Methods: Clinical and histopathological data of patients with AID-LPD between 2004 and 2013 were analyzed retrospectively. Factors associated with regression of LPD after withdrawal of MTX and progression free survival (PFS) were analyzed statistically.
Results: A total of 75 cases of AID-LPD were identified. Among this cohort, 69 patients (92%) were with rheumatoid arthritis, and 73 (97%) developed AID-LPD in the course of treatment with MTX. The histology of LPD were as follows; diffuse large B cell lymphoma (n=42, 60%), polymorphic LPD (n=13, 19%), classical Hodgkin lymphoma (cHL, n=6, 9%). Epstein–Barr virus (EBV) was detected by *in situ* hybridization with the EBV-encoded small RNA (EBER) probes in 45% (25/55) of all AID-LPD, 73% (8/11) of polymorphic LPD and 75% (3/4) of cHL. Thirty two patients (43%) had stage IV diseases and 49 (65%) had extranodal diseases. Most frequent extranodal involvement was seen in the lung (12 cases). In 63% (35/55) of patients, withdrawal of MTX induced regression of LPD, and this was significantly found in patients with EBER positive (OR 7.097, 95%CI 1.045-77.86, p<0.05). 2 year PFS and overall survival of all patients were 63% and 83%, respectively. Poor PFS was associated with high-intermediate or high international prognostic index (HR 3.015, 95%CI: 1.155-6.987, p<0.05), soluble IL-2 receptor >1000 U/ml (HR 2.837, 95%CI: 1.098-7.399, p<0.05), abnormal pattern of EBV-related antibodies (HR 3.760, 95%CI: 1.350-28.30, p<0.05) and cHL (HR 4.946, 95%CI: 2.640-79.73, p<0.005).
Summary and Conclusion: EBV positivity with EBER probe is beneficial for predicting the successful regression after withdrawal of MTX, and we speculated that reactivation of EBV may enhance disease progression in patients with AID-LPD.

Stem cell transplantation - Clinical 2

P1100

THE PERIPHERAL BLOOD STEM CELL COLLECTION BY EDAP FOLLOWING INITIAL THERAPY WITH COMBINING BORTEZOMIB AND DEXAMETHASONE IS EFFECTIVE IN YOUNG MULTIPLE MYELOMA PATIENTS

N Takezako[1,*], N Sekiguchi[1], A Nagata[1], N Takahashi [2], A Miwa[3]
[1]Hematology, Disaster medical center of Japan, Tachikawa, [2]Hematology, Nephrology, and, Rheumatology, Akita University Graduate School of Medicine, Akita, [3]Hematology, National Center of Global Health and Medicine, Tokyo, Japan

Background: Bortezomib is first generation proteasome inhibitor which is used as induction therapy for multiple myeloma (MM) patients. Combination of bortezomib and dexamethasone therapy (BD) has significant efficacy in previously untreated myeloma patients. MM is not incurable disease, however, autologous stem cell transplantation is important therapy because of efficacy for the long-term survival. Stem cell mobilization for myeloma patients is primarily performed using granulocyte-colony stimulating factor (G-CSF) alone or after chemotherapy. A minimum of 2 × 10^6 $CD34^+$ cells/kg has been traditionally used for the support of one cycle of autologous stem cell transplantation (ASCT). In addition, the patients who were not obtained at least a very good partial response (VGPR) after the first ASCT have a survival benefit from tandem ASCT. Therefore, it is important to obtain high amounts of $CD34^+$ cells. Most trials suggest that more $CD34^+$ cells can be collected after chemo-mobilization than after G-CSF only mobilization. In addition, the median number of $CD34^+$ cells harvested in the bortezomib–dexamethasone induction therapy was significantly lower without impairing the ability of performing ASCT in comparison with VAD therapy. Therefore, novel mobilization strategies need to improve yields and efficiency. Here, we analyze separately mobilization and collection of HPC using EDAP regimen, which was included to target a more immature myeloma cells.
Aims: To investigate the efficacy of EDAP as stem cell collection protocol is the purpose of this study.
Methods: According to the IMW criteria□patients younger than 65 years with symptomatic multiple myeloma, and signed research consents approved by the Institutional Review Board could be in this study. The exclusion criteria were a serum creatinine level of 2.05 mg/dL or more at time of collection; liver insufficiency, for example, a serum total bilirubin level of 2.0 mg/dL or more, serum aspartate/alanine aminotransferase levels or alkaline phosphatases levels more than 2.5 times the upper limit of normal; poor performance status (grade 3 or worth); and a history of any other malignant disease with the exception of basal cell carcinoma and stage I cervical cancer. All patients received 4 cycles of BD (Bortezomib 1.3 mg/m^2×4d; Dexamethasone 20mg×8d) therapy as induction therapy. EDAP (Etoposide (100 mg/m^2/d×4d); cis-Platin (25mg/m^2/d×4d); Arabinosyl-cytosine (1g/m^2/d×1); Dexamethasone 40 mg d1-5) regimen which was described in total therapy 1 (B. Barlogie *et al.*). All patients received lenoglastim (5μg/kg once a day. Cells were collected on a Fresenius AS-204 apheresis machine.
Results: 62 patients (40 male, 22 female) were enrolled in this trial from November 2008 to December 2012. In all patients, the number of collected cells was sufficient (median 23.4×10^6 $CD34^+$ cells/kg). The overall response rate (ORR) was raised to 88% including 10% CR and 38% very good partial remission according to IMWG criteria. Seven patients had a minimal response. The most common side effects were mucocitis (40%), hematological toxicities (neutropenia and thrombocytopenia), and FN. These were usually mild (almost >grade 3). Peripheral neuropathy was observed in 43 cases after induction therapy, however additive case was not observed during collection phase. 55 patients received high dose melphalan containing pre-conditioning regimen supported by sufficient amount of $CD34^+$ cells.

Table 1. Results of stem cell collection

Median collection day	Day 21 (20-24)
Median $CD34^+$ cells yield (×10^6 /kg)	23.4 (6-36)
Median aphaeresis cycles	2 (1-3)
Median times of G-CSF injection	4 (1-8)

Summary and Conclusion: All patients yielded high numbers of $CD34^+$ cells. Furthermore, the ORR improved from 66% after BD to 88% after EDAP. EDAP following initial therapy with BD produces high response rates, improves stem cell collection, and overcomes the need for intensification before autologous transplantation.

P1101

DEVELOPMENT OF AN ALPHA/BETA T- CELL DEPLETED ALLOGENEIC STEM CELL TRANSPLANTATION PROTOCOL FROM MATCHED RELATED AND UNRELATED DONOR GRAFTS IN PATIENTS WITH POOR RISK LEUKEMIA

M de Witte[1,*], L te Boome[1], L van der Wagen [1], K Westinga[2], I Slaper-Cortenbach[2], J Kuball[1]
[1]Hematology/Immunology, [2]Gene and Cell Therapy Facility, University Medical Center Utrecht, Utrecht, Netherlands

Background: αβT- cell depleted allogeneic haematopoietic stem cell transplantations (allo-SCT) have so far been reported in haploidentical stem cell transplantations. First results have been promising with a good engraftment and low incidence of graft-*versus*-host disease (GVHD). Within the context of matched related (MRD) and unrelated (MUD) donors, high rates of life-threatening GVHD are still observed. Therefore we aimed extend αβT- cell depleted allo-SCT to patients with a MRD or MUD.
Aims: To develop an 'innate allo-SCT' protocol defined as αβT- cell depleted stem cell support from MRD and MUD in patients with poor risk leukemia.
Methods: Initial proof runs for the generation of αβT-cell and CD19 depleted grafts have been performed in 4 healthy donors. Grafts for transplantation of the first 5 patients (cohort I) have been depleted with GMP-grade anti-αβTCR and anti-CD19 antibodies. The subsequent grafts for patients in cohort II (n=4) and III (n=5) have been selectively depleted with GMP-grade anti-αβTCRs antibodies. Three conditioning regimens have been investigated (I): fludarabine 120 mg/m^2 + cyclophosfamide 4800 mg/m^2, (II): fludarabine 120 mg/m^2 + busilvex AUC=90 and (III): ATG (Genzyme®) 4 mg/m^2 + fludarabine 120 mg/m^2 + busilvex AUC=90 followed by αβT- cell depleted grafts from matched related or unrelated donors. No additional immune suppression was given after allo-SCT. Main study parameters/endpoints: (1) Feasibility to generate an αβT-cell depleted graft form MRD and MUD. (2) Engraftment and reconstitution of T-cells within the context of different transplantation regimens.
Results: Products for 14 patients have been successfully processed and used for αβT-cell depleted allo-SCT between 2011 and 2013. A ~4 log depletion of αβT-cells has been observed in the product with a recovery of ~75% of CD34+ cells. In cohort I, primary engraftment (chimerism >95%) was 40%. Engrafted patients showed a rapid reconstitution of γδT-cells and αβT-cells with a broad αβT-cell repertoire as determined by spectratyping. Therefore the next cohort was dose-intensified and the CD19-depletion omitted (cohort II). 75% of cohort II showed a swift engraftment. Again a dominance of γδT-cells was observed which associated with a rapidly reconstituting αβT-cell repertoire. Omitting CD19-depletion did not result in severe EBV-reactivations. One patient had an EBV reactivation under a short course of prednisone; however EBV was rapidly cleared after tapering steroids. In order to further increase engraftment cohort III (N=4) was additionally treated with an early application of ATG (day -10/-9). Within this last cohort, all patients showed hematological recovery within 3 weeks and none of these patients experienced serious toxicity within the first 28 days. All patients reached a donor chimerism >95% within 2 months. One patient develop cGVHD of the liver, in the other 3 patients a 'low dose DLI' (1x10^5 T cells) was administered. These patients showed no sign of GVHD ≥ grade II post DLI.
Summary and Conclusion: αβT-cell depletion is feasible in the context of MRD and MUD. αβT-cell depletion associates with a swift and dominant reconstitution of γδT-cells as well as a rapidly restoring αβT-cell repertoire. An intensified conditioning with additional host T-cell depletion seems to be beneficial for a profound engraftment and can be combined with a 'low dose DLI' in 3 months. These results let to the development of a phase I/II study, in which safety of an innate allo-SCT defined as abT-cell depleted stem cell support combined with a 'low dose DLI' is tested in a larger cohort of patients.

P1102

AUTOLOGOUS BONE MARROW MONONUCLEAR CELLS AND PLATELET-RICH PLASMA ENHANCED RECONSTRUCTION OF THE MAXILLOFACIAL BONY DEFECTS

AE Saad Abdelhamid[1,*], E A Elsharrawy[2], O A adly[3], M AS abdelhamid[4], M M ghoniem[5]
[1]Clinical Pathology, Faculty of Medicine, Suez Canal University, [2]Anesthiology, Faculty of Dentistry, Suez Canal University, [3]plastic surgery, Faculty of Medicine, Suez Canal University, [4]community medicine, Faculty of Medicine, Suez Canal University, Ismailia, Egypt, [5]oral and maxillofacial, Faculty of Dentistry, Suez Canal University, Ismailia, Egypt

Background: enriched hematopoietic components and platelet-rich plasma offer potential benefits in oral and maxillofacial surgery including rapid wound healing and bone regeneration.
Aims: The present study was designed to assess autologous bone marrow mononuclear cells and platelet-rich plasma in bone reconstruction of bony defects resulting from enucleation of pathological lesions in maxillofacial region.
Methods: twenty patients diagnosed with acquired maxillofacial bony defects, following conventional surgical excision of the underlying lesion, the selected patients were randomly divided into two equal groups: Group-1 (the study group) ten patients were included, after enucleation of the pathological lesions the bony cavities were grafted by autologous bone marrow mononuclear cells and platelet-rich plasma. Group-2 (control group): ten patients were included, after enucleation of the pathological lesions the bony cavities were allowed to heal spontaneously. Radiographic assessment were carried out using the digital panoramic radiography using diagora software; (postoperatively at one, three, six and twelve months).
Results: Radiographic assessment of the mean bone density in the studied group in comparison to the control group carried out sequentially at: immediate postoperatively and at one, three, six and twelve months showed the following data: immediate postoperative (59.1 ± 13.61, 60.1 ± 15.61 (P-value >0.001) meaning non-significant difference, while significant differences wewr detected in the following assessment sessions: one month (40.2 ± 12.88, 46.3± 13.28 (P-value >0.001), three months: 28.9 ± 8.96, 34.2± 9.91 (P-value >0.001), six months: 19.3 ± 6.98, 24.3 ± 7.78 (P-value >0.001), and after one year :13.5 ± 5.36, 19.1± 5.11 (P-value >0.001).

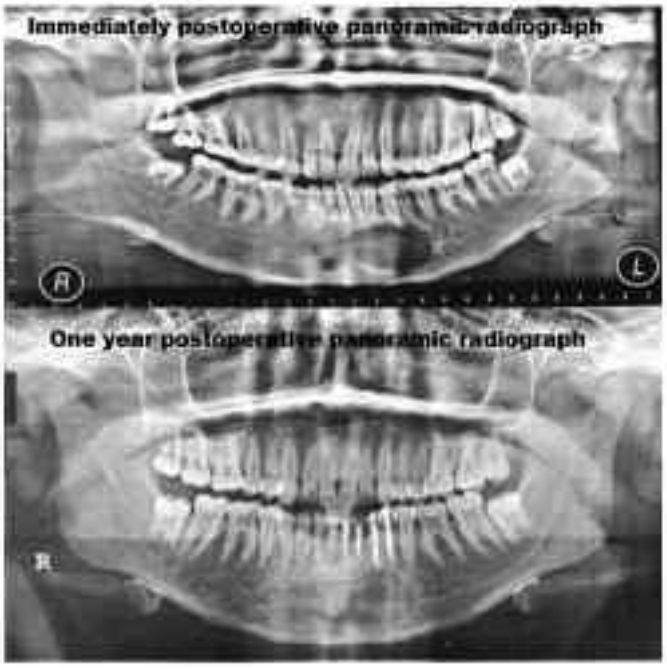

Figure 1.

Summary and Conclusion: Autologous bone marrow mononuclear cells and platelet-rich plasma showed evident neocortex formation that coincided with objective improvements which potentially enhanced reconstruction of the maxillofacial bony defects.

P1103

EPSTEIN-BARR VIRUS INFECTION AFTER ALLOGENEIC HEMATOPOIETIC STEM CELL TRANSPLANTATION: THE ROLE OF CYTOMEGALOVIRUS

Q Liu[1,*], R Lin[1], C Liu[1], M Wu[1], L Xuan[1], X Jiang[1], Z Fan[1], Y Zhang[1], F Huang[1], H Zhou[1], M Dai[1], J Sun[1]
[1]Department of Hematology, Nanfang Hospital, Southern Medical University, Guangzhou, China

Background: Epstein-Barr virus (EBV) infection is a common and severe complication after allogeneic hematopoietic stem cell transplantation (allo-HSCT). EBV infection may result in a spectrum of diseases in recipients of allo-HSCT including fatal post-transplant lymphoproliferative disorders (PTLD) and other EBV-associated diseases. Several studies suggested that cytomegalovirus (CMV) might play a role in PTLD.
Aims: In this study, the association between CMV and EBV DNA-emia as well as EBV-associated diseases was evaluated in the recipients of allo-HSCT.
Methods: Four hundred and seven patients undergoing allo-HSCT were enrolled in this study between July 2008 and December 2013. The diagnosis of PTLD was according to the criteria of World Health Organization (WHO). The diagnosis of EBV-associated other diseases, which included EBV-associated fever without tissue involvement and EBV-associated end-organ diseases, was based on the criteria of the European Conference on Infections in Leukemia. The EBV-DNA and CMV-DNA levels in blood and secretion were monitored by quantitative real-time polymerase chain reaction (RQ-PCR) before and after transplantation regularly. EBV and CMV DNA-emia were diagnosed when EBV-DNA or CMV-DNA in the blood was positive twice consecutively.
Results: During the follow-up period, 107 patients (26.3%) developed EBV

DNA-emia and 43 (10.6%) developed EBV-associated diseases including 28 EBV-associated PTLD and 16 other EBV-associated diseases. One hundred and sixty-nine patients (39.3%) developed CMV DNA-emia and 11 (2.7%) developed CMV-associated diseases. Of the 107 patients who developed EBV DNA-emia, 57 had CMV DNA-emia before EBV DNA-emia, and the median time from occurrence of CMV DNA-emia to EBV DNA-emia and EBV-associated diseases were 11 (range, 0-269) days and 23 (range, 0-255) days, respectively. Seven patients developed co-existing CMV DNA-emia at the time of EBV-associated diseases diagnosed. DNA-emia before EBV infection had positive correlation with EBV DNA-emia (r=0.23, p<0.001) and EBV-associated diseases (r=0.19, p<0.001), but both correlation coefficients were weak. There was a strong positive correlation between EBV DNA-emia and EBV-associated diseases (r=0.56, p<0.001). The patients with CMV DNA-emia had a higher risk of developing EBV infection than those without (OR 2.884, 95% confidence interval [CI] 1.8290-4.54627, p<0.001). Besides, CMV DNA-emia was the risk factor for EBV-associated diseases (OR=3.402, 95% confidence interval [CI] 1.737-6.663, p<0.001). After EBV infection occurred, 17 patients developed CMV DNA-emia, including 5 developed CMV-associated diseases, at a median time of 36 days (range, 12-50 days). EBV infection was not related to CMV DNA-emia (p=0.89) or CMV associated diseases (p=0.43) occurring after EBV infection.

Summary and Conclusion: The results suggest that CMV may play a contributory role in the development of EBV DNA-emia and EBV-associated diseases.

P1104

INTENSIFIED CONDITIONING REGIMEN WITH HIGH-DOSE ETOPOSIDE HEMATOPOIETIC STEM CELL TRANSPLANTATION YIELDED PROMISING SURVIVAL FOR HIGH-RISK AND REFRACTORY/RELAPSED ADULT ACUTE LYMPHOBLASTIC LEUKEMIA

H Zhou[1,*], Z Fan[1], F Huang[1], Y Zhang[1], M Dai[1], N Xu[1], G Yu[1], D Xu[1], Q Jiang[1], J Sun[1], Q Liu[1]
[1]Department of Hematology, Nanfang Hospital, Southern Medical University, Guangzhou, China

Background: Allogeneic hematopoietic stem cell transplantation plays an important role in treatment strategy of adult ALL. It's established that GVL effect was weak in ALL and patient shows poor response for DLI.

Aims: Intensified conditioning regimen is aimed to overcome resistance, reduce recurrence rate and improve survival.

Methods: A single-center, open-label, prospective study of intensified conditioning regimen with high-dose-etoposide allo-HSCT for adult ALL in China was performed from 2011 to 2013 in Nanfang hospital according to HDE-ALL-2011 (NCT01457040). The protocol was approved by ethics committee of Nanfang hospital of southern medical university and informed consent was obtained from each subject.

Results: A total of 104 patients were enrolled, 34 cases (32.7%) were refractory and/or relapsed patients. Forty-nine patients (47.1%) received HLA-matched sibling allo-HSCT, 27 patients (26.0%) underwent HLA-matched unrelated donor transplantation, 15 patients (14.4%) received HLA-haploidentical allo-HSCT and 13 patients (12.5%) received HLA-mismatched sibling transplantation. One hundred and one patients (97.1%) achieved complete engraftment and full-donor chimerism with a median of 14 days for neutrophils and 15 days for platelet, 3 patients failed to obtain engraftment. Forty-three patients (41.3%) received one to four pre-emptive and/or MRD-guided DLI from 2 or 3 months after transplantation. Acute III-IV grade graft-*versus*-host disease (GVHD) occurred in 15 patients, including 4 cases of DLI-induced GVHD, as 9 cases occurred in matched-sibling allo-HSCT arm (9/49, 18.4%), 3 cases in MUD allo-HSCT (3/27, 11.1%) and 3 cases in HLA-haploidentical/mismatched allo-HSCT group (3/28, 10.7%). Twelve patients with III-IV GVHD attained durable complete remission with cyclosporine A, tacrolimus, methylprednisolone, cyclophosphamide, methotrexate, anti-CD25 antibody and mesenchymal stem cells (MSC). The overall incidence of EBV viremia was 30.7% (n=32) and 50.0% percent (n=16) of patients received rituximab preemptive therapy. Seven patients (6.7%) developed EBV-related post-transplant lymphoproliferative disorders (PTLD) and durable complete remission was achieved in 6 out of 7 PTLD after integrated treatment with reduction in immunosuppression, rituximab-containing chemotherapies and donor-lymphocyte-infusion. CMV viremia occurred in 41.3% patients (n=43), 6 of them progressed to CMV-related interstitial pneumonia (IP, n=6), which accounted for 17.1% of transplantation-related mortality (TRM). Eleven patients relapsed after transplantation, representing the major cause of TRM (n=11), followed by CMV-IP (n=6), rapidly progressive brochiolitis obliterans (BO) after donor lymphocyte infusion (n=3), severe GVHD (n=3), severe infection (n=3), diffuse alveolar hemorrhage(n=2), thrombotic microangiopathy (TMA, n=2), SOS/VOD (n=1), PTLD (n=1), engraftment dysfunction (n=1), mitochondrial encephalopathy (n=1), and cerebral hemorrhage (n=1). With 2 year of Kaplan-Meier estimate of potential follow-up (KM-PF), 2-year overall survival (OS) of the whole cohort was 60.1%, with no significant difference (p=0.624) between patients in complete remission (59.3%) and refractory/relapsed patients (61.5%) before transplantation.

Summary and Conclusion: Intensified conditioning regimen with high-dose-etoposide allo-HSCT, HDE-ALL-2011, yielded a promising overall survival for high-risk and refractory/relapsed adult ALL.

P1106

AUTOLOGOUS OR ALLOGENEIC HEMATOPOIETIC STEM CELL TRANSPLANTATION FOR PATIENTS WITH HIGH-RISK AGGRESSIVE LYMPHOMAS: RETROSPECTIVE ANALYSIS IN A SINGLE CENTER IN KOREA

JH Yoon[1,*], YW Jeon[1], JH Kim[1], SH Shin[1], SE Lee[1], KS Eom[1], YJ Kim[1], S Lee[1], HJ Kim[1], CK Min[1], DW Kim[1], JW Lee[1], WS Min[1], CW Park[1], SG Cho[1]
[1]Department of Hematology, Catholic BMT Center, Seoul St. Mary's Hospital, Seoul, Korea, Republic Of

Background: In relapsed/refractory lymphomas, allogeneic hematopoietic stem cell transplantation (allo-HSCT) was introduced to present graft *versus* lymphoma activity that resulted lower incidence of relapse. However, treatment-related mortality (TRM) is an important factor to overcome. Also, high-dose chemotherapy (HDT) followed by autologous (auto-) HSCT has been considered as a frontline therapy for high-risk lymphomas, while the role of auto-HSCT was already proved for sensitive-relapsed lymphomas.

Aims: We analyzed the clinical outcomes of HSCT in high-risk or relapsed/refractory lymphomas, and tried to introduce our reduced-intensity conditioning (RIC) regimen for allo-HSCT, and a HDT regimen 'BuMelTT' which was dose-reduced by 20% compared to the original protocol [Schiffman *et al.* Biol Blood Marrow Transplant 1997;3:261-266.] to avoid excessive toxicity previously reported.

Methods: From 2007 to 2013, we treated 141 lymphomas (40years, range: 18-65) with HSCT. We treated 57 high-risk lymphomas with frontline auto-HSCT. And we also performed auto-HSCT in 56 sensitive-relapsed lymphomas, and allo-HSCT was performed for 28 relapsed/refractory lymphomas. High-risk patients were selected by aaIPI scoring ≥ 2 mainly based on high LDH level and higher Ann-Arbor stage III~IV at diagnosis. For HDT regimen followed by auto-HSCT, we used 'BuMelTT' which consisted of intravenous busulfan (BU, 2.4mg/kg/day for 3d) and melphalan (MEL, 40mg/BSA/day for 2d) and thiotepa (TT, 200mg/BSA/day for 2d). We used RIC regimen for allo-HSCT which consisted of fludarabine (FLU, 30mg/BSA/day for 6d) and melphalan (MEL, 70mg/BSA/day for 1d) with or without total-body irradiation (TBI, 400cGy/2Fx/day for 2d). Stem cells were collected from fully matched sibling (n=10) or suitably matched (<2 allele-mismatched) unrelated donors (n=18). We used acyclovir and itraconazole for viral and fungal prophylaxes, and ciprofloxacin was also used for prophylactic gut decontamination.

Results: In the frontline auto-HSCT group, 37 patients were B-cell type and 20 were T-cell type, and in the sensitive-relapsed group treated with auto-HSCT, 37 were B-cell type and 19 were T-cell type. In the relapsed/refractory group treated with allo-HSCT, there were 8 DLBCL, 7 PTCL, 5 various T-cell lymphomas, 4 T-lymphoblastic lymphoma (TLL), 2 MCL, 1 BLL and 1 plasmablastic lymphoma. Among the relapsed/refractory group, 13 were primary refractory, 5 were relapsed after chemotherapy with refractoriness and 10 were relapsed after auto-HSCT. Only 4 patients (14.2%) were in complete response (CR) before allo-HSCT, and CR was achieved in 22 patients (78.5%) after allo-HSCT. We calculated clinical outcomes for the 3 groups (frontline auto-HSCT, sensitive-relapsed group treated with auto-HSCT and relapsed/refractory group treated with allo-HSCT) after a median follow-up of 25.6 months (3.5-84.0). Five-year OS was 85%, 66%, and 63% and 5-year DFS was 76%, 47%, and 55% respectively. Cumulative incidence of relapse at 5-year was 23%, 53%, and 30% respectively. TRM at 5-year was 21% after RIC-allo-HSCT, whereas there was only 1 case of TRM (0.8%) after using 'BuMelTT' regimen. The benefit of frontline auto-HSCT was significant for B-cell lymphomas, but the survival outcomes of sensitive-relapsed group treated with auto-HSCT or relapsed/refractory group treated with allo-HSCT were comparable with frontline auto-HSCT in the T-cell lymphoma subgroup.

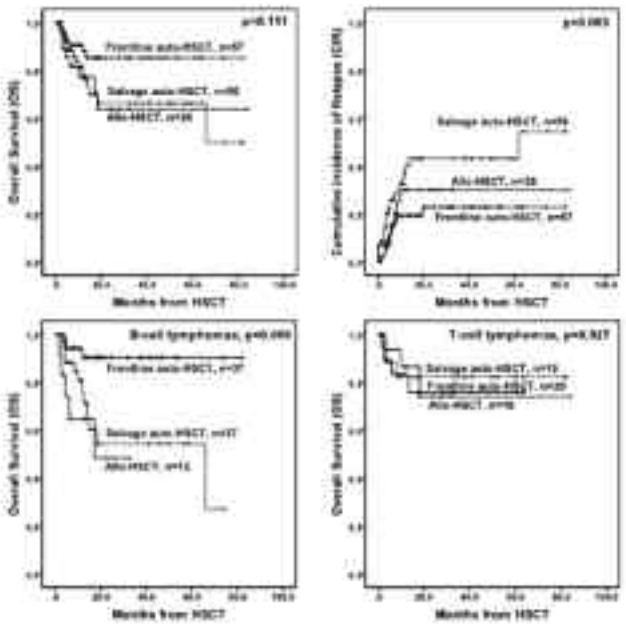

Figure 1.

Summary and Conclusion: Our data showed acceptable clinical outcomes of FLU+MEL+TBI for RIC-allo-HSCT and 'BuMelTT' for HDT for high-risk and sensitive-relapsed aggressive lymphomas. Further risk-adapted treatment approach using HSCT according to the type of lymphomas should be validated.

P1107

PROPHYLAXIS OF CMV INFECTION AFTER ALLOGENEIC STEM CELL TRANSPLANTATION WITH NILOTINIB : A PHASE II TRIAL

CT Lin[1,2,*], SJ Wu[1], CC Li[1,2], BS Ko[1], M Yao[1], WP Lin[1], JL Tang[1,2], HF Tien[1]
[1]Division of hematology, Department of internal medicine, National Taiwan University Hospital, [2]Tai-Cheng stem cell therapy center, National Taiwan University, Taipei, Taiwan, Republic of China

Background: Cytomegalovirus (CMV) infection is an important complication which can arise after allogeneic stem cell transplantation (allo-SCT), especially in Taiwan, where the CMV sero-positive rate is more than 90% in adults. (Lu SC, Kaohsiung J Med Sci. 1999) Platelet-derived growth factor-alpha (PDGFRa) activation has been reported to be critical for CMV infection, (Soroceanu L, Nature 2008) a finding that provides a possible prophylactic approach to address CMV infection.
Aims: This trial is aimed to test whether PDGFRa inhibition by nilotinib could effectively protect patients from CMV infection after allo-SCT.
Methods: Patients with signs of engraftment, undetectable CMV copies, and no other anti-CMV medicine exposure were eligible. Nilotinib (200 mg/day) was given continuously. Plasma CMV DNA-copies were monitored at least once a week by real-time, quantitative-PCR in which the lowest detection limit was 150 copies/mL. Failure of prophylaxis by nilotinib was defined as plasma CMV copies higher than 10,000 copies/mL or, regardless of levels, initiation of anti-CMV treatments for definite or clinically suspected CMV disease during nilotinib administration. Primary endpoint was defined as rate of successful prophylaxis, *i.e.* free from failure of prophylaxis, by day+100 after transplant. A Simon two-stage design, in stage 2, considered the treatment unfeasible if CMV infection was successfully prevented in less than 22 patients among a total of 31 evaluable patients. The ClinicalTrial.gov identifier for this study is NCT01252017.
Results: Between Dec. 2010 and Jan. 2014, 37 patients were enrolled. All patients and donors were CMV sero-positive. Six patients were not evaluable because of their early withdrawal from the trial within 10 days of nilotinib administration: five were for adverse events (AEs) not related to nilotinib, and one, nilotinib-associated idiosyncratic reaction. The 31 evaluable patients, median age 46 years, contained 17 males and 14 females. Twenty-six patients received grafts from matched-siblings; fourteen patients received non-myeloablative transplant; and antithymocyte globulin (ATG) was used in 12 patients. The median time of starting nilotnib administration was day+23; the median duration of nilotinib administration was 79 days. Among the evaluable patients, none had nilotinib-associated grade 3/4 AEs or had early trial discontinuation for nilotinib-associated AEs. Twenty-five patients fulfilled the pre-defined successful prophylaxis criteria: in 12, plasma CMV was continuously undetectable; and in the other 13, there were detectable, but less than 10,000 copies/mL of CMV which later resolved spontaneously without development of CMV diseases. For the six patients whose plasma CMV copies were higher than 10,000 copies/mL, one elected to continue nilotinib treatment, four switched to ganciclovir treatment, and one received add-on ganciclovir therapy. Among them, one patient developed CMV colitis, whereas the other five patients' CMV levels declined smoothly later without development of CMV disease during follow-ups.

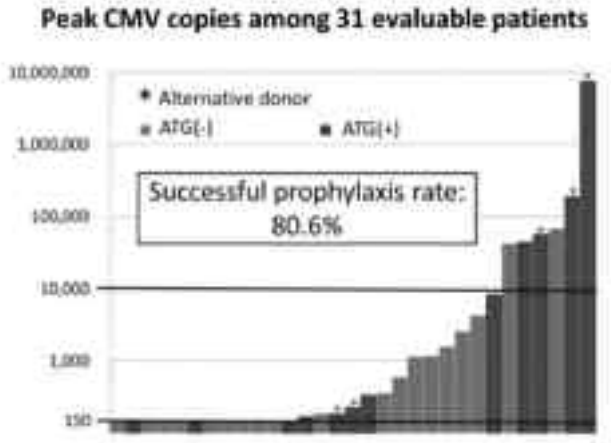

Figure 1.

Summary and Conclusion: Nilotinib is well tolerated and effective for prophylaxis of post allo-SCT CMV infection. Accordingly, the current result warrants further large, confirmatory studies.

Mazzoni Hospital, Hematology, Ascoli Piceno, [12]University of Bari Medical School, Division of Hematology, Bari, [13]IRCCS-Casa Sollievo della Sofferenza Hospital, Hematology, San Giovanni Rotondo, [14]Infermi Hospital, Hematology, Rimini, [15]Urbino University, Institute of Biomathematics, Urbino, Italy

Background: We previously demonstrated (Visani et al, Blood 2011) the safety of a new conditioning regimen with bendamustine, etoposide, cytarabine, and melphalan (BeEAM) prior to autologous stem cell transplant (ASCT) in resistant/relapsed lymphoma patients. The regimen showed long-lasting significant anti-lymphoma activity, with a 3-year PFS of 75%.
Aims: We designed a phase II study to confirm the effectiveness of BeEAM as a preparative regimen for autologous stem cell transplantation in resistant/relapsed aggressive B-cell non-Hodgkin lymphoma patients. The study was registered at EMEA with the EUDRACT no 2011-001246-14.The primary end-point of the study is to evaluate the 1-year complete remission rate. Fixing the lowest acceptable rate as 55% and the successful rate as 70%, with a significance level a=0.05 and a power 1-b=0.90, the sample size was estimated in 88 patients.
Methods: until now, 37 patients (median age 56 years, range 19-69) with resistant/relapsed diffuse large B cell (32) or grade III B follicular (5) non-Hodgkin lymphoma were consecutively enrolled in the study. Briefly, 27 patients had advanced stage disease (III-IV), 12 were primary refractory and 25 had relapsed after a median number of 2 lines of therapy (range: 2-3). Thirty-three patients had good performance status (WHO 0-1), and 11 patients presented with 1 or more relevant comorbidities (range: 1-5). Nineteen patients were in II or subsequent CR after salvage therapy, whereas 16 were in PR and 2 had progressive disease.
Results: A median number of $5.84x10^6CD34^+$/kg cells (range 2.8-8.8) collected from peripheral blood was reinfused to patients. All patients engrafted, with a

median time to ANC>0.5x10^9/l of 10 days. Median times to achieve a platelet count >20x10^9/l and >50x10^9/l were 12 and 16 days respectively. Eight out of 37 patients presented a fever of unknown origin (21.6%), whereas 19 patients (51%) presented a clinically documented infection. All patients received G-CSF after transplant for a median time of 8 days (range: 8-13). One patient died due to an incomplete hematological recovery after transplant, producing an overall transplant related mortality of 2.7%. Twenty-seven out of 37 patients are evaluable up to now for response to treatment. 22/27 (81.5%) obtained a CR, 2/27 a PR, whereas 3/27 did not respond to therapy. After a median follow-up of 9 months from transplant (range 2-24), 5/24 patients relapsed, whereas 19/24 (79.1%) are still alive, in continuous CR.

Summary and Conclusion: The BeEAM regimen preliminary confirmed its safety (TRM 2.7%) and its promising efficacy in resistant-relapsed aggressive B-cell lymphomas.

Acknowledgements: We kindly acknowledge Mundipharma Europe and Mundipharma Italy for providing the drug for the study. The study was supported in part by AIL Pesaro Onlus.

USE OF AZATHIOPRINE FOR GRAFT-VERSUS-HOST DISEASE IS THE MAJOR RISK FOR DEVELOPMENT OF SECONDARY PRIMARY MALIGNANCIES AFTER HEMATOPOIETIC STEM CELL TRANSPLANTATION

SH Chien[1,*], CJ Liu[1], JP Gau[1], YW Hu[2], TJ Chiou[1], CH Tzeng[1]
[1]Division of Hematology and Oncology, Department of Medicine, [2]Cancer center, Taipei Veterans General Hospital, Taipei, Taiwan, Republic of China

Background: Since 1983, hematopoietic stem cell transplantation (HSCT) has been widely used to treat and cure many malignant and benign hematological diseases in Taiwan. As more patients are treated by hematopoietic stem cell transplantation (HSCT), the development of secondary primary malignancy (SPM) is an increasingly common issue in long-term survivors.

Aims: To explore the incidence and identify the risk of SPM for patients treated with HSCT.

Methods: A nationwide population-based study of the Taiwanese population was performed to analyze patients who received HSCT between January 1997 and December 2010. Standardized incidence ratios (SIRs) were used to compare the risk of SPM in HSCT patients and the general population. Multivariate analysis was performed to identify independent predictors of SPM. A time-dependent covariate analysis was used to evaluate the association between cumulative doses of immunosuppressant and SPM.

Results: Patients receiving HSCT had a significantly greater risk of developing SPM (SIR 2.00; 95% confidence interval [CI] 1.45–2.69; p<0.001). Specifically, SPM incidence increased for cancers of the oral cavity (SIR 14.18) and esophagus (SIR 14.75) after allogeneic HSCT. Multivariate analysis revealed an increased SIR for cancer in patients who received the immunosuppressant azathioprine. The risk of SPM also increased with greater cumulative doses of azathioprine, especially those with exceeding 15,100 mg. Figure 1 demonstrated the cumulative incidence of SPM after transplantation.

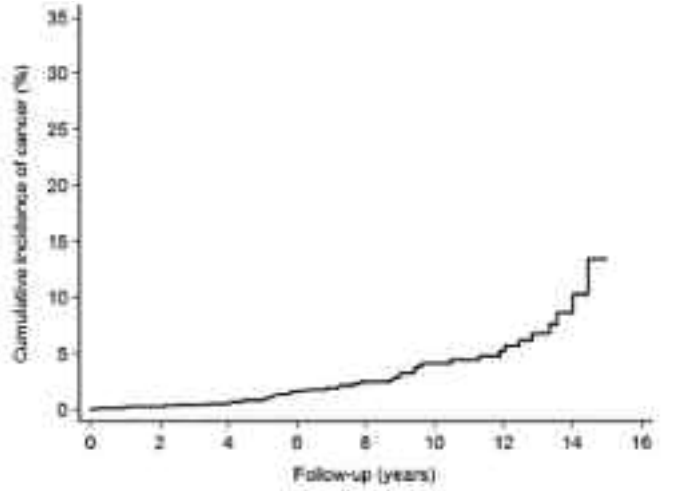

Figure 1.

Summary and Conclusion: This study demonstrates an increased incidence of SPM in Taiwanese patients who received allogeneic HSCT, especially for cancers of the oral cavity and esophagus. This finding is different from results in populations in Western countries. Physicians should be cautious about azathioprine use for graft-*versus*-host disease after HSCT. Long-term survivors who received HSCT should be carefully monitored for cancer development and targeted with preventive care strategies.

P1110

NEW FACTORS PREDICTING GRAFT FAILURE AND THE LOSING UNIT AFTER DOUBLE UMBILICAL CORD BLOOD ALLOGENEIC STEM CELL TRANSPLANTATION IN ADULTS

A Le Bourgeois[1,*], M Labopin[2], T Guillaume[1], J Delaunay[1], Y Foucher[3], B Tessoulin[1], F Malard[1], P Peterlin[1], S Derenne[4], A Cesbron[4], K Gagne[4], L Lodé[5], M Illiaquer[6], BM Imbert-Marcille[6], S Le Gouill[1], P Moreau[1], M Mohty[2], P Chevallier[1]
[1]hematology, CHU, Nantes, [2]hematology, Hôpital saint Antoine, Paris, [3]university, [4]Laboratoire d'histocompatibilité et d'immunogénétique, EFS Pays de la Loire, [5]hematological biology, [6]virology, CHU, Nantes, France

Background: Only few factors that predict engraftment or single-unit predominance after double umbilical cord blood (dUCB) allogeneic stem-cell transplant (allo-SCT) have been reported so far.

Aims: Our main objective here was to consider new factors, such as HHV-6 reactivation, age of the CB unit or the unit/unit matching, together with other well known factors, to examine if they can influence engraftment and single-unit predominance after dUCB allo-SCT.

Methods: We made a retrospective, single-center study included all patients receiving dUCB allo-SCT in Nantes hospital (France).

Results: This retrospective study included 77 patients (male: n=40; median age: 52 years, myeloid diseases n=43; complete remission at transplant n=46, previous autograft n=20) who had received a dUCB allo-SCT between June 2006 and December 2012 at the CHU of Nantes. The majority of patients received a reduced-intensity conditioning regimen (n=69) with a median interval between diagnosis and transplant of 11 months. Our main objective was to exhaustively determine factors associated with engraftment and single-unit predominance after this type of graft. With a median follow up of 40 months for survivors, 3-year OS, DFS, RI and TRM were 55+-6%, 44+-6%, 33+-5% and 23+-4%, respectively. Cumulative incidence (CI) of engraftment was 78±4% at day 60. CI of grade II-IV and III-IV acute GVHD were 27+-5% and 9+-3%, respectively. 3-year CI of chronic GVHD was 26+-5% (limited n=14; extensive n=5). In multivariate analysis, HHV6 reactivation during aplasia (HR=2.63; 95% CI: 1.64-4.17; p<0.001), younger recipient age (<53 years; HR=1.97; 95% CI: 1.16-3.35; p=0.012) and lower HLA matching between the 2 units (3/6 or 4/6, HR=2.09; 95% CI: 1.22-3.59; p=0.013) were factors independently associated with graft failure. Regarding single-unit predominance, multivariate analyses identified younger CB unit age (continuous, HR=1.01; 95% CI: 1-1.02; p=0.03), lower infused CD34+ cell doses (<=0.8 10^5/Kg; HR=2.55; 95% CI: 1.05-6.16; p=0.04) and ABO incompatibility between a CB unit and the recipient (OR: 2.53; 95% CI: 1-15-5.53; p=0.02) as unfavorable predictive factors.

Summary and Conclusion: Thus, HHV-6 reactivation during aplasia and younger cord blood age may represent new parameters to take into account after dUCB allo-SCT. These results have to be confirmed prospectively as they may influence units selection and outcomes of patients.

P1111

A SINGLE-CENTER RETROSPECTIVE ANALYSIS OF RECOMBINANT HUMAN SOLUBLE THROMBOMODULIN FOR THE TREATMENT OF HEPATIC SINUSOIDAL OBSTRUCTIVE SYNDROME AFTER HEMATOPOIETIC STEM CELL TRANSPLANTATION

N Takahashi[1,*], H Saitoh[1,2], M Nara[1], N Fujishima[1], M Fujishima[1], Y Kameoka[1], H Tagawa[1], K Sawada[1]
[1]Hematology, AKITA UNIV., [2]Hematology, Japanese Red Cross Akita Hospital, Akita, Japan

Background: Hepatic sinusoidal obstructive syndrome (SOS) is recognized as a lethal complication of stem cell transplantation (SCT). There is no specific therapy directed at this sinusoidal pathology, which affects sinusoidal endothelial cells and causes sinusoidal vasoconstriction and ischemic hepatocyte necrosis. Recently, recombinant human soluble thrombomodulin (rTM) has been approved for the treatment of disseminated intravascular coagulation in Japan.

Aims: The purpose of this study was to examine the effect of rTM on SOS prognosis and to identify other prognostic factors for SOS.

Methods: We retrospectively analyzed 16 patients with SOS after SCT (allo-SCT, n=13; auto-SCT, n=3) who were treated at Akita University Hospital between February 2001 and December 2013. SOS was defined according to Modified Seattle criteria and/or Baltimore criteria. The study was conducted in accordance with the principles of the Declaration of Helsinki and was approved by the institutional review board of Akita University Hospital.

Results: We analyzed 16 patients who received SCT for the treatment of hematological malignancies. The median age was 48.5 years. The ratio of men to women was 12:4. All patients were treated with ursodeoxycholic acid and heparin as prophylaxis for SOS. Of these, 7 patients were administered rTM via intravenous drip injection at a dose of 380 units per kg for 7 days. The recovery rate from SOS was 75% at 100 days after hematopoietic SCT, and the median recovery time was approximately 40 days after the diagnosis of SOS. The administration of rTM was significantly correlated with recovery from

SOS (*P*=0.044). Moreover, several risk factors for SOS among the 12 factors previously reported, including hepatic or renal dysfunction before SOS; prior infection; administration of busulfan, cytarabine, cyclophosphamide, or methotrexate for SCT; allo-SCT; human leucocyte antigen-mismatch transplantation; lung disease complication; second transplantation; and radiation therapy to the abdomen before SCT, were significantly associated with recovery from SOS (*P*=0.020). Hyperbilirubinemia (maximum value) during SOS was also significantly associated with recovery from SOS (*P*=0.020).

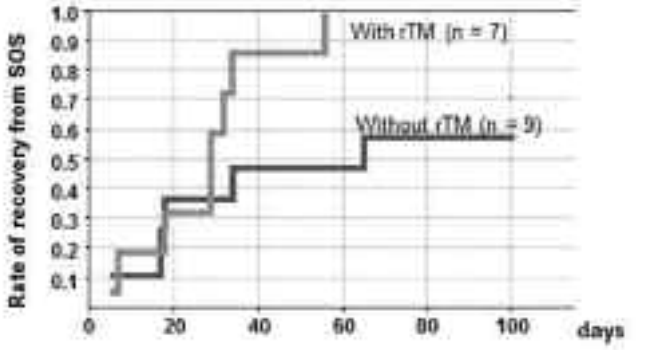

Figure 1.

Summary and Conclusion: According to previous reports, rTM directly repairs vascular endothelial injury or improves inflammation via the anti-high-mobility group protein B1 effect. Although a prospective study will be necessary to confirm our results, this retrospective analysis indicated that rTM might be a promising therapy for patients with SOS.

P1112

OUTCOME OF PATIENTS WITH HIGH RISK ACUTE MYELOID LEUKAEMIA RELAPSED AFTER RELATED AND UNRELATED STEM CELL TRANSPLATATION. SINGLE CENTER EXPERIENCE

K Steinerova[1,*], P Jindra[1], M Karas[1], D Lysak[1], S Vokurka[1]
[1]Department of Haematology and Oncology, Charles University Hospital Pilsen, Pilsen, Czech Republic

Background: Disease relapse is the most common cause of treatment failure after stem cell transplantation (SCT) for advanced myeloid malignancies, and generally carries a poor prognosis with short median survival without active treatment.
Aims: We describe treatment and outcomes for patients (pts) who relapse following SCT and compare the outcome of the group of pts transplanted with related and unrelated donor.
Methods: In a retrospective single center study we analyzed 204 pts (73 pts after related and 131 pts after unrelated SCT) with high risk AML transplanted between the years 2000 and 2013. 24 pts (33%) relapsed after related SCT and 37 pts (28%) relapsed after unrelated SCT (p=0.5288). Median of relaps was 3 months in the group of related SCT(1-28 months) and 8 months (1-52) in the group of unrelated SCT (p=0.0031). Both groups were comparable according to age, disease status, prognostic factors and the type of conditioning (myeloblative *vs*. reduced intensity conditioning, p=0,3401). 33 pts (54%) received aggressive treatment for relapse (12/24 and 21/37, p=0,7929) including donor lymphocyte infusion alone (DLI) (9/24 and 6/37, p=0.0740), chemotherapy alone (2/24 and 6/37, p=0.4621), chemotherapy with DLI (0/24 and 7/37, p=0.0358) and second transplantation (1/24 and 2/37, p=1,0).
Results: 11 pts (18%) archieved complete response (CR) after treatment for relapse (10 pts after DLI with or without chemotherapy and 1 pt after second transplantation), 1 pts transplanted with related donor and 10 pts transplanted with unrelated donor, p=0.0380. 5 pts still alive (1 from group of related SCT and 4 from group of unrelated SCT) 4-99 months after SCT with median of overall suvival(OS) 5 months after related SCT and 11 month after unrelated SCT, the probability of 1 year OS 8% and 22% (p=0,0293). 50 pts died, most of them due to disease progression (47/50, 94%), 1 pts died due to GVHD after DLI, 1 pts due to respiratory failure and 1 pts due to suicide. We did not observe difference in the outcome among pts treated with DLI alone, chemotherapy alone and second transplantation, better outcome had group of pts relapsed after unrelated transplant treated with chemotherapy and subsequent DLI.
Summary and Conclusion: Salvage chemotherapy, cellular therapy or second transplantation for AML relapse after SCT is feasible with low treatment-related mortality, but optimal management of the therapy for AML relapsing after SCT still remains to be defined. Comparing the group of pts transplanted with related donor and pts transplanted with unrelated donor better outcome was found in the group of unrelated transplantation treated with chemotherapy and DLI for AML relapse.

P1113

UNRELATED BONE MARROW TRANSPLANTATION WITH REDUCED INTENSITY CONDITIONING REGIMEN FOR ELDERLY PATIENTS WITH ADULT T-CELL LEUKEMIA/LYMPHOMA, FEASIBILITY STUDY WITH TWO-YEAR FOLLOW UP DATA

I Choi[1,*], T Eto[2], R Tanosaki[3], M Shimokawa[4], Y Takatsuka[5], A Utsunomiya[5], S Takemoto[6], J Taguchi[7], T Fukushima[8], K Kato[9], T Teshima[10], H Nakamae[11], Y Suehiro[12], T Yamanaka[13], J Okamura[14], N Uike[12]
[1]Division of Hematology, National Kyushu Cancer Center, Fukuoka, Japan, [2]Department of hematology, Hamanomachi Hospital, Fukuoka, [3]Department of Pathology and Clinical Laboratories, National Cancer Center Hospital, Tokyo, [4]Institute for Clinical Research, National Kyushu Cancer Center, Fukuoka, Japan, Fukuoka, [5]Department of Hematology, Imamura Bun-in Hospital, Kagoshima, [6]Department of Hematology and Special Diseases Laboratory in Clinical Research Institute, National Hospital Organization Kumamoto Medical Center, Kumamoto, [7]Department of Hematology, Atomic Bomb Disease and Hibakusha Medicine Unit, Atomic Bomb Disease Institute, Nagasaki University, Nagasaki, [8]Laboratory of Hematoimmunology, School of Health Sciences, Faculty of Medicine, University of the Ryukyus, Okinawa, [9]Medicine and Biosystemic Science, Kyushu University Graduate School of Medical Sciences, Fukuoka, [10]Department of Hematology, Hokkaido University, Sapporo, [11]Department of Hematology, Osaka City University, Osaka, [12]Division of Hematology, National Kyushu Cancer Center, Fukuoka, [13]Exploratory Oncology Research & Clinical trial Center, National Cancer Center, Tokyo, [14]Institute for Clinical Research, National Kyushu Cancer Center, Fukuoka, Japan

Background: Adult T-cell Leukemia Lymphoma (ATL) is a peripheral T-cell malignancy that is caused by human T-lymphotropic virus type 1 (HTLV-1) infection and commonly affects individuals at an average age of 67 years. Since the prognosis of elderly patients with the disease has been unsatisfactory by conventional chemotherapy, we had so far conducted two clinical trials of allogeneic hematopoietic stem cell transplantation (allo-SCT) using G-CSF-mobilized peripheral blood stem cells from HLA-identical sibling donors combined with reduced-intensity conditioning regimen (RIC) and reported promising results (Okamura *et al*, *Blood*, 2005; Tanosaki *et al*, *Biol Blood Marrow Transplant*, 2008; Choi *et al*, *Bone Marrow Transplant*, 2011). The availability of suitable sibling donors, however, becomes difficult probably due to aging as well as complications of donors. Therefore, we conducted a clinical trial to evaluate the feasibility of an alternative strategy of allo-SCT using bone marrow cells from unrelated donors, and we reported the results in ASH meeting 2011 (San Diego, CA). Here we report the results of two-year follow up.
Aims: We conducted a clinical trial to evaluate the feasibility of an alternative strategy of allo-SCT using bone marrow cells from unrelated donors, and we reported the results in ASH meeting 2011 (San Diego, CA). Here we report the results of two-year follow up.
Methods: Fifteen patients, median age of 58 (range, 51-62), were transplanted between February 2009 and April 2011. Seven were male, 12 were acute type and 3 were lymphoma type. At the time of registration, seven were in complete and 8 were in partial remission after chemotherapy. The conditioning regimen consisted of fludarabine (180 mg/m^2), intravenous busulfan (6.4 mg/kg) and low dose total body irradiation (2Gy). Bone marrow grafts from the Japan Marrow Donor Program, whose HLA-A, B and DR loci were genotypically matched or DR one locus-mismatched donors, were transplanted on day 0. To prevent graft *versus* host disease (GVHD), tacrolimus (0.03 mg/kg/day) and short-term methotrexate were administered. The degrees of donor-recipient chimerism and HTLV-1 proviral DNA in peripheral blood mononuclear cells were quantified by published methods.
Results: Thirteen of 15 patients achieved the primary objective, achievement of complete donor chimerism before day 100 and survival at day 100 after SCT and we concluded that SCT using bone marrow cells with RIC from unrelated donors is a feasible therapeutic procedure for elderly patients with ATL. In the results of two-year follow up after transplantation, relapse was observed in 4 patients days 39, 59, 161, and 336 after transplant, respectively and all died of disease. Acute GVHD (aGVHD) was observed in 10 of 15 patients where 2/6/2 patients experienced grade III/II/I, and chronic GVHD was observed in 10 of 14 patients who survived more than 100 days after transplantation where 6 patients experienced extensive type. The two-year progression free survival (PFS) and overall survival (OS) were 65.5±25.0% and 66.7±23.9% respectively. The HTLV-1 proviral load after SCT decreased to an undetectable level (<0.5 copies) at least at once in 13 of 15 patients, and 9 of 10 were remaining undetectable in two years after transplantation. The presence of aGVHD grade I-II was to be favorable prognostic factor for PFS or OS in the patients with ATL undergoing allo-SCT from HLA-identical sibling donors, but in the present study, we could not confirm them in the setting of unrelated bone marrow donors, probably because the event was too small.
Summary and Conclusion: This study indicated that allo-SCT using bone marrow cells with RIC from unrelated donors is a feasible and potent highly effective therapeutic procedure for elderly patients with ATL. (UMIN000001355)

P1114

BIOSIMILAR VERSUS ORIGINATOR G-CSF FOR AUTOLOGOUS STEM CELL MOBILIZATION IN HEMATOLOGIC PATIENTS. AN EXPERIENCE FROM THE PHARMACOVIGILANCE GROUP OF "RETE EMATOLOGICA LOMBARDA" (FARMAREL)

AM Pelizzari[1,*], P Tozzi[1], F Bocchio[2], M Bonfichi[2], S Artuso[3], N Fracchiolla[3], S Voltolini[4], V Conti[5], P Ferremi[6], C Almici[6], D Bettoni[7], G Rossi[1], G Muti[8]
[1]Hematology, SPEDALI CIVILI, Brescia, [2]Hematology Oncology, Fondazione IRCCS Policlinico San Matteo, Pavia, [3]Hematology, Fondazione IRCCS Cà Granda, Ospedale Maggiore Policlinico, Milano, [4]Oncology Hematology, AO Carlo Poma, Mantova, [5]Regional Centre for Pharmacovigilance, Lombardy Region, Milano, [6]Transfusion Medicine, Spedali Civili, [7]Pharmacy, Spedali Civili, Brescia, [8]Quality and Risk Management, REL, Ospedale Niguarda Ca' Granda, Milano, Italy

Background: The use of G-CSF biosimilars in the context of stem cell harvest was approved by the European Medicines Agency (EMA), even if its therapeutic equivalence has been extrapolated in the absence of "ad hoc" studies.
Aims: To assess the efficacy and safety profile of biosimilar compared with originator G-CSF on PBSC autologous mobilization in association with chemotherapy (CT) in hematologic pts treated in the Hematology Units of REL.
Methods: Data were retrospectively collected from consecutive pts with Hodgkin disease (HD), non-Hodgkin lymphoma (NHL) and multiple myeloma (MM) undergoing PBSC harvest after CT with biosimilar filgrastim between July 2012 and December 2013; furthermore lymphoma cases were compared with a historical control group treated with originator filgrastim between August 2007 and December 2008. The Shapiro-Wilk test was used to assess normality of data: p-values were derived from Mann–Whitney U-test.
Results: One hundred-five leukapheresis from 96 consecutive pts including 3 HD, 50 NHL (45 HIV-negative and 5 HIV-positive) and 43 MM cases were analyzed. Median age was 57 yrs (19-73); 56 cases were male (58 %). Mobilization was planned as part of first line CT in 65% pts; only one case was mobilized during 3rd line CT. Fourty-five cases (47 %) had been previously treated with alkylating drugs (47 %), three (3 %) with fludarabine-containing regimens. Biosimilar filgrastim was used at doses ranging from 5 (MM and lymphoma HIV-negative) to 10 mcg/kg/d (lymphoma HIV-positive) subcutaneously, starting from the day after the end of CT until the end of leukapheresis. Mobilization started a median of 13 days after CT (range 10-21) and was completed in a median of one procedure (range 1-4); median number of CD34+ cells x 10^6/Kg/pt collected was 9, ranging from 3,05 to 47. Planned end-point was reached in all but 2 cases (3 %). During mobilization, median peak of circulating white blood cells (WBC) and of CD34+ cells count were 12,740 x 10^9/l (range 2,160-66,580) and 90,5 x 10^9/l (range 15-1435), respectively. Biosimilar filgrastim use was generally well tolerated: mild bone pain (WHO grade 1-2) was frequently reported (16 pts, 23 %); two pts needed treatment with acetaminophen for headache (1) and bone pain (1), both WHO grade 3. Data from 53 lymphoma pts were compared with a control group of 58 pts mobilized with originator G-CSF (filgrastim or lenograstim) between August 2007 to December 2008 (Table, part A), differing for a higher frequency of mobilization with high-dose cyclophosphamide (24 % *vs*. 4 %, p<0.001; Table, part B) only. Median number of procedures, CD34+ count peak and CD34+ collected were similar in both groups, however a statistically significant difference in median WBC count peak during leukapheresis was documented (Table, part C).

Table 1.

Summary and Conclusion: We confirm efficacy and safety of biosimilar filgrastim for autologous PBSC mobilization in lymphoma and myeloma pts. The lower WBC count peak after biosimilars compared to reference products in spite of similar efficiency in CD34+ cells mobilization is interesting and needs to be confirmed in larger studies.

P1115

COMPARISON OF UNRELATED CORD BLOOD TRANSPLANTATION AND HLA-MATCHED SIBLING HEMATOPOIETIC STEM CELL TRANSPLANTATION FOR PATIENTS WITH CHRONIC MYELOID LEUKEMIA IN ADVANCED STAGE

C Zheng[1,*], B Tang[1], X Zhu[1], H Liu[1], W Yao[1], K Song[1], J Tong[1], L Geng[1], Z Sun[1]
[1]Department of Hematology, Anhui Provincial Hospital, Hefei, China

Background: Patients with chronic myeloid leukemia (CML) in accelerated phase (AP) and blast crisis (BC) are generally considered as having a poor prognosis, and allogeneic hematopoietic stem cell transplantation (HSCT) remains the only curative option. However, the majority of the published studies are based on the results obtained by human leukocyte antigen (HLA)-matched related allogeneic peripheral blood stem cell (PBSC) or bone marrow (BM) transplantation (allo-PBSCT/BMT), and few studies have evaluated the treatment effect of unrelated cord blood transplantation (CBT).
Aims: In the present retrospective single-center study, we report a clinical comparison of unrelated CBT and HLA-matched sibling allo-PBSCT/BMT for patients with CML in the advanced stage.
Methods: A total of 35 consecutive patients with advanced CML received unrelated CBT (n=18) or HLA-matched sibling allogeneic peripheral blood stem cell or bone marrow transplantation (allo-PBSCT/BMT) (n=17) between 22 March 2002 and 11 November 2012.
Results: The median day to neutrophil engraftment and platelet engraftment were longer in the unrelated CBT group (21.3d of CBT *vs* 12.8d of allo-PBSCT/BMT, p=0.01; 42.8d of CBT *vs* 15.9 d of allo-PBSCT/BMT, p=0.006). The cumulative incidence of grades I-II acute GVHD (aGVHD), III- IV aGVHD and chronic GVHD (cGVHD) did not differ significantly between the 2 cohorts: the day +100 cumulative incidence of grades I-II acute GVHD (aGVHD) was 30.4% [95% confidence interval (CI), 21.6- 39.5%] for CBT patients and 36.9% (95% CI, 27.6- 45.8%) for allo-PBSCT/BMT patients (p=0.65), and III-IV aGVHD was 23.8% (95% CI, 13.9-32.6%) for CBT patients and 16.9% (95% CI, 8.4-24.2%) for allo-PBSCT/BMT (p=0.19). The cumulative incidence of chronic GVHD (cGVHD) was 18.2% (95% CI, 11.4-28.9%) in the CBT group and 32.6% (95% CI, 21.8-41.5%) in the allo-PBSCT/BMT group (p=0.14). The cumulative incidence of transplant-related mortality (TRM) at d+180 (early TRM) was higher in CBT group (36.2% *vs* 12.5%, p=0.015). The risk of relapse was lower in CBT patients compared with that of allo-PBSCT/BMT patients (12.8% *vs* 39.6%, p=0.02). The long-term survival in CBT group patients was slightly better than allo-PBSCT/BMT group although the difference did not reach statistical significance: the 5-year overall survival (OS) for CBT patients and allo-PBSCT/BMT patients was 63.4% and 50.1%, respectively (p=0.11), while the 5-year leukemia-free-survival (LFS) rate was 54.8% and 44.3%, respectively (p=0.15).
Summary and Conclusion: Our comparisons suggested that patients with advanced CML receiving unrelated CBT had a lower relapse rate, a slightly better long-term survival, but a higher early TRM than HLA-matched related allo-PBSCT/BMT.

P1116

SEQUENTIAL CHEMOTHERAPY FOLLOWED BY REDUCED INTENSITY CONDITIONING AND ALLOGENEIC HSCT FOR HIGH RISK AML PATIENTS IN FIRST COMPLETE REMISSION: A PROSPECTIVE PILOT STUDY

M Michallet[1,*], M Sobh[1], S Ducastelle[1], L Gilis[1], I Tigaud[2], S Hayette[2], M El-hamri[1], H Labussière[1], F Barraco[1], F E Nicolini[1], X Thomas[1]
[1]Hematology, [2]Biology, Centre Hospitalier Lyon Sud, PIERRE BENITE CEDEX, France

Background: High-risk acute myeloid leukemia (AML) patients still have a poor outcome, the only therapeutic strategy with curative potential remains allogeneic HSCT.
Aims: With the aim to improve the effect of allo-HSCT by sequential use of chemotherapy followed by reduced intensity conditioning (RIC), we conducted a prospective pilot study in high-risk AML patients in first complete remission (CR1).
Methods: The chemotherapy sequential regimen consisted in fludarabine 30 mg/m², high-dose cytarabine 2 g/m², and amsacrine 100 mg/m² from days -12 to -9 (FLAMSA). After 3 days of rest, RIC consisted of 4 Gy total-body irradiation (TBI) on day -5, cyclophosphamide (40 mg/kg with HLA-identical sibling, 60 mg/kg for unrelated or mismatched donors) on days -4 and -3, and rabbit antithymocyte globulin (ATG, Genzyme) (5 mg/kg total dose) from day -3 to day -1. As a new experimental approach, we replaced TBI by iv. busulfan (BU) (Busilvex, Pierre Fabre) 3.2 mg/kg/d during either 4 or 2 days according to patient age (>55 years) (from day -7 to -4 or from day -5 to -4). GvHD prophylaxis consisted in ciclosporine from day −1, and mycophenolate mofetil (15 mg/kg bid), starting from day 0. Except for cord blood transplantation, patients received 3 prophylactic increased doses of donor lymphocyte infusions (DLI) if they were in CR and GvHD-free at day +120 or 30 days after discontinuation of immunosuppressive agents starting at 1x10^6 CD3+ cells/kg.

Results: Between August 2010 and March 2013, 26 consecutive patients were included; 11 males and 15 females with a median age at allo-HSCT of 55 years (24-67), 19 (73%) were *de novo* AML and 7 (27%) secondary AML. According to cytogenetics and molecular markers, 22 (85%) were unfavourable and 4 (15%) were in intermediate II category. Stem cell source was PBSC for 23 (88%) patients, CB for 2 and BM for 1 patient. Donors were 10/10 HLA matched siblings in 9 (35%) patients, 10/10 HLA matched unrelated in 8 (31%) patients and HLA mismatched for the rest of patients [unrelated 9/10 (n=7), CB 4/6 (n=2)]. For ABO compatibility, 13 (50%) were compatible, 5 (19%) had minor incompatibility and 8 (31%) had major incompatibility. For conditioning, 6 (23%) patients received TBI, 13 (50%) received 4 days BU and 7 (27%) received 2 days BU. After transplantation, 23 (88%) patients engrafted, 3 patients died early (1 at day 1 and 1 at day 2 both from septic shock; 1 at day 8 from pneumonia and pericardial effusion). At day 90 post-allo-HSCT, 18 (78%) showed total donor chimerism and 5 (22%) had mixed chimerism and all patients were in CR. There were 6/23 (26%) patients with acute GvHD [2 gr I, 2 gr II and 2 gr III] and 5/23 (22%) chronic GvHD [4 limited and 1 extensive], all before DLI. After a median follow-up of 9 months (0.03-35), the 2-years probability of overall survival (OS) for the whole population was 58% (47-69) and the 2 years cumulative incidence of relapse was 18% (confidence interval: 17-19). At the latest follow-up, 16/23 (70%) engrafted patients were alive, 4/23 (17%) patients relapsed and died later and 3/23 (13%) patients died from transplant related infectious complications. No statistical difference in terms of OS and relapse incidence was found between the 3 types of conditioning.
Summary and Conclusion: FLAMSA-RIC regimen followed by allo-HSCT showed promising results in high-risk CR1 AML patients. Because of some early severe infections, an efficient prophylactic anti-infectious strategy is recommended. The use of BU instead of TBI does not impact on transplant outcomes.

P1117

"REAL LIFE" USE OF PLERIXAFOR: A MULTICENTER NORTH EAST ITALY EXPERIENCE

F Lessi[1,*], A Colpo[2], L Pavan[1], L Astolfi[3], A Frigato[4], PM Stefani[5], S Imbergamo[6], G De Fusco[7], R Raimondi[8], E Zanetti[9], L Vicentini[10], A Billio[11], C Rinaldi[12], C Savignano[12], M Michieli[13], M Mazzucato[14], T Tison[2]
[1]Department of Medicine, University of Padua, Hematology and Clinical Immunology Unit, [2]Department of Transfusion Medicine, Padua University Hospital, [3]Department of Neurosciences, University of Padua, Bioacustics Research Laboratory, Padua, [4]Transfusion Medicine, [5]Stem Cell Transplantation Unit, Hematology Unit, Ca' Foncello Hospital, Treviso, [6]Hematology, [7]Transfusion Medicine, Ospedale dell'Angelo, Mestre (VE), [8]Department of Hematology and Cell Therapy, [9]Transfusion Medicine, San Bortolo Hospital, Vicenza, [10]Transfusion Medicine, [11]Hematology and Stem Cell Transplantation, S Maurizio Hospital, Bolzano, [12]Transfusion Medicine, Santa Maria della Misericordia University Hospital, Udine, [13]Unit of High Dose Chemotherapy and Cellular Therapies, [14]Unit of Stem Cell Collection and Processing, C.R.O. Aviano, Aviano, Italy

Background: Plerixafor is a reversible inhibitor of chemokine stromal cell derived factor 1 alpha (SDF1a) binding to chemokine (C-X-C motif) receptor 4 (CXCR4). Interruption of the CXCR4/SDF 1-a interaction enhances CD34+ haematopoietic stem cells (HSCs) mobilization with G-CSF alone or G-CSF plus chemotherapy to the peripheral blood where stem cells can be collected. The efficacy of Plerixafor has been demonstrated in patients affected with Hodgkin Lymphoma (HL), non Hodgkin Lymphoma (nHL) and Multiple Myeloma (MM). Besides, there is a lack of standardized criteria on how and when to use Plerixafor and each center develops its own treatment plan.
Aims: The aim of our survey was to study the "real life" use of plerixafor.
Methods: A questionnaire for each dose of Plerixafor has been filled by hematologists and apheresis physicians of each center. The retrospective survey involved all the patients treated between January 2010 and June 2013 in 7 centers of HSCs collection and transplantation in north-east Italy.
Results: Plerixafor was administered at the dose of 0.24 mg/kg. 65% of patients were affected with nHL, 24% with MM, 5% with HL, 3% with AL Amyloidosis, 2% with POEMS syndrome, 1% with Acute Lymphoblastic Leukemia. 76% were "proven poor mobilizers" and 24% were "predicted poor mobilizer" according to the GITMO criteria. 31% of patients were mobilized by G-CSF alone, 69% received G-CSF plus chemotherapy. According registration studies, 70% of patients collected at least 2.0 x10^6 cells/kg, and 66% reached a CD34+ peak of more than 20 cells /µl. We did not find any statistically significant difference in CD34+ peak between predicted and proven poor mobilizers. 48% of patients reached the target with one dose of the drug and 48% with two doses. When baseline CD34+ cell count was more than 6 cells/ml we observed a four-fold increase of baseline CD34+ cell count after Plerixafor administration. When baseline CD34+ count was below 6 cells/ml we observed a seven-fold increase in CD34+ cell count. Interestingly, a baseline CD34+ count below 2 cells/ml was associated, in our experience, with failure to achieve the endpoint of collection of at least 2.0x10^6 CD34+/kg. A ROC curve has allowed to estimate a discrimination threshold of 6 CD34+ cells/µL for a successful mobilization with Plerixafor (collection of more than 2.0x10^6 CD34+/kg). Only one serious adverse event was reported: a spontaneous splenic rupture in a patient affected with AL amyloidosis. 34% of our patients underwent stem cell transplantation, and neutrophils and platelets engraftment were on expected time (10,8 days and 18,9 days, respectively).
Summary and Conclusion: Our study showed that, in our experience, plerixafor has the same efficacy as the registration studies With the limitations of a retrospective study, our work documented that a CD34+ cell count below 2.0x106 cells is associated with collection failure in 100% of patients. Considering the cost, the use of Plerixafor in such patients may require careful evaluation. The development of standardized criteria for patients selection and timing of Plerixafor administration is needed.

P1118

TREATMENT OF CHRONIC GRAFT VERSUS HOST DISEASE (CGVHD) WITH RITUXIMAB AND NILOTINIB, FIRST RESULTS OF ONGOING CLINICAL TRIAL

L Van Der Wagen[1,2], L te Boome[2], M Schoordijk[3], E Meijer[3], J Kuball[1,2,*]
[1]Immunology, [2]Hematology, UMC UTRECHT, Utrecht, [3]Hematology, VU MC, Amsterdam, Netherlands

Background: About 60% of all patients receiving an allo-SCT and surviving beyond day 100 develop cGvHD, assuring high morbidity within this patient group. For this reason, chronic GvHD is associated with a substantial impairment in quality of life and loss of employment in long-term allo-SCT survivors. For physicians, cGvHD poses a big challenge to treat adequately and satisfactory. The current treatment relies heavily on corticosteroids, however refractoriness is a big problem as well as the unwanted effects of longterm corticosteroid use. Therefore, new therapies are urgently needed. Earlier studies by others and us[1] have demonstrated amelioration of chronic GvHD symptoms by B-cell depletion. In addition inhibition of the PDGF pathway by tyrosine kinase inhibitors also provided provocative data. However, complete resolution of cGVHD is usually not reported with single drug therapies and cGvHD with ulcera has so far been refractory to most experimental therapies.
Aims: We aim to test whether the sequential therapy of the anti-CD20 antibody Rituximab followed by a 6 month period of treatment with the tyrosine kinase inhibitor Nilotinib can further improve response rates.
Methods: 30 patients are treated with a combination of 4 weekly infusions of the anti-CD20 antibody Rituximab followed by a 6 month period of treatment with the tyrosine kinase inhibitor Nilotinib. Patients have been evaluated monthly.
Results: 4 patients have completed the study period whilst 11 patients are still being treated. Three out of four patients who completed the study showed a partial response. Two patients showed complete resolution of ulcerative skin lesions. Response rates for the remaining patients will be available shortly.
Summary and Conclusion: The sequential therapy of B-cell depletion and tyrosine kinase inhibition might show for the first time a complete resolution of ulcerative cGvHD and provides a new and interesting alternative treatment option for this difficult patient category.

P1119

INCREASED RISK OF SEVERE ACUTE GRAFT-VERSUS-HOST DISEASE IN LOW BODY MASS INDEX PATIENTS UNDERGOING HAPLOIDENTICAL ALLOGENEIC STEM CELL TRANSPLANTATION

Y Chen[1,*], L P Xu[1], D H Liu[1], K Y Liu[1], H Chen[1], X H Zhang[1], F R Wang[1], J Z Wang[1], Y Wang[1], W Han[1], Y H Chen[1], C H Yan[1], T Zhao[1], X J Huang[1]
[1]Institute of Hematology, Peking University People's Hospital, Beijing, China

Background: Previous investigations reported miscellaneous impacts of body mass index(BMI) on outcomes in allogeneic stem cell transplantation(allo-HSCT).
Aims: To investigate the impact of pretransplantation BMI on clinical outcomes in haploidentical allo-HSCT.
Methods: We performed a retrospective cohort study of 253 adult patients with acute or chronic leukemia from Aug 2008 to Dec 2011. All patients received bulsufan based myeloablatvie conditiong regimen. Patients were stratified according to BMI values (low BMI: BMI<18kg/m2; normal BMI: 18≤BMI<25kg/m^2, overweight: BMI≥ 25kg/m^2). Other possible factors correlated with the occurence of major events also included recipient and donor age,donor and recipient gender, HLA disparity, relationship between donor and recipient, diagnosis, the status of the disease, ATG dose in conditioning regime (10mg/kg, 6mg/kg), mononuclear cells (MNC), $CD34^+$ and $CD3^+$ cell dose from granulocyte colony-stimulating factor (G-CSF) primed bone marrow grafts (G-BM) and G-CSF mobilized peripheral blood grafts (G-PB).
Results: Median age of 253 patients was 31 years (18-56) years. Among these patients, there were 128 (50.6%) with AML, 95 (37.5%) with ALL, and 30 (11.9%) with CML. According to primary disease, 185 (73.1%) cases were classified in the normal-risk group and 68 (26.9%) were in the high-risk group. Median follow-up was 929 days (range: 48-1762 days) post-transplantation. 252 (99.6%) recipients attained engraftment and the median time for granulocyte recovery and platelet recovery was 12 days (ranging from 9 to 45 days) and 16

days (ranging from 5 to 86 days), respectively. Cumulative incidences of acute GVHD was 33.2% with median time of 25 days (range: 13-88 days). Cumulative incidences of acute GVHD accoding to BMI group were similar for grades II–IV (low BMI: 52.9%; normal: 31.8%; overweight: 31.6%; *P*=0.252), but significantly different for grades III-IV (low BMI: 35.3%; normal: 8.9%; overweight: 10.16%; *P*=0.040). Multivariate analysis identified low BMI was associated with an increased risk of grade III-IV acute GVHD (*P*=0.003, HR=5.736, 95% CI: 1.779-18.491). There were no difference in the occurrence of other graft-*versus*-host reactions, treatment related mortality (TRM), relapse or overall survival (OS) among BMI groups.

Summary and Conclusion: Our findings demonstrate a correlation between pre transplant BMI and clinical outcome post-transplant. An unhealthy BMI was associated with increased risk of severe acute GVHD in haploidenctical allo-HSCT. Meticulous supportive care with nutritional support pre-transplantation should be required for these patients.

Stem cell transplantation - Clinical 3

P1120

DEFIBROTIDE AS PHOPHYLAXIS OF LIVER TOXICITY DURING ALLOGENEIC HSC TRANSPLANTATION IN ACUTE LEUKEMIA PATIENTS

G Milone[1,*], P Spina[1], D Berritta[1], M Parisi[1], S Leotta[1], A Cupri[1], A La Fauci[1]
[1]Hematology, BMT UNIT, Catania, Italy

Background: Beneficial effects of a Prophylaxis using Defibrotide after allogeneic transplantation has not clearly established yet.
Aims: To determine clinical results of a prophylaxis with Defibrotide in adult acute leukemia patients receiving allogeneic HSC transplantation after myeloablative conditioning.
Methods: 51 patients received prophylaxis with Defibrotide from commencement of conditioning to discharge. Controls were 56 patients who did not receive this prophylaxis. Defibrotide was used in all patients treated from year 2000 to 2008, while all patients treated from 2008 to 2013 did not receive prophylaxis with Defibrotide. The two groups were comparable for age (p=0.18), diagnosis of AML *vs* ALL (p=0.9), percentage having active disease at transplant (p=0.9), percentage having received a previous transplant (p=0.4) and bilirubin level at admission (p=0.20), BU-FLU was administered in 53% of "No Defibrotide" group *versus* 25% of "Defibrotide treated", (p=0.02). MUD transplants were more frequent in "No Defibrotide" group (42%) than in group treated with Defibrotide (20%), (p=0.01).
Results: Overall, cumulative incidence of TRM at 3 years was 20%. It was not influenced by Diagnosis (p=0.7), type of conditioning (p=0.6), age of patients (p=0.18) and disease activity at time of transplantation (p=0.7). TRM at 3 y was higher in MUD transplants (30%) compared to family donor transplants (10%), p=0.05. Taking competing risks into account, cumulative incidence of TRM at 3 y was 30% in "No Defibrotide" group, compared to 10% in "Defibrotide treated" group (log-rank p=0.02). When significant factors, such as MUD donor and Defibrotide use, were included in multivariate analysis "No Defibrotide" remained significant for an increased risk of TRM at 3y (OR: 2.822, p=0.05). Overall PFS at 3 y was 60%, with no difference between Defibrotide treated and untreated (PFS was 65% in "No Defibrotide" *versus* 55% in Defibrotide treated groups, p=0.15). OS was 50% at 3 years: 55% in "Defibrotide treated" and 45% in "No Defibrotide" groups (p=0.6). No patient suffered severe liver toxicity, clinically mild SOS was diagnosed in 5.3% of "No Defibrotide" group and in 3.9% of patients treated with Defibrotide (p=0.7); Bilirubin above 2.0 mg/dl was registered during the first 30 days in 21% of patients in "No Defibrotide" group and in 15% of "Defibrotide treated" group (p=0.4).

Table 1.

Summary and Conclusion: Prophylaxis using Defibrotide after allogeneic hematopoietic transplantation with myeloablative conditioning determined, in adults patients, a significant reduction in TRM. Reduction in liver toxicity was not statistically significant, thus effect on TRM is independent of any reduction in liver toxicity and may depend on modulation of allo-reactivity.

P1121

IMPACT OF NATURAL KILLER (NK) CELL KIR LIGAND MISMATCH AND B SCORE ON THE OUTCOME OF HAPLOIDENTICAL TRANSPLANTATION WITH POSTTRANSPLANTATION CYCLOPHOSPHAMIDE (PTCY) IN APLASTIC ANEMIA

SR Jaiswal[1,*], S Chatterjee[2], S Mukherjee[3], K Ray[3], S Chakrbarti[1,4]
[1]DEPARTMENT OF BMT, DHARAMSHILA HOSPITAL AND RESEARCH CENTRE, DELHI, [2]Apollo Gleneagles Hospital, [3]Dept of Human and Molecular Genetics, CSIR-Indian Institute of Chemical Biology, [4]MANASHI CHAKRBARTI FOUNDATION, KOLKATA, India

Background: NK Cell KIR Ligand Mismatch (KIRLMM) has been shown to reduce the risk of relapse in acute myeloid leukemia (AML) following myeloablative T cell depleted (TCD) Haploidentical BMT (HAPLO). However, there is no data on the impact of KIRLMM or KIR B-score based on centromeric and telomeric distribution of inhibitory and activating genes in HAPLO for Severe Aplastic Anemia (SAA) with or without TCD.
Aims: We prospectively evaluated the impact of KIRLMM and B-score in 10 consecutive patients undergoing HAPLO with PTCY for SAA following unmanipulated PBSC graft, and compared with 15 patients undergoing the same for AML.
Methods: Donors were not selected based on KIRLMM initially. The patients with High-Risk (HR) AML (n=15) received myeloablative conditioning with Flu-

IVBu6.4-Mel140 (n=10) and those with SAA received Flu-ATG-Cy- Mel120. In patients with AML, 11 were transplanted with active disease and 4 with HR cytogenetics were transplanted in CR1/CR2. The median age was 41 (6-46) years for SAA and 32 years (8-48 yrs) for AML. Patients with SAA were heavily transfused (median 35 *vs* 10 in AML).
Results: All but one engrafted in both groups within 2 weeks. aGVHD/cGVHD ocurred in 2/2 and 1/1 patient in AML and SAA groups respectively. The incidence of relapse was 10% in patients receiving transplant from a KIRLMM donor with a B-score >2 (n=8), *versus* 90% in patients without the same (n=7), with a DFS at 2 years of 80% *versus* 10% (p=0.04). In patients with SAA, all patients with KIRLMM donors with B-score>2 (n=4) had early alloreactivity and TRM within 100 days, whereas those without the same (n=6) had 100% DFS at 2yrs (n=0.007). We documented early lymphocyte proliferation with full donor chimerism in patients with SAA between days 2 and 5 post transplant, compared to muted proliferation in patients with AML with mixed chimerism (p=0.01).
Summary and Conclusion: This pilot study on the effect of NK cell on HAPLO PBSCT with PTCY highlights the adverse impact of KIRLMM donor with high B-score in patients with SAA, in contrast to the favourable impact in AML. Based on these findings, we hypothesise that the lack of previous cytotoxic therapy and less intense conditioning spares recipient dendritic cells which are matured rather than inhibited in a high DC:NK ratio, promoting proliferation of donor alloreactive T cells. This process is enhanced further by NK cell mediated killing of host T cells (more effective as there is no leukemic target) as demonstrated by complete donor chimerism of T lymphocytes before day 5 in patients with SAA, compared to mixed chimerism in patients with AML. This unique finding, we hope, will play a major role in donor selection and improving the outcome of patients with SAA undergoing Haploidentical HCT. We suggest, patients with SAA undergoing Haploidentical HCT with KIRLMM donor should receive a TCD graft, whereas those with nonKIRLMM donors can receive unmanipulated graft with PTCY with excellent outcome.

P1122

THE JOINT IMPACT OF HLA MATCH AND TOTAL NUCLEATED CELL DOSE ON OUTCOME OF SINGLE UNIT UNRELATED CORD BLOOD TRANSPLANTATION

S Guangyu[1,*], S Zimin[1], L Huilan[1], T Baolin[1], Z Changcheng[1]
[1]Anhui Provincial Hospital, Hefei, China

Background: It's accepted that higher total nucleated cell (TNC) dose and less human leukocyte antigen (HLA) mismatch(mm) may produce a satisfactory outcome in recipients conducted cord blood (CB) transplantation. However, there is no consensus that whether the higher TNC dose can compensate the adverse impact of HLA mm.We tried to explain the joint impact of HLA match and TNC dose on outcome of single unit unrelated cord blood.
Aims: To retrospectively study the joint impact of TNC dose and HLA match between donor and recipient on outcome of single unit unrelated cord blood transplantation (sUCBT).
Methods: 139 patients with hematological malignancies remedied with sUCBT in single center from May 2008 to August 2013 were analyzed. Of 139 patients at enrollment, 22 were 0 mm,69 were 1mm, 48 were 2mm by low-resolution HLA-A, -B, and high-resolution (HR) DRB1. All patients's conditioning regimen was myeloablative,and a combination of cyclosporine A(CsA) and mycophenolate mofetil (MMF) was given for graft-*versus*-host disease (GVHD) prophylaxis for all patients. The follow-up assessment was conducted before February 1,2014.
Results: Patients 0mm had a statistically significant higher cumulative incidence of neutrophil engraftment by day 42 than those 1 and 2mm(*P*=0.042 and 0.002),patients 0mm had a statistically significant higher cumulative incidence of neutrophil engraftment by day 42 than those 2mm with a higher prefreeze total nucleated cell(TNC) dose(>5×10^7/Kg) and lower dose(<5×10^7/Kg)(*P*=0.01 and 0.02). Patients 0mm had a statistically significant lower cumulative incidence of acute GVHD by day 100 than those 1 and 2mm(*P*=0.006 and 0.001).The difference of transplant-related mortality(TRM) by 1 year between 0 and 2mm patients was statistically significant(*P*=0.03). Patients 2mm given CB units with a TNC dose less than 5×10^7/Kg had a higher TRM by 1 year than 0mm patients(*P*=0.03). Patients 0mm had a statistically significant higher disease free survival (DFS)by 3 years than those 2mm (*P*=0.03), compared with patients 2mm given CB units with a TNC dose less than 5×10^7/Kg, 0mm patients and 1mm patients given CB units with a TNC dose greater than 4×10^7/Kg had a higher DFS rate (*P*=0.02 and 0.02).
Summary and Conclusion: The HLA typing mismatching between donor and recipient had a great impact on neutrophil engraftment and long term DFS after sUCBT,2mm cord blood unit with less TNC(<5×10^7/Kg) was not an optimum CB graft.

P1123

(90)Y IBRITUMOMAB TIUXETAN (ZEVALIN) FOLLOWED BY BEAM (Z-BEAM) AND AUTOLOGOUS TRANSPLANT (ASCT) IN POOR PROGNOSIS RELAPSED/REFRACTORY NON-HODGKIN LYMPHOMA (NHL): A SINGLE INSTITUTION EXPERIENCE

C Pecoraro[1], C Ciochetto[1], B Botto[1,*], M Bellò[2], R Passera[2], G Benevolo[1], C Boccomini[1], A Castellino[1], A Chiappella[1], R Freilone[1], F Giunta[2], M Nicolosi[1], L Orsucci[1], P Pregno[1], P Riccomagno[1], G Bisi[2], U Vitolo[1]
[1]SC Hematology, [2]Nuclear Medicine, Citta della Salute e della Scienza, Torino, Italy

Background: High dose chemotherapy (HDC) and ASCT is considered the most effective treatment for relapsed aggressive NHL. Radioimmunotherapy (RIT) with standard dose Zevalin (0.4 mCi/kg) combined with conventional BEAM (Z-BEAM) has been employed as conditioning regimen for the treatment of high risk relapsed/resistant NHL.
Aims: We performed a single institution retrospective study to determine the feasibility and to explore the possible implemented effect of the addition of standard dose Zevalin to a BEAM regimen in pts with high risk advanced stage NHL, who relapsed or failed to respond after previous line chemoimmunotherapy. A comparative analysis with an hystorical group of patients treated with standard BEAM without Zevalin was planned as secondary end point.
Methods: Patients were included into the study and considered at high risk of failure if showed: progression or early relapse (<1 year) from previous Rituximab containing chemotherapy or multiple relapses. Standard dose DHAP or ICE with Rituximab were used as salvage chemotherapy and mobilizing regimen. Between October 2006 and January 2013, 37 patients were treated with Zevalin (day –14) followed by standard dose BEAM (day –7 to –1) and ASCT.
Results: Clinical characteristics were: 19 refractory and 18 early or multiple relapse; 9 grade I-II follicular, 26 PML/DLBCL, 3 MCL and 2 indolent non follicular; 9 stage II and 28 stage III-IV; 16 patients received only one previous line of treatment and 21 were treated with 2 or more lines before Z-BEAM, all containing Rituximab. Response status after R-DHAP/R-ICE was: complete remission (CR) 16 (43%), partial remission (PR) 13 (35%) stable/progressive disease (SD/PD) 8 (22%). At the end of Z-BEAM response status was: CR 22 (59%), PR 10 (27%), PD 4 (11%), TD 1 (3%). Three-year progression free survival (PFS) from the start of salvage treatment was 68% and overall survival (OS) was 65%. Twelve patients relapsed or progressed after Z-BEAM and 15 pts died, 12 of them for lymphoma. One patient died during treatment due to infective toxicity (Aspergillosis+H1N1 pneumonia). Two patients in CR died because of progressive multifocal leukoencephalopathy (PML) and heart failure. We retrospectively compared this population with an hystorical matched group of 21 pts treated with BEAM alone. No significant differences in clinical presentation at relapse or in response rate were showed. A trend in favour of Z-BEAM was observed for 3 years-PFS (68% *vs* 48%, p=ns, figure 1) and a significant benefit with the addition of RIT was shown for patients with relapsed disease (72% Z-BEAM *vs* 22% BEAM p=0.01) and for those with CR at the end of salvage treatment prior ASCT (100% Z-BEAM *vs* 76% BEAM p=0.02).

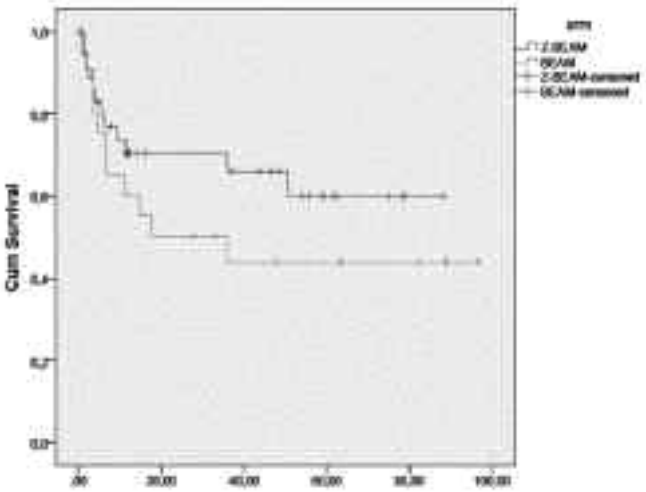

Figure 1.

Summary and Conclusion: In this group of patients with high risk relapsed/resistant NHL Z-BEAM+ASCT is able to achieve a high response and 3-yrs PFS rate. With the limit of a non randomized study, the comparison with the cohort of patients treated with BEAM suggests that the benefit of RIT was seen in patients with early or multiple relapses or with CR at the end of salvage treatment. Novel approaches are needed for patients with refractory disease to Rituximab-chemotherapy or with residual disease prior ASCT.

P1124

QUANTIFICATION OF THE TIME AND EFFORT ASSOCIATED WITH AUTOLOGOUS PERIPHERAL BLOOD STEM CELL MOBILIZATION: A EUROPEAN PERSPECTIVE

K Hübel[1,*], N Azar[2], J Reitan[3], R P Kadota[4], S Naoshy[5], Z Xiao[5], M Mohty[6]
[1]University Hospital of Cologne, Cologne, Germany, [2]Hematologie Clinique, Hôpital de la Pitié-Sâlpétrière, Paris, France, [3]RJM Group LLC, Crown Point, [4]Global Oncology Medical Affairs, [5]Global Evidence & Value Development, Sanofi, Cambridge, United States, [6]Saint-Antoine Hospital, Paris, France

Background: Plerixafor is indicated in combination with G-CSF to enhance mobilization of hematopoietic stem cells to the peripheral blood (PBSC) for collection and subsequent autologous transplantation in patients with lymphoma (Non-Hodgkin's Lymphoma (NHL)) and multiple myeloma whose cells mobilize poorly. This agent may reduce the failure rate and/or the number of apheresis procedures required without increased toxicity, which may reduce total transplant costs.
Aims: With this background, the aim of this non-interventional study was to assess resource utilization to document provider costs associated with PBSC mobilization and apheresis. The study aimed to evaluate the impact on the time, effort and costs to the hospital when using plerixafor (P) with a primary focus to compare measures of time and effort of patients drawn from the Pre-P *versus* P eras.
Methods: The study population included patients aged ≥18 years, with a primary diagnosis of NHL, and who underwent PBSC mobilization in different European centers. Part I of the study is an ongoing retrospective medical record review of 200 NHL patients from 7 centers across France and Germany. Selected patients are evenly divided between two eras: 1) prior to approval of plerixafor (until June 1, 2009)="Pre-P era"; 2) after approval of plerixafor (July 1, 2010 and onwards)="P era". Patient characteristics will be reported. Outcome measures include number of visits for administration of mobilizing agents; duration (days) of administration of mobilizing agents; agents used as mobilizing agents; adverse events (AEs) detected during mobilization; number of apheresis sessions; hours of apheresis sessions; attainment of CD34+ target (yes, no) and days until CD 34+ target level was met. Part II of the analysis is an ongoing prospective study consisting of time and motion evaluation of actual apheresis, with 20 events recorded at each center. The actual apheresis events are being measured in consecutive patients scheduled to be candidates for PBSC mobilization and consent was obtained from these patients. The time-motion assessments will be obtained retrospectively (Part I) and prospectively (Part II) and will include the total time to prepare the patient, perform apheresis and manage AEs. Costs will be evaluated and quantified in terms of micro-costing group interviews with local hospital administration in each of the sites. The primary study end point is difference in mean time/effort to perform apheresis (including apheresis related AEs, if any) and total costs associated with mobilization to the hospital in terms of micro-costing per patient, between patients in the "Pre-P" *versus* "P eras".
Results: At time of abstract submission, data collection is still ongoing in all of the centers and final study results will be presented during the meeting. It is hypothesized that the key findings of this study will demonstrate the favorable impact of novel interventions on the number of apheresis procedures required to reach a target PBSC, and failure rate of mobilization, thus translating into reduced total transplant costs without increasing toxicity.
Summary and Conclusion: The financial implications for transplant centers could be significant and may lead to further studies aiming to optimize staff time and resource utilization related to apheresis in real-world practice. Funding provided by Sanofi.

P1125

PLERIXAFOR (MOZOBIL) FOR AUTOLOGOUS PERIPHERAL BLOOD STEM CELL TRANSPLANTATION (ASCT) IN HARD TO MOBILIZE NHL AND HL PATIENTS: A PHASE IIB STUDY

I Danylesko[1], R Sareli[1], N Varda-Bloom[1], R Yerushalmi[1], N Shem-Tov[1], A Shimoni[1], A Nagler[1,*]
[1]Hematology Division and Bone Marrow Transplantation, Chaim Sheba Medical Centre, Ramat Gan, Israel

Background: Plerixafor (Mozobil®) is a novel CXCR4 antagonist. Upfront use of plerixafor may be indicated in patients with predicting factors for failing mobilization such as receiving multiple previous lines of chemotherapy, radiation or stem cell toxic drugs like Fludarabine, as well as advanced age.
Aims: We, therefore, initiated a prospective study assessing the use of plerixafor for mobilization of $CD34^+$ PB HSC in elderly or heavily pretreated patients with NHL or HL, eligible for ASCT (NCT01164345).
Methods: Twenty pts (M-9, F-11), median age 63 (range, 23-70 y) with NHL or HL eligible for ASCT were investigated. The predicting factors for failing mobilization were age above 60 (17/20), multiple courses of chemotherapy (3/20) or both (n=6). Pts received G-CSF (10µg/kg s.c.) x 4 days. Starting the evening of day 4, they received plerixafor 0.24mg/kg s.c. Apheresis was initiated in the morning, 12h after the dose of plerixafor. The target cumulative yield of CD34+ cells/kg was≥5 × 10^6 and the minimum number of cells required for transplant was≥2 × 10^6 CD34+ cells/kg. Seventeen out of the 20 pts underwent ASCT after BEAM protocol. Efficacy was evaluated by the number of PB CD34+ cells/µL, CD34+ cells/kg and myeloid and platelet engraftment.
Results: Mobilization and apheresis yields**:** The addition of Plerixafor to G-CSF resulted in a median 2.26-fold increase in PB CD34+ cell number from pre plerixafor (14.4cells/µL) to post plerixafor administration (32.6cells/µL). The median number of CD34+ cells collected by the first collection was 7.6 × 10^6cells/kg (range, 0.47-20.3). Fifteen of 20 pts met the target CD34+ cell collection of >5 × 10^6cells/kg in the first collection. Four additional pts collect >5 × 10^6CD34+ cells/kg after 2nd collection. Only 1 patient did not reach the minimum target of >2 × 10^6 after 3 days of stem cell collections.Transplant and engraftment: 17/20 pts underwent ASCT (3 were not transplanted due to disease progression-1;<2 × 10^6 CD34+ cells/kg -1; refused – 1). A median 5 × 10_6 CD34+ cells/kg (range, 2.08 -7) were infused at ASCT. Pts engrafted PMN and PLT within a median of 12 days (range, 9-18) and 14 days (range, 12-38), respectively. Safety: 8/20 pts suffered from AEs after Mozobil injections. These pts complained for headache (n=2), bone pain (n=2), abdominal pain (n=1), nausea (n=4), vomiting (n=1) and fever (n=3). Overall, the plerixafor related AEs were mild (grade I-II) and transient. The most common AEs post plerixafor were headache, bone and abdominal pain, fever, vomiting. The main transplant related toxicities were mucositis and infections (n-14). 10/17 pts (59%) suffered from mucositis usually grade II-III (grade II-III -9, grade IV-1). One patient developed acute coronary syndrome during BCNU treatment, 1 suffered from atrial fibrillation, 2 from fluid retention and other 2 from bacterial sepsis.
Summary and Conclusion: Our study indicates that upfront plerixafor is safe and efficient for HSCs mobilization in elderly and heavily pretreated NHL and HL pts predicted to fail mobilization with G-CSF. The vast majority of the pts (19/20 -95%) achieved the target CD34+ cell dose, 15 of them with 1 a pheresis procedure. All pts promptly engrafted post high dose chemotherapy using the plerixafor mobilized CD34+ cells. Plerixafor mobilization in these high risk heavily pre-treated pts was safe with only mild transient expected side effects.
Table: Efficacy of stem cell collection: Mean number of leukapheresis procedures - 1.3; PB CD34+ cells/µl prior first plerixafor - 14.4 (range, 0-54.17); PB CD34+ cells/µl post first plerixafor - 32.6 (range, 7.18-91); CD34+ cells/kg in the graft - 5 (range, 2.08 -7); CD34+ × 10^6 cells/kg in the first stems cell collection - 7.6 (range, 0.47-20.3).

P1126

COMPARISON OF UNRELATED CORD BLOOD WITH BONE MARROW AS A STEM CELL SOURCE FOR MYELOABLATIVE CONDITIONING TRANSPLANTATION IN PATIENTS WITH PEDIATRIC ACUTE LEUKEMIA: A RETROSPECTIVE COHORT STUDY

Y Arakawa[1,*], M Kato[1], K Koh[1], R Hanada[1]
[1]Hematology/Oncology, Saitama Children's Medical Center, Saitama, Japan

Aims: To investigate the role of cord blood as an alternative stem cell source for hematopoietic stem cell transplantation (HSCT) in patients with pediatric leukemia.
Methods: We retrospectively analyzed the outcomes of unrelated cord blood transplantation (UCBT; n=35) and unrelated bone marrow transplantation (UBMT; n=56) with myeloablative conditioning for pediatric acute leukemia in our institute.
Results: The probability of overall survival (OS) (95% confidence interval) at 5 years was 49.8% (35.6%–62.4%) with UBMT and 53.8% (34.0%–70.1%) with UCBT (p=0.92). The non relapse mortality (NRM) at 5 years was 12.9% (5.6%–23.4%) with UBMT and 14.7% (5.3%–28.8%) with UCBT (p=0.56). The cumulative incidence of acute graft-*versus*-host disease (GVHD) (grade II to IV) was 48.2% (34.5%–60.6%) with UBMT and 43.4% (26.4%–59.2%) with UCBT (p=0.60). Engraftment probability was 90.7% (78.2–96.2) with UBMT and 93.9% (73.0–98.8) with UCBT (p=0.67). There was no statistically significant difference in OS, cumulative incidence of acute GVHD, NRM, and engraftment probability between the two groups. Median time from confirmation of transplant indication to day 0 was 208 days with UBMT and 161 days with UCBT (p=0.048). In cord blood grafts, the median number of nucleated cells was 7.4 (1.5–17) × 10^7/kg (n=35), while the median number of CD34-positive cells was 2.1 (0.3–7.6) × 10^5/kg (n=29). The cumulative incidence of engraftment was significantly higher, with the total cell number being ≥4 × 10^7/kg (n=28) and the CD34-positive cell number being ≥2 × 10^5 /kg (n=13).
Summary and Conclusion: Cord blood grafts are easily available because they have already been collected. UCBT can function as an important alternative to UBMT in patients with pediatric acute leukemia.

P1127

AUTOLOGOUS STEM CELL TRANSPLANTATION IN PATIENTS WITH MULTIPLE MYELOMA: CONTRIBUTION OF NEW PHARMACOLOGICAL HAEMATOPOIESIS SUPPORT

M Fominykh[1,*], V Shuvaev[1], S Voloshin[1], A Schmidt[1], A Kuvshinov[1], A Kuzyaeva[1], I Zapreeva[1], K Abdulkadyrov[1]
[1]Clinical department, Russian Research Institute of Hematology and Transfusiology, Saint-Petersburg, Russian Federation

Background: High-dose chemotherapy (HDCT) followed by autologous hematopoietic stem cell transplantation (HSCT) is the only curative therapy for some patients with recurrent Hodgkin's disease, non-Hodgkin's lymphoma, leukemia, and germ-cell tumors. HSCT has been shown to prolong survival in multiple myeloma (MM). The risks of HDCT include bleeding from thrombocytopenia followed by severe anemia. Thrombocytopenia occurring after HSCT may be isolated and prolonged. Blood product support can be complicated by iron overload, infectious disease transmission, and transfusion reactions. Romiplostim has been approved for the treatment of refractory idiopathic thrombocytopenic purpura, demonstrating a favorable safety profile and has been tested in delayed platelet recovery post-SCT. To address this question we have initiated a study to assess the efficacy and safety of romiplostim support at HSCT in MM patients.
Methods: Ten patients (median age, 53 years; range 42-63; 9 male and 1 female) with MM underwent HSCT with romiplostim support [romiplostim group]. The conditioning regimens were as follows: 200 mg/m^2 melphalan (n=8) and BEAM (n=2). The median dose of CD34+ cells infused was 2.4x10^6 cells/kg (range 1.3–3.6x10^6 CD34+ cells/kg). All the patients received 250 µg of the thrombopoietin receptor agonist romiplostim on day of HSC infusion. Thirty patients (median age, 51.4 years; range 26-63; 14 male and 16 female) with MM were assessed as a control group (without romiplostim support). The conditioning regimens were: MEL-200 (n=27) and BEAM (n=3). The mean of CD34+ cells infused was 2.7x10^6 CD34+/kg (range, 1.3–5.2x10^6 CD34+/kg). The endpoints of the study were: time to platelet count >25x10^9/l and >50x10^9/l, days (TPC); duration of grade 4 thrombocytopenia (<25x10^9/l) and grade 3 (<50x10^9/l), days (DT); patient-day, days (PD); platelet nadir (PN); and platelet transfusion volume, ml (PTV). Statistical analysis was conducted with nonparametric statistical methods (Mann-Whithey U test for continuous variables and Fisher exact and Chi-square tests for categorical variables).
Results: The DT grade 3 was 8.0 days in the romiplostim group in comparison with 10.2 days in the control group (*p=0.374*). DT grade 4 was 4.0 days for romiplostim group and 7.4 days for the control group (*p=0.003*), fig. 1. TPC >25x10^9/l was 10.4 days for romiplostim group and 13.0 days for the control group (*p=0.025*). TPC >50x10^9/l was 12.8 for romiplostim group and 14.5 days in control group (*p=0.594*). PD was 24.0 in the romiplostim group in comparison with 25.9 days in the control group (*p=1.0*). PN was 9.5x10^9/l and 10.9x10^9/l (*p=0.706*), respectively. PTV was 1022 ml for romiplostim group and 1071 ml for the control group (*p=0.257*). No significant adverse events of romiplostim administration were observed.

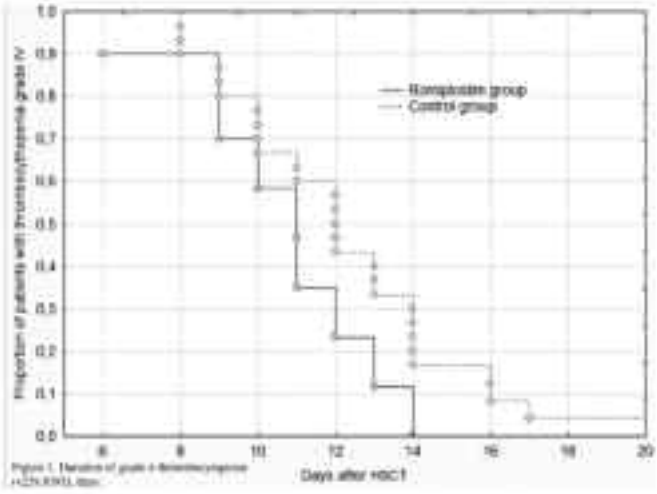

Figure 1.

Summary and Conclusion: The duration of grade 4 thrombocytopenia and the time to platelet count >25x10^9/l are significantly reduced when romiplostim is administered at HDCT. All another endpoints were favorable but not statistically significant in romiplostim group. It could be influenced by the limited number of patients. These tendencies confirm the rationale for further studies of romiplostim in setting of HSCT.

P1128

ANTI-THYMOCYTE GLOBULIN (ATG) COULD IMPROVE THE OUTCOME OF ALLOGENEIC HEMATOPOIETIC STEM CELL TRANSPLANTATION IN PATIENTS WITH AGGRESSIVE T CELL TUMORS

Y Juan[1,*], W chun[1], J jieling[1], W liping[1], C yu[1], Y shike[2]
[1]hematology, Shanghai Jiaotong University affiliated Shanghai First People's Hospital, [2]hematology, Shanghai Jiaotong University affiliated Shanghai First People's Hospital, shanghai, China, shanghai, China

Background: Aggressive T-cell lymphomas represent 10% to 15% of non-Hodgkin's lymphomas in adults. Patients withrelapsed or refractory disease are generally considered incurable with conventional therapies. ATG had been used in theconditioning regimen to reduce the incidence of GvHD for a long time especially in the matched unrelated donor HSCT.The early experiment result in our hospital showed that ATG inhibited the proliferation of lymphoid tumor cells in a dosedependentmanner especially in the T cell tumors.
Aims: We used the ATG as the part of the conditioning regimen in the allpatients and to evaluate the long-term anti-leukemia effect, the safety and complication in the patients with relapsed orhigh-risk T cell lymphomas.
Methods: 18 patients(male 9, female 9) were enrolled into this study. Median patient age atthe time of transplantation was 28 years (range, 7–55 years). At the time of transplant, 4 patients reached first orsubsequent complete response (CR) with conventional therapy or the salvage therapy, 4 patients had a partialremission(PR), 7 patients had relapsed disease not responding to salvage therapy or progressive disease, and 3 patientshad primary refractory disease. Donors were 10/10 HLA matched related (5), 10/10 matched unrelated (3), 8/10 matchedunrelated (5) and mismatched related (5). The median number of CD34+ cells within the allografts was 9.31/kg bodyweight (BW) (range,4.6–24.85/kg BW). Rabbit antithymocyte globulin (ATG 2.5 mg/kg×4 days) and total-body irradiation (10 Gy in five fractions) were used in all 18 patients. All patients but one also underwent cyclophosphamide (120 mg/kg).The only one who did not receive CTX had experienced with autologous transplantation. Fifteen high risk patients were inadditional use of VP 16 or VM26 30-40mg/kg. Two patients in CR1 and one patient who were 55 years old had notreceived VP16. Graft-*versus*-host disease (GVHD) prophylaxis was cyclosporine based, usually in combination withmethotrexate. Quantitative chimerism analyzes were performed using short-tandem-repeat-based polymerase chainreaction techniques at regular intervals for every 4 weeks after transplantation in bone marrow at the first six months.
Results: All patients but one achieved a complete remission in the first three months after allogeneic HSCT. One patientachieved PR on month 1 and soon died from progressive disease. The CR rate after transplantation was 94.4%. At amedian follow-up time of 13 months, fourteen(77.8%) patients are alive. OS at three years was 71%. Still four patientswere died after transplantation, two from relapse and two from treatment related complications. Acute GvHD grades II-IVoccurred in eight patients(50%) and grades III-IV in four patients. Two patients suffering from acute GvHD grade IV dieddue to treatment-related complications. The maximum cumulative incidence of cGVHD was 42.8%. The high levels ofCMV DNA were detected in seventeen patients in the first three months after transplant. Two of them gradually envolvedinto viral haemorrhagic cystitis. One patient suffered from aspergillus pneumonia while another two suffered frombacterial pneumonia. There was no case of venous occlusive disease.

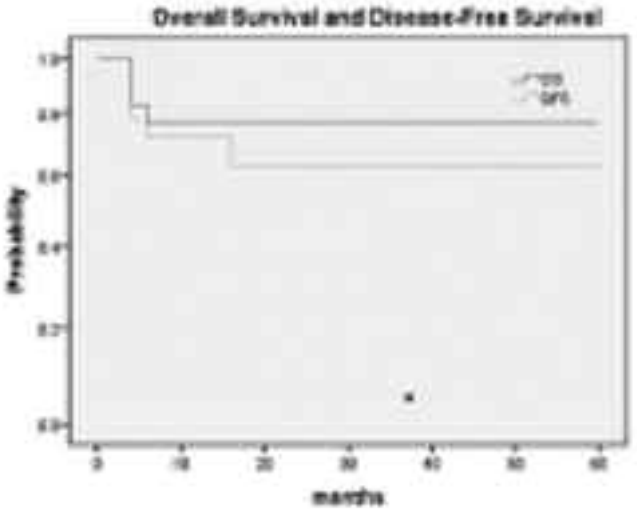

Figure 1.

Summary and Conclusion: Anti-thymocyte globulin (ATG) could improve the outcome of allogeneic hematopoietic stem celltransplantation in patients with aggressive T cell tumors.

P1129

SAFETY AND EFFICACY OF BRENTUXIMAB VEDOTIN (SGN-35) IN HODGKIN LYMPHOMA PATIENTS UNDERGOING REDUCED INTENSITY ALLOGENEIC STEM CELL TRANSPLANT FOLLOWING A RELAPSE AFTER AUTOLOGOUS TRANSPLANT

F Zallio[1,*], A Busca[2], N Mordini[3], F Ferrando[2], B Bruno[2], F Salvi[1], A Levis[1], M Pini[1]
[1]Onco-hematology, Hematology Division, Alessandria, [2]Hematology, Bone

Marrow Transplant Center, Torino, [3]Hematology, Hematology Division, Cuneo, Italy

Background: The prognosis of patients with Hodgkin lymphoma (HL) who relapse following autologous stem cell transplantation (ASCT) is generally poor, with long-term progression free-survival of about 20-30%. Allo-SCT continues to be recommended in this subset of patients because of the relatively young age and because it can induce some durable remissions; however the application of this procedure is actually limited by a difficulty to obtain an objective response before allotransplant. It was recently shown that Brentuximab vedotin, a new generation antibody-drug conjugate, is able to induce nearly 30% of complete remission in HL patients relapsing after autologous transplant; therefore this agent could effectively work in relapses after ASCT as a platform to allow a better disease control in order to improve the outcome of the allografting procedure.

Aims: Aim of this study was to analyze retrospectively the safety and the efficacy of brentuximab vedotin administered as single agent as a bridge to allogeneic transplant in HL patients relapsing after ASCT.

Methods: Between August 2011 and September 2013, 8 out of 12 patients, treated with allo-SCT at four hematologic Divisions of Northern Italy for HL relapse after ASCT, had received brentuximab vedotin as a bridge to the allografting procedure. Median age was 32 years (range 21-61) and median number of prior regimens was 5, including ASCT. Patients received a median of 6 cycles (range 4-7) of brentuximab vedotin administered every 3 weeks as a 30-minute outpatient IV infusion; median time between the last dose of brentuximab vedotin and the allo-SCT was 1 month (range 1-5 months). No patient experienced progression during treatment with brentuximab vedotin (2 complete remissions and 6 partial remission/stable disease). All but one patients did not have a HLA identical sibling, so they required a matched unrelated (4 patients) or haploidentical donor (3 patients); peripheral stem cells were the source in patients with HLA identical sibling or unrelated, whereas bone marrow was used in the haplo setting. Reduced-intensity was the conditioning regimen performed in all patients. Post transplant cyclophosphamide plus mycophenolate mofetil/tacrolimus was the graft-*versus*-host disease (GVHD) prophylaxis of the haplo setting, while Metotrexate/cyclosporine was administered in the other patients. Patients were monitored for engraftment, aGVHD, chimerism, and infectious complications per institutional standards.

Results: One patient had primary graft failure with autologous reconstitution; she was a patient with a high body-mass index, in whom the drug's doses of the conditioning regimen were underestimated in order to avoid excessive toxicity. All the other patients engrafted; median time to neutrophil recovery was 20 days (range 15-26). There was no delay of engraftment or increased incidence of CMV reactivations or other type of infections. No cases of worsening neuropathy or grade III-IV extrahematologic toxicities were reported after allo-SCT. Non-relapse mortality at 1 year was 0%. Only one patient had a relapse at 8 months after allo-SCT, whereas the others are alive and progression-free at a median follow up of 12 months.

Summary and Conclusion: These data suggest that brentuximab vedotin can be safely and effectively administered prior to RIC allo-HCT in HL patients relapsing after ASCT. It can provide an objective disease control in order to allow patients to undergo alloSCT. Furthermore we did not observe delays in engraftment, increase in non-relapse mortality, and post transplant infectious complications. Further clinical trials with larger number of patients and longer follow-up are recommended to confirm the promising role of brentuximab as a bridge to alloSCT.

P1130

VORICONAZOLE PROPHYLAXIS OF INVASIVE FUNGAL INFECTION IN HAPLOIDENTICAL ALLOGENIC STEM CELL TRANSPLANTATION

S Sarghi[1,*], F Lorentino[1], F Giglio[1], C Zuanelli Brambilla[1], L Crucitti[1], G Levati[1], R Greco[1], C Messina[1], A Forcina[1], MT Lupo Stanghellini[1], L Vago[1], S Marktel[1], M Marcatti[1], A Assanelli[1], M Bernardi[1], J Peccatori[1], C Corti[1], F Ciceri[1]
[1]Hematology, IRCCS Ospedale San Raffaele, Milano, Italy, Milano, Italy

Background: Haploidentical allogenic stem cell transplantation recipients are a heavily treated high risk population for infectious complications and the invasive fungal infection (IFI) represents one of the major causes of infectious-related deaths. An appropriate strategy of IFI prophylaxis must be applied in such context. Voriconazole, a third generation azole has already proved its large spectrum and good tolerance in the matched related and unrelated (MUD) stem cell transplant patients.

Aims: To evaluate the efficacy and tolerance of voriconazole primary and secondary prophylaxis for invasive fungal infection in haploidentical stem cell transplant recipients of our center.

Methods: From January 2008 to July 2010, voriconazole was used as primary prophylaxis of invasive fungal infection (IFI) during haploidentical transplant in 43 patients with a median age of 38 years [min 10, max 71] and as secondary prophylaxis in other 19 haploidentical transplant recipients in remission of a previous/probable/possible previous IFI, median age 51 years [min 25, max 61]. The main endpoint for the primary prophylaxis was defined as the ability to tolerate the fungal prophylaxis more than 100 days and the absence of probable/proven fungal infection at day 180. The principal objective for secondary prophylaxis was the incidence of proven/probable IFI.

Results: Primary prophylaxis: The median duration of voriconazole prophylaxis was 94 days (range: 13-356 days), adapted to individual infectious risk. Fungal infection free-survivals at day 100 and day 180 were 62% and 58%. 28% patients received treatment for a new IFI. In the context of concomitant triple graft *versus* host disease prophylaxis by sirolimus, mofetil mycophenolate and cyclosporine, 6 patients (14%) stopped the treatment for liver toxicity, only 2 (4.6%) of them before day 100. Overall cumulative survival was 67% at day 100, 60% at day 180 and 45% at 1 year. **Secondary prophylaxis:** In 68.4% of the patients (13 cases) voriconazole was the treatment for the previous infection. Median duration of voriconazole prophylaxis was 92 days (range: 18-359 days). Cumulative survival at one year 32%. IFI occurred in 7 cases post transplant (37%), all previously treated with voriconazole. Successful secondary prophylaxis at one year 20%. Only one patient out of nineteen (5.2%) had toxicity (hepatic) after 124 days of prophylaxis.

Summary and Conclusion: Voriconazole is efficacious and well tolerated in haploidentical SCT; simultaneously administration of enzymatic competitors as sirolimus is feasible although requires immunosuppressive drug monitoring.

P1131

ALLOGENEIC HEMATOPOIETIC STEM CELL TRANSPLANTATION FOR ELDERLY PATIENTS WITH MYELOID MALIGNANCY WITH A MYELOABLATIVE CONDITIONING CONSISTING OF TBI AND G-CSF-COMBINED CYTARABINE

T Toyama[1,*], T Mori[1], Y Koda[1], S Kohashi[1], T Kikuchi[1], J Kato[1], S Okamoto[1]
[1]Division of Hematology, Keio University School of Medicine, Tokyo, Japan

Background: We previously reported that allogeneic hematopoietic stem cell transplantation (HSCT) with a conditioning consisting of total body irradiation (TBI) and granulocyte colony-stimulating factor (G-CSF)-combined cytarabine for myeloid malignancy contributed to a favorable outcome due to a low transplant-related mortality and disease relapse (Bone Marrow Transplant 2007; Biol Blood Marrow Transplant 2008). However, efficacy and safety of this conditioning for elderly patients has not been evaluated.

Aims: To evaluate the efficacy and safety of the myeloablative conditioning consisting of TBI and G-CSF-combined cytarabine in allogeneic HSCT for elderly patients with myeloid malignancy.

Methods: We retrospectively evaluated the outcomes of patients aged 50 years or older who underwent allogeneic HSCT at Keio University Hospital (Tokyo, Japan) between January 1995 and May 2011 after being conditioned with TBI (12 Gy) followed by high-dose cytarabine (3 g/m^2) every 12 hours for 4 days in combination with the continuous administration of G-CSF. Cyclosporine or tacrolimus with short-term methotrexate was given for GVHD prophylaxis. Transplant outcomes were compared with those of patients aged 49 or younger who underwent the same transplant procedures during the study period.

Results: Thirty-five elderly patients (median age, 52 years; range, 50-58) were enrolled into analysis. Diseases were acute myeloid leukemia (n=16: CR1, n=5; CR2, n=6; not in CR, n=5), advanced myelodysplastic syndromes (n=16), and myeloproliferative neoplasms (n=3). Stem cell sources were bone marrow/peripheral blood stem cells from human leukocyte antigen (HLA)-identical siblings (n=11/3), bone marrow (n=17) and cord blood (n=4) from unrelated donors. Of the 34 evaluable patients, graft rejection occurred in one patient. Eighteen were alive at the date of analysis with a median follow-up of 9.4 years (range, 3.6-18.5). Causes of death were disease relapse in 7 patients, infection in 4, graft-*versus*-host disease (GVHD) in 3, and post-transplant lymphoproliferative disorder, liver failure and graft rejection each in 1. In all patients, 5-year overall survival (OS) and progression-free survival (PFS) rates were 51.4% (95%CI: 34.0-66.4) and 48.6% (95%CI: 31.4-63.7), respectively, which were comparable with those of 88 younger patients (67.7% (95%CI: 56.7-76.5, p=0.117) and 63.4% (95%CI: 52.3-72.5, p=0.140)).

Summary and Conclusion: These results suggest that TBI and G-CSF-combined cytarabine could be a tolerable and promising conditioning for allogeneic HSCT for elderly patients aged between 50 and 60 years with myeloid malignancy.

P1132

FIRST FRENCH EXPERIENCES OF TOTAL BODY IRRADIATION USING HELICAL TOMOTHERAPY

R Sun[1,*], M Chea[1], C Jenny[1], R Itti[2], JP Vernant[3], JJ Mazeron[1], X Cuenca[1]
[1]Radiation oncology, Pitié Salpétrière Hospital, [2]Radiation oncology, Saint Louis Hospital, [3]Hematology, Pitié Salpétrière Hospital, Paris, France

Background: Total Body Irradiation (TBI) is widely used as a preparatory regime before BMT. Nevertheless, current accepted techniques of TBI are laborious, time-consuming and cumbersome. In addition, dose prescription and verification is usually limited to single-point measurements. The advent of

dynamic conformal radiotherapy in the form of helical tomotherapy (HT) offers a new and more quantitative paradigm for TBI dose planning and delivery.
Aims: Treatment planning, delivery, dose verification of the 6 first French experiences of TBI using HT are presented.
Methods: A review was performed on 6 TBI where HT was used. The conditioning regimen consisted of Fludarabine 30 mg / m² Day D1 to D3 followed by TBI 2 Gy D4 with the allograft D6. Patients were immobilized in a supine position using a whole body vacuum bag and a thermoplastic head mask (3 points). Two sets of planning kilovoltage CT with a 5 mm slice thickness were acquired: one for the upper body HFS oriented (from vertex to knees) and one for the lower body FFS oriented (from feet to pelvis). The target volume (PTV) was delineated with the external contours for lower and upper parts. The junction has been marked at mid-thighs. We prescribed 2 Gy to the PTV. In order to control the dose gradient in the junction region, we used five 2 cm transition volumes. In each transition volume, the sum dose prescribed of each plan (upper and lower) was 2 Gy. For the treatment planning we chose a 5 cm field width, a pitch of 0.43 and a Modulation Factor of 1.8. For quality insurance (QA), each plan was checked with delivery QA performed with cylindrical phantom, ionization chamber for absolute dose and film for relative dose. *in vivo* dosimetry was performed with thermoluminescent dosimeters and the junction region homogeneity was checked with radiochromic films.
Results: Five of the 6 patients planified received the treatment. We included all the 6 patients for the dosimetric analysis. A total dose of 2 Gy was delivered to the PTV in Helical Tomotherapy. ICRU criteria were achieved for 5 of 6 patients: V95% was covered by D95%, V2% did not exceed D107%. For 1 patient, $V_{95\%}$was 91.1% and $V_{107\%\%}$ was 6.4%. For each delivery QA, the difference between measured and calculated absolute dose was<2,5% (mean :1%) For relative dose, Gamma Index (3%; 3 mm) was<1 for at least 94% of the points (mean: 95.8%) Junction region inhomogeneity was less than ± 7.5% (mean: 5.8). Among 15 points, difference between *in vivo* measurements and calculated dose was >5% for 2 points with a maximum at 10% (mean: 0.42 %, standard deviation 1.2%). The total realization of TBI lasted 120 min with a beam on time of 17.2 min for the upper and 11.2 min for the lower part of the body. We needed 3 or 4 MVCT (mean 3.5) to replace the patient with accuracy: the deviation between expected and realized position was less than 1 mm in all directions.
Summary and Conclusion: Those were the first French experiences of TBI using HT. This technique guarantees high dose homogeneity throughout the body and dose verification is achievable, showing small difference between planed and delivered doses. The treatment was achievable in a confortable way for the patients and with accuracy. In view of these results, the use of HT should be a standard if TBI is recommended. Improved conformality with HT may offer new opportunities with regard to this therapy.

Gene therapy, cellular immunotherapy and vaccination

EFFECTIVE AND SUSTAINED CELLULAR IMMUNOTHERAPY TO ACUTE MYELOID LEUKEMIA USING T-CELL-RECEPTOR REDIRECTED EBV-SPECIFIC CD8+ T CELLS WITH MEMORY STEM-LIKE AND CENTRAL MEMORY PROPERTIES

I Weber[1], J Petry[1], S A Khan[1], A Mades[1], Y Xu[1], J Albrecht[1], M Theobald[1], U F Hartwig[1,*]
[1]III. Dept. of Medicine - Hematology, Internal Oncology & Pneumology, University Medical Center Mainz, Mainz, Germany

Background: Adoptive cellular therapy using donor-derived cytolytic T lymphocytes (CTL) directed to leukemia or herpesvirus has evolved as a promising strategy to confer adoptive antiviral immunity and improve graft-*versus*-leukemia (GvL) effects in immunocompromised patients following allogeneic hematopoietic stem cell transplantation (AHSCT). However, durable clinical responses are often hampered by detrimental graft-*versus*-host (GvH)-reactivity and limited capability of transferred, fully differentiated effector T cells (T_{EFF}) to establish persistent antileukemia immunity.
Aims: In the present study we therefore explored the memory formation and tumoricidal features of *in vitro* generated EBV-specific T memory stem cells (T_{SCM}) and central memory T cells (T_{CM}), T cell-receptor (TCR) redirected to acute myeloid leukemia (AML), for improved immunotherapy by adoptive transfer into a patient-tailored minimal residual leukemia NSG-mouse model.
Methods: EBV-specific T_{SCM} and T_{CM} were generated by stimulation of healthy donor derived, purified naïve $CD8^+CD45RA^+$ T cells with EBV-peptide mix loaded autologous stimulators or EBV-transformed B cells (B-LCL) derived from the HLA-class I-matched AML patient in the presence of Interleukin (IL)-12, -7, -15, -21, and inhibitors targeting glycogen synthase kinase-3β involved in the Wnt-signaling pathway. EBV-specific CTL from unselected $CD8^+$ T cells were established as controls. Phenotype, cytolytic activity as well as metabolic and migratory properties of unmodified and LV-transduced T_{SCM}/T_{CM} was analyzed by flow cytometry, IFN-γ ELISpot and ^{51}Cr-release assays, glucose uptake and transmigration analyses. αβ-TCR genes isolated from AML-reactive CTL (Albrecht *et al.* Cancer Immunol. Immunother. 2011) and lentiviral (LV) transduction of EBV-CTL was performed according to standard procedures. $eGFP^+$ $TCRV\beta7.1^+$ and $TCRV\beta21.3^+$ LV-transduced T_{SCM}/T_{CM} were monitored for AML-reactivity. To evaluate bioactivity *in vivo*, redirected Luciferase $(Luc)^+$ T cells were adoptively transferred into AML- and B-LCL-engrafted NSG mice, respectively, and monitored for engraftment, persistence and antileukemia reactivity.
Results: Following 3 to 4 weekly stimulations T_{SCM} and T_{CM} expressing a $CD8^+$ $CD45RA^+$ $CD45RO^-$ $CD95^+$ $CD27^+$ $CD28^+$ $CD62L^+$ $CCR7^+$ and $CD8^+$ $CD45RA^-$ $CD45RO^+$ $CD95^+$ $CD27^+$ $CD28^+$ $CD62L^+$ $CCR7^+$ phenotype elicited strong and to $CD8^+$ T_{EFF} EBV-specific cells comparable reactivity to B-LCL generated from the HLA class I-matched AML-patient. In line with recently described features of early differentiated memory T cells both unmodified and LV-transduced T_{SCM} and T_{CM} additionally showed reduced glucose uptake but enhanced migration properties in CCL-21 driven transmigration assays. Moreover, TCR-redirected EBV-specific T cells elicited comparable reactivity to AML blasts derived from the same patient as the B-LCL when compared with the original AML-reactive T cell clone. Adoptive transfer of redirected CTL into AML-engrafted NSG mice resulted in strong reduction of AML-burden. Moreover, these T cells persisted for more than 90 days in NSG mice. Additional studies on boosting antileukemia immunity by additional transfer of irradiated EBV-blasts into treated mice or supporting T cell homeostasis by weekly i.p. injection of a IL-15 superagonist are currently in progress.
Summary and Conclusion: In conclusion, this study demonstrates that stem-cell-like and central memory EBV-specific CTLs redirected towards AML-reactivity can induce sustained antileukemia immunity and thus might represent a promising tool to improve cellular immunotherapy within AHSCT

P1134

THE AB-DNTS IN LYMPH NODES, BONE MARROW AND PERIPHERAL BLOOD OF LYMPHOMA PATIENTS: POTENTIAL PROGNOSTIC FACTOR OF CLINICAL OUTCOME

G De Tullio[1,*], C Minoia[1], S Serrati' [1]G Loseto[1], N sgherza[1], V De Fazio[1], A Rana[1], P Iacopino[1], A Guarini[1]
[1]Department of Clinical and Experimental Oncology, Haematology Unit, Advanced Cell Therapy Center, National Cancer Research Centre, Istituto Tumori "Giovanni Paolo II", BARI, Italy

Background: The mutual interactions between the host immune system and lymphoma cells may either promote or control lymphomagenesis. The Double negative T cells (DNTs) have emerged as new subset of T cells that contribute specifically to anti-tumor immunity since they are involved in immune regulation

and tolerance acting as regulatory T cells (Treg) and/or cytotoxic T cells. DNTs express either αβ or γδ T-cell receptors (TCR) and lack CD4, CD8 and CD56. Functional studies showed that DNTs might have a direct *in vitro* anti-tumor activity against lymphoma cells. However no data are available on their role in human anti-Lymphoma immunity as well as their prognostic significance in lymphomas and how they are modulated during the therapy response.
Aims: The aim of this study was to evaluate the modulation of DNT expression during therapy response, from the diagnosis to the remission or relapse/progression, in lymph nodes (LN), bone marrow (BM) and peripheral blood(PB)of lymphoma patients in order to assess their role on clinical outcome and progression.
Methods: PB and BM samples of 72 Lymphoma patients (pts), with non-Hodgkin's Lymphomas and classical Hodgkin Lymphoma were collected at diagnosis and prospectively during the follow-up (1-6-12 months after chemo- or immuno-chemotherapy therapy) as well as at the relapse/progression. As control PB samples of 16 healthy donors were collected. Twenty fresh LN tissue from pts clinically suggestive of lymphoma was quickly processed. The ontogeny, functional attitude and TCR clonality of DNT subsets (TCRαβ+ and TCRγδ+) were evaluated in PB, BM and LN by following monoclonal antibodies: CD3, CD4, CD8, CD56, CD45, TCRαβ, CD45Ra, CD45Ro, CCR7, CD27, CD28, CD30, CD69, GITR, CD95, CD178, CD152, IFN-γ, TNF-α, perforin and granzymeB. For functional studies, DNTs were purified from PBMCs by LN and PB of pts through a negative selection and then cultured for 2 weeks. Other immune cells such as MDSCs and Treg was in parallel detected to evaluate the correlation with DNTs. 7 cases of LNs received a finally diagnosis of reactive follicular hyperplasia (RFH) so they was considered as LN controls. All pts provided their informed consent in accordance with the Declaration of Helsinki.
Results: The frequency of DNTs in BM of Lymphoma pts was less than in PB,but we observed a significant decrease (p=0.006) of αβ-DNTs in the PB of pts with untreated lymphoma (20.5 ± 4.8 SE) (Mean + SE) as compared with healthy controls (31.3 ± 3.4), and their number correlated with both disease relapse/progression or stage of therapy. (fig.1-2). In Hodgkin's Lymphoma pts the αβ-DNT frequencies were significantly increased as compared with other histotypes (p=0.005) (fig. 4) and if compared with subcategory of lymphoma such as indolent or aggressive (p=0.0001) (fig.3). The frequency of αβ-DNTs in 1-month post-cht or disease relapsed pts samples was significantly decreased (p=0.006) as compared with diagnosis.Interestingly, after *ex vivo* expansion, DNTs acquired an immunomodulatory cytokine profile, characterized by the secretion of IFN-γ and granzyme B which are known as central components of anti-tumor immune responses.More interesting the DNTs in pathologic LNs are significantly reduced compared to RFH-LNs (p=0.006) and are realated to the aggressiveness of the disease (fig.5-6).

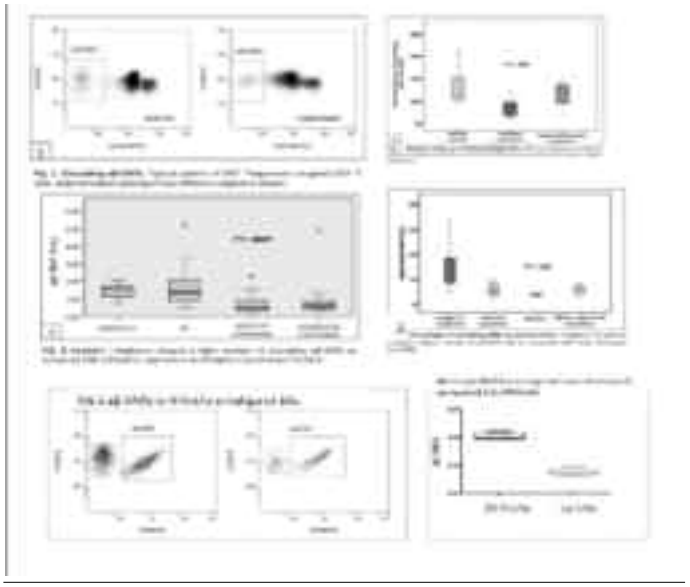

Figure 1.

Summary and Conclusion: Our study has demonstrated for the first time that αβ-DNTs could play an important role in both the development and the progression of lymphomas. This is the first study that evaluate the DNTs in LNs of Lymphoma patients,where the disease originates. More functional studies in malignant LN will help to more understanding the role of DNT in Lymphoma pathogenesis. In addition, based on our preliminary results, it is likely that ex-vivo expanded DNTs exert an anti-tumor activity thus suggesting their possible use as a new strategy for adoptive immune-therapy.

P1135

TOWARDS CLINICAL GAMMA DELTA TCR GENE TRANSFER: A BROADLY APPLICABLE T-CELL PRODUCT FOR CANCER PATIENTS

T Straetemans[1], C Gründer[1], S Heijhuurs[1], S Hol[1], K Scholten[1], Z Sebestyen[1], I Slaper[1], J Kuball[1,*]
[1]Laboratories for Translational Immunology, UMC Utrecht, UTRECHT, Netherlands

Background: γδT cells are innate immune cells with strong anti-tumor activity and provide anti-tumor receptors that are interesting tools in immune therapy against cancer. The introduction of γδTCR genes into αβT-cells allows the adoptive transfer of T cells that are not limited by HLA-restriction, in any patient with any cancer (Marcu-Malina *et al.* Blood 2011, 50). Combinatorial γδTCR-exchange (CTE) has been applied to design a γ9δ2 TCR with strong and broad anti-tumor reactivity, referred to as TCR γ9-G115/δ2-cl5 (Gründer *et al.* Blood 2012, 5153).
Aims: Aim of the study is to design a clinical grade procedure which guarantees an efficient expression of the introduced γδTCR, an adequate enrichment of transduced cells, as well as functional efficacy.
Methods: Firstly, we introduced both γ and δ chains into the retroviral vector pMP71, separated by a 2A peptide sequence. Gene-engineered human αβT-cells expressed the γδTCR and recognized tumors of different hematological origin as well as solid tumors. Secondly, the orientation of the γ and δ chains and the particular 2A peptide sequence influenced TCR expression as well as anti-tumor function as previously demonstrated for αβTCR genes.
Results: Thirdly, introduction of the optimal γδTCR transgene cassette into αβT cells was followed by the depletion of untransduced αβTCR positive cells using a clinical grade anti-αβTCR antibody before rapid T cell expansion. This depletion procedure resulted in a highly pure population of γδTCR-engineered T cells with increased γδTCR expression, and improved anti-tumor function both *in vitro* but also *in vivo* in a humanized mouse model. Importantly, introduction of a γδTCR into αβT cells followed by clinical-grade depletion of non-transduced and transduced T-cells expressing higher levels of αβTCRs abolished residual allo-reactivity.
Summary and Conclusion: All together, we developed a clinical grade GMP vector which allowed a deliberate choice for the most potent clinical γδTCR receptor cassette. In addition, the clinical grade depletion of non-transduced and transduced T-cells expressing high levels of endogenous αβTCRs results in a potent γδTCR-engineered T cell product suitable for an autologous but also allogeneic clinical scenario.

ADOPTIVE TRANSFER OF RAPIDLY GENERATED EBV-CTLS FOR THE TREATMENT OF HIGH RISK ASSOCIATED EBV MALIGNANCIES

S Perna[1,*], M Ngo[1], N Lapteva[1], S Sharma[1], J Ando[1], L Rollins[1], O Diouf[2], A Leen[3], J Vera[4], V Torrano[1], S Gottschalk[1], C Ramos[1], C Bollard[1], C Rooney[5], H Heslop[6]
[1]Center for Cell And Gene Therapy, Baylor College of Medicine, Houston Methodist Hospital and Texas Children Hospital, [2]Cell Medica, [3]Center for Cell And Gene Therapy, Dept. of Pediatrics, [4]Center for Cell And Gene Therapy, Dept. of Medicine, [5]Center for Cell And Gene Therapy, Dept. of Pediatrics, Dept. of Molecular Virology and Microbiology, [6]Center for Cell And Gene Therapy, Dept. of Pediatrics, Dept. of Medicine, Baylor College of Medicine, Houston Methodist Hospital and Texas Children Hospital, Houston, United States

Background: Adoptive immunotherapies with virus-specific T cells (VSTs) are showing increasing success for the treatment of viral-associated malignancies. We have previously demonstrated that the administration of Epstein-Barr Virus (EBV) -specific T-cells directed against the EBV latent cycle antigens, LMP1 and LMP2, resulted in over 50% of complete responses in patients with multiply relapsed or refractory EBV+ Hodgkin and non-Hodgkin lymphomas (HL and NHL). Unfortunately, the manufacturing procedures of those VSTs pose several impediments to the wider applicability of our strategy. These include the use of live virus (EBV) and adenoviral (Ad) vectors and the difficulty of generating EBV-transformed B-cell lines (EBV-LCL) for use as antigen-presenting cells (APCs) from patients with B-lymphoma who have received rituxan.
Aims: To simplify the manufacture and make our approach more broadly applicable, we have replaced EBV antigens expressed from the Ad vectors with overlapping 15mer peptide libraries (pepmixes) spanning LMP 1/2, as well as EBNA1 and BARF1, and used pepmix-pulsed dendritic cells for the first stimulation followed by pepmix-pulsed, autologous activated T cells (aATCs) and irradiated costimulatory cells (HLA-negative K562 cells expressing CD80, CD86, CD83 and 41BB-ligand [K562-CS] as transgenes) for further expansion. We hypothesized that the administration of VSTs generated using our new, pepmixes-based method, would be safely tolerated and control the progression of the disease in patients with high-risk EBV-associated malignancies.
Results: To date we have enrolled 17 patients in our IRB and FDA approved clinical trial (NCT01555892). We successfully expanded T-cells from 14/17 patients. In one case we did not isolate sufficient cells to start production, and

two VST lines are still under production. 8/14 VSTs lines showed EBV-specific activity against at least one of the four antigens used during the generation of the lines, as determined by ELISpot. The lines were highly enriched in CD3 (92% ± 11%), with a mix of CD4 and CD8 (55%% ± 15% and 34% ± 18%, respectively) and although the lines were predominantly composed of effector memory cells (45% ± 9%), we observed a persistence of a significant population expressing a central memory phenotype (CD45RO, CCR7 and CD62L) (33% ± 12%). Ten patients received 2 infusions of VSTs (range 0.2-1 x10e8/m2). We did not observe any toxicities related to the VSTs. Two patients are too early to evaluate response. Of 8 evaluable patients 3 patients treated while in complete remission remain in CR (follow up: 10, 6 and 2 months post infusion). Of five patients treated with active disease, 3 progressed while one had stable disease for 3 months and one had a partial response, which was sustained 5.5 months before showing signs of disease progression.
Summary and Conclusion: The administration of VSTs generated in the presence of viral pepmixes appears to be safe and well tolerated. Although we have seen activity in two patients, further data are needed to determine if rapidly generated and Ad/LCL-generated VSTs have similar anti-tumor efficacy.

P1137

GENERATION OF MULTIVIRUS-SPECIFIC T CELLS BY A SINGLE STIMULATION OF PBMCS WITH A PEPTIDE MIXTURE UTILIZING SERUM-FREE MEDIUM

Y Fujita[1,*], T Ono[2], N Ochiai[3], A Kawana-Tachikawa[4], A M Leen[5], H E Heslop[5], T Morio[2,3], S Takahashi[1]
[1]Division of Molecular Therapy, Advanced Clinical Research Center, The Institute of Medical Science, The University of Tokyo, [2]Department of Pediatrics and Developmental Biology, Tokyo Medical and Dental University, Graduate School of Medical and Dental Sciences, [3]Center for Cell Therapy, Tokyo Medical and Dental University, [4]The University of Tokyo, The Institute of Medical Science, Advanced Clinical Research Center, Division of Infectious Disease, Tokyo, Japan, [5]Center for Cell and Gene Therapy, Baylor College of Medicine, Houston Methodist Hospital and Texas Children's Hospital, Houston, TX, United States

Background: Extension to donors other than HLA-matched siblings following advanced immunosuppressive treatment has resulted in the emergence of viral infections as major contributors to morbidity and mortality after hematopoietic stem cell transplantation (HSCT). While pharmacological agents are standard therapy for some, they have substantial toxicities, generate resistant variants, and are frequently ineffective. Moreover, immune reconstitution is necessary for long-term protection against pathogens after HSCT. Restoration of virus-specific immunity offers an attractive alternative to conventional drugs. Adoptive transfer of virus-specific CTLs from stem cell donors has been proved to be safe and effective in treatment of viral infection. Recently, the system for rapid generation of multivirus-specific T cells has been reported (Gerdemann, U, 2012). With this technique, polyclonal CTLs specific for multivirus antigens can be produced after single stimulation of PBMCs with a peptide mixture spanning the target antigens in the presence of IL4 and IL7.
Aims: We introduced and verified this system to apply for clinical use in Japan. To conform regulation by the Japanese FDA, we attempted to generate multivirus-specific T cells in serum-free medium. To meet the requirement for the viral infections after HSCT by broad virus species, we extended the target antigens to cytomegalovirus (CMV), EBV, adenovirus (AdV), HHV-6, BKV, JC virus and VZV.
Methods: 20×10^6 of PBMCs were stimulated with peptide mixture spanning the target antigens of 3 (CMV, EBV, AdV) or 7 (CMV, EBV, AdV, HHV-6, BKV, JC virus and VZV) viruses and cultured in serum-free medium with cocktail of IL4 and IL7 for 9-12 days.
Results: 20 x 10^6 PBMCs were stimulated with each antigen of CMV, EBV and AdV and cultured for 9-12 days in serum free medium or in RPMI1640 + 5% human serum (HS). We obtained average of 144.9×10^6 cells in RPMI with 5% HS and average of 92.0×10^6 cells in serum-free medium (n=4), which were statistically significant (p=0.025). Most of the prepared cells were positive for CD3, mainly consisted of CD4+ central memory cells in each condition. The average percentage of T cell subsets were as follows; CD3+ 97.7%, CD4+ 84.8%, CD8+ 11.7%, CD3+CD62L+CD45RO+ 89.0% in RPMI+5% HS and CD3+98.9%, CD4+ 74.4%, CD8+ 14.8%, CD3+CD62L+CD45RO+ 93.2% in serum-free medium. We observed no significant difference in specificity toward the CMV, EBV and AdV antigens between the cells cultured in medium with HS and in serum-free medium. IFNγ production was observed in average of 9.83% of the prepared cells (19.1 ×10^6 cells) in RPMI+5%HS and in average of 7.93% (10.0 ×10^6 cells) in serum-free medium when assessed by intracellular cytokine staining (ICS). We next tried to generate 7 viruses-specific T cells in the serum-free culture system. 20x 10^6 PBMCs were stimulated with each antigens of CMV, EBV, AdV, HHV-6, BKV, JC virus and VZV and cultured for 10-12 days yielding 151.9±39.6 ×10^6 cells (n=5). 95.6% of the cells after the expansion were CD3+ and contained both CD4+ and CD8+ cells. The average percentage of CD4 positivity was 74.1% and that for CD8 was 20.8%. 80% of CD3+ cells expressed central memory phenotype. These single stimulated and cultured cells contained average of 21.2% CD4+IFNγ+ cells and 5.1% CD8+IFNγ+ cells measured by ICS and showed specificity toward all the 7 virus antigens (n=4).
Summary and Conclusion: Our approach can be readily introduced to clinical practice and is expected to be introduced to countries in which the use of serum for cellular products are restricted as an alternative treatment/ prevention for viral infection after HSCT. We also seek a way to eventually establish a system to prepare multivirus-specific T cells by this rapid, easy and cost-effective method for the third party use.

GENETIC CORRECTION OF DIFFERENTLY MOBILIZED HEMATOPOIETIC STEM CELLS FROM PATIENTS WITH THALASSEMIA AND ENGRAFTMENT KINETICS AFTER XENOTRANSPLANTATION

G Karponi[1,*], P Papayanni[1], C W Lederer[2], N Psatha[1], F Zervou[1], N Zogas[1], C Tsatalas[3], A Anagnostopoulos[1], M Sadelain[4], I Riviere[5], G Stamatoyannopoulos[6], E Yannaki[1]
[1]GENE AND CELL THERAPY CENTER, HEMATOLOGY-BMT UNIT, GEORGE PAPANICOLAOU HOSPITAL, Thessaloniki, Greece, [2]Molecular Genetics Thalassaemia Department, The Cyprus Institute of Neurology and Genetics, Nikosia, Cyprus, [3]School of Medicine, Democritus University of Thrace, Alexandroupolis, Greece, [4]Center for Cell Engineering, [5]Cell Therapy and Cell Engineering Facility, Memorial Sloan-Kettering Cancer Center, New York, [6]Department of Medicine and Markey Molecular Medicine Center, University of Washington, Seattle, United States

Background: Gene therapy is anticipated to render patients with beta-thalassemia transfusion-independent, through autologous transplantation of genetically-modified hematopoietic stem cells (CD34+).
Aims: In view of a forthcoming gene therapy clinical trial for thalassemia, we sought to determine, on the basis of CD34+cell yields, transduction efficiency, beta-globin expression and engraftment rates in xenografts, the optimal autologous graft source in thalassemic individuals mobilized with various strategies (G-CSF-alone, Hydroxyurea (HU)+G-CSF, Plerixafor-alone and Plerixafor+G-CSF).
Methods: The differently-mobilized CD34+ cells, obtained in two clinical trials, were transduced with research grade lots of the TNS9.3.55 beta-globin lentiviral vector and compared in terms of gene transfer rates, clonogenicity, restoration of the beta-globin expression *in vitro* and multilineage engrafting capacity after xenotransplantation of equal numbers of CD34+ cells into, partially myeloablated, IL2Rgamma^{null} mice. In addition and since for clinical gene therapy it will be necessary to freeze the CD34$^+$ cells at least once before administration, the effect of freezing/thawing courses on the transducibility and clonogenicity of hematopoietic stem/progenitor cells was tested.
Results: The combination of Plerixafor+G-CSF yielded the highest CD34+ cell doses per apheresis over the rest mobilization approaches (mean CD34+cells/apheresis: G-CSF 3.44±1.14 *vs* HU+G 3.31±1.00 *vs* Plerixafor 3.61±2.05 *vs* Plerixafor+G-CSF 8.85±2.88 X10^6/kg, p=0.0003). The differently mobilized CD34$^+$ cells generated similar numbers of colony forming units (CFU) after transduction. CD34$^+$cells transduced fresh or after one freeze/thaw cycle yielded similar clonogenic and gene transfer frequencies. Repeated freeze/thaw cycles of cultured, but not of unmanipulated cells, were marked by significant colony loss, with no impact on viability or transduction rates. Plerixafor-mobilized cells tended towards higher transduction rates, a feature probably associated with the higher content in cells at the G1 phase of cell cycle as compared to all other differently mobilized cells. Despite that Plerixafor+G-CSF cells displayed a significantly lower colony vector copy number (VCN)/cell (p<0.0001), they produced the highest β-globin output/VCN (p=0.04). All mobilized CD34$^+$ cells averaged 47.5%±2.9% vector-positive CFU and 1.92±0.04 VCN with expression approximating the one-copy normal β-globin output. *In vivo*, multilineage engraftment was encountered in all groups and the average VCN/cell measured in mouse blood ranged from 3.4 in the 1st month to 1.82 in the 5th month post transplantation. The Plerixafor+G-CSF-mobilized cells achieved superior short-term (p<0.004) and a trend towards superior long-term (p=0.05) engraftment rates over all other differently mobilized cells.
Summary and Conclusion: Overall, TNS9.3.55 gene transfer in variously-mobilized thalassemic CD34$^+$ cells was effective and stable.Plerixafor+G-CSF mobilization not only results in very high numbers of CD34+cells obtained by single apheresis but it also yields a CD34+cell population that, despite its lower susceptibility to transduction, provides increased β-globin expression/VCN and enhanced human chimerism in xenografts under a non-myeloablative setting. Consequently, Plerixafor+G-CSF-mobilized CD34+cells potentially represent the optimal autologous graft for thalassemia gene therapy and stem cell gene therapy applications in general.

P1139

NEXT-GENERATION DENDRITIC CELL VACCINATION AS POSTREMISSION THERAPY FOR AML PATIENTS WITH A NON-FAVORABLE RISK PROFILE

F S Lichtenegger[1,2,*], C Geiger[3], F M Schnorfeil[1,2], B Beck[1,2], T Koehnke[1,2], V Buecklein[1,2], T Altmann[1,2], B Wagner[4], R Henschler[4], I Bigalke[3,5], G Kvalheim[5], W Hiddemann[1], D J Schendel[3], M Subklewe[1,2]

[1]Department of Internal Medicine III, Klinikum der Universität München, [2]Clinical Cooperation Group Immunotherapy, [3]Institute of Molecular Immunology, Helmholtz Zentrum München, [4]Department of Transfusion Medicine, Cellular Therapeutics and Hemostaseology, Klinikum der Universität München, Munich, Germany, [5]Department of Cellular Therapy, The Norwegian Radium Hospital, Oslo University Hospital, Oslo, Norway

Background: Post-remission therapy of patients with acute myeloid leukemia (AML) is critical for the elimination of minimal residual disease (MRD) and a prerequisite for achieving cure. Cellular immunotherapy is a highly effective treatment option as demonstrated by the low relapse rate after allogeneic stem cell transplantation (SCT). However, many patients are not eligible for this treatment. Therapeutic vaccination with autologous, antigen-loaded dendritic cells (DCs) is a promising strategy to induce cellular and humoral immune responses. Within recent years, we have developed a GMP-compliant protocol for the generation of *next-generation* DCs. A short, 3-day differentiation period is combined with a novel maturation cocktail that includes a TLR7/8 agonist. The resulting DCs are characterized by a positive costimulatory profile and a high production of bioactive IL-12p70. Both *in vitro* and *in vivo*, they have been shown to polarize $CD4^+$ T cells into Th1, to induce antigen-specific $CD8^+$ T cells and to activate NK cells.
Aims: Proof-of-concept phase I/II clinical trial evaluating *next-generation* DCs as postremission therapy for AML patients with a non-favorable risk profile.
Methods: Patients with AML and non-favorable risk profile in complete remission (CR) after intensive induction therapy are able to enroll. Standard exclusion criteria apply, and patients have to be ineligible for allogeneic SCT. DCs are generated from monocytes of the patients and then loaded with ivt-RNA encoding the leukemia-associated antigens WT1 and PRAME. Additionally, DCs transfected with RNA encoding CMV-pp65 are included as an adjuvant and surrogate antigen. Patients are vaccinated intradermally with one batch of $5x10^6$ DCs for each of the three antigens up to 10 times within 26 weeks, starting with weekly and continuing with monthly intervals. The primary endpoint of the trial is feasibility and safety. Secondary endpoints are immune responses and disease control, with particular focus on MRD conversion. Phase I will include 6 patients, and phase II another 14 patients.
Results: So far, two patients have been enrolled into the phase I of the trial. Pt. 1 was a 72 year-old man in CR with an adverse genetic risk profile (complex karyotype) and not eligible for allogeneic SCT. The differential blood count showed 11% monocytes of 7,6 G/l leukocytes (836 monocytes/µl). The leukapheresis yielded $3,4x10^9$ monocytes in total, and 14 vials of DCs per antigen were generated for clinical application. Pt. 2 was a 54 year-old man in CRi with an intermediate genetic risk group (cytogenetic abnormality not classified as favorable or adverse) and no HLA-matched donor. The differential blood count showed 7% monocytes of 5,9 G/l leukocytes (413 monocytes/µl). The leukapheresis yielded $2,2x10^9$ monocytes in total, and 6 vials of DCs per antigen were generated for clinical application. For both patients, the DCs fulfilled all quality criteria (cell count, viability, purity, sterility, phenotype). No adverse events have been observed so far except for slight erythema at the injection site.
Summary and Conclusion: We are currently conducting a proof-of-concept phase I/II clinical trial evaluating *next-generation* DCs as postremission therapy for AML patients with a non-favorable risk profile (NCT01734304). We report on the feasibility and safety of this protocol in phase I. Up-to-date clinical and immunomonitoring data will be presented.

P1140

FUNCTIONAL EVALUATION OF T-CELLS GENERATED FROM WT1-TCR TRANSDUCED HUMAN HEMATOPOIETIC STEM CELLS USING THE OP9-DL1 COCULTURE SYSTEM

S Bonte[1], S Snauwaert[1], G Goetgeluk[2], M Heemskerk[3], H Stauss[4], B Vandekerckhove[5], T Kerre[1,*]
[1]Hematology and Immunology, [2]Immunology, Ghent University Hospital, Gent, Belgium, [3]Leiden University Medical Center, Leiden, Netherlands, [4]University College London, London, United Kingdom, [5]Immunology, University College London, Gent, Belgium

Background: Chemotherapy leads to cure of acute myeloid leukemia (AML) in less than half of the patients. Stem cell transplantation can be used as an immunotherapeutic treatment to cure the patient, but carries a high risk of toxicity and mortality, especially in older patients with comorbidities. Moreover, not all patients have a suitable donor. We have developed a novel immunotherapeutic treatment, in which we generate *in vitro*, starting from mobilized peripheral blood or cord blood hematopoietic precursor cells, T-cells that recognize WT1, a tumor antigen that is overexpressed on 70% of the AMLs.
Aims: In this study we have evaluated the functionality and specificity of the generated WT1-directed T-cells both *in vitro* and *in vivo*. The ultimate goal is to use these cells in patients, as this form of immunotherapy is promising and could be an option for cure in patients who should be treated with stem cell transplantation, but are not eligible. In contrast to the more widely used immunotherapy using TCR-transduced peripheral T-cells, our therapy is expected to be more effective and carry less risk of autoreactivity (due to the presence of only one TCR). Moreover, chimeric antigen receptor (CAR) T-cell therapy, which seems very promising in the treatment of lymphoid malignancies expressing a good, discriminating surface antigen, will probably not be able to be used for AML, because of the lack of a good surface antigen that is not present on normal myeloid cells, which coulld result in unacceptable toxicity.
Methods: $CD34^+$ cells isolated from cord blood and mobilized peripheral blood mononuclear cells were cultured on OP9-DL1 in the presence of the cytokines IL-7, Flt3-L and SCF, for 2 weeks, until T-cell commitment. Subsequently, they were transduced with a WT1-TCR, and again co-cultured until $CD4^+CD8^+$ double positive cells were abundantly present (generally after another 2-3 weeks). At that point, the agonist peptide WT1 was added to the culture together with IL-7, and 5 days later cells were harvested and expanded polyclonally or using agonist peptide,in the presence of IL-2, or IL-7+IL-15. *In vitro* evaluation: T-cells were evaluated using a ^{51}Chromium release assy, for cytotoxicity against WT1 and HLA-A2 positive and negative targets. Also,upon activation, production of IFN-g was evaluated using ELISA. *In vivo* evaluation: Immunodeficient 6-8 weeks old NSG mice were irradiated (200 cGy), and 24 hours later injected intravenously with a luciferase-positive, WT1, HLA-A2 transduced K562 cell line (R. Stripecke), together with $5x10^6$ or 10^7 WT1+ T-cells or CMV+ T-cells (negative control). Mice are evaluated using the IVIS bioluminescence assay.
Results: We observed that the highest number of WT1-TCR CD8+ T cells was generated if the cells were expanded after harvest from the coculture using the combination of the agonist peptide, IL-7 and IL-15. Using ^{51}Cr release assay and ELISA, we could show that upon activation, the T-cells showed specific cytokine production and efficient killing of tumor cells. Currently, experiments are ongoing evaluating the function of these cells on the expansion of WT1-HLA-A2+ K562 cells *in vivo* and survival of these mice.
Summary and Conclusion: We have shown that, using the OP9-DL1 model, we are able to generate large numbers of high-avidity tumor-specific naïve and resting T-cells, after a proicess similar to thymic positive selection. After expansion, polyclonal or antigen specific in the present of the agonist peptide) and activation, these cells show specificity and functionality *in vitro* and are currently evaluated in an *in vivo* immunodeficient mouse model.

P1141

OPTIMIZING TUMOR-REACTIVE SINGLE-CHAIN T CELL RECEPTORS FOR ADOPTIVE T CELL TRANSFER

B Hauptrock[1,*], J Trumpler[1], C Gonzalez[1], E Antunes[1], M T Glomski[1], RH Voss[1,2], H Echchannaoui[1], M Theobald[1]
[1]Hematology, [2]TRON, Universitätsmedizin Mainz, Mainz, Germany

Background: Adoptive transfer of T cells modified by tumor antigen-specific T cell receptor (TCR) gene transfer is a promising strategy to induce tumor regression in cancer patients. The safety and efficiency of TCR gene transfer can be compromised by mispairing of the introduced TCRα or -β chains with the endogenously expressed TCR chains.
Aims: To reduce TCR mispairing and to increase expression and functionality of transferred TCR we aimed at the optimization of a human TCR specific for the melanoma antigen gp100.
Methods: We constructed a single chain (sc) TCR by covalently linking the variable domain of the TCRα-chain to the TCRβ-chain and co-expressed the constant domain of the TCRα-chain (Cα) to achieve stable scTCR expression. Since the human scTCR/Cα was not expressed at the cell surface due to instability, we substituted the constant TCR domains by mouse TCR domains (chim scTCR/Cα). As mouse-derived proteins could be immunogenic in patients, we minimally murinized the constant domains by replacing only selected amino acids in the human constant domains of the scTCR/Cα by their corresponding mouse amino acids (mm scTCR/Cα). To increase stability, additional disulfide bonds between scTCR and Cα were introduced. For further improvement, we linked the gene of the scTCR with the Cα by a 2A-element and expressed it on one retroviral vector.
Results: After retroviral transduction of human T cells with the scTCR/Cα, we detected a high cell surface expression for the chim scTCR/Cα and the mm scTCR/Cα. T cells transduced with the different TCR constructs were able to lyse melanoma cells and cell lines generated from melanoma metastases. T cell degranulation induced by incubation with gp100 peptide loaded cells was equal in T cells transduced with the chim scTCR/Cα and the mm scTCR/Cα. This assay also showed a degranulation of CD4 T cells, indicating that the TCR reacts CD8-independent. Affinity of both constructs as determined by K_D measurement with different tetramer concentrations was equivalent. Furthermore we are currently running an *in vivo* experiment to prove rejection of melanomas by the scTCR/Cα constructs in a mouse model. Therefore, melanoma cells were transduced with a luciferase gene to detect tumor growth and metastasis by *in vivo* imaging. A control of melanoma growth is especially seen in mice with a high frequency of transferred T cells in the blood. During the experiment, we plan also to scan for a panel of cytokines and chemokines to reveal potential immune escape mechanisms.
Summary and Conclusion: Our results show equal expression and functionality of mm and chim scTCR/Cα. These optimized gp100-specific TCRs

represent promising candidates for adoptive T cell transfer by providing effective antitumor responses. For the future it would be interesting to extend this TCR optimization technique to TCR recognizing antigens of leukemia or other hematologic malignancies.

P1142

COMBINING ADOPTIVE TCR IMMUNOTHERAPY AND ARGININE DEPLETION IN OSTEOSARCOMA XENOGRAFT MODEL

H Echchannaoui[1,2,*], E Antunes[2], B Hauptrock[2], A Habermeier[3], E I Closs[3], J Bomalaski[4], M Munder[2], M Theobald[1,2]
[1]German Cancer Consortium (DKTK), German Cancer Research (DKFZ), Frankfurt/Mainz, [2]Third Medical Department (Hematology, Oncology and Pneumology), [3]Department of Pharmacology, University Medical Center of the Johannes Gutenberg University Mainz, Mainz, Germany, [4]Polaris Pharmaceuticals Inc, San Diego, CA, United States

Background: The adoptive transfer of TCR-engineered T cells is a promising approach in the treatment of human malignancies. However, a safety concern of TCR gene transfer is the risk of pairing between introduced and the naturally expressed endogenous TCR chains, resulting in the generation of self-reactive T cells. Moreover, after adoptive transfer of tumor-reactive T cell the anti-tumor effectiveness in cancer models and in patients remains very limited due to various tumor immune escape mechanisms. Targeted therapies against tumors and immunotherapy have recently proven clinical synergistic effect when combined together.
Aims: We aim at improving adoptive T cell-based tumor immunotherapy by (1) combining novel optimized specific TCR with enhanced tumor recognition as well as reduced potential for self-reactivity (2) pharmacological intervention to deplete arginine, an amino acid crucial for tumor cell metabolism and growth.
Methods: To overcome TCR mispairing formation, we designed a single chain (sc) TCR format by connecting the variable TCRa domain to the TCRb chain via a short peptide linker co-expressed with a truncated constant TCR a domain. To further enhance preferential TCR pairing, cell surface expression and TCR function, we introduced additional cysteine residues into the TCR α and β chain constant domains along with codon-optimization of the TCR sequences and cloning of the TCR constructs into one single 2A-based retroviral vector. This molecular design was applied to an HLA.A*02.01 (A2.1)-restricted p53(264-272)-specific TCR as promising antigen-driven immunotherapy for both solid tumors and hematologic malignancies. To deplete specifically arginine in tumor milieu, we used the pegylated form of arginine deiminase (ADI-PEG20), a drug successfully used in clinical trials. To study the *in vivo* efficacy of combined arginine depletion and scTCR gene transfer, we developed a NOD/SCID/γc^{null} (NSG) xenograft model of osteosarcoma.
Results: *in vitro* studies demonstrated that, scp53TCR-modified T cells display similar high-avidity compared to the full-length TCR and mediate specific lysis of $p53^{+}A2.1^{+}$ tumor cells. Importantly, scp53TCR-engineered T cells showed anti-tumor activity without inducing graft-*versus*-host disease (GVHD) in NSG mice inoculated with p53 mutant osteosarcoma cells. To enhance the anti-tumor response observed in the osteosarcoma model after transfer of T cells, tumor-engrafted NSG mice received repetitive injections of ADI-PEG20 and subsequently infused with TCR-redirected T cells. Unexpectedly, this therapeutic combination resulted in the abrogation of the anti-tumor response mediated by transferred T cells. Further analysis demonstrated that arginine depletion in the tumor micromilieu upon ADI-PEG20 treatment was associated with a downregulation of p53 tumor antigens. These results were confirmed *in vitro*. Preliminary results suggested that downregulation of tumor antigens upon arginine starvation is regulated at the transcriptional level.
Summary and Conclusion: Our study provided evidence that an optimized high-affinity scTCR-specific for the broadly expressed tumor-associated antigen p53(264-272) mediates anti-tumor response *in vivo* without inducing GVHD. Interestingly, arginine starvation affects the expression of tumor antigens in this oseosarcoma model. In the light of these new data, further studies are required to better understand the exact mechanisms.

P1143

HDAC6 INHIBITION AUGMENTS THE EFFICACY OF ANTI-CD20 MONOCLONAL ANTIBODIES BY UP-REGULATING CD20 LEVEL IN MALIGNANT B-CELLS

M Bobrowicz[1,*], M Dwojak[1], K Bojarczuk[1], M Siernicka[1], M Winiarska[1], J Golab[1,2]
[1]Department of Immunology, Medical University of Warsaw, [2] Institute of Physical Chemistry, Polish Academy of Sciences, Warsaw, Poland

Background: CD20, an integrate membrane protein expressed on the surface of normal and malignant B-cells is widely used as a molecular target for monoclonal antibodies (mAbs) in the therapy of non-Hodgkin's lymphomas and chronic lymphocytic leukemia (CLL). Accumulating evidence indicates that CD20 can be modulated at several levels, both transcriptional and posttranscriptional and its up-regulation would result in increased efficacy of anti-CD20 mAbs. CD20 antigen has been reported to be regulated epigenetically *e.g.* by histone deacetylases (HDACs).
Aims: The aim of our project was to check if specific inhibition of HDAC6 can influence CD20 level and improve the efficacy of anti-CD20 mAbs.
Results: The results of our preliminary experiments show that blocking the activity of a single HDAC isoform - HDAC6 with selective inhibitors (tubacin, ACY-1215 and tubastatin) leads to up-regulation of CD20 protein in B-cell lymphoma cell lines, EBV-transformed B-cells and primary cells from CLL patients but not in normal B-cells. The observed up-regulation of CD20 level correlates with increased efficacy of anti-CD20 mAbs - rituximab and ofatumumab in complement-dependent cytotoxicity (CDC) assays, but does not influence antibody-dependent cellular cytotoxicity (ADCC). We observed that HDAC6 silencing with shRNA also increases CD20 surface level, although overexpression of HDAC6 does not induce changes in CD20 level. HDAC6 inhibition and silencing lead to increase in total CD20 protein level assessed in Western blotting. Neither tubacin nor HDAC6 silencing with shRNA does alter the expression of complement inhibitors. In order to elucidate the mechanism by which HDAC6 inhibition increases CD20 level we performed qRT-PCR experiments using SyBR Green and hydrolysis probes. We observed that HDAC6 inhibition with tubacin and its silencing with shRNA do not alter CD20 mRNA. Accordingly, HDAC6 inhibition does not change CD20 promoter activity and leads to increase of CD20-tagged protein level expressed in Raji independently of CD20 promoter. HDAC6 is a unique member of HDAC family reported to be engaged mainly in the acetylation of non-histone substrates, protein degradation and transport. Since the effect of HDAC6 inhibition on CD20 molecule does not rely on transcriptional mechanisms we sought to determine HDAC6 role in CD20 protein transport. Using nocodazole – a microtubule disrupting agent we observed that the effect of HDAC6 on CD20 depends on the stability of microtubules. What is more, we observed that blocking protein anterograde protein transport with Golgistop abrogates tubacin effect on CD20 regulation. These results suggest that HDAC6 may be implicated in CD20 transport/degradation pathways. Nevertheless, extensive experiments aiming at elucidating this problem have to be performed.

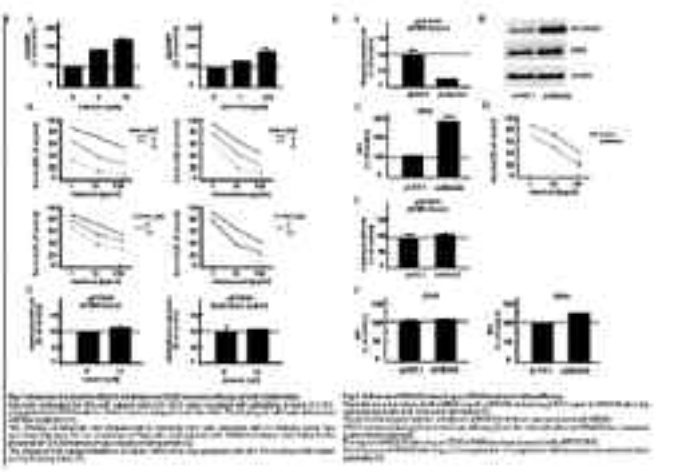

Figure 1.

Summary and Conclusion: The results of our study strongly suggest that combining HDACi with anti-CD20 antibodies can be a successful therapeutic modality for patients suffering from B-cell malignancies. The use of isoform-selective inhibitors of HDAC6 may be an effective strategy in enhancing the efficacy of anti-CD20 mAbs. Potentially these compounds would have less adverse effects than HDAC pan-inhibitors. However, their use in the therapy requires further investigation.

P1144

ADOPTIVE CIK CELLS IN PATIENTS WITH LEUKEMIA RELAPSE AFTER ALLOGENEIC STEM CELL TRANSPLANTATION

Q Li[1,*], X Zhu[1], Z Zhong[1], Y You[1], P Zou[1]
[1]Institute of Hematology, Union Hospital, Tongji medical college, Huazhong University of Science and Technology, wuhan, China

Background: Allogeneic hematopoietic stem cell transplantation (allo-HSCT) remains a curative treatment of many hematologic malignancies. Leukemia relapses imply failure of the transplantation and poor prognosis as none proved treatment was found. It is reported that allogeneic cytokines induced killer (CIK) cells have showed superiority in the effect of graft *versus* tumor/leukemia (GVT/GVL) with rare occurrence of graft-*versus*-host disease (GVHD).
Aims: We conducted a Phase I study to test the safety and feasibility of infusions of CIK cells to 11 patients who suffered leukemia relapse after allo-HSCT. Informed consent was obtained.
Methods: The median age of patients was 31.9 years (range 17-49) and their

diagnoses were acute myelogenous leukemia (AML, n=3), pre-B acute lymphoblastic leukemia (pre-B ALL, n=1), T acute lymphoblastic leukemia (T-ALL, n=2), chronic myeloid leukemia (CML-CP, n=1) and B acute lymphoblastic leukemia (B-ALL, n=4). 8/11 received allo-HSCT from HLA identical siblings, and the other 3 received it from unrelated donors. The mononuclear cells used for CIK induction were extracted from the patients themselves (n=9) and HSCT donor (n=2), respectively.
Results: The CIK cells were successfully amplified *in vitro* for all the 11 patients. For the patients with hematologic recurrence or extramedullary relapse of leukemia or loss of full donor chimerism, tapering of cyclosporine A(CsA) and the most appropriate chemotherapy treatment could be performed to achieve the best hematologic response and to allow the laboratory preparation of CIK cells. CsA were all withdrawn prior to infusion of CIK. The average amount of infused CIK cells was 1.56×10^5/site (*in situ* injection), or 3×10^9/d (intravenous injection) in two successive days. 1/11 patient performed as multiple subcutaneous mass in the head, which was not suitable for surgery and radiation. 1/11 patient was found increased thymic shadow in anterior mediastinum by PET-CT. 1/11 suffered both extramedullary and hematological relapse. The left 8 patients suffered from hematological relapse, with increased leukemia cells found in the bone marrow. The mass in the head turned flat and gradually disappeared after *in situ* injection of CIK cells. 10/11 patients received intravenous injection of CIK cells. For those 2 with anterior mediastinum, thymic shadow gradually disappeared after intravenous infusion of CIK cells. 10/10 patients achieved hematological remission after intravenous injection. The 2-year overall survival of patients after relapsed is 7/11. For the patients with intravenous injection, neither acute toxicity nor new-onset or worsening GVHD was observed. Acute GVHD was observed in 8 patients, after infusion of CIK, GVHD symptoms relieved.
Summary and Conclusion: In this study we have shown that large numbers of allogeneic CIK cells can be produced in a 12-days time period and safely given to patients who have relapsed after allogeneic transplantation. This is the first report, to our knowledge, of CIK cells *in situ* injection for extramedullary relapse. The results initially proved that CIK cell therapy for extramedullary relapse after allo-HSCT is not only feasible, but has a good security.

P1145

CYTOMEGALOVIRUS-SPECIFIC CYTOTOXIC T LYMPHOCYTES RESTRICTED TO HLA-A2 OR HLA-A24 CAN BE EFFICIENTLY GENERATED BY USING GENE-ENGINEERED ARTIFICIAL ANTIGEN-PRESENTING CELLS

M Ogasawara[1,*], S Ota[1], N Hirano[2]
[1]Department of Internal Medicine, Sapporo Hokuyu Hospital, Sapporo, Japan, [2]Department of Immunology, University of Toronto, Toronto, Canada

Background: Reactivation of cytomegalovirus (CMV) is a major cause of morbidity after allogeneic hematopoietic stem cell transplantation. Adoptive transfer of CMV-specific cytotoxic T lymphocytes (CTLs) is a promising therapy to treat reactivation and prevent viral disease. However this noble modality has been hampered by the difficulty of consistently generating potent anti-CMV lymphocytes in a timely manner for every patient. To overcome this, we previously reported a culture system that can reproducibly generate antigen-specific CTL by using K562-based artificial antigen-presenting cells (aAPCs).
Aims: In the present study, we have applied the culture system to CMV and examined whether HLA-A*02:01 (A2) (a major HLA-A phenotype among Caucasian) or A*24:02 (A24) (a major HLA-A phenotype among Japanese)-restricted CMV-specific CTL can be generated using aAPCs.
Methods: HLA-A2 or A24-positive peripheral blood mononuclear cells were obtained from leukemia or cancer patients (n=11). To establish CMV-specific T cells, $CD8^+$ T cells were purified by positive selection using a magnetic beads method (Miltenyi Biotec). aAPCs expressing either HLA-A2 or HLA-A24 were pulsed with HLA-A2 or HLA-A24 restricted, CMV-pp65 immunodominant peptides (NLVPMVATV for HLA-A2 and QYDPVAALF for HLA-A24). aAPCs were then irradiated with 200 Gy and added to purified $CD8^+$ T cells at a ratio of 1:10 in 24-well plates in PRMI1640 supplemented with 10% human AB serum. Between stimulations, IL-2 (10 U/ml) and IL-15 (10 ng/ml) (both from Peprotec) were added to the cultures.
Results: Following 3 rounds of weekly stimulation with peptide-pulsed aAPCs, CMV-specific CTLs were evaluated by a tetramer staining. The percentage of HLA-A2 tetramer-positive cells was 0.05±0.05% before culture. It increased to 8.98±8.73% (176 fold increase) following the third stimulation. On the other hand, the percentage of HLA-A24 tetramer-positive cells before and after stimulation was 0.03±0.05% and 11.0±16.5% (367 fold increase), respectively. A kinetic study revealed that the percentage of tetramer-positive cells was 0.02±0.01% before stimulation. It increased to 2.10±1.72% (105 fold increase) and 9.14±8.13% (457 fold increase) following the second and the third stimulation, respectively, indicating a rapid increase in CMV tetramer-positive $CD8^+$ T cells. $CD8^+$ T cells stimulated with HLA-A2 CMV-peptide-pulsed aAPC were negative for both A24/CMV and A2/HIV tetramers, confirming HLA restriction and antigen specificity. And the opposite is also true for $CD8^+$ T cells stimulated with HLA-A24 CMV-peptide-pulsed aAPC. FACS analysis revealed that majority of CMV-specific CTLs expanded with CMV-peptide-pulsed aAPCs expressed a memory phenotype.
Summary and Conclusion: These results demonstrated that HLA-A2 or A24-restrited CMV-specific CTLs with a memory phenotype can be generated ex-vivo using peptide-pulsed gene-engineered aAPCs within a short period of time for clinical use.

P1146

DESIGNING TCR SPECIFIC FOR HUMAN MDM2 TUMOR-ASSOCIATED ANTIGEN FOR ADOPTIVE IMMUNOTHERAPY AGAINST MELANOMA AND MULTIPLE MYELOMA

E Amann[1,*], E Antunes[1], M Theobald[1,2], H Echchannaoui[1,2]
[1]Third Medical Department (Hematology, Oncology and Pneumology), University Medical Center of the Johannes Gutenberg University, Mainz, [2]German Cancer Consortium (DKTK), German Cancer Research (DKFZ), Frankfurt/Mainz, Germany

Background: Adoptive T cell immunotherapy is an attractive approach to treat cancer patients. However, isolating high-affinity tumor-associated antigen (TAA)-specific T cell receptors (TCRs) from the patient is often hampered by self tolerance mechanisms. We have already described that using HLA-A*0201 (A2.1) transgenic mice can circumvent self tolerance to TAAs. The TAA MDM2, the human homologous of the murine double-minute 2 protein, is abnormally up-regulated in soft tissue sarcoma (especially in liposarcoma), multiple myeloma (MM) and melanoma. We generated an HLA.A2-restricted CD8-dependent MDM2 (81-88)-specific TCR from a high-avidity murine CTL clone derived from CD8 x $A2K^b$ transgenic mice to redirect human T cells via retroviral gene transfer. TCR gene transfer however can result in the formation of mixed TCR heterodimers between introduced and native TCR chains leading to potentially self-reactive T cells.
Aims: Our aim is to establish a new approach in adoptive T cell immunotherapy where tumors overexpressing MDM2 can be targeted by human T cells engineered with MDM2 (81-88)-specific TCR. Therefore we aim to design the optimized TCR format.
Methods: For transduction of human T cells we used on the one hand the unmodified wild-type (wt) MDM2-TCR. On the other hand we optimized the wt MDM2-TCR-construct via several molecular modifications. To increase the expression level of transduced TCR we codon-optimized the sequence and cloned it in a bicistronic retroviral vector containing the self-cleaving 2A virus-derived peptide. The risk of formation of heterodimer TCR was reduced via addition of an inter-chain disulfide bond between TCR α and β constant domains. We analyzed the TCR expression level by flow cytometry. The affinity to bind HLA.A2 molecules loaded with the MDM2 (81-88)-peptide was measured by using labeled tetramers. The MDM2 expression of various tumor cell lines was determined by Western Blot. Finally we analyzed the capacity of recognition and killing of tumor cells in a standard cytolytic assay.
Results: We screened melanoma and MM cell lines for MDM2 and HLA.A2 expression. Cell lines which are highly HLA.A2 positive and also expressing MDM2 were tested for recognition by the wt MDM2 (81-88)-specific TCR in a ^{51}Chromium-release assay. Our data demonstrated that these cell lines were efficiently lysed by human T cells transduced with wt MDM2-TCR compared to melanoma or MM cell lines which do not express HLA.A2 or harbor weak MDM2 levels.
Summary and Conclusion: Our data show that the TAA MDM2 is a potential candidate to target melanoma and MM. Adoptive T cell therapy with T cell retrovirally transduced with MDM2 (81-88)-specific TCR may represent a novel approach for treating cancer cells overexpressing MDM2. To prevent the formation of mixed heterodimer TCRs and to improve consequently safety we are also planning to engineer an optimized single chain MDM2-TCR.

