPUT SEQUENCING TO MONITOR T CELL RECONSTITUTION FOLLOWING CORD BLOOD TRANSPLANT

C Delaney[1], R Emerson[2], F Milano[1], A Sherwood[2], A Papermaster[1], K Guthrie[1], C Carlson[1], E Warren[1], H Robins[1,*]
[1]Fred Hutchinson Cancer Research Center, [2]Adaptive Biotechnologies, Seattle, United States

Background: Cord blood transplant (CBT) recipients are at increased risk of transplant related mortality, in part due to delayed hematopoietic and immune system recovery resulting in increased infectious complications. However, without direct clinical measures of immunocompetence, the specific role of delayed immunity on CBT outcomes is not easily determined and intervention studies not possible.
Aims: We apply high-throughput sequencing of rearranged T cell receptor genes to monitor cellular adaptive immune reconstitution after myeloablative cord blood transplant. We compare our results to other available methods of assessing T cell reconstitution (TREC, CD3+ counts, spectratyping), and correlate our results with clinical outcomes.
Methods: We collected peripheral blood at several time-points (pre-transplant and at days 28, 56, 100, 180 and 365 post-transplant) in 34 consecutive patients undergoing myeloablative cord blood transplant for treatment of hematologic malignancies at Fred Hutchinson Cancer Research Center. All samples were subjected to multiplex amplification and high-throughput sequencing of somatically-rearranged T cell receptor loci. From these data, clonal presence and abundance of hundreds of thousands of clones were tracked for each time-point and total T cell diversity was estimated. Basic clinical outcomes for all patients were also determined, including GvHD, overall survival, disease free survival, regimen related toxicities and infectious complications.
Results: The results from high-throughput T cell receptor sequencing were generally concordant with spectratyping results when assessing patient T cell repertoire clonality post-transplant. However, the ability to track individual T cell clones demonstrated tremendous oscillation after cord blood transplant, with an almost entirely new T cell repertoire appearing at least monthly in CBT recipients. Furthermore, in contrast to healthy controls whose blood was sampled on a similar time-course, where the most frequent T cell clone at one time point remains dominant at subsequent time points, the largest clones observed early post-transplant in CBT recipients subsequently dropped below detection within weeks of direct measurement. Of the 34 patients studied, 19 died within one year of transplant. Despite the fact that most mortality was observed

≥100 days post-transplant, our estimated total T cell repertoire diversity values for these six patients were lower than those of the remaining patients by 100 days post-transplant (p-value=0.019 by permutation, see Figure 1). Neither TREC values nor absolute peripheral CD3+ counts showed a significant difference between outcome groups at 100 days post-transplant.

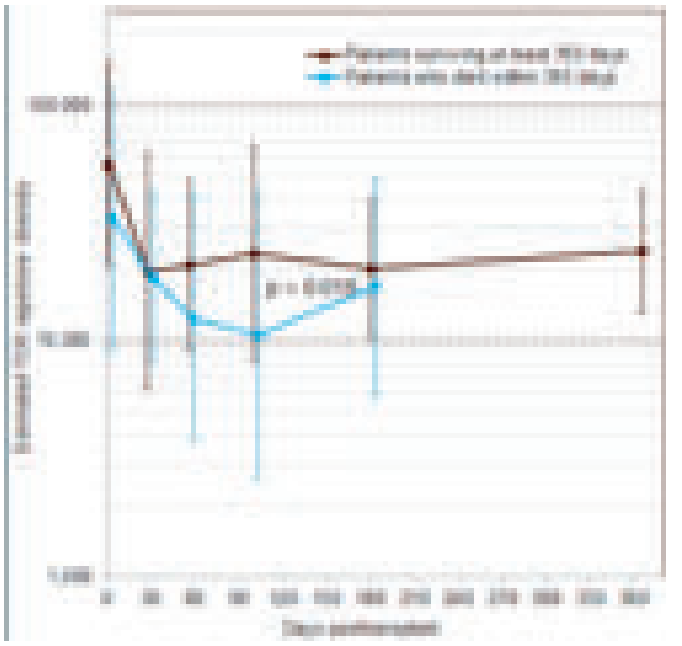

Figure 1.

Summary and Conclusions: The peripheral T cell repertoire is exceptionally dynamic following myeloablative cord blood transplant, with many T cell clones rising to high frequency and then receding to an undetectably low level in a matter of weeks. By three months after transplant, T cell diversity was correlated with clinical outcomes in this patient cohort, suggesting that diversity of the T cell repertoire may be useful in guiding clinical decision making in patients undergoing cord blood transplant.

PROPHYLACTIC CD8 DEPLETED DLI OR PREEMPTIVE CD3POS DLI? – ON THE WAY TO AN INDIVIDUALIZED IMMUNOTHERAPY AFTER ALLOGENEIC HSCT

L Eichholz[1,*] W Herr[2], D Wehler[1], B Hauptrock[1], K Kolbe[1], R G Meyer[1], M Theobald[1], EM Wagner[1]
[1]Department of Medicine III, Hematology and Oncology, Johannes Gutenberg-University, Mainz, [2]Department of Internal Medicine III, Hematology and Internal Oncology, University Hospital, Regensburg, Germany

Background: The combination of reduced-intensity conditioning (RIC) and *in vivo* T-cell depletion by Alemtuzumab prior to hematopoietic stem cell transplantation (HSCT) has demonstrated efficient engraftment and reduced graft-*versus*-host disease (GVHD). However, this regimen is associated with slow lymphocyte recovery leading to a delayed anti-infectious and anti-malignant immunity. DLI can be used to improve immune reconstitution.
Aims: Here we investigate on the impact of prophylactic use of CD8-depleted *vs* preemptive use of unmanipulated (CD3pos) DLI in these patients.
Methods: 188 patients with different hematologic malignancies were planned for treatment with DLI after allogeneic HSCT with a reduced intensity conditioning (Fludarabin 30mg/m² d-7 till d-3, Melphalan 140mg/m² d-2, Alemtuzumab20mg d-8 till -4). The calcineurin-inhibitor used for GVHD-prophylaxis was intended to be tapered until day+50 post HSCT. 134 patients should receive CD8depl DLI prophylactically after day +60 (Group A), 54 patients were planned for CD3pos DLI in a preemptive setting after day +100 in case of mixed donor chimerism or minimal residual disease (MRD). Both groups received DLI in escalating doses every 60 to 90 days. DLI application was stopped when GVHD occurs (Group A and B) or a full donor chimerism was achieved (in Group B). Both patient-groups did not differ in median age (A:56 years, B:57 years). The majority of patients either suffered from acute leukemia/MDS, lymphoma or myeloma.
Results: Of 134 patients (Group A) 41% received CD8depl DLI prophylactically, of 54 patients (Group B) 31% received preemptive CD3pos DLI. Overall survival (OS) significantly increased in all patients after DLI (74% with DLI, 45% without DLI) and relapse rate was reduced after DLI (17% after DLI, 37% without DLI). CD8depl prophylactic DLI did not induce less GVHD than CD3pos preemptive DLI (64% after CD8depl DLI *vs* 67% in Group B). After 2 years OS (50% *vs* 54%), relapse rate (33% *vs* 26%) and non-relapse mortality (NRM 34% *vs* 37%) did not differ between both groups. Analyzing distinct disease groups, there are significant differences in the outcome of lymphoma and acute leukemia patients for group A and B: With an OS of100% (*vs.* 56% Group A), relapse rate 0% (*vs.* 30%) and NRM 0% (*vs* 31%) the results for lymphoma patients are better in the preemptive DLI setting (Group B). Patients suffering from acute leukemia benefit from prophylactic CD8 depleted DLI (Group A): OS after 2 years was 59% in Group A *vs* 41% in group B (not stat. significant), progression free survival 54% *vs* 34%, NRM 27% *vs* 54%.
Summary and Conclusions: In summary, the application of DLI (prophylactic CD8depl and preemptive CD3pos DLI) after RIC in combination with Alemtuzumab is useful in regard to OS and disease control.
The differences in OS, NRM and disease control for acute leukemia and lymphoma patients concerning the different DLI modalities is remarkable. Our data strongly support a randomized trial, comparing prophylactic *vs.* preemptive/therapeutic DLI application for different disease groups in the context of T-cell depleted HSCT.

Acute myeloid leukemia - Biology 1

FLT3-ITD INDUCED MYELOPROLIFERATION CAUSES A CELL EXTRINSIC DEPLETION OF HAEMATOPOIETIC STEM CELLS

A J Mead[1,*] D Atkinson[1], S Kharazi[2], O Chowdhury[1], SA Clark[1], S Matsuoka[3], T Bouriez-Jones[1], R Facchini[1], C Booth[1], P Woll[1], T Suda[3], C Nerlov[4], SE Jacobsen[1]

[1]Haematopoietic Stem Cell Biology, WIMM, University of Oxford, Oxford, United Kingdom, [2]Karolinska Institute, Stockholm, Sweden, [3]Keio University, Tokyo, Japan, [4]University of Oxford, Oxford, United Kingdom

Background: Constitutively activating internal tandem duplications (ITDs) of FLT3 frequently occur in acute myeloid leukaemia (AML) and are associated with a high relapse risk. Thus, understanding which cells might propagate Flt3-ITD associated myeloid disease is of considerable importance. However, the ability of Flt3-ITDs to transform progenitor cells and impact of mutant Flt3 within the haematopoietic stem cell (HSC) compartment is unclear.
Aims: 1. To investigate whether Flt3-ITDs confer aberrant self-renewal properties to progenitor cells.
2. To determine the expression pattern of Flt3 and impact of Flt3-ITDs on the HSC compartment.
Methods: Using a murine knock-in model of Flt3-ITD myeloproliferation, we employed phenotypic and functional stem cell assays as well as single-cell gene expression analysis of over 1000 haematopoietic stem/progenitor cells to understand the expression pattern and impact of this mutation on HSCs.
Results: Phenotypic analysis demonstrated that numbers of HSCs (LSKCD48-CD150+) were markedly reduced in adult Flt3-ITD mice (x0.24; P<0.001). The loss of HSCs occurred in parallel to the development of myeloproliferation, beginning from 2 weeks of age, with normal numbers of HSCs in Flt3-ITD fetal livers. Competitive transplantation of 1 million BM cells confirmed a marked loss of functional HSCs in adult Flt3-ITD mice. Furthermore, purified multipotent and granulocyte macrophage progenitors failed to sustain long-term engraftment of Flt3-ITD myeloproliferation. In order to explore whether Flt3-ITDs cell-intrinsically impacted on HSCs, we employed single cell gene expression analysis of wild-type and Flt3-ITD murine HSCs, which do not express cell-surface Flt3, to explore heterogeneity of *Flt3* expression. This analysis demonstrated that in two-thirds of wild-type murine HSCs, *Flt3* mRNA transcript was not detected, even using nanofluidic cell capture (Fluidigm C1 Autoprep System) with sensitivity to the single molecule level. These *Flt3*-negative HSCs more frequently expressed stem cell associated genes such as *Vwf* (Sanjuan-Pla *et al.*, Nature, 2013), *Slamf1* and *Bmi1* than Flt3-positive counterparts (P<0.001). Single HSCs from Flt3-ITD mice did not show evidence of aberrant Flt3 signalling but did show less frequent expression of stem-cell associated genes. Analysis of human HSCs revealed lack of *FLT3* expression in one half of phenotypic HSCs at the single cell level with a similar negative correlation between *FLT3* and HSC-associated gene expression. Competitive transplantation using Flt3-ITD fetal liver cells, with wild-type vWF-EGFP competitor cells, resulted in Flt3-ITD myeloproliferation and an associated, marked cell-extrinsic suppression of wild-type competitor vWF-EGFP +ve HSCs (x0.05; P<0.01). To explore a possible mechanistic basis for this, we analysed key components of the BM niche. Flt3-ITD mice showed loss of endothelial cells (x0.28; P<0.05) and mesenchymal stem cells (x0.26; P<0.01) both of which displayed aberrant gene expression. Immunohistochemistry confirmed disruption of these niche elements, together providing a putative mechanism for the extrinsic suppression of HSCs by Flt3-ITDs.
Summary and Conclusions: These data provide insight into the mechanism by which Flt3-ITDs might exert a clonal advantage over normal haematopoietic cells, by expanding aberrant myeloid-biased multipotent progenitors (Mead *et al.*, Cell Reports, 2013) which drive myeloid disease, whilst causing an extrinsic suppression of non-malignant, Flt3-negative HSCs through disruption of the niche. That Flt3-ITD myeloid disease can be propagated by rare HSCs, which do not express the mutation, raises a new challenge for efforts to therapeutically target this poor prognostic mutation.

S718

NPM1 AND FLT3-ITD MUTATIONS COOPERATE TO IMPAIR HEMATOPOIETIC STEM/PROGENITOR CELLS DIFFERENTIATION AND DEREGULATE GATA1 IN A MOUSE MODEL OF AML

P Sportoletti[1,*] E Varasano[1], R Rossi[1], L Celani[1], C Rompietti[1], F Strozzini[1], A Alunni Proietti[1], B Del Papa[1], E Bonifacio[1], O Bereshchenko[2], MP Martelli[1], F Falzetti[1], B Falini[1]

[1]Institute of Hematology, [2]Section of Pharmacology Toxicology and Chemotherapy, University of Perugia, Perugia, Italy

Background: Nucleophosmin (NPM1) and FMS-like tyrosine kinase 3 (FLT3) internal tandem duplication (ITD) mutations frequently occur together in human acute myeloid leukemia (AML) with normal cytogenetics suggesting cooperative leukemogenesis. Recently, compound NPM1/FLT3-ITD mutations were reported to induce leukemia in mice, however the molecular and cellular mechanisms of mutation cooperation remain unclear.
Aims: We generated an AML model using knock-in mouse strains to (1) study the mechanisms of NPM1 and FLT3-ITD mutations cooperation, (2) characterize the cellular origin of leukemia and (3) identify novel molecular targets of NPM1/FLT3-ITD mutations-driven leukemia.
Methods: We crossed NPM1 mutant (Sportoletti *et al.*, Blood 2013) and FLT3-ITD mice (Lee *et al.*, Cancer Cell 2007) and used: 1) FACS analysis to study the hematopoietic stem/progenitor cell compartment in bone marrow (BM); 2) real-time PCR and Western blot analysis to measure GATA1 mRNA and protein expression; 3) the FLT3 inhibitor AC220 for *in vitro* and *in vivo* treatment experiments.
Results: Concomitant expressions of NPM1 and FLT3-ITD mutant proteins in hematopoietic cells led to leukemia development with massive splenomegaly, leukocytosis, anemia and thrombocytopenia. Leukemia penetrance and latency depended on mutation dosage: NPM1/FLT3-ITD double heterozygous mice die after 1 year, while mice with two NPM1 mutant alleles and heterozygous for FLT3-ITD displayed a median survival of 3.5 months. Prior to the leukemia onset, NPM1/FLT3-ITD double heterozygous mice exhibited leukocytosis (WBC $20.8\pm18x10^9$/L; N=20) due to increased neutrophils (29.34%±6.5) and macrocytosis (MCV 58.74±5.6 fl). Notably, flow cytometry revealed significant alteration in the hematopoietic stem/progenitor cell compartment in NPM1/FLT3-ITD mutant mice. In particular, pre-leukemic mice display a significant reduction of long term hematopoietic stem cells (LT-HSC) (0.017%±0.009 *vs* 0.094%±0.02 *vs* 0.12%±0.04 *vs* 0.11%±0.07) and a significant increase in frequency of multipotent progenitor (MPP) cells (0.51%±0.21 *vs* 0.25%±0.03 *vs* 0.26%±0.06 *vs* 0.1%±0.009) compared to mice bearing NPM1 or FLT3-ITD mutations in heterozygosity and wild type controls. Common myeloid progenitor (CMP) and granulocyte-macrophage progenitor (GMP) compartments were expanded more than two-fold in NPM1/FLT3-ITD mice while the immature megakaryocytic and erythroid compartments (including MEP, preMegE, MKPs, pre-CFU-E, CFU-E) were significantly reduced compared to other genotypes. These results prompted us to analyze the status of GATA1, the master regulator of erythroid and megakaryocytic differentiation. Strikingly, cellular changes were accompanied by complete loss of GATA1 expression in the BM both at the mRNA and protein levels (Figure 1). Additional gene expression analysis revealed deregulation of different genes involved in megakaryocytic and erythroid development. The mechanism of GATA1 deregulation is currently under investigation. We then explored the effects of FLT3 inhibition on the cellular and molecular changes of NPM1/FLT3-ITD mice. *In vitro* treatment with the FLT3 inhibitor AC220 significantly reduced viability of BM cells isolated from NPM1/FLT3-ITD preleukemic or leukemic mice. *In vivo*, AC220 induced a reduction of WBC counts accompanied by a partial GATA1 re-expression in NPM1/FLT3-ITD mice peripheral blood cells.

Figure 1.

Summary and Conclusions: We found that NPM1 and FLT3-ITD mutations cooperate to AML development *in vivo* by inducing a "preleukemic state" characterized by leukocytosis and macrocytosis due to the expansion of immature granulocytes and reduction of megakaryocytic and erythroid progenitors. We correlated this cellular effect to GATA1 loss, which could be manipulated using a novel FLT3 inhibitor. These findings will allow for further exploration of novel potential therapeutic targets in AML.

S719

NPM1 HAPLOINSUFFICIENCY IS SUFFICIENT TO INDUCE AML IN COLLABORATION WITH MEIS1 IN MICE

A Muranyi[1,*] A Kechter[1], M Mulaw[1], A Mupo[2], G Vassiliou[2], C Buske[1]

[1]Institute for Experimental Cancer Research, University Clinic Ulm, Ulm, Germany, [2]Haematological Cancer Genetics, Wellcome Trust Sanger Institute, Cambridge, United Kingdom

Background: Nucleophosmin-1 (*NPM1)* mutations are among the most frequent mutations in AML, occurring in up to 50% of CN-AML patients. Several different mutations in the *NPM1* gene exist, all of which lead to aberrant cytoplasmic localization of the nuclear shuttling protein (*NPM1*c+) and a reduction of its presence in the nucleus. Thus, the mutation of *NPM1* induces a) a haploinsufficiency for the wildtype NPM1 and b) expression of the mutated protein. So far it is not clear to which extent this haploinsufficiency of NPM1 contributes to AML development. Experimental models have shown that Npm1c+ alone only generates leukemia after a long latency. In this report we now demonstrate that *Npm1* haploinsufficiency is sufficient to rapidly cause AML with high pen-

etrance in collaboration with the homeobox gene *Meis1*, whose aberrant expression is one of the molecular hallmarks of NPM1c+ human AML.
Aims: To dissect the functional relevance of NPM1 haploinsufficiency in the leukemogenesis of NPM1c+ AML, and to understand the role of MEIS1 in this process.
Methods: 5-FU mobilized murine stem and progenitor cells isolated from Npm1$^{+/+}$ wildtype, Npm1$^{+/-}$, haploinsufficient and Npm1$^{+/c+}$ humanized knock-in mice were retrovirally engineered to express *Meis1* or YFP (control) and transplanted in lethally irradiated Npm1$^{+/+}$ recipients. OCI-AML3 cells were used to test the effects of MEIS1 knockdown or drug treatment on human cells. Taqman PCR, and RNA-Seq expression data from the TCGA Acute Myeloid Leukemia dataset was used for gene expression analysis.
Results: Analysis of RNA-Seq expression data from NPM1c+ AML patient samples demonstrated high expression of *MEIS1*, which has not been previously identified as a collaborating partner for NPM1c+ in leukemogenesis. To test our hypothesis that NPM1 haploinsufficiency is an essential driver in NPM1c+ AML we transplanted Meis1 overexpressing murine stem and progenitor cells from Npm1$^{+/+}$, Npm1$^{+/-}$, and Npm1$^{+/c+}$ bone marrow into recipient mice: Overexpression of Meis1 in Npm1$^{+/+}$ cells was not able to cause disease. In contrast, mice transplanted with Npm1$^{+/c+}$ cells transduced with Meis1 developed AML with a median latency of 98 days, demonstrating that Meis1 acts as a strong collaborator in NPM1c+ AML. Surprisingly, Npm1$^{+/-}$ cells overexpressing Meis1 also induced AML with a median latency of 111 days, illustrating that haploinsufficiency was sufficient for AML development in this model. In the control arms, only cells from Npm1$^{+/c+}$ transduced with the YFP vector were able induce AML in transplanted animals, with a delayed median latency 184 days. To further test the dependency of NPM1c+ AML on MEIS1, we knocked down MEIS1 in the NPM1 mutated human cell line OCI-AML3, which led to a significant decrease in colony formation and cell growth. Meis1 induced an overexpression of cKit and Flt3 in the murine Npm1 models, and expression of *MEIS1* and *FLT3* highly correlated in human NPM1c+ FLT3-ITD- AML samples (r=0.63, p<0.05 Pearson test). In line with this, treatment of OCI-AML3 cells with midostaurin, which targets FLT3, led to a 24 and 75% reduction in cell growth at 50 and 100 nM concentrations.
Summary and Conclusions: Together this data demonstrates that Npm1 haploinsufficiency is sufficient, in collaboration with Meis1, to cause AML in mice, emphasizing that depletion of the nuclear Npm1 wildtype pool by loss of one wildtype *Npm1* allele or by the cytoplasmic shift of the Npm1 protein is a driving factor in this AML genotype. It furthermore highlights the key role of MEIS1 overexpression in NPM1c+ AML, at least partly by inducing FLT3 expression.

S720

IDENTIFICATION OF A POTENTIALLY NOVEL TUMOR SUPPRESSOR IN AML

S Post[1,*] M Gallardo[1], H J Lee[2], C Bueso-Ramos[3], J Martinez Lopez[4], A Quintas-Cardama[1]
[1]Leukemia, [2]Lymphoma, [3]Hematopathology, MD Anderson, Houston, United States, [4]Haematology, Hospital Universitario 12 de Octubre, Madrid, Spain

Background: In acute myeloid leukemia (AML) genetic alterations that deregulate cellular proliferation, apoptosis and differentiation contribute to disease progression. Chromosomal deletions are often observed in AML; however, in many instances, we lack a full understanding of how specific genes within these deleted regions impact the pathobiology of the disease. For example, loss of the 9q21.32 locus is commonly observed in a subset of AML patients, suggesting a tumor suppressor must reside within this region. Genetic studies have mapped only several candidate genes to the minimally deleted region (MDR) of 9q21.32. However, these studies have been unable to definitively identify the putative tumor suppressor. Currently, the most intriguing candidate in the MDR is heterogeneous nuclear ribonucleoprotein K (hnRNP K). hnRNP K is a DNA and RNA binding protein thought to control cellular proliferation and differentiation programs through its transcriptional and translational activities. In support of the notion that hnRNP K may be the tumor suppressor at 9q21.32, a recent TCGA study showed that when hnRNP K is mutated it has the potential to drive AML progression.
Aims: To precisely determine the genetic alteration responsible for 9q21.32-dependent AML an *in vivo* model is needed. To this end, we generated a novel *hnRNP K* knockout mouse model that will allow us to understand how hnRNP K directly influences hematopoietic homeostasis and leukemic progression. This model potentially mimics the haploinsufficiency observed in AML patients with 9q21.32 deletions.
Methods: We are currently using mouse models to examine how aberrant hnRNP K expression impacts tumorigenesis, hematopoiesis, and the interaction between hnRNP K and the p53/p21- and C/EBP- pathways. Using AML patient sample carrying a 9q21.32 deletion, we are evaluating the impact of 9q21.32 deletions on hnRNP K expression and interrogating changes in the hnRNP K allele.
Results: Haploinsufficient *hnRNP K* mice (*hnRNP K*$^{+/-}$) have a significant reduction in survival, a highly penetrant malignant phenotype, and a significant expansion of the myeloid compartment. Our data also suggest these *hnRNP K*$^{+/-}$-dependent phenotypes result from its inability to activate p53-dependent p21 expression (proliferation program) and properly regulate expression of C/EBPβ and δ (differentiation program). Likewise, our preliminary clinical data suggest patients with 9q-deletions have reduced hnRNP K expression. These results suggest that hnRNP K is a critical regulator of the p53- and C/EBP- pathways and may be the illusive tumor suppressor located at the 9q21.32 locus.
Summary and Conclusions: These studies will allow us to determine whether hnRNP K is in fact the tumor suppressor residing at the 9q21.32 locus and will advance our understanding of how hnRNP K controls cellular differentiation and proliferation programs. These findings will also assist us in determining if hnRNP K loss can serve as a prognostic biomarker and a possible therapeutic target.

Background: In the WHO 2008 classification of acute myeloid leukemia (AML), a large proportion of AML is now classified according to their underlying genetic abnormalities. For the first time, two new provisional entities defined by the presence of gene mutations were added, "AML with mutated *NPM1*" and "AML with mutated *CEBPA*". With the advent of the new sequencing technologies, the genomic landscape has now been more or less deciphered and the most frequently mutated genes in AML are known. With this increased knowledge important questions arise, for example, are there specific mutations that define unique subgroups that may be incorporated in the WHO classification or in the genetic stratification of the European LeukemiaNet (ELN). Mutations in the *RUNX1* gene (*RUNX1*^{mut}) have been identified as recurrent mutations in myeloid malignancies, such as myelodysplastic syndrome (MDS) and AML, and they have been associated with distinct clinical characteristics and poor outcome.
Aims: To evaluate the genetic and clinical characteristics of AML with *RUNX1*^{mut} in a large cohort of adult AML patients (pts; 16-84 years of age) who were entered on four consecutive AMLSG treatment protocols [AML HD98A (n=804; NCT00146120), AMLSG 07-04 (n=885; NCT00151242), AML HD98B (n=307), AMLSG 06-04 (n=443)].
Methods: *RUNX1*^{mut} screening was performed in 2.439 AML pts (*de novo* AML, n=2.114; secondary AML [s-AML], n=157; therapy-related AML [t-AML], n=143; unknown, n=25) using a DNA-based PCR assay covering exons 1 to 8 followed by direct sequencing.
Results: Overall, 280 *RUNX1*^{mut}, were found in 245 of the 2.439 pts (10.1%). Mutations clustered in exon 4 and 8, but were also found in other exons. Clinically, *RUNX1*^{mut} were associated with higher age (p<0.0001), male gender (p=0.015), s-AML (p<0.0001), higher platelet counts (p=0.007), lower LDH levels (p<0.0001), and FAB morphology (FAB M0, p=0.046). *RUNX1*^{mut} were almost mutually exclusive of the primary recurrent genetic abnormalities as listed in the 2008 WHO classification. *RUNX1*^{mut} were mainly found in the European LeukemiaNet (ELN) intermediate-I (47.6%) and intermediate-II (30.7%) genetic groups; specific cytogenetic associations were found with +13 (p=0.001) and del(7q) (p=0.041). With respect to cooperating mutations, *RUNX1*^{mut} significantly co-occurred with mutations in *ASXL1* (p<0.0001), *MLL* (partial tandem duplications [PTD]; p<0.001), and *IDH2* (p=0.023). Following induction therapy, AML with *RUNX1*^{mut} were associated with a lower complete remission rate (48.4% *vs* 68.1%; p<0.0001) due to a higher rate of refractory disease (40.6% *vs* 23.4%; p<0.0001) as compared to AML with *RUNX1*^{wt}. Univariable analysis revealed *RUNX1*^{mut} to be associated with inferior event-free (EFS, p<0.001), relapse-free (RFS, p<0.001), and overall survival (OS, p<0.001); in general, this negative prognostic impact was seen for pts 18-60 years of age (OS, p=0.001; RFS, p=0.007; EFS, p<0.001) and for pts above 60 years (EFS, p<0.001; OS, p=0.09). In multivariable analysis, *RUNX1*^{mut} was an independent prognostic marker for inferior EFS (p=0.001) and in trend for a worse OS (p=0.097).
Summary and Conclusions: *RUNX1*^{mut} are among the most frequent recurrent gene mutations in AML. They are mutually exclusive of the recurrent primary genetic abnormalities and cooperate with mutations in particular affecting epigenetic modifiers. *RUNX1*^{mut} are associated with distinct clinical features such as older age, prior MDS, and more immature phenotype, and poor outcome. Due to these unique characteristics, *RUNX1*^{mut} may be considered as a clinico-pathologic entity of AML.

Acute lymphoblastic leukemia - Clinical 1

Background: Blinatumomab is an investigational bispecific T-cell engager (BiTE®) antibody that directs T-cells to $CD19^+$ cells, resulting in serial lysis of B cells. An exploratory phase 2 study of blinatumomab in adult patients with relapsed/refractory B-precursor ALL (r/r ALL) previously demonstrated antileukemia activity (Topp MS, *et al.* Blood. 2012;120:abstract 670).
Aims: The objective of this large multicenter phase 2 study was to evaluate the efficacy and toxicity of blinatumomab as a single-agent treatment for adult patients with r/r ALL.
Methods: Eligible patients (≥18 years) had Ph-negative r/r ALL and any of the following characteristics: patients were primary refractory (induction failure), had experienced their first relapse within 12 months of first remission, had relapsed within 12 months of allogeneic hematopoietic stem cell transplantation (HSCT), or received blinatumomab as ≥2 salvage treatment. Patients with late first relapse (>12 months after first CR) were not eligible. Blinatumomab was administered by continuous IV infusion (4 weeks on/2 weeks off) for up to five cycles. During cycle 1, blinatumomab was administered at 9 µg/d on days 1 through 7, then at 28 µg/d on days 8 through 28. A constant dose of 28 µg/d was used for all subsequent cycles. The primary endpoint was complete remission (CR) or CR with partial hematologic recovery (CRh*) within the first two cycles.
Results: One hundred eighty-nine patients received blinatumomab; median (range) age was 39 (18–79) years. Median number of treatment cycles was 2 (1–5). Forty-three percent (95% CI, 36%–50%) of patients achieved CR/CRh*; 79% of these responses occurred within cycle 1. Within the first two cycles, 33% of patients achieved CR and 10% achieved CRh*. Among patients with prior allogeneic HSCT, 45% (29 of 64) achieved CR/CRh*. Among patients without prior allogeneic HSCT, CR/CRh* rates were 41% (12 of 29) for those who received blinatumomab as first early salvage, 49% (27 of 55) for those who received blinatumomab as second salvage, and 32% (13 of 41) for those who received blinatumomab as third or later salvage therapy. Median relapse-free survival was 5.9 months (95% CI, 4.8–8.3 months). Irrespective of causality, the most frequently occurring adverse events (AEs) were pyrexia (60%), headache (34%), and febrile neutropenia (28%). The most frequently occurring grade ≥3 AEs included febrile neutropenia (25%), neutropenia (16%), and anemia (14%). Grade ≥3 cytokine release syndrome occurred in 2% of patients. Headache (4%), encephalopathy (3%) and ataxia (2%) were the most frequently occurring grade ≥3 nervous system disorders. Three (2%) patients had grade 5 AEs (sepsis, n=2; candida infection, n=1) that were considered treatment-related.
Summary and Conclusions: This phase 2 study confirmed the antileukemia activity of blinatumomab as a single agent in an adult patient population with r/r ALL who had responded poorly to prior therapies.

S723

CLINICAL IMPACT OF ABL1 KINASE AND IKZF1 MUTATIONS IN ADULTS WITH PHILADELPHIA CHROMOSOME-POSITIVE (PH+) ACUTE LYMPHOBLASTIC LEUKEMIA (ALL): MOLECULAR ANALYSIS OF CALGB 10001 AND 9665 (ALLIANCE)

R DeBoer[1,*] F Mulkey[2], G Koval[3], M Wetzler[4], G Marcucci[5], RM Stone[6], RA Larson[1], S Geyer[7], C Mullighan[8], W Stock[1]

[1]University of Chicago, Chicago, [2]Alliance Statistics and Data Center, Duke University, Durham, [3]Indiana University, Gary, [4]Roswell Park Cancer Institute, Buffalo, [5]Ohio State University Medical Center, Columbus, [6]Dana-Farber Cancer Institute, Boston, [7]Alliance Statistics and Data Center, Ohio State University Medical Center, Columbus, [8]St. Jude Children's Hospital, Memphis, United States

Background: Despite improvement in outcomes with tyrosine kinase inhibitors (TKIs), a majority of adults with Ph+ ALL relapse and overall prognosis remains poor. Recent genomic studies in Ph+ ALL have identified oncogenic lesions that cooperate with *BCR-ABL1* to induce ALL as well as *ABL1* kinase domain mutations that confer resistance to TKIs. Here we sought to determine the incidence and clinical impact of these lesions in Ph+ ALL patients (pts) enrolled on CALGB 10001, a previously reported phase II study of imatinib and allogeneic (allo) or autologous (auto) stem cell transplantation (SCT), and companion Leukemia Tissue Bank protocol CALGB 9665.
Aims: One aim was to determine the incidence of *ABL1* kinase mutations at relapse and to monitor the kinetics of resistant clones. A second aim was to correlate oncogenic mutations in *IKZF1*, *CDKN2A/B*, and *PAX5* with clinical outcome and other biological variables, including *BCR/ABL1* fusion transcript (p190 *versus* p210).
Methods: Of the 58 pts enrolled on CALGB 10001, 22 pts relapsed, and 20 relapsed samples were evaluated for *ABL1* kinase mutations by direct sequencing and mutation-specific quantitative PCR (q-PCR) assays if a mutation was present. 28 pre-treatment samples from eligible pts were available for assessment of *IKZF1*, *CDKN2A/B*, and *PAX5* mutations using high-resolution SNP arrays and genomic DNA sequencing. Correlation with clinical outcome and other biological variables was estimated. Informed consent was obtained from all pts enrolled on CALGB 10001 and 9665.
Results: An *ABL1* kinase mutation was present at relapse in 13 out of 20 pts (65%) by direct sequencing. Using mutation-specific q-PCR, these mutations were detectable prior to relapse in 8 of 13 pts, and in 5 cases were present at diagnosis (Dx). All mutations were either P-loop (Y253H, E255K/V) or T315I, binding site mutations known to induce imatinib resistance. In 31 of 32 non-relapsed pts with available samples, no kinase mutations were detected at Dx using q-PCR. Kinase mutation at relapse was associated with worse disease-free survival (DFS; p=0.012; HR 4.54). In 28 available pre-treatment samples, 22 (78.6%) had an *IKZF1* deletion, 12 (42.9%) had a *CDKN2A/B* deletion, and 7 (25%) had a *PAX5* deletion. Among pts with *IKZF1* deletion, 17 of 22 (77.3%) had a p190 *BCR/ABL1* fusion transcript, which was associated with significantly better DFS compared to p210 in this subset (p<0.0001); see Figure 1. Adjusting for fusion transcript, *IKZF1* deletion was associated with worse DFS (p=0.011; HR 7.042). Median DFS in pts with *IKZF1* deletion was 13.2 months *versus* 53.1 months in pts without *IKZF1* deletion, although this difference did not reach statistical significance (p=0.18). In contrast to other reports, *CDKN2A/B* deletion did not affect survival in pts with *IKZF1* deletion. WBC level greater than 20,000 at Dx (p=0.021; HR 2.52) and minimal residual disease (MRD) at day 120 greater than 0.001 (p=0.013; HR 7.84) were associated with significantly worse DFS. No significant association was found between *IKZF1* deletion and presence of kinase mutation at relapse (p=0.18), *BCR/ABL1* fusion transcript type (p=0.31), WBC level at Dx (p=0.64), and MRD following induction (p=0.85) or at day 120 (p=0.77).

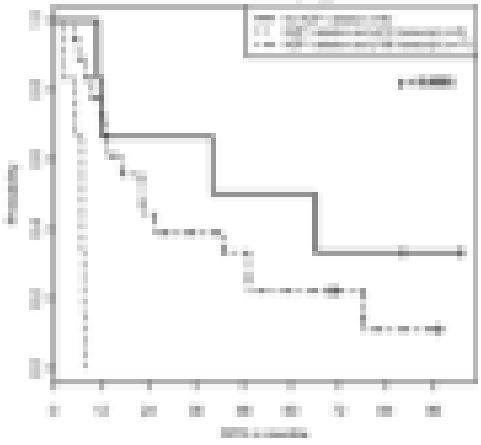

Figure 1. DFS stratified by IKZF1 deletion and BCR/ABL1 fusion transcript type.

Summary and Conclusions: *ABL1* kinase mutations conferring imatinib resistance were detectable at Dx or early during treatment in a majority (62%) of relapsed pts. Early identification using sensitive q-PCR may allow appropriate choice of TKI to avoid emergence of the resistant clone and relapse. *IKZF1* deletions, previously shown to have a pathogenic role in Ph+ ALL, were present in a majority of pts and associated with worse outcomes after adjusting for *BCR/ABL1* fusion transcript. Larger studies are needed to confirm these observations. Novel strategies to target *IKZF1* are being examined.

S724

PHASE II STUDY OF COMBINATION OF HYPERCVAD WITH PONATINIB IN FRONT LINE THERAPY OF PATIENTS (PTS) WITH PHILADELPHIA CHROMOSOME (PH) POSITIVE ACUTE LYMPHOBLASTIC LEUKEMIA (ALL)

E Jabbour[1,*] H Kantarjian[1], D Thomas[1], F Ravandi[1], J Cortes[1], D Hoehn[2], N Pemmaraju[1], T Kadia[1], R Garris[1], G Garcia-Manero[1], G Borthakur[1], W Wierda[1], S O'Brien[1]

[1]Leukemia, MD Anderson Cancer Center, Houston, [2]Clinical Pathology and Cell Biology, Columbia University Medical Center, New York, United States

Background: Combination of cytotoxic chemotherapy with TKIs is effective in the treatment of Ph+ ALL. Ponatinib is a more potent BCR-ABL inhibitor. It also suppresses the T315I clones, a common cause of relapse in pts with Ph+ ALL.

Aims: The combination of chemotherapy and ponatinib may be associated with better response rates and higher likelihood of eradication of minimal residual disease (MRD) than those reported with imatinib or dasatinib and chemotherapy.

Methods: Pts with newly diagnosed Ph+ ALL received 8 cycles of hyperCVAD alternating with high dose MTX/cytarabine every 21 days. Ponatinib was given at 45 mg po daily for the first 14 days of cycle 1 then continuously for the subsequent cycles. Pts in CR received maintenance with ponatinib 45 mg po daily with vincristine/prednisone monthly for 2 yrs followed by ponatinib indefinitely. MRD monitoring was conducted.

Results: 34 pts with untreated Ph+ ALL and 3 pts previously treated (2 with 1 prior cycle of chemotherapy before Ph+/BCR-ABL status was known, not in CR, and 1 post HCVAD-dasatinib in CR) have received a median of 6 cycles (2-8) of therapy; 12 pts are receiving maintenance in CR. Median age was 51 years (27–75). Median WBC at diagnosis was $8.0x10^9$/L. All pts were in CR after cycle 1. 30 of the 32 pts (94%) with Ph+ metaphases by cytogenetic analysis at baseline achieved a CCyR after 1 cycle; 1 had a mCyR only and 1 had no cytogenetic analysis at CR, both of them achieved a CCyR after cycle 2; 5 had a diploid karyotype at the start of therapy (two in CCyR post previous chemotherapy and 3 diploid by standard G-banding technique and positive by FISH and PCR). To date, 35 pts (95%) have achieved a MMR, of whom 26 (70%) a CMR at a median of 10 weeks from initiation of treatment (2 -28). MRD assessment by flow cytometry is negative in 35/36 (97%) pts, in whom a sample was sent for MRD assessment, at a median of 3 weeks (3-14). Median time to neutrophil and platelet recovery for cycle 1 was 18 and 23 days, and 16 and 22 days for subsequent cycles, respectively. 8 pts have undergone allogeneic stem cell transplantation (ASCT) after a median of 4 courses (3-10). Grade ≥3 toxicity included infections during induction in 18 pts (49%), increased LFT's in 13 pts (35%), thrombotic events in 3 (8%, 1 renal vein thrombosis and 2 pulmonary emboli), myocardial infarction (MI) in 3 (8%, 2 unexplained, and 1 in the context of sepsis), skin rash in 4 (11%), and pancreatitis in 6 (16%). With a median follow up of 13 months (4-26), 31 pts are alive and in CR; 1 pt died in CR from an unrelated cardiac event after being taken off therapy and placed on imatinib, 1 pt died from MOF post sepsis (C2D13), 1 from non-ST elevation MI (NSTEMI) post cycle 2 (C2D41), 1 from potential MI at C4D42, 1 from head injury sustained after a fall at C4D13, and 1 from sepsis and MOF post ASCT. At the last follow-up, 7 pts (19%) are alive post ASCT; 15 pts (41%) are alive on ponatinib at 15 mg daily in 14 and 30 mg daily in 1; Of the other 9 alive pts, 7 were switched to dasatinib, one was switched to imatinib, and one is no longer receiving treatment. The 1-year PFS and OS rates were 100% and 86%, respectively.

Summary and Conclusions: The combination of hyperCVAD with ponatinib is highly effective in achieving molecular remissions in pts with Ph+ ALL. Due to the recent report of increased vascular events with ponatinib and occurrence of 2 MI on this trial, some pts switched to alternative TKI as noted above. In pts electing to stay on ponatinib, the dose was modified to 30 mg daily during consolidation with subsequent reduction to 15 mg in pts in CMR.

S725

ITALIAN GIMEMA 1308 PROTOCOL. TREATMENT OF ACUTE LYMPHOBLASTIC LEUKEMIA (ALL) IN ADOLESCENTS AND YOUNG ADULT (AYA): INTENSIFICATION OF TREATMENT BASED ON THE PEDIATRIC AIEOP ALL 2000 PROTOCOL

AM Testi[1,*] A Piciocchi[2], M D'Angiò[1], A Vitale[1], AR Guarini[1], MS De Propris[1], I Lastarza[1], V Nunes[1], A Carella[3], A Cuneo[4], P Fazi[2], A Fornaro[5], M Luppi[6], E Rinaldi[7], F Ronco[8], A Candoni[9], M Vignetti[2], R Foà[1]

Ematologia Clinica, Azienda USL, Pescara, [6]Centro Oncologico Modenese, Dipartimento di Oncoematologia, Modena, [7]Divisione di Ematologia Ospedale A. Perrino, Brindisi, [8]Dipartimento Emato-Oncologia, A.O."Bianchi-Melacrino-Morelli", Reggio Calabria, [9]Azienda ospedaliera universitaria, divisione di ematologia, Udine, Italy

Background: Adolescents and young adults (AYA) with acute lymphoblastic leukemia (ALL) have unique genetic, immunophenotypic and clinical features that differ from those of pediatric and older adults, and with outcomesthat fall somewhere between these two populations.In the last years, pediatric-inspired treatment approaches have improved the results in AYA.

Aims: The aim of the study is to test the efficacy and tolerability of a pediatric-inspired therapy in AYA and to compare the results with the historical GIMEMA ALL trials in patients with the same range of age. The study was registered at clinicaltrials.gov (NCT01156883).

Methods: The Italian GIMEMA 1308trial for the treatment of patients aged 18-35 years, with the exclusion of B-mature and Ph+ ALL, is derived from the childhood AIEOP ALL 2000 protocol. All patients receive a 7 day pre-phase with prednisone and 1 i.t. dose of Methotrexate (MTX), followed by induction IA and IB. From day 8, patients with T-ALL receive also dexamethasone.Minimal residual disease (MRD)by flow-cytometry (FC) and immunoglobulin/T-cell receptor gene rearrangement (Ig/TCR) is tested at time point 1 (TP1, end of IA) and2 (TP2, end of IB). Patients are stratified into two risk groups.Patients with at least one of the following criteria -t(4;11), prednisone-poor response (PPR),failure to achieve complete remission (CR) at TP1,Ig/TCR-MRD levels $\geq 10^{-3}$ at TP2 - are defined as high-risk (HR); all other are considered asstandard-risk (SR). Consolidation consists of 4 high-dose (HD)-MTX courses and of 3 blocks of non-cross resistant drugs for SR and HR, respectively. Reinduction II (IIA+IIB) follows consolidation for all patients.Standard maintenance isscheduled for a total of 24 months from diagnosis. Central nervous system (CNS)-directed therapy (i.t. MTX)is given during all treatment preceding cranial radiotherapy (CRT) for patients at HR and SR with T-ALL and a WBC>$100x10^9$/l or with CNS involvement at diagnosis. An allogeneic hematopoietic stem cell transplant (HSCT) from a matched family or unrelated donorisindicated for HR patients with t(4;11), not in CR at the end of IA or withIg/TCR-MRD levels$\geq 10^{-2}$at TP1 or $\geq 10^{-3}$ at TP2.

Results: All patients have given a signed informed consent.From September 2010 to January 2014, 66 patients have registered in the trial. Sixty-one are eligible and 54 are evaluable for steroid response: 42prednisone-good responders (PGR) and 12 PPR. Of the 50 patients evaluable for IA, 46 (92%) achieveda CR and 4 (8%) proved resistant; 46of the 47 patients (98%) evaluable for IB achieved a CR and 1 was resistant.Eleven severe adverse events (SAE) have been recorded: 8 with IA and 3 with IB.These include 6 Asparaginase-related adverse events and 5 infections.The median levels of FC-MRD at TP1 and TP2 are $10^{-4}$and 0; the median Ig/TCR-MRD levels at TP1 and TP2are 10^{-3} and 10^{-6}, respectively. Among the 46 patients in CR, 20 (43.5%) are classified as HR and 26 (56.5%) as SR. At 24 months, the overall survival (OS) for the entire group of patients is estimated to be 72.3% (95% CI 57.3–91). These results wereretrospectively compared with those achieved in AYA treated with the GIMEMA ALL 2000 and 0904trials.The CR rate (98%) is higher in the ongoing study compared to the previous ones(84% and 83%, respectively). At 24 months, the OS is 72.3, 61and 72%, in the 1308, 0904 and 2000 protocols.

Summary and Conclusions: The results presented suggest that the intensified protocol is effective and well tolerate in AYA; larger studies and a longer follow-up are necessary to conclusively confirm the role of intensified strategy on the clinical management of AYA.

S726

ENHANCED SURVIVAL IN ADULT PHILADELPHIA-NEGATIVE ACUTE LYMPHOBLASTIC LEUKEMIA (PH- ALL) WITH AN UPDATED PEDIATRIC-DERIVED MINIMAL RESIDUAL DISEASE (MRD)/RISK-SPECIFIC TREATMENT STRATEGY: NILG STUDY 10

Background: The use of pediatric-derived therapeutic elements (PDT) in association with an MRD/risk-specific strategy could improve outcome of adult Ph-ALL.

Aims: To evaluate the results of a recent trial of the Northern Italy Leukemia Group (NILG 10/07).

Methods: PDT elements were added to a pilot study with an MRD/risk-based treatment design (ClinicalTrials.gov NCT-00795756). All patients signed an informed consent. PDT consisted of 3 modified BFM-type blocks and 3 lineage-targeted MTX blocks (LTM: B-precursor: 2.5 g/m^2; T-precursor: 5 g/m^2; age >55 years: 1.5 g/m^2) to obtain a MTX plasma concentration of ~35 and ~65 micromol/L in B- and T-ALL, respectively, according to St. Jude's Hospital studies. Central nervous system (CNS) prophylaxis compared standard intrathecal therapy with liposomal Ara-C, and MRD was evaluated molecularly at weeks (w) 4,10,16 and 22, to optimize risk stratification and indications for allogeneic stem cell transplantation (allo-SCT). The study sequence consisted of prephase (PDN/CY)/induction (IDA/VCR/L-Asp/DEX) and w4 MRD → PDT1 (CY/VCR/IDA/DEX/Ara-C/6MP) → LTM1/HD-Ara-C and w10 MRD → PDT2 → LTM2/L-Asp/6MP and w16 MRD → PDT3 → LTM3/HD-Ara-C and w22 MRD → reinduction (IDA/VCR/CY/PDN/DEX). Risk classes were standard (SR: non pro-B and WBC <30; cortical/CD1a+ T and WBC <100; CR cycle 1 and non-adverse cytogenetics) and high (HR). An early allo-SCT was prescribed to HR patients without molecular study, with highly adverse features (poor risk cytogenetics, WBC >100, early/mature T) or w10 MRD ≥10^{-4}; other MRD+ patients were eligible to post-consolidation allo-SCT or auto-SCT plus maintenance if allo-SCT was not feasible. Patients with w10 MRD <10^{-4} and negative w22

MRD were eligible to standard maintenance, and those lacking the MRD study were managed according to clinical risk class.
Results: Among 201 patients enroled from January '08 to August '12 (median age 41.4 years; range 17.8-67.7), 159 had Ph- ALL (117 B-ALL [SR 53%], 42 T-ALL [SR 26.2%]). CR rate was 97.6% in T- and 82.9% in B-ALL, due to greater toxicity in older patients; 65 patients eventually had a SCT (57 allo, 8 auto). Of 106 CR patients (76.8%) evaluable for MRD at w10 (as main prognostic timepoint), 77 reached a major MRD response $<10^{-4}$ (72%). With a maximum follow-up of 5+ years, projected overall survival (OS) at 4 years is 61% (101 survivors), 55% in B-ALL and 76% in T-ALL, respectively, and disease-free survival (DFS) 64% (89 survivors in CR1), 57% in B-ALL and 68% in T-ALL, respectively. DFS of 77 w10 MRD responders is 74% *vs.* 30.4% in 29 MRD-resistant (P<0.0001). Relapse rate was 26.8% (26/97) and 24.4% (10/41) in B- and T-ALL, respectively, whereas cumulative treatment mortality (TRM) was 17%, 4.7% (2/42) in T-ALL and 21.4% (25/117) in B-ALL (P=0.01), the latter correlating with age >60 (P=0.0001). Therefore, OS and DFS are 64.6% and 63.1% in patients aged 60 years and less *vs.* 35.5% and 41.6% in older ones (P=0.0001 and P=0.57).
Summary and Conclusions: This regimen yielded a CR rate close to 90% in unselected adults aged up to 65 years, obtaining an early MRD response of 72%. The associated toxicity mandated for a reduction of treatment intensity in older patients. Otherwise the PDT/LTM sequence proved feasible and the MRD/risk-oriented design achieved remarkable 4-year OS/DFS rates in patients aged 18-60 years, especially in T-ALL and w10 MRD responders, improving significantly over prior NILG data. Overall results remain suboptimal in MRD+ patients.

Background: The main indications to haematopoietic stem cell transplantation (HSCT) in patients affected with severe congenital neutropenia (SCN) are transformation to myelodysplasia or leukaemia (MDS/AL) and lack or partial response to Granulocyte Colony Stimulating Factor (G-CSF). Indication to HSCT in low or good responders to G-CSF is discussed because the experience in the field is limited.The EBMT data base offers an unique opportunity to address some unanswered questions in a large cohort.
Aims: To describe the outcome and risk factors of HSCT in a large cohort of SCN
Methods: All patients registered in the EBMT data base affected with SCN (early occurrence in life, block at promyelocyte stage, G-CSF dependence) were considered eligible to the study. Data regarding HSCT and outcome were derived from the "MED B EBMT form", while specific additional data regarding history before HSCT, were collected through a specific CRF (Med C) sent to all the participating centers.
Results: A total of 132 patients from 19 participating countries entered the study. Females were 49% of the cohort. Median age at diagnosis of neutropenia was 0.36 years (0-35-5yrs), while median age at first transplant was 4.5 years (range 0.2-43.1y). Eleven patients were affected with myelodysplasia (MDS) and acute leukemia(AL) at time of transplant. The cell source was bone marrow (BM) in 57%, peripheral blood (PB) in 25% and cord blood (CB) 18%. Fifty percent of patients were engrafted from a matched related and 50% from a matched unrelated donor. Conditioning regimen was myeloablative in 86% and reduced intensity (RIC) in 14% of the cohort. Engraftment was documented in 91% of subjects: 6% had primary graft failure and 3% lost the engraftment. Overall 24 patients (18%) died while the remaining 108 were alive (82%). Causes of death were: GVDH in 33% of patients, infections in 21%, organ failure in 17% and combination of previous causes in 21% and relapse/progression of the disease in 8%. Transplant related mortality occurred in 17% of the whole cohort. Acute GVDH grade 1-2 was documented in 31%, grade 3-4 in 15%. The 5-year OS and EFS (death,relapse,primary and secondary graft failure being the events) were 79% and 71% respectively. The 5-year OS according to donor type was 83% and 84% (p=0.76) for HLA identical family *vs* unrelated donor. Also the 5-year OS according to source of cells did not significantly differ (CB 92%, PB 65% and BM 82%p=0.12); the same held true also for 5-year EFS (CB 70% BM 79% and PB 54%p =0.068) even if it a worse trend was observed in PB recipients.The 5-years OS of patients affected with MDS/AL at HSCT, was not different to the one calculated in subjects without neoplastic transformation.Five year OS was significantly higher in patients transplanted before age

10 years (84% in age 0-5 yrs, 86% in age 5-10 yrs and 64% in age above 10 yrsp=0.035), The 5-years OS calculated according to time of HSCT was significantly better after year 2000(63% in patients transplanted before year 2000, 76% in subjects between 2001-2007 and 91% after year 2008 p=0.02).
Summary and Conclusions: This is the largest study ever conducted on a population of patients affected with SCN. It shows that the 5-year survival in transplanted SCN patients is close to 80% with no difference between matched related and unrelated donor. TRM, close to 17%, is still not negligible. Survival improved after year 2000 probably because of better donor typing techniques, but not for patients older than 10 years. Peripheral blood infusion seem to be less favourable than cord blood or marrow cells. MDS/AL at HSCT does not seem to influence the final outcome. Overall, this study provides the first solid evidence that HSCT in SCN, either from family or unrelated HLA matched donor, is a reasonably good rescue option in patients poorly responding to G-CSF or who transformed into MDS/AL.
On behalf of Severe Aplastic Anemia, Inborns Error and Pediatrics Diseases Working Parties.

Background: Acquired aplastic anemia (AA) is a prototype of idiopathic bone marrow failure, in which immune-mediated destruction of hematopoietic progenitors plays a central role but also characterized by frequent evolution to clonal myeloid disorders. Recently, we and other groups reported frequent somatic mutations in genes commonly mutated in myeloid malignancies, including *DNMT3A, ASXL1* and *BCOR*. However, the chronological behavior of the clonality and its link to the development of myeloid neoplasms has not been fully explored.
Aims: We aimed to define the clonality and its chronological behavior in acquired AA in terms of gene mutations and also investigate their pathogenetic link between myeloid malignancies.
Methods: We sought somatic mutations in a panel of 106 genes known mutational targets in myeloid neoplasms by whole exome sequencing (N=13) and/or targeted deep sequencing (N=178) of peripheral blood DNA from 188 patients with AA who had received immune-suppressive therapies (IST), using a SureSelect custom kit. Chronological alterations in variant allele frequencies of detected mutations were also investigated in 38 cases.
Results: In total, 84 high probability somatic mutations were detected in 33% (N=51) of 178 AA cases with varying variant allele frequencies, of which 10.8% of the cases harbored multiple mutations. The spectrum of mutations were substantially different from that observed in myeloid malignancies, such as acute myeloid leukemia (AML) and melodysplastic syndromes (MDS) and most frequently found in *DNMT3A* (12.1%), *BCOR* (4.3%), *PIGA* (3.3%), *ASXL1* (2.9%) and biased to nonsense (21%), frameshift (26%) and splice site changes (9%), supporting their driver roles. Mutations were associated with older age (p=0.0004), but not with response to treatment or progression to MDS/AML. Conspicuously, multiple independent mutations involving *DNMT3A,* and *ZRSR2* were identified in 2 cases, strongly suggesting their driver roles in clonal selection. Among 26 cases, in which serial samples are available for the targeted deep sequencing, 13 mutations were detected in 5 cases after IST. Nine out of the 13 mutations increased in their clone size and the remaining 4 maintained their clone size or decreased over time. None of the 5 cases developed MDS/AML at the time of the latest follow-up, even though mutations were found in common myeloid targets such as *TET2, ASXL1, DNMT3A, U2AF1, BCOR* and *SETBP1*. To further characterize clonal evolution in AA patients, we performed whole exome sequencing of multiple samples taken from 13 cases, for whom sequential samples (N=2~3) were available. The detected mutations were confirmed in all serial samples by deep sequencing. Somatic mutations were detected 8 out of the 13 cases at the time of diagnosis of AA and/or after IST with the mean number of mutations of 4.5 per specimen. Most of the mutations were present at the time of diagnosis and their allele frequencies increased during the clinical course, although some mutations in the diagnostic samples disappeared over time. Progression to MDS was confirmed in 5 cases, in which multiple round of acquisition of new mutations and subsequent clonal selection were indicated.
Summary and Conclusions: In AA, genes commonly mutated myeloid neoplasms were frequently mutated and were thought to be responsible for clonal evolution. The spectrum of mutations in AA was substantially different from that of MDS/AML, in which mutations in *PIGA, DNMT3A, ASXL1* and *BOCR* were predominant with rare mutations in *TET2, SF3B1* and other signaling pathway genes. Mutations were frequently detected prior to IST and increased their clone size over time after IST. Detection of clonality may or may not be associated with progression to MDS/AML, even though clonal evolution was evident, indicating complex pathogenesis of secondary MDS in AA.

S729

STRESS-INDUCED EXIT FROM QUIESCENCE INDUCES *DE NOVO* DNA DAMAGE IN HEMATOPOIETIC STEM CELLS AND RESULTS IN BONE MARROW FAILURE IN THE ABSENCE OF A FUNCTIONAL FANCONI ANEMIA SIGNALLING PATHWAY

D Walter[1,*] A Lier[1], A Geiselhart[2], S Huntscha[1], D Brocks[2], I Bayindir[2], P Kaschutnig[2], K Müdder[1], T Holland-Letz[2], P Schmezer[2], S Lane[3], MAG Essers[1,2], DA Williams[4], DA Williams[4,5,6,7], A Trumpp[1,2], MD Milsom[1,2]
[1]Heidelberg Institute for Stem Cell Technology and Experimental Medicine (HI-STEM), [2]German Cancer Research Center (DKFZ), Heidelberg, Germany, [3]Queensland Institute for Medical Research, Brisbane, Australia, [4]Boston Children's Hospital, [5]Harvard Medical School, [6]Dana Faber Cancer Institute, [7]Harvard Stem Cell Institute, Boston, United States

Background: Fanconi anemia (FA) patients harbour germ line inactivating mutations in an epistatic signalling pathway that mediates DNA repair, resulting in a highly penetrant bone marrow failure syndrome driven by an accelerated loss of hematopoietic stem cells (HSCs). Knockout mouse models of FA have exactly the same DNA repair defect as cells isolated from FA patients. However these mice never spontaneously develop aplastic anemia, leading us to speculate that laboratory mice are not subject to the same source of DNA damage as patients. Proliferative stress has been proposed to be a near universal source of DNA damage in somatic cells but HSC are known to predominantly reside in a state of long-term quiescence, which would preclude them from acquiring extensive DNA damage via this route. Recently, it has been recognised that murine HSC exit this quiescent state *in vivo* in response to stress stimuli such as infections or blood loss.
Aims: To test whether stress-induced exit from quiescence comprises a physiologic source of DNA damage in HSCs.
Methods: Wild type (WT) and *Fanca*$^{-/-}$ mice were injected with either the synthetic double stranded RNA mimetic polyI:polyC (pI:pC), to simulate viral infection and promote HSC proliferation, or a range of other pro-proliferative agonists (pI:pC; Interferon-α; G-CSF; TPO; and serial bleeding). DNA damage was evaluated by both enumeration of γ-H2AX foci and Comet assay.
Results: Treatment of WT mice with any of the individual stress-inducing agonists led to a robust induction of *in vivo* HSC cycle entry, resulting in a 3-5-fold induction of DNA damage in highly purified HSCs across all stimuli ($p<0.01$). On a mechanistic level, stress-induced HSC exit from quiescence resulted in elevated mitochondrial membrane potential (2-fold increase, $p<0.01$) and a 50% increase in 8-Oxo-dG lesions on DNA, suggesting that mitochondrial reactive oxygen species (ROS) directly precipitated DNA damage. Critically, retroviral overexpression of the ROS-detoxifying enzymes catalase and superoxide dismutase 2 completely rescued stress-induced DNA damage in HSCs *in vivo*. Analysis of the FA signalling pathway revealed a 4-fold induction in nuclear FANCD2 foci ($p<0.01$) in the HSCs of pI:pC-treated mice, consistent with this pathway being involved in the repair of stress-induced DNA damage. Indeed, treatment of *Fanca*$^{-/-}$ mice with pI:pC led to a 2-fold higher level of stress-induced DNA damage compared to WT HSCs ($p<0.05$). Four rounds of treatment with pI:pC led to a two- or four-fold depletion of transplantable HSC in WT or *Fanca*$^{-/-}$ mice, respectively ($p<0.01$). Further rounds of treatment led to the onset of severe aplastic anemia in all *Fanca*$^{-/-}$ mice but not in any of the WT pI:pC-treated controls nor the age matched PBS-treated *Fanca*$^{-/-}$ mice ($p<0.01$). Bone marrow failure (BMF) was characterized by profound neutropenia, thrombocytopenia and anemia and a >60% reduction in bone marrow cellularity corresponding to an almost complete depletion of all HSCs as well as multipotent and committed progenitors.
Summary and Conclusions: Our data strongly implicates stress-induced exit from quiescence as a cause of physiologic DNA damage in HSCs *in vivo* and provides a novel link between pro-inflammatory cytokines, DNA damage and BMF. Furthermore, we demonstrate that, contrary to previous suggestions, Fanconi knockout mouse models are likely to be useful for dissecting the etiology of this disease if they are subject to the same stress stimuli that FA patients are likely to encounter.

TCIRG1 ASSOCIATED CONGENITAL NEUTROPENIA

V Makaryan[1], E Rosenthal[1], AA Bolyard[1], ML Kelley[1], E Chi[2], GP Jarvik[1], D Dale[1,*]
[1]Medicine, [2]Pathology, University of Washington, Seattle, United States

Background: Severe congenital neutropenia (SCN) is a rare hematopoietic disorder; the genetic basis for >30% of cases remains unknown. We have recently reported a five-generation SCN family of European descent with a novel sin-

gle nucleotide variant (SNV) R736S in *TCIRG1* which perfectly co-segregated between neutropenic and normal members. (Makaryan *et al.* Blood 2013;122:440)
Aims: To describe the clinical/ laboratory features of *TCIRG1* associated neutropenia and its underlying pathophysiological mechanisms.
Methods: We utilized clinical data, blood/ bone marrow samples, routine blood counts, histochemical staining, electron microscopy, immune-magnetic bead cell separation, FACS analysis, Western and Northern analysis for this study.
Results: The median blood neutrophil count (ANC) was $0.524x10^9$/L, range 0.074 to $1.1x10^9$/L for 13 affected members and $3.819x10^9$/L, range 2.343 to $6.5x10^9$/L, for 8 unaffected members. Classification by ANC levels showed a pattern of frequent and more severe infections and morbidity in members with ANC $<1.0x10^9$/L. Bone marrow aspirates from three affected members (none on G-CSF) showed only modest reductions in mature neutrophils. However, by electron microscopy there were major changes in cell cytoplasm (abnormal vacuoles), organelles (mitochondrial membrane disruptions) and cell membranes (loss of villous structures) consistent with apoptosis of myelocytes and more mature marrow neutrophils. Analysis by FACS showed increased annexin V staining of peripheral blood neutrophils and CD 33^+ marrow cells. *TCIRG1* encodes OC116, the vacuolar H+-ATPase a3 subunit, expressed in myeloid progenitors and essential for bone tissue homeostasis. Through alternative splicing and usage of an alternative initiation codon, this same gene also encodes another protein, TIRC7, which plays an important role for T-lymphocyte activation. Recent publications suggest additional splice variants expressed in various tissues with as yet poorly defined functions. To examine the molecular defect and its effect on cell functions, we used commercially available polyclonal antibodies and Western blot analysis of peripheral blood cells from affected and normal members to determine expression of TCIRG1 protein. We found that ~45kDa TCIRG1 product was down-regulated by 26%, 49%, and 35% in the 3 affected individuals, compared to 2 normal controls. An antibody against the TCIRG1 fragment 121aa-220aa, detects a ~120 kDa protein band with similar expression levels in affected individuals and healthy controls. Because of the known role of vacuolar H+-ATPase in acidification of intracellular organelles, we stained peripheral blood neutrophils and bone marrow myeloid progenitors with LysoSensor Green. There was no difference between the patients' and normal cells. We quantitatively examined the effect of mutant TCIRG1 on neutrophil oxidative burst using flow cytometry-based PMA stimulated DHR 123 assay. These studies show no abnormality.
Summary and Conclusions: We conclude that *TCIRG1* associated neutropenia is attributable to impaired neutrophil production due to apoptosis of developing neutrophils and their precursors in the bone marrow. Our findings also suggest that clinical problems or recurrent infection is due to defective production and not abnormal neutrophil function. Our current work is directed toward understanding the molecular and cellular mechanisms leading to intramedullary myeloid apoptosis and a search for molecularly directed therapies.

S731

CYTOGENETIC EVOLUTION AND CLONAL COMPOSITION: PROGNOSTIC IMPACT IN PATIENTS WITH MYELODYSPLASTIC SYNDROMES AND ACUTE MYELOID LEUKEMIA FOLLOWING MDS

N Cevik[1], D Haase[1], J Schanz[1,*]
[1]Hematology and Medical Oncology, University Medicine of Göttingen, Göttingen, Germany

Background: It is known for several years that the occurrence of cytogenetic evolution correlates with an adverse prognosis in patients with Myelodysplastic Syndromes (MDS). The phenomenon of clonal evolution can be observed either at diagnosis or at disease progression.
Aims: The main goal of the present study was to analyze the impact of clonal evolution and its modulation by clonal composition in patients with MDS and AML following MDS (s-AML).
Methods: 538 patients with MDS/s-AML and complete clinical data were included from a single institution. In 227 patients, sequential cytogenetic analyses were performed. Cytogenetic evolution, defined as gain of additional cytogenetic abnormalities, increase of the clone size or occurrence of additional clones was observed in 72 cases. Patients with clonal evolution were clustered according to the clonal composition (NN=no abnormal metaphases; NA: mosaic of normal and abnormal metaphases; AA: only abnormal metaphases). To allow a comparison, patients without cytogenetic evolution (n=466) were also classified according to these cytogenetic criteria. Both of the groups were analyzed in a univariate model regarding overall survival by the method of Kaplan- Meier.
Results: The median survival of patients in the group with cytogenetic evolution and NA and AA karyotypes was significantly reduced ($p<0.01$) in comparison to patients without cytogenetic evolution. Median survival for patients with cytogenetic evolution and NA- karyotype (n=43) was 18 months. The proof of AA-karyotypes and cytogenetic evolution is associated with a median survival of 6,6 (n=27) months only. Survival differences in pair-wise comparisons between patients with cytogenetic evolution with NA and AA cells and those without were also significant (Figure 1). Interestingly, patients with an early occurrence of clonal evolution (<365 days) show a considerably impaired prognosis (median survival 5.3 months) as compared to patients with a later appearance of the evolution (median survival 21.9 months; $p<0.01$).

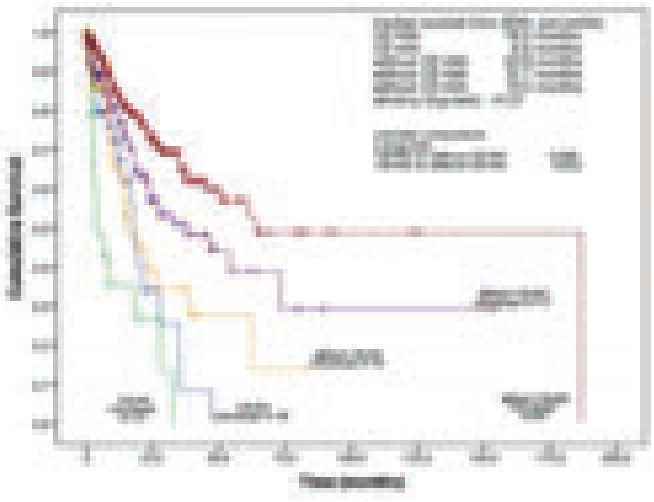

Figure 1.

Summary and Conclusions: Based on survival data of 538 patients, we present the prognostic impact of the clonal composition among patients with cytogenetic evolution and their worse outcome compared to those without cytogenetic evolution. Further data will be presented in detail.

Platelet disorders

Background: Eltrombopag (EPAG) is an oral non-peptide thrombopoietin-receptor agonist licensed for the treatment of thrombocytopenia in adults with chronic immune thrombocytopenia (cITP). In children with cITP, there is no agreed-upon standard treatment, and the risks of long-term consequences from current treatments are unacceptable to many families and physicians.
Aims: This phase III study was conducted to confirm the efficacy, safety, and tolerability of EPAG in children with cITP. The primary objective was to assess the efficacy of EPAG relative to placebo (PBO) in achieving a consistent platelet response defined as counts ≥50 Gi/L (without rescue) for ≥6 out of 8 weeks between weeks 5 and 12 when administered to pediatric subjects with insufficient response to prior ITP treatment.
Methods: Subjects were aged between 1 and <18 years with a confirmed diagnosis of cITP (duration >12 months) and platelet count <30 Gi/L at day 1. Informed consent (and assent as appropriate) was provided. Subjects were stratified as: 12-17 years (Cohort 1), 6-11 years (Cohort 2), and 1-5 years (Cohort 3). Part 1 was a 13-week, double-blind (DB), 2:1 randomization to EPAG or PBO. Subjects could continue stable baseline ITP medications. DB treatment was unblinded at week 13 then subjects began 24 weeks of open-label (OL) treatment with EPAG. Subjects aged 6-17 years weighing ≥27 kg started treatment at 50 mg, and those weighing <27 kg at 37.5 mg. Subjects aged 1-5 years started treatment at 1.2 mg/kg. Dosing at all ages was reduced for East Asian subjects. Dose was adjusted based on platelet counts to a maximum of 75 mg daily.

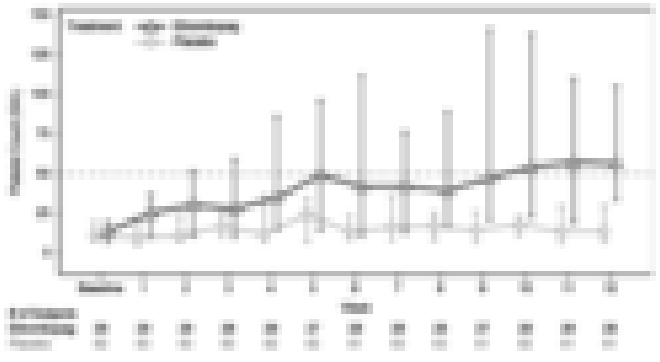

Figure 1. Median (IQR) platelet counts during double-blind treatment in part 1.

Results: 92 subjects were enrolled: 33 to Cohort 1, 39 Cohort 2, and 20 Cohort 3. 63 and 29 subjects were randomized to EPAG and PBO, respectively. 3.4% of subjects on PBO entered the study on ITP treatment compared to 20.6% on EPAG; 6.3% on EPAG had previously undergone splenectomy compared to none on PBO. Dosing regimens: During the DB phase, 63.5% of subjects on EPAG required ≥2 dose adjustments. The median daily dose during the OL phase was 67.7 mg for Cohort 1, 56.9 mg for Cohort 2, and 42.8 mg for Cohort 3. Efficacy: 39.7% of subjects on EPAG met the primary endpoint of consistent response compared to 3.4% on PBO (P<0.001). Response rates were similar across age cohorts at 39% for Cohort 1, 42% Cohort 2, and 36% Cohort 3. 74.6% of subjects on EPAG achieved platelet counts ≥50 Gi/L at least once during the first 12 weeks compared to 20.7% on PBO (P<0.001) (Figure 1). Clinically significant bleeding (World Health Organization grade 2-4) was present at baseline in 28.6% on EPAG and 13.8% on PBO compared to 4.8% at the end of DB phase on EPAG and 6.9% on PBO. In the OL phase, 80.5% of subjects achieved platelet counts ≥50 Gi/L at least once during 24 weeks. Safety: The most common adverse events (AEs) that occurred more frequently on EPAG than PBO included nasopharyngitis, rhinitis, cough, and upper respiratory tract infection. Grade 3/4 AEs occurred in 12.7% of EPAG and 10.3% of PBO subjects. Serious AEs were reported in 8% of subjects on EPAG compared to 14% on PBO. In Part 1, 2 subjects (3%) on EPAG discontinued treatment due to AEs of increased liver transaminases, compared to 1 subject (3%) on PBO who discontinued due to bleeding. Safety in the OL phase was consistent with that in the DB phase. No deaths were reported.
Summary and Conclusions: PETIT2 met its primary endpoint, demonstrating that a consistent response to EPAG can be achieved in children with cITP. There were no new safety concerns and few discontinuations due to AEs.

S733

ELTROMBOPAG TREATMENT OF CHILDHOOD PERSISTENT AND CHRONIC IMMUNE THROMBOCYTOPENIA: FINAL RESULTS OF THE PETIT STUDY (TRA108062), A PHASE 2, PLACEBO-CONTROLLED CLINICAL TRIAL

JB Bussel[1,*] P Garcia de Miguel[2], J Despotovic[3], JD Grainger[4], J Sevilla Navarro[5], V Blanchette[6], P Connor[7], M David[8], D Matthews[9], L Marcello[10], M Iyengar[10], G Chan[10], K Chagin[10], D Theodore[11], C K Bailey[10], K K Bakshi[10]

[1]Weill Medical College of Cornell University, New York, United States, [2]Hospital La Paz, Madrid, Spain, [3]Baylor College of Medicine, Houston, United States, [4]Royal Manchester Children's Hospital, University of Manchester, Manchester, United Kingdom, [5]Hospital del Nino Jesus, Madrid, Spain, [6]The Hospital for Sick Children, Toronto, Canada, [7]Children's Hospital for Wales, Cardiff, United Kingdom, [8]CHU Sainte-Justine, Montreal, Canada, [9]Seattle Children's Hospital, Seattle, [10]GlaxoSmithKline, Collegeville, [11]GlaxoSmithKline, Research Triangle Park, United States

Background: Eltrombopag (EPAG), an oral, non-peptide, thrombopoietin-receptor agonist, is approved for treating thrombocytopenia in adults with chronic immune thrombocytopenia (ITP) with insufficient response to prior therapy. However, there is no data describing the role of EPAG in pediatric ITP.
Aims: PETIT was a placebo-controlled, randomized, double-blind (DB) trial in 3 parts, designed to investigate the efficacy and safety of EPAG in subjects with persistent and chronic ITP and platelets <30 Gi/L. The primary objective was the proportion achieving platelet counts ≥50 Gi/L at least once (without rescue) between days 8 and 43 during the DB part of the study.
Methods: Subjects with ITP of >6 months duration and a platelet count <30 Gi/L who received ≥1 prior treatment were enrolled. Informed consent (and assent as appropriate) was provided. In Part 1, subjects were enrolled in an open-label (OL) dose-finding phase (Cohorts 1, 2, and 3 were aged 12-17, 6-11, and 1-5 years, respectively).[1] In Part 2, DB phase, subjects not participating in Part 1 were randomized 2:1 to EPAG:placebo (PBO) and stratified by age (Cohorts 1-3). After 7 weeks of treatment in Part 2, subjects entered Part 3 where EPAG and PBO subjects received 17 and 24 weeks of OL EPAG, respectively.[1]
Results: 45 and 22 subjects were randomized to EPAG and PBO, respectively. At baseline, 14.9% of subjects had persistent ITP and 85.1% had chronic ITP. 11.1% of EPAG and none of the PBO subjects were splenectomized. The primary endpoint was met by 62.2% and 31.8% of EPAG and PBO subjects, respectively (odds ratio 4.31; 95% CI: 1.4, 13.3; P=0.011). A higher proportion of EPAG-treated subjects responded at each week compared to PBO (Figure 1). Responses in individual cohorts were consistent with the overall response. Secondary endpoints achieved with EPAG and PBO, respectively, included reduced grade 2-4 bleeding on the World Health Organization scale (27% *vs* 59%) and less need for rescue (13.3% *vs* 50%). Platelet response in Part 3 was consistent with Part 2. Median dose in the OL phase was 64.25 mg, 59.05 mg, and 34.0 mg of EPAG daily for Cohorts 1, 2 and 3, respectively. The average of the maximum daily dosing in the OL phase was highest in the youngest cohort (Cohort 1, 1.2 mg/kg; Cohort 2, 1.9 mg/kg; Cohort 3, 2.9 mg/kg). The most common adverse events (AEs) in the EPAG *vs* PBO group, respectively, were headache (29.5% *vs* 42.9%), upper respiratory tract infection (15.9% *vs* 9.5%), and diarrhea (15.9% *vs* 4.8%). No subjects withdrew during Part 2 due to AEs. Grade 3/4 events occurred in 11% and 19% of EPAG and PBO subjects, respectively. Grade 4 events, occurring in similar proportions in each group (4.5% EPAG *vs* 4.7% PBO), included neutropenia and febrile neutropenia in 1 (2.3%) EPAG subject each, and abdominal pain in 1 (4.7%) PBO subject. 15.9% of EPAG subjects and 38.1% of PBO subjects had any bleeding event. Serious AEs (SAEs) were similar in both groups (9.1% EPAG and 9.5% PBO). No fatal AEs occurred. 65 subjects entered Part 3. The majority of AEs in Part 3 were consistent with Part 2. Two subjects withdrew due to Grade 3 increased alanine aminotransferase (ALT) (1 was a SAE), and 1 additional subject had ALT ≥3× ULN. These events resolved.

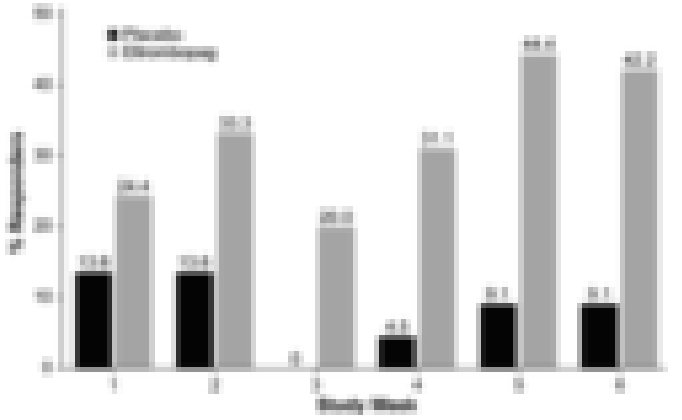

Figure 1. Summary of percent responders (platelet count ≥50K without rescue) during the double-blind period.

Summary and Conclusions: EPAG was an effective treatment in subjects with persistent and chronic ITP. Treatment with EPAG was well tolerated through the study as evidenced by the low incidence of SAEs, Grade 3/4 events, and withdrawals. No new safety concerns were identified.

GFI1B MUTATION CAUSES A NOVEL HUMAN PLATELET DEFECT WITH COMPLEX CHANGES OBSERVED IN ALPHA-GRANULES AND MITOCHONDRIA ASSOCIATED WITH ALTERED EXPRESSION OF PLATELET PROTEINS

W Stevenson[1,*] MC Morel-Kopp[1], Q Chen[1], D Rabbolini[1], A Ng[2], A Roberts[2], M Bahlo[3], C Ward[1]

[1]Haematology, UNIVERSITY OF SYDNEY, Sydney, [2]Cancer and Haematology, [3]Bioinformatics, Walter and Eliza Hall Institute of Medical Research, Melbourne, Australia

Background: Mutation of the human transcription factor GFI1B causes macrothrombocytopenia with variable platelet alpha-granule deficiency and red cell shape change.
Aims: Study of a four generation pedigree with an autosomal dominant bleeding disorder was conducted to identify the causative mutation and characterise the functional platelet defect.
Methods: Genetic linkage analysis followed by massively parallel sequencing was conducted to identify the mutation. Functional studies were then performed in primary human platelets and megakaryocytic cell lines.
Results: Bleeding scores for affected individuals were increased and most affected patients experienced excessive bleeding after surgery. PFA100 closure times were prolonged in affected family members and all affected individuals demonstrated markedly impaired platelet aggregation responses to collagen. Genotyping with a SNP array followed by massively parallel sequencing on telomeric chromosome 9 identified a single nucleotide insertion in exon 7 of GFI1B leading to a frameshift mutation. This mutation disrupts the DNA-binding region of the fifth zinc finger domain. The identified mutation in GFI1B alters the transcriptional function of the protein in a dominant negative manner with the introduction of mutant transcript de-repressing the promoter of the validated GFI1B target gene TGFBR3 and GFI1B itself in megakaryocytic cell lines as measured by a luciferase assay (TGFBR3 16.6 *vs* 23.8, P=0.03; GFI1B 0.73 *vs* 2.24, P<0.01). RNAseq performed on platelets from affected (n=3) and unaffected (n=3) members of this family showed transcriptional changes with 179 transcripts significantly increased and 84 transcripts significantly decreased (P<0.01). CD34 transcript was increased in affected platelets and this was associated with increased CD34 expression on platelets by flow cytometry. Transcripts related to mitochondrial function were significantly increased in the affected cohort and this was validated by morphological analysis by electron microscopy showing an absolute increase in mitochondrial number in GFI1B mutant platelets (3.0 *vs* 2.2, P<0.01). Marked reductions in expression of P-selectin and fibrinogen observed in mutant platelets were not associated with transcriptional changes as measured by RNAseq suggesting that these protein levels are altered via the relative deficiency of alpha-granules observed in GFI1B mutant platelets.
Summary and Conclusions: GFI1B is predicted to bind to more than 2000 gene promoters in haematopoietic cells. RNAseq predicts some protein changes observed in GFI1B mutant platelets whereas other platelet protein changes are secondary to the deficiency of alpha-granules. GFI1B mutation produces a novel human platelet defect with complex changes observed in granule and mitochondrial content associated with altered expression of platelet proteins.

Background: Partum-related hemorrhage is the leading cause of morbidity and mortality among pregnant women resulting in more than a thousand deaths/year both in low and high resource countries. In women with inherited thrombocytopenias (ITs), bleedings are expected to be even more frequent and severe because of the association of thrombocytopenia and possible defects of platelet function. However, medical management of this condition cannot be based on evidence because of the lack of consistent information in the literature.
Aims: Gain information on maternal and neonatal bleeding risk in different forms of IT.
Methods: 181 women with 13 different forms of IT confirmed by genetic analysis were enrolled in this study carried out on behalf of the European Hematology Association-Scientific Working Group on Thrombocytopenias and Platelet Function Disorders: data from a total of 339 pregnancies and 156 IT newborns were collected from 45 institutions worldwide. Bleedings at delivery were defined as "excessive bleeding requiring blood transfusion" (EBBT), based on transfusion of platelets and/or red blood cells during or after delivery to treat bleeding, and "all excessive bleedings" (AEB) based on transfusion of blood products or the judgment of the treating physician that blood loss was larger than normal.
Results: Thrombocytopenia and bleeding tendency in the mothers did not worsen during pregnancy. The course of gestation was uneventful in 304 cases while miscarriages and preterm births occurred with a frequency similar to that of healthy women (10.1% and 9.9%, respectively). Comparison of platelet counts in newborns affected by IT with those in their mothers revealed that the degree of thrombocytopenia was similar. Only 5 IT newborns experienced minor bleeding diathesis, while 2 newborns, both born by vaginal delivery to *MYH9*-RD mothers, experienced a fatal cerebral hemorrhage. Prophylactic platelet transfusions were given in preparation for delivery in 46 of 301 evaluable cases, while other prophylactic treatments were given in 17 cases. One hundred and sixteen of 303 births were by cesarean section. General anesthesia was performed in 27.7% of cases and spinal or epidural anesthesia in 15.9%. No bleeding complications related to these procedures were reported. EBBT and AEB occurred in 6.8% of deliveries (CI 4.17-10.2) and 14.2% of deliveries (CI 10.4-18.7), respectively, with a frequency much higher than in general population. However, no women died from complications of childbirth or required hysterectomy to stop bleeding. EBBT was not less frequent in vaginal deliveries than in cesarean sections and was not reduced in women who

received prophylactic platelet transfusions prior to childbirth. The latter observation may be explained by the lower platelet count in women given platelet transfusions. EBBT at delivery correlated significantly with a history of grade 3 or 4 (OR 5.32, CI 1.22-23.11) and grade 4 (OR 24.50, CI 4.75-126.41) of WHO bleeding scale. ROC analysis identified the value of $50x10^9$ platelets/L as the optimal cut-off of platelet count for the identification of patients with a higher risk for EBBT (OR 7.61, CI 1.55-37.60). Similar results were obtained for AEB.
Summary and Conclusions: Delivery-related bleeding risk was higher in subjects with ITs than in healthy population for both the mothers and the affected newborns. However, childbirth was free from bleeding complications in the vast majority of mothers and neonates. The degree of thrombocytopenia and a history of severe bleeding tendency in the mother have been identified as useful parameters to predict the risk of delivery-related bleedings.

PLATELET PHOSPHATIDYLSERINE EXTERNALIZATION MAY PLAY A CAUSATIVE ROLE IN IMMUNE THROMBOCYTOPENIA

D Sollazzo[1], N Polverelli[1], F Palandri[1], R M Lemoli[2], N Vianelli[1], M Cavo[1], L Catani[1,*]
[1]Department of Specialty, Diagnostic and Experimental Medicine, University of Bologna, Bologna, Italy, Institute of Hematology "L. e A. Seràgnoli", Bologna, [2]Dipartimento di Medicina Interna e Specialità Mediche, Unità Operativa di Ematologia, Genova, Italy

Background: Based on a mouse model, it has recently been shown that an intrinsic program for apoptosis controls platelet survival and dictates their lifespan. Specifically, pro-survival Bcl-xL counteracts the pro-apoptotic activity of Bak to maintain platelet survival, but as Bcl-xL degrades, aged platelets are primed for death. Thus, platelets are genetically programmed to die by apoptosis and the antagonistic balance between Bcl-xL and Bak constitutes a molecular clock that determines platelet life-span (Mason, 2007). In addition, data in a mouse model suggest that antibodies against platelet surface glycoproteins (GP) participate in the triggering of platelet apoptosis (Leytin, 2006). Interestingly, these mechanisms of regulation of platelet survival have never been characterized in patients with Immune Thrombocytopenia (ITP).
Aims: We aim to characterize whether in ITP: 1) abnormalities of the intrinsic pathway of apoptosis, specifically the Bcl-xL/Bak system, may play a pathogenetic role; 2) antiplatelet antibodies participate in the triggering of platelet apoptosis.
Methods: We studied 30 patients with active chronic ITP. Apoptosis together with the expression of Bcl-xL and Bak proteins and cytochrome-c release have been characterized at flow cytometry on freshly isolated and *in vitro* aged platelets of healthy subjects and ITP patients. A flow cytometry analysis of apoptosis induced by ABT-737, a selective Bcl-xL-inhibitor, was also investigated. Platelet apoptosis has also been characterized after incubation of normal platelets with platelet poor plasma (PPP) from antiplatelet antibodies-positive (Ab+) or antibodies-negative (Ab-) ITP patients or from healthy subjects. In addition, *in vitro* studies with monoclonal antibodies (MoAb) against platelet GPIIb (CD41) and GPIb (CD42b) have been also performed.
Results: We demonstrate that platelets from ITP patients, freshly isolated ($p<0.05$) and *in vitro* aged ($p<0.02$) in the presence of autologous plasma, show higher phosphatidylserine (PS) exposure in comparison to their normal counterparts. The MIF value of Bcl-xL protein in fresh platelets was similar between patients and controls. However, it was significantly reduced in *in vitro* aged platelets of patients as compared to that of healthy subjects ($p<0.04$). By contrast, we found no significant differences in Bak expression between patients and controls or between aged and fresh platelets. *In vitro* aged platelets from ITP patients showed significantly reduced expression of cytochrome-c ($p<0.02$). Pharmacological inhibition of Bcl-xL by ABT-737 induced a dose-dependent increase in PS exposure, which was significantly reduced in treated platelets from patients as compared to their normal counterparts ($p<0.02$). Healthy platelets incubated with PPP from antiplatelet Ab+ patients showed a significant increase in PS exposure compared with those incubated with PPP from antiplatelet Ab- patients or normal subjects ($p<0.03$). Same results were obtained when platelets from patients or healthy subjects were incubated *in vitro* with the MoAb anti-CD42b ($p<0.01$). At the opposite, PS exposure did not change significantly after incubation with the anti-CD41 MoAb.
Summary and Conclusions: Our results demonstrate that a deregulated intrinsically programmed cell death is the hallmark of *in vitro* aged platelets from ITP patients and suggest that it may play a role in the pathogenesis of the disease.

Hematopoietic disorders and transfusion

25 YEAR-UPDATE ON THE LONG-TERM SAFETY OF TREATMENT WITH RECOMBINANT HUMAN GRANULOCYTE-COLONY STIMULATING FACTOR IN PATIENTS WITH SEVERE CONGENITAL NEUTROPENIAS IN EUROPE

C Zeidler[1,*] S Mellor-Heineke[1], A Nickel[1], U Grote[1], K Welte[1]
[1]Molecular Hematopoiesis, OE6790, Medical School Hannover, Hannover, Germany

Background: Congenital neutropenias (CN) include a heterogenous group of diseases characterized by a decrease in circulating neutrophils and different underlying germline gene mutations. Since 1988 recombinant human G-CSF (Filgrastim, Lenograstim) is available for the treatment of severe chronic neutropenia patients. In phase I/II/III studies in patients with severe congenital and cyclic neutropenia, treatment with G-CSF (Filgrastim) resulted in a rise in the absolute neutrophil counts (ANC) and a reduction in infections.
Aims: As an update on the long-term safety of subcutaneous G-CSF administration we now report on 443 neutropenia patients (congenital n=366, cyclic n=77) evaluated over the past 25 years by the European Branch of the Severe Chronic Neutropenia International Registry (SCNIR), Hannover, Germany, on behalf of the Local Liaison Physicians in 22 European countries.
Results: 368 of 443 patients (median age 13 years) receive long-term daily subcutaneous G-CSF treatment for a median duration of 7 years (maximum 24,7 years). Our cohort includes even 20 patients receiving G-CSF treatment for more than 20 years. A sustained ANC response was seen in the majority of severe congenital neutropenia and cyclic neutropenia patients documenting that there is no exhaustion of myelopoiesis in the bone marrow and no immune reaction with neutralizing antibody production. Eighteen patients completely failed to respond to G-CSF treatment and required immediate stem cell transplantation. Median G-CSF doses vary by neutropenia subtype and gene mutation. Up to now more than ten different germline mutations were identified (*ELANE, HAX1, G6PC3*, etc.) which can cause congenital neutropenias. Patients with congenital neutropenia revealing *ELANE* mutations require the highest G-CSF doses compared to other subtypes (median G-CSF dose 5 µg/kg/day in 88 patients). Four patients (including two patients with Shwachman-Diamond syndrome) developed pancytopenia under G-CSF and also received SCT. Significant adverse events noted which may or may not be related to therapy included: osteopenia, splenomegaly, vasculitis, glomerulonephritis, BM fibrosis and MDS/leukaemia. Independent of the genetic subtype patients with congenital neutropenia have a risk of more than 10% to develop leukemia which documents that CN is a preleukemic syndrome. There is an association of G-CSF dose with the relative hazard of MDS/AML documenting the correlation between the severity of the underlying disease as judged by the requirement of the G-CSF dose and the risk for malignant transformation. Recently we identified an unique pathway of leukemogenesis, namely that acquired *CSF3R* mutations followed by mutations in the gene for the transcription factor *RUNX1* are present in the majority of patients with secondary leukemias (Skokowa, *et al.*, Blood 2014). SCT is the only treatment of choice to achieve long-term remission in these patients. None of the 77 patients with cyclic neutropenia developed leukemia documenting that G-CSF treatment by itself does not cause leukemias.
Summary and Conclusions: In summary, a significant decrease in the incidence of severe infections and the need for intravenous antibiotics was noted in these patients. G-CSF treatment has been well tolerated in the majority of patients and resulted in a long-term improvement in their clinical status, prolonged survival, and improved the quality of life. As a proof of the benefit of G-CSF treatment a total 109 of the 363 congenital and 38 of the 77 cyclic neutropenia patients have meanwhile reached adulthood, including 16 women and 8 men who became parent. The long-term safety of G-CSF has been well documented by this 25-year follow-up study.

S738

LOSS-OF-FUNCTION COMPOUND HETEROZYGOUS MUTATIONS IN THE CSF3R GENE IN A PATIENT WITH SEVERE CONGENITAL NEUTROPENIA: SUCCESSFUL TREATMENT WITH GM-CSF

M Klimiankou[1,*] O Klimenkova[1], M Ünalan[1], S Kandabarau[1], C Zeidler[1], J Skokowa[1], K Welte[1]
[1]Department of Molecular Hematopoiesis, Hannover Medical School, Hannover, Germany

Background: Previously we have presented a clinical case of 10 year old female severe congenital neutropenia patient who did not respond to the treatment with G-CSF (Filgrastim) in a dose up to 100 µg/kg/day. Since the birth this patient has severe neutropenia with reduced myelopoiesis in the bone marrow (BM) without maturation arrest at promyelocytes/myelocytes stage. No mutations in *ELANE*, *HAX1,* and *G6PC3* genes were detected and no involvement of other organs was documented. At age of 7 months treatment with GM-CSF (4 µg/kg/week) was applied and patient responded with ANC between 1000/µl and 2000/µl. At age of 6 years therapy was replaced by G-CSF with no response. CFU assay of BM MNC from this patient showed that G-CSF was not able to induce CFU-G, CFU-M and CFU-GM colonies due to diminished surface expression levels of G-CSFR and abrogated G-CSFR-triggered intracellular signaling pathways (e. g. phErk1/2, phSTAT5). In sharp contrast, bone marrow progenitors treated *in vitro* with 10ng/ml GM-CSF differentiated to all type of CFU colonies.
Aims: To search the reasons of the G-CSF unresponsiveness, we sequenced the exons of the *CSF3R* gene and identified inherited heterozygous stop-codon mutation p.W547* (NP_000751), C1641T (NM_000760) in the extracellular part of the G-CSFR protein within the fifth fibronectin type III domain. Since heterozygous *CSF3R* mutation does not explain completely unresponsiveness to G-CSF therapy, we aimed to identify additional abnormalities in G-CSFR by sequencing the whole *CSF3R* gene including introns and 3`- and 5`-UTRs by means of SOLID 5500xl. To evaluate the intracellular signaling pathways required for GM-CSF-triggered neutrophilic granulopoiesis in the absence of G-CSF signaling, we performed gene expression microarray analysis using RNA isolated from $CD33^+$ BM myeloid cells of affected individual in comparison to the cells of G-CSF- treated CN patients.
Methods: Next generationg sequencing, Sanger sequencing, PCR, RT-PCR, gene expression microarray analysis, real-time PCR, FACS, CFU assay.
Results: We identified a second mutation at the 3′ splice-acceptor site of intron 8 of the *CSF3R* gene. Sanger sequencing of DNA from the patient's parents confirmed that both *CSF3R* mutations are inherited: the non-sense mutation was inherited from the father, whereas the mutation at 3′ splice-acceptor site was detected in mother's DNA. Amplification of CSF3R RNA from patient's blood sample revealed the presence of the smaller abnormal *CSF3R* transcript additionally to the full-length transcript. The abnormal transcript appears presumably due to exon 8 skipping what is one of the most common consequences of the splice site mutations. We analyzed the microarray data by Ingenuity Systems Pathway Analysis (IPA). Intriguingly, neutrophil differentiation upon GM-CSF treatment was associated with highly upregulated expression (more than 3 fold) of neutrophil granule proteins (MPO, ELANE, CTSG, DEFA4, LCN2, OLFM4, etc.) and transcription factor C/EBPε in $CD33^+$ bone marrow myeloid cells, as compared to the cells of G-CSF-treated CN patients. However, in contrast to CN patients, we found no upregulation of the activators of emergency pathway responsible for neutrophilic granulopoiesis (NAMPT and C/EBPß).
Summary and Conclusions: Taken together, we reported here a patient with compound heterozygous mutations in the *CSF3R* gene leading to the complete "loss-of-function" of G-CSFR protein. Since the majority of studies on the *CSF3R* mutations are targeting the cytoplasmic part of the receptor only, we would suggest that in CN patients who do not respond to G-CSF whole *CSF3R* gene should be tested. Therapeutic application of granulopoietic cytokines other then G-CSF (*e.g.* GM-CSF) to activate alternative mechanisms of granulopoiesis (*e.g.* via C/EBPε) in this group of patients should be considered.

S739

ELUCIDATION OF THE INTRACELLULAR DEFECTS LEADING TO THE ABROGATED GM-CSF-TRIGGERED GRANULOPOIESIS IN CN PATIENTS

C Koch[1], S Kandabarau[1], K Welte[1,*] J Skokowa[1]
[1]Molecular Hematopoiesis, Hannover Medical School, Hannover, Germany

Background: G-CSF is successfully used to treat patients with severe congenital neutropenia (CN) but GM-CSF failed to increase neutrophil numbers in the majority of these patients (Welte, el al, Blood 1990). GM-CSF induces monocytosis and eosinophilia in CN patients to the levels comparable to GM-CSF treated healthy individuals. This suggests isolated defects in the GM-CSF downstream signaling responsive for neutrophilic granulopoiesis in CN.
Aims: We aimed to evaluate why GM-CSF-triggered neutrophil granulopoiesis is abrogated.
Methods: We performed *in vitro* differentiation of CD34+ hematopoietic cells, stimulated hematopoietic cells with GM-CSF and further evaluated downstream signaling by ELISA, qRT-PCR and GeneExpression microarrays from Affymetrix.
Results: Recently, we demonstrated severely diminished expression levels of LEF-1 and C/EBPa transcription factors in CN myeloid cells leading to abrogated "steady-state" neutrophil granulopoiesis (Skokowa, *et al.*, Nat Med 2006). After inhibition of LEF-1 in $CD34^+$ cells from healthy individuals by shRNA GM-CSF was not able to induce neutrophil granulopoiesis, but activated monocytopoiesis. Previously we found that in CN patients G-CSF induces C/EBPß-triggered "emergency" granulocytic differentiation by activation of NAMPT/SIRT1 signaling (Skokowa, *et al.*, Nat Med 2009). NAMPT is important for GM-CSF-triggered neutrophilic granulopoiesis: (1) GM-CSF induces NAMPT, SIRT1 and C/EBPß in hematopoietic cells of healthy individuals; (2) GM-CSF failed to induce CFU-G after pre-treatment of hematopoietic cells from healthy individuals with the specific NAMPT inhibitor FK866. GM-CSF only slightly induced expression of NAMPT, SIRT1 and C/EBPß in CN hematopoietic cells, in comparison to the pronounced effects of G-CSF. We concluded, that GM-CSF is not able to induce neutrophilic granulopoiesis in CN patients due to a lack of LEF-1/C/EBPα and its inability to induce NAMPT/SIRT1/C/EBPß.

To better understand the intracellular signaling pathways activated by GM-CSF/NAMPT we performed microarray studies. We compared gene expression signature of GM-CSF treated CD33+ myeloid progenitor cells of CN patients and healthy individuals. In one group of CD33+ cells of healthy individuals we additionally blocked NAMPT signaling by treatment of cells with FK866, to mimic the "CN-like phenotype". We selected a list of genes that were up- or downregulated in GM-CSF- treated CD33+ cells of healthy individuals but were not modified by GM-CSF in NAMPT-deficient healthy controls and in cells of CN patients. We assumed that these genes are normally activated by GM-CSF/NAMPT and could not be regulated by GM-CSF in CN patients due to a lack of NAMPT activation. We applied the obtained gene list for the Ingenuity Pathway Analysis (IPA) and found that the IL-13R signaling pathway was most significantly affected (activation z-score=0,333; p-value of overlap=0,0000546). GM-CSF regulated the components of IL-13R signaling (incl. ADAM28, ARNTL2, CD209, CLEC4A, CXCL5, CYBB, IL1B, IL1RN, SLC16A6) in healthy individuals, but failed to do it after inhibition of NAMPT and in cells of CN patients. To prove the link between NAMPT and IL-13 signaling, we activated NAMPT by treatment of healthy individuals with nicotinamide and measured IL-13 synthesis in plasma. Indeed, we found significant increased levels of IL-13 in plasma of treated individuals (p=0,003), suggesting activation of IL-13 by nicotinamide. Moreover, IL-13 downstream molecules mentioned above were regulated in CD33+ cells from healthy individuals treated with nicotinamide *in vitro*. The involvement of IL-13 in the GM-CSF/NAMPT triggered granulopoiesis is novel and interesting but is not fully understood yet.

Summary and Conclusions: Taken together, GM-CSF failed to induce granulopoiesis in CN patients due to its inability to activate NAMPT/C/EBPß-dependent "emergency granulopoiesis" and to regulate NAMPT/IL-13R signaling.

S740

COMPARISON OF TWO DOSE-REGIMENS OF PROTHROMBIN COMPLEX CONCENTRATES IN URGENT ANTICOAGULATION REVERSAL. A PROSPECTIVE, RANDOMISED STUDY.

G Papakitsos[1,*] A Kapsali[2], T Papakitsou[3], A Roimba[4]
[1]ANESTHETIC, [2]GHARTA, ARTA, [3]Haematologic, GHMesologi, Mesologi, [4]ED, St Paul GH Thessaloniki, Thessaloniki, Greece

Background: Prothrombin Complex Concentrates (PCC) are haemostatic blood preparations indicated for urgent anticoagulation reversal, though the optimal dose for effective reversal is still under debate. The latest generations of PCC's include four coagulation factors, the socalled 4-factor PCC.

Aims: The aim of this study was to compare the efficacy and safety of two doses, 25 and 40 IU/kg, of 4-factor PCC in vitamin K antagonist (VKA) associated intracranial haemorrhage.

Methods: We performed a prospective, randomised study including patients with objectively diagnosed VKA-associated intracranial haemorrhage between February 2008 and April 2012. Patients were randomised to receive 25 or 40 IU/kg of 4-factor PCC. The primary endpoint was the International Normalised Ratio (INR) 10 minutes after the end of 4-factor PCC infusion. Secondary endpoints were changes in coagulation factors, global clinical outcomes and incidence of adverse events (AEs).

Results: A total of 58 patients were randomised: 28 in the 25 IU/kg and 30 in the 40 IU/kg group. Baseline demographics and clinical characteristics were comparable between the groups. The mean INR was significantly reduced to 1.2 and 1.5 in all patients of both groups -10 min after 4-factor PCC infusion. The INR in the 40 IU/kg group was significantly lower than in the 25 IU/kg group 10 min (p=0.001), 1 hour (p=0.001) and 3 hours (p=0.02) after infusion. The 40 IU/kg dose was also effective in replacing coagulation factors such as PT (p=0.038), FII (p=0.001), FX (p<0.001), protein C (p=0.002) and protein S (0.043), 10 min after infusion. However, no differences were found in haematoma volume or global clinical outcomes between the groups. Incidence of death and thrombotic events was similar between the groups.

Summary and Conclusions: Rapid infusion of both doses of 4-factor PCC achieved an INR of 1.5 or less in all patients with a lower INR observed in the 40 IU/kg group. No safety concerns were raised by the 40 IU/kg dose. Further trials are needed to evaluate the impact of the high dose of 4factor PCC on functional outcomes and mortality.

S741

TREATMENT OF REFRACTORY HYPERHEMOLYTIC TRANSFUSION REACTION IN HEMOGLOBINOPATHIES WITH CYCLOSPORIN

CE Mactier[1,*] A Luqmani[1], M Rowley[1], DM Layton[1]
[1]Haematology, Imperial College, London, United Kingdom

Background: Hyperhemolytic transfusion reaction (HHTR) is a rare but potentially fatal complication of blood transfusion the distinguishing characteristic of which is severe hemolysis with a fall in hemoglobin (Hb) to below pre-transfusion level due to destruction of both transfused and recipient red cells and/or reticulocytopenia. First and most frequently reported in sickle cell disease HHTR has also been described in thalassemia disorders and patients without hemoglobinopathies. Proposed mechanisms include bystander haemolysis, suppression of erythropoiesis and destruction of red cells by activated macrophages. The mainstay of management in HHTR is avoidance of transfusion which exacerbates hemolysis with in severe cases steroids and high dose intravenous immunoglobulin (IVIG) +/- erythropoietin (EPO). If despite this further transfusion proves necessary IVIG and methylprednisolone (MP) may limit the risk of hemolysis. Cases of HHTR refractory to such measures pose a considerable challenge. Various treatment modalities including cyclophosphamide, rituximab, splenectomy, plasma exchange, and allogeneic hematopoietic stem cell transplantation have been advocated in individual cases. We describe the successful use of cyclosporin (CsA) for treatment of life-threatening refractory HHTR in sickle cell and thalassemia disorders.

Aims: To assess the efficacy of cyclosporin for treatment of refractory HHTR. Primary endpoints were Hb and transfusion requirement.

Methods: Patients with refractory HHTR treated in our tertiary haemoglobinopathy centre between 2007 and 2013 were identified retrospectively. HHTR was defined as post-transfusion hemolysis with a fall in Hb to below pre-transfusion value in the absence of other cause and refractory HHTR as the persistence or recurrence of severe anemia following transfusion despite treatment with steroids and IVIG +/- rituximab. Case notes, pathology results and transfusion laboratory records were reviewed.

Results: Three patients fulfilled the inclusion criteria (Table 1). Mean age was 30 years. HHTR developed between 5-21 days after initial transfusion of 2-4 red cell units with a fall in Hb to 28-34 g/L, on average 18±4% below pre-transfusion level. In all cases the direct anti-globulin test (DAT) was positive and multiple red cell alloantibodies were detected. In cases 1 and 3 the antibody profile reflected previous alloimmunisation. In case 2 there was no known history of alloimmunisation. Despite concurrent administration of IVIG+MP with transfusion of phenotype and cross-match compatible red cell units, EPO, prednisolone (cases 1 and 3), and rituximab (case 1) profound anemia developed with a Hb of 21-29 g/L, on average 20±6% below the initial nadir. Bone marrow examination undertaken in cases 1 and 3 revealed erythroid hyperplasia. CsA was commenced with a target level of 150-200 µg/L 2 weeks-8 months after the onset of HHTR and continued for 3-12 months. A gradual increment was observed in Hb which stabilised after 3 months at 55-69 g/L within or slightly below the patient's previous steady state range. Prior to commencing CsA therapy patients had received between 7 and 19 red cell units following the development of HHTR. CsA was associated a significant reduction in transfusion requirement. Two cases received no further transfusion after initiation of CsA therapy. Case 2 received one further transfusion within 2 weeks of commencing CsA and further transfusion was given for pregnancy related complication but after the post-partum period no further transfusion was required while receiving CsA. Following cessation of CsA therapy a reduction in Hb was observed after 6, 2.5 and 36 weeks. In two patients (cases 2 and 3) the Hb level was restored following reintroduction of CsA which in case 2 was discontinued after 6 months with no recurrence of hyperhemolysis during follow up over 5 years. One patient (case 1) died from sepsis and multiorgan failure.

Table 1.

Summary and Conclusions: This is the first case series reporting the use of the calcineurin inhibitor cyclosporin A in the treatment of refractory HHTR. This novel approach was associated with recovery in Hb and abrogation of transfusion requirements in patients with both sickle cell and thalassemia disorders with this potentially life-threatening complication. The optimal duration of CsA therapy in HHTR remains to be defined.

Gene & cell therapy

Background: In patients with β-thalassemia major, haematopoietic stem cell (HSC) gene therapy has the potential to induce production of β-globin, γ-globin or modified β-globin in the RBC lineage and reduce or stop the need for transfusions. A prior clinical trial (LG001) demonstrated benefit of autologous CD34+ cells transduced with a replication-defective, self-inactivating lentiviral vector (HPV569) containing an engineered β-globin gene ($\beta^{A\text{-}T87Q}$). A further modified $\beta^{A\text{-}T87Q}$, vector (LentiGlobin BB305) has achieved greater transduction efficiency and a similar pre-clinical safety profile. LentiGlobin BB305 is now being evaluated in the HGB-205 clinical trial.
Aims: To provide (i) long-term follow-up data on two subjects treated in LG001 and (ii) initial results from the HGB-205 study.
Methods: After the provision of informed consent, subjects with β-thalassemia major underwent HSC collection via peripheral blood apheresis and CD34+ cells were selected. Estimation of the mean *ex vivo* vector copy number (VCN) was obtained by qPCR performed on pooled *in vitro* colony-forming progenitors. Subjects underwent myeloablation with intravenous busulfan, followed by infusion of transduced CD34+ cells. Subjects were monitored for haematological engraftment, $\beta^{A\text{-}T87Q}$, expression (by HPLC) and transfusion requirements. Integration site analysis (by LAM-PCR and high-throughput sequencing on nucleated cells) and replication-competent lentivirus assays were performed.
Results: In LG001, two subjects (#1003 and #1004) with β^{E}/β^{0}, thalassemia major successfully engrafted following gene therapy with autologous HSCs transduced with HPV569. Neither subject experienced a cell infusion related adverse event. As reported previously (*Nature* 2010), #1003 became transfusion-independent one year post–transplant and remains so 5 years later, with the production of 2.5 - 3.5 g/dL $\beta^{A\text{-}T87Q}$-globin (~30% of total haemoglobin). The most recent VCN in #1003's peripheral neutrophils is 0.23. Subject #1003 also demonstrated partial dominance of a clone with vector integration within the HMGA2 gene that peaked at 4 years post-treatment (22% of the nucleated cells) and has now fallen to 6.8% while maintaining transfusion independence. For #1004, the current VCN (2 years post-treatment) in neutrophils is 0.016 and $\beta^{A\text{-}T87Q}$–globin accounts for ~5% of total haemoglobin. This subject remains transfusion dependent. Two subjects with β^{E}/β^{0}, thalassemia major (#1201 and #1202) have enrolled in the current HGB-205 trial and one has undergone transplantation. Transduction efficiency of the new BB305 vector compared to HPV569 is shown in Table 1. Data on the transplant outcomes and up to 6 months of follow-up in subjects treated in the HGB-205 trial will be presented at the meeting.

Table1. Comparison of gene transfer efficiencies and transplantation outcomes with HPV569 *vs.* BB305 $\beta^{A\text{-}T87Q}$-LentiGlobin vectors

Summary and Conclusions: Long-term transfusion independence is achievable with gene therapy for β thalassemia major. Use of the LentiGlobin BB305 vector has resulted in substantially higher VCN in CD34+ cells. It remains to be seen how the clinical outcomes will reflect this improvement.

S743

PHASE I TRIAL OF AUTOLOGOUS CD19-TARGETED CAR-MODIFIED T CELLS AS CONSOLIDATION AFTER PURINE ANALOG-BASED FIRST-LINE THERAPY IN PATIENTS WITH PREVIOUSLY UNTREATED CLL

JH Park[1,*] I Riviere[2], X Wang[2], S Bartido[2], M Sadelain[2], R J Brentjens[2]
[1]Leukemia Service, [2]Memorial Sloan-Kettering Cancer Center, New York, United States

Background: Patient T cells may be genetically modified to express chimeric antigen receptors (CARs) targeted to antigens expressed on tumor cells. We have previously reported initial results from a phase I clinical trial treating patients with chemotherapy refractory and relapsed CLL with autologous T cells modified to express the 19-28z CAR targeted to the CD19 antigen expressed on most B cell malignancies (Brentjens RJ *et al.*, Blood 2011). While the anti-tumor activity of the CD19-targeted CAR-modified (CAR^+) T cells has been modest in the setting of rapidly progressive and chemotherapy refractory disease, we have observed significantly increased rates of durable responses in CLL patients with reduced disease burden and chemotherapy-sensitive disease (Park JP *et al.*, ASH Abstract 2011).
Aims: In order to address the previously recognized limitation of autologous T cells modified to express CAR targeting CD19 in patients with chemotherapy refractory and relapsed CLL, we designed a phase I trial wherein CLL pts with residual disease following the first-line chemotherapy will receive the CD19-targeted CAR^+ T cells as a consolidative therapy.
Methods: Patients with CLL who have achieved either partial (PR) or complete response (CR) with detectable minimal residual disease (MRD) to the first-line therapy consisting of 6 cycles of pentostatin, cyclophosphamide and rituximab (PCR) were enrolled. Autologous T cells were transduced with a retroviral vector encoding the anti-CD19 scFv linked to CD28 co-stimulatory and CD3ζ signaling domains (19-28z). Patients received cyclophosphamide conditioning therapy followed by 3 escalating doses of CAR^+ T cells. Response was assessed at 3 months according to the NCI-WG criteria. Serial bone marrow aspirate and blood samples were assessed for the modified T cell persistence (assessed by flow and RT-PCR) and cytokine profile analysis
Results: To date, 7 patients have received the CAR^+ T cells in 3 dose cohorts ($3x10^6$ - $3x10^7$ CAR^+ T cells/kg). 6 patients had unmutated IgHV and 2 patients had del11q. All 7 patients achieved PR following the PCR chemotherapy. 4 patients had palpable lymphadenopathy (1 pt with bulky lymph nodes) prior to the T cell infusion. Median follow-up was 11 months (range, 3 – 17 mos). No DLT was observed. Mild and self-limiting cytokine release syndrome (CRS) was observed in 3 patients, and there was a positive correlation between the development of CRS and the CAR^+ T cell persistence. 1 patient achieved CR; 2 patients achieved CR in the bone marrow (1 MRD negative CR) but had progressive disease in lymph node only; 3 patients achieved PR; and 1 patient had progressive disease but this pt had rapidly rising ALC at the time of T cell infusion.
Summary and Conclusions: Autologous CD19-targeted CAR^+ T cells appear to be safe and have promising anti-tumor efficacy in patients with high-risk CLL undergoing first-line chemoimmunotherapy. Our findings suggest that the CD19-targeted CAR^+ T cells are more effective in eradicating disease in the marrow *versus* lymph nodes, and further studies are being conducted to better understand the mechanism of resistance.

S744

LIVER-DIRECTED LENTIVIRAL GENE THERAPY PROVIDES STABLE BENEFIT IN HEMOPHILIA B DOGS WITHOUT EVIDENCE OF GENOTOXICITY IN SENSITIZED MOUSE MODELS

A Cantore[1,2,*]M Ranzani[1,2], C Bartholomae[3], M Volpin[1,2], P Della Valle[4], F Sanvito[5], L Sergi Sergi[1], P Gallina[1], F Benedicenti[1], D Bellinger[6], A D'Angelo[4], T VandenDriessche[7], M Schmidt[3], T Nichols[6], E Montini[1], L Naldini[1,2]
[1]San Raffaele - Telethon Institute for Gene Therapy, [2]Vita Salute San Raffaele University, Milan, Italy, [3]German Cancer Research Center, Heidelberg, Germany, [4]Coagulation Service, [5]Pathology Unit, San Raffaele Scientific Institute, Milan, Italy, [6]University of North Carolina, Chapel Hill, United States, [7]Free University of Brussels, Brussels, Belgium

Background: Lentiviral vectors (LVs) are attractive vehicles for liver-directed gene therapy by virtue of their ability to stably integrate in the genome of target cells and the lack of pre-existing humoral and cellular immunity against vector components in most humans. Over the past years, we have developed a LV platform that can achieve stable transgene expression in the liver, induce transgene-specific immune tolerance and establish correction of hemophilia in mouse models upon systemic administration. This LV is designed to stringently target transgene expression to hepatocytes through transcriptional and microRNA-mediated regulation.
Aims: Although encouraging, these results were obtained in small animal models and it is crucial to assess the feasibility and safety of scaling-up liver-directed LV gene therapy in large animal models before clinical translation. In addition, whereas liver gene transfer by L*Vs* appeared to be safe in the treated mice, concerns remain regarding the risks associated with vector insertional mutagenesis and studies in more stringent models are warranted. Here we address these issues exploiting the large-scale manufacturing process of L*Vs* for clinical testing and tumor-prone mouse models to enhance the sensitivity of testing vector genotoxicity.
Methods: We produced 3 large-scale batches of L*Vs* qualified for *in vivo* administration according to methods and specifications previously set for use in clinical trials. Each LV batch was infused entirely in one adult hemophilia B dog by portal vein administration. We challenged the safety of lentiviral integration in liver cells, in different settings of escalating stringency, by analysis of LV integration site (IS) distribution in the genome of hemophilia B mice at different times and neonatal administration in 2 sensitive mouse models of genotoxicity.
Results: We observed long-term stable reconstitution of coagulation factor IX (FIX) activity up to 1% of normal and significant amelioration of the clinical phenotype in 3 treated dogs (>6 years cumulative follow up). LV infusion was associated with transient signs of inflammation and mild hepatotoxicity which could be abrogated by pretreatment with anti-inflammatory drugs. There was no detectable long-term toxicity or development of FIX inhibitors. Concerning integration safety, the analysis of genomic LV IS at different times after administration showed that any deviation from random represented LV-intrinsic integration biases and not the outcome of *in vivo* selection. We then exploited 2 sensitive mouse models of genotoxicity and an aptly designed genotoxic LV as a positive control for insertional mutagenesis. While this LV induced hepatocellular carcinoma (HCC) at high frequency, the therapeutic LV did not increase the spontaneous occurrence of HCCs in these mice. We retrieved >9,500 unique IS and did not detect any evidence of selection of cells transduced by the therapeutic LV. These studies did not uncover any biological or molecular evidence of genotoxicity by the therapeutic LV even after administration to newborn tumor-prone or tumor-promoted mice.
Summary and Conclusions: Overall, our study positions LV-mediated liver gene therapy for further pre-clinical development and future clinical translation. L*Vs* may thus complement other available vectors to address some of the outstanding challenges posed by liver gene therapy of hemophilia and conceivably other diseases.

S745

ACTIVITY OF RAPIDLY-GENERATED BROAD-SPECTRUM T CELLS AS TREATMENT FOR ADENOVIRUS, EBV, CMV, BK VIRUS AND HHV6 INFECTIONS AFTER ALLOGENEIC HEMATOPOIETIC STEM CELL TRANSPLANTATION

A Papadopoulou[1,*] U Gerdemann[1], U Katari[1], I Tzannou[1], H Liu[1], C Martinez[1], K Leung[1], G Carrum[1], A Gee[1], V Juan[1], R Krance[1], M Brenner[1], C Rooney[1], H Heslop[1], A Leen[1]
[1]Center for Cell and Gene Therapy, Houston Methodist Hospital, Texas Children's Hospital, Baylor College of Medicine, Houston, United States

Background: Viral infections remain a major cause of morbidity and mortality after allogeneic hematopoietic stem cell transplantation (HSCT). We have previously demonstrated that the adoptive transfer of small numbers of *ex vivo*-expanded trivirus-specific T-cells (tVSTs) targeting EBV, CMV, and Adv is safe, effective and protective *in vivo*. However, broader implementation is limited by a manufacturing process that is prolonged (8-12wks), complex and requires infectious virus (EBV) and vector (Adv). Moreover, antigenic competition limits extension to additional viruses.
Aims: To generate T-cell lines with activity against 5 common post-transplant viruses (EBV, CMV, Adv, BK, HHV6), using a simplified 10-day procedure that excludes viral components, and show that a single line can be clinically effective against multiple viruses.
Methods: With NHLBI-PACT support 48 clinical-grade donor-derived multivirus (m)VSTs have been generated by exposing $3x10^7$ PBMCs to overlapping peptide libraries spanning Adv (Hexon, Penton), CMV (pp65, IE1), EBV (LMP2, EBNA1, BZLF1), BKV (Large T, VP1) and HHV6 (U11, U14, U90) antigens.
Results: We expanded a median of $35.7x10^7$ cells (range: $9.9\text{-}82.5x10^7$) over 9-11 days. The lines were polyclonal, comprising both CD4+ (57±2%) and CD8+ (35±2%) cells, that expressed central CD45RO+CD62L+ (62±3%) and effector memory markers CD45RO+/CD62L- (10±1%). mVST specificity was dependent on the donor's prior viral exposure; 45/48 lines had Adv activity (Hexon: 470±71; Penton: 366±86 SFC/$2x10^5$), 26/48 against CMV (IE1: 356±157; pp65: 1048±446), 37/48 against EBV (LMP2: 137±76; EBNA1: 123±52; BZLF1: 99±75), 28/48 against BKV (Large T: 123±61; VP1: 208±89) and 29/48 against HHV6 (U90: 109±78; U11: 37±17; U14: 84±26). None of the lines reacted against recipient PHA blasts. Eleven allogeneic HSCT recipients have received mVSTs in a dose escalation study with informed consent; 4 on DL1 ($5x10^6/m^2$), 4 on DL2 ($1x10^7/m^2$) and 3 on DL3 ($2x10^7/m^2$). There were no immediate infusion-related toxicities. One patient developed *de novo* Grade II GvHD of the skin 4 weeks after mVSTs, which improved with the administration of topical steroids. Three patients received the cells prophylactically and remained infection free up to 3 months post-pVSTs. The other 8 patients were treated for one or more active infections. Based on viral load measurements a single infusion successfully controlled active infections associated with all our targeted viruses: CMV (2 CR, 1 PR); EBV (5 CR, including a frank PTLD case); Adv (1 CR); HHV6 (2 CR) and BKV (5 CR, 1 PR, 1 NR). Of note, all 3 patients with BKV hemorrhagic cystitis had marked improvement/disappearance of hematuria post-pVSTs. One subject had transient but severe bladder pain with inflammation, seen on cytoscopy, and a 5-log fall in urine BK viral load with detection of BKV-specific T-cells in his bladder. Our only partially non-responding patient had 3 viral infections (EBV, HHV6, BKV) and cleared EBV and HHV6 but not BKV following the infusion of a line that lacked specificity for this virus, likely reflecting the seronegative status of the donor.
Summary and Conclusions: Thus, infusion of mVSTs has been safe and clinically effective (94% overall response) against up to 4 simultaneous/sequential infections in a single HSCT recipient. We are currently extending this platform to include other clinically relevant viruses and are planning to assess the activity of "off the shelf" 3rd party mVSTs for broader implementation.

S746

SLEEPING BEAUTY-MEDIATED ENGINEERING OF CYTOKINE INDUCED KILLER (CIK) CELLS WITH CHIMERIC ANTIGEN RECEPTORS (CARS) FOR IMMUNOTHERAPY OF ACUTE LEUKEMIAS

CFF Magnani[1,*] N Turazzi[1], F Benedicenti[2], S Tettamanti [1]GMP Giordano Attianese[1,3], V Rossi[1], E Montini[2], LJ Cooper[3], A Aiuti[2], A Biondi[1], E Biagi[1]
[1]Centro Ricerca Tettamanti, Clinica Pediatrica, Università Milano Bicocca, Osp. San Gerardo/Fondazione MBBM, Monza, [2]San Raffaele Telethon Institute for Gene Therapy (HSR-TIGET), Milano, Italy, [3]University of Texas, MD Anderson Cancer Center, Houston, United States

Background: T cell engineering with CARs has been recently proved to be effective in redirecting effector activity towards leukemic blasts.
Aims: Since the profile of efficacy, safety and feasibility of cell manufacturing and gene therapy by viral vectors still remain major concerns, we explored here the use of Sleeping Beauty (SB) Transposon-mediated gene transfer in CIK cells for targeting Acute Leukemias.
Methods: With an optimized clinical-grade stimulation protocol, we genetically modified CIK cells to express two distinct 3rd generation CARs specific for myelogenous leukemia (AML) CD123+ or acute lymphoblastic leukemia (ALL) CD19+ blasts.
Results: The nucleofection minimally affected the phenotype of CIK cells, and the optimized protocol was effective in inducing T-cell expansion, with a fold increase sufficient to be translated into adoptive cell therapy clinical protocols (Figure 1, panel A, proliferation of CIK cells followed overtime by cell count). Modified CIK cells displayed stable expression of CD123.CAR or CD19.CAR with a frequency of 51.4%±2.9 (n=13) and 48.8%±6.8 (n=7), respectively (Figure 1, panel B, CAR expression determined at day 21 of differentiation), and exerted efficient lysis of leukemic cell lines and primary blasts (Figure 1, panel C, apoptosis detection, 5:1 Effector:Target ratio). Interestingly, CAR triggering by the antigen expressed by leukemic cells promoted specific cytokine secretion and proliferation that was restricted to the modified fraction of CIK cells, suggesting activation and selection of modified CIK cells upon encounter with cancer cells in the patients. The loss of the expression of transposase during the differentiation was assessed to assure the genome stability of the cellular product treated by SB system by absolute quantification through RT-PCR. Finally, preliminary insertion-site analysis by LAM-PCR confirmed that the integrations in the genome of SB system do not correlate with the genes-enriched regions.

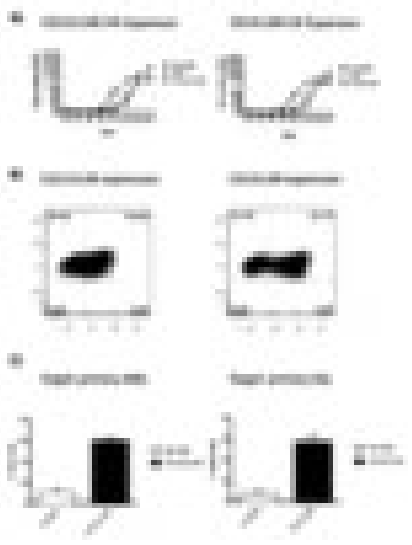

Figure 1.

Summary and Conclusions: In conclusion, SB system together with an optimized method of differentiation efficiently expand modified CD123.CAR+ and CD19.CAR+ CIK cells, redirect their activity towards AML and ALL cells, respectively, and retain a safe pattern of integrations in the genome. An easy clinical-grade adoptive cell therapy platform based on an innovative non viral method of gene transfer will be fundamental to improve the range of applications of immunotherapy to control relapse in leukemic patients. the genome of SB system do not correlate with the genes-enriched regions.

POSTER SESSION II

Acute lymphoblastic leukemia - Biology 2

P747

TARGETING THE DOPAMINE RECEPTOR SIGNALING REDUCES THE POLYCOMB PROTEIN BMI1 AND LIMITS THE SELF-RENEWAL OF BCR-ABL1 POSITIVE LEUKEMIA CELLS

T Tauchi[1,*], S Okabe[1], S Katagiri[1], K Ohyashiki[1]
[1]Internal Medicine, TOKYO MEDICAL UNIVERSITY, Tokyo, Japan

Background: Hematopoietic stem cells and leukemic stem cells share common features, including self-renewal, the capacity to differentiate, resistance to apoptosis, and limitless proliferative potential. Using a discovery platform that reveals differences between neoplastic and normal human pluripotent stem cells, the norvel dopamine receptor antagonist, thioridazine, was identified from libraries of known compounds that induce differentiation to overcome neoplastic self-renewal (Cell 149, 1284, 2012).
Aims: We investigated the molecular mechanisms by which dompamine receptor antagonist, thioridizine, regulates the self-renewal of primary BCR-ABL1 positive leukemia cells *in vivo*.
Methods: To identify the leukemia-propagating cell fraction of BCR-ABL1-positive leukemia, we serially transplanted human leukemia cells from patients with chronic myeloid leukemia blast crisis (n=1; T315I BCR-ABL1) or ponatinib-resistant Ph-positive acute lymphoblastic leukemia (n=2, Y253H/E255K/T315I BCR-ABL1 and T315I BCR-ABL1) into NOD/SCID/IL-2γc-/- mice. The cell fractions with CD34+ CD19+ could self-renew and transfer the leukemia in NOD/SCID mice. To investigate the effects of the domamine receptor antagonist on self-renewal and the relevance as a therapeutic target in ABL-tyrosine kinase-resistant BCR-ABL1 positive leukemia, we examined the activity of thioridazine against CD34+CD38-CD19+, CD34+CD38+CD19+ fractions transferred NOD/SCID mice *in vivo*.
Results: NOD/SCID mice were injected intravenously with BCR-ABL1 positive cells then treated with thioridazine (20 mg/kg; p.o.) for 28 days. All mice demonstrated the engraftment of leukemia by flow cytometry. However, the treatment with thioridazine reduced the population of CD34+CD38- positive cells. We isolated human CD45+ cells from the spleen of mice from each treatment group and injected equivalent numbers of leukemia cells into secondary recipients. Following 30 days, all mice received BCR-ABL1 cells from vehicle treated mice engrafted with leukemia. In contrast, leukemia engraftment was not detected in recipient mice (n=6) from thioridazine-treated donors. These results demonstrate the persistent effects of domapine receptor signaling inhibition on long term self-renewing BCR-ABL1-positive leukemia cells. We further examined the effects of hedgehog pathway modulation on *in vitro* clonogenic growth. CD34+CD38-CD19+ cells from T315I BCR-ABL1 (n=2) and WT-BCR-ABL1 (n=1) cells were treated with 5 μM of thiorizaxine for 72 hrs, washed free of drugs, and plated in quadruplicate in methylcellulose. At 14 days, colonies were counted as initial plating. The representative plate was then washed and cells were re-suspended and re-plated. After an additional 14 days, colonies were counted as secondary re-plating. Clonogenic recovery of untreated cells was normalized to 100% and plating results from all treatment groups were expressed as % control. Dopamine receptor pathway inhibition by thioridazine had only minimum effects on colony formation after initial plating over control cells. However, upon serial re-plating, secondary colony formations were significantly inhibited by thioridazine ($p<0.001$). To identify the mechanisms that limit the self-renewal of BCR-ABL1-positive cells by thioridazine, NOD/SCID mice engrafted with T315I -BCR-ABL1- positive CD34+ CD19+ fractions were treated with thoridazine (20 mg/kg; p.o.) for 14 days. Thioridazine induced the expressions of p21Cip1 and reduced the expression of polycomb protein BMI-1.
Summary and Conclusion: Our preclinical results indicate that thioridazine have potential as an important option for controlling the drug-resistant leukemia initiating cells in BCR-ABL1 positive leukemia. It is expected that the domapine receptor antagonist may become extremely useful therapeutic interventions in a number of hematological neoplasms, including BCR-ABL1 positive leukemia, where the persistence of cancer stem cells.

COMPLEX GENETIC HETEROGENEITY INFLUENCES PROGNOSIS IN ADULT B-CELL PRECURSOR ACUTE LYMPHOBLASTIC LEUKEMIA NEGATIVE FOR RECURRENT FUSION GENES

I Iacobucci[1,*], A Ferrari[1], M Perricone[1], V Robustelli[1], C Papayannidis[1], R Zuntini[2], MC Abbenante[1], C Venturi[1], C Baldazzi[1], E Ottaviani[1], B Giannini[3], A Ghelli Luserna Di Rorà[1], A Lonetti[4], A Vitale[5], L Elia[5], V Guadagnuolo[1], N Testoni[1], S Soverini[1], S Paolini[1], S Parisi[1], C Sartor[1], F Cattina[1], D Russo[6], R Foà[5], S Chiaretti[5], A Kohlmann[7], G Martinelli[1]

Genetica Medica - Genetica molecolare oncoematologica, Pievesestina di Cesena (FC), [4]Department of Biomedical and Neuromotor Sciences, University of Bologna, Bologna, [5]Division of Hematology, Department of Cellular Biotechnologies and Hematology, "Sapienza" University of Rome, Rome, [6]Chair of Hematology, University of Brescia, Brescia, Italy, [7]MLL Munich Leukemia Laboratory, Munich, Germany

Background: Although recent high-resolution genome-wide profiling analysis of B-cell precursor acute lymphoblastic leukemia (BCP-ALL) samples has contributed to the identification of many novel somatic genetic alterations, a deep molecular characterization of adult ALL is still challenging, especially for those cases lacking recurrent fusion genes.
Aims: In order to better molecularly dissect this ALL subgroup, we performed an integrative molecular approach including gene-candidate high-resolution screening and genome-wide profiling analyses.
Methods: We retrospectively analyzed 28 newly diagnosed *BCR-ABL1*-negative BCP-ALL subjects (19 males/9 females; median age 41.5 years; negative for known fusion genes) and 28 *BCR-ABL1*-positive BCP-ALL subjects as a comparison group. In *BCR-ABL1*-negative ALL karyotype was normal in 10/28 (36%). Copy number alterations (CNA) of know leukemia-related genes, such as *IKZF1, CDKN2A/B, PAX5, EBF1, ETV6, BTG1, RB1*, and genes within *PAR1*: *CRLF2, CSF2RA, IL3RA* have been assessed by the SALSA MLPA kit P335 IKZF1 (MRC Holland). In addition, sequence mutations have been investigated in *TP53, CRLF2, JAK2, LEF1, PAX5* and *IL7R* by next-generation deep-sequencing (NGS) (Roche Applied Science; IRON-II study oligonucleotide primer plates). Positivity for newly described *BCR-JAK2, PAX5-JAK2, ETV6-ABL1, EBF1-PDGFRB, NUP-ABL1* gene fusions occurring in *BCR-ABL1*-like ALL (Roberts KG *et al.*, Cancer Cell. 2012) was assessed by PCR amplification and sequencing. Finally, SNP arrays (SNP 6.0, Affymetrix), gene expression profile analyses (GeneChip® Human Transcriptome Array 2.0) and whole exome sequencing (Illumina) were performed to more fully assess genomic complexity.
Results: Overall, 76% of *BCR-ABL1*-negative subjects showed an abnormality of at least one of the analyzed known leukemia genes: 7 (25%) had one, 4 (14%) had two, 6 (21%) had three, and 6 (21%) had four or more alterations. In subjects showing no abnormalities, SNP arrays analysis revealed amplifications of chromosome 1q in 2/6 cases (33%). Deletions of *CDKN2A/B* were the most frequent (39%) and in 73%, they occurred together with other abnormalities, suggesting that multiple events are needed to induce the full leukemia phenotype. Other common CNA included: deletions of *IKZF1* (25%), *ETV6* (25%), *PAX5* (14%), *EBF1* (11%), *PAR1* region (11%) and *RB1* (7%). NGS showed mutations of *JAK2* and *CRLF2* in 7% (R683S/G) and 4% (F232C), respectively. No positivity for newly described fusion genes activating tyrosine kinase was confirmed. Importantly, subjects with no abnormalities showed better survival rates compared to those with one or more molecular alterations ($p<0.01$). The *BCR-ABL1*-positive subgroup shared the same CNA of *BCR-ABL1*-negative cases, such as deletions of *IKZF1* (71%), *CDKN2A/B* (21%), *PAX5* (14%), *BTG1* (11%), *EBF1* (11%), and *ETV6* (4%), but they did not show mutations in the analyzed genes.
Summary and Conclusion: BCP-ALL lacking recurrent fusion genes is a highly heterogeneous and complex disease. Current diagnostic procedures need to be revised to improve risk assessment and to guide therapeutic decisions.

MODELING RESISTANCE TO TYROSINE KINASE INHIBITORS IN TEL/ABL+ ACUTE LYMPHOBLASTIC LEUKEMIA

O Zimmermannova[1,*], J Zuna[1], K Machova[2], L Lizcova[3], Z Zemanova[3], J Falkenburg[4], R Harvey[5], IM Chen[5], C L Willman[5], J Trka[1], M Zaliova[1]
[1]CLIP, Childhood Leukaemia Investigation Prague, 2nd Faculty of Medicine, Charles University, [2]Institute of Hematology and Blood Transfusion, [3]Institute of Clinical Biochemistry and Laboratory Diagnostics, Center of Oncocytogenetics, 1st Faculty of Medicine, Charles University, Prague, Czech Republic, [4]Department of Hematology, Leiden University Medical Center, Leiden, Netherlands, [5]Cancer center, Department of Pathology, University of New Mexico, Albuquerque, United States

Background: TEL/ABL+ acute lymphoblastic leukemia (ALL) represents a rare leukemia subtype with unfavorable prognosis. The activity of fusion kinase can be inhibited by tyrosine kinase inhibitors (TKI), which might be beneficial in the therapy of this ALL.
Aims: We aimed to study potential mechanism of TKI resistance in TEL/ABL+ ALL.
Results: Via long-term exposure of parental sensitive TEL/ABL+ cell line to slowly increasing doses of imatinib mesylate (IM) we have established panTKI-resistant daughter cell line. To control for the effect of long-term culturing, daughter sensitive cell line was established in parallel to resistant one and always used together with parental sensitive cell line in analyses comparing cells with resistant and sensitive phenotype. Using deep sequencing, FISH, qPCR and Western blot we excluded the most common mechanisms of IM

resistance described in BCR/ABL+ ALL (kinase domain mutations, genomic amplification or enhanced fusion gene expression) as the cause of resistance in our model. To study genomic background of resistance, we performed genomic profiling and whole exome sequencing. First round of profiling on high density SNP arrays did not reveal any changes acquired by resistant cells compared to sensitive cells. Second round of profiling on SNP array with different coverage revealed that the resistant cells acquired a 60 kb intragenic deletion in KDM6A gene encoding lysine-specific histone demethylase. This deletion is predicted to result in either the expression of aberrant KDM6A or in loss of function and we are currently studying its impact on transcript and protein level. Whole exome sequencing identified 25 non-synonymous nucleotide variants (SNVs) within gene coding regions that were gained by resistant cells and not detected in sensitive cells. Twelve SNVs affect genes expressed in the studied cell line and annotated to various biological processes including intracellular signaling (*e.g.* G protein GNB1 or JAK/STAT signaling component STAM2). These genes have not been associated with TKI resistance before and their potential contribution to resistance needs to be further clarified. To study gene expression changes associated with resistance we have performed gene expression profiling on microarrays and identified a set of genes differentially expressed between resistant and sensitive cells. The expression data for the top up/down-regulated genes were confirmed by qPCR on a set of multiple independently harvested and processed samples. The expression of several candidates was further assessed with regard to the presence of IM in growth media and 2 different expression patterns were observed. First group of genes, represented by SORBS2, was differentially expressed in resistant cells compared to sensitive cells irrespective of IM presence. In contrary, the change in expression of second subgroup of genes (involving BCL6 and SOCS2) was induced in resistant but not sensitive cells by high but still completely tolerated IM levels. Of interest, upregulation of BCL6 was recently described as a cause of IM resistance in BCR/ABL+ cells and its inhibition was shown to restore IM response (Duy, Nature, 2011).

Summary and Conclusion: To conclude, we have established a new model of TKI-resistance that is not driven by the most common resistance mechanisms described so far. Using genomic and expression profiling we have identified several genetic alterations and gene expression changes associated with resistant phenotype that may contribute to resistance mechanism and will be further studied.

COMPARISON BETWEEN QUANTITATIVE CLONAL IG TARGETS AND FUSION TRANSCRIPTS IN THE DETECTION OF MINIMAL RESIDUAL DISEASE IN ACUTE LYMPHOBLASTIC LEUKEMIA

DC Liang[1,*], LY Shih[2,3], YJ Huang[4], MC Kuo[4], HW Kao[4], CP Yang[5], SH Chen[5], ST Liang[1], CH Lin[1], YH Huang[3], CL Lai[4], CH Chang[4]
[1]Mackay Memorial Hospital, [2]Chang Gung Memorial Hospital, Taipei, [3]Chang Gung University, [4]Chang Gung Memorial Hospital, [5]Chang Gung Children's Hospital, Taoyuan, Taiwan, Republic of China

Background: Minimal residual disease (MRD) is a powerful prognostic indicator in acute lymphoblastic leukemia (ALL). Quantification of clonal antigen-receptor gene rearrangements by real time polymerase chain reaction (QPCR) is considered to be the standard methodology for MRD monitoring in ALL. An alternative less labor-intensive and less expensive approach is the quantification of fusion transcripts in those carrying recurrent chromosomal translocations by real time reverse transcriptase PCR (RQ-PCR) assay. Data of correlation between simultaneous measurements of clonal immunoglobulin (*Ig*) gene and common fusion transcripts have been very rare.

Aims: We aimed to compare the sensitivity between the two PCR-based assays for *Ig* targets and RQ-PCR for the 3 major fusion transcripts in MRD monitoring in ALL patients with t(12;21)/*ETV6-RUNX1*, t(9;22)/*BCR-ABL1* and t(1;19)/*TCF3-PBX1*.

Methods: Bone marrow mononuclear cells were collected at diagnosis and at different time points after therapy in 28 pediatric *ETV6-RUNX1* ALL patients with 44 follow-up samples; 10 children and 13 adults carrying *BCR-ABL1* (17 P190 and 6 P210) with 60 follow-up samples; and 12 children and 3 adults harboring *TCF3-PBX1* with 39 follow-up samples. Totally, 143 follow-up samples were examined simultaneously by using two PCR-based assays for each sample. RQ-PCR with TaqMan® assay was performed with *ABL1* gene as control for the measurement of 3 fusion transcripts according to the Europe Against Cancer Program. QPCR assay for clonal *Ig* targets was carried out following the Guidelines of the European Study Group on MRD detection in ALL. The detection sensitivity of *Ig*-QPCR assay was 10^{-5} in 62.1% of patients; the remaining patients had a sensitivity of 10^{-4}. The detection sensitivity of RQ-PCR for all three fusion transcripts was 10^{-5}. MRD-negative was defined as <0.01%.

Results: The overall correlation between *Ig*-PCR and RQ-PCR for fusion transcripts was good (correlation coefficient R^2=0.754, P<0.0001). A comparison between *Ig*-QPCR and *ETV6-RUNX1* RQ-PCR assays showed that MRD was positive in 15 samples (R^2=0.688, P=0.0001) and negative in 22 samples for both assays, whereas *ETV6-RUNX1* MRD (+)/*Ig*-MRD (-) was found in 6 samples and *ETV6-RUNX1* MRD (-)/*Ig*-MRD (+) was detected in 1 sample (Kappa 0.678; concordance 84.1%). For patients with *TCF3-PBX1,* MRD was both positive in 10 samples (R^2=0.877, P<0.0001) and both negative in 29 samples examined by *Ig*-QPCR and *TCF3-PBX1* RQ-PCR assays (Kappa 1; concordance 100%). Of the 60 samples with *BCR-ABL1* transcripts, both assays showed positive MRD in 35 samples (R^2=0.627, P<0.0001) and both negative in 11 samples (Kappa 0.478; concordance 76.7%). Fourteen samples had *BCR-ABL1*-MRD (+) and *Ig*-MRD (-), and none had *BCR-ABL1*-MRD (-) and *Ig*-MRD (+). There was no difference in the sensitivity between P190 and P210 subtypes of *BCR-ABL1* (Kappa 0.457 *vs* 0.353 with concordance 73.7% *vs* 77.3%, P=0.292). Taking together, MRD was positive when assayed with RQ-PCR in 20 of 104 ALL samples with *ETV6-RUNX1* or *BCR-ABL1* but negative with *Ig*-PCR assay.

Summary and Conclusion: The present study showed that *TCF3-PBX1* ALL exhibited an excellent concordance (100%) between QPCR assay for *Ig* targets and *TCF3-PBX1* RQ-PCR assay. In 19% of samples, RQ-PCR assay for *ETV6-RUNX1* or *BCR-ABL1* transcripts was more sensitive that *Ig*-QPCR assay for MRD monitoring.

P751

MEK1 INHIBITOR SELUMETINIB SENSITIZES B-CELL ACUTE LYMPHOBLASTIC LEUKEMIA (B-ALL) CELLS TO DEXAMETHASONE BY MODULATING AUTOPHAGY

A Polak[1,*], P Kiliszek[1], T Sewastianik[1], M Szydlowski[1], E Jablonska[1], W Prusisz[1], E Bialopiotrowicz[1], S Markowicz[2], E Nowak[2], M Grygorowicz[2], D Nowis[3], K Bojarczuk[3], J Golab[3], P Juszczynski[1]
[1]Dept. of Diagnostic Hematology, Institute of Hematology and Transfusion Medicine, [2]Dept. of Immunology, Maria Sklodowska-Curie Memorial Cancer Center – Institute of Oncology, [3]Dept. of Immunology, Center of Biostructure Research, Medical University of Warsaw, Warsaw, Poland

Background: Glucocorticoids (GC) have been extensively used as important therapeutic agents in the treatment of B-cell acute lymphoblastic leukemia (B-ALL). GCs in B-ALL induce cell death that involves autophagy and apoptosis. Although resistance to GCs has been recognized as a major adverse prognostic factor, the molecular mechanisms leading to GC resistance are not fully understood.

Aims: To elucidate the molecular mechanisms responsible for GC resistance in B-ALL and characterize the consequences of targeted intervention in these mechanisms for sensitivity of leukemic cells to GCs.

Methods: Bioinformatics analyses of GC-sensitive and -resistant B-ALL blasts were carried out using publicly available gene expression datasets and GenePattern program. GC-resistant B-ALL SEMK2 cells and GC-sensitive RS4;11 cells were incubated with dexamethasone (DEX, 0,05 or 2 μg/mL) in the presence or absence of MEK1 inhibitor, selumetinib (SEL, 200nM). Cell apoptosis was assessed using annexinV/PI staining and FACS analysis. The activities of ERK, mTORC1 and 4EBP-1 were determined with Western blotting and phospho-specific antibodies. Autophagy was measured by the presence of LC3II form using Western blot and by monodansylcadaverine (MDC) staining. Beclin-1 (BCN1) knockdown was achieved by retroviral infection of SEMK2 cells with BCN1-specific shRNA.

Results: To elucidate the molecular mechanisms of GC resistance in B-ALL blasts, we performed gene set enrichment analysis of gene expression profiles obtained from GC-resistant and -sensitive primary B-ALL blasts. These analyses revealed that GC-resistant cells exhibit significantly higher expression of MAPK/ERK pathway components, compared to sensitive cells (p<.001, FDR=0.17). To confirm these findings, we assessed DEX sensitivity in cells with high (SEMK2) or undetectable (RS4;11) activity of MAPK/ERK pathway. SEMK2 cells were resistant to DEX, whereas RS4;11 were highly sensitive to this drug. In SEMK2 cells, SEL completely abrogated ERK1/2 phosphorylation and increased cellular sensitivity to glucocorticoids by 1.8-2.6-fold (p<0.01). Since DEX toxicity in B-ALL cells involves induction of autophagy, we assessed LC3 processing in SEMK2 cells incubated with either DEX, SEL or combination of SEL/DEX. Either drug alone did not change the level of LC3II, but their combination significantly increased the LC3II abundance. Similar results were obtained with MDC staining, a dye that marks autophagolysosomes. Since mTORC1 is the critical regulator of autophagy, we assessed the levels of p-mTORC1 (Ser2448), which reflects the activity of this kinase. In RS4;11 cells, DEX decreased the level of p-mTORC1. In contrast, DEX or SEL alone had no effect on mTORC1 activity in SEMK2 cells, but incubation of SEMK2 cells with DEX/SEL combination decreased activity of mTORC1 and mTORC1 substrate, 4EBP-1. Finally, to assess whether the induction of autophagy is required for the observed synergy between SEL and DEX, we silenced BCN1, a gene required for autophagosome formation, in SEMK2 cells. In cells transduced with non-targeting shRNA vector, SEL sensitized cells to DEX, but in BCN1-deficient cells, the synergy of DEX and SEL was markedly decreased.

Summary and Conclusion: Taken together, we show that MEK1 inhibitor selumetinib sensitizes DEX resistant B-ALL cells to glucocorticoid treatment. The underlying mechanism of this synergy involves inhibition of mTORC1 signaling pathway and induction of autophagy that leads to cell death.

DISEASE EVOLUTION CORRELATED WITH EX VIVO DRUG SENSITIVITY AND RESISTANCE IN TCF3-PBX1 DRIVEN ACUTE LYMPHOBLASTIC LEUKEMIA

S Eldfors[1,*], M Kontro[2,3], M M Majumder[1], A Parsons[1], J M Lopez-Martí[1], H Edgren[1], T Pemovska[1], S Lagström[1], M Lepistö[1], A Palva[1], H Almusa[1], M Suvela[1], R Karjalainen[1], P Mattila[1,4], I Västrik[1], J Knowles[1], K Wennerberg[1], O Kallioniemi[1], N Gökbuget[5], T Burmeister[6], K Porkka[2,3], C Heckman[1]
[1]Institute for Molecular Medicine Finland, [2]Hematology Research Unit Helsinki, University of Helsinki, [3]Department of Hematology, University Central Hospital Cancer Center, [4]Haartman Institute, University of Helsinki, Helsinki, Finland, [5]Frankfurt University Hospital Cancer Center, Department of Medicine II, Hematology and Oncology, Frankfurt, [6]Universtätsmedizin Berlin, Department of Hematology, Oncology and Tumorimmunology, Berlin, Germany

Background: The t(1;19)(q23;p13) translocation occurs in 3% of adult patients with acute lymphoblastic leukemia (ALL) and results in rearrangement of the *TCF3*(*E2A*) transcription factor and *PBX1* homeobox genes. The TCF3-PBX1 fusion protein is an activating transcription factor that drives oncogenesis by deregulating gene expression. The prognosis of adult t(1;19) ALL patients is comparable to other forms of adult ALL. However, relapse and chemotherapy related toxicity remain a problem.
Aims: We aimed to determine the *ex vivo* drug sensitivity profile of a t(1;19) positive pre-B-ALL of a 25 year old male with relapsed disease. In addition, we aimed to identify molecular markers linked to drug sensitivity and resistance in the tumor. Furthermore, we sought to understand evolution of the tumor during disease progression by deep molecular profiling of serial samples.
Methods: Bone marrow (BM) aspirates were obtained after informed consent and the mononuclear cell fraction was used for analyses. Two relapse samples were profiled by *ex vivo* drug sensitivity testing, exome and RNA sequencing. In addition, we sequenced the exomes of a diagnostic sample, and a skin biopsy sample, which was the germline control for somatic mutation calling. *Ex vivo* drug sensitivity testing was done using a library of 306 of investigational and approved antineoplastic drugs in 5 concentrations to generate dose response curves. The leukemia specific drug responses were compared to those obtained for healthy BM samples.
Results: Exome sequencing detected a novel somatic in-frame codon insertion mutation in *MTOR* (p.M1724MW), a loss of function mutation in *PHF6* and a heterozygous deletion of *CDKN2A,* which were clonal at diagnosis and relapse. We also identified two relapse specific mutations in *TP53* as well as a subclonal deletion of 17p encompassing *TP53*. RNA-sequencing revealed extremely high expression of *CXCR4* in both relapse samples. To determine if high expression of *CXCR4* is common in TCF3-PBX1 driven ALLs we assessed CXCR4 gene expression levels in 19 TCF3-PBX1 driven adult ALLs by qRT-PCR. Results indicated that only the index patient's relapse samples had aberrantly high *CXCR4* expression, suggesting that TCF3-PBX1 alone is not sufficient to deregulate expression of this gene. *Ex vivo* drug sensitivity screening showed that the cells were markedly sensitive to several investigational mTORC1 inhibitors, including GSK2126458, AZD8055, PF-04691502, MLN0128, as well as the mTOR inhibitor everolimus, approved for other indications. In addition, the cells were selectively sensitive to glucocorticoids, as well as BCL-2 inhibitors ABT-199 and navitoclax, which corresponded to *BCL2* and *BCL2L1* gene expression.
Summary and Conclusion: The presence of the *MTOR* mutation in the tumor suggests a link to the *ex vivo* drug sensitivity phenotype. *CXCR4* mediated binding of leukemic cells to the bone marrow stroma can increase resistance to chemotherapy, thus the aberrantly high *CXCR4* expression levels observed in the index patient's tumor may have contributed to disease relapse. Furthermore, loss of p53 is associated with drug resistance in cell line models through impairment of apoptotic signaling. The emergence of several relapse specific *TP53* mutations in the index patient's tumor suggests that relapse and therapy resistance were also caused by progressive loss of *TP53* during tumor evolution. Although the TCF3-PBX1 is an important driving event in disease development, additional acquired mutations and changes in gene expression in t(1;19) pre-B-ALL may contribute to overall treatment response and outcome.

P753

THE DIFFERENCE OF RCSD1-ABL1-LEUKEMOGENICITY BETWEEN EXON3 OF RCSD1/EXON 4 OF ABL1 AND EXON 2 OF RCSD1/EXON 4 OF ABL1

H Tamai[1,*], K Miyake[2], H Yamaguchi[1], K Dan[3], K Inokuchi[1]
[1]Hematology, [2]Biochemistry and Molecular Biology, Division of Gene Therapy Research, Nippon Medical School, Tokyo, [3]Medical Education Center, Ryotokuji University, Urayasu, Japan

Background: The RCSD1 gene, located at 1q23 involved in t(1;9)(q23;q34) translocation in acute lymphoblastic leukemia (ALL) is known as a novel gene fusion partner of ABL1 gene. We have previously reported that there are two types of fusion genes in a case of RCSD1-ABL1-positive ALL. One is the fusion of exon 2 of RCSD1/exon 4 of ABL1 (R2A4; 2952bp) and another one is the fusion of exon 3 of RCSD1/exon 4 of ABL1 (R3A4; 3042bp).
Aims: The aim of this study is to examine the leukemogenicity of two kinds of fusion genes of RCSD1-ABL1.
Methods: We generated echotrophic retroviral vector expressing R2A4 or R3A4 and transduced with Ba/F3 murine interleukin-3 (IL-3) dependent cell line, and examined the multiplication activity and the IL-3 dependency of each transduced Ba/F3 cells. To analyze the leukemogenicity, $2x10^8$ of each Ba/F3 cells were intraperitonealy injected into SCID mice and examined the overall survivals (OS) and histopathology of each mice. Moreover, we examined phosphorylation receptor tyrosine kinase activity of each Ba/F3 without IL3 by Phosphorylation Antibody Array.
Results: Only R3A4 transduced Ba/F3 acquired significant independency of IL3. (Control *vs* R3A4; P=0.001 and Control *vs* R2A4; P=0.90). *In vivo* analysis, R3A4 transduced Ba/F3 injected mice showed significantly shorter survivals in comparison with those of control or R2A4 transduced Ba/F3 injected mice (42days *vs* >100days; P=0.0009). Leukemic change and splenomegaly were observed in only R3A4 transduced Ba/F3 injected mice but not R2A4 transduced Ba/F3 injected mice. Phosphorylation Antibody Array showed that ABL1 were activated only in R3A4 transduced Ba/F3.
Summary and Conclusion: Since R3A4 has leukemogenicity but not R2A4, the 90bp of difference may be the key of leukemogenicity and the leukemogenicity seems to be related to the phosphorylation of ABL1. This 90bp may be a promising target to treat RCSD1-ABL1-positive ALL.

P754

CD20 EXPRESSION IN ADULTS WITH PRECURSOR B-CELL ACUTE LYMPHOBLASTIC LEUKEMIA (B-ALL) FROM UKALL14, ITS REGULATION BY DEXAMETHASONE AND RITUXIMAB INDUCED CYTOTOXICITY

B Beaton[1,*], B Patel[1], A Dey[1], A Castleton[1], A Moorman[2], A McMillan[3], C Rowntree[4], D Marks[5], T Menne[6], L Micklewright[7], P Smith[7], S Purnell[7], A K Fielding[1]
[1]Haematology, University College London, London, [2]Northern Institute for Cancer Research, Newcastle University, Newcastle, [3]Centre for Clinical Haematology, Nottingham City Hospital, Nottingham, [4]Haematology, University Hospital of Wales, Cardiff, [5]Haematology, University Hospitals NHS Foundation Trust, Bristol, [6]Haematology, Newcastle upon Tyne Hospitals NHS Foundation Trust, Newcastle upon Tyne, [7]CRUK Cancer Trials Centre, London, United Kingdom

Background: UKALL14 is an on-going randomized trial for newly diagnosed adult ALL. All patients with B-ALL, regardless of CD20 expression, are randomized, after a dexamethasone pre-phase, to standard treatment alone or standard treatment plus rituximab (off-label use) during induction. CD20 expression will be quantified and related to MRD and clinical outcome. CD20 has been shown to be up-regulated by prednisolone *in vitro* and *in vivo* in paediatric B-ALL (Dworzak et al 2008). This correlated with increased rituximab-induced complement-mediated cytotoxicity.
Aims: To quantify CD20 expression at diagnosis in adult patients with B-ALL enrolled on UKALL14. To assess whether dexamethasone (compared to prednisolone) induces CD20 up-regulation in-vitro in both cell lines and primary diagnostic cells cultured on a stromal cell layer. To assess whether up-regulation of CD20 correlates with enhanced rituximab-induced complement-mediated cytotoxicity.
Methods: UKALL14 trail patients gave informed consent. CD20 was quantified using a PE-conjugated antibody after careful gating on viable B-ALL cells. The percentage of blasts expressing CD20 and mean fluorescence intensity (MFI) were determined. MFI was normalized to antibodies bound per cell (ABC) using a standard curve created by BD Quantibrite fluorescence beads. Eight adult primary B-ALL and 5 B-ALL cell lines (NALM-6, SEM, 697, REH and NALM-16) were cultured with or without different concentration of dexamethasone for 3 days, followed by CD20 quantification. The Burkitt's cell line, Raji, was used as a positive control. Primary cells were cultured on hTERT expressing human bone marrow mesenchymal stromal cells. Complement-mediated cytotoxicity was assessed by Promega CytoTox-Fluor Cytotoxicity Assay with and without rituximab by adding fresh donor serum to the media.
Results: Fifty nine patients, 33 males and 26 females, median age of 44 years (range 23-64) were included. Twenty seven (45.8%) patients were defined as "CD20 positive" by commonly accepted criteria defined as a leukemic population with greater than 20% of cells expressing CD20. Median CD20 expression was 17.8% (range: 0.4-99.9%). The median quantity of CD20 was 455 antibodies/cell (range: 92-30552). Of eight specimens which could be cultured *in vitro*, four showed significant up-regulation of both percentage of cells expressing CD20 and quantity of expression in response to dexamethasone, as shown in Figure 1. Of the cells that up-regulated CD20 expression, baseline CD20 expression was 25-30% prior to exposure to dexamethasone. The findings from the B cell lines were similar. Raji cells had a 100% baseline level of CD20 expression, but nonetheless showed marked increase in ABC upon dexamethasone exposure. The other cell lines showed no significant change in CD20 expression upon dexamethasone exposure.
Complement-mediated cytotoxicity data showed a trend toward additional rituximab-induced cytotoxicity after CD20 up-regulation by steroid. Further samples are currently being analysed.

Summary and Conclusion: We have shown that all of the 59 samples of B-ALL tested expressed some level CD20 albeit at lower levels than are considered 'positive' by conventional criteria. Dexamethasone can up-regulate both percentage of cells expressing CD20 and quantity of antigen expression but does not do so in all specimens. A relationship between basal expression and up-regulation remains to be confirmed. On-going work will determine the relationship with rituximab-induced complement-mediated cytotoxicity. The relationship between CD20 expression at diagnosis and anti-leukaemia response to rituximab in adults is unlikely to be linear and may be influenced by prior exposure to steroid.

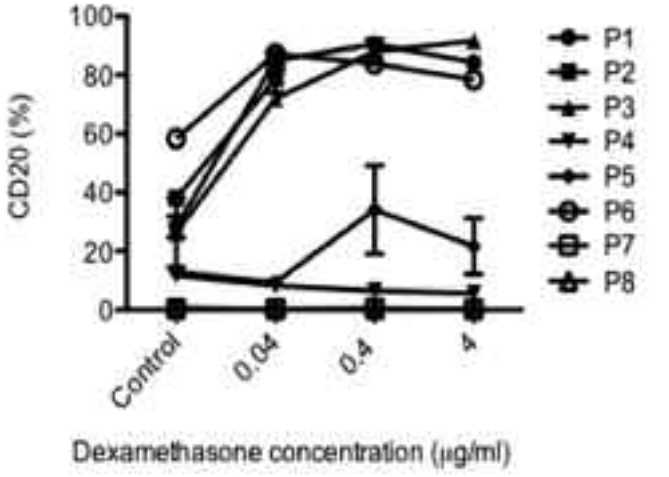

Figure 1. 8 diagnostic samples (P1-P8) showing percentage of blasts expressing CD20 following 3 days of incubation. Mean and standard error of duplicates shown.

P755

INHIBITION OF CLASS I PHOSPHATIDYLINOSITOL 3-KINASES (PI3KS) ISOFORMS IN T-CELL ACUTE LYMPHOBLASTIC LEUKEMIA (T-ALL): WHICH IS THE BEST THERAPEUTIC STRATEGY?

A Lonetti[1,*], A Cappellini[2], A. Spartà[1], D Bressanin[1], B Francesca[1], C Francesca[3,4], C Evangelisti[1,3,4], E Orsini[1], A. Martelli[1]
[1]Department of Biomedical and Neuromotor Sciences, University of Bologna, Bologna, [2]Department of Human, Social and Health Sciences, University of Cassino, Cassino, [3]National Research Council, Institute of Molecular Genetics, [4]IOR, Muscoloskeletal Cell Biology Laboratory, Bologna, Italy

Background: Class I phosphatidylinositol 3-kinases (PI3Ks) are heterodimeric lipid kinases consisting of a regulatory subunit and one of four catalytic subunits (p110α, p110β, p110γ or p110δ). p110γ/p110δ PI3Ks are highly enriched in leukocytes. In general, PI3Ks regulate a variety of cellular processes including cell proliferation, survival and metabolism, by generating the second messenger phosphatidylinositol-3,4,5-trisphosphate (PIP3). Their activity is tightly regulated by the phosphatase and tensin homolog (PTEN) lipid phosphatase. PI3Ks are widely implicated in human cancers, and in particular are upregulated in T-cell acute lymphoblastic leukemia (T-ALL), mainly due to loss of PTEN function. At present different compounds which target single or multiple PI3K isoforms have entered clinical trials.
Aims: To explore the role of the different PI3K isoforms in T-ALL, in order to identify the most effective targeted therapy strategy.
Methods: Both PTEN wt (ALL-SIL and DND-41) and PTEN deleted (Jurkat and Loucy) T-ALL cell lines were treated with class I pan-PI3K inhibitors (BKM120 and ZSTK454) or p110α (A-66), p110β (TGX-221), p110γ (AS-605240), p110δ (CAL-101) and p110γ/δ (IPI-145) selective inhibitors (all purchased from Selleck Chemicals, Houston TX, USA), and their effects were evaluated.
Results: In the tested cell lines, flow cytometry analysis evidenced a slight reduction in PIP3 levels after treatment with all the single-isoform inhibitors, whereas pan-PI3K and p110γ/δ inhibition significantly decreased PIP3 level. However, only pan-PI3K inhibition significantly affected cell viability in a dose and time-dependent manner after 48h treatment, with IC_{50} values ranging between 1 and 4 µM, for both BKM120 and ZSTK454, whereas for all the other drugs IC_{50} values were not attained. This finding was confirmed by a time-course analysis of viable cells, which revealed a rapid and drastic antiproliferative effect of the pan-PI3K inhibitors. Only after prolonged drug-exposure (64h) the combined p110γ/δ inhibition exerted a significant antiproliferative effect, in agreement with PIP3 decrease. Consistent with these results, Annexin V/PI staining analysis showed a significant increase of apoptosis after 48h treatment in both PTEN wt and deleted cell lines only after treatment with pan-PI3K inhibitors, whereas cell cycle was not affected either following pan- or single-isoform inhibition. PI3K signaling pathway analysis revealed the inactivation of the main downstream targets already after 1h treatment with pan-PI3K inhibitors, as evidenced by decrease of p-Akt, both at Thr308 and Ser473, p-P70S6K and p-S6RP. Of note, p110γ and p110δ inhibition slightly affected these PI3K targets, but only in some cell lines. Overall, no difference emerged in relationship with PTEN status.
Summary and Conclusion: Due to the roles played by PI3Ks in cancer, many efforts have tried to address the identification of compounds which specifically target PI3K isoforms for a better effectiveness and a lower toxicity. Here we demonstrated that, irrespective of PTEN status, only pan-class I PI3K inhibition is cytotoxic in T-ALL cells, implying that any isoform could sustain leukemic cell proliferation, and suggesting a redundant role played by each isoform. Therefore, our findings strongly support clinical application of pan-class I PI3K rather than single-isoform inhibitors in T-ALL treatment.

P756

CHARACTERIZATION OF CDKN1B-DELETED CHILDHOOD T-CELL ACUTE LYMPHOBLASTIC LEUKEMIA

S Colomer-Lahiguera[1,*], M König[1], M Pisecker[1], R Ullmann[2], S Strehl[1]
[1]CCRI, Children's Cancer Research Institute, St. Anna Kinderkrebsforschung e.V., Vienna, Austria, [2]MPIMG, Max Planck Institute for Molecular Genetics, Berlin, Germany

Background: T-cell acute lymphoblastic leukemia (T-ALL) accounts for 10-15% of pediatric leukemia. According to genetic alterations and gene expression signatures, T-ALL is subdivided into major subtypes comprising the *TAL/LMO*, *TLX1*, *TLX3*, and *HOXA* clusters. Furthermore, a multitude of genetic aberrations, which either occur across all subtypes or are specifically associated with one or the other, collaborate in the pathogenesis of the disease. Recent studies have revealed heterozygous deletions of *CDKN1B*-$p27^{KIP1}$ as one of the most frequent copy number alterations occurring in about 12% of pediatric T-ALL. However, it has not been determined yet whether *CDKN1B* deletions are associated with any of the major subtypes and/or specific mutation patterns.
Aims: The aim of our study was to genetically characterize pediatric T-ALL harboring deletions of the *CDKN1B* gene and to determine whether other recurrent aberrations found in T-ALL may also have an impact on its regulation.
Results: Array comparative genomic hybridization (aCGH) analysis of 102 pediatric T-ALL patients registered in the Austrian ALL-BFM 90, 95, and 2000 trials substantiated the high incidence of *CDKN1B* deletions in this disease. The data obtained by aCGH were confirmed by quantitative genomic PCR, which in one of the cases even revealed a homozygous deletion. In terms of other copy number alterations, the incidence of *CDKN2A/B* deletions in *CDKN1B*-deleted cases was significantly lower as compared to wild-type cases. Furthermore, fluorescence *in situ* hybridization (FISH) and RT-PCR were used to classify patient samples into the major molecular-genetic subtypes (*TLX1*, *TLX3*, *HOXA,* and *TAL/LMO*) based on chromosomal rearrangements. Out of 14 *CDKN1B*-deleted samples, three (21%) belonged to the *HOXA* and only one (7%) to the *TLX3* subtype, which usually account for 10% and 20-25% of cases, respectively. One case each harbored a *TRAD@-MYC* rearrangement and a cryptic *LMO2*-activating deletion. Intriguingly, 45% (5/11) of the *CDKN1B*-deleted patients showed increased *MEF2C* expression levels and were, therefore, assigned to the immature T-ALL subtype, which accounts for roughly 10% of T-ALL. Whereas in one of these cases a *BCL11B* rearrangement and in another case a potential *MEF2C* activating deletion were observed, in the other three patients the underlying genetic alterations resulting in up-regulation of *MEF2C* remain to be determined. To date, in all remaining cases none of the most frequent T-ALL-specific alterations has been detected. In order to assess the *CDKN1B* expression levels, the samples were subjected to quantitative RT-PCR and in several of them *CDKN1B* showed lower transcript levels than expected in cases of heterozygous deletions. Since several genes, such as *NOTCH1, FBXW7*, and *PTEN*, which are frequently affected in T-ALL, may be implicated in *CDKN1B* regulation, a mutation screening was conducted; however, no correlation between mutation patterns and *CDKN1B* expression levels was found.
Summary and Conclusion: Together our data show that *CDKN1B* deletions are a frequent event in T-ALL, that they commonly arise in the *HOXA*/immature subtype, and that *CDKN1B*-deleted cases have a significantly lower incidence of *CDKN2A/B* deletions. This work is supported by the Anniversary Fund of the Austrian National Bank; OeNB Project No. 14444.

"GENOMIC INVERSE PCR FOR EXPLORATION OF LIGATED BREAKPOINTS" (GIPFEL) - A NEW METHOD TO DETECT THE MOST COMMON TRANSLOCATIONS IN CHILDHOOD LEUKEMIA

J I Hoell[1,*], E Füller[2], D Schäfer[1], U Fischer[1], P F Krell[1], M Stanulla[3], A Borkhardt[1], R Slany[2]
[1]Department of Pediatric Oncology, Hematology and Clinical Immunology, Heinrich Heine University, Duesseldorf, [2]Department of Genetics, Friedrich-

Alexander-Universität, Erlangen, [3]Department of Pediatric Hematology and Oncology, Hannover Medical School, Hannover, Germany

Background: Detection of pre-leukemic cells is only possible in children who subsequently developed full-blown leukemia *e.g.* by backtracking leukemic fusion genes in Guthrie cards or cord blood samples. It remains enigmatic, however, if and at what frequency children with pre-leukemic cells remain healthy and leukemia-free in later life.
Aims: To enable the a priori detection of chromosomal breakpoints without any knowledge of its exact molecular make-up, we developed a PCR based method that allows the prospective detection of the five most common gene fusions associated with childhood leukemia (MLL-AF4, MLL-AF9, MLL-ENL, ETV6-RUNX1, and TCF3-PBX1).
Methods: The "Genomic Inverse PCR for Exploration of Ligated Breakpoints" (GIPFEL) method exploits the unique presence of a genomic translocation joining two different chromosomes. These fragments can be digested and re-circularized by ligation creating a junction across the restriction site whose sequence can be predicted from published genome data. Importantly, the ligation site is independent of the exact translocation position within the individual DNA circle. Published breakpoint regions of all genes involved in the respective translocations were analyzed *in silico* for restriction sites that allow digestion of all possible translocation events to yield fragments smaller than 50 kb. This condition was met for MLL breakpoints (digestion with BamHI), for ETV6-RUNX1 (SacI) and for TCF3-PBX1 (MfeI). Primer pairs were designed amplifying the complete set of theoretically predicted circularized fragments, requiring between 8 and 37 primers depending on the translocation. Genomic DNA was prepared from cell lines and diagnostic specimens by column purification. The equivalent of approximately 4x10e5 cells (2.5 µg DNA) was subjected to the appropriate restriction digest, ligated and removal of remaining linear DNA by exonuclease III. After ethanol precipitation the reaction products were subjected to a partially multiplexed, semi-nested PCR to quantify all possible ligation/junction products specific for the respective translocation. An internal genomic ligation product served as quality control and allowed relative quantification of the specific translocation product.
Results: Cell dilution and mixing studies with cell lines revealed that approximately 40 translocation positive cells in the entire input are sufficient to produce a reliable positive output signal. The method was then tested in a blinded study with 23, 20 and 22 samples obtained from MLL translocation patients and 60, and 30 samples for ETV6-RUNX1 and TCF3-PBX1 cases. There was no false positive result. Detection coverage was 83.3% for MLL-AF4, 66.6% for MLL-AF9, 60% for ETV6-RUNX1, 40% for TCF3-PBX1. MLL-ENL success rates were lower at 23.5 %. This phenomenon was accompanied by the serendipitous detection of more complex genomic rearrangements in two MLL-ENL cases where additional material from other chromosomes was fused to MLL. Taking into consideration the overall frequency of the individual translocations in childhood leukemia, GIPFEL is able to detect an estimated 40% of B-precursor acute lymphoblastic leukemia (ALL) and 30% of all childhood cases.
Summary and Conclusion: GIPFEL is able to uncover and to quantify the presence of common translocations in blood cells without prior knowledge of the exact breakpoint positions. About 4x10e5 nucleated cells are required per translocation to detect a leukemic clone at a frequency of 10e-4. In a defined clinical setting such as the prospective surveillance of patients at risk for leukemia (*e.g.* after previous treatment with topoisomerase inhibitors or following exposure to ionizing radiation) this method represents a valuable addition to the available diagnostic repertoire.

P758

BAFF-RECEPTOR EXPRESSION IN CHILDHOOD B CELL PRECURSOR ACUTE LYMPHOBLASTIC LEUKEMIA

G Fazio[1,*], V Cazzaniga[1], M Kreuzaler[2], O Maglia[1], S Sala[1], G Gaipa[1], A Rolink[2], A Biondi[1], G Cazzaniga[1]
[1]Pediatric Clinic - University of Milan-Bicocca, Tettamanti Research Center, Monza, Italy, [2]Department of Biomedicine, University of Basel, Basel, Switzerland

Background: B cell-activating factor (BAFF) and its close relative proliferation-inducing ligand (APRIL) belong to the tumor necrosis factor (TNF) family. Physiologically, BAFF mediates the behavior of most B cells through interactions with their family receptors. Among them, only the BAFF receptor (BAFF-R) interacts specifically with BAFF, being the main responsible for primary B cell survival, selection and differentiation, in physiology and in disease conditions.
Aims: We aimed to investigate the potential role of BAFF/BAFF-R axis in Acute Lymphoblastic Leukemia involving B-Cell Precursor (BCP-ALL). With this purpose, we analyzed the pathway in hematological tumor cell lines as well as in primary BM and PB samples from children affected by BCP-ALL.
Methods: RT-PCR assays have been developed to determine BAFF and BAFF-R expression in cell lines. We implemented flow cytometry analysis to assess BAFF-R expression and to analyze the phenotype and the percentage of blast cells in BM and PB diagnosis and follow-up samples of BCP-ALL patients. ELISA analysis has been used to valuate BAFF concentration in plasma samples.
Results: Preliminary results demonstrated that BAFF-R is highly expressed in the B-lymphoid leukemic cell lines, such as REH, TOM1 and NALM-6 (RT-PCR analyses). Its expression is also detectable, although at lower levels, in mixed lymphoid/myeloid phenotype cell lines (such as THP1 and RS4;11), in myeloid K562 cells as well as in U937 histiocytic lymphoma cell lines. Supported by this data, we further collected BM and/or PB of 26 consecutive diagnostic samples of Pediatric BCP-ALL. We analyzed BAFF-R expression by flow cytometry, by indirect staining using a biotinylated antibody anti-BAFF-R and which was revealed by PE conjugated streptavidin antibody. In the same sample we assessed the CD19, CD10 and CD45 direct staining to recognize leukemic blast cells among the residual of normal cells. For each patient, in addition to the diagnostic sample, we analyzed at least one follow up sample (*i.e.* at day+8 or +15). We detected high levels of BAFF-R on CD19+CD10+CD45dim leukemic cells, which persisted during the follow up treatment. Moreover, we separated plasma by centrifugation of n=16 patients to analyze BAFF cytokine levels by ELISA technique, both in BM and PB samples. More interestingly, the ratio of BAFF level (ng/ml) over the number CD19+ blast cells (n°/mmc) revealed that the cytokine is consumed by blast cells at diagnosis and its level reaches physiological threshold after leukemic cell clearance, in follow up samples.
Summary and Conclusion: We assessed the expression of BAFF-R on leukemic blast cells of BCP-ALL patients. Of note, its expression is maintained on residual tumor cells during the early drug treatment, suggesting the potential targeting of this molecule in future advanced treatment approaches. All together, BAFF/BAFF-R axis could have a role in BCP-ALL, although additional studies are required to comprehend its role in the pathogenesis of leukemia.

P759

SIGNIFICANCE OF ADDITIONAL STRUCTURAL ABERRATIONS IN BONE MARROW CELLS OF 115 CHILDREN WITH ACUTE LYMPHOBLASTIC LEUKEMIA AND HIGH HYPERDIPLOIDY

L Lizcova[1,*], Z Zemanova[1], L Bartu[1], E Malinova[1], H Buryova[1], L Pavlistova[1], I Janotova[2], E Mejstrikova[3], J Stary[2], K Michalova[1]
[1]Center of Oncocytogenetics, Institute of Medical Biochemistry and Laboratory Diagnostics, General University Hospital and 1st Faculty of Medicine, Charles University in Prague, [2]Department of Paediatric Haematology and Oncology, [3]CLIP - Childhood Leukaemia Investigation Prague, Department of Paediatric Haematology and Oncology, Second Faculty of Medicine, Charles University, Prague and University Hospital Motol, Prague, Czech Republic

Background: High hyperdiploidy (HeH), defined as the presence of 51 to 67 chromosomes in karyotype, is the most common cytogenetic finding in bone marrow cells of childhood B-cell precursor acute lymphoblastic leukemia (B-ALL), occurring in 25-30% of cases. HeH is characterized by nonrandom gain of specific chromosomes and clinically by favorable prognosis. Nevertheless, around a quarter of these children will suffer an adverse event within 5 years after diagnosis, which could be caused by increased genomic instability of leukemic cells leading to creation of additional cryptic structural aberration.
Aims: The aim of this study was to determine the frequency and the recurrence of structural chromosomal aberrations in hyperdiploid cells and to evaluate the impact of these aberrations for prognosis of children with ALL and HeH.
Methods: Karyotypes of all patients were analyzed at the time of diagnosis by conventional cytogenetic analysis and interphase fluorescence *in situ* hybridization (I-FISH) with a panel of Vysis DNA probes (Abbott Molecular) in order to detect heteroploid cells. In patients with structural or suspected cryptic aberrations multicolor FISH and multicolor banding (24*X*Cyte/*X*Cyte Probe Kit; MetaSystems) and array CGH (Cytochip Cancer 4x180K; BlueGnome) were performed. For overall and event free survival Kaplan-Maier analysis and Mantel-Cox test were done.
Results: During the years 1997-2013 we examined 115 children with B-ALL and high hyperdiploidy. This group included 64 boys and 51 girls with median of age 4 years (range 1 - 17) and median of the follow up to 82 months (range 1 - 210). Cryptic structural chromosomal rearrangements were found in 27 (23,5%) of them. Patients with ALL-specific chromosomal aberrations were excluded from the cohort. The majority of structural aberrations were unbalanced and chromosomes the most frequently affected were found to be Nos.: 1, 13, 6, 7 and 21. The most common recurrent abnormality was the duplication of the long arm of chromosome 1 (9x). The minimal duplicated region in all patients was 1q31 to 1q32.3 (22.5 Mb). In addition, the deletion of the long arm of chromosome 13 (5x), rearrangements of the long arm of chromosome 21 (3x) and the deletion of the long arm of chromosome 6 (2x) were proved. Event (relapse and/or exitus) occurred in six patients with high hyperdiploidy and five patients with high hyperdiploidy and structural aberrations, respectively. There was no difference in overall survival between these two cohorts. However, patients with cryptic structural changes showed a tendency to shorter event free survival (p=0,082).
Summary and Conclusion: Non-random structural abnormalities were found in approximately a quarter of children with B-ALL and high hyperdiploidy. Although high hyperdiploidy is well known as a powerful favorable prognostic marker in childhood ALL, our study demonstrates that prognosis may be

influenced by the presence of these structural aberrations. Therefore, a detailed cytogenetic analysis of every patient with high hyperdiploid cell clones by all available methods is necessary to identify those at an increased risk of relapse.
Supported by grants RVO-VFN64165/2012 and GACR-P302/12/G157/1.

IMMUNE STATUS IN RELATION TO THE TREATMENT OF CHILDHOOD BCP-ALL ACCORDING TO THE NOPHO ALL2008 PROTOCOL

B FS Shah[1,*], L P Ryder[1], N F Øbro[1], T L Frandsen[2], B K Albertsen[3], P S Wehner[4], S Rosthøj[5], K Schmiegelow[2], H V Marquart[1]
[1]Department of Clinical Immunology Section 7631, [2]Child and Youth Clinic Section 5054, University Hospital Rigshospitalet, Copenhagen, [3]Department of Pediatrics, Aarhus University Hospital Skejby, Aarhus, [4]Department of Pediatric Hematology and Oncology, H. C. Andersen Children's Hospital, Odense University Hospital, Odense, [5]Department of Pediatrics, Aalborg University Hospital, Aalborg, Denmark

Background: Acute lymphoblastic leukaemia (ALL) is the most common type of cancer in children. All children with leukaemia in the Nordic countries are treated according to the common NOPHO ALL2008 protocol. Patients are allocated into risk/treatment groups based on karyotype and levels of minimal residual leukemic (MRD) cells in bone marrow after 1 and 3 months of chemotherapy. Even though the general outcome of the treatment in children with ALL is considered good (5-years EFS: 85%), severe side effects are frequently seen, not least potentially life-threatening infections due to the immune suppression.
Aims: To monitor the immune suppression in childhood B-cell precursor (BCP) ALL to investigate if immune status can predict severe/life-threatening infections.
Methods: A total of 299 samples from 49 Danish ALL patients treated according to NOPHO ALL 2008 treatment protocol were analysed. Consecutive blood samples were collected at diagnosis and at days 0, 15, 29, 79, 92 and during high-risk ALL block therapy (LHR). Lymphocyte subsets including B, T, NK, and CD4 RTE (Recent Thymic Emigrants) cells were quantified by single platform flow cytometry (BD TruCount beads). Data was evaluated in relation to initial treatment stratification of the patients in standard–risk/intermediate-risk (SR/IR), High-Risk (HR) and late HR-treatment (LHR).
Results: Preliminary results show a nadir in all lymphocyte subset counts at treatment-day 15, 29 and LHR, the most severe suppression found in the LHR group. The median CD4 T-cell count at day 15 in the SR/IR group is 200 cells per µL increasing through d29, d79 and d92 to 430, 720, and 930 cells per µL respectively. In the LHR group the CD4 T cell count is severely reduced with a median of 130 cells per µL. The CD4RTE cell count is moderately reduced in the SR/IR group on d15 and approaches normal levels at d29, and reach normal level at d79. In the LHR group, the median CD4RTE cell count is severely reduced throughout the intensive block therapy. For all time points the median B cell count (CD19posCD20pos) is reduced to below normal range (400 cells per µL) compared to age-matched controls without signs of reconstitution. In the LHR group the B cell counts (CD19 pos, CD20 pos) are severely reduced with a median of 5 and 4 cells per µL, respectively.
Summary and Conclusion: The CD4 T-cell count is reduced to critical levels during early induction therapy (d15) and during LHR block treatment. The CD4RTE cell count indicates close-to-normal thymus function in the SR/IR group from the end of induction therapy, while patients during LHR block treatment exhibit suppressed thymus function. B cell counts are reduced at all time-points during treatment and do not normalise throughout treatment. The relation to severe infectious event is currently under investigation, and may indicate when monitoring of CD4 T-cell count can be valuable.

P761

A COMPREHENSIVE NEW DNA TEST FOR DETECTION OF FUSION GENES IN LEUKEMIA

E Van Den Berg-De Ruiter[1,*], M van Min[2], A Mulder[3], E Vellenga[4], E Splinter[2], E de Wit[2], P Klous[2], P van der Vlies[1], D Weening[1], C van Diemen[1], R Sijmons[1], R Sinke[1], B Raddatz[1]
[1]Genetics, University Medical Center Groningen, Groningen, [2]Cergentis, Utrecht, [3]Laboratory Medicin, [4]Haematology, University Medical Center Groningen, Groningen, Netherlands

Background: Leukemia patients carry a wide range of chromosomal abnormalities, which affect their prognosis and treatment options. Thus, a full and rapid diagnosis of these abnormalities is essential. Testing for this wide range of abnormalities is currently performed by a combination of techniques, including karyotyping, array, FISH, and RT-PCR. At the moment, the tests used are challenging to perform and at times inadequate. Given the sensitivity, specificity, costs and speed of current testing, there is an urgent need for improvement. The development of new technologies based on next generation sequencing (NGS) promises comprehensive analysis of all mutations and chromosomal abnormalities.
Aims: Recently a new technology, Targeted Locus Amplification (TLA), is developed uniquely enabling the targeted complete amplification and NGS of genes of interest including any Single Nucleotide Variants and/or structural variants that might occur. A such, the TLA technology enables the targeted comprehensive NGS of gene-fusions and will detect gene fusions irrespective of the position of the breakpoint and the identity of the fusion partner.
Methods: In a proof-of–principle, a TLA assay was developed for the *MLL* gene, having more than 50 translocation partners and involved in gene fusions in AML patients. We used four cell-lines, positive for a *MLL* gene fusion, namely a *MLL-AF4*, a *MLL-ELN*, a *MLL-AF6*, and a *MLL-AF9* gene fusion. TLA primers were designed on 5 positions across the *MLL* gene. DNA of the cells from the cell lines was cross-linked, digested, religated and TLA amplifications were performed with all 5 primers. The TLA amplicons were then sequenced on an Illumina MiSeq machine. Generated sequences were processed and mapped.
Results: The fusion partner of the MLL gene was correctly identified in all the samples. TLA was also performed in different mixtures of gene-fusion positive and healthy cells to determine the sensitivity. With the current protocol and existing data-analysis tools a sensitivity of 5% was already established. Results from bone marrow samples positive and negative for a MLL rearrangement will be presented.
Summary and Conclusion: Our first results demonstrate the capability of TLA in detection of structural abnormalities. Based on this results diagnostic assays can be developed which will simultaneously detect all types of structural genetic abnormalities and other aberrations relevant to almost all types of leukemia.

AUTOPHAGY INDUCED BY DEXAMETHASONE MEDIATES GLUCOCORTICOID RESISTANCE IN LYMPHOID MALIGNANCY CELLS

L Jiang[1], M Fang[1,*]
[1]Department of Hematology, the First Affiliated Hospital of Dalian Medical University, Dalian, China

Background: Glucocorticoid (GC) resistance remains a major obstacle to the successful treatment of lymphoid malignancies, but the precise mechanism of this resistance has not yet been elucidated.
Aims: To explore the role of autophagy in dexamethasone (Dex) induced resistance of human lymphoid malignancy cells.
Methods: Flow cytometer (FCM) analysis was carried out to determine the GC-sensitive cells and GC-resistant cells. The effect of Dex on cell cycle was measured by FCM and western blot (WB) analysis. Autophagy of lymphoid malignancy cell lines CCRF-CEM, Raji and U-937 were detected by transmission electron microscopy (TEM), WB and MDC staining. WB was also carried out to evaluate the effects of Dex on phosphorylation of Akt, P70S6K and 4E-BP1 in Raji and U-937 cells. The effects of Dex combined with autophagic inhibitor chloroquine (CQ) or 3-methyladenine (3-MA) on cell viability and apoptosis were measured by CCK-8 assay and WB.
Results: Dex could significantly induced apoptosis in GC-sensitive CCRF-CEM cells but not in GC-resistant Raji and U-937 cells. Dex could significantly inhibited CCRF-CEM and Raji cell cycle at the G0/G1 phase, but not in U-937 cells. Dex triggered autophagy in Raji and U-937 cells: autophagosome formation was detected by TEM, LC3-I to LC3-II conversion and down-regulation of P62 were measured by WB, and the formation of acidic autophagic vacuoles was determined by MDC staining. Dex didn't induce autophagy in CCRF-CEM cells. WB showed a dramatic reduction of p-Akt, p-P70S6K and p-4E-BP1 expression in Dex-treated Raji and U-937 cells. CCK-8 assay and WB showed no significant effect on cell viability and apoptosis of Raji and U-937 cells treated with Dex, CQ or 3-MA separately, while combination Dex and autophagy inhibitors enhanced the effects of Dex on cell viability and apoptosis.
Summary and Conclusion: Dex induced autophagy in GC-resistant Raji and U-937 cells while failing to trigger autophagy in GC-sensitive CCRF-CEM cell. PI3K-AKT-mTOR pathway was involved in the autophagy induced by Dex. Pharmacological inhibition of autophagy enhanced the effects of Dex on viability and apoptosis in GC-resistant Raji and U-937 cells. Manipulation of autophagy has the potential to improve GC resistance therapeutics, might be offer a new strategy to overcome GC resistance.

EXTREMELY HIGH RATE OF COMPLETE HAEMATOLOGICAL RESPONSE OF ELDERLY PH+ ACUTE LYMPHOBLASTIC LEUKEMIA (ALL) PATIENTS BY INNOVATIVE SEQUENTIAL USE OF NILOTINIB AND IMATINIB

[1]Department of Experimental, Diagnostic and Specialty Medicine (DIMES), University of Bologna, Bologna, [2]Gimema Data Center, Rome, [3]Department of Clinical and Molecular Bio-Medicine, Sections of Hematology, Oncology and General Pathology, University of Catania, Catania, [4]Department of Medicine, Section of Hematology, University of Verona, Verona, [5]Division of Hematology "San Martino" Hospital, University of Genova, Genova, [6]Division of Hematology, Fondazione IRCCS Policlinico San Matteo, University of Pavia, Pavia, [7]Department of Hematology, University of Ferrara, Ferrara, [8]Division of Hematology, Nuovo Ospedale "Torrette", Ancona, [9]Department of Oncology and Hematology, University of Modena, Modena, [10]Division of Hematology, "Ca Granda Niguarda Hospital", Milan, [11]Department of Hematology, University of Bari, Bari, [12]Division of Hematology, University "Sapienza", Rome, Italy

Background: We have explored if the administration of two TKIs, Nilotinib (NIL) and Imatinib (IM) can improve the results without increasing the toxicity in the elderly Ph+ Acute Lymphoblastic Leukemia (ALL) patients.
Aims: We investigate the type and number of BCR-ABL kinase domain mutations developing during and after the study.
Methods: We have designed a study (ClinicalTrials.gov. NCT01025505) in which patients more than 60 years old or unfit for intensive chemotherapy and SCT where treated with two TKIs, NIL 400 mg twice daily, and IM 300 mg twice daily, alternating for 6 weeks for a minimum of 24 weeks (study core) and indefinitely in case of response. The 6-weeks rotation schedule was respected, irrespectively of temporary discontinuations. The primary end-point was the rate of Disease Free Survival (DFS) at 24 weeks (4 courses of treatment); the secondary end points included the evaluation of CHR, CCgR and CMR rates.
Results: 39 patients have been enrolled in 15 Italian hematologic Centers (median age 66 years, range 28-84). Among these, 8 patients were unfit for standard chemotherapy or SCT (median age 50 years, range 28-59). 27 patients were p190, 5 were p210 and 7 were p190/p210. After 6 weeks of treatment, 36 patients were evaluable for response: 34 were in CHR (94%) and 2 in PHR (6%). 23 patients have already completed the study core (24 weeks), 87% were in CHR and 17 are currently continuing therapy in the protocol extension phase. Thus, the OS at 1 year is 79%, and 64% at 2 years. Overall, 1 patient was primarily resistant and 13 patients have relapsed, with a median time to relapse of 7.6 months (range 0.8-16.1 months), for a DFS of 51.3% at 12 months.
Summary and Conclusion: In this small cohort of Ph+ ALL elderly/unfit patients, the rates of relapse and progression were not likely to be different from the rates observed with Imatinib alone.

GENETIC VARIATION IN FOLATE RELATED GENES AND THEIR ASSOCIATION WITH OUTCOME OF METHOTREXATE THERAPY IN CHILDREN WITH ACUTE LYMPHOBLASTIC LEUKEMIA

W A El-Neanaey[1,*], H hassab[2], D EL-neily[1]
[1]clinical pathology, [2]pediatric, faculty of medicine-alexandria university, egypt, alexandria, Egypt

Background: Methotrexate (MTX) is an important component of maintenance therapy in childhood acute lymphoblastic leukemia (ALL). However, some patients can develop resistance or adverse drug effects, which may hamper the efficacy of treatment or require drug discontinuation
Aims: Following the hypothesis that gene variants of the MTX action pathway can affect outcome of ALL, we analyzed the influence of thymidylate synthase (TS) enhancer 28-bp tandem repeat and reduced folate carrier gene (RFC80G>A) polymorphism on risk of relapse and toxicity in pediatric ALL.
Methods: The present study was conducted on 99 pediatric ALL patients (67 patients on maintenance therapy for two years and 32 relapsed patients within two years of diagnosis. Detection of TS tandem repeat polymorphism was done by PCR and RFC80G>A polymorphism by PCR – RFLP analysis.
Results: There was no significant association between the genotype frequency of both TS tandem repeats and RFC 80G>A with different grades of hematological and hepatic toxicity. Regarding risk of relapse in childhood ALL, a significant Odds ratio was found for the homozygous triple repeat 3R3R and heterozygous 3R2R compared with homozygous double repeat 2R2R and also, a significant Odds ratio was found for the homozygous AA genotypes compared with GG genotype.
Summary and Conclusion: carriers of TS 3R allele and RFC A allele have an increased risk of relapse. However, these alleles are not associated with toxicity of MTX therapy in childhood ALL. These findings open the possibility of drug dose adjustment and the patients who have lower frequency of chemotherapy toxicity might benefit from an increase in drug dose.

P766

6-MERCAPTOPURINE DOSAGE REDUCTION AND TPMT POLYMORPHISMS IN THE TREATMENT OF CHILDREN ACUTE LYMPHOBLASTIC LEUKEMIA

A Ferreira Baptista[1,*], M Coucelo[1], T Garrido[1], MJ Mendes[1], S Marini[1], H Saturnino[1], S Silva[2], MJ Brito[3], M Benedito[1], ML Ribeiro[1]
[1]Serviço de Hematologia, Centro Hospitalar e Universitário de Coimbra, [2]Serviço de Oncologia Pediátrica, Hospital Pediátrico, Centro Hospitalar e Universitário de Coimbra, [3]Serviço de Oncologia Pediátrica, Hospital Pediátrico, Centro Hospitalar e Universitário de Coimbra, Coimbra, Portugal

Background: 6-Mercaptopurine (6MP) is used in the treatment of children with Acute Lymphoblastic Leukemia (ALL) for a long period of time (approximately 2 years). Thiopurine S-methyltransferase (TPMT) catalyzes methylation, deactivating this way the 6MP action. That enzyme is affected by functional polymorphisms which produce a defective enzyme altering 6MP intracellular metabolism and resulting in higher levels of thioguanine nucleotides and therefore in higher levels of toxicity.
Aims: To investigate the association between TPMT-deficient polymorphisms and the needed 6MP dose adjustments, as well as the prevalence of known side-effects such as hematotoxicity, infections, and mucositis.
Methods: We retrospectively studied a group of 47 children receiving 6MP as part of the DFCI 05-01 protocol between 2006 and 2013; 46 children were diagnosed with ALL and 1 with Lymphoblastic Lymphoma B; 22 patients were classified as standard risk, 19 as high risk and 6 as very high risk. This study focused on the continuation phase with a planned duration of 72 weeks, consisting of 24 three-week chemotherapy cycles. 6-MP dose adjustments were made to maintain white blood cell counts between 2 - 3 $x10^3$/mL or whenever related side effects were observed. We analyzed the following parameters: 6MP dose (mg/m^2/day), 6MP dose adjustments, hemoglobin level, leukocyte and platelet counts, infectious episodes, and mucositis. The infectious episodes were graded from 1 to 4: 1 if minor infection requiring no treatment; grade 2 if moderate infection requiring treatment; grade 3 if major infection requiring hospitalization and grade 4 if there was hypotension. *TPMT* genotype (*1, *2, *3A, *3B, *3C) was performed by direct sequencing (ABI3130, AB) in DNA extracted from whole blood.
Results: We studied 47 children, 28 boys and 19 girls, mean age 6.7 ± 3.7 (range 1-17 years). By the time of this first analysis, 40 (85%) had finished treatment, with a median of 24 continuation cycles (range 9-27). The average 6MP dosage was 45.57± 17.47 mg/m^2/day. Of the 47 patients, 44 (93.6%) were *TPMT* wild-type homozygotes and 3 (6.4%) were variant allele carriers: 2 *TPMT*1/*2* and 1 *TPMT*1/*3A*. In a univariate analysis, there was a positive association between 6MP dosage and leukocyte (r=0.6, P<0,0001), neutrophil (r=0.56, P<0,0001) and platelet counts (r=0.58, P<0,0001). Patients with *TPMT* variant alleles had a higher percentage of cycles with average dosage reduction of >50% (P=0.018). The group of patients with *TPMT* variant alleles presented higher percentage of cycles with infectious episodes, particularly grade 2 or more, although no statistically significant differences were found. Regarding the incidence of mucositis no differences were observed between groups.
Summary and Conclusion: Our data show that higher leukocyte and platelet counts are correlated with higher 6MP dosage, suggesting that even though dosage adjustments were made they may not have been enough to maintain white blood cell counts in the target range. Similar results have been reported in previous published studies. In our group, 6.4% of the patients were *TMPT* variant allele carriers, as it has been shown in other series. These individuals needed a significantly higher reduction in the 6MP dosage and showed a tendency to more infectious episodes. Despite these results, we are aware of the limitations of a small study group and therefore we plan to include more patients and analyze other variables in the forthcoming research.

Background: 4-5% of adult ALL patients have central nervous system (CNS) involvement at diagnosis, assessed by cytologic analysis of cerebrospinal fluid (CSF). The frequency and clinical significance of occult CNS involvement as assessed by multiparameter flow cytometry –MCF- in adult ALL patients with a negative cytologic study of CSF, remains unknown.
Aims: To analyze the frequency and clinical significance of occult CNS leukemia at diagnosis in adult ALL patients.
Methods: CSF samples obtained at diagnosis from 61 adult patients with ALL were studied. Conventional cytologic (CC) analysis was performed in each participating center and the CC was considered positive if leukemic blast cells were observed after discard of traumatic punctures. MFC analysis was performed centrally. CSF cells were stained using fluorochrome-conjugated antibodies against various B-cell or T-cell antigens depending upon the immunophenotype of the leukemia at diagnosis. From 61 patients, 16 cases showing CC+ and MFC+ were excluded from the study. From the remaining 45 cases, patients with either CC-/MFC+ (occult CNS involvement) or CC-/MFC- (no CNS involvement) were compared.
Results: Median (range) patient age was of 43 (15,78) years and 26 (58%) cases were males. Eight patients (18%) had occult CNS involvement. No differences were found between CC-/MFC+ and CC-/MFC- groups in the clinical, hematologic, phenotypic and cytogenetic characteristics at diagnosis. In addition, no significant differences were observed in terms of complete remission (CR) rates (100% for CC-/MFC+ *vs*. 92% for CC-/MFC- patients, p=0.99), minimal residual disease (MRD) level<0.1% at the end of induction (71% *vs*. 67%, p=0.99) or<0.01% at the end of induction (57% *vs*. 37%, p=0.410), disease-free survival (DFS) at 3-yrs. (58% *vs*. 44%, p=0.522) or overall survival (OS) at 3-yrs (71% *vs*. 49%, p=0.354).
Summary and Conclusion: Although in this small series of adult patients with ALL occult CNS involvement at diagnosis was frequent, it had no impact on CR attainment, MRD level after induction, OS or DFS. Supported in part by Grant RD12/0036/0029 and RD12/0036/0048 from RTICC, Instituto de Salud Carlos III, Spain.

TREATMENT OF RELAPSED ACUTE LEUKEMIA AFTER ALLO-HSCT BY SALVAGE CHEMOTHERAPY WITH LOW-DOSE CYTARABINE AND ACLARUBICIN COMBINED WITH G-CSF PRIMING: MORE EFFECTIVE AND LESS TOXIC?

H Zhou[1], A Sun[1], X Zhu[1], H Qiu[1], Z Jin[1], M Miao[1], C Fu[1], X Ma[1], F Chen[1], S Xue[1], C Ruan[1], D Wu[1], X Tang[1,*]
[1]the First Affiliated Hospital of Soochow University, Suzhou, China

Background: Recurrence is a major cause of treatment failure after allogeneic hematopoietic stem cell transplantation (allo-HSCT) for acute leukemia, and subsequential treatment options are very limited.
Aims: We evaluate the efficacy and toxicity of cytarabine and aclarubicin combined with granulocyte colony-stimulating factor priming (CAG regimen), consisting of concurrent use of granulocyte colony-stimulating factor (G-CSF) with low-dose cytarabine and aclarubicin, as a salvage therapy for acute leukemia patients who relapsed after allo-HSCT.
Methods: Fifty-nine patients (32 male and 27 female) with acute leukemia, with a median age of 27 years, relapsed post allo-HSCT and received salvage chemotherapy. Twenty-seven patients received CAG regimen while 32 patients received non-CAG regimen such as intensive chemotherapy.
Results: The overall response rate (ORR) of CAG was significantly superior to that of non-CAG groups (55.6% *vs* 28.1%, p=0.033). With regard to the disease type, comparing with non-CAG group, ORR of AML patients in CAG group was significantly higher (64.3% *vs* 20%, p=0.025).(When AML and acute lymphocytic leukemia (ALL) cases were analyzed separately, ORR in CAG group was significantly higher than that in non-CAG group among AML cases(64.3% *vs* 20%, p=0.025)). However, ORR of ALL in CAG group was similar with that in non-CAG group (50% and 35.2% respectively; P=0.471). Median overall survival (OS) from the starting of CAG chemotherapy and 2-year OS of CAG group were 9 (1-27) months and 16.1%. Meanwhile, median OS and 2-year survival of non-CAG group were 4 (1-49) months and 8.8%. Moreover, the median duration of neutropenia and thrombocytopenia of CAG group were significantly shorter than that of non CAG group, 6 (1-12) *vs* 11 (5-28) days (P=0.000) and 8(1-14) *vs* 14 (7-35) days (P=0.000). For the patients who received donor lymphocyte infusion (DLI) as a subsequential therapy, two-year OS of CAG and non-CAG group were 17.2% and 12.5% respectively (P=0.577). Treatment related mortality (TRM) was found in 2 cases in CAG group compared with 10 cases in non-CAG group. For CAG group, impact on ORR was significantly associated with the leukocyte level, and medullar blast percentage at relapse (p=0.005 and p=0.000 respectively).(For CAG group, characteristic associated with a higher likelihood of ORR on univariate analysis was lower tumor burden manifested by leukocyte level (p=0.005) and medullar blast percentage (p=0.000) at post-transplant relapse. Furthermore, the response to chemotherapy shown by multivariate analysis was the only factor that correlated with better survival (p=0.016, HR 0.426, 95%CI (0.213, 0.853))
Summary and Conclusion: CAG regimen as a salvage chemotherapy for relapsed acute leukemia post allo-HSCT could effectively reduce tumor burden with mild toxicity, especially for hypoplastic acute leukemia patients. For certain type of relapsed acute leukemia patients post allo-HSCT, CAG regimen may be an optimal choice as the bridge therapy followed by DLI or second allo-HSCT.

P769

QUANTITATIVE ULTRASOUND OF PROXIMAL PHALANXES IN CHILDHOOD ACUTE LYMPHOBLASTIC LEUKEMIA SURVIVORS

A De Matteo[1], F Petruzziello[1,*], A Esposito[2], R Parasole[1], A Mangione[1], L Marano[1], V Poggi[1], A Del Puente[2]
[1]Pediatric Hemato-oncology, Santobono-Pausilipon Hospital, [2]Rheumatology Unit, University Federico II, Naples, Italy

Background: The long term treatment related morbidities among the growing population of survivors from childhood acute lymphoblastic leukemia (ALL) are a matter of significant concern. Bone mineral density (BMD) impairment is a well-known complication in childhood ALL survivors. The optimal method to assess bone condition is still debated. Quantitative Ultrasound (QUS) of proximal phalanxes is a validated technique to assess BMD in children.
Aims: The aim of our study is to use QUS to assess BMD in ALL survivors and to evaluate the role of cytotoxic dosage in the development of long term bone damage.
Methods: From November 2012 to December 2013, 72 ALL survivors (40 female/32 male) were enrolled in the study in a single Pediatric Hemato-Oncology center. Mean age at diagnosis was 61 ± 45 months (95% CI, 51;41) while median age at QUS was 10.5 ± 4.3 years (95% CI, 9.49; 11.45); the mean period of follow-up from therapy completion was 41.2 ± 37.8 months (95% CI, 32.45; 55.89). Amplitude-dependent speed of sound (AD-SoS) was measured at the phalanxes of the non-dominant hand and expressed as a z-score. Linear correlation with cumulative dosages of cytotoxic agents, age at ALL treatment, Body mass index (BMI) and duration of follow-up were sought.
Results: Median AD-SoS z-score was -1,22 ± 1,19 (95% CI, -1,5; -0,94). Ten subjects (13.8%) presented z-score below -2 S.D. Vitamin D implementation was required in 9/72 (12.5%) survivors. A negative correlation was found between AD-SoS z-score and BMI (P=0.0001), as reported in literature, and age at diagnosis (P=0.01). Positive correlation was observed with duration of follow-up (P=0.01) (Figure 1). No significant correlation was found between z-score and cytotoxic dosage, corrected by sex, age and BMI.

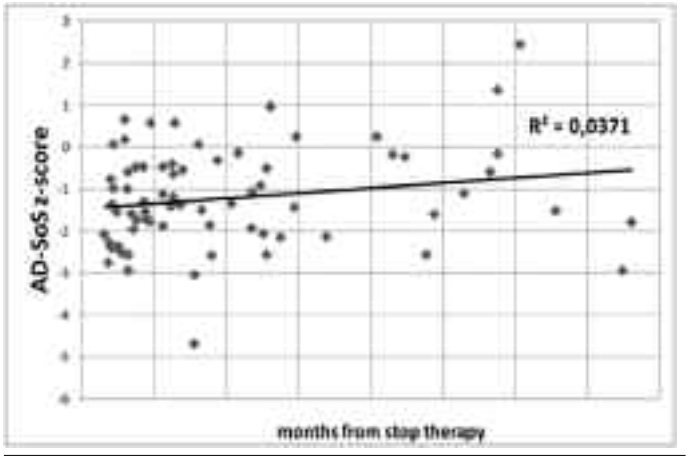

Figure 1.

Summary and Conclusion: Our report represents the largest cohort of childhood ALL survivors submitted to QUS after the stopping of therapy. As reported in Literature, QUS permits an early detection of bone impairment during childhood ALL treatment. In the present study, using QUS, we found that 13.8% of ALL survivors shows a BMD significantly lower than age-sex matched reference population. This effect decreases with duration of disease-free follow-up. No correlation was found with cytotoxic cumulative dosage, while age at

the onset of disease significantly affects BMD. Our data suggest that the major determinants of bone impairment are the disease itself and the phase of bone growth on which disease occurs.

P770

RELATIONSHIP BETWEEN MTHFR POLYMORPHISM AND SIDE EFFECTS OF HIGH-DOSE METHOTREXATE IN PEDIATRIC ACUTE LYMPHOBLASTIC LEUKEMIA

S M Ragab[1,*], F H El- Rashedy[1], A A Dawood[2], M A El-Hawy[1]
[1]Pediatrics, [2]Clinical biochemistry, Menoufia Faculty of Medicine, Shebeen El-Koom, Egypt

Background: Acute lymphoblastic leukemia (ALL) is the most common type of cancer in children. Administration of with high-dose methotrexate (HDMTX) followed by leucovorin rescue is an important component in the treatment of childhood ALL. methotrexate (MTX) toxicity includes mucositis, myelosuppression, and hepatic toxicity. MTX toxicity can vary with genetic variability in folate-metabolizing enzyme methylenetetrahydrofolate reductase (MTHFR).
Aims: To study the relationship between (MTHFR) gene polymorphism, and the occurrence of complications associated with (HDMTX) in pediatric acute lymphoblastic leukemia (ALL).
Methods: A total of 26 ALL children were studied. Clinical assessments, complete blood count liver and renal functions before and after HDMTX, MTX level measurement after HDMTX, and PCR (restriction fragment length polymorphism) for the MTHFR (C677T and A1298C) polymorphism were carried out. Informed consent was obtained from the legal guardians of the included children.
Results: Plasma MTX level had a relation to HDMTX toxicity specially mucositis. Regarding the C677T MTHFR allele, 14 patients (53.8%) had CT (heterozygous) polymorphism while 7 patients (26.9%) had TT (homozygous - mutant) polymorphism and 5 patients (19.2%) had CC (homozygous -wild) polymorphism. For A1298C allele, 18 patients (69.2%) had AC (heterozygous) polymorphism while 5 patients (19.2%) had AA(homozygous -wild) polymorphism and 3 patients (11.5%) had CC (homozygous -mutant) polymorphism. For C677TMTHFR allele, neutrophils recovery days were higher in TT followed by CT then CC polymorphism, platelet recovery days were higher in TT followed by CT then CC patients and days required for plasma MTX level to decrease to less than 0.1 µmol/l were higher in TT followed by CT then CC polymorphism. For A1298C allele, post-infusion platelet counts were lower in AA than AC and CC polymorphism, platelet recovery days was lower in AA than CC and AC patients. Neutrophils recovery days and days required for plasma MTX level to decrease to less than 0.1 µmol/l were higher in AA followed by AC then CC patients. For A1298C polymorphism, AC patients had the significant higher overall survival in relation to CC and AA patients (Log Rank=6.268, p value<0.05).
Summary and Conclusion: The increase in plasma MTX level after HDMTX might be associated with an increase in the risk for complications. Genotyping of folate polymorphisms might be useful in ALL children to optimize MTX therapy, reducing the associated toxicity with possible effects on survival.

P771

A PHASE I DOSE-ESCALATION STUDY OF MPEG-R-CRISANTASPASE ADMINISTERED BY INTRAVENOUS INFUSION IN ADULT PATIENTS WITH RELAPSED OR REFRACTORY HEMATOLOGICAL MALIGNANCIES

G Salles[1,*], S Lepretre[2], S Le Gouill[3], F Rigal-Huguet[4], C Haioun[5], S Balouet [6], T Corn[7], X Thomas[1]
[1]Hospices Civils de Lyon – Université Claude Bernard Lyon, Pierre-Bénite cedex, [2]Centre Henri Becquerel, Rouen, [3]Centre Hospitalier Universitaire de Nantes, Nantes, [4]Centre Hospitalier Universitaire de Toulouse, Toulouse, [5]Centre Hospitalier Universitaire Henri Mondor, Créteil, [6]The Lymphoma Academic Research Organisation (LYSARC), Pierre-Bénite cedex, France, [7]EUSA Pharma, Oxford, United Kingdom

Background: Asparaginase (ASNase) is an important component of multiagent chemotherapy for treatment of acute lymphoblastic leukemia and lymphoma in children and young adults. However, hypersensitivity reactions still occur in 10% to 30% of patients receiving *Escherichia coli*–derived ASNases, often resulting in treatment discontinuation. To maintain clinical outcomes, patients may be switched to ASNase *Erwinia chrysanthemi,* an immunologically distinct ASNase. Due to the short half-life of ASNase *Erwinia chrysanthemi*, each two-week course of therapy requires 3 administrations a week. To improve pharmacokinetic properties and reduce immunogenicity, recombinant PEGylation technology was used to create a new *Erwinia chrysanthemi*–ASNase, mPEG-r-crisantaspase.
Aims: This is an open-label, multicenter, dose-escalation study to determine the maximum tolerated dose, safety, and pharmacokinetics of mPEG-r-crisantaspase in patients with relapsed or refractory hematological malignancies.
Methods: Patients were eligible for the study if they were aged 18 to 50 years with relapsed or refractory hematological malignancy for which standard curative or life-prolonging treatment was not an option. This study met institutional review board approval and all patients provided written consent. Exclusion criteria included active central nervous system disease or a previous allergic reaction (grade ≥2) to ASNase *Erwinia chrysanthemi*. All patients received 2 intravenous infusions over 60 minutes of mPEG-r-crisantaspase once every 2 to 4 weeks. Patients were allowed to continue dosing until disease progression if judged appropriate by the investigator. Based on preclinical data, 500 IU/m^2 was selected as the initial dose. Dose escalation was based on the number of patients experiencing a dose-limiting toxicity (DLT) within 14 days of the first infusion. If a given dose resulted in ASNase activity ≥0.1 IU/mL for ≥10 days, up to 6 patients could be enrolled at that dose.
Results: Ten patients (mean age 40.6 years) have been enrolled to date; planned enrollment is 36 patients. The study included 5 patients diagnosed with Hodgkin's lymphoma, 3 patients with diffuse large B-cell lymphoma, 1 patient with acute lymphoblastic leukemia, and 1 patient with acute myeloid leukemia. All patients have failed multiple lines of therapies. As the first 3 patients dosed at 500 IU/m^2 maintained ASNase activity >0.1 IU/mL at 14 days, an additional 3 patients were enrolled at this level. No DLT was observed and all 6 patients showed ASNase activity >0.1 IU/mL at 14 days (Figure 1). Fourteen days after the second dose, ASNase activity levels were generally higher compared to 14 days after the first dose, with several patients maintaining target activity levels ≥5 weeks. The Independent Dose Escalation Committee agreed to dose 3 patients at 750 IU/m^2 with a 21-day interval. These patients maintained enzymatic activity >0.1 IU/mL at 14 days, with 1 DLT observed (neutropenia lasting more than 7 days). The most common adverse events (>30%) were diarrhea, anemia, hypoalbuminemia, decreased antithrombin III, and nausea. Three deaths occurred following administration of 500 IU/m^2 mPEG-r-crisantaspase (1 due to cerebral hemorrhage and 2 due to disease progression), and 1 death occurred after infusion of 750 IU/m^2 (disease progression).
Summary and Conclusion: At a dose of 500 IU/m^2, mPEG-r-crisantaspase provides effective serum ASNase activity for 14 days following intravenous infusion. The safety data for 500 IU/m^2 and 750 IU/m^2 are consistent with the known safety profile of ASNase treatment and with comorbidities and disease progression in this patient population.

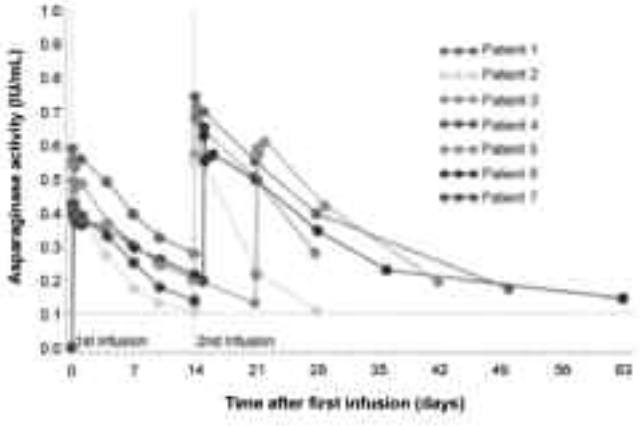

Figure 1. Asparaginase activity following 500 IU/m^2 mPEG-r-crisantaspase (One additional patient was recruited following the death of a patient due to disease progression after the first infusion).

Support: Study funded by Jazz Pharmaceuticals plc or its subsidiaries and conducted in 5 LYSA centers (registration N°NCT01551524).

MINIMAL RESIDUAL DISEASE IN ADULTS WITH PHILADELPHIA NEGATIVE B-CELL PRECURSOR ACUTE LYMPHOBLASTIC LEUKEMIA - A SWEDISH POPULATION-BASED STUDY

E Bergfelt[1,*], P Kozlowski[2], L Ahlberg[3], E Hulegårdh[4], H Hägglund[1,5], K Karlsson[6], A Markuszewska-Kuczymska[7], B Tomaszewska-Toporska[6], B Smedmyr[1], M Åström[2], RM Amini[8], H Hallböök[1]
[1]Division of Hematology, Dept of Medical Science, Uppsala University Hospital, Uppsala, [2]Hematology Section, Department of Medicine, Örebro University Hospital, Örebro, [3]Dept of Hematology, University Hospital of Linköping, Linköping, [4]Dept of Hematology and Coagulation, Sahlgrenska University, Göteborg, [5]Division of Hematology, Department of Medicine Huddinge, Karolinska Institutet, Karolinska University Hospital, Stockholm, [6]Dept of Hematology, Skåne University Hospital, Lund, [7]Dept of Hematology, Cancer Center, University Hospital of Umeå, Umeå, [8]Dept of Immunology,Genetics and Pathology, Uppsala University, Uppsala, Sweden

Background: Minimal Residual Disease (MRD) is an independent risk factor

for acute lymphoblastic leukemia (ALL). In Sweden, MRD is determined by flow cytometry in Philadelphia negative B-cell precursor ALL (Ph- BCP-ALL). Conversion to high risk protocol, *i.e.* allogeneic stem cell transplantation, is recommended when MRD levels are >1% after remission induction (MRD1) and/or do not reach<0.1% after consolidation therapy, even in the absence of conventional risk factors (WBC >30x10^9/L, t(4;11) or late remission).
Aims: To evaluate the introduction of MRD measurements for Ph- BCP-ALL in Sweden outside randomized controlled trials, in terms of feasibility, cut-off adequacy and correlation to relapse and overall survival in a population-based cohort >45 years old.
Methods: All patients diagnosed with ALL are reported to the Swedish ALL registry where clinical data is assembled prospectively. We included patients diagnosed with Ph- BCP-ALL from 2007 to 2011, aged >45 years and treated with ABCDV/VABA with curative intention. Statistical analysis and Kaplan Meier survival curves were calculated using StatView and SPSS, 95% confidence intervals (CI) were obtained. Overall survival (OS) was defined as time from diagnosis until last follow up or death. Continuous complete remission (CCR) was defined as time from morphologic complete remission to relapse, death in remission or date of last follow-up. The study was approved by the regional ethical committee in Uppsala.
Results: Thirty-five patients, 12 men and 23 women with a median age of 61(range 46-79) years, were included. Twenty-seven of them had a WHO-score 0-1 and eight patients scored 2 or higher. Four patients presented with t(4;11), nine had WBC >30x10^9/L and one had CNS leukemia. Thirty patients (86%) achieved morphologic complete remission (CR) after the first course and another two after the second. Among the responders to the first course, MRD1 was measured in 22 patients and evaluable in 20. Eight of these patients had no detectable MRD (reported as<0,1 or<0,01%) whereas twelve patients had a residual disease (five reported as 0,01-0,099%, two 0,1-0,09%, five >1%). Sixteen patients had an MRD measurement after the second course and twelve after the third. One patient was converted to the high-risk group solely due to MRD-levels. OS at 3 years was 53 (CI 36-79)% and at 5 years 45 (CI 27-62)%. Three patients died in CR because of therapy related complications. Eleven patients received only 1-2 courses and 24 patients followed the protocol. The OS was significantly lower in the former group (p=0,04). OS did not differ significantly between the patients with MRD1 >0.1% and<0,1%. Looking at CCR a good-risk group was identified with MRD1<0,1% and CCR at 3y was 83 (CI 62-100)%. Allogeneic stem cell transplantation was performed in ten patients. Five patients were transplanted in CR1 and five in CR2, no patient in the latter group survived.
Summary and Conclusion: MRD measured by flow cytometry is feasible but it has been proven difficult to obtain samples from all patients when outside a clinical study. Our results are compromised by this fact. The high intensity protocol was tolerable for most of the patients and incomplete treatment corresponded to adverse prognosis. We assume that the stipulated MRD cut-off levels are too high, since only one patient was converted to the high-risk group due to MRD. Patients with MRD<0,1% after remission induction seem to have a favorable prognosis, but validation is needed from a larger cohort.

P773

INVASIVE FUNGAL INFECTIONS IN PEDIATRIC PATIENTS WITH ACUTE LEUKEMIA: RESULTS FROM AN UNIVERSITY HOSPITAL, 2005 TO 2013
Z Şahbudak Bal[1], D Yilmaz Karapinar[1], N Karadas Ozdemir[1], S Sen[1], Z Onder Sivis[1], A B Akinci[1], C Balkan[1], K Kavaklı[1], F Vardar[1], Y Aydınok [1,*]
[1]Pediatrics, Ege University School of Medicine, Izmir, Turkey

Background: Invasive fungal infections (IFIs) are important causes of morbidity and mortality in children with leukemia. Few reports available in the literature about IFI in pediatric patients with leukemia.
Aims: The aim of the study was to delineate the epidemiologic, clinical features, risk factors, and outcome of invasive fungal infections in this population.
Methods: The medical records of the patients with acute lymphoblastic (n=125) and acute myeloblastic leukemia (n=30) who were treated at Pediatric Hematology Department of Ege University School of Medicine, between 2005 and 2013 were retrospectively reviewed to determine the rate, causative agents, and the outcome of IFI in children.
Results: A total of 57 IFI episodes were recorded in 48 (male/ female=24/24) patients. The rate of IFI among the patients with acute leukemia was 57/155 (36.7%). Patients did not receive primary prophlaxis except four patients with relapsed AML. The median age of the patients was 8.2 (range 1.5-16) years. IFI was classified as proven in 18 (31,5%), probable in 14 (24,5%) and possible in 25 (43,8%) episodes. The causative fungus was microbiologically documented in 17 proven IFI episodes. In 13 of 18 proven IFI episodes *Candida spp. (3 albicans, 4 parapsilosis, 1 krusei, 1 guilliermondii, 3 tropicalis, 1 pellucilosa*) and in 3 proven IFI episodes *Geotrichum capitatum*, in 1 proven IFI episode *G.candidum* and in 1 proven IFI episode *T.asahii* was isolated from blood culture. In 1 episode, deep tissue infection with *Mucor* spp. was histopathologically documented. To be in the induction phase, prolonged and severe neutropenia were found to be major risk factors for IFI. Three month survival of these patients after the diagnosis of IFI was (87,7%). IFI was the main cause of death in 4 patients (7%).
Summary and Conclusion: Our results indicate that non-albicans *Candida* spp. was the most common fungi as the causative agent for IFI. The risk factors for IFI; severe and prolonged neutropenia and to be in the agressive phase of chemotherapy. Prevention, early detection, and advanced treatment strategies are needed to improve the outcome of IFI in children.

P774

ASPARAGINASE-ASSOCIATED PANCREATITIS (AAP) DURING TREATMENT FOR CHILDHOOD ACUTE LYMPHOBLASTIC LEUKEMIA (ALL)
T Garrido[1,*], M Mendes[1], S Silva[2], M Brito[2], M Benedito[1], L Ribeiro[1]
[1]Serviço de Hematologia, [2]Serviço de Oncologia Pediátrica, Centro Hospitalar e Universitário de Coimbra, Coimbra, Portugal

Background: In spite of being a key agent in the treatment of ALL, Asparaginase has serious and possibly fatal adverse effects, such as AAP.
Aims: To look for adverse effects of Asparaginase treatment, particularly AAP, as well as possible factors related to its occurrence.
Methods: We assessed the clinical records of 80 children diagnosed with ALL in a single centre between 2002 and 2013, treated with DFCI protocol 91-01 and 05-01 who were able to complete Consolidation II – 30 weeks of Asparaginase (children under 1-year old, Philadelphia-positive ALL, refractory leukemia after induction, relapse before consolidation II and cases of early death were excluded of the analysis, as well as children with FAB L3). The median follow-up was 52 months [6;135].
Results: The median age at diagnosis was 5 years-old [1;17]; 53.8% were male. Patients presented with signs/symptoms related to cytopenias (86.1%), lymphadenopathy (47.4%), organomegaly (47.4%) and bone pain (19.5%); two (2.5%) had CNS involvement. Median haemoglobin was 8.0 g/dL and median platelet count was 46.5x10^6/L; 16 (20%) patients had >50x10^6/L leucocytes at diagnosis (median: 9.95x10^6/L). Immunophenotype was compatible with precursor B-ALL in 72 (90%) patients. Hyperdiploid karyotype (21.3%) and t(12;21) (18.4%) were the most frequent cytogenetic findings; 4 (5.3%) patients had MLL gene rearrangements. Twelve (16.9%) patients had minimal residual disease >0.01% at the end of remission induction. Patients were treated by standard (51.3%), high (32.6%) and very high risk (17.5%) regimens. Eighteen (22.5%) patients were treated with Native E.coli Asparaginase and 73 (91.3%) with PEG-Asparaginase; three patients had to switch to Erwinase due to allergic reaction. Twelve (15%) patients had a thrombotic event; 61.3% had hepatotoxicity. Eight (10%) patients had AAP; all were treated with the pegylated formulation. Median time to AAP was 21weeks [3;34] after beginning of consolidation treatment; 50% of patients had AAP after the 10th administration. Among the AAP group, 7(87.5%) patients had hypertriglyceridemia, compared to 29(40.3%) in the remaining group (p=.05). Seven (87.5%) had asymptomatic elevation of pancreatic enzymes previously to the AAP episode (p<.0001). Two (25%) patients of those with AAP had T-cell lineage, compared to only 8.3% in the remaining group (p=.035). Five (62.5%) were high/very high risk, compared to 47.2% in the not-AAP group. Two patients died, one (12.5%) due to septic shock (along with pancreatitis); and one other after relapse. The 5-year overall survival was inferior for patients with AAP (98.6% *vs.* 87.5%; p=.05).
Summary and Conclusion: In our group of patients, the incidence of AAP was 10%. Even if clinical or laboratorial parameters cannot predict AAP, close monitoring of pancreatic enzymes and triglyceridemia still play a very important role. The high/very high risk patients may have an increased likelihood of AAP, possibly due to the more aggressive chemotherapy regimens.

P775

MOLECULAR CYTOGENETIC ANALYSIS IN 108 CHILDHOOD ACUTE LEUKEMIA PATIENTS FROM SAUDI ARABIA: CORRELATION TO MOLECULAR AND OTHER BIOLOGIC FACTORS
G Elyamany[1,2,*], Y Elborai[3,4], N Alkhayat[4], I ben-abdallah Bouhajar[1], M Awad[1], H Elghezal[1], K AL-Fayez[1], O Alsuhaibani[1], O Al-Sharif[4], M Al-Shahrani[4], A Elarja[1], A Al-Abulaaly[1]
[1]Dept. of Pathology and Laboratory Medicine, Prince Sultan Military Medical City (PSMMC), Riyadh, Saudi Arabia, [2]Department of Hematology and Blood Bank, Theodor Bilharz Research Institute, [3]Pediatric Hem/Onc and Stem Cell Transplant, National Cancer Institute (NCI), Cairo University, Cairo, Egypt, [4]Pediatric Hem/Onc and Stem Cell Transplant, Prince Sultan Military Medical City (PSMMC), Riyadh, Saudi Arabia

Background: Pediatric acute leukemias are generally characterized by recurrent molecular and cytogenetic abnormalities in both childhood acute lymphoblastic leukemia (ALL) and acute myeloid leukemia (AML). The identification of those abnormalities is clinically important because they are considered significant risk-stratifying markers.
Aims: No sufficient data exist regarding cytogenetic profile in Saudi acute pediatric leukemia patients. 108 cases of acute childhood leukemia were examined to determine cytogenetic profile, *FLT3* mutations and frequency of the most chromosomal abnormalities associated with pediatric ALL and AML, and did correlations to other biologic factors and patient outcome.

Methods: *Patients:* from 2004 to 2013, we reviewed all cases with established diagnosis of childhood ALL and AML. Of the 108 patients, 75 were B-lineage ALL, 24 AML and 9 T-cell ALL. ALL patients were treated according to UKALL 2003 protocol while AML according to UKAML 12 protocol. Informed consent was obtained from parents. *Cytogenetic Analysis:* Chromosome banding analysis and fluorescence *in situ* hybridization (FISH) were used to detect genetic aberrations. *Analysis of FLT3 mutations:* Bone marrow or blood samples were screened for *FLT3* mutations (internal tandem duplications, ITDs and point mutations, D835) using polymerase chain reaction methods (PCR).
Results: Table 1 summarizes patient's characteristics and patient's outcome. Cytogenetic analysis showed chromosomal anomalies in 59 out of 92 cases (68 ALL and 24 AML) with overall incidence 64.1% (43/68, 63.2% in ALL and 16/24, 66.7% in AML). The most frequent chromosomal anomalies in ALL were trisomy 21, t(9;22), and t(12;21) while t(8;21), t(15;17), trisomy 8, and MLL in AML. Our data are in accordance with those published showed that *FLT3*-ITD mutation have a strong bad prognostic factor in pediatric AML patients and associated disease progression while t(9;22) and MLL gene rearrangements were signs of a bad prognosis in childhood ALL, with high rate of relapse, shorter overall survival; (P=0.031) and event-free survival (EFS) was also worse (P=0.040) compared to standard risk group.
Summary and Conclusion: These data confirm that the frequencies of cytogenetic abnormalities and its prognostic significance were similar to those reported in the literatures. FLT3 mutations occur in a significant percentage of Saudi Pediatric AML and had bad prognostic relevance while not common in pediatric ALL and did not affect clinical outcome.

Table 1. Patient's characteristics and cytogenetic profile.

Clinical features and outcome			FLT3 Mutations and Cytogenetic alterations		
Parameter	**ALL**	**AML**	**Parameter**	**ALL**	**AML**

LENALIDOMIDE FOR TREATMENT OF REFRACTORY/RELAPSED ADULT B-ALL PATIENTS: RESULTS OF A MULTICENTRIC PHASE 2 STUDY

E Tavernier-Tardy[1,2,*], J Cornillon[1], C Moluçon-Chabrot[3], JY Cahn[4], O Tournilhac[3], D Guyotat[1], K Augeul-Meunier[1], J Beuvelot[1], F Tinquaut[1], A Bourmaud[1], X Thomas[5]
[1]Hematology, Institut de Cancérologie Lucien Neuwirth, Saint Priest en Jarez, [2]Université Jean Monnet, Saint Etienne, [3]Hematology, CHU Clermont-Ferrand, Clermont-Ferrand, [4]Hematology, CHU Grenoble, Grenoble, [5]Hematology, CHU Lyon, Lyon, France

Background: The prognosis of refractory/relapsed adult patients with acute lymphoblastic leukemia (ALL) remains very poor. With conventional therapies, less than half of these patients will achieve a second remission and few will be eligible for allogeneic HSCT, which is regarded as the treatment of choice at this stage of the disease. Novel agents are needed to improve outcomes. Lenalidomide is an immunomodulatory agent with promising results in the treatment of patients with B-cell malignancies. In the past, polychemotherapy (VAD regimen) had demonstrated significant antitumor activity both in ALL and in multiple myeloma. Lenalidomide in combination with dexamethasone is indicated for the treatment of multiple myeloma in relapse.
Aims: Based on pre-clinical data in B-cell malignancies and clinical data in multiple myeloma, this study was conducted to evaluate the safety and efficacy (CR, CRp, PR) of lenalidomide in combination with dexamethasone for the treatment of adult patients with refractory or relapsed B-cell lineage ALL.
Methods: Eight patients with B-ALL (6 patients with precursor B-lymphoblastic ALL and 2 patients with Phi+ ALL with a T315I mutation) were enrolled between February 2010 and August 2013. Lenalidomide was given orally at a dose of 25 mg/day on days 1 through 21 of 28-day cycles, in combination with dexamethasone 40 mg per os once daily on days 1,8,15,22 until achievement of CR, disease progression or intolerable toxicity. One subject was not evaluable because of his death by hemorrhagic complication before the beginning of the treatment. Therefore, only 7 patients were included in the analysis.
Results: Patients had a median age of 63.5 years (range, 46 to 74 years), a median of 2 prior therapies (range, one to three therapies), and received a median of 2 treatment cycles (range, one to four cycles) of therapy. The overall response rate was 28.6% with 2 patients achieving partial response after one course. Three other patients who had shown sufficient treatment activity (with a blast decrease ≥ 50% from the baseline in the peripheral blood) carried on with a second cycle of treatment. Response duration was short and no patient could undergo bone marrow transplant procedure. The hematologic toxicity included grade 4 neutropenia and grade 4 thrombopenia in 4 and 5 patients, respectively. The median duration of ANC<0.5 G/l and platelets<20 G/l were 15 and 13 days, respectively. Infectious complications requiring hospitalization occurred in 5 patients (gram-negative bacteremia, *Listeria monocytogenes* bacteremia, pneumococcal bacteremia and 2 pneumonias not otherwise specified). No patient experienced tumor lysis syndrome or thrombotic complications. Median OS was 92 days and death was the result of progressive disease in all patients.
Summary and Conclusion: Although the lenalidomide-dexamethasone regimen failed to improve the outcome of this very high risk population, this study showed some responses to lenalidomide with a manageable toxicity, comparable to any other anti-leukemic treatment. Combination of lenalidomide with chemotherapy or monoclonal antibodies should be tested in the future.

ENDOCRINE SIDE EFFECTS AFTER CHEMOTHERAPY IN PATIENTS WITH ACUTE LYMPHOBLASTIC LEUKEMIA

B Uysal[1,*], Y Oymak[2], K Demir[3], T Hilkay Karapinar[1], Y Ay[1], S Gozmen[1], B Demirağ[4], O Carti[1], G Özek[5], B Tatli Gunes[1], E Özcan[1], E Töret[2], D İnce[4], R C Vergin[1]
[1]Pediatric Hematology, Dr. Behcet Uz Children's Hospital, [2]Pediatric Hematology, Dr.Behcet Uz Children's Hospital, [3]Pediatric Endocrinology, [4]Pediatric Oncology, Dr. Behcet Uz Children's Hospital, [5]Pediatric Hematology, Dr. Behcet Uz Chilren's Hospital, Izmir, Turkey

Background: Focus on long-term side-effects after cancer therapy in childhood has become of the crucial importance. The exposure of chemotherapy at young ages has increased vulnerability to long-term treatment induced sequelae. Also contribution of radiation may increase adverse sequelae.
Aims: We aimed to evaluate endocrine side effects in patients with acute lymphoblastic leukemia being followed-up 1-5 years after treatment at İzmir Dr. Behçet Uz Children's Hospital. Study included 41 patients (M/F=20/21) and 20 of them were applied prophylactic cranial RT and remaned weren't.
Methods: Patients were screened for endocrine side effects, growth, blood glucose metabolism, lipid metabolism abnormalities, sexual development, thyroid metabolism, bone mineral density and adrenal insufficiency. Height, weigth, biochemical parameters (Ca, P, ALP, preprandial blood glucose, serum lipid profile), hormones parameters (PTH, 25-OH D vitamine, FSH, LH, Testosteron, Estrogen, TSH, fT3, fT4, thyroid antibody, ACTH, Cortisol), IGF-1 and IGFB-3 were noted from patient records. Thyroid ultrasound, pelvic

ultrasound in girls, DEXA Z for bone mineral density (BMD) were analized. Body mass index, HOMA-IR, glucose/insuline were calculated with the data gathered from patient files. All of the patients were evaluated fort he effects of RT and chemotherapy (KT).
Results: Mean age of the patients were 10±3,1 years. In 35 of 41 (85,3%) patients at least one endocrine complication was detected. One patient's (2,4%) height was under 3 percentile, 12 (29,3%) patients were obese. All the patients had normal preprandial blood glucose but 14 (34,1%) patients had insuline resistance. Three (7,3%) patients had IGF levels under -2 SDS, 2 (4,9%) patients had high FSH-LH levels. There was no puberte precox or tarda. One (2,4%) patient had subclinical hypothyroidy, one (2,4%) patient had positive thyroid antibodies. Eight (19,5%) patients had thyroiditis, three (7,3%) patients had nodules, two (4,9%) patients had cysts at thyroid ultrasound. Twenty (48,9%) patients had low levels of cortisol. All patients had normal levels of DEXA Z scores. Six (14,6%) patients had subclinical D vitamine deficiency, two (4,9%) patients had subclinical hyperparathyroidy, three (7,3%) patients had isolated hypercalcemia. Only insulin resistance rate was higher in patient who were apllied RT than those who weren't apllied RT. Endocrine side effects were evaluated according to the time elapsed after treatment only D vitamine had significant difference. In our study, RT only posesed a risk for insulin resistance. This could be because of low RT dose and short time interval after RT treatment. In our study, lack of difference in obesity rate between patients who were and weren't apllied RT, and obesity prevalance being higher than general population suggest the contribution of CT, especially steroids with well known effect. Due to low numbers of patients with T-cell ALL and/or HRG, which are treated with high doses of chemotherapeutic agents, the relation between side effects and CT doses could not be evaluated. Although endocrine side effects were more common in the 4-5 years after treatment, significant increase was seen in the second year also these side effects are expected to be more frequent as the time after treatment increase.
Summary and Conclusion: Endocrine side effects were observed in ALL patients who survived after treatment. These patients should be followed-up closely for endocrinological side effects, and early diagnosis and treatment should be performed for endocrinological disases which may develop later in life.

P778

TRANSFUSION IRON INTAKE IN TRANSPLANT ELIGIBLE PATIENTS WITH ACUTE LYMPHOBLASTIC LEUKEMIA: RETROSPECTIVE ANALYSIS OF IRON LOAD AT THE END OF CHEMOTHERAPY PROGRAM AND BEFORE TRANSPLANTATION

A Belotti[1,*], S Realini[1], E Doni[1], L Borin[2], E Elli[1], M Fumagalli[2], P Perfetti[2], L Verga[2], M Carrera[3], P Pioltelli[2], E Pogliani[2]
[1]Division of Hematology, [2]Ospedale San Gerardo – Università degli Studi Milano Bicocca, MONZA, Italy, [3]transfusion and hematology lab, Ospedale San Gerardo – Università degli Studi Milano Bicocca, MONZA, Italy

Background: Iron overload is an important adverse prognostic factor for patients undergoing hematopoietic stem cell transplantation (HSCT), increasing the risk of infections, veno-occlusive disease and hepatic dysfunction. Moreover, it seems from literature that elevated pretransplant ferritin levels are associated with higher non relapse mortality following HSCT and might influence the risk of acute and chronic GVHD. The majority of data derives from studies regarding patients with thalassemia and myelodysplastic syndromes, with established iron chelation strategies in these diseases. On the contrary, the extent of transfusion iron overload in transplant eligible acute lymphoblastic leukemia (ALL) and the need of iron chelation therapy (ICT) in this patients remains debated.
Aims: To evaluate transfusional iron intake in potentially transplant eligible patients with ALL treated with conventional chemotherapy regimens, focusing on patients who underwent HSCT or completed consolidation chemotherapy courses.
Methods: we retrospectively analysed 29 potentially transplant eligible ALL patients from January 2010 to February 2014 (15 males, 14 females, median age 46years): 24 were B-ALL, 8 of them Philadelphia (Ph) positive; 5 were T-ALL. All patients completed their treatment program: 16 of them were treated with induction and consolidation chemotherapy followed by HSCT, while 13 patients received only chemotherapy. All patients underwent induction therapy according to IVAP regimen (prednisone, cyclophosphamide, idarubicin, vincristine, L-asparaginase, dexamethasone), followed by sequential consolidation therapy: high dose MTX/cytarabine or MTX/L-asparaginase, alternated with low dose chemotherapy. Ph positive patients received TKI in association with standard chemotherapy, omitting L-asparaginase. Iron intake until HSCT or until the end of consolidation chemotherapy, expressed in mg of iron, was calculated as total amount of red blood cells (RBCs) transfused X 1.08. Ferritin levels at the end of the treatment were also evaluated.
Results: Mean transfusional iron intake was 0.45 mg/kg per day, among a mean reatment period of 7.62 months. Mean ferritin level at the end of the treatment or before transplant conditioning regimen was 1380 µg/L (median 1051 µg/L).
Summary and Conclusion: This retrospective evaluation confirms a relevant transfusion iron load in ALL in a short time interval; of note, patients with β-thalassemia major or other refractory anemias receiving 2-4 units of blood per month have a transfusion iron intake of 0.3-0.6 mg/kg per day. It is known that serum ferritin is not specific for iron overload and is a poor predictor of body iron burden, and maybe it is even less specific in ALL as a reliable marker in monitoring iron loading. Moreover, the optimal ICT in ALL patients is still to be defined: subcutaneous deferoxamine infusion is inconvenient and troublesome due to thrombocytopenia and neutropenia, while oral deferasirox administred in proven iron overloaded patients may not be sufficiently rapid in his action if we consider the short time available before transplantation and concomitant toxicity of chemotherapy administred, particularly on hepatic function. Efficacy of early low dose deferasirox administration at the beginning of chemotherapy in ALL patients could be an interesting field of investigation; special attention to the possible interactions with chemotherapy suggests appropriate clinical studies with monitoring of safety.

Acute myeloid leukemia - Biology 3

P779

DECREASE EXPRESSION OF MIR-20A PROMOTES CANCER CELL PROLIFERATION AND PREDICTS POOR SURVIVAL OF ACUTE MYELOID LEUKEMIA

P Li[1], D Ning[1], X Dahai[1], Z Nan[1,*], L Xiaoliang[1], W Yang[1], Z Xiuxian[1], C Hongli[1]
[1]Emergency Department, First Hospital of Jilin University, changchun, China

Background: MicroRNAs (miRNAs) are a family of 19- to 25-nucleotides non-coding small RNAs that primarily function as gene regulators. Growing evidences indicate miRNAs play important roles in cancer development, progression, metastasis and may constitute robust biomarkers for cancer prognosis. To date, although certain miRNAs have been established a clear oncogenic role in hematological malignancies, other individual miRNAs potentially involved in human leukemogenesis still remain elusive.
Aims: This study aimed to determine the clinical characteristics and prognostic significance of microRNA-20a (miR-20a) in adult de novo acute myeloid leukemia (AML) patients.
Methods: The expression levels of miR-20a in bone marrow mononuclear cells were measured in 98 newly diagnosed AML patients and 20 cases of normal healthy donors by real-time quantitative polymerase chain reaction. Kaplan-Meier and Cox proportional regression analyses were utilized to determine the association of miR-20a with survival of patients. The potential functions of miR-20a on proliferation were evaluated by proliferation and flow cytometry analysis. The direct target gene of miR-20a was also identified by luciferase reporter assays.
Results: miR-20a was expressed at significantly lower levels in the bone marrow of AML patients compared with normal controls. Patients with lower miR-20a expression had significantly poorer complete remission (CR) rates (Log rank p<0.001), relapse-free survival (RFS, Log rank p<0.001) and overall survival (OS, Log rank p<0.001). Low miR-20a expressers had lower CR rates and OS within the Southwest Oncology Group classification. Multivariate analysis revealed that lower miR-20a was an independent predictor of poor prognosis. MiR-20a restoration could result in low levels of cAMP and weak activity of PKA, thus relieving the inhibitory effect of PKA on mononuclear-leukemic cell proliferation. Subsequent investigations revealed that miR-20a directly reduced the endogenous protein level of myeloid cell leukemia sequence 1 (Mcl-1) in mononuclear-leukemic cell.
Summary and Conclusion: MiR-20a is decreased in AML and correlates with AML prognosis. Down-regulation of miR-20a increases the proliferation abilities of AML cells. Our findings suggest miR-20a may represent a novel potential therapeutic target and biomarker for survival of AML patients.

P780

COPY NUMBER GAINS OF CHROMOSOME 1P36 LEAD TO PRDM16 OVEREXPRESSION IN AML PATIENTS

C Baldazzi[1,*], E Ottaviani[1], S Luatti[1], G Marzocchi[1], G Ameli[1], C Papayannidis[1], C Gamberini[1], E Franchini[1], M Cavo[1], G Martinelli[1], N Testoni[1]
[1]Institute of Hematology and Medical Oncology "L. e A. Seràgnoli", S.Orsola-Malpighi Hospital, Bologna, Italy

Background: PRDM16 gene (1p36) is rearranged in AML/MDS with t(1;3)(p36;q21), t(1;21)(p36;q22) and t(1;12)(p36;p13). These translocation resulted in PRDM16 overexpression through juxtaposition to the enhancer of RPN1 at 3q21 or through fusion transcript formation with RUNX1at 21q22 or ETV6 at 12p13, respectively. AML/MDS with t(1;3)(p36;q21) showed similar clinical and prognostic characteristics with AML/MDS with inv(3)/t(3;3) and EVI1 rearrangements. PRDM16 overexpression has been reported in AML in absence of 1p36 rearrangements, but the mechanisms are still unknown and the studies not conclusive.
Aims: To characterize PRDM16 in cases with 1p36 abnormalities and to assess PRDM16 expression in a cohort of AML without 1p36 involvement.
Methods: The study group was composed of 14 AML and MDS cases with 1p36 abnormalities and a cohort of 80 AML without 1p36 involvement by conventional cytogenetic (CC) and were analysed by relative RQ-PCR and FISH using 3 BAC probes covering PRDM16 and its flanking regions (BlueGnome Ltd. Cambridge, UK).
Results: We identified 14 cases with 1p36 abnormalities: FISH analysis of 13 available samples identified 4 cases with PRDM16 rearrangement. Two cases showed a t(1;3)(p36;q21), one a t(1;21)(p36;q22) and the last one an add(1)(p36) in CC. In 3 cases the breakpoint was at 5' of PRDM16, whereas in t(1;21) it was at 3' of PRDM16, which is a rare event. We were not able to identify the chromosome partner involved in the case with add(1)(p36). Other 3 cases showed copy number gains of PRDM16 identified as the presence from 3 to 5 signals with all the three probes used in interphase FISH. To exclude the amplification of the whole p arm we used a control probe on 1p32 that did not show amplification. Metaphases FISH localized the site of amplification on the der(1)(p36) in two cases, whereas it was localized on unidentified chromosome in the last one. Rearrangements and amplification of PRDM16 were associated with overexpression by RQ-PCR. High levels of PRDM16 expression (greater that three standard deviations above the mean 2-ΔΔCt of 10 normal bone marrow controls) were observed in a significant subset of AML with normal karyotype (AML-NK) (12/25;48%) and with adverse cytogenetic prognostic group (3/11;27.3%) but they were also associated with isolated rare translocations (4/10;40%). In 3 cases with a complex karyotype FISH analysis detected an extra copy of PRDM16. Cases with gene amplification were associated with older age, complex karyotype involving chromosome 5 and 7 abnormalities, higher WBC and AML compared to cases with PRDM16 translocations.
Summary and Conclusion: PRDM16 gene is a frequent target of 1p36 abnormalities in AML. Copy number gain of PRDM16 is a recurrent genetic abnormality in AML with 1p36 abnormalities and, although less common, in AML with complex karyotype but undetectable 1p36 abnormalities. Copy number gain of chromosome 1p36 has not been previously associated with PRDM16 overexpression in patients with myeloid malignancies. We also demonstrated overexpression of PRDM16 in different subgroups of AML without PRDM16 rearrangements or amplification, especially in AML-NK subset. Since the poor prognosis associated to PRDM16, the role and prevalence of PRDM16 expression should be addressed further in a larger cohort of patient. Although the limited case series, amplification seems to be associated with distinct cytogenetic and clinical features and could reflect a different pathway or role of PRDM16 in the pathogenesis of these AML patients. *Supported by University of Bologna RFO, BolognAil and Coop Reno.*

P781

CHARACTERIZATION OF THE RARE TRANSLOCATION T(3;10)(Q26;Q21) IN AN ACUTE MYELOID LEUKEMIA PATIENT

T Jancuskova[1,*], R Plachy[1], J Stika[1], D W Hardekopf[1], L Zejskova[1], I Praulich[2], KA Kreuzer[2], N Kosyakova[3], T Liehr[3], S Pekova[1]
[1]Laboratory for Molecular Diagnostics, synlab genetics s.r.o., Prague, Czech Republic, [2]Department I of Internal Medicine, University at Cologne, Cologne, [3]Institute of Human Genetics, Jena University Hospital, Jena, Germany

Background: Recently, we introduced a flexible strategy for mapping cytogenetically identified unique abnormalities down to the single nucleotide level. This strategy has enabled us to design clone-specific assays for sensitive minimal residual disease (MRD) monitoring in acute leukemia patients (Jancuskova *et al*. Leuk Res. 2013) as well as to elucidate regions/genes involved in congenital chromosomal aberrations (unpublished data). Here we characterize the rare chromosomal translocation t(3;10)(q26;q21), involving the *MECOM* gene (MDS and EVI1 complex locus located in band 3q26), identified in an acute myeloid leukemia (AML) patient.
Aims: Our aim was to use our strategy to identify the fusion partner on chromosome 10q21 and to characterize the precise nucleotide sequence of the chromosomal breakpoint.
Methods: The chromosomal translocation was revealed by standard cytogenetic techniques (G-banding, mFISH), and involvement of the *MECOM* gene was confirmed by FISH with the use of a commercially available probe set. The derivative chromosome 10 was isolated using fine-needle microdissection followed by whole genome amplification (WGA). Ten dissected fragments were sequenced on the GS-Junior next-generation sequencing platform. The reads obtained were aligned to reference sequences of chromosomes 3 and 10 using in-house developed software. The last mapped reads from both chromosomes were used as docking sites for primers for long-range PCR to amplify the putative breakpoint. The long-range PCR products were directly sequenced using Sanger sequencing to reveal the precise nucleotide sequence of the breakpoint.
Results: Using a combination of cytogenetic and molecular approaches, we mapped the t(3;10)(q26;q21) to the single nucleotide level, revealing a fusion of the *MECOM* gene (3q26.2) and *C10orf107* (10q21.2).
Summary and Conclusion: In AML patients, the *MECOM* gene can be rearranged with a variety of other partner chromosomes and partner genes. According to the Mitelman database, only one case with a t(3;10)(q26;q21) translocation has been reported, but neither the fusion partner of the *MECOM* gene nor DNA sequence were identified. The approach described here opens up new possibilities in characterizing acquired as well as congenital chromosomal aberrations. In addition, DNA sequences of chromosomal breakpoints may be a useful tool for unique molecular MRD target identification in acute leukemia patients.

GSX2 DEREGULATION IN CD7+ ACUTE MYELOID LEUKEMIA BEARING 4Q12 TRANSLOCATIONS WITHOUT FUSION GENES

D Di Giacomo[1,*], R La Starza[1], V Pierini[1], G Barba[1], F Forghieri[2], E Borlenghi[3], C Mecucci[1]

[1]Haematology and Bone Marrow Transplantation Unit, University of Perugia, Perugia, [2]Department of Surgical and Medical Sciences, University of Modena-Reggio Emilia, Modena, [3]Department of Haematology, Ospedali Civili, Brescia, Italy

Background: CD7 positivity (CD7+) in approximately 30% of acute myeloid leukemias (AML) is assumed to arise from an early precursor maintaining both myeloid and T-lymphoid potentialities[1]. Interestingly, several chromosome translocations in AML were associated with CD7 expression[2,3,4]. One is the rare t(4;12)(q12;p13), with an estimated incidence of under 1% of adult AML, which is characterized by immature phenotype and poor clinical outcome[2]. Molecular characterization of t(4;12)(q12;p13)[3] showed that 12p13 breakpoints fell within *ETV6* gene, while 4q12 breakpoints involved either *CHIC2* or no genes. Whatever genomic site recombined with 4q12, the pathogenetic effect appeared to be linked to ectopic *GSX2* gene expression[3]. This homeobox gene is normally expressed only in neural stem cells as a key regulator of neurogenesis[5].

Aims: To investigate molecular features of translocations with 4q12 breakpoint in CD7+ acute myeloid leukemias.

Methods: FISH and expression studies were performed on bone marrow cells from two patients with AML-M0 and a 4q12 chromosomal breakpoint. Both had small pseudo-lymphoid blasts[6] with agranular basophilic cytoplasm and CD7 expression. Karyotypes were: 37-46, XX, del(3) (p?), t(4;12) (q12;p13), del (5) (q13q31), -15, -16, del (17) (q21q22), del (22) (q?), +mar1, +mar2 [cp9]/46, XX in patient 1 and 46, XY, t(4;17) (q12;q22)[12]/46, XY[8] in patient 2. The 4q12 region was investigated with LSI 4q12 Tricolor Rearrangement Probe (Vysis, Abbott Molecular) and with homebrew BAC and fosmids (Figure 1). A break apart FISH assay (RP11-434C1 for the 5' and RP11-418C2+RP11-297N18 for the 3') investigated *ETV6* at 12p13 in patient 1; fosmids used for 17q22 in patient 2 are listed in Figure 1. qRT-PCR was performed using Light Cycler 480 (Roche) and TaqMan assay probe (Applied Biosystems) Hs00370195_m1for *GSX2* gene. *ABL1*(Hs00245445_m1) was the endogenous reference control. RNA from GL15 cell line was our positive control for *GSX2* expression (http://www.ncbi.nlm.nih.gov/UniGene/). In silico analysis was performed using ucsc database (http://genome.ucsc.edu/).

Results: Breakpoints at 4q12 fell about 15 kb centromeric to *GSX2* in patient 1, and 50kb telomeric to *GSX2* in patient 2. Translocation partners were, respectively, *ETV6* (12p13) and *MSI2* (17q22). *GSX2* was significantly over-expressed in both cases compared with healthy donors and a group of CD7+ AML without 4q12 involvement.

Summary and Conclusion: *GSX2* de-regulation derived from two different recombinations involving 4q12 and *ETV6* or *MSI2* respectively. A t(4;17)(q12;q22) with a *MSI2* rearrangement has never been reported so far, although in myeloid malignancies with a t(3;17) translocation over-expressed *EVI1* rearranged with MSI2[7]. Interestingly, haematological features of all the available cases suggest that *GSX2* ectopic expression delineates a genetic subgroup among CD7+ AML. Although the fine mechanisms of *GSX2* de-regulation remain to be understood, in our cases we hypothesize that they are related to inactivation of silencers located close to *GSX2,* at 5' in patient 1 and at 3' in patient 2.

TELOMERE LENGTH IS SIGNIFICANTLY SHORTENED IN AML PATIENTS IN CYTOGENETIC REMISSION: POSSIBLE IMPLICATIONS ON THE ORIGIN OF AML

MS Ventura Ferreira[1,*], M Crysandt[1], P Ziegler[1], J Kaufmann[1], S Hummel[1], S Wilop[1], E Jost[1], T H Brümmendorf[1], F Beier[1]

[1]Department of Hematology, Oncology and Stem Cell Transplantation, RWTH Aachen University, Aachen, Germany

Background: Telomere length (TL) reflects the replicative history of cells and represents an established marker for tissue aging. Critical short telomeres have been found to play an important role in the development of chromosomal instability and malignant transformation. Acute myeloid leukemia (AML) is a malignant, genetically heterogeneous disease primarily occurring in later adulthood. Despite of tremendous progress, the origin of AML and especially the relationship to aging is not well understood.

Aims: The question whether AML originates from prematurely aged hematopoietic stem cells (HSC) is still unclear. In the present study, we address this issue by sequentially analyzing TL in AML patients at diagnosis, in remission and during refractory disease or relapse.

Methods: TL of bone marrow (BM, n=88) and peripheral blood (PB, n=9) of 45 newly diagnosed AML patients was analyzed using monochrome multiplex quantitative-PCR. PB leukocytes of 87 healthy controls were used for age-adaption of TL. Mean age of the analyzed AML patients was 50.4 years (range 21-75). Follow-up included the following timepoints: at diagnosis (n=20), after two cycles of induction chemotherapy (IC, n=42), after three additional cycles of consolidation chemotherapy (CC, n=30) and one year after diagnosis (n=5).

Results: Newly diagnosed AML patients showed a significantly shortened age-adapted TL (mean±SE: -0.65±0.2 T/S ratio, p=0.001). After induction chemotherapy and compared to TL at diagnosis, TL increased in patients with complete remission (CR, -0.33±0.1 T/S ratio, n=34), but still remained moderately shortened compared to age-matched controls (p=0.001). In comparison, patients with persistent AML showed no change in TL (-0.61±0.2

T/S ratio, n=8). TL of patients in CR remained stable following three additional cycles of consolidation chemotherapy (-0.23±0.1 T/S ratio, n=26, p=0.03) as well as after one year (-0.25±0.1 T/S ratio, n=5, p=0.28). Patients with relapse after consolidation chemotherapy remained substantially shortened (-1.0±0.2 T/S ratio, n=4, p=0.04). To exclude treatment related effects as a predominant reason for TL shortening, we longitudinally followed selected individual patients. We found no evidence for accelerated TL shortening in CR after induction (-0.28±0.1 T/S ratio, n=24), after consolidation chemotherapy (-0.18±0.1 T/S ratio, n=24) and at one year follow-up (-0.25±0.1 T/S ratio, n=5) supporting the notion that chemotherapy does not influence TL during CR.
Summary and Conclusion: In this study we show that TL of AML at diagnosis is substantially short and increases - reaching cytogenetic remission - mostly due to a shift from leukemic cells (with shortened TL) to non-clonal cells. However, age-adapted TL of patients in cytogenetic remission is still significantly short in first CR and remains stably shortened after further treatment up until one year of follow-up. In summary, our data provides first evidence that AML possibly originates from HSC with prematurely shortened TL. The degree of TL shortening found in non-clonal cells during first CR can be translated into approx. 22.6 years of additional aging.

P784

COMPLEX CHROMOSOMAL REARRANGEMENTS LEADING TO EVI1 OVEREXPRESSION ARE RECURRENT MECHANISMS IN CASES WITH VARIOUS 3Q ABNORMALITIES

C Baldazzi[1,*], E Ottaviani[1], S Luatti[1], G Marzocchi[1], G Ameli[1], C Papayannidis[1], C Gamberini[1], E Zuffa[1], M Cavo[1], G Martinelli[1], N Testoni[1]
[1]Institute of Hematology and Medical Oncology "L. e A. Seràgnoli", S.Orsola-Malpighi Hospital, Bologna, Italy

Background: Chromosomal rearrangements involving 3q26 region are a recurrent finding in myeloid malignancies. These abnormalities lead to up-regulation of EVI1 gene that has been associated with a very poor prognosis. EVI1 is also overexpressed in different subgroups of AML without cytogenetic abnormalities of 3q26, such as AML with -7/7q- abnormalities, which are also the most frequent additional abnormalities to EVI1 rearrangements. In some cases, FISH analysis revealed cryptic EVI1 rearrangements.
Aims: To identify EVI1 rearrangements in cases with myeloid malignancies and 3q or -7/7q- abnormalities.
Methods: The cases were selected according to the presence of 3q abnormalities or -7/7q- by conventional cytogenetics (CC) and were analysed by FISH using EVI1 breakapart probes (Cytocell, UK), and by relative RQ-PCR.
Results: We analysed 97 AML, 28 SMD and 9 MPD cases with 3q (n=75) or -7/7q- (n=60) abnormalities. Among cases with 3q abnormalities, 24 showed inv(3)/t(3;3), 13 balanced 3q26 translocations, 11 balanced 3q21 translocations and 27 various 3q abnormalities involving different loci from 3q26. EVI1 rearrangements were detected in 32/37 (86.5%) cases with 3q26 abnormalities, whereas 5/37 (13.5%) had 3q26 abnormalities without EVI1 involvement suggesting the presence of other genes implicated in leukemogenesis. Unexpectedly, 4/11 (36.4%) cases with balanced t(3q21) displayed EVI1 rearrangements. To better characterize these latter cases, metaphase FISH analyses was performed and revealed that EVI1 rearrangements were the consequence of complex mechanisms involving multiple breakpoints on 3q arm that masked 3q26 region involvement. Multiple breakpoints were also identified in a t(3;8)(q26;q22) by interphase FISH suggesting that this mechanism can occur in apparent classical 3q26 translocation, too. EVI1 rearrangement was also detected in 2/27 (7.4%) cases with various 3q abnormalities: metaphase FISH revealed a t(3;6)(q26;q25) and a t(1;3;13)(p34;q26;q14) that were cryptic because of suboptimal quality of metaphases. All cases with EVI1 rearrangements detected by FISH showed overexpression by RQ-PCR compared to 10 normal bone marrow samples. Among cases with 7/7q- abnormalities, only one case demonstrated EVI1 involvement by FISH. A further examination of the karyotype allowed the identification of a sub-clone with 3q abnormality harbouring EVI1 gene amplification (>50 copies) not previously identified. Gene amplification is a mechanism leading to overexpression that has been rarely described for EVI1. Other 8 cases showed elevated EVI1 expression without EVI1 rearrangements. Thirty-nine cases showed EVI1 rearrangement. In 12 (30.8%) cases it was the sole cytogenetic abnormality; -7/7q- was found in 25 cases (64.1%); del(5q) was seen in 7 cases (17.9%) and complex karyotype in 10 cases (25.6%). The majority of patients were diagnosed as *de novo* AML or MDS (61.5%), median age was 51 years; 24 were male and 15 female. Only 5 of 24 treated patients (20.8%) achieved a complete cytogenetic remission after more than one cycle of chemotherapy. The median survival of EVI1 rearranged cases was 10.2 months, with an overall survival of 33% at 1 year, and 5% at 3 and 5 years.
Summary and Conclusion: Although 3q26 abnormalities are strictly associated with EVI1 rearrangements, FISH and RQ-PCR identified cases with 3q26 abnormalities involving EVI1 and cases with EVI1 rearrangements without involvement of 3q26 by CC. These events could be the consequence of a low quality of metaphases, but they were often the result of complex chromosomal rearrangements that occurred frequently in t(3q21) cases. Because of poor prognosis of EVI1 overexpression, a screening for EVI1 rearrangements should be performed in myeloid malignancies with chromosome 3q abnormalities. Furthermore, FISH should be performed in cases with 7q abnormalities when the quality of metaphases is suboptimal. *Supported by University of Bologna RFO, BolognAIL and Coop Reno.*

DEVELOPMENT OF MOLECULAR BEACON BASED PCR ASSAY FOR EASY DETECTION AND QUANTIFICATION OF CHIMERIC TRANSCRIPTS OF AML-ETO [T(8;21)] IN ACUTE MYELOID LEUKEMIA PATIENTS

R Arora[1,*], S Jetly[1], S Bakhshi[2], S saluja[3], D Saluja[1]
[1]Biomedical Sciences, Dr. B. R. Ambedkar Centre for Biomedical Research, University of Delhi, [2]Medical Oncology, All India Instiiute of Medical sciences, [3]Hematology, Vardhaman Mahavir Medical college and Safdarjung hospital, New Delhi, India

Background: *Acute myeloid leukemia* (AML) is a malignant disease of blood arising as a result of cancer transformation and disorders in differentiation of hematopoietic cells on the level of myeloid cell precursor cells. Tumor cells of such patients often contain mutant forms of certain oncogenes, and therefore mutations in these genes are believed to be responsible for malignization of the hematopoietic system. In 20% of patients with AML, leukemic cells carry a translocation between chromosomes 21 and 8 resulting in formation of the chimeric oncogene *AML1-ETO,* producing a fused protein AML1-ETO, which has the activity of a transcription factor. Molecular rearrangements are constant and occur in exon 5 of the *AML1* gene and in exon 2 of the *ETO* gene. Protein AML1-ETO contains the N-terminal region of AML1 protein, which includes the DNA and Core Binding Factor β (CBFβ)-binding Runt Homology Domain (RHD), whereas the C-terminal part belongs to ETO protein including its four Nervy Homology Region (NHR) domains. AML1 activates transcription and thus promots differentiation of granulocytes due to transactivation of series-specific target genes while formation of the fused protein, AML1-ETO, results in the replacement of the AML1 activation domain by the ETO repressor domain. The fused protein AML1-ETO binds with DNA *via* the RHD domain of the AML1 moiety and effectively recruits corepressor complex *via* the NHR domain of ETO moiety, and thus inhibits the expression of *AML1* target genes instead of activating them. Patients having AML-ETO translocation have a relatively favourable prognosis and thus its detection helps the clinician to take better therapeutic decisions. Cytogenetic analysis by G-banding (karyotyping) is required at the time of diagnosis of all AML patients; however this method is often time-consuming as it requires culturing of leukemic cells and their capture at metaphase. FISH analysis for AML1-ETO fusion can also be performed using locus-specific probes. Dual color probes against AML1 and ETO resulting in fusion-signals are commercially available and commonly used but are not cost effective. qPCR is a quick and sensitive method that is recommended for detection of the fusion transcript but is highly expensive and requires infrastructure as well as expertise. Most of these methods are therefore not performed routinely in developing countries and therefore, it becomes imperative to develop a cost effective and highly sensitive method for the detection of AML-ETO translocation [t(8;21)] in Acute Myeloid Leukemia patients in developing countries.
Aims: To develop a PCR based easy to visualize quantitative assay for detection of AML-ETO translocation [t(8;21)] in Acute Myeloid Leukemia patients.
Methods: Peripheral blood samples were collected from untreated AML patients from Safdarjung and AIIMS hospital. Cost effective RNA isolation was standardized from these blood samples by comparing expression of four housekeeping genes in leukocytes. In-house primers and molecular beacons were designed for the detection of AML-ETO transcript and PCR assay was standardized for quantification of transcript using beacon strategy. The assay was evaluated against qPCR using published primers.
Results: Using the technique of molecular beacons, we successfully developed a cost effective and highly specific and sensitive reverse transcriptase-PCR assay for AML-ETO detection. Our assay could detect as low as 100fg of AML-ETO chimeric DNA and shows a linear increase in fluorescence with increase in template concentration (Figure 1). The specificity of our assay was confirmed using competition experiments. The clinical evaluation of the assay has been carried out using 100 leukemic samples.
Summary and Conclusion: We envisage that the current method is as sensitive and specific as commercially available method. Since the method is highly cost effective, and does not require expensive infrastructure and expertise, it can be used in resource poor settings.

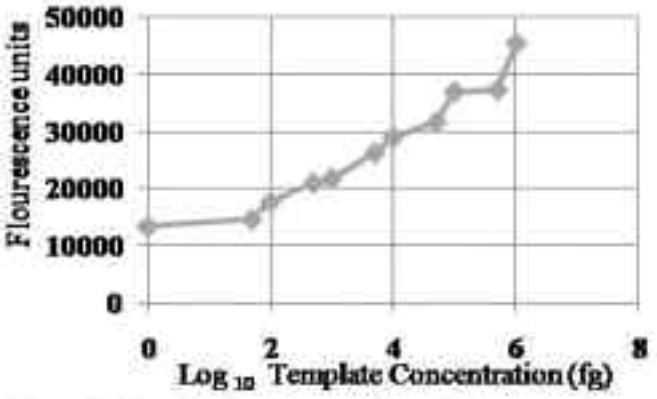

Figure 1. Graphical representation of fluorescent intensity of product obtained by carring in-house standardized AML-ETO specific PCR with different concentrations of positive close (TA vector containing AML-ETO insert), with 50nM beacon added to each, measured on Elisa reader (at 550,590nm).

P786

ANALYSIS OF NPM1 SPLICE VARIANTS REVEALS DIFFERENTIAL EXPRESSION PATTERNS OF PROGNOSTIC VALUE IN ACUTE MYELOID LEUKEMIA

M Zajac[1,*], A Dolnik[2], M Schunn[2], S Correa[2, 3, 4], E Glodkowska-Mrowka[5], R Chakkarappan Sundaram[2], O Jankowska[6], R Schlenk[2], K Dohner[2], L Bullinger[2], K Giannopoulos[1,6]

[1]Experimental Hematooncology Department, Medical University of Lublin, Lublin, Poland, [2]Department of Internal Medicine III, University of Ulm, Ulm, Germany, [3]Institute of Biophysics Carlos Chagas Filho, Federal University of Rio de Janeiro, [4]Stem-cell Laboratory, Bone Marrow Transplantation Unit, National Cancer Institute, Rio de Janeiro, Brazil, [5]Department of Immunology, Medical University of Warsaw, Warsaw, [6]Department of Hematooncology and Bone Marrow Transplantation Unit, Medical University of Lublin, Lublin, Poland

Background: The process of mRNA splicing has been reported to play an important role in human disease development and many cancer-related genes are regulated by alternative splicing. In addition, first analyses of alternatively splicing in bone marrow of AML samples identified novel splice variants specific for AML patients in comparison to normal cells.
Aims: Since splicing variants play an important role in cellular functioning the current study focuses on the characterization of *NPM1* splicing variants expression as well as its impact on the biology and prognosis of AML patients.
Methods: For the first cohort of patients (104 samples) qRT-PCR was performed and total expression (Rt) as well as levels of the three splice variants of *NPM1* were evaluated: R1 (exons 1- 9 and 11-12), R2 (exons 1- 10), R3 (exons 1-7, 9 and 11-12). We found prognostic significance of the expression level of R2, therefore we decided to validate it in independent cohort of AML patients. We consolidated 104 patients previously analyzed with 97 patients from the new cohort of total 201 cases and preformed the final analysis for R2. The existence of R2 at the protein level was evaluated with the use of Western Blot technique. To investigate whether R2 might disrupt localization of the NPM1 wild type protein, immunohistochemistry analysis for NPM1 in 23 AML cases was performed.
Results: Total expression as well as expression of R1 and R3 were significantly higher in 104 AML patients compared to healthy volunteers (HVs) with a median expression of 8.59 *vs* 0.93 (p=0.001), 1.73 *vs* 0.55 (p=0.014), and 2.54 *vs* 0.11 (p<0.001), respectively. We evaluated the existence of R2 at the protein level in AML patients samples and AML cell lines. We found that the expression of R2 was significantly higher in all AML patients compared to HVs with a median expression of 1.64 *vs* 0.33 (p=0.009). High R2 expression was associated with longer OS when CN-AML patients were analyzed (880 *vs* 438 days, p=0.028). Longer OS was observed in CN-AML patients with high R2 expression without concomitant *FLT3*-ITD mutations compared to the rest of groups. Most importantly, in CN-AML cases survival differences seen between the established ELN groups according to a *NPM1*/*FLT3*-ITD stratification were less impressive (p=0.03) than between groups stratified according to R2 expression/*FLT3*-ITD mutational status (p=0.003). Multivariate analysis revealed R2 expression (HR, 0.470; 95%>CI, 0.098 to 0.842; p=0.042), *FLT3*-ITD alteration (HR, 3.325; 95%>CI, 3.000 to 3.650; p<0.001), and age (HR, 1.035; 95%>CI, 1.023 to 1.047, p=0.004), but not WBC or *NPM1*mut as significant variables for OS. Finally, in cases with high R2 expression we were able to determine a cytoplasmic localization of NPM1 even in the absence of *NPM1* mutation. Therefore, we provide further evidence that the cytoplasmic localization of NPM1 might depend not only on its mutational status, but might also be influenced by the distribution of its splice variants.

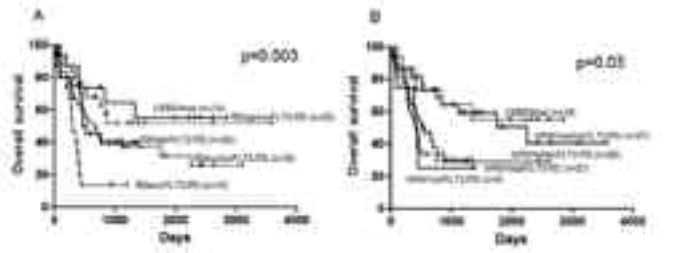

Figure 1. (A) OS in five groups of CN-AML patients: R2high/noFLT3-ITD, R2low/noFLT3-ITD, R2low/FLT3-ITD, R2high/FLT3-ITD and CEBPAmut. (B) OS in five groups of CN-AML patients: NPM1mut/noFLT3-ITD, NPM1wt/noFLT3-ITD, NPM1wt/FLT3-ITD, NPM1mut/FLT3-ITD and CEBPA-mut.

Summary and Conclusion: In our study we found that the expression level of R2 was elevated compared to HVs suggesting that not only *NPM1* mutation but also its splice variant expression might play some role in the process of the tumorigenesis. As the R2 represents a truncated form of *NPM1* gene, this isoform mostly localizes in the nucleoplasm, and thus might also have a biological impact in the malignant cells. In our cohort of cases survival differences seen between the established ELN groups according to a *NPM1*/*FLT3*-ITD stratification were less impressive than between groups stratified according to R2 expression/*FLT3*-ITD mutational status. In summary, the expression of R2 might be of biological importance for CN-AML patients. Moreover, R2 splice variant provides prognostic value for CN-AML patients and it might give information in addition to the *NPM1* mutational status.

P787

HIGH LEVELS OF HOTAIRM1, A LONG INTERGENIC NON-CODING RNA RELATED TO HOX GENES, IS ASSOCIATED WITH POOR PROGNOSIS AND A DISTINCTIVE MICRORNA SIGNATURE IN INTERMEDIATE-RISK ACUTE MYELOID LEUKEMIA

M Diaz Beya[1,*], A Navarro[2], M Pratcorona[1], M Nomdedeu[1], R M Risueño[3], M Monzo[2], J Esteve[1]

[1]Hematology Department,, Hospital Clínic, IDIBAPS, Barcelona, Spain, [2]Molecular Oncology and Embryology Laboratory, Human Anatomy Unit,, School of Medicine, University of Barcelona, [3]1Josep Carreras Leukaemia Research Institute, Barcelona, Spain

Background: During the last years non-coding RNAs (ncRNAs) have emerged as key regulators of diverse cellular processes. They are classified according to their size in short (*i.e.* microRNAs) and long (*i.e.* lincRNAs) ncRNAs. LincRNAs are long ncRNAs located in intergenic regions with multiple regulatory functions including gene expression regulation. Interestingly, an active crosstalk between microRNAs and lincRNAs has been shown. LincRNAs are known to be deregulated in some cancers but their potential importance in acute myeloid leukemia (AML) is so far unknown. HOX genes play an important role in hematopoiesis and are deregulated in AML. Some lincRNAs, including *HOTAIRM1, HOTTIP and HOTAIR,* are located in the HOX genomic regions, but their expression level and prognosis role have not been studied in patients with AML. Since the intermediate risk cytogenetic (IR)-AML is a group with highly diverse prognosis; we analyzed the prognosis value of expression of these lincRNAs in this subgroup of patients.
Aims: To investigate whether the expression of HOX-related lincRNAs is associated with molecular characteristics, miRNA expression, and clinical outcome in IR-AML.
Methods: We have analyzed bone marrow samples from 77 IR-AML patients (median age, 52; 51% males) who received intensive chemotherapy following CETLAM trials in a single institution. Forty-two patients harbored NPM1 mutation (*NPM1*mut, 54%), 35 *FLT3*-ITD (45%) and 7 patients, a biallelic *CEBPA* mutation (9%). The expression of HOTAIRM1 (Hs03296533_g1), *HOTAIR* (Hs03296631_m1) and *HOTTIP* (Hs00955374_s1) was analyzed using TaqMan® Gene Expression Assay (Applied Biosystems). Statistical analysis was performed with BRB Array Tools, SPSS v15.0.1. MaxStat program from R software was used to determine the optimal cutoff point.
Results: *HOTTIP* and *HOTAIRM1*, but not *HOTAIR*, were expressed in most of our AML samples. *HOTAIRM1* expression was associated with *NPM1*mut (p=0.005). In the entire cohort, high *HOTAIRM1* expression was associated with shorter 5-year survival (OS) (p=0.003, 14±18% *vs*.44±14%), shorter 5-year disease-free survival (p=0.002, 52±12% *vs*.91±26%), and a higher risk of relapse at 5 year (p=0.012, 85±25% *vs*.35±14%). This effect was maintained both within the subgroup of *NPM1* mutated patients (OS, p=0.013, 20% ±24% *vs*. 52±18%) and within subgroup lacking favorable molecular features (*i.e.*, absence of *NPM1* mutation and *CEBPA* biallelic mutation and/or *FLT3*-ITD) (OS, p=0.017, 10±18% *vs*.40±15%). In the multivariate analysis including age, WBC, *NPM1*mut, *FLT3*-ITD as covariates, *HOTAIRM1* expression level showed independent prognostic significance (p=0.003; HR=3.052, 95% CI: 1.5-6.3)

both in the entire cohort and the unfavorable molecular subgroup (p=0.017; HR=2.8, 95% CI: 1.2-6.5). Supervised analysis by means of t-test based on multiplex permutations revealed a distinctive 33-miRNA signature which correlated with *HOTAIRM1* expression. Importantly, a positive correlation was observed between *HOTAIRM1* and miR-196b (p<0.001), a miRNA located in the same HOX genomic region.

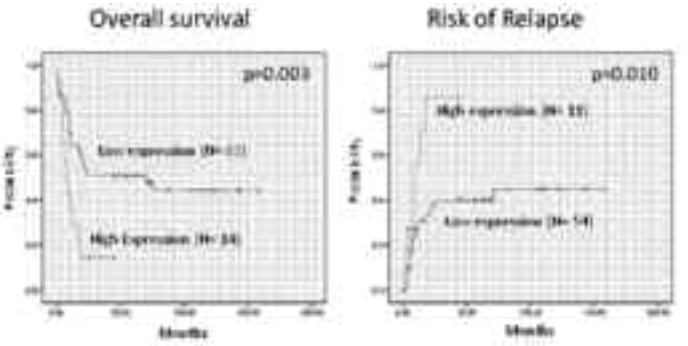

Figure 1. Prognostic value of HOTAIRM1 levels.

Summary and Conclusion: In this series of IR-AML patients, *HOTTIP* and *HOTAIRM1* were expressed in most patients. The expression level of the HOX-related lincRNA *HOTAIRM1* showed independent prognostic value. Interestingly, *HOTAIRM1* expression levels showed a strong positive correlation with its neighboring gene miR-196b. Nonetheless, confirmation of the prognostic impact of this lincRNA and search of potential underlying mechanisms accounting for this prognostic effect is warranted.

CD123 (IL-3Rα) IS CONSISTENTLY EXPRESSED ON ACUTE MYELOID LEUKEMIA (AML) CARRYING NUCLEOPHOSMIN (NPM1) GENE MUTATION

L Brunetti[1,*], I Gionfriddo[1], R Roberta[1], F Mezzasoma[1], F Milano[1], C Vetro[2], F Di Raimondo[2], B Falini[1], MP Martelli[1]
[1]Hematology, University of Perugia, Perugia, [2]Hematology, University of Catania, Catania, Italy

Background: Antibody-based immunotherapy is a promising strategy to target and eliminate chemoresistant leukemic cells. Bispecific T cell engaging antibodies (BiTEs) are a novel class of antibodies which recruit *in vivo* the patient's own cytotoxic T cells and retarget them directly at specific surface antigens on leukemic cells. The interleukin-3 receptor a chain (CD123) has been identified as a potential immunotherapeutic target because it is overexpressed in AML compared to normal hematopoietic stem cells. Notably, CD123 is selectively overexpressed not only on AML blasts, but also on CD34+CD38- AML leukemic stem cells (LSCs) that are considered to be major players in chemotherapy drug resistance and leukemia relapse. CD123 as immunotherapeutic target in AML has been validated in preclinical studies with either CD123xCD3 bispecific antibodies or CD123 CAR-engineered T cells and clinical trials with these agents are expected in the next future. *Nucleophosmin (NPM1)* mutation is the most common genetic lesion in AML accounting for about 30% of cases. Immunohistochemical studies, have previously shown that in *NPM1*-mutated as well as in FLT3-ITD AMLs, CD123 is more frequently expressed. However, a comprehensive and quantitative evaluation of CD123 expression in AML has not been reported.
Aims: Here, we quantified CD123 expression by flow cytometry correlating expression intensity with cytogenetic and molecular disease characteristics in order to identify patient cohorts suitable for CD123-targeted therapy.
Methods: CD123 expression levels were evaluated by flow cytometry in fresh samples from 130 consecutive adult AML patients at diagnosis, using an antibody combination including CD34-FITC/CD123-PE/CD45-PerCP-Cy5.5/CD38-APC, acquiring at least 50000 events and reporting both percentage of CD123 positive cells (PPC) and CD123 median fluorescence intensity (MedFI) in both bulk and CD34+CD38- cell population. Blasts were gated using both FSC/SSC and CD45/SSC dot-plots. For all patients *NPM1* gene mutation status was assessed by immunohistochemistry, Western Blot and/or molecular analysis. FLT3 mutational status was assessed by RT-PCR. 60/130 (46%) carried *NPM1* gene mutation; 27/93 (25%) were *FLT3*-ITD mutated.
Results: According to karyotype (n=94), CD123 was more expressed in AML with normal karyotype than in AML with one or more karyotype abnormalities (mean values of MedFI 36.2 *vs* 19.5, p<0.01, Mann-Whitney). According to *NPM1* gene status (n=130), *NPM1*-mutated (NPMmut) AML showed brighter CD123 expression as compared to *NPM1* wild type (NPMwt) (mean values of MedFI 43.3 *vs* 22.1, p<0.01, Mann-Whitney). According to *FLT3* gene status (n=93), *FLT3*-ITD AML were associated with higher CD123 expression when compared to the *FLT3* wild-type (FLT3wt) counterparts (mean values of MedFI 49 *vs* 25.1, p<0.01, Mann-Whitney). As shown in Fig.1 the highest expression was reported in *NPM*mut/*FLT3*-ITD genotype AML in both bulk and CD34+CD38- leukemic cell populations (mean value of MedFI 55.1 and 93.6, respectively).

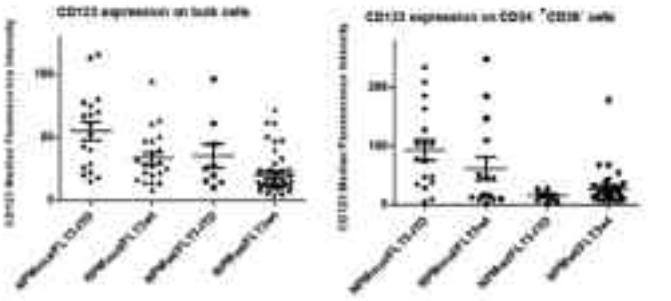

Figure 1.

Summary and Conclusion: Our results indicate that *NPM1* and *FLT3*-ITD mutations correlate with higher CD123 expression levels in AML. Although CD123 was globally positive in most cases of AML in our series, it was markedly expressed in AML carrying mutations of both *NPM1* and *FLT3* either on leukemic bulk cells as well as on CD34+CD38- putative LSCs, making this AML subtype a suitable candidate for CD123-targeted immunotherapy.

THE PROGNOSTIC VALUE OF LEUKEMIC STEM CELLS IN PEDIATRIC AML

B De Caluwé[1,*], R Wouters[2], V De Haas[3], J G te Marvelde[4], B De Moerloose[5], E S de Bont[6], B Denys[1], A De Jong[3], G Kaspers[7], J Philippé[1], J Cloos[2], V H van der Velden[4]
[1]Department of Clinical Biology, Microbiology and Immunology, University of Ghent, Ghent, Belgium, [2]Pediatrics, VU University Medical Center, Amsterdam, [3]DCOG, The Hague, [4]Immunology, Erasmus Medical Center, Rotterdam, Netherlands, [5]Pediatrics, University of Ghent, Ghent, Belgium, [6]Pediatrics, UMCG, Groningen, [7]Pediatric Oncology/Hematology and Hematology, VU University Medical Center, Amsterdam, Netherlands

Background: Pediatric acute myeloid leukemia (AML) patients exhibit a high risk of relapse (30-40%) and therapy related mortality (5-15%), resulting in a 5 year overall survival rate of only 65-70%. Because of the rarity of AML in children, little is known about the pathogenesis and few adequate prognostic parameters have been identified. The cancer stem cell model proposes that AML cells are hierarchically organized into compartments that contain leukemic stem cells (LSC) which have unlimited self-renewal capacity and are capable of propagating leukemia and relapse. Although in adult AML it has convincingly been demonstrated that the number of LSC (CD34+CD38-) at diagnosis is an important prognostic factor[1], this has not thoroughly been investigated in pediatric AML.
Aims: Despite complete remission rates of about 70%, the majority of pediatric patients with AML relapses within 3-5 years from diagnosis. Therefore, there is great need of identifying more sensitive prognostic factors that can predict relapse (originating from LSC outgrowth). We explored whether the number of LSC at diagnosis, detected with flow cytometry, is correlated with the risk of relapse and time to relapse.
Methods: Within the framework of the DB-AML01 treatment protocol (a collaboration between BSPHO and DCOG), serial samples from diagnosis till end of treatment were collected. Sixty-seven Dutch and 42 Belgium diagnostic samples were available for flow cytometric analysis. Our initial analyses included the Dutch samples. Stem cells were analyzed using the labeling CD45-CD34-CD117-CD38-CD2+56-CD123-CD7-HLA DR. LSC were defined as CD34+/CD38- cells (fixed cut-off values 10^3 and $3x10^3$, respectively) and expressed as a percentage of the total amount of CD34+ cells. For all analyses the Infinicyt software was used. Statistics were performed using SPSS (version 22.0).
Results: Mann Whitney U-Test showed that the percentage of LSC was significantly associated with the risk of relapse (p=0,034) and the risk of adverse event (relapse or death) (p=0,023). ROC curve analysis showed that at a cut-off of 23,5%, relapse can be predicted with a sensitivity of 69% and a specificity of 75%. Kaplan-Meier survival analysis showed that this percentage was significantly associated with relapse free survival (p=0,006). Neither the percentage of blasts, the percentage of CD34+ cells, the number of white blood cells (WBC) or the presence of genetic abnormalities (inv(16), FLT3, NPM1 and t(8;21) at diagnosis proved to be significantly associated with the risk of relapse or relapse free survival. ROC curve analysis showed that at a cut-off of 17,1% LSC, the occurrence of an adverse event can be predicted with a sensitivity of 76% and a specificity of 72%. Kaplan-Meier survival analysis showed that this percentage was significantly associated with event free survival

(p=0,002). Kaplan-Meier survival analysis also showed that the amount of WBC was significantly associated with event free survival (p=0,002).

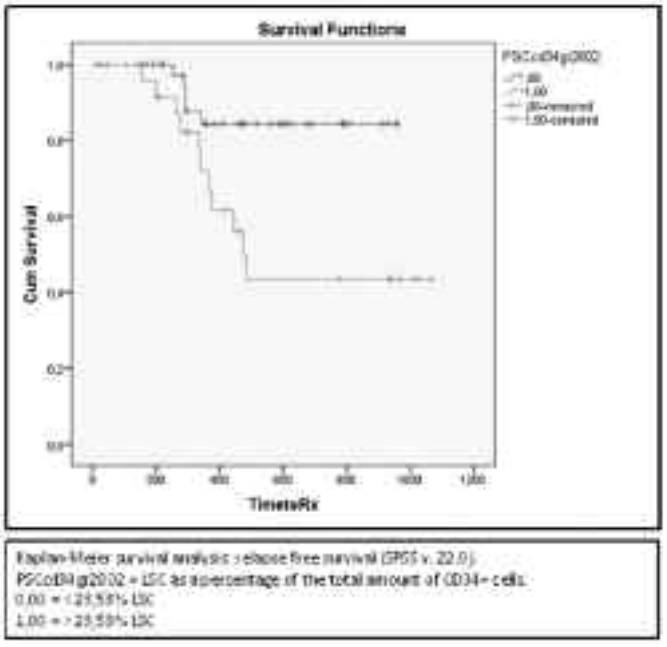

Figure 1.

Summary and Conclusion: The percentage of stem cells, detected at diagnosis with flow cytometry, is a prognostic factor for relapse in pediatric AML patients. Our current studies focus on refinement of the analysis strategy which will be applied to the 42 Belgian patients at diagnosis. In addition, the value of measuring LSC in the MRD setting will be evaluated. Furthermore, these studies will be extended in the recently started NOPHO-DBH AML 2012 trial. Background: *BCL11B*/14q32 belongs to kruppel zinc finger family of transcription factors directly binding a GC-rich consensus sequence in target genes. It interacts with the Nucleosome Remodelling Deacetylase (NuRD) complex and is a subunit of mammalian SWI/SNF, the most frequently mutated chromatin-regulatory complex in human cancer. [1,2] In hematological diseases, *BCL11B* might behave as tumor suppressor gene or oncogene. It is downregulated by mono-allelic deletions or mutations in 10-15% of T-ALL[3,4] and in cases with inv(14)(q11q32)/t(14;14)(q11;q32).[5,6] *O*ver-expression occurred in 4 AML cases.[7]

Aims: To investigate AML with 14q32 reciprocal translocations

Methods: Karyotyping identified t(2;14)(q22;q32) and t(6;14)(q25;q32) respectively in 6 and 2 *FLT3* mutated AML, with CD2 positivity. Other expressed T-antigens were CD7 and/or cyCD3. Fluorescence *in situ* hybridization (FISH), RT-PCR, cloning and sequencing investigated partner gene breakpoints. qRT-PCR (Light Cycler 480, Roche) evaluated *BCL11B* expression. Affymetrix SNPa, (Cytogenetics Whole-Genome 2.7M Array Platform), Exome and RNA sequencing (Hiseq 2000, Illumina) were performed. FISH studied cryptic *BCL11B* rearrangements in 689 cases.

Results: 14q32 breakpoints fell at the *BCL11B* gene 5' end in all cases. 2q22.3 breakpoints involved the Zinc finger E-box Binding homeobox 2 (*ZEB2*) gene. *ZEB2* exon 2 was fused in-frame to *BCL11B* exon 2. Western blotting detected 2 *ZEB2-BCL11B* splicing isoforms with or without *BCL11B* exon 3. Breakpoints at 6q25 fell in a region where no genes have been mapped. *ZEB2-BCL11B* and *BCL11B* expression was high in t(2;14) and t(6;14) AML, respectively. SNP analysis confirmed all karyotypic changes and detected non-recurrent copy number variations. High Throughput Sequencing did not find any other common fusion or mutation. Genes like DNMT3A, TET2, WT1, EP300 were involved in 6/8 patients. Gene Expression Profiling identified a specific *BCL11B* translocation signature. Differential expression of 14/39 BCL11B targets indicated common downstream targets in t(2;14) and t(6;14). No cryptic *BCL11B* translocations were found.

Summary and Conclusion: Two recurrent translocations, (2;14)(q22.3;q32) and t(6;14)(q25;q32), deregulated *BCL11B* in a CD2+, FLT3+, AML and have a specific gene expression signature. In the t(2;14) the BCL11B involved in the ZEB2/BCL11B fusion was overexpressed. Notably the ZEB2-BCL11B protein and BCL11B share a RRKQXXP NuRD interaction motif at the N-terminal[1,8] and the same C-terminal containing BCL11B C2H2-zinc finger DNA binding domain. The mechanism of BCL11B up-regulation in the t(6;14) remains to be determined. A super enhancer mapped at 6q25, however, is an interesting candidate. In our study we showed that as a consequence of these translocations BCL11B and ZEB2-BCL11B may act as similar transcription factors.

PSEUDO-EXHAUSTION OF T CELLS IN RELAPSED AML

F S Lichtenegger[1,2,*], F M Schnorfeil[1,2], K Emmerig[1,2], M Schlueter[1,2], J S Neitz[1,2], R Draenert[3], W Hiddemann[1], M Subklewe[1,2]

[1]Department of Internal Medicine III, Klinikum der Universität München, [2]Clinical Cooperation Group Immunotherapy, Helmholtz Zentrum München, [3]Division of Clinical Infectiology, Department of Internal Medicine IV, Klinikum der Universität München, Munich, Germany

Background: The prognosis of acute myeloid leukemia (AML), particularly when associated with adverse chromosomal or molecular aberrations, is poor due to a high relapse rate after induction chemotherapy. Postremission therapy for elimination of minimal residual disease remains a major challenge. Immunotherapeutic strategies aim at the stimulation of AML-specific immunity, especially of $CD8^+$ T cells. However, the functionality of these cells in AML patients is not well described. T cell exhaustion has been suggested to contribute to immune evasion in various solid and hematological malignancies. Primarily demonstrated in chronic viral infections, exhausted T cells are characterized by an increased expression of several inhibitory molecules, reduced proliferation and an impaired capability of cytokine secretion and cytotoxicity.

Aims: To characterize T cell phenotype and function in AML patients at different stages of disease.

Methods: $CD8^+$ and $CD4^+$ T cells from AML patients at primary diagnosis, with refractory disease, at relapse and at relapse after allogeneic stem cell transplantation (alloSCT) (23, 4, 9 and 7 individuals, respectively) were analyzed by flow cytometry-based assays. Surface expression of CD244, CD160, PD-1, TIM-3 and LAG-3 was determined. T cell proliferation and production of the cytokines IFN-γ, TNF-α and IL-2 were measured in response to different stimuli. Results were compared to healthy controls (HC) (30 individuals), while untreated HIV-infected patients (10 individuals) served as positive controls for an exhausted T cell state.

Results: In HIV-infected patients, we observed a pronounced upregulation of the inhibitory molecules CD244, CD160 and PD-1 on $CD4^+$ and $CD8^+$ T cells as well as globally impaired cytokine production, clearly indicating T cell exhaustion. In contrast, T cells from AML patients at primary diagnosis showed an expression pattern of inhibitory surface molecules that was similar to T cells from age-matched HCs. Interestingly, AML patients with a relapse after alloSCT showed a 3- and 6-fold increased overall expression of PD-1 on $CD8^+$ ($p=0.0084$) and $CD4^+$ ($p<0.0001$) T cells, respectively. This PD-1 expression pattern correlated to an increased proportion of memory T cells, which have an inherently higher expression of PD-1. Both, relapsed patients after conventional chemotherapy and relapsed patients after alloSCT, displayed a shift from the naïve towards the memory T cell compartment, indicating reinforced T cell differentiation. Functionally, no defect in T cell proliferation in any of the AML patient cohorts was detected. Of note, however, we observed a 2-fold decrease ($p=0.0068$) in IFN-γ production by $CD4^+$ T cells exclusively in patients at primary diagnosis.

Summary and Conclusion: We show that T cells of newly diagnosed and relapsed AML patients are fully functional. Moreover, we demonstrate enhanced T cell differentiation in relapsed AML patients. We therefore hypothesize that bulk T cells in AML are in a status of activation, not exhaustion. Thus, immunotherapies that aim at eliciting tumor-specific immune responses, *e.g.* dendritic cell based vaccines, may be particularly suited for postremission therapy.

P792

PROSPECTIVE LONG-TERM MINIMAL RESIDUAL DISEASE MONITORING ON PERIPHERAL BLOOD IN RUNX1-RUNX1T1 ACUTE MYELOID LEUKEMIA: RESULTS OF THE FRENCH CBF-2006 TRIAL

C Willekens[1,*], O Blanchet[2], A Renneville[1], P Cornillet-Lefebvre[3], E Jourdan[4], C Pautas[5], R Guièze[6], N Vey[7], H Dombret[8], N Ifrah[2], C Preudhomme[1], N Boissel[8]
[1]Centre Hospitalier Regional Universitaire, Lille, [2]Centre Hospitalier Universitaire, Angers, [3]Centre Hospitalier Universitaire, Reims, [4]Centre Hospitalier Universitaire, Nimes, [5]Centre Hospitalier Universitaire, Créteil, [6]Centre Hospitalier Universitaire, Clermont-Ferrand, [7]Institut Paoli Calmette, Marseille, [8]Hopital Saint Louis, Paris, France

Background: Core-binding factor acute myeloid leukemias (AML) are associated with a favorable prognosis. However, around one third of patients will present hematological relapse. In AML with translocation t(8;21)(q22;q22), quantification of *RUNX1-RUNX1T1* fusion transcript with real-time quantitative polymerase chain reaction (RQ-PCR) allows to monitor minimal residual disease (MRD) during and after therapy. In the CBF2006 trial, we showed that early MRD response was a major prognostic factor (Jourdan E. et al, Blood 2013). Until now, the prognosis of MRD long-term follow-up has been rarely explored in prospective trials.
Aims: The main objective of the study was to assess the usefulness of prospective MRD monitoring on peripheral blood (PB) by RQ-PCR to predict relapse.
Methods: In the multicenter CBF-2006 study, 96 patients with t(8;21) AML in complete remission after intensive chemotherapy entered a prospective peripheral blood (every 3 months) and bone marrow (every year) MRD monitoring for 2 years. Transcript ratios were normalized to *ABL* as (*RUNX1-RUNX1T1/ABL*) x 100 and complete molecular response (CMR) was defined by a transcript ratio ≤0.001% on peripheral blood. Prognostic impact of CMR and loss of CMR on cumulative incidence of relapse (CIR) and overall survival (OS) were evaluated in a time-dependent manner (Mantel-Byar analyzes).
Results: During the 2-year follow up, 77 patients reached CMR. Median time between complete remission and CMR was 2.5 months [IQ: 1.4 – 4.6] up to 16 months. As expected, CMR achievement was associated with significantly reduced incidence of relapse (3-year CIR: 23% *vs* 51%, P=.001) and better overall survival (3-year OS: 90% *vs* 56%, P=.008). However, time to CMR was not predictive of CIR or OS. Among the 77 patients who achieved CMR, 23 patients presented a positive MRD (>0.001%) with a median time of 6.9 months [IQ, 3.9 – 13.3] up to 23 months after CMR achievement. Loss of CMR was confirmed on a second sample in 13/23 patients (57%). Cumulative incidence of relapse was significantly higher in patients with a confirmed loss of CMR when compared to patients with a non confirmed loss of CMR (3-years CIR, 83% *vs* 14%, p=.03) with no difference in overall survival. In patients with confirmed loss of CMR, time between first positive MRD and hematological relapse was 3.9 months [IQ: 3.3 – 6.9].
Summary and Conclusion: Contrarily to early MRD reduction on therapy, time to CMR achievement is not predictive of relapse in patients with *RUNX1-RUNX1T1* AML. Monitoring peripheral blood MRD every 3 months up to 2 years after CR allowed to predict and anticipate hematological relapse.

P793

FREQUENT MUTATIONS IN PML-RARA IN RELAPSED ACUTE PROMYELOCYTIC LEUKEMIA

A Fasan[1,*], C Haferlach[1], E Sirch[1], W Kern[1], T Haferlach[1], S Schnittger[1]
[1]MLL Munich Leukemia Laboratory, Munich, Germany

Background: Two therapeutic agents, ATRA and arsenic trioxide (ATO), induce differentiation of promyelocytes *in vivo* and clinical remission of acute promyelocytic leukemia (APL) patients. However, mutations in the *RARA* and *PML* parts of the *PML-RARA* fusion gene have been reported to confer resistance to ATRA (Imaizumi *et al.*, Blood 1998) and ATO (Goto *et al.*, Blood 2011), respectively.
Aims: The evaluation of mutations within the *PML-RARA* fusion gene in relapsed APL.
Methods: We screened 12 cases with APL who showed hematologic or molecular relapse for mutations within the *PML-RARA* fusion transcript. Amplified *PML-RARA* fusion transcript was analyzed by direct Sanger sequencing. The detection limit of this analysis was 1:10 allowing the detection of 1 mutated allele in a background of 10 wildtype alleles. Eight patients were male and four patients were female with a median age of 47.15 years (range: 16.7-73.2 years).
Results: Overall, in 7/12 relapsed patients (Pt) (58.3%), mutations within the *PML-RARA* fusion transcript were detected. In these seven patients we performed mutation analysis also in samples taken at primary diagnosis. In none of the cases these mutations were detectable at initial diagnosis and thus all were acquired mutations. All mutations were missense mutations with mutation loads of 10-100%. Two of seven patients were treated with ATRA and had a mutation in the RARA region of *PML-RARA*. One of these mutations was previously described (p.Ser287Leu), whereas the other was novel (p.Val135Leu). Five of seven patients were treated with ATRA and ATO and harbored mutations in the *PML* region of *PML-RARA.* All five patients had at least two and up to four mutations in the *PML* region of *PML-RARA* (Pt1: p.Gly269Ser + p.Val301Met + p.Ala303Val; Pt2: p.Leu81Pro + p.Glu277Lys + p.Ala303Thr + p.Gln354Arg; Pt3: p.Ala263Ser + p.Glu296*; Pt4: p.Ala125Thr + p.Arg282His + p.Val287Ile; Pt5: p.Glu281X + p.Gly317Asp). All *PML* mutations were located in functional domains and were not described before. In three patients material from different relapse time points was available. In the first patient three relapses occurred and all three mutations in the *PML* region of *PML-RARA* were for the first time detectable at the time point of third relapse after treatment with ATRA and ATO. The second patient had two relapses. Four mutations in the *PML* region of *PML-RARA* were detected at first relapse after treatment with ATRA and were not detectable at the time point of second relapse after treatment with ATRA and ATO. The third patient also had two relapses (no treatment information available). Mutations in the PML region of *PML-RARA* were detected at first relapse and were not detectable at second relapse.
Summary and Conclusion: We demonstrate a high incidence of acquired mutations within the *PML-RARA* fusion transcript in relapsed APL patients. Although functional data is still missing, these mutations may confer resistance to ATRA and ATO. These data may have implications for further treatment strategies of such patients.

Acute myeloid leukemia - Biology 4

NFATC1 MEDIATES SORAFENIB RESISTANCE IN FLT3-ITD POSITIVE ACUTE MYELOID LEUKEMIA

C Michel[1,*], S Metzelder[1], M Bonin[2], M Rehberger[3], E Hessmann[4], C Brendel[1], T Stiewe[3], V Ellenrieder[4], T Haferlach[5], M Bornhäuser[6], A Neubauer[1], A Burchert[1]
[1]Hematology/Oncology/Immunology, University Hospital Marburg, Marburg, [2]University Hospital, Dresden, [3]Philipps University Marburg, [4]University Hospital Marburg, Marburg, [5]Munich Leukemia Laboratory, Munich, [6]University Hospital Dresden, Dresden, Germany

Background: Internal tandem duplications (ITD) in the fms-related tyrosine kinase 3 (FLT3) are the most frequent mutations in normal karyotype acute myeloid leukemia (AML). FLT3-ITD is associated with a dismal prognosis. Although FLT3 inhibition with sorafenib is rational and clinically effective in chemotherapy-refractory FLT3-ITD+ AML patients, sorafenib resistance essentially always develops after rather short latency. Mechanisms of sorafenib resistance are not well defined. The transcription factor, nuclear factor of activated T-cells (NFATc1) is expressed in pancreatic cancer and certain lymphatic leukemias. It was recently shown that inhibiting NFATc1 with the immune suppressant and calcineurin inhibitor cyclosporine A (CsA) regulates imatinib resistance in BCR-ABL-positive leukemia cells.
Aims: Here we characterized NFATc1 expression in AML. We subsequently asked, whether NFATc1 has a role in the regulation of sorafenib response of FLT3-ITD positive AML.
Methods: NFATc1 mRNA expression level were screened using cDNA array data of 47 FLT3-ITD$^+$ and 222 FLT3-ITD$^-$ AML patients. NFATc1 mRNA and protein expression was analyzed in 14 AML cell lines and primary AML patient material. The role of NFATc1 in regulating sorafenib response was studied *in vitro* by conducting proliferation and apoptosis assays: sorafenib-sensitive and –resistant FLT3-ITD-positive MV4-11 cells and primary patient blasts were treated with sorafenib, NFATc1 inhibitors (VIVIT, CsA) or both. The role of NFATc1 in controlling sorafenib response was also studied *in vitro* and *in vivo* by genetic knock down of NFATc1 using NFATc1-specific shRNA vectors or by expression of a constitutively nuclear (active) NFATc1 variant.
Results: NFATc1 mRNA and the nuclear (active) NFATc1 protein were found to be overexpressed in AML cell lines and primary cells, especially if they were FLT3-ITD+. NFATc1 regulated sorafenib sensitivity of FLT3-ITD+ cells: pharmacological inhibition or genetic knockdown of NFATc1 using CsA/VIVIT or inducible shRNA constructs, respectively, synergized with sorafenib in mediating proliferation inhibition and apoptosis induction of sorafenib-sensitive FLT3-ITD+ MV4-11 cells. Moreover, in derived sorafenib-resistant MV4-11 clones, blocking NFATc1 with CsA overcame resistance. The magnitude of this effect correlated with the extent of NFATc1 overexpression. Vice versa, co-expression of a constitutively nuclear NFATc1-mutant with FLT3-ITD in myeloid progenitor cells (32D-FLT3/ITD-NFATc1), resulted in instant and FLT3-ITD-independent sorafenib resistance *in vitro* and in a syngenic mouse model *in vivo*. Finally, AML blasts derived from sorafenib-resistant FLT3-ITD-positive AML patients could be resensitized to sorafenib in presence of CsA *in vitro*.
Summary and Conclusion: CsA may improve sorafenib treatment outcome of FLT3-ITD-positive AML patients by overcoming or delaying sorafenib resistance development. Our results also imply a so far unrecognized anti-leukemic role of the routine clinical application of CsA as immune suppressant post allogenic stem cell transplantation. This may warrant reconsideration of the CsA tapering practice in FLT3-ITD positive AML.

P795

EXPRESSION OF FLT3-ITD DYSREGULATES THE DBC1-SIRT1-P53 SIGNALING AND PROMOTES THERAPY RESISTANCE

D Sasca[1,*], P S Haehnel[1], L Bullinger[2], M Theobald[1], T Kindler[1]
[1]III. Medical Department (Hematology, Oncology, Pneumology), University Medical Center of the Johannes Gutenberg University, Mainz, [2]Department of Internal Medicine III, University Hospital of Ulm, Ulm, Germany

Background: SIRT1 is a NAD+ dependent histone deacetylase, which has been shown to act as an important regulator of apoptosis, DNA-repair and genomic integrity under conditions of stress. Beside deacetylation of histones SIRT1 has several other substrates including KU70, FOXO1 or p53. SIRT1 deacetylates p53 at lysine 382 thereby reducing its transcriptional activity followed by loss of p53 dependent apoptosis in response to cell damage. TP53 mutations represent one of the most common genetic events in human cancers. Interestingly, TP53 alterations are rarely detected in acute myeloid leukemia (AML). Recent reports have shown high expression of SIRT1 in CML cells. In previous work we and others demonstrated increased SIRT1 protein expression in AML samples harboring activating mutations in signal transduction pathways such as FLT3-ITD, c-KIT or RAS-GTPases (EHA Abstract Book 2013, Blood 2013 vol. 122 no. 21 3789). Expression was regulated by FLT3 tyrosine kinase activity and regulated at protein but not RNA levels.
Aims: In this study we aim at understanding mechanisms of FLT3-ITD mediated SIRT1 regulation, the role of p53 as an effector protein and SIRT1 as a therapeutic target.
Methods: We established a doxycycline-inducible system enabling pharmacologic control of shRNA expression targeting SIRT1 in several AML-cell lines. In addition AML cells were treated with Tenovin-6 or EX527 with and without genotoxic agents. Cell death was analyzed by Annexin-V staining and cell cycle analysis. To investigate the functional role of p53 upon pharmacologic SIRT1-inhibition cells were transduced with lentivirus expressing p53-shRNA. Finally, to gain insight into *in vivo* effects upon SIRT1-inhibition, we performed xenotransplantation assays using SIRT1-shRNA-expressing MV4-11 cells. Transplanted animals were treated with doxycycline to induce SIRT1-knockdown and PKC412 alone or in combination.
Results: Targeting SIRT1 using the SIRT1/2 inhibitor Tenovin-6 (TV-6), EX527 or knockdown of SIRT1 resulted in a slight increase in apoptotic cell death in primary AML samples and cell lines. In contrast, inhibition of SIRT1 significantly sensitized leukemic blasts to FLT3 inhibitor therapy or genotoxic agents. In TP53-wildtype cells this effect was strongly dependent on p53, as knockdown of p53 cells abrogated the inhibitor effects. However, SIRT1 inhibition also sensitized TP53-mutant cells suggesting alternative downstream targets of SIRT1. In colony assays using murine leukemia models driven by MLL-AF9 and FLT3-ITD SIRT1 acts as a safeguard to counteract oncogenic stress and leukemic blasts become dependent on SIRT1 activity. Further, pharmacologic inhibition of SIRT1 attenuates the replating capacity without affecting cell death. *in vivo*, knockdown of SIRT1 in the AML cell line MV4-11 expressing a doxycycline-regulated SIRT1-shRNA resulted in prolonged survival in a xenotransplantation model and survival was further enhanced upon PKC412 combination therapy. Finally, we were interested to investigate the role of mutated FLT3 in SIRT1 regulation. Inhibition of FLT3-ITD kinase activity caused an increased phosphorylation of the physiological SIRT1-inhibitor DBC1 followed by binding of SIRT1 as revealed by co-immunoprecipitation experiments. We also noticed a slight increase in ATM/ATR phosphorylation and an increase in ATM-DBC1 binding upon FLT3-ITD inhibition indicating SIRT1 inhibition via the ATM-DBC1-SIRT1 axis. These effects were substantially enhanced upon treatment with genotoxic agents (cytarabine; irradiation) in combination with PKC412 compared to either agent alone.
Summary and Conclusion: Pharmacologic targeting of SIRT1 sensitizes AML cells to TKI therapy or genotoxic agents and partially restores the FLT3-ITD associated defective stress response pathway ATM-DBC1-SIRT1 resulting in activation of p53. In murine xenotransplantation models, inhibition of SIRT1 in combination with PKC412 treatment significantly prolonged survival of transplanted mice. These data suggest that SIRT1 represents a promising target in AML therapy.

P796

THE COMBINATION OF SELINEXOR (KPT-330), A SELECTIVE INHIBITOR OF NUCLEAR EXPORT (SINE), & THE FLT3 INHIBITOR QUIZATINIB SHOWS ANTI-TUMOR ACTIVITY IN ACUTE MYELOID LEUKEMIA (AML) *IN VITRO* AND *IN VIVO*

R Carlson[1,*], W Senapedis[1], Y Landesman[1], S Shacham[1]
[1]Karyopharm Therapeutics, Natick; Massachusetts, United States

Background: AML cells overexpress the nuclear exporter Exportin 1 (XPO1/CRM1) and higher XPO1 levels correlate with poor outcomes in AML and other cancers. Selinexor (KPT-330), a novel SINE, antagonizes XPO1 and shows potent cytotoxicity for AML cells *in-vitro* and *in-vivo*, independent of genotype, while largely sparing normal hematopoietic cells. Mechanistic studies show that selinexor induces nuclear localization and activation of multiple tumor suppressor proteins (TSPs) and reduces levels of oncoproteins such as FLT3 and KIT, leading to rapid apoptosis of AML cells. We have recently reported preliminary Phase 1 results in which treatment with oral selinexor has led to durable disease stabilization and responses in patients with relapsed/refractory AML across multiple genotypes. Quizartinib is a selective inhibitor of FLT3, a receptor tyrosine kinase for which the FLT3-ITD mutant is frequently a driver for AML. Quizartinib has shown significant activity in AML and the drug is scheduled to enter Phase 3 in FLT3-ITD+ AML patients this year. We report here the results of *in-vitro* and *in-vivo* studies of Selinexor and quizartinib alone or in combination on proliferation and survival of MV4-11 AML cells.
Aims: To characterize the *in-vitro* and *in-vivo* effects of combining selinexor with quizartinib on AML cell survival relative to treatment with either drug alone.
Methods: FLT3-ITD+ MV4-11 AML cells were used for cell culture and xenograft studies. MTT was used to measure *in-vitro* cell proliferation. For xenograft studies, MV4-11 cells were grown as subcutaneous tumors in NOD-SCID mice.
Results: Selinexor and quizartinib each showed highly potent inhibition of MV4-11 proliferation *in-vitro*, and the combination had additive efficacy. In the MV4-11 AML xenograft model in NOD-SCID mice, a combination of selinexor with quizartinib had an apparently synergistic effect on tumor growth relative to the drugs administered as monotherapies. Suboptimal doses of selinexor

(5 or 10 mg/kg PO QODX3) had no effect or induced a 60% median tumor growth inhibition (TGI), respectively, by the end of the study. Quizartinib at 0.5 or 10 mg/kg QDX7 PO induced 60% TGI or 91% regression, respectively, over the same timeframe. The combination of the suboptimal doses of Selinexor (5 mg/kg) and quizartinib (0.5 mg/kg) induced 67% tumor regression. While 10 mg/kg quizartinib induced modest weight loss, selinexor, 0.5mg/kg quizartinib, and the combination were well-tolerated with expected weight gain and full survival.

Summary and Conclusion: Selinexor is a potent inhibitor of *in-vitro* and *in-vivo* AML cell survival and functions by nuclear localization / activation of TSPs and reduction in FLT3 and other oncogproteins. Direct FLT3 inhibition with quizartinib also results in killing of FLT3 abnormal AML cells. The combination of selinexor and quizartenib shows additive cytotoxicity on AML cells *in-vitro*. Moreover, the combination of suboptimal doses of selinexor with quizartinib *in-vivo* was well tolerated and was dramatically more effective than either drug alone, leading to robust xenograft regression. This synergistic effect provides rationale for the investigation of a selinexor/quizartinib combination in the clinic with the potential for enhanced efficacy in AML relative to treatment with these drugs as monotherapies.

P797

CABOZANTINIB IS SELECTIVELY CYTOTOXIC IN ACUTE MYELOID LEUKEMIA CELLS WITH INTERNAL TANDEM DUPLICATION OF FLT3 (FLT3-ITD)

A Wang[1,*], JW Lu[1], HA Hou[2], CY Chen[2], CY Hu[1], DL Ou[3], YC Ko[4], HF Tien[2], LI Lin[1]

[1]Clinical Laboratory Sciences And Medical Biotechnology, National Taiwan University, [2]Internal Medicine, National Taiwan University Hospital, [3]Oncology, National Taiwan University, Taipei, [4]Radiological Technology, Yuanpei University, Hsinchu, Taiwan, Republic of China

Background: Internal tandem duplication of *FLT3* (*FLT3*-ITD), one of the most common mutations in acute myeloid leukemia (AML), is found in approximately 30% of AML patients and is associated with poor prognosis. *FLT3*-ITD is a potential target for drug development. Cabozantinib (XL-184, *N*-(4-((6, 7-Dimethoxyquinolin-4-yl) oxy) phenyl)-*N*-(4-fluorophenyl) cyclopropane-1, 1-dicarboxamide) is an oral multikinase inhibitor that targets MET, VEGF2, RET, KIT, TIE2, and FLT3. Previous studies showed that cabozantinib inhibited multiple receptor tyrosine kinases and cell viability in various cancer cell lines, and exhibited effective anti-tumor activity in many cancer models. The US FDA approved cabozantinib for the treatment of medullary thyroid cancer in 2012. Clinical trials for treatment of prostate cancer, renal cell carcinoma, hepatocellular carcinoma, and non-small cell lung cancer are ongoing. However, there is very little information about the application of cabozantinib in leukemia.

Aims: We aim to elucidate the efficacy and mechanism of action of cabozantinib in acute myeloid leukemia.

Methods: Human leukemia MV-4-11, MOLM-13, OCI-AML3, THP-1 cell lines, and leukemia cells from patients with AML were used. MTS assay was performed to assess growth suppression of cabozantinib on AML cells. Western blotting, flow cytometry and quantitative real-time PCR were applied to elucidate potential molecular mechanism. Leukemic cell xenografts in zebrafish embryo were used for investigating efficacy of cabozantinib as *in vivo* model. The study was approved by the institutional review board of National Taiwan University Hospital and written informed consents were obtained from all participants in accordance with the Declaration of Helsinki.

Results: Cabozantinib was significantly cytotoxic in MV4-11 and MOLM-13 cells, both harboring *FLT3*-ITD, with IC_{50} of 2.4nM and 2.0nM, respectively. On the other hand, K562, OCI-AML3 and THP-1 were resistant to cabozantinib, with IC_{50} at the micromolar range. In addition, cabozantinib, up to 20μM, had no toxic to peripheral blood mononuclear cells from healthy controls, suggesting drug potency with biosecurity and cell line-specificity. Cabozantinib arrested MV4-11 cell growth at G_0/G_1 cell cycle within 24hrs, and the cell cycle phase changes are associated with decreased phosphorylation of FLT3, STAT5, AKT and ERK. In addition, annexin-V and PI staining analysis revealed that cabozantinib induced MV4-11 cell apoptosis in a dose-dependent manner; cleavage of caspase 3 and PARP-1 were also observed. Further investigations on apoptosis-related proteins revealed that cabozantinib-induced apoptosis was accompanied by down-regulation of anti-apoptotic proteins survivin and Mcl-1 and up-regulation of pro-apoptotic protein Bak. In zebrafish model, cabozantinib decrease the leukemic burden in embryos xenografted with MV4-11 or MOLM-13 leukemic cells, but did not demonstrate any toxicity or anti-angiogenesis effect on normal embryos with up to concentration of 100nM.

Summary and Conclusion: Cabozantinib is selectively cytotoxic to leukemia cell with *FLT3*-ITD, but not those without this mutation. Although the mechanism of action is unclear, the growth suppression is related to cell cycle phase arrest and apoptosis. Our results suggest that clinical trials for the efficacy of cabozantinib in AML with *FLT3*-ITD are indicated.

P798

PRE-CLINICAL ACTIVITY OF THE PI3K INHIBITOR BKM120 ON ACUTE MYELOID LEUKEMIA

M Allegretti[1,*], MR Ricciardi[1], R Licchetta[1], S Mirabilii[1], S Amadori[2], R Foà[1], A Tafuri[3]

[1]Cellular Biotechnologies and Hematology, Sapienza University of Rome, [2]Hematology, Tor Vergata University Hospital, [3]Clinical and Molecular Medicine, Sapienza University of Rome, Rome, Italy

Background: Acute myeloid leukemia (AML) is frequently characterized by genetic and molecular alterations that induce constitutive activation of different signal transduction pathways such as PI3K/Akt/mTOR. Its inhibition through several small molecules, alone or in combination with chemotherapy, represents an attractive strategy to improve current treatment regimens. BKM120 is a highly selective pan-class I PI3K inhibitor which has been evaluated with encouraging results on various solid tumors and hematological malignancies, particularly T acute lymphoblastic leukemia (T-ALL).

Aims: In the present study we aimed at investigating pre-clinically the activity of BKM120 on AML cell lines and primary samples.

Methods: BKM120, kindly provided by Novartis, was tested on several AML cell lines and on 9 primary AML samples at concentrations ranging from 0.5 to 5μM. Cell cycle changes and apoptosis rate were analyzed by Acridine-Orange (AO) and Annexin V (AnnV)/PI staining. Western blot analysis was performed to evaluate intracellular signaling modulations induced by BKM120 up to 24h.

Results: Basal expression and phosphorylation levels of critical PI3K/Akt/mTOR pathway components were first assessed by western blot analysis. Despite some heterogeneity, AML cell lines (U937, NB4, OCI-AML2, HL-60/MX2, MOLM-13, OCI-AML3, HL-60 and KG-1) displayed a constitutive activation of the PI3K/Akt/mTOR axis, as documented by higher levels of p-Akt (Ser473), p-GSKα/β (Ser21/9), p-mTOR (Ser2448 and Ser2481), p-p70S6K (Ser371) and p-4EBP1 (Thr37/41) in comparison to normal peripheral blood lymphocytes (NPBLs). Three hours of BKM120 exposure induced a dose-dependent dephosphorylation of Akt (Ser473) in all cell lines, although with different sensitivity profiles. Akt dephosphorylation was associated with the downregulation of p-GSKα/β (Ser21/9) expression indicating a functional blockade of the PI3K pathway. BKM120 also affected both mTORC1 and mTORC2 activity inducing the dephosphorylation of p-mTOR (Ser2448), p-p70S6K (Ser371) and p-4EBP1 (Thr37/41) (mTORC1 downstream targets) and of p-mTOR (Ser2481) (mTORC2). Selective inhibition of the PI3K/Akt/mTOR pathway correlated with a marked reduction of cell growth (IC50s at 72h ranging from 0.7 for U937 to 1.2μM for KG-1) and with a significant ($p<0.005$) dose- and time-dependent induction of apoptosis in all cell lines. Analysis of cell cycle revealed, at 24h, a temporary accumulation of cells in G2/M phase which, at 72h, turns into apoptosis, as documented by the dramatic increase of the sub G0/G1 peak. Efficacy of BKM120 was then confirmed *ex-vivo* on 9 primary AML samples. At 144h, a mean increase of AnnV positive cells from 18.7% ± 0.1 (vehicle) to 26.4% ± 0.12, 31.6% ± 0.14, 40.4% ± 0.13 ($p<0.001$) and 45.4% ± 0.14 ($p<0.001$) was obtained at 0.5, 1, 2 and 5μM, respectively. Only 2 out 9 samples showed a limited increase of apoptosis induction (<15%). BKM120 was also tested on normal and activated PBMCs isolated from 5 healthy volunteers failing to show induction of apoptosis (8.0% and 4.4% apoptosis net increase at 5μM, respectively).

Summary and Conclusion: BKM120 treatment significantly impaired proliferation and induced apoptosis in all AML cell lines and in the majority of primary AML samples tested by selective inhibition of PI3K/Akt/mTOR signaling, suggesting the potential therapeutic activity of this molecule in AML.

P799

THE CXCR4 ANTAGONIST BL-8040 SYNERGIZES WITH THE FLT3 INHIBITOR AC220 TO INDUCE APOPTOSIS AND REDUCE MINIMAL RESIDUAL DISEASE OF AML CELLS *IN VIVO*

M Abraham[1,*], H Wald[1], O Eizenberg[1], B Bulvik[1], S Tavor[2], K Beider[3], A Nagler[3], Y Pereg[4], L Klapper[4], A Peled[1,2]

[1]Biokine Therapeutics Ltd, Ness Ziona, [2]Goldyne Savad Institute of Gene Therapy, Hebrew University Hospital, Jerusalem, [3]Hematology Division, Chaim Sheba Medical Center and Tel Aviv University, Tel-Aviv, [4]BioLineRx LTD, Jerusalem, Israel

Background: Acute Myeloid Leukemia (AML) is a heterogeneous group of diseases characterized by the uncontrolled proliferation of hematopoietic stem cells and progenitors with a reduced capacity to differentiate into mature cells. While many patients with AML achieve a complete remission with traditional chemotherapy, the majority eventually relapse within a year. FLT3 is a class III receptor tyrosine kinase that is expressed on early hematopoietic stem cells/progenitors and is vital for development of normal levels of mature myeloid and lymphoid cells. FLT3 gene mutations represent one of the most common molecular perturbations in AML, accounting for ~30% of de novo cases. FLT3 internal tandem duplication (ITD) mutation in AML patients confers poor response to chemotherapy, high relapse rates and only transient response to FLT3 inhibitors. CXCL12 and its receptor CXCR4 are key players in mediating the interactions between the BM microenvironment and AML cells. CXCL12,

which is constitutively secreted from the BM stroma and AML cells, is critical for the survival and retention of AML cells within the BM. CXCR4 expression is associated with poor prognosis in AML patients with or without a mutated FLT3 gene, and inhibition of CXCR4 was shown to sensitize AML blasts toward chemotherapy. It was found that FLT3-ITD mutation activate CXCR4 signaling and is associated with increased CXCR4 expression in primary AML cells.
Aims: In this work we studied the effect of the high affinity CXCR4 antagonist BL-8040 on the survival of AML cells with FLT3-ITD mutation alone or in combination with the FLT3 inhibitor AC220 (Quizartinib).
Methods: In this study, human AML MV4-11 cells *(FLT3-ITD*) were used. Cells were incubated in-vitro for 48 hrs in the presence of BL-8040 (20μM), AC220 (50nM) or their combination. Cells viability and the percentage of apoptotic events were evaluated by FACS analysis. In the in-vivo study an AML model of NOD scid gamma (NSG) mice engrafted with MV4-11 cells was used. Three weeks after the engraftment mice were treated daily for seven consecutive days with SC injections of BL-8040 (400ug/mouse) or with oral administration of AC220 (10mg/Kg) or their combination. The survival and apoptosis of AML cells were examined in the blood, BM and spleen of the engrafted mice.
Results: In-vitro, treatment of AML cells with BL-8040 directly inhibited cell growth by 35% and increased cell death by 40%. AC220 was found to induce cell death in 60% of the cells and the combination of BL-8040 with AC220 further increased the apoptotic effect achieving 97% reduction in cell viability and inducing cell death by 93% of the AML cells. In-vivo, BL-8040 was found to reduce the AML blasts in the blood from 13.5% in the control to 1.7%. Treatment with AC220 with or without BL-8040 reduced this level to 0.1%. Interestingly, the level of total mouse WBC following AC220 was significantly reduced in 65% compared to the control. This deep reduction in normal WBC was prevented when AC220 was combined with BL-8040. BL-8040 was found to decrease the number of AML cells in the BM to 2.6% compared to 12.6% in the control mice while AC220 reduced this level to 0.05%. The combination of AC220 with BL-8040 was found to further decrease this level to as low as 0.006% of AML cell in the BM. In 3/5 mice in this group the combination treatment completely eliminated the AML cells from the BM. Similar effect was observed in the spleen when BL-8040 reduced the level of AML cells from 21% in the control to 0.4% and AC220 reduced this level to 0.09%. The combination of AC220 with BL-8040 was further decreasing this level to 0.02%. The reduction in the number of AML cells in the blood, BM and spleen was accompanied with the induction of AML cells apoptosis.
Summary and Conclusion: The CXCR4 antagonist BL-8040 rapidly and efficiently induces cell death of AML cells both in-vitro and in-vivo. The combination of BL-8040 and AC220 was found to reduce the minimal residual disease of AML cells in this mice model. These results suggest potential therapeutic advantages of BL-8040 in AML patients with the FLT3-ITD-mutations by targeting not only AML anchorage in the BM but also AML survival. Furthermore, it could provide a rational basis for BL-8040 therapy in combination with the FLT3 inhibitor AC220 in this patient population.

Background: To aid in the identification of effective treatments for individual patients, *ex vivo* assays for detecting cell death inducible by drugs for hematological malignancies have been in development for over 20 years. We have developed an automated flow cytometry-based platform (ExviTech) that can address previous artifacts thus providing clinically predictive pharmacological data measuring leukemic cell depletion analyzed with pharmacodynamic population models.
Aims: The purpose of this study is to derive the *ex vivo* pharmacological profiles across the AML patient population of single drugs and combination treatments as a tool for individualized treatment selection.
Methods: Bone-marrow samples from 180 patients diagnosed with AML were sent to Vivia from 24 hospitals across Spain within 24 hrs. The plates were incubated for 48-hours prior to analysis with ExviTech. The percentage of leukemic cell death was determined via labeling with monoclonal antibodies and AnnexinV-FITC. Dose-response curves of cytarabine, idarubicin, daunorubicin, mitoxantrone, etoposide, fludarabine, clofarabine, and 6-thioguanine were measured in these patient samples. The added benefit of combining these drugs into 12 combination treatments was assessed by measuring their synergy in each individual patient.
Results: There was a large range of interpatient variability in the response to a single drug and even larger in the synergism between drugs. Alternative treatments are found even among CYT-(IDA/DAU/MIT). The Population Pharmacological Profiles for an individual patient is shown on the figure below. The relative drug potency in terms of their percentile ranking within the population is shown in the left panel from 0 (weakest) to 100 (most potent). Green lines represent the individual patient potency relative to the population ranking, with confidence intervals. Third column lists when a drug leaves a significant % of leukemic cells alive, potential resistant clones. The panel on the right side shows the synergism of the drug combinations treatments shown as box-plots at 10-25-75-90% to highlight their distribution. The synergism value for an individual patient in each combination is shown in green, with confidence interval as parallel dotted green lines. This representation of the Pharmacological Profile of an individual patient sample quickly identifies extreme values, when a drug or combination is very sensitive (rightward shift green lines, green boxes) or very resistant (leftward shift green lines, red boxes). This patient showed average sensitivities for most drugs though highly resistant to Clofarabine (red box) that leaves 45% alive. However this patient showed lack of synergism in multiple treatments (right, red boxes). CYT and IDA show average potencies but lack of synergism, suggesting CYT-DAU might be a more efficient treatment. These representations lead to clear guidelines in >90% samples.

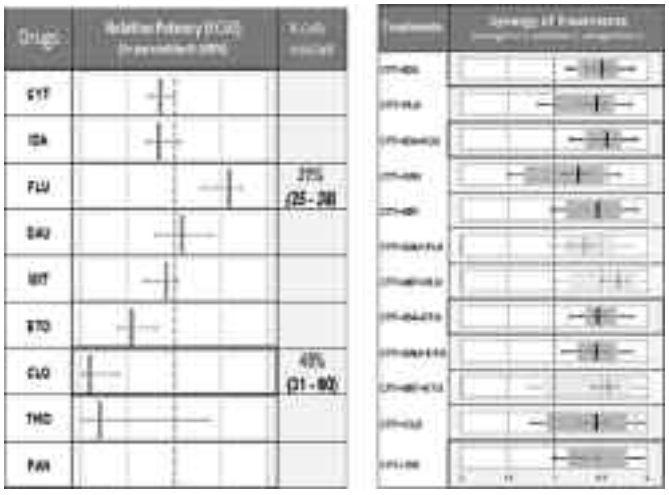

Figure 1.

Summary and Conclusion: We have developed an improved a methodology to measure the pharmacological activity of drugs and drug combinations in AML patient samples as well as modeling their pharmacological behavior. This information may be useful in selecting the optimal treatment for the individual patient, especially relapse/refractory patients in need of therapeutic alternatives. By testing the drugs used in the treatment protocols for AML directly on patient samples, a pharmacological based model has been developed to infer drug resistance or sensitivity, patient by patient.

P801

XPO1 INHIBITION USING SELINEXOR RESTORES TOPOISOMERASE IIA (TOPO IIA) LOCALIZATION TO THE NUCLEUS AND SENSITIZE PIMARY REFRACTORY AND RELAPSED ACUTE MYELOID LEUKEMIA (AML) BLASTS TO CHEMOTHERAPY

X Yu[1], P Ranganathan[1], B Bhatnagar[1], J Hofstetter[1], S Shacham[2], M Kauffman[2], W Blum[1], R Garzon[1,*]
[1]Medicine, The ohio State University, Columbus, [2]Karyopharm Therapeutics Inc, Natick, United States

Background: Inhibitors of topoisomerase IIα (topo IIα) are clinically effective in the management of AML. The efficacy of drugs targeting topo II is often limited by resistance and patients with primary refractory (PR) or relapsed (R) AML after induction therapy with cytarabine and Topo IIα inhibitors have a poor prognosis. Several *in vitro* studies have provided insights on potential mechanisms. Among them, a shift in Topo IIα localization from the nucleus to the cytoplasm could potentially lead to resistance to Topo IIα inhibitors. When Topo IIα is exported to the cytoplasm, it is not in contact with DNA, and Topo IIα inhibitors such as anthracyclines are unable to induce DNA-cleavage complexes and cell death. Topo IIα is exported from the nucleus by exportin-1 (XPO1), which is a nuclear protein export receptor that is over-expressed in AML. Selinexor, a selective inhibitor of XPO1 nuclear export, is currently being tested in a Phase 1 clinical trial in AML. Here, we hypothesize that increasing Topo IIα nuclear accumulation, by using Selinexor, may sensitize PR/R AML blasts to Topo IIα inhibitors.
Aims: To assess Topo IIα protein cell localization in PR/R AML blasts and to investigate the anti-leukemic activity of Selinexor in combination with Topo IIα inhibitors in AML cell lines and PR/R AML blasts.
Methods: Topo IIα cell localization was measured by Western Blotting (WB) and confocal microscopy. IC50 values for Selinexor and Topo IIα inhibitors were determined using MTS assays in AML cells lines and PR/R AML samples obtained from the OSU leukemia tissue bank. Synergy was calculated using the Chou-Talalay method. Idarubicin resistant MV4-11 cell line (R-MV4-11) was generated by exposing MV4-11 cells to low doses of idarubicin overtime (R: IC50 10 nM *vs*. no-R: 3 nM).
Results: To assess Topo IIα cell localization in PR/R AML, we examined 10 patient samples (5 PR, 5 R) by using WB and confocal microscopy. While Topo IIα expression was mostly nuclear we found variable expression of Topo IIα in the cytoplasm in 7 cases. We also found that R- MV4-11 cells exhibit a significantly higher cytoplasmic localization than MV4-11 cell lines (3 fold, $p<0.01$). While we did not found any correlation between CRM1 levels and Topo IIα expression in cell lines and patients, CRM1 inhibition using Selinexor restored nuclear localization of Topo IIα in all cell lines and PR/R AML samples. To evaluate whether the combination of Selinexor and idarubicin induce synergy, we treated the AML cell lines; MOLM-13, MV4-11, R-MV4-11 and 4 PR/R patient's blasts with Selinexor and idarubicin at two-fold dilutions of their individual IC50 values, and measured cell proliferation/cytotoxicity using the MTS assay. We found that concomitant treatment of Selinexor with idarubicin resulted in synergy (combination index (CI) values<1) in all cell lines and patient samples. These studies were repeated in MOLM-13 and MV4-11 AML cell lines using two other different Topo IIα inhibitors; etoposide and mitoxantrone. We observed synergy for all compounds (CI<1). For one patient, pretreatment and at relapse samples were available. While in the pretreatment sample, Topo IIα was exclusively nuclear, in the relapse sample Topo IIα was mostly localized in the cytoplasm. Interestingly, this patient initially received anthracycline based induction therapy and achieved complete remission. However, the patient's leukemia was refractory following a second induction using anthracyclines at relapse several months later. Treatment with Selinexor restored Topo IIα nuclear localization in this patient sample *in vitro* and strongly synergized with idarubicin (CI: 0.2).
Summary and Conclusion: Treatment with Selinexor restores nuclear localization of Topo IIα and sensitizes PR/R AML blasts to Topo IIα inhibitors.

P802

IMGN779: A CD33-TARGETED ANTIBODY-DRUG CONJUGATE (ADC) UTILIZING A NOVEL DNA ALKYLATOR, DGN462, IS HIGHLY ACTIVE IN VITRO AGAINST PRIMARY PATIENT AML CELLS AND IN VIVO AGAINST AML XENOGRAFTS IN MICE

K R Whiteman[1,*], P Noordhuis[2], G J Schuurhuis[2], Y Kovtun[1], L Harvey[1], C Audette[1], E Maloney[1], H A Johnson[1], N Fishkin[1], G J Ossenkoppele[2], R J Lutz[1]
[1]ImmunoGen, Inc., Waltham, United States, [2]Hematology, VU University Medical Center, Amsterdam, Netherlands

Background: Despite high initial response rates (about 80%) to chemotherapy, many acute myeloid leukemia (AML) patients experience a relapse of the disease, thought to be due to the outgrowth of persistent leukemic stem cells (LSC). The differential expression of CD33 on LSC compared to normal hematopoietic stem cells (HSC) makes CD33 an attractive target for treatment of AML with antibody-drug conjugates (ADCs). We have developed a new highly potent DNA alkylator, DGN462, which consists of an indolino-benzodiazepine dimer containing a mono-imine moiety. IMGN779 is an ADC comprising DGN462 conjugated to the anti-huCD33 antibody, Z4681A, via a cleavable disulfide linker.
Aims: To evaluate the *in vitro* and *in vivo* activity of the ADC IMGN779 as a potential therapeutic for CD33-positive AML.
Methods: CD33 levels and P-glycoprotein (Pgp) activity were measured by flow cytometry. Cytotoxic potencies of DGN462 and IMGN779 in AML cell lines were evaluated using continuous exposure up to 7 days, with WST-8 viability staining. Potency of IMGN779 against primary AML samples and normal bone marrow (NBM) was evaluated using colony formation assays after 24-hour exposure and after long term liquid culture to assess the potency in leukemic progenitors and LSC, respectively. The antitumor activity of IMGN779 was assessed in SCID mice bearing subcutaneous HL60/QC and EOL-1 xenografts. Pharmacokinetic parameters in CD-1 mice were determined from plasma concentrations of IMGN779 conjugate and its total Z4681A antibody component at various time points, measured by ELISA. The bioactivity of a subset of these plasma samples was confirmed by assay of cytotoxic potency against AML cells. The tolerability of IMGN779 was evaluated in CD-1 mice, with measurements of body weight, clinical observations and clinical chemistries.
Results: IMGN779 demonstrates highly potent and CD33-specific *in vitro* cytotoxicity against primary patient AML cells isolated from peripheral blood or bone marrow samples. IC_{50} values ranged from 10 to 1500 pM with the highest activity generally observed in samples with CD33 expression levels >5000 antigens per cell. In long term cultures, IMGN779 showed a dose dependent decrease of leukemic colony formation in patient AML samples. In contrast, colony formation increased in NBM, indicating that HSCs were spared. Pgp activity inversely correlated with CD33-expression levels and IMGN779 cytotoxicity. IMGN779 was highly active against AML cell lines, including Pgp-expressing cell lines, with IC_{50} values ranging from 2 to 3000 pM. IMGN779 was highly active against AML xenografts, with a minimal efficacious dose (MED) of 0.6 mg/kg (conjugate dose). Conjugate half-life was approximately 3-4 days in mice, with bioactivity maintained for at least 3 days, indicating that the conjugate remains intact and active during circulation. IMGN779 had favorable tolerability in mice (maximum tolerated dose of 40 mg/kg) without delayed toxicity or liver toxicity.
Summary and Conclusion: IMGN779 is a CD33-targeted ADC utilizing a novel DNA-alkylating agent, DGN462. Its favorable preclinical tolerability profile suggests that IMGN779 may confer a therapeutic advantage over existing clinical agents for AML that demonstrate activity, but with significant toxicity. The highly potent, CD33-targeted activity of IMGN779 against AML cell lines and primary patient AML cells *in vitro*, the anti-tumor activity observed against AML xenografts in mice and the favorable safety profile support its advancement as a potential treatment for AML.

VALIDATION OF BI-SPECIFIC T-CELL ENGAGER (BITE®) ANTIBODY ACTIVITY IN VITRO AND IN VIVO AGAINST DIFFERENTIALLY EXPRESSED CELL SURFACE TARGETS IN ACUTE MYELOID LEUKEMIA

A M Sinclair[1,*], A A Nazarian[2], O Homann[3], S Zhang[1], I Archibeque[1], L Busse[1], P Koppikar[1], K Hale[4], K Newhall[4], D Powers[2], I Foltz[5], J Moriguchi[1], T McElroy[1], K Manchulenko[5], G Moody[1], A Bakker[6]
[1]Oncology Research, [2]Therapeutic Discovery, Amgen, Inc., Thousand Oaks, [3]Genome Analysis Unit, Amgen, Inc., South San Francisco, [4]Molecular Sciences, Amgen, Inc., Seattle, United States, [5]Therapeutic Discovery, Amgen, Inc., Burnaby, Canada, [6]Therapeutic Discovery, Amgen, Inc., South San Francisco, United States

Background: BiTE® antibodies bind both tumor-associated surface antigens and CD3 on cytotoxic T-cells, and induce specific lysis of target positive cells. BiTE® AMG 330, targeting CD33, is being developed to treat acute myeloid leukemia (AML). However, BiTE® antibodies to other AML targets are needed to mitigate potential resistance mechanisms, target CD33 negative clones and/or be potentially combined with AMG 330.
Aims: These studies aimed to identify differentially expressed and restricted cell surface targets in AML and screen new BiTE® antibodies for efficacy *in vitro* and *in vivo*.
Methods: Next generation RNA sequencing analysis was used to screen AML patient samples, normal hematopoietic and non-hematopoietic tissues for differentially expressed and restricted targets then surface expression confirmed by flow cytometry. Human monoclonal antibodies to targets were generated in XenoMouse® and converted into BiTE® antibodies. An automated, robust high-throughput T-cell dependent cytotoxicity (TDCC) screening platform was developed using Steady-Glo® to quantify live luciferase-tagged AML cell lines after 48hrs incubation with non-activated human pan T-cells with an E:T ratio of 10:1. CHO cells expressing human and cynomolgus (cyno) targets were also screened with human TDCC assays. Cytokine release was measured using MSD V-plex assays and T-cell activation markers were assessed by flow cytometry. Activity was evaluated using a xenograft model with activated human T-cells mixed with luciferase tagged U937 cell line, implanted into athymic *nude* mice subcutaneously with daily BiTE® antibody administration at 500, 250, 100 and 50 µg/kg for 10 days. Tumors were measured by bioluminescence and caliper measurements.
Results: Two hematopoietic-restricted target RNAs were overexpressed in AML patient samples but were absent or low in essential normal non-hematopoietic tissues. Target surface expression was confirmed in AML cell lines and patient samples by flow cytometry. A high throughput TDCC assay was developed to screen BiTE® antibodies and was validated with a tool CD33/CD3 BiTE®. CD33 positive and negative cell lines were tested with the tool CD33/CD3 BiTE® and assays were reproducible and robust (signal/background 10 - 500 fold, Z'=0.75 - 0.85; EC_{50}=1 - 10 pM). Six Target A and nine Target B BiTE® antibodies were generated from human monoclonal antibodies and

several candidates bound human and cyno targets. In human TDCC assays with AML cell lines the potency of BiTE® antibodies to Target A were 0.42-4.9 pM (top candidates n=2) and Target B 0.64–929 pM (top candidates n=5). BiTE® antibody potency correlated with target expression levels and cyno T cells were also activated (potency shift<10 fold *vs*. human T-cells). Potency correlated with IFNγ and TNFα secretion and CD25, CD69, CD54 and CD71 expression on T cells. Little/no background activity was found in target negative cell lines suggesting BiTE® antibodies were specific. All doses of a Target A BiTE® completely inhibited U937 tumor growth in a xenograft model equivalent to the CD33/CD3 tool BiTE® and no evidence of tumor growth was identified out to 26 days.
Summary and Conclusion: Two differentially and overexpressed AML BiTE® targets have been identified and BiTE® antibodies to these targets are potent inducers of human and cyno T-cell activation, lyse AML cells in a target selective and proportional manner *in vitro* and a Target A BiTE® has efficacy *in vivo*. BiTE® antibodies to these targets may provide alternative therapeutic options in AML patients.

P804

A NOVEL CLEC12AXCD3 BISPECIFIC ANTIBODY EFFICIENTLY INDUCES T-CELL MEDIATED LYSIS OF CLEC12A+ AML BLASTS

B N Hangalapura[1,*], PF van Loo[2], M Leenders[1], J de Kruif[2], A B Bakker[2], H Dolstra[1]
[1]Laboratory Medicine, Radboud UMC, Nijmegen, [2]Merus BV, Utrecht, Netherlands

Background: Acute myeloid leukemia (AML) is the most common type of acute leukemia occurring in adults. Despite improvements in chemotherapy and supportive care, AML patients still have a very poor prognosis. Therefore, novel targeted therapies that can effectively eradicate both AML blasts and their progenitor cells are much needed. CLEC12A (also known as CLL1 and hMICL) is a myeloid differentiation antigen that is expressed on >90% of de novo and relapsed AML. Moreover, CLEC12A is selectively expressed on leukemic stem cells but not on normal hematopoietic stem cells. Therefore, CLEC12A is an attractive antigen for developing targeted therapeutic approaches for AML. Bispecific antibodies (BiAb) can be used to activate and redirect cytotoxic T cells to tumor cells to mediate efficient tumor cell killing. A novel T cell-redirecting full length human BiAb was generated, that binds CD3 on T cells with one arm while the second arm binds CLEC12A on AML tumor cells. The current studies describe the functional characterization of this CLEC12AxCD3 BiAb.
Aims: To evaluate the *ex vivo* functional activities of CLEC12AxCD3 BiAb in terms of target cell binding, target specific activation of resting T cells and target specific induction of T cell mediated lysis of CLEC12A$^+$ target cells.
Methods: The specific binding characteristics of CLEC12AxCD3 BiAb was evaluated by multicolor flow cytometry using T and AML cell lines, and healthy donor derived peripheral blood and bone marrow samples. The functional activity of CLEC12AxCD3 BiAb in terms of activation of resting T cells and induction of T cell mediated lysis of CLEC12A$^+$ target cells was evaluated by flow cytometery based cytotoxicity assays using resting T cells, purified from peripheral blood of either healthy donors or AML patients, as effectors and AML cell lines or patient derived primary AML blast samples as target cells. Cytokine levels in the supernatants of the cytotoxicity assays were analyzed by Luminex using the human 10-plex cytokine panel.
Results: The *ex vivo* functional characterization data revealed that CLEC12AxCD3 BiAb binds specifically to CLEC12A expressing myeloid cells and CD3 expressing T cells present in both peripheral blood and bone marrow samples, activates T cells (induction of CD25 and CD69 expression on CD4$^+$ and CD8$^+$ T cells) in a target cell dependent manner and efficiently induces T cell-mediated lysis of CLEC12A antigen expressing target cells. An initial version of the CLEC12AxCD3 BiAb with wild-type CH2 domain induced the release of non-specific pro-inflammatory cytokines such as IL-1β, IL-2, IL-6, IL-8, TNF-α and IFN-γ involved in Fcγ receptor interactions via the human IgG1 Fc-tail. To circumvent this, the CH2 domain of the heavy chain constant region was modified to abrogate Fcγ receptor binding while retaining its binding to FcRn for long *in vivo* half life. Analysis of this Fc-silenced CLEC12AxCD3 BiAb revealed that it completely abrogated the release of non-specific pro-inflammatory cytokines, while retaining its full capacity to induce antigen specific T cell proliferation as well as antigen specific redirected lysis of AML target cells. The CLEC12AxCD3 BiAb was able to activate and redirect AML patient-derived T cells to CLEC12A positive target cells as potently as that of healthy donor-derived T cells. Most importantly, co-incubation experiments of primary AML tumor cells with autologous resting patient T cells showed that Fc-silenced CLEC12AxCD3 BiAb can very effectively induce AML blast lysis (Figure 1).

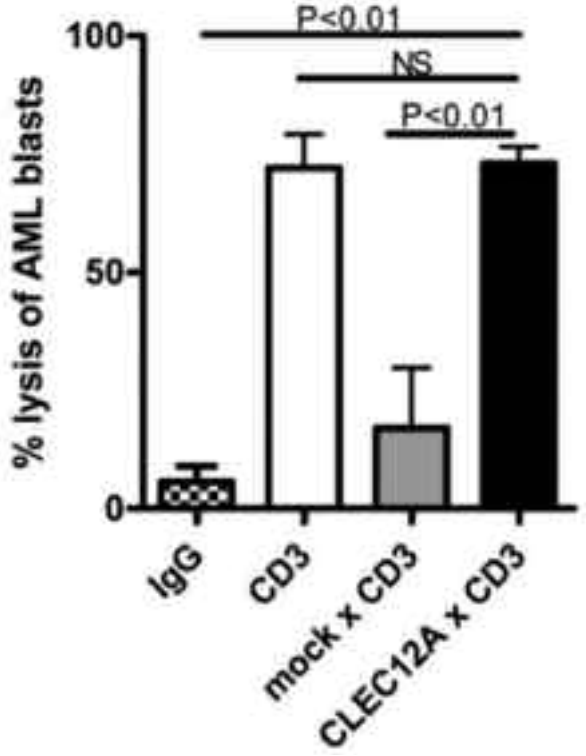

Figure 1. CLEC12AxCD3 BiAb induced specific lysis of AML blasts by autologous T cells.

Summary and Conclusion: The novel Fc-silenced CLEC12AxCD3 BiAb efficiently activates resting AML patient T cells and redirects them to specifically lyse AML blasts expressing the CLEC12A myeloid differentiation antigen. The specific and potent functional activities of this CLEC12AxCD3 BiAb warrant its further development for the treatment of AML.

P805

CATHECHOLAMINES DIFFERENTLY REGULATE HUMAN AML AND NORMAL HEMATOPOIETIC PROGENITOR CELL MOTILITY VIA MIR126 AND RGS16

C Medaglia[1,*], A Kalinkovich[1], T Itkin[1], A Nagler[2], T Lapidot[1], A Avigdor[2]
[1]Department of Immunology, Weizmann Institute of Science, Rehovot, [2]Division of Hematology and Bone Marrow Transplantation, Sheba Medical Center, Tel-Hashomer, Israel

Background: Motility, proliferation, bone marrow (BM) retention and egress to the circulation of hematopoietic stem and progenitor cells (HSPCs) are key elements in normal hematopoiesis and also in the pathogenesis of acute myeloid leukemia (AML). HSPCs are tightly regulated in the BM niche by various molecules. We have previously found that normal human HSPCs functionally express beta2-adrenergic receptors (β2-AR) that are up-regulated by myeloid cytokines such as G-CSF. The catecholaminergic neurotransmitters, epinephrine and norepinephrine (NE), activate both Wnt and GSK3β signaling pathways via β2-AR, leading to enhanced HSPC proliferation, motility and BM repopulation (Spiegel et al, Nat Immunol 2007; Lapid et al, JCI 2013). These findings indicate HSPC regulation by dynamic interactions of the sympathetic nervous and hematopoietic systems. However, the role of catecholamines in regulation of AML remains elusive.
Aims: The main objective of this study is to determine the role of cathecholamines in regulation of HSPC and AML cell motility.
Results: We found that human primary AML cells and several human AML cell lines from different FAB subtypes express β2-AR. NE, a β2-AR activating ligand, increased β2-AR expression and the CXCL12-induced migration of human AML primary cells and cell lines. NE treatment significantly enhanced CXCL12 induced actin polymerization, which drives most of the cellular movements. Three to five daily injections of NE to NSG mice, previously engrafted with human AML cells, enhanced the egress of these cells from the BM to the peripheral blood. Looking for downstream effectors of β2-AR, we focused on RGS16, a G-protein signaling regulator, which negatively regulates CXCL12/CXCR4 axis (Berthebaud *et al.*, Blood 2005). We found that NE decreased RGS16 expression (both in protein and mRNA level) in monocytic AML cells concurrently with an increase in cell migration. However, no effect on either cell migration or RGS16 expression was observed in non-monocytic AML cells. One of the regulators of RGS16 levels is miR126, which is highly

expressed in AML and normal HSPCs and involves in mobilization and proliferation of normal HSPCs. Indeed, in search for the mechanisms underlying the above observed differences, we found that the enhancing effect of NE on CXCL12-induced migration of monocytic AML cells was accompanied by up-regulation of miR126 expression concomitantly with down-regulation of RGS16 expression, whereas in non-monocytic AML cells we observed the opposite effects, suggesting that NE differently regulates AML cells belonging to different FAB subtypes. Importantly, over-expression of miR126 by lentivirus transduction in several AML cell lines resulted in upregulation of their CXCL12-induced migration. Contrary to AML cells, normal HSPCs expressed low levels of β2-AR and NE did not affect either RGS16 expression or CXCL12-induced migration of both mononuclear and CD34+ cells derived from human cord blood and BM.
Summary and Conclusion: Our results demonstrate that while normal and AML cells share common mechanisms that govern their motility, there are unrevealed yet mechanisms, apparently cell-type dependent, which uniquely lead to opposite effects in normal HSPCs, monocytic and non-monocytic AML cells. Altogether, these findings suggest that targeting of miR126 and RGS16 pathways by specific agonists and antagonists may serve as a new approach for selective eradication of leukemia-inducing stem cells.

P806

CELL-TO-CELL COMMUNICATION IN ACUTE MYELOID LEUKEMIA BY TUNNELING NANOTUBES

M Omsland[1,*], Ø Bruserud[1, 2], B T Gjertsen[1, 2], V Andresen[1]
[1]Department of Clinical Science, University of Bergen, [2]Department of Internal Medicine, Hematology Section, Haukeland University Hospital, Bergen, Norway

Background: Acute myeloid leukemia (AML) is a heterogeneous and aggressive blood cancer originating in the bone marrow. Conventional therapy is not well tolerated by elderly patients and the survival rate is limited. An improved understanding of cellular communication in AML could provide new information with respect to disease-linked mechanisms, progression, treatment and resistance. The tunneling nanotube (TNT) is a novel type of cell-to-cell communicator, 50-200 nm in diameter, F-actin containing structure connecting two or more cells. TNTs have been observed in a variety of cells including macrophages, B and T-cells, different cancer cells and osteoclasts. It has been shown to transport various cell components including mitochondria, in addition to spread pathogens like viruses and bacteria. TNT has also been suggested to have a role in transfer of multi-drug resistance genes. The exact molecular mechanisms behind TNT formation are still unclear, but the TNFαIP2 protein, found to be important in hematopoiesis, is one of the suggested molecules needed for TNT formation.
Aims: To identify and quantify TNTs in AML cell lines and AML patient cells and investigate the possible functional role of TNT following chemotherapy. Further map the molecular mechanisms responsible for TNT formation and regulation in AML.
Methods: The following cell lines were studied: OCI-AML3, NB4, HL-60, MV4-11 and MOLM-13. Primary cells: PBMCs from nine AML patients with more than 70% blasts in the blood and PBMCs from six healthy donors. The cells were investigated for TNT formation by fluorescence microscopy. For TNT verification the cell membranes were stained with lectin staining and the presence of F-actin by phalloidin staining. Both cell lines and primary AML patient cells were treated with cytarabine (AraC) alone (6 and 24h) or in combination with the two anthracyclines idarubicin and daunorubicin (4 and 24h). Also the effect of all-trans retinoic acid (ATRA) on TNFαIP2 (by immuno blotting) and TNT formation was investigated (24h).
Results: We found that all investigated cell types expressed TNT connections. The cell lines have small variation in percentage TNTs (0.3-7.8) as well as the PBMCs derived from six healthy donors (3.6-8.3) while the PBMCs derived from the nine AML patients showed greater variation (0-11.5). Treatment of cells with AraC resulted in a significant decrease in TNT numbers both in AML cell lines and in two of three investigated AML patients. Interestingly, idarubicin seems to have an antagonizing effect on AraC with more effect compared to daunorubicin (24h). Treatment with ATRA caused an increased expression of TNFαIP2 in MOLM-13, NB4 and HL-60, this correlated with TNT numbers in two cell lines. The level of TNFαIP2 seemed to correlate with TNT number in the cell lines investigated.
Summary and Conclusion: We demonstrated the existence of TNTs in both AML cell lines and primary AML cells. We observed a variance in TNT numbers between the different cell types and greatest deviation was observed in the patient samples. The chemotherapeutics daunorubicin and idarubicin demonstrated a tendency of TNT increase while AraC quenched TNT formation. The functional impact of TNT in bone marrow and the potential role in AML therapy together with the role TNT play in drug transfer will be further investigated.

P807

TIGAR COOPERATES WITH GLYCOLYSIS TO INHIBIT LEUKEMIA CELLS APOPTOSIS AND PREDICTS POOR PROGNOSIS IN PATIENTS WITH CYTOGENETICALLY NORMAL ACUTE MYELOID LEUKEMIA

M Hong[1], Y Zhu[1], J Li[1], S Qian[2,*]
[1]hematology, the First Affiliated Hospital of Nanjing Medical University, Jiangsu Province Hospital, [2] hematology, The First Affiliated Hospital of Nanjing Medical University, Jiangsu Province Hospital,, nanjing, China

Background: Recent studies has suggested that high levels of glycolytic metabolism in AML blasts were associated with resistance to chemotherapy and pateints's survival. TP53-induced glycolysis and apoptosis regulator (TIGAR) inhibits glycolysis and promotes tumor cells survival. Some studies have reported elevated expression of TIGAR in a few solid tumor types, suggestive of an important association.
Aims: The studies concerning mechanism of TIGAR and glycolysis inhibiting apoptosis and clinical implications of TIGAR expression in AML patients remained unknown.
Methods: Firstly we assessed expression level of TIGAR, by RQ-PCR, in the mononuclear cells from 116 patients with newly diagnosed cytogenetically normal AML (CN-AML) at diagnosis, and its clinical significance. All patients received cytarabine-based intensive chemotherapy. Patients with TIGAR expression values above the median of all patients were defined as high TIGAR expression ($TIGAR^{high}$), and all other patients were considered to have low TIGAR expression ($TIGAR^{low}$). Clinical and biological characteristics such as gene mutations were compared between $TIGAR^{high}$ and $TIGAR^{low}$ patients. Secondly we investigated the TIGAR functions in 3 leukemic cell lines and cells transducted with siRNA-TIGAR. CoCl2 and 2-DG were used to induce and block glycolysis, respectively. All study procedures and informed consent forms were approved by the institutional review board.
Results: There was no significant difference in most of the clinical characteristics between $TIGAR^{high}$ and $TIGAR^{low}$ patients. $TIGAR^{high}$ and $TIGAR^{low}$ patients had similar rate of complete remission (74.5% *vs* 72.7%). $TIGAR^{high}$ patients showed a trend towards a higher relapse rate than $TIGAR^{low}$ patients (29.1% *vs* 18.2%) but the difference was not significant. $TIGAR^{low}$ patients had significantly longer OS and DFS than $TIGAR^{high}$ patients (Fig1). Cumulative relapse incidence of $TIGAR^{high}$ patients was significantly higher than $TIGAR^{low}$ patients (P=0.044). Cox regression analysis showed that lower TIGAR expression was associated with a reduction of the risk of death (P=0.039), representing an independent prognostic factor. TIGAR mRNA expression and protein level were increased in all 3 leukemia lines. Treatment of leukemia cells with CoCl2 increased TIGAR expression, whereas inhibition of glycolysis with 2-DG decreased TIGAR expression. After siRNA-induced downregulation of TIGAR, PFKFB3 expression and ROS levels were elevated, while GSH content was reduced. Stimulation of glycolysis decreased PFKFB3 expression, while inhibition of glycolysis had the opposite effect. These data suggest that TIGAR could simultaneously inhibit glycolysis, decrease ROS and increase GSH levels in leukemia cells. Combining glycolysis inhibition and TIGAR knockdown yielded an extremely high level of apoptosis (88.0%). p53 only slightly upregulates TIGAR expression in leukemia cells, and that p53 activation promotes apoptosis, whereas TIGAR inhibits apoptosis.

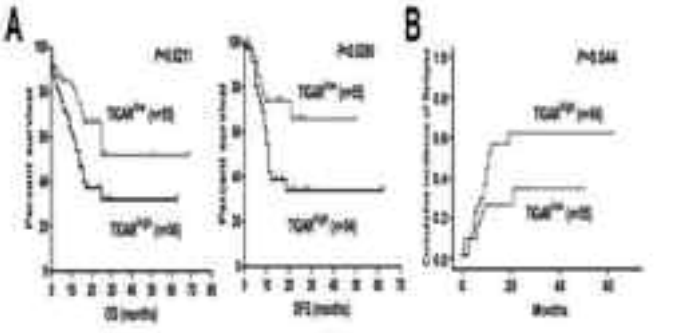

Figure 1.

Summary and Conclusion: High expression of TIGAR is associated with poor prognostic factor for OS and DFS in CN-AML patients. TIGAR was increased in leukemic cell lines and protected leukemia lines from apoptosis. TIGAR knowdown or block glycolysis alone could enhance leukemia cells apoptosis. Sustained TIGAR activation, uncoupled from p53, may support AML cell growth and survival. TIGAR in cooperation with glycolysis has a strong anti-apoptotic effect in AML cells, suggesting that combinations of TIGAR inhibitors with anti-glycolytic agents could prove to be powerful novel therapies for future clinical use.

P808

GLYCOLYSIS INHIBITION ON ACUTE MYELOID LEUKEMIA

S Mirabili[1,*], MR Ricciardi[1], M Allegretti[1], R Licchetta[1], R Foà[1], A Tafuri[2]
[1]Cellular Biotechnologies and Hematology, [2]Clinical and Molecular Medicine, Sapienza University of Rome, Rome, Italy

Background: Growing evidences show that upregulation of glycolysis occurs

also in leukemia cells. This metabolic peculiarity has been connected to signalling pathway alterations, especially those involving PI3K/Akt/mTOR, HIF1a, Ras/Raf/MEK/ERK. Thus, the current scenario depicts a crosstalk between proteins and metabolites that tends to the acquisition of a transformed metabolic profile conferring a proliferative advantage on leukemia cells. Therefore, targeting energetic pathways may represent a novel strategy for therapeutic intervention on leukemia.

Aims: Here we investigate whether (i) acute myeloid leukemia (AML) primary samples and cell lines are characterized by an increased glycolytic rate, (ii) the Pyruvate Dehydrogenase Kinase inhibitor, a pyruvate-mimetic molecule, the dichloroacetate (DCA), modifies glycolytic profile and (iii) affects proliferation and apoptosis of leukemic cells.

Methods: We investigated the glycolytic rate on resting and activated normal peripheral blood lymphocytes (NPBLs) and on AML cell lines. The effects of DCA exposure were evaluated on 4 human AML cell lines (U937, OCI-AML3, HL-60, MOLM13), on primary samples obtained from 4 AML patients and on NPBLs. Cell counts, apoptosis induction (AnnV) and changes in glucose and lactate culture medium levels (GEM4000, Instrumentation Laboratory, UK) were measured. Glucose consumption rate (GCR) and lactate production rate (LPR) were calculated according to Li *et al.* (Biotechnol. Appl. Biochem., 2005). Moreover, extracellular acidification rate (ECAR), directly related to the amount of lactate excretion, were obtained using an XF24 Analyzer (Seahorse Bioscience, USA), which allows real time analysis of metabolic fluxes.

Results: Resting NPBLs were characterized by a very low glycolytic rate, according to their quiescent state, while cultured phytohemagglutinin-activated NPBLs displayed a remarkable increase in glycolytic rate: the GCR calculated over 72 hours showed a 25 fold-increase, while LPR had a 10 fold-increase. All AML cell lines showed an even higher glucose catabolism when compared to activated NPBLs: at 24h the U937 cell line had a 6.7 fold higher GCR, while the OCI-AML3 cell line showed a 4-fold increase. XF24 real time metabolic measurement underlined differences in cell line glycolytic rates: after glucose injection (10mM), U937 showed doubled ECAR values as compared to HL60 (51±8,1mpH/min *vs* 25±6,3mpH/min, respectively). We then evaluated the effects of glycolysis inhibition on AML cells by DCA. By using XF Analyzer we demonstrated a 44% drop in ECAR following 5mM DCA injection in U937 cell line (from 107±10,2 mpH/min to 60±4,6mpH/min). Functional effect induced by DCA (1-7,5mM) showed cell growth arrest and apoptosis induction on 3 out of 4 AML models, in a dose- and time-dependent fashion. In fact, the IC50 of DCA exposure at 72h on U937, MOLM-13 and OCI-AML3 were 2,6mM, 5,1mM, 5,8mM, respectively. Conversely, HL-60 proved resistant (IC50 n.d.), as expected from the lower glycolytic rate characterizing this cell line. A similar pro-apoptotic activity was observed at 72h of DCA *in vitro* exposure on 4 out 4 primary samples: AnnV positive cells ranged from 14,1±8,9% (vehicle) to 25,3%±15,1% (1mM), 33±19,3% (2,5mM), 48,5±35,9% (5mM), 59,3±24,4% (7,5mM). Conversely, no significant effects were observed on both normal and activated NPBLs.

Summary and Conclusion: In this pre-clinical study, we documented that AML cells are characterized by higher glycolytic rates compared to normal cells. The DCA activity proved effective in modifying glycolysis rates and this effect is associated with apoptosis induction on primary AML and on cell lines.

P809

SK053 – AN ALLOSTERIC PROTEIN DISULPHIDE ISOMERASE INHIBITOR INDUCES DIFFERENTIATION OF HUMAN ACUTE MYELOID LEUKEMIA CELLS

J Golab[1,*], J Chlebowska[1], M Firczuk[1], K Furs[1], A Muchowicz[1], R Sadowski[1], S Klossowski[2], R Ostaszewski[2], K Giannopoulos[3], D Nowis[1,4]

[1]Department of Immunology, Medical University of Warsaw, [2]Institute of Organic Chemistry, Polish Academy of Sciences, Warsaw, [3]Department of Experimental Hematooncology, Medical University of Lublin, Lublin, [4]Department of General, Transplant and Liver Surgery, Medical University of Warsaw, Warsaw, Poland

Background: The use of differentiation-inducing agents including all-trans retinoic acid and arsenic trioxide in acute promyelocytic leukemia was a remarkable therapeutic breakthrough resulting in cure rates exceeding 80%. However, there is no such significant progress in the treatment of other acute myeloid leukemia (AML) types. Thus search for new agents exerting anti-leukemic effects by targeting novel and unique cellular mechanisms is of utmost clinical importance. Numerous human proteins involved in tumor formation contain allosteric disulfide bonds that are cleaved by oxidoreductases or by thiol-disulfide exchange. Targeting of allosteric disulfide bonds is a novel promising strategy in cancer therapy. We have developed SK053, a small molecule inhibitor of enzymes involved in allosteric disulfide bonds formation such as protein disulfide isomerase (PDI).

Aims: The aim of the studies was to determine if targeting the formation of allosteric disulfide bonds with SK053 can induce antitumor effects in AML.

Methods: Precipitation of proteins binding to biotinylated form of SK053 (SK231) followed by mass spectrometry analysis was used to identify molecular targets in AML cells. Enzymatic assays with recombinant proteins was used to validate targeting activity of SK053. Trypan blue exclusion was used to determine cytostatic/cytotoxic effects of SK053 in AML cells. May-Grünwald-Giemsa staining, nitro blue tetrazolium (NBT) reduction assay and flow cytometry analysis of membrane differentiation markers were used to determine differentiation of AML cells incubated with SK053. Quantitative RT-PCR and immunoblotting were used to determine changes in gene expression and protein levels. Lentiviral transduction with shRNA targeting PDI was used to determine the role of these proteins in differentiation-inducing activity of SK053.

Results: SK231 precipitated PDI from human AML NB4 cells, and mass spectrometry analysis revealed that SK053 covalently binds to PDI. In a turbidimetric assay of insulin disulfide reduction SK053 inhibits the enzymatic activity of PDI with IC_{50} of 10 μM. Since PDI blocks translation of CCAAT enhancer binding protein alpha (CEBPA), a transcription factor involved in neutrophils maturation, we set out to evaluate the activity of SK053 in human AML cells to see whether it can induce differentiation and cytostatic/cytotoxic effects against these cells. We observed that SK053 exerts significant cytostatic/cytotoxic activity in various types of human AML cells (HL60, NB4, KG-1 and MOLM14), and induces differentiation of AML blasts into more mature myeloid cells as evidenced morphologically in May-Grünwald-Giemsa staining, nitro blue tetrazolium (NBT) reduction assay as well as by increased expression of cell membrane differentiation markers (CD11b, CD14 and CD15), measured with flow cytometry. Moreover, incubation of AML cells with SK053 induces expression of CEBPA and hexokinase 3 mRNA, decreases levels of SOX4 mRNA in quantitative RT-PCR and increases amount of CEBPA protein in nuclear fraction measured with immunoblotting. Moreover, differentiation of AML cells was associated with induction of ER stress. Finally, SK053 induces differentiation of primary leukemic cells freshly isolated from AML patients.

Summary and Conclusion: SK053 targets PDI and thioredoxin/thioredoxin reductase system, has significant anti-leukemic activity and induces differentiation of various types of human AML cells. Thus, targeting of enzymes involved in allosteric disulfide bonds formation with small molecule inhibitors presents a novel and promising therapeutic strategy in acute myeloid leukemia.

P810

THE ROS/SUMO AXIS IS INVOLVED IN ACUTE MYELOID LEUKEMIA (AML) CELLS RESPONSE TO CHEMOTHERAPEUTIC DRUGS AND CONSTITUTES A POTENTIAL TARGET TO OVERCOME CHEMORESISTANCE IN AML

G Bossis[1,*], JE Sarry[2], C Kifagi[1], M Ristic[1], E Saland[2], F Vergez[2], T Salem[1], H Boutzen[2], H Baik[1], F Brockly[1], M Pelegrin[1], C Récher[2], S Manenti[2], M Piechaczyk[1]

Background: Small Ubiquitin-related MOdifier (SUMO) is a post-translational modifier of the ubiquitin family that has recently emerged as a critical regulator of protein function and fate. Moreover, increasing evidence suggest SUMO has important roles in cancer.

Aims: The goal of this study was to determine the role of the SUMO pathway in the response of Acute Myeloid Leukemia cells to the chemotherapeutic drugs used in the clinic and the relevance of its targeting to overcome chemoresistance, which is responsible for the poor prognosis of this cancer.

Results: We report that cytarabine (Ara-C) and daunorubicin (DNR) induce a fast deconjugation of SUMO from its target proteins in AML cell lines and patient samples. This desumoylation is due to Reactive Oxygen Species(ROS)-dependent inhibition of the SUMO-conjugating enzymes through the formation of a disulfide-bond between E1 and E2 catalytic cysteines. One of the important roles of sumoylation is the control of gene expression. To identify genes induced by desumoylation, we carried out transcriptomic analysis in AML cells treated with anacardic acid, an inhibitor of the SUMO E1. Among the highly induced genes, we studied *DDIT3,* a gene known to induced by chemotherapeutic drugs and involved in AML apoptosis. We could show that genotoxics-induced desumoylation of the proteins present on its promoter participate in its transcriptional activation by Ara-C. Importantly, preventing desumoylation also delayed entry of the cells in apoptosis. In chemoresistant AML cells, chemotherapeutic drugs do not induce this ROS/SUMO axis. However, its reactivation by pro-oxidants or inhibition of the SUMO pathway with anacardic acid restores both *DDIT3* expression and apoptosis in chemoresistant cell lines and patient samples. In particular, anacardic acid target leukemic stem cells, which are resistant to Ara-C and thought to be responsible of patient relapse. Finally, inhibition of the SUMO pathway decreases tumor growth in mice xenografted with chemoresistant AML cells.

Summary and Conclusion: In conclusion our data show that the ROS/SUMO axis is involved in genotoxics-induced death of AML cells, in particular through the control of specific transcriptional programs. Moreover, targeting the ROS/SUMO axis might constitute a novel therapeutic strategy for AML patients resistant to conventional chemotherapies.

ARSENIC TRIOXIDE AND FUCOIDAN SYNERGIZE TO INDUCE APOPTOSIS IN ACUTE PROMYELOCYTIC LEUKEMIA

F Atashrazm[1,*], R Lowenthal[1], J Dickinson[1], A Holloway[1], G Woods[1]
[1]Menzies Research Institute Tasmania, Hobart, Australia

Background: Acute promyelocytic leukemia (APL) represents a subtype of acute myeloid leukemia (AML) characterized by clonal expansion of malignant promyelocytes whose differentiation is blocked through t(15;17) translocation. Although arsenic trioxide (ATO) treatment has dramatically increased the survival rate of APL patients, its use and that of ATRA (another standard APL agent) can cause undesirable side effects such as the so-called differentiation syndrome characterized by fever, acute respiratory distress, acute renal failure and death. Therefore, the need to develop new less toxic strategies and/or use lower doses of ATRA and ATO is of great interest. Fucoidan is a sulphated polysaccharide which is extracted from brown seaweeds and has shown promising anti-tumor activities in various tumor cells. In the present study, we examined the anti-growth effect of fucoidan on a human APL cell line and also investigated the synergistic activity of fucoidan and ATO in APL, in order to reduce ATO doses and its related side effects.
Aims: 1. To determine the anti-growth effect of fucoidan on human APL cells. 2. To determine the probable synergistic effect of fucoidan with ATO on APL cells
Methods: Human APL cells (NB4 cell line) characterized by t(15;17) were treated with various concentrations of (i) fucoidan, (ii) both clinical and lower doses of ATO and (iii) a combination of the two agents. The proliferation rate, apoptosis, DNA content and DNA fragmentation were measured. Western blots were used to measure the expression level of apoptosis-related proteins. To determine whether the anti-growth effect of ATO and fucoidan is specific for APL cells, we treated t(8;21) translocation positive kasumi cell line with similar doses of fucoidan and ATO and measured the cells proliferation rate after 24, 48 and 96 hours.
Results: We found that fucoidan inhibited the growth of NB4 cells in a time and dose dependent manner. Cell cycle and apoptosis studies revealed increase of sub-G0/G1 population, DNA fragmentation and annexin V positive apoptotic. Activated caspase 3 and nuclear protein PARP (downstream target of activated caspase 3) increased in treated cells. In synergy studies, we found that the combination of fucoidan and ATO markedly decreased the amount of viable cells in the cytotoxicity assay compared to fucoidan or ATO only. These results were then confirmed with: elevated sub G0/G1 population in DNA content analysis, increased annexin V apoptotic cells and a significantly increased amount of fragmented DNA in cells treated with ATO+fucoidan compared to fucoidan and ATO only. The described effect was observed in cells treated with low dose ATO + fucoidan as well. To determine the specificity of ATO, we treated AML-M2 kasumi cells and observed that neither combined ATO/fucoidan nor single treatment with fucoidan and ATO decreased the proliferation of kasumi cells after 96 hours.
Summary and Conclusion: The results from our *in vitro* studies indicate that - Fucoidan induces a caspase-related apoptosis in APL cells - The *in vitro* combination of fucoidan and ATO (in both clinical and low doses) synergistically suppress the growth of APL cells - Such an effect is specific in APL cells as the two agents did not suppress the growth of AML1/ETO positive kasumi cells over 96 hours. Our data suggests that the combination of fucoidan and ATO should be investigated as a possible low-toxicity treatment of acute promyelocytic leukemia.