P1147

AN EFFICIENT AND COST EFFECTIVE METHOD FOR THE GENERATION OF CLINICALLY RELEVANT NUMBERS OF MYELOID CORD BLOOD-DERIVED DENDRITIC CELLS BY EMPLOYING CLINICALLY APPROVED AGENTS

E Gounari[1,*], A Papadopoulou[1], N Zogas[1], F Zervou[1], A Anagnostopoulos[1], E Yannaki[1], P Kaloyannidis[1]
[1]Gene and cell therapy center, Hematology-BMT unit, G.Papanicolaou Hospital, THESSALONIKI, Greece

Background: The wide clinical application of T-cell based cancer therapy is hampered by the large number of dendritic cells (DCs) required to induce tumor- or virus – specific cytotoxic T lymphocytes and the cost and complexity of existing methods of DC production. New methods and sources are needed in order to obtain clinically relevant numbers of DCs (10^6-10^8) capable to prime naïve T-cells for cytotoxic activity.
Aims: We investigated the potential to generate myeloid DCs at large scale from CD34+cells derived from non-transplantable CB units - obtained under a signed informed consent from the parents.
Methods: Instead of the standard culture dishes or flasks, we used the G-Rex10 bioreactors. To address the ability of DCs expanded from CB-derived

CD34+cells to induce Th1 responses by employing clinically approved stimulating agents, we performed 24h- or 48h- DCs activation by commonly used vaccines [Act-HIV (bacterial form of influenza), Influvac (viral form of influenza), Typhim Vi and BCG] which contain Toll-Like Receptor ligands (TLR-Ls) as adjuvants, in comparison to TLR-L3+TLR-L7/8–stimulation. The mature phenotype of DCs was determined by flow cytometry (CD40, HLA-DR, CD83, and CD86) and the levels of IL-12p70, TNF-α, IL-6 and IL-10 were measured by ELISA. The endophagocytotic activity of DCs was assessed by a dead yeast engulfment assay.
Results: CD34+cells were enriched to more than 90% purity from CB units (n=5) after immunomagnetic separation and cultured in the presence of AB-serum (ABS) and media supplemented with SCF and GM-CSF for 4 weeks followed by IL-4 plus GM-CSF for 1 additional week. The cells were initially plated in a 6-well plate (10^5cells/well) and once they expanded up to $5x10^6$, half were transferred into a G-Rex10 bioreactor and half were cultured in conventional plates in the presence of conditioned medium. The cells were splited at confluency in the culture plates and every 3 days in the G-Rex. The median absolute number of myeloid DCs (CD33+/CD11+) obtained by a 5 week-G-REX10 culture was $1.5x10^9$ whereas the conventionally cultured DCs did not exceed a median number of $10x10^6$ cells. A strong potential for Th1 responses by the expanded myeloid DCs upon stimulation with vaccines was demonstrated by the increased levels of IL-12p70, TNF-α and IL-6 and low to undetectable IL-10 levels which was comparable to TLR-L-induced activation. Importantly, the peak response induced by Act-HIV vaccine was reached after 24h-stimulation, thus preserving the cells from exhaustion in culture. DCs, stimulated by either way, highly expressed the CD40, CD86 and CD83 surface markers and demonstrated significant phagocytotic activity within 1 minute upon stimulation.
Summary and Conclusion: In conclusion, we report for first time an efficient and cost-effective approach for over a 10^4 fold expansion of myeloid DCs from CB-derived CD34+cells displaying high potentiality of Th1 responses induced by clinically approved vaccines. This new method could contribute to a wide application of T-cell based cancer therapy.

P1148

HYPOMETHYLATING AGENT AZACITIDINE INDUCES FOXP3 NEGATIVE HLA-G EXPRESSING IMMUNOREGULATORY T CELLS
P Stamou[1,*], A Vittoraki[1], D Marioli[1], D Kokkinou[1], V Goudogianni[1], E Theofani[1], A Delastic[1], P Zikos[2], A Spyridonidis[1]
[1]Bone Marrow Transplantation Unit, University Hospital of Patras, [2]Department of Hematology, Agios Andreas Hospital, Patras, Greece

Background: A major caveat of FOXP3+ T regulatory cells in immunotherapy against GVHD is their low numbers in circulation and the lack of specific cell surface markers for efficient purification. DNA methylation plays a key role in the regulation of T-cell effector function and cytokine gene expression, indicating a promising role of hypomethylating agents in immunomodulation. Recently it was shown that in-vitro treatment of conventional T-cells with the hypomethylating agent azacitidine (aza) induced FoxP3 expression and converted $CD4^+CD25^-$ cells into immunosuppressive T-cells, the suppressor function of which is independent of FoxP3 expression (Blood 2010;116:129-139), suggesting that aza induced suppressor function depends on the modification of other hypomethylated genes. Human leukocyte antigen-G (HLA-G) is a non-classical HLA class I molecule, shown to exert immunoregulatory functions, the expression of which is epigenetically regulated.
Aims: In this study we investigated whether aza can induce $HLA\text{-}G^+$ immunoregulatory T cells.
Methods: Negative selected T cells from peripheral blood of healthy individuals were stimulated with anti-CD3 plus anti-CD28 coated beads, then treated for 72 hours with aza (0.5-15 mM) in the presence of 50U/ml inteleukin-2 (IL-2). Phenotypical characterization of aza treated cells was performed with flow cytomentry. The effect of aza on HLA-G mRNA transcription and methylation of upstream regulatory HLA-G gene DNA sequence was quantitated with Real time PCR and bisulfite pyrosequencing respectively. Aza-induced $HLA\text{-}G^+$ T cells, were irradiated and then used as third party cells in CFSE based suppression assay. For the analysis of the in-vivo effect of aza on HLA-G expression, peripheral blood mononuclear cells (PBMC) of patients with myelodysplastic syndrome (MDS) were isolated at baseline and after Vidaza treatment and were analyzed for HLA-G expression.
Results: In-vitro treatment of $CD3^+$ T cells with aza induces, dose dependent, de-novo HLA-G expression on stimulated peripheral T cells of healthy individuals. The optimum aza concentration for maximum HLA-G induction with the lowest toxicity in CD3 T cells was determined at 5 mM (surface expressing HLA-G cells: 6,88±3,9%, p=0,0022, fold increase in HLA-G mRNA relevant expression: 18,32±2,33). Aza treatment of FACS-sorted $CD4^+CD25^{neg}HLA\text{-}G^{neg}$ cells induced $CD4^{low}$ $CD25^+$ HLA-G positive cells, revealing that aza induced $HLA\text{-}G^+$ cells are not the result of a selectively expanded preexisting $HLA\text{-}G^+$ population. Methylation analysis of upstream regulatory HLA-G gene DNA sequences and stability assays revealed that induced HLA-G expression is dependent on the presence of aza, and seems to be stabilized by progesterone. In-vitro Aza induced $HLA\text{-}G^+$ cells are immunosuppressive and HLA-G blocking experiments further confirmed that their suppressive function is HLA-G dependent. Phenotypic analysis revealed that aza induced $CD4^+HLA\text{-}G^+$ are FoxP3 negative $CD4^{low}CD25^{high}$. Data regarding surface HLA-G expression on T cells from peripheral blood samples of (MDS) patients under Vidaza treatment, show high intra-variability.
Summary and Conclusion: Conclusively, by using hypomethylating agent aza in-vitro, we generated a $CD4^{low}FoxP3^{neg}$ immunoregulatory population, which expresses extracellular HLA-G and therefore can be easily isolated for adaptive immunotherapies.

P1149

IMMUNOPHENOTYPIC PROFILE AND FUNCTIONAL CHARACTERISTICS OF NK CELLS EXPANDED FROM CYTOMEGALOVIRUS SEROPOSITIVE AND SERONEGATIVE DONORS: IMPLICATIONS FOR NEW STRATEGIES OF ADOPTIVE CELLULAR THERAPIES
N Peragine[1,*], S Pauselli[1], P Mariglia[1], L Piro[2], G Girelli[2], A Guarini[1], R Foà[1], G F Torelli[1]
[1]Department of Cellular Biotechnology and Hematology, [2]Department of Transfusional Medicine, Sapienza University, Rome, Italy

Background: Cytomegalovirus (CMV) infection represents one of the main causes of morbidity and mortality after an allogeneic stem cell transplantation (SCT). Natural killer (NK) cells are known to exert a protective role in CMV infection following SCT. During CMV viremia, proliferation of NK cells is characterized by an increased expression of specific activating receptors such as the NKG2C molecule in association with the CD57 marker; it appears that NKG2C+CD57+ NK cells preferentially expand and exert antiviral activity when isolated from CMV seropositive (+) donors, being therefore identified as memory-like NK cells.
Aims: Aim of our study is to compare the immunophenotypic profile, with particular attention to those antigens involved in anti-CMV response, of NK cells isolated from CMV seronegative (-) and CMV+ donors before and after *ex-vivo* expansion with a GMP-compliant method. The expansion capacity and cytotoxic activity of NK cells expanded from CMV- and CMV+ donors are also compared.
Methods: PBMCs were collected from 14 healthy donors (7 CMV- and 5 CMV+). For NK cell enrichment, $CD3^+$ cell depletion was followed by $CD56^+$ cell selection. Isolated NK cells were cultured for 14 days with autologous plasma, IL-2, IL-15 and irradiated autologous feeder cells. The phenotype of freshly-isolated and expanded NK cells was assessed using mAbs against the CD3, CD16 and CD56 antigens, activating and inhibitory receptors (CD158, CD158a, CD158e, NKp30, NKp44, NKp46, NKG2A, NKG2C, NKG2D and DNAM-1) and activation and maturation markers (CD25, CD69, CD62L, CD57). The cytolytic properties of expanded NK cells against the K562 cell line were tested in a ^{51}Cr release assay.
Results: Freshly-isolated NK cells from CMV- donors were characterized by a significantly reduced proportion of $NKG2C^+$ and $NKG2C^+CD57^+$ cells compared to CMV+ donors (12.9±9.6% *vs* 43.8±25.9%, p=.016 and 4.9±4.2 *vs* 23.5±17.2% p=.002, respectively). Both CMV- and CMV+ donor NK cells could be efficiently expanded *in vitro* under GMP conditions (expansion fold mean 19.9±9.2 and 22.2±11.8, respectively). After expansion, the percentages of $NKG2C^+$ and $NKG2C^+CD57^+$ cells increased significantly only in CMV- donors (p=.017 and p=.023, respectively), becoming comparable to the percentage observed in CMV+ donors (55.5±31.6% *vs* 67.2±36.9%, p=n.s. and 47.7±35.1% *vs* 64.2±34.5%, p=n.s, respectively). In addition, no relationship was observed between the serologic status for CMV and the expression of most of the NK receptors, activation and maturation markers. Finally, no differences were observed in the cytolytic activity against the K562 cell line of expanded NK cells from CMV- and CMV+ donors (mean cytotoxicity at a 50:1 E:T ratio 77±17% and 71±8%, respectively).
Summary and Conclusion: The results hereby presented confirm that a previous contact with CMV induces a specific antigen expression profile of memory-like NK cells active in controlling viral replication. Similar immunophenotypic characteristics, with an increment of $NKG2C^+$ and $NKG2C^+CD57^+$ cells, are also acquired by NK cells isolated from CMV- donors after expansion in GMP-compliant methods. NK cells expanded from CMV- and CMV+ donors present a similar expansion and cytotoxic capacity. Further studies are underway to define whether the acquisition of a specific antigen expression profile by NK cells expanded from CMV- donors corresponds to an increased capacity to control CMV replication. The ultimate goal is to verify whether NK cells expanded from CMV- and CMV+ donors are transplantable and exert clinically relevant antiviral activities.

P1150

GENERATION OF PATIENT-INDIVIDUALIZED AML-REACTIVE DONOR CD8+ T CELLS UNDER GMP-COMPLIANT CONDITIONS FOR ADOPTIVE TRANSFER IN LEUKEMIA PATIENTS AFTER ALLOGENEIC HEMATOPOIETIC STEM CELL TRANSPLANTATION
B Chung-Ueck[1,*], M Frey[1], A Richter[2], M Haak[2], K Langeveld[2], B Busse[2], M Assenmacher[2], H Bönig[3], J Albrecht[1], W Herr[4], U F Hartwig[1]

[1]3rd Department of Medicine – Hematology, Internal Oncology & Pneumology, University Medical Center Mainz, Mainz, [2]Miltenyi Biotec GmbH, Gergisch Gladbach, [3]German Red Cross Blood Donor Service Baden Wuerttember - Hessen, Frankfurt, [4]Department of Internal Medicine III - Hematology & Internal Oncology, University Hospital Regensburg, Regensburg, Germany

Background: Effective treatment of patients undergoing allogeneic hematopoietic stem cell transplantation (AHSCT) for chemo-refractory acute myeloid leukemia (AML) depends on the graft-*versus*-leukemia (GvL) effect mainly mediated by donor T cells. Unfortunately, this effect is frequently hampered by alloreactivity of donor lymphocytes resulting in graft-*versus*-host disease (GvHD) and insufficient GvL-reactivity to prevent relapse. Thus, protocols that include additional cellular therapy to improve antileukemia responses are warranted.
Aims: In the present study we therefore sought to establish a GMP-compliant manufacturing protocol for producing highly AML-reactive, patient-individualized donor CD8$^+$ T lymphocytes to confer sustained antileukemic immunity while reducing the risk of GvHD in leukemia patients post AHSCT.
Methods: Based on a reliable protocol published previously (Albrecht *et al.*, 2011, Cancer Immunol. Immunother.) naïve CD45RA$^+$CD8$^+$ T cells from healthy donors were immuno-magnetically isolated by the MACS^{TM} technology and stimulated with fully HLA class I-matched, primary AML blasts under optimized cytokine conditions comprising Interleukin (IL)-7/-12/-15 and -21 in allogeneic mixed lymphocyte/leukemia cultures (MLLCs) for 28 – 42 days (d). IL-12 was replaced by IL-2 after 14d of culture. In comparative studies MLLCs were then substituted with research-grade reagents or available GMP-grade components (IL-2, -7, -15, -21, TexMACS® medium, human serum) to define optimal GMP-culture conditions. Moreover, a newly developed 96/24 well micro structured cell culture system was tested in first studies to allow the setup of GMP-compliant MLLCs.
Results: So far, five different HLA class I-identical patient-donor MLLCs using naive CD8$^+$ T cells either isolated by the non-GMP-grade *Naïve CD8 T cell isolation Kit* or a GMP-guided *CD45RO depletion/CD8 isolation* procedure were performed and compared for purity of CD45RA$^+$CD8$^+$ cells, growth/expansion rates and numbers of individual AML-reactive T cell populations obtained from these MLLCs following culture in titrated standard research-grade *versus* (*vs*) GMP-grade components. In addition, we examined AML-reactivity of these individual populations by IFN-g ELISpot analyses. While purity was slightly higher (~100% *vs* ~90%) using the *Naïve CD8 T cell isolation Kit*, the frequency and AML-reactivity of T cells obtained upon culture in the presence of research-grade *vs* GMP-grade cytokines was overall comparable. Finally, generation of leukemia-reactive T cells required the presence of human serum despite the use of T cell compatible GMP-medium.
Summary and Conclusion: In summary, AML-reactive T cells can be generated *in vitro* under GMP-grade conditions with comparable frequency and reactivity when compared to antileukemic T cells cultured at standard research-grade level. Further studies to evaluate the biological activity of these GMP-compliant T cells in a patient-tailored preclinical AML xenograft model and to validate the upscaling procedure are in progress.

P1151

LOW-DOSE BORTEZOMIB SENSITIZES MULTIPLE MEYLOMA TO GAMMA-DELTA T CELLS LYSIS

J Cui[1,*], C Niu[1], S Hao[1], H Jin[1], W Han[1], W Li[1]
[1]Cancer center, The first hospital of Jilin University, Changchun, China

Background: Multiple myeloma (MM) is a plasma cell neoplasm that is currently incurable. There is increasing evidence that gamma-delta (γδ) T cells have a potential role in the control of MM. γδ T cells are potent effector lymphocytes of innate immunity involved in anti-tumor immune surveillance. Its lytic activity depends on expression of stress-induced ligands on tumor cells and endogenous pyrophosphate molecules that are overproduced in transformed cells. Low expression of stress-induced ligands, such as NKG2D ligands and TRAIL receptors on MM cells, is one of the mechanisms involved in the immune escape and reducing the response to γδT cells adoptive therapy in MM patients. An interesting therapeutic strategy for MM is the modification of MM cell sensitivity to killing.
Aims: Bortezomib is a proteasome inhibitor to be used in the treatment of MM as first line therapy or after relapse. It can not only induce apoptosis of MM cells, but also some studies have shown that it can enhance the immunogenicity of MM cells. The aim of this study was to investigate the immunomodulatory effects of bortezomib in sensitizing MM cells to the cytotoxicity of γδT cells.
Methods: The proliferation and apoptosis of U266 cells (MM cell line) treated with bortezomib was detected by MTT method and Annexin V in conjunction with propidium iodide (PI) staining method using flow cytometry (FCM) respectively. The expression of NKG2D ligands (ULBP1, ULBP2, ULBP3 and MICA/B) and TNF-related apoptosis-inducing ligand (TRAIL) receptors (DR4, DR5) on the surface of U266 cells pretreated with or without low-dose (10nM) bortezomib for 12h was detected by FCM. γδT cells were induced and expanded by zoledronate and IL-2 from peripheral blood mononuclear cells derived from one MM patient. The expression of Vγ9, CD3, CD69, NKG2D and TRAIL on γδT cells was detected by FCM. The cytotoxicity of γδT cells incubated with or without antibodies of NKG2D and TRAIL against U266 cells pretreated with or without bortezomib was measured by calcein-AM assay.
Results: Low-dose (10nM) bortezomib has little effects on the proliferation and apoptosis on U266 cells compared with those of higher doses of bortezomib. But the expression of ULBP1, ULBP2, ULBP3, MICA/B, DR4 and DR5 on U266 cells was increased after 12 hours' pre-incubation with low-dose bortezomib. γδT cells were successfully induced and expanded *in vitro*. After induction, the percentage of γδT cells was much higher than that prior to induction (89.62±7.51% *vs* 5.23±2.13%, P<0.05). The percentage of the induced γδT cells expressing NKG2D(80.26±6.76%), CD69 (60.36±8.16%) and TRAIL (30.21±5.36%), was also significantly increased. The cytotoxic effect of induced γδT cells on U266 cells pretreated with low-dose bortezomib was much higher than that in untreated group (49.93±4.11% *vs* 21.54±2.81%, P<0.05). The cytotoxicity of γδT cells blocked by NKG2D or TRAIL antibody, against U266 cells pretreated with low-dose bortezomib was much lower than that of γδT cells without being blocked by the antibodies (35.53±3.97% or 40.63±3.22% *vs* 49.93±4.11%, P<0.05), but it was higher than that of γδT cells against the untreated U266 cells (35.53±3.97% or 40.63±3.22% *vs* 21.54±2.81%, P<0.05).

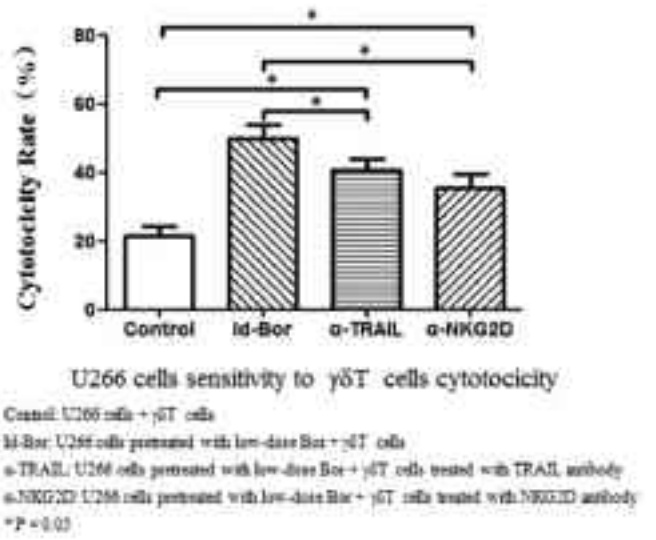

Figure 1.

Summary and Conclusion: These data demonstrated that low-dose bortezomib could increase the sensitivity of MM cells to γδT cells, partly by the upregulation of NKG2D and TRAIL ligands on U266 cells. Low-dose bortezomib might be rational to be used in this study to confirm its immunomodulatory effects without apoptotic effect on MM cells. It also implied that it could be practical and ensure the safety in the clinical application, because the dosage is much lower than that administered in the treatment protocol for MM. This study provides a novel approach for the treatment of MM, and it is worthwhile exploring this combination strategy in the clinical settings.

HUMAN MONOCYTE-DERIVED DENDRITIC CELLS EXPOSED TO HYPERTHERMIA SHOW A DISTINCT GENE EXPRESSION PROFILE AND SELECTIVE UPREGULATION OF IGFBP-6

A Liso[1,*], F Massenzio[1], A Pucciarini[2], B Bigerna[2], P De Luca[3], P Zoppoli[3], F Castiglione[4], M C Palumbo[4], M Conese[5], S Castellani[5], F Stracci[2], M Landriscina[5], G Specchia[6], L Bach[7], B Falini[2]
[1]Medicine, University of Foggia, Foggia, [2]University of Perugia, Perugia, [3]BIOGEM IRGS, Ariano Irpino, [4]National Research Council, Rome, [5]University of Foggia, Foggia, [6]University of Bari, Bari, Italy, [7]Monash University, Melbourne, Australia

Background: Dendritic cells (DCs) have been used for immunotherapy of cancer but their immunostimulatory functions are still incompletely understood. Fever plays a role in activating innate immunity while its relevance in activating adaptive immunity is less clear. Even brief exposure to elevated temperatures significantly impact on the immunostimulatory capacity of DCs, but the molecular mechanisms underlying this effect and their consequences on immune response remain unclear.
Aims: We investigated whether exposure to 39°C induces a distinct gene expression profile program in monocyte-derived DCs and whether this allows identification of genes, not previously known to be part of response to hyperthermia.

Methods: We analyzed the gene expression profiles of normal human monocyte-derived DCs in paired samples from nine healthy adults subjected either to fever-like thermal conditions (39°C) or to normal temperature (37°C) for just 180 minutes.
Results: Short exposure of DCs to 39°C caused upregulation of 43 genes and downregulation of 24 genes. Functionally, the up/downregulated genes are involved in post-translational modification, protein folding, cell death and survival, and cellular movement. Notably, when compared to monocytes, DCs differentially upregulated transcription of the secreted protein IGFBP-6, not previously known to be specifically linked to hyperthermia. Indeed, DCs exposed to 39°C secreted IGFBP-6 which was found to induce chemotaxis of monocytes and T lymphocytes, but not of B lymphocytes.
Summary and Conclusion: Temperature regulates complex biological DCs' functions that most likely contribute to their ability to induce an efficient adaptive immune response. Our data indicate that IGFBP-6 may have relevance in cellular immunity, promoting the extravasation of monocytes and different lymphocyte subpopulations during the immune response.

P1153

ROLE OF LONG PENTRAXIN 3 (PTX3) IN WOUND CLOSURE INDUCED BY BONE MARROW-DERIVED MESENCHYMAL STROMAL CELLS
C Cappuzzello[1,*], A Doni[2], E Dander[1], F Pasqualini[2], M Nebuloni[3], B Bottazzi[2], A Mantovani[2], A Biondi[1], C Garlanda[2], G D'Amico[1]
[1]Centro Ricerca Tettamanti, Clinica Pediatrica, Università Milano Bicocca, Osp. San Gerardo/Fondazione MBBM, Monza, [2]Istituto Clinico Humanitas, IRCCS, [3]Pathology Unit, L. Sacco Department of Biomedical and Clinical Sciences, L. Sacco Hospital, Università degli Studi di Milano, Milan, Italy

Background: Although several studies have shown the capacity of mesenchymal stromal cells (MSCs) to repair and regenerate different tissues, the mechanisms underlying these processes are not understood. Long Pentraxin 3 (PTX3) is a multifunctional protein produced by MSCs and other cell subsets upon activation with inflammatory cytokines. PTX3 is involved in innate immunity, inflammation and extracellular matrix deposition.
Aims: In the present study we analyzed the potential role of PTX3 in wound repair process induced by MSCs.
Methods: PTX3 knockout MSCs (PTX3$^{-/-}$MSCs) were collected from bone marrow of PTX3$^{-/-}$ mice. After 3-5 culture passages the expression of surface markers was analyzed by flow cytometry and their osteogenic and adipogenic differentiation capacity was detected by alizarin red O and oil red S staining, respectively. The ability of PTX3$^{-/-}$MSCs to abrogate T cell proliferation was evaluated by co-culturing MSCs and PBMCs previously activated with Phytohaemagglutinin. Finally, equal number of both PTX3$^{-/-}$MSCs and wild type (WT) MSCs were implanted into excisional wounds created by a biopsy punch on the back of allogenic WT and PTX3$^{-/-}$ mice. Wound area was measured up to 14 day and calculated using an image analysis program. The wound specimens were collected at 2, 7 and 14 days and processed for histological analysis.
Results: We demonstrated that PTX3$^{-/-}$ MSCs, similarly to WT MSCs, displayed typical fibroblastoid morphology and expressed common MSC markers such as CD29, CD90, CD44 and ScaI. Moreover, no contamination by hematopoietic and myeloid components (*i.e.* CD45, CD117, CD11b) was evidenced in both samples. When cultured in adipogenic and osteogenic medium PTX3-deficient MSCs confirmed their ability to differentiate into adipocytes and osteoblasts as well as control cells In addition, they drastically decreased the mitogen-induced proliferation of lymphocyte. Importantly, in a mouse model of wound healing, PTX3$^{-/-}$ MSCs showed a highly significant defect in wound closure compared to WT MSCs, at each time point. Histological evaluation of skin samples treated with PTX3$^{-/-}$ MSCs displayed a reduction of the granulation tissue and an excessive accumulation of fibrin at the 2nd day after injury. Accordingly, PTX3$^{-/-}$ MSCs showed a defective ability to degrade the fibrin matrix *in vitro*. Finally, PTX3$^{-/-}$ MSCs failed to close the ulcers in PTX3$^{-/-}$ mice.
Summary and Conclusion: In conclusion**,** we demonstrated that PTX3 deficiency does not alter the phenotype and the capacity of MSCs to differentiate into mesengetic lineages; however, the production of PTX3 represents an essential requirement for MSC ability of enhancing tissue repair.

Thalassemia major

CHANGES IN ALTERNATIVE IRON OVERLOAD PARAMETERS FOLLOWING 1 YEAR OF DEFERASIROX THERAPY IN PATIENTS WITH NON-TRANSFUSION-DEPENDENT THALASSEMIA: A LONGITUDINAL ANALYSIS FROM THE THALASSA STUDY
J B Porter[1,*], MD Cappellini[2], A Kattamis[3], V Viprakasit[4], K M Musallam[5], Z Zhu[6], A T Taher[7]
[1]University College London, London, United Kingdom, [2]Università di Milano, Ca Granda Foundation IRCCS, Milan, Italy, [3]First Department of Pediatrics, University of Athens, Athens, Greece, [4]Department of Pediatrics and Thalassemia Center, Siriraj Hospital, Mahidol University, Bangkok, Thailand, [5]Novartis Pharma AG, Basel, Switzerland, [6]Novartis Pharmaceuticals, East Hanover, United States, [7]American University of Beirut, Beirut, Lebanon

Background: Patients with non-transfusion-dependent thalassemia (NTDT) can develop iron overload, primarily through a combination of ineffective erythropoiesis, anemia and hypoxia, which increases intestinal iron absorption. The effect of iron chelation therapy on iron overload parameters associated with the NTDT phenotype other than liver iron concentration (LIC) and serum ferritin (SF) has not been extensively studied. THALASSA was a 1-year randomized, placebo-controlled Phase II clinical trial of deferasirox that enrolled 166 NTDT patients with iron overload (LIC ≥5 mg Fe/g dw) (Taher *et al. Blood* 2012). Deferasirox significantly reduced iron overload compared with placebo as shown by dose-dependent reductions in LIC and SF. The same large, controlled dataset has now been used to study the effects of deferasirox on other iron overload parameters.
Aims: To assess the effects of deferasirox over 1 year on alternative iron overload parameters associated with the NTDT phenotype.
Methods: Detailed study design and inclusion/exclusion criteria for THALASSA have previously been described. Briefly, patients aged ≥10 years with NTDT and iron overload (LIC ≥5 mg Fe/g dw) and SF levels >300 ng/mL were enrolled. Patients had not received transfusions within 6 months or chelation therapy within 1 month of study entry. Unplanned transfusions during the study were allowed. Data were summarized descriptively from patients with a value at both baseline and Month 12 of deferasirox or placebo and Pearson's correlation analyses were performed between parameter changes at Month 12 from baseline.
Results: 166 patients with β-thalassemia intermedia (n=95), HbE/β-thalassemia (n=49) or αthalassemia (n=22) were randomized to starting deferasirox doses 5 mg/kg/day (n=55) or 10 mg/kg/day (n=55) with matching placebo at 5 or 10 mg/kg/day (n=56). Alternative iron overload parameters assessed at baseline and Month 12, including absolute change from baseline, are summarized in the Table. Mean change from baseline in the deferasirox 5 or 10 mg/kg/day and placebo groups for pre-dose labile plasma iron (LPI; –0.11, –0.11 and 0.03 Units, respectively), non-transferrin-bound iron (NTBI; –1.17, –0.69, –0.11 µmol/L) and transferrin saturation (TfSat; –6.0, –3.0, 3.0%) indicate greater decreases with deferasirox *versus* placebo. There was also an apparent dose-dependent reduction in hepcidin with deferasirox *versus* placebo, in parallel with reductions in LIC and SF; however, change in hepcidin did not correlate linearly with the change in LIC or SF in the deferasirox 5, 10 mg/kg/day or placebo group (LIC: r=–0.0637, r=–0.0340 and r=–0.2239, respectively; SF: r=–0.0506, r=–0.0574 and r=–0.0388, respectively).

Table 1. Summary of mean (SD) alternative iron parameters at baseline and month 12 of deferasirox treatment or placebo

	Deferasirox		Placebo
	5 mg/kg/day (n=55)	10 mg/kg/day (n=55)	5 and 10 mg/kg/day (n=56)
LPI pre-dose (LPI unit)			
Baseline	0.15 (0.54)	0.15 (0.34)	0.30 (0.61)
Month 12	0.12 (0.31)	0.06 (0.13)	0.33 (0.60)
Change from baseline	–0.11 (0.48)	–0.11 (0.30)	0.03 (0.46)
NTBI pre-dose (µmol/L)			
Baseline	1.76 (2.54)	1.74 (2.14)	1.63 (2.32)
Month 12	0.60 (2.10)	1.06 (3.08)	1.54 (2.34)
Change from baseline	–1.17 (1.88)	–0.69 (2.55)	–0.11 (1.66)
TfSat measured (%)			
Baseline	81.2 (16.6)	83.1 (20.8)	81.6 (21.3)
Month 12	75.3 (24.3)	79.3 (23.7)	83.2 (24.0)
Change from baseline	–6.0 (18.0)	–3.0 (27.0)	3.0 (15.0)
Plasma hepcidin (ng/mL)			
Baseline	6.8 (6.3)	7.0 (9.4)	5.4 (3.6)
Month 12	8.1 (5.2)	4.4 (3.1)	5.8 (7.5)
Change from baseline	–0.3 (9.8)	–2.8 (9.1)	–0.03 (9.7)

SD, standard deviation; LPI, labile plasma iron; NTBI, non-transferrin-bound iron; TfSat, transferrin saturation

Summary and Conclusion: Treatment with deferasirox compared with placebo appeared to reduce TfSat and NTBI as well as LPI, a subfraction of NTBI that is redox-active. The observed reductions in TfSat, NTBI and LPI reflect a range

of actions of deferasirox on cellular and plasma iron pools. Correlations between hepcidin and LIC or SF changes were not robust enough to suggest the clinical utility of hepcidin as a predictor of chelation response; the observed changes in hepcidin require further investigation. Changes in the alternative iron parameters studied here over 1 year in patients treated with deferasirox or placebo were modest and subject to considerable variability. While they provide mechanistic insights into the effects of iron chelation with deferasirox, their clinical utility for monitoring patients is not demonstrated in this analysis. Based on these data, LIC and SF remain the most robust markers of response to chelation therapy in NTDT patients.

P1155

QUANTITATIVE T2* MRI FOR BONE MARROW IRON OVERLOAD ASSESSMENT IN A LARGE COHORT OF THALASSEMIA MAJOR PATIENTS

A Meloni[1], G Restaino[2], G Valeri[3], M Missere[2], V Positano[1], R Renni[4], M Lendini[5], B Piraino[6], A Pepe[1,*]
[1]Cardiovascular MR Unit, Fondazione G. Monasterio CNR-Regione Toscana, Pisa, [2]Dipartimento di Radiologia, Centro di Ricerca e Formazione ad Alta Tecnologia "G. Paolo II", Campobasso, [3]Dipartimento di Radiologia, Azienda Ospedaliero-Universitaria Ospedali Riuniti "Umberto I-Lancisi-Salesi, Ancona, [4]Day Hospital, Ospedale Civile "F. Ferrari", Casarano, [5]Centro trasfusionale, Osp. Giovanni Paolo II, Olbia, [6]U.O. Genetica e Immunologia Pediatrica, Policlinico "G. Martino", Messina, Italy

Background: Multiecho T2* MRI is a well-established technique for cardiac and hepatic iron overload assessment, but there are limited data on its potential to quantify iron in organs other than the liver and heart.
Aims: The aims of this study were to describe for the first time the T2* values of the bone marrow in patients with thalassemia major (TM) and to investigate the correlation between bone marrow T2* and iron deposition in myocardium, liver and spleen.
Methods: 283 TM patients (139 men and 144 women, 8-57 years old, mean age 32.25±8.28 years) enrolled in the Myocardial Iron Overload in Thalassemia (MIOT) network underwent MRI (1.5T). For the measurement of iron overload, fast-gradient-echo multiecho T2* sequences were used. Bone marrow T2* values were obtained on a circular regions of interest (ROI) located in the visible body of the first or second lumbar vertebra. The left ventricle was segmented into a 16-segment standardized model and the T2* value on each segment was calculated as well as the global value. In the liver the T2* value was assessed in a single ROI defined in a homogeneous area of the parenchyma and it was converted into liver iron concentration (LIC). Splenic T2* was estimated in a circular ROI located at the periphery of the posterior segment of splenic parenchyma.
Results: Mean bone marrow T2* was 8.42 ± 6.53 ms. Bone marrow T2* values increased with age in a significant manner (R=0.343, P<0.0001) and were significantly lower in females than in males (Figure 1, left). A weak positive association was found between bone marrow and global heart T2* values (R=0.143, P=0.016). Bone marrow T2* values were negatively correlated with LIC values (R=-0.439, P<0.0001) and mean serum ferritin levels (R=-0.582, P<0.0001). 166 patients (58.7%) were splenectomised and splenectomised patients showed significantly higher bone marrow T2* values than non splenectomised patients (9.78± 6.78 ms *vs* 4.61±3.85 ms, P<0.0001; Figure 1, right). The difference remained significant also correcting for the age, significantly higher in splenectomised patients. For the 87/117 patients with the spleen, the splenic T2* value was assessed (mean value: 17.54±11.76 ms). A significant correlation was detected between bone marrow and spleen T2* values (R=0.448, P<0.0001).

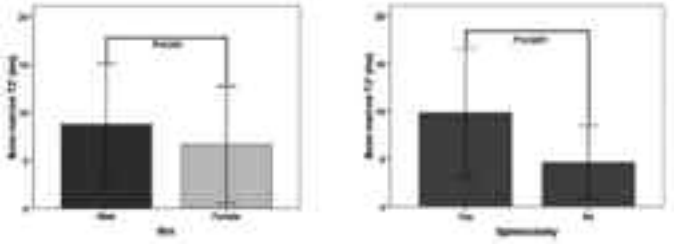

Figure 1.

Summary and Conclusion: In TM patients bone marrow T2* values increased with age. Males showed significantly higher T2* values. Gender-differences of iron deposition were have not been found in other organs, so this difference may be due to the fact that the male sex is associated with severely low bone mass, which can influence the T2* values. However further studies are needed to better characterize the relationship between bone marrow T2* values and bone mineral density (BMD). Bone marrow T2* values were associated with heart, liver and spleen T2* values. Our results are in agreement with that ones of Papakonstantinou et al, who found positive correlations between the degree of hepatic, splenic, and bone marrow siderosis, as expressed by respective R2 values. Splenectomised TM patients showed higher bone marrow T2* values. The bone marrow contains reticuloendothelial cells and, of consequence, it is among the first organs to be affected by iron overload. Splenectomy is normally performed in TM patients with hypersplenism to reduce transfusion requirements.

P1156

BONE MINERAL DENSITY IMPROVEMENT IN PATIENTS WITH THALASSEMIA MAJOR ON LONG-TERM CHELATION THERAPY WITH DEFERASIROX

M Casale[1,*], S Citarella[1], G Amendola[2], G Iolascon[3], S Costantini[4], E De Michele[5], U Pugliese[1], I Tartaglione[1], F Gallicola[1], P Cinque[4], A Filosa[4], S Perrotta[1]
[1]Dipartimento della Donna, del Bambino e di Chirurgia Generale e Specialistica, Seconda Università di Napoli, Naples, [2]Dipartimento di Pediatria, Ospedale Umberto 1, Nocera Inferiore, [3]Diaprtimento di Medicina Fisica e Riabilitativa, Seconda Università di Napoli, [4]UOSD Microcitemia, AORN "A. Cardarelli", Naples, [5]Medicina Immunotrasfusionale, Ospedale San Giovanni di Dio e Ruggi d'Aragona, Salerno, Italy

Background: Osteopenia and osteoporosis represent significant causes of morbidity among patients with thalassemia major (TM). Abnormalities in bone mineral density (BMD) result in high risk for fractures, which can greatly impact patients' quality of life. To date, despite preventative measures, the progressive loss of bone mass, as part of the natural history of TM, cannot be halted. The once-daily oral iron chelator deferasirox (DFX) was shown to be effective in chelating cardiac and hepatic iron with associated clinical benefits. Furthermore, we observed a low prevalence and progression of endocrine diseases in TM patients on long term therapy with DFX, thus suggesting a possible role of this drug in bone metabolism.
Aims: Our aim was to investigate the effect of long-term therapy with DFX on BMD change in patients with TM.
Methods: This was a retrospective cohort study of TM patients followed up in 4 Italian centers. Inclusion criteria were: continuous treatment with DFX for at least 3 years and ≥ 2 DEXA scans (one at the baseline and at least one post baseline) during the study period. Absolute values in g/cm^2 were used for comparative analyses of femoral and lumbar BMD at the baseline and at the end of study in addition to BMD T- score and laboratory values for calcium and phosphorus. The diagnosis of bone disease was based on the indications of the International Committee for Standards in Bone Measurements (ICSBM).
Results: Forty-nine patients (mean age 39 ± 7.3 years) were enrolled. The mean exposure time to DFX and the mean dose were 4.4 ±1.6 years (range: 3-10) and 25.4 ± 5.2 mg/kg/day (range: 16-33), respectively. The mean calcium value remained stable (from 9.3 ± 0.5 mg/dL to 9.2 ± 0.43 mg/dL, p=0.8) and a significant reduction in mean phosphorus (from 4.5 ± 0.7 mg/dL to 4.1 ± 0.6 mg/dL, p<0.001) occurred. A significant increase in mean lumbar spine BMD g/cm^2 was observed (0.895 ± 0.160 g/cm^2 *versus* 0.972 ± 0.150 g/cm^2 – P=<0.001) and the number of patients with diagnosis of osteoporosis in lumbar spine significantly decreased (22 *versus* 13 patients [P=0.02], OR 0.443). With regard to femoral neck assessment, the mean BMD value (0.777 ± 0.155 g/cm^2 at baseline to 0.794 ± 0.124 g/cm^2 at end of study- P=0.190) and the number of osteoporotic patients (17 *versus* 12 patients [P=0.227], OR 0.611) remained stable with a trend towards improvement in both analyses (Table 1). There was no association between bisphosphonate therapy, calcium or vitamin D supplementation and BMD improvement (P>0.100).

Table 1.

Value	Baseline	End of Study	p
Lumbar spine BMD g/cm²	0.895 ± 0.160	0.972 ± 0.150	<0.001
No. of patients with lumbar osteoporosis	22	13	0.02
Femoral neck BMD g/cm²	0.777 ± 0.155	0.794 ± 0.124	0.19
No. of patients with femoral osteoporosis	17	12	0.22

Summary and Conclusion: This is the first study suggesting a beneficial role of long-term chelation with DFX on bone metabolism in TM. These results are clinically relevant, especially considering the available data on the progressive and relentless "aging" of bone, beginning in early childhood. The maintenance of bone mass, as resulted at femoral neck, appears indeed as a success. Furthermore the significant rise in BMD at lumbar spine without association with bisphosphonate therapy achieves an exciting result. As the pathogenesis of TM osteopathy is multifactorial, it is unclear the exact mechanism by which DFX acts on the bone. It probably works through several factors, such as the

maintenance of a good endocrine function and a better compliance with long-life chelation therapy. A specific effect of DFX on bone metabolism is likely, and it needs to be investigated further.

P1157

DEFERASIROX IN PATIENTS WITH TRANSFUSION-DEPENDENT THALASSEMIA RECEIVING LOW TRANSFUSION INTENSITIES

MD Cappellini[1,*], A T Taher[2], A Kattamis[3], A Piga[4], A Al-Jefri[5], C Rose[6], A Vorog[7], E Quebe-Fehling[8], J B Porter[9]
[1]Università di Milano, Ca Granda Foundation IRCCS, Milan, Italy, [2]American University Beirut, Beirut, Lebanon, [3]First Dept of Pediatrics, University of Athens, Athens, Greece, [4]Universitá di Torino, Turin, Italy, [5]King Faisal Specialist Hospital & Research Center, Riyadh, Saudi Arabia, [6]Hôpital Saint-Vincent de Paul, Lille, France, [7]Novartis Pharmaceuticals, East Hanover, United States, [8]Novartis Pharma AG, Basel, Switzerland, [9]University College London, London, United Kingdom

Background: Within the broad spectrum of thalassemia disease severity, transfusion requirement varies substantially, due to splenectomy or local transfusion policy, for example. Blood intake can be relatively low even in some patients with transfusion-dependent thalassemia (TDT). Thus, it is important to assess the safety and efficacy of iron chelation therapy with deferasirox in patients with low blood intake in relation to the rest of the TDT population. The threshold of<7 mL packed red blood cells (pRBC)/kg/month (<7 mL) can be used to define low blood intake, based on the transfusion intensity definition in the deferasirox summary of product characteristics.
Aims: To review the safety and efficacy of deferasirox in TDT patients with low transfusion intensity in parallel to the rest of the study population, as assessed by monthly blood intake.
Methods: Patient data from 6 previously published studies of 1- to 5-year duration in TDT patients treated with deferasirox were pooled; dose regimen varied across studies. Blood intake was calculated and categorized for each year at the threshold of 7 mL pRBC/kg/month. Endpoints were adverse events (AEs; year of onset) and selected laboratory parameters (end of each year). Data are summarized descriptively by year, blood intake of that year and dose. Data are presented for low blood intake patients (<7 mL) in parallel to the rest of the population receiving ≥7 mL pRBC/kg/month (≥7 mL).
Results: Among 2102 included β-thalassemia patients, 10–15% had low blood intake (<7 mL) in each year up to 5 years. Mean age was 22.4 years (≥7 mL patients: 16.9 years). Distribution of these patients in Year 1 by deferasirox dose categories (mg/kg/day) was: ≤10: 3.2%; >10–20: 29.4%; >20–30: 53.5%; and >30: 14%, which was similar to the rest of the study population. Serum ferritin (SF) decreased after 5 years of treatment; from 3171 ng/mL (range 322–18,614; n=306) at baseline to 1188 ng/mL (231–11,307; n=45) (≥7 mL patients: 2728 ng/mL [252–32,068; n=1744] to 1147 ng/mL [107–8531; n=205]). Overall, a dose-response effect was apparent (Figure). Most common (≥5%) AEs suspected related to deferasirox in Year 1 were 7.8% increased blood creatinine (≥7 mL: 6.1%), 7.8% diarrhea (6.1%), 5.2% nausea (4.8%) and 6.5% rash (9.0%). In Year 1, 6/11 patients (54.5%) on ≤10 mg/kg/day had a drug-related AE *vs* 11/48 patients (22.9%) on >30 mg/kg/day (≥7 mL: 31.5 *vs* 43.4%, respectively). Serious AEs (SAEs; ≥0.5%) regardless of causality in Year 1 were 1.6% pyrexia (≥7 mL: 0.6%), 1.0% cholelithiasis (0.3%), 0.7% gastroenteritis (0.5%), 0.7% headache (0.1%), 0.7% gastric ulcer (0.1%) and 0.3% abdominal pain (0.5%). Frequency of AEs and SAEs decreased yearly up to 5 years. Creatinine clearance (CrCl) after 1 year was 152.8±47.7 mL/min (–23.1±37.7) (≥7 mL: 146.4±49.0 mL/min [–21.9±37.3]); this initial reduction was followed by increases in subsequent years. After 1 year, absolute CrCl for patients on ≤10 mg/kg/day was 143.8±57.3 mL/min (≥7 mL: 138.4±46.9 mL/min) and 149.1±37.6 mL/min (≥7 mL: 143.8±46.6 mL/min) for patients on >30 mg/kg/day. The greatest alanine aminotransferase (ALT) improvement of –37.4±73.0 to 55.9±33.8 U/L was seen at doses >30 mg/kg/day after 1 year (≥7 mL: –9.7±51.2 to 53.9±52.6 U/L). After 5 years, the mean ALT was 40.4±40.4 U/L (≥7 mL: 30.2±30.6 U/L).

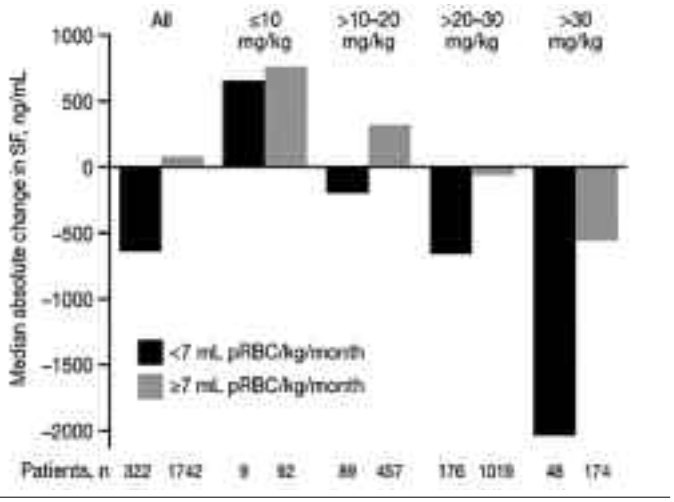

Figure 1.

Summary and Conclusion: Baseline iron burden in patients with low blood intake was substantial and similar to patients receiving ≥7 mL pRBC/kg/month, with the majority of patients receiving >20–30 mg/kg/day deferasirox. High iron burden in low blood intake patients may be due to older age or suboptimal prior chelation. Deferasirox was effective for iron removal in all patients over the long term, with dose adjustment to trends in iron load likely contributing to the degree of iron reduction. While this analysis is limited by heterogeneity of included studies and retrospective categorization of patients, results indicate that when patients are dosed according to the range of iron burden observed here, the 5-year safety profile of deferasirox is consistent across the spectrum of transfusion intensity.

P1158

18 MONTHS DATA OF A RANDOMIZED CONTROLLED TRIAL OF COMBINED DEFERIPRONE (DFP) AND DEFERASIROX (DFX) VERSUS COMBINED DEFERIPRONE AND DEFEROXAMINE (DFO), IN YOUNG B-THALASSEMIA MAJOR

M Elalfy[1], Y Walli[2], A Adly[1,*]Y Henawy[1]
[1]Ain Shams University, cairo, Egypt, [2]Kabbos university, oman, Oman

Background: B-Thalassemia major (B-TM) patients with severe iron overload may require a more efficient therapy for reduction of iron burden. Combined chelation using deferoxamine (DFO) and deferiprone (DFP) is widely used, but the inconvenience of parenteral administration of DFO reduces the effectiveness of this regimen. Minimal data are available on safety and efficacy of the combined two orally active chelators.
Aims: Prospective randomized comparison of safety, efficacy, compliance, treatment satisfaction, and quality of life (QoL) associated with two combination chelation regimens: DFP and DFO *versus* DFP and deferasirox (DFX).
Methods: An open-label trial registered as (NCT01511848) conducted at 2 treatment centers in 96 patients aged ≤18 years with β-TM and severe iron overload (serum ferritin (SF)>2500 µg/ L on chelation monotherapy, with 50% uptrend over last year). Patients were randomly allocated to one of two 18-month treatment regimens. All patients received DFP on 75 mg/kg/day. Those in Arm 1 additionally received DFO on 40 mg/kg/d, while those in Arm 2 additionally received DFX on 20 mg/kg/d. The primary efficacy endpoints were the difference between treatment groups in the change from baseline to 18 months of SF, liver iron concentration (LIC), and cardiac MRI. Safety endpoint was the occurrence of serious adverse events (SAEs). Secondary efficacy endpoints were the changes in QoL, compliance and patient-reported outcomes (PROs).
Results: All the studied patients were comparable regarding baseline clinical and hematological parameters. Observed changes in each arm during therapy were compared using two-way ANOVA for repeated measures. **In DFP and DFO** patients mean SF at 18 months were significantly lower compared to 6, 12 months (P=0.002) and baseline (P=0.01) with percentage of changes of -11.46% and -24.05% respectively. Mean LIC levels at 18 months were significantly lower compared to 6, 12 months (P=0.01) and baseline(P=0.01) with percentage of changes of -18.65% and -39% respectively. Significantly higher mean cardiac T2* at 18 months compared to 6,12 months (P=0.003) and baseline (P=0.002) with percentage of changes + 12.08% and +19.52% respectively. **In DFP and DFX** patients mean serum SF at 18 months were significantly lower compared to 6 and 12 months (P=0.01) and baseline (P=0.002) with percentage of changes of - 17.8% and -36.59% respectively. Mean LIC at 18 months were significantly lower compared to 6 months (P=0.001) and baseline (P=0.003) with percentage of changes of -13.24% and -27.98% respectively. Significantly higher mean cardiac T2* at 18 months

compared to 6 months (P=0.01) and baseline (P=0.004) with percentage of changes + 17.8% and +39.5% respectively. Patients receiving DFP+DFX had significantly lower SF and higher global heart T2* at study end compared to DFP+DFO patients(P=0.001,p=0.002). QoL was significantly improved in both arms while treatment compliance and patients satisfaction were significantly higher in arm 2 compared to arm 1(p<0.001). No SAEs necessitating discontinuation or interruption of therapy in both arms.
Summary and Conclusion: No mortality was reported in this randomized trial. Both forms of combination therapy were effective in reducing iron overload, DFP and DFX patients showed a higher decline in SF, greater improvement in cardiac T2*,higher treatment satisfaction and better compliance than did DFP and DFO patients, with no increased toxicity.

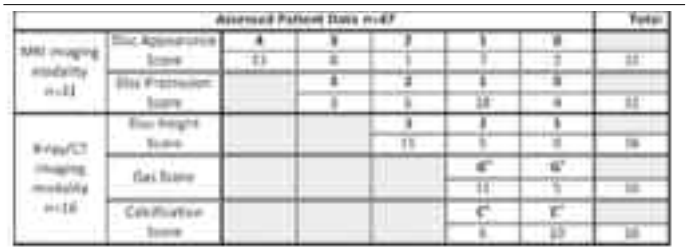
P1159

HIGH PREVALENCE, EXTENT AND SEVERITY OF SPINAL DEGENERATIVE CHANGES IN ADULT THALASSAEMIA PATIENTS PRESENTING WITH BACK PAIN

S Daroge[1,*], Z Moledina[2], MN Syed[3], R Hussain[3], B A Davis[4], E Prescott[4], F Shah[4], J Kumaradevan[5]
[1]medical school, kings college london, [2]medical school, university college London, [3]school of biomedical sciences, St Georges, University of London, [4]Department of Haematology, [5]Department of Radiology, Whittington Hospital, London, United Kingdom

Background: Increasing numbers of adult thalassaemia major (TM) patients present with chronic back or joint pain. Imaging for this shows an increased frequency of severe degenerative changes in spine and a resulting reduction in the quality of life in the most severely affected patients The degenerative changes are thought to be multifactorial with iron chelation, osteoporosis, vitamin D deficiency all thought to play a role.
Aims: To assess the severity of the degenerative changes on imaging and assess factors that may predispose to these in comparison to patients who had not warranted imaging.
Methods: An audit was conducted on the number of adult TM patients routinely transfused at Whittington Hospital who had undergone spinal imaging for back pain. All images were rescored with a standardised scoring system (1) and Table 1. Data on chelation history and co-morbidities including hypogonadism, hypoparathyroidism, vitamin D deficiency and osteoporosis were also collected from medical notes and pathology reports.
Results: Of 106 patient records reviewed, 47 had undergone imaging of the spine because of back pain at a median age of 45 years. The median age of the remaining 59 patients who had not required investigation was 35 years. Of the imaged cohort, 31 had been assessed using MRI and 16 by means of CT or plain x-rays. Of the MRI patients, 13/31 (42%) were found to have the most severe degree of disc degeneration with respect to disc appearance (grade 4) often at multiple levels. In terms of disc displacement, 18/31 had grade 1 change (annular disc bulge) and 9/31 patients had focal disc protrusion or extrusion (grade 2 and 3, respectively). Moderate to marked reduction in disc height (grade 2 and 3) was demonstrated in all 16 patients who had undergone plain x-rays or CT. The prevalence of degenerative spinal changes among the entire cohort of 106 patients was highest in patients >40 years, with 60% of this age group being affected; however, these changes were also evident in 35% of patients aged<30 years and 35% of those aged between 31-40 years. 32% of affected patients received physiotherapy, 19% received spinal and/or nerve root injections and 9% underwent surgery. All patients with signs of degenerative disease were previously chelated with desferrioxamine and 87% had also received deferiprone. 11% had documented skeletal complications with desferrioxamine, and 19% had a history of knee pain with deferiprone.
When comparing imaged patients to those who were not imaged, imaged cohort 79% had osteoporosis *versus* 70% not imaged; 79% were hypogonadal *versus* 66%, 83% were vitamin D deficient *versus* 95% and 21% had hypoparathyroidism *versus* 15%. 81% were on bisphosphonates *versus* 66%. Surprisingly, 17% of these patients had concurrent extramedullary haematopoiesis despite optimal transfusion.

Table 1.



Summary and Conclusion: These findings show that multi-level degenerative disc disease was present in 94% of the patients imaged and was present in all age groups with increasing frequency in those over the age of 40 years. These changes are more common in patients with osteoporosis, hypogonadism and hypoparathyroidism, suggesting that these may be contributory factors. These along with iron chelation and bone protection therapy may have a role in the early onset and increased prevalence of degenerative joint disease. 1. Desigan S, Hall-Craggs MA, Ho CP, Eliahoo J, Porter JB. Degenerative disc disease as a cause of back pain in the thalassaemic population: a case-control study using MRI and plain radiographs. Monasterio CNR-Regione Toscana, Pisa, [3]Pediatria, Adolescentologia e Talassemia, Arcispedale "S.Anna", Ferrara, [4]Centro Talassemie ed Emoglobinopatie, Ospedale Meyer, Firenze, [5]U.O.S. Talassemia, A.O. Umberto I, Siracusa, [6]Pediatria, Ospedale "G. Da Saliceto", Piacenza, [7]Dipartimento Materno-Infantile U.O. Pediatria Oncoematologia, Azienda Ospedaliero-Universitaria di Parma, Parma, [8]"Unità Operativa Semplice di Talassemia", P.O. Lentini ASP 8 Siracusa, Lentini, [9]Struttura Complessa di Cardioradiologia, P.O. "Giovanni Paolo II, Lamezia Terme, Italy

Background: Pathophisiology and timing of body iron burden in pediatric thalassemia major (TM) patients is so far not well known. Moreover, there are no prospective studies comparing the effectiveness of the three iron chelators commercially available in preventing or decreasing iron overloading in the heart and liver.
Aims: The aim of this study was to evaluate prospectively the effectiveness of 3 iron chelators in monotherapy in pediatric TM patients by quantitative magnetic resonance imaging (MRI) in the heart and in the liver over a follow up at 18 months.
Methods: Among the first 1545 TM patients consecutively enrolled in the MIOT (Myocardial Iron Overload in Thalassemia) network, we evaluated the fifty-two pediatric patients (31 male, mean age 14.06 ± 2.77–range 7.1-17.8 years) who had been received only one chelator in monotherapies between the two MRI scans. Cardiac and liver iron overload was determined as variation of the MRI signal in multiecho T2* sequences. Biventricular function parameters were quantitatively evaluated by SSFP cine images. Due to the low sample size no inter-treatment comparisons were performed and intra-treatment comparison was performed only in the DFX group.
Results: Three groups of patients were identified: 6 patients (mean age 10.02 ± 2.17 years) treated with desferioxamine (DFO – mean dosage 43.67± 6,77 mg/kg/die**),** 7 patients (mean age 15.51 ± 1.73 years) treated with deferiprone (DFP– mean dosage 75± 9,23 mg/kg/die) and 34 patients (mean age 14.49 ± 2.66) treated with deferasirox (DFX – mean dosage 27,17 ± 6,55 mg/kg/die). Compliance was excellent/good in all three groups. At baseline in DFO and in DFP group no patient showed a global heart T2* value lower than 20 ms. In all 3 groups all patients who showed no cardiac iron overload at baseline maintained at follow-up (FU) the same status. At baseline in DFX group 6 patients (17.6%) had pathological heart T2* values; at FU 4 pts (66.7%) showed normal global heart T2* values (≥ 20 ms), while 2 pts (33.3%) maintained pathological global heart T2* values. Patients in DFP had higher global heart T2* values at baseline (DFP 35.25 ± 4.98 ms >DFX 33.18 ± 5.47 ms >DFO 31.86 ± 10.53 ms) and at follow-up (DFP 39.45 ± 6.07 ms >DFX 36.46 ± 5.84 ms >DFO 33.65 ± 7.88 ms). In the DFO group at baseline 1 patient showed pathological LVEF and he recovered at the follow up. In the DFP group at baseline 2 patients showed pathological LVEF and both recovered at the follow up. In the DFX group at baseline 3 patients showed pathological LVEF and 2 recovered at the follow up, conversely 7 patients with normal LVEF at baseline showed pathological LVEF at the follow up. In the DFO group the percentage of patients with MRI LIC >3 mg/g/dw went up from 83% to 100%. In the DFP group all patients showed MRI LIC >3 mg/g/dw at baseline and they maintained this status at the FU. In the DFX group the percentage of patients with MRI LIC >3 mg/g/dw went down from 70% to 50%. The MRI LIC mean difference was -2.00 ± 4.53 mg/g/dw (P=0.004).

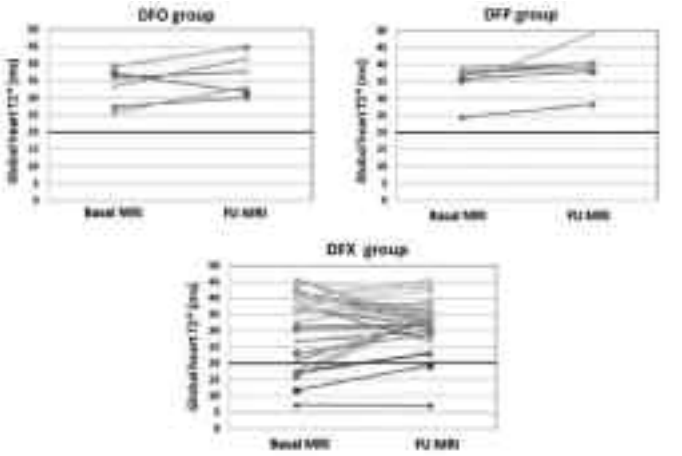

Figure 1.

Summary and Conclusion: This longitudinal analysis confirms significant rate of iron overload even in very young TM population, in particular in the liver. In this population, DFP seems to be more effective in heart with a concordant positive effect on the global systolic function. Conversely, DFX seems to be more effective in the liver. However, further prospective trials are needed on larger study population to confirm the data.

P1161

TISSUE IRON DEPOSITION AND MARKERS OF GLUCOSE DYSREGULATION IN THALASSEMIA MAJOR

N Karadas[1,*], S Bayraktaroglu[2], Z O Sivis[1], D Karapinar[1], C Balkan[1], K Kavakli[1], Y Aydinok[1]
[1]Pediatric Hematology, [2]Radiology, Ege University Hospital, Izmir, Turkey

Background: Impaired glucose tolerance (IGT) and diabetes mellitus (DM) remain a significant problem for thalassemia major (TM). Iron toxicity induced insulin resistance and decreased insulin secretion contribute to glucose dysregulation (GD) in TM.
Aims: The aim of this study is to evaluate somatic iron depositions and biochemical markers of glucose metabolism in TM for having an insight for early identification of patients with increased risk for GD.
Methods: TM patients aged ≥8 years and without insulin dependent DM were invited to participate to the study. Homeostatic model assessment and oral glucose tolerance test (OGTT) were performed. MRI was used to assess hepatic, pancreatic and cardiac iron burdens. Cardiac T2*<20 msec and pancreas R2*>50 Hz was considered as cardiac and pancreatic iron loading. Glucose metabolism assessed by OGTT classified according to WHO criteria. HOMA-IR ≥2.5, insulinogenic index (II)<0.4 and disposition index (DI)<1 was associated with insulin resistance, decline in insulin secretion and impaired beta cell function respectively. Relationship between iron stores and markers of glucose metabolism was analyzed by using correlation and sample T test procedures. Differences were considered statistically significant at a level of p<0.05.
Results: The patient cohort (24 male, 18 female) ranged from 10–33 years of age (19.7±6.4) and was on regular transfusion for 18±7.5 years and on chelation therapy. Family history indicated DM in 42% of the cohort. Patients had ferritin (SF) of 1972±1968 ng/ml (291-8757), liver iron (LIC) of 6.8 ±9.1 mg/g (0.4-38.7) and cardiac T2* of 23±6.7 msec (6.2-33.7). Normal liver (<3.2mg/g) and cardiac (T2*>20 msec) iron was observed in 50% and 70% of patients, respectively. LIC was 3.2-7mg/g in 17.5%, 7-15 mg/g in 20% and >15 mg/g in 12.5% of the cohort. All patients had normal cardiac function and none had chronic liver disease. The patient cohort had BMI of 19.9 ±3.2 kg/m^2, only 2 patients were overweight. OGTT revealed IGT in 8 (18.5%) and DM in 3 (7%) patients. The patients with GD were significantly older and had a higher prevalence for family history of DM than those of normal glucose metabolism. Most patients with GD (8/11, 73%) had decline in insulin secretion and the rest of them (3/11, 27%) had insulin resistance. All patients with IGT and DM had a pancreas R2*>50Hz. Although, no patient with normal OGTT had insulin resistance, 13/25 (50%) had decline in insulin secretion in whom only 3 had a pancreas R2*>50Hz. In this cohort, 6 of 25 (25%) with normal insulin secretion had a pancreas R2*>50Hz. The cohort with abnormal OGTT showed a significantly higher pancreas R2* (p=0.001) than those of normal OGTT. Mean SF, LIC and cardiac T2* did not differ significantly between patients with abnormal and normal OGTT. None of the patients with pancreas R2*<50 Hz had a cardiac T2*<20ms. Although, LIC showed a negative correlation with cardiac T2* (r=-0.47, p<0.005), there was no significant correlation between LIC and pancreas R2*. Patients' age showed a positive correlation with pancreas R2* (r=0.43, p<0.01) but no correlation with LIC or cardiac T2*.
Summary and Conclusion: Age and family history in TM have an impact on GD. This study confirmed that impaired insulin secretion was more prevalent than insulin resistance and pancreas R2* provide useful information for predicting risk for GD in TM. Patients with pancreas R2*>50 Hz but still preserve normal insulin secretion may have benefit from intensive iron chelation for reserving pancreatic function. Prospective follow up is required in patients with impaired insulin secretion while pancreas R2*<50 Hz to determine its functional significance on developing GD.

P1162

PRESENCE OF THE IVS1-6 MUTATED ALLELE PREDISPOSES PATIENTS WITH MAJOR B THALASSAEMIA TO EXTRAMEDULLARY HAEMATOPOISES

E Vlachaki[1,*], D Adamidou[1], A Agapidou[1], S Theodoridou[1], E Voskaridou[2], G Spanos[1], F Klonizakis[1], L Maniati[1], N Sousos[1], K Psarras[1], P Boura[1]
[1]Ippokratio Hospital, Thessaloniki, [2]Laiko Hospital, Athens, Greece

Background: Since the initiation of regular transfusion programmes from an early age for all major thalassaemic patients, extramedullary haematopoises (EMH) has not been considered a clinical issue any more. In contrast, haematopoises at sites other than the bone marrow is sporadically described only within the intermedia thalassaemia cohort.
Aims: To record the incidence of EMH in chronically transfused major thalassaemic patients followed at our institution and investigate for possible risk factors associated with its occurrence.
Methods: We retrospectively analysed the medical notes and images of 104 major thalassaemic patients (45 male /59 female) with a median age of 32(19-47) years followed in our comprehensive care unit for a period of 30(18-45) years. Time point for the evaluation of all relevant demographic and biological factors was either the first positive or the last negative MRI scan for patients with or without EMH respectively. Age at first transfusion was 1.3(0.1-6.2) years and are regularly transfused (2 units RBC/15days) in keeping with current recommendations and targeting pre-transfusion Hb above 9-10mg/dl. 35/104 underwent splenectomy at the age of 17(8-27) years and 66 had cleaved HCV with no active HCV case in the present. In terms of ABO/Rh blood group 45 were A, 16 O, 8 B, 21 AB while 95 were Rh/D positive with 11/104 being alloimmunized against RBC antigens. We applied MRI T2* for the evaluation of liver and cardiac iron accumulation and patients were grouped in terms of severity based on readings. Chelation therapy was deferasirox for 58 patients, 14 received Desferrioxamine (DFO), 9 Ferriprox and 23 combination of DFO+Ferriprox. Ferritin levels were 1580(195-6320) ng/ml. Within the female group 13/59 had at least one successful pregnancy. With regard to genotype patients were categorized as follows: 19 IVS 1-110/IVS1-110, 12 IVS 1-110/cd 39, 8 cd39/cd39, 34 IVS 1-110/other, 22 IVS 1-6/other, 24 various and 7 unknown. We used the annual routine MRI scanning for the detection of possible EMH sites.
Results: EMH was revealed in 15/104(14%) patients, 10 female/5 male, aged 30(23-39) years. In all cases EMH was an incidental finding across the spinal cord without any clinical signs of compression or inadequacy to retain pre-transfusion Hb levels. The median period from last negative to first positive MRI scan was 2.6 (1-5) years and the follow up period since the first EMH detection is 2(0.2-2.7) years without signs of radiological or clinical progression. In a univariate analysis we found that the presence of IVS 1-6 either in homozygosity or compound heterozygosity was significantly related with the development of EMH (p<0.05). None of all the other demographic and biological factors was found to be related with the presence of EMH. Of note, splenectomy despite what was expected was not correlated with EMH.
Summary and Conclusion: To date, we first record a profound incidence of asymptomatic extramedullary haematopoiesis in well transfused major thalassaemic patients, detected mainly within the last 5 years. Whether this finding is related to amelioration in imaging techniques or truly constitutes a new emerging phenomenon genetically determined, particularly for patients carrying the IVS1-6 mutation, merits further investigation.

P1163

BONE MINERALIZATION AND ENDOCRINE DISEASE IN PATIENTS WITH BETA-THALASSEMIA INTERMEDIA (TI)

M Baldini[1], G Graziadei[1,*], A Marcon[1], S Forti[1], R Cassin[1], A Orsatti[2], MD Cappellini[2]
[1]Medicine and Medical Specialties, IRCCS Foundation Ca' Granda Ospedale Maggiore Policlinico, [2]Clinical Sciences and Community Health, University of Milan, IRCCS Foundation Ca' Granda Ospedale Maggiore Policlinico, Milan, Italy

Background: Osteopathy and endocrine disease are well-studied complications in β-thalassemia Major (β-TM), while prevalence in β-thalassemia intermedia (β-TI), a non-transfusion dependent thalassemia (NTDT), is less known.
Aims: To retrospectively evaluate bone mineralization, endocrine function and thalassemia-related factors in a series of TI patients (pts).
Methods: Seventy TI patients (37 M, 33 F; 41±12 years) were evaluated.

Among them, 37 (52%) had never been transfused, 33 (66%) had been transfused (24 [34.2%] occasionally, 9 [12.8%] regularly every 90 to 120 days); 34 (48.5%) had undergone splenectomy, 39 (55.7%) were on chelating drugs, and 11 (15.7%) were on hydroxycarbamide. The patients were scanned by dual energy X-ray absorptiometry at vertebral and femoral sites; in addition, blood and urine tests were performed to evaluate the following endocrine glands: pituitary, thyroid, parathyroids, gonads, adrenals and pancreas. Univariate and multivariate statistical analysis were used to analyze the relationships between bone mineralization and the following variables: demographic, clinical, hematological, and endocrine-metabolic data; iron status with liver iron concentration (LIC from T2*); and treatment.
Results: The prevalence of bone demineralization was high in the β-TI patients studied; conversely, the prevalence of endocrine defects was no different from that expected in the general population.

Table 1.

T-score V*†	Z-score V§+	T-score FT*	Z-score FT§	T-score FC†	Z-score FC+
-2.0±1.3	-1.7±1.3	-1.0±1.0	-0.8±1.0	-1.1±1.0	-0.7±1.0

***** *p<0.01;* † *p<0.01;* § *p<0.01,* + *p<0.01*

As shown in the table, bone mineralization indices were significantly lower in the lumbar spine than at femoral sites; there were no gender differences. Osteopenia was found in 29 (41%) pts and osteoporosis in 25 (36%), with selective vertebral localization in 19 (27%), and femoral localization in 1 (1%); both sites were affected in 5 pts (7%). The most significant correlation found with multivariate analysis was between bone mineralization and splenectomy, with splenectomized pts showing a worse bone status at all sites. A significant correlation was also found between bone mineral density indices and iron chelation therapy, irrespective of the drug used. The presence of a more favourable bone condition in non-chelated pts may be due to better iron status. Among the pts with LIC >3, significant differences were found in spine mineralization, BMD, T-score and Z-score lower in the group with LIC >7 *vs* those with LIC between 3 and 7. By contrast, modulation of fetal haemoglobin production with hydroxycarbamide appeared uncorrelated to bone condition.
Summary and Conclusion: from the present study, osteopathy appears to be an important complication of β-TI, with major involvement of axial bone. On the other hand, the high prevalence of endocrinopathies well described in β-TM was not confirmed in our pts with β-TI. As both the severity of anemia and the clinical sequelae span a broad spectrum in this disease, the main factors related to the risk of developing osteopathy and/or endocrinopathy should be better clarified through clinical studies. Close surveillance, preventive intervention and early management are essential to secure bone health and improve quality of life in this NTDT.

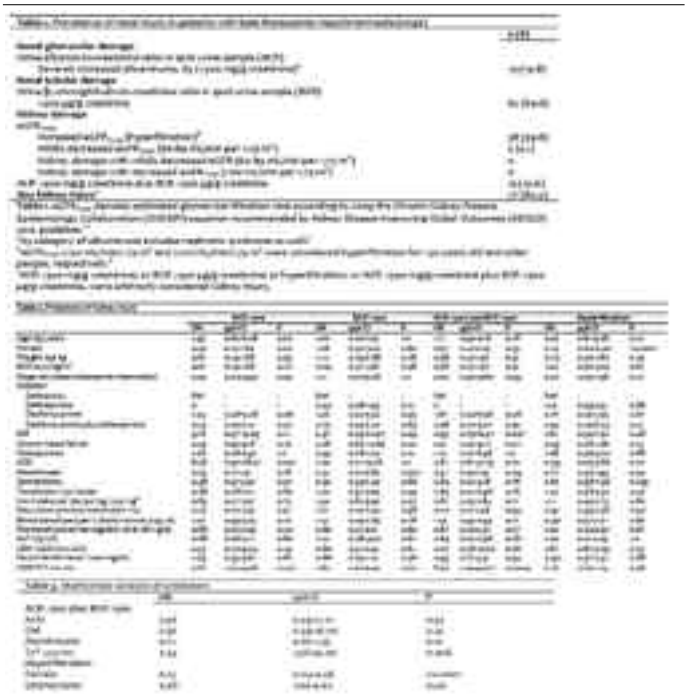
P1164

INVESTIGATION OF RENAL FUNCTION DISORDERS IN PATIENTS WITH THALASSEMIA AND THEIR RELATION WITH IRON OVERLOAD

B Deveci[1], A Kurtoglu[2], E Kurtoglu[3,*], T Toptas[4]
[1]hematology, ali osman sonmez oncology hospital bursa, bursa, [2]Biochemistry, [3]hematology, Antalya Education and Research Hospital, Antalya, [4]hematology, Van Education and Research Hospital, Van, Turkey

Background: Thalassemia major is an inherited disease that is characterised with defective globulin chains of hemoglobin molecule and it causes tissue and organ damage by ineffective erythropoiesis, chronical hypoxia, transfusion dependency and oxidative stress.
Aims: We planned to evaluate the organ involvement in thalassemia, primarily kidney.
Methods: 96 individuals with diagnosis of thalassemia major and transfusion dependent thalassemia intermedia were included. All of the patients were adults and duration of transfusion dependency was over 10 years. In addition to routine examination, spot urine beta-2 microglobulin levels were measured.
Results: Among 96 thalassemic patients prevalence of any kidney injury was 80,2% (Table 1). When kidney injury is evaluated as, Renal glomerular damage, Renal tubular damage and Kidney damage; Renal tubular damage is the overriding form between them (%64,6) (Table 1). According to our study, predictors of Renal glomerular damage, Renal tubular damage and Kidney damage and hyperfiltration were; Cardiac T2* value ≤20 ms [Odds ratio (OR): 3.87, 95% Confidence Interval (95% CI): 1.10-13.46, p=0.013]; alendronate medication [OR: 0.31, 95% CI: 0.12-0.80, p=0.007]; female gender [OR: 0.13, 95% CI: 0.04-0.38, p<0.0001] and splenectomy [OR: 3.08, 95% CI: 1.04-9.93, p=0.04] respectively (Table 2-3).

Table 1.



Summary and Conclusion: Our study is one of the few studies which evaluates renal involvement in thalassemia in adults. It is concluded that, renal damage prevalence is higher in thalassemic patients. It was observed that, degree of cardiac iron overload, male gender, splenectomy and not to use alendronate increase the risk of renal involvement. At the end of this study prevalence of kidney injury was found higher than previous studies but exact interpretation could not be made about physiopathology of possible causes. Therefore in thalassemia, new studies with large groups of patients are needed to evaluate kidney injury with other physiopathological mechanisms aside from iron overload such as oxidative stress.

ASSOCIATION OF OR51B2 SEQUENCE VARIATIONS WITH RESPONSE TO HYDROXYUREA THERAPY IN IRANIAN PATIENTS AFFECTED WITH BETA-THALASSEMIA INTERMEDIA

M Karimi[1,*], M Khavari[2], T Zarei[1], S Haghpanah[1], HR Miri[2], A Ebrahimi[1], M Moghadam[1]
[1]Hematology Research Center, Shiraz University of Medical Sciences,, Shiraz, [2]clinical Biochemistry department of biology faculty of sciences university of Zabo, Zabol, Iran

Background: Enhanced fetal hemoglobin (HbF) production in β-globin gene disorders improves the clinical symptoms of the underlying disease such as β-thalassemia intermedia (β-TI). Hydroxyurea (HU) activates γ-globin gene, results in increasing of HbF synthesis. The olfactory receptors (ORs) are members of a G-protein-coupled receptors (GPCRs) large family, which arising from single coding-exon genes. Elements of the ORs gene cluster might play a regulatory role in γ-globin gene expression.
Aims: We aimed to assess the possible relationship between response to HU and *OR51B2* gene sequence variations in Iranian patients affected with β-TI.
Methods: In this cross sectional study 100 patients affected with β-TI from Southern Iran were randomly enrolled between February 2012 and October 2013. All patients were treated with HU. Based on the need to blood transfusion and hemoglobin level, our patients were divided into two groups: good responder and poor responder.
Results: We compared demographic and clinical variables between good and poor responders. Only Nucleated Red Blood Cells showed a significant association with response to HU (P=0.045). From all evaluated SNPs, only rs10837814 SNP in *OR51B2* gene was significantly associated with response

to HU, as a significantly higher frequency of CT genotype (89.3%) was observed in patients with good response compared with CC (67.3%) and TT genotype (88.2%) (P=0.038). We also find three novel nucleotide variations (-665 (A→C), -1301 (T→G),-1199 delA) who had good response to HU therapy in our study.
Summary and Conclusion: It seems that rs10837814 SNP in OR51B2 gene probably can be used as a marker for response to HU in β-TI patients, but further studies by larger study groups is needed for more evaluation in future.

P1166

LEFT VENTRICULAR GLOBAL FUNCTION INDEX BY CMR IS MORE STRONGLY ASSOCIATED TO DIFFERENT PATTERNS OF MYOCARDIAL IRON OVERLOAD THAN THE GLOBAL SYSTOLIC FUNCTION

A Meloni[1], V Positano[1], M Benni[2], G Serra[3], N Romano[4], C Salvatori[5], A Vallone[6], C Tudisca[7], D De Marchi[1], A Pepe[1,*]
[1]Cardiovascular MR Unit, Fondazione G. Monasterio CNR-Regione Toscana, Pisa, Italy, Pisa, [2]Servizio di Immunoematologia e Centro Trasfusionale, Policlinico S. Orsola "L. e A. Seragnoli", Bologna, [3]Presidio Osp. n.2 "S. Giuseppe da Copertino", Copertino (LE), [4]S.C. Medicina Trasfusionale, AO Arcispedale "S. Maria Nuova", Reggio Emilia, [5]Unità Operativa Sistemi Informatici, Fondazione G. Monasterio CNR-Regione Toscana, Pisa, Italy, Pisa, [6]Istituto di Radiologia, Az. Osp. "Garibaldi" Presidio Ospedaliero Nesima, Catania, [7]Istituto di Radiologia, Policlinico "Paolo Giaccone", Palermo, Italy

Background: The Cardiovascular Magnetic Resonance by the multislice multiecho T2* technique allows to detect different patterns of myocardial iron overload (MIO). Moreover, the analysis of cine images allows the quantification of the left ventricular global function index (LVGFI) that combines the LV stroke volume, endsystolic and end-diastolic volumes, as well as LV mass. A LVGFI<37% was shown to be strongly predictive of cardiovascular events.
Aims: We aimed to verify the association between different patterns of MIO and the LVGFI *vs* the LV ejection fraction (EF) in thalassemia major (TM) patients.
Methods: We considered 812 TM patients (391 M, 30.4±8.6 years), consecutively enrolled in the Myocardial Iron Overload in Thalassemia (MIOT) network. The T2* value in all the 16 cardiac segments was evaluated. LVGFI and LVEF were quantitatively evaluated by SSFP cine images. Heart dysfunction was diagnosed in presence of LVEF<2 standard deviations (SD) from the mean value normalized to age and gender.
Results: We identified 4 groups of patients: 138 with homogeneous MIO (all segments with T2*<20 ms), 97 with heterogeneous MIO (some segments with T2*<20 ms, others with T2*≥20 ms) and significant global heart iron (global heart T2*<20 ms), 238 with heterogeneous MIO and no significant global heart iron, and 339 with no MIO (all segments with T2*≥20 ms). The mean LVFGI was significantly different among the 4 groups (Figure, up). Compared to the group with no MIO, all the other 3 groups were significantly more likely to have a LVGFI<37%, conversely, only the groups with homogeneous MIO and with heterogeneous MIO and significant global heart iron showed a significant higher risk to have LV dysfunction. For all groups the association between different patterns of MIO with a LVGFI<37%, was stronger than the association with a LV dysfunction (Figure, bottom).

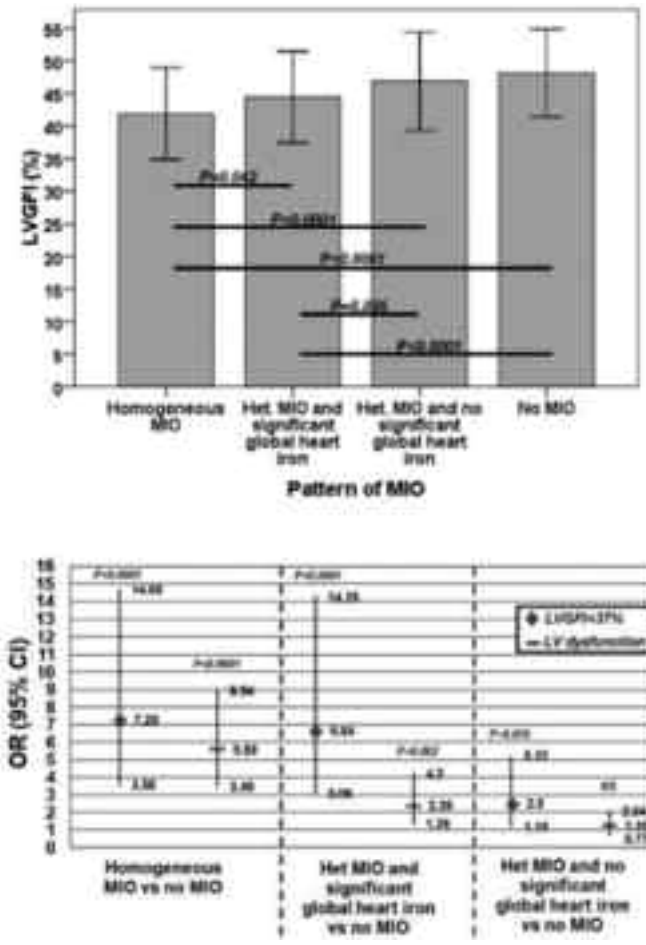

Figure 1.

Summary and Conclusion: LVGFI is a functional parameter integrating structural as well as mechanical behaviour more strongly associated to different patterns of MIO than the LVEF. Thus, a LVGFI<37% could better identify a significant higher risk of adverse cardiovascular events beyond heart failure in iron loaded patients.

P1167

PROSPECTIVE MRI STUDY IN PEDIATRIC THALASSEMIA MAJOR (TM) PATIENTS IN THE MIOT NETWORK: A TOOL TO STRENGTHEN MEDICAL DECISIONS

M Casale[1], A Meloni[2], L Cuccia[3], D D'Ascola[4], V Caruso[5], A Quarta[6], MC Putti[7], C Tudisca[8], A Filosa[1], A Pepe[2,*]

Ematologia con Talassemia, ARNAS Ospedale Civico, Palermo, [4]U.O. Microcitemie, A.O. "Bianchi-Melacrino-Morelli", Reggio Calabria, [5]Centro Microcitemia, ARNAS Garibaldi P.O. Garibaldi-Centro, Catania, [6]Ematologia, Osp. "A. Perrino", SS per Mesagne, Km 7 Brindisi, [7]Clin. di Emato-Oncologia Pediatrica - Dip. di Pediatria, Università di Padova / Azienda Ospedaliera, Padova, [8]Istituto di Radiologia, Policlinico "Paolo Giaccone", Palermo, Italy

Background: Iron overload, due to regular blood transfusions, leads to significant morbidity and mortality in TM patients. Recent MRI studies have demonstrated significant hepatic, cardiac and pancreatic iron overload even in TM patients less than 2 years, contradicting historical belief that children younger than 10 years would be at low risk for developing systemic iron loading. MRI deployment alongside appropriate modification of patients' and doctors' approach to chelation therapy were shown to be the most likely cause for reduction in morbidity and mortality in adult TM patients but to date very little is known about the evolution of iron overload in children with TM and the impact of MRI implementation on pediatric hematologists' behavior.
Aims: Our aim was to investigate the effect of MRI deployment on the longitudinal evolution of iron overload and on the alteration in management of chelation therapy in a large cohort of TM children.
Methods: This was a prospective MRI survey of TM children (<18 years) enrolled in the MIOT (Myocardial Iron Overload in Thalassemia) Network who performed a baseline and a follow-up (18 +/- 3 months) MRI scan. Myocardial

and hepatic iron burdens were quantified by the T2* technique and liver T2* was converted into liver iron concentration (LIC). Clinical and laboratory details were collected in a web based database for each patient included into the study.
Results: At the baseline mean age of the 68 TM children (42 M) was 13.74 ± 3.09 years. Patients started regular transfusions and chelation therapy at a mean age of 1.57 ± 0.82 and 2.95 ± 1.08 years, respectively. Table 1 shows the evolution of different iron overload risk classes between the baseline and the FU. The percentage of liver iron overloaded patients who achieved a normal LIC value was 18.5% *versus* 35.7% of patients with baseline normal LIC who switched to pathological LIC at the FU. Regarding cardiac iron burden, 25% of overloaded patients achieved a normal T2* value at the FU *versus* 1.9% of patients who newly developed cardiac iron overload. Adjustments in chelation therapy were made only in 28% of patients with hepatic iron overload but in 56% of patients with cardiac iron overload at baseline (P=0.105 and P<0.001, respectively).

Table 1.

		FU LIC			
		<3 mg/g dw	3-7 mg/g dw	7-15 mg/g dw	≥15 mg/g dw
Baseline LIC	<3 mg/g dw (N=14)	9	4	1	0
	3-7 mg/g dw (N=21)	6	10	4	1
	7-15 mg/g dw (N=15)	3	5	6	1
	≥15 mg/g dw (N=18)	0	3	2	13
Total at the FU		18	22	13	15
		FU global heart T2*			
		≥20 ms	10-20 ms	<10 ms	
Baseline global heart T2*	≥ 20 (N=52)	51	1	0	
	10-20 ms (N=12)	4	7	1	
	< 10 ms (N=4)	0	3	1	
Total at the FU		55	11	2	

Summary and Conclusion: No longitudinal study on liver and heart iron in TM children are available in literature. This analysis confirms significant rate of liver and cardiac iron overload even in very young children. This could reflect a conservative approach to chelation therapy in pediatric population. Clinicians tend to be more worried for cardiac than hepatic iron overload and they adjust chelation therapy more frequently if cardiac iron accumulation is present. The data can support a chelation therapy approach timely tailored to iron burden in order to achieve a safe level and avoid detrimental evolution.

P1168

THE ROLE OF LEFT VENTRICULAR GLOBAL FUNCTION INDEX FOR THE PREDICTION OF CARDIAC COMPLICATIONS IN THALASSEMIA MAJOR

A Meloni[1], G Rossi[2], B Piraino[3], S Armari[4], A Quota[5], V Positano[1], G Valeri[6], MC Resta[7], P Keilberg[1], A Pepe[1,*]
[1]Cardiovascular MR Unit, Fondazione G. Monasterio CNR-Regione Toscana, [2]Epidemiology and Biostatistics Unit, Institute of Clinical Physiology, CNR, Pisa, [3]U.O. Genetica e Immunologia Pediatrica, Policlinico "G. Martino", Messina, [4]Reparto di Pediatria, Azienda Ospedaliera di Legnago, Legnago, [5]Serv. Talassemia, Osp. "V. Emanuele III", Gela, [6]Dipartimento di Radiologia, Azienda Ospedaliero-Universitaria Ospedali Riuniti "Umberto I-Lancisi-Salesi", Ancona, [7]Struttura Complessa di Radiologia, OSP. SS. Annunziata ASL Taranto, Taranto, Italy

Background: Cardiac complications are one of the main causes of death in thalassemia major (TM) patients. Recently, the MESA study showed the strong predictive value of the left ventricular global function index (LVGFI) evaluated by cardiovascular magnetic resonance (CMR) in the prediction of the of cardiovascular events. LVGFI is a functional parameter integrating structural as well as mechanical behaviour derived from the analysis of cine SSFP images.
Aims: We evaluated the predictive value of LVGFI and other CMR parameters for cardiac complications in thalassemia major (TM).
Methods: We followed prospectively 537 white TM patients enrolled in the MIOT network. Fifty patients were excluded from the analysis because a cardiac complication was present at the time of the first CMR. All prognostic variables associated with the outcome at the univariate Cox model were placed in the multivariate model and were ruled out if they did not significantly improve the adjustment.
Results: At baseline the mean age was 29.5±9.0 years and 222 patients were males. The mean follow-up time was 58±18 months. After the first CMR only the 37.8% of the patients did not change the chelation regimen or the frequency/dosage. We recorded 40 cardiac complications: 19 episodes of HF, 19 arrhythmias, all supraventicular hyperhyperkinetic, and 2 pulmonary hypertensions. A LVGFI<37% was a significant univariate prognosticator of cardiac complications (HR=3.42, 95%CI=1.56-7.52, P=0.002). The other significant univariate prognosticators were heart iron, atrial dilatation, ventricular dysfunction evaluated by the left ventricular ejection fraction (LVEF), and myocardial fibrosis. Serum ferritin and liver iron by T2* MR were not predictive factors for cardiac complications. In the multivariate analysis the independent predictive factors were a LVGFI<37% (HR=3.08, 95%CI=1.32-7.20, P=0.010), an homogeneous pattern of MIO (compared to no MIO) (HR=3.95, 95%CI=1.56-10.04, P=0.001), and myocardial fibrosis (HR=3.45, 95%CI=1.68-7.09, P=0.001).
Summary and Conclusion: We detected few cardiac events thanks to a CMR-guided, patient-specific adjustment of the chelation therapy. A LVGFI<37%, severe and homogeneous MIO, and myocardial fibrosis identify patients at high risk of cardiac complications globally considered. Importantly, the dysfunction evaluated by the LVEF lose its predictive value for cardiac complications when included in a multivariate model.

P1169

RIGHT VENTRICULAR WALL MOTION ABNORMALITIES IN PATIENTS WITH THALASSEMIA MAJOR AND INTERMEDIA

A Meloni[1], MG Batzella[2], R Mattei[3], L Frizziero[4], D De Marchi[1], E Chiodi[5], P Toia[6], V Positano[1], A Pepe[1,*]
[1]Cardiovascular MR Unit, Fondazione G. Monasterio CNR-Regione Toscana, Pisa, [2]Centro trasfusionale, Ospedale San Gavino, San Gavino Monreale, [3]U.O. Pediatria, U.L.S.S. 19, Adria, [4]Clin. di Emato-Oncologia Pediatrica - Dip. di Pediatria, Università di Padova / Azienda Ospedaliera, Padova, [5]Servizio Radiologia Ospedaliera-Universitaria, Arcispedale "S. Anna", Ferrara, [6]Istituto di Radiologia, Policlinico "Paolo Giaccone", Palermo, Italy

Background: The role of the right ventricle (RV) is gaining ground in thalassemia patients and the magnetic resonance imaging (MRI) is the gold-standard for the study of its anatomy and function.
Aims: In this study we investigated for the first time the relationship between RV motion abnormalities, volumes and function in both thalassemia major (TM) and thalassemia intermedia (TI) patients.
Methods: CMR was performed in 1369 TM patients (537 males; 30.9±8.9 years) and 266 TI patients (38.5±11.5 years) enrolled in the Myocardial Iron Overload in Thalassemia Network. Cine images were acquired to evaluate wall motion and to quantify RV volumes and ejection fraction (EF).
Results: The presence of RV motion abnormalities was comparable between TM and TI patients (3.0% *vs* 4.5%; P=0.201). Out of the 41 TM patients with abnormal RV motion, 35 were hypokinetic, 5 were dyskinetic and 1 was akynetic. Out of the 12 TI patients with abnormal RV motion, 8 were hypokinetic and 4 were dyskinetic. Table 1 and Table 2 show the comparison between TM patients with normal and abnormal RV motion and between TI patients with normal and abnormal RV motion, respectively. TM patients with abnormal RV motion were older and they were more frequently males. Regarless by the form of thalassemia, right volumes were significantly higher in patients with abnormal RV motion while the EF was significantly lower.

Table 1. Comparison between TM patients with abnormal and normal RV motion

	Abnormal RV motion	Normal RV motion	P
Age	34.7 ± 5.8	30.9 ± 8.9	0.005
Sex (M/F)	31.10	633/695	<0.0001
RV EDVI (ml/m2)	109.0 ± 45.9	82.7 ± 16.9	<0.0001
RV ESVI (ml/m2)	60.7 ± 28.9	32.1 ± 11.2	<0.0001
RV EF (%)	45.2 ± 10.1	61.5 ± 7.7	<0.0001

Table 2. Comparison between TI patients with abnormal and normal RV motion

	Abnormal RV motion	Normal RV motion	P
Age (years)	41.3 ± 9.2	38.4 ± 11.6	0.307
Sex (M/F)	7/5	128/126	0.591
RV EDVI (ml/m2)	111.6 ± 35.3	83.4 ± 19.2	0.012
RV ESVI (ml/m2)	55.7 ± 32.6	31.5 ± 10.1	<0.0001
RV EF (%)	51.0 ± 14.8	63.9 ± 7.3	0.001

Summary and Conclusion: Conclusions. Movement abormalities of the right ventricle are not common in thalassemia and have a comparable frequency between TM and TI patients. In both the forms of thalasemia, movement

abormalities of the right ventricle were associated with RV dilation and dysfunction.

P1170

TROPONINE T AS A MARKER OF CARDIAC IMPAIRMENT IN PATIENTS SUFFERING THALASSEMIA

C Vetro[1,*], R Rosso[1], G Colletta[1], M Romeo[1], M Romeo[1], B Ximenes[1], C Conticello[1], A Romano[1], I Monte[2], C R Meli[1], F Di Raimondo[1]
[1]Division of Hematology, Unit of Thalassemia, A.O. "Policlinico-Vittorio Emanuele", University of Catania, [2]U.O. Ecocardiografia Clinica, A.O.U. Policlinico Vittorio Emanuele, Presidio "Gaspare Rodolico", Catania, Italy

Background: Heart failure (HF) resulting from myocardial iron loading is the leading cause of death in β-thalassemia major (β-TM) patients. A prompt diagnosis of HF is crucial in determining the survival of these patients.
Aims: We aimed to evaluate myocardial impairment dosing the levels of troponine-T (TnT) in peripheral blood of (β-TM) patients relating these findings with iron overload indices and echocardiographic measurements.
Methods: This pilot cross-sectional study recruited 50 consecutive β-TM patients from June 2013 to January 2014 recruited at Our Institution. Male/Female ratio was 1:1; Median age was 32 years (ranged between 16 and 48 years). All of them were affected by β-TM, except 2 male patients affected by Severe Intermedia Thalassemia. All echocardiographic measurements were carried out according to the recommendations of the American Society of Echocardiography by an external investigator, who was kept blind to the biochemical results. Left ventricular mass (LVM) was calculated according to the Devereux formula and indexed to height. Left Ventricular Hypertrophy (LVH) was defined by a LVM index >47 g/m in women or >50 g/m in men. HF was defined if clinically evident signs or symptoms were present. Informed consent was given to participants.
Results: Information on LVM was available for 46 out of 50 patients. All of them presented a LVH, except 2 female patients, both presenting normal levels of TnT. Median value of TnT was 3,925 ng/L, ranged between 3 and 60,3. Overall, 5 patients presented levels of Tnt greater than 14. Troponine-T concentrations was related with the level of LVM (Left Ventricular Mass) (Correlation coefficient r: 0,36; p=0,01; 95% CI for r: 0,07-0,59) while no relationship was found with iron overload markers (Ferritin; Saturation Index; T2* of the Liver) neither with the average Haemoglobin Level of the patient and the Ejection Fraction at Echography. The best cutoff for LVH was at 3 ng/L (sensitivity: 60.47%, specificity: 100%; Area Under the Curve: 0,802; p=0,0001). Additionally, the presence of an HF was related with higher levels of TnT with a cutoff value of 5,21 ng/L (sensitivity: 100%, specificity: 66,7%; AUC: 0,81; p=0,0002).
Summary and Conclusion: Taken together, our findings suggest that in (β-TM) patients TnT appeared to be a sensitive index of myocardial dysfunction.

THE ANTI-HEPCIDIN SPIEGELMER® LEXAPTEPID PEGOL (NOX-H94) AS TREATMENT OF ANEMIA OF CHRONIC DISEASE IN PATIENTS WITH MULTIPLE MYELOMA, LOW GRADE LYMPHOMA, AND CLL: A PHASE II PILOT STUDY

P Georgiev[1], M Lazaroiu[2], L Ocroteala[3], J Grudeva-Popova[1], E Gheorghita[4], M Vasilica[5], S Popescu[6], A Cucuianu [7], L Summo[8], S Vauléon[8], S Zöllner[8], F Schwoebel[8], K Riecke[8,*], H Ludwig[9]
[1]University Hospital "St. George", Plovdiv, Bulgaria, [2]Country Emergency Clinical Hospital, Brasov, [3]Municipal Clinical Hospital "Filantropia", Craiova, [4]County Emergency Clinical Hospital, Brasov, [5]"Fundeni" Clinical Institute, Bucharest, [6]University of Medicine and Pharmacy of Craiova, Craiova, [7]Oncology Institute, Cluj, Romania, [8]NOXXON Pharma AG, Berlin, Germany, [9]Center for Oncology and Hematology, Vienna, Austria

Background: Lexaptepid pegol (LP) is a PEGylated L-stereoisomer RNA aptamer that binds and neutralizes hepcidin. Hepcidin, a 25 amino acid peptide induced by inflammatory stimuli is a pivotal regulator of iron resorption and iron release from intracellular stores, which are severely impaired in anemia of chronic disease. Disturbances in iron metabolism resulting in functional iron deficiency are a key component of anemia of chronic disease which frequently complicates malignant disease.
Aims: We evaluated the pharmacokinetics, pharmacodynamics, safety and efficacy of hepcidin blockade by LP as sole treatment of anemia of chronic disease in patients with multiple myeloma, low grade lymphoma, and CLL.
Methods: Twelve patients with functional iron deficiency anemia with the following baseline characteristics, presented as median (range), were enrolled: age 64 years (35-77), hemoglobin (Hb) 9.6 g/dL (8.0-10.7), serum ferritin 317 µg/L (193-2805), serum iron 29 µg/dL (18-97), and transferrin saturation 12% (6-46). LP was injected i.v. at a dose of 1.2 mg/mg, TIW for 4 weeks. Blood counts, serum biochemistry, and iron status were evaluated weekly until two weeks post treatment and at week four after the end of therapy. The primary endpoint was increase in Hb by ≥1 g/dL at any time between start of therapy until 1 week after end of treatment. The study has the clinicaltrials.gov identifier NCT 01691040.
Results: Five of the 12 patients reached the target Hb increase of ≥1 g/dL, 3 patients achieved this goal within 2 weeks. Four of the 5 responding patients had hypochromic red cells (MCH 22-26 pg) and moderately increased baseline ferritin levels (200-350 µg/L). Median serum ferritin decreased from 317 to 232 µg/L (p=0.014) in the entire cohort of patients, and from 253 to 203 µg/L in responders (p=n.s). Reticulocyte hemoglobin (Chr) increased from 22.0 to 25.2 pg (p=0.019) in responding patients, while in non-responders no increase was noted (30.0 to 30.1 pg). Similarly, a tendency towards increased reticulocyte indices was observed in the responding patients (0.9 to 1.3, p=n.s.) only. Soluble transferrin receptor levels (sTfR) did not vary significantly in the entire group and in the responders as well (10.6 to 10.3 mg/L, p=n.s.). Baseline hepcidin levels of 12.7 nM (4.9-54.5) were increased in patients in comparison to those obtained in healthy volunteers in former clinical trials (1.78 nM (0.37-7.26). Patients with mean corpuscular volume (MCV) or Chr baseline levels below the lower limit of the normal range (MCV<82fL, Chr<28pg) represent 75% of the responders, respectively, and all patients with high baseline sTfR levels (>8 mg/L) reached the primary endpoint. Treatment with LP was well tolerated without major adverse reactions.

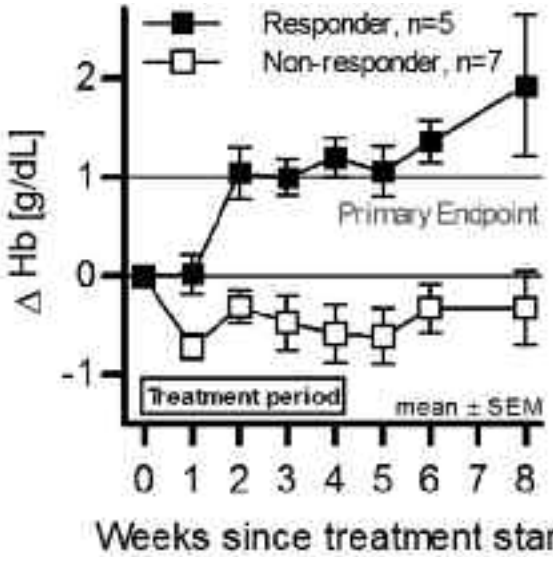

Figure 1.

Summary and Conclusion: Treatment with LP resulted in a significant increase in Hb levels (≥1 g/dL) in 5 of 12 patients supporting the concept of hepcidin inhibition as valuable treatment of chronic anemia of cancer. Responding patients showed an increase in reticulocyte hemoglobin. Baseline levels of MCV, Chr and sTfR were identified as potential diagnostic predictors that could support the selection of patients with an increased susceptibility for this therapy. After confirmation in additional clinical trials these predictive markers could help to increase response rates in this indication.

P1173

CLINICAL HETEROGENEITY OF AUTOIMMUNE HEMOLYTIC ANEMIA: A GIMEMA STUDY OF 308 PATIENTS

W Barcellini[1,*], B Fattizzo[1], T Radice[1], I Nichele[2], E Di Bona[2], A Zaninoni[1], M Lunghi[3], C Tassinari[4], F Alfinito[5], A Ferrari[6], A Leporace[6], P Niscola[7], M Carpenedo[8], C Boschetti[1], N Revelli[9], MA Villa[9], D Consonni[10], L Scaramucci[7], P De Fabritiis [7], G Tagariello[11], A Cortelezzi[1,12], G Gaidano[3], F Rodeghiero[13], A Zanella[1]

Eugenio, Roma, [8]UO Ematologia e Trapianto, Ospedale S. Gerardo di Monza e Università degli Studi di Milano Bicocca, Monza, [9]UO Laboratorio Centrale, [10]UO Epidemiologia, Fondazione IRCCS Ca' Granda Ospedale Maggiore Policlinico, MIlano, [11]Centro Trasfusionale e Ematologia, Centro Regionale per le malattie del sangue, Castelfranco Veneto, [12]Università degli Studi, Milano, [13]Dipartimento di Terapie Cellulari ed Ematologia, Ospedale San Bortolo, Vicenza, Italy

Background: Autoimmune haemolytic anaemia (AIHA), usually classified as warm (WAIHA), cold (CHD), mixed, and atypical forms, is a greatly heterogeneous condition both in terms of clinical presentation and response to treatment.
Aims: To correlate serological characteristics and severity of anaemia with type and response to treatments, clinical outcome, and occurrence of acute complications.
Methods: 308 patients from 8 Italian Centres, diagnosed between 1978 and 2013, were included in this retrospective study, and classified according to DAT-positivity and Hb levels at onset (≤6, 6.1-8, 8.1-10, >10 g/dL). The following therapy lines were recorded: steroids±IvIg, immunosuppressors, rituximab, splenectomy, plasma-exchange, and erythropoietin. Clinical outcome (recovery, relapse, death) and occurrence of infections, thrombosis, and renal failure were evaluated.
Results: Patients (112 M and 196 F, median age at diagnosis 63, range 1-97) had been followed-up for a median of 33 months (range 12-372); 49% of cases were WAIHA (DAT+ for IgG), 27% CHD (DAT+ for C), 19% mixed (DAT+ for IgG and C), and 5% atypical (14 DAT- and 1 DAT+ for IgA only). Considering the degree of anemia at onset, 27% of cases had Hb levels ≤6, 37% Hb 6.1-8, 24% Hb 8.1-10, and 12% Hb>10 g/dL; mixed and atypical forms (mean Hb 6.6±1.9 and 6.5±1.7 g/dL, respectively) were more severe than WAIHA and CHD (mean Hb 7.3±2.3 and 8.6±2.2g/dL, respectively, P=0.0001). The mean reticulocytes progressively increased with the worsening of anemia (144±95, 160±122, and 242±156x10^9/L for Hb>10, Hb 8.1-10, and Hb 6.1-8g/dL, respectively), but not in cases with Hb<6 g/dL (192±128 x10^9/L, p=0.0001), possibly contributing to the clinical severity. Concerning therapy, steroids were administered in 273 cases (88%), mostly WAIHA (N=144), mixed (N=56) and atypical (N=14) (CR 43-50% and PR 27-36%); 59 CHD were treated with steroids, with lower CR (27%). As regards second line therapy, splenectomy was performed in 33 cases (11%), mostly severe warm or mixed forms (p=0.027), with a response rate of 71%; splenectomy had been performed in 3 CHD and was ineffective in 2. Cytotoxic drugs were administered in 77 patients (25%) (azathioprine 29% CR, 41% PR; cyclophosphamide 35% CR, 37% PR; cyclosporine 30% CR, 20% PR). Rituximab was administered in 55 cases (18%) (45% CR, 35% PR), more frequently in cold and mixed severe forms. Plasma-exchange was performed in 4 cases, and erythropoietin administered in 14, mostly severe forms, their efficacy being not evaluable because of concomitant therapies. Transfusions were given to 38% of patients.

Table 1.

N° Therapy lines	Serological AIHA type			
	Warm	Cold	Mixed	Atypical
0	8/153 (5%)	20/83 (24%)	1/57 (2%)	3/15 (7%)
1	90/153 (59%)	28/83 (34%)	18/57 (32%)	8/13 (60%)
2	35/153 (23%)	19/83 (22%)	25/57 (44%)	2/15 (13%)
3	15/153 (10%)	13/83 (16%)	11/57 (19%)	2/23 (13%)
4	5/153 (3%)	4/83 (4%)	2/57 (3%)	1/15 (7%)
	Hb levels at onset			
	>10 g/dL	8.1-10 g/dL	6.1-8 g/dL	<6 g/dL
0	15/38 (39%)	9/73 (12%)	5/112 (4%)	0
1	15/38 (39%)	39/73 (53%)	51/112 (46%)	40/82 (49%)
2	6/38 (16%)	15/73 (21%)	32/112 (29%)	23/82 (30%)
3	2/38 (5%)	10/73 (14%)	19/112 (17%)	10/82 (12%)
4	0	0	5/112 (4%)	7/82 (9%)

Summary and Conclusion: AIHAs showed a marked clinical heterogeneity, 1/3 of cases with a severe onset and 1/10 with life threatening complications. These cases are frequently mixed or atypical forms and refractory to different therapies.

P1174

REDUCED 25-OH VITAMIN D LEVELS IN PATIENTS WITH AUTOIMMUNE CITOPENIAS: CORRELATION WITH HAEMATOLOGICAL PARAMETERS AND CLINICAL SEVERITY

B Fattizzo[1,*], A Zaninoni[1], F Nesa[1], B Motta[1], A Cortelezzi[1], W Barcellini[1]
[1]UO Oncoematologia, Ospedale Maggiore Policlinico Regina Elena, via F. Sforza, Milano, Italy, Milano, Italy

Background: 25-OH vitamin D plays a crucial role in calcium and bone homeostasis, but it has also been shown to regulate several immune functions by acting on Th1/Th2 balance, T-reg activation and cytokine production. Vitamin D has been reported to be decreased in various autoimmune diseases such as multiple sclerosis and type 1 diabetes mellitus and to correlate with clinical outcomes.
Aims: To evaluate 25-OH vitamin D values in patients with autoimmune cytopenias, namely primary immune thrombocytopenia (ITP), autoimmune hemolytic anemia (AIHA) and chronic idiopathic neutropenia (CIN), and to relate them with clinical severity and hematologic parameters.
Methods: Clinical history, physical examination, complete blood count, serum samples and informed consent were collected at the time of enrolment, starting from January 2013. Hematologic parameters were also recorded at the time of the diagnosis. The number of immunosuppressive therapy lines (steroids, immunosuppressors, rituximab, splenectomy, and thrombopoietin agonists for ITP) and infectious episodes were retrospectively collected. Bleeding history was recorded for ITP. 25-OH vitamin D levels were evaluated in all patients and in 40 age and sex matched healthy controls, using an ELISA kit. Statistical analysis was performed using Student't test for continuous variables and chi-square test for categorical variables.
Results: Ninety-eight patients were enrolled, median age 59 years (range 17-86), 32 males and 71 females. As regard hematologic parameters at enrollment, ITP patients (N=44) showed median platelets values of 73x10^3/mmc (7-349x10^3/mmc) and vitamin D levels of 1.42 ng/mmc (0.21-8.69 ng/mmc), AIHA patients (N=35) displayed median Hb values of 11.6 g/dL (7.1-16.8 g/dL) and vitamin D levels of 1.94 ng/mL (0.09-6.71 ng/mL), and CIN cases (N=19) showed median ANCs values of 1.2x10^3/mmc (0.25-7x10^3/mmc) and vitamin D levels of 1.55 ng/mL (0.25-4.28ng/mL). As shown in figure 1, serum 25-OH vitamin D levels were significantly lower in patients than in controls (2.3±1.8 *vs* 6±6 ng/mL, mean values±SD, p<0.001), particularly in AIHA cases, regardless sex and age; considering the number of therapy lines vitamin D levels were reduced in AIHA patients who underwent two or more lines compared to cases with 0 or 1 line of therapy (1.7+1 ng/mL *vs* 2.8+1.8 ng/mL, p=0.04). As regards hematologic values at the time of diagnosis, all patients with vitamin D levels lower than 4 ng/mL showed significantly reduced Hb levels (9.3±3.5 *vs* 13.1±1.9 g/dL, mean values±SD, p<0.001) and absolute neutrophil counts (2.9±1.9 x10^3/mmc *vs* 4.3±2.1 x10^3/mmc, mean values±SD, p=0.001); the latter was particularly evident in CIN patients (0.57±0.3 x10^3/mmc *vs* 1.3±1.9 x10^3/mmc, mean values±SD, p<0.001). No relationship was found between hematologic

parameters at diagnosis or at enrollment and vitamin D levels in patients with ITP. Considering infections, 15 grade 2 episodes occurred during the study time, of whom 6 in CIN patients, without relationship with hematologic parameters or with 25-OH vitamin D levels.

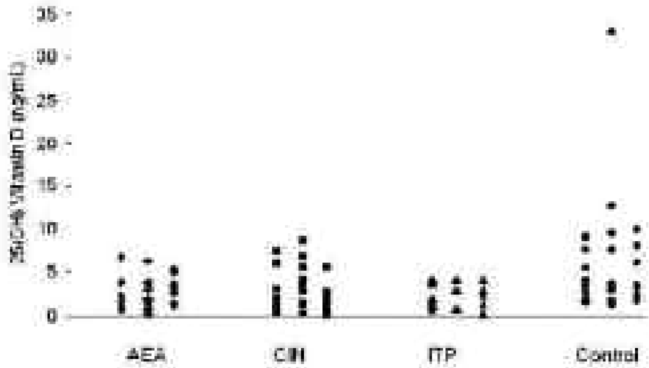

Figure 1.

Summary and Conclusion: This is the first demonstration of reduced values of vitamin D in autoimmune hematologic cytopenias. The reduction is particularly evident in AIHA cases with severe clinical picture and/or refractory to first line therapy and in CIN patients with more marked neutropenia. These data suggest a possible pathogenic role of reduced vitamin D in immune disregulation and provide hints for therapeutic options.

P1175

ASSESSMENT OF LIVER AND CARDIAC IRON OVERLOAD USING MAGNETIC RESONANCE IMAGING (MRI) IN PATIENTS WITH CHRONIC ANEMIAS IN LATIN AMERICAN COUNTRIES: RESULTS FROM ASIMILA STUDY

R Cancado[1,*], N Watman[2], C Lobo[3], Z Chona[4], F Manzur[5], F Traina[6], M Park[7], G Drelichman[8], JP Zarate[9], L Marfil[10]
[1]Department of Hematology/Oncology, Santa Casa of Sao Paulo Medical School, Sao Paulo, Brazil, [2]Hospital General de Agudos Dr. Ramos Mejía, Buenos Aires, Argentina, [3]Instituto Estadual de Hematologia Arthur de Siqueira Cavalcanti, Rio de Janeiro, Brazil, [4]Hospital Universitario de Caracas, Caracas, Venezuela, [5]Universidad de Cartagena, Cartagena, Colombia, [6]University of Campinas, [7]Sao Paulo Hematology Center, Sao Paulo, Brazil, [8]Hospital de Niños Dr. R. Gutierrez, Buenos Aires, Argentina, [9]Novartis Pharmaceuticals, East Hanover, United States, [10]Hospital Universitario, Monterrey, Nuevo Leon, Mexico

Background: Patients receiving regular transfusions are at risk of developing iron overload (IOL) which can lead to increased morbidity and mortality.Therefore, accurate assessment of IOL is required for diagnoses and management with iron chelation therapy. Traditionally, IOL has been evaluated by serum ferritin (SF) levels or direct measurement of liver iron concentration (LIC) using biopsy (Taher *et al. Am J Hematol* 2013). Use of magnetic resonance imaging (MRI) has been extensively evaluated in many clinical trials (Pennell *et al. Haematologica* 2012) and has enabled accurate and non-invasive monitoring of IOL of liver and heart (Wood, *Hematology* 2011).
Aims: In this trial, MRI R2 and T2* techniques complemented SF to determine the prevalence and severity of liver and cardiac IOL, in transfusion-dependent patients with chronic anemias, excluding thalassemia.
Methods: This multicenter, observational study conducted in Latin America, enrolled male or female patients, aged >10 years, with sickle cell disease (SCD), low risk and intermediate-I myelodysplastic syndromes (MDS), aplastic anemia (AA), Diamond Blackfan anemia (DBA), congenital sideroblastic anemia or other rare anemias, with a lifetime history of >20 units of RBC transfusions and/or SF level >2000 ng/mL. All patients underwent liver MRI at Day 15 of study entry. Cardiac MRI was to be performed based on physician's criteria and cardiac MRI availability across all diseases except SCD, for which it was not required. The primary endpoint, incidence of IOL, was defined as percentage of patients with liver R2 MRI >2 mg Fe/g dw and/or cardiac T2* MRI<20 ms among patients who underwent a liver and/or cardiac IOL assessment as per protocol, respectively. Secondary endpoints included correlation between SF, LIC, and cardiac T2*.
Results: Of the 212 patients screened, 175 were considered eligible for the present analysis, who met the inclusion / exclusion criteria and performed cardiac and / or liver MRI per protocol. The mean age was 34.6 ± 17.0 years (range: 11 to 81 years) and consisted of Caucasians (31.4%), Hispanics (31.4%), and Africans (29.1%). Majority of patients had SCD (52%), followed by AA (17.7%), MDS (8.6%), DBA (4%), pure red cell aplasia (1.1%), and others (16.6%). Prior to study entry, the most common method for IOL assessment was SF (89.1%), followed by transferrin saturation (66.9%), echocardiogram (29.7%), liver MRI (24%), and cardiac MRI (8.6%).
In the current study, liver IOL (>2 mg Fe/g dw) was observed in 76.4% (n=133/174; mean liver R2 MRI, 14 ± 14 mg Fe/g dw) patients, while cardiac IOL (T2*<20 ms) was seen in 19.2% (n=14/73; mean T2*, 27.3 ± 10.7 ms). The incidence of liver IOL in patients by disease was: SCD, 80.2%; MDS, 73.3%; AA, 77.4%; pure red cell aplasia, 100%; DBA, 71.4%; and other transfusion disorders, 65.5%. Overall, patients demonstrated high SF, high LIC, and normal cardiac T2*, with notable variability within and across diseases (Table 1). Treatment for IOL was reported by 103 (58.9%) patients that included deferasirox (50.3%), deferoxamine (8.6%), deferiprone (4.0%), and other treatments (4.6%). A moderate correlation between LIC and SF was observed in SCD and MDS patients (r=0.47 [95%CI: 0.29, 0.61] and r=0.61 [95%CI: 0.14, 0.86], respectively). However, no correlation was observed between cardiac T2* and SF. There were no significant safety findings during the 15-day study period.

Table 1.

	All patients	Sickle – Cell disease (homozygous)	Myelodysplastic syndrome	Aplastic anemia	Pure red cell aplasia	Diamond-Blackfan anemia	Other transfusion dependent disorder
Serum Ferritin (ng/mL)							
n	175	91	15	31	2	7	29
Mean ± SD	2099.7 ± 2221.8	2612.6 ± 2279.1	2023.8 ± 1212.5	1731.4 ± 2264.4	1026 ± 1050	1144.3 ± 1042.9	1891.7 ± 1912.6
Median	1801	[illegible]	1818	1076	1026	661	111
LIC (mg Fe/g dw)							
n	174	91	15	31	2	7	28
Mean ± SD	14 ± 14	14.3 ± 13.6	19 ± 14.6	16.5 ± 15.8	13.8 ± 12.2	5.6 ± 4.8	10.2 ± 12.8
Median	9	9	18	10	13	6	4
Cardiac T2* (ms)							
n	73	3	12	24	0	7	27
Mean ± SD	27.3 ± 10.7	18.4 ± 9.8	21.9 ± 10.9	27.8 ± 10.1	-	25.1 ± 6.7	29.4 ± 5.2
Median	28	13	23	28	-	29	30

Summary and Conclusion: Assessment of IOL by MRI in regularly transfused patients from the Latin American region showed a high prevalence of liver IOL. Notably, high LIC values were observed across all diseases, most evident in MDS, SCD, and AA patients. Interestingly, unlike thalassemia patients, most patients across diseases had normal cardiac T2*. The use of chelation therapy in only some patients may have contributed to the range of IOL observed. Overall, the assessment of IOL by MRI of the liver and heart continues to demonstrate value in complementing SF measurements, both in patients with or without iron chelation therapy.

P1176

SIROLIMUS AS TREATMENT OF STEROID DEPENDENT/RESISTANT AUTOIMMUNE HAEMOLYTIC ANEMIA/PURE RED CELL ANEMIA IN CHILDREN

M Miano[1,*], M Calvillo[1], E Palmisani[1], F Fioredda[1], C Micalizzi[1], J Svahn[1], M Scalzone[2], G Russo[3], C Dufour[1]
[1]Haematology Unit, [2]Current transient address Haematology Unit, G Gaslini Children's Hospital, Genoa, [3]Paediatric Haematology/Oncology, University of Catania, Catania, Italy

Background: Autoimmune Haemolytic Anaemia (AIHA) is a rare disease in children. In most cases, it is secondary to infections, immunologic diseases or malignancies whereas about 40% of children suffer from an idiopathic/primitive disease. Although steroid treatment routinely used as first line approach is successful in about 80% of cases, relapsed/resistant disease may became a burning issue due to the absence of controlled studies on second and further line treatments to manage a potential life-threatening disease. Moreover, in children who experience a chronic clinical evolution of the disease, a long term treatment with medium/low dosage of steroid is often needed. The possibility to use a light and tolerable immunosuppressive therapy as maintenance in this setting could help to manage a steroid-dependent disease and the steroid-associated side-effects. Sirolimus has been reported to be useful in several cases of post-transplant AIHA, in few patients with immune-mediated cytopaenia secondary to Autoimmune Lymphoproliphrative Syndrome (ALPS), and in one case of multi-resistant Pure Red Cell Anaemia/AIHA.
Aims: The aim of this report is to retrospectively evaluate the fficacy and safety of Sirolimus given as maintenance treatment for steroid-dependent/resistant AIHA/PRCA in paediatric patients.
Methods: We evaluated the records of 4 children with AIHA/PRCA who were administered Sirolimus at the starting dose of 2mg/m^2 (then modulated according to blood levels) as maintenance treatment in steroid-dependent/resistant disease. The drug was given off-label and informed consent was obtained from parents. All patients were screened to identify any infective or immunological underlying disease including ALPS. Response to the treatment was defined as Hb and Reticulocyte within normal range for age.

Results: Four children (aged 5-25 months) afftected with and AIHA (3) and PRCA (1) received Sirolimus for refractory (1) or steroid-dependent (3) disease. All patients but one affected with ALPS, had idiopathic disease. Hb at diagnosis ranged between 2 and 6.4 gr/dl. First line treatment included Prednisone (PDN) in all cases. One patient with AIHA received Sirolimus as second line treatment for steroid dependent disease. The patient affected with PRCA received it as third line treatment for refractory disease after failure of PDN and mycofenolate. The remaining 2 children were administered Sirolimus as maintainance treatment in a steroid dependent disease after failure of PDN and rituximab associated to Cyclosporine in one case. Complete remission was achieved in all cases after 1-3 months of treatment and the drug was well tolerated in all patients. At last follow-up 2 patients had just stopped Sirolimus treatment given for 24 months at full dose and 6 months tapering. One patient was still receiving treatment after 9 months and the child with ALPS was receiving Sirolimus for 40 months.
Summary and Conclusion: Prospective trials on treatment of AIHA are lacking and will be hardly built up. Anecdotal data are available on the use of Sirolimus AIHA/PRCA. This experience contributes further on the usefulness of its use in both ALPS and non-ALPS children with AIHA and PRCA who may benefit of a tool to overcome steroid-dependency and chronic disease. This study also outlines the need of trial in very rare disease aimed to optimize different line treatments.

P1177

ANALYSIS OF CAUSES OF ANAEMIA FOUND IN A GENERAL PRACTICE POPULATION: PREVALENCE AND SURVIVAL

K Stouten[1,*], J Riedl[1], MD Levin[2]
[1]Clinical Chemistry, [2]Internal Medicine, Albert Schweitzer Hospital, Dordrecht, Netherlands

Background: Information on the causes of anaemia found in general practice is limited. A prospective cohort study with general practice patients diagnosed with anaemia was set up to increase knowledge and improve quality of care for anaemia patients.
Aims: An evaluation of the causes of anaemia found in a cohort of general practice patients.
Methods: Between the 1st of February 2007 and the 1st of February 2013 patients presenting to one of the 63 participating general practitioners with a newly diagnosed anaemia (*i.e.* no anaemia in the preceding two years) were included in the study. Men were included when 18 years or older and women were included when 50 years or older to prevent an overabundance of hypermenorrhea as a cause of the anaemia.
A wide range of parameters was analysed for each patient to aid diagnosis. Two experts independently reviewed the laboratory results of all patients included and established the underlying cause of anaemia. In case of discordance, the experts deliberated until a consensus was reached.
Survival in months after entry into the study was determined per gender and for patients with microcytic, normocytic and macrocytic anaemia.
Results: A total number of 2738 patients were included in the study. A single cause of anaemia was found in 2493 patients (91.1 %). Anaemia of chronic disease was established in 899 patients (29.8 %), haemoglobinopathy in 24 patients (0.8 %), renal anaemia in 342 patients (11.3 %), haemolysis in 18 patients (0.6 %), possible bone marrow disease in 117 patients (3.9 %) and other causes were found in 119 patients (4.0 %). Iron deficiency was established in 552 patients (18.3 %), vitamin B12 deficiency in 122 patients (4.1 %) and folic acid deficiency in 24 patients (0.8 %). When no cause could be established it was classified as unknown, which was found in 797 patients (26.4 %). Overall survival of the cohort was 66.2 months (95% CI 65.2-67.3) after entry into the study. Men (N=1463, mean age at entry 66.8 years) demonstrated an overall survival of 66.5 months (95% CI 65.1-67.9) and women (N=1275, mean age at entry 75.1 years) a survival of 65.2 months (95% CI 63.6-66.7) (p=0.637). The survival for patients with microcytic (N=335, mean age at entry 65.1 years), normocytic (N=2213, mean age at entry 71.2 years) and macrocytic anaemia (N=190, mean age at entry 74.1 years) was 65.5 (95% CI 62.6-68.4), 66.9 (95% CI 65.7-68.0) and 57.9 (95% CI 53.4-62.5) months respectively. The survival of both microcytic and normocytic patients was significantly longer than the survival of patients with a macrocytic anaemia (p=0.005 and p<0.001 respectively).
Summary and Conclusion: Over a six year time period an extensive database of general practice patients diagnosed with anaemia was created. Besides supplying information on the prevalence of different causes of anaemia in this population, the data will also be used to develop a new guideline for the diagnosis of anaemia.

P1178

RENAL FUNCTIONAL AND STRUCTURAL INTEGRITY IN CHILDREN WITH IRON DEFICIENCY ANEMIA: RESPONSE TO IRON THERAPY

M S El Shimy[1,*], R A El-Farrash[1], E A Ismail[2], I A El Safty[3], O AM El Gamel[2], Y M Salem[1]
[1]Pediatrics Department, [2]Clinical Pathology Department, Faculty of Medicine-Ain Shams University, [3]Chemisrty Department, Faculty of Education-Ain Shams University, Cairo, Egypt

Background: Background: Iron deficiency anemia (IDA) is the most common hematological disease of infancy and childhood. Researchers have investigated the deleterious effects of IDA on the cardiovascular and nervous systems, but the impact of this condition on renal function has not been examined in depth.
Aims: This study aimed to assess renal functional and structural integrity in 50 children with IDA compared to 50 age- and sex-matched healthy controls and evaluate their response to oral iron therapy.
Methods: IDA patients were studied stressing on symptoms and signs of anemia, anthropometric measures, evidence of renal, hepatic or cardiac disease, hematological profile, serum iron studies, urinary sodium and creatinine with calculating the fractional excretion of sodium (FeNa), urinary albumin excretion, leucine aminopeptidase (LAP), urinary excretion of trace elements (iron, copper, zinc, calcium and magnesium). Patients received oral iron therapy and were followed-up both clinical and laboratory for 3 months.
Results: IDA patients had significantly lower hemoglobin, red blood cell indices, iron, ferritin and transferrin saturation (p<0.001) with higher white blood cells (p=0.014) and platelets (p=0.006) than healthy controls. All the studied urinary markers including urinary trace elements were markedly increased among IDA patients compared to controls (p<0.001). Upon comparing the studied hematological parameters among IDA patients pre- and post-iron therapy, a significant increase in hemoglobin (p=0.001), mean corpuscular hemoglobin (p=0.011) and ferritin levels (p=0.005) was found. As regards urinary markers, a significant decrease in FeNa (p=0.017), urinary microalbumin (p=0.048), LAP (p=0.023), iron (p=0.007), copper (p=0.023), zinc (p=0.006) and calcium (p=0.042) was also found after therapy. Although urinary magnesium was decreased post- therapy (median, 246.3 with a range of 141.2-368.1) compared to baseline levels (median, 290.7 with a range of 168.9-834.9), the difference did not reach a significant level (p=0.156). No significant correlation was found between the studied urinary parameters and baseline levels of baseline levels of serum iron, Total iron binding capacity (TIBC), ferritin or transferrin saturation (p>0.05) except for a positive correlation between TIBC and urinary calcium (r=0.457, p=0.026). A significant positive correlation was found between urinary microalbumin and urinary LAP (r=0.437, p=0.025). Baseline urinary LAP was also positively correlated to all the studied trace elements (p<0.001 for all). Urinary copper levels were positively correlated to urinary microalbumin (r=0.437, p=0.029) while urinary magnesium levels was positively correlated to FeNa (r=0.426, p=0.034). Moreover, significant positive correlations were found between all the studied urinary trace elements (p<0.001 for all).
Summary and Conclusion: We suggest that IDA wields an adverse influence on renal functional and structural integrity. Improvement of IDA could protect against glomerular and tubular damage. Urinary excretion of albumin and LAP in IDA can be used as potential biological markers for renal dysfunction and for monitoring the response to therapy. Increased loss of trace elements in urine of IDA patients denotes that these metals could be reliable indicators and risk predictors of renal damage. Further longitudinal studies are needed to verify the effect of iron therapy on renal functions.

P1179

MULTIFACTORIAL PATHOGENESIS OF ANEMIA IN PREGNANCY

V Demikhov[1,*], E Demikhova[1], O Zhurina[1], O Golovitsyna[1]
[1]Ryazan Branch, Federal Clinical Research Center for Pediatric Hematology, Oncology and Immunology named D. Rogachev, Ryazan, Russian Federation

Background: It is known that iron deficiency is one of the main pathogenic factors of anemia in pregnancy (AP). But own investigations results and some other researchers' data in field of AP give the bases to believe that AP has more complex (multifactorial) pathogenesis than ineffective erythropoiesis, caused by iron or folate deficiency. Recombinant human erythropoietin (rHuEPO) is very effective (up to 85%) for the treatment of AP which often are resistant to an iron therapy alone. If AP relate to iron deficiency anemia (IDA) only, then rHuEPO therapy of the anemia has not been such beneficial indeed. Blunt erythropoiesis is one of some AP causes. But of data about blunt erythropoiesis prevalence in AP insufficiently.
Aims: In the present study, we investigated the adequacy of the EPO production for the degree of anemia in pregnancy. We evaluated role of estrogens and hepcidin in multifactorial pathogenesis of AP.
Methods: To investigate the adequacy of the EPO production for the degree of anemia in pregnant women total 133 anemic pregnant women (105 - iron deficiency anemia (IDA) and 28 - non-IDA) and 47 normal Hb level pregnants were tested. Control group consisted of 22 non-pregnant women with iron-deficiency anemia (IDA). EPO values were measured immunoenzymometrically by using ELISA-EPO kits. Serum levels of estradiol and hepcidin were determined in anemic pregnants and in 47 healthy non-pregnant women in addition. The adequacy of EPO level in relation to the degree of anemia was evaluated individually by computing the ratio between the logarithm of the observed value and the logarithm of the expected result [O/E log (EPO) ratio] according to the regression line constructed with the control group.

Results: The ratio of observed/predicted (O/P) serum EPO was inadequate (<0.8) for the degree of anemia in 51 (48.6%) of 105 IDA pregnants and in 11 (39.3%) of 28 non-IDA pregnants. The significant elevated serum levels of estradiol were observed at all anemic pregnant women *versus* healthy pregnant women with normal Hb (Table). Serum hepcidin concentration in non-IDA pregnant women was significant higher than in IDA pregnants group: 34.8±6.1 μg/L and 3.9±1.2 μg/L respectively (p<.001). Serum INF-γ concentration in IDA pregnant women was significant higher than in non-IDA pregnants: 240.2±80.37 ng/L and 84.2±30.59 ng/L respectively (p<.05).

Table 1. Serum levels of iron deficiency indices and anemia of inflammation markers

Anemia in pregnancy	Serum ferritin (SF), mcg/l	Transferrin saturation, %	sTfR/ log SF	Hepcidin μg/l	Estradiol nmol/l	INF-γ ng/l (previously published data)
IDA (n=105)	8,3±0,3*	17,4±1,4*	3,9	3,9±1,2*	16,1±1,0*	240,2*
non-IDA (n=28)	78,1±16	37,6±4,6	1,4	34,8±6,1	14,7±1,3	84,2
Healthy pregnants (normal Hb level) (n=47)	–	–	–	12,3±1,5	7,8±1,0	70,3

*: p < .05

Summary and Conclusion: Thus inadequately low production of EPO for the degree of the anemia is important mechanism in pathogenesis of AP. Some AP (non-IDA) relate to systemic proinflammatory response developing during pregnancy and associate with increased production of hepcidin. Blunted erythropoiesis in IDA pregnants seems has relation to elevated production of and other cytokines with placenta in hypoxia. T-lymphocytes stimulated with estrogens can be sources of INF-γ too. That is why rHuEPO therapy of AP is high effective. Complex algorithm is necessary to provide optimal guidance in management of AP. Main therapeutic options are oral iron, intravenous iron and ESA. Response to iron therapy of AP (oral or intravenous) isn't above 50% usually. In our opinion so resistance to iron relate to inadequately low production of EPO to degree of anemia. RHuEPO combined with intravenous iron is more effective therapeutic option in this case.

P1180

THE IMPACT OF LIFESTYLE FACTORS ON RAISED RED CELL MEAN CORPUSCULAR VOLUME IN AN IRISH POPULATION-NOT JUST A 'HAEMATOLOGY' PROBLEM

M A O'Reilly[1,*], J M Harrington[2], C M Buckley[2], I J Perry[2], M R Cahill[1]
[1]Haematology, Cork University Hospital, [2]Epidemiology and Public Health, University College Cork, Cork, Ireland

Background: The prevalence of macrocytosis in adults is estimated between 1.7% and 8%. Its diagnosis may warrant an extensive work-up for vitamin deficiency, haematological malignancy, heavy alcohol intake, liver disease, myelodysplasia and myeloma. The degree to which lifestyle factors contribute to clinically significant macrocytosis (MCV≥99fl) has not been extensively reported in the literature. An independent link between smoking and macrocytosis has been previously observed (McNamee *et al.* Haematinic deficiency and macrocytosis in middle aged and older adults. PLoS One. 2013; 8(11): e77743).
Aims: To study the determinants of clinically significant macrocytosis with particular reference to the independent effects of lifestyle factors in a cohort 2,047 Irish patients aged 50-69 years sampled from a primary care centre in southern Ireland.
Methods: Details of the Mitchelstown Cohort study have been previously described (Kearney *et al.* Int. J. Epidemiol. (2012) doi: 10.1093/ije/dys131). The study is based in a primary care centre serving a defined population in Southern Ireland. Vitamin B12 and folate, fasting plasma glucose (FPG) and lipid profiles, HbA1c, liver function and full blood counts were measured using standard laboratory methods. Smoking status and alcohol intake were recorded using a validated questionnaire. The metabolic syndrome (MS) was defined using the International Diabetes Federation (IDF) 2006 criteria. Blood pressure, body mass index (BMI) and waist circumferences were measured. Statistical analysis was performed using Stata©. Multivariate logistic regression was used to estimate prevalence odds ratios with 95% Confidence Intervals (OR, 95%CI) for macrocytosis and its potential determinants. Population attributable fractions (PAF) were estimated for variables that were significantly associated with macrocytosis in multivariate analyses.
Results: The prevalence of MCV≥99fl in this sample of 2,047 patients was 1.6%. The prevalence of B12 deficiency was 2.4%, folate deficiency, 1.5%, elevated gamma-glutamyltransferase (GGT), 18%, elevated alanine aminotransferase (ALT), 8%, elevated aspartate aminotransferase (AST), 4.7%, current smoking, 15% and MS, 31%. In multivariate logistic regression analysis with adjustment for age and gender the following variables were significantly associated with MCV ≥99fl; folate deficiency OR 8.2 (95% CI 2.3-29.0), elevated AST OR 8.0 (95% CI 3.5-18.6), B12 deficiency OR 6.1 (95% CI: 2.0-18.4), current smoker OR 6.0 (95% CI 2.8-12.5), MS OR 3.4 (95% CI 1.6-6.9), elevated GGT OR 2.3 (95% CI 1.0-4.9) and elevated TG OR 2.3 (95%CI 1.1-4.7).. Central obesity, BMI, elevated FPG, low HDL and self-reported alcohol intake did not reach significance. In further analyses adjusted for all significant variables, the association of macrocytosis with both smoking and MS was essentially unchanged, OR 5.7 (95%CI 2.6-12.7) and OR 3.0 (95%CI 1.3-6.9) respectively. PAF for smoking was 38.4%, followed by elevated AST, 22.9%, MS, 13.8%, vitamin B12, 11.7% and folate deficiency, 7.0%.
Summary and Conclusion: Attention should be given to the impact of lifestyle factors on MCV. Our findings suggest that smoking is an important cause of macrocytosis. Potential mechanisms include the direct toxic effect on erythrocytes of acetaldehyde in tobacco smoke and the response to reduced oxygen-carrying capacity. We also observed an independent association between macrocytosis and the MS. Non-alcoholic fatty liver disease is strongly linked to the MS. However we have demonstrated an association independent of abnormal liver indices. As the obesity epidemic escalates worldwide, GPs, physicians and haematologists should consider its potential impact on red cell mean corpuscular volume before embarking on haematological work-up.

P1181

THROMBOEMBOLISM OCCURRED REGARDLESS OF HEMOLYSIS IN PATIENTS WITH PAROXYSMAL NOCTURNAL HAEMOGLOBINURIA– A PROSPECTIVE STUDY OF 464 PATIENTS IN A MULTICENTER CHINESE REGISTRY

Z Shao[1,*], B Han[2], H Zhu[3], F Zhang[4], G He[5], Y Chen[6], J Ma[7], H Shi[8]
[1]Tianjin Medical University General Hospital, Tianjin, [2]Peking Union Medical College Hospital, Beijing, [3]West China Hospital, Sichuan University, Chengdu, [4]Institute of Hematology, Chinese Academy of Medical Sciences, Tianjin, [5]The First Affiliate Hospital, Nanjing Medical University, Jiangsu Province Hospital, Nanjing, [6]Ruijin Hospital, Jiaotong University, Shanghai, [7]Harbin Institute of Hematology and Oncology, Haerbin, [8]Peking University People's Hospital, Beijing, China

Background: Thromboembolism (TE) has been well recognized as the most common cause of death in patients with paroxysmal nocturnal haemoglobinuria (PNH). Recent studies showed that PNH patients with elevated hemolysis indicated by lactate dehydrogenase levels (LDH) ≥ 1.5 times the upper limit of normal (ULN) at diagnosis were at significantly high risk for TE than patients with LDH<1.5×ULN. However, the pathogenesis of thrombosis in PNH patients tends to be multifactorial, not only through intravascular hemolysis.
Aims: To better undstand the natural history of PNH and the correlation between TE and hemolysis in Chinese population, a prospective, non-interventional PNH registry was conducted in 8 centers.
Methods: PNH diagnosis was confirmed using a consistent flow cytometry protocol based on 2010 ICCS guideline: fluorescent aerolysin (FLAER) and one more reagent against GPI-anchored proteins were used in white blood cell testing; CD59 was used in erythrocyte testing. Patients with a detectable PNH clone irrespective of treatment were enrolled in the study and would be followed every six months. Clinical characteristics, quality of life, complications including TE events were recorded and analyzed.
Results: Total 464 PNH patients were enrolled in the study from Nov 2011 to Dec 2013. The median age at diagnosis was 37 years (range 6-84), male to female ratio was 1.07:1, median duration of PNH was 3 months (range 0.03-307 months); 86% patients's PNH history was less than 3 years. 50.8% patients were classical PNH, 42.5% patients were PNH with bone marrow failure and 6.6% were subclinical PNH. All of the patients received conventional therapy (67% patients used corticosteroids). The average PNH clone size was 53% in granulocytes and 32% in erythrocytes. The mean LDH level was 992 U/L at average 4.0 folds of ULN. 60 thrombosis events (TE) were reported in 38 patients, of whom 42% had multiple TE. The TE event rate with conventional therapy was 7.19 events/100 patient- years. TE events accounted for 36.4% (4/11) of deaths during the study period. TE occurred at both venous (70%) and arterial (30%) sites. Deep vein thrombosis of the limbs was most common at 32%, hepatic/portal vein was 23%, cerebral artery was 15%. There was no statistical difference in the prevalence of TE events between patients with granulocyte clone size ≥50% and patients with 10-50% clone (9.4% *vs* 8.5%, p=0.788). Median age at first TE was 42.9 years. There was no significant difference in age and gender between the patients with or without TE. TE events occurred in PNH patients at any age, but most commonly were seen in patients at age 31-40 years (26%). TE occurred regardless of hemolysis status. 10 TE events (19.6%) occurred in 5/38 (13.2%) patients with LDH<1.5×ULN; these patients' median granulocyte clone size was 40.3% and mean LDH was 0.86×ULN. These 10 TE events were myocoardia infaction (1), DVT of the lower limbs (3), portal/hepatic vein (3), pulmonary embolism (1), stroke (1) and unstable angina (1). ROC analysis showed that LDH ≥1.2×ULN represented the most sensitive threshold to detect 90.6% of the patients with TE; LDH ≥1.5×ULN or ≥3.0×ULN as cut-off only detected 84.4% or 56.3% of the population with TE. Univariate analysis showed patients with LDH ≥1.2×ULN had a significantly increased incidence of TE compared with patients with LDH<1.2×ULN (OR 4.17; 95% CI 1.24-13.97, P=0.013)
Summary and Conclusion: TE is a major contributor to the morbidity and mortality in Chinese PNH patients on conventional therapies. TE occurrence

was not correlated with patients' age or gender. TE could happen when PNH patients didn't have significant hemolysis. Attention need to be paid to these PNH patients without elevated LDH because other mechanisms are involved in the pathogenesis of thrombosis.

P1182

NEW RED BLOOD CELL AUTOMATED PARAMETERS FOR IRON DEFICIENCY SCREENING IN CHRONIC INFLAMMATORY DISEASE

E Lazarova[1,2,*], A Heinrichs[2], L Filippin[2], O Pradier[3], D Franchimont[4], B Gulbis[2]
[1]Laboratory of Transfusion, [2]Department of Clinical Chemistry, [3]Laboratory of Haematology, [4]Department of Gastroenterology, CUB Erasme Hospital ULB, Brussels, Belgium

Background: New red blood cell parameters are available on Beckman-Coulter Unicel DxH800 instrument, *i.e.* LHD% (Low Haemoglobin Density %), RSf (Red cell Size factor) and MAF (Microcytic Anaemia Factor). Previous studies showed that those parameters might be useful for iron deficiency diagnosis, especially in order to detect iron depletion in the context of chronic inflammation.
Aims: The aim of our study was to evaluate those parameters for assessing latent iron deficiency and iron deficiency anaemia associated with chronic inflammatory disease.
Methods: During six weeks, adult patients' samples (n=182) from the daily laboratory workflow, with a dosage of haemoglobin (Hb), ferritin (FET), C-reactive protein (CRP) and with a normal renal function (creatinine<1mg/dL or<1.2mg/dL for women and men, respectively) were included. A control group (n=267), with all parameters within the reference range values, was also constituted. Subjects were separated into five groups based on iron deficiency (ferritin<30 µg/L or<40 µg/L in presence of chronic disease), anaemia (women, Hb<120 g/L and men, Hb<130 g/L), and inflammation (CRP >10 mg/L):
• IDA Iron Deficient Anaemia without inflammation (n=49);
• LID Latent Iron Deficiency without anaemia nor inflammation (n=69);
• ACD-ID Anaemia of Chronic Disease–Iron Deficient (n=21);
• ACD-PID Anaemia of Chronic Disease–Possibly Iron Deficient (n=30);
• ACD Anaemia of Chronic Disease without iron deficiency (n=13).
Soluble transferrin receptor concentration (sTfR, Roche Diagnostics, Vilvoorde, Belgium) was measured for the groups with anaemia of chronic disease *i.e.* ACD-ID, ACD-PID and ACD. Furthermore, some 81 patients with a diagnosis of inflammatory bowel disease (IBD) were included in the study and were separated into seven groups: IDA (n=3); LID (n=14); ACD-ID (n=1); ACD-PID (n=5), ACD (n=4), non-anaemic patients with ferritin>40µg/L, CRP<10mg/L (n=42), and non-anaemic patients with ferritin>40µg/L, CRP>10mg/L (n=15). Mann-Whitney test, unpaired t test and one-way ANOVA were used for statistical analysis.
Results: The patients (n=64) from the first part of the study with ACD-ID, ACD-PID, and ACD were further characterized by sTfR; statistically significant differences ($p<0.05$) were found between ACD-ID and ACD-PID, and between ACD-ID and ACD. Concerning the three automated parameters (LHD%, RSf and MAF), a statistically significant difference was observed between the control group and the five studied groups. To assess latent iron deficiency, we compared IDA and LID, and all three parameters showed a difference between those two groups ($p<0.05$). Concerning anaemia of chronic disease-groups (ACD-groups), only MAF and RSf showed a statistically significant difference between the three ACD-groups (ACD *vs* ACD-ID *vs* ACD-PID). Analysing the IBD groups, only MAF showed a statistically significant difference between the groups of IDA and LID. Concerning groups ACD, ACD-ID, and ACD-PID of IBD patients, no statistically significant difference was found. Comparing the control group of the first part of the study (n=267) with IBD patients without anaemia and no inflammation (n=42), LHD% demonstrated a statistical difference ($p<0.05$), contrary to MAF. Comparing the control group (n=267) with IBD patients with inflammation and without anaemia (n=15), both LHD% and MAF demonstrated a statistically significant difference.
Summary and Conclusion: This study demonstrates that LHD%, MAF and RSf could be used as screening tests of latent iron deficiency; MAF and RSf could reflect iron depletion in patients with anaemia of chronic disease. After testing the validity of these findings in the settings of IBD, we selected MAF as the most suitable haematological parameter for latent iron deficiency differentiation.

P1183

ROLE OF BMI IN PREDICTING PREVALENCE OF IRON DEFICIENCY ANEMIA

N Tun[1,2,*], M Austin[3]
[1]Internal Medicine, Easton Hospital, Easton, [2]Affiliated with Drexel University, Philadelphia, [3]Hematology and Oncology, Easton Hospital, Easton, United States

Background: Iron deficiency anemia is the most common anemia worldwide. Interestingly, overweight and obese children and adolescents are found to have a higher incidence of iron deficiency anemia. Overweight and obese children and adolescents have been shown to have higher hepcidin levels, and inadequate responses to oral iron therapy. Hepcidin produced from hepatocytes is one of the key regulators of iron hemostasis. Hepcidin inhibits expression of iron transporter, ferroportin, in enterocytes, macrophages and hepatocytes. Inhibition of ferroportin action results in iron sequestration in the enterocytes with diminished release of iron into the circulation, thereby decreasing iron absorption. Hepcidin levels are upregulated by inflammation and iron storage but downregulated by anemia. Obesity triggers inflammatory response with increased release of cytokines and acute phase reactants in multiple organs. Obese patients are found to express higher levels of hepcidin. Therefore, we are assessing whether adult patients with high BMI (BMI≥30) are more prone to develop iron deficiency anemia.
Aims: Iron deficiency is thought to be more common in patients who have poor nutrition and low iron intake. However, there have been observations of an inverse relationship between body weight and iron saturation. Therefore, we are assessing whether Body Mass Index (BMI) can affect serum iron levels.
Methods: This is a retrospective case control study where 78 adult patients from age 18-98 years with iron deficiency anemia from Eaton Hospital in-patients as well as a community care clinic in Easton were assessed with regard to their body weight (*i.e.* BMI). Hemoglobin, serum iron, ferritin, iron binding capacity and iron saturation were measured and correlated with patients' BMI. Patients with any ongoing blood loss such as hematuria, severe menorrhagia, hematochezia or history of gastrointestinal bleeding including peptic ulcer disease, variceal bleeding, hemorrhoidal bleeding, diverticular bleeding, arteriovenous malformation were excluded. Patients who had inflammatory bowel disease, celiac disease, post-surgical malabsorption problems, gastric bypass surgery, gastrointestinal tract malignancy, chronic kidney disease, repeated blood donations, as well as pregnant patients were also excluded from the study.
Results: 67 female patients and 11 male patients aged 18-98 years with iron deficiency anemia were evaluated for body mass index. 40 patients had high BMI (BMI ≥30) and 38 patients had low BMI (BMI<30). The median age was 55. The mean hemoglobin of patients in this study was 10.8g/dL. The mean iron level in the high BMI group was 40.6, *versus* 57.92 µg/dL in the low BMI group, p value=0.08. In addition, the mean ferritin level in the high BMI group was 76.92 *versus* 198.8 ng/ml in the low BMI group (p value=0.09), using the Welch two sample t-test. The mean TIBC was slightly higher at 352.8 µg/dL in obese patients whereas patients with a low BMI had a lower mean TIBC at 312.72 µg/dL, p value 0.06. Patients with a high BMI had a mean iron saturation of 11.25%, compared to a mean iron saturation of 18.71% in the low BMI group, p value 0.007 (Fig 1).

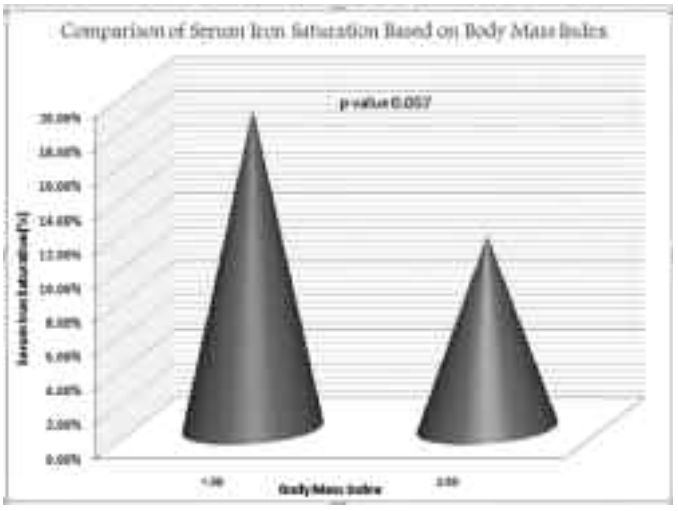

Figure 1.

Summary and Conclusion: In our study, obese patients (BMI≥30) had a higher prevalence of iron deficiency anemia in comparison to patients with BMI<30, after excluding patients with potential blood loss or iron malabsorption. Therefore, BMI is a significant predictor of iron saturation.

P1184

MICROCYTIC ANAEMIA AND IRON METABOLISM IN ERYTHROPOIETIC PROTOPORPHYRIA

D Spinelli[1,*], G Graziadei[2], V Brancaleoni[3], F Granata[3], S Fustinoni[3], A Marcon[2], M D Cappellini[4], E Di Pierro[3]
[1]Department of Clinical Sciences and Community Health, Specialty in Internal Medicine, University of Milan, Fondazione IRCCS Ca' Granda, Milan, [2]Department of Medicine and Medical Specialities, [3]Department of Clinical Sciences and Community Health, University of Milan, [4]Department of Medicine

and Medical Specialities - Department of Clinical Sciences and Community Health, University of Milan, Fondazione IRCCS Ca' Granda Ospedale Maggiore Policlinico, Milan, Italy

Background: Erythropoietic Protoporphyria (EPP) is a cutaneous porphyria, due to ferrochelatase (*FECH*) gene alterations. The *FECH* gene encodes the last enzyme in the heme synthesis which catalyses for insertion of iron into protoporphyrin IX (PPIX) to form heme. EPP is clinically characterized by painful long-life severe photosensitivity usually with a childhood onset and in some cases it is associated with microcytic anaemia. Accumulation of PPIX in blood red cells, plasma, skin and liver is associated with burning, pain, itching followed by erythema and oedema of the skin and elevated transaminases up to liver failure. A negative correlation between PPIX and iron and transferrin (Tf) saturation has been reported. The molecular basis for an overt phenotype are: - co-inheritance of a null mutation in the ferrochelatase (*FECH*) gene trans to a GTC haplotype, reducing expression of the remaining wild-type allele. This combination is responsible to decrease *FECH* activity to<35%; - X-linked transmission, a rarer variant of EPP called X linked-protoporphyria (XLPP), due to gain-of-function mutations in the 5-aminolaevulinate synthase 2 (*ALAS2)* gene on the X chromosome encoding the first enzyme in the heme synthesis which produces 5-aminolaevulinic acid (ALA) starting from glycin and succinyl-CoA.
Aims: The aim of this study was to re-evaluate iron status of 22 subjects (age at diagnosis: 23.5±15.7; 8-61 years) diagnosed as affected by EPP attending the Rare Disease Centre at Fondazione Ca' Granda in Milan from January 2009 to December 2013.
Methods: EPP diagnosis was first suspected by anamnesis, signs, the increase of erythrocyte protoporphyrins and the presence of a fluorescence emission peak at 632-634 nm in the plasma. The diagnosis was confirmed by direct sequencing and MLPA of *FECH* gene starting from genomic DNA extracted from peripheral blood. In all patients, we also measured iron, ferritin, Tf, Tf saturation, haemoglobin (Hb), mean corpuscular volume (MCV) and the relative percentage of free (PPIX) and zinc-protoporphyrins (ZnPP) in peripheral venous blood.
Results: Fifteen patients inherited a null mutation trans to a low expressed allele, two subjects showed the homozygous GTC haplotype and a 61 year-old man carrying only a null mutation complained cutaneous symptoms after myelodisplastic syndrome onset. In the remaining four patients *ALAS2* alteration was detected. Thirteen (59 %) of our patients presented a slight microcytic anaemia (in females Hb 12.3±1 g/dl, range 10.5-14 g/dl and MCV: 77.1±7.6 fl, range 60.4-87.1 fl; in males Hb 13.4±1.2 g/dl, range 10.9-15.1 g/dl and MCV 76.4±8.0 fl, range 63.1-95.9 fl). Ferritin was reduced in 63.6% of cases (in females 35.4±51 ng/ml, range 3-192 ng/ml; in males 41.3±31.8 ng/ml, range 10-112 ng/ml; normal values 15-150), Tf and serum iron (Fe) values were in the normal range (respectively in females Tf 309.3±39.9 mg/dl and in males 298±21.1 mg/dl; normal values 200-360; in females Fe 68.9±40.3 mcg/dl and in males 84±25.7 mcg/dl; normal values 37-145) while Tf saturation was indicative for iron deficiency only in females. A 29 year-old girl presented X-linked protoporphyria in association to Iron Refractory Iron Deficiency Anaemia (IRIDA) and in contrast to EPP patients she had no exacerbation of skin symptoms during intravenous iron treatment, as reported in literature.
Summary and Conclusion: This study confirms a relationship between EPP and iron deficiency anaemia which requires further investigation involving the iron metabolism regulation.

P1185

SIGNIFICANT IMPACT OF IRON CHELATION AFTER ALLOGENEIC HEMATOPOETIC STEM CELL TRANSPLANTATION ON DISEASE RECURRENCE: POTENTIAL ANTI-LEUKEMIC ACTIVITY

M Michallet[1,*], M Sobh[1], S Ducastelle[1], L Gilis[1], H Labussière[1], F Barraco[1], X Thomas[1], F E Nicolini[1], C Chapuis-Cellier[2]
[1]Hematology, [2]Biochemistry, Centre Hospitalier Lyon Sud, PIERRE BENITE CEDEX, France

Background: Iron overload (IO), primarily related to multiple red blood cell transfusions, is a relatively common complication in allogeneic hematopoietic stem cell transplant (allo-HSCT) recipients. Elevated pre-transplant ferritin level, a surrogate marker of iron overload, was demonstrated to be an important cause of mortality and morbidity in patients who have undergone allo-HSCT. Excessive iron accumulation results in tissue damage and organ failure, mainly as a result of the generation of free radicals that cause oxidative damage and organ dysfunction. Iron chelators have been widely used leading to normalisation for ferritine level and lower IO-related complications. As iron has a fundamental role in cell survival affecting pathways involved in DNA synthesis, cell differentiation, and apoptosis, some studies evaluated the anti-proliferative activity of iron chelators in cancer and leukemia patients on disease recurrence.
Aims: The objective of this study was to determine at a first time the impact of serum ferritin level measured at time of allogeneic HSCT in adult patients with hematological disorders on the different outcomes and to investigate at a second time the role of iron chelation on relapse incidence.
Methods: We included 158 patients, 100 males and 58 females with a median age of 45 years (18-67) who underwent allo-HSCT between 2002 and 2010. There were 83 acute myeloid leukemias, 10 chronic myeloid leukemias, 11 myelodysplastic syndromes, 7 myeloproliferative disorders, 19 myelomas, 9 non-Hodgkin lymphomas, 6 Hodgkin diseases, 5 aplastic anemias and 3 hemoglobinopathies. Sixty-seven (42%) patients were sex mismatched (F→M:37; M→F:30); for ABO compatibility, 61% were compatible, 18% had minor incompatibility and 21% had major incompatibility. Concerning the HSCT procedures, 60 patients (38%) received peripheral blood stem cell and 98 (62%) received bone marrow from 97 (61%) HLA related donors [matched, n=76; mismatched, n=21], and 61 (39%) HLA unrelated donors [matched, n=36; mismatched, n=25] after myeloablative [n=64, (41%)] or reduced intensity conditioning [n=94, (59%)]. At transplantation, 91 (58%) were in complete remission (CR) or chronic phase [CR1: n=61 (67%); ≥CR2: n=30 (33%)]. The median serum ferritin level at HSCT was 1327 microg./l (26-14136); 31(20%) patients had a level 26-500, 33 (21%) had a level 500-2500, and 94 (59%) >2500. There was no significant correlation between the different ferritin levels, disease kind and status at HSCT. After transplantation, 23 patients received iron chelating agents after a serum ferritine level of 1000 microg/l and stopped when the level decreased below 1000.
Results: The cumulative incidence of acute GVHD ≥ II at 3 months was 14% (11-16.5) with 10.5% (8-13) for grade III and 7% (5-9) for grade IV; the 1 year cumulative incidence of limited and extensive chronic GVHD were 4% (2-6) and 12.4% (9-16) respectively. After a median follow-up of 18 months (1-106), the 5 years OS probability was 65% for patients with ferritin level below 500 microg./l, 39% for level between 500 and 2500 microg./l and 28% for level >2500 micog./l, [Hazard ratio=3.5 (1.5-8.1), p=0.002]; this was explained by a significant higher TRM in patients with level >2500 [Hazard ratio=4.3 (1.02-18), p=0.04]. Interestingly, we found in multivariate analysis that patients receiving iron chelators had significantly better OS [5 years OS=59% *vs*. 34% for non-chelated patients, Hazard ratio=0.34 (0.15-0.76), p=0.008], (Figure 1a), and experienced less disease relapse [5 years relapse incidence=18% *vs*. 41% for non-chelated patients, Hazard ratio=0.22 (0.07-0.73), p=0.012], (Figure 1b).

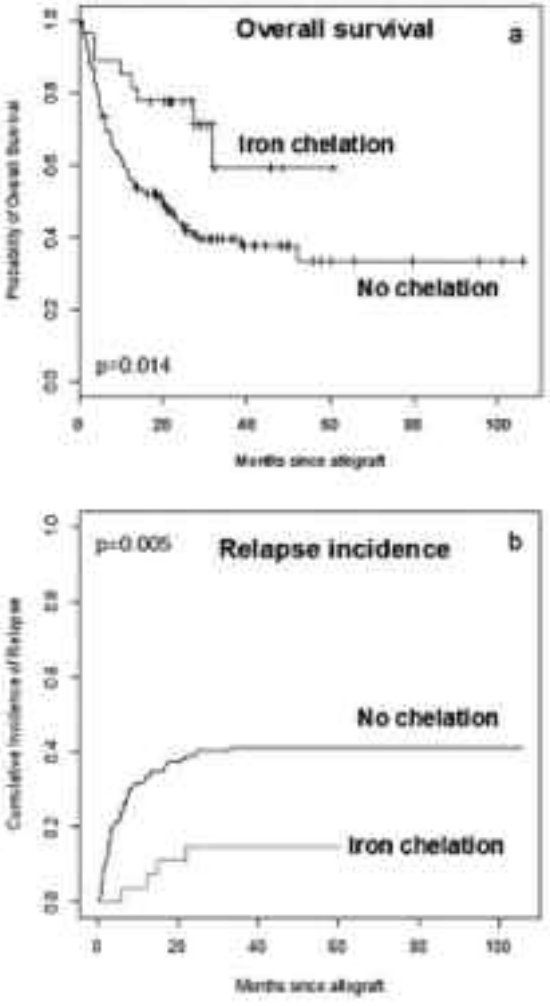

Figure 1.

Summary and Conclusion: We confirmed the negative impact of iron overload on the outcomes allo-HSCT recipients. More importantly, we demonstrated that iron chelators have a positive impact in reducing disease relapse by the possible mechanism of iron deprivation in leukemic cells. This clinical observation needs to be confirmed by prospective randomized trials.

Infectious diseases, supportive care 2

INVESTIGATION ON THE EARLIEST SIGN OF INVASIVE PULMONARY ASPERGILLOSIS (IPA) AND THE ONSET, WITH ROUTINE NON-PYREXIA PHASE CT BASED DIAGNOSTIC STRATEGY, A COHORT STUDY

K Kyo[1,*], K Toishigawa[1], T Ochi[1], T Okatani[1], R Imanaka[1], M Itagaki[1], Y Katayama[1], K Iwato[1], H Asaoku[1], T Kyo[1]
[1]Hematology, Hiroshima Red Cross and Atomic-bomb Survivors Hospital, Hiroshima, Japan

Background: IPA is an aerial infection, beginning from airwayinvasive phase (AWIP) and then developing to angioinvasive phase (AGIP). However, during neutropenia, the start of AGIP, halo sign (HS), is still considered the earliest sign of IPA. No attempt has been made to detect IPA in AWIP, much remains unknown about the onset.
Aims: Since the late 2000s, galactomannan (GM) has improved dramatically; decreased cut off (0.5) and routine measurement from admission irrespective of pyrexia are now well accepted. Conversely, chest CT (CT), considered as an earlier diagnosis method than GM, is still conducted only post pyrexia. Even on the Pyrexia Day One CT, progressed pneumonia can be detected in many cases. Therefore, we hypothesized that the earliest sign before HS can be captured by CTs in the non-pyrexia phase. This study investigates the hypothesis.
Methods: From 12/10/2010 to 9/12/2013, all acute leukemia (AL) patients without the history of IPA who received induction chemotherapy in our hospital were included. Informed consent was obtained. GM was routinely conducted twice weekly. ≥0.5 was positive. We defined the non-pyrexia phase as max temperature ≤37.3. Routine non-pyrexia phase CT (R-CT)s were conducted at admission and repeatedly conducted at 7 day intervals. Additional CTs were also conducted when GM ≥0.4, the first day of ≥38.0 pyrexia and in cases of persisting pyrexia every 3 days. All images were analyzed by senior radiologists. Abnormalities suggesting IPA were strictly determined combining all CTs and patients clinical course. EORTC/MSG criteria was used for diagnosis. Clean room entry, prophylaxis (itraconazole or voriconazole) and treatment strategy (voriconazole alone or combination) were completely unified.
Results: 220 successive AL patients were analyzed, of them, 61 patients (27.7%) were diagnosed as IPA (all probable, no proven). Patient characteristics, IPA group *vs* non-IPA group, are as follows (data is presented as median (range)). Age; 74 (46-91) *vs* 66.5 (13-93), days of absolute neutrophil counts ≤500; 27 (10-387) *vs* 24 (9-373), days of hospitalization; 41 (25-462) *vs* 35 (24-375), number of CTs; 6 (2-19) *vs* 5 (1-16) and overall mortality; 11.4% (7/61) *vs* 5.0% (8/159). IPA was successfully treated in all patients and no IPA related fatalities were observed. 4 patients were excluded for reasons such as mucor superinfection. As the earliest IPA CT sign, 98% (56/57) of patients showed airwayinvasive pattern, furthermore, only 15.7% (9/57) progressed to angioinvasive pattern. Figure shows IPA onset determined by CT for all 61 patients. Of them, 60.6% (37/61) cases were diagnosed with R-CT. CT could make diagnosis earlier than GM (5.5 (1-28) *vs* 13 (2-53)). Furthermore, figure implies IPA preexistence; the diagnosis rate rapidly falls as the days from admission increases with 81.9% (50/61) diagnosis by day 15.

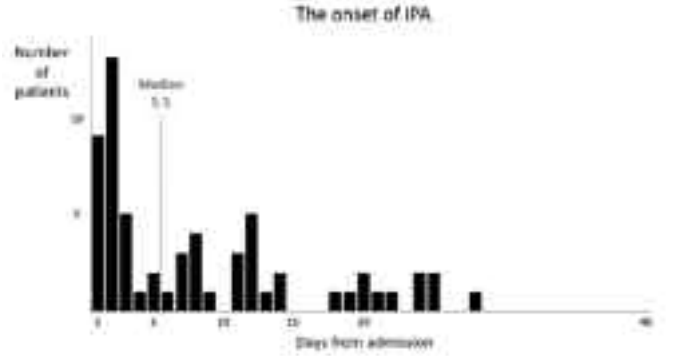

Figure 1.

Summary and Conclusion: Logically, pyrexia appears from progressed phase of infection, therefore the existence of pneumonia in the non-pyrexia phase is not unexpected. Unlike X-p, CT is not portable, which may be the main reason why R-CT has not previously been conducted. For AL patients without complete remission, immunosuppression has already occurred before admission. Therefore, IPA preexistence can be expected. We expect these new findings to be accepted in the near future. In Hematologica 2013 (98(11)), Marcio et al propose the importance of AWIP recognition; our initial study analysis was quoted as the first clinical study indicating AWIP as the earliest phase during neutropenia. In AWIP, in addition to lower fungal burden, the full advantage of excellent drug migration can be realized. Therapy from AWIP is vital; irrespective of the highest recorded risk patient background, IPA was successfully treated in all.

P1187

EFFICACY AND SAFETY OF ANIDULAFUNGIN IN THE TREATMENT OF INVASIVE CANDIDIASIS IN NEUTROPENIC PATIENTS: ANALYSIS OF POOLED DATA FROM FIVE PROSPECTIVE STUDIES

R Herbrecht[1,*], U Conte[2], P Biswas[2], R Capparella[3], J Aram[2]
[1]Department of Oncology and Hematology, Hôpital de Hautepierre, Strasbourg, France, [2]Anti-Infectives Division, Pfizer Inc., New York, United States, [3]Anti-Infectives Division, Pfizer Inc., Paris, France

Background: Invasive candidiasis is associated with high morbidity and mortality, especially in relation to neutropenia. Anidulafungin has been studied primarily in non-neutropenic patients.
Aims: Here we present the results of a pooled analysis of data from one randomized, double-blind, comparative study and four open-label, non-comparative studies to determine the efficacy and safety of intravenous (IV) anidulafungin in the treatment of invasive candidiasis (IC) in patients with neutropenia.
Methods: Data from neutropenic patients (baseline absolute neutrophil count [ANC] ≤500 cells/mm^3 or classified as neutropenic by the investigator) with microbiologically confirmed IC were pooled. Patients received a single IV loading dose of anidulafungin 200 mg on Day 1, followed by a once-daily maintenance dose of 100 mg for at least 14 days after the last positive culture for *Candida* species and symptom resolution. A switch to oral therapy (fluconazole or voriconazole) was permitted after at least 5–10 days of treatment with IV anidulafungin. The primary endpoint was global response (based on investigator assessment of clinical and microbiological response) at the End of IV Therapy (EOIVT) in the modified intent-to-treat population (patients who received treatment and had microbiologically confirmed *Candida* infection). Global response at the End of (all) Treatment (EOT) was a secondary endpoint. Global response of success was defined as a clinical response of cure/improvement and a microbiologic response of eradication/presumed eradication.
Results: In total, 46 anidulafungin-treated patients (mean age 56 years) were included in the analysis. The most common *Candida* species were: *C. tropicalis*, 16 (34.8%); *C. krusei*, 9 (19.6%); *C. parapsilosis*, 8 (17.4%); *C. albicans*, 7 (15.2%), *C. glabrata*, 7 (15.2%), and *C. kefyr*, 4 (8.7%). Sites of infection were: blood only, 39 (84.8%); blood and other sterile site, 2 (4.3%); and other sterile site only, 5 (10.9%). The median duration of neutropenia (in the 28 patients who had baseline and post-baseline ANC) was 16.0 days (range 1–43). The global response success rate at EOIVT was 56.5% (95% CI 42.2, 70.8). Similarly, the global response success rate at EOT was 52.2% (95% CI 37.7, 66.6). In patients with resolved or persistent neutropenia at the time of the last dose of study treatment, the global response success rate at EOIVT was 80.0% (12/15; 95% CI 59.8, 100.0) and 53.8% (7/13; 95% CI 26.7, 80.9), respectively. The safety profile was similar to previous studies. All-cause mortality by Day 14 and Day 28 post-treatment was 19.6% (9/46) and 23.9% (11/46), respectively.
Summary and Conclusion: In this group of 46 neutropenic patients with IC treated with anidulafungin, the global response success rate was comparable to published reports in which resolution of neutropenia was associated with a favourable response to treatment.

P1188

USE OF ANTIFUNGAL DRUGS IN REAL CONDITIONS OF MEDICAL PRACTICE IN HAEMATOLOGY: A FRENCH MULTICENTER PROSPECTIVE STUDY (AFHEM)

M Michallet[1,*], J EL Cheikh[2], I Yakoub-Agha[3], D Caillot[4], JP Gangneux[5]
[1]CHU Lyon-Sud, Pierre-Bénite, [2]Institut Paoli-Calmettes, Marseille, [3]CHRU, Lille, [4]CHU, Dijon, [5]CHU, Rennes, France

Background: The mortality rate associated with invasive fungal infections (IFI) remains very high (≥ 40 %), justifying the necessity of gaining a strong understanding of medical practices in terms of systemic antifungal therapies. This is particularly important in haematology units that closely follow the most highly exposed populations such as long term neutropenic patients or recipients of allogeneic HSC transplantation.
Aims: Assess the use of antifungal drugs in real conditions of medical practice in haematology in France.
Methods: Multicenter, cross-sectional, prospective French observational study conducted in 24 haematology units (717 beds including 368 sterile beds with about 20% of paediatric beds) over 5 consecutive days on adult or paediatric patients suffering from haematological malignancies and hospitalized during the 5-day period.
Results: Six hundred and fifty-five patients were enrolled in the register. Among evaluable patients (N=627), 276 (44%) received at least one systemic antifungal drug during the 5 days as prophylaxis (N=215, 78%), as empirical

treatment (N=30, 11%) and as curative or pre-emptive treatment (N=40, 14%). Overall, 494 patients (paediatrics, 13%) signed a consent form to participate into the extended study, with 38% of patients transplanted (including 25% of allogeneic HSCT, 8% of autologous transplant, and 5% of both) and 63% put into a sterile room. At inclusion, 87% of patients had not developed a previous IFI, 90% did not present a persistent fever on antibiotics and 74% had no neutropenia exceeding 10 days. At inclusion 50% of the patients received both antibiotic and antiviral treatment at inclusion and 82% were administered chemotherapy and/or monoclonal antibodies and/or immunosuppressive treatment. Forty-one percent of ALL, AML or MDS patients had no antifungal treatment, 43% received antifungal prophylaxis, 6% received empirical treatment and 10% received either pre-emptive or curative treatment. Of the NHL, HL, CLL or Myeloma 68% of patients did not receive any antifungal therapy and 84% of those who received an antifungal drug received prophylaxis. As expected, transplanted patients, patients presenting neutropenia for at least 10 days and patients in partial or complete remission were more likely to receive an antifungal drug (74%, 65% and 56% of these patients, respectively). Multivariate analysis showed that persistent fever refractory to antibiotherapy, duration of hospitalization over 30 days and ALL, AML or MDS are predictive factors for documented treatment (either curative or pre-emptive). Focusing on antifungal prophylaxis, this early strategy was associated with allogeneic HSCT, entry in sterile room and antibiotherapy.

Summary and Conclusion: As IFIs are life threatening and their early diagnosis is difficult to establish, primary antifungal prophylaxis is highly recommended in current guidelines (ECIL, IDSA, ASBMT). This study shows that one third of patients hospitalised in haematological units receive antifungal prophylaxis and about half receive systemic antifungal drugs. Globally, these data provide new insights into the management of IFIs in French haematology units, which can help to improve patient management, especially identifying those who are more likely to require antifungal treatments. Empirical treatment is no longer predominating in antifungal strategy and is replaced by prophylaxis. Factors associated with antifungal prophylaxis were allograft (74% of patients), prolonged neutropenia (65%) and partial or complete response to chemotherapy (56%).

P1189

AEROSOLIZED LIPOSOMAL AMPHOTERICIN-B TO PREVENT INVASIVE PULMONARY ASPERGILLOSIS IN ACUTE MYELOID LEUKEMIA. EFFICACY AND COST-EFFECTIVENESS IN REAL-LIFE

GL Chong[1,*], F Broekman[2], S Polinder[3], J Doorduijn[1], P Lugtenburg[1], A Verbon[2], J Cornelissen[1], B Rijnders[2]
[1]Department of Internal Medicine, Hematology, [2]Departments of Internal Medicine, Section of Infectious Diseases, [3]Departments of Public Health, Erasmus Medical Centre, Rotterdam, Netherlands

Background: Chemotherapy induced neutropenia can be complicated by invasive pulmonary aspergillosis (IPA). In 2008, liposomal amphotericin-B (L-AmB) inhalation was shown to prevent IPA in a placebo controlled trial. Patients with acute myeloid leukemia (AML) are the subset of hematology patients at highest risk for IPA. In 2008, L-AmB inhalation prophylaxis became standard of care for all AML patients in our hospital.

Aims: In this study, we evaluated the efficacy and cost-effectiveness of L-AmB inhalations in a prospective cohort of AML patients.

Methods: 127 consecutive AML patients received chemotherapy and prophylactically inhaled L-AmB during their first and second chemotherapy course. 108 patients treated for AML at the same sites from 2005 to 2008 served as controls. A standardized diagnostic protocol was used and probable or proven IPA served as the primary endpoint. Also, diagnostic and therapeutic costs were comprehensively analyzed and compared.

Results: A significant decrease in probable/proven IPA in the L-AmB inhalation group was observed(L-AmB 9%, control 23%, p=0.0064). Systemic antifungal therapy given at any time during the entire AML therapy decreased from 49· 5% to 27· 0%. Per patient equipment and drug costs for the L-AmB inhalation (1292 euro/patient) were more than compensated by a decrease in costs for diagnostics and therapeutic voriconazole use (minus 1816 euro). No L-AmB inhalation related serious adverse events were seen.

Summary and Conclusion: In an unselected AML patient group, L-AmB inhalation resulted in a significant and substantial decrease in IPA and was cost saving. Now that azole resistant becomes more frequent, non-azole based prophylaxis may become an attractive strategy.

P1190

HIGH RISK OF INVASIVE FUNGAL INFECTIONS (IFI) IN ACUTE LYMPHOBLASTIC LEUKEMIA (ALL) PATIENTS RECEIVING INDUCTION AND SALVAGE CHEMOTHERAPY WITH ITRACONAZOLE PROPHYLAXIS – TIME TO CHANGE GAME PLAN

GC Wong[1,*], B M Keng[2], C H Keng[3], B Tan[4]
[1]Hematology, Singapore General Hospital, [2]Raffles Institution, [3]Raffles Girls' School, [4]Infectious Diseases, Singapore General Hospital, Singapore, Singapore

Background: Background: IFI is a major cause of morbidity and mortality in patients receiving chemotherapy for hematologic malignancies. It is well reported in acute myeloid leukemia (AML) patients and patients undergoing bone marrow transplant. IFI in acute lymphoblastic leukemia (ALL) patients is less well studied, despite more intensive use of steroids in chemotherapy regimens for these patients.

Aims: Aims: We aim to determine IFI incidence in adolescent and adult ALL patients receiving chemotherapy, examine the clinical features and outcomes of patients with IFI and efficacy of itraconazole as antifungal prophylaxis.

Methods: Methods: Patients treated with chemotherapy for ALL diagnosed between January 1999 and May 2013 were included in the study. A retrospective review of casenotes and data in Leukemia Registry (institutional board approved) was made for clinical profile, disease characteristics and IFI management. IFI was defined using EORTC criteria (De Pauw, CID 2008).

Results: Results: Twenty nine cases of IFI were diagnosed, giving an incidence of 13.9%, using patients undergoing chemotherapy as a denominator. The median age for patients developing IFI was 36 years (19-61). The main chemotherapy regimens used included HCVAD (hyperfractionated cyclophosphamide, vincristine, doxorubicin, dexamethasone, methotrexate, cytarabine), FLAG (fludarabine, cytarabine, GCSF) and HK-SG ALL protocol. Itraconazole was the antifungal prophylaxis used in all cases. Nineteen (65.5%) cases occurred during induction and salvage chemotherapy. Eighteen cases (62%) had a duration of neutropenia (ANC<500/mm3) lasting longer than 14 days in the admission with IFI. There were 25 proven (86.2%) and 4 probable cases. There was no significant difference in incidence of IFI during the period of heavy construction around haematological wards in May 2007-2013 compared to the period 1999 – April 2007. The IFI incidence was 13.6% and 14.2% respectively. CT thorax was done in 26/29 (89.7%) of cases, with 12/26 (46.2%) demonstrating classical criteria of IFI (halo, air crescent sign, cavity in consolidation). Amongst the cases, aspergillosis accounted for 10, Candida bacteremia in 4, fusariosis in 2, mucormycosis in 1, trichosporon infection in 1, cryptoccoccal infection in 1 and other moulds in 4. IFI did not result in a delay in chemotherapy in only 17.2% of cases. Mortality attributable to IFI was 31.3%, with patients surviving less than 6 months from IFI diagnosis.

Summary and Conclusion: Conclusions/Summary: The incidence of IFI in ALL patients on induction and salvage chemotherapy is unacceptably high (13.9%). This incidence in AML patients receiving chemotherapy for the same period was 8.9%. The majority of infections occurred during induction and salvage chemotherapy, with patients having prolonged neutropenia. These invasive fungal infections resulted in significant delay in chemotherapy. Mortality directly attributable to IFI was high at 31.3%. Alternative antifungal prophylaxis, rather than itraconazole use, is urgently indicated.

P1191

A SINGLE-INSTITUTION RETROSPECTIVE ANALYSIS OF ANTIFUNGAL TREATMENTS IN ONCO-HEMATOLOGIC PATIENTS

N S Fracchiolla[1,*], F Guidotti[1], N Orofino[1], A Cortelezzi[1]
[1]UOC Oncoematologia, Fondazione IRCCS Ca'Granda - Ospedale Maggiore Policlinico, Milan, Italy

Background: Invasive fungal infections (IFIs) are a leading cause of morbidity and mortality in hematologic patients (pts). The European Organization for Research and Treatment of Cancer/Invasive Fungal Infections Cooperative Group and the National Institute of Allergy and Infectious Diseases Mycoses Study Group (EORTC/MSG), have classified IFIs as proven, probable or possible based on diagnostic certainty.

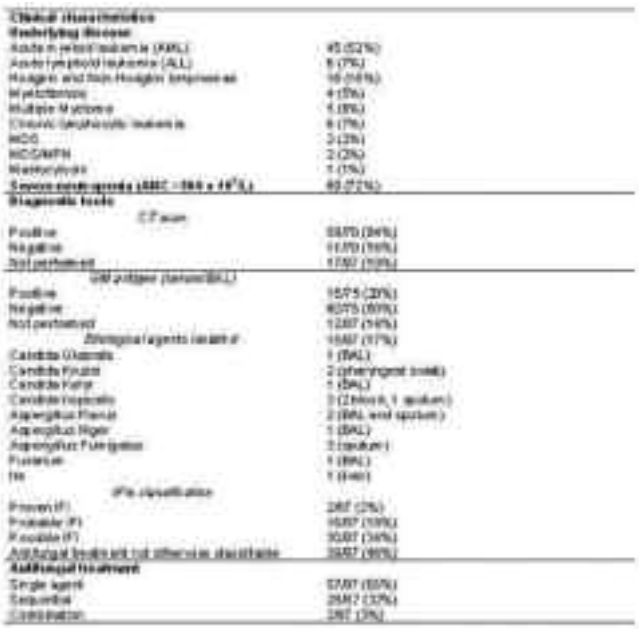
Aims: To describe antifungal treatments (AFtx) in a series of consecutive hematologic pts; to test the applicability of the EORTC/MSG criteria in a real life clinical setting.

Methods: Among 700 consecutive pts admitted to our Unit from January 2010 until July 2013, we selected those who underwent AFtx, for a total of 87 AFtx: 83 pts received AFtx, 4 was treated twice during 2 different hospitalizations. The clinical variables analyzed were: hematologic disease, neutropenia, CT scan (CTs), galactomannan antigen (GMa), mycological cultures, EORTC/MSG criteria, AFtx type (single agent, sequential, combination) and outcome.

Results: Table 1 summarizes prognostic factors, diagnostic results, IFIs classification and AFtx performed in our pts. Chest CTs (cCTs) results were distributed as follows: 25/45 AMLs were positive, 8 negative and 11 not done; 3/6 ALLs were positive and 3 negative; 13/16 lymphomas were positive, 1 negative, and 2 not done; finally, 16/20 of the group of "other hematologic malignancies" were positive and 4 not done. Two pts (1 AML, 1 ALL) underwent abdomen CTs and laparoscopic biopsies for hepatosplenic mycoses. Serum or BAL GMa was positive in 6/38 (16%) AMLs, 1/6 (17%) ALLs, 4/15 (27%) lymphomas and 4/16 (25%) "other hematologic malignancies". GMa was positive in 13 (24%) and negative in 41 (76%) of the 54 positive CTs. Conversely, GMa was positive only in one of the 11 negative CTs (9%). Yeasts were isolated in 7, moulds in 8 cases; GMa was positive in 3 (20%) of these (A niger, BAL; A fumigatus, sputum; Fusarium, BAL). The 87 cases could be classified according to EORTC/MSG criteria as follows: 2 proven (2%), 16 probable (18%) and 30 possible (35%); nevertheless, 39 pts (45%) could not

be classified because they lacked alternatively clinical or host criteria. Multiple AFtx were administered to 16/45 (36%) AMLs; 6/16 (37%) lymphomas; 9/20 (45%) "other hematologic malignancies". During hospitalization, 13 pts died (15%) and presented the following characteristics: CTs: 7 positive (54%), 1 negative (8%), 5 not performed (38%); GMa: 9 negative (69%), 4 not searched (31%); mycological cultures: 1 positive (A flavus, sputum); IFIs classification according to EORTC/MSG criteria: 4 cases (31%) classified as possible, while 9 (69%) were not classifiable; 9 pts (69%) were treated with mono AFtx, 4 (31%) with sequential or combination AFtx.

Table 1.



Summary and Conclusion: In our series the prevalence of AFtx was 12% (87/700) in 43 months. The worst outcome was observed in complex cases with a poor diagnostic definition characterized by requirement of combination AFtx, CTs and GMa search not performed, no mycological isolates, not applicability of EORTC/MSG criteria. The fact that 39 cases could not be classified according to EORTC/MSG criteria should be further investigated: it may reflect a low discriminating power of these criteria in onco-hematologic setting or may highlight the need for clinical studies and/or new diagnostic tools (such as 1-3-β-D-glucan determination) in order to diminish the number of cases in whom an AFtx is inappropiately delivered or, on the contrary, dangerously postponed.

P1192

COMPARISON OF GALACTOMANNAN DETECTED IN SERUM/ BRONCHOALVEOLAR LAVAGE FLUID AND TYPE OF ABNORMALITY ON PULMONARY HIGH RESOLUTION COMPUTER TOMOGRAPHY IN PATIENTS WITH PULMONARY INVASIVE ASPERGILLOSIS

Background: Up to now there have been missing data in the literature concerning relationship of galactomannan (GM) detected in bronchoalveolar lavage (BAL) fluid and type of abnormality on pulmonary high resolution computer tomography (HRCT) in patients (pts.) with pulmonary invasive aspergillosis (IPA).
Aims: To evaluate relationship between sensitivity of GM detected in BAL fluid and serum (S-GM) and type of abnormality on pulmonary HRCT in pts. with IPA.
Methods: We retrospectively analyzed mentioned relationship in pts. with probable and proven IPA entered in Fungal InfectioN Database (FIND)" *aspergillus* between 2001 and 2012.
Results: In total there were 143 IPA cases with GM detected in BAL fluid analyzed at the time of diagnosis. Overall positivity of GM in BAL fluid (1 sample ≥ 0.5 IP) was 86% in these pts. Sensitivity of GM in BAL fluid was significantly higher in pts. with pulmonary nodules than infiltrates on HRCT (89.7% *vs.* 76.2%; p=0.043). There was no statistically significant relationship between value of GM in BAL fluid and type of HRCT finding (p=0.690). S-GM was detected in 312 pts. with IPA. Overall positivity of S-GM (2 consecutive samples ≥ 0.5 IP) was 68.6% in these pts. Similarly to GM in BAL fluid there were proved statistically significant difference in sensitivity of S-GM in pts. with nodules and infiltrates on HRCT (78.0% *vs.* 62.0%; p=0.004). There was also found no statistically significant relationship between value of S-GM and type of HRCT finding (p=0.321).
Summary and Conclusion: Our study proved higher sensitivity of both GM in BAL fluid and S-GM in IPA pts. with more specific findings – nodules compare to non specific findings – infiltrates on HRCT.

P1193

CLINICAL EFFECTIVENESS OF PROPHYLACTIC VORICONAZOLE IN CHILDREN TREATED FOR HAEMATOLOGICAL MALIGNANCIES

V Fragandrea-Sidi[1], M Kourti[1,*], E Roilides[2], D Koliouskas[1]

[1]Pediatric Oncology Department, Hippokration General Hospital, [2]Third University Department of Pediatrics, Aristotle University of Thessaloniki, Thessaloniki, Greece

Background: Invasive fungal infections (IFI) have become high prevalence in patients with haematologic malignancies receiving chemotherapy. The risk of IFI is associated with the degree and duration of neutropenia, the disruption of mucosal barriers and the prolonged use of antibiotics and corticosteroids. Prophylaxis includes the use of antifungal drugs in all patients at risk. Voriconazole is a triazol antifungal agent that exhibits broad antifungal activity against both Aspergillus and Candida (including non – albicans) species, which has been used for the treatment of invasive candidiasis and aspergillosis. Its use as a prophylactic agent is under study, especially in children
Aims: The aim of the study was to evaluate the efficacy and safety of voriconazole as antifungal prophylaxis in children suffering from haematological malignancies with chemotherapy induced neutropenia.
Methods: The files of 136 children were retrospectively reviewed. They divided into two groups: group A of 69 children [42 Acute Lymphoblastic Leukemia (ALL), 1 mature B ALL, 8 Acute Myelogenous Leukemia (AML), 16 Non – Hodgkin Lymphoma (NHL), 2 Hodgkin Disease (HD) and group B of 67 [40 ALL, 1 mature B ALL, 5 AML, 14 NHL, 7 HD]. All patients were treated at a single institution, between January 2006 and December 2013 and received at a fungal prophylaxis with voriconazole during chemotherapy induced neutropenia. Age, gender, diagnosis, treatment regimen and laboratory investigations (WBC counts and liver function tests) were recorded. Voriconazole was at a dose of 4mg/Kg bid in group A and 7mg/Kg bid in group B, intravenously or orally.
Results: In total, 467 patient – cycles (236 in group A and 231 in group B) were studied. Median duration of neutropenia after chemotherapy during which time voriconazole prophylaxis was administered, was 17 days. Treatment success rate defined as absence of proven, probable, possible or suspected IFI was 97.8% [95.64% (229/236) for group A, 98.2 (231/227) for group B]. Proven IFI was documented in two patients with ALL (1 pulmonary aspergillosis, 1 Candida albicans fungemia, group A), 2 had probable IFI, (splenic candidiasis, 1 group A and 1 group B) and in 7 cases were considered suspected IFIs (4 group A and 3 group B). No severe adverse reactions or interactions with concurrent medications were observed that could be attributed to voriconazole administration.
Summary and Conclusion: These results suggest that voriconazole is an effective and well – tolerated alternative for antifungal prophylaxis in children with hematological malignancies during chemotherapy induced neutropenia. Randomized, double – blind, case control studies are needed to confirm the efficacy of this approach in comparison to standard treatments.

P1194

IMPACT OF TOLL-LIKE RECEPTOR 4 POLYMORPHISMS ON INFECTIOUS COMPLICATIONS IN PATIENTS WITH ACUTE MYELOID LEUKEMIA

U Schnetzke[1,*], B Spies-Weisshart[1], O Yomade[1], M Fischer[1], T Rachow[1], K Schrenk[1], A Glaser[2], M von Lilienfeld-Toal[1], A Hochhaus[1], S Scholl[1]
[1]Internal Medicine II/ Oncology and Hematology, [2]Department of Human Genetics, University Hospital Jena, Jena, Germany

Background: Infectious complications continue to be one of the major causes of morbidity and mortality in patients with acute myeloid leukemia (AML). Several single nucleotide polymorphisms (SNPs) may contribute to genetic susceptibility to infections or even sepsis. Recent studies have identified a potential association of two SNPs of the Toll-like receptor 4 (TLR-4) gene (Asp299Gly and Thr399Ile) and infectious events.
Aims: We sought to investigate the impact of these TLR-4 SNPs on developing infections in 172 patients with newly diagnosed AML during anthracycline-based induction chemotherapy (cytarabine combined with idarubicin or mitoxantrone). The incidences of neutropenic fever, blood stream infections, pneumonia, central venous catheter infections and the occurrence of sepsis were analysed.
Methods: Analysis of TLR-4 SNPs was performed by pyrosequencing and revealed 151 of 172 patients to be homozygous for the wild-type genotype. In contrast, 20 patients (11.6 %) were heterozygous for both SNPs while one patient (0.6 %) was heterozygous for the Thr399Ile SNP.
Results: We can demonstrate that patients carrying the TLR-4 SNPs developed significantly more episodes of neutropenic fever (p=0.031) and the duration of fever was significantly longer (p=0.032). The probability of pneumonia was also significantly higher among patients carrying the polymorphisms (28% *vs*. 65%, p=0.004). In contrast, no difference was found between patients with TLR-4 wild-type genotype and those heterozygous for both SNPs with regard to blood stream infections and the occurrence of central venous catheter infections. Importantly, the detection of TLR-4 SNPs shows a strong association with the development of sepsis (40% *vs*. 85%, p=0.00019).
Summary and Conclusion: To our best knowledge, this study represents the first analysis demonstrating that a haplotype containing two commonly segregated polymorphisms (Asp299Gly and Thr399Ile) of the human TLR-4 gene influences the risk of serious infections in patients with acute myeloid leukemia undergoing induction chemotherapy.

P1195

THE EXPRESSION OF TOLL-LIKE RECEPTORS AND DEVELOPMENT OF SEVERE SEPSIS IN PATIENTS WITH ACUTE MYELOID LEUKEMIAS

J Rybka[1,*], T Wróbel[1], A Butrym[1], B Jaźwiec[1], E Stefanko[1], O Dobrzyńska[1], K Kuliczkowski[1]
[1]Wroclaw Medical University, Wroclaw, Poland

Background: Toll-like receptors (TLRs) play an important role in the host defense against microorganisms. TLRs are mainly expressed in human immune related cells such as monocytes, neutrophils, macrophages, dendritic cells, T cells, B cells and NK cells. They effect is connected with secretion of cytokines and chemokines that recruit immune cells death that limits microbe expanding. Sepsis remains a common cause of mortality in patients with acute myeloid leukemia (AML) treated with intensive induction chemotherapy. Toll-like receptors play a key role in the mediation of systemic responses to pathogens during sepsis. The expression of TLRs and their association with the development of sepsis in patients with acute myeloid leukemia remains unclear.
Aims: The aim of this study was to investigate the possible associations between expression of TLR2, TLR4 and TLR9 and occurrence of sepsis in patients treated with intensive induction chemotherapy for AML.
Methods: 103 patients with newly diagnosed acute myeloid leukemia (AML) were evaluated (47 females and 56 males). The median age of patients was 51 years. The diagnosis was performed according to the WHO criteria for AML. The healthy control group included 20 age-matched individuals (9 females and 11 males). Bone marrow samples were taken before induction therapy. Using quantitative reverse transcriptase PCR, the mRNA expression of genes TLR2, TLR4 and TLR9 was measured. The relative quantitation was indicated by cycle threshold (Ct) values. The Ct value of the target genes was normalized (*Δ*Ct) to the Ct value of the GUS gene of the samples. The results were statistically analysed using 'STATISTICA 8,0'. Statistical analysis was performed by means of Mann-Whitney's U-test and p<0,05 indicated a significant difference.
Results: All patients with AML were treated with intensive induction chemotherapy. Prophylactic oral chinolones were used in all patients. Neutropenic fever occured in 98 patients (95%). In 62 patients (60%) infectious agent was found. We identified 20 episodes of severe sepsis (20%). 10 patients with symptoms of severe sepsis died from infection. Gram-negative bacteria were more commonly found in patients with sepsis. TLR2 and TLR4 mRNA expression was higher in patients with neutropenic fever than in group with neutropenia without sign and symptoms of infection after chemotherapy although the difference was not statistically significant. Among the patients with neutropenic fever the mRNA expression of TLR2 and TLR4 was significant higher in septic patients than in patients without sepsis symptoms (ΔCt TLR2 0,93±0,82 *vs* 0,78±0,85 and *Δ*Ct TLR4 0,35±0,29 *vs* 0,38±0,25). Moreover we observed that expression of TLR2 and TLR4 was significant higher in patients with AML and bacterial infection in comparison to group with separate fungal infection (ΔCt TLR2 1,15±1,06 *vs* 0,66±0,51 and *Δ*Ct TLR4 0,45±0,38 *vs* 0,21±0,19). The results are shown in table 1.

Table 1. Correlation between mRNA expression of TLRs and sepsis in AML patients.

	Sepsis n=20	No sepsis n=83	p
ΔCt TLR2	0,93±0,82	0,78±0,85	<0,01
ΔCt TLR4	0,35±0,29	0,38±0,25	<0,01
ΔCt TLR9	0,002±0,001	0,004±0,003	ns
	Bacterial infection n=43	**Fungal infection n=20**	**p**
ΔCt TLR2	1,15±1,06	0,66±0,51	<0,01
ΔCt TLR4	0,45±0,38	0,21±0,19	<0,01
ΔCt TLR9	0,002±0,001	0,001±0,002	ns

n=number of patients
ns=not significant

Summary and Conclusion: Our results suggest that TLRs could be an independent factor for development of sepsis in patients with acute myeloid leukemias after intensive induction chemotherapy. This observation should be validated by larger study.

P1196

ANTIBACTERIAL PROPHYLAXIS AND EMERGING RESISTANT STRAINS IMPACT ON EPIDEMIOLOGY AND OUTCOME OF BLOODSTREAM INFECTIONS IN ACUTE LEUKAEMIA: A PROSPECTIVE STUDY BY THE RETE EMATOLOGICA LOMBARDA (REL)

C Cattaneo[1,*], P Zappasodi[2], M Mazzucchelli[3], L Verga[4], F Pavesi[5], G Mometto[6], E Todisco[7], C Skert[8], V Saccà[9], A Ferrario[10], A Nosari[3], G Rossi[1]
[1]Hematology, Spedali Civili, Brescia, [2]Hematology, Policlinico S. Matteo, Pavia, [3]Hematology, Niguarda Ca' Granda Hospital, Milano, [4]Hematology, Ospedale S. Gerardo, Monza, [5]Hematology, Ospedale S. Raffaele, [6]UOC Oncoematologia, Fondazione IRCCS Ospedale Maggiore Policlinico, Milano, [7]Hematology, Humanitas Cancer Center, Rozzano, [8]Stem Cell Transplantation Unit, University of Brescia, Spedali Civili, Brescia, [9]Hematology, Ospedale Valduce, Como, [10]Department of Medicine, Hematology, Azienda Ospedaliera Universitaria, Ospedale di Circolo e Fondazione Macchi, Varese, Italy

Background: Bloodstream infections (BSI) are a considerable problem in acute leukaemia (AL) patients (pts), with mortality ranging from 5 to 10%. Moreover, Gram-negative rods (GNR) and multiresistant (multiR) bacteria are emerging pathogens and may negatively impact on the epidemiologic scenario.
Aims: In order to better define the very recent epidemiology and outcome of BSI in a real-life setting, we planned a prospective study collecting all consecutive febrile/infectious episodes occurring in AL pts admitted to 9 haematological institutions participating to REL, representing about 75% of the entire AL population treated in Lombardy.
Methods: From Dec-2012 to Jan-2014, all febrile/infectious episodes were recorded. The following data concerning BSI were analysed: age, gender, type and phase of leukaemia, neutropenia, fluoroquinolone (Fq) prophylaxis, presence of central venous catheter (CVC), concomitant pulmonary infiltrates, antibiotic resistance.
Results: In 158 AL pts (M/F 92/66; median age 54y, range 19-78; AML/ALL 132/24), 216BSI were diagnosed. In 120 (55%) BSI occurred in pts on Fq prophylaxis. In 48 (22.2%) pneumonia was also present. CVC-related BSI were observed in 29.2% of cases. Gram positive cocci (GPC) were isolated in 93/216 BSI (43.1%); GNR in 88 (40.7%), polymicrobial (PMB) aetiology in 33 (15.3%) and fungi (F) in 2 (0.9%). Coagulase-negative staphylococci (CoNS) were the most frequent GPC (69/216, 31.9%); *S. aureus*, *S. viridans* and enterococci were observed in 6 (2.8%), 11 (5.1%) and 20 (9.3%) cases, respectively. Methicillin-resistant strains accounted for 90.6% of all staphylococci and vancomycin-resistant strains for 10% of enterococci. CVC-rel BSI was independently correlated with GPC aetiology (GPC 60% *vs* GNR 36.5%) (p=0.001). Considering GNR, enterobacteriaceae were isolated in 88/216 BSI (40.7%) and *P. aeruginosa* in 20 (9.3%). GNR occurred more frequently during consolidation cycles (49% *vs* 34.2%) and in pts not on Fq prophylaxis (47.9% *vs* 35%). Both conditions were independent risk factors at multivariate analysis (p=0.009 and p=0.004, respectively). Fq resistant strains were recorded in 91% of isolates. ESBL+ strains, which accounted for 25% of enterobacteriaceae, were also more frequent in consolidation cycles (16.7% *vs* 4.7%, p=0.005) and Fq prophylaxis (14.2% *vs* 5.2%, p=0.03). Carbapenemase producing (CP)

strains occurred in 8% of enterobacteriaceae. Among *P. aeruginosa* strains, 15% were multiR. Thirty-day mortality was 6.5% (14/216); it was lower for GPC (3.2%) and similar for GNR and PMB BSI (9.1%). CP enterobacteriaceae or multiR *P. aeruginosa* BSI (30d mortality: 41.7%; OR 71.2, CI 8.7-580.8, p<0.0001) but not ESBL+ strains were independent predictors of death. Furthermore, having relapsed/resistant AL (15.6%; OR 10.5, CI 2.0-55.3, p=0.006), and the presence of concomitant pulmonary infiltrates (20.8%; OR 15.3, CI 3.0-77.9, p=0.001) significantly correlated with the risk of death at multivariate analysis.
Summary and Conclusion: In our real-life prospective study, the very recent bacterial epidemiology of AL pts was sustained by similar percentages of GPC and GNR. Fq prophylaxis was nearly ubiquitous and significantly predicted GNR and ESBL+ aetiology, which occurred even during consolidation cycles. While ESBL+ did not impact on survival, both multiR- and CP-bacteria correlated with a higher risk of death. Interestingly, also a concomitant diagnosis of pneumonia during BSI was a strong predictor of a poorer outcome. The usefulness of Fq prophylaxis has to be reanalysed in this new epidemiologic scenario.

P1197

NOSOCOMIAL MULTIDRUG-RESISTANT KLEBSIELLA PNEUMONIAE SPREAD AS THE MAJOR CAUSE OF SEVERE INFECTIONS IN PATIENTS WITH HAEMATOLOGICAL MALIGNANCIES
B Martino[1,*], A Barbaro[2], D Ielo[1], E A Martino[1], C Alati[1], B S Rogolino[2], F Ronco[1], D Rotilio[1]
[1]Hematology, [2]Microbiology, Ospedali Riuniti, Reggio Calabria, Italy

Background: Bacterial infections are more frequent in persons with impaired function of the immune system and/or with neutropenia. In neutropenic patients with haematological malignancies the use of chemotherapeutic drugs contributes to a further immunosuppression with reduction of body's defence mechanisms. In the last few years multidrug resitant *K.pnemoniae* is an emerging threat as nosocomial pathogen.
Aims: The aim of this study was to determine the prevalence of *Klebsiella pneumoniae* strains in patients with haematological malignancies in our ward, its spread, the origin of the infectious agent and in future to assess the clinical significance.
Methods: More than 1600 inpatients have been investigated in our haematological ward during three years; from 2010 up to October 2013. Hemocultures from 460 hospitalized patients with suspected blood stream infection were performed and isolated strains were identified by standard microbiological procedures.
Results: In 170 inpatients (37%) the presence of isolated strains was revealed. *Klebsiella pneumoniae* was present in 20% of the patients (n=35); 22 out of 35 cases occurred in acute myeloid leukaemia patients (AML) all presenting with severe neutropenia. The 90% of the isolates belonged to a multidrug-resistant strain showing *in vitro* resistance mainly to carbapenems and fluoroquinolones. Around 70% of all the resistant *Klebsiella pneumoniae* isolates were sensitive only to colistin. The mortality among hospitalized patients with K *pneumoniae* was of 40% (n=14) and 93% of them were affected by multidrug resistant K *pneumoniae* while the 89% of multidrug resistant K *pneumoniae* was detected in 60% of patients (n=21) with a good outcome. During the four year study period there has been a dramatic increase in the prevalence of K. *pneumonia spp* of about five-fold.
Summary and Conclusion: The first strain of multidrug resistant K *pneumoniae* was identified in our ward in 2010, since then there has been a dramatic spread in the occurrence of this pathogen during the study period. The infections due to K. *pneumonia* occurred almost in patients treated with aggressive therapy or in pluritreated patients presenting with profound and prolonged cytopenia. Further, this study will allow us to evaluate emergence of multidrug resistant strains among K *pneumoniae* species in our ward in order to implement efficient infection control to limit the spread of this pathogen.
Keywords: *Klebsiella pneumoniae,* multidrug-resistant strain, haematological malignancy

P1198

THE INCREASING PROBLEM OF BLOODSTREAM INFECTIONS CAUSED BY MULTI-DRUG RESISTANT BACTERIA IN HEMATOLOGIC AND HSCT PATIENTS
ME Zannier[1,*], A Candoni[1], D Lazzarotto[1], E Simeone[1], C Scarparo[2], R Fanin[1]
[1]Division of Hematology and SCT, University of Udine, IT, [2]Division of Microbiology, University Hospital, Udine, Italy

Background: Multi-drug resistant (MDR) bacteria infections are an increasing problem in recent years.
Aims: We evaluate the incidence and outcome of bloodstream infections (BSI) caused by multi-drug resistant (MDR) bacteria in patients (pts) with hematologic diseases and in hematopoietic stem cell transplantation (HSCT) recipients.
Methods: 256 BSI have been recorded between october 2008 and october 2013 in 187 pts. The characteristics and outcome of MDR-BSIs have been evaluated. MDR-BSIs and multi-drug-sensible bacteria-BSI (MDS-BSI) have been compared. Moreover the results were evaluated according to the status of underling hematologic disease and the HSCT.
Results: 316 isolates have been documented in 256 BSIs. Among these, 55 (17%) bacteria were MDR and 261 (83%) were MDS. MDR isolates were: MDR *Pseudomonas aeruginosa*, 28/55 (51%); *Escherichia coli* ESBL, 16/55 (29%); *Stenotrophomonas maltophilia*, 6/55 (11%); *Klebsiella pneumoniae*-KPC, 4/55 (7%); *Enterococcus sp*-VRE, 1/55 (2%). A progressive increase of MDR-BSI was documented in the last two years (with 2 episodes/month in 2013). Septic shock and infection related mortality were significantly higher in the MDR-BSI compared to MDS-BSI group (36% *vs* 12% and 35% *vs* 11%, respectively – P less than 0,001). Occurrence of septic shock was particularly elevated in KPC-BSI (75%) and in MDR- *Pseudomonas aeruginosa*-BSI (50%). Pts with refractory/relapsed hematologic disease had higher infection mortality rate (70%). In the MDR-BSI group, a higher mortality rate was observed in HSCT recipients, (52% in HSCT *vs* 20% in not-HSCT, P less than 0,05).
Summary and Conclusion: MDR-BSI (particularly MDR-*Pseudomonas aeruginosa*-BSI and KPC-BSI) are a serious and growing problem in hematologic pts. The onset of MDR-BSI is often associated with septic shock and with high mortality rate, despite a target and combined antibiotic therapy. Mortality MDR-BSI related is particularly high in HSCT recipients (52%) and in pts with refractory/relapsed hematologic disease (70%). These results underline the urgent need of guidelines for surveillance and treatment of hematologic and HSCT pts with MDR bacteria colonization or/and with MDR active infection.

P1199

INTERVENTIONAL STRATEGIES TO CONTAIN COLONIZATION AND INFECTIONS CAUSED BY CARBAPENEMASE PRODUCING KLEBSIELLA PNEUMONIA IN HAEMATOLOGICAL MALIGNANCIES:A SINGLE CENTRE EXPERIENCE
A Malato[1,*], F Acquaviva[1], R Felice[1], S Magrin[1], M Sciacca[1], MT Baldi[2], MG Donà[1], F Fabbiano[1]
[1]UOC di Ematologia con UTMO, Ospedali Riuniti Villa Sofia-Cervello, [2]Institute of Microbiology, Ospedali Riuniti Villa Sofia-Cervello, Palermo, Italy

Background: The emergence and dissemination of Carbapenemase producing *Klebsiella pneumoniae* (KPC) represent a serious threat to public health and is associated with high mortality rates in patients with hematologic malignancies. Several risk factors (prior exposure to or current use of antibiotics, extended stay in hospital, neutropenia, sharing a room with a know carrier etc) have been identified for colonization in hematological patients. However, data on how to contain their spread in haematological setting are still surprisingly limited.
Aims: We carried out a prospective investigation to assess the prevalence of KPC colonization among hematologic patients, the impact of a strategy control to limit the spread and to evaluate the efficacy of an implementation of more extensive active surveillance.
Methods: Infections caused by multiresistant pathogens have been recorded in our Unit for a two year period (January 2012-December 2013). From January 2012 to July 2013, we developed an intensive control infection program, (Plan A): 1. Weekly colonization screening for KPC. 2. Educate healthcare personnel about KPC. 3. Promotion of hand hygiene. 4. Physical separation of carriers from non-carriers. 5. A double-carbapenem plus colistin therapeutic empiric regimen was given for blood stream infections. Since July 2013, we decided to implement additional measures, including (Plan B): 1. Drastic reduction in the number of beds. 2. 2% chlorhexidine body washing for colonized patients. 3. Ensure access to adequate hand hygiene stations (*i.e.*, clean sinks and/or alcohol) and ensure they are well stocked with supplies (*e.g.* towels, soap, etc.). 4. Donning gown and gloves before entering the affected patient's room and removing the gown and gloves and performing hand hygiene prior to exiting the affected patient's room.
Results: Since January 2012 perianal swabs were obtained weekly from 466 consecutive patients, for a total of 831 admissions and 10.125 days of hospital stay. KPC colonization was present in 40 out of 466 screened patients at some time during their (often multiple) hospitalizations (8.58%); 10 bloodstream infections were reported in 9 patients (25%). Three deaths (3/10, 33%) due to KPC were reported before implementation screening (overall mortality rate was 8% of colonized patients). KPC spontaneous decolonisation was achieved in 8/40 pts (20%) after a median duration of 85 days (range 21-115 days). Most patients who recovered from KPC infection or were just colonized by KPC went on to receive additional chemotherapy without any life threatening KPC infection occurring (only one patient reported two septic episodes). Since screening cultures or further clinical cultures identified a progressive increase KPC-colonized or -infected patients (see in table 1) we decided to implement additional measures (Plan B). Therefore, from fourth trimester of study, the rate of new colonizations was very low: 2 patients (4.17%) have been reported, *vs* 15 patients (30%) in the third trimester.

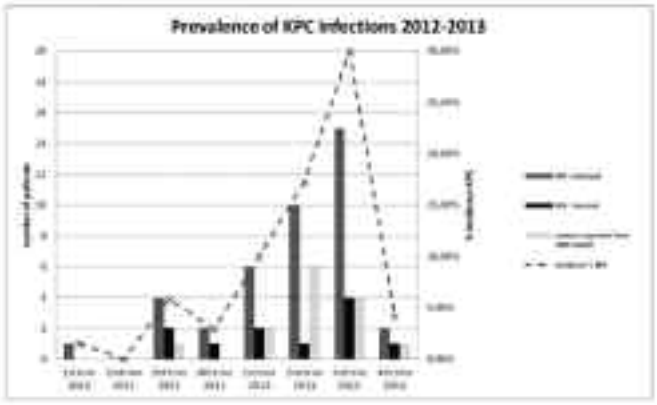

Figure 1.

Summary and Conclusion: The prevalence of KPC colonization in our hospital is high among patients with hematologic diseases. An implementation of additional measures, sharing the patients in single bed-rooms and consequently limiting transfer of cases from other wards, was able to contain KPC colonization and infection. However, the success of our preliminary interventions should be monitored constantly; besides, to prevent the emergence and further spread of KPC, a coordinated regional control effort among healthcare facilities should be recommended.

P1200

CLOSTRIDIUM DIFFICILE INFECTIONS IN PATIENTS WITH HEMATOLOGICAL MALIGNANCY IN CZECH AND SLOVAK REPUBLIC – A RETROSPECTIVE ANALYSIS

M Palackova[1], M Rolencova[1], A Zavrelova[2], L Drgona[3], M Kouba[4], M Hricinova[4], I Kocmanova[5], B Weinbergerova[1,*], L Semerad[1], M Hadrabova[1], J Bouchnerova[1], P Cetkovsky[4], P Zak[2], J Mayer[1], Z Racil[1]
[1]Department of Internal Medicine, Hematology and Oncology, Masaryk University and University Hospital Brno, Brno, [2]4th Department of Internal Medicine-Haematology, Charles University and University Hospital Hradec Kralove, Hradec Kralove, Czech Republic, [3]2nd Department of Oncology, Comenius University and National Cancer Institute, Bratislava, Slovakia, [4]Institute of Hematology and Blood Transfusion, Prague, [5]Department of Clinical Microbiology, University Hospital Brno, Brno, Czech Republic

Background: *Clostridium difficile* infections (CDI) with associated diarrhea represent an important cause of morbidity and mortality. Despite its importance, there is still lack of data about this infection in the group of hematological patients.
Aims: To analyze the risk factors, clinical manifestation, treatment and its outcome in this high risk patients group.
Methods: We performed a retrospective analysis of CDI episodes in 4 hematological centers in Czech and Slovak Republic occurred between 1/2007 and 12/2012. CDI was defined as a diarrhea and/or ileus and/or toxic megacolon and microbiological evidence of toxin-producing *Clostridium difficile* in stool without evidence of another cause of these symptoms. Pts. with targeted antibiotic therapy shorter than 3 days were excluded from analysis of treatment outcome. Recurrence was defined as reappearance of diarrhea and other symptoms within 1 month after therapy.
Results: 208 episodes that occurred in 193 pts. were analyzed (male 38.5%, female 61.5%, mean age 57.3 years [18 - 88] years,). 76 pts. (36.5%) received induction/consolidation therapy for acute leukemia, 26 pts. (12.5%) underwent allogeneic stem cell transplantation (SCT) and 21 pts. (10%) autologous transplantation before CDI onset. Neutropenia was present in 102 pts. (49%) and 82 pts. (39.5%) had neutropenia grade 3 and 4 CTCAE 4.0. Before CDI onset, 132 pts. (63.5%) had antibiotic therapy (prophylactic or curative for another infection) - 23% quinolones, 11% penicillins, 19% cephalosporins, 46% combination, 1% others. 24 pts. (11.5%) were on parenteral nutrition. 49% of all episodes fulfilled criteria for severe CDI and 51% were mild/moderate CDI episodes. In pts. without neutropenia were 42.8% severe CDI, with neutropenia gr. 3 and 4 were 58.5% severe CDI and in pts. after SCT were 34.5% severe CDI. Initial therapy for CDI was: oral metronidazole 77%; intravenous metronidazole 4.8%; oral and intravenous metronidazole 1.4%; oral vancomycin 0.5%; intravenous vancomycin 2.4%; oral metronidazole and oral vancomycin 4.3%; oral metronidazole and intravenous vancomycin 4.3%; intravenous metronidazole and oral vancomycin 3.3%; intravenous metronidazole and intravenous vancomycin 2%. Colectomy was necessary in one case. Time to initial response was 6 days (mean). Overall cure rate was 92% and recurrence rate 8.3%. For oral metronidazole cure rate was 95% and recurrence rate 7.9% and for intravenous metronidazole 80% and 0%, respectively. Overall cure rate in pts. with neutropenia was 87.8% and recurrence rate 8.3%. In non-neutropenic pts. cure rate was 95.2% and recurrence rate 8.3%. In the group of pts. after allogeneic SCT was cure rate 96.1% and recurrence rate 4%.
Summary and Conclusion: Our study proved severe morbidity of CDI in pts. with hematological malignancy, where half of episodes were severe infections. Surprisingly, the overall cure rate using standard therapy (metronidazole +/- vancomycin) and frequency of recurrence was similar to non-hematological populations. Supported by Masaryk University MUNI/A/0830/2013, supported by *CELL*, supported by unrestricted grant of Astellas ltd.

P1201

INCIDENCE AND OUTCOME OF INFECTIOUS COMPLICATIONS AMONG PEDIATRIC CANCER PATIENTS RELATED TO PERMANENT CENTRAL VENOUS CATHETERS

A Elhemaly[1,2,*]
[1]pediatric oncology, national cancer institute, [2]pediatric oncology, children cancer hospital of egypt, ELMANIAL, Egypt

Background: Background: Central venous access is an important treatment modality in the current management of critically ill patients. Recent studies suggest that by strict adherence to current guidelines for insertion an maintenance, the incidence of CLA-BSI can be dramatically reduced. Proper diagnosis and treatment of CLA-BSI can reduce the morbidity and mortality associated with infection.
Aims: To asses the incidence of permanent catheter –related morbidities including blood stream infections and catheter related septicemia, systemic infection as toxic endocarditis, toxic myocarditis among immunocompromised pediatric patients, finally outcome of portcath infection(regarding salvalgibilty of the line and mortality related to central line infection.
Methods: A study done on 78 out of 151 pediatric cancer patient below age of 18 years who inserted portcath receiving chemotherapy with microbiological documented permentant central line infection in the period between 1st of October 2010 till the end of March 2012.Each episode was analyzed regarding causative organism, morbidities related as septicemia, toxic myocarditis and endocarditis, cause of removal of central line and mortality related to central line infection.
Results: There is total number of 107 episodes of portcath infection, gram + ve organisms 60/107(56%), gram – ve organisms 45/107(42%) and finally candida 2/107(2%). The most common organisms was coagulase – ve staph (28.03%).Among patients with gram + ve organisms(40 patients) 34patients(34/40)(85%) had normal echo, four patients 4/40(10 %) had septic myocarditis in form of impaired contractility,two patients 2/40 (5%) with impaired contractility &valvular affection with vegetations& valvular regurge.Regarding patients with gram – ve organisms episodes (38 patients (33/38)(86.8%) had normal echo, three patients (7.89%) had septic myocarditis and finally two patients(5.2%) with impaired contractility &valvular affection with vegetations. Porta- cath were removed in 53 patients (67.9%)due to failure of sterilization(45.3%) and sepsis(54.7%) while in 25 patients (32.1%) portcath were salvaged. 7 patient died from central line infection (9%), 5 patient died from septic shock with multiorgan failure, while 2 patient died from heart failure with impaired cardiac contractility & severe valvular affection, gram + ve were isolated in 5 patients who died while gram – ve were isolated in 2 patients.
Summary and Conclusion: gram + ve pathogens are most common cause of permenant central line(portacath) infection which required better infection control, high mortality rate related to portcath systemic infection enforce us to select patients who are in urgent need for portcath insetion.

Non-malignant hematologic disorders

P1202

A SINGLE-INSTITUTION EXPERIENCE OF PERIPHERAL INSERTED CENTRAL VENOUS CATHETERS IN ONCO-HEMATOLOGIC PATIENTS

N Fracchiolla[1,*], F Guidotti[1], P Monni[1], G Bocale[1], R Cannio[1], C Cardone[1], G Mangiameli[1], M Meli[1], L Ottani[1], A Cortelezzi[1]
[1]UOC Oncoematologia, Fondazione IRCCS Ca'Granda - Ospedale Maggiore Policlinico, Milan, Italy

Background: Peripherally inserted central catheters (PICCs) represent intravenous accesses with a duration intermediate between short term (jugular or subclavian central venous catheters, CVCs), and long term devices (port-a-caths). PICCs are inserted in a peripheral vein of the arm, preferentially the basilic vein in the upper third of it, without general anesthesia or sedation. PICCs are easier to insert and safer than conventional percutaneously inserted CVCs or port-a-cath. PICC lines provide a reliable central venous access in different categories of patients, but only few prospective studies have been performed in onco-hematologic patients.
Aims: To evaluate the feasibility and the safety of the positioning and use of PICCs in onco-hematologic patients by a "Hematology Unit" team.
Methods: We evaluated 53 patients affected by hematologic malignancies (23 non-Hodgkin's lymphomas, 20 acute myeloid leukaemia, 2 acute lymphoblastic leukaemia, 4 mycosis fungoides and 2 Hodgkin's lymphomas) who required a central line insertion: 51 cases were eligible for PICC positioning. Informed consent was obtained from all patients. Thirteen PICCs were single-lumen, 38 were bi-lumen; all were of power-injectable polyurethane, except one, represented by a valved silicone PICC. All PICCs were positioned by a specifically trained team composed of one hematologist physician and 3 nurses. They were inserted by ultrasound-guided venipuncture and the microintroducer technique, under strict asepsis and maximal barrier precautions. Peripheral veins of the arm were cannulated under local anesthesia, without sedation. Chest X-ray was routinely performed to verify a correct location of the tip (ideally in the proximity of cavo-atrial junction).
Results: Of the 53 patients evaluated, 51 received PICC insertion (24 females and 27 males; median age 53, range 22-83); two patients were judged not suitable for the procedure because of inadequate vein diameter. PICC remained in place for a median period of 105 days. No major insertion-related complications were observed. Late complications were infections (5/51 patients, 10%) and thrombosis (12/51 patients, 23%). Infections represented a cause of PICC removal in 5 (10%) cases, thrombosis in 7 (14%) cases. After observing in the first 28 patients a thrombosis incidence of 32%, we started performing a 7 days prophylaxis with LMWH following PICC insertion. In the next consecutive 23 patients we reported a great reduction in thrombosis rate (from 32% to 13%) and in no cases thrombosis represented a removal cause. We compared the PICC results with those of a series of 390 jugular/subclavian CVCs inserted at our Unit from 2009 to 2012 and, regarding removal causes, we observed a lower incidence of both infections (9.8% PICC *vs* 22.5% CVC) and thrombosis, after the introduction of LMWH prophylaxis (0 *vs* 2.4%).
Summary and Conclusion: Our data suggest that PICCs are a safe and effective alternative to conventional CVC in patients receiving chemotherapy for hematologic malignancies, characterized by an higher risk of septic and coagulative (hemorrhagic/thrombotic) complications. In particular, regarding removal reasons, we observed that infections and thrombosis, when LMWH prophylaxis is performed, are significantly lower in PICCs compared to jugular/subclavian vein positioned CVCs. Furthermore, we demonstrated that this procedure may be successfully pursued by a team composed of Hematologic Unit personnel adequately trained, with positive results in terms of team motivation and improvement of the clinical processes.

P1203

USEFULNESS OF PRESEPSIN (SOLUBLE CD14-ST) AS A AN EARLY DIAGNOSTIC MARKER OF SEPSIS IN LEUKEMIA

M Elsawy[1,*]
[1]Alborglaboratories UAE, Dubai, United Arab Emirates

Background: Chemotherapy-related febrile neutropenia (FN) is a frequent complication in patients with acute leukemia. Neutropenia is a major risk factor for infection in these patients. Among patients with FN, the main symptom of infection upon initial presentation may be fever only. Therefore, a standard approach for these patients includes immediate hospitalization, empirical treatment with intravenous broad-spectrum antibiotics until they become afebrile and neutrophil count has recovered. However, in only 20–30% of children with FN a bacterial infection is determined, which results in overtreatment of these patients with consequent increasing risk of bacterial resistance development. Therefore, biomarkers having the potential to predict infectious process in FN leukemic patients are of great interest. To date, there have been many studies performed in FN patients, which assessed various inflammation-related biomarkers in terms of prediction of severe infection, however, due to a heterogeneity between the studies, limited data describing the predictive value of different biomarkers is available. Currently, Procalcitonin (PCT) is used as a marker to diagnose sepsis or severe sepsis. In comparison to other markers that have traditionally been reported, PCT gives a high rate of specificity for sepsis diagnosis. However, the concentration of PCT in the human blood is elevated in various conditions, such as in severe trauma, surgical invasive procedures, and critical burn injury, which leads to SIRS. It is also necessary to be aware of false-positive results. Therefore, more reliable biomarkers for the diagnosis of sepsis are needed. C-reactive protein (CRP) has been used for many years but its specificity has been challenged. CD14 is a cell surface glycoprotein, which is constitutively expressed in a majority of innate immune response cells and exists either in an anchored membrane form, or in a soluble form (sCD14-ST, presepsin). Presepsin, which is approximately 13 kDa, has been identified as a protein whose levels increase during sepsis and systemic inflammatory response syndrome. Presepsin is a more specific and sensitive marker for the diagnosis of sepsis compared with interleukin-6 (IL-6) and PCT. Presepsin concentrations in blood were increased faster than PCT and CRP in sepsis patients. Additionally, the measurement of Presepsin concentrations is useful for evaluating the severity of sepsis. In this study, we evaluated the diagnostic efficacy of Presepsin POCT assay system based on the chemiluminescent enzyme immunoassay (CLEIA) principle and its usefulness in the early diagnosis of infection in acute leukemic patients.
Aims: Was to study the circulating level of Presepsin and to correlate this level with patients' body temperature, complete blood count(CBC) items and CRP level as an inflammatory marker, in AML patients presenting with manifestations of sepsis.
Methods: 160 AML subjects with manifestations of sepsis (group I) and 40 healthy controls (groupII) were subjected to full history taking, complete physical examination and laboratory investigations including CBC, CRP and Presepsin.
Results: It was found that the mean value of Presepsin is higher in patients with sepsis than in healthy controls with a statistical significance. Using a cutoff level of 198 pg/ml yielded a sensitivity of 82.5% and specificity 90% with AUC 0.895. The mean cutoff level in controls was 132.5 pg/ml. Presepsin performance was better than CRP, where a 96 mg/L cutoff had to be set to obtain similar specificity and sensitivity while mean cutoff in healthy subjects was 2.3 mg/L. Also, there was a significant positive correlation between Presepsin level and patients' body temperature, total WBCs count, absolute neutrophil count.
Summary and Conclusion: it was found that Presepsin level is a mirror to the degree of severity of sepsis. To our knowledge this is the first study performed in hematological malignancies related sepsis evaluating Presepsin diagnostic power as a new promising biomarker

P1204

SEPTIC MARKERS IN HEMATO-ONCOLOGY: PROCALCITONIN IS MORE SPECIFIC THAN C-REACTIVE PROTEIN IN THE STUDY OF FEVER IN PATIENTS WITH HEMATOLOGIC DISORDERS

M Pereira[1,1,*], G Marques[2], N Silva[2], E Cortesão[1], A Espadana[1], C Geraldes[1], L Ribeiro[1], G Ribeiro[2]
[1]Clinical Hematology Department, [2]Clinical Pathology Department, Coimbra University Hospital Centre, Coimbra, Portugal

Background: Fever is one of the most frequent, relevant and non-specific clinical findings in hemato-oncology patients, in whom it can be secondary to the neoplastic disease, or result from a concurrent infectious complication. Biomarkers used to clarify the etiology of a fever include C-reactive protein (CRP), an acute-phase protein that is non-specifically elevated in neoplastic disease, and procalcitonin (ProCT), whose high specificity for bacterial infection can help reduce the inappropriate use or duration of antibiotherapy. Although its validity has been demonstrated, the use of ProCT in clinical practice in hemato-oncology is non-standardized and irregular.
Aims: We aim to analyze the value added by ProCT to the management of hematology patients with a fever.
Methods: We reviewed all simultaneous determinations of CRP and ProCT in our center in the 5 years since its introduction into our Lab. Patients were stratified as "Hematologic" and "Non-Heme", "ProCT+" (≥0.5ng/mL), "CRP+" (≥0.5mg/dL) and "RF" (renal failure, creatinine≥1.2 mg/dL); microbiological culture was the gold-standard comparator.
Results: We analyzed 8512 patient-events (pts), 165 of whom were Hematologic, with a rate of ProCT+ higher than Non-Heme pts (53.3% *vs* 34.8%, p<0.001), a similar mean ProCT (4.6 *vs* 3.1ng/mL, p=NS), but a higher mean CRP (15.1 *vs* 10.9 mg/dL, p<0.001). In 61.7% of Non-Heme pts, CRP and ProCT results were discordant: 64.1% of CRP+ pts were ProCT- and 9.6% of CRP- were ProCT+. In Hematologic pts, discordance was only 45.4% (p<0.001) and no CRP- Hematologic pts were ProCT+; however, 46.0% of CRP+ pts were ProCT- (p<0.001) – this CRP+/ProCT- discordance was found in 25.0% of multiple myelomas, 26.9% of lymphomas, 53.5% of acute leukemias, 68.6% of auto-stem-cell transplants (SCT) and 72.7% of benign cytopenias (p<0.001). ProCT+ Hematologic pts were twice as likely as ProCT- pts to have positive bacterial cultures (37.5% *vs* 15.6%, p<0.001), with a further 11.4% of ProCT+ patients (but 0% of ProCT-Negative) positive for fungi, for a

total of 48.9% *vs* 16.7% positive cultures (p<0.001). In comparison, only 33.7% (27.6%+6.1%) of PCR+ pts had positive cultures (p<0.001). ProCT-/CRP+ positive-cultures were found in *Pseudomonas aeruginosa* colonization of sputum, coagulase-negative *Staphylococci* contamination and patients under antibiotherapy for 4-7 days. The percentage of CRP+ and CRP- pts with RF was comparable (30.8% *vs* 27.3%, p=NS); however, ProCT+ pts were twice as likely to have RF (47.6% *vs* 21.5%, p<0.001), leading to a false-positive rate of 41% in patients with RF, findings which were replicated in the Non-Heme population and in multivariate analysis.
Summary and Conclusion: The hematologic population had a higher mean CPR than the general population, with a higher rate of false-positives with CRP than with ProCT; only ProCT was able to identify respiratory tract colonization, culture contamination by commensals and good-response to antibiotherapy. Only a third of CRP+ auto-SCT recipients and half of CRP+ acute leukemias were ProCT+, suggesting that the value of ProCT as an infectious marker may be particularly relevant in these subpopulations. Renal failure increased the rate of false positives with ProCT, while not influencing CRP, suggesting that ProCT's utility may be lessened in renal patients. In conclusion, we suggest that ProCT is a valid septic marker in Hematologic patients, with higher specificity than CRP in the identification of infectious fever, and appears to be particularly useful in acute leukemia or auto-transplant patients without renal failure.

P1205

NOVEL HOMOZYGOUS MUTATION AFFECTING THE INTERNAL TRANSLATIONAL START SITE OF THE VON HIPPEL-LINDAU TUMOR SUPPRESSOR GENE IS ASSOCIATED WITH CONGENITAL ERYTHROCYTOSIS

M Bartels[1], M M van der Zalm[1], B A van Oirschot[2], F S Lee[3], R H Giles[4], M J Kruip[5], W W van Solinge[2], M Bierings[1], R van Wijk[2,*]
[1]Department of Pediatric Hematology/Oncology, [2]Clinical Chemistry and Haematology, University Medical Center Utrecht, Utrecht, Netherlands, [3]Department of Pathology and Lab Medicine, Perelman School of Medicine, University of Pennsylvania, Pennsylvania, PA, United States, [4]Department of Nephrology, University Medical Center Utrecht, Utrecht, [5]Department of Hematology, Erasmus Medical Center, Rotterdam, Netherlands

Background: Erythrocytosis is characterized by increased red blood cell mass. It is a heterogeneous disorder, which can either be acquired or congenital. An important cause of congenital erythrocytosis involves genetic defects in the oxygen sensing pathway, in particular, the PHD2 (HIF-prolyhydroxylase-2) – von Hippel-Lindau tumorsuppressor (VHL) – Hypoxia-Inducible Factor (HIF)-2α axis. Defective oxygen sensing ultimately results in inappropriately increased production of erythropoietin (EPO), a key regulator of erythropoiesis. Mutations in PHD2 and HIF-2α show a dominant pattern of inheritance, whereas mutations in VHL that are associated with erythrocytosis are generally inherited in an autosomal recessive manner. The most frequenct cause of congenital erythrocytosis is Chuvash erythrocytosis, caused by a p.Arg200Trp change in VHL. Intriguingly, mutations in VHL can also cause von Hippel-Lindau syndrome. This dominantly inherited disease predisposes affected individuals to the development of specific benign or malignant tumors.
Aims: We set out to investigate the molecular basis of apparantly congenital secondary erythrocytosis in three patients from two unrelated families. Both families originated from adjacent regions in Northern Morocco. All three patients displayed extremely high EPO levels, ranging from 9,000-13,500 U/L. None of the patients or family members involved in this study was diagnosed with VHL-associated tumors.
Methods: Coding regions of the genes encoding hemoglobin (α-globin, genes: *HBA1, HBA2,* and β-globin, gene: *HBB*), bisphosphoglycerate mutase (BPGM, gene: *BPGM*), HIF-prolyl hydroxylase 2 (PHD2, gene: *EGLN1*), Von Hippel-Lindau tumor suppressor (VHL, gene: *VHL*), and HIF-2a (HIF2A, gene: *EPAS1*) were investigated for mutations by PCR and subsequent DNA sequence analysis.
Results: A novel mutation was detected in exon 1 of the *VHL* gene: c.162G>C. All three affected individuals were homozygous for this mutation, which predicts the substition of methionine by isoleucine at position 54 of the long isoform of VHL, pVHL30. Apart from encoding this rather conservative amino acid change, c.162G>C also abolishes the internal translational start codon that directs transcription of the second and shorter isoform of pVHL, pVHL19. The c.162G>C mutation is therefore expected to result in the exclusive production of only the long pVHL30 isoform, rendering our patients *de facto* natural "knock-outs" for the pVHL19 isoform.
Summary and Conclusion: We report on a novel c.162G>C (p.Met54Ile) mutation in *VHL*. This mutation co-segregated with the phenotype of erythrocytosis in three patients from 2 unrelated families. c.162G>C is the most upstream *VHL* mutation so far described in patients with congenital erythrocytosis. Apart from encoding a p.Met54Ile change the mutation is predicted to result in the complete loss of the pVHL19 isoform. Because of our patients' extremely high EPO levels which were, on average, 800 times higher than reported on other patients with erythrocytosis, in particular Chuvash erythrocytosis, we postulate that pVHL19 is an important regulator of EPO production, whereas pVHL30 may be the more potent tumor suppressor.

P1206

NICOTINAMIDE (VITAMIN B3) TREATMENT INCREASES RESPONSE TO G-CSF IN SEVERE CONGENITAL NEUTROPENIA PATIENTS

A Shcherbina[1,*], J Skokowa[2], E Diordieva[1], G Strauß[3], K Welte[4], A Maschan[5]
[1]Immunology, Federal Scientific Clinical Center Of Hematology, Oncology And Immunology Named After D.Rogachev, Moscow, Russian Federation, [2]Molecular Hematopoiesis, Hannover Medical School, Hannover, [3]Clinic for Pediatrics/Oncology & Hematology, Charitè, Berlin, [4]Molecular Hematopoiesis, Hannover Medical School, Hannover, Germany, [5]hematology, Federal Scientific Clinical Center Of Hematology, Oncology And Immunology Named After D.Rogachev, Moscow, Russian Federation

Background: Severe congenital neutropenia (SCN) often manifests with life-threatening bacterial infections. G-CSF treatment is aimed at keeping neutrophil levels of at 1000/ul to prevent infectious complications. Some SCN patients require high doses of G-CSF to reach this goal, which makes the treatment more painful, especially in small children and increases the costs. A small group of SCN patients is not responsive to G-CSF therapy at all. There is also some evidence that higher doses of G-CSF increase the risk of leukemic transformation in SCN. Other therapeutic options in addition to or in combination with G-CSF are required. Previously we demonstrated that nicotinamide (vitamin B3) increases neutrophil counts in healthy volunteers, acting through NAD^+/SIRT1 protein deacetylation pathway (Skokowa J. et al, Nature Medicine 2009). We aimed to evaluate whether nicotinamide treatment of SCN patients will lead to neutrophil production.
Aims: To asess the effect of nicotinamide treatment in SCN patients.
Results: We treated 2 newly diagnosed patients with SCN with nicotinamide alone, and even though we observed significant increase in mean neutrophil counts (from average 100 to 350 cells/µl), its effect was not enough to ameliorate the risk of infectious complications and the standard G-CSF treatment was applied. Five patients with SCN, receiving G-CSF, were additionally treated with nicotinamide (20 mg/kg/d). One of them had a poor response to G-CSF in a dose of 40 µg/kg/d. Upon nicotinamide treatment the desired neutrophil counts were achieved without further increase of the G-CSF dose. Upon continuous treatment of this patient we managed to decrease the G-CSF dose to 15 µg/kg/d, with good clinical and laboratory results. Overall in our group of patients, nicotinamide treatment allowed to decrease G-CSF dose 2.1 fold. We also used nicotinamide treatment in two cyclic neutropenia (CyN) patients. In one patient complete replacement of G-CSF by nicotinamide could be achieved. This patient is being treated with 5 mg/kg/day of nicotinamide for more than three years now. In another CyN patient treatment with nicotinamide increased the neutrophil counts during the nadir of the cycles from average 100 to average 400 cells/µl and improved the her quality of life.
Summary and Conclusion: Taken together, in our group of SCN and CyN patients nicotinamide treatment allowed to significantly decrease the G-CSF dose with continuous clinical and laboratory responses. We propose that use of nicotinamide in combination with a reduced dose of G-CSF for treatment of neutropenia patients is promising and should further be investigated.

P1207

LONG-TERM OUTCOME OF 100 CHILDREN WITH MODERATE APLASTIC ANEMIA TREATED WITH HORSE ANTITHYMOCYTE GLOBULIN AND CYCLOSPORINE

H Yagasaki[1,*], H Yabe[2], A Ohara[3], Y Kosaka[4], K Kudo[5], R Kobayashi[6], S Ohaga[7], A Morimoto[8], K Watanabe[9], H Muramatsu[10], Y Takahashi[10], S Kojima[10]
[1]Pediatrics, Nihon University, Tokyo, [2]Tokai University, Isehara, [3]Toho University, Tokyo, [4]Hyogo Children Hospital, Hyogo, [5]Shizuoka Children Hospital, Shizuoka, [6]Hokuyu Hospital, Sapporo, [7]Kyushu University, Fukuoka, [8]Jichi University, Tochigi, [9]Kyoto University, Kyoto, [10]Nagoya University, Nagoya, Japan

Background: The proportion of patients with moderate aplastic anemia (MAA) is relatively small, ranging from 8% to 25% in pediatric series of AA. British guidelines recommend only observation without specific therapies until patients with MAA become transfusion dependent. Because the duration of aplasia before immunosuppressive therapy (IST) correlates inversely with the response, the response to IST is generally poor in patients who progress slowly from MAA to severe AA. The prospective randomized EBMT study demonstrated the superiority of a combination of antithymocyte globulin (ATG) and cyclosporine (CsA) over CsA alone in terms of the hematopoietic response and failure-free survival (FFS). We adopted this strategy and treated 100 MAA children with ATG and CsA.
Aims: To clarify the long-term outcome of children with moderate aplastic anemia treated with horse antithymocyte globulin and cyclosporine.
Methods: From October 1992 to December 2010, 100 children with newly diagnosed MAA were enrolled in successive studies. The eligibility criteria were<18 years old, recently diagnosed with MAA (within 180 days), and no prior treatment for AA. MAA was defined if at least two of the following criteria were fulfilled: absolute neutrophil count<1.0×10^9/L, reticulocyte count<60×10^9/L, or platelet count<50×10^9/L, with hypocellular bone marrow.

Patients who filled the criteria for severe AA and those with congenital bone marrow syndrome were excluded. All patients received first-line therapy with horse ATG (lymphoglobulin) and CsA. The hematologic response rate at 3 and 6 months after IST, 10-year overall survival (OS), and FFS were analyzed. Treatment failure was defined as the need for salvage therapy (second IST and stem cell transplantation [SCT]) for non-response, relapse, development of a clonal disease (myelodysplastic syndrome [MDS], leukemia, or paroximal nocturnal hemoglobinuria) or death, whichever came first.
Results: At 3 months, 8 patients achieved complete response (CR) and 36 achieved partial response (PR), with an overall response rate of 44%. At 6 months, 13 patients achieved CR and 41 achieved PR, with an overall response rate of 54%. Treatment failure was observed in 50 patients; 37 received salvage therapy, 11 relapsed and 2 developed to MDS. As a result, the probability of 10-year FFS was 48.4% (95% confidence interval [CI]; 38.9-60.1%). At the time of analysis, 17 patients received a second IST, of whom 7 patients responded. A total of 40 patients received SCT as second- or third-line therapy (unrelated donor, n=15; HLA-matched sibling donor, n=20; HLA-mismatched related donor, n=3; and cord blood, n=2). Although 37 patients were rescued by SCT, 3 died after unrelated donor transplantation due to cardiotoxicity, graft failure and graft-*versus*-host disease. Consequently, the probability of 10-year OS was 96.9% (95% CI, 93.5–100%) with a median follow up of 93 (range, 29–221) months. Median age in the treatment failure group was significantly lower than in the failure-free group (7.5 and 10 years, respectively; p=0.041). Median disease duration in the treatment failure group was significantly longer than in the failure-free group (27.5 and 17 days, respectively; p=0.004). The response rate at 3 and 6 months in the failure-free group was significantly higher than in the treatment failure group (62% and 76% *versus* 26% and 32%; p<0.001).
Summary and Conclusion: Although the long-term OS of MAA children treated with horse ATG and CsA was excellent, 40% of the patients required salvage therapy with SCT. Development of more effective non-SCT therapies is necessary for children with MAA.

P1208

CLINICAL FEATURES, GENETICS AND OUTCOME OF PEDIATRIC PATIENTS WITH HEMOPHAGOCYTIC LYMPHOHISTIOCYTOSIS IN KOREA: REPORT OF A NATIONWIDE SURVEY FROM KOREA HISTIOCYTOSIS WORKING PARTY

SW Lee[1,*], KN Koh[1], HJ Im[1], NG Chung[2], B Cho[2], HJ Kang[3], HY Shin[3], CJ Lyu[4], HH Koo[5], HJ Kim[6], H Kook[7], HS Yoon[8], YT Lim[9], HS Kim[10], JJ Seo[1]
[1]Department of Pediatrics, University of Ulsan College of Medicine, Asan Medical Center Children's Hospital, [2]Department of Pediatrics, The Catholic University of Korea College of Medicine, [3]Department of Pediatrics, Cancer Research Institute, Seoul National University College of Medicine, [4]Department of Pediatrics, Yonsei University College of Medicine, [5]Department of Pediatrics, [6]Department of Laboratory Medicine, Sungkyunkwan University School of Medicine, Seoul, [7]Department of Pediatrics, Chonnam National University College of Medicine, Gwangju, [8]Department of Pediatrics, Kyung Hee University College of Medicine, Seoul, [9]Department of Pediatrics, Pusan National University College of Medicine, Busan, [10]Department of Pediatrics, Keimyung University College of Medicine, Daegu, Korea, Republic Of

Background: Hemophagocytic lymphohistiocytosis (HLH) is a potentially fatal disease caused by dysregulated immune responses and overwhelming inflammation. Although our understanding of HLH has increased significantly, a large-scale, nationwide study of this heterogeneous disease is still lacking.
Aims: We analyzed a nationwide registry of pediatric hemophagocytic lymphohistiocytosis (HLH) patients in Korea to assess the clinical and genetic features and treatment outcomes in pediatric HLH.
Methods: The Korea Histiocytosis Working Party retrospectively analyzed data on 251 pediatric patients diagnosed with HLH between 1996 and 2011.
Results: In the study cohort, 31 cases were categorized with familial HLH, 61 with presumed secondary HLH, and 159 with unspecified HLH. Of 217 evaluable patients, 91 (42%) had concomitant Epstein-Barr virus infection. Of 238 evaluable patients, central nervous system (CNS) involvement, which was more frequent in the familial group, was evident in 81 cases (34%). Genetic tests revealed a predominant UNC13D mutation with a high incidence of two recurrent splicing mutations (c.118-308C>T and c.754-1G>C). The 5-year overall survival rate was 68% (43% in the familial group, 80% in the presumed secondary group). The 5-year overall survival rate among 32 patients who underwent allogeneic hematopoietic stem cell transplantation was 64%. The type of donor and conditioning regimen did not influence the outcome, while cord blood graft tended to be associated with a poorer outcome, but without statistical significance (P=0.115). In multivariate analysis, a younger age at diagnosis, severe cholestasis, and a coagulation abnormality were independent prognostic factors for survival. Responses during initial treatments were also significant indicators of outcome.
Summary and Conclusion: Our study showed the unique predominance of a UNC13D mutation and vulnerability to Epstein-Barr virus infection in Korean children with HLH, and emphasizes the prognostic significance of age, liver dysfunction, and treatment responses in this disease. A multicenter prospective trial that builds on the present results is warranted to identify subgroups of patients with a poor prognosis and identify optimal treatments.

P1209

IMPROVEMENTS IN HEMOGLOBIN LEVELS AND FATIGUE IN A RANDOMIZED, DOUBLE BLINDED, PLACEBO CONTROLLED STUDY (MCD3282001) OF SILTUXIMAB IN PATIENTS WITH MULTICENTRIC CASTLEMAN'S DISEASE (MCD)

F Van Rhee[1,*], A Fossså[2], H van de Velde[3], M Qi[4], KF Ho[5], S Fleming[6], J Vermeulen[7], M Rothman[8], C Casper[9]
[1]Myeloma Institute for Research and Therapy, University of Arkansas for Medical Sciences, Little Rock, AR, United States, [2]Oslo University Hospital, Oslo, Norway, [3]Janssen Research & Development, Beerse, Belgium, [4]Janssen Research & Development, Spring House, PA, United States, [5]STAT-TU Inc., Toronto, ON, Canada, [6]Janssen Global Services, Raritan, NJ, United States, [7]Janssen Research & Development, Leiden, Netherlands, [8]Janssen Research & Development, Washington, GA, [9]Fred Hutchinson Cancer Research Center, Seattle, WA, United States

Background: MCD is a rare lymphoproliferative disorder characterized by excess interleukin (IL)-6 production. Symptoms include anemia, fatigue, weakness, and loss of appetite. Siltuximab, a chimeric mAb against human IL-6, is undergoing clinical trials in MCD.
Aims: To evaluate the relationship of fatigue by patient reported outcomes (PROs) and changes from baseline in hemoglobin (Hb) levels in study CNTO328MCD2001 in MCD patients.
Methods: Patients received best supportive care and were randomly assigned 2:1 to siltuximab 11 mg/kg (n=53) or placebo (n=26) given by 1-hour intravenous infusions every 3 weeks. Primary endpoint was durable tumor and symptomatic response by independent radiological review and improvement/stabilization in clinician reported MCD-related symptoms for ≥18 weeks. PRO measures included an MCD-symptom scale (SS) developed for this study, FACIT-F (a measure of patient reported fatigue where higher scores indicate less fatigue) and SF-36. The MCD-SS fatigue domain included items related to tiredness, fatigue, lack of energy and feeling weak. Descriptive statistics were obtained at each cycle. Association between fatigue and Hb levels were explored by area under the curve analysis (AUC).
Results: Median age was 48 years, 48% were Asian, 39% were white, 66% were male, 58% had prior systemic therapy, 30% were on corticosteroids. MCD symptoms at baseline (siltuximab/placebo) included fatigue (89%/81%), malaise (62%/58%), and night sweats (47%/62%). For the primary endpoint a higher percentage of durable tumor and clinician-reported symptomatic response was observed with siltuximab compared with placebo (34% *vs*. 0%; *P*=0.0012). Of patients with anemia at baseline 19/31 (siltuximab; 61%) and 0/11 (placebo; 0%) showed a ≥15 g/L Hb increase at Week 13 (95% CI: 28.3, 85.1; *P*=0.0002). Of patients with baseline Hb levels below the lower limit of normal, 13 (42%; 95% CI: 24.5, 60.9) in the siltuximab group and none in the placebo group had Hb values return to normal or higher at Week 13. For the MCD-SS fatigue component, patients treated with siltuximab improved more than placebo (AUC, *P*=0.02, Figure). Improvements in FACIT-F scores at Cycle 4 Day 1 were positively associated with the Hb response at Week 13. Patients with an increase in Hb of ≥15 g/L (n=19) reported more improvement in fatigue (FACIT-F mean [± SD] change from baseline score of 9.6 [±10.04]) compared with patients with Hb increases of<15 g/L (n=23; mean change of 1.0 [±8.92]). For SF-36, 5 of 8 domain scores statistically favored siltuximab (role physical and role emotional, vitality, bodily pain, and mental health). Improvements in fatigue were supported by enhancements in other aspects of functioning and well-being, providing broad support for the significance of fatigue reduction on functional status and well-being. As reported previously, the overall safety profile was similar between treatment arms despite longer treatment with siltuximab.

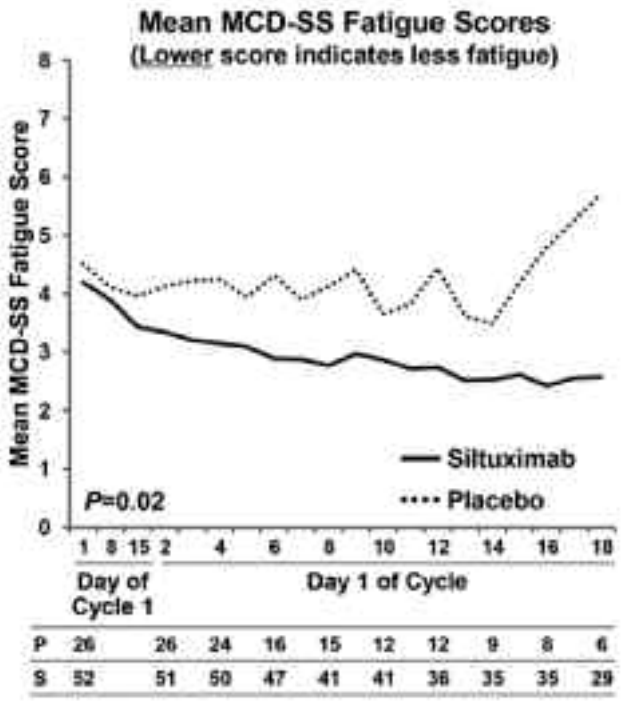

Figure 1.

Summary and Conclusion: MCD patients treated with siltuximab reported significantly greater improvements in fatigue than placebo patients measured by multiple PRO instruments. Improvements with fatigue were positively associated with increases in Hb from baseline.

P1210

RITUXIMAB IS THE FIRST-LINE THERAPY FOR IDIOPATHIC MULTICENTRIC CASTLEMAN'S DISEASE: TWELVE YEARS EXPERIENCE IN A SINGLE INSTITUTE

M Ide[1,*], T Fukumoto[1], H Ohnishi[1]
[1]hematology, Takamatsu Red Cross Hospital, Takamatsu, Japan

Background: Multicentric Castleman's disease (MCD) is an indolent lymphoproliferative disorder of unknown etiology. Most cases of MCD are HIV-associated, and patients with HIV-negative idiopathic Castleman's disease (iMCD) are few and far between. Therefore, no established optimal treatment is available for iMCD. In Japan, almost all patients with Castleman's disease are HIV-negative, and they are mainly treated by corticosteroids and tocilizumab (anti-IL6 receptor antibody).
Aims: We have reported on rituximab therapy for iMCD (Br J Haematology 2003, Eur J Haematology 2006). Therefore, we reviewed the records of all iMCD patients at our hospital treated with rituximab therapy, and compared them with those of patients who received tocilizumab therapy (median follow-up period 64 months, range 5 to 133 months).
Methods: Eight HIV-negative patients with iMCD (4 men and 4 women, median age 49 years, range 26-61 years) were referred to Takamatsu Red Cross Hospital over a twelve-year period. Six patients were initially treated by rituximab, and two were treated by tocilizumab. After clinical evaluation, rituximab was administered intravenously at the standard dose of 375 mg/m^2 weekly for 4 or 8 times without chemotherapy, and two patients were administrated tocilizumab at 8mg/kg biweekly. We analyzed the clinical course of iMCD after therapy in the follow-up period.
Results: In the follow-up at 43 to 133 months, three of the six patients (50%) with iMCD achieved almost complete remission with 4 rituximab infusions. Two of three rituximab-resistant patients received second-line therapy at 2 and 56 months (melphalan and tocilizumab).Under repeated tocilizumab infusion, three patients treated by tocilizumab (two patients with first-line therapy and one patient with second-line therapy after rituximab) did not require other therapy. However, one patient needed a dose escalation of tocilizumab (8mg/kg biweekly to 8mg/kg weekly). All eight patients survived and were living well during the observation period.
Summary and Conclusion: Four rituximab infusions achieved durable response in 50% of rituximab-treated iMCD patients without additional rituximab therapy. Tocilizumab is as effective as rituximab, but durable repeated infusion is necessary to maintain IL6-antagonist induced remission. Therefore, rituximab is the most appropriate first-line therapy in iMCD.

P1211

INFLAMMATORY AND ANEMIA-RELATED MARKERS IN A PHASE 2, RANDOMIZED, DOUBLE-BLIND, PLACEBO-CONTROLLED STUDY OF SILTUXIMAB (ANTI-IL-6 MONOCLONAL ANTIBODY) IN MULTICENTRIC CASTLEMAN'S DISEASE PATIENTS

C Casper[1,*], S Chaturvedi[2], N Munshi[3], R Wong[4], M Qi[2], M Schaffer[2], R Bandekar[2], Y Huang[2], B Hall[2], J Vermeulen[5], M Reddy[2], F Van Rhee[6]
[1]Fred Hutchinson Cancer Research Center, Seattle, WA, [2]Janssen Research & Development, Spring House, PA, [3]Dana-Farber Cancer Institute, Harvard Medical School, Boston, MA, United States, [4]Prince of Wales Hospital, The Chinese University of Hong Kong, Hong Kong, Hong Kong, [5]Janssen Research & Development, Leiden, Netherlands, [6]Myeloma Institute for Research and Therapy, University of Arkansas for Medical Sciences, Little Rock, AR, United States

Background: Multicentric Castleman's disease (MCD) is a rare, lymphoproliferative disease driven by dysregulated interleukin (IL)-6 production. A double-blind placebo controlled study in MCD showed significant improvement in durable tumor and symptomatic response (34.0% *vs* 0.0% with placebo; *P*=0.001), and consistent improvement in secondary endpoints with similar frequencies of adverse events, despite longer drug exposure in the siltuximab group (Wong *et al.* 2013 Blood 122:21; 505). Herein, we examine siltuximab-induced changes in inflammatory and anemia-associated markers.
Aims: The clinical study's primary objective was to demonstrate that siltuximab plus best supportive care (BSC) is superior to BSC in terms of durable tumor and symptomatic response in MCD patients. The secondary objectives included biomarker evaluation apart from other measures of efficacy. The effects of siltuximab neutralization of IL-6 on C-reactive protein (CRP), hemoglobin (Hb), hepcidin, and iron parameters were studied.
Methods: Subjects (N=79) were randomly assigned 2:1 to siltuximab 11 mg/kg every 3 weeks (n=53) or placebo (n=26). IL-6, CRP, Hb, iron, transferrin saturation, ferritin, and hepcidin were measured in a central laboratory. Association of these markers with clinical response was determined by appropriate statistical methods.
Results: Systemic levels of IL-6 at baseline (median IL-6 level was 6.78 pg/mL, range 0.38-50.64 pg/mL) and CRP (median 11.20 mg/L, range 0.10-181.00 mg/L) were significantly correlated (r=0.708; *P*<0.0001). Posttreatment IL-6 levels were not evaluated due to assay interference by siltuximab-IL-6 complexes. Thus, CRP was measured as an indicator of bioactive IL-6. CRP levels rapidly decreased (median decrease of 92%) post treatment by Cycle (C) 1 Day (D) 8 with sustained suppression until end-of-treatment in the siltuximab group compared with 3% increase at C1D8 in the placebo group. Baseline CRP levels differed between responders and non-responders by durable tumor and symptomatic response (median values 34.50 *vs*. 6.32 mg/L, *P*=0.0522), and by best tumor response (median values 38.00 *vs*. 5.09 mg/L, *P*=0.0118) in the siltuximab group, wherein *P* values refer to the log transformed values. A prediction of durable tumor and symptomatic response based on log transformed baseline CRP value using a logistic model applied to siltuximab treated subjects showed a sensitivity of 28% and specificity of 83%. Hb response (change from baseline of ≥15 g/L at Week 13) was observed in 61% of subjects in the siltuximab group and 0% in the placebo group (*P*=0.0002). Levels of the iron regulating peptide hormone, hepcidin showed a median decrease of 47% (from 127.70 to 59.65 ng/mL) from baseline as early as C1D8 in the siltuximab group and 11% increase from baseline in the placebo group (from 110.00 to 112.10 ng/mL). A trend in Hb improvement with decrease in hepcidin was observed (r=-0.298; *P*=0.0336). Analysis of posttreatment changes in hepcidin levels at C1D8 (maximum change) with changes in iron parameters at C2D1 (maximum change) indicated statistically significant correlations for Hb (r=-0.395; *P*=0.0061), total iron binding capacity (TIBC) (r=-0.354, *P*=0.0169, and ferritin (r=0.599, *P*<0.0001) only in the siltuximab group. Further, higher median changes from baseline in ferritin (>2 fold decrease), Hb (4 fold increase), and TIBC (2 fold increase) were observed in anemic subjects compared to non-anemic subjects in the siltuximab group.
Summary and Conclusion: Siltuximab is an active agent in MCD. Sustained suppression of CRP, decreased hepcidin levels, significant Hb increases and improved iron parameters such as, TIBC and ferritin were observed. These results support normalization of inflammatory markers by IL-6 neutralization as reflected by the suppression of CRP levels and indicate inhibition of the IL-6-hepcidin pathway as one of the mechanisms by which anemia is resolved following siltuximab treatment.

Platelet disorders

OXIDANT STATUS IN PATIENTS WITH IMMUNE THROMBOCYTOPENIA (ITP) AND THE ROLE OF AN ADJUVANT ANTIOXIDANT THERAPY

M S Elalfy[1,*], Y Elhenawy[1], S Maher[1], M Hegazy[2], A Sabra[1], Y Abdelaziz[1]
[1]Pediatrics department-Faculty of Medicine, [2]Biochemistry departement-Faculty of Science, Ain Shams University, cairo, Egypt

Background: Free oxygen radicals may have an effect on the structural and functional behavior of platelets and might play a role in pathogenesis of thrombocytopenia in both, newly diagnosed (ND) and chronic ITP.
Aims: To assess oxidant -antioxidant systems initially in patients with (ND) and chronic (ITP) and evaluate effect of antioxidant therapy on, platelet count, bleeding score (BS) and oxidant status during 6 months follow-up.
Methods: An interventional 6 months prospective randomized open-labeled study registered as (NCT 01763658); in patients aged 1-18 years with ITP; ND and chronic. Patients were randomly allocated to one of two groups. Group 1(interventional arm) included 52 ITP patients (26 ND ITP patients and 26chronic ITP patients), all received antioxidant therapy; one tablet/ 20 kg (1 tablet contains: Vit. A 2000 IU, Vit C 90 mg, Vit E 15 mg and selenium 55 ug),while Group 2 (non-intervention arm), included 26 ITP patients;13(ND) and 13 chronic ITP, did not receive the antioxidant therapy. Both groups were comparable and matched with healthy controls (n=30).The primary efficacy endpoints were the difference between both groups in the change from baseline to 6 months in BS using ITP specific bleeding assessment tool (ITP-BAT), mean platelet count, total antioxidant capacity (TAC), catalase (CAT), reduced glutathione (GSH)(markers of antioxidant status) and serum malondialdehyde (MDA) levels. The safety endpoint was the occurrence of serious or life threatening bleeding, complete response to therapy, and adverse events related to therapy.
Results: Baseline platelet count and markers of antioxidant status were significantly lower in (ND) ITP patients than both healthy controls (P<0.001) and chronic ITP patients (p<0.05). In addition, in this group, baseline MDA, was significantly higher than both healthy controls and chronic ITP patients (P<0.001). In chronic ITP group, although baseline platelet count and markers of antioxidant status were significantly lower than those in the control groups (P<0.001), MDA was significantly higher (P<0.001). In (ND) ITP patients, end of study levels of TAC, CAT, GSH and BS were significantly higher in patients receiving antioxidant (p<0.05) whereas MDA was statistically lower (P<0.001). No difference in both groups regarding mean platelet count (p=0.227).In chronic ITP patients, end of study levels of TAC, CAT, GSH (p<0.001), mean platelet count(p=0.03) and BS(p=0.04) were statistically higher in patients receiving antioxidant whereas MDA was statistically lower (P<0.001). A positive correlation was found between platelet count and TAC in ITP patients (r: 0.408, P<0.05) and a negative correlation between platelet count and MDA levels in ITP patients(r: 0.491, P<0.004).
Summary and Conclusion: High oxidative stress was reported in newly diagnosed ITP and may be an association and plays role in its pathophysiology. Scavenging of oxygen free radicals ameliorated the oxidative stress, thrombocytopenia and bleeding in ITP patients.

P1213

EPIDEMIOLOGY OF INCIDENT IMMUNE THROMBOCYTOPENIA IN FRANCE: A NATIONWIDE POPULATION-BASED STUDY

G Moulis[1,2,*], A Palmaro[2], D Adoue[1], M Lapeyre-Mestre[2], L Sailler[1]
[1]Internal Medicine, Toulouse University Hospital, [2]UMR 1027, Pharmacoepidemiology unit, INSERM-University of Toulouse, Toulouse, France

Background: Epidemiology of immune thrombocytopenia (ITP) is not well known.
Aims: The purpose of this study is to assess ITP incidence at a nationwide level (France) with recent data (mid-2009 to mid-2011, corresponding to 129 248 543 person-years).
Methods: Data source is French health insurance database, which collects prospectively data regarding demographic characteristics, out-hospital expenditures (including drugs) and hospital stays for every patient. We selected ITP patients through hospital stays and long-term disease diagnosis codes (D69.3 code of the ICD-10). Date of diagnosis was refined thanks to out-hospital ITP drug dispensing. We studied incidence by age, gender, calendar month and administrative regions. To detect the regions of low and high incidence, we used Local Indicators of Spatial Associations method after direct standardization on age and gender repartition in France. We also assessed 1) the proportion of secondary ITPs through long-term disease and in-hospital diagnosis codes, 2) the percentage of ITPs becoming persistent or chronic (defined as a long-term disease attribution, two hospital stays more than three months apart, splenectomy or rituximab exposure, or a more than 3-months out-hospital drug dispensing), and 3) the percentage of severe bleeding at disease onset, assuming that all patients with severe bleeding were hospitalized.
Results: We identified 3771 incident ITP patients. ITP incidence was 2.9/100 000 person-years (95% confidence interval: 2.83-3.01) with peaks among children and after 60 years. ITP was more frequent among males in these subgroups especially after 75 years (9/100 000 person-years). It was significantly lower in overseas Caribbean French departments, suggesting a lower incidence among Afro-American people. Seasonal variations were observed (peak in winter, nadir in summer). Incidence was statistically lower in north-west France and higher in south France. Persistence or chronicity occurred in 36% of pediatric ITP cases, compared with 67% of adults. Among adults, 18% of ITP cases were secondary. Malignant lymphoid disorders (mainly lymphoma and B-cell chronic leukemia) were observed in 5.9% of incident adult ITPs. Other main causes of secondary ITP were connective tissue diseases (2.5%, mainly systemic lupus erythematosus), myelodysplastic syndromes (2.3%), immune deficiencies (excluding HIV infection, 1.7%), and HIV infection (0.9%). Forty-seven patients (1.63%) had Evans' syndrome. ITP was secondary in 2,4% of children cases. Severe gastrointestinal or central nervous system bleeding at ITP onset were rare (<1%), increasing with age.
Summary and Conclusion: This study adds new information on ITP epidemiology, *i.e.* seasonal variations, a north-south gradient in France and a lower incidence in a dominant Afro-American population (Caribbean area). It confirms age and gender repartition, the frequency of classical causes of secondary ITP and rarity of severe bleeding at disease onset.

P1214

RITUXIMAB REVERSED THE INCREASE IN SPLENIC T FOLLICULAR HELPER CELLS DURING IMMUNE THROMBOCYTOPENIA

S Audia[1,2,3,*], M Rossato[3], M Trad[2], K Santegoets[3], N Janikashvili[2], B Bonnotte[1,2], T Radstake[3]
[1]Internal Medicine and Clinical Immunology, Dijon University Hospital, [2]Immunoregulation and Immunopathology, CR INSERM 1098, Dijon, France, [3]Infection and Immunity FOCIS Center of Excellence, University Medical Center, Utrecht, Netherlands

Background: Mainly localized into secondary lymphoid organs, T follicular helper cells (TFH) have been recognized as the major T cell subset that promotes B cell proliferation and differentiation into plasma cells, and thus, the production of immunoglobulins. Animal models and the expansion of blood TFH during systemic lupus erythematosus and Sjögren syndrome give arguments for their involvement during auto-immune diseases (AID).
Aims: Taking advantage of splenectomy as part of the treatment of immune thrombocytopenia (ITP), we analyzed TFH within a secondary lymphoid organ during a human AID. Our aim was to characterize and localize splenic TFH and to study their interaction with B cells. The effect of rituximab, a B cell depleting therapy, on TFH was also investigated.
Methods: The spleens of 23 primary ITP patients, among which 10 were previously treated with rituximab, were compared to 8 controls. All patients gave a written informed consent before being included. The study was approved by our institutional review board and ethics committee. TFH were characterized and quantified by flow cytometry. Chemokine and cytokine expression was measured by quantitative PCR. The location of TFH within the spleen was determined by immunohistochemistry. TFH were also quantified in the blood of 10 ITP patients before and after rituximab. Results are given by median with interquartile range. Mann-Whitney *U* test and Wilcoxon's signed-rank test were used as appropriate. Spearman's rank correlation test was used for correlation analyses.
Results: Splenic TFH, defined as $CD3^+CD4^+CXCR5^+ICOS^+PD\text{-}1^+$, displayed a phenotype of memory cells ($CD45RO^+$), were activated ($CD69^+$) and expressed the transcription factor Bcl-6. Upon stimulation, splenic TFH expressed CD154 (CD40 ligand) and were the main producer of IL-21 within the spleen. Consistent with their $CCR7^-CXCR4^+$ phenotype, TFH were located within germinal centers (GC) of secondary follicles. Splenic TFH frequency was increased during ITP (2.04 [1.4-3.2] *vs.* 0.5 [0.3-0.6] % of $CD4^+$ T cells, p=0.003) and associated with an increase in CXCL13 (214 [57.3-418.2] *vs.* 34.9 [13.1-78.8], p=0.02) and IL-21 expressions (12.8 [7.3-17.7] *vs.* 4.4 [3.4-4.6], p=0.009) among $CD4^+$ T cells. ITP patients also displayed higher frequencies of GC B cells ($CD19^+IgD^-CD38^+$; 11.6 [9.9-13.3] *vs.* 4.8% [3-6.2] of B cells, p=0.004), pre-GC B cells ($CD19^+IgD^+CD38^+$; 14.3 [12.3-24] *vs.* 5.7% [3.8-10.6], p=0.002) and plasma cells ($CD19^+IgD^-CD38^{++}$; 2.2 [1.6-2.8] *vs.* 0.7% [0.4-1.3], p=0.003) compared to controls. Interestingly, splenic TFH percentage correlated with the percentage of GC (R=0.7, p=0.003), preGC B cells (R=0.8, p=0.0002) and plasma cells (R=0.7, p=0.003). *In vitro*, the differentiation of splenic B cells into plasma cells together with antibody secretion depended on the use of a CD40 agonist in presence of IL-21, pointing out the involvement of TFH that both expressed CD154 and IL-21. Although they represented only a minor part of $CD4^+$ T cells, circulating TFH were increased during ITP (0.09 [0.04-0.13] *vs.* 0.01% [0.004-0.04] of $CD4^+$ T cells, p=0.005). Blood and splenic B cell depletion following rituximab therapy was associated with a decrease in TFH frequency in the blood (0.09 [0.04-0.13] *vs.* 0.05 [0.02-0.07] % of circulating $CD4^+$ T cells, p=0.04) and in the spleen (0.13 [0.05-0.23] % of $CD4^+$ T cells in rituximab-treated *vs.* 2.04 [1.4-3.2] in ITP patients, p<0.0001).

Summary and Conclusion: Our results showing an increase in splenic and circulating TFH strongly support a role for TFH in the differentiation of pathogenic B cells during ITP. Interestingly, rituximab treatment is associated with a decrease in splenic and blood TFH.

P1215

SUSTAINED RESPONSE AFTER THROMBOPOIETIN RECEPTOR AGONISTS DISCONTINUATION IN 5 PATIENTS AFFECTED BY PRIMARY IMMUNE THROMBOCYTOPENIA

C Santoro[1,*], F De Angelis[1], E Baldacci[1], L Parlanti[1], R Foà[1], MG Mazzucconi[1]
[1]Cellular Biotechnology and Hematology, Hematology Sapienza University, Rome, Italy

Background: The efficacy of the thrombopoietin receptor agonists (TPO-RAs) in the treatment of primary immune thrombocytopenia (pITP) patients (pts) has been already demonstrated. The two available TPO-RAs for the treatment of pITP, Romiplostim and Eltrombopag, have been approved by EMA for the treatment of chronic and refractory (post-splenectomy) pITP pts. Although it is well known that these drugs have to be chronically administered to maintain a platelet response, in the last few years case reports on sustained responses off treatment in pITP pts have been reported.
Aims: To retrospectively report our experience of sustained response after TPO-RA discontinuation in pITP patients.
Methods: Data were examined for patients who received a TPO-RA and maintained a response after discontinuation of treatment in the absence of other concomitant medications. Response was defined as a platelet (plt) count ≥50x10^9/L and at least a 2-fold increase of the baseline value; complete response (CR) as a plt count ≥100x10^9/L; sustained response as a plt count ≥50x10^9/L and at least a 2-fold increase of the baseline value, off treatment. Period in response during TPO-RA treatment was expressed as the percentage of weeks in response/weeks on treatment. Phases of pITP were defined in relation to the diagnosis as follows: acute, within 3 months; persistent, between 3 and 12 months; chronic, more than 12 months.
Results: Since February 2009, 39 pITP patients (25 F, 14 M) resistant to one or more therapy lines have been treated with TPO-RAs. Globally, 30/39 (77%) patients obtained a response without concomitant treatment. Five/30 (16.6%) responder pts obtained a sustained response after TPO-RA discontinuation. They were 4 females, 1 male. The median number of therapy lines prior to the start of the TPO-RA administration was 3 (2-5): prednisone, dexamethasone, azathioprine, rituximab, splenectomy, interferon. Two patients started the TPO-RA while still in the acute phase. They were severely symptomatic and resistant to high dose steroids and intravenous immunoglobulins. The other 3 patients were in a chronic phase and they started the TPO-RA at 2.4, 15.1 and 38.7 years from pITP diagnosis, respectively. Two patients had been previously splenectomized 36.9 and 0.25 years before the start of the TPO-RA. They have been all treated with Romiplostim. The characteristics at the start of the TPO-RA were: median age 50 years (41-77); median plt count 11x10^9/L (2-13). Steroids were a concomitant treatment in all patients. The median number of weeks on TPO-RA treatment was 18 (5-133), the median time to obtain a response in absence of concomitant medications was 7 weeks (4-11) and the median Romiplostim dosage was 4 µg/dose (1-6). The median percentage of weeks in response/weeks on treatment, was 64% (40-100). They all stopped TPO-RA treatment having achieved a CR and there was no further indication to continue TPO-RA therapy. The median period in response off treatment is 2.3 years (0.8-3.4). No patient experienced side effects or severe adverse events.
Summary and Conclusion: Five/30 (16.6%) pITP pts treated with Romiplostim have maintained a sustained response after therapy discontinuation. They were either acute or chronic pts. So far, few literature data are reported about sustained response after TPO-RAs discontinuation in pITP pts. Large controlled retrospective and prospective follow-up studies are required.

P1216

NOVEL MUTATIONS AT GPIIB/GPIIIA GENES FROM TURKISH PATIENTS WITH GLANZMANN THROMBASTHENIA SYNDROME

DT Özkan[1,*], Ü Çalışkan[2], N Akar[3]
[1]Medical Laboratory Technology, Okan University, İstanbul, [2]Hematology, Necmettin Erbakan University, Konya, [3]Pediatrics, TOBB-Economy and Technology University Hospital, Ankara, Turkey

Background: Glanzmann Thrombasthenia (GT) is a congenital hereditary hemorrhagic disorder, characterized by a defective platelet integrin alpha IIB, beta3 receptor. The autosomal recessive bleeding disorder caused by qualitative or quantitative abnormalities of platelet glycoprotein IIB/IIIA leading to excessive bleeding. The integrin receptor is a heterodimer consisting of alpha IIa and beta 3 subunits found in an inactive state in resting platelets. When platelets are stimulated, in the transmembrane and extracellular domain occurs conformational change then activated integrin alpha IIB/IIIA binds to fibrinogen and von Willebrand factor and some other molecules such as vitronectin, fibronectin. vWf or fibrinogen bring about crosslink between GpIIB/IIIA complex and multipl platelets and this suggesting the formation of the platelet plug at the damaged site. GT has autosomal recessive inheritance and glycoprotein IIB and glycoprotein IIIA genes are determined as associated with this disease. These genes are closely located at chromosome 17q21.31-32. While GpIIB consist of 30 exon and encoding α chain, GpIIIA has eight exon and encoding β chain. Up to now, according to Human Gene Mutation Database 151 mutations at GpIIIA gene, 92 mutations at GpIIB gene have been indentified and large proportion of these mutations constitute missense and nonsense mutations.
Aims: In this study, we aimed to analyze mutations GpIIB and GpIIIA genes in Turkish population as a clinically diagnosed with Glanzmann Thrombasthenia Syndrome.
Methods: A total of 20 Glanzmann Thrombasthenia patients diagnosed at Selcuk University Hematology Department sent to our laboratory for the evaluation of the gene. Peripheral blood was collected from patients and a written informed consent for genetic analysis was obtained from parents. DNA was isolated from by proteinase K and phenol/chloroform extraction. GpIIB and GpIIIA genes were screened by polymerase chain (PCR) reaction. After then, PCR products were cleaned with DNA Purification Kit (Roche DNA Purification Kit) and then samples was sequenced using an automatic DNA Sequencer (Beckman Coulter, USA).
Results: Screening the exons of the GpIIB gene from Turkish patient, we detected five novel mutations in three different region and 2 mutations defined previously within the gene (Figure). These changes are at exon 4; c.438 G>T alteration, at exon 13 c.1277 T>A, c.1291 G>T alterations, at exon 19 c.1921A>G alterations. And from the start point of exon 14, behind 107 base, we detected a heterozygous alteration at Thymine to Guanine. According to Polyphen Database program and NCBI Multipl Aligment Tool Database; five transitions are conserved at evolutionary process, so we can say that these transitions are novel mutations. c. 507T>G alteration at exon 4 and c. 1378 T>A alteration was reported to HGMD (Human Gene Mutation Database) previously. Screening the exons of the GpIIIA gene from the same patient groups, we reported a novel missense mutation at exon 5, at nucleotide 680. At the protein level, the resulting missense mutation leads a change of Leucine to Isoleucine at codon 221 of the GpIIIA gene, also involved a highly conserved aminoacid residue.

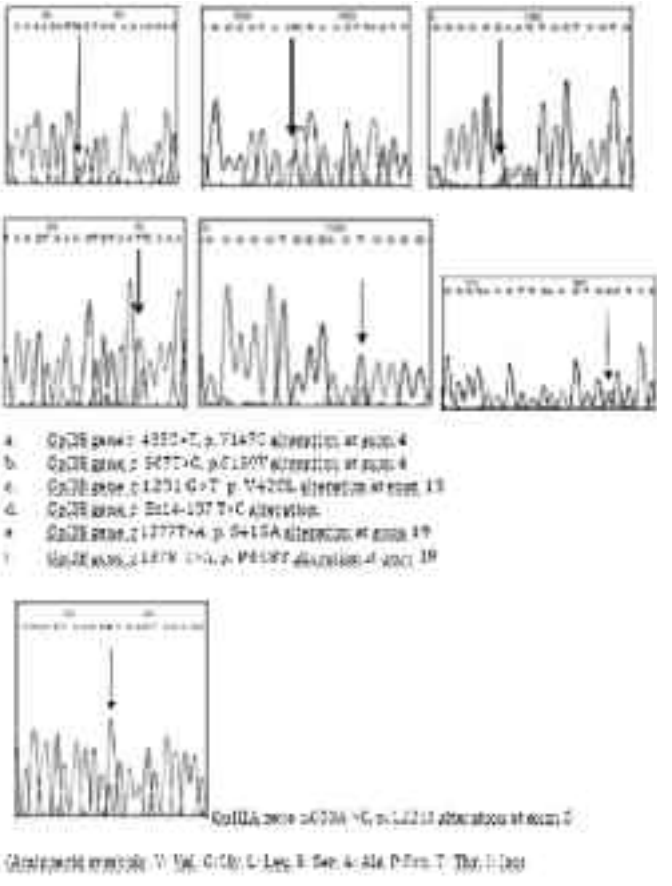

Figure 1.

Summary and Conclusion: These mutations were described for the first time in Turkish population and all novel mutations are not defined HGMD previously. Further collaborative studies are needed for the population point of view.

P1217

NEXT GENERATION SEQUENCING OF NBEAL2 GENE MUTATIONS IN GRAY PLATELET SYNDROME

E SK Ma[1,*], R HS Liang[2], D N Ho[1], C H Au[1], T L Chan[1]
[1]Pathology, [2]Medicine, Hong Kong Sanatorium & Hospital, Happy Valley, Hong Kong

Background: Gray platelet syndrome (GPS) is an inherited platelet disorder characterized by variable thrombocytopenia, large platelets, absence of α-granules in platelets and autosomal recessive inheritance. Three simultaneous papers in July 2011 identified biallelic mutations of the *NBEAL2* on chromosome 3p21 as the genetic basis of GPS.
Aims: We report *NBEAL2* gene mutation detection in a Chinese patient with GPS by next generation sequencing (NGS).
Methods: A 49-year old female presented with a history of thrombocytopenia for 10 years without bleeding symptom. She complained of left upper quadrant pain and was found to have splenomegaly of 3 cm below the left costal margin, which showed diffuse enlargement on computed tomography. Complete blood counts showed: hemoglobin 11.6 g/dL, MCV 85.8 fL, white cell count 3.25 x 10^9/L, platelets 48 x 10^9/L and reticulocytes 1.13%. Blood smear review showed large and hypogranular platelets. The bone marrow aspirate was a dry tap. Trephine biopsy showed hyperplastic marrow in association with active trilineage haemopoiesis and reticulin fibrosis. Electron microscopy of the blood platelets showed absence of α-granule but preservation of dense granules and other organelles. The complete *NBEAL2* gene from exons 1 – 54 was subject to Fluidigm access array amplification followed by 454 sequencing, and variants were confirmed by Sanger sequencing.
Results: A heterozygous novel nonsense mutation was identified at exon 23 (c.3226C→T p.Gln1076*) with over 800 fold coverage. Two variants of unknown significance (VUS) were also identified at exon 12 (c.1271G→T p.Arg424Leu) and exon 33 (c.5350C→T p.Arg1784Cys) respectively. The exon 12 VUS was annotated to the ARM domain. *In-silico* analysis showed that the exon 12 VUS was likely benign while the exon 33 VUS was likely damaging. These three variants were all present in the DNA from buccal mucosa cells and of germline nature. The mother and two elder siblings of the patients were alive without bleeding history and family study was being arranged.
Summary and Conclusion: We confirm the pan-ethnic nature of *NBEAL2* gene defect in GPS. Furthermore, since the *NBEAL2* gene does not account for all cases of phenotypic GPS and an autosomal dominant form involving the *GFI1B* gene is recently described, we illustrate that the NGS approach is a clinically useful and practical option for the genetic diagnosis of GPS and a gene panel can be developed.

P1218

IS HIGHER IL-21 LEVEL PREDICTIVE OF RELAPSES IN IMMUNE THROMBOCYTOPENIA AND IS IT ASSOCIATED WITH ACTIVATION OF THE COMPLEMENT SYSTEM?

G E Pamuk[1,*], B Sahip[1], M S Uyanik[1], M Demir[1], O N Pamuk[2]
[1]Department of Hematology, [2]Department of Rheumatology, Trakya University Medical Faculty, Istanbul, Turkey

Background: Immune thrombocytopenia (ITP) is a disease the pathogenesis of which involves multiple mechanisms. There is contradictory data on whether the antigen-antibody complexes activate the complement system or not.
Aims: We evaluated complement activation and its relationship with recently defined T cell markers. Anti-complement 1q antibody (anti-C1q), complement factor H (CFH), complement fragments Bb, plasma stromal-derived factor (SDF-1), and interleukin-21 (IL-21) levels were determined. C1q plays a role in the activation of the classic complement pathway and is associated with autoimmune diseases, like lupus nephritis. CFH inhibits C3b convertase which takes part in the activation of the alternative complement pathway. Complement fragments Bb show activation of the alternative pathway. Plasma SDF-1 level is associated with lectin pathway. It was recently shown that helper T cells from ITP patients synthesized IL-21.
Methods: We included 92 ITP patients (66 females, 26 males, mean age: 47.3±7.5) and 48 controls (33 females, 15 males, mean age: 44.9±17.6). Ethical committee approval and written informed consent were obtained. Patients' demographic and clinical data were retrieved from medical files. Anti-C1q, CFH, complement fragments Bb, SDF-1, and IL-21 levels were determined in ITP patients' plasma when platelets were<100000/mm3 and also in controls with normal platelets. The same parameters were evaluated in 61 ITP patients whose platelet counts became >100000/mm3 after treatment.
Results: Sixtyfour (69.6%) ITP patients had bleeding symptoms. In 22 (23.9%) patients, platelet counts were<30000/mm3. ITP patients had significantly higher IL-21 [(median and range: 165.8 pg/ml (0-422) *vs*. 83.2 pg/ml (0-2396), p=0.027)], and anti-C1q [(median and range: 3.97 ng/ml (1.07-8.81) *vs*. 2.99 ng/ml (1.06-9.92), p=0.022)] levels than controls. On the other hand, CFH [(median and range: 2.78 ng/ml (1.15-9.97) *vs*. 5.3 ng/ml (1.13-9.68), p<0.001)], and complement fragments Bb [(median and range: 0.16 µg/ml (0-17) *vs*. 0.23 µg/ml (0.1-0.65), p=0.012)] were significantly lower in the ITP group. SDF-1 levels were similar in ITP and control groups (p=0.12). When the values of the evaluated parameters in ITP patients with low (<100000/mm3) *vs*. normal platelet counts (>100000/mm3) were compared, it was observed that IL-21 level decreased significantly (median: 156.9 pg/ml *vs*. 101.9 pg/ml); CFH (median: 3.83 ng/ml *vs*. 5.22 ng/ml) and SDF-1 (median: 247.9 pg/ml *vs*. 456.1 pg/ml) levels incresed significantly (all p values<0.001). There were no changes in anti-C1q and complement fragments Bb levels after therapy. We also compared the initial values of all parameters in 46 ITP patients who obtained either a partial (platelets >50000/mm3) or a complete response (platelets >100000/mm3) with first-line therapy with the initial values of 23 ITP patients who did not respond to first-line therapy; and found no significant differences. Initial IL-21 levels in ITP patients who relapsed after first-line therapy were significantly higher than those who did not relapse (p=0.03).
Summary and Conclusion: Our results suggest that complement activation might be playing a role in the pathogenesis of ITP. It was interesting that CFH and SDF-1 levels decreased significantly after therapy. Our results confirmed the increase in IL-21 level in ITP, and this increase persisted after therapy. There was no association between IL-21 level and complement activation; however, high IL-21 level at initial diagnosis might be used as a marker to predict relapses in ITP.

P1219

BASELINE CHARACTERISTICS, PLATELET COUNT PROGRESSION AND OCCURRENCE OF COMORBIDITIES AMONG ADULT PATIENTS WITH PRIMARY IMMUNE THROMBOCYTOPENIA (ITP): UPDATED RESULTS FROM THE UK ITP REGISTRY

D Bennett[1,*], U Doobaree[2], R Nandigam[2], A Newland[2], D Provan[2]
[1]WWEpidemiology, GlaxoSmithKline, Collegeville, United States, [2]Department of Haematology, Blizard Institute, Barts and The London School of Medicine and Dentistry, London, United Kingdom

Background: Primary immune thrombocytopenia (ITP) is a rare, autoimmune blood disorder that manifests itself with bleeding symptoms which is usually associated with a drop in platelet count (<100×10^9/L). The United Kingdom ITP (UKITP) Registry continues with its role in providing contemporary research findings on the epidemiology of ITP, natural progression of the disease, including the development of comorbidities and platelet count changes, and ITP treatment patterns and their effectiveness. Such data from large, representative population is sparse and the Registry is achieving its objective of conducting its research using larger sample size, on which this present study is based.
Aims: In this updated analysis, we described the cohort at baseline (at initial ITP presentation) and platelet count progression following ITP diagnosis, and estimated the rate of certain comorbid occurrences after diagnosis of ITP.
Methods: The registry, based at the Royal London Hospital, collects extensive demographic and clinical data (historical and prospective) on its enrolees through a network of 46 collaborating haematology regional centres. Apart from describing the ITP cohort at initial ITP presentation, the Registry is able to estimate the rate of occurrence of specific comorbidities and platelet progression at or following ITP diagnosis.
Results: The 822 enrolees of the UKITP Registry had a median age at ITP diagnosis of 51.8 years old and 57.7% were females. The majority of enrolees were found to be of European ancestry (79%) followed by African ancestry (3.2%). Prevalence of thromboembolism (TE) was 6.6% where arterial TE was more prevalent than venous TE in the entire cohort (5.4% *vs*. 1.2%). Males were found to have more events of arterial TE whereas females had more venous TE. About 2% of the cohort was found to have cataract prior to ITP diagnosis. Prevalence of cataracts was higher among males 2.3% *vs*. 1.7% among females. As for haematological malignancies, about 1% of the cohort had such a history prior to diagnosis of ITP. The mean and median minimum platelet count for the enrolees at ITP presentation (7days before and 1 day after ITP diagnosis) was 38.3 and 20.0 x 10^9/L, respectively. About 30% of enrolees had their minimum platelet count between 0 and 9 x 10^9/L at the time of diagnosis. The mean platelet count rose above 100 x 10^9/L over the next 6 months but dropped just below this threshold at around 2 years to 86.9 x 10^9/L and 3 years to 99.0 x 10^9/L. In the period of time after the diagnosis of primary ITP, rates of events per 10,000 person-years was 104.8 (95% CI: 75.6-145.3) for TE, 68.3 (95% CI: 45.4-102.8) for cataracts. The rate of haematological malignancies was higher among patients 45 years of age or older [23.6 (95% CI: 7.6-73.3)] compared to patients less than 45 years [9.7 (95% CI: 2.4-38.9)].
Summary and Conclusion: This population based registry provides more knowledge and evidence on the natural history of primary ITP than previously known. Prior to or at the time of the diagnosis of primary ITP, about 7 out of every 100 patients had experienced a thromboembolic event and a lower prevalence of having had cataract and haematological malignancies were found in this cohort.

P1220

CLINICO-PATHOLOGIC FEATURES OF COMMON VARIABLE IMMUNODEFICIENCY (CVID) PATIENTS MANIFESTING CYTOPENIAS

V Srirangam[1,*], S Burns[2], C McNamara[3]
[1]University College London (UCL), [2]Department of Immunology, [3]Department of Haematology, The Royal Free London NHS Foundation Trust, London, United Kingdom

Background: Common variable immunodeficiency (CVID) is a primary immunodeficiency disorder characterized by recurrent infections and multiple immune defects. The full range of diagnostic problems is poorly described.
Aims: We aim to outline the clinical and laboratory features of patients with cytopenias encountered in a CVID cohort in a single centre.
Methods: An established database was used to identify patients over a 15 year period who had one or more cytopenias (Hb<135g/L in men and<115g/l in women, neutrophils<2.0x10*9/L, platelets<140x10*9/L) that could not be explained and that persisted for more than 2 weeks. The outcome of haematology assessment and bone marrow biopsy were noted.
Results: Of 183 CVID patients 64 (median age 49.5; range 32-86, M:F 0.8:1) were noted to have a cytopenia (55 thrombocytopenia; 28 anaemia; 19 patients had both). Regarding thrombocytopenia (median count 98; range1-136) idiopathic thrombocytopenia purpura (ITP) was presumed to be the cause in 34.6%. Two thirds of ITP patients with CVID experienced a recurrence of thrombocytopenia. Hypersplenism was considered to be contributory to thrombocytopenia in 50%. Two patients had a lymphoma diagnosed following identification of thrombocytopenia. Eleven had a bone marrow aspirate and trephine biopsy (BMAT). Eighteen required intervention - steroids in 13, rituximab 7, variation in immunoglobulin administration 7, splenectomy 6, anti-D immunoglobulin 1. There were 17 bleeding complications reported. Anaemia was reported in 28 patients and a cause identified in 24- autoimmune haemolytic anaemia (AIHA) in 8, pernicious anaemia in 3 and iron deficient erythropoiesis in 11 (of which 5 were secondary to CVID enteropathy-related malabsorption). A BMAT was performed in 6 patients with anaemia. Of the patients with AIHA, 6 required intervention in the form of steroids, rituximab and/or IV Immunoglobulin and 6 required one or more blood transfusions.
Summary and Conclusion: Cytopenias have a high prevalence in CVID patients and can be expected to present in haematology practice where CVID patients are managed. The majority of patients are managed without bone marrow biopsy. ITP and AIHA have well-characterised causal links with cytopenias in patients with CVID. However, other pathologies such as hypersplenism, malabsorption and pernicious anaemia that are common in this group of patients must be excluded.

P1221

PRIMARY VERSUS SECONDARY ITP IN ADULTS; A COMPARATIVE ANALYSIS OF CLINICAL AND LABORTORY ATTRIBURTES IN NEWLY DIAGNOSED PATIENTS IN AN ASIAN POPULATION

S M Irfan[1,*], J Uddin[1], R Zeeshan[1], S Sultan[1]
[1]Hematology, Liaquat National Hospital, Karachi, Pakistan

Background: Immune thrombocytopenic purpura (ITP) is a hemorrhagic diathesis, resulting in escalated platelets destruction alongside impaired production in bone marrow. Patients from Asian regions often exhibit distinctive characteristics in comparison to the patients from the western countries. We accomplished this study to determine the spectrum of ITP in an Asian population.
Aims: The aim of this study is to evaluate the prevalence of primary *versus* secondary ITP along with comparative analysis of both the disease groups. The secondary objective is to determine the etiological spectrum of secondary ITP in Asian patients.
Methods: We illustrate the results of a prospective study in a population based large cohort of newly diagnosed adults (≥13 years) with platelet count<100x10^9/l at presentation. The study extended from January 2009 till December 2013. Complete blood counts, peripheral smear examination, HbsAg, Anti HCV, ANA and stool for Helicobacter pylori were analyzed by standard laboratory methodology. HIV, TSH, double stranded DNA, RA factor, Antiphospholipid antibodies and direct coombs test were done where indicated clinically. Bone marrow examination was carried out above 60 years and in those where it was deemed necessary.We computed percentages for the prevalence of primary and secondary ITP. Independent sample t- test were applied for comparative analysis of age and hematological parameters. We also computed pearson Chi-square correlation at 5% level of significance to identify association between categorical data.
Results: A total of 417 patients were incorporated with a mean age of 40.95±14.82 years. Primarily disease is observed in 3rd decade of life. Male to female ratio is 2:3 with a bimodal peak in females. The mean hemoglobin was 11.68±1.75g/dl while mean platelets count was 46.21±27.45x109/l. At diagnosis 43.16% (n=180) patients had hemorrhagic manifestations whilst 56.8% (n=237) were asymptomatic at presentation. Cutaneous bleeding was appreciated in 37.4% patients while epistaxis, gum bleeding and mennorhagia were detected in 23%, 18.7% and 5.7% respectively. None of patient presented with visceral, retropharyngeal or intracranial bleed. 24.4% had platelets<20x109/l, while 33.9% and 41.7% had platelets count between 21-50 and >50 respectively. Severe thrombocytopenia (<20x109/l) was significantly associated with amplified bleeding tendency (P<0.001). The prevalence of secondary ITP was substantially higher(65%) as compared to primary ITP (35%). Secondary ITP was predominantly seen in HCV reactive patients (24%), followed by helicobacter pylori infection (11%). Nevertheless 17% patients had underlying autoimmune disorders (SLE, RA, Evans syndrome and others). Drug induced thrombocytopenia and lymphoproliferative disorder (CLL & NHL) were detected in 5%&2% respectively. Providentially no study subject was found to be HIV reactive. Comparative analysis of primary *versus* secondary ITP revealed statistically significant difference in bleeding tendency and platelets counts(P<0.05). Also secondaryITP was exceedingly distinctive and divulged positive association with advancing age(P<0.05).

Table 1.

Parameters	Primary ITP(n= 147)	Secondary ITP(n= 270)	P- value
Age	37.52±14.82	42.83±14.56	0.043
Hemoglobin	12.21± 1.47 gm/dl	11.38 ±1.82 gm/dl	0.01
Platelets	51.56±21.94 x 10⁹/l	54.11± 26.96x 10⁹/l	0.000
Dry/wet purpura	57.1% / 49%	26.7% / 25.6%	0.001 / 0.008

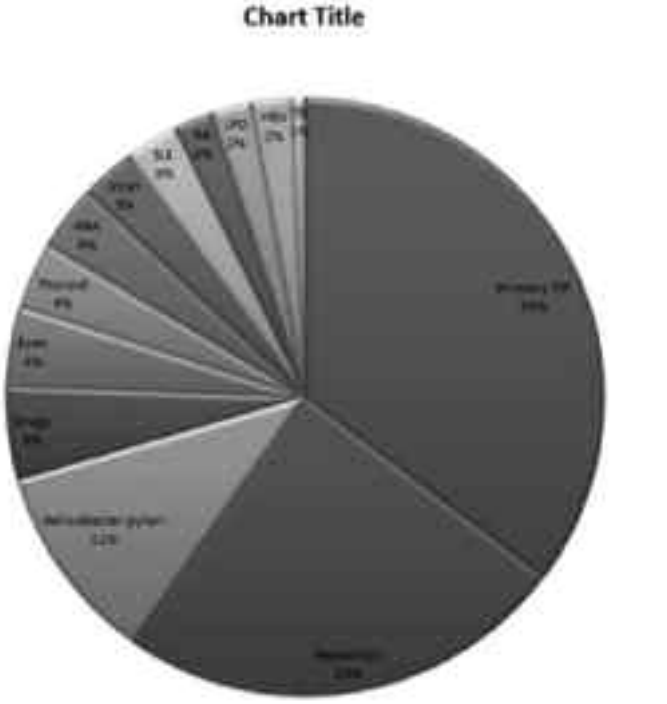

Figure 1.

Summary and Conclusion: Our study revealed predominance of secondary ITP with preponderance of older population. However bleeding manifestations and degree of thrombocytopenia were high in primary ITP cases. Infectious etiology (HCV, H.pylori, HBV,Tuberculosis) followed by autoimmune disorders are mainly implicated for secondary ITP in our setting.

P1222

ROUTINE BONE MARROW EXAMINATIONS MAY NOT BE NECESSARY IN THE EVALUATION OF PATIENTS WITH INMUNE THROMBOCYTOPENIA

P Olivera[1,*], I Valcarce[1], L Gallur[1], F Bosch[1], D Valcárcel[1]
[1]Department of Hematology, University Hospital Vall d'Hebron, Barcelona, Spain

Background: The role of bone marrow examination (BME) in adults with immune thrombocytopenia (ITP) is not well established. The great majority of international guidelines recommend that the BME should be performed in patients who present with additional cytopenias or other hematological abnormalities, in patients with systemic symptoms or in those whom splenectomy or other second-line therapies are considered. Despite these recommendations, there are few studies performing comprehensive analysis of BME results in patients with ITP.
Aims: The objective of this study was to analyze bone marrow findings and to determine the usefulness of BME for the diagnosis (patients with isolated thrombocytopenia) and prognosis stratification in adult patients with ITP.
Methods: We included all consecutive ITP patients diagnosed of ITP in our

hospital between January 2010 and December 2013. Bone marrow aspirate was performed and we described bone marrow cellularity and morphology, and special attention to megakaryocyte number and morphology. Normal limits were established following the Wintrobe method. Cytogenetics and flow cytometry was performed in some patients as physician discretion.
Results: A total of 161 patients; median age was 61 years (range 16-90), 55.9% female. Eighty patients (49.7%) had newly diagnosed ITP, 11 (6.8 %) had persistent and 70 (43.5%) had chronic ITP at the time of the study. Median survivor´s follow-up was 16 months. At last follow-up 77 patients (47.8%) had undergone BME after a median of 2 months (range 0-44) from the first medical visit. The median platelet count at the time of BME was 27 x 109/L. Patients older than 60 years of age (64.9%), cases in which splenectomy or other second lines were considered (28.6%), and cases had hematologic abnormalities (6.5%) were the reasons why BME was performed. The morphology of megakaryocytes and bone marrow cellularity are listed in Table 1. Abnormal findings were evidenced in only 2 of the cases. In one additional case bone marrow was not assessable because the sample was limited. Of the 2 patients with pathological bone marrow, one patient had acute myelogenous leukemia (AML) and the other one a myelodysplastic syndrome (MDS). The AML patient had an isolated thrombocytopenia with a normal peripheral blood examination, but in a week developed a severe pancytopenia. Patient with MDS developed monocytosis during follow up. Flow cytometry study was performed in 66 patients (85.7%); it was normal in 58 patients (70.1%). Cytogenetics was performed in 39 patients (50.6%) and it was normal in 36 patients. Both techniques were helpful in the diagnosis of AML (See Table 1). BME findings implied a different diagnosis in 2.6% of patients who underwent the procedure and 1.24% of the entire cohort. None of the other patients developed any other hematological disease during the follow-up.

Table 1. Myelogram features and additional testing

Summary and Conclusion: Bone marrow examination is rarely informative in patients with isolated thrombocytopenia but proved to be useful in patients in whom there are other abnormalities in peripheral blood. Flow cytometry was useful to find clonal population B, undetectable by morphology in the bone marrow aspirate.

P1223

RITUXIMAB SALVAGE THERAPY IN ADULTS WITH CHRONIC IMMUNE THROMBOCYTOPENIA: EFFICACY AND SAFETY
E Reboursiere[1,*], H Fouques[1], G Maigne[2], AC Gac[1], S Chantepie[1], O Reman[1], M Macro[1], H Johnson[1], K Benabed[1], X Troussard[1], S Cheze[1]
[1]Hematology, [2]Internal Medicine, University Hospital of Caen, Caen, France

Background: Chronic immune thrombocytopenia (ITP) treatment recommended after corticosteroid failure remains splenectomy because of a large experience of its efficacy and a long-term follow-up. Despite this, post-surgery complications and risk of infection lead to the arrival of new agents such as Rituximab.
Aims: The purpose of this study is to assess efficacy and tolerance to Rituximab, a monoclonal anti-CD20 antibody.
Methods: We conducted a retrospective study in University Hospital of Caen of all patients treated with Rituximab therapy because of refractory or in relapse ITP from January 2004 to August 2013.
Results: Thirty-five patients with a median age of 49 years old (range 20-82) were enrolled. They all had active disease in relapse or refractory to a first line therapy and received 375mg/m^2 Rituximab dose weekly, for four weeks. Median time from diagnosis to first infusion was 16 months (range 1-362) and median time observation was 33 months (range 5-114).
Efficacy: Overall response rate (ORR) was about 54% of patients one and two years after the first infusion, with 26 and 27% of complete response, respectively, with median time response duration of 24 months (range 1-104). About 45,7% of patients are still maintaining durable and significant platelet response, with a median of 32,5 months (range 5-104) from the first infusion, 81% of them for more than 1 year. Ten of 35 patients (29%) had undergone splenectomy, 4 of them before Rituximab, one of them had responded to Rituximab and still maintained partial response at 17 months from the initial infusion. Durable response after Rituximab was observed in 78,6% of patients in second line therapy (11/14) against 35.7% of patients in third line therapy (5/14) (p=0,05; odds ratio 6.1[1; 51.7]$_{95\%}$).
Toxicity: Two patients suffered from pneumonia. Seven of 17 patients (41%) declared hypogammaglobulinaemia after Rituximab therapy, without clinical infectious consequence. One patient suffered from Guillain-Barre syndrome 18 months after Rituximab therapy. Four patients declared malignancies.
Summary and Conclusion: Rituximab can be considered as an alternative to splenectomy for 54% of patients who respond after more than 1 year and 27% for 5-year follow-up. Its safety profile should lead us to choose this medical option therapy before surgery. This encouraging data should be confirmed by prospective randomized trials and by most retrospective studies with long-term follow-up.

P1224

INTERNATIONAL ITP REGISTRY WITH FOCUS ON THE ASIA PACIFIC REGION: PRELIMINARY FINDINGS OF EPIDEMIOLOGICAL AND CLINICAL DATA
B H Chong[1], JW Lee[2], TJ Chiou[3], R Marouf[4], JH Jang[5], SC Ng[6], AS Goh[7], S Okamoto[8], P Angchaisuksiri[9], O Ilhan[10], LH Lee[11], D Bennett[12], S Davidson[13], R Odegbami[14], T Brears[14,*]
[1]Department of Haematology, St George Hospital, Sydney, Australia, [2]Seoul St Mary's Hospital, Seoul, Korea, Republic Of, [3]Taipei Veterans General Hospital, Taipei, Taiwan, Republic of China, [4]Mubarak Alkabeer Hospital, Jabriya, Kuwait, [5]Samsung Medical Centre, Seoul, Korea, Republic Of, [6]Sime Darby Medical Centre, Subang-Jaya, [7]Penang Hospital, Penang, Malaysia, [8]Keio University, Tokyo, Japan, [9]Ramathibodi Hospital, Bangkok, Thailand, [10]Ankara University, Ankara, Turkey, [11]Singapore General Hospital, Singapore, Singapore, [12]GlaxoSmithKline, Pennsylvania, United States, [13]Centre for Thrombotic and Bleeding Disorder Research, St George Hospital, Sydney, Australia, [14]GlaxoSmithKline, London, United Kingdom

Background: Immune thrombocytopenia (ITP) is an autoimmune disorder characterized by auto-antibody induced platelet (PLT) destruction and reduced PLT production, leading to a low PLT count (<100 x 10^9/L). The availability of robust epidemiological and clinical data outside of Europe and the United States for ITP are very limited. Additionally, there is little uniformity in regards to the treatment of ITP leaving physicians to make treatment decisions based on their experience and institutional protocols. The International ITP-Registry is a prospective cohort study which seeks to collect real-world data on the epidemiological and clinical data of adult ITP predominantly from the Asia-Pacific region.
Aims: The aims of the study are: 1. To compile an anonymous centralised database of demographic, ITP-specific, and co-morbid disease information on ITP patients; 2. To collect data on the presentation and complications of the disease; 3. To document local treatment practices across multiple countries and regions and responses to treatments; 4. To develop and test a prognostic model for major bleeding among adult patients with ITP; 5. To identify factors that predict life-threatening bleeding.
Methods: Recruitment began in 2011. Patients ≥ 18 years old with a recent diagnosis of primary ITP (≤ 6 months since initial diagnosis) are enrolled prospectively upon provision of informed consent. The primary data collected are: patient demographics, laboratory investigations, co-morbidities, bleeding events, blood products used, interventional procedures, pharmacotherapeutic agents administered, response to treatment and adverse events. Data is collected at baseline, after months 6 and 12 and then annually.
Results: As of 31 August 2013, 140 patients had been enrolled at 24 sites across 7 countries in the Asia-Pacific Region and Middle East. At the time of data analysis, 80 patients had reached 6 month and annual follow-up time points with the remaining 60 patients having been enrolled for less than six months from baseline data collection. Sixty per cent were female with a median age of 48 years (range 18 – 96 years). Mean PLT count at baseline was 24 x 10^9/L (range 0 – 94 x 10^9/L). Haematology, coagulation and biochemistry tests were within normal ranges. Prior to enrolment 77 patients had bleeding events recorded. This decreased to 10 events in the follow-up period. Corticosteroids were the most frequently used first-line treatment (59% of patients) achieving

a partial (PR; ≥ 50 x 10^9/l but ≤ 100 x 10^9/l & 2 x pre-treatment) or complete (CR; ≥ 100 x 10^9/l & x 2 pre-treatment) PLT response (82%) and cessation of bleeding (100%) during the 6 month follow-up period. IVIg was also reported as a first line treatment in 14% of patients, achieving a PLT response in 47% and cessation of bleeding in 82% treated. Second line therapies used included splenectomy (n=3; PR=1, CR=2), TPO-receptor agonists (n=2; PR=1, CR=1). 22 patients received Immunotherapy, 14 had a PLT response.
Summary and Conclusion: Enrolled patients have a female predominance with median age of 48 years. Bleeding appears frequently at diagnosis (36%) with symptoms abating with first line treatments. Corticosteroids are the most frequently used first line treatment (59% of patients treated). Splenectomy appears uncommon and was performed in only 3 patients (14% of cohort) with immunotherapies the most often used second line therapy. Data collection and analysis for this study is ongoing.

P1225

CMV INFECTION DOES NOT HAVE AN IMPACT ON BLEEDING MANIFESTATIONS OR PROGNOSIS OF IDIOPATHIC THROMBOCYTOPENIA

G M Mokhtar[1], I Ragab[1,*], S Bakr[2], A M Afifi[1]
[1]Pediatrics, Ain Shams University, Cairo, [2]hematology and chemical pathology, Ain Shams University, Fayoum, Egypt

Background: Human cytomegalovirus (CMV) modulates host immunity, and CMV-infected patients often develop signs of immune dysfunction; Several reports have implicated cytomegalovirus (CMV) in the pathogenesis of ITP.
Aims: Our Study aimed to evaluate frequency of CMV positivity among pediatric patients with acute and chronic ITP and its impact on severity of bleeding, response to treatment and development of chronic disease.
Methods: A cross-sectional study was conducted including 40 patients with ITP diagnosed and/or following at Ain-Shams university pediatrics hospital hematology unit in the period between August 2012 and April 2013. Recording of clinical presentation was done for manifestations suggestive of viral infection *e.g.*pneumonitis, hepatitis, petechial rashes, mononucleosis-like syndrome, hepatosplenomegaly, elevated liver enzymes, atypical lymphocytosis, any persistent fever, morbilliform rash; bleeding signs and and severity were assessed using Edslev *et al.* 2007**,** Treatment details and response were included in the study and CMV-PCR was done for all patients.
Results: CMV-PCR was positive in 72% of studied patients with ITP, (85% of patients with acute ITP and 60% of chronic ITP). No significant difference was found in median age at diagnosis according to CMV status (P>0.005). 72.7% of patients with CMV- PCR positive had a chronic ITP compared to 41.4% in CMV -PCR negative patients (p=0.077), and no gender difference. No difference in the initial clinical presentation or bleeding scores according to CMV-PCR status. Two patients with CMV-PCR positive had intracranial bleeding, however, no significant difference were encountered in other bleeding manifestations. Refractory cases formed 36.4% of CMV-PCR negative patients compared to 17.2% in CMV-PCR positive patients (P=0.29) with no significant difference in outcome. No statistically significant difference between patients by CMV PCR positivity as regards first-line of treatment, response to first-line treatment, and refractoriness to treatment. No statistically significant difference in WBC count, lymphocytic count,neutrophil count or platelet count at sampling according to CMV-PCR status. Sensitivity of serology of CMV in comparison to CMV-PCR was 20.69 %, specificity 72.37 % with positive predictive value 66.67% and negative predictive value 25.81%.
Summary and Conclusion: CMV-PCR positivity formed 72% of patients with ITP; CMV IgM serology was not a good indicative of CMV infection. CMV-PCR positivity did not have a significant impact on clinical presentation, bleeding manifestations or outcome of ITP patients

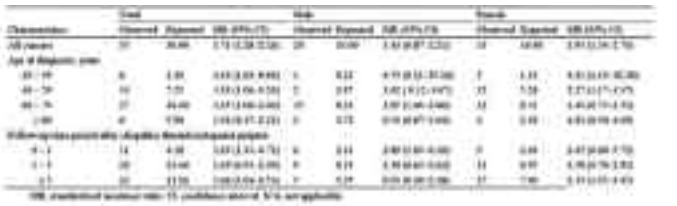
P1226

THE RISK OF CANCER IN PATIENTS WITH IMMUNE THROMBOCYTOPENIA (ITP): A NATIONWIDE POPULATION-BASED STUDY

MH Hu[1,2,*]
[1]Division of Haematology and Oncology, Department of Medicine, Cardinal Tien Hospital, New Taipei City, [2]Division of Haematology and Oncology, Department of Medicine, Taipei Veteran General Hospital, Taipei City, Taiwan, Republic of China

Background: Patients with immune thrombocytopenia (ITP) may have increased risk of develop solid malignancy.
Aims: To evaluate the risk of cancer among patients with ITP.
Methods: A population-based, retrospective cohort study was conducted that included patients diagnosed with ITP. These patients were registered in the National Health Insurance Research Database in Taiwan between 1997 and 2010. Standardized incidence ratios (SIRs) of solid malignancy were calculated to compare the cancer incidence of these patients with those of general populations. Risk factors for cancer development were analyzed by Cox proportional hazards models adjusting for competing mortality.
Results: During the 14-year study period, 53 cancers developed among 816 recruited ITP patients, with a follow-up of 5,396.88 person-years. The SIR for all cancers was 1.71 [95% confidence interval (CI) 1.28–2.24]. The SIRs of follow-up periods were 2.63 (95% CI 1.31–4.71), 1.49 (95% CI 0.91–2.30), and 1.66 (95% CI 1.04–2.51) at 0 – 1 years, 1 – 5 years, and ≥ 5 years, respectively. After exclusion of cancer within 1 year of diagnosis of ITP, a significant higher SIR of cancer was seen in cancers of the digestive (SIR 1.72; 95% CI 1.02–2.71). Multivariate analysis showed that age ≥50 years (hazard ratio [HR] 2.24; 95% CI 1.18–4.24) and diabetes mellitus (HR 2.01; 95% CI 1.00–4.03) were significant risk factors.

Table 1. Standardized incidence ration according to gender, age at diagnostic and duration of immune thrombocytopents



Summary and Conclusion: Patients with ITP are at increased risk of developing solid malignancy. Age ≥50 years and diabetes mellitus are independent risk factors.

P1227

HELICOBACTER PYLORI INFECTION IN PATIENTS WITH IMMUNE THROMBOCYTOPENIA

R Jimenez-Barcenas[1,*], M Ruiz-Mercado[1], MA Dominguez-Muñoz[1], FJ Rodriguez-Martorell[1], M Vinuesa-Vilella[1]
[1]Hospital Universitario Virgen del Rocio, Sevilla, Spain

Background: Eradication of Helicobacter Pylori (HP) infection has been proposed as a therapeutic alternative in the management of immune thrombocytopenia (ITP). Even it is postulated its possible use as an adjuvant therapy in patients with ITP without HP infection, due to immune-modulator effect of some antibiotics.
Aims: This study analyses the possible association ITP-HP and the eventual rol of eradication therapy in the increasement of platelet count.
Methods: 217 patients with primary or secondary immune thrombocytopenia are evaluated: 140 women and 77 men. Age median 56 years old (18-90) and platelet count median 31 x10e9/L. In 64 patients we perform 13C-Urea breath test for the detection of HP infection as a part of the first diagnostic work up. We use the classic eradication scheme OCA (omeprazole, claritromycin, amoxycilin). We check eradication of HP and platelet count increasement up to one month after treatment. The chi-square test and the Student's t-test were used for comparison of proportions and means respectively.
Results: 33 of 64 assessable patients (52%) have a positive 13C-Urea breath test. 31 of them receive eradication therapy. 6 (19%) achieve platelet response; they all with primary ITP, platelet count median 49 x10e9/L *vs* 20 x10e9/L in non-responders (p=0.03), age median 72 years *vs* 57 years in non-responders (p=0.04) and digestive symptoms. Despite the breath test is negative in 31 of 64 patients, 7 receive eradication therapy, without any platelet response. 19 patients receive eradication therapy without performing previous breath test for high clinical suspect. In none of them, platelets increase. In conclusion, 19% patients with positive breath test achieves platelet response after eradication therapy *vs* 0% patients with negative or not performed test. Breath test is repeated in 21 patients who received OCA therapy to confirm eradication of HP. It is negative in 16 of them, including 6 responders.

Table 1.

Platelet response after OCA	Responders (n=6)	Non-responders (n=25)	p-value
Sex (male/female)	2/4	6/19	0.84
Age (median/range)	72(47-85)	57(23-84)	**0.04**
Diagnosis (Primary/secondary IT)	6/0	19/6	0.10
Platelet count (median/range), x10e9/L	49(16-100)	20(1-100)	**0.03**
Digestive Symptoms (yes/no)	6/0	5/20	**0.0002**

Summary and Conclusion: In our series, patients with ITP and HP infection and who are responders to eradication therapy have common features concerning age, platelet counts and digestive symptomatology. According to these results we propose to mark this profile as high pre-test clinical probability of ITP-HP association, performing breath test in these patients and eradication therapy if test is positive.

P1228

RITUXIMAB IN ACQUIRED THROMBOTIC THROMBOCYTOPENIC PURPURA: A SARDINIAN SINGLE CENTER EXPERIENCE

MP Simula[1,*], AM Mamusa[1], E Angelucci[1]
[1]Ematologia e CTMO Ospedale Oncologico Cagliari, Cagliari, Italy

Background: Acquired thrombotic thrombocytopenic purpura (TTP) is an acute, life-threatening disease characterized by thrombocytopenia associated to microangiopathic anemia and often signs of organ dysfunction with neurologic, cardiac, renal or abdominal symptoms. TTP required a prompt diagnosis and immediate treatment with plasma exchange (PEX). Though the majority of patients recovered after standard PEX and steroids therapy a minority of them needs adjuvant therapy. In the last decade, being immunological origin postulated, the monoclonal antibody anti CD 20 have shown efficacy in the management of refractory and relapsed TTP.
Aims: Since August 2010 to January 2014 a total of 9 (4 males and 5 females) patients with TTP received Rituximab in our Institution. Median age at diagnosis was 39 years (range 19-56), median age at infusion of Rituximab was 44.5 y (19-62). Five patients had Rituximab during a relapse, the other 4 underwent immunotherapy in their first episode of disease because of refractoriness to standard therapy (lack of response after seven days, exarcebation or progression of symptoms or transient response). Rituximab has been administered at standard dose (375 mg/m^2 weekly for 4 total infusions). In refractory patients, Rituximab was started in association to PEX; in the relapsed and PEX-responder patients, was given after the last PEX as "consolidation" therapy.
Results: All the patients showed response to Rituximab, the median time to response was 5 days (range 0-27). All the 4 patients who had Rituximab as part of the first line therapy are still in complete remission showing a median duration of continuous disease free survival of 27.6 months (range 4.4-30.4). At the time of Rituximab administration 2 of the relapsed patients were in their 10th and 6thepisode of TTP respectively, while 3 of them were in the 5th one. Four of the 5 relapsed patients (80%) experienced a new recurrence of disease after Rituximab and 3 of them received a other course of Rituximab when the episode resolves. The median time between relapses of TTP before Rituximab administration in the 5 relapsed patients was respectively 11(3-25), 16(2-24), 12(12-21), 22.5(13-26) and 17(7-41) months. The first 4 patients relapsed again after Rituximab and the duration of response was respectively 30, 22, 12 and 33 months, so in 3 out of 4 relapsed post immunotherapy the interval between relapses was longer compared to previous ones. One out of 5 is still on remission after 36 months from first Rituximab infusion. Only in 1 patient, also affected by Kabuki Syndrome, we observed a serious side effect namely a pneumonia with respiratory failure and a severe hypogammaglobulinemia recovered after antibacterial and intravenous immunoglobulin infusions. At the moment of the writing all the 9 patients were in remission.
Summary and Conclusion: Our experience confirms the data regarding the efficacy and safety of Rituximab in the management of TTP. In particular shows that Rituximab can extend the time of remission in relapsed patients and can be combined successfully with PEX in refractory cases.

P1229

CLINICAL ANALYSIS OF EFFECT OF HELICOBACTER PYLORI ERADICATION IN PATIENTS WITH CHRONIC IDIOPATHIC THROMBOCYTOPENIC PURPURA

F Hongqiong[1,*], Y yan[1], L xinyue[1], Y changji[1], L wei[1]
[1]Department of Haematology and oncology, First Hospital of Jilin University-Changchun China, changchun□jilin province, China

Background: Idiopathic thrombocytopenic purpura (ITP), an autoimmune disease caused by sensitization of platelets by autoantibodies leading to platelet destruction, has been associated with some infectious agents, including Helicobacter pylori. Eradication of Helicobacter pylori was reported to increase the platelet counts in some H. pylori-positive patients with chronic idiopathic thrombocytopenic purpura (cITP). However, the efficacy of the eradication was quite different and the mechanismwas not very clearly according to the previous reports.
Aims: To analysis the effect of Helicobacter pylori eradication in patients with chronic idiopathic thrombocytopenic purpura and to investigate the possible pathogenic mechanisms and to predict the platelet response after eradication of H. pylori. in each cITP patient.
Methods: 86 patients with cITP underwent gastroscopy and Pathological examination, 67(78%) of them were detected H. pylori infection positive. 37 patients with H. pylori infection positive had received the treatment of eradication of H. Pylori, the other 30 patients with H. pylori infection positive had not.The eradication group received a standard triple antibiotic therapy for H. pylori. platelet-associated immunoglobulin G (PAIgG) levels were detected by flow cytometry,and Anti-CagA IgG antibody titer of each patient's serum was measured by ELISA
Results: Of the 37 ITP patients with H. pylori infection positive, 30 (81.1%) of them achieved pylori and eradication. 17 (56.7%) of which showed increased platelet counts within the 4 months following treatment. It was significantly different compare with non-eradication group (0%). Completely responsive patients also showed significant declines in platelet-associated immunoglobulin G (PAIgG) levels after eradication therapy. We also detected the H. pylori cytotoxin-associated gene A (CagA) protein in each patients, we found that The titers of anti-CagA antibodies in the responders were significantly higher than those in the nonresponders,but the levels of anti-CagA antibody declined after eradication therapy.
Summary and Conclusion: H. pylori eradication treatment was an effective therapeutic option for H. pylori-positive patients with cITP. the lever of serum anti-CagA antibody may be a good predictor of platelet recovery, Moreover, the Cross-reactivity between PAIgG and H. pylori CagA protein suggests that molecular mimicry by CagA plays a key role in the pathogenesis of a subset of cITP patients.

A SMALL PROTEIN THAT INHIBITS COMPLEMENT ACTIVITY PROVIDES A POTENTIAL NOVEL ANTI-THROMBOTIC AGENT

S Machin[1,*], P Hillmen[2], JP Westwood[1], S Richards[3], I Mackie[1], W Weston-Davies[4], R Prudo[4]
[1]Haemostasis Research Unit, Haematology, University College London, London, [2]Haematology Dept., [3]National PNH Service, Haematology, St James's University Hospital, Leeds, United Kingdom, [4]Volution Immuno Pharmaceuticals (VIP) SA, Geneva, Switzerland

Background: A recombinant protein molecule (16.7kDa) known as coversin, is derived from a salivary molecule from the *Ornithodros moubata* tick where it assists the parasite to feed without provoking a host immunological response. It binds complement C5 and leukotriene B4 (LTB4) independently and with high affinity. It is not an antibody and can therefore be manufactured in prokaryotic cells such as *E. coli* leading to a potential reduction in manufacturing costs compared to monoclonal antibody production. It is considered to be a promising therapeutic approach to thrombotic and haemolytic diseases due to disordered complement activation including atypical haemolytic uraemic syndrome (aHUS), other thrombotic microangiopathies, catastrophic anti-phospholipid syndrome and paroxysmal nocturnal haemoglobinuria (PNH).
Aims: We aimed to perform initial *in vitro* titration experiments of coversin using PNH cells, before commencing a Phase I clinical trial in healthy normal subjects.
Results: Using PNH cells, the maximum inhibition of *in vitro* haemolysis compared to control occurred at a coversin concentration of approximately 10mcg/mL. Further experiments showed the effectiveness of coversin in blocking *in vitro* haemolysis in PNH cases that had both type III (complete GPI-deficiency) and type II (partial GPI deficiency) red cells. Using flow cytometry to demonstrate the deposition and accumulation of significant amounts of C'3d on both type II and type III PNH red cells, these experiments showed therapeutically effective inhibition of *in vitro* haemolysis by coversin. Coversin 10mcg/mL was found to be equivalent to eculizumab 50mcg/mL suggesting a 1:1 binding of the former to C5 and a 1:2 binding of the latter. Coversin has completed a Phase I clinical trial in healthy normal subjects, with informed consent, in which total blockade of complement C5 was achieved following s.c. injection at a dose of 0.57mg/kg. Activity fell below 5% and remained below 50% for 48 hours suggesting that dosing every 2 days is feasible. Additional studies with repeated daily s.c. dosing, at a lower maintenance dose will follow. No drug related clinical or routine laboratory side effects were noted.
Summary and Conclusion: The ability of patients to self-inject, together with potentially lower manufacturing costs and fewer antibody-like adverse reactions makes coversin a promising therapeutic agent for complement-associated thrombotic disorders. Phase II/III multicentre clinical trials are planned, initially with PNH and aHUS patients.

P1231

IMPROVED SURVIVAL WITH ONGOING ECULIZUMAB VERSUS SUPPORTIVE CARE IN PATIENTS WITH ATYPICAL HEMOLYTIC UREMIC SYNDROME

S Johnson[1], G Khursigara[2,*], J Yen[2], J Wang[2], N Silliman[2], C L Bedrosian[2]
[1]Medicus Economics LLC, Boston, MA, [2]Alexion Pharmaceuticals, Cheshire, CT, United States

Background: Atypical hemolytic uremic syndrome (aHUS) is a rare and life-threatening condition associated with chronic uncontrolled complement activation and thrombotic microangiopathy (TMA). Prognosis for patients with aHUS is poor; they face progressive organ damage due to TMA and are at constant risk of sudden death. aHUS patients reaching ESRD tend to be confined to long-term dialysis due to high renal graft rejection. The 5-year overall mortality rate is estimated to be 61% for all patients on chronic dialysis. In addition, data from aHUS and TMA registries report mortality rates for defined aHUS patients of 8% (1 year follow-up), 13% (mean follow-up, 17.8 months) and 32% (median follow-up, 4.4 years), despite the provision of supportive care, including PE/PI. The patients enrolled in these registries were not receiving eculizumab treatment. Pivotal prospective clinical studies demonstrate that sustained eculizumab treatment is associated with clinically meaningful improvements in hematologic and renal outcomes in patients with aHUS; at the same time, it has not been demonstrated if these outcomes translate into survival benefits for these patients.
Aims: To evaluate whether ongoing eculizumab treatment improves survival in patients with aHUS enrolled in pivotal studies of eculizumab.
Methods: A Markov model was developed to track progression through three stages of chronic kidney disease (CKD; estimated glomerular filtration rate ≥60, 15–59 and<15), plus transplant and death. Eculizumab treatment outcomes in the model were estimated using observed data from the eculizumab treatment period in prospective studies. These were compared with the outcomes on supportive care, which were estimated by an unbalanced panel fixed effects regression model with robust standard errors clustered at the patient level, using data from the pre□eculizumab treatment period in the same studies. It was assumed that all patients with aHUS and CKD5/ESRD have a mortality rate consistent with patients in the UK Renal Registry (1-year age-adjusted survival, 89.8%). The model assumes three causes of mortality: age, ESRD/dialysis and TMA-related causes other than renal disease.
Results: Pre-treatment (supportive care) data were available for 37 patients; the mean number of days of observation was 352 (range, 1–702). During supportive care, the estimated glomerular filtration rate (eGFR) declined by 5.5 mL/min/1.73m^2 (p<0.01) every 6 months. In contrast, there was a mean increase in eGFR in patients treated with eculizumab at 6 months (32 and 6 mL/min/1.73m^2 for patients with progressing TMA and long disease duration of disease, p=0.001 and p<0.001 respectively). Using the Markov model, the estimated mortality rate for patients receiving supportive care was 8.6% at 1 year and 25.6% at 3 years. During eculizumab treatment, there was one reported death at a median follow-up of 37 months, corresponding to an annual mortality rate of 1.4%. Eculizumab reduced the risk of mortality by 83% and 89% at 2 and 3 years, respectively, compared to the estimated mortality on supportive care only; relative risks were 17% (95% CI, 2–132%) at 2 years and 11% (95% CI, 1–83%) at 3 years (p=0.107 and p=0.014, respectively).
Summary and Conclusion: In the current analysis, eculizumab substantially improved survival in patients with aHUS compared with predicted outcomes for patients receiving long-term supportive care only. By completely blocking uncontrolled complement activity, ongoing eculizumab treatment reduced the mortality rate by 89% at 3 years.

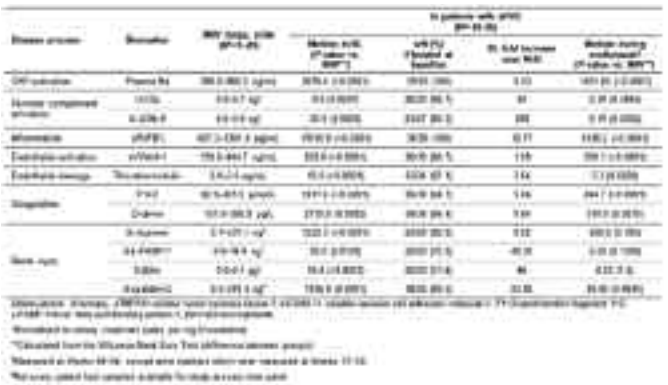
P1232

REDUCTION OF BIOMARKERS RELATED TO THROMBOTIC MICROANGIOPATHY IN PATIENTS WITH AHUS TREATED WITH ECULIZUMAB

S J Faas[1,*], R Cofiell[1], A Kukreja[1], K Bedard[1], Y Yan[1], A Mickle[1], M Ogawa[1], C L Bedrosian[1]
[1]Alexion Pharmaceuticals, Cheshire, CT, United States

Background: aHUS is a genetic, life-threatening disease of chronic, uncontrolled complement activation, leading to systemic thrombotic microangiopathy (TMA) and organ damage. Eculizumab (Ecu) has been shown in prospective clinical trials to block terminal complement (TC), inhibit TMA, normalize platelets and improve renal function in patients (pts) with aHUS.
Aims: To evaluate the effect of eculizumab on biomarkers of complement and endothelial cell (EC) activation, inflammation, thrombosis and renal injury in pts with aHUS.
Methods: Adult pts (≥18 years; N=41) with aHUS were treated with Ecu in a single-arm, open-label, multicentre trial (NCT01194973). Biomarker levels were measured prior to Ecu (baseline; BL) and at regular intervals during one year of Ecu treatment in pts and compared with levels in normal healthy volunteers (NHV).
Results: Biomarker data were available for 9-20 NHV and 26-38 pts with aHUS treated with eculizumab. At BL, all biomarker levels were significantly elevated in the majority of pts with aHUS (Table), including in pts with prior plasma exchange/infusion (PE/PI), or those with normal BL platelet, lactate dehydrogenase or haptoglobin levels. After treatment with Ecu, TC markers (C5a, sC5b-9) and all renal injury markers normalized (Table). Markers of inflammation (sTNFR1), endothelial damage (thrombomodulin) and coagulation (F1+2 and D-dimer) significantly decreased by up to 99%. Ba and sVCAM-1 levels, which reflect complement alternative pathway (CAP) and EC activation, decreased by 30% and up to 60%, respectively, but remained elevated relative to NHV (Table).

Table 1. Biomarker levels in patients with aHUS compared with normal healthy volunteeter (NHV)



Summary and Conclusion: At baseline, complement activation and elevated biomarkers of inflammation, coagulation, endothelial activation, and renal injury

were evident in the majority of pts with aHUS, including those with prior PE/PI or normal clinical laboratory values. Ecu treatment normalized TC markers, potently reduced markers of EC damage to near-normal levels, markedly reduced inflammatory and thrombosis markers and eliminated signs of ongoing renal injury. These benefits were sustained with ongoing Ecu. Ecu reduced but did not normalize plasma Ba and sVCAM-1, reflecting ongoing CAP and EC activation that was not pathogenic in the presence of Ecu. These data underscore the chronic complement dysregulation and ongoing risk of systemic TMA and organ damage in pts with aHUS, and the requirement for continued TC blockade with Ecu, even when clinical laboratory values have improved.

P1233

DIAGNOSTIC CHALLENGES IN THROMBOTIC MICROANGIOPATHIES (TMAS): DATA FROM A TARGETED ANALYSIS OF THE AUSTRALIAN / NEW ZEALAND TMA REGISTRY

D Pepperell[1,*], R Best[2], S Engelbrecht[2,3], R Kadane[2], Z McQuilten[2], P Cannell[4], D Hsu[5], N Isbel[6], J Kausman[7], S Opat[8], L Phillips[9], M Polizzotto[10], D Roxby[11], C Ward[12], E Wood[10], S Cohney[13]
[1]Northern Blood Research Centre, Kolling Institute, Royal North Shore Hospital, Sydney, [2]Transfusion Outcomes Research Collaborative, Monash University, [3]Australian Red Cross Blood Service, Melbourne, [4]Haematology, Royal Perth Hospital, Perth, [5]Haematology, Liverpool Hospital, Sydney, [6]Princess Alexandra Hospital, Brisbane, [7]Royal Children's Hospital, [8]Monash Health, [9]Calembeena Consulting, [10]Monash University, Melbourne, [11]Flinders Medical Centre, Adelaide, [12]Northern Research Blood Centre, Kolling Institute, Royal North Shore Hospital, Sydney, [13]Nephrology, Western Hospital, Melbourne, Australia

Background: Advances in the understanding of the pathogenesis of TMAs have led to recognition of distinct clinical entities: TTP (thrombotic thrombocytopenic purpura), STEC-HUS (Shiga-like toxin producing E.Coli hemolytic uremic syndrome) and atypical HUS. Where once precise classification of TMAs made little difference to the management plan, specific treatment strategies are now available for each disease, and consequently it is critical that a rapid and accurate diagnosis is made. This can be achieved, for example, when pre-plasma exchange ADAMTS13 activity levels are found to be<10%, diagnosing TTP. However, many patients with a TMA remain diagnostically challenging, including those with aHUS (primary complement dysregulation) and secondary TMAs (*e.g.* due to drugs, infections). Potential pitfalls to accurate diagnosis include the overlapping clinical symptomology of the syndromes and the lack of readily available diagnostic tests for aHUS; in particular, genetic analysis of complement mutations may not be rapidly available. Treatment as for aHUS (*e.g.* with eculizumab) in all TMA cases with ADAMTS13 activity >10% until another cause is identified has been suggested, but would incur substantial costs. Further study of the spectrum of TMAs presenting clinically is required to target areas where practice can be improved and develop viable strategies.
Aims: To analyze data from a multicenter TMA registry to identify patients without low ADAMTS13 activity at presentation, and examine their clinical course through investigations, diagnosis, management and outcomes.
Methods: Monash University in Melbourne, Australia hosts a national multicenter TTP Registry that was expanded in 2012 to incorporate all TMAs. In 2013, senior clinicians with hematology or nephrology backgrounds undertook validation of cases in the registry targeted at 13 sites that had entered patients with ADAMTS13 activity levels of >10%, excluding patients positive for STEC.
Results: A total of 68 cases were examined in detail: 37 patients had ADAMTS13 activity of >10% at presentation, 14 had no ADAMTS13 result, and 17 had low levels<10%. Comparing patients with TTP to those without low ADAMTS13 results, 82% *versus* 50% had neurological involvement, and 35% *versus* 70% had renal impairment. Excluding patients with low ADAMTS13, 85% had a possible secondary cause for the TMA identified by the validator, 90% received plasma exchange, 41% dialysis and two thirds immunosuppression. A diagnosis of aHUS was rarely made by treating physicians, with TTP or 'TTP-HUS' the most common categories; the validator disagreed with the original diagnosis in approximately 30% of cases. Subsequently, 25% had died at a mean 3 months and 27% had ongoing renal impairment or treatment needs.
Summary and Conclusion: The TMA Registry data demonstrate a marked heterogeneity, particularly in those cases without low ADAMTS13 activity, underlining the diagnostic challenge in these patients. Applying published criteria using platelet and creatinine thresholds is not helpful in this group. Secondary TMA cases outnumber likely aHUS presentations, although the difference between a precipitating event and a secondary TMA is poorly defined, and early decisions on which patients might benefit from eculizumab are therefore difficult. Despite great advances in understanding of TMAs, accurate diagnosis in 'real world' clinical settings remains challenging, with important consequences for clinical management and healthcare costs.

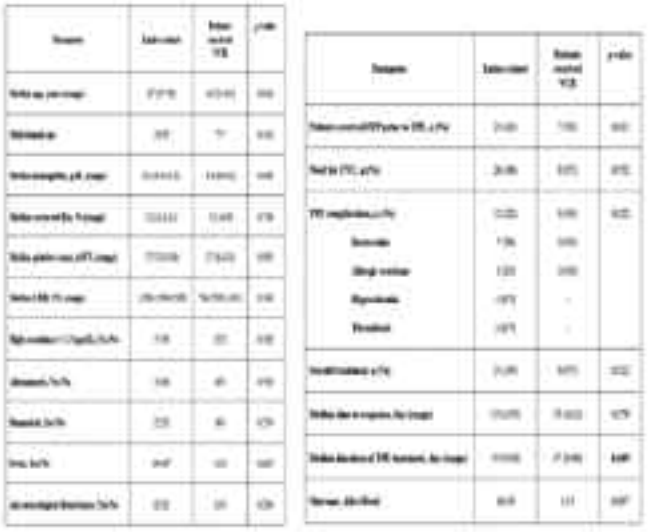
P1234

THE EFFICACY OF VINCRISTINE IN THE TREATMENT OF PATIENTS WITH RELAPSED/REFRACTORY THROMBOTIC THROMBOCYTOPENIC PURPURA

S Ongoren Aydin[1,*], S Sadri[2], T Apaydin[2], A Salihoglu[1], AE Eskazan[1], FF Yalniz[1], T Elverdi[1], MC Ar[1], Z Baslar[1], T Soysal[1], Y Aydin[1]
[1]Department of Internal Medicine, Division of Hematology, [2]Department of Internal Medicine, Istanbul University Cerrahpasa Faculty of Medicine, Istanbul, Turkey

Background: Thrombotic thrombocytopenic purpura (TTP) is a life-threatening disease, unless it is recognized promptly and treated agressively. Therapeutic plasma exchange (TPE) therapy has dramatically improved prognosis of TTP, decreasing the mortality rate from 90% to less than 20%. However, a subset of patients with acquired TTP requires long-term TPE to prevent fatal outcome and to achieve a sustained remission. In these patients complementary treatments, including various immunosuppressive agents including vincristine (VCR) have been proposed. Despite all therapeutic options, however, recurrent acute episodes occur in approximately 40% of patients with acquired ADAMTS13 deficiency.
Aims: The aim of this study was to evaluate the efficacy of VCR when used as an adjunct to TPE in patients with relapsed/refractory TTP. And to compare the characteristics of patients who received TPE plus VCR with the entire cohort.
Methods: Fifty-four patients who were diagnosed as TTP between October 1991 and January 2014 were enrolled in the study. Patients' demographics, treatments, complications, follow-up periods and outcomes were noted from the patients' files retrospectively.
Results: The study cohort consisted of 54 patients (male/female: 19/35), and the median age was 37 years (range, 17-78 years). The patients' demographics were displayed in Table 1. Forty-eight patients had a single episode whereas 8 had relapsed (6 cases had two episodes, and two had 3 episodes) giving a total number of sixty-four acute TTP episodes. Fourteen patients (26%) [male/female: 7/7, median age 34 years (range, 21-65 years)] had received VCR as an adjunct to TPE in 17 acute episodes. In eleven of these patients, VCR was administered due to refractory disease in the first episode, and the remaining 6 had received VCR in the recurrence (in one patient with 2 relapses, VCR was used in both recurrences). The treatment modalities, complications, and outcomes were shown in Table 2. Peripheral (n:1) and autonomic (n:1) neuropathies, and constipation/paralytic ileus (n:2/n:1) were observed in patients receiving VCR. Among 6 patients, TTP was diagnosed during pregnancy, and in two VCR was administered which induced a durable remission but the pregnancies were terminated. There was no history for any medication that might play a role in the pathogenesis of TTP among patients who received VCR. There were five patients in the entire cohort with an autoimmune disease (Behçet's disease n;1, Hashimoto's thyroiditis n;1, ulcerative colitis n:1, scleroderma n:1, systemic lupus eritematosus (SLE) n:1). VCR was administered in the patient with SLE, and a durable remission was gained. Among the fourteen relapsed/refractory patients who received VCR as an adjunct to TPE, 11 had achieved a remission, but three of them died due to TTP.

Table 1.



Summary and Conclusion: Although the prognosis of TTP has improved with TPE, there are still relapsed/refractory patients, which can be difficult to manage. In patients with relapsed/refractory disease, immunosuppressive agents including VCR can be a reasonable choice with minimal toxicities when used as an adjunct to TPE which might induce durable remissions.

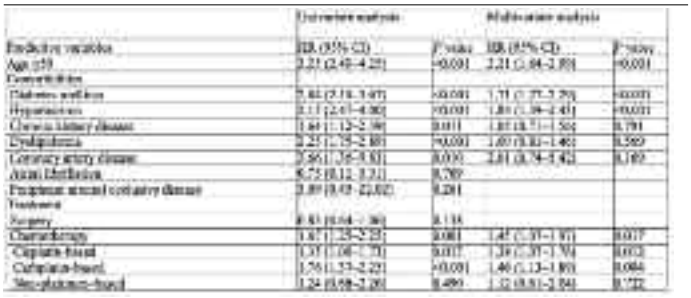
P1235

RISK OF THROMBOEMBOLIC STROKE IN PATIENTS WITH OVARIAN CANCER: A NATIONWIDE POPULATION-BASED STUDY IN TAIWAN

CJ Teng[1], SC Chen[2,*], CJ Liu[2], AS Kuan[3], TJ Chen[4], CH Tzeng[2]
[1]Division of Oncology and Hematology, Department of Medicine, Far Eastern Memorial Hospital, New Taipei City, [2]Division of Hematology and Oncology, Department of Medicine, [3]Department of Neurosurgery, Neurological Institute, [4]Department of Family Medicine, Taipei Veterans General Hospital, Taipei City, Taiwan, Republic of China

Background: Cancer patients are at risk of thromboembolism. Ovarian cancer is the most common cause of cancer death from gynecologic tumors, and more than 225,000 new ovarian cancers are diagnosed each year. The presence of disseminated intravascular coagulation in ovarian cancer patients may indicate a hypercoagulative status. However, studies investigating the relationship between ovarian cancer and thromboembolic stroke (TES) are lacking.
Aims: This study aimed to assess the association between ovarian cancer and TES, and to determine the predictive risk factors.
Methods: Ovarian cancer patients aged ≥20 years, without antecedent TES events, and who were followed up for >1 year between January 1, 2003 and December 31, 2011 were recruited from the Taiwan National Health Insurance database. Hazard ratios (HRs) of TES risk for ovarian cancer patients compared with an age- and comorbidity-matched cohort were calculated by Cox proportional regression analysis. The difference in cumulative TES incidence between the two cohorts was analyzed with the Kaplan-Meier method and tested with the log-rank test.
Results: Each cohort (ovarian cancer and matched cohort) consisted of 8,810 individuals, with a median age of 49 years. Between the two groups there was no difference in TES-related comorbidities as listed in Table 1. In the ovarian cancer cohort, 6,160 patients (69.9%) received surgery, and 6,590 patients (74.8%) received chemotherapy including cisplatin- (n=3,095; 35.1%) or carboplatin-based (n=5,041; 57.2%) regimens. We found that the TES incidence was 1.38-fold higher in the ovarian cancer cohort than in the matched cohort (9.4 *vs.* 6.8/1000 person-years), with an age- and comorbidity-adjusted HR of 1.49 (*P*<0.001). The TES risk imposed by ovarian cancer was more prominent in patients<50 years (HR 2.28; *P*<0.001) compared to patients ≥50 years (HR 1.33; *P*=0.005). Significant risk factors predicting TES development were age ≥50 years (HR 2.21; *P*<0.001), hypertension (HR 1.84; *P*<0.001), diabetes mellitus (HR 1.71; *P*<0.001), and treatment with chemotherapy (HR 1.45; *P*=0.017), especially platinum-based regimens (Table 1).

Table 1. Analyses of risk factors for thromboembolic stroke (TES) in patients with ovarian cancer



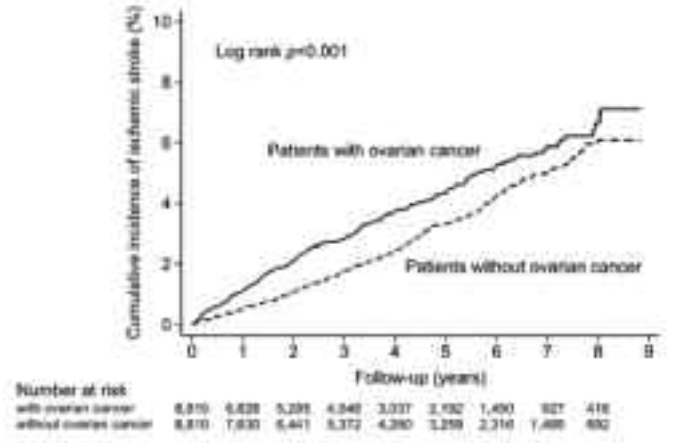


Figure 1.

Summary and Conclusion: Ovarian cancer patients were at an increased risk of developing TES. Age, hypertension, diabetes, and chemotherapy treatment were independent risk factors.

P1236

THE EFFECT OF MORBID OBESITY ON THROMBIN GENERATION AND SENSITIVITY TO THE ANTICOAGULANT ACTIVATED PROTEIN C IN PREGNANT WOMEN

B Kevane[1,*], H O' Connor[2], S Cooley[2], K Egan[3], K Flood[2], F Ní Áinle[1,3]
[1]Haematology, [2]Obstetrics, Rotunda Hospital, [3]Medicine and Medical Science, University College Dublin, Dublin, Ireland

Background: Obese pregnant women have greatly increased risk of venous thromboembolism (VTE). However, the precise mechanisms underlying this increased risk are poorly understood. To address this, plasma samples were obtained with consent from pregnant women of varying body mass index (BMI) and analysed using an assay that characterises pro-and anticoagulant pathways.
Aims: To characterise the effect of obesity on thrombin generation and sensitivity to activated protein C in pregnant women.
Methods: Blood samples were collected in citrated tubes containing corn trypsin inhibitor (to inhibit contact-mediated coagulation activation) and platelet poor plasma was prepared. Tissue factor (TF)-stimulated thrombin generation was determined by measuring cleavage of a thrombin-specific fluorogenic substrate using Thrombinoscope™ software. Thrombin generation was also assessed in the absence of an exogenous TF stimulus.
Results: 13 women of similar third trimester gestation (BMI 20-29 kg/m^2, n=6; 30-39 kg/m^2, n=4; >40 kg/m^2, n=3) and 2 non-pregnant volunteers were recruited. Mean endogenous thrombin potential (area under the thrombin generation curve; 0.5 pM TF stimulus) was significantly higher in BMI>40kg/m^2 (2056 +/- 88 nm*min) compared with 20-29 kg/m^2 (1350+/-97 nm*min; p=0.003), 30-39 kg/m^2 (1259+/-253.4nm*min; p=0.049) and non-pregnant volunteers (1084+/-264.8 nm*min; p=0.0235). Peak thrombin generation was also greater in the BMI >40kg/m^2 group (158.6+/-11.61nm) than that observed in the BMI 30-39kg/m^2 group (100+/-29.39nm) and in the BMI 20-29kg/m^2 group (95.68+/-22.11nm) and was significantly greater than that measured in the non-pregnant controls (46.17+/-10.33nm, p=0.0069). In addition, a tendency toward shorter lag time to initiation of thrombin generation and to peak thrombin generation were observed in the BMI>40kg/m^2 group compared to the other test groups. To address the hypothesis that circulating plasma TF activity contributed to these observed differences, thrombin generation was initiated in the absence of a TF stimulus. No significant thrombin generation was seen in any group. Characterisation of the anticoagulant protein C pathway was performed by incubation with activated protein C (APC; 5nM; 1pM TF trigger). Remarkably, while APC resistance was observed in all pregnant plasma samples, those of BMI >40 kg/m^2 were most resistant to APC- induced attenuation of thrombin generation compared with patients of BMI 30-40 and 20-30 kg/m^2. In these three groups, pre-incubation with APC attenuated ETP by 20%, 57% and 70% respectively.
Summary and Conclusion: VTE is a potentially life-threatening complication of pregnancy. Morbidly obese pregnant women have pro-and anticoagulant pathways variations that may represent potential mechanisms underlying the observed high VTE risk in these patients.

P1237

HYPOXIA CONTRIBUTES TO PROCOAGULANT ACTIVITY OF BREAST CANCER CELLS

X Cui[1,*], G Skretting[1], A Dahm[1], B Stavik[1], N Iversen[1], PM Sandset[1]
[1]Oslo university hospital, Oslo, Norway

Background: Venous thrombosis is one of the main causes of morbidity and mortality in cancer patients. This common complication ofcancer is triggered by tissue factor (TF), which also plays an important role in angiogenesis and metastasis. TF pathway inhibitor(TFPI) is the endogenous inhibitor of TF induced coagulation, and has been shown to exhibit anti-angiogenic and anti-metastaticeffects.Hypoxia microenvironment, resulting from aberrant hemoperfusion and high oxygen consumption, is a commonfeature of solid tumors. As an important microenvironment factor, hypoxia facilitates tumor metastasis and propagation. Hypoxiainducible factor 1a (HIF1a) is the main mediator of hypoxia and regulates many gene transcriptions to promote tumor cell survival,which is closely related to tumor propagation and poor prognosis.The correlation between thrombosis and hypoxia is not clearly understood. We focused on the effect of hypoxicmicroenvironment on the procoagulant activity of breast cancer cells and putative mechanisms.
Aims: Our aim was to detect the procoagulant status of breast cancer cells grown in an hypoxix environment and the mechanisms of hypoxic gene regulation.
Methods: Breast cancer cell lines, SKBR3 and MCF7, were either treated with cobalt chloride to mimic hypoxia or cultured in 1% oxygen tension. Cells grown in normoxic conditions (21% oxygen tension) were used as control. Expression of TF and TFPI was detected by RT-PCR, western blot and ELISA. HIF1a and HIF2a expression were measured by western blot. TFPI promoter activity was measured by luciferase reporter assay. The luciferase plasmids were constructed by cloning TFPI promoter region into the pGL3 basic vector.
Results: TF mRNA and protein level was up-regulated in a time- and dose-

dependent way in hypoxia or after CoCl2 treatment. TFPI mRNA and protein level was down-regulated in a time- and dose-dependent way in hypoxia or after CoCl2 treatment. The effects of hypoxia on TF and TFPI expression were impaired when HIF inhibitor was used. The luciferase reporter assay showed reduced luciferase activity of TFPI promoter following hypoxic stimulation. The reduction of luciferase activity of TFPI promoter was also observed when HIF1a was overexpressed.
Summary and Conclusion: The hypoxic microenvironment may contribute to the procoagulant in breast cancer, and HIF1a may be new candidates for the treatment of thromboembolic complications in cancer.

P1238

IMPACT OF RECOMBINANT THROMBOMODULIN ON THE OUTCOME OF NEONATES WITH DISSEMINATED INTRAVASCULAR COAGULATION DIFFERS ACCORDING TO APGAR SCORE

Y Taguchi[1,*], H Yagasaki[1,1], S Hosono[1], S Takahashi[1]
[1]Pediatrics, Nihon University, Tokyo, Japan

Background: Recombinant thrombomodulin (rTM) was developed as a new type of treatment for disseminated intravascular coagulation (DIC), which inhibits coagulation factors Va and VIIIa by activating protein C. Since July 2009, we have used rTM in newborns with DIC as front-line therapy. To date, however, few data are available in neonatal medicine. Because the etiology of DIC in newborns is quite different from that in other children and adults, more evidence is needed before rTM can be approved as a standard treatment in this age group.
Aims: To elucidate predictive factors for outcome in newborns with DIC treated with rTM as front-line therapy.
Methods: This retrospective study included 23 newborns (13 boys, 10 girls; median age, 1 day; range, 0–13 days). Median gestational age was 37 weeks (range, 23 weeks 6 days–41 weeks 1 day). Median birth weight was 2296 g (range, 708–3853 g). Diagnosis of DIC was made according to the diagnostic criteria of the Japanese Ministry of Health, Labour, and Welfare. rTM (380 U/kg) was administered daily (median, 5 days; range, 2–16 days) as front-line therapy. Antithrombin (AT) was used concomitantly in 15 patients. Flesh frozen plasma and platelet transfusions were also given to 19 patients. The underlying diseases were hematological disorders (n=5), infection (n=3), asphyxia (n=7), and other (n=8). Treatment failure was defined as death or serious bleeding within 28 days of rTM treatment.
Results: Although 20 patients (87%) were alive 28 days after rTM treatment, pulmonary or intracranial bleeding was observed in 7 (30%). Consequently, failure-free survival was 65%. Median Apgar scores at1 and 3 min in the failure-free group were significantly higher than in the treatment failure group (8 and 9 *versus* 5 and 6.5; p=0.040 and p=0.027, respectively). Other factors including gestational age, birth weight, DIC score, platelet count, prothrombin time, fibrinogen, fibrin and fibrinogen degradation products, D-dimer, and AT activity were not associated with treatment response.
Summary and Conclusion: The incidence of bleeding events was extremely high in neonates. rTM-based treatment is extremely promising for the subgroup with high Apgar scores. In contrast, additional treatment to prevent life-threatening bleeding must be explored in those with a low Apgar score. This concern remains to be solved in this rTM era.

P1239

RESISTANCE TO ACTIVATION OF ENDOGENOUS PROTEIN C ASSOCIATED WITH ANTI-PROTEIN C ANTIBODIES MAY BE A MARKER OF A MORE SEVERE THROMBOTIC PHENOTYPE IN ANTIPHOSPHOLIPID SYNDROME

D Jayakody Arachchillage[1,*], M Efthymiou[1], I Mackie[1], A Lawrie[1], S Machin[1], H Cohen[1,2]
[1]Department of Haematology, Haemostasis Research Unit,University College London, [2]Department of Haematology, University College Hospitals NHS Foundation Trust, London, United Kingdom

Background: Antiphospholipid antibodies (aPL) may interfere with the anticoagulant activity of activated protein C (APC) to induce APC resistance (APCr) and this phenomenon has been proposed as a mechanism of thrombosis in antiphospholipid syndrome (APS).
Aims: We investigated the frequency and characteristics of APCr using exogenous APC and activation of endogenous protein C (PC) with Protac, in a thrombin generation (TG) system in thrombotic APS patients with venous thromboembolism (VTE).
Methods: Resistance to exogenous human APC (rhAPC) and Protac® activated, endogenous PC was studied in 51 APS and 51 non-APS VTE patients on warfarin and 51 normal controls (NC), using the Calibrated Automated Thrombogram® (CAT) system with 5pM tissue factor. Patients with heritable thrombophilia or patients/NC receiving oestrogen were excluded. INR values were comparable (median [range]): 2.4 (1.8-4.2) in APS and 2.3 (1.8-4.3) in non-APS patients. For TG, plasma was mixed 1:1 with PNP to correct factor deficiency. APC resistance (APCr) was calculated as % inhibition of TG by dividing the ETP with rhAPC or Protac® by that for buffer, normalising with PNP (lower % values indicate greater APCr). PC antibodies were measured by ELISA and their avidity was assessed by increasing the salt concentration (NaCl 0.1-6M) in sample dilution buffer.
Results: APS patients showed greater resistance to rhAPC (median [range]: (90% [18-109] [p=0.0006]) than non-APS patients (99% [47-131]) and NC (94% [56-132]), mainly due to a subgroup of 6 patients with little inhibition of thrombin generation with APC. Both APS (median [range] (72% [4-98]) and non-APS (81% [12-136]) patients showed greater APCr with Protac® (p<0.0001) compared to NC (100% [63-141]), but resistance was greater in APS than in non-APS patients (p=0.0034). PC antibodies were more frequent in APS (25/51) than non-APS patients (5/51, p<0.0001). Investigation of the avidity of antibodies demonstrated two clear groups of patients. Ten APS patients had low avidity PC antibodies and 15 had higher avidity antibodies. The percentage of maximum binding to PC in these two groups reached statistical significance at 1M NaCl (mean residual binding 39.7% for the higher avidity samples, compared to 16.5% for the low avidity (p<0.0001). Patients with higher avidity PC antibodies had greater APCr with Protac® than those with low avidity PC antibodies (median [range] 43.3% (3.7 -58.1) and 74.1% (60.9-90.93), Fisher's exact test p<0.0001). Six APS patients with marked APCr using both rhAPC (17.6-35.2%) and Protac® (3.7-33.9%) also had higher avidity PC antibodies and exhibited more severe thrombotic disease *i.e.* arterial as well as VTE or recurrent thrombosis whilst on therapeutic anticoagulation.
Summary and Conclusion: In conclusion, thrombotic APS patients have greater APCr using both exogenous APC and activation of endogenous PC. Those patients with greatest resistance to activation of endogenous PC had higher avidity PC antibodies and a more severe clinical course. The presence of higher avidity PC antibodies might therefore provide a marker for a more severe thrombotic phenotype.