Acute myeloid leukemia - Clinical 3

THE PROGNOSTIC RELEVANCE OF THE 2008 WHO CLASSIFICATION OF MYELOID NEOPLASMS IN CHILDHOOD ACUTE MYELOID LEUKEMIA

A Kinoshita[1,*], H Miyachi[2], H Matsushita[2], M Yabe[2], T Taki[3], T Watanabe[4], A M Saito[5], D Tomizawa[6], T Taga[7], H Takahashi[8], H Matsuo[9], K Kodama[9], K Ohki[10], Y Hayashi[10], A Tawa[11], K Horibe[12], S Adachi[9]
[1]Pediatric hematology/oncology, St. Marianna University School of Medicine, Kawasaki, [2]Labotatory Medicine, Tokai University School of Medicine, Isehara, [3]Molecular diagnostics and therapeutics, Kyoto Prefectural University of medicine, Kyoto, [4]Nutrition and health, Aichi-gakuen university, Aichi, [5]Clinical Research center, Nagoya National Hospital Organization, Nagoya, [6]Pediatrics, Tokyo medical and dental university, Tokyo, [7]Shiga University of medical science, Ohtu, [8]Toho University, Tokyo, [9]Human Health Sciences, Kyoto University, Kyoto, [10]Hematology/Oncology, Gumma Children's Medical Center, Gumma, [11]Pediatrics, National Hospital Organization, Osaka Medical Center, Osaka, [12]Clinical Research Center, Natinal Hospital Organization, Nagoya, Nagoya, Japan

Background: In 2008, the World Health Organization (WHO) classification of myeloid neoplasms was revised combining morphologic, cytogenetic, and molecular data into a system relevant for prognosis. However, its prognostic relevance in pediatric population remains to be clarified.
Aims: Thus, we analyzed 453 pediatric patients categorized according to the 2008 WHO classification on a clinical trial for *de novo* acute myeloid leukemia (AML).
Methods: Between November 2006 and December 2010, 485 consecutive patients aged<18 years with suspected AML excluding acute promyelocytic leukemia, Down syndrome, secondary AML, myeloid/natural killer cell leukemia, and myeloid sarcoma were registered in AML-05 which was conducted by the Japanese Pediatric Leukemia/Lymphoma Study Group. The diagnosis according to the 2008 WHO classification was determined centrally by integrating morphologic, cytogenetic immunologic, molecular and clinical parameters. Although *FLT3*-ITD was prospectively analyzed for all patients, *NPM1* and *CEBPA* mutation was retrospectively analyzed using preserved samples.
Results: Of the 485 patients registered, 32 patients were excluded because of misdiagnosis or refusal by the guardians. Of the 453 eligible patients, 235 patients (48.5%) were identified as AML with recurrent genetic abnormalities, 93 patients (20.5%) as AML with myelodysplasia-related changes, and 111 patients (24.5%) as AML, not otherwise specified, and 7 (1.5%) as mixed phenotype acute leukemia. Among the 235 patients showing recurrent cytogenetic abnormalities, 126 patients had t(8;21)(q22;q22);*RNX1-RUNX1T1*, 32 had inv(16)(p13q22) or t(16;16)(p13;q22);*CBFB-MYH11*, 39 had t(9;11)(p22;q23); *MLLT3-MLL*, 30 had variant MLL translocations, 4 had t(6;9)(p23;q34); *DEK-NUP214*, 2 had inv(3)(q21q26), and 2 had t(1;22)(p13;q13);*RBM15-MKL1*. AML with mutated *NPM1* was found in 13 of 336 (3.9%) patients and AML with mutated *CEBPA* was found in 47 of 323 (14.6%). The 3-year event-free survival (3y-EFS) and 3-year overall survival (3y-OS) of patients with t(8;21)(q22;q22);*RNX1-RUNX1T1* was 67.5% and 91.2%, respectively. The 3y-EFS and 3y- OS of patients with inv(16)(p13q22) or t(16;16)(p13;q22);*CBFB-MYH11* was 76.7% and 96.9%, respectively. The 3y-EFS and 3y- OS of patients with t(9;11)(p22;q23); *MLLT3-MLL* was 58.6% and 71.1%, respectively. The 3y-EFS and 3y- OS of patients with variant MLL translocations was 49.2% and 65.2%, respectively. The outcomes for other subtypes of recurrent genetic abnormalities could not be determined because of the small number of patients. AML with myelodysplasia-related changes showed a significantly worse 3y-EFS compared with AML, not otherwise specified (37.1% *vs* 53.8%, p=0.02), but 3y-OS was not significantly different (56.8% *vs* 68.9%, p=0.05).
Summary and Conclusion: Almost half patients with pediatric AML were identified as AML with recurrent genetic abnormalities, while other half were identified as either AML with myelodysplasia-related changes or AML, not otherwise specified. The outcome for the core binding factor AML was excellent and the outcome for t(9;11)(p22;q23) was good as well. On the other hand, AML with myelodysplasia-related changes indicated a poorer outcome compared with AML, not otherwise specified. The outcomes for other AML subtypes should be determined in larger studies.

P813

REVISITING THE CLONAL DYNAMICS OF TRISOMY 21 AND MONOSOMY 7 MOSAICISM IN CONGENITAL NEUTROPENIA AML

M Ünalan[1,*], S Kandabarau[1], M Stanulla[2], C Zeidler[1], J Skokowa[1], K Welte[1]
[1]Molecular Hematopoesis, [2]Pediatric Hematology and Oncology, Hannover Medical School, Hannover, Germany

Background: It has been shown that congenital neutropenia patients enter a step-wise progression towards AML. Interestingly single gene mutations precede chromosomal abnormalities, while ploidy changes are foreshadowing

the acute stage of myeloid leukemia. The early detection of the latter is important as it can be of high prognostic value. The classical cytogenetic techniques, on which this knowledge has been based, have a known limited sensitivity and assay-to-assay variation.
Aims: To fully understand the time kinetics and the propensity of chromosomal changes, we decided to re-evaluate the ploidy mosaicism of CN AML samples with high sensitivity.
Methods: To this end we subjected bone marrow or peripheral blood of 59 CN patients to Affymetrix GenomeWideSNP arrays. Notable, eight individuals later progressed to AML OR MDS. First, to our surprise we failed to confirm chromosomal aberrations in prior cytogenetically verified samples with the Genotyping Console(TM) software. We therefore developed a custom workflow by comparing the signal of the copy number markers to the reference from the HAPMAP project and process the log2ratio in the R software package. The main statistical procedure was to recalibrate the signal intensities to autosomes and infere clonal ploidy mosaicism by fitting to exponential normal curves derived from XY chromosome log2ratio values from male and female samples.
Results: With this novel approach, we could confirm three previously characterized chromosomal changes in patients which later developed leukemia, and could detect a pre-leukemic clone earlier. In particular, one CN patient presented monosomy 7 (70% positive cells) already twenty month before AML M2/M4 diagnosis (pat#1), while in another case 68% of cells harboured this defect (pat#2) at AML M0 diagnosis. Additionally, the new method redated the occurance of trisomy 21 (14.9% positives) prior to AML M1 diagnosis eleven month before overt leukemia (pat#3). This is particular significant as this patient has been previously described by us as having developed monosomy 7 first, while we now identified trisomy 21 as the founding ploidy change prior AML with this more sensitive assay.

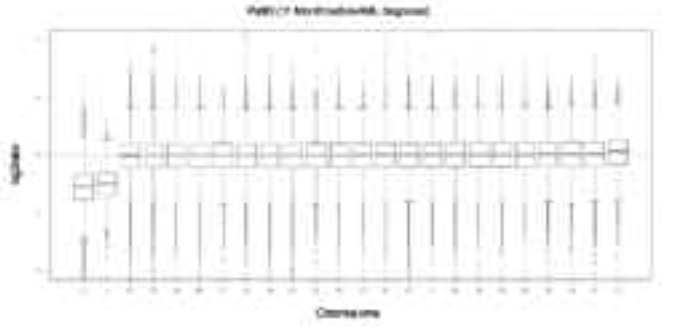

Figure 1.

Summary and Conclusion: Overall our results clarify the role of chromosomal abnormalities in CN and underscore its relevance in the dynamic towards AML progression. It is discussed that our statistical workflow is superior to conventional CNV calling algorithms to detect chromosomal cell clones prior overt leukemia. SNP Chip-based techniques should be considered as an high sensitive tool for ploidy monitoring in pre-leukemic syndromes in general.

P814

A SIMPLE AND EFFECTIVE STRATEGY TO DECREASE EARLY DEATHS IN ACUTE PROMYELOCYTIC LEUKEMIA USING A STREAMLINED SET OF GUIDELINES PAIRED WITH EXPERT SUPPORT

A Jillella[1,*], B Lane[1], Y Rosshandler[1], J H Khoury[1], M Arellano[1], K Natrajan[2], R Kolhe[3], K T Bradley[4], A Bashey[5], R Stuart[6], V Kota[2]
[1]Hematology and Oncology, Winship Cancer Institute of Emory University, Atlanta, [2]Hematology Oncology, Georgia Regents University Cancer Center, [3]Pathology, Georgia Regents University, Augusta, [4]Pathology, Emory University School of Medicine, [5]Bone Marrow Transplant, Northside Hospital, Atlanta, [6]Hematology Oncology, Hollings Cancer Institute, MUSC, Charleston, United States

Background: Large cooperative group studies have reported survival of acute promyelocytic (APL) leukemia at 90%, with low early mortality rates of approximately 5%. The recent Italian GIMEMA trial, in non-high risk patients, showed a survival rate of 98% in the ATRA/Arsenic trioxide arm. These spectacular results are not evident in studies from cancer registry data. The United States SEER data shows the relative survival rates in APL patients as 71% (one year) and 65% (five year). Studies from the Swedish registry, Brazil and other single institutions, show the early mortality as high as 30%. The common causes of death are hemorrhagic complications (HC), differentiation syndrome (DS), infection and multi-organ failure. We report our results showing early deaths can be decreased by using a set of streamlined treatment guidelines along with support from APL experts.
Aims: 1. To decrease early deaths in APL with a streamlined algorithm and expert support. 2. To improve overall survival in APL across the general population.
Methods: We performed a retrospective chart review of APL patients at Georgia Regents University Medical Center (GRU) and Emory University Hospital (EUH) between July 2005 and June 2009. Seven of 19 patients (37%) treated at GRU had died, an unusually high mortality rate. This high early death rate prompted the GRU group to develop simple treatment guidelines (1.5 pages) with emphases on quick diagnosis, prompt therapy, and proactive management of the major causes of death during induction. More importantly we made our treatment guidelines available to other leukemia treatment centers in Georgia and South Carolina and assisted treating oncologists with patient management during induction. We implemented this algorithm in 10/2010.
Results: From July 2005 through June 2009, a total of 59 patients, aged 18-89 years were seen; 19 at GRU and 40 at EUH. These included 21 high-risk and 38 low-risk patients. Patients were considered high-risk based on a presenting white cell count of >10,000. There were a total of 16 deaths (27%); ten in the high-risk group and six in the low-risk group. At Emory the death rate was 17.5%, with two of the nine deaths being patients transferred at a late stage of the illness. Nine deaths were secondary to hemorrhagic complications, five were DS related and two were from infection. Three patients died within five days of presentation to the hospital. From 11/2010 to 01/2014 the new algorithm was implemented. Ten patients were treated at GRU and 31 patients were at 10 other centers. All patients were either under direct care of an expert or co-managed with an APL expert. Age range was 21-73 years. 11 patients were high-risk and 30 low-risk. There were 2 deaths (4.8%) during induction both from hemorrhagic complications; one of these patients refused transfusions for religious reasons.

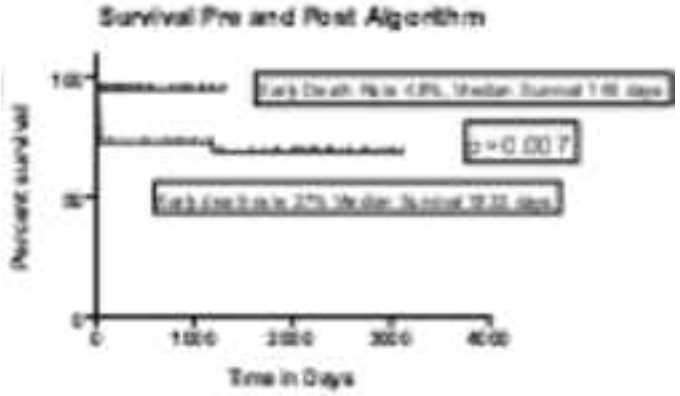

Figure 1.

Summary and Conclusion: Our own experience and multiple other studies show that early mortality is a significant problem globally in APL. We show that use of our streamlined treatment algorithm, developed independently due to poor outcome at GRU, along with support from experts will lead to better outcomes in this curable disease. Education and networking can lead to improved treatment outside of tertiary hospitals and prevent late stage transfers. A similar approach pioneered by investigators in Brazil shows this to be an effective model. We believe our experience warrants large scale implementation of our strategy to decrease early mortality in developed and emerging countries. We are recipients of a $1.68 million grant by the Leukemia Lymphoma Society to decrease early mortality in the states of Georgia and South Carolina with a population of 15 million over a 3-year period.

P815

INCIDENCE AND TYPE OF IDH1 AND IDH2 MUTATIONS IN AML-NK PATIENTS AND THEIR PROGNOSTIC IMPACT ON TREATMENT OUTCOME

HJ Kim[1,*], YK Kim[1], H Kook[1], IK Lee[2], N Kim[3], DDH Kim[4], HJ Kim[5], CW Jung[6], JH Jang[6], JH Moon[7], SK Sohn[7], JH Won[8], SH Kim[9], J Huh[10], SH Jung[1], JS Ahn[1], DH Yang[1], JJ Lee[1]
[1]Chonnam National University Hwasun Hospital, Jeollanam-do, Korea, Republic Of, [2]Genome Research Center for Haematopoietic Diseases, Chonnam National University Hwasun Hospital, Jeollanam-do, [3]Korean Bioinformation Center, Korea Research Institute of Bioscience and Biotechnology, University of Science and Technology, Daejeon, Korea, Republic Of, [4]Princess Margaret Hospital, University of Toronto, Toronto, ON, Canada, [5]The Catholic University of Korea, Seoul St Mary's Hospital, [6]Samsung Medical Center, Sungkyunkwan University School of Medicine, Seoul, [7]Kyungpook National University Hospital, Daegu, [8]Soon Chun Hyang University Hospital, Seoul, [9]Dong-A University College of Medicine, Busan, [10]Ewha Womans University School of Medicine, Seoul, Korea, Republic Of

Background: The isocitrate dehydrogenase (*IDH)1* and *IDH2* mutations have been described as frequent recurrent aberrations in acute myeloid leukemia (AML), particularly in those with normal cytogenetics. Types of these mutations and their clinical impact on treatment outcome have not yet been fully understood.

Aims: In this study we performed an analysis of the clinical and prognostic impact of *IDH1* and *IDH2* mutations combined with other frequently occurred mutations.
Methods: In a total of 67 nomral karyotype acute myeloid leukemia (AML-NK) patients achieved complete remission (CR), candidate mutations in 21 genes were identified by whole exome sequencing which has 41-89X coverage and by single-nucleotide polymorphism array analysis using marrow mononuclear cells at diagnosis of AML-NK. Subsequently, mutation analyses of other genes (*i.e. NPM1, CEBPα* double mutation*, FLT3*/ITD*, DNMT3A, IDH1, IDH2*) were performed using Sanger sequencing in another subset of 527 AML-NK patients as a validation cohort.
Results: Of 594 patients in total (median age: 57, ranges: 15-85). *IDH1* and *IDH2* mutations were identified in 7.0% and 14.6% of the patients, respectively. *IDH2* mutation was associated with lower leukocytes counts at presentation of AML-NK (P<0.01). In *IDH1* mutation, R132C (3.4%) was the most frequent alteration. In addition, R132H (2.2%), R132S (0.5%), R132G (0.3%), K87K (0.2%), R82K (0.2%), P78H (0.2%) were detected. In *IDH2*, R140Q (11.3%), R172K (1.7%), R140W (0.5%), R140L (0.5%), I142L (0.2%), T146T (0.2%), G176G (0.2%) were identified. *IDH1* mutation was associated with higher incidence of *DNMT3A* mutation (46.3% *vs*. 29.3%, P<0.05). *IDH2* mutation was associated with higher rate of *NPM1* mutation (52.3% *vs*. 39.6%, P<0.05), whereas it also showed lower rate of *CEBPα* double mutation (4.7% *vs*. 12.4%. P<0.05). In 455 patients who received standard remission induction (RI) chemotherapy, *IDH1*^{R132} mutation was associated with higher rate of relapse (62.5% *vs*. 37.9%, P<0.05) and shorter leukemic-free surival (LFS) (median 12.5 ms. *vs*. *N.A*., P<0.01). On the other hand, *IDH2*$^{R140Q\ or\ R172K}$ mutation was an independent prognostic factor for longer LFS in univariate and multivariate analyses, adjusted by other variables including age, leukocyte counts at diagnosis, transplantation and other genetic mutations (P<0.05, Hazard ratio, HR 1.896, 95% confidence interval, 95% CI=1.040-3.455). Further, all patients divided into four groups according to the *IDH1*^{R132} and *IDH2*^{R140Q} or ^{R172K} mutation status - G1 (n=60): *IDH1*$^{R132-}$ & *IDH2*$^{R140Q+\ or\ R172K+}$, G2 (n=364): *IDH1*$^{R132-}$ & *IDH2* $^{R140Q-\&\ R172K-}$, G3 (n=31): *IDH1*$^{R132+}$ & *IDH2*$^{R140Q-\ \&\ R172K-}$, G4 (n=0): IDH1^{R132+} & *IDH2*$^{R140Q+\ or\ R172K+}$. G1 (27.3%) patients revealed lower rate of relapse than G2 (39.1%) or G3 (62.5%) (P<0.05). G1 patients also showed significantly better LFS than G2 (P<0.05, HR 1.933, 95% CI 1.058-3.532) or G3 (P<0.01, HR 3.157, 95% CI 1.460-6.830)(Fig. 1).

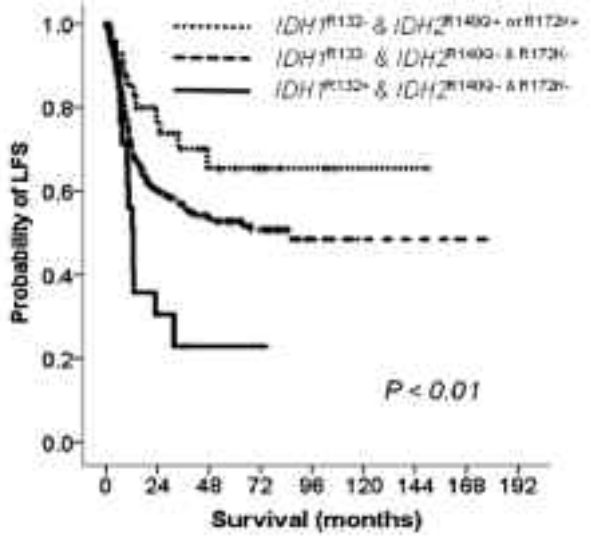

Figure 1.

Summary and Conclusion: Our study revealed that the incidence and characteristics of *IDH1* and *IDH2* mutations in AML-NK patients. We also found that *IDH1*^{R132} and *IDH2*$^{R140Q\ or\ R172K}$ had different prognostic effects on treatment outcome in these patients.

P816

SCREENING OF TP53 (TUMOR PROTEIN 53) MUTATIONS IN ADULT ACUTE MYELOID LEUKEMIA (AML) PATIENTS REVEALS A STRONG ASSOCIATION WITH COMPLEX KARYOTYPE AND POOR OUTCOME

A Ferrari[1,*], I Iacobucci[1], C Papayannidis[1], C Baldazzi[1], C Sartor[1], E Ottaviani[1], N Testoni[1], V Robustelli[1], M Perricone[1], C Venturi[1], MC Abbenante[1], V Guadagnuolo[1], A Padella[1], G Simonetti[1], F Cattina[2], D Russo[2], G Martinelli[1]
[1]Department of Experimental, Diagnostic and Specialty Medicine, Institute of Hematology "L. e A. Seràgnoli", Bologna, [2]University of Brescia, Hematology and BMT Unit, Brescia, Italy

Background: AML is a heterogeneous disease with various chromosomal aberrations. The karyotype at diagnosis provides important prognostic information that influences therapy and outcome. The *TP53* gene is the most frequently mutated gene in human tumors. The reported *TP53* mutation rate in AML is low (2.1%). In contrast, the incidence of *TP53* mutations in AML with a complex aberrant karyotype (CK-AML) is higher (69-78%).
Aims: to investigate the frequency and the prognostic role of *TP53* mutations in adult AML patients (pts) focusing the screening on subgroups of pts with chromosome abnormalities.
Methods: 106 adult AML pts with FAB-M0, M1, M2, M3, M4, M5, miscellaneous cytogenetic abnormalities and normal karyotype (nK-AML, 14/106 pts) were examined. Forty-four pts (41.1%) showed 3 or more chromosome abnormalities (CK-AML), 42 (39.6%) presented one or two cytogenetic abnormalities (other-AML) and in 6 cases the karyotype was not available. Genomic DNA and/or cDNA were isolated from mononuclear AML blast cells. *TP53* mutation screening was performed on all 106 AML pts, in particular in 42 from exon (ex) 2 to 11, in 48 from ex 4 to 11 and in 16 pts from ex 2 to 8. Analysis was focused on coding sequences (RefSeq GRCh37/hg19 NG_017013.2).
Results: By PCR and subsequent Sanger sequencing, mutations of *TP53* were detected in 23 pts (21.1%). Seven pts revealed 2 mutations. 83% of all mutated pts had CK (19/23) by contrast the frequency of mutations was very low in "no CK-AML" pts (6.5%). Overall, mutated patients included 19/44 with CK-AML (43.2%); 1/6 (16.7%) with nK and 3/42 (7.1%) with other-AML. 26 *TP53* point mutations [19 missense, 1 silent, 5 intron and 1 3' untranslated region (UTR)] and 4 *TP53* deletions were found. Twenty-six out of 30 mutations/deletions (86.6%) were located in the DNA binding domain, 2 in the carboxyl-terminal tetramerization and regulatory domains and 2 in the transcriptional activation domain. All mutations in coding regions were classified by the IARC database (http://p53.iarc.fr/TP53GeneVariations.aspx) as deleterious.Of note, alterations of TP53 were significantly associated with poor outcomes in terms of overall survival and disease free-survival (P<0.0001).
Summary and Conclusion: Our data demonstrated that mutations of TP53 occur in 21.7% of AML with a higher frequency in the subgroup of CK-AML (p<0.0001–Fischer's exact test). Since *TP53* mutations have predicted to be deleterious and significantly correlated with prognosis, *TP53* mutation screening should be recommended in CK-AML pts. Supported by: EuropeanLeukemiaNet, AIL, AIRC, PRIN 2010-2011, Fondazione del Monte di Bologna e Ravenna, European Union Seventh Framework Programme [FP7/2007-2013],Progetto Regione-Università 2010-12 (L.Bolondi).

P817

ADULT PATIENTS WITH ACUTE MYELOID LEUKEMIA (AML) WHO REQUIRE TWO COURSES OF INDUCTION THERAPY TO ACHIEVE COMPLETE REMISSION (CR) SHOULD UNDERGO ALLOGENEIC TRANSPLANT (ALLO-SCT) DURING THE FIRST CR

H Shimizu[1,*], H Handa[1], N Hatsumi[2], S Takada[2], A Yokohama[1], T Saitoh[1], T Sakura[2], Y Nojima[1]
[1]Gunma University, [2]Saiseikai Maebashi Hospital, Maebashi, Gunma, Japan

Background: Although primary induction failure has been considered as one of the strongest negative prognostic factors and an indication for allo-SCT in adult patients with AML, the definition of this subgroup has not been clearly established. It was reported that AML patients who were unable to achieve CR after the second induction therapy should proceed to allo-SCT, whereas the allo-SCT indication for patients in CR after two courses of induction therapy has not been elucidated. Therefore, we conducted this large-scale retrospective study to address this unresolved issue.
Aims: The aim of this study was to clarify the clinical course and the appropriate therapeutic strategy of adult AML patients who obtained CR after two courses of induction therapy.
Methods: Among 310 consecutive AML patients who received anthracycline plus standard-dose Ara-C as the initial induction therapy between the years 1990 and 2010, 231 patients (median age, 50 years; age range, 15–65 years) who achieved CR within two courses of induction chemotherapy were included in this study. The Fisher's exact test was used for comparison of binary variables. The Mann-Whitney U-test was used for comparison of continuous variables. Overall survival (OS) rates were estimated by the Kaplan-Meier method and compared using the log-rank test. The Cox proportional hazards regression model was used for multivariate analysis. P<0.05 was considered to represent statistical significance.
Results: Of the 231 AML patients involved in this study, 186 achieved CR after the initial induction therapy (CR-1), and 45 achieved CR after the second induction therapy (CR-2). There were no significant differences in the baseline characteristics, including age, cytogenetic risk groups, white blood cell (WBC) counts at diagnosis, and the number of patients undergoing allo-SCT, when comparing the CR-1 and CR-2 groups. The 5-year OS rate of the CR-2 group was significantly inferior to that of the CR-1 group (33% *vs*. 52%, respectively; p=0.02). Of the 205 patients who did not undergo all-SCT during the first CR, patients in the CR-2 group had a tendency towards a higher relapse rate when compared with the CR-1 group (79% *vs*. 64%, respectively; p=0.09). Notably, a significant difference in the second CR rates was observed when comparing the CR-2 and CR-1 group (36% *vs*. 74%, respectively; p<0.01). Of the 45

patients (median age, 50 years; age range, 18–65 years) in the CR-2 group, 27 patients received a standard-dose Ara-C regimen as the second induction therapy, and 18 received a high-dose Ara-C regimen. In univariate analysis for OS in the CR-2 group, only allo-SCT was extracted as a significant prognostic factor (5-year OS rates with or without allo-SCT: 49% *vs*. 17%, respectively; p<0.01), while age, cytogenetic risk groups, WBC count, and the type of the second induction therapy did not reach the level of statistical significance. Furthermore, the prognostic significance of allo-SCT was also confirmed within multivariate analysis.
Summary and Conclusion: These findings suggest that the CR-2 patients have inferior outcomes when compared with CR-1 patients, possibly due to the higher relapse rate and lower second CR rate. Because CR-2 patients who underwent allo-SCT achieved excellent outcomes, donor research should be started for adult AML patients who have not achieved CR after initial induction therapy. If a suitable donor and good disease control are available, patients should undergo allo-SCT, preferably in the first CR. This strategy requires confirmation via appropriate prospective study.

P818

ALLOGENEIC TRANSPLANT FOR ACUTE MYELOID LEUKEMIA: CUT OFF LEVELS OF WT1 EXPRESSION AND PRE-EMPTIVE THERAPY OF RELAPSE

A Bacigalupo[1,*], S Pozzil[1], C Di Grazia[1]
[1]Divisione Ematologia e Trapianto di Midollo, IRCCS San Martino-IST, GENOVA, Italy

Background: Leukemia relapse remains an unsolved problem for patients with acute myeloid leukemia (AML), undergoing an allogeneic stem cell transplant (HSCT). In a previous study (BJH 2013, 160:503) pre-emptive therapy with donor lymphocyte infusions (DLI) was triggered when the expression of WT1 on marrow cells, exceeded 180 copies x10^4 abl, with a marrow in remission. Survival was improved for patients receiving DLI, as compared to patients not receiving DLI (44% *vs* 14%, p=0.004). However, hematologic relapse was not significantly reduced for DLI patients (65% *vs* 74%). In the same study we also showed that 100 copies of WT1 was a better predictor of hematologic relapse.
Aims: Design of the study: We therefore asked whether pre-emptive therapy, triggered at a lower level of WT1 expression, (100 as opposed to 180 copies in the previous study) would be more effective in preventing leukemia relapse in AML post-HSCT.
Methods: Patients: 51 AML patients undergoing an allogeneic HSCT were studied: the median age was 43 years (17-74); the conditioning regimen was myeloablative in 92% of the patients. The donor was an identical sib (29%), a haploidentical family member (51%), an unrelated donor (13%) or an unrelated cord blood (7%). Patients were monitored for WT1 expression (x10^4 abl copies) on bone marrow cells, before and after transplant on days +30,+60, +90, +120, then every 2 months until 1 year and then at every outpatient visit. 2833). If WT1 expression exceeded 100 copies with a marrow in remission, the patient was eligible for pre-emptive therapy: this consisted of abrupt discontinuation of cyclosporine (CyA) and /or DLI.
Results: After HSCT WT1 expression was always<100 copies in 22 patients, and 4 relapsed (18%); it was between 101 and 179 copies in 19 patients, and 6 relapsed (31%); WT1 expression was over 180 copies in 10 patients, and 6 relapsed (60%) (p<0.001). The group we are interested is the one with WT1 expression between 101 and 179, since this was the group with the lower WT1 level triggering treatment.
Pre-emptive therapy: Of the 19 patients with WT1 101-179, 5 were non treated for several reasons: 4 relapsed. 14 patients received pre-emptive therapy (CyA discontinuation/DLI) and 2 relapsed (14%). We compared the relapse rate of these 14 patients treated at a WT1 cut off of 100, with the previous group treated at a WT1 cut off of 180 (BJH 2013): the relapse rate is significantly different (14% *vs* 64%, p=0.01) and survival is 86% *vs* 41% (p=0.01).
Summary and Conclusion: These data confirm our previous study, suggesting that WT1 levels post HSCT are predictive of hematologic relapse. In addition it seems that pre-emptive therapy triggered at a lower level of WT1 (100 copies) is more protective against leukemia relapse as compared to pre-emptive therapy triggered at a higher WT1 level (180 copies).

P819

THE PROGNOSTIC IMPACT OF CYTOGENETIC AND GENETIC ABNORMALITY FOR THE ACHIEVEMENT OF THE SECOND COMPLETE REMISSION IN ADULT PATIENTS WITH ACUTE MYELOID LEUKEMIA

K Fukunaga[1,*], H Yamaguchi[1], S Wakita[1], I Omori[1], S Yui[1], T Ryotokuji[1], T Hirakawa[1], K Arai[1], T Kitano[1], F Kosaka[1], K Dan[2], K Inokuchi[1]
[1]Division of Hematology, Department of Internal Medicine, Nippon Medical School, [2]Medical Education Center, Ryotokuji University, Tokyo, Japan

Background: Although, about 80% of patients with acute myeloid leukemia (AML) achieve first complete remission (CR1) with induction chemotherapy, after relapse, the probability of achieving a second complete remission (CR2) becomes lower. Concerning the allogeneic hematopoietic stem cell transplantation (Allo SCT) for patients with AML after first relapse, their prognoses are greatly different whether they are in CR2 or not. Several studies revealed that age, relapse-free interval, cytogenetic risks and previous allo SCT were independent prognostic factors for patients with AML after first relapse. Recently prognostically important mutations have also been identified, but the gene mutation affecting the CR2 rate is not still clear. In this study we analyzed the prognostic impact of gene mutations for the achievement of CR2 in adult patients with AML.
Aims: The purpose of this study is to clarify prognostic impact of gene mutations for the achievement of CR2 in adult patients with AML.
Methods: We retrospectively analyzed 64 patients of de novo AML who relapsed after treatment with conventional chemotherapy alone at Nippon Medical School Hospital and its affiliated facilities from 2000 to 2010. We excluded the patients received AlloSCT in CR1 and the patients with M3 in FAB classification. Bone marrow or peripheral blood samples containing 20% or more blast cells at diagnosis and first relapse were used for analyses. Mutation analyses were performed using PCR method for *FLT3-ITD*, *FLT3-TKD* and *MLL-PTD*, and direct sequence for *NPM1*, *C/EBPα*, *DNMT3A*, *IDH1/2*, *TET2* and *N/K-RAS*.
Results: The CR2 rate with the salvage chemotherapy for AML after first relapse was 30/64 (46.9%). The significant difference was not found in clinical and laboratory data such as age, white-cell count, percentage of blast cells, serum lactate dehydrogenase value at both initial diagnosis and first relapse between CR2 group and non-remission group. The patients with FAB classification M4E (5/5, 100%: p=0.02), inv(16) (4/4, 100%: p=0.04), and favorable karyotypes (14/19, 73.7%: p<0.01) attained significantly high CR2 rate. Although *FLT3-ITD* is known to be a poor prognosis, the CR2 rate was not significantly different whether the mutation was present or not at diagnosis. However the CR2 rate of the patients with *FLT3-ITD* at first relapse was significantly lower than the patients without it (1/11, 9%: p<0.01). Concerning the mutations of epigenetics modifying genes such as *DNMT3A*, *IDH1/2*, and *TET2*, the CR2 rate of the patients with *DNMT3A* mutation at diagnosis tend to be lower (2/8, 25%; p=0.07), Intriguingly, the CR2 rate of the patients with the mutations of epigenetics modifying genes at diagnosis as a whole was significantly lower than without them. (3/11, 27%; p=0.05).
Summary and Conclusion: Although our results showed *FLT3-ITD* at diagnosis could not predict the achievement of CR2, mutations of epigenetics modifying genes at diagnosis could predict it. We recently showed that the possibility that mutations in epigenetics modifying genes may cause genetic instability and induce *FLT3-ITD* mutations, leading to resistance to therapy and relapse (Leukemia. 2013;27(5):1044-52). Moreover, the 3 cases in which *FLT3-ITD* were observed only at relapse may have low level FLT3-ITD at diagnosis undetectable by standard method. Now we developed a highly sensitive mutation detection method known as Mutation Biased PCR (MB-PCR) and are now performing re-analyses of the relationship between *FLT3-ITD* at diagnosis and CR2.

P820

COMPREHENSIVE GENETIC CHARACTERIZATION OF AML CELL LINES AND CLINICAL SAMPLES USING A NOVEL AML TARGETED SEQUENCING STRATEGY

A R Carson[1,2,*], B A Patay[2], S M Graham[2], AR Cubbon[3,4], J E Miller[1,2,3,4]
[1]Invivoscribe Technologies, Inc., [2]Genection, Inc., San Diego, United States, [3]LabPMM GmbH, Martinsried, Germany, [4]LabPMM LLC, San Diego, United States

Background: Next generation sequencing (NGS) has revealed much of the common genomic architecture of Acute Myeloid Leukemia (AML). However, the high cost of NGS and its interpretation limits specificity and coverage in most sequencing strategies. This prevents broad adoption of NGS for characterizing AML samples and cell lines. Instead, investigators use more limited assays that fail to fully characterize complex variants such as structural variants and internal tandem duplications in *FLT3*. Complete characterization of variants in AML cell lines and clinical samples is essential to understand disease development and progression. In cell lines, accurate mutation identification is critical for their use in modeling cancer pathogenesis, developing therapeutics, and standardizing diagnostic performance. Similarly, mutations and their consequences need to be precisely defined in clinical samples to correctly stratify disease types and select appropriate treatments or clinical trials. Furthermore, understanding mutations in the context of clonal architecture may prove crucial for personalized therapies.
Aims: To illustrate the increased capacity and resolution of a novel NGS AML targeting strategy for the comprehensive characterization of AML samples via a sequence analysis of the "AMLome" (a complement of 194 genes known or predicted to be involved in AML pathogenesis) of AML cell lines and clinical samples.
Methods: We targeted coding exons (from 171 genes in version 1; 194 genes in version 2) and potential genomic breakpoints within known somatic gene fusions (34 genes in version 1; 36 genes in version 2) comprising the MyAML™

gene panel. We sequenced target loci on the Illumina MiSeq platform to an average depth of coverage >350x for cell lines (using MyAML™ version 1) and >500x for clinical samples using (MyAML™ version 2). Using a custom bioinformatics pipeline, we performed thorough mutation detection analyses to identify single nucleotide variants (SNVs), indels, inversions and translocations. In addition, we calculated allelic frequencies to investigate potential aneuploidy and clonality.

Results: Analyses of targeted sequencing results from 12 AML cell lines identified the published genomic variants within MyAML™ targeted genes. These variants were more fully characterized for their precise genomic breakpoints and inserted sequence content. For example, in cell line MV4-11, both the t(4;11) translocation and 30bp *FLT3* internal tandem duplication were accurately detected and their sequences and breakpoints were fully characterized. Previously unreported genomic variants were detected that have the potential to significantly impact interpretations from experiments using these cell lines. These mutations include potential activating missense SNVs in oncogenes, damaging missense SNVs and frameshift indels in tumor suppressors and translocations creating possible fusion genes. Based on our results from AML cell lines, we extended our analyses to AML clinical samples. From these samples, we identified and characterized both previously reported and novel mutations.

Summary and Conclusion: By specifically targeting the AMLome using the MyAML™ gene panel, we can comprehensively characterize mutations within AML cells. Our results also suggest that this strategy can be utilized for the characterization of both AML cell lines and clinical samples with the potential to identify hitherto undetected therapeutic targets.

P821

PROGNOSTIC VALUE OF MINIMAL RESIDUAL DISEASE BEFORE ALLOGENEIC MARROW TRANSPLANTATION IN ACUTE MYELOID LEUKEMIA BY COMBINEDWT1 EXPRESSION LEVELS AND FLOW CYTOMETRY ASSESMENT

F Guolo[1,*], P Minetto[1], F Galaverna[1], L Giannoni[1], C Ghiggi[2], M Clavio[1], G Beltrami[2], A Ibatici[2], C Di Grazia[3], AM Raiola[3], L Mitscheunig[1], R Grasso[1], N Colombo[1], E De Astis[1], D Avenoso[1], F Cruciani[1], D Lovera[1], G Pastori[1], F Ballerini[1], S Aquino[1], A Kunkl[1], M Miglino[1], R M Lemoli[1], M Gobbi[1], A M Carella[2], A Bacigalupo[3]
[1]Clinical Hematology, [2]Hematology 1, [3]Bone Marrow Transplantation Unit, IRCCS AOU San Martino Hospital-IST, Genova, Italy

Background: Allogeneic bone marrow transplantation (BMT) offers the greatest chance of cure for most patients affected by acute myeloid leukemia (AML). Persistence of disease or high levels of pre BMT minimal residual disease (MRD) have been reported to predict disease relapse after BMT.WT1 expression levels and multicolor flow cytometry (MFC) are widely used as markers of MRD.We recently reported that combined evaluation of MRD by WT1 and MFC after induction therapy has a strong impact on relapse risk in AML patients.

Aims: The aim of the present study was to apply the same MRD assessment in pre BMT setting to evaluate its reliability in predicting relapse.

Methods: We retrospectively analyzed BMT outcome of 66 AML patients with both WT1-based and MFC-based MRD evaluation on bone marrow samples before transplant. Median age at transplant was 44 years. Forty-two patients were transplanted in first and 24 in second or subsequent complete remission. Induction regimens included fludarabine-containing regimens or standard "3+7" induction. Median follow-up was 24 months (range 1-117 months). Disease-free survival (DFS) was calculated from the time of transplantation until last follow-up or documented leukemic relapse. A positive MFC MRD was defined by the presence of no less than 25 clustered leukemic cells /10^5 total events (threshold of $2.5x10^{-4}$ residual leukemic cells) at four-color flow-cytometry. Real-time PCR for WT1 was performed on DNA Engine 2 (Opticon®, MJ Research®). WT1 copy number/Abl copy number $1000x10^4$ was used as cut-off value for high WT1 expression.

Results: Twenty-five relapses (37.9%) were observed. Median DFS was 31 months. Our preliminary analysis shows that the probability of disease relapse was significantly influenced only by disease status (first or subsequent CR) and MRD status at transplantation. Specifically, MFC-MRD was the strongest predictor of longer disease free survival ($p<0.001$) since no relapses occurred in the eleven MFC-MRD negative patients. Among MFC-MRD positive patients a further stratification of risk is obtained by the evaluation of WT1 MRD status that was able toidentify patients with significantly worse DFS. ($p<0.01$, fig.1).The predictive value of MRD resulted independent from different induction schedules; furthermore undergoing BMT in second or subsequent remission did not affect the positive prognostic value of gaining a negative MRD status.

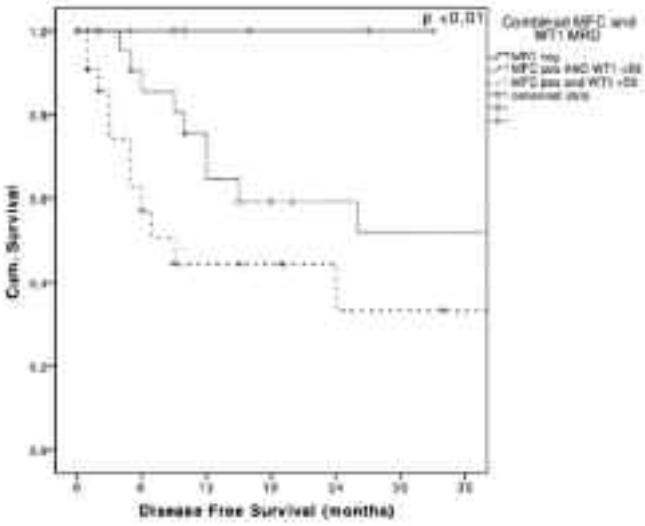

Figure 1.

Summary and Conclusion: Pre BMT evaluation of MRD by WT1 and MFCon bone marrow samples is a reliable predictor of relapse risk. Patients with negative pre-BMT MRD have a significantly longer DFS, while patients with both MRD markers display an higher risk of relapse.Identifyingpatients athigher risk may allow to modulate post BMT follow up, to detect earlier disease recurrence and perhaps to apply pre-emptive therapeutic strategies in order to delay or avoid AML relapse.

P822

VALIDATION OF SIE/SIES/GITMO "FITNESS CRITERIA" FOR ELDERLY PATIENTS WITH ACUTE MYELOID LEUKEMIA: APPLICABILITY AND OUTCOME ANALYSIS ACCORDING TO FITNESS AND TO TREATMENT RECEIVED

E Borlenghi[1,*], C Pagani[1], E Cerqui[1], M Petullà[1], C Lamorgese[1], C Cattaneo[1], A Passi[1], F Antoniazzi[1], F Schieppati[1], P Tozzi[1], G Rossi[1]
[1]Hematology, Spedali Civili, BRESCIA, Italy

Background: Acute myeloid leukemia (AML) is a disease of the elderly with a median age of 69-72 years (y) in population studies (SEER, 2012; Juliusson, 2009). Because of the adverse biologic features of leukemia and the high frequency of comorbidities that reduce patients (pts) tolerance it is difficult to find a balance between treatment efficacy and pts safety. In 2013, SIE/SIES/GITMO experts proposed objective criteria to define pts "fitness" to conventional intensive chemotherapy (i-CT) or non-intensive chemotherapy (ni-CT) as a tool for therapy decision making (Ferrara, Leukemia, 2013).

Aims: The applicability and the adherence to these "fitness criteria" in clinical practice as well as the outcome according to "fitness" and treatment received were evaluated in a consecutive series of AML pts (no M3).

Methods: From Jan 2008 to Sep 2012, 141 patients aged >65 y were diagnosed at our Institution. Median age was 74 y (range 65-88 y), 43% were >75 y. ECOG PS was evaluable in 130 pts (93%) and was >3 in 33 (23%). The classification according to "fitness criteria" was performed through review of electronic medical records. ELN prognostic criteria were also applied to 88 "de novo" AML: 15 (17%) favorable, 28 (32%) intermediate-I, 8 (9%) intermediate-II and 37 (42%) adverse risk. ELN criteria were not applicable in 16 pts (15%) with missing karyotype. Therapy-related or secondary AML (37 pts: 26%) were defined as adverse clinical risk. According to institutional policy, favorable and intermediate-I pts had received i-CT. Ni-CT with low-dose arac, azacytidine or experimental non-myelotoxic drugs, was given to the other pts. Pts with major comorbidities received best supportive care (BSC).

Results:

Table 1.

	i-CT	ni-CT	BSC
Total	30 (22%)	26 (19%)	82 (59%)
Fit (55 pts, 40%)	26 (47%)	12 (22%)	17 (315)
Unfit (67 pts, 49%)	4 (6%)	12 (18%)	51 (76%)
Frail (16 pts, 12%)	0	2 (12.5%)	14 (87.5%)

"Fitness criteria" could be retrospectively applied in 138/141 pts (98%): 55 pts (40%) were fit to i-CT (FIT), 67 pts (48.5%) unfit to i-CT (UNFIT), 16 (11.5%) unfit to ni-CT (FRAIL). Thirty pts (21.5%) had actually received i-CT, 26 (18.5%) ni-CT and 85 (60%) BSC. Treatment intensity distribution across different "fitness" groups is shown in table 1. Overall, median survival (OS) in FIT, UNFIT and

FRAIL pts was 11, 4 and 3.5 months (p 0.0001). Across all fitness groups, the higher the treatment intensity the longer was OS. In FIT pts treated with i-CT, ni-CT and BSC, median OS was 22, 9.5 and 4 months, (p<0.0001); in UNFIT pts 16, 9.5 and 2 months, respectively (p<0.0001). In FRAIL pts treated with ni-CT or BSC, OS was 9 and 2 months, respectively (p:NS) (Fig. 1). Considering adherence to "fitness" criteria, only 4 UNFIT (6%) and 2 FRAIL (12,5%) pts were actually overtreated, with i-CT or ni-CT. Their median OS (15 mo.) was better than expected. Four of them had ELN low-int-1 risk *vs* 5/22 treated adhering to fitness criteria (P<.05). Among FIT pts, 53% were actually undertreated (ni-CT 22% or BSC 31%); they belonged more often to ELN or clinical adverse groups (85% *vs* 10%; P<.001). Among undertreated pts OS was significantly better in pts receiving ni-CT than BSC, in spite of similar distribution among ELN risk groups. Among UNFIT pts, 76% were undertreated with BSC and fared worse than patients receiving ni-CT in spite of similar ELN risk.

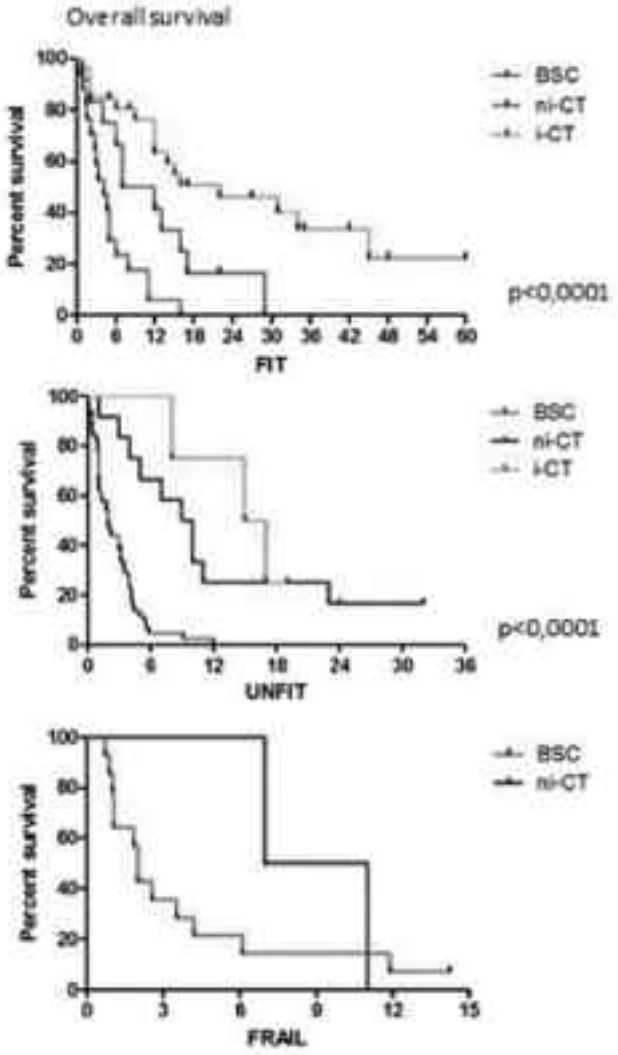

Figure 1.

Summary and Conclusion: The "fitness criteria" were easily applicable also retrospectively in the majority of AML pts. Intensity of care seems to favourably impact on outcome across all "fitness" categories. Particularly UNFIT ELN low-int risk patients should be offered i-CT, whereas undertreatment with ni-CT/BSC in FIT pts or BSC in UNFIT pts should be avoided. Further multicenter studies are needed to validate these data.

P823

C-KIT MUTATION IN CORE BINDING FACTOR ACUTE MYELOID LEUKEMIA: PREVALENCE AND PROGNOSTIC ROLE IN TAIWAN. EXPERIENCE OF ONE SINGLE INSTITUTION

L Lee[1,*], TJ Chiou[1], JP Gau[1], PM Chen[1], LT Hsiao[1]
[1]Hematology, Veteran general hospital of taipei, Taipei, Taiwan, Republic of China

Background: Core-binding-factor acute myeloid leukemia (CBF-AML) include those with t(8;21) and inv16, and is associated with a favorable prognosis. However, the up-to 40% of these cases harbor *c-KIT* mutations mainly involving exon 8 and 17, and are shown associated with a poor prognosis, and proper post-remission therapy in this group of patients is still not clear.

Aims: Current study is to examine the benefit of different post-remission therapy in patients with CBF-AML and c-KIT mutations.

Methods: For de novo AML patients diagnosed between 1999 and 2011 in Taipei Veterans General Hospital, those with cytogenetic abnormalities at diagnosis including (8;21) and inv16 and/or having fusion genes - AML1-ETO and CBFβ-MYH11 were identified, among whom those with archived DNA of bone marrow at diagnosis and relapse were enrolled. The data - clinical features, treatment modalities including post-remission therapy and outcome were collected. Mutation analysis of c-KIT gene was performed using exon-specific PCR and additional treatments by restriction enzymes (exon 17 D816 and N822). In addition, they were further validated by direct sequencing and cloning in selected cases. The impact of c-KIT mutations was analyzed comparing clinical features and outcome including overall (OS) and relapse free survival (RFS) of CBF-AML patients with wild *vs*. mutated c-KIT.

Results: There were 40 patients (male/female=27/13, median age=36 years) enrolled, including t(8;21)/AML1-ETO and inv(16)/CBF-MYH11in 31 (77.5%) and 9 cases (22.5%), respectively. At diagnosis, 12 patients (30%) had c-*KIT* mutation at diagnosis including 10 (32.3% of 31) and 2 (22.2% of 9) in patients with t(8;21)/AML1-ETO and inv(16)/CBFβ-MYH11, respectively. In the t(8;21)/AML1-ETO subgroup, the mutations involved exon 8 (2 cases, 6.4%), exon 17 (8 cases, 25.9%; included mutations at D816 [n=5] and N822 [n=3]) and, in the inv(16)/CBFβ-MYH11 one, they involved exon 8 mutation (2 cases) only. In terms of clinic-hematologic features at diagnosis, there was no significant difference comparing those with wild and mutated *c-KIT,* except for a male predominance in the c-KIT wild patients (*P*=0.027). 32 patients (80% of 40) received induction chemotherapy and 27 patients (84.4%) achieved complete remission. Post-remission therapy were usually given with 2-4 cycles of high-dose cytarabine, and in addition, hematopietic stem cell transplantation (HSCT) was further given in 14 patients, including autologous and allogeneic in 2 and 12 patients (sibling/unrelated donors=7/5), repectively. At the last follow, 20 patients were alive with median OS 23.0 months (range, 0.8 ~ 115 months). In terms of prognostic impact, the difference of OS and CR rate is not significantly different between patients with wild and mutated c-KIT at diagnosis. In patients who received induction chemotherapy and achieved CR, mutated *c-KIT* CBF-AML had a shorter RFS [median RFS: 74 months in wild type c-KIT, 6.6 months in exon 8 mutation, 5.4 months in exon 17 (D816) mutation and 2.5 months in exon 17 (N822) mutation, p=0.015]. For Patients with mutated *c-KIT* mutation, who received HSCT had a trend for longer RFS (9.2 months *vs*. 5.3 months, *P*=0.082), especially for those receiving allogeneic HSCT. In Cox regression analysis, Initial high white blood cell (WBC) count and mutated c-KIT were independent poor risk factors in terms of relapse free survival.

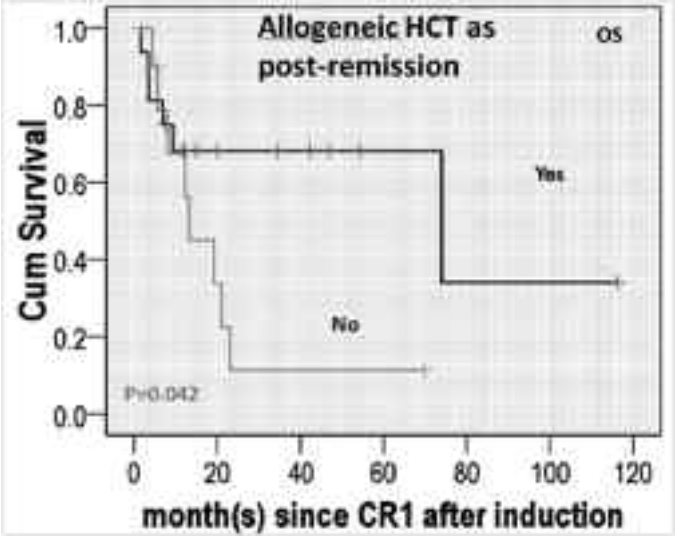

Figure 1.

Summary and Conclusion: CBF-AML with *c-KIT* mutations confers inferior RFS, which is possibly overcome by the use of HSCT as post-remission therapy, especially for allogeneic ones. The screen of *c-KIT* mutation status at diagnosis of CBF-AML is highlighted.

P824

ADVERSE PROGNOSTIC IMPACT OF IDH MUTATIONS ON OUTCOME IN ACUTE MYELOID LEUKEMIA WITH NORMAL KARYOTYPE

M Virijevic[1,*], N Suvajdzic Vukovic[1,2], I Djunic[1], N Tosic[3], A Novkovic[4], N Colovic[1,2], A Vidovic[1,2], S Pavlovic[3], D Tomin[1,2]

[1]Clinic of Hematology, Clinical Center of Serbia, [2]Faculty of Medicine, University of Belgrade, [3]Institute of Molecular Genetics and Genetic Engineering, University of Belgrade, [4]Clinical-hospital Center Zemun, Belgrade, Serbia

Background: Recent studies showed that the isocitrate dehydrogenase 1 (IDH1) and IDH2 mutations are associated with high risk of relapse and shorter survival in patients with acute myeloid leukemia with normal karyotype (AML-NK). They also confer adverse prognosis in the subset of AML-NK patients identified as NPM1-mutated/ FLT3 internal tandem duplication (ITD) negative.
Aims: To assess the incidence and clinicopathological features of *IDH1*/*IDH2* mutations, and to analyze the prognostic impact of IDH1/IDH2 mutations on overall survival (OS), complete remission rate (CR), early death (ED) rate and disease-free survival (DFS) in *de novo* AML-NK patients.
Methods: Diagnostic bone marrow samples from 110 adult *de novo* AML-NK patients were analyzed for *IDH1* and *IDH2* mutations by DNA polymerase chain reaction amplification/sequencing. All of the patients (median age 52 years, range 19-78; male/female 62/48; median follow-up 48 months) were managed at the Clinic of Hematology from 2009 to 2013 according to the Medical Research Council (MRC) 10 protocol. Statistical analysis included: the Fisher exact test, chi-square test and Kaplan-Meier method.
Results: *IDH* mutations were found in 26 (21.7%) patients: *IDH1*- 9 patients (7.5%); *IDH2* - 17 patients (14.2%). IDH1 mutation was associated with higher white blood cell (WBC) count (p=0.050), concomitant NPM1 mutation (p=0.050) higher ED rate (p<0.001) and lower CR rate (p=0.010). IDH2 mutation was associated with older age (p=0.050) and higher peripheral blood blast percentage (p=0.002). ED rate in our series was (20/108) 18.5%. Risk factors for ED by univariate analysis were higher WBC count (p=0.023), IDH1 mutation (p<0.001) and *IDH1*/*IDH2*+ status[1] (p=0.003). Multivariate analysis identified *IDH1*/*IDH2*+ status as independent prognostic factor for ED (p=0.001 HR 2.486 95%CI: 1.480-4.176). In addition, our *IDH1*/ *IDH2*+ patients had shorter OS (1 *vs* 9 months; p<0.001) and shorter DFS (11 *vs* 18 months; p=0.036) in comparison with patients without IDH mutations. Similarly, our *IDH1*/ *IDH2*+ patients had a lower CR rate compared to AML patients without IDH mutations (28% *vs* 63.9%; p=0.002). The subset of our patients identified as *NPM1*-mutated/*FLT3* ITD$^-$ with concurrent IDH1 mutation had lower CR rate compared to the counterpart without IDH1 mutation (12.5% *vs* 71.4%, p=0.024), higher ED rate (75% *vs* 16.7%, p=0.046), shorter OS (0 *vs* 6 months p=0.007) and shorter DFS (2 *vs* 7 p=0.036).
Summary and Conclusion: The study confirmed that *IDH1* and *IDH2* mutations confer poor prognosis in AML-NK patients regarding OS, DFS, CR and ED rate. In addition, IDH1 mutations confere poor prognosis even in the subset of the molecular low-risk group such as NPM1-mutated/FLT3-ITD negative patients.

Background: Diagnosis of acute myeloid leukemia (AML) at an elderly age generally predicts poor clinical outcomes. Elderly acute myeloid leukemia (AML) patients usually have a bad prognosis. Because the most treatment strategies are the result of came out from the data of studies in younger patients, those strategies cannot be directly applied to elderly patients. The exact benefit of induction and consolidation therapy in elderly AML patients has not yet been confirmed in elderly AML patients by randomized clinical trials.
Aims: This study aimed to find the role of induction and consolidation therapy in elderly patients.
Methods: We retrospectively collected data of 477 patients who were aged over 60 years at the time of AML diagnosis. Patients were divided into 2 groups.
Results: The induction group (n=266) included patients who received intensive induction treatment, and the best supportive care (BSC) group (n=211) received low-dose cytarabine or another conservative treatment. In the induction group, the complete remission (CR) rate was 58.3%, and treatment-related death was 15.4%. A factor associated with achievement of CR was good performance status (Eastern Cooperative Oncology Group [ECOG]<2) (hazard ratio [HR] 3.215; 95% confidence interval [CI], 1.508–6.853; *P*=0.002). The median overall survival was 339 days in the induction group and 86 days in the BSC group (*P*<0.001). In the induction group, failure to achieve CR (HR 4.059; 95% CI, 2.398–6.949; *P*<0.001) and poor performance status (ECOG >2) (HR 2.731; 95% CI, 1.073–6.949; *P*=0.035) were significantly associated with mortality. In the BSC group, bone marrow blasts (≥ 50%) (HR 1.965; 95% CI, 1.049–3.681; *P*=0.035) and poor risk karyotype were associated with mortality (*P*=0.004). Among patients who achieved CR, poor karyotype (HR 1.767; 95% CI, 1.018–3.067; *P*=0.043) and not receiving consolidation therapy (HR 2.313; 95% CI, 1.333–4.011; *P*=0.003) were related to mortality. At least more than 1 cycle of consolidation chemotherapy was associated with a better median OS (1 cycle: 471 days *vs*. >1 cycle: 847 days; *P*<0.001). In patients who failed to achieve CR, lack of salvage therapy was associated with mortality (HR 3.223; 95% CI, 1.426–7.285; *P*=0.005).

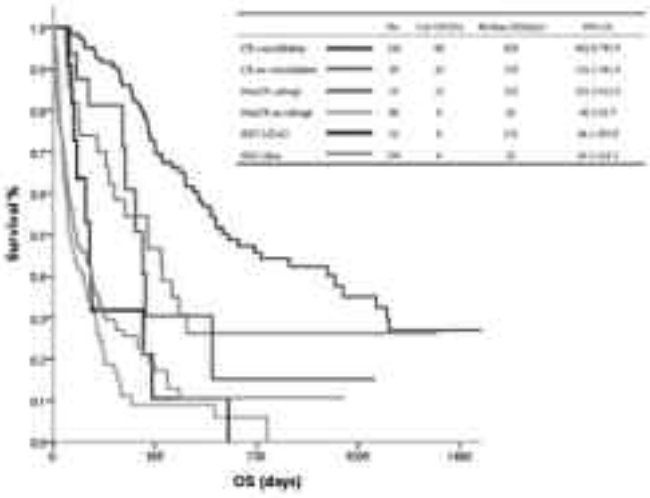

Figure 1.

Summary and Conclusion: In conclusion, appropriate induction chemotherapy for elderly AML patients with good performance status and more than 1 cycle of consolidation chemotherapy for patients who achieve CR are the best treatment strategies for improving OS in this patient population.

P826

COMBINED USE OF MULTI-COLOR FCM AND PCR ANALYSIS CAN DETECT LESS THAN 0.01% PATHOLOGICAL CELLS IN THE VAST MAJORITY OF DE NOVO AML CASES

Y Kazuma[1,*], H Maruoka[2], Y Ochi[1], Y Koba[1], Y Nagahata[1], J Takeda[1], N Yamauchi[1], Y Funayama[1], Y Ono[1], N Hiramoto[1], S Tabata[1], N Yonetani[1], A Matsushita[1], T Ishikawa[1]
[1]Department of Hematology, [2]Department of Clinical Laboratory, Kobe City Medical Center General Hospital, Kobe, Japan

Background: A large proportion of acute myeloid leukemia (AML) patients achieve complete remission (CR); however, half of them ultimately relapse. Several retrospective studies show that monitoring minimal residual disease (MRD) can identify those patients at high risk of relapse. Both polymerase-chain reaction (PCR)- and flow cytometry (FCM)-based methods have been used to detect MRD. Although the recent introduction of multi-color (4–10 color) FCM has enabled more sensitive detection of AML than conventional 3-color FCM, it still cannot reproducibly detect MRD in the bone marrow of a significant proportion of patients, especially of those whose blasts lack CD34 antigen.
Aims: To develop strategies to detect MRD in the majority of AML patients.
Methods: PCR of disease-specific transcripts was used to detect MRD in acute promyelocytic leukemia (APL) and core binding factor leukemia (CBFL) patients. For other AML, two types of MRD assay were performed. One method detected leukemia-associated immunophenotypes (LAIPs). LAIPs were examined at the time of diagnosis using six or eight monoclonal antibody (MAb) panels comprising 26 or 32 different MAbs, respectively, and by 6-color FCM. For those patients with LAIPs, MRD was monitored using a patient-specific MAb panel. The second method involved PCR amplification of the nucleophosmin-1 (NPM-1) mutation. The presence or absence of the NPM-1 mutation was examined at the time of diagnosis and nucleotide sequencing was

performed if the mutation was detected. MRD was monitored in a real-time PCR assay using patient-specific probes. The limit of detection in above-mentioned MRD assays reached less than or equal to 0.01%.
Results: Between October 2010 and December 2013, 81 consecutive patients with de novo AML were tested for MRD. The median age of the patients was 63 years, and 19 (nine with APL and ten with CBFL) harbored disease-specific fusion transcripts. Of the remaining 62 patients, 53 (85.5%) had distinctive LAIPs. The most common LAIPs were characterized by abnormal antigen expression (lineage infidelity); for example, the expression of CD200, CD96, CD7, CD25 and CD56 on CD34-positive blasts. The NPM-1 mutation was detected in 19 out of 62 patients. Of 32 patients whose blasts expressed the CD34 antigen, 31 had LAIPs and one harbored the NPM-1 mutation. By contrast, of the 30 patients whose blasts lacked CD34, 22 had LAIPs and 18 harbored the NPM-1 mutation. When three MRD assays were combined, all patients but one harbored targets for MRD monitoring. A patient did not show disease-specific transcript, LAIPs nor the NPM-1 mutation. Morphological complete remission (CR) was achieved in 49 patients after induction chemotherapy. MRD assays using bone marrow cells performed at the time when CR had just obtained revealed residual AML cells in all patients. 19 patients harbored disease-specific transcripts and 13 patients showed mutated NPM-1 transcript. Multi-color FCM analysis of 26 patients who possessed LAIPs and entered in morphological CR revealed MRD in every patients. The limit of detection in multi-color FCM was confirmed to be 0.01%.
Summary and Conclusion: Combined use of PCR and FCM can enables us to detect MRD at a level of 0.01% in the vast majority of AML.

P827

INDOLEAMINE 2,3-DIOXYGENASE-1 (IDO-1) IS ASSOCIATED WITH HIGH INCIDENCE OF CHEMOREFRACTORY DISEASE IN ACUTE MYELOID LEUKEMIA (AML) PATIENTS

S Parisi[1,*], S Trabanelli[1], D Ocadlikova[1], S Paolini[1], C Papayannidis[1], E Ottaviani[1], G Martinelli[1], M Cavo[1], A Curti[1]
[1]Hematology, Bologna, Italy

Background: Indoleamine 2,3-dioxygenase (IDO) is a heme-containing enzyme that catalyzes the first and rate-limiting step in tryptophan degradation along the kynurenine pathway. IDO is able to inhibit T-cell function and to induce the transformation of T-cells into regulatory T-cells. Several studies demonstrated that IDO expression is involved in immune tolerance induction during pregnancy, infection, transplantation, autoimmune diseases and neoplasias, including acute myeloid leukemia (AML). In particular, our and other groups demonstrated IDO expression in a significant proportion of AML patients and that it increases along with disease progression.
Aims: Here, we addressed the correlation between IDO expression by AML cells, risk factors at diagnosis and patients' outcome.
Methods: Adult AML patients from the Hematology Institute "L. and A. Seràgnoli" in Bologna were analyzed for risk characteristics at diagnosis and for IDO expression by RT-PCR and by Western-Blot analysis. Patients were stratified according to age at diagnosis, d*e novo* or secondary disease (pre-existing myelodysplastic syndrome or radio-chemotherapy), leucocytosis, cytogenetics (on the basis of cytogenetic characteristics patients were divided into low, intermediate and high risk groups) and FLT3 and NPM mutational status.
Results: Fifty-two patients with AML at diagnosis were analyzed for IDO expression both at gene and protein level. According to IDO transcript levels, the patients were divided into IDO-negative (21%) and IDO positive (79%). Positive patients were further subdivided into three different subgroups according to the IDO level: IDO-low expression (78%), IDO-intermediate expression (10%) and IDO-high expression (12%) patients. When IDO protein was assessed, we found a correlation between IDO mRNA level and the detection of IDO protein. In particular, IDO protein was detectable only in IDO-high-expressing patients. No statistically significant differences in the recurrence of prognostic characteristics at diagnosis between the groups considered were observed, even though IDO-negative and IDO-low expressing patients showed a higher median age at diagnosis than those expressing IDO at low and intermediate level and an increased frequency of high-risk cytogenetics was found in IDO-high expressing patients. Response to induction chemotherapy regimen was then analyzed among the four groups of patients. Only patients who received cytotoxic chemotherapy were evaluated for response. Intriguingly, we found that refractory patients were 60% among patients who express IDO at high level and 27% among IDO-negative patients.
Summary and Conclusion: In conclusion, IDO-high expressing patients show an increased proportion of refractory disease than IDO negative patients. To support our preliminary findings, a multivariate analysis on a larger cohort of patients is currently ongoing.

P828

MINIMAL RESIDUAL DISEASE IN ACUTE MYELOID LEUKEMIA DETECTED BY WILMS TUMOR GENE 1 EXPRESSION AND MULTIPARAMETER FLOW CYTOMETRY

C Frairia[1,*], S Aydin[1], L Riera[2], S Aliberti[2], B Allione[1], E Audisio[1], D Stefano[1], A Demurtas[2], P Francia di celle[2], B Nicolino[1], C Pecoraro[1], A Stacchini[2], F Marmont[1], U Vitolo[1]
[1]Oncology and Hematology, [2]Pathology, Città della Salute e della Scienza, TURIN, Italy

Background: Evaluation of minimal residual disease (MRD) in acute myeloid leukemia (AML) is an important strategy to asses therapy response. Several techniques have been investigated for an accurate MRD detection. Recently, beside multiparameter flow-cytometry (MFC), Wilms Tumor gene 1 (WT1) expression was suggested to reflect MRD. However, despite its potential role, at the moment there is no consensus on its clinical application.
Aims: Aim of this study was to investigate the role WT1 expression and leukemia associated immunophenotype (LAIP) in MRD assessment after intensive induction chemotherapy.
Methods: A total of 137 clinically and molecularly well characterized consecutive AML patients were treated from 2008 to 2013 with intensive induction chemotherapy according to age, performance status and co-morbidities in a single hematology center. Therapy response was defined according to ELN criteria. WT1 expression by real time polymerase chain reaction (RT-PCR), using the standardized European LeukemiaNet method, and LAIP using a six (19 patients) or eight (118 patients) colour multi parameter flow-cytometry (MFC) were performed on bone marrow samples at diagnosis and after induction chemotherapy. LAIP was defined as positive when ≥ 1 leukemic cell per 10^4 of normal cells was detected. Both parameters were compared with clinical and therapy related variables of the patient cohort. Disease-free survival (DFS) was studied by Kaplan-Meier analysis and the statistical difference between the curves was quantified by the Wilcoxon test.
Results: Ninety-seven patients (71%) achieved a complete remission after induction chemotherapy, whereas 34 patients (25%) were non responders and 6 (4%) died. WT1 expression at diagnosis was determined in the bone marrow of all patients with a mean value of 12952 copies (range 2-83200 copies) and repeated after induction chemotherapy in 94 patients (69%) with a mean value of 1601 copies (range 0-29274 copies). Twenty-two patients with high WT1 expression (≥250 copies) after induction chemotherapy showed a significantly reduced DFS with a median of 36 months (range: 2-44) compared to 64 patients with low (<250) WT1 expression showing a median DFS of 57,9 months (range: 3-63), p=0.00057. Moreover, after induction chemotherapy a MFC was performed in 96 patients resulting in 77 assessable LAIP; 57 becoming negative and 20 remaining positive. Next, the level of LAIP was compared with DFS. Fifty-seven patients with positive LAIP after induction chemotherapy had a significantly shorter DSF than patients with a negative LAIP with a median of 18,5 *vs* 36,3 months, respectively (p=0,04).
Summary and Conclusion: In conclusion, the patient subgroup that failed to obtain a significant reduction of bone marrow WT1 expression after induction chemotherapy showed a significantly shorter DFS than the subgroup with a negative post-treatment WT1 level. Similar results were achieved measuring bone marrow LAIP expression after induction therapy. Patients with a still positive LAIP had a significantly shorter DFS than patients becoming negative, although the statistical significance was not that strong as in the analysis of WT1 expression.These results may encourage the consideration of WT1 expression beside LAIP in the bone marrow as an important MRD tool in therapy response evaluation and therefore risk stratification of AML patients.

Background: The prognostic interest of cytogenetic remission (CyCR) and Fluorescence *in situ* (FISH) evaluation in patients treated for Acute Myeloid Leukemia and who reached complete remission have been poorly studied.
Aims: To evaluate the prognostic value of CyCR and FISH evaluation in AML patients who reached cytological CR after one induction cycle.
Methods: 198 intensively treated AML patients with abnormal karyotype, who reached cytological CR and were evaluated with conventionnal G banding cytogenetic method after one course, have been identified in our institution between 1989 and 2012. 61 were also evaluated with FISH. T(9 ;22)(q34 ;q11.2) and promyelocytic leukemia cases were excluded. Most patients were treated according to EORTC AML10, AML12 or AML13 protocols. Probabilities of DFS and OS according to CyCR and FISH CR were estimated with the Kaplan-Meier method, and differences between survival distributions were evaluated by the log-rank test. A Cox proportional hazards model was constructed to determine if CyCR was associated with outcome, when adjusting for other prognostic variables. Median follow-up was 52 months for patients still alive.
Results: In the 198 patients who reached cytological CR, median age was 48 (range 17-81). Sixty-two (31%) patients harbored favorable karyotype (*i.e.* core-binding factor AML), 84 (42%) harbored unfavorable karyotype, and 52 (26%) intermediate karyotype. One hundred and seventy four patients (88%) reached CyCR, when 24 (12%) did not. In univariate analysis, reaching CyCR wasn't associated with Disease-Free Survival (25+/-9% *vs* 39+/-4% after 5 years ; p=0.17) and Overall Survival tended to be higher in patients who reached CyCR than in other patients (51+/-4% *vs*. 27+/-10% at 5 years; p=0.08). In multivariate analyses including all variables with p value<0.1, only cytogenetic group was an independent factor for OS, when reaching CyCR was not (p=0.14). As nearly all patients with favorable karyotype reached CyCR, a subgroup analysis was performed in the 136 patients with intermediate or unfavorable karyotype. In this subgroup, reaching CyCR wasn't associated with DFS or OS in univariate analyses. In multivariate analyses, reaching CyCR was not associated with DFS or OS. In order to evaluate if FISH could provide more prognosis information than conventional cytogenetic after induction, we focused in patients who reached cytological CR and CyCR, and who were evaluated with FISH (52 patients). 32 of the 52 patients (61%) reached FISH CR after induction, when 20 (39%) did not. In univariate analysis, reaching FISH CR tended to be associated with better DFS (45+/-9% *vs*. 21+/-9% at 5 years; p=0.08), and was strongly associated with better OS (67+/-9% *vs*. 25+/-10% at 5 years, p=0.004). When focusing in the 36 patients with intermediate or unfavorable karyotype, reaching FISH CR was associated with a trend to better OS (47+/-12% *vs*. 29+/-11% at 3 years, p=0.08) and no significant difference for DFS (41+/-12% *vs*. 23+/-10% at 3 years, p=0.23).
Summary and Conclusion: Cytogenetic remission didn't significantly impact prognosis in 198 AML patients who reached cytological Complete Remission after one induction cycle. Evaluation with FISH at the time of cytological CR seems to be able to provide prognosis information, and might be useful for MRD detection. Larger prospective studies are needed to confirm these data.

P830

ACUTE MYELOID LEUKEMIA IN PATIENTS OLDER THAN 75: PROGNOSTIC IMPACT OF FLT3-ITD AND NPM1 MUTATIONS

P Hirsch[1,2,3,4,*], G Qassa[3], R Tang[2,3], C Marzac[2,5], JY Perrot[5], F Isnard[2,3], M Mothy[1,2,3,4], JP Marie[2,3], O Legrand[1,2,3,4]

[1]Sorbonnes Universités, UPMC Univ Paris 06, UMR_S 938, CDR Saint-Antoine, [2]UPMC, Univ Paris 06, GRC n°7, Groupe de Recherche Clinique sur les Myéloprolifération Aiguës et Chroniques MYPAC, [3]Service d'hématologie clinique et de thérapie cellulaire, APHP - Hôpital Saint-Antoine, [4]INSERM, UMR_S 938, CDR Saint Antoine, [5]Laboratoire d'Immunologie et Hématologie biologique, APHP - Hôpital Saint-Antoine, Paris, France

Background: The benefit associated with chemotherapy in older patients with acute myeloid leukemia is debated. The prognostic impact of molecular mutations in these patients is unknown.
Aims: To evaluate the outcome of AML patients aged more than 75, to identify prognosis factors, and to evaluate if *NPM1, CEBPA* and *FLT3-ITD* status have prognostic value in intensively treated patients.
Methods: We conducted a retrospective analysis of 79 consecutive AML patients aged more than 75 years admitted in our unit between 1998 and 2012. APL were excluded. Patients received either intensive regimens or supportive care only. Cytogenetic analysis at the time of diagnosis was performed in most patients. *FLT3-ITD, NPM1* and *CEBPA* mutations detection were retrospectively performed from frozen cells from diagnosis.
Survival probabilities were estimated with the method of Kaplan and Meier, and compared using the log-rank test. A Cox model was constructed to determine if *FLT3-ITD* was associated with outcome, when adjusting for other prognostic variables. Median follow-up time was 87 weeks for patients still alive.
Results: The median age at diagnosis was 78 years (range 75-92). Median OS was 13.8 weeks. 81% of patients died in the first year following diagnosis (23% during the first hospitalization following diagnosis). Overall, 42 patients (53%) received chemotherapy. Treated patients were significantly younger than the overall sample (p=0.008), and had significantly lower ECOG PS (p=0.004). Patients with poor cytogenetic were less likely to be intensively treated (p=0.006). Median overall survival of treated patients was 36.3 weeks *vs*. 5.7 weeks for other patients. OS at 1 year was 33 % +/- 7 % for treated patients, *vs*. 7 % +/- 4 % for others (p<0.001). Among the 42 intensively treated patients, 19 achieved CR (45 %). Achievement of CR was significantly related to OS (p<0.001). Early death (during the first 30 days) occurred in 8 (19 %) of the 42 treated patients. In univariate analyses, age, ECOG PS, prior myelodysplasia, ABCB1 activity, WBC, or cytogenetic group did not influenced CR and OS in this group. *FLT3-ITD* was analyzed in 35 treated patients, *NPM1* status in 33 of them and *CEBPA* in 18. 11 patients (31%) harbored *FLT3-ITD* and 7 patients (21%) harbored *NPM1* mutation. No *CEBPA* mutations were identified. In univariate analyses, *FLT3-ITD* and *NPM1* status were not associated with OS or DFS. *FLT3-ITD* did not influence CR rate, when *NPM1* mutations tended to be associated with higher CR rate (p=0.12). A multivariate analysis for OS was performed. CR achievement (p=0.0003) and *FLT3-ITD (*p=0.04) were independently associated with OS. To evaluate more accurately the influence of *FLT3-ITD* and *NPM1* mutations on disease evolution and prolonged survival, we performed a second analysis excluding patients who experienced early death. *FLT3-ITD* was identified in 10/28 (35%) patients and was associated with worse survival (p=0.036). *NPM1* mutations tended to be associated with CR (p=0.09). Patients harboring *FLT3-ITD* without *NPM1* mutation (5 patients on 26) had significantly worse OS than other patients (p=0.02)
Summary and Conclusion: Age should not be a limitation for intensive treatments in elderly AML people, as reaching CR is associated with longer OS. A proper selection of patients, with adapted evaluation of comorbidities and disease characteristics should be performed before treatment to avoid early death and to maximize CR reaching chances. *FLT3-ITD* or *NPM1* status might be useful to predict survival in elderly patients. Larger studies are needed to conclude.

P831

MOLECULAR RELEVANCE OF THE NERVE GROWTH FACTOR RECEPTOR GENE (NTRK1) EXPRESSION IN AML-RELATED MYELOID SARCOMA

F Lazzaroni[1,*], E Zucchetti[2], M Turrini[2], M Bernardi[3], N Fracchiolla[4], M Rossi[5], P Zappasodi[5], C Cattaneo[6], L Marbello[2], R Cairoli[7], A Beghini[1]

[1]Department of Medical Biotechnologies and Traslational Medicine, University of Milan, [2]Department of Oncology, NIGUARDA Hospital, [3]Hematology and BMT Unit, San Raffaele Hospital, [4]Department of Hematology, IRCCS Cà Granda–Maggiore Policlinico Hospital Foundation, Milan, [5]Division of Hematology, IRCCS Policlinico San Matteo Foundation, Pavia, [6]Department of Hematology, Spedali Civili, Brescia, [7]Division of Internal Medicine-Clinical Hematology, Ospedale Valduce, como, Italy

Background: Myeloid sarcoma (MS), also called granulocytic sarcoma, is a rare condition characterized by the occurrence of tumor masses constituted by immature precursors from the granulocytic series in an extramedullary localization. MS may be diagnosed *de novo*, although most often coincides with different malignant blood diseases involving the granulocytic series, acute myeloid leukemia (AML) being the most frequent. The most common localization of MS is in the paravertebral region, subperiosteal space of the skull, peritoneum, and pelvis. Approximately 10% of t(8;21) AML patients will develop MS, as a consequence, the relative RUNX1-RUNX1T1 transcript represent the most common cytogenetic and molecular abnormalities. The t(8;21) and the other core-binding factor related leukemias were frequently

associated with KIT mutations. Moreover, the murine model showed that RUNX1-RUNX1T1;c-Kit^{D814V} coexpression resulted in AML of relatively short latency and frequent MS was observed.
Aims: To understand the molecular basis for the MS prevalence in RUNX1-RUNX1T1 expressing human AMLs, we examined the tyrosine receptor kinase A (TRKA) nerve growth factor (NGF) receptor gene (NTRK1) expression as a target gene up-regulated by the expression of RUNX1-RUNX1T1, allowing nerve growth factor-induced CD34$^+$ cells expansion. NGF is normally expressed by bone marrow stromal cells, whereas TRKA is expressed in hematopoietic progenitor cells.
Methods: To evaluate the clinical and molecular relevance of these findings in MS development, we analysed NTRK1 expression in 32 primary AML samples by qualitative and quantitative RT-qPCR.
Results: We observed strong NTRK1 expression only in the 23 samples derived by AML patients associated with MS at a prevalent paravertebral region localization.

Table 1.

Summary and Conclusion: In summary, our data identify a functionally relevant target gene overexpressed in AML clinically positive for paraspinal or ileal MS localization and not expressed in AML without MS. These observations suggest a possible MS-promoting activity of the NGF/TRKA signaling in AML cells competent to respond to NGF ligand.

ELN FAVORABLE ACUTE MYELOID LEUKEMIA SHARE THE SAME GOOD PROGNOSIS ACROSS CYTOGENETIC/MOLECULAR SUBGROUPS: PRELIMINARY RETROSPECTIVE REAL-LIFE ANALYSIS OF THE RETE EMATOLOGICA LOMBARDA (REL)

P Zappasodi[1,*], E Cerqui[2], L Marbello[3], M Fumagalli[4], M Bernardi[5], N Fracchiolla[6], M Da Vià[1], M Rossi[1], F Antoniazzi[2], E Ravano[3], V Ferretti[1], E Sant'Antonio[1], G Rossi[2], C Castagnola[1]
[1]Department of Hematology, Foundation, IRCCS Policlinico San Matteo, University of Pavia, Pavia, [2]Department of Hematology, Spedali Civili, Brescia, [3]Department of Hematology, Niguarda Ca' Granda Hospital, Milano, [4]Department of Hematology, Ospedale San Gerardo, Monza, [5]Hematology and Bone Marrow Unit, San Raffaele Scientific Institute, [6]Department of Hematology, Foundation, IRCCS Ca' Granda Ospedale Maggiore Policlinico, Milano, Italy

Background: The European Leukemia Net (ELN) stratification classifies as favorable prognosis four subgroups of acute myeloid leukemia (AML) with specific cytogenetic/molecular abnormalities. These forms are potentially curable with standard chemotherapy, even though a substantial proportion of patients still relapse. Several clinical trials report a relapse rate (RR) of about 30% and an overall survival (OS) of about 60% at 5 years.
Aims: The purpose of this study was to assess in a real life setting the response rate and OS of newly diagnosed AML patients with t(8;21)(q22;q22)/*RUNX1-RUNX1T1*, inv(16)(p13q22) or t(16;16)(p13q22)/*CBFbeta-MIH11*, normal karyotype and mutated *NPM1* and negative *FLT3*-ITD or double mutated *CEBPA* (*CEBPA*dm). Data were collected from hematological centers of the regional network REL (Rete Ematologica Lombarda).
Methods: We analyzed adult patients diagnosed with AML with favorable prognosis at 6 REL centers between 2007 and 2013. All patients received standard induction chemotherapy followed by consolidation cycles and/or autologous transplant. Clinical and molecular data were analyzed at diagnosis, after induction, and at the end of treatment. The Kaplan-Meier product-limit method was used to estimate survival curves, and the log-rank test was adopted to evaluate differences between groups of patients.
Results: We studied 148 AML patients (81 males and 67 females) with a median age of 55 years (range 20-80): 24 with t(8;21) (group 1), 28 with inv(16) or t(16;16) (group 2), 85 with normal karyotype and *NPM1*mut *FLT3*-ITDneg (group 3), and 11 with normal karyotype and *CEBPA*dm (group 4). After induction chemotherapy, 8% of patients received no consolidation cycles, while the remaining received a median of 3 cycles (range: 1-5), which were based on high dose cytarabine in 74% of cases. Complete remission (CR), evaluated in 142 patients, was achieved in 130 (92%): 21(91%), 25(93%), 74(91%), 10(91%) respectively in group 1, 2, 3, 4. Post-induction and post-consolidation molecular assessment were available in 115 (78%) and 131 patients (89%) respectively. Molecular CR was obtained in 63% of responders. Half of them achieved molecular CR already after induction, with a significant difference between group 3 and combined group 1 and 2 (57.5% *vs* 25%, p=0.019). However, this difference was no longer significant after consolidation (68% *vs* 62%, p=0.53). With a median follow up of 1.6 years, the RR was 40% without any difference between groups, whereas three years disease free survival (DFS), event free survival (EFS) and OS were respectively: 48%, 40% and 69% with no significant difference between groups. Age (<60 years) was the only parameter that affected EFS (p=0.038) and OS (p<0.001).
Summary and Conclusion: This study, conducted in a non selected population of favorable risk AML patients, confirms high CR rate and the prognostic value of age, favoring patients younger than 60 years. RR is higher than reported in literature, but the OS is comparable. Earlier molecular response was obtained in *NPM1* mutated patients, but the incidence of relapse and survival did not differ from the other groups. In conclusion, although data collection is not yet complete and follow up is short, these results confirm that the ELN classification identifies a clinically homogeneous group of good risk AML patients that share comparable outcome, with a significant proportion of long-term survivors with chemotherapy alone even outside clinical trials.

P833

A POST-REMISSION MAINTENANCE TREATMENT WITH LOW-DOSE CHEMOTHERAPY + RETINOIDS AND DIHYDROXYLATED VITAMIN D3 MAY IMPROVE THE SURVIVAL OF POOR-PROGNOSIS AML/MDS PATIENTS

D Ferrero[1,*], E Crisà[1], F Marmont[2], E Audisio[2], C Frairia[3], V Giai[1], T Gatti[1], M Festuccia[1], B Bruno[1], L Riera[4], R Passera[5], M Boccadoro[1]
[1]Division of Hematology, Università degli Studi di Torino, [2]Division of Hematology, [3]Division of Hematoloy, Azienda Ospedaliera-Universitaria "Città della Salute e della Scienza", [4]Molecular Biotechnology and Health Sciences, Pathology Section, Università degli Studi di Torino, [5]Nuclear Medicine Division, Azienda Ospedaliera-Universitaria "Città della Salute e della Scienza", Turin, Italy

Background: Acute myeloid leukemia (AML) patients over 60 or with secondary / therapy-related disease still have, despite aggressive treatments, a poor outcome, only some 5-15% of these patients becoming long-term survivors. The same is true for high risk myelodysplastic syndrome (MDS) patients ineligible to allogeneic stem cell transplantation (Juliusson G. *et al.*: Blood 2009; Bello C. *et al.*: Cancer 2011; Kayser S. *et al.*: Blood 2011).
Aims: On the basis of our previous encouraging experience with a combination of low dose chemotherapy + retinoids and dihydroxylated vitamin D3 on MDS and AML patients uneligible to standard chemotherapy (Ferrero D. *et al.*: Leuk Res 1996; Haematologica 2004), we wished to evaluate the same approach as a maintenance treatment on AML/MDS who had obtained a complete remission (CR) after intensive chemotherapy but had poor prognosis features (age over 60 and/or secondary AML, therapy-related AML, previous relapse, high risk MDS).
Methods: From January 1997 to December 2012, 261 high risk (according to the above described criteria) AML or MDS patients were treated in the two hematology wards of the same hospital, with CR- aimed induction chemotherapy +/- consolidation. Overall, 169 (64.8%) of these patients obtained a CR that was maintained for at least 2 months (mo) in 161 (61.7%). Fifty-three patients underwent an allograft and 14 received other different maintenance treatments, without differentiating agents. Forty-five patients (35 AML and 10 MDS, median age 64, 87% with documented intermediate/ high-risk caryotype) received, in one of the two hematology wards, the maintenance therapy based on 2 alternated schedules: a) 6-thioguanine + 13-cis retinoic acid + dihydroxylated vitamin D3; b) low-dose cytarabine + 6-mercaptopurine + all-trans retinoic acid + dihydroxylated vitamin D3. The treatment was continued until relapse or 3.5 – 4 years of continuous CR. Three patients in first CR who later found a donor and underwent allografting were censored at that time. We retrospectively compared, at a median follow up of 57 months, the outcome of patients who received the maintenance therapy, to that of a matched population of 49 patients treated in the same years in the other hematology ward who stopped treatments after consolidation. Minimal residual disease was evaluated before and during maintenance in 8 patients by WT-1 or CBFβ-MYH11 transcript.
Results: Maintenance therapy was generally well tolerated. Main toxicities included mild oral and cutaneous dryness, occasional nausea /vomiting and mild to moderate cytopenia (11 patients). Only two patients discontinued

treatment because of these effects and no therapy related deaths were observed. Maintenance group had a lower relapse incidence (70.3% *vs*. 86.4% at 5 years p=0.007) and a longer disease-free survival (median 21.2 *vs*. 8.7 months, p=0.017). The relapse reduction improved overall survival: median 40.4 months (34 % at 5 years) for maintenance group *vs*. 15.8 (14.2 % at 5 years) for controls (p=0.005). At multivariate Cox analysis both cytogenetic and maintenance therapy resulted independent outcome predictors for overall survival. Maintenance treatment also reduced minimal residual disease (detected by WT1 and CBFβ-MYH11) in 5 of 8 evaluable patients.
Summary and Conclusion: Although maintenance has never been regarded as a standard strategy in AML treatment, some randomized studies reported a significant benefit with ARA-C employed as a long-term maintenance (Löwenberg B. *et al.*: J Clin Oncol 1998; Büchner T. *et al.*: J Clin Oncol 2003). The present results, although obtained in a non-randomized study, suggest that our strategy of low-dose chemotherapy + retinoids and dihydroxylated vitamin D3 as maintenance therapy might improve the outcome of poor risk AML/MDS patients.

P834

MDRO INFECTION THE ‘’MAJOR HURDLE TO ACUTE MYELOID LEUKEMIA INDUCTION THERAPY’’ EXPERIENCE OF A TERTIARY CARE COMPREHENSIVE CANCER CENTER FROM INDIA

A Chakrapani[1,*], M Chandy[1], S Bhattacharya[2], D Mishra[3]
[1]Clinical Hematology, [2]Clinical Microbiology, [3]Lab Hematology, TATA MEDICAL CENTER, KOLKATA, India

Background: Infection and febrile neutropenia remains a major challenge in patient undergoing intensive chemotherapy for AML in developing countries.
Aims: To review the cultures for multidrug resistance organism (MDROs) in our AML induction patients and their morbidity and mortality.
Methods: We analyzed our 44 consecutive AML patient who underwent 7+3 Induction chemotherapy. Fecal Surveillance cultures were taken in 29 patients prior to chemotherapy and were carried out by a method based on Landman D et al(J Clin Microbiology 2005). During febrile periods multiple blood, urine, secretions cultures were taken.
Results: From Sept 2012 to Jan 2014, information on AML patients who underwent standard 7+3 Induction was reviewed. 44 patients[27 males and 17females] of median age 37 years[range 16yr-63yr] were treated. The median WBC count at diagnosis was 13500 cells/micL[range 800-1,34,000 cells/micL] and the peripheral blood blast was 47%[range 10%>96%].The cytogenetic was done in 42 patients and 27/42[64%] had intermediate risk. Surveillance culture done in 29 [55%] patients and MDRO were detected in 23[79%] patients.The pattern of resitance shown in table1. During febrile episodes organism isolated in 31[70%] patients. Postive blood cultures 27[87%],positive sputum or ET aspirate culture 6[19%], and positive Pus cultures in 5[16%]patients.The pattern is shown in table2.The median duration of hospital stay was 26 days[range 10day-51days].20[47%] patients required intensive care support, 21[47%] patients needed ionotropic support for septic shock and 14[31%] invasive ventilation. Post induction Day+10 or +14 bone marrow showed<5% blast in 41[93%] patients and 31[70%] patient had complete remission at day+28. 9[20.5%] patient died during induction chemotherapy. In 7/9 patient the cause of death was attributed to MDRO septicemia and related organ failure.

Table 1. Resistance pattern for survillace culture isolates.

Isolates	Meropenem	Colistin	Oxacillin	Linezolid
Ecoli (20)	10	1	NA	NA
Klb.Pneumonae(8)	7	NIL	NA	NA
Enterococcus(5)	NA	NA	5	NIL
Crysobact(1)	1	1	NA	NA

Table 2.

Isolates(No)	Meropenem	Colistin	Tigecycline	Amikacin
Kleb.Pneumonae(17)	15	4	1	3
Pseudomonas(3)	1	nil	nil	1
Acenobacter(2)	2	nil	nil	nil
Strephomonas(2)	nil	nil	nil	nil
Chrysobacterium(1)	1	1	nil	nil
Proteus(1)	nil	1	nil	nil
Isolates(No)	Oxacillin	Linezolid	Vancomycin	
Staphylococcus(7)	5	nil	1	
Eentrococcus(2)	2	1	1	

Summary and Conclusion: The high level of antimicrobial resistance in enteric flora in newly diagnosed AML patient is a concern at diagnosis and the major cause for mortality and morbidity in AML patient in developing world is MDROs.

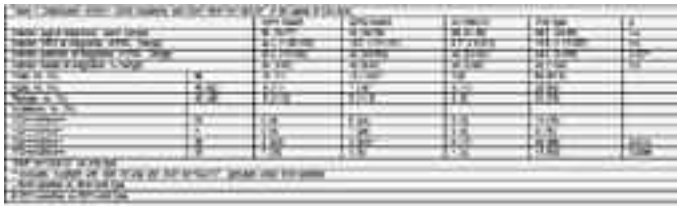
P835

ACQUIRED IDH1 AND IDH2 MUTATIONS IN CYTOGENETICALLY NORMAL ACUTE MYELOID LEUKAEMIA: THEIR PREVALENCE AND ASSOCIATION WITH OTHER GENE MUTATIONS – A SINGLE CENTRE EXPERIENCE

GF How[1,*], SJ Khoo[1], LT Tan[1], C Chuah[1]
[1]Singapore General Hospital, Singapore, Singapore

Background: In recent years, the prognosis of patients with acute myeloid leukaemia (AML) and cytogenetically normal (CN)-AML has been refined by the identification of genetic alterations. Recently, mutations in Isocitrate dehydrogenase (IDH) genes, first reported in malignant gliomas, have been evidenced in AML by whole genome sequencing. Recurring mutations in IDH genes occur in approximately 15%>20% of patients with newly diagnosed AML, and are associated with the normal karyotype.
Aims: In this study, we assessed the prevalence of IDH1 and IDH2 mutations including the IDH1 SNP rs11554137 in bone marrow and peripheral blood specimens collected from CN-AML patients during 2009-2012. We also compared the patient characteristics and other genetic alterations in relation to IDH mutations.
Methods: Exons 4 of IDH1 and IDH2 genes were directly sequenced in 89 CN-AML patients and 20 healthy donors. FLT3/ITD and NPM1 mutation status were also determined in the AML patients.
Results: A total of 23 IDH mutations were identified among the 89 CN-AML patients. The prevalence of IDH1 and IDH2 mutations were 11% (10/89) and 14.5% (13/89) respectively. IDH1 SNP rs11554137, a polymorphism which had been reported to be an adverse prognostic factor, was detected in 7 patients, one of whom also had an IDH2 R140Q mutation. This polymorphism without the presence of IDH1 or IDH2 mutation was also detected in 2 healthy donors. The 10 IDH1 mutations detected were R132H (n=4), R132C (n=3), R132L (n=2) and R132G (n=1). R140Q was the predominant IDH2 mutation detected in this cohort of patients (12/13), the other mutation was R140W (n=1). The relation between the IDH mutations and various patient characteristics were determined by the Student *t* test, equal variances not assumed (continuous variables) and the Fisher exact test (categorical variables) (details in Table 1). The platelet counts were significantly lower in the SNP-positive patients than in the patients with no IDH mutation or SNP (*p=0.027*). Other clinical parameters showed no significant difference between the IDH- or SNP-positive groups and the wild type group. In this study, all 10 IDH1 mutations were found in patients who were $FLT3/ITD^{neg}$ while all but 3 were NPM1 mutant-positive. IDH1 mutations were significantly associated with the low risk group $ITD^{neg}/NPM1^{mut}$, as compared to the IDH1-wild type group (*p=0.005*). The association of the IDH2 mutations with ITD/NPM1 mutation status was less defined. In contrast, SNP rs11554137 appeared to be associated with $ITD^{neg}/NPM1^{wt}$ status (6/7) and one such patient also had a R140Q mutation. This association was determined to be statistically significant (*p=0.014,* SNP-positive *vs* SNP-wild type).

Table 1.



Summary and Conclusion: Conflicting findings regarding the impact of IDH mutations on clinical outcomes had been reported. One study found IDH mutations to be a poor prognostic factor in CN-AML with $NPM1^{mut}/ITD^{neg}$ while another suggested worse outcome in patients with $NPM1^{wt}$ without FLT3/ITD. There was yet another study which suggested IDH1 single nucleotide polymorphism rs11554137 to be associated with an inferior outcome in adult CN-AML, most pronounced in NPM1/ITD high risk group while the IDH1 (R132) mutations were not. As the prognostic implications remain controversial, it would be important for our centre to continue this study with a larger patient cohort and perform a longer follow up to further correlate IDH mutation status, particularly IDH1 R132 and SNP rs11554137 as they appeared to be highly associated with the low risk and intermediate groups respectively, with other genetic alterations and prognosis.

P836

CLINICAL USEFULNESS OF WT1 MRNA EXPRESSION IN BONE MARROW DETECTED USING A NEW WT1 MRNA ASSAY KIT FOR MONITORING ACUTE MYELOID LEUKEMIA: A COMPARISON WITH PERIPHERAL BLOOD WT1 MRNA EXPRESSIONS

Background: The Wilms' tumor gene 1 (WT1) is highly expressed in acute myeloid leukemia (AML). Many studies have reported the usefulness of WT1 mRNA expression as a monitoring marker of minimal residual disease (MRD). We previously assessed the clinical usefulness of WT1 mRNA expression in the peripheral blood (PB) of 191 patients using the WT1 mRNA assay kit and reported that WT1 mRNA expression in PB is useful as an MRD monitoring marker in AML patients. However, the usefulness of WT1 mRNA expression in the bone marrow (BM) has been investigated only in a small number of subjects. Since the WT1 mRNA Assay Kit has been newly developed, we decided to investigate the clinical usefulness of WT1 mRNA expression in BM by comparing the expression with that in PB in a larger number of subjects.
Aims: This study aimed to assess the performance of the newly developed WT1 mRNA assay kit and to evaluate the clinical usefulness of WT1 mRNA expression in BM.
Methods: The new kit is based on one-step multiplex quantitative RT-PCR. Thus, the component reagents are limited to 2 types in order to simplify the measurement operation, and the RT and PCR reaction are performed continuously in one step to amplify GAPDH (Internal standard) and WT1 in the same tube. Table 1 compares the new and former kits used in this study. Informed consent was obtained from 164 blood disease patients including 118 AML patients. Using the new and former kits, WT1 mRNA expression in BM and PB was determined to assess the performance of the new kit in comparison with the former kit. Additionally, the clinical usefulness of WT1 mRNA expression in BM was assessed on the basis of comparison with the expression in PB. In addition, human genomic DNA was applied as the sample instead of RNA, and WT1 mRNA and GAPDH mRNA were determined by both kits to evaluate cross-reactivity with human genomic DNA.
Results: The results showed a favorable correlation between the new and former kits, with r=0.9849 and y=0.9260x + 0.1119 in 163 PB samples and r=0.9568 and y=0.9035x + 0.2396 in 158 BM samples, demonstrating that the performance of the new kit is equivalent to that of the former kit. As for the usefulness of the new kit in investigating the clinical usefulness of WT1 mRNA expression in BM on the basis of comparison with the expression in PB, correlation between WT1 mRNA expression in BM and PB was investigated in 115 AML patients from whom both BM and PB were collected. The results showed a favorable correlation, with r=0.9048 and y=0.7378x + 1.4041. As observed in PB, WT1 expression in BM was significantly lower (P<0.01) in the remission stage compared to the levels in 3 disease stages (pretreatment, post-treatment relapse, and refractory stages) (Fig. 1). In AML patients from whom it was possible to collect multiple samples during the course of the study, changes in WT1 mRNA expression in BM reflected the disease status and demonstrated fluctuations mostly similar to those in the case of PB. No cross-reactivity with human genomic DNA was detected in both kits.

Table 1. Compearison of the new kit with the formerly used kit.

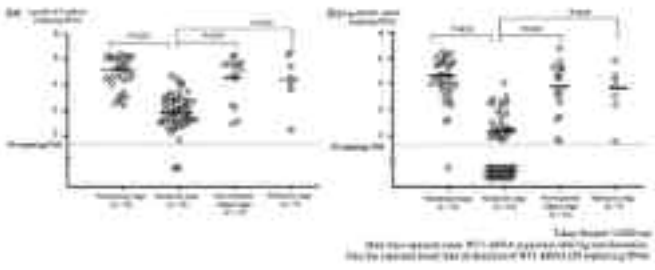

Figure 1. Compearison between WT1mRNA expression levels in BM and PB in each AML disease stage (a) in BM at each disease stage, (b) in PB at each disease stage.

Summary and Conclusion: The new kit demonstrated a performance equivalent to that of the former kit. WT1 mRNA expression in BM was highly correlated to that in PB and demonstrated changes that reflected the AML status, as observed with WT1 mRNA expression in PB, indicating that WT1 mRNA expression in BM is useful as an MRD monitoring marker.

P837

MENINGIOMA 1 (MN1) EXPRESSION: REFINED RISK STRATIFICATION IN ACUTE MYELOID LEUKEMIA WITH NORMAL CYTOGENETICS

L Ibrahem[1,*], S Aref[1], E Azmy[2]
[1]clinical pathology department (haematology unit), [2]haematology, Mansoura faculty of medicine, mansoura, Egypt

Background: Prognostic stratification of cytogenetically normal acute myeloid leukemia (CN-AML) is a point of intensive research.
Aims: was to determine the prognostic importance of the meningioma 1 (MN1) gene expression levels in CN-AML.
Methods: One Hundred patients with AML were diagnosed, MN1 expression were analyzed using quantitative real time (QRT) PCR.
Results: High expression was detected in 48 (48%) patients (range: 2.35-31.99, mean: 13.9 ± 8.49) in comparison to 52 (52%) patients with low expression (range: 0.02-2.3, mean: 0.68 ± 0.77). The course of the disease in patients with high MN1 expression was unfavorable. Patients with high MN1 expression was associated with significant low complete remission (CR) rate (62.5% *vs*. 88.4%, high *vs*. low MN1, P=0.001) and high mortality rate (75% *vs* 46.1, P=0.03).AML patients with high MN1 expression tended to be refractory (37.5% *vs* 19.2, P=0.00) and relapse risk (54.1% *vs* 23%, P=0.02). Multivariable analysis confirmed high MN1 expression as an independent risk factor for disease free survival (DFS) and overall survival (OS).
Summary and Conclusion: MN1 is one of the most potent hematopoietic oncogenes. MN1 promote self-renewal and proliferation; block differentiation and is associated with repression of genes associated with differentiation and cell-cycle arrest. **Heuser et al** found that MN1overexpression is associated with treatment failure, specifically a significantly worse day 15 response rate; higher relapse rate, and shorter relapse-free and overall survivals. MN1 over expression independently predicts bad clinical outcome in CN-AML patients. MN1 over expression is associated with poor induction response, shorter relapse-free survival, and shorter overall survival. This leads to improve risk stratification of this heterogeneous group of patients with AML.

P838

THE TREATMENT'S OUTCOMES OF THE SECONDARY ACUTE MYELOID LEUKEMIA– RETROSPECTIVE MULTICENTER PALG STUDY

S Grosicki[1,*], E Bodzenta[1], S Ilona[1], A Wierzbowska[2], M Kuydowicz[2], M Joks[3], A Czyz[3], E Patkowska[4], K Warzocha[4], M Watek[5], M Pasiarski[5], B Piatkowska-Jakubas[6]
[1]Department of Hematology, SPZOZ ZSM w Chorzowie, Chorzow, [2]Department of Hematology, Medical University, Lodz, [3]Department of Hematology, Medical University, Poznan, [4]Department of Hematology, Institute of Hematology and Transfusiology, Warsaw, [5]Department of Hematology, Swiętokrzyskie Centrum Onkologii, Kielce, [6]Department of Hematology, Jagiellonian University, Cracow, Poland

Background: The secondary, to the previous treatment of the other cancers, acute myeloid leukemia (sAML) is still a clinical challenge. The prognosis in this group of patients is particularly bad.
Aims: The goal of this retrospective, multicenter PALG study was assessment of the outcomes of the secondary AML treatment in Poland.
Methods: Eighty six patients, 58% female with median of age 59 (18-84) diagnosed on 2004-2013 in 6 PALG centers were included to the study. Median time from the diagnosis of primary tumors to the development of sAML was 4 years. Median WBC at the diagnosis of sAML was 14,55 G/l. Cytogenetic risk

was low in 10,5%, intermediate 30%, high in 15%, unknown in 44.5% of patients. According to FAB classification they were M0 in 6%, M1 in 24%, M2 in 30%, M3 in 2%, M4 in 30%, M5 in 6%, M6 in 2%. In 70% of cases the diagnosis of sAML was preceded by the solid cancers (the most frequent was breast cancer in 32%), in 30% hematologic neoplasms. In 78% chemotherapy, in 49% radiotherapy, in 37% both before diagnosis of sAML were given. In 63% younger patients the intensive induction chemotherapy (group 1: DAC – daunorubicin/araC/cladribine 3+7+5 or DA - daunorubicin/araC 3+7), and in the other 37% palliative chemotherapy (group 2: low dose cytarabine – based) were given. In 8 patients intensively treated after complete remission (CR) assessment allogeneic hematopoietic stem cell transplantation (alloHSCT) was carried out.
Results: After induction CR was obtained in 53% *vs*. 11% patients in group 1 *vs*. 2 respectively, p<0.001. Eleven percent of patients in both groups expired during post induction pancytopenia. Median progression free survival (PFS) was reached after 12 *vs*. 3 months, and 33% *vs*. 29% patients were PFS after 4 years, respectively, p=0.23. Median OS was reached after 6 *vs*. 3 months, and 4% *vs*. 3% patients were alive in group 1 *vs*. 2 respectively after 4 years, p=0.11.
Summary and Conclusion: Secondary AML incidence increases because of the more effective treatment of the other cancers. The diagnosis of the secondary AML is burdened with a poor prognosis. In our study effective induction chemotherapy and using alloHSCT does not improve survival in the secondary AML patients in comparison to low dose chemotherapy supplemented by supportive care despite of the higher percentage of CR. This observation requires further studies.

P839

TIME FROM DIAGNOSIS TO TREATMENT (TDT) INITIATION AFFECTS PROGNOSIS OF ACUTE MYELOID LEUKEMIA (AML) IN YOUNGER ADULTS

J Schuh[1,*], R Gerivaz[1], S G Leocádio[1], C Gaspar[1], A Tomé[1], P Almeida[1], L Monteiro[1], M Silva[1], L Carande[1], J Caldas[1], F Costa[1], A Monteiro[1], G Ferreira[1], P Ribeiro[1], E Cruz[1], MH Sousa[1], M Prata[1], I Poças[1], I Costa[1], A Botelho de Sousa[1]
[1]Serviço de Hematologia, Hospital dos Capuchos, Lisboa, Portugal

Background: Starting intensive chemotherapy immediately after a diagnosis of AML is believed to be crucial to improve outcome. This recommendation is included in the recent *ELN* guidelines, on the basis of a single study (Sekeres 2009) in which a TDT ≥ 5 days had an unfavorable impact on complete remission (CR) rate and overall survival (OS) in patients (pts) ≤ 60 years. This strategy was recently put in doubt by a study reaching opposite conclusions (Bertoli 2013) and arguing that a longer TDT is necessary to stabilize the pts and to allow treatment to be tailored to genetic results.
Aims: To observe the effect of TDT on CR rate and OS of AML pts ≤ 60 years.
Methods: We analyzed 304 consecutive pts aged ≤ 60 years, treated with an uniform regimen from May 1998 to May 2013. We evaluated the influence of the following variables on CR rate and OS: TDT (<*vs* ≥ 5 days), age (≤ *vs* >40 years), secondary *vs de novo* AML, genetic risk group and white blood cell count (WBC) at diagnosis (≤ *vs* >$50x10^9$/L).
Results: Median age was 47 (14-60), 250 pts had *de novo* AML; among the 165 cases with a complete genetic characterization, 33% were favorable, 56% intermediate and 10% unfavorable; 31% had a WBC >$50x10^9$/L. The median TDT was 4 days (1-49), and 57% of the pts had a TDT<5 days. The CR rate was 76%, higher for *de novo* AML (80% *vs* 56%, *p*<0.001) and for the favorable genetic group (98% *vs* 74%, *p*<0.001). The remaining variables did not influence the CR rate. With a median follow-up of 62 months, OS was 32% at 5 years (median 16 months; CI 12.0-19.9). In multivariate analysis, a negative impact on OS was found for a TDT ≥ 5 days (HR 1.34; *p*=0.04), for age >40 years (HR 1.45; *p*=0.02), for secondary AML (HR 1.82; *p*<0.001) and for unfavorable genetics (HR 3.71; *p*<0.001).
Summary and Conclusion: A TDT ≥ 5 days has an independent negative impact on OS for younger pts. In this population, delaying chemotherapy should be an exception.

Background: Acute Myeloid Leukemia (AML) accounts for 15% of pediatric leukemia. Improvements of prognosis achieved in the last twenty years are also due to a better stratification of patients into risk groups that allowed to deliver tailored treatment. The AIEOP LAM 2002/01 protocol classified patients with t(8;21)(q22,q22)*AML1-ETO* and inv(16)(p13;q22)*CBFB-MYH11,* who responded to induction therapy as belonging to the Standard-Risk (SR) group. These patients were considered at good prognosis; unfortunately, although they all reached morphological complete remission (CR) after the first induction course, they showed a high incidence of relapse (24%) (Pession A. *et al*., Blood 2013). At present, little is known about the kinetics of relapse or the development of resistance mechanisms; moreover, in many studies post-remission therapy in AML does not take into account the level of residual leukemia.
Aims: Here, we evaluate the prognostic impact of molecular minimal residual disease (MRD) levels in terms of onset of relapse. We studied bone marrow of 49 and 27 patients carrying either t(8;21) or inv(16) abnormalities, respectively, at time of diagnosis, and at the end of first and second course of induction therapy (ICE).
Methods: MRD was evaluated as number of fusion transcripts by quantitative RT-PCR using absolute quantification, and calculated as logarithmic (Log) disease reduction after the first and second ICE course as compared to diagnosis. The prognostic impact was assessed by the calculation of the cumulative incidence of relapse (CIR) according to the different MRD levels.
Results: Results revealed that after I ICE, 21 out of 49 t(8;21)-rearranged patients (43%) showed a low MRD reduction (<2 Logs), and ten of them remained low responders also at the end of second course (20.5%). We found that a reduction of MRD lower than 2 Log conferred a higher CIR after I and II ICE (50% at 10 years). The *CBFB-MYH11* patients achieved higher MRD level reduction since the end of I ICE course (always >2 Logs). Inv(16) rearranged patients were all alive at last follow-up, and CIR never showed statistically significant differences for MRD levels in inv(16)-rearranged patients after the induction therapy. The impact of copy numbers (*i.e.* transcript levels) at diagnosis and after induction courses on relapse risk never showed significant results in both subgroups of *CBF*-rearranged patients.
Summary and Conclusion: In conclusion this is the first study for MRD evaluation performed by absolute quantification of fusion transcripts in pediatric AML. Results revealed that MRD evaluation using quantitative PCR is an important diagnostic tool that permits the assessment of response to CR and the identification of patients at greater risk of relapse after induction therapy for *AML1-ETO* rearranged patients. We propose that at the end of induction therapy the *cut-off* of MRD<2 Log to be used to guide therapeutic decisions for this subgroup of SR patients. On the contrary, MRD levels of *CBFB-MYH11* rearranged patients do not have prognostic value on CIR after induction therapy, this suggesting that novel molecular features should be investigated for this subgroup of AML.

P841

NEWLY DIAGNOSED ACUTE MYELOID LEUKEMIA PATIENTS CAN BENEFIT FROM A SIGNIFICANT BETTER SURVIVAL WHEN INCLUDED IN CLINICAL TRIALS

M Michallet[1,*], M Sobh[1], J Monfray[1], H Labussière[1], S Ducastelle[1], M El-hamri[1], L Lebras[1], L Gilis[1], I Tigaud[2], S Hayette[2], F Barraco[1], V Dubois[3], F E Nicolini[1], X Thomas[1]
[1]Hematology, [2]Biology, Centre Hospitalier Lyon Sud, PIERRE BENITE CEDEX, [3]HLA laboratory, Etablissement Français du Sang, Lyon, France

Background: Advances in chemotherapy have improved the prognosis of patients with acute myeloid leukemia (AML), however, with the fast emergence of new molecules and treatment strategies, these advances can be open only to a proportion of patients who are included in clinical trials waiting for the availability/validation of the new therapy.
Aims: The aim of this study is to evaluate the impact of being included in a clinical trial on survival outcome of newly diagnosed AML patients.
Methods: Between July 2007 and September 2013, 572 consecutive newly diagnosed AML patients were included in this study; there were 311 (54%) males and 261 females with a median age of 63 years (range: 20-92), 249 (44%) were less than 60 years old, 216 (38%) were between 60 and 75 years, and 107 (18%) were older than 75 years; 406 (71%) were *de novo* AML and 166 (29%) secondary AML. The patients were divided into risk groups according to both cytogenetic and molecular biology data as proposed by the European LeukemiaNet (Dohner *et al.* Blood 2010). Accordingly, 335 (59%) patients were unfavorable, 83 (15%) favorable, 48 (8%) intermediate I and 106 (18%) were in intermediate II category. 186 (32%) were included in a clinical trial (CT patients) and the rest of patients were treated outside clinical trials [No CT patients, N=386 (68%)]. In CT patients, the treatment procedure consisted on induction chemotherapy followed by consolidation, among them, 58 (31%) received allogeneic hematopoietic stem cell transplantation (allo-HSCT). No CT

patients, received in majority of cases (N=222, 58%) induction chemotherapy + consolidation treatment and in the rest of cases they received other chemo/palliative treatment; in this group, 87 (23%) received allo-HSCT.
Results: We have compared the overall survival (OS) of CT and No CT patients after stratification on age and cytogenetics/molecular biology risk groups. After a median follow-up of 22 months (range: 1-77) for CT patients and 10 months (range: 0.03-77) for No CT patients, the 2-years OS probability of overall survival (OS) for CT unfavorable risk patients all age included was 44.4% *vs*. 25% for the same population but No CT (p=0.002) and it was 95% *vs*. 80% for CT and No CT patients with favorable risk all age included respectively (p=0.002) (Figure). Accordingly, this was still valid when we studied the group of patients aged less than 60 years with 2 years OS for CT unfavorable risk patients of 62.3% *vs*. 45% for the same population but No CT (p=0.007). OS outcome was better in the other groups of age within the CT arm and stratified according to risk group but was not statistically different. In addition, allo-HSCT was well distributed between CT and No CT patients, thus it did not influence on the outcome.

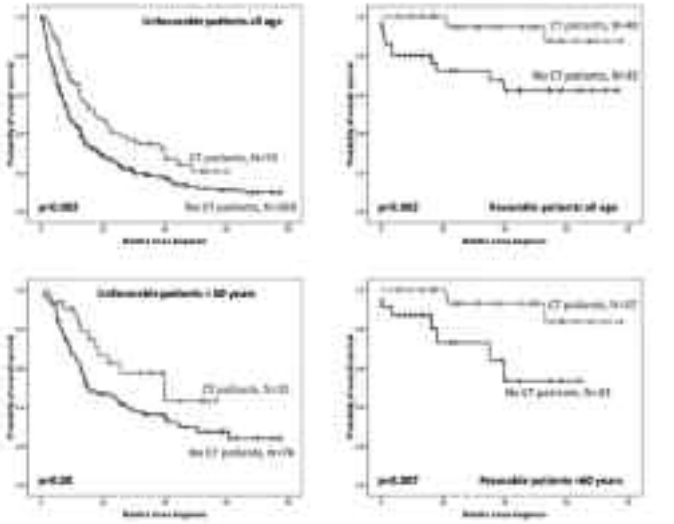

Figure 1.

Summary and Conclusion: We showed that newly diagnosed AML patients can benefit from a better overall survival when included in clinical trials; this can essentially be due to the emergence of new anti-leukemic molecules and to the strict follow-up and adherence to the protocol not only by the patient but also the by the medical team.

P842

CHARACTERIZATION OF FLT3 AND NPM1 MUTATIONS IN AML SAMPLES USING A HIGH THROUGHPUT AMPLICON SEQUENCING ASSAY

Z Xie[1,*], A R Carson[1], M Klass[1], J E Miller[1]
[1]Invivoscribe Technologies, Inc., San Diego, United States

Background: Acute Myeloid Leukemia (AML) is the most common acute leukemia in adults. In Europe the yearly incidence is approximately 3 cases per 100,000 individuals, while in the US approximately 18,860 new cases are expected to be diagnosed in 2014. Mutations in fms-related tyrosine kinase 3 (*FLT3)* and nucleophosmin (*NPM1)* are observed in over one third of all AML patients. These mutations include *FLT3* internal tandem duplications (ITD) within the juxtamembrane domain (15-30% of patients) and substitutions within the tyrosine kinase domain (TKD; 5-10% of patients), as well as 4bp insertions (15-30% of patients) within the C-terminal domain of *NPM1*. These mutations have significant impacts on prognosis; patients with *FLT3*-ITDs have poor prognosis while patients with *NPM1* mutations without an associated *FLT3*-ITD mutation have better long-term outcomes. Characterization of these mutations is critical for accurate therapeutic decisions. In addition, as new therapies arise, such as tyrosine kinase inhibitors targeting constitutively active *FLT3*, accurate mutation detection and characterization is critical to identify presence of resistance mutations and to stratify patients for clinical trials.
Aims: To develop a deep sequencing assay targeting the exons of *FLT3* and *NPM1* corresponding to regions with mutations known to be critical for stratifying patients with AML and potentially containing novel resistance mutations to FLT3 targeted therapies.
Methods: We designed an assay that combines amplicons targeting exons 14, 15, 16, 17 and 20 in *FLT3* and exon 12 in *NPM1* that identifies the major AML related mutations in these two genes. Following multiplex PCR amplification, amplicons were normalized and pooled. These pools were then sequenced on the Illumina MiSeq platform. Coupled with a multiplex PCR step, 24 samples were tested per run. Each MiSeq run of the 24-sample pool generated a minimum depth of coverage of 50,000x for each targeted region. Custom bioinformatics was used to identify *FLT3*-TKD1 & TKD2 region mutations, *FLT3*-IDT mutations, and insertion mutations within *NPM1*.
Results: Accurate detection of *FLT3* and *NPM1* mutations was obtained from positive and negative cell lines and known clinical samples as confirmed by parallel testing using PCR capillary electrophoresis and Sanger sequencing. These analyses correctly characterize each of the known mutations, including an *FLT3*-ITD insertion as large as 192 bases. Allelic ratios were also determined in each case. Unlike capillary electrophoresis methods, this assay provides the exact inserted sequences for *FLT*-ITD and *NPM1* mutations. Furthermore, serial dilutions of the positive controls with negative control DNA showed sensitivity down to 1%. From these analyses, we determined that our novel amplicon based sequencing assay was able to accurately identify *FLT3* and *NPM1* mutations in these samples.
Summary and Conclusion: A novel high throughput NGS assay that utilizes multiplex PCR amplification of exons in *FLT3* and *NPM1* was developed to identify AML mutations. This assay detects *FLT3*-TKD1 and TKD2 region single and multiple nucleotide substitutions, as well as *FLT3*-ITD and *NPM1* insertions. The additional information provided by this assay allows mutations to be further characterized by exact location and sequence. Lastly, due to the extensive depth of coverage provided by this assay, our results indicate that the mutation detection sensitivity can accurately distinguish mutations at a frequency as low as 1%. In conclusion, this assay provides a robust and accurate method for characterizing *FLT3* and *NPM1* mutations in AML cells.

P843

COMPARATIVE ANALYSIS OF FOUR COURSES OF STANDARD-DOSE CONSOLIDATION WITHOUT MAINTENANCE *VERSUS* THREE COURSES OF LOW-INTENSITY CONSOLIDATION WITH MAINTENANCE IN ADULTS WITH ACUTE MIELOID LEUKEMIA

S Semochkin[1,*], T Tolstykh[2], V Lunin[3], N Huageva[3], M Pochtar[3], V Ivanova[3], E Arshanskay[3], S Chernysh[3], S Kulikova[1], A Rumiantsev[2]
[1]Russian National Research Medical University named after N.I.Pirogov, [2]Federal Scientific and Clinical Centre of Pediatric Hematology, Oncology and Immunology named after Dmitry Rogachev, [3]City Clinical Hospital named after S.P.Botkin, Moscow, Russian Federation

Background: The key problem in the treatment of adult patients with acute myeloid leukemia (AML) is to prevent disease recurrences. Although intensive consolidation therapy has proven useful, the practicability of maintenance therapy remains controversial.
Aims: To examine the efficacy of standard-dose consolidation *versus* low-intensity consolidation with maintenance therapy for patients with AML.
Methods: A total of 198 patients with median age 43.9 years (range, 15-64) with de novo AML which did not receive allogeneic hematopoietic stem cell transplantation (HSCT) were enrolled in this report. Of these, 97 patients during 2000-2009 were assigned to receive 2 cycles of induction "3+7" (daunorubicin 45 mg/m^2 on days 1-3; cytarabine 100 mg/m^2 every 12 hours [q12h] on days 1-7) and consolidation of 3 cycles "1+5" (daunorubicin plus cytarabine) following by maintenance chemotherapy also cycles for 2 years (local trial AML-2000). Other 101 patients during 2007-2012 were treated 2 cycles of induction "3+7" or "3+7" plus HAM (cytarabine 3 g/m^2 per q12h on days 1-3; mitoxantrone 10 mg/m^2 on days 3-5) if the complete response (CR) was not documented after the first cycle. Then there were 4 cycles of consolidation HiDAC (3 g/m^2 per q12h on days 1-3) without following maintenance (local trial AML-2007).
Results: In total, 57.1% of patients achieved CR. The 5-year overall survival (OS) rate was 20.4 ± 3.3%, and the relapse-free survival (RFS) rate for the 113 patients who achieved CR was 36.3 ± 5.0%. No statistical difference was observed either in the 5-year OS rate (21.2 ± 4.3% *vs*. 22.2 ± 5.2%; P=0.184) or in the 5-year DFS rate (33.7 ± 6.5% *vs*. 44.3 ± 6.8%; P=0.781) between the two trials. However, the incidence of late recurrence was higher for trial AML-2000 (26.0% *vs*. 8.6%; P=0.047). The median length of follow-up of surviving patients was 3.1 and 9.4 years respectively. The probability of achieving CR (42.6% *vs*. 74.0%: HR 0.26; 95% CI 0.11-0.61; P=0.002) and 5-year OS rate (24.0 ± 9.8% *vs*. 37.7 ± 8.4%; P=0.054) were lower for patients ≥ 46 *versus*<46 years. Furthermore 5-year OS rate was worse for patients achieve CR after two cycles of therapy *versus* one cycle of therapy (17.3 ± 9.0% *vs*. 44.1 ± 9.4%; P=0.007). Standard-dose consolidation compared with low-intensity concolidation was accompanied by a higher frequency of adverse events III/IV degree, including neutropenia (100% *vs*. 68.9%; P<0.001), thrombocytopenia (100% *vs*. 55.2%; P=0.012) and enteropathy (29.4% *vs*. 0%; P=0.001).
Summary and Conclusion: Both the concept of post-remission therapy for adults with AML were demonstrated an equivalent efficacy. Maintenance therapy is justified at least for patients who did not receive intensive consolidation and allogeneic HSCT.

P844

MN1 OVEREXPRESSION IS A POWERFUL PREDICTOR OF FAILURE OF INDUCTION CHEMOTHERAPY IN ACUTE MYELOID LEUKEMIAS SUCH AS CONVENTIONAL CYTOGENETICS AND AGE

C Rodríguez-Medina[1,*], G Santana-Lopez[2], N Cruz[1], M Torres[1], MT Gomez-Casares[1], C Bilbao[1], H Luzardo[1], A Suarez[1], S Bravo de Laguna[1], T Molero[1]
[1]Hematology, [2]Medicina Preventiva, Hospital universitario Gran Canaria Dr Negrin, Las Palmas de Gran Canaria, Spain

Background: Acute myeloblastic leukemia (AML) is a heterogeneous group of conditions characterized by the proliferation of hematopoietic progenitors committed to the myeloid lineage. For the last 30 years, induction therapy, is the combination of cytarabine and an anthracycline, being well established poor prognosis conferred by this treatment failure in overall survival (OS) of patients, therefore given the morbidity and mortality associated with this therapeutic approach has identified several variables such as age, cytogenetics (CG) able to predict this failure to make a proper allocation of appropriate therapy for each patient.
Aims: Identify clinical or biological variables that are associated with higher failure rate to induction therapy and compared with established factors such as age and CG.
Methods: We analyzed 20 variables in a cohort of 120 patients with AML who received induction chemotherapy with the intention of complete remission (CR). We assume treatment failure not achieve CR after the first cycle. To define CR modified Cheson guideline were used and we assign CG risk according to the MRC (1999) and 2010 European Leukemia Net (ELN) criteria. The variables analyzed were: *FLT3* mutation, *NPM1* mutation, *DNMT3A* mutation, *CEBPA* mutation, total leukocyte count, hemoglobin, platelets, blasts in peripheral blood, bone marrow blasts percentage, CD34 expression on blasts, LDH, creatinine, overexpression of genes *EVI, BAALC, WT1, MN1*, cytogenetic risk according to MRC and ELN, age and sex.
Results: In our cohort of 120 patients, 62% were male in 38% of women. The mean age at diagnosis was 54 years, with 59.3 for those with persistent disease and 47.5 years for reaching CR (t-student p=0.000064). In bivariate analysis the relative risk (RR) was significant for known variables such as age, considered as dichotomous in>55 years (RR=2.62 (1.59 to 4.29) χ^2 p=0.000024) and>65 years (RR=2.69 (1.81 to 3.98) χ^2 p=0.0000019) and CG (adverse risk against good risk group, RR=7.00 (1.93 to 9.58) p=χ^2 0.009), and Intermediate risk group as compared to the good ELN criteria, RR=4.46 (1.92 to 6.80) χ^2 p=0.002). Of the other variables analyzed reached statistical significance only mutated *NPM1* as a protective factor (RR=0.47 (0.23 to 0.97) χ^2 value p=0.017)) and overexpression of *MN1* (RR=4.71 (1.84 to 12.03) χ^2 value p=0.000017)). In multivariate analysis, all three variables confirmed and maintained their statistical significance (Odds Ratios (OR): CG: 18,479, 95% CI (1.148 to 297.516), Age: 1,058 95% CI (1.017 to 1.101), *MN1*: 9,411, 95% CI (2.645 to 33.482).
Summary and Conclusion: In our series consisted of 120 patients, confirmed the prognostic value of age (>55 years CR rate: 35%, RR=2.62 (1.59 to 4.29),>65 years CR rate: 21% RR=2.69 (1.81 to 3.98)) and risk CG (CG adverse CR rate: 30%, RR=7.00 (1.93 to 9.58)) have for failure to induction therapy and also confirm previous findings of other cooperative groups as CALGB, wherein overexpression of MN1 (CR rate: 40%, RR=4.71 (1.84 to 12.03) were associated with an increased risk of failure with conventional chemotherapeutic schemes.

Chronic lymphocytic leukemia and related disorders - Biology 3

P845

A PHENOTYPIC STUDY OF MONOCLONAL B-CELL LYMPHOCYTOSIS, WITH EMPHASIS ON BIPHENOTYPIC CASES

I Kostopoulos[1,*], G Paterakis[2], K Papadimitriou[2], D Pavlidis[3], S Papadhimitriou[3], O Tsitsilonis[4]
[1]Haematology Laboratory/ Center of Immunology and Transplantation, Regional Hospital of Athens “G. Gennimatas” / Biomedical Research Foundation of the Academy Of Athens, [2]Flow Cytometry Laboratory, [3]Haematology Laboratory, Regional Hospital of Athens “G. Gennimatas”, [4]Department of Animal and Human Physiology, National and Kapodistrian University of Athens/ Faculty of Biology, ATHENS, Greece

Background: Monoclonal B-cell lymphocytosis (MBL) has attracted a significant research interest as the prelude of chronic lymphoproliferative disorders. Recently, technical advances and the wide application of flow cytometry have allowed for the identification of the disorder in an increasing number of cases. Immunophemotypically, the MBL cases are usually classified according to the expression of CD5 and CD23. However, data from a complete immunophenotypic analysis and the comparison of phenotypic profiles with those of clinical lymphoproliferations are available for a limited number of cases only.
Aims: In this study, we present the immunophenotypic profiles of 70 MBL cases, analyzed with multi-parameter flow cytometry. In addition, we have applied interphase FISH (i-FISH) for the investigation of chromosomal aberration frequently observed in chronic lymphoproliferations.
Methods: The study included 49 men and 31 women with MBL, according to the currently established diagnostic criteria. Multi-parameter flow cytometry was performed on a peripheral blood sample, with the use of a wide panel of antibodies for surface and cytoplasmic markers, currently applied in the characterization of B-CLL and related low-grade B-cell lymphomas. i-FISH was also performed in all samples, for the detection of del(13q14), +12, -11/11q-, 17/17p-, -6/6q-, t(11;14)(q13;q32) and rearrangement of BCL2 and IGH genes, regardless of the morphological features or the phenotype. In cases with a B-cell count<15% of total WBC, the i-FISH study was performed on highly purified B-cells, after immunomagnetic separation targeting CD19.
Results: Our cases were classified into 4 main categories: i) CD5+CD23+ (35 cases), ii) CD5+CD23- (12 cases), iii) CD5- (18 cases) and iv) MBL with two distinct monoclonal B cell populations (5 cases). 23/35 cases in the first category had a typical B-CLL phenotype, while 7 and 5 cases presented a phenotypic profile closely related to the features of LPL and MZL respectively. In 21/35 (60%) cases, a single cytogenetic abnormality was identified by i-FISH: 16 cases showed del(13q14) (hemizygous in 12 and homozygous in 4) and 5 cases had +12. All 12 cases of the second category were found with a MCL phenotype and in half of them (6) t(11;14)(q13;q32) was found as the sole aberration. CD5- MBLs was the most heterogenous group with immunophenotypic feautures ranging from LPL, to MZL and atypical B-CLL. FISH testing showed del(13q14) in 5/18 CD5- MBL cases. Lastly, the analysis of the biphenotypic cases revealed an interesting immunophenotypic pattern with the coexistence of a $CD5^-CD20^+$ MZL-like population and a $CD5^+CD20^-$ B-CLL-like population in 4 cases, expressing the same light chain isotype in three of them and a different one in the fourth. The fifth case in this group comprised an IgG+ HCL-like and an IgMD+ MZL-like population, with the same light chain restriction. No cytogenetic aberration was identified among the bipenotypic cases and, therefore, a separate clonal origin of the two distinct could not be verified.
Summary and Conclusion: Our results indicate that MBL is a highly heterogenous disorder, and that its phenotypic features may correspond to various chronic lymphoproliferations. The presence of t(11;14) among cases with a consistent phenotype is perhaps equivalent to the diagnosis of the recently described “indolent” MCL. Long term follow up of MBL cases, with a phenotype deviating from that of typical B-CLL, could reveal a preclinical stage in other chronic lymphomas, as well. Moreover, it could prove informative for possible phenotypic changes during disease progression. The presence of biphenotypic MBL cases leads to the assumption that different subsets of normal B cells in the same individual may be targets for oncogenetic events involved in lymphomagenesis. An extensive genetic study and follow-up of these individuals will hopefully allow for the distinction between biphenotypic and biclonal cases and help in our understanding of the pathogenetic mechanisms in B-cell lymphoproliferative diseases.

TARGETED ARRAYCGH USED FOR DETERMINING MINIMALLY DELETED REGION ON CHROMOSOME 6Q IN CHRONIC LYMPHOCYTIC LEUKEMIA PATIENTS

M Jarosova[1,*], M Hruba[2], A Oltova[3], H Urbankova[1], L Kruzova[1], E Kriegova[4],

M Holzerova[1], V Prochazka[1], R Urbanova[1], T Papajik[1], M Doubek[3], V Vozobulova[2], K Indrak[1]
[1]Hemato-oncology, University Hospital, Olomouc, [2]Hemato-oncology, University Hospital, Plzen, [3]Hemato-oncology, University Hospital, Brno, [4]Immunology, University Hospital, Olomouc, Czech Republic

Background: Cytogenetic abnormalities such as del(13q), del(11q), trisomy 12, del(17p), 14q32 translocations or a complex karyotype and the mutational status of *TP53, SF3B1, NOTCH1*, and *BIRC3* have improved present-day risk stratification in chronic lymphocytic leukemia (CLL). Recurrent cytogenetic abnormalities also include chromosome 6q deletion. It occurs at a relatively low frequency (3-6%) and its prognostic significance remains controversial; the same holds true for the extent of deletion and the candidate genes in the deleted region.
Aims: The objectives were to analyze a group of CLL patients with chromosome 6q deletion using arrayCGH, to determine the minimally deleted region (MDR) and the candidate genes located within the region, and to try to determine their relative gene expression, and evaluate some clinical characteristics.
Methods: The peripheral blood/bone marrow samples from a group of 1055 CLL patients in three hematology centers in the Czech Republic (Olomouc, Plzen and Brno) were analysed using conventional cytogenetics and FISH, and 6q deletion was found in 70 (6.6%) of the patients. ArrayCGH with chromosome 6 specific and oligonucleotide microarrays was performed in 52 patients (36 M/16 F; median age 61 years, Binet stage A (n=19), stage B (n=18), stage C (n=15), 25 pts at diagnosis, 27 pts in the course of the disease; 29 untreated and 23 treated; unmutated *IGVH* 41 pts). *FOXO3, NF-kB*, *TBX21*, *IL-2* and *BCL10* gene expression was assessed by quantititative RT-PCR in peripheral blood mononuclear cells obtained from CLL patients with/without 6q deletion (n=17/n=30) and in healthy controls (n=19); PGK1 as a normaliser.
Results: 6q deletion, as a single aberration, was observed in 9 (17%) patients and in 20 (38.4%) patients as part of complex karyotype. In one patient, chromothripsis of chromosome 6 was observed. arrayCGH confirmed high heterogeneity of the range of 6q deletion and MDR of 1.4 Mb was determined in the q21 region spanning eight genes (*FOXO3, SOBP*, *SCML4*, *SEC63*, *OSTM1*, *NR2E1*, *LACE1*, and *ARMC2)*. Expression profiling of *FOXO3*, a regulator of cell cycle and/or apoptosis, revealed a lower number of *FOXO3* transcripts in CLL patients with 6q deletion than in those without 6q deletion (p=0.03) and healthy subjects (p<0.0001). Of the genes (*NF-kB*, *TBX21*, *IL-2* and *BCL10*) possibly influenced by *FOXO3* levels, increased mRNA expression of *NF-kB* was detected in CLL patients with 6q deletion compared to patients without 6q deletion (p=0.03) and healthy controls (p<0.0001). Cytokine *IL-2* expression was lower in patients with 6q deletion, but reached significance only between CLL patients with 6q deletion and controls (p=0.0003). The clinical evaluation of the deletion showed that 6q deletion was more prevalent in males; the patients had unmutated *IGVH* and were in more advanced clinical stages (Binet B and C).
Summary and Conclusion: In our CLL patients with 6q deletion, we determined MDR of 1.4Mb involving eight genes including *FOXO3*. Deletion of 6q was more frequently observed in males, patients with unmutated *IGVH* and in more advanced stages of the disease. The observed low mRNA expression of *FOXO3* and high expression of *NF-kB* in CLL patients with 6q deletion demands further investigation. INCORPORATION OF NEXT-GENERATION SEQUENCING INTO ATM GENE ANALYSIS IN PATIENTS WITH CLL AND MCL

V Navrkalova[1,*], A Mareckova[2], A Janikova[2], M Doubek[1], J Mayer[2], S Pospisilova[1], M Trbusek[1]
[1]Molecular medecine, CEITEC, MU, Brno, [2]Internal Medicine-Hematology and Oncology, University hospital Brno, Brno, Czech Republic

Background: ATM kinase plays a key role in p53 activation after dsDNA breaks. Germinal *ATM* inactivation leads to neurodegenerative syndrome Ataxia telangiectasia and heterozygous mutations to predisposition for breast cancer and lymphoid tumors, particularly chronic lymphocytic leukemia (CLL) and mantle cell lymphoma (MCL). In CLL, *ATM* defects (11q- and/or mutation) are at diagnosis the most frequent aberrations (20% of patients) associated with negative prognosis. Regarding MCL, hallmark translocation t(11;14) is commonly accompanied by *TP53* mutation and even more frequently by *ATM* inactivation (40-56% of patients), but information about clinical impact is still limited.
Aims: Our aims were: (1) to introduce next-generation sequencing (NGS) mutation analysis of *ATM* in CLL and MCL samples, (2) to correlate disclosed mutations with the ATM functional status in CLL.
Methods: The following samples were selected for NGS analysis: (a) 16 CLL samples according to the ATM functional status (determined by functional test reported by us previously) including 15 dysfunctional or borderline samples and one sample with normal ATM function; (b) 14 initial MCL samples that were chosen randomly. Three of the 16 CLL samples had known *ATM* mutation status and served as controls. Primers for all coding exons (n=62) and adjacent splicing sites were designed for multiplex PCR setting. Some exons had to be divided to obtain amplicons of similar length (350±50 bp). The amplicon library per sample was prepared through 15 multiplex PCR reactions, purification and pooling. Nextera XT kit (Illumina) was used for library tagmentation and normalization and sequencing ran on MiSeq instrument (Illumina). Final data was analyzed by software CLC Genomic Workbench and Annovar. The median coverage was 4025 and cut-off value for variant frequency was set to 5%.
Results: We identified 5 CLL patients with presumably pathogenic *ATM* mutations. Two of these samples were positive controls, in which NGS confirmed mutations previously identified by Sanger sequencing and moreover detected one additional minor mutation. The third mutated sample harbored frameshift alteration p.2613_2616del (allelic frequency (AF) 83%) and the next one manifested non-synonymous variation p.1570A (AF 33%) together with silent alteration V245V (AF 18%) leading to partially aberrant skipping of exon 10. The last mutated sample exhibited missense and frameshift mutation leading to substitution p.I323K (AF 88%) and p.A1211fs (AF 5%), respectively. All remaining samples were wild-type according to NGS output. Importantly, all three new samples with *ATM* mutation(s) showed dysfunction in functional test. On the other hand, there were 9 samples with predicted ATM dysfunction that do not harbor any pathogenic alteration in analyzed region. Concerning MCL samples, we identified 6 *ATM* mutations in 4 patients, namely p.Q2522H (AF 41%), p.Y2833fs (AF 38%), p.Q2730L (AF 32%), p.R2871T (AF 32%), p.E1724G (AF 15%), p.E590fs (AF 7%). In most of samples we detected several common polymorphisms that should not significantly affect ATM stability and function.
Summary and Conclusion: We implemented NGS analysis enabling effective and sensitive *ATM* mutation detection. ATM dysfunction can be connected with mutations in coding region but possibly with other defects in non-coding regions or in some other part of ATM-p53 pathway as well. [1]CEITEC - Central European Institute of Technology, [2]University Hospital Brno, [3]University of Veterinary and Pharmaceutical Sciences, Brno, Czech Republic

Background: Xenograft models represent very promising biological tools to study the molecular basis and pathogenesis of many hematological malignancies. To establish a reliable and appropriate *in vivo* model of human leukemia we used immunodeficient NOD/SCID gamma (NSG) mice. These mice lack a functional receptor for interleukins and do not have functional T, B and NK cells, in contrast to NOD/SCID mice that retain NK cells. Here we report a study concerning mouse xenograft models using TP53- or ATM-deficient B-cell lines MEC-1, SU-DHL-4, JEKO-1, GRANTA-519 and REC-1.
Aims: The present study was designed to compare engraftments in NSG mice of TP53- or ATM-deficient B-cell lines. Our goal was to create a mouse xenograft model by transplanting cells of five cell lines, including chronic lymphocytic leukemia (CLL) and mantle cell lymphoma (MCL) into NSG mice. We would then analyze the engraftment potential of these cell lines. The current study shows that B-cell lines-engrafted NSG mice can be successfully used for investigating the pathogenesis of hematological malignancies with potential for application in tailored therapy.
Methods: In total, 30 six to eight-week-old non-irradiated mice (n=6 per experimental group) were injected with 5x10e6 malignant cells in phosphate-buffered, saline (PBS). The injections were given intraperitoneally (IP, n=3) or subcutaneously (SC, n=3). Six control mice (one per group) were injected with PBS only. All animals were monitored individually throughout the experiment. After 4 weeks, all recipient mice were sacrificed by cervical dislocation and peripheral blood (PB), bone marrow (BM) and tissue samples (spleen, liver, tumor) were analyzed by histology, immunohistochemistry and flow cytometry analysis.
Results: All malignant cell lines except SU-DHL-4 injected IP or SC into NSG mice successfully engrafted. Three to four weeks after SC injection, four cell lines produced rapidly growing subcutaneous tumors in both male and female mice. Immunophenotype of all engrafted cell lines corresponded to human mature B cells expressing CD10-19+20+HLA-DR+ except for SU-DHL-4 and REC-1 cells which were moreover CD10+ and HLA-DR- respectively. In two lines, MEC-1 (CLL in transformation) and GRANTA-519 (MCL), we observed highly efficient engraftment of leukemic cells with very aggressive growth. MEC-1 IP injection led to significant weight loss (P=0.03), mild hepatomegaly and huge splenomegaly and death in one case. In GRANTA-519, there was huge tumor found in abdominal cavity or subcutaneously in all mice. Intraperitoneal tumor filled always the entire abdominal cavity. Immunohistological and flow cytometric analysis revealed a massive infiltration of liver, spleen and bone marrow by human CD19 and CD20 positive cells with high proliferative index. Noteworthy, only with GRANTA-519 it was observed that transplantation of

human tumor cells resulted in prominently higher infiltration of the bone marrow regardless of administration route. It might be due to wild-type TP53 status in combination with mutated ATM. In the other cell lines tested, the mutation status of ATM is unknown while TP53 is mutated.
Summary and Conclusion: According to our results, GRANTA-519 and MEC-1 cell lines appears to be the most suitable for xenograft model of human B-cell malignancies and would be a criterion for future use of selected lymphoid xenotransplant for chemical agent-based treatment experiments. P849

COPY NUMBER ALTERATIONS AND NOTCH1 MUTATIONS PREDICT THE OUTCOME OF PATIENTS WITH CHRONIC LYMPHOCYTIC LEUKAEMIA AND NORMAL FISH

R Santacruz[1], I Salaverría[2], A Navarro[2], C Royo[2], T Baumann[1], M González[3], A R Payer[4], MJ Terol[5], E Conde[6], C López[2], M Pinyol[2], N Villamor[2], M Aymerich[2], D Colomer[2], A Carrió[2], D Costa[2], E Giné[1], A López-Guillermo[1], E Campo[2], S Beà[2], J Delgado[1,*]
[1]Hematology, [2]Hematopathology, Hospital Clínic, IDIBAPS, Barcelona, [3]Hematology, Hospital Clinico, Salamanca, [4]Hematology, Hospital Central de Asturias, Oviedo, [5]Hematology, Hospital Clinico, Valencia, [6]Hematology, Hospital Marques de Valdecilla, Santander, Spain

Background: Fluorescent in-situ hybridization (FISH) is the gold-standard method for cytogenetic assessment in chronic lymphocytic leukaemia (CLL), although commercial FISH panels only screen four specific aberrations (trisomy 12, deletions of 13q14, 11q22-q23*/ATM* and 17p13/*TP53*). Patients whose tumour cells harbour none of these aberrations are considered to have an intermediate-favourable outcome, but there are significant differences among them. On the other hand, copy number (CN) arrays scan unbalanced aberrations of the whole genome and could be a suitable alternative for FISH. Conventional cytogenetics after incubation with novel mitogens (DSP30 + IL-2) has also proven useful in these patients.
Aims: The purpose of this study was to analyse through CN arrays all consecutive patients from our database who had a normal FISH result at diagnosis and DNA available for analysis.
Methods: We identified 79 consecutive patients with CLL and a normal FISH result at diagnosis. Conventional cytogenetics was performed on Giemsa-banded chromosomes obtained after a 72-hour culture and stimulation with tetradecanoyl-phorbol-acetate (TPA). FISH studies for 11q, 13q and 17p deletions and trisomy 12 were performed using the Vysis CLL probe kit. *IGHV* mutational status and *TP53* mutation analysis were performed by Sanger sequencing. Exon 34 of *NOTCH1* and exons 14, 15, 16 and 18 of *SF3B1* were also sequenced. Copy number alterations (CNAs) were evaluated using high resolution CN array platforms (Affymetrix 6.0). Maximally selected rank statistics (maxstat) were used to identify the best cutpoint for CNAs. Time to first treatment (TTFT) was evaluated using cumulative incidence curves and considering death without therapy as a competing risk, while overall survival (OS) was evaluated using Kaplan-Meier plots and the log-rank test. Multivariate modeling of TTFT and OS were performed using Fine & Gray and Cox regression methods. Both outcomes were evaluated from the time of DNA sampling.
Results: Of all 79 patients with normal FISH results, 42% had at least one alteration: 14% had 1, 10% had 2, 9% had 3 and 9% had 4 or more CNAs. The most common losses were 18p, 14q, and 13q (each detected in 3 patients); and the most common gain was 2p (3 patients). Moreover, 18% patients had an abnormal karyotype by CBA, 40% had unmutated *IGHV* genes, 2/53 (4%) had *TP53* mutations, 6/51 (12%) had *SF3B1* mutations and 5/65 (8%) had *NOTCH1* mutations. Maxstat analysis revealed that the best cutpoint for genomic complexity was 1 (*i.e.* 0-1 *vs*. 2 or more). Univariate analysis revealed that the following covariates were associated with TTFT: genomic complexity (p<.001), unmutated *IGHV* (p<.001), high ZAP70 expression (p<.001), high CD38 expression (p<.001), *TP53* mutations (p<.006), *NOTCH1* mutations (p=.018); while there was a trend toward a shorter TTFT for patients who had abnormal cytogenetics (p=.10). Multivariate analysis confirmed that genomic complexity and *IGHV* mutational status both had an independent impact on TTFT (p=.044 and p=.003, respectively). In terms of overall survival, the covariates with a significant effect by univariate analysis were *NOTCH1* mutations (p=.001), genomic complexity (p=.039) and *TP53* mutations (p=.38), while there was a trend for *IGHV* mutational status (p=.052). Multivariate analysis showed that presence of *NOTCH1* mutations was the only factor independently associated with OS (p=.003).
Summary and Conclusion: The outcome of patients with CLL and normal FISH results is modulated by genomic complexity as determined by copy number arrays, as well as other molecular abnormalities such as *NOTCH1* mutations and the *IGHV* mutational status. These results may be taken into account when designing risk-adapted therapeutic approaches.

TAP63 IS EPIGENETICALLY REGULATED AND HIGHLY OVEREXPRESSED IN AGGRESSIVE CLL STEREOTYPED SUBSET #8

N Papakonstantinou[1,*], S Ntoufa[1], M Tsagiopoulou[1], E Stalika[1], A Malousi[2], M Karypidou[3], D Rossi[4], N Maglaveras[2], A Anagnostopoulos[3], G Gaidano[4], F Davi[5], P Ghia[6], C Belessi[7], C Pott[8], K Stamatopoulos[1]

Background: CLL stereotyped subsets #6 (IGHV1-69/IGKV3-20) and #8 (IGHV4-39/IGKV1(D)-39) both express unmutated BCRs yet exhibit different clinical behavior with subset #6 being less aggressive compared to subset #8, which exhibits the highest risk for development of Richter's syndrome among all CLL. No explanation is available for this difference, thus prompting investigation into the underlying mechanisms.
Aims: Taking the above into consideration and also given our recent finding that subsets #6 and #8 display differential DNA methylation profiles, we here explored the impact of this phenomenon on gene expression with the aim of obtaining insight that would assist in unraveling their pathobiology.
Methods: Five genes with the most striking differences in methylation status were chosen for comparative gene expression profiling in 8 subset #6 *versus* 10 subset #8 cases: ZNF300, EP400, PRDM16, TP63, HOXA5. TP63 isoform expression was assessed by RT-PCR with appropriate primers in a cohort of 64 cases, while determination of the Tap63 isoform in the same cohort was performed by RQ-PCR. Quantitative measurements were performed on negatively selected CD19+ B cells from peripheral blood samples obtained at diagnosis or before any treatment. TP53 mutational screening was performed by bidirectional Sanger sequencing.
Results: Differential DNA methylation between the two stereotyped subsets was linked to differential gene expression. Among the differentially expressed genes, TP63 showed the highest difference (FD=52.5, p<0.001) and was overexpressed (while in parallel hypomethylated) in subset #8 *vs* #6. This initial study concerned total mRNA *i.e.* could not discriminate between TP63 isoforms. Therefore, in order to identify which p63 isoforms are expressed in CLL, we screened by RT-PCR with appropriate primers 64 CLL cases, of whom 41 carried unmutated IGHV genes (U-CLL, including 10 subset #8 and 8 subset #6 cases), while 23 carried mutated IGHV genes (M-CLL). We detected mRNA of the TAp63 isoform only, whereas the ΔNp63 isoform was not expressed in any case. This is noteworthy, given recent reports that TAp63 not only directly affects cell survival but also influences the migratory and invasive properties of CLL cells to the bone marrow, indirectly regulating their survival as well. In order to investigate potential correlations with immunogenetic features of the leukemic clones, we quantitated TAp63 mRNA expression in the same cases and observed significantly higher TAp63 mRNA levels in U-CLL *versus* M-CLL (p<0.01). Interestingly, subset #8 showed significantly (p<0.001) higher TAp63 expression compared to all other subgroups under study, including the remaining U-CLL. Considering that mutant p53 binds to, and inhibits the activity of TAp63, we also performed TP53 mutational analysis and found only 4/55 cases bearing mutations; of note, none of these mutations located in the region responsible for the formation of aggregates with TAp63.
Summary and Conclusion: In conclusion, differential DNA methylation underlies varying expression of the TP63 gene, more specifically its TAp63 isoform, in CLL subgroups with distinct immunogenetic profiles. Overexpression of Tap63 in CLL subset #8 may represent a novel relevant pathomechanism of aggressiveness for this particular subset.

Papanicolaou Hospital, [11]Institute of Applied Biosciences, CERTH, Thessaloniki, Greece

Background: Recently, next generation sequencing (NGS) studies have revealed a number of novel recurrent mutations in CLL, the prime examples being mutations within NOTCH1, SF3B1 and BIRC3, with higher frequencies in patients with a more aggressive disease and a poor clinical outcome. Considering the increasing number of prognostically relevant genes and the relatively high cost and laborious nature of Sanger sequencing, we aimed at exploring targeted NGS as a novel strategy to assess the mutation status of several genes with prognostic potential. Major advantages with this approach revolve around its capacity to screen a large number of genes and patient samples simultaneously (currently up to 96 samples). Aside from the ability to multiplex both genes and patient samples, the high sequence depth achievable also enables tracking minor subclonal populations over time. Since subclonal dynamics are partially shaped by the treatment regimen received, this will become important as new therapies enter the clinic. An additional favorable attribute of targeted NGS is the ability to analyze all coding exons within a gene regardless of length. This is noteworthy since the size of several prognostic genes, such as ATM, would hinder comprehensive gene analysis within a clinical setting.
Aims: To this end, we designed a HaloPlex gene panel (Agilent Technologies) focusing on 10 genes (mean coverage 99%); TP53, ATM, SF3B1, NOTCH1, BIRC3, MYD88 and POT1 have been linked to CLL prognosis, while XPO1, KLHL6, LRP1B are less characterized but were observed in various NGS studies.
Methods: A total of 168 high risk CLL patients were investigated (unmutated IGHV, n=119; IGHV3-21 subset #2, n=49). Sequencing libraries were run on the Illumina 2000 HiSeq instrument and a mean read depth of ~1500 reads/base within the regions of interest was obtained. Data were analyzed using our in-house bioinformatics pipeline that required the following conditions to be met for a variant to pass all filtering steps: (i) exonic or in a splicing region; (ii) non-synonymous or resulting in a frameshift; (iii) not listed in dbSNP137; (iv) variant allele frequency >0.1; and, (v) variant allele read depth >10.
Results: Using the conservative cut-off of 10% for the mutant allele, we found that 105/168 (62.5%) patients carried at least one mutation; ATM (n=33; 20%), BIRC3 (n=5; 3%), NOTCH1 (n=28; 17%), SF3B1 (n=34; 20%) and TP53 (n=17; 10%). Collectively, mutations within these 5 genes accounted for 131/171 (77%) of all mutations observed. Fifty-three patients had more than 1 mutation and 45/53 harbored mutations within more than one gene. We selected 63 mutations for validation, with mutant allele frequencies ranging from 0.10-0.98, and were able to confirm all of them by Sanger sequencing (Table 1).

Table 1.

Gene	No. of cases with mutation	No. of mutations	Selected for validation	No. validated
ATM	33	43	0	0
BIRC3	5	6	4	4/4
KLHL6	1	1	0	0
LRP1B	18	19	0	0
MYD88	2	2	0	0
NOTCH1	28	29	17	17/17
POT1	7	8	0	0
SF3B1	34	35	29	29/29
TP53	17	18	13	13/13
XPO1	9	10	0	0
Sum		171	63	

Summary and Conclusion: With the prognosis of CLL becoming increasingly dependent on an understanding of the molecular landscape of the disease, mutational screening within clinical practice will soon become routine. However, given the large number of potentially significant genetic mutations increasingly being identified, it is apparent that a high-throughput tailored approach is vital in order to efficiently acquire and utilize this data. This study demonstrates the applicability of targeted NGS as a new approach for mutational screening within clinical routine. In the future the need to confirm NGS results by Sanger sequencing will decrease dramatically thereby significantly reducing the amount of labor and costs for clinical laboratories wishing to use NGS technologies.

P853

CYTOGENETIC EVOLUTION PATTERNS IN CHRONIC LYMPHOCYTIC LEUKEMIA

M Iskas[1,*], G Papaioannou[1], P Baliakas[2], M Gaitatzi[1], Z Lazarou[1], E Stalika[3], K Stamatopoulos[3], A Anagnostopoulos[1], A Athanasiadou[1]
[1]Hematology Department & HCT Unit, G. Papanicolaou Hospital, Thessaloniki, Greece, [2]Department of Immunology, Genetics and Pathology, Rudbeck Laboratory, Uppsala University, Uppsala, Sweden, [3]Institute of Applied Biosciences, Centre for Research and Technology, Thessaloniki, Greece

Background: Among the various prognostic factors reported as relevant in chronic lymphocytic leukemia (CLL), specific cytogenetic abnormalities have a prominent role and can be correlated to distinct clinical course and response to treatment.
Aims: The importance of the emergence of new chromosomal aberrations in different disease timepoints is still under investigation.
Methods: We studied 88 CLL patients with available cytogenetic data at both diagnosis and disease progression. Cohort characteristics were as follows: male/female: 67/21 | Binet stage at diagnosis A/B/C: 60/19/6 | unmutated IGHV genes: 50/87 (57.4%) | CD38 positivity: 39/84 (46.4%) | ZAP-70 positivity: 22/44 (50%). Cytogenetic abnormalities detected by fluorescence *in situ* hybridization (FISH) at diagnosis were: 13q deletion: 30/65 (46.1%), 11q deletion: 6/63 (9.5%), 17p deletion: 9/65 (13.8%), trisomy 12: 9/59 (15.2%). 41/88 (50%) patients had abnormal karyotype at diagnosis. Secondary malignancies were reported in 12/88 (13.6%) of the cases. Patients were divided in two groups, regarding the presence (32/88, 36%, group A) or not (56/88, 64%, group B) of additional cytogenetic aberrations in the karyotype obtained at disease progression.
Results: The additional aberrations observed in group A patients concerned 20 translocations, 19 additions, 21 deletions and 36 multiple numerical aberrations; 19 patients had ≤2 new aberrations and 12 had ≥3, the latter being considered as the emergence of a complex karyotype. Most common breakpoints involved chromosomes 14 (8 breakpoints), 17 (6 breakpoints), 18, 11 and 1 (5 breakpoints). Additional chromosomes involved mostly chromosomes 6 and 21 (4 and 3 cases respectively), whereas chromosome monosomies concerned chromosomes 17 (3 cases) and 9, 10, 13, 16, 18 (2 cases each). No statistically significant difference was observed between the two groups concerning stage at diagnosis, gender, IGHV mutational status or CD38 positivity. On the contrary, group A cases had significantly increased ZAP-70 expression (p=0.03). No correlation was noted concerning the presence of 11q deletion, 13q deletion, 17p deletion or *TP53* mutation and *NOTCH1* mutation at diagnosis. However, patients with trisomy 12 at diagnosis had significantly more frequent occurrence of additional cytogenetic abnormalities at disease progression (p=0.02). Within group A patients, the emergence of a complex karyotype (≥3 abnormalities) at disease progression was identified as prognostically adverse, decreasing overall survival (5-year survival 78% *vs* 91%, p=0.024). In addition, group A patients had a remarkably higher prevalence of secondary malignancies (7/32, 21% *vs* 3/56, 5.3%, p=0.02), regardless of follow up duration. More specifically, in group A, 3 patients developed a second hematologic malignancy (2 acute myeloid leukemia, 1 polycythemia vera) and 4 solid organ malignancies (stomach, bile duct and 2 lung cancer cases), whereas in group B had only 3 cases with skin, prostate and lung cancer, respectively. Survival analysis showed similar survival rates in both groups, (5-year survival 87.5% *vs* 84.1%) irrespectively of CLL-related death or not.
Summary and Conclusion: In conclusion, clonal evolution at disease progression of CLL can provide prognostic information in selected patients *i.e.* those with karyotype complexity and may be associated with genomic instability and intensified cell signaling, as reflected by the high frequency of secondary malignancy and ZAP-70 expression, respectively.

P854

CHARACTERIZATION AND SIGNIFICANCE OF RARE BALANCED IMMUNOGLOBULIN TRANSLOCATIONS IN CHRONIC LYMPHOCYTIC LEUKEMIA

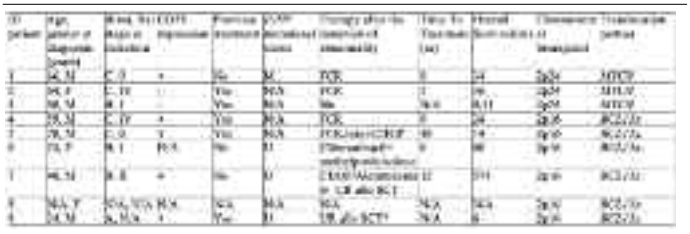
F Van Obbergh[1,*], N Put[1], F Mugneret[2], A Bidet[3], L Veronese[4], M Janssen[5], P Vandenberghe[1], L Michaux[1]
[1]Centrum voor Menselijke Erfelijkheid, K.U.Leuven, Leuven, Belgium, [2]Laboratoire de Cytogénétique, Centre Hospitalier Universitaire, Dijon, [3]Hematologie, Hôpital Haut-Lévèque, Bordeaux, [4]Service de Cytogénétique, CHU Estaing, Clermont-Ferrand, France, [5]Hematologie, Ziekenhuis Oost-Limburg, Genk, Belgium

Background: The type of cytogenetic aberrations can predict outcome in chronic lymphocytic leukemia (CLL). Recent studies suggested that translocations may have a negative impact on response to therapy and survival, especially when unbalanced. Balanced translocations involving immunoglobulin (IG) genes are commonly observed in B-cell non Hodgkin lymphoma, and in only 5-7% of CLL cases. In this entity, their exact characterization seems important since the outcome may vary according to the partner gene.
Aims: To characterize two partners (*BCL11a* and *MYCN*) in unbalanced translocation involving IgH.

Methods: The Belgian Cytogenetic Group for Hemato-Oncology (BCGHo) and the Groupe Francophone de Cytogénétique Hématologique (GFCH) retrospectively reviewed files of patients referred for cytogenetic characterization of CLL between 2004 and 2012. Inclusion criteria were (i) morphological and immunophenotypical (defined as a Matutes score ≥ 3/5) diagnosis of CLL, (ii) a karyotype showing a t(2;14) and (iii) involvement of *MYCN* or *BCL11a* confirmed by fluorescence *in situ* hybridization (FISH). FISH was performed using (i) a probe containing LSI N-MYC [Abbott, labeled in spectrum orange (SO)] and 3 pooled bacterial artificial chromosomes (BAC) located on *IGH* [labeled in spectrum green (SG), *i.e.* RP11-1087P08, RP11-346I20, and RP11-675H01], (ii) a 632 kb break-apart probe containing BACs located at the 3' (RP11-604J13 and RP11-785E21) and at the 5' (RP11-573O13 and RP11-418N22) end of *BCL11a* and (iii) commercially available probes to investigate the common "CLL loci".

Results: Nine patients were collected, 3 with a translocation involving *MYCN* and 6 with a translocation involving *BCL11a*. Their median age was 59 years with a male/female sex ratio of 6/3. Except for one patient, all cases with available data needed therapy. The time to treatment was relatively short (0 to 48 months) in most of the patients. In 2 cases with *MYCN*, there was an associated del(13q). Three of 6 cases with *BCL11a* displayed trisomy 12. Most *BCL11a* abnormalities were associated with a non-complex karyotype.

Table 1: Clinical patient characteristics at the time of the detection of the IG abnormality



ID:identification, M: male, F: female, (m): months, FCR: fludarabine, cyclophosphamide, rituximab, CHOP: cyclophosphamide, adriamycine, vincristine, prednisone, UR: unrelated, allo SCT: allogeneic stem cell transplantation, *: scheduled, N/A: not available, †: dead.

Summary and Conclusion: Among *IG* translocations in CLL, we identified a novel rare partner, *MYCN*. Due to the limited amount of cases, it is impossible to draw conclusions on its prognostic significance at the present time. Another recurring IG translocation partner is *BCLL11a*, associated with an unmutated *IGVH* and expression of CD38. This work is supported by the Salus Sanguinis Foundation.

IMPACT OF TWO CYTOGENETIC LESIONS ON THE OUTCOME OF PATIENTS WITH CHRONIC LYMPHOCYTIC LEUKEMIA

A Visentin[1,2,*], M Facco[1,2], L Bonaldi[3], M Castelli[1,2], F Frezzato[1,2], C Gattazzo[1,2], V Trimarco[1,2], V Martini[1,2], F Severin[1,2], G Chiodin[1,2], A Martines[3], I Gianesello[1], R Zambello[1,2], G Semenzato[1,2], L Trentin[1,2]

[1]Department of Medicine, Hematology and Clinical Immunology branch, Padua University School of Medicine, [2]Venetian Institute of Medicine, Centro di Eccellenza per la Ricerca Biomedica Avanzata, [3]Immunology and Molecular Diagnostic Oncology Unit, Istituto Oncologico Veneto, Padua, Italy

Background: Chronic lymphocytic leukemia (CLL) is the most common leukemia in western country and is characterized by heterogeneous clinical and biological features. The most important prognostic factors are represented by mutational status of immunoglobulin heavy chain variable region gene (IGHV) and genomic aberrations evaluated by fluorescent *in situ* hybridization (FISH), *i.e.* deletion of 11q (11q-), 13q (13q-), 17p (17p-) and 12 trisomy (+12). These chromosome lesions provide prognostic information when classified according the model proposed by Döhner *et al.* (2000). These authors analyzed patients with none, defined as "normal", and 1 genetic lesion; in particular, those harboring 11q- or 17p- had an unfavorable prognosis. However, the daily application of FISH to clinical practice shows that a subset of patients harbors more than one recurrent abnormality.

Aims: The aim of this study was to define the impact of two cytogenetic lesion on CLL patients' outcome.

Methods: In this study we retrospectively analyzed 727 CLL patients referred to the Hematology and Clinical Immunology Unit of Padua University Hospital since 1988. Criteria for inclusion were i) diagnosis of CLL according to iwCLL/NCI criteria and ii) cytogenetic analyses with FISH on bone marrow or peripheral blood sample before starting treatment. Patients with 11q- or 17p- were grouped together. Test *t* Student was used to compare continuous variables. Chi square and Fisher exact tests were used to compare categorical variables. Log-rank test was used to compare survival. Cox proportional hazards model was used to identify independent prognostic factors.

Results: 422 patients fulfilled all inclusion's criteria and were recruited in this study; 124 (30%) had a normal FISH (group 0), 255 (60%) had one FISH aberration (group 1) and 43 (10%) had two cytogenetic lesions (group 2). With respect to patients belonging to the first two groups, group 2 patients had a shorter treatment free survival (TFS, p<0.0001) and overall survival (OS, p<0.0001) in univariate analyses, and a higher risk to underwent treatment (HR 1.00 *vs* 1.15 *vs* 2.52, for group 0,1 and 2 respectively) and death (1.00 *vs* 1.25 *vs* 3.18) in multivariate analyses. Moreover, differences in outcomes among the three groups were also consistent with the expression of unfavorable clinical and biological features at presentation. In particular, patients with two cytogenetic abnormalities were at a more advanced Rai (p<0.0001) and Binet (p=0.0392) stage at diagnosis, had a higher white blood cell count (WBC) and absolute lymphocyte count (ALC) at initial presentation (p<0.0001), and lower percentage of mutated IGHV gene (p<0.0074) than the other two subsets. Furthermore, we characterized patients with 2-FISH lesions and we defined as 13q HR (high-risk) patients harboring 13q- and 11p- or 17p- (*i.e.* high-risk cytogenetic lesions), and +12 HR those carrying +12 and a high-risk deletion. 27 patients, *i.e.* 6.4% of the cohort and 12% of all 13q- subjects, were re-classified as 13q HR. Their median TFS and OS were intermediate between patients harboring only 13q- and those harboring high-risk cytogenetic lesions, 13.82 *vs* 2.50 *vs* 0.81 (p<0.0001) and not reached *vs* 14.76 *vs* 8.62 (p<0.0001), respectively. In addition, they had three times higher risk of treatment (p<0.0001) and death (p=0.0038), presented with a more advance stage (Rai p=0.0200, Binet p=0.0681), higher male/female ratio (p=0.0134), WBC (p=0.0005), ALC (p<0.0001 and percentage of unmutated IGHV (78% *vs* 26%, p<0.0001) that 13q- patients. Considering +12 HR patients, who account for 1.4% of the cohort and for 10% of all subjects with 12 trisomy, are characterized by disease aggressiveness intermediate between those harboring +12 and 11q- or 17p- patients (p<0.0001 for TFS and p=0.0124 for OS). +12 HR patients have a similar risk to underwent treatment, but four times higher risk of death than +12 (p=0.0410); no differences were found among clino-biological features.

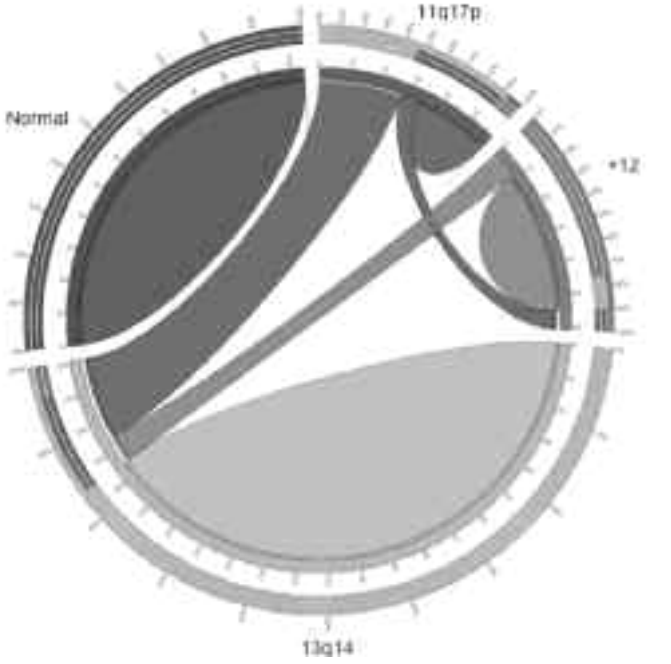

Figure 1.

Summary and Conclusion: This study i) defines new cytogenetic classes, ii) identifies subsets of patients with a more aggressive disease, iii) discloses the prognostic implications of 2 cytogenetic lesions and iv) allows a better prediction of CLL patients' prognosis and outcome.

P856

SF3B1 MUTATIONS IN CLL ARE ASSOCIATED WITH A DEFECTIVE DNA DAMAGE RESPONSE

E Eldering[1,*], D te Raa[2], I Derks[1], V Navrkalova[3], A Skowronska[4], C Oldreive[4], P Moerland[5], J Malcikova[3], M Trbusek[3], J Hullein[6], A Jethwa[6], T Zenz[6], S Pospisilova[3], T Stankovic[4], M van Oers[2], A Kater[2]

[1]Experimental Immunology, [2]Hematology, Academic Medical Center, Amsterdam, Netherlands, [3]Central European Institute of Technology, Brno, Czech Republic, [4]School of Cancer Sciences, Birmingham, United Kingdom, [5]KEBB, Academic Medical Center, Amsterdam, Netherlands, [6]Translational Oncology, National Center for Tumor Diseases, Heidelberg, Germany

Background: Mutations or deletions in *TP53* or *ATM* are well-known determinants of poor prognosis in Chronic Lymphocytic Leukemia (CLL), but

only account for approximately 40% of chemo-resistant patients. Genome-wide sequencing has uncovered novel mutations in the splicing factor sf3b1, that were in part associated with *ATM* aberrations, suggesting functional synergy.
Aims: To uncover the mechanism underlying the contribution of SF3B1 mutation to CLL pathogenesis.
Methods: Detailed genetic and sequence analyses were done in a CLL cohort (n=105) containing *ATM*, *SF3B1* and *TP53* gene defects. Functional analyses were performed: a) p53/ATM target gene induction by multiplex assay, b) apoptosis responses to irradiation and chemotherapeutics, and c) γH2AX focus formation as marker for DNA damage by FACS and microscopy.
Results: There was considerable overlap between *ATM* and *SF3B1* lesions; 18/29 of *SF3B1* mutated cases carried concurrent 11q deletion and/or *ATM* mutation. Combined *TP53* and *SF3B1* mutations were found in 3/29 cases. In this report, we focus on the ten patients where single *SF3B1* lesions were identified. Functionally, the single *SF3B1* (sSF3B1) mutated samples resembled *ATM* mutated CLL in displaying defective ATM/p53 transcriptional and apoptosis response to various DNA-damaging regimens (Fig1A). In *ATM* mutated cases, sensitivity to fludarabine can be restored by nutlin-3a. This was also found for *sSF3B1* mutations (Fig1B), although ATM kinase function remained intact. Finally, γH2AX formation was increased both at baseline and upon irradiation in *SF3B1* mutated cases. The observed effects could not be explained by defective splicing of ATM in *SF3B1* mutated cases.

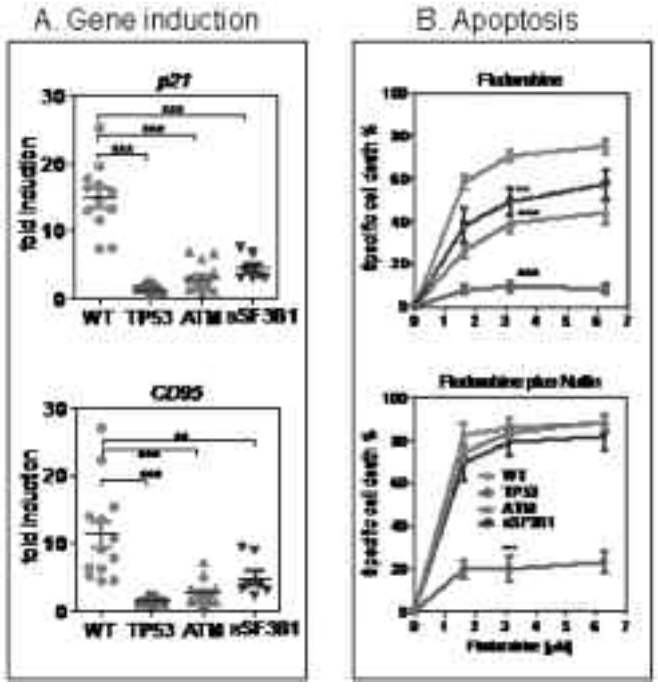

Figure 1.

Summary and Conclusion: Our data demonstrate that single mutations in *SF3B1* are associated with increased DNA damage and/or aberrant response to DNA damage. Combined, our observations suggest an explanation for the poor prognosis of affected patients, and may lead to new treatment strategies.

Background: The impact of mutations and pathway deregulation on drug sensitivity in cancer is only partly understood.
Aims: To identify relevant pathway dependencies that are exploitable by targeted treatment approaches we systematically investigated heterogeneity of drug response and their association with genetic lesions in primary lymphoid malignancies.
Methods: Primary leukemia / lymphoma cells obtained from peripheral blood were characterized with an *ex vivo* high-throughput drug screening platform. Cell viability was assessed by colorimetric quantification of ATP (CellTiterGlo®) at 48 hours of drug exposure. Heat inactivated human serum was supplemented to mimic micro-environmental conditions. In an initial screen 2000-3000 different compounds were tested for cytotoxicity on a cohort of 36 patients (27 chronic lymphocytic leukemia (CLL), 6 T-cell prolymphocytic leukemia (T-PLL), 3 non-CLL B-Non-Hodgkin-Lymphoma (B-NHL)). 67 promising compounds targeting different pathways were further characterized on an extended cohort (n=111; 97 CLL, 5 T-PLL, 6 non-CLL B-NHL, mononuclear cells of 3 healthy donors). To understand heterogeneous pathway dependencies, drug sensitivity was assessed for relations with somatic genetic variants. Genetic characterization was performed by FISH, targeted sequencing of recurrent aberrations (*BRAF, MYD88, NOTCH1, SF3B1, TP53*) as well as whole exome sequencing.
Results: Compounds dependent on functional p53 (Nutlin-3 and fludarabine) induced cell death more efficiently in CLL cells with wild-type (n=80) than with mutated p53 (n=17; Nutlin-3 10μM: 51±18 *vs* 80±18; fludarabine 10μM: 40±36 *vs* 67±23 [% viability of untreated control], both p<0.001). In addition, compounds with related targets, *e.g.* in the B-cell receptor pathway, showed similar response profiles (Fig. 1a). Based on the sensitivity data, we derived a hierarchy of compounds with preferential sensitivity for specific genetic subgroups. We identified compounds with increased activity in groups with high risk aberrations (*e.g. TP53* mutation, 11q deletion, unmutated *IGHV*; Fig. 1b). Validation of the top hit with increased sensitivity in *TP53*-mutated CLL (wt *vs* mut*TP53*: 58±31 *vs* 37±18 [% viability of untreated control], p<0.01) confirmed genotype-specific cytotoxicity across concentration ranges (0.1-10μM). Other compounds inhibiting the same target support our observation. The effect was reproducible in co-culture of CLL cells with HS-5 stroma cells (66±16 *vs* 32±13 [% viability of untreated control], p<0.05).

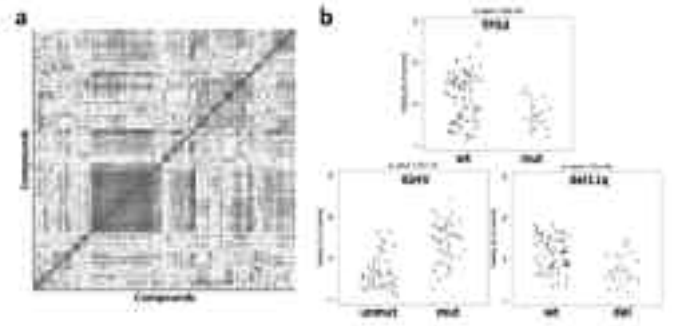

Figure 1.

Summary and Conclusion: Our data provide a comprehensive map of biologically determined drug sensitivity in lymphoid malignancies. The work offers a novel functional classification of lymphoma based on drug sensitivity and identifies potential vulnerabilities of high risk CLL.

P858

TRISOMY 12 IS ASSOCIATED WITH A DISTINCT PATTERN OF LYMPHOCYTOSIS DURING TREATMENT OF CLL WITH IBRUTINIB, WHICH DOES NOT AFFECT RESPONSE DEPTH OR DURATION

P A Thompson[1,*], J A Burger[1], W G Wierda[1], S M O'Brien[1], M J Keating[1]
[1]Department of Leukemia, UT MD Anderson Cancer Center, Houston, United States

Background: Treatment with ibrutinib (Ibr) results in transient lymphocytosis, which likely relates to disruption of CLL cell-microenvironment interactions, including integrin-mediated adhesion. Mutated *IGHV* gene and 13q deletion were reported by Woyach *et al.* (*Blood* 2014) to be associated with prolonged lymphocytosis, but not associated with survival endpoints. It is unclear whether this phenomenon correlates with clinical efficacy.
Aims: We sought to identify associations between patterns of lymphocytosis in Ibr-treated patients (pts) and baseline prognostic factors, which may provide insight into the mechanism of action of Ibr.
Methods: 89 pts were treated with Ibr monotherapy on investigational protocols at MD Anderson Cancer Center between June 2010 and August 2013. 40 of

89 were treatment-naïve. We evaluated time-to-peak (TTPeak) absolute lymphocyte count (ALC), % rise in ALC from baseline (%rise), time to 50% reduction in ALC from baseline (TT50%) and time to normalization or nadir of ALC (TTNadir), according to baseline prognostic variables.
Results: Median TTPeak was 28 days, median %rise was 108%, median TT50% was 16 weeks and median TTNadir was 24 weeks for the total cohort (Table).

Table 1.

* IQR=interquartile range.

Pts with trisomy 12 (T12) showed a distinct pattern of lymphocytosis (Figure), independent of additional chromosomal abnormalities (17p- was also present in 10/16 cases). A brief and modest rise in ALC was seen (median TTPeak 7 days, p=0.02, median %rise of 56%, p=0.02) followed by a rapid reduction to<50% of baseline at a median of 6 weeks, p<0.001 (Figure). There was no difference in response rates or progression-free survival in T12 *versus* other FISH categories. Pts with 11q- showed delayed TTNadir (51 weeks *vs* 24 weeks, p=0.002), while pts with fludarabine-refractory disease showed a trend toward delayed TTPeak (49 *vs* 28 days, p=0.051) and more prolonged lymphocytosis (median TT50% 32 weeks *vs* 16 weeks, p=0.052). Pts with mutated *IGHV* gene showed a trend toward delayed TT50% (16 *vs* 24 weeks, p=0.086), while no difference in any analyzed parameter was seen for pts with 13q-.

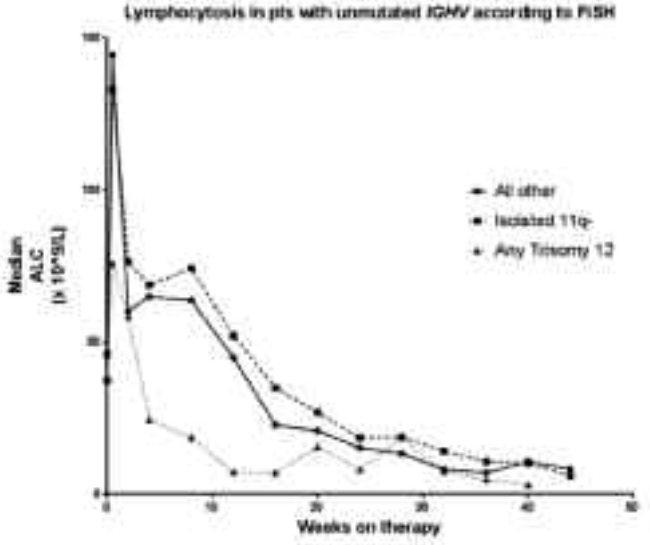

Figure 1.

Summary and Conclusion: Trisomy 12 CLL was associated with a unique pattern of lymphocytosis during ibrutinib monotherapy. The mechanism of this is unclear. However, T12 CLL cells universally overexpress CD49d, the α-4 subunit of the α4β1 integrin heterodimer, (Zucchetto, A *et al. Blood* 2013;122:3317), which is important in adhesion to VCAM-1 and fibronectin in the tissues. This overexpression may confer relative resistance to mobilization. The equivalent response in T12 pts to those without, despite the attenuated lymphocytosis, suggests that reduction in proliferation and/or induction of apoptosis within tissue sites may significantly contribute to therapeutic efficacy.

P859

INTEGRATION OF NOVEL GENE MUTATIONS INTO KARYOTYPE-BASED SUBGROUPS AS A PROGNOSTIC RISK STRATIFICATION TOOL IN CHRONIC LYMPHOCYTIC LEUKEMIA

I Del Giudice[1,2,3,*], G M Rigolin[2], M Marinelli[3], S Tavolaro[3], A Bardi[2], E Tammiso[2], E Volta[2], C Ilari[3], L Cafforio[3], M Negrini[1], E Saccenti[2], S Raponi[3], S Bonina[3], E Boldrini[3], E Radwan[3], M Messina[3], S Chiaretti[3], A Guarini[3], R Foà[3], A Cuneo[2]

[1]Laboratory for Technologies of Advanced Therapies (LTTA) and Department of Morphology, Surgery and Experimental Medicine, University of Ferrara, [2]Section of Hematology, Azienda Ospedaliero-Universitaria,Arcispedale S. Anna, University of Ferrara, Ferrara, [3]Hematology, Department of Cellular Biotechnologies and Hematology,Sapienza University, Rome, Italy

Background: Cytogenetics with novel mitogens has allowed to reveal chromosomal aberrations in regions uncovered by standard fluorescence *in situ* hybridization (FISH) and to identify novel genetic subgroups with prognostic relevance among patients with chronic lymphocytic leukemia (CLL) (Rigolin et al, Blood 2012). Whole exome sequencing (WES) approaches have identified previously unknown gene mutations with prognostic impact in CLL patients (*i.e. NOTCH1*, *SF3B1*, *BIRC3*) and have allowed to refine the FISH-based prognostic categories (Rossi et al, Blood 2013). Little is known about the integration of novel gene mutations and FISH into karyotype-based subgroups.
Aims: 1) To identify in CLL patients karyotype-defined categories using novel mitogens; 2) to screen the novel gene mutations into karyotype-defined categories; 3) to identify specific CLL subgroups defined by a combined FISH, molecular and cytogenetic approach, with the aim of further improving the prognostic stratification currently in use.
Methods: The study has so far included 153 CLL patients at diagnosis. FISH and cytogenetics with novel mitogens have been performed as previously described (Bardi et al, J Biomed Biotechnol 2011). The mutational screening of *NOTCH1*, *SF3B1*, *BIRC3* and *TP53* were performed by Sanger sequencing, as described (Rossi et al, Blood 2013).
Results: FISH was evaluable in all 153 cases. 17p- (5, 3.3%) showed adverse mutations in 80% of cases, 11q- (13, 8.5%) in 38.5% of cases, +12 (19, 12.4%) in 36.8% of cases, normal FISH (46, 30%) in 17.4% of cases and del13q- only (70, 45.8%) in 11.4% of cases. Karyotype with novel mitogens was performed in 146 cases and evaluable in 144 (98.63%). A normal karyotype was present in 40 cases (27.8%), del13q- only in 33 (22.9%), one lesion (other than 13q-) in 28 (19.4%), two lesions in 24 (16.7%), ≥3 lesions in 19 (13.2%). Low risk (normal karyotype and 13q-), intermediate risk (1 or 2 lesions) and high risk (≥3 lesions) accounted for 50.7%, 36.1% and 13.2% of cases, respectively. *NOTCH1* (n=12), *SF3B1* (n=13), *BIRC3* (n=4) and *TP53* (n=4) mutations distributed across the three karyotypic categories, with the exception of *TP53*, more frequently mutated in the high risk group. Overall, there was an increase in the incidence of unfavorable mutations between low risk (11/73, 15.1%), intermediate risk (13/52, 25%) and high risk (9/19, 47.4%), significant only between low and high risk (p=0.0047). Integrating FISH, mutations and karyotype, we showed that the best CLL prognostic category, *i.e.* CLL with 13q- only by FISH and wild-type (WT) for *NOTCH1*, *SF3B1*, *BIRC3* and *TP53* (n=59), showed additional karyotypic lesions in 32.2% of cases (1 additional lesion in 9, 2 lesions in 8, ≥3 lesions in 2 cases). Moreover, CLL with normal FISH and WT for mutations (n=34) showed karyotypic lesions in 32.3% of cases (1 lesion in 5, 2 lesions in 3, ≥3 lesions in 3 cases). Analogous figures were demonstrated in an independent cohort of 82 CLL in first progression. The assessment of the prognostic impact of this refined classification is ongoing.
Summary and Conclusion: FISH, gene mutations and karyotype using novel mitogens provide complementary prognostic information in CLL patients. Karyotype may further refine patients prognostic stratification in one third of cases belonging to good prognosis categories. A more refined prognostic risk assessment and a personalized management is becoming a realistic upcoming prospect for CLL patients.

Chronic lymphocytic leukemia and related disorders - Clinical 2

CD4+CD16- LGL LEUKEMIA SHOWED DISTINCTIVE BIOLOGICAL AND CLINICAL FEATURES

G Barilà[1,2], A Teramo[1,2], C Gattazzo[1,2], A Cabrelle[1], E Boscaro[2], M Facco[1,2], L Trentin[1,2], G C Semenzato[1,2], R Zambello[1,2,*]
[1]Venetian Institute of Molecular Medicine (VIMM), [2]Dept of Medicine, Hematology and Clinical Immunology section, Padua University School of Medicine, Padua, Italy

Background: T-cell Large Granular Lymphocyte Leukemia (T-LGLL) is a chronic lymphoproliferative disorder characterized by the clonal expansion of CD3+ Large Granular Lymphocyte (LGL). Most patients have an indolent course with neutropenia present in about 50-60% of patients, representing the major feature of the disease. Recently, somatic STAT3 mutations conferring constitutive activation of JAK-STAT pathway have been discovered in approximately 30% of patients with T-LGLL. Patients generally express CD3, CD8, CD16 and CD57 but rare forms of CD4+ LGLL are well known and characterized by CD4+/CD8- or dim/Vb13.1 expression, and a pathogenetic relationship with CMV.
Aims: Aim of this study is to identify different biological and clinical subsets of T-LGLL patients through immunophenotype analysis and STAT-3 mutational analysis of T-LGLs.
Methods: LGLs in 41 patients with more than 50% clonal LGL in PBMCs were analysed by flow cytometry using antibody for CD3, CD4, CD8, CD16, CD56, CD57, Vb repertoire, CD158a, CD158b, CD158e, CD94, CD159a. DNA samples from these 41 patients were available for STAT-3 mutation analysis through Sanger sequencing and PCR ARMS for Y640F and D661Y mutations.
Results: By FACS analysis we found 14/41 patients CD4+ with 100% CD56+/CD57+ double positive; among them, 11 were CD4+/CD8+, while 3 patients were CD4+/CD8-. CD16 expression was present in 22/41 patients; 20/22 were also CD3+/CD8+/CD57+ while only 2/41 were CD3+/CD4+/CD8+/CD57+, these last were excluded from CD4+ and CD16+ subgroup. Vb13.1 expression was found in 4/12 CD4+CD16- patients (33%) but in any of CD4-CD16+. KIRs and Lectin type receptors expression was found in 60% and 70% of CD4-CD16+ LGLs, respectively (with CD158b expressed in half of cases and CD94 in 60% of cases), but only in 17% and 33% of CD4+CD16-LGLs, respectively. Neutropenia (Absolute Neutrophil Count, ANC,<1500/mm^3) was present in 21/41 patients (51%), with 14/41 (29%) experienced severe neutropenia (ANC<500/mm^3). Among CD4-CD16+ patients, 90% experienced neutropenia while CD4+CD16- patients did not; consistently, CD4-CD16+ patients had ANC level significantly lower than CD4+CD16- patients (mean ANC of CD16+: 690/mm^3; mean ANC of CD4+ 2817/mm^3; p=0,05). Finally we investigated somatic STAT-3 mutation through Sanger sequencing and ARMS PCR for Y640F and D661Y mutations in these 41 patients. We identified 9/41 (22%) patients mutated by sequencing (6 with Y640F and 3 with D661Y) and 11/41 (27%) by PCR ARMS (7 with Y640F and 4 with D661Y). All mutated patients were CD4-/CD16+ while in samples from CD4+CD16- patients of T-LGLL no one mutation was found.
Summary and Conclusion: In this cohort, a high frequency of CD4+CD16- type of T-LGLL was recognized, characterized by reduced NK receptor expression, low incidence of neutropenia and absence of STAT3 mutations. This subset of patients is clearly separated by the more classical CD4-/CD16+ subgroup of T-LGLL, characterized by high incidence of neutropenia, skewed expression of NK receptor and presence of somatic STAT-3 mutations. These data suggest different pathogenetic mechanisms and clinical courses of these two types of T-LGLL and identify in CD4-/CD16+ LGLL type a subset with different biology and more aggressive course as compared to the CD4+/CD16- LGLL subgroup.