P1240

HIGH INCINDENE OF CEREBRAL LEISIONS IN ADULT PATIENTS WITH BETA-THALASSEMIA MAJOR

I Pazgal[1,*], E Inbar[2], M Cohen[3], O Shpilberg[4], P Raanani[4], E Rachmilewitz[1], P Stark[1]
[1]Comprehensive Center of Thalassemia, Hemoglobinopathies and Rare Anemias, Beilinson Hospital, Rabin Medical Center, [2]Section of Neuroradiology, Department of Radiology, Beilinson Hospital, Rabin medical Center, [3]Department of Radiology, Beilinson Hospital, Rabin medical Center, [4]Institute of Hematology, Beilinson Hospital, Rabin medical Center, Petah Tikva, Israel

Background: Survival of beta thalassemia major patients has improved significantly over the past few decades as better treatment became available. Subsequently, previously undescribed complications have been recognized, including thromboembolic complications such as cerebral thrombotic events. Incidence as high as 27-60% of asymptomatic silent cerebral infarctions (SCI) have been already demonstrated by MRI studies in patients with beta thalassemia intermedia (TI) (*KM Musallam, et al. Thromb. Res. 130:695-702, 2012*). However, less data is available for the incidence of SCI in transfusion dependent (TD) beta thalassemia major (TM).
Aims: Determination of SCI incidence in TD patients with beta TM.
Methods: The study included 21 patients with TD beta TM, 12 males and 9 females, 21-42 years old. All patients except 2 were splenectomized (SPX). Patients with diabetes mellitus, history of any thromboembolic event or on aspirin or anticoagulation were not included in the study. After obtaining a signed informed consent, brain MRI studies were performed prior to receiving blood transfusion, using 3T Ingenia (Philips) system in SET1 TSET2 diffusion SWI (5mm slice) and 3DFLAIR (1.1 mm slice).
Results: Average pre-transfusion hemoglobin level was 10.0 gm/dL (range 8.7-11.0). Average platelet count in SPX patients was 578 K/micl (range 270-1100 K), and in 2 non SPX 242 K/micl (164-320K). Average ferritin level was 1800 ng/ml (range 251-7431). Thrombophilia complete workup, including lupus anticoagulant and anti cardiolipin antibodies, was normal in all, except 4 cases heterozygous for Factor V Leiden mutation. Fourteen (67%) out of 21 patients had focal bright lesions in the cerebral white matter. Twelve SPX patients had 1-73 (mean 14) lesions, while 2 non SPX patients had 1 and 53 lesions. Seven SPX patients had no lesions. Most of the lesions were in frontal lobes and bilateral, maximal diameter up to 7 mm. All lesions were negative in diffusion with no susceptibility artifacts. No significant correlation was found between MRI findings and all evaluated clinical and laboratory parameters. However, ferritin levels, *i.e.* median level of 1117 ng/ml and mean level of 1925 ng/ml (range 251-7431) among patients with SCI lesions compared to 875 ng/ml and 1551 ng/ml (range 295-4294), respectively, among patients without lesions, were observed. Moreover, 6 (60.0%) out of 10 patients with ferritin levels<1000 ng/ml had a mean number of 5.2 lesions, while 8 (72.7%) out of 11 patients with ferritin level >1000 ng/ml had a mean number of 23.9 (4.6 fold) lesions.
Summary and Conclusion: The results demonstrate an incidence as high as 67% of asymptomatic SCI in TD TM patients. Accounting for the technical differences, the lesions were similar in size and anatomical location to those already observed in TI. These findings may suggest that the increased number

of pathological circulating RBC's in TI may not be the only pathophysiologic factor in the etiology of SCI. In addition to increased number of activated platelets in SPX patients, other factors, such as severity of iron overload demonstrated by higher ferritin levels, may also play a role in the etiology of hypercoagulability in thalassemia. In conclusion, in addition to effective iron chelation therapy, anti platelet drugs, such as low dose aspirin, should be given routinely also to TD beta TM patients.

P1241

PLATELET THROMBUS FORMATION UNDER FLOW CONDITION IS INCREASED IN MYELOPROLIFERATIVE NEOPLASMS (MPNS)

A Vignoli[1,*], S Tessarolo[1], C Giaccherini[1], M Marchetti[1], P van der Mejden[2], F Swieringa[2], H ten Cate[3], G Finazzi[4], A Rambaldi[4], J Heemskerk[2], A Falanga[1]
[1]Division of Immunohematology and Transfusion Medicine, Hospital Papa Giovanni XXIII, Bergamo, Italy, [2]Department of Biochemistry, [3]Department of Internal Medicine, CARIM, Maastricht University, Maastricht, Netherlands, [4]Division of Hematology, Hospital Papa Giovanni XXIII, Bergamo, Italy

Background: Essential Thrombocythemia (ET) and Polycythemia Vera (PV) are MPNs at high risk for arterial and venous thrombotic events. Previous studies report on platelet (PLT) abnormalities in these patients, but little data are available on PLT thrombus formation capability in these MPNs.
Aims: In this study we wanted to evaluate whether and to what extent PLT interactions with vessel wall components, assayed in a dynamic system, are altered in ET and PV patients. The influence of V617F JAK2 mutation, cytoreductive therapy, hematological parameters and von Willebrand Factor (vWF) levels on PLT adhesion was also considered.
Methods: Eighteen ET (6M/12F; age range 37-81 years) and 12 PV (6M/6F; 58-87 years) patients were enrolled into the study upon informed consent. Thirteen healthy subjects (CTR; 6M/7F; 35-55 years) acted as control group (CTR). Peripheral venous whole blood was withdrawn in sodium citrate, recalcified with heparin and perfused over a collagen matrix for 4 minutes at 1,000 s^{-1} shear rate using a parallel flow chamber connected to EVOS (AMG) fluorescence microscope. Adherent PLTs were then stained with anti-P-selectin-FITC antibody as PLT activation index, and with annexinV-AlexaFluor647 as a measure of procoagulant phosphatidylserine exposure. Then, phase contrast and fluorescence images were taken in random fields by EVOS. Results are reported as mean±SD of the % of area covered by PLTs, or as % of adherent PLTs positive for either P-selectin or annexinV. Plasma vWF antigen and activity levels were measured by ELISA. Statistical analysis has been performed by SPSS software package.
Results: In ET and PV patients, PLT adhesion was significantly greater compared to CTR ($p<0.001$) (ET: 49.1±12.0%, PV: 51.6±12.5% and CTR: 33.7±8.4%). The adhesion capacity was related to V617F JAK2 mutational status, with greater values found in the homozygous subjects (60.7±4.5%) compared to the mutation-negative ones (43.8±9.0%; $p<0.01$). Patients on hydroxyurea (HU) therapy (n=17) tended to have a lower PLT adhesion (47.6±12.6%) as compared to non-HU-treated patients (n=11; 55.0±9.6%, p=n.s.). The percentage of PLT adhesion was significantly correlated with both PLT ($r=0.508$, $p<0.001$) and leukocyte ($r=0.404$, $p<0.01$) counts, but not with vWF plasma levels. PLT count and V617F JAK2 mutation resulted to be significant determinants of PLT adhesion in the multivariate analysis of the data, adjusted for age, sex and HU therapy. Despite the greater adhesion, the exposure of phosphatidylserine (potentially procoagulant) on adherent PLT was reduced in ET (10.1±6.1% positive platelets) and PV patients (11.3±7.1%) compared to CTR (19.4±7.5%, $p<0.01$ *vs* either ET and PV).
Summary and Conclusion: This study shows that blood from MPN patients produces more platelet thrombi on collagen surface at high shear rate flow conditions compared to controls, and that this is significantly influenced by the V617F JAK2 mutation burden and platelet count. Of interest, adherent PLTs of patients form thrombi that express less phosphatidylserine than controls, suggesting that they may be less capable to generate procoagulant activity. Further studies are warranted to investigate the correlation between PLT thrombus formation potential and thrombotic risk in MPN patients.

P1242

CDC42 REGULATES PROPLATELET FORMATION NOT BY WASP BUT VIA N-WASP

A Palazzo[1,2,3,*], O Bluteau[1,2,3], K Messaoudi[1,2,3], A Ali[1,2,3], N Baylin[1,2,3], P Rameau[4], Y Lecluse[5], E Solary[1,2,3], Y Chang[1,2,3], H Raslova[1,2,3], W Vainchenker[1,2,3], N Debili[1,2,3]
[1]U1009, INSERM, [2]Gustave Roussy, [3]Université Paris-Sud, [4]Photon Imaging and Flow Cytometry Facility, [5]Photon Imaging and Flow Cytometry Facility, Gustave roussy, Villejuif, France

Background: To produce platelets, the highly specialized bone marrow megakaryocyte (MK) precursor cells, elaborate long branched cytoplasmic extensions, called proplatelets (PPTs). Platelet release essentially relies on cytoskeleton changes, including actin dynamics. We have previously shown that the Rho/Rock pathway is a negative regulator of the proplatelet formation (PPF) through MLC phosphorylation during human megakaryopoiesis.
Aims: Cdc42 and Rho/Rock have been shown to have opposite effects in many cellular processes. Thus, we focused our study on the role of Cdc42 in human MK differentiation.
Methods: $CD34^+$ cells were cultured in serum-free liquid medium in the presence of TPO ± Casin, a specific Cdc42 inhibitor provided by Yi Zheng, Cincinnati, OH, USAi). Cdc42 activity is studied by G-Lisa technique and MKs migration study is performed in the presence of SDF-1. Invalidation of N-WASP and PAK2 were obtained by shRNA strategy. The overexpression of N-WASP was obtained by a lentiviral vector encoding N-WASP cDNA with a SNP not recognized by the shRNA.
Results: We show that Cdc42 activity increases in late stages of the MK differentiation. The Cdc42 dominant-negative construct and the specific chemical Cdc42 inhibitor Casin, both led to a decrease in PPF, indicating that Cdc42 activation could stimulate PPF. To determine the molecular pathway involved in Cdc42-induced PPF, we knocked down its main effector PAK2 by a shRNA strategy and showed that it was not involved in the PPF. The same results were obtained with two chemical inhibitors (IPA-3 and Pak18) targeting both PAK1 and 2. We next investigated the role of the WASP family. We previously showed that WASP did not play a role in PPF, and thus we focused on its family related member N-WASP. Phosphorylation of N-WASP increased during MK differentiation. Its knocked down by shRNA led to a sharp decline in the formation of the PPs despite the fact that MKs express much lower level of N-WASP than WASP. This was associated with an increase in the formation of stress fibers, as revealed by confocal microscopy. Altogether, these results suggest that Cdc42 plays a positive role in the formation of the PPs by inhibiting Rho *via* the N-WASP pathway. These results were reinforced by rescuing the formation of PPs in N-WASP knocked down MKs by re-expressing N-WASP. Interestingly, Cdc42 inhibition by Casin leads to a decrease in N-WASP phosphorylation (pN-WASP^{Y256}) and both invalidation of N-WASP and Casin treatment leads to pMLC2^{Ser19} increment. Furthermore, inhibitors of Src family kinases (PP2, Dasatinib and SU6656) have opposite effects on PPF and pN -WASP^{Y256}. While SU6656 increases PPF, PP2 or Dasatinib inhibit its by inducing an increase or an inhibition of pN -WASP ^{Y256} respectively, suggesting that yet unidentified members of Src family kinase play a crucial and opposite role in this regulation.
Summary and Conclusion: In conclusion, our results show for the first time in human that the Cdc42/N-WASP pathway positively regulates the PPF and suggest a possible retro-regulation of the Rho/Rock pathway *via* N-WASP. It also shows that WASP and N-WASP are not two fully redundant molecules in the MKs by mechanisms that remain to be determined, but which may be related to their differential regulation of the phosphorylation by members of the Src kinase family.

P1243

INCREASED FIBRINOGEN LEVELS AND TESTOSTERONE DEFICIENCY HAVE AN ADDITIVE DETRIMENTAL EFFECT ON CAROTID WALL THICKNESS IN ESSENTIAL HYPERTENSIVE PATIENTS

Z Pallantza[1,*], N Ioakeimidis[2], C Vlachopoulos[3], E Andronopoulou[1], M Tsekoura[1], D Gazi[1], P Karampella[1], G Vyssoulis[2], C Stefanadis[2], Z Pallantza[1]
[1]Haematology, [2]1st Cardiology Unit, [3]1stCardiology Unit, Hipoocratio General Hospital, Athens, Greece

Background: Increased fibrinogen levels and testosterone deficiency have an additive detrimental effect on carotid wall thickness in essential hypertensive patients.
Aims: We investigated the combined effect of fibrinogen and testosterone on carotid atherosclerosis in hypertensive subjects.
Methods: Fibrinogen and total testosterone levels were measured in 127 untreated hypertensive men. All participants underwent B-mode *ultrasonographic* measurements of the carotid intima media thickness (I*MT)* which is a marker of early atherosclerosis.
Results: Patients with high compared with those with low fibrinogen exhibited greater IMT (by 0.13 mm, $P<0.001$), whereas patients with low compared with those with high testosterone had higher IMT (by 0.08 mm, $P<0.01$). Regression analysis revealed that age, systolic BP, fibrinogen and testosterone were independent predictors of IMT. The distributions of fibrinogen and testosterone were split by the median (290 mg/dL and 4.06 ng/mL, respectively) and accordingly subjects were stratified into those with high and low values. A significant interaction between fibrinogen and testosterone on IMT is reflected by the finding that the subgroup of high fibrinogen/low testosterone exhibited the higher IMT compared with the subgroups of high fibrinogen/high testosterone, low fibrinogen /low testosterone, and low fibrinogen/high testosterone ($P<0.001$).
Summary and Conclusion: In hypertensive males, elevated fibrinogen and low androgen level exert an additive detrimental effect on peripheral vascular structure, accelerating the atherosclerotic process.

P1244

FUNCTIONAL EVALUATION OF TISSUE FACTOR IN FLOW-DEPENDENT THROMBUS FORMATION ON IMMOBILIZED VON WILLEBRAND FACTOR

Y Matsunari[1], H Matsui[2], M Kawaguchi[1], M Sugimoto[2,*]
[1]Anesthesiology, [2]Regulatory Medicine for Thrombosis, Nara Medical University, Kashihara, Japan

Background: Mural thrombus formation at injured vessel wall is fundamentals for both physiologic haemostasis and pathological thrombosis. Although tissue factor (TF) is up-regulated upon vessel wall damage and plays a pivotal role in this process, little is known about its functional relevance under physiologic blood flow conditions.
Aims: Using an *in vitro* perfusion chamber system, we studied the relevant role of TF on von Willebrand factor (VWF)-dependent thrombus formation, illustrating the functional link between soluble or immobilized TF and VWF under whole blood flow conditions with varying shear rates.
Methods: Recombinant human TF (Innovin; Dade) were co-coated with VWF onto a glass plate to prepare 'surface-immobilized TF/VWF complex'. Surface density of immobilized TF, evaluated by the ELISA-based assay using an anti-TF monoclonal antibody, increased in a concentration-dependent and saturated manner by soluble TF (1-100 pM) added on a plate.Citrated whole blood, recalcified with 8 mM $CaCl_2$ prior to perfusion, was perfused over a VWF-surface in the presence or absence of surface-immobilized TF. Platelet adhesion and aggregation were evaluated by the surface coverage of thrombi in a defined area after 5-min perfusion. The mural thrombi formed on VWF-surface was double-stained with fluorescently labeled anti-fibrin and anti-fibrinogen antibodies. Fibrin generation was evaluated by confocal laser scanning microscopy as a ratio of fibrin relative to fibrinogen fluorescence within mural thrombi.
Results: Surface-immobilized TF significantly augmented flow-dependent fibrin generation as a function of increasing surface density of TF under both low (250 s^{-1}) and high (1500 s^{-1}) shear rate conditions. In this regard, soluble TF, when added to sample blood, similarly increased intra-thrombus fibrin generation in a dose-dependent manner in the absence of immobilized TF. However, coagula formation in sample blood was enormously amplified by soluble TF during perfusion, as judged by the flow-path occlusion time. In addition, immobilized TF significantly up-regulated VWF-dependent platelet adhesion and aggregation under high shear rate conditions, albeit with no appreciable effects under low shear rate conditions.
Summary and Conclusion: With the present experimental approach, we evaluated thrombogenic potentials of two distinct forms of (soluble or surface-immobilized) TF in flow-dependent thrombus formation on the VWF surface. Our results suggest that surface-immobilized TF plays a role in concert with VWF on mural thrombus formation under high shear rate conditions, with a lower risk of systemic hypercoagulability such as disseminated intravascular coagulation which may be caused by circulating soluble TF.

P1245

CLINICAL SIGNIFICANCE OF THE NEUTROPHIL-LYMPHOCYTE RATIO IN VENOUS THROMBOEMBOLISM PATIENTS WITH LUNG CANCER

GW Lee[1,*], SI Go[1]
[1]Internal Medicine, Gyeongsang National University School of Medicine, Jinju, Korea, Republic Of

Background: The neutrophil-lymphocyte ratio (NLR) has been identified as a potentially useful marker for predicting clinical outcome in patients with cardiovascular disease, diabetes, and various malignancies. The aim of this study was to determine whether NLR at the time of venous thromboembolism (VTE) diagnosis is a prognostic factor for the response to anticoagulation and survival in lung cancer patients treated with anticoagulation for VTE
Aims: The aim of this study was to determine whether NLR at the time of venous thromboembolism (VTE) diagnosis is a prognostic factor for the response to anticoagulation and survival in lung cancer patients treated with anticoagulation for VTE.
Methods: We retrospectively analyzed the clinical characteristics, laboratory parameters, and NLR in 114 lung cancer patients newly diagnosed with VTE, among 991 patients pathologically confirmed for lung cancer between July 2008 and August 2013.
Results: High NLR was significantly associated with high hematocrit (p=0.028), high C-reactive protein (p=0.002), and low albumin (p=0.001). Compared with the low NLR group, stage IV non-small cell lung cancer (NSCLC) at the time of VTE diagnosis (55.6 *vs*. 74.6%, p=0.055), central nervous system metastasis (5.8 *vs*. 25.8%, p=0.004), and cancer progression (14.3 *vs*. 38.8%, p=0.008) at the time of VTE diagnosis were also significant in the high NLR group. Moreover, the poor response to anticoagulation was statistically correlated with patients with NSCLC (p=0.037), high NLR (p=0.004), and low albumin (p=0.029).
Summary and Conclusion: The results demonstrate that the NLR at the time of VTE diagnosis could be a useful biomarker for predicting the response and prognosis following anticoagulation in patients with lung cancer and VTE.

P1246

PATTERNS OF DIFFERING THROMBIN GENERATION AND SENSITIVITY TO THE ANTICOAGULANT ACTIVATED PROTEIN C IN PATIENTS WITH MYELOMA AND MONOCLONAL GAMMOPATHY OF UNDETERMINED SIGNIFICANCE

MP Crowley[1,2,*], B Kevane[3], S I O'Shea[1], J A Eustace[2], S Quinn[1], K Egan[4], O M Gilligan[1], F Ni Ainle[3,4]
[1]Haematology, Cork University Hospital, [2]HRB Clinical Research Facility, University College Cork, Cork, [3]Haematology, Rotunda Hospital and Mater Misericordiae University Hospital, [4]School of Medicine and Medical Science, University College Dublin, Dublin, Ireland

Background: Patients with multiple myeloma are at an increased risk of venous thromboembolism, however the precise mechanisms underlying this prothrombotic phenotype are poorly understood. Monoclonal gammopathy of undetermined significance (MGUS), a related condition, represents a pre-malignant state in which abnormal production of a monoclonal immunoglobulin arises from a plasma cell clone in the absence of end-organ pathology. To date, the identification of molecular mechanisms potentially associated with a prothrombotic state in MGUS have not been characterised in detail.
Aims: To characterise plasma thrombin generation in plasma from patients with newly diagnosed or newly relapsed myeloma, MGUS and healthy volunteers.
Methods: Blood samples were collected in citrated blood tubes from patients with myeloma (prior to commencement of chemotherapy), MGUS and age and sex-matched healthy volunteers. Platelet poor plasma was prepared from whole blood by centrifugation. Calibrated automated thrombography was used to determine parameters of thrombin generation following incubation of plasma in the presence of phospholipid and soluble tissue factor (TF). Analysis of thrombin generation parameters was performed using Thrombinoscope™ software. Statistical analysis was performed using the statistical software package, Prism™.
Results: Eight patients with newly diagnosed or newly relapsed myeloma were identified and recruited with consent. Age and gender-matched patients with MGUS and healthy volunteers were also identified and recruited (n=8 per group). Thrombin generation was assessed following initiation of coagulation by soluble TF (0.5pm). Peak thrombin generation was significantly lower in plasma from healthy volunteers (276.7+/-20.8nm) compared with myeloma patients (383.4+/-33.4nm, P<0.005) and compared with MGUS patients (353.4+/-16.59nm, P<0.05). A non-significant trend towards higher endogenous thrombin potential (ETP), shorter time to initiation of thrombin generation and shorter time to peak thrombin generation was observed in both myeloma and MGUS patients compared with healthy controls. A non-significant trend towards higher ETP and peak thrombin generation was also observed in myeloma patients compared with MGUS patients. Characterisation of the anticoagulant protein C pathway was performed by incubation of plasma with human activated protein C (APC; 10nM; 1pM TF trigger). While ETP was attenuated in all groups, the ETP observed in the healthy volunteer group (ETP 228.6+/-44.32nm*min) was significantly lower than that in either the myeloma group (ETP 866.2+/-241.3nm*min, p=0.009) or the MGUS group (627+/-91.49nm*min, p=0.0025). In these three groups, APC attenuated ETP by 88% (healthy volunteers), 68% (MGUS patients) and 59.27% (myeloma patients) respectively.
Summary and Conclusion: Plasma thrombin generation is significantly enhanced in both myeloma and in MGUS in comparison to healthy controls. Activated protein C resistance may contribute to the prothrombotic phenotype in both conditions. The precise mechanisms underlying activated protein C resistance in these related conditions has yet to be determined.

P1247

EVALUATION OF THE THROMBOSIS TENDENCY IN THALASSEMIA MAJOR PATIENTS WITH THROMBIN GENERATION TEST, PROCOAGULANT PHOSPHOLIPID ACTIVITY AND ENDOTHELIAL MICROPARTICLES LEVELS

I Eker[1,*], O Gursel[1], N Yarali[2], B Tunc[2], A Pekel[3], Z Ertas[4], C Acıkel[5], A E Kurekci[1]
[1]Pediatric Hematology, Gulhane Military Medical Faculty, [2]Pediatric Hematology Oncology, SB Ankara Children's Hematology Oncology Training and Research Hospital, [3]Immunology and Allergy, [4]Hematology, [5]Biostatistics, Gulhane Military Medical Faculty, Ankara, Turkey

Background: There are increasing evidences that there is a thrombosis tendency in thalassemia like diseases going on with chronic hemolysis. Although a lot of etiological factors have a role in this tendency, it is thought that the vascular endothelial activation under the effect of chronic oxidative stress existing in these patients has the most effect on this tendency.
Aims: Our aim was to evaluate in thalassemia major (TM) patients the procoagulant activity of endothelial microparticles (EMP), which are generated by the vascular endothelial activation.
Methods: Subjects of 31 TM patients who were regularly transfused and chelated, had known not to having in his/her and/or family history

hemorrhagic/thrombotic diseases or other conditions known to alter the hemostatic balance, had not used ever any oral anticoagulants or other antithrombotic drugs or oral contraceptives, had not used any drug that interferences with hemostasis during the last month of transfusion and had not had a splenectomy were included to our study with 50 healthy controls who sustained the same criterias. Procoagulant phospholipid activity tests and thrombin generation tests were done which are the most advisable tests for the evaluation of the *in vivo* hemostasis and endothelial microparticles levels were calculated in both groups. The results of TM patients are compared with the results of the healthy controls.
Results: Endothelial microparticle levels of the TM patients (191,7 ± 108,9 / µl) were statistically significantly higher than the healthy controls (86,6 ± 8,2 /µl) (p=0.0001) and there were statistically significant positive correlation between ferritin and EMP levels (r=0.357, p=0.048). Procoagulant phospholipid activity of TM patients (65.6 ± 12.3 sn) were statistically significantly longer than the healthy controls (59.5 ± 15.2 sn) (p=0.049). Endogenous thrombin potentials of TM patients (1129,8 ± 187,4 nM thrombin.min) were statistically significantly lower than the healthy controls (1260,1 ± 267,7 nM thrombin.min) (p=0,012). In addition, aPTT (34,8 ± 7,8 sn) and PT levels (15,4 ± 2,8 sn) of the TM patients were statistically significantly longer than aPTT (31,1 ± 5,7 sn) and PT levels (13,2 ± 0,8 sn) of the healthy controls (p=0,016; p=0,0001, respectively), but there were not difference in terms of platelet and fibrinogen levels between groups. Again there were statistically significant positive correlation between ferritin and aPTT and INR levels (r=0.417, p=0.019; r=0.466, p=0.009, respectively). These results have shown that there is not a procoagulan activity, in contrast there is an anticoagulan activity in regularly transfused, chelated, nonsplenectomized TM patients.
Summary and Conclusion: In recent years, the existence of an EMP dependent anticoagulant and profibrinolytic compensatory mechanisms has been demonstrated. These compensatory mechanisms may counterbalance their classical known procoagulant phenotype. In conclusion, these results of non-splenectomized, regularly transfused and chelated children with TM in our research have shown that, the thrombosis tendency in the nature of this illness may be compensated via EMP dependent anticoagulant mechanisms and also may be via profibrinolytic compensatory mechanisms.

HAEMATOLOGICAL MORBIDITY IN OBSTETRIC PATIENTS WITH CARDIAC DISEASE

B Kevane[1,2,*], P McKenna[3], K Walsh[4], J C Donnelly[3], K Flood[3], M Cullen[3], M Bowen[5,6], P Thornton[5,6], J Loughrey[5,6], F Ní Áinle[1,2]
[1]Haematology, Rotunda Hospital, [2]Haematology, Mater Misericordiae University Hospital, [3]Obstetrics, Rotunda Hospital, [4]Cardiology, Mater Misericordiae University Hospital, [5]Anaesthetics, Rotunda Hospital, [6]Anaesthetics, Mater Misericordiae University Hospital, Dublin, Ireland

Background: Cardiac disease is the leading cause of maternal mortality in the United Kingdom. An increased risk of venous thromboembolic (VTE) and haemorrhagic events in pregnant women with cardiac disease has been described, however little published evidence exists to guide the management of these competing risks, particularly in the setting of operative delivery. Currently published guidelines on optimal mangement of these patients recommend that a haematologist participates in the care of this high risk group. The Rotunda hospital is a large, maternity university hospital in Dublin, Ireland, accommodating over 9000 deliveries per year. Within this institution, the multidisciplinary management of pregnant patients with cardiac disease includes collaboration between obstetricians, obstetric haematologists, cardiologists, anaesthetists and paediatricians. In addition to formulating individualized management plans, this multidisciplinary service also facilitates the emergency management of acute bleeding or thrombotic complications and streamlines management of blood transfusion.
Aims: The aim of this study was to evaluate the prevention, incidence and management of haematological morbidity in pregnant women with congenital and acquired cardiac disease.
Methods: Patients were identified from a database compiled by the obstetric cardiology multidisciplinary service that listed all pregnant patients referred for specialist cardiology assessment to the Rotunda hospital during the period 2004 to 2011. Patients with underlying cardiac disease of moderate to high complexity as defined by international consensus guidelines and those at high risk due to the presence of mechanical heart valves were included. Baseline information collected from the database included age, medical history, nature of the underlying cardiac disease, regular medications and obstetric history. Further data were obtained from the medical and obstetric case notes relating to antenatal complications, details of perinatal care and postnatal complications.
Results: From 2004-2011, 451 patients with cardiac disease were referred for obstetric care to the Rotunda hospital. 59 patients were identified as having moderate to high risk cardiac disease. Each of these patients was discussed regularly at a formal multi-disciplinary team meeting, where an individualized care pathway was formulated and an agreed, written delivery plan recorded in the medical notes. Nine patients were receiving treatment with anticoagulant or antiplatelet agents pre-conception, including two patients receiving warfarin and one patient receiving therapeutic dose low molecular weight heparin (LMWH). During the peripartum period, 3 women were receiving therapeutic dose LMWH/unfractionated heparin, 12 were receiving prophylactic LMWH and 1 woman was taking an antiplatelet agent. The mean estimated blood loss at delivery was 371 (100-2000) ml and the rate of postpartum haemorrhage (approx. 5%) was similar to that reported in the general obstetric population. Regional anaesthesia was utilized in 54 cases with no local bleeding complications. No VTE events occurred. Moreover, during the 8 year period, there were no maternal deaths among this cohort.
Summary and Conclusion: Few previously published case series have focused upon haematological complications in pregnant patients with cardiac disease. Within our institution the multidisciplinary approach to management facilitates decision making among senior clinicians at an early stage in pregnancy, allowing pre-emptive measures to be taken against the anticipated risks in each pregnancy as well as producing care plans to provide guidance to junior colleagues. This is of particular importance in scenarios where there is limited published evidence to guide management. In the absence of further additions to the evidence base in this area, improvements in the provision of obstetric care to patients with cardiac disease will likely be dependent upon close co-operation between clinicians and other stakeholders involved in delivering care to this challenging patient group.

Venous thrombosis

P1249

PREVALENCE OF VENOUS THROMBOEMBOLISM IN PATIENTS WITH DIFFUSE LARGE B-CELL LYMPHOMA: A DANISH FOLLOW-UP STUDY

MT Severinsen[1,*], I H Hahn[1], J Madsen[1]
[1]Department of Haematology, Aalborg Universityhospital, Aalborg, Denmark

Background: Venous thromboembolism (VTE); *i.e.* deep venous thrombosis (DVT) and pulmonary embolism (PE) is a critical and common complication in patients with cancer. However, the information on VTE among patients with haematological malignancies such as diffuse large B-cell lymphoma (DLBCL) is sparse.
Aims: The aim of this study was to evaluate the incidence of VTE in patients with DLBCL in a two year period from date of lymphoma. Furthermore the aim was to evaluate the quality of registry data on VTE among DLBCL patients.
Methods: We conducted this singlecenter study to investigate the incidence of VTE among patients with a first time diagnose with DLBCL at the Department of Haematology Aalborg University Hospital from January 1, 2007 to December 31, 2013. The follow-up of patients were from date of DLBCL until two years later, date of death or November 1, 2013 whatever occurred first. The entire medical records were reviewed for all DLBCL patients and data on lifestyle factors, medication with anticoagulation and confirmed episodes of VTE by imaging were retracted. Furthermore we retracted data on VTE risk factors, platelet count, haemoglobin and leukocyte count at date of VTE. We further evaluated the data quality on VTE discharge diagnosis in the Danish National Registry of Patients among DLBCL patients. We retracted register data on VTE discharge diagnosis among all patients included in our study. These data were compared with information from medical records on VTE events.
Results: A total of 296 patients were identified with a first time diagnosis of DLBCL at the Department of Haematology Aalborg University Hospital during the study period. Of the 296 DLBCL patients 32 (10.8%) had a VTE confirmed by imaging within a two-year follow up. This included 19 cases (59%) of DVTs and 13 cases (41%) of PEs of which three were found on routine CT scan whereas 10 were symptomatic. Of the 19 DVTs, seven were located at the upper extremities (six were associated with central vein catheter). The platelet count was subnormal in 44% of patients and 12% of VTE patients had a platelet count below $50*10^9$ per L at time of VTE. In the discharge register 20 of the 296 patients had a diagnosis of VTE during a two years follow-up period of which 17 were confirmed by review of the medical records. The positive predictive value of a VTE discharge diagnosis among patients with DLCBL was 85%. Only 17 of the 32 confirmed VTE cases were registered in the discharge register. The sensitivity of a VTE discharge diagnosis was 53% which means that the incidence of VTE among DLBCL patients is underestimated by using register data.
Summary and Conclusion: We found an incidence of 10.8 % of VTE among DLBCL patients during two years of follow-up from date of DLBCL. Register data on VTE discharge diagnosis is valid among patients with DLBCL with a positive predictive value of 85%. The sensitivity of a VTE discharge diagnosis among DLCBL patients is only 53%.

P1250

CONSENSUS PAPER ON: "PLATELET CUT-OFF FOR ANTICOAGULANT THERAPY IN CANCER PATIENTS WITH VENOUS THROMBOEMBOLISM AND THROMBOCYTOPENIA"

G Saccullo[1,*], M Marietta[2], M Carpenedo[3], V De Stefano[4], A Falanga[5], A Federici[6], F Rodeghiero[7], A Tosetto[7], S Siragusa[1,8]
[1]University of Palermo, Palermo, [2]University of Modena, Modena, [3]San Gerardo Hospital, Monza, [4]University of Rome, Rome, [5]Hospital Papa Giovanni XXIII, Bergamo, [6]University of Milan, Milan, [7]San Bartolo Hospital, Vicenza, [8]Hematology Unit, university of palermo, palermo, Italy

Background: Cancer-related Venous Thromboembolism (VTE) requires treatment with Low Molecular Weight Heparin (LMWH), which is more effective and safer than warfarin; however, the risk of major hemorrhage still remains clinically relevant (up to 5%). This rate is even higher in case of impaired hemostasis, such as it may occur during thrombocytopenia (due to myelosuppression or chemo-therapy) where the bleeding risk is directly related to the values of platelet count. At the present, no guidelines are available regarding the best management of patients with acute or non-acute cancer-related VTE during thrombocytopenia.
Aims: To develop a consensus about the platelet cut-off for safely administering LMWH in cancer patients with acute (no lather then 1 month) and non acute VTE and thrombocytopenia, based on RAND/UCLA Appropriateness Method (RAM).
Methods: A systematic review of the literature was performed via electronic databases. Topics and research terms were cancer, venous thromboembolism, platelets, risk of bleeding, anticoagulant drugs, low-molecular-weight heparin and treatments. A questionnaire of appropriateness of the use of different doses of LMWH, according to the platelet count, was produced. A panel of experts was identified; the literature review and the list of indications were sent to all members of this panel. For each indication, the panel members rate the benefit-to-harm ratio of the procedure on a scale of 1 to 9, where 1 means that the expected harms greatly outweigh the expected benefits, and 9 means that the expected benefits greatly outweigh the expected harms. A middle rating of 5 can mean either that the harms and benefits are about equal or that the rater cannot make the judge for the patient described in the indication.
Results: The panel of expert reached the following consensus.
Appropriate:
- In acute VTE (including catheter-related VTE): Full dosage of LMWH if platelets >50,000<100,000/mm^3 **(9/9)**; Reduced dose to 50% of full dose, if platelet >30,000<50,000/mm^3; The discontinuation of LMWH treatment if platelets<30,000/mm^3 **(6/9)**; and, in case of DVT of the lower limbs, the positioning of IVC filter **(6/9)**.
- In non-acute VTE (including catheter-related VTE): LMWH reduced to 75% of full dosage, if platelets >50,000<100,000/mm^3 **(7/9)**; The discontinuation of LMWH treatment if platelets<30,000/mm^3 **(7/9)**.
Uncertain:
- In acute VTE (including catheter-related VTE): Full dose of LMWH if platelets >30,000<50,000/mm^3 **(7/9)**.
- In non acute VTE (including catheter-related VTE): LMWH reduced to 75% of full dosage if platelets >30,000<50,000/mm^3 **(7/9)**; LMWH discontinuation and insertion of IVC (in case of DVT), if platelets<30,000/mm^3 **(5/9)**; LMWH reduced to 75% of full dosage if platelets >30,000<50,000/mm^3 **(6/9)**.
Inappropriate:
- In acute VTE (including catheter-related VTE): Full dose of LMWH if platelets<30,000/mm^3 **(9/9)**; The discontinuation of LMWH if platelets count >30,000<50,000/mm^3 **(6/9)**.
- In non acute VTE (including catheter-related VTE)**:** Reduced dose to 75% LMWH if platelets<30,000/mm^3 **(7/9)**; The discontinuation of LMWH if platelets count >30,000<50,000/mm^3 **(5/9)**.
Summary and Conclusion: This is the first expert opinion based on RAM to establish the safe platelet cut-off to administer LMWH therapy in patients affected by acute and non-acute VTE. The present panel of expert suggests as appropriate the use of dose-adjusted LMWH according to platelets count. Further investigations by means of well designed prospective clinical trials are needed to establish the best management of cancer-related VTE in patients with thrombocytopenia.

P1251

A SINGLE CENTRE RETROSPECTIVE ANALYSIS OF THE INCIDENCE OF MAJOR BLEEDING IN OVER 1000 PATIENTS COMMENCED ON RIVAROXABAN FOR NON-VALVULAR ATRIAL FIBRILLATION AND VENOUS THROMBOEMBOLISM

S Jenkins[1], M Mushkbar[1,*], R Koghar[1]
[1]Haematology Dept., Dudley Group NHS trust, Dudley, United Kingdom

Background: The novel oral anticoagulant rivaroxaban has been NICE approved in the UK for anticoagulation in patients with Non-Valvular Atrial Fibrillation (AF) since May 2012, Deep Vein Thrombosis (DVT) since July 2012 and Pulmonary Embolism (PE) since June 2013. Despite published randomised trial data comparing rivaroxaban to warfarin, questions remain as to the incidence and pattern of major bleeding in patients on rivaroxaban in the post authorisation setting. Furthermore there is no clearly identified mechanism to reverse its action in the event of major bleeding. In our institution we have approved use of a single dose of Prothrombin Complex Concentrate (PCC) in the event of major, life threatening and ongoing bleed. In addition we have recommended not commencing rivaroxaban in patients with an estimated Glomerular Filtration Rate (eFGR) of<30ml/min.
Aims: To ascertain the incidence and pattern of major bleeding in over 1000 unselected patients commencing rivaroxaban in our institute. To contrast this by collecting data on the rate and pattern of major bleeding requiring reversal with PCC in the >6400 patients taking warfarin who are monitored by our institution.
Methods: We retrospectively analysed clinical and laboratory data for episodes of major bleeding in 1002 patients commencing rivaroxaban in our institution between 8th of November 2012 and the 18th of February 2014. Basic demographics were collected and the ISTH criteria for major bleeding (including >=2g/dl fall in Haemoglobin and/or the transfusion of >=2 units of packed red blood cells) was used. Haemoglobin at presentation of major bleeding was compared to Haemoglobin at commencement of rivaroxaban. The site and outcome (fatal *versus* non-fatal) of major bleeding was recorded. Use of PCC was recorded in both the rivaroxaban and warfarin groups.
Results: 1002 patients were commenced on rivaroxaban in this time frame. 845 patients were commenced on rivaroxaban 20mg od and 157 patients were commenced on rivaroxaban 15mg od due to eGFR being<50ml/min. The indication for anticoagulation was AF in 886 patients and DVT/PE in 116 patients. The median age was 75 years (range 21-100 years). In the rivaroxaban group we did not identify any intracranial haemorrhage requiring reversal of anticoagulation with PCC. However 1 patient presented with an intracranial haemorrhage at 3 days following their last dose of rivaroxaban with normal renal function and thus did not require attempted reversal of anitcoagulation with

PCC. The outcome of this event is non-fatal at the time of authorship. 10 patients were identified who fulfilled the major bleeding criteria. One of these major bleeding events had a fatal outcome where a genitourinary bleed was a contributory factor to death. However this patient did not receive PCC. Four of these major bleeding events were confirmed as Upper Gastro-Intestinal (GI) bleeds, though only one of these events required reversal with PCC. There was one further suspected, though not proven GI bleed. In the remaining 4 events no bleeding source was identified. Within the same time frame PCC was administerd to 86 patients in the warfarin group. There were 28 deaths within this group, 17 of which were due to intracranial haemorrhage. In total 34 of the 86 patients receiving PCC had had an intracranial haemorrhage.
Summary and Conclusion: Our analysis is in keeping with published randomised trial data in respect to the incidence of major bleeding, including intracranial haemorrhage, for patients taking rivaroxaban. Furthermore this contrasts positively to our own experience (as well as historical published data) with respect to bleeding events on warfarin, in particular the rate of intracranial haemorrhage. The authors suggest that limiting use of rivaroxaban to patients with eGFR of >=30 in their institution, plus the routine counselling and standardised information provided to patients and primary care physicians when commencing rivaroxaban, may have contributed to the favourable outcome of this analysis.

P1252

ANTICOAGULANT MANAGEMENT OF PREGNANT WOMEN WITH MECHANICAL HEART VALVES: A RETROSPECTIVE COHORT STUDY

L Oskam[1,*], M de Laat[2], B Bouma[3], S Middeldorp[1]
[1]Vascular Medicine, [2]Obstetrics, [3]Cardiology, AMC, Amsterdam, Netherlands

Background: The anticoagulant management of pregnant women with mechanical heart valves is challenging since they face a high risk of valve thrombosis and death of systemic embolism. Unfortunately, no trials are available, and only limited data on the risk associated with different anticoagulant regimens are available.
Aims: The aim of this study was to determine maternal and fetal outcomes in pregnant women with mechanical heart valves managed with anticoagulation at a tertiary referral hospital in the Netherlands.
Methods: We conducted a retrospective cohort study of pregnant women with mechanical heart valves receiving different anticoagulant regimes. We identified patients using laboratory, cardiology and obstetric databases of our tertiary referral center and captured all women treated between 1995 and 2013. We studied maternal thromboembolic and hemorrhagic complications, pregnancy and fetal outcomes.
Results: We included 26 pregnancies in 13 women (Table). Sixteen pregnancies (62%) continued after 20 weeks gestation. In 6 of these 16 (38%) pregnancies, low-molecular-weight heparin (LMWH) was the predominant anticoagulant used throughout pregnancy. In 10 (63%) of these pregnancies, women received mainly vitamin K antagonists (VKA), with LMWH given only in the first trimester and peri-delivery or unfractionated heparin (UFH) given only peri-delivery. Five (19% of all pregnancies) thromboembolic complications (TEC) occurred, 4 in women with a mechanical valve in the aortic and 1 in a woman with a valve in the pulmonalis position. Three TEC occurred during LMWH treatment. One woman underwent valve replacement. There were no deaths. Antenatal and postpartum maternal hemorrhagic complications occurred in three (12%) and seven (27%) of all pregnancies, respectively. Of pregnancies continuing beyond 20 weeks, 83% (5 of 6) of women treated with LMWH during pregnancy had a surviving infant compared to 90% (9 of 10) of those treated with VKA. There were five preterm births before a gestational age of 37 weeks, four in pregnancies managed with VKA.

Table

Summary and Conclusion: In conclusion, the risk of thromboembolic and hemorrhagic complications in pregnant women with mechanical heart valves was high, regardless of the type of anticoagulant. Close monitoring of treatment is essential.

P1253

MICROPARTICLE-ASSOCIATED TISSUE FACTOR ACTIVITY IN PATIENTS WITH ACUTE UNPROVOKED DEEP VEIN THROMBOSIS AND DURING THE COURSE OF ONE YEAR

J Thaler [1,*], R Koppensteiner[1], I Pabinger[1], C Ay[1], T Gremmel[1]
[1]Medical University of Vienna, Vienna, Austria

Background: Tissue factor (TF) is the main *in-vivo* initiator of blood coagulation. Microparticles (MPs) are small procoagulant membrane vesicles. Elevated TF-bearing MPs have been found in different prothrombotic conditions and MP-associated TF activity may contribute to the pathogenesis of unprovoked deep vein thrombosis (DVT).
Aims: To determine MP-TF activity levels at diagnosis of DVT and at four additional time points during the course of one year in a well- defined group of patients with unprovoked DVT of the lower limb.
Methods: In this study, 41 patients with acute unilateral symptomatic and unprovoked DVT of the lower limb were included and followed for 1 year. Venous blood samples for determination of MP-TF activity were drawn at diagnosis of acute DVT, and 1-, 3-, 6-, and 12 months later. In addition, 10 young and healthy control subjects were included.
Results: The median MP-TF activity was 0.06 pg/mL (25^{th}-75^{th} percentile: 0.0-0.53) in patients with acute DVT and 0.18 pg/mL (0.07-0.33) in healthy controls, and did not differ significantly (p=0.35). No significant changes in MP-TF activity were found in the follow-up measurements. MP-TF activity did also not differ significantly between patients with proximal- or distal DVT and between those with- or without residual DVT after 6 months.
Summary and Conclusion: MP-TF activity is low at the acute event in patients with unprovoked DVT of the lower limb and remains unchanged during the course of the disease. Our data do not support the hypothesis that TF-bearing MPs play a determining role in the pathogenesis of unprovoked DVT.

P1254

DEVELOPMENT OF A PHARMACOGENETIC-BASED WARFARIN DOSING ALGORITHM IN BRAZILIAN PATIENTS

P Santos[1,*], R Soares[1], N Duarte[1], L Marcatto[1], C Strunz[1], J Krieger[1], A Pereira[1]
[1]University of Sao Paulo, Sao Paulo, Brazil

Background: In 2007, the Food and Drug Administration added pharmacogenetic information to the warfarin product label and consequently trials have recently been performed to test whether knowledge of *CYP2C9* and *VKORC1* variants improve the outcomes for patients.
Aims: To develop a pharmacogenetic-based warfarin dosing algorithm from a Brazilian patient cohort with stable dose and to perform comparisons with other cohorts from patients without stable dose. and *VKORC1* variants improve the outcomes for patients.
Methods: This retrospective cohort study included 1037 patients treated with warfarin for at least 12 months at the Heart Institute (Incor), University of São Paulo, São Paulo, Brazil. The development was based on patients on stable warfarin dose, *i.e.*, achievement of the therapeutic target defined as three consecutive values of INR between 1.8 and 3.2 (including the current test). Dose-prediction algorithmic model was performed with 10,000 randomized analyses in a derivation cohort formed for patients with stable dose. A testing cohort formed for patients who had not stable dose were analyzed. In a multiple linear regression were included the variables age, gender, weight (Kg), height (cm), self-declared "race/color", amiodarone use, enzyme inducers use, *VKORC1* genotypes, and predicted phenotypes due to *CYP2C9* polymorphisms (EM, IM or PM). were analyzed.
Results: The algorithmic model was developed with a derivation cohort formed for patients on stable warfarin dose. The construction of the model achieved a moderate multiple R2 including 9 variables. Also, a moderate correlation between predicted dose by IWPC algorithm and predicted dose by our algorithm was observed (r=0.54, p<0.001). Mean warfarin dose was significantly lower in patients carrying IM+PM predicted phenotypes (25.8±0.8 mg/week) compared to EM patients (29.7±0.5 mg/week) (p<0.001). For the *VKORC1* polymorphism, patients carrying GG genotype had higher mean warfarin dose (32.3±0.6 mg/week) compared to patients carrying AA genotype (21.5±1.2 mg/week) (p<0.001).
Summary and Conclusion: These information is a step towards implementation of a genotype-guide dosing of warfarin and it could be very useful to identify or not improvement in the initial anticoagulation therapy in a multi-ethnic population.

P1255

CURRENT MANAGEMENT AND OUTCOMES OF VENOUS THROMBOEMBOLISM IN AUSTRALIA: INITIAL RESULTS FROM THE VENOUS THROMBOEMBOLISM COHORT STUDY

N Aoki[1,*], E Wood[1,2,3], C Weller[1], S Chunilal[2], S Sirdesai[4], A Arumugaswamy[2], H Tran[1,2,3,4]
[1]Monash University, [2]Monash Medical Centre, [3]Australian Centre for Blood Diseases, [4]Alfred Hospital, Melbourne, Australia

Background: Venous thromboembolism (VTE), including deep vein thrombosis (DVT) and pulmonary embolism (PE), is a common and important cause of morbidity and mortality.
Aims: The VTE Cohort Study is a prospective observational registry established by Monash University to describe VTE epidemiology, current therapeutic strategies and patient outcomes in Australia.
Methods: Between July 2011 and February 2014, data from diagnosis to last follow-up were prospectively collected on patients, aged 18 years or older, at two Haemostasis and Thrombosis Clinics in Melbourne, Australia. Data collection was undertaken by clinicians and included the patients' clinical presentation, acute and long-term therapy and outcomes, including VTE recurrence.
Results: A total of 236 presentations of VTE in 235 patients (1 patient had a second presentation) were registered. Median age was 54 years [IQR 39-68], 48% were male and 88% were of European descent. The majority of patients (62%) presented with an isolated lower extremity DVT (calf alone=29%; proximal alone=32%), 4% presented with upper limb thrombosis, 1% with cerebral vein thrombosis, 24% with PE alone, and 9% patients with both DVT and PE. A history of VTE (6%), obesity (BMI≥30) (52%), major surgery (within 4 weeks) or bedridden (27%), oral contraceptive pill (17%), active cancer (7%), and inherited thrombophilia (7%) were reported risk factors. Post-thrombotic syndrome (PTS) was reported in 17.5% of patients. Of these, 68% had mild, 23% had moderate and 9% had severe PTS according to the Villalta scale. The presence of an ulcer was reported in 1 patient. Median time of PTS onset was 1 month (IQR 1-5; range=0-13) after diagnosis. In the acute phase, treatment consisted of low molecular weight heparin (LMWH) (93%) for a median duration of 7 days [IQR 7-10]. Rivaroxaban was prescribed for acute therapy in only 3.3% of patients. Few patients had an inferior vena cava filter inserted (3%) or had thrombolytic therapy (1.8%). Long-term therapy included warfarin (68%), LMWH (19%) or rivaroxaban (5.8%). Stockings were prescribed for 47 % of patients with DVT. Bleeding occurred in 6.8% of patients of which 23% was considered a major or life-threatening bleed and 77% a minor bleed. Pulmonary hypertension was reported in 4.5% of patients with a PE with or without a DVT. No deaths were reported in the study period.
Summary and Conclusion: Prospectively collected data from the VTE Cohort Study are contributing to documenting and understanding factors that influence clinical outcomes of VTE to better define optimal management. *This study is supported by the Australian Centre for Blood Diseases, Monash University and Bayer Australia*

P1256

IN-VIVO REVERSAL OF THE ANTICOAGULANT EFFECT OF APIXABAN WITH 4-FACTOR PROTHROMBIN COMPLEX CONCENTRATE

Y W Cheung[1,*], S L Barco[1], B A Hutten[2], J C Meijers[3], S Middeldorp[1], M Coppens[1]
[1]Department of Vascular Medicine, [2]Clinical Epidemiology, Biostatistics & Bioinformatics, [3]Experimental Vascular Medicine, Academic Medical Center, Amsterdam, Netherlands

Background: The ability of non-specific prohaemostatic agents to reverse the anticoagulant effect of apixaban has never been assessed in humans. Previously, 50 U/kg of 4-factor prothrombin complex concentrate (PCC) restored endogenous thrombin potential (ETP) and prothrombin time (PT) to baseline values in rivaroxaban treated healthy volunteers. Animal models suggest that lower PCC doses are equally effective for reversal of rivaroxaban as well as for apixaban.
Aims: In this experiment, we assessed whether infusion with doses of 37.5 and 25 U/kg of PCC (off label use) are able to reverse the effect of a high dose of apixaban.
Methods: In a randomized, double blind, placebo-controlled, crossover study, 6 healthy volunteers took apixaban 10 mg twice daily. Three hours after the last dose of apixaban they received either a single bolus of PCC 37.5 U/kg, PCC 25 U/kg or placebo, with a wash-out period of 18 days in between infusions. Outcome was the effect of PCC on ETP (15 min after the PCC/placebo infusion and over 24 h) and PT (at 15 min). All volunteers gave written informed consent.
Results: Fifteen min after 25 U/kg PCC, ETP increased from 44% ± 12% to 51% ± 15% (p=0.03). After 37.5 U/kg PCC, ETP increased from 41% ± 11% to 56% ± 23% (p=0.06). Placebo did not increase ETP (45% ± 10% to 44% ± 11%, p=0.8). Over the 24 h observation period, ETP was significantly higher in 25 U/kg and 37.5 U/kg PCC doses compared with placebo (p=0.04 and p<0.001, respectively). Both 25 U/kg and 37.5 U/kg of PCC lowered the PT to baseline values after 15 min (p=0.001 and p=0.000 respectively), whereas placebo did not (p=0.442).

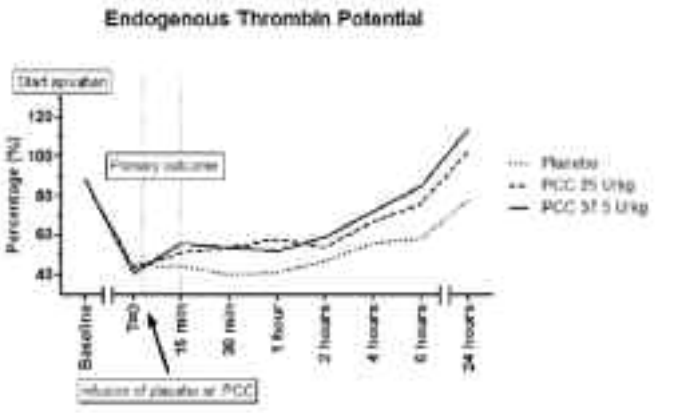

Figure 1.

Summary and Conclusion: PCC in a dose of 25 U/kg and 37.5 U/kg increases ETP and normalises PT in patients treated with a high dose of apixaban, indicating partial reversal of the anticoagulant effect.

P1257

EFFICACY OF REPEAT DUPLEX ULTRASOUND IN PATIENTS WITH SUSPECTED DEEP VENOUS THROMBOSIS

B Scholtes[1,*], F Erdkamp[1], R V Kampen[1], F Peters[1]
[1]Internal medicine, Orbis Medical centre, Sittard-Geleen, Netherlands

Background: About 300 patients a year are referred to our outpatient clinic at Orbis Medical Centre for suspected DVT. Referring general practitioners (GP's) use a primary decision rule combined with D-dimer testing to stratify patients who should undergo a duplex ultrasound to safely exclude a deep vein thrombosis (DVT). In all patients with a negative duplex ultrasound but elevated D-dimer test and/or high clinical suspicion, guidelines advice to perform a second duplex ultrasound.
Aims: In this study, we investigate prevalence of DVT after GP referral and the effectiveness of repeat ultrasound in case of elevated D-dimer test in these patients.
Methods: We performed a single centre, prospective analysis of GP referred patients suspected of DVT. Inclusion was started at July 17th 2012 and still ongoing, a preliminary analysis was performed after inclusion of 150 patients. All patients underwent clinical investigations to determine Wells-score, D-dimer testing and a duplex ultrasound. In case of elevated D-dimer test and/or a persisting clinical suspicion for DVT repeat duplex ultrasound after 5-7 days was performed in all patients.
Results: During a period of 5.5 months, 153 GP referred patients were seen to rule out a DVT. Of these 153 patients effectively 28.8% had a DVT and in 7.8% of cases a thrombophlebitis was diagnosed. Negative duplex ultrasound results for thrombosis were seen in 97 patients. In these patients 56 had a repeat duplex ultrasound 5-7 days later. The repeat ultrasound was positive for DVT in 3.6% (n=2) of cases. All patients with a primary Wells score >4 had a positive duplex ultrasound, in two cases only the second duplex ultrasound. 41 patients had no repeat ultrasound performed; 29.3% had a normal D-dimer test, 43.9% had an alternative diagnosis and 19.5% had low Wells scores in combination with a D-dimer test<750. Two patients refused additional ultrasound.
Summary and Conclusion: At our outpatient clinic 28.8% of GP referred patients had a comfirmed deep vein thrombosis by duplex ultrasound. Deep venous thrombosis was diagnosed in only 3.6% of patients after repeat duplex ultrasound. All patients with a Wells score above 4 had a positive duplex ultrasound, including the patients with a positive second duplex ultrasound. In conclusion a repeat duplex ultrasound seems effective in GP referred patients with high Wells scores (>4) and a primary negative duplex ultrasound. Efficacy and effectiveness of repeat ultrasound will be further analysed in our prospective cohort study

P1258

SPANISH REGISTRY OF THROMBOEMBOLIC DISEASE (TD) RELATED WITH HORMONAL THERAPY, PREGNANCY, OBSTETRICS COMPLICATIONS OR ASSISTED REPRODUCTIVE TECHNIQUES IN WOMEN (ARP): RESULTS OF THE TEAM PROJECT

A Santamaria[1,*], A Redondo-Izal[2], I De Diego[3], OBOTT Project[4]
[1]haemostasis and thrombosis Unit. Haematology., hospital de Vall d´Hebron, barcelona, [2]hematology, hospital Navarra, Navarra, [3]Mutua Terrasa, [4]Spanish Society Thrombosis and Heamostasis, barcelona, Spain

Background: There is a lack of information regarding thromboembolism, thrombophilia and clinical management in different specific clinical settings

such as vascular obstetric complication in women in the clinical practice. In this context, we are conducting a national registry of women in those situations, the so-called TEAM Project: a multicenter observational cohort study. (See website: www.SETH.es).
Aims: To obtain information about the clincal management of women and the presence or not of thrombophilia that develop thrombosis during pregnancy or vascular placental complications in the Spanish population.
Methods: From 2009 since now, almost 60 Centers from Spain and also now, Uruguay have been including patients. The inclusion criteria are women with hormonal therapy or pregnancy-related thrombosis disease, vascular placental complications (VPC) or ischemic placental disease or ART and women with thrombophilia, that will undergo or not thromboprophylaxis during pregnancy or ART The study has been approved by the Ethical Committee of each Center. Among the primary outcomes, the investigation will focus on the incidence, prophylaxis and treatment of TD, hormonal or antineoplasic therapies or ART, as well as the management of vascular placental complications or thrombosis in those situations.
Results: We have already recruited 329 patients from 20 Centers. 10% were women with thrombosis during pregnancy, 14% were women with VPC, 36% were included for thrombosis prophylaxis during pregnancy, 26% for prophylaxis of VPC during pregnancy and 2% had recurrent implantation failure.The thrombophilia test revealed that the most common risks factor were homozygous for F12 46C/T polymorphism, Factor V Leiden and high levels of Factor VIIIc. In general, 70% women received heparin for prophylaxis, some of them 30,6% received aspirin alone or in combination, of treatments during pregnancy. Heparin was used as treatment (11%) and prevention (89%), being tinzaparin 45% and enoxaparin (30%) the most indicated, along with bemiparin (20,5%) or dalteparin (4.5%). Clinical outcomes, in terms of relapse of thrombosis or VPC, showed only 1 case of thombosis and 9 of CVG.
Summary and Conclusion: The preliminary results from the Team Project reflects the clinical practice, and the differences among investigators in thromboprophylaxis, indication of thrombophilia testing and treatment in the clinical setting. Also new risk biological factors in women's issues such as FVIIIc or homozygous for F12 46C/T polymorphism. The information of this ongoing registry will allow us to make the translation from clinical practice to clinical and biological investigation.

P1259

RETROSPECTIVE AUDIT OF INCIDENCE OF PICC LINE RELATED DEEP VEIN THROMBOSIS IN HAEM-ONCOLOGY PATIENTS
P Sriskandarajah[1,*], K Davis[2], N Pepper[1]
[1]Haem-Oncology, [2]Royal Marsden NHS Foundation Trust, Sutton, United Kingdom

Background: The use of Peripherally Inserted Central Catheters (PICCs) have become increasingly popular as the procedure is quick and it provides long-term access for the administration of chemotherapy or stem cell rescue in hem-oncology patients. However, concerns have been raised regarding the potential complications associated with this procedure, in particular the development of a deep vein thrombosis (DVT). This can have a detrimental effect on the patient's therapy plan, by delaying further chemotherapy or stem cell transplant, placing them at risk of early disease relapse. Additionally, the diagnosis of a DVT can affect the patient's quality of life through further complications, including infection and pulmonary embolism. As a result, there has been increasing interest in the use of prophylactic anti-thrombotic agents to prevent this complication. Few studies have reviewed the incidence of thrombotic events in this group of patients, and the decision to use prophylactic anticoagulation is usually left to the prescribing clinician. However, there is increasing data to suggest that the benefits of using low molecular weight heparin to prevent a thrombosis outweigh the risk of a bleeding event.
Aims: To estimate the prevalence of thromboembolic events in our hem-oncology population and assess the risk factors associated with this. Additionally we wished to identify the impact of a thromboembolic event on the patient's long-term treatment plan.
Methods: The electronic and paper medical records of all hem-oncology patients who had a PICC line inserted in our day unit between 1st January 2010 to 1st January 2013 were retrospectively reviewed. Data collected included gender; age; underlying hematological malignancy; previous history of thromboembolic event; any concurrent anti-thrombotic medication; when DVT diagnosed through ultrasound; whether any therapy was delayed; any further complications as a result of the thrombosis.
Results: 346 patients were identified. The median age was 49.7 years with a range of 18 to 77 years. The incidence of thrombotic events was 6% (20) with the majority being women 60% (12). Notably the frequency of DVTs in patients was increasing each year from only 4 patients in 2010 to 11 patients in 2012. The most common underlying malignancy associated with DVT was AML 40%, followed by ALL 20%, NHL 20%, HL 10% and Multiple Myeloma 10%. Only 2 patients had previous history of thrombosis with one already established on anticoagulation. All thrombotic events occurred an average 32.8 days following PICC line insertion. The majority of patients developed a thrombosis following treatment. However 3 patients presented prior to their next course of chemotherapy with 1 patient presenting a few days prior to their stem cell transplant. All of these patients had their therapy delayed an average 13.8 days. All patients had complications following diagnosis of a DVT with 80% (16) having their line removed and 45% (9) developing sepsis. One patient required admission to critical care due to septic shock and their line was removed on ICU.
Summary and Conclusion: The prevalence of DVT events was similar to that described in other published studies of this patient population. However, notably the incidence in our hospital was increasing, despite the average number of patients analyzed each year remaining the same. The most likely risk factors associated with a thrombotic event included female gender, age 40-50 years and AML. The complication rate was higher compared to those previously reported. Overall it was suggested that all patients should have a risk assessment prior to PICC line insertion and considered for short-term thromboprophylaxis, since previous studies have shown that, despite thrombocytopenia, the risk of a bleeding event is low. Furthermore, given the delay in diagnosis and management, it was felt that both junior staff and patients need to be re-educated on how to recognize early signs and symptoms of a thrombosis, and the prompt management of this.

P1260

THREE YEAR MORTALITY ASSOCIATED WITH VENOUS THROMBOEMBOLISM (VTE): COMPARISON OF HOSPITAL ACQUIRED, COMMUNITY ACQUIRED AND INCIDENTAL FINDINGS
H Rowswell[1,*], T Nokes[1]
[1]Haematology, Plymouth Hospitals Nhs Trust, Plymouth, United Kingdom

Background: Outcome data has previously been produced showing significantly higher one-year mortality associated with hospital acquired thrombosis (HAT) at 29% compared with community acquired thrombosis (CAT) 12% (p-value<0.0001) occurring in 2010. The CAT value for mortality at one year is closer to that from Dr Foster health episode statistics (HES), which describes 15% mortality one year from VTE diagnosis. Data is now presented for the same patient group for mortality at three years from VTE diagnosis. In addition, mortality associated with incidental VTE (IFT) findings over the same timescale was also investigated. The aim being to detect whether differences in mortality are maintained over three years and how the mortality associated with incidental findings compares to other VTE events.
Aims: The aim of this project was to look again at mortality associated with VTE events that were diagnosed in 2010 at three years from diagnosis. Looking at hospital acquired VTE, Incidental VTE findings and community acquired VTE to see if there are differences in mortality associated with each group and if the mortality numbers previously identified after year 1 were continued in the following two years.
Methods: The hospital radiological reporting system (CRIS) was used to identify positive VTE events over 2010, including both targeted VTE investigations and CT scans for incidental findings. The positive cases were then cross-checked with the patient information system to establish whether they met the criteria for HAT. Mortality was derived from the same patient management system for the preceding twelve months to produce data for three consecutive years. This outcome data was then analysed using the SPSS Statistics package to determine any statistically significant trends in mortality data.
Results: Table 1 shows total VTE events for the three thrombotic types in 2010 and the consecutive 12 month mortality figures for subsequent years 1 to 3 for each cohort. HAT has a significantly increased association with mortality over three years when compared with CAT (p-value<0.0001). Both HAT (p-value<0.0001) and IFT (p-value<0.0001) have significantly increased mortality rates at 12 months when compared with all VTE events over the same period. It was not possible to carry out further analysis of IFT events because the very high twelve mortality of 74% did not allow this. The majority of these events were cancer related. Mortality occurs predominantly within the first 12 months for all three VTE cohorts. The odds ratio (OR) for CAT mortality from year one to year two is 0.68 and to year three is 0.61. For HAT over the same periods, 0.65 and 0.52. This demonstrates statistically significant mortality within 12 months of diagnosis for all VTE types compared with subsequent years.

Table 1.

Summary and Conclusion: Both HAT and IFT have significantly greater association with mortality at twelve months, compared to CAT. The majority of

patients did not receive a post mortem so it was not possible to accurately determine the cause of death across all VTE groups. However, the majority of IFR events were cancer associated, so this might explain the relatively high associated death rates. Mortality data for five years from VTE diagnosis is planned to see if the pattern changes.

P1261

INFLAMMATORY RESPONSE AMONG PATIENTS WITH SUSPECTED VENOUS THROMBOEMBOLISM

KA Mosevoll[1,2,*], H Reikvam[1,2,3], R Lindås[2], Ø Bruserud[1,2]
[1]Department of Clinical Science, University of Bergen, [2]Department of Medicine, [3]Department of Immunology and Transfusion Medicine, Haukeland University Hospital, Bergen, Norway

Background: Deep venous thrombosis (DVT) is still a diagnostic challenge, and D-dimer in combination with Well's score and ultrasound are used to diagnose or exclude DVT. Recent studies have emphasized the importance of the local inflammatory response mediated mainly by monocyte and neutrophil activation. The serum levels of several inflammatory cytokines are increased in patients diagnosed DVT; however previous studies have examined one or only a few mediators.
Aims: In the present study we investigated 44 different mediators to get a broader characterization of the inflammatory process.
Methods: A cohort of 169 patients with suspected DVT was included in the study after written informed consent. The diagnosis was based on clinical evaluation (*i.e.* Well's score), D-dimer, ultrasound and eventually venography if a leg vein thrombosis was suspected. Plasma samples from the first 89 consecutive patients and 20 healthy controls were analyzed with Luminex multiplex determining plasma concentration of 44 mediators: 13 interleukins, 3 immunomodulatory cytokines, 8 chemokines, 8 growth factors, 4 adhesion molecules and 8 matrix metalloproteases. The last 80 consecutive patients were used as a validation group, and samples were analyzed using ELISA to verify observations from the first group of patients. For statistical analysis we used the Mann-Whitney test, and we used unsupervised hierarchical clustering to examine relationship and cytokine expression patterns.
Results: 34 of 169 (18%) of referred patients were diagnosed DVT. Main differential diagnoses were thrombophlebitis, stasis, infection, inflammatory, traumatic and non-inflammatory or unknown. In the first cohort, mainly referred during winter months, 13 (26%) of 89 patients were diagnosed DVT. In the second cohort, mainly referred during summer months, 13 (16%) of 80 patients were diagnosed DVT. Four different mediators differed significantly when comparing patients with DVT *versus* patients without DVT: P-selectin ($p<0.0001$) and VCAM-1 ($p=0.0009$) show the strongest significance whereas the significance was weaker for hepatocyte growth factor (HGF, $p=0.0415$) and matrix metalloprotease 8 (MMP8, $p=0.0151$). However, for all mediators there were a considerable overlap between patients and healthy individuals. Subgroup analysis show less discriminative differences between the patients with more inflammatory conditions. Unsupervised hierarchical clustering analysis including the first 89 patients demonstrated that DVT patients were mainly included in certain clusters. When comparing DVT patients with healthy controls we observed statistically significant differences for several mediator including both interleukin (IL1ra), growth factors (EGF, HGF and Leptin), chemokine (CXCL10), adhesion molecules (ICAM-1, P-selectin and VCAM-1) and matrix metalloproteases (MMP2/3/7/8/9). HGF ($p<0.0001$), P-selectin ($p=0.0009$), VCAM-1 ($p<0.0001$) and all the MMPs (all $p<0.0014$) showed the strongest significant differences. DVT above the femoral band compared to lower DVT showed increased levels of P-selectin ($p=0.0434$), HGF ($p=0.0193$), MMP8 ($p=0.0213$) and D-dimer ($p=0.0152$), reflecting larger thrombosis.
Summary and Conclusion: Serum levels of several inflammatory mediators (*i.e.* interleukins, chemokines, soluble adhesion molecules, proteases) are increased in DVT patients compared with healthy controls; this is consistent with a DVT-induced inflammatory response reflected in these serum levels. However, there is a considerable overlap in serum levels for DVT patients and other patients admitted to hospital with suspected DVT, and for this reason analysis of single mediators or mediator profiles seems to have a limited value in the differential diagnostic evaluation of patients with suspected DVT.

P1262

REDUCTIONS IN VENOUS THROMBOEBOLISM EVENTS, ASSOCIATED WITH RADIOLOGICAL DATA PROVIDING REAL-TIME FEEDBACK TO CLINICIANS ABOUT HOSPITAL ACQUIRED THROMBOSIS, GIVEN INADEQUATE PREVENTATIVE MEASURES

H Rowswell[1,*], T Nokes[1]
[1]Haematology, Plymouth Hospitals Nhs Trust, Plymouth, United Kingdom

Background: Since 2010, metrics for Venous Thromboembolism (VTE) events diagnosed within a large teaching hospital have been produced using the hospital radiological system. All targeted investigations (computed tomography pulmonary angiogram CTPA, Doppler ultrasound scans and ventilation perfusion scans) are included together with incidental findings from CT of thorax abdomen and pelvis. Positive scans are cross-checked against the patient information system to ensure criteria for hospital acquired thrombosis (HAT) are met. This is defined as a VTE diagnosed as an inpatient but not present on admission, or any VTE event within 90 days of hospital discharge.
Aims: The aim was to collect outcome data on VTE events diagnosed within the Trust and how many of these met the established criteria to be termed hospital acquired thrombosis. In addition by undertaking a root cause analysis we wanted to look at whether appropriate preventative measures were used and to reduce the incidence of this.
Methods: All HAT events receive a basic root cause analysis. Including VTE risk assessment, appropriateness of prophylaxis, VTE risk factors, admission speciality and whether appropriate thromboprophylaxis (TP) for VTE took place according to hospital guidelines. These outcome metrics were used to identify areas where HAT was more prevalent, to target education around VTE prevention measures. Feedback about the event is then given to the admitting consultant, highlighting areas of concern. Inadequate TP covers absent, wrong dose or missed prescribed dose of anticoagulant. Clinical teams are often not aware of HAT events occurring in their patients as the event often presents post discharge and treated by other clinicians and teams. In addition HAT events associated with inadequate treatment may be preventable, may cause death and may leave hospitals open to litigation claims.
Results: Results are shared with the Thrombosis Committee (a multi disciplinary group including patient representation), providing monthly reports. Errors identified including inappropriate preventative measures or missed prescribed doses of anticoagulant TP, are included on an incident form, requiring the appropriate team or admitting ward to investigate the error. Reports were submitted to the hospital safe care group when common themes were identified. There is a particular focus on inappropriate TP associated with positive HAT events. Presentations were made to the pharmacy department, consultant meetings and within the annual Trust update for all staff. To further raise the profile of HAT throughout the hospital, a presence from the VTE prevention team was developed in many clinical areas. This included working with the medical admissions unit, where over 95% of medical patients are admitted, to ensure appropriate risk assessment and prescribing of TP. In surgery, targeting the pre-operative assessment unit ensured patients received both written and verbal information about VTE, empowering them to ensure prophylaxis was given. Snap shot audits on all wards across the hospital was undertaken to determine levels of VTE risk assessment and prevention, giving real time feedback to clinical staff. Data on total VTE and percentage HAT events has been determined since 2010 in table 1.

Table 1.

Summary and Conclusion: The overall VTE prevention initiative locally, has led to reductions in total HAT, HAT as a percentage of total VTE and reduction in HAT associated with inadequate TP. In 2011, focus was made on appropriate prescribing which dramatically improved but with a large rise in missed doses that year. In 2012 work was intensified on reducing all inappropriate TP, a theme that continued in 2013, with positive outcomes. This service improvement has been achieved within a relatively short time-frame, using radiological data to provide real-time feedback and work with clinical teams to drive change.

P1263

SCREENING FOR MALIGNANCY IN PATIENTS WITH UNPROVOKED VENOUS THROMBOEMBOLISM

S Sinha[1,*], U Hossain[2], P MacCallum[2]
[1]Haematology, Whipps Cross Hospital, Barts Health NHS Trust, [2]Haematology, Barts Health NHS Trust, London, United Kingdom

Background: Whipps Cross Hospital is a district general teaching hospital serving a local population of approximately 400,000 in North East London. Patients newly diagnosed with venous thromboembolism (VTE) within the hospital are referred to a physician-led anticoagulation clinic. Each new patient diagnosed with venous thromboembolic disease is reviewed by a haematology consultant or specialist registrar. The National Institute For Health and Care Excellence (NICE) has recently produced national guidelines for the management of VTE[1] in England. It recommends that patients with unprovoked deep vein thrombosis (DVT) or pulmonary embolism (PE) who are not already known to have an underlying malignancy are offered timely investigations for cancer. This has implications for management with low-molecular-weight heparin rather than a vitamin K antagonist in up to 11% of such patients who

may have an underlying malignancy. A clinical benefit of early cancer diagnosis with screening is also inferred. In addition to a physical examination guided by the history, all patients with unprovoked DVT or PE should have a bloods tests (full blood count, liver function and serum calcium), urinalysis and a chest X-ray performed. Further investigations for cancer with an abdomino-pelvic CT scan (and a mammogram for women) should also be considered in all patients over 40 years with a first unprovoked DVT or PE. This strategy was felt to be cost effective, whereas additional investigations such as abdominal ultrasound and tumour markers were not. The National Health Service (NHS) waiting time target for investigations for people with suspected malignancy is two weeks.
Aims: We evaluated our practice retrospectively against this standard by evaluating clinical records. Over a six month period (June - November 2013) there were 52 (20 male) patients newly diagnosed (45 first episodes, 7 recurrences) with DVT (n=33) or PE(n=19). We will illustrate the age ranges by decade of this cohort. The ages ranged from 27-92 years, with the commonest age group affected between 60-69 years.
Results: The commonest risk factors identified were surgery (13 patients) and recent medical hospital admission (9 patients); see figure. The second largest group identified were patients with unprovoked episodes of VTE (n=12 (22%)), although travel related VTE may have been a factor in a small number. Combining first and recurrent episodes would make this the largest group within our cohort. Only four (25%) of these patients had a documented screen for malignancy carried out by the haematologist reviewing them in the anticoagulation clinic on their first visit. The remaining 75% did have limited investigations (100% had relevant blood tests, 58% a chest X-ray) following diagnosis of VTE. Additional investigations by acute medical teams included abdominal ultrasound scans and tumour markers. The investigations performed in each of the 12 cases and the origin of the requests will be explored further. One patient was subsequently diagnosed with advanced metastatic pancreatic malignancy as a result of self-directed screening and we will present a illustrative case summary of this.

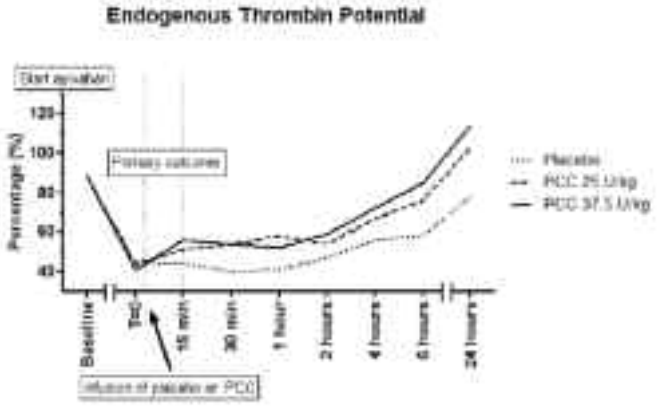

Figure 1.

Summary and Conclusion: This audit has demonstrated the practical difficulties in implementation of the NICE standard. The guideline does not give advice as to where the responsibility for screening lies. Our practice has been varied. Some patients are investigated in-house whilst for others a referral was made to the patient's general practitioner (GP) for this purpose. There has been resistance from some GPs due to limited access to imaging facilities. Some investigations are carried out by the admitting medical team although apart from blood tests this is not on a consistent basis. Our practice suggests that these difficulties may not be an isolated example. It is common practice for anticoagulant services to be led by clinical nurse specialists or pharmacists or to be managed predominantly by community-based staff and a risk of screening being overlooked. A clear joint pathway, with interdisciplinary involvement between general and acute physicians, ambulatory or Emergency Department staff and general practitioners is key in addressing this unmet need which has significant public health and economic implications.

P1264

LONG-TERM OUTCOME OF NON-CENTRAL-VENOUS-LINE-RELATED DEEP VEIN THROMBOSES LOCATED AT LOWER LIMBS IN CHILDREN
H Pergantou[1,*], M Avgeri[2], Z Kapsimali[2], A Komitopoulou[3], P Xafaki[3], M Mazarakis[3], H Karelioti[3], H Platokouki[2]
[1]Haemophilia Centre/Haemostasis and Thrombosis Unit, Aghia Sophia Children's Hospital, [2]Haemophilia Centre/Haemostasis and Thrombosis Unit, Aghia Sophia Children's Hospital, [3]Haemophilia Centre/Haemostasis and Thrombosis Unit, Aghia Sophia Children's Hospital, Athens, Greece

Background: The true frequency of adverse outcomes, such as recurrences and the development of postthrombotic syndrome (PTS), following deep vein thrombosis (DVT) in lower limbs in children have not been broadly studied.
Aims: The aim was to investigate morbidity and outcomes in neonates and children diagnosed with non-central-venous-line-related DVTs in lower limbs in our Centre.
Methods: We retrospectively analyzed the data of 29 children (58.6% males) whereof 3 neonates referred from 1/1999 to 1/2014. Children suffered malignancies and followed at oncology departments of our hospital were excluded from the analysis, due to incomplete data. Ultrasound (US) was used to diagnose DVT while for evaluation of severity of PTS the modified Vilalta scoring system was applied.
Results: The mean age was 7.4 years (2 months- 15 years) for children and 8 days (2-14 days) for neonates. The primary location of DVTs was: left femoral vein (n:10), right femoral vein (n:7), bilateral femoral veins (n:4), left popliteal vein (n:3), right popliteal vein (n:2), bilateral iliac veins (n:3). DVTs extended to inferior vena cava in 9 patients (31%) while concomitant pulmonary embolism was present in three patients (10%), all non-neonate children. The mean follow-up period was 7 years (3-15 y). All patients (100%) survived thrombosis; one patient succumbed during the follow-up period because of an underlying congenital heart disease. Recurrence rates were 27.5% (8/29) in children and zero in neonates. Recurrences at the primary location were present only in two cases. All children who suffered recurrences had either a strong congenital (PS deficiency n:1, FVLeiden heterozygosity n:1) or acquired (Lupus Anticoagulant n:1) thrombophilic factor or an underlying disease predisposing to DVT (n:7). Positive family history of DVT or thrombophilia was reported in 5 cases with no recurrence. PTS was developed in 9 patients (31%) -5/9 were boys- after a median period of 3 months (1-12 months) following DVT. Additionally, one neonate endured amputation of both his limbs due to extensive necrosis. According to modified Vilalta scale, PTS was initially mild in 6 children and moderate in 3. Elevation in D-dimers was present in all nine cases at DVT diagnosis. Extensive occlusion (n=9), presence of thrombophilic factors - especially a natural inhibitor deficiency (n=4) - and recurrence of DVT (n=4) were associated with development of PTS. All PTS patients had been treated upon DVT diagnosis with anticoagulants for a mean period of 24 months (3-60 months), while graduated elastic compression stockings were applied in 8/9 for 1-4 years, soon after PTS development. Appropriate diet was initiated in one obese female adolescent for achieving the optimal body weight. In a mean observational period of 6 years (3-12 y), the outcome of PTS was complete recovery in one boy with moderate PTS, improvement from moderate to mild in one boy with initially diagnosed moderate PTS, while no change on PTS grade was defined in all 6 patients with mild and in one with moderate PTS. There are 11 children still on long-term anticoagulation because of a recurrent DVT or an underlying disease.
Summary and Conclusion: Non-CVL-related DVTs in lower limbs in children are rare events that may be complicated with adverse outcomes affecting the patients' quality of life. Future studies must aim to define a risk-stratified approach to anticoagulation in order to improve long-term outcomes.

P1265

MORTALITY AND INCIDENCE OF VENOUS THROMBOEMBOLISM (VTE) IN PATIENTS WITH HEMATOLOGICAL MALIGNANCIES AND RELATION TO LABORATORY BIOMARKERS: AN UPDATE OF A SINGLE CENTER STUDY
S Elmoamly[1,*], M Mattar[1], S N Amin[2], M F Yacoub[1], A Afif[2]
[1]Internal Medicine & Hematology department, [2]Clinical pathology department, Kasr Alainy Faculty of Medicine, Cairo University, Giza, Egypt

Background: Venous Thromboembolism (VTE) is a well-recognized complication of cancer, which aggravates the clinical course and leads to additional morbidity and increased mortality. However, primary thrombophrophylaxis in cancer patients is challenging, as the risk of VTE is not equal in all patients, and as anticoagulation in those patients is associated with increased bleeding complications compared with patients without cancer.
Aims: to study whether vascular and inflammatory biomarkers (as well as clinical variables) can be used as predictors of mortality and VTE in patients with hematological malignancies.
Methods: This study is a prospective observational cohort study; it was conducted on a group of 171 patients with malignant hematological conditions. They have been followed up for an average period of 416.82 days with an endpoint of mortality or VTE. **Exclusion criteria included** Overt infection within the last 2 weeks, Venous or arterial thromboembolism within the last 3 months, continuous use of oral or subcutaneous anticoagulants. Hypercoagulability and inflammation were assessed at the initiation of the study by measuring the circulating levels of the following parameters: Coagulation and fibrinolysis activation markers (D-dimer, Fibrinogen, Antithrombin, plasminogen activator inhibitor 1 [PAI-1]); Endothelium and platelet activation markers(von Willebrand Factor [vWF], soluble P-selectin); and inflammation markers (Tumor necrosis factor α, Interleukin-6).
Results: Out of 171 patients, 48 (28.1%) were diagnosed to have Lymphoproliferative disorders, 40 (23.4%) were diagnosed to have Myeloproliferative neoplasms, 38 (22.2%) were diagnosed to have AML (or MDS progressed to AML), 19 (11.1%) were diagnosed to have ALL, 26 (15.2%) were diagnosed to have Paraproteinaemias. Incidence of symptomatic VTE in patients with hematological malignancies was 7%. There were statistically significant

associations between mortality and ECOG performance status (P value:<0.001), presence of co morbidities (P value: 0.047) duration of hospital stay (P value: 0.006), Hemoglobin level (P value: 0.003), platelet count (P value: 0.001), serum albumin (P value: 0.011), ESR (P value: 0.004), Antithrombin (P value: 0.012), vWF (P value: 0.002). For prediction of mortality, ROC Curve of Albumin level showed that a level of 3.35 g/dl showed the highest likelihood ratio (LR) of 1.78 with sensitivity of 62.7% and specificity of 64.8%. ROC Curve of ESR showed that a level of 118 mm/hr showed the highest LR of 1.52 with sensitivity of 57.9% and specificity of 62%. ROC Curve of Antithrombin level showed that a level of 16.25 mg/dl showed the highest LR of 1.34 with sensitivity of 55.9% and specificity of 61%. ROC Curve of vWF level for showed that a level of 1.87mU/ml showed the highest LR of 1.35 with sensitivity of 64.9% and specificity of 52%. There were statistically significant associations between VTE occurrence and CVAD insertion (P value: 0.014), Prothrombin time (P value: 0.037), ESR (P value: 0.05). For prediction of VTE occurrence, ROC Curve of ESR showed that a level of 106.5 mm/hr showed the highest LR of 1.44 with sensitivity of 66.7% and specificity of 53.8%.

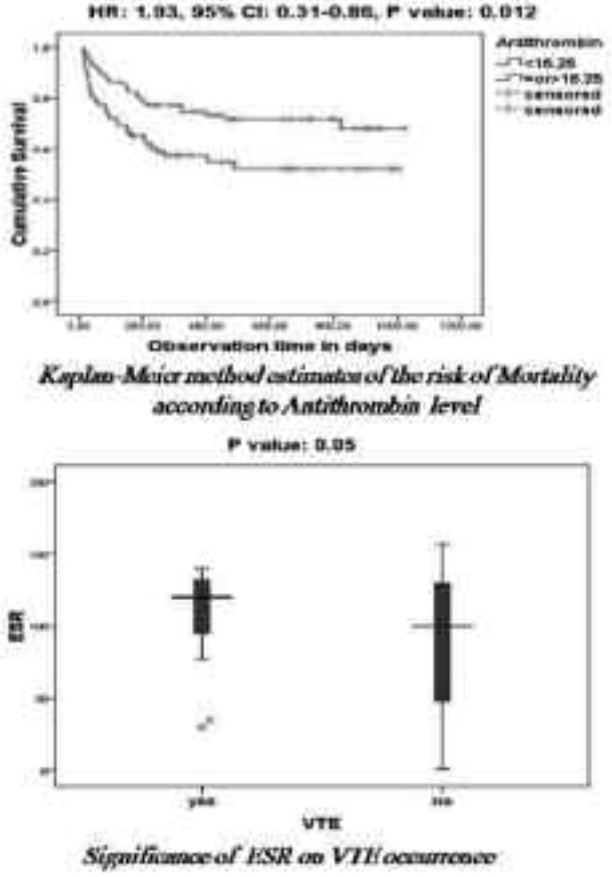

Figure 1.

Summary and Conclusion: Incidence of symptomatic VTE in patients with hematological malignancies was 7%. Initial Poor ECOG performance status, presence of co morbidities, duration of hospital stay, Hemoglobin level, platelet count and initial levels of Albumin below 3.35g/dl, ESR above 118 mm/hr, Antithrombin below 16.25 mg/dl, vWF above 1.87mU/ml are associated with poor outcome with increased mortality. There were statistically significant associations between VTE occurrence and CVAD insertion, Prothrombin time, ESR. ESR above 106.5 mm/hr is associated with increased VTE occurrence.

P1266

GENETIC AND ACQUIRED PREDICTORS OF POSTTHROMBOTIC SYNDROME IN YOUNG PATIENTS WITH DVT IN THE NORTH-WEST REGION OF RUSSIA

A Demyanenko[1,*], S Kapustin[2], P Chechulov[1]
[1]Vascular surgery, Emergency research institute, [2]vascular biology, 2Russian Research Institute of Hematology and Transfusiology, St. Petersburg, Russia, St. Petersburg, Russian Federation

Background: Postthrombotic syndrome (PTS) is frequent and severe complication of deep vein thrombosis (DVT), which leads to a resistant disability. The role of acquired and hereditary risk factors in formation of PTS is studied insufficiently.
Aims: To identify genetic and acquired predictors of severe PTS in young patients with DVT originated from the North-Western region of Russia

Methods: Retrospective «case-control» study included 120 adults up to 45 years old (men − 57, women − 63, middle age − 37.4) with DVT diagnosed during the period from 2000 to 2011. For grading PTS, we used the clinical scale of chronic venous insufficiency ($CEAP_{0-6}$). Sixty seven (55.8%) patients were genotyped for nine polymorphisms: factor I (FI) –455 G/A, FI Thr312Ala, FII 20210 G/A, FV 1691 G/A, FXII 46 C/T, FXIII Val34Leu, PAI-1 –675 4G/5G, TPA 311 bp I/D, EPCR Ser219Gly, that were discriminated by PCR-RFLP method. All results were analyzed with the SPSS software version 17.0 (SPSS Inc, Chicago, IL, USA).The differences in genotype distributions were estimated by Fisher's exact test with calculating odds ratios (OR), their 95% confidence intervals (CI) and p-value. The discriminant function analysis was used to define the predictors of severe PTS
Results: Severe PTS ($CEAP_{4-6}$) was registered in 15 out of 67 patients (22.4%). The risk of severe PTS was increased dramatically in patients with established genetic risk factors, in particular, G20210A mutation (OR=4.3; 95%CI: 1.3-14.1; p=0.01), FV Leiden variant (OR=2.6; 95%CI: 0.9-7.1; p=0.057) and the homozygous FXIII 34Leu/Leu genotype (OR=6.9; 95%CI: 0.7-67.5; p=0.057). However, the discriminant function analysis with inclusion of additional criteria (clinical and acquired) had shown that none of these DNA variations played a significant role in the outcome of DVT: FV 1691GA (p=0.160), FII 20210GA (p=0.501), FXIII 34Leu/Leu (p=0.141). On the contrary, such external factors as recurrence of DVT on the same leg (p=0.075), obesity (p=0.002), varicose veins (p=0.087) and short courses of anticoagulant therapy (less than 3 months) (p=0.030) were associated with the risk of severe PTS
Summary and Conclusion: Genetic variations FII 20210 G/A, FV 1691 G/A and FXIII 34Leu/Leu can increase the risk of severe PTS but, probably, don't play a crucial role in the development of this complication. Instead, short courses of anticoagulant therapy (less than 3 months), obesity, ipsilateral recurrence of DVT and varicose veins may be predictive factors for PTS.

P1267

EFFICACY, SAFETY AND CLINICAL MANAGEMENT OF THE NEW GENERATION ORAL ANTICOAGULANTS (NOAS) IN THE CLINICAL PRACTICE: "THE REAL LIFE COHORT STUDY"

P Olivera[1,*], I Valcarce[1], R García-Consuegra[1], L López-Andreoni[1], V Pons[1], F Bosch[1], A Santamaría[1]
[1]Department of Hematology, University Hospital Vall d'Hebron, Barcelona, Spain

Background: The NOAs in clinical trials have shown to be at least as effective and safe as warfarin for stroke prevention in non-valvular atrial fibrillation (NVAF).
Aims: In our centre, we have initiated "The Real Life Cohort study" which is an ongoing observational cohort study to analyse the efficacy and safety as well as other clinical aspects such as bridging therapy of NOAs after their introduction in daily clinical practice since they have been approved in Spain.
Methods: Since 2010 we have included consecutively patients under treatment with NOAs. Inclusion criteria were patients with NVAF, with or without a history of stroke. Exclusion criteria are those who do not meet the criteria for the prescription of the Catalan Institute of Health. All of them gave their informed consent. Follow-up consisted in outpatient visits each 3 months and thereafter efficacy and safety data were collected.
Results: Until October 31th 2013, 184 patients have enrolled in our registry. Out of these, 93 (50.5%) patients received dabigatran, 72 (39.1%) received rivaroxaban and 19 (10.3%) received apixaban. Median age of 77 years-old (range: 24-94) with 51.6% females; 82% of the patients had a CHA2DS2-VASc score greater than or equal to 3, the 75% a HASBLED score greater than or equal to 3. During follow-up, in the dabigatran group, ischemic strokes occurred in 4.3% (n=4) and only one of them with 150 mg. Twenty five patients (26.8%) reported bleeding complications (60% minor, 28 % non-major, clinically relevant and 12% major bleeding). For non-major bleedings, mucosal and gastrointestinal bleeding were the most common bleeding sites (72% of all bleedings), in our cohort occurred mostly in patients with doses of 110 mg. Patients with CNS hemorrhage (n=2) received prothrombin complex concentrate with good evolution. The non-hemorrhagic adverse envents were: dyspepsia 15%, diarrhea 2.2%, urticaria 2.2% and peripheral edema 1.1%. As rivaroxaban an apixaban were approved later, results from these cohorts are still under the observational period.
Summary and Conclusion: The preliminary results of the ongoing "REAL LIFE" Cohort study in the dabigatran group showed that are higher incidence of ischemic stroke and total bleeding compared with those published in clinical assays. Although we have no data from other groups, this study will give us some clues about the behavior of these NOAs and their best management in "REAL LIFE".

P1268

COST-EFFECTIVENESS OF EDOXABAN, APIXABAN, RIVAROXABAN AND DABIGATRAN VERSUS WARFARIN FOR STROKE PREVENTION IN NONVALVULAR ATRIAL FIBRILLATION

M Marchetti[1,*], N L Liberato[2], C Rognoni[3], S Quaglini[3]
[1]Hematology Unit, Ospedale Cardinal Massaia, Asti, [2]Medicine Unit, Az Ospedaliera Pavia, Casorate Primo, [3]Department of Electrical, Computer and Biomedical Engineering, University of Pavia, Pavia, Italy

Background: Non-valvular atrial fibrillation (NVAF) causes one fifth of overall ischemic strokes, therefore, oral anticoagulation with warfarin is recommended since it can prevent about one third of the events. Novel oral anticoagulants (NAO), *i.e.* oral inhibitors of thrombin or factor Xa, compete with warfarin in this setting since a simplified monitoring is required and intracranial beedings are significantly reduced.
Aims: We aimed at assessing the cost-effectiveness of NAOs (dabigatran, apixaban, rivaroxaban, edoxaban), *versus* warfarin, for stroke prevention in NVAF patients with CHADS2 score ≥2.
Methods: We built a Markov decision model including 11 health-states. Quarterly transition probabilities among states were estimated based on data from published randomized trials. Quality of life estimations for each event or health-state were derived from reference studies. For each therapeutic strategy, the model estimated expected quality-adjusted life-years (QALY) in the lifetime horizon. The economic analysis was performed in the perspective of the Italian National Health System. Quarterly drug cost of NAOs was €198 *versus* €3.9 of warfarin. Future life years and costs were discounted by 3.5% per year, according to international guidelines. Incremental cost per QALY gained (ICUR) as compared with warfarin was calculated for each NAO. First- and second-order (probabilistic) sensitivity analyses were run. The model was developed and run by TreeAge SW.
Results: NAOs increased quality-adjusted life expectancy by 0.405-0.753 discounted years, as compared with warfarin. Incremental lifetime health-care costs of patients assigned to NAOS ranged from €3,439 to €4,923. The cost-effectiveness of NAOs *versus* warfarin ranged from €4,567/QALY (80%CI: 2,129-8,993) for apixaban to €12,156/QALY (80%CI: 5,147-33,200) for rivaroxaban. Dabigatran and edoxaban reported intermediate ICUR values: €6,307/QALY (80%CI: 3,034-13,421) and € €7,713/QALY (80%CI: €3,909-€17,963), respectively. Second-order sentivity analysis showed that the results were robust: over 90% of the simulations provided an incremental-cost-effectiveness ratio lower than €50,000/QALY, irrspectively of the NAO being compared with warfarin. The results were sensitive to the time in warfarin therapeutic range, the analysed time horizon, and the impact of anticoagulants onto quality of life. NAO cost variation by 20% induced ICUR variations by about €3,000/QALY.
Summary and Conclusion: NAOs are cost-effective drugs for stroke prevention in moderate-high risk patients with NVAF. Lacking head-to-head studies, the relative cost-effectiveness of one NAO *versus* another one is surrounded by a wide undcertainty. Economic sustainability of widespread NAO adoption in industrialized countries still needs to be assessed, therefore phase 4 studies should investigate clinical and economic outcomes in specific patient subgroups, *i.e.* warfarin-treated patients with a high rate of time-in-treatment-range.

P1269

ECONOMIC VALUE CREATED BY ADDING RITUXIMAB TO CHEMOTHERAPY IN THE UNITED STATES FROM 1998-2013

C Reyes[1,*], M Danese[2], M Gleeson[2], M Halperin[2], S Skettino[3], J Mikhael[4]
[1]Genentech Inc, South San Francisco CA, [2]Outcomes Insights, Westlake Village CA, [3]Genentech, Inc, South San Francisco CA, [4]Mayo Clinic, Scottsdale AZ, United States

Background: Rituximab has become the standard in diffuse large B-cell lymphoma (DLBCL), follicular lymphoma (FL), and chronic lymphocytic leukemia (CLL). The incremental cost of adding rituximab to existing chemotherapy and the value of the life years saved have not been estimated at the population level.
Aims: Our objective is to estimate the net economic value of rituximab in the United States for policy decision-makers.
Methods: We constructed a population effectiveness model from 1998-2013. Age group, gender, and year-specific incidence rates for each cancer were estimated from the Surveillance, Epidemiology, and End Results (SEER) program. Incidence rates were multiplied by Census estimates to calculate total diagnosed patient counts. Utilization, survival and cost inputs were estimated using SEER Medicare merged data for patients diagnosed 1999-2009 and followed through 2010, extrapolated through 2013. First-line utilization of rituximab plus chemotherapy (R+Chemo) and Chemo Alone were calculated as a proportion of all diagnosed patients to estimate treated patient counts. Differences in mean survival between R+Chemo and Chemo Alone for each cancer were estimated using flexible parametric survival models. The incremental cost of R+Chemo *versus* Chemo Alone for each cancer was based on Medicare paid amounts for all Part A and B services using regression, accounting for censoring. Costs were computed over 72-months to capture short and long-term effects, and inflated to 2013 US dollars. The value of a life year saved ($90,941 in 2013 dollars) was based on published literature (Lee, *et al.* 2009). Monte Carlo sampling was used to estimate the 95% uncertainty intervals (UI).
Results: Across all three cancers from 1998 to 2013, there were 280,819 cumulative life years saved (95% UI, 269,136-293,345). The additional total costs of care for R+Chemo were $33,525, $23,511, and $31,435 in DLBCL, FL, and CLL, respectively. Across all 3 tumors, the incremental direct medical cost of R+Chemo compared to Chemo Alone was $7.0 billion (95% UI $5.8-$8.2 billion), and the resulting economic value of the life years saved was $25.5 billion (95% UI $11.7-$69.1 billion).
Summary and Conclusion: For DLBCL, FL and CLL patients treated with R+Chemo in the US from 1998-2013, 281,000 life years were saved that created a net economic value of $18.5 billion.

P1270

COST-EFFECTIVENESS ANALYSIS OF BENDAMUSTINE PLUS RITUXIMAB AS FIRST-LINE TREATMENT FOR PATIENTS WITH FOLLICULAR LYMPHOMA. PRELIMINARY RESULTS

E Sabater[1], A Rueda[2], A Salar[3], A López-Guillermo[4], I Oyagüez[1], JM Collar[5,*]
[1]Pharmacoeconomics & Outcomes Research Iberia, Madrid, [2]Oncology Department, Hospital Costa del Sol, Marbella, [3]Hematology Department, Hospital del Mar, [4]Hematology Department, Hospital Clinic, Barcelona, [5]Medical Department, Mundipharma Pharmaceuticals, Madrid, Spain

Background: Follicular lymphoma (FL) is the most common type of indolent non-Hodgkin´s lymphomas (NHL), and despite substantial improvement in survival, it is usually incurable in most cases. The disease characteriscally responds well to first-line therapy but typically manifests repeated relapses with the need of recurrent therapeutic interventions, with disease-free intervals. Patients with FL in advanced stages and high-tumour burden usually receive front-line chemoimmunotherapy, rituximab (R) + chemotherapy, during the so called induction phase, followed by maintenance therapy with R in patients who achieve at least a partial response after the induction phase, as it is recommended by several Clinical Guidelines.
Aims: To evaluate the cost-effectiveness of rituximab-bendamustine (R-B) compared with R-CHOP (rituximab, cyclophosphamide, doxorubicin, vincristine, prednisone) as first-line treatment for patients with advanced FL in Spain.
Methods: A Markov model was built to simulate a patient cohort with FL during a time horizon of 25 years (4 weeks-cycle length). Clinical data were adapted from two phase III randomized trials, one with the FL patients analyzed by the German Study group indolent Lymphomas (StiL) which compared R-B with R-CHOP during the induction phase, followed by the data obtained in the PRIMA trial during the maintenance therapy with R. Four health states were considered: progression-free survival (including induction and maintenance), first relapse, second relapse and death. Transition probabilities were obtained from progression-free survival curves available in the literature. Mortality rates were obtained from GLOBOCAN registry and from recently published epidemiological data after the "rituximab era". The Study Perspective was the Spanish National Health System (NHS) and only direct healthcare costs were considered. Resources consumed during patients treatment and follow-up where identified by panel of Spanish experts in FL. Unitary costs were obtained from the Drug Catalogue and e-Salud Database. Drug costs were calculated based on ex-factory prices with mandatory 7.5% rebate. All costs were updated to € 2013. Utilities for each health state were obtained from the literature. The final efficacy measure was quality-adjusted life-years (QALYs). Costs and health outcomes were discounted at a 3% annual discount rate. To check for the robustness of the results, a probabilistic sensitivity analysis was performed with 10,000 Monte Carlo simulations.
Results: The initial treatment and administration costs during the induction phase were higher with R-B (€16,481.63) compared to R-CHOP (€10,793.97). Nevertheless, at the end of the 25 year period, in the deterministic analysis, and considering only the GLOBOCAN registry mortality rate, R-B first line strategy accounted a total cost of €686,848.46 compared to €725,450.80 for R-CHOP. Health benefits measured as QALYs was higher in R-B with 14.25 QALYs than in R-CHOP with 13.95 QALYs. In the probabilistic analysis, R-B was a dominant strategy compared to R-CHOP in 99.9% of the simulations.

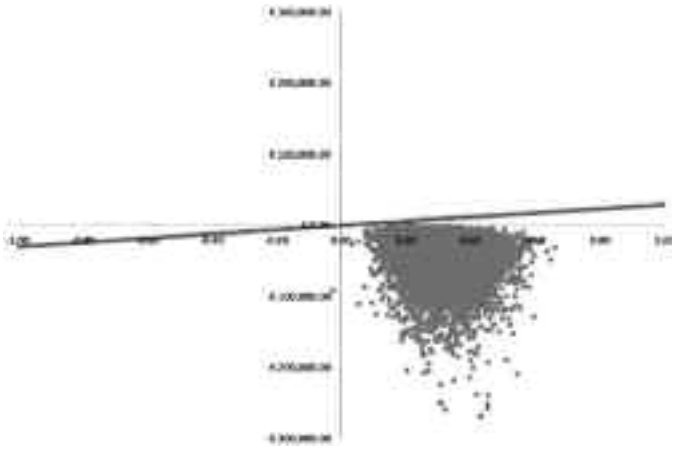

Figure 1.

Summary and Conclusion: First line treatment with R-B in FL patients is a dominant strategy compared to R-CHOP, showing cost savings and higher health benefits for the Spanish NHS, despite its higher initial cost.

P1271

IS OBINUTUZUMAB COST-EFFECTIVE FOR PREVIOUSLY UNTREATED CHRONIC LYMPHOCYTIC LEUKEMIA IN THE UNITED STATES?

C Reyes[1,*], D Veenstra[2], S Ramsey[3]
[1]Genentech, Inc, South San Francisco CA, [2]University of Washington, [3]Fred Hutchinson Cancer Research Center, Seattle WA, United States

Background: Obinutuzumab, also known as GA101 (G), is a novel therapy shown to have improved PFS in combination with chlorambucil (GClb) compared to rituximab + chlorambucil (RClb) in the recent CLL-11 trial for previously untreated CLL. The incremental value of G *vs*. rituximab (R) has not been studied.
Aims: The objective is to evaluate the cost-effectiveness of GClb *vs*. RClb in the United States for previously untreated CLL.
Methods: Patient outcomes were simulated using a 3-state Markov model that included PFS, progression, and death. The patient population was assumed to be analogous to that studied in the CLL-11 trial. Efficacy parameters were 1) probability of progression, and 2) probability of dying after disease progression. The model parameters were fitted to the observed trial data. Drug utilization and adverse events were incorporated based on trial data, and costs were based on Medicare reimbursements and drug wholesale acquisition costs. Sensitivity analyses were conducted to assess uncertainty in the results.
Results: Treatment with GClb led to an increase in average life years (+0.61y) and quality-adjusted life years (QALYs)(+0.56 y) relative to RClb, respectively. The average total costs were similar, with higher drug and adverse event costs for GClb being offset by higher cost of disease progression with RClb.

Table 1.

Outcome	GClb	RClb	Difference
Average life years	5.05	4.44	0.61
Average QALYs	3.36	2.80	0.56
Total drug cost	$37,460	$34,875	$2,585
Drug administration	$1,134	$803	$330
Supportive care	$128	$75	$52
Adverse events	$9,851	$6,766	$3,085
Cost of progression	$40,004	$46,075	-$6,070
Average total cost	$88,577	$88,595	-$18

In probabilistic sensitivity analyses, the difference in QALYs ranged from 0.03 to 1.02, and the difference in total cost ranged from approximately -$53,000 to $56,0000. There was an 89% probability that G+Clb was cost-effective at the $100,000 per QALY threshold.
Summary and Conclusion: Based on the results of the CLL-11 trial, our analysis suggests treatment with GClb compared to RClb is likely cost-effective. Further analyses based on indirect comparisons with other treatment options, as well as updated follow-up data, will help inform coverage and reimbursement policy decisions.

P1272

HOME CARE MANAGEMENT FOR HEMATOLOGICAL PATIENTS: RESULTS OF A SURVEY CONDUCTED ON A REGIONAL SCALE BY THE R.E.D.E.R. NETWORK

P Alfieri[1,*], G Daghia[2], A Dizdari[3], N Lombini[4], G Pelloni[5], O Sofritti[2], E Tamagnini[6], L Vignolo[6], V Favale[1]
[1]Servizio di Cure Domiciliari AIL Modena Onlus, U.O. Ematologia - Azienda Ospedaliero-Universitaria Policlinico, Modena, [2]Assistenza Domiciliare AIL Ferrara, U.O. Ematologia - Arcispedale Sant'Anna, Ferrara, [3]Assistenza Domiciliare BolognAIL Onlus, U.O. Ematologia "Seragnoli" - Policlinico S. Orsola-Malpighi, Bologna, [4]Assistenza Domiciliare AIL Forlì Cesena, Forlì, [5]Assistenza Domiciliare Ravenna AIL, U.O. Ematologia - Azienda Ospedaliera, Ravenna, [6]Assistenza Domiciliare GRADE, U.O. Ematologia - Arcispedale Santa Maria Nuova, Reggio Emilia, Italy

Background: In the last decade home care has achieved a relevant role in the global management of patients with blood malignancies reducing heath care costs, improving quality of life and preventing discomfort due to prolonged hospitalization, driving distances and long waiting times. Owing to the empirical nature of these evidences, few data have been published in this setting of care and some clinical issues remain unexplored.
Aims: In order to collect experiences and promote mutual partnership in the field of home care for unfit and frail hematological patients, the R.E.D.E.R. project ("Rete Ematologica Domiciliare Emilia-Romagna") was informally established in 2013 by six groups operating in the Italian region Emilia-Romagna on behalf of six local no-profit associations directly involved in sustaining domiciliary programs of supportive and palliative care (Bologna=BO, Ferrara=FE, Forlì=FC, Modena=MO, Ravenna=RA, Reggio Emilia=RE).
Here we present the results of a preliminary survey conducted with the purpose to evaluate the main key activity indicators in this setting of care.
Methods: At the beginning of 2014 each consultant hematologist representing a group was requested to fill a multiple-items form divided in two sections: in the first one it was required to indicate the overall number of patients enrolled during 2013 and their outcome; in the second section doctors were asked to "take a snapshot" of their activity and provide an overview at that precise moment focused on clinical features of patients, transfusion requirements, use of central venous catheters and incidence of pain.
Results: During the year 2013 a total of 521 hematology patients (BO=115, FE=50, FC=71, MO=170, RA=26, RE=89) was referred to the home care network. 271 were newly-referred patients, 250 were patients already followed in the previous years. 195 (37.4% of all patients) died as part of the home care cycle, 86 at home (44.1%) and 109 in hospice or in a hospital ward (55.9%). 42 patients (8%) were referred back to the hospital hematology unit. At the beginning of 2014 the total of patients assisted simultaneously was 274. The median age was 78.4 with a 47/53% male/female gender distribution. According to the phase of disease and to the type of treatment 90 patients (32.8%) were still under active therapy, 123 (44.9%) were chronically ill, 61 (22.3%) were terminally ill. According to diagnosis there were 56 patients with myelodisplastic syndromes (MDS=20.4%), 51 with lymphoma (NHL/HL=18.6%), 48 with myeloma (MM=17.5%), 44 with chronic myeloproliferative neoplasms (MPN=16.2%), 31 with acute leukemia (AML/ALL=11.1%), 44 with other blood malignancies or benign conditions (other=16.2%). 107 patients (39.1%) were transfusion-dependent (BO=27, FE=7, FC=13, MO=28, RA=5, RE=27), 34 needing both packed red blood cells (RBC) and platelets concentrats (PC), 70 only RBC, 3 only PC. 14 patients (13.1%) had transfusion requirement of at least 2 RBC units per week. 11 patients (10.3%) were under iron chelation therapy. A central venous line was available for 32 patients (PICC=24, Hickman=6, Port-a-cath=2). 65 patients (23.7%) needed around-the-clock opiod drugs for moderate-to-severe pain management (oxycodone+/-naloxone=37, transdermal fentanyl=13, continuous subcutaneous morphine=12, other=3).
Summary and Conclusion: In Emilia-Romagna home care management for hematological patients is almost entirely financed by no-profit fundraising organizations, without which hundreds of unfit and frail patients would inevitably redound upon hospital wards, day units and outpatient clinics. The R.E.D.E.R. network project, open to new entries and new challenges, was conceived with the primary goal, on a local/regional scale, to update the state-of-the-art, share professional expertise, perform cost-benefit analysis and eventually provide guidelines on best practices (quality-of-life assessment, home transfusions, end-of-life care).

P1273

SENSITIVITY COST ANALYSIS OF TYROSINE KINASE INHIBITORS IN PHARMACOECONOMIC MODELING OF CML TREATMENT

V Shuvaev[1,*], I Martynkevich[1], A Schmidt[1], M Fominykh[1], K Abdulkadyrov[1]
[1]Russian Research Institute of Hematology and Transfusiology, Saint-Petersburg, Russian Federation

Background: The use of second-generation tyrosine kinase inhibitors (TKI) in treatment of newly diagnosed chronic myelogenous leukemia (CML) patients showed their advantages over imatinib in respect of tolerability, rate and

promptness of deep molecular responses obtaining. Long lasting complete molecular response (CMR) is a major predisposing factor for successful cessation of TKI. The main obstacle for the wide use of second generation TKIs in first-line setting is their higher cost in comparison with imatinib. The TKI cost may change dramatically in the nearest future due to marketing policy, generic substitution, etc. Pharmacoeconomic modeling of CML treatment can establish limits when various strategies will become cost saving.

Aims: The aim of our study was to conduct sensitivity analysis of TKI costs in CML treatment.

Methods: We have used previously constructed Markov chain models[1] to compare CML first-line treatment strategies with imatinib or nilotinib with subsequent therapy cessation in cases of CMR. The input parameters and transition rates were selected from several clinical trials (IRIS, ENESTnd, DASISION, ENACT, CA180013, STIM, FILMC group), our own data, and experts' opinions. We have chosen the model population size of 800 newly diagnosed CML patients in Russian Federation annually. 20-years' time horizon was used. We calculated total cost for the next twenty-year period (2014-2033) including the expenses for existing and newly diagnosed CML patients. We have recalculated the total cost in Euros to make our results more representative. Simulation model was used for statistical analysis.

Results: The different TKIs prices substitution allowed us to construct the function of cost-saving limits. The function plot presented on fig.1. The first-line treatment with Nilotinib was always cost-saving in case of Imatinib price is more than half-price of Nilotinib.

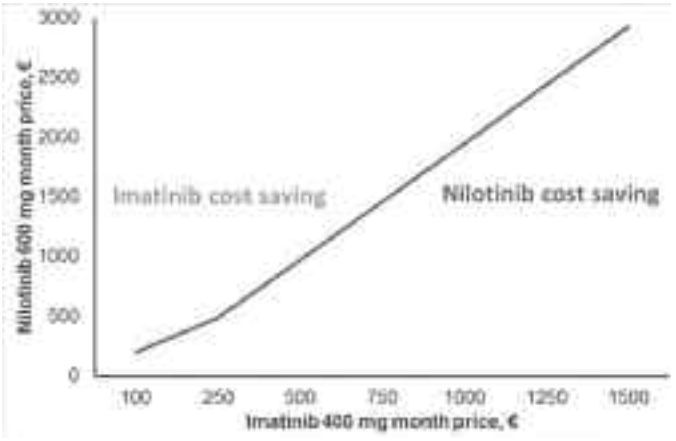

Figure 1. Cost saving function plot for Nilotinib and Imatinib first-line in CML treatment

Summary and Conclusion: Sensitivity analyses in pharmacoeconomic modelling can establish limits when one treatment strategy have some advantages over another one. The results of such analyses could be of value for decision-making process for healthcare authorities.

DIRECT COST ANALYSIS ABOUT THE THREE CHELATORS FOR THE TREATMENT OF THALASSEMIA PATIENTS WITH CHRONIC IRON OVERLOAD: AN ITALIAN PERSPECTIVE FROM THE MIOT NETWORK

A Pepe[1,*], A Meloni[1], G Rossi[2], A Cardinale[3], A Pietrapertosa[4], G R Giugno[5], P Preziosi[6], S Renne[7], C Salvatori[8], A Filosa[9]

[1]Cardiovascular MR Unit, Fondazione G. Monasterio CNR-Regione Toscana, [2]Epidemiology and Biostatistics Unit, Institute of Clinical Physiology, CNR, Pisa, [3]UO Pediatria, Ospedale S Maria alla Gruccia, Montevarchi, [4]Servizio Regionale Talassemie, Policlinico di Bari, Bari, [5]U.O.C. Pediatria e neonatologia, AO Gravina, Caltagirone, [6]U.O.C. Diagnostica per Immagini e Interventistica, Policlinico "Casilino", Roma, [7]Struttura Complessa di Cardioradiologia, P.O. "Giovanni Paolo II", Lamezia Terme, [8]Unità Operativa Sistemi Informatici, Fondazione G. Monasterio CNR-Regione Toscana, Pisa, [9]UOSD Centro per le Microcitemie, AORN Cardarelli, Napoli, Italy

Background: In thalassemia major (TM) three iron chelators in monotherapy are available to treat chronic iron overload due to blood transfusions: subcutaneous desferrioxamine (DFO) introduced in the 1960s, oral deferiprone introduced in 1999 and oral deferasirox (DFX) licensed in 2006. Nowadays pharmacoeconomics analysis are frequently required by the health authorities due to the actual economic crisis. The aim should be to ensure to the whole community the sustainability for health care of proved quality.

Aims: The objective of this study was to determine the costs of the three chelators in monotherapy in a cohort of 193 TM patients followed prospectively for 18 ± 3 months.

Methods: Within the MIOT (Myocardial Iron Overload in Thalassemia) network, we evaluated prospectively 193 TM patients who had been received one chelator alone between the 2 Magnetic Resonance scans and we calculated the direct costs (drug, administration and monitoring) for each patient treated with DFX, DFO and DFP. We used the cost values for the year 2007. For the drugs we considered the cost ex-factory. For the oral chelators the administration cost was considered null. For the DFO we calculated the costs for the administration (pump, infusion set, syringes and gauzes) using the tariffs applied in Veneto Region, Italy. For the monitoring costs we considered the exams suggested in the technical sheet for each drug; we considered the tariffs by the Veneto Region, Italy. In Italy Veneto Region was proved to be one of the most upright region in the health costs management. In the analysis we considered the drug cost for the standard dosage reported in the technical sheet: 40 mg/kg/d for DFO, 75 mg/kg/d for DFP and 30 mg/kg/d for DFX. Based on the mean weight of the patients we referred the drug cost to a patient of 60 Kg.

Results: In the clinical practice the dose of DFX was 26±7 mg/kg/d, DFP was 73±13 mg/kg/d and DFO was 41±6 mg/kg for 5.5 d/wk. Excellent/good levels of compliance were similar in the 3 groups (DFX 99%, DFP 95%; DFO 96%, P=0.6). The cost/mg was € 0.006 for Generic DFO, € 0.003 for Ferriprox® (DFP) and € 0.047 for Exjade® (DFX). For 18 months of treatment the total costs for DFO were € 10.465,8 (administration and monitoring costs € 3.965,1 + drug cost 6.500,7), for DFP were € 8.292,9 (administration and monitoring costs € 460,8 + drug cost 7.832,2), for DFX were € 46.461,2 (administration and monitoring costs € 211,14 + drug cost 46.249,8). The details about the administration and monitoring costs for DFO, DFP and DFX are reported in the table.

Table 1.

	Unit Cost (€)	Number /year	Cost/ 18 months (€)

DFP			
Neutrophil count	4.35	52	339.3
Serum creatinine	1.6	12	27.9
AST and ALT	5.2	12	93.6
DFX			
Audiometry	18.6	1	27.9
Ophthalmology	18.6	1	27.9
Serum creatinine	1.55	17	39.5
Proteinuria	1.3	12	22.5
AST and ALT	5.2	12	93.6

Summary and Conclusion: In this analysis, for managing chronic iron overload the direct costs for oral DFP appeared to be the less expensive. The limit of this study is that a cost-utility analysis taking into account efficacy, adverse events and route of administration was not performed.

P1275

TREATMENT PATTERNS OF PATIENTS WITH CLL INCLUDING PATTERNS OF RITUXIMAB USE BY CLINICIANS ACROSS FIVE EUROPEAN COUNTRIES: REAL WORLD EVALUATION UTILIZING IPSOS HEALTHCARE SURVEY

L Ysebaert[1], A Yong[2,*], S Stilgenbauer[3]

[1]Centre de Recherches en Cancérologie de Toulouse, Toulouse, France, [2]Medical Affairs Oncology, Gilead Sciences, Uxbridge, United Kingdom, [3]Internal Medicine III, Ulm University, Ulm, Germany

Background: Chronic lymphocytic leukemia (CLL) is a disease that predominantly afflicts the elderly and represents the most common leukemia in Europe. CLL is considered incurable and is characterized by disease relapses and refractoriness to earlier lines of treatments. Anti-CD20 agents, such as rituximab is commonly used for CLL treatment. In several real world studies, rituximab is frequently used as single agent and in combination therapy with other agents in the US for elderly or unfit CLL patients. In Europe, rituximab is also recommended for use in combination therapy but no real world usage pattern in Europe has been reported.

Aims: We sought to evaluate the real-world treatment patterns of CLL examining the use of treatment agents and regimens in all lines of treatment across five European countries during the years of 2012-2013.

Methods: IPSOS Healthcare Global Oncology Monitor conducted a survey of 509 oncologists across Germany, France, UK, Spain and Italy who completed

patient chart review and provided information on how they managed patients in everyday practice. Of these, 104 physicians provided CLL patient information across first, second and third-line CLL treatments.
Results: Survey data estimated approximately 37,119 patients who received treatment for CLL in a period from July 2012 to June 2013. Patients receiving treatment were predominantly male (62.3%), with a total population mean age of 71 years. Patients treated were of ECOG performance status 0 (33.9%), 1 (51.9%), 2 (10.8%) and 3 (0.65%). The majority of these patients (23.1%) were estimated to have received fludarabine-cyclophosphamide-rituximab followed by bendamustine-rituximab (17.4%), chlorambucil (16.2%), fludarabine (7.2%), single-agent rituximab (5.8%), and chlorambucil-rituximab (5.6%). The data show higher rituximab monotherapy share in later lines of therapy for CLL (first line, 0.3%; second line, 8.2%, third line or more, 22.1%) irrespective of age. In later lines of therapy, rituximab monotherapy (22%) treatment was the second most commonly used treatment option after bendamustine plus rituximab (31%), followed by chlorambucil monotherapy (9%), prednisolone (7%) and ofatumumab (6%). Patients who received rituximab monotherapy had a mean age of 70.2 years. 70% and 26% of these patients were of ECOG performance status 0 and 1, respectively. The most commonly reported co-morbidities were hypertension (24%), diabetes (13%) and cardiovascular disease (12%).
Summary and Conclusion: This survey has shown that there is a wide range of CLL treatment regimens used across Europe, over different lines of treatment. The most commonly used anti-CD20 is rituximab, which is utilized either in combination therapy or as single agent. Single agent rituximab is increasingly more commonly used in later lines of treatment. Real world results such as this may be useful in helping the design of appropriate clinical trial programs or in interpreting their subsequent outcomes.

P1276

PATTERN OF ADVERSE DRUG REACTIONS IN ONCO-HEMATOLOGIC PATIENTS: RESULTS FROM THE ITALIAN PHARMACOVIGILANCE PROJECT NAMED "FARMAREL"

N S Fracchiolla[1,*], S Artuso[1], A Cortelezzi[1], G Muti[2], C Bacci[3], G Berini[4], F Bocchio[5], D Boghi[6], M Bonfichi[5], C Corti[7], E De Rosa[8], N Frungillo[9], R Gaiardoni[10], L Gargantini[8], G Gritti[11], C Grumi[12], E Lanzi[13], M L La Targia[4], M Magagnoli[14], M C Pasquini[15], A Pastore[6], A M Pelizzari[16], L Prestini[17], Quaresmini[11], A Ragazzi[18], S Sammassimo[9], M C Vilardo[19], S Voltolini[10], A L Rivolta[20]

Background: Adverse drug reactions (ADRs) are an important cause of hospitalization and inpatient complications. Probability of ADRs occurrence in onco-hematologic patients is notable, as they are treated with multiple antineoplastic agents within complex therapeutic schedules. Post marketing spontaneous reporting of ADRs is crucial for a deeper knowledge of drugs safety profile, once they are used in real clinical practice, but it is not widespread.
Aims: The Italian regional project FarmaRel has been implemented to create awareness on the importance of ADR monitoring and to encourage the voluntary reporting culture among onco-hematology health care professionals.
Methods: In 13 Haematology Units, an "ADR monitor" has been designed with specifically allocated grants to promote pharmacovigilance procedures among clinicians and nurses and supporting them in ADRs reporting. A retrospective analysis of all ADRs collected from January 2009 to May 2012, stored in an electronic database**,** has been performed considering various parameters as patient demographics, drug and reaction characteristics, ADRs seriousness, outcome, treatment strategy and detection setting.
Results: The total number of ADRs reports over the audit period was 1060, with a an average of around 25 reports per month. Regarding patient demographics in the reported ADRs, 471 (44%) were female and 589 (56%) were male. Number of patients in young (0–29 years), adult (30-65 years) and geriatric (>65 years) groups were respectively 58 (5%), 518 (49%), 484 (46%). The majority of the ADRs reported involved non Hodgkin lymphoma patients (394; 37%), followed by multiple myeloma (266; 25%) and chronic lymphatic leukemia patients (102; 10%). The drug class most frequently involved in the ADRs was, as expected, antineoplastic agents (ATC L01) and among them, rituximab was the undisputed leader of suspected drugs having collected 276 citations as drug potentially related to ADR; in the list of suspected drugs, cyclophosphamide, doxorubicin and bortezomib were the subsequent. More than half of the reactions (584; 55%) were classified as serious according to the WHO definition: 463 caused hospitalization or prolonged hospital stay, 60 life threatening event, 27 severe or persistent disability, 34 patient death. Overall, in 598/1060 (57%) reports, patient recovered (526 completely; 72 partially) from the reaction, in 260 (24%) only a clinical improvement was observed, in 67 (6%) cases, reaction was defined unchanged or worsened, in 34 reports patient died (in the remaining 101 reports, outcome was not available). Blood and lymphatic disorders were signaled in 190 reports, infections and infestations in 97, skin disorders in 87, but in majority of cases (258) a mix of reactions affecting different system organ class were reported. Regarding ADR management, in 461 cases the suspected drug was stopped, in 62 was reduced, in 489 an additional treatment was prescribed (in some cases more than one action has been adopted). The majority of ADRs (588; 56%) have been detected during scheduled Day Hospital access or outpatient visit, while a small but not negligible number, in emergency room (98; 9%) or during not planned hospitalization (72; 7%).
Summary and Conclusion: The employment of people dedicated to pharmacovigilance activities has proved to be a successful strategy to improve number and quality of ADR reports. The project FarmaRel significantly contributed to reach and overcome, in Italy, the "Gold Standard" for pharmacovigilance, set by WHO in 300 reported cases per 1 million inhabitants.

P1277

PLERIXAFOR IS COST-EFFECTIVE FOR FIRST LINE STEM CELL MOBILISATION: INDIVIDUAL PATIENT COSTING ANALYSIS OF THE LIVERPOOL PHANTASTIC TRIAL

A Haycox[1,*], S Richards[1], R E Clark[2]
[1]University of Liverpool Management School, Liverpool Health Economics, [2]Molecular and Clinical Cancer Medicine, Institute of Translational Medicine, University of Liverpool, Liverpool, United Kingdom

Background: This report provides results of the first stage of this process by evaluating clinical and cost-effectiveness of plerixafor in enhancing the mobilisation of sufficient additional stem cells to facilitate successful stem cell transplantation.
Aims: Assessing the 'value' of first line plerixafor in improving stem cell mobilisation is a two stage process. First evaluate the extent to which the collection of stem cells is enhanced and at what cost and second evaluate the impact on the quantity and quality of life experienced by patients. Such analyses aim to identify 'marginal' improvements resulting from plerixafor in comparison to standard care. Economic analysis compared cost-effectiveness underlying the PHANTASTIC clinical trial of first line plerixafor (clinical data reported at EHA 2013 [Vithanarachchi U et al] and submitted) with patients mobilised by conventional chemotherapy
Methods: Economic analysis was integrated into the PHANTASTIC trial of first line plerixafor. The primary outcome captured the extent to which an 'adequate' cell harvest had been achieved. 'Adequacy' was interpreted as being ≥4 x 10^6 $CD34^+$/kg in no more than 2 stem cell collection days with no evidence of neutropenia (<1.0 x 10^9 / Litre) in the 3 weeks following initiation of mobilisation. The historic control data set consisted of 151 consecutive patients treated in Liverpool after November 2006. Active treatment arm consisted of 98 patients mobilised by first line plerixafor between April 2010 and July 2012. A detailed Micro-costing analysis identified, measured and valued resources consumed by each patient in both the plerixafor and standard care arms of the study. Outcome data (adequacy of stem cell collection) were directly derived from the clinical trial.
Results: Nature and severity of adverse events differed significantly between the two groups. In the standard care arm nineteen patients experienced a serious adverse event which required some form of hospital treatment. These SAEs included neutropenic sepsis, haemorrhage, urinary tract infections, upper respiratory tract infections and severe chest infections. In the plerixafor group only three patients required treatment due to non-severe adverse events (one patient had low levels of potassium, one had nausea and pain and one required platelets). In terms of treatment efficacy 71% of patients achieved the primary outcome in the plerixafor arm compared to 32% in the control arm. Average cost of patients in the plerixafor arm was £13859 compared to £11763 in the comparator arm. Comparative costs for plerixafor *vs*. control in each subgroup were £11763 *vs*. £4762 for myeloma, £16890 *vs* £18083 for non-Hodgkin lymphoma and £12155 *vs*. £19378 for Hodgkin's disease.
Summary and Conclusion: Plerixafor is an effective means of enhancing stem cell harvests. Economic results emphasize that in many patients these benefits can be obtained at a 'reasonable' cost as significant resource savings occur elsewhere in the patient pathway. However, at this stage, the results obtained should be treated with caution. The analysis was not randomized and although propensity matching techniques were used to obtain 'like with like' comparisons a number of confounding factors may remain. Despite this the economic analysis offers encouraging signs that Plerixafor may be effective at enhancing cell harvests at an acceptable cost. Further work is

under way to investigate the extent to which this enhanced harvest of cells translates into an improved quality and quantity of life experienced by patients in each subgroup.

P1278

NUMBER NEEDED TO TREAT & RELATED COSTS FOR ACHIEVING 1 MR 4.5 (BCR-ABL≤ 0.0032%) UNDER DIFFERENT TKIS IN GREECE

M Geitona[1,*], S Delimpasi[2], M Hatzikou[3], N Harhalakis[4]
[1]Social Policy and Health Economics, University of Peloponnese, Corinth, [2]Hematology, Evangelismos Hospital, Athens, [3]Health Economics, Novartis Hellas S.A., Metamorfosis, [4]Hematology, Evangelismos, Athens, Greece

Background: Innovative treatments have transformed CML into a chronic disease mostly managed in outpatient care. The main reason for hospitalization is due to blast crisis or the management of adverse events.
Aims: This study aimed to estimate the cost for achieving a MR 4.5 (BCR-ABL≤0.0032%) at 4 and 5 years of treatment under different Tyrosine Kinase Inhibitors (TKIs) in Greece.
Methods: The Number Needed to Treat (NNT) approach has been used in order to estimate the number of patients needed to treat to prevent one extra person having one bad outcome.i NNT is calculated as the inverse of the Absolute Risk Reduction (ARR) (NNT=1/ARR)[i]. In the current analysis as ARR the MR 4.5 rate by 48 & 60 months was considered (NNT=1/MR4.5). A NNT of 1 means that the preferable outcome occurs in every patient given the treatment. The higher the NNT, the less effective is the treatment. i-[ii] MR4.5 and Adverse Events (AEs) rates were extracted from the DASISION (Kantarjian 2012[iii]) and ENESTnd (Larson 2013[iv]) clinical trials in newly diagnosed CP-CML patients, by evaluating efficacy and safety. The estimation of each TKI cost of treatment has been performed based on 2014 NHS hospital prices in Euros. The estimation of the cost per MR 4.5 is the product of NNT of each TKI treatment cost. Additionally, the cost of treating AEs has been estimated in order to calculate the overall cost of treatment on a per patient basis. The cost of 5 year treatment with dasatinib wasn't estimated since there is not yet data available.
Results: The cost of 4 and 5 years treatment with nilotinib was estimated at €116.507 and €145.634 respectively, for imatinib €87.236 and €109.045 respectively and for dasatinib was considered at €130.929 for the 4y treatment. In order to achieve 1 MR 4.5 at 48 month interval 2.50 patients need to be treated with nilotinib, 4.35 or 4.76 patients with imatinib and 2.94 patients with dasatinib. At 60 month interval 1.85 patients need to be treated with nilotinib and 3,23 with imatinib. The cost for achieving a MR 4.5 for 48 months nilotinib appears to be less costly (€291,268) than imatinib(€379,286 and/or 415,408) and dasanitib (€385,084) and for 60 months €269.692 for nilotinib and €351.757 for imatinib. Mean hospitalization cost per patient due to the treatment of adverse events is as follows: for anemia €2.193 and neutropenia of €1.312.
Summary and Conclusion: Innovative treatments for CML have resulted in treating patients in outpatient care with lower adverse events and consequently, lower cost. Study findings suggest that greater proportion of CML patients on nilotinib achieve target (MR4.5) in a shorter period of time than dasatinib and imatinib resulting in a significant burden reduction of the National Health Care budget. Background: It is well known that adverse drug reactions (ADRs) cause considerable morbidity and mortality. Preventable adverse drug events reactions (pADRs) have been reported to be common in both outpatient and inpatient clinical practice. However, the rate of pADRs varies considerably in different studies, even when conducted in the same settings, depending on methods adopted for assessing ADRs preventability.
Aims: Our aim is to analyze the preventability of ADRs in oncohematology patients, comparing two different approaches: the judgment of one or more investigators *vs* the pre-defined explicit criteria of Schumock and Thornton (S&T).
Methods: ADRs collected by the pharmacovigilance project FarmaRel from January 2009 to December 2012 have been included in the study. At time of ADR reporting, the hematologist gave his personal judgment regarding event preventability. Retrospectively, a second preventability assessment was performed by two independent expert reviewers applying S&T criteria, considering ADRs preventable if one or more of the following conditions occurred: patient had a history of allergy or previous reactions to the suspected drug; drug involved or its dose, route or frequency of administration was inappropriate for patient's clinical condition; required therapeutic drug monitoring or other necessary laboratory test was not performed; a drug interaction or poor compliance was involved in the ADR; a toxic serum concentration or a pathologic laboratory monitoring test was documented.
Results: The total number of pADRs applying S&T criteria or hematologist judgment was 115, and the concordance between the two approaches occurred only in 5 cases (5/115; 4%). To note, out of 887 ADRs evaluated, hematologist considered preventable 17 (2%), compared to 103 (12%) applying S&T criteria. In the S&T pADRs, drug interactions were the preventability cause in 39, inappropriate therapy in 3, history of allergy or previous reactions to the suspected drug in 46, and finally in 15 reports more than one criteria of preventability were identified. More than half (70/103; 68%) of the pADRs were serious. Complete, partial resolution or improvement was observed in 78% of the cases (55/70). When considering the not preventable ADRs, they were 799/887 (90%) for hematologist and 752/887 (85%) with S&T criteria. The two methods were in accordance for 680 out of the 871 ADRs judged not preventable by S&T criteria or hematologist judgment (78%)(see attached table for summary data).

Table 1.

	METHODS	
ADR PREVENTABILITY	Schumock and Thornton	Hematologist
Not preventable	752 (85%)	799 (90%)
Preventable	103 (12%)	17 (2%)
Not assessable	32 (3%)	71 (8%)
TOTAL	887 (100%)	887 (100%)

Summary and Conclusion: The high variability of pADRs rate assessed by the two different methods is a burning topic of discussion: it possible that hematologist evaluation underestimates pADRs, or, as well, that S&T criteria may be only partially applicable to oncohematology. Indeed, since in this setting treatments are often life-saving, other criteria should be taken into account: the purpose of therapy administered (disease treatment or palliative care), the possible alternative treatments available, and, finally, the specific drug risk/benefit ratio.

P1280

COMPARATIVE ANALYSIS OF ADVERSE REACTIONS ARISING FROM THE ADMINISTRATION OF CONVENTIONAL CYTOTOXIC DRUGS AND RECENT TARGETED AGENTS, ALONE OR IN ASSOCIATION, IN ONCOHEMATOLOGIC PATIENTS

Background: In the last decade a large number of new therapeutic agents, as monoclonal antibodies, biological and immunomodulatory drugs, has been introduced in onco-hematology. Because of their fast introduction and spread in clinical use, post marketing safety data should be collected. They are frequently employed in association with conventional cytotoxic agents to enhance the therapeutic efficacy, representing a potential risk factor for cumulative unexpected toxicities.
Aims: To compare adverse drugs reactions (ADRs) arising from the administration of conventional chemotherapeutic agents, recent targeted drugs, and their association, in terms of severity, outcome, detection setting, treatment strategy, organ or system affected.
Methods: We retrospectively analyzed ADRs collected by the pharmacovigilance project FarmaRel. ADRs were divided into three groups according to the suspected drugs: "C" (conventional), "T" (targeted) and "C+T" (in case both a C and a T drug was suspected). In the C group we considered conventional cytotoxic drugs as cyclophosphamide, doxorubicin, cisplatin, while monoclonal antibodies, immunomodulatory drugs and targeted therapies have been classified in the T group.
Results: A total of 1060 ADRs have been considered for analysis. Of these, 424 (40%) have been ascribed to T drugs, 428 (40%) to C agents and 208 (20%) to the combined employment of C+T drugs. Considering seriousness, the highest percentage of serious reactions has been observed in C (285/428; 67%) and in C+T (133/208; 64%) groups, while T drugs resulted associated to serious reactions only in 166/424 (39%) cases. The death rate was respectively 4% in C, 3% in C+T, and 2% in T classes. ADRs causing patient hospitalization were more frequent with C (232/428; 54%) and C+T (108/208; 52%) than with T drugs (123/424; 29%). Differently from seriousness, outcome did not differ significantly among drug groups. Regarding treatment strategy, withdrawal of suspected drug has been applied more frequently for T drugs (227/424; 54%), while dose reduction has been adopted with similar frequencies in all groups. As far as detection setting is concerned, a considerable percentage of reactions related to C+T drugs (35/208; 16%) has been reported in emergency room; the majority of ADRs from T drugs (319/424; 75%) has been collected during scheduled accesses in outpatient or Day Hospital services, while ADRs from C drugs have more frequently been observed during programmed hospitalization (166/428; 39%). Also organ or system affected by ADRs varied significantly among the three classes: for example, infections resulted more frequently reported in C+T class, nervous system disorders in T group. For full data review, see attached table.

Table 1.

		T	C	C+T	Total	χ2 P value
Severity	Not severe	206 (61%)	143 (33%)	75 (36%)	476	
	Death	11 (3%)	17 (4%)	6 (3%)	34

	Total	424 (100%)	428 (100%)	208 (100%)	1060	

Summary and Conclusion: Our study shows that ADRs arising from the administration of conventional, new drugs and their association, varied significantly for most of the parameters considered. Interestingly, we found that cytotoxic drugs are more often associated with serious events; ADRs from new agents has been more frequently approached with drug suspension, for reasons that need to be clarified, and that accesses to emergency room for ADRs are more frequently reported when targeted and conventional drugs are combined. In conclusion, these data confirmed the importance of post-marketing surveillance of drugs, whether they are new, conventional or employed in association.

P1281

SOCIETAL ECONOMIC BURDEN OF IRON DEFICIENCY INDUCED FATIGUE

PR Blank[1,*], T D Szucs[2]
[1]University of Zurich/ Institute of Social and Preventive Medicine, Zurich, [2]University of Basel, Institute of Pharmaceutical Medicine ECPM, Basel, Switzerland

Background: Fatigue is a common symptom in general practice, affecting up to one-third of the population. Similarly, iron deficiency (ID) is a disorder affecting about one-fourth of menstruating women. A deeper understanding of the association between ID, fatigue and its societal burden is important for patients, physicians and health care decision makers.
Aims: The aim of this project was to estimate ID-conditioned sick leaves and their impact on the social burden of the disease among the female working population. In addition, correlations between national GDP (2011) and total costs or annual days of sick-leave were assessed by Spearman's correlation coefficients.
Methods: An online survey was conducted among female consumer panels aged 18-50 years suffering from fatigue (July 2013). Fourteen different countries were included (Australia, Austria, Brazil, Belgium, Greece, Israel, Italy, Netherlands, Portugal, Singapore, S. Korea, Spain, Sweden, Turkey). Participants were included for symptomatic iron deficiency and asked to fill in a standardized questionnaire in regard to demographic information, conditions related to fatigue and to time lost at work due to fatigue.
Results: In total, 1'401 participants completed the survey (mean age: 32 years). Most predominant condition was un-refreshing sleep (81%) followed by lack of concentration/ memory impairment (66%). Across all countries, 1'039 (74%) women were in the workforce. On average, 29% had to take sick-leaves due to fatigue symptoms (range: 7% in Portugal, to 42% in Singapore). The median length of sick-leave per patient ranged from 12 days (Singapore) to 84 days (Turkey) per year. Assuming a 9% prevalence of ID in the female population (CDC, USA) of whom 10% are assumed to show fatigue symptoms (Favrat 2014), the estimated total annual social burden ranged between 4.1M USD (Singapore) to 197.7M USD (Australia) with a human capital approach. Using the friction method (elasticity for annual labor time *versus* labor productivity=0.8), the social economic burden would lead to costs between 3.3M USD (Singapore) and 158.1M USD (Australia) (Tab 1). The total costs were positively correlated with the national GDP (Spearman's rho: 0.793, p=0.001), whereas the number of sick-leaves due to fatigue showed no correlation with GDP.
Summary and Conclusion: The present study has some limitations including the small sample size, the qualitative approach of the survey and the study design, which might be prone for bias. Nevertheless this is a first study analyzing the social burden of sick-leaves among fatigue women in the work force and further studies are needed in this area to validate our results. The potential societal burden of ID-conditioned sick-leaves seems to be very high and should get awareness of employers and payers. It is of uttermost importance that ID in women with fatigue is diagnosed and treated in a timely manner.

P1282

WILL SUBSTITUTION OF TKI GENERIC BRING THE CML TREATMENT FUTURE TO THE PAST? PHARMACOECONOMIC MODELING OF CML TREATMENT WITH OWN GENERIC USE EXPERIENCE

V Shuvaev[1,*], I Martynkevich[1], I Martynkevich[1], A Schmidt[1], M Fominykh[1], K Abdulkadyrov[1]
[1]Russian Research Institute of Hematology and Transfusiology, Saint-Petersburg, Russian Federation

Background: Shift from imatinib to second-generation tyrosine kinase inhibitors (TKI) in the treatment of newly diagnosed chronic myelogenous leukemia (CML) patients showed the encouraging results with reduction frequencies of adverse events (AE) and substantial improvement of the rate and promptness of deep molecular responses obtaining. At present, the patients with complete molecular responses (CMR) are considered as candidates for therapy cessation in the setting of clinical trials. Exclusive patent protection expiring led to substitution of imatinib with generic in Russia since August 2012. To date, the cost of generics is more than a half lower than original imatinib.

Some patients and doctors fear that more efficient and modern second generation TKIs could be substituted by less expensive imatinib analogues.
Aims: The aim of our study was to compare the costs of first and second generation TKI in first-line CML treatment in era of generic substitution.
Methods: We have used previously constructed Markov chain models[1] to compare CML first-line treatment strategies with imatinib or nilotinib with subsequent therapy cessation in cases of CMR. Government registered and obtained during state procurement TKI's (imatinib generics, nilotinib, dasatinib) costs were used. Imatinib generics' substitution experience was used as scenario for the second generation TKI's. We have chosen the model population size of 800 newly diagnosed CML patients in Russia annually. 20-years' time horizon was used. We have tried to assess the treatment cost for one patient and cumulative budget burden for the entire Russian CML population. The total cost included the direct costs of diagnostic procedures to establish diagnosis, residual disease monitoring, costs of medications (TKI and concomitant drugs for AE management), allogeneic stem cell transplantation. We have chosen the discount rate as 3% per annum. We have recalculated the total cost in Euros to make our results more representative. Simulation model was used for statistical analysis.
Results: The results of our analysis showed that the average total cost per one patient in case of nilotinib use instead of imatinib becomes cheaper in three years of CML treatment. It caused by more frequent successful therapy cessation in spite of the use of imatinib generics. Similarly, total CML budget burden in case of nilotinib 1st line treatment was higher than imatinib during first eight years. Subsequently, more frequent therapy cessation and second generation TKI's generic substitution results in cost saving (fig.1). Importantly that the use of nilotinib in 1st line could save more than 500 CML patients' lives without any additional expenses. The results of our analysis are strongly depend on input parameters values, which could be changed in the nearest future.

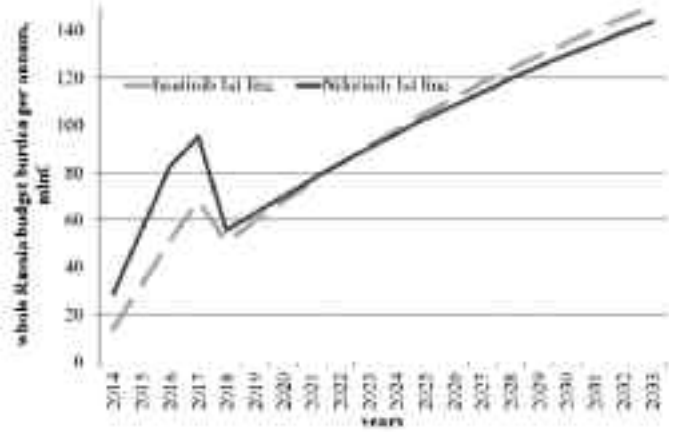

Figure 1. Nilotinib and Imatinib with generic substitution in first-line CML treatment, Russian budget burden

Summary and Conclusion: Pharmacoeconomic modelling can simulate budget burden and its future dynamics on the individual and national level in various economic situations. The results of such modelling could be of value in decision-making process for the national guidelines development.

EXAMINATION OF REAL WORLD INDUCTION THERAPY AMONG OLDER PATIENTS WITH ACUTE MYELOID LEUKEMIA IN THE UNITED STATES
BD Smith[1,*], S Dacosta Byfield[2], R Song[2], C Bartiromo[3], D Mahmoud[3]
[1]The Sidney Kimmel Comprehensive Cancer Center, Johns Hopkins, Baltimore, MD, [2]Health Economics and Outcomes Research, Optum, Eden Prairie, MN, [3]Hematology and Oncology Global Market Access and Outcomes Research, Celgene Corporation, Summit, NJ, United States

Background: Acute myeloid leukemia (AML) is the most common form of acute leukemia in the US, and incidence of the disease increases over age 65. While US guidelines recommend specific treatment options for older patients, including cytarabine-based therapy, hypomethylating agents, clinical trials or supportive care, information on real-world treatment patterns is limited.
Aims: The objective of this study was to examine real-world data on induction anti-cancer therapy received among older AML patients (≥ 65 years old).
Methods: Commercial and Medicare Advantage enrollees with a diagnosis of AML (≥1 medical claim with ICD-9-CM code of 205.0x) between 1/2007 and 7/2013, were identified from a large, national US health plan claims database. The date of the first claim with an AML diagnosis was the index date. Patients were required to be continuously enrolled in the health plan for 6 mos prior to the index date (baseline period) and at least 3 mos after the index date until the earliest of death, disenrollment from the health plan or the end of the study period on 31 July 2013. Patients were excluded from analysis if they had a claim for remission or relapse (ICD-9-CM 205.01 or 205.02) on the index date, or had evidence of AML or other cancer during the baseline period. Patients ≥65 years old who initiated therapy within 3 mos of the index date were examined. The first anti-cancer systemic therapy observed was considered the start of induction therapy and the regimen included all agents received in the 10 days following therapy initiation. Evidence of hematopoietic stem cell transplant (HSCT) and radiation therapy was assessed.
Results: A total of 712 newly diagnosed AML patients were identified; 45% (n=321) were ≥65 years old. Among the older patients, 57% (n=182) were male, 78% (n=251) were Medicare Advantage enrollees, mean (SD) baseline Charlson Comorbidity Index (CCI) was 1.2 (1.5) and mean (SD) follow-up was 371 (333) days. Overall, 16 patients (5%) received radiotherapy and 17 patients (5%) had a HSCT during the follow-up period. A total 157 (49%) patients had evidence of initiating anti-cancer systemic therapy. Among these 157 patients, mean (SD) age was 74 (6) years, 59% were male, mean (SD) baseline CCI was 1.0 (1.4), 13 (8%) received HSCT and 4% (n=7) received initial therapy during an inpatient stay. The most common agents were azacitidine (58%, n=91), decitabine (39%, n=61) and cytarabine (11%, n=18). Monotherapy with azacitidine (n=83, 53%) or decitabine (n=50, 32%) were the most common initial therapy. Patients who initiated therapy with azacitidine (age 76 [SD 6]) or decitabine (age 74 [SD 6]) were older than those who initiated cytarabine-based therapy (age 69 [SD 5]). Time to initial therapy was a mean of 66 days (median 25).
Summary and Conclusion: A substantial portion of the studied population appears not to have received induction therapy for AML. This is similar to the results of a previously published study (Oran et al, Haematologica 2012) which reported only 38.6% of Medicare patients were treated within 3 months of diagnosis. Among treated patients, azacitidine and decitabine were more widely used than cytarabine-based therapy, and time to initiation of any therapy was longer than expected. An important limitation of this data is an inability to capture therapy delivered as part of a clinical trial.

P1284

REAL-WORLD SAFETY DATA FOR TBO-FILGRASTIM
N Lang[1,*], A Lammerich[1], U Mueller[2], P Bias[1]
[1]Merckle GmbH, [2]Teva Pharmaceuticals, Ulm, Germany

Background: Medical products registered in the European Union (EU) are subject to Periodic Safety Update Reports (PSURs), which provide comprehensive worldwide safety data assessments and benefit-risk analyses.
Aims: The present PSUR for tbo-filgrastim-containing products within the TEVA group analyzed safety data accumulated between April 1, 2012 and March 31, 2013 in 38 countries.
Methods: Cumulative data were collected from clinical trials and post-marketing sources from September 15, 2008 (initial approval) to the end of the current PSUR period, March 31, 2013. Data were collected from spontaneous reports from healthcare professionals, consumers, scientific literature, competent authorities, and solicited case reports. Adverse reactions were categorized by system organ class (SOC), source, and seriousness. Teva pharmacovigilance requires screening of all adverse reaction reports and antibody assessment for cases of suspected immunogenicity.
Results: From September 15, 2008 (initial approval) to the end of the current PSUR period, March 31, 2013, the estimated cumulative exposure to products containing tbo-filgrastim was ~4,474,929 patient-days. Estimated cumulative exposure to tbo-filgrastim in clinical trials in healthy subjects and patients with cancer was 190 and 22,099 patient-days, respectively. The global safety database processed 254 tbo-filgrastim case reports from initial product approval through March 31, 2013 (~4.5 years), including 61 (24%) from the PSUR period. Post-marketing data sources cumulatively reported 461 adverse reactions, 131 (28%) from the PSUR period. The most commonly occurring preferred terms in association with important identified and potential risks over the cumulative period were allergic type reactions (11), interstitial pneumonia (4), and splenomegaly (2). Eleven new cases were identified that required immunogenicity testing during the PSUR period. The most common reasons for requiring testing were lack of efficacy (n=7) and type II hypersensitivity (n=2).
Summary and Conclusion: No new safety risks were identified for tbo-filgrastim based on PSUR data from the most recent reporting period ending March 31, 2013.

PROGNOSTIC VALUE OF DEEP SEQUENCING APPROACH FOR MINIMAL RESIDUAL DISEASE (MRD) DETECTION IN MULTIPLE MYELOMA PATIENTS

J Martinez-Lopez[1,*], J J Lahuerta[1], F Pepin[2], M Gonzalez[3], S Barrio[1], R Ayala[1], N Puig[3], M A Montalban[1], B Paiva[3], L Weng[2], C Jimenez[3], M Sopena[1], T Cedena[1], I Rapado[1], M V Mateo[3], L Rosinol[4], A Oriol[5], M J Blanchard[6], R Martinez[7], J Blade[4], J San Miguel[3], M Faham[2], R Garcia-Sanz[3]
[1]Hospital 12 de Octubre, Madrid, Spain, [2]Sequenta, Inc., South San Francisco, United States, [3]Clinico de Salamanca, Salamanca, [4]Hospital Clinic i Provincial, Barcelona, [5]Hospital German i Trials, [6]Hospital Ramon y Cajal, [7]Clinico de Madrid, Madrid, Spain

Background: The assessment of minimal residual disease (MRD) is an emerging component of response evaluation in multiple myeloma (MM) patients.
Aims: We compared the prognostic value of traditional response criteria with MRD measured by three different methods: a sequencing-based method, termed the LymphoSIGHT™ platform, multiparameter flow cytometry (MFC) and ASO-PCR of immunoglobulin (Ig) genes in a cohort of 133 uniformly-treated MM patients from the Spanish Myeloma Group trials.
Methods: Bone marrow samples were obtained from 133 patients at diagnostic and post-treatment time points on GEM clinical trials (GEM00 and GEM05). All 133 patients were either in CR or VGPR at the post-treatment time point. Using the sequencing assay, we identified clonal rearrangements of immunoglobulin (*IGH-VDJ, IGH-DJ*, and *IGK*) genes in diagnostic samples. We then assessed MRD in follow-up samples, analyzing concordance between: sequencing, MFC and ASO-PCR of Ig genes MRD results, and comparing the prognostic value of each method with traditional response criteria.
Results: The sequencing assay detected the presence of a myeloma-specific gene rearrangement in diagnostic samples from 121 of 133 (91%) patients. We tested MRD in follow-up time points in 110 of the 121 patients. Of the 110 patients, 80 were positive by sequencing at MRD levels of 10^{-5} or higher and 30 were MRD negative. A high correlation between MFC and sequencing MRD results was observed (r^2=0.87); as well as between ASO-PCR of Ig genes and sequencing (r^2=0.89). The Time to Tumor Progression (TTP) and Overall Survival (OS) were significantly longer in the MRD negative group compared with the MRD positive group by sequencing (TTP, median 80 *vs*. 31 months, p<0.0001; and OS, median not reached *vs*. 81 months p=0.02). When restricting the analysis to the 62 patients that were in conventional CR (negative immunofixation), 36 of 62 patients were positive by sequencing at MRD levels at 10^{-5} and higher and 26 were MRD negative. There was a significantly improved TTP in the MRD negative group compared with the MRD positive group (median 131 *vs*. 35 months, p=0.0009). Patients were grouped into 3 categories according to their MRD levels by sequencing: i) ≥10^{-3} (n=43), ii) 10^{-3} to 10^{-5} (n=37) and iii)<10^{-5} (n=30). The median TTP were: 27 months, 48 months, and 80 months, respectively (*P* from 0.003 to 0.0001) (Figure 1). This sensitivity analysis was extended to assess OS across the 3 categories of MRD levels. Similar to the TTP analysis, MRD levels of<10^{-5} were associated with significantly longer OS compared to patients with high MRD level (defined as >10^{-3}) (median not reached *vs*. 55 months, *P*=0.002). Similar results were found when comparing patients with MRD levels of 10^{-3} to 10^{-5} to patients with high MRD level (>10^{-3}) (median not reach *vs*. 55 months, *P*=0.02).
Figure 1. Time to Progression of the series stratified according to different minimal residual disease (MRD) levels (>10^{-3} *vs*. 10^{-3} to 10^{-5} *vs*.<10^{-5}) as determined by deep sequencing.

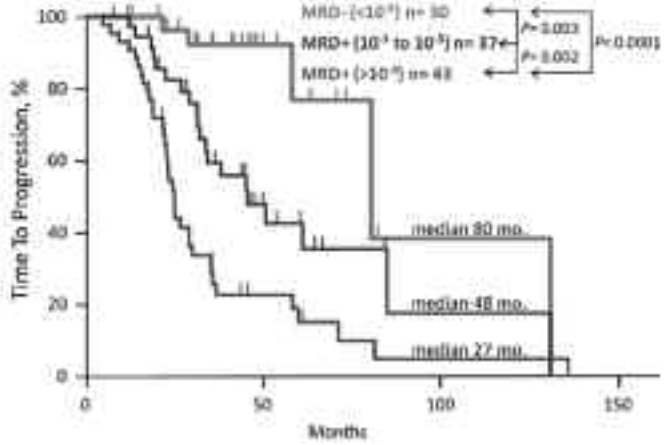

Figure 1.

Summary and Conclusion: The sequencing applicability for MRD studies in MM is 91%, which is essentially equivalent with that of MFC (96% Rawstron AC et al, JCO 2013). There is a high correlation between MRD levels by sequencing, ASO-PCR and MFC. These results demonstrate that MRD assessment by sequencing is highly prognostic even in patients who are in CR. Thus, MRD assessment by sequencing is a useful method for patient risk stratification and can be used to determine molecular CR in MM.

S1286

PROTEASOME INHIBITOR TREATMENT RESPONSE CAN BE PREDICTED BY GENE EXPRESSION PROFILING IN MULTIPLE MYELOMA

MH Van Vliet[1,*], R Kuiper[2], A Broijl[2], M Van Duin[2], L de Best[1], EH van Beers[1], P Sonneveld[2]
[1]SkylineDx BV, [2]Department of Hematology, Erasmus MC Cancer Institute, Rotterdam, Netherlands

Background: Multiple Myeloma (MM) is a heterogeneous disease in terms of genetic background, survival and treatment response for which more and more 'novel agents' become available. However, there is a large diversity between subgroups of patients in treatment response and survival. This signifies an ever increasing need for predictive markers for MM that may allow identification of such subgroups at time of diagnosis. Gene Expression Profiling (GEP) studies have resulted in several markers, such as the EMC92/SKY92 high risk signature, virtual karyotyping (t(4;14), t(11;14), etc.), and the GEP clusters (MS, MF, etc.).
Aims: To identify predictive GEP based markers capable of distinguishing patients that benefit from proteasome inhibitor based treatment.
Methods: The data from the HOVON-65/GMMG-HD4 phase 3 trial was used, in which bortezomib, doxorubicin, and dexamethasone (PAD), followed by high dose melphalan (HDM)/autologous stem cell transplantation (ASCT) and bortezomib maintenance was compared with vincristine, doxorubicin, and dexamethasone (VAD) followed by HDM/ASCT and thalidomide maintenance. GEP was performed (Affymetrix U133 Plus 2.0 GeneChip; algorithms: MMprofiler assay) for 329 MM patients. A subset of this dataset was previously used as a training set for the EMC92/SKY92 signature (290 patients), for the signatures of the 12 clusters (320 patients), as well as for the signatures for chromosomal aberrations (virtual karyotyping of t(4;14), t(11;14), t(14;16)/t(14;20), add1q, add9q. del13, and del17, number of patients depending on the FISH). The predictive power for Overall Survival (OS) of those markers in relation to the PAD/VAD treatment arms was assessed. For each marker, a Cox Proportional Hazards model was fit on the patients that are positive for that marker, with samples split into PAD/VAD as covariate. A Hazard Ratio (HR) larger than 1 indicates that PAD patients had longer OS than those treated with VAD (uncorrected p values also reported).
Results: The predictive power of the EMC92/SKY92 signature, markers for the various chromosomal aberrations and GEP clusters was assessed by comparing VAD with PAD. Five markers, EMC92/SKY92, t(14;16)/t(14;20), add1q21, MF and CD2 cluster, were found to have longer OS when treated with PAD (HR ranging from 2.2 to 12.9, p<0.05, Figure 1A). t(4;14) shows improved survival when treated with PAD (HR=1.8), but is not significant (p=0.15). These markers capture different biological mechanisms, and therefore different sets of patients. For example, the EMC92/SKY92 (23.1% of patients) and cluster MF (6.4% of patients) together identify 26.1% of patients with an HR of 2.7 (Figure 1A and B). These results indicate that GEP markers may provide a good predictive marker for proteasome inhibition therapy.

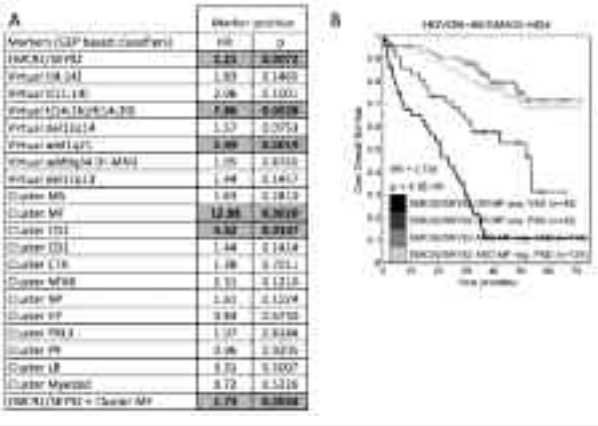

Figure 1. A) Predictive hazards ratios of all MMprofiler markers and one marker combination (VAD *versus* PAD treatments arms). Bold text indicates p<0.05. B) Kaplan-Meier curve for the combination of EMC92/SKY92 and MF cluster split out for the two treatment arms. The Hazard Ratio compares the treatment arms within the "EMC92/SKY92 positive OR MF cluster positive" group.

Summary and Conclusion: Five GEP markers have been found that can predict longer OS in subsets of MM patients when treated with proteasome inhibitors (PAD/Bortezomib), suggesting that they may serve as a predictive marker. The predictive power of these markers must be validated in the EMN-02/HOVON-95 clinical trial which will include a bortezomib based induction regimen, and consolidation regimen.

S1287

PROGNOSTIC HETEROGENEITY AMONG HIGH RISK MULTIPLE MYELOMA PATIENTS (T(4-14) AND DEL17P) ACCORDING TO ADDITIONAL CYTOGENETIC ABNORMALITIES, THE IFM EXPERIENCE

Background: Molecular heterogeneity is a hallmark of multiple myeloma (MM) disease. Recent works using genome sequencing reveal a new dimension on the knowledge and complexity of MM physiopathology. However there's not clear impact on patient management especially the evaluation of individual risk remains a challenge. Usually t(4-14) and del17p are considered as bad prognosis cytogenetics abnormalities (CA) and hyperdiploidy as good prognostic. However situation is increasingly more complex and prognostic of patient should be more tailored using whole acquired cytogenetic characteristics.
Aims: To illustrate this we analyzed by SNP array for 242 high risk patients (t(4-14) and/or de(l17p)) from the IFM data base to evaluate the prognostic impact of additionally CA detected.
Methods: We analyzed 242 high risk MM patients (147 with del17p, 110 with t(4-14) and 25 with both). All patients gave their informed consent. SNP array were performed on affymetrix platform (Santa Clara CA). Data were analysed in univariate and multivariate analysis in a cox model adjusted on age, treatment, beta2microglobulin (b2m) and del(13). There was in the t(4-14) group: 147 patients, median age 59.4 years, 129 (82.2%) treated with autologous stem cell transplantation (ASCT), 144 (92.3%) relapses and 103 deaths (65.6%). In the del17p group there was 110 patients, median age 60 years, 83.7% treated with ASCT, 90.8% have relapsed and 83 (76.1%) deaths. Repartition of CA in both groups will be provided during EHA meeting. Main additionnally analysed CA were hyperdiploidy, structural chromosomal changes, del(13), del (1p12), del(1p32), 1q gain, 6p gain, del(6q), del(8p), del(12p), del(14q), monosomy14, dl16q, del(22), nullisomy Y.
Results: t(4-14) group: Median follow up was 4.6 years, progression free survival (PFS) was 1.4 years and overall survival (OS) was 3.5 years. In the multivariate analyses, PFS was shorter in patients with del(6q) and low b2m (HR=3.14), but longer in patients with monosomy 14 (HR=0.49). For OS, the significant factors were molecular karyotype complexity, del(13) (HR=3.25), del(1p32) (HR=6.31), and del(12p) (HR=1.74). Hyperdiploidy or individual trisomies did not impact neither the PFS, nor the OS. Thus, in this large series of patients with t(4;14), we were not able to identify "good-risk" parameters. In contrast, several chromosomal changes are associated with a worst prognosis. Del17p group: Median follow up was 5.2 years, PFS 1.3 years and OS 2.7 years. For OS, univariate analyses identified the following most significant parameters: del(13) (HR=2.11), del(1p32 (HR=1.95), del(8p) (HR=1.62), del(16q) (HR=1.79), nullisomy Y (HR=2.09), and at least one trisomy (HR=0.57. In the multivariate analyses, PFS was shorter in patients with del(6q) (HR=2.14), and longer for patients with monosomy 14 (HR=0.42). For OS, no chromosomal factor significantly impact survival (despite some trends) in the multivariate analyses certainly due to the small size of the cohort.

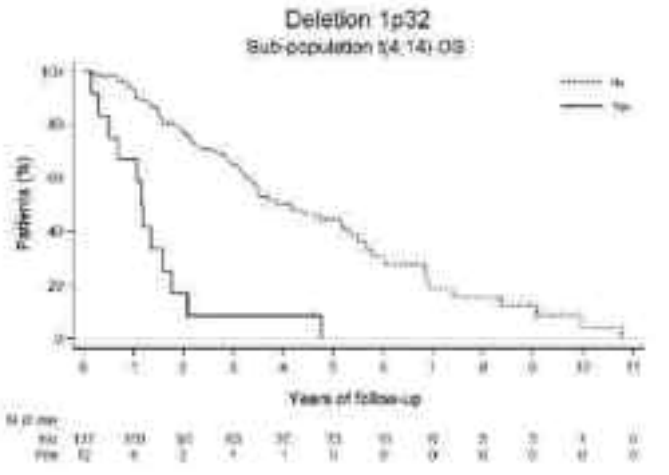

Figure 1.

Summary and Conclusion: this study in a large series of high-risk patients, analyzed with the most modern genomic technique, does not confirm the Mayo Clinic data which suggested that trisomies/hyperdiploidy may overcome the poor prognosis of t(4;14) and del(17p). In contrast, we did identify CA that worsen the prognosis of t(4;14) like del1p32, del12p, molecular karyotype complexity, or del(13). However as some abnormalities are not frequent those data have to be confirmed in a larger cohort of patients.

S1288

PET/CT IS A USEFUL TOOL FOR BOTH REFINING THE DEFINITION OF CR IN MM AND DETECTING OTHERWISE UNREVEALED PROGRESSION DURING THE FOLLOW-UP OF THE DISEASE: A SINGLE CENTRE EXPERIENCE ON 282 PATIENTS(PTS)

E Zamagni[1,*], C Nanni[2], A Pezzi[1], K Mancuso[1], P Tacchetti[1], L Pantani[1], B Zannetti[1], A Brioli[1], S Rocchi[1], G Marzocchi[1], N Testoni[1], C Terragna[1], S Fanti[2], M Cavo[1]
[1]Ospedale S. Orsola-Malpighi, Istituto di Ematologia Seragnoli, [2]Ospedale S. Orsola-Malpighi, Institute of Nuclear Medicine, Bologna, Italy

Background: PET/CT is a valuable tool at the onset of MM for predicting outcomes in transplant (ASCT) candidates pts. However, the prognostic role of PET/CT after treatment and/or during the follow up of the disease, as well as in the non ASCT setting, still remains less defined.
Aims: To address these issues, we retrospectively analyzed 282 symptomatic MM pts, with a median age of 58 yo, (range 22-83), who were treated in a single institution between 2002 and 2012, and were followed for a median of 66 months. Treatment included ASCT in 70%, novel agents in 77% and was bortezomib-based in 37% of the cases.
Methods: All the pts were studied with PET/CT at baseline, then every 12-18 months during follow-up, and at the time of each subsequent relapse; for 189 of them PET/CT at baseline and 3 months after the end of first line treatment was available. The number of focal lesions (FLs), their associated standardized uptake value (SUVmax) and presence of extra-medullary disease (EMD) were recorded.
Results: 42% of the pts at diagnosis had >3 FLs and in 50% of them SUVmax was >4.2; EMD was present in 5% of the cases. On multivariate analysis, these 3 variables adversely affected PFS and OS, independently of the treatment received (including or not ASCT, bortezomib- or non-bortezomib-based). On multivariate analysis, ISS stage 3, presence of >3 FLs at PET/CT and failure to achieve CR during or after first line treatment were the leading factors independently associated with shorter PFS and OS. These 3 variables enabled the definition of a scoring system, based on the number of risk factors simultaneously present (score O: none of the 3 adverse factors, 31% of the pts; score 1: only one out of the 3, 37%, score 2+: 2 or 3 factors, whatever of them, 32%), that predicted for PFS and OS. After treatment, PET/CT negativity (PET-CR) was observed in 70% of the pts, while conventionally-defined CR was achieved in 53% of them. Attainment of PET-CR favorably influenced PFS and OS, both in uni and multivariate analyses. Notably, 29% of the pts who achieved CR according to conventional criteria still had positive PET/CT scans: their median PFS was 50 mos as compared with 90 mos for those pts who also achieved PET-CR (P=0.01) (fig. 1). OS was significantly inferior, as well, for pts not achieving PET-CR, with 6-year estimate of 65% in comparison to 90% for PET negative pts (P=0.0035) (fig. 1). On multivariate analysis, PET-CR was an independent factor predicting for prolonged PFS (P=0.004) and OS (P=0.02) within the conventionally-defined CR group. 63% of the pts experienced relapse or progression, after a median of 56 mos from the end of first-line treatment. In 37% of them, progression was only serological, both serological and skeletal

in 48%, only skeletal in 15% and in 12% of these latter patients it was exclusively detected by systematic PET/CT during the follow-up (no pain or pathological fractures). A logistic regression analysis of baseline and post treatment features revealed that persistence of SUVmax >4.2 after the end of first line treatment was independently associated with exclusive PET/CT progression.

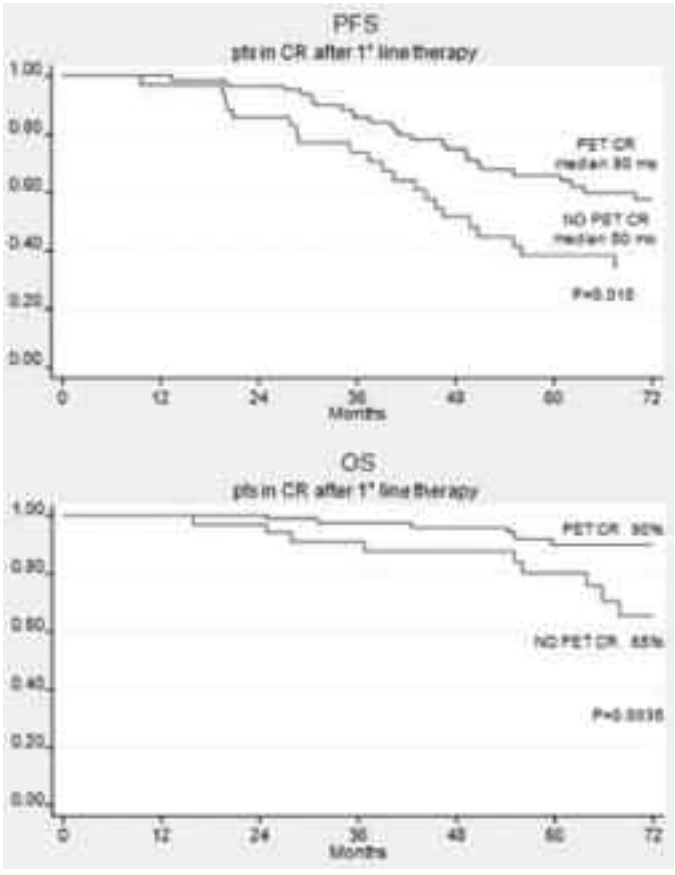

Figure 1.

Summary and Conclusion: In conclusion, PET/CT was confirmed as a reliable predictor of outcome in newly diagnosed MM pts. Importantly, PET/CT contributed to a more careful and deep evaluation of CR, going beyond the conventionally defined level. Finally, in pts with a persistent high glucose metabolism after first line treatment, PET/CT can be recommended during the follow-up, in order to point out possible progression, not otherwise identifiable.

S1289

REVISED-INTERNATIONAL STAGING SYSTEM (R-ISS): A NEW AND SIMPLE PROGNOSTIC ASSESSMENT FOR MULTIPLE MYELOMA

S Oliva[1,*], S Caltagirone[1], R Passera[2], B Van der Holt[3], I Hardan[4], A Nozza[5], E Zamagni[5], P Musto[5], P Omedè[1], S Zweegman[6], L Baldini[5], S Bringhen[1], H Lokhorst[7], R Ria[5], R Zambello[5], M Ruggeri[1], A Broijl[3], S Pezzatti[5], R Hajek[8], P Tacchetti[5], S Pozzi[5], P Cornelissen[3], A Spencer[9], M Boccadoro[1], M Cavo[5], P Sonneveld[3], A Palumbo[1]

[1]Myeloma Unit, Division of Hematology, University of Torino, [2]Division of Nuclear Medicine, San Giovanni Battista Hospital, University of Turin, Torino, Italy, [3]Department of Hematology, Erasmus MC, Rotterdam, Netherlands, [4]Meir Medical Center, Kfar-Saba, Israel, [5]Italian Multiple Myeloma Network, GIMEMA, Italy, [6]Department of Hematology, VU University Medical Center, Amsterdam, [7]Department of Hematology, University Medical Center Utrecht, Utrecht, Netherlands, [8]University Hospital Brno and Faculty of Medicine OU, Ostrava, Czech Republic, [9]Department of Clinical Haematology, Alfred Health, Melbourne, Australia

Background: Multiple myeloma (MM) is a heterogeneous disease and the thought that there are different diseases with variable outcome led to a definition of prognostic tools. The International Staging System (ISS) is a simple and widely used staging model, but it does not take into account the biology of MM (such as the presence of chromosomal abnormalities) and other important prognostic markers such serum LDH levels.

Aims: To evaluate the combined role of three established prognostic factors (ISS, chromosomal abnormalities and serum LDH levels) in newly diagnosed Multiple Myeloma (NDMM) patients.

Methods: Data from NDMM patients enrolled in nine international multicenter trials were pooled together and retrospectively analyzed. All patients received new drugs up-front in association with standard chemotherapy or in pre-transplant induction and post-transplant maintenance strategies. Patients evaluable for ISS stage, interphase Fluorescence *in situ* Hybridization (iFISH) and serum LDH levels were included in the analysis. The K-adaptive partitioning was used to identify the ISS/iFISH/LDH groups. Multivariate analyses of OS and PFS were performed.

Results: Median age was 63 years; 2159 (60%) patients were younger than 65 years. 1791 (50%) patients received IMIDs, 1370 (38%) proteasome inhibitors and 1606 (45%) underwent autologous stem cell transplantation (ASCT). A total of 2359 patients were evaluable for ISS, iFISH and LDH: 570 (24%) patients presented at baseline with ISS stage III, 612 (26%) had High-Risk (HR) iFISH profile [presence of del(17p) and/or t(4;14) and/or t(14;16)] and 285 (12%) had LDH values higher than the normal limit (LDH high). The recursive partitioning procedure gave an optimal number of 3 ISS/iFISH/LDH groups, defined as revised ISS [R-ISS] stages: R-ISS stage 1 [n=636 (27%)] included patients with ISS I, no HR-iFISH and low LDH; R-ISS stage III [n=246 (11%)] patients with ISS III and HR-iFISH or LDH high; R-ISS stage II included all the other patients [n=1477 (62%)]. After a median follow-up of 4 years, 5-year OS was 81% in the R-ISS I, 62% in the R-ISS II and 39% in the R-ISS III groups. The 5-year PFS was 56% in the R-ISS II, 37% in the R-ISS II and 20% in the R-ISS III groups (median PFS was 65, 41 and 25 months, respectively). Multivariate analyses of OS and PFS confirmed the strong prognostic role of R-ISS. The mortality risk was clearly increased for R-ISS II *vs* I (HR 3.02), as well as for R-ISS III *vs* I (HR 7.44). Similarly, the risk of progression was higher for R-ISS II *vs* I (HR 2.07), as well as for R-ISS Stage III *vs* I (HR 4.04).

Summary and Conclusion: The R-ISS considerably improved the risk assessment in comparison with the individual ISS, iFISH and LDH evaluations. The R-ISS is a new risk model, that includes simple and widely used prognostic markers, it is easily applicable in clinical practice and identifies three different MM entities with clearly different outcomes.

IMPACT OF BLEOMYCIN AND DACARBAZINE WITHIN THE ABVD REGIMEN IN THE TREATMENT OF EARLY-STAGE FAVORABLE HODGKIN LYMPHOMA: FINAL RESULTS OF THE GHSG HD13 TRIAL

K Behringer[1,*], H Goergen[1], P Borchmann[1], V Diehl[2], M Fuchs[1], A Lohri[3], F Hitz[4], J M Zijlstra[5], R Greil[6], J Markova[7], M S Topp[8], M Soekler[9], S Mathas[10], J Meissner[11], B von Tresckow[1], B Boell[1], A Engert[1],
[1]First Department of Internal Medicine, First Department of Internal Medicine, German Hodgkin Study Group (GHSG)/University Hospital Cologne, [2]German Hodgkin Study Group (GHSG)/University Hospital Cologne, Cologne, Germany, [3]Hematology, Oncology, Cantonal Hospital, Liestal, [4]Hematology, Oncology, Cantonal Hospital, St Gallen, Switzerland, [5]VU University Medical Centre Amsterdam, Amsterdam, Netherlands, [6]University of Salzburg, Salzburg, Austria, [7]University Hospital Kralovske Vinohrady, Third Faculty of Medicine, Charles University Prague, Prague, Czech Republic, [8]Department II of Internal Medicine, University of Wuerzburg, Wuerzburg, [9]Hematology, Oncology, University of Tuebingen, Tuebingen, [10]Campus Virchow Klinikum, Berlin, [11]Department V; Hematology, Oncology, University of Heidelberg, Heidelberg, Germany

Background: Combined modality treatment consisting of two cycles of ABVD (doxorubicin, bleomycin, vinblastine, dacarbazine) followed by involved-field radiotherapy (IFRT) is regarded as standard of care for early-stage favorable Hodgkin Lymphoma (HL).
Aims: To analyze the impact of bleomycin and dacarbazine within the ABVD regimen.
Methods: The GHSG HD13 study compared two cycles of ABVD with a dacarbazine-deleted variant (ABV), a bleomycin-deleted variant (AVD), and a variant in which both, dacarbazine and bleomycin were deleted (AV). In each treatment arm, chemotherapy was followed by IFRT of 30 Gy. Primary objective was to demonstrate non-inferiority of the three experimental variants compared to ABVD regarding the primary endpoint freedom from treatment failure (FFTF) by excluding a difference of 6% after 5 years, corresponding to a non-inferiority margin of 1.72 for the Hazard Ratio, via a 95% confidence interval (CI). Recruitment started in 01/2003. In our continuously performed safety analyses, higher event rates were observed with AV and ABV. Thus, these two arms were closed early in 09/2005 and 02/2006, respectively. Randomization between ABVD and AVD continued until 09/2009 with a total of 1710 patients. Two hundred eight patients were excluded from the final analysis due to revision of HL diagnosis, loss to follow-up before start of treatment, revision of staging, or violation of other inclusion criteria. Of 1502 qualified patients analyzed for therapy adherence, toxicity, and efficacy, 566 were randomized into the standard arm and 198, 571, and 167 patients were randomized to receive experimental chemotherapy with ABV, AVD, or AV, respectively.
Results: Patient characteristics were well balanced between the four treatment arms: median age was 39 years, 67% had stage II disease, and there were more male patients included (60%). The most frequent histologic subtypes were mixed cellularity and nodular sclerosis (40% and 37%, respectively). The rate of acute toxicities ranged between 26.3% with AVD and 32.7% with ABVD; leukopenia (14.4%), hair loss (10.9%), and nausea/vomiting (5.8%) were most frequently observed. Interestingly, pulmonary toxicity was observed in four patients only, including one patient receiving AV. Only moderate reduction in acute toxicities was observed when omitting Bleomycin (leukopenia) and Dacarbazine (nausea/vomiting). FFTF at five years was 93.1%, 81.4%, 89.2%, and 77.1% after treatment with ABVD, ABV, AVD, and AV, respectively. Inferiority of the early closed treatment arms without dacarbazine was confirmed in this final analysis with five-year-differences in FFTF of 11.5% (95% - CI 4.7% to 18.3%) with ABV and 15.2% (95% - CI 7.4% to 23.0%) with AV compared to ABVD, respectively. In addition, non-inferiority of AVD compared to ABVD could not be confirmed, with a five-year-difference in FFTF of 3.9% (95% - CI 0.1% to 7.7%). The respective Hazard Ratio was 1.5 with a 95% - CI ranging from 1.0 to 2.3, including the pre-specified non-inferiority margin. Overall survival was excellent and did not differ between treatment arms, with five-year-estimates of 97.6%, 94.1%, 97.6%, and 98.1% after treatment with ABVD, ABV, AVD, and AV, respectively.
Summary and Conclusion: Dacarbazine cannot be deleted from the ABVD regimen without a significant loss of efficacy. With respect to the predefined non-inferiority margin of 6% after 5 years, also Bleomycin cannot be safely omitted. Importantly, the reduction in tumor control in the experimental arms did not translate into inferior overall survival.