P861

DEVELOPMENT AND VALIDATION OF A NOTCH CUSTOM NGS ASSAY FOR IDENTIFYING NOTCH1 MUTATIONS IN CHRONIC LYMPHOCYTIC LEUKEMIA AND OTHER LYMPHOID MALIGNANCIES

P Fang[1,*], Z Yan[1], A Darwanto[1], J Kristof[1], J Staha[1], K Sakrison[1], C Hilburn[1], K Anoe[1], W Liu[1], M Wang[2], L Garrard[2], E Idusogie[2], A M Kapoun[2], C Spittle[1], C Galderisi[1], J Li[1]
[1]MolecularMD Corp, Portland, [2]OncoMed Pharmaceuticals, Redwood City, United States

Background: NOTCH1 is known to be activated by oncogenic mutations in both hematologic and solid tumors including chronic lymphocytic leukemia (CLL), mantle cell lymphoma (MCL), T cell acute lymphoblastic leukemia (T-ALL), non-small cell lung cancer (NSCLC) and breast cancer. In CLL, Notch 1 mutations were detected in ~12% of patients at the time of diagnosis and at a higher rate during disease progression to Richter's transformation. As such, NOTCH1 may be a valuable biomarker of therapeutic efficacy, or clinical candidacy, for novel anti-cancer agents or regimens. For prospective evaluation of NOTCH1's utility as a biomarker, it is critical to have a sufficiently sensitive, specific, and comprehensive assay to detect NOTCH1 mutations in clinical specimens. Compared to Sanger sequencing, a targeted Next Generation DNA Sequencing (NGS) assay is more comprehensive, sensitive, and specific, and is therefore better suited for clinical applications with limited specimen availability.
Aims: We have developed a custom NGS assay on the Ion Torrent PGM platform for evaluating NOTCH1 mutation status. With this validation study we determined whether the Notch NGS Assay could semi-quantitatively detect NOTCH1 activating mutations at the limit of detection (LOD) of 5% allele frequency in blood and FFPE tumor tissue collected from patients with various lymphoid malignancies.
Methods: The region of interest (ROI) includes the coding exons of Notch1 (34 exons). Primers were designed using Ion AmpliSeq™ Designer in combination with MolecularMD's proprietary primer design method. The data were analyzed with Torrent Suite 3.4.2 and the MolecularMD analysis pipeline. Cell lines containing known NOTCH1 mutations and Horizon Diagnostics NOTCH1 L1600P mutation standards were used, along with clinical samples from several sources.
Results: Accuracy: The allele frequencies of the NOTCH1 activating mutations detected, including single base substitutions (SBS) and insertions/deletions (indel), correspond with those reported by droplet digital PCR (ddPCR) of NOTCH1 mutation standards, or those reported by Sanger sequencing of serially diluted fresh or contrived FFPE DNA samples. Precision: Seven NOTCH1 activating mutations with allele frequencies above 5% LOD (3 SBS, 2 insertions, 2 deletions) were all reproducibly detected with CVs of less than 30% in 3 independent sequencing runs using serial dilution of both fresh and FFPE DNA samples respectively. LOD: The LOD of the assay is 5% for SBS and indels, as determined by sequencing 20 replicates of fresh DNA samples and 20 replicates of contrived FFPE DNA samples containing NOTCH1 activating mutations with an expected 5% allele frequency. False Positive and False Negative Rates: NOTCH1 mutations detected by NGS and Sanger or Sanger with enrichment methods in 30 blood samples (4 contrived, 26 clinical) and 32 FFPE samples (4 contrived, 28 clinical) are being compared to determine analytical sensitivity and confirm specificity.
Summary and Conclusion: This validation study demonstrates that with only 30ng DNA input, the Notch NGS Assay is capable of accurately detecting NOTCH1 activating mutations, including SBS and small indels in blood and FFPE tissue specimens. Collectively, our results indicate that the custom targeted NGS assay is suitable for mutation profiling of clinical samples. The assay is designed for use in screening clinical trial patients, and the NGS platform further accommodates expansion for multiplexed evaluation of additional genes within the same clinical specimen.

P862

ITALIAN VALIDATION OF THE MDACC PROGNOSTIC INDEX FOR CHRONIC LYMPHOCYTIC LEUKEMIA (CLL) PATIENTS: ANALYSIS OF 1502 CASES

M Gentile[1,*], F R Mauro[2], D Rossi[3], I Vincelli[4], S Bossio[1], F Trastulli[2], A G Recchia[1], M Campanelli[2], G Gaidano[3], R Foà[2], F Morabito[1]
[1]UOC Ematologia di Cosenza, Cosenza, [2]Hematology, Department of Cellular Biotechnologies and Hematology, Sapienza University, Rome, Italy, Roma, [3]Division of Hematology, Department of Translational Medicine, Amedeo Avogadro University of Eastern Piedmont, Novara, Italy, Novara, [4]UOC di Ematologia, Reggio Calabria, Reggio Calabria, Italy

Background: The clinical course of CLL is notable for its marked variability: some patients present with highly aggressive disease requiring immediate therapy and poor survival (death within 1-2 years of diagnosis), whereas others live therapy-free for decades. In 2007, Wierda et al proposed a predictive nomogram and a simplified prognostic index built on basic clinical characteristics (age, sex, Rai stage, number of lymph node groups) and laboratory parameters [β2-microglobulin (β2M) and absolute lymphocyte count (ALC)] universally applicable to previously untreated CLL patients to predict survival.
Aims: We performed a validation of the MDACC index in an independent series of Italian patients.
Methods: Databases of 4 Italian centers including roughly 3000 CLL patients diagnosed between 1980 and 2013 were used to evaluate the validity and reproducibility of the MDACC prognostic index. Data regarding age, sex, Rai stage, ALC and number of lymph node sites involved was complete for all patients, while β2M values were available for 1502. Nomogram and prognostic index score were calculated using the method proposed by Wierda et al (Figure 1). Progression free survival (PFS) and overall survival (OS) analyses were performed using the Kaplan-Meier method. The prognostic impact for the outcome variable was investigated by univariate and multiple Cox regression analysis.
Results: The median age of the 1502 patients was 67 years (range 27-94) with 55.7% male. The majority of patients had Binet stage A (82.9%), 847 cases (56.4%) had Rai stage 0; moreover 151 cases (10.1%) satisfied the 2008

NCI/WG criteria for cMBL (<5.0x10^9 B lymphocytes/L in the peripheral blood and no apparent lymph node, spleen or liver enlargement). All 6 parameters involved in the prognostic index were found to be independently associated with survival in this analysis (age: HR 1.085, 95%CI 1.071-1.1, P<0.0001; sex: HR 1.548 95%CI 1.204-1.989, P=0.001; ALC: HR 1.006, 95%CI 1.003-1.01, P<0.0001; number of lymph node groups: HR 2.222, 95%CI 1.671-2.956, P<0.0001; b2M: HR 1.216 95%CI 1.16-1.275, P<0.0001). The median nomogram score was 87 (range 27.4-181.8). Furthermore, when the score was evaluated as continuous variable (ie, by measuring the risk of each point increase), the total point score was associated with the OS (HR, 1.058; 95% CI, 1.053-1.064; P<.0001). According to the prognostic index 38.7% of patients were classified as low, 58.3% as intermediate and 3% as high risk. The estimated median survival times were: not reached for low risk, 13.4 years for intermediate risk, and 3.4 years for high risk. Percentage of 5- and 10-year survival probabilities were 0.983 (SE 0.006) and 0.954 (SE 0.012) for low-risk cases, 0.818 (SE 0.015) and 0.65 (SE 0.023) for intermediate-risk and 0.443 (SE 0.081) and 0.101 (SE 0.064) for high-risk. The estimated median and 5- and 10-year survival by prognostic index risk category were similar to those originally reported. The prognostic index remained significantly associated with OS also when patients were sub-grouped by period of diagnosis (1980-1995, P<0.0001; 1996-2004, P<0.0001; 2005-2013, P<0.0001). The prognostic index risk category remained a predictor of survival when analysis was limited to Rai stage 0 (P<0.0001) and cMBLs (P=0.009). Finally the prognostic index also allowed prediction of PFS in all 1502 patients (P<0.0001), in Rai 0 cases (P<0.0001) and in cMBLs (P=0.035).

Table 1. Proposed CLL prognostic index and nomogram score.

Characteristics	Point contribution			
	0	1	2	3
Age, y	-	<50	50-65	>65
β2M, mg/L	<ULN	1-2 x ULN	>2 x ULN	-
ALC, 10^9/L	<20	20-50	>50	-
Sex	female	Male	-	-
Rai stage	0-II	III-IV	-	-
No. of lymph node groups	≤2	≥3	-	-

ULN indicates upper limit of normal; ALC, absolute lymphocyte count.
*Patient total score determined by adding up the scores of the 6 components. Patients with a score of 0 to 3 were considered to be at low risk, those with a score of 4 to 7 were considered to be at intermediate risk, and those with a score ≥8 were considered to be at high risk.
Adapted from: Wierda WG, O'Brien S, Wang X, et al. Prognostic nomograms and index for overall survival in previously untreated patients with chronic lymphocytic leukemia. Blood. 2007;109:4679-85.

The formula to calculate the nomogram score for a patient is: -12.5 + [1.25 x age] + [8.32 x (β2M)] + [8.62 x (ALC, 10^9/L/100)] + [7.34 x I (sex: male)] + [11.00 x I (Rai III or IV)] + [10.84 x I (nodes 3)] where I() is the indicator function, equal to 1 if the condition in the parenthesis is met and 0 if not.

Summary and Conclusion: Our results confirm the ability of the MDACC prognostic index to predict survival among patients with previously untreated CLL. The study also extended the utility of the index by demonstrating that it retains prognostic value when applied exclusively to Rai stage 0 and cMBL patients and predicts PFS. Finally, the period of diagnosis does not seem to modify the capability of this index to predict prognosis of CLL patients.

P863

FLUDARABINE, CYCLOPHOSPHAMIDE AND LENALIDOMIDE IN RELAPSED/REFRACTORY PATIENTS WITH CLL, PRELIMINARY RESULTS OF THE PHASE1-2 GIMEMA CLL0606 STUDY

Maria Misericordia Hospital, University of Udine, Udine, [9]U.O. Ematologia con Trapianto, Università degli Studi Aldo Moro, Bari, [10]Hematology Unit, Department of Oncology and Hematology, Rimini, [11]Department of Hematology, Arcispedale Sant'Anna, Ferrara, Italy

Background: The restoration of immuno-mediated functions seems the primary mechanism of action of lenalidomide in chronic lymphocytic leukemia (CLL).
Aims: The combination of lenalidomide with an effective regimen in CLL, such as fludarabine and cyclophosphamide (FC), might result in an increased activity preserving the immune function. The activity and toxicity of schedule combining lenalidomide and FC for the treatment of relapsed/refractory patients with CLL have been evaluated in a prospective phase I/II study.
Methods: Forty patients with a median age of 66 years (range: 47-77) and a median follow-up of 14.31 months (range 3-56) have been included in the study. The median number of prior treatments was 1 (range: 1-3), 82% of patients received a prior treatment with FC or FCR. The baseline median absolute lymphocyte count was >60 x 10^9/L in 49% of cases, increased B2M values were observed in 53%, Binet stage C in 26% of cases and bulky nodes (≥5 cm) in 29% of cases. Poor-risk genetic features were present in the majority of patients, 65% were IGVH unmutated,15% showed a del11q and 25% a del17p. Treatment consisted of 6 monthly courses of FC (fudarabine: 30 mg/m^2 iv; cyclophosphamide: 250 mg/m^2, days 1-3) combined with 14 consecutive days of lenalidomide administration (days1-14). Lenalidomide was given at the starting dose of 2.5 mg daily during the first course of therapy. Subsequently, the dose has been escalated to 5 mg, the dose that was defined in the prior phase 1 of the study as the maximum tolerated dose of lenalidomide given in combination with FC. As infection prophylaxis patients received bactrim and valacyclovir and as primary prophylaxis of granulocytopenia filgrastim. Tumor lysis syndrome (TLS) prophylaxis included oral hydration and allopurinol. Patients with an increased risk of thromboembolic events received low molecular weight heparin while low-dose aspirin was given to the other cases. Patients signed a written informed consent. CLL diagnosis, treatment requirement and response were assessed according to the 2008 IWCLL guidelines. In addition, in all CR patients, CT scan evaluation was included in the response assessment.
Results: Patients received a median number of 6 treatment cycles (range, 1-6). The most common treatment extra-hematologic adverse events (AEs) of any grade (≥10% of subjects) were fatigue, stipsis, pyrexia, muscle spams and skin rash. Grade ≥3 extra-hematologic toxicities were recorded in 5 patients (12.5%; fatigue, 1 case; stipsis,1; transient increases of transaminases, 1; atrial fibrillation, 1; accidental brain injury, 1). A mild, grade 1, tumor flare reaction was observed in 1 patient, while no case of TLS or thrombosis was recorded. The most frequent grade 3/4 hematologic toxicity was represented by neutropenia (65% of cases). However, only 3 cases (7.5%) of grade ≥3 infection (pneumonia) were recorded. On an intention-to treat basis, the overall response rate is 64.1% (CR, 23%; PR 41%). One of the 5 patients with del17p achieved a CR and one a PR. At 24 months the progression-free survival is 50% (95% CI, 32.9 - 76.8%) and the overall survival 80% (95% CI, 64.8 - 99%).
Summary and Conclusion: Taken together, the preliminary results of this study suggest that the combination of FC with lenalidomide given at the maximum tolerated dose of 5 mg, may be considered an active salvage regimen with acceptable toxicity, particularly in terms of infections, in relapsed and refractory CLL patients with adverse genetic features.

P864

SKIN CANCERS ARE COMMON AND CAUSE CONSIDERABLE MORBIDITY IN PATIENTS TREATED WITH FLUDARABINE, CYCLOPHOSPHAMIDE AND RITUXIMAB FOR CHRONIC LYMPHOCYTIC LEUKAEMIA

L Raiti[1], S Raj[1,*], D Carney[1], M Wolf[1], S Harrison[1], D Westerman[1], K Burbury[1], C McCormack[1], HM Prince[1], J Seymour[1], C Tam[1]

[1]Peter MacCallum Cancer Centre, East Melbourne, Australia

Background: The combination of fludarabine, cyclophosphamide and rituximab (FCR) is considered standard of care in chronic lymphocytic leukaemia (CLL), achieving durable remissions and long survival in most patients. However, the combination of fludarabine and cyclophosphamide (FC) impair DNA repair in experimental models, and causes prolonged T-cell lymphopenia in patients. Thus, FCR may simultaneously induce mutagenesis and compound CLL-associated immunosuppression, increasing the risk of second malignancies. Australia has high UV exposure and high incidence of sun-related skin cancers.
Aims: We sought to describe the epidemiology and clinical outcomes of skin cancers occurring in patients with CLL treated with FCR at an Australian center.
Methods: Single-center, retrospective study of patients treated with FCR for CLL between January 2001 and September 2008. All patients were assessed for the presence of second malignancies at their first presentation. We reviewed the records of consecutive patients whose cancer was managed primarily at our center, and documented the occurrence and histology of skin lesions following FCR treatment until death or last follow-up, irrespective of relapses or subsequent therapies.
Results: The median age of the 67 study patients (44M, 23F) was 58 years (range 26-84), and 48% were in Rai stages 3 or 4 at the time of FCR therapy. The median time from diagnosis of CLL to FCR chemotherapy was 46 (range 0.2 to 179) months. Due to restrictions surrounding the funding of rituximab during the study period, only 35 (52%) of patients received FCR frontline, and the rest had FCR after failing a median of 1 (range 1-3) previous therapies. Prior to first FCR exposure, 8 (12%) of patients had an antecedent diagnosis of skin cancer, including 4 squamous cell cancer (SCC), 1 basal cell cancer (BCC), and 3 malignant melanoma. Following FCR (median follow-up 19 months, range 1 – 48), 18 (27%) patients developed one or more skin cancer, with the first skin

cancer post chemotherapy being SCC in 11 (16%), BCC in 5 (8%), and melanoma in 2 (both with antecedent history of melanoma, and metastatic recurrence at 36 and 89 months post FCR). Forty-four percent of patients with skin cancer had more than one histological subtype, with the second subtype occurring a median of 18 months after the first. The clinical consequences of SCC or BCC development were (in increasing order of seriousness): local excision or cryotherapy in 47%, extensive excision under general anaesthetic and/or requiring skin flaps in 33%, and metastatic disease in 20%. All metastatic disease amongst patients with SCC or BCC was found to be SCC only.
Summary and Conclusion: Skin cancers are common following FCR chemotherapy for CLL. The clinical consequences of skin cancers in this population can be serious, and include requirement for major surgery and/or development of metastatic disease in over 50%. Clinicians should remain vigilant for the emergence of skin cancers following FCR treatment for CLL and initiate management of these at an early stage.

P865

A POPULATION BASED EXPERIENCE ON THE USE OF RCD OR RCVP IN AUTOIMMUNE HEMOLYTIC ANEMIA IN CLL

A Sharma[1], M Geirnaert[2], V Banerji[1,3], J Johnston[1,3], R Kumar[1,3,*]
[1]Internal Medicine, University of Manitoba, [2]Pharmacy, [3]Medical Oncology and Hematology, CancerCare Manitoba, Winnipeg, Canada

Background: Autoimmune cytopenias occur in 5 to 10% of patients with CLL and have a tendency to recur, with each relapse being more difficult to treat. These cytopenias occur as a result of immune dysregulation and can be triggered by some chemotherapeutic agents. The diagnosis and management can be challenging, as diagnostic criteria may overlap with CLL presentation. The combination of cyclophosphamide and rituximab has been used in small series of referred patients, but its efficacy in the population-based setting is not known. CancerCare Manitoba (CCMB) is the sole agency in the province of Manitoba (population 1.2 million) providing approval and provision for rituximab therapy for cancer patients; hence its database can be used to assess the efficacy of rituximab in the population setting.
Aims: To determine the population-based experience of the rituximab containing chemotherapy regimens, RCD/R-CVP, in the management of autoimmune hemolytic anemia (AIHA) in Manitoba.
Methods: The CCMB pharmacy database was analyzed from 1st January 2003 to 31st December 2011 to identify all rituximab based regimens used in the treatment of CLL with autoimmune cytopenias. Patients with a diagnosis of AIHA, with or without immune thrombocytopenia (ITP), were chosen for analysis. These included therapy related AIHA. Isolated ITP or other cytopenias were excluded. AIHA related to CLL was defined as: hemoglobin (Hb)<110 g/L with (a) a single marker of hemolysis (unconjugated hyperbilirubinemia in the absence of liver disease, elevated LDH, reticulocytosis, increased bone marrow erythropoiesis without bleeding) and a positive DAT or cold agglutinin or (b) two markers of hemolysis without concomitant bleeding or hypersplenism. AIHA was defined as 'simple' if it was not associated with active CLL or 'complex' if associated with progressive lymphadenopathy, rapid lymphocyte doubling within 6 months, or the presence of 'B' symptoms. The regimens used were (a) RCD: rituximab 375mg/m^2 intravenously (IV) on day 1, cyclophosphamide 750 mg/m^2 IV on day 1, and dexamethasone 20mg on day 1 and 12 mg daily from day 2-7 per cycle, which was repeated every 4 weeks, until best response with 4-6 cycles planned or (b) R-CVP. Response criteria were defined as (a) complete response (CR), if Hb >120g/L and platelets >100 x10^9/L, without transfusion requirements and normalization of LDH and reticulocytes; (b) partial response (PR) if Hb rise was ≥ 20g/L and platelets within 50-100 x 10^9/L, with a decrease in transfusion needs and (c) no response (NR) if the above requirements were not met (Leuk Lymph 2011; 52: 1401-03).
Results: Twenty four patients received RCD or R-CVP in Manitoba for AIHA +/- ITP. Two patients were excluded, as data was insufficient for analysis. In the 22 patients reviewed (M:F; 1:1), the median age at diagnosis of CLL was 63 yrs (range 46-87). Median age at therapy was 75 yrs (range 50-90). AIHA was 'complex' in 77% cases. Previous treatment for CLL was observed in 91% patients and consisted of chlorambucil in 59%, and fludarabine (F) or F + cyclophosphamide (without rituximab) in 23%. RCD was used in 20 cases and R-CVP in 2 patients. Previous therapies for AIHA consisted of prednisone in 100%, cyclosporin in 27% and splenectomy in one patient. The median Hb value prior to therapy in this cohort was 93g/L (range 61-105). The median number of cycles of RCD/R-CVP given was 4 (range 1-7), with a CR in 9/22 (41%), PR in 8/22 (36%) and NR in 23%. Median time to maximum response was 7 months (range 1-24). The peak value of Hb in patients with CR/PR was 133g/L (range 109-157). Median duration of response was 15 months (range 2-48 months). Relapse occurred in 4 patients (18%). Of these, 2 were retreated with RCD and one had a response. Complications included: 2 febrile neutropenia episodes, one cellulitis and one sepsis, which recovered with antimicrobial therapy. There were no deaths attributable to treatment for AIHA.
Summary and Conclusion: Relapsing AIHA is difficult to treat in CLL. However, this population-based study confirms the effectiveness of the RCD/R-CVP regimens in these patients with an overall response rate of 77% (41% CR) and relapse-free response of 60 percent.

P866

OPPOSITE PROGNOSTIC SIGNIFICANCE OF CELLULAR AND SERUM CIRCULATING MICRORNA-150 IN CHRONIC LYMPHOCYTIC LEUKEMIA PATIENTS

B Stamatopoulos[1,*], N Meuleman[2], E Crompot[1], M Van Damme[1], B Dessars[3], H El Housni[3], P Mineur[4], D Bron[2], L Lagneaux[1]
[1]Laboratory of Clinical Cell Therapy, [2]Hematology, Jules Bordet Institute, ULB, [3]Molecular genetics, Hôpital Erasme, ULB, Brussels, [4]Onco-Hematology, Grand Hôpital de Charleroi, Gilly, Belgium

Background: MicroRNAs (miRs) are a new class of tumor suppressors frequently deregulated in cancer. We previously reported the deregulation of microRNA-29c and 223 in Chronic Lymphocytic Leukemia (CLL) cells. CLL is characterized by a clinical heterogeneity that can be predicted by several prognostic factors. In addition, recent studies have shown that circulating microRNA in body fluids can also be used as prognostic biomarker.
Aims: Here, we would like to investigate the expression of cellular and serum circulating microRNA-150 in CLL and to correlate these expressions with prognosis.
Methods: We investigated the expression of cellular and serum circulating microRNA-150 by real-time PCR (qPCR) from CD19+ cells or from CLL serums in a cohort of 273/252 CLL patients with a median follow-up of 78 months (range, 7-380) and correlated it to other biological or clinical parameters.
Results: We showed that miR-150 was significantly overexpressed in CLL cells (3.0 fold, P=0.0009) and CLL serum (7.5 fold, P<0.0001) compared to healthy subjects. Among CLL patients, low cellular miR-150 expression levels was associated with tumor burden markers (LDT<1year, high sCD23 and high B-2M) but also disease aggressiveness: cellular miR-150 level decreased significantly with progression from Binet Stage A to C (P<0.0085). In addition, low level of cellular miR-150 is found in poor prognostic subgroups defined by IgVH mutational status (P<0.0001), ZAP70 (P=0.0004), LPL (P<0.0001), CD38 (P<0.0001) expression and cytogenetic abnormalities (P=0.0121). In contrast, a high level of serum circulating miR-150 was associated with patient requiring a treatment (P<0.0001) or patient died during the study (P<0.0001). Patients considered positive for B2M, sCD23 or with a LDT<1year also presented a significant higher level of miR-150 in the serum. Cellular and serum miR-150 were associated with treatment-free (TFS) and overall survival (OS) with an opposite manner: patients with a low cellular miR-150 expression have a median TFS of 40 months compared with high level patients who have a median TFS of 122 months (P<0.0001). Patients with a low serum miR-150 expression have a median TFS of 111 months compared with high level patients who have a median TFS of 60 months (P=0.0066). Similar results have been observed for OS. Interestingly, no correlation was found between cellular and serum circulating miR-150. In other words, patients with high level of miR-150 in the cell were not necessary patients with low level in the serum indicating that these two parameters were independent. In addition, we observed that during disease evolution, an increase of lymphocytosis is associated to a decrease of miR-150 in the cell but with an increase of miR-150 in the serum.
Summary and Conclusion: Downregulation of cellular and upregulation of serum circulating miR-150 are associated with poor clinical evolution in CLL. However these two parameters were independent. We concluded that cellular/serum miR-150 level could be used to monitor molecularly disease evolution and as a new prognostic factor in CLL.

P867

IMPROVING SURVIVAL IN PATIENTS WITH CHRONIC LYMPHOCYTIC LEUKEMIA OVER A 40-YEAR PERIOD (1971-2011): A SINGLE INSTITUTION EXPERIENCE

S Molica[1,*], L Levato[1], R Mirabelli[1], M Lentini[1], D Giannarelli[2]
[1]Hematology-Oncology, Azienda Ospedaliera Pugliese-Ciaccio, Catanzaro, [2]Biostatistic Unit, IRCCS Regina Elena, Roma, Italy

Background: Whether the availability of new treatments, along with with better general care, translate into an improvement of survival of patients with chronic lymphocytic leukemia (CLL) is not completely clear.
Aims: We analysed pattern of presentation and survival in 782 patients followed from 1971 and 2011 at a single institution (Department Hematology-Oncology, Azienda Ospedaliera Pugliese-Ciaccio, Catanzaro, Italy).
Methods: For this purpose the whole cohort was split into two groups reflecting the time of diagnosis: the period 1971-1994 (n=386) and in the period 1995-2011 (n=402).
Results: Distribution by age groups showed a shift toward an older age at diagnosis in more recent cohort (median age, 69 *vs* 68 years; P=0.02), with a significant increase of patients older than 70 years (50% *vs* 40.9%; P=0.01). Moreover, the proportion of patients in low-risk clinical stage (Binet A) at diagnosis was significantly higher from 1995-2011 than in the previous period (73.1% *vs* 52.9%:P<0.0001). After a median follow-up time of 4 years (range, 0.1-23.3 years), 315 (40.3%) of the 782 assessable patients have died. Of those censored alive, 385 were still alive and 85 (10.5%) were lost to follow-up. Median survival for the whole series was 7.6 years from diagnosis (95% CI:

7.0-8.3 years) and 15% of patients were projected to survive 16 years or longer. Patients' stratification according to the Binet staging system allowed identification of different clinical outcome (P<0.0001). Furthermore, the impact of CLL on the patients' life expectancy was clear after adjustment for age, sex and year of diagnosis. Indeed survival of patients at 5,10 and 15 years from diagnosis was 85%,64% and 55% of that expected in the general population. A direct comparison of overall survival of patients diagnosed in the period 1971-1994 and 1995-2011 revealed an increase of 10-year survival from 30% to 60% (P<0.0001)(see figure below). This improvement was observed in patients younger (P<0.0001) and older (P<0.0001) than 70 years, as well as in Binet stage A (P<0.0001) and in Binet stage B or C (P<0.0001) patients.

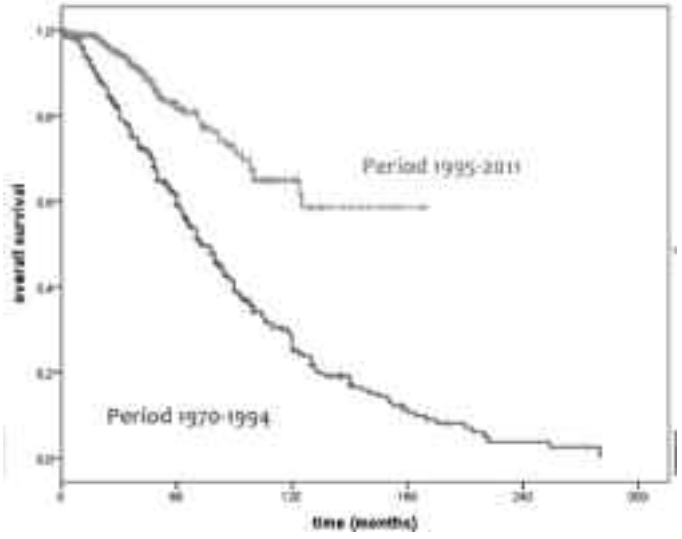

Figure 1.

Summary and Conclusion: In conclusion, this study based on a single center patient cohort demonstrates that survival in CLL is steadily improving. These results suggest also that newer treatment are changing the prognosis of CLL patients with active disease. The greater attention to regular check-ups in the last decades contributes to the survival improvements observed in Binet stage A patients who generally die because of non –CLL related causes (*i.e.*, cardiovascular diseases, second neoplasms).

P868

REDUCTION OF TUMOR LYSIS SYNDROME (TLS) RISK IN CHRONIC LYMPHOCYTIC LEUKEMIA (CLL) PATIENTS TREATED WITH ABT-199 (GDC-0199): RESULTS OF MODIFICATIONS TO DOSING SCHEDULE AND TLS PROPHYLAXIS

J Seymour[1,*], A Roberts[2], S Stilgenbauer[3], L A Gressick[4], N K Rudersdorf[4], T Busman[4], W Munasinghe[4], S Wong[4], M Desai[4], A E Best[4], E Cerri[4], S H Enschede[4], R A Humerickhouse[4]

[1]Peter MacCallum Cancer Centre, [2]Royal Melbourne Hospital and Waltern and Eliza Hall Institute of Medical Research, Melbourne, Australia, [3]University of Ulm, Ulm, Germany, [4]AbbVie, North Chicago, United States

Background: CLL cells have been described as "primed for death" due to over-expression of BCL-2 and abundance of BCL-2:BIM complexes. ABT-199 is a selective, potent, orally bioavailable small molecule BCL-2 inhibitor being studied as a single agent and in combination in CLL and other B-cell malignancies. In early clinical studies in patients (pts) with relapsed/refractory CLL, events of TLS were observed, including 2 deaths and one event of acute renal failure, and adjustments to scheduling were required.
Aims: A detailed analysis was performed to identify pre-treatment risk factors for TLS, and to assess the impact of the revised ABT-199 scheduling on TLS incidence.
Methods: Data from 135 CLL pts treated with ABT-199 in 4 studies were analyzed, including all pts treated before the introduction of revised scheduling in April 2013 (n=77), and the first 58 pts treated subsequently. Pts with TLS were identified using Cairo-Bishop criteria, and medically adjudicated according to a pre-specified TLS case definition. Predictive modeling and CART analyses, PK, and clinical data were used to categorize risk and to revise dosing regimen and TLS risk mitigation measures.
Results: Among the initial 77 pts, 19 (24.7%) were identified as having had TLS: 3 clinical TLS (2 deaths and 1 acute renal failure), 16 laboratory TLS (LTLS, as designated by investigators or by medical adjudication), 9 with related adverse events and 7 with no intervention and no AE reported. TLS first manifested within 24 hrs of the 1st dose in 14 pts, 4 at 24 – 48 hrs, and 1 TLS related AE reported after a dose increase. Bulky abdominal nodes ≥ 5 cm, ALC ≥ 38k, and CrCl<80 were identified as individual risk factors for developing LTLS, but a combination of **both** lymph nodes (LN) ≥ 5 cm and ALC ≥ 38k identified all pts with clinically relevant LTLS. Using LN size and ALC (>25K to be consistent with historical cut-off) pts were classified into 3 risk groups: low risk - ALC<25k and all LN<5 cm; medium risk - ALC ≥ 25k **or** LN ≥ 5 cm but<10 cm; high risk - ALC ≥ 25k **and** LN ≥ 5 cm but<10 cm or any pt with LN ≥10 cm. Of the 19 pts with TLS, 0%, 32%, and 68% (including 3 pts with clinical TLS) were in each respective risk group. In addition, ABT-199 median C_{max} and AUC were higher among the subjects experiencing TLS. These findings led to changes to ongoing protocols. As the TLS risk was largely restricted to the first dose, changes to the dosing regimen included a reduction in the starting dose from 50 to 20 mg. Also, a change from a 3-step to a more gradual, 5-step dose ramp-up (20, 50, 100, 200, final dose) was implemented and the maximum dose was limited to 600 mg. Hospitalization to monitor and collect laboratory data was mandated at the 20 mg and 50 mg doses for all pts and at subsequent dose increases for pts in the high risk group. Detailed guidance on interventions for specific electrolyte changes and a pt management checklist were provided. As of Dec 20, 2013, 58 pts had been treated using the new monitoring and dosing schedule. No events of clinical TLS were reported and 8 pts were identified as meeting Cairo-Bishop criteria for LTLS (13.8%). Three of these pts had AEs reported; all were grade 1 and managed with rapid resolution. In general, lab changes were primarily elevations of phosphate/decreases in calcium, not potassium elevations.
Summary and Conclusion: Changes implemented in the ABT-199 dosing schedule and pt monitoring reduce the risk of clinically relevant TLS. Optimization of monitoring and prophylaxis measures is currently ongoing.

P869

OPEN LABEL MULTICENTER STUDY OF ELTROMBOPAG FOR THE TREATMENT OF IMMUNE THROMBOCYTOPENIA SECONDARY TO LYMPHOPROLIFERATIVE DISORDERS

C Visco[1,*], S Finotto[1], G Quaresmini[2], A Romano[3], G Motta[3], R Santi[4], M Merli[5], F Valeri[6], A Borchiellini[6], F Passamonti[5], A Rambaldi[2], M Ruggeri[1], F Rodeghiero[1]

[1]Hematology and Cell Therapy, San Bortolo Hospital, Vicenza, [2]Hematology and Bone Marrow Transplant Unit, Azienda Ospedaliera Papa Giovanni XXIII, Bergamo, [3]Hematology, Azienda Ospedaliera Universitaria, Catania, [4]Hematology, SS. Antonio e Biagio e Cesare Arrigo, Alessandria, [5]Hematology, University Hospital Ospedale di Circolo e Fondazione Macchi, Varese, [6]Hematology and Oncology, Città della Salute e della Scienza, Torino, Italy

Background: Immune ThrombocytoPenia (ITP) secondary to Lymphoproliferative Disorders (LPDs) is a condition poorly responsive to conventional treatments [*i.e.* Intravenous immunoglobulin (IVIG), steroids] with an overall response rate (ORR) generally lower than in primary ITP, and usually less than 50%. Therefore, new treatment strategies are needed. Eltrombopag, a thrombopoietin mimetic effective in primary ITP, might represent a new treatment sparing these severely immunocompromised patients from inappropriate cytotoxic therapies or steroids, not otherwise demanded by the underlying disease.
Aims: The aim of this phase 2, single arm, open-label, prospective, multicenter, safety/efficacy study was to assess the proportion of responders to eltrombopag and its safety profile in patients with LPDs.
Methods: To be included patients had to be diagnosed with ITP following predefined criteria (Visco et al, Blood 2008), do not necessitate any cytotoxic treatment for the following 6 months, have platelet count less than 30 x 10^9/L, or between 30 and 50 x 10^9/L in case of bleeding manifestations. Subjects initiated study medication at an oral dose of 50 mg/day, with dose adjustments allowed every 2 weeks (+/- 25 mg) for toxicity, non-response or platelet count below 60 x 10^9/L or over 400 x 10^9/L. Maximum allowed dose was 150 mg/day. Response was defined according to International Working Group definitions (Rodeghiero et al, Blood 2009). A total of 18 patients are scheduled to be enrolled with the optimal two-stage design. Eltrombopag was kindly provided by GlaxoSmithKline, Italy.
Results: Between the 1st of october 2012 and the 31st of december 2013, 10 patients have been enrolled by 6 centers. Informed consent was obtained by all patients. Median age was 63 years (43-80), five were females, 9 had chronic lymphocytic leukemia (CLL), and one had Hodgkin's lymphoma in remission status. Median time from LPD diagnosis and start of eltrombopag was 57 months (2-152). Four of the 10 patients had received cytotoxic treatments directed to the LPD, at least 14 months before enrollment. At the time of study entry, all patients had received previous treatments for ITP (all had steroids, 7 had IVIG, 5 had previous rituximab, 3 had cyclosporine, 2 had azathioprine). Last treatment for ITP had been delivered at least 2 months before study entry, apart from steroids. Steroids were maintained by the treating physician at a stable dose despite platelet count below 30 x 10^9/L with tapering within 2 weeks of eltrombopag initiation. Median time from first diagnosis of ITP and start of study medication was 7 months (1-77), with 7 of the 10 patients having chronic ITP. All patients except one were refractory to steroids. Median lymphocyte count at study entry for patients with CLL was 7.2 x 10^9/L (3.4-43.4), and median platelet number was 18 x 10^9/L (7-28). Overall, eltrombopag was well tolerated. The study drug was administered for a median time of 5.8 months (1.3-9), with

6 of the 10 patients still on treatment. One patient had mild itching while assuming the drug that was well controlled with symptomatics. No ≥ grade 2 adverse events were reported. No significant increase of bone marrow reticulin was documented in patients treated for more than 24 weeks. All patients were evaluable for early response (measured after 4 weeks of eltrombopag), while 6 patients were evaluable for response after 24 weeks. The ORR was 80% at 4 weeks, with 60% achieving complete remission (CR), at a median eltrombopag dose of 50 mg. The ORR after 24 weeks was 60% (all CR) with a median dose of 50 mg. The line chart of average response in terms of median platelet number ± interquartile range (IQR) is shown in Figure 1.

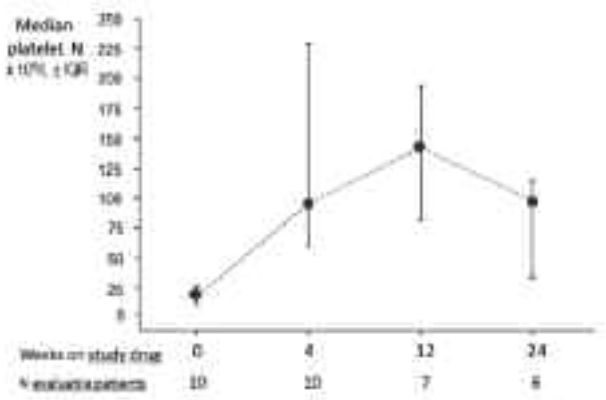

Figure 1.

Summary and Conclusion: This preliminary data show that eltrombopag is active and well tolerated in ITP secondary to LPDs. This trial was registered at ClinicalTrials.gov Identifier: NCT01610180.

P870

IS ZAP-70 STILL A KEY PROGNOSTIC FACTOR IN EARLY STAGE CHRONIC LYMPHOCYTIC LEUKEMIA? RESULTS OF THE ANALYSIS FROM A PROSPECTIVE MULTICENTER OBSERVATIONAL STUDY

Background: The most popular markers in chronic lymphocytic leukemia (CLL) focus on the identification of aggressive disease and include CD38, *IGHV* mutational status and ZAP-70; however evaluation of the latter is often inconsistent due to lack of standardization consensus.
Aims: We investigated i) the most accurate methods of identifying ZAP-70 expression levels; ii) the predictive power of ZAP-70 for *IGHV* mutational status; iii) the ability to predict progression free survival (PFS); and iv) novel gene markers which may surrogate *IGHV* mutational status.
Methods: A cohort of 487 newly diagnosed Binet stage A patients were prospectively enrolled (clinicaltrial.gov ID: NCT00917540). ZAP-70 expression was evaluated using: 1) Western blotting, 2) flow cytometry (FC), using an isotype-matched antibody as negative control (ZAP-70 I/C) or ZAP-70 expression in normal T cells (ZAP-70 T) as an internal positive control. ZAP-70 expression was also determined as MFI ratio between T- and B-cells (ZAP-70 T/B). Highly-purified B-cells were employed for GEP analysis (GeneChip® Gene 1.0 ST Array, Affymetrix Inc., Santa Clara, CA).
Results: Cases were randomly split into CLL-Training and CLL-Validation cohorts. ZAP-70 WB strong, ZAP-70 I/C 40%, ZAP-70 T 40% and ZAP-70 T/B of 1.5 significantly predicted PFS in both the training and validation sets. In a Cox multivariate analysis, in which ZAP-70 WB strong, ZAP-70 I/C 40%, ZAP-70 T 40% and ZAP-70 T/B 1.5 were forced, the latter remained the sole variable maintaining an independent association with PFS. In Cox multivariate analysis, when all ZAP-70 procedures were forced together with *IGHV* mutational status, ZAP-70 T/B 1.5 lost its predictive power, while *IGHV* mutational status maintained an independent association with PFS. Three-year re-assessment of ZAP-70 levels showed that ZAP-70 expression differed in 26%>50% of patients. Finally, we performed an independent supervised analysis by *IGHV* mutational status in CLL-Training (102 cases) and CLL-Validation (114 cases) sets taking into consideration all those genes showing a fold change superior or equal to that of *ZAP70*. Thirty-one genes (23 up-and 8 down-regulated) and 23 genes (18 up- and 5 down-regulated) showed a fold change superior or equal to that of *ZAP70* in CLL-Training and CLL–Validation sets, respectively; notably, 20 common genes (15 up and 5 down) overall were found to be differentially regulated in the 2 cohorts analysed. Two (*SNORA70F* and *NRIP1*) of the 5 down-modulated and 6 (*SEPT10*, *ZNF667*, *TGFBR3*, *MBOAT1*, *LPL* and *CRY1*) of the 15 up-modulated genes were found to be significantly associated with a reduced risk of disease progression in both training and validation sets. Notably, when all of the above mentioned genes were forced in a Cox multivariate model together with *IGHV* mutational status, only CRY1 (H.R. 2.3, 95% C.I. 1.1-4.9, P=.027) and MBOAT1 (H.R. 2.1, 95% C.I. 1.1-3.7, P=.018) maintained their independent prognostic impact, while *IGHV* and *SNORA70F* lost their prognostic power, supporting the hypothesis that these two genes could surrogate the predictive value of *IGHV* mutational status.
Summary and Conclusion: Regardless of the detection method adopted, the independent predictive power of ZAP-70 expression for progression in early-stage CLL remained unconfirmed. Moreover, ZAP-70 expression proved relatively unstable over time. Novel gene markers, *i.e.* CRY1 and MBOAT1, may surrogate IGHV mutational status and be involved in natural progression of CLL.

P871

EVALUATION OF IMMUNE RESPONSE TO 13-VALENT PNEUMOCOCCAL CONJUGATED VACCINE (PCV13) IN PATIENTS WITH CHRONIC LYMPHOCYTIC LEUKAEMIA

M Pasiarski[1], A Stelmach-Goldys[1], S Gozdz[1,2], E Grywalska[3], I Hus[4], J Rolinski[3,*]

[1]Department of Clinical Oncology, Holycross Cancer Center, [2]Faculty of Health Science, The Jan Kochanowski University, Kielce, [3]Department of Clinical Immunology, [4]Department of Clinical Transplantology, Medical University of Lublin, Lublin, Poland

Background: Chronic lymphocytic leukemia (CLL) is a lymphoproliferative disorder associated with severe impairment of the immune system in a substantial proportion of patients. This is directly linked with an increase in susceptibility to bacterial and viral infections. About 50 to 80% of patients diagnosed with CLL die from infectious complications. Most infections in CLL patients is caused by capsular bacteria: Streptococcus pneumoniae and Haemophilus influenzae. Patients with CLL who have low levels of antipneumococcal antibody are particularly at risk for severe and recurrent pneumococcal infections. In the U.S. and in many EU countries, vaccinations against Streptococcus pneumoniae are recommended for immunocompromised patients, such as patients with CLL. For many years, 23-valent pneumococcal polysaccharide vaccine (PPV23) was used. Antibody responses to PPV23 vaccine are inadequate in most patients with CLL, that induced response only in about 20-25 % of patients. Since 2012, in the prevention of pneumoccocal infections in immunocompromised adults, 13-valent pneumococcal conjugate vaccine (PCV13) has been used that efficacy in patients with CLL has not yet been studied.
Aims: The aim of this study was to assess the efficacy of vaccination in patients with CLL using PCV13.
Methods: The study included 24 previously untreated patients with CLL in stage 0 - 2 according to Rai calssification and 15 healthy subjects as a control group. The percentage of plasma cells, defined as CD19+/++IgD/CD27, was analysed before vaccination and 7 days after the immunization, the level of specific anti-pneumococcal antibodies and the level of IgG and IgG1, IgG2, IgG3, IgG4 immunoglobulin subclasses were evaluated prior to vaccination and 4 weeks after vaccination.
Results: The positive response to vaccination was defined as at least a two-fold increase in specific anti-pneumococcal (anticapsular) antibody titers as compared to the titer prior to the vaccination. Such a criterion of response was fulfilled in 100% of healthy subjects and in 58.3% of the patients with CLL. The percentage of plasma cells after vaccination was significantly lower ($p<0.0001$) in patients with CLL comparing to the control group. Both in patients with CLL as well as healthy subjects, there was a statistically significant increase in the level of IgG2 subclass after vaccination ($p=0.0301$). The patients with adequate antibody response to PCV13 had significantly less advanced stages of CLL, higher total IgG levels and IgG2 and IgG4 subclass levels. There was no no significant vaccine-related reactions, no increase in peripheral blood lymphocyte count and no changes in laboratory markers of disease activity.
Summary and Conclusion: Protective immunization of patients with CLL using the PCV13 is safe and induces an effective immune response in a large proportion of patients. To achieve the optimal postvaccinal response it is recommended to the use the PCV13 as early as possible after the diagnosis of CLL with determination of post-vaccination antibody levels.

P872

INITIAL CHARACTERISTICS, TREATMENT AND PROGNOSIS ACCORDING TO AGE IN CHRONIC LYMPHOCYTIC LEUKEMIA (CLL): A SINGLE-CENTER ANALYSIS BASED ON 949 PATIENTS

T Baumann[1,2,*], J Delgado[2], R Santacruz[2], A Martinez-Trillos[1,2], C Royo[1], A Navarro[1], M Pinyol[1], M Rozman[1], A Pereira[3], N Villamor[1], M Aymerich[1], C Lopez[1], A Carrio[4], E Montserrat[2]

[1]Hematopathology Unit, Department of Pathology, [2]Hematology Department, [3]Department of Hemotherapy and Hemostasis, [4]Hospital Clínic Barcelona, IDIBAPS, University of Barcelona, Barcelona, Spain

Background: There is little information about the characteristics, treatment, and prognosis of large series of patients with CLL according their age at diagnosis.
Aims: To investigate clinico-biological features, outcomes, and prognosis in patients with CLL according to their age.
Methods: 949 patients diagnosed with CLL between 1990 and 2012 in a single center according to IWCLL criteria were categorized by age at diagnosis into four groups:<59 years (n=345), 60-69years (n=237), 70-79 years (n=234) and ≥ 80 years (n=133). Disease-attributable mortality was calculated using the *relsurv* package (R software environment). Several models (additive, multiplicative and transformed) were tested as appropriate and their goodness-of-fit estimated using Brownian bridge statistics.
Results: Baseline characteristics of patients are shown in the Table. Median follow-up time was 7.8 years (0.1-23.2) for the overall series. In contrast to younger patients, both sexes were equally distributed within the elderly (p<.05). While younger patients presented more often with intermediate clinical stage (Binet B, Rai I/II; p<.05) and higher absolute blood lymphocyte counts (p<.05), patients above 80 years were more likely to be diagnosed in either initial (Binet A, Rai 0; p<.05) or advanced disease (Binet C, Rai III-IV; p<.05), lower Hb levels (p<.05) and higher B2M (p<.05). No biological differences (FISH cytogenetics, *IGHV*, ZAP-70, CD38, *NOTCH1, SF3B1*) were found among different groups of age. Elderly patients were treated later than younger ones (median TTFT 3.1 *vs*. 7.0 *vs*. 8.4 years *vs*. not reached; p<.05). In addition, treatment given changed significantly with increasing age: alkylating agents (32% *vs*. 45% *vs*. 69% *vs*. 72%), purine analogs (35% *vs*. 25% *vs*. 12% *vs*. 5%), chemoimmunotherapy (27% *vs*. 20% *vs*. 8% *vs*. 0%), other (72% *vs*. 5% *vs*. 0% *vs*. 23%) (all p<.05). Consequently, response rates decreased with rising age (72% ORR with 32% CR *vs*. 63% ORR with 29% CR *vs*. 55% ORR with 16% CR *vs*. 35% ORR with 12% CR; p<.05). Finally, actuarial overall survival (OS) was shorter in older patients (15.7 *vs*. 11.9 *vs*. 7.9 *vs*. 4.3 years; p<.05), but, of note, disease-specific mortality was not significantly different across age groups (27% *vs*. 25% *vs*. 23% *vs*. 19% at 8 years; p=.26).

Table 1.

	<59 years (n=345)	60-69 years (n=237)	70-79 years (n=234)	≥80 years (n=133)	p-value
Sex, male (%)	225 (65)	140 (59)	120 (51)	70 (53)	.004
Creatinine clear (mL/min)	79 [34-136]	77 [44-123]	69 [19-120]	64 [26-120]	<.001
Binet (%) A	253/335 (75)	191/231 (84)	190/227 (84)	108/131 (82)	<.001
B	66/335 (20)	28/231 (12)	20/227 (9)	5/131 (4)	
C	16/335 (5)	10/231 (4)	17/227 (8)	18/131 (14)	
B2M mg/ml	2.34±1.53	2.51±1.35	3.24±1.99	3.78±1.94	<.001
ZAP-70 high (%)	102/256 (40)	59/178 (33)	52/165 (32)	16/62 (26)	NS
IGHV/UM (%)	118/231 (51)	56/144 (39)	51/117 (44)	17/40 (43)	NS
FISH (%)					
13q-	80/252 (32)	67/175 (38)	61/157 (39)	24/57 (42)	NS
Normal	69/252 (27)	52/175 (30)	45/157 (29)	17/57 (30)	
+12	35/252 (14)	23/175 (13)	24/157 (15)	5/57 (9)	
11q-	29/252 (12)	11/175 (6)	11/157 (7)	4/57 (7)	
17p-	39/252 (15)	17/175 (10)	16/157 (10)	7/57 (12)	

Summary and Conclusion: While younger patients tended to be diagnosed in intermediate stages (stage B and I/II) and with higher blood lymphocyte counts, older patients were diagnosed at more advanced phases of the disease. However, no significant differences in the distribution of biological risk markers according to patients' age were found and no differences in disease-specific mortality were observed.

Background: Cytogenetic abnormalities in chronic lymphocytic leukemia (CLL) establish subgroups of patients with different prognosis and survival. In addition, CLL patients with a high number of losses in 11q or 13q have a worse prognosis. Trisomy 12 (+12) have been classically considered as harboring an intermediate prognosis. However, their exact clinical characteristics and outcome along with additional prognostic factors have not been ascertained in large series.
Aims: To analyze in a multicentric study whether the number of +12 lymphocytes in patients with CLL has an influence in overall survival (OS) and time to first therapy (TFT).
Methods: A total of 2,561 patients registered in DataBase of CLL of GCECGH and GELLC were included. Clinical and biological data, FISH information (11q, 12, 13q and 17p probes) and follow-up were recorded.
Results: 355 patients (13.9%) presented the +12. The final analysis was limited to 289 cases (178 males) after excluding patients with monoclonal B-cell lymphocytosis, those that had +12 as clonal evolution or cases with inadequate follow-up. Most of patients (71%) were in Binet's clinical stage A. At the time of the analysis, 22% of the patients had dead and 53 % had progressed. Median OS of patients with +12 was 129 months (CI95%, 100-148) and TFT was 66 months (CI95%, 55-76). A total of 174 patients (60.2 %) presented the +12 in<60% of cells. Interestingly, median OS was 159 months (CI95%, 119-182), while it was of 96 months (CI95%, 58-134) for those with +12 ≥60% of cells (P=0.015) (Figure). In addition, advanced Binet's clinical stage (P<0.0001), lymphadenopathy (P=0.001), splenomegaly (P=0.001), lymphocyte count >30x10^9/L (P=0.04), high serum LDH (P=0.009), high $\beta_2$microglobulin levels (P<0.0001) and expression of CD38 (P=0.04) were associated with a short OS. In the multivariate analysis, only Binet's stage (P=0.002) and high serum $\beta_2$microglobulin (P=0.02) resulted significant in predicting OS. Regarding TFT, in patients with<60% +12, the median TFT was 72 months (CI95%, 58-86) *vs* 57 months in cases with ≥60% (P=0.007) (Figure). Other significant variables for TFT were Binet's clinical stage (P<0.0001), B symptoms (P=0.02), lymphadenopathy (P=0.02), splenomegaly (P=0.001), high lymphocyte count (>30x10^9/L) (P<0.0001) and high LDH (P=0.007). In the multivariate analysis, only clinical stage (P=0.01) and a number of +12 in ≥60% of cells (P=0.013; HR: 1.58; CI95%, 1,2-2,3) resulted of significance in predicting TFT.

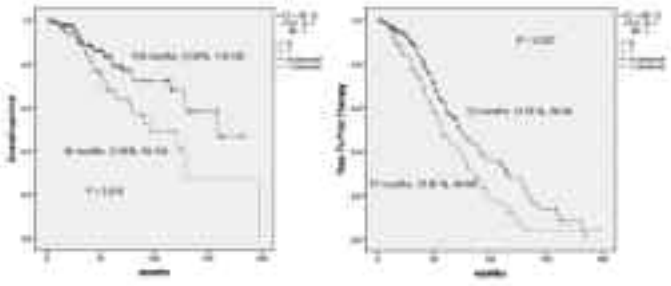

Figure 1.

Summary and Conclusion: In patients with CLL, a high percentage of cells with +12 is associated with a shorter TFT and OS. FIS: PI 12/00281, FEHH 2013-2014 and 'Junta de Castilla y León' (MH).

Departamento de Medicina, Fundación Centro de Investigación del Cáncer. Salamanca, Salamanca, Spain

Background: Immunochemotherapy may improve the life expectancy of chronic lymphocytic leukemia (CLL) patients and has proven to be more efficient than chemotherapy alone in depleting malignant cells. Despite this, little is known about its precise immunomodulatory effects and immune toxicity *vs* standard regimens.

Aims: To evaluate the effects of bendamustine *plus* rituximab (BR) *vs* fludarabine *plus* cyclophosphamide *plus* rituximab (FCR) on the distribution of pathological and normal leucocyte subsets in peripheral blood (PB) from advanced-stage CLL patients.

Methods: PB neoplastic and normal immune cell subsets were analyzed in 97 CLL patients (Binet B/C) before treatment; from these, 72 patients were treated with BR and 25 with FCR. Leukocyte subsets were identified (prior therapy: M0; after 1 course: M1; and at 3 months after treatment: M2) by flow cytometry, with antibodies against CD3, CD4, CD5, CD8, TCRgd, CD19, CD20, CD27, CD38, CD45, CD56, sIgM, sIgA, sIgG, sIgl and sIgk.

Results: At M0, no clinical differences (p>0.05) were found between patients who were later treated with BR *vs* FCR, although a fewer patients treated with BR had not been previously treated *vs* the FCR group (50% *vs* 80%; p>0.05). Also, the absolute count of PB malignant cells was lower in BR *vs* FCR group at M0 (59,953±70,168 *vs* 88,500±79,297 cells/uL, p<0.05); as expected, in each group, a reduction (p<0.05) of all PB leukocyte subsets was achieved at M2, in comparison to basal levels from the corresponding group. Upon comparing the efficacy of each protocol in depleting pathological cells after treatment, the number of tumor B cells was lower in FCR *vs* BR patients (175±630 *vs* 1,541±6,740; p=0.006); actually, in comparison to M0 levels, a much higher rate of reduction of clonal cells was seen with FCR than with BR (500-fold of reduction *vs* 40-fold). This finding was consistent with the fact that patients treated with FCR had a higher rate of cases with minimal residual disease<0.01% at M2 *vs* BR-patients (61% *vs* 29%; p=0.01), although the complete remission rate was similar (40% *vs* 41%, p>0.05). Differences were also found between both groups as regards the absolute number of PB normal leukocyte subsets (Fig1), mainly after the first course. In particular, FCR-treated patients had higher counts of normal B-cells at M1 than those treated with BR, being the differences statistically significant (p≤0.05) for naïve, IgG memory B cells and total plasma cells (Fig1). In addition, dendritic and NK cells were significantly increased at M1 in patients treated with FCR. However, after finishing treatment (M2), the degree of reduction of normal PB leukocyte subsets was in general more intense than at M1, but without statistically significant differences between the two groups of patients, with the exception of circulating plasma cells and monocytes, found to be significantly lower among FCR patients (Fig1). However, the reduction rate at M2 was more profound with FCR *vs* BR, particularly for normal total B cells (>1000-fold *vs* 12-fold reduction) and CD4+ T cells (>12-fold *vs* 6-fold reduction).

Summary and Conclusion: Despite all PB leucocyte subsets are affected by BR and FCR, both pathological and normal B cells (as well as CD4+ T cells) are more efficiently depleted by FCR, although this effect is reached slower in comparison to BR. Further studies will offer more accurate insights into the biology of cell recovery and the clinical impact of neoplastic/normal B-cell depletion during and after therapy in CLL.

Oncologico A. Businco, Cagliari, Italy

Background: The front-line therapy for CLL young patients is chemo-immunotherapy with Fludarabine-Cyclophosphamide and Rituximab (FCR). Recently the German CLL study group reported an interim analysis of CLL10 trial, who compared FCR *vs* BR. Both treatment showed high response rate, no firm recommendation of one regimen over the other can be given at the present time regarding the first line use in CLL patients with good physical fitness. FCR regimen can result in a significant myelosuppression and a high rate of early and late infections, suggesting that it may be too toxic and therefore unsuitable for this large subpopulation of patients. However, many CLL patients are elderly and with comorbidities. Bendamustine (B) in association with Rituximab (RTX) (Benda-R) have shown to be efficacious and safe as frontline therapy in elderly and or unfit patients. Insufficient data are available in patients older than 75 years regarding the efficacy and safety, nevertheless more incidence of extra-hematological toxicity was noted in this subgroup.

Aims: We report our multicentre retrospective study focusing on responses and toxicities rate in elderly patients with CLL.

Methods: We report data of 66 patients with age ≥ 65 years previously untreated CLL observed in 12 Italian centres from November 2000 to December 2013. All patients were assigned to receive 6 courses of Bendamustine (90 mg/sm for 2 consecutive days) and RTX (375 mg/sm for the first course and 500 mg/sm for subsequent cycles) every 28 days. The primary end points were the ORR (complete response CR and partial response PR) and haematological or extrahematological toxicities. Forty-three male and twenty-three female with a median age of 72 years (range, 65-87 years) were included in the study. Six patients were unfit with a CIRS score of 7 or more. All patients had ECOG less than 2. Eleven patients were Binet A, 28 Binet B and 27 Binet C stage. The median lymphocytes count at diagnosis was 33.203/mmc (range, 2.200-140.000). Fish analysis was performed in 50/66 patients: 35 patients showed normal karyotype, del13q14 or +12, 13 pts del11qand 2 pts del17p. The analysis of the IGHV status, available in 46 patients, showed 24 patients with somatic mutation and 22 patients with germ-line sequences.

Results: A mean number of 5.46 courses of BR was given and the Bendamustine dose was reduced by more than 10% in 36 patients (54.5%). The ORR rate was 86.3%: twenty-one patients (31.8%) obtained a complete response and thirty-six patients (54.5%) obtained a partial response. Gender, age (65-69, 70-74, >75

years), Binet stage, fitness status, lymphocyte counts, del11, IGHV status did not show impact on response and time dependent variables. Only the presence of del17 had an impact in terms of response to therapy (p=0.023) and progression free survival (p<0.001). Grade III/IV hematological toxicity was recorded in 24 patients (36.4%). Extra-hematological toxicity grade I-III (skin reactions, gastrointestinal and cardiovascular symptoms, infusion related reactions, etc). was noticed in 33 patients. Nine patients were admitted to the hospital. Progression Free Survival was 79% at 2 years, Time To Retreatment was 90.3% at 2 years and Overall Survival was 89.6% at 2 years.
Summary and Conclusion: Retrospective data from this group of elderly CLL patients indicate that Benda-R front-line at standard dose provides a high response rate with a good safety profile, even if more than 50% of patients experienced a Bendamustine dose reduction until 70 mg/sm. Even in this cohort of patients we confirmed del17 as a bad prognostic parameter.

Background: Despite recent therapeutic advances, chronic lymphocytic leukemia (CLL) remains an incurable disease and patients (pt) experience multiple relapses. CLL pt are generally ≥ 70 and have comorbidities. Rituximab (R) is approved in relapsed CLL in combination with chemotherapy based on the REACH study results which was conducted in young pt (median age 62 years) and combined with the standard of care FC-R (Fludarabine-Cyclophosphamide-Rituximab) only. The benefit of FC-R in old pt is still debated, and efficacy and safety of other R-based regimens in pt previously treated with R is not clearly defined.
Aims: The aim of this French non-interventional study is to describe the management in daily practice of relapsed/refractory CLL pt previously treated with rituximab in 1st or 2nd line and retreated with a R based regimen.
Methods: In this prospective, multicenter, longitudinal, national, non-interventional ongoing study, 320 pt with relapse/refractory CLL, treated again with a rituximab-based regimen are planned to be recruited.
The primary objective is to describe the different chemotherapy regimens combined with rituximab. Secondary objectives include efficacy (overall response rate, complete response rate, partial response rate, progression free survival, time to next treatment, overall survival); description of rituximab use (doses, number of cycles, etc.), chemotherapy regimens combined with R by subgroup (refractory pt, elderly pt ≥ 70 years old, 17p and 11q deletions) and safety. Pt will be followed-up for up to 2 years. In the current analysis we focused on the induction treatment data of the first 200 pt included.
Results: From April 2011 to March 2013, 200 pt have been included and 192 were evaluable in the interim analysis for the primary objective. Median age is 72 years [35-89], and 56% are ≥ 70 years old. Seventy-one percent of the pt are men. Twenty four (13%) pt have 17p deletion and 28 (15%) pt have 11q deletions. A hundred and six (55%) pt are in first relapse, 86 (45%) in second relapse and 12 (6%) pt are refractory. Subgroup analyses were not done due to the limited number of pt in each subgroup. The median time between diagnosis and 1st treatment is 2 years, and is not different whether pt are in 1st or 2nd relapse. The main treatments administered are as follows: 38 pt (21%) received R + purine based regimen, among them 29 received FCR regimen, 101 pt (56%) R-Bendamustine, and 34 pt (19%) R+alkylating agent including 13 treated with R-Chlorambucil (R-Chl). Response is based on investigators assessment. The ORR is 75%, 90% in R-FC pt 75% in R-Bendamustine pt and 69% in R-Chl pt. Twenty two pt (11%) have stable disease, and 26 (14%) have progressive disease during induction treatment. Most frequent adverse events (all grades) are hematologic (24%) including neutropenia (11%), and infectious (13%). AEs leading to treatment discontinuation occurred in 16 pt (8%), and 14 pt (7%) died during induction treatment, 8 due to disease progression and 6 due to AE (2 aspergillosis, 1 progressive multifocal leukoencephalopathy, 1 septic shock, 1 pneumonia, and 1 anuria).
Summary and Conclusion: In this non interventional study, interim results show a median age of 72 years which is consistent with the median age of CLL pt. The main induction treatment prescribed is R-Bendamustine for 56% of pt. The ORR is higher when assessed using centers usual practices. The study is still ongoing, further data will be available on induction treatments and to assess PFS, OS and safety.

P877

ANALYSIS OF MERKEL CELL POLYOMAVIRUS PROGNOSTIC SIGNIFICANCE IN CHRONIC LYMPHOCYTIC LEUKEMIA

M Doubek[1,2,*], J Srovnal[3], K Plevova[1], J Trizuljak[2], Y Brychtova[2], L Semerad[2], E Letalova[2], A Benedikova[3], J Mayer[2], M Hajduch[3], S Pospisilova[1]
[1]MASARYK UNIVERSITY - CEITEC, [2]University Hospital, Brno, [3]Institute of Molecular and Translational Medicine, Olomouc, Czech Republic

Background: Merkel Cell polyomavirus (MCPyV), a ubiquitous DNA tumor virus, has been found to be associated with Merkel cell carcinoma and chronic lymphocytic leukaemia (CLL). Previous studies have reported conflicting results on the frequency and potential pathogenetic role of MCPyV in CLL. Moreover, the prognostic significance of MCPyV is unknown in CLL.
Aims: The aim of this study was to evaluate the association of MCPyV with CLL and to investigate the occurrence of MCPyV infection in relation to the course of CLL.
Methods: DNA CLL samples consecutively obtained from CLL patients (n=119) before treatment was tested for MCPyV using both quantitative real-time polymerase chain reaction analysis and next-generation sequencing. Furthermore, 21 patients were tested repeatedly after CLL therapy. Therefore, 140 samples were tested in total. Only samples being positive by both methods were considered to really be positive for MCPyV. The MCPyV have been compared with classical and biological prognostic CLL factors.
Results: We found that 13/119 CLL cases (11%) were positive for MCPyV. Between the groups of MCPyV-positive and -negative patients, there was no significant difference in the sex (5 positive females from 49; 8 positive males from 70); age (median age 60.5 years for positive and 60 years for negative patients); cytogenetics (unfavorable cytogenetics (del 17p or 11q) in 38% of positive patients and 24% of negative patients); presence of p53 defect (23% of positive patients *vs*. 20% of negative patients); *IGHV* mutational status (unmutated in 69% of positive patients and 76% of negative patients). Ad baseline, advanced Rai stage (III and IV) was found more frequently in MCPyV negative patients (15% *vs*. 41%; P=0.04). Therapy (FCR regimen or alemtuzumab) was also initiated more frequently in the negative group (46% *vs*. 68%; P=NS). There was no difference in overall response rate (86% in positive patients *vs*. 80% in negative patients), median progression-free survival (20 months in MCPyV negative *vs*. 24 months in MCPyV positive patients), and overall survival (not reached) between both groups. One CLL patient positive for MCPyV also developed Merkel cell carcinoma. Interestingly, in six initially MCPyV positive patients repeatedly tested, the virus was undetectable after treatment in four of them. We did not observe any new positivity after treatment in initially MCPyV negative patients.
Summary and Conclusion: This study provides the first analysis of the prognostic role of MCPyV in CLL. The occurrence with MCPyV seems to be a relatively rare event during the natural history of CLL. MCPyV is also unlikely to influence the outcome of CLL patients and MCPyV positivity may often disappear after CLL therapy. A PATHOLOGICAL ABDOMINAL ULTRASONOGRAPHY AT DIAGNOSIS OF CLL SIGNIFICANTLY REDUCES THE TIME TO PROGRESSION IN PATIENTS WITH RAI 0 OR 1 DISEASE

F Farina[1], F Rossini[1,*], C Cecchetti[1], A Perego[2], M Sassone[1], A Belotti[1], E Doni[1], S Bozzani[1], S Pezzatti[1], C Scollo[1], I Casaroli[1], S Bolis[1], P Pioltelli[1]
[1]hematology unit, s. gerardo hospital, monza, [2]Medical Unit, Desio Hospital, DESIO, Italy

Background: The most common staging systems for CLL were developed in 1975 and 1981 and rely on standard blood cell count and the presence of enlarged lymph nodes by physical examination. While different imaging procedures are often performed in CLL patients (pts), their role has never yet validated. Recently some study have evaluated the role of computered tomography (CT) as a prognostic significance in pts with early stage disease or after first-line therapy; however CT cannot be used routinely, especially in pts with early stage CLL whose life expectancy may be very long.
Aims: Aims of the study were to investigate if ultrasonography (US) could be useful at diagnosis and in follow up and if a pathologic US (PU) showing the presence of abdominal lymphadenopathy at diagnosis could identify pts with different risk of evolution.
Methods: Between 1999 and 2011, 255 pts with Rai 0 or Rai 1 CLL had a US performed at diagnosis. Lymph nodes more than 10 mm in diameter were considered abnormal.
Results: Median age was 67 (range 41-85). 195 pts had Rai stage 0 (76.5%) disease and 60 Rai stage 1 (23.5%). Median absolute lymphocyte count was 16.7 x 10^9/L (range 5.1-199). Overall, PU were present in 53/255 (20.8%) pts, with lymph nodes up to 120 mm. PU were significantly more frequent in

pts with Rai 1 disease (24/60 – 40%) than in Rai 0 (29/195 – 14.9%) disease (p<0.01), in patients with unmutated disease (19/51 – 37.3%) than in pts with mutated disease (19/127 - 15%) (p=0.002) and in pts with absolute lymphocyte count (ALC) at diagnosis >20 x 10^9/L (20/61 – 32.8%) than in pts with ACL<20 x 10^9/L (33/194 – 17%) (p=0.03). No significant differences were present in age, hemoglobin concentration, absolute neutrophil count, platelet count or CD38 positivity. Pts with PU had a shorter time to progression (median 62 months *vs* not reached - p<0.001). (fig. 1). If the whole population is divided in three groups, pts with Rai 0 disease and no PU (group A), with Rai 0 disease and PU (group B) or pts with Rai 1 (group C), the time to progression (TTP) is significantly different, with median TTP not reached for group A, 73 months for group B and 37 months for group C (p<0.001). Among patients with Rai 1 disease, median TTP was 60 months in pts with PU and 18 months in pts without PU (p=0.056). PU had shown a prognostic significance also in pts with unmutated disease with median TTP of 63 *vs.* 19 months (p=0.04). Among patients with mutated disease, there was no significant difference in median TTP (108 months for pts with PU and not reached for pts without PU). No differences in overall survival could be shown. In 13 pts progression of lymphadenopaties or splenomegaly were shown by US as indication of an immediate treatment: in 4/13 pts this was confirmed by CT and in 10/13 pts an increase of ACL was also present but not yet indicative for treatment.

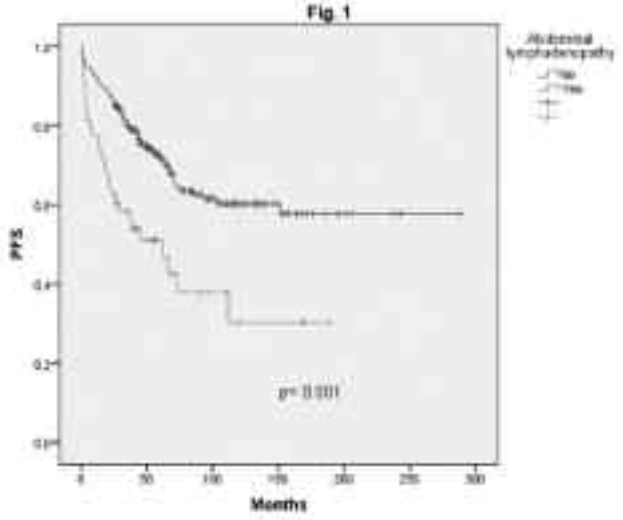

Figure 1.

Summary and Conclusion: The presence of PU at diagnosis can identify a subgroup of Rai 0 CLL with shorter TTP; this confirms results reported with CT. PU retains its importance also when unmutated pts are considered; among mutated pts, a statistically significant difference could not be shown, also due to the low number of events in this group (7/19 pts). An US performed at diagnosis appears to be useful in low-risk CLL patients: it is a non-toxic imaging technique that can identify subgroups of low-risk pts at diagnosis and it can be repeated in follow-up to evidence progressive abdominal disease.

P879

IN VITRO COMPARATIVE STUDY ON DIRECT KILLING OF CLL CELLS BY SMALL TARGETED THERAPEUTIC MOLECULES

S Eketorp Sylvan[1,2,*], H Skribek[3], S Norin[1,4], R Otvos[3], O Muhari[3], L Szekely[3], A Österborg[1,2]

[1]Departments of Hematology and Oncology, Karolinska University Hospital Solna, [2]Department of Oncology-Pathology, [3]Department of Microbiology, Tumor and Cell Biology and Center for Integrative Recognition in the Immune System, [4]Department of Medicine Huddinge, Karolinska Institutet, Stockholm, Sweden

Background: In chronic lymphocytic leukemia (CLL), molecular studies point to the involvement of the deregulation of important cellular signaling pathways. New drugs affecting those pathways are currently developed. For drugs in early clinical testing it is important to analyze their *in vitro* killing capacity in pharma-independent head-to-head comparative experiments.

Aims: This study evaluates *in vitro* sensitivity of CLL cells to emerging targeted therapeutics and compared with conventional cytostatic agents using a high-throughput drug-sensitivity screening system based on automated fluorescence digital microscopy. The system is particularly suited for testing drug sensitivity on primary tumor cells from hematological malignancies and has been developed and validated on CLL cells.

Methods: Fresh primary CLL cells from 42 consecutive patients with CLL (22 indolent and 20 progressive or refractory), were analyzed. Informed consent was obtained from each patient. Cells were cultured for 72h on microtiter plates in a total human blood lysate-based medium. The anti-tumor effects of 30 small therapeutic molecules and of 30 cytostatic agents were measured at 4 different concentrations in triplicates in a short-term fluorescence survival assay. An equimolar concentration range was applied for the small targeted molecules in order to allow head –to-head comparison whereas for the cytostatic agents it was selected by approximating the *in vivo* achieved concentrations. Killing Efficiency (KE%), a value graded from 0 to 100, was calculated for each drug. KE% is a weighted sum of dose dependent killing-capacity where the weighting factors are the logarithms of the individual drug dilutions.

Results: Results are depicted in fig 1. The highest direct killing capacity among the small molecules tested was observed for two Bcl-2 inhibitors (ABT-199 andABT-737), one survivin inhibitor (YM-155), and one selective CDK inhibitor (dinaciclib). Small molecules, in contrast to cytostatic agents, were equally effective in cells from indolent and progressive CLL. Clinically promising drugs such as ibrutinib, lenalidomide and idelalisib showed a relatively low direct KE, in line with some previous observations and suggesting partly other mechanisms of action. The killing-capacity of cytostatic agents confirms the findings from a previous study with a notable effect for vinorelbine and daunorubicin. The sensitivity difference between cells from indolent and progressive patients was statistically significant for 10/40 tested cytostatic agents tested (p<0.05)) but no such difference was observed for the small therapeutic molecules. As expected, CLL cells from progressive, and in particular refractory CLL, had limited or no sensitivity to fludarabine, bendamustine and chlorambucil. There was no dose dependent drug sensitivity for dexamethasone or prednisone.

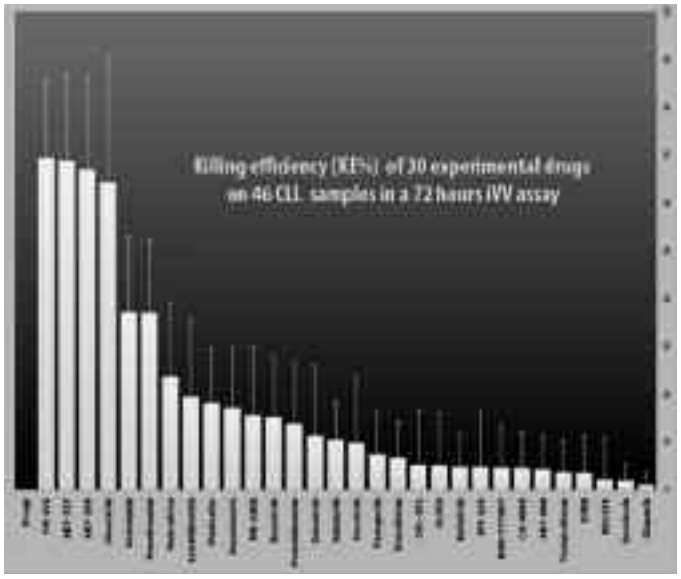

Figure 1.

Summary and Conclusion: This study provides a comparative *in vitro* testing under standardized conditions of the direct cytotoxic capacity of small therapeutic molecules in pipeline for CLL. Such analyses may help to identify drugs of particular interest to explore further, alone and in combination.

P880

UBLITUXIMAB (TG-1101), A NOVEL GLYCOENGINEERED ANTI-CD20 MAB, IN COMBINATION WITH IBRUTINIB IN PATIENTS WITH CLL AND MCL; RESULTS OF AN ONGOING PHASE II TRIAL

J P Sharman, MD[1,*], C M Farber, MD, PhD[2], D Mahadevan, MD PhD[3], M T Schreeder, MD[4], M Mackenzie, RN[2], M Brotherton, RN[3], E K Pauli, Pharm D[4], K Cutter, RN[4], P Sportelli[5], H P Miskin, MS[5], O A O'Connor, MD, PhD[6]

[1]Willamette Valley Cancer Institute/US Oncology Research, Springfield, OR, [2]Carol G. Simon Cancer Center, Morristown, NJ, [3]West Clinic, Memphis, TN, [4]Clearview Cancer Institute, Huntsville, AL, [5]TG Therapeutics, Inc., [6]Columbia University Medical Center, New York, NY, United States

Background: Ublituximab (UTX) is a novel, chimeric mAb targeting a unique epitope on the CD20 antigen, glycolengineered to enhance affinity to FcγRIIIa receptors, thereby demonstrating significantly greater ADCC than rituximab (RTX). Glycoengineered anti-CD20 mAbs have recently demonstrated greater efficacy (ORR, PFS) than RTX in CLL (NEJM, 2014). A Phase I/Ib trial with UTX monotherapy in patients with relapsed/refractory CLL reported an ORR of 45% with rapid and sustained lymphocyte depletion. Data with ibrutinib (IB) + rituximab shows high response rates however, CR and minimal residual disease (MRD) negativity rates remain low. To potentially accelerate and improve responses, IB was combined with UTX.

Aims: Herein we report data from the Phase 2 of UTX + IB in patients with relapsed/refractory CLL and MCL.
Methods: Eligible patients have relapsed/refractory CLL or MCL, with an ECOG PS<3. Informed consent was obtained in all patients. Study Design: 6 patient safety run-in followed by open enrollment. UTX (2 cohorts at 600 and 900 mg for CLL and 1 cohort at 900 mg for MCL patients) is administered weekly x 3 in Cycle 1 followed by Day 1 of Cycles 2 - 6. IB is started on Day 1 and continued daily at 420 mg for CLL and 560 mg for MCL patients. MRD assessed via central lab. Primary endpoint: Safety and Dose Limiting Toxicities (DLT). Secondary endpoint: Efficacy (ORR, CR rate, MRD).
Results: As of Feb 26, 2014, 4 CLL and 2 MCL patients have been enrolled: Median age 72 years old (range 52-76); all male. Median prior Tx=3 (range 1-4); Median ECOG PS: 1 (range 0 – 2). All patients are evaluable for safety; no DLTs or safety concerns have been observed. The most frequent AE has been Cycle 1/Day 1 infusion related reactions in CLL patients. Clinical activity has been observed in the CLL patients by physical exam (efficacy evaluation too early for MCL patients). Anticipated enrollment of 20+ patients by June 2014.
Summary and Conclusion: UTX + IB has been well tolerated to date with early clinical activity observed. Known lymphocytosis caused by IB in CLL patients has been minimized with the addition of UTX. MRD and full response analysis will be presented at the meeting. Additional studies are ongoing in patients with CLL and NHL with UTX in combination with other novel targeted agents including PI3Kδ inhibitors.

Chronic myeloid leukemia - Clinical 2

Background: In the latest recommendations of the European LeukemiaNet guidelines for the management of chronic-phase Chronic Myeloid Leukemia suboptimal responses have been reclassified as "warning responses". In contrast to previous recommendations current guidance advises close monitoring without changing therapy. There is little literature available regarding the potential benefit of changing treatment of patients categorized as late warning responders (patients with complete cytogenetic response (CCyR) without major molecular response (MMR)), and even more importantly, most of the published data focuses on patients classified according to previous editions of ELN recommendations (after 18 months of treatment).
Aims: The aim of this study was to describe outcomes of late warning patients, classified by the latest ELN recommendations, in order to explore the potential benefit of treatment switching in these patients.
Methods: Our registry includes a cohort of 945 CP-CML patients that are treated with first-line imatinib and are not involved in clinical trials. Registries were approved by the corresponding Ethical committees, and all the procedures were performed in accordance with international legislation. The monitoring and treatment strategies were chosen at the hematologist's discretion and thus reflect the actual treatment of CML patients outside clinical trials. All data was recorded by data managers that operated independently from the physicians taking care of the patients. From this cohort we identified 198 patients with a warning response after 12 months of treatment (patients with a complete cytogenetic response but no major molecular response [MMR]). Patients who underwent treatment change due to intolerance were identified but not categorized as late warning responders.
Results: One hundred and fourty six patients (group 1) remained on imatinib, while 52 patients (group 2) changed treatment to a Second Generation Tyrosine Kinase Inhibitor (2GTKI). The overall probabilities of obtaining MMR and $MR^{4.5}$ by 24 months on an intention-to-treat basis were 10% *vs*. 21 % respectively, whereas by 48 months the corresponding probabilities were: 21% *vs*. 44%.

Overall survival (OS) was 97% *vs.* 92% by 24 and 48 months respectively, whereas progresion free survival (PFS) was 98% *vs.* 96% for the same periods of time.Changing therapy resulted in a significant improvement in the probability of a MMR: 24% *vs.* 42% by 12 months and 43% *vs.* 64% by 24 months (p=.002); as well as the probability of achieving a deep molecular responses ($MR^{4.5}$): 1% *vs.* 19% and 7% *vs.* 23% by 12 and 24 months respectively (p=<0.001). Treatment change was also associated with an increased stability of cytogenetic responses, reflected by the observation that 17 patients (11%) in group 1 lost CCyR, compared to 2 patients (3%) in group 2 (p=.001). Similarly, treatment change significantly influenced the probability of remaining in MMR and $MR^{4.5}$ at the last follow-up: 36% *vs.* 49% and 14% *vs.* 25% implying a relative risk of 1.5 (1.2; 1.9) for MMR and a relative risk of 1.8(1.0; 3.3) for $MR^{4.5}$ in the group of patients who changed treatment *vs.* patients continuing imatinib. These improvements did not correlate with an increase in overall survival (OS) or progression-free survival (PFS).Treatment change was generally well tolerated. However, 10 patients in Group 2 (19%) discontinued treatment due to side effects with long-term side effects leading to 4 patients (2%) discontinuing imatinib.

Summary and Conclusion: To our knowledge our study represents the largest study of late warning patients treated with imatinib (including the published data regarding outcomes of late suboptimal responders under the old classification scheme). Our study shows how late warning responders had an excellent prognosis in terms of PFS and OS, and offers an empirical demonstration of the adequacy of classifying these responses as a warning, if survival outcomes are the objectives of the treatment. However, if the objectives include lowering (mitigating) the probability of treatment failure as well as obtaining deeper molecular responses, our study demonstrates that switching to a 2GTKI is the preferred option.

Background: Clinical trials have shown that nilotinib (NIL) is superior to imatinib (IM) as frontline treatment for chronic myeloid leukemia in chronic phase (CML-CP) and can improve responses in pts resistant or intolerant to IM, but the optimal treatment for patients (pts) with suboptimal response (SoR) to IM is unclear.
Aims: The Study to Evaluate Nilotinib in CML pts with SubOptimal Response (SENSOR, NCT0104387) was designed to evaluate the safety and efficacy of NIL in pts with CML-CP with SoR to frontline IM. Results of the planned 12-mo interim analysis are presented.
Methods: SENSOR is a multicenter, phase 4, open-label study in which adult pts with SoR to firstline IM switched to NIL 400 mg twice daily, with planned 24-mo follow-up. Per European LeukemiaNet 2009 criteria, SoR was defined as complete cytogenetic response, but no major molecular response (MMR; BCR-ABL ≤ 0.1% on the International Scale [IS]) after at least 18 mo. MMR rate at 12 mo was the primary endpoint. BCR-ABL^{IS} transcript levels were assessed by a central laboratory at screening, monthly for 3 mo, and every 3 mo thereafter. Mutation analyses (using direct sequencing and the polymerase chain reaction invader method), were conducted centrally at baseline (BL) and end of study in all pts; additional analyses were done every 3 mo for pts with BL mutations and in pts not in MMR with a ≥ 5-fold increase in BCR-ABL from the lowest level. The invader method, introduced to detect 25 IM-resistant point mutations with increased sensitivity, cannot detect other mutations or alternative splicing abnormalities.
Results: Between Dec 2009 and Feb 2012, 45 pts enrolled. At BL, median BCR-ABL/ABL^{IS} ratio was 0.24% (range, 0.11%>3.49%) after a median of 23.0 mo (range, 17.0-103.3) of IM. At the data cutoff, 19 pts (42%) completed the 24-mo study, 21 (47%) were ongoing, and 5 (11%) discontinued. At 12 mo, 51% of pts achieved MMR and 4.4% achieved BCR-ABL^{IS} ≤ 0.0032%. The cumulative rate of MMR by 12 mo was 67%. Most pts with mutations at any time (12/15) achieved MMR. Direct sequencing detected point mutations and alternative splicing abnormalities, such as exon 7 deletion (del) and exon 8/9 35 base pair insertion (bp ins). Twelve pts had newly detected mutations during the study; of these, 9 pts achieved MMR (6 with exon 8/9 35 bp ins, and 1 each with either E459K, Y393C, or T319A). These mutations were identified by direct sequencing, not the invader method. One pt had a newly detected T315I mutation using both methods; this pt progressed at 5.4 mo and died at 9.4 mo, never achieving MMR. This was the only pt who progressed or died. Thus, the 12-mo progression-free survival and overall survival (95% CI) were 97.8% (85.3%>99.7%) and 97.7% (84.9%>99.7%), respectively. Safety data were consistent with other studies of pts who switched to NIL after prior IM. The most common any-grade drug-related adverse events were hyperbilirubinemia (53.3%), increased ALT level (28.9%), headache (28.9%), hypophosphatemia (26.7%), rash (26.7%), and increased lipase level (24.4%).

Table 1.

Pt No.	BL Mutation Analysis: Direct Sequencing	BL Mutation Analysis: Invader Method*	Post-BL Mutation Analysis: Direct Sequencing	Post-BL Mutation Analysis: Invader Method*	MMR Achieved
1	E459K + exon 8/9 35 bp ins	E459K	E459K	E459K	Yes
2	Exon 7 del	–	–	–	Yes
3	–	Q252H	–	–	Yes
4	E255K	E255K	E255K + exon 8/9 35 bp insertion†	E255K	Yes
5	M244V	M244V	E459K†	–	Yes
6	–	–	Y393C†	–	Yes
7	–	–	T319A†	–	Yes
8	–	–	Exon 8/9 35 bp ins†	–	Yes
9	–	–	Exon 8/9 35 bp ins†	–	Yes
10	–	–	Exon 8/9 35 bp ins†	–	Yes
11	–	–	Exon 8/9 35 bp ins†	–	Yes
12	–	–	Exon 8/9 35 bp ins†	–	Yes
13	–	–	Exon 8/9 35 bp ins†	–	No
14	–	–	Exon 8/9 35 bp ins†	–	No
15‡	–	–	T315I†	T315I†	No

Gray highlight indicates pts with BL mutations using either method. Bold text indicates mutations able to be detected by the invader method.
* The invader method was used to detect the following IM-resistant point mutations: M244V, L248V/R, G250E, Q252H/R, Y253F/H, E255K/V, E274K, F311L, T315A/I, F317L, M351T, F359V, V379I, L387M, H396P/R, S417Y, E459K, and F486S.
† Newly detected mutation during study.
‡ This pt progressed to blast crisis at 5.4 mo and died at 9.4 mo.

Summary and Conclusion: After switch to NIL for 12 mo, 51% of pts with SoR to frontline IM achieved MMR. Additional follow-up is required to evaluate long-term outcomes. These results support data from other international studies (eg, ENESTcmr) showing that switch to NIL improves responses in pts with detectable disease on IM. Direct sequencing and the invader method complemented each other in detection of certain point mutations, but direct sequencing detected additional mutations and alternative splicing abnormalities in pts with SoR to frontline IM. Most pts in this study with point mutations detected at any time (with any method) achieved MMR with NIL.

P883

TYROSINE KINASE INHIBITOR (TKI) SWITCHING: EXPERIENCE FROM SIMPLICITY, A PROSPECTIVE OBSERVATIONAL STUDY OF CHRONIC-PHASE CHRONIC MYELOID LEUKEMIA (CP-CML) PATIENTS IN CLINICAL PRACTICE

R Hehlmann[1,*], J Cortes[2], C Gambacorti-Passerini[3], S L Goldberg[4], HJ Khoury[5], M Mauro[6], M Michallet[7], H Mohamed[8], T Powell[9], R Paquette[10], B Simonsson[11], M Subar[8], T Zyczynski[8]
[1]Universität Heidelberg, Mannheim, Germany, [2]The University of Texas, MD Anderson Cancer Centre, Houston, United States, [3]University of Milano Biocca, San Gerardo Hospital, Monza, Italy, [4]John Theurer Cancer Center, Hackensack University Medical Center, Hackensack, United States, [5]Emory University, Atlanta, United States, [6]Memorial Sloan-Kettering Cancer Center, New York, United States, [7]Centre Hospitalier Lyon-Sud, Lyon, France, [8]Bristol-Myers Squibb Co, Princeton, United States, [9]ICON Clinical Research, Biostatistics & Programming, San Diego, United States, [10]UCLA Medical Center, Los Angeles, United States, [11]Uppsala Universitet, Upsala, Sweden

Background: Few data from clinical practice describe treatment switching patterns in patients (pts) with CP-CML treated with TKIs.
Aims: To investigate patterns of, and reasons for, TKI switching in pts with CP-CML who discontinued first-line treatment.
Methods: SIMPLICITY is an ongoing observational cohort study of adult pts with newly diagnosed CP-CML receiving first-line treatment with imatinib (IM), dasatinib (DAS) or nilotinib (NIL) in Europe (Eu) and the United States (US) and outside of clinical trials (NCT01244750). The primary study objective is to understand TKI management patterns in clinical practice. The study includes three prospective cohorts of pts treated with IM, DAS or NIL as initial therapy since 2010 (the study opened after first-line approval of all three TKIs) and a historical cohort treated with IM since 2008. Data on treatment discontinuation and treatment switching in all pts with ≥12 months of follow-up are presented for prospective cohorts.

Results: 949 pts (Eu: 34%, US: 66%) were enrolled through 3 October 2013, initially treated with IM (N=415), DAS (N=275) or NIL (N=259). Median follow-up was 1.6 years. Demographics were consistent across all cohorts (median age: 56 years of age at first-line TKI, 56% male). Across all regions, 733 of 949 pts were followed for ≥12 months after initiation of first-line TKI (IM: n=375, DAS: n=178 or NIL: n=180). Of these, 30.1%, 17.4% and 22.8% of patients discontinued IM, DAS and NIL, respectively, within a year of initiation. The main reason for TKI discontinuation was physician-reported intolerance (IM: 62.8%, DAS: 80.6%, NIL: 87.8%). Physician-reported primary resistance, leading to discontinuation, was only noted in IM-treated pts (8.8%). Median time to first discontinuation varied by TKI (IM: 127 days, DAS: 129 days, NIL: 56 days). A proportion of pts who discontinued first-line TKI within 12 months switched to a second-line TKI (IM: 70.8%, DAS: 54.8%, NIL: 58.5%), while no further TKI treatment information was available for the remaining pts at the time of data lock (IM: 29.2%, DAS: 45.2%, NIL: 41.5%). Of pts who switched to a second-line TKI within 12 months, 55.0% and 45.0% of IM-treated pts switched to DAS and NIL, respectively; most DAS-treated pts switched to IM (70.6% *vs.* 29.4% to NIL) and 54.2% and 45.8% of NIL-treated pts switched to DAS and IM, respectively. In Eu, the proportion of pts discontinuing was highest in the IM cohort (IM: 27.7%, DAS: 6.1%, NIL: 11.4%); in the US, the proportion of pts discontinuing was more evenly distributed (IM: 31.6%, DAS: 20.0%, NIL: 26.5%). Few pts, all in the US, discontinued therapy due to financial reasons (IM: 6.8%, DAS: 3.4%, NIL: 2.8%). Median time to first discontinuation was consistently higher in the US, with the exception of median time to discontinuation of IM, which was longer in Eu (130.0 *vs.* 122.5 days in the USA). Among pts in Eu who received a second-generation TKI as second-line therapy, NIL predominated (16/26 NIL *vs.* 10/26 DAS), whereas, in the US, DAS predominated (47/78 DAS *vs.* 25/71 NIL).

Summary and Conclusion: The proportion of pts discontinuing first-line treatment for CP-CML, and reasons for discontinuation, vary by TKI. While intolerance was the primary reason for treatment discontinuation in all TKI cohorts during the first 12 months, primary resistance was reported in IM-treated pts only. Additional analyses will be presented that identify further differences between TKI cohorts, as well as types of intolerances leading to first-line treatment discontinuation.

P884

SAFETY AND TOLERABILITY OF DASATINIB IN PATIENTS WITH CHRONIC MYELOID LEUKEMIA (CML) AND PHILADELPHIA CHROMOSOME–POSITIVE ACUTE LYMPHOBLASTIC LEUKEMIA (PH+ ALL): POOLED ANALYSIS OF OVER 2400 PATIENTS

G Saglio[1,*], P le Coutre[2], J Cortes [3], J Mayer [4], P Rowlings [5], M Subar [6], J Preston[7], N Shah[8]

[1]University of Torino, Ospedale San Luigi Gonzaga, Orbassano-Torino, Italy, [2]Charité, Campus Virchow Klinikum, Universitätsmedizin Berlin, Berlin, Germany, [3]The University of Texas MD Anderson Cancer Center, Houston, Texas, United States, [4]Department of Internal Medicine, Hematology and Oncology, University Hospital Brno, Brno, Czech Republic, [5]Calvary Mater Newcastle Hospital, University of Newcastle, Waratah, New South Wales, Australia, [6]Bristol-Myers Squibb, Lawrenceville, New Jersey, [7]Bristol-Myers Squibb, Hopewell, New Jersey, [8]UCSF School of Medicine, San Francisco, California, United States

Background: CML has become a manageable chronic disease for the majority of patients (pts). However, several rare, severe, and irreversible adverse events (AEs) have been reported in tyrosine kinase inhibitor (TKI)-treated populations. To better understand the incidence of such events previously reported in the context of individual trials, a large pooled dataset from Ph+ leukemic pts treated with dasatinib was interrogated for the incidence of reversible or irreversible nonhematologic AEs.

Aims: The objective of this analysis is to report clinical safety data from a large adult population of dasatinib-treated pts (n=2440) derived from 9 single-arm or comparative clinical trials of CML or Ph+ ALL resistant or intolerant to imatinib (IM; n=2182) or newly diagnosed CML in chronic phase (CML-CP; n=258).

Methods: All pts who received ≥1 dose of dasatinib 100 mg once daily, 140 mg once daily, 50 mg twice daily, or 70 mg twice daily are included. Duration of treatment was defined as the interval from the first to the last dose of study drug and may include intermittent dose interruptions. AEs were graded using NCI CTCAE Version 3.0, and investigator AE terms were coded and grouped by System Organ Class using MedDRA Version 12.1. AEs that were determined by the investigator to have a certain, probable, or possible relationship to the study drug were defined as drug-related. Very common AEs (frequency ≥10%) and AEs of interest (eg, AEs with known association with dasatinib or other TKIs, clinical significance warranting evaluation, or nonclinical data suggesting an association) were analyzed.

Results: The median duration of therapy was 37 months (range<1 to 50 months) in pts with newly diagnosed CML-CP (n=258) and 15 months (range 0 to 65.6 months) in pts with IM-resistant or -intolerant CML or Ph+ ALL (n=2182). In this pooled analysis, minimum follow-up was 3 years and 5 years in the first-line DASISION (n=258) and second-line CA180-034 (n=662) CML-CP trials, respectively. On-study drug-related AEs with frequency ≥10% (any grade; n=2440) were diarrhea, pleural effusion, headache, dyspnea, rash, fatigue, nausea, peripheral edema, musculoskeletal pain, hemorrhage, pyrexia, vomiting, abdominal pain, infection, and cough. Drug-related AEs, such as pleural effusion, thrombocytopenia, or neutropenia, led to discontinuation in 16% of the 2440 pts. Fluid-related AEs (drug-related, any grade) were reported in 44% of pts and included: pleural effusion (30%), superficial edema (22%), pericardial effusion (5%), generalized edema (4%), congestive heart failure/cardiac dysfunction (3%), pulmonary edema (2%), pulmonary hypertension (1%), and ascites (0.5%). The single pulmonary arterial hypertension AE reported was not considered drug-related. Cardiac AEs, including ischemic AEs, rhythm abnormalities, and congestion were infrequent (Table), as were other AEs that may be related to vascular thrombosis. All-cause cerebrovascular accidents and transient ischemic attacks (TIAs) were reported in 0.6% and 0.4% of pts, respectively, and were rarely drug-related. Peripheral arterial occlusive disease (PAOD) and PAOD-related AEs have been reported (le Coutre *Blood* 2013;122:1489) in 0.3% of pts in a larger, 11-study dataset (n=2705).

Table 1. Drug-related cardiac AEs

	First-line CML-CP n=258			CML or Ph+ ALL post-IM n=2182		
	Any grade	Grade 3-4	Grade 5	Any grade	Grade 3-4	Grade 5
Drug-related cardiac AEs, n (%)	18 (7.0)	3 (1.2)	1 (0.4)	282 (13.4)	89 (4.1)	8 (0.3)
Pericardial effusion	7 (2.7)	2 (0.8)	0	112 (5.1)	33 (1.5)	1 (<0.1)
Congestive heart failure/cardiac dysfunction	4 (1.6)	1 (0.4)	0	67 (3.1)	37 (1.7)	4 (0.2)
Palpitations	4 (1.6)	0	0	45 (2.1)	0	0
Arrhythmia	3 (1.2)	1 (0.4)	0	74 (3.4)	9 (0.4)	1 (<0.1)
Myocardial infarction	1 (0.4)	0	1 (0.4)	4 (0.2)	4 (0.2)	0
Cardiomegaly	1 (0.4)	0	0	11 (0.5)	0	0
Angina pectoris	0	0	0	13 (0.6)	8 (0.3)	0
Pericarditis	0	0	0	12 (0.5)	2 (<0.1)	0
Ventricular arrhythmia	0	0	0	5 (0.2)	0	0
Acute coronary syndrome	0	0	0	2 (<0.1)	2 (<0.1)	0
Cor pulmonale	0	0	0	2 (<0.1)	2 (<0.1)	0
Myocarditis	0	0	0	2 (<0.1)	2 (<0.1)	0
Drug-related QT prolongation, n (%)	1 (0.4)	1 (0.4)	0	15 (0.7)	8 (0.4)	0

Summary and Conclusion: Analysis of a large pooled dataset from dasatinib clinical trials did not identify new safety signals. Although pleural effusions are considered common (frequency >10%), they are generally reversible. AEs that are potentially irreversible, including vascular occlusive AEs, were rarely reported in dasatinib-treated pts.

P885

DASATINIB PHARMACOKINETICS AND ITS CORRELATION WITH CLINICAL RESPONSE IN CHRONIC MYELOID LEUKEMIA: A SUBANALYSIS OF THE DARIA-01 STUDY

K Miyao[1,*], M Sawa[1], S Mizuta[2], K Matsumoto[3], H Tsurumi[4], T Takahashi[5], T Hara[4], R Sakemura[6], A Kohno[7], H Kojima[8], K Ohbayashi[9], M S Oba[10], S Morita[11], J Sakamoto[12], N Emi[2]

[1]Hematology&Oncology, Anjo Kosei Hospital, Anjo, [2]Hematology&Medical Oncology, Fujita Health University Hospital, Toyoake, [3]Doshisha Women's College of Liberal Arts, Kyoto, [4]1st Department of Internal Medicine, Gifu University Graduate School of Medicine, [5]Hematology, Gifu Municipal Hospital, Gifu, [6]Hematology&Oncology, Nagoya University Graduate School of Medicine, Nagoya, [7]Hematology&Oncology, Konan Kosei Hospital, Konan, [8]Hematology, Daido Hospital, Nagoya, [9]Hematology, Nishio Munisipal Hospital, Nishio, [10]Biostatistics and Epidemiology, Yokohama City University Graduate School of Medicine, Yokohama, [11]Biomedical Statistics and Bioinformatics, Kyoto University Graduate School of Medicine, Kyoto, [12]Tokai Central Hospital, Kakamigahara, Japan

Background: In the International Randomized Study of IFN *versus* STI571 study, imatinib plasma exposure, measured following the first month of treatment with the standard dose, correlated with therapeutic efficiency. However, there have been a few reports regarding the relationship between dasatinib plasma concentration and clinical results.

Aims: To characterize the relationship between dasatinib pharmacokinetic exposure, efficacy, and tolerability with data from the DARIA-01 study.

Methods: We conducted a multicenter, open label, phase 2 study of mid-term continuation and effectiveness of dasatinib therapy in patients with chronic myeloid leukemia in chronic phase (CML-CP). Plasma trough levels were obtained on day 28 (steady state).

Results: Thirty-two CML-CP patients were included in the study. The median

age was 52.5 years (range 20–86). Twenty-four (75.0%) previously untreated CML-CP patients and the remaining eight (25.0%) were switched from other tyrosine-kinase inhibitors (imatinib, five patients; nilotinib, three patients) because of intolerance or resistance to these drugs. Dasatinib treatment was initiated at a dose of 100 mg/day. During the initial 28 days, 28 patients continued with the 100 mg/day treatment and four received doses of 50 mg/day. Age significantly correlated with C_{min} on day 28 (p=0.0138), and was more significant after an adjustment in the dasatinib dose according to the weight of the patients on day 28 (C/D ratio; p=0.0088; Fig.1). The C/D ratio on day 28 (>1.6) significantly correlated with a higher incidence of pleural effusion during the first month (p=0.049) and/or dose reduction or interruption during the initial 3 months (p=0.009). On the other hand, the higher C/D ratio on day28 was not statistically-significant increase of major molecular response achievement at 3 months.

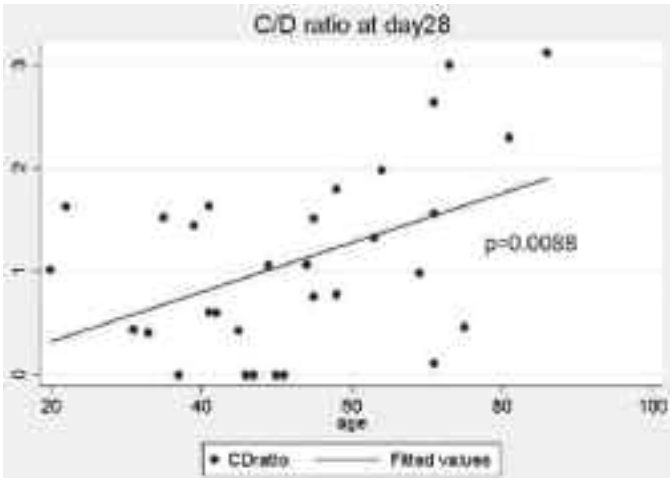

Figure 1.

Summary and Conclusion: Our finding reveals that the C/D ratio on day 28 appeared to have a predictive value for pleural effusion and dose reduction or interruption during the initial 3 months. Thus, pharmacokinetic monitoring could be beneficial in determining optimal therapy conditions for CML treatment, particularly in elderly patients.

P886

LONG-TERM FOLLOW-UP OF PATIENTS WITH CHRONIC MYELOGENOUS LEUKEMIA IN COMPLETE MOLECULAR RESPONSE WITH ALPHA-INTERFERON AFTER TREATMENT DISCONTINUATION

R Latagliata[1,*], A Romano[1], M Mancini[1], M Breccia[1], I Carmosino[1], F Vozella[1], C Montagna[1], P Volpicelli[1], L Petrucci[1], A Serao[1], M Molica[1], A Salaroli[1], D Diverio[1], A Tafuri[1], G Alimena[1]

[1]Cellular Biotechnologies and Hematology, University Sapienza, Rome, Italy

Background: Treatment with alpha-interferon (IFN) has been widely employed before the advent of Tyrosine-kinase inhibitors in patients (pts) with Chronic Myelogenous Leukemia (CML), leading to the achievement in few cases of a prolonged Complete Molecular Response (CMolR) and to IFN discontinuation.
Aims: To evaluate the long-term follow-up after IFN discontinuation, 23 pts (M/F 11/12) who achieved CMolR at RT- nested PCR with IFN at our Institution have been revised.
Methods: Median age at diagnosis was 43,3 years [Interquartile Range (IR) 35.8 – 51.3], Sokal score was low in 18 pts, Intermediate in 3 and not evaluable in 2, median WBC at diagnosis was 39.9 x 10^9/l (IR 24.4 – 67.6). IFN was given alone in 16 pts or in association with autologous bone marrow transplantation (ABMT) in 7 pts (ABMT at onset followed by IFN in 4 pts, IFN followed by ABMT in 3 pts). Median time to Complete Cytogenetic Response was 21.4 months (IR 14.4 – 37.4), median time to CMolR was 63.7 months (IR 30.3 – 106.0).
Results: After a median period of IFN treatment of 105.8 months (IR 56.1 – 127.3), all pts discontinued IFN due to medical decision for prolonged CMolR (12 pts), intolerance (8 pts) or planned ABMT (3 pts). After 12.5 months from IFN discontinuation, 1 patient developed a sudden extramedullar lymphoid blast crisis and died from disease progression. Four pts needed to start a new treatment with imatinib [2 for cytogenetic relapse after 24,8 and 44,0 months, 1 for molecular relapse after 39,8 months and 1 for progressive rise in molecular transcript but still in Major Molecular Response (MMolR) after 39,7 months], all achieving a new molecular response which was complete in 3 out 4. The remaining 18 pts are still off-therapy after a median time from IFN discontinuation of 125.5 months (IR 86.9 – 205.3); among them, 5 pts resulted always negative at the molecular follow-up, 6 pts presented a sporadic positivity but always resulted in MMolR with bcr-abl ratio<0.1 and 7 showed a mild rise of transcript levels with a long-lasting stable positivity (bcr-abl ratio<0,5 without further increments). At the last molecular evaluation, 11/18 pts were in CMolR, 4/18 in MMolR and 3 had bcr-abl ratio between 0.5 and 0.1. The 5-year and 10-year cumulative overall survival was 95.5%. The cumulative 5-year event-free survival was 77.4%, with a stable plateau in the subsequent follow-up (last event recorded 39.8 months after IFN discontinuation).
Summary and Conclusion: Our data show that CML pts who achieved a prolonged CMolR with IFN and discontinued the treatment had a very low risk of disease recurrence; it is worth of note that in many cases the reappearance of a bcr-abl positivity<0.5 did not precede a disease relapse but was sporadic or stable over long time, suggesting a possible role for immunological mechanisms induced by IFN.

P887

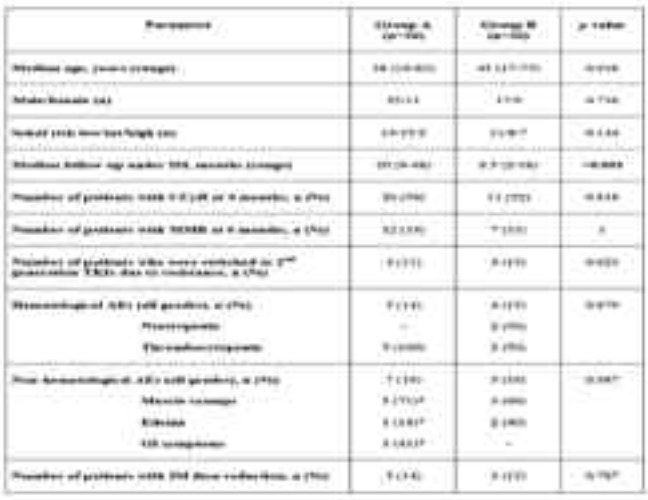
FIRST LINE TREATMENT OF CHRONIC PHASE CHRONIC MYELOID LEUKEMIA PATIENTS WITH THE GENERIC FORMULATIONS OF IMATINIB MESYLATE

AE Eskazan[1], Z Baslar[1,*], M Ayer[2], B Kantarcioglu[3], D Arica[3], N Demirel[3], D Aydin[3], FF Yalniz[1], T Elverdi[1], A Salihoglu[1], MC Ar[1], S Ongoren Aydin[1], Y Aydin[1], N Tuzuner[4], U Ozbek[5], T Soysal[1]

[1]Department of Internal Medicine, Division of Hematology, Istanbul University Cerrahpasa Faculty of Medicine, [2]Department of Hematology, Haseki Training and Research Hospital, [3]Department of Hematology, Okmeydani Training and Research Hospital, [4]Department of Pathology, Istanbul University Cerrahpasa Faculty of Medicine, [5]Department of Genetics, Istanbul University Institute of Experimental Medicine (DETAE), Istanbul, Turkey

Background: The high cost of tyrosine kinase inhibitors (TKIs) developed for chronic myeloid leukemia (CML) is a major concern for the health care payers, especially in countries with restricted resources. Reimbursement policies encourage generic drug use to lower the prices. It is true that generics lead to considerable cost savings but they also give rise to questions associated with their efficacy, safety and quality. In Turkey, there are three commercially available generics of imatinib mesylate (IM) in the market, which are approved for the treatment of CML. There is a price difference between the original IM (Glivec) and generics, and due to the reimbursement policy in Turkey, patients who prefer to receive the original molecule, should pay the price difference.
Aims: The aim of this multicenter study was to evaluate the efficacy and tolerability of generics of IM, and to compare these with Glivec when used among patients with chronic phase (CP) CML in the upfront setting.
Methods: There were two study groups, thirty-six patients who started TKI treatment between January 2010 and June 2013 with Glivec (Group A), and 26 patients who were diagnosed between August 2012 (when generics became available in Turkey) and December 2013, in which a generic of IM was initiated upfront (Group B). Patients' demographics, imatinib dose, Sokal risk scores, adverse events (AEs), and follow-up periods were noted from the patients' files retrospectively. Imatinib response was evaluated according to the criteria recommended by the European LeukemiaNet. Molecular response (MR) was classified based on *BCR-ABL1* to control gene transcript ratios, expressed on the International Scale. Major molecular response (MMR) was defined as ratios ≤0.1%, and the MMR and complete cytogenetic response (CCyR) rates of both arms were calculated.
Results: The two groups were balanced regarding age, gender, and Sokal risk scores (Table 1). Patients in group A had a longer median follow-up under IM than patients in group B (20 months *vs*. 8.5 months). There were five patients in group B with a follow-up duration less than 6 months. They all have complete hematological response (CHR), but while calculating the CCyR and MMR rates, these patients were excluded. The CCyR rates at 6 months for groups A and B were 56% and 52%, respectively. There was no significant difference between the groups regarding MMR rates at 6 months of IM treatment (33% *vs*. 33%). During the follow-up, four patients in group A, and 4 in group B were switched to 2nd generation TKIs due to resistance (p=0.623). The rates of hematological and non-hematological AEs were similar in both groups (Table 1), and the percent of patients who needed a lower dose of IM (300 mg daily) due to AEs were 14% and 12% for groups A and B, respectively. There was no switch to 2nd generation TKIs in the both study groups due to intolerance. After a median follow-up of 29 months under the original molecule, eight patients were switched to a generic due to the reimbursement policy. They were all in MMR at the time of the switch, and they maintained their responses during the follow-up.
Summary and Conclusion: TKIs are now the mainstay of treatment of CML, and patients with CML live close to normal life spans. The current prices of TKIs are high, and the launch of generics might reduce health care costs. Among our patient cohort, the generics were at least non-inferior to the original molecule regarding efficacy and tolerability when used in the upfront setting. Prospective randomized trials with larger number of patients are needed to address the efficacy of generics of IM in patients with CML.

Table 1. The characteristic of patients in both groups (AE, adverse event; CCyR, complete cytogenetic response; GI, gastrointestinal; IM, imatinib mesylate; MMR, major molecular responser) *There were 3 patients with more than one AE (one with both GI symptoms and muscle cramps, and the other had edema and muscle cramps), so the rates of non-hematological AEs in this patient group were added up to >100%.



P888

LONG-TERM RESULTS OF A PROSPECTIVE RANDOMIZED TRIAL OF HIGH-DOSE IMATINIB WITH OR WITHOUT INTERFERON-A IN PATIENTS WITH NEWLY DIAGNOSED CHRONIC MYELOID LEUKEMIA IN CHRONIC PHASE

K Sasaki[1,*], H Kantarjian[1], E Jabbour[1], F Ravandi[1], G Borthakur[1], W Wierda[1], G Garcia-Manero[1], Z Estrov[1], S Pierce[1], S O'Brien[1], J Cortes[1]
[1]Department of Leukemia, MD Anderson Cancer Center, Houston, United States

Background: Before tyrosine kinase inhibitors (TKIs) became the standard frontline therapy, interferon-α (IFN-α) achieved durable cytogenetic responses in occasional patients with chronic myeloid leukemia in chronic phase (CML-CP). Trials of the combination of imatinib and IFN- α have yielded conflicting results.
Aims: We report the long-term outcome of a randomized trial of imatinib ± IFN-α, with a minimum follow-up of 104 months (last patient, first visit 06/2005).
Methods: We conducted a prospective, randomized clinical trial on newly diagnosed CML-CP randomized to receive 800 mg of imatinib daily with (IM800+IFN; n=43) or without (IM800; n=48) weekly subcutaneous injections of 0.5 μg/kg polyethylene glycol (PEG)–IFN-α-2b. Administration of IFN-α-2b started 6 months after the start of imatinib for patient randomized to that arm. Patients aged ≥18 years with CML-CP were eligible if performance status ≤2 by the Eastern Cooperative Oncology Group, serum creatinine and total bilirubin<1.5 x the upper limit of normal. The Kaplan-Meier method was used to calculate overall survival (OS; dated from the start of imatinib until death from any cause), event-free survival (EFS; from the start of imatinib to loss of complete hematologic response, loss of major cytogenetic response, transformation to accelerated [AP] or blast phase [BP], or death from any cause), transformation-free survival (TFS; from the start of imatinib to transformation to AP or BP or death), and failure-free survival (FFS; from the start of imatinib to any event defined above, imatinib discontinuation for any reason, or death.) The chi-square test was used to compare response rates between groups and a log-rank test was used for univariate comparisons.
Results: The median follow-up duration was 107 months (range, 6-121 months). Cumulative response rates and rates of OS, EFS, TFS, and FFS are given in Table 1. The median duration of PEG–IFN-α-2b therapy was 335 days (range, 7-1191 days), and all patients discontinued PEG–IFN-α-2b. The complete cytogenetic response rate (CCyR), major molecular response (MMR), major response ≥4.5-log reduction (MR4.5), and complete molecular response rate(CMR) at 6 months after high-dose imatinib treatment before PEG–IFN-α-2b therapy in IM800 + IFN group were 74%, 60%, 21% and 2% compared to comparable rates of 83%, 67%, 21% and 6% in IM800 group, respectively(*P*=0.877). The CCyR, MMR, MR4.5 and CMR at 12 months from start of all therapy in IM800 + IFN group were 77%, 65%, 26% and 7% compared to comparable rates of 83%, 73%, 21% and 10% in IM800 group, respectively (*P*=0.888). The groups' best response rates and rates of 10-year FFS, TFS, EFS, and OS did not differ significantly.

Table 1. Patient Characteristics and Outcomes

	IM800 + IFN [n=43]	IM800 [n=48]	P value
Cumulative Response, %			
CMR	58	60	0.825
MR4.5	67	75	0.426
MMR	81	88	0.420
CCyR	86	88	0.838
10-y Outcome, %			
FFS	60	67	0.436
TFS	97	95	0.639
EFS	61	88	0.094
OS	88	91	0.873

Summary and Conclusion: The addition of PEG–IFN-α-2b to high-dose imatinib as a frontline therapy does not confer a clinical benefit in patients with CML-CP.

P889

FOUR-YEAR FOLLOW-UP OF PATIENTS WITH IMATINIB-RESISTANT OR -INTOLERANT CHRONIC-PHASE CHRONIC MYELOID LEUKEMIA RECEIVING DASATINIB: EFFICACY AND SAFETY

X Huang[1], J Hu[2], J Li[3], J Jin[4], F Meng[5], Z Shen[6], T Liu[7], D Wu[8], J Wang[9], J Wang[10,*]
[1]Peking University People's Hospital, Beijing, [2]Fujian Medical University Union Hospital, Fuzhou, [3]The First Affiliated Hospital with Nanjing Medical University, Nanjing, [4]The First Affiliated Hospital of The College of Medicine, Zhejiang University, Hangzhou, [5]Guangzhou Nanfang Hospital, Guangzhou, [6]Shanghai Ruijin Hospital, Shanghai, [7]West China Hospital, Sichuan University, Chengdu, [8]The First Affiliated Hospital of Soochow University, Suzhou, [9]Changhai Hospital of Shanghai, Shanghai, [10]The Institute of Hematology & Blood Diseases Hospital, Chinese Academy of Medical Science & Peking Union Medical College, Tianjin, China

Background: The Chinese dasatinib registration study, initiated in 2007, enrolled 119 chronic myeloid leukemia (CML) patients (pts) intolerant of, or resistant to, imatinib, including 59 pts with chronic-phase (CP) CML. After 18 months of follow-up, 50.8% and 91.5% of pts with CML-CP achieved a major cytogenetic response (MCyR) or complete hematologic response (CHR), respectively. Furthermore, none of the CML-CP pts who achieved a MCyR died or experienced disease progression at 18 months. The safety findings supported prior Phase 1/2 trials, with common adverse events (AEs) including neutropenia and thrombocytopenia. Here we present the efficacy and safety results from the 4-year follow-up of this pivotal Chinese study.
Aims: To evaluate the long-term efficacy and safety of dasatinib for the treatment of Chinese pts with CML-CP who were resistant or intolerant to imatinib, and to investigate the association between pre/on-treatment factors and treatment efficacy after 4 years of follow-up.
Methods: This was a single-arm, Phase 2 study conducted at 10 centers in China. Adult, Chinese pts with imatinib-resistant or -intolerant CML-CP received oral dasatinib 100 mg/d until disease progression, unacceptable toxicity, or at the investigator/patient's discretion. The primary endpoint was the rate of MCyR and secondary endpoints included time to MCyR, rate of progression-free survival (PFS), and incidence of AEs. Pts who discontinued treatment were not routinely followed up, therefore disease progression and survival data are not available for these pts post study departure. The association between pre- and on-treatment factors and complete cytogenetic response (CCyR) was investigated by univariate regression. Written, informed consent was obtained from all pts and the study was registered at clinicaltrials.gov (NCT00529763).
Results: After 4 years of follow-up, 72.9% (43/59) of pts remained on treatment. The cumulative rate of the primary endpoint, MCyR, was 66.1% (39/59; 95% CI, 52.6–77.9); an increase of 30% from that observed at 18 months (50.8% [30/59]). Median time to MCyR was 12.7 weeks (range, 4.3–206.1). Interestingly, all pts who achieved MCyR also met the criteria for CCyR.
The 4-year PFS was 85.7% (95% CI, 77.0–95.4), and rates at 12, 24 and 36 months were 94.7%, 91.2% and 85.7%, respectively; no pts experienced disease progression between 36 and 48 months. After 4 years of follow-up there had been 5 deaths on study, none of which were considered to be treatment-related. None of the 20 pts who achieved an early response (MCyR within 90 days of treatment initiation) had experienced disease progression after 4 years (Figure), and these pts had a greater likelihood of achieving a CCyR than those without an early response (odds ratio 42.1, 95% CI 2.37–746.84; *P*=0.01). Dasatinib was generally well tolerated; 11.9% (7/59) of pts discontinued treatment due to AEs. Drug-related AEs of any grade were experienced by 69.5% (41/59) of pts, and Grade 3–4 by 18.6% (11/59). Reported AEs included pleural effusion (23.7% [14/59]; Grade 3–4: 3.4% [2/59]), thrombocytopenia (11.9% [7/59]; Grade 3–4: 11.9% [7/59]), and neutropenia (6.8% [4/59]; Grade 3–4: 6.8% [4/59]). Pulmonary hypertension was reported in 6.8% (4/59) of pts (Grade 3–4: 1.7% [1/59]).

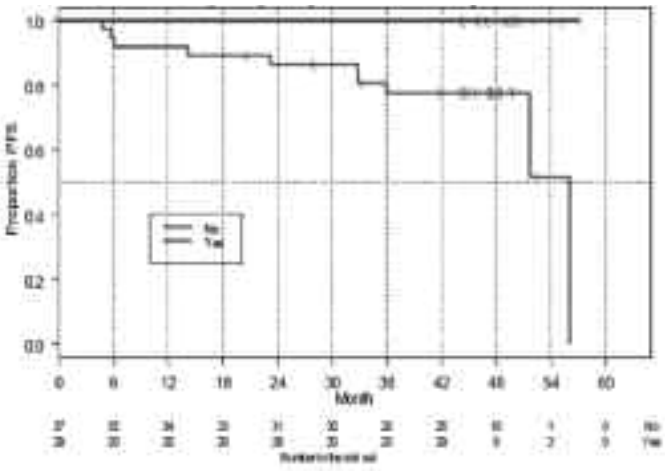


Figure: Kaplan–Meier PFS curve by early response (MCyR within 90 days of treatment initiation; green line) or no early response (red line)

Figure 1. Kaplan-Meier PFS curve by early response (MCyR within 90 days of treatment initiation; green line) or no early response (red line).

Summary and Conclusion: This 4-year follow-up study supports dasatinib treatment in Chinese pts with imatinib-resistant or -intolerant CML-CP: 72.9% of pts remained on treatment, 66.1% achieved a MCyR, and high rates of PFS were sustained from 36 months through 4 years. Dasatinib was well tolerated, with a low rate of discontinuations and a safety profile that supports previous clinical trial data.

P890

ABNORMALITY OF GLUCOSE AND LIPID METABOLISM DURING NILOTINIB THERAPY – RESULTS OF ENIGMA 2 STUDY

L Semerad[1,*], Z Racil[1], P Belohlavkova[2], O Cerna[3], P Cetkovsky[4], E Faber[5], H Klamova[4], L Malaskova[6], R Minarik[1], J Prochazkova[1], T Sacha[7], J Voglova[2], D Zackova[1], P Zak[2], J Mayer[1]

[1]Department of Internal Medicine, Hematology and Oncology, Masaryk University and University Hospital Brno, Brno, [2]4th Department of Internal Medicine-Hematology, Charles University and University Hospital Hradec Kralove, Hradec Kralove, [3]Department of Clinical Hematology, Charles University and University Hospital Kralovské Vinohrady, [4]Institute of Hematology and Blood Transfusion, Praha, [5]Department of Hemato-Oncology, Palacký University and University Hospital Olomouc, Olomouc, [6]Department of Clinical Biochemistry, University Hospital Brno, Brno, Czech Republic, [7]Department of Hematology, University Hospital Kraków, Kraków, Poland

Background: Recently we have published results of pilot study on CML patients demonstrating fast development of hyperinsulinaemia, peripheral insulin resistance, hypoadiponectinaemia and hypercholesterolemia during nilotinib therapy.
Aims: To analyze preliminary results from follow up study ENIGMA 2 to confirm or exclude result from the pilot study, as well as to analyze whether these abnormalities are detected in control group of patients treated with imatinib.
Methods: Patients received intensive laboratory workup before the start of TKI and after 3 month of therapy. This included fasting insulin, glucose, adiponectin and lipid serum concentration, HbA1c and oral glucose tolerance test.
Results: Between 2/2011-11/2013 twenty two CML patients initiated therapy with nilotinib and 4 with imatinib. Patients treated with nilotinib developed significant hypersinulinaemia and hyperglycaemia. We also proved significant development of insulin resistance using HOMA-2 index, that significantly increased after 3 month of nilotinib therapy (medians - 1,8 *vs*. 2,5; p=0,0098). More over, we have proved significant decrease of adiponectin concentration as well as significant increase in total cholesterol concentration. Details are presented in Table. Contrary – none of these abnormalities was detected in the control group of patients treated with imatinib, including any change in insulin resistance measured by HOMA-2 index (medians - 0,5 *vs*. 0,8; p=0,3750).

Table 1.

NILOTINIB THERAPY (n=22)			
	Start median (range)	Month 3 median (range)	p
Fasting glucose [mmol/l]	5.25 (4.8-6.1)	5.7 (4.8-6.1)	0.0003
Fasting insulin [mIU/l]	23.55 (2.4-89.0)	29.05 (3.50-84.90)	0.2482
Fasting C-peptide [pmol/ml]	0.85 (0.50-2.40)	0.85 (0.60-1.30)	0.0064
Fasting HbA1c [mmol/mol]	38 (34-50)	37 (30-51)	0.0221
Fasting adiponectin [mg/l]	3.86 (0.66-43.14)	6.34 (1.01-22.35)	0.0094
Total cholesterol [mmol/l]	5.00 (2.60-6.60)	5.65 (4.50-7.70)	0.0004
Triglycerides [mmol/l]	1.68 (0.58-5.27)	2.46 (0.62-4.38)	0.1840
HDL cholesterol [mmol/l]	1.10 (0.50-2.30)	1.50 (0.80-2.30)	0.0002
LDL cholesterol [mmol/l]	2.65 (1.20-4.40)	3.20 (1.10-5.70)	0.0007
Non-HDL cholesterol [mmol/l]	3.50 (1.50-5.30)	4.05 (2.50-6.20)	0.0025
IMATINIB THERAPY (n=4)			
	Start median (range)	Month 3 median (range)	p
Fasting glucose [mmol/l]	5.0 (4.70-5.10)	5.35 (4.90-5.70)	0.1250
Fasting insulin [mIU/l]	4.05 (2.60-5.90)	8.10 (2.50-37.90)	0.2500
Fasting C-peptide [pmol/ml]	0.60 (0.50-0.70)	0.50 (0.40-0.60)	0.2500
Fasting HbA1c [mmol/mol]	38.5 (35.0-42.0)	35.5 (33.0-37.0)	0.0938
Fasting adiponectin [mg/l]	6.27 (2.21-13.30)	13.35 (5.00-35.30)	0.1250
Total cholesterol [mmol/l]	5.50 (5.30-6.10)	4.80 (4.20-5.60)	0.1250
Triglycerides [mmol/l]	2.135 (0.940-2.680)	0.900 (0.560-1.230)	0.1250
HDL cholesterol [mmol/l]	1.30 (1.00-1.50)	1.70 (1.30-1.90)	0.0938
LDL cholesterol [mmol/l]	3.70 (3.40-4.30)	2.55 (2.10-2.80)	0.1250
Non-HDL cholesterol [mmol/l]	4.30 (4.00-4.70)	3.25 (2.70-4.00)	0.0938

Summary and Conclusion: Our preliminary results from presented study proved fast development of peripheral insulin resistance already during the first 3 month of nilotinib therapy as underlying cause of glucose and secondary also lipid metabolism impairment during nilotinib treatment. Moreover, this was not proved for patients treated with imatinib. Final data from target of 40 patients on nilotinib and 10 patients on imatinib will be presented during the meeting.

P891

HIGHER RATE OF MAJOR MOLECULAR RESPONSE (MMR) WITH NILOTINIB *vs* IMATINIB IN CHINESE PATIENTS (PTS) WITH NEWLY DIAGNOSED CHRONIC MYELOID LEUKEMIA IN CHRONIC PHASE (CML-CP): ENESTCHINA 24-MO UPDATE

ZX Shen[1,*], X Huang[2], M Baccarani[3], CE Ortmann[4], S Hertle[4], Y Yuan[5], P Bourquelot[4], G Saglio[6], J Wang[7]

[1]Shanghai Ruijin Hospital, Shanghai, [2]Peking University People's Hospital, Beijing, China, [3]University of Bologna, Bologna, Iraq, [4]Novartis Pharma AG, Basel, Switzerland, [5]Beijing Novartis Pharma Co., Ltd., Beijing, China, [6]University of Turin, Orbassano, Italy, [7]Institute of Hematology, Tianjin, China

Background: In the global ENESTnd study, nilotinib resulted in superior efficacy *vs* imatinib in pts with newly diagnosed CML-CP. ENESTchina is a local, randomized, multicenter phase 3 study of nilotinib *vs* imatinib in Chinese pts with newly diagnosed CML-CP. ENESTchina met its primary endpoint with a significantly higher rate of MMR at 12 mo in the nilotinib arm (52.2%) *vs* the imatinib arm (27.8%; *P*<0.0001).
Aims: This analysis aims to evaluate the safety and efficacy of nilotinib *vs* imatinib in ENESTchina after all pts completed the mo 24 visit or discontinued early.
Methods: Adult Chinese pts (N=267) with newly diagnosed (≤ 6 mo) CML-CP were randomized to nilotinib 300 mg twice daily (n=134) or imatinib 400 mg once daily (n=133; dose escalation to 600 mg/day was allowed). Randomization was stratified by Sokal risk score and prior interferon therapy. Response rates were compared between arms using a stratified Cochran-Mantel-Haenszel test. Freedom from progression to accelerated phase/blast crisis (AP/BC) and overall survival (OS) were estimated by Kaplan-Meier analysis and compared between arms using a stratified log-rank test. *P* values for secondary endpoints were not adjusted for multiple comparisons and are provided for descriptive purposes only.
Results: In the nilotinib and imatinib arms, respectively, the median age was 41 y and 39 y, and 67.9% and 60.9% of pts were male. Median dose intensities were nilotinib 579.4 mg/day (range, 167-600) and imatinib 399.4 mg/day (range, 247-574). By the data cutoff, 18 pts (13.4%) in the nilotinib arm and 15 pts (11.3%) in the imatinib arm discontinued treatment, most commonly due to suboptimal response/treatment failure (nilotinib, n=6; imatinib, n=4) or disease progression (per investigator's judgment; nilotinib, n=4; imatinib, n=6). Compared with imatinib, nilotinib resulted in higher rates of MMR by 24 mo (Table; *P*=0.0096), MMR at 24 mo (*P*=0.0395), and durable MMR at 24 mo (defined in table footnote d; *P*=0.0001). Rates of MMR by 24 mo were higher on nilotinib *vs* imatinib across all Sokal risk groups. Median time to first MMR

among pts who achieved MMR was shorter on nilotinib *vs* imatinib. Rates of complete cytogenetic response (CCyR) were high and comparable in both arms. Four pts in the nilotinib arm and 5 pts in the imatinib arm progressed to AP/BC (calculated) on treatment; estimated 2-y freedom from progression to AP/BC was 96.8% on nilotinib and 96.1% on imatinib (*P*=0.7481). Two pts in each arm died on study (due to cerebral hemorrhage and disease progression [1 each] in the nilotinib arm and non-Hodgkin's lymphoma and disease progression [1 each] in the imatinib arm), all after discontinuing treatment. Estimated 2-y OS was 98.5% in each arm. Both drugs were well tolerated, and no new safety signals were identified. No cases of peripheral artery disease were reported in either arm; 1 pt (nilotinib arm) with a history of cerebral infarction had an ischemic cerebrovascular event, and 1 pt (imatinib arm) had an asymptomatic creatinine kinase-MB elevation with no clinical or electrocardiographic findings. New or worsening biochemical abnormalities were typically grade 1/2, including all cholesterol elevations and all glucose elevations except 2 (both in the nilotinib arm). New or worsening grade 3/4 biochemical abnormalities occurring in ≥ 5% of pts in either arm included elevated lipase (14.3% and 6.8% of pts on nilotinib and imatinib, respectively), elevated magnesium (6.0% and 5.3%, respectively), and decreased phosphate (4.5% and 5.3%, respectively).

Table 1.

	Nilotinib n = 134	Imatinib n = 132
Response rates, n (%)		
MMR by 24 mo	91 (67.9)	70 (53.0)
Low Sokal risk score[a]	52 (75.4)	41 (59.4)
Intermediate Sokal risk score[a]	29 (65.9)	24 (55.8)
High Sokal risk score[a]	10 (47.6)	5 (23.8)
MMR at 24 mo	82 (61.2)	65 (49.2)
Durable MMR at 24 mo[b]	66 (56.7)	57 (37.9)
CCyR by 24 mo	112 (83.6)	103 (78.0)
Median time to MMR,[c] mo (25th-75th percentiles)	6.00 (5.39-8.31)	10.86 (5.45-14.53)
Nonhematologic adverse events of any grade in ≥ 10% of pts in either arm regardless of relationship to study drug, n (%)[d]		
Rash	47 (35.3)	17 (12.9)
Myalgia	16 (12.0)	9 (6.1)
Nasopharyngitis	14 (10.5)	22 (16.7)
Eyelid edema	4 (3.0)	23 (17.4)
Diarrhea	4 (3.0)	15 (11.4)
New or worsening biochemical abnormalities of any grade in ≥ 30% of pts in either arm, n (%)[e]		
Bilirubin (total)	116 (87.2)	25 (18.9)
Alanine aminotransferase	77 (57.9)	47 (35.6)
Phosphate (inorganic phosphorus)	66 (49.6)	95 (72.0)
Cholesterol (total)	66 (49.6)	11 (8.3)
Lipase (blood)	55 (41.4)	59 (44.7)
Glucose – high	47 (35.3)	36 (27.3)
Calcium – low	46 (34.6)	67 (50.8)
Aspartate aminotransferase	43 (32.3)	27 (20.5)
Potassium – low	28 (21.1)	66 (50.0)
New or worsening grade 3/4 hematologic abnormalities in ≥ 5% of pts in either arm, n (%)[f]		
Thrombocytopenia	34 (25.6)	40 (30.3)
Neutropenia	28 (21.1)	29 (22.0)
Leukopenia	13 (9.8)	23 (17.4)
Lymphopenia	6 (4.5)	16 (13.6)
Anemia	5 (3.8)	8 (6.1)

[a] Pts with low Sokal risk scores: nilotinib, n = 69; imatinib, n = 69. [b] Pts with intermediate Sokal risk scores: nilotinib, n = 44; imatinib, n = 43. [c] Pts with high Sokal risk scores: nilotinib, n = 21; imatinib, n = 21. [d] Defined as MMR at both 12 and 24 mo with no confirmed loss of MMR in between. [e] Among pts who achieved MMR. [f] Among pts who received ≥ 1 dose of study drug (nilotinib, n = 133; imatinib, n = 132).

Summary and Conclusion: Through 24 mo of follow-up, MMR rates were consistently higher on nilotinib *vs* imatinib. This study confirms the superiority of nilotinib over imatinib for the treatment of pts with newly diagnosed CML-CP, as initially demonstrated in ENESTnd.

P892

FOUR-YEAR OUTCOME OF 215 NEWLY DIAGNOSED CHRONIC MYELOID LEUKEMIA PATIENTS TREATED WITH NILOTINIB FRONTLINE: A GIMEMA CML WORKING PARTY ANALYSIS

Eugenio Hospital, Roma, [14]Hematology Unit, Santa Maria Nuova Hospital, Reggio Emilia, [15]University of Bologna, Bologna, Italy

Background: Nilotinib (NIL) is a potent and selective BCR-ABL inhibitor approved for the frontline treatment of chronic myeloid leukemia (CML) based on the results of the ENESTnd study. The sustained superiority of NIL *vs*. imatinib (IM) was confirmed after 5 years of follow-up (Saglio et al, abs. 92, ASH 2013). However, few data are available on pts treated frontline with NIL outside of company-initiated trials.

Aims: To analyze the response rates and outcome in a large, independent cohort of newly diagnosed CML pts treated frontline with NIL-based regimens.

Methods: We analyzed 215 early chronic phase pts, enrolled in 2 multicenter phase II studies conducted by the GIMEMA CML WP (ClinicalTrials.gov. NCT00481052 and NCT00769327) or treated at the Bologna University Hospital, with NIL 300 mg or 400 mg BID as initial treatment; 123 pts received a sequential treatment with NIL and IM, with a 3-months rotation period. The median age was 53 years (range 18–86). Ten out of 215 pts (5%) had a high EUTOS score. The median follow-up was 43 months (range 18–69 months). We assessed: the rates of Complete Cytogenetic Response (CCyR) and Major Molecular Response (MMR); the rates of optimal responders at each milestone according to ELN 2013 recommendations; the overall survival (OS; any death included), progression-free survival (PFS; progression to accelerated/blast phase [AP/BP] and deaths for any cause), failure-free survival (FFS; failures according to ELN 2013 recommendations and deaths for any cause), and event-free survival (EFS; events: failures, permanent discontinuation of NIL for any cause, including deaths). All analysis was made according to the intention-to-treat principle.

Results: The cumulative rates of CCyR and MMR were 93% and 88%, respectively. At 3 months, 82% of the pts were in Partial Cytogenetic Response and 90% had a BCR-ABL/ABL (IS)<10%; at 6 months, 86% were in CCyR and 83% had a BCR-ABL/ABL (IS)<1%; at 12 months, 72% were in MMR; all these pts were optimal responders according to ELN 2013 recommendations. Overall, 64 (30%) pts permanently discontinued NIL: 31 (14%) for adverse events or intolerance; 22 (10%) for failures (figure); 11 (5%) for other reasons. In detail, 10 (4.6%) pts discontinued NIL for cardiovascular events, including 3 for peripheral arterial occlusive disease and 2 for acute myocardial infarction. Eight (3.7%) pts progressed to AP/BP, all during the 1st year of therapy, and all pts subsequently died (after a median of 13 months, range 1- 34 months). NIL-resistant mutations were identified in 5 of these pts (4 T315I; 1 Y253H). No difference in the rate of progression to AP/BP was observed between pts receiving NIL alone or NIL and IM in sequential schedule. During the follow-up, 8 patients developed a secondary resistance (3 loss of CHR, 3 loss of CCyR, and 2 confirmed loss of MMR). Overall, 15 (7%) pts died, in 7 cases for reasons unrelated to CML progression. The estimated 4-year OS, PFS, FFS, and EFS were 93%, 93%, 86%, and 69%, respectively.

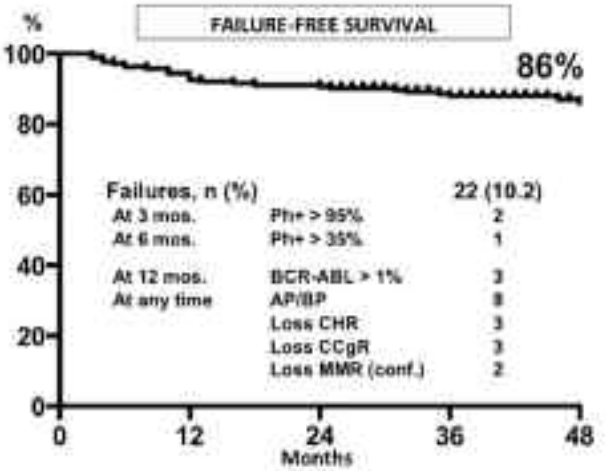

Figure 1.

Summary and Conclusion: Our National experience confirmed that pts treated frontline with NIL-based regimens obtained fast and high rates of complete cytogenetic and major molecular response, and most pts were optimal responders according to ELN recommendations. Of note, all progressions to AP/BP occurred early (in the first year). Overall, 93% of the pts were estimated to be alive and progression-free at 4-years, with 69% of the pts still on NIL.

Background: Ponatinib is a potent oral pan–BCR-ABL inhibitor with activity against native and mutant forms of BCR-ABL, including the resistant T315I mutant.
Aims: The efficacy and safety of ponatinib (45 mg QD) were evaluated in the phase 2 PACE trial.
Methods: 449 pts resistant or intolerant (R/I) to dasatinib or nilotinib or with the T315I mutation were enrolled and gave informed consent. Data are as of 3 Sept 2013; median (range) follow-up was 24 (0.1-35) months. NCT01207440.
Results: Pts were heavily pretreated: 58% received ≥3 prior tyrosine kinase inhibitors. At analysis, 42% remained on study (55% chronic-phase chronic myeloid leukemia [CP-CML]). The most common reasons for discontinuation were progressive disease (21%) and adverse events (AEs) (14%; most common was thrombocytopenia, 4%). The table shows response rates at any time. In CP-CML, 89% of pts maintained major cytogenetic response (MCyR) for at least 2 yrs; progression-free survival (PFS) and overall survival (OS) at 2 yrs were 67% and 86%, respectively. For accelerated-phase (AP) CML, blast-phase (BP) CML, and Ph+ acute lymphoblastic leukemia (ALL), OS at 2 yrs was 72%, 18%, and 21%, respectively. The most common treatment-emergent AEs (≥30%) were thrombocytopenia (43%), rash (40%), abdominal pain (40%), headache (36%), constipation (36%), and dry skin (36%). Pancreatitis and pneumonia were the most common serious AEs (SAEs; both 6%). Vascular occlusive AEs [SAEs] were reported as follows: overall 20% [14%], including cardiovascular 9% [6%], cerebrovascular 6% [4%], peripheral vascular 6% [4%] (collectively, arterial thrombotic events [ATEs]), and venous thromboembolic 5% [3%]. In a multivariate analysis, higher dose intensity, older age, and cardiovascular risk factors were associated with a higher likelihood of an ATE; pts with and without cardiovascular risk factors experienced these events. OS at 2 yrs was not reduced in pts with an ATE (73%) *vs* without an ATE (69%); MCyR in CP-CML pts with *vs* without an ATE was 70% *vs* 51%.
Summary and Conclusion: Ponatinib has substantial clinical activity in heavily pretreated pts with Ph+ leukemias. Vascular occlusive events were observed. Ponatinib is an important treatment option for pts in whom the need and benefit outweigh the risk.

Background: Ponatinib is a potent oral pan–BCR-ABL tyrosine kinase inhibitor with clinical activity in pretreated pts with Ph+ leukemias. Dose modification of ponatinib was used to manage adverse events (AEs).
Aims: This post hoc analysis assessed the clinical impact of dose modification and dose intensity on outcomes of pts in the phase 2 PACE trial.
Methods: All pts provided informed consent. Ponatinib starting dose was 45 mg QD. Dose reduction was defined as any reduction below 45 mg/day; dose interruption was defined as treatment withheld for ≥3 consecutive days. Efficacy analyses were performed on chronic-phase chronic myeloid leukemia (CP-CML) pts (N=267). Analysis of arterial thrombotic events (ATEs) included all pts (CP-CML, blast-phase CML, accelerated-phase CML, Ph+ acute lymphoblastic leukemia; N=449). Data are as of 3 Sept 2013; median (range) follow-up was 24 (0.1-35) months for all pts. NCT01207440.
Results: 78% of CP-CML pts had dose modification within the first 12 months (82% at any time). Responses in pts with and pts without modification were comparable (Table). Of 149 responders, 87 (58%) achieved major cytogenetic response (MCyR) at 45 mg/day, 46 (31%) at 30 mg/day, and 16 (11%) at 15 mg/day. Most pts who had a dose reduction after achieving a response maintained that response: 97% maintained MCyR; 96% maintained complete cytogenetic response (CCyR); and 92% maintained major molecular response (MMR). Among pts with a dose reduction lasting ≥6 months after achieving a response at a higher dose, 100% (33/33) maintained MCyR (96% [26/27] CCyR and 93% [13/14] MMR). While dose intensity was the most significant predictor of MCyR by 12 months (multivariate analysis), substantial responses occurred at lower doses; estimated response rates were ~75% at 45 mg/day, ~60% at 30 mg/day, and ~30% at 15 mg/day. ATEs occurred in 17% of pts; each 15 mg/day reduction in average daily dose is predicted, by multivariate analysis, to lead to ~40% reduction in risk of ATE. 2-yr overall survival was similar for CP-CML pts who had dose modifications (86%) and those who did not (86%), and for pts who had ATEs (85%) and those who did not (87%). Of pts with ATEs, 46% had dose modifications.
Summary and Conclusion: Most of the CP-CML pts in the PACE trial had dose modifications. Pts who underwent dose modification still responded to treatment. Dose modification was an effective management tool for CP-CML patients. Careful consideration of the potential benefits and risks of ponatinib should guide treatment decisions.

Table 1.

LONGER-TERM FOLLOW-UP OF A PHASE 1 STUDY OF PONATINIB IN PATIENTS (PTS) WITH PHILADELPHIA CHROMOSOME-POSITIVE (PH+) LEUKEMIAS

J Cortes[1,*], M Talpaz[2], H M Kantarjian[1], N P Shah[3], D Bixby[2], I W Flinn[4], T O'Hare[5], S Hu[6], V Rivera[6], T Clackson[6], C Turner[6], F Haluska[6], B J Druker[7], M W Deininger[5], M J Mauro[8]
[1]The University of Texas MD Anderson Cancer Center, Houston, [2]Comprehensive Cancer Center, University of Michigan, Ann Arbor, [3]University of California San Francisco, San Francisco, [4]Sarah Cannon Research Institute, Nashville, [5]Huntsman Cancer Institute, University of Utah, Salt Lake City, [6]ARIAD Pharmaceuticals, Inc., Cambridge, [7]Oregon Health & Science University, Knight Cancer Institute, [8]Oregon Health & Science University Knight Cancer Institute, Portland, United States

Background: Ponatinib is a potent oral pan–BCR-ABL tyrosine kinase inhibitor (TKI) that is active against native and mutated forms of BCR-ABL.
Aims: The safety and anti-leukemic activity of ponatinib in pts with chronic myeloid leukemia (CML) or Ph+ acute lymphoblastic leukemia were evaluated in a phase 1 clinical trial.
Methods: Pts (N=81) with resistant/refractory hematologic malignancies were enrolled and gave informed consent in this ongoing, open-label, dose-escalation, phase 1 study. Ponatinib was dosed once daily (2–60 mg). 65 pts had Ph+ leukemia and are included in this analysis (data as of 15 Oct 2013). Median (range) follow-up for 25 pts still on treatment was 45 (38–57) months. NCT00660920.
Results: The median age of pts was 55 yrs; median time since diagnosis was 6.5 yrs. Pts were heavily pretreated (94% had received ≥2 prior TKIs, 62% ≥3). 65% had baseline BCR-ABL mutations (29% with T315I). 38% (58% chronic phase [CP] CML) of pts remained on study at the time of analysis. Adverse events (AEs) and progression were the most common reasons for discontinuation (20% and 17%, respectively). The most common treatment-emergent AEs were rash (52%), fatigue (52%), abdominal pain (51%), headache (48%), and arthralgia (46%). Treatment-emergent vascular occlusive events were observed in 23% (serious events) and 37% (all events) of pts, including cardiovascular (15% serious, 23% all) peripheral vascular (5%, 9%), cerebrovascular (5%, 8%), and venous thrombotic (0%, 5%) events. Significant anti-leukemic activity was observed: among CP-CML pts, major cytogenetic response (MCyR), complete cytogenetic response (CCyR), and major molecular response (MMR) rates were 72%, 65%, and 51%, respectively; 75% of pts with MCyR, 69% with CCyR, and 53% with MMR are estimated (Kaplan-Meier [KM]) to maintain response for at least 3 yrs (4-yr KM estimates: 75% MCyR, 53% MMR). Of 28 CP-CML pts with CCyR, 23 remained on study at analysis (17 with continuous CCyR); of 22 pts with MMR, 20 remained on study at analysis (12 with continuous MMR).
Summary and Conclusion: Substantial and durable responses were observed with ponatinib in heavily pretreated CP-CML pts. Vascular occlusive events were observed. Risk and benefit considerations should be evaluated when utilizing ponatinib in this patient population.

P896

A NATIONAL EXPERIENCE OF THE USE OF PONATINIB IN PATIENTS FAILING MULTIPLE TYROSINE KINASE INHIBITORS CONFIRMS EFFICACY IN A HEAVILY PRE-TREATED COHORT OF PATIENTS WITH PH+ LEUKAEMIAS

D Milojkovic[1,*], A Bakir[2], L Whitehead[2], J Byrne[3], R E Clark[4], M Copland[5], H de Lavallade[6], M Dennis[7], J Ewing[8], L Foroni[1], D Gillett[9], D Marin[2], A Mead[10], P Mehta[11], L Mitchell[12], H Oakervee[13], G Smith[14], P Srinivas[15], J Tighe[16], J Apperley[2]
[1]Haematology, Imperial College Healthcare NHS Trust, [2]Haematology, Imperial College London, London, [3]Haematology, Nottingham University Hospitals Trust, Nottingham, [4]Haematology, Royal Liverpool University Hospital, Liverpool, [5]Haematology, University of Glasgow, Glasgow, [6]Haematology, Kings College Hospital NHS Foundation Trust, London, [7]Haematology, The Christie NHS Foundation Trust, Manchester, [8]Heart of England NHS Trust, Birmingham, [9]Maidstone and Tunbridge Wells NHS Trust, Maidstone, [10]University of Oxford, Oxford, [11]University Hospital Bristol, Bristol, [12]Monklands Hospital NHS Lanarkshire, Lanarkshire, [13]Barts Health NHS Trust, London, [14]Leeds Teaching Hospitals NHS Trust, Leeds, [15]University Hospital of North Staffordshire, Stoke-on-Trent, [16]Aberdeen Royal Infirmary, Aberdeen, United Kingdom

Background: Ponatinib is a highly potent third generation tyrosine kinase inhibitor(TKI) licensed for use in patients with Ph positive leukaemias who have failed two or more prior TKI and/or have a documented T315I kinase domain mutation. Ponatinib first became available in the United Kingdom in 2011 through the phase II PACE study and subsequently through an expanded access scheme.
Aims: To examine efficacy of Ponatinib in Patients failing Multiple Tyrosine Kinase Inhibitors.
Methods: From May 2011 to September 2012, 66 patients received ponatinib for chronic myeloid leukaemia (CML) in chronic phase (CP) (n=57), accelerated phase (n=3), second or subsequent CP (n=3), blast crisis (n=1) or Ph positive ALL (n=2). Of the patients treated in CP, 10/57 had the T315I mutation. Six patients received ponatinib for relapse after allogeneic stem cell transplantation and in 4 of these the T315I mutation had been identified before and/or after transplant. In the 51 patients treated without transplant, a T315I mutation was identified in 6 and all had received two prior TKI. However the majority of these patients (45/51) received ponatinib for poor responses and/or intolerance of other TKI without evidence of kinase domain mutations, 4 after failing a single second generation TKI, 14 after failing two TKI and 27 after 3-4 prior TKI.
Results: Focussing on the 51 patients who received ponatinib in CP and without a previous transplant, the median age was 62 years (range 20-78 yrs). The median duration of ponatinib treatment was 9 months (range 0.25-31 mths). 21/51 (41%) and 20/51 (39%) patients remained on ponatinib at 12 and 24 months respectively. The reasons for discontinuation were resistance only in 8, intolerance only in 5 and resistance and intolerance in 15 patients. Patients were considered evaluable for response if they received at least 3 months of therapy (n=48). Six patients commenced treatment in complete cytogenetic remission (CCyR) (4 of whom were also in major molecular response - MMR) and all 6 maintained these levels of response. Achievement of CCyR was seen in 15 of the remaining 42 patients including 3 of the 6 patients with a T315I mutation at the start of treatment. CCyR and MMR were seen in 12/36 (33%) and 3/36 (8%) of patients without and 3/6 (50%) and 3/6 (50%) with the T315I mutation.
Summary and Conclusion: More precise data collection for the type and grade of toxicities is on-going. Our national experience reflects the data emerging from the phase II PACE study confirming useful efficacy of ponatinib in a previously heavily treated patient cohort in whom the need and benefit outweigh the risk.

P897

OUTCOMES OF THIRD-LINE BCR-ABL1 TYROSINE KINASE INHIBITORS IN THE TREATMENT FAILED CHRONIC PHASE CHRONIC MYELOID LEUKEMIA PATIENTS WHO HAVE RECEIVED TWO PRIOR TKIS

SE Lee[1,2,*], SY Choi[2], SH Kim[2], YJ Oh[2], MJ Chae[2], HY Song[2], HL Yoo[2], MY Lee[2], EJ Jang[2], KH Jeong[2], JS Lee[2], DW Kim[1,2]
[1]Department of Hematology, Seoul St. Mary's Hospital, The Catholic University of Korea, [2]Cancer Research Institute, The Catholic University of Korea, Seoul, Korea, Republic Of

Background: With the availability of several TKIs, in patients who have failed to 2 prior TKIs, anyone of the remaining TKIs can be considered for salvage therapy. However, further evaluation on the use of a novel TKI as third-line therapy is needed.
Aims: The aim of this study was to evaluate the response rates and outcomes of third-line TKI therapy in the treatment failed patients with chronic phase chronic myeloid leukemia who have received 2 prior TKIs.
Methods: We evaluated 100 CP CML patients who failed to 2 prior TKIs. Main study objectives were to evaluate major cytogenetic response (MCyR) by 12 months, cumulative incidence (CI) of major molecular response (MMR), progression-free survival, and overall survival. Molecular responses were monitored using qRT-PCR assay in3-month intervals, and then 6-month intervals after achieving major molecular response (MMR). MMR was defined as a BCR-ABL1 transcript level of 0.1% or lower on the international scale (IS).
Results: A total of 100 patients were received third-line therapy with dasatinib (n=48), radotinib (n=28), nilotinib (n=14), and bosutinib (n=10). 65 men and 35 women were included and their median age was 41 years (range, 18-73). The percentages of patients with low, intermediate and high Sokal risk scores were 19%, 30% and 17%, respectively with unknown risk score in 34%. 93 patients received IM as first-line therapy and 7 patients received 2G-TKI as first-line therapy. At the start of first-line therapy, 92 patients were in CP, 7 in AP, and 1 in BP. As second-line therapy, IM (n=7), dasatinib (n=43), nilotinib (n=24), radotinib (n=22), and bosutinib (n=4) were used. At the start of second-line therapy, 84 patients were in CP, 14 in AP, and 2 in BP. With a median follow-up of 20.1 months (range, 0.2-81.6 months) since the start of the third-line TKI, 55 patients continue on third-line TKI therapy. Forty-five patients were permanently discontinued from third-line TKI treatment due to intolerance (n=18), failure (n=6), progression (n=14), death (n=3) and others (n=4).Overall, 18 patients died. MCyR rate at 12 months after third-line TKI, in 31 patients with cytogenetic assessments at 12 months was 74.2% (23/31 patients). The3-year OS and PFS after third-line TKI were 81.1%and 76.0%, respectively. 50 patients with MCyR at the time of third-line TKI had a better 3-year OS (100% *vs*. 69%, P<0.001) and PFS (95.5% *vs*. 51.3%, P<0.001) than those of 50 patients without MCyR.
Summary and Conclusion: Our data showed the favorable outcomes of CP CML patients treated with a third-line TKI. The patients with MCyR at the time of third-line TKI showed a better outcome. It implies that the use of anyone of remaining TKI, as third-line therapy may induce feasible outcomes in CP patients. Further study focusing on selecting the patients who may benefit from a third-line TKI is needed.

P898

PREDICTIVE FACTORS FOR OUTCOME TO NOVEL BCR-ABL1 TYROSINE KINASE INHIBITORS IN IMATINIB FAILED CHRONIC PHASE CHRONIC MYELOID LEUKEMIA

SE Lee[1,2,*], SY Choi[2], SH Kim[2], YJ Oh[2], MJ Chae [2], HY Song[2], HL Yoo[2], MY Lee[2], EJ Jang[2], KH Jeong[2], JS Lee[2], DW Kim[1,2]
[1]Department of Hematology, Seoul St. Mary's Hospital, The Catholic University of Korea, [2]Cancer Research Institute, The Catholic University of Korea, Seoul, Korea, Republic Of

Background: The first BCR-ABL1tyrosine kinase inhibitor (TKI), imatinib mesylate (IM), has become a first-line therapy for chronic phase (CP) chronic myeloid leukemia (CML).However, approximately one third of IM-treated patients discontinue therapy due to an inadequate response or adverse event. More potent novel TKIs such as dasatinib, nilotinib, radotinib, bosutinib and ponatinib have developed and these agents have shown high rates of hematologic and cytogenetic responses after failure of IM therapy. However, factors associated with long-term benefit from 2nd line therapy are not confirmed.
Aims: The aim of this study was to evaluate the predictive factors for outcome to novel TKIs in IM failed CP CML.
Methods: We evaluated 328 imatinib failed CP CML patients who had been treated with novel TKIs. Predictive factors for failure-free survival (FFS), progression-free survival (PFS), and overall survival (OS) were evaluated. FFS was measured from the day of 2ndline therapy initiation to death, progression to AP or BC, treatment failure according to 2013 ELN recommendations or contact, whichever came first. OS included any death regardless of causes, and PFS included progression to AP or BC as well as death resulting from any reason. OS and PFS were also collected on patients who were treated with other TKIs after 2nd-line TKI discontinuation.
Results: A total of 328 patients were treated with 2nd line TKI, dasatinib (n=131), nilotinib (n=103), radotinib (n=76), bosutinib (n=16), and ponatinib (n=2). 205 men and 123 women were included and their median age was 43 years (range, 15-77). The percentages of patients with low, intermediate and high Sokal risk scores were 23%, 31% and 24%, respectively with unknown Sokal risk scores in 22%. At diagnosis, 315 patients were in CP, 9 in AP, and 4 in BP. With a median follow-up of 28.4 months (range, 0.2-108.6 months) since the start of 2nd line TKI, 194 patients continue on therapy. 134 patients were permanently discontinued due to intolerance (n=74), failure (n=31), warning (n=1), progression (n=18), death (n=3) and others (n=7).The3-year FFS, PFS, and OS were 79.7%, 85.1%, and 89.1%, respectively. After adjusting for factors affecting FFS on univariate analyses, multivariate analyses showed that AP/BP at diagnosis and presence of BCR-ABL1 kinase domain abnormalities (KDA) at baseline were associated with a lower FFS. Less than PCyR on IM had a lower FFS, compared with those with CCyR on IM (RR of 3.25, P=0.016). AP/BP at diagnosis, presence of KDA at baseline and less than PCyR on IM were also associated with a lower PFS and OS. Increasing age was a predictive factor for lower OS.
Summary and Conclusion: Our data showed the predictive factors for outcome to secondline TKIs in imatinib failed CP CML. Disease phase at diagnosis, previously cytogenetic response on IM, and presence of KDA at baseline had the value of predicting the outcomes. It implies that the patients with these factors may require more precise monitoring on secondline therapy. Further study focusing on selecting the patients who may benefit from a third-line TKI is needed.

Background: Therapy approaches during pregnancy in females with chronic myeloid leukemia (CML) are still discussable, practical experience is limited. Preventing of CML progression and fetus safety are main issues in management of CML at pregnancy.
Aims: To analyze pregnancy outcomes and management of CML during pregnancy.
Methods: A retrospective and prospective information about adult patients with Ph+ positive CML and pregnancy was gathered. Cases for CML females have been collected since 2006 till February 2014 from database of Hematology Research Center (Moscow) and clinics of Russian Federation. Data structure regarded CML treatment and monitoring, pregnancy data and outcomes, newborns characteristics and follow-up.
Results: An information about 54 completed cases has been recorded in 46 female patients (8 patients had 2 subsequent pregnancies). Chronic phase (CP) CML at diagnosis was in 44 women, accelerated phase (AP) was in 2 women. In 38 (70,4%) cases healthy children were born, 5 (9,3%) pregnancies resulted in spontaneous abortion, 2(3,7%) ended in premature delivery with death of children; in 9 (16,6%) cases an elective abortion was performed. In 28(74%) of 38 cases of successful delivery patients conceived during tyrosine kinase inhibitors (TKI) uptake: 23 on imatinib, 3 on dasatinib, 2 on nilotinib; 10 (26%) of 38 conceived without TKI therapy (5 of 10 with newly diagnosed CML). In 26 of 28 cases TKI treatment was discontinued immediately after pregnancy confirmation within the 1st trimester. Generally in 14 of 38 cases females were observed without therapy after the 1st trimester and for whole pregnancy period. In 13 of 14 cases deep remission at pregnancy diagnostics was achieved: molecular response 4 logs (MR4), major molecular response (MMR). In 1 of 14 cases therapy was postponed till delivery for woman with newly diagnosed CML in 3rd trimester. In 24 of 38 cases treatment interventions for CML were performed in 2nd – 3rd trimester due to lack of remission or for newly diagnosed CML. Females got the following therapy: interferon alpha in 9 cases, hydroxycarbamide in 2 and TKI in 12 cases (10 –imatinib, 2-nilotinib). In 2 of 12 cases TKI were used for whole pregnancy period. The infants born under TKI exposure had no birth abnormalities. However, a low weight (≤2500 g) was observed in 6 of 12 newborns exposed to TKI after 2nd trimester and/or for whole pregnancy. In 5 of 6 those cases there was a premature delivery. Further weight recovery and development of children were normal. Two cases of premature delivery and death of children were in females non-compliant to TKI with no treatment at pregnancy and hematologic relapse. Among 5 cases of spontaneous abortions 3 patients conceived on imatinib, for 2 data were not obtained. In 9 cases of elective abortions 6 were performed in women on imatinib, 2 on dasatinib, 1 case in newly diagnosed CML.
Summary and Conclusion: Management of CML at pregnancy is based on careful assessment of risks for female and fetus. Treatment approaches highly depend on grade of remission and pregnancy terms Choice of therapeutic interventions in patients with significant leukemic burden is a problem without standard decision. Although successful outcomes are possible in cases of using TKI on late stages of pregnancy, risks of TKI exposure at human fetus remain unknown. A safe way for risks minimization for women with childbearing potential with CML is to avoid pregnancy until achieving stable deep molecular remission.

P900

LONG-TERM EVALUATION OF VASCULAR TOXICITY IN PATIENTS WITH PH+ LEUKEMIAS TREATED WITH BOSUTINIB

J E Cortes[1,*], H Kantarjian[1], HJ Khoury[2], T H Brümmendorf[3,4], M G Conlan[5], K Wang[6], K D Fly[7], M Shapiro[8], J H Lipton[9], JB Durand[1], C Gambacorti-Passerini[10]

Aachen, RWTH, Aachen, Germany, [5]Pfizer Inc, La Jolla, CA, [6]Pfizer Inc, Pearl River, NJ, [7]Pfizer Inc, Groton, CT, [8]Pfizer Inc, Cambridge, MA, United States, [9]Princess Margaret Hospital, Toronto, ON, Canada, [10]University of Milano-Bicocca, Monza, Italy

Background: Vascular toxicities (eg, peripheral arterial occlusive disease [PAOD]) have been associated with BCR-ABL tyrosine kinase inhibitor (TKI) treatment (tx).
Aims: We evaluated vascular (peripheral, cardiovascular, and cerebrovascular) toxicities based on tx-emergent adverse events (TEAEs) with bosutinib (BOS) in 2 ongoing studies.
Methods: This analysis included data from a phase 1/2 study of BOS 2nd/3rd/4th-line tx (2L/3L/4L, up to 3 y) in Ph+ leukemia patients (pts) resistant/intolerant to prior TKIs and a phase 3 study in chronic phase CML pts of BOS *vs* imatinib (IM) 1st-line tx (1L; up to 2 y).
Results: 12.7% of BOS pts had vascular TEAEs (**Table**), with no significant differences for BOS *vs* IM in the randomized frontline BELA study (1L: $P \geq 0.122$). Individual cardiovascular TEAE incidences were low; only angina pectoris (1.2%) and coronary artery disease (CAD 1.2%) occurred in >1% of BOS pts. No individual cerebrovascular TEAE occurred in >3 BOS pts. Individual peripheral vascular TEAEs were uncommon; only hypertension (6.4%) occurred in >2 BOS pts (1L: 6.0% [BOS] *vs* 4.4% [IM], $P=0.427$). Only 1 pt had PAOD (BOS 3L; y 1). Newly occurring vascular TEAE rates decreased with longer BOS tx (2L/3L/4L: y1, 40/570 [7.0%]; y 2, 21/273 [7.7%]; y 3, 8/208 [3.8%]; 1L [BOS *vs* IM]: y 1, 16/248 [6.5%] *vs* 9/251 [3.6%]; y 2, 5/183 [2.7%] *vs* 5/209 [2.4%]). Risk factors for vascular TEAEs ($P \leq 0.036$) were age ≥65 y (both studies) and history of vascular disorders (2L/3L/4L). Vascular TEAEs were managed mostly by concomitant medication (61.5% of affected pts); few pts required dose delays (n=15) or reductions (n=1). Discontinuation due to vascular TEAEs occurred in 6 (0.7%) BOS pts (2L/3L/4L: CAD n=2, myocardial infarction n=2, cerebrovascular accident n=1; 1L: cerebral haemorrhage n=1 [*vs* 0 IM, $P=0.497$]).

Table 1.

	Pooled	2L/3L/4L	1L	
	BOS* (n=813)	BOS* (n=570)	BOS* (n=248)	IM† (n=251)
Median (range) tx duration, mo	–	11.1 (0.03–83.4)	13.1 (0.03–49.6)	13.9 (0.3–46.9)
Vascular TEAEs, %	12.7	13.5	10.9	7.6
Cardiovascular	3.4	4.2	1.6	1.2
Cerebrovascular	1.8	2.3	0.8	0.4
Peripheral vascular	8.7	8.7	8.1	4.8

*200 or †400 mg/d starting dose

Summary and Conclusion: Vascular TEAE incidences with BOS in Ph+ leukemia pts were low individually and overall and not significantly different *vs* IM (1L). Peripheral vascular TEAEs, except hypertension (occurring in 6% of patients), are uncommon with BOS.

P901

CHROMOSOMAL ABNORMALITIES IN PHILADELPHIA CHROMOSOME (PH)-NEGATIVE METAPHASES IN NEWLY DIAGNOSED PATIENTS WITH CHRONIC MYELOID LEUKEMIA IN CHRONIC PHASE TREATED FRONTLINE WITH NILOTINIB OR DASATINIB

S Shah[1,*], H Kantarjian[1], S O'Brien[1], G Borthakur[1], J Burger[1], T Kadia[1], N Pemmaraju[1], C DiNardo[1], E Jabbour[1], J Cortes[1]
[1]Leukemia, M D Anderson Cancer Center, Houston, United States

Background: Patients(pts) with CML develop chromosomal abnormalities in Ph-negative metaphases while on treatment with tyrosine kinase inhibitors(TKI). Previous reports have focused on these events in pts treated with imatinib, but there is limited information on this phenomena among pts treated with nilotinib or dasatinib.
Aims: To determine the frequency of appearance of chromosomal abnormalities(CA) in Philadelphia chromosome-negative metaphases in newly diagnosed CML patients treated with nilotinib or dasatinib and to describe the significance of such events.
Methods: We conducted a retrospective analysis of all newly diagnosed CML pts treated with nilotinib or dasatinib as initial therapy in prospective trials at our institution between from July 2005 to August 2012. A review of all cytogenetic analyses was performed and pts who developed chromosomal abnormalities in Philadelphia chromosome-negative metaphases at any point in therapy were identified. Characteristics of such abnormalities such as time of appearance, number of metaphases in which they were seen and duration of persistence were noted.
Results: 245 pts were treated with nilotinib (n=124) or dasatinib (n=121). Out of these, 52 (21%) pts developed chromosomal abnormalities in Ph-negative metaphases. 35 (67%) were male. Median follow-up was 51 months. Median time from initiation of TKI to appearance of CA was 19.5 months. Frontline therapy was nilotinib in 33 (63%; 27% of all pts treated with nilotinib) and dasatinib in 19 (37%; 16% of all pts treated with dasatinib) patients. Nine (17%) pts had more than one CA either simultaneously or consecutively, for a total of 68 abnormalities. The most common CA was alterations of chromosome Y (deletion or addition) in 9 (17%) pts; the most common autosomal abnormality was deletion 10 in 3 pts. 44 (65%) events were seen in one metaphase only out of which 39 (89%) never reappeared. The remaining five the persisted were all sex chromosome abnormalities. 24 (35%) events were clonal, most commonly +8 and -Y, (3 pts each). 16 (67%) pts with clonal CA in Ph-negative metaphases continued to maintain chronic phase of disease during entire follow-up period. The rates of MMR and CMR (transcript ratio less than $10^{-4.5}$) in these patients were 90% and 58%, respectively, for pts with clonal CA; 97% and 55% for those with non-clonal CA; and 92% and 54% in those with no CA. Progression to accelerated or blast phase was seen in three (15%), five (16%) and 25 (13%) pts, respectively. A total of three pts with clonal CA in this analysis died: one in complete cytogenetic remission and two in major molecular remission at time of death. Causes of death were complication of esophageal cancer, myocardial infarction and sepsis, respectively. Only one pt received stem cell transplant for transformation to a lymphoid blast phase and continued to be in remission at last follow-up. None of the pts with CA has developed a second leukemia.

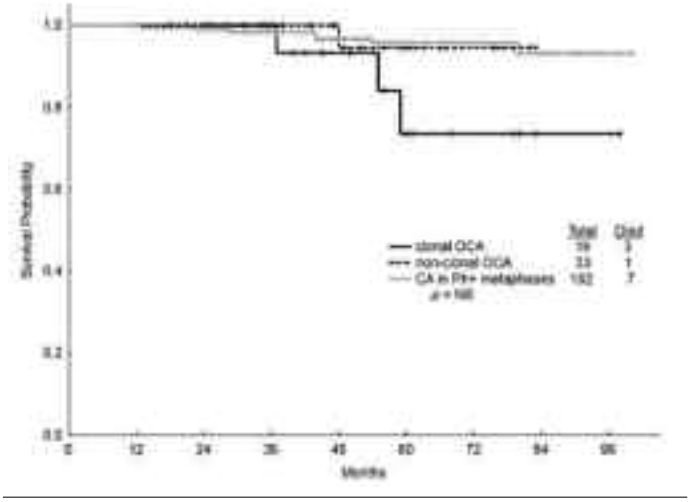

Figure 1.

Summary and Conclusion: Chromosomal abnormalities in Ph-negative metaphases in pts with newly diagnosed CML-CP treated with 2nd generation TKI are relatively common but bear no adverse consequences. In particular, no occurrence of second leukemias has been detected. Continued monitoring is required to better define significance of these events.

Background: Bosutinib (BOS) is a dual Src/Abl tyrosine kinase inhibitor that has confirmed a potent activity in patients (pts) resistant or intolerant to previous tyrosine kinase (TKI) inhibitors with a good safety profile. However, the European Medical Agency has approved BOS only for patients (pts) resistant or intolerant to imatinib (IM) and for whom nilotinib (NI) and dasatinib (DA) are not considered appropriate treatment options. Efficacy and safety data have been published of 115 pts who had been pretreated with IM and DA or NI, however only data of 3 pts have been collected in fourth-line setting.
Aims: The aim of this study is to present the first data reported of pts treated in Spain with BOS in previous heavily treated patients.
Methods: We have collected data of 29 pts among the 35 pts (85%) that have been treated with BOS since 2012 under a Spanish Compassionate Use Program in 16 centers. The study was approved by regulatory authorities and all pts signed informed consent document. Four patients (13%) received BOS in third line (after failure or intolerance to IM and NI or DA) while 25 pts were treated with BOS after receiving IM, DA and NI (one also received ponatinib). The most common indication was pts intolerant to three previous TKI (38%), while 24% were resistant to the 3 TKIs. Patients disposition and main baseline characteristics are shown in table 1.
Results: Considering those pts in fourth line (25), the median follow up was 7.23 months RI=[3,67_9,17]. Time to best response was 5.13 months RI=[2.10-8.32]. BOS was discontinued in 3 pts (12%): 1 death (after progression to advanced phase) (4%), 1 resistance (4%) and 1 intolerance (4%). Event free survival (Guilhot J, *et al.* Blood 119(25): 5963-5971) was 88%. BOS was usually well tolerated. Grade 3-4 anemia, neutropenia and thrombocytopenia occurred in 6%, 8% and 8% respectively. The most common nonhematological toxicities were diarrhea (48%), nausea (20%), rash (8%), increased ALT/AST (12%) and abdominal pain (12%). Grade 3-4 nonhematological toxicities were observed in 4 pts (1 nausea, 1 gastrointestinal bleeding, 1 ALT/AST elevation and 1 diarrhea). BOS has been proved to be a useful treatment option regardless the indication of use. Patients were classified according to the status when BOS was started. Group 1 consisted of 12 patients (46%) who started treatment as failures (less than CCyR); while 13 patients in group 2 (54%) started treatment with at least CCyR. Responses in group 1 were: CCyR 25% (3/12), MMR 16% (2/12), 75% (9/12) maintained baseline response and 8% (1 patient) progressed. For patients in group 2, probabilities of improve molecular response, sustained baseline response and progression were: 50% (4/8), 77% (10/13) and 15% (2/13) respectively.

Table 1.

Pts, N(%)		3 (13)	7 (24)	11 (38)	4 (14)	4 (14)	29 (100)
Age of diagnosis, med yr		43	47	55	61	54	54
Age of BOS initiation, med yr		47	61	67	72	61	61
Sokal index at diagnosis, N	high	0	1	0	1	0	2
	intermediate	1	2	5	1	1	10
	low	1	4	6	1	3	14
Time from first TKI to BOS, med yr		6	10	10	11	11	10
Duration of IM treatment, med, mo		16	16	23	62	87	60
Duration of DA treatment, med, mo		17	16	26	27	27	23
Duration of NI treatment, med, mo		10	14	10	29	24	16

Summary and Conclusion: We are presenting (to our knowledge) the largest series of patients treated with BOS forth line. Our study shows the results in 25 patients treated with bosutinib after failure or intolerance to 3 previous TKIs. In resistant patients, BOS has shown probabilities of CCyR and MMR (25% and 16%, respectively), similar to those described in third line. Bosutinib has also shown a very good safety profile in patients intolerant to 3 previous TKI, and one-half of them improved the response after switching to Bosutinib. Our results show Bosutinib is a safe and effective option for those patients in 4rd line of TKIs, Ongoing analysis of a larger series will be presented at the meeting.

P903

LONG-TERM ASSESSMENT OF CARDIAC TOXICITY IN PATIENTS WITH PH+ LEUKEMIAS TREATED WITH BOSUTINIB

C Gambacorti-Passerini[1,*], H Kantarjian[2], HJ Khoury[3], T H Brümmendorf[4,5], M G Conlan[6], K Wang[7], K D Fly[8], M Shapiro[9], J H Lipton[10], JB Durand[2], J E Cortes[2]
[1]University of Milano-Bicocca, Monza, Italy, [2]University of Texas MD Anderson Cancer Center, Houston, TX, [3]Winship Cancer Institute of Emory University, Atlanta, GA, United States, [4]Universitätsklinikum Aachen, RWTH, Aachen, [5]Universitätsklinikum Hamburg-Eppendorf, Hamburg, Germany, [6]Pfizer Inc, La Jolla, CA, [7]Pfizer Inc, Pearl River, NJ, [8]Pfizer Inc, Groton, CT, [9]Pfizer Inc, Cambridge, MA, United States, [10]Princess Margaret Hospital, Toronto, ON, Canada

Background: Cardiac toxicities are a potential concern for long-term treatment (tx) with BCR-ABL tyrosine kinase inhibitors (TKI).
Aims: We evaluated cardiac toxicities based on reported tx-emergent adverse events (TEAEs) in 2 ongoing studies of bosutinib (BOS).
Methods: This analysis included data from a phase 1/2 study of Ph+ leukemia patients (pts) resistant/intolerant to prior TKIs (all with prior imatinib [IM]) on BOS 2nd/3rd/4th-line tx (>1L; up to 3 y) and a phase 3 study in chronic phase CML pts on BOS or IM 1st-line tx (1L; up to 2 y). A logistic regression analysis was performed.
Results: Factors associated with cardiac TEAEs were history (hx) of hyperlipidemia/increased cholesterol (both studies); age ≥65 y, hx of cardiac disorder, ECOG >0 (>1L); and hx hypertension (1L). A numerically higher incidence of cardiac TEAEs **(Table)** was seen in BOS- *vs* IM-treated pts (1L; not statistically significant [NS; Fisher's exact]). Individual cardiac TEAE incidences were low with BOS and NS *vs* IM (1L). In the 1L study, ECG QT prolonged was the only individual TEAE reported in >2% of BOS or IM pts (2.8% *vs* 3.2%). Newly occurring cardiac TEAE rates decreased over time on BOS (>1L: 11.2% [y 1], 7.0% [y 2], 6.3% [y 3]; 1L [BOS *vs* IM]: 8.5% *vs* 6.0% [y 1], 3.8% *vs* 2.4% [y 2]) for pts on tx during that year. Cardiac TEAEs were managed mainly by concomitant medication (40.3% of affected pts) and dose delays (25.8% of affected pts). Cardiac TEAEs leading to BOS discontinuation were low (2.0%; 12 pts >1L; 4 pts 1L): cardiac arrhythmias n=1, coronary artery disorders n=4, heart failures n=5, pericardial disorders n=5, ECG QT prolonged n=1; NS *vs* IM (1L: 4 *vs* 0; *P*=0.06).

Table 1.

	Pooled	>1L	1L	
	BOS* (n=418)	BOS* (n=370)	BOS* (n=248)	IM† (n=251)
Median (range) tx duration, mo	–	11.1 (0.03-83.4)	11.1 (0.03-49.6)	13.3 (0.1-48.9)
Cardiac TEAEs (any grade, HLGT), %	15.2	16.5	12.1	9.6
Cardiac arrhythmia	5.7	6.5	4.8	2.8
Coronary artery disorder	3.4	4.2	1.6	1.2
Heart failure	2.9	3.9	0.8	0.8
Myocardial disorder	2.1	2.8	0.4	0
Pericardial disorder	2.9	3.5	1.6	0
ECG QT prolonged, %	1.1	0.7	1.6	3.2

*500 or †400 mg/d starting dose

Summary and Conclusion: Cardiac TEAE incidences were generally low in BOS-treated Ph+ leukemia pts. Overall, high level and individual cardiac TEAE incidences were NS *vs* IM (1L). Heart failure incidence was low with BOS and similar to IM.

P904

DESIGN OF RAPID FLUORESCENT MOLECULAR BEACON BASED PCR ASSAY FOR DETECTION AND QUANTIFICATION OF BCR –ABL TRANSCRIPTS IN CHRONIC MYELOID LEUKEMIA PATIENTS

S Jetly[1,*], R Arora[1]
[1]Of biotechnology, Dr B.R.Ambedkar center for Biomedical Research, Delhi, India

Background: Chronic myeloid leukemia(CML) is clonal myeloproliferative neoplasm of hematopoietic stem cells which is consistently associated with balanced reciprocal translocatiion between chromosome 9 and 22. This creates a minute 22 chromosome called Philadelphia chromosome having the fusion gene BCR-ABL. In 95% of patients BCR-ABL fusion gene codes for oncogenic fusion protein with constitutive tyrosine kinase activity which is causal of morphological and clinical manifestations of the CML. Apart from 5% of atypical cases, a clear detection of BCR-ABL fusion gene/transcript qualifies a person to be a patient of CML. The treatment mainly involves Tyrosine Kinase Inhibitors(TKIs) like imatinib that results in complete remission in 60-70% of patients and also increases the overall survival. A peripheral blood smear with cytogenetics of bone marrow is the gold standard for initial detection worldwide. In developing countries like India except peripheral smear,cytogenetics diagnostic is not always tenable. Lack of proper laboratory facilities and cost of undergoing cytogenetics initially and at regular intervals is unaffordable by substantial population of patients. Moreover the sensitivity of the technique is not more than 1-5%, and disadvantages also include high cost,dependence on metaphases and the fact that it is an invasive procedure. Another technique which is recommended by WHO/ELN is real time RT-PCR for dose response monitoring and MRD (minimal residual disease) detection. Realtime RT-PCR is very expensive and time consuming given the prolong nature of disease

which warrants regular detection at defined intervals.Therefore once again it is not the method of choice in developing countries like India

Aims: To design a rapid, inexpensive, easy visualization method for detection and quantification of BCR-ABL transcripts in chronic myeloid leukemia patients.

Methods: Peripheral blood samples of untreated patients were collected after informed consent. RNA was isolated by trizol method and cDNA prepared using commercial kit.The quality of the cDNA was tested with five housekeeping genes. In house primers were designed for BCR–ABL amplification. Specific molecular beacons were used to detect and quantify transcripts by measuring fluorescence in an ELISA reader. The assay was evaluated against qPCR using published primers. The study was approved by the institutional committee sofAIIMS, Safdurjung Hospital No. 14-11-EC (19/26) and ACBR (No. F.50-/Eth.com/ACBR/11/2106).

Results: An molecular beacon based PCR assay was developed for easy and quick visualization of BCR-ABL transcripts. The specificity of the assay was confirmed by competitive experiments. The assay was found to be sensitive enough to detect 500 fg of plasmid containing the chimeric cDNA. A linear increase in fluorescence was observed with increase in template concentration in the PCR reaction (Figure 1:Semi log plot of Plasmid DNA (clone containing the BCR-ABL insert) concentration *vs* fluorescent intensity obtained by hybridization of 65 nM of molecular beacon with amplicon b2a2 obtained by PCR of BCR-ABL plasmid). Clinical evaluation of assay was done using 50 patient samples.

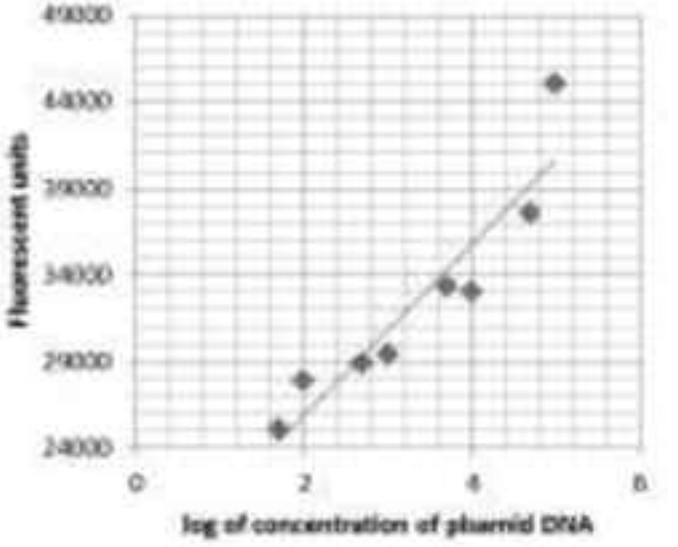

Figure 1.

Summary and Conclusion: We propose that beacon based method can simultaneously detect and quantify the BCR-ABL transcripts in rapid and easy manner when the patient approaches for diagnosis thus eliminating the need for cytogenetics and qPCR. The current method is as sensitive and specific as commercially available qPCR. Since the method is cost effective, and does not require expertise, therefore we envisage that we can use it in resource poor settings.

P905

HYPOPHOSPHATEMIA AS A PREDICTOR OF RESPONSE IN CHRONIC MYELOID LEUKEMIA (CML) TREATED WITH IMATINIB

T Garrido[1,*], M Amorim[1], P Gomes[1], F Trigo[1], J Guimarães[1]
[1]Serviço de Hematologia Clínica, Centro Hospitalar São João, Porto, Portugal

Background: Response to treatment with Imatinib is uneven among patients with CML. Hypophosphatemia has been described has an adverse effect and, although its pathogenesis is still unclear (Imatinib-induced renal tubulopathy, dysregulation of bone remodelling, secondary hyperparathyroidism) it may also play a role in monitoring adherence, efficacy, and even predicting response.

Aims: To look for clinical/laboratorial factors associated with hematologic (CHR), complete cytogenetic (CCyR), major (MMR) and complete molecular remission (CMR).

Methods: We assessed clinical records of 135 patients with chronic phase CML diagnosed in a single centre between 2001 and 2012. Median follow-up from start of Imatinib was 69months [8;168].

Results: The median age at diagnosis was 51years [16;89], and 73(54.1%) patients were male. 28 patients showed resistance to Imatinib, less frequently in those with hypophosphatemia (<2.7mg/dL) during the first year of treatment (p=.008). 103(73.7%) patients achieved complete hematologic remission (CHR) within 3months; 64(47.4%%) achieved CCyR within 6 months; 40(29.6%) reached MMR within 18months; and 32(23.7%) achieved CMR. Among these 32 patients, 59.4% were female (p=.048); 62.5% reached CCyR within 6 months (p=.026); and 50% had MMR within 18months (p=.006); additionally, there was an inferior median LDH at diagnosis for this group (626 *vs*. 743U/L; p=.025). The presence of hypophosphatemia at 6 and 12months of treatment was correlated with a higher probability of achieving CCyR within 6months (p=.001) and MMR within 18months (p=.04), respectively. 81.8% of the patients achieving CMR had hypophosphatemia during the first year of treatment (p=.08). On the other hand, age, Sokal/Hasford risk stratification, and other laboratory parameters at diagnosis were not correlated with response. Seventeen (12.5%) patients progressed to accelerated disease, 14 had blast crisis; and 21(15.6%) died (11 due to CML). The 10-year progression-free survival (PFS)/ overall survival (OS) were superior in those patients with CCyR (PFS: 88.6% *vs*. 0%; p<.0001/ OS: 83.1% *vs*. 29.9%; p<.0001); MMR (PFS: 96.5% *vs*. 23.5%; p<.0001/ OS: 86.6% *vs*. 41.8%; p<.0001); CMR (PFS 100% *vs*. 56.2%; p<.0001/ OS: 100% *vs*. 72.5%; p=.005); as well as those with hypophosphatemia during the first year of treatment (PFS: 82.9% *vs*. 58.3%; p=.012/ OS: 86.8% *vs*. 53.9%; p=.021).

Summary and Conclusion: In our group of patients, hyphosphatemia seems to correlate with early, deeper responses and improved survival, so it may establish itself as an important biomarker while monitoring patients treated with Imatinib.

P906

RISK AND IMPACT OF TUBERCULOSIS IN PATIENTS WITH CHRONIC MYELOID LEUKEMIA: A NATIONWIDE POPULATION-BASED STUDY IN TAIWAN

CJ Liu[1,2,*], JP Gau[1], YC Hong[3], CJ Teng[4], FC Ku[5], SC Chen[1], SH Chien[1], TJ Chiou[6], CH Tzeng[1]
[1]Division of Hematology and Oncology, Taipei Veterans General Hospital, [2]Department of Public Health, National Yang-Ming University, Taipei, [3]Division of Hematology and Oncology, Kaohsiung Veterans General Hospital, Kaohsiung, [4]Division of Oncology and Hematology, Far Eastern Memorial Hospital, New Taipei City, [5]Department of Hematology and Oncology, Show Chwan Memorial Hospital, Changhua, [6]Division of Transfusion Medicine, Taipei Veterans General Hospital, Taipei, Taiwan, Republic of China

Background: BCR-ABL tyrosine kinase inhibitors (BCR-ABL TKIs) have greatly improved treatment responses, overall survival, and disease-free survival in patients with chronic myeloid leukemia (CML). Some recent studies have reported an increased risk of tuberculosis (TB) infection during BCR-ABL TKI treatment, but none of these studies contained adequate comparison groups. Moreover, inferring increased TB risk during BCR-ABL TKI therapy is questionable because BCR-ABL TKIs improve hematopoietic function and patient immunity. It is impossible to conduct randomized studies that compare TB risk during BCR-ABL TKI treatment with a placebo group due to ethical issues of withholding TKI therapy. Therefore, a well-designed large-scale study is the best way to address this issue.

Aims: We aim to evaluate the relationship between CML and TB, and to determine the risk and the impact of TB development.

Methods: A national survey included 1,082 CML patients retrieved from the Taiwan National Health Insurance database between 1998 and 2011. A total of 10,820 subjects without CML that were matched for age, sex, and comorbidities comprised the matched non-exposed cohort. TB development was the main outcome; its impact was measured by the overall mortality, and the risk factors were identified by a multivariate Cox proportional hazards model.

Results: We found that the risk of TB was higher in the CML cohort (adjusted HR 3.76, 95% CI 2.24–6.31, p=0.001), for both pulmonary (adjusted HR 3.23, 95% CI 1.82–5.73, p<0.001) and extrapulmonary (adjusted HR 9.77, 95% CI 2.61–36.59, p=0.001) TB. Specific risk factors were age 60 or older (HR 3.24, 95% CI 1.19–8.83, p=0.022),being male (HR 13.49, 95% CI 1.79–101.54, p=0.012), receiving hematopoietic stem cell transplantation (HR 10.50, 95% CI 2.77–39.80, p=0.001), and interferon-α therapy (HR 3.34, 95% CI 1.32–8.47, p=0.011). BCR-ABL TKIs did not increase the risk of TB in patients with CML (HR 0.51, 95% CI 0.19–1.38, p=0.184). CML patients with TB had a higher mortality rate than those without (adjusted HR 2.04, 95% CI 1.02–4.08, p=0.043).

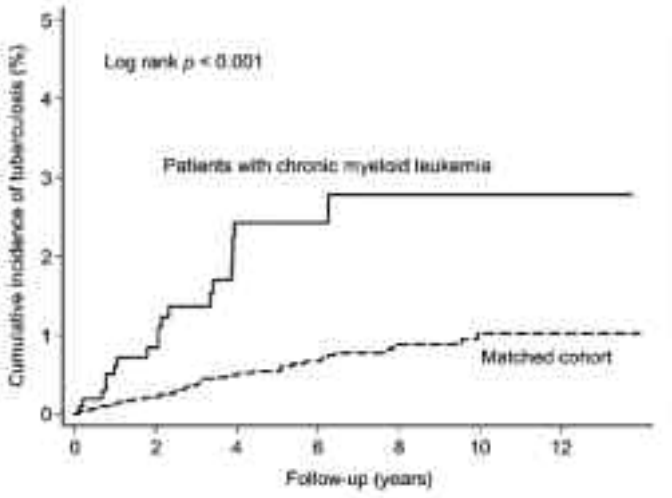

Figure 1.

Summary and Conclusion: The incidence of TB is significantly higher in CML patients, especially for patients that are male, aged 60 or older, or those who received either hematopoietic stem cell transplantation or interferon-α treatment. Careful screening strategies for TB should be considered for high-risk CML patients.

P907

MULTICENTER CLINICAL STUDY TO EVALUATE A UTILITY OF FRET-BASED DRUG SENRITIVITY TEST THAT PREDICTS EARLY MOLECULAR RESPONSE IN NEWLY DIAGNOSED CML PATIENTS TREATED WITH NILOTINIB

T Kondo[1,*], Y Ohba[2], SI Fujisawa[3], T Miyagishima[4], A Mori[5], H Iwasaki[6], M Shindo[7], Y Kakinoki[8], N Kobayashi[9], S Yamamoto[10], Y Haseyama[11], S Ando[12], N Fujimoto[13], M Nishio[14], M Kurosawa[15], Y Kohgo[7], T Teshima[1]
[1]Hematology, [2]Cell Physiology, Hokkaido University Graduate School of Medicine, [3]Laboratory and Transfusion Medicine, Hokkaido University Hospital, Sapporo, [4]Hematology, Kushiro Rosai Hospital, Kushiro, [5]Hematology, Aiiku Hospital, [6]Hematology, Sapporo Kosei Hospital, Sapporo, [7]Gastroenterology and Hematology/Oncology, Asahikawa Medical University, [8]Hematology, Asahikawa City Hospital, Asahikawa, [9]Hematology, Hokuyu Hospital, [10]Hematology, Sapporo City General Hospital, [11]Hematology, KKR Tonan Hospital, [12]Hematology, Teine Keijinkai Hospital, [13]Hematology, Kaisei Hospital, [14]Hematology, NTT East Corp. Hospital, [15]Hematology, National Hospital Organization Hokkaido Cancer Center, Sapporo, Japan

Background: The tyrosine kinase inhibitors (TKIs), imatinib, nilotinib and dasatinib are used as the first-line therapy for newly diagnosed chronic myeloid leukemia (CML). To predict a clinical outcome, Sokal, Hasford and EUTOS scores are widely used. But it is controversial that these methods are useful in 2nd generation TKI era. We have developed a FRET (fluorescence resonance image transfer)-based method to evaluate sensitivity of CML cells to TKIs (Mizutani *et al.* Clin Cancer Res. 2010).
Aims: In this study, we evaluate a clinical utility of FRET-based drug sensitivity test in newly-diagnosed CML-CP patients treated with nilotinib.
Methods: We conducted Eso-FANTA study (Estimation of outcome by FRET Analysis for Newly diagnosed CML-CP patients treated with Tasigna). In this multicenter phase II clinical trial, nilotinib (300 mg BID) was administered and the molecular responses were monitored. FRET analysis was performed to analyze the drug-sensitivity at the diagnosis. Bone marrow mononuclear cells were isolated and transfected with FRET probe. After 18 to 24 hours of transfection, the cells were treated with 2 microM nilotinib and then subjected to microscopic analysis to determine FRET efficiency. RQ-PCR evaluation of BCR-ABL mRNA was performed to monitor the clinical efficacy of nilotinib.
Results: From October 2010 to January 2014, 31 patients were registered in the study, and the median follow-up period was 9 months (range: 1-24). Nilotinib sensitivity was evaluated in 30 patients. By FRET analysis, 22 patients were determined nilotinib-sensitive, and 8 patients were nilotinib-insensitive. There was no significant difference of Sokal Low/Intermediate and High Risk distribution in two groups. Compared nilotinib-sensitive patients with nilotinib-insensitive patients, the rates of MMR were significantly higher; 91% *vs* 43% at 6 months (p=0.031) and 100% *vs* 43% at 9 months (p=0.023).

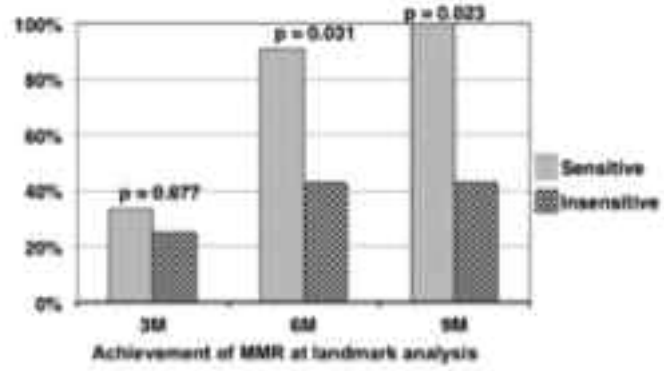

Figure 1.

Summary and Conclusion: The FRET analysis could predict the clinical efficacy of treatment with nilotinib before starting treatment. Our method will add the new tool to stratify the patients with newly-diagnosed CML-CP.

P908

FIRST PRELIMINARY REPORT OF ARAB LEUKEMIA NET (ALN) REGISTRY FOR CHRONIC MYELOID LEUKAEMIA (CML) IN THE MIDDLE EAST &NORTH AFRICA REGION.PART I EPIDEMIOLOGY OF CML IN EGYPT

M O Azzazi[1,*], M mattar[2], A alghandour[3], S shehata[4], M A shazly[1], A alghamaz[1]
[1]hematology and BMT., Ain Shams University, [2]hematology and BMT., cairo university, Cairo, [3]hematology and BMT., alexandria university, alexandria, [4]hematology and BMT., asut university, asut, Egypt

Background: Little is known about burden of CML in Middle East/ North Africa region. unpublished observations sugested a much younger incidence and the presence of diseae clusters in certain localities.Reliable epidemiological information on BCR-ABL-positive CML, is rare.Geographic and/or ethnic variations contribute to the variability of incidences among registries. Prevalence rate has increased by use of TKIs. In practice,reliable data concerning response rates to therapy in Arab nations is lacking. some CML management areas are not in line with the current recommendations. Other problematic areas are sub-optimal timing of treatment decisions under monitoring, unawareness and/or lack of new molecular monitoring techniques and of beneficial newTKIs. Median age differs between cancer registries and clinical trials by 10-20 years. Reports of clinical studies underestimate the true age of the CML population depending on the ease of access to medical servises that show great diversity in Middle East/ North Africa region.
Aims: Objective To understand and compare studies results of the previous and future and to translate their conclusion into clinical practice, there is a need for reliable basic epidemioloic data collected and analyzed through standardised CML studies designed according to recognized recommendations.
Methods: Method We analyzed data of 350 CML Egyptian patients (171 male and 179 female) Data were collected according to ELN and EUTOS recommendations by using a multicenter web based data registery portal, the ALN. (**www.aln-afme.com**).
Results: Patients Mean age at presentation was 41y (40y for males, 41y for females), The age specific rates were highest for the age group of 30-35 years. At diagnosis 84% patients were in chronic phase CML, 9.1% in accelerated, and 6.9% in blastic phase. Results of Sokal score were: Low risk 55.8% Intermediate risk 24.5%High risk 17.7% and Unknown in 2%. EURO (Hasford) score (56.3% Low risk, 18.4%Intermediate risk and13.6%High risk while 2.7% Unknown).Female patients presented with lower hemoglobin, higher platelet counts and smaller spleen size (P<0.0001).BCR-ABL transcript level was performed to 96.6%of cases Cytogenetics by FISH to 77.6%. All patients recived TKI therapy,(61% imatinib,24 nilotinib and 15 dasatinib).96%of patients achived hematologic respone,87% achived PCYR,64% achived. CCYR, and 60%MMR within a peroid of 4 years follow-up. The transplantation rate was 14% for female and 22% for male patients. Median survival /progression-free survival were equal in female and male patients.
Summary and Conclusion: We examined the demographic and clinical features of CML patients presenting at Medical Centers in Middle East/ North Africa region by analyzing data reported to ALN web portal. The study demonstrates that age-specific rates for CML are highest in age group of 30-34 years,that is much lower compared to western populations.No gender differance was found. PFS were equal in female and male patients.

P909

UPDATED REPORT OF THE AUSTRIAN CML REGISTRY

S Schmidt[1,*], H Sill[2], R Greil[3], S Burgstaller[4], E Schlögl[5], A Petzer[6]
[1]Hematology / Oncology, Medical University Innsbruck, Innsbruck, [2]Hematology, Medical University Graz, Graz, [3]3. Universitätsklinik für Innere Medizin, Paracelsus Universität Salzburg, Salzburg, [4]Abteilung für Innere Medizin IV, Klinikum Wels-Grieskirchen, Wels, [5]3. Medizinische Abteilung, Hanusch Krankenhaus, Wien, [6]1. Interne Abteilung, Krankenhaus der Barmherzigen Schwestern, Linz, Austria

Background: Recommendations for treatment of chronic myeloid leukemia (CML) have been constantly revised since tyrosine kinase inhibitors (TKIs) have become standard of care. While treatment goals have become more stringent and the achievement of early and deep molecular responses as well as TKI treatment discontinuation strategies are being evaluated in clinical trials, population based data on treatment, response and survival of patients treated throughout that period reflect the real life situation.
Aims: The Austrian CML registry aims to monitor and analyse outcome, disease course and management as well as related toxicities in a nationwide unselected patient cohort to provide data reflecting general pratice and contrast these results with clinical trial data.
Methods: The Austrian CML registry is an ethics committee approved online database with a web-based tool for data entry. Participating centres can contribute patient data after having obtained written informed consent. The collected data comprise diagnostic parameters, CML phase, concomitant diseases, CML specific treatment including stem cell transplantation and adverse effects.
Results: Here we summarize the CML registry data as of January 2014 with a focus on treatment, response and survival. The CML registry cohort comprises a total of 410 patients (evaluable n=400) with a total of 3300 follow-up visits. At diagnosis most patients (n=374) were in chronic phase (early, late, secondary), whereas only 9 were in accelerated phase, 3 in blast crisis. A total of 354 patients were treated at least once with imatinib and 73 and 50 patients received at least once nilotinib or dasatinib, respectively. Other treatment modalities included chemotherapy, interferons and stem cell transplantation (SCT). Calculcated overall survival at 108 months was 84.2% (CI: 78.3.2-90.5). We will present an updated response analysis according to ELN recommendations 2013 and TKI usage.
Summary and Conclusion: The majority of patients is treated with imatinib and overall survival in this population based cohort is comparable to what has been observed in clinical trials. Second generation TKIs are being used predominantly in second line treatment, their usage in front line therapy is still limited.

P910

10 YEARS EXPERIENCE OF TYROSINE KINASE INHIBITOR THERAPY FOR CML IN A SINGLE UK CENTRE: COMPARISON WITH PRE-TKI ERA AND EVALUATION OF 2013 ELN GUIDELINES

D Khan[1,*], N Roy[1], V Bari[1], G Vallance[1], H Dreau[1], T Littlewood[1], A Peniket[1], P Vyas[1], L Foroni[2], A Schuh[1], A Mead[1]
[1]Department Of Haematology, Oxford University Hospitals' NHS Trust, Oxford, [2]Department of Haematology, Imperial College Healthcare NHS Trust, London, United Kingdom

Background: Routine use of tyrosine kinase inhibitor (TKI) therapy for chronic myeloid leukaemia (CML) was approved in the UK in 2002, transforming the treatment of this disorder. European LeukaemiaNet (ELN) 2013 guidelines include a new emphasis on early markers of response to guide switch to second generation TKIs, with important clinical and financial implications given the imminent loss of patent exclusivity on imatinib.
Aims: To assess the impact of TKIs on overall survival (OS) of CML at our institution & benchmark the outcome of TKI treated patients with 2013 ELN guidelines in a "real world" cohort.
Methods: We retrospectively reviewed outcome of all chronic phase CML patients treated in our centre in 2 cohorts; a 1990-1995 (pre-TKI) cohort and a 2000-2014 (post-TKI) cohort.
Results: Outcome of 102 CML patients was examined. There were 26 patients in the pre-TKI cohort and 76 patients in the post-TKI cohort, of whom 66 received first line TKI therapy with imatinib (n=56), nilotinib (n=6), dasatinib (n=3) and ponatinib (n=1). 10 had allogeneic bone marrow transplants as first line therapy and were excluded from analysis of TKI response. The median age was 52 (18-86) and 50 years (24-81) in the pre- and post-TKI groups respectively. Comparison of pre- and post-TKI cohorts demonstrated a dramatic improvement in survival post approval of imatinib in the UK with an 8 year survival of 14.8% and 91.1% respectively and median survival of 2.3 years and 'unreached' respectively (P<0.0001; Figure 1). Indeed, with a median follow-up of 4.6 years, only 4 deaths occurred in the post-TKI cohort, none related to CML. Accelerated phase (AP) and blast crisis (BC) occurred in 2 and 1 patient respectively. Allogeneic bone marrow transplant was carried out in two and the other patient in AP continued on first line TKI to complete cytogenetic remission (CCyR). Sufficient data to allow assessment of ELN response criteria was available in 57 patients. Optimal response throughout treatment was observed in 18 patients, with only 2 requiring switch to second line therapy due to intolerance. Major molecular remission (MMR3) was achieved in 16 (89%) with 10 (56%) complete molecular responses (CMR). ELN defined "warning" (without subsequently meeting criteria for failure) was observed in 17 patients. No progression to AP or BC was observed. Only 3 patients switched therapy for inadequate response (n=2) and intolerance (n=1). CCyR was achieved in 12 (71%), with 11 (65%) MMR3 and 1 (6%) CMR. ELN defined treatment failure at any time was observed in 22 patients, of whom 16 had a preceding ELN defined "warning". AP or BC subsequently occurred in 3 (14%; P<0.01 *vs* non-failure patients). 3 patients developed kinase domain mutations. 14 patients were switched to second line therapy, only 2 due to intolerance. CCyR was achieved in 7 (32%), with 2 (9%) MMR3 and 0 CMR. 5 patients proceeded to allogeneic bone marrow transplant. Non-relapse mortality occurred in one patient and 4 are alive and in CMR. Molecular response data was available on 31 patients at 3 months. A warning (>10% BCR-ABL), without meeting failure criteria, occurred in 14 patients. Of these early warnings, 11 patients out of 14 have achieved CCyR (79%), of whom 3 (21%) achieved MMR; 6 of these CCyR were achieved without switching therapy.

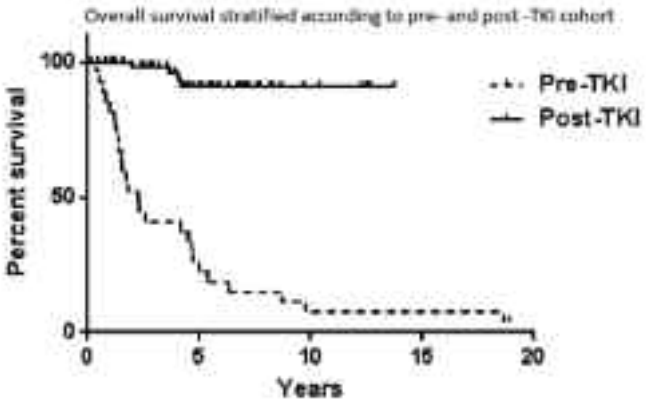

Figure 1.

Summary and Conclusion: In our single-institutional experience, first-line TKI therapy has dramatically improved OS in CML. Despite optimal response in only 32% of patients, disease progression events were rare. Most patients with "warning" at 3 months achieved CCyR, including patients who did not switch therapy, supporting ELN guidance that a "warning" should prompt close monitoring but only "failure" should prompt switch in therapy. This retrospective analysis is being extended to a further 100 patients across the Thames Valley and these results will be presented at the congress.

P911

CHALLENGES OF COMPOSITE ENDPOINTS FOR CML TRIAL EXECUTION, STATISTICAL ANALYSIS AND INTERPRETATION

J Hasford[1,*]
[1]IBE, Dept. for Medical Biometry and Epidemiology, Ludwig Maximilians-Universität München, München, Germany

Background: Recent years have seen an exceptional improvement of overall survival (OS) in patients with chronic myeloid leukemia. Thus clinical trials using classical endpoints like OS would need either huge sample sizes or very long observation times. Composite endpoints (CE), combining survival with events like progression, not achieving complete cytogenetic or molecular remission within a certain time period (typically 12 or 18 months) or loss of remission, called progression-free survival (PFS) or failure-free survival (FFS) were introduced to allow for a faster evaluation of new treatments.
Aims: To elucidate and discuss the challenges of CE for CML trial execution, statistical analysis and interpretation.
Methods: Challenging issues of CEs in particular for the comparative interpretation of CML trials will be exemplarily discussed on the basis of two major CML trials published in 2010 (Saglio G *et al.* NEJM 2010;362:2251-59, and Kantarjian HM *et al.* NEJM 2010;362;2260-70).
Results: FFS subsumes ~ 10 singleton events ranging from death to loss of response. FFS is thus difficult to interpret and provides limited value only for informing clinical decisions as the relevance of the singleton events is very heterogeneous. Hence drug authorities like the FDA ask that CE do not mix disease outcomes with clinical management decisions. An often neglected issue is that the intention to treat analysis of CEs requires that all singleton events have been properly monitored and assessed at the time points specified in advance in the trial protocol. Thus in a large CML trial out of 1466 evaluable patients only 571 were available for the analysis of FFS (Lauseker M *et al.* Frontiers Meeting 2012). Including in the statistical analysis patients with missing information on singleton events may seriously bias results. Yet another

problem is the common lack of widely accepted uniform definitions of CEs precluding a comparative assessment accross trials, *e.g.* the definition of PFS differs between the two CML trials mentioned above.
Summary and Conclusion: There is an urgent need for consented CEs and for the development of more suitable alternatives to CEs.

P912

GENOMIC BCR-ABL1 FUSION CHARACTERISATION AND SNPS IDENTIFICATION UPSTREAM AND DOWNSTREAM OF THE BREAKPOINTS IN BCR AND ABL1 GENES OF CML PATIENTS USING NEXT GENERATION SEQUENCING

J Linhartova[1], L Hovorkova[2], S Soverini[3], A Benesova[1], M Jaruskova[1], H Klamova[1], J Zuna[2], K Machova Polakova[1,*]
[1]INSTITUTE OF HEMATOLOGY AND BLOOD TRANSFUSION, [2]CLIP, Department of Paediatric Haematology and Oncology, 2nd Faculty of Medicine, Charles University in Prague, Prague, Czech Republic, [3]Department of Experimental, Diagnostic and Specialty Medicine, Institute of Hematology "L. e A. Seràgnoli", University of Bologna, Bologna, Italy

Background: BCR-ABL1 genomic fusion sequences represent clone-specific markers for each patient with chronic myeloid leukemia (CML). Their identification allows more sensitive monitoring of minimal residual disease at DNA level. As BCR-ABL1 is a large fusion gene the characterization of DNA breakpoints is challenging. In this study we used multiplex long-range PCR (mLR-PCR) with primers enabling to amplify large PCR products (>10 kb) carrying BCR-ABL1 breakpoints. LR-PCR products were directly sequenced using next generation sequencing (NGS). Amplification of large regions upstream and downstream of the breakpoints allows identification of SNPs and other sequence features.
Aims: We aimed to characterize genomic BCR-ABL1 breakpoints and to identify SNPs in CML patients.
Methods: Two BCR-ABL1 positive cell lines (K562; JURL-MK1) and 48 CML patients who achieved a deep molecular response were included in this study. DNA was isolated from leukocytes of peripheral blood at diagnosis. We performed 2 rounds of mLR-PCR. In the 1st round, 1 forward primer located in BCR exon 13 and 10 primers located in intron 1 of ABL1 (Lange et al 1999) were used. LR-PCR products were obtained in 28/49 cases. The 2nd round of mLR-PCR was performed for the rest of samples using 1 BCR and 20 ABL1 primers (Krumbholz et al 2012, Ross et al 2010, Score et al 2010). LR-PCR products were fragmented and rapid library was prepared for 454 NGS technology (Roche Applied Science). NextGENe software (Softgenetics) was used for sequence analysis, breakpoints characterisation and SNP calling. NCBI database and reference sequences for BCR and ABL1 genes were used for breakpoints localization and SNP calling.
Results: Median length of LR-PCR products was 6 kb (range 1.5-10kb). NGS was performed in 41 samples. Characterized breakpoints were confirmed by Sanger sequencing. BCR breakpoints were located in intron 14 in 32/39 patients and in both cell lines, all carrying e14a2 mRNA, and in intron 13 in 7/39 patients with e13a2 mRNA. All ABL1 breakpoints were dispersed across intron 1. In BCR region upstream of the breakpoints, 17 annotated SNPs (1 SNP located in exon 13, 4 in intron 13 and 12 in intron 14) were detected among patients and cell lines with e14a2 mRNA (median 3 SNPs/patient or cell line, range 1-12). The frequency of minor alleles of detected SNPs varies from 0.5% to 30.7% in the 1000Genome phase 1 population (NCBI SNP database). Novel SNPs were identified in 3 patients with e14a2 mRNA in exon 13, intron 13 and exon 14. Interestingly, we did not detect any SNPs upstream of the BCR breakpoints among patients with e13a2 mRNA, except one with 3 SNPs detected. Based on SNP profiles in the BCR region we performed hierarchical clustering analysis showing 3 main distant clusters of patients; the cluster consisted of patients with e13a2 mRNA was distant to other 2 clusters which consisted of patients with e14a2 mRNA. In the downstream region of the breakpoints in intron 1 of ABL1, 51 different SNPs were identified in 12/39 patients and JURL-MK1.
Summary and Conclusion: Sanger sequencing is not suitable for sequencing of long PCR products, thus an alternative approach had to be sought for BCR-ABL1 fusion identification. The mLR-PCR followed by NGS accelerated the whole process. Moreover, this approach enabled to analyse long sequences downstream and upstream of the BCR-ABL1 fusion and to identify other sequence features. SNPs in introns may alter gene splicing and coding SNPs may alter protein conformation. Interestingly, we identified multiple SNPs upstream of the genomic breakpoints in BCR gene in all CML patients with e14a2 mRNA. No SNPs were observed in all but one patient with e13a2 mRNA. Based on the SNP profile in the BCR region upstream of the breakpoints, 3 main distinct patient clusters were formed. Further studies are warranted to find the potential association between the SNP profile, patient characteristics and outcome. Supported by IGA/NT11555 and the project for conceptual development of research organization (00023736) from the Ministry of Health of the Czech Republic.

P913

THE EFFECT OF DELAYED TKI TREATMENT ON CYTOGENETIC AND MOLECULAR RESPONSES: 8 YEAR FOLLOW-UP STUDY IN BOSNIA

A Kurtovic[1,*], A K Kozaric[2], S Kurtovic[3], V Bijedic[3], H Nefic[1], M Kozaric[4], F Colakovic[5], N Skobic Bovan[6]
[1]Department of Biology, Faculty of Natural Sciences, [2]Department of Pathology, [3]Hematology Clinic, [4]Department of Biology, Clinical Center of the University of Sarajevo, Sarajevo, [5]Hematology Clinic, Cantonal Hospital Zenica, Zenica, [6]Department of Internal Medicine, Clinical Hospital Mostar, Mostar, Bosnia and Herzegovina

Background: Due to the inadequate health care system in Bosnia, CML patients do not get TKI therapy immediately after diagnosis. Only 16% of patients received immediate TKI treatment (within 3 months of diagnosis) from 07/2005-12/2013. About 66% of patients received therapy after 14-month median wait period.
Aims: We systematically studied the effect of delayed TKI (imatinib and nilotinib) treatment on cytogenetic and molecular responses.
Methods: This is a multicenter retrospective cohort study of all CML patients (n=135) in Federation of Bosnia and Herzegovina from 07/2005-12/2013. Patients received imatinib (once daily 400 mg or 600 mg), nilotinib (twice daily 300 mg or 400 mg) or no TKI therapy. The cutoff date was 31.12.2013, on the basis of 18 month median time on nilotinib therapy. Patients were grouped based on the length of treatment delay: immediate (0-3 months), 4-6 months, 7-12 months, and >13 month delay. Patient data was collected and analyzed in SPSS v.18.
Results: We stratified patients (n=135) into following groups: immediate therapy (16%), 4-6 month wait (13%), 7-12 month wait (15%), >13 month wait (37%), and never received TKI therapy (18%). Basic cohort characteristics and distribution of EUTOS risk score in the studied groups were well balanced. The median duration of treatment for imatinib was 36 months and nilotinib 18 months. At 60 months, the estimated rate of survival was 0% for patients who never received TKI, 91% for immediate TKI treatment (0-3 months), 80% for patients who waited 4-6 months, 86% for patients who waited 7-12 months, and 64% for patients who waited >13 months ($p<0.001$). Cytogenetic responses had highly significant associations with delayed TKI treatment. At 12 months, complete cytogenetic response (CCyR) was achieved by 70% of patients with immediate TKI treatment (nilotinib or imatinib), compared to 25% of patients with >13 month wait ($p<0.001$). At 36 months, 92% of patients with immediate treatment achieved CCyR compared to 47% of patients with >13 month wait. Molecular responses also showed highly significant associations with delayed treatment. At 24 months, 56% of patients with immediate treatment achieved MMR, compared to 26% of patients who waited >13 months ($p<0.01$). Since patients were treated with two different TKIs, imatinib and nilotinib, we further categorized patients according to the treatment drug. CCyR of patients treated with imatinib alone showed significant differences. At 12 months, 67% of patients in the immediate imatinib treatment group achieved CCyR compared to 15% of patients in >13 month wait group ($p<0.005$). The achievement of MMR showed even more drastic changes. MMR at 12 months occurred in 53% of patients with immediate treatment compared to 0% of patients in >13 month wait group ($p<0.02$). The achievement of CCyR and MMR in patients treated with nilotinib as the first line showed no association with length of treatment delay. Patients who waited >13 months had same response rates as those who received immediate treatment (86% v. 75% at 6 months or 86% v. 80% at 12 months, respectively). Similarly, MMR rates in patients treated with nilotinib in different wait groups were indistinguishable. At 12 months, 43% of patients with immediate treatment achieved MMR compared to 50% of patients who waited >13 months.
Summary and Conclusion: Patients achieved much better CCyR and MMR on nilotinib than imatinib, regardless of the length of delay to therapy. Patients on imatinib had worse response rates if they waited for treatment. Our recommendation is that if treatment is delayed for more than 3 months, the preferred treatment drug is nilotinib.

P914

THE TYROSINE KINASE INHIBITOR AXITINIB TARGETS T315I-MUTANT BCR-ABL DRIVEN LEUKEMIAS IN VITRO AND IN VIVO

T Pemovska[1,*], M Kontro[2], G A Repasky[1], B W Murray[3], K Porkka[2], K Wennerberg[1]
[1]Institute for Molecular Medicine Finland (FIMM), University of Helsinki, [2]Hematology Research Unit, Helsinki University Central Hospital and University of Helsinki, Helsinki, Finland, [3]Oncology Research Unit, Pfizer Worldwide Research & Development, San Diego, United States

Background: The use of ABL1 kinase inhibitors has dramatically improved the outcome for chronic myeloid leukemia (CML) and Philadelphia-positive (Ph+) acute lymphoblastic leukemia (ALL) patients. However, resistance after treatment still poses a major clinical challenge. The most common resistance mechanism following treatment with first or second line therapy is the occurrence of a T315I mutation in the kinase domain of BCR-ABL1. Only one

clinically available ABL1 inhibitor, ponatinib, has been shown to target this gatekeeper mutation, but has recently been associated with significant adverse effects. Hence, there is an unmet need for new and improved therapies for patients with T315I BCR-ABL1 leukemias.
Aims: In this study we set out to functionally and molecularly profile BCR-ABL1 T315I-driven CML/Ph+ALL patient samples to understand the disease pathogenesis and identify novel therapies with a drug sensitivity and resistance testing (DSRT) platform covering 306 approved and investigational oncology compounds.
Methods: Mononuclear cells isolated from patient bone marrow were plated with drugs on 384-well plates. Each compound was tested for its effect on cell growth and survival in a 10.000-fold concentration range enabling the generation of dose response curves and by comparing to healthy donor mononuclear cells, selective drug sensitivity scores (sDSS).
Results: *Ex vivo* DSRT results of one CML and two Ph+ALL patient samples with the T315I mutation revealed a marked and specific sensitivity (IC50 30-40nM) to the tyrosine kinase inhibitor axitinib, originally developed as a VEGFR inhibitor. Strikingly, sensitivity to axitinib was higher in these T315I positive patient samples than in T315I negative CML or ALL patient samples or any other leukemic samples. Supporting the notion that axitinib is a direct T315I BCR-ABL1 inhibitor we observed that Ba/F3 cells transformed with T315I BCR-ABL1 were sensitive to axitinib while the same cells transformed with wild type BCR-ABL1 were not. Finally, we discovered that axitinib has been described to have selective binding towards T315I ABL1 compared to the wild type kinase (Kd 1.5 nM *vs*. 36 nM, respectively, Davis *et al.* 2011, Nat. Biotechnol. 29:1046-1051). Based on this information, the T315I CML patient mentioned above was compassionately treated with axitinib for 2 weeks resulting in a rapid 4-fold reduction of the mutated transcript levels in blood suggesting targeted *in vivo* activity of the drug.
Summary and Conclusion: In summary, we demonstrated that axitinib is a potent BCR-ABL1 T315I inhibitor both *in vitro* and *in vivo*. In light to the fact that axitinib is currently approved as a second line therapy for renal cell carcinoma and is well tolerated in patients, there is an opportunity to repurpose axitinib for Ph+ leukemia patients with T315I mutations with significantly shorter clinical development time.

P915

BCR-ABL1 KINASE DOMAIN MUTATION ANALYSIS USING AMPLICON DEEP SEQUENCING ON THE ION TORRENT PLATFORM

HE Foong[1,2,*], M Alikian[1,2], T Myint[1], P Foskett[1], D Milojkovic[2], J Apperley[2], L Foroni[1,2], G Gerrard[1,2]
[1]Imperial Molecular Pathology, Imperial Healthcare Trust, Hammersmith Hospital, [2]Cenre for Haematilogy, Faculty of Medicine, Imperial College London, London, United Kingdom

Background: *BCR-ABL1* mutation analysis is an important factor in CML therapy intervention. The majority of the mutations identified are associated to some degree with resistance to imatinib, which is the main therapy available upfront for CML patients. 2nd and 3rd generation tyrosine kinase inhibitors, which have been widely used as 2nd line following imatinib failure and recently have been approved as a first line therapy, have been shown to having selective inhibitory action on some mutations while being ineffective against others. T315I, F359V/C, F311L mutations for instance are associated with resistance to dasatinib whereas T315I, V299L, T317L/I, T315A, M351T show resistance to nilotinib. The most potent TKI inhibitor, ponatinib has shown an inhibitory effect on all mutations, including the pan resistant T315I mutation. However, its inhibitory effect has been shown to be compromised in the presence of compound mutations. The current gold standard method for mutations analysis is Sanger sequencing, which has a limit of detection of 10-20%. Although it is capable of detecting compound mutations present at levels below its limit of detection, it is incapable of discriminating whether these mutations are in-cis or in-trans –information important to understand the underlying complexity of these mutations. Additionally, Sanger seq is only semi-quantitative and relatively low throughput.
Aims: in the era of high throughput sequencing our aim is to validate the Ion Torrent PGM platform for feasibility, sensitivity and compatibility with the gold standard and implement the workflow in routine diagnostic service.
Methods: 32 clinical samples were included in the study. Samples were chosen on the basis of having either compound mutations or increasing mutational load in progressive samples identified by Sanger or pyro sequencing (n=23/32). Of these, 13/23 had compound mutations identified by Sanger and/or Pyrosequencing, 7/32 had mutations identified only by Sanger sequencing, 3/32 had mutations identified only by pyrosequencing. 6/32 had more than two compound mutations and 9/32 had no mutations identified by either method. We used 6 pairs of primers previously optimized for TKD mutation detection on the Roche GS-Junior platform as part of the IRON-II study. We used the Ion Plus Fragment Library kit and the Ion Xpress Barcode Adapters 1-16 Kit for library prep, Ion PGM Template OT2 400 Kit for templating and the Ion PGM Sequencing 400 Kit for sequencing. Data were analysed using the NextSeq software from sequence Pilot, JSI medical systems with predefined settings as a collaborative effort within the IRON-II study and a sensitivity of 1%, in addition to the Ion Reporter data analysis tool hosted by Life Technologies.
Results: There was a 100% concordance amongst results obtained by NGS *vs* Sanger and/or pyrosequencing. However, NGS detected low level mutations ranging from 2-4% in two patients, rendering them from single to compound mutation holders. The coverage was at least 2000 reads per mutation hotspot and the mutant alleles were at least 20 reads (1%) in either direction. Compound mutational status varied between cis and trans. There was no significant difference in the results obtained using both software, however the Ion Reporter software occasionally missed the F299L mutation, despite being at relatively high levels (~20%).
Summary and Conclusion: We demonstrate the feasibility and comparability of the assay we have developed on the Ion Torrent PGM next generation sequencing platform to be deployed in routine diagnostic labs providing this test. In addition, we emphasise the need for extensive standardization of settings depending on the software to be used for data analysis using appropriate quality controls.

Myelodysplastic syndromes - Clinical 2

P916

THE INFLUENCE OF DISEASE AND COMORBIDITY RISK ASSESSMENTS ON THE SURVIVAL OF MDS PATIENTS TREATED WITH 5-AZACITIDINE

A Molteni[1,*], L Borin[2], M Bernardi[3], A Pellizzari[4], A Freyrie [5], M Della Porta[6], M Nichelatti[7], E Ravano[1], M Riva[1], G Quaresmini[8], M Jacopo[9], D Caramazza[10], M Ubezio[6], S Guarco[5], F Gigli[11], R Greco[1], E Morra[1]

[1]Hematology, AO Niguarda Ca' Granda, Milan, [2]Hematology, Ospedale San Gerardo, Monza, [3]Hematology, Ospedale San Raffaele, Milan, [4]Hematology, Spedali Civili, Brescia, [5]Hematology, Ospedale Maggiore Policlinico, Milan, [6]Hematology, Policlinico San Matteo, Pavia, [7]Bio-statistics, AO Niguarda Ca' Granda, Milan, [8]Hematology, Ospedale Papa Giovanni XXIII, Bergamo, [9]Transfusion and Hematology, AO "Treviglio-Caravaggio", Treviglio, [10]Hematology, Ospedale di Circolo e Fondazione Macchi, Varese, [11]Hematology, Istituto Europeo di Oncologia, Milan, Italy

Background: The use of 5-azacitidine (5-aza) can prolong survival in patients (pts) affected by high-risk myelodysplastic syndrome (MDS), not candidate to allogeneic stem cell transplantation. The influence of the MDS specific comorbidity index on survival of these pts has been documented (Breccia, Haematologica 2012).
Aims: To evaluate if the current prognostic assessments of disease or comorbidity have an impact on the survival in this setting.
Methods: A retrospective analysis of MDS patients treated with 5-aza in 10 centers in Lombardia region was carried out. The disease risk indexes (IPSS, WPSS and IPSS-R) and the comorbidity MDS specific index (MDS-CI) were calculated at the moment of the beginning of 5-aza therapy. The Kaplan Meier method, followed by the logrank test was applied to evaluate the survival, starting from the beginning of treatment, in relationship to IPSS, WPSS, IPSS-R risk and MDS-CI risk.
Results: Data about 198 pts were collected. Median age was 70 (range 23-88). The median number of 5-aza courses administered was 6 (range 1-35). A response to the treatment (including the cases of "stable disease" maintenance) was achieved in 111 cases on 173 evaluable. The analysis showed that pts with an IPSS "high" risk at starting treatment time (evaluable in 43 pts) in comparison to pts with "intermediate-2" IPSS risk (104 pts), did not have different survival (p=0.164). On the contrary, a "very high" WPSS risk (evaluable in 42 pts) in relation to a WPSS "high" risk (85 pts) was associated to a shorter survival (p=0.049). In fact, median survival was 13.7 months for "very high" risk pts and 23.2 months for "high risk" pts. Furthermore, an IPSS-R "very high" risk at baseline (evaluable in 73 pts), in comparison to an IPSS-R "high" risk (41 pts), was associated to a strongly significant reduction in survival (p=0.0007, fig1). In this case median survival was 12.9 months for "very high" risk patients and 33.8 months for "high" risk patients. According to MDS-CI, the pts were stratified in 134 "low" risk cases, 42 "intermediate" risk cases and 11 "high" risk cases. The analysis showed that the MDS-CI category of membership did not influence the survival of these patients (p=0.672, fig 2).

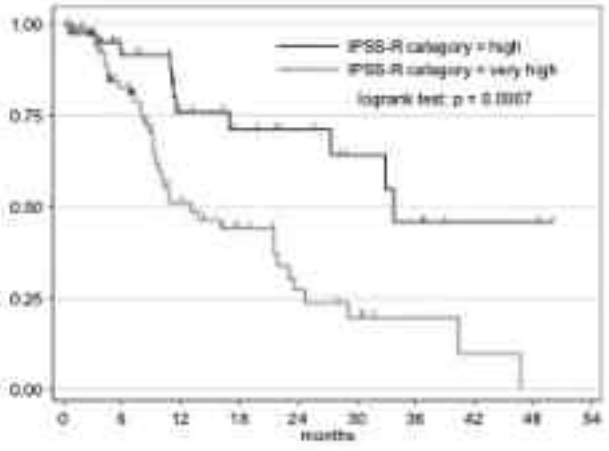

Figure 1.

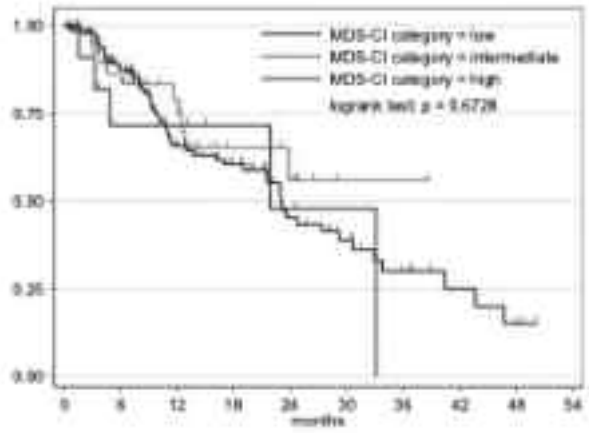

Figure 2.

Summary and Conclusion: Consistent with these data, identification of WPSS and, above all, IPSS-R risk category is useful to identify MDS pts who can have better outcome with 5-aza. The comorbidity assessment with MDS-CI did not influence the survival in the studied pts. This last result, in contrast to the other already quoted series, may be influenced by the preponderance of pts with a "low" MDS-CI risk in the described population.

Background: Iron-chelating therapy (ICT) is usually employed in transfusion-dependent myelodysplastic syndromes (MDS) with iron overload and lower risk disease. Indeed, with the exception of some studies focused on patients who undergo allogeneic stem cell transplantation, few specific data are currently available on the use of ICT, and in particular of the oral chelator Deferarisox (DFX), in higher risk MDS.
Aims: We aimed to evaluate practical use, efficacy, tolerability and possible effects on hematopoiesis of DFX in higher risk MDS treated in the real-life setting.
Methods: We retrospectively collected clinical data from 14 hematologic centers, all belonging to the two major Italian MDS registries (FISM and GROM) and to GIMEMA MDS Working Party. Overall, 58 patients (41 males, 17 females; median age 67 years, range 35-83) were evaluated. A well defined WHO diagnosis was obtained in 53 patients: RA (1.7%), RCMD (5.1%), RAEB-1 (19%), RAEB-2 (62%) and CMML (3.4%). R-IPSS at diagnosis was intermediate in 12.3%, high in 52.6%, and very high in 26.3% of patients, respectively. R-IPSS was not available in 5 patients. Median time from diagnosis to ICT was 10.5 months (range 0-159.5). The median number of red cell transfusions received before starting DFX was 24.5 (range 2-63), while the median levels of serum ferritin and Hb were 1688 ng/ml (range 460-7423) and 8.2 g/dl (range 6.5-10.8), respectively. Forty-one patients had previously received recombinant erythropoietin (13.4%), azacitidine (31%), or both (25.9%).
Results: DFX was administered orally at the median dose of 1000 mg per day (range 375-2500 mg), for a median time of 11 months (range 0.4-75). The initial

daily dose/kg was 5 mg in 8.8%, 10 mg in 42.1%, 20 mg in 47.4% and 30 mg in 1.7% of patients (mean dose: 14.7 mg/kg +/- 5.9). The dose was reduced in 10 patients and increased in 4 patients, due to intolerance or inefficacy, respectively. Eight patients (13.8%) showed grade 2 (5 renal, 3 gastrointestinal) and one patient (1.7%) developed grade 3 (gastrointestinal) toxicities. DFX was definitively interrupted in 7 patients (three renal and one gastrointestinal toxicities, three because of progressive disease). One patient stopped DFX after reaching normal ferritin values. In evaluable patients, median ferritin levels decreased from 1688 ng/ml at baseline (n. 55, range 460-7423), to 1396 ng/ml after one month of DFX treatment (n.47, 443-8513), to 1298 ng/ml at 6 months (n.36, 439-10112) and to 1198 ng/ml at 12 months (n.23, 198-4282) (Figure). Eight of 17 patients (47%) improved or normalized baseline increased ALT/AST levels under ICT. Thirty-one patients continued or started concomitant therapies with azacitidine, recombinant erythropoietin or lenalidomide during ICT and 4 patients received allogeneic stem cell transplantation after DFX. One patient evidenced a durable and complete trilineage response according to IWG criteria, without receiving any other active treatment in addition to DFX when hematological improvement occurred. With a median follow up of 27 months from diagnosis and 14 months after the start of ICT, median overall survival was 38 months and 24.1 months, respectively.

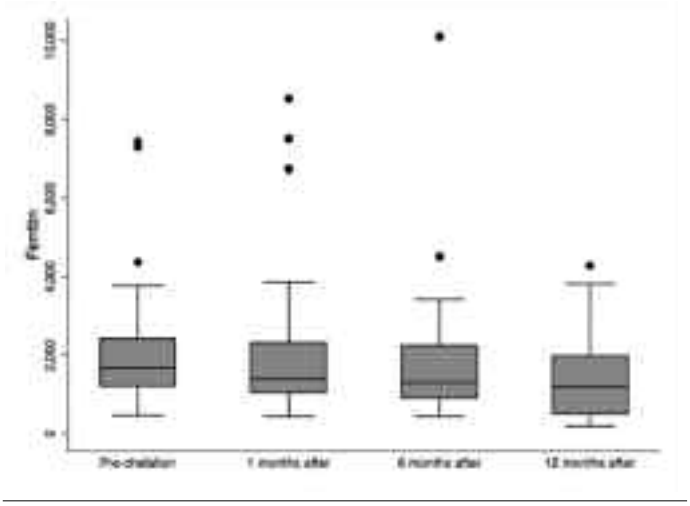

Figure 1.

Summary and Conclusion: This study specifically assessed the role of DFX in higher risk MDS patients. Though the number of patients is quite limited, in this real-world evaluation we showed that such a treatment is feasible, may be effective in lowering serum ferritin levels and, probably, in improving hepatic function. DFX may be safely administered also in patients who are receiving or are planned to receive other active therapies, including allogeneic stem cell transplantation. The effects on survival and the possibility that, as seen in lower risk MDS, DFX may induce hematological responses in higher risk cases as well, remains to be better investigated in a larger, prospective study.

P918

MYELODYSPLASTIC SYNDROMES: AN INTEGRATED MOLECULAR/ CYTOGENETIC WORKUP FOR A CORRECT PATIENTS' RISK STRATIFICATION

S Galimberti[1,*], E Ciabatti[1,2], S Grassi[1], MI Ferreri[3], A valetto[3], F Guerrini[1], A Guazzelli[3], A Azzarà[1], MR Metelli[4], P Simi[3], M Petrini[1]
[1]clinical and experimental medicine, hematology, pisa, [2]GenOMEC, University of Siena, Siena, [3]AOUP, molecular cytogenetics, [4]AOUP, hematology, pisa, Italy

Background: In MDS, cytogenetics is fundamental for the risk stratification, but in this setting non-informative karyotypes represent up to 15-20% of cases. The aCGH is able to detect new abnormalities in up to 80% of cases already tested by conventional karyotype, but it is not enclosed in the routinary diagnostic workup. More recently, the whole genome sequencing methods detected in MDS relevant mutations involving TET2, ASXL1, EZH2, CBL, IDH1/IDH2, DNMT3A. TET2 mutations have been related to a better survival in patients receiving 5-azacitidine, whereas ASXL1, TP53, and EZH2 mutations have been associated with worse outcome. Moreover, down-regulation of RPS14, associated with a good response to lenalidomide, characterizes also an elevated percentage of no 5q- MDS, with different prognostic significance in different risk categories. Finally, high WT1 expression levels have been related to shorter OS.
Aims: The aim of the study was to determine the adjuctive value offered by FISH, aCGH, and somatic mutation assays in respect of the conventional cytogenetics and to determine if the proposed new diagnostic workup will reach good sensitivity and specificity, necessary for a routinary application in the "real-life".
Methods: In this study, we assessed 50 new MDS cases by different techniques: a) conventional cytogenetics; b) FISH for chromosome 5, 7, PDGFRA, and PDGFRB rearrangements; c) aCGH; d) specific real-time PCR assay for ASXL1, EZH2, TP53, and TET2 gene mutations.
Results: After Giemsa banding, one third of our samples showed chromosomal aberrations, including +8, del(7), del(5), -Y, +6, del(13), +14, del(20), and complex karyotypes. After the FISH analysis, 17% of patients showed chromosomal abnormalities, including 5q- and del(13) that were not detected by the Giemsa banding. The aGCH allowed to detect quantitative chromosomal aberrations in 46% of cases (del(13), -7, del(12), del(16), del(17), del(11), del(8), dupl(14), 5q-). After the RT-PCR assessment, 22% of patients resulted mutated for TP53 gene; the involved nucleotides were 844 (C>T), 733 (G>A), 742 (C>T), and 853 (G>A). Four of these TP53 mutated patients showed normal karyotype, and resulted unmutated also by FISH and aCGH. The WT1 gene was over-expressed (in comparison to healthy subjects) in the 25% of the assessed cases; 50% of these patients presented with RAEB and IPSS intermediate-2/high and had a worse outcome. The half of these patients had a normal karyotype. The RPS14 gene was under-expressed in 77% of cases, analogously to the percentage already reported by our group. Clinical correlations and evaluation of the outcome of these patients are being performed at this time, but we already reported that lower RPS14 and higher WT1 levels did negatively impact on the outcome.
Summary and Conclusion: In conclusion, these data sustain the fundamental role of the integrated diagnostic work-up for MDS: indeed, 2 cases, correctly classified as affected by the 5q- syndrome after the FISH analysis, received lenalidomide. In one third of the remaining cases, the identification of TP53 and ASXL1 mutations, in addition to the abnormalities of chromosome 17, 8, 11, and 16 detected after aCGH, allowed us to scoring patients as at higher risk. These patients are now candidate to receive azacitidine.

P919

PROGNOSTIC IMPLICATION OF IPSS AND IPSS-R FOR PATIENTS WITH LOWER-RISK MDS TREATED WITH HYPOMETHYLATING AGENTS

JH Moon[1,*], SK Sohn[1], A Jae Sook[2], HJ Kim[2], MK Song[3], JS Chung[3], SN Lim[4], SH Bae[5]
[1]Hematology/Oncology, Kyungpook National University Hospital, Deagu, [2]Hematology/Oncology, Cheonnam National University Hwasun Hospital, Cheonnam, [3]Hematology/Oncology, Busan National University Hospital, [4]Hematology/Oncology, Inje University Paik Hospital, Busan, [5]Hematology/Oncology, Daegu Catholic University Medical Center, Deagu, Korea, Republic Of

Background: Prognosis of patients with myelodysplastic syndrome (MDS) can be calculated using a number of scoring systems. The most commonly used system is the International Prognostic Scoring System (IPSS), and the treatment decision using hypomethylating agents (HMA) has been based on IPSS risk groups. The hypomethylating agents (HMA) are usually recommended for patients with lower-risk MDS who is not responsive to other therapies. However, some of the patients showed the deteriorating course even though they were categorized to lower risk IPSS, and the role of HMA for these patients are still on debate.
Aims: This study was conducted to know whether it is rational to treat HMA for patients with IPSS lower-risk (low and intermediate-1), and IPSS-R further discriminates the prognosis of lower-risk patients treated with HMA.
Methods: From 2006 Jan to 2012 Dec, the data of 334 patients who were diagnosed with IPSS lower risk (39 low and 295 intermediate-1) were retrospectively reviewed. The prognosis of lower-risk by IPSS and IPSS-R were analyzed in terms of overall survival (OS) and prognostic power was calculated with time-dependent Cox-hazard models. To define the role of HMA for patients with lower-risk IPSS, we categorized the lower risk patients into No-HMA group, early HMA group (HMA within 2 mo.), and late HMA group (HMA after 2 mo).
Results: Among 334 lower-risk patients (39 low and 295 intermediate-1), 195 patients (58.4%) were treated with HMA (HMA group) and 139 (41.6%) best supportive care (non-HMA group). Median time to HMA treatment was 43 days (range 0-1778 days). 3yr-OS rate was not significantly different between HMA group (43.1±4.2%) and non-HMA group (62.3±5.9%) (p=0.099). Early HMA treatment (3yr-OS 36.4±5.4%) didn't show survival benefits compared to late HMA group (54.6±6.3%) or no-HMA group (62.3±5.9%) (p=0.003). Furthermore, HMA response (CR/PR/HI) didn't guarantee OS benefits: 3yr-OS of 45.2±7.4% in responders (CR/PR/HI, n=74) and 43.4±5.0 in non-responders (SD/PD, n=121) (p=0.239). Among 39 patients with IPSS low, 11 patients (28.2%) were revised into IPSS-R very low, 24 (61.5%) into low, 3 (7.7%) into intermediate, and 1 (2.6%) into high. Among 295 patients with IPSS intermediate-1, 4 patients (1.4%) were revised into IPSS-R very low, 84 (28.5%) into low, 133 (45.1%) into intermediate, 71 (24.1%) into high and 3 (1.0%) into very high. IPSS-R could further discriminate the IPSS lower-risk patients with regard to OS: 3yr-OS rates of 100% in very low, 64.5±5.9% in low, 46.1±5.5% in intermediate, 26.1±6.6% in high, and 0% in very high (p<0.001). The survival benefits of HMA for lower risk groups (very low and low) defined by IPSS-R (n=123) was

not defined in the current study, where 3yr-OS was 83.8±6.4% in no-HMA group (n=60) *vs.* 60.5±7.1% in HMA group (n=63) (p=0.198).
Summary and Conclusion: The use of IPSS as a therapeutic decision making for HMA among lower-risk (low and intermediate-1) patients needs further investigation. The prognosis of the patients with lower-risk IPSS was successfully refined by IPSS-R, where the IPSS intermediate-1 risk was heterogeneous group, which subdivided into very low to very high by IPSS-R. However, the beneficial effect of HMA for patients with lower-risk MDS defined by IPSS-R (very low and low) also needs to be elucidated in the future studies.

P920

HIGHER BONE MARROW LGALS3 EXPRESSION PREDICTS FAVORABLE PROGNOSIS IN ADULT PATIENTS WITH MYELODYSPLASTIC SYNDROME

HA Hou[1,*], YC Hung[1], WC chou[1], YY Kuo[2], CY Liu[3], LI Lin[4], CY Chen[1], MC Liu[5], CW Liu[5], JL Tang[1], M Yao[1], SY Huang[1], BS Ko[1], SC Hsu[1], SJ Wu[1], W Tsay[1], YC Chen[1], HF Tien[1], FT Liu[6]
[1]National Taiwan University Hsopital, [2]Graduate Institute of Oncology, NTU, [3]Biostatistics Consulting Laboratory, Department of Nursing, National Taipei College of Nursing, [4]Department of Clinical Laboratory Sciences and Medical Biotechnology, College of Medicine, [5]Pathology, National Taiwan University Hsopital, [6]Institute of Biomedical Sciences, Academia Sinica,, Taipei, Taiwan, Republic of China

Background: Galectin-3, a member of the *β*-galactoside-binding gene family, is a multifunctional protein implicated in cell adhesion, proliferation, and apoptosis. Alterations of galectin-3 expression are often seen in cancers and may contribute to angiogenesis, tumorigenesis and cancer progression. However, the clinical implication of Galectin-3 expression in myelodysplastic syndrome (MDS) remains unclear.
Aims: We aimed to investigate the clinical relevance of Galectin-3 expression in the patients with myelodysplastic syndrome.
Methods: In this study, we sought to investigate the prognostic relevance of *LGALS3*, the gene encoding Galectin-3, in 266 adult patients with newly diagnosed primary MDS, including 196 in original cohort and 70 in validation cohort. Thirty healthy transplantation donors were used as normal controls. *LGALS3* expression in bone marrow (BM) mononuclear cells was analyzed by quantitative real-time polymerase chain reaction. The results were correlated with FAB/WHO subtypes, clinical features, cytogenetics, other genetic alterations, and clinical outcome.
Results: *LGALS3* expression was higher in MDS patients than that of normal controls (P=0.0343). The median value of BM *LGALS3* expression in MDS patients was used as the cut-off point to define lower- and higher-expression groups. Patients with higher *LGALS3* expression had lower platelet count than those with lower expression (P=0.039). There was no difference in other clinical parameters, including age, sex, hemoglobin level, white blood cell count, and lactate dehydrogenase level between the two groups. Higher *LGALS3* expression occurred more frequently in patients with refractory anemia (RA) and RA with ring sideroblasts (RARS) than in those with RA with excess blasts (RAEB) and RAEB in transformation (RAEBT) (P<0.0001) based on the FAB classification. Regarding international prognosis scoring system (IPSS) classification MDS patients harboring higher *LGALS3* expression had higher incidence of lower-risk characteristics. However, there was no statistical difference of *LGALS3* expression in different cytogenetic groups or mutational profiles. With a median follow-up time of 57.7 months (range 0.1 to 217.3), the patients bearing higher *LGALS3* expression had lower probability of disease transformation to acute leukemia compared to those bearing lower *LGALS3* expression (P<0.001). Moreover, the patients with higher *LGALS3* expression had better overall survival (OS) than those with lower expression (median 63.1 months *vs.* 21 months, P=0.003). Similar result could be demonstrated in the 161 patients diagnosed according to WHO classification (median 72.2 months *vs.* 23.5 months, P=0.022). We distinctly identified higher *LGALS3* expression as an independent favorable prognostic factor for OS (relative risk 0.639; 95% CI, 0.421-0.970, P=0.036) irrespective of age, sex, cytogenetics and IPSS classification. This result was also validated in an independent cohort (n=70).
Summary and Conclusion: MDS patients with higher *LGALS3* expression had distinct clinic-biologic features and favorable outcome. BM *LGALS3* expression may serve as a new biomarker to risk stratify the MDS patients.

P921

VALUE OF THE MULTIPARAMETRIC FLOW CYTOMETRY IN MYELODYSPLASTIC SYNDROMES AND CHRONIC MYELOMONOCYTIC LEUKEMIA UNDER HYPOMETHYLATING AGENT THERAPY

V Barcala[1], M Iastrebner[2,*], J Arbelbide[3], M Tamashiro[2], D Fantl[3], E Nucifora[3]
[1]Laboratory / Flow Cytometry, CITOMLAB, [2]Hematology, Sanatorio Sagrado Corazón / OSECAC, [3]Hematology, Hospital Italiano de Buenos Aires, Ciudad de Buenos Aires, Argentina

Background: Clinical response criteria published by the International Working Group (IWG) are mainly based on cytomorphological changes, but in real life, it is very common to see inter-observer variability. Multiparametric Flow Cytometry (MFC) should allow physicians to systematize and standardize this assessment in Myelodysplastic Syndromes (MDS) and Chronic Myelomonocytic Leukemia (CMML).
Aims: To analyze, by using MFC, immunophenotypic changes that occur during hypomethylating (HMT) agent therapy in MDS and CMML.
Methods: This study included MDS and CMML adult patients (pts) under hypomethylation, and used FAB, WHO, IPSS and IWG classifications. Two bone marrow samples were taken, the first one at diagnosis, and the second, after the 4th cycle of treatment. An eight-color MFC and a specific MDS panel validated by Euroflow and Infinicyt® program were applied. Granulocytic maturation was classified into 3 groups according to precise stops or blocking maturation observed in myeloblasts (stage 1), in promyelocytes or metamyelocytes (stage 2), and without any blocking (stage 3). Blasts count (CD34), peripheral cytopenia, clonal cytogenetic evolution, AML progression, and mortality rate were also studied.
Results: Twenty-six pts with MDS (16) and CMML (10) were assessed. Response to HMT were: CR 9 (35%), PR 5 (19%), and No Response (NR) 12 (46%); the mean number of cycles received was 9 (range 4-22). CD34 precursors study confirmed an increase in NR group: 5.66% (range 0.26 - 15.85), while PR and CR groups showed 2.46% (range: 0.61 - 6.59%) and 1.68% (range 0. 13 - 9.38) respectively. Responders showed a drop in blocking maturation and an increase in mature neutrophils (from 44 to 66%), and those NR patients kept blocking maturation (from 75 to 62%). Non Responder CMML patients increased blocking maturation, specifically in monocyte lineage (from 33 to 50%), and there were no changes during treatment in CR or PR CMML patients.
Summary and Conclusion: The use of MFC proved to be objective and reproducible by standards. Immunophenotypic changes during HMT treatment in MDS and CMML were closely correlated with clinical response according to IWG.

P922

CLINICAL VALUE OF MONOSOMAL KARYOTYPE AND COMPLEX KARYOTYPE AS PROGNOSTIC PARAMETER IN PATIENTS WITH IPSS INTERMEDIATE-2 AND HIGH RISK MYELODYSPLASTIC SYNDROMES TREATED WITH AZACITIDINE

MK Song[1,*], JS Chung[2], JH Moon[3], JS Ahn[4], IC Song[5], J Hong[6], GW Lee[7], HJ Shin[1]
[1]Hematology, [2]Pusan National University Hospital, Busan, [3]Hematology, Kyungpook National University Hospital, Daegu, [4]Hematology, Chonnam National University Hwasun Hospital, Hwasun, [5]Hematology, Chungnam Nastional Ujnversity Hospital, Daejon, [6]Hematology, Gachon University Gil Medical Center, Incheon, [7]Hematology, Gyeong-Sang National University Hospital, Jinju, Korea, Republic Of

Background: Azacitidine (AZA) is standard care in patients with MDS not allow allogeneic stem cell transplantation. Rencetly, chromosomal abnormality (CA) including complex karyotype (CK) or monosomal karyotype (MK) is known to be associated with clinical outcome in myelodysplastic syndrome (MDS).
Aims: The present study was investigated which prognostic factor including CAs would predict the response and survival in patients with international prognostic scoring system (IPSS) higher risk (intermediate-2, and high risk) MDS treated with AZA.
Methods: Patients with IPSS higher risk MDS treated with AZA were enrolled. CK was defined as the presence of three or more numerical or structural CAs. MK was defined as the presence of two or more distinct autosomal monosomies or single autosomal monosomy with at least one additional structural CA.
Results: A total of 243 patients were enrolled. Median follow-up time was 24.2 months Median age was 65 years. Median cycle of AZA treatment was 6 cycles and overall response rate was 57.2 %. CK was present in 124 patients and MK was 90 in patients. -5/del(5q) was identified in 124 patients, and -7/del(7q) was 35 patients. In the whole patients, bone marrow blast 15 or more percent, and CK were associated with poorer response (BM blast 15 or more percent, *p*=0.038; CK, *p*=0.007) and OS (BM blast 15 or more percent, p<0.001; CK, p<0.001), independently. Although MK in CK group was not associated with the outcome, non-MK status in non-CK group reflected favorable OS (*p*=0.005). According to number of CAs, the group including more than 3 CAs was associated with worst OS (group including less than three CAs *vs*. only three CAs, *p*=0.001; group more than three CAs *vs*. only three CAs, *p*=0.001).
Summary and Conclusion: CK, but not MK was an important prognostic parameter associated with worse outcome. However, MK in non-CK status may predict poor survival. In Addition, more high number of CAs was associated with poorer survival.

COEXPRESSION OF CD7 AND LINEAGE INFIDELITY OF MYELOID PRECURSORS CORRELATES WITH RESPONSE TO AZACITIDINE IN IPSS HIGH RISK MDS PATIENTS

E Cannizzo[1,*], S Bencini[1], F Mannelli[1], A Valencia[1], A Sanna[1], E Masala[1],

A Rossi[1], F Buchi[1], A Bosi[1], D Gargano[2], V Santini[1]
[1]Experimental and Clinical Medicine Department, University of Florence, [2]SOD Diagnostica Genetica, AOU Careggi, Florence, Italy

Background: Flow Cytometry (FC) has been recommended by ELN guidelines as an important co-criterion in diagnosis of myelodysplastic syndromes (MDS). Very recently, the absence of immunophenotypically aberrant myeloid progenitors has been correlated with good response to Epo and azacitidine (AZA). In general, association of FC with other parameters such as cytogenetics, morphology, response to therapies, has been evaluated as a FC scoring considering different immunophenotipical anomalies. However, little is known about a specific FC feature in poor prognosis MDS patients (i.e complex karyotypes and non-responders to AZA therapy).
Aims: In this study, we evaluated the FC features of 56 high risk MDS patients undergoing AZA therapy. We stratified them according to cytogenetic subgroups to evaluate possible differences in FC parameters and their predictive role for AZA response.
Methods: We evaluated 56 consecutive patients with higher-risk MDS (IPSS: Int-1, n=8 ; Int-2: n=33; High: n=15) treated with AZA (75 mg/m2/d x 7d, q28d). FC and cytogenetics were studied prior to AZA treatment and at the first evaluation post-therapy. Response to AZA was evaluated according IWG 2006 criteria. We classified our patients in four cytogenetic subgroups: chromosome 7 anomalies (n=5), complex karyotype(n=11), trisomy 8 (n=10), other intermediates (n=4) and normal karyotype (n=26). FC features analyzed were: 1) percentage of granulocytes, monocytes, erythrocytes and myeloid progenitors, 2) maturation pattern of granulocytes, monocytes and erythrocytes, 3) expression of lineage infidelity markers on granulocytes, monocytes and myeloid progenitors, 4) upper or lower expression of normal myeloid markers on all populations and abnormal (often lower) granularity in granulocytes, expressed as low SSC. Acquisition of flow data was performed on a FACS Canto II (Becton Dickinson).
Results: We observed that the expression of lineage infidelity markers (T/NK lineage markers, such as CD7, CD56 or TdT) on myeloid progenitors was a common feature on all patients with complex karyotype. After 6 months of AZA therapy, 40% of the patients achieved a response to AZA and 60% did not. A constant feature observed in non-responder patients was the expression of T/NK lineage infidelity markers. In particular, CD7 was expressed by myeloid progenitors half of these patients. This characteristic was present prior and after AZA treatment. This is in line with what observed recently (Alhan, et al 2014): moreover, in our group of MDS cases, generally aberrant markers on progenitor cells were significantly more frequent in non-responders patients. Abnormal maturation pattern on granulocytes and erythrocytes, together with an abnormal granularity on granulocytes (SSC low) were equally present in non-responder and responder cases.
Summary and Conclusion: We confirm here that the presence of abnormal myeloid progenitors is associated with unfavorable response to AZA in higher risk MDS. In particular, we observed that all non-responder MDS patients expressed lineage infidelity markers on myeloid progenitors, and indeed CD7 was the most frequent marker detected. This observation deserves further analysis and physio-pathological interpretation. We also demonstrated that MDS cases presenting with complex karyotype constantly expressed T/NK markers.

P924

A PHASE II STUDY EXPLORING THE FEASIBILITY OF AZACITIDINE AND LENALIDOMIDE USE (COMBINATION *vs* SEQUENTIAL TREATMENT) FOR HIGHER-RISK MYELODYSPLASTIC SYNDROMES (IPSS RISK: HIGH OR INT-2)

Salvatore, Pesaro, Italy

Background: Azacitidine (AZA) is able to induce hematologic responses in 50-60 % of patients (pts) with Myelodysplastic Syndromes (MDS) and moreover to prolong survival in higher risk MDS pts. However, there is a clear unmet need to improve the clinical outcome of high-risk MDS pts, as the duration of therapeutic response to AZA is limited, with a median survival advantage of only 9.5 months. Lenalidomide (LEN), approved for low-risk MDS with del(5q), also showed some activity either in MDS without del(5q), or in del(5q) acute myeloid leukemia (AML). Recently, several studies have evaluated the efficacy and safety of combining, in high-risk MDS pts, AZA with LEN, either administered concurrently *(Sekeres, 2010; 2012)*, or sequentially *(Platzbecker, 2013)*, in both cases showing promising results, although in a limited number of pts.
Aims: To evaluate the feasibility of the combination AZA + LEN *vs* the sequential use of AZA and LEN in high risk MDS (IPSS score risk : High or INT-2) pts. Primary endpoint: ORR, defined as the Rate of Complete Remission (CR), Partial Remission (PR) and Hematological Improvement (HI), following the International Working Group (IWG) criteria *(Cheson, 2006)*.
Methods: This is a randomized, phase II, multicenter, open label study, including pts with MDS (according to WHO 2008 classification) with International Prognostic Scoring System (IPSS) risk High or Intermediate-2, without previous treatment with AZA or LEN. **ARM 1 (combined treatment)**: AZA: 75 mg/m^2/day (days 1-5) I.C. + LEN: 10 mg/day (days 1-21), orally, every 4 weeks. **ARM 2 (sequential treatment):** AZA: 75 mg/m^2/day (days 1-5) I.C. + LEN: 10 mg/day (days 6-21), orally, every 4 weeks. The treatment for both arms was planned for 8 cycles (32 weeks) in the absence of disease progression or unacceptable toxicity. A sample size of 44 pts was planned.
Results: From March 2013, 34 pts (19 males), with a median age of 72 (48-83 yrs) were enrolled, from 13 hematologic italian Centers. At baseline, WHO diagnosis was: Refractory Cytopenia with Multilineage Dysplasia (RCMD): 3 pts; Refractory Anemia with Excess of Blasts-1 (RAEB-1): 8 pts; RAEB-2: 21 pts; MDS-unclassified (MDS-U): 2 pts; IPSS-risk was: Intermediate-2: 27 pts; High: 6 pts; not determined (N.D.) (because of lack of cytogenetic data): 1 pt. Karnofsky Performance Status was: 100%: 12 pts; 90%: 9 pts; 80%: 7 pts; 70%: 2 pts; 60%: 4 pts. 21 pts were transfusion-dependent at baseline. 15 pts were randomly assigned to ARM 1, and 19 pts to ARM 2. At the time of this analysis, 15/34 pts (44.1%) completed ≥ 6 cycles of treatment, and are evaluable for response. 11/15 pts (73.3%) showed a favourable response to treatment, following IWG criteria: 2 pts achieved CR, 2 pts attained PR, and 7 pts showed HI, while the 4 non responder pts maintained a Stable Disease (SD). Responder pts were 7/8 (87.5%) in ARM 1, and 4/7 (57.1%) in ARM 1, respectively. Median time to response: 2 (2-7) months. 4 pts showed a >100% increase of platelet count after 1st cycle. A significant toxicity (grade >2) was observed in 10/34 (29.4%) pts. 14/34 pts (41.2%) had a dose reduction of LEN because of hematologic or non-hematologic toxicity.
Summary and Conclusion: Our results, although preliminary, seem to confirm the feasibility of the combination AZA + LEN in high-risk MDS pts. More data are needed in order to compare the efficacy and safety of combined *vs* sequential treatment. Moreover, a possible relationship with signal transduction pathways will be evaluated.

P925

IMPACT OF GRAFT-VERSUS-HOST DISEASE ON OUTCOME OF ALLOGENEIC HEMATOPOIETIC STEM CELL TRANSPLANTATION FOR LOW-RISK MYELODYSPLASTIC SYNDROMES

Background: Allogeneic hematopoietic stem cell transplantation (allo-HSCT) is a treatment option for low-risk myelodysplastic syndromes (MDS) patients with severe cytopenia or poor prognostic factors. A previous study reported that low-risk MDS patients had a low relapse rate and the primary cause of transplant failure among these patients was non-relapse mortality (NRM). It is thus considered that the graft-*versus*-MDS effect is limited and the development of graft-*versus*-host disease (GVHD) results in a worse transplant outcome. However, the impact of GVHD on allo-HSCT for low-risk MDS patients remains unclear.
Aims: With this background, we conducted a retrospective analysis to elucidate the influence of GVHD on outcome for low-risk MDS patients receiving allo-HSCT.
Methods: Clinical data were collected from the registry database of the Japan

Society for Hematopoietic Cell Transplantation. Low-risk MDS was defined as refractory anemia or refractory anemia with ring sideroblasts according to the FAB classification. Patients with low-risk MDS aged over 15 years, who underwent allo-HSCT for the first time between January 1993 and December 2011, were extracted from the database the Japan Society for Hematopoietic Cell Transplantation. Patients who did not achieve neutrophil engraftment were excluded. Effects of acute and chronic GVHD on OS, relapse and NRM were analyzed using landmark analysis at days 60 and 150, respectively. To evaluate the association of patient characteristics with GVHD, Cox proportional hazards model was used for multivariate analyses.
Results: There were 431 patients with low-risk MDS who received first allo-HSCT. Of those, 397 patients achieved neutrophil engraftment. The median age was 44 years (range 16-72 years). There were 232 males and 165 females. Grade II-IV acute GVHD and chronic GVHD were observed in 152 and 154 patients, respectively. Grade II-IV GVHD significantly increased NRM (p<0.001), leading to worse OS (p<0.001). The 3-year OS, cumulative incidence of relapse and NRM in patients with and without grade II-IV acute GVHD were 64.0, 2.6 and 31.1% and 76.9, 7.0 and 15.0%, respectively. Chronic GVHD did not affect OS, relapse and NRM. The 3-years OS, cumulative incidence of relapse and NRM of patients with and without chronic GVHD were 77.6, 5.1 and 17.2% and 80.4, 3.6 and 14.0%, respectively. In multivariate analysis, grade II-IV acute GVHD was associated with high NRM and poor OS and chronic GVHD was not associated with OS, relapse and NRM after adjusting for age, gender, donor source, HLA mismatch, conditioning regimen, GVHD prophylaxis, previous transfusion amount, gender mismatch, ABO mismatch and disease duration before allo-HSCT. Multivariate analysis revealed that predictive factors for grade II-IV acute GVHD were donor source, unrelated donor bone morrow and intermediate or poor cytogenetic risk category.
Summary and Conclusion: This study showed that grade II-IV acute GVHD had an adverse impact on allo-HSCT for low-risk MDS patients. These results suggest intensive GVHD prophylaxis might be required after allo-HSCT for low-risk MDS patients.

P926

IMPACT OF TP53 MUTATION ON OUTCOME OF MDS PATIENTS UNDERGOING ALLOGENEIC TRASPLANT

M Díez Campelo[1,2,*], J C Caballero[3], M del Rey[4], K Janusz[4], E Lumbreras[4], M Abáigar[4], C Robledo[4], A Jeréz[5], D Valcárcel[6], C Calderón-Cabrera[7], J M Hernández-Rivas[1,4], M C del Cañizo[1,8]
[1]Hematology, Hospital Universitario de Salamanca, [2]Biología molecular y celular en hemopatías, IBSAL, [3]Hematology, IBSAL, Hospital Universitario de Salamanca, [4]Unidad de Diagnóstico Molecular y Celular del Cáncer, IBSAL, IBMCC-Centro de Investigación del Cáncer (USAL-CSIC), Salamanca, [5]Hematology and Oncology, Hospital Universitario Morales Meseguer, Murcia, [6]Hematology, Hospital Universitario Vall d´Hebron, Barcelona, [7]Hematology, Hospital Universitario Virgen del Rocío, Instituto de Biomedicina de Sevilla (IBIS)/Universidad de Sevilla, Sevilla, [8]Área de Terapia Génica y celular, IBSAL, Salamanca, Spain

Background: Although new agents have been approved for the treatment of MDS, the only curative approach for these patients is allogeneic hematopoietic stem cell transplantation (HSCT). Nevertheless, in these patients this aproach only obtain 40-60% of overall survival. Several prognostic factors have demostrated to impact on trasplant outcome (blast percentage, cytogenetics, age, etc...). Somatic mutations in MDS have recently been analyzed in order to confirm clonality and also prognostic impact in those patients. In this regard, *TP53* mutated gene is present in MDS in less than 10% of patients and is associated with advanced disease and high risk features.
Aims: Impact on outcome of the mutational status of *TP53* have not been analized and is the purpose of the present study.
Methods: We have retrospectively analyzed the results of HSCT in 67 MDS patients (out of a 100 patient series) from 4 centers in Spain in order to define if the mutational status of *TP53* gene could have impact on clinical evolution after transplantation. The samples from these patients were collected 1 month prior to transplant. The genomic DNA from mononuclear bone marrow cells was screened for somatic mutations in *TP53* gene. The study was performed by NGS on a GS Junior Instrument (Roche Applied Science) according to an amplicon sequencing design. For each sample, seven exons (5-11) were amplified from 280 ng of DNA with preconfigured primer plates provided within the IRON II study network. Data were analyzed for sequence alignment and variant detection using the Sequence Pilot software version 3.5.2 (JSI Medical Systems) and GS Amplicon Variant Analyzer software, versions 2.7 and 2.9 (Roche Applied Science). Minimun coverage of sequenced exons was 100 reads and the sensitivity of variant detection was set to a lower limit of >2% for bidirectional reads. Overall survival (OS) and relapse-free survival (RFS) were calculated using the Kaplan-Meier method. The log-rank test was used for comparisons of Kaplan-Meier curves and multivariate analyses were performed using logistic Cox regression analysis. P value was considered significant if it was less than 0.05 and the multivariate analysis included all variables that in the univariate analysis had P value less than 0.1. All calculations were done using SPSS 18.0.
Results: Median age of patients was 51 years (range 22-70 years), 75% of them were "de novo" MDS. Regarding IPSS risk, 47% of them were included in the low and intermediate-1 risk while 53% were in the intermediate-2 and high-risk category. Seventy one percent of patients had received treatment (Azacitidine 35% and intensive chemotherapy 65%) before transplant. Disease status at transplant was stable disease in 30% (no treatment), CR in 24%, PR in 13%, NR in 21% and progression in 10%. The source of the HSCT was PB in 94% of patients, 66% received matched related donor and HLA was identical in 81% of the patients. Most of them received reduced intensity conditioning regimen (68%). Mutational status of *TP53* was tested in the pre-transplant evaluation, 11 patients (21%) were mutated and 42 (79%) were not mutated. After a median follow up of 1.4 years, median OS at 1 and 2 years was 64 and 54% and RFS was 78% and 76%, respectively (median not reached). Mutational status of *TP53* at the time of the transplant setting trends to impact on survival in the univariate analysis, median OS for patients with mutated gene was 0.6 years *vs* not reached for patients without mutated *TP53* (OS at 1y 62% *vs* 49% for patients without *vs* mutated *TP53* gene, p=0.2). In the multivariate analysis, *TP53* status, cytogenetics, IPSS-R, FAB and previous treatment impact on OS. Regarding relapse free survival, the presence of mutated *TP53* also trend to have an impact in the univariate analysis, RFS of 86% among patients without mutated *vs* 60% for patients with mutated gene (p=0.2).
Summary and Conclusion: The present study suggests that mutational disease status pre-transplant (*TP53* gene) as well as disease characteristics could have a significant impact on transplant outcome. Uploaded analysis of 100 patients and mutational status at different time points could be ready to be presented at the meeting.

ISOCHROMOSOME 17Q10 IN MYELOID NEOPLASMS IS FREQUENTLY ASSOCIATED WITH MULTIPLE MUTATIONS AND TRANSFORMATION TO ACUTE MEGAKARYOBLASTIC LEUKEMIA

H Zhou[1,*], L Liao[1], L Zhou[1], H Li[1], R Cao[1], R Lin[1], X Xu[1], M Dai[1], Q Wang[1], N Xu[1], Y Deng[2], Y Tian[3], Q Liu[1], D Xu[1], X Liu[1], J Sun[1], R Feng[1], B Xu[1], F Meng[1]
[1]Department of Hematology, [2]Department of Pathology, [3]PET center, Nanfang Hospital, Southern Medical University, Guangzhou, China

Background: Isochromosome 17q, or "i(17q)," which results in a loss of the short arm 17p and duplication of the long arm 17q, represents the most common isochromosome in human neoplasms. It's generally established that i(17q) confers poor prognosis and high-risk of leukemia transformation in myeloid neoplasms, but limited knowledge is available regarding either the subsequent leukemia subset or the associated molecular genetic consequences.
Aims: Herein we performed a retrospective analysis on 10 cases of myeloid neoplasms with i(17q10) to shed light to the converging features of this rare neoplasm.
Methods: The patients of myeloid neoplasms harboring i(17q10), except CML and de novo AML, were collected for retrospective analysis upon review of the clinical and cytogenetics databases at nanfang hospital from JAN 2003 to MAY 2012. Diagnosis of MDS, MPN and MDS/MPN were based on WHO classification. The diagnosis of AMKL was established on the basis of the FAB criteria by studies of cell morphology, cytochemistry and further confirmed with immunophenotyping by flow cytometry or immunocytochemistry staining. Integrated genetic mutations profiling analysis were performed on preserved DNA specimens from bone marrow with conventional Sanger sequencing approach on PCR amplification of genes of interest.
Results: Herein we presented 10 cases of i(17q10)-positive myeloid neoplasm, including 3 cases of myelodysplastic syndrome (MDS) and 7 cases of acute leukemia secondary to MDS, myeloproliferative neoplasm (MPN) and MDS/MPN. I(17q10) was sole cytogenetic abnormality in 7 of 10 cases. Marked megakaryocytic hyperplasia, dysplasia and myelofibrosis were frequently observed in bone marrow smear and biopsies. Five of 7 secondary leukemia cases were diagnosed as acute megakaryoblastic leukemia (AMKL) by flow cytometry and immunohistochemical analysis. Integrated genomic mutation analysis on 10 DNA samples revealed frequent *TET2* (n=7), *SRSF2* (n=4), *CEBPA* (n=3), *JAK2V617F* (n=2), *SH2B3* (n=2), *IDH1* (n=1), *TP53* (n=1), *DNMT3A* (n=1) and *WT1* (n=1). A median time to blast transformation was 12 months (range 2-84). These cases showed poor response to anthracycline-based chemotherapies, with a median overall survival of 16.5 months (range 8-90).
Summary and Conclusion: Our results showed i(17q10)-positive myeloid neoplasms is frequently associated with multiple mutations and transformation to AMKL and it deserves more researches.

P928

COMBINED ASSESSMENT OF WT1 AND BAALC EXPRESSION LEVELS IMPROVES RISK STRATIFICATION IN MYELODYSPLASTIC SYNDROMES

P Minetto[1,*], F Guolo[1], M Clavio[1], L Mitscheunig[1], R Grasso[1], N Colombo[1], E De Astis[1], D Avenoso[1], M Bergamaschi[1], L Giannoni[1], L Del Corso[2],

E Balleari[2], E Arboscello[2], G Pastori[1], S Aquino[1], F Ballerini[1], R M Lemoli[1], M Gobbi[1], M Miglino[1]
[1]Clinical Hematology, [2]Clinical Internal Medicine, IRCCS AOU San Martino Hospital-IST, Genova, Italy

Background: In patients with myelodysplastic syndromes (MDS) several validated prognostic scores, such as IPSS and R-IPSS,are available to assess the risk of AML progression and predict overall survival (OS) as well as leukemia-free survival (LFS). A number of molecular aberrations can be identified in MDS. However, differently from AML, none of current prognostic indexes takes into account molecular profile at diagnosis. WT1 expression has often been evaluated in acute leukemias and MDS. High WT1 expression levels on bone marrow at diagnosis have been reported to identify MDS patients who are at high risk of progression to AML. BAALC (Brain And Acute Leukemia Cytoplasmic) hyper-expression has been associated with a poor prognosis in AML patients, whereas its prognostic value in MDS is not yet clearly defined.
Aims: The aim of our study was to determine if combined assessment of WT1 and BAALC expression levels at diagnosis could be predictive of leukemic evolution.
Methods: We selected 86 patients with available WT1 and BAALC expression levels on BM samples at diagnosis. According to IPSS score, 22 patient were considered low-risk, 27 intermediate-1 and 28 intermediate-2 or high risk. Patients underwent different treatment schedules including supportive care, erythropoietin, hypomethylating and immunomodulating agents, according to their risk group. Median follow-up was 20 months (range 4 -121 months). Leukemia-free survival (LFS) was calculated from the diagnosis until last follow-up or documented leukemic progression as defined in literature. LFS was estimated using the Kaplan–Meier method. All Real-Time PCR were performed on DNA Engine 2 (Opticon®, MJ Research®). WT1 copy number/Abl copy number $1000x10^4$ was used as cut-off value for high WT1 expression, a level of $1000x10^4$ BAALC copy number/Abl copy number was set as cut-off for BAALC hyper-expression.
Results: Twenty-nine leukemic evolutions were observed. Median LFS was 34 months. The probability of leukemic evolution was significantly affected by karyotype, IPSS and R-IPSS scores, diagnosis according to WHO classification, and molecular profile at diagnosis. According to our data WT1 and BAALC combined expression levels could further enhance prognostic stratification. In IPSS Int-1, Int-2/high and in R-IPSS high risk groups, low levels of expression resulted in significantly lower probability of leukemic progression, whereas high levels predicted poor outcome. Furthermore, in patients assigned to IPSS unfavorable prognostic groups, low levels of WT1 and BAALC seem to predict a significantly longer LFS. In the univariate analysis LFS duration was significantly affected by WT1 and BAALC expression levels, IPSS and R-IPSS scores, karyotype and WHO classification at diagnosis. A multivariate Cox Regression model showed that LFS duration was significantly influenced only by molecular profile at diagnosis and R-IPSS risk group ($p<0.001$ and $p<0.01$, respectively).

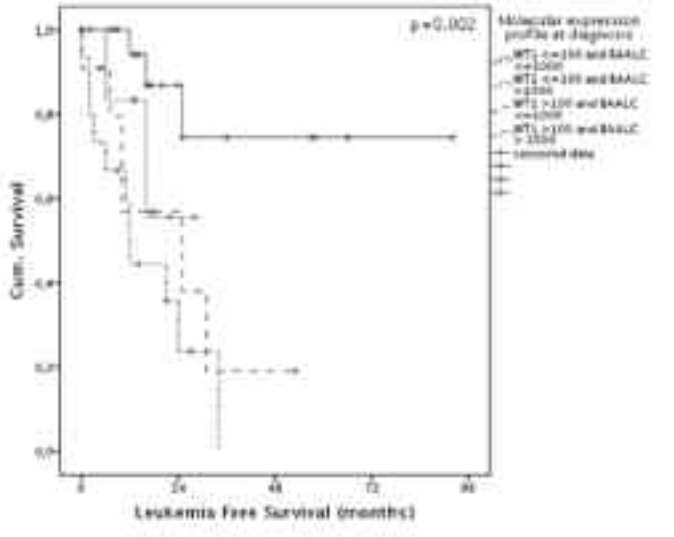

Figure 1.

Summary and Conclusion: In MDS patients combined WT1 and BAALC expression levels on bone marrow samples at diagnosis is a reliable predictor of risk of AML progression. This can improve risk stratification especially in intermediate and high risk groups and may lead to a risk tailored therapy.

P929

IMPACT OF HIGH-DOSE RADIATION EXPOSURE ON NAGASAKI ATOMIC BOMB SURVIVORS WITH MYELODYSPLASTIC SYNDROMES TREATED WITH AZACITIDINE

T Jo[1,*], K Horio[1], M Tomonaga[1]
[1]Hematology, Japanese Red Cross Society Nagasaki Genbaku Hospital, Nagasaki, Japan

Background: Myelodysplastic syndromes (MDS) are clonal hematopoietic stem cell disorders that may arise de novo or secondarily after treatment with chemotherapy and/or radiation therapy for other cancers or, rarely, after environmental exposure. High-dose radiation exposure (such as that resulting from an atomic bomb explosion or nuclear reactor accident) increases an individual's risk of developing MDS. The risk of developing MDS increases at least 45 years after acute radiation exposure, along with the relative risk of acute myeloid leukemia–related mortality. Azacitidine (AZA), a hypomethylating agent, is the standard therapy for MDS in Japan. However, no reports have investigated the efficacy of AZA in atomic bomb survivors with MDS.
Aims: We retrospectively evaluated 33 patients (including 13 atomic bomb survivors) diagnosed with MDS between April 2011 and April 2013 at Nagasaki Genbaku Hospital. All patients received AZA. The primary objective was to estimate the overall survival (OS) rates.
Results: The Table summarizes baseline patient characteristics and response rates. The median age of Nagasaki atomic bomb survivors (A) was 74 (range, 68–84) years, whereas that of patients who did not experience an atomic bomb explosion (non-A) was 68 (range, 46–87) years. The median numbers of administered AZA cycles were 5.4 (range, 1–19) in A patients and 8.2 (range, 1–21) in non-A patients. According to the World Health Organization diagnostic criteria, the following diagnoses were made: refractory cytopenia with multilineage dysplasia (RCMD) in 7 (54%) and 13 (65%), refractory anemia with excess blasts-1 (RAEB)-1 in 2 (15%) and 5 (25%), and RAEB-2 in 4 (31%) and 2 (10%) A and non-A patients, respectively. International Prognostic Scoring System scores were Int-1 in 5 (38%), Int-2 in 6 (46%), and High in 2 (15%) A patients, and Int-1 in 8 (40%), Int-2 in 10 (50%), and High in 2 (10%) non-A patients. Cytogenetic risk was intermediate in 3 (23%) and poor in 3 (23%) A patients, and intermediate in 2 (10%) and poor in 10 (50%) non-A patients. The best curative effect was evaluated and overall response rates (ORR) (CR + marrow CR + PR) were 38% in A patients and 40% in non-A patients. There was no clear difference in the background characteristics except for age (P=0.0258) between A and non-A patients. Although the ORR did not differ (P=0.2635), the median OS in November 2013 was significantly different between the 2 groups (13 months for A *vs*. undefined for non-A patients, P=0.0429).

Table 1.

		Atomic bomb survivors (A) n = 13	Non-atomic bomb survivors (non-A) n = 20	*P* value
Age (median)		68–84 (74)	46–87 (68)	0.0258
WHO subtype	RCMD	7 (54%)	13 (65%)	0.3051
	RAEB-1	2 (15%)	5 (25%)	
	RAEB-2	4 (31%)	2 (10%)	
IPSS at diagnosis	Int-1	5 (38%)	8 (40%)	0.2857
	Int-2	6 (46%)	10 (50%)	
	High	2 (15%)	2 (10%)	
Cytogenetics	Good	7 (54%)	8 (40%)	0.0029
	Intermediate	3 (23%)	2 (10%)	
	Poor	3 (23%)	10 (50%)	
Blood transfusion dependence	+	10 (77%)	16 (80%)	1.0000
	-	3 (23%)	4 (20%)	
Response rate	CR	5 (38%)	7 (35%)	0.2635
	marrow CR	1 (8%)	1 (5%)	
	PR	3 (38%)	0 (0%)	
	SD	4 (62%)	12 (60%)	
AZA cycle (median)		5.4 (1–19)	8.2 (1–21)	0.1860

Summary and Conclusion: These data demonstrate that despite the same ORR, the OS of Nagasaki atomic bomb survivors with MDS was significantly shorter compared to that of patients with MDS who did not experience an atomic bomb explosion. A certain influence of atomic bomb exposure is suggested; however, further studies to clarify the cause of this phenomenon are warranted.

P930

TREG CELLS NUMBER FROM HIGH-RISK MYELODISPLASTIC SYNDROME PATIENTS IS INCREASE, BUT ITS SUPRESSION HABILITY IS IMPARED

A DSB Perazzio[1,*], MDL LF Chauffaille[1], MR R Silva[2]
[1]HEMATOLOGY, [2]PATOLOGIA, UNIFESP, São Paulo, Brazil

Background: The Myelodysplastic Syndromes (MDS) are characterized by clonal proliferation of bone marrow cells with inefficient production and its pathogenesis is still unknown. Studies show abnormal immune function and also describe some patients with autoimmune phenomena. In the last years, special attention in immunological evaluation has been devoted, which may be related to the pathogenesis of MDS.
Aims: The study aimed to evaluate a broad scrutiny of regulatory T cells function and markers in healthy controls and patients with MDS, associating with autoimmune manifestations and prognostic scores.
Methods: Peripheral and bone marrow (BM) T regulatory (Treg) cells of 37 patients and 18 healthy controls (HC) were obtained. Treg were sorted by flow citometry and co cultured for 7 days with T effector cells (Teff) in different concentration to evaluate cell-mediate suppression and quantify IL2, IL4, IL6, IL10, IL17, TNFa and IFNg production in culture supernatant by CBA. Genetic expression of Foxp3 and IRF-1 was performed by qRT-PCR in peripheral and BM Treg cells. Proteic expression of Foxp3 and IRF-1 was performed by immunohistochemistry in BM Treg cells.
Results: MDS group presented median age of 74 years (23–93y) and gender ratio (M:F)=1:1.6. Median hemoglobin was 9.6g/dL (5.3-14.8g/dL) and 36.8% of the patients were transfusion-dependents. 35.2% showed altered karyotype. According to the WHO classification (2008), 17 patients were CRDM, 3 CRDM-SA, 2 AR, 7 RARS, 3 RAEB-I, 4 RAEB-II and 1 patient was 5q-syndrome. There was a trend toward a higher number of Treg in MDS group compared to HC ($p=0.14$). IPSS score low/intermediate 1 risk patients ($p<0.043$) and WPSS ($p<0.025$) and IPSS-R ($p<0.007$) scores intermediate/high risk patients presented a higher number of Treg cells. There was no difference in Treg number regarding the presence of altered karyotype ($p=0.46$). HC presented higher number of Teff cells compared to MDS patients ($p<0.01$). Treg cell-mediate suppression was decreased in the high-risk group compared to the low-risk ($p<0.01$). The expression of IRF-1 exons 2 ($p<0.01$) and 4/5 ($p<0.01$) proved to be decreased in MDS patients Treg cells compared to HC. Additional results (cytokine production, immunohistochemistry analysis and Foxp3 genetic expression) will be described later.
Summary and Conclusion: This study describes a decrease of Treg cell-mediate suppression was in the high-risk patients, showing an inadequate function in tolerance mechanism. However, paradoxically there was a higher Treg cells number in the same group. Although the last finding is in consonance to previous papers, explaining a higher tolerance to the neoplastic clone and leading to disease progression, we postulate that it could be secondary to suppression impairment. On the other hand, the reduced expression of IRF-1 in MDS patients decreases its tumor suppressor power and may also cause disease progression. IRF-1 is involved in several immune functions and higher expression was described in MDS patients with autoimmune manifestations. Associated with this feature was described, in mice, that IRF-1 plays inhibition of Foxp3 expression in Treg cells, which may suggest that decreased expression of IRF-1 in patients with high-risk MDS, for example, may lead to an increase in the number of Tregs but that the change in cell suppression may have other intrinsic mechanism involved. In summary, we originally described a decreased tolerance mechanism in high-risk MDS patients, represented by a lower Treg cell-mediate suppression.

METHYLATION PATTERNS IN PATIENTS WITH HIGH-RISK MYELODYSPLASTIC SINDROMES AND SECONDARY ACUTE MYELOID LEUKEMIA TREATED WITH HIPOMETHYLANT AGENTS (HIGH-RISK MDS 2009 PROTOCOL OF CETLAM GROUP)

M Cabezón[1,*], J Bargay[2], B Xicoy[1], S Marcé[1], G Fernández[3], T Vavouri[3], R Guàrdia[4], S Brunet[5], C Pedro[6], M Tormo[7], V Marco[8], L Escoda[9], L Font[10], E Rámila[11], D Valcárcel[12], JM Martí[13], J Borràs[2], L Sanmiguel[1], E Feliu[1], F Millá[1], L Zamora[1]
[1]ICO-Hospital Germans Trias i Pujol. IJC, Badalona, [2]Hospital Son Llàtzer, Palma de Mallorca, [3]Institut de Medicina Predictiva i Personalitzada del Càncer- IMPPC, Badalona, [4]ICO- Hospital Josep Trueta, Girona, [5]Hospital de Sant Pau, [6]Hospital del Mar, Barcelona, [7]Hospital Clínic de València, València, [8]Hospital Arnau de Vilanova, Lleida, [9]Hospital Joan XXIII, Tarragona, [10]Hospital Verge de la Cinta, Tortosa, [11]Hospital Parc Taulí, Sabadell, [12]Hospital Vall d'Hebron, Barcelona, [13]Mutua de Terrassa, Terrassa, Spain

Background: Myelodysplastic syndromes (MDS) are a group of hematologic disorders characterized by ineffective hematopoiesis and increased risk of transformation to acute myeloid leukemia (AML). Aberrant DNA methylation is the dominant and most well-studied epigenetic alteration in MDS. Various genes, including cell cycle regulators, apoptotic genes, and DNA repair genes, are epigenetically silenced and have roles in pathogenesis and transformation to leukemia. Clinical response of MDS and AML to drugs that change the aberrant hipermethylation, such as 5-aza-2´-deoxicitidine and 5-azacitidine (AZA), suggests that this hipermethylation has an important role in the disease and it is not a secondary effect to other mechanisms.
Aims: The aim of this study was to define the methylation pattern of DNA at diagnosis in patients with high-risk MDS and secondary AML treated with the same protocol (high-risk MDS 09 of CETLAM Group) in order to determine if there are some predicting pattern of relapse or response to AZA treatment.
Methods: Genomic DNA was obtained from bone marrow of 74 patients at diagnosis, 70 samples at follow-up and 12 control samples (bone marrow donors). Genome-wide DNA methylation profiling was performed using the Illumina Infinium HD methylation array (450K). We have used RnBeads program to find predicting pattern of relapse or response to AZA treatment. This program allow to remove patient related SNPs.
Results: The global methylation dendogram suggests that control samples had the most similar methylation pattern. Diagnosis and follow-up samples cluster for patients and not for cytological group or treatment response. Although we have not found significant differences in the methylation patterns of the patients at diagnosis *versus* the same patient after treatment, we have been able to observe a decrease in the state of global methylation in the samples that have received AZA. No methylation pattern at diagnosis was associated to those patients who respond to AZA.
Summary and Conclusion: The methylation arrays are a good methodology to study the methylation pattern of cells. It would be necessary to increase the number of patients with MDS treated with AZA and their follow-ups, to confirm that the hipermethylation decrease along the treatment with AZA and the responders patients keep this hipomethylation whereas the nonresponders patients lose this hipomethylation.

HIF-1A INHIBITION BLOCKS THE CROSS TALK BETWEEN MULTIPLE MYELOMA PLASMA CELLS AND TUMOR MICROENVIRONMENT

E Borsi[1,*], G Perrone[2], C Terragna[1], M Martello[1], A F Dico[1], E Zamagni[1], P Tacchetti[1], L Pantani[1], A Brioli[1], G Martinelli[1], M Cavo[1]
[1]Department of Experimental Diagnostic and Specialty Medicine - DIMES, Institute of Hematology "L.&A.Seràgnoli", Bologna, [2]Hematology Department, Fondazione IRCCS Istituto Nazionale dei Tumori, Milano, Italy

Background: Multiple Myeloma (MM) is a clonal B-cell malignancy characterized by accumulation of malignant plasma cells (PCs) within the bone marrow (BM) in close contact with stromal cells (SCs) which secrete growth factors and cytokines, promoting tumor cell growth and survival. The rapid progression of MM is dependent upon cellular interactions within the BM microenvironment, and novel agents targeting this interaction appear to be promising therapeutic strategies for the treatment of MM tumor expansion.
Unlike most other organs, the BM microenvironment is physiologically hypoxic, a pre-requisite for normal BM hematopoiesis. It is well established that hypoxia is an important selective force in the evolution of tumor cells and a stabilization of HIF-1α protein has been documented in several human cancers. While the role of hypoxia in the pathogenesis of hematologic malignancies has yet to be elucidated, recent animal studies have shown that changes in oxygen levels within the BM microenvironment support the survival and expansion of MM cells. Furthermore, some drugs active in MM, such as Bortezomib and Lenalidomide, are believed to exert their effects in part by interfering with hypoxia-induced signaling cascades.
Aims: Given the importance of the BM microenvironment in MM pathogenesis, we investigated the possible involvement of HIF-1α in the PCs-BMSCs interplay.
Methods: A panel of MM cell lines (MM1.S, U266, OPM-2, RPMI8226) and primary samples from MM patients were cultured *in vitro* in the presence of clinically achievable doses of EZN-2968 (a small 3rd generation antisense oligonucleotide against HIF-1α, to inhibit HIF-1α functions) in normoxia ($p0_2$ 21%) culture conditions.
Results: We have already shown that EZN-2968 is highly specific for HIF-1α mRNA and it results in a long lasting and time dependent inhibition of HIF-1α protein level. Herein, we provide evidence that the interaction between MM cells and BMSCs is drastically reduced upon HIF-1α down-modulation. Notably, we showed that upon exposure to HIF-1α inhibitor, neither the incubation with IL-6 nor the co-culture with BMSCs were able to revert the anti-proliferative effect induced by EZN-2968. Moreover, we observed that EZN-2968 down-modulates cytokine-induced signaling cascades after a short incubation, and seems to induce a negative modulation of those transcripts previously shown to reflect the activation state of specific tumor cell pathways (cell proliferation and survival). This observation was also supported by gene expression profile experiments. One of the key finding of our study is that PC attachment to the extracellular matrix protein was markedly reduced in the presence of EZN-2968. The effects of HIF inhibition on MM cell adhesion are quite intriguing, since MM pathogenesis is dependent upon the interaction of MM cells with the SCs.
Summary and Conclusion: Taken together, these results strongly support the concept that HIF-1α plays a critical role in the interactions between BMSCs and PCs in MM. We conclude that HIF inhibition may be an attractive therapeutic target for MM.

THE NOTCH PATHWAY CONTROLS MULTIPLE MYELOMA CROSSTALK WITH THE OSTEOCLASTOGENIC NICHE

M Colombo[1,*], S Garavelli[1], K Todoerti[2], E Lazzari[1], S Ravaioli[1], N Platonova[1], L Apicella[1], M Lancellotti[1], S Galletti[3], A Neri[3], R Chiaramonte[1]
[1]Dept. of Helath Sciences, Università degli Studi di Milano, Milano, [2]Laboratory of Pre-Clinical and Translantional Research, IRCCS-CROB, Referral Cancer Center of Basilicata,, Rionero in Vulture, [3]Dept. of Clinical Sciences and Community Health, Università degli Studi di Milano, Milano, Italy

Background: Multiple myeloma (MM) is an incurable hematological tumor stemming from malignant plasma cells that accumulate in the bone marrow (BM) and establish interactions with BM stroma, promoting tumor survival and bone disease due to unbalanced bone deposition and resorption. The Notch family consists of 4 receptors, Notch1 to 4, which once activated, act as transcription factors. The activation is triggered by Jag1-2 and DLL1-3-4 ligands. Notch plays a key role in bone tissue remodeling and skeletal development. Notch signaling is deregulated in MM and plays a role in MM pathogenesis by modulating tumor cell biology, as well as pathological interactions with BM niche. The myeloma-associated alteration of Notch signaling consists in the aberrant expression of the ligands Jag1 and Jag2 by MM cells, resulting in Notch signaling activation in both tumor cells and BM stroma cells.
Aims: The aim of this work was to investigate the role of Notch signaling in MM-driven osteoclastogenesis. To address this issue we assessed:
• The role of Notch in osteoclast (OCL) differentiation and activity;
• The contribute of different Notch isoforms in OCL development;
• The involvement of Notch pathway in MM cell osteoclastogenic properties.
Methods: Cells were maintained in complete DMEM medium with 10% heat inactivated FBS. DAPT was added to the medium at a final concentration of 50μM. Recombinant mouse RANKL was used at the final concentration of 50ng/ml. Jagged1 recombinant peptide was used at 0.5μg/ml. anti-RANKL neutralizing antibody was used at 0.1μg/ml. OCL differentiation of Raw264.7 cells was induced by treating them with mRANKL or co-culturing with MM cells or their conditioned medium (CM). After 5-7days cells were stained using the TRAP Kit and counted. For bone resorption assay, Raw264.7 cells were cultured on Osteo Assay Surface plates under differentiation conditions. After 7-10 days, the plates were washed in 5% sodium hypochlorite solution. Images of the resorbed areas on the plates were captured and the percentage of resorbed area was measured by using the Wimasis image analysis software (Wimasis GmbH). Select RNAi™ siRNA system (Invitrogen) was used according to the manufacturer's guidelines for the selective knock-down of Jag1 and Jag2. Transfection was performed by electroporation using two plasmid carrying intracellular Notch1 (ICN1) and Notch2 (ICN2). Total RNA was isolated using TRI-Reagent. cDNA was prepared through MMLV reverse transcriptase, then quantitative PCR (qPCR) was performed by Maxima SYBR Green qPCR Master Mix. ELISA Assay was performed using biotin-conjugated goat anti-human RANKL (Merck-Millipore) and Streptavidin-HRP-labeled secondary antibody.
Results: We demonstrates that Notch signaling drives MM cell-induced osteoclastogenesis. The underlying molecular mechanisms is based on MM cell-derived Jagged ligands ability to efficiently drive osteoclastogenesis by contemporaneously activating Notch signaling on tumor cells and osteoclasts. Notch signaling activation in MM cell promote the release of the osteoclastogenic receptor activator of NF-kB ligand (RANKL). RANKL, in turn, promotes within OCL precursors Notch2 signaling which drives osteoclastogenesis completion by promoting the transcription of osteoclastogenic master genes, such as *Tartrate-resistant acid phosphatase* (TRAP) and *Receptor Activator of Nuclear Factor κ B (*RANK) and the autonomous secretion of RANKL by OCL precursors. Remarkably, MM-induced osteoclastogenesis can be disrupted by silencing Jagged1 and Jagged2 Notch ligands in MM cells.
Summary and Conclusion: Our findings make Jagged1 and Jagged2 new promising therapeutic targets to hamper MM-associated bone disease and co-morbidities, lacking the toxicity of the currently used drugs which contemporaneously affect the signaling of all Notch receptors.

P934

JAGGED-INDUCED NOTCH SIGNALING PROMOTES ENDOGENOUS AND BONE MARROW-MEDIATED DRUG RESISTANCE IN MULTIPLE MYELOMA

S Garavelli[1,*], E Lazzari[1], M Colombo[1], S Ravaioli[1], N Platonova[1],L Lancellotti[1], L Apicella[1], L Mirandola[1], S Galletti[2], K Todoerti[3], A Neri[2], R Chiaramonte[1]
[1]Department of Health Sciences, [2]Department of Clinical Sciences, University of Milano, milano, [3]Laboratory of Pre-Clinical and Translational Research, IRCCS-CROB, Referral Cancer Center of Basilicata, Rionero in Vulture, Italy

Background: Multiple myeloma (MM) represents 10% of all hematological malignancies. Malignant plasma cells accumulate in the bone marrow. Although in the last 10 years new drugs such as immunomodulators or proteasome inhibitors increased patients' survival, MM remains still incurable mainly due to the development of endogenous or BM mediated drug resistance. Therefore it is crucial to find new therapeutic targets. The deregulated expression of two Notch ligands, Jagged1 and 2, activates Notch pathway both in MM cells and in bone marrow stromal cell (BMSC) which express Notch receptors. Several Notch downstream effectors are involved in MM cell growth, survival and proliferation, *i.e.* IL-6, SDF-1alfa, CXCR4, NF-kB, VEGF and IGF.
Aims: The aim of this study was to evaluate the role of Notch signaling in endogenous and BMSC-promoted drug resistance in MM, focusing on the contribution of the chemokine axis CXCR4/SDF-1alfa.
Methods: The human MM cell lines, U266 and OPM2, were cultured alone in complete RPMI-1640 medium or co-cultured with murine (NIH3T3) or human (HS5) BMSC cell lines in DMEM medium supplemented with 10% V/V FBS. U266 and OPM2 cells were either kept in suspension for 24 hours at 3 x 10^5/mL or plated on BMSC monolayer for 24h, then treatments with drugs (1-2 mM Mitoxantrone, 5-8 nM Bortezomib or 100-30 mM Melphalan) or 50μM AMD3100 were applied for additional 24 hours. Apoptosis assay: HS5 cells were colored with PKH26 red fluorescent dye (Sigma-Aldrich) before co-culturing to allowed flow-cytometric detection of MM cells co-cultured with BMSCs. At the end of the treatment, cells were stained with Annexin V-FITC (ImmunoTools) and processed with Cytomics FC500 software (Beckman Coulter). RNA interference: specific knock-down of Jagged1 and 2 was obtained by transient expression of specific siRNAs for Jagged1-2 (Stealth Select RNAiTM siRNA system, Life Technologies). MM cell lines were seeded at 350.000 cells/ml and,

after 24h, Jagged1 and 2 genes were simultaneously silenced. Every 48h cells were diluted and transfected again. Quantitative PCR reactions were carried out on a 7500 Fast Real-time PCR system (Applied Biosystems) using the Maxima™ SYBR Green/ROX qPCR Master Mix (Dasit).
Results: RNA interference for Jagged-1 and 2 in OPM-2 and U266 cells resulted in the reduced expression of anti-apoptotic genes such as SDF-1alfa, CXCR4, Bcl-XL, Bcl-2, Survivin and ABCC1. At the same time, MM cells with reduced levels of Jagged-1 and 2 showed an increased sensivity to different drugs commonly used in MM therapy such as Bortezomib, Mitoxantrone and Melphalan. By co-culturing MM cell lines and BMSCs in the presence or the absence of chemotherapeutic agents we observed that BMSCs were able to protect MM cells from apoptosis. We investigated the underlying mechanism showing that MM cells and BMSC interaction resulted in the activation of Notch signaling in both cell types. MM cells-driven Notch signaling activation in BMSCs resulted in the increased expression of soluble growth factors relevant for MM cell growth and survival, such as SDF-1alfa and VEGF. On the other side, BMSCs increased in MM cells the expression of several anti-apoptotic genes, *i.e.* Bcl-XL, Bcl-2, Survivin and ABCC1. Interestingly, Jagged-1 and 2 silencing in MM cells could reverse all gene expression changes and BMSC protective effect. Finally, the CXCR4 antagonist AMD3100 could partially reverse the protective effect of BMSCs to drugs-induced apoptosis in MM cells, suggesting that Jagged ligands deregulation observed in MM is necessary to BM-promoted drug resistance by activating the SDF1alfa/CXCR4 chemokine signaling.
Summary and Conclusion: The evidence that anti-Jagged-1 and 2 siRNAs affect endogenous and BMSC-induced drug resistance in MM cells suggests that a Jagged-directed approach could be effective in MM therapy alone or in a combined treatment with commonly used drugs.

P935

NOTCH PATHWAY PROMOTES MULTIPLE MYELOMA CELL IL-6 INDEPENDENCE

S Galletti[1,*], S Ravaioli[2], M Colombo[2], S Garavelli[2], K Todoerti[3], N Platonova[2], M D'Anca[1], M Manzoni[1], A Neri[1], R Chiaramonte[2]
[1]Department of Clinical Sciences and Community Health, [2]Department of Healt Sciences, Università degli Studi di Milano, Milano, [3]Laboratory of Pre-Clinical and Translantional Research, IRCCS-CROB, Referral Cancer Center of Basilicata, Rionero in Vulture, Italy

Background: Multiple myeloma (MM) is a malignant plasma cells (PC) disorder accounting for approximately 10% of hematologic cancers. Even though advanced chemotherapeutic regimens have increased the median time of survival to 5 years after diagnosis, myeloma remains incurable. Once immortalized, the survival and proliferation of myeloma cells strictly depend on a complex interaction with the bone marrow (BM) microenvironment, which is mediated both by adhesion molecules and production of several cytokines, especially interleukin-6 (IL-6). Following MM progression, at the stage of plasma cell leukemia, the malignant PC acquires autonomous proliferative ability, becomes indipendent on growth factors like IL-6 and is no longer confined in the BM. Several recent evidences point to a possible role for Notch signaling in mediating critical events in MM progression. The Notch pathway is highly conserved and plays a crucial role in cell-fate decision, tissue patterning and morphogenesis. Recently, Notch receptors and ligands have been shown to be upregulated during MM progression and their signaling positively regulates cell proliferation, drug resistance and BM infiltration.
Aims: The ability of Notch signaling to regulate proliferation and survival pathways (*i.e.* NF-kB, AKT, Myc, and the same IL-6) prompted us to study if its up-regulation during MM progression may play a role in the acquirement of IL-6 independence. To this end we used two opposite approaches. Specifically, we verified if Notch signaling upregulation in IL-6 dependent cell lines promotes their independence and assessed if, upon Notch inihibition, IL-6 independent MM cell lines lost self-sufficient proliferation.
Methods: Cell culture and cell growth analysis: HMCL CMA03, INA-6 and XG-1 were maintained in complete RPMI-1640 medium supplemented with 10% V/V FBS and IL-6 10, 2.5 or 1 ng/mL, respectivetly. OPM2, CMA03/06 and U266 cell lines were cultured in the same conditions without IL-6 addition. The number and viability of cells were assessed by means of trypan blue exclusion assay. The Notch inihibitor, DAPT, was added to the medium at the final concentration of 50mM. Soluble Jagged1 was used at 5mg/mL.
Flow cytometry analysis: Apoptosys analysis was perfomed by AnnexinV-FITC/Propidium Iodide staining. Cell cycle analysis was performed by Propidium Iodide staining.
Real time-PCR: Quantitative PCR reactions were carried out using the Maxima™ SYBR Green/ROX qPCR Master Mix.
Results: To evaluate if Notch pathway upregulation is involved in the development of IL-6 independence in MM cells, we activated the Notch signaling in three MM cell lines, CMA03, INA-6 and XG-1, strictly dependent on IL-6. At this purpose, MM cells were cultured with the soluble form of the Notch ligand Jagged1. We demonstrated that Jagged1 stimulation partially rescued the reduced cell growth due to IL-6 withdrawal. On the other hand, three different IL-6 independent cell lines, CMA03/06, OPM2 and U266, treated with a gamma-secretase inhibitor (DAPT) which causes Notch pathway blockade, displayed a significant decrease in cell growth. Remarkably, this effect could be reverted by the addition of IL-6 in the culture medium. The mechanisms underlying Notch-IL-6 crosstalking was partially investigated. Preliminary results indicate that Notch signalling is required for MM cell autonomous IL-6 production.
Summary and Conclusion: The present results suggest that Notch pathway activation may contribute to the transition from IL-6-dependent to IL-6-independent MM cell growth. Furthermore, the inhibition of the Notch patwhay may lead to a decrease in MM cells proliferation in part due to the reduction of IL-6 expression. Even though studies are necessary to identify further mechanisms of IL-6 independence possibly involving other Notch downstrem pathways, these preliminary results support the rationale for a Notch-directed approach in plasma cell dyscrasias.

P936

PROTEASOME INHIBITORS MODULATE OSTEOCYTE DEATH AND AUTOPHAGY IN MULTIPLE MYELOMA

D Toscani[1], C Palumbo[2], A Ciullo[1], M Ferretti[2], M Bolzoni[1], D Guasco[1], B Dalla Palma[1], F Aversa[1], N Giuliani[1,*]
[1]Clincal and Experimental Medicine, Hematology, University of Parma, Parma, [2]Human Anatomy, University of Modena, Modena, Italy

Background: Cell death and autophagy are the main cellular processes involved in the regulation of bone remodeling by osteocytes. Recently we have demonstrated that an increased osteocyte death is involved in multiple myeloma (MM)-induced osteolysis through the upregulation of osteoclast recruitment.
Aims: Because proteasome inhibitors including Bortezomib (BOR) are known to be able to target osteoblasts in this study we have investigated the potential effect of these drugs on osteocytes and their cell death and autophagy.
Methods: Firstly the effect of the proteasome inhibitors BOR and MG262 on osteocyte viability was evaluated *in vitro* in murine osteocytic cell line MLO-Y4 and in the human pre-osteocytic one HOB-01. Both cell lines were co-coltured for 48 hours in the presence or absence of the human myeloma cell lines (HMCLs) RPMI8226 and JJN3, placed in a transwell insert in the presence or the absence of BOR or MG262. Moreover the effect of proteasome inhibitors on dexamethasone (DEX)-induced MLO-Y4 death, obtained at high doses (10^{-5}-10^{-6}M), was checked in combination with PTH(1-34). To evaluate the presence of autophagy and apoptosis in osteocytes, we checked the expression of both autophagic marker LC3 and apoptotic marker APAF-1 by confocal microscopy in the co-colture system with MLO-Y4 and RPMI-8226. Finally we performed a retrospective histological evaluation on bone biopsies of a cohort of 31 newly diagnosis MM underwent to different treatments including BOR-based regimen. Bone biopsies were obtained at the diagnosis and after an average time of 12 months of treatment. Osteocyte viability was evaluated in a total of 500 lacunae per histological sections.
Results: The *in vitro* treatment with BOR or MG262 significantly blunted MLO-Y4 and HOB-01 cell death. Similarly, DEX-induced MLO-Y4 death was reduced by proteasome inhibitors. Interestingly, we found that both proteasome inhibitors potentiated the PTH (1-34) short-term effects on DEX-induced osteocyte death. Prevalence of autophagic cell death compared to apoptosis was observed in this system. In line with these data, we showed that neither the HMCLs nor treatment with DEX increase the apoptotic death and caspase 3 activation in both MLO-Y4 and HOB-01 cell lines. BOR treatment increased the basal level of LC3 indicating a pro-survival and protective function of autophagy against the BOR-induce stress. On the contrary, when the cells undergo to a stronger stress such as in the presence of HMCLs or by treatment with high dose of DEX we found that both proteasome inhibitors blocked autophagic cell death in osteocytes. In the *in vivo* study we found a significant increase of the number of viable osteocytes in MM patients treated with BOR-based regimen as compared to those treated without BOR (% median increase: +6% *vs*. +1.30%; p=0.017). Patients treated with BOR alone showed the highest increase of osteocyte viability, as compared to those either treated without BOR (+11.6% *vs*. +1.3%, p=0.0019) or treated with BOR plus DEX (+11.6% *vs*. +4.4%, p=0.01). On the other hand, any significant difference was not observed in patients treated with Thalidomide (THAL) or Immunomodulatory drugs (IMiDs) than in those untreated with these drugs (p=0.7). A multiple regression non-parametric analysis showed that BOR had a significant positive impact on osteocyte viability (p=0.042) whereas THAL/IMiDs as well as Zoledronic acid (ZOL) treatments have not (p=0.2). BOR also counterbalanced the negative effect of DEX treatment (p=0.035).
Summary and Conclusion: Our data suggest that proteasome inhibitors blunted osteocyte cell death induced by MM cells and DEX through the modulation of the autophagy and potentiated the effect of PTH. Overall our *in vitro* and *in vivo* data support the use of BOR to improve bone integrity in MM patients.

P937

THE METABOLIC STRESS INDUCED BY CYCLIN D1 IMPACTS CELL ADHESION, MIGRATION AND CELL ADHESION-MEDIATED DRUG RESISTANCE (CAM-DR) IN MYELOMA CELLS

S Bustany[1,*]G Tchakarska[1], B Sola[1]
[1]EA4652, UNICAEN, CAEN, France

Background: The interactions of multiple myeloma (MM) cells with their microenvironment are crucial in MM pathogenesis. Direct interaction between MM cells and bone marrow cells activates pleiotropic signaling pathways that mediate growth, survival, drug resistance, migration of MM cells and angiogenesis. But the molecular profiles of MM could also induce alterations at the transcriptional and proteomic levels that mediate the protective effects of the bone marrow microenvironment on MM cells.
Aims: In this study, we induced constitutive cyclin D1 expression in MM cell line and assessed how cyclin D1 impacts microenvironment interactions of MM cells.
Methods: Cyclin D1 expression were induced in RPMI 8226 cell line and checked by flow cytometry and western blotting. A gene expression profiling assay was performed on cyclin D1 positive *versus* control clones and confirmed by quantitative PCR. Cell adhesion was assessed by fluorescence after adhesion to stroma cells or fibronectin. Chemotaxism was determinated by boyden chamber assay and chemokine secretion by human cytokine antibody arrays. Protein intracellular localization and F-actin stabilization were confirmed by immunofluorescence staining and western blotting. Apoptosis was quantified by flow cytometry after APO2.7 staining. Student's *t*-test was used to determine the significance of differences between two experimental groups. Data were analyzed with a two-sided test. $p<0.05$ was considered significant.
Results: The constitutive expression of cyclin D1 in RPMI 8226 cell line increased cell adhesion to stromal cells and fibronectin, enhanced chemotaxism and chemokine secretion. Global gene expression analysis revealed that cyclin D1 expression was associated with the modification of genes controlling DNA synthesis and metabolism. Unexpectedly, the expression of genes encoding adhesion molecules was not modified. Cyclin D1 expression induced the downregulation of cyctochrome c oxidase subunit VII (*COX7*) expression and the upregulation of adenylate cyclase 1 (*ADCY1*) and glutathione S-transferase omega (*GSTO*) expression. Consequently, cyclin D1 disrupted the redox balance by inhibiting mitochondrial activity and modifying intracellular ATP/ADP and NADPH/NADP+ ratios. This metabolic stress activated the ERK and p70S6K pathways, stabilized F-actin stress fibers and in turn, enhanced cell adhesion to fibronectin and stromal cells. Pomalidomide is an immunomodulator actively tested in MM. Control and cyclin D1-expressing RPMI 8226 clones were resistant to pomalidomide treatment. However, the CAM-DR of cyclin D1-expressing cells was specifically inhibited after pomalidomide treatment opening new perspectives for cyclin D1-expressing MM patients.
Summary and Conclusion: Our data demonstrated for the first time that metabolism regulates microenvironment interactions of MM cells and that pomalidomide could enhance drug sensitivity by inhibiting metabolic stress-induced cell adhesion.

CYCLIN D1 CONSTITUTIVE EXPRESSION SENSITIZES MULTIPLE MYELOMA CELLS TO BORTEZOMIB BY INHIBITING HEAT SHOCK PROTEINS

S Bustany[1,*], J Cahu[1], C Pellat-Deceunynck[2], B Sola[1]
[1]EA4256, UNICAEN, CAEN, [2]CRCNA, INSERM892, CNRS6299, Nantes, France

Background: Multiple myeloma (MM) is characterized by genetic instability with frequent translocations in more than 50 % of cases. Gene expression profiling assays have segregated MM patients into 7 groups exhibiting different prognostic values and responses to treatment. Cyclin D1 expression is associated with a good prognosis and a prolonged overall survival.
Aims: For understanding its mechanism of action and identifying therapeutic targets, we introduced cyclin D1-GFP fusion protein in MM cell lines characterized by adverse prognostic markers such as *MAF* or *MMSET* overexpression.
Methods: We generated from MM cell lines several clones expressing either cyclin D1-GFP or GFP. Cellular viability and apoptosis were measured by MTT assay and flow cytometry after APO2.7 staining. Regulators of the unfolded protein response and apoptosis were evaluated by real-time PCR and western blotting. Student's *t*-test was used to determine the significance of differences between two experimental groups. Data were analyzed with a two-sided test. $p<0.05$ was considered significant. Combination indexes were calculated according to the Chou and Talalay's method.
Results: In all cell lines tested, the presence of cyclin D1 was associated with increased apoptotic response after treatments with either dexamethasone or bortezomib but not lenalidomide. The expression of cyclin D1 enhanced a caspase-dependent apoptosis belonging to both intrinsic and extrinsic pathways. It also increased endoplasmic reticulum-stress leading to the induction of apoptosis-mediated unfolded protein response (UPR). Besides cyclin D1 co-immunoprecipitated with heat shock proteins (HSP) and inhibited their anti-apoptotic effects. We futher showed that HSP70 rather than HSP90 inhibitors synergized with anti-myeloma drugs to trigger apoptosis in coculture cellular models and in MM primary cells.
Summary and Conclusion: Ours results strongly suggest that HSP 70 inhibitors should be included in clinical protocols to improve the response to treatment of refractory or relapsed patients.

SERUM LEVELS OF DICKKOPF-1 PREDICT PROGRESSION FREE SURVIVAL IN MULTIPLE MYELOMA PATIENTS TREATED WITH AUTOLOGOUS STEM CELL TRANSPLANTAT BUT ITS PROGNOSTIC VALUE IS OVERCOME BY THE USE OF NOVEL DRUGS

J Minarik[1,*], P Petrova[2], J Bacovsky[1], T Pika[1], J Zapletalova[3], V Scudla[1]
[1]Department of Internal Medicine III, [2]Department of Clinical Biochemistry, [3]Department of Medical Biophysics and Statistics,, University Hospital and Palacky University Olomouc, Olomouc, Czech Republic

Background: Dickkopf-1 glycoprotein (DKK-1) is one of the key regulators of bone homeostasis. It is highly expressed in multiple myeloma and its overexpression leads to the development of myeloma bone disease by the inhibition of Wnt signalling pathway, thus inhibiting osteoblasts and activating osteoclasts.
Aims: The aim of our study was to compare the relationship of serum levels of DKK-1 to other parameters of bone marrow microenvironment, and to assess the potential prognostic value of DKK-1 in patients treated with or without the support of autologous stem cell transplantation, and in patients treated with thalidomide and bortezomib based regimens.
Methods: We assessed 128 patients with newly diagnosed symptomatic multiple myeloma at our department during 2008-2013. Serum levels of DKK-1 were measured at the time of diagnosis before therapy, and correlated to serum levels of thymidine kinase (TK), osteocalcin (OC), bone fraction of alkaline phosphatase (bALP), parathormone (PTH), C-terminal telopeptide type I collagen (ICTP), procollagen I intact N-terminal (PINP), insulin-like growth factor-1 (IGF-1), hepatocyte growth factor (HGF), interleukin-6 receptor (IL-6R), syndecan-1 (SYN), vascular endothelial growth factor (VEGF), osteoprotegerin (OPG), endostatin (END), macrophage inhibitory protein 1α and 1β (MIP-1α, MIP-1β), and angiogenin (ANG). Also, we evaluated progression free survival and overall survival with regard to DKK-1 levels and therapeutic approach used.
Results: Spearman correlation analysis revealed weak positive relationship between serum levels of DKK-1 and TK (r=0,274; p=0,045); there was no other significant correlation in comparison of all other selected parameters, *i.e.* DKK-1 and OC, bALP, PTH, ICTP, PINP, IGF-1, HGF, IL-6R, SYN, VEGF, OPG, END, MIP-1α, MIP-1β and ANG. In the whole cohort of patients, DKK-1 was not found a suitable predictor of progression, the area under curve (AUC)=0,540 (<0,75). The Cox regression analysis revealed that DKK-1 is not a suitable prognostic factor of PFS and OS for the whole cohort of patients, RR=0,96 (95%CI: 0,57-1,62; p=0,876). In the subgroup of patients treated using autologous stem cell transplantation (ASCT, n=30), ROC analysis found DKK-1 as a convenient progression predictor with AUC=0,861 (>0,75). The optimal cut-off level was 9399ng/l (91% sensitivity, 74% specificity). Cox regression analysis followed by Kaplan-Meier analysis confirmed significant shorter PFS in patients with DKK-1<9399ng/l than in patients with DKK-1 ≥9399ng/l (2,6 *vs* 4,2 years, p=0,008). Due to short follow up we were not able to assess OS as the patients did not reach median OS yet. There was no significant difference in either OS or PFS in patients treated with thalidomide based regimens (n=62) or bortezomib based regimens (n=49).
Summary and Conclusion: Our data suggest that serum levels of DKK-1 are independent prognostic factor in MM patients treated with autologous stem cell transplantation. Patients with low DKK-1 had shorter PFS than patients with high serum levels of DKK-1. The use of novel biological drugs, however, overcomes its prognostic significance, suggesting a distinct interference of these drugs with bone marrow microenvironment. IMPACT OF EXONIZED ALUS ON SOLUBLE RANKL MRNA TRANSLATIONAL DYNAMICS

S Papamichos[1,*], M Papoutselis[2]
[1]Laboratory of Molecular Biology and Genetics, School of Medicine, Aristotle University of Thessaloniki, Thessaloniki, [2]Unit of Preventive Medicine, Social Security Institute, Alexandroupolis, Greece

Background: Alu retrotransponsons (Alus) are known to exert a broad evolutionary impact by affecting both the splicing motifs and the expression patterns of genes. TNFSF11, the gene encoding for RANKL, generates by alternative splicing two mRNA variants. TNFSF11 variant 1 (NM_003701) contains five exons and encodes for the membrane-bound form of RANKL. TNFSF11 variant 2 (NM_033012), including a total of seven exons, contains a

set of alternative 5′ exons; interestingly, this variant lacks the exon encoding for both the 5′ untranslated region (5′ UTR) as well as the intracellular and transmembrane domains of membrane-bound RANKL. Originally identified in two distinct squamous cell carcinoma cell lines, it has been suggested that variant 2 is predominantly expressed in malignant cell types. Recently, novel transcript variants of TNFSF11 were identified while it was shown that the longest open reading frame of variant 2 can be directly translated into the soluble form of RANKL, a protein linked causatively to induction of bone loss at distant sites in the skeleton. Importantly, translational dynamics of TNFSF11 variant 2 remain, yet, shadowy.

Aims: Provide, via bioinformatics analysis, novel insights on TNFSF11 variant 2 (soluble RANKL mRNA) translational dynamics; *id est* introduce this variant as a molecule of low translational efficiency. Highlight that a, yet unprecedented, shorter TNFSF11 variant could likely be translated into soluble RANKL in a more efficient manner.

Methods: Translational efficiency of TNFSF11 variant 2 was estimated with regard to the size of the 5′ UTR, the tendency of this region for forming stable secondary structures and the number of pseudosignals; 5′ UTR tendency for forming stable stem-loop structures was accessed via *pknotsRG-mfe* program. Soluble RANKL mRNA sequence was scanned for the presence of exonized Alus by *BLAST* and *Repeat Masker*. Search for uORFs was performed with the *ORF Finder* program; search parameters were set as previously suggested [Calvo *et al.,* 2009]. Alignment of corresponding sequences was schematically reproduced with the *Multalin* program.

Results: TNFSF11 variant 2 (Figure 1A, upper panel) represents a molecule of, likely, low translational efficiency, especially as compared to variant 1 (Figure 1B, 1C). Exons 1B and 1C of TNFSF11 variant 2 contain exonized Alus, of sense and antisense orientation, respectively (Figure 1A, upper panel). The exonized Alus potentially synergize in the formation of a complex stem-loop structure that could significantly impair translational efficiency, as indicated by the value for the secondary structures' minimum free energy (MFE) (Figure 1B, right panel). An evolutionary-induced single-nucleotide variation of the integrated AluSz element allows for the mutational gain of an upstream AUG trinucleotide (Figure 1A, green boxes) that demarcates the longest out of the five upstream open reading frames (uORFs) present in soluble RANKL mRNA. Both the start and stop codons of this uORF are conserved among higher primates (Figure 1A, lower panel) while, according to dbSNP, are not polymorphic in human. In addition, out of the 12 known polymorphic sites included within this uORF, all representing single nucleotide substitutions, none induces an in-frame nonsense codon; all the above could suggest an important biological role of this uORF, mainly in the context of post-transcriptional regulation. An alternative splicing event, exon 1C skipping, allows for the generation of a shorter TNFSF11 transcript variant (Figure 1D). Originally identified in the human osteoblast-like cell line Saos-2 and the human T cell line Jurkat Clone E6 [Walsh *et al.*, 2013], this variant contains also the primary ORF that encodes for the full length extracellular domain of RANKL (soluble RANKL). However exclusion of exon 1C results in, markedly, shortening the length and increasing the MFE of the 5' UTR while disrupts the uORF, described above.

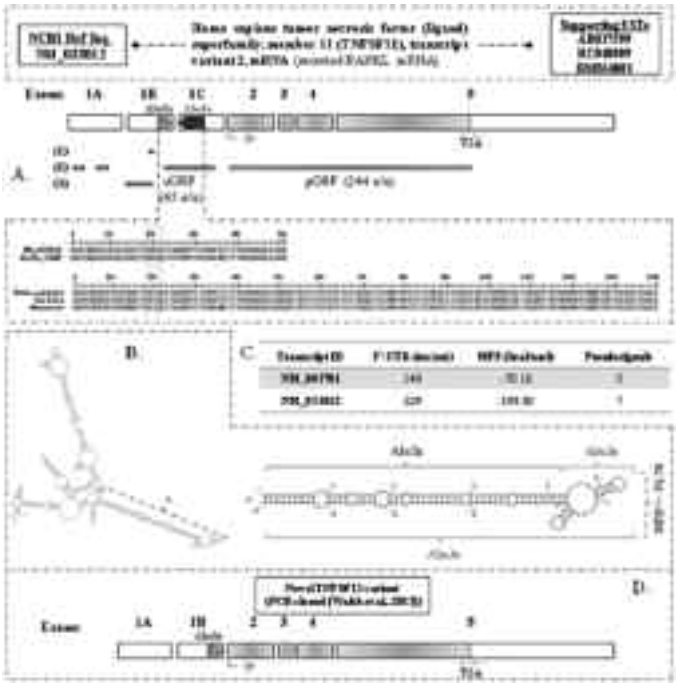

Figure 1.

Summary and Conclusion: Intriguingly, natural selection seems to have induced the assembly of stringent biological mechanisms that could significantly impair the translation of TNFSF11 variant 2. However a novel TNFSF11 variant, partially bypassing these constraints, could efficiently encode for soluble RANKL; *id est* this novel variant could be the one encoding for soluble RANKL, instead of TNFSF11 variant 2 as previously assumed.

FIBROBLAST ACTIVATION PROTEIN PROTECTS BORTEZOMIB INDUCED APOPTOSIS IN MULTIPLE MYELOMA CELLS THROUGH B-CATENIN SIGNALING PATHWAY

Z Cai[1,*], J He[1], L Yang[1], X Han[1], G Zheng[1], W Zheng[1], G Wei[1], W Wu[1], X Ye[1], J Shi[1], W Xie[1], L Li[1], J Zhang[1], W Huang[1], H Huang[1], X Zhang[2], J Fu[3]
[1]Hematology & Bone Marrow Transplantation, The First Affiliated Hospital of Medical School, Zhejiang University, [2]Hematology, Hangzhou Red Cross Hospital, Hanghzou, [3]Hematology, The People's Hospital of Shaoxing, Shaoxing, China

Background: Multiple myeloma(MM), a malignant plasma cells proliferative disease, is characterized by increased blood calcium level, renal insufficiency, anemia, and bone lesions(CRAB). The coevolution of MM cells with bone marrow stromal cells plays an important role in MM cells growth, survival and drug resistance. Fibroblast activation protein(FAP), a vital transmembrane protein which is expressed in 90% epithelial tumor stroma, has been reported to be involved in mediating drug resistance, tumor progression, immune evasion, invasion and metastasis of tumor cells. However, the expression and function of FAP in MM is still less known.

Methods: Bone marrow mesenchymal stem cells(BMMSCs) from MM patients, normal donors and the cell line of human BMMSCs were analyzed for expression of the FAP protein by semiquantitative real time-polymerase chain(qRT-PCR), flow cytometry(FCM) and immunofluorescence(IF). Tumor cell-conditioned medium (TCCM) from supernatant of MM cell lines were added to BMMSCs or MM cells coculture with BMMSCs to observe the effect of TCCM or MM cells stimulation for the expression of FAP. We further studied the function and mechanism of FAP in bortezomib induced apoptosis of myeloma cells by silencing FAP with small interfering RNA(siRNA). Apoptotic cells of MM cells were detected by APC-CD138/annexin V-FITC using flow cytometry analysis. Western blotting was used to elucidate the signaling pathway that FAP may be involved in mediating apoptosis of MM cells induced by bortezomib.

Results: There was no significant difference in the expression of FAP in hBMMSCs isolated from MM patients and normal donors($p \square 0.05$) as determined by qRT-PCR, and FCM. BMMSCs stimulated by TCCM or coculture with MM cells displayed an elevated expression of FAP as detected by qRT-PCR($p \square 0.05$). In the presence of 30nM bortezomib, MM cell lines RPMI8226 or CAG cells co-cultured with BMMSCs in which FAP was knockdown or not by siRNA for 48h demonstrated that FAP is capable of protecting RPMI8226 and CAG cells induced by bortezomib from apoptosis as determined by FCM(NC siRNA *vs* FAP siRNA, $p \square 0.05$). Further study showed that the activity of β-catenin was significantly elevated in RPMI8226 and CAG cells after co-cultured with BMMSC in the presence of bortezomib. Knockdown FAP can reduce the expression of β-catenin and its downstream target proteins, such as c-myc, survivin, cyclin D1 in RPMI8226 and CAG cells detected by western blot. The activation of β-catenin need MM-BMMSCs direct contact other than separated by transwell.

Summary and Conclusion: Taken together, our data indicated that the expression level of FAP was no difference between the BMMSCs isolated from MM patients and normal donors. The expression of FAP can be increased by TCCM stimulation or coculture with MM cells. Further study demonstrated that FAP can protect MM cells from apoptosis induced by bortizomib, which is likely through β-catenin signaling pathway. This protection need direct contact with BMMSCs.

P942

PRECLINICAL ANTIMYELOMA ACTIVITY OF THE ALKYLATING-HDACI FUSION MOLECULE EDO-S101 THROUGH DNA-DAMAGING AND HDACI EFFECTS

AA López-Iglesias[1,*], L San-Segundo[1], L González[1], S Hernández[1], D Primo[2], M Garayoa[1], T Paíno[1], A García-Gómez[1], T Mehrling[3], MV Mateos[1], EM Ocio[1]
[1]Hematology, University Hospital of Salamanca and Cancer Institute Research (IBSAL), Salamanca, [2]Vivia Biotech, Madrid, Spain, Madrid, Spain, [3]Mundipharma, Berlin, Germany

Background: Alkylators such as melphalan are part of the backbone treatment of young and also elderly MM patients. Moreover, novel ones such as bendamustine have been used in several combinations with either proteasome inhibitors or IMIDs. EDO-S101 is a novel drug resulting from the fusion of a molecule of bendamustine with a vorinostat one, with the aim of increasing the efficacy of the alkylator through the HDACi-mediated chromatin relaxation that would make DNA more accessible to the damaging effect of bendamustine.

Aims: To study the efficacy and mechanism of action of EDO-S101 in human myeloma cell lines (HMCL) either alkylator sensitive and resistant, in freshly isolated MM patient cells and in a xenograft model of human MM.
Methods: Sensitivity to EDO-S101 was assessed by MTT in HMCLs and by flow cytometry in freshly isolated cells from 5 MM patients. *in vivo* efficacy was analyzed in a xenograft plasmocitoma model of MM1S in CB-17 SCID mice. For the evaluation of the mechanism of action several techniques were used to analyze apoptosis and changes in the cell cycle profile. Western blot and immunohistochemistry in tumors excised from treated mice were also employed. Calcusyn program was used to calculate synergy or additive effect with other anti-MM drugs.
Results: Among a panel of 6 HMCLs representative of MM heterogeneity, high sensitivity to EDO-S101 was observed in all of them independently of p53 status (IC50 values ranging from 1 to 5μM). Furthermore EDO-S101 was also active in cells isolated from MM patients, with median IC50 of 5 μM (ranging from 1,8 to 8 μM) and, interestingly, EDO-S101 could overcame alkylators-resistance as it was active in melphalan resistant cells (U266-LR7 and RPMI8226-LR5). Regarding the *in vivo* efficacy, three weekly doses of EDO-S101 (60 mg/Kg iv) were able to significantly decrease tumor growth (time to reach 1.000 mm^3 of 20 days for the control group as compared with 60 days for the treated mice) and also to prolong survival ($p<0.05$). Importantly, EDO-S101 was also active in mice bearing big tumors (3.000 mm^3). With regards to toxicity, only some body weight loss was observed in the treated mice. Regarding the mechanism of action, EDO-S101 induced apoptosis *in vitro* as assessed by Annexin-V staining, loss of mitochondrial membrane potential and cleavage of caspases 8, 9, 7, 3 and PARP. Cell cycle profile showed an S and G2M arrest. Specifically, EDOS-101 induced apoptosis was dependent of a dual alkylating and HDACi mechanisms. As far as the alkylating mechanism is concerned, EDO-S101 induced double strand breaks (DSBs) as demonstrated by comet assay by immunofluorescence and by an increase in pH2AX by western blot, both *in vitro*, and *in vivo* by immunohistochemistry in tumors from treated mice. As a result, an activation of the DNA damage checkpoints was also demonstrated with clear increases in p53, p-CHK1 and p-CHK2. As mentioned, an HDACi effect could also be proven, as an increase in the acetylation of histones H3 and H4 were observed both *in vitro* and *in vivo*. Finally, among different combinations tested, EDO-S101, was synergistic when combined with bortezomib and with dexamethasone in double and also in triple combination (EDO-S101 + bortezomib + dexamethasone).
Summary and Conclusion: The *in vitro*, *ex vivo* and *in vivo* efficacy of EDO-S101 through an alkylator and a HDACi effect, provides the rationale for the investigations of this compound in clinical trials in MM. Probably a potential clinically relevant combination would be that including bortezomib + dexamethasone.

P943

SAR650984, A HUMANIZED ANTI-CD38 ANTIBODY, POTENTLY TARGETS CANCER CELLS THROUGH MULTIPLE MECHANISMS

T Cai[1,*], B Zhang[1], G Yang[1], Z Song[1], S Dai[1], T He[1], D Simard[1], S Licht[1], F Adrian[1], H Cheng[1], K Corzo[1]
[1]Sanofi, Cambridge, United States

Background: CD38 is a type II transmembrane glycoprotein with both ectozyme activity and receptor function that has been implicated in cancer cell adhesion, signal transduction and calcium signaling. CD38 is highly expressed at the surface of many hematological cancer cells. SAR650984 is a humanized IgG1 antibody targeting CD38 in early clinical development to treat patients with $CD38^+$ hematological malignancies. Several mechanisms of action of SAR650984 have been identified including antibody-dependent cell-mediated cytotoxicity (ADCC), complement-dependent cytotoxicity (CDC), and direct cell death induction (ASH 2008 Abstract #2756). In addition, SAR650984 displays potent inhibition of recombinant CD38 ADP-ribosyl cyclase activity in a biochemical assay (AACR 2013, Abstract #4735).
Aims: To further characterize the mechanism of direct cell death induction and extracellular nucleotide modulation by SAR650984.
Results: The direct effects of SAR650984 on cancer cells were evaluated in a panel of multiple myeloma (MM) and diffuse large B-cell lymphoma (DLBCL) cells. In cancer cells with high CD38 expression levels, Annexin V positive staining increased significantly after SAR650984 treatment, which correlated with strong cell proliferation inhibition. Cell death induced by SAR650984 was further confirmed by detection of released cell death biomarker HMGB1 and Cyclophilin A in culture medium. SAR650984 induced cell death was independent of caspase activation and BCL2 family protein alterations but associated with homotypic cell adhesion, which was similar to the reported activity of anti-CD20 type II antibody GA101 (Blood, 117:4519, 2011). These findings reveal that unlike other anti-CD38 antibodies, SAR650984 is able to directly induce novel mode of cell death in the absence of cross-linker or immune cells which potentially will lead to improved tumor cell killing *in vivo*. To explore the impact of SAR650984 on CD38 ecto-enzymatic activities in cancer cells, we have developed a robust LC-MS-based cellular CD38 enzymatic assay that monitors the depletion of CD38 substrates nicotinamide adenosine dinucleotide (NAD) and the production of cyclic adenosine diphosphoribose (cADPR) and adenosine diphosphoribose (ADPR) from CD38 cyclase and CD38 NAD glycohydrolyase activities, respectively. Preliminary results demonstrate that in response to the treatment of SAR650984, CD38 cyclase activity in multiple myeloma and lymphoma cancer cells was significantly inhibited by more than 90% as shown by a rapid and dose-dependent decrease in the rate of both substrate NAD depletion as well as extracellular cADPR production. Interestingly, a significant reduction of intracellular cADPR (over 60%) was also observed after SAR650984 treatment. Emerging data suggest that nucleotides such as NAD and cADPR are important regulators of cell growth, survival and immune responses. The altered levels of nucleotides resulting from CD38 enzymatic inhibition by SAR65084 in tumor microenvironment therefore could contribute to the anti-tumor efficacy of the antibody. Additional studies to elucidate this activity are currently ongoing.
Summary and Conclusion: SAR650984 demonstrated unique properties of direct cell death induction and potent CD38 enzymatic inhibition on cancer cells in addition to its complement and immune cells mediated cytotoxicity. These results provide new insights toward understanding the multiple antitumor mechanisms of SAR650984.

NETWORK OF MICRO RNA AND EPIGENETICS ARE ASSOCIATED WITH THE PROGRESSION OF MGUS AND MULTIPLE MYELOMA

H Handa[1,*], Y Masuda[2], H Hattori[2], A Kaneko[2], I Suda[2], L Alkebsi[2], T Saitoh[2], H Iriuchishima[1], M Takizawa[1], H Koiso[3], A Isoda[4], M Matsumoto[4], M Sawamura[4], KI Tahara[1], T Ishizaki[1], T Mitsui[1], H Shimizu[1], A Yokohama[5], N Tsukamoto[3], Y Nojima[1], H Murakami[2]
[1]Department of Medicine and Clinical Science, [2]Health Science, [3]Oncology Center, Gunma University, Maebashi, [4]Hematology, National Nishi-Gunma Hospital, Shibukawa, [5]Blood Transfusion Service, Gunma University, Maebashi, Japan

Background: Micro RNAs (miRs) are small non-coding RNAs of 19-25 bases in length having ability to modulate gene expression and involved in carcinogenesis. Transcriptional silencing of tumor suppressor genes (TSG) in cancer cells is often associated with DNA methylation and histone deacetylation carried out by epigenetic modifiers DNMTs and HDACs. miRs can regulate DNMTs expression and promoters of several miRs are also hypermethylated suggesting network of miR and epigenetics in cancer cells.
Aims: To understand the interaction of miRs and epigenetics in multiple myeloma (MM) progression, we investigated correlation between miR and epigenetic modifiers expressions and promoter methylation of TSG and miRs in plasma cells in MM and MGUS.
Methods: Purified plasma cells of BM obtained from 71 of MM patients 29 of MGUS patients and 11 of control patients are subjected to the study after informed consent. This study was approved by IRB, MiRs and epigenetic modifiers' mRNA values were determined by real time PCR with Taqman probe or SYBR green and $2^{-\Delta\Delta}$method. Methylation status of DNA were determined by methylation specific PCR (MSP).
Results: We found significant reduction of miRs 15a (mean values; 52.36, 85.95, 110.71; MM, MGUS and control respectively, $p<0.001$), 15b (55.05, 79.97, 103.86, $p<0.001$), 16a (55.53, 87.62, 101.14, $p<0.001$), 29a (55.91, 84.19, 97.14, $p<0.001$), 29b (58.14, 83.67, 103.00, $p<0.001$), 29c (10.91, 14.94, 59.50, $p<0.001$), 34a (103.11, 132.78, 1617.25, $p<0.001$), 34b (21.73, 71.43, 56.73, $p<0.001$), 34c (1771.02, 12816.17, 7830.79, $p<0.001$) along with elevation DNMT1, 3A and HDAC3, 5, 7, 9 in MM. DNMT1, 3A were elevated in MM than in MGUS and control subjects ($p=0.03$). DNMT3B expression was not different among subjects. In the MM cell lines, miR 29a and 29b expression were inversely correlated with DNMT1 mRNA expression ($r=0.96$, $p=0.0003$: $r=0.86$, $p=0.014$). In the patient samples, DNMT1 was inversely correlated with miR15a, miR15b, miR16, miR29a, miR29b ($r=-0.435$, $p=0.003$; $r=-0.341$, $p=0.02$, $r=-0.332$, $p=0.03$, $r=-0.419$, $p=0.005$, $r=-0.407$, $p=0.006$), DNMT3A was inversely correlated with miR15a, miR29a, miR29b, miR29c ($r=-0.365$, $p=0.02$; $r=-0.315$, $p=0.04$; $r=-0.371$, $p=0.01$; $r=-0.315$, $p=0.04$), DNMT3B was inversely correlated with miR15a, miR15b, miR29a, miR29b ($r=-0.418$, $p=0.005$; $r=-0.385$, $p=0.01$; $r=-0.353$, $p=0.02$; $r=-0.358$, $p=0.02$). HDAC3, 7, 9 expression were elevated in MM than in MGUS ($p=0.03$, $p=0.001$, $p=0.001$) and normal subjects (0.18, 1.1, 20.8) ($p=0.01$, $p=0.017$, $p=0.012$). HDAC1, 3, 7 were inversely correlated only with miR15a ($r=-0.25$, $p=0.039$, $r=-0.27$, $p=0.025$, $r=-0.25$, $p=0.038$). The sequential samples during the treatment showed opposite direction change between miRs and epigenetic modifiers, associating with refractoriness. The rate of methylation in TSG was higher in MM and interestingly putative tumor suppressor miR 34a, b/c were also methylated. There were significant positive correlations among miRs expressions; miR29a-29b $r=0.832$, 29a-29c $r=0.616$, 29a-34a $r=0.448$, $p<0.001$, 29a-34b $r=0.309$, $p=0.001$, miR29a-miR34c $r=0.414$, $p<0.001$, miR29b-29c $r=0.659$, 29b-34a $r=0.500$, $p<0.001$, 29b-34b $r=0.297$, $p=0.002$, 29b-34c $r=0.392$, $p<0.001$, 29c-34a $r=0.432$, 29c-34b $r=396$, $r=0.655$, 29c-34c $r=0.398$, $p<0.001$. Covariance structure analysis revealed the complex network between miRs and epigenetics. When the cell lines were treated with 5 deoxy-azacytidine, miR34a, b, c expression levels increased after the treatment.
Summary and Conclusion: We found significant reduction of miRs expression

in MM and the reduction in part associated with methylation. Correlations in between miR expression, methylation and DNMT imply an important role of them in MM progression. Our study suggests the existence of network between miR and epigenetics, and further investigation would be valuable for understanding the nature of disease progression.

P945

CHARACTERIZATION OF SERUM AND GLUCOCORTICOID-INDUCIBLE KINASE 3 (SGK-3) AS A POTENTIAL ONCOGENIC ALTERNATIVE TO SIGNALLING VIA AKT IN MULTIPLE MYELOMA

R Seggewiss-Bernhardt[1,*], S Hausmann[1], H Einsele[1], R C Bargou[2], T Stühmer[1]
[1]Department of Internal Medicine II, Division of Hematology and Oncology, [2]Comprehensive Cancer Center Mainfranken, University Hospital of Würzburg, Würzburg, Germany

Background: We have previously shown that multiple myeloma (MM) tends to segregate in two groups: those that heavily depend on oncogenic Akt activity for their survival, and those that are relatively Akt-independent (Zöllinger et al, Blood, 2008). SGK-3 has been implicated as mediator of phosphoinositide-3-kinase (PI3K)-dependent, but Akt-independent signalling in breast cancer (Vasudevan *et al.*, Cancer Cell, 2009). These observations provide a rationale to investigate if SGK-3 might serve either as stand-alone or as combination therapeutic target downstream of PI3K in (particular subgroups of) MM.
Aims: Analysis and characterization of the potential functional roles of SGK-3 in multiple myeloma.
Methods: SGK-3 expression analyses at mRNA and protein levels were conducted in phospho-Akt-positive and -negative MM cell lines (n=10) and in CD138-purified primary myeloma samples (n=10). SiRNA-mediated knockdown of SGK-3 was performed by electroporation and subsequent purification of affected cells. Cell death and proliferation measurements were conducted with SGK-3 knockdown cells with and without further addition of pharmacologic inhibitors of potentially interconnected oncogenic signalling pathways.
Results: SGK-3 was found expressed in all MM cell lines and in primary MM cells. Electroporation proved a powerful means to achieve extensive transient siRNA-mediated SGK-3 knockdown (>95%) in MM cell lines (AMO-1, U-266, JJN-3, L-363, MM.1S) and the effect lasted for at least five days before protein levels began to recover. SGK-3 knockdown did not lead to substantial changes in the levels of phosphorylated Akt (positions Thr308 and Ser473), or of other PI3K-downstream targets, such as phospho-GSK-3beta, phospho-PRAS40 or phospho-FOXO3A in either phospho-Akt-positive (JJN-3, L-363, MM.1S) or phospho-Akt-negative (AMO-1, U-266) MM cells. SGK-3 depleted MM cells were not noticeably impaired regarding either proliferation/metabolism (AlamarBlue assay) or survival (annexin V-positivity determined by FACS analysis) when compared to cells treated likewise but transfected with an innocuous siRNA against EGFP. We are currently investigating if in addition to SGK-3 blockade the parallel pharmacologic and/or siRNA-mediated inhibition of other signalling pathways either directly downstream of PI3K (Akt, Bruton tyrosine kinase) or indirectly connected to it (MEK/MAPK, JAK/STAT3) provides a means for enhanced anti-myeloma activity, and the respective results will be presented.
Summary and Conclusion: We have so far not found evidence for a prominent direct role of SGK-3 in the survival and/or proliferation of either phospho-Akt-positive or phospho-Akt-negative MM cells. Although our results are exclusively based on SGK-3 knockdown studies (no specific pharmacological SGK-3 inhibitors exist), this is in clear contrast to the situation with Akt (specifically: Akt1 and Akt2; Zöllinger, Blood, 2008) and also PI3K-alpha (Hofmann, BJH, in the press) where siRNA-mediated target depletion can result in substantial induction of MM cell apoptosis. While an indirect role of SGK-3 in interconnection with other oncogenic signaling pathways is still being investigated, our preliminary data would argue against SGK-3 as a significant potential therapeutic target in MM.

P946

ORAL STATIN USE ASSOCIATED WITH REDUCED RISK OF MONOCLONAL GAMMOPATHY OF UNDETERMINED SIGNIFICANCE AND MULTIPLE MYELOMA: A POPULATION BASED NESTED CASE-CONTROL STUDY

C Mcshane[1,*], C Tapper[1], L J Murray[1], O Landgren[2], M Bradley[3], C Hughes[4], L A Anderson[1]
[1]Centre for Public Health, Queens University Belfast, BELFAST, United Kingdom, [2]Multiple Myeloma Section, National Cancer Institute, Bethesda, [3]Cancer Prevention Fellowship Program, National Cancer Institute, Rockville, United States, [4]School of Pharmacy, Queens University Belfast, BELFAST, United Kingdom

Background: Several studies have suggested statin-mediated inhibition of the mevalonate pathway is tumour-suppressive, with a pronounced effect in haematological malignancies reported. To date, there have been few investigations of the associations between statin use and monoclonal gammopathy of undetermined significance (MGUS) and/or multiple myeloma (MM). As all cases of MM arise from MGUS, preventing the development of MM provides an opportunity to combat global increases in incidence with a well-tolerated class of drugs.
Aims: To investigate the association between prior oral statin use and risk of MGUS and MM using the UK Clinical Practice Research Datalink (CPRD).
Methods: Conditional logistic regression models were used to estimate odds ratios (OR) and associated 95% Confidence Intervals (CI) excluding 12 months prior to MGUS/MM diagnosis. Findings were adjusted for a number of potential confounders including age at diagnosis, comorbidities, prior cancer, number of GP consultations and lifestyle variables.
Results: In total, 4,654 MGUS and 3,801 MM patients matched to 23,101 and 18,991 controls respectively were identified. In adjusted analyses, statin users were found to have a 19% reduced risk of developing MGUS (OR, 0.81; 95% Confidence Interval (95% CI), 0.74-0.88) and a 23% reduced risk of developing MM (OR, 0.77; 95% CI, 0.69-0.85). Only lipophilic statins were significantly associated with a reduced risk of both MGUS and MM. A dose response relationship between prior statin use and risk of both MGUS and MM was also evident.
Summary and Conclusion: Statin usage was associated with a reduced risk of developing both MGUS and MM in this large population-based study. Statins may therefore have a role to play in preventing progression of MGUS to MM or associated lymphoproliferative malignancies. Further investigation and clinical trials are however needed to confirm this.

P947

CHRONIC INFECTION, A NEGLECTED CAUSE OF DEVELOPMENT OF MONOCLONAL GAMMOPATHY OF UNDETERMINED SIGNIFICANCE (MGUS) AND MYELOMA

D Feron[1,*], P Lehebel[2], C Charlier[3], D Caillot[4], C Rossi[4], L Garderet[5], M Coste-Burel[6], P Moreau[7], M Hamidou[8], F Girodon[9], P Weigel[3], S Hermouet[9], E Bigot-Corbel[10]
[1]UMR InsermU892/CNRS 6299, Université, [2]UMR Inserm 892/CNRS 6299, University of Nantes, [3]IMPACT, Université, Nantes, [4]Service d'Hématologie, Centre Hospitalier Universitaire, Dijon, [5]Service d'Hématologie, Centre Hospitalier Universitaire, Paris, [6]Laboratoire de Virologie, [7]Service d'Hématologie Clinique, [8]Service de Médecine Interne, [9]Laboratoire d'Hématologie, [10]Laboratoire de Biochimie Générale, Centre Hospitalier Universitaire, Nantes, France

Background: Chronic infection can lead to B-cell malignancy via the direct transformation of infected B-lymphocytes or indirectly via cell transformation consecutive to chronic antigen-driven stimulation; the two mechanisms may occur simultaneously [1,2]. Numerous studies have established that viruses (Epstein-Barr virus (EBV), human herpes virus 8, hepatitis C virus (HCV)) or bacteria (*H. pylori*) can induce lymphoma and chronic lymphocytic leukemia (CLL). In contrast, the role of chronic infection in the pathogenesis of myeloma is rarely investigated. Yet monoclonal immunoglobulins (mc Ig) that arise in HCV-positive myeloma patients typically target the virus [2]. Thus HCV infection may lead to monoclonal gammopathy of undetermined significance (MGUS) and eventually, myeloma.
Aims: The present study shows that mc Ig also target EBV, *H. pylori* and Varicella Zoster Virus (VZV) and that HCV is not the only germ involved.
Methods: In order to study the specificity of mc Ig, we designed a new assay based on a multiplexed infectious antigen microarray (MIAA) that combines representative epitopes of a panel of germs that included HCV, EBV, *H. pylori* and 5 other germs, spotted in triplicate on nitrocellulose-coated slides [3]. Slides were first incubated with either serum or purified mc Ig, then with an infrared dyed (IRD)-labeled secondary antibody, and fluorescence signals were detected and quantified.
Results: The specificity of purified mc Ig from 110 patients diagnosed with MGUS (n=34) or myeloma (n=76) was analysed using the 8-germs MIAA assay. We found that 17.6% of MGUS and 23.6% of myeloma patients presented with a mc Ig that was specific for an antigen from HCV (10 cases), EBV (11 cases), *H. Pylori* (2 cases) or VZV (1 case). In contrast, none of the mc Ig studied targeted CMV, a virus against which a majority of individuals possess antibodies. Gathering our previous studies [1,2], 10/11 HCV-positive patients had mc Ig directed against HCV, either the core (n=7) or NS-4 (n=3) proteins. Interestingly, EBV-specific mc Ig all targeted a single antigen. Regarding EBV-positive patients, the mc Ig was specific in 17.7% cases (11/62), and in all cases the mc Ig targeted Epstein Barr nuclear antigen (EBNA). For 7% (2/28) of *H. pylori*-positive patients, the mc Ig targeted different antigens of *H. Pylori*. Only one mc Ig targeted glycoprotein E of VZV.
Summary and Conclusion: Altogether, 24 of the 110 MGUS and myeloma patients (21.8 %) examined presented a mc Ig specific for a pathogen (HCV, EBV, *H. pylori* or VZV). Thus as described for lymphoma and CLL, chronic infection can also induce MGUS and eventually, trigger the pathogenic processes that lead to myeloma. Efforts should be made to identify the subsets of patients with mc Ig specific for HCV, EBV, *H. pylori* and VZV, preferably at the MGUS stage, as anti-infection treatment could cure MGUS and prevent progression toward myeloma.

P948

IMMUNE IMPAIRMENTS IN MULTIPLE MYELOMA BONE-MARROW MESENCHYMAL STROMAL CELLS

T André[1,*], M Najar[1], B Stamatopoulos[1], K Peeters[1], O Pradier[2], D Bron[3], N Meuleman[3], L Lagneaux[1]
[1]LTCC, Jules Bordet Institute - ULB, [2]Laboratory of Hematology, Erasmus Hospital, Anderlecht, [3]Departement of Hematology, Jules Bordet Institute - ULB, Bruxelles, Belgium

Background: In multiple myeloma, bone marrow mesenchymal stromal cells play an important role in pathogenesis and disease progression by supporting myeloma cell growth and immune escape. Previous studies suggested that direct and indirect interactions between malignant cells and mesenchymal stromal cells result in constitutive abnormal immunomodulatory capacities in mesenchymal stromal cells.
Aims: The aims of this study were to further study and to investigate the mechanisms that underlie these MM BM-MSC abnormalities.
Methods: We analyzed MM BM-MSCs expression of a variety of adhesion molecules and immune effectors and compared the results to MSCs from healthy donors (HD BM-MSCs). We measured the concentrations of immunoregulatory cytokines in co-cultures of T cells and MM BM-MSCs. Finally, we evaluated the fate of T cells co-cultured with MM BM-MSCs.
Results: We demonstrated that myeloma mesenchymal stromal cells exhibit abnormal expression of CD40/40L, VCAM1, ICAM-1, LFA-3, HLA-DR and HLA-ABC. We observed an overproduction of IL-6 and a reduced secretion of IL-10 when myeloma mesenchymal stromal cells were co-cultured with T lymphocytes compared to co-cultures with healthy donors mesenchymal stromal cells. An increased Th17/Treg ratio was observed when T cells were co-cultured with myeloma mesenchymal stromal cells compared to co-cultures with healthy donors mesenchymal stromal cells.
Summary and Conclusion: Our observations demonstrated that altered immunomodulation capacities of myeloma mesenchymal stromal cells were linked to variations in their immunogenicity and secretion profile. These alterations lead not only to a reduced inhibition of T cell proliferation but also to a shift in the Th17/Treg balance. We identified factors that are potentially responsible for these alterations, such as IL-6, VCAM-1 and CD40/40L which could also be associated with myeloma pathogenesis and progression.

P949

MALAT-1, A LONG NON-CODING RNA, IS OVER-EXPRESSED IN MULTIPLE MYELOMA AND IS A PREDICTOR OF EARLY PROGRESSION

SF Cho[1,*], CS Chang[1], SF Lin[1], YC Liu[1], HH Hsiao[1], TC Liu[1]
[1]Department of hematology/oncology, Kaohsiung Medical University Hospital,Kaohsiung city, Taiwan, Kaohsiung city, Taiwan, Republic of China

Background: The pathogenesis of multiple myeloma involves complex genomic and epi-genomic events.
Aims: The purpose of this study was to investigate the role and clinical significance of long non-coding RNA in multiple myeloma.
Methods: Forty long non-coding RNAs (length >5000 nucleotides) selected from a bio-informatics database were used. The clinical characteristics and associations of these long non-coding RNAs were analyzed
Results: Initial screening revealed that a long non-coding RNA, MALAT-1, showed consistent and significant changes between newly-diagnosed and post-treatment patients (mean ΔC_T: -5.26±0.85 *vs*. -3.74±1.38; p=0.02). In the validation test, MALAT-1 was over-expressed in newly-diagnosed patients with myeloma originating from bone marrow compared with extramedullary myeloma (mean ΔC_T: -5.58±0.21 *vs*. -3.83±0.23; p<0.01). In the patients with myeloma originating from bone marrow, the expression of MALAT-1 changed dynamically during treatment and follow-up. The expression of MALAT-1 decreased significantly after induction treatment and then increased significantly when the disease was in progression. The magnitude of the change in MALAT-1 after treatment was clinically significant. The patients with early progression had a significantly smaller change in MALAT-1 compared with the patients with late progression (mean ΔC_T change:1.25±1.12 *vs*.2.37±0.81, p<0.01). A cut-off value of MALAT-1 change(ΔC_T change:1.5) was obtained, and could predict the risk of early progression even in VGPR or CR status (OR 5.44, 95% CI 1.78-16.63; p<0.01).
Summary and Conclusion: MALAT-1, a non-coding RNA with very long length, was over-expressed in patients with myeloma originating from bone marrow, and may play a role in the pathogenesis of this disease. In addition, MALAT-1 may serve as a molecular predictor of early progression.

P950

PREVALENCE AND PROGNOSIS SIGNIFICANCE OF THE MYD88 (L265P) MUTATION IN IGM MONOCLONAL GAMMOPATHY OF UNDETERMINED SIGNIFICANCE AND SMOLDERING WALDENSTRÖM MACROGLOBULINEMIA

J G Correa[1,*], C Fernández de Larrea[1], MT Cibeira[1], N Tovar[1], F Pedrosa[1], L Magnano[1], L Rosiñol[1], J Bladé[1]
[1]Amyloidosis and Myeloma Unit. Department of Hematology., Hospital Clinic. IDIBAPS, Barcelona, Spain

Background: Waldenström macroglobulinemia (WM) is a clonal lymphoproliferative disorder characterized by the accumulation of lymphocytes and plasma cells producing an excess of IgM monoclonal immunoglobulin protein, resulting in symptoms either from bone marrow infiltration or from blood alterations due to the paraprotein. *MYD88* (L265P) is a highly prevalent somatic mutation in WM patients. WM is usually preceded by an IgM monoclonal gammopathy of undetermined significance (MGUS) and/or smoldering WM (SMW). It has been reported that *MYD88* mutation is present in almost half of IgM MGUS patients.
Aims: To ascertain the prevalence of *MYD88* (L265P) mutation in IgM MGUS, SMW and MW patients, evaluating also the clinical, biological and prognostic impact of this mutation in a series of patients from a single institution.
Methods: We studied ninety-eight patients (45F/53M; median age 70 years, range 33 to 92) diagnosed with an IgM MGUS, SMW or MW between May 1982 and November 2011. According to the Mayo Clinic guidelines, SWM was defined by a bone marrow lymphoplasmacytic infiltration over 10% and/or a serum IgM monoclonal protein ≥30 g/L, with no evidence of end-organ damage or symptoms attributed to the lymphoproliferative disorder. Patients with less tumoral burden were classified as IgM MGUS, and those with any evidence of symptomatic disease attributed to the monoclonal gammopathy were diagnosed with WM. Genomic DNA was isolated from bone marrow slides using a commercial kit (Qiagen). *MYD88* (L265P) mutation was analyzed using a quantitative real-time PCR technology (qBiomarker Somatic Mutation PCR Assay, Qiagen) using ARMS® (Amplification Refractory Mutation System) primer-based allele discrimination with negative and positive controls in each plate. Sensitive detection of the intended mutation is as low as 1% mutant sample on a wild-type sample background. Time to progression (TTP) and overall survival (OS) were measured in MGUS and SWM patients from diagnosis until progression to symptomatic gammopathy or death, respectively.
Results: Fifty-six patients (57.1%) were classified as IgM MGUS, 30 (30.6%) as SWM and 12 as symptomatic WM (12.2%). Light-chain isotype was mainly kappa (63.3%), followed by lambda (31.6%) and few biclonal cases (5.1%). After a median follow-up of 4 years for alive patients (range, 3 months to 25 years), only 5.4% patients with IgM MGUS as compared to 23.3% with SWM developed symptomatic WM (p=0.029). Most of these patients progressing to symptomatic WM carried the *MYD88* (L256P) mutation (2 out of 3 MGUS; 6 out of 7 SWM). Median TTP was longer in patients with MGUS than those with SWM (21 *vs*. 12 years; p=0.001). Median OS of patients with MGUS and SWM was significantly longer than WM cases (19.9 and 17.2 *vs*. 5 years; p<0,001). MYD88 mutation was found in 88.3%, 80% and 23.6% of patients diagnosed with WM, SWM and MGUS, respectively (p<0,001). Regarding our 86 patients with asymptomatic IgM monoclonal gammopathy, we observed no difference in bone marrow plasma cell infiltration but a higher lymphocytic infiltration in mutated compared with wild-type MYD88 patients (20% *vs*. 9%; p<0.001). MYD88 carriers were also significantly older (p=0.02), had higher ESR (p=0.025) and showed a trend towards higher serum M-spike (p=0.07). TTP was shorter in mutated *vs*. wild-type patients (median not reached *vs*. 22 years, p=0.067) (Figure). However, MYD88 status did not influence survival in our series.

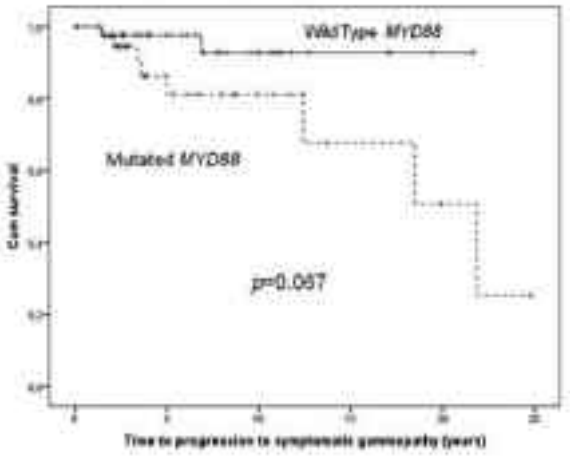

Figure 1. Time to progression from asymptomatic IgM monoclonal gammopathies (MGUS and smoldering Waldenström macroglobulinemia) to symptomatic disease, according to the presence of L265P mutation in MYD88.

Summary and Conclusion: We observed a high prevalence of *MYD88* L265P mutation in asymptomatic IgM gammopathies, in agreement with previous series, as well as a significantly higher tumour burden in patients carrying the mutation. In our series with a long follow-up, patients with asymptomatic IgM gammopathies carrying the mutation showed a trend towards a shorter time to progression than patients with wild-type genotype. Our results support the potential role of *MYD88* status to identify asymptomatic IgM gammopathies at higher risk of progression to symptomatic disease.

P951

INHIBITION OF NAMPT AUGMENTS IBRUTINIB INDUCED KILLING IN MYD88 L265P EXPRESSING WALDENSTROM`S MACROGLOBULINEMIA CELLS

A Cagnetta[1,*], M Cea[1,2], M Fulciniti[1], T Yu-Tzu[1], D Chauhan[1], M Gobbi[2], S Treon[1], K C Anderson[1]
[1]Medical Oncology, Dana Farber Cancer Institute, Boston, United States, [2]Medical Oncology, I.R.C.C.S. A.O.U. San Martino -IST, Genoa, Italy

Background: Whole-genome sequencing studies have revealed that >90% of Waldenström macroglobulinemia (WM) patients exhibit a recurrent somatic mutation in MYD88 (L265P). The presence of MYD88 L265P distinguishes WM from overlapping IgM secreting lymphoproliferative disorders including marginal zone lymphoma, chronic lymphocytic leukemia and multiple myeloma (MM), wherein MYD88 L265P is either absent, or infrequent (<10%). MYD88 is an adaptor molecule for Toll-like and IL-1 receptors which promotes IRAK1/4/TRAF6 as well as BTK mediated NFκB signaling. The BTK inhibitor, Ibrutinib, has shown remarkable pre-clinical and clinical activity in WM. Since nicotinamide phosphoribosyl transferase (Nampt) is a key enzyme involved in NAD+ directed NFkB signaling in MM cells, we evaluated its role in WM growth and survival, and sought to clarify its potential as a target for WM related therapy, alone and in combination with Ibrutinib.
Aims: In this study, we aim to identify a new potential therapeutic target in MYD88 L265P-expressing WM cells.
Methods: The expression levels of Nampt transcript (probe ID 217739_s_at) as well as its prognostic role was evaluated by analysis of microarray databases in WM patients. A panel of WM cell lines as well as purified WM-LPCs cells obtained from WM patients was used in the study. The antitumor effect of the Nampt inhibitor, FK866, alone and combined with BTK inhibitor, ibrutinib, was investigated by Annexin-V/propidium iodide staining. Intracellular NAD+ level and NF-kB activity were quantified by specific assays. Mechanistic studies were performed with thymidine incorporation, western-blotting, lentivirus-mediated shRNAs and immunofluorescence assay. Synergistic interactions were assessed by CalcuSyn software.
Results: Proteomic analysis of WM cell lines and primary tumor cells showed wide overexpression of Nampt. Using sRNAi against Nampt, we observed significant decrease in WM cell growth (BCWM.1 and MWCL-1) confirming a pivotal role in tumor growth. Treatment of WM cells with the NAD+ depleting agent FK866 with ibrutinib induced synergistic anti-WM cell death in both WM cell lines and primary WM LPCs with a CI<1. This effect was associated with: 1) more robust inhibition of NFkB signaling; 2) activation of caspase-8, caspase-9, caspase-3, and PARP and 3) enhanced intracellular NAD+ depletion. Lastly, knockdown of Nampt significantly enhanced the anti-WM effects of ibrutinib which can be rescued by ectopic overexpression of Nampt.
Summary and Conclusion: Our *in vitro* findings demonstrate that Nampt has a crucial role in MYD88 L265P-expressing WM cell biology. Indeed, intracellular NAD+ levels represent a major determinant in promoting constitutive NFkB activation observed in MYD88 L265P expressing WM cells. Consistent with these findings, the anti-WM effect of Nampt inhibition was enhanced by BTK inhibition in a synergistic fashion. Our studies therefore provide the rationale for clinical protocols evaluating Nampt inhibitors such as FK866 together with ibrutinib to improve clinical outcome in WM.

MOLECULAR PROFILING OF PATIENT-DERIVED MYELOMA XENOGRAFTS

Y Koh[1,*], HJ Kim[2], HJ Lee[3], WJ Jung[4], C Lee[4], HJ Yoon[5], KS Ahn[4], SS Yoon[1]
[1]Internal Medicine, Seoul National University Hospital, Seoul, [2]Internal Medicine, Hallym University Sacred Heart Hospital, Anyang, [3]Internal Medicine, Dongguk University Ilsan Hospital, Goyang, [4]Cancer Research Institute, Seoul National University College of Medicine, [5]Internal Medicine, Kyunghee University College of Medicine, Seoul, Korea, Republic Of

Background: Multiple myeloma (MM) is caused by clonal expansion of malignant plasma cells within the bone marrow caused by acquired genetic mutations within myeloma cells. Interactions with bone marrow stromal cells (BMSCs) contribute to disease progression. Dynamic interplays lead to dysregulation of key processes resulting in treatment failure. For overcoming these problems, development of new therapeutic agents for MM is urgently required in a preclinical model that reproduces *in vivo* environment.
Aims: We tried to establish clinically relevant human myeloma xenograft that can contribute to the understanding of MM cells' biologic behaviors. We also intended to characterize genomic profile of these xenograft.
Methods: To establish patient-derived MM xenograft, mononuclear cells obtained from MM patient's bone marrow were directly injected via tail vein in a NRG/SCID mouse. Fourteen weeks after the injection, tumor developed at subcutis of the mouse. The engraftment of MM cells into mouse bone marrow (BM) was also observed. We separated cells from these two sites (subcutis and BM). Molecular characterization of patient tumors and xenografts was performed using whole exome sequencing.
Results: After the separation of cells from these two sites (subcutis and BM) we performed various analysis including genomic profiling. In cytogenetic analysis, karyotype of newly established both MM xenograft showed tetraploidy which is different from the karyotype of the patient (duploidy) indicating clonal evolution. In FASC analysis, the expression of CD138 and CD45 was detected in both xenografts. Whole exome sequencing showed that less than 2% of genes had recurrent variations between patient tumors and their respective xenografts. Comparison analysis showed that unique 28 somatic mutations from xenografts growing at subcutis and unique 29 somatic mutations from xenografts growing at bone marrow were found, respectively. These unique mutations govern the biologic behaviours of MM cells such as the sites of tumor growths. These genes are largely responsible for the progression of MM. Finally, analysis of successive passages of the same MM cells showed that sequential mouse-to-mouse tumor grafts did not affect genomic rearrangements or patterns of somatic mutations, suggesting stability of genetic alterations of these models over time. These xenograft models, therefore, represent a valid model for preclinical investigation of new therapeutic agents.
Summary and Conclusion: Xenograft of different sites from a single patient showed differences in karyotype and genomic profile. Xenograft modeling as used in our study would help understanding the biology of multiple myeloma.

Myeloma and other monoclonal gammopathies - Clinical 3

ANTI-TUMOR ACTIVITY OF SELINEXOR (KPT-330), AN ORAL SELECTIVE INHIBITOR OF NUCLEAR EXPORT (SINE), ± DEXAMETHASONE IN MULTIPLE MYELOMA PRECLINICAL MODELS & TRANSLATION IN PATIENTS WITH MULTIPLE MYELOMA

C Chen[1,*], M Gutierrez[2], P Brown[3], N Gabrail[4], R Baz[5], D Reece[1], I Flinn[6], S Trudel[7], D Siegel[2], M Mau-Sorensen[8], J Kuruvilla[1], R Carlson[9], D McCauley[9], E Shacham[9], JR Saint-Martin[9], J McCartney[9], T Marshall[9], Y Landesman[9], S Friedlander[9], G Pond[10], S Rebello[10], T Rashal[9], S Shacham[9], M Kauffman[9], M Mirza[9]

[1]Medical Oncology and Hematology, Princess Margaret Cancer Center, Toronto; Ontario, Canada, [2]Hackensack University Medical Center, Hackensack; New Jersey, United States, [3]Department of Hematology, Rigshospitalet University Hospital, Copenhagen, Denmark, [4]Gabrail Cancer Center, Canton; Ohio, [5]H. Lee Moffitt Cancer Center & Research Institute, Tampa; Florida, [6]Sarah Cannon Research Institute, Nashville; Tennessee, United States, [7]Princess Margaret Cancer Center, Toronto; Ontario, Canada, [8]Department of Oncology, Rigshospitalet University Hospital, Copenhagen, Denmark, [9]Karyopharm Therapeutics, Natick; Massachusetts, United States, [10]Ozmosis Research, Toronto; Ontario, Canada

Background: Selinexor (KPT-330) is a potent, oral selective inhibitor of exportin 1 (XPO1) mediated nuclear export (SINE) that restores tumor suppressor proteins (TSPs) to the nucleus, causing their activation, inducing apoptosis of neoplastic cells. Selinexor also controls the nuclear export of the glucocorticoid receptor and may enhance the anti-tumor effects of dexamethasone (DEX). Selinexor has previously shown activity in patients (pts) with heavily pretreated multiple myeloma (MM) in an ongoing Phase 1 study. The main side effects of selinexor are anorexia, nausea, and fatigue. DEX has clear anti-myeloma activity and could mitigate the main side effects of selinexor.
Aims: Here we investigate the combination of selinexor with DEX in preclinical models and present updated results of selinexor ± DEX in patients with MM.
Methods: MM1.S human MM cells were used for nonclinical studies. MTT assay was used to measure *in vitro* cell survival. Xenograft studies involved subcutaneous tumors in NOD-SCID mice. Pts with advanced, relapsed/refractory (rel/ref) MM were dosed with oral selinexor at doses of 3 to 60mg/m^2 (8-10 doses/4 wk cycle) ± DEX (20mg PO 2X/wk), as part of a broad Phase 1 program in advanced hematological malignancies. Appetite stimulants and anti-emetics were used as supportive care.
Results: Selinexor or DEX alone inhibited MM1.S *in vitro* proliferation with nanomolar potency and the combination was additive. In the MM1.S MM xenograft model, suboptimal doses of selinexor (7.5 mg/kg PO QODX3/wk) or DEX (1 mg/kg IP QDX5/wk) induced tumor growth inhibition (TGI) of 25% and 32%, respectively. The selinexor/DEX combination was synergistic with 82% TGI. Thirty-four MM pts (18 M, 16 F; median age 61 yrs; median prior regimens: 5.6 (1-13); ECOG 0/1/2: 5/28/1) received selinexor across 10 dose levels (3 to 60mg/m^2) an additional 4 pts received selinexor 45mg/m^2+DEX 20mg. Cycle 1 Grade 3/4 adverse events (AEs) in >1 pt included: thrombocytopenia (6pts), nausea (3pts), and neutropenia (3pts). The most common Cycle 1 Grade 1/2 AEs for 8 / 10 doses were GI-related including nausea (71% / 70%), fatigue (54% / 50%), anorexia (42% / 50%) & vomiting (42% / 20%). Dosing is ongoing at 60mg/m^2 twice weekly and MTD has not been reached. No clinically significant cumulative drug toxicities have been noted. Tumor biopsies confirmed nuclear localization of TSPs, reduced MM proliferation, cell cycle arrest, apoptosis and reduced osteoclast differentiation following selinexor treatment. Response was evaluable in 28 MM pts on selinexor alone: Partial Response 1 pt (3%), Minor Response 4 pts (14%), Stable Disease 17 pts (61%), Progressive Disease 6 pts (21%). Several pts have continued on monotherapy with selinexor >8 months. Four pts have received combined selinexor + DEX with no unexpected toxicities to date; anti-tumor effects are pending.
Summary and Conclusion: Combined treatment of selinexor with DEX enhanced antitumor activity *in vitro* and were synergistic in a MM mouse model. Oral selinexor treatment is generally well tolerated and has prolonged single agent disease control in heavily pretreated pts with progressive, rel/ref MM. Clinical results show single agent selinexor activity and preliminary observations suggest improved tolerability with selinexor and "low dose" DEX. Additional patients are being enrolled on the combination.

COMPARISON OF THE N-LATEX AND FREELITE ASSAYS FOR SERUM FREE LIGHT CHAIN: CLINICAL PERFORMANCE IN AL AMYLOIDOSIS

G Palladini[1,*], A Jaccard[2], P Milani[1], D Lavergne[2], A Foli[1], S Bender[2], F Lavatelli[1], T Bosoni[3], V Valentini[1], L Pirolini[3], R Albertini[3], R Moratti[4], M Cogne[2], G Merlini[1]

[1]Department of Molecular Medicine, University of Pavia, Pavia, Italy, [2]Service d'Hématologie Clinique, Université de Limoges, Limoges, France, [3]Clinical Chemistry Laboratory, [4]Scientific Direction, Fondazione IRCCS Policlnico San Matteo, Pavia, Italy

Background: The measurement of circulating free light chain (FLC) is essential in the diagnosis, prognostic stratification, and evaluation of response to therapy in light chain (AL) amyloidosis. In this disease FLC are not only a clonal marker, but they are the pathogenic agent causing organ damage. For more than 10 years this has been done with an immunonephelometric assay based on polyclonal antibodies (Freelite). Recently, a new assay based on monoclonal antibodies (N latex FLC) has been marketed in Europe and Australia.
Aims: To evaluate the performance of the N latex FLC assay in the diagnosis, prognostication of survival, and assessment of response to therapy in AL amyloidosis.
Methods: We compared the clinical performance of the assays in 426 patients with newly-diagnosed AL amyloidosis from the Pavia Amyloidosis Research and Treatment Center (353 patients) and from the Limoges Centre de Référence des Amyloses Primitives et des Autres Maladies de Dépôts d'Immunoglobuline Monoclonale (73 patients). All the patients gave written informed consent.
Results: We found poor agreement between the two methods (84% for k and 88% for l), with median normalized (percent) differences between Freelite and N latex FLC measurements increasing with the concentration of clonal FLC, particularly in patients with k clones. The diagnostic sensitivity of the Freelite (82%) and N latex FLC (84%) assays was similar, and both improved to 98% in combination with serum and urine immunofixation, indicating that the identification of amyloidogenic FLC requires the combination of high-sensitivity assays including urine immunofixation. The concentration of FLC measured with both methods had prognostic significance, with slightly different cutoffs (180 mg/L for the Freelite test, and 165 mg/L for N latex FLC). The dFLC percent reduction best predicting survival was 50% with the Freelite assay, as expected; whereas it was lower, *i.e.* 33%, with the N latex FLC test. Response, defined as a >50% dFLC decrease by Freelite and by a >33% dFLC decrease by N latex FLC, translated in a significant survival advantage. With these cutoffs, the concordance of the two assays in the discrimination of responders was 84% (95%CI 78-89%).
Summary and Conclusion: The two assays have similar diagnostic and prognostic performance. With the N latex FLC method variations after treatment are smaller. The two assays are not interchangeable and follow-up should be done with either one. New response criteria are needed for the N-latex assay.

P955

CYSTATIN C BASED ESTIMATION OF GLOMERULAR FILTRATION RATE IN AL AMYLOIDOSIS

P Milani[1,*], A Foli[1], T Bosoni[2], L Pirolini[2], M Vidus Rosin[1], R Albertini[2], V Valentini[2], M Basset[1], G Palladini[1], G Merlini[1]

[1]Department of Molecular Medicine, University of Pavia, [2]Clinical Chemistry Laboratory, Fondazione IRCCS Policlnico San Matteo, Pavia, Italy

Background: Cystatin C-based eGFR (eGFR-cy) has been proven superior to creatinine based eGFR (eGFR-cr) in predicting death and progression to end stage renal disease in general populations and in patients with chronic kidney disease. The kidney is involved in approximately 70% of patients with AL amyloidosis, and is responsible for significant morbidity and treatment limitations.
Aims: To evaluate the performance of different formulas for estimation of eGFR in AL amyloidosis.
Methods: We compared eGFR-cr, eGFR-cy, and the estimation based on both creatinine and cystatin C (eGFR-cr/cy) in 362 consecutive newly-diagnosed (between 2004 and 2012) patients with renal AL amyloidosis. All the patients gave written informed consent. Sixty-five percent had also cardiac involvement (cardiac stage III in 30%). Patients who died off-dialysis were censored for the analysis of renal survival.
Results: Median (interquartile range) creatinine was 1.11 mg/dL (0.65-1.62 mg/dL) and cystatin C 1.2 mg/L (1.0-1.8 mg/L). Forty-nine percent of patients died and 15% initiated dialysis. Median survival was 43 months. There was no difference between the equations in predicting progression to dialysis (Table). However, Cystatin C-based estimations were predicors of patients' survival, while eGFR-cr had no impact on survival. Subjects with eGFR-cy<90 mL/min had shorter survival (median 28 months *vs*. not reached, P<0.001). Comparing patients (n=33) with eGFR-cr but not eGFR-cy<90 mL/min with patients (n=39) with eGFR-cy but not eGFR-cr<90 mL/min there was no difference in progression to dialysis, while the latter had shorter survival (P<0.001). At multivariate analysis cardiac stage III (HR 3.34, P<0.001) and eGFR-cy (but not eGFR-cr)<90 mL/min (HR 2.51, P=0.001) were independent prognostic determinants.