S1291

FINAL ANALYSIS OF A RANDOMIZED PHASE II STUDY WITH PREDNISONE, VINBLASTINE, DOXORUBICIN, AND GEMCITABINE IN PATIENTS WITH EARLY UNFAVORABLE HODGKIN LYMPHOMA -PVAG-14 PILOT-

M Fuchs[1,*], D Wongso[1], A Plütschow[1], M Feuring-Buske[2], B Hertenstein[3], HG Höffkes[4], M Vogelhuber[5], B von Tresckow[1], H Biersack[6], H Link[7], M S Topp[8], N Fischer[9], H Bredenfeld[10], S Sasse[1], K Behringer[1], B Böll[1], P Borchmann[1], A Engert[1]
[1]Department of Internal Medicine I, University Hospital of Cologne, Cologne, [2]Department of Internal Medicine III, University Hospital Ulm, Ulm, [3]Medical Clinic I, Klinikum Bremen Mitte, Bremen, [4]Tumorklinik, Klinikum Fulda, Fulda, [5]Haematology/Oncology, University Hospital Regensburg, Regensburg, [6]Medical Clinic I, University Hospital Schleswig-Holstein, Lübeck, [7]Department of Internal Medicine I, Westpfalz Klinikum, Kaiserslautern, [8]Medical Clinic II, University Hospital Würzburg, Würzburg, [9]Haematology/Oncology, Klinikum Schwabing, München, [10]Medizinische Klinik, Evangelisches Krankenhaus Düsseldorf, Düsseldorf, Germany

Background: Optimal treatment of early unfavorable Hodgkin lymphoma (HL) is still a matter of debate, since improved tumor control in terms of longer progression free survival (PFS) has to be weighed against possible adverse effects of the most effective treatment. With PVAG-14, the German Hodgkin Study Group (GHSG) designed a new chemotherapy regimen that included gemcitabine which is an effective drug in relapsed or refractory HL patients.
Aims: The aims of this phase-II trial were to assess toxicity and activity of PVAG-14 (benchmarks:<50% hematological grade III/IV toxicities; >50% complete responders). Secondary objectives were feasibility, efficacy and safety.
Methods: Patients with first diagnosis of early unfavorable HL according to GHSG criteria were randomized to receive eight cycles of prednisone, vinblastine, doxorubicin and gemcitabine with two different doses of doxorubicin (25 or 35 mg/m2) followed by 30 Gy involved-field radiotherapy. Between November 2008 and May 2011, 41 patients were included and the trial was prematurely closed due to poor recruitment and the initiation of HD17 trial. The patients' age at initial diagnosis ranged from 18 to 57 years (median 38 years), and 49% were male. Most of the patients were in stage IIA (76%) and had a WHO-Index of 0 (76%). Large mediastinal mass (LMM) was present in 20% of the patients.
Results: Most patients (40/41) received eight cycles of PVAG-14 with a median dose intensity of 97%, and 27 of these patients were treated with G-CSF in each cycle according to protocol. One patient switched to ABVD after three courses of PVAG-14. Grade III/IV leukopenia occurred in 4/41 patients (<10%) including one patient with grade IV leukopenia. No treatment-associated anemia or thrombocytopenia was documented. The upper 95%>confidence limit of this toxicity rate is estimated at 23%, which is markedly lower than anticipated in the trial protocol. Three patients had grade III infections (one in cycle 5, two in cycle 8), no grade IV infection was observed. All in all, 37% of the patients experienced a grade III/IV toxicity (haematological and non-haematological). Only one patient received a red blood cell transfusion, platelet transfusion was not necessary in any patient. All patients except one (98%) achieved a complete remission (CR or CRu) as final treatment result. The lower 95%>confidence limit of the complete response rate is 87% and excludes the benchmark for inefficacy defined in the protocol. One patient had progressive disease at 5 months, another patient relapsed 15 months after the end of treatment. With a median observation time of 27 months, the 2-year PFS was 94% [95%>CI: 86%>100%] and the overall survival 100%. Due to the low number of patients a comparison of the different doxorubicin doses was not possible.
Summary and Conclusion: Both endpoints for efficacy and toxicity as predefined in the protocol were met despite the premature closure of the trial. Although fewer patients than expected were included in this trial, the results are compelling. PVAG-14 is an efficient and well tolerated regimen for patients with early unfavorable HL. The observed toxicity is remarkably low. Based on these results, PVAG-14 might challenge present treatments of choice in this group of patients. A randomized trial is thus warranted.

S1292

TARGETED BEACOPP VARIANTS IN PATIENTS WITH NEWLY DIAGNOSED ADVANCED STAGE CLASSICAL HODGKIN LYMPHOMA: INTERIM RESULTS OF A RANDOMIZED PHASE II STUDY

P Borchmann[1,*], D Eichenauer[1], A Pluetschow[2], S Kreissl[1], M Fuchs[2], M Soekler[3], N Engel[4], S Mathas[5], K Behringer[1], C Kobe[6], M Dietlein[6], V Diehl[7], A Engert[1]
[1]1st Depatment of Internal Medicine, [2]German Hodgkin Study Group, University of Cologne, Koeln, [3]2nd Department of Internal Medicine, University of Tuebingen, Tuebingen, [4]3rd Depatment of Internal Medicine, University of Munich, Munich, [5]Depatment of Internal Medicine, Charite - Campus Virchow Klinik, Berlin, [6]Department of Nuclear Medicine, University of Cologne, [7]1st Depatment of Internal Medicine, Universtiy of Cologe, Koeln, Germany

Background: $BEACOPP_{escalated}$ (bleomycin, etoposide, doxorubicin, cyclophosphamide, vincristine, procarbazine, and prednisone) has substantially

improved the outcome for patients with advanced stage Hodgkin Lymphoma (HL). However, there still is concern about the toxicities of this intensified chemotherapy regimen. Brentuximab vedotin (BV) is an anti-CD30 directed antibody-drug conjugate that has shown very promising single-agent activity and good tolerability in HL.

Aims: We introduced BV into the BEACOPP regimen in order to improve its toxicity profile of $BEACOPP_{escalated}$ while maintaining its efficacy.

Methods: Two modified BEACOPP regimens were developed. In a more conservative variant (BrECAPP: BV, etoposide, cyclophosphamide, doxorubicin, procarbazine, prednisone), vincristine was replaced by BV and bleomycin omitted. In the more experimental variant (BrECADD: BV, etoposide, cyclophosphamide, doxorubicin, dacarbazine, dexamethasone) we additionally replaced procarbazine by dacarbazine to reduce gonadal toxicity, reduced the dose of etoposide to decrease risk of second acute myeloid leukemia while slightly increasing the dose of doxorubicin to maintain efficacy, and introduced dexamethasone (day 1-4) substituting for prednisone (day 1-14) to avoid immunosuppressive steroid treatment during neutropenia. Both regimens are administered q21d for 6 cycles. This is an ongoing randomized phase II study with the combined primary endpoint being the PET-based complete response rate after chemotherapy and the complete remission rate at final restaging including early follow-up. Here we report on the first 48 patients (planned n=100).

Results: The study started in October 2012. 75 patients have been enrolled by December 2013 and are included in this analysis. Median age is 30 years (range 18-60 years), 57% are male, and 80% have Ann-Arbor stage III or IV disease. 46 patients have been staged after 6 cycles of chemotherapy, 24 in the BrECAPP and 22 in the BrECADD arm. Four of these patients have not reached a complete response (9%, 95% CI: 2%>21%). 41 patients (91%, 95% CI: 83%>99%) achieved a CR or PET negative PR. 65 patients have received at least two cycles of chemotherapy and are evaluable for safety analyses. Hematological toxicity grade 3 or 4 of the targeted BEACOPP variants was documented in 60 of 65 patients (93%, corresponding number for 4-6 cycles of $BEACOPP_{escalated}$ in the GHSG HD15 study: 91.7%). Grade 3 or 4 organ toxicity occurred in 4/31 patients treated with BrECAPP (13%, GHSG HD15 study: 14.1%), and in 0/34 patients after treatment with BrECADD. 13/46 patients who had completed treatment showed grade 1 or 2 sensory neurotoxicity (28%). No severe neurotoxicity was reported.

Summary and Conclusion: This is the largest study of BV in combination with chemotherapy in the first line treatment of HL reported so far. Both anti-CD30 targeted BEACOPP variants are well feasible without compromising the efficacy associated with $BEACOPP_{escalated}$. Enrollment will be finished by March 2014 (at end of February 97 of 100 patients have been enrolled) and updated results will be presented.

S1293

BRENTUXIMAB VEDOTIN AS SINGLE AGENT IN REFRACTORY OR RELAPSED CD30-POSITIVE HODGKIN LYMPHOMA: THE FRENCH NAME PATIENT PROGRAM EXPERIENCE IN 241 PATIENTS

A Perrot[1,*], H Monjanel[2], R Bouabdallah[3], G Cartron[4], G Salles[5], M Bernard[6], H Tilly[7], C Borel[8], K Bouabdallah[9], C Sebban[10], F Morshhauser[11], P Brice[2]
[1]Hôpital de Brabois, Vandoeuvre-lès-Nancy, [2]Hôpital Saint-Louis, Paris, [3]Institut Paoli Calmette, Marseille, [4]Hôpital Saint Eloi, Montpellier, [5]Centre Hospitalier Lyon Sud, Pierre-Bénite, [6]Hôpital Pontchaillou, Rennes, [7]Hôpital Charles Nicolle, Rouen, [8]Hôpital Purpan, Toulouse, [9]Hôpital Haut Lévêque, Pessac, [10]Centre Léon Bérard, Lyon, [11]Hôpital Claude Huriez, Lille, France

Background: Brentuximab vedotin (BV), comprising an anti-CD30 antibody conjugated to the potent anti-microtubule agent, monomethyl auristatin E, was reported effective and safe in several refractory or relapsed CD30-positive Hodgkin's Lymphoma (HL) cohorts including 12 to 102 patients (*Younes A, JCO 2012*).

Aims: Here is presented the French experience of BV used as single agent in refractory or relapsed CD30+ HL patients enrolled in the name patient program (NPP).

Methods: 241 patients (median age at 34 years [range 17-79]) treated between January 2011 and January 2014 were retrospectively analysed using specific files. All patients had histological documented CD30+ HL and 59% have an Ann Arbor stage III-IV disease at initial diagnosis. All patients received first line chemotherapy (CT)(ABVD: 83% or BEACOPP: 12%) and 74% were primary refractory (no response to CT or response duration<12 months). After a median of 3 lines of CT [range 1-13], BV was administrated by intravenous infusion at 1.8 mg/kg every 3 weeks. BV response assessment was determined according to Cheson 1999 criteria for 22% of patients and to Cheson revised criteria for 78%. The primary endpoint was the best response after BV treatment. Response at the end of BV treatment, duration of response, disease-free survival (DFS), progression-free survival (PFS), overall survival (OS) and toxicity profile were secondary endpoints.

Results: At initiation of BV, 77% of patients had a stage III-IV disease and performance status was less than 2 in 81% of patients. 8% of them had a preexistant peripheral neuropathy. The median time since diagnosis was 31 months [range 3-335] and median time since last line of treatment 2 months [range 0.1-132] with 47% of patients progressive to the last CT. 61% of patients had received at least one transplant (including 36% who received two transplants), allogeneic transplantation was performed in 16% of patients and 45% relapsed less than 6 months after transplant. Patients received a median of 6 cycles of BV [range 1-16]; 17% of them needed at least one dose adaptation and 7% had a CT with BV. At the analysis date, 222 patients (92%) discontinued BV treatment, mostly because of progression (54%), but also to perform a transplant (25%) and 5% for adverse event. Among the 241 patients, 70 received a consolidation treatment after BV: radiotherapy in 11 cases, autologous transplant in 29 cases, allogeneic regimen in 27 cases. The primary endpoint, best response was observed after a median of 4 cycles in 223 patients: CR/uCR in 32% of patients, PR in 26% (ORR 58%, 43% according to Cheson 1999 and 68% according to Cheson 2007). At the end of treatment, CR/uCR rate was 23%, and PR rate was 9% (ORR 32%). Median duration of response was 8 months [95% CI 6-14] in the 140 patients in CR/uCR/PR; median DFS of 19 months [95% CI 13-NR]. With a median follow-up of 16 months, median PFS was 7 months [95% CI 6-8] and median OS was not reached (estimated 1 yr-OS at 76%, 2 yr-OS at 58%). Among the 75 patients who died, most common causes of death were lymphoma progression (68%), concurrent illness (9%), toxicity of additional treatment (5%). No deaths have been linked to BV toxicity. The most common treatment-related adverse events were peripheral sensory neuropathy (26% grade 1-2 ; 2% grade 3-4), anemia (39%), thrombocytopenia (27%), neutropenia (23%, with 7% of grade 3-4 infections) and diarrhea (14%).

Summary and Conclusion: This largest retrospective analysis supports the previously reported efficacy of BV in heavily pretreated CD30+ HL patients with manageable toxicity. Due to a short duration of response, the use of autologous or allogeneic transplantation should be considered quickly in responder patients as a consolidation approach to cure the disease.

S1294

BENDAMUSTINE-CONTAINING REGIMEN (BEGEV) EFFICIENTLY MOBILIZES CD34+ HEMATOPOIETIC CELLS IN RELAPSED/REFRACTORY HODGKIN LYMPHOMA

S Gandolfi[1,*], C Carlo- Stella[1,2], A Anastasia[3], A Pulsoni[4], A Re[3], R Mazza[1], M Gotti[5], M Bonfichi[5], F Merli[6], G Annechini[4], A M Liberati[7], C Gabutti[8], F Salvi[9], E Brusamolino[1], L Castagna[1], A Santoro[1]
[1]Department of Hematology and Oncology, Humanitas Cancer Center, Humanitas Clinical and Research Center, Rozzano (MI), [2]Department of Medical Biotechnology and Translational Medicine, University of Milano, Milan, [3]Hematology, Spedali Civili di Brescia, Brescia, [4]Department of Cellular Biotechnologies and Hematology, "Sapienza" University, Rome, [5]Division of Hematology, Fondazione IRCCS Policlinico San Matteo, Pavia, [6]Hematology,, Azienda Ospedaliera Arcispedale S.Maria Nuova IRCCS, Reggio Emilia, [7]Haematology, AO S.Maria Policlinico Monteluce, Terni, [8]Division of Hematology, Niguarda Ca' Granda Hospital, Milan, [9]Division of Hematology, AO SS Antonio e Biagio e C. Arrigo, Alessandria, Italy

Background: Bendamustine has demonstrated clinical activity as single agent in a variety of lymphoproliferative disorders, including Hodgkin lymphoma (HL). Despite the wide use of this compound alone or in combination, limited data are so far available to support its capacity to mobilize peripheral blood stem cells (PBSC).

Aims: A phase II open-label prospective study is currently ongoing to evaluate the efficacy of the BeGEV (Bendamustine, Gemcitabine and Vinorelbine) regimen as induction chemotherapy before autologous stem cell transplant (ASCT). One of the study objectives is to investigate the stem cell mobilization activity of this Bendamustine-containing regimen.

Methods: Between August 2011 and January 2014, 40 consecutive patients with relapsed/refractory HL were enrolled in this phase II open-label prospective study with BeGEV followed by ASCT. The treatment schedule was: Bendamustine (90 mg/sqm, days 2-3), Gemcitabine (800 mg/sqm, day 1 and 4) and Vinorelbine (25 mg/sqm, day 1) plus G-CSF 10 µg/Kg beginning on day 7 and continued daily until collection of the target CD34+ cell yield (3 x 10^6 CD34+ cells/kg body weight). PBSC collection was planned after cycle 1 or cycle 3 in case of bone marrow involvement. Readout of PBSC harvesting included the absolute number of collected CD34+ cells/Kg, the number of leukapheresis (LK) per cycle, the value of pre-leukapheresis circulating CD34+ cells/µL, white blood cell (WBC) counts and the day of first collection. Adverse events were also recorded. All patients provided written informed consent at the time of study inclusion.

Results: Of the 40 patients enrolled, 37 underwent PBSC mobilization and harvesting and are evaluable. Two patients stopped treatment due to disease progression, while the other patient is currently receiving the first cycle of therapy. Successful PBSC mobilization was observed in 36 out of 37 evaluable patients who achieved the target yield of 3 x 10^6 CD34+/Kg. The median yield of CD34+ cells/Kg was 8.6 x 10^6 CD34+/Kg (range, 3.6- 56) after a median of 1 procedure (range, 1-2). Median values of pre-collection CD34+ cells/µL and WBC count/µL were 82/µL (range, 22-339) and 24,380/µL (range, 5,400-87,000), respectively. PBSC collection was performed after a median of 12 days (range, 9-15). Twenty-one patients underwent LK at cycle 1, 10 after cycle

2 (due to logistic reasons in 9 patients and Cytomegalovirus reactivation in 1 case), 5 after cycle 3 and one patient collected CD34+ cells after 4th cycle. Grade 1/2 hematologic and non-hematologic side effects were limited and no toxic death occurred. One patient developed grade 1 hypotension during LK, but she was able to complete the procedure. To date, 25 patients (67%) have been autografted, achieving neutrophils and platelets recovery on day 10 (range 9-21) day 12 (range 9-26), respectively.

Summary and Conclusion: This is the first prospective study evaluating the mobilizing activity of a Bendamustine-containing regimen in relapsed/refractory HL patients undergoing ASCT. Our results demonstrate that Bendamustine has neither stem cell toxicity nor detrimental effects on stem cell mobilization, and that BeGEV regimen has a high PBSC mobilizing activity.

Myelodysplastic syndromes - Clinical

S1295

THE ADDITION OF LENALIDOMIDE TO AZACITIDINE IN HIGHER RISK MDS IS DELIVERABLE WITH HIGHER RESPONSE RATES; FIRST ANALYSIS OF THE ALLG MDS4 RANDOMISED PHASE II STUDY

M Kenealy[1,*], W Benson[2], W Stevenson[3], R Eek[4], D Zantomio[5], I Cunningham[6], D Hiwase[7], S Vlachos[8], D Zannino[8], J F Seymour[8]

[1]Cabrini Hospital, Melbourne, [2]Westmead Hospital, [3]Royal North Shore Hospital, Sydney, [4]Border Medical Oncology, Wodonga, [5]Austin Hospital, Melbourne, [6]Concord Hospital, Sydney, [7]Royal Adelaide Hospital, Adelaide, [8]Peter MacCallum Cancer Centre, Melbourne, Australia

Background: Azacitidine (AZA) improves OS compared to conventional care regimens in high risk MDS; lower risk MDS obtain clinically relevant responses. Virtually all patients (pts) however ultimately progress with poor prognosis. AZA with lenalidomide (LEN) is a rational combination to investigate for these pts, given the differing mechanisms and established single agent activities. Early phase trials have developed dose and schedule with acceptable toxicity. We present a first analysis of secondary endpoints of the ALLG MDS4 – a randomised phase II study comparing AZA +/- LEN in higher risk MDS and low blast AML.

Aims: 1. assess response rates of AZA and AZA + LEN 2. describe toxicity and deliverability of this combination.

Methods: Thirty centres participated; eligible pts provided informed consent and had low blast, non-proliferative AML, MDS (and RCUD and RARS with at least one clinically significant cytopenia) or non-proliferative CMML, with no prior demethylating agent or IMiD. Pts were stratified according to IPSS, site, diagnosis, and randomised 1:1. Treatment for all pts was AZA 75mg/m^2/d sc 5-2-2 schedule until progression or intolerance; those randomised to combination therapy began LEN at cycle3, 10mg oral D1-21 of each 28d cycle for total 10 cycles with AZA reduced to 5d schedule. Primary endpoint of the study (not analysed to date) is rate of clinical benefit (alive with absence PD) at 12mths. Close-out date for this analysis is Dec31 2013. Responses reported according to IWG criteria and ITT (only 1 pt received no drug).

Table 1.

	AZA (n=77)	AZA+LEN (n=76)
Male	65%	74%
Median age (yrs)	69.1 (42.5-85.9)	71.4 (44.1-87.2)
Median from diagnosis	0.5 (0.1-13.1) yrs	0.4 (0.0-9.4) yrs

SD	29%	21%
PD	4%	5%
Not evaluable/missing	16%	8%

*Note patients could have HI response in more than one lineage

Results: Between March 2011 and March 2013 160 pts were randomized; for those continuing on study, only pts ≥12 months from study commencement are included (n=153). Median follow up is 11.7mths (0.7-26.7), median number

cycles aza=11 (AZA) v 10 (AZA+LEN); median cycles LEN in combination arm=8. Number AZA cycles dose reduced 2.5% AZA v 2.4% AZA+LEN. A mean of 3.2% per patient LEN cycles were dosed<10mg. See table for baseline data and best responses. ORR (CR to HI) 52% (AZA) v 66% (AZA+LEN) (p=0.08). Median time to first response 2.8mths (AZA) v 2.7mths (AZA+LEN) and to best response 5.5mths (AZA) v 4.7mths (AZA+LEN) (p=0.13). Median PFS 14.4mths (AZA) v 16.4mths (AZA+LEN). Overall rate Gr3+ nonhaem AEs 61% (AZA) v 68% (AZA+LEN); Gr3+ infections 43% (AZA) v 45% (AZA+LEN) including febrile neutropenia 20% both arms. Only other Gr3+ AE >5% pts was raised GGT in AZA+LEN 15%, to be further assessed. Emerging Gr3+ haematologic toxicity: new Hb<80g/L in 41% both AZA and AZA+LEN, neutrophils<1x10^9/L 43% AZA v 49% AZA+LEN, platelets<50x10^9/L in 37% AZA v 40% AZA+LEN. Most haematologic toxicity was seen in the first 2-4 cycles.
Summary and Conclusion: The regimen of concurrent AZA+LEN in pts with higher risk MDS/low blast AML/CMML is deliverable with numerically higher response rates and a trend for shorter time to best response than AZA alone. Toxicity is not excessive, with similar rates of emerging haematologic toxicity and infections. We await main analysis for assessment of primary endpoint of clinical benefit at 12mths treatment and OS.

S1296

ACE-536 INCREASES HEMOGLOBIN LEVELS IN PATIENTS WITH LOW OR INTERMEDIATE-1 RISK MYELODYSPLASTIC SYNDROMES (MDS): PRELIMINARY RESULTS FROM A PHASE 2 STUDY

U Platzbecker[1,*], U Germing[2], A Giagounidis[3], K Götze [4], P Kiewe[5], K Mayer[6], O Ottmann[7], M Radsak[8], T Wolff[9], M Hankin[10], D Wilson[10], M Sherman[10], K Attie[10]
[1]Universitätsklinikum Carl Gustav Carus, Dresden, [2]Universitätsklinikum Düsseldorf, [3]Marien Hospital Düsseldorf, Düsseldorf, [4]Technical University of Munich, Munich, [5]Onkologischer Schwerpunkt am Oskar-Helene-Heim, Berlin, [6]Universitätsklinikum Bonn, Bonn, [7]Klinikum der J.W. Goethe-Universität Frankfurt, Frankfurt/Main, [8]University Medical Center - Johannes Gutenberg-Universität, Mainz, [9]OncoResearch Lerchenfeld UG, Hamburg, Germany, [10]Acceleron Pharma, Cambridge, MA, United States

Background: ACE-536 is a recombinant fusion protein containing modified activin receptor type IIB, being developed for the treatment of anemias due to ineffective erythropoiesis, such as myelodysplastic syndromes (MDS). Patients with MDS often have elevated levels of erythropoietin (EPO) and may be non-responsive/refractory to erythropoiesis-stimulating agents (ESAs). ACE-536 binds to ligands in the TGF-ß superfamily and promotes late-stage erythroid differentiation via a mechanism distinct from ESAs. In a healthy volunteer study, ACE-536 was well-tolerated and increased hemoglobin (Hgb) levels (Attie K *et al.*, Am J Hematol 2014). RAP-536 (murine ortholog of ACE-536) increased Hgb levels and decreased bone marrow erythroid hyperplasia in a mouse model of MDS (Suragani R *et al.*, Blood 2012;120:3796).
Aims: This is an ongoing, phase 2, multicenter, open-label, dose-finding study to evaluate the effects of ACE-536 on anemia in patients with transfusion-dependent (TD) or non-transfusion dependent (NTD) low or int-1 risk MDS. Study outcomes include erythroid response (either Hgb increase in NTD patients or reduced transfusion burden in TD patients), safety, tolerability, PK, and PD biomarkers.
Methods: Inclusion criteria included low or int-1 risk MDS, age ≥ 18 yr, with anemia defined as either Hgb<10.0 g/dL (NTD, defined as<4 units RBCs/8 wks prior to baseline) or ≥4 units RBCs/8 weeks prior to baseline (TD), EPO >500 U/L or non-responsive/refractory to ESAs, no prior azacitidine or decitabine, and no current treatment with ESA, G-CSF, GM-CSF, or lenalidomide. ACE-536 was administered by subcutaneous (SC) injection once every 3 weeks in sequential cohorts (n=3-6) at dose levels ranging from 0.125 to 1.33 mg/kg for up to 5 doses with a 3-month follow-up. Further possible dose escalation and an expansion cohort (n=30) are planned, contingent on periodic safety data review.
Results: Preliminary data were available for 21 patients (12F/9M, 6 NTD/15 TD) enrolled as of 13Feb2014. Median age was 71 yr (range: 27-88 yr). 48% had prior EPO therapy and 19% had prior lenalidomide. Mean (SD) baseline Hgb for NTD patients (n=6) was 9.0 (0.4) g/dL. Mean (SD) units RBCs transfused in the 8 weeks prior to baseline for TD patients (n=15) was 6.2 (2.5) units. Preliminary efficacy data were available for the 15 patients (5 NTD/10 TD) treated in the first 4 cohorts (0.125, 0.25, 0.5, or 0.75 mg/kg). The 5 NTD patients demonstrated dose-dependent increases in Hgb on treatment, with maximum Hgb increase ranging from 0.8 to 3.3 g/dL. The 3 NTD pts in the 0.75 mg/kg group were either ESA refractory or non-responders and had maximum Hgb increases of 1.6, 1.9, and 3.3 g/dL. One NTD patient in this group had a Hgb increase ≥1.5 g/dL sustained for ~15 weeks. Four of the 10 TD patients had a ≥50% reduction in units transfused during an 8-week interval on treatment compared to the 8 weeks prior to treatment, including 1 pt, previously ESA and lenalidomide non-responsive, who was transfusion-free while on study (~22 weeks). Transient increases in reticulocytes and/or neutrophils were observed in some patients. ACE-536 was generally well tolerated. No related serious AEs have been reported to date. No patients discontinued treatment early due to a related AE.
Summary and Conclusion: Based on preliminary data in low or int-1 MDS patients with high baseline EPO levels or lack of response to ESA treatment, ACE-536 administered SC every 3 weeks increased Hgb levels in NTD patients and decreased transfusion requirement in some TD patients, with a favorable safety profile. These data support further evaluation of ACE-536 in patients with MDS.

S1297

MUTATIONAL ANALYSIS AND LONG TERM OUTCOME IN ADVANCED CHRONIC MYELOMONOCYTIC LEUKEMIA (CMML) TREATED BY DECITABINE: AN UPDATE OF THE GFM-CMML-2007 PHASE II TRIAL

T Braun[1,*], R Itzykson[1], N Droin[1], A Renneville[1], B de Renzis[1], F Dreyfus[1], K Laribi[1], K Bouabdallah[1], C Cordonnier[1], C Recher[1], N Vey[1], JN Bastie[1], O Beyne-Rauzy[1], B Jolie[1], E Jourdan[1], L Legros[1], Z Marjanovic[1], L Sanhes[1], G Tertian[1], I Vaida[1], C Gardin[1], L Ades[1], E Solary[1], P Fenaux[1]
[1]Groupe Francophone des Myelodysplasies, Bobigny, France

Background: Treatment of advanced CMML remains a challenge with no standard approach except HSCT for a minority of patients. Recently, we and others reported that the hypomethylating agents decitabine (DAC) (Braun et al, Blood 2011) and azacitidine (AZA) (Costa et al, Cancer 2011; Adès et al, Leuk Res, 2013) yield responses ranging from 35 to 45% in this setting.
Aims: Here we analyzed long term outcome in our previously published prospective phase II trial of DAC of advanced CMML (Braun et al, Blood 2011) to identify prognostic factors.
Methods: Between Nov 2008 and June 2009, 39 CMML patients (according to WHO) were included in this clinical trial if they had the following poor prognostic factors, based on a previous prognostic analysis (Wattel et al, Blood 1996): WBC<13G/l and IPSS 1.5; or WBC 13G/l, and two of the following criteria: marrow blasts 5%, Hb<10g/dl, plts<100G/l, abnormal cytogenetics, splenomegaly (SMG) >5cm below costal margin, (SMG>5cm), extra medullary disease (EMD),. Patients received DAC 20mg/m2/d IV for 5 days every 28 days for at least 3 cycles. Response criteria were based on IWG 2006 for patients with WBC<13G/L and also included evolution of WBC, SMG and EMD for patients with WBC ≥ 13 G/L. Data were analyzed 48 months after the last inclusion. For mutational analysis, DNA could be extracted for 37 patients from total BM nucleated cells or PB monocytes, and the following genes studied: ASXL1, CBL, FLT3 mutation and ITD, JAK2, NRAS and K RAS, RUNX1 and TET2. Statistical analysis was performed on Stata SE 10.1 (StataCorp, College Station, TX, USA).
Results: Median age was 71 years M/F: 30/9. 17 patients had CMML 1 and 22 had CMML 2. Nine patients had WBC<13G/l and 30 WBC ≥13G/l. Abnormal karyotype was found in 18 (46.2%) patients, including +8 and -7 in 7 and 1 case, respectively. 15 patients (38.6%) had SMG >5cm and 8 (20.5%) EMD. 58% patients were mutated for ASXL1, 50% for TET2, 31% for RAS (6 NRAS/5 KRAS), 28% for RUNX1, 14% for CBL, 6% for FLT3-ITD, 3% for FLT3 mutation and 3% for JAK2. 58% patients had at least 2 mutations. Overall Response Rate (ORR) was 38.6% with 4 (10.3%) CR, 8 (20.5%) marrow CR and 3 (7.7%) Stable Disease (SD). Median overall survival (OS) was 18 months. WBC, monocytes, Hb level, marrow blast %, SMG or EMD were not significantly prognostic of ORR, response duration or OS. 7/11 (63.6%) RAS mutated patients responded *vs* 8/27 (29.6.%) RAS germline patients (p=0.07). In univariate analysis, RAS mutation, known to have in CMML an unfavorable outcome (at least for NRAS) was associated with better OS (28 *vs* 17 months; p=0.05) and longer response duration (17.8 *vs* 9.2 months, p=0.056) compared to RAS germline. The ORR was 38.1% and 29.4%, and median OS was 18.2 months and 18.4 months in patients with ASXL1 mutations (an overall poor prognostic factor in CMML) and ASXL1 germline patients, respectively (p=0.28 and p=0.36, respectively). 6 patients had prolonged response to DAC of 18, 18, 39, 39, 48 and 58 months respectively. All those 6 patients had ASXL1 mutation, and 4 had concomitant RAS mutation. Another patient was allografted after 6 cycles in CR and was still alive (56+ months).
Summary and Conclusion: In this study of 39 advanced CMML treated with DAC with long term follow up, no conventional prognostic factor of response or survival to DAC emerged, while RAS mutations were associated with a better outcome and ASXL1 had no prognostic value. This possibly suggested a positive effect of DAC in CMML cases with RAS and/or ASXL1 mutation (ie with poor prognostic features), which however requires confirmation in larger series.

S1298

ISOLATED TOTAL MONOSOMY 7 IS ASSOCIATED WITH BETTER PROGNOSIS IN A LARGE COHORT OF MDS PATIENTS COMPARED WITH OTHER ABNORMALITIES OF CHROMOSOME 7- A SINGLE INSTITUTE EXPERIENCE

E Crisà[1,*], A Kulasekararaj[1], V Potter[1], K Raj[1], R Ireland[1], H De Lavallade[1], D McLornan[1], B Czepulkowski[2], J Marsh[1], G Mufti[1]
[1]Haematology, [2]Cytogenetics, King's College Hospital, London, United Kingdom

Background: Karyotype is a strong independent prognostic factor in myeloid

neoplasms and abnormalities of chromosome 7 are the second commonest abnormality in MDS. The differential impact of monosomy 7, del7q (partial loss) and -7 (total loss) on prognosis has been demonstrated and hence incorporated into separate groups in revised IPSS.
Aims: To evaluate the clinical features, treatment and outcome of a large cohort of myelodysplastic syndromes (MDS) and related myeloid neoplasms in patients with cytogenetic aberration involving chromosome 7.
Methods: We retrospectively analysed 168 MDS patients who presented at diagnosis (147) or acquired during follow-up (21) any abnormality of chromosome 7. Patients were diagnosed between 1995 and 2013 at our institution.
Results: Median follow-up was 17 months (mo). Median age at diagnosis was 59 (range 16-91) years; 60% males and 60% more than 60 years. Denovo MDS were 118 (11 RA, 2 RARS, 56 RCMD, 23 RAEB1, 26 RAEB2), 12 had MDS/MPN, 38 AML including 15 secondary to MDS. Overall, 27 MDS/AML were therapy-related. According to IPSS, 15 % were at low, 48% intermediate 1, 19% intermediate 2 and 19% high risk. According to karyotype 4 subgroups were identified: -7 as a single abnormality (39%), -7 associated with other chromosomal aberrations (47%), del(7q) plus other chromosomal aberrations (5%) and patients with add(7) or translocations between 7 and other chromosomes [t(1:7),t(7:17),t(7:21),t(4:7)] (9%). Eighty-six (51%) patients had complex karyotype and 57 (34%) monosomal karyotype. Fifty-seven patients were treated in first line with intensive chemotherapy (IC), 55 with azacytidine (AZA), 32 with other therapies (including lenalidomide, low dose cytarabine) and 23 with best supportive care (BSC). Fifty-four patients underwent allogeneic haematopoietic stem cell transplantation (HSCT); 31 after IC, 15 after AZA and 8 as upfront. Median overall survival (OS) was 19 mo (range 1 to 166) and was significantly affected by karyotype: in isolated -7 group was 27 mo, in -7 plus other abnormalities group 16 mo, in del(7q) group 15 mo and in add(7)/t(7;?) group 8 mo (p<0.016). Moreover, as expected, both complex karyotype (p<0.001) and monosomal karyotype (p<0.002) were poor prognostic factors (median OS 11 and 15 mo, respectively). Patients treated with AZA as front line therapy had a better OS (27 mo) compared to patients who received IC (17 mo), other therapies (19 mo) or BSC (7mo) (p<0.041). As expected, patient who underwent HSCT had a longer survival (25 mo *vs* 18 mo, p 0.022), regardless the pre-HSCT treatment. This could be due of the positive selection of patients who survived and responded to induction therapy. In the MDS subgroup, in addition to the above described prognostic factors, IPSS, WPSS and IPSS-R too were significant outcome predictors (p 0.001). Median progression free survival was 12 mo and was affected by complex karyotype (7 mo *vs* 16 mo, p<0.001), type of 7 abnormality (-7 alone 18 mo, -7 plus other abnormalities 10 mo, del (7) 2mo and add (7)/t (7 ;?) 13 mo, p<0.001), IPSS (p<0.017) but not by therapy. Cumulative incidence of AML was 33% and 40% at 24 and 60 months, respectively.
Summary and Conclusion: In our study isolated -7 had a positive impact on OS compared to other abnormalities of 7, including del7q. This finding is discordant to recently published data, possibly due to fewer patients with isolated del7q, less untreated patients and the younger age of our cohort. AZA seemed to be good treatment option for these patients, even if the better outcome was associated with HSCT, an option for a selected group of patients.

S1299

IDENTIFICATION OF BIOMARKERS WHICH COULD PREDICT THE HEMATOLOGICAL RESPONSE OF NON DEL(5Q) LOW-RISK MDS PATIENTS TREATED BY LENALIDOMIDE ; THE GFM EXPERIENCE

V Chesnais[1], A Renneville[2], V Sardnal[1], J Delaunay[3], C Rose[2], A Stamatoulas[4], O Beyne-Rauzy[5], P Fenaux[6], A Toma[7], F Drefyus[8], C Preudhomme[2], O Kosmider[1,8,*], M Fontenay[1,8]
[1]Cochin Institute, Paris, [2]CHRU Lille, Lille, [3]Hopital Bicetre, Le Kremlin-Bicêtre, [4]CHU Rouen, Rouen, [5]CHU Toulouse, Toulouse, [6]Hopital Saint Louis, Paris, [7]Hopital Henri Mondor, Creteil, [8]Hopital Cochin, Paris, France

Background: Lenalidomide (Len) is a successful therapy used to treat anemia of patients with MDS del(5q) in half of the cases. Treatment by Len also induces an erythroid response in ~25% of non del(5q) low-risk or int-1 MDS patients. Len targets the protein Cereblon, a receptor for the substrates of the E3 ubiquitin ligase Cul4A-DDB1-Roc1, including Ikaros (IKZF1) and Aiolos (IKZF3) encoded by the *CRBN* gene.
Aims: Predictive biomarkers of the erythroid response to Len are needed to avoid inappropriate exposition to the risk of severe neutropenia or thrombocytopenia.
Methods: This was investigated in a cohort of 132 non del(5q) MDS patients (IPSS low and int-1), non-responders to a previous treatment by erythropoiesis-stimulating agent (ESA), enrolled in the Groupe Francophone des Myelodysplasies GFM-LenEpo 08 clinical trial (NCT01718379). Patients were randomized to Len 10mg/day 21 days/28 (L-arm) or Len 10 mg/d 21 d/28 plus Epoetin beta (60,000 units/w) (LE-arm) and evaluated after 4 cycles. Ninety-nine/132 patients were enrolled in the biological study including 41 responders and 58 non responders. We have previously reported a significantly HI-E according to IWG2006 in LE-arm (52%) *vs*. L-arm (31%) (p=0.031) (1). Extensive genotyping study of 26 genes (*ASXL1, CBL, DNMT3A, ETV6, EZH2, FLT3, IDH1, IDH2, JAK2, KIT, KRAS, MPL, NPM1, NRAS, PHF6, PTPN11, RIT1, RUNX1, SETBP1, SF3B1, SRSF2, TET2, TP53, U2AF1, WT1, ZRSR2*) was conducted by a NGS approach (AmpliSeq, Life technologies). Mutations were considered as clonal when the VAF was >50%, and subclonal when 5
Results: The most frequently mutated genes were SF3B1 (73%), TET2 (45%?), ASXL1 (20%) and DNMT3A (20%), none of them influencing the response to Len or Len+Epo. Analysis of erythropoiesis based on the ratio of BFU-E/CFU-GM and the GEP signatures delineated two groups of responders patients: (i) a first group with impaired erythropoiesis, as already reported (2) and a second group with still effective erythropoiesis before treatment as assessed by normal or subnormal BFU-E number and the expression of erythroid genes. Using *Gene Set Enrichment Analysis (GSEA), the* comparison of GEP in 24 paired samples obtained before and after 4 cycles of treatment linked the response in L-arm or LE-arm to a signature of 32 up-regulated genes exclusively involved in the immune response. A supervised GSEA analysis of GEP before treatment identified a predictive signature of 36 up-regulated genes mainly involved in translation, cellular division and DNA repair. The basal expression level of 2/36 genes of this signature, further quantified by qPCR in a larger set of patients, was predictive of the response in L-arm or LE-arm (p<0.001) with a sensitivity >65% and a specificity >92%. The efficacy of Len or Len+Epo was independent of the basal expression level of CRBN, IKZF1 and IKZF3. However, a A>G polymorphism in the 5'UTR region of *CRBN* gene (rs1672753) was significantly associated with HI-E in the whole cohort (41.5% in responders *vs*. 22.4% in non-responders; p=0.048).
Summary and Conclusion: In conclusion, we have identified three biomarkers predictive of the erythroid response to Len or Len+Epo. 1. A Toma *et al.* Oral Presentation, ASCO Annual Meeting 2013 (#7002), 2. Ebert BL *et al.* PLoS Med. 2008 Feb;5(2):e35.

THE BRAF-MEK-ERK PATHWAY IN HAIRY CELL LEUKEMIA: A COMPREHENSIVE DISSECTION IN PRIMARY LEUKEMIC CELLS OF ITS BIOLOGICAL AND THERAPEUTIC RELEVANCE

A Santi^[1,*], V Pettirossi^ [1]E Imperi[1], G Russo[1], A Pucciarini[1], B Bigerna[1], E Fortini[1], R Mannucci[2], G Schiavoni[1], I Nicoletti[2], MP Martelli[1], L Klein-Hitpass[3], B Falini° [1]E Tiacci°[1]

[1]Institute of Hematology, Department of Medicine, University of Perugia, Italy, [2]Institute of Internal Medicine and Oncologic Sciences, Department of Medicine, University of Perugia, Perugia, Italy, [3]Biochip Laboratory, Institute for Cell Biology-Tumor Research, University of Duisburg-Essen, Essen, Germany

Background: Hairy cell leukemia (HCL) is a distinct, chronic B-cell neoplasm with a unique morphology, immunophenotype and molecular signature among other B-cell leukemias/lymphomas. Recently, we identified BRAF-V600E as the mutation underlying HCL and distinguishing it from HCL-like neoplasms (*e.g.*, HCL-variant and splenic marginal zone lymphoma) (Tiacci et al, NEJM 2011;364:2305). Because in solid tumors the BRAF-V600E activating kinase mutation leads to constitutive phosphorylation of MEK and, in turn, ERK, the BRAF-MEK-ERK pathway appears an ideal candidate to shed light on the unique biology of HCL and an ideal therapeutic target to be attacked by BRAF or MEK inhibitors, which recently proved effective in clinical trials of BRAF-V600E+ melanoma patients. However, a thorough dissection of the biological effects of the BRAF-MEK-ERK pathway in HCL is so far lacking, as are mechanistic studies on the effects of these drugs in HCL.

Aims: To study *in vitro* the effects of BRAF and MEK inhibitors on the specific biochemical, molecular, morphological and anti-apoptotic features of HCL, using patients' hairy cells (as the putative "HCL" cell lines described in the literature do not carry the BRAF-V600E mutation and are unlikely to be of true HCL origin - Tiacci et al, Blood 2012;119:5332).

Methods: Primary leukemic cells, purified (≥90%) from 23 HCL patient and 13 HCL-like patients, were exposed *in vitro* to active BRAF inhibitors (Vemurafenib, Dabrafenib or PLX4720) or the MEK inhibitor Trametinib for 15 minutes to 96 hours at various concentrations (up to 1 μM), and were then monitored for: *i)* activation status of MEK and ERK by Western blotting; *ii)* downstream transcriptional changes by genome-wide expression profiling (in 6 HCL patients); *iii*) surface morphology changes by confocal microscopy after phalloidin/Annexin-V staining to highlight the F-actin-rich hairy projections in still living cells (in 8 HCL and 5 HCL-like patients); *iv)* viability (by MTT or WST metabolic assays) and apoptosis (by AnnexinV/PI staining) in 14 HCL and 5 HCL-like patients.

Results: In all HCL patients, treatment with each BRAF inhibitor resulted in a consistent, sustained and dose-dependent dephosphorylation of MEK and ERK at all time points and at all drug concentrations tested, as compared to vehicle-treated cells and to inhibitor-treated HCL-like cells. Also Trametinib produced a strong downregulation of phospho-ERKs levels in HCL cells. Notably, gene expression profiling after 48h and 72h of BRAF-inhibition by Vemurafenib showed not only a silencing of the RAF-MEK-ERK pathway transcriptional output previously described in solid tumors, but also a loss of the HCL-specific gene expression signature previously identified by us (Basso et al, JEM 2004;199:59), as well as the downregulation of the HCL immunophenotypical markers CD25, TRAP and cyclin-D1. These *in vitro* mRNA data were validated at the protein level and *in vivo* by documenting loss of surface CD25 expression and of nuclear cyclin-D1 expression in the leukemic cells of two pluri-relapsed HCL patients being treated with Vemurafenib in our HCL-PG01 phase-2 clinical trial (EudraCT 2011-005487-13). Also interesting was the silencing of some genes important for generating cell membrane projections (*e.g.*, ACTB and LST1) and the induction of pro-apoptotic genes (*e.g.*, BCL2L11/BIM and CDKN1C/p57-Kip2). Indeed, the biochemical and transcriptional events triggered by BRAF inhibition were followed by a consistent and statistically significant ($p<0.05$): *i)* loss of the hairy projections in still viable (AnnexinV-negative) leukemic cells (see Figure); *ii)* reduction of metabolic viability (up to 51.7% relative to the drug vehicle); and *iii)* decrease of living, non-apoptotic (ANXA5/PI-negative) cells (up to 84.4% relative reduction), all of this occurring specifically in leukemic cells of the vast majority of HCL patients as opposed to none of the HCL-like patients.

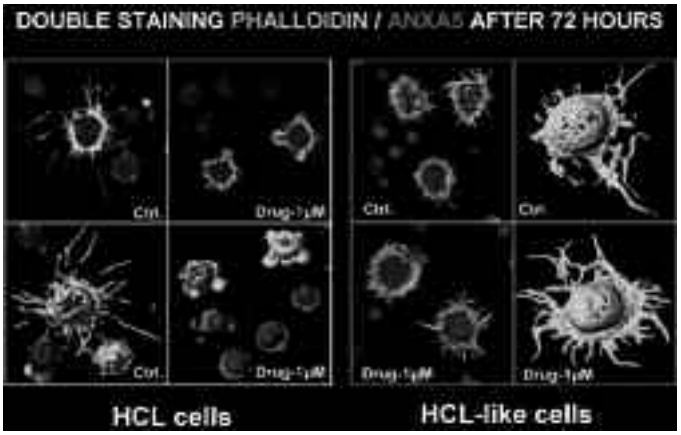

Figure 1.

Summary and Conclusion: These results represent a comprehensive biological and pre-clinical dissection of: ***i)*** the pronounced role of the BRAF-V600E mutation in driving the specific transcriptional signature, morphology and immunophenotype of HCL among other mature B-cell neoplasms; ***ii)*** the significant anti-leukemic activity obtained through inhibition of the BRAF-MEK-ERK pathway in HCL.

A NOVEL ACTIVATING SOMATIC MUTATION OF CXCR4 PLAYS A CRUCIAL ROLE IN MODULATING WALDENSTROM MACROGLOBULINEMIA BIOLOGY

A Roccaro[1,*], A Sacco[1], C Jimenez[2], P Maiso[1], M Moschetta[1], Y Mishima[1], Y Alajawai[1], M Kuhne[3], P Cardarelli[3], L Cohen[4], J San Miguel[5], R Garcia-Sanz[2], I Ghobrial[1]

[1]Dana-Farber Cancer Institute, Boston, United States, [2]University of Salamanca, Salamanca, Spain, [3]Bristol-Myers Squibb, Redwood City, [4]Bristol-Myers Squibb, Lawrenceville, United States, [5]University of Navarra, Pamplona, Spain

Background: Whole-genome sequencing has enhanced our understanding of the molecular mechanisms that may contribute to WM pathogenesis. Specifically, *L265P/MYD88* has been described as a prevalent somatic mutation in WM patients; and shown to increase tumor cells growth. However, *L265P/MYD88* did not predict progression or resistance to therapy, indicating that other genetic alterations may be critical for tumor progression and dissemination to distant organs. CXCR4 represents the main regulators of tumor B-cell homing to the BM. We therefore evaluated the mutational status of CXCR4 in 429 patients with B-cell lymphoproliferative disorders; and define its functional role in WM *in vivo*.

Aims: 1) To screen the CXCR4 mutational status in 429 patients with B-cell lymphoproliferative disorders. 2) To define the biological role of the C1013G/CXCR4 variant in WM, *in vivo*. 3) To evaluate the anti-tumor activity of the novel anti-CXCR4 monoclonal antibody, BMS-936564, against both mutated and wild-type WM cells, *in vivo*.

Methods: Allele-specific(AS) PCR was performed on bone marrow (BM)-derived tumor cells of patients with WM (n: 142); IgM-MGUS (n: 40); as well as in patients with DLBCL (n: 75), splenic marginal zone lymphoma (SMZL; n: 14), B-CLL (n: 37), hairy cell leukemia (HCL; n: 35), multiple myeloma (MM; n: 36), IgA/IgG MGUS (n: 22), lymphoplasmacytic lymphoma without WM criteria (n: 13), and amyloidosis (n: 6). healthy subjects have been also studied (n: 32). CXCR4-loss and -gain of function studies were performed on WM cells stably expressing either shRNA-CXCR4, CXCR4-ORF-GFP-tagged or scramble-RFP-tagged (lentiviral infection). Lentivirus-based infection was used to generate the *C1013G/CXCR4* mutant protein in WM cells. CXCR4-overexpressing or *C1013G/CXCR4*-mutated cells and the corresponding controls were injected i.v. into SCID/Bg mice and tumor dissemination was evaluated *ex vivo* by IHC (hCD20; h-CXCR4). *C1013G/CXCR4*-mutated cells were characterized at mRNA levels (U133 plus2) using GSEA. A novel human anti-CXCR4 mAb (BMS-936564) was tested *in vitro* (cell proliferation, MTT, adhesion, migration to primary WM BM mesenchymal stromal cells) and *in vivo*. Tumor growth was evaluated by IHC *ex vivo* (hCD20; hCXCR4) and by immunofluorescence.

Results: The somatic C1013G/CXCR4 variant was detected in 28% of the 142 WM cases evaluated. The mutation was also present at IgM-MGUS stage (20%); while it was present in a minority of patients with DLBCL (1%) and SMZL (7%); and absent in all MM, IgA/IgG MGUS, B-CLL, HCL patients and it was not detected in healthy subjects. Mice injected with C1013G/CXCR4-cells

presented with a significant dissemination of tumor cells, demonstrating involvement of liver, bone marrow, lymph nodes, kidney and lung. IHC showed the presence of CXCR4+ and CD20+ cells in all the tissues examined; and quantification of CXCR4 and CD20 positivity was higher in C1013G/CXCR4-cells-, compared to parental(p)-WM cell-injected mice (P<.05). C1013G/CXCR4-cells were further characterized *in vitro*, showing increased adhesion and cell proliferation in the presence of primary WM BM-MSCs. These findings were also confirmed using CXCR4-overexpressing cells. GSEA demonstrated that genes related to invasiveness, cell proliferation, anti-apoptosis, and oncogenesis were enriched in C1013G/CXCR4-cells compared to parental-WM cells. These findings let us hypothesize that C1013G/CXCR4 may act as an activating mutation in WM cells. Indeed, CXCR4 over-expressing cells were injected into mice, showing similar phenotype to the one observed upon C1013G/CXCR4-WM cell-injected-mice. Finally, the novel anti-CXCR4 antibody (BMS-936564) exerted anti-WM activity both *in vitro* and *in vivo*, with anti-tumor effects observed also against the mutated variant, with inhibition of pro-survival pathways (p-ERK; p-AKT); induction of pro-apototic proteins (cleaved-PARP and -caspase-9); up-regulation of p-GSK3beta, p-beta catenin and subsequent beta catenin degradation.

Summary and Conclusion: *C1013G/CXCR4* acts as an activating mutation in WM; and it is targetable by using BMS-936564 thus providing the basis for translating these observations into clinical trials for WM patients.

S1302

NORDIC MCL2-3 TRIALS: MIRNA-18B OVEREXPRESSION IDENTIFIES A MANTLE CELL LYMPHOMA SUBGROUP WITH POOR SURVIVAL AND IMPROVES MIPI-B PREDICTION OF PROGNOSIS

S Husby[1,*], U Ralfkiær[1], C Garde[2], S Ek[3], A Kolstad[4], M Jerkeman[5], A Laurell[3], R Räty[6], M Ehinger[3], C Sundström[7], ML Karjalainen-Lindsberg[6], J Delabie[4], E Clasen-Linde[8], P DN Brown[1], C T Workman[2], C H Geisler[1], K Grønbæk[1]
[1]Department of Hematology, Rigshospitalet, Copenhagen, [2]Department of Systems Biology, Technical University of Denmark, Lyngby, Denmark, [3]Department of Pathology, Skåne University Hospital, Lund, Sweden, [4]Departments of Oncology and Pathology, Rikshospitalet, Oslo, Norway, [5]Department of Oncology, Skåne University Hospital, Lund, Sweden, [6]Department of Hematology and Pathology, Helsinki University Central Hospital, Helsinki, Finland, [7]Department of Immunology, Genetics and Pathology, Uppsala University Hospital, Uppsala, Sweden, [8]Department of Pathology, Rigshospitalet, Copenhagen, Denmark

Background: Mantle cell lymphoma (MCL) is an aggressive NHL subtype with a variable clinical course. Based on long-term follow-up 57% of younger MCL patients (≤65 years) relapse during a 10-year period. Risk-stratification is therefore of great importance in order to identify patients who are eligible for novel or alternative treatment regimens. The current prognosticator (the MIPI-B) does however not identify specific biological pathways associated with aggressive subtypes of MCL. Over the last five years, several studies have shown that miRNAs delineate aberrant molecular pathways and predict survival in MCL patients. However, there is little coherence between the clinical studies, and at this point, miRNA expression in MCL has not yet been examined (or validated) in large, prospective, uniformly treated patient cohorts.
Aims: We assessed whether MCL miRNA expression could identify patients with poor survival and improve current prognostication of MCL patients.
Methods: Diagnostic MCL samples from 172 patients in the Nordic MCL2 and MCL3 clinical trials were retrieved. All patients had confirmed CyclinD1 overexpression and received almost identical high dose immunochemotherapy followed by ASCT. The only difference between the two regimens was that MCL3 patients with unconfirmed complete remission (CRu) or partial remission (PR) received ^{90}Y-Ibritumomab-Tiuxetan (Zevalin), which did not have any impact on survival or adverse events. The median follow-up was 6.4 years for the MCL2 cohort and 3.7 years for the MCL3 cohort. Genome-wide miRNA microarray profiling covering 1846 miRNAs was performed in 74 patients of the screening cohort (MCL2). Differentially expressed miRNAs (adjusted p-value<0.05) were re-analyzed by qRT-PCR. Prognostic miRNAs were validated by qRT-PCR in 94 patients of the validation cohort (MCL3). The main endpoint was cause-specific survival.
Results: In the screening cohort 17 miRNAs were differentially expressed by microarray analysis in patients who died from MCL. Follow-up qRT-PCR analysis of the 17 miRNAs in the validation cohort showed that three (miR-18b, miR-92a, miR378d) were differentially expressed in patients who died from MCL. Based on the screening cohort, feature selection and leave-one-out cross-validation, miR-18b was identified to hold the highest prognostic value. Multivariate analysis confirmed miR-18b as an independent prognostic variable. We generated a new MIPI-B-miR prognostic score, by combining expression-levels of miR-18b with MIPI-B data, with a significantly higher predictive value than the current gold standard MIPI-B with regards to cause-specific survival (p=0.015), overall survival (p=0.006), and progression-free survival (p<0.001).

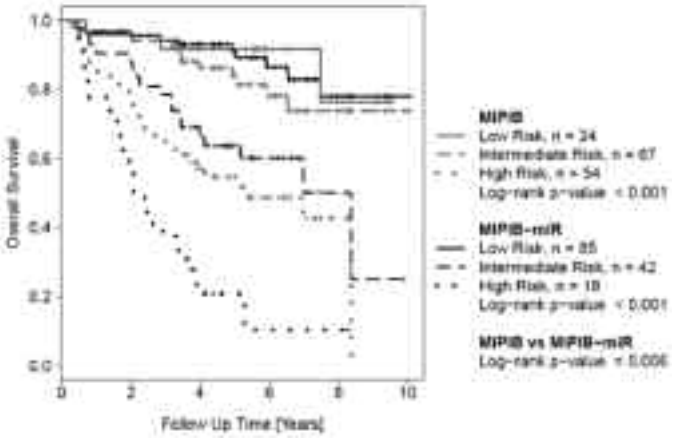

Figure 1.

Summary and Conclusion: Overexpression of miR-18b identifies patients with poor prognosis in two large prospective MCL cohorts and adds prognostic information to the MIPI-B score.

S1303

DISTINCT PATTERNS OF RHOA MUTATIONS IN ADULT T-CELL LEUKEMIA/LMPHOMA AND OTHER PERIPHERAL T-CELL LYMPHOMAS

K Kataoka[1,*], N Yasunobu[1], T Enami[2], A Kitanaka[3], M Sakata-Yanagimoto[2], M Sanada[1], A Sato[1], Y Shiraishi[4], K Chiba[4], H Tanaka[5], T Yoshizato[1], A Kon[1], K Yoshida[1], K Ishiyama[6], S Miyawaki[6], S Miyano[4, 5], S Chiba[2], K Shimoda[3], T Watanabe[7], S Ogawa[1]
[1]Department of Pathology and Tumor Biology, Graduate School of Medicine, Kyoto University, Kyoto, [2]Department of Hematology, Faculty of Medicine, University of Tsukuba, Tsukuba, [3]Division of Gastroenterology and Hematology, Department of Internal Medicine, Faculty of Medicine, Miyazaki University, Miyazaki, [4]Laboratory of DNA Information Analysis, Human Genome Center, Institute of Medical Science, [5]Laboratory of Sequence Analysis, Human Genome Center, Institute of Medical Science, The University of Tokyo, [6]Division of Hematology, Tokyo Metropolitan Ohtsuka Hospital, [7]Department of Medical Genome Sciences, Graduate School of Frontier Sciences, The University of Tokyo, Tokyo, Japan

Background: Adult T-cell leukemia/lymphoma (ATL) is a distinct form of peripheral T-cell lymphoma (PTCL), which is etiologically associated with human T-lymphotropic virus type I (HTLV-1) infection during early infancy. Although the presence of a long latency period before the onset of ATL in late adult life suggests a critical role of accumulating genetic events in HTLV-1-infected T-cells, little is known about their gene targets. Recently, frequent somatic mutations in *RHOA*, as well as *TET2, DNMT3A*, and *IDH2* genes, were reported in angioimmunoblastic T cell lymphoma (AITL) and other PTCL characterized by follicular helper T-cell phenotypes. Most of the *RHOA* mutations invariably cause an identical amino acid change (Gly17Val), which was shown to inhibit wild-type RHOA function in a dominant-negative manner.
Aims: We aimed to investigate the mutational status of *RHOA*, as well as *TET2*, *IDH2*, *DNMT3A*, and *SF3B1* in ATL cases, which were compared with that in other PTCL, in terms of the type of mutations and their functional impact on RHOA functions.
Methods: We performed targeted deep sequencing in 205 ATL cases with different subtypes, and compared them with AITL (N=72) and PTCL-not otherwise specified (NOS) cases (N=87). Also, we analyzed the function of different RHOA mutants using luciferase assay and actin filament staining.
Results: In total, we identified 42 *RHOA* mutations in 38 (18.5%) ATL cases. Unexpectedly, however, showing a stalk contrast to AITL and other PTCL-NOS, in which *RHOA* mutations almost exclusively involved Gly17 within the GTP binding domain, *RHOA* mutations were widely distributed across all the GTP-binding domains in ATL cases. Among them, Cys16 located in exon 2 was most frequently mutated (N=11; 5.4%), while only four (1.9%) cases harbored Gly17Val mutation. These results suggest that the *RHOA* mutations act as a driver of ATL lymphomagenesis, but in a different manner from AITL and PTCL-NOS. We found no differences of *RHOA* mutational status among ATL subtypes, and no significant prognostic impact of *RHOA* mutations on survival. In AITL/PTCL-NOS, all *RHOA* mutated cases were accompanied by *TET2* mutations and often had *DNMT3A* and *IDH2* mutations, whereas no significant correlation between *RHOA* and *TET2* mutations was observed in our ATL cohort, although TET2 was also commonly mutated in 21 ATL cases (10.2%). *IDH2*, *DNMT3A*, and *SF3B1* were very rare in ATL cases. *RHOA* encodes a ras-related GTP-binding protein that functions as a molecular switch in a variety of biological processes. Modeling of three-dimensional structures suggested these mutations could affect the GTP-binding ability of RHOA protein. Indeed,

luciferase assay showed, unlike dominant-negative Gly17Val RHOA mutant, the Cys16Arg RHOA mutant enhanced transcriptional activity, suggesting gain-of-function mechanisms of this mutant. In addition, Gly17Val RHOA attenuated actin stress fiber formation in NIH3T3 cells, whereas Cys16Arg RHOA did not. These results suggest ATL-specific RHOA mutants act in an opposite manner to those characteristic of AITL and PTCL-NOS.
Summary and Conclusion: Our finding highlights a unique role of *RHOA* mutations in the development of peripheral T-cell neoplasms; as is the case with other PTCL, including AITL and other PTCL-NOS, *RHOA* mutations were also common in ATL. Nevertheless, the distribution and functional impacts of these *RHOA* mutations in ATL were distinct from the canonical *RHOA* Gly17Val mutation found in AITL and other PTCL-NOS, suggesting their distinct role in the pathogenesis of different PTCL. Further investigation should be warranted to clarify the exact role of RHOA in both normal and malignant T-cells.

S1304

DISCRIMINATION OF MUTATIONS ARISING IN PRE-MALIGNANT CELLS AND THOSE IN LYMPHOMA CELLS IN ANGIOIMMUNOBLASITC T-CELL LYMPHOMA

M Sakata-Yanagimoto[1,*], Y Asabe[1], K Yoshida[2], H Muto[1], R Nakamoto-Matsubara[1], K Izutsu[3], N Nakamura[4], K Takeuchi[5], S Ogawa[2], S Chiba[1]
[1]Department of Hematology, University of Tsukuba, Tsukuba, [2]Department of Pathology and Tumor Biology, Kyoto University, Kyoto, [3]Department of Hematology, Toranomon Hospital, Tokyo, [4]Department of Pathology, Tokai University School of Medicine, Isehara, [5]Pathology Project for Molecular Targets, The Cancer Institute, Tokyo, Japan

Background: Angioimmunoblastic T-cell lymphoma (AITL) is a distinct subtype of peripheral T-cell lymphoma, characterized by generalized lymphadenopathy and autoimmune-like manifestations. Regarding genetic lesions of AITL, frequent mutations in *TET2*, *IDH2* and *DNMT3A* have been identified, although all these mutations were also found in myeloid malignancies. Recently, we and others identified disease specific G17V *RHOA* mutations in AITL and AITL-related cancer.
Aims: We performed this study to further identify specific gene mutational profiles and origins in AITL and AITL-related cancer.
Methods: Targeted sequencing was analyzed for 76 genes in 79 PTCL samples. Mutational origin was analyzed by cell sorting and laser microdissection.
Results: Targeted sequencing identified 168 mutations in 33 genes, including those in *TET2* (54/79 [68.4%]), *RHOA* (39/79 [49.4] %), *DNMT3A* (21/79[26.6%]), and *IDH2* (14/79[17.7%]). Allele frequencies of *TET2* mutations were higher than those in *RHOA* or *IDH2*, while comparable to those of *DNMT3A* mutations, suggesting that *TET2/DNMT3A* mutations should precede *RHOA/IDH2* mutations. Allele frequencies of mutations in most of newly identified gene mutations were smaller than those of *TET2*, suggesting that many of these mutations should occur later than *TET2* mutations. Cell sorting and laser microdissection, followed by amplicon sequencing, revealed that *TET2/DNMT3A* mutations were found in tumor and non-tumor cells, while *RHOA* mutations and *IDH2* mutations were found only in the tumor cells. Newly identified mutations were classified into 2 types: those identified both in tumors and non-tumors, and those confined to tumors.
Summary and Conclusion: These data provide insight into more profound understanding of the genomic structure and multi-lineage involvement in development of AITL.

Stem cell transplantation - Clinical

S1305

LONG-TERM RESULTS OF 174 PATIENTS WITH SYSTEMIC AL AMYLOIDOSIS TREATED WITH HIGH-DOSE MELPHALAN AND AUTOLOGOUS STEM CELL TRANSPLANTATION: A SINGLE CENTER EXPERIENCE

U Hegenbart[1,*], T Bochtler[1], P Dreger[2], C Kimmich[1], R Ziehl[2], H Goldschmidt[2], A Ho[2], S Schönland[1]
[1]Amyloidosis Center, [2]University Hospital, Heidelberg, Germany

Background: About 40% of patients (pts) with amyloid light chain amyloidosis (AL) achieve a complete remission (CR) of their underlying monoclonal plasma cell disorder following high-dose melphalan (HDM) and autologous stem cell transplantation, these pts have an excellent survival (Cibeira, *Blood* 2011).
Aims: We report our single center experience of HDM in AL since 1998.
Methods: 174 pts were transplanted between 1998 and 2013. Inclusion criteria were age<70 years, NYHA stage<III, creatinine clearance >30 ml/min (or on dialysis) and WHO performance status<3. Median age was 56 years. Median number of involved organs was 2. Ten patients had previous cardiac transplantation. In those patients, stem cells were mobilized after G-CSF administration; in almost all other patients after chemotherapy. Furthermore, 95 patients received chemotherapy prior HDM. Patients were treated with melphalan 200 mg/m2 in median. Fifty-nine of 136 evaluable patients were Cardiac Mayo stage 1, 53 patients stage 2 and 24 patients stage 3, respectively
Results: The estimated median follow-up after transplantation is 75 months. Median overall survival (OS) is 136 months. Four patients (2%) died due to cardiac and infectious complication of HDM. Hematological remission (HR) was achieved in 80% (38% CR) and organ response in 40% of evaluable patients, respectively. For pts in PR or CR after HDM median OS is not reached
Summary and Conclusion: For HDM, identification of eligible patients is crucial. We observed a very low TRM of 2% in our center. The long-term survival is excellent. In our opinion, HDM and ASCT is the treatment of choice in younger patients who fit strict inclusion criteria.

S1306

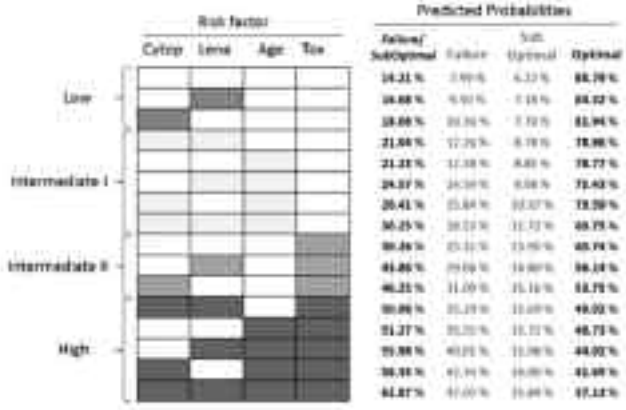
PREDICTING UNSATISFACTORY PERIPHERAL BLOOD STEM CELL COLLECTIONS IN MYELOMA PATIENTS RECEIVING NEW DRUGS AS INDUCTION AND CYCLOPHOSPHAMIDE + G-CSF AS MOBILIZING REGIMEN: A GIMEMA MYELOMA-WP STUDY

P Musto[1,*], V Simeon[2], A Grossi[3], F Cavallo[4], R Guariglia[5], G Pietrantuono[5], O Villani[5], C Cuomo[5], C Musto[6], F Morabito[7], MT Petrucci[8], M Offidani[9], E Zamagni[10], P Tacchetti[10], C Conticello[11], G Milone[12], A Palumbo[4], M Cavo[10], M Boccadoro[13]
[1]Scientific Direction, [2]Laboratory of Pre-clinical and Translational Research, IRCCS, Referral Cancer Center of Basilicata, Rionero In Vulture (Pz), [3]Hematology, Centro Oncologico Fiorentino, Florence, [4]Myeloma Unit, AOU Citta della Salute e della Scienza, Turin, [5]Hematology and Stem Cell Transplantation, IRCCS, Referral Cancer Center of Basilicata, Rionero In Vulture (Pz), [6]Transfusional Service, S. Carlo Hospital, Potenza, [7]Hematology, AO Cosenza, Cosenza, [8]Hematology, La Sapienza University, Rome, [9]Hematology, AO Umberto I, Ancona, [10]Seràgnoli Institute of Hematology, University School of Medicine, Bologna, [11]Hematology, University of Catania, [12]Hemopoietic Transplant Program, AOU Policlinico Vittorio Emanuele, Catania, [13]Department of Experimental Medicine and Oncology, AOU Citta della Salute e della Scienza, Turin, Italy

Background: Patients with multiple myeloma (MM) may fail to collect adequate amounts of CD34+ peripheral blood stem cells (PBSC) for single or multiple autologous transplantation. The percentage of “poor mobilizers”, however, differs across studies, depending on definitions, criteria to evaluate collections, age, disease phase and characteristics, treatments applied, objectives to reach, and practices for mobilization and apheresis.
Aims: We aimed to evaluate, define and forecast unsatisfactory PBSC collections in newly diagnosed MM patients receiving novel agents as induction therapy and a homogeneous mobilization procedure.
Methods: We retrospectively analyzed the role of 4 parameters potentially considered able to negatively affect releasing of PBSC and to impair their collection in MM: age (>60 years); initial use of lenalidomide; cytopenia at diagnosis (Hb<10 g/dl, neutrophil count<1.000/µl, platelet count<100.000/µl); grade 3-4 hematological toxicity during induction therapy. Overall, 1.348 patients enrolled in 5 consecutive clinical trials conducted by GIMEMA/MM Italian Network were evaluated. In all cases, the mobilizing regimen was cyclophosphamide (3-4 g/sqm) + G-CSF (10 mcg/kg). An absolute number of PBSC >20/µl was the threshold to start apheresis. According to different studies, induction regimens were TD (316 patients), VTD (258 patients), RD (396 patients) and PAD (86 patients). 292 patients received a modified VAD-regimen, without novel agents. PBSC total amounts<2 x 10^6/kg and<5 x 10^6/kg

after a single mobilization procedure were considered "failures" or "sub-optimal" results, respectively. Risk factors were analyzed by univariate and multivariate logistic regression models; the final results were internally validated using the bootstrap method. ROC curves were constructed to assess a model discriminatory power for the predictive probability, Predicted probabilities of outcomes (optimal *vs* suboptimal *vs* failure), were used to generate a risk heatmap.
Results: 946 patients (70.1%) showed at least one "negative" parameter: 560 patients (41.5%) were older than 60 years, 332 (24.6%) had baseline cytopenia, 356 (26.4%) were treated with lenalidomide and 88 (6.5%) developed grade 3-4 hematological toxicity under induction therapy. Overall, 630 patients (46.7%) had only one parameter, while 319 showed a combination of 2 (252, 18.6%), 3 (54, 4 %) or 4 (10, 0.7%) parameters, respectively. After a single mobilization (median number of apheresis: 2; range: 0-4), 280 patients (20.7 %) collected an insufficient number of PBSC (167 failures, 12.3%, and 113 sub-optimal, 8.3%). All parameters negatively influenced PBSC collection at univariate analysis, but only hematological toxicity during induction and age >60 maintained a detrimental effect at multivariate analysis (p<0.0001). The figure reports the risk heatmap obtained when the 4 parameters were pooled and weighted according to their relevance as single or combined variables. According to the cumulative probability of unsuccessful collections (failures + suboptimal), 4 risk areas were identified: low (range 14-18%), intermediate-1 (21-30%), intermediate-2 (39-46%), and high (50-63 %). In particular, the risk of failure was 9% for low-risk and 40% for high-risk patients.

Table 1.



Summary and Conclusion: In this series, about 20% of newly diagnosed MM patients showed unsatisfactory PBSC collections. Our simple model, based on a large number of patients treated frontline with novel agents and receiving the most popular mobilizing approach currently employed in Europe, provides a reliable measure for the early identification of a "poor mobilizer" phenotype, applicable in individual patients.

S1307

UPDATED EUROPEAN EXPERIENCE ON AUTOLOGOUS STEM CELL TRANSPLANTATION FOR WALDENSTROM'S MACROGLOBULINEMIA/ LYMPHOPLASMACYTIC LYMPHOMA PATIENTS. A RETROSPECTIVE STUDY OF THE EBMT LYMPHOMA WORKING PARTY

C Kyriakou[1,*], A Boumendil[2], H Finel[3], JJ Luan[3], JP Vernant[4], J Cornelissen[5], C Thieblemont[6], P Chevallier[7], P Mazza[8], P Zachee[9], D Niederwieser[10], A Sureda[11], S Montoto[12], P Dreger[13]
[1]Haematology, Royal Free Hospital, London, United Kingdom, [2]Statistics, [3]Data Management, EBMT LWP, [4]Haematology, Pitié salpêtrière Hospital, Paris, France, [5]Haematology, Erasmus MC Cancer Center, Rotterdam, Netherlands, [6]Haematology, Hôpital Saint Louis, Paris, [7]Haematology, Nantes University Hospital, Nantes, France, [8]Haematology, Ospedal SS Annunziata, Taranto, Italy, [9]Haematology, Ziekenhuis Netwerk Antwerpen Stuivenberg, Antwerpen, Belgium, [10]Haematology, Universitätsklinikum Leipzig, Leipzig, Germany, [11]Haematology, Institut Català d'Oncologia, Barcelona, Spain, [12]Haematology, St Bartholomew's Hospital, London, United Kingdom, [13]Department of Internal Medicine, Heidelberg University Hospital, Heidenberg, Germany

Background: Waldenstrom's Macroglobulinemia (WM) is a rare distinct clinicopathological entity. Although it is classified as an indolent disease, its treatment remains a major challenge The role and timing of autologous stem cell transplantation (ASCT) in the management of WM patients has not been well established.
Aims: The aim of this retrospective study was to analyse the outcome of ASCT for WM.
Methods: Between 1995 and 2011, 615 patients with WM (70% were male) were reported to the European Society for Blood and Marrow Transplantation registry. The median age at ASCT was 54 years and median time from diagnosis to ASCT was 19 months (291 patients–47% - underwent ASCT within<18 months from diagnosis). Disease status at ASCT was first partial (PR1), very good partial (VGPR1) and complete remission (CR1) in 325 patients (53%). 176 (29%) patients were autografted in second, third or later CR, PR or sensitive relapse, whereas 47 (8%) patients had primary refractory or progressive disease at ASCT. Conditioning regimens were chemotherapy based in 595 patients (97%) with the majority of them receiving BEAM chemotherapy. The stem cell source was from peripheral blood in 598 patients (97%).
Results: Within a median follow up of 29.5 months, 216 patients had disease relapse or progression. The relapse rate (RR) at 5 years was 47% and it was significantly lower (p=0.001) in patients undergoing transplantation in first response (CR1, VGPR1, PR1). Disease-free survival (DFS) was 46% at 5 years and this was significantly better for patients receiving the transplant in less than 18 months from diagnosis (p=0.004), and for those transplanted in PR1, VGPR1 or CR1. The non-relapse mortality (NRM) was 2.6 % and 7.1% at 1 and 5 years respectively. The median overall survival (OS) was 112 months. Disease progression was the cause of death in 84 patients. Nine patients died of secondary malignancy. The estimated OS was 65% at 5 years and was significantly superior (p=0.033) for patients in PR1, VGPR1 and CR1 at the time of ASCT,than those transplanted in other disease status.
Summary and Conclusion: ASCT is a feasible and effective treatment in patients with WM who are transplant eligible. The outcomes are significantly better when the autologous transplantation is offered early in the course of the disease in good responders. However, the appropiate place of ASCT in the treatment algorithm of WM in the era of B cell receptor signalling inhibitors and other targeted drugs needs to be defined by additional studies.

S1308

SEQUENTIAL INTENSIfiED CONDITIONING FOLLOWED BY TAPERING OF PROPHYLACTIC IMMUNOSUPRESSANTS AND DONOR LYMPHOCYTE INFUSIONS IN ALLOGENEIC HEMATOPOIETIC STEM CELL TRANSPLANTATION FOR REFRACTORY LEUKEMIA

Q Liu[1,*], L Xuan[1], Y Zhang[1], Z Fan[1], H Zhou[1], F Huang[1], M Dai[1], D Nie[2], D Lin[3], Y Xiao[4], J Sun[1]
[1]Department of Hematology, Nanfang Hospital, Southern Medical University, [2]Sun Yat-Sen Memorial Hospital, Sun Yat-Sen University, [3] the Third Affiliated Hospital, Sun Yat-Sen University, [4]Guangzhou General Hospital of Guangzhou Military Command, Guangzhou, China

Background: Allogeneic hematopoietic stem cell transplantation (allo-HSCT) is perceived as the only curative option for refractory acute leukemia. However, the relapse rate exceeds 50% in these patients undergoing allo-HSCT with standard myeloablative regimen. To improve outcomes of allo-HSCT for refractory leukemia, we previously introduced a strategy of sequential intensified conditioning and early rapid tapering of prophylactic immunosupressants for graft-*versus*-host disease (GVHD). The results indicated this strategy could improve outcomes of refractory leukemia, with 5-year overall survival (OS) and disease-free survival (DFS) of 44.6% ± 8.1% and 38.2% ± 7.7%. However, the 3-year cumulative incidence of leukemia relapse reached to 33.3%. To reduce the relapse rate but without increasing regimen-related toxicities (RRT), we increased the dose of etoposide (VP-16) in conditioning and infused donor lymphocytes (DLI).
Aims: To assess the feasibility and efficacy of this modified strategy in patients with refractory acute leukemia.
Methods: A total of 123 patients with refractory acute leukemia undergoing allo-HSCT from January 2009 to December 2012 were enrolled. Ninety-four patients received related (73 sibling and 21 family donors), 29 unrelated donor transplants; 73 were HLA locus matched, 50 mismatched. Modified sequential intensified conditioning regimen was: fludarabine (30 mg/m^2/day, -10 to -6 days) + cytarabine (2.0 g/m^2/day, -10 to -6 days) plus TBI (total body irradiation, 4.5 Gy/day, -5, -4 days) + cyclophosphamide (60 mg/kg/ day, -3, -2 days) + VP-16 (15 mg/kg/day, -3, -2 days). Cyclosporine A (CsA) was withdrawn rapidly in a stepwise fashion (total dose reduced by 20%/week) if patients who did not experience acute GVHD (aGVHD) by day +30 post-transplantation. Donor lymphocytes (1.0×10^8/kg, once a month, 4 doses totally) would be infused in patients without II° or more than II° aGVHD by day + 60 post-transplantation.
Results: All patients achieved hematopoietic engraftment, except for two who died of infections and one who died of RRT during conditioning. All 120 evaluable patients achieved complete remission (CR) at the time of neutrophil engraftment and achieved complete donor chimerism by day +30 post-transplantation. The incidence of total RRT was 100%, and III-IV RRT was 22.0%. Within the first 100 days post-transplantation, 67 patients developed 95 episodes of infections. Twenty-one had bacterial infections, 7 had invasive fungal infections, 9 had viral infections except cytomegalovirus (CMV) and Epstein-Barr virus (EBV) viremia, 24 had mixed infections and 6 had infections of unknown etiology. Moreover, 48 patients had CMV viremia, 3 developed CMV pneumonia; 41 had EBV viremia, 13 developed EBV-associated diseases. Of the 120 evaluable patients, aGVHD occurred in 31 cases by day +30. Of the 89 patients who did not develop GVHD by day +30, 28 developed aGVHD after CsA withdrawal. Of the 66 patients who received DLI by day +60, 20 developed aGVHD, and 43 developed chronic GVHD (cGVHD, including 13 migrating

from aGVHD). cGVHD occurred in 65 of 102 patients who survived more than 100 days, including 43 after DLI. Twenty-three patients experienced leukemia relapse (hematologic in 16, genetic in 4, central nervous system in 2 and extramedullary in 1) at a median time of 165 (range, 28 to 479) days post-transplantation. The 3-year cumulative incidence of relapse was 25.3 ± 4.8%. Of the 23 patients who relapsed, 6 abandoned treatment and 17 received treatment, including 9 with chemotherapy and DLI, 6 only with chemotherapy, 1 only with DLI, and 1 with chemotherapy and radiotherapy. Only two of the 17 cases achieved CR after treatment, and the others all died of disease progress. With a median follow up of 316 (range, 7 to 1589) days post-transplantation, 75 patients survived and 48 died. Causes of death included leukemia relapse (n=21), infections (n=12), GVHD (n=8), EBV-associated diseases (n=5), cerebral hemorrhage (n=1) and secondary dyshematopoiesis (n=1). The 3-year OS and DFS was 58.8% ± 4.7% and 57.0% ± 4.8%.

Summary and Conclusion: For patients with refractory leukemia undergoing allo-HSCT, the modified strategy of sequential intensified conditioning followed by tapering of prophylactic immunosupressants and DLI not only improves OS and DFS, but also reduces leukemia relapse.

Background: T cell lymphomas (TCL) are heterogeneous diseases, lightly sensitive to chemotherapy, with an adverse outcome and a 5-years survival rate of about 30%. Allogeneic hematopoietic stem cell transplant (allo-SCT) can lead to durable remission, even for patients with a poor response to chemotherapy. Several observations, generally reported on small samples of patients, argue for a Graft *Versus* Lymphoma (GVL) effect in TCL. However allo-SCT is not consensually recommended, at least in first line therapy.

Aims: The aim of the current study is to highlight GVL effect in TCL. To do so, we analysed the outcome of patients with relapse after allo-SCT, to evaluate the benefits of immunomodulation on disease control (donor lymphocyte infusions (DLI) and immunosuppressive therapy tapering).

Methods: Between 1988 and 2012, sixty-four patients in relapse for a TCL after allogeneic SCT were identified in 21 SFGM cooperative centers (Société Française de Greffe de Moelle). Exhaustive data were completed in 51 patients. The median age at transplant was 44 years old, 24% were cutaneous TCL (3 Sezary syndrome and 9 mycosis fongoides), whereas 76% were not (16 T nos, 11 anaplasic TCL, 5 angio-immunoblastic TCL, 4 NK/T lymphomas, 2 HTLV1 TCL and 1 EIATL). At transplant, 35% were in complete remission (CR), 49% in partial remission (PR) and 16% had progressive disease (PD). Regiment was myeloablative for 19 patients and non-myeloablative for 32. At relapse, patients were treated with either non immunologic-based strategy (chemotherapy, radiotherapy, PUVA therapy) or immunomodulation (DLI and/or discontinuation of immunosuppressive therapy), or both. We compared their outcomes according to the treatment they received at relapse.

Results: Relapse occurred at a median time of 2.7 months after transplant (from 0.5 to 18.6 months) and 14 patients had a localized cutaneous relapse (7 MF, 3 anaplasic TCL, 2 T nos, 1 AITCL and 1 NK/T lymphoma). Among the 13 patients who received DLI (DLI alone: 5, DLI + radio/chemotherapy: 8), 9 obtained a response (7CR, 2 PR) and 6 are still alive, with a median follow up of 3 years. For the 38 who did not receive DLI, immunosuppressive therapy was tapered or stopped for 23 and led to a prolonged remission, for 2 of them, along with extensive chronic GVHD. In the non-DLI group, 22/38 received a radio/chemotherapy treatment with a response rate of 50% and a 1-year survival rate of 25%. Among the 8/38 patients who experienced a response in this group, five developed a chronic GVHD. Median overall survival was 144 days in the non-DLI-group and 557 days in the DLI-group (p=0.01). In univariate analysis, time from transplant to relapse (p=0.015), chronic GVHD after relapse (p=0.036) and receiving DLI (p=0.016) were associated to a better overall survival (OS). In multivariate analysis, DLI was the only remaining factor associated with OS (p=0.005). Disease status at transplant, regiment's intensity, patient's age and relapse localization (cutaneous or disseminated, p=0.08) were not found to be associated with OS.

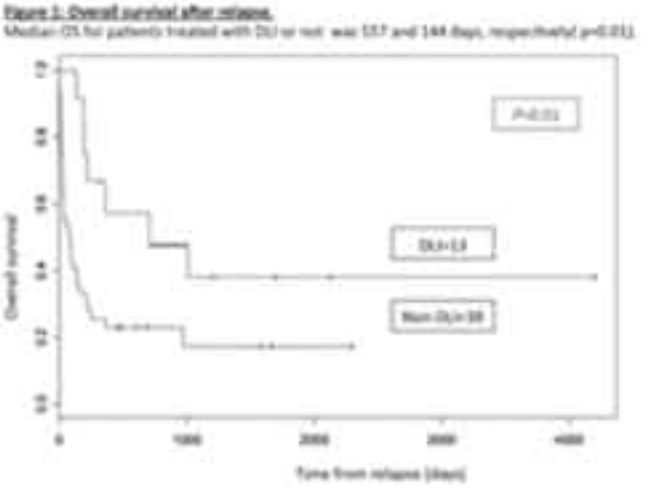

Figure 1.

Summary and Conclusion: The benefit of DLI in case of relapsing T-cell lymphomas after transplant is suggested in this study and represent an argument in favour of the existence of GVL effect in these diseases. These findings could lead to the set up of an active immunomodulation strategy after transplant for patients with high-risk disease, even if the short delay from transplant to relapse, currently observed, can limit this therapeutic option.

Acute lymphoblastic leukemia - Clinical 2

S1310

CONCURRENT DELETIONS OF IKZF1 AND PAX5, CDKN2A, CDKN2B OR PAR1 (IKZF1-PLUS) CONFER A VERY POOR PROGNOSIS IN PEDIATRIC ACUTE LYMPHOBLASTIC LEUKEMIA

M Zaliova[1,*], E Dagdan[2], P Dörge[2], A Möricke[3], M Zimmermann[2], A Teigler-Schlegel[4], R Koehler[5], C R Bartram[5], R Ratei[6], WD Ludwig[6], J Alten[3], D Schewe[3], C Kratz[2], R S Houlston[7], M Schrappe[3], G Cario[3], M Stanulla[2]
[1]CLIP—Childhood Leukemia Investigation Prague, Department of Pediatric Hematology and Oncology, 2nd Faculty of Medicine, Charles University in Prague and University Hospital Motol, Prague, Czech Republic, [2]Pediatric Hematology and Oncology, Hannover Medical School, Hannover, [3]Department of Pediatrics, University Hospital Schleswig-Holstein, Kiel, [4]Oncogenetic laboratory, Pediatric Hematology and Oncology, University of Giessen, Giessen, [5]Department of Human Genetics, University of Heidelberg, Heidelberg, [6]Department of Hematology, Oncology and Tumor Immunology, HELIOS-Clinic Berlin-Buch, Berlin, Germany, [7]Division of Genetics and Epidemiology, Institut of Cancer Research, Sutton, United Kingdom

Background: Recent technical advances in the field of genomic analyses have stimulated a large number of discovery studies on etiological and clinical endpoints in acute lymphoblastic leukemia (ALL). Recently, *GATA3* was described as a new susceptibility locus for pediatric ALL (Migliorini *et al.* Blood 2013;122:3298-3307). The variant GATA3 allele (rs3824662) was found to be specifically associated with B-other ALL (B-lineage ALL lacking recurrent chromosomal translocations and hyperdiploidy) and to confer a dismal outcome.
Aims: Analysis of somatic genetic aberrations describing B-other ALLs associated with rs3824662 to characterize the leukemia genetics underlying the prognostic germline *GATA3* ALL risk-allele.
Methods: Clinical epidemiological analysis of 500 patients treated on trial AIEOP-BFM 2000 having information on rs3824662 genotype and leukemia genetic characteristics including MLPA (SALSA kit P335-A3; MRC-Holland) and *ERG* deletion. Validation of results by employing an independent cohort of 599 patients from trial AIEOP-BFM 2000. Treatment outcome was analyzed excluding *BCR/ABL1*-positive patients.
Results: *GATA3* rs3824662 genotype was negatively associated with hyperdiploidy and positively associated with prednisone poor-response, higher loads of minimal residual disease (MRD), and deletions of *IKZF1*, *PAX5*, *CDKN2A* and *CDKN2B*. Out of the 476 patients from the discovery cohort, 88 (18.5%) bore an *IKZF1* deletion, 98 (20.6%) a *PAX5* deletion, 61 (12.8%) a heterozygous and 69 (14.5%) a homozygous deletion of *CDKN2A*, 61 (12.8%) a heterozygous and 60 (12.6%) a homozygous deletion of *CDKN2B*. Similar numbers were observed in the validation cohort. When single marker analyses were conducted, *IKZF1* deletion was the strongest determinator of outcome. In *CDKN2A*- and *CDKN2B*-deleted patients, the prognostic impact was restricted to those with homozygous deletions. When *IKZF1* deletions were analyzed in the discovery and validation cohorts in combination with *PAX5*, *CDKN2A* and *CDKN2B* deletions, patients displaying an additional deletion to that of *IKZF1* had the worst event-free survival (EFS) and highest cumulative incidence of relapse (CIR). We also analyzed *IKZF1* deletion in association with *PAR1* deletions leading to *P2RY8-CRLF2* fusion, which we previously described as prognostically relevant in our patient population (Cario *et al.* Blood 2010;115:5293-5397) and detected similar combinatorial effects as described above. Consequently, we defined a group by presence of *IKZF1* deletion and at least one additional deletion in *PAX5*, *CDKN2A*, *CDKN2B* or *PAR1*. This group comprising 6% of B-lineage ALL patients was termed *IKZF1plus* and had a very poor clinical outcome: 5y-EFS 55%±0.07 compared to 85%±0.01 in *IKZF1plus*-negatives (p<0.0001); 5y-CIR 42%±0.07 compared to 11%±0.01 (p<0.0001). In multivariate analyses including MRD, slow early response, prednisone response, ETV6/RUNX1 status, and WBC (≥100.000/µl), *IKZF1plus* displayed the highest hazard ratio for relapse (3.29; 95% CI 2.01-5.38; p<0.001).
Summary and Conclusion: The previously described effect on clinical outcome of GATA3 SNP rs3824662 is due to its association with distinct prognostic leukemic lesions. Combinatorial analysis of deletions in *IKZF1*, *PAX5*, *CDKN2A*, *CDKN2B* and *PAR1* allowed description of a very poor prognostic subgroup of ALL – termed *IKZF1plus* – with significantly worse outcome compared to the use of *IKZF1* deletion or others as a sole marker. The definition of *IKZF1plus* is likely to aid in the practical implementation of newly detected markers for risk stratification in childhood ALL. Grant support: TRANSCALL (EU FP7 - TRANSCAN, FKZ01KT1312), GACR-P302/12/G101, UNCE204012.

MINIMAL RESIDUAL DISEASE STRATIFICATION BY NEXT GENERATION SEQUENCING PROFILING OF IMMUNOGLOBULIN GENE REARRANGEMENTS AS AN ALTERNATIVE TO CLASSICAL QPCR-BASED TECHNIQUE IN CHILDHOOD ALL

M Kotrová[1,*], K Mužíková[1], E Mejstříková[1], M Nováková[1], V Bakardjieva-Mihyalova[1], K Fišer[1], J Stuchlý[1], C Pott[2], M Brüggemann[2], J Trka[1], E Froňková[1], S Jan[3]
[1]CLIP, Department of Pediatric Hematology and Oncology, 2nd Medical School and University Hospital Motol, Prague, Czech Republic, [2]Second Medical Department, University Hospital, Schleswig-Holstein, Kiel, Germany, [3]Department of Pediatric Hematology and Oncology, 2nd Medical School and University Hospital Motol, Prague, Austria

Background: MRD negativity at both day 33 and 78 is required for stratification into standard risk (SR) group in pediatric BFM protocols. Quantitative PCR (qPCR) for immunoglobulin (Ig) and T-cell receptor (TCR) gene rearrangements had been standardized within the EuroMRD consortium. Next generation sequencing (NGS) of Ig/TCR repertoire is a rapidly expanding method that enables monitoring of the malignant clone, but can also show the picture of normal lymphoid cells during the treatment. Moreover, the NGS would avoid qPCR optimization for every patient, which should markedly reduce costs and handling time.
Aims: To establish the detection of multiple Ig heavy chain (IGH) rearrangements using the Ion Torrent PGM/Ion Proton platforms and to compare the NGS results with qPCR at the crucial stratification time points used in childhood BFM trials.
Methods: The sequencing libraries were created from 450 ng of bone marrow DNA mixed with 50 ng of polyclonal DNA using multiplex PCR with IGH FR3 BIOMED-2 primers. The sequencing adapters together with different multiplex identifiers allowing for parallel sequencing of different samples were introduced and sequencing was performed using the Ion Torrent 318 and Ion Proton PI chips. Bioinformatic algorithm was developed to define numbers of reads with V-D-J marker sequences selected according to their clonality in the diagnostic sample among total reads of expected size.
Results: In total 56 samples (28 x day 33, 28x day 78) from 28 patients treated according to Interim BFM 2007 protocol were sequenced with median coverage of 428,648 reads. Thirty-six samples (64%) were concordantly negative by NGS and qPCR. Five samples (9%) were negative by NGS and positive by qPCR and four samples (7%) were negative by PCR and positive by NGS (Fig.1). This would cause a shift from IR to SR in 4 patients, from SR to IR in 2 patients and from slow early response (SER) group to IR in one patient. In the 11 double-positive samples the quantitative values correlated, but the MRD levels were higher in NGS than in PCR in all but one sample (median 7x, range 1-124x). This was likely caused by the fact that NGS quantitates leukemic IGH rearrangements within the B cells only while qPCR is performed in a bulk of all mononuclear cells. Importantly, the quantitative differences would not change the stratification into treatment risk groups in any patient. After correction for percentage of $CD19^{pos}$ cells assessed by flow cytometry (FC) at respective time points the correlation with qPCR improved (R^2=0.77).

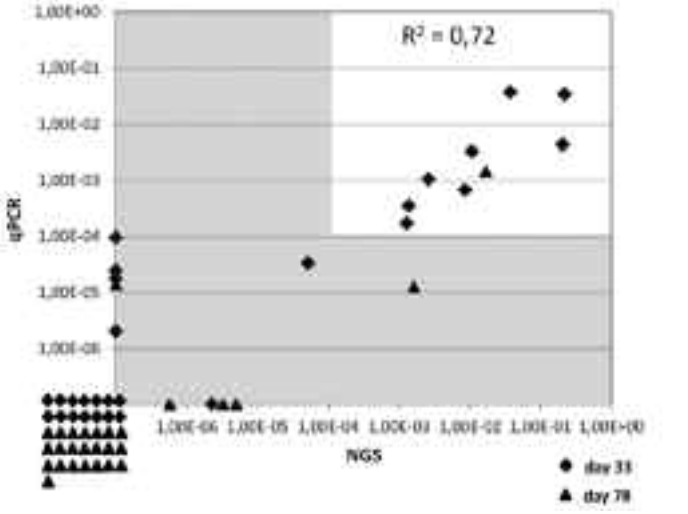

Figure 1.

Summary and Conclusion: In the NGS design we used, the sensitivity of NGS was comparable to qPCR, showing the most differences in the "grey zone" consisting of weakly positive samples. This caused a shift between risk groups in 7/28 (25%) patients, mostly from IR to SR. More investigated samples are needed to find out whether the differences in the risk group assignment would have clinical consequences. The NGS has a great potential for replacing antigen receptor-based qPCR in clinical decisions for ALL. At present, the main

drawback of Ig/TCR-exploring NGS methods is lack of standardization both in the experimental setting and in data analysis. Therefore, recently a European network, the EuroClonality NGS Consortium, has been formed to standardize the whole workflow of analytics, pre-analytics and bioinformatics not only for MRD quantification but also for clonality assessment in lymphoid neoplasms and for repertoire analysis. Supported by IGA NT14343, NT/12397 and GACR P302/12/G101.

S1312

HIGH-THROUGHPUT SEQUENCING TO DETECT MINIMAL RESIDUAL DISEASE IN ACUTE LYMPHOBLASTIC LEUKEMIA

A Sherwood[1], D Wu[2], R O Emerson[1], M L Loh[3], J Fromm[2], S S Winter[4], K P Dunsmore[5], A Angiolillo[6], B Howie[1], J Vogt[1], M Rieder[1], I Kirsch[1], C Carlson[1], D Williamson[1], H A Greisman[2], D E Sabath[2], B L Wood[2], H Robins[7,*]
[1]Adaptive Biotechnologies, [2]University of Washington, Seattle, [3]University of California, San Francisco, San Francisco, [4]University of New Mexico Health Sciences Center, Albuquerque, [5]University of Virginia, Charlottesville, [6]Children's National Medical Center, The George Washington University of Medicine, Washington DC, [7]Fred Hutchinson Cancer Research Center, Seattle, United States

Background: Trials indicate that for Acute Lymphoblastic Leukemia patients, minimal residual disease (MRD) is a better predictor of relapse risk than pre-treatment risk factors. Several methods are used clinically to detect MRD including flow cytometry and qPCR. However, flow detects MRD in the range of 1:10,000 cells while the more sensitive qPCR assays need to be personalized for each patient. Amplifying and sequencing, at high-throughput, rearranged TCR and Ig CDR3 chains has the potential to be a universal assay with high-sensitivity.
Aims: Here we test the utility of detecting MRD using high-throughput sequencing (HTS) of the variable regions of T-cell receptor Beta (TCRB) and Immunoglobulin Heavy chain (IGH).
Methods: Pre-treatment and 29 days post-treatment samples were collected at University of Washington's Hematopathology Laboratory from 43 patients diagnosed with T-ALL and 99 patients diagnosed with B-ALL enrolled in the Children's Oncology Group AALL0434 and AALL0932 trials, respectively. As part of the trials, multi parametric flow cytometry (mpFC) was used to monitor MRD. Adaptive Biotechnologies developed and offers a method that amplifies rearranged TCR and BCR CDR3 sequences and uses high-throughput sequencing (HTS) to sequence tens of thousands of chains simultaneously, named immunoSEQ. Adaptive used the immunoSEQ assay to amplify and sequence the TCRB or IGH repertoire, dependent on diagnosis, from unselected de-identified residual material. MRD detected using HTS immunoSEQ assay was not used for clinical decisions.
Results: Pre-treatment samples were used to identify and define clonal TCRB or IGH CDR3 sequences. Twenty-nine days following treatment, samples were evaluated for MRD by surveying the TCRB or IGH repertoire for the presence and frequency of the previously identified clonal sequence(s). These data were compared to mpFC data that was used to identify abnormal T or B lymphoblasts for both pre and post samples. For patients diagnosed with T-ALL; using HTS, 31 of the 43 samples had a clonal TCRB and by mpFC, five of the 43 cases had a pre-treatment immunophenotype compatible with early thymic precursor (ETP) T-ALL and nine had an ETP-like immunophenotype that we designate as, "near-ETP". All five of the ETP phenotype samples and six of the nine samples with a nETP phenotype lacked a TCRB clone by HTS. In the 31 post-samples for which there was a pre-treatment TCRB clone, HTS detected MRD in 22 of the 31 samples while mpFC detected MRD in 12 of the 31 samples. For patients diagnosed with B-ALL using HTS detected a clonal IGH rearrangement in 91 of the 98 pre-treatment samples. In the 91 post-samples for which there was a pre-treatment IGH clone, HTS detected MRD in 51 of the 91 samples while mpFC detected MRD in 23 of the 91 cases. For both patient groups, HTS detected MRD in every case for which mpFC detected MRD. However, HTS detected MRD in an additional 10 samples for the T-ALL study and 28 cases in the B-ALL study.
Summary and Conclusion: HTS is a viable technology to detect clonality and track MRD in T-ALL and could allow lower detection thresholds for MRD.

S1313

IMMUNOPHENOTYPIC STUDIES IN INFANT ACUTE LEUKEMIA

A Popov[1,2,*], G Tsaur[1,2], T Verzhbitskaya[1,2], O Streneva[1,2], E Shorikov[1,2], L Saveliev[1,2,3], L Fechina[1,2]
[1]Pediatric Oncology and Hematology Center, Regional Children Hospital, [2]Research Institute of Medical Cell Technologies, [3]Ural State Medical University, Ekaterinburg, Russian Federation

Background: Acute leukemia (AL) in children less than 1 year old is the relatively rare disease with specific biological features and poor outcome. It is also characterized by high incidence of *MLL* gene rearrangements. Immunophenotype of infants' leukemia varies due to presence or absence of *MLL* gene rearrangements.
Aims: Description of immunophenotype in infant acute lymphoblastic and acute myeloid leukemia (ALL and AML respectively).
Methods: Totally 540 cases of pediatric AL were studied. 113 patients (77 with ALL, 31 with AML and 5 with MPAL) aged from 5 days to 11 months were included in the study group. Their data was compared to 427 cases of acute leukemia in older children. Tumor cells immunophenotyping was performed by 6-8-color flow cytometry. Detection of various types of *MLL*-gene rearrangements was done by fluorescence in-situ hybridization, reverse-transcriptase polymerase chain reaction (PCR) and long-distance inverse PCR.
Results: ALL was found less frequently in infants than in older children (68.1% and 86.9% respectively, p<0.001) while percentage of acute myeloid leukemia cases was higher in infants (27.4% and 11.5% respectively, p<0.001). Significant immunophenotypic differences were observed in patients with and without *MLL* gene rearrangements in both ALL and AML. Number of ALL cases in those tumor cells expressed CD10, CD20, CD45, CD133, CD15, CD65 NG2 significantly varied between *MLL*-positive and *MLL*-negative groups (p<0.001, p<0.001, p=0.002, p<0.001, p=0.004, p=0.019 and p<0.001 respectively). NG2-positivity represented the highest overall correct prediction (OCP) rate for presence of *MLL*-rearrangements (90.6%). Diagnostic accuracy of CD20-negativity and CD45-positivity was lower (81.2% and 81.9% respectively) while OCP for CD10-negativity (76.4%), CD133-positivity (76.5%) CD15-positivity (67.7%) and CD65-positivity (53.7) was not sufficient enough. Nevertheless CD10-positive BCP-ALL with *MLL*-rearrangements differed from CD10(+) cases in *MLL*-germline group. CD10 homogeneous expression was noted frequently in *MLL*-germline cases *MLL*-rearranged than in ones (p=0.001). Although there were found no significant differences in CD22-positive patients' number, CD22(+)-cells percentage was significantly lower in *MLL*-positive cases (median 89.9%, range 25.2-99.7% and median 99.9%, range 96.0-99.9% respectively, p=0.003). Thus CD20-negativity, CD10-negativity/low expression, high CD45, CD15, CD65, CD133 and NG2 expression, decreased CD22-expression are immunophenotypic signatures of *MLL*-rearranged infant ALL, although NG2 has the highest diagnostic efficacy. Interestingly CD10-negativity and positivity for CD34, CD15 and CD65 could be able to distinguish *MLL-AF4*-positive cases from patients carrying other types of *MLL*-rearrangements. Number of AML cases in those tumor cells expressed CD99, CD133, CD15, CD65, CD4, CD56, CD61, NG2 varied between *MLL*-positive and *MLL*-negative groups ((p=0.019, p=0.012, p=0.002, p=0.008, p=0.013, p=0.012 and p<0.001 respectively). Thus CD61-negativity, high CD99, CD15, CD133 and NG2 expression were immunophenotypic signatures of *MLL*-rearranged infant AML, although NG2 and CD65 had the highest diagnostic efficacy (89.7% and 83.3% respectively).
Summary and Conclusion: Thus immunophenotype of AL in children less than 1 year old differs significantly from patients of older age groups. Infants' ALL and AML immunophenotype varies greatly due to the presence of *MLL* gene rearrangements. Complex diagnostic immunophenotyping of infants' AL allows predicting presence of *MLL* rearrangements and NG2 is the most applicable single marker.

Background: Molecular response, determined by evaluation of minimal residual disease (MRD), is a strong predictor of outcomes in de novo ALL but limited data are available for adult r/r ALL. Blinatumomab, an investigational bispecific T-cell engager (BiTE®) antibody, directs T cells to $CD19^+$ B cells, resulting in serial lysis. In an exploratory study, 80% of patients (pts) with MRD-positive ALL were MRD-negative within 1 cycle of blinatumomab. The study described herein has evaluated efficacy and toxicity of blinatumomab in adult r/r ALL (results from the primary analysis are presented separately).
Aims: The objective of this analysis was to evaluate the efficacy of single-agent blinatumomab in terms of molecular response in adult pts with r/r ALL.
Methods: Eligible pts (≥18 yrs old) had Ph-negative r/r ALL, including primary refractory disease after standard induction, 1st salvage in early 1st relapse

(within 12 months), relapse within 12 months of allogeneic stem cell transplantation (SCT), refractory or later relapses. Pts received blinatumomab by continuous IV infusion (4 wks on/2 wks off), for up to 5 cycles at a dose of 28 µg/d (cycle 1 only: 9 µg/d on days 1-7, 28 µg/d on days 8-28). The primary endpoint was complete remission (CR) or CR with partial hematologic recovery (CRh*: platelets >50,000/µL, neutrophils >500/µL) within the first 2 treatment cycles (assessed on day 29 of each cycle). MRD in bone marrow was assessed using allele-specific real-time quantitative PCR for clonally rearranged Ig and/or TCR genes, with a sensitivity of at least 10^{-4} (central laboratory). MRD response (fewer than 10^{-4} detectable blasts) and complete MRD response (no detectable blasts) within the first 2 treatment cycles were exploratory endpoints.
Results: 189 pts from 37 centers in Europe and the US were treated; median (range) age was 39 (18–79) yrs. 64 pts (34%) had prior SCT. 81 pts had a CR (n=63) or CRh* (n=18) during the first 2 treatment cycles. 17 pts had a morphologically blast-free or aplastic bone marrow. 73 of 81 pts (90%) with CR/CRh* and 10 of 17 pts (59%) with blast-free bone marrow had evaluable MRD results. Of those, 60 pts (82%) with CR/CRh* had an MRD response; 51 (70%) had a complete MRD response. MRD and complete MRD responses occurred in pts with CR and CRh*. 5 of the 10 pts (50%) with blast-free marrow and CR/CRh* had an MRD response (**Table**). Among pts who achieved CR/CRh*, the rate of MRD response was 81% in pts without and 85% in pts with prior SCT. Across the study population, the most frequent grade ≥3 adverse events regardless of causality included febrile neutropenia (25%), neutropenia (16%), and anemia (14%).
Summary and Conclusion: This is the largest adult patient population with r/r ALL to date with PCR-based MRD assessment using a central laboratory. The method was feasible in the setting of an international multicenter trial. High MRD response rates (82%) were observed in pts with CR or CRh*, and a proportion of pts with blast-free bone marrow showed MRD response. Analyses of MRD in subtypes of relapses, the role of MRD assessment in different types of cytologic response, and the impact of MRD response on outcome are ongoing.

Table 1.

Response	Pts with best hematologic response and MRD data n	Pts with MRD response n (%)[a,b]	Pts with MRD complete response n (%)[a,b]
CR/CRh*	73	60 (82)	51 (70)
CR	58	50 (86)	43 (74)
CRh*	15	10 (67)	8 (53)
Blast-free hypoplastic or aplastic bone marrow	10	5 (50)	2 (20)

RECURRENT KIT D816V MUTATION IN ATYPICAL CHRONIC MYELOID LEUKEMIA

R Piazza[1,*], S Redaelli[1], A Pirola[1], S Valletta[1], V Magistroni[1], N Cross[2], D Rea[3], C Gambacorti Passerini[1,4]
[1]Dept Health Sciences, University Milano Bicocca, Monza, Italy, [2]University of Southampton, Salisbury, United Kingdom, [3]Service d'Hématologie adulte, Hôpital Saint-Louis, Paris, France, [4]Division of haematology, San Gerardo Hospital, Monza, Italy

Background: Atypical Chronic Myeloid Leukemia (aCML) is a heterogeneous disorder belonging to the group of myelodysplastic/myeloproliferative syndromes. Since 2013, no recurrent somatic mutation was specifically associated with aCML. By applying Next Generation Sequencing (NGS) technologies on 8 aCML cases, we demonstrated the presence of recurrent somatic mutations in the *SETBP1* gene. These mutations were identified in approximately 30% of aCML cases, which suggested the presence of other yet unknown pro-oncogenic events in the remaining 70%
Aims: To gain insight into the molecular lesions responsible for the occurrence of the *SETBP1*-negative aCML cases, we applied whole-exome and transcriptome sequencing to a total of 16 matched samples taken at onset of the disease
Methods: Whole-exome and transcriptome sequencing data were generated using an Illumina Genome Analyzer IIx following standard library-prep protocols. Alignment to the reference GRCh37/hg19 genome was performed using BWA. Alignment data were processed using Samtools. Single nucleotide and small indels detection was performed using in-house software. Copy number analyses from whole-exome data were generated using CEQer and gene fusions transcriptome data were screened using FusionAnalyser
Results: The application of NGS techniques to a large cohort of aCML cases led to the identification of a somatic, non-synonymous single-nucleotide mutation (chr4:g.55599321A>T) in the *KIT* gene in 1/16 (6%) cases. At protein level this mutation translated into the D816V variant. KIT D816V has been already found in several clonal disorders, among them in systemic mastocitosis, gastrointestinal stromal tumors and acute myeloid leukemia and it is responsible for the constitutive activation of the pro-oncogenic tyrosine kinase activity of the KIT protein. To assess whether the mutation identified by NGS was recurrent, we performed targeted Sanger sequencing on a larger cohort of aCML patients, comprising a total of 52 cases. This analysis revealed the presence of *KIT* mutations in additional 3 patients, indicating that they are recurrent in aCML. Notably, all the *KIT* mutations identified so far translate to the D816V variant at protein level, suggesting that the activation of the KIT tyrosine kinase signaling plays an important role in this subset of aCML patients. It is known from the literature that KIT D816V is highly sensitive to the tyrosine kinase inhibitor dasatinib. To test if dasatinib was able to impair cell growth of the leukemic clone in KIT+ aCML cases, we performed *ex vivo* tritiated thymidine proliferation assays on bone marrow cells from one of the KIT D816V aCML patients in presence of either dasatinib, imatinib or vehicle alone: the proliferation assay showed that dasatinib was able to inhibit the proliferation of the leukemic clone with an IC50 of 1nM, while neither imatinib nor vehicle alone were able to significantly impair cell growth. In line with these data, western blot with an Anti-Phospho-KIT antibody on KIT+ lysates after treatment with increasing concentration of dasatinib showed that the drug was highly effective in inhibiting KIT autophosphorylation.

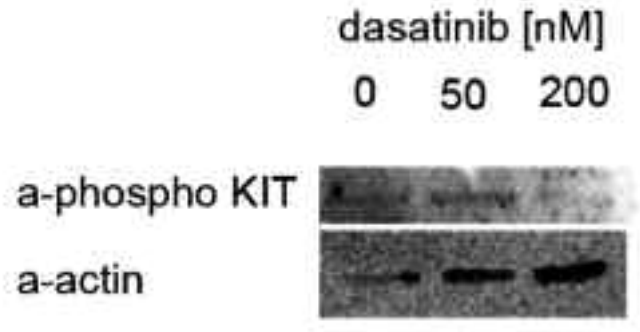

Figure 1.

Summary and Conclusion: These data indicate that KIT D816V is a pro-oncogenic lesion recurrently present in aCML, albeit with low frequency (4/68, 6%) and that aCML cells bearing this mutation are highly sensitive to dasatinib, *in vitro*. Given the very poor prognosis of this disorder, these findings suggest a new, highly efficient targeted treatment for a subset of aCML patients.

TRANSCRIPT LEVELS OF THE HEDGEHOG PATHWAY MEMBERS PTCH1 AND SMO ARE PREDICTIVE OF IMATINIB FAILURE IN PRE-TREATMENT CHRONIC MYELOID LEUKAEMIA

G Gerrard[1,*], N C Hagkarim[1], R Szydlo[1], M Alikian[1], J M Alonso-Dominguez[2], J Grinfeld[1], C Hedgley[3], S O'Brien[3], R E Clark[4], J Apperley[1], L Foroni[1]
[1]Haematology, Imperial College London, London, United Kingdom, [2]Facultativo Especialista de Área de Hematología, Laboratorio Central de la Comunidad de Madrid, Madrid, Spain, [3]Northern Institute for Cancer Research, Newcastle University Medical School, Newcastle Upon Tyne, [4]Haematology, Royal Liverpool University Hospital, Liverpool, United Kingdom

Background: Chronic myeloid leukaemia (CML) is characterised by the *BCR-ABL1* fusion gene and resultant dysregulated tyrosine kinase oncoprotein. First-line treatment is the tyrosine kinase inhibitor (TKI), imatinib (IM), to which 60-70% of patients will have an adequate response. 2nd generation TKIs are available, which exhibit greater potency, but their use upfront is controversial because of their adverse event profiles and greater cost. Biomarkers for IM response are therefore needed to optimise TKI usage upfront; the current best indicator of response is *BCR-ABL1* level by RT-qPCR at 3 months from start of treatment. *PTCH1* and *SMO* are genes encoding protein members of the Hedgehog signalling pathway. Previous work showed that gene-expression levels of *PTCH1* are predictive of IM response in CML and since signalling via SMO is inhibited by non-Hedgehog ligated PTCH1, it was reasoned that transcript levels of *SMO* would also be predictive. It was also hypothesised that since 2nd generation TKIs, such as dasatinib (DAS), are more potent BCR-ABL1 inhibitors, and their failure is characterised more by intolerance than progression, gene-expression biomarkers would be therefore less predictive in DAS recipients.
Aims: To evaluate PTCH1 and SMO as biomarkers for response to TKI therapy in CML
Methods: 438 pre-treatment cDNA samples from patients enrolled on the SPIRIT2 clinical trial (randomised to IM 400mg or DAS 100mg) were utilised, with appropriate consent. Custom TaqMan probes and primers for *PTCH1* and *SMO* were used in multiplex RT-qPCR reactions with 3 control genes (*GUSB*, *B2M* and *18S*) and run in fast-mode on a Step-One-Plus analyser. The geometric mean of the control genes was used to generate a relative expression metric using the delta-Cq method. The data were analysed separately for the IM and DAS, with TKI failure free survival (TFFS) as the primary endpoint; patients failing treatment because of intolerance were excluded from analysis. Patients were grouped into good and poor responders by attainment of<9.84% *BCR-ABL1* (international scale, IS) at 3 months and receiver operating characteristic (ROC) used to determine optimal expression cut-off for high and low categorisation. Outcome data from each expression group were then assessed by Kaplan-Meier (K-M) analyses to determine if gene expression, either alone or in combination, was predictive for TFFS.
Results: 354 patients were assessable (180 IM and 174 DAS); 145 IM and 190 DAS were<9.84% IS by 3mnth RT-qPCR (good); 46 IM and 14 DAS were >=9.84% (poor). The median delta-Cq for the IM good and poor groups were: *PTCH1,* 1.088 and 0.0062, respectively (P=0.006); SMO, 0.0997 and 0.1622 (P=0.22); *PTCH1/SMO* ratio, 9.642 and 2.786 (P=0.008). For the DAS good and poor groups delta-Cq: *PTCH1*, 0.9350 and 0.4460, respectively (P=0.038); *SMO*, 0.0972 and 0.1804 (P=0.15); PTCH1/SMO, 7.109 and 2.749 (P=0.093). The ROC cut-offs for IM were:<0.51 for *PTCH1*, >0.16 *SMO*; and<2.81 *PTCH1/SMO*. For DAS, the ROC cut-offs were:<0.47 *PTCH1*, >0.11 *SMO* and<3.31 *PTCH1/SMO*. K-M analysis of the IM patients showed that high *PTCH1* expression (P=0.029), low SMO expression (P=0.013) and high *PTCH1/SMO* ratio (P<0.0001; Figure 1A) were predictive of TFFS with hazard ratios of 2.002, 0.4522 and 3.328, respectively. The K-M for DAS showed that neither the single genes nor the ratio were predictive (all P>0.05; Figure 1B).

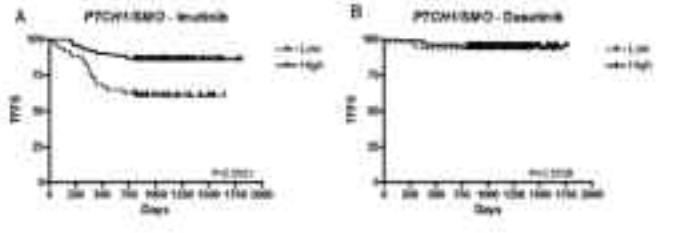

Figure 1. Kaplan-Meier analysis showing TKI Failure Free Survival (TFFS) of patients on A: imatinib and B: dasanitib, with high and low PTCH1/SMO expression ratio.

Summary and Conclusion: High *PTCH1* and low *SMO* expression levels are both predictive for response to IM and this predictive power seems to be enhanced by using the two in combination (higher hazard ratio and lower P-value). There was no predictive power for patients on DAS, suggesting that the greater potency of this TKI was able to overcome the inherent genetic disposition to IM failure. There is a need for inexpensive and robust assays to assist in the implementation of stratified medicine in CML. In this study, we demonstrate a simple multiplex RT-qPCR assay that can be used to identify those patients who may be expected to experience a sub-optimal response to IM and who therefore may benefit from a more potent 2nd generation TKI upfront.

S1317

PRO-ATHEROGENIC AND ANTI-ANGIOGENIC EFFECTS OF NILOTINIB ON ENDOTHELIAL CELLS: A POTENTIAL MECHANISM TO EXPLAIN VASCULOPATHIES IN CML PATIENTS TREATED WITH NILOTINIB

E Hadzijusufovic[1,2,3,*], K Albrecht-Schgoer[4], K Huber[5], F Grebien[5], G Eisenwort[1], W Schgoer[4], V Ghanim[1], C Kaun[6], S Herndlhofer[1], M Theurl[4], S Cerny-Reiterer[1], I Sadovnik[1], G Hoermann[7], B Jilma[8], W R Sperr[1], U Rix[5], J Wojta[6], D Wolf[9], G Superti-Furga[5], R Kirchmair[4], P Valent[1]
[1]Department of Medicine I, [2]Ludwig Boltzmann Cluster Oncology, Medical University of Vienna, [3]Department/Clinic for Companion Animals and Horses, University of Veterinary Medicine Vienna, Vienna, [4]Department of Internal Medicine I, Medical University of Innsbruck, Innsbruck, [5]Research Center for Molecular Medicine (CeMM), [6]Department of Internal Medicine II, [7]Department of Laboratory Medicine, [8]Department of Clinical Pharmacology, Medical University of Vienna, Vienna, Austria, [9]Department of Hematology & Oncology, University Hospital Bonn, Bonn, Germany

Background: The BCR/ABL1 inhibitor nilotinib is increasingly used to treat patients with chronic myeloid leukemia (CML). However, nilotinib has been associated with metabolic changes, including an increase in the fasting glucose level. In addition, vascular adverse events, including peripheral arterial occlusive disease (AOD), have been reported in nilotinib-treated patients.
Aims: We reviewed and updated AOD events in our CML patients receiving nilotinib (n=34) and initiated *in vitro* and *in vivo* studies to evaluate potential targets and mechanisms.
Results: After a median observation time (MOT) of 24 months, the frequency of AOD (26.5%) and severe AOD requiring surgical intervention and/or prolonged hospitalization (17.6%) was higher in nilotinib-treated patients compared to risk factor-, observation time-, and age-matched controls (34 imatinib-treated patients with CML, 34 with myelodysplastic syndromes, 34 with JAK2-mutated MPN and 34 with lymphoid neoplasms;<5% AOD, p<0.05). After a MOT of 36 months, the frequency of AOD amounted to 36.1% and the frequency of severe AOD was 19.4%. We next examined the *in vitro* effects of nilotinib on cultured human umbilical vein endothelial cells (HUVEC), human coronary artery-derived endothelial cells (HCAEC), and the human microvascular endothelial cell line HMEC-1. Nilotinib was found to inhibit the proliferation of endothelial cells in a dose-dependent manner, with pharmacologically relevant IC_{50} values obtained in HUVEC (1.0 µM), HCAEC (100 nM), and HMEC-1 (1.0 µM), whereas imatinib showed little if any effect. Moreover, nilotinib was found to inhibit the migration of HUVEC in a wound-scratch-assay as well as angiogenesis in a tube-formation assay (relative capillary tubes: VEGF+control: 1.8±0.1, VEGF+nilotinib (100 nM): 1.3±0.1, VEGF+imatinib (100 nM): 1.7±0.05; n=3, p<0.01 for VEGF alone *vs* VEGF+nilotinib). In a mouse model of hindlimb ischemia, nilotinib (75 mg/kg/day p.o. for 28 days) was found to slow blood flow-recovery after induction of ischemia whereas imatinib (100 mg/kg/day p.o. for 28 days) showed no comparable effect (laser Doppler perfusion imaging ratio ischemic/control leg: control mice: 0.81±0.03, imatinib-treated mice: 0.79±0.04, nilotinib-treated mice: 0.68±0.04; n=13/group; p<0.05 for nilotinib *vs* control and for nilotinib *vs* imatinib). The decreased blood perfusion was accompanied by an increased rate of limb necrosis (necrosis score: control: 1.15±0.08, imatinib: 1.17±0.05, nilotinib: 1.54±0.18; p<0.05 for nilotinib *vs* control and nilotinib *vs* imatinib). Moreover, microvessel density was significantly lower in the affected hind limb in nilotinib-treated mice compared to imatinib-treated mice (p<0.05). In addition, we found that nilotinib, but not imatinib, promotes the expression of pro-atherogenic cytoadhesion molecules on HUVEC, including ICAM-1, VCAM-1 and E-Selectin. As assessed by proteomics profiling and phospho-array analysis, several angiogenesis-related antigens, including TEK, ABL2, JAK1, and BRAF were identified as targets of nilotinib, whereas imatinib did not bind to these proteins in endothelial cells. Neither nilotinib nor imatinib showed *in vitro* or *in vivo* effects on platelet adhesion or platelet aggregation.
Summary and Conclusion: In conclusion, nilotinib exerts multiple effects on vascular endothelial cells, presumably through multiple mechanisms and targets. We hypothesize that these effects may contribute to nilotinib-induced vasculopathy in CML.

S1318

IDENTIFICATION OF RECURRENT GENETIC ALTERATIONS ASSOCIATED WITH BLAST CRISIS TRANSFORMATION IN CHRONIC MYELOID LEUKEMIA

V Magistroni[1,*], R Piazza[1], N Sharma[1], W Parker[2], A Pirola[1], D Yeung[2], A Schreiber[2], P Wang[2], S S Hamish[2], K Dong-Wook[3], S Branford[2], C Gambacorti-Passerini[1]

[1]University of Milano Bicocca, Monza, Italy, [2]SA Pathology, Center for Cancer Biology, Adelaide, Australia, [3]Dept. of Hematology, Catholic University, Seoul, Korea, Republic Of

Background: Chronic Myeloid Leukemia (CML) is caused by the appearance of the BCR/ABL fusion gene, as a result of a reciprocal translocation between chromosome 9 and 22 t(9;22)(q34;q11). The hybrid gene translates into an oncogenic fusion protein which is characterized by the constitutive activation of its tyrosine kinase activity, being responsible for malignant transformation. CML evolves from a druggable chronic phase (CP) to an aggressive advanced phase (blast phase-BP). Despite the aggressiveness of BP and the poor overall survival of BP patients, little is known about the molecular mechanisms responsible for the progression of the disease.

Aims: To gain insight into the molecular lesions responsible for BP, we present here the results obtained from the whole-exome and RNA-seq analysis of paired CP/BP CML samples from patients that underwent progression to blast crisis after standard therapy. The access to matched CP/BP samples renders this data highly valuable.

Methods: We performed whole-exome sequencing and RNA-seq analysis using high-throughput technologies (Illumina Genome Analyzer IIx) from genomic DNA and total RNA of paired samples. The cross-match between BP and CP exomes was performed with dedicated in-house software. The mutations identified were confirmed through standard sequencing methodologies. Evaluation of copy number abnormalities was achieved using CEQer (Comparative-Exonic-Quantification-Analyzer) while fusions were analysed by using FusionAnalyser.

Results: We evaluated 11 paired CP (used as a control) and BP samples by comparing exome-sequences. The median time between CP and BP samples was 36 months (range 1-73 months). We found a total of 38 single nucleotide mutations occurring in BP samples that were absent in the paired CP, corresponding to an average of 3 mutations/patient (range of 0-8 mutations). Most of the mutations found (n=21) scored positively in the GeneRanker software. By using this approach we found recurrent, somatic, single nucleotide mutations in *RUNX1* and *UBE2A* in 2 out of 10 BP samples. Detailed data are presented in Table 1. CEQer analysis of 6 matched BP/CP exomes reveals the presence of 6 chromosomal alterations. In one of the patients without acquired mutations we found the presence of a Philadelphia chromosome duplication. Data obtained after CEQer analysis also indicated that 2 out of 6 patients had complete loss of chromosome 7. In patient #1 and #4 respectively, two major regulators of the cell cycle control (CDKN2A and p53) were also deleted. The analysis of RNA-seq data of 6 patients with FusionAnalyser did not show any new fusion event specific for transformation.

Table 1.

Summary and Conclusion: Our study shows the presence of a limited number of acquired mutations in the blast crisis samples when compared with matched chronic phase. Notably, we were able to find 2 recurrently mutated genes associated with blastic transformation, RUNX1 and UBE2A, with the last one never been detected in CML samples. Ongoing analysis on additional BP/CP samples and *in vitro* experiments will help to clarify the role of UBE2A mutations in CML progression.

S1319

MYC::MAX HETERODIMER ACTS ON BCR PROMOTER TO MODULATE BCR AND BCR-ABL EXPRESSION

N Sharma[1,*], V Magistroni[1], R Piazza[1], C Gambacorti[1]
[1]Dept. of Health Sciences, University of Milan Bicocca, Monza (MB), Italy

Background: Chronic Myeloid Leukemia (CML) is caused by the BCR/ABL fusion gene, the product of is so called Philadelphia (Ph) chromosome. If untreated CML progresses within 3 years from a mild and easy to control form, called chronic phase (CP), into an aggressive and deadly acute leukemia called blast crisis (BC). BC is marked, as any acute leukemia, by a complete differentiation block and the ensuing accumulation of blasts with frequent over-expression of BCR/ABL protein. After the oncogenic translocation, the BCR-ABL gene is under the transcriptional control of BCR promoter. In spite of all the research performed in the field, the molecular mechanisms involved in the regulation of BCR promoter are mostly unknown Therefore we need to understand what are the transcription factors or the mechanisms that regulate BCR-ABL expression.

Aims: To identify the transcription factors which are binding to the BCR promoter and modulate BCR-ABL expression.

Methods: *In silico* analysis was performed to identify putative binding sites of transcription factors on BCR promoter through Jasper database (http://jaspar.genereg.net/), and TRANSFAC Biobase (http://www.biobase-international.com/product/transcription-factor-binding-sites).Chromatin Immunoprecipitation assays were used to confirm *in silico* data. To determine the role of selected transcription factors on BCR and BCR/ABL expression, the K562 BCR/ABL positive CML cell line was transfected with specific eukaryotic expression vectors. mRNA and protein expression level of BCR and BCR-ABL were detected by real time PCR and Western blotting. BCR reporter activity was also analyzed by luciferase assay.

Results: Several putative protein binding sites (PBS) for different transcription factors have been identified along the sequence of BCR promoter by *in silico* analysis. Criteria for selecting the transcription factors (TF) for subsequent studies were: 1) TF have role in haematopoiesis or differentiation of hematopoietic progenitors; 2) TF binds to a DNase protected area of BCR promoter. Hereby, we found that **MYC and MAX proteins** putatively bind to BCR promoter at four different loci: PBS1 (- 1354 to -1341 from ATG codon), PBS2 (-1283 to -1263) PBS3 (- 813 to -801) and PBS4 (-768 to -756). By using Chromatin Immunoprecipitation we confirmed the binding of MYC and MAX on BCR promoter to all the above mentioned sites. Quantitative PCR and Western Blot showed that, when overexpressed, MYC::MAX heterodimer significantly up-regulates the BCR (MYCMAX 2.33±1.08) and BCR-ABL (MYCMAX 2.61±0.3) expression in comparison with K562 empty cells. This induction seems to be stronger when both the MYC and MAX gene are over-expressed (BCR expression in MAX: 0.75±0.2, MYC: 1.40±0.4, MYCMAX 2.33±1.08) and BCR-ABL (MAX: 1.28±0.20, MYC: 2.32±0.4, MYCMAX 2.61±0.3). By using a luciferase reporter assay we saw 3.5 fold increase in the luciferase activity when K562 MYC::MAX transfectants were cotrasfected with the full BCR promoter (-1444 base pair from the ATG starting site cloned in the pGL3 promoter comprising all the 4 putative PBS) in contrast to K562 not over-expressing MYC::MAX. This indicates that MYC::MAX overexpression induces an up-regulation of BCR promoter activity, when all the four putative MYC::MAX binding sites (PBS1, PBS2, PBS3 and PBS4) are present. In contrast when PBS3 and PBS4 were deleted, a minimal decrease of luciferase activity was observed, thus identifying these two regions as critical for BCR and BCR/ABL regulation.

Summary and Conclusion: These data demonstrate that binding of MYC::MAX heterocomplex to the BCR promoter leads to upregulation of BCR and BCR-ABL expression at both transcriptional and protein level. Since MYC is frequently over-expressed in BC, this phenomenon could be responsible for the BCR/ABL upregulation and thus ensuring differentiation block.

CONSTITUTIVE EXPRESSION OF IRF8 INHIBITS MN1 INDUCED AML: ROLE OF IMMUNE GENES IN DIFFERENTIATION

A Sharma[1,*], H Yun[1], N Jyotsana[1], A Chaturvedi[1], A Schwarzer[2], E Yung[3], F Kuchenbauer[4], B Argiropoulos[5], K Goerlich[1], A Ganser[1], R Humphries[3], M Heuser[1]
[1]Department of Hematology, Hemostasis, Oncology and Stem cell Transplantation, [2]Department of experimental hematology, Hannover Medical School, Hannover, Germany, [3]Terry Fox laboratory, British Columbia Cancer agency, Vancouver, Canada, [4]Department of Internal Medicine III, University Hospital Medical Center, ULM, Germany, [5]Department of Medical Genetics, University of Calgary, Calgary, Canada

Background: Acute myeloid leukemia (AML) is characterized by an increase in the number of myeloid cells in the marrow and an arrest in their maturation, due to sequential accumulation of multiple rare genetic or epigenetic events. Functionally, disrupted transcription factors are one of the most important causes of abrogated differentiation of hematopoietic stem cells. MN1 (a transcriptional regulator) protein is one such factor, whose overexpression serves as a prognostically important factor in AML patients. Overexpression of MN1 induces AML in mice and causes resistance to cytarabine and all-trans-retinoic acid (ATRA) induced cytotoxic/differentiation effects.
Aims: To investigate whether MN1 plays a role in myeloid differentiation through transcriptional activation or repression, we fused transcriptional activation (VP16) and repression (M33) domains with MN1 for functional analyses. In order to evaluate, whether re-expression of repressed genes (Ccl9 and Irf8) could overcome the MN1-induced leukemia in mice, we overexpressed Ccl9 and Irf8 in MN1 expressing cells and evaluated their effects *in vitro* and *in vivo*.
Results: Transcriptional activation of MN1 target genes by the MN1VP16 fusion gene induced myeloproliferative disease with long latency (median 146 days compared to 35 days for MN1 expressing cells, P<0.001), and full differentiation potential to mature neutrophils *in vivo*. Conversely, transcriptional repression of MN1 target genes by the MN1M33 fusion gene induced AML with the same latency as MN1 (median 39days, P=0.6). Gene expression profiling identified a large proportion of differentially expressed genes between leukemic MN1 and differentiation-permissive MN1VP16 cells that belonged to the immune response pathway including Irf8 and Ccl9. As MN1 is a co-factor of the transcription factors MEIS1 and RARA, we compared chromatin occupancy between these genes. Immune response genes that were upregulated in MN1VP16 cells were co-targeted by MN1 and MEIS1, but not RARA, suggesting that myeloid differentiation is blocked through transcriptional repression of shared target genes of MN1 and MEIS1. Constitutive expression of Irf8 or its target gene Ccl9 identified these genes as potent inhibitors of MN1-induced leukemia. Ectopic expression of Irf8 and Ccl9 in MN1 leukemic cells induced partial differentiation, prevented leukemic outgrowth and significantly extended survival of mice (P<0.001). Specifically, 60% of the mice transplanted with MN1+Irf8 showed no leukemic phenotype and 40% mice developed myeloproliferative disease but not AML. In addition, we utilized NOD/SCID/IL2rg^{null} mice model to preclude the role of adaptive immunity for the leukemic inhibition, wherein we observed that inhibition of leukemia by IRF8 was independent of an immune response.
Summary and Conclusion: Our data shows that MN1 prevents activation of the immune response pathway, and suggests restoration of Irf8 signalling as a novel therapeutic mechanism in AML.

CD99 IS A STEM CELL MARKER AND THERAPEUTIC TARGET IN AML/MDS

S S Chung[1], S M Devlin[2], V M Klimek[1], A Melnick[3], C Park[4,*]
[1]Department of Medicine, Leukemia Service, [2]Department of Epidemiology and Biostatistics, Memorial Sloan Kettering Cancer Center, [3]Medicine/Hematology-Oncology and Pharmacology, Weill Cornell Medical College, [4]Human Oncology and Pathogenesis Program and Pathology, Memorial Sloan Kettering Cancer Center, New York, United States

Background: The myelodysplastic syndromes (MDS) and acute myeloid leukemia (AML) are initiated and sustained by self-renewing stem cells. These cells are likely resistant to conventional therapies, and they may represent the reservoir of minimal residual disease (MRD) that leads to disease relapse.
Aims: We sought to identify aberrant cell surface proteins on MDS and AML disease-initiating cells since they may serve as biomarkers of disease status as well as serve as potential therapeutic targets.
Methods: Flow cytometry was performed on *de novo* and therapy-related MDS and AML samples to assess cell surface expression of CD99, originally identified in a prior transcriptome analysis of purified hematopoietic stem cells (HSCs) from MDS patients. AML cell lines overexpressing CD99 cDNA or CD99 shRNA were transplantation into sublethally irradiated, NSG immunodeficient mice or evaluated in transendothelial migration assays. Anti-CD99 clones H036-1.1 and 12E7 were obtained from commercial sources. For cytotoxicity assays, AML cell lines and primary cells were incubated with these antibodies for 72 hrs, with cell number quantitated by flow cytometry.
Results: Flow cytometry of MDS patient bone marrow (BM) samples (n=26) confirmed that CD99 is frequently increased on MDS HSCs (85%). Assessment of 78 paired diagnosis/relapse AML specimens revealed that CD99 is also frequently overexpressed at diagnosis (81%) and relapse (83%). Providing support for CD99 as a leukemia stem cell (LSC) marker in AML, CD99 surface expression is higher in the LSC-enriched CD34+CD38- fraction compared to bulk blasts (p=0.003), as well as in relapsed as compared to diagnostic specimens (p=0.007). In addition, CD99 high cells exhibit a CD34+CD38-CD90-CD45RA+ LMPP-like immunophenotype, previously shown to be enriched for LSC activity. To determine the function of CD99 in AML, we transduced MOLM13 AML cells with a CD99 shRNA (8.0-fold knockdown). NSG mice transplanted with these cells showed improved survival compared to vector controls (58d *vs*. 34d, p=0.02). Consistent with its role in leukocyte trafficking, AML cell lines overexpressing CD99 showed increased transendothelial migration in transwell assays, and CD99 expression was higher on AML patient PB blasts than BM blasts (p=0.03). Unexpectedly, CD99 transcript expression in the ECOG 1900 AML patient cohort (n=308) positively correlated with survival (p=0.001). We propose that CD99 may improve survival in the context of chemotherapy by promoting mobilization and thus chemosensitivity of AML cells. To determine whether CD99 may be therapeutically target, we tested the ability of monoclonal antibodies (mAb) against CD99 to induce direct cytotoxicity *in vitro*. Anti-CD99 mAbs induced significant cell death in 11 AML and two MDS-derived cell lines, as well as in primary AML blasts (n=7) and MDS HSCs/CD34+ cells (n=3), with relative sparing of primary human HSCs and endothelial cells. Pre-coating of primary human LSCs with anti-CD99 mAb prior to transplantation into NSG mice led to impaired engraftment (20% *vs*. 67%, p=0.009) and improved survival (p=0.05). Immunofluorescence demonstrated that mAb ligation promotes clustering of CD99, and this clustering appears to be critical for cytotoxicity. Anti-CD99 mAb treatment was also associated with activation of Src-family kinases, and inhibitors of Src signaling attenuate anti-CD99 mAb induced cytotoxicity.
Summary and Conclusion: Our results establish CD99 as a cell surface marker expressed in AML and MDS stem cells, as a mediator of transendothelial migration, and as a promising therapeutic target for direct targeting by mAbs. Further studies are needed to evaluate the potential of targeting CD99 in AML/MDS *in vivo* and to further characterize the mechanisms of CD99 mediated cell death.

S1322

GENOME-WIDE DNA METHYLATION PROFILING REVEALS A RARE CPG ISLAND METHYLATOR PHENOTYPE IN AML

C Gebhard[1,*], L S Schwarzfischer[1], D Glatz[1], D Heudobler[1], S Pohl[1], R Andreesen[1], G Ehninger[2], R Delwel[3], C Thiede[2], M Rehli[1]
[1]Internal Medicine III, University Hospital, Regensburg, [2]Medical Department I, University Hospital, Dresden, Germany, [3]Department of Hematology, Erasmus University Medical Center, Rotterdam, Netherlands

Background: Acute myeloid leukemia (AML) represents a clonal myeloid stem cell disorder. The combination of differentiation arrest and excessive proliferation of the immature progenitor pool results in the accumulation of non-functional progenitor cells in the bone marrow and peripheral blood where they hamper the production or functions of normal blood cells. It has become evident that besides genetic alterations, epigenetic changes play an essential role in leukemogenesis.
Aims: To increase our understanding of how DNA methylation may affect leukemic transformation in AML, and to define marker genes for improved patient outcome prediction, diagnosis and prognosis we performed a systematically genome-wide screening of DNA methylation profiles.
Methods: Initially we analyzed the DNA methylation status of about 23.000 CpG islands of 28 acute myeloid leukemia samples using the Methyl-CpG-Immunoprecipitation assay combined to CpG island microarrays (MCIp-chip). These profiles were then used to select a subset of aberrantly methylated CpG islands (380 regions covering 15.000 individual CpGs) for quantitative DNA methylation profiling in a larger cohort of 185 AML patients (50% normal karyotype) using MALDI-TOF analysis of bisulfite-treated DNA.
Results: Meta analysis clearly separated a subgroup of CpG island regions showing highly correlated DNA methylation changes that were also marked by histone H3 lysine 27 trimethylation in normal hematopoietic progenitor cells (HPC). The residual group of CpG islands not targeted by polycomb group (PcG) repressors in HPC displayed heterogeneous methylation patterns across patients that (in contrast to the PcG target group) clustered with genetic markers, including oncofusion proteins (CBFB-MYH11, AML-ETO), or certain mutations (NPM1, CEBPA, IDH1/2). A fraction of AML patients (5/185) displayed aberrant hypermethylation at almost all studied loci, representing a rare CpG island methylator phenotype (CIMP) in AML. These patients present immature

leukemia (FAB MO, M1) with various chromosomal aberrations but very few mutations (*e.g.* no IDH1/2, KRAS, DNMT3A) that might explain the CIMP phenotype. The patient group that we identified shows high resemblance with a recently reported CEBPA methylated subgroup displaying a similar strong methylation signature (Wouters et al, 2007 and Figueroa et al, 2009). DNA methylation analysis revealed that most of these CEBPA-silenced cases fall into our CIMP category. To further characterize this interesting group of hypermethylated patients from both studies we performed in-depth global DNA methylation analyses (MCIp-seq) and detected more than 3000 genes that were specifically methylated in the patients of the CIMP-cluster. Interestingly, hypermethylated gene promoters represent many transcriptional regulators that are involved in the differentiation of myeloid lineages (including CEBPA, CEBPD, IRF8, GATA2, KLF4, MITF or MAFB). In addition, these patients frequently show hypermethylation of the TET2 promoter, which could result in a loss of maintenance DNA demethylation and successive hypermethylation at CpG islands.

Summary and Conclusion: It is likely that the aberrant silencing of key lineage regulators facilitates/stabilizes the differentiation arrest in these cells, and that these patients may particularly benefit from therapies that revert DNA methylation. To test whether the DNA methylation phenotype correlates with common genetic alterations we are systematically analyzing and correlating genetic and epigenetic alterations of these patients.

REQUIREMENT FOR CDK6 IN MLL-REARRANGED ACUTE MYELOID LEUKEMIA

T Placke[1], K Faber[2], A Nonami[3], S Putwain[4], H Salih[5], F Heidel[6], A Krämer[7], D Root[8], D Barbie[3], S Armstrong[9], W Hahn[3], B Huntly[4], S Sykes[10], M Milsom[7], C Scholl[2], S Fröhling[1,*]

[1]National Center for Tumor Diseases, Heidelberg, [2]Ulm University, Ulm, Germany, [3]Dana-Farber Cancer Institute, Boston, United States, [4]Cambridge Institute of Medical Research, Cambridge, United Kingdom, [5]Tübingen University, Tübingen, [6]Magdeburg University, Magdeburg, [7]German Cancer Research Center, Heidelberg, Germany, [8]Broad Institute of Harvard and MIT, Cambridge, [9]Memorial Sloan-Kettering Cancer Center, New York, [10]Fox Chase Cancer Center, Philadelphia, United States

Background: Chromosomal rearrangements involving the H3K4 methyltransferase MLL trigger aberrant gene expression in hematopoietic progenitors and give rise to an aggressive subtype of acute myeloid leukemia (AML). Insights into MLL fusion-mediated leukemogenesis have not yet translated into better therapies, because MLL is difficult to target directly and the identity of the genes downstream of MLL whose altered transcription mediates leukemic transformation are poorly annotated.

Aims: To search for essential signaling pathways in MLL-rearranged AML that might serve as new therapeutic targets, we performed loss-of-function RNA interference (RNAi) screens in 5 AML cell lines (NOMO-1, THP-1, OCI-AML3, HL-60, U937) using a lentiviral short hairpin RNA (shRNA) library.

Results: We observed that MLL-AF9-driven NOMO-1 and THP-1 cells are exceptionally reliant on the cell cycle regulator CDK6, but not its functional homolog CDK4. The enhanced CDK6 dependence of MLL-rearranged cells was confirmed in an expanded panel of AML cell lines (MLL-rearranged, n=6; MLL wildtype [WT], n=4) that also included cell lines harboring alternate MLL fusions (MLL-AF4 and MLL-AF6), and the RNAi-induced phenotype was countered by overexpression of an shRNA-resistant *CDK6* cDNA. Stable knockdown of MLL-AF9 in MLL-AF9-positive cell lines and overexpression of MLL-AF9 in WT MLL-expressing cell lines, normal human CD34-positive cells, or Ba/F3 murine pro-B cells led to concordant changes in CDK6 mRNA and protein levels that resembled those of HOXA9, a known MLL-AF9 target. Furthermore, chromatin immunoprecipitation-sequencing analysis demonstrated that MLL-AF9 binds to the *Cdk6* locus in mouse bone marrow (BM) cells transduced with MLL-AF9 and in MLL-AF9-driven murine AML, indicating that CDK6 is rendered essential via direct targeting by truncated MLL. Analysis of cell cycle, apoptosis, and myeloid differentiation demonstrated that the differential growth-inhibitory effect of CDK6 suppression was mainly attributable to myeloid differentiation, as MLL-rearranged cell lines upregulated CD11b expression and assumed a more mature, macrophage-like morphology upon CDK6 knockdown, effects not observed in WT MLL-expressing cells. Furthermore, the immature phenotype of MLL-rearranged cells was rescued by overexpression of an shRNA-resistant *CDK6* cDNA. Knockdown of Cdk6 also impaired the proliferation and *in vitro* clonogenic activity of primary murine BM cells stably transduced with MLL-AF9, whereas cells expressing another leukemogenic fusion gene (*MOZ-TIF2*) and Ba/F3 cells were largely unaffected. We also expressed MLL-AF9 in unfractionated BM derived from *Cdk6* knockout mice and observed that colony numbers were gradually reduced in cultures initiated with $Cdk6^{+/-}$ and $Cdk6^{-/-}$ BM compared to WT BM. Finally, depletion of Cdk6 was found to overcome the differentiation block of MLL-AF9-driven AML and prolonged survival in a murine BM transplantation model of MLL-AF9-induced leukemia. The context-dependent effects of lowering CDK6 expression were closely phenocopied in cell lines and primary human AML specimens by palbociclib (also known as PD-0332991), a small-molecule inhibitor of CDK4 and CDK6 enzymatic activity that is in clinical development as an anticancer agent.

Summary and Conclusion: These data identify CDK6 as critical effector of MLL fusions in leukemogenesis that might be targeted to overcome the differentiation block associated with MLL-rearranged AML, and underscore that cell cycle regulators may have distinct, non-canonical and non-redundant functions in different contexts.

REVERSE ENGINEERING OF HEMATOPOIETIC TRANSFORMATION: DECONSTRUCTING MIXED LINEAGE LEUKEMIA BY GENOME WIDE TECHNIQUES

MP Garcia-Cuellar[1], K Hetzner[1], E Fueller[1], J Steger[1], C Bartenhagen[2], M Dugas[2], R Slany[1,*]

[1]University Erlangen, Erlangen, [2]University Muenster, Muenster, Germany

Background: For a complete understanding of the pathomechanism leading to a neoplastic disease it is necessary to elucidate the primary events that convert a normal differentiating cell into a malignant self-renewable entity. Simply cataloging the differences between the end-stage of the neoplastic development and normal tissue suffers from several pitfalls. Tissue and tumor heterogeneity, the unknown nature of the "normal" target for transformation as well as the multi-tiered nature of biochemical processes with unclear inter-dependencies makes the identification of the primary causative events very cumbersome. Using mixed lineage leukemia (MLL) as an example we are using a "reverse engineering" strategy to avoid this problems enabling us to pinpoint the earliest changes that cause a normal hematopoietic cell to deviate towards a transformed fate.

Aims: MLL is caused by the presence of MLL fusion proteins. These aberrant transcription factors are potent leukemogenic agents that are created by chromosomal translocations joining the N-terminus of the histone methyltransferase MLL to a variety of different fusion partners. As a consequence a transcriptional elongation and chromatin modification complex is recruited to an unknown number of target genes leading to ectopic expression and eventually a block in differentiation. Here we wanted to elucidate the genome-wide genetic changes that accompany transformation by a MLL fusion protein.

Methods: We used a genetically modified mouse with an inducible knock-in of a MLL fusion into the natural MLL locus. With this model we were able to generate large numbers of hematopoietic cells harboring a single transforming mutation. Inactivation of the conditional MLL fusion leads to reversion of the neoplastic phenotype enabling access to a matched malignant/normal population thus obviating the need to identify and isolate the rare primary target of initial transformation. We employed genome wide techniques of ChIP-Seq and nascent RNA-Seq to determine changes in RNA synthesis rate, chromatin modification and transcription factor occupancy during this reversal to normal.

Results: A kinetic sampling across several time points allowed a hierarchical classification of the observed changes and an exact correlation to the physiological state of the cell. In this way a comprehensive list of 109 MLL target genes could be assembled. Next to well-known genes under control of MLL fusions like the HOXA and HOXB cluster and their cooperation partners MEIS1 and PBX3 a significant number of hitherto unknown targets could be identified. Most importantly the kinetic data allowed the identification of an "early changing" group that can be seamlessly assembled into a molecular network controlling cell cycle and differentiation. Biochemical studies probing the significance of individual net-nodes for the overall transformation process are under way.

Summary and Conclusion: In summary we present a generally applicable method to deconvolute the tangled development towards a neoplastic state. This approach may potentially reveal sensitive points for therapeutical intervention.

THE JAK-INHIBITOR RUXOLITINIB SUBSTANTIALLY AFFECTS NK CELL BIOLOGY

J Rudolph[1,*], K Schönberg[1], I Cornez[1], P Brossart[1], D Wolf[1]
[1]University Hospital of Bonn, Department of Internal Medicine III, Oncology, Hematology and Rheumatology, Bonn, Germany

Background: Ruxolitinib is a potent JAK-inhibitor, approved for the treatment of myelofibrosis (MF). It exerts strong anti-inflammatory activities, thereby improving splenomegaly and cytokine-mediated symptoms but also increases infection rates in these patients. NK cells are critical for cancer-immune surveillance and cytokine-mediated signals are central for proper NK cell activation.
Aims: We aimed to characterize in detail the effects of JAK inhibition on human NK cells by phenotypic and functional analysis.
Methods: Highly purified NK cells from human peripheral buffy coats were exposed to increasing concentrations of ruxolitinib (0.1-10 µM). Cytokine (1000U/ml IL-2, 25ng/ml IL-15)-induced NK cell proliferation was analyzed by CFSE dilution. Phenotypic and functional NK cell activation markers (NKp46, NKG2D, Granzyme B, CD16, and CD69) were analyzed by flow cytometry (including CD107a expression for degranulation). NK cell function was tested by flow-cytometry-based killing assays and quantification of IFN-γ production upon stimulation with either MHC class I-deficient K562 target cells or cytokines (IL-12, IL-18). In addition, phenotypic and functional analyses were also tested during NK receptor activation via plate-bound activating NKp46 antibodies. Signaling events were analyzed by phospho-flow technology to evaluate ruxolitinib-mediated changes of cytokine-dependent signalling cascades (pS6, pSTAT1, pSTAT3, pSTAT5, pERK, pAKT, pP38, and pZAP70). Synapse formation of ruxolitinib exposed NK-92 cells towards the target cell K562 was tested either by flow cytometry with differentially labelled cells or by confocal microscopy with additional staining of perforin and filamentous actin.
Results: Our results provide first evidence that ruxolitinib profoundly affects cytokine-induced NK cell activation. This includes a significant and dose-dependent reduction of NK cell proliferation, reduced induction of activation-associated surface markers as well as impaired killing activity against the classical NK target cell line K562. In addition, all main functional activities of NK cells are down-regulated as shown by reduced cytotoxic capacity, impaired degranulation, IFN-γ production and synapse formation without affecting cell viability. After wash-out, the inhibitory effects of ruxolitinib on NK cells are fully reversible, as shown by proper re-activation by cytokines. In contrast to cytokine-mediated NK cell activation, stimulation *via* the NK-specific receptor NKp46 is not affected by ruxolitinib. On a molecular level, phospho-flow analyses revealed that cytokine associated signaling events, such as phosphorylation of STAT5 and S6 were dose-dependently reduced by ruxolitinib in primary human NK cells.
Summary and Conclusion: Ruxolitinib strongly inhibits NK cell activation leading to impaired proliferation and functional activity. Experiments verifying these effects in patients are currently ongoing. Our findings may have important clinical implications, when considering the application of ruxolitinib as GvHD therapy as NK cells are critically involved in the GvL effect after allogeneic stem cell transplantation.

THE KI-1 ANTIGEN (CD30) IS A NOVEL MARKER AND POTENTIAL THERAPEUTIC TARGET IN ADVANCED SYSTEMIC MASTOCYTOSIS

K Blatt[1,*], S Cerny-Reiterer[1,2], K Sotlar[3], J Schwaab[4], G Hoermann[5], M Mayerhofer[6], E Hadzijusufovic[1,2,7], M Willmann[7], A Reiter[4], HP Horny[3], P Valent[1,2]
[1]Department of Internal Medicine I, Division of Hematology & Hemostaseology, [2]Ludwig Boltzmann Cluster Oncology, Medical University of Vienna, Vienna, Austria, [3]Institute of Pathology, Ludwig-Maximilians-University Munich, Munich, [4]III. Medical Department, University Medical Centre Mannheim, Mannheim, Germany, [5]Department of Laboratory Medicine, Medical University of Vienna, [6]Ludwig Boltzmann Institute of Osteology, Hanusch-Hospital, [7]Department for Companion Animals and Horses, Clinic for Small Animals, Clinical Unit of Internal Medicine, University of Veterinary Medicine Vienna, Vienna, Austria

Background: Systemic mastocytosis (SM) is a hematologic neoplasm characterized by increased expansion and pathologic accumulation of neoplastic mast cells (MC) in various organs. In most patients, neoplastic cells exhibit the transforming *KIT* mutation D816V. The Ki-1 antigen (CD30) is an established therapeutic target in Hodgkin´s lymphoma and anaplastic large cell lymphoma. Recent data suggest that neoplastic MC in patients with aggressive SM (ASM) and mast cell leukemia (MCL) express substantial amounts of cytoplasmic CD30.
Aims: In the present study, we examined the expression of CD30 in various human MC lines (HMC-1, MCPV) and in primary neoplastic MC in patients with indolent SM (ISM, n=11) and advanced SM (ASM, n=5; MCL, n=2). In addition, we asked whether CD30 serves as a potential therapeutic target in SM.
Results: As assessed by flow cytometry, neoplastic MC were found to express cell surface CD30 in most patients with SM, namely in 10/11 patients with ISM and in 4/7 patients with ASM/MCL. The immature, RAS-transformed MCL line MCPV (KIT D816V-negative) also expressed cell surface CD30, whereas the MCL line HMC-1.1 (lacking KIT D816V) expressed only low amounts of CD30, and the HMC-1.2 subclone (KIT D816V+) was found to stain negative for CD30. We next applied the CD30-targeting drug brentuximab vedotin (provided by Millennium: The Takeda Oncology Company, Cambridge, MA, USA) which is an antibody-conjugate consisting of a chimeric anti-CD30 antibody and the microtuble inhibitor monomethyl auristatin E (MMAE). Brentuximab vedotin has recently been described to induce dose-dependent growth-arrest in human CD30+ lymphoblastic cell lines. In the present study, brentuximab vedotin was found to inhibit the proliferation of MCPV and HMC-1 cells in a dose-dependent manner, with lower IC50 values found in CD30+ MCPV and HMC-1.1 cells (5 µg/ml) than in CD30− HMC-1.2 cells (10 µg/ml). As assessed by AnnexinV/PI staining and staining for active-caspase-3, brentuximab vedotin also induced dose-dependent apoptosis in MCPV and HMC-1.1 cells, but did not induce substantial apoptosis in CD30− HMC-1.2 cells. Brentuximab vedotin also induced growth inhibition and apoptosis in the CD30+ canine-mastocytoma cell line C2. Furthermore, brentuximab vedotin was found to downregulate anti-IgE induced histamine release in basophils. We next examined the effects of brentuximab vedotin on *in vitro* survival (apoptosis) of primary neoplastic MC in patients with CD30− SM (n=3) and in patients with CD30+ SM (n=3). In these experiments, brentuximab vedotin was found to induce dose-dependent apoptosis in neoplastic MC in patients with CD30+ SM at pharmacologically relevant concentrations, whereas no drug effects were seen in patients with CD30− SM. Finally, we examined the effects of a drug combination consisting of brentuximab vedotin and the KIT D816V-targeting drug PKC412 (midostaurin). We found that both drugs synergize with each other in inhibiting the *in vitro* proliferation of CD30+ MCPV cells.
Summary and Conclusion: In conclusion, our data provide evidence that CD30 is expressed on the surface of neoplastic MC in patients with indolent and advanced SM. Our data also show that the CD30-targeting antibody brentuximab vedotin induces growth arrest and apoptosis in neoplastic MC and synergizes with midostaurin in inhibiting the growth of CD30+ neoplastic MC. Whether these effects also occur *in vivo* in patients with advanced mastocytosis, remains to be determined in clinical trials.

S1327

THE EPIGENETIC READER BRD4 SERVES AS A NOVEL MARKER AND TARGET IN AGGRESSIVE SYSTEMIC MASTOCYTOSIS AND MAST CELL LEUKEMIA

G Wedeh[1,2,*], S Cerny-Reiterer[2,3], E Hadzijusufovic[2,3,4], H Herrmann[3], K Blatt[2], G Eisenwort[3], G Hoermann[5], W R Sperr[2,3], L Muellauer[6], C R Vakoc[7], J E Bradner[8], HP Horny[9], J Zuber[10], M Arock[1], P Valent[2,3]
[1]Ecole Normale Supérieure de Cachan, LBPA, Cachan, France, [2]Department of Medicine I, Division of Hematology and Hemostaseology, [3]Ludwig Boltzmann Cluster Oncology (LB-CO), Medical University of Vienna, [4]Department/Clinic for Companion Animals and Horses, Clinic for Small Animals, Clinical Unit of Internal Medicine, University of Veterinary Medicine, [5]Department of Laboratory Medicine, [6]Department of Clinical Pathology, Medical university of Vienna, Vienna, Austria, [7]Cold Spring Harbor Laboratory, Cold Spring Harbor, [8]Department of Medical Oncology, Dana-Farber Cancer Institute, Harvard Medical School, Boston, United States, [9]Institute of Pathology, Ludwig-Maximilians-University (LMU), Munich, Germany, [10]Research Institute of Molecular Pathology (IMP), Vienna, Austria

Background: Advanced mast cell (MC) neoplasms are characterized by uncontrolled growth and rapid expansion of neoplastic MC in various organ systems and a poor prognosis. In human patients, advanced systemic mastocytosis (SM) is rare and usually presents as aggressive SM (ASM) or mast cell leukemia (MCL). Unfortunately, so far, no effective treatment concept has been established for these patients. This is due to the fact that neoplastic MC in advanced SM usually are resistant against various cytoreductive agents. Therefore, research is currently focusing on potential drug targets and the effects of novel targeted drugs on neoplastic MC. We have recently identified the bromodomain-containing protein-4 (BRD4) as a promising new drug target expressed by neoplastic cells in acute myeloid leukemia (Zuber et al, Nature 2011;478:524-528).
Aims: In the present study, we examined BRD4 as a potential therapeutic target in ASM and MCL
Methods: Immunocytochemistry (ICC) and immunohistochemistry (IHC), Flow cytometric evaluation of apoptosis, qPCR,^{3}H-thymidine uptak, Flow cytometry
Results: As assessed by immunohistochemistry, neoplastic MC expressed substantial amounts of cytoplasmic and nuclear BRD4 in ASM and MCL, whereas in indolent SM (ISM), MC expressed low amounts of BRD4 or did not express cytoplasmic BRD4. All human MCL lines tested, including HMC-1.1 (KIT D816V-), HMC-1.2 (KIT D816V+), $ROSA_{wt\ KIT}$ (KIT D816V-) and $ROSA_{KIT\ D816V}$ (KIT D816V+) also expressed cytoplasmic BRD4. In order to study the

potential biological function of BRD4, we applied a BRD4-specific shRNA. The shRNA-induced knockdown of BRD4 was found to be associated with a markedly reduced proliferation of neoplastic MC. Correspondingly, JQ1, a BRD4-targeting drug, induced dose-dependent growth inhibition in all MC lines examined, with IC50 values of about 1.0 μM. As assessed by morphology and AnnexinV/PI staining, JQ1 also produced apoptosis in neoplastic MCs (Figure). The apoptosis-inducing effect of JQ1 was also demonstrable by staining for active caspase 3. Furthermore, JQ1 was found to downregulate the expression of CD63 and CD71 in HMC-1 cells, and CD63, CD71 and FceRI in ROSA cells. Moreover, JQ1 was found to suppress proliferation of primary neoplastic MCs obtained from patients with ASM or MCL (IC_{50} 0.1-0.5 μM). We next screened for potential drug partners that would potentiate the anti-neoplastic effects of JQ1. Of all drugs tested, all-trans retinoic acid (ATRA) and PKC412 were identified as most potent drug partners of JQ1. These drugs were found to act highly synergistic with JQ1 in producing apoptosis and growth inhibition in HMC-1.1 and HMC-1.2 cells (Figure).

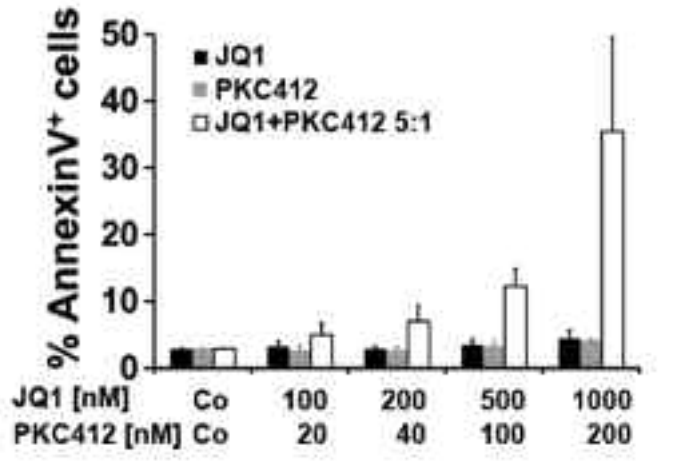

Figure 1.

Summary and Conclusion: Together, BRD4 is a novel marker and promising target in advanced SM. Whether JQ1 or other BET bromodomain inhibitors are effective *in vivo* in patients with advanced SM or canine MCT remains to be elucidated.
Legends to Figure: HMC-1.2 cells were incubated in control medium (Co) or in various concentrations of JQ1 (black bars), PKC412 (gray bars), or a combination of both agents at a ratio of 5:1 (white bars) at 37°C for 48 hours. Then, AnnexinV/propidium iodide (PI) staining was performed. The percentage of AnnexinV+ cells was determined by flow cytometry. Results represent the mean±S.D. of 3 independent experiments.

MUTATIONAL PROFILE IN ESSENTIAL THROMBOCYTEMIA (ET) « NEGATIVE » FOR JAK2 AND MPL

X Cabagnols[1,*], JC Ianotto[2], O Bluteau[1], C Marzac[3], JP Le Couédic[1], N Droin[1], M Diop[1], J Merlevede[1], N Casadevall[1], C Bellanné-Chantelot[4], E Solary[1], O Bernard[5], I Plo[1], V Ugo[6], W Vainchenker[1]
[1]Inserm - U1009 "Hématopoïèse Normale et Pathologique", Gustave Roussy, Villejuif, [2]Service Clinique d'Hématologie, Centre Hospitalier Universitaire, Brest, [3]Laboratoire d'Hématologie et Immunologie Biologiques, Hôpital Saint-Antoine, [4]Département Génétique, Groupe Hospitalier Pitie- Salpétrière, Paris, [5]Inserm - U985 "Génétique des tumeurs", Gustave Roussy, Villejuif, [6]Laboratoire d'Hématolgie, Centre Hospitalier Universitaire, Brest, France

Background: Until recently, in about 40% of ET, the driver mutations targeting signaling pathway responsible for thrombocytosis were unknown. Indeed, JAK2 V617F is present in about 50% of ET and primary myelofibrosis (PMF) patients, *MPL* mutations, particularly (W515), in 3%>5% ET and PMF and mutations in *SH2B3* and *CBL* in around 1%. In addition, mutations in other pathways are rare in ET and usually associated with mutations in *JAK2* or *MPL*. These additional mutations may play a role in initiation of the disease but also in disease progression.
Aims: Find out new driver mutations responsible of the thrombocytosis
Methods: 36 ET and 3 MF patients were studied who were selected on the absence of JAK2V617F and MPLW515K/L mutations in the granulocytes, except one PMF patient with a MPLW515K, whose sample was used as a positive control. Whole Exome Sequencing (WES) was performed on granulocytes (tumoral sample) and on T cells (germline control). An exon capture sequencing was performed with Agilent technique using a HiSeq 2000 in granulocytes and T cells. Identified mutations were validated by Sanger sequencing and the *CALR* mutations by Sanger sequencing and high-resolution sizing of fluorescent dye–labeled PCR products.
Results: We performed sequencing of 39 patients by WES with a mean depth of 100. A total of 119 mutations were confirmed by Sanger sequencing, with a median of 2 mutations per patients (from 0 to 15). In the ET patients, most of the mutations found concerned genes involved in signaling. We found that 21 patients presented *CALR* mutations with a majority of 52pb deletion in exon9. This type of mutation appeared as a 1bp deletion in WES analysis, even if the mutation was present at homozygous state in one patient. In contrast, the insertion of 5bp could be correctly detected. 3 patients displayed previously described MPL mutations, two in exon 10 (MPL W515R, MPL S505N), and one in exon 4 (S204P). Furthermore, 1 patient showed a homozygous nonsense mutation in *SH2B3*. In addition, we identified 2 new mutations in genes coding for PI3K pathway, both associated with *CALR* mutations. We also found mutations in epigenetic regulators such as *DNMT3A, ASXL1, TET2, IDH1* and *SETDB1* and in spliceosome or translation such as *SF3B1, SRSF1* and *PHF6*, but generally in the context of disease progression (myelofibrosis or myelodysplastic syndrome). Nevertheless, *CALR* mutation was associated either with *ASXL1* or *TET2* mutation in two isolated chronic forms of ET. Seventeen ET patients remain negative for signaling mutations; however 10 of them showed a clonal hematopoiesis in granulocytes. Seven patients had no clonal mutations and were considered as polyclonal although they have all clinico-biological criteria for a myeloproliferative neoplasm. Therefore, we hypothesize that some "polyclonal" ET may have a clonal hematopoiesis, but only in the megakaryocyte lineage. In two of these cases, we detected JAK2V617F in platelets, bringing more arguments in favor of this hypothesis.
Summary and Conclusion: This study further demonstrates that ET are very early disorders in the occurrence of malignancies with a very low numbers of mutations, and that the discovery of *CALR* mutations has drastically reduced the number of patients with unknown "driver" mutations, called triple negative. Some of them may correspond to a clonal hematopoiesis restricted to the platelet/megakaryocyte lineage.

S1329

CHARACTERIZATION OF CULTURED ENDOTHELIAL CELLS FROM PATIENTS WITH POLYCYTHEMIA VERA WITH AND WITHOUT PRIOR THROMBOSIS BY GENE EXPRESSION ANALYSIS

A Pham[1,*], M Haubitz[1], B Huegli[2], G M Baerlocher[1,2], E Oppliger Leibundgut[1,2]
[1]Department of Clinical Research Experimental Hematology, University Bern, [2]University Clinic of Hematology and Central Hematology Laboratory, University Hospital Bern, Bern, Switzerland

Background: In polycythemia vera (PV) the major cause of morbidity and mortality are thrombotic complications with frequent splanchnic thrombosis, especially Budd-Chiari syndrome. Association of the JAK2 V617F mutation with thrombosis has been shown in different studies, suggesting an involvement of the malignant clone. In addition to activated thrombocytes and leukocytes, pathological bone marrow-derived endothelial cells (EC) have been shown to be involved.
Aims: Our aim was to investigate EC from patients with PV and to define their role in thrombosis formation.
Methods: Endothelial colony forming cells (ECFC) were cultured from peripheral blood mononuclear cells of 24 patients with PV carrying the JAK2 V617F mutation. Patients were grouped according to the prior occurrence of thromboembolic events. Immunocytochemical staining for vascular endothelial growth factor receptor 2 (VEGFR2) and von Willebrand factor (vWF) was applied to confirm endothelial cell nature. Total RNA was extracted from ECFC. Gene expression analysis of genes related to endothelial cell biology was performed by real-time RT-PCR. ECFC were analyzed for the JAK2 V617F mutation by allele-specific PCR. DNA from blood samples and corresponding ECFC was screened for additional mutations by next generation sequencing (Ion Torrent PGM™). We designed a panel including the genes ASXL1, DNMT3A, EZH2, IDH1, IDH2, JAK2, MPL, SOCS1 and TET2.
Results: The mRNA expression of 29 genes involved in endothelial cell activation and function showed a significant upregulation (>2.5 fold) compared to human umbilical vein endothelial cells (HUVEC). When compared to liver endothelial cells, 22 genes were higher expressed. The expression of the adhesion molecules VCAM-1, ICAM-1, E-Selectin and PECAM-1 was increased up to 1000□fold and also the cytokines TNFα and IL-1β that play a role in the regulation of the adhesion molecules were highly expressed. Many of the adhesion related genes were higher expressed in ECFC of patients with prior thrombosis compared to patients without thrombosis, *i.e.* ICAM-1 (3.7-fold, median) and VCAM-1 (2.2-fold) as well as the cytokines TNFα (3.8-fold) and IL-1β (3.4-fold). PECAM-1 was lower expressed (0.7fold). The JAK2 V617F mutation was present in 8/24 EC cultures. Screening for additional mutations identified mutations in the ASXL1 and SOCS1 genes that were present in blood samples and corresponding ECFC. Five mutations in ASXL1, IDH1 and MPL were detected in ECFC only implying a clonal origin of EC in these patients.
Summary and Conclusion: We found increased expression of genes involved in endothelial cell activation and function in ECFC from patients with PV indicating endothelial cell activation. In particular, adhesion molecules and their regulators were overexpressed. A specific pattern of higher expression of ICAM-1, VCAM-1, and lower PECAM-1 expression was identified in ECFC from

patients with prior thrombosis. In accordance with published results, the JAK2 V617F mutation is only present in a minority of ECFC. Additional mutations in ASXL1 and SOCS1 were identified that could drive malignant hemopoiesis and endothelial cell development from hemangioblasts. In conclusion, our results suggest a contribution of dysfunctional endothelial cells to a prothrombotic state in patients with PV.

Quality of life

S1330

A RANDOMIZED PHASE III TRIAL OF RETINOIC ACID AND ARSENIC TRIOXIDE VERSUS RETINOIC ACID AND CHEMOTHERAPY IN ACUTE PROMYELOCYTIC LEUKEMIA PATIENTS: HEALTH-RELATED QUALITY OF LIFE OUTCOMES

Background: Recently, a randomized clinical trial (RCT) compared efficacy and toxicity of ATRA plus chemotherapy *versus* ATRA plus arsenic trioxide (ATO) in patients with newly diagnosed, low-intermediate risk APL (Lo Coco *et al.*, *N Engl J Med*. 2013;369:111-121).
Aims: As potential clinical benefits of newer experimental treatments need to be weighed against possible patients' burden and given the lack of published data on the impact of ATO on patients' symptoms and wellbeing, health-related quality of life (HRQOL) assessment was included as a secondary endpoint of this RCT. We herein report HRQOL findings of this study.
Methods: The study was a prospective**,** randomized, multicenter, open-label, phase-III non-inferiority trial. The study was designed to show that ATRA-arsenic trioxide was not inferior to ATRA-chemotherapy with respect to the event-free survival rate at 2 years. HRQOL was a secondary endpoint of this trial. The EORTC QLQ-C30 was used to assess HRQOL at the end of induction and after the consolidation therapy. This validated questionnaire consists of five functioning scales: physical, role, emotional, cognitive and social; three symptom scales: fatigue, nausea/ vomiting and pain; six single item scales: dyspnoea, sleep disturbance, appetite loss, constipation, diarrhea and financial impact; and the global QOL scale. All analyses were based on the intention-to-treat principle, the groups defined according to the randomly assigned treatment. Primary analysis was performed estimating mean HRQOL scores over time, and their differences between treatment arms by a linear mixed model with an unrestricted covariance structure.
Results: Out of 156 patients analyzed in the primary clinical analysis, 150 were eligible for HRQOL evaluation at the end of induction phase and one hundred forty two at the end of consolidation phase. Overall compliance with HRQOL forms was 80.1%. After induction, 115 HRQOL forms were received out of 150 expected (compliance of 77%) while after consolidation phase 119 forms were received out of 142 expected (compliance of 84%). No statistically significant differences were found in compliance rates between treatment arms. The largest difference, favoring patients treated with ATRA-ATO was found for fatigue severity (mean score difference of -9.3, confidence interval [CI] of -17.8 and -0.7, P=.033), at the end of induction therapy. All other symptoms, except for pain, were favoring patients treated with ATRA plus ATO. Similarly, except for social functioning, all functional and global HRQOL scores favored patients treated with ATRA plus ATO. A comparison by treatment group, each of which *versus* their respective peers in the general population, revealed greater HRQOL impairments in patients treated with ATRA plus chemotherapy in several symptom and functional scales. Large impairments (*i.e.*, effect size (ES) of ≥.8) were noted in physical (ES=.85), role (ES=.83), and social functioning (ES=.84) as well as fatigue (ES=.95) only for patients treated with ATRA plus chemotherapy. HRQOL differences between treatment arms at the end of consolidation showed that, for several scales, differences between treatment arms were marginal.
Summary and Conclusion: The HRQOL benefits of ATRA plus ATO therapy over standard ATRA plus chemotherapy, are mainly relevant at the end of induction phase. Current HRQOL results, extend previous clinical findings, and can help physicians to make more informed treatment decisions on first line therapy for their newly diagnosed APL patients.