Table 1. ROC analysis based on progression to dialysis at 2 years

Formulas	AUC	95%CI
eGFRcr/MDRD	0.86	0.79/0.93
eGFRcr/CKDEPI	0.85	0.78/0.92
eGFRcy	0.83	0.76/0.90
eGFRcr/cy	0.85	0.78/0.92

Summary and Conclusion: The different eGFR formulas perform similarly in assessing risk of progression to dialysis. However, eGFR-cy is an independent marker of patients' survival.

P956

A PROFILE OF 140 LONG-TERM SURVIVORS WITH SYSTEMIC AL AMYLOIDOSIS

S Sachchithanantham[1], S Mahmood[1], R Sayed[1], K Patel[1], J Gillmore[1], H Lachmann[1], T Lane[1], D Foard[1], L Rannigan[1], P N Hawkins[1], A Wechalekar[1,*]
[1]National Amyloidosis Centre, University College London, London, United Kingdom

Background: Diagnosis of AL amyloidosis is widely regarded to incompatible with long term survival consequently, very little has been reported on the long term outcome in this group of patients. The mayo group reported a 5 year survival of 16% for patients diagnosed between 1966 and 1987 and the Italian group reported a median survival of 46 months.
Aims: We report the largest series of long term surviving patients with systemic AL amyloidosis from the UK National Amyloidosis centre (NAC).
Methods: All patients with systemic AL amyloidosis seen at the NAC, diagnosed between 1979-2003, who had survived for longer than 10 years from diagnosis were included in this study. AL amyloidosis was confirmed histologically in all patients with exclusion of hereditary amyloidosis. Organ involvement and responses were defined as per the international consensus criteria.
Results: 913 patients with AL amyloidosis were seen at NAC upto August 2003. 140 (15%) patients survived for longer than 10 years of which 111(79%) had renal, 34 (24%) had cardiac and 46 (33%) had liver involvement. 32 patients lived >15 years, 5 for >20 years and the longest surviving patient is alive at 34 years after diagnosis. Median age at diagnosis was 54.9yrs (28.9-76.3) and the male:female ratio was 0.89. The median creatinine was 91umol/L (47-850) and 24 hour proteinuria was 4.91g (<0.15-27.30g), LV septal wall thinness of 10mm(8-19) and ALP of 89IU/L (36-1814). 68% patients had nephrotic range proteinuria. 4 presented with end stage renal failure (ESRF) and 1 has had a renal transplant at presentation. Median number of lines of treatment was 2 (1-7). 49 (37%) patients had autologous stem cell transplant (ASCT), of which 5 patients had 2 ASCTs and 2 had allograft. There were also 17 renal, 3 cardiac and 1 liver transplantation. 36 (31%) patients developed ESRF (73% established on HD and 28% on PD) and the median time to ESRF was 4.18 years (0.01-16.4 years). Of the 17 patients who underwent renal transplant, the mean time to transplant was 5.7 years (0.5-16.76 years) from diagnosis. 2 patients had amyloid recurrence in the graft. Median OS was 18.3yrs. Patients with cardiac involvement had a poorer outcome compared to the non-cardiac cohort (14.7 years *vs* 22 years, p=0.005). Those who had achieved a VGPR or better had a significantly better median OS than non responders (not reached *vs* 13.1yrs respectively, p=0.001, figure 1) and those who had required 2 or less lines of treatment had a significantly superior outcome compared to those requiring multiple therapies (22yrs *vs* 15.9yrs, p=0.001). Those who underwent ASCT at any time also had a better median OS compared to those treated with chemotherapy alone (NR *vs* 15.9, p=0.018).

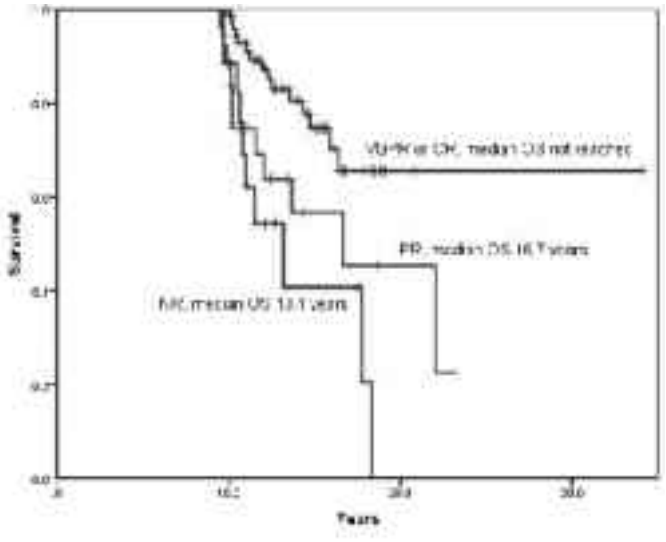

Figure 1.

Summary and Conclusion: In conclusion long terms survival is possible for 16% of patients with AL amyloidosis and the majority (80%) of these have renal involvement. Despite surviving over 10 years, patient with cardiac involvement continue to have an inferior outcome compared to those without. Achieving a deep clonal response improves survival and on multivariate analysis, ASCT at any time and<2 line of total therapy remained significant independent factors of survival.

P957

FIRST-LINE THERAPY FOR MULTIPLE MYELOMA (MM): RESULTS FROM THE SECOND INTERIM ANALYSIS OF THE REAL-WORLD, INTERNATIONAL, NON-INTERVENTIONAL EMMOS STUDY

Background: Objective data on country-to-country variation in therapies for MM are lacking.
Aims: The prospective, observational EMMOS study (NCT01241396) aimed to collect data on MM treatments at different disease stages in routine clinical practice.
Methods: Consenting adult patients (pts) initiating any new line of MM therapy, regardless of treatment line at inclusion or type of chosen therapy, were eligible. A multi-staged site/pt recruitment model was applied to minimize selection bias; enrolment was stratified by country, region, and practice type. At baseline, pts' medical and disease features, treatment history, and current remission status were documented. Prospective data, including information on treatment, efficacy, and safety, were electronically captured every 3 mos until 3 yrs after the last pt enrolled. Responses were physician-assessed after each cycle; no predefined response criteria were mandated. Retrospective data on adverse drug reactions (ADRs) were collected, and treatment-emergent adverse events (AEs) were recorded prospectively. Here we present results of the second interim analysis, focusing on first-line therapy in pts who had not yet undergone autologous stem cell transplantation (ASCT) at the time of data extraction.
Results: At data cut-off (30 Apr 2013), 2447 pts had been enrolled in 22 countries in Europe and Africa, including 1642 non-ASCT pts. Median follow-up was 20 mos from diagnosis and 12 mos from study entry. Median age at study entry was 69 yrs (range, 32–91). 49% of pts were male and 63% were diagnosed in 2011–12. 38%, 32%, 17%, and 13% were enrolled at academic, regional, private, and local clinics, respectively. 67% had bone lesions, and 18% had severe renal impairment. Of 348 pts with cytogenetic testing, 7% were positive for del 17p and 7% for t(4;14). First-line therapy data were available for 1596 non-ASCT pts of whom 1104 (69%) received novel agent-based therapy, including 775 (49%) with bortezomib (208 pts prior to study entry; 567 pts during the prospective phase). Most common first-line regimens received

were bortezomib-melphalan-prednisone (VMP, 18%), bortezomib-dexamethasone (VD, 12%), melphalan-prednisone alone (MP, 12%), and melphalan-prednisone-thalidomide (MPT, 7%). In pts aged<65 yrs (n=622), the most common first-line regimens were MP, VD, and vincristine-doxorubicin-dexamethasone (each 11%), and cyclophosphamide-dexamethasone-thalidomide (10%), and in ≥65 yrs (n=971), VMP (27%), VD (13%), MP (12%), and MPT (11%). Best response by first-line therapy is shown in the table. ORRs appeared higher with bortezomib-based than with non-bortezomib-based first-line therapy. Retrospective data for 208 pts who had received first-line bortezomib showed that 23% had ≥1 ADR, mainly nervous system (13%) and gastrointestinal disorders (5%); 3% had ≥1 serious ADRs. Of 567 pts who received first-line bortezomib in the prospective phase, 69% had ≥1 AE, including 14% thrombocytopenia, 8% leucopenia, 7% diarrhea, and 6% peripheral neuropathy; 26% had ≥1 serious AE and 6% died due to AEs.

Table 1.

First-line combination regimen received (n [%] of all pts receiving regimen)	All response-evaluable pts (n=1274)		Pts aged <65 yrs (n=603)		Pts aged ≥65 yrs (n=771)	
	ORR (≥PR), %	≥VGPR, %	ORR (≥PR), %	≥VGPR, %	ORR (≥PR), %	≥VGPR, %
Bortezomib + IMiD-based (n=62 [5%])	79	48	78	60	80	43
Bortezomib, non-IMiD-based (n=590 [43%])	78	36	77	37	78	35
IMiD, non-bortezomib-based (n=272 [21%])	66	28	66	32	66	25
Other combinations (n=350 [31%])	53	12	54	13	52	10

IMiD, immunomodulatory drug (thalidomide or lenalidomide); ORR, overall response rate; VGPR, very good partial response; PR, partial response.

Summary and Conclusion: Data from this real-world study appear to reflect results from the clinical trial setting. First-line bortezomib, received by 49% of non-ASCT pts, produced substantial response rates with no new safety signals. Ongoing analyses will provide longer follow-up and additional data about MM treatments (*e.g.* sequencing, ASCT pts) in routine clinical practice.

P958

SUBCUTANEOUS (SC) VERSUS INTRAVENOUS (IV) BORTEZOMIB IN PATIENTS WITH RELAPSED MULTIPLE MYELOMA (MM): SUBANALYSIS OF PATIENTS WITH RENAL IMPAIRMENT IN THE PHASE 3 MMY-3021 STUDY

P Moreau[1,*], H Pylypenko[2], S Grosicki[3], I Karamanesht[4], X Leleu[5], G Rekhtman[6], P Robak[7], DL Esseltine[8], H Feng[9], W Deraedt[10], H van de Velde[10], B Arnulf[11]

[1]University Hospital, Nantes, France, [2]Cherkassy Regional Oncology Dispensary, Cherkassy, Ukraine, [3]Oddzial Hematologiczny ZSM, Chorzow, Poland, [4]Kiev BMT Center, Kiev, Ukraine, [5]Hopital Huriez, CHRU, Lille, France, [6]Khmelnitskiy Regional Hospital, Khmelnitskiy, Ukraine, [7]Medical University of Lodz, Lodz, Poland, [8]Takeda Pharmaceuticals International Co., Cambridge, MA, [9]Biostatistics, Janssen Research & Development, LLC, Raritan, NJ, United States, [10]Clinical Research, Janssen Research & Development, Division of Janssen Pharmaceutica NV, Beerse, Belgium, [11]Immuno-hématologie Department, Hôpital Saint-Louis, Paris, France

Background: The randomized, open-label phase 3 MMY-3021 study (NCT00722566) in 222 patients (pts) with relapsed MM determined non-inferiority of SC *vs* IV bortezomib (Btz) dosing, with an improved safety profile (Moreau P, *et al.* Lancet Oncol 2011;12:431–40).
Aims: This subanalysis in pts with renal impairment investigated the effect of SC *vs* IV Btz dosing on response rates (CR+PR by EBMT), time to response (TTR), rates of renal impairment reversal, long-term outcomes, and safety profiles.
Methods: Consenting adults with measurable MM and 1–3 prior lines were randomized 2:1 (stratified by ISS and number of prior lines) to receive eight 21-d cycles of Btz 1.3 mg/m^2 d 1, 4, 8, 11 by SC or IV injection. Within each arm, pts were categorized into subgroups: baseline creatinine clearance (CrCl) ≤50 mL/min (moderate to severe renal impairment) or >50 mL/min (mild or no renal impairment). Renal impairment reversal was defined as achievement of post-baseline CrCl >60 mL/min.
Results: Of 148/74 pts randomized to SC/IV Btz, 33/13 (22%/18%) had CrCl ≤50 mL/min. Baseline characteristics for SC *vs* IV pts in the CrCl >50 and ≤50 mL/min groups were generally well balanced except for median age (71 *vs* 78 yrs), ISS stage III disease (52% *vs* 77%), and 1 prior therapy (73% *vs* 62%) in the CrCl ≤50 mL/min group. In pts with CrCl ≤50 *vs* >50 mL/min, the median number of cycles received was 8 *vs* 8 for pts on SC Btz, and 3 *vs* 8 for pts on IV Btz. ORR in SC/IV pts with CrCl ≤50 mL/min was 53%/31% (RR 1.73; CR 6%/0%). In pts with CrCl >50 mL/min, ORR for SC/IV was 52%/57% (RR 0.92; CR 15%/15%). Median TTR for SC/IV pts was 2.3/3.3 mos (HR 1.205) and 3.5/3.5 mos (HR 1.021) for pts with CrCl ≤50 and >50 mL/min, respectively (Figure). In pts with CrCl ≤50 mL/min, renal impairment was reversed in 10/33 (30%) *vs* 2/13 (15%) pts with SC *vs* IV Btz. IV arm results were consistent with unpublished data from the APEX study (renal impairment reversal in 8/62 (13%) pts on IV Btz). After 17.3 (SC) and 17.8 (IV) mos' follow-up, median PFS for SC *vs* IV pts with CrCl ≤50 mL/min was 8.6 *vs* 6.3 mos (HR 0.388), and 9.5 *vs* 9.6 mos (HR 0.949) for pts with CrCl >50 mL/min. For SC *vs* IV pts with CrCl ≤50 mL/min, 1-yr overall survival was 70% *vs* 46%, compared with 78% *vs* 85% for pts with CrCl >50 mL/min. In pts with CrCl ≤50 mL/min, 70% receiving SC *vs* 77% IV had Gr ³3 adverse events (AEs); most common Gr ≥3 AEs were neutropenia 21% *vs* 8%, thrombocytopenia 15% *vs* 8%, anemia 18% *vs* 8%, and asthenia 3% *vs* 15%. In pts with CrCl >50 mL/min, 54% *vs* 69% had Gr ³3 AEs with SC *vs* IV dosing. In the SC *vs* IV arms, serious AEs occurred in 39% *vs* 46% of pts with CrCl ≤50 mL/min, and in 35% *vs* 33% of pts with CrCl >50 mL/min; AEs leading to treatment discontinuation occurred in 24% *vs* 23% of pts with ≤50 mL/min and in 22% *vs* 28% of pts with CrCl >50 mL/min. In pts with CrCl ≤50 mL/min, 2 pts (6%) on SC and 3 pts (23%) on IV Btz died due to AEs. In pts with CrCl ≤50 mL/min, peripheral neuropathy (PN) occurred in 45% *vs* 31% pts in the SC *vs* IV arms, consistent with lower Btz exposure in the IV arm; Gr ³3 PN occurred in 9% *vs* 8% pts.

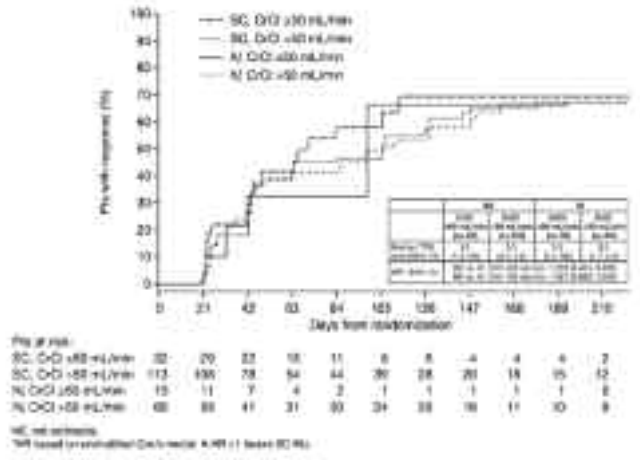

Figure 1.

Summary and Conclusion: In the MMY-3021 study, SC Btz dosing in pts with renal impairment was associated with a more rapid TTR and higher response rates than with IV dosing, and more patients receiving the planned number of cycles. This was accompanied by higher rates of renal impairment reversal with SC Btz.

P959

A PHASE II SINGLE-ARM SAFETY STUDY OF ELOTUZUMAB IN COMBINATION WITH THALIDOMIDE AND LOW DOSE DEXAMETHASONE IN PATIENTS WITH RELAPSED AND/OR REFRACTORY MULTIPLE MYELOMA

MV Mateos[1,*], M Granell[2], A Oriol Rocafiguera[3], J Martinez Lopez[4], J Bladé[5], M T Hernandez[6], J Martin Sanchez[7], M Gironella[8], M Lynch[9], E Bleickardt[9], P Paliwal[9], A Singhal[10], J San Miguel[11]

[1]Hospital Clínico Universitario de Salamanca, Salamanca, [2]Hospital de la Santa Creu i Sant Pau, Barcelona, [3]Institut Catalá d´Oncologia, Badalona, [4]H.U. 12 de Octubre, Madrid, [5]Hospital Clinic i Provincial, IDIBAPS, Barcelona, [6]Complejo Hospitalario Universitario de Canarias, Santa Cruz de Tenerife, [7]Hospital Universitario Virgen del Rocío, Sevilla, [8]Hospital Universitario Vall d´Hebron, Barcelona, Spain, [9]Bristol-Myers Squibb, Wallingford, CT, [10]AbbVie Biotherapeutics Inc, Redwood City, CA, United States, [11]Clinica Universidad de Navarra, Pamplona, Spain

Background: Elotuzumab (E) is a humanized monoclonal IgG1 antibody targeting the cell surface glycoprotein SLAMF7 (CS1, CRACC, CD319, 19A24), which is highly expressed (>95%) on multiple myeloma (MM) cells. Thalidomide, in combination with dexamethasone (Td) is a therapy used in relapsed disease and is associated with grade ≥3 nonhematologic toxicities in 63% of patients. The most common toxicities associated with Td include thromboembolic events, fatigue, constipation, and neuropathy (Rajkumar V. J Clin Oncol 2006;24:431-36).
Aims: To evaluate the safety and tolerability of adding elotuzumab to Td (E-Td) in MM patients with relapsed and/or refractory MM.
Methods: Patients were treated with E-Td in 28 day cycles. During cycle 1 and

2, a weekly loading dose of E was given at 10 mg/kg IV on days 1, 8, 15, and 22, with a dose escalation of T from 50 to 200 mg po qhs. From cycle 3 and beyond, E was given on a biweekly schedule on days 1 and 15. Dexamethasone was given weekly at 40 mg po. Patients who did not achieve ≥partial response by cycle 5 or progressed between cycles 2 and 5 could add cyclophosphamide (C) 50 mg po qd to E-Td (E-TdC). Treatment was continued until disease progression, unacceptable toxicity, or death. The primary endpoint was the proportion of patients who experienced ≥1 severe (≥Grade 3) nonhematological toxicity. Secondary and exploratory endpoints included additional safety parameters and efficacy by IMWG criteria.

Results: Forty patients signed informed consents and were treated. Median age was 64 years, with 63% males. The median time from diagnosis to treatment was 5.0 years (range 0.25-14.4 years). The median number of prior therapies was 3 (range 1-8). Seventeen (43%) patients received ≥4 prior therapies. Prior treatments included: bortezomib 39 (98%), melphalan 30 (75%), lenalidomide 29 (73%), vincristine 20 (50%), cyclophosphamide 19 (48%), doxorubicin 19 (48%), BCNU 18 (45%), and thalidomide 8 (20%). The number (%) of patients refractory or intolerant to prior bortezomib, lenalidomide or both were 24 (60%), 22 (55%), and 14 (35%), respectively. Median duration of study treatment was 4 months (range 0.1-15 months). Eleven patients received E-TdC, primarily due to progressive disease between cycles 2 and 5. Grade ≥3 nonhematologic events were reported in 62.5% of patients, and the most common events (≥20%) were asthenia (35%), peripheral edema (25%), fever (25%), respiratory tract infection (23%), neuropathy (20%), back pain (20%), and constipation (20%). Grade 3-4 neutropenia, anemia, and thrombocytopenia were noted in 13%, 21%, and 11%, respectively. Six patients experienced an infusion reaction; however, no patient discontinued due to these events. The clinical benefit rate was 58% (7 MR, 9 PR, 4 VGPR, 2 CR, and 1 sCR). Among patients with a PR or better, 63% maintained their response at 1 year.

Summary and Conclusion: Elotuzumab can be safely combined with Td or TdC. The grade ≥3 nonhematological toxicities observed in this study are consistent with toxicities observed with Td alone. Minimal incremental toxicity was observed with the addition of E to Td or TdC except for E-related infusion reactions which responded to supportive care and did not lead to discontinuation of therapy. Although the trial was performed in more heavily pretreated MM population in comparison with the results reported for Td trials, the clinical benefit rate is encouraging.

P960

EFFECTS OF SINGLE-AGENT BORTEZOMIB (BTZ) AS POST-TRANSPLANT CONSOLIDATION ON MULTIPLE MYELOMA (MM)-RELATED BONE DISEASE: FIRST RESULTS FROM A MULTICENTER, RANDOMIZED PHASE 2 STUDY

Background: Lytic bone destruction is a debilitating manifestation of MM. In addition to its anti-MM activity, data suggest that Btz inhibits osteoclastogenesis and stimulates osteoblast activity, exerting positive effects on bone metabolism that may be bone-specific and independent of the effects on MM. This is the first randomized study of Btz with a bone-specific endpoint.

Aims: This study is evaluating the effects of Btz consolidation *vs* observation (Obs) on bone health in newly diagnosed MM patients (pts) who underwent prior high-dose therapy with autologous stem cell transplant (HDT-ASCT) (NCT01286077). Primary endpoint was baseline to end-of-treatment (EOT) change in bone mineral density (BMD). Secondary endpoints included changes in bone biomarkers, skeletal events, new bone lesions, and safety.

Methods: Consenting adults with newly diagnosed MM who had achieved partial response or better (≥PR) after single/double HDT-ASCT were eligible. Pts were randomized 1:1 (stratified by age [<65 *vs* ≥65 yrs] and baseline bisphosphonate [BPP] use), to 4 x 35-d cycles of Btz 1.6 mg/m^2 IV on d 1, 8, 15, 22, or Obs alone. BMD was measured in spine/femur at baseline, after 2 cycles, and at EOT by dual energy X-ray absorptometry; data were centrally assessed. Serum samples were acquired at these same time points for bone biomarker and M-protein measurement. For pts with missing assessments, a last observation carried forward (LOCF) approach was used. Response was assessed by IMWG 2009 criteria. Adverse events (AEs) were graded by NCI-CTCAE v3.0. Analysis was mainly by intent-to-treat (ITT), including all randomized pts who received ≥1 dose of Btz (Btz arm), and in pts who had a baseline and ≥1 post-baseline BMD assessment.

Results: Between July 2009 and May 2012, 106 pts from 8 countries were randomized (52 Btz, 54 Obs). The ITT population included 104 pts (51 Btz, 53 Obs); median age 58 *vs* 57 yrs, 12% *vs* 15% aged ≥65 yrs, 65% *vs* 58% male, 77% *vs* 74% baseline BPP use. A similar proportion of pts in the Btz (71%) and Obs (66%) arms had received Btz-based induction prior to HDT-ASCT. Post-HDT-ASCT, rates of complete response [CR]/PR were 16%/82% (Btz) and 15%/83% (Obs). 78% *vs* 85% of pts completed Btz consolidation and Obs, respectively. Baseline characteristics were generally well balanced between arms, but 69% (Btz) *vs* 75% (Obs) of pts received BBPs; 39% *vs* 60% zoledronic acid and 29% *vs* 19% pamidronic/ibandronic/clodronic acid. Median baseline to EOT change in BMD is shown in the table; no differences were observed between the arms regardless of age or baseline BPP use. Further, there were no differences between the arms in median baseline to EOT change in bone biomarkers (Table), or incidence of skeletal events or number of new bone lesions. Post-consolidation rates of CR/PR/progressive disease [PD] were 22%/69%/8% (Btz) and 11%/66%/21% (Obs). Rates of grade ≥3 AEs were 10% (Btz) *vs* 6% (Obs) and serious AEs 12% (Btz) *vs* 6% (Obs); no new safety signals for Btz were observed.

Table 1.

Percentage change from baseline to EOT*	Btz		Obs	
BMD†	N evaluable	Median (IQR)	N evaluable	Median (IQR)
Spine	38	+1.89 (+0.17, +3.38)	38	+1.19 (-0.01, +3.73)
Femur (neck)	43	+0.38 (-1.24, +2.03)	45	+0.29 (-1.56, +1.88)
Femur (total)	43	+0.74 (-0.25, +1.84)	45	+1.77 (-0.48, +2.92)
Bone biomarkers‡	N evaluable	Median (IQR)	N evaluable	Median (IQR)
C-terminal cross-linking telopeptide of type I collagen (CTX-I)	48	-29.60 (-62.63, 0)	49	-26.64 (-49.69, 0)
C-terminal cross-linking telopeptide of type I collagen generated by MMPs (CTX)	48	-29.75 (-42.56, -12.21)	49	-25.79 (-38.44, -4.14)
Dickkopf homolog 1 (DKK-1)	48	-12.14 (-34.88, +48.91)	49	-8.94 (-49.62, +43.00)
Bone specific alkaline phosphatase (BALP)	48	-13.94 (-28.30, +13.10)	49	-8.67 (-28.94, +10.68)
Osteocalcin (Oc)	48	-26.21 (-52.79, -8.69)	49	-30.71 (-40.36, -12.80)

EOT, end of treatment; IQR, interquartile range.
*Noncompleting LOCF.
†Analyzed in pts with a baseline assessment and at least one post-baseline assessment of BMD (N=95).
‡Analyzed in the ITT population (N=104).

Summary and Conclusion: Single-agent Btz consolidation and Obs produced comparable changes in BMD and bone biomarkers. Btz consolidation was generally well tolerated, and appeared to improve response depth relative to post-ASCT response and reduce PD rates. Prior Btz-based induction, prior HDT-ASCT, and concomitant BPP use represent possible confounding factors in this analysis. Long-term follow-up is ongoing.

P961

BENDAMUSTINE AND PREDNISONE IN COMBINATION WITH BORTEZOMIB (BPV) IN THE TREATMENT OF PATIENTS WITH NEWLY DIAGNOSED/UNTREATED MULTIPLE MYELOMA

W Poenisch[1,*], B Holzvogt[1], M Plötze[1], M Andrea[1], T Lange[1], D Niederwieser[1]
[1]Hematology/Oncology, University of Leipzig, Leipzig, Germany

Background: Multiple Myeloma (MM) is a generalized malignant disease of plasma cells. In Germany, the incidence of myeloma is approximately 8 cases per 100,000 of the population with around 6200 newly diagnosed patients each year (Robert Koch-Institut 2013). The introduction of thalidomide, lenalidomide and bortezomib into standard therapy has had a positive effect on the complete response rate, progression free survival and overall survival of MM patients.

Aims: Bortezomib is a proteasome inhibitor that has shown important clinical efficacy either as a single agent or in combination in patients with multiple myeloma (MM). In the present protocol, bortezomib was combined with other active substances like bendamustine and prednisone, in order to assess the efficacy and toxicity of this combination therapy in patients with newly diagnosed/untreated MM.

Methods: Between June 2006 and October 2013, 49 patients with newly diagnosed/untreated MM were treated with bendamustine 60 mg/m^2 on days 1 and 2, bortezomib 1.3 mg/m^2 on days 1, 4, 8 and 11, and prednisone 100 mg on days 1, 2, 4, 8 and 11 (BPV). Patients were divided into three groups: group A (n=19) consisted of patients with normal renal function or mild dysfunction (eGFR ≥ 60 ml/min), group B (n=15) patients with moderate or severe renal dysfunction (eGFR 15–59 ml/min) and group C (n=15) patients with renal failure/dialysis (eGFR<15 ml/min).
Results: A median number of two (range 1 – 5) BPV treatment cycles were given to the patients. The majority of the patients (n=40, 82 %) responded after at least one cycle of BPV-therapy with 5 sCR, 9 nCR, 12 VGPR, and 14 PR. Five patients had MR, 3 stable and 1 progressive disease. The BPV regimen caused a rapid decrease in the M-protein, with 13 (27 %) patients reaching the best response after the first cycle and a further 20 (41 %) patients after the second cycle. The median time to first hematological response (≥ PR) was 14 days, and the median time to best response was 42 days. Importantly, the rapidity of response of patients in group A with normal renal function or mild renal dysfunction was not different from that of the patients in group B with moderate or severe renal dysfunction and group C with renal failure/dialysis. After a median observation time of the surviving patients of 13 months, PFS at 12 months was 92 % and OS 94 % for patients with normal renal function or mild renal dysfunction as well as 83 % and 93 % for patients with moderate or severe renal dysfunction. Outcome for these patients was slightly better, albeit not statistically significant, compared to patients with renal failure/dialysis with a PFS, and OS of 66 % (p=0.08) and 73 % (p=0.05), respectively. The regimen was well tolerated with few significant haematological and nonhaematological side effects. The most common grade 3/4 hematological toxicities were leukocytopenia (n=12, 25 %), neutropenia (n=3, 6 %), thrombocytopenia (n=11, 22 %), and anemia (n=8, 16 %). There was a moderate difference in leukocytopenia (p=0.09) and neutropenia (p<0.01) between group A/B and group C, with correspondingly more moderate to severe infections in group C (p<0.01).
Summary and Conclusion: These results indicate that this BPV-combination is feasible, effective and well tolerated in patients with newly diagnosed MM.

P962

WHOLE-BODY LOW-DOSE CT (WBLDCT) IS USEFUL FOR DETECTION, STAGING, RESPONSE EVALUATION AND FOLLOW-UP IN MYELOMA PATIENTS

S Pezzatti[1,*], F Rossini[1], F Cocito[2], S Bozzani[1], C Cecchetti[1], A Pompa[2], A Belotti[1], E Doni[1], S Mangiacavalli[2], F Farina[1], D Ippolito[3], A Corso[2]
[1]hematology unit, s. gerardo hospital, monza, [2]Division of Hematology, Fondazione IRCCS Policlinico San Matteo, Università di Pavia., Pavia, [3]Department of Diagnostic Radiology, s. gerardo hospital, monza, Italy

Background: Conventional skeletal Xray is still considered the standard approach for the evaluation of bone disease in MM due to its wide availability and cost-effectiveness, although several studies have demonstrated that. Whole body low-dose TAC (WBLDTC) has higher sensitivity, reducing the risk of false negative. It can detect extraosseous disease; it is well tolerated also by compromised patients because it does not need painful positions and acquisition time is short (few minutes). When a low-dose tecnique was developed, whole body TAC could be introduced in the clinical practice.
Aims: We report a group of 318 patients studied from diagnosis with WBLDCT.
Methods: A WBLDCT was performed at diagnosis and repeated at the end of induction therapy (including transplantation), at relapse, and, in the observational period every 12-18 months. In our WBLDCT protocol, the overall dose delivered to each patient was 4.2 mSv.
Results: WBLDCT was positive in 191/318 patients at diagnosis. The distribution of the observed osteolytic lesions (OLs) is reported in table 1. Among patients with a positive WBLDCT at diagnosis, in 94/191 patients this represented the only reason to classify MM as symptomatic. On the contrary, in 97/191 patients, one or more concomitant CRAB symptoms were present at diagnosis. In 149/191 patients a WBLDCT at the end of induction therapy was available. Of these, 29/149 showed an improvement; 109/149 were unchanged; 11 showed a progressions of bone disease. In 7 out of these last, this was the only criterion of progression. In 127 pts initial WBLDCT was negative: 81/127 pts had a symptomatyic MM and received induction therapy and 46 pts had an asymptomatic MM. Among treated patients, 67 were re-evaluated with a WBLDTC at the end of induction therapy: 3 of them showed a progression of bone disease (1 progression defined only by bone disease), and 64 were unchanged. Among patients with asymptomatic myeloma, three were lost to follow-up, 31 remained asymtomatic after a median of 34 months (range 2-89), 12 progressed to symtomatic myeloma after a median of 32 months (range 8-60). In 11 patients a WBLDCT was performed at the time of evolution: in 8 patients WBLDTC was positive and in 3 of them this was the only reason to define progression. In 27 patients unexpected parenchymal lesions were seen, in most cases parenchymal lung lesions, generally interpreted as infectious; 3 patients had asymptomatic kidney masses. In three cases "abdominal lymphadenopathies" were observed: two of them regressed after therapy; in one case the lesions were still present at restaging and, when biopsied, they were shown to be extramedullary disease of myeloma.

Table 1.

Bone segment	Number	(% of positive TC)
Skull	100	49,8
Spine	161	80,1
Sternum	64	31,8
Ribs	98	48,8
Claviculae	57	28,4
Scapulae	52	25,9
Humeri	51	25,4
Femuri	62	30,8
Pelvis	94	46,8
Total	739	

Summary and Conclusion: In conclusion whole-body low-dose CT protocol is feasible and reliably evaluates bone disease at diagnosis and in follow-up. Its higher sensitivity allows earlier detection of bone and extramedullary disease.

P963

PANOBINOSTAT IN COMBINATION WITH BORTEZOMIB AND DEXAMETHASONE (VPD) AS INDUCTION THERAPY IN PATIENTS WITH MULTIPLE MYELOMA CANDIDATES TO AUTOLOGOUS TRANSPLANT

S Mangiacavalli[1,*], V montefusco[2], L pochintesta[1], L baldini[3], V ferretti[1], L farina[2], F cocito[1], E ravelli[4], ML La targia[5], R cairoli[4], A corso[1]
[1]Hematology, IRCCS Fondazione Policlinico San Matteo, Pavia, [2]Hematology, IRCCS Fondazione Istituto Nazionale Tumori, [3]hematology, Policlinico Ospedale Maggiore, Milano, [4]Hematology, Ospedale Valduce, como, [5]Hematology, Ospedale di Circolo, Busto Arsizio, Italy

Background: Autologous transplant (tx) is considered the gold standard for young patients (pts) with multiple myeloma (MM). Novel agents containing schemes has significantly improved pre-tx good response rate (≥VGPR). The combination of panobinostat plus bortezomib and dexamethasone, effective in heavily pre-treated MM patients, hasn't yet been tested as pre-tx induction.
Aims: To test the efficacy in terms of pre-tx ≥VGPR rate of the three drugs combination panobinostat, bortezomib and dexamethasone (VPD) in previously untreated symptomatic MM pts.
Methods: This is a phase II multicenter study approved by the local ethic committees, registered on EudraCT registry (I.D. *2011-005847-29)* and conducted according to the Helsinki Declaration. All patients provided written informed consent. Pts with untreated symptomatic MM ≤65 years with measurable disease and no significant comorbidities were eligible. Treatment schedule included 4 VPD cycles with panobinostat 20 mg given orally on days 1, 3, 5, 8, 10, 12, bortezomib 1.3 mg/m2 by intravenous bolus on days 1, 4, 8, and 11 and dexamethasone 40 mg by intravenous bolus on days 1, 4, 8, 11 of each 21-day cycle. All patients were planned to undergo Tx with melphalan at 200 mg/m^2. Pts were monitored for efficacy at the beginning of each VPD cycle. Adverse events were graded according to the NCI CTCAE, Version 4.0 (http://ctep.cancer.gov). These are results of the interim analysis performed after the enrollment of sixteen out of 65 originally planned patients, which led to early closure of the study.
Results: Sixteen pts were analyzed. **One patient withdrawn informed consent during the first cycle and thus was not evaluable.** Eleven out 15 evaluable patients (73%) completed the VPD induction phase; 4 patients (27%) completed VPD cycles at full dose; 4 patients went off study for toxicity (27%). Overall response rate after 4 VPD cycles was 66.7% (1 CR+ 3 VGPR+6 PR); only 26.7% patients achieved ≥VGPR, with no benefit with respect to good response rate previously reported for bortezomib combinations (61%>71% ≥VGPR) (Cavo et al, 2010; Corso et al, 2010; Rosiñol et al, 2012). **Regarding toxicity, s**ixty-three adverse events of any grade were observed: 17.5% (N=11) were hematologic and 82.5% (N=52) non hematologic. The median number of adverse events per patients was 3.5 (range 2-15) with 20% of patients experienced ≥6 adverse events. Common grade 3/4 adverse events included neutropenia (20%), thrombocytopenia (20%) and diarrhea (20%). No grade 3/4 peripheral neuropathy was observed. Due to the low rate of **≥VGPR** achieved at the end of VPD induction the study was closed in advance. **Main reason for** results **lower than expected** has been identified in high rate of dose

reduction/delays (80%) and discontinuation (27%). In I cycle, 10 pts received VPD at full doses, 4 pts required delay/reduction, 1 pts went off study for toxicity. In II cycle, 8 pts received full doses, 4 pts required dose delay/reduction, 2 pts went off study for toxicity. In III cycle, 7 pts received full doses, 4 pts required dose delay/reduction, 1 pts went off study for toxicity. In IV cycle, 6 pts received full doses, 5 pts required dose delay/reduction.
Summary and Conclusion: Given the low rate of good quality response observed in this study after VPD induction, the combination of panobinostat+bortezomib+ dexamethasone might not be suitable for transplant canditates MM patients, in whom reaching a fast and profound response before transplant is crucial.

P964

EXPOSURE-SAFETY-EFFICACY ANALYSIS OF ORAL IXAZOMIB CITRATE (MLN9708) IN RELAPSED/ REFRACTORY MULTIPLE MYELOMA (MM): PHASE 3 DOSE SELECTION FOR MAINTENANCE POST AUTOLOGOUS STEM CELL TRANSPLANT

N Gupta[1,*], R Labotka[2], G Liu[3], AM Hui[4], K Venkatakrishnan[1]
[1]Clinical Pharmacology, [2]Clinical Research, [3]Biostatistics, Takeda Pharmaceuticals International Co., [4]Clinical Research, Millennium: The Takeda Oncology Company, Cambridge, MA, United States

Background: Ongoing phase 3 trials of ixazomib citrate with lenalidomide and dexamethasone in MM are enrolling patients (pts) at a dose of 4 mg weekly (one dose level below the maximum tolerated dose [MTD] of 5.5 mg). A phase 3, randomized, placebo-controlled, double-blind study of oral ixazomib citrate maintenance therapy in MM pts following autologous stem cell transplant is planned. The balance of benefit *vs*. risk is paramount for maintenance therapy when pts already have a clinical response to high-dose therapy, will likely be symptom-free from their disease, and will not have had prior exposure to ixazomib citrate before starting maintenance.
Aims: To identify optimal ixazomib citrate dose to balance benefit *vs*. risk for evaluation in a phase 3 trial of ixazomib citrate maintenance therapy in MM pts following autologous stem cell transplant.
Methods: Safety (S) and efficacy (E) data from pts enrolled in a phase 1/2 study of weekly single-agent ixazomib citrate in relapsed/refractory MM (NCT00963820) were used (N=44); the ixazomib citrate dose range investigated was 1–8.9 mg. The metric of exposure was AUC per day (derived from individual clearance values using population pharmacokinetics) for both exposure (Ex)/S and Ex/E logistic regression analyses. Ex/S analysis was done on 7 adverse events (AEs): hematologic (H) (anemia, thrombocytopenia, neutropenia) and non-hematologic (non-H) (fatigue, rash, peripheral neuropathy, diarrhea). The non-H AE data were categorized into grade ≥2 *vs*. grade ≤1 groups while H AE data were grouped into grade ≥3 *vs*. grade ≤2. The data were categorized in this way as maintenance treatment should have a tolerable AE profile and contribute to acceptable quality of life (QoL). Different cut-offs were used for H and non-H AEs because grade 3 H AE may have less impact on QoL and be more manageable than grade 2 non-H AE (diarrhea). For Ex/E, data were categorized as: ≥stable disease (SD) *vs*. progressive disease (PD). Clinical benefit rate including SD achieved in relapsed/refractory pts may be a meaningful predictor of expected response in a maintenance setting. The logistic regression analyses were done using SPLUS software version 8.1.
Results: The $t_{1/2}$ of ixazomib after multiple dosing ranged from 4 to 8 days, based on an analysis of data from 6 ongoing phase 1 studies, supporting a weekly dosing schedule. Statistically significant relationships to Ex ($p<0.05$) were observed for 5 AEs (fatigue, rash, diarrhea, thrombocytopenia, neutropenia) and clinical benefit rate (≥SD) (Figure). At a starting dose of 3 mg weekly (54% of MTD), the model predicts ~33% ≥SD, and incidence of grade ≥2 non-H AEs (rash 16%, diarrhea and fatigue 19% each) and grade ≥3 H AEs (neutropenia 10%, thrombocytopenia 22%). Further, the 3 mg dose is within the therapeutic range and represents one dose level below the starting dose used in ongoing phase 3 trials in relapsed/refractory and previously untreated MM.

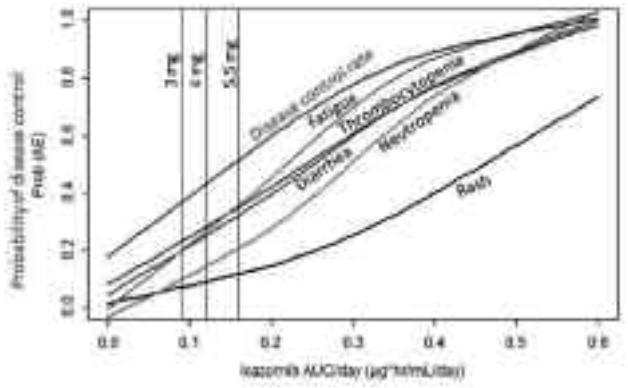

Figure 1.

Summary and Conclusion: The Ex/response relationships indicate that a favorable benefit *vs*. risk may be achieved at doses of 3 mg and 4 mg, below the MTD. Therefore, in the maintenance therapy study, pts will initiate ixazomib citrate at a once-weekly dose of 3 mg, increased to 4 mg if acceptable tolerability after 4 cycles, to provide maximum clinical benefit.

P965

PHASE 3 STUDY OF POMALIDOMIDE + LOW-DOSE DEXAMETHASONE VS. HIGH-DOSE DEXAMETHASONE IN RELAPSED/REFRACTORY MULTIPLE MYELOMA: MM-003 SUBANALYSIS OF ELDERLY PATIENTS (>65 AND >70 YEARS OF AGE)

Botkin, Moscow, Russian Federation, [13]Hospital Universitario del la Princesa, [14]Hospital Universitario 12 de Octubre, Madrid, Spain, [15]Princess Margaret Hospital, Toronto, Canada, [16]Hematology and Oncology, Wurzburg University Medical Center, Wurzburg, Germany, [17]Celgene Corporation, Summit, United States, [18]Alexandra Hospital, University of Athens School of Medicine, Athens, Greece

Background: Overall survival (OS) is markedly shortened in patients (pts) with relapsed/refractory multiple myeloma (RRMM) who have exhausted bortezomib (BORT), lenalidomide (LEN), or thalidomide treatment (Tx) (Kumar SK, *et al*. *Leukemia*. 2012). Pomalidomide (POM) + low-dose dexamethasone (LoDEX) has demonstrated clinical benefit in pts ≤ 65 yrs and >65 yrs (Jagannath S. EHA. 2013; Leleu X. *Blood*. 2013). MM-003, a randomized phase 3 study, demonstrated significant progression-free survival (PFS) and OS benefits for POM + LoDEX *vs*. high-dose dexamethasone (HiDEX), despite half of HiDEX pts subsequently receiving POM (San Miguel J. *Lancet Oncol*. 2013).
Aims: This subanalysis of MM-003 examined pt outcomes based on age.
Methods: Pts had to be refractory to last prior Tx (progressive disease [PD] during Tx or within 60 days) and exhausted BORT and LEN after ≥ 2 consecutive cycles of each alone or in combination. Pts were randomized 2:1 to receive 28-day cycles of POM 4 mg on days 1-21/28 day cycle + DEX 40 mg (20 mg for pts >75 yrs) weekly or DEX 40 mg (20 mg for pts >75 yrs) on days 1-4, 9-12, and 17-20. Tx continued until PD or unacceptable adverse events (AEs). The primary endpoint was PFS. Secondary endpoints included OS, overall response rate (ORR; ≥ partial response), and safety. All pts provided informed consent.
Results: 455 pts were randomized to POM + LoDEX (n=302) or HiDEX (n=153). This analysis focused on pts ≤ 65 yrs *vs*. >65 yrs since only 8% of pts were >75 yrs; an efficacy comparison between pts ≤ 70 yrs *vs*. >70 yrs was added as an exploratory analysis. Pts ≤ 65 yrs were more likely to have prior stem cell transplant (91% *vs*. 45%), to have better renal function (CrCl ≥ 60 mL/min: 78% *vs*. 51%), and less advanced disease (ISS stage III: 28% *vs*. 37%). All groups had a median of 5 prior Tx, and the median follow-up was 15.4 mos. Consistent with the overall population, POM + LoDEX resulted in significantly extended PFS (Figure A) and favorable OS (Figure B) across all age subgroups. The ORR was significantly higher for POM + LoDEX *vs*. HiDEX in all pts (32% *vs*. 11%), and in all age subgroups: ≤ 65 yrs (32% *vs*. 11%), >65 yrs (33% *vs*. 11%), ≤ 70 yrs (31% *vs*. 13%), and >70 yrs (35% *vs*. 7%); *P*<.001 for all comparisons. The most common grade 3-4 AEs for pts ≤ 65 yrs (POM + LoDEX *vs*. HiDEX) were neutropenia (51% *vs*. 22%), anemia (35% *vs*. 41%), and infections (34% *vs*. 20%). For pts >65 yrs, neutropenia (45% *vs*. 13%), anemia (30% *vs*. 37%), and infections (31% *vs*. 30%) were also the most frequent grade 3-4 AEs. Overall, grade 3-4 deep vein thrombosis or pulmonary embolism was infrequent (POM + LoDEX *vs*. HiDEX): 1% *vs*. 0% (≤ 65 yrs) and 2% *vs*. 0% (>65 yrs). Grade 3-4 peripheral neuropathy was also infrequent: 1% *vs*. 3% (≤ 65 yrs) and 2% *vs*. 0% (>65 yrs). Discontinuation due to AE was low in pts ≤ 65 yrs (POM + LoDEX: 6%; HiDEX 10%) and >65 yrs (POM + LoDEX: 13%; HiDEX: 11%). Median duration of POM Tx was 4.4 mos and 4.0 mos in pts ≤ 65 yrs and >65 yrs respectively and relative POM dose intensity was 90% for both age groups.

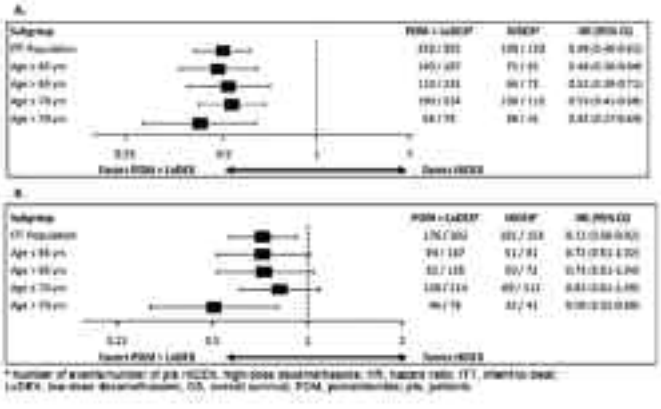

Figure 1.

Summary and Conclusion: PFS and OS benefits of POM + LoDEX were similar to those of the overall pt population and favored POM + LoDEX in the age subgroups analyzed. Tolerability profiles were consistent regardless of age group. POM at 4 mg is an appropriate starting dose for pts aged >65 yrs. These data support considering POM + LoDEX as a standard Tx option in RRMM pts of any age.

Background: Patients (pts) with relapsed/refractory multiple myeloma (RRMM) have few treatment (Tx) options and short overall survival (OS) after exhausting novel agents. Pts with high-risk cytogenetic abnormalities have shorter OS (Kumar SK. *Leukemia.* 2012). The immunomodulatory agent pomalidomide (POM) combined with low-dose dexamethasone (LoDEX), showed significant progression-free survival (PFS) and OS benefits in RRMM pts who failed bortezomib (BORT) and lenalidomide (LEN; San Miguel J. *Lancet Oncol*. 2013).
Aims: Update survival data and address the impact of cytogenetics on outcomes.
Methods: Pts were refractory to last prior Tx (progressive disease [PD] during Tx or within 60 days) and failed BORT and LEN after ≥ 2 consecutive cycles of each (alone or in combination). Pts were randomized 2:1 to receive 28-day cycles of POM 4 mg D1-21 + LoDEX 40 mg (20 mg for pts >75 yrs) weekly or HiDEX 40 mg (20 mg for pts >75 yrs) on D1-4, 9-12, and 17-20. Tx continued until PD or unacceptable adverse event (AE). The primary endpoint was PFS; other endpoints included OS, overall response rate (ORR; ≥ partial response), duration of response (DoR), safety, and cytogenetics. Modified high-risk cytogenetics were defined as the presence of del(17) and/or t(4;14) by conventional or FISH analysis at the time of screening.
Results: 455 pts were randomized to POM + LoDEX (n=302) or HiDEX (n=153). Modified high-risk cytogenetics were present in 77 POM + LoDEX pts (25%) and 35 HiDEX pts (23%). 44 POM + LoDEX pts had del(17p) and 44 had t(4;14). Median follow-up was 15.4 mos. POM + LoDEX significantly extended PFS and OS *vs*. HiDEX (Figure), despite 56% of HiDEX pts receiving subsequent POM. ORR was significantly higher (32% *vs*. 11%; *P*<.001), and median DoR was significantly longer (7.5 *vs*. 5.1 mos; *P*=.031) for POM + LoDEX *vs*. HiDEX. By multivariate analysis, Tx with POM + LoDEX, normal serum albumin levels, and normal lactate dehydrogenase (LDH) levels correlated with longer OS. Longer (>12 mos *vs* ≤ 3 mos) duration of POM + LoDEX Tx and OS were associated with better ECOG PS, absence of plasmacytoma, lower ISS stage, and normal LDH, hemoglobin, and platelet levels. ORR and median PFS advantages were seen for POM + LoDEX *vs*. HiDEX for both modified high-risk (ORR: 25% *vs*. 9%, *P*=.071; PFS: 3.8 *vs*. 1.1 mos, HR=0.44, *P*<.001) and standard-risk cytogenetics (ORR: 35% *vs*. 10%, *P*<.001; PFS: 4.2 *vs*. 2.3 mos, HR=0.55, *P*<.001). Within the POM + LoDEX arm, PFS was similar for modified high-risk *vs*. standard-risk cytogenetics (3.8 *vs*. 4.2 mos, *P*=.217) but differed between pts with t(4;14) *vs*. del(17p) (2.8 *vs*. 4.6 mos, *P*=.011). Median OS favored POM + LoDEX *vs*. HiDEX (modified high risk: 9.9 *vs*. 4.9 mos, HR=0.67, *P*=.092; standard risk: 14.0 *vs*. 9.0 mos, HR=0.85, *P*=.38). OS was shorter for POM + LoDEX pts with modified high-risk *vs*. standard-risk cytogenetics (9.9 *vs*. 14.0 mos, *P*=.041) and did not vastly differ but favored del(17p) *vs*. t(4;14) (12.6 *vs*. 7.5 mos, *P*=.133). The most frequent grade 3-4 AEs for POM + LoDEX *vs*. HiDEX were neutropenia (49% *vs*. 17%), anemia (33% *vs*. 39%), and infections (33% *vs*. 25%). Grade 3-4 DVT/PE (1% *vs*. 0%) and peripheral neuropathy (1% *vs*. 1%) were infrequent. Discontinuation due to AEs was low: 9% *vs*. 10%.

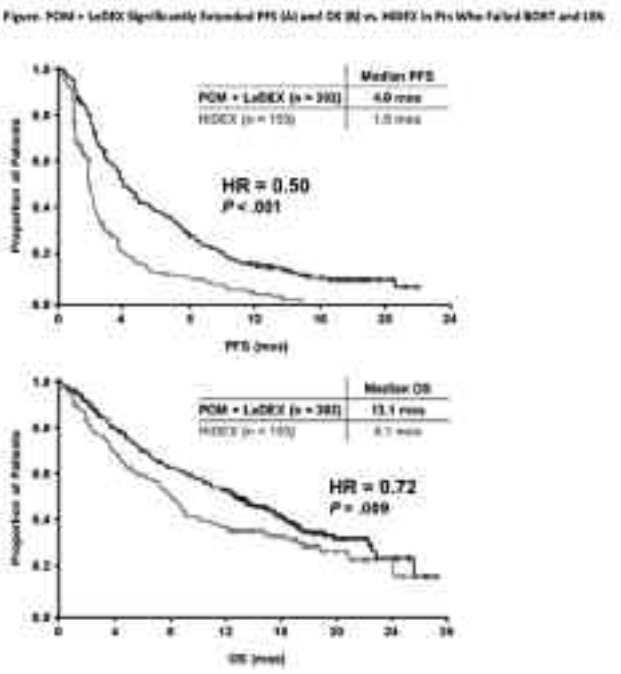

Figure 1. POM + LoDEX Significantly Extended PFS (A) and OS (B) vs. HiDEX in Pts Who Failed BORT and LEN

Summary and Conclusion: This analysis confirms the significant PFS and OS benefits for POM + LoDEX *vs*. HiDEX, which were consistent across cytogenetic groups. Median PFS for pts receiving POM + LoDEX was not impacted by cytogenetics. POM + LoDEX is a new standard Tx option in pts with RRMM who failed BORT and LEN.

P967

OVERALL SURVIVAL OF PATIENTS WITH RELAPSED AND REFRACTORY MULTIPLE MYELOMA: ADJUSTING FOR CROSSOVER IN THE MM-003 TRIAL FOR POMALIDOMIDE PLUS LOW-DOSE DEXAMETHASONE VS. HIGH-DOSE DEXAMETHASONE

G Morgan[1,*], J F San Miguel[2], S Dhanasiri[3], D Lee[4], A Palumbo[5], T Facon[6], M Zaki[7], X Yu[7], L Sternas[7], C Jacques[7], K Weisel[8], F Offner[9], M Dimopoulos[10]

[1]Myeloma Unit, Royal Marsden Hospital, Sutton, United Kingdom, [2]Universidad de Navarra, Pamplona, Spain, [3]Celgene Limited, Uxbridge, [4]BresMed, Sheffield, United Kingdom, [5]Via University of Torino, Torino, Italy, [6]Service des Maladies du Sang, Lille Cedex, France, [7]Celgene Corporation, Summit, United States, [8]Department of Hematology and Oncology, University of Tuebingen, Tuebingen, Germany, [9]Universitair Ziekenhuis Gent, Gent, Belgium, [10]Alexandra Hospital, University of Athens School of Medicine, Athens, Greece

Background: Multiple myeloma is a chronic and an incurable relapsing haematological malignancy. After exposure to treatments (Txs) such as thalidomide, bortezomib, and lenalidomide, patients (pts) with relapsed and refractory multiple myeloma (RRMM) have very poor overall survival (OS); one multinational study reported a median OS of 9 months (N=286; Kumar et al,

2012). MM-003 was an open-label, randomized, phase 3 trial undertaken to compare pomalidomide plus low-dose dexamethasone (POM + LoDEX; n=302) *vs*. high-dose dexamethasone (HiDEX; n=153) in the Tx of RRMM pts who had received prior bortezomib and lenalidomide (San Miguel et al, 2013). Median progression-free survival (PFS) and OS were significantly longer with POM + LoDEX than with HiDEX. Median OS in MM-003 was 12.7 and 8.1 months in the POM + LoDEX and HiDEX groups, respectively (intent-to-treat [ITT] analysis; HR=0.74; *P*=.0285). Following disease progression approximately 50% of pts from the MM-003 HiDEX arm crossed over to POM + LoDEX or to POM monotherapy.

Aims: In the presence of extensive crossover, conventional ITT survival analysis methods are biased, therefore, our study aims to estimate the OS difference between POM + LoDEX and HiDEX after adjusting for crossover.

Methods: A 2-stage Weibull method (Latimer et al, 2013) was used to estimate counterfactual adjusted OS data for the HiDEX arm. First, a data set containing only information for HiDEX pts from the point of progression was created. A survival acceleration factor (AF) was calculated for this patient group using a parametric accelerated failure time model with Tx as a binary explanatory variable to distinguish between pts who crossed over and those who did not. Second, the AF was applied to the survival times of all pts in the HiDEX group who crossed over. This method allows reconstruction of the Kaplan-Meier curve as though crossover had not occurred and estimation of OS from the start of Tx until the last observation. The best fitting parametric model was identified using the new Kaplan-Meier curve and standard model selection methods. Mean OS was extracted from the model, as required for use in health-economic evaluation.

Results: After adjusting for crossover, the difference in median OS in the POM + LoDEX and HiDEX groups was 7.0 months (12.7 *vs*. 5.7 months; Table 1; Figure 1). Extrapolation using a log-normal model fitted to the adjusted OS data produced an estimated difference in mean survival time of 14.6 months (28.0 *vs*. 13.4 months; Figure 1). Predicted survival at 3 years was 21% for pts treated with POM + LoDEX compared with 8% for those receiving HiDEX.

Table 1. ROC analysis based on progression to dialysis at 2 years

	Overall survival, months		
Analysis	**POM + LoDEX (n=302)**	**HiDEX (n=153)**	**Difference**
Intent-to-treat, median (95% CI)	12.7 (10.4-15.5)	8.1 (6.9-10.8)	4.6
Crossover adjustment, median (95% CI)	12.7 (10.4-15.5)	5.7 (4.2-7.5)	7.0

POM, pomalidomide; LoDEX, low-dose dexamethasone; HiDEX, high-dose dexamethasone.

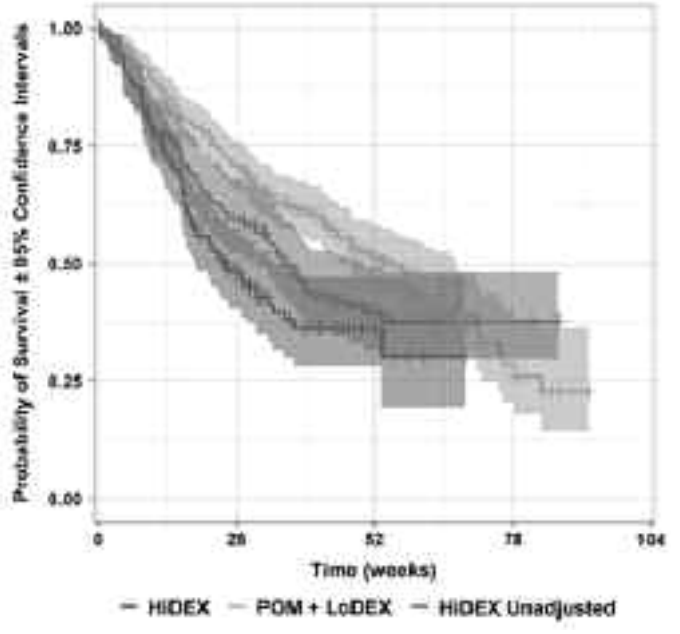

Figure 1.

Summary and Conclusion: The MM-003 ITT analysis showed a significant increase in median PFS and OS for POM + LoDEX *vs*. HiDEX. Survival adjusted for crossover in the HiDEX arm is comparable to 2 observational studies of RRMM pts refractory to current Tx, which reported median OS of 3.9 months (Tarant et al, 2013) and 5.3 months (Gooding et al, 2013). Our analysis suggests that median OS with POM + LoDEX is double that with HiDEX after accounting for crossover. Extrapolation over a lifetime horizon predicts a mean survival difference between POM + LoDEX and HiDEX of more than 14 months. The study provides important evidence for understanding the clinical efficacy and evaluating the overall economic value of POM in the Tx of RRMM pts.

P968

MICRORNA (MIRNA) EXPRESSION PROFILING IN PATIENTS WITH NEWLY DIAGNOSED MULTIPLE MYELOMA (NDMM) TREATED WITH CARFILZOMIB, LENALIDOMIDE, AND DEXAMETHASONE (CRD)

J K Jasielec[1,*], J L Chen[2], S Rosebeck[1], D Dytfeld[1], K Griffith[3], M Alonge[1], K McDonnell[1], M Mietzel[3], D Couriel[3], M Kaminski[3], A Jakubowiak[1]
[1]The University of Chicago, Chicago, [2]The Ohio State University, Columbus, [3]University of Michigan, Ann Arbor, United States

Background: Circulating miRNAs are emerging as new diagnostic and predictive markers in hematologic malignancies, including multiple myeloma and may add additional prognostic information to cytogenetics. In our recent update of the phase 1/2 CRd trial in NDMM (NCT01029054) we reported a trend towards lower 3-year progression-free survival (PFS) in patients with high-risk cytogenetics and a trend towards inferior outcome in those with a high-risk SKY92 signature (Jasielec et al, ASH 2013). Here we report serum miRNA profiling results in a cohort of patients from our study.

Aims: The aim of this study was to identify circulating miRNAs that may serve as prognostic markers in patients with NDMM treated with CRd.

Methods: Patients (pts) received 28-day (d) cycles of carfilzomib (CFZ) 20–36 mg/m^2 IV (d1, 2, 8, 9, 15, 16), lenalidomide (LEN) 25 mg PO (d1–21), and dexamethasone 40/20 mg PO once weekly (cycles 1–4/5–8). For cycles 8–24, CRd was given with a modified CFZ schedule (d1, 2, 15, 16), followed by LEN alone after cycle 24 (Jakubowiak *et al.* Blood 2012). All pts provided written informed consent. Serum samples from 30 pts were collected prior to starting therapy and retrospectively analyzed for miRNA expression by real-time (RT) PCR using Exiqon serum/plasma LNA Universal RT miRNA PCR panels. Detectable miRNAs in all samples were mean-normalized. Univariate Cox regression of PFS was performed to derive a nominal *P*-value. Differences in mean miRNA expression in cytogenetic and international staging system (ISS) subgroups were explored using a two-sided *t* test and ANOVA, respectively.

Results: In the 30 pts with available serum samples, median age was 62 y (range, 39–81), 20 (67%) had ISS stage II/III disease, and 8 (27%) had high-risk cytogenetics, including 5 (17%) pts with del17p. All 30 serum samples were successfully analyzed for miRNA expression with 79 miRNAs identified in ≥80% of samples and an average of 104 miRNAs per sample. Four miRNAs of interest were associated with PFS in univariate Cox regression. Two of the four miRNAs were associated with increased risk for progression: miR-378 (hazard ratio [HR]=2.87; p=0.03) and miR-99 (HR=17.24; *P*=0.02); the other two were associated with decreased risk: miR-103a (HR=0.0025; *P*=0.005) and miR-199 (HR=0.41; *P*=0.04). Further analysis revealed a statistically significant difference in PFS based on miR-99/miR-199 expression ratio (p=0.008) (Figure). There was no difference in mean expression of the four miRNAs between pts with high-risk and standard-risk cytogenetics and pts with and without del17p. MiR-99 expression based on ISS staging exhibited a trend for significance by ANOVA (*P*=0.07) with higher miR-99 expression in ISS stages II and III. Subsequent *t* test analyses revealed significant differences between ISS stage I and III (*P*=0.04) and II and III (*P*=0.04).

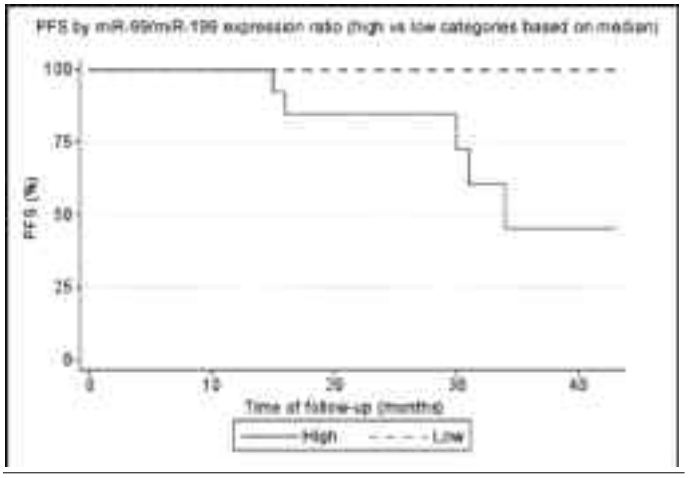

Figure 1.

Summary and Conclusion: In our cohort, miRs-99, -199, 103a, and 378 were associated with different PFS in pts treated with CRd. The expression profile of these biomarkers, especially their combinations, may serve as powerful prognostic markers in NDMM and merit further validation.

P969

IMPACT OF CONSOLIDATION WITH BORTEZOMIB-THALIDOMIDE-DEXAMETHASONE (VTD) UPFRONT IN MULTIPLE MYELOMA (MM) WITH PARTIAL RESPONSE (PR) AT COMPLETION OF INDUCTION WITH VTD

G Fouquet [1]b Hebraud [2]s Garciaz [3]am Stoppa [3]m Roussel [2]d Caillot [4]ml Chretien [4]b Arnulf [5]r Szalat [5]l Garderet [6]l Benajiba [6]b Pegourie [7]c Regny [7]b Royer [8]a Caulier [8]c Touzeau [9]b Tessoulin [9]jp Fermand [5]t Facon [1]m Attal [2]h Avet-Loiseau [2]p Moreau [9]x Leleu[1,*]
[1]Service des maladies du sang, Hôpital Huriez, CHRU, Lille, [2]Hôpital Purpan, CHU, Toulouse, [3]Institut Paoli Calmette, Marseille, [4]Hôpital du Bocage, CHU, Dijon, [5]Hôpital St Louis, [6]Hôpital St Antoine, Paris, [7]Hôpital Michallon, CHU, Grenoble, [8]Hôpital Sud, CHU, Amiens, [9]CHRU Hôtel Dieu, Nantes, France

Background: The impact of consolidation on response rates and PFS has recently been demonstrated after induction and autotransplantation upfront in Multiple Myeloma (MM). We further showed that patients in ≥ VGPR following the intensification procedure benefited most from consolidation.
Aims: Question remains as to the benefit of consolidation for patients in PR at completion of induction – feature of partial resistance to the induction regimen.
Methods: This study has included a group of 121 newly diagnosed MM patients that underwent auto from 2009 to 2011 across 9 IFM centers. Patients were to be eligible for auto in first-line of treatment, aged less than 65 years old and treated with VTd-auto-VTd regimen. We then collected data from the 54 patients that reached only PR at completion of the induction procedure.
Results: The median age was 57 years, the sex ratio was 1,25, 58% had ISS 2 and 3, 25% had adverse FISH, including t(4;14) and/or del17p (similar in the 2 groups). Overall, 37 patients (n=37/54, 68%) improved depth of response (at least VGPR) at completion of consolidation (in relation to transplantation and consolidation) in this series, including 33% (18/54) and 35% (19/54) that reached VGPR and CR, respectively. Respectively 57% (31/54) and 30% (16/54) of patients improved the depth of response after ASCT (at least VGPR) and after consolidation (at least VGPR if PR after ASCT, or CR if VGPR after ASCT). With a median follow-up of 40 months, improved depth of response translated into lower relapse rate compared with patients remaining in PR, 19% *vs.* 36%. This difference was more striking in patients that reached CR *vs.* other, 8% and 38%, respectively (p=0.039). The median TTP was prolonged in patients that improved depth of response after consolidation (p=0.012), with a 3-year TTP of 87% *vs.* 18% otherwise. In multivariate analysis, lack of improved depth of response to consolidation independently predicted shorten median TTP [OR=4.4, 95%CI=1-21; p=0.039], with elevated LDH and beta2m, and adverse FISH. The safety profile of VTd consolidation in this population was similar to that reported.
Summary and Conclusion: This study showed an improved response rate in relation to the VTd consolidation phase in patients that partially responded to the induction VTd regimen. This improved quality of responses translated into a lower relapse rate with a prolonged TTP and PFS. This study shows that VTd consolidation should be recommended to patients solely on PR at completion of induction with VTd, feature of lower sensitivity to VTd.

P970

FACTORS INFLUENCING EXTRA-MEDULLARY RELAPSE AFTER ALLOGENEIC TRANSPLANTATION FOR MULTIPLE MYELOMA

L Vincent[1,*], P Ceballos[1], N Fegueux[1], C Passot[2], JC Méniane[3], A Sirvent[1], P Quittet[1], R Navarro[1], C Cyteval[1], V Szablewski[1], P Portales[1], Y Hichri[1], C Quinquenet[1], B Klein[4], G Cartron[1]
[1]CHU de Montpellier, [2]IURC, MONTPELLIER, [3]CHU de Fort de France, Fort de France, [4]Unité INSERM 1040, Institut de Recherche en Biothérapie, Montpellier, France

Background: Despite a graft *versus* myeloma (MM) effect observed in several studies, relapse remains a major concern after allogeneic hematopoietic stem cell transplantation (allo-SCT).
Aims: We analysed risk factors, incidence and prognosis of MM extra-medullary relapses (EMR) after allo-SCT.
Methods: A retrospective, continuous, single-center cohort, including 79 patients who received an allo-SCT between 2000 and 2010 for MM (n=70) or plasma cell leukemia (n=9), was analysed. Median age at transplantation was 56 years (34-65). Allo-SCT was performed either in first line (14%) (14% including 6% of tandem auto allo-SCT), or in second line (46%) including 6% of patients with primary refractory disease and 40% of patients with chemo-sensitive post auto-SCT relapse, relapse having occurred at median 2,1 years post auto-SCT), or in third line or later (41%). Reduced-intensity conditionings were used in most cases (97%). Donors were siblings in 42%, matched unrelated in 29% (including 7% HLA 9/10 mismatches) and 29% of grafts were cord blood units. Other grafts were mainly peripheral blood stem cells (PBSC) (68%) or bone marrow (3%). Median follow-up after transplant was 4,8 years for living patients (3,0-12,8).
Results: Pathological examination was performed in 8 cases (42%). Other cases were diagnosed by MRI (47%), CT-scan (42%) and/or ultrasound (10%). In one patient, EMR was in soft tissues, not adjacent to the bone (EMS) and in 17 patients, bone plasmocytomas were observed (EMB). One patient had both types of EMR. EMS was pleural or hepatic. EMB involved mainly long bones (7/18) or skull/orbits (4/18). EMR occurred at a median of 1.3 year post allo-SCT (0-2.1 years), most of the time at first relapse (84%). Factors associated with a significantly increased incidence of EMR in a multivariate logistic regression were CD4 lymphocytes count before allo-SCT superior to 0.212 G/L and absence of pre-allo-SCT exposure to lenalidomide. Rescue treatments allowed a 41% response rate (CR : 21%, PR : 20%). Median survival after relapse was 1.57 year [0.26 ; 3.01] in EMR group not significantly different from that of patients with post allo-SCT relapse without EMR (1.56 year [0.63 ; 2.58]).
Summary and Conclusion: EMR is a frequent event after allo-SCT for multiple myeloma. Although, prognosis is poor, it is not different from non-EMR post allo relapses. Higher CD4+ T-Lymphocyte count before allo-SCT and no pre-allo-SCT lenalidomide exposure were associated with increased incidence of EMR.

P971

IMPACT OF 18 FDG-PET/CT ON THE OUTCOME OF MULTIPLE MYELOMA

N Meuleman[1,*], K Muylle[2], M Maerevoet[1], P Lewalle[1], P Antoine[1], L Ysebrant[1], J Dallemagne[1], P Flamen[2], D Bron[1]
[1]Hematology, [2]Nuclear Medicine, INSTITUT JULES BORDET, Bruxelles, Belgium

Background: Several studies have reported the interest of PET/CT for the clinical and prognostic evaluation of multiple myeloma patients (MM). Although its routine use is not recommended, it is a common practice for the management of MM patients. However, few data are available on the clinical impact of such a practice.
Aims: The aim of this study is to identify the indications for PET/CT in MM patients in daily practice and its impact on the therapeutic management of these patients.
Methods: We retrospectively reviewed all PET/CTs performed in our center from January 2005 to December 2013 for MM patients. We analyzed the clinical indications justifying the PET/CT request as well as the clinical signs and the biological status at the time of the prescription. The results and their therapeutic implications were also analyzed.
Results: 267 PET/CTs were performed for 74 MM patients during the period studied. The clinical indications were the evaluation of the disease at diagnosis (13.1%, n=35), the assessment of treatment response (33.7%, n=90), the assessment of disease progression (44.8%, n=120), the assessment of progression of MGUS or SMM to symptomatic myeloma (6%, n=16). At diagnosis, 67% of the patients had a positive PET/CT. Concerning the treatment response assessment, 48% of the reviewed PET/CTs showed complete metabolic responses, 33% showed partial remissions, 3% gave equivocal results and 16% showed progressive disease while undergoing treatment. All patients undergoing first-line treatment had a PET/CT showing complete or partial metabolic response; these results did not change the therapeutic approach. Concerning the search for relapse, 41 % (n=49) of PET/CTs were performed in asymptomatic patients, 21 % (n=25) in patients with pain reported as nonspecific, and 29 % (n=35) in patients with symptoms suggestive of relapse. In the group of asymptomatic patients, the PET/CT results lead to a change in treatment in 18 % (n=8) of the cases; 6 of these 8 patients had a progression of their monoclonal peak and two had multi-treated disease with extramedullary relapse. All asymptomatic patients with no other signs of progression had a negative PET/CT. In patients with nonspecific symptoms, 88% of the PET/CTs did not provide useful information and didn't result in a change of treatment, whereas 12% of the PET/CTs were positive and corresponded to patients with biological progression of their disease. For patients with symptoms suggestive of relapse, 88% of their PET/CTs were positive and led to a change in treatment.
Summary and Conclusion: Our retrospective study on the position of PET/CT for the management of MM patients suggests that: 1) PET/CT is already routinely used in the management of MM patients and in some cases, replaces other radiological investigations. 2) The use of PET/CT for the evaluation of response to first-line treatment does not lead to any change in the therapeutic attitude. 3) In the context of the search for an eventual relapse, PET/CT is of little use in patients with no characteristic clinical signs of progression and should not be used in the follow up of patients unless there is a high suspicion of progression.

Myeloma and other monoclonal gammopathies - Clinical 4

AN INTERNATIONAL, MULTICENTER, PROSPECTIVE, OBSERVATIONAL STUDY OF NEUTROPENIA IN PATIENTS BEING TREATED WITH LENALIDOMIDE + DEXAMETHASONE FOR RELAPSED OR RELAPSED/REFRACTORY MULTIPLE MYELOMA (RR-MM)

X Leleu[1,*], E Terpos[2], R García Sanz[3], J Cooney[4], P O'Gorman[5], J Minarik[6], R Greil[7], C Williams[8], D Gray[9], Z Szabo[10]
[1]Department of Haematology, Hôpital Claude Huriez, Lille, France, [2]Department of Clinical Therapeutics, National and Kapodistrian University of Athens, School of Medicine, Athens, Greece, [3]Department of Hematology, Hospital Universitario de Salamanca, Salamanca, Spain, [4]Department of Haematology, Royal Perth Hospital, Perth, Australia, [5]Mater University Hospital, UCD School of Medicine and Medical Science, Dublin, Ireland, [6]Department of Internal Medicine III, Palacky University and University Hospital Olomouc, Olomouc, Czech Republic, [7]Department of Internal Medicine III, Paracelsus Medical University, Salzburg, Austria, [8]Centre for Clinical Haematology, Nottingham University Hospitals, Nottingham, [9]Consultant Biostatistician, Cambridge, United Kingdom, [10]Research and Development, Amgen (Europe) GmbH, Zug, Switzerland

Background: Neutropenia is a common dose-limiting toxicity in patients with multiple myeloma receiving lenalidomide regimens. At the present time, little information is available regarding the characterization of neutropenia events and their optimal management in this setting.
Aims: This prospective observational study was designed to characterize neutropenia, its management, and its impact on delivery of lenalidomide regimens in patients with RR-MM in a clinical practice setting.
Methods: Eligible patients were ≥ age 18, had been diagnosed with relapsed or relapsed and refractory MM, and provided informed consent where required by local regulations. Patients were either starting treatment with lenalidomide plus dexamethasone or were still in their first cycle at the time of enrollment. Patients were observed from the start of lenalidomide treatment for up to 12 months. Data collected at each routine office visit included: lenalidomide administration, including any dose interruptions or reductions; absolute neutrophil count and body temperature if noted; G-CSF use; and hospitalizations related to MM. The primary outcome was the incidence of grade 3/4 neutropenia.
Results: A total of 198 eligible patients were enrolled between February 2011 and July 2012 at 34 centers in 9 countries (Australia, Austria, Czech Republic, France, Germany, Greece, Ireland, Spain, and UK). All patients were included in the primary analysis set and 69 (35%) completed the 12-month observational period. The most common reasons for early withdrawal were disease progression (21%), tolerability issues with lenalidomide (15%), and death (12%). Fifty-four percent of patients were men and the median age was 70. Most patients (83%) had a current diagnosis of relapsed MM, and the median time from the initial to current diagnosis was 36 months. At baseline, 21% of patients were stage III per the International Staging System. Most (60%) had 1-2 prior therapies and comorbidities were present in 84% of patients. Most patients (68%) received 25 mg/d lenalidomide in the standard schedule (days 1-21), 61% of patients received the dexamethasone dose and schedule included in the lenalidomide prescribing information. For the primary outcome, 62 patients (31%; 95% CI: 25 - 38%) had at least one grade 3/4 neutropenia event and the median time to first grade 3/4 neutropenia was 8.8 weeks (Q1, Q3: 5.9 – 17.3 weeks); half the patients with grade 3/4 neutropenia had 3 or more events. Six patients (3%) experienced febrile neutropenia. G-CSF was used in 23% of patients; filgrastim was administered for a mean of 6.9 days and a median of 1.0 day (range: 1-141). More patients with than without grade 3/4 neutropenia experienced lenalidomide dose reduction (37% *vs* 18%), received G-CSF (40% *vs* 15%), and experienced unplanned hospitalizations (50% *vs* 42%).
Summary and Conclusion: Incidence of grade 3/4 neutropenia in patients with RR-MM receiving lenalidomide and dexamethasone in clinical practice was similar to that reported in phase 3 studies. Grade 3/4 neutropenia events occurred in later cycles than the cytotoxic chemotherapy setting; therefore, different neutropenia monitoring and management may be required. G-CSF use was reactive rather than prophylactic. While lenalidomide toxicity is usually first managed with dose modifications per consensus panel guidelines (Dimopoulos et al, 2011), G-CSF support may be important for patients to maintain optimal dosing for continued response.

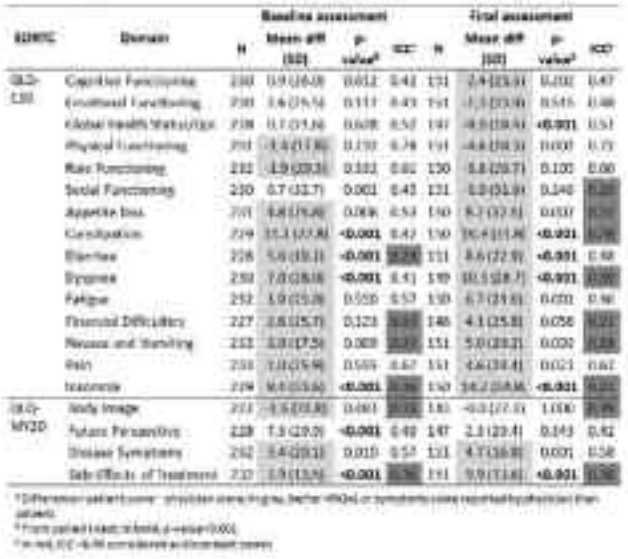
P973

LONGITUDINAL COMPARISON OF PATIENTS' AND PHYSICIANS' PERCEPTIONS OF PATIENTS' HEALTH-RELATED QUALITY OF LIFE IN RELAPSED/REFRACTORY MULTIPLE MYELOMA

I Vande Broek[1,*], MT Petrucci[2], X Leleu[3], P Murphy[4], M Welslau[5], P Bacon[6], P Lewis[7], H Gilet[8], B Arnould[8], C Kyriakou[9]
[1]Iridium Kankernetwerk, Sint-Niklaas, Belgium, [2]Division of Hematology, Department of Cellular Biotechnology and Hematology, Sapienza University, Rome, Italy, [3]CHRU-Hôpital Huriez, Lille, France, [4]Beaumont Hospital, Dublin, Ireland, [5]Studienzentrum Hämatologie, Aschaffenburg, Germany, [6]Celgene International Sarl, Boudry, Switzerland, [7]Celgene GmbH, Munich, Germany, [8]HEOR & Strategic Market Access, Mapi, Lyon, France, [9]Royal Free and Northwick Park hospitals, London, United Kingdom

Background: The use of novel therapeutic agents has significantly improved both progression-free and overall survival in multiple myeloma (MM) patients. In this context, it is important to evaluate health-related quality of life (HRQoL). Particularly, exploring the level of concordance between physicians' and patients' perceptions of patients' HRQoL could improve physicians' understanding of patients' feelings and may help in the management of a patient's routine care.
Aims: To compare, on several occasions, physicians' and patients' perceptions of patients' HRQoL in relapsed/refractory MM (RRMM) context.
Methods: A multicenter, observational study is being conducted in Italy, Germany, France, UK, Ireland and Belgium in RRMM patients starting 2nd or 3rd line treatment. Both physicians and patients completed the following EORTC questionnaires at baseline, month 3, and month 6 or discontinuation visit: 1) the Quality-of-Life Questionnaire Core (QLQ-C30), including 15 domains: Global Health Status/QOL, Physical Functioning, Role Functioning, Emotional Functioning, Cognitive Functioning, Social Functioning, Fatigue, Nausea and Vomiting, Pain, Dyspnea, Insomnia, Appetite Loss, Constipation, Diarrhea and Financial Difficulties; and 2) the QLQ-Multiple Myeloma (QLQ-MY20), including four domains: Disease Symptoms, Side-Effects of Treatment, Body Image and Future Perspective. Paired t-tests and Intra-Class Correlation Coefficients (ICC) were calculated to compare patient- and physician-reported scores at the baseline assessment and then at final assessment (month 6 or discontinuation). Discordant scores were defined as those with an ICC<0.40.
Results: As of November 2013, this interim analysis included 32 physicians who had enrolled 244 patients in the study (mean age=70; 53% male). At baseline, the average time since diagnosis was 3 years, 16% of patients were ECOG performance status ≥2 and 94% of patients were starting 2nd line treatment. At baseline assessment, 236 (97%) EORTC questionnaires were completed by physicians and 235 (96%) by patients. At final assessment, 154 (63%) EORTC questionnaires were completed by physicians and 153 (63%) by patients. According to ICC (Table 1), discordance was observed at baseline assessment between patients and physicians for five symptom domains (Diarrhea, Financial Difficulties, Nausea and Vomiting, Insomnia, Side-Effects of Treatment) and one HRQoL domain (Body Image). Discordance was still observed at final assessment for all these domains except for Diarrhea. Discordance was also observed at final assessment for three additional symptom domains (Appetite Loss, Constipation, Dyspnea) and one additional HRQoL domain (Social Functioning). For all these domains, physicians reported better scores for their patients, indicating better perception of HRQoL and symptoms than reported by the patients themselves.

Table 1. Comparison of EORTC scores at baseline and final assessments



Summary and Conclusion: While no major discordance was observed between patients' and physicians' ratings of functioning and HRQoL domains, there was substantial discordance between the perceptions of physicians and patients for the symptoms and side effect domains. In this interim analysis, physicians underestimated the detriment of RRMM disease and treatment on patients' HRQoL as well as possible negative effects of prior treatment as compared to the individual patient's experience. This discordance persisted when ratings were repeated over time.

P974

TRANSIENT ELEVATION OF AST OR LDH AS AN EARLY PHARMACODYNAMIC BIOMARKER OF RECOMBINANT CIRCULARLY PERMUTED TRAIL (CPT) IN TREATING PATIENTS WITH RELAPSED OR REFRACTORY MULTIPLE MYELOMA

P Wei[1], S Yang[2,*], X Zheng[2], W Chen[3], L Qiu[4], J Hou[5], X Zhang[6], Z Wang[7], X Ke[8], L Pan[9], H Pang[1]
[1]Pharmacology, [2]Beijing Sunbio Biotech Co. Ltd., [3]Hematology, Chaoyang Hospital of Capital Medical University, [4]State Key Lab. of Experimental Hematology, Institute of Hematology and Blood Diseases Hospital, Beijing, [5]Hematology, Chang Zheng Hospital, Second Military Medical University, Shanghai, [6]Hematology, The second hospital of Hebei medical university, Shijiazhuang, [7]Hematology, Beijing Friendship Hospital, Capital Medical University, [8]Hematology, Peking University Third Hospital, Beijing, [9]Hematology, West China Hospital of Sichuan University, Chengdu, China

Background: Circularly permuted TRAIL (CPT), a recombinant mutant of human Apo2L/TRAIL, selectively induces tumor cell apoptosis by activating pro-apoptotic receptors DR4 and DR5. CPT was found to be effective and well tolerated for patients with relapsed or refractory multiple myeloma (RRMM) in Phase1/2 clinical trials. Transient elevations of serum AST and LDH were observed early after CPT treatment in most response patients, but not in the non-respondent, which could not be simply ascribed to liver injuries. It was assumed that the increased AST and LDH might be associated with CPT therapy responses.
Aims: To determine the relationship between the elevation of AST or LDH and the clinical responses to CPT in RRMM patients, and to evaluate the predictive value of AST or LDH elevation as a pharmacodynamic biomarker of CPT.
Methods: We retrospectively analyzed the data from three Phase1/2 studies of CPT. The relationship between $AST_{D2/3}$, $LDH_{D2/3}$ or $ALT_{D2/3}$ (AST, LDH or ALT level assayed on day 2 or day 3 after initial CPT dosing) and the best clinical responses was evaluated. Statistical analyses were performed to evaluate whether ΔAST/ΔALT ratio or ΔLDH/ΔALT ratio (ΔAST, ΔLDH or ΔALT: ratio of $AST_{D2/3}$, $LDH_{D2/3}$ or $ALT_{D2/3}$ to baseline value) was a potential biomarker in predicting therapy responses, and to determine the cut-off point. Two myeloma cell lines sensitive to CPT (RPMI8226, NCI-H929) and one resistant (U266B1) were cultured, and the concentrations of AST, ALT and LDH in the cytoplasma or the medium of CPT-treated cells were detected to determine whether CPT-induced myeloma cell death could result in an elevation of AST or LDH.
Results: Of 93 CPT-treated RRMM patients, 24.7% achieved a partial response (PR) or better and 36.4% achieved a minimal response (MR) or better with an average serum $AST_{D2/3}$ of 222.03±332.10 U/L and 164.23±269.60 U/L, respectively. Both $AST_{D2/3}$ levels were much higher than that in non-respondent patients (*P*=0.025, *P*=0.013, respectively). It was the same with $LDH_{D2/3}$ (*P*=0.033, *P*=0.011, respectively), but not with $ALT_{D2/3}$ (*P*=0.358, *P*=0.556, respectively) (Table 1). The elevation of AST or LDH was transient with a peak on day 2 or day 3 after CPT treatment, and usually disappeared within one week for AST or two for LDH, which was uniquely observed in the first therapy cycle. The average ΔAST in patients with ≥PR or in those with ≥MR was higher than that in non-respondent ones (*P*=0.031, *P*=0.025, respectively). So it was with ΔLDH (*P*=0.008, *P*=0.004, respectively), but not with ΔALT (*P*=0.062, *P*=0.202, respectively) (Table 1). The average ΔAST/ΔALT or ΔLDH/ΔALT in response patients was significantly higher than that in the non-respondent (*P*=0.001, *P*=0.007, respectively) (Table 1). ΔAST/ΔALT was found to be an applicable biomarker for predicting responses of ≥MR by logistic regression (*P*=0.005), while ΔLDH/ΔALT was not (*P*=0.771) since there were some missing data of LDH. Receiver operating characteristic curve analysis showed that ΔAST/ΔALT with 1.64 as the cut-off point could differentiate between response and non-response with the sensitivity of 63.6% and the specificity of 80.00%. All the three cell lines were verified to contain abundant AST (633.33±290.66 U/L) and LDH (1618.67±571.36 U/L) but only detectable level of ALT (19.33±6.43 U/L). In CPT-sensitive cells, the AST or LDH released into the medium of CPT-treated cells was about three times that of vehicle control, much higher than in resistant cells. However, there was no notable change of ALT in any cell line. It was suggested that the transient elevations of AST and LDH in RRMM patients were most likely resulted from CPT-induced myeloma cell death.

Table 1. Serum AST, ALT and LDH in patients treated with CPT

	Response		Non-response	*P* value
	≥ PR	≥ MR		
$AST_{D2/3}$ U/L	222.03±332.10	164.23±269.60	40.50±43.31	0.025, 0.013
$LDH_{D2/3}$ U/L	926.23±1082.74	718.65±882.27	198.87±240.55	0.033, 0.011
$ALT_{D2/3}$ U/L	34.04±40.25	30.19±32.69	26.20±28.18	0.358, 0.556
ΔAST	13.23±21.64	9.13±17.81	1.94±1.72	0.031, 0.025
ΔLDH	7.29±7.00	5.15±5.55	1.13±0.87	0.008, 0.004
ΔALT	2.41±2.50	1.97±1.45	1.44±1.62	0.062, 0.202
ΔAST/ΔALT	-	4.06±3.70	1.65±1.35	0.001
ΔLDH/ΔALT	-	3.71±3.83	1.30±0.76	0.007

$AST_{D2/3}$, $ALT_{D2/3}$ or $LDH_{D2/3}$: serum AST, ALT or LDH detected on day 2 or day 3 after initial CPT dosing. ΔAST, ΔLDH or ΔALT: ratio of $AST_{D2/3}$, $LDH_{D2/3}$ or $ALT_{D2/3}$ to baseline value. Data are expressed as mean±SD. Independent *t* tests were conducted to compare the differences between response (≥ PR or ≥ MR) and non-response.

Summary and Conclusion: Our results demonstrated for the first time that the early transient elevations of serum AST and LDH after CPT treatment were probably due to the cell apoptosis induced by CPT, and were positively related to the therapy responses of CPT. ΔAST/ΔALT ratio could be a useful pharmacodynamic biomarker for CPT therapy in RRMM patients.

P975

LONG TERM CRYOPRESERVED AUTOLOGOUS BLOOD STEM CELLS FOR SALVAGE AUTOLOGOUS STEM CELL TRANSPLANTATION (ASCT) IN RELAPSED MULTIPLE MYELOMA PATIENTS

N Areethamsirikul[1,*], E Mashi-Khan[1], A Winter[1], V Jimenez-Zepeda[1], D E Reece[1], C Chen[1], S Trudel[1], R Tiedemann[1], V Kukreti[1]
[1]Department of Medical Oncology and Hematology, Princess Margaret Cancer Center (PMCC), Toronto, Canada

Background: Second ASCT (ASCT2) has been considered to be a safe and feasible treatment option for relapsed Multiple Myeloma (MM) patients (pts), especially those who have had durable remissions after first ASCT (ASCT1). The long-term stability of cryopreserved stem cells (SCs) collected prior to ASCT1 has therefore become an important issue in pts who require ASCT2 after a prolonged period of disease remission. There is limited data with small numbers of pts that describe the viability of long-term stored SCs, especially in novel therapy era that immunodulators and proteasome inhibitors have been increasingly utilized as induction or re-induction before ASCT.
Aims: Our study aims to evaluate the stability and engraftment of long-term cryopreserved SCs for salvage ASCTs in a larger number of pts and to assess the effect of novel agent therpy on engraftment parameters after ASCT2.
Methods: We retrospectively reviewed 102 relapsed MM pts who underwent salvage ASCT2 using SCs collected before ASCT1 at PMCC between January 2003 to June 2013. Patient demographics, disease characteristics, chemotherapy treatment and ASCT details were obtained from pts medical charts and transplant database. Neutrophil engraftment was defined as the first of 3 consecutive days that neutrophil counts were ≥0.5x10^9/L. Platelet engraftment was defined as day of platelet counts ≥20 x10^9/L without supportive transfusion. Paired simple T-test was used to compare time to engraftment between transplantations.
Results: One hundred and two pts (65 males, 64%) underwent ASCT2 as salvage treatment for relapsed MM. Median age at diagnosis, ASCT1 and ASCT2 were 56, 57 and 61 years, respectively. MM subtypes included IgG 47%, IgA 23%, light chain disease 26% and others 4%. Majority (98%) of pts received high dose cyclophosphamide followed by G-CSF for SC mobilization and melphalan 200mg/m^2 for conditioning. All collected SCs were cryopreserved in 10% DMSO. SC storage times were 1.9 (0.4-24.7) and 47.2 (15-131) months for ASCT1 and ASCT2. Median time duration between the two transplants was 45 (14-128) months. Median numbers of CD34+cells infused at ASCT1 were 6.43x10^6/kg (2.6-33.2) and 5.7x10^6/kg (1.2-16.9) at ASCT2. There was no significant difference in median time to engraftment between ASCT1 and ASCT2; 12 (6-16) *vs* 11 (10-15) days for neutrophil engraftment (p=0.33) and 11 (10-20) *vs* 11 (10-20) days for platelet engraftment (p=0.26). There was no delayed engraftment of greater than 21 days in any pts. We further investigated the stability of SCs based on years of cryopreservation at ASCT2. There was no difference in time to neutrophil (p=0.06) and platelet engraftment (p=0.74) between groups of pts who were given short (<6years) and long (≥6years) term cryopreserved SCs. We also compared 26 pts who received novel agent-based induction (bortezomib=10 pts, thalidomide=18 pts and lenalidomide=1 pt) prior to SC collection with 76 pts who were never exposed to novel agent treatment; no significant differences in time to engraftment were noted. After median time to relapse of 38 (19-119)months, 68 pts (67%) were treated with novel agents (bortezomib=34 pts, thalidomide=21 pts and lenalidomide=18 pts) for re-induction before proceeding to ASCT2. Similarly, there was no significant difference in engraftment between pts who had novel agents at relapse when compared to those who were not treated with novel agents. Although we found no time to engraftment differences between two ASCTs, we did observe pts who received higher number of CD34+ SCs (≥5x10^6/kg) engrafted faster in ASCT1 (neutrophil p=0.005; platelet p=0.03). For ASCT2, neutrophils engrafted significantly faster (p=0.006) but platelet recovery did not reach significance (p=0.17) for ≥5x10^6/kg SCs infused.
Summary and Conclusion: Long-term cryopreserved SCs can be safely used in salvage ASCT in relapsed MM pts even in the era of novel agents. Cryopreservation of SCs for >6 years results in no loss of viability as determined by comparable times to engraftment in both upfront and salvage ASCT. Additionally, treatment with the novel agents does not interfere with stem cell quality.

P976

MULTIPLE MYELOMA OF ELDERLY: COMORBIDITY INDEXES, SCALES, AND PERSONALIZED TREATMENT

V Djurasinovic[1,*], J Bila[1,2], J Jelicic[1], V Vukovic[1], A Sretenovic[1], B Andjelic[1], D Antic[1,3], M Todorovic[1,3], B Mihaljević[1,3]
[1]hematology, institute of hematology, [2]Faculty of medecine, University of

Belgrade, [3]hematology, Faculty of medecine, University of Belgrade, Belgrade, Serbia

Background: The necessity of personalized treatment approach has been emerged after the introduction of the various new treatment modalities for multiple myeloma (MM). Consideration of comorbidity, disability and frailty represents significant part of the treatment in the elderly population of patients (pts).
Aims: The aim of study was to analyse the impact of the Charlson Comorbidity Index (CCI) and scale of Instrumental Activities of Daily Living (IADL) on the course of disease, and propose a model of personalized approach based on those parameters.
Methods: The study included 110 newly diagnosed MM pts (age of ≥ 65yrs: 55 male/55 female, mean age 71 yrs, range 65-81). IgG myeloma had 68pts (61,8%), IgA 25pts (22,7%), light chains 15pts (13,6%), IgD 1pts (0,9%), and non-secretory 1pts (0,9%). According to the clinical stage, distribution was: I 5pts (4,7%), II 21pts (19,6%); III 81pts (75,7%). Regarding ISS score, 12,4%pts had ISS1 score; 31,5% ISS2; and 56,2% had ISS3. Renal impairment existed in 36pts (34%). According to the CCI, median score was 1 (range 0-5). Median age adjusted CCI (aaCCI) score was 5 (range 3-9). Most of the pts had CCI 0-1 (82pts, 74,5%); 2-3 had 21pts (19,1%); 4-5 had 7pts (6,4%). In a view of aaCCI, 49pts (44,5%) had aaCCI 3-4; 5-6 had 51pts (46,4%); aaCCI ≥7 had 10pts (9,1%). Median IADL score was 6 (range 0-8), with IADL ≥6 in 70pts (64,2%); 3-5 in 26pts (23,9%); and 0-2 in 13pts (11,9%). Thalidomide combinations were applied in 63pts (57,3%); 5pts (4,6%) were treated with bortezomib; and 42pts (38,1%) with conventional chemotherapy.
Results: ISS3 correlated with high scores of CCI or aaCCI (R=0,314, p<0,003; R=0,317, p<0,002), and lower IADL (R=0,259, p<0,007). The probability of adverse events (AE) was 70% higher for CCI ≥2 score (OR=1,72); and 28% for aaCCI (OR=1,28). There was 2x higher probability of the AE for IADL<3 (OR=2,25). Treatment response (CR/VGPR/PR/MR) was achieved in 81pts (73,6%) with median duration 14m (range 3-85m). The median overall survival (OS) for the group was 36m (range 6-98m). Patients with CCI 0-1 had significantly longer duration of remission (Breslow 4,37; p<0,037), and OS (Log Rank 1,738; p 0,187). Patients with aaCCI ≥5 had significantly shorter OS (Log Rank 4,209; p<0,040). The OS was found significantly longer in pts with IADL >3 (Log Rank 6,62; p<0,001). Furthermore, aaCCI ≥5 and IADL >3 scores were indicated as major variables in the proposed model for the personalized treatment approach with clear impact on the OS of elderly MM pts (Omnibus test of Model Coefficients, Chi-square 8,46, p=0,037; Hazard rate: IADL ≥3 0,46; 95% CI 0,24-0,9; aaCCI ≥5 1,43; 95% CI 0,76-2,71).
Summary and Conclusion: Age adjusted Comorbidity Index and scale of Instrumental Activities of Daily Living represents important parameters for the treatment and course of disease in elderly myeloma patients, indicating variables as aaCCI ≥5 and IADL >3 of importance for the appropriate treatment choice and possible dose adjustment.

P977

SMOULDERING MULTIPLE MYELOMA RISK FACTORS FOR PROGRESSION. AN ANALYSIS OF 289 CASES IN THE DANISH MULTIPLE MYELOMA REGISTRY

R Sørrig[1,*], T W Klausen[2], UC Frølund[3], H Gregersen[4], C Helleberg[5], D L Kristensen[6], N F Andersen[7], T Plesner[8], S Pulczynski[9], N Albildgaard[10], T Mourits-Andersen[11], N T Clausen[5], A Vangsted[1], M Salomo[1], P Gimsing[1]
[1]Dept. of Hematology, Rlgshospitalet, Copenhagen, [2]Hematological Research Laboratory, Herlev Hospital, Herlev, [3]Dept. of Hematology, Roskilde Sygehus, Roskilde, [4]Dept. of Hematology, Aalborg Universitetshospital, Aalborg, [5]Dept. of Hematology, Herlev Hospital, Herlev, [6]Dept. of Oncology, Næstved Sygehus, Næstved, [7]Dept. of Hematology, Aarhus Universitetshospital, Aarhus, [8]Dept. of Hematology, Vejle Sygehus, Vejle, [9]Dept. of Hematology, Holstebro Sygehus, Holstebro, [10]Dept. of Hematology, Odense Universitetshospital, Odense, [11]Dept. of Hematology, Sydvestjysk Sygehus, Esbjerg, Denmark

Background: There is a need for models of how to stratify Smouldering Multiple Myeloma (SMM) patients at risk of progression to Multiple Myeloma as new clinical trails show that some patients may benefit from early treatment. Major risk models for progression includes presence of immunoparesis (reduction in one or more of the non M-protein immunoglobulin) and abbarent plasma cell percentage (PC)% >95% or bone marrow PC% >10% together with abnormal free light chain ratio (FLCr) and M-protein ≥ 3g/dL and also recently including chromosomal aberrations[1–5]. However, currently there is no consensus on how to classify low, intermediate or high risk disease[6].
Aims: To analyze risk factors for progression and overall survival (OS) for SMM in a population based cohort of patients and to develop a new proposal for a scoring system for time to progression (TTP) to symptomatic multiple myeloma.
Methods: We conducted a study of the 289 newly diagnosed SMM patients registered within the Danish Multiple Myeloma Registry for OS between 2005 and 2013. The median follow-up for TTP and OS was 25,6 mo. and 31.9 mo., respectively. First we made a univariate cox regression analysis to estimate risk factors for TTP and OS. Secondly we calculated a multivariable cox regression including univariat significant risk factors.
Results: Of the registered data a M-protein ≥ 3g/dL resulted in a markedly shortening TTP (HR 3,8 P<0.0001). Furthermore the presence of immunoparesis of 1 or more of the non M-protein immunoglobulins and high level of Clonal Plasma Cell percentage (PC%) were associated with a significantly shorter TTP (P=0.0006 and P=0.01 respectively). The multivariable analysis showed that both an M-protein ≥ 3g/dL and immunoparesis were associated with significantly shorter TTP. Neither M-protein size nor immunoparesis or PC% had an effect on overall survival (OS) (table 1). Using immunoparesis, M-protein ≥ 3g/dL and PC% ≥ 10%, we created a scoring system of 1, 2 or all 3 of the variables and identified a low-risk (1), intermediate (2) and high-risk (3) population. Applying this model we predicted a median TTP of 32 months for the highrisk group *versus* not reached for the intermediate and low risk groups.

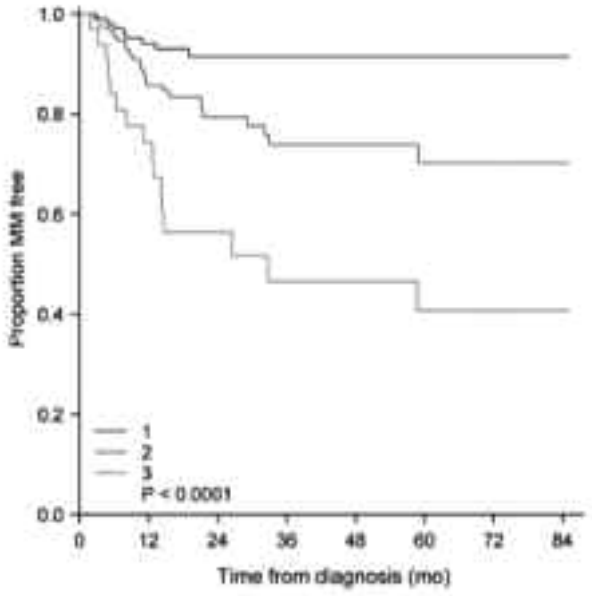


Figure 1. Time to progression (TTP) to symptomatic disease having either 1, 2 or 3 of the risk factors; immunoparesis, M-protein≥ 3g/dL and PC% ≥ 10%. Low-risk; 1, intermediate risk; 2, and high-risk; 3. The model predicted a median TTP of 32 mo. for the high-risk group.

Summary and Conclusion: Our study concludes that the presence of an M-protein ≥ 3g/dL and immunoparesis in SMM patients remains important risk factors for progression to Multiple Myeloma. We found that none of the risk factors for TTP influenced OS. To our knowledge this is the largest retrospective population based cohort study of risk factors for SMM patients. The model did not include a FLC ratio nor presence of abbarant %PC ≥ 95%.

Background: EU PASS is an observational non-interventional study designed to investigate the safety of lenalidomide (LEN) and other approved treatments (Txs) for relapsed/refractory multiple myeloma (RRMM) patients (pts) in a true-to-life setting.
Aims: To compare the incidence of adverse events (AEs) and second primary malignancies (SPMs) in RRMM pts treated with LEN + dexamethasone (DEX) or other anti-myeloma Txs in routine clinical practice in the UK and Ireland.
Methods: This multicentre, post-authorisation safety study included RRMM pts who had received ≥1 prior Tx. Pts were enrolled at investigator's discretion into a LEN cohort (LEN + DEX: approved combination for RRMM Tx) or a background cohort (all other Txs, including novel agents). AEs were graded according to NCI-CTCAE (v3) and SPMs were defined using MedDRA terms under Neoplasms SOC. Assessments for SPMs were conducted up to 36 months (mos) after Tx discontinuation.
Results: A total of 388 pts across institutions in the UK (n=23) and Ireland (n=2) were enrolled. Of these, 35% (n=136) received LEN, 58% (n=225) received bortezomib (BORT), 5% (n=19) received thalidomide (THAL) and 2% (n=8) received other Txs. Baseline demographics were similar with the exception that more pts in the LEN cohort received ≥2 prior lines of Tx (81%) *versus* BORT (38%) and THAL (47%) (a reflection of standard UK pathways). Median age was 69 yrs (range 30–91) and 59% (n=229) were male. Overall, 58% (n=223) of pts had a good performance status (ECOG score 0–1), 14% (n=56) had an ECOG score 2–4 and 28% of pts had missing or unknown ECOG scores. In the LEN cohort 38% of pts (n=52) were treated for >12 mos and 14% (n=19) for >24 mos. Median Tx durations were 8 mos (range 0–34), 4 mos (range 0–22), and 5 mos (range 1–9) for the LEN, BORT and THAL cohorts, respectively. Median overall follow-up was 5.4 mos (range 0.1–35). The proportion of pts having at least one grade (Gr) 3–4 AE was 60% (n=82), 44% (n=99) and 47% (n=9) in the LEN, BORT, and THAL cohorts, respectively. Gr 3–4 neutropenia was reported in 13% (n=18), 1% (n=2) and 5% (n=1) of pts, and Gr 3-4 thrombocytopenia occurred in 4% (n=5), 3% (n=6) and 0% of pts in the LEN, BORT and THAL cohorts, respectively. The incidences of Gr 3-4 peripheral neuropathy (PN) during the study was the lowest in the LEN cohort (1.5%, n=2), the highest in the BORT cohort (9.3%, n=21), and 5.3 % (n=1) in the THAL cohort. The percentage of pts with all grades peripheral neuropathy (PN) at baseline was 38% (n=52), 24% (n=55) and 11% (n=2) for the LEN, BORT and THAL cohorts respectively. Subsequently, 1.5% (n=2), 4% (n=9) and 0% (n=0) of pts developed Gr 3-4 PN in the LEN, BORT and THAL cohorts, respectively. Study discontinuation rates due to AEs were 14% (n=19), 26% (n=58) and 21% (n=4) in the LEN, BORT and THAL cohorts, respectively. The percentage of pts with SPMs was low with 3% (n=4) in the LEN, 1% (n=2) in the BORT and none in the THAL cohort.
Summary and Conclusion: Results of this study in RRMM show that the incidences of Gr 3–4 AEs are the highest in the LEN cohort, with the exception of PN which was higher in the BORT cohort. The rates of study discontinuation due to AEs were the lowest in the LEN cohort. In general, the incidences of SPMs were low in all cohorts with similar incidences of invasive and non-invasive SPMs observed in both the LEN (1.5%, n=2) and BORT (0.4%, n=1) cohorts.

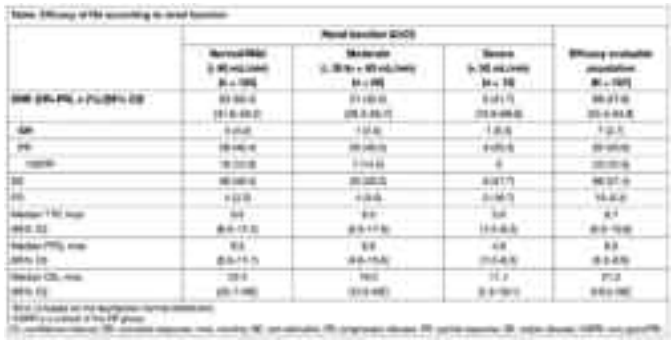
P979

IMPACT OF RENAL IMPAIRMENT ON THE EFFICACY AND SAFETY OF LENALIDOMIDE PLUS LOW-DOSE DEXAMETHASONE (RD) IN CHINESE PATIENTS (PTS) WITH RELAPSED AND REFRACTORY MULTIPLE MYELOMA (RRMM): MM-021 TRIAL

DB Zhou[1,*], L Yu[2], X Du[3], J Jin[4], Z Cai[4], F Chen[5], X Li[6], D Wu[7], F Meng[8], H Ai[9], J Zhang[10], H Wortman-Vayn[10], J Mei[10], J Wang[11], J Hou[12]
[1]Peking Union Medical College Hospital, [2]The 301 Military Hospital, Beijing, [3]Guangdong General Hospital, Guangzhou, [4]The First Affiliated Hospital, Zhejiang University, Hangzhou, [5]Xiangya Hospital of Central South University, Changsha, [6]Shanghai Sixth People's Hospital, Shanghai, [7]The First Affiliated Hospital of Soochow University, Suzhou, [8]Nanfang Hospital, Southern Medicine University, Guangzhou, [9]The 307 PLA Hospital, Beijing, China, [10]Celgene Corporation, Summit, NJ, United States, [11]Changhai Hospital, [12]Shanghai Changzheng Hospital, Shanghai, China

Background: Renal impairment (RI) is a common complication of multiple myeloma. In China, based on the pivotal MM-021 trial, the Rd regimen is approved for the treatment (Tx) of RRMM pts who have received ≥ 1 prior Tx (Hou, J Hematol Oncol 2013). As lenalidomide (LEN) is mainly excreted by the kidney, its plasma concentration and half-life are longer in pts with RI; therefore, dose adjustment is recommended in these pts.
Aims: To evaluate the efficacy and safety of Rd in RRMM pts with RI from the MM-021 trial.
Methods: MM-021 was a phase 2, multicenter, single-arm, open-label study. RRMM pts received LEN (25 mg on D1–21/28 day cycle) plus low-dose dexamethasone (40 mg/day on D1, 8, 15, and 22) until disease progression or discontinuation. The starting dose of LEN was adjusted according to baseline renal function: 25 mg/day for pts with normal/mild renal function (creatinine clearance [CrCl] ≥ 60 mL/min); 10 mg/day for moderate RI (CrCl 30–60 mL/min); and 15 mg every other day for those with severe RI (CrCl<30 mL/min, not requiring dialysis). Thromboprophylaxis was mandatory during the study. The primary endpoint was overall response rate (ORR) defined as the percentage of pts who achieved a best response of partial response or better. Secondary endpoints included time to progression (TTP), progression-free survival (PFS), overall survival (OS), and safety.
Results: A total of 199 pts were enrolled (intent-to-treat population) and 187 pts were evaluable for efficacy. At baseline, 66% of pts (n=131) had normal/mild renal function, 27% (n=54) had moderate RI, and 7% (n=14) had severe RI. The ORR was 50% in pts with normal/mild renal function compared with 42% in those with moderate or severe RI (Table). With a median follow-up of 17.6 months, 42 pts completed their Tx and 157 discontinued. Compared with pts with normal/mild RI, impaired renal function was associated with shorter TTP, PFS, and OS (Table). Pts with normal/mild renal function and moderate RI had similar rates of treatment-emergent adverse events (TEAEs), including grade 3–4 neutropenia (26% and 20%, respectively), anemia (21% and 30%), and thrombocytopenia (11% and 13.0%). The incidences of grade 3–4 neutropenia, anemia, and thrombocytopenia were higher in pts with severe RI (36%, 57%, and 57%, respectively). Few pts (n=2) experienced grade 3–4 peripheral neuropathy. TEAEs led to Tx discontinuation in 5% of pts (n=7) with normal/mild renal function, 13% of those with moderate RI (n=7), and 29% of pts with severe RI (n=4).

Table 1. Efficacy of Rd according to renal function



Summary and Conclusion: This subgroup analysis from the MM-021 study showed that in heavily pretreated RRMM pts with RI, Rd improved clinical outcomes and was generally well tolerated regardless of renal function. For Chinese pts with normal/mild RI, LEN 25 mg/day is the appropriate approved starting dose. Dose adjustments should be made based on CrCl at the start of Tx and renal function should be monitored on a regular basis.

P980

SUPPRESSION OF THE NON-INVOLVED HLC PAIR CORRELATES WITH SURVIVAL IN NEWLY DIAGNOSED AND RELAPSED/REFRACTORY PATIENTS WITH MYELOMA

H Ludwig[1,*], D Milosavljevic[2], N Zojer[3], O Berlanga[4], W Hübl[2], S Harding[4]
[1]Wilhelminen Cancer Research Institute, [2]Central Laboratory, [3]Department of Internal Medicine I, Center for Oncology and Hematology and Palliative Care, Wilhelminenhospital, Vienna, Austria, [4]The BindingSite Ltd., Birmingham, United Kingdom

Background: Immune suppression is linked to short survival in multiple myeloma (MM) patients (Bryant, C *et al.* Blood Cancer Journal, 2013). A novel immunoparesis was recently identified as a risk marker for MGUS transformation to MM which relied upon the assessment of isotype matched immunoglobulin concentrations *i.e.* measurement of IgGκ concentration in patients producing monoclonal IgGλ (heavy/light (HLC) pair suppression.
Aims: Here we evaluate the role of HLC pair suppression in MM patients and comment on the potential of a disease specific risk stratification model.
Methods: 203 patients with multiple myeloma and measurable disease were enrolled. 156 patients were newly diagnosed: median age: 66 (32-94) years, male/female: 82/74, ISS stage I: 59, II: 63, and III: 34; 63 IgGκ, 37 IgGλ and 33 IgAκ, 23 IgAλ. 47 were relapsed/refractory (median age: 63 (40-86) years, male/female: 24/23, ISS stage I: 20, II: 17, III: 10; 19 IgGκ, 14 IgGλ, 8 IgAκ, 6 IgAλ. Patients in the first cohort received different treatment regimens and those in the second cohort were treated with Bendamustine-Bortezomib-Dexamethason. Median follow-up: 46 months in the first and 21 months in the latter group. HLC pair suppression was described as 50% reduction below the published normal range (IgGκ<1.67, IgGλ<0.951, IgAκ<0.285, IgAλ<0.22) and

systemic immunoparesis described as 50% below published normal ranges (IgG<3g/L, IgA<0.2g/L, IgM<0.1g/L). Results were compared to ISS stage, bone marrow plasma cell infiltration and high risk cytogenetics t(4;14), t(4;16) del17p, ampl 1q21) and correlated with survival. Kaplan Meier survival curves were compared using log-rank test, univariate and multivariate analysis was performed using Cox proportional regression analysis (SPSS, version 18).
Results: 100/100 IgG and 56/56 IgA MM patients had an abnormal Ig'κ/Ig'λ ratio at presentation, with 33/33 IgG and 14/14 IgA MM patients having an abnormal Ig'κ/Ig'λ ratio at relapse. HLC pair suppression was identified in 59/100 IgG and 23/56 IgA patients at presentation and 21/32 IgG and 6/14 IgA patients in the relapsed refractory setting. HLC pair immunosuppression correlated significantly with OS both in patients with newly diagnosed (median: 53 months *vs*. not reached, p=0.04; figure 1a) and relapsed/refractory disease (median OS: 22.8 months *vs*. not reached, p=0.006, figure 1b). HLC pair suppression showed a stronger correlation in patients with IgG (p=0.042) as compared to those with IgA-components, where only a tendency of shorter survival was noted (p=0.091). Immunosuppression of the HLC pair was not correlated with suppression of the non-involved isotypes both in the newly diagnosed and in the pre-treated patients. Univariate analysis showed a significant correlation between HLC pair suppression and high risk cytogenetics (p=0.038) but not with plasma cell bone marrow infiltration (p=0.144). A three factor tiered model employing HLC pair suppression and ß2microglobulin (≥5.5mg/dl) revealed significantly different survival estimates both in newly diagnosed (0 factor. 75% OS: 40 months, 1 factor, 75% OS: 25 months, 2 factors, 75% OS: 12 months, p<0.001) and in pre-treated patients. (0 factor, 75% OS not reached, 1 factor, 75% OS: 21 months, 2 factors, 75% OS: 8 months, p<0.0001). As previously reported, survival was significantly lower in patients with highly abnormal HLC ratio (<0.022;>45) compared to those with less abnormal HLC ratios (17.6 *vs*. 56.6 months, p<0.006) in newly diagnosed and also in previously treated patients (21.7 months *vs*. not reached, p<0.001).

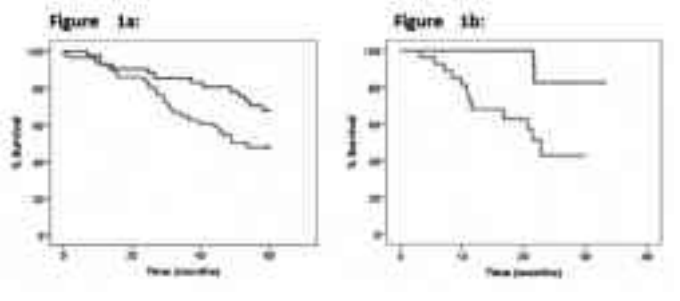


Figure 1. (a) OS in HLC pair suppression in previously untreated patients (n=100); (b) OS in HLC pair suppression in patients with relapsed/refractory MM (n=47)

Summary and Conclusion: Severe suppression of the HLC pair of the involved isotype of the M-component is a significant risk factor for shorter survival, both in newly diagnosed and previously treated patients while for non-involved isotypes no correlation was noted.

P981

PHASE 1 PHARMACOKINETIC (PK) STUDY OF IXAZOMIB CITRATE (MLN9708) PLUS LENALIDOMIDE AND DEXAMETHASONE IN ASIAN PATIENTS (PTS) WITH RELAPSED/REFRACTORY MULTIPLE MYELOMA (RRMM)

N Gupta[1,*], YT Goh[2], CK Min[3], JH Lee[4], C Suh[5], K Kim[6], R Wong[7], J Chim[8], M J Hanley[1], H Yang[9], K Venkatakrishnan[9], AM Hui[10], C Schusterbauer[11], WJ Chng[12]

Background: Despite progress in the treatment of MM, the prognosis for pts with RRMM remains poor, with variable, often diminishing responses to subsequent therapies following first-line treatment. Ixazomib citrate is an oral proteasome inhibitor in phase 3 development for the treatment of pts with MM or amyloidosis. However, all clinical experience thus far has been in Western populations.
Aims: This open-label phase 1 PK study (NCT01645930) was conducted to determine the plasma PK parameters of ixazomib when administered in combination with lenalidomide and low-dose dexamethasone in Asian pts with RRMM. The study also evaluated the safety profile of ixazomib citrate, recommended phase 2 dose, and response rates.
Methods: East Asian pts, from Singapore, South Korea, and Hong Kong, aged ≥18 years, with RRMM following 1–3 prior therapies and an ECOG PS of 0–2 were enrolled. Pts received ixazomib citrate 4 mg PO on days 1, 8, and 15 of 28-day cycles; lenalidomide 25 mg PO on days 1–21; and dexamethasone 40 mg PO on days 1, 8, 15, and 22. The maximum tolerated dose (MTD) of ixazomib citrate (defined as the highest dose at which ≤33.3% of pts per dose group experienced a DLT) was evaluated following a standard 3×3 de-escalation schedule during cycle 1, starting at 4 mg. Treatment continued until disease progression or unacceptable toxicity. Blood samples for PK analysis were collected throughout cycle 1 and before dosing on day 1 of cycle 2. AEs were graded according to NCI-CTCAE v4.03.
Results: Twenty-nine pts were enrolled from centers in East Asia (ethnicity: Chinese, 45%; Korean, 31%; Other, 24%) and received ixazomib citrate. Median age was 62 years (range 38–75), 52% were male, and 21%/48%/24% had ISS stage I/II/III MM (7% unknown). Cycle 1 DLTs occurred in two pts: elevated ALT (grades 2 and 3), ALP (grade 2), and GGT (grade 2) in one pt; and diarrhea (grade 3) in the second pt. All enrolled pts received 4 mg and the MTD of ixazomib citrate in combination with lenalidomide and dexamethasone was 4 mg. Maximum plasma concentration (C_{max}) of ixazomib was 7.07 and 11.8 ng/mL/mg on days 1 and 15, respectively. The area under the concentration-time curve (AUC_{0-168}) increased from 188 to 429 h· ng/mL/mg between days 1 and 15. Median time to maximum plasma concentration (T_{max}) was 1.5 and 2.0 hours on days 1 and 15, respectively. PK parameters were consistent across all Asian ethnicities evaluated. Best confirmed response rate (≥PR) was 35% (10% ≥VGPR, including 1 pt with a CR), after a median of 2 cycles (range 1–12). AEs occurred in 26 pts (90%), resulting in dose reductions in 13 pts. The most common AEs (any grade) included diarrhea (45%), anemia (31%), and dizziness (31%). Nineteen pts (66%) experienced grade 3/4 AEs; the most common were diarrhea (28%), anemia (24%), and neutropenia (17%). Serious AEs occurred in 11 pts (38%; treatment-related in 7 pts), with one treatment-related death (pneumonia).
Summary and Conclusion: Ixazomib citrate in combination with lenalidomide and low-dose dexamethasone demonstrated clinical activity in Asian RRMM pts with a manageable AE profile. The study is ongoing for further evaluation of response. The recommended dose of ixazomib citrate in Asian pts is 4 mg, the same as in Caucasian pts, with a similar toxicity and tolerability profile. Asian pts are currently being enrolled in ongoing phase 3 studies (NCT01850524, NCT01564537, NCT01659658).

P982

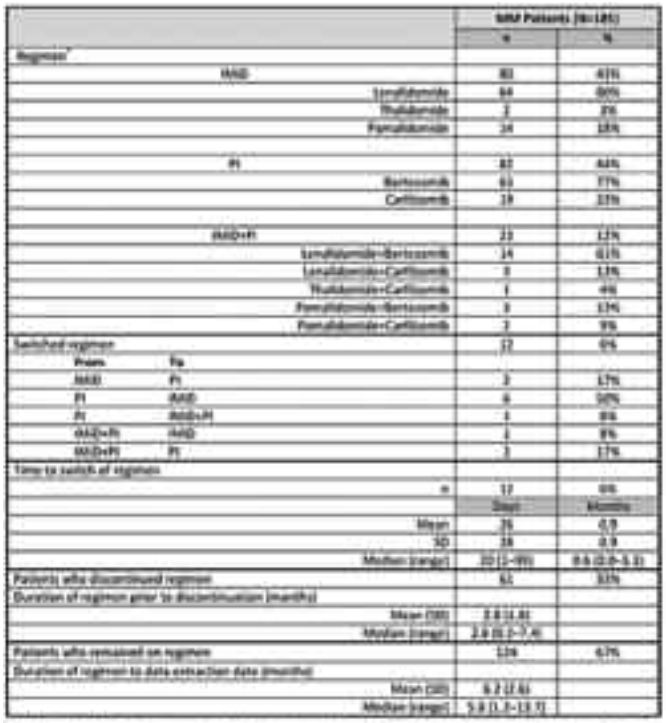
A MULTINATIONAL OBSERVATIONAL STUDY IN MULTIPLE MYELOMA (PREAMBLE): INITIAL RESULTS OF TREATMENT PATTERNS

R Vij[1,*], L Annemans[2], H Goldschmidt[3], P Moreau[4], G Cook[5], A Palumbo[6], B Durie[7], D Cella[8], D Reece[9], JB Bartlett[10], TK Le[10], C Davis[10]
[1]Washington University School of Medicine, St. Louis, MO, United States, [2]Ghent University and Brussels University, Gent, Belgium, [3]Universitätsklinikum Heidelberg, Heidelberg, Germany, [4]University Hospital of Nantes, Nantes, France, [5]St. James University Hospital, Leeds, West Yorkshire, United Kingdom, [6]University of Torino, Torino, Italy, [7]Cedar-Sinai Medical Center/International Myeloma Foundation, West Hollywood, CA, [8]Northwestern University, Evanston, IL, United States, [9]Princess Margaret Hospital, Toronto, Ontario, Canada, [10]Bristol-Myers Squibb Company, Princeton, NJ, United States

Background: Therapeutic options have improved for patients with multiple myeloma (MM) in the past decade, with regulatory approvals of several agents from two therapeutic classes, immunomodulatory drugs (IMiDs) and proteasome inhibitors (PIs). However, there are limited data on the real-world effectiveness of these agents in the setting of relapsed and/or refractory (R/R) MM.
Aims: PREAMBLE (Prospective Research Assessment in Multiple Myeloma: an Observational Evaluation) is a multinational, observational cohort study undertaken to prospectively evaluate the real-world effectiveness, healthcare resource utilization, and patient-reported outcomes associated with IMiD, PI, and IMiD+PI use in patients with R/R MM. Here, we report initial data on treatment patterns for patients enrolled in PREAMBLE.
Methods: This study includes patients with R/R MM who received ≥1 prior therapy and were treated with IMiD, PI, or IMiD+PI within 90 days prior to or 30 days after study enrollment. Treatment was administered according to the standard practice of participating physicians. Data are collected every 6 months during a 3-year observational period. At the time of the last data cut-off (November 22, 2013), 185 enrolled patients were on treatment and were eligible for evaluation. Median follow-up time was 6.2 months.
Results: Median number of prior therapies received among the 185 patients was 1 (range: 1–10), with 34 (18.4%) having received ≥3 prior therapies. On PREAMBLE, 43% of patients were treated with an IMiD (80% received

lenalidomide), 44% with a PI (77% received bortezomib), and 12% with IMiD+PI (61% received lenalidomide plus bortezomib) [Table]. Sixty-one patients (33%) had discontinued the regimen (for reasons other than death) after a median of 2.6 months. Twelve patients (6%) switched regimens within the first month.

Table 1. Treatment patterns for R/R MM.



Summary and Conclusion: The PREAMBLE study provides valuable real-world information regarding treatment patterns for R/R MM. This report shows that 1/3 of patients were not able to remain on their treatment for R/R MM. Additional analyses will address the reasons for treatment switch and discontinuation.

P983

A COMBINATION THERAPY WITH BORTEZOMIB (BOR) AND THALIDOMIDE IN NEWLY DIAGNOSED MYELOMA PATIENTS IS ASSOCIATED WITH A LOW INCIDENCE OF SECOND PRIMARY MALIGNANCIES (SPMS)

A Brioli[1,*], M Galli[2], P Tacchetti[1], C Crippa[3], T Spadano[4], A Pezzi[1], N Pescosta[5], L Baldini[6], B A Zannetti[1], C Terragna[1], C Cellini[7], S Rocchi[1], A Falcone[8], C Nozzoli[9], G Marzocchi[1], F Dico[1], L Masini[10], A Palumbo[11], M Cavo[1]
[1]Bologna University, School of Medicine, Seràgnoli Institute of Hematology, Bologna, [2]GIMEMA Italian Myeloma Network, Bergamo, [3]GIMEMA Italian Myeloma Network, Brescia, [4]GIMEMA Italian Myeloma Network, Pescara, [5]GIMEMA Italian Myeloma Network, Bolzano, [6]GIMEMA Italian Myeloma Network, Milano, [7]GIMEMA Italian Myeloma Network, Ravenna, [8]GIMEMA Italian Myeloma Network, Foggia, [9]GIMEMA Italian Myeloma Network, Firenze, [10]GIMEMA Italian Myeloma Network, Reggio Emilia, [11]GIMEMA Italian Myeloma Network, Torino, Italy

Background: The availability of novel drugs (immunomodulatory drugs, IMiDs, and proteasome inhibitors, PI) for the front line treatment of Multiple Myeloma (MM) has dramatically changed patients' outcomes translating into extended progression free (PFS) and overall survival (OS). Despite these impressive results, concerns have been raised regarding the increased risk of SPMs among patients receiving IMiDs (lenalidomide and thalidomide), especially when associated with alkylating agents such as melphalan (MEL). It has long been known that the use of MEL can result in an increased incidence of SPMs, whilst the use of PI in newly diagnosed MM (NDMM) patients (pts) was not associated with an increased risk of SPMs in a phase III study aimed at comparing BOR, MEL and prednisone (MP) *vs* MP. However the impact of an upfront treatment containing both a PI and an IMiD in association with high dose MEL still has to be investigated.
Aims: To answer the question whether the association of an IMiD and a PI can result in an increase risk of developing SPMs in transplant eligible NDMM we have evaluated the incidence of SPMs in pts enrolled in the GIMEMA 26866138-MMY-3006 multicentre phase III study aimed at comparing BOR, thalidomide and dexamethasone (VTD) *versus* TD as induction before and consolidation after 2 sequential courses of high dose MEL.
Methods: The trial enrolled 480 transplant eligible NDMM, of which 474 received assigned treatment. For the purpose of the present analysis, data on the incidence of SPMs were specifically chased and were available for 63% of the overall population (148 VTD and 151 TD).
Results: With median follow up of 73 months, 25/299 pts (8%) developed a SPM: 7 (2%) SPMs were hematologic and 18 (6%) were non hematologic. SPMs are detailed in table 1. The median time from trial entry to development of the SPM was 36 months (range 8.4-69.0). The number of pts developing a SPM was lower in VTD arm (5%) compared to TD arm (11%, p=0.068). Among pts developing a SPM, the proportion of solid and hematologic SPMs was similar between treatment arms, with 75% and 25% of VTD pts *vs* 71% and 29% of TD pts developing a solid or a hematologic SPM, respectively. On the overall population the incidence rate (IR) of developing a SPM was 1% at 1 year and 9.9% at 6 years (yrs). This incidence was lower in patients randomised to VTD compared with patients randomised to TD (6% *vs* 13% at 6 yrs, p=0.037); when looking at the IR of solid tumours a trend was seen for a lower incidence of developing a second malignancy in those pts that received BOR based treatment (5% *vs* 9.6% at 6 yrs for VTD and TD, respectively); similarly, a trend towards a lower incidence of hematologic SPMs in the BOR arm was observed (1% *vs* 4% at 6 yrs for VTD and TD, respectively).

Table 1. SPMs details

SPM	Number	Time to SPM development (mo) in the 2 arms	
Solid			
		TD	VTD
Colon	3	44.4/53.5/69.0	
Melanoma	3	10.2	8.4/27.9
Prostate	2	29.6/35.4	
Breast	2		31.6/41.5
Colangiocarcinoma	1	14.5	
Pancreatic adenocarcinoma	1	38.3	
Head and neck	2	25.0	61.1
Astrocytoma	1	11.9	
Lung	1	26.5	
Mesothelioma	1	59.0	
Tumour nos	1		61.3
Hematologic			
		TD	VTD
LH+LNH	1	54.6	
LNH	2	31.1/37.2	
LAM	4	33.4/40.7	68.8/UNK

mo: months; NOS: not other specified; UNK: unknown

Summary and Conclusion: Our data compare favourably with those previously reported on the incidence of developing SPMs in NDMM treated with BOR frontline in association with MEL and provide demonstration that, with a follow up of 6 years, VTD combined with two sequential courses of high-dose MEL was associated with a low risk of developing SPM. Interestingly our data support the possibility that an IMiD-based treatment incorporating BORT might decrease the risk of developing a second malignancy compared to thalidomide. Randomised trials with PI and IMiDs treatment should prospectively address this issue. More extensive data will be presented at the meeting.

P984

DIFFERENT OUTCOMES AFTER AUTOLOGOUS STEM CELL TRANSPLANTATION ACCORDING TO INVOLVED SITES IN MYELOMA PATIENTS WITH EXTRAMEDULLARY PLASMACYTOMA: BONE VERSUS SOFT TISSUE PLASMACYTOMA

HJ Shin[1,*], K Kim[2], JW Lee[1], MK Song[1], JJ Lee[3], HS Lee[4], WS Lee[5], JS Chung[1]
[1]Pusan National University Hospital, Busan, [2]Samsung Seoul Hospital, Seoul, [3]Chonnam National University Hwasun Hospital, Hwasun, [4]Kosin University Gospel Hospital, [5]Busan Baik Hospital, Busan, Korea, Republic Of

Background: Few reports have published the outcomes of autologous stem cell transplantation (ASCT) in multiple myeloma (MM) patients with extramedullary plasmacytoma (EP). Furthermore, no published studies have analyzed the results of ASCT in MM patients with EP based on whether the patients had plasmacytomas (PCs) located in the bone *versus* the soft tissue.
Aims: The aims of this study were to compare the characteristics of bone and soft tissue PCs, and to analyze the relapse pattern, clinical outcomes, and prognostic factors for ASCT in MM patients with EP.
Methods: We retrospectively reviewed 93 MM patients with EP detected at

diagnosis or during the course of the disease who underwent ASCT between October 2000 and July 2013 at 5 hospitals in Korea.
Results: This study included 51 men and 42 women, with a median age of 53 years (range, 22–67 years) at the time of diagnosis. Soft tissue PC (*n*=29) was found to be slightly more frequent in male patients, more commonly had an IgD monoclonal component, and occurred more often as light chain disease with increased lambda chain expression compared to the bone PC group (*n*=64). A greater percentage of patients with bone PC achieved either stringent complete remission (sCR) or CR after ASCT than patients with soft tissue PC (51.5% *vs.* 31.0%). After a median follow-up of 26 months following ASCT, progression-free survival (PFS) and overall survival (OS) were better in the bone PC group than in the soft tissue group (median PFS, 27.7 months *vs.* 12.3 months [*P*=0.001]; median OS, 66.9 months *vs.* 37.1 months [*P*=0.035]). Patients who attained sCR or CR after ASCT had improved PFS compared to those who did not achieve CR, while OS times were not significantly different between the groups. We divided the patients into 4 different groups based on whether they had soft tissue PC *versus* bone PC, and whether the patients achieved sCR or CR after ASCT. In this analysis, patients with bone PC who achieved sCR or CR had improved PFS and OS compared to those without CR after ASCT (estimated 3-year PFS rate, 45.3% ± 9.6% *vs.* 30.2% ± 9.0%; estimated 3-year OS rate, 85.3% ± 7.0% *vs.* 69.9% ± 9.0%). Patients with soft tissue PC who attained sCR or CR also had marginally improved PFS and OS than patients without a CR (estimated 3-year PFS rate, 22.1% ± 11.0% *vs.* 0%; estimated 3-year OS rate, 49.7% ± 15.7% *vs.* 29.2% ± 22.9%). Interestingly, patients with soft tissue PC who achieved sCR or CR after ASCT did not have improved survival compared to patients with bone PC who did not achieve CR after ASCT. These results reflect the fact that, even though ASCT led to a greater response in MM patients with soft tissue PC, the presence of EP contributed to poor prognosis after ASCT, and this could not be overcome by ASCT. Multivariate analysis identified abnormal cytogenetics, soft tissue PC, no CR after ASCT, and advanced stage on the International Staging System at diagnosis as factors that predicted poor PFS and OS after ASCT.
Summary and Conclusion: These results indicate that additional treatments such as consolidation therapy, maintenance therapy, or tandem ASCT might be needed to overcome the poor outcome of ASCT in MM patients with soft tissue PC identified at diagnosis or during the disease course.

P985

EARLY MORTALITY TREND IN MULTIPLE MYELOMA: A THIRTY-YEAR POPULATION-BASED STUDY

R Ríos-Tamayo[1,2,*], J Sáinz Pérez[1,2], Y Moatassim de la Torre[1], R Leyva Ferrer[1], F López Jiménez[1], AM Alba Sosa[1], MJ Sánchez Pérez[3], E Molina Portillo[3], A Romero Aguilar[1], L Moratalla López[1], JM de Pablos Gallego[1], P López Garrido[1], JM Puerta Puerta[1], P Garrido Collado[1], E López Fernández[1], JL García de Veas Silva[4], T Rodríguez Ruiz[4], JJ Jiménez Moleón[5], JA Pérez González[1], AJ Cruz Díaz[1], M Jurado Chacón[1,2]
[1]Hematology, University Hospital Virgen de las Nieves, [2]Genomic Oncology department, Pfizer - Universidad de Granada - Junta de Andalucía Centre for Genomics and Oncological Research (GENYO), [3]Granada Cancer Registry, Andalusian School of Public Health, [4]Inmunology, University Hospital Virgen de las Nieves, [5]Preventive Medicine and Epidemiology, University of Granada, Granada, Spain

Background: Overall survival (OS) is progressively increasing in multiple myeloma (MM) in the era of new agents. However, early mortality (within the first two months from diagnosis) remains a serious problem. Early mortality occurred in 10 % of patients registered onto MRC trials (Augustson) and may reach 12 % in patients with severe renal impairment (Dimopoulos)
Aims: In order to highlight the impact and pattern of early death in real-life MM patients, we analyzed our registry over the past 30 years.
Methods: All patients with symptomatic MM were consecutively included in the Granada population-based registry since 1985. Patients with smoldering MM, plasma cell leukemia or those with only palliative care were excluded. The patients were divided into three 10-year groups according to the date of diagnosis: 1985-1994, 1995-2004 and 2005-2014.
Results: 518 patients were included, 247 men and 271 women (52,3%), median age 66 years (12-91). 507 patients were valuables, and 67 of them (13,21 %) had early death. OS was 20, 25 and 36,6 months respectively in the three periods of time. Percentage of early deaths was 16,4%, 15,3% and 9% respectively in the three groups. Early death was associated in univariate analysis with age (median 69 years, p=0,002), body mass index (median 25,7 Kg/m^2; p=0,031), ISS III (73,7 %, p<0,001) and renal impairment (median creatinine 3,86 mg/dl; p<0,001). In the multivariate regression analysis, only renal impairment (p=0,013) behaves as an independent predictor of early death, whereas age shows only a marginal effect (p=0,09). An alternative analysis of six 5-year periods demonstrated similar outcomes. Patients diagnosed over the last five years showed 6,9 % of early death and their median OS was not reached.
Summary and Conclusion: As expected, early mortality in real-life MM patients could be higher that reflected in clinical trials. Early death remains a serious problem in real-life MM patients. The clinical results over the three periods of time are encouraging, with OS being progressively improved whereas early death is trending downward. Early death is frequently related to older age and ISS 3, but is only significantly associated with severe renal impairment. Renal failure in MM is a medical emergency which requires immediate therapy.

P986

INCREMENTAL PROGNOSTIC VALUE OF BONE MARROW ABNORMALITIES IN APPENDICULAR SKELETONS DETECTED BY WHOLE-BODY MULTIDETECTOR CT IN PATIENTS WITH MULTIPLE MYELOMA

Y Nishida[1,*], Y Matsue[2], M Fujisawa[1], K Fukumoto[1], Y Suehara[1], K Seike[1], H Sugihara[1], M Takeuchi[1], M Fukaya[1], K Matsue[1]
[1]Division of Hematology/Oncology, Department of Medicine,, [2]Division of Cardiology, Department of Medicine, Kameda Medical Center, Kamogawa, Japan

Background: Imaging by multidetector CT (MDCT) and/or MRI have been utilized for detecting lytic bone lesion or myelomatous lesions, mainly axial skeletons, in the evaluation of multiple myeloma, however, bone marrow involvement in appendicular skeletons (AS) can be directly visualized by MDCT with shorter acquisition time. The presences of these bone marrow abnormalities in AS could correlate clinical variables which thought to relevant to prognosis in myeloma.
Aims: In this study, we report a clinical and prognostic implication of abnormal bone marrow lesions (ABLs) in AS detected by MDCT in patients with newly diagnosed multiple myeloma (NDMM).
Methods: We included 98 newly diagnosed multiple myeloma from February 2008 to December 2013. All the patients were received MDCT as an initial workup for lytic bone lesion of MM and CT value of ABLs in AS were measured using circular lesion of interest and expressed by Hounsfield Units (HU). The highest CT value (CTv), expressed in HU, was recorded in each patient. Receiver operating characteristics (ROC) curves of ABL for prediction of death event was constructed and appropriate cut-off point was determined. From the analysis, we set the cut-off point as 5.3 HU as a most relevant CT value for survival. Patients with ABLs in AS with higher than 5.3 HU considered as a high-CTv group and lower were considered Low-CTv group. Survival analysis was also performed using this cut-off point.
Results: There were 50 male and 48 female patients with median age of 72 years. The median follow-up duration was 19.2 months (range: 0.5 to 72 months). The number of patients with Durie-Salmon (D-S) stage 3 and international staging system (ISS) stage 3 was 62 (64%) and 43 (55%), respectively. Patients with myeloma subtype of IgG, IgA, light chain only and non-secretary subtypes were 55, 31, 11 and 1, respectively. Using the cut-off value 5.3 HU, 50 (51%) patients were defined as High-CTv group. There were significantly more patients with D-S and ISS III, and with high-risk features (del13q, del13 or del17p in cytogenetics and t(4;14), t(14;16) and del17p in interphase FISH) in High-CTv group compared with Low-CTv group. High-CTv group showed significantly shorter survival (median OS, not reached in both groups, p=0.006) by Kaplan-Meyer analysis compare to those with Low-CTv group. ABLs with CTv ≥5.3 HU was an independent prognostic factor for OS in both univariate (HR: 10.3; 95% CI: 1.3-81.1; p=0.027) and multivariate (HR 10.1; 95% CI: 1.3-82.2; p=0.030 after adjusting for ISS, high-risk features and age) analysis. ROC analysis to predict the death event was performed using four logistic regression models of ISS only (Model 1), ISS + high-risk features (Model 2), ISS + high-risk features + age (Model 3), and ISS + high-risk features + age + High-CTv group (Model 4). In Model 4, significant incremental predictive ability was shown compared to other three models by net reclassification improvement and integrated discrimination improvement (**Table**).

Table 1. NRI and IDI analysis for four prognostic models

Models	Model 1	Model 2	Model 3
Model 1			
Model 2			
Model 3			
Model 4			

Abbreviations: AUC: area under curve, NRI: net reclassification improvement, IDI: integrated discrimination improvement

Summary and Conclusion: Our study showed that ABLs with High-CTv associate with myeloma tumor burden and high-risk features. Patients with Hig-CTv had poorer prognosis compared to those with Low-CTv. By adding to other pre-existing risk factors including ISS, cytogenetically high-risk features, and age, the findings of MDCT can provide the incremental predictive ability in patients with NDMM.

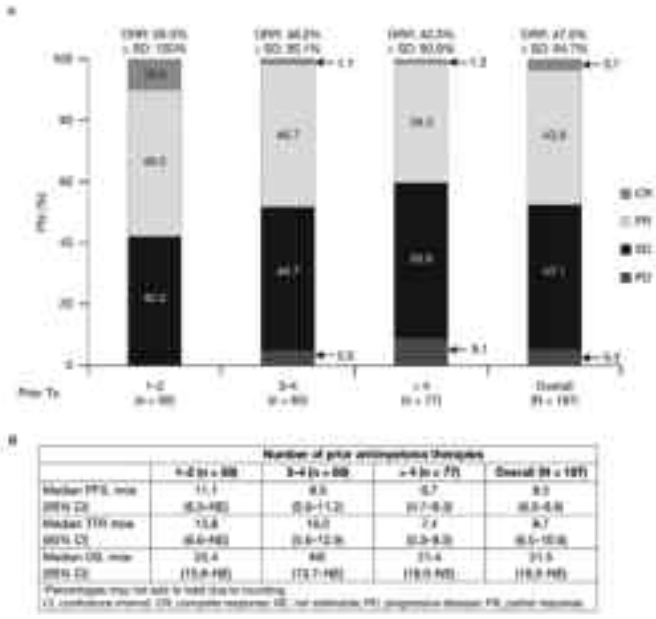
P987

IMPACT OF PRIOR THERAPY (TX) ON THE EFFICACY AND SAFETY OF LENALIDOMIDE PLUS LOW-DOSE DEXAMETHASONE (RD) IN CHINESE PATIENTS (PTS) WITH RELAPSED AND REFRACTORY MULTIPLE MYELOMA (RRMM): MM-021 TRIAL

J Jin[1,*], X Du[2], Z Cai[1], F Chen[3], DB Zhou[4], L Yu[5], X Li[6], D Wu[7], F Meng[8], H Ai[9], J Wang[10], J Zhang[11], H Wortman-Vayn[11], J Mei[11], J Hou[12]
[1]The First Affiliated Hospital, Zhejiang University, Hangzhou, [2]Guangdong General Hospital, Guangzhou, [3]Xiangya Hospital of Central South University, Changsha, [4]Peking Union Medical College Hospital, [5]The 301 Military Hospital, Beijing, [6]Shanghai Sixth People's Hospital, Shanghai, [7]The First Affiliated Hospital of Soochow University, Suzhou, [8]Nanfang Hospital, Southern Medicine University, Guangzhou, [9]The 307 PLA Hospital, Beijing, [10]Changhai Hospital, Shanghai, China, [11]Celgene Corporation, Summit, NJ, United States, [12]Shanghai Changzheng Hospital, Shanghai, China

Background: The MM-021 registration trial demonstrated the efficacy and safety of the Rd regimen in Chinese RRMM pts (Hou, J Hematol Oncol 2013). Following the trial, Rd was approved in China for the Tx of RRMM pts who have received ≥ 1 prior Tx. Pts in the MM-021 trial had received between 1 and 15 prior regimens (median: 4). Evidence suggests LEN + DEX is more effective when used at first relapse (Stadtmauer, Eur J Haematol 2009).
Aims: To evaluate the impact of the number of prior antimyeloma Tx on outcomes in the MM-021 study.
Methods: MM-021 was a phase 2, multicenter, single-arm, open-label registration study in which RRMM pts received lenalidomide (LEN; 25 mg/day on D1–21/28 day cycle) and low-dose dexamethasone (40 mg/day on D1, 8, 15, and 22) cycles until disease progression or discontinuation. All pts received thromboprophylaxis during the study. The primary endpoint was overall response rate (ORR), defined as a partial response or better. Secondary endpoints included progression-free survival (PFS), time to progression (TTP), overall survival (OS), and safety. Data were analyzed according to the number of Tx that pts received prior to study screening: 1–2, 3–4, or >4.
Results: A total of 199 pts were enrolled; all were included in the safety analysis and 187 were included in the efficacy-evaluable (EE) population. The median age was 59 years (range 35–81), 63% were male, and most pts (86%) had Durie-Salmon stage III disease. Overall, 41% of pts had received >4 prior antimyeloma Tx, 33% had received 3–4, and 26% had received 1–2. Most pts had received prior Tx with thalidomide (THAL; 69%) or bortezomib (BORT; 64%) or both (45%; separately or in combination); only 13% of pts had had no prior exposure to THAL or BORT. With a median follow-up of 17.6 months (mos), the median Tx duration was 8.3 mos (range 0.9–24.8). The ORR was 48% in the EE population and highest in pts who had received 1–2 prior Tx; however, pts responded in each category (Figure). Median PFS, TTP, and OS were longer in pts who had received 1–2 prior Tx *vs*. those who had received 3–4 and >4 prior Tx (Figure). The most common grade 3–4 treatment-emergent adverse events (TEAEs) were anemia (26%), neutropenia (25%), thrombocytopenia (15%), pneumonia (13%), and leukopenia (10%). The incidence of grade 3–4 TEAEs was lowest in pts with 1–2 prior Tx (60%); the incidences in pts who had received 3–4 (71%) and >4 (75%) prior Tx were comparable with that in the overall safety population (70%). TEAEs led to discontinuation of LEN in 6%, 11%, and 10% of pts who had received 1–2, 3–4, and >4 prior Tx, respectively.

Table 1. Efficacy of Rd according to number of prior therapies (efficacy evaluable population)



Summary and Conclusion: This sub-analysis showed that Rd is an effective Tx option for Chinese RRMM pts who have relapsed after ≥ 1 prior Tx, including THAL and/or BORT. Rd efficacy was greatest in pts who had received 1–2 prior Tx. Tolerability was similar in heavily and less heavily pretreated pts, with anemia and neutropenia the most common TEAEs. Discontinuations were infrequent (≤ 11%) even in heavily pretreated pts who had received >4 prior Tx.

P988

AN ONGOING OPEN-LABEL PHASE 1/2A STUDY OF THE SAFETY AND EFFICACY OF MELFLUFEN AND DEXAMETHASONE COMBINATION FOR PATIENTS WITH RELAPSED AND RELAPSED-REFRACTORY MULTIPLE MYELOMA (RRMM)

UH Mellqvist[1,*], C Paba-Prada[2], A Palumbo[3], T Plesner[4], P Sonneveld[5], P Voorhees[6], C Byrne[7], J Harmenberg[8], E Nordström[8], P G Richardson[2]
[1]Borås Hospital, Borås, Sweden, [2]Dana Farber Cancer Institute, Boston, MA, United States, [3]Turin Hospital, Turin, Italy, [4]Vejle Hospital, Vejle, Denmark, [5]Erasmus, Rotterdam, Netherlands, [6]University of North Carolina, Chapel Hill, NC, [7]Oncopeptides AB, Miami, United States, [8]Oncopeptides AB, Stockholm, Sweden

Background: Melflufen (L-melphalanyl-p-L-fluorophenylalanine ethyl ester hydrochloride (MF)), is a targeted analogue of melphalan. The mechanism of action is targeted alkylation of tumor cell DNA: transport of MF into cells is rapid and once inside the cytoplasm, peptidases, often overexpressed in malignant cells, will rapidly cleave MF releasing melphalan. Treatment with melflufen results in efficient intracellular trapping of melphalan preferentially in tumor cells, due to the higher enzymatic activity and the differential rate of transport of MF into cells (rapid) and melphalan out of cells (slow). It has been demonstrated that treatment with MF results in at least a 10-20 fold higher intracellular concentration of melphalan compared with direct treatment with equimolar doses of melphalan. When studied in cultures of human tumor cells representing approximately 20 different human cancers, including MM, MF showed 50 to 100 fold higher cytotoxicity and tumor growth suppression compared with that of melphalan. In efficacy studies conducted in mice and rats, superior antitumor activity of MF over melphalan was observed with comparable toxicity (Wickström 2010, Chauhan 2013). In a first-in-man study, a total of 45 patients with advanced solid tumors received a total of 141 cycles of MF at doses of 25-130 mg, with a safety profile which was similar to that of melphalan in equimolar doses.
Aims: To study the safety and efficacy of melflufen and dexamethasone (dex) combination for patients with RRMM.
Methods: This is an ongoing open-label, phase I/IIa, multicenter trial of MF plus dex currently enrolling patients with RRMM (NCT01897714). Phase I follows the standard 3 + 3 modified Fibonacci design with 3 to 6 patients in each cohort, depending on dose limiting toxicity (DLT) observed. Up to 4 dose levels will be tested; IV MF at 15 mg, 25 mg, 40 mg and 55 mg, given on day 1, with a fixed dose of dex 40 mg PO or IV on days 1, 8 and 15 of each 21 day cycle. An additional 20 patients will be treated at the MTD in the Phase IIa part of the study. The primary objectives are to determine the MTD in Phase I and the Objective Response Rate in Phase IIa. Adult patients with measureable disease, ≥ 2 lines of prior therapy, life expectancy ≥ 6 months, ECOG ≤2,

absolute neutrophil count ≥ 1.0 x 10^9/L, platelet count ≥ 75 x 10^9/L, hemoglobin ≥ 8.0 g/dl, total bilirubin ≤ 1.5 x upper limit of normal (ULN), estimated CrCL ≥ 45 ml/min, serum Cr ≤ 2.5 mg/dL and AST/ALT ≤ 3.0 x ULN are eligible for the study. All patients are required to provide signed informed consent.
Results: To date (Feb 20), 9 patients have received a total of 24 cycles of MF in doses up to 25 mg. The median number of cycles administered is 2.7 (range 1-7) with 4 patients remaining on treatment. The patient population has a median age of 68, and has received a median of 5.2 (range 3-10) previous lines of treatment, with 100% of patients being exposed to both an IMiD and bortezomib. The first two dose levels have been administered without DLT's. 3 patients have reported 5 Grade 3/4 treatment related adverse events (TRAE); G3 thrombocytopenia, G3 pneumonia, G4 febrile neutropenia, G3 nausea and G3 neutropenia. No patient has discontinued due to TRAE. Initial PK data support the expected pattern with an increased rate of distribution of MF to peripheral tissues during the infusion, and a delayed redistribution of melphalan formed peripherally.
Summary and Conclusion: Updated information will be presented at the time of the conference.

P989

A PHASE 1 STUDY OF THE EFFECT OF A HIGH-FAT MEAL ON THE PHARMACOKINETICS OF IXAZOMIB CITRATE (MLN9708), AN INVESTIGATIONAL ORAL PROTEASOME INHIBITOR, IN PATIENTS WITH ADVANCED SOLID TUMORS OR LYMPHOMA

N Gupta[1,*], M J Hanley[1], K Venkatakrishnan[1], B Wang[1], J Kinley[2], S Sharma[3], A Bessudo[4], Y Shou[1], J Nemunaitis[5]
[1]Takeda Pharmaceuticals International Co., Cambridge, MA, United States, [2]Takeda Global Research & Development Centre (Europe), London, United Kingdom, [3]Huntsman Cancer Institute, University of Utah, Salt Lake City, UT, [4]California Cancer Associates for Research and Excellence, San Diego, CA, [5]Mary Crowley Cancer Research Center, Dallas, TX, United States

Background: Ixazomib citrate is an oral proteasome inhibitor under phase 3 investigation in patients (pts) with multiple myeloma (MM) and amyloidosis. Ixazomib citrate immediately hydrolyzes to the active moiety ixazomib in aqueous solutions or plasma. In ongoing clinical studies, ixazomib citrate is taken on an empty stomach.
Aims: To characterize the effect of a high-fat meal on the single-dose pharmacokinetics (PK) of ixazomib.
Methods: This is a phase 1, single-dose, open-label, randomized, multicenter, two-period, two-sequence, cross-over study (NCT01454076). Pts were randomized to receive a single 4 mg dose of ixazomib citrate with or without a standard high-fat breakfast on Day 1, followed by administration under the respective alternate food intake condition (fasted to fed, or fed to fasted) on Day 15 of Cycle 1. Serial blood samples were collected over 0–216 hr after ixazomib citrate dosing on Days 1 and 15 for PK characterization. From Cycle 2, ixazomib citrate 4 mg was administered on an empty stomach on Days 1, 8, and 15 of a 28-day cycle. Plasma PK parameters were estimated by non-compartmental methods using Phoenix WinNonlin version 6.2. Effects of the high fat-meal on ixazomib AUC_{0-216} and C_{max} were evaluated by analyses of variance on log-transformed values. Safety and response data after multiple dosing were also collected.
Results: 24 pts (19 Caucasian, 4 African American, 1 Hispanic; 13 M, 11 F; 22 solid tumor, 2 lymphoma) were enrolled. Mean age was 62 years (range 46–85), mean weight 74 kg (range 43–112), and mean body surface area 1.9 m^2 (range 1.4–2.4). Final data from 15 PK-evaluable pts were used to assess the impact of food on ixazomib PK. Following a single dose of ixazomib citrate, median T_{max} was 1 and 4 hr for fasted and fed treatment, respectively. Administration of ixazomib citrate with food resulted in an approximately 28% decrease in AUC and 69% decrease in C_{max} (Table). Although relatively modest, the observed decrease in AUC is inferred to be of potential clinical significance as, when dosed at 4 mg with a high-fat meal, ixazomib exposures would be expected to approximate those achieved at 3 mg (the first dose level reduction for pts experiencing drug-related toxicity). As of January 2014, 19 (79%) pts experienced drug-related adverse events (AEs) in Cycle 2 and beyond following multiple dosing with ixazomib citrate on a weekly schedule, including 6 drug-related grade 3 AEs in 5 pts (anemia, n=2; dehydration, fatigue, peripheral edema, and vomiting, each n=1); no drug-related grade 4 AEs were reported.

Table 1.

N=15	Fasted	Fed	Fed vs. fasted, least square geometric mean ratio (90% CI)
C_{max}, ng/mL*	77.8 (57.4)	22.8 (54.4)	0.31 (0.21–0.45)
AUC_{0-216}, ng*hr/mL*	1488 (48.6)	887 (79.8)	0.72 (0.58–0.89)
T_{max}, hr*	1 (0.5–4)	4 (2–8)	–

*Geometric mean (%CV); †Median (range); CI, confidence interval

Summary and Conclusion: Administration of ixazomib citrate 4 mg after a high-fat meal resulted in a decrease in the rate and extent of oral absorption, with an approximately 30% reduction in total systemic exposure. These results support the continued administration of ixazomib citrate on an empty stomach (no food for 2 hr before and 1 hr post dose) in ongoing phase 3 studies in relapsed/refractory MM, newly diagnosed MM, and amyloidosis.

P990

ROLE OF IMMUNOHISTOCHEMISTRY IN THE DIAGNOSIS OF SYSTEMIC IMMUNOGLOBULIN LIGHT-CHAIN AMYLOIDOSIS: RESULTS IN A SERIES FROM A SINGLE INSTITUTION

C Fernández de Larrea[1,*], M Solé[2], MT Cibeira[1], N Tovar[1], L Rosiñol[1], M Elena[3], J I Aróstegui[4], J Yagüe[4], J Bladé[1]
[1]Amyloidosis and Myeloma Unit. Department of Hematology., [2]Amyloidosis and Myeloma Unit. Department of Pathology., [3]Amyloidosis and Myeloma Unit. Department of Biochemistry, [4]Amyloidosis and Myeloma Unit. Department of Immunology, Hospital Clinic. IDIBAPS, Barcelona, Spain

Background: Amyloidosis constitutes a heterogeneous group of diseases characterized by the deposition of amyloid fibrils in organs and tissues. Accurate identification of precursor protein is essential, given the diverse prognosis and therapeutic approach. The diagnosis and classification are based on histologic demonstration of amyloid deposits and characterization of the amyloid precursor. Immunohistochemistry is the classical method for amyloid typing. However, reported technical limitations of immunohistochemistry gave rise to the introduction of strategies such as immunoelectron microscopy and proteomic analysis.
Aims: To describe the role of immunohistochemistry in the diagnosis of 82 patients with immunoglobulin light chain (AL) amyloidosis diagnosed and treated at a single institution between 1995 and 2013.
Methods: At the time of diagnosis, all patients were systematically investigated by clinical and laboratory evaluation. Diagnosis of AL amyloidosis required amyloid demonstration by Congo red stain in a biopsy specimen. All Congo-red positive biopsies were tested for the four most common amyloid proteins (kappa, lambda, AA and TTR), using commercial antibodies
Results: Eighty-two patients were included in the study (42M/40F). The involved light-chain isotype was lambda in the majority of patients (76.8%). Immunohistochemistry allowed a definite diagnosis of AL amyloidosis in 70 patients (85.4%). Positive tissue was more frequently kidney (29 patients), followed by abdominal fat aspiration (9 patients), liver (7), tongue (5), gastrointestinal tract (5), heart (5), skin (2), lung (2), salivary glands (2), with bone marrow, lymphadenopathy, muscle and bladder in one case each. More than one tissue was biopsied in 33 patients. All immunohistochemistry results were concordant with serum and/or urine monoclonal protein and among diferent samples from the same patient when available. In 51 patients with subcutaneous fat aspiration available, only 32 showed Congo red positivity by optical microscopy, allowing amyloid proten by immunohistochemistry in 14 cases (27.4%). In those patients without effective amyloid typing (12), diagnosis of AL amyloidosis was firmly established based on the presence of typical clinical signs in combination with a monoclonal gammopathy and a Congo red positive biopsy.
Summary and Conclusion: Immunohistochemistry performed by an experienced pathologist, combined with clinical and laboratory information and genotyping, allows AL amyloidosis diagnosis in the majority of daily practice cases. Nowadays, this is the standard in our institution, saving more complex diagnostic techniques for patients in whom the diagnosis is not clear.

Myeloma and other monoclonal gammopathies - Clinical 5

P991

SAFETY PROFILE OF BORTEZOMIB IMPACTS SURVIVAL OF CARDIACAL

Z Van De Wyngaert[1], G Vanoutryve[1], G Fouquet[1], S Guidez [1], C Herbaux [2], H Demarquette [1], S Bonnet [1], D Beauvais [1], D Launay [2], L Terriou [2], B Hivert [1], M Wemeau[3], N Lamblin[4], T Facon[1], E Hachulla[2], X Leleu[1,*]
[1]Service des Maladies du Sang, [2]Service de Médecine Interne, Hôpital Huriez, CHRU, Lille, [3]Service des maladies du sang, CH, Arras, [4]Hôpital Cardiologique, CHRU, Lille, France

Background: Light chain amyloidosis (AL) is characterized by a median overall survival (OS) from diagnosis of approximately 3 years, but with clinically overt cardiac involvement this is reduced to 1 year. Bortezomib (B) has shown great promise in the treatment of AL, especially of cardiac involvement. However, efficacy might be hampered by severe safety issues with use of B, primarily of neuropathy type.
Aims: We sought to study the prognostic impact of the safety profile of B in AL with attention to cardiac involvement.
Methods: This study has included 27 patients with AL, of these 18 had cardiac and 9 kidney but no cardiac involvement. AL was diagnosed as outline in international consensus criteria, as to the hematologic and organ responses. B was given IV twice weekly at the starting dose of 1.3 mg/m², in combination to weekly cyclophosphamide in 13 patients (52%).
Results: The median age was 63, sex ratio was 18/9, all cardiac AL had Mayo Cardiac Stage III but 3. 70% were at diagnostic. Seven patients died during the first month, all of them but one had cardiac AL. The overall hematologic response rate was 56% and at least VGPR 41%. The responses were 56% and 39% in cardiac AL, similar to patients with no cardiac involvement (56% and 44%), respectively. The median duration of response was 13 months overall, 10 and 20 months in cardiac and in no cardiac AL, respectively (p=NS). With a median follow-up of 41 months from start of B, 70% relapsed and 59% died in the study as a whole, and 67% and 67% in the cardiac group, respectively. The median time to progression was 20 (95CI 4;35.5) months as a whole, and 13 (9;17) months and 20 (0;43) months in cardiac and in no cardiac AL (p=NS). The estimated 4-year OS was 55%, 62% and 50% as a whole, in patients with no cardiac involvement, and with cardiac AL, respectively. Interestingly, all cardiac AL that survived beyond 6 months remain alive at F-up date. We then looked at the safety profile of B in the studied population, and found that 25% and 75% experienced some degree of hematotoxicity in cardiac and in no cardiac AL (p=NS). The non hematology toxicity rate was 62% and 38%, respectively (p=NS). 26% of patients needed dose reduction of B and 33% dose interruption of B in the study before cycle 4, all related to non hematological toxicity of neuropathy, fatigue and GI AEs; and was similar in cardiac as compared to no cardiac AL. The safety profile did not impact the response rate or the duration of response. Several variables negatively impacted survival in univariate analysis in the group with cardiac AL, including decreased *LVEF (p=0.025), NYHA greater than 2 (p=0.007),* Mayo Cardiac Stage III (p=0.028), no hematological (p=0.002) and no organ responses (p=0.05), occurrence of non hematological toxicity (p=0.002) with the consequence of dose reduction of B (p=0.09) and dose interruption of B (p=0.04). In multivariate analysis, independent variables that impacted survival were hematological response (OR=5.1, 95%CI=1.5-18; p=0.011) and non hematological toxicity (OR=3.6, 95%CI=0.8-14; p=0.05).
Summary and Conclusion: Bortezomib is a very rapid and effective therapy for AL particularly of cardiac involvement. However, patients may develop severe side effects with Bortezomib that preclude efficacy of Bortezomib given IV, and consequently impact negatively survival. This data favours use of sub cutaneous Bortezomib in AL although not validated in this indication yet.

P992

IMPACT OF INITIAL FGD-PET CT AND SERUM FREE LIGHT CHAIN ON TRANSFORMATION OF CONVENTIONALLY DEFINED SOLITARY PLASMACYTOMA TO MULTIPLE MYELOMA

G Fouquet[1,*], S Guidez[2], C Herbaux[1], Z Van de Wyngaert[1], S Bonnet[1], D Beauvais[1], H Demarquette[1], S Adib[3], B Hivert[1], M Wemeau[4], C Berthon[2], L Terriou[2], V Coiteux[2], M Macro[5], O Decaux[6], T Facon[2], D Huglo[7], X Leleu[2]
[1]Hematology, Hôpital Huriez, CHRU Lille, France, [2]Hematology, Hôpital Huriez, CHRU Lille, [3]Nuclear medicine, Hôpital Huriez, CHRU Lille, France, LILLE, [4]Hematology, Centre hospitalier d'Arras, Arras, [5]Hematology, Hôpital Côte de Nacre, CHU, Caen, [6]Hematology, CHU Rennes, Rennes, [7]Nuclear medicine, Hôpital Huriez, CHRU Lille, Lille, France

Background: Solitary plasmacytoma (SP) is a localized proliferation of monoclonal plasma cells resulting in a mass in either bone (SBP: Solitary Bone Plasmacytoma) or soft tissue (EMP: Extra-Medullary Plasmacytoma), without evidence of Multiple Myeloma (MM) but with high risk of transformation to MM. Presence of focal lesions on magnetic resonance imaging (MRI) has been demonstrated to favor progression to MM in patients (pts) with plasmacytoma. FGD-PET CT (PET) provides additional valuable information to assess plasmacytoma in the context of MM, compared with MRI, but its exact role remains debatable.
Aims: We aimed to determine the impact of PET pre and post therapy on the risk of transformation of SP to overt MM.
Methods: This retrospective study included 43 pts diagnosed with one SP clinically, confirmed with histology, either EMP (10 pts) or SBP (33 pts). All pts were treated locally with surgery and/or radiotherapy and had PET and MRI performed at diagnosis prior to (initial) and at the end of therapy. SP was diagnosed as outlined in international consensus criteria.
Results: The median age was 57.5 years with 33% pts older than 65, the sex ratio was 1.8, 48% pts had abnormal involved serum free light chain (isFLC) value and 64% had abnormal sFLC ratio (K/L). 33% had ≥2 hypermetabolic lesions on initial PET, and 20% had ≥2 focal lesions on initial MRI. With a median follow-up of 50 months, the median overall survival (OS) was not reached for the whole cohort, with a 6-year OS at 79.4%. 14 patients transformed to MM with a median time to MM progression (TTMM) of 71 months (95%CI : 59;101). The TTMM for the ≥2 hypermetabolic lesions on initial PET group was 23 months (9;37) *vs* not reached otherwise (p=0.003). Conversely, the median TTMM for the ≥2 focal lesions on initial MRI group was 30 months (9;51) *vs* not reached otherwise, without significant difference. Abnormal initial K/L ratio (p=0.022) and abnormal initial isFLC (p=0.002) impacted TTMM, 36 months (14;58) and 21 months (0;42) *vs* not reached otherwise, respectively. A normalized PET at completion of treatment did not reach significance, as to normalized MRI, but the absence of normalized isFLC value also negatively impacted TTMM, 21 months (10;32) *vs* not reached otherwise (p=0.016). Using multivariate analysis, independent variables that shortened TTMM were initial PET (OR=5, 95%CI=0-9; p=0.032) and abnormal initial isFLC (OR=10, 95%CI=1-87; p=0.008). Interestingly, initial PET did not influenced OS, median 71 months for the ≥2 hypermetabolic lesions on initial PET group *vs* not reached otherwise, respectively (p=ns).
Summary and Conclusion: An abnormal involved sFLC value and the presence of at least 2 hypermetabolic lesions on PET/CT at diagnosis of SP were the 2 predictors of early evolution to myeloma in our series. This data analysis will need confirmation in a larger study, and the study of these 2 risk factors may lead to a different management of patients with SP in the future.

P993

NEGATIVE FLOW CYTOMETRY IS ASSOCIATED WITH A BETTER PROGRESSION-FREE SURVIVAL IN TREATED MULTIPLE MYELOMA PATIENTS: THE SINGLE-CENTER EXPERIENCE OF CHU DE CAEN IN A DAILY PRACTICE

Q Cabrera[1,*], V Salaun[2], E Cornet[2], X Troussard[1], M Macro[1]
[1]Hématologie Clinique, [2]Hématologie biologique, CHU de Caen, Caen, France

Background: Multiple Myeloma (MM) is an hematologic malignancy characterized by bone marrow plasma cell infiltration and a serum monoclonal component. It is usually preceded by a non-active stage (smoldering myeloma, SM) based on international CRAB criteria. The response depth under treatment, defined in International Myeloma Working Group (IMWG) guidelines as partial response (PR), very good partial response (VGPR), complete response (CR) and stringent CR (sCR) is associated with a better outcome in overall and progression-free survival. Flow cytometry is a useful tool for the diagnosis, prognostic and high sensitivity minimal residual disease (MRD) evaluation in plasma cell diseases. Furthermore, it can define a better-outcome group of patients with CR and negative MRD (immunophenotyping CR, iCR).
Aims: For more than two years, we prospectively characterized in our center (CHU de Caen, France) 208 bone marrow samples of 127 patients in 4-color flow cytometry (127 at diagnosis, 23 at relapse and 58 MRD or protocol post-treatment samples).
Methods: We used a CD38/138/SSC/45 primary gating and CD19, CD20, CD56, CD117, CD33, CD28 and intra Kappa/lambda antibodies panel. Samples retained for analysis must have more than 20,000 nucleated cells per panel (mean 150,000 nucleated cells per tube approximately), and antibody positivity in a cell population was noted if more than 20% of these cells expressed the antibody.
Results: Disease status at diagnosis was active MM (61%), SM (13%) and MGUS (23%). We found in a daily practice that the most frequent phenotype was CD19-/CD20-/CD56+/CD117+/CD33-/CD28- (22% of cases), with high heterogeneity. With a median follow-up of 20,4 months in active MM (n=89), no single-marker prognostic value was found. More than 85% of these active MM patients received a multiple-agent therapy including Bortezomib (V): V-Thalidomide-Dexamethasone (16,8%), V-Lenalidomide-Dexamethasone (23,5%), V-Cyclophosphamide-Dexamethasone (9%) and V-Melphalan-Dexamethasone or V-Dexamethasone (32,8%). Autologous stem-cell transplantation was performed in 36 patients (40,4%) with a very good overall survival (98% at 100 months). We evaluated post-treatment MRD by cytology and flow cytometry in 21 patients, including 11 patients with only VGPR: 2 VGPR patients had a negative MRD, and 9 MRD-negative patients (41%) had

plasma cells in cytology (1-4%). We found that negative MRD in at least VGPR patients was associated with a largely better PFS (p=0,003, median PFS not reached *vs*. 27,8 months).

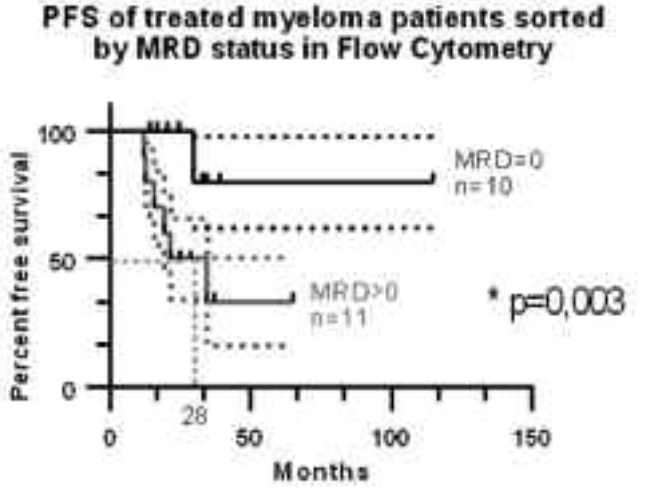


Figure 1.

Summary and Conclusion: In this prospective real-life study we confirm the important role of flow cytometry in multiple myeloma for the MRD evaluation of treated patients.

P994

HIGH INCIDENCE OF INTACT IMMUNOGLOBULIN OR FRAGMENTS THEREOF IN URINE OF PATIENTS WITH MULTIPLE MYELOMA

M Kraj[1,*], B Kruk[1], E Lech - Maranda[1], K Warzocha[1], M Prochorec - Sobieszek[1]
[1]Institute of Hematology and Transfusion Medicine, Warsawa, Poland

Background: Intact immunoglobulin or fragments thereof (intact / fragmented Ig) can be found in the urine due to nephrotic injury or the preferential scavenging of albumin by the renal FcRn receptor leading to immunoglobulin catabolism (Sarav *et al.* JASN 2009; 20: 1941). Intact/fragmented Ig can be detected in urine in a proportion of patients with multiple myeloma (MM) at presentation and are associated with reduced survival (Ludwig *et al.* ASH 2012 abstract 1828).
Aims: To determine the incidence of intact /fragmented Ig and Bence Jones protein (BJP) in urine and compare to concentrations of serum free light chains (sFLC) in MM patients at diagnosis.
Methods: 215 patients with MM, median age 66 years old (range 47-82) with a male/female ratio 100/115, 163 IgG (104 IgGκ/59 IgGλ), 48 IgA (25 IgAκ/23 IgAλ), 3 IgDλ and 1 IgEκ were evaluated. Immunofixation was performed using Hydrasys 2 apparatus (Sebia, France) and antisera from the same company. sFLC were measured using Siemens BN™ II nephelometer and immunoassays (Freelite™, The Binding Site, Birmingham, UK).
Results: In 45/163 (27%) IgG MM patients urine immunofixation (uIFE) revealed presence of intact /fragmented IgG (including 25 IgG + BJP, 17 IgG + albumins, 3 only IgG). Overall monoclonal protein was detected in uIFE of 100/163 (60%) IgG MM patients (including 41 BJP, 25 BJP + IgG, 17 IgG + albumins, 3 IgG, 14 BJP + albumins). Abnormal sFLCκ/λ ratio was found in 100/130 (77%) IgG MM patients (increased monoclonal sFLC in 104 (80%) patients and decreased alternate sFLC in 30 (23%) patients. In 12/48 (25%) IgA MM patients uIFE revealed presence of intact/fragmented IgA (including 8 IgA + BJP, 11 IgA + albumins). Overall monoclonal protein was detected in uIFE of 37/48 (77%) IgA MM patients (including 13 BJP, 8 BJP + IgA, 12 BJP + albumins, 4 IgA). Abnormal sFLC ratio was found in 39/43 (90%) IgA MM patients (increased monoclonal sFLC in 38 (88%) patients and decreased alternate sFLC in 22 (51%)) patients. In 1/3 IgDλ MM patients uIFE revealed presence of IgD (1 IgD + BJP + albumins, 2 BJP). In 3 IgD MM patients sFLC ratio was abnormal, monoclonal sFLC was increased and alternate sFLC was decreased. In the only 1 IgEκ MM patient uIFE revealed presence of BJP and albumins; sFLC ratio was abnormal, monoclonal sFLC was increased and alternate sFLC was decreased. There was no difference in serum creatinine concentrations between patients with or without intact/fragmented Ig in urine.
Summary and Conclusion: In one fourth of IgG, IgA and IgD MM patients intact/fragmented Ig can be detected in urine at diagnosis. Urine immunofixation detects monoclonal protein (FLC and intact/fragmented Ig) in 60% to 77% while serum free light chain assay in 80% to 90% of IgG and IgA MM patients, however the last one is inadequate for detection of intact/fragmented Ig in urine. Prognostic significance of the presence of intact/fragmented Ig in urine is under investigation.

P995

VALIDATION OF THE SPECIFIC HEMATOPOIETIC-CELL-TRANSPLANTATION COMORBIDITY INDEX IN PATIENTS WITH MULTIPLE MYELOMA

J Jelicic[1,*], J Bila[1], V Djurasinovic[1], V Vukovic[1], A Sretenovic[1], B Andjelic[1], D Antic[1], M Todorovic[1], B Mihaljevic[1]
[1]Clinical Center of Serbia, University of Belgrade, Clinic of Hematology, Belgrade, Serbia

Background: Major step forward in the treatment of multiple myeloma (MM) has been achieved with intensification of treatment in terms of high-doses therapy followed by the autologous stem cell transplantation (ASCT). Introduction of various new drugs for multiple myeloma (MM) has appointed the necessity of personalized approach.
Aims: The goal of study was to compare and validate the impact of the Hematopoietic-Cell-Transplantation Comorbidity Index (HCT-CI), and Charlson Comorbidity Index (CCI) on the course of disease in MM pts.
Methods: The study included 146 newly diagnosed MM pts (age of ≤65yrs: 73 male/73 female, mean age 57yrs, range 35-65). IgG myeloma had 93pts (63,7%), IgA 25pts (17,1%), light chains 23pts (15,7%), IgD 3pts (2,1%), and non-secretory 2pts (1,4%). According to the clinical stage, distribution was: I 5pts (3,4%), II 28pts (19,2%); III 113pts (77,4%). Renal impairment existed in 35pts (24%). Regarding ISS score, 28,2%pts had ISS1 score; 30% ISS2; and 41,8% had ISS3. Most of the patients had HCT-CI 0-1, 114pts (78 %, range 0-6), while score ≥2 had 32pts (22%). Charlson comorbidity index (CCI) score 0-1 had 116pts (79,5%), CCI≥2 was found in 30pts (20,5%). Age adjusted CCI (aaCCI) score 0-1 had 22pts (15,1%), aaCCI 2 had 55pts (37,7%), and 69pts (47,3%) had aaCCI≥3 (range 0-7). In the induction treatment, thalidomide combinations were applied in 70pts (47,9%). Five patients (3,4%) were treated with bortezomib; and 66pts (45,2%) with conventional chemotherapy. High-dose therapy (HDT) with Melphalan 200mg/m² followed by the ASCT was applied in 58pts (39,7%).
Results: Treatment response (CR/VGPR/PR/MR) was achieved in 54pts (93%) treated with HDT+ASCT with median duration 24m (range 6-92m), comparing to the 88pts (60,3%) that were not included in the programme of the HDT+ASCT (56 pts, 63,6%, median duration 15m, range 1-88m). The mean overall survival (OS) of patient treated with HDT+ASCT was 71,4m (range 10-92m) with probability of 5-years survival in 63% pts, while pts treated out of ASCT program had median OS 38m (range 7-98) with probability of 5-years survival in 35% pts. Patients with HCT-CI 0-2 had significantly longer OS in comparison to the patients with HCT-CI ≥3 (median 48m *vs*. 30m; Log Rank 5,45; p=0,02). Similarly, patients with CCI 0-2 had significantly longer OS in comparison to the patients with CCI ≥3 (median 48m *vs*. 30m; Log Rank 4,41; p=0,036). Furthermore, in the proposed model for personalized treatment approach among variables HCT-CI≥2, CCI≥2, and ISS≥2, only ISS≥2 was indicated as major factor with significant impact on the OS of younger MM pts (χ^2 7,89; p=0,048; HR 2,067; 95% CI 0,99-4,29).
Summary and Conclusion: High values of Hematopoietic-Cell-Transplantation Comorbidity Index and Charlson Comorbidity Index (HCT-CI/CCI≥2) are of the similar importance for the course of disease in younger myeloma patients, while the treatment outcome and overall survival of these patients in proposed model is mainly influenced by the level of disease aggressiveness based on ISS system.

P996

RELATIONSHIP BETWEEN CHROMOSOMAL ABERRATIONS AND CLINICAL OR LABORATORY VARIABLES IN MULTIPLE MYELOMA

E Wawrzyniak[1,*], N Niezgodka[1], M Siemieniuk-Rys[2], J Blonski[1], H Urbanska-Rys[2], O Zych[2], A Lakoma-Rakowska[2], T Robak[1]
[1]Hematology Department, Medical University, [2]Hematology Department, Copernicus Memorial Hospital, Lodz, Poland

Background: Clinical significance of some chromosomal aberrations (CA) detected at diagnosis in multiple myeloma (MM) is well established. However, the relationship between different types of CA and some clinical or laboratory variables is less known and sometimes controversial.
Aims: The aim of our study was to assess the type and frequency of CA detected by FISH combined with cytoplasmic light chain detection (cIg-FISH) in MM patients, and their associations with clinical and laboratory parameters. In addition, significance of abnormal karyotype detected by chromosome banding analysis (CBA) was analyzed.
Methods: A total of 65 patients with MM at diagnosis were included into the study. Probes for cIg-FISH were chosen to detect t(4;14), t(14;16), t(11;14), deletion of 1p32, 13q14, 16q23, gain of 1q21, trisomy of 5/9/15. All cases were divided into hyperdiploid MM (H-MM) or non-hyperdiploid MM (NH-MM). The laboratory and clinical assessments included: age, gender, bone marrow plasmocytes, hemoglobin, albumin, β2microglobulin, creatinine, LDH, type of secreted heavy and light chains, serum free light chains (sFLC), sFLC ratio (sFLCR), bone lesions. Additionally, in 56 patients CBA was performed.
Results: The median age of 65 patients (29 males, 36 females) was 60 (range

37-79). The frequency of CA detected by clg-FISH was as follows: t(4;14) in 16/65 (24.6%), t(14;16) in 4/65 (6.1%), t(11;14) in 6/35 (17.1%), del(13q) in 36/65 (55.4%), del(16q) in 12/65 (18.5%), del(17p) in 8/65 (12.3%), del(1p) in 6/60 (10.0%), and amp(1q) in 31/65 (47.7%) of patients. H-MM by clg-FISH was established in 30/61 (49.2%) patients. Abnormal karyotype by CBA was detected in 18/56 (32%) of patients, 9 cases with hyperdiploidy and 9 with hypo/pseudodiploidy. In all but one abnormal karyotype was complex. The H-MM and NH-MM status evaluated by clg-FISH and by CBA were consistent in all cases. Translocation t(4;14) was detected in 37.9% of males and 13.9% of females (p=0.030), and amp(1q) in 69.0% of males and 13.9% females (p=0.001), respectively. All together, the high-risk aberrations, *i.e.* t(4;14) or t(14;16) or del(17p) were observed in 52% of males and 21% of females (p=0.010). The frequency of t(4;14) and amp(1q) was also dependent on the age (p=0.023 and p=0.043, respectively). Regarding group of patients with t(4;14) or t(14;16) together, 42% of patients younger than 60 years had one of two translocations as compared with 18% for older ones (p=0.037). Translocation t(4;14), amp(1q), del(16q) and NH-MM were significantly more often observed in cases producing λ than κ chains, and the frequencies in λ-MM *vs*. κ-MM were as follows: 37.5% *vs*. 13.5% (p=0.029), 64.0% *vs*. 27.9% (p=0.007), 33.3% *vs*. 10.8% (p=0.031) and 73.9% *vs*. 40.0% (p=0.013), respectively. Among many laboratory variables only sFLC level was associated with CA detected by clg-FISH. High sFLC level was related to amp(1q) (p=0.039). However abnormal karyotype detected by CBA was associated with Hb<10 mg/dl (p=0.014) and β2microglobulin >5.5 mg/l (p=0.002) as well as ISS stage 3 (p=0.002). Abnormal metaphases were observed in 2/24 (8%) patients in ISS stage 1-2 and in 14/26 (56%) patients in ISS stage 3 (p=0.001). Advanced bone lesions were present in 6/7 (86%) patients with del(17p) and 21/54 (39%) patients without this anomaly (p=0.052).

Summary and Conclusion: We found gender- and age-dependent differences in prevalence of high-risk aberrations in newly diagnosed MM patients, with t(4;14) and amp(1q) being more common in men and younger patients. Additionally, MM with λ chains was related to high-risk aberrations.

P997

COST-EFFECTIVENESS IN NEWLY DIAGNOSED MULTIPLE MYELOMA (NDMM): LENALIDOMIDE PLUS LOW-DOSE DEXAMETHASONE (RD) VERSUS BORTEZOMIB PLUS MELPHALAN AND PREDNISONE (VMP)

JD Cavenagh[1,*], AR Belch[2], C Hulin[3], S Basu[4], D White[5], A Ervin-Haynes[6], J Marek[6], CG Pelligra[7], S Guo[7], G Binder[6], MS Monzini[6], T Facon[8]

[1]Department of Haematology, St. Bartholomew's Hospital, London, United Kingdom, [2]Cross Cancer Institute, University of Alberta, Edmonton, AB, Canada, [3]University Medical Center, Nancy, France, [4]Royal Wolverhampton Hospitals NHS Trust, Wolverhampton, United Kingdom, [5]QEII Health Sciences Center, Halifax, NS, Canada, [6]Celgene Corporation, Summit, NJ, [7]Evidera, Lexington, MA, United States, [8]Service des Maladies du Sang, Hôpital Huriez, Lille, France

Background: Treatment paradigms in multiple myeloma are evolving, with new evidence indicating that health gains are maintained through continuous treatment. The FIRST trial showed that continuous Rd significantly improved progression-free survival (PFS) and provided an overall survival (OS) benefit at interim analysis, compared to a fixed duration of either 18 months of Rd or the combination of melphalan- prednisone - thalidomide (MPT) in transplant-ineligible NDMM patients (Facon, *et al.* Blood 2013). Fixed treatment duration of VMP, approved by the Food and Drug Administration in the United States (US) for this population, also demonstrated superior efficacy to MP (San Miguel, *et al.* N. Engl. J. Med 2008) (San Miguel, *et al.* J Clin Oncol 2013) and similar to MPT through indirect comparison (Kumar, *et al.* Am J Hematol 2001) (NICE 2011). Given the different available treatment options, questions arise regarding the balance between the costs and benefits of continuous *versus* fixed duration therapy.

Aims: To conduct a cost-effectiveness analysis in order to evaluate the costs and benefits of continuous Rd *versus* fixed duration VMP in NDMM patients.

Methods: A partitioned survival model was developed to perform this analysis from a US payer perspective over a lifetime horizon. The model projected average lifetime PFS and OS associated with each treatment using observed trial data and estimated quality-adjusted life-years (QALY) based on treatment-specific utility weights for each health state. Continuous Rd outcomes were taken from the FIRST trial, while VMP outcomes came from the VISTA study. In order to establish relative efficacy between Rd and VMP, the OS for VMP was set to be the same as that observed in the MPT arm of the FIRST Trial, based on the NICE guidance of VMP similarity *versus* MPT in first-line multiple myeloma (NICE 2011). Costs, including for drugs, administration, medical care, second- and third-line anti-myeloma regimens, and management of toxicity, were calculated in 2014 US dollars based on resource utilization within the respective trials, and published literature. Both clinical and cost outcomes were discounted at 3% per annum.

Results: Continuous treatment with Rd was estimated to result in 6.81 life-years (LY; discounted), relative to 5.53 for fixed treatment duration of VMP. QALYs were estimated to be 4.33 and 3.42 (discounted), respectively. Discounted lifetime costs were $349,331 for patients starting with Rd *versus* $270,991 for patients starting with VMP. Incremental cost-effectiveness ratios for continuous Rd relative to VMP were $86,126 per QALY gained and $61,509 per LY gained.