S1331

CLINICAL BENEFIT OF LENALIDOMIDE TREATMENT FOR LOW AND INTERMEDIATE-1 IPSS RISK MYELODYSPLASTIC SYNDROME WITH DEL(5Q) BEFORE TRANSFUSION DEPENDENCE

E Oliva[1,*], M Lauseker[2], M A Aloe Spiriti[3], A Poloni[4], A Cortelezzi[5], G Palumbo[6], E Balleari[7], G Sanpaolo[8], A Volpe[9], A Ricco[10], F Ronco[1], C Alati[1], I Santacaterina[1], A Kündgen[11], U Germing[11], R Latagliata[12]
[1]Azienda Ospedaliera B-M-M, Reggio Calabria, Italy, [2]Institute for Medical Information Science, Biometry and Epidemiology, Ludwig-Maximilians-University, Munich, Germany, [3]Dipartimento medicina clinica e molecolare, La Sapienza University, Rome, [4]Università Politecnica delle Marche,, Ancona, [5]Fondazione IRCCS Ca' Granda Ospedale Maggiore Policlinico, University of Milan, Milan, [6]Azienda Ospedaliero-Universitaria "Policlinico-Vittorio Emanuele", Catania, [7]Hematology Unit, Ospedale San Martino, Genova, [8]Hematology Division, Ospedale Casa Sollievo della Sofferenza, San Giovanni Rotondo, [9]Azienda Ospedaliera San G. Moscati, Avellino, [10]University of Bari, Bari, Italy, [11]Dept. of Hematology, Oncology and Clinical Immunology, Heinrich-Heine-University of Düsseldorf, Düsseldorf, Germany, [12]Department of Cellular Biotechnology and Hematology, La Sapienza University, Rome, Italy

Background: Lenalidomide is approved for the treatment of transfusion-dependent (TD) patients with anemia due to International Prognostic Scoring System (IPSS)-defined Low- or Intermediate-1- (Int-1)-risk myelodysplastic syndromes (MDS) associated with a deletion of the long arm of chromosome 5 [del(5q)]. Treatment induces erythroid and cytogenetic responses in a high proportion of patients associated with an advantage in survival. Quality of life (QoL) benefit has also been shown in clinical trials. Whether early lenalidomide treatment be of benefit in MDS with del5q transfusion-free (TF) patients with moderate anemia has not been explored.
Aims: To evaluate objective and subjective clinical outcomes in TF patients with MDS with del(5q) treated with lenalidomide.
Methods: Untreated patients (N=381) with MDS and del5q from the report by Germing, et al (Leukemia, 2012) were divided in 3 groups : TD patients (N=316), TI patients with Hb ≥ 10 g/dl (N=88) and TI patients with Hb<10 g/dl (N=96) for the purpose of comparison for survival and incidence of non-leukemic deaths (NLD). Anemic patients with Hb<10 g/dL enrolled in the phase II, multicenter, non-randomized, open-label RevMDS trial on the efficacy and safety of lenalidomide in IPSS Low- or Int-1-risk MDS associated with del(5q) (Oliva et al, 2012) were evaluated for safety, efficacy and changes in QoL during treatment, using the QOL-E instrument. Secondary endpoints included efficacy and survival. Patients received oral lenalidomide 10 mg once-daily continuous dosing for up to 12 months. Twelve patients enrolled were TF at baseline according to current MDS criteria and had a baseline Hb value<10 g/dL with sufficient QoL data to form the subset for the present report.
Results: *Results from the German cohort*: The hazard ratio (HR) of death for the patients with Hb≥10 g/dl *versus* the TD patients was 0.441 (95%>CI: 0.286-0.678, p<0.001).; the HR for the TF patients with Hb<10 g/dl *versus* the TD patients was 0.552 (95%>CI: 0.376-0.810, p=0.002). The HR of non-leukemic death for the TF patients with Hb≥10 g/dl *versus* the TD patients was 0.343 (95%>CI: 0.192-0.614, p<0.001); the HR for the TF patients with Hb<10 g/dl *versus* the TD patients was 0.424 (95%>CI: 0.253-0.709, p=0.001). On the whole, these data pointed to the identification of TI patients with lower Hb levels as an intermediate-risk category. However, there was no significant difference in survival between the two TF groups. *Results from the RevMDS trial*: TF patients experienced earlier Hb increases at 12 weeks (3.6 ± 1.6 g/dl *versus* 1.9 ± 2.1 g/dl, P=0.01) and 24 weeks (4.5±1.6 g/dl *versus* 3.1±2.2 g/dl, P=0.04) compared to TD patients. All deaths occurred only in TD patients. There was no difference in the risk of disease progression between TD and TI. Nine TF patients perceived poor QoL (score<60) at baseline in at least one dimension. Baseline Hb levels correlated with QoL-E physical (r=0.666, p=0.035) and fatigue scores (r=0.604, p=0.049). One patient refused to continue in study because she was discouraged by the drug.-related myelosuppression during the first weeks of treatment. All other patients were erythroid responders (an Hb increase of at least 1.5 g/dL). Overall, within the first 8 weeks, improvements in mean physical QoL scores (45 ± SD 25 to 58 ± SD 26, p=0.068) and fatigue (73 ± 13 to 81 ± 8, p=0.062) were observed. Changes at 12 weeks became significant for physical QoL scores (67 ± 13, p=0.005); in fact, 5 out of 6 patients with decreased baseline QoL experienced improvements in physical QoL.
Summary and Conclusion: Though advantages of early lenalidomide treatment in terms of morbidity and mortality need to be explored in a randomized study, patient reported outcomes (QoL assessment) may guide therapeutic choice. In particular, patients with moderate anemia and with poor physical QoL perceive that they require treatment before transfusion-dependence has taken over. This report highlights the utility of patient-reported outcomes for the guidance of treatment in the individual patient.

S1332

AEROBIC PHYSICAL EXERCISE FOR PATIENTS WITH HAEMTOLOGICAL MALIGNANCIES. A SYSTEMATIC REVIEW AND META-ANALYSIS

N Skoetz[1,*], N Bergenthal[1], A Will[1], F Streckmann[2], I Monsef[1], KD Wolkewitz[3], T Elter[4], A Engert[4]
[1]Cochrane Haematological Malignancies Group, Department I Of Internal Medicine, University Hospital of Cologne, [2]Institute of Cardiovascular Research and Sport Medicine, German Sport University, Cologne, [3]none, Wetzlar, [4]Department I Of Internal Medicine, University Hospital of Cologne, Cologne, Germany

Background: Though patients with hematological malignancies have to endure long phases of therapy and immobility which is known to diminish their physical performance level, the advice to rest and avoid intensive exercises is still circulating. This recommendation is partly due to severe anemia and thrombocytopenia that many patients suffer from. The inability to perform activities of daily living restricts patients, diminishes their quality of life and may influence medical therapy.
Aims: To evaluate the efficacy and safety of aerobic physical exercise for adult patients suffering from hematological malignancies.
Methods: We searched Cochrane Central Register of Controlled Trials (CENTRAL; 01.2014) and MEDLINE (1950 to 28.01.2014) as well as conference proceedings for randomized controlled trials (RCTs). We included RCTs comparing aerobic physical exercise interventions in addition to standard care to standard care only for adult patients suffering from hematological malignancies. Moreover, we included studies that evaluated aerobic exercise in addition to strength training. We excluded studies that investigated the effect of training programs that were composed of Yoga, Tai chi chuan, or similar types of exercise. We also excluded studies solely exploring the influence of strength training. Two review authors independently screened search results, extracted data and assessed the quality of trials. Two review authors independently screened search results, extracted data and assessed the quality of trials.
Results: We included nine RCTs involving 818 patients. The majority of patients suffered from acute leukemia, lymphoma and multiple myeloma, six trials randomized patients receiving stem cell transplantation. The exercise intervention consisted mostly of walking interventions with divergent duration and intensity levels. There is no evidence for a difference in terms of mortality between patients exercising and those in the control group (RR 0.93; 95% CI 0.59 to 1.47; P=0.75). Four trials analyzed the influence of exercise intervention on quality of life (QoL). Excluding one trial with serious baseline imbalances, physical exercise improves QoL (SMD 0.26; 95% CI 0.03 to 0.49; P=0.03). This positive effect of exercise was also found in the sub-scales physical functioning (SMD 0.33; 95% CI 0.13 to 0.52; P=0.0009) and depression (SMD 0.25; 95% CI -0.00 to 0.50; P=0.05). However, there is no evidence for a difference between additional exercise and standard treatment for anxiety (SMD -0.18; 95% CI -0.64 to 0.28; P=0.45). Seven trials (N=692) evaluated fatigue. There is moderate quality evidence that exercise improves fatigue (SMD 0.24; 95% CI 0.08 to 0.40; P=0.003) (see figure 1). There is no evidence for a difference between both arms in terms of SAEs (RR 1.44; 95% CI 0.96 to 2.18; P=0.08) or AEs (RR 7.23; 95% CI 0.38 to 137.05; P=0.19).

Table 1.

Summary and Conclusion: There is no evidence for differences in mortality between both arms. Physical exercise in addition to standard care can improve quality of life, especially physical functioning and depression, and fatigue. Currently, there is inconclusive evidence regarding anxiety, serious adverse events and adverse events. Further trials with a larger sample-size and longer follow-up periods are needed to further evaluate the effects of exercise interventions for patients suffering from hematological malignancies.

S1333

PSYCHOMETRIC EVALUATION OF EORTC QUALITY-OF-LIFE CORE (QLQ-C30) AND QLQ-MULTIPLE MYELOMA (QLQ-MY20) QUESTIONNAIRES TO ASSESS PHYSICIAN PERCEPTION IN PATIENTS WITH RELAPSED/REFRACTORY MULTIPLE MYELOMA

P Murphy[1,*], X Leleu[2], C Kyriakou[3], I Vande Broek[4], M Welslau[5], P Bacon[6], P Lewis[7], H Gilet[8], B Arnould[8], MT Petrucci[9]
[1]Beaumont Hospital, Dublin, Ireland, [2]CHRU-Hôpital Huriez, Lille, France, [3]Royal Free and Northwick Park hospitals, London, United Kingdom, [4]Iridium Kankernetwerk, Sint-Niklaas, Belgium, [5]Studienzentrum Hämatologie, Aschaffenburg, Germany, [6]Celgene International Sarl, Boudry, Switzerland, [7]Celgene GmbH, Munich, Germany, [8]HEOR & Strategic Market Access, Mapi, Lyon, France, [9]Division of Hematology, Department of Cellular Biotechnology and Hematology, Sapienza University, Rome, Italy

Background: With the increased use of novel therapeutic agents and extended life expectancy of multiple myeloma (MM) patients, it is extremely important to focus on patients' Health-Related Quality of Life (HRQoL) and physicians' awareness of their patients' well-being. In particular, comparing patient-reported outcomes (PROs) to clinician-reported outcomes (ClinROs) could help physicians better understand patients' perception of their own health status, symptom burden and overall well-being. Validated ClinROs are needed to perform comparisons between patients' and physicians' perceptions of HRQoL using appropriate measures.
Aims: To evaluate the psychometric properties of the EORTC Quality-of-Life Core (QLQ-C30) and QLQ-Multiple Myeloma (QLQ-MY20) questionnaires adapted to be completed by physicians in an observational study in relapsed/refractory MM (RRMM) patients.
Methods: A European, multicenter, observational study is being conducted in RRMM patients starting 2nd or 3rd line treatment. For this study, the EORTC questionnaires QLQ-C30 and QLQ-MY20 were adapted following a rigorous methodology to be completed by physicians in order to evaluate their patients' health status. During the study, physicians responded to both questionnaires at baseline, month 3, and month 6 or discontinuation visit. The QLQ-C30 includes 15 domains (Global Health Status/QOL, Physical Functioning, Role Functioning, Emotional Functioning, Cognitive Functioning, Social Functioning, Fatigue, Nausea and Vomiting, Pain, Dyspnea, Insomnia, Appetite Loss, Constipation, Diarrhea and Financial Difficulties); and the QLQ-MY20 includes four domains (Disease Symptoms, Side-Effects of Treatment, Body Image and Future Perspective). Construct validity was evaluated at baseline by confirming the structure using multitrait analysis and by assessing clinical validity against ECOG performance status. Internal consistency reliability was evaluated at baseline using Cronbach's alpha.
Results: As of November 2013, 32 physicians had enrolled 244 patients in the study who were included in this interim analysis. The mean age was 70, with 53% male and an average time since diagnosis of 3.2 years; 94% of patients started 2nd line treatment. At baseline, 236 (97%) EORTC questionnaires were returned by physicians for the 244 patients included. Both EORTC questionnaires were well completed at baseline: 93% of QLQ-C30 questionnaires were completed by physicians with no missing items, and 92% of QLQ-MY20 questionnaires were completed with no missing items. At baseline, physicians reported the best possible score for a high percentage of patients for the majority of HRQoL and symptoms domains, in particular for Appetite Loss (64%), Constipation (68%), Diarrhea (93%), Dyspnea (59%), Financial Difficulties (72%), Nausea and Vomiting (81%), Insomnia (54%) and Body Image (59%). The structure of multi-item QLQ-C30 and QLQ-MY20 domains was confirmed. Clinical validity of both QLQ-C30 and QLQ-MY20 was established against baseline ECOG performance status (Figure 1). Reliability was confirmed with Cronbach's alpha >0.70, except for QLQ-C30 Nausea and Vomiting (0.61).

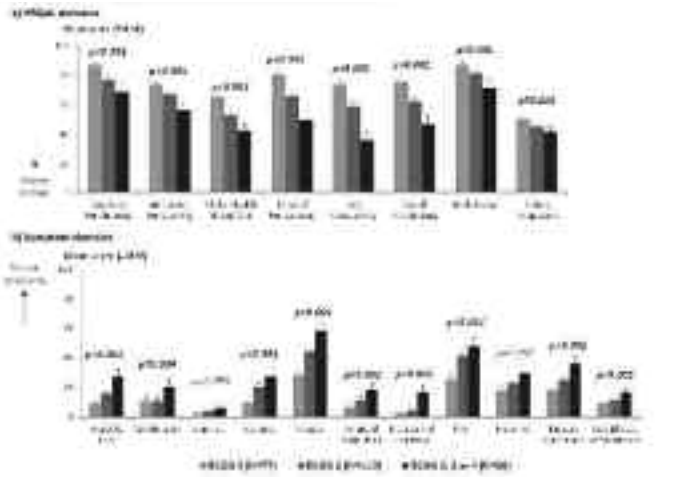

Figure 1. Clinical validity according to ECOG performance status at baseline

Summary and Conclusion: This interim analysis showed that the adapted EORTC QLQ-C30 and QLQ-MY20 questionnaires completed by physicians demonstrated satisfactory psychometric properties in terms of validity and reliability. Further investigation compared the physicians' perception to that of the patients to evaluate if physicians interpret the health of their patients differently from the patients themselves.

S1334

IMPACT OF ECOG PERFORMANCE STATUS ON OVERALL SURVIVAL AND HRQOL IN RELAPSED/REFRACTORY MULTIPLE MYELOMA PATIENTS FROM THE MM-003 TRIAL OF POMALIDOMIDE + LOW-DOSE DEXAMETHASONE (DEX) *vs* HIGH-DOSE DEX

K Weisel[1,*], J San Miguel[2], K Song[3], M Delforge[4], P Lewis[5], X Yu[6], M Zaki[6], L Sternas[6], M Dimopoulos[7]
[1]Department of Hematology and Oncology, University of Tuebingen, Tuebingen, Germany, [2]Universidad de Navarra, Pamplona, Spain, [3]Vancouver General Hospital, Vancouver, Canada, [4]University Hospital Leuven, Leuven, Belgium, [5]Celgene GmbH, Munich, Germany, [6]Celgene Corporation, Summit, United States, [7]Alexandra Hospital, University of Athens School of Medicine, Athens, Greece

Background: Eastern Cooperative Oncology Group performance status (ECOG PS) is often measured in multiple myeloma (MM), but the relevance to patients of improvements in ECOG PS has not previously been shown. ECOG PS data were collected as part of the MM-003 trial comparing pomalidomide and low-dose DEX (POM + LoDEX) with high-dose DEX (HiDEX) in patients with relapsed/refractory MM (RRMM) who failed both bortezomib and lenalidomide treatment.
Aims: 1) Correlate ECOG PS with overall survival (OS) and 2) evaluate the impact of baseline ECOG PS on changes in health-related quality of life (HRQoL) in patients with RRMM from the MM-003 trial.
Methods: A Cox proportional hazards model was analyzed with OS as dependent variable (model 1) and treatment arm (POM + LoDEX *vs*. HiDEX) and ECOG PS improvement from baseline (yes *vs*. no) as covariates. ECOG PS was analyzed as a time-dependent variable. Two other variables associated with OS were added to model 1 as time-dependent variables (model 2) to adjust for progressive disease (PD) (yes *vs*. no) and subsequent POM treatment (yes *vs*. no). Upon unblinding and at PD, HiDEX patients could choose to receive POM treatment—56% of HiDEX patients subsequently received POM. Another analysis compared HRQoL results across time points for patients with ECOG PS 0, 1, or ≥ 2 at baseline, regardless of treatment. Twenty HRQoL domains from a combination of HRQoL instruments collected as part of the MM-003 trial (European Organisation for Research and Treatment of Cancer [EORTC] Quality of Life Questionnaire [QLQ] C30 and MY20 and EuroQol 5 Dimensions [EQ-5D]) were examined: Global Health Status/QoL, Physical, Emotional, Social, Role and Cognitive Functioning, Pain, Fatigue, Nausea/Vomiting, Insomnia, Constipation, Diarrhea, Dyspnea, Appetite Loss and Financial Difficulties (from EORTC QLQ-C30); Disease Symptoms, Side Effects of Treatment, Body Image and Future Perspective (from EORTC QLQ-MY20); and Utility (from EQ-5D).
Results: Both models 1 and 2 showed a significant positive impact of ECOG PS improvement on OS (model 1: HR=0.62 [95% CI, 0.44-0.86], *P*=.004; model 2: HR=0.61 [0.44-0.85], *P*=.004). POM + LoDEX treatment significantly improved OS (model 1: HR=0.75 [0.58-0.95], *P*=.019; model 2: HR=0.62 [0.48-0.79], *P*<.001). In model 2, PD increased the risk of death almost 5-fold (HR=4.97 [2.99-8.25], *P*<.001), whereas crossover lowered the risk of death (HR=0.12 [0.05-0.30], *P*<.001). Differentiating HRQoL by baseline ECOG PS showed an association between better (ie, lower) ECOG PS and better function/reduced symptom burden. Eighteen of 20 HRQoL domains demonstrated associations at baseline, all with the exception of Diarrhea and Financial Difficulties. This association continued across cycles for most HRQoL domains, with interpretation increasingly difficult in later cycles due to reduced sample sizes in the HiDEX arm.

Table 1. Individual determinants of overall survival (Cox proportional hazards model)

	Model 1			Model 2		
	Hazard Ratio	95% CI	P Value	Hazard Ratio	95% CI	P Value
Treatment	0.75	0.58-0.95	.019	0.62	0.48-0.79	<.001
ECOG improvement	0.62	0.44-0.86	.004	0.61	0.44-0.85	.004
PD		NA		4.97	2.99-8.25	<.001
Crossover		NA		0.12	0.05-0.30	<.001

Summary and Conclusion: In MM-003, improvement in ECOG PS was directly associated with improved OS and is a valuable additional endpoint. Better baseline ECOG PS status was associated with better HRQoL at baseline and over time. Similar exploratory analyses should be conducted in future studies to broadly establish the value of ECOG PS as a relevant endpoint in MM.

Myeloma and other monoclonal gammopathies - Clinical 3

S1335

IMPACT OF CONTINUOUS TREATMENT *vs* FIXED DURATION OF THERAPY IN NEWLY DIAGNOSED MYELOMA PATIENTS: PFS1, PFS2, OS ENDPOINTS

F Gay[1,*], F Cavallo[1], F Di Raimondo[2], I Hardan[3], A Nagler[4], M T Petrucci[2], P Corradini[2], R Hajek[5], S Pezzati[2], M Delforge[6], F Patriarca[2], F Donato[1], L Pantani[2], C Nozzoli[2], Z Yu[7], L Boccadifuoco[1], T Caravita[2], C Jacques[7], G Benevolo[2], M A Dimopoulos[8], T Guglielmelli[2], D Vincelli[2], G Ciccone[9], P Musto[2], M Boccadoro[1], A Palumbo[1]

[1]Myeloma Unit, Division of Hematology, University of Torino, Torino, [2]Italian Multiple Myeloma Network, GIMEMA, Italy, [3]Hematology Division, Meir Medical Center, Kfar-Saba, [4]Director Division of Hematology Chaim Sheba Medical Center, Tel Hashomer, Israel, [5]University Hospital Brno and Faculty of Medicine OU, Ostrava, Czech Republic, [6]University Hospital Leuven, Leuven, Belgium, [7]Celgene Corporation, Summit, United States, [8]Department of Clinical Therapeutics, University of Athens School of Medicine, Alexandra Hospital, Athens, Greece, [9]Unit of Clinical Epidemiology, University of Torino, Torino, Italy

Background: Continuous therapy significantly prolongs remission duration, but chemo-resistant relapse may reduce the duration of subsequent remissions, with negative impact on OS. In such situations, OS rather than PFS is the preferable endpoint. However, this is often deemed not feasible, thus endpoints such as PFS2 should be of importance (EMA guideline). PFS1 defines the time from randomization until the occurrence of 1st relapse. PFS2 defines the time from randomization until the occurrence of 2nd relapse, and incorporates the duration of both 1st and 2nd remissions.
Aims: To compare PFS1, PFS2 and OS in newly diagnosed multiple myeloma (NDMM) patients who received continuous treatment (CT) or fixed duration of therapy (FDT) upfront.
Methods: We included patients enrolled in 3 phase III randomized trials, comparing CT *vs*. FDT upfront (GIMEMA RV-MM-209: lenalidomide-based induction, consolidation, followed by maintenance [CT] *vs* lenalidomide-based induction, consolidation, no maintenance [FDT]; GIMEMA 0305: bortezomib-based induction followed by maintenance (CT) *vs*. bortezomib-based induction, no maintenance [FDT]; MM-015: lenalidomide-based induction, followed by maintenance [CT] *vs*. lenalidomide-based induction/melphalan-prednisone, no maintenance [FDT]). The analysis was performed on the intention-to-treat population. We evaluated PFS1 (time from randomization at diagnosis to 1st relapse), PFS2 (time from randomization at diagnosis to 2nd relapse), and OS (time from randomization at diagnosis to death) through a stratified analysis by protocol. At 1st relapse we tested 2nd PFS (time from 1st relapse to 2nd relapse) and survival from relapse (time from 1st relapse to death).
Results: In the pooled analysis, 604 patients were randomized to CT and 768 patients to FDT. The median follow-up for survivors was 48 months. CT significantly prolonged PFS1 (median 34 *vs*. 19 months, HR=0.52, 95% CI: 0.45-0.60, P<0.001), PFS2 (median 54 *vs* 38 months, HR=0.70, 95% CI: 0.61-0.82, p<0.001) and OS (median OS not reached *vs*. 60 months, HR=0.78, 95% CI: 0.65-0.93, P=0.006) in comparison with FDT. 392 patients who received CT upfront experienced 1st relapse in comparison with 626 patients who received FDT upfront. No differences in 2nd PFS and OS from relapse between patients who received CT or FDT upfront was noticed. Results were similar when the source studies were analyzed separately.
Summary and Conclusion: In NDMM patients, CT significantly improved PFS1, PFS2 and OS. Prolongation of PFS2 suggests that the clinical benefit observed during 1st remission is not cancelled by a very short 2nd remission. PFS2 should be included in all future trials to evaluate the impact of chemo-resistant relapse.

S1336

A PHASE I TRIAL OF SAR650984, A CD38 MONOCLONAL ANTIBODY, IN RELAPSED OR REFRACTORY MULTIPLE MYELOMA

T Martin[1,*], S Strickland[2], M Glen[3], J Maikhael[4], E Charpentier[5], K Hsu[5]

[1]Hematology, University of California, San Francisco, San Francisco, [2]Hematology, Vanderbilt-Ingram Cancer center, Nashville, [3]Hematology, University of Utah, Salt Lake City, [4]Hematology, Mayo Clinic, Scottsdale, [5]Sanofi Oncology, Sanofi, Cambridge, United States

Background: SAR650984 (SAR) is a naked humanized IgG1 monoclonal antibody that binds to the CD38 receptor. SAR kills tumor cells via ADCC, CDC, direct apoptosis without secondary crosslinking and allosteric inhibition on CD38 enzymatic activity. Data on relapsed /refractory multiple myeloma (RRMM) patients (pts) in the dose escalation phase of the study are reported. (NCT01084252)
Aims: To determine the safety profile of SAR650984 in heavily pre-treated patients with relapsing and refractory multiple myeloma.
Methods: SAR was given IV weekly (QW) or every 2 weeks (Q2W). Dose levels (DL) 0.3, 1, 3, 5, 10 and 20 mg/kg Q2W and 10 mg/kg QW using the classic 3+3 design were evaluated. All patients signed an IRB approved informed consent
Results: 35 pts with RRMM were treated; median age 64 yrs (40-76); median lines of therapy were 6 (2-14), 34/35 received an IMiD® and a proteasome inhibitor (57% had carfilzomib (C) and/or pomalidomide (P). MTD was not reached at any DL. Adverse events in ≥ 10% of pts at all DL, regardless of causality, were fatigue (48.6%), nausea (34.3%), pyrexia (28.6%), anemia (28.6%), cough (25.7%), headache (25.7%), upper respiratory infection and chills (22.9%), dyspnea (20%), constipation (17.1%), diarrhea and vomiting (14.3%) and bone pain, chest discomfort, muscle spasms, thrombocytopenia and hypokalemia in 11.4% of pts. SAR related ≥ G 3 adverse events included pneumonia (n=3), with hyperglycemia, hypophosphatemia, pyrexia, apnea, fatigue, thrombocytopenia and lymphopenia in 1 pt each. Investigator assessment by EBMT response criteria (ORR ≥ PR) among 34 evaluable pts was 24% (CR n=2, PR n=6). Responses occurred at all DL ≥ 1 mg/kg. Clinical benefit response (≥ MR) was 29% with 41% SD. In the ≥10 mg/kg cohort ORR was 33% (n=6/18) and CBR was 39% (n=7/18). The time to response was 4.6 weeks and time on treatment was 9.9 weeks (2-81). 10 pts remain on treatment. The expansion cohort dose was selected based on efficacy, safety, and receptor occupancy data.

Table 1.

Response EBMT * (n=18)	All DL (n=34)	DL ≥10mg/kg
ORR	(8) 24%	(6) 33%
CBR	(10) 29%	(7) 39%
PD	(10) 29%	(4) 22%
SD	(14) 41%	(7)39%
MR	(2) 6%	(1) 5%
PR	(6) 18%	(4) 22%
CR	(2) 6%	(2) 11%

*Investigator assessment of response as of Dec 31, 2013

Summary and Conclusion: The Maximum Tolerated Dose of SAR650984 was not reached. SAR demonstrates encouraging and durable single agent efficacy in heavily pretreated RRMM pts, including those with prior (C) and (P) and warrants further evaluation.

S1337

AGE-RELATED TRENDS IN AUTOLOGOUS HAEMATOPOIETIC CELL TRANSPLANTATION FOR MULTIPLE MYELOMA IN EUROPE 1991-2010 - A STUDY BY THE EBMT CHRONIC MALIGNANCIES WORKING PARTY

H W Auner[1,*], R Szydlo[1], J Hoek[2], H Goldschmidt[3], AM Stoppa[4], G Morgan[5], P Moreau[6], M Attal[7], G Marit[8], N Russell[9], M Brune[10], G Cook[11], P Sonneveld[12], S Schönland[3], L Garderet[13], N Kröger[14]

[1]Imperial College London, London, United Kingdom, [2]Leiden University Medical Center, Leiden, Netherlands, [3]Universitaetsklinikum Heidelberg, Heidelberg, Germany, [4]Institut Paoli Calmette, Marseille, France, [5]The Royal Marsden Hospital, London, United Kingdom, [6]CHU Nantes, Nantes, [7]CHU Toulouse, Toulouse, [8]CHU Bordeaux, Bordeaux, France, [9]Nottingham City Hospital, Nottingham, United Kingdom, [10]Sahlgrenska University Hospital, Göteborg, Sweden, [11]St. James's Institute of Oncology, Leeds, United Kingdom, [12]Daniel den Hoed Cancer Centre, Rotterdam, Netherlands, [13]Hopital Saint-Antoine, Paris, France, [14]Universitätsklinikum Hamburg-Eppendorf, Hamburg, Germany

Background: Autologous haematopoietic cell transplantation (AHCT) has been linked to improved survival in multiple myeloma (MM) and is a standard of care in patients aged<65 years. The role of AHCT in older patients is unclear.
Aims: The aim of this study was to investigate age-related trends in utilisation and outcome of AHCT for MM.
Methods: We analysed 53675 patients from 31 countries and 497 centres reported to the EBMT for undergoing a first AHCT for treatment of MM in 1991-2010. Patients were grouped into four 5-year calendar periods by time of first AHCT (1991-1995, 1996-2000, 2001-2005, and 2006-2010), and into 6 age groups based on their age at the time of AHCT (<40, 40-49, 50-59, 60-64, 65-69, ≥70 years).
Results: Median age at AHCT increased from 52.8 to 59 years (p<.001). The number of patients undergoing a first AHCT increased throughout all 4 calendar periods. The highest proportional increase was observed for patients aged 65-69 and ≥70 years. These two age groups together accounted for 3% of AHCTs in 1991-1995, and for 18.8% in 2006-2010. There was a noticeable increase in patients transplanted in >PR in 2006-2010 (26.6%) compared to previous calendar periods (12.3% in 2001-2005). Utilisation of early 2nd AHCT ≤ 6 months after the 1st transplant, generally indicating a tandem AHCT approach, peaked in 2001-2005 in all age groups. While the number of tandem AHCTs decreased in 2006-2010 in all age groups, patients aged ≥70 years showed the smallest decrease and had the highest rate of tandem transplants in this calendar period. Survival rates after AHCT increased in all age groups from

1991-1995 to 2006-2010. However, we observed considerable differences between age groups in the changes of 2-year and 5-year survival. The greatest improvement in 2-year survival was observed in patients aged 65-69 years (27.6%; from 55.3% in 1991-1995 to 82.9% in 2006-2010). The improvement in 2-year survival progressively decreased with every age bracket and was smallest in patients aged<40 years (3.7%; from 82.2% in 1991-1995 to 85.9% in 2006-2010). Remarkably, a 2-year survival of >80% was observed only in patients<40 years in the first 2 calendar periods, in patients up to the age of 64 years in 2001-2005, and in all age groups in 2006-2010. 5-year survival showed similar increases from 1991-1995 to 2006-2010. However, 5-year survival for patients aged<40 and 40-49 years decreased in the most recent calendar period compared to the previous one. In patients aged<40 years, 5-year survival decreased by 11% (from 72.5% in 2001-2005 to 61.5% in 2006-2010). Over the entire observation period, factors associated with an increased risk of death after AHCT in a proportional hazards regression analysis were higher patient age, earlier calendar period, poorer remission status at AHCT, male gender, and a greater time interval between diagnosis and AHCT (p<.001 for all parameters).

Summary and Conclusion: The data demonstrate that utilisation of AHCT for MM has continued to increase in all age groups in the era of novel agents, predominantly in patients aged 65-69 and ≥70 years. Survival after AHCT has improved considerably more in older than in younger patients, resulting in a substantial narrowing of the gap in survival rates between age groups. Furthermore, our investigation reveals an emerging trend in decreasing late survival after AHCT in the youngest patient groups. AHCT is a commonly used treatment strategy with good outcome in MM patients aged ≥ 65 years.

S1338

EARLY AUTOLOGOUS STEM CELL TRANSPLANTATION IMPROVES SURVIVAL IN NEWLY DIAGNOSED MULTIPLE MYELOMA PATIENTS

F Cavallo[1,*], A Spencer[2], F Gay[1], R Hajek[3], MT Petrucci[4], D Ben Yehuda[5], AM Carella[4], LM Vallone[4], S Oliva[1], D Petrò[4], C Crippa[4], A Siniscalchi[4], M Gilestro[1], L Pour[6], L Maracci[4], N Pescosta[4], M Liberati[4], V Magarotto[1], V Ščudla[7], G Benevolo[4], S Pulini[4], T Caravita[4], I Hardan[8], M Boccadoro[1], A Palumbo[1]

[1]Myeloma Unit, Division of Hematology, University of Torino, Torino, Italy, [2]Department of Clinical Haematology, Alfred Health, Melbourne, Australia, [3]University Hospital Brno and Faculty of Medicine OU, Ostrava, Czech Republic, [4]Italian Multiple Myeloma Network, GIMEMA, Italy, [5]Hematology Division, Hadassah Medical Center, Jerusalem, Israel, [6]BRNO University Hospital Brno and Faculty of Medicine MU, Brno, [7]Department of Internal Medicine, University of Hospital Olomouk, Olomouk, Czech Republic, [8]Meir Medical Center, Kfar-Saba, Israel

Background: Autologous stem cell transplantation (ASCT) improved outcome compared to conventional chemotherapy in newly diagnosed multiple myeloma (NDMM) patients. The role and timing of ASCT in the era of novel agents is a crucial question. PFS1 defines the time from start of therapy until the occurrence of 1st relapse. PFS2 defines the time from start of therapy until the occurrence of 2nd relapse, incorporating the duration of both 1st and 2nd remission.

Aims: To compare early ASCT *versus* ASCT at relapse in terms of PFS1, PFS2 and OS.

Methods: We analyzed pooled data from two phase III multicenter randomized trials including NDMM patients younger than 65 years (RVMM209: lenalidomide-based induction followed by ASCT *vs* chemotherapy plus lenalidomide consolidation and subsequent lenalidomide maintenance *vs* no maintenance; RVMMEMN441**:** lenalidomide-based induction followed by ASCT *vs* chemotherapy plus lenalidomide consolidation and subsequent lenalidomide-dexamethasone *vs* lenalidomide alone maintenance). In both trials, patients randomized to chemotherapy plus lenalidomide consolidation arm (CC group) who experienced progressive disease during treatment were allowed to receive ASCT at relapse. Patients randomized to ASCT consolidation arm (ASCT group) received treatment at relapse at the physician's discretion. We evaluated PFS1 (time from start of consolidation to 1st relapse), PFS2 (time from start of consolidation to 2nd relapse), and OS (time from randomization at diagnosis to death) through a stratified analysis by protocol. At 1st relapse, 2nd PFS (time from 1st relapse to 2nd relapse) and survival from relapse (time from 1st relapse to death) were evaluated. Intention to treat analysis was performed including patients who were eligible for consolidation. A subgroup analysis of PFS1, PFS2 and OS in patients who received early ASCT *vs* ASCT at relapse according to age, gender, protocol, ISS stage, cytogenetic profile and maintenance regimen was conducted.

Results: A total of 791 patients were enrolled in the two trials and 529 were eligible for consolidation: 268 in the ASCT group and 261 in the CC group. Baseline characteristic were equally distributed in the two groups. Median follow-up for survivors was 44.5 months. Early ASCT significantly improved PFS1 (3-year rate: 59% *vs* 35%, HR 0.48, CI 95% 0.37-0.62, P<0.001) and PFS2 (3-year rate: 77% *vs* 68%, HR 0.59, CI 95% 0.39-0.89, P=0.012), and marginally OS (4-year rate: 83% *vs* 72%, HR 0.64, CI 95% 0.38-1.08, P=0.096) in comparison with ASCT at relapse (Figure). 99 patients in the ASCT group experienced 1st relapsed in comparison with 159 patients in the CC group. 42% of patients in the CC group did not receive ASCT at relapse. No differences in 2nd PFS and OS from relapse between patients in the ASCT group or the CC group was noticed. The advantage of early ASCT was also observed when the two trials were analyzed separately and was confirmed in the subgroup analysis.

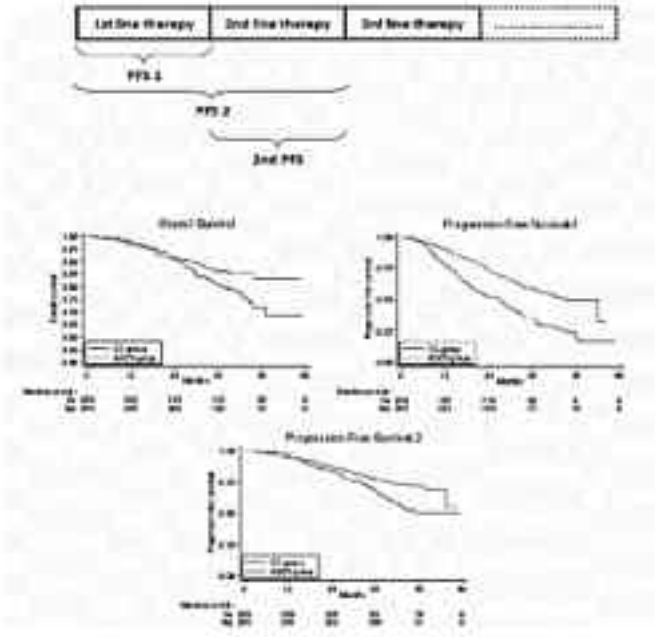

Figure 1.

Summary and Conclusion: In this pooled analysis, early ASCT improved PFS1, PFS2 and OS in NDMM patients. These results confirm the importance of ASCT as 1st line therapy even in the era of novel agents.

Chronic lymphocytic leukemia and related disorders - Clinical 2

S1340

DISEASE PROGRESSION ON IBRUTINIB THERAPY IS UNCOMMON AND IS ASSOCIATED WITH THE ACQUISITION OF RESISTANCE MUTATIONS: A SINGLE CENTER EXPERIENCE OF 267 PATIENTS

K Maddocks[1,*], A S Ruppert[1], G Lozanski[1], A Lozanski[1], N A Heerema[1], N A Heerema[1], N A Heerema[1], L Abruzzo[1], A Gordon[1], J A Jones[1], J M Flynn[1], S M Jaglowski[1], L A Andritsos[1], F Awan[1], K A Blum[1], M R Grever[1], A J Johnson[1], J C Byrd[1], J A Woyach[1]
[1]The Ohio State University, Columbus, United States

Background: The Bruton's Tyrosine Kinase (BTK) inhibitor ibrutinib (I) is very effective in chronic lymphocytic leukemia (CLL), with progression free survival of 76% at 26 months (mo) for patients (pts) with relapsed disease (Byrd et al, NEJM 2013).
Aims: We evaluated pts treated with I to explore features associated with progressive disease (PD) and subsequent outcomes.
Methods: 267 pts from The Ohio State University Comprehensive Cancer Center participating in 3 Institutional Review Board approved trials of I were included; 196 pts received single agent I and 71 received I plus ofatumumab. Adjusting for type of therapy, a proportional hazards model was fit using forward selection to identify variables associated with time to discontinuation of study as measured from the date of first treatment. Similarly, Fine and Gray models of cumulative incidence were fit to identify variables associated with a particular type of failure and in the presence of competing risks. Pts who had not discontinued study were censored at date of last contact; pts who went off study for transplant or to continue treatment elsewhere (n=6) were also censored at that time. A subset of pts with PD had Ion Torrent deep sequencing (DS) performed on peripheral blood at baseline and relapse.
Results: With a median follow-up of 16.6 mo (<1 mo-42 mo), 201 pts remain on I, and 66 have discontinued due to PD (24), infection (22), toxicity (8), transplant (4), or other (8). When adjusted for treatment, number of prior therapies and complex cytogenetics were associated with discontinuation from study. While increased LDH and complex cytogenetics were associated with risk of PD, increased age and number of prior therapies were associated with higher risk of discontinuation for all other reasons. PD includes Richter's transformation (RT; n=16) or progressive CLL (n=8). RT tended to occur early, with 10 pts transforming prior to 12 mo of I. Of pts with RT, 12 developed diffuse large B cell lymphoma, 1 Hodgkin lymphoma, 1 composite B and T cell lymphoma, 1 peripheral T cell lymphoma, and 1 plasmablastic lymphoma. CLL progression tended to occur later, with 1 pt relapsing prior to 12 mo of I. 9 RT pts have died, with a median survival from date off study of 134 days. Five deaths occurred without pts receiving further therapy and within 1 month of RT diagnosis. With therapy, deaths occurred at day 68, 106, 134, and 413 post RT diagnosis. Of pts with CLL PD, median survival from date off study has not been reached; only 3 of 8 pts have died at day 25, 142, and 180 following PD and 3 pts have survived >1 year after PD. 6 pts with CLL PD received further therapy<2 mo post PD, most in ≤ 2 weeks. DS on 6 pts with CLL PD revealed BTK or PLCγ2 mutations in all. 1 pt had both BTK C481S and 3 mutations of PLCγ2, 2 had BTK C481S (1 previously reported; Chang B, ASCO 2013), 1 had BTK C481F, and 1 had PLCγ2 R665W (previously reported). An additional 2 pts who have relapsed outside of these studies both have BTK C481S.
Summary and Conclusion: This single institution experience with I confirms it to be a well tolerated and effective therapy. Patients with PD had a short time to requiring next treatment. These DS results confirm initial reports associating mutations in BTK and PLCγ2 with PD, and require further study in larger populations.

S1341

EFFICACY OF IDELALISIB IN CLL SUBPOPULATIONS HARBORING DEL(17P) AND OTHER ADVERSE PROGNOSTIC FACTORS: RESULTS FROM A PHASE 3, RANDOMIZED, DOUBLE-BLIND, PLACEBO-CONTROLLED TRIAL

Background: Idelalisib (IDELA) is a potent and selective inhibitor of PI3Kδ, which is critical for activation, proliferation and survival of B cells and their homing and retention in lymphoid tissues. An unmet need exists for effective therapies in patients with CLL positive for del(17p) and other adverse prognostic factors.
Aims: This report describes the efficacy of IDELA in combination with rituximab (R) in patients with high-risk relapsed CLL.
Methods: Samples for del(17p), del(11q), TP53mut, IGHVmut, ZAP70 and CD38 expression, and β2-microglobulin were collected prospectively and tested using standard methods. Patients were stratified based on presence of del(17p) and/or TP53mut, and on IGHV mutational status. The endpoints evaluated in the high-risk subpopulations in the preplanned 1st interim analysis include progression-free-survival (PFS) and overall response rate (ORR). The primary study analysis was reported in NEJM 2014.
Results: IDELA+R retained robust efficacy across all high-risk subpopulations (see Table). Importantly, IDELA+R achieved 76.5% ORR and PFS HR 0.13 in the highest risk patients who were positive for both del(17p) and TP53mut, compared to 80.4% ORR and PFS HR 0.17 in those who had neither present.

Table 1.

	PFS		ORR			
	IDELA+R		IDELA+R		Placebo+R	
	HR	95%CI	n	%ORR	n	%ORR
Overall	0.16	0.09,0.28	88	80.7	88	12.5
Rai stage III or IV	0.12	0.05,0.27	52	75.0	60	11.7
Binet Stage C	0.13	0.06,0.30	47	74.5	51	13.7
Del(17p)	0.14	0.04,0.47	20	85.0	24	0.0
TP53mut	0.11	0.04,0.31	34	79.4	30	10.0
Del(17p) and/or TP53mut						
: Both	0.13	0.04,0.47	17	76.5	15	0.0
: Either one alone	0.09	0.02,0.42	20	85.0	24	12.5
: Neither	0.17	0.07,0.43	51	80.4	49	16.3
Del(11q)	0.10	0.02,0.46	28	82.1	29	6.9
IGHV unmutated	0.13	0.06,0.27	71	78.9	72	12.5
ZAP70+	0.13	0.06,0.26	77	79.2	74	12.2
CD38+	0.13	0.05,0.34	43	83.7	34	17.6
β2-microglobulin > 4mg/L	0.14	0.07,0.27	75	77.3	66	10.3

Summary and Conclusion: These results confirm the retained robust efficacy of IDELA in high-risk CLL subpopulations and support IDELA as a potentially important novel treatment for patients with CLL positive for del(17p) and other adverse prognostic factors.

S1342

IBRUTINIB INTERFERES WITH THE CELL-MEDIATED ANTI-TUMOUR ACTIVITIES OF THERAPEUTIC CD20 ANTIBODIES: IMPLICATIONS FOR COMBINATION THERAPY

F Da Roit[1], P J Engelberts[2], R P Taylor[3], E Breij[2], G Gritti[1], A Rambaldi[1], M Introna[1], P W Parren[2], F J Beurskens[2], J Golay[1,*]
[1]Hematology, Azienda Ospedaliera Papa Giovanni XXIII, Bergamo, Italy, [2]Genmab BV, Utrecht, Netherlands, [3]Department of Biochemistry and Molecular Genetics, University of Virginia School of Medicine, Charlottesville, United States

Background: The novel Bruton tyrosine kinase inhibitor ibrutinib and the PI3K-δ inhibitor idelalisib, both acting downstream of the B-cell receptor (BCR), are promising drugs for CLL and B-NHL alone or in combination with rituximab (RTX) or new generation CD20 monoclonal antibodies (mAbs). Type I CD20 mAbs act mostly through complement dependent cytotoxicity (CDC) and cell-mediated effector mechanisms, whereas Type II CD20 mAbs may induce direct cell death in addition to cell-mediated cytotoxicity, but are less effective in inducing CDC.
Aims: The aim of this study was to investigate the effect of ibrutinib and idelalisib treatment on all effector mechanisms of both Type I and Type II CD20 mAbs, using both cell lines and freshly isolated cell samples from patients with CLL.
Methods: Cell death was measured by propidium iodide (PI) or 7AAD staining based on flow cytometry, or using the alamar blue vital dye. Apoptosis was analysed by annexin V and activated caspase-3 staining. Induction of CDC in purified CLL cells or cell lines was assessed by 7AAD/CD19 staining in whole blood assays. NK cell degranulation was determined by CD107a/CD56 double staining and flow cytometry, whereas ADCC was measured by standard chromium release assays. Macrophages-mediated phagocytosis was measured by flow cytometry, using monocyte-derived macrophages and anti-CD20-opsonised CLL. PMN activation was measured as CD11b induction and phagocytosis by flow cytometry, using purified PMN or in whole blood. The type I CD20 RTX and ofatumumab (OFA) and the Type II CD20 mAb obinutuzumab (OBZ) CD20 mAbs were used throughout.

Results: Ibrutinib alone induced apoptosis of cell lines and CLL samples, but this effect was not enhanced by CD20 mAbs. Pre-treatment with ibrutinib for 1 hour did not affect complement activation or CDC of MEC-1, DOHH-2 cell lines or CLL cells. After prolongued exposure (24-72 hours) to 0.1-1 μM ibrutinib, CDC in DOHH-2 and MEC-1 cells was unaffected, although at 10 μM ibrutinib the combination of CDC and ibrunitib-mediated cytotoxicy was less than additive. This may be due to the increased expression of the complement inhibitor CD55 and decreased expression of CD20 by ibrutinib. Importantly, ibrutinib strongly inhibited all cell-mediated mechanisms induced by CD20 antibodies RTX, OFA or OBZ, either in purified systems or whole blood assays. NK cell activation and ADCC, as well as phagocytosis by macrophages or PMN were all inhibited by ibrutinib with EC_{50} of 0.3-3 μM. Analysis of CD20-mediated activation of NK cells isolated from a patient treated with oral ibrutinib suggested that repeated drug dosing inhibits NK cell activation *in vivo*. Finally we show that the PI3K-δ inhibitor idelalisib similarly inhibits CD20 mAb cell-mediated effector mechanisms, although the inhibitory effects of this drug at 10μM were weaker than those observed with ibrutinib at the same concentration (about 50% inhibition compared to over 90%).
Summary and Conclusion: The combination of ibrutinib with type II CD20 mAbs does not lead to enhanced direct cytotoxicity *in vitro*. In contrast, it inhibits all cell-mediated cytotoxic mechanisms of action of CD20 antibodies and has minor effects on CDC. Idelalisib has similar, albeit weaker, inhibitory activity on the cell-mediated effector mechanisms of CD20 mAbs. The design of combined treatment schedules with these kinase inhibitors and anti-CD20 antibodies should therefore consider the multiple negative interactions between these two classes of agents.

S1343

A PHASE 2 STUDY OF THE BTK INHIBITOR IBRUTINIB IN GENETIC RISK-STRATIFIED RELAPSED AND REFRACTORY PATIENTS WITH CHRONIC LYMPHOCYTIC LEUKEMIA (CLL)/SMALL LYMPHOCYTIC LYMPHOMA (SLL)

K Maddocks[1,*], J M Flynn[1], L A Andritsos[1], F Awan[1], J A Woyach[1], M R Grever[1], M Stefanos[1], J Lynch[1], A J Johnson[1], J C Byrd[1], J A Jones[1]
[1]The Ohio State University, Columbus, United States

Background: Ibrutinib is an orally available BTK inhibitor that has demonstrated significant activity in CLL patients (pts), with an overall response rate (ORR) of 71%, an additional 20% of patients achieving partial response (PR) with lymphocytosis (420 mg approved dose) [Byrd et al, NEJM 2013]. Responses seen were independent of high-risk disease features including 17p13.1 deletion (del17p).
Aims: This phase II, single institution, non-randomized study was designed to evaluate the clinical efficacy and durable disease control of ibrutinib administered to pts with relapsed CLL/SLL of all genomic risk with patients having del17p independently evaluated.
Methods: Eligibility included pts with relapsed CLL/SLL with ≥ one prior therapy, required treatment with prior ofatumumab and allowed patients with any degree of cytopenias if attributed to bone marrow involvement by CLL. All pts had interphase cytogenetics performed prior to enrollment and were enrolled into the arm of the study that characterized their risk, del17p present or all other cytogenetic risk.
Results: 72 pts were enrolled in the study. Median age was 65 (range 37-83); median number of prior therapies was 4 (range 1-16); 27 pts (38%) had del17p and 45 (62%) pts had all other cytogenetic abnormalities. Median follow-up is 17 mos (range 10 mos-20 mos). Most frequent adverse events (AEs) considered possibly related to treatment were infection (35%), diarrhea (32%), myalgias (29%), thrombocytopenia (28%), neutropenia (26%) and bruising (22%). Grade 3-4 AEs considered possibly related to therapy occurred in 31 (43%) pts the most common including neutropenia (19%), infections (14%), and thrombocytopenia (7%). 25 pts have discontinued treatment (35%), 15 (21%) with all other cytogenetic risk and 10 (14%) with del17p. Reason for discontinuation included disease progression in 6 pts (8%); investigator or pt preference in 8 pts (11%); adverse events in 5 pts (7%) including 3 pts with pneumonia, 1 pt with progressive multifocal leukoencephalopathy (PML) and 1 pt with bilateral spontaneous subdural hematoma and death in 6 pts (8%). Of the 6 pts with disease progression, 4 had Richter's transformation (3 DLBCL and 1 HD) and 2 had progression of CLL. Of the 6 pt deaths, 3 were considered possibly related to therapy and included two pts with sepsis and one pt with a major bleed from a psoas muscle hematomahematoma. 18 of these 25 pts have died. 68 pts were evaluable for response per protocol (response assessment at 3 mos), 40 other and 28 del17p. Best ORR per investigator was 48% - all of which were PR, with an additional 24% of pts having PR with lymphocytosis. The ORR in the cohort of pts with del17p was 46% with an additional 21% having PR with lymphocytosis and ORR in the other cytogenetic risk group was 50% with an additional 25% having PR with lymphocytosis. Progression free survival (PFS) at 12 mos was 72% in the entire cohort, 68% in the del17p cohort and 79% in the other cytogenetic risk.
Summary and Conclusion: Ibrutinib therapy was well-tolerated with toxicities similar to those previously reported. One pt developed PML during cycle #12 which has not previously been reported with ibrutinib. This pt had prior rituximab with last exposure >1 yr. The ORR in pts with high-risk disease characterized by del17p was not significantly different than those pts with all other cytogenetic risk. The best ORR was lower than previously reported (48% *vs* 71%), possibly related to differences in pts at baseline, although 12 mo PFS remained high and responses may improve with time.

S1344

SF3B1 MUTATIONS AND OUTCOME IN CLL PATIENTS TREATED WITH CHLORAMBUCIL (CHL) OR OFATUMUMAB-CHL (O+CHL): RESULTS FROM THE PHASE III STUDY COMPLEMENT 1 (OMB110911)

E Tausch[1,*], C Galler[1], R F Schlenk[1], P Hillmen[2], F Offner[3], A Janssens[4], K Govindbabu[5], S Grosicki[6], J Mayer[7], P Panagiotidis[8], A McKeown[9], P D Winter[10], I V Gupta[11], H Döhner[1], S Stilgenbauer[1]
[1]Department of Internal Medicine III, University of Ulm, Ulm, Germany, [2]Department of Haematology, St. James's University Hospital, Leeds, United Kingdom, [3]Universitair Ziekenhuis Gent, Gent, [4]Universitair Ziekenhuis Leuven, Leuven, Belgium, [5]Kidwai Memorial Institute of Oncology,, Bangalore, India, [6]SPZOZ Zespol Szpitali Miejskich, Chorzow, Poland, [7]Department of Haematol-Oncology, University Hospital Brno, Brno, Czech Republic, [8]Laikon General Hospital, University of Athens, Athens, Greece, [9]GlaxoSmithKline, Uxbridge, [10]GlaxoSmithKline, London, United Kingdom, [11]GlaxoSmithKline, Collegeville, United States

Background: Mutations in *SF3B1* (*SF3B1^{mut}*), a gene of the spliceosome machinery, have been found in CLL with an incidence of 10 to 20% and have been associated with male gender, CD38 positivity, unmutated *IGHV*, 11q-, absence of +12q and poor outcome. In the UK CLL4 and GCLLSG CLL8 trials *SF3B1^{mut}* was found as an independent unfavorable prognostic factor for progression free survival (PFS).
Aims: We assessed the incidence and impact of *SF3B1^{mut}* in the OMB110911 trial (1st line Chl *vs*. O+Chl) in patients considered inappropriate for fludarabine-based therapy.
Methods: Pretreatment samples were available from 376 (84.1%) patients with informed consent and representative for the full trial population (signed informed consent). We performed Illumina MiSeq amplicon based NGS for exons 14, 15, 16 and 18 of *SF3B1*. Exact variant frequency calling of the mutant allele was possible due to deep sequencing with a median depth of 2278x.

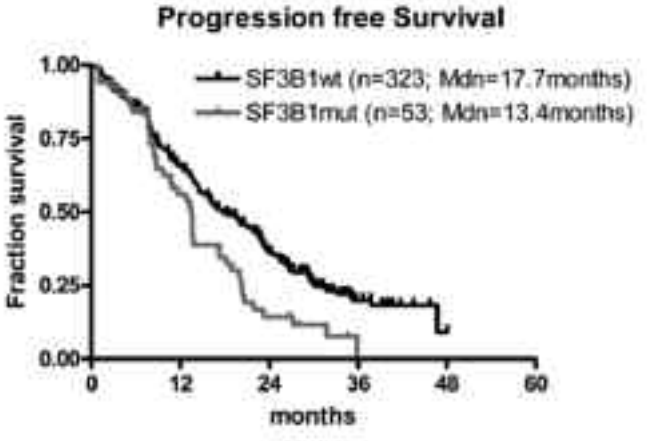

Figure 1.

Results: In total, 56 mutations in *SF3B1* were found in 53 of 376 patients (14.1%). All mutations were missense variants, and 50 of 56 mutations have been previously reported in CLL. Mean variant fraction among patients with one *SF3B1^{mut}* was 0.31 whereas it was 0.16 in 3 patients carrying two distinct *SF3B1^{mut}* mutations, indicating different subclones. *SF3B1^{mut}* was significantly associated with higher white blood cell count (WBC) at baseline (129G/L *vs*. 90G/L, p=0.01), male sex (p=0.02) and a trend to absence of +12q (p=0.06) and 17p- (p=0.09). Mutations in *NOTCH1* and *SF3B1* were mutually exclusive (p=0.01). There was no association of *SF3B1^{mut}* with age, Binet stage, B symptoms, splenomegaly, lymph node size, CIRS, ECOG, ß2-MG, *IGHV* status, deletion of 6q, 11q, and 13q. Regarding response to treatment, *SF3B1^{mut}* had no significant impact on OR or CR rate in both arms. At a median follow-up time of 29.0 months, there were 249 (66.2%) events for PFS and 63 (16.8%) for OS. *SF3B1^{mut}* was associated with shorter PFS (median 13.4 *vs*. 17.7 months, HR 1.662, p<0.01) and this impact was found in both treatment arms (O+Chl: HR=1.652 *vs*. Chl: HR=1.515). Comparison of treatments confirmed the beneficial effect of O+Chl in the subgroup with *SF3B1^{mut}* (median 17.3 *vs*. 10.8 months, HR=0.496, p=0.03). To identify factors of independent prognostic impact, we performed multivariable Cox regressions for PFS and OS including the following variables: treatment, sex, age, Binet stage, ECOG

status, CIRS, B symptoms, WBC, ß2-MG, 11q, 17p, *IGHV*, *NOTCH1 and SF3B1*. For PFS, the following independent prognostic factors were identified: O+Chl (HR 0.40, p<0.001), WBC >50Gl/l (HR 2.59, p<0.001), CIRS Score >8 (HR 1.66 p<0.01), male gender (HR 1.40 p=0.04), unmutated *IGHV* (HR 1.38 p=0.04), 17p- (HR 3.32 p<0.001) and *NOTCH1^{mut}* (HR 1.46 p=0.04), but not SF3B1 (HR=1.10 p=0.62). Interestingly, multivariable analysis with exclusion of WBC, as was frequently performed in previous studies, led to inclusion of *SF3B1^{mut}* as an independent adverse prognostic factor (HR 1.45, p=0.04). Regarding OS, WBC >50Gl/l (HR 2.60 p=0.01), ß2-MG >5mg/l (HR 2.56 p<0.01), Binet Stage C (HR 2.16 p=0.01), 17p- (HR 4.83 p=0.001) and unmutated *IGHV* (HR 1.90 p=0.05) were identified as independent prognostic factors. There was no significant impact of *SF3B1^{mut}* on OS, neither in univariate (median survival not reached, HR 1.26, p=0.5) nor in multivariate analysis, and independently of WBC inclusion.

Summary and Conclusion: In the OMB110911 trial evaluating 1st line O+Chl against Chl, *SF3B1^{mut}* was associated with high WBC, male sex, absence of *NOTCH1^{mut}* and showed a trend to absence of +12q and 17p-. *SF3B1^{mut}* was significantly associated with shorter PFS in univariate analysis but not in multivariable analysis possibly due to its association with high WBC. Subjects with *SF3B1^{mut}* benefited from the addition of Ofatumumab to Chl (O+Chl).

Aggressive Non-Hodgkin lymphoma - Clinical

Background: MCL is an incurable type of aggressive non-Hodgkin lymphoma. Progression-free survival (PFS) is limited with standard frontline therapy (*e.g.* R-CHOP) in newly diagnosed MCL patients (pts). Bortezomib (V) is approved for relapsed MCL in the US and >50 other countries. Incorporating V into frontline combination therapy may improve outcomes in MCL pts.

Aims: This study determined if adding V in place of vincristine in R-CHOP improved outcomes in newly diagnosed MCL pts unsuitable for bone marrow transplantation (NCT00722137).

Methods: Consenting adults with measurable stage II–IV MCL and ECOG PS 0–2 were randomized 1:1 (stratified by IPI score and disease stage) to 6–8 21-d cycles of rituximab 375 mg/m^2, cyclophosphamide 750 mg/m^2, doxorubicin 50 mg/m^2, all IV d 1, and prednisone 100 mg/m^2 PO d 1–5, plus V 1.3 mg/m^2 IV d 1, 4, 8, 11 (VR-CAP) or vincristine 1.4 mg/m^2 (max 2 mg) IV d 1 (R-CHOP). Primary endpoint was PFS by independent radiology review (IRC). Secondary endpoints were time to progression (TTP), time to next anti-lymphoma therapy (TTNT), overall survival (OS), response by modified IWRC, and safety. 486 pts were planned for 295 PFS events.

Results: Between May 2008 and Dec 2011, 244 pts were randomized to R-CHOP and 243 to VR-CAP; in all 487 pts, median age was 66 yrs, 74% were male, 74% had stage IV MCL, and 54% had an IPI score of ≥3. 97% of pts had MCL diagnosis confirmed centrally. Pts received a median of 6 cycles. After 40 mos' median follow-up, median PFS by IRC (298 PFS events) was 14.4 *vs* 24.7 mos with R-CHOP *vs* VR-CAP (Figure), and by investigator assessment (307 PFS events) was 16.1 *vs* 30.7 mos (hazard ratio [HR]=.51, *P*<.001). Median TTP by IRC was 16.1 *vs* 30.5 mos (R-CHOP *vs* VR-CAP; HR=.58, *P*<.001) and by investigator was 16.8 *vs* 35.0 mos (HR=.47, *P*<.001); median TTNT was 24.8 *vs* 44.5 mos (HR=.50, *P*<.001), and median OS was 56.3 mos *vs* not yet reached (HR=.80, *P*=.173; 4-yr OS rates: 54% *vs* 64%). By IRC, complete response (CR) + unconfirmed CR (CR+CRu) rates (bone marrow and LDH verified) were 42% *vs* 53% (R-CHOP *vs* VR-CAP; odds ratio [OR]=1.7, *P*=.007); by IRC, radiological CR+CRu rates were 71% *vs* 83% (OR=2.0, *P*=.002) and overall response rates (ORRs; CR+CRu+partial response [PR]) were 90% *vs* 92% (OR=1.4, *P*=.27). By investigator, CR+CRu rates were 28% *vs* 42% (R-CHOP *vs* VR-CAP; OR=1.9, *P*=.002) and ORRs were 92% *vs* 96% (OR=2.0, *P*=.07). Median duration of radiological response with R-CHOP *vs* VR-CAP was 18.1 *vs* 36.5 mos in pts with CR+CRu+PR by IRC and 16.6 *vs* 39.2 mos in pts with CR+CRu by IRC. For R-CHOP *vs* VR-CAP, 85% *vs* 93% of pts had grade (G) ≥3 adverse events (AEs); those in ≥10% of pts in either arm were neutropenia 67% *vs* 85%, leukopenia 29% *vs* 44%, thrombocytopenia 6% *vs* 57%, lymphopenia 9% *vs* 28%, anemia 14% *vs* 15%, and febrile neutropenia 14% *vs* 15%. Despite the difference in thrombocytopenia rates, rates of bleeding events were similar for R-CHOP *vs* VR-CAP (any G: 5% *vs* 6%; G ≥3: 3 pts *vs* 4 pts). Peripheral neuropathy rates were 29% *vs* 30% (any G) and 4% *vs* 8% (G ≥3). With R-CHOP *vs* VR-CAP, 30% *vs* 38% of pts had serious AEs, 7% *vs* 9% discontinued due to AEs, and there were 3% *vs* 2% on-treatment drug-related deaths.

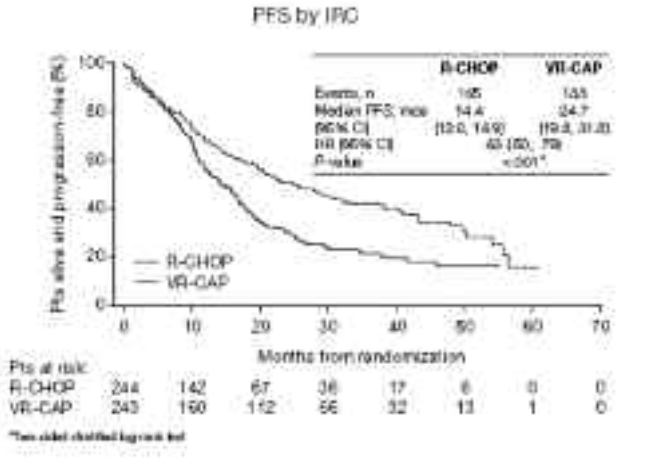

Figure 1.

Summary and Conclusion: PFS was significantly prolonged and secondary efficacy endpoints consistently improved with VR-CAP *vs* R-CHOP, with additional but manageable toxicity, in newly diagnosed MCL pts.

S1346

PROGNOSTIC MODELS FOR PRIMARY MEDIASTINAL B-CELL LYMPHOMA DERIVED FROM 18-FDG PET/CT QUANTITATIVE PARAMETERS IN THE IELSG-26 STUDY

E Zucca[1,*], M Martelli[2], PL Zinzani[3], A JM Ferreri[4], E Russo[2], S Montoto[5], A Lopez Guillermo[6], A J Davies[7], P WM Johnson[7], L Giovanella[8], F Cavalli[1], L Ceriani[8]

[1]Oncology, IOSI - Oncology Institute of Southern Switzerland, Bellinzona, Switzerland, [2]Dep. of Cellular Biotechnologies and Hematology, La Sapienza University, Roma, [3]Institute of Hematology and Medical Oncology, Policlinico S.Orsola-Malpighi, Bologna, [4]Unit of Lymphoid Malignancies, Dep. of Onco-Hematology, San Raffaele Scientific Institute, Milano, Italy, [5]Centre for Haemato-Oncology, Barts Cancer Institute, London, United Kingdom, [6]Haematology, Hospital Clinic, Barcelona, Spain, [7]Cancer Research UK Centre, Southampton General Hospital, Southampton, United Kingdom, [8]Nuclear Medicine, IOSI - Oncology Institute of Southern Switzerland, Bellinzona, Switzerland

Background: The IELSG-26 study was designed to evaluate the role of 18-Fluorodeoxyglucose Positron-Emission Tomography/computed tomography (18FDG PET/CT) in the treatment of primary mediastinal large B-cell lymphoma (PMBCL), a distinct subtype with better outcome than other diffuse large B-cell lymphomas. However, salvage treatment for the few relapsing patients has poor results, as a consequence of rapidly-emerging chemorefractory disease. Identification of poor-prognosis patients would allow risk-stratified approaches but the international prognostic index has little value in this entity and there is a need for novel and reliable prognostic markers. We have previously shown that a Deauville score (DS) of 3 defined by a liver uptake cut-point in the post chemoimmunotherapy PET scans can accurately identify the patients who will be likely cured (Martelli et al JCO 2014, in press). We report here an analysis of the prognostic impact of quantitative PET parameters and their combination with the standard qualitative analysis.

Aims: To assess, in a prospective cohort of uniformly treated PMBCL patients, the utility of the main 18FDG PET-derived quantitative parameters alone and combined together or with visual analysis for to predict progression-free survival (PFS).

Methods: Maximum Standard Uptake Value (SUVmax), metabolic tumor volume (MTV) and total lesion glycolysis (TLG) were measured in 100 patients baseline and after the combination chemoimmunotherapy with doxorubicin and rituximab-based regimens; 93 patients also underwent consolidation radiotherapy. Cut-off value of the MTV, TLG and SUVmax and their changes (Δ) during treatment were calculated using the ROC curve. The metabolic response after treatment was also visually evaluated with a 5-point scale (Deauville score - DS).

Results: After a median follow-up of 36 months the PFS rate was 90%. All the individual quantitative parameters considered had very high NPV (0.94-1.0) but low PPV (0.18–0.45). Most patients (86%) had an initial mediastinal mass >7.5cm and nearly all (90%) had a residual morphological lesion at the end of chemoimmunotherapy. SUV max, MTV and TLG at the end of therapy performed better in predicting PDF than the same values estimated at baseline and their changes during immunochemotherapy. The end-of-therapy TLG was the best individual PFS predictor, but the combination of baseline TLG and end of treatment DS resulted in a better PPV without a detrimental effect on the NPV. The combination of these parameters can identify the patients at risk of poor PFS (Figure 1). The univariate analysis of PFS according to the main PET parameters is summarized in the following table:

Table 1.

Parameter		Cut-off	Sensitivity (%)	Specificity (%)	NPV (%)	PPV (%)	Log-rank test (p-value)
Deauville Score	(best cut-point)	3	93	77	99	39	<0.0001
SUV max	baseline	22.33	60	76.6	94	27	0.037
	end-of-therapy	2.6	93	71	98	28	<0.0001
	Δ	78%	60	89	94	53	0.004
MTV	baseline	607 ml	80	80	97	31	<0.0001
	end-of-therapy	35 ml	100	78.9	100	34	<0.0001
	Δ	94%	100	49	100	18	0.0034
TLG	baseline	5814	93	77	99	35	<0.0001
	end-of-therapy	84.4	100	88.7	100	45	<0.0001
	Δ	98%	60	85	95	29	0.0012
baseline TLG + Deauville Score		-	80	92	98	53	<0.0001
end-of-therapy TLG + Deauville Score		-	93	89	99	47	<0.0001

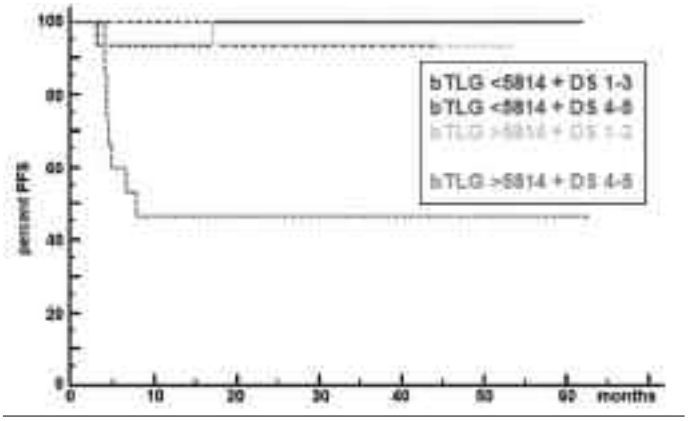

Figure 1. PFS according to baseline TLG and Deauville Score

Summary and Conclusion: Both visual analysis (Deauville qualitative scale) and PET-derived quantitative parameters can predict PFS in patients with PMBCL. In comparison with each parameter alone, combination of baseline TLG and end of treatment DS showed a high PPV and may be used to build a model that can accurately identify the poor-risk patients (Figure 1).

S1347

INCREASED RITUXIMAB (R) DOSES ELIMINATE INCREASED RISK AND IMPROVE OUTCOME OF ELDERLY MALE PATIENTS WITH AGGRESSIVE CD20+ B-CELL LYMPHOMAS: THE SEXIE-R-CHOP-14 TRIAL OF THE DSHNHL

M Pfreundschuh[1,*], G Held[1], S Zeynalova[2], C Zwick[1], M Haenel[3], L Truemper[4], M H Dreyling[5], J Dierlamm[6], M Loeffler[2], N Schmitz[7], N Murawski[1]

[1]Internal Medicine I, Saarland University Medical School, Homburg, [2]IMISE, University of Leipzig, Leipzig, [3]Internal Medicine III, Chemnitz Hospital, Chemnitz, [4]Haematology/Oncology, University Medicine Goettingen, Goettingen, [5]Internal Medicine III, University Hospital Grosshadern, Muenchen, [6]Internal Medicine II, University Medical Center Hamburg-Eppendorf, [7]Haematology/Oncology, Asklepios Hospital St. Georg, Hamburg, Germany

Background: Elderly male patients have significantly lower R serum levels, shorter exposure times and a worse outcome in RICOVER-60, RICOVER-noRTh, and Pegfilgrastim trials (Blood 2012, 119:3276; Blood 2014, 123:640-646).

Aims: To test increasing R doses, male patients received 500 instead of 375 mg/m^2 in the SEXIE-R-CHOP-14 trial which also compared six cycles of CHOP-14 in combination with eight 2-week applications with eight upfront dose-dense applications of R (days -1, 0, 3, 7, 14, 21, 28, 42) in a randomized phase-II trial. 271 patients (61-80 years) were randomized, 268 patients are evaluable. 148 patients males received 500 mg/m^2, 120 females 375 mg/m^2 R.

Results: Protocol adherence was excellent with median relative doses of R and myelosuppressive drugs >98%. During the treatment period, the increased R dose in males resulted in slightly higher trough serum levels than in females; however, R levels dropped faster in males resulting in very similar serum levels thereafter and a only a marginally longer overall R exposure time. The increased R dose in males was not associated with increased toxicities. 3-year PFS was 74% in males and 68% in females (p=0.396), 3-year OS was 80% in males and 72% in females (p=0.111). In a multivariable analysis adjusting for IPI factors, male hazard was 0.9 (p=0.817) for PFS, and 0.8 for OS (p=0.317). In a historical comparison by multivariable analysis adjusting IPI risk factors and age >70 years, of 148 elderly males who received 500 mg/m^2 in SEXIE-R-

CHOP-14 and 250 males who received 375 mg/m^2 in RICOVER-60, the increased dose of R was associated with a reduced risk for an event in PFS (HR=0.7; p=0.128) and in OS (HR=0.7; p=0.223).
Summary and Conclusion: Increasing R dose by one third from 375 mg/m^2 to 500 mg/m^2 eliminated the increased risk of elderly males. That the increased R dose significantly improves outcome not only of elderly male patients, but also of young male and female patients who have a R pharmacokinetics similar to elderly males should be confirmed in a larger randomized study of these subpopulations with aggressive CD20$^+$ B-cell lymphomas. *Supported by Roche and Deutsche Krebshilfe.*

S1348

PHASE I STUDY OF ABT-199 (GDC-0199) IN PATIENTS WITH RELAPSED/REFRACTORY NON-HODGKIN LYMPHOMA: RESPONSES OBSERVED IN DIFFUSE LARGE B-CELL (DLBCL) AND FOLLICULAR LYMPHOMA (FL) AT HIGHER COHORT DOSES

M S Davids[1,*], J F Seymour[2], J F Gerecitano[3], B S Kahl[4], J M Pagel[5], W G Wierda[6], MA Anderson[7], N K Rudersdorf[8], L A Gressick[8], N P Montalvo[8], J Yang[8], M Zhu[8], M Dunbar[8], E Cerri[8], S H Enschede[8], R A Humerickhouse[8], A W Roberts[7]
[1]Dana Farber Cancer Institute, Boston, United States, [2]Peter MacCullum Cancer Center, Melbourne, Australia, [3]Memorial Sloan-Kettering Cancer Center, New York, [4]University of Wisconsin, Madison, [5]University of Washington, Seattle, [6]University of Texas, Houston, United States, [7]Royal Melbourne Hospital and Walter and Eliza Hall Institute of Medical Research, Melbourne, Australia, [8]AbbVie, North Chicago, United States

Background: The anti-apoptotic protein BCL-2 is highly expressed in Non-Hodgkin Lymphoma (NHL) and contributes to chemotherapy resistance. ABT-199 is a selective, orally bioavailable, small molecule BCL-2 inhibitor that is a promising agent for the treatment of patients (pts) with NHL.
Aims: Objectives of this Phase I, dose-escalation study include evaluations of safety, pharmacokinetics (PK), and preliminary efficacy in pts with relapsed/refractory (R/R) NHL.
Methods: ABT-199 was given on Week 1 Day -7 (W1D-7), followed by continuous, once-daily dosing from W1D1 until progressive disease or unacceptable toxicity. A 2 to 3 week ramp-up period with stepwise dose increases was implemented. Final cohort doses of 200 - 900 mg have been evaluated.
Results: As of December 4, 2013, 44 pts have been enrolled, 15 (35%) with mantle cell lymphoma (MCL), 11 (26%) with FL, 10 (23%) with DLBCL, 4 (9%) with Waldenström macroglobulinemia (WM), 2 (5%) with marginal zone (MZL), 1 (2%) with primary mediastinal B-cell lymphoma (PMBCL), and 1 (2%) with multiple myeloma (MM). The most common AEs (≥20% of pts) were nausea (34%), upper respiratory tract infection (27%), diarrhea (25%), and fatigue (21%). Grade (G) 3/4 AEs occurring in >3 pts were anemia (14%), neutropenia (11%), and thrombocytopenia (9%). G 3/4 thrombocytopenia was not dose-dependent or dose-limiting. Two of 10 pts in cohort 5 experienced a DLT (G3 febrile neutropenia and G4 neutropenia) at the target dose of 600 mg. G3 laboratory tumor lysis syndrome was seen after the initial dose in 1 pt with bulky MCL (elevations in phosphate and potassium only) and 1 pt with DLBCL (elevations in phosphate and uric acid only). For the 40 pts evaluable for efficacy, the overall response rate was 48%, 9/12 MCL (1 CR); 3/11 FL; 3/9 DLBCL (1 CR); 3/4 WM (1 CR); 1/2 MZL; 0/1 PMBCL; 0/1 MM. All responses in DLBCL and FL pts were observed at doses ≥600 mg; 3/8 DLBCL (38%) and 3/6 FL (50%).
Summary and Conclusion: ABT-199 monotherapy showed anti-tumor activity across the range of ABT-199 cohort doses for several NHL subtypes, most notably in MCL and WM. In DLBCL and FL, responses were observed at higher doses. Dose escalation is continuing to determine the maximum tolerated dose and recommended phase two dose.

S1349

PRELIMINARY RESULTS OF A PHASE II RANDOMIZED STUDY (ROMULUS) OF POLATUZUMAB VEDOTIN OR PINATUZUMAB VEDOTIN PLUS RITUXIMAB IN PATIENTS WITH RELAPSED/REFRACTORY NON-HODGKIN LYMPHOMA (NHL)

F Morschhauser[1,*], I Flinn[2], R Advani[3], L Sehn[4], K Kolibaba[5], O Press[6], G Salles[7], C Diefenbach[8], H Tilly[9], S Assouline[10], A Chen[11], M Dreyling[12], A Hagenbeek[13], PL Zinzani[14], B D Cheson[15], S Yalamanchili[16], D Lu[16], A Chai[16], YW Chu[16], J Sharman[17]

Background: Polatuzumab vedotin (PoV) and pinatuzumab vedotin (PiV), antibody drug conjugates (ADC) containing the anti-mitotic MMAE targeting CD79b (PoV) and CD22 (PiV), respectively, showed clinical activity in Phase I studies of patients with relapsed/refractory (R/R) diffuse large B-cell lymphoma (DLBCL) and indolent NHL.
Aims: The current study aims to compare PoV and PiV, each in combination with rituximab (RTX) in R/R DLBCL and follicular lymphoma (FL).
Methods: Patients were randomized to receive PoV + RTX or PiV + RTX (ADC 2.4 mg/kg + RTX 375 mg/m^2) every 21 days until disease progression or unacceptable toxicity to a maximum of one year. Tumor assessments were performed every 3 months per revised IWG criteria.
Results: As of 8 November 2013, 58 patients received PoV + RTX (38 DLBCL; 20 FL), and 63 patients received PiV + RTX (42 DLBCL; 21 FL). Median prior therapies [DLBCL, 3 (1-10); FL, 2 (1-8)] were balanced between the two treatment arms for both disease subtypes. 46% of all patients were RTX refractory. The median number of treatment cycles administered in DLBCL patients was 5 for both ADC (1-15); in FL the median number of treatment cycles administered was 8.5 for PoV (3-15) and 6 for PiV (1-13). Overall safety profiles of both regimens were similar. Treatment-emergent adverse events (AE) in >25% of patients included fatigue (52%), diarrhea (42%), nausea (37%), peripheral neuropathy (PN) (32%), and constipation (26%). Grade ≥ 3 AE in >3% of patients included neutropenia (21%), diarrhea (6%), dyspnea (4%), febrile neutropenia (4%), hyperglycemia (4%) and PN (4%). Serious AE were reported in 36% of patients. Thirty-eight patients (31%) discontinued study treatment for AE after a median 5 doses (range 1-14); 16 patients discontinued study treatment for PN. Treatment delays and ADC dose reductions reported in 27% and 22%, respectively. Two of 7 deaths (sepsis, urosepsis) unrelated to NHL were attributed to PiV. Complete (CR) and partial (PR) responses, n (%) [% 95% CI]:

Table 1.

	PoV (CD79b) + RTX [95% CI]	PiV (CD22) + RTX [95% CI]
R/R DLBCL	N=37	N=37
ORR	19 (51%) [34, 68]	20 (54%) [37, 71]
CR	5 (14%) [5, 29]	7 (19%) [8, 35]
PR	14 (38%) [23, 55]	13 (35%) [20, 53]
R/R FL	N=20	N=21
ORR	12 (60%) [36, 81]	14 (67%) [43, 85]
CR	6 (30%) [12, 54]	1 (5%) [0.1, 24]
PR	6 (30%) [12, 54]	13 (62%) [38, 82]

Pharmacokinetic profiles were similar for both ADCs across DLBCL and FL with no free MMAE accumulation.
Summary and Conclusion: PoV and PiV + RTX were generally well-tolerated with similar toxicity profiles. Neutropenia, PN and diarrhea were principal toxicities. Similar efficacy was observed with both ADCs in heavily pretreated patients with DLBCL. The higher CR rate with PoV + RTX suggests greater clinical activity in R/R FL. Combination studies of RTX + PoV with chemotherapy and with ADC schedules to reduce PN are ongoing or in planning.

Acute myeloid leukemia - Clinical 2

TARGETING LEUKEMIC STEM CELLS IN AML USING THE BISPECIFIC CD33/CD3 BITE® ANTIBODY AMG 330

C Krupka[1,2,*], P Kufer[3], R Kischel[3], T Köhnke[1,2], G Zugmaier[3], P Bäuerle[3], B Vick[4], N Konstandin[2,5], I Jeremias[4,6], K Spiekermann[2,5], G Riethmüller[7], W Hiddemann[2,5], M Subklewe[1,2]
[1]Clinical Cooperation Group Immunotherapy, Helmholtz Institute Munich, [2]Department of Internal Medicine III, Klinikum der Universität München, [3]AMGEN Research (Munich) GmbH, [4]Helmholtz Institute Munich, Munich, Germany, [5]Clinical Cooperation Group Leukemia, Helmholtz Institute Munich, [6]Department of Oncology / Hematology, Dr. von Haunersches Kinderspital, [7]Institute for Immunology, Ludwig-Maximilians-University, Munich, Germany

Background: Antibody-based immunotherapy represents a promising strategy to target and eliminate chemoresistant leukemic cells in AML. In our previous work, we evaluated the cytotoxic effect of AMG 330 on AML cells. Using an AML long-term culture system, we could show efficient elimination of primary AML cells through AMG 330 activated and expanded autologous T-cells.
Aims: As relapse rates in AML are high and are proposed to be caused by leukemic stem cells (LSCs), the ability of AMG 330 to redirect T-cells to LSCs was evaluated by assessing CD33 expression pattern within the LSC compartment as well as by limiting dilution transplantation assays in NOD SCID gamma null (NSG) mice.
Results: CD33 expression intensity on AML cells was assessed by flow cytometry (specific fluorescence intensity, SFI) and by surface antigen quantification (specific antigen binding sites, SABC). Median SFI and corresponding SABC was significantly higher on AML bulk cells compared to $CD34^+/CD38^-$ LSCs (AML bulk: SFI: 59.1, SABC: 47280; LSC SFI: 30.7, SABC: 24560, n=24, *p<0.001*). Importantly, we could show significantly higher CD33 expression on LSCs compared to hematopoietic stem cells (HSC) (median SFI 8.1, 6480 SABC, n=7, *p=0.047*). To further investigate how many CD33 molecules were needed for efficient AMG 330 mediated lysis, $CD33^{BRIGHT}$ cells (MV4-11: SFI 31) were mixed with $CD33^{DIM}$ cells (OCI-AML3: SFI 3) and co-incubated with healthy donor (HD) T-cells (E:T ratio 1:1, 5ng/ml AMG 330 or control BiTE®). Lysis kinetics revealed a dependency on CD33 expression level (24h: OCI-AML3: 93%, MV4-11: 16%). However after 48 hours both cell lines were completely lysed suggesting that AMG 330 is active at low antigen density. Genetic variations of CD33 could also impact CD33 targeted therapy. We therefore genotyped 4 CD33 single nucleotide polymorphisms (SNPs) in 13 primary AML patient samples. Patients homozygous for the reference allele GG of rs35112940 and CC of rs12459419 showed a trend towards higher CD33 expression compared to the other genotypes. As low CD33 expression levels might be sufficient for AMG 330 mediated lysis, we evaluated unwanted on-target toxicity in a colony-forming unit (CFU) assay. No significant difference in CFUs was detected between HD bone marrow samples pretreated with AMG 330 or control BiTE® *(p=0.12)*. Limiting Dilution Transplantation (LDTA) assays were performed to test the potential of AMG 330 to effectively mediate lysis of LSCs. Patient-derived AML cells were lentivirally transduced with luciferase as a transgene, re-transplanted into NSG mice for cell amplification, enriched for transgenic cells by flow cytometry and co-cultured with HD T-cells and either AMG 330 or control BiTE® for 7 days. Residual $CD3^-$ cells were injected into NSG mice and monitored for AML outgrowth by *in-vivo* imaging and peripheral blood analysis. Control mice developed leukemia within 21 days post injection (3/3). In contrast, surviving cells from AMG 330 treated cultures did not initiate leukemia in NSG mice (engraftment in 0/6 mice; median follow up 119 days).
Summary and Conclusion: We conclude from our data that AMG 330 has the potential to eliminate LSCs, while potentially sparing primitive HSCs. Since our previous analysis of 621 AML patients demonstrated a highly variable CD33 expression pattern, we anticipate that AMG 330 mediated lysis will also differ between individual patients. Further investigations and clinical studies are needed to elucidate the impact of CD33 expression on response to AMG 330 mediated immunotherapy.

S1351

IMPACT OF THE COMPOSITION OF SALVAGE REGIMENS ON RESPONSE AND OVERALL SURVIVAL IN PRIMARY REFRACTORY ACUTE MYELOID LEUKEMIA

Background: Several studies have shown that nonresponse to the first induction therapy is a major unfavourable prognostic factor for outcome, and conventional chemotherapy offers almost no chance of cure for these patients. Therefore, allogeneic hematopoietic stem cell transplantation (HSCT) has been used for these patients. However, outcome even after allogeneic HSCT remains unfavourable and one major reason for this is that only a minority of these patients achieve a complete (CR) or partial (PR) remission before transplant. Thus, more effective salvage regimens in these primary refractory patients prior to transplant may improve outcome.
Aims: To evaluate the effectiveness of different salvage therapies in primary refractory patients in a cohort analysis of the German-Austrian AMLSG.
Methods: A total of n=3324 patients (age 18-60 years, n=2377; age >60 years, n=947) were accrued between 1993 and 2008 in 5 prospective treatment trials of the AMLSG. After first induction therapy with ICE, n=848 patients (26%) had primary refractory disease (age 18-60 years, 22%; age >60 years, 34%). Salvage therapies had been documented as well as further treatment including allogeneic HSCT. The following salvage regimens were used: 7+3-based (n=59), high-dose cytarabine-based (HiDAC) in the majority of patients combined with mitoxantrone (n=531), in combination with all-trans retinoic acid (ATRA) (n=357) and gemtuzumab ozogamicin (GO) (n=129) or fludarabine (FLU) within the FLA(G) regimen +/- idarubicine/mitoxantrone (n=73), as well as other intensive regimens (n=68), experimental treatment (n=26), and best supportive care (n=124). A total of 380 patients proceeded to an allogeneic HSCT, in 40 patients as a direct salvage therapy.
Results: Of 848 patients, 724 received intensive salvage therapy (85%; age 18-60 years, 96%; age >60 years, 68%). Response to salvage therapy in patients intensively treated was 37% CR and 9% PR resulting in an overall response rate of 46% (age 18-60 years, 56%; age >60 years, 22%). Multivariable regression models on the endpoint overall response in younger intensively treated adults (age 18-60 years) revealed salvage regimens including ATRA (OR, 2.23; p=0.0005), GO (OR, 3.05; p<0.0001), FLU (OR, 2.60; p=0.02) as well as direct allogeneic HSCT (OR, 5.56; p=0.0001) as favourable parameters, whereas high-risk cytogenetics (OR, 0.51; p=0.001) and log(10) white blood count (WBC) (OR 0.72, p=0.02) as unfavourable parameters. In older patients (age >60 years) again salvage regimens including FLU (OR, 3.37; p=0.003) was associated with better overall response. An extended Cox regression model (Andersen-Gill) on the endpoint overall survival in all patients including allogeneic HSCT as a time-dependent covariable revealed allogeneic HSCT (HR, 0.58; p<0.0001), salvage regimens including ATRA in combination with GO (HR, 0.61; p=0.05) and FLU (HR, 0.48, p=0.005) as favourable prognostic markers, whereas high-risk cytogenetics (HR, 2.05; p<0.0001), log(10)WBC (HR, 1.37; p<0.0001) and *FLT3*-ITD (OR, 1.40; p=0.007) were unfavourable covariables. Overall survival for patients proceeding to allogeneic HSCT after 4 years was 34% (95%>CI, 29-40%) and compared favourable to that of patients not proceeding to allogeneic HSCT with 8% (95%>CI, 2-13%, p<0.0001).
Summary and Conclusion: ATRA, GO and FLU as adjunct to intensive HiDAC-based salvage therapy improved response to salvage therapy and prolonged survival in primary refractory AML.

S1352

PHASE I/II PANOBIDARA STUDY OF PANOBINOSTAT IN COMBINATION WITH IDARUBICIN AND CYTARABINE IN PATIENTS AGED 65 YEARS OR OLDER WITH NEWLY DIAGNOSED ACUTE MYELOBLASTIC LEUKAEMIA (AML)

EM Ocio[1,*], P Herrera[2], MT Olave[3], MP Martinez[4], JA Perez-Simon[5], S Brunet[6], A Oriol[7], M Mateos[8], MÁ Sanz[9], J López[2], MV Mateos[1], J F San Miguel[10]
[1]Hematology, University Hospital of Salamanca-IBSAL, IBMCC (USAL-CSIC), Salamanca, Spain;, Salamanca, [2]Hematology, Hospital Ramón y Cajal, Madrid, [3]Hematology, Hospital Lozano Blesa, Zaragoza, [4]Hematology, Hospital Universitario 12 de Octubre, Madrid, [5]Hematology, Hospital Virgen del Rocío, Sevilla, [6]Hematology, Hospital de la Santa Creu y Sant Pau, Barcelona, [7]Hematology, Hospital Germans Trias i Pujol, Badalona, [8]Hematology, Hospital San Carlos, Madrid, [9]Hematology, Hospital Universitario La Fe, Valencia, [10]Hematology, Clínica Universidad de Navarra; Centro de Investigaciones Médicas Aplicadas (CIMA), Pamplona, Spain

Background: Elderly patients with Acute Myeloblastic Leukemia (AML) represent an unmet medical need and new strategies are required to improve CR rates and, most importantly, to prolong the TTP and OS. Panobinostat is a pan-deacetylase inhibitor, which has demonstrated *in vitro* antileukemic activity and high synergy with anthracyclines (Maiso *et al.* Leukemia 2009).
Aims: A dose-escalating phase I to define the MTD of panobinostat in this combination was followed by a phase 2 expansion phase. The initial schema included one or two induction cycles with idarubicine (8 mg/m^2 days 1-3) + cytarabine (100 mg/m^2 days 1-7) in combination with three weeks of oral panobinostat (days 8, 10, 12, 15, 17, 19, 22, 24, 26). Patients achieving CR/CRi received an identical consolidation cycle and afterwards maintenance with 40 mg oral panobinostat (3 days/week) for 3 weeks on and 1 week off. After the six first patients, panobinostat was reduced to two weeks in the cycles in combination and to every other week in the maintenance phase.
For comparison we have used an historical control of elderly patients treated in the Pethema group, using the same induction and consolidation without panobinostat, followed by an intensification with cytarabine + daunorubicine.
Results: 38 patients were included in the final schedule, 20 in the phase I and 18 in the phase II. Median age was 71 (65-83) with 32% of patients being ≥75. Median % blasts was 45 (20-93). Displastic features, adverse cytogenetics and hyperleucocytosis were present in 26%, 17% and 30% of patients respectively. Panobinostat 20 mg during induction resulted in 2/6 DLTs (G3 hyperbilirrubinaemia in both, and one of them also G3 oedema), and, accordingly the dose was reduced to 10 mg, without further DLTs. Despite the advanced age of this patient population, treatment was well tolerated in the intensive cycles with the toxicity typical of standard induction chemotherapy. Only 4 (11%) deaths were observed during induction (tumoral lysis syndrome, respiratory infection, acute pulmonary oedema and head trauma). Three more patients died in CR during consolidation due to infectious SAEs. Maintenance phase with panobinostat monotherapy was also well tolerated, being GI toxicity, haematological and asthenia the most frequent AEs (mostly G1-2). Seven out of the 19 patients in maintenance required dose reduction of panobinostat. The causes of reduction were haematological toxicity (2), GI (2); both hematological and GI (2) and a Clostridium difficile infection (1). No patient required panobinostat discontinuation. In terms of efficacy, 22 patients (58%) achieved CR plus 2 more (5%) CRi. With a median follow up of 13.5 months (range 5-29), median survival is 13 months (0-27) for the global population and has not been reached for patients achieving CR. This is superior to the 7.6 months (14.5 for patients in CR) observed in our historical control. Importantly, one of the main objectives was to test if panobinostat maintenance was able to prolong TTP in responding patients. Among the 22 patients that achieved CR, 9 have progressed to date, yielding a TTP of 17.0 months, that improves the 11.7 months of our historical control. Moreover, in at least two patients that started maintenance with positive MRD, panobinostat was able to eliminate the residual blasts.
Summary and Conclusion: This combination was shown to be safe at the MTD. Preliminary efficacy results are encouraging, particularly for the potential benefit of the maintenance phase, in prolonging TTP and subsequently OS in this poor prognostic population.

S1353

A PHASE 1 DOSE ESCALATION STUDY OF THE ORAL SELECTIVE INHIBITOR OF NUCLEAR EXPORT (SINE) SELINEXOR (KPT-330) IN PATIENTS (PTS) WITH RELAPSED / REFRACTORY ACUTE MYELOID LEUKEMIA (AML)

R Garzon[1,*], I Flinn[2], J Berdeja[2], D DeAngelo[3], M Wadleigh[3], K Yee[4], A Schuh[4], M Mau-Sorensen[5], P Brown[6], J Lancet[7], B Shah[7], M Gutierrez[8], N Gabrail[9], N Wagner-Johnston[10], W Blum[1], R Carlson[11], B Klebanov[11], D McCauley[11], E Shacham[11], J McCartney[11], T Marshall[11], JR Saint-Martin[11], S Rebello[12], T Rashal[11], M Kauffman[11], S Shacham[11], M Mirza[11], R Stone[3]
[1]The Ohio State University, Columbus; Ohio, [2]Sarah Cannon Research Institute, Nashville; Tennessee, [3]Dana Farber Cancer Institute, Boston; Massachusetts, United States, [4]Princess Margaret Cancer Center, Toronto; Ontario, Canada, [5]Department of Oncology, [6]Department of Hematology, Rigshospitalet University Hospital, Copenhagen, Denmark, [7]H. Lee Moffitt Cancer Center & Research Institute, Tampa; Florida, [8]Hackensack University Medical Center, Hackensack; New Jersey, [9]Gabrail Cancer Center, Canton; Ohio, [10]School of Medicine, Washington University, St. Louis; Missouri, [11]Karyopharm Therapeutics, Natick; Massachusetts, United States, [12]Ozmosis Research, Toronto; Ontario, Canada

Background: Selinexor (KPT-330) is a slowly reversible exportin 1 (XPO1) inhibitor that forces the nuclear retention and activation of >10 tumor suppressor proteins (TSP) including p53, and reduction in protein levels of the oncogenes Flt3 and Kit, and induces AML cell death while sparing normal hematopoietic cells.
Aims: Here we investigate the effect of selinexor on p53 and Flt3 in AML patient bone marrow (BM) biopsies as well as present updated results of selinexor in patients with AML.
Methods: Oral selinexor was given at 8-10 doses per 28-day cycle to patients with relapsed/refractory AML. Elevation in leukocyte XPO1 mRNA following XPO1 inhibition was used as a pharmacodynamic (PDn) marker for selinexor activity. Other PDn endpoints such as p53 and Flt3 were assessed in bone marrow (BM) before treatment and at Day 24 of Cycle 1. Pharmacokinetic (PK) analyses were performed. Appetite stimulants and anti-emetics were given as part of supportive care.
Results: Fifty-two heavily pretreated pts (median 3 prior regimens [range 1-7]; 25 M / 27 F; median age 67 yrs; ECOG PS 0/1: 13/39 received selinexor (8-10 doses / 4-week cycle) across 5 dose levels (16.8 - 55 mg/m^2). There have been no DLTs. Dosing at 70mg/m^2 is ongoing. Cycle 1 Grade 3/4 non-DLT, non-hematologic adverse events (AEs) in >1 pt included: fatigue (8%) and nausea (4%). The most common Cycle 1 Grade 1/2 AEs for 8 / 10 doses were diarrhea (42%/30%), anorexia (28%/42%), nausea (32%/46%), & fatigue (28%/29%). Prolonged administration (>4 months) of selinexor was feasible in 4 patients. PK and PD analyses showed dose-dependent increases in C_{max} / $AUC_{0\text{-}inf}$ ($T_{1/2}$ ~6 hrs) and increases in XPO1 mRNA. p53 accumulation and Flt3 protein down-regulation was observed in BM blasts of 10 patients after treatment with selinexor. Treatment with oral selinexor was associated with reductions in BM blast counts in 13 patients with post-baseline blast counts, and was observed across different AML subtypes (Figure 1). Overall response rate (ORR) including complete remission (CR), CR with incomplete hematological recovery (CRi), bone marrow CR (CRm), partial responses (PR) and morphological leukemia free state (MLFS) was 17% with a duration of responses of 6-13 weeks. Responses included: CR: 4 pts (8%); CRm in chloroma: 1 pt (2%); CRi: 1 pt (2%), MLFS: 1 pt (2%) and PR: 2 pts (4%). Twelve (23%) of the remaining pts have experienced stable disease for >30 days (including 1 pt for >10 months), 14 (27%) had progressive disease and 16 patients did not complete cycle 1 due to consent withdrawal, infections, deaths, or other reasons (31%). Infections were considered to be non-drug related, and there were no reported drug-associated Grade 5 events on study to date.

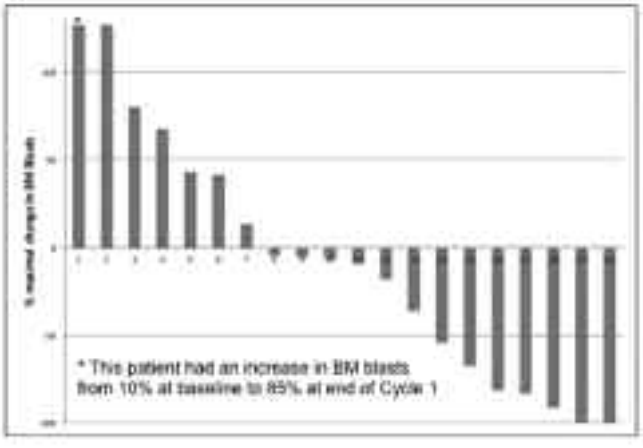

Figure 1. Maximum Change in Bone Marrow Blast Percentage vs. Baseline

Summary and Conclusion: Oral selinexor can be given over months and induce remissions in pts with heavily pretreated AML. A randomized study of selinexor *vs* available agents in older, chemotherapy-ineligible relapsed AML patients is being initiated.

S1354

PROGNOSTIC SIGNIFICANCE OF MINIMAL RESIDUAL DISEASE ASSESSED BY MULTIPARAMETRIC FLOW-CYTOMETRY IN CHILDHOOD ACUTE MYELOID LEUKEMIA

F Rizzati[1,*], B Buldini[1], R Rondelli[2], R Masetti[2], A Zangrando[1], S Disarò[1], P Scarparo[1], E Bortoloso[1], A Pession[2], F Locatelli[3], G Basso[1]
[1]Departement of Woman and Child Health, PEDIATRIC ONCO-HEMATOLGY PADUA, PADUA, [2]Department of Pediatrics, Pediatric Oncology-Haematology Lalla Seràgnoli, Bologna, [3]Pediatric Oncology-Haematology, IRCCS Ospedale Pediatrico Bambino Gesù, Roma, Università degli Studi di Pavia, Pavia, Italy

Background: Achievement of morphologic complete remission (CR) is a prerequisite for cure in acute myeloid leukemia (AML), but patients in morphological CR may still have variable levels of occult leukemia, defined as minimal residual disease (MRD). Over the last 2-3 decades, much effort has been made to develop accurate and sensitive methods that could determinate response to treatment more precisely than morphology, and to detect residual leukemia in patients considered in morphologic CR. MRD monitoring by multiparametric flow-cytometry (MFC) relies on expression of "leukemia-associated immunophenotypes" (LAIPs), defined as the presence of a combination of antigens and/or flow cytometric physical abnormalities that are absent or very infrequent in normal bone marrow (BM).
Aims: Aim of this study is to evaluate the prognostic impact of MRD assessed by MFC in childhood AML.
Methods: Patients younger than 18 years affected by *de novo* AML (diagnosis May 2003-May 2011), enrolled in AIEOP-LAM 2002 protocol, were eligible for this study. Bone marrow aspirates from 142 patients were collected at diagnosis (n=142), at the end of induction 1 (n=142), and at the end of induction 2 (n=94), according to samples availability. MRD was assessed during follow-up, by five-color MFC, through the detection of patient-specific leukaemia associated aberrant phenotypes, defined for each patient at diagnosis. We used during follow-up 1-3 combinations per patient and each combination included the following common antigen backbone CD45(ECD)/CD33(PEcy5)/CD34(PEcy7) and two specific antigens defined for each patient at diagnosis, according to patient specific LAIPs. SYTO16 combination (SYTO16/GLY-A/CD45/7AAD) was used to assess nucleated cells (SYTO16+) and to identify dead cells (7AAD+) in each sample.
Results: Among the 142 patients recruited to this study, at the end of induction 1 35.9% presented MRD≥1%, 11.3% MRD 0.1-1% and 48.6% MRD<0.1%; samples from 6 patients were not evaluable. We assessed the correlation between levels of MFC-MRD and disease-free-survival (DFS), by means of the Kaplan-Meier method. Presence of MRD≥0.1%, at the end of induction 1, was associated with a DFS of 35.29±7.23% at 6 years, whereas MRD<0.1% with a DFS of 73.16±5.62% at 6 years (p<0.01). MFC-MRD was assessed also after induction 2 in 94 (66.2%) of the 142 patients. We evaluate the correlation between levels of MFC-MRD at the end of induction 2 and DFS, by means of the Kaplan-Meier method. The 6 years DFS-probability, assessed in the 36 (38.3%) patients with MRD data ≥0.1% at the end of induction 1, was 45.4% (SE 16.7) for patients with MRD<0.1% at the end of induction 2, and 22.8% (SE 8.9) for patients who were MRD≥0.1% at the end of induction 2 (p 0.10).
Summary and Conclusion: Our study revealed a significant correlation between MFC-MRD at the end of induction 1, and the patient's outcome: MRD≥0.1% appeared to be predictive of poor outcome (MRD≥0.1%, at the end of induction 1, was associated with a DFS of 35.29±7.23% at 6 years, whereas MRD<0.1% with a DFS of 73.16±5.62% at 6 years). Our data suggest that MFC-MRD at the end of induction 1 provides important prognostic informations that may be used to a better stratification and to guide therapy of childhood AML.

Myeloproliferative neoplasms - Clinical 1

CALR MUTATION IS A STRONG INDEPENDENT FAVORABLE PROGNOSTIC VARIABLE IN PRIMARY MYELOFIBROSIS

P Guglielmelli[1,*], G Rotunno[1], C Mannarelli[1], A Pacilli[1], T Fanelli[1], A Pancrazzi[1], L Pieri[1], R Fjerza[1], A Bosi[1], E Rumi[2], D Pietra[2], V Rosti[3], G Barosi[3], M Cazzola[2], A M Vannucchi[1]
[1]Department of Experimental and Clinical Medicine, University of Florence, Florence, [2]Department of Hematology Oncology, Fondazione IRCCS Policlinico San Matteo, University of Pavia, [3]Center for the Study of Myelofibrosis, Biotechnology Research Area, IRCCS Policlinico San Matteo Foundation, Pavia, Italy

Background: Mutations in the calreticulin (CALR) gene were recently discovered in approx. 60% of patients (pts) with primary myelofibrosis (PMF) unmutated for JAK2V617F and MPLW515. In retrospective studies, CALR mutated PMF had better overall survival (OS) compared with JAK2V617F or MPLW515 mutated. A prognostic synergism between CALR and ASXL1 mutations was recently reported, highlighting the inferior OS associated with "CALR–ASXL1+" mutation status. We previously also reported that mutations in any one of ASXL1, EZH2, IDH1/2 and SRSF2 identify a High Molecular Risk category (HMR) in PMF predicting for worse OS and leukemia free survival (LFS).
Aims: In this study involving a series of 274 PMF pts from 3 Italian centers we aimed to investigate the prognostic role of CALR mutations in relation to the presence of additional subclonal mutations.
Methods: PMF diagnosis was according to 2008 WHO criteria and all pts provided an informed consent. Genotyping for CALR, JAK2V617F, MPLW515, EZH2, ASXL1, TET2, IDH1/2, DNMT3A, CBL, SRSF2 was performed in granulocytes using allele specific RTQ-PCR, HRM or direct sequencing. The prognostic value of the molecular variables with regard to OS was estimated by the Kaplan-Meier method and Cox regression.
Results: Pts median age was 58y. Median follow-up was 3.8y. Death occurred in 85 pts (31%). IPSS risk category: low-risk 45.5%, Int-1 25.9%, Int-2 16.5%, High-risk 12%. Frequency of mutations was: CALR 24.8%, *JAK2*V617F 56.2%; *MPL*W515 6.6%; *EZH2* 3.3%; *ASXL1* 19.3%; *TET2* 10.3%; *IDH1-2* 1.5%; *DNMT3A* 5.5%; *CBL* 6.0%; *SRSF2* 7.5%. Seventy-three pts (26.6%) were included in the HMR category, while 18 (6.5%) were unmutated for all genes assessed ("all mutations negative"). Median OS in the entire series was 11.7y; 23y in low-risk, 6.5y Int-1, 4.2y Int-2, 2.3y high-risk (P<0.0001). CALR mutated pts showed a significantly better OS with a median of 20.2y (HR 0.46, 95% CI 0.27-0.78) compared with WT pts (median 8.2y; P=0.003). IPSS-adjusted multivariable analysis confirmed the independent prognostic relevance of CALR mutations for OS (HR 0.14, 95% CI 0.27-0.86; P<0.0001) in the lower (low and intermediate-1) IPSS risk categories (median survival, 27.7y *vs* 21.7y, respectively for CALR+ and CALR wt; P=0.02) while the difference was borderline in the higher (intermediate-2 and high risk; 4.2y *vs* 2.6y, respectively; P=0.09) risk categories. HMR-adjusted multivariable analysis showed an independent prognostic role of CALR mutations for OS (HR 0.44, 95% CI 0.26-0.77; P<0.0001) in both HMR (17.7y *vs* 4.2y, respectively; P=0.008) and LMR (20.2y *vs* 8.2y, respectively; P=0.003) categories. Frequency of HMR-subclonal mutations was similar in CALR (22.2%) and JAK2V617F (23.0%) mutated patients. We analyzed the individual impact of any of the 10 genotyped genes in CALR mutated pts and found that the positive effect of CALR mutation was not influenced by any of the additional subclonal mutated genes. We also observed that "all mutations negative" pts constituted a worse prognosis group with OS similar to HMR+ category (9.2y and 6.7yr, respectively; P<0.0001 *vs* LMR, median survival 20.2y).
Summary and Conclusion: Overall, these results confirm the favorable outcome of CALR mutated PMF patients and show that additional subclonal mutations do not impair such positive impact, reinforcing the idea that CALR+ PMF is a distinct entity in terms of prognosis. The adverse outcome associated with "all mutations negative" pts suggests the presence of novel molecular abnormalities that remain to be identified.

S1356

CLINICAL EFFECT OF FOUNDING DRIVER MUTATIONS IN PATIENTS WITH PRIMARY MYELOFIBROSIS: A BASIS FOR MOLECULAR CLASSIFICATION AND PROGNOSTICATION

E Rumi[1,*], D Pietra[1], P Guglielmelli[2], A Martínez-Trillos[3], I Casetti[1], D Colomer[3], L Pieri[2], M Pratcorona[3], G Rotunno[2], E Sant'Antonio[1], M Bellini[1], C Cavalloni[1], C Mannarelli[2], C Milanesi[1], E Boveri[4], V Ferretti[1], C Pascutto[1], C Astori[1], V Rosti[5], F Cervantes[3], G Barosi[5], A Vannucchi[2], M Cazzola[1]
[1]Department of Hematology Oncology, Fondazione IRCCS Policlinico San Matteo, and Department of Molecular Medicine, University of Pavia, Pavia, [2]Department of Experimental and Clinical Medicine, University of Florence, Florence, Italy, [3]Hematology Department, Hospital Clinic, University of Barcelona, Barcelona, Spain, [4]Anatomic Pathology Section, Fondazione IRCCS Policlinico San Matteo, Pavia, [5]Center for the Study of Myelofibrosis, Fondazione IRCCS Policlinico San Matteo, Pavia, Pavia, Italy

Background: Primary myelofibrosis (PMF) is the Philadelphia-negative myeloproliferative neoplasm (MPN) with the worst prognosis, with a median survival of 6.5 years. Current prognostication at diagnosis is based on the International Prognostic Scoring System (IPSS), which includes anemia, age, constitutional symptoms, leukocytosis, and circulating blasts. The dynamic IPSS (DIPSS) can be used at any time during the clinical course of the disease. The vast majority of PMF patients has now a molecular marker: *JAK2* or *MPL* mutations are found in 60-70% of patients, whereas *CALR* (calreticulin gene) mutations account for the majority of the remaining cases. The molecular characterization of patients with nonmutated *JAK2*, *CALR*, and *MPL* remains an important unanswered question.
Aims: In a large cohort of PMF patients, we studied the impact of the three founding driver mutations (*JAK2*, *MPL*, and *CALR*) on clinical phenotype, risk of evolution into acute myeloid leukemia (AML) and overall survival (OS).
Methods: Inclusion in the current study required availability of clinical data at diagnosis to calculate IPSS and at least one DNA sample to assess mutation status of the above driver genes. A total of 629 patients with PMF were recruited from 4 centers. Diagnosis of PMF and that of AML were done according to WHO criteria. All patients were screened for *JAK2*, *MPL* and *CALR* mutations with methods previously reported. The 4 genotypic subgroups (*JAK2* mutated, *MPL* mutated, *CALR* mutated, and triple negative) were compared in terms of phenotype at diagnosis, cumulative incidence (CI) of leukemic evolution, and OS.
Results: Of 629 PMF patients studied, 407 (64.7%) carried *JAK2* (V617F), 141 (22.4%) carried *CALR* mutations, 25 (4%) carried *MPL* mutations, and 56 (8.9%) were triple-negative. Within *CALR* mutated patients, 72% had the 52-bp deletion (type 1 mutation): this frequency is significantly higher than that we previously found in patients with essential thrombocythemia (46%, *P*<.001). The clinical phenotype at diagnosis differed according to mutation status: in particular, *CALR* mutated patients had younger age, lower leukocyte count, higher platelet count, and lower IPSS and DIPSS risk distribution (*P*<.001 in all comparisons).The founding driver mutation had a major impact on both leukemic evolution and OS. Seventy-six out of 629 (12%) patients developed AML. Triple-negative patients had the highest CI of leukemic evolution whereas *CALR* mutated patients had the lowest CI (the 10-years CI of AML was 31.9% *vs* 9.5%, respectively, *P*=.028).In univariate analysis, the OS of *CALR* mutated patients was longer (median survival equal to 18 years) than that of *JAK2* mutated subjects (median survival 9 years, HR 2.3, *P*<.001), *MPL* mutated subjects (median survival 9 years, HR 2.6, *P*=.009), and triple negative subjects (median survival 4 years, HR 5.2, *P*<.001). The impact of the founding mutation on OS was independent of IPSS at diagnosis, DIPSS at diagnosis, and time-dependent DIPSS (max *P*=.021).
Summary and Conclusion: Accounting for *JAK2*, *CALR*, and *MPL* mutation status is of fundamental diagnostic and prognostic relevance in myeloid neoplasms with bone marrow fibrosis. The high frequency of *CALR* type 1 mutation in PMF suggests a particularly active role of the 52 bp-deletion in determining marrow fibrosis and extramedullary hematopoiesis. Patients with nonmutated *JAK2*, *CALR*, and *MPL* have a myeloid neoplasm that combines myelodisplastic features with bone marrow fibrosis and has a very poor prognosis with a particularly high risk of leukemic evolution.

S1357

CLINICAL AND MOLECULAR RESPONSE TO INTERFERON ALPHA THERAPY IN ESSENTIAL THROMBOCYTHEMIA PATIENTS WITH CALR MUTATIONS

E Verger[1,2,*], B Cassinat[1], C Dosquet[1], A Andreoli[3], MH schlageter[1], C Chomienne[1,2], JJ Kiladjian[2,3]
[1]Service de Biologie Cellulaire, Hopital Saint-Louis, AP-HP, [2]Universite Paris-Diderot, [3]Centre d'Investigations Cliniques, Hopital Saint-Louis, AP-HP, Paris, France

Background: Somatic mutations in the calreticulin encoding gene (*CALR*) were recently described in the majority of patients (pts) with myeloproliferative neoplasms (MPNs) with non-mutated *JAK2* gene. These mutations represent the second most frequent molecular marker for pts with essential thrombocythemia (ET) and myelofibrosis (MF). We, followed by other groups, have previously shown that interferon-alpha (IFNa) induces complete hematological responses in *JAK2* mutated MPN pts. We showed that IFNa may reduce the *JAK2*-mutated clone and induce complete molecular responses in selected pts. We have also reported that *TET2* mutated clones could be resistant to IFNa therapy.
Aims: As the impact of IFNa on clones with molecular lesions other than *JAK2* mutations is thus uncertain and wild type calreticulin is reported to be involved in the resistance to IFNa in viral hepatitis infection, we analyzed the impact of IFNa therapy in *CALR* mutated MPN pts.
Methods: Total DNA was extracted from blood samples using Qiagen blood DNA mini kits. The following analyses were performed in MPN pts treated with peg-IFNa-2a in our Hospital after informed consent. First, *CALR* gene mutations were searched using direct Sanger sequencing of the exon 9. Then *CALR* mutant allele burden was evaluated by fragment analysis, allowing to determine the peak area ratio between mutant and wild type alleles (GeneMapper software, Life technologies). Both sequencing and fragment analysis were performed on a 3500xL DX Genetic Analyser (Life technologies). Finally mutations in *TET2*, *ASXL1*, *EZH2*, *SRSF2*, *IDH1* and *IDH2* were searched through a Next Generation Sequencing (NGS) approach on a MiSeq instrument using a TruSeq custom amplicon approach (Illumina).
Results: We identified 35 ET pts treated by peg-IFNa-2a with no detectable *JAK2* or *MPL* mutations. Direct sequencing of the *CALR* gene exon 9 identified the presence of mutations in 26/35 pts, and sequential DNA samples taken before and during IFNa treatment were available in 14 of them. In 5 of these 14 pts, the mutation was the 52bp deletion (p.L367fs*46) and in 6 pts, the 5bp insertion (p.K385fs*47) while less frequent mutations were detected in 3 pts (p.Q365fs*50 and K375fs*49). The search for additional mutations by a NGS approach is ongoing, with other mutations detected in some pts. Complete results of NGS analyses will be presented at the meeting. Median IFNa treatment duration was 26.5 months (range: 10-96). All of the 14 pts achieved complete hematological response (ELN criteria). Using a quantitative fragment analysis approach we measured the mutant *CALR* allele burden (%*CALR*) in samples taken before, during and after treatment discontinuation. The median %*CALR* was 43% (range: 8-51) before IFNa and 19% (rage: 3-49) in the last available sample (p=0.018). Duration of treatment could influence the molecular response: the %*CALR* dramatically dropped by more than 90% in 4 pts with a long exposure to IFNa (median of 60 months), while no significant difference was observed in 7 pts with shorter exposure (median of 18 months). Finally, a re-increase of the %*CALR* from 18 to 46% was observed in a patient with evolution to post-ET MF 28 months after IFNa discontinuation.
Summary and Conclusion: IFNa therapy is highly effective in ET patients with *CALR* mutations, inducing a high rate of hematological and molecular responses. These results also suggest that CALR-mutant allele burden could be a useful biomarker for monitoring disease evolution and response to therapy.

S1358

ASSESSING THE SAFETY AND EFFICACY OF RUXOLITINIB IN AN OPEN-LABEL, MULTICENTER, EXPANDED-ACCESS STUDY IN PATIENTS WITH MYELOFIBROSIS: A 520-PATIENT UPDATE

HK Al-Ali[1,*], P Le Coutre[2], R Schlag[3], M Griesshammer[4], R Tavares[5], B Martino[6], A M Vannucchi[7], PG Castellano[8], L Foltz[9], P Raanani[10], B Tannir[11], J Ghosh[12], JP Ronco[11], V Gupta[13]

Schöttker, Würzburg, [4]Johannes-Wesling Academic Medical Center, University of Hannover Teaching Hospital, Minden, Germany, [5]Universidade Federal de Goiania, Goiania, Brazil, [6]Az.Osp. Bianchi-Melacrino'-Morelli, Reggio Calabria, [7]University of Florence, Florence, Italy, [8]Miguel Servet University Hospital and Centro de Investigación Biomédica en Red de Enfermedades Raras (CIBERER), Zaragoza, Spain, [9]St. Paul's Hospital, University of British Columbia, Vancouver, Canada, [10]Rabin Medical Center, Petah Tikva, Israel, [11]Novartis Pharma AG, Basel, Switzerland, [12]Novartis Pharmaceuticals Corporation, East Hanover, United States, [13]Princess Margaret Cancer Centre, Toronto, Canada

Background: Ruxolitinib (RUX) is a potent JAK1/JAK2-inhibitor that has demonstrated durable improvements in splenomegaly, myelofibrosis (MF)-related symptoms, and quality of life, and has been associated with improved survival in patients (pts) with MF. For countries with no access to RUX outside of a clinical trial, the phase 3b expanded-access JAK Inhibitor Ruxolitinib in Myelofibrosis Patients (JUMP) trial was designed to assess the safety and efficacy of RUX in pts with primary MF (PMF), post–polycythemia vera MF (PPV-MF), or post–essential thrombocythemia MF (PET-MF) who are treatment naive, had progressed, or are intolerant of prior therapy. As of December 2, 2013, 1784 pts have been enrolled in 25 countries.
Aims: To report the safety and efficacy of RUX in pts enrolled in the JUMP study.
Methods: Pts with PMF, PPV-MF, or PET-MF classified as high-risk, intermediate (int)-2 risk, or int-1 risk with an enlarged spleen (≥ 5 cm from costal margin) were included. The primary endpoint is to assess the safety of RUX. Additional endpoints include the proportion of pts with a >50% reduction in palpable spleen length, progression-free survival (PFS), leukemia-free survival (LFS), and overall survival (OS).

Results: 520 enrolled pts (PMF, n=313; PPV-MF, n=122; PET-MF, n=84; missing, n=1) with a median exposure of 11 months were evaluable at time of data cutoff (March 31, 2013). The median age was 68 years (range, 32-88 years) and 51.5% (n=268) were male. At time of data cutoff, most pts were ongoing or had completed treatment as per protocol, including transition to commercial drug (28.3% [n=145] and 42.9% [n=223], respectively); 29.2% (n=152) had discontinued treatment for other reasons. Due to adverse events (AEs), 59.1% of pts experienced a dose reduction/interruption. Overall, 14.6% of pts (n=76) experienced an AE that led to study drug discontinuation, most commonly due to anemia (1.9%, n=10) or thrombocytopenia (1.4%, n=7). The most common hematologic grade ≥ 3 AEs were anemia (32.5%, n=169) and thrombocytopenia (10.8%, n=56). Mean hemoglobin levels declined from baseline (BL; 107.2 g/L) to a nadir of 94.2 g/L at approximately 12 weeks of therapy and increased to 98.4 g/L by week 24. Rates of nonhematologic grade ≥ 3 AEs regardless of study drug relationship were low overall (**Table 1**). At week 24, 56.2% (n=182) and 24.0% (n=78) of pts experienced ≥ 50% reduction and 25% to 50% reduction in palpable spleen length from BL, respectively. Best response from BL in palpable spleen length by week 24 for each patient is shown in **Figure 1**. The estimated probability of PFS, LFS, and OS at 48 weeks was 0.88 (95% CI, 0.84-0.91), 0.91 (95% CI, 0.88-0.94), and 0.92 (95% CI, 0.89-0.94), respectively.

Table 1. Nonhematologic Grade ≥ 3 AEs Regardless of Study Drug Relationship (>1%)

Preferred Term	All Pts; N=520; n (%)
Pneumonia	19 (3.7)
Dyspnea	9 (1.7)
Diarrhea	8 (1.5)
Pyrexia	8 (1.5)
General physical health deterioration	7 (1.4)
Abdominal pain	6 (1.2)
Urinary tract infection	6 (1.2)
Arthralgia	6 (1.2)

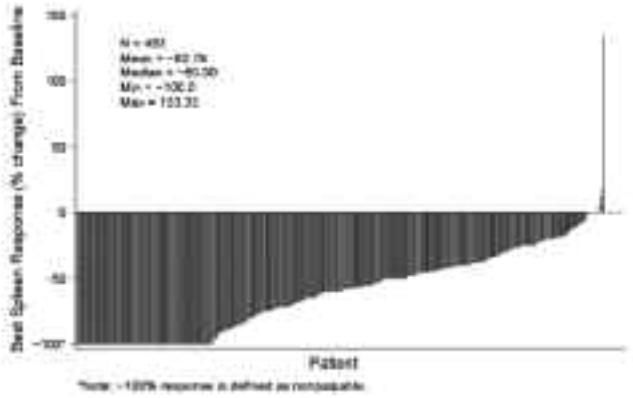

Figure 1. Best Spleen Response from Baseline by Week 24 for Each Patient (% Change in Palpable Spleen Length)

Summary and Conclusion: The JUMP study includes the largest cohort of MF pts treated with RUX reported to date. Consistent with RUX's mechanism of action, the most common AEs were anemia and thrombocytopenia; however, these AEs led to discontinuation in only 10 and 7 pts, respectively. As observed in other studies with RUX, the majority of pts in JUMP experienced spleen size reductions. The safety and efficacy of RUX in JUMP is consistent with the phase 3 COMFORT studies.

S1359

A PHASE I/II, OPEN-LABEL STUDY EVALUATING TWICE-DAILY ADMINISTRATION OF MOMELOTINIB (GS-0387, CYT387) IN PRIMARY MYELOFIBROSIS OR POST-POLYCYTHEMIA VERA OR POST-ESSENTIAL THROMBOCYTHEMIA MYELOFIBROSIS

V Gupta[1,*], R Mesa[2], M Deininger[3], C Rivera[4], S Sirhan[5], J Kawashima[6], L Shao[7], H Collins[8], S Verstovsek[9]

[1]Princess Margaret Cancer Center, Toronto, Canada, [2]Mayo Clinic Cancer Center, Scottsdale, Arizona, [3]Division of Hematology and Hematologic Malignancies, Huntsman Cancer Institute, Salt Lake City, Utah, [4]Mayo Clinic Cancer Center, Jacksonville, Florida, United States, [5]Division of Hematology, Jewish General Hospital, Montreal, Canada, [6]Department of Safety and Public Health, [7]Biostatistics, [8]Oncology Therapeutics, Gilead Sciences, Foster City, [9]MD Anderson Cancer Center, Houston, Texas, United States

Background: Momelotinib (MMB) is a JAK1/2 inhibitor under investigation for the treatment of MF. Results from a phase 1/2 study identified a maximum tolerated dose of 300 mg orally once daily (QD).

Aims: To investigate if additional benefit might be achieved with MMB in a twice daily (BID) regimen, further dose escalation was carried out in this Phase 1/2 study. Remaining patients (pts) have reached a minimum of 12 mos on study as of this interim analysis, 1 Nov 2013.

Methods: Pts with MF categorized as IPSS high risk, int-2 risk, or int-1 risk with symptomatic splenomegaly or hepatomegaly, and platelet (plt) ≥ 50 x 10^9/L, were enrolled and provided written informed consent. Following a dose escalation phase, pts were treated on a dose expansion phase until loss of clinical benefit or intolerance. Spleen responses by physical examination were assessed for pts with baseline splenomegaly >5 cm and by MRI for all pts with spleens. Transfusion (txn) independence, hemoglobin (Hb) and symptoms were documented at baseline and subsequent visits.

Results: 61 pts were administered MMB at initial doses of 200 mg BID (n=54) or 250 mg BID (n=7); 47% pts had IPSS high risk and 40% int-2 risk. Median palpable spleen size was 14 cm and 32% pts were txn dependent. Prior treatment included JAK inhibitors in 23% of pts and immunomodulators in 26%. Median time on MMB was 335 days (range 2 - 674). The most common reasons for ending study were adverse events (AEs) (n=17), consent withdrawal (n=7) and disease progression (n=5). AEs were peripheral neuropathy (n=4), dysaethesias (n=1), declining performance status (n=2), elevated creatinine (n=1), prolonged QTc (n=1), acute coronary syndrome (n=1) and transaminase increase (n=2). Fatal AEs were CNS bleed (n=3), pneumonia (n=1) and MF progression (n=1), none drug related.

No dose limiting toxicity was identified at the 250 mg BID dose, but as it required dose interruptions and modifications most commonly due to thrombocytopenia (n=4), the safety committee chose 200 mg BID for dose-expansion. The most common ≥ Grade 3 AEs were thrombocytopenia (28%), pneumonia (12%), fatigue (12%), elevated lipase (8%), and anemia (7%). 49% of pts reported an AE on the first day, which generally consisted of G1/G2 dizziness, headache and/or hypotension which resolved without intervention. Nausea from all causes was reported in 34% of pts; 26% G1, 6% G2, 2% G3. Diarrhea from all causes was reported in 48% of pts; 33% G1, 11% G2, 3% G3. Cardiac disorders were reported in 21% of pts; including 3% heart failure, 5% atrial fib/flutter, 1 pt (previous heart transplant) with AV block and ventricular tachycardia, 1 pt with sick sinus syndrome, and 2 pts with G1 bradycardia. Additionally, 1 pt with prolonged QTc at baseline became more prolonged (G1). Peripheral neuropathy was reported in 46% of pts; 20% G1, 25% G2 and 2% G3. Only 1/12 pts who were txn independent with Hb ≥ 10gm/dL at baseline reported an AE of anemia (G1) in the first 6 mos. 4/53 pts with baseline plt count ≥ 75 x 10^9, reported a plt count<25 x 10^9.

Table 1.

EFFICACY ANALYSIS TABLE	Number of Patients (%)
Received at least one dose of MMB and underwent at least one evaluation for response	60 (100)
Spleen Response by physical examination	
Baseline palpable splenomegaly > 5 cm	30 (83.3)
≥ 50% reduction in palpable splenomegaly that lasted ≥ 8 weeks for baseline splenomegaly ≥ 10 cm: A (n= 30)	26
Resolution of palpable splenomegaly that lasts ≥ 8 weeks for baseline splenomegaly > 5 and < 10 cm: B (n = 12)	7
Spleen Response: A + B	33 (66.0)
Median time to onset of spleen response (n = 33)	43 days (8-511)
Median duration of spleen response (range) (n = 33)	288 (56 – 630 +)
Spleen Response by MRI	
Baseline MRI (pts without prior splenectomy)	38 (84.7)
≥ 35% reduction in spleen volume by MRI at 24 weeks	27 (48.6)
Anemia Response	
Transfusion dependent at baseline, Cole criteria (≥ 4 units for the 12 weeks prior and ≥ 1 unit in 28 days prior to the first dose of MMB)	19 (31.7)
Achieved transfusion independence ≥ 12 weeks: A (A/19)	6 (31.6)
Median time to onset of transfusion independence, Cole criteria (range) (n = 6)	136 days (1-239)
Median duration of transfusion independence, Cole criteria (range) (n = 6)	Not reached (85 – 64 + days)
Transfusion independent with Hb < 10 g/dL at baseline	8 (13.3)
Rise in Hb ≥ 2 g/dL for ≥ 12 weeks: B (n=8)	1 (12.5)
Overall anemia response A + B (A + B/27)	7 (25.9)
Constitutional Symptoms (MFSAF) Best response for patients with baseline symptom and at least one follow-up assessment	**Patients with ≥ 50% decrease in baseline**
Total Symptom Score, (n = 32)	20 (55.6)
Abdominal discomfort (n = 39)	32 (82.1)
Abdominal pain (n = 29)	20 (69.7)
Bone Pain (n= 30)	25 (83.3)
Itching (n = 25)	25 (100)
Night Sweats: (n=33)	32 (91.4)
Early Satiety: (n=48)	34 (70.8)
Worst Feeling of previous 24 hrs (n= 54)	32 (59.3)
TSS ≥ 50% decrease in baseline at 6 months (n = 25)	12 (48.0)

Summary and Conclusion: MMB at a 200 mg BID dose has an acceptable toxicity profile, and is effective in reducing splenomegaly, in ameliorating

constitutional symptoms, and further demonstrates beneficial effect on anemia. Although comparisons between small single arm studies should be interpreted with caution, no additional therapeutic benefit was observed compared to previous reports at the total daily dose of 300 mg. The results of this study support selection of the 300 mg QD capsule formulation as the starting dose for the phase 3 study of MMB in pts with MF

Chronic myeloid leukemia - Clinical 2

S1360

OVERALL SURVIVAL AND PROGNOSIS IN 2190 PATIENTS WITH FIRST-LINE IMATINIB TREATMENT CONSIDERING DEATH DUE TO CHRONIC MYELOID LEUKAEMIA AS THE ONLY EVENT

M Pfirrmann[1,*], S Saussele[2], M Baccarani[3], J Guilhot[4], F Cervantes[5], G Ossenkoppele[6], D Lindoerfer[1], *vs* Hoffmann[1], F Castagnetti[3], R Hehlmann[2], B Simonsson[7]

[1]Institut für Medizinische Informationsverarbeitung, Biometrie und Epidemiologie (IBE), LMU München, München, [2]III. Medizinische Klinik, Universitätsmedizin Mannheim, Universität Heidelberg, Mannheim, Germany, [3]Hematology and Oncology L. and A. Seragnoli, S. Orsola-Malpighi Hospital, University of Bologna, Bologna, Italy, [4]Clinical Investigation Centre - INSERM CIC 0802, University Hospital of Poitiers, Poitiers, France, [5]Hematology Department, Hospital Clinic, IDIBAPS, University of Barcelona, Barcelona, Spain, [6]Department of Haematology, VU University Medical Center, Amsterdam, Netherlands, [7]University of Uppsala, Uppsala, Sweden

Background: The IN-study section of the European Treatment and Outcome Study (EUTOS) registry comprises data on 2410 patients with chronic myeloid leukaemia (CML) who were enrolled between 2002 and 2006 in prospective, controlled clinical trials. All patients had Philadelphia chromosome-positive chronic-phase (CP) CML and were on first-line imatinib-based treatment within half a year after diagnosis.

Aims: To describe long-term survival and identify variables with a prognostic influence on overall survival (OS) when death due to CML is considered as the only event.

Methods: Survival was censored at the time of allogeneic stem cell transplantation (SCT) in first CP. Only death after recorded disease progression was regarded as death due to CML. Cumulative incidence probabilities (CIPs) of death due to CML were estimated, treating death due to any other cause as a competing event. All prognostic factors were measured at baseline. Their influence on the cause-specific hazard of dying from CML was analyzed using Cox regression, allowing fractional polynomials for continuous variables. Candidate variables were age, sex, spleen size enlargement, haemoglobin, platelets, leukocytes, and percentages of blasts, eosinophils, and basophils in peripheral blood. Risk groups of the final model were identified by using the minimal p-value approach with adjustment for multiple testing. Overall level of significance was 0.05.

Results: Patients of study groups in Germany, France, Italy, Spain, the Netherlands, and the Nordic study group had sufficient follow-up with a common median observation time of 6.4 years; 2190 patients had complete data for all candidate prognostic factors. Allogeneic SCT in first CP was performed in 92 patients (4%, 24 died). Without prior SCT in first CP, 193 patients died, 8-year CIP was 11% [95%>confidence interval (CI): 9-13%]. In 86 cases (45% of 193), cause of death was CML (not due to CML: n=96, 50%, unknown cause: n=11, 6%). Eight-year CIP due to CML was 4% [95%>CI: 3-5%] and 7% [95%>CI: 5-8%] due to other causes including unknown. Higher age, more blasts, a bigger spleen size enlargement, and low platelet counts significantly increased the hazard of dying from CML. The four factors were combined in a new prognostic model. Use of the minimal p-value approach resulted in three risk groups with statistically significantly different CIPs due to CML. Eight-year CIPs were 2% [n=1082, 95%>C.I.: 1-3%], 5% [n=759, 95%>C.I.: 4-7%], and 11% [n=349, 95%>C.I.: 8-15%]. The risk groups according to the Sokal score had 8-year CIPs of 3% [95%>C.I.: 2-4%], 4% [95%>C.I.: 3-6%], and 7% [n=497, 95%>C.I.: 5-10%]. The Euro score resulted in three groups with 8-year CIPs of 4% [95%>C.I.: 3-5%], 3% [95%>C.I.: 2-4%], and 12% [n=221, 95%>C.I.: 8-17%]. The EUTOS score suggested two groups with 8-year CIPs of 4% [95%>C.I.: 3-5%], and 9% [n=230, 95%>C.I.: 5-14%].

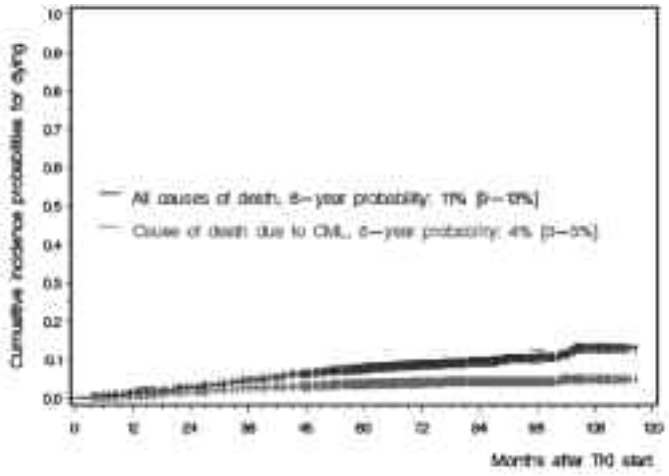

Figure 1.

Summary and Conclusion: For assessment of comparability between patient samples, prognostic models built from baseline variables remain important. In relation to other significant variables, in the new prognostic model, the importance of age was distinctly reduced when compared to models where all causes of death counted as an event. The risk groups also had significantly different CIPs when all causes of death or only progression were considered as event. In comparison to other scores, only the new model identified three risk groups with pairwise significantly different CIPs. The new model led to the largest patient groups with an 8-year CIP above 10%. Independent data for further comparisons are collected.

EARLY MOLECULAR RESPONSE PREDICTS ACHIEVEMENT OF UNDETECTABLE BCR-ABL IN PATIENTS (PTS) WITH CHRONIC MYELOID LEUKEMIA IN CHRONIC PHASE (CML-CP) TREATED WITH NILOTINIB: 3-YEAR FOLLOW-UP OF ENESTCMR

Ltd., Hyderabad, India, [12]Novartis Pharmaceuticals Corporation, East Hanover, United States, [13]Hospital Clínic, IDIBAPS, University of Barcelona, Barcelona, Spain

Background: ENESTcmr demonstrated that switching to nilotinib resulted in deeper and faster molecular responses (MRs) in CML-CP pts with detectable BCR-ABL on long-term imatinib therapy.
Aims: We present 3-y results, with a focus on predictors of response in nilotinib-treated pts.
Methods: Pts treated with imatinib for ≥ 2 y with complete cytogenetic response but detectable BCR-ABL were randomized to nilotinib 400 mg twice daily (n=104) or to continue imatinib (400 or 600 mg once daily; n=103). Crossover from imatinib to nilotinib was allowed for detectable BCR-ABL at 2 y or treatment failure/confirmed loss of response at any time. The association between early MR and achievement of confirmed (in 2 consecutive samples) undetectable (by RQ-PCR with sensitivity of ≥ 4.5 logs) BCR-ABL by 2 y was analyzed in the 91 nilotinib-treated pts with detectable BCR-ABL at study start who remained on study and had available samples at 3 mo. Confirmed undetectable BCR-ABL by 2 y was analyzed by (1) BCR-ABL level at 3 mo (≤ 0.005% or >0.005%) and (2) whether BCR-ABL level at mo 3 was half of baseline (BL) BCR-ABL (halving time ≤ or >90 d). The BCR-ABL ≤ 0.005% threshold was chosen because it represented the lowest quartile BCR-ABL value at 3 mo in nilotinib-treated pts.
Results: Switching to nilotinib continued to result in higher rates of $MR^{4.5}$ ($BCR\text{-}ABL^{IS}$ ≤ 0.0032%) *vs* remaining on imatinib (cumulative incidence of $MR^{4.5}$ by 3 y in pts without $MR^{4.5}$ at BL, 47% v 33% in the nilotinib and imatinib arms, respectively; *P*=.045; intention-to-treat analysis). Median time to $MR^{4.5}$ was 2 y in the nilotinib arm and was not reached in the imatinib arm by 3 y. 46 pts in the imatinib arm crossed over to nilotinib. Including only responses up to crossover in patients without $MR^{4.5}$ at BL, 47% of pts in the nilotinib arm *vs* 24% in the imatinib arm achieved $MR^{4.5}$ by 3 y (*P*=.0003). At 2 y, 52 pts on nilotinib and 78 pts on imatinib had detectable disease; 4/52 who continued nilotinib, 0/35 who continued imatinib, and 11/43 who crossed over from imatinib to nilotinib achieved undetectable BCR-ABL by 3 y. The rate of $MR^{4.5}$ in pts without $MR^{4.5}$ at BL was higher in pts randomized to nilotinib (33% by 1 y) than in pts who crossed over from imatinib to nilotinib with similar follow-up (21%). The safety profiles of nilotinib and imatinib were comparable to the 1-y report. By 36 mo, selected cardiovascular events of interest were experienced by 12 pts in the nilotinib arm (ischemic heart disease [IHD], 7; cerebrovascular event [CVE], 3; peripheral arterial disease [PAD], 7), 2 pts in the imatinib arm (IHD, 1; CVE, 1), and 2 pts who crossed over from imatinib to nilotinib (IHD, 1; PAD, 1). Mean BCR-ABL level at mo 3 in the 91 nilotinib-treated pts with detectable BCR-ABL at study start who remained on study and had evaluable samples was 0.08%. 19 of 91 (21%) achieved confirmed undetectable BCR-ABL by 2 y. Pts with BCR-ABL ≤ 0.005% at 3 mo had significantly higher rates of undetectable BCR-ABL by 2 y than those with BCR-ABL >0.005% at 3 mo (Figure A), as did pts with a BCR-ABL halving time of ≤ 90 d (*vs* >90 d) (Figure B).

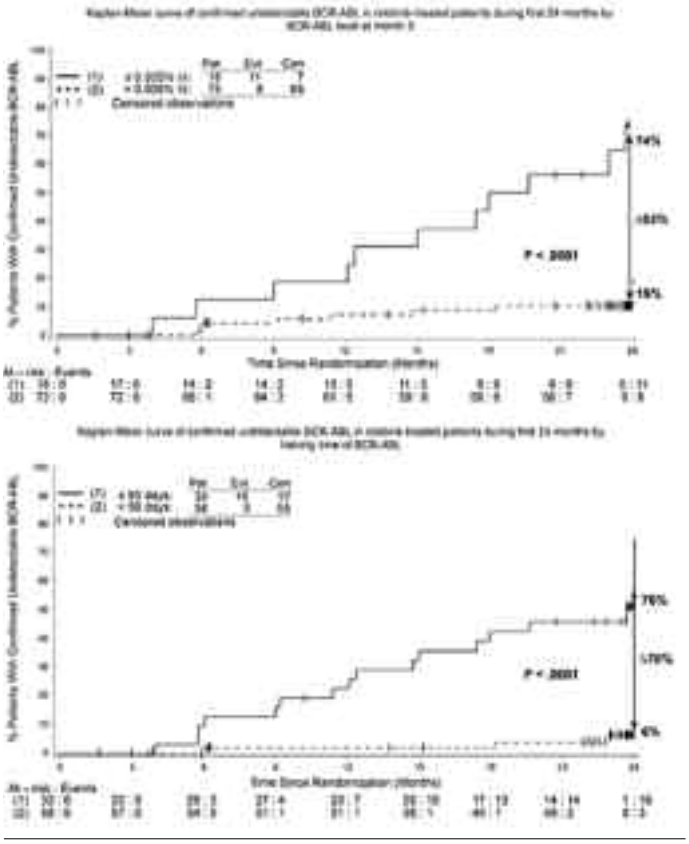

Figure 1.

Summary and Conclusion: With 3 y of follow-up, switching to nilotinib in pts with minimal residual disease on long-term imatinib therapy continued to result in deeper and faster MRs *vs* remaining on imatinib. Achieving either a threshold of BCR-ABL ≤ 0.005% at 3 mo or a rapid decrease in BCR-ABL from BL (halving time ≤ 90 d) was significantly associated with confirmed undetectable BCR-ABL by 2 y in nilotinib-treated pts—an entry criteria for treatment-free remission trials.

S1362

LONGER-TERM FOLLOW-UP OF THE IMPACT OF BASELINE (BL) MUTATIONS ON PONATINIB RESPONSE AND END OF TREATMENT (EOT) MUTATION ANALYSIS IN PATIENTS (PTS) WITH CHRONIC PHASE CHRONIC MYELOID LEUKEMIA (CP-CML)

Orsola-Malpighi Hospital, University of Bologna, Bologna, Italy, [8]Universitätsmedizin Mannheim, Mannheim, Germany, [9]MolecularMD, Portland, [10]ARIAD Pharmaceuticals, Inc., Cambridge, United States, [11]CHU de Poitiers, University Hospital, Poitiers, France, [12]Universitätsklinikum Jena, Jena, Germany, [13]Institute of Medicine and Veterinary Science, [14]School of Medicine and School of Molecular and Biomedical Science, University of Adelaide, Adelaide, Australia

Background: In CML, the presence of BCR-ABL kinase domain (KD) mutations, including low-level (LL) mutations, can predict clinical responses to second-line BCR-ABL tyrosine kinase inhibitors (TKIs), and sequential treatment with TKIs can lead to development of highly TKI-resistant compound mutations (≥2 mutations in the same BCR-ABL allele). Ponatinib is a potent BCR-ABL TKI that has *in vitro* activity against all BCR-ABL mutants tested and suppresses the emergence of any single mutation at clinically achievable concentrations (40 nM with ≥30 mg/d).
Aims: We evaluated the impact of BL single, LL, and compound mutations on responses to ponatinib and EOT mutations in CP-CML pts in the phase 2 PACE trial.
Methods: Pts with CP-CML (94% ≥2 prior TKIs; 60% ≥3 prior TKIs) resistant or intolerant to dasatinib and/or nilotinib (N=203) or with T315I at BL (N=64) were enrolled, gave informed consent, and were included in the efficacy analysis. The primary endpoint was major cytogenetic response (MCyR) by 12 mos. Median follow-up (7 Oct 2013) for the safety population (N=270) was 27.4 (0.1-36.3) mos. Next generation sequencing (NGS) was conducted on all BL samples (N=267) with the Ion Torrent PGM allowing read lengths ≤400 bp for detection of compound mutations; mutations observed at a frequency >1% are reported. Sanger sequencing (SS) was conducted on both BL and EOT samples.
Results: By NGS at BL, 266 mutations (substitutions in the ABL KD [M237-E507]) were detected in 163 (61%) pts; 105 (39%) mutations were LL mutations not detected by SS. 75 unique single mutations were detected by NGS. 27 of the 75 were also detected by SS, and all 27 have been associated with resistance to TKIs other than ponatinib. Of the 48 LL mutations detected only by NGS, 5 have previously been associated with resistance to TKIs. 12% of pts had only LL mutations. Overall, no mutations were detected in 39% of pts, 1 mutation in 38%, and ≥2 mutations in 23%. Compound mutations were detected in 15% of pts overall. 48 unique compound mutations were observed; T315I, F317L, and F359C/I/V were the most commonly observed components of compound mutations. Ponatinib responses were seen in pts with each of the 20 unique single mutations present in ≥2 pts at BL by NGS. Responses were observed regardless of overall NGS BL mutation status (**table**). Of the 123 pts who discontinued, 95 had successful mutation assessments by SS at or near the EOT visit. 7 pts had mutations at EOT that were not detected by NGS at BL; 5 involved compound mutations and 2 involved gain of T315I. Of 30 pts without MCyR who remained on study at time of analysis, 1 gained a mutation (T315I) at 1 yr. Of 3 pts who lost MCyR but remained on study at the time of analysis, 0 had gains at time of MCyR loss. Of the 53 pts who had mutations detected post-BL, the same mutations were detected at BL in 38 pts by SS and in 45 pts by NGS.

Table 1.

Summary and Conclusion: Responses to ponatinib were observed regardless of BL mutation status. Response rates tended to be lower in pts without mutations, suggesting that BCR-ABL independent resistance mechanisms may be involved. In general, ponatinib activity was not adversely affected by the presence of compound mutations at BL. Rarely, the development of compound mutations was observed at EOT, with one of the involved mutations observed at BL or by history. No single mutation that consistently confers primary and/or secondary resistance to ponatinib in CP-CML has been observed to date. NCT01207440.

S1363

ATHEROTHROMBOTIC RISK ASSESSMENT DURING TYROSINE KINASE INHIBITORS TREATMENT IN CHRONIC MYELOID LEUKEMIA PATIENTS: NEW INSIGHT?

M Bocchia[1,*], S Galimberti[2], L Aprile[1], A Gozzini[3], F Santilli[4], A Sicuranza[1], E Abruzzese[5], M Defina[1], C Baratè[2], B Scappini[3], A Gozzetti[1], A Bosi[3], M Petrini[2], L Puccetti[1]
[1]AOUS, University of Siena, Siena, [2]University of Pisa, Pisa, [3]AOU Careggi, University of Firenze, Firenze, [4]University of Chieti, Chieti, [5]S. Eugenio Hospital, Tor Vergata University, Roma, Italy

Background: Peripheral Arterial Occlusive Disease (PAOD) has been reported in chronic myeloid leukemia (CML) patients (pts) treated with second generation Tyrosine Kinase inhibitor (TKI) nilotinib (NIL).
Aims: To explore potential underlining mechanisms, we investigated genetic and biochemical traits associated with vascular events, in CML pts treated with TKIs.
Methods: 110 CML pts, 58 on imatinib (IM) and 52 on NIL (median treatment time 84 mos, range 12-180, and 56 mos, range 3-228, respectively), all in complete cytogenetic response, were studied. Pts were screened for PAOD a/o other atherothrombotic episodes and evaluated for: traditional cardiovascular risk factors (TCRF) (Diabetes Mellitus, Dyslipidemia, Blood Pressure, Body Mass Index, Smoke, Familiarity); sCD40L, Endogenous Thrombin Potential (ETP); oxidized LDL (oxLDL) level; IL6, IL10 and TNFα pro/anti-inflammatory cytokines network; intron 4 IVS4-14 A>G polymorphisms of OLR1 (rs3736235), encoding for the oxidized LDL receptor 1 (LOX1) to evaluate the distribution of genotypes AA (cardiovascular low risk), AG and GG (cardiovascular high risk).
Results: The distribution of classical risk factors showed a slight prevalence of dyslipidemia in the NIL cohort. Similarly, the presence of 3 or more TCRF was more frequent in the NIL group. In the IM cohort 3/58 (5%) pts experienced an atherothrombotic event (1 PAOD, 2 carotid occlusion major than 50%), while in the NIL cohort 14/52 (27%) atherothrombotic events were documented (9 PAOD, 5 acute coronary syndrome) (p=0.00011). LOX-1 polymorphism was evaluated in all 110 pts and genotype frequency respected the Hardy-Weinberg equilibrium with other populations of ancestral Caucasian origin. However, when considering the genotype frequency according to TKI treatment, we found a slight excess of homozygotes A/A in the IM group and a significant excess of homozygotes G/G in the NIL treated cohort. Interestingly the homozygotes G/G clustered in the NIL sub-group with history of atherothrombotic events during treatment. Multivariate analysis showed that once corrected for age, sex, BMI and each applicable, biochemical and genetic data available at the moment of event recording or clinical observation if event-free; the single influencing risk factor was the G/G homozygosis for IVS4-14A/G of OLR1 in the NIL group (Fig.1). No significant influence was detected for each single traditional risk factor, despite the slight increase of dyslipidemic subjects in the NIL group (Fig.1). Furthermore, the clustering of 2 or ≥3 TCRF was not associated with the increased risk of cardiovascular events during treatment with both TKIs (Fig. 1). In addition, we found significant differences in many biochemical parameters evaluated: oxLDL, sCD40L level and ETP were significantly higher in NIL *vs* IM treated group, while IL10 level, inversely related to oxLDL, sCD40L and ETP, was significantly lower.
Summary and Conclusion: Our data suggest no influence of classical risk factors in atherothrombotic risk during TKI treatment, while an unbalance of pro/anti-inflammatory cytokines network observed in NIL pts, together with genetic pro-atherothrombotic predisposition conferred by LOX1, may have a role in the increased incidence of vascular events. With the ultimate intent to achieve a "personalized" TKI treatment, we are conducting a prospective study, in newly diagnosed CML pts treated front line with any TKIs, in order to identify a genetic/biochemical tool able to early detect pts at potential increased atherothrombotic risk.

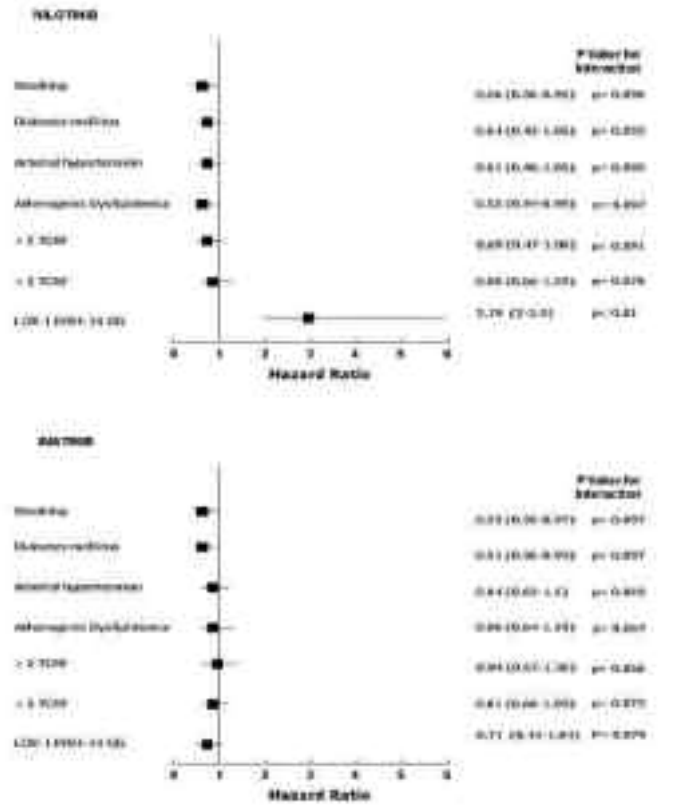

Figure 1.

S1364

CRIZOTINIB IS AN ALLOSTERIC ABL-INHIBITOR ABLE TO TARGET BOTH NATIVE BCR/ABL AND BCR/ABL-T315I IN VITRO AND IN VIVO MODELS OF PH+ LEUKEMIA

A A Mian[1,*]I Haberbosch[1], A Rafiei[1], H Khamaisie[2], A Agbarya[3], N Ruimi[2], E Eshel[4], D Najib[4], L Pietsch[5,6], O G Ottmann[1], R Biondi[6], J Mahajna[2], M Ruthardt[1]

[1]Hematology, Goethe University, Frankfurt, Germany, [2]Cancer Drug Discovery Program, Migal-Galilee Research Institute, Kiryat Shmona, [3]Thoracic Oncology Clinic, Rambam Health Care Campus, Haifa, [4]Hematology, Ziv Medical Center, Zfat, Israel, [5]DKTK, DKFZ, Heidelberg, [6]Gastroenterolgy, Goethe University, Frankfurt, Germany

Background: Targeting BCR/ABL with tyrosine kinase inhibitors (TKIs) is a proven concept for the treatment of Philadelphia chromosome-positive (Ph+) leukemias. Resistance attributable to either kinase mutations in BCR/ABL or non-mutational mechanisms remains the major clinical challenge. With the exception of Ponatinib, all approved TKIs are unable to inhibit the "gatekeeper" mutation T315I. However, a broad spectrum of kinase inhibition increases the off target effects of TKIs and may be responsible for cardiovascular issues of Ponatinib. Thus, there is an urgent need for additional therapy options for resistant Ph+ leukemias. Crizotinib, a kinase inhibitor designed to target c-MET and ALK for the treatment of lung cancer, exhibits activity also against the ABL-kinase in cell free systems.

Aims: We investigated the therapeutic potential of Crizotinib for the treatment of Ph+ leukemia patients with advanced and therapy-resistant disease.

Methods: Inhibition of BCR/ABL kinase and *in vitro* efficacy of Crizotinib were investigated i.) in Ph+ and Ph- leukemia cell lines (K562, SupB15, BV173 and Jurkat, U937, respectively); ii.) in primary patient-derived long term culture (PD-LTCs) of Ph+ALL patients with different levels of responsiveness to TKI and one harboring the T315I; iii.) in Ba/F3 cells rendered factor independent by the expression of native BCR/ABL or BCR/ABL-T315I. Furthermore we compared the *in vivo* efficacy of Crizotinib with that of Ponatinib in syngeneic mouse models of BCR/ABL- or BCR/ABL-T315I-driven CML or ALL. Based on the particular binding properties to both c-MET and ALK we investigated the mechanisms by which Crizotinib inhibits the BCR/ABL kinase in an AlphaScreen ABL/myristoil-peptide interaction-displacement assay.

Results: Here we show that Crizotinib not only inhibited autophosphorylation of BCR/ABL in all tested cell lines but also efficiently suppressed growth of Ph+ cell lines with an IC50 of 50-100nM, whereas Ph- cell lines did not respond to concentrations even >1μM. Furthermore K562 underwent erythroid differentiation upon Crizotinib to the same extent as Imatinib. It abolished factor independent growth of both BCR/ABL- and BCR/ABL-T315I-positive Ba/F3 cells. The growth suppression by Crizotinib (IC50 50-100nM) in Ph+ PD-LTCs was completely independent of the responsiveness/resistance to other TKIs or to the presence of T315I. This might be due to the fact that Crizotinib boundn to the myristoil binding pocket (MBP) of ABL even with an higher affinity as compared to GNF-2 as revealed by an AlphaScreen drug/protein interaction assay. The *in vitro* efficacy of Crizotinib was confirmed *in vivo* in both syngeneic models of BCR/ABL- or BCR/ABL-T315I-driven CML and in BCR/ABL-driven ALL. At 100mg/kg o.d. for 14 days it significantly prolonged survival to nearly exactly same extent as Ponatinib at 25mg/kg o.d for 14 days, without apparent toxicity.

Summary and Conclusion: These findings strongly indicate that Crizotinib is an allosteric inhibitor of BCR/ABL and its resistance mutants and suggest the clinical evaluation of Crizotinib for the treatment of advanced and therapy-resistant Ph+ leukemia.

Stem cell transplantation - Experimental

S1365

CIRCULATING MIR-586 PARTICIPATES IN OCCURRENCE OF ACUTE GRAFT-VERSUS-HOST-DISEASE BY DOWN-REGULATING INDOLEAMINE-2,3-DIOXYGENASE

X Zhao[1,*], J Wan[2], M Lv[1], L Xu[1], X Zhang[1], X Huang[1]
[1]Hematology, Peking University Institute of Hematology, Beijing, [2]Biomedical Research Institute, Medical Center of Peking University-Hong Kong University of Science and Technology, Shenzhen, China

Background: Indoleamine-2,3-dioxygenase (IDO) is able to catalyze the first and rate-limiting step in the catabolism of tryptophan, which is the essential amino acid for T cell proliferation. It played important roles in immunosurppression associated with maternal-fetal immune tolerance, tumor immunity, autoimmunity and chronic infection. During acute graft-*versus*-host-disease (aGVHD) after allogeneic hematopoietic stem cell transplantation (allo-HSCT), donor T cells will be activated and lead to tissue injury. IDO has been proved to be involved in the occurrence of aGVHD through its immunosurppressive function. Our previous work also demonstrated that plasma IDO level was correlated with the severity of aGVHD. Increased IDO expression would serve as a protective molecular during aGVHD. However, the exact regulatory mechanism of IDO is still unclear. MicroRNAs (miRNAs) are a class of small non-coding RNA that negatively regulate gene expression by translational repression or induction of mRNA degradation. Recently, circulating miRNAs have been reported to be the promising biomarkers for various kinds of diseases.
Aims: This study is to find the potential regulatory miRNA of IDO and investigate the correlation between plasma miRNA expression and aGVHD.
Methods: The potential regulatory miRNA for IDO was identified through bioinformatics analysis using TargetScan, Miranda and DIANA-microT. The regulatory function of target miRNA on IDO protein and gene was confirmed by Western Blot analysis and luciferase assay. The plasma of 25 patients undergoing allo-HSCT was prospectively collected at +7 day(d), +14d, +21d, +30d, +45d, +60d, +90d and the occurrence of aGVHD. Real-time quantitative PCR (RQ-PCR) analysis was performed to examine the miRNA expression of plasma at different time points posttransplant. Receiver operating characteristic (ROC) analysis was employed to determine the optimal cut-off value for predict the occurrence of aGVHD.
Results: Through bioinformatics analysis, miRNA-586 was found to be the putative regulatory miRNA for IDO. The intracellular IDO protein would be reduced when miRNA-586 was transfected into interferon-gamma-treated Hela cells. While, the mRNA expression level of IDO was not affected obviously. In addition, luciferase assay in 293T cells showed that miRNA-586 was able to bind directly to the promoter region of IDO gene and affect its transcription. However, when the potential binding sites were mutated, this phenomenon could not be observed. Among the 25 patients who underwent allo-HSCT, 10 patients developed into aGVHD and 15 patients did not. Based on their miRNA-586 expression levels at designed time points, we found that the levels of miRNA-586 at +7d posttransplantation were significantly different between these two groups (P=0.001). The results of ROC analysis showed that the patients whose miRNA-586 levels were higher than $4.5x10^4$copies/ul were more prone to develop into aGVHD (AUC=0.898,P<0.001).
Summary and Conclusion: Our study suggested that miRNA-586 might participate in occurrence of aGVHD by down regulating IDO and might be a putative target for novel aGVHD therapy. The plasma level of miRNA-586 at +7d after allo-HSCT would be a good biomarker for predicting the occurrence of aGVHD.

S1366

SERUM MIR-29A IS UP-REGULATED IN ACUTE GRAFT VERSUS HOST DISEASE (AGVHD) AFTER ALLOGENEIC HEMATOPOIETIC STEM CELL TRANSPLANTATION (ALLO HSCT) AND ACTIVATES DENDRITIC CELLS (DCS)

Y Efebera[1], P Ranganathan[1], X Yu[1], J Hofstetter[1], S Garman[1], K B Challagundla[2], S M Devine[1], M Fabbri[2], R Garzon[1,*]
[1]Medicine, The ohio State University, Columbus, [2]Pediatrics, University of Southern California- Keck School of Medicine, Los Angeles, United States

Background: aGVHD is one of the most frequent and lethal complications after allo HSCT, underscoring the need to develop novel therapies. To achieve this goal, aGVHD mechanisms needs to be further elucidated. Recently it was reported that miRNAs modulate aGVHD.We hypothesize that serum miRNAs expression is deregulated in aGVHD and could play a role in aGVHD pathogenesis.
Aims: To asses serum miRNAs expression in aGVHD and dissect their functional role.
Methods: We performed serum miRNA expression analysis using deep-sequencing (Solid Platform) from allo HSCT recipients samples. Peripheral blood samples were collected weekly until day 100+ and at the time of clinical diagnosis of aGVHD. A mouse model of aGVHD (B6 donor into F1 recipients) was used to assess serum miRNA expression in animals with aGVHD. Functional studies were performed using miR-29a and miR-16 Dotap formulations using mouse dendritic and T cells. Cytokines were measured using ELISA.
Results: We included 10 patients with aGVHD (bowel n=2; skin (n=5) and both skin/bowel (n=3)). Conditioning regimens were mainly non-myeloablative (n=9) using unrelated donors (n=9). Allo HSCT patients with no aGVHD, matched for age, disease, conditioning regimen, donor and timing of sample collection were used as controls. We compared miRNA expression between all patients with aGVHD (n=10) and controls (n=7) using class comparison. Among the 7 miRNAs up-regulated in aGVHD samples we found miR-29a (Fold change (FC) >2, p<0.01). Since miR-29a is involved in immune regulation we validated this miR by RT-PCR in the B6-F1 model of murine aGVHD (miR-29a levels were 4.9 higher in aGVHD mice (n=6) than controls (n=4) p<0.01). Since our group reported before that miR-29a binds as ligands to TLR7/8, we hypothesized that serum miR-29a could bind to TLR7/8 of APCs activating NFkB and enhancing alloreactive responses during aGVHD. First, we examined whether extracellular miR-29a could activate dendritic cells (DCs). B6D2F1 splenocytes were stimulated with Dotap formulations (mimicking exosomes) of miR-29a. We found that CD69 expression measured by FACS is significantly elevated in CD11c+ DCs/CD4+ and CD8+ T cells treated with miR-29a compared to controls (Dotap alone or Dotap-miR16). To investigate whether T cells could be activated by the miR alone, untouched resting T cells from mouse spleen were isolated and stimulated with Dotap-miR-29a or controls. CD69 was not up-regulated indicating that the activation of T cells was dependent on APC activation. To further confirm that miR-29a could activate DCs, we isolated murine DCs and repeated the above experiment. We found that miR-29a stimulation of DCs but not controls induced the up-regulation of canonical DC maturation and activation markers, CD40, CD80 and CD86. Furthermore, miR-29a Dotap treatment of DCs alone stimulated the release of TNFα (114.2±14 pg/ml *vs*. mir16-Dotap 26.98±2. pg/ml, p<0.01) and IL-6 (103.83±7pg/ml *vs*. 37.01±1 pg/ml mir16-Dotap, p<0.05) in the supernatant. To show that the release of pro-inflammatory cytokines by miR-29a is through the TLR7 pathway, we repeated the experiment using DCs isolated from TLR7-/- mice, and saw no upregulation of activation/maturation markers and no release of pro-inflammatory cytokines. Interestingly, B6D2F1 dendritic cells stimulated with miR-29a elicited a stronger alloreactive proliferative response from CFSE labeled B6 T cells as opposed to control treated DCs underscoring the importance of miR-29a in driving an alloreactive response.
Summary and Conclusion: Our results indicate that serum miR-29a is up-regulated during aGVHD and activates DCs, likely by direct binding to TLR7/8. NFkB activation by miR-29a results in the release of TNF-a and IL-6 and elicits a stronger allo-reactive T cell proliferative response.

S1367

ALLOGENEIC (ALLO) HEMATOPOIETIC STEM CELL TRANSPLANTATION (HSCT) IN PATIENTS OLDER THAN 60 YEARS: COMPARISON OF HAPLOIDENTICAL T-REPLETE HSCT FOLLOWED WITH POST-TRANSPLANT HIGH DOSE CYCLOPHOSPHAMIDE

D Blaise[1,*], L Castagna[2], S Fürst[1], R Crocchiolo[2], R Devillier[1], S Bramanti[2], J El Cheikh[1], A Granata[1], B Sarina[2], S Harbi[1], R Bouabdallah[3], B Mohty[1], C Lemarie[4], C Carlo Stella[2], C Chabannon[4], N Vey[3], A Santoro[2]
[1]Unité de Greffe, Institut Paoli-Calmettes, Marseille, France, [2]Hematology, HUMANITAS, MILAN, Italy, [3]Hematology, [4]Therapie Cellulaire, Institut Paoli-Calmettes, Marseille, France

Background: The identification of a donor has always limited the extent of allo HSCT. Recently it has been shown by different teams that a haploidentical donor could be a valid option to perform allo HSCT given adapted immunosuppression is used. Notably the use of PT-HDCy), after T-replete HSCT following reduced intensity (RIC) or non-myeloablative (NMAC) conditioning, has been associated with promising results. However little data exist concerning elderly population when this population is characterized by a lack of HLA matched sibling and a higher incidence of severe GVHD and non-relapse mortality.
Aims: Using this strategy in a joined program between two institutions we recently transplanted 33 patients over the age of 60 years and compare their outcome with patients of the same age transplanted from a MRD or MUD.
Methods: 70% of the patients in haplo group were prepared with Flu-TBI 2gy (NMAC) while all patients in other groups received the same RIC (Fludarabine (150 mg/m2) –Busilvex (2 days) –rabbit ATG (2 days)). Patients in haplo group received post graft Immunosuppression with PT-HDCy (50 mg/kg on D 3 and 4) followed with CSA and MMF while patients in other groups received either CSA (70%) or Tacrolimus starting on D1.
Results: Patients in the haplo group have trends to present higher comorbidities and more severe diseases (Table). Haplo and MRD HSCT patients present with a similar lower NRM than MUD patients while Haplo patients present a relapse rate intermediate between MRD and MUD. Overall there is a trend for better PFS after Haplo HSCT (Figure 1) which is even higher when analyzing the progression and severe cGVHD free survival (Figure 2).

	Haplo HSCT	MRD HSCT	MUD HSCT
N	33	34	42
Age: Median (range)	63 (60-73)	63 (60-67)	63 (60-68)
HCT-comorbidity Index > 2	64%	32%	42%
Myeloid Malignancies	42%	59%	43%
High/Very high disease Risk index (DRI)	42%	41%	19%
PBSC	100%	100%	100%
Graft Failure	1	0	0
100 days 3-4 aGVHD	9%	14%	21%
1 Year severe cGVHD	0%	14%	19%
Overall NRM	12%	11%	33%
Overall relapse	36%	54%	13%

Figure 1.

Summary and Conclusion: We conclude that T-replete Haplo HSCT after RIC and followed by PT-HDCy seems associated with promising results notably as compared with MUD HSCT. The low rate of severe aGVHD and the absence of severe cGVHD are likely to conduct to lower complications and better quality of life. The reduction of donor search duration and the absence of graft acquisition fees represent potential additional benefits. in this persepcetive, the place of Haplo HSCT in patients beyond 60 years of age should now be prospectively addressed.

S1368

ALLOGENEIC BONE MARROW TRANSPLANTATION INDUCES MYELOID-DERIVED SUPPRESSOR CELLS (MDSCS), WHICH PREVENT T CELL PROLIFERATION IN VITRO BUT ARE UNABLE TO SUPPRESS T CELL FUNCTIONS AND GVHD IN VIVO

J Messmann[1], F Leithäuser[2], M B Lutz[3], KM Debatin[1], G Strauss[1,*]
[1]Department of Pediatrics and Adolescent Medicine, University Medical Center Ulm, [2]Institute of Pathology, University of Ulm, Ulm, [3]Institute of Virology and Immunobiology, University of Würzburg, Würzburg, Germany

Background: Allogeneic bone marrow transplantations (BMT) are always associated with pro-inflammatory responses due to conditioning regimens and the development of alloantigen-specific T cells. These activated, donor-derived T cells attack recipient organs leading to tissue destruction and the development of graft-*versus*-host disease (GVHD). GVHD-induced inflammation is associated with enhanced T cell proliferation and cytotoxicity and increased serum levels of pro-inflammatory cytokines. Inflammatory responses frequently induce the development of myeloid-derived-suppressor cells (MDSCs), a heterogeneous population of immature myeloid-derived cells able to prevent T cell activation and proliferation. Murine MDSCs are characterized by the co-expression of CD11b and Gr-1, the up-regulation of arginase-1 and iNOS, and most importantly their ability to inhibit T cell-mediated immunity.
Aims: Therefore, we analyzed whether GVHD development induces MDSCs able to suppress T cell functions *in vitro* and *in vivo*.
Methods: GVHD was induced in two different murine allogeneic BMT models by transplantation of allogeneic BM and T cells. During the course of disease the induction of MDSCs in bone marrow and spleen of transplanted mice was analyzed and MDSCs were characterized phenotypically by flow cytomety, molecularly by the expression of iNOS and arginase-1 RNA, both molecules required for T cell suppression, and functionally by their capability to inhibit T cell functions *in vitro* and *in vivo*.
Results: In the BM and spleen of transplanted mice MDSCs were detectable as early as 5 days after transplantation. Numbers of MDSCs increased continuously up to day 10 and ranged between $6x10^6$ and $2x10^7$ MDSCs /spleen depending on the BMT model used. Interestingly, at this time point the numbers of MDSCs in the spleen were three times higher than the numbers of allogeneic T cells. MDSCs declined after day 10 but were still detectable more than 40 days after BMT. Despite the high numbers of MDSCs mice developed GVHD indicating that these MDSCs might probably not be fully activated. However, MDSCs isolated from the spleens of transplanted mice exhibited high expression of arginase-1 and iNOS and most importantly efficiently prevented allogeneic T cell proliferation *in vitro*. To test their functionality *in vivo*, we isolated MDSCs from GVHD-developing mice at day 10 after BMT and adoptively transferred these MDSCs in mice receiving allogeneic BM cells and spleen cells. Surprisingly, although these MDSCs efficiently prevented T cell proliferation *in vitro*, they were unable to prevent GVHD *in vivo*. However, the transfer of MDSCs, which were generated *in vitro* by incubating bone marrow cells with GM-CSF, totally inhibited clinical GVHD.
Summary and Conclusion: In summary, the development of GVHD is strongly correlated with a fulminant induction of donor-derived MDSCs, which prevent T cell activation and proliferation *in vitro*. However, these MDSCs are not functional *in vivo* showing that the presence of MDSCs in pathological conditions does not necessarily reflect their functionality. Future studies will show, whether treatment with growth factors or cytokines can further mature and activate MDSCs *in vivo* in such a way that they prevent GVHD development.

S1369

THE ACUTE GRAFT VERSUS HOST DISEASE CAN BE EFFECTIVELY PREVENTED BY TOLL-LIKE RECEPTOR 7-MEDIATED TOLERANCE IN A MISMATCHED TRANSPLANTATION MOUSE MODEL

N Zogas[1,*], V Paraskevas[1], G Karponi[1], F Iordanidis[2], S Malasidis[1], A Anagnostopoulos[1], E Yannaki[1]
[1]GENE AND CELL THERAPY CENTER, HEMATOLOGY-BMT UNIT, [2]Pathology Department, GEORGE PAPANICOLAOU HOSPITAL, Thessaloniki, Greece

Background: Graft *vs* Host Disease (GvHD) is the leading cause of non-relapse mortality and morbidity following allogeneic stem cell transplantation (alloHSCT) adversely affecting the outcome. Tissue damage in GvHD is caused by alloreactive T-cell-mediated immune attack, thus immunosuppression is commonly used as anti-GvHD prophylaxis, increasing patients' susceptibility to opportunistic infections. Toll-like receptors (TLRs) are innate immune receptors able to detect pathogen-associated molecular patterns (PAMPs) and endogenous self-antigens, implicated in the development of infectious and autoimmune diseases, respectively. The conditioning-induced loss of intestinal track integrity, followed by LPS-TLR4 interaction, is a key event for acute GvHD initiation. Polymorphisms of the TLR4/9 encoding genes in alloHSCT recipients have been associated with the GvHD severity, while TLR tolerance induction by direct low-dose TLR agonist injections to the donors or recipients prevent experimental autoimmunity.
Aims: In order to address whether TLR tolerance induction could also prevent alloreactivity and aGvHD, by a clinically applicable approach, we investigated the ex-vivo TLR tolerance induction to donor lymphocytes.
Methods: We investigated the *in vitro* TLR2,4,7 tolerance induction in mouse splenocytes (mSPLCs) repeatedly exposed to low-dose TLR-specific agonists followed by an high-dose challenge. A non-specific high-dose challenge was also used to check for cross-tolerance among TLRs. The induced hyporesponsiveness was assayed by TNFα quantification in mSPLCs culture supernatants and the optimal dose/duration for each agonist to induce maximum tolerance was determined. The capacity of the ex-vivo TLR7-tolerized donor lymphocytes to prevent aGvHD was investigated in a fully mismatched transplantation mouse model (C57BL/6 to Balb/c irradiated recipients) where aGvHD appears within 45 days post-transplantation. A 10-point murine GvHD scoring system based on 5, daily evaluated, parameters was used for the clinical assessment of aGvHD.
Results: Maximum TLR2,4,7 tolerance induction was achieved in mSPLCs *in vitro* by a 3 day-exposure of cells to LPS, R848 and Pam3CSK4 (10ng, 14mM and 1000ng/ml respectively, $p<0.001$). TLR7-mediated "desensitization" of mSPCs by R848 was also associated with a strong cross-tolerance effect to TLR2/4 as it was demonstrated by the hyporesponsiveness of TLR7-tolerized mSPLCs to Pam3CSK4 or LPS challenge. In a mismatched transplantation model, the recipients were administered : T-cell depleted bone marrow cells (TCD-BM) without or with mSPLCs (Groups I, II, respectively) and TCD-BM+mSPLCs tolerized with Pam3CKS4, LPS and R848 (Groups III,IV and V respectively). The successful "desensitization" of the transplanted mSPCs was checked before transplantation in Groups III-V by high-dose specific challenge. No animal from Groups II,III and IV survived beyond day 25 post-transplantation, whereas Groups I,V showed significantly lower aGvHD score ($p<0.001$), rapid weight recovery ($p<0.05$) and higher survival rates ($p<0.001$) at the end of the experiment. Upon sacrifice, histopathology in skin and gastrointestinal tract sections demonstrated severe aGvHD lesions in Groups II,III, IV whereas normal findings were seen in Groups I,V. Significantly higher IFNγ mRNA levels were measured in PBMCs of Groups II-IV over Groups I,V. When mSPLCs from sacrificed, at day20, representative animals from all groups were challenged with R848, group V T-cells demonstrated a strong hyporesponsiveness whereas normal TLR activation was observed in mSPLCs from all other groups.
Summary and Conclusion: In summary, the ex-vivo tolerance induction to TLR7 (but not TLR2 or 4) in donor lymphocytes could serve as a clinically applicable tool for aGvHD prophylaxis.

Thrombosis and vascular biology

MORTALITY AND CARDIOVASCULAR DISEASE AFTER A FIRST EPISODE OF VENOUS THROMBOEMBOLISM IN YOUNG AND MIDDLE-AGED WOMEN

M Ljungqvist[1,*], K Sonnevi[2], J Odeberg[2], M Holmström[3], H Kieler[4], G Lärfars[1]
[1]Department of Clinical Science and Education, Södersjukhuset, [2]Department of Hematology, Karolinska University Hospital, [3]Department of Hematology, Karolinska University Hospital, Department of Medicine, Solna, [4]Center for Pharmacoepidemiology, Department of Medicine, Solna, Karolinska Institutet, Stockholm, Sweden

Background: Cardiovascular disease is one of the leading causes of death in the developed world. Patients with a history of venous thromboembolism (VTE) seem to have increased risk of myocardial infarction and stroke. Little is known about this risk in young and middle aged women.
Aims: To evaluate the risk of arterial cardiovascular disease and death in women, aged 18-64 years, after a first episode of VTE.
Methods: We performed a cohort study including 1438 women with a previous first episode of VTE (exposed) and 1406 age-matched women without any history of VTE (unexposed). The cohort was derived from TEHS, a Swedish population-based case-control study on risk factors for VTE, and the women were recruited in Sweden 2002-2009. During 2011 a letter was sent to the participants in TEHS as an invitation to participate in this follow-up. Information of myocardial infarction and ischemic stroke was obtained from a questionnaire or from data recorded in the Swedish Patient Register. Data on death was obtained from the Cause of Death Register. Comparisons between exposed and unexposed were calculated in a Cox regression model and are presented by hazard ratios (HRs). Adjustment was made for age, smoking, BMI and occurrence of diabetes mellitus.
Results: 2118 women (mean age 47 ± 13 years) accepted participation in this study. The median follow-up time was 70 months. 38 (3.5%) of the exposed and 12 (1.2%) of the unexposed had died during the follow-up period. The incidence of myocardial infarction and stroke was higher among the exposed than the non-exposed (2.2 % *vs* 1 %, p=0.02). The adjusted HR for myocardial infarction and stroke was 2.3 (95% CI 1.0-5.2, p 0.04) for women with a previous episode of VTE compared with unexposed. The hazard ratios were similar in patients with VTE provoked by cast/surgery, oestrogen treatment or unprovoked VTE.
Summary and Conclusion: In our study young and middle-aged women have increased risks of death, myocardial infarction and stroke after a first event of VTE. Better assessment of cardiovascular risk factors and life style intervention could be beneficial for this patient group to decrease the risk of cardiovascular disease in the future.

S1371

INHIBITION OF COMPLEMENT-MEDIATED THROMBOTIC MICROANGIOPATHY WITH ECULIZUMAB IMPROVES HEMATOLOGICAL AND RENAL OUTCOMES IN ADULT PATIENTS WITH ATYPICAL HEMOLYTIC UREMIC SYNDROME

E Minetti[1,*], C Legendre[2], M Hourmant[3], J M Campistol[4], M Espinosa[5], AO Gaber[6], J Menne[7], F Provot[8], E Rondeau[9], P Ruggenenti[10], M Ogawa[11], C L Bedrosian[11], F Fakhouri[12]
[1]Careggi University Hospital, Florence, Italy, [2]Unversité Paris Descartes and Hôpital Necker, Paris, [3]Institut d'ImmunoTransplantation Urologie et Nephrologie, Nantes, France, [4]Servicio de Nefrología, Hospital Clínic, Barcelona, [5]Hospital Universitario Reina Sofía, Córdoba, Spain, [6]Methodist Hospital, Houston, TX, United States, [7]Hannover Medical School, Hannover, Germany, [8]CHU Lille, Lille, [9]Hôpital Tenon, Paris, France, [10]IRCCS-Istituto di Ricerche Farmacologiche Mario Negri, Centro Anna Maria Astori, Bergamo, Italy, [11]Alexion Pharmaceuticals, Cheshire, CT, United States, [12]Department of Nephrology and Immunology, CHU de Nantes, Nantes, France

Background: Atypical hemolytic uremic syndrome (aHUS) is a rare and life-threatening condition. It is caused by genetic abnormalities in the complement system, leading to chronic, uncontrolled complement activation. This results in systemic thrombotic microangiopathy (TMA), ischemia and severe damage to organs. Outcomes with plasma exchange/plasma infusion (PE/PI) are suboptimal in aHUS, as up to 65% of patients have permanent renal damage or die. Eculizumab is a terminal complement inhibitor and is the first and only approved treatment for aHUS.
Aims: To report efficacy and safety data on eculizumab from an ongoing study; the largest clinical trial in aHUS conducted to date.
Methods: This is an open-label, prospective, multicenter, multinational single-arm study in adults (≥18 years) with aHUS. Inclusion criteria included platelet count<150 × 10^9/L, hemoglobin ≤ lower limit of normal, lactate dehydrogenase (LDH) ≥1.5 × upper limit of normal (ULN) and serum creatinine ≥ULN at screening. Patients with Shiga toxin□producing *E. coli* (STEC-HUS) or ADAMTS-13 activity<5% were excluded, and identification of a complement mutation was not required for admission. Eculizumab was administered intravenously at 900 mg/week for 4 weeks, 1200 mg in Week 5 and 1200 mg every 2 weeks thereafter. The primary endpoint was proportion of patients with complete TMA response at 26 weeks (platelet and LDH normalization and<25% increase in serum creatinine from baseline).
Results: Of 41 patients treated with eculizumab (mean age 40.3 years, 68% female, 73% newly diagnosed), 38 (93%) completed 26 weeks of treatment. At baseline, 20 patients (49%) had no identified complement mutation, CHFR1/3 polymorphism or CFH antibody and mean (SD) platelet count and serum creatinine was 119.1 (66.1) × 10^9/L and 411 (264.6) µmol/L respectively. Eculizumab was initiated within 2 weeks (median) of patient's current manifestation and was associated with improvements in hematologic and renal outcomes (Table). Of the 24 patients on dialysis at baseline, 20 (83%) were able to stop dialysis during the study; 5 within 3 weeks prior to the first dose of eculizumab. Of the 35 patients receiving PE/PI at baseline, 26 (74%) were able to discontinue PE/PI. The most common adverse events (AEs) were headache (37%) and diarrhea (32%); most AEs were mild or moderate. Two patients had meningococcal infections; both recovered and one continued with eculizumab.

Table 1. Efficacy outcomes through 26 weeks' treatment with eculizumab in patients with aHUS (n=41)

Efficacy outcome	Results
Complete TMA response, n (%) [95% CI]	30 (73) [57.1–85.8]
Hematologic normalization, n (%) [95% CI]	38 (88) [73.8–95.9]
Platelet count normalization, n (%) [95% CI]	40 (98) [87.1–99.9]
Mean (SD) increase in platelet count from baseline, × 10^9/L	135 (114); p<0.0001
Mean (SD) increase in eGFR from baseline	29.3 (25.6); p<0.0001
eGFR increase ≥15 mL/min/1.73 m² from baseline, n (%)	22 (54)

CI, confidence interval; eGFR, estimated glomerular filtration rate; SD, standard deviation; TMA, thrombotic microangiopathy

Summary and Conclusion: In adult patients with aHUS, sustained inhibition of complement-mediated TMA with eculizumab led to clinically meaningful improvements in key hematologic and renal outcomes. There were no unexpected safety concerns with eculizumab. No patients died. These results support the importance of early and accurate differential diagnosis and rapid initiation of eculizumab in adult patients with aHUS.

S1372

IMPROVING OUR UNDERSTANDING OF ATYPICAL HEMOLYTIC UREMIC SYNDROME (AHUS): INITIAL PATIENT CHARACTERISTICS FROM AN INTERNATIONAL REGISTRY

G Ariceta[1,*], J Van de Walle[2], S Johnson[3], G Ardissino[4], D Cohen[5], L A Greenbaum[6], M Ogawa[7], F Schaefer[8], C Licht[9]
[1]Hospital Vall d'Hebron, Barcelona, Spain, [2]University Hospital Ghent, Ghent, Belgium, [3]Great North Children's Hospital, Newcastle upon Tyne, United Kingdom, [4]Fondazione IRCCS Cà Granda, Ospedale Maggiore Policlinico, Milan, Italy, [5]Columbia University, New York, [6]Emory University, Atlanta, GA, [7]Alexion Pharmaceuticals, Cheshire, CT, United States, [8]Pediatric Nephrology Clinic, Heidelberg University, Heidelberg, Germany, [9]The Hospital for Sick Children, Toronto, Canada

Background: Atypical hemolytic uremic syndrome (aHUS) is a life-threatening genetic disease; in most cases, it is caused by chronic, uncontrolled complement activation. It causes thrombotic microangiopathy, which leads to ischemia and severe end-organ damage. Collecting data on the epidemiology and outcomes of treatment for this rare disease will be imperative to maximize future patient care.
Aims: To enhance our understanding of the natural history and progression of aHUS by creating an international registry of patients with a clinical diagnosis of aHUS. The registry will also provide long-term safety and efficacy data on eculizumab, a terminal complement inhibitor. Here, we report baseline characteristics of the first 211 patients enrolled into the registry.
Methods: The aHUS Registry is an observational, non-interventional, multicenter, global registry (NCT01522183) initiated in April 2012. Patients with a clinical diagnosis of aHUS are eligible for inclusion regardless of age, treatment modality and availability of a genetic diagnosis. Patients with severe deficiency of ADAMTS13 activity (<5%) and evidence of STEC-HUS are excluded. Data on demography, medical history and disease management (including efficacy and safety outcomes) are collected at enrollment and then prospectively at 6-monthly intervals.
Results: As of 18 September 2013, 211 patients from 12 countries in Europe, the USA and Australia had been enrolled into the registry. Baseline characteristics are summarized in the Table. Approximately half of the patients are female and approximately half are adults. A genetic complement mutation

or complement autoantibody was identified in 59% of the screened patients. Many have renal impairment, with 43% having received dialysis and 16% having received a kidney transplant. A total of 43% have received plasma exchange/infusion prior to registry entry, and approximately half have received eculizumab.

Table 1. Baseline characteristics of the first 211 patients enrolled into the aHUS Regi September 2013

	Eculizumab treatment		
	Yes (N=104)	No (N=107)	Total (N=211)
Mean (SD) age at diagnosis, years	23.9 (21.4), n=94	17.1 (16.8), n=75	20.9 (19.6), n=169
Mean (SD) age at initial symptoms, years	23.6 (21.4) n=93	17.1 (16.4) n=76	20.8 (19.5) n=169
Age at enrollment, n (%)			
<2 years	17 (16.3)	2 (1.9)	19 (9.0)
≥2 to <5 years	8 (7.7)	7 (6.5)	15 (7.1)
≥5 to <12 years	15 (14.4)	18 (16.8)	33 (15.6)
≥12 to <18 years	5 (4.8)	16 (15.0)	21 (10.0)
≥18 years	55 (52.9)	55 (51.4)	110 (52.1)
N/A	4 (3.8)	9 (8.4)	13 (6.2)
Female patients, n (%)	58 (55.8)	45 (42.1)	103 (48.8)
Stated family history of aHUS, n yes (%)	16 (15.4)	20 (18.7)	36 (17.1)
Complement mutation/auto-antibody, n/N screened (%)	47/88 (53)	46/89 (52)	93/157 (59)
Prior kidney transplant, n (%)	14 (13.5)	20 (18.7)	34 (16.1)
Prior dialysis, n (%)	58 (55.8)	33 (30.8)	91 (43.1)
Prior plasma exchange/infusion, n (%)	59 (56.7)	31 (29.0)	90 (42.7)

Summary and Conclusion: Patient registries are useful for collecting real-world data, particularly for rare conditions. The aHUS Registry will enhance our understanding of aHUS and provide useful safety and efficacy data on the use of eculizumab in this condition. Ultimately, we hope this will improve the management of patients with aHUS. We encourage physicians to enroll eligible patients into the registry.

S1373

DOMAIN SPECIFICITY AND INHIBITORY POTENTIAL OF ANTI-ADAMTS13 ANTIBODIES AT PRESENTATION AND RELAPSE IN THROMBOTIC THROMBOCYTOPENIC PURPURA (TTP)

M Thomas[1,*], J Crawley[2], S Machin[1], M Scully[3]
[1]Haematology, University College London, [2]Haematology, Imperial College, [3]Haematology, University College Hospital, London, United Kingdom

Background: Acquired TTP is a life-threatening autoimmune disease associated with the development of autoantibodies (auto-Ab) against the metalloprotease, ADAMTS13. Little is known about the pathogenicity of auto-Ab directed against different domains and how domain specificity alters between presentation and remission/relapse.
Aims: To develop novel assays to determine domain specificity of anti-ADAMTS13 IgG and investigate the relationship with clinical outcomes using UK TTP Registry samples.
Methods: Full-length ADAMTS13 and ADAMTS13 fragments [MDTCS (N-terminal domains); TSR2-8 and CUB1/2 (C-terminal domains)] were expressed in HEK293T cells and purified. Microtitre plates were coated with ADAMTS13 or ADAMTS13 fragments, incubated with diluted TTP plasmas and bound IgG detected. Domain specificity was further analysed by pre-incubation of samples with soluble ADAMTS13 fragments to compete for ADAMTS13 binding.
Results: In a cohort of 60 acquired TTP patients at initial presentation, all had auto-Ab that recognised ADAMTS13 N-terminal domains (MDTCS). 17/60 patients also had auto-Ab against TSR2-8 and 17/60 against CUB1/2 domains respectively, whereas 26/60 had auto-Ab that only recognised MDTCS. In a preliminary analysis of 37 patients, there was no correlation between auto-Ab specificity and total anti-ADAMTS13 IgG titre; age; number of plasma exchanges to remission and, in contrast to previous reports, anti-C-terminal auto-Ab were not associated with lower platelets at presentation. 24% (4/17) patients with anti-C-terminal and 14% (2/14) with only anti-N-terminal auto-Ab at presentation relapsed after rituximab. 8 relapse patients were investigated further: 6/8 exhibited altered auto-Ab domain specificity upon relapse, most frequently with loss of anti-C-terminal reactivity. One patient with persistently high anti-ADAMTS13 IgG and normal ADAMTS13 activity during remission had predominantly anti-TSR2-8 antibodies, suggesting these were non-inhibitory. Functional analysis of domain specific antibodies suggests that anti-spacer auto-Ab are the primary pathogenic species.
Summary and Conclusion: These novel assays enable analysis of the auto-Ab repertoire in acquired TTP and how this may change with relapse. Our findings suggest that there is continual development of the autoimmune response during treatment that can result in altered domain specificity at relapse.

S1374

PREDICTIVE VALUE OF ADAMTS-13 ACTIVITY IN PATIENTS WITH THROMBOTIC THROMBOCYTOPENIC PURPURA (TTP)

M Marchetti[1,*], L Russo[1], F Piras[1], M Testa[1], L Barcella[1], A Rambaldi[2], M Carpenedo[3], M Noris[4], C Savignano[5], S Cortelazzo[6], M Bruno Franco[7], A Falanga[1]
[1]Div. Immunohematology and Transfusion Medicine, [2]Div. Hematology, Hospital Papa Giovanni XXIII, Bergamo, [3]Div. Hematology, Hospital San Gerardo, Monza, [4]Clinical Research Center for Rare Diseases,, Mario Negri Institute, Bergamo, [5]Div. Transfusion Medicine, University Hospital, Udine, [6]Div. Hematology, San Maurizio Regional Hospital, Bolzano, [7]Div. Immunohematology and Transfusion Medicine, ASL 1, Imperia, Italy

Background: Thrombotic thrombocytopenic purpura (TTP) is a rare life-threatening disorder associated with a severe deficiency of the VWF-cleaving protease ADAMTS-13 causing persistence of highly adhesive ultra-large VWF (ULVWF). Several studies are evaluating the predictive value for disease recurrence of ADAMTS-13 activity and its inhibitors.
Aims: To characterize the levels of ADAMTS-13 activity and its inhibitors and establish the prognostic values of these biomarkers for recurrences in TTP patients.
Methods: Between Jan 2001 and Jan 2014, 52 consecutive patients (39F/13M) with clinical diagnosis of TTP were prospectively enrolled after informed consent. Venous blood samples were obtained from 46 patients with idiopathic TTP (35 at the acute phase and at subsequent time points until clinical and hematological remission, and 11 patients at complete remission only), 3 patients with drug-induced TTP (2 thienopyridine-associated and 1 fludarabine-associated) and 3 with bone marrow transplantation (BMT)-associated TTP. ADAMTS-13 activity (by chromogenic assay, Technoclone), inhibitors (by mixing studies), and anti-ADAMTS-13 antibodies (by ELISA kit, Technoclone) were measured in plasma samples.
Results: A complete ADAMTS-13 activity deficiency (*i.e.*<5%) was detected in plasma from the 35 idiopathic TTP patients at the acute phase. In 30/35 patients the deficiency was associated to inhibitory activity against ADAMTS-13 (range: 52-100%) and anti-ADAMTS-13 antibodies (range: 26-209 U/ml). At remission, 16 patients showed normal (*i.e.* >50%), 5 moderate (*i.e.* 20-50%), 2 severe (*i.e.* 5-20%), and 4 complete deficiency (*i.e.*<5%) of ADAMTS-13 activity. In the majority of cases, the normalization or the partial recovery of ADAMTS-13 activity was associated to the reduction in both the inhibitory activity and the anti-ADAMTS-13 antibodies. All of the 6 patients with ADAMTS-13 activity<20% at clinical remission had at least one relapse, as compared to only 9 out of the 21 patients with ADAMTS-13 activity >20% ($p<0.05$). A similar pattern, though not statistically significant, was observed with ADAMTS-13 activity inhibition: *i.e.* relapses occurred in 67% of patients with a detectable inhibition during remission, compared to 37% of patients with no inhibition. In 5 TTP patients, we could not detect any inhibitory activity and anti-ADAMTS-13 antibodies at the acute phase, at clinical remission, and upon relapse. These patients were therefore identified as possible carriers of a true constitutive ADAMTS-13 deficiency. The 3 patients with BMT-associated TTP showed moderate reduction in plasma ADAMTS-13 activity, without measurable anti-ADAMTS-13 antibodies. Differently, all of the 3 patients with drug-associated TTP, showed severe ADAMTS-13 deficiency in the acute phase with anti-ADAMTS-13 antibody positivity. These 3 patients had normal ADAMTS-13 activity on remission.
Summary and Conclusion: Our data demonstrate that, during the acute phase, the measurement of ADAMTS-13 does not distinguish the idiopathic TTP from the drug-induced form, but helps to identify the BMT-associated TTP. Importantly, during remission, the persistent deficiency of ADAMTS-13 activity is predictive of recurrences in these patients. Due to the high risk of relapse, ADAMTS-13 monitoring is recommended in TTP patients follow-up.

Acute lymphoblastic leukemia - Biology 2

S1375

EXPRESSION OF MEF2C AT DN1/DN2 STAGES IS REQUIRED FOR PROPER PROGRESSION THROUGH THE DN2/DN3 STAGES OF T-CELL DEVELOPMENT

K Canté-Barrett[1,*], R Mendes[1], E Farahbakhshian[1], W Smits[1], R Pieters[1,2], J Meijerink[1]
[1]Pediatric Oncology/Hematology, Erasmus MC - Sophia Children's Hospital, Rotterdam, [2]Prinses Maxima Center, Utrecht, Netherlands

Background: The transcription factor myocyte enhancer factor 2C (MEF2C) is essential to the development of many tissues, including muscle, brain, and the immune system. In the immune system, Mef2c plays a role in the development of both myeloid and lymphoid cells. Mef2c guides megakaryocyte development and directs granulocyte-monocyte progenitors towards the monocytic cell fate. In the lymphoid lineage, Mef2c plays roles in B-cell development and the activation of mature B-cells. To date, no function has been identified for Mef2c in normal T-cell development. In T-cell acute lymphoblastic leukemia (T-ALL), MEF2C has recently been identified as a driving oncogene in patients arrested at an immature developmental stage. This immature cluster is equivalent to early thymic progenitor ALL (ETP-ALL). Understanding the genetic and molecular-biological basis of T-ALL subtypes is essential for the design of future tailored therapies in patient care to improve cure while minimizing adverse late-treatment effects.
Aims: One of our goals is therefore to understand the oncogenic role of MEF2C that results in ETP-ALL. Identification of MEF2C targets normally activated during very early thymocyte development can give insight in oncogenic mechanisms activated by prolonged *MEF2C* expression in ETP-ALL. In this study, we investigate a role for Mef2c in normal T-cell development.
Results: First, we assessed *MEF2C* gene expression in human T cell development stages from *in vitro* OP9-DL1 co-cultures as well as in murine thymocyte subsets. We collected gene expression data from 10 flow-sorted co-culture fractions ranging from human umbilical cord blood-derived hematopoietic stem cells to CD4+CD8+ double-positive (DP) subsets. *MEF2C* is expressed in the early CD34+CD7+, CD34-CD7+ and CD34-CD7+CD5+ fractions while not expressed in the more mature CD7+CD5+CD1+CD4-CD8- and CD4+CD8+ DP stages. These observations are in line with our observation of murine *Mef2c* expression in early T-cell development (DN1-DN2) and with recent gene expression data on mouse thymocyte subsets (Mingueneau *et al.*, 2013). Next, we analyzed the effect of ablation of the *Mef2c* gene on T-cell development *in vivo* using Mef2c conditional knockout mice. These mice were crossed with Lck-Cre or CD2-Cre mice. Lck-Cre is expressed in the DN2 and subsequent thymocyte stages, while CD2-Cre is expressed during the entire T- and B-cell development. As expected, the CD2-Cre-mediated deletion of Mef2c impaired B-cell development in the bone marrow and reduced the number of peripheral B-cells. Remarkably, deleting Mef2c by either CD2-Cre or Lck-Cre impaired T-cell development at the DN2-DN3 developmental stage resulting in an accumulation of DN2-DN3 thymocytes. Accordingly, the DN4 and DP thymocyte percentages were reduced. In addition, the number of peripheral CD4 and CD8 T-cells was severely reduced in the absence of Mef2c, with a more pronounced reduction of CD8 T-cells in comparison to CD4 T cells.
Summary and Conclusion: In summary, we conclude that Mef2c is critical for normal early T-cell development and acts at the DN1-DN2 stage.

Misericordia, Perugia, Italy, [5]U944 INSERM and Hematology laboratory, St-Louis Hospital, APHP, Hematology University Institute, University Paris-Diderot, Paris, France

Background: T-cell acute lymphoblastic leukemia (T-ALL) arises as result of a multistep oncogenic process involving overexpression of specific transcription factors, deletion of *CDKN2A*, and mutations of many different genes including *NOTCH1*, *FBXW7* and *PHF6*. Next-generation sequencing has recently led to the identification of additional T-ALL driver genes. However, the frequency of these mutations and their co-occurrence remains unknown.
Aims: The aim of this study is to gain insight into the spectrum and association of gene mutations in T-ALL.
Methods: We investigated two independent series of T-ALL (n=80 and n=75). Customized biotinylated oligonucleotide probes (Haloplex, Agilent) were used to select the target regions. We performed 100-bp paired-end sequencing on an Illumina HiSeq2000 instrument. Analysis of the sequence reads was performed using the NextGENe® software. For a variant call we required a read depth of 20 and an allele frequency of 20%. Polymorphisms annotated in dbSNP135 were excluded. The targeted regions comprised 115 genes previously identified as mutated in ALL or candidate oncogenes. Statistical analyses were performed using SPSS.
Results: In the first cohort of 80 T-ALL (including 34 adult cases) we found 356 single nucleotide variants (SNV) and small indels. The median number of mutations per patient was 4. Gene mutations previously identified by Sanger sequencing were also detected by this targeted resequencing approach, validating the quality of the data. Deletions of *CDKN2A, CDKN2B, PHF6, PTEN* and *PTPN2* were also detected based on reduced read depth. Twenty-seven genes were mutated in more than 5% of the cases. As expected, the highest mutation rate was found for *NOTCH1* (55%). Mutation frequencies of *PHF6* (18%), *FBXW7* (14%), *BCL11B* (10%) and *WT1* (7.5%) were in the range of reported frequencies. Interestingly, genes newly mutated in T-ALL included *TDRD6* (6%), *TET3* (6%), *ODZ2* (5%) and *CNOT1* (5%). In the second cohort (n=75, including 10 adult cases) we identified 314 SNV and indels, with a median of 3 mutations per patient. Twenty-two genes were mutated in more than 5% of the cases. In this series, genes newly mutated in T-ALL included *CREBBP* (12%) and *ODZ2* (8%). In both cohorts, the *JAK-IL7R* axis was confirmed to be an important oncogenic pathway as mutations in the *JAK1-JAK3-IL7R* genes were found in 24.5% (38 of 155) of T-ALL. We found that 33% of mutant cases carried two different mutations in *JAK3*. Most significant associations in cohort 1 included positive correlations between mutations in *CNOT1*/*CNOT3* and *BCL11B* genes (*p=0.007*) and mutations in *JAK1*/*JAK3* and *PHF6* (*p=0.002*). In cohort 2, this relationship was not statistically significant, but it was clear that mutations of *JAK1/JAK3* were enriched in *PHF6* aberrant cases (30.8% *versus* 16.1% of cases). A positive correlation between *JAK1*/*JAK3* and *SUZ12* mutations (*p=0.004*) was found in cohort 2. Conversely, *JAK1/JAK3* mutant cases were negatively associated with *TAL/LMO* related patients (cohort 1 *p=0.014*, cohort 2 *p=0.003*).
Summary and Conclusion: Our comprehensive sequence analysis in 155 T-ALL cases has identified the *JAK1-JAK3-IL7R* signaling complex as a potential therapeutic target in 25% of T-ALL. High levels of heterogeneity regarding the spectrum of mutations were observed, with 40 genes being mutated in at least 5% of cases, for which specific associations were also detected.

S1377

ABT-199 MEDIATED INHIBITION OF BCL2 AS A NOVEL THERAPEUTIC STRATEGY IN T-CELL ACUTE LYMPHOBLASTIC LEUKEMIA

S Peirs[1,*], F Matthijssens[1], S Goossens[2], C De Bock[3,4], K Canté-Barrett[5], T Lammens[6], I Van de Walle[7], B De Moerloose[6], Y Benoît[6], B Poppe[1], T Taghon[7], J Cools[3,4], J Meijerink[5], J Soulier[8], F Speleman[1], P Van Vlierberghe[1]
[1]Center for Medical Genetics, [2]VIB Inflammation Research Center, Ghent University, Ghent, [3]Center for the Biology of Disease, VIB, [4]Center for Human Genetics, KU Leuven, Leuven, Belgium, [5]Department of Pediatric Oncology/Hematology, Erasmus Medical Center, Rotterdam, Netherlands, [6]Department of Pediatric Hemato-Oncology, Ghent University Hospital, [7]Department of Clinical Chemistry, Microbiology and Immunology, Ghent University, Ghent, Belgium, [8]APHP Hematology Laboratory, Hôpital Saint-Louis, Paris, France

Background: T-cell acute lymphoblastic leukemia (T-ALL) is a high-risk subtype of ALL with survival rates that gradually improved over the last years mainly through introduction of intensified chemotherapy. However, the clinical outcome of resistant or refractory T-ALL remains extremely poor.
Aims: In this study, we investigated whether targeting BCL2 by the specific inhibitor ABT-199 might serve as a new therapeutic strategy in human T-ALL.
Methods: Two independent T-ALL patient cohorts as well as independent sets of sorted normal T-cell populations were analyzed by gene expression profiling and/or western blot analysis. IC_{50} values for ABT-199 were determined in a panel of T-ALL cell lines and in a series of genetically well-characterized primary T-ALL samples. Xenografts of luciferase positive human T-ALLs were used to evaluate the *in vivo* sensitivity of human T-ALL towards ABT-199 in immunodeficient NSG mice.
Results: Gene expression profiling analysis in a large panel of primary T-ALL samples confirmed that high expression of anti-apoptotic *BCL2* is a hallmark of immature subtypes of T-ALL. As normal T-cell development serves as the conceptual framework for the understanding of T-ALL biology, we wondered whether high *BCL2* expression in immature T-ALL is merely a reflection of the spatiotemporal regulation of BCL2 during T-cell development. Indeed, *BCL2* expression is high in $CD34^+$ T cell progenitors and gradually decreases upon differentiation with the lowest values in $CD4^+$ $CD8^+$ double positive T-cells. Interestingly, *BCL2L1* expression showed an opposite trend, suggesting an anti-apoptotic switch from BCL2 to Bcl-xL during T-cell maturation. Next, we determined the IC_{50} values for ABT-199 in a panel of 11 human T-ALL cell lines and observed a strong negative correlation between the IC_{50} values and *BCL2* mRNA (Spearman r=-0.85, p-value=0.0015) and BCL2 protein (Spearman r=-0.7, p-value=0.0204) levels. Mature T-ALL cell lines showed modest responses

towards ABT-199 treatment with IC_{50} values ranging from 0.2 to 10μM. However and most notably, the cell line LOUCY, which shows a transcriptional program highly related to early immature T-ALLs, was highly sensitive towards ABT-199 treatment (IC_{50}=13.9nM). As expected, induction of apoptosis upon ABT-199 treatment in LOUCY cells was associated with a strong induction of caspase activity. Subsequently, we selected primary T-ALL samples that represent major molecular genetic subtypes of T-ALL in order to determine *in vitro* ABT-199 sensitivity of immature, *TLX1*/*TLX3*, *HOXA* or *TAL1/LMO2* positive T-cell leukemias. Most (5 out of 6) *TAL1/LMO2* positive leukemias showed limited response to ABT-199 treatment. In contrast, half of the immature, *TLX3* and *HOXA* positive primary leukemias were highly sensitive to ABT-199 with low IC_{50} values (<50nM). Thus, it is clear that ABT-199 sensitivity is not uniform within a particular molecular genetic T-ALL subtype. Therefore, we hypothesize that BCL2 dependency in human T-ALL is initially determined by its cell of origin, but will ultimately be defined by the additional cooperative genetic defects that occur in each T-ALL patient sample. Finally, we performed xenograft experiments using luciferase positive LOUCY cells in which leukemic growth of LOUCY cells was visualized using bioluminescence. Treatment of established xenograft tumors with 100 mg ABT-199/kg for 4 days resulted in a significant reduction of leukemic burden (p-value=0.0295).
Summary and Conclusion: In conclusion, our study highlights BCL2 as an attractive molecular target in specific subtypes of human T-ALL, which could be exploited by the BH3-mimetic drug ABT-199.

S1378

A MECHANISTIC ROLE FOR MIR-126, A HEMATOPOIETIC STEM CELL MICRORNA, IN ACUTE LEUKEMIAS

S Nucera[1,*], A Giustacchini[1], C Fanciullo[1], T Plati[1], A Calabria[1], F Benedicenti[1], F Boccalatte[1], A Ranghetti[1], M Ponzoni[2], F Ciceri[3], E Montini[1], L Naldini[1], B Gentner[1]
[1]San Raffaele - Telethon Institute for Gene Therapy, [2]Pathology Unit, [3]Hematology and BMT Unit, San Raffaele Scientific Institute, Milano, Italy

Background: We recently showed that miR-126 expression faithfully identifies the engrafting fraction of bone marrow (BM) and cord blood (Gentner et al, Sci Transl Med 2010), in which it regulates hematopoietic stem cell (HSC) pool size by modulating cell cycle progression. Antagonizing miR-126 expands HSC by enhancing PI3K/AKT signaling, without causing their exhaustion or transformation (Lechman *et al.*, Cells Stem Cell 2012).
Aims: Here we adress the role of miR-126 in human and murine leukemogenesis.
Results: By reconstituting mice with lentivirally transduced BM cells ectopically expressing miR-126, we noted differential effects in HSC and progenitors: while miR-126 overexpressing (126OE) HSC were more quiescent and outcompeted by HSC with physiologic miR-126 expression, progenitor subsets were increased in number and proliferated more upon 126OE. Unexpectedly, 40% of mice (n=49) developed vector-marked, high-grade neoplasms in a 1 year time window (n=15 B cell precursor NPL, n=4 myeloproliferative NPL), while not a single vector-related malignancy was observed in mice transplanted with control vector transduced cells (n=30). Next, we reconstituted mice with BM cells carrying a tetracycline-regulated, conditional miR-126OE vector (n=26). B cell NPL developed in 40% of mice that were kept off doxycycline (miR-126 ON configuration; n=15), while all mice treated with doxycycline (miR-126 off; n=11) remained tumor-free over >8 months. Remarkably, mice with end-stage leukemia (WBC 150/nl, Hb 4g/dl, Plt 20/nl) fully recovered after a short course of doxycycline treatment (n=9), demonstrating that miR-126 is an oncogenic driver lesion. Mechanistically, miR-126OE significantly reduced apoptosis in B cell precursors and blocked differentiation at the immature B cell stage, and miR-126 withdrawal in established tumors rapidly triggered apoptosis. At least part of this effect was due to interference of miR-126 with p53 activation by directly targeting its upstream regulator Cdkn2aip. To establish the relevance of miR-126 in human disease, we measured miR-126 expression in blasts from 16 adult patients with acute lymphoblastic leukemia (ALL). miR-126 was highly expressed in most studied ALL cases (Phil+: n=11, Phil-: n=5) and was in the range of levels found in CD34+ HSC. We then perturbed miR-126 expression by transducing primary ALL blasts from 3 representative patients with lentiviral vectors overexpressing or knocking down miR-126 (miR-126OE or KD, respectively) and compared *in vitro* growth, apoptosis and engraftment potential in NSG mice with control vector transduced cells. Transduction efficiency was similar among groups (mean: 40%). Both miR-126OE and KD significantly increased apoptosis and reduced engraftment in all 3 diseases. We then collected the ALL graft from the BM of the transplanted mice and performed secondary transplantation. Using different readouts (%transduced cells at engraftment, limiting dilution assay, survival analysis), we confirmed a strong disadvantage of ALL blasts in which miR-126 expression was perturbed. These data strongly argue for an obligate dependence of ALL on a specific miR-126 expression level. Most interestingly, when analyzing miR-126 expression with single cell resolution using a lentiviral miR-126 reporter vector, we found substantial intrapatient heterogeneity, with 7 out of 12 patients showing 2-4 distinct cell clusters that maintained their specific miR-126 expression when purified and xenotransplanted. These clusters might correspond to ALL subclones present in individual patients.
Summary and Conclusion: We conclude that miR-126 is pathogenetically relevant in ALL and warrants further investigation as a biomarker and a therapeutic target.

LOW CELLULAR ENERGY METABOLISM IS ASSOCIATED WITH INCREASED LEUKEMIA INITIATING POTENTIAL IN ACUTE LYMPHOBLASTIC LEUKEMIA

L Trentin[1,*], M Queudeville[1], SM Eckhoff[1], KM Debatin[1], L H Meyer[1]
[1]Ulm University, Ulm, Germany

Background: In acute lymphoblastic leukemia (ALL) leukemia initiating cells (LICs) have been considered to be organized in an hierarchical fashion with only few immature cells capable to propagate leukemia upon transplantation onto immunodeficient mice. Recent data demonstrating LIC-activity also in more committed cells are supportive of a stochastic model in which all cells would possess stem cell properties. However, as a common strategy these studies are based on assessing engraftment potentials of cellular sub-populations defined by expression of distinct surface marker profiles. Nevertheless, so far the nature of leukemia initiating cells in ALL is still unclear. Aberrant energy metabolism has been described to be characteristic for cancer cells including recent reports on alterations in the oxidative state of malignant cell's, describing lower levels of reactive oxygen species (ROS) in breast cancer and myeloid leukemia cells associated with stem cell properties.
Aims: In order to further characterize LICs in ALL we investigated the cellular redox state of primary leukemia cells and analyzed whether energy metabolism of ALL cells determines leukemia initiating cell activity.
Methods: Levels of reactive oxygen species (ROS) were analyzed by detection of oxidation-specific fluorescence of chloromethyl-dichlorodihydrofluorescein diacetate (CM-H2DCFDA) in patient derived xenograft B-cell precursor (BCP) ALL samples. In combination with ROS levels, leukemia cells were stained for their DNA and RNA content allowing determination of distinct cell cycle phases. Moreover, cellular sub-fractions sorted according to high or low ROS levels were analyzed for their potential to repopulate immunodeficient mice using our NOD/SCID/huALL xenograft model.
Results: First, we analyzed cellular energy metabolism along with cell cycle distribution and assessed ROS levels in cellular sub-fractions defined by distinct cell cycle phases, which had been functionally characterized with respect their NOD/SCID mouse repopulating activities. Most interestingly, low ROS levels indicating low oxidative state were identified in leukemia cell fractions of early G0/G1 cell cycle phases, which also showed increased NOD/SCID repopulating activity in functional assays. In contrast, leukemic cell populations of late G2/M cell cycle phases characterized by prolonged engraftment and lower leukemia initiating capacity, displayed increased ROS levels. Vice versa, analysis of cell cycle distribution with respect to energy metabolism showed that ROS^{low} cells are allocated to early cell cycle whereas the majority of ROS^{high} cells originate from later cell cycle phases, suggesting that the ALL cell's oxidative state is indicative for its leukemia initiating activity. To further functionally address this hypothesis, two patient-derived leukemia samples were investigated. Cells were sorted according to high or low levels of ROS and transplanted onto NOD/SCID mice. Both sub-fractions led to leukemia engraftment. Most interestingly, ROS^{low} cells showed an higher activity to engraft and repopulate recipient animals as compared to ROS^{high} ALL cells as shown by significantly prolonged leukemia free survival of mice transplanted with ALL cells of an high oxidative state.
Summary and Conclusion: In conclusion, our data indicate that all cells in ALL show LIC activity, with cells of low energy metabolism representing the driving leukemia initiating cell compartment, thus pointing to redox modulation as a potential therapeutic target in ALL.

MTORC1 PATHWAY IS ACTIVATED BY BOTH SCF AND EPO AND REGULATES RIBOSOME BIOGENESIS DURING ERYTHROPOIESIS

A Raimbault[1,*], C Floquet[1], B Guyot[2], O Kosmider[1,3], F Morle[2], P Mayeux[1], M Fontenay[1,3]
[1]Inserm U1016, Institut Cochin, PARIS, [2]CGPhiMC CNRS UMR5534, Université Claude Bernard Lyon1, LYON, [3]Service d'Hématologie Biologique, AP-HP, HUPC, PARIS, France

Background: Erythropoiesis requires the renewal of erythroid progenitors with cell size maintenance and their maturation with size reduction during 3 last rapid cell divisions. The first step is supported by the Stem Cell Factor (SCF) which promotes the proliferation and survival of the progenitors and the second step depends on erythropoietin (EPO). Inherited Diamond Blackfan Anemia (DBA) and acquired *5q-* syndrome are characterized by defective ribosome biogenesis resulting in a profound anemia, confirming the important role of ribosome in erythropoiesis. Indeed, active ribosome biogenesis under the control of the mTORC1 pathway has been implicated in the regulation of cell growth before division and maintenance of cell size. Thus, we suspect that ribosome biogenesis may stop for cells to maturate with size reduction at each division.
Aims: The aim is to study the regulation of ribosome biogenesis by SCF and EPO signals during erythropoiesis and to investigate the regulatory role of ribosome biogenesis for differentiation.
Methods: We used two *in vitro* systems of expansion and differentiation of erythroblasts (E) deriving either from human $CD34^+$ of cytapheresis, or from mouse fetal liver. Structure of the nucleolus was studied by electron and immunofluorescence microscopy. Ribosomal biogenesis was quantified by a pulsed SILAC (Stable Isotopic Labeling by Amino acids in Culture cell) proteomic assay as percentage of ribosome renewal, and also by detection and quantification of ribosomal RNA (rRNA) precursors by FISH and by qPCR. Signaling pathways were studied by western blot.
Results: Proerythroblasts (proE) maintained under SCF and EPO, added together, demonstrate a maximal ribosome biogenesis with a rate of renewal of 60% and 50% every 14h or 24h in murin and human erythroblasts, respectively. Ribosome biogenesis decreases with the disappearance of proE and basophilic E. A dramatic reduction of nucleolus size and changes of structure is also observed at the stage of orthochromatophilic E suggesting that it becomes non-functional. Compared to SCF or EPO alone, the effect of the two cytokines is additive and responsible for a strong activation of mTORC1 pathway as judged by the phosphorylation of p70S6K1. This later kinase has been directly involved in the regulation of ribosome biogenesis by promoting rDNA transcription. By contrast, SCF and EPO had no additive effect on the phosphorylation of 4-EBP1, another mTORC1 substrate which is implicated in the initiation of 5'TOP mRNA translation initiation. Moreover, specific inhibition of p70S6K1phosphorylation by rapamycin leads to a decrease of ribosome biogenesis and an acceleration of erythroid differentiation.
Summary and Conclusion: This study shows that optimal ribosome biogenesis upon activation of mTORC1 pathway by SCF and EPO is required to maintain immature erythroblasts. The extinction of mTORC1 pathway drives cell to terminal erythroid differentiation and our results show that this effect could be caused directly by a drastic decrease of ribosome biogenesis. Our results show that p70S6K1 activity is a key player of the erythroid differentiation process.

S1381

CIRCULATING EXTRACELLULAR DNA MEDIATES VASO-OCCLUSIONS IN SICKLE CELL DISEASE

S Le Jeune[1], P Bonnin[2,3], D Charue[1,4], JB Arlet[5], F Lionnet[6], PL Tharaux[1,4], C Boulanger[1,4], O Blanc-Brude[1,4,*]
[1]INSERM UMRs970 ParCC, [2]UMRs965, INSERM, [3]AP-HP Hôpital Lariboisière - Explorations vasculaires, AP-HP, [4]Université Paris-Descartes, PRES Sorbonne-Paris-Cité, [5]AP-HP Hôpital Européen Georges Pompidou- Médecine Interne, [6]AP-HP Hôpital Tenon - Médecine Interne, AP-HP, Paris, France

Background: It was recently reported that circulating extracellular DNA (cirDNA) is increased in sickle cell disease (SCD). CirDNA apears to be associated to intravascular hemolysis and cell-free heme in plasma. But nothing is known of the physiopathological impact of cirDNA in SCD, nor its exact source.
Aims: Here, we aimed to define a role and possible origin of cirDNA in SCD. In particular, we hypothesized that cirDNA may be connected with and favor red blood cell (RBC) aggregation, vaso-occlusive crises (VOC) and ischemic events.
Methods: A blood collection from SCD patients and matched healthy volunteers was built. Platelet-free plsama, RBCs and neutrophils were separated by centrifugation. We cultured human neutrophils *in vitro* and monitored NETs formation. We also quantified extracellular DNA with a fluorescent intercalant probe. We used our model of renal vaso-occlusions induced by infusion of heme-loaded RBC microparticles in humanized SAD transgenic mice which share many features of human SCD.
Results: In SCD patients at steady state, cirDNA was increased by 300% over health, and a further 100% during VOC. Interestingly, cirDNA failed to increase when patients were treated with hydroxyurea, suggesting that increases in hemolysis and cirDNA may be connected during SCD. Next, we treated cultured neutrophils and endothelial cells with purified heme. Heme induced neutrophil extracellular traps (NETs) and endothelial apoptosis, with release of genomic DNA in supernatants. Next, we purified neutrophil DNA, added it to whole blood and studied RBC aggregation by laser-assisted optical red blood cell aggregometry. DNA induced RBC aggregation in SCD blood, but not healthy blood. Conversely, DNase-1 added to SCD blood collected during VOC reduced RBC aggregation back to steady state levels. Next, we triggered renal vaso-occlusions in SAD transgenic mice, and cirDNA levels were increased by 200% within 30 minutes. Moreover, one intravenous bolus of DNase-1, administered after inducing the occlusions, accelerated renal reperfusion back to normal levels in under 20 minutes. In contrast, spontaneous reperfusion with vehicle injection took over 90 minutes.
Summary and Conclusion: Our data reveal a novel mechanism of vascular occlusion in SCD: CirDNA may bind RBCs in blood, promote their aggregation and favor small vessel occlusions and reduced tissue perfusion. CirDNA and NETs may thus bridge intravascular hemolysis, inflammation and ischemic tissue injury in SCD. Interestingly, DNase digestion of plasma DNA and NETs may prove an unexpected but powerful novel pharmaceutical approach to manage vaso-occlusive events.

S1382

THE REGULATORY ROLE OF THE SECOND TRANSFERRIN RECEPTOR IN ERYTHROPOIESIS

A Nai[1,2,*], MR Lidonnici[2,3], M Rausa[1,2], G Mandelli[3], A Pagani[1,2], L Silvestri[1,2], G Ferrari[2,3], C Camaschella[1,2]
[1]Division of Genetics and Cell Biology, San Raffaele Scientific Institute, [2]Vita-Salute University, [3]San Raffaele Telethon Institute for Gene Therapy (HSR-TIGET), Division of Regenerative Medicine, Gene Therapy and Stem Cells, San Raffaele Scientific Institute, Milan, Italy

Background: Transferrin receptor 2 (TFR2) is a transmembrane protein, expressed in the liver and in the erythroid compartment, mutated in hemochromatosis type 3. Hepatic TFR2 is an activator of the master iron regulator, hepcidin (*HAMP),* while erythroid TFR2 is a partner of the erythropoietin receptor (EpoR), required for its efficient transport to the cell surface. In erythroid precursors *TFR2* silencing delays the erythroid differentiation. The *Tfr2*$^{-/-}$ mice lacking the hepcidin inhibitor *Tmprss6* shows iron deficiency and erythrocytosis, which is absent when *Tfr2* is specifically deleted in the liver suggesting that TFR2 is a limiting factor for erythropoiesis particularly in iron-deficiency.
Aims: To clarify the erythroid function of Tfr2 we generated and analyzed a mouse model specifically lacking *Tfr2* in the bone marrow (*Tfr2*^{BMKO}).
Methods: Lethally irradiated wild type (wt) male mice were transplanted with bone marrow cells from wt or *Tfr2*$^{-/-}$ donors. We evaluated the hematological parameters from 2 to 6 months after bone marrow transplantation (BMT) in mice fed a normal or iron-deficient (ID) diet, the iron parameters, the hepatic iron-genes expression and the rate of differentiation and apoptosis of the erythroid precursors at sacrifice.
Results: *Tfr2*^{BMKO} mice show Transferrin Saturation (TS), liver (LIC) and spleen (SIC) iron content comparable to wt controls. The ID diet induces a similar decrease of TS and SIC in both genotypes, while LIC was unchanged. The expression of *Bmp6,* the iron *Hamp* activator, is similar in wt and *Tfr2*^{BMKO}, compatible with the normal iron burden of *Tfr2*^{BMKO} mice. At each time point *Tfr2*^{BMKO} mice have higher Hb levels and RBCs count, but lower MCV and MCH than wt controls, a condition more evident in iron-deficiency. Four months after BMT *Tfr2*^{BMKO} have a higher proportion of nucleated erythroid precursors and reduced apoptosis of late erythroblasts than wt controls, in the presence of comparable Epo levels. At this time *Hamp* is lower in *Tfr2*^{BMKO} than in wt mice. Iron-deficiency increases the proportion of erythroid precursors, reduces apoptosis and increases Epo levels in wt mice, while the phenotype of *Tfr2*^{BMKO} animals remains unchanged.
Summary and Conclusion: Erythroid Tfr2 is not involved in systemic iron metabolism and in iron-mediated *Hamp* modulation as its hepatic counterpart. The reduced *Hamp* expression in *Tfr2*^{BMKO} animals 4 months after BMT irrespective of Epo levels, is likely related to the erythroid expansion and reduced apoptosis of late erythroblasts. Tfr2 behaves as a modulator of erythropoiesis in keeping with its function as an EpoR partner. By modulating the Epo sensitivity of the erythroid precursors, Tfr2 might adjust the erythrocyte number in order to balance their production according to the available iron, particularly in iron-deficiency. The lack of a phenotype change in iron-deficient *Tfr2*^{BMKO} mice further supports the hypothesis that Tfr2 is required for the correct erythroid response to iron deprivation. Ongoing full characterization of *Tfr2*^{BMKO} mice erythropoiesis and evaluation of the Epo-EpoR signaling pathway at different maturation stages of the erythroid precursors will help to clarify the underlying mechanisms.

S1383

MONOCYTE CHEMOATTRACTANT PROTEIN (MCP-1) IS A NOVEL MODIFIER OF TISSUE IRON LEVELS AND A PREDICTOR OF DISEASE SEVERITY IN HEREDITARY HEMOCHROMATOSIS

K Mleczko-Sanecka[1,2,3], O Marques[4,5], S Altamura[1,2], M Vujic Spasic[1,2], C Guida[1,2], R Pepperkok[1,3], H Runz[1,2], U Maus[6], J P Pinto[5], M Lawless[7], D Swinkels[8], WP Chen[9], C McLaren[9], M Lima[10], G Porto[5,10], M U Muckenthaler[1,2,*]

Background: Most patients with the iron overload disorder Hereditary Hemochromatosis (HH) are homozygous for the p.Cys282Tyr mutation in the *HFE* gene, but only a small percentage develops severe clinical symptoms. Environmental or genetic factors are thought to modify tissue iron overload and disease severity in these patients.
Aims: To identify and validate genetic modifiers of systemic iron levels
Methods: In a search for genetic modifiers of iron levels we performed a targeted RNAi screen for genes that affect transferrin uptake. Validation experiments were performed in MCP-1 knock-out mice and a phenotypically well characterized cohort of HH patients.
Results: We identified the monocyte chemoattractant protein (MCP-1), a chemokine known to be decreased in the serum of HH patient, as a critical suppressor of transferrin uptake in human cells. We next analyzed whether MCP1-deficiency alters iron homeostasis in MCP-1 knock-out mice. Interestingly, the lack of MCP-1 causes decreased serum iron levels and transferrin saturation, massive iron-overload in the spleen as well as mild iron accumulation in the liver. The iron imbalance in MCP-1-deficient mice is unlikely explained by an aberrant immune cell composition of the spleen or by an impairment of the hepcidin/ferroportin regulatory system: hepcidin mRNA expression is unaltered, splenic ferroportin protein expression is strongly increased in MCP-1 deficient mice, as would be expected as a consequence of iron overload. Consistent with our findings in the cellular assays, we observe inappropriately high levels of TfR1 in the MCP-1-depleted spleen paralleled by an increased expression of globin/heme biosynthesis genes and Epo production. This observation raises the possibility that augmented TfR1-mediated iron uptake from the plasma may be responsible at least in part for splenic iron accumulation. Finally, MCP-1 levels were shown to modify disease severity in patients with HH. Among individuals homozygous for the p.Cys282Tyr *HFE* mutation MCP-1 levels negatively correlate with liver iron overload and clinical manifestation of HH at the time of diagnosis.
Summary and Conclusion: Taken together our results suggest that appropriate MCP-1 expression is required to prevent excessive iron accumulation and that a low MCP-1 profile may be used as a novel biomarker predicting symptomatic disease in HH. These findings broaden the growing spectrum of homeostatic roles of MCP-1 that reach beyond its originally identified functions in immune cells recruitment.

SOLUBLE TRANSFERRIN RECEPTOR 2 IS SHED FROM PLASMA MEMBRANE AS AN EARLY SIGNAL OF IRON DEFICIENCY

A Pagani[1,*], M Vieillevoye[2,3], A Nai[1], M Rausa[1], M Ladli[2,3], C Lacombe[2,3], P Mayeux[2,3], F Verdier[2,3], L Silvestri[1], C Camaschella[1]

[1]Vita Salute University and San Raffaele Scientific Institute, Milan, Italy, [2]Institut Cochin, INSERM, U1016, Université Paris Descartes, CNRS (UMR8104), [3]Ligue National contre le Cancer, Paris, France

Background: Transferrin receptor-2 (TFR2) is a transmembrane protein, homologous to the iron importer transferrin receptor-1 (TFR1), with a restricted expression to hepatocytes and erythroblasts. TFR2 is the proposed sensor of diferric transferrin (holo-TF) with a regulatory role in iron homeostasis. The manifestation of *TFR2* mutations, responsible for type 3 hemochromatosis in humans, and *Tfr2* inactivation in mice (*Tfr2-/-*), is systemic iron overload with inappropriately low levels of hepcidin, the master regulator of body iron distribution. The binding of holo-TF favors the receptor recycling and its stabilization on the cell surface. In cultured hepatoma cell lines TFR2 interacts with hemochromatosis proteins HFE and HJV to activate hepcidin expression. In erythroid cells TFR2 interacts with erythropoietin receptor (EpoR) for efficient transport of EpoR to the cell surface. Both *TFR2*-hemochromatosis patients and *Tfr2-/-* mice have no evident hematologic abnormalities. However, *TFR2* silencing in human erythroid progenitors delays their terminal differentiation.
Aims: Since TFR1 is released into plasma as a marker of iron deficiency and erythropoietic activity, we searched for a soluble form of TFR2 and investigated its features and function.
Methods: The supernatants of TFR2-transfected cells (HeLa, HuH7, CHO-Trvb-0) and TFR2 competent cells (UT7 and CD36+ human erythroid progenitors) were analyzed by western blot for the presence of soluble TFR2 (sTFR2) and its modulation in response to cell iron changes. We studied the function of sTFR2, evaluating its activity on hepcidin promoter in a luciferase assay in hepatoma cell lines (HuH7 and Hep3B) and its effect on Epo-EpoR interaction in erythroid cells.
Results: sTFR2 is released in the culture media and the shedding is inhibited in a dose dependent manner by holo-TF. The ligand might interfere with the cleavage likely changing TFR2 folding; the $TFR2^{G679A}$ variant, that abolishes the ligand binding motif, releases sTFR2 even in the presence of holo-TF. sTFR2 shedding occurs at the membrane level; a mutated dynamin, that blocks endocytosis, increases sTFR2 release, while brefeldin-A, that blocks intracellular trafficking, inhibits TFR2 shedding. To define the protease involved in the cleavage we tested different protease inhibitors: sTFR2 decreases in the presence of the proconvertase inhibitor cloromethylchetone (CMK). The overexpression of furin (that cleaves HJV) and PCSK7 (responsible for TFR1 shedding) did not modify the amount of sTFR2 suggesting that a different CMK-sensitive protease is involved in the process. Since the cleavage site remains unknown we generated an artificial soluble TFR2 (sTFR2*) spanning the entire ectodomain (696 aa) compatible with the size of the released form. sTFR2* interacts with the iron related proteins HJV and HFE and partially reduces both basal and HJV-mediated hepcidin promoter activation *in vitro*. sTFR2* does not affect EpoR expression or Epo binding in erythroid cells.
Summary and Conclusion: We identified a previously unrecognized soluble form of TFR2 that is shed from plasma membrane both in transfected hepatoma cells and in TFR2-expressing erythroid cells, a process regulated by the ligand holo-TF. We suggest distinct local effects for hepatic and erythroid sTFR2. When transferrin is unsaturated sTFR2 could interfere with the hemochromatosis proteins in the liver, with a modest decoy function on hepcidin activation. At the same time, because of TFR2 low affinity for holo-TF and its interaction with EpoR, the release of erythroid sTFR2 might signal iron deficiency earlier than sTFR1.

CD45 ANTIGEN NEGATIVITY CORRELATES WITH PTPRC MUTATION

S Raponi[1,*] V Gianfelici[1], S Chiaretti[1], F Brugnoletti[1], MS De Propris[1], M Marinelli[1], G Hulselmans[2], S Aerts[2], E Geerdens[3], J Cools[3], R Foà[1], A Guarini[1]
[1]Haematology and Cellular Biotechnology, Sapienza University of Rome, Rome, Italy, [2]Center for Human Genetics, KU Leuven, [3]Center for Human Genetics and Center for the Biology of Disease, KU Leuven and VIB Leuven, Leuven, Belgium

Background: The protein tyrosine phosphatase CD45, encoded by the *PTPRC* gene, is a well known regulator of B- and T-cell receptor signaling. *PTPRC* loss-of-function mutations have been described together with activating mutations of *JAK1*, *IL7R alpha* and *LCK* in T-ALL cell lines, and the consequent down-regulation of CD45 expression resulted in increased downstream signals. CD45 negativity has been described in a small proportion of pediatric T-cell acute lymphoblastic leukemias (T-ALL). We have recently identified a 49 year-old CD45 negative male T-ALL patient. He was a prednisone poor responder and showed a slow blast clearance after induction therapy. To our knowledge, this represents the only adult case so far reported.
Aims: To get insights into the *PTPRC* mutational status we used a combined analysis that could be useful to define a peculiar and rare T-ALL subset.
Methods: Diagnosis of T-ALL was established according to the World Health Organization. Flow cytometry analysis on bone marrow cells was conducted using FACSCanto II instrument (Becton Dickinson, San Josè, CA). CD45 expression was investigated using a PE-conjugated CD45 monoclonal antibody (clone 2D1) (BD Biosciences). gDNA samples of matched tumor (bone marrow) and germline (salivary) were analyzed by whole exome sequencing (WES, Illumina HiSeq2000). Whole transcriptome analysis (RNAseq) was also performed to identify alternative transcripts, fusion transcripts, single nucleotide variants (SNVs) and to quantify gene expression levels. Normal thymus cells from healthy donors were used as negative controls. Validation of SN*Vs* was performed by Sanger sequencing.
Results: Flow cytometry analysis on bone marrow cells revealed an 84% infiltration by T-lineage blast cells: CD7/CD99/TdT/cyCD3/CD5+, with a partial expression of CD2 and CD34, and negative for CD3/CD1a/CD4/CD8/TCRαβ/TCRγδ and for myeloid antigens. The CD45 antigen was also absent. Conventional cytogenetics revealed a normal karyotype, while molecular biology failed to show any recurrent fusion transcripts nor any specific TCR gene rearrangement. WES identified an essential splice site mutation at the end of intron 15-16 of *PTPRC* gene (c.1721-2A>G, *ref.* ENST00000442510) with a variant allele frequency of 0.8125. Validation by PCR and Sanger sequencing confirmed that the *PTPRC* mutation was somatically acquired. RNAseq data indicated that in the majority of mRNA's introns 15 and 16 were retained, while this was not the case for other T-ALL cases or normal thymus cells. In addition, splicing of exon 15 to the middle of exon 16 or a newly used exon was observed, all indicative of erroneous splicing. Notably, a *JAK1* R724H mutation was also detected by WES and RNAseq.
Summary and Conclusions: Overall, this study highlights that the absence of CD45 can be associated with *PTPRC* mutations. The low *PTPRC* expression, together with the lack of CD45 antigen, lead to speculate that none of these alternative transcripts will produce normal proteins but rather unstable proteins prone to be degraded. The study of additional CD45 negative T-ALL cases would help to better define the role of these phenotypic features on the clinical behavior of this peculiar and rare subset. Given the role of CD45 in the regulation of JAK/STAT signaling, further investigations are warranted to clarify if cells harboring CD45 lesion might be sensitive to JAK inhibitors.

UPREGULATION OF MIR-181A/C PREDICTS POOR PROGNOSIS IN PATIENTS WITH T-CELL ACUTE LYMPHOBLASTIC LEUKEMIA

P Li[1], X Dahai[1], Z Nan[1,*] D Ning[1], C Hongli[1], L Xiaoliang[1], W Yang[1], Z Xiuxian[1]
[1]Emergency Department, First Hospital of Jilin University, changchun, China

Background: MicroRNAs (miRNAs) play an important role in lymphoid differentiation, and aberrant miRNA expression has been demonstrated as a frequent event in lymphoid malignancies.
Aims: The aim of this study was to investigate the expression status of miR-181a/c and its clinical significance in adult de novo T-cell acute lymphoblastic leukemia (T-ALL) patients.
Methods: The expression levels of miR-181a/c in bone marrow lymphoid cells were measured in 86 newly diagnosed T-ALL patients and 20 cases of normal healthy donors by real-time quantitative polymerase chain reaction. The prognostic values of miR-181a/c in T-ALL were also analyzed.
Results: Compared with normal controls, upregulation of miR-181a/c in the bone marrow of T-ALL patients with statistically significant differences ($P<0.001$) was found. miR-181a/c upregulation was identified in 62 of 86 (72.1%) T-ALL patients. The patients with miR-181a/c upregulation had lower hemoglobin level than those without miR-181a/c upregulation (64 *versus* 79 g/L, respectively, p=0.008). Moreover, multivariate analyses revealed that miR-181a/c upregulation was associated with worse complete remission (CR) rates (p=0.01), relapse-free survival (RFS; p=0.02), and overall survival (OS) (p=0.03) in T-ALL patients.
Summary and Conclusions: miR-181a/c upregulation is a common event, and its association with poor CR rates, RFS, and OS. These findings suggest that miR-181a/c upregulation may be used as an unfavorable prognostic marker in T-ALL.

OPTIMIZATION OF LENTIVIRAL TRANSDUCTION IN PATIENT-DERIVED ACUTE LEUKEMIA CELLS GROWING IN MICE

C Finkenzeller[1,*] M Carlet[1], I Jeremias[1]
[1]Helmholtz Zentrum Munich, Munich, Germany

Background: Acute leukemia is a frequent disease in children and adults and remains difficult to treat in many patients. Novel therapeutic options are intensively desired and require preclinical testing in adequate model systems. For preclinical testing of new treatment strategies our lab uses the individual xenograft mouse model to amplify primary patient cells in severely immunocompromised mice. We recently established genetic manipulation of patient-derived xenograft (Pdx) cells using third-generation lentiviral vectors to express various transgenes in Pdx cells (Terziyska *et al.*, PLOS one, 2012).
Aims: Nevertheless, lentiviral transduction remains challenging in leukemia cells in general and in patient-derived cells in particular, as these cells are reluctant towards *in vitro* growth. Here, we aimed at improving lentiviral transduction in order to obtain higher transduction efficiencies in Pdx cells.
Methods: Expression of fluorescent proteins and cell surface markers (*e.g.* NGF-receptor) allow flow cytometry-based cell enrichment and sample purification over magnetic columns using magnetic beads. Luciferase expression enables direct visualization of Pdx cells growing in mice by bioluminiscence *in vivo* imaging. Lentivirus production was improved to achieve titers of 10^{9-10} infectious units/mL on B-ALL Nalm6 cell line cells by using pre-coated flasks for culture of HEK-293T cells followed by concentration of the virus supernatant by factor 150 - 200. Using feeder cells, *in vitro* co-culture enabled prolonged culture of transduced Pdx cells *in vitro* in parallel to re-transplantation into NSG mice. Irradiated mouse stromal cell lines EL08 or OP9 allowed *in vitro* culture until the transgene was expressed.
Results: Lentivirus production was improved and the transduction protocol for Pdx cells was optimized by increasing multiplicity of infection (virus to cell ratio) to 1.000 - 1.500 and culturing Pdx cells on laminin-coated plates during infection. If 2 transgenes were to be expressed concomitantly, simultaneous transduction with 2 small constructs was more efficient than a single transduction with a large construct. Although the Pdx cells did not cycle in the co-culture, they produced the transgene, e. g., a fluorescent protein, which could be measured in flow cytometry usually 3 - 6 days after transduction. The data obtained after co-culture nicely correlated with data obtained upon transplantation of lentivirally transduced Pdx cells into mice and were thus predictive for the transduction rate measured after *in vivo* cell amplification. In some, but not all samples and constructs, *in vitro* co-culture even enabled enrichment of transgenic cells directly after lentiviral transduction and spared one passage of cell amplification in mice.
Summary and Conclusions: Taken together and upon optimization of virus production, cell infection and cell culture, transduction efficiencies are now high enough to allow enrichment to above 95% transgenic Pdx cells at best even within a single mouse passage.

THE LEVELS OF IKZF1-DELETION IN CHINESE ADULTS WITH ACUTE LYMPHOBLASTIC LEUKEMIA

GR Ruan[1,*] QM Yao[1], N Li[1], X Leng[1], LD Li[1], JL Li[1], Y Chang[1], YZ Qin[1], YR Liu[1], SS Chen[1], KY Liu[1], XJ Huang[1]
[1]Peking University People's Hospital and Institute of Hematology,Beijing Key Laboratory of Hematopoietic Stem Cell Transplantation, Beijing, China

Background: The deletion of IKZF1 has been shown to be a hallmark of ALL and early studies suggest it is associated with a poor prognosis. Most IKZF1 intragenic deletions encompass exons 4 to 7, 4 to 8, 2 to 7 and 2 to 8 (thereafter named Δ4-7, Δ4-8, Δ2-7 and Δ2-8, respectively). The deletion breakpoints for these alterations are usually located within a few nucleotides, suggested the feasibility of detecting the levels of IKZF1-deletion based on real-time quantitative polymerase chain reaction (RQ-PCR).
Aims: To detect the levels of IKZF1-deletion in the leukemic cells from Chinese adults with acute lymphoblastic leukemia by using the multiplex RQ-PCR.
Methods: This study involved untreated 328 adult ALL patients at Peking University People's Hospital from 2007-2012. Leukemia cells from 412 ALL patients were obtained at diagnosis and/or relapse from bone marrow or blood samples. In order to detect IKZF1 Δ4-7, Δ4-8, Δ2-7 and Δ2-8 alterations, DNA from the samples were examined by using the multiplex RQ-PCR, multiplex fluorescent PCR and sequence analysis. Plasmid standards of albumin (ALB) gene and IKZF1 Δ4-7 deletions were prepared, and six serial plasmid dilutions (10^7-10^2 copies) were amplified by RQ-PCR to construct a standard curve for the absolute quantitative assessment of copy number. The IKZF1 deletion copy number in 100 ALB copies was used as the IKZF1-deletion gene content.
Results: The results for amplified the IKZF1 Δ4-7 deletion plasmids revealed that all correlation coefficients were above 0.99, and the sensitivity of detection was one copy. In eight DNA samples of IKZF1 Δ4-7-positive patients, the Ct value was in the linear range for a tenfold dilution series (10^0-10^{-5}) and the deletions were detected with a sensitivity of 10^{-4} or 10^{-5}. High correlation coefficients allowed accurate assessment of the quantity of IKZF1 deletions in unknown samples. The detection rate of IKZF1-deletion in untreated 328 ALL patients was 36.28%, including 66 (68.75%) with BCR-ABL1-positive ALL, 46 (22.44%) with BCR-ABL1-negative ALL. In 119 IKZF1-deletion positive specimens, the average IKZF1-deletion copies/ALB copy was 138.54% (0.11%–697.93%). Eighteen IKZF1-deletion-positive patients (84 samples in total) were followed up after treatment, among them, 14 patients in hematologic remission continued to test negative for IKZF1-deletion within 9–66 weeks of follow-up. In three relapsed cases and in one case with no remission, the IKZF1-deletion copies/ALB copies (%) value was obvious increase as compared with the baseline (Figure1). Sequence analysis and multiplex fluorescent PCR revealed that the 119 positive cases included 80 (67.2%) cases with type Δ4-7, 29 (24.4%) cases with type Δ2-7, seven (5.9%) cases with type Δ4-8, three (2.5%) cases with type Δ2-8, and eight cases with deletion of both alleles. Patients with 284 B-ALL subtype had a higher IKZF1-deletion rate (118/284, 41.5%) than those (1/44, 2.3%) with 44 T-ALL subtype (P<0.01). IKZF1 deletions were significantly associated with higher initial white blood cell counts in the peripheral blood(P<0.01),but not with age, gender, blast in the bone marrow, hemoglobin and platelet counts in the peripheral blood.
Summary and Conclusions: The results demonstrated that multiplex RQ-PCR was a reliable and sensitive method for detecting IKZF1 deletions and for the quantitative analysis of minimal residual diseases. Multiplex RQ-PCR should be considered as a routine screening assay for IKZF1 deletions in adult ALL.

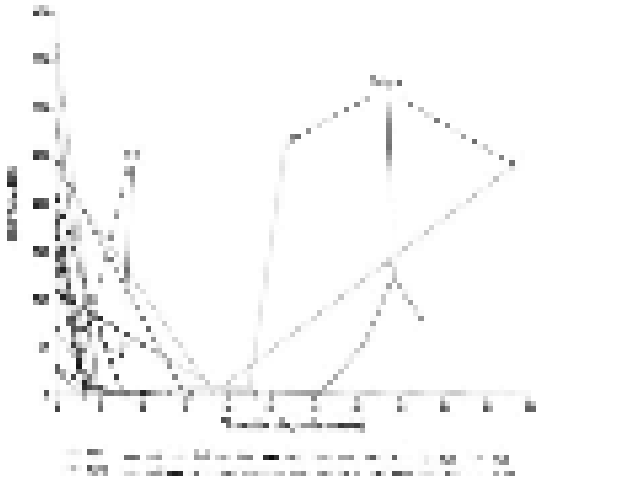

Figure 1. IKZF1 detected copies/ALB copies (%) at diagnosis, after induction therapy, and during follow-up in ALL partients with IKZF1 detection. NR, no hematological remission; Relapse, hematological relapse.

PB1390

GENOMIC ANALYSIS OF NOTCH MUTATIONS IN A CASE OF ALAGILLE SYNDROME WITH ACUTE LYMPHOBLASTIC LEUKEMIA

B Simona[1], P Tononi[1], S Marin Vargas[1], G Bassi[1], O Perbellini[1], A Ambrosetti[1], V Meneghini[1], L Scaffidi[1], I Ferrarini[1], A Bonalumi[1], G Martinelli[2], I Iacobucci[1], D Russo[3], G Pizzolo[1], M Delledonne[1], M Krampera[1*]
[1]University of Verona, Verona, [2]University of Bologna, Bologna, [3]University of Brescia, Brescia, Italy

Background: Alagille syndrome (ALGS), or arteriohepatic dysplasia, is a congenital multisystem disease due to Notch signalling pathway mutations, most commonly affecting JAG1 (ALGS type 1), and more rarely NOTCH2 (ALGS type 2), leading to hepatic, lung, renal and ocular dysfunction (chronic cholestasis, peripheral pulmonary artery stenosis, dysplastic kidneys pigmentary retinopathy), and skeletal abnormalies (minor vertebral segmentation, characteristic facies, posterior embryotoxon/anterior segment defects). ALGS is an autosomal dominant disease, but it is characterized also by variable penetrance and clinical expression and somatic/germline mosaicism. A 20-year-old man with ALGS was admitted to the University Hospital of Verona because of pancytopenia. Following analyses led to the diagnosis of Philadelphia chromosome/bcr-abl-negative, CD10-positive, B-lineage acute lymphoblastic leukemia (common B-ALL).
Aims: The occurrence in the same patient of both congenital Notch pathway mutations (ALGS) and acquired neoplastic disease related to the Notch signalling (B-ALL) is quite an exceptional event that offers a great opportunity to investigate the role of Notch in the predisposition to, onset and development of leukemia. In order to identify the genetic components involved in this complex phenotype, we sequenced the exome of a bone marrow sample collected from the patient.
Results: By genome interpretation with Knome pipeline applied to the reference genome UCSC hg19, we found missense variants both in NOTCH2 (E38K) and JAG1 (P871R) genes that are mainly involved in the syndrome, although their effect on protein function was predicted not to be deleterious. We detected putative damaging mutations in genes such as PAX5 (R38H) and NOTCH1 (K1821N) which might be strongly related to the observed disease. In fact, PAX5 is a member of PAX protein family of transcription factors implicated into regulation of early development, that binds NOTCH2 and likely altering its functionality. On the other hand, NOTCH1 is involved in cell growth and proliferation and thus the predicted alteration of function of the corresponding protein may have an important role in neoplastic transformation.
Summary and Conclusions: Overall, this study provides novel insights in the pathogenetic development of B-ALL in a patient with dysregulated Notch signalling due to ALGS. On the basis of the genetic abnormalities found and here discussed, we suggest a model that may explain the molecular link among the different signalling pathways involved in the development and relapse of B-ALL.

PB1391

EVALUATION OF NEW MARKERS FOR FLOW CYTOMETRIC MONITORING OF MINIMAL RESIDUAL DISEASE IN CHILDHOOD B-CELL PRECURSOR ACUTE LYMPHOBLASTIC LEUKEMIA

L Sędek[1,*], A Sonsala[1], M Twardoch[1], VH Van der Velden[2], A Orfao[3], E Mejstrikova[4], T Szczepański[1]
[1]Pediatric Hematology and Oncology, Medical University of Silesia, Zabrze, Poland, [2]Department of Immunology, Erasmus MC, University Medical Center Rotterdam, Rotterdam, Netherlands, [3]Cancer Research Center (IBMCC-CSIC), Department of Medicine and Cytometry Service, University of Salamanca (USAL) and Institute of Biomedical Research of Salamanca (IBSAL), Salamanca, Spain, [4]Department of Pediatric Hematology and Oncology, 2nd Faculty of Medicine, Charles University, Prague, Czech Republic

Background: B-cell precursor acute lymphoblastic leukemia (BCP-ALL) is the most common cancer of childhood. Initial diagnostics of this disease is currently established with multiparametric flow cytometry, *e.g.* using EuroFlow Consortium approach. Flow cytometry is also successfully applied for treatment monitoring, through the detection of minimal residual disease (MRD) at different treatment timepoints. The initial response to the induction treatment, ie. degree of reduction of leukemic cell burden during the first 4-6 weeks of chemotherapy as measured by MRD is particularly crucial for stratification of patients into risk groups.
Aims: The aim of the study was to assess the expression of newly identified markers of blast cells in childhood BCP-ALL, CD304 and CD86 which are not expressed by normal B-cell precursor cells. The stability of expression of these markers was assessed in terms of usefulness for MRD monitoring.
Methods: Bone marrow samples of 99 consecutive children with BCP-ALL were stained at initial diagnosis with four 8-color combinations of monoclonal antibodies, including the new markers CD304 and CD86. In 53 patients, bone marrow samples were analysed at day 15 of the induction treatment and in 25 patients also at day 33.
Results: The expression of CD304 was observed in 56.4% of patients at diagnosis. High expression of CD304 was observed in 27.4% of patients

whereas in 29.0% of patients the expression of CD304 was weak. The expression of CD86 was found in 32.7% of patients at diagnosis. High expression of CD86 was observed in 12.7% of patients while in 20.0% of patients the expression of CD86 was low. The examination of bone marrow samples at day 15 and 33 of the induction treatment revealed that the level of expression of both CD304 and CD86 during treatment was similar as compared to the diagnosis. No cases of disappearance of either of the two examined antigens were found.

Summary and Conclusions: Both tested markers appeared to be useful for MRD monitoring, particularly CD304. More accurate definition of the phenotype of leukemic blasts enables more precise assessmet of leukemic blasts numbers during early treatment timepoints, which is important for proper stratification of BCP-ALL patients into risk groups.

This work was supported by funding from ERA-NET PRIOMEDCHILD (grant 40-41800-98-027) and Internal Grant from the Medical University of Silesia.

BOTANICAL ALKYL HYDROQUINONE HQ17(3) IS CYTOTOXIC TO T(9;22) PHILADELPHIA CHROMOSOME SUP-B15 ALL CELLS THROUGH INDUCING OXIDATIVE STRESS AND IRON-DEPENDENT AUTOPHAGY-ASSOCIATED LYSOSOMAL EVENTS

CY Hu[1,*] YJ Chang[1], LI Lin[1], SB Lin[1], DT Lin[2]
[1]Department of Clinical Laboratory Sciences and Medical Biotechnology, College of Medicine, National Taiwan University, [2]Departments of Pediatrics and Laboratory Medicine, National Taiwn University Hospital, College of Medicine, National Taiwan University, Taipei, Taiwan, Republic of China

Background: Acute lymphoblastic leukemia with Philadelphia chromosome (Ph^+-ALL)(t(9;22)*BCR-ABL*) is a very high risk (VHR) hematological neoplasm. Multiple genetic lesions together with constitutively active BCR-ABL oncoprotein contribute to a very aggressive clinical cause. Tyrosine kinase inhibitors (TKIs) fail to convey long-term control of the disease. Searching for agents with higher specificity to leukemias and investigating the molecule mechanisms involved in the selective ibhibitory effects on leukemic cells will help to find new anti-leukemic therapeutics for the Ph^+-ALL. HQ17(3) [10'(Z),13'(E),15'(E)-heptadecatrienyl-hydroquinone], a natural product isolated from the sap of *Rhus succedanea*, exhibited very effective cytotoxic effect on the TKI-resistant Ph^+-ALL cell line SUP-B15 (IC_{50}: 1.9 μM), but spared normal peripheral blood mononuclear cells.

Aims: To investigate the characters of, and the molecular pathways involved in the HQ17(3)-induced cytotoxic effects in Ph^+-ALL SUP-B15 cells.

Methods: HQ17(3)-treated and control SUP-B15 cells were stained and analyzed by flow cyteometry: 1) membrane lipid disturbance was analyzed by Annexin V/PI stain, 2) DNA fragmentation was defined as sub-G1 fraction of cellular DNA content after the PI staining, 3) mitochondrial membrane potential (MMP) loss were stained by DiOC6(3). Pan-caspase inhibitor (zVAD-fmk), receptor interacting protein 1 (RIP1) inhibitor (necrostatin-1, Nec-1), iron-chelator (deferroxamine, DFO), 3-methyladenine (3MA) or chloroquine (CQ) (autophagy inhibitors), and lysosomal protease inhibitors were used in combination with HQ17(3) in some experiment. Acridine orange stain and confocal microscopy are used to visualize the changes of lysosomes in the presence of HQ17(3). Autophagic flow in response to HQ17(3) was revealed by accumulation of LC3B-II visualized by western blot analysis.

Results: Introduction of HQ17(3) induced rapid (within 24 hours) and extensive cell death characterized by losing plasma membrane integrity (PI^+) concomitant with PS exposure (Annexin V^+), which was not prevented by zVAD-fmk and/or Nec-1, indicating a caspase-independent necrotic death program. HQ17(3)-induced cell death displays MMP loss and profound nuclear DNA fragmentation that could be attenuated by ROS scavengers. ROS production/oxidative stress account for important part of the cell demise. DFO abolished the HQ17(3)-induced cell death, suggesting iron-dependent event(s) is critical for the HQ17(3)-induced cell destruction. Both the number and size of acidic vesicles are significantly increased 4 hours after treatment of HQ17(3) then diminished when cell death is evident. Application of AEBSF (serine protease inh.) and/or pepstatin/CA074-Me (cathepsin D/B inh.) did not rescue cells from death, thus rule out the lysosomal membrane permeability (LMP)-mediated death program. Autophagic flow was enhanced in HQ17(3)-treated cells. Further, autophagy inhibitors (3MA and CQ) showed a modest protective effect.

Summary and Conclusions: Naturally-derived HQ17(3) displayed selective, and significant cytotoxicity in Ph^+ ALL SUP-B15 cells. HQ17(3) induces extensive iron-dependent and autophagy-related lysosomal events followed by necrotic-like cell demise. The cell death program is caspase-independent, and different from necroptosis or LMP-mediated cell death. ROS production contributes to this potent cell destruction process. These results suggest that agents selectively induce or sustain ROS in leukemic cells may induce autophagy-associated cell death, and would potentially augment the treatment for VHR-ALL with t(9;22) translocation.

PB1393

INTRA-TUMORAL HETEROGENEITY OF T-ALL LEUKEMIC BLASTS AT DIAGNOSIS AND FOLLOW-UP; IMPLICATIONS FOR MINIMAL RESIDUAL DISEASE MONITORING

NF Øbro[1,*] L P Ryder[1], H O Madsen[1], B K Albertsen[2], P S Wehner[3], S Rosthøj[4], N Toft[5], K Schmiegelow[6], H V Marquart[1]
[1]Dept. of Clinical Immunology, Copenhagen University Hospital, Rigshospitalet, Copenhagen, [2]Department of Pediatrics, Aarhus University Hospital Skejby, Aarhus, [3]Department of Pediatric Hematology and Oncology, Odense University Hospital, Odense, [4]Pediatric Department, Aalborg University Hospital, Aalborg, [5]Department of Hematology, Herlev University Hospital, Herlev, [6]Department of Pediatric and Adolescent Medicine, Copenhagen University Hospital, Rigshospitalet, Copenhagen, Denmark

Background: Heterogeneity of T-cell acute lymphoblastic leukemia (T-ALL) blasts may compromise minimal residual disease (MRD) monitoring, the most important prognostic tool in T-ALL. PCR is currently used for MRD monitoring, but potentially both PCR- and flow cytometry (FC)-based MRD methods might miss blast subpopulations that differ from the dominating clone at diagnosis, which is important if subpopulations have divergent chemo-sensitivity.

Aims: We aimed to investigate the intra-tumoral heterogeneity of the leukemia-associated immunophenotype (LAIP) in T-ALL patients and the implications for MRD detection.

Methods: We investigated the LAIP by 8-color FC in diagnostic bone marrow (BM) samples from 49 T-ALL patients (NOPHO ALL-2008). 22 of these were also analyzed for diversity of T-cell receptor (TCR) gene-rearrangements in flow-sorted blast subpopulations. MRD LAIP markers were evaluated by PCR TCR-marker detection in flow-sorted cells (61 follow-up BM samples from 30 pts). LAIP modulation patterns seen by FC during early induction treatment were further evaluated in 18 patients MRD-positive >0.1% (PCR-MRD day29).

Results: >80% of the T-ALL patients had at diagnosis heterogeneous LAIPs with bimodal marker expression, most often of CD1a, CD4, and TdT. Dominant TCR clonal gene rearrangements were generally conserved across the phenotypically diverse blasts (21 out of 22 patients), except in one patient. We did not detect an association between a high number of blast subpopulations at diagnosis (>two markers bimodally expressed) and high MRD level (PCR-MRD day29 >0.1%). The percentage of predicted LAIP-defined sorted MRD cells being PCR-positive was: 94% in patients with fully informative LAIP and 76% in patients with partly informative LAIPs (not all blasts having aberrant marker expression). The percentage of cells classified as normal cells being PCR-negative when sorted was: 93-95% (in patients with informative LAIP) or 62-75% (in patients with partly informative LAIP).

At early follow-up, we observed significant LAIP changes in several markers, including loss of CD1a and TdT and CD4 decrease.

Summary and Conclusions: Intra-tumoral heterogeneity of immaturity and T-linage markers was common in T-ALL. The phenotypically diverse blasts generally had invariable dominant TCR gene-rearrangements; accordingly PCR-MRD would detect all subpopulations. When all blasts of heterogeneous LAIPs were informative, MRD identified by FC was highly concordant with cells positive for TCR MRD markers. The T-ALL blasts showed changes in LAIP at early follow-up, most significant in reduction of immaturity markers, which can affect MRD by FC. Whether changes in heterogeneous LAIPs at follow-up are due to divergent subpopulation chemo-sensitivity or modulations of expression in surviving blasts need to be elucidated.

PB1394

CHARACTERIZATION OF SET-NUP214 REARRANGEMENT IN T-ACUTE LYMPHOBLASTIC LEUKAEMIA. SINGLE CENTRE EXPERIENCE

J Chi[1], C Prokopiou[2], A Barmpouti[1], S Koumas[2], N Neokleous[2,*] L Koumas[1], O Seimeni[2], M Manoloukos[1], P A Costeas[1]
[1]Centre of Study of Hematological Malignancy, Karaiskakio Foundation, Nicosia, [2]Hematology Department, General Hospital of Limassol, Limassol, Cyprus

Background: SET-NUP214 rearrangement was first reported in 1990, but with increasing strong association with T-ALL. Recently it was reported that this specific rearrangement could not be by itself leukemogenic.

Aims: We present two cases of acute leukaemia with SET-NUP214 rearrangement and complex karyotype.

Methods: To characterize the SET-NUP214 rearrangement 41 adult ALL patients were screened using hemaVisoin kit (DNA Technology, Denmark) and two were found SET-NUP214 positive with incidence of 4.9% which is equal to previous study. The first patient, female, 48 years old, was admitted to the hospital due to general lymphadenopathy. Her blood count indicated anaemia and leukopenia and film examination showed 59% large size blasts. Bone marrow biopsy and biopsy from the cervical node have been done. The diagnosis of early T ALL was made (CD7+, CD5 dim, sCD3-, cCD3+, CD4-, CD8-, CD34+, HLADR+, CD117+, MPO+). Cytogenetic analysis showed complex karyotype deletion of chromosomes 13, 17, 12 and 18. The second patient, male, 45 years old, was

admitted to the hospital due to easy tiredness and osteoalgia. His blood count indicated lymphocytosis and film examination revealed 63% large size blasts. His bone marrow biopsy was dry tap. His computed tomography revealed general lymphadenopathy. The diagnosis of early T ALL was made by both bone marrow biopsy and immunophenotypic analysis of peripheral blood (CD7+, CD38+, CD34+, CD3+, CD4-, CD8-, CD33+, CD1a-).

Results: In both cases, a single SET-NUP214 transcript was amplified by RT-PCR and sequencing of the fusion transcript revealed fusion of the exon 7 of SET to exon 18 through exon 32 of NUP214. This fusion transcript is identical to that described in the previously published cases (Image 1). In order to further investigate this rare rearrangement we performed array-CGH analysis. Apart from del(9)(q34.11-34.11) which generated the SET-NUP214 rearrangement both patients were found to harbour multiple genomic losses and gains. Twenty additional genomic regions on chromosomes 2, 6, 8, 9, 11, 12, 16, 17 were deleted in the first patient and thirteen genomic imbalances located on chromosomes 1, 4, 6, 7, 9, 12, 13, 17, 18, 20 were identified in the second patient. Both patients shared del (17)(q11.2), del(6)(q16.1-q21) and del(12)(p12.1-13.1) –spanning the ETV6 and CDKN1B gene loci– , that have been also described in other published cases with SET-NUP214. The female patient received combined chemotherapy followed by transplantation from her fully matched sibling. After one year she relapsed and died during the induction therapy. The male patient received also combined chemotherapy followed by transplantation from a fully matched unrelated donor. He died six months after the transplantation.

Summary and Conclusions: SET-NUP214 rearrangement is recently reported to early T ALL and to acute undifferentiated leukaemia. The reported cases are still few to make inferences but since this rearrangement is insufficient to develop leukaemia in mice, it needs additional chromosomal aberrations to induce leukemogenesis. It seems that the complex karyotype and possibly the ETV6 and CDKN1B deletions, detected in the many cases with SET-NUP214 are critical to the phenotype and to prognosis of this type of acute leukaemia.

PB1395

EVIDENCE OF ANTITUMOR ACTIVITY OF MACROPHAGES IN CULTURE

T Saralidze[1,*] T Saralidze[2], T Shvelidze[3], L Mokhevishvili[4]
[1]Faculty of Medicine, AIETI Medical School, [2]Department of Internal Medicine, Tbilisi State Medical University, [3]Department of Clinical Laboratory, Medical Center JUNONA, [4]Department of Reanimatology, Children's Hospital, Tbilisi, Georgia

Background: For a long time macrophages are considered as the main cells defending the organism from infection agents, but their role in the struggle against tumor isn't always evident. Study of macrophage-lymphocyte contacts in blood leukocyte cultures of patients with different diseases revealed that macrophage-lymphocyte rosettes (MLRos) formation *in vitro* represents immune reactivity of organism. Their low indices show decrease of immunity, whereas their high level reflects immune conflict in the course of the disease. [Shvelidze T., Saralidze T., Saralidze N., Mokhevishvili L. (2013) Atlas of Hematology, Preclinical Diagnosis. //www.e-bookland.ge/medical/ATLAS-of-HEMATOLOGY]. Our previous investigations showed that amount of MLRos in patients with malignant solid tumor diseases equaled 54,5±1,1%, while in healthy donors the general amount of MLRos is 37,4±2,2%; among them macrophages contacted with 1 lymphocyte composes 20,7±1,1%, macrophages contacted with 2 lymphocytes - 11,8±1,0%, and macrophages contacted with 3 and more lymphocytes 4,8±0,7%. Though in patients with malignant solid tumor macrophages were contacted with one or rarely with two lymphocytes, increase of total amount of MLRos was considered as reaction of immunocompetent cells to abnormal for organism tumor cells. In patients treated with a-interpherone MLRos increased to 81,0+4%, and macrophages were contacted with 3 and more lymphocytes that confirmed activation of immune system. This data coincided with improvement of the patients.

Aims: Based on the abovementioned results we decided to estimate the role of macrophages in the cases of acute lymphoblastic leukemia.

Methods: For this aim was used a method of cultivation of blood and bone marrow cells worked out by Saralidze T., Shvelidze T. (1998), that gives opportunity to monitor hemopoiesis in norm and pathological states.

Results: Foresaid method supports proliferation of macrophages in norm and proliferation of blast cells in the cases of acute lymphoblastic leukemia according to the type and form of the disease. In peripheral blood and bone marrow leukocyte cultures (3 -9 –days) of the patients with acute lymphoblastic leukemia proliferation of blast cells was accompanied by formation of macrophage-lymphocyte and blast-macrophage rosettes. Besides lysis and degradation of blast cells contacting with macrophages without their endophagocytosis (that is characteristical for the digestion of strepto- and staphylococci by the macrophages) was observed. These facts point on the antitumor role of macrophages in the cases of acute lymphoblastic leukemia in culture. *in vitro* proliferation and mitosis of macrophages was confirmed by incorporation of H^3-thymidine in them.

Summary and Conclusions: Multiplication of macrophages *in vitro* and their antitumor action against blast cells in the cases of acute lymphoblastic leukemia, makes it possible to think about formation of individual macrophage banks for clinical use.

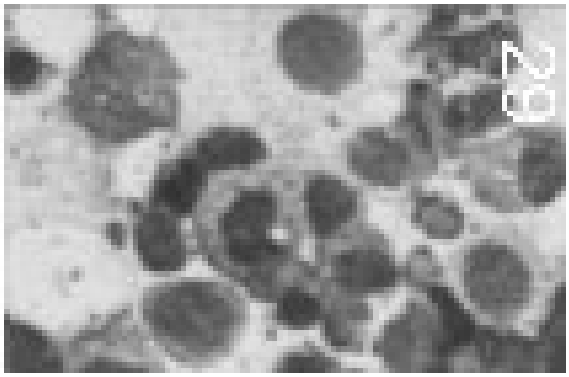

Figure 1. Abundance of lymphoid blast cells. Contact of lymphoid cells with macrophage – blast-macrophage rosette (center). 5-day-culture of bone marrow aspirate of a patient with acute B lymphoblastic leukemia. May-Grünwald-Giemsa stain. X 1000.

PB1396

THE FREQUENCY OF HLA -A, B, DRB1 ALLELES ACCORDİNG TO RISK GROUPS IN CHILDREN WITH B-CELL PRECURSOR ACUTE LYMPHOBLASTIC LEUKEMİA

T Patıroglu[1,*] H Akar[2]
[1]Pediatric Hematology, [2]Department of Pediatric Immunolgy, Erciyes University School of Medicine, Kayseri, Turkey

Background: Previous studies have demonstrated some significant differences in HLA allele frequencies in leukemic patients and normal subjects.

Aims: The purpose of this study is to evaluate the frequencies of HLA class I (A, B) and class II (DRB1) alleles in patients with acute lymphoblastic leukemia and compare to unrelated healthy subjects in Central Anatolia of Turkey.

Methods: This study was performed in 90 children with ALL, whose ages were ranging between 1-18 years. Twenty nine of 90 patients had standard risk group (SRG) of ALL, 37 moderate risk group (MRG), and 24 high risk group (HRG) respectively according to Berlin Frankfurt Münster (BFM) standards. We have typed for HLA-A, B, DRB1* alleles in patients with ALL and 90 unrelated normal subjects in Central Anatolia of Turkey. PCR-SSO low resolution method (Luminex technology) was used for HLA typing.

Results: Allele frequencies of HLA-A*01,HLA-A*29 and DRB1*07 were higher in patients with ALL compared to the control group (p=0.008, p=0.032, and p=0.000, respectively). On the contrary, HLA-B*08 and DRB1*08 alleles frequencies in patients with ALL lower than controls (p=0.010, p=0.016, respectively). DRB1*04 allele was higher in HRG ALL and MRG ALL than in SRG ALL (p=0.009). DRB1*07 allele was higher in SRG ALL than in HRG and MRG ALL (p=0.007). The most observed haplotype was A*02, B*35, DRB1*13 (p=0.023) in patients with ALL. We could not find any haplotypes negatively associated with ALL. The most observed homozygous allele was A*24 (p=0.043) in the presented cohort.

Summary and Conclusions: These results suggest that HLA-A*01, A*29, DRB1*07 alleles may play a presumptive predisposing factor in ALL , whereas HLA-B*08 and DRB1*08 alleles have been found to be negatively associated with ALL. In addition, DRB1*04 allele has been found as associated with HRG and MRG ALL. Also, DRB1*07 allele may play a presumptive predisposing factor for SRG ALL.

PB1398

HIGHER INCIDENCE OF HYPERDIPLOIDY AND BETTER PROGNOSIS FOR HIGH HYPERDIPLOIDY IN OUR COHORT OF PEDIATRIC B-ACUTE LYMPHOBLASTIC LEUKEMIA: A FLOW CYTOMETRY BASED PILOT STUDY FROM NORTHERN INDIA

P Bhatia[1*] D bansal[1], A trehan[1], RK Marwaha[1]
[1]Pediatric Hematology-oncology, PGIMER, chandigarh, India

Background: The numerical and structural genetic aberrations are an important prognostic indicator in pediatric ALL. DNA ploidy assessment forms an important method to detect numerical genetic abnormalities and patients are categorized into favorable or unfavorable risk groups based on high hyperdiploid (>51 chromosomes) or hypodiploid (<46 chromosomes) DNA index respectively.
Aims: To standardize and note the frequency of DNA ploidy abnormalities in pediatric B-ALL and to correlate the same with response to chemotherapy.
Methods: DNA ploidy assessment was done in 40 pediatric B-ALL cases confirmed on bone marrow and immunophenotyping before start of chemotherapy. 40 non-leukemic controls were run with each sample. Samples were processed using DNA ploidy kit reagents (Cycletest DNA ploidy kit; BD biosciences) and analysis was done on a flow cytometer (LSR-II; BD biosciences). The DI (DNA index) was calculated using the Mofit software. The results were compared with standard risk criteria and chemotherapy outcome (modified UK-ALL protocol).
Results: A hyperdiploid cell line was noted in 33/40 (82.5%). 7/40 (17.5%) cases had diploid cell line. None of the cases showed a hypodiploid population. DI of 1.01-1.15 (Hyperdiploid A) was seen in 17/33 (51.5%), DI between 1.16-1.6 in 11/33 (33.3%) and 4/33 (15.2%) had a DI>1.90 (tetraploidy range). Cases with DI >1.16 had significantly better response to treatment than with those having diploid DI or DI between 1.06-1.16 ($p<0.05$). Significant prognostic factors on Cox analysis were DI>1.16, age between 2-9 years, WBC count< 50,000 and Hb<9.0.

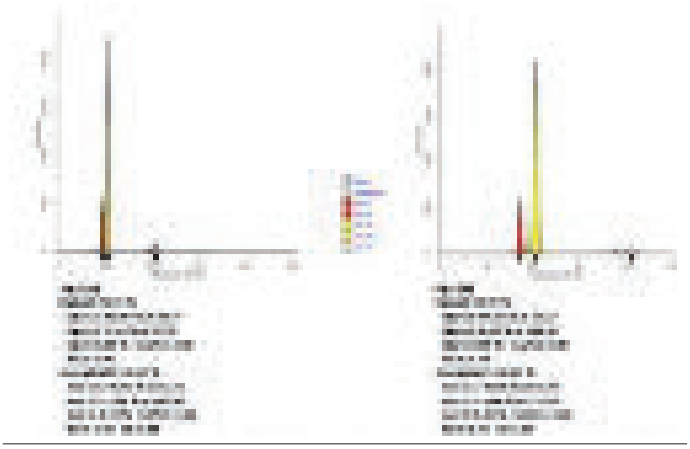

Figure 1. a) and b) showing Hyperdiploid A and Hyperdiploid B cases with DI 1.08 and 1,19 respectevely.

Summary and Conclusions: There is a relatively high frequency of hyperdiploidy cell line in our cohort of B-ALL patients. Cases with DI>1.16 and WBC count <50,000 at presentation are likely to respond better to chemotherapy with less risk of relapse. However, prospective studies on a large cohort of B-ALL cases in our population are needed to derive definitive conclusions and make individualized treatment decisions.

PB1399

SAFETY AND TOLERABILITY OF INTRATHECAL ADMINISTRSTION OF LIPOSOMAL CYTARABINE IN COMBINATION WITH DEXAMETHASONE AS CNS INVOLVEMENT PROPHYLAXIS AND TREATMENT IN LEUKEMIA/ LYMPHOMA PATIENT

J Piszcz[1,*] L Bolkun[1], M Szkiladz[1], D Lemancewicz[1], J Kloczko[1]
[1]Haematology Department, Medical University, Bialystok, Poland

Background: Prophylaxis or treatment of central nervous system (CNS) involvement is a part of therapy of adults with acute lymphoblastic leukemia (ALL) and aggressive non Hodgkin lymphoma (NHL) patients. The treatment strategy includes cytostatics and steroids administered intrathecally (i.t.) by lumbar puncture. In the past few years, the new formulation of slow-release liposomal cytarabine (DepoCyte, Mundipharma, Cambridge, UK) was introduced. The drug is characterized by prolonged activity in the cerebro-spinal fluid that may increase compliance in prophylaxis and reduce of the total number of i.t. injections in treatment of leukemia/lymphoma meningitis. One of the most common adverse reaction connected to liposomal cytarabine administration is arachnoiditis. However, its incidence can be significantly reduced by concurrent steroids administration. Additionally, steroids given orally or intra venous prevent arachnoiditis but have very limited antineoplastic activity for tumor cells located in CNS.
Aims: The purpose of our study was to evaluate safety and tolerability of liposomal cytarabine and dexamethasone intrathecal administration.
Methods: Thirty patient (15 with ALL and 15 with aggressive NHL) aged 19-76 years (median 49) were treated i.t. with a total 121 (median 3 for a patient) single doses of 50mg liposomal cytarabine. Fifty three lumbar punctures also included 4 mg of dexamethasone administration. All of the patients received additionally steroids orally (dexamethasone or prednisone) for minimum 5 days.
Results: In the whole group no serious adverse event was present. Only in two cases (both in arm without dexamethason i.t.) mild headache were noted without long –term neurological side effects.
Summary and Conclusions: In conclusion, concurrent administration of dexamethasone with liposomal cytarabine intrathecally is feasible and well tolerated manner of CNS prophylaxis or treatment in ALL and aggressive NHL patients. The effectiveness of such treatment strategy needs further evaluation.

PB1400

EVALUATION OF SERUM LEVELS OF SELECTED CYTOKINES IN PATIENTS WITH NEWLY DIAGNOSED ACUTE LYMPHOBLASTIC LEUKEMIA USING BIOCHIP ARRAY TECHNOLOGY

JM Horacek[1,2,*] T Kupsa[1,2], I Karesova[3], L Jebavy[1,2], P Zak[1]
[1]Internal Medicine IV - Hematology, University Hospital, [2]Internal Medicine, FMHS, [3]Clinical Biochemistry and Diagnostics, University Hospital, Hradec Kralove, Czech Republic

Background: Cytokines have been studied as markers of immune system activation in various diseases including hematological malignancies. Alterations in this interacting functional network may have direct effect on the malignant cells or have indirect effect on leukemogenesis through altered functions of bone marrow stromal elements. The knowledge gained from multi-analytical determination of cytokines could allow better diagnosis and management of hematological malignancies, since cytokines or their receptors may also represent a target for specific anticancer therapy at the molecular level. Recently, some studies reported the possible diagnostic and prognostic use of cytokine levels in newly diagnosed acute leukemias.
Aims: The aim of our study was to evaluate serum levels of selected cytokines in patients with newly diagnosed acute lymphoblastic leukemia (ALL) and in healthy subjects using the innovative biochip array technology. This approach allows simultaneous detection of multiple cytokines from a single sample.
Methods: Serum samples of 21 newly diagnosed ALL patients (median age 46, range 24 - 75 years, 17 males and 4 females, 20 B-ALL, 1 T-ALL) and 15 healthy subjects (median age 41, range 25 - 58 years, 11 males and 4 females) were analyzed. We evaluated serum levels of the following cytokines: interleukin-5 (IL-5), interleukin-15 (IL-15), granulocyte macrophage colony stimulating factor (GM-CSF), macrophage inflammatory protein-1 alpha (MIP-1 alpha), soluble IL-2 receptor alpha (sIL-2R alpha), soluble IL-6 receptor (sIL-6R), soluble tumour necrosis factor receptor I (sTNFR-I), soluble tumour necrosis factor receptor II (sTNFR-II), matrix metalloproteinase-9 (MMP-9). All analytes were measured by biochip array technology using chemiluminescent sandwich immunoassays applied to the Evidence Investigator analyzer (Randox). Probability values (p)<0.01 were considered statistically significant.
Results: In newly diagnosed ALL patients, we found significant increase in serum IL-15 (1.74±0.97 ng/L *vs.* 0.81±0.16 ng/L; p=0.0008), MIP-1 alpha (6.36±3.26 ng/L *vs.* 2.68±1.47 ng/L; p=0.0003), sIL-6R (2.29±1.80 mcg/L *vs.* 0.89±0.39 mcg/L; p=0.006), sTNFR-I (0.96±0.50 mcg/L *vs.* 0.25±0.07 mcg/L; p=0.000005), sTNFR-II (0.73±0.51 mcg/L *vs.* 0.29±0.14 mcg/L; p=0.003). Serum levels of other evaluated cytokines were without significant differences.
Summary and Conclusions: Our results indicate that serum levels of some cytokines (IL-15, MIP-1 alpha, sIL-6R, sTNFR-I, sTNFR-II) are significantly altered in patients with newly diagnosed ALL, reflecting activity of the disease. Further investigation is needed to establish if the alterations observed in the levels of these molecules could be used as a prognostic indicator for ALL.
The work was supported by a long-term organization development plan 1011 (FMHS).

PB1401

HIGH-HYPERDIPLOID CHILDHOOD ACUTE LYMPHOBLASTIC LEUKEMIA, SINGLE CENTRE EXPERIENCE

M Kourti[1,*] A Athanassiadou[2], V Sidi[1], L Maria[1], E Papakonstantinou[1], K Stamatopoulos[2], D Koliouskas[1]
[1]Pediatric Oncology Department, Hippokration General Hospital, Thessaloniki, [2]Hematology and HCT Department, Papanikolaou General Hospital, Exohi, Thessaloniki, Greece

Background: High hyperdiploidy (HeH) (51-67chromosomes), characterized by non-random gain of chromosomes, is a distinct subgroup of pediatric B-cell precursor acute lymphoblastic leukemia (ALL) which is generally associated with favorable prognosis.
Aims: In order to address the important issue of clinical and genetic factors associated with HeH and their relation with established favorable prognostic factors we performed a retrospective analysis of patients with HeH who were treated for B-cell precursor childhood ALL in our department in the last 5 years and their cytogenetic analysis was available.
Methods: Prettreatment bone marrow samples were cultured and analyzed by standard cytogenetic methods. Targeted analyses for t(1;19), t(9;22), der(11q23), and t(12;21) by FISH, or reverse transcriptase-polymerase chain reaction (PCR) were carried out. A total of 20 children (11 girls and 9 boys) displayed G-banded karyotypes with 51-67 chromosomes that were also informative for molecular studies, were included for analysis.
Results: The most frequently gained chromosomes were X (100%), 21 (95%), 14 (55,5%), 17 (55,5%), 6 (50%), 4 (38,8%%), 18 (38,8%) and 10 (38,8%). Triple trisomy (+4, +10,+17) were identified in 33,33% cases. The triple trisomy-positive cases had a median of 57 chromosomes (range, 51-65), whereas the negative cases had a median of 54 chromosomes (range, 51-57) Translocation-positive high hyperdiploidy (t-HeH) was identified in only 2 cases with t(12;21). None of the HeH cases had evidence of extramedullary (central nervous system, mediastinal mass or testes) leukemia at diagnosis. Median age at diagnosis was 4.7 years (range: 1.5-13 years). Median WBCx109/L was 2.100 (range: 1200-17000). Only 3 cases were stratified as high-risk patients because they were prednisone poor responders and their minimal residual disease (MRD) in bone marrow on day 15 was LOG-1 but on day 33 they all achieved complete remission with MRD of LOG-4. All patients are in continuous complete remission with event-free and overall survival of 100%.
Summary and Conclusions: Our results are consistent with literature that HeH is the largest cytogenetic subgroup in childhood B-cell ALL and is associated with other favorable clinical features. The impact of triple trisomy (+4, +10,+17) in the context of high hyperdiploidy warrants further investigation in order to explore the potential of treatment deescalation allocating less intensive therapies and reducing toxicity in the frame of international collaborative studies.

PB1402

EXTRAMEDULLARY RELAPSE OF ACUTE LEUKEMIA AFTER ALLOGENEIC HEMATOPOIETIC STEM CELL TRANSPLANTATION: DIFFERENT CHARACTERISTICS BETWEEN ACUTE MYELOID LEUKEMIA AND ACUTE LYMPHOBLASTIC LEUKEMIA

L Ge[1], F Ye[1], X Mao[1], J Chen[1], A Sun[1], X Zhu[1], H Qiu[1], Z Jin[1], M Miao[1], C Fu[1], X Ma[1], F Chen[1], S Xue[1], C Ruan[1], D Wu[1], X Tang[1,*]
[1]the First Affiliated Hospital of Soochow University, Suzhou, China

Background: Extramedullary relapse (EMR) of Acute Leukemia (AL) following allogeneic hematopoietic stem cell transplantation (allo-HSCT) is a contributor to post-transplant mortality and remains poorly understood, especially the different characteristics of EMR between acute myeloid leukemia (AML) and acute lymphoblastic leukemia (ALL) patients.
Aims: In order to investigate the incidence, risk factor and clinical outcome of EMR for AML and ALL, we performed a retrospective analysis on 362 patients with AL who underwent allo-HSCT at the First affiliated Hospital of Soochow Univesity from January 2001 to March 2012.
Methods: We retrospectively studied 362 patients with AL, who underwent allo-HSCT at our center during these 11 years.
Results: (1) Compared with AML, ALL patients had a higher incidence of EMR (12.9% *vs* 4.6%, p=0.009); (2) The most common site of EMR was central nervous system (CNS) especially in the ALL group; (3) Multivariate analyses showed that the risk factors of EMR for AML patients included: advanced disease status at HSCT, hyperleukocytosis at diagnosis, a history of extramedullary (EM) leukemia prior to HSCT and conditioning regimen (total body irradiation [TBI]–based). While the top risk factors of EMR for ALL patients included hyperleukocytosis at diagnosis, adverse cytogenetics, and peripheral blood stem cell (PBSC) as stem cell source; (4) The prognosis of EMR of AL was poor. However, the estimated 3-year overall survival (OS) in AML patients with EMR was significantly lower than that in ALL patients (0 *vs* 18.5%, p=0.000).
Summary and Conclusions: The prognosis of EMR of AL was poor, and the treatment options were very limited. The characteristics of EMR post allo-HSCT between AML and ALL patients were different in our study which maybe suggested that there were different pathogenetic mechanisms for EMR of AML *versus* ALL after allo-HSCT. More studies are needed to investigate the pathogenetic mechanism, define risk factors, and establish treatment guidelines.

PB1403

SECONDARY NEOPLASMS IN ADULT ACUTE LYMPHOBLASTIC LEUKEMIA: A NATIONWIDE POPULATION-BASED STUDY IN TAIWAN

S Chen[1,*] CJ Teng[2], YW Hu[3], CM Yeh[4], CH Tzeng[5], CJ Liu[5]
[1]Division of Hematology and Oncology, Department of Medicine, Taipei Veterans General Hospital, Taipei, Taiwan, [2]Division of Hematology and Oncology, Department of Medicine, Far Eastern Memorial Hospital, [3]Cancer Center, Taipei Veterans General Hospital, Taipei, Taiwan, [4]Department of Family Medicine, [5]Division of Hematology and Oncology, Department of Medicine, Taipei Veterans General Hospital, Taipei City, Taiwan, Republic of China

Background: Acute lymphoblastic leukemia (ALL) in the most common leukemia in children, but it is less common in adults. With the improvement of survival in last decades, secondary neoplasms (SNs) were observed. In childhood ALL, it had been reported the increased cumulative incidence of SN with long time follow-up. CNS tumor is the most common SN and associated with cranial irradiation. However, only one study reported the SN of solid tumor in adult ALL. For investigation of the small number of adult ALL, using the nationwide population-based dataset has an advatage on this issue.
Aims: To evaluate the risk of SN among adult ALL patients.
Methods: Patients who had been newly diagnosed with ALL between 1997 and 2011 were recruited from the Taiwan National Health Insurance database. Those who had age<20 years, antecedent or combined malignancies, subsequent hematologic malignancies were excluded. Standardized incidence ratios (SIRs) of SNs were calculated by comparing with the cancer incidence in the general population. Risk factors for cancer development were analyzed by Cox proportional hazards models. Effects of chemotherapy, radiotherapy, stem cell transplantation were regarded as time-dependent variables to prevent immortal time bias.

Table 1. Risk factors for SN among adult ALL after adjusting for competing mortality (N=1,381).

	Univariate analysis		Multivariate analysis	
Variables	HR (95% CI)	p value	HR (95% CI)	
Age≥ 40	0.45 (0.11–1.79)	0.257	0.43 (0.06–3.20)	0.409
Sex (male)	0.44 (0.11–1.77)	0.249	0.39 (0.09–1.69)	0.206
Comorbidities				
COPD	1.65 (0.35–7.91)	0.530		
ESRD	7.06 (0.92–53.98)	0.060	27.62 (1.42–538.30)	0.029
Dyslipidemia	0.73 (0.09–5.75)	0.769		
Treatment				
Anthracyclines	0.58 (0.16–2.14)	0.415		
Akylating agents	0.92 (0.26–3.29)	0.893		
Antimetabolites	2.03 (0.48–8.61)	0.336		
Etoposide	1.59 (0.40–6.29)	0.508		
Asparaginase	0.85 (0.24–3.07)	0.807		
Radiotherapy (except TBI)	5.98 (1.72–20.80)	0.005	6.68 (1.41–31.76)	0.017
TBI	2.51 (0.50–12.55)	0.262		
HSCT	3.03 (0.73–12.64)	0.128		

Chronic obstructive pulmonary disease (COPD); End-stage renal disease (ESRD); Total body irradiation (TBI);hematopoietic stem cell transplantation (HSCT).

Results: During the 15-year study period, 1,391 adult ALL patients were recruited. Overall, only night patients developed SNs with a follow-up of 3,100 person-years. The SIR for all cancers was 1.08 [95% confidence interval (CI) 0.50–2.06]. Four SNs developed within five years and the other five SNs developed thereafter. These SNs included cancers of breasts (3), head and neck (2), CNS (1), lung and mediastinum (1), uterus (1), and bladder (1). Multivariate analysis showed ESRD and the treatment of radiotherapy were independent risk factors.
Summary and Conclusions: In conclusion, we demonstrate that the incidence of SN is relatively low among the adult ALL patients. To treat these patients should firstly consider the treatment intensity by the risk group of their underlying disease rather than the risk of SN.

PB1404

EVALUATION OF ATTENTION DEFICIT AMONG CHILDREN WITH ACUTE LYMPHOBLASTIC LEUKEMIA

G Aydogan[1,*] O Akcal [1], A Akcay[1], D Tugcu[1], Z Salcioglu[1], F Akici[1], H Sen[1], M Gundogdu[1], G Keskindemirci[1], N Ayaz[1]
[1]Pediatric Hematology, Kanuni Sultan Suleyman Education and Research Hospital, Istanbul, Turkey

Background: The cognitive late effects experienced by many survivors of pediatric acute lymphoblastic leukemia (ALL) are well-established. The most commonly reported deficit is difficulty with attention. The factors, which cause attention deficit were not well evaluated.
Aims: In this study, we aimed to determine the frequency of attention deficit in ALL patients, who were treated with modified BFM 2000 protocol and the risk factors for the attention deficit.
Methods: 64 ALL patients between ages of 8-14 years, who were treated with modified BFM 2000 protocol and 30 healthy children between ages of 8-14 years were enrolled in this study. There were 36 girls and 28 boys in the patient group and the mean age was 10.63±2.26. There were 21 girls and 9 boys in the control group and the mean age was 10.80±1.85. Attention deficit in patient and control groups were assessed by the Benton Visuel Retention Test. Attention deficit was evaluated also according to the ALL risk group, cell type, central nervous system involvement, radiotherapy and high dose methotrexate therapy. Descriptive analysis was done. Paired groups were compared with independent t test, chi-square test and Fisher exact test.
Results: The prevalance of attention deficit was found to be% 32 in the patient group and%13 in the control group. The difference was statistically significant. Attention deficit was found to be significantly high among T-ALL patients, patients with central nervous system involvement and patients having high dose methotrexate therapy.
Summary and Conclusions: Attention deficit may be related to the disease itself or secondary to chemotherapy. Infiltration of cerebrospinal fluid by leukemic cells, intravenous perfusion of high dose methotrexate and having T-ALL were found to be risk factors for attention deficit among ALL patients.

PB1405

T-CELL ACUTE LYMPHOBLASTIC LEUKEMIA IN DAILY HEMATOLOGICAL PRACTICE

F Folber[1,*] S Hrabovsky[1], M Hadrabova[1], J Mayer[1], M Doubek[1]
[1]Department of Internal Medicine, Hematology and Oncology, University Hospital Brno, Brno, Czech Republic

Background: Adult patients with T-cell acute lymphoblastic leukemia (T-ALL) or T-cell lymphoblastic lymphoma (T-LBL) form a subgroup of patients with inferior outcome compared to patients with B-cell precursor lymphoid malignancies.
Aims: Aim of this analysis was to describe features and outcome of patients with T-ALL or T-LBL treated using two similar protocols including consolidation by an allogeneic or autologous stem cell transplantation.
Methods: All adult patients diagnosed with T-ALL or T-LBL at our centre between 1997 and 2013 were included into this analysis. We describe baseline features of these patients, treatment options and treatment outcomes. The data were analysed for response and relapse rate and factors affecting survival.
Results: A total number of 44 patients aged 17 to 77 years (median age 31 years) at the time of diagnosis were included into this analysis; thirty (68%) patients with T-ALL and fourteen (32%) with T-LBL, thirty-three (75%) men and 11 (25%) women. Older, less intensive treatment protocol was used in 29 (66%) cases, whereas a newer, slightly more intensive one was used in 15 (34%) patients. Allogeneic hematopoietic stem cell transplantation (SCT) was performed in 6 (14%) patients, autologous SCT followed by maintenance therapy in 9 (20%) patients. Thirty-seven (88%) out of 42 evaluable patients achieved a complete hematologic remission (CR) in the median time of 28 days (range 9 to 121 days). Twenty-two (55%) patients in CR or partial remission (PR) eventually relapsed. The prognosis of these relapsed patients was extremely dismal; nineteen (86%) of them died irrespectively of the salvage treatment used. During the follow-up period with a median of 16.4 months (range 1 to 173 months) twenty-five (57%) patients died. Most common causes of death were disease progression (48%), infection (32%) and non-infectious treatment toxicity (8%). Nineteen (43%) patients remain alive in follow-up. Five-year progression-free (PFS) and overall survival (OS) in the whole cohort were 30% and 37%, respectively. The survival was not influenced by age, diagnosis (T-ALL *vs.* T-LBL) nor the treatment protocol used. As expected, the most significant risk factor for shorter OS was occurrence of relapse; 5-year OS in patients with relapse *vs.* without relapse was 14% *vs.* 87%, respectively, and median OS was 14.5 months *vs.* not reached, respectively, p<0.002. Allogeneic SCT was superior to chemotherapy alone; 5-year PFS 63% *vs.* 18% (p=0.02), 5-year OS 63% *vs.* 21% (p=0.01). Autologous SCT followed by maintenance therapy offers similar non-inferior survival improvement with 5-year PFS 45% and 5-year OS 67%. This difference remains statistically significant even in the transplant-eligible subgroup of patients under the age of 35.
Summary and Conclusions: Adult patients with T-cell acute lymphoblastic leukemia or T-cell lymphoblastic lymphoma form a less common subgroup of patients with inferior outcome. Autologous stem cell transplant followed by maintenance therapy offers a promising option for transplant-eligible patients without a donor. The prognosis of relapsed patients is extremely poor and these patients are therefore candidates for further analyses.

PB1406

DIFFICULTIES OF MINIMAL RESIDUAL DISEASE MONITORING BY NESTED PCR IN TEL-AML1 POSITIVE ACUTE LYMPHOBLASTIC LEUKEMIA IN CHILDREN

A Colita[1,*] LE Radu[1], J Dumitru[2], M Dragomir[2], C Jardan[3], A Gheorghe[4], D Coriu[5], C Arion[1]
[1]Pediatric Hemato-oncology, [2]Molecular biology laboratory, [3]Genetic laboratory, [4]Immunophenotyping laboratory, [5]Hematology, Fundeni Clinical Institute, Bucharest, Romania

Background: The TEL/AML1 (ETV6/RUNX1) fusion gene secondary to t(12;21)(p13;q22) is the most frequent chromosomal structural abnormality in childhood ALL and can be found in up to 28% of B-lineage ALL patients, especially in younger children. It was also observed in up to 1% of newborns, as it occurs a prenatal event in utero. Multiple studies demonstrated the independent, favorable prognostic factor value, with a 5-year event-free-survival (EFS) of up to 97.6% and an overall survival (OS) of 98.9%. Despite this general trend, up to 20% of ALL TEL-AML1 patients relapse. There is no consensus regarding the value of TEL-AML1 positivity, using highly sensitive PCR tecniques for minimal residual disease (MRD) monitorinhg, as negative predictive factor for EFS and OS.
Aims: To analyze the results of MRD monitoring using Nested-PCR and RT-PCR for TEL-AML in pediatric acute lymphoblastic leukemia and to evaluate the impact of MRD Nested-PCR positivity on clinical and hematological outcome.
Methods: We analyzed 19 patients with TEL-AML ALL admitted in Fundeni Clinical Institute, Bucharest Romania between 2009-2013; for TEL-AML detection we used a multiplex PCR technique and for MRD monitoring the Nested-PCR; for positive Nested-PCR probes we continued with quantitative RT-PCR. All patients were treated according to BFM-ALLIC 2004 protocol; the MRD analysis has been performed at day 33, day 78, at the beginning of II protocol and every 3 months during maintenance protocol.
Results: Nineteen children, 9M/10F, median age 3y, range 2-14y were included in this study. The clinico-biological aspects at diagnosis showed: 19/19 cases L1 morphology, immunophenotype B common: 17 cases, preB: 2 cases, cytogenetic analysis: normal kariotype 17 cases, 2 abnormal kariotypes: 47 XY, mosaicism 46 XX and 46XY; 15 patients were assigned to standard risc group and 4 to the intermediate group. The Nested-PCR MRD monitoring showed: on day +33- 2 positive results, on day +78-1 positive result, and before protocol II – 2 positive results. We also observed positive results in at least one determination in 15 patients during maintenance protocol. The RT-PCR, performed in positive Nested-PCR cases, showed the presence of 1 or maximum 2 TEL-AML copies, without hematological relapse. All patients are in complete hematological remission during a median follow -up of 23 months.
Summary and Conclusions: The TEL-AML1 abnormality is associated with a favorable outcome. The MRD monitoring with Nested PCR for TEL-AML1 was very sensitive, being positive even in the presence of only 1 copy of the molecular abnormality; there is no correlation between MRD positivity using Nested-PCR and hematological or clinical relapse during a medium time of follow-up, suggesting that this approach is of limited value in predicting outcome.

PB1407

ESTIMATION OF CLINICAL EFFICIENCY OF BFM-ALL-2000 AND BM-ALL-2008 PROTOCOLS IN CHILDREN WITH ACUTE LYMPHOBLASTIC LEUKEMIA

S Daghbashyan[1,2], A Zakharyan[2,3,*] L Sahakyan[4], M Anastasiady[3], A Pepanyan[4], L Simonyan[4]
[1]Director of Haematology center, Center of Haematology, [2]Haematology faculty, YSMU, [3]Children department, [4]Department of Science, Center of Haematology, Yerevan, Armenia

Background: Detection of minimal residual disease (MRD) has the value of evaluating the therapy in many hematologic malignancies, including acute lymphoblastic leukemia (ALL).
Aims: Estimation of clinical efficiency of BFM-ALL-2000 and BM-ALL-2008 protocols in children with ALL.
Methods: 19 patients with ALL were monitored for MRD after the achievement of complete remission (33 day after therapy). 8(42.1%) of them were treated with the BFM-ALL-2000 program (first group), and 11(57.9%) - with the BM-ALL-2008 (second group). Using multi parametric flow cytometry we compared the levels of MRD in patients of BM and PB after induction and consolidation, respectively.
Results: After induction and consolidation therapy in the first group persons the cut-off value of residual leukemic cells in BM and PB which correlated with outcome was 1.18×10^{-4}. Three of 8 (37.5%) patients with $>1.5\times10^{-4}$residual leukemic cells in PB after induction had a relapse, whereas the five patients (62.5%) with lower levels (0.48×10^{-4}) did not (p=0.0001). After therapy in the second group persons, 2(18.2%) patients had a level of MRD $>1.5\times10^{-4}$ and 1(9.1%) had a relapse; eight (72.7%) out of the remaining eleven patients, whose levels of MRD were below 1.5×10^{-4}, are still relapse-free (p=0.0001). In multivariate analysis, PB MRD status at the end of consolidation was found to have a significant effect on relapse-free survival (p=0.036). It`s remarkable that the treatment of the BM-ALL-2008 program had resulted in a rapid decline in MRD after induction therapy.
Summary and Conclusions: These preliminary results indicate that: BM-ALL-2008 program does not concede on clinical efficacy of accepted BFM-ALL-2000 program. Furthermore it is characterized by a rapid decline in MRD after induction therapy.

PB1408

CLINICAL SIGNIFICANCE OF MINIMAL RESIDUAL DISEASE IN YOUNG ADULTS WITH STANDARD RISK/ PH-NEGATIVE PRECURSOR B-ACUTE LYMPHOBLASTIC LEUKEMIA: RESULTS OF PROSPECTIVE STUDY

M Salah-Eldin[1,*] N Abousamra[2], H Azzam[2]
[1]Medical Oncology, Oncology Center, Mansoura University, [2]Clinical Pathology, Hematology Unit, Faculty of Medicine. Mansoura University, Mansoura, Egypt

Background: Clinical risk classification is inaccurate in predicting outcome in adult patients with acute lymphoblastic leukemia (ALL), sometimes resulting in patients receiving inappropriate chemotherapy or stem cell transplantation (SCT).
Aims: To identify complementary markers suitable for further treatment stratification in patients with standard-risk (SR)/ philadelphia-negative (Ph-negative) precursor B-ALL
Methods: we evaluated the predictive value of minimal residual disease (MRD) after induction and consolidation chemotherapy in strictly defined SR/Ph-negative precursor B-ALL patients who were treated with a standard protocol using quantitative real-time PCR with the rearranged immunoglobulin heavy chain gene as a molecular marker
Results: The cytologic complete response (CR) rate was 92.3% after induction. At this time point the molecular CR rate was 73.9%. Patients with molecular CR (MolCR) after induction had a significantly higher probability of disease-free survival (DFS; 78.8% *vs* 30.8%; p=.001) and of overall survival (OS; 82.4% *vs* 41.7%; *P*<.0001) compared with patients with molecular failure (MolFail). MRD at end consolidation had the same significance. Quantitative MRD assessment identified patients with MolFail after induction and/or consolidation as a high-risk group, with 3-year DFS and OS rates of 28.6% and 35.7%, respectively. Patients with MolCR after induction and consolidation were classified as low-risk and had 3-year DFS rate of 89.7% and OS rate of 93.3%.
Summary and Conclusions: MRD quantification during treatment identified prognostic subgroups within the otherwise homogeneous SR/Ph-negative precursor B-ALL population who may benefit from individualized treatment.

PB1409

IMPACT OF MYELOID ANTIGEN EXPRESSION ON OUTCOMES OF PATIENTS WITH T-CELL ACUTE LYMPHOBLASTIC LEUKEMIA

M Al Zaabi[1,*] M Al Khabori[1], N Fawaz[1], S Al Lamki[2], M Al Bulushi[2],M Al Hunieni[1], M Al Riyami[2], S Al Hashami[2], A Al Riyami[1], M Al Tarshi[2], K Al Farsi[1], M Al Muslahi[2], S Al Kindi[1]
[1]Sultan Qaboos University Hospital, [2]Royal Hospital, Muscat, Oman

Background: Several factors have been implicated in risk assessment of adult patients with T-cell acute lymphoblastic leukemia (T-ALL). These include age, sex, white blood cell (WBC) count, mediastinal mass, central nervous system (CNS) involvement as well as cytogenetic, molecular and immunophenotyic characteristics. Yet, their value in predicting outcome is not well established as compared to B-ALL subtype.
Aims: The objective of this study was to evaluate the impact of myeloid antigen expression on complete remission (CR), event-free survival (EFS) and overall survival (OS) in patients with T-ALL treated with intensive chemotherapy.
Methods: We retrospectively reviewed the charts of 39 consecutive patients with T-ALL diagnosed and treated in two tertiary centers. The diagnosis of T-ALL was established by French-American-British classification or WHO criteria. Patients were considered having myeloid antigen expression if they expressed CD13, CD33 or both.
Results: Median follow-up was 12 months for all patients and 14 months for those still alive. Of the 32 patients assessable for response to induction therapy, 29 (91%) achieved CR with one or two courses of chemotherapy. The difference between those with and without myeloid antigen expression was not statistically significant (p=0.88). Twenty five percent (5/20) of patients with no myeloid markers required two courses of induction chemotherapy to achieve CR, whereas 58% (7/12) of the other group required two induction courses and this difference was statistically significant (p=0.04). In multivariable analysis, there was no statistically significant predictor of CR using age, gender, initial WBC count, CNS disease or co-expression of myeloid antigens. There was no significant difference in the EFS and OS between the two groups in the univariable and multivariable models.
Summary and Conclusions: Our analysis suggests that patients with T-ALL and positive myeloid antigen expression required more than one cycle of induction chemotherapy to achieve CR. No significant impact on EFS or OS was seen. However, our study is limited by small sample size and short follow-up period. Thus, larger prospective trials are required to confirm these findings.

PB1410

INFECTIOUS EVENTS DURING INTENSIVE TREATMENT IN CHILDHOOD ACUTE LYMPHOBLASTIC LEUKEMIA

K Martinova[1,*] B Coneska[1], S Kocheva[1], A Jovanovska[1], E Bojadgieva[2]
[1]Hematology and Oncology, University Children's Hospital, Skopje, [2]Faculty of Medical Sciences, University Goce Delcev, Stip, Macedonia, The Former Yugoslav Republic Of Republic of Korea

Background: Many children with acute lymphoblastic leukemia (ALL) experience one or more infectious complications during treatment. Infections are important to study in children with ALL because they continue to contribute to morbidity and mortality, affect quality of life for children and their families and require considerable health resources to prevent and treat.
Aims: To analyze the characteristics of infective episodes (*I.E.*) during intensive treatment (Protocol I, M and II) in children with ALL.
Methods: Objective of this study ware 55 patients with ALL who were treated according to ALL-BFM 90 and ALL-BFM 95 Protocol between January 2000 and December 2007 at the University Children's Hospital in Skopje. We explored the characteristics of *I.E.*, together with the causative pathogens, the episodes of febrile neutropenia (FN), the length of antibiotic treatments and the treatments with G-CSF during intensive phases of treatment (Protocol I, M and II).
Results: From 55 analyzed records 24 (43.64%) were male and 31 (56.36%) were female. Mean age at diagnosis was 6.0 years (1.1-15.0). Majority of the patients 43 (78%) were under 10 years and 12 (22%) were over 10 years. All of them experienced 132, 52 and 73 *I.E.* with 2.4, 0.9, and 1.3 infections per patient during Protocol I, M and II respectively. Regarding to the pathogens 184 (71.5%) were bacterial (102, 30 and 52 in Protocol I, M and II), 45 (17.5%) were viral (20, 14 and 11 in Protocol I, M and II) and 28 (10.8%) were fungal (10, 8, 10 in the three intensive phases respectively). There was a slight predominance of gram positive bacteria in Protocol I [Gram positive 42 (51.85%) *versus* gram negative 34 (41.97%)], and a very slight predominance of gram negative bacteria in Protocol II [Gram positive 16 (45.71% *versus* Gram negative 18 (51.42%)]. The infections were treated with antibiotic treatment in average of 23.69, 11 and 15.05 days and the number of treatments with G-CSF were in average 7.22, 2.44 and 9.20 per patient respectively in Protocol I, M and II. The number of episodes of FN in these three phases was 16.4 (29.1%), 4 (7.3%) and 22 (40%).
Summary and Conclusions: Evaluation of the characteristics of *I.E.* presented that the majority of infectious events were observed in Protocol I and also the length of antibiotic treatment was longer in this phase. But the episodes of FN together with the treatments with G-CSF were higher in Protocol II possible due to the cumulative effect of chemotherapy.

PB1411

SAFE AND EFFECTIVE ADMINISTRATION OF BORTEZOMIB IN ASSOCIATION WITH RITUXIMAB IN A CHILD WITH RELAPSED/RESISTANT B-CELL PRECURSOR ACUTE LYMPHOBLASTIC LEUKEMIA (BCP-ALL)

L Lo Nigro[1,*] E Cannata[1], P Samperi[2], C Cimino[1], S Marino[2], S Munda[1], G Russo[1]
[1]Center of Pediatric Hematology Oncology, [2]Azienda Policlinico - OVE, Catania, Italy

Background: Childhood B-lineage ALL is associated with a very good prognosis. Despite a high cure rate, 20% of children still relapse. In this setting, allogeneic hematopoietic stem cell transplantation (A-HSCT) is effective when a complete remission is obtained. Few cases showed a poor response to second line treatment. To overcome this therapy resistance, alternative or experimental drugs are needed. Recently, Bortezomib, a proteasome inhibitor, was successfully administered to a cohort of children with resistant BCP-ALL (Messinger Y, Blood 2012). Moreover, high risk ALL is characterized by the increasing expression of CD20 (Dworzak MN, Blood 2008).
Aims: We here report on a child who was given a course of treatment including Bortezomib and Rituximab, prior to receive an A-HSCT from an HLA-identical familiar donor.
Results: We report on a 6 year-old boy with a pre-B ALL, which was firstly diagnosed in October 2006, at the age of 2 years, and enrolled in AIEOP ALL R-2006 protocol. He showed a prednisone good-response (PGR) at day 8, resulting as a standard risk (SR) based on the detection of minimal residual disease (MRD) at the end of Induction. He went off-therapy on October 2008. Eight months later, he presented an isolated bone marrow (BM) relapse, with a different clone, backtracked to diagnosis. He was enrolled in protocol AIEOP-REC-2003, risk S2. After the first two blocks (F1+F2) he still presented with 15% of blasts at BM. We addressed him to a more intensive treatment including FLA-DNX (Fludarabin-Aracytin-DaunoXome), followed by BFM-like blocks 1, 2 and 3. Then, he showed an increasing signal of MRD, which became a hematological relapse. We administered a CLOVE (Clofarabine-VP16-Ciclophosphamide) schema. The child recovered in the BM with a 25% of blasts presenting with a complex karyotype [46,XY[27]/45,XY,del(6)(p21).-7,-17,+mar[3]/46,XY,del(6)(p21),-7,-17,+mar,+mar[3]/46,XY,-7,-17,+mar,+mar[2]. As salvage therapy, we decided to administer the following schedule: Bortezomib [1,3 mg/mq intravenously (i.v.) days +8, +11, +15 and +18]; Dexametazone (10 mg/mq/day i.v. for 14 days); Erwinase (20.000 UI/mq i.v. days +1, +3, +5, +8, +10, +12, +15); Vincristine (1,5 mg/mq i.v. in 1 hour-infusion, days +8, +15). The child presented a grade II peripheral neurological toxicity, as adverse event. BM aspirate (BMA) at the end of cycle showed a morphological remission, but not at molecular level. For this reason, we decided to add on top of the previous cycle, the administration of Rituximab (375 mg/mq i.v. days 0, +3, +10, +17, +25), based on the high expression of CD20 in the leukemic blasts. BMA at the end of this re-induction cycle showed a $1x10^{-3}$ MRD detection. He underwent a TBI-VP16-Cyclophosphamide conditioning regimen followed by a $3x10^6$/kg of $CD34^+$ cell dose, harvested from bone marrow of an HLA-identical familiar donor. He remained in complete remission and full donor chimerism for 8 months, until he presented a bone marrow isolated relapse. He was given a protocol B-modified (with prednisone) and surprisingly achieved a complete molecular remission. For this reason we performed a second A-HSCT, using the same familiar donor and a Busulphan/Melphalan-based regimen. Unfortunately the child presented a severe pulmonary graft-*versus* host disease associated with a recurrence of disease. He died at 6 months from 2nd A-HSCT.
Summary and Conclusions: Our experience strongly demonstrated that Bortezomib and Rituximab could be safely administered with an effective result in children with resistant and/or relapsed BCP-ALL. We also suggest that the earlier the better.

Acute myeloid leukemia - Biology

PB1412

TELOMERASE REVERSE TRANSCRIPTASE (TERT) A1062T MUTATION AS A PROGNOSTIC FACTOR IN EGYPTIAN PATIENTS WITH ACUTE MYELOID LEUKEMIA (AML)

S Aref[1], M Ali[2,*] M El-Ghonemy[1], T Abouzeid[3], A El-Sabbagh[4]
[1]Hematology Unit, Clinical pathology Department, [2]Medical Oncology and Hematology Unit, [3]Clinical Hematology unit, Oncology Center Mansoura University, [4]Medical Microbioloy and immunology, Faculity of medicine, Mansoura University, Mansoura, Egypt

Background: Acute myeloid leukemia (AML) is a clonal malignant disease of haematopoietic tissue that is characterized by the proliferation of abnormal myeloblast cells in marrow and impaired production of normal blood cells. Telomeres are complex structures capping the ends of all eukaryotic cell chromosomes. In vertebrates, telomeres consist of thousands of double-stranded tandem TTAGGG nucleotide repeats shielded by various proteins that seal the DNA structure.
Aims: This study aimed to evaluate the incidence, clinical and prognostic impact of the most common *TERT* mutation A1062T in AML patients treated in Mansoura Oncology Center, EGYPT.
Methods: Mutation screening for *TERT* (A1062T) mutation in exon 15 of the *TERT* gene was performed on diagnostic DNA samples from 153 AML patients, age range from 17-65 years, by using sequence specific primers.
Results: *TERT* (A1062T) mutation was detected in 18 cases out of 153 patients (11.8%). There was no difference between the two groups as regard sex, French-American-British subtypes, cytogenitcs status **(**favorable or intermediate/adverse), hemoglobin concentration and platelet count. On the other hand, there were a statistical differences in age, type of leukemia (de novo or secondary), extramedullary disease and performance status. There was a statistically difference in the rates of complete remission (CR) (16.7% *vs* 53.3%) between *TERT* (A1062T) mutant and wild type patients, respectively. Also there was a statistically difference in the rate of relapse (62.5% *vs* 28.2%) between *TERT* (A1062T) mutant and wild type patients, respectively. As regard the overall survival (OS), the patients with *TERT* (A1062T) mutations had shorter overall survival (OS) than patients with wild type (p=0.001). In a multivariable analysis, *TERT* (A1062T) mutational status is independently worse predictor factor (p=0.007) when controlling for cytogenetic status (p=<0.001), denovo or secondary AML (p=0.001) and bone marrow blast cells (p=0.001).
Summary and Conclusions: TERT A1062T mutation is an independent negative prognostic factor in AML patients. Therefore, molecular testing for *TERT* A1062T mutation in patients with AML is recommended in order to delineate their prognostic status.

PB1413

HEDGEHOG INHIBITOR NVP-LDE225 ENHANCES SENSITIVITY OF CHEMORESISTANT ACUTE MYELOID LEUKEMIA CELLS TO CHEMOTHERAPEUTICS BY DOWN-REGULATING MRP1 VIA A MECHANISM INVOLVING IGF-1R/PI3K/AKT SIGNALING

F Meng[1,*] K Huang[1], X Jiang[1], Z Wang[1]
[1]Department of hematology, Nanfang hospital, Guangzhou, China

Background: Although a great progress has made in the treatment of acute myeloid leukemia(AML), drug resistance and relapse remain a therapeutic challenge. The poor prognosis is mainly due to multidrug resistance (MDR) characterized by disregulated signaling cascades.We have proven that LBH589 combined with Bortezomib had synergistic effects on proliferation, apoptosis and sensitivity to cytotoxic drugs via AKT and NF-κB pathways in chemoresistant HL60/ADR cells and refractory AML primary cells. Using gene chip analysis, we found that among those disregulated pathways, Hedgehog(Hh) signaling pathway was probably the upstream paths which could regulate others.
Aims: The purpose of the study was to investigate the activation of Hh pathway between chemosensitive and chemoresistant AML cell lines and primary cells. Also researches on Hh pathway inhibitor NVP-LDE225 in reversing drug-resistance in multiple drug-resistant HL60/ADR cells and refractory or relapse primary acute myeloid leukemia cells were done.Besides the mechanisms were further investigated.
Methods: Western blot assay were used to determine the protein levels of Ptch, Smo, Gli-1, Shh in HL60 and HL60/ADR cell lines also primary AML cells . HL60/ADR cells and refractory primary cells were treated with signal drug NVP-LDE225(concentration among 0-20 μM).Proliferation were evaluated by 3-(4,5)-dimethylthiahiazo (-z-yl)-3,5-di-phenytetrazoliumromide (MTT) assay and cell apoptosis were analyzed by Annexin V-FITC/PI staining through flow-cytometry(FCM). Intercellular adriamycin accumulation(MFI) were analyzed by

FCM. The changes in protein levels of Gli-1, IGF-1R, p-IGF-1R, Akt, p-Akt, MRP-1 were detected by Western blot.
Results: We found that the chemotherapy-resistant phenotype of myeloid leukemia cells correlated with activation of the Hh pathway, however in chemosensitive cells or non-refractory primary cells, such activation was less pronounced(a). NVP-LDE225, a potent and selective Hh inhibitor, significantly reverted resistance of chemotherapeutics, increased the intracellular adriamycin accumulation, inhibited MRP1 protein suppression both in cell lines and primary cells(b and c). These effects were likely to be mediated via inhibition of IGF-1R/PI3K/Akt pathway(d).
Summary and Conclusions: These findings provided evidence that targeting the Hh pathway might be a therapeutic avenue for overcoming MDR resistance in myeloid leukemia.

Background: Acute myeloid leukemia (AML) is a heterogeneous disease, often characterized by coexistence of more than one subpopulation of blast cells with different immunophenotypes.
Aims: The aim of our study was to evaluate the AML heterogeneity expression in the different blast cell subpopulations detected at diagnosis in a group of 151 adult *de novo* AML patients (pts) (M3 excluded) by multiparametric flow cytometry (MFC).
Methods: We analyzed the prognostic impact of percentage of positive cells (%) and mean fluorescence intensity (MFI) expression of several immaturity cell surface markers (CD34, CD117, CD7, and CD123) on leukemic blasts by MFC treated according to the multicenter CETLAM AML-03 protocol (clinicaltrials.govNCT01723657). We also determined its correlation with other clinical and biological variables and the prognostic significance in terms of overall survival (OS), leukemia-free survival (LFS) and cumulative incidence of relapse (CIR) in the whole AML series, and latter focussing on clinico-biological characteristics of 151 heterogeneously AML cases using plots displaying data in a 3D density to better assignement blast intraleukemia heterogeneity.

Table 1.

Results: CD34$^+$ measured as the percentage (≥2.88%) and MFI (≥284, arbitrary units (a.u.)) expression had prognostic impact in terms of OS (P=0.005, P=0.003), LFS (P=0.011, P<0.001) and CIR (P<0.014, P=0.001). The percentage of CD117$^+$ cells (≥61.29%) was associated with shorter LFS (P=0.043), and CD117 MFI (≥146 a.u.) expression was associated with a shorter OS (P=0.033) and LFS (P=0.028). High CD7 MFI (≥15 a.u.) expression showed prognostic relevance in terms of LFS (P=0.015) and CIR (P<0.001). In the multivariate analysis, high CD34 MFI expression levels retained the independent value as a predictor of LFS and CIR (P=0.012; HR=1.59, 95% CI=1.11-2.228 and P=0.045; HR=1.58, 95% CI=1.01–2.46). High percentage of CD117$^+$ cells and CD117 MFI expression levels were independent predictors of a shorter OS (P=0.010; HR=1.49, 95% CI=1.09-2.01; P=0.038; HR=1.32, 95% CI=1.01–1.71) and LFS (P=0.004; HR=1.66, 95% CI=1.17-2.37; P=0.035; HR=1.40, 95% CI=1.02–1.91). Focussing on immunophenotypically different blast cell heterogeneity patients (n=151) these correspond to 6/151 cases (4 phenotypically distinct subpopulations), 5/151 cases (3 clusters), and in 140/151 cases (2 clusters) were detected and gated.There were significant differences in high heterogeneity expression by gender (P=0.001) and MRC (P=0.004). Regarding the expression profile, except for higher CD34 MFI expression levels (P=0.001),% of CD34$^+$ cells (P=0.003) and CD123 MFI expression levels (P=0.003), no other significant differences were found. No statistically significant differences in heterogeneity AML cases *vs.* homogenously cases were found in terms of OS, LFS and CIR (P=NS). Interestingly, combined antigenic into 5 groups composed based on MFI immature measurements (CD34, CD117, CD7 and/or CD123) showed prognostic impact in AML in terms of OS (P=0.001, P<0.001,P=0.003, P<0.001, P=0.007), LFS (all P<0.001) and CIR (P=0.005, P<0.001, P=0.001, P<0.001, P=0.003).
Summary and Conclusions: Our findings suggest that prognosis information

of the immunophenotypic patterns in AML could be based in a complex analysis as it can be provided by improved quantitative analysis of antigenic surface expression patterns and combined of heterogeneous immature cell subpopulations based on MoAbs combinations.

PB1415

CPI203 (BET INHIBITOR) SHOWS POTENT SINGLE AGENT ACTIVITY AGAINST AML CELL LINES AND SYNERGIZES WITH CYTARABINE AND NUTLIN-3

AL Latif[1,*] L McGarry[2], H Morrison[3], E Normant[4], P Sandy[5], E Shanks[2], P Adams[1], M Copland[3]
[1]Beatson Institute for Cancer Research, [2]Wolfson Wohl Cancer Research Centre, [3]Paul O'Gorman Leukaemia Research Centre, University of Glasgow, Glasgow, United Kingdom, [4]Director of Pharmacology, [5]Pharmacology, Constellation Pharmaceuticals, Cambridge, United States

Background: There remains a critical requirement for novel therapies for Acute Myeloid Leukemia (AML); the backbone of AML therapy still comprises conventional cytotoxic agents and five-year survival rates remain below 50% at five years. Bromodomain and extra-terminal domain (BET) inhibitors are emerging as exciting therapeutic agents for hematopoietic malignancies. Pharmacological inhibition of bromodomains targets malignant cells by preventing reading of acetylated lysine residues, thus disrupting chromatin-mediated signal transduction, which reduces transcription at oncogene loci, most notably Myc.
Aims: We sought to assess the activity of CPI203 (Constellation Pharmaceuticals), a BET inhibitor, against 4 heterogeneous AML cell lines (AML3, KASUMI-1, THP1 and KG1a) both as a single agent and in combination with standard (cytarabine) and targeted (nutlin-3) therapies.
Methods: Cell viability was assessed using resazurin (Alamar blue dye) and analysed using the Envision Fluorescent Reader. IC50 values were subsequently calculated using GraphPad Prism (version 6.0) and drug combinations were evaluated using Calcusyn (version 2.0). Apoptosis was assessed using flow cytometry staining for Annexin V and propidium iodide (PI). Protein expression was determined using Western blotting. All experiments were performed in triplicate.
Results: Following 24 hours (h) of treatment with CPI203, there was a dose-dependent decrease in MYC in all four cell lines tested and a dose-dependent increase in p53, MDM2 and p21 in AML3 (p53 wild-type) cells treated with nutlin-3 for 24h. IC50 values after 72h treatment with CPI203 for AML3, KASUMI-1, THP1 and KG1a cell lines were: 40.3nM, 45.80nM, 102nM and 128nM respectively. Resazurin analysis revealed synergistic effects of combining CPI203 with cytarabine, most notably at a 1:10 ratio (25nM to 400nM CPI203 with 250nM to 4μM cytarabine). Mean combination index (CI) for AML3 was 0.78, (moderately synergistic), the optimal dose combination was 200nM CPI203 with 2μM cytarabine (CI 0.47 *i.e.* synergistic), which demonstrated a 20% increase in apoptosis compared with single agent treatment. Mean CI for KASUMI1 cells across 1:10 dose ranges was 0.45 (synergistic) with an increase in apoptotic cells from 58% and 44% for single agent 25nM CPI203 and 250nM cytarabine, respectively, to 88% for the combination. THP1 cells also showed enhanced apoptosis with the combination at a 1:10 ratio, increasing from 26% and 23% for THP1 cells treated with 200nM CPI203 or 2μM cytarabine, respectively, to 42% for the combination. KG1a cells (which possess the highest IC50 value of the series for CPI203) were only slightly synergistic at a 1:10 ratio with a mean CI of 0.86. In the AML3 cell line, resazurin analysis demonstrated that combining CPI203 with nutlin-3 was potently synergistic for a 1:12.5 (mean CI=0.07) and 1:25 (mean CI=0.299), and synergistic for a 1:50(mean CI=0.44) and 1:100(mean CI= 0.66) ratios. Apoptosis was enhanced in combination treated cells at ratios of 1:50 and 1:100. For example, apoptosis increased from 19% and 10% for single agent 50nM CPI203 and 5μM nutlin-3 respectively to 51% for the combination and 71% and 29% for single agent 100nM and 10μM nutlin-3 and 90% for the combination.
Summary and Conclusions: The BET inhibitor CPI203 potently induces apoptosis of AML cell lines and acts synergistically with cytarabine and nutlin-3. These combinations are currently being assessed in primary samples.

PB1416

CLONAL EVOLUTION IN PRIMARY RESISTANT AML ASSESSED BY GENETIC AND MOLECULAR PROFILING, SINGLE CELL SIGNALLING PROFILING AND EX VIVO DRUG SENSITIVITY AND RESISTANCE TESTING

C Engen[1,*] S Eldfors[2], E Aasebø[3], A Brendehaug[4], Ø Bruserud[5], SE Gullaksen[1], R Karjalainen[2], R Hovland[4], E Kristoffersen[1], E M Larsen[4], M M Majumder[2], E McCormack[1], A Parson[2], T Pemovska[2], M Popa[1], F Selheim[3], A Sulen[1], C Heckman[2], BT Gjertsen[1]
[1]Department of Clinical Science, University of Bergen, Bergen, Norway, [2]Institute for Molecular Medicine Finland, FIMM, University of Helsinki, Helsinki, Finland, [3]Department of Biomedicine, Proteomics Unit, University of Bergen, [4]Center for Medical Genetics and Molecular Medicine, [5]Department of Internal Medicine, Hematology Section, Haukeland University Hospital, Bergen, Norway

Background: Acute myeloid leukemia (AML) is a heterogeneous disease, with substantial variation in genotype and phenotype often including various clones of malignant myeloid cells evolving within the same individual over time. This clonal diversity represents a serious challenge to both conventional as well as targeted therapy.
Aims: To better understand disease progression mechanisms and drug response for future improved and individualized treatment protocols, we present the course of AML development in a 68-year-old male AML patient in correlation with deep molecular profiling and functional assessment.
Methods: The mononuclear cell fraction from the patient's peripheral blood was obtained at diagnosis, early relapse, and late relapse. Cytogenetic assessment, exome sequencing, copy number analysis, targeted PCR, RNA sequencing and super-SILAC protein analysis were performed. Functional evaluation further included immunophenotyping, single cell profiling of intracellular signalling pathways by phosphospecific flow cytometry and *ex vivo* drug sensitivity and resistance testing (DSRT). Clonal evolution was further characterized by serial xenografting in NSG mice.
Results: At diagnosis (normal karyotype, FLT3-ITD) copy number analysis revealed a heterozygous deletion of 2,1Mb on 21q22.11q22.12 including RUNX1 and on 18q21.2 including TCF4. The former aberration is believed to be a founding event. Identification of clusters of mutations with similar variant allele frequencies in the exome sequencing data demonstrated a diverse clonal architecture already at the time of diagnosis with several genetically distinct subclones. The dominant clones at diagnosis were found to carry mutations in NRAS and ASXL1, both being frequent driver lesions in AML. Targeted PCR showed a FLT3-ITD mutation with a ITD/wild-type ratio of 0,03, indicating that the NRAS and FLT3-ITD mutations were mutually exclusive, and that only a small subpopulation harboured FLT3-ITD. *Ex vivo* DSRT screening showed selective sensitivity to MEK-inhibitors. At relapse the genotype of the AML cells was altered, now comprising complex karyotype 46,XY,del(6)(q14q22), der(7)t(7;8)(q21,q23),t(11;18)(q21;q22)[7]/46,idem,t(3;15)(p?21;q?23)[3]. Targeted PCR demonstrated a FLT3-ITD/wild-type ratio of 0,57 indicating that the FLT3-ITD positive clone at this time point dominated the blast population. This was well reflected in the DSRT data by increased sensitivity to tyrosine kinase inhibitors compared to the diagnostic sample. The NRAS and ASXL1 variant allele frequencies were correspondingly low. At late relapse there was a marked increase in genomic complexity, now indicating that the NRAS and ASXL1 clone again was dominating, but co-occurring with a substantial FLT3-ITD clone. This was supported by the DSRT profile that was very similar to the diagnostic sample. Hydroxyurea (HU) and 6-Mercaptopurine (6MP), both well established cytoreductive agents, failed when administered as monotherapy and in DSRT. However, when provided as combination treatment, HU and 6MP repeatedly resulted in controlled leukocyte counts. Reduction of the FLT3-ITD clone towards late relapse suggests that combination treatment with HU and 6MP selective targets the FLT3-ITD clone.
Summary and Conclusions: Thorough investigation of serial patient samples offers an efficient tool for understanding AML biology, disease evolution and limitations in treatment response. We hypothesize that the combination of HU and 6MP works synergistically in FLT3-ITD positive AML, representing a treatment option for selected AML patients.

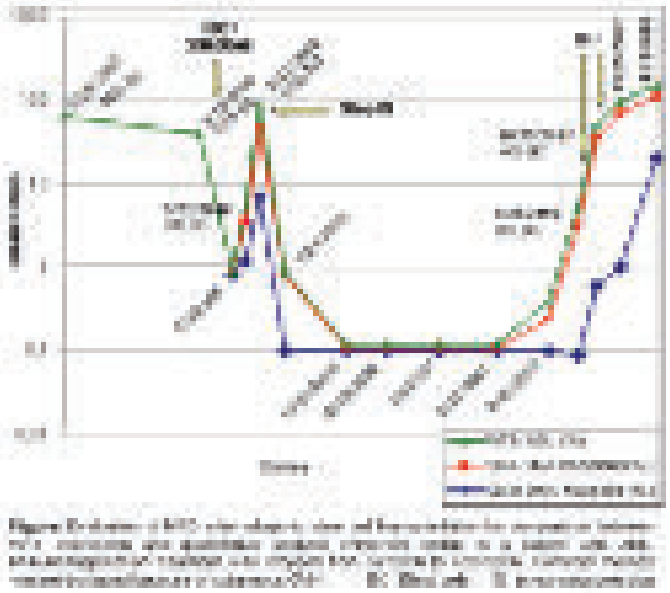
MONITORING OF CHIMERISM IN PATIENTS WITH ACUTE MYELOID LEUKEMIA AFTER HEMATOPOIETIC STEM CELL TRANSPLANTATION BY QUANTITATIVE ASSESSMENT: THE BEST TOOL FOR MONITORING OF MINIMAL RESIDUAL DISEASE?

A Bouvier[1,*] S Thépot[2], S François[2], P Guardiola[3], A Tanguy-Schmidt[2], A Beucher[1], F Geneviève[1], M Hunault-Berger[2], M Zandecki[1], N Ifrah[2], O Blanchet[1]
[1]Laboratoire d'Hématologie, [2]Service des Maladies du Sang, [3]Plateforme STE, CHU, Angers, France

Background: Minimal residual disease detection (MRD) by the analysis of acute myeloid leukemia (AML) specific molecular markers is a critical issue for the monitoring of the disease response to treatment. MRD testing by quantifying fusion genes or gene mutations is not possible for all AML patients. Hematopoietic chimerism study after allogeneic stem cell transplantation enables assessing the engraftment rate and its evolution over time, on both CD3-positive and CD3-negative circulating blood cells through cell sorting/selection.
Aims: The aim of this prospective study was to assess whether quantitative chimerism kinetic was of some use, not only as a marker of engraftment, for detecting disease recurrence in AML patients after hematopoietic stem cell transplantation when compared to the quantification of classic MRD markers such as WT1, mutated NPM1 of fusion genes.



Methods: We prospectively studied 47 AML patients transplanted between 2006 and 2013 who had available ARN samples for specific molecular marker (*i.e.*, fusion gene, NPM1 mutation, WT1 overexpression). The quantitative assessment of the fusion gene, NPM1 mutation and WT1 transcript was performed by real-time quantitative polymerase chain reaction (RQ-PCR). The determination of chimerism was performed by RQ-PCR using TaqMan Technology® of single nucleotide polymorphism (Alizadeh M. *et al*, 2002). Our RQ-PCR assay was performed on DNA extracted from CD3-positive cells and CD3-negative peripheral blood mononuclear cells, separately. We used manual magnetic separation of T cells using magnetic beads directly conjugated with anti-CD3 monoclonal antibody (Dynal®). Since 2011, CD3 cells were isolated using a Robosep® and EasySep® Positive Selection Human CD3 positive Selection Kit (Stemcell technologies®). The CD3-negative fraction was "the waste" of the magnetic selection, allowing an indirect enrichment in AML cells in case of disease recurrence.
Results: For all the patients, we found a good agreement between the monitoring of chimerism analysis and MRD as evaluated either by fusion gene, NPM1 mutation or WT1 expression. Out of 47 patients transplanted, 24 experienced haematological relapse, whereas 23 patients remained in complete remission. The CD3-negative fraction chimerism analysis could be accurately used to predict early AML relapse (Figure 1). The limits of the technique were (i) the detection of donor cell leukemia in patient with complete chimerism, an exceptional event, (ii) the maintenance of mixed chimerism in normal hematopoietic cells. Out of the 47 patients, we have only one patient with stable MC (1%) on CD3-negative fraction and 40% on CD3-positive cells with fusion transcript undetectable (RUNX1-RUNX1T1).
Summary and Conclusions: This study highlights the interest of monitoring chimerism by RQ-PCR assessment as an indicator of early AML relapse, especially in patients without specific molecular marker available. Although our population of patients is relatively small, this quantitative chimerism method appears as at least as sensitive as classical MRD analysis.

PB1418

HAPLOTYPE ANALYSIS OF CYP2B6 CYTOCHROME P450 GENE IN CORRELATION WITH AML SUSCEPTIBILITY

A Daraki[1,2], K Kakosaiou[2], S Zachaki[2], C Sambani[2], V Aleporou-Marinou[1] P Kollia[1], K Manola[2*]
[1]Genetics & Biotechnology, National and Kapodistrian University of Athens, [2]Cytogenetic, NCSR "Demokritos", Athens, Greece

Background: Acute myeloid leukemia (AML), the most frequent acute leukemia in adults, constitutes a broad range of disorders with marked clinical and biological heterogeneity. The etiology of the disease is currently unknown; however, the interaction between environmental exposure and genetic individual's background has been postulated to be a possible cause for the development of AML. Certain detoxification genes encoding antioxidant enzymes such as cytochrome P450 genes comprise well-known AML risk factors. *CYP2B6* is a highly variable and polymorphic cytochrome P450 gene. The encoding enzyme plays a vital role in the degradation of some genotoxic exogenous and endogenous xenobiotics and harmful compounds. Single-nucleotide polymorphisms (SNPs) of *CYP2B6* gene result in lower CYP2B6 protein activity and some of them have been associated with various types of cancers. In view of the fact that AML may be related to the exposure of exogenous chemicals, the *CYP2B6* SNPs may be a risk factor for the pathogenesis of AML.
Aims: In the present study, we analysed three polymorphisms of the *CYP2B6* gene (516G>T in exon 4, 777C>A and 785A>G in exon 5) in 71 AML patients and 109 healthy donors (case-control study). Furthermore, we investigated the co-existence of the above SNPs in order to determine the *CYP2B6* high-risk haplotype in AML susceptibility.
Methods: Genotyping was performed by Real-Time PCR (Roche) using the LightSNip technology.
Results: Our analysis revealed that 516G>T variant genotypes (*GT* and *TT*) had statistically higher frequency in AML patients compared to the controls (*GT*:43.7% *vs* 29.4% and *TT:15.5*% *vs* 3% respectively, $p<0.001$). Moreover, a higher incidence of the 785A>G heterozygotes was observed in patients compared to healthy donors (57.7% *vs* 21.1% respectively, $p<0.001$), while the polymorphic site 777C>A showed the same allelic and genotype frequency between patients and controls. Haplotype distribution of *CYP2B6* gene was different between patients and controls ($p<0.0001$). Specifically, the frequency of the CYP2B6*1 haplotype, indicating wild type status for all sites, was significantly increased in the control group compared to AML patients (78.9% *vs* 59.9%, respectively, $p<0.001$) suggesting that AML patients have a 2.5-fold increased risk of carrying at least one of the three *CYP2B6* polymorphisms (516G>T, 777C>A and 785A>G). In AML patients' group, 6 haplotypes with mutated alleles were found: 4 have already been characterized as CYP2B6*3 (777C>A), CYP2B6*4 (785A>G), CYP2B6*6 (516G>T and 785A>G) and CYP2B6*9 (516G>T), while 2 new haplotypes were described for the first time in the current study. The first one includes the mutated alleles of 777C>A and 785A>G polymorphic sites and the other one carries all three mutated alleles (516G>T, 777C>A and 785A>G). Interestingly, among AML patients the most frequent haplotype was the new one that simultaneously harbours the three mutated alleles (16.9%), while only 2.3% of control group carried this haplotype. Statistical analysis showed that this new haplotype was strongly correlated with AML patients (10-fold higher than in controls).
Summary and Conclusions: This is the first study of haplotype analysis (516G>T, 777C>A and 785A>G) of *CYP2B6* gene in combination with AML. Our data provide evidence for a simultaneously presence of the mutated alleles of the polymorphic sites of *CYP2B6* gene in AML patients, indicating their positive implication in AML development.

PB1419

ACQUIRED CHEMO-RESISTANCE IN FANCONI ANAEMIA-DERIVED ACUTE MYELOID LEUKAEMIA

M Schneider[1,*] R Paredes[1], A Stevens[2], B Gonzalez-Sanchez[1], DJ White[1], B Godthelp[3], A D Whetton[1], S Meyer[1,4,5]
[1]Stem Cell and Leukaemia Proteomics Laboratory, Institute of Cancer Sciences, University of Manchester, [2]Department of Endocrinology, Royal Manchester Children's Hospital, Manchester, United Kingdom, [3]Department of Toxicogenetics, Leiden University Medical Center, Leiden, Netherlands, [4]Department of Paediatric Oncology, Royal Manchester Children's Hospital, Manchster, [5]Department of Paediatric and Adolescent Oncology, University of Manchester, Manchester, United Kingdom

Background: Fanconi anaemia (FA) is caused by a defect in a DNA damage response pathway (FA/BRCA pathway) and is associated with mitomycin C (MMC) sensitivity, chromosomal instability and an extreme predisposition to acute myeloid leukaemia (AML). In addition, heterozygous carrier status of *FANCD1/BRCA2* is associated with familial breast and ovarian cancer. Acquired resistance to chemotherapeutic agents is a common problem in cancers associated with a FA/BRCA pathway defect and sporadic leukaemias. In order to understand phenotype reversion and acquired chemo resistance, we compared FA-derived AML and MMC resistant progeny we have derived.
Aims: Molecular and cellular characterisation of MMC resistance phenomena in FA using specific AML cell lines we have generated.
Methods: From the FA-derived AML cell line SB1690CB with bi-allelic disruption in *FANCD1/BRCA2* caused by the mutations IVS7+2G>T and c.3827delGT the MMC resistant sub clone SBRes was generated under hypoxic conditions and low dose MMC. Conservation of identical genetic background of MMC resistant clone was confirmed by DNA fingerprinting. Differences between chemo-sensitive and resistant cells were determined by systems biology approaches (expression array and proteomics) and cell biological assays.
Results: MMC sensitive cells showed higher levels of spontaneous γH2AX labelling in flow cytometry assays and slower proliferation compared to resistant cells. There were 420 differentially expressed genes in resistant SBRes cells compared to sensitive SB1690CB. VAC values of 113 genes were indicating alternative splicing in sensitive compared to resistant cells. Proteomic analysis identified 131 proteins that were differentially expressed between the 2 cell

populations. Integrated network analysis of gene expression and proteomic datasets suggests impact of acquired chemo resistance on multiple signalling networks linked to the DNA damage response.
Summary and Conclusions: We have generated a model for investigations of acquired chemo resistance in AML that can be used for further investigations into acquired chemo-resistance in AML.

PB1420

THE UTILITY OF MULTIPLEX RT-PCR AND MUTATIONAL ANALYSIS FOR DIAGNOSIS AND RISK STRATIFICATION IN PATIENTS WITH ACUTE LEUKEMIA

YU Cho[1,*] C Hyun-Sook[2], S Jang[2], EJ Seo[2], CJ Park[2]
[1]Laboratory Medicine, [2]Asan Medical Center, Seoul, Korea, Republic of Korea

Background: The chromosomal rearrangements and a few mutations of the blasts is a milestone for prognostication in acute leukemia. Recent advances include an introduction of multiplex RT-PCR platform to simultaneous screen for recurrent genetic abnormalities and rapid molecular screen for mutations. These have been expected to be valuable for early risk stratification and refining karyotype-based risk stratification.
Aims: The aims of this study were to report our data on combined molecular platforms composed of multiplex RT-PCR and mutational analysis for the detection of prognostically important genetic changes, and to reveal the clinical utility of this approach.
Methods: A total of 847 consecutive specimens from 756 patients with acute leukemia were investigated for genetic alterations using a commercial multiplex RT-PCR kit (HemaVision, DNA Technology) for the detection of clinically relevant fusion transcripts and, for patients with acute myeloid leukemia (AML) without any abnormal bands in multiplex RT-PCR, by GeneScan analysis followed by direct sequencing for the detection of *NPM1*, *FLT3*-ITD, and *CEBPA* mutations. We then compared the results from molecular testing with cytogenetic findings.
Results: A total of 267 samples (31.5%) were diagnosed as showing recurrent genetic abnormalities. The concordance rate between molecular testing and cytogenetics was 97.8%. Cryptic translocations were detected in 19 samples (2.2%) including ETV6-RUNX1, BCR-ABL1, and MLL rearrangements. Additional information by multiplex RT-PCR included an identification of submicroscopic aberrations such as STIL-TAL1 (N = 3) and SET-NUP214 (N = 5). Furthermore, multiplex RT-PCR revealed very rare rearrangements including CBFB-MYH11 type D (N = 2), FUS-ERG (N = 1), MPM1-MLF1 (N = 1), RUNX1-MDS1 (N = 1), and coexistence of RUNX1-RUNX1T1 and ETV6-MN1 (N = 1). However, multiplex RT-PCR missed translocations of rare breakpoints including t(11;17)(q23;q25) (N = 1) and t(8;21)(q24.3;q22) (N = 1). The frequencies of important mutations among multiplex RT-PCR-negative AML were 26.2% for NPM1, 20.9% for FLT3-ITD, and 7.0% for CEBPA. In particular, 16.2% of multiplex RT-PCR-negative AML was classified into favorable risk group owing to NPM1-positive and FLT3-ITD negative by molecular testing.
Summary and Conclusions: Our results demonstrate that molecular testing performed simultaneously with morphologic evaluation of acute leukemia provides relevant prognostic information, especially for the identification of favorable risk in patients with AML. This approach can enable physicians to make a prompt decision when determining optimal therapeutic modalities at a remission stage. Moreover, additional information including submicroscopic or cryptic translocations can be obtained from molecular testing.

PB1421

DNA METHYLATION INHIBITORS INDUCE TELOMERE DYSFUNCTION AND APOPTOSIS IN HUMAN LEUKEMIA CELLS THAT IS ATTENUATED BY OVER-EXPRESSION OF TELOMERASE REVERSE TRANSCRIPTASE (TERT)

D Xu[1,*] N de Jonge[1], X Zhang[1], B Li[1], M Björkholm[1]
[1]Karolinska, Stockholm, Sweden

Background: DNA methyltransferase inhibitors (DNMTi) such as 5-azacytidine (5-AZA) and decitabine have been applied to the treatment of acute myeloid leukemia (AML) and other malignancies. Inhibition of global/gene-specific DNA methylation is widely accepted as the key mechanism behind the anti-tumor activity. It is currently unclear whether other mechanisms are involved in DNMTi's action.
Aims: Because telomerase activation or telomerase reverse transcriptase (TERT) is essential for unlimited proliferation of malignant cells by elongating telomeres, and TERT or telomerase has been shown to confer chemo- or radio-resistance to cancer cells, we determined whether DNMTi affects telomere function and whether TERT interferes with its efficacy against AML cells.
Methods: AML cell lines and primary AML cells were treated with 5-azacytidine (5-AZA). TERT and telomerase activity was assessed. The TERT expression lenti-viral vector was used to make a TERT-over-expressing cell lines. Apoptosis was determined using flow cytometry and telomere dysfunction was detected using Q-FISH combined with immunofluorescence.
Results: 5-AZA induces telomere dysfunction in AML cell lines and primary AML cells by demonstrating the co-localization of 53-BP1 and TRF1 foci. Telomere dysfunction was coupled with substantial apoptosis in 5-AZA-treated cells. TERT over-expression significantly attenuated 5-AZA-mediated telomere dysfunction and apoptosis of AML cells.
Summary and Conclusions: 5-AZA-mediated telomere dysfunction may represent a novel mechanism behind its AML therapeutic efficacy, and targeting both DNA methyltransferases and telomerase or TERT may synergistically kill AML cells.

PB1422

INHIBITION OF LSD1 REACTIVATES THE RESPONSE TO ALL-TRANS-RETINOIC ACID IN AML

T Schenk[1,*] WC Chen[2], S Göllner[3], JE Dick[2], C Müller-Tidow[3], K Petrie[1], A Zelent[4]
[1]Molecular Pathology, The Institute of Cancer Research, Sutton, United Kingdom, [2]Division of Stem Cell and Developmental Biology, Campbell Family Cancer Research Institute, Ontario, Canada, [3]Hematology and Oncology, University of Münster, Münster, Germany, [4]Division of Hemato-Oncology, Sylvester Comprehensive Cancer Center, Miami, United States

Background: Acute promyelocytic leukemia (APL), a cytogenetically distinct subtype of acute myeloid leukemia (AML), characterized by the t(15;17)-associated *PML-RARA* fusion, has been successfully treated with therapy utilizing all-*trans*-retinoic acid (ATRA) to differentiate leukemic blasts. However, among patients with non-APL AML, ATRA-based treatment has not been effective. We previously reported that expression of RARα isoforms, particularly ATRA-inducible RARα2, are down-regulated in AML (Blood. 2008; 111:2374). Epigenetic analysis of patient samples revealed that relative to normal $CD33^+$ cells, the loss of RARα2 in AML is associated with a diminution in levels of histone histone H3 lysine 4 dimethylation ($H3K4^{me2}$) on the ATRA-responsive *RARA2* promoter (a modification associated with transcriptional activation). Interestingly, the $H3K4^{me1/me2}$ demethylase LSD1/KDM1 (*AOF2*) is highly expressed in AML, as well as other cancers. Additionally, LSD1 has been demonstrated to play a role in stem/progenitor cell self renewal.
Aims: The overall goal of our research is the development of better translational approaches to cancer treatment through elucidation of the molecular mechanisms, in particular epigenetic processes, underlying transcriptional deregulation and pathogenesis of acute myeloid leukemia (AML).
Results: We show that in part through epigenetic reprogramming, inhibitors of LSD1 (LSD1i), including tranylcypromine (a monoamine oxidase used as an antidepressant and anxiolytic agent in the clinical treatment of mood and anxiety disorders, respectively), as well as newly-developed, highly specific compounds, unlocked the ATRA-driven therapeutic response in non-APL AML. LSD1 inhibition did not lead to a large-scale increase in histone 3 Lys4 dimethylation ($H3K4^{me2}$) across the genome, but increased $H3K4^{me2}$ and expression of myeloid-differentiation-associated genes. The combination of ATRA plus LSD1i also led to the downregulation of expression of genes important in AML pathogenesis and treatment response such as *BCL11A*, *BCL2* and *MYC*. Furthermore, our recent studies indicate non-genomic effects of LSD1 inhibition also contribute directly to the therapeutic response.
Notably, treatment with ATRA plus LSD1i markedly diminished the clonogenic capacity of AML cells *in vitro* and engraftment of primary human AML cells *in vivo* in nonobese diabetic (NOD)-severe combined immunodeficient (SCID) mice, suggesting that ATRA in combination with LSD1i may target leukemia-initiating cells. Furthermore, initiation of ATRA plus LSD1i treatment 15 days after engraftment of human AML cells in NOD-SCID gamma (with interleukin-2 (IL-2) receptor gamma chain deficiency) mice also revealed the ATRA plus LSD1i drug combination to have a potent anti-leukemic effect that was superior to treatment with either drug alone.
Summary and Conclusions: These data identify LSD1 as a therapeutic target and strongly suggest that it may contribute to AML pathogenesis by inhibiting the normal pro-differentiative function of ATRA, paving the way for new combinatorial therapies for AML.

PB1423

ALDH STAINING IS CORRELATED TO THE EXPRESSION OF GENES INVOLVED IN STEM CELL MAINTENANCE OR MYELOID COMMITMENT IN AML WITH DIFFERENT GENE REARRANGEMENTS.

E Rego[1,*] MTL Benicio[1], PS Scheucher[1], AB Garcia[1], RP Falcão[1]
[1]Internal Medicine, Hematology Division, University of São Paulo, Medical School of Ribeirão Preto, Ribeirão Preto, Brazil

Background: Leukemia Stem Cells (LSCs) are described as being the

responsible for chemotherapy failure and recidive/recurrence due to their self-renewal properties. The fact that cells harbouring identical gene rearrangement and derived from the same tumour can behave in a functionally distinct manner suggests a role for additional mechanisms which confer advantage to specific cell subsets. Aldehyde dehydrogenase (ALDH) is an enzyme that protects stem cells from alkylation. Increased activity of ALDH has proven to be a successful strategy to identify acute myeloid leukemia (AML) LSC among the leukemic bulk in bone marrow samples. Different studies have reported that cells with intermediate ALDH activity have self-renewal properties and clonogenic potencial. In contrast, cells with high ALDH activity were able to generated committed progenitors of different hematopoietic lineages, therefore resembling the normal hematopoietic stem cells (HSCs)

Aims: To compare the expression of genes regulatiing stemness and myeloid commitment in AML cells expressing high or intermediate ($ALDH^{hi}$ and $ALDH^{lo/int}$) ALDH activity.

Methods: We took advantage of Aldefluor reagent to identify LSC among cell lines representative of AML with different prognosis, based on their higher activity of ALDH: Kasumi-1, THP-1, MV-4;11, NB4 and OCI-AML3. Cell subsets presenting high ALDH activity ($ALDH^{hi}$) were identified in Kasumi-1 (13%), THP-1 (25%) and OCI-AML3 (12%). To assess if the ALDH staining was correlated to the expression of genes involved in stem cell maintenance or myeloid commitment, cell lines were further sorted in $ALDH^{hi}$ and $ALDH^{lo/int}$ subsets, and the expression levels of *CEBPA*, *BMI-1*, *NOTCH-1*, *C-MYC*, *HOXA9*, *E2F1*, *NANOG* and *OCT3/4* were evaluated by RQ-PCR, by using the DDCt method.

Results: *CEBPA, BMI-1* and *NOTCH-1* were upregulated (9, 2.3 and 2 fold, respectively) in Kasumi-1 $ALDH^{hi}$ cells in comparison to $ALDH^{lo/int}$, whereas *C-MYC* and *E2F1* were downregulated (0.3 and 0.5 fold, respectively). Some molecular mechanisms responsible for self-renewal, like Bmi-1 and Notch signaling pathways, were found to be shared by both HSC and LSC, suggesting that the higher expression of both in $ALDH^{hi}$ cells would be in accordance with stemness properties. Still, the lower levels of *C-MYC* and *E2F1* expression in $ALDH^{hi}$ cells suggest that they are somehow more quiescent, supporting the idea that LSC underexpress cell cycle genes.

Summary and Conclusions: Our results reveal an important correlation between ALDH activity and the expression of genes associated with stemness properties in identifying stem-like cells in Kasumi-1.

EVALUATION OF TNF SUPERFAMILY MOLECULES IN ACUTE MYELOID LEUKEMIA PATIENTS: CORRELATION WITH BIOLOGICAL AND CLINICAL FEATURES

L Bolkun[1,*] D Lemancewicz[1], A Szumowska[1], E Jablonska[2], J Piszcz[1], J Dzieciol[3], J Kloczko[1]

[1]Hematology, [2]Immunology, [3]Human Anatomy, Medical University, Bialystok, Poland

Background: Two decades ago, the existence of receptors activated by the tumor necrosis factor alpha (TNF-α) has been demonstrated for several hematological diseases including acute myeloid leukemia cells (AML). B-cell activating factor (BAFF), a proliferation-inducing ligand (APRIL) and apoptosis inducing ligand (TRAIL), all members of the tumor necrosis factor family can directly activate the NF – κB pathway, which is constitutively activated in AML blasts. Therefore, the inhibitors of NF-κB have emerged as potential therapies against AML. BAFF, APRIL and TRAIL molecules were detected in monocytes /macrophages, dendrite cells and activated T lymphocytes. Neutrophils, taking part in an early stage of an anti-cancer response, are also a significant source of these molecules.

Aims: The purpose of the present study was to evaluate serum levels of BAFF, APRIL and TRAIL in healthy volunteers and in AML patients to determine whether there was any correlation between ligands and some prognostic biological parameters of AML patients, and to explore their clinical significance in predicting the disease activity of AML.

Methods: 74 patients with newly diagnosed AML were included in the study. Median age of patients at the time of sample collection was 45, and the range was 19-65. Diagnoses were established according to the WHO classification system. Patients were treated with the seven days induction chemotherapy with a standard therapy based on Polish Adult Leukaemia Group: DAC schedule. The control group consisted of 40 healthy volunteers, age- and sex-matched. Quantitative assessments of cytokines were performed by commercially available ELISA assays.

Results: Pre-treatment AML patients had significantly higher serum concentration compared to healthy volunteers: BAFF (6847.7±6071.3pg/ml *vs* 309.2±216.1pg/ml, p<0.001), APRIL (9.14±8.71ng/ml *vs* 1.94±1.51ng/ml, p<0.001) and lower for TRAIL (67.44±21.45pg/ml *vs* 80.28±16.24pg/ml, p=0.04). The analyses did not exhibit marked differences in concentration of cytokines according to FAB classification for all studied cytokines (p > 0.05) and a subgroup of patient with different cytogenetic risk except the TRAIL (80.13±18.11, 64.56±21.45 and 62.64±20.57 pg/ml, p=0.03). Furthermore, the concentrations after the treatment were found to be lower in the subgroup of patients with CR compared to the NR: for BAFF 4025.7±1704.1pg/ml *vs* 6520.1±4972.1pg/ml, p=0.001, APRIL 7.21±5.05ng/ml *vs* 13.26±9.59ng/ml, p=0.04. On the other hand the concentration of TRAIL was found to be higher in a patient with CR compared to NR: 72.3±34.52pg/ml *vs* 53.12±17.68pg/ml, p=0.02. Furthermore, the study demonstrated statistically positive correlations between the BAFF concentration and WBC, neutrophils and monocytes counts (for all, p=0.04) and negative for TRAIL (for all, p<0.001). More importantly the study showed the positive correlation between concentration of APRIL and counts of blastic cells in a bone marrow smear (p=0.001) and negative between TRAIL concentration and blastic cells counts in peripheral blood (p=0.002). In addition, the concentration of BAFF was found to correlate significantly and positively with the concentration of APRIL and negatively with TRAIL (p=0.001). Additionally, we observed that pre-treatment AML patients with serum BAFF values higher than the median (3615.14pg/ml) and with serum TRAIL values lower than the median (68.54 pg/ml) had significantly shorter overall survival (OS) than patients with higher values: for BAFF and TRAIL, p=0.03. There were no statistically significant differences between OS values in the subgroups of AML patients with regard to the median values (5.96 ng/ml) of APRIL, p=0.6. Multivariate Cox proportional showed that only BAFF can be considered as independent risk factor.

Summary and Conclusions: In conclusion, our results have demonstrated that serum concentrations of BAFF and TRAIL (but not APRIL) could be a useful biomarker of AML disease activity and progression. Pre-treatment concentrations of BAFF could also serve as a prognostic factor of OS. Both ligands may therefore be a novel therapeutic target in AML.

INVESTIGATION OF MECHANISMS INVOLVED IN APOPTOSIS CAUSED BY A SYNTHETIC NAPHTHYLCHALCONE IN ACUTE LEUKEMIA CELL LINES

M F Maioral[1,*] K R Sgambatti[1], A Bigolin[1], AC R de Moraes[1], P C Gaspar[1], A Mascarello[2], L D Chiaradia-Delatorre[2], R A Yunes[2], R J Nunes[2], MC Santos-Silva[1]

[1]Pharmacy and Biochemistry, [2]Chemistry, Federal University of Santa Catarina, Florianopolis, Brazil

Background: Acute leukemia is a disorder of the hematopoietic system characterized by the expansion of a clonal cell population that may arise at distinct differentiation stages of the lymphoid and myeloid precursors. Despite being the most effective treatment for leukemia, standard chemotherapy is still associated with patient relapse and high morbidity and mortality rates. The killing of tumor cells by these therapies is mediated primarily by apoptosis, a regulated type of cell death. Previous studies reported the cytotoxic effects of chalcone A1, derived from 1-naphthaldehyde, in leukemia cell lines. Chalcone A1 significantly reduced cell viability of K562, Jurkat, Kasumi, U937, CEM and NB4 cells in a concentration and time-dependent manner (IC_{50} between ~1.5 μM and 40 μM) and it was non-cytotoxic to PBL cells. It also caused significant cell cycle arrest and increased the proportion of cells in subG0/G1 phase, which has been confirmed to be apoptosis.