Summary and Conclusion: Continuous Rd was estimated to result in 23% to 27% more LYs and QALYs relative to VMP in transplant-ineligible NDMM patients. Despite the additional costs incurred with continuous treatment, Rd was cost-effective relative to fixed duration therapy with VMP, with cost-effectiveness ratios well within levels published for other recent advances in front-line oncology setting.

P998

SYSTEMIC MASTOCYTOSIS WITH MONOCLONAL GAMMOPATHY

A Talbot[1,*]

[1]Hematology, Hopital Necker, PARIS, France

Background: Mastocytosis is due to a clonal neoplastic proliferation of mast cells that accumulate in one or more organ systems. It is a rare disease associated to a somatic mutation of the proto-oncogene c-kit(KIT). Systemic mastocytosis with associated clonal hematologica non-mast celle lineage disease is a unique subtype of mast cell neoplasm. While associated myeloid neoplasm is frequent, associated with lymphoproliferative disorders are rare. Some cases of systemic aggressive with plasma cell myeloma are reported in the littérature.

Aims: We aimed to determine the frequency of monoclonal gammopathy in patients with systemic mastocytosis and compare the mast cell infiltration in mastocytosis disease with Waldenstrom macroglobulinemia (percentage of mast cell, morphologic and immunohistochemical in bone marrow biopsy)

Methods: We retrosepctly analyzed the data of 1500 patients included in french protocol CEREMAST (Blood Protein Electrophoresis,Immunoelectrophoresis, bone marrow biopsy and aspiration).

Results: All the date are not analysed (late breakng abstract).

Summary and Conclusion: Plasma cell dyscrasia is not rare in patients with systemic mastocytosis (about 5%). Some patients died du to clonal evolution with multiple myeloma. The immunoglobulin isotype is frequently IgA or IgM suggesting a hyperexpression of TGFb. Some studies comparing systemic mastocytosis with monoclonal gammopathy and lymphoplasmacytic lymphoma (Waldenström's macroglobulinemia) may be interesting to see the difference in the mast cell infiltration.

MANAGEMENT OF RENAL IMPAIRMENT IN PATIENTS WITH RELAPSED MULTIPLE MYELOMA: PRELIMINARY DATA OF A LARGE OBSERVATIONAL, PROSPECTIVE STUDY

A Garcia[1,*], E Morales[2], F Escalante[3], MS Durán[4], M Gironella[5], T J González[6], M Pérez[7], I Español[8], E Cabezudo[9], R Martínez[10], J A Márquez[11], M Durán[12], J de la Rubia[13]

[1]Hospital Universitari Arnau de Vilanova, Lleida, [2]Hospital 12 de Octubre, Madrid, [3]Hospital de León, León, [4]Hospital Universitario Ciudad de Jaén, Jaén, [5]Hospital Vall d'Hebrón, Barcelona, [6]Hospital Universitario de Burgos, Burgos, [7]Complejo Hospitalario Universitario de Santiago, Santiago de Compostela, [8]Hospital Santa Lucía, Cartagena, [9]Hospital Althaia, Manresa, [10]Hospital Clínico San Carlos, Madrid, [11]Hospital de Basurto, Bilbao, [12]Celgene S.L., Madrid, [13]Hospital Universitario La Fe, Valencia, Spain

Background: Impaired renal function (IR) is commonly observed in patients (pts) with relapsed refractory multiple myeloma (RRMM) and it is associated with a shorter survival. No prospective description of the renal response to new anti-myeloma drugs within the clinical practice has been performed so far in the RRMM setting.

Aims: To describe renal responses in pts with RRMM presenting with moderate or severe IR (creatinine clearance (CrCl)<50 ml/min). Secondary objectives include myeloma response, overall survival, safety and health resource utilization. We present a descriptive analysis with baseline data of the first 100 pts included.

Methods: An observational, prospective, multicentre study is currently ongoing with 300 pts with RRMM and IR planned to be included, 225 with moderate (30 ≤ CrCl<50 ml/min) and 75 with severe (CrCl<30 ml/min) renal insufficiency, measured in 24h urine. Signed informed consent is required. A follow up of 36 months after end of treatment is planned for every pt. Renal and myeloma responses will be evaluated according to the International Myeloma Working Group (IMWG) criteria.

Results: Of the 100 pts included, 50% had moderate and 50% severe IR. Comorbidities affecting renal function were arterial hypertension (47%) and diabetes mellitus (23%), and other comorbidities were: 21% motor or sensory neuropathy, 17% primary malignancy, 10% heart failure. The mean (standard deviation) CrCl (Cockroft-Gault) was 31.4 (11.9) and the mean eGFR was 32.7 (15.1) and 32.6 (15.3) ml/min according to the MDRD-4 and CKD-Epi formulas, respectively. Kidney disease classification according to MDRD-4 was: 3.3% of pts at stage 2 (eGFR 60-90); 16.5% at stage 3a (45-59); 39.6% at stage 3b (30-44); 26.4% at stage 4 (15-29) and 14.3% at stage 5 (<15). Mean age was 73.6

(8.5) y and 55% were men. Myeloma subtypes were: 57% IgG, 20% IgA, 17% Bence-Jones, 3% non-secretory, 1% IgD, and 1% IgM (1% not available (NA)). At relapse 40% of pts had detectable urine M-protein, 51% κ and 49% λ. At relapse, 47% of patients were ISS 3, 27% ISS 2, and 8% ISS 1 (NA in 15%). 13 (13%) patients had high-risk cytogenetic findings at time of relapse. At study entry, 50% of the pts were in first relapse, 34% in second relapse, and 16% in third or subsequent relapse. Main findings at relapse were: anemia (64%), bone lesions (37%), hypercalcemia (19%), and extramedullary plasmacytomas in 11% of pts. Main first-line anti-MM therapies were bortezomib in 80% of the pts, alkylating agents in 40% of the pts, autologous hematopoietic stem-cell transplantation in 12% and lenalidomide in 8%. In pts with a first relapse, a bortezomib or a lenalidomide-based therapy was administered in 38% and 46% of the patients, respectively.

Summary and Conclusion: Pts with RRMM and renal impairment are usually elderly with high ISS and present concomitant hypertension or diabetes. Evaluation of renal function by 24h urine is feasible in this population. The most frequent therapies in these pts are lenalidomide or bortezomib plus dexamethasone. Further analysis will be available as more pts are included in the study.

P1000

NUTRITIONAL COUNSELING IN SYSTEMIC IMMUNOGLOBULIN LIGHT-CHAIN (AL) AMYLOIDOSIS: A PROSPECTIVE RANDOMIZED, CONTROLLED TRIAL

R Caccialanza[1], G Palladini[2,*], E Cereda[1], C Bonardi[1], P Milani[2], B Cameletti[1], L Quarleri[1], S Cappello[1], M Vidus Rosin[2], A Foli[2], F Lavatelli[2], C Klersy[3], G Merlini[2]

[1]Nutrition and Dietetics Service, Fondazione IRCCS Policlinico San Matteo, [2]Department of Molecular Medicine, University of Pavia, [3]Scientific Direction, Fondazione IRCCS Policlinico San Matteo, Pavia, Italy

Background: Poor nutritional status is common in patients with systemic immunoglobulin light-chain (AL) amyloidosis and has been associated with mortality and impaired quality of life (QoL).

Aims: We investigated whether nutritional counseling is beneficial to the maintenance of nutritional status and QoL in AL outpatients.

Methods: We performed a single-center, randomized, controlled trial (July 2009 - October 2013). Adult (≥18 year-old) AL treatment-naïve outpatients (N=144) at diagnosis were randomized (1:1) to ad-libitum food intake (usual care; N=72) and nutritional counseling (personalized dietary prescription, regular dietetic advise by a registered dietician; N=72). All the patients gave written informed consent. The primary endpoint was the change in body weight at 12 months. Secondary endpoints included change in QoL evaluated by the Medical Outcomes Study 36-item Short Form General Health Survey (SF-36) and overall survival.

Results: Forty-one patients (N=25 usual care, N=16 nutritional counseling) died before the first follow-up visit. In the modified intention-to-treat population (patients who underwent at least one control visit during the study [month 3]; N=103), body weight remained stable in patients assigned to nutritional counseling ([N=56]; WL=0.8±4.9 kg; P=0.214), whereas in the usual care group a significant decrease in body weight was observed ([N=47]; WL=2.4±5.5 kg; P=0.003). Moreover, we observed a significant increase in the mental component summary of QoL assessment in patients randomized to nutritional counselling (8.1 [95%CI: 2.3, 13.9]; P=0.007). In all randomized patients, nutritional counselling significantly improved survival (HR=0.57 [95%CI: 0.35, 0.94]; P=0.028). In the multivariable model, after adjusting for baseline body mass index, hematologic response to treatment and cardiac stage, a trend in reduced mortality was still observed for patients undergoing nutritional counseling (HR=0.62 [95%CI: 0.37, 1.05]; P=0.074).

Summary and Conclusion: Nutritional counseling is helpful in maintaining nutritional status and effective in improving mental quality of life in AL outpatients.

P1001

ISOTYPE MATCHED IMMUNOGLOBULIN SUPPRESSION IN COMBINATION WITH CYTOGENETIC MARKERS PREDICTS OUTCOME IN MULTIPLE MYELOMA PATIENTS

V Teleanu[1], M Kull[1], M Graf[1], P Schwazwälder[1], P Liebisch[2], C Langer[1,*]

[1]Innere Medizin, Universitätsklinikum Ulm, Ulm, [2]Onkologie Moers, Moers, Germany

Background: The IMWG-consensus report on risk stratification in multiple myeloma (MM) recommends the definition of low risk patients (pat.) using cytogenetic markers in combination with serum albumin and β2M concentrations (Chng et al, 2014). However, using the proposed model, there are still a considerable number of low risk pat. progressing after autologous stem cell transplantation (autoPBSCT). Immunosuppression has been associated with poorer outcome in MM patients (Bryant et al, 2013) and recent evidence shows that isotype matched immunosuppression may provide additional prognostic power.

Aims: To assess whether uninvolved immunoglobulin suppression can improve stratification of MM patients.

Methods: Presentation samples from 83 MM pat. treated uniformly receiving at least one autoPBSCT were analysed for serum heavy-/light-chain (HLC) levels using commercially available immunoassays (The Binding Site, UK). HLC measurements were compared to published normal ranges. Median age was 59 (28-72) years and median follow up 26 (2-153) months (mo). 61 pat. presented with an IgG isotype (IgG kappa 69%, 42/61 pat.; IgG lambda 31%, 19/61 pat.) and 22 pat. with an IgA isotype (IgA kappa 73%, 16/22 pat.; IgA lambda 27%, 6/22 pat.). Cytogenetic aberrations included: t(4;14) (15%; 13/83 pat.); del17p13 (7%; 6/83 pat.); 1q21+ (18%; 15/83 pat.) and t(14;16) (2%; 2/83 pat.). Risk models combining ISS stage and cytogenetic markers were those from IMWG (Avet-Loiseau, 2013), IMWG-consensus (Chng 2013) and MRC (Boyd, 2012); two-tier (low-risk v intermediate / high-risk patients) models were tested for progression free survival (PFS). Kaplan-Meier survival curves were compared using the log-rank test; univariate analyses were performed using Cox proportional regression. ROC analysis was used to identify isotype matched immunoglobulin suppression (uHLC) cut-offs for survival studies.

Results: All pat. presented with an abnormal HLC ratio with the majority of pat. (84%; 70/83 pat.) also presenting with an uHLC. There was no association between uHLC levels and the detection of a t(4;14) (p=0.155), del17p13 (p=0.927) or 1q21+ (0.775). uHLC levels associated with PFS, both when tested as a continuous (hazard ratio (HR): 1.06; p=0.086), or as a categorical (HR: 1.84; p=0.062) variable using uHLC levels<0.26 (for IgG) and<0.36 (for IgA) g/L as cut-offs; with results approaching significance. Different models combining ISS and cytogenetic markers showed a trend towards better PFS for low-risk compared to intermediate / high-risk patients: IMWG (not reached (n=50) v 30.3 (n=33) mo; p=0.139); IMWG-consensus (not reached (n=19) v 31.9 (n=64) mo; p=0.165); MRC (not reached (n=42) v 30.3 (n=41) mo; p=0.056). In contrast, the addition of uHLC as a risk factor identified an increased number of intermediate / high-risk patients previously deemed as low-risk and improved the stratification of patients: IMWG + uHLC (not reached (n=38) v 28.4 (n=45) mo; p=0.015); IMWG-consensus + uHLC (not reached (n=16) v 31.4 (n=67) mo; p=0.105); MRC + uHLC (not reached (n=31) v 29.2 (n=52) mo; p=0.009).

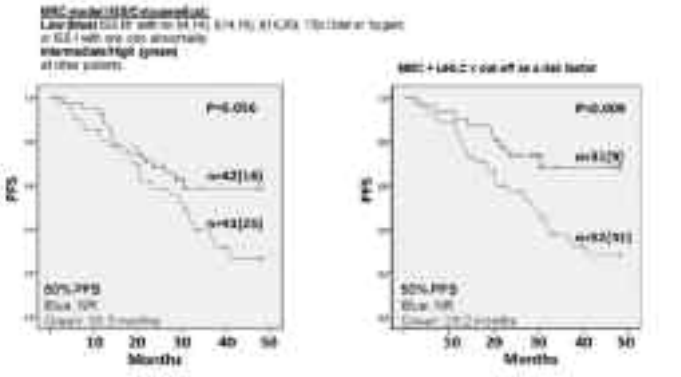

Figure 1.

Summary and Conclusion: Incorporation of the isotype matched immunoglobulin suppression refines current risk models in MM after autoPBSCT and identifies pat. with a particular good prognosis.

P1002

BONE MARROW ASPIRATION SIGNIFICANTLY UNDERESTIMATES THE BURDEN OF DISEASE IN MULTIPLE MYELOMA AT DIAGNOSIS AND FOLLOW UP COMPARED WITH THE BONE MARROW TREPHINE

A Thomas[1,*], D A Hughes[1], A Mehta[1], A Wechalekar[1], C McNamara[1]

[1]Haematology, Royal Free Hospital, London, United Kingdom

Background: The estimation of plasma cell percentage (PC%) on bone marrow biopsies (BM) remains a key feature in the laboratory diagnosis and monitoring of multiple myeloma (MM). BM aspirates (BMA) and BM trephines (BMT) are often reported independently. There is a perception that both techniques give different estimates of disease burden. Not only do BM represent a significant workload to laboratories but lack of standardisation and integrated reporting risks misdiagnosis and mis-classification of response.

Aims: To evaluate the difference in estimation of PC% on BMA and BMT and the potential clinical significance of these differences in the diagnosis and management of patients with MM.

Methods: Patients attending the myeloma clinic at the Royal Free Hospital who had BM biopsies performed from 1999-2014 were identified. Results were retrieved from the pathology results system to identify patients who had had both a BMA and BMT performed. The absolute difference in reported PC% between BMA and BMT, performed at different time points during diagnosis and

management was calculated and the ratio of PC% in the BMT to BMA calculated. The bone marrow criteria of the International Working Group on Myeloma for diagnosis (≥10% PC) and response (<5% PC) were used to assess the potential clinical significance of differences in PC%.
Results: 528 paired BMA and BMT were performed. 68 (12.9%) BMA were dilute/aparticulate and 12 (2.3%) trephines were inadequate for diagnosis; qualitative rather than quantitative reports were issued for 41 samples. PC% was reported on 136 diagnostic samples. The median PC% on BMA and BMT was 18.5% (range 0.5-98%) and 40% (range 5-95%) respectively with a mean difference in PC% between BMA and BMT of 22.6% (range -15% to 75%, p<0.0001); reported PC% was on average 4.03 times higher in BMT than BMA (range 0.67-70). In 40/136 (29.3%) cases the PC% was<10% on the BMA but ≥10% on the BMT. PC% was reported for 142 BM performed to assess treatment response. The median PC% on BMA and BMT was 3% (range<0.5-79%) and 10% (range 4-95%) respectively with a mean difference in PC% between BMT and BMA of 12.6% (range -15% to 78%, p<0.0001); reported PC% was on average 8.04 times higher in BMT than BMA (range 0.25-60). In 44/142 (31%) cases, the BMA was consistent with a CR, but this was not supported by the BMT. In only 1 case was the BMT consistent with a CR but the aspirate was not. PC% was reported for 113 BM performed for possible relapse. The median PC% on BMA and BMT was 14% (range 0.5-77%) and 30% (range 1-100%) respectively with a mean difference in PC% between BMA and BMT of 18.2% (range -28% to 81%, p<0.0001); PC% was on average 3.5 times higher in BMT than BMA (range 0.33-35). 18 BM were performed for cytopenias in 9 patients. Two patients had developed acute myeloid leukaemia, with circulating blasts on the peripheral blood film and one had developed MDS. In other patients cytopenias were attributed to either disease infiltration (3) or treatment effects (3).
Summary and Conclusion: There is a clinically significant discordance between PC% reported on BMA or BMT, manifesting either as under-estimation of disease burden by BMA or over-estimation by BMT, both at diagnosis and in assessment of treatment response. International consensus is needed to develop guidance on estimation of PC% in the BM in MM to ensure uniformity of reporting and to rationalise laboratory workloads.

P1003

AUTOIMMUNE DISEASES IN COURSE OF IMIDS: SELECTIVE OCCURRENCE AFTER LENALIDOMIDE

V Montefusco[1,*], M Galli[2], F Spina[1], F Rezzonico[1], A Mussetti[1], G Perrone[1], C De Philippis[1], S Dalto[1], F Maura[1], L Roncari[1], A Dodero[1], L Farina[1], C Caprioli[2], P Stefanoni[2], A Corso[3], P Corradini[4]
[1]Hematology and Pediatric Oncohematology, FONDAZIONE IRCCS ISTITUTO NAZIONALE TUMORI, Milano, [2]Hematology, Ospedali Riuniti, Bergamo, [3]Hematology, Ospedale San Matteo, Pavia, [4]Chair of Hematology, University of Milan, Milano, Italy

Background: Immunomodulatory drugs (IMiDs) are active drug for the treatment of multiple myeloma (MM), and have important immunomodulatory properties. This activity may contribute to autoimmune diseases (ADs) occurrence. Despite some case reports, a systematic evaluation on ADs after IMiDs is still lacking.
Aims: To evaluate the occurrence of ADs and describe their characteristics in a cohort of patients affected by MM treated with IMIDs.
Methods: We conducted a retrospective study on consecutive IMID-treated MM patients at two Italian hematologic referral centers. Patients were grouped into three classes depending on the type of IMID used. The first group was composed of patients treated only with thalidomide (Thal) (n=474), the second group with lenalidomide (Len) (n=140), and the patients in the third group were first treated with Thal and then with Len (Thal-Len) (n=94).
Results: A previous AD before MM diagnosis was documented in 7 out of 474 patients (1.5%) in the Thal group, in 8 out of 140 patients (6%) in the Len group, and in one (1%) in the Thal-Len. The median line of therapy in which the IMID was used was 1 (range 1-4) in the Thal group, 1 (range 1-4) in the Len group, while in the third group the median line of therapy for Thal was 1 (range 1-3), and 3 for Len (range 1-6). Median therapy duration of IMIDs in the Thal group was 6 months (range 1-161), and 9 months (range 1-89) in the Len group. In the third group Thal treatment had a median duration of 6 months (range 1-94), and of 5 months (range 1-62) for Len. Two (0.4%) ADs cases have been observed in the Thal group: one autoimmune anemia (AHA) at 6 months and one vasculitis at 5 months. In the Len group 6 (4%) patients developed an AD, in particular: one AHA at 3 months, one idiopatic thrombocytopenic purpura (ITP) at 2 months, one Evans syndrome (combination of AHA and ITP) at 3 months, one optic neuritis at one month, one Grave's disease at one month, and one polymiositis at 42 months. In the Thal-Len group no ADs were observed after Thal, while one case of ITP occurred after Len at one month. All ADs were managed with Len discontinuation and steroid treatment, except for Grave's disease, which required thyroidectomy, and the polymiositis, which was fatal. Absolute risk of developing an AD was 0.4% for patients treated with Thal, 4.3% for Len, and 1.1% for the Thal-Len group. In univariate analysis ADs occurrence was more common after autologous transplantation (p=0.003), while history of ADs, previous number of therapy lines, disease status at AD occurrence, previous allogeneic transplantation, and type of drugs in combination with the IMiD had not impact. Also in multivariate analysis a previous autologous transplantation was the only factor associated with an increased risk of ADs (p=0.01). Interestingly, the timing of AD occurrence revealed a double pattern, with a clustering in the first 3 months in 6 out 9 cases, and a later occurrence in the remaining patients.
Summary and Conclusion: This is the first report to describe the occurrence of ADs in a large cohort of IMiD treated patient. Despite low, the incidence was not negligible in Len-treated patients, and a previous autologous transplant was shown to be a significant risk factor. ADs consisted mainly of autoimmune cytopenias, but other organs can be involved. In most cases the AD resolved after IMiD discontinuation and steroid treatment, however, a case of polymiositis was fatal. Our data may be helpful to the clinician in the interpretation of specific clinical conditions, such as cytopenias that occur in the early phase of treatment, and, more generally, in the clinical management of MM Len-treated patients.

P1004

IMPACT OF NFKB1-94INS/DEL ATTG POLYMORPHISM ON DISEASE CHARACTERISTICS AND TREATMENT OUTCOME ON BORTEZOMIB BASED THERAPY IN PATIENTS WITH MULTIPLE MYELOMA

G Varga[1,*], H Andrikovics[2], M Koszarska[2], A Bors[2], T Krahling[2], A Kozma[3], E Adam[3], G Mikala[3], M Peto[3], Z Farkas[3], J Fabian[3], A Tordai[2], T Masszi[3]
[1]Semmelweis University, [2]Hungarian National Blood Transfusion Service, [3]St. Istvan and St. Laszlo Hospital, Budapest, Hungary

Background: NFκB1 complex plays important role in pathogenesis of multiple myeloma (MM), as it is associated with the immune response, inflammatory, apoptosis as well as with growth and survival of malignant plasma cells. NFκB1 -94ins/delATTG polymorphism affects promoter activity of the NFκB1 gene.
Aims: To find association between NFκB1 -94ins/delATTG and the MM susceptibility, age at diagnosis, the presence of bone lesion, the type of monoclonal protein, cytogenetics and prognostic stratification according to the International Staging System (ISS) and to investigate the treatment outcome in symptomatic myeloma patients with upfront bortezomib based therapy.
Methods: NFκB1 -94ins/del ATTG were tested applying PCR restriction fragment length polymorphism (RFLP) technique in a group of 315 patients diagnosed with multiple myeloma and 148 healthy blood donors. Treatment outcome was investigated in a selected subcohort, consisting of 153 patients, receiving upfront bortezomib based therapy.
Results: Allele frequency (±95%CI) of 94ins/delATTG was 40.5±3.9% in MM patients and 38.6±5.6% in healthy controls (p=0.5). No association has been found between NFκB1 polymorphism and age at diagnosis, the type of the monoclonal protein (non secretory MM, light chain only, light and heavy chain complex) or cytogenetics (hyperdiploid *vs*. immunoglobulin heavy chain translocations). Patients with homozygous insertion (I/I genotype) tended to be diagnosed in more advanced stages (stage 2 and 3 according to the ISS) compared to deletion carriers (I/D and D/D genotypes) [73% (66/91) *vs*. 61% (107/176), p=0.06]. In case of upfront bortezomib therapy I/I patients (n=45) had significantly better progression free survival (PFS) comparing to deletion carriers (n=66) [64.6±7.7% *vs*. 47.3±7.3% at 2 years, p=0.035]. ISS before bortezomib therapy was also proved to be a significant prognostic factor [ISS1 65.7±8.2% (n=40) *vs*. ISS2 62.7±9.0% (n=37) *vs*. ISS3 44.2±6.2% (n=76) at 2 years, p=0.007]. NFκB1 polymorphism influenced survival in non-advanced stages (ISS1; p=0.024 and ISS2; p=0.033), but not in ISS3 (p=0.551). In multivariate analysis NFκB1 polymorphism was proven to be an independent prognostic factor regarding PFS in patients with upfront bortezomib based therapy, in addition to ISS and age [HR: 0.564 (0.328-0969); p=0.038]. Similar therapeutic impact of NFκB1 polymorphism could not be observed in patients who received bortezomib at relapse or therapy resistance.
Summary and Conclusion: NFκB1 -94ins/delATTG is not a susceptibility factor for the development of MM, and it does not influence the clinical characteristics at diagnosis. NFκB1 -94ins/delATTG insertion homozygous patients experience a progression-free survival benefit on bortezomib based upfront therapy.

P1005

THIRD AUTOLOGOUS SALVAGE STEM CELL TRANSPLANT IN SUBJECTS WITH ADVANCED MULTIPLE MYELOMA

S Strifler[1,*], M Kleber[2], L Rasche[1], M Schreder[1], S Danhof[1], M Engelhardt[1], H Einsele[1], S Knop[1]
[1]University hospital of Wuerzburg, Wuerzburg, [2]Universitiy hospital of Freiburg, Freiburg, Germany

Background: High-dose chemotherapy followed by autologous stem cell transplantation (ASCT) has remained a standard of care in first-line treatment of multiple myeloma (MM) since the late 1990s. Virtually all patients (pts), however, will experience disease progression requiring active salvage treatments. As thalidomide, bortezomib, and lenalidomide alone or in combination are liberally used, pts will eventually present with resistant relapse. In addition to the long interval since the initial administration of melphalan,

exhausted bone marrow function may be a good reason to consider a further autotransplant. A second ASCT has proven feasible and effective in several retrospective series.
Aims: Whether a third salvage transplant is of comparable value to patients who have initially received tandem ASCT (still frequently used in Germany as initial treatment approach) is unclear. Therefore, we assessed the outcomes of pts receiving a third salvage ASCT (ASCT3) from two large German myeloma centres.
Methods: We queried the databases of Wuerzburg and Freiburg University Medical Centres for cases that were offered a third autotransplant after unique melphalan-based tandem ASCT as their first line therapies.
Results: We identified 37 pts with a median age of 63 (range, 48 – 77) years at their third salvage ASCT which occurred at a median of 58 (range, 72 – 349) mos. from myeloma primary diagnosis and a median interval from initial tandem autotransplant of 47 (range, 5 – 115) mos.. Median progression-free survival (PFS) from primary tandem ASCT had been 20 (range, 26 – 3) months. 31 pts (84%) had received IMiDs and/or bortezomib (27 had received both, 7 had been IMiD-naïve and 6 Bortezomib-naïve, respectively. 23 pts. (62%) had been refractory to lenalidomide, as well as 62% to bortezomib, 19% of the pts even had been double-refractory to both "novel compounds" prior to their 3rd transplant. At ASCT3, 32 pts received autografts which had been harvested at first-line treatment and 5 pts had undergone additional stem cell mobilisation. Median number of reinfused CD34+ cells was 3.15 (1 – 8.2) x10exp6/kg body weight with all patients achieving stable engraftment measured by improvement of platelet (PLT) and haemoglobine (Hb) count within 3 mos. of ASCT3 (PLT improvement in 65% and Hb improvement in 73%, respectively). Within 12 mos. from ASCT3 one patient died due to non-relapse associated cause (non-relapse mortality 2.7%). Overall response rate (partial response [PR] or better) was 54%; 4 pts achieved CR, 5 pts VGPR, respectively; 11 pts reached PR after ASCT3.
Summary and Conclusion: This retrospective analysis shows ASCT3 to be a very well tolerated salvage option in pts who have exhausted "novel compound"-based treatments in earlier relapse of MM. Interestingly, median duration of storage of their autografts of 46 (range, 1 – 152) mos. did not impair engraftment after salvage transplant. Median OS of 10 mos. from ASCT3 indicates that further salvage options still might be of some value in these "very late stage" MM pts.

P1006

TREATMENT WITH THE BILE-ACID SEQUESTRANT COLESEVELAM IMPROVES LENALIDOMIDE ASSOCIATED DIARRHOEA IN MYELOMA PATIENTS

C Pawlyn[1,*], M S Khan[2], F E Davies[1], P Sriskandarajah[1], M Kaiser[1], J Andreyev[2], G J Morgan[1]
[1]Centre for Myeloma Research, Institute of Cancer Research and Royal Marsden Hospital, [2]Gastroenterology, Royal Marsden Hospital, London, United Kingdom

Background: There is increasing evidence for the long term use of lenalidomide for the treatment of multiple myeloma at induction, relapse and as maintenance following ASCT. In studies at all stages of disease maximum benefit has been gained by continuing treatment beyond best response until relapse, requiring patients to remain on treatment long term and making the management of side effects particularly important. The side effect profile of lenalidomide is predominantly early with skin rash and myelosuppression dominating, however later during treatment a proportion of patients develop diarrhoea that can be difficult to manage.
Aims: To identify the cause of diarrhoea associated with lenalidomide treatment for myeloma.
Methods: In our institution, all patients with gastrointestinal (GI) symptoms arising during and after chemotherapy treatment are seen and investigated in a specialist Gastroenterology/Oncology clinic using a peer-reviewed algorithm. All patients underwent investigations for the presence of coeliac disease, inflammatory bowel disease, colonic neoplasia, small bowel bacterial overgrowth and bile acid malabsorption using SeHCAT scanning. SeHCAT (^{75}selenium homocholic acid taurine) scanning is a simple non-invasive test for bile acid malabsorption with a sensitivity of 90-98% and specificity of 100%. We carried out a retrospective analysis of all myeloma patients referred to the clinic between April 2011 and April 2013 with diarrhoea whilst on lenalidomide, in order to audit their investigations and outcomes and identify the cause of their diarrhoea.
Results: 4 male and 7 female patients (median age 66 years, range 48-79) who developed diarrhoea while on lenalidomide treatment for myeloma were referred to the gastroenterologist. 45% had normal bowel function before starting lenalidomide, 55% had a degree of mild gastrointestinal dysfunction with a tendency to occasional loose stools before treatment but had not undergone previous GI investigations. Worsening GI symptoms started a median of 5 months (range 1-15) after lenalidomide initiation. These symptoms included diarrhoea (100%), urgency (91%), faecal incontinence (64%) and abdominal cramps (45%). A positive glucose hydrogen methane breath test raised the possibility of bacterial overgrowth in some cases but empirical antibiotic treatment did not resolve the diarrhoea. SeHCAT results confirmed bile acid malabsorption (BAM) in all cases, 8 had severe BAM (<5% SeHCAT seven day retention), 2 moderate (5-10%) and 1 mild (10-15%). To confirm BAM as the cause of the diarrhoea, patients were treated with advice to reduce dietary fat intake to 20% of total calories or colesevelam, a bile acid sequestrant or both. Nine patients were started on colesevelam. This was given at a dose of 625mg 3 times per day, building up to 6 times per day. All patients had a significant improvement in symptoms, often within just a few weeks. Two patients had resolution of diarrhoea on a low fat diet alone and did not require colesevelam. With these strategies no patient needed lenalidomide dose reduction or to stop treatment due to their diarrhoea.
Summary and Conclusion: Bile acids are reabsorbed predominantly via passive diffusion in the small intestine with additional active absorption at the terminal ileum. Normally, 95% are reabsorbed. When this process is disrupted and higher levels of bile acids reach the colon there is an increase in watery stool leading to diarrhoea. We describe a link between lenalidomide treatment and BAM that is easily identified and managed thereby improving the tolerance of lenalidomide and enabling patients to remain on treatment long term. Research to establish the molecular mechanism whereby lenalidomide induces BAM should be performed.

P1007

PHASE II TRIAL TO INVESTIGATE EFFICACY AND SAFETY OF BENDAMUSTINE, DEXAMETHASONE AND THALIDOMIDE IN RELAPSED OR REFRACTORY MULTIPLE MYELOMA PATIENTS AFTER TREATMENT WITH LENALIDOMIDE AND BORTEZOMIB

M Mian[1,*], N Pescosta[2], S Luminari[3], S Badiali[3], L Marcheselli[3], F Patriarca[4], R Zambello[5], P Mondello[6], A Pascarella[7], A Marabese[1], V Pitini[6], S Cortelazzo[8]
[1]Hematology & CBMT, [2]Hospital of Bolzano, Bolzano, [3]Department of Oncology and Hematology, University of Modena and Reggio Emilia, Modena, [4]Azienda Ospedaliera-Universitaria, Udine, [5]Padua University School of Medicine, Padova, [6]University of Messina, Messina, [7]Ospedaledell'Angelo, Venezia-Mestre, Mestre, [8]Humanitas/Gavazzeni Cancer Center, Bergamo, Italy

Background: Despite the introduction of new and efficient drugs for multiple myeloma (MM) treatment, mainly bortezomib-based multidrug regimens, most patients relapse and lenalidomide based also provide only a temporary disease free state. After the third relapse the prognosis is usually dismal and new therapeutic approaches are needed.
Aims: The aim of this trial is to assess the tolerability and efficacy of bendamustine in association with dexamethasone and thalidomide (BDT) in relapsed/refractory patients after lenalidomide and bortezomib or who are ineligible to these drugs.
Methods: The primary endpoints of this multicenter phase II trial were the assessment of efficacy, in an intention to treat analysis, and toxicity. Treatment consisted of bendamustine (60mg/m^2, d 1, 8, 15), dexamethasone (20mg, d 1, 8, 15, 22) and thalidomide (100mg, d1-28) repeated every 28 days for 6 cycles.
Results: Up to now 18 of the planned 30 patients were enrolled and completed at least the first therapy cycle. They underwent a median of 2 previous treatment lines (range 1-6). Median age was 60 years and most patients presented with an ISS-1 (61%), a good performance status (50%) and had a IgG kappa monoclonal component (33%). 4 patients completed the planned treatment and another 4 underwent ≥4 treatment cycles. Treatment was usually well-tolerated and overall only 4 patients experienced grade 3/4 hematologic toxicity. During 53 cycles, 5 treatment related serious adverse events (9%) were recorded (3 cases of pneumonia, 1 cerebral hemorrhage, 1 deep vein thrombosis and 1 pulmonary embolism), leading to death in 2 patients (4%). Of note note, no grade 3/4 neurologic toxicity has been observed. Up to now the ORR was 5/9 (55%): 3 very good partial remissions and 2 partial remissions. Other 2 patients had stable disease and 2 progressed during treatment after 2 and 4 treatment cycles, respectively and died.

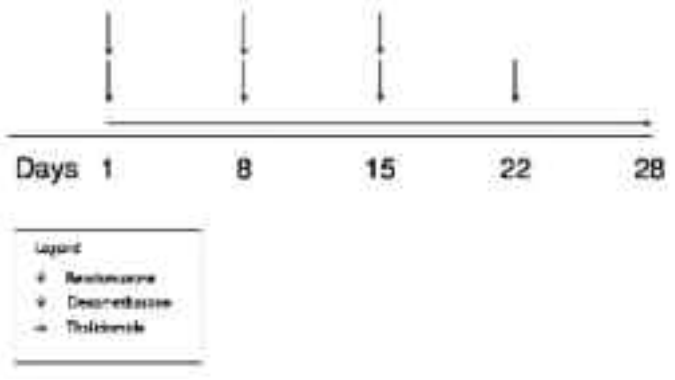

Figure 1.

Summary and Conclusion: In this interim analysis, BDT demonstrated to be an effective regimen for relapsed/refractory MM patients. The toxicity, as expected, in these heavily pretreated patients was not negligible, but manageable and no grade 3/4 neurologic side effect was observed.

P1008

PROGNOSTIC IMPACT OF IMMUNOPHENOTYPIC RESPONSE AND NORMALIZATION OF SERUM FREE LIGHT CHAIN AMONG PATIENTS WITH MULTIPLE MYELOMA

M Fukaya[1,*], Y Suehara[1], K Seike[1], K Fukumoto[1], M Fujisawa[1], H Sugihara[1], Y Nishida[1], M Takeuchi[1], K Matsue[1]
[1]Hematology, Kameda Medical Center, Kamogawa city, Japan

Background: With the development of novel therapeutic agents, more than 30% of patients with multiple myeloma (MM) achieve complete response (CR) as defined by the International Myeloma Working Group (IMWG). However, most patients that achieve CR ultimately die due to relapse, suggesting the presence of minimal residual disease (MRD) in these patients. Multicolor flow cytometry (FCM) allows the detection of$<10^{-4}$ clonal plasma cells in normal bone marrow cells and has been used for detecting MRD after treatment. FCM-defined immunophenotypic response (IR) has emerged as a more relevant prognostic factor in patients with MM. However, the relevance of the prognostic impact of IR and the normalization of serum free light chain (sFLC) ratio remain unclear.
Aims: We retrospectively analyzed the impact of FCM-defined CR (iCR), conventional immunofixation negative CR (CR), and CR plus FLC κ/λ normal CR (sCR) on the prognosis of 86 patients with MM who obtained more than very good partial response (VGPR) at Kameda Medical Center, Kamogawa, Japan.
Methods: Among the 164 patients treated at our hospital between April 2005 and December 2013, 86 patients that achieved more than VGPR (50 CR, 36 VGPR) were included in this study. The study population consisted of 50 males and 36 females with a median age of 71 years. All patients received at least one course of novel agent-containing therapeutic regimen. Treatment responses were assessed using the IMWG criteria, and the best response to treatment during the course of disease was assessed by simultaneous analysis by serum immunofixation, sFLC measurements, and FCM analysis of bone marrow plasma cells. FCM-defined MRD was evaluated by single-tube 6-color FCM, CD45-CD38 gating strategy, and combination analysis by CD19, CD56, and cytoplasmic κ/λ. Negativity of clonal PCs was defined as less than 10^{-4} neoplastic PCs in bone marrow samples determined by FCM. Overall survival (OS) and progression-free survival (PFS) were analyzed by the Kaplan–Meier method, and differences between curves were calculated by two-sided log-rank test. Subjects were classified into four categories, *i.e.*, MFC positive or negative and κ-λ ratio normal or abnormal, and PFS and OS were compared between groups.
Results: At a median follow-up of 38.7 months, 3- and 5-year overall survival rates of all of the patients with more than VGPR were 94% and 79.2%, respectively. Achievement of normal sFLC ratio was observed among 64% of the CR patients and 55% of VGPR patients. Kaplan–Meier estimated 3- and 5-year OS in patients with CR were 100% and 76%, respectively. Among 50 patients with CR, normalization of sFLC κ/λ and MRD negativity were achieved in 31 (62%) and 19 (34%) patients, respectively. Among 31 CR patients with normal sFLC κ/λ, 12 were MFC-negative and 19 were MFC-positive. MFC was positive in 12 (63%) and negative in 7 patients (37%) among the 19 CR patients with abnormal sFLC κ/λ. Among 36 patients with VGPR, 20 patients (55%) obtained normal sFLC κ/λ and 5 (14%) obtained MFC negativity. Seventeen of 31 MFC-positive patients with VGPR had normal sFLC κ/λ. Patients who achieved FCM negativity did not relapse within a median observation period of 82.6 months, and they were superior PFS and OS compared to those who did not, especially in the group that achieved CR ($P = 0.016$ and $P = 0.003$, respectively). In the VGPR group, although achievement of normal sFLC κ/λ or MFC negativity did not show survival advantage in PFS, they tended to exhibit superior survival compared to those who did not.
Summary and Conclusion: Although both normalization of sFLC κ/λ and achievement of FCM negativity are important for longer PFS and OS, obtaining MFC negativity seems to have greater implications for longer survival.

P1009

EVALUATION OF VAD PROTOCOL IN MULTIPLE MYELOMA OVER A PERIOD OF 10 YEARS

B Fatiha[1,*], M hanan[1], AA nacera[1], T farida[1], A naima[1], B fateh[1], T amina[1], A sabrina[1], H RM[1]
[1]Hematology and Bone Marrow Transplant, Pierre and Marie Curie Center, Algiers, Algeria

Background: In Algeria, multiple myeloma (MM) is ranged with non-Hodgkin's lymphoma at the 3rd place of hematological malignancies with an incidence of 0.63/100000 inhabitants. Treatment is necessary for the symptomatic myeloma. The treatment choice depends largely on the patient's age. VAD (vincristine, adriamycin, dexamethasone) has long been the reference induction treatment of young patients, in whom high dose chemotherapy (HDC) therapy with autologous stem cell transplantation (ASCT) is planned. We report in this study the results of VAD treatment in a series of patients under 66 years old of age over 11 years of follow up.
Aims: Over a period of 11 years (2000-2010), 410 pts with MM were diagnosed and156 pts aged less than 66 years treated with VAD: 83 male and 73 female (sex ratio: 1.1). The median age was 54 years (32-65). Thirteen pts (08%)<40 years old. The most frequent sign at diagnosis is pain syndrome 129 pts (83%), anemia syndrome: 12 pts (8%) and plasma cell mass: 5 pts.
Methods: The median time to diagnosis: 5 months (0-24 months). The median rate of Hb: 9g/dl (3-14), hyper calcemia >120 mg /l: 37 pts (24%), serum creatinine>20 mg /l: 52 pts (33%). Rate of albumin<35g /l in 71 pts (45%). Monoclonal peak: 128 pts (82%), with a peak ≥ 50 g /l: 55 pts (43%), which is represented by an IgG: 88 pts (56%), IgA: 29 pts (18%), IgD: 3, biclonal IgG / IgA: 1pt, 25 cases of light chains MM, non-secreting: 3 pts and unspecified type in 7 pts. On radiology, diffuse bone lesions: 139 pts (89%) and spinal cord compression: 19 pts (12%). According to Salmon-Durie staging system: stage III: 150 pts (96%) including 52 pts (33%) stage B, stage II: 4 pts and stage I: 2 pts, Stage A: 104 pts (67%). International Staging System(ISS) used in 59 pts (38%) I: 17 pts, II: 16 pts, III: 26 pts. At December 2012, the median follow-up is 68 months (26-144).
Results: Thirty-four pts are no evaluable because early death after 1-2 cycles. One hundred and twenty two pts are evaluable, the average of overall response (OR) after 4 cycles was 71% (87 pts) with 22% (27 pts) in complete remission (CR) and 49 % (60 pts) in partial remission (PR). Twenty-nine percent (35 pts) was in treatment failure. HDC with ASCT: 63 pts (51%), with status before autologous: 23 CR, 27P R, 13in treatment failure. After HDC with ASCT: 4 pts died during the procedure (3 infectious syndromes and one pulmonary embolism), 47in CR, 10 in PR and 2in procedure failure. At December 2012: 17 pts were still alive (10 CR, 6 PR, 1 failure) and 46 pts died. The overall actuarial survival and the event-free survival are res 22% and 18% pectively
Summary and Conclusion: Conclusion: In this study, it appears that VAD induce a good immediate response but not permanent over time, which implies the need for a maintenance treatment also for pts with or without HDC.

Bone marrow failure syndromes & PNH

P1010

A SIMPLE METHOD TO DETECT COPY NUMBER-NEUTRAL 6P-LOH IN PATIENTS WITH ACQUIRED APLASTIC ANEMIA USING DUPLEX QUANTITATIVE PCR

Y Zaimoku[1,*], H Maruyama[1], A Amano[1], N Nakagawa[1], C Saito[1], T Katagiri[1], H Takamatsu[1], H Yamazaki[1], K Kashiwase[2], S Nakao[1]
[1]Cellular Transplantation Biology, Kanazawa University, Kanazawa, [2]Japanese Red Cross Kanto-Koshinetsu Block Blood Center, Tokyo, Japan

Background: The presence of HLA allele-lacking leukocytes (HLA-LLs) due to copy number neutral loss of heterozygosity (LOH) as a result of uniparental disomy in the short arm of chromosome 6 (CNN-6pLOH) is compelling evidence for the immune pathophysiology of acquired aplastic anemia (AA), and may serve as a predictor of the response to immunosuppressive therapy. However, the high expenses associated with the SNP array analysis hinder the popularization of detecting 6pLOH in the management of AA. The presence of 6pLOH can also be estimated by detecting HLA-LLs using flow cytometry with monoclonal antibodies specific for HLA-A alleles, but this assay cannot be applied for a substantial number of homozygotes for the HLA-A allele, or for those harboring HLA-B*40:02, an allele closely associated with the immune pathophysiology of AA, against which monoclonal antibodies are not available.
Aims: To establish a cost-effective and reliable method for detecting 6pLOH involving class I HLAs, especially the one involving HLA-B*40:02, in the leukocytes of AA patients, we examined the usefulness of duplex quantitative real-time PCR (2qPCR), and applied this method to detect 6pLOH involving HLA-B and -C loci.
Methods: 2qPCR was designed to compare the copy number of each allele in individuals heterozygous for the HLA-B or -C alleles. The 2qPCR allows the simultaneous amplification of each HLA-allele from genomic DNA in a single reaction. The PCR mixture contains two different TaqMan probes that are complementary to respective SNP sequences specific for individual HLA alleles, which are labeled with different fluorochromes (FAM and VIC), as well as one primer pair complementary to consensus sequences. Fluorescent intensity for each allele was plotted on the X-axis and Y-axis. The presence of 6pLOH led to deviation of tested samples from standard line generated from the heterozygotes, and 6pLOH clones were regarded to be significant if the distance of the sample dots from the standard line exceeded that of control dots that occurred as a result of nonspecific dispersion. The 6pLOH clone size could be estimated by the degree of deviation. The TaqMan probe mixtures (mixtures B and C) were designed to distinguish HLA-B*40:02 from the majority of the other HLA-B alleles, and HLA-C*03 from the other HLA-C alleles, respectively: HLA-C*03:03 and *03:04 are highly associated with HLA-B*40:02 due to linkage disequilibrium in Japanese population. Approximately 50% of Japanese individuals and 90% of those possessing at least one HLA-B*40:02 allele were expected be analyzable using the B or C reaction mixtures.
Results: Six 6pLOH (+) cases that had previously been identified by the SNP array were found to be positive for 6pLOH by the 2qPCR analysis. The estimated 6pLOH clone sizes were similar between the SNP array (range, 5.6% to 53.9%, median 19.6%) and the 2qPCR analysis (range, 11% to 48%, median 13%). When a new AA patient set was analyzed by 2qPCR, 6pLOH was found in 10 of 68 patients (15%), and the median clone size was 14% (range, 4%–50%). Six of the ten 6pLOH (+) cases were heterozygous for the HLA-A allele and were therefore analyzable with flow cytometry. HLA-LLs were detectable in all of the six patients. Consistent with our previous data, HLA loss due to 6pLOH was more frequently found in HLA-B*40:02 allele, compared to those with the other HLA-B alleles (20%, 6/30 *vs* 3.8%, 4/106; *P*=0.008). The 2qPCR assay was completed within three hours after DNA preparation.
Summary and Conclusion: A rapid and cost effective method for detecting 6pLOH with high sensitivity and specificity was established. We are conducting mass screening of AA patients' samples for the presence of 6pLOH. The 2qPCR method confirmed the preferential loss of HLA-B*40:02 due to 6pLOH in AA. Further studies to clarify the pathogenic antigens presented by HLA-B*40:02 are therefore warranted.

P1011

EPIGENETIC ALTERATIONS IN FANCONI ANAEMIA: ROLE IN DISEASE PROGRESSION AND THERAPEUTIC POTENTIAL

H Belo[1,*], G Silva[1], B A Cardoso[1], B Porto[2], J Barbot[3], J Coutinho[3], J Bueren[4], J Surralles[5], J Casado[4], M Benedito[6], H Saturnino[6], E Costa[3], A Almeida[1]
[1]Institute Portuguese of Oncology, Lisbon, [2]Laboratório de Citogenética do Instituto de Ciências Biomédicas de Abel Salazar, [3]Unidade de Hematologia Pediátrica do Centro Hospitalar do Porto, Porto, Portugal, [4]Hematopoiesis and Gene Therapy Division, CIEMAT, Madrid, [5]Genetics and Microbiology, Universidad Autonoma, Barcelona, Spain, [6]Serviço de hematologia do Centro Hospitalar e Universitário de Coimbra, Coimbra, Portugal

Background: Fanconi anaemia (FA) is an inherited disorder characterized by chromosomal instability, progressive bone marrow failure and increased incidence of haematological and non-haematological malignancies. Mutations in 16 FA genes have been identified which disrupt a DNA repair complex, resulting in increased chromosomal fragility. However, the phenotype is variable even amongst patients from the same family and with the same mutation. This raises the possibility that other factors, such as epigenetic modifications, may affect the disease phenotype. Epigenetic changes play an important role in oncogenesis of several haematological malignancies and solid tumours. These changes may be pharmacologically manipulated with DNA hypomethylating agents and histone deacetylase inhibitors.
Aims: The aim of our project was to explore whether the epigenetic profiles in FA differ from non-FA individuals and whether these could be manipulated to alter the disease phenotype.
Methods: We assessed the expression level of Epigenetic genes by Q-PCR on twelve blood samples from FA patients and 15 healthy volunteers using an 84 epigenetic gene PCR array. The same samples were used in a methylation array to study the DNA methylation profile of tumour suppressor genes. To test the effect of Vorinostat on chromosomal instability in FA, we treated mononuclear blood cells from different patients with Vorinostat and quantified the percentage of DEB-induced chromosomal breakages by cytogenetic analysis.
Results: As compared to unaffected cells, FA patients had decreased expression levels of genes involved in DNA methylation (DNMT1, DNM3Tβ), genes encoding proteins that regulate the activity of histones by acetylation (CIITA), phosphorylation (PAK1), ubiquitination (RNF20), deacetylation (HDAC2, HDCA8, HDAC9, HDAC10, HDAC11) and methylation (SETD6). We also assessed methylation status of tumor suppressor gene promoters in one FA patient and found that the FA patient had global hypomethylation in the promoter regions of tumour suppressor genes as compared to non-FA individuals, which is a frequent early event in cancer, and correlates with severity of disease. Following incubation with Vorinostat, FA cells exhibited increased expression of DNM3Tβ, but reduced expression of CIITA, HDAC9, PAK1, and USP16, all involved in different aspects of epigenetic and immune regulation. Given the ability of Vorinostat to modulate epigenetic genes in FA patients, we investigated its functional effects on the FA phenotype. Treatment of FA cells with Vorinostat significantly reduced the number of DEB-induced breaks per cell and decreased by 80% the number of aberrant cells produced by this DNA cross-linking agent.
Summary and Conclusion: We identified different epigenetic patterns in FA cells relative to non-FA cells, indicating that epigenetic changes might play a role in the pathophysiology of FA. The reduction in chromosomal breaks by Vorinostat suggests it might have a therapeutic effect in FA. The use of Vorinostat is attractive in the context of FA since FA patients are extremely sensitive to chemotherapy and radiotherapy commonly used to treat tumors of these patients.

CHRONIC IDIOPATHIC NEUTROPENIA DOES NOT DISPLAY FREQUENT STAT3 MUTATIONS: IMPLICATIONS FOR DIFFERENTIAL DIAGNOSIS FROM OTHER CLINICAL SYNDROMES WITH T-CELL-MEDIATED SUPPRESSION OF HEMATOPOIESIS

E Stalika[1,2,*], I Mavroudi[3], K Gemenetzi[2], A Anagnostopoulos[2], A Makris[1], S Mastrodemou[3], P Kanellou[3], H Papadaki[3], K Stamatopoulos[1,2,4]
[1]Institute of Applied Biosciences, CERTH, [2]Hematology Department and HCT Unit, G. Papanicolaou Hospital, Thessaloniki, [3]Department of Haematology, University of Crete, Heraklion, Greece, [4]Department of Immunology, Genetics and Pathology, Science for Life Laboratory, Uppsala University, Uppsala, Sweden

Background: Chronic Idiopathic Neutropenia (CIN) is a benign disorder of granulopoiesis characterized by prolonged and unexplained reduction in the number of circulating neutrophils. The pathogenetic cause of neutropenia in CIN is attributed to impaired BM granulopoiesis of multifactorial origin. That said, our recent studies strongly implicate expanded T-cell populations in both PB and BM in the development of CIN. Such expansions are more prominent in the BM CD8+ subset and can display pronounced repertoire skewing, often verging on monoclonality. This raises diagnostic uncertainties given that severe cytopenias can also develop in a range of clinical syndromes associated with chronic $CD8^+$ expansions, most notably T-large granular lymphocyte (T-LGL) leukemia. Recently, STAT3 mutations predominantly clustering in exon 21, encoding the Src homology 2 (SH2) domain which mediates the dimerization and activation of the STAT protein, were found to be frequent in chronic lymphoproliferative disorders of natural killer cells (CLPD-NKs) and T-LGL leukemias, helping to discriminate them from reactive expansions. The available information about the frequency of STAT3 mutations in CIN is very limited.
Aims: Taking all the above into consideration, here we aimed at obtaining deeper insight into the role of STAT3 dysregulation in CIN pathogenesis, with obvious implications for improved understanding of the true nature of cytotoxic T-cell expansions in CIN.
Methods: We screened for STAT3 mutations a large and well-annotated cohort

of 167 patients, including 19 males and 148 females with a median age of 54 years. All patients had an absolute neutrophil count below 1500/μL, normal karyotype, lack of anti-neutrophil antibodies and no clinical, serologic or ultrasonic evidence of any underlying disease that might be associated with neutropenia. Exon 21 sequences of the STAT3 gene were amplified on genomic DNA from mononuclear cells of (mostly) PB and BM samples. PCR products were subjected to bidirectional Sanger sequencing and sequence data were analyzed using the Vector NTI alignment tool. The sensitivity of our approach for detecting STAT3 mutations was 15%.
Results: Overall, only 4/167 cases (2.4%) were found to carry STAT3 exon 21 mutations. Two of 4 concerned single nucleotide insertions at position 963, leading to frameshift; the remaining two concerned: (i) c.1169G>A, p.K685K (silent) and (ii) c.1033A>T leading to the Y640F substitution, a recurrent lesion in malignant T/NK lymphoproliferations that is associated with STAT3 phosphorylation and, consequently, increased transcriptional activity of STAT3.
Summary and Conclusion: In conclusion, we demonstrate that STAT3 mutations are very infrequent in CIN despite its almost consistent association with cytotoxic T-cell expansions. From a pathogenetic perspective, this finding indicates that CIN may justifiably be considered as distinct from malignant T/NK lymphoproliferations, though sharing similar clinical presentation. From a diagnostic perspective, our results offer hints that STAT3 mutations may be a useful tool to discriminate malignant lymphoproliferations from reactive expansions, helping to establish a reliable diagnosis of CIN.

P1013

GENOTYPING STRATEGIES FOR DIAMOND BLACKFAN ANEMIA PATIENTS IN CANADA

B Zlateska[1,*]
[1]Hematology/Oncology, The Hospital for Sick Children, Toronto, Canada

Background: Diamond Blackfan anemia (DBA) is characterized by a variable phenotype, which mainly includes anemia, craniofacial malformations, thumb and other limb abnormalities, cardiac defects, urogenital malformations, and a modestly increased risk of leukemia and other malignancies. Mutations in multiple genes can cause DBA; hence the genetic diagnostic process is often lengthy and costly.
Aims: The aim of the present study is to compare which methods of genetic testing are most effective in identifying mutations in DBA patients.
Methods: Patients were enrolled on the Canadian Inherited Marrow Failure Registry (CIMFR), which is a multicenter prospective cohort study of inherited bone marrow failure syndromes (IBMFS). The following methods for genetic testing were used: targeted gene sequencing (TGS), comparative genomic hybridization (CGH) array, single nucleotide polymorphism (SNP) array, and a next generation sequencing panel (NGSP) that was developed in our laboratory. Specific genotype data were extracted from the registry and categorized as causal, most-likely causal (novel), most-likely not causal and not causal based on published data and *in-silico* analysis A correlation between the method of testing and identification of a genotype was determined by Pearson test.
Results: The most common IBMFS among the 399 patients enrolled on the CIMFR is DBA (N=64). Diagnostic criteria were based on clinical features, blood counts, fetal hemoglobin, marrow findings, erythrocyte adenosine deaminase levels and genetic testing. Of the 64 patients, 42 had genetic testing using at least one of the methods: TGS (34), NGSP (12), CGH arrays (8 patients). NGSP was used in 4 patients without previous testing by other methods and in 8 patients who had already been tested for at least on DBA gene. As well, CGH/SNP arrays were used in 2 patients who had not been previously tested by other methods and in 6 patients who had already been tested for at least one DBA gene. Overall, previously published causal mutations or novel most likely causal mutations were identified in a total of 33 of the 42 patients tested (79%). These include mutations in RPS19 (10 patients), RPS26 (7), RPL11 (5), RPL5 (2), RPS24 (2), RPL35a (2), RPS7 (1). The mutations included frame shift (12 patients), missense (6), nonsense (4), splicing site (3), small indels (2), and large deletions (6). Among patients tested by NGS 75%, causal or most likely causal mutations were successfully identified in 75%, by TGS in 55%, and by SNP/CGH arrays in 50%, (R=0.1306, p>0.05).
Summary and Conclusion: The majority (80%) of Canadian patients can now be genotyped based on known genes and the methods described. The most commonly mutated DBA genes in Canada are *RPS19*, *RPS26* and *RPL11*. Our findings suggest that NGSP combined with methods to detect deletions are the most effective method to detect mutations in known DBA genes.

P1014

PARAMETERS OF CELL IMMUNITY IN PATIENTS WITH APLASTIC ANEMIA AND THEIR RELATION TO PNH-CLONE

O Rozanova[1,*], T Glazanova[1], E Shilova[2], Z Chubukina[1], I Pavlova[1], L Bubnova[1]
[1]laboratory of immunohematology, [2]hematology department, Research Institute of hematology and transfusiology, Saint-Petersburg, Russian Federation

Background: It is known that immune-mediated suppression of hemopoiesis serves as a basis for pathogenesis of aplastic anemia (AA) in most cases. Therefore, the immunosuppressive therapy is the main method for AA treatment. According to present views, PNH-clone can be present in more than half of AA patients. It is also known that immunosuppressive treatment efficacy is higher in patients with PNH-clone associated AA, possibly due to specific features of immunopathogenesis in this category of patients.
Aims: Aim – to compare the main parameters of cell immunity in AA patients without PNH-clone or with PNH-clone of different size.
Methods: We have evaluated 41 patients with AA, different size PNH-clone has been revealed in 59,6% of cases. Detection of PNH-clone and immune parameters of peripheral blood was performed using multicolor flow cytometry. PNH diagnostics was performed using CD235a/CD59 for red blood cells, FLAER/CD24/CD15/CD45 for granulocytes and FLAER/CD14/CD64/CD45 for monocytes. Also we have measured the main peripheral blood lymphoid subsets: T-, B- and NK-cells.
Results: The results of comparative evaluation of lymphoid subsets in groups of AA patients without PNH-clone and with PNH-clone of different size (0-10% and >10%) have revealed similar tendencies. Nevertheless, typical for AA increase of CD3+ and CD8+- T-cells (87,4% and 39,2% *vs*. 69,04% and 23,07%, respectively, in norm, p<0,05) and decrease of NK-cells and CD19+ B-cells (7,31% and 4,7% *vs*. 13,12% *и* 13,22% in norm) was more pronounced in subjects with larger PNH-clone. As for minor lymphoid subsets, the level of T-regulatory cells (CD4+/CD25+) was decreased both in patients with PNH- and without PNH-clone, and NKT-cells were also increased similarly in both groups. While activated T-cells (HLA-DR+CD3+) were significantly increased in patients with large PNH-clone – 5,50% *vs*. 1,83% in norm (p<0,05).
Summary and Conclusion: Thus, along with similar tendencies, we have revealed some diversities in lymphoid subsets impairment in AA patients with or without PNH-clone. It can be supposed, that these diversities serve as conditioning factors for the different clinical features and therapeutic response in patients with aplastic anaemia.

P1015

ABNORMAL METABOLITES RELATED TO BONE MARROW FAILURE IN APLASTIC ANEMIA PATIENTS

C Xing[1,*], W D Li[2], L Kui[2], H X Feng[2], C S Yuan[2], W Xin[3]
[1]Department of Hematology, Post-doctoral research station of clinical medical, Shandong University, [2]Affiliated Hospital of Shandong University of Traditional Chinese Medicine, [3] Provincial Hospital Affiliated to Shandong University, Jinan, China

Background: Metabolomics is the identification and quantitation of the small molecules that are involved in metabolic reactions. As a stem cell disease, aplastic anemia(AA) is extremely instructive and provides insights into the function and quantity of normal hematopoietic stem cells (HSCs) and their ability to regenerate.In this study, metabonomic analyses were performed to investigate the mechanisms that might influence the renewal and proliferation of HSCs in AA patients.
Aims: We aimed to characterize themetabolic pathways associated with bone marrow failure of aplastic anemia patients.
Methods: From September 2010 to February 2013, 40 AA patients (23 males and 17 females, median age of 39.95 years; range 11–64 years) were compared with 40 healthy control subjects (17 males and 23 females, median age of 38.50 years; range 15–68 years). Serum metabolites of aplastic anemia (AA) patients and healthy controls were investigated by using LC-MS. A wavelet-based method was utilized to find and align LC-MS peaks. Principal component analysis (PCA), partial least squares discriminant analysis (PLS-DA), and optimized potential for liquid simulations (OPLS) were used to identify differences in metabolite levels and to reveal useful biomarkers.
Results: We obtained 32 metabolites in all and 23 most significantly altered metabolites were identified. In AA patients, metabolites involved in the biosynthesis of amino acids (L-glutamine, L-methionine, L-ornithine, L-tryptophan, L-phenylalanine, L-tyrosine, L-leucine, L-proline, and L-valine), aminoacyl-tRNA biosynthesis (L-glutamine, L-methionine, L-tryptophan, L-phenylalanine, L-tyrosine, L-leucine, L-proline, and L-valine), and ATP-binding cassette transporters (ABC transporters) pathways(L-glutamine, L-ornithine, L-phenylalanine, L-leucine, L-proline, and L-valine) were higher than normal, while the levels of metabolites involved in TCA cycle pathways(citric acid, succinic acid, and isocitric acid) were lower. Representative chromatograms are shown in Fig.A(AA patient group) and Fig.B(Normal patient group).PCA score scatter plot (Fig.C), PLS-DA score scatter plot (Fig.D), and OPLS score scatter plot (Fig. E) for two components, indicating separation between the AA patient group (A) and the normal group (B).

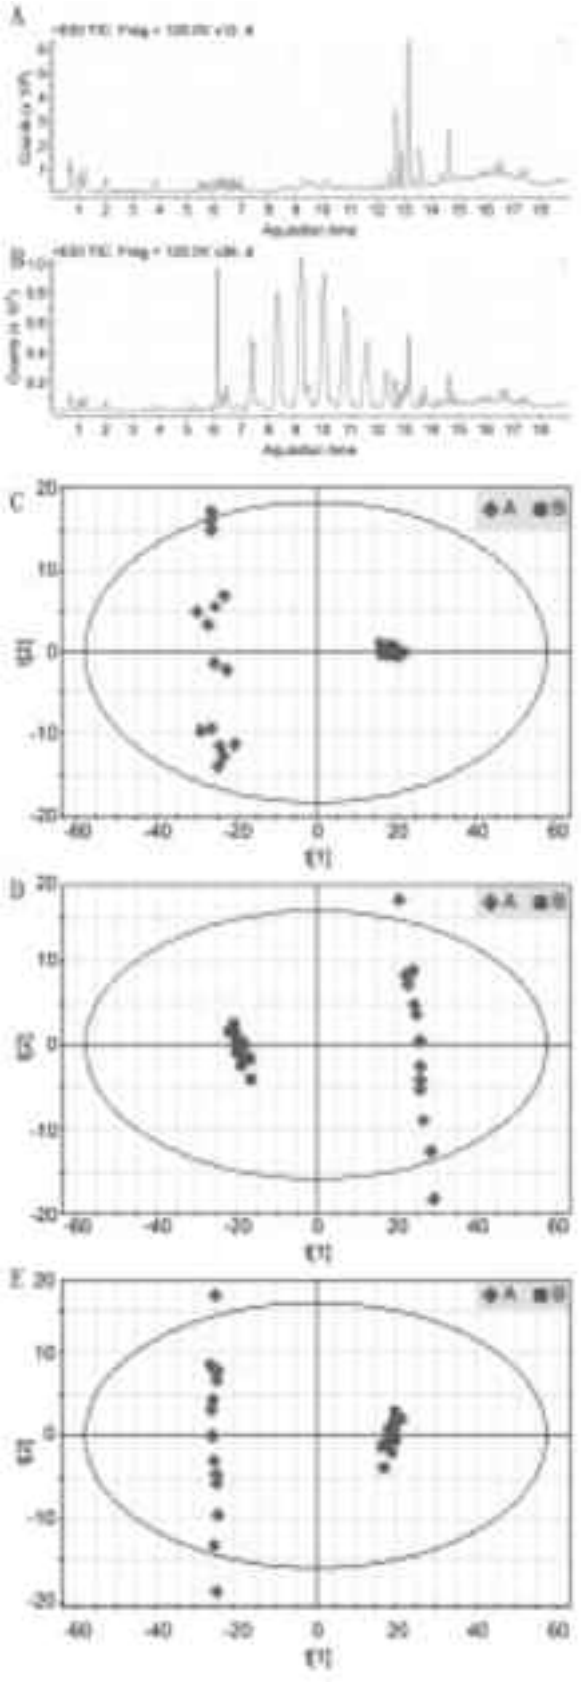

Figure 1.

Summary and Conclusion: In conclusion, our findings indicate that levels of amino acids involved in aminoacyl-tRNA, ABC transporter, and TCA cycle metabolism are aberrant in AA patients in comparison to the normal control. The underlying mechanism for these differences may be related to abnormal of mitochondria function and influence self-renewal and differentiation of HSC, so these changes may be the primary cause to result in bone marrow failure in AA.

P1016

PAROXYSMAL NOCTURNAL HEMOGLOBINURIA: CLINICAL EXPRESSION AND RESPONSE TO TREATMENT ARE MODIFIED BY A UNIQUE INTERACTION WITH CO-EXISTING GLUCOSE 6-PHOSPHATE DEHYDROGENASE DEFICIENCY

M Sica[1,*], A Pellecchia[1], M Berardi[1], L Gargiulo[1], T A Olutogun[1], G Caocci[2], G La Nasa[2], M De Angioletti[1,3], L Luzzatto[4], R Notaro[1]
[1]Core Research Laboratori - ITT, Istituto Toscano Tumori - AOU Careggi, Firenze, [2]Hematology, Department of Medical Science, University of Cagliari, Cagliari, [3]ICCOM, CNR, Sesto Fiorentino, [4]Scientific Direction, Istituto Toscano Tumori, Firenze, Italy

Background: Paroxysmal Nocturnal Hemoglobinuria (PNH) is a rare acquired clonal hemolytic disorder that results from a somatic mutation of the X-linked *PIGA* gene, producing deficiency of complement (C)-regulatory proteins in the membrane with consequent hyper-susceptibility of the red cells to lysis by activated C. Glucose 6-phosphate dehydrogenase (G6PD) deficiency is an inherited abnormality of the X-linked *G6PD* gene that makes the red cell hyper-susceptible to oxidative damage with consequent risk of acute hemolysis. The clinical expression of PNH can be influenced by inherited factors: for instance, we have shown recently that a polymorphism of the complement receptor 1 (CR1) gene correlates with the blood trasfusion requirement of PNH patients on the anti-C5 moAB eculizumab (Rondelli *et al*, Haematologica 2014).
Aims: To illustrate, through the first report of a patient who has both PNH and G6PD deficiency, how the two abnormalities can interact.
Methods: Routine blood test, including flow cytometry for GPI-linked proteins. Quantitative enzyme analysis and genetic tests for G6PD deficiency.
Results: A 40yo woman from Sardinia (Italy) originally presented with mild anemia (Hb, 9.5-10.0 g/L), thrombocytopenia (40x10^9/L) and granulocytes at the low end of the normal range; at that time there were no signs of hemolysis and no GPI-negative cells were present. After relative stability for 2 years the patient developed signs of intravascular hemolysis (dark urine, LDH up to 5x upper normal level): the Hb level dropped and there was a high reticulocytosis: 59% of granulocytes were GPI-negative and a diagnosis of PNH was made. Over the following 6 months the size of the GPI-negative granulocyte population increased to 95%, with a parallel increase of intravascular hemolysis; meanwhile, the platelets returned to normal (320x10^9/L). The patient needed a first red cell transfusion, and on the same day she was started on eculizumab. LDH levels promptly returned to normal, but reticulocyte counts remained high (about 250x10^9/L) and transfusion requirement was not abrogated (6 units in the last 6 months). C3 fragment was present on 35% of GPI-negative red cells, despite the fact that the patient had a CR1 genotype associated with good hematological response to eculizumab. The peripheral blood smear revealed marked anisocytosis with spherocytes, macrocytes and hemighosts: a picture consistent with oxidative damage as seen in G6PD deficient patients during a hemolytic attack. In spite of high reticulocytes, the red cell G6PD activity was only about one-half of normal (5 IU/g Hb). DNA analysis revealed heterozygosity for the G6PD Mediterranean (Med) variant. However, mRNA sequence analysis showed that the GPI-negative clone expressed only the G6PD Med allele, suggesting that the PIG-A mutation took place in a stem cell in which the normal G6PD gene was inactive.
Summary and Conclusion: 1) In this patient we have witnessed the evolution from aplastic anemia to PNH – probably the rule rather than the exception; and we have further documented the gradual expansion of the GPI-negative populations, that entailed the correction of thrombocytopenia and neutropenia, but with the payload of increased intravascular hemolysis. 2) In this patient the poor response to eculizumab probably results from a unique interaction, whereby a large red cell population has both the PNH abnormality and G6PD deficiency. We hypothesize that complement activation on the surface of GPI-negative red cells results in oxidative damage, which these red cells, being G6PD deficient, are unable to cope.

P1017

INTERIM REPORT OF THE OPTIMA {OBSERVATION OF GPI-ANCHORED PROTEIN DEFICIENT (PNH-TYPE) CELLS IN JAPANESE PATIENTS WITH BONE MARROW FAILURE SYNDROME AND IN THOSE SUSPECTED OF HAVING PNH} STUDY

C Sugimori[1,2,*], K Hosokawa[2,3], H Noji[2,4], T Shichishima[2,4], N Obara[2,5], S Chiba[2,5], Y Nakamura[2,6], K Ando[2,6], M Yamamoto[2,7], Y Yonemura[2,8], T Kawaguchi[2,9], H Ninomiya[2,5], JI Nishimura[2,7], Y Kanakura[2,7], S Nakao[2,3]
[1]Hematology, Ishikawa Prefectural Central Hospital, Kanazawa, [2]Japan PNH Study Group, Tokyo, [3]Cellular Transplantation Biology, Kanazawa University, Kanazawa, [4]Cardiology and Hematology, Fukushima Medical University, Fukushima, [5]Hematology, Tukuba University, Tukuba, [6]Hematology and Oncology, Tokai University, Isehara, [7]Hematology and Oncology, Osaka University, Osaka, [8]Transfusion Medicine and Cell Therapy, [9]Hematology and Infectious Diseases, Kumamoto University, Kumamoto, Japan

Background: Paroxysmal nocturnal hemoglobinuria (PNH) phenotype cells are derived from hematopoietic stem cells with an acquired mutation of the

phosphatidylinositol glycan class A (*PIGA*) gene. In patients with aplastic anemia (AA) or low-risk types of myelodysplastic syndromes (MDS), glycosylphosphatidylinositol-anchored protein deficient (PNH-type) cells are often detected at low frequencies with high-resolution flow cytometry-based methods. Because such bone marrow failure patients possessing increased PNH-type cells are reported to have a good prognosis and show a high response rate to immunosuppressive therapies as opposed to the other patient groups lacking PNH-type cells, detection of these cells may be potentially useful in determining an optimal treatment for patients with bone marrow failure.
Aims: To determine the prevalence and clinical significance of PNH-type cells in bone marrow failure patients, we conducted a nationwide multi-center prospective observational study named OPTIMA.
Methods: From July 2011, Japanese patients with AA, MDS and bone marrow failures suspected of having PNH were prospectively enrolled in OPTIMA. Six laboratories in different universities were assigned as a regional analyzing center. The percentage of PNH-type cells was measured by a high-resolution flow cytometry-based method that was originally established by Kanazawa University. A negative sample and a positive sample containing approximately 0.01% PNH-type cells were periodically sent to the six laboratories without any notice to check the quality of the individual flow cytometry assay. A liquid FLAER method (≥0.003%) and a cocktail method (≥0.005%) with anti-CD55 and anti-CD59 antibodies were used for the detection of PNH-type granulocytes and erythrocytes, respectively.
Results: As of July 2013, flow cytometry data on 1210 cases were collected for this interim analysis. Diagnoses were AA in 386, MDS in 339, PNH in 55, and 430 in undiagnosed bone marrow failure according to the case report forms. Periodic blind validation tests revealed inter-laboratory differences in the PNH-type cell percentage to be always within 0.02%. A total of 457 (37.8%) were found to be positive for PNH-type cells and 148 (12.2%) had ≥1% PNH-type cells. PNH-type cells were detected in 57%, 19.8% and 100% of patients with AA, MDS and PNH, respectively. In a half of patients having ≥1% PNH-type cells, lactate dehydrogenase levels exceeded the ≥1.5×upper limits of normal. Among different subsets of patients with MDS, increased PNH-type cells were detectable in 20 (21.3%) of 94 patients with RCUD, 33 (21.7%) of 152 with RCMD, and 5 (27%) of 22 with MDS-U, but not in any of 14 RARS and 32 RAEB patients.
Summary and Conclusion: A high-resolution flow cytometry-based method that enables the detection of minimal PNH-type cells below 0.01% was successfully transferred from Kanazawa University to other laboratories in Japan. Also, by implementing a uniform protocol to six individual laboratories across the country, a reliable system was established for bone marrow failure patients to undergo the flow cytometry test with equal accuracy in all of these laboratories. Our interim analysis confirmed previous findings that PNH-type cells were exclusively detectable in patients with benign types of bone marrow failure. Further accumulation of cases and prolonged observations are required to determine the clinical significance of the minimal PNH-type cells, especially in terms of their relation to response to immunosuppressive therapy.

P1018

PAROXYSMAL NOCTURNAL HEMOGLOBINURIA CLONES EMERGED AFTER IMMUNOSUPPRESSIVE THERAPY IN PATIENTS WITH SEVERE OR NON-SEVERE APLASTIC ANEMIA

G He[1,*], W Shen[1], H Zhu[1], J Li[1], P Hillmen[2]
[1]Department of Haematology, The First Affiliate Hospital of Nanjing Medical University, Jiangsu Province Hospital,, Nanjing, China, [2]Department of Haematology, St. James' University Hospital, Leeds, United Kingdom

Background: Paroxysmal nocturnal hemoglobinuria (PNH) is a rare acquired hematopoietic stem disorder caused by clonal expansion of a *PIG-A* mutated stem cell, and consequent the defective synthesis of glycosyl phosphatidyl-inositol-anchored proteins. Acquired aplastic anemia (AA) and PNH are closely related bone marrow failure disorders, and PNH often arises from AA. Retrospective studies have mostly investigated severe aplastic anemia (SAA) patients with PNH clones following immunosuppressive therapy (IST) such as antithymocyte globulin and ciclosporin (ATG/CsA) or high dose cyclophosphamide. However, the natural history of PNH clones emerged after IST, especially in non-SAA patients following CsA has not been documented.
Aims: The purpose of this study is to compare the fate and clinical relevance of PNH clones in patients with SAA and non-SAA (NSAA) after IST with ATG/CsA or only CsA.
Methods: A total of 174 patients diagnosed as AA were enrolled in this study from 2008 to 2012. 53 cases of SAA (age at diagnosis 10-65 years, median=39 yers, male 33, female 20) were treated with ATG/CsA, 121 cases of NSAA (age at diagnosis 19-70 years, median=36 years, male 64, female 57) were treated with CsA alone. There were no significant difference in age and gender. All patients were screened for PNH clone pro-treatment and followed-up for 18 to 76 months after treatment, and the median time was 22 months. Peripheral blood PNH cells were detected by lack of CD55 and CD59 expression on red cells and granulocytes by a two-color flow cytometry analysis from 2008 to 2009. Since 2010, PNH cells were defined as CD59 negative erythrocytes and FLAER negative granulocytes, monocytes (CD45/24/14/FLAER). PNH clone size was defined as percentage of GPI-AP deficient granulocytes in whole peripheral blood.
Results: After IST with ATG/CsA or CsA, positive PNH clones were detected in the ten SAA (18.2%) patients, significantly more than that of non-SAA group [nine patients (6.9%), *t=5.0408*, *P=0.025*]. PNH clones emerged in SAA group at 4 months to 65 months (median 7.5 months) after IST, while it was at 2 months to 124 months (median 12 months) in NSAA group (*t=1.118□P=0.279*). The number of AA patients developed with PNH clones in SAA group at 6, 12, 18, 24, and >24 months were 4, 7, 9, 9, 10 respectively, significantly higher than those of non-SAA patients (4, 5, 6, 7, 9, all values<0.05). PNH clone size of SAA group at 6, 12, 24, and >24 months were 13.38%, 14.88%, 20.0%, and 18.85% respectively, also significantly higher than those of non-SAA patients (14.88%, 5.31%, 5.47%, and 9.08%, all values<0.05). 2 patients of SAA group developed typical PNH with intravascular hemolysis during the observation periods 4.5 months and 65 months respectively. In NSAA group, 3 patients developed typical PNH at 12 months, 37 and 76 months respectively. None of the patients developed thrombosis over the period of observation. In SAA group, 80%of patients (8/10) with PNH colne responded to IST, and it was 74.4% (32/43 cases)in patients without PNH clone (*P=1.000*); while 55.6% (5/9) of NSAA patients with PNH clone responded to CsA, 38.9%(44/113) in NSAA patients without PNH clone (*P=0.482*).
Summary and Conclusion: PNH clone can emerge in SAA or NSAA patients after IST with combining with ATG and CsA, or only CsA. More and larger PNH clone developed in patients with SAA than in NSAA patients. PNH clone occurrence did not affect the therapeutic efficacy of IST for AA.

P1019

IDENTIFICATION OF MUTATIONS IN GENES OF THE TELOMERE COMPLEX IN PATIENTS WITH SHORT TELOMERES AND SUSPECTED TELOMEROPATHIES

M Haubitz[1,*], E Oppliger Leibundgut[1,2], I Helsen[1], H Baumgartner[1], N A Porret[2], G M Baerlocher[1,2]
[1]Department of Clinical Research, University of Bern, [2]Department of Hematology, University Hospital and University of Bern, Bern, Switzerland

Background: Telomeres are involved in cellular replication and senescence. At any given time point, telomere length reflects the balance between the loss of telomere repeats with cell division and the addition of telomere sequences by telomerase. Pathological loss of telomere repeats due to telomerase insufficiency can lead to telomeropathies. The phenotype ranges from mild cytopenias to dyskeratosis congenita (DC), isolated or combined severe bone marrow failure (BMF), lung fibrosis, liver cirrhosis, vasculopathies, bone lesions and brain cysts. The identification of patients (pts) with telomeropathies is relevant to define an adequate therapeutic and monitoring strategy, since such pts are at a higher risk for stem cell deficiencies, malignancies, treatment-related mortality and immunosenescence. Mutations in genes of the telomerase or telomere-associated proteins DKC1, TERC, TERT, TINF2, NOP10, NHP2, TCAB1 and CTC1 have been described as pathogenic.
Aims: We aimed to 1) screen suspected individuals and pts for telomere length (TL), 2) search for mutations in genes of the telomere complex in pts with short telomeres and 3) identify short telomeres and mutations in relatives.
Methods: TL values were determined by automated multicolor flow-FISH (Baerlocher *et al.*, Nat Protoc. 2006). TL values were defined as very low (VL) and low (L) when below the 1st and 10th percentile of age-matched healthy individuals, respectively. Mutations in the genes of the telomere complex were analyzed by Sanger sequencing and/or next generation sequencing using the Ion PGM system with a custom Ion AmpliSeq panel.
Results: TL values were measured in blood samples from 100 pts and 63 relatives. TL values were VL or L in 87 pts and 40 affected or non-affected relatives. 42 pts and 22 relatives were screened for mutations. Three novel mutations were detected in the TERC gene in three pts with severe phenotypes (DC and/or BMF) and in two affected and two non-affected relatives; all of them had VL TL. The mutations were located in the functionally important pseudoknot/template and CR4/CR5 domains. In the TCAB1 gene, three novel mutations were detected in three pts with VL or L TL and BMF. A known pathogenic mutation in TINF2 was identified in a family with two brothers and their father all of whom had DC and VL TL. Fife pts with L and VL TL and various phenotypes carry mutations in the TERT, NHP2 and CTC1 genes, one of whom was compound heterozygous for two mutations in CTC1 and in addition carried a mutation in NHP2 that was also present in two asymptomatic siblings. 45% of the pts carry the G allele of the gene variant TERC n.514A>G (rs2293607) that has been shown to be associated with short telomeres. Furthermore, 25 pts carry at least one of three frequent gene variants in the TERT or TCAB1 gene that have been associated with various tumors.
Summary and Conclusion: We identified three known and nine novel putative pathogenic mutations in genes of the telomere complex in pts with L or VL TL, confirming the genetic basis of the suspected telomeropathy. In addition, we found a high frequency of gene variants associated with L TL values or various cancers. A careful diagnostic work-up including telomere length measurement and mutation analysis is useful to establish the diagnosis of hereditary telomeropathies, and close monitoring and adequate treatment strategies are highly recommended for such pts and their relatives.

P1020

INCREASED BONE MARROW (BM) PLASMA LEVELS OF SOLUBLE CD30 CORRELATE WITH BM PLASMA LEVELS OF INTERFERON (IFN)-GAMMA, CD4/CD8 T-CELL RATIO AND DISEASE SEVERITY IN APLASTIC ANEMIA

J Zhang[1,*], Y Zheng[1]
[1]State Key Laboratory of Experimental Hematology, Institute of Hematology & Blood Diseases Hospital, Chinese Academy of Medical Science & Peking Union Medical College, Tianjin, China

Background: Immunologic abnormalities in patients with acquired aplastic anemia (AA) include decreased lymphocyte counts, inverted CD4/CD8 ratio and increased IFN-γ-producing T cells in peripheral blood (PB) and bone marrow (BM). CD30, a cell-surface molecule belonging to tumor necrosis factor receptor (TNFR) superfamily, was up-regulated on T cells which exposed to allogeneic antigens, and these $CD30^+$ T cells were the major sources of IFN-γ. Quickly after stimulation, surface CD30 was proteolytically cleaved by metallo proteinases and released into bloodstream as soluble CD30 (sCD30). Therefore, circulating sCD30 was thought to be reflective activation of the immune system.
Aims: The aim of this study was to evaluate the role of CD30 in the pathogenesis of AA.
Methods: Fifty-six AA patients (median age 28 years, 29 males), and twenty BM donors (median age 27 years, 10 males) were enrolled in the study. Of these patients, thirty-two patients were analyzed at diagnosis, and twenty-four patients in complete response (CR) after immunosuppressive therapy (IST) of the combination of antithymocyte globulin (ATG) plus CSA. Written informed consent was obtained from all the enrolled patients. The plasma and culture supernatants were stored at -80°C. The concentrations of sCD30 and IFN-γ were detected by commercially available ELISA kit, according to the manufacturer's instructions. The mRNA levels of CD30 in BMMNCs were detected by real-time PCR. The induction expression of CD30 expression on T-cell subsets from SAA patients and healthy controls were detected by Flow cytometry. Cell sorting was performed by using BD FACS Canto II (BD Biosciences).
Results: BM plasma sCD30 levels were found to be positively correlated with the severity of AA. The median plasma sCD30 levels in healthy controls, Non-SAA, SAA and VSAA patients were as of 30ng/mL, 32ng/mL, 46ng/mL and 62ng/mL, respectively. In addition, sCD30 level in BM plasma was higher than its corresponding PB level in each SAA patient, but healthy controls had comparable levels of sCD30 between BM and PB. We further analysed the mRNA levels of CD30 in BMMNCs by real-time PCR, which also revealed significantly increased CD30 expression in BMMNCs of SAA patients. In the group of SAA patients, BM plasma sCD30 levels were positively correlated with BM plasma IFN-γ levels, and negatively correlated with absolute lymphocyte counts (ALC), absolute neutrophil count (ANC) and CD4/CD8 T-cell ratio. Patients in CR had significantly lower levels of sCD30 than patients at diagnosis. BM samples pre- and post-IST were collected from 6 SAA patients who had responded to IST, and all patients had significant decrease in sCD30 levels after successful IST. *in vitro*, we stimulated T cells with alloantigen and found that T cells from AA patients could be induced to express higher level of CD30 on cell surface, and released more sCD30 and IFN-γ into culture supernatants. Allogeneic stimulated T cells were separated by FACS, and $CD30^+$ and $CD30^-$ T cells were separately cultured for 2 days. Culture supernatants of $CD30^+$ T cells contained significantly more IFN-γ than that of $CD30^-$ T cells both in healthy controls and SAA patients. When evaluated the cell-surface expression of CD30 on T-cell subpopulations, we found $CD4^+$ T cells from SAA patients and healthy controls expressed comparable level of cell-surface CD30, but $CD8^+$ T cells from SAA patients expressed significantly higher level of cell-surface CD30 than healthy controls. CsA significantly inhibited CD30 expression by $CD3^+CD8^-$ and $CD3^+CD8^+$ T cells from SAA patients and healthy controls.
Summary and Conclusion: Taken together, CD30 seems to be an important molecule that participates in mediating overproduction of IFN-γ in AA. The associations between sCD30 and ALC and CD4/CD8 T-cell ratio in AA warrant further study.

P1021

EVALUATION OF GENETIC TESTING FOR FANCONI ANAEMIA: FROM SANGER TO NEXT GENERATION SEQUENCE ANALYSIS

A Goodeve[1,*], N Beauchamp[1]
[1]Sheffield Diagnostic Genetics Service, Sheffield Children's NHS Foundation Trust, Sheffield, United Kingdom

Background: Fanconi anaemia (FA) is a rare inherited disorder that leads to bone marrow failure, physical abnormalities and increased malignancy risk. Physical abnormalities present in up to 75% cases include short stature, abnormal skin pigmentation, malformations of limbs and organs and developmental delay. In most populations FA affects ~1:360,000 births, with a ~1:300 carrier frequency and autosomal recessive inheritance for all genes except *FANCB* which is X-linked recessive. Sheffield Diagnostic Genetics Service has offered genetic analysis for FA since 2009. Analysis included Sanger sequencing of *FANCA, FANCC* and *FANCG* plus dosage analysis of *FANCA* using multiplex ligation-dependent probe amplification (MLPA). Next generation DNA sequencing (NGS) is now being introduced for all 16 known FA genes.
Aims: To evaluate the outcome of service provision to date to provide a comparator with the new NGS service.
Methods: All previously reported index cases (IC) and their relatives' records were examined for referral reason, genes analysed and mutations detected. Where requested, IC were sequentially analysed. *FANCA* was analysed by Sanger sequencing followed by dosage analysis to detect large deletions/duplications. This was followed by Sanger sequencing of *FANCC* and *FANCG*. For NGS validation purposes, in five previously analysed IC the FA-associated genes sequenced before were re-investigated. In a further 2 IC in whom no mutation had previously been identified, all 16 FA-associated genes in the TruSight Inherited Cancer Panel (Illumina) were analysed. In all IC investigated by NGS, sequence variants identified were compared with those previously documented by Sanger sequencing.
Results: Among 39 families referred, 35 IC required diagnostic confirmation of FA, 2 sought mutations where the IC was unavailable, 1 required only *FANCA* MLPA and 1 was referred to confirm research findings. Complementation suggested *FANCA* in 3 and *FANCC* in 1 IC, confirmed by mutation analysis. Pending bone marrow transplant was amongst referral reasons for 3 IC. In 15/34 IC, *FANCA* PCR/sequencing identified 2 mutated alleles but only 1 mutation in 2 IC. Subsequent *FANCA* MLPA in 14 IC confirmed 2 homozygous large deletions and identified a heterozygous deletion in a further IC. 8/16 IC were homozygous for *FANCA* mutations, 7 compound heterozygous and 1 simple heterozygous. 11 IC were subsequently analysed for *FANCC* mutations and 2 homozygous and 1 heterozygous mutations were identified. Lastly 6 IC were analysed for *FANCG* mutations and 1 homozygous mutation was found. Overall, of 35 IC, 18 had mutation(s) identified that confirmed their diagnosis of FA (51%), but in 2 IC, only a single heterozygous mutation was identified and although reversion may have occurred, revertant mosaicism was not observed. 11 IC were homozygous for their mutations and 7 compound heterozygous. After analysis of all 3 genes, 4 of 5 IC remained mutation negative. Parents of IC were analysed for mutations in 5 families and mutations identified in all; additionally of 11 other relatives analysed, 9 were heterozygous and 2 homozygous affected. TruSight NGS analysis of 7 IC confirmed 100 previously identified sequence variants and mutations (52 unique variants) and identified a homozygous *BRIP1* mutation in one IC and a putative heterozygous splice mutation in *FANCI* in another. Sanger sequencing was used to confirm the identified mutations and to fill 7 small gaps in sequence coverage.
Summary and Conclusion: Previous Sanger sequencing used sequentially on FA IC identified both mutations in only 51% of 35 IC referred. However in 19 IC, only *FANCA* sequencing was requested. The analysis process was slow where a mutation was not originally identified in the *FANCA* gene, with turnaround times (TAT) of 8 weeks/gene. Recent introduction of NGS with an initial 12 week TAT will speed up analysis and should identify mutations in a higher proportion of referred cases where phenotypic diagnosis is sound.

P1022

DIAMOND-BLACKFAN ANEMIA IN RUSSIAN FEDERATION

N Smetanina[1,*], G S Ovsyannikova[1], I M Mersiyanova[2], L A Hachyatryan[3], M A Kurnikova[4], V O Bobrynina[2], M A Maschan[5], G A Novichkova[6]
[1]Outpatient Hematology/Oncology, [2]Laboratory of molecular biology, [3]Pediatric Hematology/Oncology, Federal Scientific and Clinical Centre of Pediatric Hematology, Oncology and Immunology named after Dmitry Rogachev, [4]Molecular biology, Evrogen, [5]Bone marrow transplantation, [6]Chief Hematologist, Federal Scientific and Clinical Centre of Pediatric Hematology, Oncology and Immunology named after Dmitry Rogachev, Moscow, Russian Federation

Background: Diamond-Blackfan anemia (DBA) is an inherited bone marrow failure syndrome with clinical and genetic heterogenity. It was shown that mutations or deletions of ribosomal proteins genes responsible for desease development.
Aims: To analyze clinical and genetic data from DBA patients in Russian Federation.
Methods: We analyzed retrospective data from 61 cases of DBA (32 male, 29 female) born in Russian Federation in a 20-year period (1993-2013). Direct sequence of 7 ribosomal proteins genes (RPS19, RPS10, RPS24, RPS26, RPL5, RPL11, RPL35a) and transcription factor GATA1 were performed for 30 unrelated probands and their first degree relatives. All coding regions and exon-intron junction sites were studied.
Results: Congenital malformation were observed in 41 patients. The clinical manifestation as severe normochromic hyporegeneratory anemia with normal platlet count on the first month of life was detected in 46 cases, at the age of 4 months - in 11 cases, and at the age of 8 months - in 4 patients. DBA was diagnosed at the age of 1-3 months in 58 cases. Up to 1 year of life 48 patients received regular blood transfusions to keep Hb level 95-120 g/l. Steroid therapy was initiated at the age of 6-8 months in 13 cases. Initially responded to steroid therepy 26 patients. Two non-responded to steroid therapy patients achived spontaneous remission at the age of 15 and 18 years.Transient response was observed in five patients, including one child who was successfully transplanted. All our DBA cases were sporadic. Different mutations in RPS19 were detected in 11 cases (one - compound heterozigote), RPS10 - 1 case, RPS24 - 1 case, and RPS26 - 1 case. Siblings and proband's parents had not have any abnormalities in RPs genes studied.

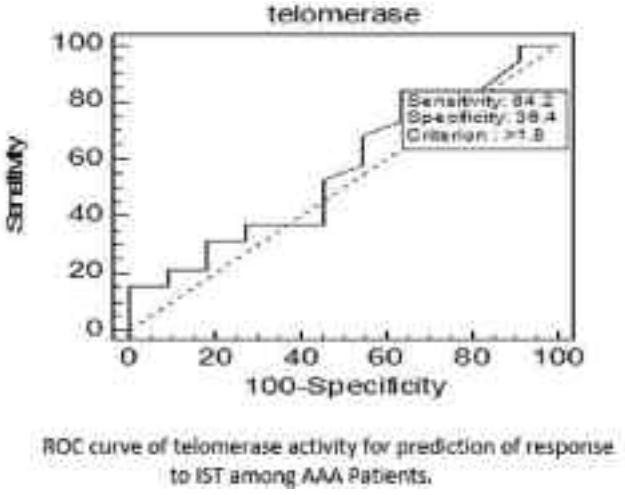
Summary and Conclusion: The most frequent abnormality was found in RPS19 gene (36,7% of cases) in our cohort of patients.

P1023

TELOMERASE ENZYME ACTIVITY IN EGYPTIAN CHILDREN WITH E ANDBONE MARROW FAILUR RESPONSE TO IMMUNESUPRESSIVE THERAPY

A Elbeshlawy[1,*], M Hamdy[1], A Abd El Salam[1], M El Ansary[2], N Abulata[2], F Said[2]
[1]Pediatric Hematology, [2]Clinical and Chemical Pathology, Cairo University, Cairo, Egypt

Background: Maintenance of the integrity of telomeres requires the telomerase ribonucleoprotein complex. Abnormal telomere maintenance is a feature of a variety of human diseases including constitutional aplastic anemia. Predisposition to the development of marrow failure has been conferred by genetic alterations results in low telomerase activity, short telomeres in leukocytes and reduced hematopoietic function.
Aims: To evaluate the telomerase functional activity in Egyptian children with inherited and acquired bone marrow failure. The relation of the severity of the acquired disease to telomerase enzyme activity and response to immunosuppressive therapy was studied.
Methods: A case-control study conducted on unrelated children (n=40) with bone marrow failure syndromes (BMFS) and forty healthy age and sex-matched controls. The diagnosis of bone marrow failure was based on the blood-count and bone marrow biopsy criteria of the International Agranulocytosis and Aplastic Anemia Study. Response to immunosuppressive therapy (IST) was evaluated after 6 months of initiation of therapy; complete response (CR) was considered if neutrophil count was >1.5×10^9/L, platelet count >100×10^9/L, and a hemoglobin level >11.0 g/dL. Telomerase activity was measured in mononuclear cells utilizing the Telomeric Repeat Amplification Protocol (TRAP) using the TeloTAGGG Telomerase PCR ELISA.
Results: Patients were acquired aplastic anemia (n=30), Fanconi anemia (n=6). Pure Red Cell Aplasia (n=2), dyskeratosis congenita one case and constitutional aplastic anemia one case. The Mean age was 11.1±4.9 years (range 3.5 to 18 years, median 11 years) and the duration of follow-up mean; 5.14 (±3.84) years (range 1-13 years). Patients with acquired aplastic anemia (n=30) received treatment with cyclosporine A monotherapy (CSA) (n=27) or cyclosporine A and ATG (n=3). The median telomerase activity was significantly lower in inherited BMF syndromes when compared to controls [5.05% (4.60 – 8.70 IQR) *vs* 11.15% (5.90-16.60 IQR), p=0.04]. In AAA the median telomerase activity was insignificantly lower than controls, p=0.228]. Inverse correlation was detected between the telomerase activity and age of the patients ***(r=-0.39, p=0.026),*** but no correlation was found between the telomerase activity and disease duration in hereditary or AAA (r=-0.303, p=0.111 and r=0.305, p=0.156 respectively). In AAA patients 7/30 (23%) had below normal telomerase activity, 6/7 (86%) had severe or very severe disease, 3/7 (43%) responded partially or completely to CSA 7-10mg/kg/day. Twenty seven patients with AAA received cyclosporine therapy, 19/27 (70.4%) were responders *versus* zero % of patients received CSA & ATG (n=3). The median telomerase of responders was 16.5 ± 4.7 % *Vs.* 11.6 ±3.8% of none responders ***(p=0.6).*** sensitivity and specificity of telomerase activity in predicting response of AAA subjects to IST at different cut off values by ROC curve found that area under the curve of telomerase was 0.569 (95% CI 0.377 to 0.748; p=0.540); indicating that the overall predictability of telomerase activity is not significant and on fixing the sensitivity or specificity of telomerase activity, we found that either its sensitivity or specificity became unsatisfactory; making its adoption as a good predictor of response of AAA subjects to IST unlikely.



ROC curve of telomerase activity for prediction of response to IST among AAA Patients.

Figure 1.

Summary and Conclusion: Telomerase activity was low in all hereditary BMFS and in 23% of AAA patients. Evaluation of telomerase activity might not be essential for therapeutic or prognostic aspects of AAA patients. However, It might be useful for selection of stem cell family donors in patients with AAA and telomerase deficiency. Cyclosporin A can be used as a monotherapy in the treatment of AAA even in the presence of decreased telomerase activity

P1024

DECREASED BONE MARROW (BM) LEVELS OF IL-12P40 CORRELATE WITH DISEASE SEVERITY IN ACQUIRED APLASTIC ANEMIA (AA)

J Zhang[1,*], Y Zheng[1]
[1]State Key Laboratory of Experimental Hematology, Institute of Hematology & Blood Diseases Hospital, Chinese, Tianjin, China

Background: Acquired aplastic anemia (aAA) is an autoimmune disease in which various pro- and anti-inflammatory cytokines play crucial pathogenic roles. These cytokines either can inhibit hematopoiesis directly or can enhance the pro-inflammatory function of autoreactive T cells. Wellknown pro-inflammatory cytokines which were found to be increased in aAA included IFN-γ, TNF-α, IL-2, IL-6, IL-8, IL-12p70, IL-17 and IL-23. Among anti-inflammatory cytokines, TGF-β1 was found to be decreased in AA, while IL-10 and IL-11 serum levels were comparable between aAA patients and healthy controls. Elevated plasma levels of IL-12p70 and IL-23 have already been reported in AA, however, IL-12p40, a natural antagonist of IL-12p70 and IL-23, has not been determined in AA.
Aims: The aim of our study was to evaluate BM plasma IL-12p40 levels in patients with aAA.
Methods: BM plasma samples of 18 newly diagnosed aAA patients (median age 29, range 12-43 years, 7 males), 10 newly diagnosed MDS patients (median age 31, range 19-45 years, 4 males) and 11 healthy subjects (median age 28, range 18-47 years, 5 males) were analysed. All patients provided written informed consent. The BM plasma was stored at -80□. The concentrations of IL-12p40 were detected by commercially available ELISA kit, according to the manufacturer's instructions.
Results: In newly diagnosed AA patients, we found BM plasma IL-12p40 levels were decreased in AA patients and correlated with disease severity. The median plasma IL-12p40 levels in healthy controls, Non-SAA, SAA and VSAA patients were as of 120±17pg/mL, 100±18pg/mL, 85±16pg/mL and 80±6pg/mL, respectively. In addition, we found significant elevated IL-12p40 (168±41pg/mL) levels in MDS patients.
Summary and Conclusion: The influence of IL-12p40 on the immune response may play crucial pathogenic role in the pathogenesis of aAA and MDS. Further studies are investigating why IL-12p40 expression is changed in aAA and MDS, and how the changed IL-12p40 will impact the immune cell of patients.

P1025

INCREASED INCIDENCE OF TRISOMY 8 IN APLASTIC ANEMIA PATIENTS COMBINED WITH BEHCET'S DISEASE COMPARED TO ACQUIRED APLASTIC ANEMIA: A SINGLE INSTITUTE EXPERIENCE

SJ Kim[1,*], JY Lee[1], YR Kim[2], SY Hyun[3], HS Park[1], JE Jang[1], JS Kim[1], JW Cheong[1], YH Min[1]
[1]Department of Internal Medicine, Yonsei University College of Medicine, [2]Department of Internal Medicine, Yonsei University College of Medicine Gangnam Severance Hospital, Seoul, [3]Department of Internal Medicine, Yonsei University Wonju College of Medicine, Wonju, Korea, Republic Of

Background: Behcet's disease (BD) is a disease of unknown cause which is clinically characterized by recurrent oral and genital ulcers, uveitis, polyarthritis, gastrointestinal involvement, and vasculitis. The prevalence of BD is reported to be higher in eastern Asia and Turkey compared to western countries. There is increasing number of case reports of which show BD associated with bone marrow failure syndromes such as myelodysplastic syndromes (MDS) or aplastic anemia (AA) accompanied with trisomy 8 mostly from eastern Asia. It is not clear that trisomy 8 is whether uniquely increased in BD patients or if it is only a chromosomal result which can be observed in a series of aplastic anemia.
Aims: Therefore, we investigated bone marrow results and chromosomal charactertistics of BD patients who underwent bone marrow studies due to various degree of cytopenia.
Methods: The medical records of Behcet's disease patients who visited the Hematology clinic of Severance Hospital from January 2000 to December 2013 were reviewed. The diagnosis of Behcet's disease was made according to the diagnostic criteria of international Behcet's disease study group or Japanese group. After review, total 40 patients, whose reason for bone marrow was peripheral cytopenia of any lineage, were selected. To compare chromosomal aberrancy pattern with acquired aplastic anemia, chromosome results of 159 aplastic anemia patients were retrospectively collected. During the bone marrow study, 10ml of bone marrow blood was aspirated and mononuclear cells from bone marrow blood were separated and cultured for 24 to 48 hours.

Chromosome analysis was done after the preparation for methaphase and Giemsa-banded. Meaningful chromosomal abnormality was defined as at least 2 cells showing same structural aberrancy such as chromosome rearrangement or extra-chromosome or loss of chromosome.
Results: Among 40 patients, 24 patients got specific hematologic diagnosis. Fifteen patients were diagnosed of AA and 2 patients were diagnosed of MDS. Three patients diagnosed of acute myeloid leukemia and 3 patients were diagnosed of immune thrombocytopenia, Chronic myelomonocytic leukemia, hemophagocytic lymphohistiocytosis and NK/T cell lymphoma was diagnosed in each 1 patient. Among 15 BD+AA, 5 showed trisomy 8 (30%) and among 1 BD+nonAA patients 1 showed trisomy 8 (4%, P=0.021). In contrast, among 152 acquired AA patients without symptoms and signs of BD, trisomy 8 was found in 3 patients, and trisomy 9 was found in 2 patients. There was statistically high incidence of trisomy 8 in BD+AA compared to BD+nonAA or acquired idiopathic AA. Intestinal involvement was more frequently observed in BD patients associated with AA of MDS (29.2% *vs*. 50%, P=0.159).
Summary and Conclusion: Trisomy 8 is frequently reported in BD patients showing asplastic feature compared to BD patients without AA or acquired idiopathic AA. The clinical meaning of trisomy 8 should be further determined in BD patients with bone marrow failure.

Background: The identification of the thrombotic risk factors in the Ph-negative MPN is still controversial, due mainly to the heterogeneity of diagnostic criteria and to the potentially confounding effects of the treatments.
Aims: This study in thrombocythemic patients reclassified according to the WHO 2008 criteria aimed to evaluate the pro-thrombotic effects of the main clinico-biological characteristics at diagnosis, by analyzing the prior thrombosis (PrTh) history, *i.e.* the thrombotic events occurring before the start of any cytoreductive treatment.
Methods: The analyzed patients of the Thrombocythemias Italian Registry (RIT) were 1745 (ET 52.5%, ep-PMF 28.3%, PMF 5.0%, PV 2.1%, U-MPN 12.1%), 678 males and 1067 females, with age at diagnosis >60y (42.5%), 40-60y (35.4%) and ≤40y (22.1%). The patients had at least one general cardiovascular risk factor (CVRF) and at least one comorbidity in 66.9% and 50.0% of cases, respectively. The PLT count (median 757 x 10^9/L) was >1000 x 10^9/L in 18.9%, and ≤700 x 10^9/L (low thrombocytosis) in 38.0% of cases. The WBC count was >10000 x 10^6/L (leukocytosis) in 20.8%, and the HCT higher level (>44% in females, and >47% in males) was observed in 22.3% of cases. Hepatomegaly, splenomegaly, and symptoms were present in 24.7%, 25.4%, and 55.6% of cases. The JAK2 V617F mutation was documented in 58.2% of 888 studied cases.
Results: A PrTh, with a median distance from diagnosis of 7 months, occurred in 320 (18.3%) patients, without difference between ET and ep-PMF (19.1 % *vs* 20.5%, p 0.533). As expected, PrTh were mainly arterial (72.8%), and were related to the thrombosis during the follow-up (p<0.001). In univariate analysis, the PrTh rate was higher in patients with male gender (p 0.006), older age (p<0.001), CVRFs (p<0.001), comorbidities (p<0.001), low thrombocytosis (p<0.001), leukocytosis (p<0.001), HCT higher level (p<0.001), and JAK2 V617F mutation (p 0.003). The figure shows, by a *logit function,* that the increasing age at diagnosis was associated to an increasing rate of prior thrombosis, CVRFs, and comorbidities. The significant relationship between PrTh and patient characteristics at diagnosis was confirmed in multivariate analysis, with exception for older age (p 0.061). Nevertheless, when the covariates CVRFs and comorbidities were excluded, the multivariate analysis documented again a significant relationship between PrTh and older age (p<0.001).

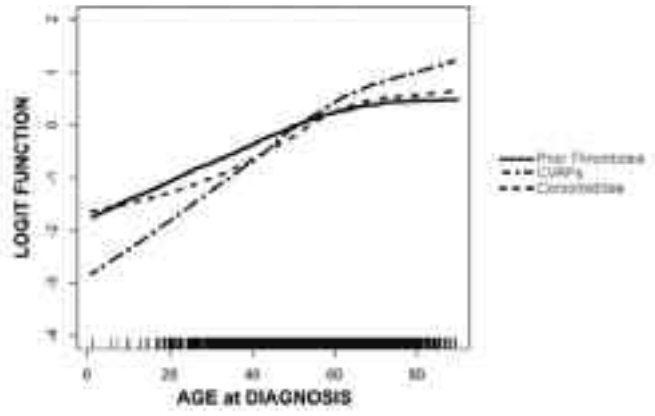

Figure 1.

Summary and Conclusion: PrTh occurrence, in ET as in ep-PMF patients, was related in multivariate analysis to male sex, CVRFs, comorbidities, low thrombocytosis, leukocytosis, higher HCT level, and JAK2 V617F mutation. The older age, whose pro-thrombotic effect appeared *de facto* supported by the CVRFs and comorbidities, seems to be in these patients not a primary but a surrogate thrombotic risk factor. Acknowledgement: this study was partially supported by the Gimema Foundation (promotor of the RIT), and by the AIL Foundation. Umberto Santoro, Rossella Miglio and Paola Monari of the Statistics Dept of the University of Bologna made the statistical analysis. Aurora Rabitti offered the technical assistance.

P1027

PHASE 2 TRIAL OF PRM-151, AN ANTI-FIBROTIC AGENT, IN PATIENTS WITH MYELOFIBROSIS: STAGE 1 RESULTS

S Verstovsek[1,*], R Mesa[2], L Foltz[3], V Gupta[4], J Mascarenhas[5], E Ritchie[6], R Hoffman[5], R Silver[6], WJ Hong[7], M Kremyanskaya[5], E Trehu[8], H Kantarjian[9], J Gotlib[7]
[1]Leukemia, MD Anderson Cancer Center, Houston, [2]Mayo Clinic, Scottsdale, United States, [3]St. Paul's Hospital, Vancouver, [4]Princess Margaret Hospital, Toronto, Canada, [5]Mt Sinai School of Medicine, [6]Weill Cornell Medical Center, New York, [7]Stanford Cancer Institute, Palo Alto, [8]Promedior, Inc., Lexington, [9]MD Anderson Cancer Center, Houston, United States

Background: PRM-151 (PRM) is a recombinant form of Pentraxin-2, an endogenous human protein that acts at sites of tissue damage, inducing macrophage differentiation to prevent and reverse fibrosis. PRM has broad anti-fibrotic activity in multiple preclinical models of established fibrotic disease and no dose limiting toxicities in Phase 1 trials.
Aims: This study investigates the potential of PRM in myelofibrosis (MF) to reduce bone marrow (BM) fibrosis and to improve key MF-related disease features including abnormal blood counts, splenomegaly, and symptoms.
Methods: Patients with Intermediate-1, intermediate-2, or high risk MF with grade ≥2 BM fibrosis, either on no current therapy or on a stable dose of ruxolitinib (RUX) for at least 12 weeks were eligible for stage 1 of this open label adaptive trial. Assignment to one of the 4 treatment arms was per investigator and patient choice: PRM IV 1-hour infusion on days 1, 3 and 5, then weekly (QW) or every 4 weeks (Q4W), alone or with continuous oral rux. Primary endpoint is overall response rate by IWG-MRT criteria (spleen by palpation). A decrease in BM fibrosis by ≥ 1 grade with otherwise stable disease is also considered a response. BM biopsies are obtained at baseline, 3 and 6 months, read by local pathologists and a blinded central reviewer. All subjects signed informed consent.
Results: 27 subjects were enrolled in Stage 1: 7 PRM QW, 7 PRM Q4W, 7 PRM QW + RUX, 6 PRM Q4W + RUX. As of January 13, 2014, 15 and 6 subjects have completed 8 and 12 wks of treatment, respectively (none have yet completed 24 wks). There was no apparent treatment-related myelosuppression, and among all AEs, only herpes labialis and anemia occurred in >1 subject. There have been 4 serious adverse events in 3 subjects: 1 with abdominal pain, 1 with hypoxia, and an 85 year old subject who died from gastroenteritis and pneumonia. Improvement in bone marrow fibrosis (Grade 3 to 1; Grade 2 to 0; read by a local pathologist) was observed in 2 of 6 subjects at the 3-month BM mark (1 on PRM Q4W, 1 on PRM Q4W + RUX).
Summary and Conclusion: In stage 1 of this phase 2 trial of MF patients, PRM has shown good tolerability both alone and in combination with RUX. Updated safety and efficacy data on all 27 subjects will be presented at the meeting, including central BM (3 and 6 month) reviews.

P1028

PKC412 (MIDOSTAURIN) IS SAFE AND HIGHLY EFFECTIVE IN SYSTEMIC MASTOCYTOSIS PATIENTS: FOLLOW UP OF A SINGLE-CENTER ITALIAN COMPASSIONATE USE

C Papayannidis[1,*], S Soverini[1], C De Benedittis[1], MC Abbenante[1], C Sartor[1], I Iacobucci[1], C Baldazzi[1], E Ottaviani[1], A Ferrari[1], V Guadagnuolo[1], G Simonetti[1], A Conficoni[1], S Paolini[1], S Parisi[1], F Frabetti[1], S Piccari[1], E Lani[1], G Martinelli[1]
[1]Department of Experimental, Diagnostic and Specialty Medicine (DIMES), University of Bologna, Bologna, Italy

Background: Mastocytosis is a myeloid neoplasm characterized by abnormal accumulation and frequent activation of mast cells (MCs) in various organs. The recent WHO classification (2008) includes an indolent form (ISM), an aggressive form (ASM) and a leukemic subvariant (MCL). The *c-kit* mutation D816V is detectable in most adult patients with SM. Treatment of SM usually focuses on symptom relief by histamine receptor antagonists and other supportive therapy. However, in aggressive and leukemic variants, cytoreductive and targeted drugs must be applied.
Aims: To evaluate safety profile (adverse events) and efficacy (remission rates and quality of response) of a cohort of ASM patients, treated with PKC412.
Methods: From 2008, 22 patients (male/female=11/11) affected by SM have been referred to our Institution. Among these, 12 (55%) presented with systemic symptoms associated with signs of organ involvement (skeletal lesions, ascites, liver function impairment or bon marrow disfunction), thus identifying an ASM. Therefore, since a first line therapy (IFNalfa, Imatinib and 2CdA in 56%, 11% and 33% of the patients, respectively) and supportive care with histamine receptor antagonists weren't followed by a significant benefit, a personalized use of PKC412 was asked and obtained for 9 out of 12 ASM patients. Thus, from March 2011 9 (M/F=3/9) patients with ASM have been treated with PKC412, administered orally, at the dosage of 100 mg twice daily, without rest periods. The median age was 60 years (range 39-75); the median time from diagnosis was 6 months (range 2-53). Median serum tryptase level was 100 mcg/L(range 19.3-1160). *C-kit* mutation D816V was present in 8 out of 9 patients. Cytogenetic analysis was normal in all the patients.
Results: Seven out of nine patients were evaluable for response. The median duration of therapy was 517 days (range 327-970+). According to European Criteria, a Major response was observed in one patient, and a partial response in 6 patients. Overall, the drug was well tolerated, and no serious adverse events were observed. All the patients obtained a quick and prolonged improvement of clinical symptoms, in terms of weight gain, bowel function and skeletal pain. At the bone marrow evaluation, the persistence of the D816V *c-kit* mutation was observed, despite a significant decrease of mast cell marrow involvement.
Summary and Conclusion: In a small cohort of ASM patient, the prolonged therapy with PKC412 is safe and effective, mainly on symptoms improvement and haematological profile. Nevertheless, the persistence of the D816V c-kit mutation, despite significant responses, suggests that many other oncogenic factors may be responsible for the pathogenesis of the disease. UDS approaches are needed in order to clarify this issue. Acknowledgments. Work supported by European LeukemiaNet, AIRC, AIL, PRIN, progetto Regione-Università 2010-12 (L. Bolondi), FP7 NGS-PTL project.

P1029

DIAGNOSTIC ACCURACY OF SERUM EPO LEVEL AND JAK2V617F ALLELE BURDEN IN POLYCYTHEMIA VERA

A Ancochea[1,*], A Álvarez-Larrán[1], C Morales[2], L Martínez-Avilés[3], A Angona[1], A Senín[1], B Bellosillo[3], C Besses[1]
[1]Hematology, Hospital del Mar, [2]Laboratori de Referencia de Catalunya, [3]Pathology, Hospital del Mar, Barcelona, Spain

Background: The diagnosis of polycythemia vera (PV) is based on criteria defined by the World Health Organization (WHO 2008) with serum erythropoietin (EPO) level below the reference range being a minor criterion. The WHO EPO criterion was established based on studies performed before the description of *JAK2*V617F mutation.
Aims: To evaluate the diagnostic accuracy of serum EPO and *JAK2*V617F allele burden as surrogate markers of PV.
Methods: Serum EPO level at diagnosis was evaluated in 287 patients, 99 of them with untreated PV, 137 with essential thrombocythemia (ET) and 51 with non-clonal erythrocytosis (NCE). Patients were diagnosed at a single center between 1995 and 2013. Before May 2006 serum EPO levels were measured by radioimmunoassay (RIA) whereas after that date it was measured by electrochemiluminescence (ECL). ECL was the technique employed in all patients with NCE. *JAK2*V617F allele burden was measured by quantitative allele-specific PCR. ROC curves were performed to evaluate the diagnostic accuracy of serum EPO level and *JAK2*V617F quantification as markers of PV. The area under de curve (AUC), the sensitivity and the specificity for EPO level and *JAK2*V617F was calculated in the whole cohort of patients and in three different clinical settings: study of erythrocytosis, confirmed myeloproliferative neoplasm (MPN) and *JAK2*V617F-positive MPN. The sensitivity and specificity

values of serum EPO level corresponded to the lower limit of normality whereas for *JAK2*V617F quantification an arbitrary cut-off based on the value that provides the highest specificity ensuring a sensitivity >80% was established.
Results: Median EPO values measured by RIA were 7.7 mUI/mL and 15.1 mUI/mL in PV and ET, respectively (p<0,001) whereas according to ECL method the corresponding values were 2.3 mUI/mL, 7.1 mUI/mL and 8.4 mUI/mL in PV, ET and NCE, respectively (p<0,001). Serum EPO level had a good diagnostic accuracy as a marker of PV as shown in the table. The EPO level measured by ECL showed a better diagnostic accuracy than RIA (AUC for ECL: 0.91, 0.84, 0.80 in erythrocytosis, confirmed MPN and *JAK2*V617F-positive respectively). The *JAK2*V617F showed an excellent diagnostic accuracy as a marker of PV being the AUC 0.98, 0.93, 0.91 in erythrocytosis, myeloproliferative neoplasms and *JAK2*V617F-positive groups respectively.

Table 1.

	No. of patients	AUC	Sensitivity	Specificity
JAK2V617F-positive MPN	194			
EPO RIA	77	0.710	11%	97%
EPO ECL	107	0.833	82%	79%
JAK2V617F	194	0.907	89%	85%
Confirmed MPN, irrespective of JAK2 status	239			
EPO RIA	109	0.765	28%	99%
EPO ECL	130	0.837	82%	79%
JAK2V617F	223	0.851	82%	82%
Study of erythrocytosis	133			
EPO RIA	NA	NA	NA	NA
EPO ECL	87	0.853	85%	89%
JAK2V617F	118	0.983	88%	96%
Whole cohort of patients	287			
EPO RIA	109	0.759	28%	99%
EPO ECL	176	0.869	82%	85%
JAK2V617F	274	0.949	82%	94%

JAK2V617F positive MPN included patients with PV and ET. Confirmed MPN included all patients with PV and ET irrespective of JAK2V617F status. Study of erythrocytosis included patients with hematocrit > 48% and >52% in men and women, respectively. RIA: radioimmunoassay; ECL: electrochemiluminescence. The sensitivity and specificity values corresponded to the lower limit of normality of serum EPO according to each technique. The sensitivity and specificity values of JAK2V617F quantification corresponded to an arbitrary cut-off set at 35% selected in the group including the whole cohort of patients based on the value that provides the highest specificity ensuring a sensitivity > 80%.

Summary and Conclusion: The quantification of the *JAK2V617F* allele burden has a better diagnostic accuracy than EPO serum level as a marker of PV.

P1030

CALR MUTATIONS IN ESSENTIAL THROMBOCYTHEMIA: INCIDENCE, CLINICAL UTILITY AND MOLECULAR DIAGNOSTIC BY HIGH RESOLUTION MELTING

M Moreno[1,*], L Torres[1], MT Gomez Casares[1], C Bilbao-Sieyro[1], G Santana[1], G Santana-Lopez[2], C Rodriguez-Medina[1], M Perera[1], S de la Iglesia[1], T Molero[1]
[1]Hematologia, [2]Medicina Preventiva, Hospital Universitario de Gran Canaria Dr. Negrin, Las Palmas de Gran Canaria, Spain

Background: Around 50-60% of patients with primary myelofibrosis (PMF) and essential thrombocythemia (ET) carry *JAK2* V617F mutations. Mutations in *MPL* have been also described in these neoplasms in 5-10% *JAK2* V617F negative patients. Recently, mutations in calreticulin gene (*CALR*) were described in *JAK2* and *MPL* unmutated cases of ET and PMF, and its clinical, cytogenetic and molecular implications are a challenge.
Aims: We studied the presence of *CALR* mutations in a series of patients with ET and thrombocytosis without *JAK2/MPL* mutations. Among ET patients, we compared clinical, demographic and molecular features of *CALR* mutated *versus JAK2/MPL* mutated subjects.
Methods: In this retrospective study, *CALR* mutation analysis was carried out in patients with wild type *JAK2* and *MPL* in 34 ET, 21 persistent thrombocytosis suggestive of myeloproliferative neoplasia (MPN) and 98 thrombocytosis secondary to other causes and clearly not MPN. We compared clinical characteristics of *CALR* positive ET patients with 45 *JAK/MPL* mutated patients. The diagnosis of ET was according to the 2008 World Health Organization criteria. *CALR* mutation analysis was performed through high resolution melting (HRM) and direct Sanger sequencing. For the statistical analysis, patient's characteristics were compared with the use of chi-square test or Fisher's exact test for categorical variables and t-test or Mann-Whitney U test for continuous variables. All analyses were two sided, and significance was set at a p-value of 0.05. SPSS statistical package (v. 15.0) was used.
Results: All HRM positive samples were confirmed by sequencing analysis. In our series of *JAK2/MPL* negative patients, *CALR* mutations were present in 44% (15/34) of ET, 14.3% of persistent thrombocytosis suggestive of MPN, and in none of the thrombocytosis unrelated to MPN (0/98). The statistical analysis showed that in ET patients: 1) *CARL* mutations were associated with lower hemoglobin levels compared to *JAK2* mutations (p=0.004). 2) *CARL* mutations presented higher platelet count than *JAK2* mutations (p=0.001). 3) Patients carrying *CALR* mutations were younger, although this association was not statistically significant (median 53.33 years for *CALR*+ and 60 years for *JAK2*+, p=0.146).
Summary and Conclusion: a) Results from the present study indicate that HRM method is an accurate, sensitive and rapid method for analyzing *CALR* mutations. b) Mutations were detected in 44% of ET patients with wild type *JAK2/MPL* which is a lower incidence than the one published in other studies. c) As has been described, *CALR* mutations were significantly associated with higher platelet count and normal hemoglobin levels, and marginally associated to younger age of diagnosis. No differences in thrombotic risk were observed in our series.

P1031

POMALIDOMIDE IN MYELOFIBROSIS: LONG TERM FOLLOW UP AND CORRELATION WITH JAK2V617F AND CALR MUTATIONS

K Begna[1,*], P Animesh[1], M Litzow[1], C Hanson[2], R Mesa[3], W Hogan[1], A Tefferi[1]
[1]Internal Medicine, Division of Hematology, [2]Division of Hematopathology, Mayo Clinic, Rochester, [3]Hematology/Oncology, Mayo Clinic, Scottsdale, United States

Background: Myelofibrosis (Primary myelofibrosis (PMF), post-polycythemia myelofibrosis and post-thrombocythemia myelofibrosis) are the commonest BCR/ABL negative myeloproliferative neoplasms without good treatments. Risk stratification is useful in identifying patients with shorter survival; and help in deciding who may benefit with medical intervention and/or enrolled to clinical trials. Immunomodulatory therapies have some utility in alleviating transfusion need. Previously we have reported the phase II clinical trial of pomalidomide in myelofibrosis (*Leukemia*. 2011;25(2):301-304)[1].
Aims: To evaluate the long term outcome of pomalidomide in myelofibrosis; and to see if there is any correlation with the newly described mutations.
Methods: After obtaining IRB approval, the data base of patients who received pomalidomide was updated till January 2014. All patients who received pomalidomide for at least one cycle without regard to dose were included.
Results: Ninety four patients took pomalidomide during phase I and II studies at the Mayo clinic from May 2007 to January 2010. The median age was 67 years (range 37-87) and males were 61 (65%). Primary myelofibrosis, post-polycythemic and post-thrombocythemic myelofibrois constitute 73 (77%), 10 (11%), and 11 (12%) of the cases respectively. Thirty six (38%) were in intermediate 2 and 57 (61%) in high risk group according to Dynamic International Prognostic Scoring System Plus risk stratification. Twenty five did have unfavorable karyotype. JAK2*V617F* mutation was identified in 71 (76%), CALR mutation in 5 (5%), and 3 double negative. The anemia response rate was 31 % (29/94), with median duration of response of 21 months (range: 5.5-71 months). Twenty four, two and one of the anemia responders were JAK2*V617F* and CALR positive, and double negative respectively (p=0.2). Five patients maintained their anemia response for more than 4 years; and currently there are 4 patients on treatment. Three of them are JAK2*V617F* positive and one of them CALR positive. Four out of 5 the long term responders did have spleen size less than 10 cm. Sixty three (67%) patients died since the start of the clinical trial. Leukemic transformation was documented in 8 (8 %) patients.
Summary and Conclusion: Pomalidomide may improve anemia in some patients with myelofibrosis, especially those with JAK2*V617F* positive and minimal enlarged spleen. Though the sample size is small, only patients with either JAK2*V617F* or CALR mutation showed long term anemia response to pomalidomide.

P1032

YOUNG AGE IS NOT PROTECTIVE AGAINST THROMBOSIS IN PATIENTS WITH POLYCYTHEMIA VERA

ML Randi[1], I Bertozzi[1,*], E Rumi[2], C Elena[2], A M Vannucchi[3], E Antonioli[3], G Finazzi[4], F Lussana[4], M Ruggeri[5], A Iurlo[6], A Tieghi[7], E Elli[8], F Fabris[1], M Cazzola[2], T Barbui[9]
[1]Dept of Medicine - DIMED, University of Padua, Padova, [2]Department of Hematology, University of Pavia, Pavia, [3]Division of Hematology, University of Florence, Firenze, [4]Hematology Division, Ospedale Papa Giovanni XXII, Bergamo, [5]Department of Hematology, Ospedale di Vicenza, Vicenza, [6]Hematology Division, Fondazione Ca Granda IRCCS Ospedale Policlinico, Milano, [7]Hematology Unit, Arcispedale Santa Maria Nuova, Reggio Emilia, [8]Hematology Division, San Gerardo Hospital, Monza, [9]Hematology Division Research Foundation, Ospedale Papa Giovanni XXII, Bergamo, Italy

Background: PV is a chronic myeloproliferative neoplasm affecting people in median/advanced age. Only 4-7% of cases are recognized before the age of 40 and little is known regarding this setting of patients. Thrombosis is the major cause of morbidity and mortality in PV, with an estimated incidence in younger patients of 1.8/100 patients/years.

Aims: The aim of our study is to evaluate in young PV patients the thrombotic risk and its relationship with previous thrombotic event.
Methods: 236 patients with PV diagnosed between 18 and 40 years were studied in 9 Italian Hematological Centers. The PVSG diagnostic criteria were used before 2001 while those of WHO were used later. In most cases, older diagnosis were confirmed with WHO criteria. The study was approved by the institutional review boards at each institution. Nominal variables were compared with the X^2 test. Thrombosis free survival curves were prepared by the Kaplan-Meier method and were compared by the log-rank test. The Cox proportional hazard regression model was used for multivariable analysis. *P* values less than 0.05 were considered significant.
Results: Baseline clinical and laboratory data of PV patients are summarized in the Table.

Table 1.

Tot patients	236
Males/females	154/82
Age (y)	33.5±5.46
Median follow-up (y)	8.95
WBC x 109/L	10.75±4.48
Hb g/L	17.94±2.27
Ht %	53.77±6.62
Platelets x 109/L	529.88±270.24
JAK2V617F/exon 12/WT (available in 171 pats)	143/11/17
thrombotic events at diagnosis	31 (13%)
thrombotic events during follow up	39 (16.5%)

Sixty-three patients out of the 236 evaluated cases (28%) suffered for at least one thrombotic event (incidence 3.8/100 pts/y). In 31 patients (13%) the thrombotic event, 12 in arterial (5 coronary, 5 cerebral, 1 peripheral and 1 splanchnic) and 19 in venous (15 splanchnic and 4 peripheral) vessels occurred at diagnosis. Thirty-nine patients (16.5%) developed a thrombotic event during follow-up: 7 patients had a re-thrombosis (18%), while 32 (9 coronary, 5 cerebral, 2 peripheral artery thrombosis and 5 DVT, 10 splanchnic and 1 cerebral veins thrombosis) did not. The incidence of thrombotic complications during follow-up was similar comparing patients with or without a previous thrombotic event (p=0.64) and no statistical differences were found in parameters at diagnosis between the two groups.
Summary and Conclusion: In the present study, the incidence of thrombotic complications in PV in young age is not different compared to all PV population, estimated 12-39%. The rate of thrombotic complications is similar to that showed in an old French study (25.8%, Najean 1987) but lower than the one found in a small Italian (68%, Frezzato 1993) and in a small Spanish study (58.3%, Perea 2001). Our data confirm that young age per se is not protective against thrombosis in PV patients and that thrombosis as presenting feature of PV seems not to determine a different thrombotic risk during follow-up, in agreement with the observation of Passamonti (Haematologica 2003) in patients younger than 50 years. Therefore, thrombotic risk criteria used for ET seem not to be useful in PV. We think that low dose aspirin may be used in young patient with a suspicion of PV, even during diagnostic evaluation to avoid the risk of thrombosis and that phlebotomies has to be associated as soon as possible. Prospective study may confirm our data.

P1033

AN INTERNATIONAL ASSESSMENT OF STANDARD MEDICAL THERAPY ON SYMPTOM BURDEN AMONG MPN POPULATIONS: PRELIMINARY FINDINGS OF THE MEASURE TRIAL

R Scherber[1,*], A Dueck[1], E Knight[1], D Ross[2], H Geyer[1], A Vannucchi[3], AK Fuentes[4], CL Andersen[5], E Ejerblad[6], G Birgegard[6], P Johansson[7], B Andreasson[6], F Sackmann[8], JL Demory[9], T Constantine[10], JJ Michiels[11], D Radia[12], C Harrison[13], A Tefferi[14], R A Mesa[1]

Background: Traditional myeloproliferative neoplasms (MPNs) are characterized by myeloid lineage cellular over- or underproduction distinct from acute leukemia. Individuals with these diseases, including polycythemia vera (PV), essential thrombocythemia (ET) and myelofibrosis (MF) suffer from excessively burdensome symptom profiles and reduced quality of life. Previous pharmacologic and venosection therapies have targeted specific hematologic responses or survival benefit. To date, the effect traditional pharmacologic therapies on symptom burden has been largely uninvestigated. Furthermore, no studies to date have utilized a seven day, serial assessment of patient-reported outcome (PRO) symptom burden to assess MPN symptom response.
Aims: The MPN Experimental Assessment of Symptoms by Utilizing Repetitive Evaluation (MEASURE) Trial aims to assess symptom change among those undergoing standard MPN therapies. It also aims to validate the daily Myeloproliferative Neoplasm Symptom Assessment Form Total Symptom Score (MPN-SAF TSS) as an assessment of MPN symptom burden over a seven day period.
Methods: The MEASURES trial is a prospective study evaluating the responsiveness of the MPN-SAF TSS in detecting symptomatic changes in target symptoms for an anticipated 180 ET, PV and MF patients initiating new non-experimental medical therapy. MPN therapies include anagrelide, aspirin, busulfan, cladribine, danazol, hydroxyurea, interferon, lenalidomide, melphalan, thalidomide, phlebotomies, prednisone, and ruxolitinib. Patients complete a packet of metrics at the time of enrollment with a second survey sent out or given in-office between 90 and 180 days after the initiation of treatment. Packet items included the MDASI (*Cancer. 2000;* 89:1634-46), EORTC QLQ-C30 (*J Natl Cancer Inst.* 1993; 85: 365-76), Global Impression of Change (*Psychiatry*. 2007; 4(7): 28–37), as well as the MPN-SAF TSS (*J Clin Oncol*. 2012 Nov 20;30(33):4098-103.). The MPN-SAF TSS assesses 10 of the most pertinent and representative MPN symptoms, and in this study is administered in a daily diary format with a 24-hour recall period for seven consecutive days. Participating institutions acquired demographic, laboratory, physical examination and radiographic data, along with serial response assessments.
Results: The study remains in recruitment phase. To date, 37 patients, including 14 international patients, have been enrolled. Recruitment has yielded 22% ET, 26% PV, and 52% MF patients (including 50% PMF, 8% post-ET MF, and 42% post-PV MF). Median age was 72 (range 39-89) and 69% were male. Most common starting therapies included aspirin (n=8), hydroxyurea (n=7), ruxolinitib (n=6), interferon (n=4), phlebotomies (n=2), anagrelide (n=1), thalidomide (n=1), danazol (n=1), and darbopoietin (n=1). To date, three patients were unsuccessful in starting new therapies, one patient is deceased, and post-treatment surveys have been received for twelve participants (4 ruxolitinib, 3 aspirin, 1 busulfan, 1 anagrelide, and 1 prednisone; Figure 1). Average diary MPN-SAF TSS score was 23.2 for pre-treatment and 19.7 for post-treatment. Further data will be presented during the EHA 2014 meeting.

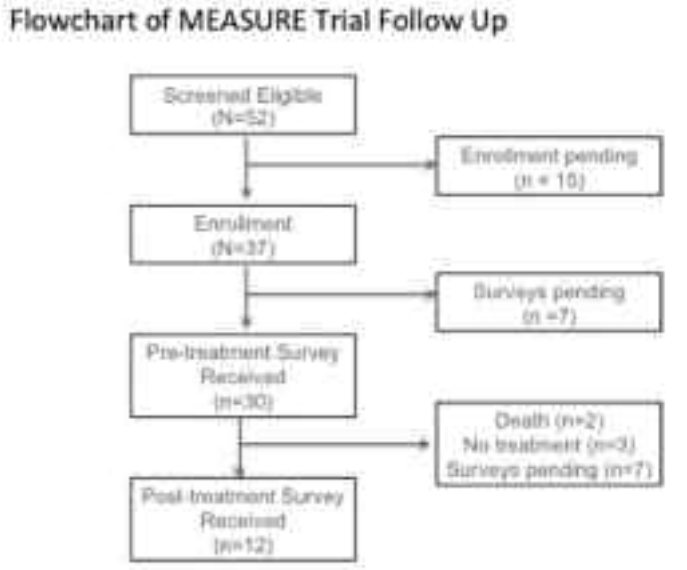

Figure 1.

Summary and Conclusion: Few studies have investigated symptom burden response to standard-of-care pharmacologic and venosection treatments among the MPNs. This study also introduces the daily diary version of the MPN-SAF TSS as a new PRO symptom burden assessment which can quantify symptoms with increased reliability. Although results are still ongoing, few effects of traditional therapies have been observed on symptom response, with the notable exceptions of steroids and ruxolitinib. Future analysis will continue to delineate the effects of traditional MPN therapies on symptom burden.

P1034

CALRETICULIN (CALR) MUTATIONS IN ESSENTIAL THROMBOCYTHAEMIA (ET) AND PRIMARY MYELOFIBROSIS (PMF): SCREENING BY HETERODUPLEX ANALYSIS IS HIGHLY SPECIFIC AND SENSITIVE

E Oppliger Leibundgut[1,2,*], N A Porret[3], M Haubitz[2], T Braschler[4], J S Goede[5], G M Baerlocher[1,2]
[1]Department of Hematology, University Hospital Bern, [2]Experimental Hematology, Department of Clinical Research, University of Bern,

[3]Departement of Hematology, University Hospital Bern, Bern, [4]Department of Hematology, Luzerner Kantonsspital, Lucerne, [5]Department of Hematology, University Hospital Zurich, Zurich, Switzerland

Background: Eight years after the *JAK2*V617F mutation, *CALR* mutations detected in 30% of patients with ET and PMF fill the molecular diagnostic gap in myeloproliferative neoplasms. Assessment of *CALR* mutations advances the current diagnostic approach for ET and PMF and is proposed to be included into the WHO criteria. Mutated calreticulin has an altered c-terminus which is an attractive target for specific treatments, *i.e.* small molecules. More than 50 different deletions and insertions in exon 9 of the *CALR* gene have been described to date, rendering the analysis challenging. Two mutation types are more prevalent: a 52 basepair-deletion (Type 1, 53%) and a 5 basepair-insertion (Type 2, 31%). 20% of mutations are infrequent, most of them being detected only in one patient. In addition to this high diversity of individual mutations, the highly repetitive sequence of exon 9 is another methodological hurdle. Currently, analysis of *CALR* mutations is performed by sequencing or fragment analysis.
Aims: We aimed to develop a fast and specific screening method for *CALR* mutation detection that can be performed with routine laboratory equipment.
Methods: DNA extracted from peripheral blood was amplified by FAST PCR, and PCR products were analyzed by heteroduplex analysis on agarose gels. All samples were sequenced.
Results: To date, 69 samples from *JAK2*V617F-negative patients with ET or PMF were analyzed. 42 patients carried *CALR* mutations of type 1 (n=23), type 2 (n=14) or individual mutations (n=5). Two homozygous mutations were identified. Individual mutations included c.1092-1124del, c.1094_1139del, c.1103_1148del, c.1147_1154delinsTGTC and c.1154_1155insATGTC. Mutant *CALR* was unambiguously represented by 2 or 3 bands while all single bands represented the wild-type sequence. Type 1 and type 2 mutations were identified by a specific pattern. Specificity and sensitivity of our screening assay are 100%, *i.e.* all mutated cases were detected, and none of the negative cases carried mutations. Analysis of more samples is ongoing to identify more rare mutations.
Summary and Conclusion: We present a specific and sensitive screening method for *CALR* mutations that is rapid and inexpensive and can easily be integrated in the routine molecular algorithm for ET and PMF.

P1035

A PROGNOSTIC MODEL TO PREDICT THROMBOSIS IN ESSENTIAL THROMBOCYTHEMIA

D Lekovic[1,*], M Gotic[1,2], N Milic[2,3], P Miljic[1,2], A Bogdanovic[1,2], V Milosevic[1], M Mitrovic[1], V Cokic[4], I Elezovic[1,2]
[1]Clinic for Hematology, Clinical Center of Serbia, [2]Medical faculty, [3]Institute for Medical Statistics, [4]Institute for Medical Research, University of Belgrade, Belgrade, Serbia

Background: Current risk stratification in essential thrombocythemia (ET) is designed to estimate the likelihood of thrombotic complications: high-risk is defined by the presence of age >60 years and/or presence of thrombosis history; low-risk is defined by the absence of these risk factors. Recent data consider some additional risk factors for thrombosis, such as JAK2 mutations and cardiovascular risk factors, but also show a loss of prognostic value of an older age in multivariate analysis.
Aims: The aim of our study was to identify prognostic factors at the time of diagnosis with an impact on prediction of thrombosis in ET patients.
Methods: We retrospectively analysed 244 WHO-defined ET pts who were completely treated and followed in our clinic from January 2000 to January 2012. The median follow-up was 83 months (range 16-156). We analyzed influence of age, gender, laboratory parameters, history of previous thrombosis, spleen size, JAK2 mutation as well as the CV risk factors including arterial hypertension, diabetes, smoking attitude and hyperlipidemia. Patients were treated as follows: 48 pts (19.7%) received low-dose aspirin, 127 (52%) cytoreductive therapy and 69 (28.3%) combination of aspirin and cytoredutive therapy. During the study, 32 patients (13.2%) died.
Results: Mean age was 56 years (range 18-85) (M/F=77/167); median Plt count was $951x10^9$/L (range 497-3672); median WBC count $9.5x10^9$/L (range 4.9-20.6); median Hb 138g/L (range 90-170); splenomegaly had 26 pts (10.7%); JAK2 was analysed in 69 pts and detected in 59.4% of evaluated pts. Distribution of CV risk factors: arterial hypertension had 142 pts (58.2%), diabetes 21 (8.6%), smoking attitude 87 (35.7%) and hyperlidemia 37 pts (15.2%). Previous thrombosis was reported in 42 pts (17.2%) with 58 thrombotic events (45 arterial, 13 venous) distributed as follows: 30 pts had arterial thrombosis, 8 venous and 4 both. During the follow up 35 pts (14.3%) had 41 thrombotic events (22 arterial, 19 venous) including 17 pts with arterial, 16 with venous and 2 with both types of thrombosis with median time to thrombotic events 50 months (range 4-144). Laboratory parameters, age>60 years and JAK2 were not statistically significant for the thrombosis development. Significant predictors of thrombosis were: CV risk factors (p=0.001) and previous thrombosis (p=0.01). Accordingly, we assigned risk scores based on multivariable analysis–derived odds ratios (OR) to 1 CV risk factor (OR=3.9; 1 point), >1 CV risk factors (OR=10.1; 2 points) and previous thrombosis (OR=2.6; 1 point). A new 4-tiered prognostic model (low-risk=0 point; intermediate-1 risk=1 point; intermediate-2 risk=2 points and high-risk=3 points) was developed with the thrombosis risk of 3.8% of pts in low, 14.4% in intermediate-1, 21.2% in intermediate-2 and 60% of pts in high risk group (p<0.001). Regarding the therapy, not using aspirin was a predictor of thrombosis (HR 0.44; p=0.03). Patients with thrombotic complications during the follow-up had a significantly shorter survival (p=0.018).
Summary and Conclusion: The worldwide-recognized prognostic role of previous thrombotic events and older age in ET pts probably deserves some deeper insight. According to our results, the new score was made, based on cardiovascular risk factors and previous thrombosis and allows better discrimination to the prognostic risk groups. The use of aspirin alone or in combination with cytoreductive therapy reduces the risk of thrombosis.

P1036

CLINICAL FEATURES OF PATIENTS WITH ESSENTIAL THROMBOCYTHEMIA DIAGNOSED BETWEEN THE AGES OF 41-59YEARS IN COMPARISON TO PATIENTS DIAGNOSED AT OR BELOW THE AGE OF 40

G Kam[1,*], R Yiu[1], A L Ang[1], G C Wong[1]
[1]Department of Haematology, Singapore General Hospital, Singapore, Singapore

Background: Patients with essential thrombocythemia (ET) below the age of 40 are generally recognized as having a low risk of thrombosis and progression to acute leukemia and myelofibrosis. Patients aged 41-59years have been classified as having an intermediate thrombotic risk in some guidelines but have not been very well defined in terms of their thrombotic risk and natural history.
Aims: In this study, we evaluated the clinical characteristics and outcomes of patients diagnosed with ET between the ages of 41-59years relative to patients diagnosed at age 40 and below.
Methods: 170 patients below the age of 60 at diagnosis were retrieved from our institution's Myeloproliferative Neoplasms (MPN) Registry and their records retrospectively reviewed. 62.4% were between the ages of 41-59 at diagnosis. Diagnosis of ET was made using either the PVSG or WHO 2008 diagnostic criteria depending on date of diagnosis. Statistical analysis was done using standard statistical methods.
Results: Median follow up for all patients was 8.8years. There was no difference in clinical features at diagnosis although more patients in the older group had a prior thrombosis (15.1%) compared to the younger group (4.7%) (p=0.037). There was no difference in the IPSET scores for survival and thrombosis. No difference in use of antiplatelet agents was found: 87.5% of younger patients compared to 91.5% of older patients (p=0.4); but more of the older (92.5%) than younger patients received cytoreduction (79.7%) (p=0.014). Patients in the older group had a worse overall survival (OS) with a median survival of 26.7years compared to 33.8years (p=0.013). 10year cumulative thrombosis rate was 10% for those aged 41-59years, and 0% for patients at age 40 or less (p=0.003). There was no difference in rates of progression to acute leukaemia or myelofibrosis and bleeding events. Incidence rates for the older group compared to the younger group for death, thrombosis, and bleeding (per 100 patient-years) were: 1.11 *versus* (*vs.*) 0.28 (Incidence rate ratio (IRR) 3.93, p=0.03), 1.39 *vs.* 0.14 (IRR 9.82, p<0.005) and 0.74 *vs.* 0.14 (IRR 5.23, p=0.04) respectively. There was no difference in the incidence rates for leukemic or myelofibrotic transformation. On univariate analysis, age 41-59 at diagnosis (p=0.013), presenting platelet count >1000 x 10^9/L (p=0.019), presenting white blood cell count ≥ 11 x 10^9/L (p=0.021) and being in the intermediate IPSET survival risk group predicted a worse OS (p<0.005). Use of antiplatelet or cytoreductive agents had no impact on OS. With multivariate analysis, age 41-59 at diagnosis (Hazard ratio (HR) 9.59, p=0.034) and a platelet >1000 x 10^9/L at diagnosis (HR 6.00, p=0.011) remained as predictors of poorer OS. For thrombotic risk, age 41-59 at diagnosis (p=0.003), prior thrombosis (p=0.015), presence of mutated JAK2 V617F (p=0.008), and presence of one or more cardiovascular risk factors (p=0.005) negatively affected risk of thrombosis (p=0.015). Being in the IPSET thrombosis low risk group also predicted lower thrombotic risk (p=0.004) but use of antiplatelet agents or cytoreduction had no impact on thrombotic risk. On multivariate analysis though, none of these factors were borne out.
Summary and Conclusion: Patients diagnosed with ET between 41-59years at diagnosis constitute a higher risk group with poorer OS and increased incidence of thrombosis. These findings should be confirmed with larger studies. The risk factors for such events and optimal management of this group of patients will also have to be delineated.

P1037

CARDIOVASCULAR EVENTS: RISK FACTORS AND CORRELATIONS WITH THE JAK2V617F ALLELE BURDEN IN PATIENTS WITH PH'-NEGATIVE MYELOPROLIFERATIVE NEOPLASMS. A MONOCENTRIC STUDY

G Fontanelli[1,*], C Baratè[1], E Ciabatti[1], F Guerrini[1], R Arici[1], S Barsotti[1], S Galimberti[1], M Petrini[1]

[1]Department of Clinical and Experimental Medicine, University of Pisa, U.O. Hematology, Pisa, Italy

Background: Myeloproliferative neoplasms (MPN) are a group of clonal diseases associated with JAK2 mutation (V617F) in a percentage varying from 50% (Essential Thrombocytemia and Myelofibrosis) to 95% (Polycitemia Vera). Treatment targets are represented by the maintenance of an adequate blood count, the reduction of the systemic symptoms, and the prevention of the cardiovascular events. Recent papers reported an association between the JAK2V617F mutation and the venous/arterial thromboses, although many studies are still in progress in order to assess whether this parameter can be considered to play an independent role in patients that often present comorbidities or already known cardiovascular risk factors.

Aims: To correlate the presence of the JAK2 mutation, or its mutated allele burden, to the vascular events in MPN patients and to weight the JAK2 significance in respect of the cardio-vascular risk factors.

Methods: We analyzed 384 patients (median age 65 years; range 20-85) affected by Ph'-negative neoplasms for the JAK2V617F mutation by using the *JAK2* Muta*Screen* kit, that is based on the TaqMan allelic discrimination technique. In the mutated cases, the *JAK2* Muta*Quant kit* was used to quantitate the mutated allele (Ipsogen, Luminy Biotech, Marseille, France). The sensitivity of these tests was $1x10^{-4}$. Some of our cases have been also assessed by mean of a new technique, the droplet digital PCR (dPCR, BIO-RAD), that allows the quantitation of the mutated allele without any reference curve.

Results: The JAK2V617F mutation has been reported in 223 (58%) of our patients: in the 57% of the patients with Essential Thrombocythemia (ET), 77% with Polycitemia Vera (PV) and 62% with Myelofibrosis (MF). The mean allele burden was 39.5%: the percentage of the mutated allele was significantly highest in the MF, followed by the PV and then by the ET ($p<0.01$), and it significantly correlated with the WBC count ($p=0.02$). Cardiovascular events have been reported in 124 out of the 223 mutated patients (56%); they were mainly distributed on the arterial side (52%), in particular myocardial infarction (35%), ictus cerebri (24%), and ischemic transitory attack (14%). Among venous events, the deep venous thromboses (44%) were predominant. The events were significantly correlated with the high risk of diseases at diagnosis ($p<0.01$), a PADUA score >4 ($p<0.01$), and dyslipidemia ($p=0.04$). On the contrary, their occurrence was independent from the smoke, diabetes, and hypertension. In addition, vascular events did not correlate with leucocyte count, hematocrit, platelet, and JAK2 allele burden.

Table 1.

Characteristics of the patients

N° patients	384
Age	20-89 (median 65)
Gender	
M	177 (46%)
F	207 (54%)
Diagnosis	
PV	51 (22%)
TE	23 (57%)
MF	14 (13%)
Not Determined	15 (3%)
JAK2V617F	223/384 (58%)
JAK2V617F with vascular events	124/223 (56%)

Summary and Conclusion: Our study showed that more than the half of patients affected by MPN presented cardio-vascular events. Their occurrence was higher in cases with WBC>11000/uL, high risk diseases, and in those showing a high PADUA score. The mutated allele burden, measured by both real-time and droplet PCR, did not significantly condition the occurrence of cardio-vascular events.

Background: Myelofibrosis(MF) is a chronic myeloproliferative neoplasm that affects approximately 12 individuals per 1 million people a year. The patients' survival depends on the severity and speed of progression of the disease and can vary from 2 years to more than 11 years.

Aims: The objective of the current research was to quantify the burden of illness(BoI) on patients and their families in Italy. The impact of MF on productivity and QoL, the impact of treatments with ruxolitinib or other therapies and the experience of caregivers were evaluated through written interviews consisting of a quantitative part and a narrative medicine part.

Methods: Target of research were patients affected by primary or secondary MF and unpaid caregivers. In 35 Italian haematological centers questionnaires were distributed under the supervision of ISTUD Foundation, between September 2012 and October 2013, with written consent form signed and an Ethic Committee approved protocol. For the quantification of the BoI, 287 questionnaire of patients and 98 of caregivers and, respectively, 210 and 62 their stories were collected.

Results: The patients' mean age was 65 years, 55% were men and 45% women. At the time of diagnosis, the most frequent feelings were fear(70%) and depression(28%); this affected the patients' mindset that is aimed primarily at living in the present tense(50%) or fearing no possible future(27%), as resulted from their stories. 48% of patients were forced to give up the gratifying movement activities mainly because of splenomegaly(70%) and fatigue(64%). In addition, 35% of patients failed to continue their work, with a mean loss of income of 8.065€ per year. Further analyses showed that patients treated with ruxolitinib had a reduction of the spleen in 71% of cases, amounting to 19% if on other therapies. 92% of patients treated with ruxolitinib improved symptoms (59% if on other therapies) and pace of work in 87% of cases(44% if on other therapies). The 98 caregivers interviewed were 41% men and 55% women with a mean age of 55 years. They declared to take care of their relatives for more than 3 hours per day in 45% of cases. As a result of the impact of MF, 87% of caregivers resulted highly stressed, as measured with the "*Caregiver self-assessment questionnaire*" of the AMA. Nevertheless, through narrative it came out that coping was present in 53% of the experience and the success factors were not only love and responsibility, but also the possibility to rely on health professionals, friend or colleagues. In terms of lost revenue due to the care they perform, caregivers declare a quantifiable loss of 4.692€ per year, mainly because only 19% of caregivers manage to maintain their pace of work; to this productivity loss, the mean annual cost of 7.302€ for those who need family support is added.

Figure 1.

Summary and Conclusion: These results suggest that MF causes a heavy loss of income for both patients and caregivers who are still in productive age, as well as high intangible costs determined by the severe limitations on the QoL of people with MF and by the high stress induced by the burden of care. Furthermore, it has been estimated that, to pay an external caregiver the average annual cost would range between 6.606 and 10.590€. Psychological burden affect both patients and caregivers. However from these data the use of ruxolitinib appears to reduce the BoI of patients with MF in terms of restarted activity, work maintenance and social and relational wellbeing. A special reward goes to the Italian hematologies, patients and their families for having partecipated to this project.

Background: The role gender plays in the development of myeloproliferative neoplasms (MPNs) and their complications has been a topic of intense investigation. Though notable differences have been observed in rates of disease occurrence, JAK2V617F mutation status and vascular risk profiles, to date no study has investigated the role of gender differences in MPN symptom development.

Aims: We sought to further analyze the relationships between gender differences and MPN disease features, disease risk, individual MPN symptom prevalence and severity, languages and overall quality of life.

Methods: Data was collected among an international cohort of patients with MPNs including essential thrombocythemia (ET), polycythemia vera (PV) and myelofibrosis (MF). Subjects completed the Brief Fatigue Inventory (BFI) and MPN Symptom Assessment Form (MPN-SAF) instruments. Demographics were compared between males and females using t-tests, Wilcoxon rank-sum tests, and chi-squared tests. Symptoms and TSS were compared between males and females using a general linear model adjusting for MPN type and age.

Results: A total of 2006 subjects with MPNs (ET=830, PV=711, MF=460) were prospectively enrolled and administered the MPN-SAF and BFI. The prevalence of each gender (M=917, F=1089) was similar. Differences between genders were observed in the distribution of MPN type (M: ET=33%, PV=42%, MF=25%; F: ET=49%, PV=30%, MF=21%; p<0.001) and MF subtype (M: PMF=75%, post-ET=14%, post-PV=11%; F: PMF=62%, post-ET=22%, post-PV=17%; p=0.01). Males were slightly older (mean 60.7 yrs [SD 12.6] *vs* mean 59.3 yrs [SD 14.4]; p=0.02), had a higher rate of requirement for red blood cell transfusion (7% *vs* 5%, p=0.02), and had higher mean white blood cell count (mean 9.5x10^9/L [SD 8.2 x10^9/L] *vs* mean 8.5 x10^9/L [SD 6.1x10^9/L]; p=0.004) relative to females. Females had a lower rate of thrombocytopenia (8% *vs* 14%, p<0.001). No differences between the genders were noted in language, MPN risk score (DIPSS, IPSET, PV Risk), anemia, leukopenia, prior thrombosis or prior hemorrhage. Adjusted mean BFI and MPN-SAF items (adjusted for MPN type and age) by gender are listed in Table 1. 15/18 symptom items were higher in females relative to males with 13 reaching statistical significance (p<0.05). Symptom differences between genders were most prominent for fatigue, bone pain, abdominal discomfort, and microvascular dysfunction. TSS was statistically significantly higher in females relative to males (adjusted mean 23.9 *vs* 20.6; p<0.001). Difference in overall quality of life (QOL) did not reach statistical significance (adjusted mean 3.1 *vs* 2.9; p=0.19).

Table 1.

MPN-SAF Item/Scale	Adjusted Mean		P-Value
	Female	Male	
WORST fatigue (BFI)	4.7	4.1	<0.001
Early satiety	2.8	2.4	0.003
Abdominal pain	1.8	1.3	<0.001
Abdominal discomfort	2.2	1.7	<0.001
Inactivity	2.7	2.4	0.03
Headache	2.2	1.8	<0.001
Concentration	2.7	2.4	0.009
Dizziness	2.3	2.0	<0.001
Numbness	2.7	2.2	<0.001
Insomnia	3.5	2.4	<0.001
Sad mood	2.8	2.3	0.009
Sexuality	3.8	3.8	0.32
Cough	1.5	1.4	0.22
Night sweats	2.5	2.0	<0.001
Itching	2.3	2.1	0.16
Bone pain	2.3	1.8	<0.001
Fever	0.5	0.5	0.79
Weight loss	1.4	1.5	0.22
Overall quality of life	3.1	2.9	0.19
MPN-SAF TSS	23.9	20.6	<0.001

Summary and Conclusion: Heterogeneity in disease features and symptom burden exist between the two genders among MPN patients. Overall, females had a statistically significantly higher adjusted symptom score mean in most symptom areas, as well as a statistically significantly higher TSS, though the magnitude of the differences in symptoms and TSS were small in terms of

clinical meaningfulness. This increased symptom burden did not translate into a difference in overall QOL. These data suggest that either females enjoy a higher QOL despite experiencing more symptoms, or, conversely, that both genders enjoy the same QOL because the symptom burden is in fact equal but females are more likely to report their symptoms.As previously reported, females described more abdominal symptoms. However, in distinction to previous reports, these symptoms were not the result of abdominal thrombosis suggesting that abdominal symptoms in females are multifactorial and worthy of additional investigation. Though higher rates of macrothrombosis have been previously documented in females, the high rates of microvascular symptoms and platelet counts suggests females may also suffer from higher rates of microthrombosis.

Hodgkin lymphoma - Clinical

P1040

OUTCOME OF PATIENTS AGED OVER 60 WITH CLASSICAL HODGKIN LYMPHOMA TREATED WITH ABVD

A Stamatoullas[1,*], P Brice[2], R Bouabdallah[3], V Camus[1], I Rahal[3], P Franchi[2], H Lanic[1], H Tilly[1]
[1]Hematology, Centre Henri Becquerel, Rouen, [2]Hematology, Hôpital Saint Louis, Paris, [3]Hematology, Institut Paoli Calmette, Marseille, France

Background: Approximately twenty percent of classical Hodgkin's Lymphoma (cHL) patients are aged over 60 years. There is no standard of care in this age group. ABVD (Doxorubicin, bleomycin, vinblastine and dacarbazine), proposed for younger patients, is also used in elderly patients but little is known about its toxicity and efficacy. Recently, the German group published his experience for early-stage cHL treated within their trials with ABVD and concluded that four cycles were associated with substantial toxicity leading to dose reduction, delay and mortality.
Aims: In order to evaluate our everyday life practice, we reviewed patients referred to three French hematological departments.
Methods: We retrospectively analyzed efficacy and toxicity of ABVD in 147 patients aged over 60 years referred to Hôpital Saint-Louis in Paris, Institut Paoli Calmette in Marseille and Centre Henri-Becquerel in Rouen between January 1997 and September 2012.
Results: Median age was 68 years (60-88), sex ratio 82M/65F. According to Ann Arbor, stage was I-II-III-IV in 16-47-42-42 patients, respectively. Performance status was 0 in 61 patients, 1 in 50, 2 in 24, and >2 in 5. B symptoms were present in 84 patients. All patients received at least 1 ABVD (1-8), 50 patients received additional radiotherapy. 120 patients achieved a CR (82%), 5 a PR, 15 had refractory disease and 7 couldn't be evaluated. Twenty-five patients relapsed and 11 of them achieved a CR2. Pulmonary toxicity occurred at a median delay of 5 months from the first cycle (range: 1-31). Early pulmonary toxicity (32 patients) led to a treatment regimen modification in 24 patients. There was no significant correlation between pulmonary toxicity and pulmonary history, tobacco use, age, G-CSF, and radiotherapy. Overall survival for the whole group at five years was estimated at 67% (95% CI 58-74). Overall survival was significantly influenced by age ≤ 70 *vs* >70, stage I-II *vs* III-IV and PS 0 *vs* ≥ 1. With a median follow-up of 58 months, 52 patients died, 18 from disease progression, 17 from toxicity, 11 from secondary tumors and 6 from unknown cause.
Summary and Conclusion: Our study confirms the efficacy of ABVD in elderly patients. The high frequency of pulmonary events let us to propose either to remove bleomycin from the regimen or to reduce the dose as no factor appears to predict the occurrence of this toxicity.

P1041

EVALUATION OF THE PROGNOSTIC ROLE OF TISSUE ASSOCIATED MACROPHAGES (TAM) IN HODGKIN LYMPHOMA AND CORRELATION WITH EARLY FDG-PET ASSESSMENT

E Cencini[1], A Fabbri[1,*], L Rigacci[2], S Lazzi[3], G Gini[4], MC Cox[5], S Mancuso[6], E Abruzzese[7], B Puccini[2], S Kovalchuk[2], G Goteri[8], A Di Napoli[9], R Bono[6], S Fratoni[10], G Bartalucci[1], L Schiattone[1], DL Simonetta[11], B Alberto[2], L Leoncini[3], M Bocchia[1]

Background: Hodgkin Lymphoma (HL) is a highly curable malignancy that mostly affects young adults; despite satisfactory results, about 20% of patients still die of relapsed/refractory disease and late toxic effects rate, often due to over treatment, continue to rise with time. Consequently, the optimal treatment should be designed based on prognostic models, but currently all of them predict outcome with scarce accuracy. Since in the last few years "early FDG-PET" and tissue macrophages infiltration in diagnostic specimens (TAM) emerged as powerful independent prognostic predictors, we previously conducted a pivotal analysis aimed to confirm these issues and looking for a possible link between the 2 tools, concluding that only early FDG-PET was a reliable prognostic factor.
Aims: The primary endpoint of this study was to investigate, in a larger cohort of patients with a longer follow-up, the prognostic role of both early-FDG PET and TAM, while the secondary endpoint was to test if early-FDG PET positivity could correlate with high TAM in diagnostic specimens.

Methods: A cohort of 200 patients (M/F: 105/95; median age 33.5 yrs) diagnosed and treated at 6 Italian hematology institutions between March 2005 and December 2012 was retrospectively analyzed. All patients, diagnosed with classic HL, completed staging with whole body CT scan, FDG-PET and bone marrow biopsy. Eleven patients had stage I disease, 92 stage II, 55 stage III and 42 stage IV. Induction treatment plan consisted, according to staging, of 2-6 courses of ABVD and, if indicated, involved field radiation therapy. Patients repeated CT scan and FDG-PET after 2 cycles and after the completion of therapy. TAM in paraffin embedded diagnostic specimens were determined by immunohistochemistry with a monoclonal antibody (anti-CD68 KP1, Dako®) and classified in 3 groups, based on the percentage of CD68+ cells, as previously reported by Steidl and coworkers (NEJM; 2010).
Results: Overall, 168 out of 200 (84%) patients achieved a complete remission (CR), while 32 (16%) failed first line treatment, with 10 partial responses (PR) and 22 non-responders (NR); among responders 20 pts (10%) relapsed. After 2 cycles of ABVD, FDG-PET was negative in 163 patients (81.5%) and positive in 37 patients (18.5%), showing a high negative predictive value of 93% (95% CI=88-96%) and a significant correlation with the achievement of CR (p<.0001 by Fisher exact probability test). After a median follow-up of 40 months 194/200 patients were alive, progression free survival (PFS) was significantly better for PET negative patients (p<.0001). CD68 expression in diagnostic specimens was low, intermediate or high in 26 (13%), 100 (50%) and 74 (37%) cases respectively; moreover TAM score among responders was low in 23/168 cases (13.7%), intermediate in 85 (50.6%) and high in 60 (35.7%), while in non-responders was low in 3/32 cases (9.4%), intermediate in 15 (46.9%) and high in 14 (43.7%). PFS analysis showed no significant difference in any score group. Analysis aimed to evidence a possible role of TAM as prognostic factor and its possible correlation with early FDG-PET resulted not statistically significant performing the Freeman-Halton extension of the Fisher exact probability test. We observed the same results when we separately analyzed both early (I and IIA) and advanced stage disease.
Summary and Conclusion: The results of this study confirm that early FDG-PET has a high prognostic power, while TAM score doesn't seem to influence the outcome of patients with HL; moreover, in contrast to our original hypothesis, doesn't correlate with FDG-PET assessment.

P1042

ROLE OF BONE MARROW BIOPSY IN HODGKIN LYMPHOMA STAGING IN THE POSITRON EMISSION TOMOGRAPHY/COMPUTED TOMOGRAPHY ERA

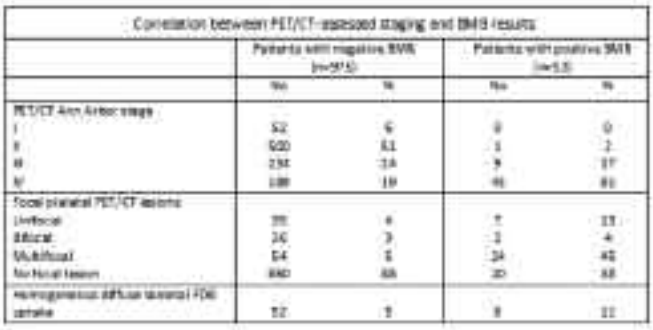
Ematologia e Trapianto, IRCCS - CRO della Basilicata, Rionero in Vulture, [12]USD - TMO Adulti Cattedra Ematologia, AO "Spedali Civili", Brescia, [13]Dipartimento di Ematologia, Azienda Sanitaria Locale, Pescara, [14]UO Oncologia Medica 2, IRCCS - Istituto Oncologico Veneto, Padova, Italy

Background: In recent years, several studies investigated the role of routine bone marrow biopsy (BMB) in newly diagnosed classic Hodgkin's lymphoma (cHL) staged with positron emission tomography (PET/CT): recently, a meta-analysis reported data of 955 cases in 9 different studies, to determine whether BMB is still necessary in patients (pts) staged at diagnosis with PET/CT.
Aims: We report data of pts with cHL assessed at diagnosis with both BMB and PET/CT in order to evaluate their concordance in the detection of bone marrow involvement from cHL.
Methods: Data from pts with cHL diagnosed consecutively since 2007 to 2013 at 14 haematology centers of the Fondazione Italiana Linfomi (FIL) were retrospectively collected, excluding those who did not performed both baseline BMB and PET/CT; Ann Arbor stage assessed only with PET/CT was then compared to stage resulting from PET/CT combined to BMB. The predictive significance of PET/CT was determined in terms of positive (PPV) and negative predictive value (NPV), sensitivity and specificity.
Results: In this survey we included 1180 pts; 152 were excluded due to the lack of baseline BMB or PET/CT. 1028 cases were evaluated, median age 33 (range, 14-80 years), 542 male (53%). Nodular sclerosis (70%) and mixed cellularity (20%) were the most common histotypes; bulky disease and B symptoms were present in 27% and 42% of pts, respectively. 148 pts (14%) presented one or more focal skeletal lesions at PET/TC and 53 (5%) had a positive BMB; other patients' characteristics are summarized in table. In 33/53 pts focal skeletal lesions evidenced by PET/CT revealed a positivity of BMB, while in 860/975 pts the absence of skeletal lesions or a diffuse skeletal FDG uptake combined with a negative BMB. Based on these data, PPV and NPV resulted to be 22% and 98%, respectively; sensitivity and specificity were 62% and 88%, respectively. Moreover, a total of 9 patients (1%), one in stage II (0.1%) and 8 in stage III (0,8%) according to PET/CT were upstaged by BMB to stage IV, inducing a change in treatment only in 1 patient (0.1%). Central revision of PET/CTs in BMB-positive cases is ongoing, and will be ready for June 2014.

Table 1.



Summary and Conclusion: Consistently to data previous reported, in stages I-II according to PET/CT, positive BMB were occasional; moreover, the NPV of PET/CT for bone marrow involvement was very high. Furthermore, the influence of BMB on the planning of treatment was minimal. On these grounds, BMB may be omitted in cHL patients staged with PET/CT.

P1044

A RANDOMIZED TRIAL OF ROUTINE SURVEILLANCE IMAGING PROCEDURES: ULTRASONOGRAPHY PLUS CHEST RADIOGRAPH *vs* FDG PET/CT FOR DETECTING RELAPSE IN PATIENTS WITH ADVANCED STAGE HODGKIN LYMPHOMA

N Pugliese[1,*], M Cirillo[2], P Zeppa[3], I Cozzolino[4], G Ciancia[4], G Pettinato[4], C Salvatore[5], M Di Perna[1], C Quintarelli[1], F Pane[1], M Picardi[1]
[1]Hematology, [2]Departments of Clinical Medicine and Surgery (, University of Naples Federico II, Naples, [3]Department of Medicine and Surgery, University Medical School, Salerno, [4]Advanced Biomedical Science, University of Naples Federico II, Naples, [5]Department of Economics, Management, Society and Institutions (C.S.), University of Molise, Campobasso, Italy

Background: Despite the high complete response (CR) rate to induction therapy with ABVD or ABVD-like regimens, about one-third of Hodgkin lymphoma (HL) patients with extensive disease at presentation are expected to relapse over time upon treatment discontinuation. Usually, 30%>50% of relapses are clinically asymptomatic, lacking any physical and/or laboratory sign. For patients at high risk of relapse, a close monitoring plan based on imaging procedures is justified, since early detection of recurrence allows a timely administration of appropriate salvage therapy. Nevertheless, only few clear indications for monitoring such patients are presently available. The existing guidelines are not evidence-based, and post-treatment follow-up is still left to "expert opinions". New imaging approaches are now available, and require validation in a randomized fashion.
Aims: This randomized study compared the benefits and pitfalls of [^{18}F] fluorodeoxyglucose positron emission tomography/computed tomography (FDG PET/CT) *vs.* ultrasonography (US) plus chest radiograph (CXR) to systematically follow-up patients with high risk HL. This study was designed as an equivalence trial.
Methods: From January 2001 to December 2009, in this single centre trial, after institutional review board approval and informed consent, patients with advanced stage HL, completely responding to first-line treatment, were randomly assigned (1:1) to either PET/CT-based or US**+**CXR-based follow-up. Follow-up imaging procedures in the US**+**CXR group comprised ultrasonographic scans for the evaluation of superficial-anterosuperior mediastinum-abdominal-pelvic (S-M-A-P) lymph nodes, and frontal and lateral CXR for the evaluation of mediastinum compartments. In the PET/CT group, total-body FDG PET/CT scans were carried out using a combined in-line system. The surveillance schedule for each arm implied 12 checkpoints, including clinical and imaging procedures, at 4, 8, 12, 16, 20, 24, 30, 36, 48, 60, 84 and 108 months after treatment discontinuation. When clinical and/or imaging procedures were positive, recurrence was histologically confirmed. The primary end-point was to compare the sensitivity of the two follow-up imaging approaches. Secondary endpoints were their specificity, positive and negative predictive values, time to recurrence detection, radiation risks and costs.
Results: Overall, 300 patients were randomized in the two arms. The study was closed after a median follow-up of 60 months, with a relapse rate of 27%.

Sensitivity in detecting HL was similar for the two follow-up approaches: 40/40 relapses were identified with FDG PET/CT (100%) *vs.* 39/40 relapses were identified with US plus CXR (97.5%; $p_{equivalence}$=0.0001). US plus CXR showed significantly higher specificity and positive predictive value than PET/CT: 96% (106/110) *vs.* 86% (95/110; p=0.02) and 91% (39/43) *vs.* 73% (40/55; p=0.01), respectively. Exposure to ionizing radiation was estimated to be 14.5 mSv per one PET/CT *vs.* 0.1 mSv per one CXR. Estimated cost per relapse diagnosed with routine PET/CT was 10-fold higher compared with routine US+CXR.
Summary and Conclusion: US and CXR are diagnostic tools that enable effective, safe and low-cost routine surveillance imaging for patients at high risk of HL relapse. This study could have an important impact on practice for the follow-up of patients with advanced stage HL in CR, making surveillance with modern US and CXR routine and decreasing the use of intensive radiological tools.

P1045

PET-ADAPTED TREATMENT MODIFICATION IN EARLY STAGE HODGKIN LYMPHOMA: A SYSTEMATIC REVIEW AND META-ANALYSIS

MT Sickinger[1,*], B von Tresckow[2], C Kobe[3], A Engert[2], P Borchmann[2], N Skoetz[1]
[1]Department I of Internal Medicine, Cochrane Hematological Malignancies Group, [2]Department I of Internal Medicine, Center of Integrated Oncology Cologne / Bonn, [3]Nuclear Medicine, Center of Integrated Oncology Cologne / Bonn, University Hospital of Cologne, Cologne, Germany

Background: Hodgkin lymphoma (HL) is one of the most common malignancies in young adults and, with cure rates of up to 90%, one of the most curable cancers worldwide. Depending on its stage, HL is treated with different regimens of chemotherapy plus radiotherapy. With FDG- PET, HL treatment is in the process of being modified: An interim PET scan, revealing good and poor responders to initial therapy, consequently leads to de- or escalated additional treatment.
Aims: It has been the aim of this systematic review and meta-analysis to assess the potential benefit of PET-adapted treatment in early stage HL patients and the more than interesting resulting question for clinical daily routine whether radiotherapy can be omitted in early stage PET-negative patients.
Methods: All randomized controlled trials (RCTs) comparing FDG-PET-adapted therapy to standard treatment in previously untreated early stage HL patients with a negative PET-scan were included. Two review authors independently screened search results and extracted relevant study data. We used hazard ratios (HR) for time-to-event data and risk rations (RR) for dichotomous data, with 95% confidence intervals (CI).
Results: Three RCTs involving a total of 1480 participants were included in the meta-analysis. Because no HRs for OS were provided, we used RR and did not pool the data. PFS at a median follow-up of 34 months manifested to be inferior in the PET-adapted arm (without radiotherapy) compared to the standard treatment arm. HR: 2.16 (95% CI 1.36 to 3.42; P=0.001) AEs were reported in one study only and showed no significant difference between both arms. There were no data on QoL and TRM available.

Figure 1.

Summary and Conclusion: Our review shows that PFS is significantly decreased if radiotherapy is omitted by performing PET-adapted therapy. Current studies do not provide any evidence for the risk to benefit assessment when balancing the risk of relapse and subsequent salvage therapy against the risk of very late toxicities from radiotherapy. Importantly, there are no data at all on the patients' preferences regarding this difficult question. Therefore, standard therapy based on scientific and academic practice includes both chemo- and radiotherapy in a combined modality approach.

P1046

PROGNOSTICATION BY FDG-PET DETECTED BONE MARROW INVOLVEMENT IN HODGKINS LYMPHOMA - A RETROSPECTIVE ANALYSIS

H Menon[1,*], B Chauhan[1], V Rangarajan[2], M Sengar[1], U Dangi[1], H Jain[1]
[1]Adult hemato-Lymphoid Unit, Department of Medical Oncology, [2]Department of Nuclear Medicine, Tata Memorial Hospital, Mumbai, India

Background: Bone marrow involvement is seen in 5–14% of Hodgkin's lymphoma (HL) patients. Currently, BMB is considered gold standard for the evaluation and documenting bone marrow (BM) involvement in HL. However, the chances of missing BM involvement on BMB are a reality especially in the setting of focal disease. With the introduction of FDG-PET into the staging procedures of HL, it became evident that the typical involvement of BM may not be homogenous but, rather, focal. The aim of the current study was to correlate BMB and PET/CT results as part of baseline staging work-up, understand the pattern of BM involvement on FDG-PET and to assess the impact of FDG-PET in the detection of bone marrow disease in patients with HL at baseline diagnosis.
Aims: The identify the concordance between baseline FDG-PET with bone marrow biopsy at initial staging of HL patients. To understand the patterns of bone marrow involvement evidenced on FDG-PET at diagnosis and to correlate outcomes of patient with BMB and FDG-PET evidence of BM involvement in terms of survival.
Methods: Patients diagnosed with HL above 15 years registered in the lymphoma clinic between June 2009 and June 2012 and having undergone both FDG-PET and BMB at baseline staging were included for final analysis. Disappearance of focal lesion in the marrow on interim PET was considered evidence of involvement. BM involvement on FDG-PET was documented as unifocal, bifocal, multifocal, or homogeneous. These were correlated with BMB findings. The log-rank test was performed to compare progression-free survival (PFS) for patients with positive BMB and those with skeletal PET/CT lesions along with negative BMB. Kaplan meier curves were used for survival analysis.
Results: 478 patients with HL were screened with 200 patients meeting the inclusion criteria. These patients were thereafter considered for further analysis. Abnormal skeletal FDG accumulation was noted in 60 (30%) patients. 28 (14%) had focal lesions (unifocal=10; bifocal=4; and multifocal=14). 32 (16%) patients had homogeneous FDG uptake in the axial and appendicular skeleton. All BMB positive patients (n=11) had either focal (n=7) or diffuse (n=3) on FDG-PET. Only one patient was upstaged based on positive BMB with negative PET. 32 patients with diffuse uptake in BM evidenced on PET yielded positivity in only 3 patients on BMB suggesting that diffuse involvement may not necessarily suggest true involvement and low sensitivity for FDG-PET in this situation. The overall sensitivity and specificity for FDG-PET in detecting positive *versus* negative BM were 91% and 73% respectively. Focal FDG-PET positive lesions yielded sensitivity of 64% and specificity of 98.4%. The median follow up period was 23 months and the overall 2 year PFS of the study cohort was 87.5%. The bone marrow biopsy positive patients had a 58.9% two year PFS as compared to 89.3% in bone marrow biopsy negative patients(P=0.08). The two year PFS in FDG-PET positive patients for BM was 73.4% as compared to 94% in FDG-PET negative patients (P=0.0001). There was no significant 2 year PFS (50%) difference between Multifocal PET BM involvement in bone marrow biopsy positive or negative cases, suggesting that these patients were equally burdened by HL.
Summary and Conclusion: Our study reiterates the high sensitivity of FDG-PET in assessing BM disease in HL. Multifocal FDG-PET uptake was a better indicator of BM involvement and correlated with similar outcomes as would for a patient with BMB positive disease. Diffuse involvement on FDG-PET may be non-specific and mostly doesn't correlate with BM involvement. We recommend that FDG-PET could safely replace BMB assessment of BM at baseline staging work up for Hodgkins lymphoma.

P1047

DOSE DENSE ABVD (DD-ABVD) AS FIRST LINE THERAPY IN EARLY-STAGE UNFAVORABLE HODGKIN LYMPHOMA (HL): PRELIMINARY RESULTS OF A PHASE II, PROSPECTIVE, ONGOING MULTI□CENTER STUDY BY FONDAZIONE ITALIANA LIN

R Mazza[1,*], G Specchia[2], M Spina[3], F Palombi[4], U Consoli[5], A Bosi[6], M Bonfichi[7], A Pulsoni[8], AM D'Arco[9], M Musso[10], F Merli[11], B Botto[12], L Giordano[13], C Carlo-Stella[1], A Santoro[1]

Background: Four cycles of ABVD plus 30 Gy on involved-field radiotherapy is the the standard of care for patients with early unfavorable Hodgkin lymphoma (HL).

Aims: Since dose-density might represent an important factor for achievement of complete remission and long-term survival, we designed a prospective, multicenter, phase II trial to investigate feasibility, safety and efficacy of dose-dense ABVD (dd-ABVD) in patients with early unfavorable HL.
Methods: Fifty-four patients (male 44%, age 18 to 70 years) with newly diagnosed stage I (6%) and II (94%) HL and unfavorable prognostic criteria according to EORTC received dd-ABVD consisting of standard dose ABVD on day 1 and 8 every 21 days instead of days 1 and 15 every 28 days. Patients with stage IIB bulky disease are excluded from the study. Granulocyte colony-stimulating factor (G-CSF) is scheduled as primary prophylaxis. Unless in progression, all patients received 4 cycles of dd-ABVD followed by 30 Gy on IFRT. In standard schedule ABVD, the proportion of patients without a dose intensity reduction is 95%. In order to exclude a dose intensity reduction in more than 10 % of pts treated with dd-ABVD, with a one-side alpha of 0.10 and beta of 0.15, 52 patients are needed. If 5 or more patients will present a dose intensity reduction, the study treatment will not be considered for further evaluation and the enrolment will be ended.
Results: Two out of 54 patients were not evaluable due to screening failure and consent withdrawal, respectively. Thirty sevent (9%) out of 416 evaluable ABVD infusions (208 cycles) were delayed due to hematological toxicity (n=10 cases), non-hematological toxicity (n=10 cases), logistic reasons (n=14), unknown reasons (n=3). One patient suspended bleomycin after first cycle. Four serious adverse events were registered: febrile neutropenia (n=2), erythematous papular skin lesion (n=1), chest pain (n=1). As compared to the planned dose intensity, the median dose intensity for doxorubicin, bleomycin, vinblastine, and dacarbazine were 97.6%, 97%, 95.7% and 97.7%, respectively. Overall 6 patients received a 100% dose-intensity, 24 patient a dose-intensity between 85% and 100% and 4 patients received a dose-intensity below 85%.
Summary and Conclusion: This feasibility analysis confirms the safety of this intensified administration schedule of dd-ABVD with G-CSF support. The main causes of therapy delay are due to logistic reason. The study is ongoing with the aim to evaluate dd-ABVD efficacy.

P1048

THE PROGNOSTIC SIGNIFICANCE OF THE ABSOLUTE LYMPHOCYTE TO ABSOLUTE MONOCYTE COUNT RATIO (ALC/AMC) IN HODGKIN LYMPHOMA (HL) UNDER TREATMENT WITH ABVD OR EQUIVALENT REGIMENS WITH OR WITHOUT RADIOTHERAPY

M Dimopoulou[1,*], K Petevi[2], M Angelopoulou[2], G Boutsikas[2], A Kanellopoulos[2], M Siakantaris[2], M Dimou[2], MC Kyrtsonis[2], T Tzenou[2], G Gainarou[2], P Flevari[2], P Panagiotidis[2], K Koutsi[2], V Telonis[2], L Papageorgiou[2], E Plata[2], P Tsafatridis[2], S Sachanas[3], G Pangalis[3], J Meletis[2], K Konstantopoulos[2], T Vassilakopoulos[2]
[1]Haematology Department, [2]Laikon General Hospital/ University of Athens, [3]Athens Medical Center, Athens, Greece

Background: Lymphocytopenia and increased CD68+ tumor-associated macrophages (TAMs) are adverse prognostic factors in HL. TAMs are derived from circulating monocytes and are possibly related to AMC. Recently, Porrata et al reported that a low ALC/AMC (<1.1) is an independent prognostic factor in HL. Subsequent studies used different cutoffs for ALC/AMC (1.5 and 2.9).
Aims: The validation of the prognostic significance of ALC/AMC in a group of homogenously treated HL patients (pts) and evaluation of various cut-offs used by different investigators.
Methods: We evaluated 507 pts with HL, treated with ABVD or equivalents (±RT), who had available data for ALC/AMC, determined by an automated blood counter at diagnosis. Median age was 32 yrs (15-87), 54% of patients were male, 36% had B-symptoms, 17% had stage IV disease, 48% had advanced stage (IB,IIB,III,IV), 31% had IPS ≥3, 79% nodular sclerosing histology and 19% mixed cellularity. Failure-free survival (FFS) was defined as time between treatment initiation and failure to achieve remission requiring switch to salvage therapy, relapse after remission or last follow-up; toxic deaths and deaths in remission of unrelated causes were not counted as events. The association between ALC/AMC and FFS was evaluated at all previously published cut-offs of as well as at the median ALC/AMC observed in the present series.
Results: Median follow-up of currently alive patients was 44 months. The median ALC/AMC was 2.24 (range 0.44-20.50, interquartile range; IQR 1.53-3.54). The median AMC was $0.653x10^9$/l (range 0.050-2.070, IQR 0.469-0.836). Lower ALC/AMC was associated with most established markers of increased tumor burden and aggressive biological behavior as well as with monocytosis and lymphocytopenia. In total 449 (89%), 390 (77%) and 183 (36%) patients had ALC/AMC ratio ≥ 1.1, ≥1.5, and ≥2.9 respectively and 20% of patients had monocytosis (≥.$0.9x10^9$/l). Ten-year FFS was 78% *vs* 56% for patients with ALC/AMC ≥1.1 and<1.1 respectively (p=0.0004), 78% *vs* 69% for patients with ALC/AMC ≥1.5 and<1.5 respectively (p=0.06), 79% *vs* 74% for patients with ALC/AMC ≥2.9 and<2.9 respectively (p=0.25) and 81% *vs* 70% for patients with ALC/AMC above and below the median value respectively (p=0.03). Patients with monocytosis (≥.$0.9x10^9$/l) had a 10-year FFS of 70% *vs* 80% for patients without monocytosis (p=0.0008).In early stages (IA/IIA) ALC/AMC had no significant effect on FFS irrespectively of the applied cutoff. In advanced stages ALC/AMC was statistically significant only at the cutoff of 1.1 (10-year FFS 69% *vs* 50% p=0.03). In multivariate analysis, ALC/AMC<1.1 was an independent prognostic factor (p=0.03) along with stage IV (p<0.001), obscuring the significance of all other IPS parameters, B-symptoms, elevated ESR and monocytosis. In a multivariate model including ALC/AMC and IPS (<3 *vs*. ≥3), both factors had independent prognostic significance (p=0.01 and p=0.03 respectively).
Summary and Conclusion: A highly reduced ALC/AMC ratio is an independent prognostic factor in HL treated with ABVD or equivalent regimens ± RT. Its prognostic impact is more profound in advanced-stage disease. In the present series, the cutoff of 1.1 appeared to be more predictive compared to other published cutoffs and the only one that had independent prognostic value in multivariate analysis. However, the prognostically inferior group comprised of only 11% of patients (*vs* ~30% in the initial study of Porrata et al). Further research is needed prior to the widespread use of this easily measurable and reproducible marker.

P1049

ABVD IN TREATMENT OF GENERATIVE AGE FEMALES WITH ADVANCED HODGKIN LYMPHOMA – A RISK FACTOR ANALYSIS

B Andjelic[1,*], M Todorovic[1,2], D Antic[1,2], J Bila[1,2], L Jakovic[1], A Sretenovic[1], V Djurasinovic[1], V Vukovic[1], J Jelicic[1], M Smiljanic[1], B Mihaljevic[1,2]
[1]Clinic for Hematology, Clinical Center of Serbia, [2]Faculty of Medicine, University of Belgrade, Belgrade, Serbia

Background: ABVD and escalated BEACOPP are currently the standard of care in patients with advanced Hodgkin Lymphoma (HL). The use of escalated BEACOPP gives better disease control but it is associated with more acute and late toxic effects, with post treatment infertility as one of the major complications. According to International prognostic score (IPS), patients with score 3-7 are considered as high risk. However, females of generative age who are at risk for infertility can have IPS score of maximum 5.
Aims: The aim of this study was to identify females of generative age with diagnosed advanced HL who should not be considered for more aggressive approach than ABVD.
Methods: A retrospective study was performed on 123 female patients younger than 40 years with advanced classical HL, diagnosed in the period June 1997-December 2008. The standard of initial care was 6-8 cycles of ABVD followed by radiotherapy. Prognostic relevance of IPS score, ESR≥50 mm/h, and presence of B symptoms, bulky disease and extranodal (EN) disease were examined.
Results: The median age of patients was 27 (range 17-40). The median follow up was 93 months. For the whole group 5-year event free survival (EFS) was 65% and 5-year overall survival (OS) was 82.1%. In univariate analysis, worse OS was found only in patients with IPS≥3 (5-year OS 60.7% *vs*. 88.4%; log rank, p=0.004), while presence of ESR≥50 mm/h, B symptoms, bulky disease or EN disease didn't influence OS (log rank; p=0.194, p=0.982, p=0.064, p=0.089, respectively). Worse EFS was found in patients with IPS≥3 (5-year EFS 46.4% *vs*. 73.7%) and EN disease (5-year EFS 48.5% *vs*.73.4%) (log rank; p=0.005, p=0.012, respectively), while presence of ESR≥50 mm/h, B symptoms or bulky disease didn't influence EFS (log rank; p=0.746, p=0.556, p=0.151, respectively). The multivariate Cox regression analysis identified only IPS≥3 as the independent prognostic factor both for OS (p=0.006) and EFS (p=0.005). Subsequently, we analyzed the subgroup of 95 patients with low IPS. In survival analysis, 29 patients without bulky disease (30.5% of low IPS patients, 23.6% of the entire group) had favorable both OS (5-year OS 100% *vs*. 81.8%, log rank, p=0.026) and EFS (5-year EFS 89.7% *vs*. 65.2%, log rank; p=0.034), with only 2 deaths until the end of follow up (figure). Based on IPS score (0, 1 or 2), presence of ESR≥50 mm/h, B symptoms and EN disease there was no difference both in OS (log rank; p=0.086, p=0.506, p=0.512, p=0.747, respectively) and EFS (log rank; p=0.102, p=0.835, p=0.414, p=0.382, respectively). Bulky disease in the subgroup of low IPS patients retained its prognostic significance in multivariate analysis both for OS (p=0.042; RR=4.674; 95% CI 1.058-20.561) and EFS (p=0.047; RR=2.920; 95% CI 1.012-8.480).

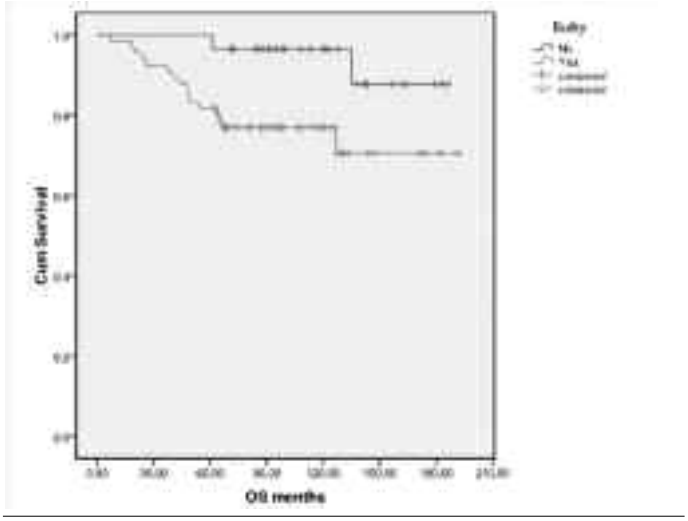

Figure 1.

Summary and Conclusion: ABVD is very effective treatment for female advanced HL patients younger than 40 years with low IPS and without bulky disease.

P1050

COMPARATIVE ASSESSMENT OF BONE MARROW INVOLVEMENT (BMI) BY BM BIOPSY (BMB) OR POSITRON EMISSION TOMOGRAPHY / COMPUTED TOMOGRAPHY (PET/CT) IN HODGKIN LYMPHOMA (HL)

T Vassilakopoulos[1,*], P Rondogianni[2], V Prasopoulos[3], S Chatziioanou[4], M Moschogiannis[5], C Poziopoulos[6], A Symeonidis[7], P Repoussis[8], C Matsouka[9], F N Kontopidou[10], V Sotiropoulos[11], E Variami[12], N A Viniou[12], P Zikos[13], K Petevi[1], G Boutsikas[1], A Kanellopoulos[1], L Papageorgiou[1], J Meletis[1], P Panayiotidis[14], G A Pangalis[5], I Datseris[2], K Konstantopoulos[1], M K Angelopoulou[1]

[1]Department of Haematology, Laikon General Hospital, [2]Department of Nuclear Medicine, Evangelismos Hospital, [3]Department of Nuclear Medicine, Hygeia Hospital, [4]Department of Nuclear Medicine, BRFAA, [5]Department of Haematology, Athens Medical Center, [6]Department of Haematology, Metropolitan Hospital of Athens, [7]Department of Haematology, University Hospital of Patras, [8]Department of Haematology, Metaxa Hospital, [9]Department of Haematology, Alexandra Hospital, [10]Department of Haematology, Ippokration Hospital, [11]Department of Nuclear Medicine, Athens Medical Center, [12]First Department of Internal Medicine, Laikon General Hospital, [13]Department of Haematology, Agios Andreas Hospital, [14]First Propedeutic Department of Internal Medicine, Laikon General Hospital, Athens, Greece

Background: BMI is observed in ~6% of HL patients (pts) at initial diagnosis and can be predicted by baseline characteristic combinations. PET/CT is a sensitive tool for HL staging. Recent data suggest that few pts may have a positive BMB in the absence of PET/CT evidence, thus questioning the need of BMB.
Aims: (1) To correlate BMB and baseline disease characteristics with BM-PET/CT findings in a series of 172 HL pts; (2) to assess the impact of our previously published clinical prediction rule (Vassilakopoulos et al, Blood. 2005;105:1875-80) on the frequency of BMI detected by either method; and (3) to assess the ability to omit BMB in selected or even all pts.
Methods: After reviewing all baseline PET/CT reports performed in Greek Centers, data regarding BMB, demographics, clinical and laboratory characteristics were retrieved from medical records. Electronic PET/CT data were reviewed by the responsible Nuclear Medicine physicians according to osseous/BM findings and were visually graded as follows: (1) no increased BM FDG uptake; (2) increased BM FDG uptake ≤liver; (3) increased BM FDG uptake >liver; (4) solitary osseous/BM focus without CT correlate; (5) multiple osseous/BM foci. Pts were also classified according to our clinical prediction rule for BMI (based on age, B-symptoms, pre-BMB stage, inguinal/iliac involvement, hemoglobin, leukocyte count) in low-, standard- and high-risk groups.
Results: Combined PET/CT and BMB data were available for 179 pts at the time of the analysis; 166 had full data for risk classification. PET/CT was negative for BMI in 148 pts (83%; 81, 33, and 34 pts with scores 1,2,3) and positive in 31 pts (17%) with multiple foci in the vast majority of them. Only 14 pts had BMI by BMB (7.8%). None of the pts of PET/CT categories 1,2,3 had a positive BMB; 14/31 pts graded as "4" or "5" had positive BMB (45%; all with score "5"). The clinical prediction rule was well validated, since the frequency of BMI by BMB was 0% in low-risk group (44 pts or 27% of the total population), 1.5% in the standard-risk group (1/65 pts or 39% of the total population) and 21.1% in the high-risk group (12/57 pts or 34% of the total population). PET/CT-based BMI was also effectively predicted: it was 0% in low-risk, 6.2% in standard-risk and 38.6% in the high-risk group. The outcome of the 14 pts with BMI by BMB was marginally inferior with 3-yr FFS 66% *vs*. 83% (p=0.16). The difference was more pronounced for the 31 pts with BMI by PET/CT (3-yr FFS 60% *vs*. 86%; p=0.004). Pts with BMI by PET/CT and negative or positive BMB had similar outcomes (3-yr FFS 57% *vs* 66%, p=0.68). Among 148 pts with negative BM by PET/CT, those with diffuse FDG uptake >liver tended to have increased "inflammatory" activity, as reflected by higher leukocyte and platelet counts, higher ESR and CRP levels.
Summary and Conclusion: PET/CT appears more efficient than BMB in detecting BMI, revealing >2 times more cases. Increased diffuse BM FDG uptake is not associated with BMI, but appears to reflect cytokine-related "inflammatory" activity. Our previously published clinical prediction rule was adequately validated regarding the prediction of BMI by either BMB or PET/CT, suggesting that the selected prognostic covariates are valid for BMI irrespective of the method of detection. There was no case of positive BMB in the absence of BMI by PET/CT. These data confirm that BMB can be safely omitted in all HL pts staged by PET/CT, since there was no high-risk group who might obtain a benefit from the combination of PET/CT and BMB.

P1051

EBV VIRAL LOAD DOES NOT IMPACT ON THE CLINICAL OUTCOME OF LOCALIZED HODGKIN LYMPHOMA (HL) – RESULTS FROM A SINGLE REFERENCE CENTER

I Barbosa[1,*], S Esteves[2], M Cunha[3], J Cabeçadas[4], M Gomes da Silva[1]

[1]Haematology Unit, [2]Clinical Research Office, [3]Virology Lab - clinical pathology, [4]Pathology, Portuguese Institute of Oncology, Lisbon, Portugal, Lisbon, Portugal

Background: Localized forms constitute 40 to 50% of all HL cases. Clinical and laboratory features are variably used by different cooperative groups (GELA, EORTC, GHLSG) to define patients with less favorable outcomes within this generally good prognosis population. EBV is present in about 40% of cases and viral circulating DNA can be detected in these patients, with a good correlation with tumor infection evaluated by EBER-ISH. Recently, plasma EBV viral load before treatment has been shown to have prognostic impact in advanced, homogeneously treated Hodgkin lymphoma.
Aims: With the aim of assessing the impact of pre-treatment plasma/serum EBV viral load in localized Hodgkin lymphoma, we retrospectively evaluated the demographic, histological and clinical characteristics (including staging, B symptoms, Erythrocyte Sedimentation Rate, presence of bulky disease, number of nodal areas involved and extra-nodal involvement) of a series of localized HL patients diagnosed and treated at our institution between 2003 and 2011 and correlated the clinical outcome (failure-free survival, FFS, from diagnosis to relapse, progression or death) with viral load determined by Real Time PCR (qPCR): amplification of 74 bp fragment from BNRF1 gene.
Methods: Wilcoxon rank sum test, Fisher's exact test and Pearson Chi square were used for comparisons between patients with and without detectable viral load (EBV+ and EBV-, respectively) as appropriate. The Kaplan-Meier method was used to estimate FFS and the log-rank test to compare the outcomes between groups. A multivariate analysis was also conducted using Cox proportional hazards model.
Results: 92 patients (51% females, median age 30, 15-76 yo) were identified with stage I (A-10%, B-1%) and II (A-73%, B-16%) HL. Classical HL constituted 97% of cases, with 80% nodular sclerosis, 7% mixed cellularity and 9% NOS. Bulky mediastinal disease was present in 15% and according to the GHLSG criteria 49% patients were early stage-favorable. Treatment was ABVD (median 6 cycles) and IF radiotherapy (30-40Gy) in 79%. Radiotherapy wasn't used in 17 patients due to progression or death during treatment (4), risk of excessive toxicity (6) or physician decision (7) and these patients received a higher number of ABVD cycles (p=0.04). Pre-treatment EBV DNA was detectable (above the laboratory cut off) in 17 patients (18%). Mean viral load was 1008 EBV copies/ml [117; 3386]. EBV+ patients were older than the EBV- (43 *versus* 28yo, p=0.017) but had otherwise similar clinical characteristics and treatment. With a median follow up of 6.2 (0.2-10.6) years, 15 patients relapsed or progressed and 3 died. FFS at 5 years was 83.2% (CI 72%>89%) and was not influenced by EBV status (log rank test stratified by GHLSG risk group p=0.77). This result was confirmed in the multivariate analysis (HR for EBV+ 0.5, CI 0.2%>2.2%) controlling for prognostic stratification (early favorable and unfavorable groups), use of radiotherapy and number of chemotherapy cycles. In this model only early-unfavorable patients and patients not receiving radiotherapy had a significantly worse FFS.
Summary and Conclusion: In this uniformly treated series, EBV DNAemia was less frequently detectable than what has been described in advanced disease and EBV+ patients were older than EBV-. EBV status did not impact in the clinical outcome as measured by FFS. Future prospective studies in larger populations may clarify the prognostic value of EBV viral load before and during therapy for early-stage HL.

P1052

PRELIMINARY RESULTS OF THE TREATMENT OF PATIENTS WITH HODGKIN'S DISEASE FROM INTERMEDIATE RISK GROUP

I Kriachok[1,*], I Titorenko[1], K Filonenko[1], A Amdiev[2], O Novosad[1], O Aleksyk[1], T Kadnikova[1], Y Pastushenko[1], H Gubareva[1], Y Stepanishina[1], E Kushchevyy[1]
[1]Oncohematology, National Cancer Institute, Kyiv, [2]Oncohematology, Crimea Republikanisch Institution Oncological Hospital, Simferopol, Ukraine

Background: Patients with HD from intermediate risk group show unsatisfactory results with ABVD treatment. Intensification of the treatment with BEACOPP-esc/BEACOPP-14 regimens showed better efficacy with high toxicity rate. The attempt to decrease toxicity rate together with preservation of efficacy was made with the inclusion of combined treatment approach of 2 cycles of BEACOPP-esc + 4 cycles of ABVD. This approach showed promising results in previous studies.
Aims: To analyze the efficacy and toxicity of different treatment approaches in patients with HD from intermediate risk group.
Methods: Treatment-naïve patients with HD from intermediate risk group were randomized into three arms: treated with 6-8 cycles of BEACOPP-esc/BEACOPP-14 (55 patients) (group 1), treated with 2 cycles of BEACOPP-esc + 4 cycles of ABVD (48 patients) (group 2) and treated with ABVD regimen (53 patients) (group 3). Recruitment of patients is in progress.
Results: Overall response rate (ORR) was better in the group 1 and group 2 compared to the group 3: 96.36%, 95.83% and 83.02%, respectively (p<0.05). Complete response rate (CRR) was higher in the group 1and group 2 compared to the group 3: 88.68%, 86.95% and 77.27%, respectively (p<0.05). Toxicity was observed in 83.03% of cycles of chemotherapy in the group 1, 50.35% - in the group 2 and 15.09% - in the group 3, p<0.001. Main toxicity type was

hematological in all groups and was detected in 81.21%, 63.19% and 12.89% of cycles, respectively, p<0.001. Anemia grade 3-4 was observed in 24.1% of cases in the group 1, 3.47% of cases in the group 2 and 1.26% of cases in the group 3, p<0.001. Neutropenia grade 3-4 was observed in 58.31% of cases in the group 1, 23.96% of cases in the group 2 and 3.77% of cases in the group 3, p<0.001. Thrombocytopenia grade 3-4 was observed only in the group 1 in 13.36% of cases, p<0.001. Nonhematological toxicity was observed in 67.88% of cycles in the group 1, in 51.39% of cases in the group 2 and in 11.63% in the group 3. 56.67% of cycles in the group 1, 47.92% - in the group 2 and 8.81% - in the group 3 were followed by episodes of gastrointestinal toxicity, p<0.05. 23.64% of cycles in the group 1, 13.54% - in the group 2 and 2.52% in the group 3 were followed by episodes of inflectional complications, p<0.01. Neurotoxicity was observed in 4.54% of cycles in the group 1 and 3.13% - in the group 2 and wasn't detected in the group 3, p<0.05. No deaths due to complications were observed. 46.06% of patients in the group 1, 26.04% of patients in the group 2 and 7.55% of patients in the group 3 had alopecia.

Summary and Conclusion: Patients treated with 6-8 cycles of BEACOPP-esc/BEACOPP-14 and 2 cycles of BEACOPP-esc + 4 cycles of ABVD achieved comparable ORR (96.36% and 95.83% respectively). ORR in the ABVD arm was lower (83.02%). Toxicity rate was 83.03% in the group of -8 cycles of BEACOPP-esc/BEACOPP-14, 50.35% in the group of BEACOPP-esc + 4 cycles of ABVD and 15.09% in the ABVD group.

P1053

SERUM IMMUNOGLOBULINS IN PATIENTS WITH HODGKIN LYMPHOMA (HL): A NEGLECTED POTENTIAL PROGNOSTIC MARKER?

T P Vassilakopoulos[1,*], G Gainaru[1], M K Angelopoulou[1], K Petevi[1], G Boutsikas[1], A Kanellopoulos[1], M Siakantaris[2], E Variami[2], M Dimou[3], MC Kyrtsonis[3], M N Dimopoulou[1], T Tzenou[3], V Bartzi[3], P Flevari[1], L Papageorgiou[1], A Koutsi[1], V Telonis[1], K Zervakis[2], I Pessach[3], A Zannou[1], N Viniou[2], V Komninaka[1], P Tsaftaridis[1], E Plata[1], P Panayiotidis[3], J Meletis[1], G A Pangalis[4], K Konstantopoulos[1]

[1]Department of Haematology, [2]First Department of Internal Medicine, [3]First Propedeutic Department of Internal Medicine, Laikon General Hospital, [4]Department of Haematology, Athens Medical Center, Athens, Greece

Background: HL is characterized by cytokine deregulation and elevation of "inflammatory" markers, such as ESR, CRP, serum ferritin as well as a_2-globulin levels. Although clinical experience suggests that hypergammablobulinemia is not infrequent in HL, serum protein electrophoresis (SPE) findings with respect to γ-globulins have not been systematically studied. Similarly, little is known regarding serum immunoglobulin levels (sIgG, sIgA, sIgM). On the other hand, there are recent data implicating serum free light chain concentration (sFLC) in the prognosis of HL, without however the concomitant evaluation of SPE and serum immunoglobulin findings.

Aims: The evaluation of the prognostic significance of SPE-γG, sIgG, sIgA, and sIgM levels and their correlation with sFLC concentration.

Methods: We evaluated 330 pts with classical HL, treated with ABVD or equivalents (±radiotherapy), who had available data for SPE-γG levels. sIgG, sIgA, and sIgM levels were also studied in 267 patients (243 also had SPE-γG levels), while sFLC levels were available in 85 patients. "High" levels were defined as ≥1.6 g/dL for SPE-γG, ≥1400 mg/dL for sIgG, ≥410 mg/dL for sIgA, ≥230 mg/dL for sIgG and ≥57.1 mg/L for the sum of sFLC κ and λ. Failure-free survival (FFS) was defined as time between treatment initiation and failure to achieve remission requiring switch to salvage therapy, relapse after remission or last follow-up; toxic deaths and deaths in remission of unrelated causes were not counted as events.

Results: High SPE-γG were observed in 36% of the patients, high sIgG in 48%, sIgA in 15% and sIgM in 8%. *CORRELATIONS:* Generally, higher SPE-γG, sIgG and sIgA levels correlated with markers of disease burden and aggressiveness, while higher SPE-γG and sIgG also correlated with lower age, female gender and nodular sclerosing histology. Higher sIgM correlated advanced age, male gender, nodular sclerosing disease and lack of B-symptoms. There was a strong correlation between SPE-γG and sIgG (Spearman's rho 0.82, p<0.001). Both SPE-γG and sIgG moderately correlated with sIgA (rho 0.35-0.50, p<0.001) and sIgM (rho 0.25-0.30, p<0.001). SPE-γG, sIgG and sIgA were all moderately correlated with ESR and a_2-globulin levels (rho 0.30-0.45, p<0.001). Finally, SPE-γG, sIgG and sIgA correlated rather strongly with sFLC κ+λ (rho 0.50-0.60, p<0.001). *PROGNOSTIC SIGNIFICANCE:* High SPE-γG levels conferred inferior prognosis in univariate analysis (5-year FFS 82% *vs* 72% p=0.02). The same applied for sIgG as well (5-year FFS 85% *vs* 76% p=0.04). Neither sIgA, sIgM nor sFLC κ+λ concentrations were predictive of the outcome (although only 85 patients had available sFLC). In multivariate analysis of established conventional prognostic factors (including a_2-globulin and ESR), "high" SPE-γG was an independent adverse prognostic factor (hazard ratio 1.8, p=0.046) along with stage IV (hazard ratio 2.6, p=0.003). Similar results were obtained for "high" sIgG as well.

Summary and Conclusion: SPE-γG and serum immunoglobulin levels are frequently elevated in untreated classical HL. "High" SPE-γG or sIgG may be "classic" but neglected independent adverse prognostic factors. Due to their rather strong association with sFLC levels, the prognostic implication of sFLC in HL needs to be examined concomitantly with SPE-γG and/or sIgG, since they may reflect the same biologic process.

P1054

BRENTUXIMAB VEDOTIN FOR HODGKIN LYMPHOMA WHO HAD FAILED ALLOGENEIC STEM CELL TRANSPLANTATION: A MULTICENTER RETROSPECTIVE STUDY

F Ricci[1,*], C Carlo-Stella[1,2], S Dalto[3], R Mazza[1], M Malagola[4], F Patriarca[5], S Viviani[6], D Russo[4], L Castagna[1], L Giordano[1], P Corradini[3,7], A Santoro[1]

[1]Hematology and Oncology, Humanitas Cancer Center, Humanitas Clinical and Research Center, [2]Department of Medical Biotechnology and Translational Medicine, University of Milano, [3]Hematology and BMT Unit, Fondazione IRCCS Istituto Nazionale Tumori, Milano, [4]Hematology and BMT Unit, University of Brescia, Brescia, [5]Clinica Ematologica, Azienda Ospedaliera-Universitaria di Udine, Udine, [6]Medical Oncology, Fondazione IRCCS Istituto Nazionale Tumori, [7]Hematology, University of Milano, Milano, Italy

Background: Brentuximab vedotin (BV) has demonstrated an extraordinary efficacy in heavily pretreated Hodgkin lymphoma (HL) patients due to the selective targeting of CD30-positive cells. The mechanism of action of BV might also involve a cytokine-mediated antitumor immune response, further suggesting that this molecule may play a key role also in HL patients recurring after allogeneic (Allo)-SCT.

Aims: Since limited data have been so far reported on the efficacy of BV in HL patients failing Allo-SCT, we retrospectively evaluated in a multicenter setting efficacy and safety of BV in HL relapsing or progressing after Allo-SCT.

Methods: From June 2011 to January 2014, 16 patients with recurrent HL were included in a compassionate-use program and were treated with BV at four Institutions. BV was given intravenously at the dose of 1.8 mg/kg every 3 weeks. The study protocol was approved by the ethical committee of each participating center.

Results: Main demographic and disease characteristics of the patients are reported in Table 1. Patients received a median of 8 BV cycles (range, 1-17) and all but one are evaluable for response. Best response to BV was achieved after a median of 4 cycles (range, 2-12) and included 5 cases (33.5%) of complete remission (CR) and 5 cases (33.5%) of partial remission (PR), for an objective response rate (ORR) of 67%. Stable disease (SD) was observed in 4 cases and progressive disease (PD) in 1 patient. Patients achieving CR showed a continuous response persisting after a median of 4 months (range, 3-24+) from BV discontinuation. Two of them received either haploidentical allotransplant (n=1) or donor lymphocyte infusion (DLI) (n=1), while the remaining 3 patients did not receive any further treatment after BV discontinuation. All patients achieving PR experienced PD after a median of 8 cycles (range, 5-17). Patients in SD progressed after a median of 3 months (range, 2 - 6). After a median follow-up of 26 months, the median progression-free survival (PFS) and overall survival (OS) were 11 and 25 months, respectively. The 2-yr PFS and OS were 22% and 48%, respectively. At the last follow-up, 10 out of the 16 patients were alive, four of them in continuous CR. Cause of death was PD in 5 patients, pulmonary GVHD while in CR in one patient. The most common adverse events were peripheral sensory neuropathy: grade 1 neuropathy in 3 cases and grade 3 neuropathy in one case. One patient developed a Guillain Barrè syndrome. Two infections (12.5 %) were documented, both sustained by gram positive bacteria. Two patients experienced FUO (12.5%).

Table 1.

Characteristics	N
Median age, y (range)	29 (22-43)
Male sex, n (%)	13(81%)
Bulky disease	3 (18.7%)
Median time from diagnosis to first dose of BV, months	81
Median time from alloSCT to first dose of BV, months	30
Median time from last therapy to first dose of BV, months	2.5
Median n. of prior regimen (range)	8 (4-13)
Median n. of regimen between alloSCT and BV (range)	4 (0-4)
Prior autoSCT	10
Prior alloSCT	10
Prior DLI	8
Prior radiation therapy	16
Refractory to last therapy before BV	14 (87.5%)

Summary and Conclusion: This retrospective study confirms that BV as single agent is safe and effective to achieve a short-term disease control in HL patients progressing after Allo-SCT. Our results do not support the capacity of BV to induce a long-lasting disease control, strongly suggesting that BV should be

used in combination with other agents in order to increase the ORR and enhance disease control.

P1055

POST-TREATMENT RESIDUAL MASSES DETECTED BY COMPUTED TOMOGRAPHY SCAN SIGNIFICANTLY AFFECT THE CLINICAL OUTCOME OF HODGKIN LYMPHOMA PATIENTS WITH NEGATIVE POSITRON EMISSION TOMOGRAPHY SCAN

M Magagnoli[1,*], E Lopci[2], F R Lutman[3], S Gandolfi[1], R Mazza[1], M Rodari[2], L Giordano[4], M Balzarotti[1], L Castagna[1], A Chiti[2], C Carlo-Stella[5], A Santoro[1]
[1]Hematology, [2]Nuclear Medicine Department, [3]Department of Radiology, [4]Biostatistic Unit, Humanitas Cancer Center, ROZZANO-MILANO, [5]Department of Medical Biotechnology and Translational Medicine, University of Milano, Milano, Italy

Background: Negativity of [^{18}F]-fluorodeoxyglucose (FDG) positron emission tomography (^{18}-FDG-PET) scan is mandatory for defining complete remission in Hodgkin lymphoma (HL) patients.The persistence of residual masses detected by computed tomography (CT) scans in PET-negative HL patients has been reported to have a controversial impact on the clinical outcome of these patients.
Aims: Thus, we retrospectively analyzed a series of HL patients to investigate whether the persistence of end-of-treatment PET-negative masses detected by CT scans might eventually affect the clinical outcome.
Methods: From May 2001 to May 2012, we identified 133 consecutive patients with primary or recurrent histologically confirmed HL according to the World Health Organization (WHO) classification who were PET negative after completion of first (98 patients) or second line (35 patients) therapy
Results: Median patient age was 33 years (range 17-80), 75 were male, 34 had B-symptoms, and 47 had bulky disease. A residual CT mass ≥2.0 cm in its greatest transverse diameter (CT-positive) was identified in 85 (64%) of 133 PET-negative patients. After a median follow-up of 36 months, 28 of 85 PET-negative/CT-positive patients (32%) relapsed whereas only 3 of 48 PET-negative/CT-negative patients (6%) relapsed (P<0.00000 by Fisher's test). Four-years disease-free survival (DFS) for PET-negative/CT-negative *vs*. PET-negative/CT-positive patients was 94% and 69%, respectively (P=0.001). Statistically significant DFS values for PET-negative/CT-negative *vs* PET-negative/CT-positive patients were detected both for patients receving first- (94% *vs* 72%, P=0.01) and second-line therapy (93% *vs* 61%, P=0.034). The size of the residual CT masses negatively influenced DFS [HR 1.03 (1.02; 1.04), P=0.001] in a continuous fashion. No difference was found in DFS between patients with one *versus* two or more residual masses (67% and 73%, P: 0.5). No difference was found in 4-year overall survival when comparing PET-negative/CT-negative *vs* PET-negative/CT-positive patients (93% *vs*. 91%, P=0.4).
Summary and Conclusion: In conclusion, the presence of a residual mass detectable by CT scan significantly affects the clinical outcome of HL patients, suggesting the that these patients might require a closer follow-up and possibly a consolidation treatment using new agents.

P1056

MYC ONCOGENE IS OVEREXPRESSED IN HODGKIN & REED STERNBERG CELLS (HRS) OF CLASSICAL HODGKIN LYMPHOMA AND CORRELATES WITH P53 EXPRESSION AND PROLIFERATION INDEX

I Xagoraris[1], A Kwiecinska[1,*], M Ghaderi[1], P Tsioli[2], E Patsouris[2], E Drakos[3], G Rassidakis[1]
[1]PATHOLOGY AND CYTOLOGY, KAROLINSKA UNIVERSITY HOSPITAL, Stockholm, Sweden, [2]First Department of Pathology, National and Kapodistrian University of Athens, Athens, [3]Department of Pathology, University of Crete, Heraklion Crete, Greece

Background: MYC is a potent transcription factor targeting numerous genes involved in cell cycle progression. MYC oncogene is involved in the t(8;14)(q24;q32) chromosomal translocation, which is detected in Burkitt lymphoma (BL) and in other aggressive non-Hodgkin lymphomas (NHL) including a subset of diffuse large B-cell lymphomas (DLBCL). In addition, MYC oncoprotein can be upregulated in hematologic malignancies in the absence of chromosomal aberrations involving the 8q24 locus. However, detection of MYC protein using routinely processed paraffin-embedded tissues wasn't reliable in the past due to lack of specificity or sensitivity of the available MYC antibodies.
Aims: This study aimed to investigate the expression levels of MYC in HRS cells of classical Hodgkin lymphoma (cHL) by immunohistochemistry using a validated antibody and correlate the findings with p53 status and tumor cell proliferation.
Methods: Seventy two cHLs including 64 nodular sclerosis (NS) and 8 mixed cellularity (MC) cases were included in the study. In addition, a series of 125 NHLs of various histologic types including 8 cases of t(8;14)-positive BL as well as 5 reactive lymph nodes were also analyzed for comparison. The antibody used for MYC detection (MAb Y69) has recently been validated for immunohistochemical studies (G. Cattoretti, J Pathol 2013; 229:430). p53 expression was assessed using the DO-7 antibody that detects both the wild-type and mutated p53 gene products. Any nuclear staining in HRS (identified by CD30 marker) was considered positive irrespective of intensity for both MYC and p53. In selected cases, *p53* mutation analysis was performed for the exons 4-8 of the gene using PCR and direct sequencing techniques. Proliferation index was assessed using the Ki67 (MIB-1) marker.
Results: MYC oncoprotein was detected in all 72 cHL tumors and its expression was restricted in the nucleus of HRS cells. The mean and median percentages of MYC-positive HRS cells were 73% and 80.5%, respectively, ranging from 30% to 88%. MYC expression did not differ statistically among histologic subtypes of cHL (NS *vs*. MC). The median percentage of p53-positive HRS cells was 76%. MYC and p53 expression levels were significantly correlated (Spearman R 0.68, p=0.004). Of note, misense mutations of the p53 gene were found in two cHL cases, both expressing p53 in 100% of HRS, and relatively low levels of MYC (<35% of HRS in both tumors). Moreover, expression of MYC in HRS cells correlated with cell proliferation index. In the group of NHLs, MYC expression was highly variable among various histologic types with the highest level (>90%) observed in Burkitt lymphoma followed by DLBCL with the latter showing high variability in MYC expression patterns. Indolent NHL types expressed MYC at low percentages of tumor cells. In reactive lymph nodes, MYC was detected in a small subset (approximately 2-10%) of germinal center (GC) cells mostly localized at the periphery of the GCs, but also in occasional small lymphocytes in interfollicular areas.
Summary and Conclusion: Our findings show that MYC oncoprotein is overexpressed in HRS cells of all cHL despite the apparent absence of *MYC* translocations. MYC expression is significantly associated with p53 levels and cell proliferation in HRS suggesting that MYC may be involved in cell cycle deregulation in cHL.

P1057

PERIPHERAL BLOOD LYMPHOCYTE/MONOCYTE RATIO AT DIAGNOSIS AS A PROGNOSTIC FACTOR OF SURVIVAL IN CLASSIC HODGKIN LYMPHOMA

R Guilherme[1,*], M Santos[1], R Silva[1], M Gomes[1], E Magalhaes[1], AI Espadana[1], B Luz[1], S Almeida[1], E Cortesão[1], C Geraldes[1], JP Carda[1], L Rito[1], L Ribeiro[1]
[1]Centro Hospitalar e Universitário de Coimbra, EPE, COIMBRA, Portugal

Background: Most patients with Hodgkin Lymphoma (HL) have an excellent prognosis. However, there is a diversity of factors that can affect their outcome. Several studies have investigated the effect of lymphocyte-monocyte ratio at diagnosis on the clinical course of patients with HL, and have demonstrated that a low ratio (with variable cut-off between studies) is associated with a worse outcome.
Aims: The aim of this study was to determine whether peripheral blood absolute lymphocyte count/absolute monocyte count (ALC/AMC) ratio at diagnosis had a prognostic impact on overall survival of patients with classical HL.
Methods: We included 266 patients with classical HL diagnosed between 01/01/1990 and 31/12/2012. Receiver operating characteristic curves and area under the curve were used to determine cut-off values for the ALC/AMC ratio at diagnosis, while Kaplan Meier analysis was used to compare overall survival based on the ALC/AMC ratio.
Results: The median follow-up period was 7.4 years (range, 0.04-22.73 years). An ALC/AMC ratio at diagnosis of 2.37 or more was the best cut-off value for survival (CI 0.509-0.694). ALC/AMC ratio at diagnosis with a cut-off of 2.37 showed a prognostic impact in overall survival (p=0.042). The studied population included 132 patients with a ALC/AMC ratio<2.37 and 134 patients with ALC/AMC ratio >=2.37. There was no significant differences in age (p=0.549), gender (p=0.269), leukocyte count (p=0.078), International Prognostic Score (IPS score) (p=0.402) between the two groups, however differences were found in factors like histologic subtype, stage, albumin and hemoglobin levels. In the population with advanced stage disease and "low risk" IPS score (IPS 0,1 and 2), the addition of ALC/AMC ratio seems to be able to divide this patients into 2 subgroups with different overall survival (although not statistically significant (p=0.351)).
Summary and Conclusion: ALC/AMC ratio at diagnosis inferior to 2.37 was identified as a negative prognostic factor in patients with HL, with impact in overall survival. Therefore, this parameter may contribute to a better stratification of patients with HL. Furthermore, in patients with advanced stage disease and low IPS could potentially add prognostic value in the outcome.

P1058

PNEUMOCYSTIS CARINII PNEUMONIA IN PATIENTS WITH HODGKIN'S LYMPHOMA

T N Moiseeva[1], H L Julhakyan[1,*], L S Al-Radi[1], N N Sharkunov[1], N G Chernova[1], G A Klyasova[1], A N Gracheva[1], E A Baryakh[1], D S Mariyin[1], I V Shitareva[1], I E Kostina[1], M N Sinitsyna[1], G M Galstyan[1], S K Kravchenko[1]
[1]HEMATOLOGICAL SCIENTIFIC CENTER, Moscow, Russian Federation

Background: Intensive chemotherapy and T-cell immunodeficiency - important risk factors for Pneumocystis carinii pneumonia (PP) in patients with Hodgkin's

lymphoma (HL). PP may occur in connection with fulminant and it was necessary prevention and early diagnosis.
Aims: The aim of this study was to investigate the incidence of Pneumocystis carinii pneumonia in patients with Hodgkin's lymphoma.
Methods: During the period from 1999 to 2013 PP occurred in 22 (3%) patients of the 741 patients with HL treated with intensive chemotherapy. Ratio of M: F was 1:1.1 and median age was 32 years (range 18-65 years). Advanced stages (IIB-IV) were archived in 82% of patients. PP diagnosis was established according to bacteriological examination (more than 5 Pneumocystis in the preparation with RNIF method) and by computed tomography (CT).
Results: PP developed after 4 or more courses of chemotherapy and has always been associated with other pathogens: Herpes simplex virus in 72% of patients, mixed bacterial and fungal flora in 33% of patients. All patients underwent combined antimicrobial therapy with high-dose intravenous Cotrimoxazole. Mechanical ventilation in the intensive care unit required 10 lung patients (45%). Overall mortality was 32% (7 patients). There was high mortality rate (80%) in patients with relapsed and refractory disease course.
Summary and Conclusion: Patients with Hodgkin's lymphoma during intensive chemotherapy need PCP prophylaxis Cotrimoxazole. When the respiratory failure and CT signs of interstitial pneumonia need for early implementation of flexible bronchoscopy with lavage complex microbiological research for early detection of Pneumocystis Carinii.

P1059

TREATMENT OF ELDERLY PATIENTS WITH HODGKIN LYMPHOMA: EXPERIENCE OF A SINGLE UNIT
F Pierdomenico[1,*], P Bernardo[1], S Esteves[2], A Nunes[1], S Carvalho[1], M G Silva[1]
[1]Hematology, [2]IPO of Lisbon, Lisboa, Portugal

Background: It is estimated that patients over 60 years of age account for about 20% of Hodgkin Lymphoma (HL) patients. Outcomes for these patients are inferior when compared with younger patients. The inferior outcome of elderly HL patients is both related to a biologically more aggressive disease, treatment toxicity and comorbidities. Although ABVD is regarded as the standard of care for most elderly HL patients, a common treatment approach is lacking and innovative approaches incorporating new drugs are awaited.
Aims: The aim of this study was to evaluate treatment approach, outcomes and toxicities in elderly patients with HL.
Methods: We retrospectively analyzed 44 HL patients referred and treated at our institution between 2003 and 2012.
Results: At diagnosis, median age was 71 years (range, 60-86 years), sex ratio 23F/21M; 45% presented in stage I-II and 55% in stage III-IV, 25% had bulky disease and 50% had B symptoms. According to risk stratification, 59% of patients were in the advanced group, and the IPS score was 0-1 for 8%, 2-3 for 46% and 4-7 for 46% of patients. ECOG was 3-4 in 7%, whereas 70% of patients had significant comorbidity. All patients received treatment, 2 with palliative and 42 with curative intent. Combined modality was used in 30% of cases, chemotherapy alone in 61% and radiotherapy alone in 5%. ABVD was the chemotherapy schedule more frequently used (78%), while 18% of patients were treated with ChlVPP. Half patients modified initial treatment and in 29% of patients treated initially with ABVD, treatment was changed to ChlVPP; toxicity was the main reason for treatment modification (81% of cases). Febrile neutropenia occurred in 30% of patients, while bleomycin lung toxicity occurred in 35% of ABVD treated patients, being fatal in 36% of cases; acute cardiac toxicity only occurred in one patient. Overall response rate (ORR) was 77% (complete response - CR 70%) in all treated patients; in 20% of patients response was not available due to early death. In the group of patients treated with ABVD like schedules, the ORR was 84% (CR 78%). With a median follow-up of 6.5 years, overall survival and progression free survival at 4 years were 56.7% and 53% respectively. Eighteen patients died, with 39% of toxic deaths. Late toxicity of treatment occurred in 8 patients, being cardiac toxicity the more frequent.
Summary and Conclusion: Despite its increased toxicity in the elderly HL patients, ABVD is still considered the standard of care, with an ORR of 84% in this study population. The impact of comorbidities and assessment of functional status may help in tailoring treatment, while the use of new drugs may both reduce toxicity and increase outcome in advanced stage disease.

Non-Hodgkin & Hodgkin lymphoma - Biology 2

P1060

IMPAIRED RHOA FUNCTION LEADS TO DEVELOPMENT OF ANGIOIMMUNOBLASTIC T-CELL LYMPHOMA
T Enami[1,*], M Sakata-Yanagimoto[1], K Yoshida[2,3], R Ishii[4], A Sato-Otsubo[2,3], Y Sato[2,3], M Sanada[2,3], O Nureki[4], S Ogawa[2,3], S Chiba[1,5]
[1]Department of Hematology, Faculty of Medicine, University of Tsukuba, Tsukuba, [2]Department of Pathology and Tumor Biology, Graduate School of Medicine, Kyoto University, Kyoto, [3]Cancer Genomics Project, Graduate School of Medicine, [4]Department of Biophysics and Biochemistry, Graduate School of Science, The University of Tokyo, Tokyo, [5]Life Science center, Tsukuba Advanced Research Alliance, University of Tsukuba, Tsukuba, Japan

Background: Angioimmunoblastic T-cell lymphoma (AITL) is a distinct subtype of peripheral T-cell lymphoma with a poor prognosis. Although frequent mutations in *TET2, IDH2*, and *DNMT3A* have been reported in AITL, the precise pathogenesis specific to AITL was unknown. We recently identified recurrent mutations in *RHOA* (p.G17V hotspot mutation, G17del, and A161E) in around 70% of AITL and PTCL-NOS harboring AITL features, but these mutations were undetected in other hematologic malignancies. This finding strongly suggested that dysregulation of RHOA contributes to the pathogenesis of AITL. RHOA is a member of the Rho family small GTPases that regulate a various biological activities. Similar to Ras proteins, Rho GTPases act as molecular switches that shuttle between an active GTP-bound state and an inactive GDP-bound state, and are activated by guanine exchange factors (GEFs).
Aims: To characterize the function of RHOA mutants identified in AITL, we evaluated the activity and the biological influence of RHOA mutants compared to wild-type RHOA.
Methods: To evaluate the level of active GTP-bound RHOA, pull-down assay was performed using GST fusion Rho-binding domain of Rhotekin. For GEF-binding assay, cell lysate was extracted from NIH3T3 cells expressing active form of ECT2, one of the Rho-specific GEFs, and then pulled down with GST fusion RHOA protein. To investigate the biological effects of RHOA mutants, serum response factor-responsive element (SRF-RE) reporter assay was performed and actin stress fibers were visualized using a fluorescence-labeled phalloidin. To analyze the function of RHOA in T cells, we established Jurkat cells inducibly expressing wild-type or G17V RHOA protein, examined cell proliferation, and performed RNA sequencing for gene expression profiling.
Results: Three-dimensional structures of the G17V RHOA predicted compromised binding of GDP/GTP. Actually, when expressed in NIH3T3 cells, a substantial fraction of wild-type RHOA protein bound GTP in the Rhotekin pull-down assay, whereas no GTP-bound form was pulled down for the G17V RHOA mutant. Moreover, the G17V RHOA mutant reduced GTP binding of wild-type RHOA proteins, suggesting dominant-negative nature of G17V RHOA. The G17V RHOA mutant more tightly bound to ECT2 than wild-type RHOA, as was previously described for the G17A RHOA. The G17del and A161E mutants also exert a dominant-negative impact on wild-type RHOA. Consistently, G17V RHOA failed to activate transcription from SRF-RE and attenuated the actin stress fiber formation in NIH3T3 cells. In Jurkat cells, wild-type RHOA suppressed cell proliferation and the G1 to S cell cycle progression, whereas G17V RHOA did not. Gene Set Enrichment Analysis revealed that SRF pathway was enriched in cells expressing wild-type RHOA, but not in those expressing G17V RHOA.
Summary and Conclusion: We demonstrated that all the RHOA mutants identified in AITL abrogate conversion to active form and further inhibit activation of wild-type RHOA in a dominant negative manner, presumably due to sequestration of RhoGEF. Moreover, wild-type RHOA has the potential to serve as a tumor suppressor in T cells, whereas G17V RHOA does not have this effect. These findings suggest that reduced activity of RHOA may play a critical role in the pathogenesis of AITL.

P1061

BRAFV600E MUTATIONS IN HEMATOPOIETIC STEM CELLS OF HAIRY CELL LEUKEMIA PATIENTS SUGGESTS A STEM CELL ORIGIN
S S Chung[1], E Kim[1], J H Park[2], YR Chung[1,2], J Feldstein[3], W Hu[1], R Rampal[2], M Patel[1], MK Kim[1], K Huberman[4], N Bouvier[1,5], M F Berger[1,5], N Rosen[6], M S Tallman[2], O Abdel-Wahab[1,2], C Y Park[1,3,*]
[1]Human Oncology and Pathogenesis Program, [2]Department of Medicine, Leukemia Service, [3]Department of Pathology, [4]Center for Molecular Oncology, [5]Pathology and Center for Molecular Oncology, [6]Molecular Pharmacology and Chemistry, Memorial Sloan Kettering Cancer Center, New York, United States

Background: Hairy cell leukemia (HCL) is a chronic lymphoproliferative disorder of mature B cells characterized by somatic *BRAF*V600E mutations, cell-surface expression of the pan-B-cell marker CD19 and monotypic surface immunoglobulins with clonal rearrangements of immunoglobulin heavy and light chains. Despite possessing these stereotypic features, the cell of origin of

HCL has been long debated, and the normal counterpart of HCL cells has not been identified.
Aims: We hypothesized that HCL may originate from immature hematopoietic cells, and therefore we sought to determine at which state of hematopoietic development somatic *BRAF*V600E mutations can be detected in HCL patient samples and how the *BRAF*V600E mutation affects normal hematopoietic development.
Methods: We utilized FACS to evaluate and purify HSCs from HCL patients bone marrow samples to assess for the presence of the *BRAF*V600E mutation, both before and after treatment with BRAF inhibitors. We also evaluated the functional consequences of conditionally expressing of *BRaf*V600E in the mouse hematopoietic system, expressing it from its endogenous locus at different stages of hematopoiesis, including in HSPCs and committed B cells.
Results: We found that the *BRAF*V600E mutation is present in hematopoietic stem cells (HSCs) in HCL patients, and that these patients exhibit marked alterations in hematopoietic stem/progenitor cell (HSPC) frequencies. Quantitative sequencing analysis revealed a mean *BRAF*V600E mutant allele frequency of 4.97% in HSCs from HCL patients. Moreover, tranplantation of *BRAF*V600E mutant HSCs from an HCL patient into immunodeficient mice resulted in stable engraftment of *BRAF*V600E mutant human hematopoietic cells revealing the functional self-renewal capacity of HCL HSCs. Consistent with the human genetic data, expression of *BRaf*V600E in mouse HSPCs resulted in a lethal hematopoietic disorder characterized by splenomegaly, anemia, thrombocytopenia, increased circulating soluble CD25 (sCD25), and increased clonogenic capacity of B-lineage cells - all classic features of human HCL. In contrast, restricting expression of *BRaf*V600E to the B-cell compartment did not result in disease. Treatment of HCL patients with vemurafenib, an inhibitor of mutated BRAF, resulted in normalization of HSPC frequencies and increased myeloid and erythroid output from HSPCs. Likewise, treatment of wildtype mice transplanted with *Mx1*Cre+ *BRaf*V600E mutant bone marrow cells revealed improvement in anemia and hepatosplenomegaly with *in vivo* therapy.
Summary and Conclusion: Overall, these studies demonstrate that specific somatic genetic abnormalities present in hairy cell leukemia are present in immature hematopoietic cells including HSCs, thereby providing support for a model in which mature B-cell malignancies can initiate in the HSC compartment. Moreover, these data suggest that the use of therapies targeting MAP kinase signaling in HCL may lead to durable remissions not only by eliminating the mature leukemic cells but also through targeted inhibition of signaling and survival in HCL initiating cells.

P1062

INTRACELLULAR SIGNALING PATHWAYS IN HAIRY CELL LEUKEMIA (HCL) AND THEIR PROGNOSTIC RELEVANCE

M K Angelopoulou[1,*], E Lakiotaki[2], G Levidou[2], G Pangalis[3], T Vassilakopoulos[1], K Anargyrou[4], G Gainaru[1], P Flevari[1], S Sachanas[3], A Saetta[2], P Tsirkinidis[5], A Sepsa[2], M Moschogiannis[3], C Kalpadakis[6], V Milionis[2], I Chatziandreou[2], S Kokoris[1], MC Kyrtsonis[7], M Siakantaris[8], P Panayiotidis[7], NA Viniou[8], P Tsaftaridis[1], M Dimopoulou[1], E Plata[1], K Konstantopoulos[1], E Patsouris[2], P Korkolopoulou[2]
[1]hematology And Bone Marrow Transplantation, [2]pathology, National And Kapodistrian University Of Athens, [3]hematology, Athens Medical Center, Psychikon Branch, [4]hematology, 251 Air Force Hospital, [5]internal Medicine, 401 Army Hospital, Athens, [6]hematology, University Of Crete, Heraklion, [7]1st Department Of Propedeutic Internal Medicine, [8]internal Medicine, National And Kapodistrian University Of Athens, Athens, Greece

Background: B-RAF mutations are considered a hallmark of HCL, pointing to constitutive activation of the corresponding signaling pathway.
Aims: To investigate the activation of various signaling pathways interacting with B-RAF mediated cascade in HCL and their potential clinical significance. We therefore evaluated the expression of molecules upstream (Akt, B-RAF, ERK) and downstream (p70, 4EBP1) of m-TOR.
Methods: p-Akt, pm-TOR, B-RAF, pERK, pp70, p4EBP1 were studied by immunohistochemistry in bone marrow trephine biopsies of HCL patients at diagnosis and were correlated to prognosis. The median values of expression of the molecules under study were used as cut-off values for defining low/high expression. The endpoint of the present study was time to 2nd treatment (TT2T).
Results: 77 HCL patients were studied: 60 males, median age: 54 years. The median percentage of infiltration by hairy cells was 80% (10-100%). All cases were annexin-1 positive, while CD11c, CD25 and CD103 were positive in 96%, 98% and 98% respectively. The majority of the patients (82%) received interferon-alpha as initial treatment. Their median follow-up was 10 years (2 months-33 years). 33/77 patients relapsed and required 2nd line treatment. Nuclear expression of pERK, pp70, p4EBP1 was largely absent. Regarding cytoplasmic expression, pAkt median (range) value was 20 (0-90%), with only 3/77 cases being completely negative. B-RAF, cytoplasmic pERK, cytoplasmic pp70 and cytoplasmic p4EBP1 were seen in the vast majority of cases with 100% as the median value for the three former molecules and 80% of positive cells for the latter, respectively. There wasn't any single negative case for B-RAF and pERK and only 5/77 and 2/77 cases were negative for pp70 and p4EBP1. Surprisingly, m-TOR was completely negative in the vast majority of cases (67/77). These findings indicate that pathways other than the classical Akt/m-TOR/4EBP1 are functional in HCL. Pathways emanating either from B-RAF/pERK or pAkt may operate in HCL, accounting for the activation of the effector molecules p70 and 4EBP1, bypassing m-TOR. Thus, among pm-TOR negative/pp70 positive cases, the majority (59/62) expressed pAkt, indicating that pAkt may activate p70 independently from m-TOR. Among pm-TOR negative/ p4EBP1 positive cases, 57/65 were positive for pERK, consistent with activation of 4EBP1 directly by pERK. Still, there were 10 pm-TOR+ cases, all of which expressing pAkt and B-RAF/pERK, indicating that Akt and RAS/B-RAF/MEK/ERK pathways lead to m-TOR activation in a minority of HCL patients. High expression of pAkt (1), pm-TOR (2) and cytoplasmic p4EBP1 (3) was significantly correlated with inferior TT2T (p=0.03, p=0.05, p=0.026, respectively). The combined expression of any two of these 3 molecules could improve the prognostic stratification of the patients [(p=0.01 (1&2), p=0.001(1&3), p<0.0001(2&3)]. Moreover the simultaneous expression of all 3 molecules could identify a subpopulation of patients with a significantly inferior TT2T compared to all other combinations of expression (p<0.0001, median TT2T: 23.4 *vs* 187.9 months respectively).
Summary and Conclusion: The classical pathway Akt/m-TOR/4EBP1 seems to be activated only in a minority of HCL patients. Alternative pathways are operational in HCL, which involve direct activation of the effector molecules p70 and 4EBP1 bypassing m-TOR, by pAkt and pERK respectively. However, the activation of pAkt/m-TOR/4EBP1 pathway confers a significantly inferior prognosis in a disease with a generally benign clinical course.

P1063

EXPRESSION PATTERN AND FUNCTIONAL ROLE OF TOLL-LIKE RECEPTORS IN SPLENIC MARGINAL ZONE LYMPHOMA

E Fonte[1,2,*], S Ntoufa[3], L Scarfò[4], P Ranghetti[1], MA Piris[5], D Oscier[6], A Tedeschi[7], A Xochelli[3], F Caligaris-Cappio[1], M Ponzoni[1], C Belessi[3], P Ghia[1], K Stamatopoulos[3], M Muzio[1]
[1]Division of Molecular Oncology, San Raffaele Scientific Institute, Milan, [2]Università degli Studi di Pavia, Pavia, Italy, [3]Institute of Applied Biosciences, Centre For Research And Technology Hellas, Thessaloniki, Greece, [4]Division of Molecular Oncology, Fondazione San Raffaele, Milan, Italy, [5]Hospital Universitario Marques de Valdecilla and Instituto de Formación e Investigación Marqués de Valdecilla, Santander, Spain, [6]Department of Haematology, Royal Bournemouth Hospital, Bournemouth, United Kingdom, [7]Ospedale Niguarda, Milan, Italy

Background: Splenic marginal zone lymphoma (SMZL) is a distinct lymphoid tumor entity that is not associated with a single specific genetic defect, although several genomic abnormalities are described. Recent studies, however, identified recurrent mutations in genes belonging to the B-cell receptor (BCR) and Toll-like receptor (TLR) signaling pathways, thus pointing to their potential central role in the biology of the disease. As for BCR stimulation, antigen selection was previously suggested by the finding of biased immunoglobulin gene usage and distinctive profiles of somatic hypermutation. In contrast, no data are available on the expression pattern and functional role of TLRs in SMZL.
Aims: We aimed at characterizing the expression pattern of TLRs in SMZL cells, and studying their functional role in the activation, proliferation and cell viability of malignant cells *in vitro*.
Methods: Negatively selected primary lymphoma cells circulating in the peripheral blood of 50 patients with SMZL were used for the following analyses: (i) assessment of TLR (TLR1 to TLR10) mRNA expression by RT-PCR and Q-PCR arrays; (ii) determination of the expression of selected TLRs by flow cytometry; (iii) *in vitro* assessment of the activation status of malignant B-cells as defined by the upregulation of CD25 and CD86 by flow cytometry analysis, before and after stimulation of TLR1/TLR2, TLR2/TLR6 and TLR9, with their respective ligands (Pam3CSK4, Malp-2 and CpG-ODN2006, respectively); (iv) analysis of BCR/TLR signaling pathways by Western blot phosphorylated *versus* unphosphorylated ERK, p38, and IKK kinases; and, (v) determination of the proliferation rate and the viability index by Ki67 staining and ATP measurement in cells treated with TLR ligands.
Results: SMZL cells expressed significant levels of TLR1, TLR6, TLR7, TLR9 and TLR10 mRNA. TLR2, TLR4 and TLR8 showed a low variable pattern of expression among patients whereas TLR3 and TLR5 mRNAs were undetectable. SMZL cells also expressed mRNA specific for several TLR signaling molecules and inhibitors (*e.g.* TIR8/SIGIRR). TLR were also studied at protein level by flow cytometry; as expected, TLR1, TLR6, TLR7, TLR8, TLR9 and TLR10 proteins were detected on SMZL cells. Nevertheless, intraclonal variability in the expression of distinct TLR was observed, as well as a certain degree of heterogeneity among different patient samples. Stimulation of TLR1/TLR2, TLR2/TLR6 and TLR9 triggered activation of distinct signaling pathways as demonstrated by the phosphorylation of the IKK and ERK kinases. Moreover, addition of Pam3CSK4, Malp-2 and CpG-ODN2006 to the cell culture induced cell activation as demonstrated by significantly higher expression of CD25 and CD86, although in a heterogeneous manner among different patient samples. Malp-2 and CpG-ODN2006 significantly increased cell viability

compared to untreated cells; Ki67 analysis revealed that cell proliferation was also significantly induced by the same ligands in a proportion of samples.
Summary and Conclusion: SMZL cells show a distinctive pattern of expression of TLR and signaling molecules. *In vitro* stimulation of TLR can induce activation and proliferation of SMZL malignant cells suggesting their possible implication in the disease biology, at least in a proportion of patient samples.

P1064

DROPLET DIGITAL PCR (DDPCR) AND REAL-TIME PCR (RQ-PCR): A HEAD TO HEAD COMPARISON FOR MRD DETECTION IN MYELOMA (MM) MANTLE CELL LYMPHOMA (MCL) AND FOLLICULAR LYMPHOMA (FL)

D Drandi[1,*], L Kubiczkovà[2], S Ferrero[1], N Dani[3], R Passera[4], B Mantoan[1], M Gambella[1], E Saraci[1], L Monitillo[1], E Genuardi[1], D Barbero[1], P Ghione[1], G Guarona[1], P Omedè[5], D Barberio[3], R Hajek[6], U Vitolo[5], S Cortelazzo[7], A Palumbo[1], M Boccadoro[1], G Inghirami[1], M Ladetto[1]
[1]Molecular Biotechnologies and Health Sciencies, University of Torino, Torino, Italy, [2]BabaK Myeloma Group, Department of Pathological Physiology, Faculty of Medicine, Masaryk University, Brno, Czech Republic, [3]Bioclarma, [4]Division of Nuclear Medicine, [5]A.O.U. San Giovanni Battista, Torino, Italy, [6]Depatment of Hemato-oncology, Faculty of Medicine, University Hospital Ostrava, Ostrava, Czech Republic, [7]A.S. Bolzano, Bolzano, Italy

Background: Minimal residual disease (MRD) detection is a well described prognostic tool for response evaluation in several hematological malignancies. Real time quantitative PCR (RQ-PCR) has an established role in Mantle cell Lymphoma (MCL), Follicular Lymphoma (FL) and Multiple Myeloma (MM). However, RQ-PCR-based MRD detection is a relative quantification approach, since it requires a reference standard curve. Droplet Digital PCR (ddPCR), based on wide sample partition and Poisson's statistic, allows for a trustworthy absolute quantification.
Aims: This study compares RQ-PCR and ddPCR in the context of IgH and Bcl-2/MBR targets detection for MRD analysis, to assess whether ddPCR could be useful in MRD setting, overcoming some RQ-PCR limits and providing at least similar performances without losing its critical advantages.
Methods: Genomic DNA (gDNA) from 18 MM, 20 MCL and 30 FL patients enrolled in clinical trials and selected for having the IgH (MM and MCL) or Bcl-2/MBR (FL) molecular marker, were employed. Overall 224 samples (179 BM and 45 PB) were analyzed: 95 MM, 69 MCL and 60 FL of whom 70 were taken at diagnosis and 154 after treatment. MRD detection was carried out by RQ-PCR as previously described, [Ladetto M *et al.* BBMT 2000, Ladetto M *et al.* Exp Hem 2001] and results were interpreted according to the Euro-MRD guidelines [van der Velden VHJ *et al.* Leukemia 2007]. ddPCR was performed by the QX100 droplet system (Bio-Rad Inc) on 500ng of gDNA combined with the same Allele Specific Oligonucleotides (ASO) or Bcl-2/MBR primers and TaqMan-probes used in the RQ-PCR. Results were expressed as amount of target copies per 1E+05 cells. ddPCR and RQ-PCR comparability was assessed by means of bivariate correlations between methods analysis (R2.15.1 package irr). Discordances were classified as follows: a positive/negative qualitative discordance was defined as major when the positive result was >1E-04 and minor when ≤1E-04; a quantitative discordance was defined as the presence of two positive results with a quantitative discrepancy >1 log.
Results: MRD analysis was successful in 97% of patients by RQ-PCR (no reliable standard curve was achieved in 2 MCL patients) and 100% by ddPCR. Overall 222/224 samples (99.1%) were evaluated by both methods and a highly significant level of concordance was observed (R^2=0.88) (Fig). MRD detection was fully concordant in 189/222 samples (Cohen's K=0.85) with 137/222 (61.7%) concordantly positive and 52/222 (23.4%) concordantly negative samples. 33/222 (14.9%) were defined as discordant. Only 4/222 (1.8%) samples showed a major qualitative discordance (2MM, 1MCL, 1FL), while 29/222 (13%) were minor qualitative discordances (16MM, 11MCL, 2FL), which most likely reflect Poisson's statistics variation related to the very low number of target copies. 6/222 (2.7%) quantitative discordances were observed (1MM, 4MCL, 1FL). Among qualitative discordances no systematic prevalence of positive cases was observed with either tools (8.6% positive or higher by RQ-PCR, 7.6% positive or higher by ddPCR). Of note, 26/222 samples (11.7%) resulted positive not quantifiable by RQ-PCR. In four of them ddPCR was able to provide a reproducible quantitative result.

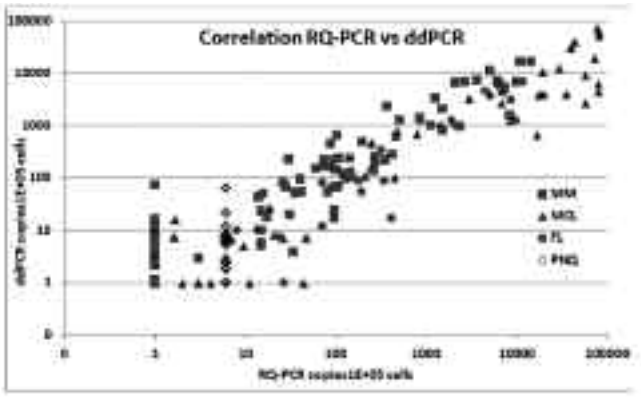

Figure 1.

Summary and Conclusion: This is the first head to head comparison between ddPCR and RQ-PCR in the context of MRD evaluation in lymphoproliferative disorders. We showed that ddPCR is a feasible tool for MRD monitoring in MM, MCL and FL, with similar sensitivity and excellent quantification ability, even at very low MRD levels. Moreover, due to its absolute quantification skill, ddPCR provided considerable technical simplification, bypassing the need of rely on a standard curve, reducing costs and sparing of valuable diagnostic tissue. These features make ddPCR a feasible and attractive alternative method to RQ-PCR for MRD assessment, potentially worthwhile of being considered for multi-lab standardization.

QUANTIFICATION OF MINIMAL RESIDUAL DISEASE IN CLONAL B-CELL NEOPLASMS USING A HIGHLY SPECIFIC AND SENSITIVE QPCR TARGETING CLONAL IGH REARRANGEMENTS BY USE OF LNA PROBE

M Schou[1,*], A T Simonsen[1], H HN Bentzen[1], C G Nyvold[1]
[1]Department of Hematology, Aarhus University Hospital, Aarhus, Denmark

Background: The rearranged immune receptor genes can be used as clonal markers in B-cell neoplasms. Although they are not prognostic for the disease progression, they can nevertheless be employed for identifying clonal populations. In this respect, previous studies have shown that about 85 % of patients with NHL and preB-ALL and the majority of CLL harbor at least one clonal immunoglobulin heavy chain (IgH) gene rearrangement detectable by PCR. A number of quantitative PCR (qPCR) assays have been developed in order to precisely quantify the amount of minimal residual disease (MRD) present in the patients. This tool is now widely used for the tight monitoring of the patients during therapy and numerous studies have shown a close correlation between the amount of MRD after induction therapy and prognosis.
Aims: The aim of this study was to establish a very sensitive and specific qPCR analysis for MRD quantification in clonal B-cell neoplasms taking advantage of the thermodynamic properties of a short locked nucleic acid (LNA) probe. This probe targeted the J genes of the IgH locus enabling short amplicons and high PCR efficiency.
Methods: Peripheral blood was collected from five patients with mantle cell lymphoma (MCL) at time of diagnosis and at follow-up. The clonal IgH rearrangement was PCR amplified and Sanger sequenced in order to design patient specific primers for the predominant IgH rearrangements. The assay encompassed a patient specific forward primer covering the VDJ junction of the IgH receptor while the short LNA probe and the reverse primer targeted the consensus sequence of the J genes.
Results: We here report a highly sensitive and specific qPCR assay for the quantification of clonal IgH rearrangements in B-cell neoplasms with a sensitivity of up to 10^{-5} taking advantage of the thermodynamic properties of LNA. The novelty of this assay is the ultra-short LNA probe that allows for placement of the probe as well as the reverse primer in the consensus part of the J genes. The MRD values obtained using this assay follow the clinical state of the patients.

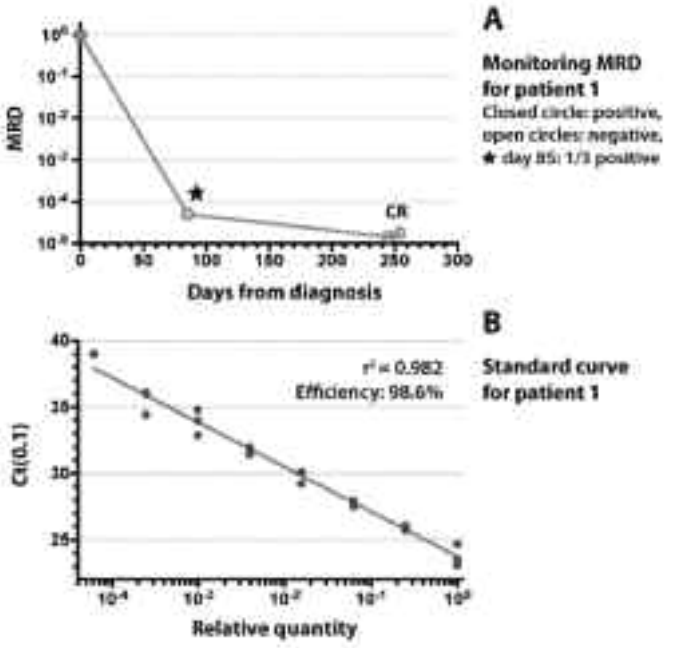

Figure 1.

Summary and Conclusion: We here report a highly sensitive and specific qPCR assay for the quantification of clonal IgH rearrangements in B-cell neoplasms with a sensitivity of up to 10^{-5} taking advantage of the thermodynamic properties of LNA. The novelty of this assay is the ultra-short LNA probe that allows for placement of the probe as well as the reverse primer in the consensus part of the J genes. The MRD values obtained using this assay follow the clinical state of the patients.

HIGH-THROUGHPUT ANALYSIS OF FULL-LENGTH IMMUNOGLOBULIN TRANSCRIPTS BY TEMPLATE-SWITCHING ANCHORED PCR AND MASSIVE PARALLEL SEQUENCING ON THE PACBIO PLATFORM

M T Koning[1,*], V Nteleah[1], M A Navarrete[1,2], H Veelken[1]
[1]Department of Hematology, Leiden University Medical Centre, Leiden, Netherlands, [2]Faculty of Humanity, Social and Health Sciences, University of Magallanes, Punta Arenas, Chile

Background: The current BIOMED-2 protocol for the analysis of rearranged immunoglobulin (Ig) genes uses multiplex PCR to amplify the clonally rearranged variable regions. However, somatic hypermutation can impair primer binding, leading from substantial amplification bias to failure to amplify any product. Indeed, BIOMED-2 primers amplify no full-length heavy chain, kappa, and lambda transcripts in 24, 8, and 69% of cases, respectively (van Dongen, 2003). Anchored PCR strategies with sets of nested isotype-specific primers (Osterroth, 1999; Bertinetti, 2006) have excellent success rates in identifying clonally rearranged Ig transcripts.
Aims: To develop a novel method using template-switching anchored PCR (TS-A-PCR) for the amplification and PacBio technology for the analysis of full-length Ig sequences.
Methods: cDNA is synthesized from isolated poly(A)-RNA (Dynabeads; Invitrogen) with gene-specific primers that anneal to the Ig constant region of interest. In the same reaction, the 3' end of the anti-sense cDNA strand is extended by switching to a synthetic oligonucleotide template containing a specific anchor sequence (SMART technology; Clontech). This anchor-tagged cDNA is then PCR-amplified with a forward primer annealing to the added anchor in combination with nested constant region-specific reverse primers. A set of nested barcoding primers further increases target specificity and enables the combination of numerous PCR products in one sequencing run. Amplified cDNA is purified (AMPure® XP beads, Beckman Coulter), dumbbell adapters are added to the termini of 250 ng of DNA and single molecules are sequenced repetitively as rolling circles on the PacBio platform (Pacific Biosciences).
Results: A single TS-A-PCR reaction of 28 cycles reliably yields a distinct band for mu, gamma, kappa and lambda transcripts from $2x10^6$ sorted B cells obtained from cell lines, lymphoma biopsies or peripheral blood. A clonal functional full-length lambda transcript could be readily identified in the Granta-519 mantle cell lymphoma cell line where BIOMED-2 primers failed (Pighi 2013; Koning, 2013). In contrast to the Illumina platform, the insert size (500-700 bp) can be completely covered with the PacBio system with over 20 repetitive reads for a single molecule. Internal alignment therefore yields a highly accurate deduced consensus sequence with very few sequencing errors: the currently observed cumulative error rate for the entire process is $1,26x10^{-4}$ as assessed by sequencing of monoclonal cell lines. Taking advantage of barcoding, just 10% of the capacity of a single PacBio SMRT cell yielded over 2000 B-cell receptor sequences from peripheral blood from a healthy donor, of which >95% were unique. TS-A-PCR performed on serial dilutions of lymphoma or EBV-transformed B-cell lines into a background of other cell lines demonstrated adequate representation of the cellular proportions in the Ig sequences obtained by PacBio sequencing.
Summary and Conclusion: TS-A-PCR is a simple novel method for reliable high-throughput identification of full-length Ig transcripts. Sample preparation can be completed in the course of one day. Avoidance of sequence-specific upstream forward primers appears to prevent potential amplification bias inherent to multiplex strategies, especially for severely hypermutated BCR sequences. Additionally, this method permits in-depth analysis of the BCR repertoire in healthy individuals and patients with lymphoma or autoimmune disease.

Mol. Biology, University Kiel, Kiel, [24]Inst. of Pathology, University of Würzburg, Würzburg, [25]Dpt. of General Int. Medicine, University Kiel, Kiel, [26]Dpt. of Computer Science a. Interdiscip. Center of Bioinformatics, Leipzig, [27]EMBL Heidelberg, Genome Biology, Heidelberg, Germany

Background: Germinal–center derived B cell lymphomas (GCB-lymphomas) represent the most common B-cell lymphomas. They include follicular (FL), diffuse large B-cell (DLBCL) and Burkitt (BL) lymphomas. The detection of numerical and structural chromosomal abnormalities in these lymphomas provides essential diagnostic, prognostic and treatment-related information. Moreover, breakpoints of chromosomal translocations can point to genes deregulated in the pathogenesis of lymphomas.
Aims: In the framework of the German BMBF-funded ICGC MMML-Seq-Project, the aim of this study is to compare the detection of chromosomal abnormalities by conventional cytogenetics (CC) and whole genome sequencing. In addition, combined whole genome and transcriptome sequencing is applied to detect hitherto unknown fusion genes.
Methods: Fourteen GCB lymphomas with aberrant karyotype by conventional cytogenetics were analyzed by fluoresence *in situ* hybridization (FISH) (LSI BCL6, LSI MYC (DC, BA), LSI IGH/MYC, CEP8 Tri-color, LSI IGH, LSI BCL2, all from Abbott Molecular), single nucleotide polymorphism (SNP)-arrays (Affymetrix 6.0), whole genome sequencing and transcriptome sequencing according to the standards of the ICGC (www.icgc.org).
Results: A total of 80 chromosomal abnormalities were detected by conventional cytogenetics in the 14 GCB lymphomas. For further analyses, these abnormalities were classified into those detected by sequencing and conventional cytogenetics (group 1; n=28), those detected by conventional cytogenetics but not by sequencing (group 2; n=52) and a third group comprising abnormalities suggested by sequencing but not by cytogenetics (n=960). Comprehensive verification analyses in group 2 were done by SNP arrays and FISH techniques to check breakpoints of abnormalities. This led us to stratify the abnormalities of that group again into two subgroups: aberrations

redefined by sequencing (n=29) and abnormalities not detected by sequencing (n=23). The latter subgroup contained somatic changes involving breakpoints in pericentromeric regions, immunoglobulin V gene breakpoints and subclonal abnormalities. Validation of the aberrations in group 3 is ongoing. From 26 abnormalities yet subjected to validation a total of 19 were verified, from which 8 were associated with fusion transcripts.
Summary and Conclusion: Complete genomic sequencing reveals a complex landscape of somatic mutations and structural aberrations in GCB-lymphomas. The combination of genomic and transcriptomic analysis allows the discovery of potential new fusion transcripts. However, whole genome sequencing might miss some somatic changes detectable by conventional cytogenetics, in particular if these are subclonal or affecting repetitive regions.

P1068

GERMLINE SMALL NON CODING RNAS, PIWIRNAS, ARE EXPRESSED IN HODGKIN LYMPHOMA: THE ROLE OF PIWIRNA-651 AS PROGNOSTIC FACTOR IN HODGKIN LYMPHOMA

A Navarro[1,*], A Cordeiro[1], A Gaya[2], B Gonzalez-Farre[3], M Diaz-Beya[2], D Fuster[1], R Tejero[1], M Ruiz[1], S Santasusagna[1], C Muñoz[1], O Caritg[1], C Martínez[2], A Martínez[3], M Monzo[1]
[1]Human Anatomy and Embryology Unit, Molecular Oncology and Embryology Laboratory,, School of Medicine, University of Barcelona, IDIBAPS, Barcelona, Spain., [2]Hematology department, Idibaps, [3]Pathology department, Hospital Clinic, Barcelona, Spain

Background: During the last years non-coding RNAs (ncRNAs), have emerged as key regulators of diverse cellular processes including cancer. Piwi-interacting RNAs (piRNAs) are a small ncRNAs (24–35 nt) necessary to protect the genome in germline cells. PiRNAs functions involve transposon repression, DNA methylation, maintaining mRNA stability, protein synthesis and chromatin and genome organization. Recently, piRNA expression has been identified in several tumors, but to date there is no evidence that they are expressed in Hodgkin Lymphoma (HL).
Aims: First, to investigate if HL cell lines and patient lymph nodes express the piRNAs piR-651, piR-20365 and piR-20582, that have been identified disregulated in several tumors. Second, to correlate piRNAs expression levels with clinical characteristics and outcome in HL patients.
Methods: The expression levels of the selected piRNAs were assessed in 5 HL cell lines (L-428, L-1236, L-540, HDLM2, HD-MY-Z), in 12 reactive lymph nodes (RLN) used as controls and 71 HL patients lymph nodes. All patients were diagnosed and treated in a single institution. Median age was 30 yrs [range, 15–89]; 57.7% were male; 32.1% were EBV+. Most frequent histological subtypes were nodular sclerosis (64.2%) and mixed cellularity (16.4%). First-line treatment was ABVD. The piRNA expression was analyzed using custom primers and the PCR product was validated by cloning in topo TA vector (Invitrogen) followed by sequencing. cDNA was synthesized using miScript II RT Kit (Qiagen) and Real time PCR was performed using miScript SYBR Green PCR Kit(Qiagen). PiRNA expression levels were calculated using 2^{-DDCt} method. Statistical analyses were performed using R v2.13 and PASW Statistics 18. Clinical outcomes analyzed were time to relapse (TTR), and overall survival (OS). After a median follow-up of 82 months (range, 2.8–182.2), overall survival was 86%.
Results: The analysis of the piRNAs (piR-651, piR-20365 and piR-20582) showed that all HL cell lines expressed the 3 piRNAs analyzed as well as the patient lymph nodes. piR-651 and piR-20582 were significantly upregulated in LN of HL patients (p=0.0008, and p=0.0001 respectively) in comparison with RLN. Interestingly, the correlation of the piRNAs expression levels with the main clinical characteristics of the patients showed that patients with high B-2-microglobulin levels had significant downregulation of the piR-651(p=0.043), piR-20365 (p=0.017) and piR-20582 (p=0.029). Moreover, a trend for lower levels of piR-20365(p=0.072) and piR-20582 (p=0.054) were correlated to leukocytosis. Interestingly, the expression levels of piR-651 in the patient lymph nodes had an impact on prognosis. First, low expression levels of piR-651 were associated with no achievement of complete response to first line treatment (p=0.007). Secondly, patients with low expression levels of piR-651 had shorter TTR (74 *vs*. 154 months, p=0.004). Finally, patients with low levels of piR-651 had shorter OS (96 *vs*. 169 months; p=0.001). The multivariate analysis identified piR-651 (analyzed as continuous variable) as an independent prognostic marker for TTR (OR, 0.251; 95%CI, 0.083-0.761; p=0.015) and OS (OR, 0.335; 95% CI, 0.11-0.97; p=0.045).
Summary and Conclusion: Low levels of piR-651 were associated with shorter TTR and shorter OS in HL. To our knowledge this is the first evidence that piRNAs are expressed in HL and have a prognostic impact. Nonetheless, further investigation of the piRNAs role in HL is required.

[1]Biological Haematology, [2]Ophtalmology, [3]Biostatistics, Pitie-Salpetriere Hospital, Paris, [4]Ophtalmology, Bretonneau Hospital, Tours, [5]Haematology, [6]Ophtalmology, Institut Curie, Paris, [7]Haematology, University Hospital, Rennes, France

Background: Primary vitreoretinal lymphoma (PVRL) is a rare and aggressive subset of primary cerebral tumors associated with poor prognosis. Ocular impairment can also be seen in systemic B-cell lymphomas. Diagnosis of PVRL is challenging and diagnostic delays are frequent. Biological diagnosis is based on cytology of vitreous samples, immunocytochemistry, and molecular biology. The quantification of soluble cytokines represents an attractive alternative and/or complementary technique. Interleukin (IL)-10, produced by lymphoma cells, is a marker of tumoral cell proliferation. In contrast, inflammatory conditions are associated with increased levels of IL-6. Nowadays, IL-10 is assessed by a sensitive flow cytometric multiplex-based technique, the *Cytometric Beads Array*® (CBA) that enables the simultaneous analysis of several cytokines without large sample volumes needed.
Aims: Reevaluating the decisional diagnosis thresholds previously reported in aqueous humor (AH) and vitreous is required for a better and earlier clinical management.
Methods: Our study included all eye fluid samples sent for cytokine analysis for the first time between January 2010 and September 2012. IL10 and IL6 were quantified in 267 AH and 130 vitreous, coming from 23 French hospitals and constituting the screening cohort. Statistical analysis of the results and comparison with final diagnosis, *i.e.* ocular lymphoma (OL) or not (no-OL), allowed us to establish a score based on a linear discriminant function. This score is pondered with a probability of suffering from an OL or not. Because all prediction models must be validated in a new set of patients before clinical practice, we carried out a validation cohort including 59 samples (41 AH and 18 vitreous).
Results: No decisional threshold of IL10 values or IL10/IL6 ratios could be clearly identified because of an overlapping zone, making the discrimination between OL and no-OL difficult. We developed a new diagnostic algorithm to improve the ability to distinguish the two groups allowing to determine a new score named ISOLD (*Interleukin Score for Ocular Lymphoma Diagnosis*). A score value >4.6 is extremely suggestive of an OL diagnosis (probability>99%) and a score value<-4.6 is highly related to a diagnosis of no-OL (probability>99%). In the range between -4.6 and +4.6 ("blurred zone"), each sample is assigned to a probability of presenting an OL which should lead to further investigation. Based on ISOLD, 94% of all samples were correctly classified (probability>99%) in both cohorts and, interestingly, no B-cell OL was underdiagnosed (probability>73%). In the screening cohort, the "blurred zone" included 3 false-positive samples (no-OL with 0<score<4,6). These three patients were considered as having a primary cerebral lymphoma and died before further investigation and treatment. We also report one T-cell OL which did not lead to an increased ISOLD as expected. The validation cohort confirmed the ISOLD relevance, as it classified correctly all OL. The "blurred zone" included 4 cases, out of them two patients were suffering from an ocular toxoplasmosis.
Summary and Conclusion: We validate ISOLD, a new sensitive diagnostic score pondered with a probability, allowing to distinguish OL from inflammatory diseases. This approach would be useful in association with other clinical and biological criteria to reinforce the diagnosis of OL.

P1070

GENOME-WIDE DNA METHYLATION ANALYSIS REVEALS ACTIVATION OF WNT SIGNALING PATHWAY IN PERIPHERAL T-CELL LYMPHOMA-NOT OTHERWISE SPECIFIED

X Zhao[1,2,*], W Zhang[1], Z Weili[1,2]
[1]State Key Laboratory of Medical Genomics, Shanghai Institute of Hematology, Shanghai Rui Jin Hospital, Shanghai Jiao Tong University School of Medicine, [2]Pôle de Recherches Sino-Français en Science du Vivant et Génomique, Laboratory of Molecular Pathology, Shanghai, China

Background: Peripheral T-cell lymphoma-not otherwise specified (PTCL-NOS) constitutes a heterogeneous group of T-cell malignancy. Resistant to conventional chemotherapy, patients usually have poor disease outcome. Epigenetic silencing of tumor suppressor genes is a major event in the pathogenesis of hematologic malignancies. Searching for biomarkers closely related to tumor progression is critical for better understanding of disease pathogenesis and developing subsequent targeted therapy.
Aims: The purpose of our study is to assess the profile of genetic methylation status in PTCL-NOS.
Methods: Whole genome methylation was analyzed using NimbleGen HG18

Deluxe Promoter HX1 Microarray on six PTCL-NOS patients and six reactive hyperplasia cases as controls. In addition, methylation status of candidate genes was investigated in an extended cohort of 80 patients with T-cell lymphoma using MassARRAY and Methylation-specific PCR (MS-PCR). Expression analysis was conducted in cases with available RNA samples. Biological function of candidate genes was studied in T-lymphoma cell lines Jurkat and H9.
Results: Genome-wide methylation analysis showed distinct DNA methylation profiles in PTCL-NOS comparing with reactive hyperplasia. Principal component analysis clearly discriminated PTCL-NOS patients from control samples. Segregated data showed that aberrant methylated genes were enriched in Wnt signaling pathway, a key signaling cascade in hematopoiesis regulation and carcinogenesis. Among these genes, MassARRAY and MS-PCR confirmed hypermethylation of *SFRP5* and *ASCL1*. *SFRP5* is an important tumor suppressor and antagonist of Wnt signaling cascade. *ASCL1*, a transcription factor, is also implicated in Wnt pathway. In the extended cohort of patients diagnosed with T-cell lymphoma, hypermethylation of *SFRP5* was identified in 32 cases (40.0%), while *ASCL1* was hypermethylated in 37 cases (46.3%). Quantitative PCR identified that gene expression of *SFRP5* and *ASCL1* were accordingly decreased in PTCL-NOS patients compared with controls. In T-lymphoma cell lines Jurkat and H9, treatment of demethylating agent 5-AZA reversed the hypermethylation status of *SFRP5* and *ASCL1*, and retrieved gene expression. Overexpression of *SFRP5* and *ASCL1* by transfection in Jurkat cells resulted in decreased cell proliferation and inhibited Wnt pathway, with decreased expression of targeted genes such as *MYC*, *CCND1* and *LEF1*.
Summary and Conclusion: Taken together, our findings demonstrated a role of aberrant genetic methylation in the pathogenesis of PTCL-NOS. Our data also suggested the involvement of Wnt pathway in tumor progression. Our study provides evidence for targeted therapeutic designs in the future.

P1071

THE RIZ1 GENE EXPRESSION IS SUPPRESSED IN T CELL LYMPHOMA AND THAT EXPRESSION IS CORRELATED WITH THE DECREASED GATA3 GENE EXPRESSION

H Shimura[1,*], N Mori[1], M Miyazaki-Ohwashi[1], YH Wang[1], M Shiseki[1], J Tanaka[1]
[1]Hematology, Tokyo Women's Medical University, Tokyo, Japan

Background: We recently reported that aberrant promoter methylation decreases retinoblastoma protein-interacting zinc finger gene (*RIZ1)* expression in adult acute T lymphoblastic leukemia (T-ALL). RIZ1 was isolated as a GATA3-binding protein and showing the characteristics of a negative tumorigenesis regulator. GATA3 is a transcription factor that is expressed very specifically in the T-cell lineage and involved at various stages of thymocyte differentiation. We also found that the *GATA3* expression was decreased in T-ALL, but it was increased by the *RIZ1* re-expression. RIZ1 may be involved in T-ALL development via the *GATA3* repression. T cell lymphoma has a heterogeneous pathogenesis, arising from various stages of T lineage cells. The *RIZ1* and *GATA3* expressions, correlation between these two genes and the *RIZ1* methylation status in T cell lymphoma have not previously been reported. Recently, a highly prevalent somatic mutation of *RHOA* encoding a Gly17Val alteration was reported in AITL and PTCL-NOS. Similar to other epigenetic modulators including *IDH2* and *DNMT3A*, the *RHOA* mutation largely overlapped *TET2* mutations and had similar allelic burdens. We also focused on aberrant *RIZ1* methylation and the *RHOA* mutations in T cell malignancies. Moreover, the *GATA3* mutations cause an autosomal dominant disorder, HDR (*h*ypoparathyroidism, sensorineural *d*eafness, and *r*enal dysplasia) syndrome. The *GATA3* mutation status in T-ALL or T cell lymphoma has not been reported.
Aims: 1) To clarify the relevance of the *RIZ1* and *GATA3* in various T cell lymphomas and compare these findings with those in T-ALL; 2) To assess the *RIZ1* expression and altered promoter methylation status in various T cell lymphomas; 3) To assess the *RHOA* mutation and altered *RIZ1* methylation in T-ALL and various T cell lymphomas; and 4) To examine the hotspot of the *GATA3* mutation in HDR syndrome in these T cell malignancies.
Methods: The *RIZ1* and *GATA3* expressions were examined by quantitative real-time reverse transcription-polymerase chain reaction (PCR) analysis in 39 adult patients newly diagnosed with T-ALL (n=10) and T cell lymphoma (angioimmunoblastic T cell lymphoma; AITL n=12, peripheral T cell lymphoma, not otherwise specified; PTCL-NOS n=9, adult T-cell leukemia/lymphoma; ATLL n=5, lymphoblastic lymphoma; LBL n=2, anaplastic large-cell lymphoma; ALCL n=1). Methylation-specific PCR was performed on the *RIZ1* gene, and mutation of the *RHOA* and *GATA3* genes were screened by direct sequencing. Correlation between the *RIZ1* expression and *GATA3* expression was analyzed by t test.
Results: Mean *RIZ1* expression in all T cell lymphoma cases (n=29) was 2.73 and that of *GATA3* was 3.28. Similar to the *RIZ1* (mean 0.61) and *GATA3* (mean 4.84) expressions in T-ALL (n=10), these gene expressions in T cell lymphoma patients were lower than those in peripheral T lymphocytes from healthy individuals (mean *RIZ1* 6.93, *GATA3* 19.28). Expressions of both *RIZ1* and *GATA3* differed in AITL (n=12, mean *RIZ1* 3.30, *GATA3* 1.75), PTCL-NOS (n=9, mean *RIZ1* 2.35, *GATA3* 2.72) and ATL (n=5, mean *RIZ1* 1.82, *GATA3* 5.35). As in T-ALL, there was a significant positive correlation between the *RIZ1* and *GATA3* expressions in AITL (P=0.004, R2=0.415) and ATL (P=0.038, R2=0.577) but the correlation in PTCL-NOS was not significant. The methylation status of the *RIZ1* in T cell lymphoma differed from that in T-ALL. Methylation of the *RIZ1* promoter was detected in 70% of T-ALL cases (7 of 10), but in only one case of LBL among all T cell lymphomas in this series. Somatic *RHOA* mutations were detected only in AITL (7 of 12, 53.8%). Most of the T-ALL samples showed the *RIZ1* methylation, but none demonstrated the *RHOA* mutations. On the contrary, 53.8% of the AITL samples demonstrated the *RHOA* mutations, but there was no *RIZ1* methylation detected. No *GATA3* mutations were found by sequence analysis in hotspots of the gene in HDR syndrome.
Summary and Conclusion: Similar to that in T-ALL, the *RIZ1* and *GATA3* expressions are frequently decreased in T cell lymphoma. This decreased *RIZ1* expression might be associated with the *GATA3* suppression in AITL and ATL, and the *RIZ1* may be involved in AITL and ATL development via *GATA3* reppression. Although decreased, the *RIZ1* and *GATA3* gene expressions remained higher than those in T-ALL, and may reflect the status of gene expressions in the normal counterpart of T cell malignancies. Even though the *RIZ1* expression was decreased in various T cell lymphomas, the *RIZ1* methylation status differed from that in T-ALL. Moreover, the *RHOA* mutation does not reflect the *RIZ1* methylation status. Silencing of the *RIZ1* may be due to aberrant promoter methylation in precursor T cell malignancies, whereas in mature T cell malignancies, methylation-independent mechanisms of *RIZ1* silencing, such as mutations in promoter sequences, loss of heterozygosity, histone methylation and microRNA, might account for low *RIZ1* expression.

P1072

BACH2 SUPPRESSION IN CD4+ T CELLS MODULATES THEIR RESISTANCE TO APOPTOSIS DEMONSTRATING ITS FUNCTION AS A TUMOR SUPPRESSOR GENE

VL Dang Chi[1,2,3,*], K Willard-Gallo[3], S Garaud[3], H Duvillier[3], M Mae Revoet[2], G Chunyan[3], D Bron[2], C Sibille[1]
[1]Molecular Pathology Department, [2]Hematology Department, [3]Immunology Molecular Unit, Jules Bordet, Brussels, Belgium

Background: Hypereosinophilic Syndromes (HES) cover a wide variety of disorders characterized by sustained hypereosinophilia inducing tissue damage and distinct from secondary causes such as allergic or parasitic conditions. Lymphocytic variant Hypereosinophilic Syndrome (L-HES) has been shown to be caused by the clonal expansion of abnormal T cells producing high levels of IL-5, which drive secondary eosinophil proliferation. Contrasting with the myeloproliferative HES variant (M-HES) associated with PDGFR gene rearrangements, the genetic defect underlying the survival of the L-HES T cell clones is still unknown. Our previous studies have shown a recurrent chromosome 6q deletion leads to repression of specific genes which are located on that deleted segment.
Aims: The goal of this study was to identify potential tumor suppressor gene(s) in the deleted 6q13-22.1 region.
Methods: Cytogenetic analyses of $CD3^{-}CD4^{+}$ T cells from L-HES patients were based on karyotype and FISH. Affymetrix U133 2.0 Plus arrays were used for gene expression profiling of the aberrant $CD3^{-}CD4^{+}$ T cell clones relative to $CD3^{+}CD4^{+}$ T cells from controls. Flow-cytometry, qRT-PCR and shRNA were used to further investigate significant findings.
Results: 6q loss was detected in the CD3-CD4+T-cell nuclei in a third of L-HES patients, thereby indicating that 6q- is the most frequent chromosomal aberration characterizing this disease in our cohort of patients. The established persistence of the 6q13-q22.1 deletion during one patient's disease progression towards lymphoma, also suggested that this abnormality could contribute to the chromosomal transformation. With the final objective of identifying a potential suppressor gene located in the 6q13-22.1 region, a correlation was made between the genes contained in the deletion and their corresponding expression level in CD3-CD4+ T cell clones from 3 L-HES patients, and eleven genes were found to be commonly repressed. As one patient progressed to T lymphoma, only one of the eleven genes, *BACH2,* was continuously repressed, making it the best candidate for tumor suppressor gene in the 6q deletion. Functional analysis using shRNA demonstrated the suppressive properties of BACH2 by showing its apoptosis modulation in $CD4^{+}$ T cells during genotoxic stress. We further demonstrated that one of the suppressive effects of BACH2 on apoptosis in $CD3^{+}CD4^{+}$ T cell lines and $CD3^{-}CD4^{+}$ patient T cells was mediated via transcriptional regulation of the *FAS-L* gene.
Summary and Conclusion: The identification of the 6q-located *BACH2* as a haploinsufficient tumor suppressor gene in $CD4^{+}$ T cells could provide the foundation for a new model of T-cell lymphomagenesis in L-HES. Moreover, by providing evidences that one of the suppressive effects of BACH2 is mediated via FAS-L, in which plays important role in the activated induced cell death (AICD) pathway, thereby suggesting that the deletion of the *BACH2* gene increases the survival of the $CD3^{-}CD4^{+}$ T cells, frequently leading to T-cell lymphoma transformation in L-HES. These data constitute the first experimental evidence that BACH2 exerts a regulatory effect on the FAS-L extrinsic apoptotic pathway in $CD4^{+}$ effector memory T cells. Further investigations on the integrity of the FAS-L pathway modulated by BACH2 in other persisting CD4+ autoimmune, infectious and lymphoproliferative diseases may prove to be rewarding. Finally, our data have demonstrated that BACH2 is a tumour suppressor gene whose repression

modulates apoptosis resistance of CD4+ T cells *in vitro*. To understand further the tumour suppressive role of BACH2 *in vivo*, it would be interesting to follow hemizygous +/- BACH2 knockout mice for autoimmune diseases and neoplastic development in a genotoxic or infectious context.

P1073

SUBMICROSCOPIC GENOMIC REARRANGEMENTS CHANGE GENE EXPRESSION IN T-CELL LARGE GRANULAR LYMPHOCYTE LEUKEMIA

K Izykowska[1,*], M Zawada[1], K Nowicka[1], P Grabarczyk[2], AW Kuss[3], R Weissmann[3], C Busemann[2], WD Ludwig[4], CA Schmidt[2], GK Przybylski[1]
[1]Institute of Human Genetics Polish Academy of Sciences, Poznan, Poland, [2]Clinic for Internal Medicine C, University Greifswald, [3]Institute for Human Genetics, University Medicine Greifswald, Greifswald, [4]Clinic for Hematology, Oncology and Tumor Immunology, HELIOS Klinikum Berlin Buch, Berlin, Germany

Background: T-cell large granular lymphocyte leukemia (T-LGL) is a rare lymphoproliferative disorder of cytotoxic lymphocytes. Most patients have a clinically indolent course and a median survival of 10 years, but there is no definitive cure or targeted therapy, and the etiology of T-LGL is still unclear. It is known that malignant cells of T-LGL patients are characterized by dysregulation of important cell signaling pathways that allow them to avoid the activated-induced cell death, and promote cell proliferation and survival. The question remains how those pathways are constantly activated and one of the possibilities may be alterations on the genomic level.
Aims: To better understand the molecular pathogenesis of this disease we decided to search for those genetic alterations in T-LGL patients and MOTN-1 cell line (established from T-LGL patient) that have an impact on gene expression and as a result can influence cell biology.
Methods: mFISH analysis of the MOTN-1 cell line was performed as well as paired-end next generation sequencing (NGS; Illumina HiSeq2000) of this cell line and one T-LGL patient. In addition, chosen 6q region was characterized using high resolution comparative genomic hybridization (FT-CGH) and LM-PCR in three T-LGL patients, as according to previous studies this region is recurrently altered in T-LGL. Gene expression was studied by RNA sequencing (RNAseq; SOLID5500).
Results: mFISH analysis of MOTN-1 revealed several translocations, including t(2;6), t(11;17) and t(12;18), that were confirmed on molecular level using NGS. Moreover, NGS analysis of the whole genome revealed many deletions and amplifications associated with complex rearrangements, most of them within regions 1p, 2q, 6q, 8q, 17q and 18q. RNAseq analysis showed that nine of these rearrangements affected gene expression, for example caused increased expression of *ZEB2* and *GTDC1* (chr2), or decreased expression of *DDI2, CLIC4* (chr1), *IFNGR1*, *MAP3K5, STK39* (chr6), *NFATC1* (chr18). FT-CGH analysis, performed for the 6q23-27 region in three patients, revealed deletion in one of them. It overlapped with the deletion detected in MOTN-1 by NGS and affected *IFNGR1* gene. Deletion was associated with two translocations (with chr14 and 22), and as a result two genes were disrupted: *MAP3K5* and *FAM83F*. In T-LGL patient, analyzed by NGS, few minor alterations were detected, but only two had impact on gene expression: a deletion within Ras oncogene *RAB32* (chr6), and amplification within 14q causing increased expression of 19 genes situated in this region, among them *FON3, RIN3, AKT1, PPP2R5C*. Moreover, whole transcriptome analysis revealed two novel fusion transcripts: *CASP8-ERBB4* in MOTN-1 and *SBF1-PKHD1L1* in one T-LGL patient, and genes differently expressed in studied samples compared to controls, among them many involved in apoptosis (*VAV3, SOCS3, TNFRSF25, BCL2, CASP8, RBM5, TLR2, TRIO, PPP3CC, DAPK2, ARHGEF12, DAPK1*).
Summary and Conclusion: Present study showed that submicroscopic genomic rearrangements change gene expression in T-LGL and thus might have an impact on cell biology. Several genes involved in rearrangements were previously linked to cancer and survival pattern that characterizes T-LGL cells. It would be worth to analyze whole genomes and transcriptomes in larger cohort of patient in order to find the connections between genome, transcriptome and signaling pathways that lead to malignant transformation and T-LGL progression.

P1074

ROLE AND RELATIONSHIP OF INTERLEUKIN-6 AND -15 IN T LARGE GRANULAR LYMPHOCYTE LEUKEMIA

A Teramo[1,2], C Gattazzo[1,2], G Barilà[2], F Passeri[1,2], A Cabrelle[1], E Boscaro[2], M Facco[1,2], L Trentin[1,2], G Semenzato[1,2], R Zambello[1,2,*]
[1]Venetian Institute of Molecular Medicine (VIMM), [2]Department of Medicine, Hematology and Clinical Immunology section, University of Padua, Padua, Italy

Background: T large granular lymphocytes leukemia (T-LGLL) is a rare disease characterized by the abnormal expansion of T large granular lymphocytes (LGLs) with cytotoxic activity. Currently, the etiology of this disease is still largely unknown. Several data support the hypothesis that the inciting event is represented by the persistence of antigenic stimulation, maintained by the abnormal release of cytokines, mainly IL-6 and IL-15, establishing an inflammation status not achieving resolution. Recently, we showed that IL-6 and soluble IL-6Ra were highly expressed and released by patients' LGL-depleted peripheral blood mononuclear cells (PBMC), accounting for a trans-signaling process. IL-6 trans-signaling is critically involved in inflammatory disease. Additionally, LGL proliferation is maintained through the activation of many survival signaling pathways, as JAK/STAT and RAS/MEK/ERK pathways. Recently, activating STAT3 mutations have been demonstrated in nearly 30% of LGLL patients.
Aims: We studied the cell source of IL-6 and IL-15, IL-15 contribution to sustain IL-6 trans-signaling, and in turn inflammation, and the role of these cytokines to induce LGL survival.
Methods: Thirty T-LGLL patients were included in this study. Patients' LGLs percentage in PBMCs ranged from 25 to 90%. In order to assess IL-6-producing cells we performed analysis by confocal microscopy using antibodies against IL-6 and CD14. Plasma IL-6 concentration was analyzed by ELISA. We analyzed cytokines expression level by Real Time (RT)-PCR and activation of ERK and STAT3 by Western Blot (WB) analysis. Finally, we assessed LGL viability in PBMCs culture following IL-6 and 15 stimulation by AnnexinV cytometer assay. Sequencing analysis was performed to study STAT3 mutations.
Results: By immunofluorescence assay, we demonstrated that IL-6 is specifically and strongly produced by CD14+ cells, as far as IL-15. According to plasma IL-6 levels, cases characterized by a disease with less than 55% circulating LGLs (low LGL burden) showed significantly higher IL-6 concentrations with respect to patients with LGLs>55% (high LGL burden) ($p<0.05$). Interestingly, we found that patients carrying STAT3 mutations were only included in this last group, characterized by low IL-6 and high LGL percentage. By RT-PCR and ELISA, we found that IL-15 strongly induced IL-6 expression in patients PBMCs, while inhibited IL-6Ra expression in leukemic LGLs, indicating that IL-15 favors IL-6 trans-signaling. By WB analysis we showed that both IL-6 and IL-15 were able to activate STAT3 and ERK, then sustaining LGL survival. To confirm that trans-signaling takes place in T-LGLL we observed that IL-6 increased its pro-survival effect when added to the culture with IL-6Ra, by reducing the percentage of apoptotic cells.
Summary and Conclusion: Our data pointed to the importance of the monocyte/macrophage lineage in LGLL patients, as source of both IL-6 and IL-15 sustaining LGL survival and inflammatory environment. Moreover, our results suggested that the progression of the disease might include two different steps: one characterized by low percentage of LGLs and high secretion of IL-6 and a second one where patients display a high burden disease with low IL-6 concentrations. Accordingly, the first one is mostly sustained by extrinsic factors contributing to the relevant inflammatory background, whereas in the subsequent step, characterized by a high lymphocytosis, LGL disease goes on independently from exogenous stimuli, likely becoming self-maintaining due to the contribution of the emerging STAT3 mutations.

P1075

IDENTIFICATION AND VALIDATION OF POTENTIAL DRUGS INHIBITING CONSTITUTIVELY ACTIVE MUTANT AND WILD TYPE STAT3 IN LARGE GRANULAR LYMPHOCYTE LEUKEMIA

H Kuusanmäki[1,2,*], H Rajala[1], AV Adrichem[2], M M Majumder[2], K Wennerberg[2], S Mustjoki[1], C Heckman[2]
[1]Hematology Research Unit, Helsinki University Central Hospital Cancer Center, [2]Institute for Molecular Medicine Finland, University of Helsinki, Helsinki, Finland, Helsinki, Finland

Background: Constitutive hyperactivation of the STAT3 transcription factor is often observed in cancer. Recently, we discovered that 40% of patients with T-cell large granular lymphocytic (LGL) leukemia had somatic activating point mutations in the Src Homology 2 (SH2) domain of the *STAT3* gene. Moreover, STAT3 appears to be phosphorylated in all LGL leukemia patient samples indicating that different molecular mechanisms activate the JAK-STAT pathway. We therefore hypothesized that inhibition of STAT3 activating kinases or STAT3 itself could induce apoptosis of LGL cells. However, it is not well known which kinases activate and which drugs inhibit STAT3 in malignant cells and whether hyperactive STAT3 mutants behave differently compared to wild type STAT3.
Aims: Here, we aimed to identify drugs that inhibit STAT3 function and determine if mutant STAT3 and wild type STAT3 react differently to these drugs. In addition, we wished to ascertain if STAT3 inhibition is sufficient to induce apoptosis in cells with constitutively active STAT3, including LGL cells.
Methods: High-throughput drug sensitivity testing was performed with a compound collection containing over 300 approved and investigational oncology drugs including many kinase inhibitors (such as JAK, SRC, VEGFR, mTOR, MEK, and CHK) and small molecule STAT3 inhibitors (Stattic, LLL12, Sta-21). All drugs were tested in eight different concentrations over a 10,000-fold concentration range. In addition to patient LGL cells (n=4), mutant STAT3 (Y640F) transformed Ba/F3 cells and HEK293 cells containing a STAT3 specific luciferase reporter gene element (HEK-SIE) were used in the screens. Patient sample cells and the Ba/F3 cells were incubated in 384-well plates for three

days with the drugs then cell viability measured with CellTiter-Glo. STAT3 induced luciferase activity in the HEK-SIE cells was analyzed after the cells were incubated for 6 or 24 hours with the drugs using the ONE-Glo luciferase assay system.
Results: Preliminary results indicate that PI3K/mTOR inhibitors such as PF-04691502 and INK128 effectively decrease the luciferase signal in both mutant Y640F and wild type STAT3 transfected HEK-SIE cells, demonstrating inhibition of STAT3 functional activity. In addition, PI3K/mTOR inhibitors significantly decreased the viability of mutant STAT3 transformed Ba/F3 cells when compared to wild type cells. Interestingly, JAK inhibitors (*e.g.* Ruxolitinib, Gandotinib) did not effectively inhibit mutant STAT3 activity in HEK-SIE cells, whereas IL6-induced wild type STAT3 activity was completely blocked. A BET family inhibitor (JQ1+), glococorticoids (Dexamethasone, Methylprednisolone) and an Aurora A kinase inhibitor (alisertib) showed specific killing against mutant STAT3 transformed Ba/F3 cells. LGL patient sample cells showed high sensitivity against glucocorticoids, the histone deacetylase inhibitor quisinostat and PF-04691502 when compared to healthy CD8+ T-cells. However, no increased apoptosis was observed with JAK or mTOR inhibitors. Of the tested small molecule STAT3 inhibitors, LLL12 showed the best efficacy against mutant and wild type STAT3 cells.
Summary and Conclusion: Our results suggest that JAK inhibitors will lack efficacy in STAT3 mutated diseases. However, our *in vitro* drug screens highlight some other promising agents including PF-04691502, alisertib and JQ1+. Additional experiments are ongoing to validate whether these drugs clearly function through the STAT pathway when causing cell death. As the STAT3 pathway is activated in many other cancer types as well, the results may be applicable to a variety of different malignancies.

P1076

COMPREHENSIVE CYTOGENETIC AND MOLECULAR GENETIC CHARACTERIZATION OF T-PLL

A Stengel[1,*], W Kern[1], T Haferlach[1], M Zenger[1], A Kohlmann[1], S Schnittger[1], C Haferlach[1]
[1]MLL Munich Leukemia Laboratory, Munich, Germany

Background: T-cell prolymphocytic leukemia (T-PLL) is a rare, mature T-cell lymphoproliferative disorder. Prognosis for patients with T-PLL remains poor, with a median overall survival of less than one year. Only few patients with T-PLL have been analyzed with regard to cytogenetic and molecular genetic aberrations. However, it is known that most T-PLL cases harbor chromosomal abnormalities including mainly chromosome 14 (involving the *TCRA/D* locus and the proto-oncogene *TCL1A*), chromosome 8 and the X-chromosome (activation of the oncogene *MTCP1*).
Aims: 1. Comprehensive cytogenetic and molecular characterization of T-PLL, 2. Identification of potential correlations between the respective markers.
Methods: The cohort comprised 57 T-PLL cases (35 male, 22 female patients). Median age was 70.8 years (range: 32.7-86.6 years). T-PLLs were characterized using immunophenotyping and cytomorphology. 57 patients were investigated using chromosome banding analysis (CBA) and 53 of these in addition by FISH for the detection of deletions of *ATM* and *TP53* and for *TCRA/D* rearrangements. Array CGH (Roche NimbleGen, Madison, WI) was performed in 46 cases, as well as mutation analyses for *BCOR*, *ATM* and *TP53* (n=37, n=42, n=44, respectively; Roche 454, Branford, CT).
Results: With respect to CBA, aberrant karyotypes were observed in 43/57 cases (75.4%), 5 patients showed a normal karyotype, whereas for 9 cases no CBA data was available due to insufficient cell proliferation. In all 5 cases with normal karyotypes and in the 9 cases without metaphases, chromosomal abnormalities or molecular mutations were detected using FISH and sequencing analyses. In more detail, combining CBA and FISH data revealed in 44/57 (77.2%) cases an inv(14)(q11q32)/t(14;14)(q11;q32) (n=40) or t(X;14)(q27;q11) (n=4), respectively. A gain of 8q was observed in 19/57 (33.3%) cases. Based on FISH data, *ATM* deletions were detected in 30/53 (56.6%), *TP53* deletions in 13/53 (24.5%) patients. By array CGH, a deletion within the *BCOR* gene (a BCL6 corepressor located on chromosome Xp11.4) was detected in 3 patients, prompting us to screen for mutations in the *BCOR* gene, which were detected in another 4/37 patients. Further, mutations in *TP53* were observed in 6/44 (13.6%) and *ATM* mutations in 29/42 (69.0%) cases. We correlated mutations in *TP53, ATM* and *BCOR* with chromosomal aberrations. In 4/6 (66.6%) patients with *TP53* mutations an accompanying *TP53* deletion was observed, while only 5/32 (15.6%) *TP53* wild-type cases harbored a *TP53* deletion (p=0.042). 18/29 (62.1%) patients with *ATM* mutations showed an *ATM* deletion, whereas only 2/13 (15.4%) *ATM* wild-type cases possessed an *ATM* deletion (p=0.011). For *BCOR* mutations, no association with any other parameter was revealed. A correlation was observed for chromosomal aberrations involving chromosomes 8 and 14, as the vast majority of cases with gain of 8q harbored a 14q11 rearrangement (17/19, 89.5%).
Summary and Conclusion: CBA, FISH and mutation analysis of *TP53, BCOR* and *ATM* revealed genetic abnormalities in all 57 analyzed cases, most frequently involving the *TCRA/D* locus (14q11) (44/57; 77.2%) activating the proto-oncogenes *TCL1A* on chromosome 14q32 or *MTCP1* on chromosome Xq28. Deletions were detected for *ATM* (56.6%) and *TP53* (24.5%), and a gain of 8q was observed in 33.3% of all cases. *ATM* mutations and *TP53* mutations were detected in 69.0% and 13.6% of patients, respectively. *BCOR* mutations were observed for the first time in a lymphoid malignancy with a frequency of 10.8%. The prognostic relevance of these aberrations has to be determined.

MIR-150 REGULATES IL-22-CCL20-CCR6 AUTOCRINE PATHWAY IN METASTATIC CUTANEOUS T- CELL LYMPHOMA

K Teshima[1,*], M Ito[1], S Ikeda[1], A Kitadate[1], M Nara[1], K Ubukawa[1], M Fujishima[1], N Fujishima[1], T Yoshioka[1], Y Kameoka[1], N Hasunuma[2], N Takahashi[1], M Hirokawa[1], K Sawada[1], H Tagawa[1]
[1]Department of Hematology, Nephrology and Rheumatology, Akita University Graduate School of Medicine, [2]Department of Community Medicine and Primary Care Development, Akita University Faculty of Medicine, Akita, Japan

Background: MicroRNA(miRNA)s are involved in regulating diverse cellular pathways. Altered expression of various oncogenic or tumor suppressive miRNAs has been identified in some lymphomas. Among these, a tumor suppressive miRNA, microRNA-150 (miR-150) has proven to be a key miRNA involved in the development of hematological malignancies. We recently showed that miR-150 expression is downregulated in cutaneous T-cell lymphoma. Inoculation of CTCL cell lines into NOD/Shi-scid IL-2γnul (NOG) mice led to CTCL cell migration to multiple organs. However, prior transfection of the cells with miR-150 substantially reduced the invasion/metastasis by directly downregulating CCR6, a specific receptor for the chemokine CCL20.
Aims: The aim of this study is to determine the relationship between a chemokine and a miRNA affecting tumor invasion and metastasis in cutaneous T-cell lymphoma.
Results: We found that IL-22 and its specific receptor subunit, IL22RA1, were aberrantly overexpressed in advanced CTCL, and that productions of IL-22 and CCL20 were increased in cultured CTCL cells. IL22RA1 knockdown specifically reduced CCL20 production in CTCL cells, suggesting IL-22 upregulation may activate production of CCL20 and its binding to CCR6, thereby enhancing the multidirectional migration potential of CTCL cells. CTCL cells also exhibited nutrition- and CCL20-dependent chemotaxis, which were inhibited by miR-150 transfection or CCR6 knockdown. CD4+ T helper cells are divided into T_H1, T_H2, T_H17, and T_H22 subsets. Among these, the TH22 subset produces only IL-22, while T_H17 cells produce both IL-17 and IL-22. Normally, IL-22 activates CCL20 transcription by binding to the IL-22RA1/IL-10RB receptor, which is not expressed in lymphoid organs or lymphocytes. In the present study, we further found that both IL-22 and its receptor subunit, IL-22RA1, are aberrantly overexpressed in advanced CTCL, but IL-17 is not expressed, suggesting CTCL is derived from the T_H22 subset. For molecular targeting therapy, we are currently studying for effects of candidate target molecules by use of anti-CCL20 antibody, siCCR6, siCCL20 or miR-150 injection against CTCL cells transplanted NOG mice.
Summary and Conclusion: We conclude that, in the presence of continuous CCR6 upregulation accompanied by miR-150 downregulation, IL-22 activation leads to continuous CCL20-CCR6 interaction in CTCL cells and, in turn, autocrine metastasis to distal organs. Our data presents the first evidences demonstrating an invasion/metastasis mechanism in advanced cutaneous T cell lymphoma.

P1078

IN VITRO AND IN VIVO EFFECT OF ATO/IFN/AZT FOR ADULT T CELL LEUKEMIA/LYMPHOMA

M Hachiman[1,*], M Yoshimitsu[1], A Kuroki[1], D Nakamura[1], N Arima[1]
[1]Division of Hematology and Immunology, Kagoshima University, Kagoshima, Japan

Background: Despite of clinical efficacy of combination chemotherapy with arsenic trioxide (ATO), interferon alpha (IFN) and zidovudine (AZT) for adult T cell leukemia lymphoma (ATL), precise mechanism of anti-ATL effect largely remain to be elucidated.
Aims: We herein explore the *in vitro* and *in vivo* effect of ATO/IFN/AZT for ATL using ATL cell line, primary ATL cell and ATL xenotransplantation model.
Methods: ATL leukemic cell line (S1T, non-Tax expressing, HTLV-1 integration site confirmed), HTLV-1-infected cell line (MT2, tax expressing) and primary ATL cells from acute and chronic type ATL patients were employed for this experiment. As an ATL xenotransplantation model, NOD/SCID/Jak3 null mice (NOJ mice) were inoculated with acute or chronic type ATL peripheral blood mononuclear cells and treated with ATO/IFN/AZT.
Results: Cell proliferation analysis against S1T and MT2 at 48 hours was performed with 1 uM of ATO, 1000U/ml of IFN and 5 uM AZT. Despite marginal inhibitory effect of IFN/AZT against MT2, substantial inhibitory effect was observed in S1T cell line In addition, combination of ATO and IFN/AZT showed synergistic effect on S1T. MT-2 cell was only sensitive to ATO treatment. ATO has been known to induce cell apoptosis through mitochondrial stress, we next assessed apoptotic effect of AZT/IFN in S1T. Treatment of S1T with AZT/IFN increased cleaved caspase-3, 7, 8, 9 and cleaved PARP expression and more

pronounced with ATO/AZT/IFN in combination; however treatment of S1T with only ATO did not clearly induced apoptosis. Cytotoxic effect of AZT/IFN was inhibited by pan-caspase inhibitor. NF-kB is known to require ATL cell survival. IFN/AZT treatment decreased phospho-IKK, phopho-IkB,and nuclear transloaction of NFkB. This pathway was mediated by decreased expression of TRAF6. IFN/AZT treatment induced robust phosphor-STAT1 expression, which lead to increased expression of IRF1, IRF7, IRF9 and p53 expression in S1T. We next established a novel experimental model for ATL using NOJ mice. Freshly isolated peripheral blood mononuclear cells from patients with ATL were inoculated intravenously into the tail vein, intraperitoneally, or subcutaneously. For cell doses of 1 x 10^7 PBMSCs/mouse, 100% of the mice succumbed to the ATL within 100 days (n=9). Additionally, increased levels of plasma soluble human IL-2 receptor were detectable as early as 2 weeks after inoculation. Immunohistochemical analyses of ATL-inoculated NOJ mice showed massive infiltration of human CD4/CD25+ leukemia cells in various organs including liver, spleen and lung. Circulating human CD4/CD25 positive cells were also detected in peripheral blood, and were also found in the inguinal region of NOJ mice where ATL cells were inoculated subcutaneously. Using this model, the effect of ATO/IFN/AZT for primary ATL cell was evaluated. 1x10^7 ATL patient PBMSCs/mouse were inoculated into NOJ mice intra-peritoneally and waited for 18 day before ATO/IFN/AZT combination therapy. With only 14 days treatment, treated group showed lower soluble IL2R receptor at day 40 and survived longer than untreated group (n=7 each group, p<0.05).
Summary and Conclusion: Conclusion: While several group reported less *in vitro* effect of AZT/IFN against ATL, we observed induction of apoptosis, inactivation of NFkB pathway and robust up-regulation of intereron related genes in an ATL leukemic cell line (S1T). This can be one of the anti-ATL mechanisms by ATO/INF/AZT. We observed only marginal anti-ATL effect in MT-2 and other ATL cell lines, thus anti-ATL effect of AZT/IFN may limit to subgroup of ATL. In addition, we first demonstrated *in vivo* effect of ATO/IFN/AZT by using NOJ xenograft model transplanted with primary ATL cells. This model can be further utilized for extracting ATO/INF/AZT sensitive ATL patients.

P1079

DOLASTATINS TARGET INTRATUMORAL DENDRITIC CELLS LEADING TO REMODELLING OF THE TUMOR MICROENVIRONMENT AND INDUCTION OF LONG-LASTING TUMOR-SPECIFIC T CELL RESPONSESS
S Theurich[1], P Mueller[2], K Martin[2], A Zippelius[2], M von Bergwelt-Baildon[1,*]
[1]Hematology, UK Cologne, Köln, Germany, [2]Medical Oncology, University of Basel, Basel, Switzerland

Background: Antibody drug conjugates (ADCs) are emerging as powerful treatment strategies with outstanding target specificity and high therapeutic activity in cancer patients. Brentuximab vedotin represents a first-in-class ADC directed against CD30-positive malignancies. We hypothesized that its sustained clinical responses could be related to the stimulation of an anti-cancer immune response. Using allogeneic stem cell transplantation of CD30+ lymphomas as clinical model we were able to establish that treatment with brentuximab vedontin +/- donor lymphocyte infusions induces tumor-specific CD4+ and CD8+ T cells leading to longterm remission.
Aims: To dissect the underlying mechanisms we combined the study of murine tumor models with an in-depth analysis of immune responses induced in patients receiving Brentuximab vedotin.
Results: We could demonstrate that the dolastatin family of microtubule inhibitors, from which the cytotoxic component of brentuximab vedotin is derived, comprises potent inducers of phenotypic and functional DC maturation. In addition to the direct cytotoxic effect on tumor cells, dolastatins efficiently promoted antigen uptake and migration of tumor-resident DCs to tumor-draining lymph nodes. Exposure of murine and human DCs to dolastatins significantly increased their capacity to prime T cells. Underlining the requirement of an intact host immune system for the full therapeutic benefit of dolastatins, the anti-tumor effect was far less pronounced in immune-compromised mice. When combining dolastatins with tumor-antigen-specific vaccination or blockade of the PD-1/PD-L1 and CTLA-4 co-inhibitory pathways, we observed substantial therapeutic synergies.
Summary and Conclusion: Our data reveal a novel mechanism of action for dolastatins and provide a strong rationale for clinical treatment regimens combining dolastatin-based therapies, such as brentuximab vedotin, with immune-based therapies.

Aggressive Non-Hodgkin lymphoma - Clinical 2

P1080

ROLE OF INTERIM-PET IN POOR PROGNOSIS YOUNG PATIENTS WITH DLBC LYMPHOMA AT DIAGNOSIS: DATA FROM A PROSPECTIVE ANCILLARY STUDY OF A RANDOMIZED PHASE III STUDY FROM THE FONDAZIONE ITALIANA LINFOMI
L Rigacci[1,*], P Pregno[2], B Puccini[1], A Evangelista[2], A Chiappella[2], G Gaidano[3], L Nassi[3], M Balzarotti[4], F Merli[5], A De Renzo[6], A Levis[7], M Spina[8], V Pavone[9], R Freilone[2], S Luminari[10], G Rossi[11], C Stelitano[12], AM Carella[13], AM D'Arco[14], P Musto[15], S Kovalchuk[16], G Benelli[16], A Bosi[16], U Vitolo[2]
[1]Haematology, AOU Careggi, Firenze, [2]on behalf of FIL, Torino, [3]on behalf of FIL, Novara, [4]on behalf of FIL, Milano, [5]on behalf of FIL, Reggio Emilia, [6]on behalf of FIL, Napoli, [7]on behalf of FIL, Alessandria, [8]on behalf of FIL, Aviano, [9]on behalf of FIL, Tricase, [10]on behalf of FIL, Modena, [11]on behalf of FIL, Brescia, [12]on behalf of FIL, Reggio Calabria, [13]on behalf of FIL, Genova, [14]on behalf of FIL, Nocera Inferiore, [15]on behalf of FIL, Rionero in Vulture, [16]AOU Careggi, Firenze, Italy

Background: The role of interim-PET (i-PET), after two cycles, in advanced stage Hodgkin's lymphoma is well defined; the same role in diffuse large B cell lymphoma (DLBCL) is still controversial.
Aims: The Fondazione Italiana Linfomi planned an ancillary prospective study during a randomized phase III trial the DLCL04 study addressed to young poor prognosis DLBCL patients at diagnosis.
Methods: The ancillary-PET study was designed to define the prognostic impact of i-PET on progression free survival (PFS) after two cycles of immunochemotherapy. Patients were stratified according to aa-IPI and randomized at diagnosis to receive: R-CHOP14+/- ASCT or R-MegaCHOP14+/-ASCT. A visual dichotomous criteria, according to Deauville, was used to define the i-PET result.
Results: From June 2005 to September 2010 130 patients were enrolled for the ancillary-PET study, 69 in the R-HDC+ASCT and 61 in R dose dense therapy respectively. The clinical characteristics were well balanced among the arms of therapy excluding a selection bias in the group of patients studied with i-PET. The i-PET result was positive in 74 patients and negative in 56 patients. In particular, in R-dose dense arm 27 were negative and 34 positive, in R-HDC+ASCT 29 were negative and 40 positive, according to immunochemotherapy scheme in R-CHOP14 29 were negative and 40 were positive, in MegaCHOP14 27 were negative and 34 were positive. With a median follow-up of 36 months no differences in PFS was reported according to i-PET result. In particular 3-year PFS were 87%(95% CI:75-94) in i-PET negative patients and 76% (95% CI: 65-85) in i-PET positive patients respectively (p: 0.09. The 3-year PFS according to I-PET results in the different treatment arm were: in the R-HDT+ASCT group i-PET negative or i-PET positive patients had a 3-year PFS of 83% (95% CI:63-92) and 79% (95% CI:63-89) respectively; in the R-dose dense i-PET negative or i-PET positive patients had a 3-year PFS of 92% (95% CI:73-98) and 72% (95% CI:54-85) (p: 0.07). I-PET negative and i-PET positive patients had a 3-year OS of 89% and 83% respectively, p=0.219.
Summary and Conclusion: In our multicenter prospective study i-PET, performed after two cycles and analyzed with a visual method, is not able to identify two different risk population. We are now performing a centralized revision of all evaluable PET.

P1081

BONE MARROW INVOLVEMENT AT DIAGNOSIS IS A POOR PROGNOSTIC FACTOR IN YOUNG PATIENTS WITH UNTREATED HIGH-RISK DIFFUSE LARGE B-CELL LYMPHOMA: SUB-ANALYSIS OF THE PHASE III RANDOMIZED FIL-DLCL04 TRIAL
A Chiappella[1,*], E Russo[1], E Brusamolino[1], E Angelucci[1], G Rossi[1], AM Carella[1], A Evangelista[1], C Stelitano[1], M Balzarotti[1], M Gotti[1], F Merli[1], G Gaidano[1], V Pavone[1], L Rigacci[1], F Zaja[1], C Rusconi[1], A De Renzo[1], G Pinotti[1], M Spina[1], M Pizzuti[1], M Cantonetti[1], G Specchia[1], P Pregno[1], C Pecoraro[1], A Tucci[1], MG Cabras[1], F Salvi[1], M Martelli[1], U Vitolo[1]
[1]On behalf of Fondazione Italiana Linfomi, Hematology, Città della Salute e della Scienza Hospital and University, Torino, Italy

Background: The bone marrow (BM) involvement in diffuse large B-cell lymphoma (DLBCL) had an adverse prognostic role (Sehn, J Clin Oncol 2011).
Aims: Aim of this analysis was to evaluate the prognostic role of BM involvement in the prospective randomized phase III trial DLCL04 by the Fondazione Italiana Linfomi (Vitolo, Blood, ASH2012).
Methods: Inclusion criteria were: age 18-65; untreated DLBCL or follicular grade IIIb; age adjusted-International Prognostic Index (aa-IPI) score 2 or 3. Patients were randomized at diagnosis to receive: Rituximab plus dose-dense chemotherapy (R-CHOP14 x 8 cycles or R-MegaCHOP14 x 6 courses), R-dose-dense group, *vs* a brief chemoimmunotherapy followed by high dose

chemotherapy plus autologous stem cell transplantation (R-CHOP14/R-MegaCHOP14 x 4 courses plus Rituximab-MAD and BEAM and ASCT), R-HDC+ASCT group. BM biopsy was mandatory at diagnosis and repeated at the end of treatment if positive. BM involvement was defined as concordant if marrow was involved by large B-cell and discordant by small B-cells.
Results: From 2005 to 2010, 399 patients were randomized to receive: 199 R-HDC+ASCT and 200 R-dose-dense chemotherapy. All patients were evaluable for analysis. BM involvement was reported in 84 patients (21%): 39 (20%) in the R-HDC+ASCT group and 45 (22%) in the R-dose-dense group. Pattern of involvement was concordant in 63 patients, discordant in 14 and not specified in 7 patients. Clinical characteristics in BM positive group compared to BM negative group were well balanced, with the exception of older patients (median age 53 years *vs* 47 years, p<.001) and higher aa-IPI score (aa-IPI 3: 36% *vs* 24%, p.024) in the BM positive patients. With a median follow-up of 49 months, 3-year progression free survival (PFS) for the whole series of 399 patients was 67% (95% CI: 62-72) and 3-year overall survival (OS) was 79% (95% CI: 75-83%). Three-year PFS in BM positive *vs* BM negative were 46% (95% CI:35-56%) *vs* 73% (95% CI:67-77%), p<.001. In a Cox-model for PFS including type of treatment, age, gender, aa-IPI, performance status, histology and BM involvement, the adverse prognostic impact of BM involvement was maintained with an adjusted Hazard Risk (aHR) of 2.22 (95% CI:1.54-3.22, p<.001).Three-year OS rates in BM positive *vs* BM negative were 65% (95% CI:53-74%) *vs* 83% (95% CI:78-87%) with an aHR 1.94 (95% CI:1.23-3.05; p=.004). The adverse prognostic impact of BM involvement on PFS was not affected by the type of treatment: 3-year PFS in BM positive R-dose-dense group was 42% *vs* 69% in BM negative with an aHR of 2.19 (95% CI: 1.35-3.54, p<.001); 3-year PFS in BM positive R-HDC+ASCT group was 51% *vs* 77% in BM negative, with an aHR of 2.27 (95% CI:1.30-3.97, p<.004). Regarding the prognostic impact of the pattern of BM involvement (concordant *vs* discordant), with the limits of small sample size of the discordant group, only concordant BM involvement maintained an adverse prognostic impact on PFS (Figure 1): in a Cox-model assuming BM negative as reference, the risk of progression was significantly increased in the concordant involvement group with an aHR of 2.48 (95% CI: 1.68-3.67, p<.001) and not affected by discordant involvement (aHR 1.05; 95% CI:0.41-2.71, p=.916).

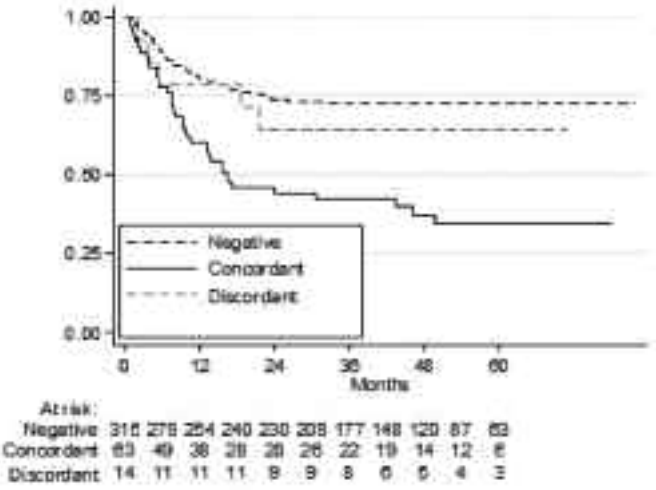

Figure 1.

Summary and Conclusion: BM involvement, namely concordant pattern, is a strong adverse predictor of outcome in young patients with untreated DLBCL at poor prognosis and its negative prognostic role is not overcome by the intensification with R-HDC+ASCT.

P1082

VITAMIN D DEFICIENCY (VDD) IMPAIRS RITUXIMAB-MEDIATED CELLULAR CYTOTOXICITY AND OUTCOME OF DLBCL PATIENTS TREATED WITH, BUT NOT WITHOUT RITUXIMAB (R)

JT Bittenbring[1,*], F Neumann[1], B Altmann[2], M Achenbach[1], J Reichrath[3], M Ziepert[2], J Geisel[4], E Regitz[1], G Held[1], M Pfreundschuh[1]
[1]Internal Medicine I, Saarland University Medical School, Homburg, [2]IMISE, University of Leipzig, Leipzig, [3]Dermatology, [4]Laboratory Medicine, Saarland University Medical School, Homburg, Germany

Background: Vitamin D deficiency has been reported to be associated with a worse outcome in patients with various malignant diseases.
Aims: The aim of this study was to investigate impact and underlying mechanisms of vitamin D-deficiency (VDD) on outcome of elderly patients with diffuse large B-cell lymphoma (DLBCL).
Methods: 359 pretreatment 25-OH-vitamin D serum levels from the RICOVER-60 trial and 63 from the RICOVER-noRTh study were determined by chemoluminescent immunoassay. Rituximab-mediated cellular cytotoxicity (RMCC) was determined by LDH release assay of CD20+ Daudi cells
Results: RICOVER-60 patients with VDD (≤8 ng/ml) treated with R had a 3-year event-free survival of 59% compared to 79% in patients with vitamin D levels >8 ng/ml; 3-year overall survival was 70% and 82%, respectively. These differences were also significant in a multivariable analysis adjusting for IPI risk factors with a hazard ratio (HR) of 2.1 (p=0.008) for event-free and 1.9 (p=0.040) for overall survival. EFS was not significantly different in patients with vitamin D levels ≤8 and >8 ng/ml (HR 1.2; p=0.388) treated without R. This was confirmed in an independent validation set of 63 RICOVER-noRTh patients. While R improved 3-year EFS of VDD patients by only 16%, patients with better vitamin D levels benefitted nearly twice as much from the addition of rituximab (31%). RMCC increased significantly (p<0.001) in 7/7 vitamin D-deficient individuals after substitution and normalization of their vitamin D levels.
Summary and Conclusion: VDD is a risk factor for elderly DLBCL patients treated with R-CHOP. The differential effect of VDD on outcome of patients treated with and without R and the fact that VDD impairs RMCC and substitution improves RMCC strongly suggest that vitamin D substitution might improve the outcome of patients treated with R. Appropriately designed prospective trials must confirm that vitamin D substitution does not only improve outcome in DLBCL, but also in diseases treated with other antibodies (*e.g.* trastuzumab in breast cancer), of which the major mechanism of action is antibody-dependent cellular cytotoxicity. *Supported by Deutsche Krebshilfe.*

P1083

COMBINING SEVERAL MOLECULAR ABNORMALITIES IN IDENTIFICATION OF HIGH-RISK DIFFUSE LARGE B-CELL LYMPHOMA IMPROVES RISK-STRATIFICATION

I Fiskvik[1,*], J Delabie[1], K Beiske[2], S Leppa[3], M Eriksson[4], E Smeland[2], H Holte[1]
[1]Norwegian Radium Hospital, [2]Oslo University Hospital, Oslo, Norway, [3]University of Helsinki, Helsinki, Finland, [4]University of Lund, Lund, Sweden

Background: Translocations in both MYC and BCL2 genes, double-hit lymphomas, are associated with poor prognosis in diffuse large B-cell lymphomas (DLBCL). Recent studies have expanded this concept by including double-hit lymphomas diagnosed by increased protein expression detected by immunohistochemistry (IHC). However, none have combined double hit with other abnormalities in trying to identify more patients with poor prognosis.
Aims: We assessed prognostic value of translocations and protein expression of MYC and BCL2, P53 protein expression and deletions of chromosome 17p (del 17p) on available tumor tissue from patients included in a prospective Nordic Lymphoma Group study. We also assessed prognostic value of different combinations of these abnormalities.
Methods: Seventy-four patients with high risk DLBCL or follicular lymphoma grade 3 were included. All patients received R-CHOEP-14 followed by CNS prophylaxis. Immunohistochemistry analyses were performed for anti-BCL2, MYC and P53. Fluorescence *in situ* hybridization (FISH) was performed for translocations in BCL2 and MYC and del17p. Overall survival (OS) and progression-free survival (PFS) were evaluated by Cox regression adjusted for International Prognostic Index (IPI) score.
Results: Seven (13%) patients had simultaneous translocations in BCL2 and MYC. A single translocation of BCL2, present in eighteen patients, was not associated with survival. Simultaneous translocations in BCL2 and MYC was associated with impaired OS (HR 5.5, 95% CI 1.2-24.0, p=0.02) and PFS (HR 3.4, 95% CI 1.0-11.1, p=0.046) in adjusted analyses. Nineteen patients had a high BCL2 and fourteen a high MYC protein-expression. These findings were not associated with survival while the six patients with co-expression of both MYC and BCL2 had impaired OS in adjusted analysis (HR 7.7, 95% CI 2.0-29.9, p=0.003) and PFS (HR 5.5, 95% CI 1.8-16.7, p=0.003). Ten patients (20%) had either a double-hit translocation and/or a double-hit protein expression. This group had impaired OS (HR 6.6, 95%CI 1.7-25.5, p=0.006) and PFS (HR 3.4, 95% CI 1.2-9.4, p=0.021) in adjusted analyses. Five-year OS and PFS was 50% and 37.5%, compared to 90% and 72 % in patients without these abnormalities. Four patients had a deletion in chromosome 17p which was associated with impaired OS (HR 13.9, 95% CI 2.6-74.8, p=0.002) and PFS (HR 6.8, 95% CI 1.7-26.9, p=0.006) in adjusted analyses. A P53 protein expression above 80%, seen in eight patients, was associated with impaired OS (HR 4.7, 95% CI, 1.3-16.4, p=0.017). Combining these two abnormalities yielded a group with higher risk: A group of eleven patients with deletion of 17p and/or high P53 protein expression had impaired OS 9.1 (95% CI 2.4-35.3, p=0.001) and PFS 3.3 (95% CI 1.1-9.8, p=0.028) in adjusted analyses. Seventeen patients had double-hit defined by translocation or protein expression and/or del17p and/or high P53. In adjusted analysis, this group had significantly impaired OS (HR 6.2, 95% CI 1.6-24.3, p=0.009). Analysis of this combined endpoint identified 70% of all deaths.

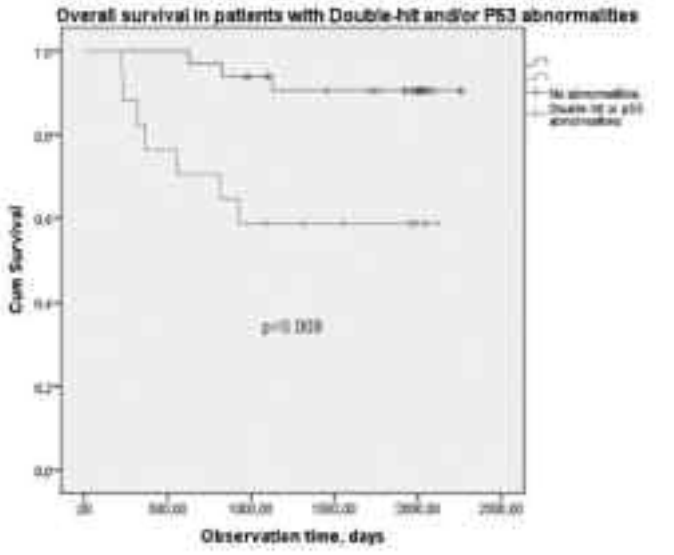

Figure 1.

Summary and Conclusion: Combining detection of MYC, BCL2 and P53 abnormalities identifies a larger proportion of patients with high-risk DLBCL than double-hit abnormalities alone.

P1084

DEFINING ACCURACY AND SENSITIVITY OF T-CELL RECEPTOR REPERTOIRE PROFILING FOR MONITORING RECURRENT/PERSISTENT DISEASE IN PATIENTS WITH MATURE T-CELL NEOPLASMS

A Sherwood[1], H Robins[2,*], J Fromm[3], H Greisman[3], D Sabath[3], MW Chung[1], C Bertucci[1], C Wilcox[1], R O Emerson[1], M Rieder[1], B wood[3], D Wu[3]
[1]Adaptive Biotechnologies, [2]Fred Hutchinson Cancer Research Center, [3]University of Washington, Seattle, United States

Background: Accurate and sensitive identification of recurrent or persistent disease in T-cell neoplasms is important for proper patient care. While there are several technologies to monitor disease, including flow, allele specific qPCR, and PCR amplification of rearranged receptors, high-throughput sequencing (HTS) of T-cell receptor (TCR) CDR3 chains is an emerging tool that combines the sensitivity of allele-specific qPCR assays with the ease of flow. We developed a method that amplifies rearranged TCR CDR3 sequences and uses high-throughput sequencing (HTS) to sequence tens of thousands of chains simultaneously. Because the technology utilizes gDNA the frequency of sequenced CDR3 chains is representative of the relative frequency of each CDR3 sequence in the sample population of T cells. Thus these assays can describe both the breadth of the T-cell receptor repertoire and quantify individual clones; enabling tracking the presence and frequency of neoplastic clones. However, HTS of TCRs is a relatively new technology with minimal data on sensitivity and accuracy.
Aims: This project aims to demonstrate the potential of this technology to monitor recurrent/persistent disease by first testing the assay's sensitivity and accuracy and then applying the technology to a set of mature T-cell lymphoma samples.
Methods: To test the sensitivity and accuracy of the assay known clones are spiked into a diverse background of lymphocyte and non-lymphocyte cells across a 100,000-fold dilution gradient. The TCR repertoire of 1,000,000 cells from each sample is subsequently amplified and sequenced, and we test if the assay 1) detected the clone across the dilution gradient, and 2) detected the clone at the right frequency. To show utility, we apply the technology to monitor persistent/recurrent disease in a set of mature T-cell lymphoma samples. To identify the neoplasm's CDR3 chain, we sequence the *TRB* and *TRG* repertoire of 35 index samples. Then, to diagnose persistent disease, we sequence the TCR repertoire of follow-up 55 matched follow-up samples and search for the neoplastic sequence. Clone frequencies lower than the sensitivity threshold were excluded.
Results: For the test of accuracy and sensitivity, the expected and observed clone frequencies were highly correlated (r2=0.98) and the clone was detected across the dilution gradient from 10^{-1} to 10^{-5}. Of the 55 samples clinical samples, 4 were MRD negative using either technique, 9 were MRD negative using traditional techniques and MRD positive using HTS, 1 was MRD positive using traditional techniques and MRD negative using HTS, and 41 were MRD positive using either technique.
Summary and Conclusion: These data indicate that HTS is a viable technology relative to currently applied routine clinical testing.

P1085

RETROSPECTIVE ANALYSIS OF TREATMENT OUTCOMES FOR 120 CASES OF NATURAL KILLER/T CELL LYMPHOMA, NASAL TYPE AT THE LARGEST SINGLE HOSPITAL OF NORTH-WESTERN CHINA

R Liang[1,*], Z Wang[2], Q X bai[1], X Q chen[1]
[1]heamatology, [2]pathology, Xijing Hospital, Xi'an, China

Background: Extranodal natural killer (NK)/T-cell lymphoma (ENKTL), nasal type, is a distinct, heterogeneous histopathologic and aggressive subtype of non-Hodgkin lymphoma (NHL) based on the clinically classification of WHO, with higher frequency in Asia than in Western countries. ENKTL is so aggressive and has high mortality rate and till now there in no standard therapy. In this study, we retrospectively analyzed the 120 cases n recent 5 years.
Aims: To improve the understanding of ENKTL with poor prognosis and provide experiential references for individual therapy via a retrospective analysis of the clinical features at the largest single hospital of north-western China.
Methods: 120 ENKTL cases from Apr.2007 to Oct 2012 in the largest hosptial of north-western China were retrospectively analyzed on their clinical manifestations. Pathological examinations were mainly depended on morphology, immunophenotype and *in situ* hybridization for EBER. PCR for the amount of EBV DNA in whole blood and TCR gene rearrangement were performed. Chemotherapy and or radiotherapy were the main treatments. CR,2 year(2y) OS and PFS according to clinical characteristics were analyzed.
Results: The median age of 120 ENKTL cases was 43.19±13.7 years old. 98 primary nasal ENKTL cases accounted for 81.4%, whose 2y OS/PFS were 88.6%/69.1% respectively. 22 non-nasal ENKTCL accounted for 18.3%, whose 2y OS/PFS were 58.8%/45.5% respectively. It was found that patients with primary intestinal or Ki67 greater than 80% were dead in first year. Patients with primary liver and intestine had higher Ki67 than patients with primary nasal. 2y OS/ PFS of 43 patients with Ki67 from 60% to 80% was 60%/36% as compared to 86.3%/57.5% for OS/PFS of 30 patients with Ki67 from 30% to 50% and 100%/78% for OS/PFS of 7 patients with Ki67 less than 30%. EBER was positive in every case. Among the 13 EBV –DNA samples detected, there were 5 samples with more than $6.1X10^7$ copies/ml with OS 60%. 2y OS and PFS of Patients with normal ferritin or β-microglobulin were longer than that with higher ferritin or β-microglobulin. 64 patients had IPI=0-2, accounting for 53.3%, 56 patients had IPI=3-5, accounting for 46.7%. 56 primary nasal patients with and IPI≤2 were more than 42 patients with IPI-2 and 7 primary non-nasal patients with IPI≤2 less than 15 patients with IPI-2. 2y OS/PFS of 98 patients with primary nasal was 88.6%/69.1%. 2y OS/PFS of 22 patients with primary non-nasal was 58.8%/57.3%. There was different survival outcome between nasal and non-nasal**.** Meanwhile 2y OS/PFS of 27 patients with local IEA was 100%. 2y OS/PFS of 33 patients with local IEB was 100%/90.9%. 2y OS/PFS of 24 patients with invasion I EB was 75%/62.5%. 10 patients with stage I received radiotherapy alone and 2y OS/PFS was 100%. 47 patients with stage II~IV received chemotherapy alone, of which 2y OS/PFS of 23 patients with stage IIEB was 91.3%/ 82.6%, 2y OS/PFS of 17 patients with stage III was 58.8%/47%. Among 34 patients who received more than 3 cycles of CHOPL + radiotherapy, 16 patients received pegaspargase because of allergic reaction of L-asparaginase. 2y OS/PFS of patients with CHOPL was 95%/81% respectively, higher than that of other patients. Among 120 patients, 11 patients received ABSCT after CR still survive and 2 patients after PR relapsed and died.
Summary and Conclusion: It was implied that Ki67, β-microglobulin, EBV-DNA and primary site was related with the prognosis of NKTCL. It needs further and more clinical observation. The chemotherapies containing asparaginase or pegasparaginase are more effective. Autologous stem cell transplantation could make patients long live and pretransplant CR status was a major prognostic factors.

P1086

ABNORMAL IMMUNOPHENOTYPE IS OF GREAT VALUE IN THE DIAGNOSIS OF AGGRESSIVE NATURAL KILLER CELL LEUKEMIA

ZY Qiu[1,*], L Fan[1], L Wang[1], C Qiao[1], YJ Wu[1], HY Zhu[1], YJ Hu[1], Y Zhuang[2], J Qian[3], YF Shen[2], KH Young[4], W Xu[1], JY Li[1]
[1]the First Affiliated Hospital of Nanjing Medical University, Jiangsu Province Hospital, Nanjing, [2]Wuxi People's Hospital Affiliated to Nanjing Medical University, Wuxi, [3]the Affiliated People's Hospital of Jiangsu University, Zhenjiang, China, [4]The University of Texas MD Anderson Cancer Center, Texas, United States

Background: Aggressive natural killer cell leukemia (ANKL) is a rare form of large granular lymphocytic leukemia (LGL) with an aggressive clinical course, and a rapid and accurate diagnosis of ANKL is a challenge. Although there have been some reports of small series of cases, reports of a large number of cases are few.
Aims: To describe the clinical features and assess the clonality by flow cytometric (FCM) analysis of Killer-cell immunoglobulin-like receptor (KIR) expression in ANKL, we conducted a prospective study of a series of patients with ANKL in China.
Methods: We described clinical features, checked serum EBV DNA level, analyzed STAT3 mutaion status and immunophenotypes at diagnosis. Nine

samples of chronic lymphoproliferative disorder of NK cells (CLPD-NK) were used as control.
Results: Our study population consisted of 36 consecutive patients recruited between September 2009 and January 2014. The clinical characteristics of 36 patients with ANKL are listed in Table 1. Pleural effusion (PE) was a common complication of ANKL, and lymphocytes observed in the PE were CD3-CD56+ leukemic cells. Thirty-four patients underwent bone marrow (BM) examination, and 32 patients showed varying degrees of BM infiltration of LGLs. Immunophenotypes of the ANKL cells were typically positive for CD2 except one patient, whereas CD1a, CD3, CD4, CD5, CD8, CD10 and CD57 were negative. CD7, CD16, CD56, CD94, CD160 and CD161were positive for 65.6%, 69.4%, 88.9%, 87.5%, 90.5% and 45.8%, respectively. Either restricted KIR expression or complete lack of KIR antigens was observed in all of the patients with ANKL (7 and 17, respectively). In the patients with CLPD-NK, CD3, CD4, CD5 and CD8 were negative; CD2 and CD7 were positive; expression of CD16, CD56, CD57, CD94, CD160 and CD161 were 88.9%, 77.8%, 55.6%, 50%, 85.7% and 0, respectively. NK cells from 5 (5/9) patients with CLPD-NK had homogenous reactivity to a single KIR receptor antibody, and 4 were complete lack of KIR antigens. By comparison, the expression of CD94 and CD161 in the ANKL patients was significantly higher (p=0.047 and p=0.019, respectively) than that in the CLPD-NK patients, but the expression of CD160 was not significant between the two groups. One patient displayed STAT3 mutations (Y640F). 89.7% of patients positive for serum EBV DNA and the quantity of serum EBV DNA ranged from 7.0×103 to 1.6×108 per milliliter at diagnosis. Seven patients who responded to chemotherapy experienced a decrease in EBV-DNA levels; however, the levels increased again when disease progression. Three cases were EBV negative, and the clinical course was less aggressive than that of conventional ANKL. All 36 cases had follow-up data with a mean follow-up of 77.1 days (range 3-720 days), and the median OS was 20 days. Twenty-thee patients received chemotherapy, and a clinical response to treatment was observed in 10 of 23 patients. In univariate analysis, the positivity of EBV-DNA (P=0.015), PS>2 (P<0.001), hemophagocytic syndrome (HPS) (P=0.001), PE/ascites (P=0.017) thrombocytopenia (P=0.021), lymphocytosis (P<0.001), neutropenia (P=0.003) was identified as an unfavorable factor of early death. Therapeutic response (P<0.001), CD56-(P=0.035) and receiving chemotherapy (P=0.038) were associated with better survival.

Table 1. Clinical and biological characteristics of 36 patients with ANKL

Characteristics	No of Patients	%
Median age (years)	43 (14-80)	
Gender		
Male	21	58.3
Female	15	41.7
Performance status (ECOG) 0-2	17	47.2
Performance status (ECOG)3-4	19	52.8
LDH (n=47)		
>245U/L	34	94.4
D-MD (n=42)		
>0.5mg/L	21	50.0
Lymphocytosis	8	22.2
Neutropenia	24	66.7
Anemia	17	47.2
Thrombocytopenia	30	83.3
Fever	36	100
Hepatomegaly	18	50
Splenomegaly	32	88.9
HPS	29	80.6
PE/ascites	18	50
Serum EBV-DNA (n=29)		
>500copies per ml/blood	26	89.7

Lymphocytosis: ALC>4.5×10⁹/L; Anemia: Hb<100 g/L;
Neutropenia: ANC<1.5×10⁹/L; Thrombocytopenia<100×10⁹/L

Summary and Conclusion: Our findings suggest that ANKL is an entity of abnormal phenotypic features and has a clonal KIR expression, and detection of KIR may have important diagnostic value. The detection of serum EBV DNA is a reliable way to monitor treatment response and outcome. To improve the poor prognosis of ANKL, we would like to emphasize three issues from our results: early diagnosis of ANKL, chemotherapy and allogeneic stem cell transplantation.

P1087

CNS PROPHYLAXIS IN PATIENTS WITH DLBCL, ARE WE TREATING OURSELVES? A RESPONSE TO THE RECENT BCSH GUIDELINE

M Griffin[1,*], K goddard[1], N Morley[1], A Fletcher[2], R Went[3], J wright[1]
[1]haematology, Haematology, Royal hallamshire hospital, Sheffield, Sheffield, [2]haematology, Chesterfield Royal Infirmary, Chesterfield, [3]haematology, Rotherham hospital, Rotherham, United Kingdom

Background: We were interested to read the recent BSCH guidelines on the role of CNS prophylaxis in the management of lymphoma. The authors concluded patients with Diffuse Large B cell Lymphoma (DLBCL) IPI 3-5 with either, a raised LDH and more than 1 extra nodal site, or involvement of certain anatomical sites (breast, testicular, epidural) should be treated with 3-6 doses of intrathecal methotrexate. The paucity of evidence for all aspects of this guidance was acknowledged. The North Trent Cancer Network covers a population of approximately 1.9 million in the towns/cities of Sheffield, Doncaster, Rotherham, Barnsley and Chesterfield. After a review of available evidence several years ago the clinicians in the network made a unanimous decision not to administer CNS prophylaxis to patients with DLBCL receiving CHOP Rituximab chemotherapy. More recently it was agreed that those with testicular lymphoma should receive high dose systemic methotrexate as part of their treatment regimen with RCHOP. Diagnosis of all new cases of DLBCL are made by the Sheffield Integrated Haemato-Oncology Diagnostic Service (HODS). Since 2006 all cases of diffuse large B cell lymphoma have been discussed at a single weekly teleconferenced region-wide MDT. Therefore centralised diagnostic and clinical data are readily available.
Aims: To determine the CNS relapse rate in North Trent, in an region that does not give CNS prophylaxis to patients with DLBCL, to determine if the policy should be changed in view of current guidelines
Methods: We have reviewed all cases of CNS relapse over a 6 year period and assessed each case with reference to the guidelines identifying those who would have been eligible to receive CNS prophylaxis. Those patients managed palliatively have not been included.
Results: Review of MDT and HODS records reveals that there were 620 de novo cases of DLBCL treated with curative intent over 6 years. 13 patients were diagnosed with CNS relapse, giving a prevalence of 2.1%. Median age was 53 (range 21-79) with 10 male patients 3 of whom had testicular disease. 9 patients had IPI<3, 3 patients did not have an LDH available, resulting in an IPI of 2, 1 other patient had an IPI of 4. According to current BCSH guidelines 4/13 patients would have received CNS directed treatment (3 testicular disease). 8 patients died of CNS disease shortly after presentation, 2 are alive with progressive lymphoma, 3 patients are in remission (2-48 months post relapse), 1 of whom has significant cognitive impairment following brain radiotherapy, reiterating the poor prognosis associated with CNS relapse.
Summary and Conclusion: In the rituximab era the CNS relapse rate in North Trent is 2.1% in de novo DLBCL. This is consistent with published figures despite our conservative approach to CNS prophylaxis. Furthermore less than a third of these cases would have received prophylactic IT methotrexate under the new guidance. This is lower than figures reported by van Besien at el 1998 who used a similar strategy to identify those at risk of CNS relapse before widespread use of rituximab. In this study approximately 50% of patients of the 605 patients meeting the criteria to receive CNS prophylaxis developed CNS relapse. The majority of the published data on CNS relapse are retrospective and of variable quality therefore reaching definitive conclusions is difficult. Evidence collected in the rituximab era suggests a reduction in the frequency of CNS relapse, perhaps because of better initial disease control. An alternative interpretation of the available evidence is that, with the possible exception of testicular disease, there is no reliable strategy for the identification of an individual at risk of CNS relapse. Similarly, the benefit of intrathecal methotrexate prophylaxis alone is unproven. Current data do not support the application of this guidance and we believe that the BCSH should reconsider its adoption. In the meantime we feel our experience may provide reassurance to others wishing to adopt alternative strategies.

P1088

MONOCLONAL AND POLYCLONAL GAMMOPATHY MEASURED BY SERUM FREE LIGHT CHAIN AND IMMUNOFIXATION SUBDIVIDE THE CLINICAL OUTCOMES OF DIFFUSE LARGE B-CELL LYMPHOMA ACCORDING TO MOLECULAR CLASSIFICATION

YR Kim[1,*], SJ Kim[1], JW Cheong[1], Y Kim[1], DY Hwang[1], JE Jang[1], SY Hyun[1], JY Lee[1], YH Min[1], JS Kim[1]
[1]Internal medicine, Severance Hospital, Yonsei University College of Medicine, Seoul, Korea, Republic Of

Background: Elevated serum free light chain (FLC) is known to be an adverse prognostic factor in diffuse large B-cell lymphoma (DLBCL).
Aims: We hypothesized that monoclonal gammopathy (MG) and polyclonal gammopathy (PG) measured by serum FLC and immunofixation (IF) would have different clinical outcome according to the molecular classification of DLBCL.
Methods: A total of 175 newly diagnosed DLBCL patients with information of serum FLC and IF were retrospectively analyzed. MG was defined as elevated

kappa (κ) or lambda (λ) FLC with abnormal κ to λ ratio or positive IF, PG was defined as elevated κ and/or λ FLC with normal κ to λ ratio and negative IF. Molecular classification of DLBCL such as GCB type and non-GCB type was performed according to the Hans algorithm.
Results: Ninety six (54.9%) patients had elevated FLC. MG was observed in 34 (19.4%) patients and PG was observed in 68 (38.9%) patients. The 2-year overall survival (OS) was 79.0% and the 2-year event-free survival (EFS) was 71.6%. In multivariate analysis, high-intermediate/high international prognostic index (IPI) and elevated FLC showed clinical significance for OS (*P*=0.002, *P*=0.005, respectively) and EFS (*P*<0.002, *P*=0.010, respectively). MG and PG were also associated with inferior OS (*P*=0.002, *P*=0.011, respectively) and EFS (*P*=0.002, *P*=0.013, respectively). Ninety six patients (73.8%) patients were classified to non-germinal center B-cell (GCB) type among 133 evaluable patients. PG showed inferior clinical outcome for OS and EFS in GCB type of DLBCL (*P*=0.006, *P*=0.035, respectively). MG was a significant poor prognostic factor for OS and EFS in non-GCB type (*P*=0.017, *P*=0.004, respectively, figure).

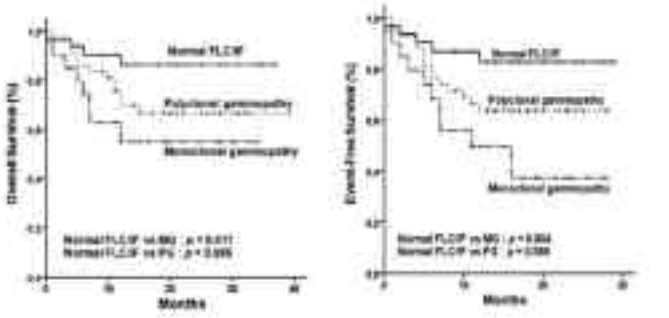

Figure 1.

Summary and Conclusion: MG measured by serum FLC and IF was associated with inferior outcome in DLBCL, especially non-GCB type.

P1089

TORISEL IN MANTLE CELL LYMPHOMA: RESULTS OF RESTOR STUDY (NON INTERVENTIONAL, LONGITUDINAL, RETROSPECTIVE, MULTICENTER AND NATIONAL STUDY ON A COHORT OF 93 PATIENTS WITH MANTLE CELL LYMPHOMA)

K Bouabdallah[1,*], A Gilleron[2], C Haioun[3], H Ould Lahssen[2], R Delarue[4], V Ribrag[5]
[1]Hematology, Service d'Hématologie clinique, PESSAC, [2]Laboratoire Pfizer, Paris, [3]Hematology, Hôpital Henri Mondor, Créteil, [4]Hematology, Hôpital Necker, PARIS, [5]Hematology, Institu Gustave Roussy, Villejuif, France

Background: Mantle Cell Lymphoma is an aggressive disease without curative option in most cases. In patients who relapse and not candidate for transplantation, there are few validated options despite a wide range of new compounds under investigation. Treatment with m-Tor inhibitor Temsirolimus (Torisel®) licensed in Europe remains an interesting option mainly in elderly.
Aims: To evaluate the survival of patients with Mantle Cell Lymphoma (MCL) treated with Torisel®.
Methods: Retsrospecive survey in 21 French hematology centers who treated at least 4 patients (pts) with Torisel® between August 1st, 2009 (date of market authorization) and December 1st, 2011. Pts were followed for ≥ 1 year after the first administration of Torisel®. Demographic, clinical and biological data at the diagnosis, treatment regimens, responses and survival data were collected. Data review and analysis were done by a scientific committee on October 31st, 2013.
Results: Ninety three pts responding to inclusion and non-inclusion criteria were identified in the 21 centers. Among these 93 pts, 84 pts (M=65) were evaluable (6 pts did not fulfill inclusion / non-inclusion criteria, 1 pts duplicate, 2 pts with empty CRFs). Median age was 51.4 (73% >65 y), median time from diagnosis to treatment with Torisel® was 4.4y (0-15). Fifty eight pts (69%) had received ≥ 3 prior treatment regimens including 14 pts (24%) who underwent autologous SCT. Sixty four pts (76%) were treated with Torisel® in monotherapy and twenty pts (24%) in combination including seventeen pts (85%) treated with Torisel®+Rituximab. Median treatment duration with Torisel® was 2, 5 months (1 day– 28,5 months). Fifty three pts (63%) received a loading dose of 175 mg. Median duration of follow up was 243, 5 days (16-1143). Among the 84 pts, 32 pts (38%) have had an objective response (IC 95% [27, 7 – 48,5]) with10 CR and 22 PR. There was no significant difference according to age (>or<65 y), number of prior treatment regimens (<ou ≥ 3) or the use of Torisel® either in combination or not. Median survival was 320 days (IC 95% [181 -521]) and median Progression free survival was 100 days (IC 95% [69 -174]). Torisel® tolerability was acceptable, except for toxicities commonly reported in particular gastrointestinal (7, 14%), pulmonary (10, 7%), hematologic (15, 5%) and infection (27, 4%). There was no toxic death attributed directly to Torisel®
Summary and Conclusion: Although this is a retrospective study, it confirms the results previously reported in the pivotal study by Hess et al (*G. Hess, JCO 2009*). These results demonstrate that the administration of Torisel® even in elderly pts for whom chemotherapy is considered potentially toxic (risk / benefit) or contraindicated is feasible. Analysis of long-term data is ongoing and results will be presented at the congress.

P1090

EVALUATION OF THE NOVEL, ORALLY BIOAVAILABLE SELECTIVE INHIBITOR OF NUCLEAR EXPORT (SINE) VERDINEXOR (KPT-335) IN SPONTANEOUS CANINE CANCERS: RESULTS OF PHASE I AND PHASE II CLINICAL TRIALS

C London[1,*], L F Bernabe[1], S Barnard[1], W C Kisseberth[1], A Borgatti[2], M Henson[2], H Wilson[3], K Jensen[2], D Ito[2], J F Modiano[2], M D Bear[1], M L Pennell[4], JR Saint-Martin[5], D McCauley[5], M Kauffman[5], S Shacham[5]
[1]College of Veterinary Medicine, The Ohio State University, Columbus; Ohio, [2]Veterinary Clinical Sciences and Masonic Cancer Center, University of Minnesota, Minneapolis/St. Paul; Minnesota, [3]Small Animal Clinical Sciences, Texas A&M University, College Station; Texas, [4]College of Public Health, The Ohio State University, Columbus; Ohio, [5]Karyopharm Therapeutics, Natick; Massachusetts, United States

Background: Selective Inhibitors of Nuclear Export (SINE) transiently block CRM1/XPO1, the major nuclear export protein in cells, forcing nuclear retention of key tumor suppressor and growth regulatory proteins ultimately resulting in tumor cell death.
Aims: Here we evaluated the *in vitro* activity of SINE against canine tumor cell lines and investigate the biologic activity of verdinexor (KPT-335) in companion dogs with spontaneous cancers as proof of principle for human clinical studies.
Methods: Cytotoxicity assays were performed in several canine tumor cell lines including those derived from non-Hodgkin lymphomas (NHL). SINE compounds induced growth inhibition and apoptosis. NHL cell lines were particularly sensitive with IC_{50s} of 2 - 42 nM. Phase 1 and Phase 2 clinical trials of oral verdinexor were given to companion dogs with mast cell tumors, osteosarcomas, or NHL at doses of 1 – 1.75mg/kg.
Results: Seventeen dogs with NHL (naive or relapsed) were enrolled in a Phase 1 clinical trial. The maximum tolerated dose was 1.75 mg/kg, given orally twice weekly (Monday/Thursday). Objective responses include Partial Responses (PR n=2) and Stable Disease (SD n=7). Responders had a median Time To Progression (TTP) of 66 days (range 35-256). An additional six dogs with NHL were given verdinexor at a dose of 1.50 mg/kg Monday/Wednesday/Friday; clinical benefit was observed in 4/6 dogs with a median TTP for responders of 83 days (range 35-354). Toxicities were primarily GI-related including anorexia, weight loss, vomiting and diarrhea. Toxicities were manageable with supportive care, dose modulation and "low dose" prednisone. A subsequent Phase 2 study was performed in 58 dogs with either newly diagnosed or relapsed NHL. Verdinexor was administered at 1.25 - 1.50 mg/kg twice weekly (Monday/Thursday). The objective response rate was 34% (1 Complete Response, 19 PR) with an additional 33 dogs experiencing SD for ≥4 weeks. While the median TTP was approximately 5 weeks, 20 dogs (34%) remained on study drug for ≥8 weeks.
Summary and Conclusion: Dogs with T cell lymphoma, a form of disease considered to be biologically aggressive and challenging to treat with cytotoxic chemotherapy, had particularly good objective responses to single agent verdinexor (71% in naïve disease, 57% in relapsed disease). Verdinexor was well tolerated, with anorexia being the most common side effect. Furthermore, the quality of life did not significantly change over the study duration in all dogs enrolled (p=0.13), in dogs that remained on study for at least 28 days (p=0.66) or in dogs that remained on study for at least 56 days (p=0.52), indicating tolerability with both short- and long-term dosing. Together, these data provide robust evidence that the novel orally bioavailable XPO1 inhibitor verdinexor exhibits single agent biologic activity in a relevant spontaneous large animal model of human NHL. It is therefore likely that other SINE compounds, such as the closely related selinexor (KPT-330) will exhibit similar tolerability and biologic activity in humans. Preliminary data on selinexor in patients with advanced NHL support this.

P1091

THE ROLE OF IMAGE GUIDED CORE BIOPSY IN THE DIAGNOSIS OF HAEMATOLOGICAL MALIGNANCY

K Bailey[1,*], N Woodward[2], D Hughes[1], K Cwynarski[1], M Leach[3], P McKay[3], C McNamara[1]
[1]Haematology, [2]Radiology, The Royal Free Hospital, London, [3]Haematology, The Beatson West of Scotland Cancer Centre, Glasgow, United Kingdom

Background: Surgical lymph node excision biopsy (EB) has been regarded as the gold-standard for lymphoma diagnosis. Image-guided core biopsy (ICB) is widely used and is included in current UK lymphoma guideline recommendations. However, concern remains regarding the yield and accuracy of this technique.

Aims: To assess the utility of ICB at two large centers, in England and Scotland, and then to survey attitudes of hematologists towards EB and ICB.
Methods: We reviewed all lymph node specimens referred with suspected lymphoma at the Royal Free Hospital (RFH) during 2012. The size of the biopsy, the diagnosis and comments on the report were recorded. We also had access to similar data from the Beatson West of Scotland Cancer Centre (BWoSCC). We composed an e-questionnaire that was e-mailed to 58 hematologists and anonymous responses were scrutinized.
Results: There were 140 samples from RFH;19 (13.6%) were EB, and 120 (86.4%) ICB. Of the ICB 101 (89%) were diagnostic compared to 18 (95%) of the EB. This was similar to the BWoSCC cohort; 83/107 (78%) of ICB were diagnostic. In many of the cases where ICB was non-diagnostic, this was due to disease associated lymph node fibrosis. In the BWoSCC cohort 11/16 (69%) of the non-diagnostic group had fibrosis in association with classical Hodgkin's lymphoma. We received 23 responses (39% response rate) to our questionnaire; of these 9 worked at level 3 centers and 2 were from level 1 centers. All had access to ICB. Sixteen (72%) of respondents estimated that the proportion of ICB providing inconclusive histology was 5-24%. It was reported that ICB could be obtained within one week by 18 (81%) compared with only 5(23%) of respondents reporting availability of EB within 1 week. Factors influencing decision for ICB varied markedly between respondents. Site of biopsy influenced choice of procedure with peripheral lymphadenopathy being more often referred for EB. The strongest factors favoring ICB were a radiology colleague known to consistently obtain adequate biopsy, intra-abdominal lymphadenopathy, speed of access and patient preference. Easily accessible peripheral lymphadenopathy and a trusted surgical colleague were most likely to lead to an EB referral with advanced age of the patient strongly influencing the decision to refer for ICB.
Summary and Conclusion: We conclude that ICB is a widely available procedure often used for lymphoma diagnosis. ICB is diagnostic in the vast majority of cases in the two centers sampled. Responses suggest that ICB can be obtained in a timely fashion, facilitating initiation of appropriate chemotherapy. The attitude of UK hematologists towards ICB is mixed. It is evident that colleagues regard ICB as having the advantage of speed of referral and safety in obtaining deep tissue samples. Expertise of the operator obtaining the specimen is perceived as more influential than the preference of the histopathologist, perhaps reflecting concern regarding adequacy of the sample. Further work is needed to ascertain the risk of diagnostic error of ICB.

P1092

CLINICAL OUTCOME AND PROGNOSIS IN PATIENTS WITH PRIMARY SINONASAL TRACT DIFFUSE LARGE B CELL LYMPHOMA TREATED WITH R-CHOP CHEMOTHERAPY: MULTICENTER RETROSPECTIVE ANALYSIS

GW Lee[1,*], CFISOL (CISL) study group[2]
[1]Internal Medicine, Gyeongsang National University School of Medicine, Jinju, [2]null, null, null, Korea, Republic Of

Background: The sinonasal tract is a rare extranodal site of diffuse large B cell lymphoma. Before the era of rituximab, sinonasal tract diffuse large B cell lymphoma (SN-DLBCL) treated with CHOP or CHOP-like chemotherapy represented high relapse rate in central nervous system (CNS) and poor clinical outcomes compared to nodal DLBCL because of its anatomical sites.
Aims: The aim of this study was to evaluate the clinical outcomes and relapse pattern in patients with primary SN-DLBCL in the era of R-CHOP chemotherapy.
Methods: We retrospectively analyzed data from 80 patients, newly diagnosed with primary SN-DLBCL treated with R-CHOP in 22 Korean Institutions between January 2004 and January 2013. Primary SN-DLBCL was defined as DLBCL localized in sinonasal tract with or without nodal disease, which included distant systemic nodal disease as well as regional nodal disease in this study and other multiple extranodal organ involvement was excluded.
Results: Median age at diagnosis was 62.0 years (range, 25-85 years). Forty-five (54.3%) patients were male. Forty-four (55.0%) patients were elderly (≥60 years). Seventy-three (91.3%) patients were Ann-Arbor stage I-II disease. Whereas three (5.8%) patients were high-intermediate to high risk of international prognostic index, nine (11.3%) patients were high-intermediate to high NK/T cell lymphoma prognostic index. Fifty-nine (73.8%) patients received R-CHOP chemotherapy alone without involved field radiotherapy (IFRT) and twenty-one (26.3%) patients were treated with R-CHOP followed by IFRT. No significant difference in response rate and OS between R-CHOP alone and R-CHOP followed by IFRT, regardless of age, sex, ECOG performance status, Ann-Arbor stage, LDH, and NK/T cell prognostic index. Seventy-four (92.5%) patients were treatment responder (CR+PR). Only one (1.9%) CNS relapsed patient and eight (11.8%) local relapsed patients were observed respectively in this study.
Summary and Conclusion: Our results show that primary SN-DLBCL patients treated with R-CHOP seems to be relatively low CNS relapse rate and better OS compared to previously reported literatures treated with CHOP or CHOP-like chemotherapy before the era of rituximab. However, further studies are warranted to validate our retrospective analysis.

Background: Recently, diffuse-large-B-cell lymphoma (DLBCL) associated with serum IgM paraproteinemia (IgM-Secreting) has been shown to be a very poor prognostic subset although, detailed pathological and molecular data are still lacking.
Aims: In the present study, the clinicopathological features and survival of IgM-secreting DLBCL were analyzed and compared to non-secreting cases in a series of 151 conventional DLBCL treated with R-CHOP.
Methods: This is a retrospective study evaluating the incidence of IgM-secreting DLBCL and comparing this subset with a non-secreting control group for clinicopathological, molecular features and survival. The study was approved by our Institutional Review Board and was conducted in accordance with the regulations of health information protection policies. A hundred and fifty-one patients diagnosed with conventional *de novo* DLBCL were analyzed for serum protein electrophoresis at disease onset, and those who had a likely monoclonal band in the serum were further investigated by serum immunofixation.
Results: IgM paraproteinemia was detected in 19 (12.5%) out of 151 patients at disease onset. In 17 of these cases secretion was likely due to the neoplastic clone, as suggested by the expression of heavy chain IgM protein in the cytoplasm of tumor cells. In IgM-secreting cases immunoblastic features (p<.0001), non-GCB-type (p=.002) stage III-IV(p=.003), ≥2 extra nodal sites (p<.0001), bone-marrow (p=.002), central-nervous-system (CNS) involvement at disease onset or relapse (p<.0001), IPI-score 3-5 (p=.009) and failure to achieve complete remission (p=.005), were significantly more frequent. FISH analyses for BCL2, BCL6 and MYC gene rearrangements detected only two cases harboring BCL2 gene translocation and in one case a concomitant BCL6 gene translocation was also observed. None of the IgM-secreting DLBCL was found to have L265P mutation of MYD88 gene. Thirty-six month event-free (11.8% *vs* 66.4% p<.0001), progression-free (23.5% *vs* 75.7%, p<.0001) and overall (47.1% *vs* 74.8%, p<.0001) survivals were significantly worse in the IgM-secreting group. In multivariate analysis IgM-secreting (p=.005, expB=0.339, CI=0.160-0.716) and IPI-score 3-5 (p=.010, expB=0.274, CI=0.102-0.737) were the only significant factors for progression-free-survival. Notably, four relapsed patients, who were treated with salvage immmunochemotherapy combined with bortezomib or lenalidomide, achieved lasting remission.
Summary and Conclusion: Our data suggests that IgM-secreting cases are a distinct subset of DLBCL, originating from activated-B-cells with terminally differentiated features, prevalent extra nodal dissemination and at high risk of CNS involvement. Authors MC Cox and A Di Napoli equal contribution

ELDERLY WOMEN WITH DIFFUSE LARGE B-CELL LYMPHOMA (DLBCL) TREATED WITH RITUXIMAB BASED CHEMOTHERAPY DO NOT HAVE BETTER OUTCOME COMPARED TO MEN

F Sedlák[1,*], R Pytlík[1], K Benešová[1], J Stříteský[2], B Procházka[3], M Trněný[1]
[1]1st Department of Medicine, [2]Institute of Pathology, General University Hospital in Prague, [3]Unit for Biostatistics and Informatics, National Institute of Public Health, Prague, Czech Republic

Background: The DLBCL patient's outcome has been significantly improved by rituximab introduction (Coiffier, 2002). The most powerful and used prognostic system remains IPI designed in pre- rituximab era (Shipp 1993), although some modifications have to be studied - *i.e.* R-IPI (Sehn 2007), NCCN-IPI (Zhou 2014). The recent publications suggest that women could have different outcome compared to men when treated with rituximab either as part of the induction (Pfreundschuh 2013) or maintenance (Jaeger 2013, Gisselbrecht 2012). The different rituximab clearance in older women compared to other gender-age subgroups could be one of the possible explanations (Muller 2012), although the data is not consistently explained by this factor only.
Aims: Evaluate the impact of different prognostic factors including IPI, gender, bulk and BMI in unselected population of DLBCL patients treated with anthracycline based chemotherapy combined with rituximab.
Methods: The unselected cohort of consecutive 611 patients with DLBCL (primary CNS lymphoma were excluded) treated with R-CHOP-like chemotherapy at General University Hospital in Prague between 2001-2012 has been retrospectively analyzed. IPI and its components, gender, bulk (7.5 cm)

and BMI were the factors tested. Statistical analysis was performed by Cox regression model and supported by univariate analysis using Kaplan-Maier estimation model. Patients: The median age was 60 years, 51.6 % men, 48.4 % women. IPI subgroups: good IPI (low or low intermediate risk) 48.8 %, poor IPI (high or high intermediate risk) 46.6 %, unknown IPI 4.6 %. R-CHOP regimen was the most frequent (77.1 %). With median follow up of 4.5 year, the median PFS and OS wasn't reached. The 5-year PFS and OS were 67.0 % ± 2.1 %, 72.6 % ± 2.0 % respectively.
Results: The following factors had significant prognostic impact on PFS and partially on OS: IPI (concurrently significant impact on OS), bulk (significant impact on OS has not been generally confirmed in multivariate analysis), but not the gender or BMI. These factors remain independent in multivariate analysis. When we analyzed younger and older population (60 years cut off) separately, for younger patients the IPI and bulky remain the independent prognostic features, however for elderly only the IPI remains the independent prognostic factor. We did not find linear relationship between BMI and patient's outcome, but for proper evaluation of this factor further analysis ought to be done. We tested separately the gender influence in elderly population of good and poor IPI subgroups. Surprisingly, the data revealed that in good IPI subgroups men (median PFS not reached) have better outcome compared to women (median PFS 6.2 years) - p=0.0347, whereas OS wasn't significantly different, and also that there is no difference in poor IPI risk subgroups.
Summary and Conclusion: We are not able to confirm the findings that elderly women have better outcome compared to men in large series of DLBCL patients. Based on these data we are not strongly convinced that it is worthwhile to change the rituximab treatment strategy according to gender in routine clinical practice. IDENTIFYING MALIGNANT LYMPH NODES BY NANOPARTICLE MODELLING AND SIMULATIONS: A PRELIMINARY INVESTIGATION

G De Tullio[1,*], D Caratelli[2], S Casciaro[3], F Conversano[3], A Massaro[4], A Guarini[1]
[1]Department of Clinical and Experimental Oncology, Haematology Unit, Advanced Cell Therapy Center, National Cancer Research Centre, Istituto Tumori "Giovanni Paolo II", BARI, Italy, [2]The Antenna Company, Nederland B.V., 2629 HD, Delft, Netherlands, [3]Nanoimaging Ultrasound LAB,Institute of Clinical Physiology, National Research Council, Lecce, [4]Italian Institute of Technology (IIT), Center for Biomolecular Nanotechnology (CBN), Arnesano (Le), Italy

Background: The fully and accurate identification and characterization of malignant lymph nodes by imaging has important therapeutic and prognostic relevance, mainly in patients with aggressive non-Hodgkin's lymphoma whose management is based on the pre-treatment staging assessment. Therefore, an accurate evaluation of nodal status and a precise staging of malignant lymph nodes represent an essential adjunct to the clinical investigation for lymphoma staging. This is in fact useful to select the appropriate therapeutic approach, as well as to determine prognosis, monitor response to therapy and provide surveillance after curative treatment. Conventional ultrasound (US) is considered the method of choice to evaluate lymph node disease, due to its high spatial resolution. However, nodal imaging would benefit from more specific and target-sensitive techniques in order to more accurately monitor therapy response and clinical outcome. The development of "smart" contrast agents able to specifically detect the neoplastic lymphoid cells in malignant lymph nodes could provide a significant contribution to the accomplishment of this goal. In this context, the nanoparticles (NPs) interfacing with biological systems have emerged as promising cellular probes for diagnostic imaging, since their surface could be easily conjugated with specific antibodies or ligands for selective recognition and binding to the target cells. Among pathological B cell associated antigens, the CD22 is expressed on more than 90% of B-cell lymphoid malignancies, suggesting that it may be a promising biomarker for the development of novel detection strategies combining US and NPs.
Aims: To test magnetic NPs functionalized with anti-CD22 (anti-CD22-NPs) as possible new contrast agents in a wireless detection system based on the implementation of nanoprobes for ultrasound in a lymph node model, in order to establish wheter this novel imaging strategy could represent a promising support in clinical investigations.
Methods: The NPs will be synthesized by means of a proper choice of silica precursor according with the required functionalization and conjugated with antibody anti-CD22. In order to improve a biocompatibility the silica NPs could be embedded in agarose material. The use of agarose/agarosel gel could be useful for a preliminary "*in vitro*" experimentation stage oriented to the comparison with numerical results. The NPs will be targeted to the "anomalous" lymph node and a high-detected NPs concentration will indicate a possible lymph nodes irregularity. The NPs will interact with the electromagnetic (EM)/ultrasound wave coming from the external ultrasonic source.
Results: The EM/ultrasound interaction is defined by means the wave reflectivity due to the presence of NPs which behave as contrast agent for imaging. The reflected EM/ultrasound wave will be detected by means of an ultrasonic probe able to map the NPs dislocation. The EM/ultrasound characterization can be performed by means of time or frequency domain numerical tools able to provide a mapping of NPs concentration and, consecutively, to indicate a strong signal reflectivity. In Fig.1 is illustrated an example of a 3D model of NPs to simulate.

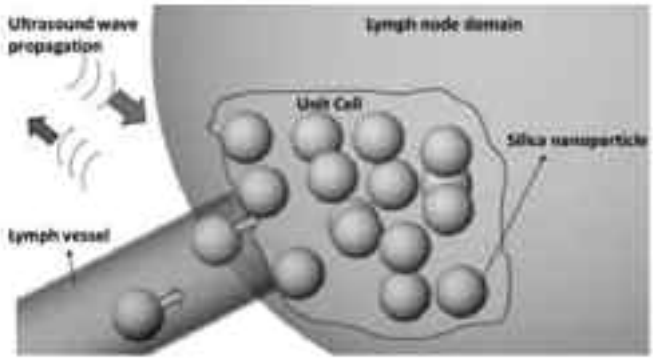

Figure 1.

Summary and Conclusion: The EM/ultrasound characterization represents the first step for the design of the whole nano-system and is useful in order to predict the real lymph node response and to understand how the magnetic NPs interact with all bio-interfaces. The numerical simulations can be used also to analyze the EM/ultrasound response of NPs cluster generated by merged NPs. The biocompatibility and the toxicity concerning the dimension of NPs or NPs clusters will be accurately studied in a future work.

INCIDENCE OF EBV-POSITIVITY IN THE VERY ELDERLY PATIENTS (AGED ≥ 80 YEARS) WITH DIFFUSE LARGE B-CELL LYMPHOMA: POSSIBLE NEW SUBTYPE OF ELDERLY DLBCL

T Tomikawa[1,*], M Tokuhira[1], R Watanabe[1], T Tabayashi[1], Y Takahashi[1], Y Kimura[1], M Sagawa[1], T Nemoto[1], S Mori[1], M Higashi[2], JI Tamaru[2], M Kizaki[1]
[1]Department of Hematology, [2]Department of Pathology, Saitama Medical Center, Saitama Medical University, Kawagoe, Japan

Background: Epstein-Barr virus (EBV)-positive diffuse large B-cell lymphoma (DLBCL) of the elderly has been described in the 2008 WHO classification as a novel provisional entity, and is defined clonal B-cell proliferation associated with EBV that occurs in patients ≥ 50 years of age in whom there is no known immunodeficiency. This unique DLBCL have an activated B-cell immunophenotype and prognosis is significantly inferior compared with EBV-negative DLBCL.
Aims: Recent studies have shown that the population of EBV-associated B-cell lymphoma is increased among patients over 50 years according to aging process. Life expectancy has been increasing consistently over the last century, and is estimated to reach over 80 years by 2030. The probability of DLBCL grows with age, and incidence increases in the elderly. However, little is known about clinical and biological characters in the very elderly patients (aged ≥ 80 years); therefore, the aim of this study was to clarify the incidence of EBV infection and its related clinicopathological features in the very elderly patients with DLBCL.
Methods: We retrospectively analyzed 190 patients with DLBCL, who were diagnosed in our institute from January 2008 to December 2013. Diagnoses were confirmed by immunohistochemistry performed on paraffin-embedded tissue sections, using selected members of a panel of monoclonal antibodies, and all cases were examined for the presence of EBV by the *in situ* hybridization detection technique, and EBV early RNAs (EBER). The comparison between EBV-positive ratio by the detection of EBER in tumor samples and each clinical and immunochemical data according to age were carried out.
Results: Of 190 DLBCL patients, the mean age was 67.2 years (range 22-97 years). The average positivity of EBER by using immunohistological studies for the EBV-latent gene products on paraffin sections was 4.6% in all patients. The mean ratio of EBV positivity of tumor samples was determined for each 10-year aged group. The ratio of EBER was 0% (20-49 years; n=25), 3.6% (50-59 years; n=32), 3.8% (60-69 years; n=38), 8.9% (70-79 years; n=61), and 3.4% (≥ 80 years; n=34), respectively. EBV-positive DLBCL of the very elderly was only one case out of 34 patients. The clinical course of this patient was progressive and died within 7days without any treatment for DLBCL. The mean prevalence of immunostaining for CD5, CD10, CD20, Bcl-2, Bcl-6, and MUM-1 in each aged group was not significant difference, suggesting this cohort was same as general population.
Summary and Conclusion: It has reported that the incidence of EBV-associated lymphoproliferative disorders (LPD) increases with advancing age and EBER-positive DLBCL in aged over 50 years showed more than 20% of patients (Shimoyama Y, *et al.* Pathology Int. 2009; 59: 835-43); however, only 4.6% of patients with DLBCL in aged over 50 years showed EBER-positivity in our study. Interestingly, the peak of EBER-positive ratio was shown in the age

group of 70-79 years (8.9%) as reported, the incidence of EBV-positive DLBCL in the very elderly patients was only 3.4%. The immunophenotypic analysis was similar to each aged group, suggesting the patient population used in this study was not deviated. In conclusion, EBV-positive DLBCL of the elderly has reported mainly identified in patients older than 50 years, the incidence in the very elderly patients is less frequent, and it might be existed in new subtype of B-cell lymphoma. Further clinical and molecular analyses are needed to clarify the pathogenesis of EBV-infection in DLBCL.

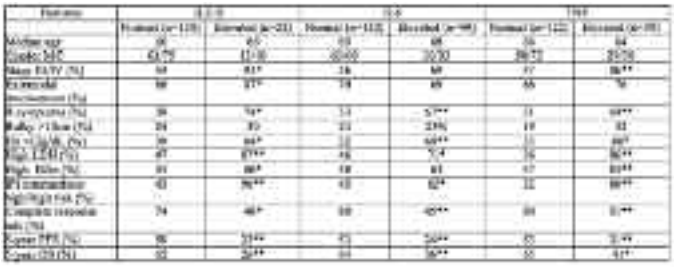
Background: Cytokine and cytokine receptors play an important role in immune regulation and tumour progression in diffuse large B cell lymphoma (DLBCL)
Aims: The aim of this study was to assess the prognostic significance of IL2-R, IL-6 and TNF serum levels in patients with DLBCL
Methods: 181 patients diagnosed with DLBCL in a single institution between 2002 and 2013 were included in the study with the only criterion of availability of cytokine data. HIV+ cases, primary central nervous system and primary mediastinal lymphomas were excluded. All patients received immunochemotherapy, mainly R-CHOP (82%). Complete remission rate, 5-year progression free survival (PFS) and 5-year overall survival (OS) were 71%, 46% and 57%, respectively. Cytokines were determined by standard enzyme-linked immunosorbent assays (ELISA). The best cut-off point for predicting OS was assessed by the Maxstat package (R statistical package)
Results: The best cut-off for OS was 4-fold upper normal limit (UNL), 9-fold UNL and 2-fold UNL for IL2-R, IL-6 and TNF, respectively. The proportion of patients with serum levels above the UNL were 23/161 (14%), 49/182 (27%) and 59/182 (32%) for, the mentioned cytokines, respectively. 50% of the patients had normal cytokines levels, while 30%, 15% and 6% had 1, 2 or 3 elevated cytokines. The main clinico-biological features, response to treatment and outcome according to the cytokines levels are detailed in the table. Regarding histological features, the only significant finding was that patients with high IL-6 levels showed more frequently CD10+ DLBCL (p=.013). In the multivariate analysis, IL2-R (HR 2.2, 95% confidence interval (CI) 1.1-3.8, p=.024) and IL-6 (HR 2.5, 95% CI 2.5-4.2; p=.001) maintained their prognostic significance for OS along with IPI score (HR 2.9, 95% CI 1.04-5.1; p<.001) and serum Beta-2 microglobulin (HR 2.5, 95% CI 1.2-4.5; p=.007).

Table 1. Main clinico-biological features



* p<.05; **p<.001

Summary and Conclusion: IL2-R, IL-6 and TNF serum levels at diagnosis significantly correlated with clinical features and outcome of DLBCL patients. These results warrant further validation in prospective series

A SERUM NUCLEAR MAGNETIC RESONANCE-BASED METABOLOMIC APPROACH TO DETERMINE POOR PROGNOSTIC DIFFUSE LARGE B-CELL LYMPHOMA PATIENTS

M Stenson[1,*], R Pinto[2,3], S Hasselblom[4], H Nilsson-Ehle[4], G Karlsson[5], PO Andersson[4]
[1]Kungälvs Hospital, Sahlgrenska Academy, Göteborg, [2]Bioinformatics for Life Sciences (BILS), [3]Computational Life Science Cluster, Department of Chemistry, Umeå University, Umeå, [4]Section of Haematology and Coagulation, Sahlgrenska University Hospital, [5]Swedish NMR Centre, Gothenburg University, Göteborg, Sweden

Background: The prognosis for diffuse large B-cell lymphoma (DLBCL) patients with early relapse or with refractory disease is very poor. The only prognostic tool used in clinical practice is the International Prognostic Index (IPI) even though it is less useful in the identification of such high-risk patients. Thus, there is an unmet need to determine reliable biological markers that can identify these poor prognostic patients. The functional levels of a biological system include the genome, transcriptome, proteome and metabolome, where the latter is the final down-stream product and therefore is most representative of the system phenotype. The latest years, metabolomics, detecting low-molecular weight molecules in body fluids or tissues, has emerged as a promising tool for diagnostic and differentiating purposes in cancer disease. The prognostic role of using metabolomics in DLBCL is, to our knowledge, not previously addressed.
Aims: To use quantitative ^{1}H nuclear magnetic resonance (NMR) spectrometry, comparing the metabolomic expression in sera from two groups of DLBCL patients treated with modern immunochemotherapy, i) early relapse/refractory patients and ii) cured patients, to determine if differences in the metabolomic profile could be correlated with clinical outcome.
Methods: Serum, prospectively collected at diagnosis and pre-treatment, from 43 DLBCL patients (early relapse, *i.e.* within 12 months or refractory patients, n=19 and cured patients, *i.e.* with a median follow-up of 5 years without relapse, n=24) were analysed using an 800 MHz ^{1}H NMR spectrometer with a 5 mm TCI cryoprobe. After the ^{1}H NMR data acquisition, spectra were aligned and peaks were integrated to a manually defined baseline. A matrix of integrated peaks was constituted and analysed using univariate t-tests and multivariate analysis (Principal Component Analysis; PCA) for a data overview and to clear the data from outliers. In addition, Orthogonal Projection to Latent Structures – Discriminant Analysis (OPLS-DA) was then used to discriminate between relapsed/refractory and cured patients.
Results: We found 69 integrated peaks, corresponding to different serum components, where 15 were significantly different between the two patient groups (t-test, p<0.05) and subsequently identified as the amino acids tyrosine, valine and pyroglutamate (where each metabolite contributes several signals in the NMR spectrum). All the significant components were found to be in higher concentration in cured patients. After correcting for False Discovery Rate (FDR) using Benjamini-Hochberg (B-H) correction, 9 components were still significant. Using OPLS-DA, a model was built with the 15 significantly differentiated components (Q2=0.26). Although not attaining complete separation of the two patient groups, its validation was positively evaluated through a permutation test and a Cross Validation(CV)-ANOVA (p=0.0014). When using only the 9 B-H components, a model was created which could separate the two groups further (CV-ANOVA p=0.0003). A correlation to IPI was found, but when extracting the NMR peaks used in the IPI discriminating model, the cured/relapsed model was still valid. Also, when modelling both factors simultaneously, using OPLS-DA, the most important component was related to the relapsed/cured model (R2X=0.46 and R2Y=0.192; Q2=0.142) while the IPI component was less important (R2X=0.123 and R2Y=0.127; Q2=0.05).
Summary and Conclusion: This study identified a metabolomic discrimination in serum, taken at diagnosis, between DLBCL patients with refractory/early relapsed disease and cured patients. Even though a limited number of included patients, our data suggest that NMR-based metabolomic profiling of serum could play a potential role in the assessment of poor prognostic disease in DLBCL and further exploration of this approach is warranted.

Background: Patients with autoimmune disease (AID) develop lymphoproliferative disorders (LPD) during treatment with immunosuppressive agents, *e.g.* methotrexate (MTX) or biological products. Some of AID-LPD improve by only withdrawal of MTX. However, prognostic factors for AID-LPD remain unclear and standard management and treatment have not been established.
Aims: The aim of this study was to identify characteristics and factors predictive of treatment response and disease progression in patients with AID-LPD.