Aims: The main purposes of this study were to investigate the apoptotic mechanisms involved in its cytotoxicity and to test the compound in *ex vivo* assays.

Table 1.

Patient	Age (years)	Diagnosis	Leukocytes /mm^3	Blast Cells (%)	IC50 (μM)
1	48	ALL	142,340	89.9	26,18±1,42
2	17	ALL	61,580	84.5	21,38±1,33
3	87	APL	20,690	24.6	7,19±0,86
4	76	AML	35,500	31.8	42,27±2,04
5	44	AML	14,890	30.0	76,51±1,88
6	18	APL	25,680	62.0	18,45±1,73
7	38	AML	25,370	59.0	16,04±1,20
8	67	AML	5,680	27.0	11,15±1,01

Methods: The mitochondrial membrane potential has been evaluated by MitoView 633 kit (Biotium®, USA). The evaluation of Bax, Bcl-2, FasR, AIF and caspase 3 protein expressions has been conducted by flow cytometry. The expression of survivin and KI67 proteins has been evaluated by immunocytochemistry using the streptavidin-biotin-peroxidase method. For *ex vivo* experiments, eight samples obtained from patients diagnosed with AL

before the first treatment have been included in this study. Patients signed an informed consent according to the ethics committee requirements. Data are presented as mean±standard deviation of at least three independent experiments and the statistical significance level was set at p<0.05.

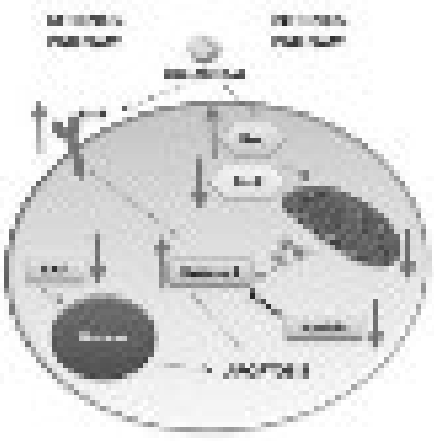

Figure 1.

Results: After treatment with chalcone A1 (12h), only 36.25±1.55% of K562 and 28.00±3.51% of Jurkat cells maintained the integrity of mitochondrial membrane. The compound significantly reduced the expression of anti-apoptotic protein Bcl-2 in K562 cells after 8h and 12h and in Jurkat cells after 12h (reduction of ~ 63%, 65% and 50% respectively). It also increased the expression of pro-apoptotic protein Bax in K562 cells after 8h and 12h and in Jurkat cells after 12h (MFI values of 173.740±16.55%, 207.21±12.43% and 138.45±6.56% respectively). These results indicate the involvement of the intrinsic pathway and a reversal in the ratio of pro-apoptotic to anti-apoptotic factors. Chalcone A1 significantly increased the expression of FasR in Jurkat cells (26%) but not in K562 cells, which suggests that in Jurkat cells both the extrinsic and the intrinsic pathways are involved in cell death, while in K562 cells only the intrinsic pathway is activated. The results also demonstrated an increased expression of effector caspase 3 after a 12h treatment in both K562 and Jurkat lines (MFI of 124.41±3.19% and 130.50±3.09%, respectively) and a decreased expression of IAP protein survivin, consistent to apoptotic cell death. The decreased expression of KI67 protein suggests that the mechanism of action of chalcone A1 also involves a decrease in cell proliferation. No significant changes in the expression of AIF have been observed, which suggests that caspase activation involves the release of other proteins. In *ex vivo* experiments, chalcone A1 reduced the cell viability of blast cells collected from eight patients with different types of acute leukemia, confirming the cytotoxicity results found *in vitro*.
Summary and Conclusions: The results obtained so far are very promising and further tests need to be performed so that compound A1 can become a prototype for the development of new anti-leukemia agents.

DYSERYTHROPOIESIS ASSOCIATED WITH GAINS OF THE ERYTHROPOIETIN RECEPTOR GENE REGION

K Gancheva[1,*] M Sekhar[2], D Brazma[2], J Howard-Reeves[2], P Kotzampaltiris[2], C Garce[1], EP Nacheva[1]
[1]Haematology, UCL Medical School, [2]Haematology, Royal Free NHS Foundation Trust, London, United Kingdom

Background: Acute erythroleukemia (AEL) is a rare subtype of acute myeloid leukemia (AML) characterized by the expansion of morphologically abnormal and malignant erythroid cells in the bone marrow (BM), referred to as AML-M6 by the French–American–British (FAB) classification. There are limited reports on the cytogenetics of AEL and common findings include hypodiploidy (47–56%) and complex karyotypes including abnormalities of the long arm regions of chromosomes 5 and 7. While MLL gene rearrangements are common in AEL, genes harbouring mutations specific for AML are rarely seen in AEL (~16%). These include FLT3 mutations reported in cases with normal chromosomes and variant TP53 in samples with highly aberrant karyotypes.
Aims: Our purpose was to obtain comprehensive genome profiles of two cases with marked dyserythropoiesis, A 80 year years old female presented with hypercellular bone marrow, consisting of predominantly (>80%) erythroid cells and blasts accounting for 8% of the total nucleated cells and gross dyserythropoiesis consistentwith AEL. The other patient, a 76 year old male with previous MDS presented with BM aspirate showing evidence for dyserythropoiesis and dysgranulopoiesis with 15% blasts, many of which had cytoplasmic bleeding, indicative of RAEB2
Methods: A range of techniques were applied from classical cytogenetics assays (G-bands and FISH) to whole genome scanning by microarrays (aCGH) and DNA variance analysis of selected genes using targeted Next Generation Sequencing (NGS).
Results: Complex hypodiploid karyotypes with clonal aberrations involving chromosomes 5, 7, 13 and 20 in were found in both cases. FISH confirms the presence of 5q and 7q deletions, while the MLL gene, frequently rearranged in AEL, was intact. NGS analysis on the coding region of 18 genes with an established role in the pathogenesis of AML, identified frameshift mutations in the TP53 gene and variances in DNMT3A gene (MDS/RAEB2) as well as FLT3 in the AEL case. aCGH identified multiple copy number aberrations (CNA) summarised in Table 1. Gain of an 865Kb sequence at chr19:10,748,354-11,613,371 within 19p13.3 gene rich region was seen in both samples, which includes the small (7,138 bp) erythropoietin receptor gene (EpoR). EpoR is a type 1 cytokine receptor lacking intrinsic tyrosine kinase activity with a role in erythropoiesis. An obvious candidate for implication in the dyserythpoiesis shared by both cases, EpoR acts through the EpoR/Jak2/Stat5 signalling axis, regulating proliferation, differentiation, and erythroid cell survival. Although EpoR acts via the kinase Jak2, the contribution of distinct EpoR/Jak2-induced signalling pathways (MAPK, PI-3, and Stat5) to functional erythropoiesis is still unclear. To date amplification of the EpoR gene has been detected in cell lines derived from AEL patients and also mice, but no evidence for such aberrations in patients' samples have been reported until now.
Summary and Conclusions: Here we present the first report for EpoR involvement in the genome profile of AEL offering a potential new diagnostic marker.

Table 1. Common gain at 19p13.3 includes the 7,138pb region of the EPOR gene.

DISTINCT FEATURES OF HLA-DR-NEGATIVE/CD34-NEGATIVE ACUTE MYELOID LEUKEMIA: INTERMEDIATE CHARACTERISTICS BETWEEN ACUTE PROMYELOCYTIC LEUKEMIA AND HLA-DR-POSITIVE/CD34-POSITIVE ACUTE MYELOID LEUKEMIA

YU Cho[1,*] HS Chi[1], S Jang[1], EJ Seo[1], CJ Park[1]
[1]Laboratory Medicine, Asan Medical Center, Seoul, Korea, Republic of Korea

Background: Negativity for HLA-DR and CD34 is a critical feature of acute promyelocytic leukemia (APL). This immunophenotype has been also described in patients with acute myeloid leukemia (AML) other than APL. Several studies previously reported that HLA-DR-/CD34- AML had distinct characteristics as compared to APL. However, there were only a few studies on comparison between HLA-DR-/CD34- AML and HLA-DR+/CD34+ AML.
Aims: The objective of this study was to investigate distinguishable features of HLA-DR-/CD34- AML from HLA-DR+/CD34+ AML as well as APL.
Methods: A consecutive series of 422 patients with AML including APL between March 2011 and January 2014 was included in the study. We retrospectively reviewed their immunophenotypes, cellular morphology, cytogenetics, molecular findings, and coagulation profiles.
Results: Of the patients analyzed, 33 were diagnosed as APL, while the remaining 389 AML patients included 33 HLA-DR-/CD34-, 253 HLA-DR+/CD34+, and 103 either HLA-DR+/CD34- or HLA-DR-/CD34+. Statistically significant differences were found between HLA-DR-/CD34- AML and HLA-DR+/CD34+ AML in CD15 negativity (63.6% and 41.1%, respectively, p=0.023) and frequencies of normal karyotype (63.6% and 26.9%, respectively, P<0.0001), *NPM1* mutation (77.8% and 5.2%, respectively, P<0.0001), and

recurrent cytogenetic abnormalities (3.0% and 28.5%, respectively, p=0.003). The frequencies of other mutations including *FLT3* ITD, *CEBPA*, and *MLL* PTD were not different. Regarding the coagulation profile, significant differences were found between HLA-DR-/CD34- AML and HLA-DR+/CD34+ AML in the levels of fibrinogen (median value: 292.5 and 347.0 mg/dL, respectively, p=0.006), FDP (median value: 38.95 and 4.4 µg/mL, respectively, P<0.0001), and D-dimer (median value: 18.085 and 1.185 µg/mL, respectively, P<0.0001). Notably, patients with HLA-DR-/CD34- AML had apparent intermediate characteristics between those with APL and HLA-DR+/CD34+ AML for the levels of fibrinogen, FDP, and D-dimer and frequencies of CD7 positivity and *FLT3*-ITD mutation (P<0.0001, P<0.0001, P<0.0001, p=0.011, and p=0.018, respectively). The medial values of D-dimer, for example, were 26.475 µg/mL in APL, 18.085 µg/mL in HLA-DR-/CD34- AML, 2.13 µg/mL in either HLA-DR-/CD34+ or HLA-DR+/CD34- AML, and 1.185 µg/mL in HLA-DR+/CD34+ AML (Figure 1).

Summary and Conclusions: The present study suggests that HLA-DR-/CD34- AML and HLA-DR+/CD34+ AML can be distinguished by immunophenotypic, molecular and coagulation laboratory characterization. Furthermore, patients with HLA-DR-/CD34- AML show intermediate characteristics between APL and HLA-DR+/CD34+ AML, particularly for the coagulation profiles. In conclusion, HLA-DR-/CD34- AML is biologically separated from HLA-DR+/CD34+ AML and may be an intermediate form between APL and HLA-DR+/CD34+ AML.

PROTEIN DISULPHIDE INHIBITORS INDUCE DIFFERENTIATION OF HUMAN ACUTE MYELOID LEUKEMIA CELLS

J Chlebowska[1,*] M Firczuk[1], K Furs[1], A Muchowicz[1], R Sadowski[1], J Gołąb[1,2] D Nowis[1,3]
[1]Department of Immunology, Medical University of Warsaw, [2]Institute of Physical Chemistry, Polish Academy of Sciences, [3]Genomic Medicine,Department of General, Transplant and Liver Surgery, Medical University of Warsaw, Warsaw, Poland

Background: Arsenic trioxide (ATO) and all-trans retinoic acid (ATRA) are highly effective, differentiation-inducing agents used in the treatment of acute promyelocytic leukemia (APL). Treatment of other acute myeloid leukemia (AML) types continues to be less effective. Thus elucidation of cellular mechanism(s) causing impaired differentiation and identification of new anti-leukemic therapeutic agents is of utmost clinical importance. There is accumulating evidence for the involvement of the unfolded protein response (UPR) in the progression of AML. Surprisingly, induction of key effector proteins of endoplasmic reticulum (ER) stress pathway in clinical AML samples is linked to a favorable patients prognosis (Schardt JA, Clin Cancer Res. 2009). AML patients with activated UPR and increased ER chaperones levels showed decreased CEBPA protein expression (Schardt JA, J Cell Mol Med. 2010). Protein disulfide isomerase (PDI), an enzyme found mainly in ER, is involved in the formation and isomerization of disulfide bonds between cysteine residues of polypeptides as they fold. Recently a unique role of PDI in the regulation of gene expression at the postranscriptional level has been described: PDI binds to the mRNA for CEBPA and inhibits its translation, leading to the blockade of differentiation of AML cells into neutrophils (Haefliger S, Blood, 2011).
Aims: The aim of this study was to investigate the effects of well-known PDI inhibitors: bacitracin and quercetin rutinoside on the survival and differentiation of human AML cells.
Methods: We evaluated the biological effects of PDI inhibitors on proliferation, differentiation, and the transcriptomic changes in human myeloid cell lines: HL60, NB4, KG1 and MOLM14.
Results: Our results suggest that PDI inhibitors reduce cell proliferation and induce differentiation towards monocytic and granulocytic lineages. Accordingly, they up-regulate expression of selected differentiation-related genes.
Summary and Conclusions: We propose a new approach in AML treatment, namely inhibition of protein disulfide isomerase activity leading to the differentiation of the human AML cells.

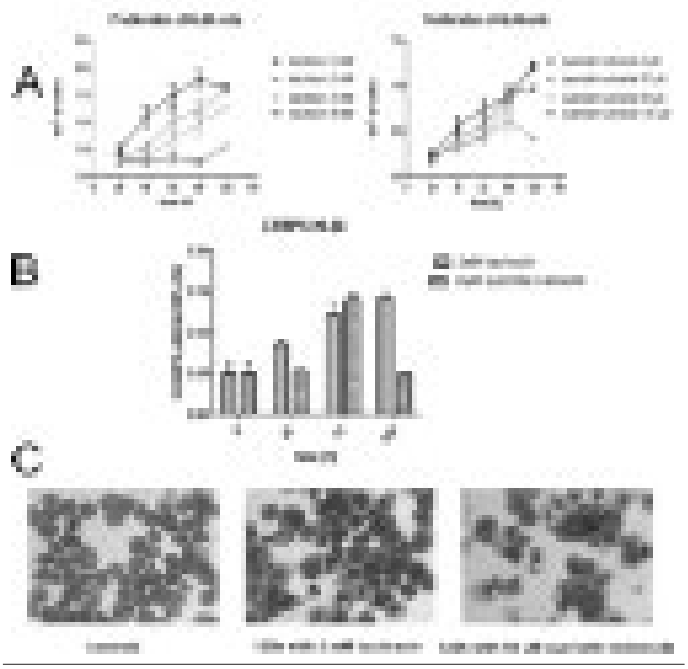

Figure 1. PDI inhibitors induce differentiation of human AML cells. (A) Cytostatic/cytotoxic activity of bacitracin and quercetin rutinoside in HL60 cells evaluated with trypan blue staining; (B) qPCR results presented as mean target-to-reference ratio±SD (left) CEBPA expression in HL60 cells incubated for indicated times with 50 µM quercetin rutnoside or 2 mM bacitracin; (C) evaluation HL60 morphology in May Grünwald-Giemsa staining; asterisks point cells with a more mature morphology.

MUTATIONS OF ASXL1 GENE IN PATIENTS WITH AML WITH AN INTERMEDIATE-RISK CYTOGENETIC PROFILE

J Marková[1,*] P Michková[1], J Soukupová Maaloufová[1], P Soukup[1], C Šálek[1], J Březinová[1], K Michalová[1], P Cetkovský[1], J Schwarz[1]
[1]Institute Hematology and Blood Transfusion, Prague 2, Czech Republic

Background: ASXL1 is a highly conserved protein which belongs into the ETP (enhancer of trithorax and polycomb) protein family which functions as an epigenetic regulator of gene transcription through the changes in the chromatin structure. *ASXL1* gene is located in the chromosomal region 20q11.21, comprises 12 exons and encodes a nuclear protein of 1541 amino acid residues. Its mutations (particularly found within exon 12) were described in patients with various kinds of myeloid malignancies including AML and MDS.
Aims: We attempted to test the prognostic impact of *ASXL1* mutations in our patient cohort.
Methods: RNA for *ASXL1* mutation analysis was available from 226 patients with AML with an intermediate-risk cytogenetic profile (defined according to Grimwade *et al.*, Blood, 2010) diagnosed at a single institution between years 1998-2011. Median age at diagnosis was 55.1 years (range 18.1-81.7), the initial median WBC count was 23.1 x 10^9/L (range 0.4-483.7). The male/female ratio was 109/117 and the median of follow-up was 13.0 months. The whole exon 12 was amplified using 4 RT-PCR reactions; PCR products were treated by ExoSAP-IT reagent and directly sequenced. Potential polymorphisms were excluded by analyzing either remission samples or DNA isolated from patients' nails.
Results: *ASXL1* mutation was detected in 26 from 226 patients (11.5%). We identified 6 different frameshift changes, 5 nonsense and 4 missense mutations;

in one patient we found two different mutations. Another 5 various missense mutations were found out to be polymorphisms. Only 4/26 (15.4%) patients harboured *ASXL1* mutation together with *FLT3*/ITD, which is the most frequent aberration in AML with intermediate prognosis, while among *ASXL1*-negative cases it was 68 from 200 (34.0%) (P=0.028). Presence of *ASXL1* mutations was not influenced by the occurrence of *DNMT3A* mutations. Patients carrying *ASXL1* mutation had significantly lower WBC counts (26.4 *vs.* 3.5 x 10^9/L; P=0.002) and lower percentage of blasts in bone marrow at diagnosis (44.1% *vs.* 70.0%; P=0.009). Mutations of *ASXL1* slightly decreased the chance to reach complete remission (CR): only 13/25 (52.0%) *ASXL1*-positive cases receiving standard induction treatment achieved CR compared to 125 from 185 (67.6%) patients without this aberration (P=0.062). The initial positivity of *ASXL1* had no impact either on the relapse rate (38.5% with mutated *ASXL1* relapsed similarly as 48.8% patients without it; P=0.239) or on the relapse free survival in patients who reached CR. Presence of *ASXL1* mutation did not influence overall survival (OS) of patients as well (P=0.770).
Summary and Conclusions: We detected *ASXL1* mutation in almost 12% of patients with intermediate-risk cytogenetics, mainly in those lacking *FLT3*/ITD. *ASXL1*-positive patients had lower WBC counts and lower CR rate which is in concordance with results published so far. Although missense mutations are often considered as polymorphisms, we identified 4 missense changes that turned out to be true mutations (disappearing when patients achieved CR and not detectable in nails' DNA). We did not prove any impact of the *ASXL1* positivity on the incidence of relapses as well as on OS. The presence of *ASXL1* mutations did not substantially worsen the prognosis of patients.

PB1432

INCIDENCE OF COLONY STIMULATING FACTOR 3 RECEPTOR MUTATION (CSF3R) IN EGYPTIAN PATIENTS WITH ACUTE MYELOID LEUKEMIA

S Aref[1], M Ali[2,*] T Abouzeid[3], M El-Ghonemy[1], A El-Sabbagh[4]
[1]Hematology Unit, Clinical pathology Department, [2]Medical Oncology and Hematology Unit, [3]Clinical Hematology unit, Oncology Center Mansoura University, [4]Medical Microbioloy and immunology, Faculity of medicine, Mansoura University, Mansoura, Egypt

Background: Acute myeloid leukemia (AML) is a clinically and genetically heterogeneous disease that accounts for 20% and 70% of acute leukemia in children and adults, respectively. There are marked differences in survival following intensive chemotherapy based on age, blast cell morphology and cytogenetic abnormalities. Colony-stimulating factor 3 (CSF3), also known as granulocyte-colony stimulating factor (G-CSF) is the main growth factor for neutrophil production. Colony-stimulating factor 3 receptor is under a dynamic balance between signal activation and attenuation to achieve a well-adjusted neutrophil output both under normal and infectious conditions.
Aims: The aim of this study was to evaluate the prevalence, clinical and prognostic impact of the colony stimulating factor 3 receptor mutations in AML patients treated at Mansoura Oncology Center, EGYPT.
Methods: This study were conducted on 179 adult patients (17-65 years old), 89 males and 90 females and *CSF3R* mutation was detected by sequencing technique.
Results: 156 patients were de novo AML and 23 patients were secondary AML on top of sever congenital neutropenia (SCN). *CSF3R* mutation was detected in two out of 156 denovo AML patients (0.012%) and 18 out of 23 secondary AML patients (78.2%). The mutant cases were younger age, have a high WBCs count, high bone marrow blasts, bad performance status, no extramedullary disease and with less induction remission rate.
Summary and Conclusions: The frequency of *CSF3R* mutations was highly prevalent among AML patients secondary to SCN. Finally, molecular testing for *CSF3R* gene mutation in patients with SCN is recommended and to follow up during the course of treatment to clarify the role of G-CSF treatment and leukomogenisis in patient with congenital neutropenia.

PB1433

A PARP INHIBITOR OLAPARIB ENHANCES THE CYTOTOXICITY OF GEMTUZUMAB OZOGAMICIN AGAINST GEMTUZUMAB-OZOGAMICIN RESISTANT LEUKEMIC CELLS IN VITRO

T Yamauchi[1,*] K Uzui[1], M Takai[1], Y Matsuda[1], T Ueda[1]
[1]Department of Hematology and Oncology, University of Fukui, Fukui, Japan

Background: Gemtuzumab ozogamicin (GO) is a humanized monoclonal antibody directed against the CD33 surface antigen that is conjugated to a derivative of the cytotoxic antibiotic calicheamicin. Because CD33 is specific to leukemic cells, GO is an attractive targeted agent for treating acute myeloid leukemia (AML). However, clinical studies have demonstrated that the therapeutic efficacy of GO is limited. Upon administration, the binding of GO to the CD33 antigen on leukemic cells results in internalization of the drug, followed by the release of calicheamicin that induces DNA strand breaks. Calicheamicin cleaves DNA and produces both double-strand and single-strand breaks. The double-strand break/single-strand break ratio in DNA is reported to be 1:1 to 1:3. If poly (ADP-ribose) polymerase (PARP), a component of the DNA single strand break repair machinery, is inhibited, unrepaired single-strand break lesions are converted into more lethal DNA double-strand breaks during DNA replication. It was therefore hypothesized that the cytotoxicity of GO against leukemic cells would be enhanced by the inhibition of PARP.
Aims: The aim of the present study was to evaluate the cytotoxic effects of GO combined with a PARP inhibitor olaparib on cultured leukemic cells *in vitro*. The cytotoxicity was compared between GO-sensitive and GO-resistant cell lines.
Methods: Human leukemia HL-60 cell line was used. A GO-resistant variant cell line was established by serially incubating HL-60 cells with escalating concentrations of GO. The initial concentration of GO was one-tenth the concentration of the 50%>inhibitory concentration (IC50) of GO. The cells were cloned using the limiting dilution method. Both cell lines were cultured in RPMI1640 media supplemented with 10% fetal calf serum in a 5% CO_2-humidified atmosphere at 37°C. The cell proliferation was determined by the XTT assay. The induction of apoptosis was determined as a sub-G1 cell cycle population and/or caspase 3/9 cleavage. The expression of CD33 was measured by flow cytometry. For comparison, human lymphoblastic cell line CCRF-CEM cells were used.
Results: The XTT assay revealed that the IC50 value was 65 ng/ml for HL-60 cells, while that of GO-resistant variant HL/GO8 cells was 510 ng/ml. This suggested HL/GO8 cells were 8-fold more GO-resistant than HL-60 cells. HL/GO8 cells were also more refractory to GO-induced apoptosis measured as the amount of sub-G1 fraction. The CD33 positivity was reduced in HL/GO8 cells. Olaparib alone did not inhibit the cell growth and did not induce apoptosis in both HL-60 cells and HL/GO8 cells at the concentrations up to 10 μM. When cells were treated with various concentrations of GO in the presence of a non-toxic concentration of olaparib (10 μM), the IC50 for HL-60 was 32 ng/ml while the value for HL/GO8 cells was 210 ng/ml, suggesting that the IC50 values were half reduced in both cell lines regardless of GO sensitivity. The combination index calculated by Chou-Talalay method revealed that the combination between GO and olaparib showed synergism. Olaparib also augmented the induction of apoptosis by GO in both cell lines. CCRF-CEM cells were insensitive to GO and olaparib, because the cell did not express CD33 antigen.
Summary and Conclusions: Olaparib enhanced the cytotoxicity of GO against human myeloid leukemic HL-60 cells and GO-resistant variant HL/GO8 cells *in vitro*. Thus, the combination between GO and olaparib would be promising for treating patients with refractory AML. Moreover, if leukemic cells are deficient for breast cancer susceptibility gene (BRCA)1/2 of DNA double-strand break repair, GO-induced DNA strand breaks and the inhibition of PARP by olaparib may induce the mechanism of synthetic lethality in the cells.

PB1434

STAT5B GENE DYSREGULATION CORRELATES WITH LEF1 GENE EXPRESSION IN ADULT ACUTE PROMYELOCYTIC LEUKEMIA

F Albano[1,*] A Zagaria[1], L Anelli[1], P Orsini[1], C F Minervini[1], L Impera[1], P Casieri[1], N Coccaro[1], G Tota[1], C Brunetti[1], A Minervini[1], D Pastore[1], P Carluccio[1], A Mestice[1], A Cellamare[1], C Cumbo[1], G Specchia[1]
[1]Hematology - University of Bari, Bari, Italy

Background: Lymphoid enhancer-binding factor 1 (*LEF1*) is a downstream effector of the Wnt/ β-catenin signaling pathway, which controls cell growth and differentiation. Dysregulation of *LEF1* expression may result in several disease patterns, as the Wnt signaling plays a pivotal role in development and cancerogenesis and also controls self-renewal, proliferation and differentiation of many types of stem cells. High *LEF1* expression has been reported as a favorable prognostic marker in cytogenetically normal acute myeloid leukemia whereas it is associated with poor prognosis in adult B precursor acute lymphoblastic leukemia and in chronic lymphocytic leukemia. Moreover, marked downregulation of *LEF1* is associated with disease progression in myelodysplastic syndromes.
Aims: Recently, our group reported LEF1 expression as a prognostic factor in adult acute promyelocytic leukemia (APL). In hematologic malignancies has been reported a link between STATs transcription factor and LEF1; as STAT5b rarely is involved in molecular rearrangement with RARa gene in APL, we investigated whether there was a relationship between LEF1 and STAT5b gene expression.
Methods: *LEF1 and STAT5b* expression was measured by real-time qPCR in 75 APL patients (median age 45 years, range 16 to 88 years). Advanced relative quantification analysis was performed using LightCycler 480 Software 1.5.1, based on the ΔΔCt method. *LEF1* expression was measured using a RealTime intron-spanning ready assay recognizing all 4 major human *LEF1* isoforms (assay ID 103366, Roche); STAT5b quantification was assessed by using specific primer selected according to Primer3 software. The β-glucuronidase (*β-GUS*) gene was employed as housekeeping gene and a pool of cDNA derived from BM cells of 5 healthy individuals was used as calibrator for normalization. APL samples were dichotomized at the median value and divided into two expression groups: low *LEF1* (39 patients) with *LEF1* values below the median

value (LEF1^{low}) and high *LEF1* (36 patients) with *LEF1* values above the median value (LEF1^{high}).
Results: Fifty-one (68%) APL patients showed a STAT5b expression that was higher than that observed in the healthy control group. Patients with *LEF1^{high}* expression had higher amount of STAT5b transcript compared to that detected in the *LEF1^{low}* patients group (2.2 *vs* 1.4 fold change; p=0.04). Moreover, there was a positive correlation between LEF1 and STAT5b gene expression (r = 0.61, p<0.0001); the relation between the two genes expression was more close in APL patients aged<60 years compared to that observed in those with > 60 years (r=0.64, p<0.0001 *vs* r=0.51, p=0.04, respectively).
Summary and Conclusions: Preliminary results from our study suggest that *LEF1* gene expression in APL is linked to STAT5b gene dysregulation. As high *LEF1* expression has recently been reported as a favorable prognostic marker in adult APL the identification of genes involved in LEF1 pathway plays a crucial role for clarifying molecular pathogenesis of APL

PB1435

ANTI-TUMOR ACTIVITY OF FUCOIDAN THROUGH INHIBITION OF AKT AND ERK ACTIVATION IN HUMAN ACUTE PROMYELOCYTIC LEUKEMIA
F Atashrazm[1,*] R Lowenthal[1], J Dickinson[1], A Holloway[1], G Woods[1]
[1]Menzies Research Institute Tasmania, Hobart, Australia

Background: Acute myelogenous leukemia (AML) is the leading cause of cancer death among patients younger than 39 years. The main treatment is cytotoxic chemotherapy. However, due to its toxicity and limited effectiveness there is considerable interest in the potential of natural agents with fewer side effects and greater compatibility with human physiology. Fucoidan is a complex sulphated polysaccharide that exists in cell wall matrix of brown seaweeds. This component has become a focus of interest because of its anti-tumor activity and low toxicity. In this study we examined the anti-proliferative activity of fucoidan on human acute myelogenous leukemia cells.
Aims: To determine whether fucoidan inhibits proliferation of malignant hematopoietic cells. To determine the underlying mechanisms of this effect
Methods: Different AML cell lines were treated with various concentrations of fucoidan. The growth-inhibitory effect of fucoidan was measured using cytotoxicity, annexin V/PI apoptosis, DNA fragmentation and cell cycle assays. To determine the underlying mechanisms, expression of apoptosis-related proteins and activation of signalling pathway molecules were analysed using western blotting.
Results: Fucoidan significantly inhibited growth of acute promyelocytic leukemia HL60 cells in a dose and time dependent manner and to a lesser extent inhibited K562 cells growth. In contrast, it failed to inhibit proliferation of KG1a cells. DNA fragmentation and annexin V positive apoptotic cells increased in HL-60 cells demonstrating that fucoidan switches on apoptosis pathway. DNA fragmentation and annexin V were negative in treated KG1a and K562 cells. Cell cycle analysis revealed marked increase in sub G0/G1 population in HL60 cells with no arrest at any stage of cell cycle. In contrast, fucoidan induced G0/G1 arrest in K562 cells.
To determine the underlying mechanisms, we examined activation of various apoptosis-related proteins in HL60 cells and observed that fucoidan decreased pro-caspases 3, 8 and 9 in treated HL60 cells. The cleaved activated caspases therefore increased and activation of caspase 3 was directly proportional to cleavage of PARP (downstream target of activated caspase 3-). The expression of death receptors DR5 and Fas clearly increased but anti-apoptotic protein Bcl-xl expression was not affected. Phosphorylation of ERK and Akt kinases clearly decreased demonstrating strong inactivation of ERK and Akt by fucoidan.
Summary and Conclusions: In this *in vitro* study of the anti-growth effect of fucoidan on AML cells we found that: Fucoidan has a selective inhibitory effect on acute promyelocytic leukaemia HL60 cell line while it does not induce apoptosis in erythroleukemia K562 and minimally differentiated acute myeloblastic leukemia KG1-a cell lines. Fucoidan decreased proliferation of K562 cells while all apoptosis assays were negative. These findings were confirmed by effects of fucoidan on cell cycle whereby it induced G0/G1 arrest in K562 cells. Both caspases 8 and 9 were activated by fucoidan demonstrating it can activate apoptosis through both intrinsic and extrinsic pathways. Fucoidan caused significant inhibition of MAPK signalling pathway molecule ERK and AKT activation. We conclude that fucoidan has potential as a possible agent in the treatment of AML. *In vivo* studies using tumor-bearing animal models are necessary.

GENOMIC ALTERATIONS IN MYELOID MALIGNANCIES WITH DOUBLE MINUTE CHROMOSOMES AND OTHERWISE NORMAL KARYOTYPE
J Knijnenburg[1,*] J van Galen[1], A van Houten[2], C Boeddha[2], J van Esser[3], T Ermens[4], S Velthuizen[1], C Hays-van Hest[1], T Zweverink-van Bodegom[1], P Valk[5], B Beverloo[1]
[1]Clinical Genetics, Erasmus Medical Center, [2]Internal Medicine, Maasstad Hospital, Rotterdam, [3]Internal Medicine, [4]Laboratory for Clinical Chemistry and Hematology, Amphia Hospital, Breda, [5]Hematology, Erasmus Medical Center, Rotterdam, Netherlands

Background: Double minute (dmin) chromosomes are small paired chromatin bodies found in various malignancies. Similar to homogenously staining regions (hsr), they consist of amplified oncogenes and may cause an elevated expression of these genes. Although frequent in cancer, the presence of these gene amplifications by hsr or dmin chromosomes in hematological malignancies is rare; the frequency in acute myeloid leukemia (AML) is estimated around 1%. Within hematological malignancies dmin are generally associated with a poor prognosis. The most common gene amplified in AML as reported in the literature is *MYC* (8q24) (44-76%). The second most commonly amplified gene is *KMT2A* (*MLL*, 11q23) (18-30%). Abnormally high expression of the *MYC* gene is found in a wide variety of human tumors and it is a well described oncogene. However, there is debate in the literature for both loci whether *MYC* and *KMT2A* are the genes of interest in amplification.
Aims: We used Fluorescence In Situ Hybridization (FISH) and Single Nucleotide Polymorphism- (SNP-) array to investigate the constitution of dmin chromosomes and possible other genomic alterations in four patients with myeloid malignancies/AML with presence of dmin chromosomes and an otherwise normal karyotype.
Results: Two patients showed amplification of the 8q24/*MYC* locus. The third patient showed amplification of the 3q26/*MECOM* locus and the fourth patient showed amplification of distal 3p. Surprisingly, next to amplification of genomic regions present in dmin, in all patients additional submicroscopic losses and/or acquired uniparental disomy (aUPD) were seen in regions and genes known to be involved in leukemogenesis or hematopoiesis. In the first patient disruptions of genes in the Wnt-signaling pathway were seen next to disruption of *MNX1 (HLXB9)* and large subclonal loss directly adjacent to 8q24/*MYC*. In the second patient additional loss of 9q21, within the critical region as reported for AML was present, combined with aUPD of 4q. In the third patient loss of the *ETV6*-region was observed in combination with *IKZF1* loss. Finally additional aUPD of 11q was seen in the fourth, suggestive for *CBL* mutations.
Summary and Conclusions: In this small cohort of 4 patients with an age range of 61 to 83 years old, additional genomic alterations to dmin chromosomes were observed in all cases. Furthermore it is known that in older patients the probability for submicroscopic genomic alterations in cytogenetically normal AML is higher compared to younger patients or children. The presence of dmin chromosomes may indicate additional structural rearrangements involved in leukemogenesis. Array based analysis of AML patients with dmin chromosomes may contribute to a better understanding of the consequences of gene amplification in myeloid malignancies and may expand the knowledge of the influence of other involved loci.

PB1437

DISSECTING THE BIOLOGICAL MECHANISMS AND THE CONSEQUENCES OF NUMERICAL CHROMOSOME ABNORMALITIES IN ACUTE MYELOID LEUKEMIA
G Simonetti[1,*] A Padella[1], V Guadagnuolo[1], C Papayannidis[1], F Volpato[1], E Ottaviani[1], A Astolfi[2], S Formica[2], I Iacobucci[1], D Remondini[3], G Martinelli[1]
[1]Department of Experimental, Diagnostic and Specialty Medicine, [2]Pediatric Oncology and Hematology Unit "L. Seràgnoli", [3]Department of Physics and Astronomy, University of Bologna, Bologna, Italy

Background: Acute Myeloid Leukemia (AML) is a heterogeneous malignancy characterized by the expansion of myeloid precursor cells with limited or abnormal differentiation capacity. A relatively common event in AML is represented by chromosome gain or loss. Numerical chromosome abnormalities, which define the aneuploid condition, have a detrimental effect in primary non-malignant cells, since they dramatically reduce cellular fitness. However evidence suggests that they have a causative role in tumorigenesis and that they are well tolerated in transformed cells belonging to the myeloid lineage.
Aims: Aim of the study is to elucidate the pathogenic mechanisms that sustain and contribute to aneuploidy in AML.
Methods: We have performed gene expression profile analysis of bone marrow cells from 49 AML patients at diagnosis, including 22 aneuploid cases and 27 cases with normal karyotype. All samples contained more than 80% blast cells. The aneuploidy cohort included AML cases carrying one (or more) monosomy, trisomy or a monosomal karyotype. Our analysis covered more than 245,000 and 40,000 coding and non-coding transcripts, respectively (the latter comprising microRNAs), and a significant number of exon-exon junctions, which allow the analysis of multiple splicing isoforms. Quality controls confirmed that the data show comparable signal values.
Results: The gene expression profile of aneuploid cases has been compared with the one obtained from normal karyotype samples. We have identified a set of coding and non-coding transcripts which are differentially expressed between the two groups ($p \leq 0.05$, including more than 20 genes with a fold difference ≥2) and defined a gene signature that allows the discrimination between aneuploid

and euploid samples in our dataset. Moreover we have identified differences between the two AML subgroups and normal bone marrow samples. The analysis of an increased number of cases will confirm the results and allow the sub-stratification of aneuploid samples according to their gene expression profile. Our data will be further validated by comparing them with published gene expression profile datasets and the gene signature will be characterized by pathway analysis.

Summary and Conclusions: By gene expression profile analysis we have identified a signature of aneuploidy in AML. This study provides novel insights into the molecular mechanism that sustain aneuploidy in AML. The biological validation of genes which are commonly and specifically deregulated in aneuploid AML patients will guide the design of future therapeutic strategies targeting key players in the disease.

MOLECULAR ANALYSIS OF IDH2, DNMT3A, EZH2, WT1 AND CBL MUTATIONS IN ACUTE MYELOID LEUKEMIA PATIENTS WITH CBFB GENE REARRANGEMENT

IS Kim[1,*] HJ Shin[2], EY Lee[3], HJ Kim[4], JH Won[5], SM Bang[6], H Kim[7]
[1]Department of laboratory medicine, Pusan National University Yangsan Hospital, Yangsan, [2]Hematology-Oncology, [3]Department of laboratory medicine, Pusan National University Hospital, Busan, [4]Chonnam National University Hwasun Hospital, Jeonnam, [5]Soonchunhyang University Hospital, [6]Seoul National University Bundang Hospital, Seoul, [7]Ulsan University Hospital, Ulsan, Korea, Republic of Korea

Background: The development of acute myeloid leukemia (AML) is a multistep process that requires at least two genetic abnormalities including epigenetic modification for the development of the disease. Although the CBFB gene rearrangement is the most common translocation in AML with favorable prognosis, 40–50% of patients relapse, emphasizing the need for risk-adapted treatment approaches. According to current findings for the identification of these gene mutations (*DNMT3A, TET2, IDH1/2, ASXL1, EZH2*, etc.), most of which are frequently found in cytogenetically normal AML, however, so far little is known about the incidence and distribution patterns of genetic and epigenetic mutation in the *CBFB* AML group.

Aims: The aim of this study is to investigate the frequencies and distributions of epigenetic mutations (*IDH2, DNMT3A,* and *EZH2*) and genetic mutations (*WT1* and *CBL*) in the *CBFB* AML group.

Methods: We searched for mutational hot spots of *IDH2, DNMT3A, EZH2, WT1* and *CBL* in 94 AML patients with the CBFB gene rearrangement using the direct DNA sequencing of exon-coding sequences.

Results: In this study, the incidences of mutational hot spots were observed for *IDH2* R140Q (2.1%), *DNMT3A* (5.4%; R882C 1.1%, M880V 4.2%), *EZH2* (3.2%), *WT1* (10.7%), and *CBL* (1.1%) genes, respectively. Compared to the reported frequencies of *IDH2(3.0-8.7%), DNMT3A (22.1%), ASXL1 (10.8%), WT1* (6.8%), and *CBL* (0.6%) in cytogenetically normal AML, the mutations of *WT1* and *CBL* gene are more frequently noted, however, the frequencies of *IDH2* and *DNMT3A* mutations are relatively lower than other studies.

Summary and Conclusions: It is reported that *WT1* mutations are correlated with poor prognosis in cytogenetically normal AML patients, the prognostic significance of the *WT1* mutated *CBFB* AML should be validated prior to clinical implementation. In addition, the low prevalence of epigenetic regulatory genes (*IDH2, DNMT3A,* and *EZH2)* associated mutations in our study highlights the differences in the pathogenesis of *CBFB* AML *versus* cytogenetically normal AML, at the genetic as well as potentially at the epigenetic level. Relatively, the *CBFB* AML specific characteristics of AML underscore the importance of studying the other genetic and epigenetic molecular biology, as the development of novel therapeutics should account for these biologic differences.

PB1439

CYTOGENETICS AND OUTCOME OF 215 CASES OF MYELOID SARCOMA PATIENTS

M Salamoon[1,2,*]M manachi[2], M kenj[3]
[1]medical oncology, [2]hematology, al Bairouni university hospital, [3]cytogenetics, kenj labs, damascus, Syrian Arab Republic

Background: Myeloid sarcoma (MS) is a tumorous aggregate of malignant immature granulocytes, monocytes, or both involving any extramedullary site. MS may occur de novo in the absence of any past history or current bone marrow involvement by acute myeloid leukemia.

Aims: To evaluate the frequency of MS in Syrian cohort, diagnostic methods and the impact of induction chemotherapy on survival.

Methods: 215 patients were diagnosed with (MS) between 2003 and 2013 at Al Bairouni university hospital in Damascus (Syria). Biopsies were taken from the primary presentation sites and diagnosed by a pathologist depending on morphology and immunohistochemistry.All patients underwent a bone marrow aspiration and biopsy to support our diagnosis by means of both Karyotype and flowcytometry.

Results: CD68, MPO, CD 117, CD34CD13, CD33, CD117 were positive in 80-90% of cases. Cytogenetic reveals 6 patients with t(8;21), 5 patients with (Inv 16), 4 with t(9;22), 23 with tri 8, 7 with t(2;3), 54 patients with cocktail of anomalies(-2,-3,-5,-7,-11,-12,+12,+8,+17,+13), however remaining 54 had normal Karyotype. The most frequent localizations are: orbit, skin, breast, groin and CNS. All patients started on induction chemotherapy with a median survival of 18 month.

Summary and Conclusions: MS is a relatively rare phenomenon, making it difficult to study its' impact in different AML subgroups. The literature suggests that patients with isolated MS may have a better prognosis compared with AML patients without MS. MS patients treated with AML-type chemotherapy regimens seem to have comparable outcomes to AML patients.

PB1440

DETECTION OF MINIMAL RESIDUAL DISEASE BY MULTIPARAMETRIC FLOW CYTOMETRY IS A USEFUL PROGNOSTIC PARAMETER IN ELN NON-FAVORABLE ACUTE MYELOID LEUKEMIA THROUGHOUT THE TREATMENT PROGRAM

M Chiarini[1,*] F Antoniazzi[2], V Giustini[1], C Lamorgese[2], E Borlenghi[2], C Pagani[2], F Schieppati[2], E Morello[2], C Cattaneo[2], F Serana[1], L Imberti[1], G Rossi[2]
[1]CREA, Diagnostic Department, [2]Department of Haematology, Spedali Civili of Brescia, Brescia, Italy

Background: Multiparametric flow cytometry (MFC) may be used to assess the level of minimal residual disease (MRD) in acute myeloid leukemia (AML).

Aims: To evaluate whether MRD can be an additional prognostic factor that helps to improve the risk assessment of AML patients during treatment.

Methods: Eighty-two consecutive, unselected, non-M3, AML patients (median age: 56, range: 18-75; M/F: 48/34), treated according to the NILG protocol (AML BG00) or the GIMEMA protocol (AML17) were enrolled at the Department of Haematology, Spedali Civili of Brescia between June 2010 and February 2014. According to cytogenetic/molecular characteristics patients were classified into the four risk categories defined by the current European LeukemiaNet recommendations. Eight-color MFC was performed on fresh bone marrow at the time of diagnosis in order to potentially identify the leukemia-associated immunophenotypes (LAIPs), and then 6-color MFC was done in the follow-up samples to detect MRD at two time points, post-induction and post-consolidation. The predefined cut-offs used to identify a MRD were 0.1% post-induction and 0.035% post-consolidation according to data from other studies showing their prognostic value (Buccisano et al, 2010; Terwijn et al, 2013). Relapse-free survival differences between MRD^+ and MRD^- patients was compared by Kaplan-Meyer analysis.

Results: LAIPs were found in 72/82 patients (88%): 28 (39%) had a favorable risk, 19 (26%) an intermediate-I risk, 9 (13%) an intermediate-II risk, and 16 (29%) an adverse risk. Complete remission (CR) was achieved in 59/72 patients (82%), with the first cycle in 46 (78%), and after two cycles in 13 (22%). Twenty-seven out of 72 patients (38%) relapsed after a median of 8.5 months (1-20 months), 45 were relapse-free after a median of 19 months (1-44 months). After 24 months one of the relapse-free patients developed a secondary AML, characterized by different immunophenotype and cytogenetic/molecular features. In the 28 patients belonging to the favorable ELN risk group, MRD detection did not add prognostically useful information since the relapse rate of MRD^+ patients was 2/15 (13%), while that of MRD^- patients was 4/13 (31%), with a similar relapse-free survival (hazard ratio: 0.318 [CI 0.062-1.640]; p=0.19). In the other ELN risk groups, 7/19 (37%) patients with intermediate-I risk, 4/9 (44%) with intermediate-II risk and 10/16 (63%) with adverse risk experienced a relapse. At post-induction MRD analysis, relapse occurred in 4/14 (29%) MRD^- patients *vs.* 17/30 (57%) MRD^+ patients. A higher relapse-free survival was demonstrated in MRD^- patients (hazard ratio: 2.444 [CI 1.010-5.914]; p: 0.047). At post-consolidation MRD analysis a relapse was seen in 3/11 (27%) MRD^- patients *vs.* 15/28 (54%) MRD^+ patients. The relapse-free survival did not reach statistical significance (hazard ratio: 2.235 [CI 0.8402-5.943]; p=0.117). However, when the analysis was performed by including only 26 patients younger than 60 years, as suggested by ELN (Mrózek et al, 2012), 10/19 (53%) MRD^+ patients experienced a relapse, whereas this was observed only in 1/7 (14%) MRD^- patients, with a significantly different relapse-free survival (hazard ratio: 3.721 [CI 1.086-12.75]; p=0.028).

Summary and Conclusions: In spite of the relatively small number of patients tested these results confirm that MRD detected by MFC can add significant prognostic information which may be useful to adapt therapeutic strategies during the treatment program of AML patients.

PB1441

SECONDARY ACUTE MYELOID LEUKEMIA PATIENTS DIFFER IN LEVELS OF INTERLEUKIN-7 AND EPIDERMAL GROWTH FACTOR FROM PRIMARY AML

T Kupsa[1,2], M Vasatova[3], L Jebavy[1,2], P Zak[2], J M Horacek[1,2*]
[1]Department of Internal Medicine, University of Defence, Faculty of Military Health Sciences, [2]4th department of Internal Medicine - Hematology, University Hospital and Charles University, Faculty of Medicine, Hradec Kralove, [3]Institute of Clinical Biochemistry and Diagnostics, University Hospital Hradec Kralove, Hradec Kralove, Czech Republic

Background: Acute myeloid leukemia (AML) shows a high degree of heterogeneity due to a variety of mutations and mechanisms involved in leukemogenesis. Cytokines are soluble molecules that take part in intercellular communication, with a specific role in cell proliferation control. Alterations in adhesion molecule network have been shown to impact prognosis of AML patients. We aimed to provide more evidence about baseline changes in cytokine and adhesion molecule profile related to age and AML origin. Further knowledge gained from multiple cytokine and adhesion molecule analysis should allow better diagnosis and disease management.
Aims: Evaluate differences in cytokine and adhesion molecule profile between primary and secondary AML.
Methods: A total of 47 newly diagnosed AML patients, mean age 52.1±13.3, median 54.9 years, 18 males and 29 females, were studied. These patients were divided according to AML origin (primary *vs.* secondary AML, n=35 *vs.* 12). All cases of secondary AML had history of MDS. We evaluated serum levels of the following 22 cytokines and adhesion molecules: interleukins (IL-1 alpha, IL-1 beta, IL-2, IL-3, IL-4, IL-6, IL-7, IL-8, IL-10, IL-12, IL-13, IL-23), vascular endothelial growth factor (VEGF), tumor necrosis factor-alpha (TNF-alpha), interferon-gamma (IFN-gamma), epidermal growth factor (EGF), monocyte chemotactic protein-1 (MCP-1), E-selectin, L-selectin, P-selectin, intercellular adhesion molecule-1 (ICAM-1), vascular cell adhesion molecule-1 (VCAM-1). All biomarkers were measured by biochip array technology on Evidence Investigator analyzer (Randox) at the diagnosis of AML. Probability values (p)<0.05 were considered statistically significant.
Results: The patients with AML of secondary origin had higher levels of IL-7 (8.68±7.07 ng/L *vs.* 3.66±2.02 ng/L; p=0.021) and EGF (22.92±21.90 ng/L *vs.* 8.46±9.03 ng/L; p=0.016) and higher age (63.3±5.6 *vs.* 48.2±14.0 years, p=0.003). Due to higher age in the secondary AML subgroup, we analysed age-related changes in cytokine and adhesion molecule levels in patients without previous history of MDS. The primary AML patients of age 65 years and higher had significantly decreased serum levels of IL-12 (1.41±1.32 ng/L *vs.* 4.51±3.87 ng/L; p=0.034) and IL-13 (2.14±3.19 ng/L *vs.* 5.55±4.02 ng/L; p=0.034) compared to younger individuals, but IL-7 and EGF levels have not been significantly altered. Serum levels of other evaluated cytokines and adhesion molecules were without significant differences.
Summary and Conclusions: Our results indicate that serum levels of IL-7 and EGF are elevated in AML originating from MDS. Elevated levels of EGF trigger upregulation in MAPK/ERK pathway. This alteration might be associated with disease aggressiveness and might be of future therapeutic importance. The role of IL-7 in the pathogenesis is not clear at the moment. To assess their predictive value for patient outcome, further studies in a larger number of patients are necessary. The work was supported by Specific research project "Analysis of defined prognostic factors in acute myeloid leukemia" (FMHS) and by a long-term organisation development plan 1011 (FMHS).

PB1442

SIGNIFICANCE OF OCT1 EXPRESSION IN ACUTE MYELOID LEUKEMIAS

E Stefanko[1,*] T Wróbel[1], J Dybko[1], B Jaźwiec[1], O Haus[1], K Kuliczkowski[1]
[1]Department of Hematology, Blood Neoplasms and Bone Marrow Transplantation, Medical University, Wrocław, Poland

Background: Acute myeloid leukemias (AMLs) belong to haematological malignancies derived from the early development stages of myeloid cells. Despite polychemotherapy and intensification of doses of cytotoxic drugs, treatment results are still unsatisfactory. Standard protocols allow to obtain complete remission in significant proportion of patients however only in small percentage of patients long-term relapse free survival is observed. Drug resistance is one of the causes leading to failure of chemotherapy. This is multifactor phenomenon which includes different mechanisms such as disturbance in intracellular transport and one of the protein involved in this phenomenon is OCT1 (*organic cation transporter 1)*. The OCT1 belongs to large family of membrane proteins - SLC (*solute carrier family)* and is involved in nutrients, metabolites and drugs transport. In addition, the OCT1 plays a role in mediating of cytostatics influx into neoplastic cells. Association of OCT1 with resistance to chemotherapy was observed in solid tumors. There are limited data on the expression and impact of this protein on the clinical course and treatment response in AML.
Aims: The aim of this study was to evaluate the expression of OCT1 mRNA in patients with de novo AML. These results were compared to healthy controls, the CD34 expression, classic prognostic factors, molecular and cytogenetic indicators and treatment results such as: obtain complete remission (CR) and overall survival (OS).
Methods: 101 non-M3 AML patients and 43 healthy individuals were included in this study. Bone marrow was assessed. The samples of bone marrow were taken before initiation of chemotherapy. The expression of OCT1 mRNA was analyzed by RQ-PCR. Results were evaluated using the STATISTICA 9.0 software.
Results: This study revealed significantly lower expression of OCT1 mRNA in AML patients compared to the control group (0.002 *vs* 0.014, p=0.0000). The OCT1 mRNA expression was correlated with degree of maturation of blast cells and was lower in the $CD34^+$ leukemias than in $CD34^-$ (0.001 *vs* 0.0025, p=0.006). There was no significant association between the OCT1 mRNA expression and cytogenetic and molecular prognostic indicators. Patients with CR after induction therapy had significantly lower OCT1 mRNA expression than in no response individuals (0.001 *vs* 0.003, p=0.036) and a decreased OCT1 mRNA level was correlated with longer OS (p< 0.05).
Summary and Conclusions: OCT1 mRNA expression is significantly decreased in AML patients compared to control group. OCT1 mRNA level correlates with degree of maturation of blast cells and is the lowest in the $CD34^+$ population. Finally, the clinical course of AML patients with lower OCT1 mRNA expression was more favorable with higher probability of CR and longer OS.

Background: The achievement of complete hematologic remission (CR) is used as predictor for treatment response in patients with myeloid leukemia (AML).However <5% blasts in the bone marrow does not reflect the presence of tumor burden precisely. Minimal residual disease (MRD) in the first complete remission (CR1) may play a critical rule in assessment of treatment response and prediction of subsequent relapse.
Aims: to investigate the efficacy of minimal residual disease as method for aml stratification and predicting outcome and collerating with cytogenetics and flt3 mutation.
Methods: Leukemia associated immunophenotyping (LAIP) for 188 patients with denovo AML monitored at diagnosis , day 14 and day28 post-induction by multiparametric flow cytometry (MFC).
Results: CR achieved in 138 patients and 50 patients did not. Among the 138 patients who achieved CR 75 were MRD negative and 63 were MRD positive at day14. Significant association between MRD detection and disease free survival (DFS) using 0.01% cut off value (P=.015). Day 28 post induction show highly significant association between MRD and DFS using 0.01% cut off value (P=0.001). Significant association between MRD detection and overall survival (50 month) at day 14 and day 28 (P=0.02, P=0.001) respectively using cut off value 0.01%. Minimal residual disease was correlated with cytogenetic. It was found that minimal residual disease outweigh cytogenetic in stratifying AML. Patients with favorable cytogenetic having positive MRD eventually relapsed and thus minimal residual disease should be integrated as standard in risk stratification of favorable cytogenetics AML. Intermediate risk and poor cytogenetics AML also had same results and positive minimal residual disease patients showing poor prognosis. Also it was correlated flt3 mutation showing that flt3 had grave prognosis and even minimal residual disease negative with positive flt3 mutation eventually relapsed. it was also found that MRD negative patients intially and have no markers to follow have much better prognosis than those with positive MRD, thus it can be used as an algorthim for stratifying patient post induction to determine treatment plan and predict outcome.
Summary and Conclusions: minimal residual disease should be used as standard for risk stratification since it out weigh cytogenetic used as standard treatment for adult AML patients. Thus we can stratify patients accordingly and those with positive MRD should recieve intensive treatment and consider allogenic BMT at earlier stage.

PB1444

SERUM LEVELS OF MULTIPLE CYTOKINES AND ADHESION MOLECULES IN PATIENTS WITH NORMAL KARYOTYPE - ACUTE MYELOID LEUKEMIA

T Kupsa[1,2], M Vasatova[3], L Jebavy[1, 2], P Zak[2], J M Horacek[1,2*]
[1]Department of Internal Medicine, University of Defence, Faculty of Military Health Sciences, [2]4th department of Internal Medicine - Hematology, University Hospital and Charles University, Faculty of Medicine, Hradec Kralove, [3]Institute of Clinical Biochemistry and Diagnostics, University Hospital Hradec Kralove, Hradec Kralove, Czech Republic

Background: Acute myeloid leukemia (AML) shows a high degree of heterogeneity due to a variety of mutations and mechanisms involved in leukemogenesis. This heterogeneity is often not fully reflected in standard treatment approaches. Cytokines are soluble molecules that take part in intercellular communication, with a specific role in cell proliferation control. Alterations in this interacting functional network may have direct effect on the malignant cells or indirect effect on leukemogenesis through altered functions of bone marrow stromal elements. Further knowledge gained from multiple cytokine and adhesion molecule analysis should allow better diagnosis and disease management.
Aims: The aim of our study was to evaluate baseline serum levels of multiple cytokines and adhesion molecules and changes related to karyotype in patients treated for AML.
Methods: A total of 51 AML patients were studied. Two subgroups comprising 24 normal karyotype (CN-AML) and 27 aberrant karyotype AML patients were studied. These two subgroups did not differ in age (49.8±12.3 *vs.* 55.3±13.4 years), mean leukocyte count (44.8±37.9 *vs.* 21.0±25.7 x 1000/μL) or mean CRP (34.7±37.2 *vs.* 32.4±30.6 mg/L) of studied subjects. Further, in the group of CN-AML, we compared findings of patients having NPM 1 mutated (n=5) to patients with FLT3-ITD and NPM 1 mutated (n=8). Similarly, there was no difference in age (50.1±14.5 *vs.* 49.8±13.6 years), mean leukocyte count (62.46±35.34 *vs.* 73.66±73.36 x 1000/μL) or CRP levels (46.2±34.6 *vs.* 43.0±33.5 mg/L) between these two CN-AML subgroups. We evaluated serum levels of the following 22 cytokines and adhesion molecules: interleukins (IL-1 alpha, IL-1 beta, IL-2, IL-3, IL-4, IL-6, IL-7, IL-8, IL-10, IL-12, IL-13, IL-23), vascular endothelial growth factor (VEGF), tumor necrosis factor-alpha (TNF-alpha), interferon-gamma (IFN-gamma), epidermal growth factor (EGF), monocyte chemotactic protein-1 (MCP-1), E-selectin, L-selectin, P-selectin, intercellular adhesion molecule-1 (ICAM-1), vascular cell adhesion molecule-1 (VCAM-1). All biomarkers were measured by biochip array technology on Evidence Investigator analyzer (Randox). Probability values (p)<0.05 were considered statistically significant.
Results: Comparing serum cytokine and adhesion molecule levels, we found in CN-AML a significant increase in serum E-selectin (34.49±18.23 mcg/L *vs.* 13.98±9.11 mcg/L; p=0.00018), L-selectin (2962.50±706.20 mcg/L *vs.* 2187.12±1060.01 mcg/L; p=0.0092) and VCAM-1 (855.34±386.02 ng/L *vs.* 600.73±180.79 ng/L; p=0.039). On the other hand the serum levels of IL-7 (3.12±1.98 ng/L *vs.* 5.81±3.66 ng/L; p=0.029) and EGF (7.36±7.06 ng/L *vs.* 21.08±23.98 ng/L; p=0.035) were significantly decreased. The presence of FLT3-ITD in CN-AML with NPM 1 mutation was associated with higher IL-1 alpha (0.66±0.16 ng/L *vs.* 0.20±0.27 ng/L; p=0.035), IL-4 (1.69±0.89 ng/L *vs.* 0.34±0.54 ng/L; p=0.046), E-selectin (54.76±16.32 mcg/L *vs.* 25.06±7.61 mcg/L; p=0.011) and P-selectin (206.21±61.44 mcg/L *vs.* 106.72±29.28 mcg/L; p=0.037) levels. Serum levels of other evaluated cytokines and adhesion molecules were without significant differences.
Summary and Conclusions: Our results indicate that serum levels of some cytokines and adhesion molecules (IL-1 alpha, IL-4, IL-7, EGF, E-, P-, L-selectin) are significantly altered in AML patients and may reflect activity of the disease based on cytogenetic and molecular genetic changes. Whether these alterations could serve as a prognostic marker for AML is not known. To assess their predictive value for patient outcome, further studies in a larger number of patients are necessary. The work was supported by Specific research project "Analysis of defined prognostic factors in acute myeloid leukemia" (FMHS) and by a long-term organisation development plan 1011 (FMHS).

REPURPOSING PHENOTHIAZINE CHLORPROMAZINE IN THERAPEUTIC TARGETING OF LEUKEMIC STEM CELLS

B S Tislevoll[1,*] C Leitch[1], M Enger[1], M Popa[1], Ø Bruserud[1,2], E McCormack[1], BT Gjertsen[1,2]
[1]Department of Clinical Science, University of Bergen, [2]Department of Internal Medicine, Hematology Section, Haukeland University Hospital, Bergen, Norway

Background: Acute myeloid leukaemia (AML) is an aggressive blood cancer of the myeloid linage involving hematopoietic stem cells. AML is clinically and molecularly a heterogeneous group of diseases predominantly affecting the elderly. Although our understanding of the disease has improved in the past decade, overall disease survival does not exceed 50% of patients. Major challenges include relapse and refractoriness to chemotherapy. Considerable evidence suggests that the initiation and sustenance of AML are due to a rare population of cells, namely leukemic stem cells (LSC). Indications that current chemotherapeutics are ineffective against LSC, may explain the frequency of relapse in AML.
Aims: We explored selective targeting of LSC as a novel therapeutic approach. The dopamine antagonist Chlorpromazine (CPZ) is a well-known antipsychotic, which belongs to the class of phenothiazines. Emerging evidence shows that CPZ possesses anti cancer properties by affecting cellular mechanisms involved in genotoxicity and autophagy. Recently it has been shown that dopamine receptors are expressed on LSC and may be important for their survival. In addition blast cells from subgroups of AML patients have been confirmed to express dopamine receptors. We hypothesise that the dopamine antagonism exerted by CPZ has the potential to target LSC in AML.

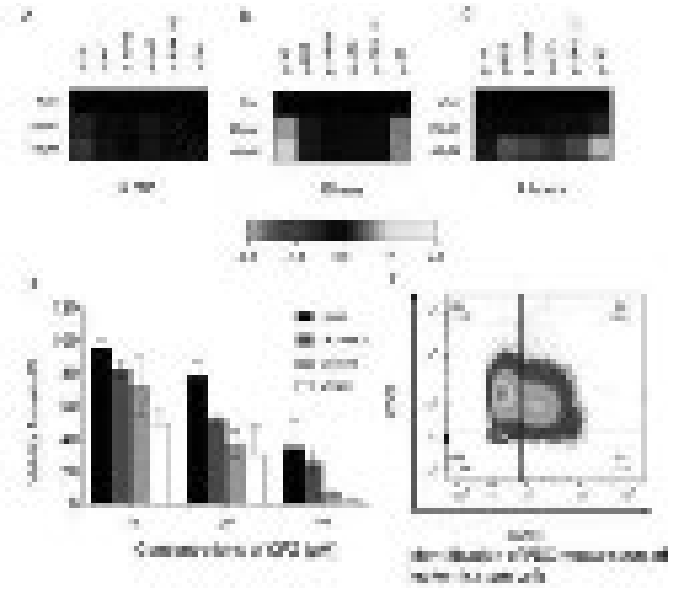

Figure 1.

Results: In order to assess CPZ´s mechanism of action we have used five leukemic cell lines to perform cell death and proliferating assays. Our data confirm the cytotoxic properties of CPZ, as it induces cell death in a dose dependent manner. In the colony-forming assay CPZ treatment resulted in reduced proliferation. Expression of dopamine receptors in the same cell lines was determined. Early CPZ-induced changes in intracellular signalling pathways were examined by single cell signal transduction profiling, employing phosphoprotein specific flow cytometry to investigate. CPZ´s ability to limit the renewability of LSC was screened in a panel of cells isolated from AML patient derived xenografts (PDX).
Summary and Conclusions: Repurposing of approved medicines has the potential to greatly accelerate the clinical application of novel therapies. The dopamine antagonist CPZ is a widely available and established drug that has been in clinical use for decades. If it is possible to utilise CPZ to target leukemic stem cells, CPZ has the potential to be an important therapeutic agent in haematological malignancies.

BATIMASTAT, A MATRIX METALLOPROTEINASE INHIBITOR, AS A THERAPEUTIC APROACH IN HEMATOLOGIC NEOPLASIAS

A Pires[1,2], R Alves[2,3,4], J Jorge[1,2], J Balça-Silva[2,4], C Domingues[2,3], AC Gonçalves[2,3,4], AB Sarmento-Ribeiro[2,3,4,5*]
[1]Faculty of Science and Techonology, University of Coimbra, [2]Applied Molecular Biology and University Clinic of Hematology, Faculty of Medicine University of Coimbra, [3]Center of Investigation on Environment Genetics and Oncobiology, Faculty of Medicine, University of Coimbra, [4]Center for Neuroscience and Cell Biology , University of Coimbra, [5]Clinical Hematology Service, Centro Hospitalar Universitário de Coimbra, Coimbra, Portugal

Background: The bone marrow microenvironment is the main support of normal hematopoiesis, although it is also important in maintenance and development of neoplastic clones, namely in hematological neoplasias. Matrix metalloproteinases (MMPs) are important players in bone marrow microenvironment, since they can degrade the protein components of the extracellular matrix. On account of that, several studies show that MMPs are also involved in cancer development and progression and could be a new therapeutic target. The majority of actual therapeutics for hematological neoplasias fails in some patients leading to relapses. Therefore the use of MMPs inhibitors (MMPIs) may become a new therapeutic approach for these patients.
Aims: The aim of this study was to evaluate the therapeutic potential of Batimastat (BB-94), a matrix metalloproteinases inhibitor, in *in vitro* models of hematological neoplasias.
Methods: For this purpose, we used four hematological neoplasias cell lines, two Acute Promyelocytic Leukemia (APL) cell lines, the NB-4 and the HL-60 cells, the first one with the translocation t(15;17) and the second without this translocation, a Multiple Myeloma cell line, the H929 cells, and a

Myelodysplastic Syndrome cell line, the F-36P cells. All cell lines were cultured in absence and presence of different concentrations of BB-94 ranged from 0,1 μM to 10 μM, in daily or single dose administration. To evaluate the effect of this inhibitor on cell viability and cell density we used the Trypan Blue Assay. Cell death was determined by optical microscopy (May-Grunwald Giemsa staining) and by flow cytometry (FC) using the Annexin V and Propidium Iodide double staining. It was also evaluated the activation of caspases, using the Apostat probe, and cell cycle by FC. In order to understand the role of BB-94 in cell proliferation, we evaluated the expression levels of proteins involved in the MAPK signaling pathway, as ERK 1/2, by Western Blotting.

Results: Our results showed that BB-94 reduces cell viability and proliferation in a time, dose and cell line dependent manner. We found that the half maximal inhibitory concentration (IC50) at 48 hours of exposure was, approximately, 7,5 μM for NB-4 and F36-P, 10 μM for H929, and between 7,5 and 10 μM for HL-60 cells. Besides that, drug daily administration schedule seems to be more effective in the reduction of cell viability and proliferation and with lower doses hen compared to the same doses in single administration, except in H929 cell line. Furthermore, BB-94 induced cell death by apoptosis with activation of caspases, in a dose-dependent manner. The cytotoxic effect of BB-94 seems to be more active in the APL cell line with t(15;17) translocation. The analysis of cell cycle progression also revealed an arrest in G_0/G_1 and S phases, in HL-60 and NB-4 cell lines, respectively. Besides cell cycle arrest, the apoptotic effect induced by BB-94 could be mediated by ERK (extracellular signal-regulated kinase) protein since we observed an increase of phosphorylated ERK expression in the cells treated with BB-94 when compared to untreated cells in every cell lines, except in H929 cells.

Summary and Conclusions: In conclusion, our results suggest that BB-94 could be a new potential therapeutic approach in hematological neoplasias and also support a role for the ERK signalling pathway in BB-94-induced apoptosis. However, therapeutic efficacy may depend on the cell type and genetic characteristics of the neoplasia, as well as the therapeutic schedule used.

ABSTRACT SUBMISSION 3. ACUTE MYELOID LEUKEMIA - BIOLOGY ABSSUB-4562 BERBERINE ACTS AS A PUTATIVE EPIGENETIC MODULATOR BY AFFECTING HISTONE CODE ZHIXIANG WANG1, LIU YUAN2, XUEJIE JIANG1, FANYI MENG* 1

Z Wang[1], L Yuan[2], X Jiang[1], F Meng[1,*] L Shuang[3]

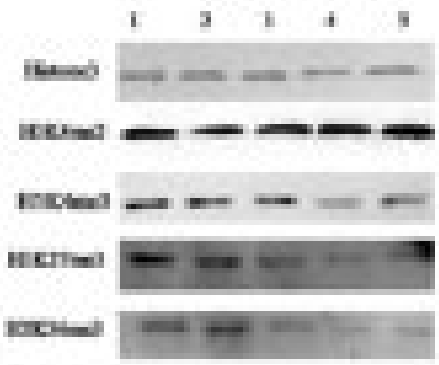
[1]department of hematology, Nanfang hospital, Guangzhou, [2]department of hematology, The First Affiliated Hospital of Nanchang University, Nanchang, [3]Southern Medical University, Guangzhou, China

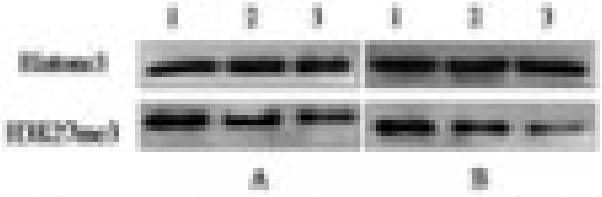
Background: Berberine, an isoquinoline plant alkaloid, has a wide range of biochemical and pharmacological effects. However, the exact mechanism of these bio-activities remains poorly understood.

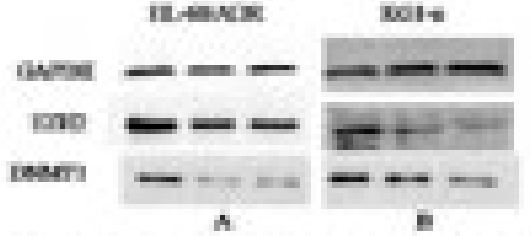
Aims: We conducted this study to explore how these molecular events are regulated by berberine.

Methods: In this study, when analyzing gene expression profile of U266 cells treated by berberine against profiles from external sources, along with PCR array,Real-time PCR (U266,HL-60/ADR and KG1-α) and Western Blot (U266,HL-60/ADR and KG1-α) .

Results: We demonstrated significant similarity between berberine and two epigenetic modulators (CG-1521 and TSA). As compared with gene expression in U266 cells without treatment, 2599 genes were up-regulated and 2155 genes were down-regulated for at least two-fold by berberine in U266 cells. Reverse-docking using berberine as a ligand for possible protein targets identified lysine-N-methyltransferase, among others, as a putative target of berberine. This suggested a possible role of berberine in epigenetic modulation. The results of epigenetic chromatin modification enzymes PCR array experiments support our hypothesis. We quantified the expression of these genes with at least 1.5-fold change in U266 cells with and without berberine. Several key observations were made: (1) Five histone acetylases represented by EP300 and CREBBP were up-regulated whereas at least two histone deacetylases HDAC2 and HDAC8 were seen reduced; (2) Lysine (K)-specific demethylase family was fairly active, among which KDM1 targets H3K9me2/1 and H3K4me2/1, KDM4 demethylates both H3K9me3/2 and H3K36me3/2, HDM5 is specific for H3K4me3/2 and KDM6 targets H3K27me3/2; (3) SET domain-containing histone methyltransferase family was also fairly active. SET1 and SET7 methylate H3K4 whereas SETB methylates H3K9. Both SET2 and SET3 methylate H3K36. SET6 mono-methylates K310 of the rela subunit NF-kB complex. SETD8 mono-methylates H3K20 and SMYD3 di- and tri-methylates H3K4. There is a discrepancy for SMYD3 expression between microarray and PCR array data. After checking by RT-qPCR, we confirmed that SMYD3 was down-, NOT up-, regulated by berberine; (4) DNA methyltransferases, which are responsible for *de novo* methylation (DNMT3) or maintenance of methylated CpG (DNMT1), were down-regulated.







Furthermore, the analysis showed that enzymes involved in histone acetylation and methylation have been impacted predominantly. Up-regulation of histone acetyltransferase CREBBP and EP300, histone deacetylase SIRT3, histone demethylase KDM6A as well as histone methyltransferase SETD7, and down-regulation of histone acetyltransferase HDAC8, histone methyltransferase WHSC1I, WHSC1II and SMYD3. In parallel, the results of western blot revealed that H3K4me3, H3K27me3 and H3K36me3 proteins decreased after berberine treatment. The results were confirmed in acute myelocytic leukemia (AML) cell lines HL-60/ADR and KG1-α. In addition to this, the results showed that berberine also inhibited the expression of EZH2 and DNMT1 in HL-60/ADR and KG1-α cells, both in protein and mRNA.

Summary and Conclusions: The results of this study suggest that berberine might modulate expression of epigenetic regulators importent for many downstream pathways, thereby manifests its various bio-activities.

PB1448

NEONATAL BLOOD SPOT ANALYSIS DEMONSTRATES EARLY EXISTENCE OF A CRYPTIC CBFB-MYH11 GENE FUSION IN A FOUR YEAR OLD AML PATIENT

PJ Poddighe[1,*] MA Veening[2], AM Ford[3], MB Mansur[3], A Loonen[4], TM Westers[4], PA Merle[4], J W Wessels[1], V de Haas[5], WA Kors[2], S L Bhola[1], MJ Wondergem[4], G L Kaspers[2]
[1]Dept of Clinical Genetics, [2]Dept of Pediatric Oncology/Hematology, VU University Medical Center, Amsterdam, Netherlands, [3]Center for Evolution and Cancer, The Institute of Cancer Research, London, United Kingdom, [4]Dept of Haematology, VU University Medical Center, Amsterdam, [5]Dutch Childhood Oncology Group, The Hague, Netherlands

Background: Acute myeloid leukemia (AML) with the inv(16) karyotype is commonly referred to as a member of the core binding factor AMLs, and is associated with a favourable prognosis, showing longer periods of complete remission and higher overall survival rates. The inv(16) results in a fusion between *CBFB* (core binding factor beta subunit*)* at 16q22 and *MYH11* (myosin heavy chain 11) at 16p13, leading to a chimeric CBFB/MYH11 protein. Additional studies soon confirmed the expression of *CBFB/MYH11* transcripts in inv(16) and in t(16;16) positive AML-M4Eo, as well as in M4 without eosinophilia.
Aims: To study whether the complex abnormal karyotype with a *CBFB/MYH11* fusion, that was found in a four year old girl, was already present neonatally.
Methods: Morphology, immunophenotyping, and cytogenetic and molecular methods were performed at diagnosis. Blood spots from Gurthrie cards were analysed to track molecular findings at birth.
Results: A four year old girl presented with pallor, a history of viral infections and pancytopenia. Bone marrow aspirate showed 2% blasts and megakaryocytic dysplasia, not indicative of acute leukaemia; serology was negative. On the basis of these results differential diagnosis was a reactive, infectious process. The patient was seen on the outpatient clinic on a regular basis. After a month the full blood count recovered without signs of cytopenia. Surprisingly cytogenetic studies on the bone marrow showed a complex abnormal karyotype of unknown significance: 46,XX,der(15)t(15;16)(q2?2;q?),?iso(16)(p10), add(16)(p?)[6]/46,XX[16]. The next cytological examination of peripheral blood smear showed, however, 12% Sudan Black positive blasts. Immunophenotyping showed 9% myeloblasts (CD34, CD117, CD13, MPO and HLA-DR positive, CD33 negative and TdT weakly positive). Morphology of the bone marrow aspirate showed 21% of blasts and dysplasia. Molecular diagnostics revealed a S/I transcript for *CBFB/MYH11*, leading to a diagnosis of CBF AML. Additional FISH confirmed the presence of a *CBFB/MYH11* fusion on one derivative chromosome 16 and the karyotype was subsequently adjusted to 46,XX,der(15)t(15;16), der(16)inv(16),der(16)t(15;16)[9]/46,XX[1]. The patient was subsequently treated according to the paediatric AML protocol. After the first course of chemotherapy complete remission was achieved with a normal karyotype 46,XX[20]. Nine months after treatment patient is still in complete remission. Since at presentation this girl showed an abnormal karyotype with a *CBFB-MYH11*-fusion but no signs of a leukaemia, we were interested whether the fusion was already present at birth. Therefore, the DNA fusion junction was cloned from diagnostic DNA and the patient-specific sequence used to investigate the neonatal blood spot. Remarkably, the identical *CBFB/MYH11* fusion product was detected in the blood spot.
Summary and Conclusions: In general practice, the detection of a *CBFB/MYH11* fusion as a result of an inv(16) or t(16;16) is indicative of CBF AML, regardless the percentage of blasts in blood or bone marrow. Here we report a patient with a neonatal *CBFB/MYH11* fusion with the leukaemia presenting four years later. This indicates that a pre-leukaemic genetic abnormality may be present for a long period and might support the hit-second hit hypothesis. The genetic abnormality is not constitutional since it disappeared after chemotherapeutic treatment and this finding allows us to perform RQ-PCR for minimal residual disease (MRD) monitoring of *CBFB/MYH11* for this patient.

EFFICACY OF PSYCHOLOGICAL NURSING ON ACUTE MYELOBLASTIC LEUKEMIA

X Dahai[1], Z Nan[1], D Ning[1], C Hongli[1,*] Z Xiuxian[1], L Xiaoliang[1], W Yang[1]
[1]Emergency Department, First Hospital of Jilin University, changchun, China

Background: Acute myeloblastic leukemia is a common and severe clinical disease.It can cause anxiety.Psychological nursing is needed on the baisis of traditional nursing.Psychological nursing supplies patients with psychological intervention to alleviate anxiety.Patients can have a good therapeutic alliance.
Aims: To analyze the efficacy of psychological nursing on acute myeloblastic leukemia.
Methods: 226 acute myeloblastic leukemia patients were divided randomly into two groups:psychological nursing group(A group) 134 cases and control group(B group) 92 cases.A group accepted routine nursing combinating with psychological nursing.B group accepted only routine nursing.Evaluate and analyze HAMA scores of each group respectively between prior treatment and aftrer 10 days of treatment and compare HAMS scores of two groups prior treatment and aftrer 10 days of treatment.
Results: Prior treatment,HAMA score of A group 20.89±5.82 points and HAMA score of B group 20.46±6.32 points,had no significant differences.After 10 days treatment,HAMA score of A group 14.26±3.45 points and HAMA score of B group 17.39±5.33 points,had signicant differences.A group and B group both had significant differences between prior treatment and posttreatment.
Summary and Conclusions: Psychological nursing can ameliorate anxiety of acute myeloblastic leukemia patients and should be advocated.

PB1450

THE ASSOCIATION OF REDUCTION OF WT1 TRANSCRIPTS IN BONE MARROW AND OUTCOMES IN ACUTE MYELOID LEUKEMIA PATIENTS

Y Shibasaki[1,*] T Tanaka[2], S Miyakoshi[2], K Fuse[2], T Kozakai[2], H Kobayashi[2], T Ushiki[2], M Moriyama[2], J Takizawa[2], M Narita[2], M Takahashi[2], H Sone[2], M Masuko[1]
[1]Department of Stem Cell Transplantation, Niigata University Medical and Dental Hospital, [2]Department of Hematology, Niigata University Faculty of Medicine, Niigata, Japan

Background: Evaluation of minimal residual disease (MRD) during chemotherapy is important for the decision on post-remission therapy for acute leukemia, including stem cell transplantation (SCT). Detection of leukemia-specific chimeric genes by real-time quantitative polymerase chain reaction is most sensitive method to quantify MRD among other methods such as karyotype analysis, fluorescence *in situ* hybridization and flow cytometry. However, because over 50% of acute myeloid leukemia (AML) patients lack suitable leukemia-specific chimeric genes for detection of MRD, other MRD makers are necessary as newly prognostic factors for greater proportion of AML patients. WT1 mRNA is overexpressed in most AML blasts. Therefore, WT1 mRNA transcript level in peripheral blood has been reported as a suitable molecular marker of MRD for most AML patients. In contrast, in acute lymphoblastic leukemia patients, it remains to be elucidated whether early reduction of tumor burden make good prognosis in AML patients.
Aims: We focused on the clinical relevance of WT1 mRNA transcript level in bone marrow (BM) as MRD during chemotherapy, and also the association between WT1 mRNA transcript level and outcome in adult AML patients.
Methods: Forty-eight AML patients who received chemotherapy at hospitals in our study group were enrolled in this study. Written informed consent was obtained from each patient before starting induction chemathrapy. We analyzed the transcript levels of WT1 mRNA in BM at diagnosis, after induction therapy and after final consolidation therapy. WT1 mRNA transcript levels were determined using the WT1 mRNA Assay Kit (Otsuka, Japan). The diagnosis and classification of AML were based on criteria according to the WHO classification. Cytogenetic risk group stratification was performed using MRC AML10. All statistical analyses were performed with EZR software (Saitama Medical Center, Jichi Medical University). This protocol was reviewed and approved by an Institutional Review Board at each hospital in our study group.
Results: Thirty-two of 48 patients achieved in complete remission (CR) after induction therapy. Twenty-four of 32 patients who achieved in CR after induction therapy completed consolidation therapies and could be quantified the transcript levels of WT1 mRNA in BM at after final consolidation therapy. Twenty patients were received allogeneic hematopoietic SCT. The median WT1 mRNA expression level at diagnosis was 16,000copies/μgRNA (range 250-400,000). The transcript levels of WT1 mRNA in BM at diagnosis was not associated with overall survival (OS) (0.099) and disease free survival (DFS) (p=0.22). The achievement of 2 log reduction of WT1 mRNA transcript level after induction

therapy in BM was associated with OS (P=0.035), but was not associated with DFS (P=0.074). The achievement of 2 log reduction of WT1 mRNA transcript level after final consolidation therapy in BM was associated with OS (P=0.006) and DFS (P=0.018). Next, we analyzed the impact of log reduction levels of WT1 mRNA transcript level for survival by multivariate analysis. We used Wd/i_log and Wd/c_log to assess the value of reduction of tumor burden. Wd/i_log was difined as a log scale of WT1 mRNA transcript level at diagnosis divided by that after induction therapy. Wd/c_log was difined as a log scale of WT1 mRNA transcript level at diagnosis divided by that after consolidation therapy. Factors were adjustment for SCT and cytogenetic risk. Wd/i_log was associated with DFS and OS. Hazard ratio for DFS and OS were 1.955 (P=0.013) and 2.911 (P=0.021), respectively, by every shallow remission level in log scale. Wd/c_log was associated with DFS, but not OS. Hazard ratio for DFS was 2.0250 (P=0.005) by every shallow remission level in log scale.
Summary and Conclusions: Our results suggest that early and deep reductions may be important for good prognosis in AML patients. In addition, Wd/i_log and Wd/c_log in WT1 mRNA transcript level in BM are useful as predictive indexes for outcome of AML patients.

PB1451

WT-1 FROM PERIPHERAL BLOOD PREDICTS RELAPSE IN AML PATIENTS UNDERGOING STEM CELL TRANSPLANTATION

M Malagola[1,*] C Skert[1], R Ribolla[1], F Cattina[1], V Cancelli[1], A Turra[1], F Schieppati[1], C Bergonzi[1], C Filì[1], G Ruggeri[2], D Russo[1]
[1]Experimental and Clinical Sciences, Chair of Hematology, Bone Marrow Transplant Unit, University of Brescia, AO Spedali Civili Brescia, [2]Laboratorio Analisi, Spedali Civili , Brescia, Italy

Background: Minimal residual disease (MRD) monitoring in acute myeloid leukemia (AML) after allogeneic stem cell transplantation (allo-SCT) is crucial to identify patients at high risk of relapse, who can be cured with early immunosuppressive therapy discontinuation and/or donor lymphocyte infusions. More than 60% of AML lack appropriate markers for MRD. The Wilm's tumor 1 gene (WT1) is over-expressed in more than 90% of cases at diagnosis and it has been proposed as a marker for MRD monitoring.
Aims: This is a retrospective single-center analysis of WT1 expression on peripheral blood (PB) of AML patients at different time-points during treatment and follow up, with the aim to assess a threshold of WT1 copies above which disease recurrence is likely.
Methods: Twenty-three AML patients with overexpression of WT1 at diagnosis, submitted to allo-SCT in our Institution from June 2009 to September 2013 were monitored for WT1 levels by RT-PCR from PB before allo-SCT, at 3rd and 6th month after allo-SCT.

Table 1. Patients' outcome according to peripheral blood WT1 levels (<or>/=5 WT1/ABLx104) evaluated at three deifferent time-points.

Results: The median age of our patients was 53 years (range 24 – 62), the median WBC count at diagnosis was 34.2 x 10^9/L (range 0.7 – 103). Forty-three percent of cases showed a normal karyotype at diagnosis, 35% a complex karyotype and 22% a mixture of the other commonly observed abnormalities. A marker of molecular biology other than WT1 was available in 13/23 cases (26%) and was Flt3-ITD in 6 cases (26%) and NPM mutation type A in 7 cases (30%). The disease status at transplant was morphological first complete remission (CR) in 14 cases (61%). Thirty-five percent of the patients (8 cases) received a transplant from a HLA compatible sibling donor, 56% from a matched unrelated donor (13 cases) and 9% from a matched single cord blood unit (2 cases). Twelve out of 23 cases (52%) received a myeloablative conditioning regimen. The median follow up is 12 months (range 3 – 38). The result of WT1 quantification was available in 22/23 cases (96%), 20/23 (87%) and 16/23 (70%) before allo-SCT, at 3rd month and at 6th month, respectively. As reported in Table 1, considering WT1/ABL x $10^4 \geq 5$ *vs* WT1/ABL x 10^4<5 before transplant, 8/10 patients (80%) and 3/12 patients (25%) relapsed, respectively (p=0.01). Similarly, considering the 3rd month, there was a trend towards a higher relapse rate for patients with a WT1/ABL x $10^4 \geq 5$ *vs* those with WT1/ABL x 10^4<5 [5/8 (62%) *vs* 4/12 (33%); p=0.19]. Finally, 5/6 patients (83%) and 2/10 patients (22%) with WT1/ABL x $10^4 \geq 5$ and WT1/ABL x 10^4<5 at 6th month respectively relapsed and this difference was statistically significant (p=0.01). The 3 years OS was 0% for patients with WT1/ABL x $10^4 \geq 5$ *vs* 54% (95% CI 7.9 – 99.8) for patients with WT1/ABL x 10^4<5 before transplant (p=0.03). When considering the WT1 levels at 3rd month, the 3 years OS was 0% for patients with WT1/ABL x $10^4 \geq 5$ *vs* 52% (95% CI 6.5 – 97.4) for patients with WT1/ABL x 10^4<5 (p=0.002). Similar results were observed for event free survival (EFS).
Summary and Conclusions: Our preliminary data, although derived from a small number of patients, strongly suggest that WT1 monitoring from PB may be a useful tool for identification of patients at high risk of relapse after allo-SCT, with a threshold represented by 5 copies of WT1/ABL x 10^4.

PB1452

ROLE OF UROKINASE-TYPE PLASMINOGEN ACTIVATOR RECEPTORS AS AN EARLY DETECTOR FOR TREATMENT OUTCOME IN AML

H R Nassar[1,*] E Z Kandeel[2], L AE Hegazy[3], A M Helal[1], T Darwish[1], S A Eltokhy[2]

[1]Medical oncology, [2]Clinical pathology, NCI, [3]Clinical pathology, faculty of medicine-Cairo university, Cairo, Egypt

Background: the urokinase-type plasminogen activator system which consist of a proteinase (the urokinase-type plasminogen activator,uPA), a receptor(the urokinase-type plasminogen activator receptor uPAR or CD87) and inhibitors (PAI-1) are enriched in several types of tumors and involved in proteolysis, cell migration and invasion. high expression of uPA and uPAR are associated with an increased relapse rate and shorter survival in breast cancer and colorectal carcinomas.
Aims: this study shed light on the expression of uPAR in adult acute myeloid leukemia(AML) and its prognostic relevance
Methods: peripheral blood and bone marrow samples are obtained from 54 newly diagnosed AML adult patients ,20 healthy controls stained with anti CD87 and estimated on flow cytometry.
Results: CD87 expression was heterogenous in different FAB subtypes of AML with high expression in monocytic leukemia(M4/M5)(Pvalue0.001). high expression of CD87 was asssociated with shorter survival and poor response to therapy(P=0.028,0.002 respectively). the most discriminating cut off value of CD87expression was 15%, patients with less than 15% expression had 4.6 times better treatment outcome than those with more than or equal to 15%. on the multivariate analysis,CD87 was the most significant single variable that affect treatment outcome compared to total leucocytic count,hemoglobin level,platelets count,cytogentic and FLTexpression.
Summary and Conclusions: high CD87 expression is an independent prognostic parameter associated with poor response and shorter overall survival in adult AML patients.

PB1453

ADRENOMEDULLIN, A HYPOXIA-RELATED PROTEIN, IS ASSOCIATED WITH PROGNOSIS OF ACUTE MYELOID LEUKEMIA

YF Lin[1,*] CY Hu[1], DL Ou[2], CY Chen[3], HF Tien[3], YC Ko[4], LI Lin[1]
[1]Clinical Laboratory Sciences And Medical Biotechnology, [2]Oncology, National Taiwan University, [3]Internal Medicine, National Taiwan University Hospital, Taipei, [4]Radiological Technology, Yuanpei University, Hsinchu, Taiwan, Republic of China

Background: Previous studies showed that hypoxia condition can promote cancer cells invasion and metastasis in solid tumors. It is known that the bone marrow microenvironment is hypoxia. However, the biologic effect of hypoxia on leukemia has not been clearly documented.
Aims: The purpose of the study was to investigate the roles of hypoxia in acute myeloid leukemia (AML).
Methods: Agilent SurePrint G3 Human GE 8X60K arrays was used to compare the gene-expression profile of the OCI/AML3 cultured under normoxic (21% O_2) and hypoxic (1% O_2) conditions for 8h. The information in Oncomine (version 4.4; http:www.oncomine.org) and PrognoScan (date of analysis: 2011-12-05; http://gibk21.bio.kyutech.ac.jp/PrognoScan/index.html) were recruited for analyses. The former was used to assess differential expression results for a gene of interest across collected data sets, and the latter enables systematic meta-analysis of the prognostic value of a gene in multiple datasets. Human leukemia cell lines U937, OCI/AML3, K562, HL-60 and primary leukemia cells from AML patient were assessed for mRNA expression under normoxic and hypoxic conditions. The study was approved by the institutional review board of National Taiwan University Hospital and written informed consents were obtained from all participants in accordance with the Declaration of Helsinki.
Results: We compared the gene expression stpectrum of OCI/AML3 leukemia cells incubated in hypoxia and in normoxia with Agilent SurePrint G3 Human GE

8X60K microarray coupled with rank consistent lowess. Adrenomedullin was the most significantly up-regulated. Further Q-RT-PCR confirmed this up-regulation of adrenomedullin with 8-200 folds increase in various leukemia cell lines and leukemia cells from patients with AML at diagnosis under hypoxia condition. ONCOMINE, a cancer microarray database and web-based data-mining platform aimed at facilitating discovery from genome-wide expression analyses. According to data from ONCOMINE, there was no significance difference of adrenomedullin expression between normal controls and patients with AML, suggesting adrenomedullin might not be a diagnostic biomarker. The PrognoScan based on the published cancer microarray datasets with clinical annotation provides a powerful platform for assessing the biological relationship between gene expression and prognosis. According to data from PrognoScan, there was the trend that survivals were longer with low adrenomedullin mRNA expression in AML patients than those with high expression (Cox *p*-value = 0.06).
Summary and Conclusions: We have identified a hypoxia-related protein, adrenomedullin, in leukemia cells lines and human leukemia samples. Expression of adrenomedullin is associated with a worse prognosis. The nature and the biologic action of adrenomedullin remain to be elucidated.

PB1454

CLINICAL IMPACT OF SNPS OF P53 GENE PATHWAY ON THE ADULT AML PATIENTS

G Ebid[1,*] T Abdel Hamid[2], M El gammal[2], M M Saber[2], N Hassan[1]
[1]Clinical Pathology, [2]Medical Oncology, National Cancer Institute, Cairo University, Cairo, Egypt

Background: Acute myeloid leukemia (AML) is a highly heterogeneous disease, with biologically and prognostically different subtypes. As one of the primary "gatekeepers" of the cell, the p53 tumor suppressor plays a major role in sensing and responding to a variety of stressors to maintain cellular homeostasis. Single nucleotide polymorphisms (SNP) in codon Arg72Pro of P53 results in impairment of the tumor suppressor activity of the gene. A similar effect is caused by a SNP in codon 31 of P21. In contrast, a SNP in position 309 of MDM2 results in increased expression due to substitution of thymine by guanine. All three polymorphisms have been associated with increased risk of tumorigenesis and alter apoptosis.
Aims: To study the impact of p53, p21 and mdm2 genes polymorphisms on clinical outcome of adult AML patients treated at National Cancer Institute (NCI) -Cairo University.
Methods: Molecular genetic analysis involving P53, MDM2 and P21 single nucleotide gene polymorphisms was done using PCR-RFLP coupled analysis for 48 patient. the work was performed accodring to Helsinki declaration, the protocol was approved by the IRB ofNCI, Cairo University and an informed consent was obtained from all subjects. Most of patients have received remission induction chemotherapy with daunorubicin (45mg/m2/day for 3 days) and standard dose cytosine arabinoside (200mg/m2/day for 7days) with or without recombinant human granulocyte colony-stimulating factor (rhGCSF).
Results: Patients with homozygous Arg/arg at codon 72 of P53 had a better median OS of 13.4 months than Arg/Pro (8.4 months) and Pro/Pro (1.5 month) [p=0.045]. patients with both P53 and P21 homozygous polymorphisms are associated with poorer OS (5 months) and P. value 0.037, however the OS for patients with both wild or either variant was 16 and 19.3 months respectively. the presence of P21 wild or MdM2 wild genotype result in abolish the poor effect of P53 Pro/Pro on the Overall survival. patients with both P53 and P21 homozygous genotype are associated with poor DFS (DFS =3.8 & P. value 0.004) however DFS was 14.5 for patients with both P53 and P21 wild genotype. Neither p21or mdm2 polymorphism alone showed an impact on OS and DFS. Complete remission was not affected by any of the three genes polymorphisms.
Summary and Conclusions: p53 pathway gene polymorphisms may affect the overall survival and disease free survival of adult AML patients specially the presence of P53 and P21 combined homozygous variant genotype was associated with a poor clinical outcome.

PB1455

INTENSIVE CONSOLIDATION AFTER STANDARD INDUCTION THERAPY CAN BENEFIT SELECTED ELDERLY PATIENTS WITH ACUTE MYELOID LEUKEMIA AND AGE ≥ 75 YEARS: A RETROSPECTIVE ANALYSIS OF THE RETE EMATOLOGICA LOMBARDA

M Bernardi[1,*] P Zappasodi[2], N Fracchiolla[3], L Marbello[4], E Todisco[5], C Pagani[6], M Carrabba[1], M Rossi[2], F Guidotti[3], V Mancini[4], A Santoro[5], E Borlenghi[6], E Morra[4], G Rossi[6]
[1]Oncology Haematology, San Raffaele Scientific Institute, Milan, [2]Haematology Oncology, Fondazione IRCCS Policlinico San Matteo, Pavia, [3]Haematology, Fondazione IRCCS Ca' Granda Ospedale Maggiore Policlinico, [4]Haematology, Niguarda Ca' Granda Hospital, Milan, [5]Haematology, Humanitas Cancer Center, Rozzano, [6]Haematology, Spedali Civili, Brescia, Italy

Background: outcome of AML patients (pts) older than 70 years is poor because of unfavourable disease characteristics and frequent comorbidities. Indeed most pts are excluded from curative therapeutic programs. When standard induction is given to pts ≥ 75 years the complete remission (CR) rate is around 50% but the best consolidation/maintenance strategy after CR is still controversial. Recent guidelines define age > 75 as the limit to consider patients unfit for aggressive therapy. However, nowadays, individualized management based on comorbidity scores and not only on age is encouraged. We collected data from haematologic centers of the regional network Rete Ematologica Lombarda (REL) to get insight into the outcome of fit AML elderly pts when treated with standard anthracyclin-containing induction and intensive consolidation programs in clinical practice.
Aims: retrospective evaluation of data from AML pts ≥ 75 yrs of age who received an intensive treatment program at different centers of the REL network
Methods: period 3/2005 to 5/2013, 33 pts, median age 76 (75-80). Summary of common characteristics of pts in the different centers: PS (ECOG) ≤ 2, renal and hepatic parameters<2 N, no active infections and cardiac ejection fraction > 50%. Diagnosis (WHO): 9 AML with MDS related changes (MDS-AML), 2 AML-M0, 6 AML-M1, 3 AML-M2, 2 AML-M4, 2 AML-M5, 1 AML with inv(16), 4 AML with mutated NPM1, 2 t-AML, 1 biphenotypic. Cytogenetic risk: 22 intermediate (16 normal karyotype), 3 poor, 1 good, 7 not evaluable. WBC at diagnosis: median 37x10e9/l (1,1-250,0).
Results: overall, 42 induction cycles were administered, 30 at "full dose" to 23 pts (3+7, MICE, ICE, FLAGIDA) and 12 at "reduced dose" to 10 pts (1+5). CR rate was 55%, 74% (17 pts) with "full dose" and 10% (1 pt) with "reduced dose" induction. One patient died after a "full dose" cycle. Intensive consolidation (16 pts): 29 cycles with intermediate or high dose cytarabine; 10 pts (62%) received two or more cycles, 3 pts an autologous transplant with myeloablative conditioning. Two pts (12,5%) died during consolidation. After consolidation, 2 pts received maintenance with 5-azacytidine. Twelve pts (675%) relapsed. Median OS from diagnosis was 325 days (5-2023), 345 days (22-2023) for the "full dose" induction pts and 137 days (5-482) for the "reduced dose" induction pts (p=ns). The 18 pts who obtained a CR had a median OS of > 2 years 788 days (range 69-2023) with 20% projected to be alive after 3 yrs. Median DFS was 245 days (27-1871). At last follow up, 5 pts are alive, 4 in CR, all after a "full dose" induction. One of the 2 pts on maintenance with 5-azacytidine is alive in CR 1114 days from diagnosis.
Summary and Conclusions: our analysis suggests that intensive consolidation approaches are feasible in selected older AML pts aged ≥ 75 and may improve survival. Also, standard *vs* reduced-dose induction treatments did not prove more toxic and were more effective. Notably, TRM was very low across the different centers. Strategies to prevent relapse, including new agents with low toxicity profile, should be explored. The criteria to be used in the selection of elderly AML pts for intensive treatment programs need to be fully defined. Age should not be "per se" an exclusion criterion. Guidelines for comprehensive geriatric assessment and the recently published consensus-based definitions of unfitness to intensive and non-intensive therapy in AML could help physicians to select and possibly address more pts with advanced age to potentially curative treatments in prospective clinical trials.

PB1456

MOLECULAR MARKERS IN DE NOVO ACUTE MYELOID LEUKEMIA

K Salem[1,*] H Aba Alkhail[1]
[1]Pathology and Laboratory Medicine, King Faisal Specialist Hospital and Research Centre, Riyadh City, Saudi Arabia

Background: Acute myeloid leukemia (AML) is a clinically, morphologically and genetically heterogeneous disease, involving one or all myeloid lineages. The heterogeneity of AML is reflected by differences in molecular abnormalities that have been recently discovered as potential prognostic factors in acute myeloid leukemia (AML). A genetic-based classification is essential for accurate diagnosis, prognostic stratification, monitoring of minimal residual disease and developing targeted therapies. Consequently, it is important that any screening panel is large enough to detect relatively rare mutations that might associate with a particular AML class or cytogenetic risk group.
Aims: To determine the frequency of different Gene Mutations in AML among Saudi Nations.
Methods: A variety of AML-specific mutations were screened, *i.e. FLT3, NPM1, IDH1, IDH2, CEPBA, DNMT3A, RUNX- , KIT , WT1, IDH1, IDH2, and PML-RARA* in bone marrow samples of 66 Adult and Pediatric new AML Patients using Sequencing technology during the period of January 2012 to December 2013 at The Molecular Genetics Laboratory, King Faisal Specialist Hospital and Research Centre, Riyadh (General organization), Saudi Arabia.
Results: A total of 66 patients (28 females and 38 males) were investigated for different gene mutations (56 cases at the time of diagnosis, 4 patient in relapse, 5 samples for patients prior to stem cell transplantation and one case post bone marrow transplantation in relapse). The positive cases represented 51% (34 cases of AML/ 28 adults and 6 pediatric patients).
Summary and Conclusions: The frequency of different gene mutation in AML

was similar to previously published studies from different international centers (*e.g.* FLT-3-ITD and NPM1 are 20% and 23% respectively), however, this is the first data presented from Saudi Arabia.

PROGNOSTIC FACTORS OF ELDERLY PATIENTS WITH ACUTE MYELOID LEUKEMIA

S Ogawa[1,*] M Seki[1], T Sakamoto[1, 2], Y Yokoyama[1], N Kurita[1], N Obara[1], M Yanagimoto Sakata[1], D Kudo[2], A Shinagawa[2], Y Hasegawa[1], S Chiba[1]
[1]Department of Hematology, University of Tsukuba, Tsukuba, [2]Department of Hematology, Hitachi General Hospital, Hitachi, Japan

Background: The incidence of acute leukemia (AML) is increasing substantially for individuals 65 years of age or older. However, no optimal treatment for elderly patients with AML has been established.
Aims: The aim of this study was to assess the outcomes of elderly patients with AML and prognostic factors.
Methods: We retrospectively analyzed 102 AML patients more than 65 years who were newly diagnosed at Tsukuba University Hospital and Hitachi General Hospital from 2008 to 2014. The median age was 73 (65-88). Diagnosis included AML, NOS (n=48), AML with MRC (n=46), therapy related AML (n=2), AML with t(8;21) (n=5), AML with inv(16) (n=1). Karyotypes according to IPSS were good (n=6), intermediate (n=59), and poor (n=37).

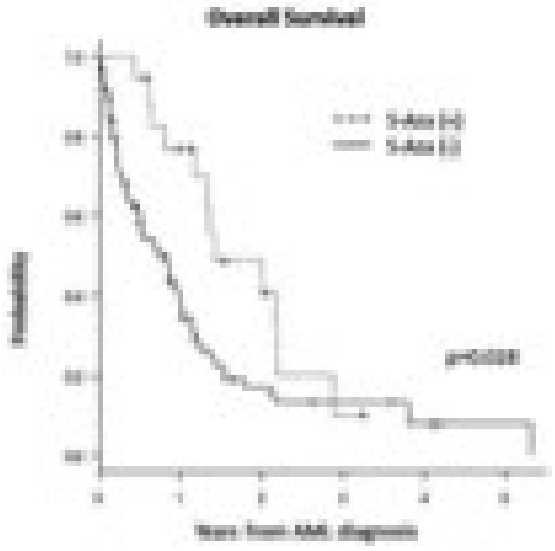

Figure 1.

Results: Intensive remission induction therapy was performed in 38 (37.2%), a less intense chemotherapy such as low-dose cytarabine was performed in 39 (38.2%) and 5-azacitidine (5-Aza) as remission induction was performed in 6 (5.8%). Complete remission (CR) was achieved in 32.3% of all treated patients and the estimated 2-year survival was 23.3%. The median duration of overall survival (OS) was 11 monthes. In univariate analyses, to perform induction therapy, CR and the usage of 5-Aza were found to be associated with good prognosis, on the other hand, poor karyotype significantly shorten the survival. The age, gender, prior to MDS were not significantly related to outcomes. In a multivariate analysis, CR (hazared ratio (HR), 0.091, 95% confidence interval (CI) 0.04-0.18, P<0.01), the usage of 5-Aza (HR 0.20, 95% CI 0.09-0.41, p<0.11) and poor karyotype (HR 1.73, 95% CI 1.06-2.82, P=0.01) were also significant.
Summary and Conclusions: The retrospective cohort analysis suggests that 5-Aza should be considered as a treatment option in elderly patients with AML.

PB1459

CEBPA MUTATIONS IN PATIENTS WITH DE NOVO ACUTE MYELOID LEUKEMIA: DATA ANALYSIS IN A CHINESE POPULATION

S Gao[1], L Su[1,*] W Li[1], Y Li[2], P Yu[1]
[1]Cancer center, The First hospital, Jilin University, [2]Department of Hematology, The central Hospital of Changchun, Changchun, China

Background: Although *CEBPA* mutations have been studied for many years in acute myeloid leukemia (AML), there is limited data about its prevalence and prognostic significance in AML patients from Chinese population.
Aims: To explore the clinical characteristics and prognoses of AML patients with *CEBPA* mutations.
Methods: Ninety patients with *de novo* AML were retrospectively analyzed in this study.
Results: *CEBPA* mutations were detected in 23 patients (25.6%), with 19 cases were double mutations, four were single mutation. In those with normal karyotype (NK), 20 cases (34.5%) were detected with *CEBPA* mutations. The following characteristics were observed in *CEBPA*-mutated patients: most (73.9%) of the *CEBPA*-mutated patients were M_1 and M_2; presented with high peripheral white blood cells [34.5 (12.6, 100.2) $\times 10^9$/L *versus* 9.16 (2.87, 48.2) $\times 10^9$/L; u = -3.085, p=0.002] and lower platelet [18.0 (12.0, 49.0) $\times 10^9$/L *versus* 31.0 (17.0, 68.0) $\times 10^9$/L; u = -1.989, p=0.047] than those without mutation; CD7 expression was higher, whereas CD34, CD56, and HLA-DR was lower. Compared with those without mutation, patients with *CEBPA* mutations had better relapse-free survival (p=0.014) and overall survival (p=0.031).
Summary and Conclusions: The frequency of *CEBPA* mutations may be high in Chinese patients with AML, and *CEBPA* mutations were one of these indictors of favorable prognoses.

PB1460

INDUCTION THERAPY IN PATIENTS WITH ACUTE MYELOID LEUKEMIA PRESENTING WITH HYPERLEUKOCYTOSIS.

V Troitskaya[1,*] P Elena[1], S Andrey[1], K Larisa[1], K Galina[1], G Tatyana[1], B Darima[1], P Evjenia[1], S Valery[1]
[1]Research Center of Hematology, Moscow, Russian Federation

Background: Most studies suggest that hyperleukocytosis (HL) is a poor prognostic factor in acute myeloid leukemia (AML). In adult patients HL at the onset of AML and ALL is diagnosed in 5-13% and in 10-30% respectively. HL is more common in AML with monocytic differentiation subtypes (M4eo, M5). During the induction chemotherapy early (first week) mortality in AML, associated with HL reaches 90%. The main reasons are leukostasis and massive tumor lysis syndrome, resulting as respiratory distress syndrome, neurological disorders, disseminated intravascular coagulopathy (DIC) with the development of life-threatening bleedings. In National research Center for Hematology we developed the treatment of AML presenting with HL, aimed for preventing cytolysis, which includes cytoreductive therapy (hydroxyurea, leukapheresis), and we employed plasmapheresis (PF) before the administration of anthracyclines on the 3-5 days of the induction-therapy (7+3), during hydroxyurea and the first days of cytarabine therapy.
Aims: To prevent the massive cytolysis during the induction therapy in patients with AML and HL at the onset of the disease.
Methods: From 2010 till 2014 in our center 75 patients (age ≤ 60) were diagnosed with *de novo* AML. Initial white blood cells (WBC) count ≥100x10^9/l were detected in 13 patients (17,3%) (100-408x10^9/l, med-127x10^9/l). M/F - 6/7. Variants of AML by FAB-classification: M0-2 patients, M1-M2 – 3 patients, M4 – 6 patients and M5 - 2 patients. Age 17-56 (med-38). Two patients had favorable-risk cytogenetics, 11 patients – intermediate-risk cytogenetics. Median of lactate dehydrogenase level was 1477 μ/l (720-6653 μ/l).
Results: In 11/13 patients (84,6%) with initial WBC count ≥100x10^9/l hepatosplenomegaly and generalized lymphadenopathy were found, in 7 /13 (53.8%) - gingival hyperplasia, in 3/13 (23%) - neuroleukemia, 1/13 (7,6%) – had specific skin lesions. All patients had infectious complications at the time of diagnosis of AML. Evidence of leukostasis had more than half of patients: respiratory distress syndrome in 5/13 patients (38,4%), neurological symptoms (headache, blurred consciousness) - in 6/13 patients (46,1%), DIC - in 6/13 patients (46,1%), including 1 - intracranial hemorrhage. Cytoreductive therapy with 1-7 days (med-2 days) hydroxyurea (10 mg/kg/day) was administered to all patients. 1-2 (med–2) LF received 8/13 patients. 1-4 (med-2). PF were performed to all patients before the introduction of Daunorubicin (during hydroxyurea-therapy and the 1st days of cytarabine-therapy). The median of WBC at the 1st day of the induction was 61x10^9/l (29-124x10^9/l). Daunorubicin was administered in 11 patients on 5-7 days, in 1 patient on 4-6 days and in 1 patient on 3-5 days. Massive cytolysis with the development of multiple organ failure were not observed. Only 5/13 patients (38,4%) showed transient signs of volemic overload which was resolved during diuretic therapy and plasmapheresis. Complete remission (CR) was achieved in 8/13 patients (61,5%), a primary refractory (after 1st course of «7+3») was registered in 38,4% (5/13) pts. Early mortality was 0%. Alive 10/13 patients (77,0%) with median follow-up 20 months (4-49 months), CR-duration - 19 months (2-48 months). Allogeneic hematopoietiec stem cell transplantation, as a postremission strategy, was performed in 6/13 patients (46%).
Summary and Conclusions: Our tactic in the induction therapy of AML-patients with HL prevents the development of severe complications such as respiratory distress syndrome, neurological disorders, disseminated

intravascular coagulopathy, that resulted in 0% early mortality without the impairment of induction therapy's results.

PB1461

INTERNAL TANDEM DUPLICATION (ITD) MUTATIONS OF THE FLT3 RECEPTOR AND CXCR4 EXPRESSION IN DE NOVO ADULT ACUTE MYELOID LEUKEMIAS (AML)

MR Villa[1,*] P Della Cioppa[1], R Cuccurullo[1], M Esposito[1], S Improta[1], L Mastrullo[1]
[1]UOC Ematologia PO San Gennaro ASL Napoli1 Centro, Naples, Italy

Background: Internal tandem duplication (ITD) mutations of the FLT3 receptor are associated with a high incidence of relapse in acute myeloid leukemia (AML). It is also known that the complete immunophenotypic characterization contributes to define the prognosis of de novo adult AML. Stromal cell-derived factor-1 (SDF-1) is a homeostatic chemokine that is constitutively secreted by marrow stromal cells. SDF-1 signals through CXCR4, which plays an important role in hematopoiesis, development and organization of the immune system. Prognostic impact of CXCR4 expression levels on the neoplastic cells has been demonstrated in breast cancer, renal cell cancer and AML.
Aims: We investigated the expression of the chemokine receptor CXCR4 on bone marrow blast cells in a group of adult de novo AML with FLT3-ITD.
Methods: We have observed 55 young adult de novo AML patients (median age: 44 years, r: 22-62) in the last 5 years, who presented FLT3-ITD-positive AML blasts in bone marrow blood. On the basis of FAB classification the patients were considered LMA-M5 (22 pts.), LMA-M2 (12 pts.), LMA-M4 (11 pts.), LMA-M1 (7 pts.) and LMA-M0 (3 pt.). 15 patients showed complex chromosomal anomalies; 23 patients presented hyperleukocytosis (WBC> 40x10(e)9/L). The clinical outcome was that one of a "high risk" AML; at the present only two patients are still alive in CR (+60 months and +66 months).
Results: We found at the diagnosis, in all cases, an high CXCR4 expression on leukemic blasts, as defined by CXCR4 mean fluorescence intensity ratio thresholds of more than 5.
Summary and Conclusions: Several studies have shown the prognostic significance of the expression of differentiation myeloid markers at the diagnosis of adult de novo AML. However, specific immunophenotype expression patterns associated with internal tandem duplication (ITD) mutations of the FLT3 receptor are still unknown. Further studies are warranted to confirm the correlation between FLT3-ITD and "CXCR4 over-expression" immunophenotypic pattern.

PB1462

INFUSION OF HLA-MISMATCHED PERIPHERAL BLOOD STEM CELLS DURING TREATMENT AML IN ELDERLY PATIENTS

Z Šustková[1,*] L Semerad[1], O Horky[1], D Dvorakova[1], Z Racil[1], J Mayer[1]
[1]Department of Internal Medicine, Hematology and Oncology, University Hospital Brno, Brno, Czech Republic

Background: The treatment of the elderly patients with AML still remains unsatisfactory. The reasons for the poor prognosis in elderly patients are the unfavorable biology of AML, incidence of relevant comorbidities and increased risk of chemotherapy-related mortality. In 2011 Mei Guo *et al.* published a study showing optimistic outcomes in treatment of the elderly AML patients with chemotherapy followed by infusion of HLA-mismatched peripheral blood stem cells. However, other studies confirming these results are lacking.
Aims: To prove efficacy, feasibility and safety of the treatment published in the study by Mei Guo *et al.*. The preliminary results are presented below.
Methods: Only the patients with de novo and secondary AML aged 60-70 were eligible for the study. Remission induction chemotherapy consisted of Ara-C 100mg/m2 daily for 7 days and daunorubicin 90 or 45mg/m2 daily for 3 days followed by the infusion of G-CSF-mobilized HLA-mismatched donor peripheral-blood stem cells 24 hours after the end of the chemotherapy. Bone marrow assessment was performed at day 15 and after hematological recovery. Patients with CR received 2 consolidations with Ara-C 1g/m2 given every 12 hours on days 1, 3 and 5 followed by the infusion of HLA-mismatched peripheral-blood stem cells 24 hours after the end of the chemotherapy. The donors of 7/8 patients were HLA haploidentical children, in case of the eighth patient, the donor was HLA haploidentical sibling. Donor microchimerism was detected in peripheral leucocytes using a real-time quantitative PCR protocol and was measured 7, 14 and 21 days after the infusion of HLA-mismatched peripheral-blood stem cells.
Results: Between 1/2013-12/2013 eight patients with median age of 65 years (60-70) were treated according to this protocol. The median follow up was 6.8 months. After induction 3/8 patients achieved CR, the other 5/8 did not and were excluded from the study. All 3 patients who achieved CR received both cycles of consolidation chemotherapy. The OS at 6 months and EFS at 6 months were 37% and 37% respectively. Two of three patients with treatment response relapsed during the first year after achieving CR. Thus only one patient is still in long term CR. All patients presented with hematological toxicity gr. 3 or more. Non-hematological toxicities gr. 3 and higher were: febrile neutropenia – 7/8, supraventricular arrhythmia – 2/8, 1/8 patient developed anti HLA antibodies, with refractoriness to platelet transfusion. Only 2 of 8 patients presented after induction with donor microchimerism at day 7 and 0/8 at day 14 and 21. Post-consolidation measurements revealed only autologous recovery in all of the three patients.
Summary and Conclusions: Our (even preliminary) results did not prove the efficacy of previously published approach, while except one, all patients did not responded or early relapsed.

PB1463

THE PROGNOSTIC VALUE OF ADENOSINE TRIPHOSPHATE ATP-BINDING CASSETTE (ABCB5) AND MULTIDRUG RESISTANCE (MDR1) GENES` EXPRESSION IN ACUTE LEUKEMIAS

H Farawela[1], M Khorshied[1], H Zawam[2], H Kassem[3], ,*N Kassem[3]
[1]Clinical pathology, Kasr Al-Aini School of Medicine, [2]Clinical oncology, [3]Clinical pathology, Kasr Al Ainy Center of Clinical Oncology and Radiation, Faculty of Medicine, Cairo University, Cairo, Egypt

Background: The goal of leukemia lines of treatment is to eradicate the leukemic clone and thus reestablish normal hematopoiesis. The resistance of human tumor to multiple chemotherapeutic drugs has been recognized as a major reason for the failure of cancer therapy and is associated with so-called *multidrug resistance (MDR)*.
Aims: The present work aimed at detecting the expression of the MDR1 and ABCB5 genes in acute leukemia patients and correlate with disease outcome.
Methods: To achieve this aim, quantitative assessment of MDR1 & ABCB5 genes expression was performed using quantitative real time polymerase chain reaction (qPCR) for 90 acute leukemia patients and 20 healthy volunteers.
Results: MDR1 gene expression was significantly higher in AML cases compared to healty volunteers (p value = 0.034). Complete remission was more prominent among patients with {MDR1 (low expression), ABCB5 (low expression), NPM1 mut.A (pos.)} (p value =0.003). In ALL, MDR1 gene expression was significantly higher in patients with resistant disease (p value = 0.001). ABCB5 gene expression level was significantly higher in ALL patients compared to the healthy volunteers (p value = 0.04) and in relapsed cases compared to de novo cases (p value = 0.027).
Summary and Conclusions: The results obtained by the current study concerning MDR1 and ABCB5 gene expression in acute leukemia patients provide additional evidence of the role played by these genes as influencing factors on the multidrug resistance status of acute leukemia cells to chemotherapy and hence clinical outcome.

PB1464

FLUCONAZOLE PROPHYLAXIS FOLLOWING INDUCTION CHEMO-THERAPY IN PATIENTS WITH ACUTE MYELOID LEUKEMIA: PATTERN OF FUNGAL INFECTIONS

RS Mohamed[1,*] HM Zoam [1]
[1]Department of Clinical Oncology, Faculty of Medicine,Cairo University, Cairo, Egypt

Background: Intensive chemotherapy may cause sever and prolonged neutropenia,which may cause potentially fatal fungal infection.Fluconazole is an effective agent for antifungal prophylaxis because of its activity against many candida species,long half life,tolerability and minimal side effects.The result of clinical trials suugest that fluconazole is superior to placebo in preventing fungal infection in neutropenic patients;but its efficacy against systemic fungal infection is not clearly defined.This retrospective review examined the pattern of fungal infections with the use of fluconazole in a dose of 400mg daily as antifungal prophylaxis in patients with acute myeloid leukemia following induction chemotherapy.
Aims: The primary end point was the ocurrance of neutropenic fever and the secondary end points were the site of fungal infection, the rate of development of peumonia and resistant fungal infection.
Methods: Patients (with age >18 years <60 years) who completed induction chemotherapy with AML protocol (between the peroid of Jan 2010 and Jan 2014) were eligible for the study if they recieved antifungal prophylaxis at least 1 day post chemotherapy.Patients were stratified based on antifungal prophylaxis *versus* no prophylaxis and all patients recieved antimicrobial prophylaxis. The patients were excluded from this study if they developed fever during induction chemotherapy or presented by fever.Fever was defined as elevation of oral temperature above 38.3 C or greater once or temperature above 38.0 C over one hour or more than one hour.Neutropenia was defined as ANC< 500/mm^2.The odds ratio with 95% confidence interval was calculated for prolonged neutropenia ,septic shock,fungemia and mortality rate.
Results: See Table 1.

Table 1.

Summary and Conclusions: From this retrospective review,we concluded that fluconazole as prophylaxis in neutropenic patients was effective and help to decrease the rate of superficial fungal infection,invasive tissue infection and with a trend toward reduction in the rate of pneumonia but not reaching a satistical significance.

PB1465

HETEROGENEITY OF ACUTE MYELOID LEUKEMIA WITH TRANSLOCATION T(8;21)(Q22;Q22)

SV Gritsaev[1,*] IS Martinkevitch[2], IS Zjuzgin [3], EV Karjagina[4], LS Martinenko[2], EV Petrova[2], NJ Tsibakova[2], MP Ivanova[2], II Kostroma[1], KM Abdulkadyrov[1]
[1]Hematological clinic, [2]Molecular genetic laboratory, Russian Institute of Hematology and Blood Transfusion, [3]Hematological department, Leningrad's Regional hospital, [4]Hematological department, City's hospital №15, St.Petersburg, Russian Federation

Background: In spite of good prognosis there are some of the patients with acute myeloid leukemia (AML) and with favorable karyotype who relapsed after a short period of complete remission (CR) or have got resistant variants. These patients as the patients with unfavorable karyotype are potential candidates to allogeneic stem cell transplantation (AlloSCT). For prolongation of overall survival (OS) it is necessarily to stratify the patients with favorable karyotype on groups with different prognosis and select the patients to AlloSCT during diagnosis or early stages of the treatment.
Aims: The aim of this retrospective study was to characterize hematological and clinical variability of AML with t(8;21) and select the signs associated with aggressive history of the disease.
Methods: The data of investigation (44 patients) and treatment (36 patients) were analyzed. Standard karyotyping and PCR methods for studying mutational status of *FLT3, NPM1, NRAS* or *c-Kit* genes were used.
Results: The median age of patients was (11-70). According to FAB classification there were M2 (82%), M1 and M4 morphological variants. One patient was diagnosed with therapy related AML. Additional chromosomal aberrations were found in 24 patients. One of sex chromosomes' loss or damage of chromosome 9 was the most frequent additional aberrations: 34.1% and 16.6%, accordingly. Complex and monosomal karyotype were determined in 6.8% and 9.1%, accordingly. Additional chromosomal aberrations were not correlated with the patients' age. Gene mutations were rare findings. The second case of c-Kit mutation was determined during AML relapse and was associated with the appearance of plural chromosomal aberrations. Three patients died after standard induction chemotherapy (IC). Complete remission (CR) was registered in 23 patients after the first course of IC, in 8 after the second IC and in 1 after the third IC. And that makes the CR rate is 96.9% (32/33 patients). Relapse was diagnosed in 8 (25.0%) patients through 2-18 months period after CR registration. These patients were characterized with the first IC course ineffectiveness (5 patients), 9 chromosome aberration (3 patients), absence of consolidation with high dose cytarabine (2 patients) or *c-Kit* mutation (2 patients). The durability of follow-up period was 5-245 months. The median OS of 32 patients with CR was not reached and the rate of 5-years OS was 57.8%. The median OS of patients with early relapse was 10 months. OS of patients with or without additional cytogenetic aberration was not significant different. OS of patients with additional chromosome 9 aberrations was significant worse: 11.5 months *versus* not reached in patients without these aberrations; p=0.003.
Summary and Conclusions: AML with t(8;21) is a heterogeneous group of patients with different age, morphological nature of blasts, variants (de novo or therapy related) and/or molecular aberrations. Patients with the ineffectiveness of the first CI course or additional chromosome 9 aberrations are the potential candidates to AlloSCT.

PB1466

PHARMACODYNAMICS OF CYTARABINE-INDUCED LEUKOPENIA: A RETROSPECTIVE COHORT STUDY

D Shepshelovich[1,*] Y Edel[1], H Goldvaser[2], O Wollach[3], P Raanani[3]
[1]Medicine A, [2]Oncology, [3]Hematology, Beilinson hospital, Rabin medical center, Petah Tikva, Israel

Background: Cytarabine is a pyrimidine analogue used to treat a variety of hematological malignancies, most notably acute myeloid leukemia (AML). Several databases such as Micromedex, BC cancer and Pfizers product monograph cite a biphasic pattern of white blood cells (WBC) count decline following cytarabine administration. This pattern was described after the administration of low and intermediate doses of cytarabine for patients with a variety of malignancies, most of them non-hematological, with a nadir on days 7-9, a brief recovery and a second nadir between days 15-24 following therapy. The pathophysiology of this phenomenon is unknown.
Aims: Our purpose was to establish whether this biphasic pattern is reproducible in AML patients treated with cytarabine using more intensive modern protocols.
Methods: We conducted a retrospective cohort study. Our study included 56 consecutive patients with AML in complete remission who received 89 cycles of intermediate or high dose cytarabine. Daily total white blood cells and neutrophils were collected during the first 15 days after the initiation of cytarabine administration and the courses were analyzed. We performed further analysis to assess possible associations of changes in blood counts with cytarabine protocols (IDAC *vs*. HiDAC) and possible confounding factors such as steroid or granulocyte colony stimulating factor (G-CSF) treatment, renal failure or active infections.
Results: Analysis of blood counts failed to reveal a biphasic pattern of descent for WBC, neutrophils, monocytes or lymphocytes, as previously described. High dose cytarabine (HiDAC) was associated with a significantly faster descent of WBC compared to intermediate dose cytarabine (IDAC). No effect of confounders was detected.
Summary and Conclusions: We conclude that in our cohort we could not verify the existence of a biphasic pattern for the decline of WBC post cytarabine therapy and that WBC decline post cytarabine was steeper for patients receiving HIDAC than for those receiving IDAC.

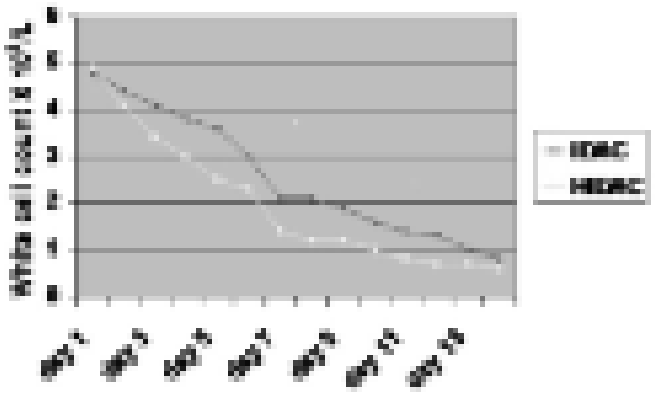

Figure 1.

PB1467

THERAPEUTIC MANAGEMENT OF CHILDHOOD AML AT MPCTRC: A SINGLE CENTER STUDY

A Mehrvar[1,2], AA Hedayati-Asl[2], M Faranoush[2,3], E Abadi[2,4], N Mehrvar[2], M Tashvighi[2,5*]
[1]Army Medical University, [2]Mahak Pediatric Cancer Treatment and Research, [3]Iran University of Medical Sciences, [4]School of Electrical and Computer Engineering, University of Tehran, Tehran, [5]Islamic Azad University, Qom Branch, Qom, Iran

Background: Mahak's Pediatric Cancer Treatment and Research Center (MPCTRC) has been started from April 2007. During these years 1300 new cases have been both diagnosed and treated at this charity center. The most prevalent diagnosis in this center is acute leukemia (n=338, 27.7%) that imply 68 (20%) childhood Acute Myeloid Leukemia (AML). Immunophenotyping by flow-cytometry pattern is the powerful method for recognizing type of AML in considered patients. During the diagnosis, screening the molecular genetic abnormalities can be a good marker for prognosis determination.
Aims: The main purpose of this study is to evaluate some basic parameters in

patients with AML who referred to MPCTRC for diagnosis and treatment in Tehran (Capital City of Iran).
Methods: This was a simple sampling study which consisted children less than 15 years old with AML who have been referred to MPCTRC since April 2007 to April 2013. There was a unique checklist for enrolled patients that implied epidemiological information (age, sex, molecular genetic abnormalities, CD markers and patient's last status) and filled for all of patients. Treatment for patients with AML at MPCTRC is according to BFM protocol that for type of M3 ATRA will be added too. Data analyzed by SPSS software version 22. Chi-square test (P-value <0.05) have been used for variables.
Results: According to inclusion criteria of this study, there was 52 cases with AML that consisted of 33 (63.5%) boys. The mean age of patients was 7.09±0.64 years (range: 6months-15years old). There was not any significant difference in the mean age of patients between boys and girls. The flow-cytometry results showed that type of AML was as: M1 (n=7, 13.4%); M2 (n=9, 17.3%); M3 (n=12, 23.1%); M4 (n=10, 19.2%); M5 (n=5, 9.6%); M6 (n=4, 7.7%); and M7 (n=5, 9.6%). Cytogenetic and molecular abnormalities was shown in 19 patients (36.5%). These abnormalities was as 12 (63.15%) translocations (t(15;17):n=6, 50% ; t(8;21):n=3, 25%; t(10;11), t(12;18) and t(14;2):n=1, (8.3%), 5 (26.31%) deletions and 2 (10.5%) trisomies. Chi-square test showed the significant relation (P-value=0.04) between genetic abnormalities and last status of the patients. Analysis revealed that 16 patients (30.76%) had relapse during their treatment that out of them, 8 cases (50%) died. 11 (68%) patients with early relapse had normal molecular genetic abnormality and the most common abnormality in the relapse patients was deletion (n=3, 18%) and all the early relapse patients with deletions has been died. Patients with subtype of M3 and t(15;17) had no early relapse. Last call of patients determined that out of enrolled patients, there were 17 (32.7%) cases with end of treatment, 8 (15.4%) cases during treatment, 17 (32.7%) cases died and 10 (19.2%) cases were loss of follow up.
Summary and Conclusions: AML is a rare malignancy in childhood leukemia in proportion to ALL. To have an appropriate criteria for the prognosis of these patients, survival rate analysis is also demanded but according to 7-years history of our center, we can have 5-years of survival rate 3 years later. Genetic mutations and flow-cytometry can be also a good marker to evaluate the risk group of childhood AML and treatment protocol selection.

PB1468

CYTOGENETIC AND MOLECULAR GENETIC ABNORMALITIES EVALUATION IN PEDIATRIC ACUTE MYELOBLASTIC LEUKEMIA

A Mehrvar[1], M Tashvighi[1,*] AA Hedayati Asl[2], M Faranoush[2], J Sabery Nejad[3], A Ramyar[3], L Kouchakzadeh[3], MS Rahiminejad[3]
[1]MAHAK's Pediatric Cancer Treatment and Research Center, [2]MAHAK's Pediatric Cancer Treatment and Research Center, [3]children center hospital, tehran, Iran

Background: Genetic abberations underlying Acute Myeloblastic Leukemia (AML), is the importance landmark for better managing the pathogenesis of disease. The classical way for investigation of chromosomal abberations is conventional karyotyping. For considering different translocations, the Real-Time Polymerase Chain Reaction will be used. Two main referral centers for childhood malignancies in Tehran (capital city of Iran) are MAHAK Pediatric Cancer Treatment and Research Center (MPCTRC) and Children Center Hospital. Children less than 15 years old with all kind of childhood malignancies will admitted in these two centers for diagnosis and therapy. Patients from all parts of Iran can refer there.
Aims: The main goal of this study was to evaluate genetical abnormalities in patients with AML for better managing this disease in future.
Methods: Enrolled Patients have been referred from all parts of Iran to two referral childhood malignancy centers in Tehran, Iran (MPCTRC, Children Center Hospital) during April 2007 to April 2013. There was a unique check list for all patients than implied basic data about sex, age, date of dead,,,. Bone marrow aspirates of 104 pediatric AML cases were analyzed by G-banding technique, karyotyping and Real Time-PCR for translocations. Finally data analysed by SPSS version 19.
Results: There were 57 boys (54.81%) out of 104 enrolled patients. The mean age of patients were 6.9±0.43 years. Immunophenotyping results showed the M4 (n=20, 19.2%) and non-M3 (n=19, 18.3%) groups as the majority phenotypes respectively. Twenty out of 104 patients (19.2%) had genetic abnormalities; t(15;17) (n=6, 30%), inversion (n=5, 25%), mosaicism with deletion (n=2, 10%), t(8;21), t(6;11), hyperdiploidy, mosaicism with translocation, mosaicism with monosomy, trisomy 8 and gene deletion (n=1, 5%). Fourthy-four patients died (42.3%) during this study. The three-years survival rate was 88%.
Summary and Conclusions: Analysis and literature reviews revealed that t(15;17) was the most prevalence abnormalities. Authors suggestion is comprehensive studies with larger patients series to confirm these evaluation. Focusing on cytogenetic abnormalities will consider prognostic significances of patients with AML that can affect treatment planning.

PB1469

PROGNOSTIC FACTORS AND TREATMENT OUTCOME OF CHILDREN WITH NEWLY DIAGNOSED ACUTE MYELOID LEUKEMIA.

K Zahra[1,*] N Ben Sayed[1], Y Ben Youssef[1], M Zaier[1], B Achour[1], H Rgaieg[1], A Khelif[1]
[1]Hematology, Hopital Farhat Hached, SOUSSE, Tunisia

Background: Acute myeloid leukemia (AML) is a heterogeneous disease that accounts for approximately 20% of acute leukemias in children and adolescents. Despite the lack of targeted therapy for most subtypes and a dearth of new agents, survival rates have reached approximately 60% for children treated on clinical trials in developed countries. Improvements on the clinical and biological stratification of AML cases allow provide background for risk-adapted treatment strategies, particularly after complete remission (CR) achievement.
Aims: The aim of this study is to evaluate the response and survival of pediatric patients with AML and factors impacting on these.
Methods: This retrospective analysis included 36 patients with newly diagnosed AML who were treated by the French protocol ELAM02 between 2002 and 2011. Clinical-biological characteristics at presentation were registered. Association between remission after one course of induction, relapse and factors at presentation such as age (< or≥ 10 years), sex, the white blood cell count (WBC) (< or ≥ 50 x10^9/L), the hemoglobin count (Hb) (< or ≥8g/dl), the platelet count (< or ≥ 50 x10^9/L), the cytologic classification FAB, the prognostic cytogenetic groups (favorable, intermediate and high risk) were evaluated by X^2 test. Event free survival (EFS) and overall survival (OS) analysis was carried out with the Kaplan-Meier method. The log-rank test and Cox regression were applied for univariate and multivariate analysis, respectively. A p value below 0,05 was considered as being statistically significant.

Table 1	Percentage
Median age (range)	9 years(1-16)
Male/female	50%/50%
Hb (g/dl):	
<8	47%
≥8	53%
WBC count(1^0 /l)	
<50	86%
≥ 50	14%
Platelet count (x10^9/l)	
<50	55.5%
≥ 50	44.5%
ClassificationFAB:	
AML0	5.5%
AML1	28 %
AML2	39 %
AML4	11%
AML5	5.5%
AML6	8%
AML7	3%
Prognostic cytogenetic groups:	
Favorable	30.5%
Intermediate	44.5%
High risk	25%

Results: Patients´ characteristics at presentation are shown in Table 1. The CR rate after one course of induction therapy was 58% (21 patients) and 80.5% after two courses (29 patients). The rate of early death was 3% and 15% after one course and two courses of induction therapy respectively. Three factors associated to CR after one course: sex (p=0.027), WBC (p= 0.02) and platelet count (p=0.046). The hematopoietic stem cell transplantation was done only in 4 patients in first remission among the 19 patients in transplant indication. The relapse rate was 55%. Two factors associated to relapse: FAB cytologic classification (p=0.04) and cytogenetic groups (p=0.03). The OS and the EFS at 24 months were 54% and 40.6%, respectively. A statistically significant correlation between the cytogenetic groups and EFS was observed (p 0.03).
Summary and Conclusions: Our results are lower than the literature. AML is a biologically and pronostically heterogeneous disease subsidiary to be approached with risk adapted strategies. Currently it is feasible to identify a substantial proportion of patients that may be cured with high-dose cytarabine consolidation or ASCT. In contrast, there are patients with adverse genetic features that need an allogeneic procedure, investigational agents or both.

PB1470

TRANSFORMATION OF CML TO ACUTE LEUKEMIA,OUR EXPERIENCE FROM A TERTIARY CARE CANCER HOSPITAL FROM PAKISTAN

S Sarwar[1,*] AH Siddiqui[1]
[1]Medical Oncology, Shaukat Khanum Memorial Cancer Hospital and Research Centre, Lahore, Pakistan

Background: Chronic myelogenous leukemia (CML) is a hematopoietic stem cell disease with a relatively stable clinical course and good prognosis after treatment. Its conversion into acute leukemia heralds an accelerated clinical course that is less responsive to treatment and has much higher mortality.
Aims: To retrospectively assess the proportion of CML patients who underwent progression to acute leukemia at a tertiary-care specialist cancer center in Lahore, Pakistan and to describe the clinical features and mortality associated with conversion.
Methods: Data was analyzed by looking at frequencies and applying t-test to continuous data and chi-square test to categorical data. Factors associated with mortality were assessed using bivariate and multivariate logistic regression analyses.
Results: A total of 240 patients were accepted for treatment between Jan 1, 2012 and December 31, 2013. Out of these patients 21 (76% males; Mean age: 37.5 years; Range: 24 to 58 years; 20 patients positive for t (9;22)(q34;q11) translocation) progressed to acute leukemia during this period. The mean blood cell count at the time of admission was 200.5 (range: 33 to 526). 76% patients received imatinib as initial treatment. The average duration between diagnosis and transformation to acute leukemia was 195 days (range: 24 to 324 days). After transformation, 12 patients were treated with chemotherapy HCVAD, 6 received DA 3+10 protocols, and 1 was offered DA 3+7 chemotherapy. 2 patients did not receive any treatment. During the study period, 11 patients died (average survival after transformation: 40.6 days; range: 2 to 172 days). Mortality was not significantly associated with the duration between diagnosis and transformation to AML or the type of treatment received.
Summary and Conclusions: Nine percent of patients diagnosed with CML progressed to acute leukemia over a period of two years. Among patients who transform to acute leukemia, the mortality is high and average life expectancy after transformation is between 1 and 2 months.

PB1471

TWENTY-FOUR KOREAN MLL LEUKEMIAS AND THEIR PARTNER GENES: A COMPARATIVE STUDY

J Yang[1,*] C Meyer[2], R Marschalek[2], TS Park[1]
[1]Department of Laboratory Medicine, Kyung Hee University Hospital, Seoul, Korea, Republic Of, [2]Institute of Pharmaceutical Biology, ZAFES, Diagnostic Center of Acute Leukemia, Goethe- University of Frankfurt, Frankfurt, Germany

Background: Rearrangements involving the *MLL* gene located at 11q23, is a dismal prognostic factor found in about 5-10% of acute leukemia. Numerous *MLL* partner genes are identified, over hundred at chromosome levels and over 70 at gene levels. While the main focus lies on the frequent fusion partner genes of their mechanisms in leukemogenesis and their potential as a molecular therapeutic target, ethnic differences in the frequency of fusion partner genes have not been studied well.
Aims: In order to gain further insights to the ethnic difference of distribution of *MLL* fusion partner genes, here we report the frequency and distribution of *MLL* partner genes from Korean patients, and compare the differences with two other groups of different ethnicity.
Methods: The *MLL* partner genes from 24 Korean *MLL* leukemia patients were analysed using long distance inverse-polymerase chain reaction (LDI-PCR) according to methods previously described (Leukemia. 2009;23:1490-9). Bone marrow specimens of all patients were analyzed by conventional karyotyping and fluorescence *in situ* hybridization (FISH). using the *MLL* LSI dual color, break-apart probes. The results were compared with two other previously published European studies. Statistical analyses were made using statistical software SPSS (SPSS Inc., Chicago, IL, USA) determining statistical significance at $P < 0.05$.
Results: Frequent partner genes of the *MLL* rearrangement detected from Korean population were *AF9* (5 cases), *ENL* (5 cases), *ELL* (3 cases) and *AF4* (3 cases). Rare *MLL* partner genes were also found, which included *CASP8AP2* (novel type), *AF17*, *SEPT9, TET1, MLLT11*, *AF10, ACTN4* and *CASC5* (total of 8 cases). It was also interesting to find three-way and four-way translocations of t(2;19;11) and t(4;11;22;10). Comparison with two other studies is summarized in table 1. While the distribution of individual partner genes were different between groups, it was notable that the six translocation partner genes of *AF4, AF9, ENL* and *ELL* were the most frequently detected partner genes in all three groups, accounting for 56.6%, 66.6% and 66.6% of all cases, respectively. Regarding the infrequent translocation partner genes, the only common genes were the *MLLT11* gene from all three groups and *SEPT9* gene detected from Korean and Portuguese groups. Other infrequent partner genes were only detected once or twice from each study groups.
Summary and Conclusions: Between the three patient groups including Korean *MLL* leukemia patient group, distribution of the frequent translocation partner genes were rather similar. The ethnic difference as a cause of the difference in distribution of infrequent partner genes has not been validated, and further studies in larger scale have to be conducted to determine the presence of an ethnical difference. It is also another limitation of this study, not being able to analyze adult and pediatric patients separately, due to small number of patients included in each study. Currently, state-of-the-art molecular techniques such as the next-generation sequencing (NGS) are being actively utilized in the field of leukemia research. Regarding *MLL* leukemia however, LDI-PCR has been the most cost-effective and precise diagnostic method employed over the past 10 years for identifying partner genes and detecting minimal residual diseases.Continuous investigation of *MLL* leukemia at its molecular level will not only benefit in determining treatment response and prediction of prognosis, but also opening the possibility of molecular targeted therapy of *MLL* leukemia, in which development of tyrosine kinase inhibitors for chronic myelogenous leukemia (CML) would be a good example.

AZACITIDINE IN THE TREATMENT OF OLDER PATIENTS AFFECTED BY ACUTE MYELOID LEUKEMIA: A REPORT BY THE RETE EMATOLOGICA PUGLIESE (REP)

M Delia[1,*] P Carluccio[1], C Buquicchio[2], C Vergine[3], G Greco[4], B Amurri[5], E Rinaldi[6], L Melillo[7], A Melpignano[6], G Tarantini[2], A Guarini[8], S Capalbo[9], N Cascavilla[7], P Mazza[5], V Pavone[4], N Di Renzo[3], G Specchia[1]
[1]Hematology - University of Bari, Bari, [2]Hematology - Barletta, Barletta, [3]Hematology - Ospedale "Vito Fazzi" - Lecce, [4]Hematology - Ospedale "Cardinale Panico" - Tricase, Lecce, [5]Hematology - Ospedale "San Giuseppe Moscati" - Taranto, Taranto, [6]Hematology - Ospedale "Perrino" - Brindisi, Brindisi, [7]Hematology - Ospedale "Casa Sollievo della Sofferenza" - San Giovanni Rotondo, Foggia, [8]Hematology - Istituto Tumori Giovanni Paolo II - Bari, Bari, [9]Hematology - Ospedali Riuniti - Foggia, Foggia, Italy

Background: The optimal treatment of older patients (>60 years) with Acute Myeloid Leukemia (AML) remains challenging in daily clinical practice; a choice has to be made between intensive chemotherapy and best supportive care. To guide physicians in their decisions, several prognostic factors have been identified and risk scores have been developed. Recently, the DNA methyltransferase inhibitor azacitidine has become available for MDS and AML patients with up to 30% bone marrow blasts. However, limited data are available on the setting of older unselected AML patients treated with azacitidine, regardless of their bone marrow blast count.
Aims: To study the impact of azacitidine treatment in older patients with AML ineligible for intensive chemotherapy, we retrospectively analysed the outcome of 110 newly diagnosed AML older patients in 9 Institutions from the Apulia Region (REP).
Methods: The study included 110 AML patients (59 males and 51 females, median age 75 years, range 61 to 90 yrs); FAB criteria subtypes were: 27 M0, 32 M1, 26 M2, 10 M4, 12 M5, 3 M6. M3 subtypes were excluded from the analysis. Cytogenetic evaluation was performed in 78 cases (71%): 44 (56%) patients were intermediate risk, 34 (44%) adverse, while no patients had a favorable prognosis. Median values of white blood cells and hemoglobin were 2.6x10e3/mmc (r: 0.6 – 72,4), 8.5 gr/dl (r: 5.4 – 12.9), respectively. The median blast count in bone marrow and peripheral blood was 33% (r 20 – 90) and 10% (r 0 – 80), respectively.
Results: After a median of 9 treatment cycles (r: 1 – 36), median OS was 18 months. Azacitidine treatment failure was documented in 46 patients (42%), while the overall response rate after a median time of 4 months treatment was 58% (36% (CR and Cri), 22% PR). Responder patients showed a better median overall survival than non responders (23 *vs* 6 months, p<.001, figure 1), while neither primary treatment failure nor bone marrow blast count (higher than

30%) were correlated with a worse overall survival (29 *vs* 22 months, p= .99; 16 *vs* 19 months, p=.96), respectively.
Summary and Conclusions: The results of our retrospective analysis seem to confirm the benefit of treatment with azacitidine for older AML patients in terms of OS, regardless of the bone marrow blast count, while primary treatment failure should not affect the continuation of treatment.

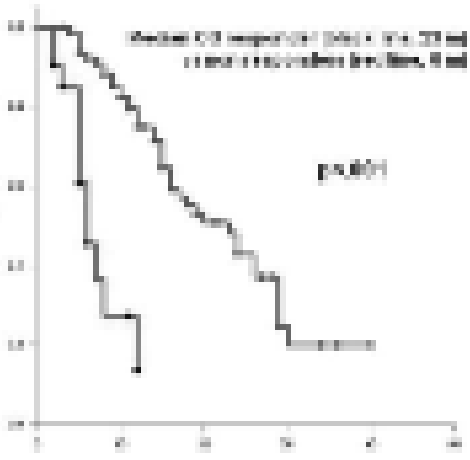

Figure 1.

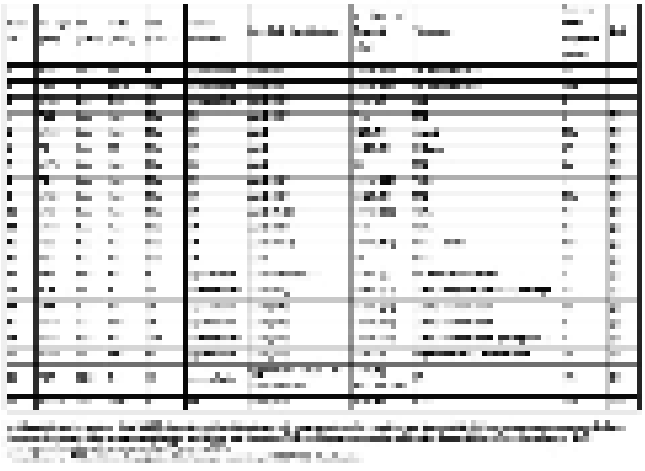
PB1473

ACUTE MYELOID LEUKEMIA WITH SOLE TRISOMY 6: CASE REPORTS AND LITERATURE REVIEW

S Yu[1,*] MJ Kwon[1], ST Lee[2], HY Woo[1], H Park[1], SH Kim[2]
[1]Laboratory Medicine, Kangbuk Samsung Hospital, [2]Laboratory Medicine and Genetics, Samsung Medical Center, Seoul, Korea, Republic of Korea

Background: Autosomal trisomies as sole cytogenetic changes have been described in several hematologic malignancies, but associations between specific morphologies with individual structural cytogenetic abnormalities have been reported less frequently. There have been several reports of trisomy 6 as the sole karyotypic abnormality in patients diagnosed with MDS, AML or MPN and has also been reported in association with bone marrow hypoplasia such as aplastic anemia (AA).
Aims: We describe three patients with AML, demonstrate that trisomy 6 is the sole clonal cytogenetic bone marrow abnormality, and review the literature on AML with sole trisomy 6 to establish a relationship between the clonality of AML with a single trisomy 6 abnormality.
Methods: We examined three patients who were diagnosed with AML having trisomy 6 about laboratory findings and clinical features. To identify reported cases of AML having trisomy 6 as the sole clonal aberration, we searched PubMed (http://www.ncbi.nlm.nih.gov/pubmed) with combinations of the search terms “AML” and “trisomy 6”.

Table 1. The laboratory findings and clinical features in AML with sole trisomy 6.



Results: We identified ten reports describing 18 cases of AML presenting with trisomy 6 as the sole karyotypic abnormality. Including those of the three cases we report, there were ten female and 11 male patients, including three children and one infant. The laboratory findings and clinical features are summarized in Table 1.
Summary and Conclusions: By reviewing the literature, we suggest that trisomy 6 is a nonrandom clonal cytogenetic marker of AML and may sometimes be the result of transformation from other myeloid disorders. In addition, further studies to establish the clonality of AML with sole trisomy 6 are needed.

PB1474

MORTALITY AND RELATED FACTORS IN ELDERLY PATIENTS WITH ACUTE MYELOID LEUKEMIA

M Demir[1,*] E Umit[1], S Uyanik[1], M Maden[1], B Tokuc[2], F Puyan[3], G Pamuk[1]
[1]Hematology, [2]Public Health, [3]Pathology , Trakya University, Edirne, Turkey

Background: Older patients with acute myeloid leukemia (AML) have significant comorbidities, a poorer performance status (PS), more unfavorable cytogenetic abnormalities, and a higher incidence of secondary AML than younger patients. Due to their age related unfavourable features, most of the patients are regardd as uneligible for intensive treatment.
Aims: The aim of our study is to assess the clinical and laboratory features of our patients with AML and over 65 years of age. With their Charlson performance score, cytogenetical analysis and the treatment given (intensive, hydroxyurea, low dose cytarabine, hypomethylating agent or no treatment), we aimed to evaluate survival and mortality rates compared with these variables.
Methods: Data of 125 patients with AML, over 65 years of age were recruited from our archives. Age, gender, Charlson performance scores, gven treatment and remission durations (months) were recorded. Descriptive and survival analysis were performed.

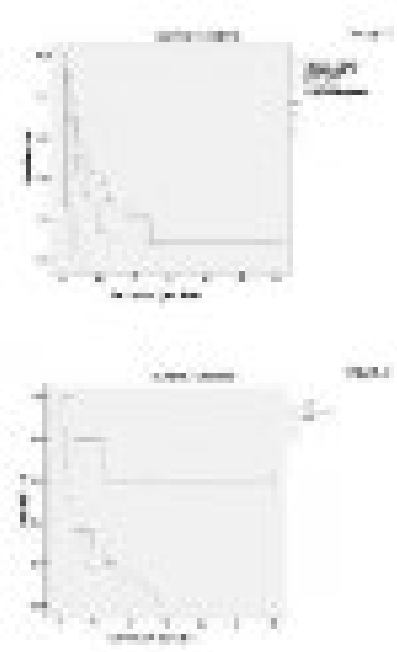


Figure 1.

Results: 50 patients were female (40%) and 75 were male (60%). Mean age 71.36 years (65-87). Charlson comorbidity scores were divided into two groups as score 5 or less (40 patients, 32%) and 6 or more(85 patients, 68%). Regarding the treatment, 45 patients received intensive treatment (36%), 22 received low dose cytarabine (ara-c) (17.6%), 38 received hydroxyurea (30.4%), 16 received hypomethylating agent (12,8%) and 4 patients did not receive any treatment (3.2%). Regarding cytogenetic profiles, 5 patients (4%) showed good, 45 patients (36%) showed intermediate and 18 patients (14.4%) showed poor cytogenetic profile. Mean survival was 7.893 months ±1.197 (95% CI 5.547 – 10.240). Survival was not related with gender or Charlson performance score but significantly related with the given treatment (Figure 11) and cytogenetic profile (Figure 2). Intensive treatment and good cytogenetic profile was observed to be related with longer survival.
Summary and Conclusions: Elder patients with AML are generally regarded as ineligible for intensive treatment because of performance status and comorbidities. More comprehensive and elaborate performance scoring systems are needed to assess these patients and to give better treatment

decisions. Intensive treatment is still related with better survival and hypomethylating agents give promising results.

PB1475

PROGNOSTIC IMPACT OF BODY MASS INDEX ON ACUTE MYELOID LEUKEMIA OUTCOME

M Virijevic[1,*] D Tomin[1,2], I Djunic[1], A Novkovic[3], A Vidovic[1,2], M Mitrovic[1], N Colovic[1,2], N Suvajdzic Vukovic[1,2]
[1]Clinic of Hematology, Clinical Center of Serbia, [2]Faculty of Medicine, University of Belgrade, [3]Clinical hospital center Zemun, Belgrade, Serbia

Background: Body mass index (BMI) has been associated with an increased incidence of various malignancies, including acute myeloid leukemia (AML). In addition, a few studies suggested that BMI might be a risk factor for outcome in AML patients.
Aims: To determine the impact of BMI at AML diagnosis on overall survival (OS), complete remission (CR) rate, early death (ED) rate disease-free survival (DFS) in patients (pts) with AML.
Methods: This single-center study involved 204 adult pts with non-promyelocytic *de novo* AML pts managed at the Clinic of Hematology during the period from 2009 to 2013. Patients were treated according to Medical Research Council (MRC) 10 protocol, with 50% reduction of the anthracycline dose for subjects aged > 60 years. According to their BMI value, the patients were categorized as: underweight (<18.5 kg/m^2), with normal weight (18.5 to<25 kg/ m^2), overweight (25 to<30 kg/ m^2) and obese (≥ 30 kg/ m^2).
Results: The mean age of the pts was 52 (19-69) years; 52% were men. Median BMI was 25.23 (range 16.10-38.8). There were 14 (6.9%) underweight pts, 79 (38.7%) with normal weight, while 68 (33.3%) were overweight and 43 (21.1%) obese. Median OS was 3 month; 6 months in pts with normal BMI, 3 months in overweight pts, 2 months in obese, and 1 month in underweight pts. The patient with normal weight showed significantly longer OS compared to underweight pts (p=0.013), overweight pts (p=0.037) and obese pts (p= 0.042). Also, normally weighted pts achieved higher CR rate compared to underweight pts (88.7% *vs* 37.5%; p= 0.023), overweight pts (88.7% *vs* 63.4%; p=0.048) and obese pts (88.7% *vs* 46.4%; p=0.036). Multivariate logistic regression analysis indicated that BMI< 18.5 kg/m^2 was the most significant factor for poor OS (p=0.004 HR1.593 95%CI: 1.162-2.185). In addition, multivariate analysis identified BMI<18.5 kg/m^2 as the most significant factor for both lower CR rate (p=0.031 HR 1.474 95%CI: 1.036-2.099) and shorter DFS (p=0.040 HR 1.445 95%CI: 1.017-2.053). Multivariate analysis identified BMI<18.5 kg/m^2 as the most significant parameter for ED (p=0.005 HR 2.617 95%CI: 1.347-5.083).
Summary and Conclusions: Our study has shown that BMI at presentation is significantly associated with clinical outcome among the non-promyelocytic AML pts.

PB1476

THE GENOMIC LANDSCAPE OF THE LEUKEMIA FROM A WOMAN PRESENTING WITH AN ATYPICAL MYELOPROLIFERATIVE DISEASE

A Hyrenius Wittsten[1,*] H Sturesson[1], M Bidgoli[2], T Jonson[2], H Lilljebjörn[1], S Scheding[3, 4], A Andersson[1]
[1]Department of Clinical Genetics, Lund University, [2]Department of Clinical Genetics, University and Regional laboratories, [3]Lund Stem Cell Center, Lund University, [4]Department of Hematology, Lund University Hospital, Lund, Sweden

Background: Recent advancements within genomics have made it possible to detect the full complement of somatic genetic lesions occurring within a cancer. We used whole exome sequencing (WES) and high-resolution single nucleotide polymorphism (SNP) arrays to characterize the leukemic sample from a 41-year old woman initially presenting with an atypical myeloproliferative disease (MPD). At diagnosis she had pronounced eosinophilia, lymphadenopathy, and a soft tissue mass in the submandibular gland. Clinical genetic diagnostics revealed a normal female karyotype, lack of *BCR-ABL1*, *FIPILI-PDGFRA* and *JAK2* mutations (V617 and exon 12). Two months after diagnosis, she developed acute myeloid leukemia (AML), received standard AML treatment and subsequently underwent allogeneic bone marrow transplantation in 1st complete remission (CR). 21 months after initial presentation, the patient relapsed with a local tumor mass in her right breast and underwent local radiation therapy. Three months after radiation therapy she is still in remission but has a small population (0.2%) of atypical monocytes in the bone marrow. Here the results of the extended genetic analysis can be used to confirm and monitor a possible bone marrow relapse, which would be helpful to make a decision on the need of systemic therapy.
Aims: To characterize the full complement of genetic lesions in a leukemic sample from a woman presenting with an atypical disease.
Methods: High resolution SNP array profiling and WES (Illumina platform) was performed on the AML sample and on cultured cells from a skin biopsy at CR (normal sample). Somatic mutations, including single nucleotide variations (SNVs) and insertion deletion mutations (indels), were identified and validation of the putative non-silent mutations and indels was performed by PCR amplification of the initial MPD, the AML and normal sample, followed by deep sequencing.
Results: The SNP array analysis of the AML sample showed a partial tandem duplication (PTD) of the *MLL* gene (*MLL*-PTD) as the only detectable imbalance. Verification of the rearrangement revealed two alternative splice variants corresponding to duplication of *MLL* exons 2-8 and of exons 5-8. Our first round of validation confirmed 11 somatic non-silent mutations (9 missense, 1 nonsense, 1 indel), including the known AML associated NRAS G13D and DNMT3A R882H. All of the validated mutations as well as the *MLL*-PTD were present at initial diagnosis. The other nine somatic mutations (SRPX2 R110H, COL19A1 F1015S, RNF123 S432F, CNTN3 R206X, POTEE R795H, BUD13 R132C, POLR3A P607S, C19orf80 R85W, and TTC39A Q524fs) are not reported in COSMIC, but mutations at other sites in these genes have previously been reported in cancer and mutations in *COL19A1* and *TTC39A* have been observed in AML.
Summary and Conclusions: Genomic characterization using high resolution SNP array profiling and whole exome sequencing of the leukemia from a woman presenting with an atypical MPD, revealed the presence of at least twelve genetic lesions including a partial tandem duplication of *MLL* and missense mutations in *NRAS* and *DNMT3A*. In AML the presence of a *MLL*-PTD or a mutation in *DNMT3A* are known poor prognostic factors. In addition, the presence of a *DNMT3A* mutation in patients with *MLL*-PTD confers an even worse prognosis. Our patient is in remission after extramedullary relapse, but her disease course together with her high-risk genetic lesions suggests a dismal prognosis and that she may benefit from alternative treatment modalities, potentially with epigenetic-targeting therapy.

PB1477

LOW FREQUENCY OF TUBERCULOSIS DISEASE IN ADULT PATIENTS WITH ACUTE LEUKEMIA

TP They They[1,*] M Lamchahab[1], S Benchekroun[1], A Quessar[1]
[1]Hematology, CHU Ibn rochd hospital, Casablanca, Morocco

Background: The major cause of mortality and morbidity in patients with acute leukemia is their predisposition to infection. During the neutropenic periods, the patient is prone to develop mainly bacterial and fungal infections; occasionally mycobacterial organisms may also cause infections. These tuberculosis infections (TB) have not been a common infection in most series.
Aims: We assess TB frequency and impact of antituberculous treatment (ATT) in the management of acute leukemia patients.
Methods: A retrospective study was conducted between May 2003 and October 2013. All patients treated for acute leukemia diagnosed on the basis of clinical features and peripheral blood film examination who developed tuberculosis on the basis of clinical features, sputum examination, and microbiologically-/ or histologically confirmed were included in our study. All patients with suspected tuberculosis in the absence of bacteriological or histological proof, or patients with good response to empiric antituberculosis treatment (ATT) started without confirmed diagnosis of tuberculosis were excluded. The medical records, microbiological, histological and radiological data of patients were reviewed. The anti-TB agents included isoniazid (H), rifampin (R), ethambutol (E) and pyrazinamide (Z) in combined form. The treatment regimens were 2 months of combined RHZE and 4 months of RH.
Results: During the study period (10 years), a total of 1,360 leukemia cases of whom 886 were acute myeloid leukemia (AML) and 474 acute lymphoid leukemia (ALL) were admitted in our unit. Then 9 patients received a confirmed diagnosis of TB. Seven patients were AML and 2 patients ALL. This corresponds to a TB frequency of 0.79% for AML and 0.42% for ALL. The median age is 30 years (with extremes ranging from 19 to 42 years). Seven were males and two were females with a male: female ratio of 1.25. The median time from diagnosis of leukemia and TB was 6 months (range 1-24). TB occurred in post-induction phase, simultaneously and before of leukemia diagnosis. TB diagnosis was made in maintenance, consolidation therapy and post-mortem. Pulmonary and extrapulmonary TB was found. Eight patients shown resolution of TB-related symptoms post ATT. Five patients achieved complete remission of leukemia. Two patients died, one in leukemia relapse and another before confirmation of TB diagnosis. One patient was included in palliative care and lost in follow up.
Summary and Conclusions: There was a low rate of TB disease in our population of patients. No delay chemotherapy or worsening of leukemia management was found with TB treatment.

PB1478

SIGNIFICANCE OF FEBRILE NEUTROPENIA RISK SCORE IN PATIENTS WITH ACUTE MYELOID LEUKEMIA

A Vidovic[1, 2, ,*]M Virijevic[2], I Djunic[2], D Tomin[1,2] N Suvajdzic Vukovic[1,2] N Colovic[1,2] M Mitrovic[2], V Arsic Arsenijevic[3], S Pavlovic[4], B Mihaljevic[1,2]
[1]School of Medicine, University of Belgrade, Serbia, [2]Clinic of Hematology, Clinical Center of Serbia, [3]Institute of Microbiology and Immunology, School of

Medicine, University of Belgrade, [4]Institute of Molecular Genetics and Genetic Engineering, Belgrade, Serbia

Background: Chemotherapy induced febrile neutropenia (FN) in patients with acute myeloid leukemia (AML) is a clinicaly important adverse event due to the impact on the course of disease and survival by causing the delay or dosage adjustment of chemotherapy. Although the myelotoxicity of the chemotherapy is the key determinant of risk for developement of the FN, it is now recognised that patient characteristics may increase this risk further.
Aims: To validate the FN mortality risk score in a population of adult AML patients undergoing intensive induction chemotherapy.
Methods: We analysed retrospectively a cohort of 118 patients (pts) with newly diagnosed AML, treated in the Clinic of Hematology during period 2011-2013. All of the pts had febrile neutropenia with absolute neutrophile count (ANC) <0,5x10^9/l after intensive induction therapy according to the …3+7" regimen. A risk score for mortality was estimated for each patient representing summary of all significant variables in a logistic regression model, including: age, sex, hemoglobin level (Hb); white blood cell count (WBC), plateled count (Plt); serum lactate dehidrogenase (LDH) level; Performance Status (PS) by Eastern Cooperative Oncology Group- Performance Status (PS); Karyotype risk group by European LeukemiaNet (ELN) recommendation; Hematopoietic Cell Transplantation Comorbidity Index (HTC-CI); duration of neutropenia; and complications (gram + /gram- sepsis, fungal infection, pneumonia, hypotension, hypoalbuminema, ARDS (acute respiratore distress sy), elevation of serum creatinine, bilirubin and transaminases level).
Results: The average age of the pts was 52 years (19-72). Female/male ratio was 68/50. Median folow up was 34 months. Favorable cytogenetic risk was found in 10 pts (8,5%); intermediate in 86 prs (73,5%) and adverse in 21 pts (17,9%). The median duration of neutropenia was 17 days (2-42). Observed complications during FN in our pts were: elevation of serum creatinine in 9 pts (7,8%); elevation of serum bilirubin level in 32 pts (27,8%); and elevated serum transaminases in 18 pts (15,7%). Furthermore, hypoalbuminemia had 62 pts (53%); pneumonia 49 pts (41,5%); fungal infection (probable/proven) was found in 41 pts (34,7%); gram + sepsis in 4 pts (3,4%); gram – sepsis in 11 pts (9,3%); hypotension in 23 pts (19,5%), and ARDS in 19 pts (16,2%). Complete remission was achived in 61 pts (53,5%). Early death (ED) rate was 33 pts (28%). There was signifficant association of FN duration with following factors: Presence of fungal infection (p=0,005); Occurance of ARDS (p=0,002); ELN Cytogenetic risk group (p=0,007); elevated serum creatinine level (p=0,017) and ECOG PS (p=0,048). Applying binary logistic regression model, we classified risk score for FN developement of into three groups: low risk (0-3); intermediate (4-7) and high (8-12). In our analysed group 19 pts (17,9%) were of low risk for FN, with mortality of 0%; 51 pts (48,1%) had intermediate risk, with mortality of 27,5% and 36 pts (34%) was in high risk, with mortality of 44,4%.
Summary and Conclusions: This validated risk model help clinicians in early identification high risk patients for more intensive supportive care measures.

PB1479

ADVERSE PROGNOSTIC SIGNIFICANCE OF WILMS TUMOR GENE 1 OVEREXPRESSION IN ACUTE PROMYELOCYTIC LEUKEMIA

M Mitrovic[1,*], N Tosic[2], N Suvajdzic[1,3], I Djunic[1], A Vidovic[1,3], M Virijevic[1], N Colovic[1,3], T Kostic[2], I Glumac[2], S Pavlovic[2], I Elezovic[1, 3], D Tomin[1,3]
[1]Clinic of Hematology, Clinical Center of Serbia, [2]Institute of Molecular Genetics and Genetic Engineering, University of Belgrade, [3]Faculty of Medicine, University of Belgrade, Belgrade, Serbia

Background: Acute promyelocytic leukemia (APL) is characterized by the highest Wilms tumor gene 1 (WT1) expression levels in comparison to other types of acute myeloid leukemia. However, data on prognostic significance of WT1 gene overexpression in APL are insufficient.
Aims: To evaluate prognostic value of WT1 overexpression in APL patients.
Methods: Data on WT1 expression in 28 *de novo* PML-RARA positive APL patients (median age 43.5 years; female/male ratio 15/13; median follow-up 27 months) were analyzed prospectively. The patients were managed in the Clinic of Hematology from 2008 to 2013 with all-trans retinoic acid combined with anthracyclines. Fresh bone marrow samples were collected at diagnosis (28 patients), after the first consolidation and after that every six months (20 patients). WT1 expression levels were quantified by RQ-PCR method, using TaqMan chemistry. Abl served as a housekeeping gene. Relative quantification analysis was performed using comparative Ct method (2-ddCt), where ddCt = dCt(sample) -dCt(healthy(median)). Using mean WT1 expression level + one SD as a cut-off-value, patients were classified into two groups: with high or low expression.
Results: Pretreatment patients' characteristics were as follows: median WBC count 1.5x10^9/L (range: 0.4-88); median platelet count 25x10^9/L (range: 4-101); Sanz' s risk stratification: high 7/28 (25%), intermediate 11/28 (39%), low 10/28 (36%); hypergranular form 27/28 (96%); additional cytogenetic abnormalities (ACA) 2/28 (7%), PML-RARA type stratification: bcr1 14/28 (50%), bcr2 2/28 (7%), bcr3 12/28 (43%); FLT3/ITD positive 6/28 (21%) and FLT/D835 positive 3/28 (10.7%). Early death (ED) rate and relapse rate were 6/28 (21.4%) and 4/22 (18.2%), respectively. WT1 expression was significantly higher in APL patients, compared to healthy controls (mean 4123.57 ±725.91, range 13.64-14164.5813.64-14164.58 *vs.* 1.95±1.18, range 0.06-8.77, p<0,001). Nine patients (32.14%) were categorized into high expression group. High WT1 expression levels were significantly associated with high WBC counts (16.34x10^9/L *vs.* 4.94x10^9/L, p=0,003), higher relapse-risk score (5/9 (55.6%) *vs.* 2/19 (10.5%), p=0,001), bcr3 transcript variant (6/9 (66.7%) *vs.* 4/19 (21.15), p=0,05), FLT3/ITD mutation (4/9 (44.4%) *vs.* 2/19 (10.5%), p=0,03), higher ED rate (4/9 (44.4%) *vs.* 2/19 (10.5%), p=0,05) and shorter overall survival (12.5 *vs.* 24.1 months, p=0,05) compared to low WT1 expression levels. However, no correlation was found with age, platelet count, percentage of peripheral blood blasts and promyelocytes, microgranular subtype, expression of the surface markers, ACA and incidence of differentiation syndrome. In the majority of the patients (N=14) >2 log reduction in WT1 expression was detected after the first consolidation with mean WT1 expression level of 24.34 ±2.52, range 0.95-72. The increase in WT1 expression of at least 1,5 log was observed in samples during relapse, at the same time or even before PML-RARA positivity.
Summary and Conclusions: Our study speaks in favor of negative prognostic value of high WT1 expression levels in APL. WT1 expression levels represent a sensitive marker for MRD monitoring, too. Further prospective trials should evaluate whether this parameter should be included in risk stratification.

PB1480

AGE OVER 40 YEARS AND RENAL FAILURE ARE PREDICTIVE OF ATRA RELATED COMPLICATIONS IN PATIENTS WITH ACUTE PROMYELOCYTIC LEUKEMIA

R Jeddi[1,*], H Ghédira[2], Y Ben Abdennebi[1], H Ben Neji[1], M Zarrouk[1], R Mansouri[1], M Bchir[1], K Kacem[1], S Zriba[2], F Msaddek[2], L Aissaoui[1], R Ben Lakhal[1], Z Belhadjali[1], H Ben Abid[1], S Mnif[3], N Ben Salah[1], R Hafsia[1], B Meddeb[1]
[1]Aziza Othmana University Hospital, [2]Military Hospital, [3]Pasteur Institute, Tunis, Tunisia

Background: ATRA is considered a major advance in the front line treatment of APL.In combination with anthracycline this drug improved rate of remission and survival but remains associated with several side effects with DS being the most serious one.
Aims: The aim of this study was to identify predictors of ATRA related side effects.
Methods: 71 consecutive genetically confirmed APL were treated in the hematology department of Aziza Othmana Hospital with an AIDA based regimen.
Results: According to Sanz score 25 (35%) ,41 (58%) and 5 pts (7%) were high, intermediate and low risk respectively.61 pts achieved complete remission (87.1%),1 pt died before treatment and 9 during induction phase from severe bleeding (3 pts), DS (4 pts), Myocardial infarct (1 pt), and Septic Shock (1 pt). Prothrombin time<50% (P=0.008) , Renal failure (P=0.021)and High risk Sanz group(P=0.041) were predictive of induction death. 24 pts developed DS which was severe in 16 pts. 2 of 18 children *vs* 22 of 52 adults developed DS (P=0.016) .Other ATRA related complications were scrotal ulcer (4 pts), oesophageal ulcer (1 pt), splenic infarct (1 pt), Sweet syndrome (3 pts) ,headache (17 pts) , myocarditis (2 pts) and myocardial infarct (1 pt). 6 pts relapsed and 2 died in CR from cardiac failure and septic shock leading to 5 years EFS and OS of 72.9 and 74.3% respectively.
Multivariate analysis revealed that high BMI >30 (P=0.031, OR=4.9), high WBC (P=0.013, OR=5.7) and renal failure (P=0.004, OR=10.5) are predictive of DS. Age over 40 years (P=0.029) and renal failure (P<0.0001) are predictive of ATRA related complications.
Summary and Conclusions: Our study suggest that probably reducing ATRA dose to 25 mg/m^2 in adults can be effective as in children but less toxic .

PB1481

PML-RARA FUSION GENE TRANSCRIPTS AND BIOLOGICAL FEATURES IN A POPULATION WITH ACUTE PROMYELOCYTIC LEUKEMIA: A SINGLE CENTRE EXPERIENCE

P César[1,*], M Pereira[1], E Cortesão[1], C Geraldes[1], A Espadana[1], M Gomes[1], M Lourenço[2], G Ribeiro[2], L Ribeiro[1]
[1]Serviço de Hematologia, [2]Serviço de Patologia Clínica, Centro Hospitalar e Universitário de Coimbra, Coimbra, Portugal

Background: Acute promyelocytic leukaemia (APL) is characterized by the t(15;17), which produces the *PML-RAR*α fusion gene. It´s a distinct subset of Acute Myeloid Leukemia, known by an excellent response to all-trans-retinoic acid (ATRA) treatment, in spite of the high prevalence of early haemorragic complications. Depending of the PML's gene breakpoint in chromosome 15, the

transcript subtypes bcr1 (long), bcr2 (variant) and bcr3 (short) can be formed. The correlation between these transcript subtypes and clinical parameters is controversial. Some studies showed that the s-bcr3 type can be related with increased white blood cell counts and shorter survival; however, other groups found different results.

Aims: To identify PML-RARα isoform frequencies and subtypes in a population of patients, to study its haematological characteristics and to analyze the correlation between them.

Methods: Data from patients with APL diagnosed between 2005 and 2013 were reviewed. Only patients with molecular identification of the PML-RARα subtype were included. Clinical features and haematological parameters were analyzed at presentation, patients were stratified by Sanz risk score and statistical analysis was made using STATA v12.0.

Results: In this study 46 patients were included, 50% men, median age of 43 years (range 14-78 years). The l-bcr1 subtype was found in 44% (20) patients, the v-bcr2 in 15% (7) and the s-bcr3 in 41% (19) patients.

Seventeen (37%) patients were in the high risk category, 21 (46%) in intermediate risk and 8 (17%) patients had a low risk APL. The mean value for haemoglobin was 9.5 g/dl, for leucocytes was $22x10^9$/L and for platelets was $35x10^9$/L. No significant differences were found between these values for the 3 isoform subtypes. As usual in APL, most patients had coagulopathy (72%), with low fibrinogen (mean value 1.7 g/L) and high d-dimers (mean value 20.09 µg/ml). No correlation was found between the coagulation values and molecular subtypes of PML-RARα. The mortality rate was 30% (14 patients). Of these, 8 were early deaths - 4 patients died of haemorragic complications, 2 of differentiation syndrome secondary to ATRA therapy, and 2 because of infectious complications. Relapse was observed in 4 patients and 2 of these had 2 consecutive relapses. One of these 4 patients is still alive and in complete molecular remission. Long-term overall survival (OS) of this population is high with 3 year OS of 77%. In this study, there were no significant differences between the OS of the 3 isoform subtype groups.

Summary and Conclusions: The most frequent PML-RARα isoforms found in this population were l-bcr1 and s-bcr3, in concordance with previous published data. The OS of this population was high as expected, in spite of the high prevalence of coagulopathy and an increased proportion of high risk patients.

However, no significant correlation was found between the haematological parameters, age, sex and OS of the 3 PML-RARα isoforms, wich can be related to the small dimension of the population analysed.

This leads us to suggest that larger, multicentric studies are needed to clarify the hypothesis presented by some groups of different clinical and survival results according to the identified molecular subtype.

PB1482

HIGH INTENSITY INDUCTION CHEMOTHERAPY IS FEASIBLE FOR ACUTE MYELOID LEUKEMIA PATIENTS OLDER THAN 60 YEARS – A SINGLE CENTER EXPERIENCE

A Shacham-Abulafia[1,2], G Itchaki[1,2], M Yeshurun[1,2], M Paul[1], A Peck[1], O Shpilberg[1,2], R Ram[1, 2], P Raanani[1,2*]

[1]Hematology, Rabin Medical Center, Petah-Tikva, [2]Sackler school of medicine, Tel-Aviv University, Ramat-Aviv, Israel

Background: Acute myeloid leukemia (AML) is most commonly diagnosed in elderly patients. Despite a progress in the treatment of young AML patients, treatment decisions in the elderly patients are still controversial. Few data are available on the outcomes of intensive chemotherapy among elderly patients with AML.

Aims: To describe the outcomes of treatment and early adverse events as well as to identify prognostic factors for the achievement of overall survival (OS) and complete remission (CR) in AML patients older than 60 years that are eligible for intensive chemotherapy.

Methods: Data from 52 electronic charts of consecutive elderly patients with newly diagnosed AML, hospitalized in our ward between April 1st 2007 and January 1st 2013 for intensive induction treatment, were collected and analyzed. 38 patients received the 3+7 regimen and the remaining 14 patients received alternative intensive regimens such as the FLAG regimen. The primary endpoint of this study was OS and the secondary end points were the rate of complete remission (CR & CRi) and disease free survival (DFS). Factors associated with OS were examined.

Results: Table 1 shows patient characteristics. 38 patients (73%) achieved CR after 1-2 courses of induction chemotherapy and overall 14 patients (27%) were considered as treatment failure. Out of the 38 patients who achieved CR, 6 patients were ineligible for further treatment, 17 patients (45%) received consolidation with chemotherapy only and 15 patients (42%) proceeded to reduced intensity conditioning allogeneic hematopoietic cell transplantation (RIC allo- HCT). The OS at 2 and 3 years for all patients was 29% and 23%, respectively. Longer OS was associated with CR achievement (19.3 *vs.* 2.32 months), allo- HCT in CR1/CR2 (19.6 *vs.* 6.13) and ECOG 0-1 (14.4 *vs.* 5.9 months) according to univariate analysis (all p<0.05). Age, disease risk according ELN and NCCN and type of induction therapy were not significantly associated with survival.

Table 1. Patient characteristics.

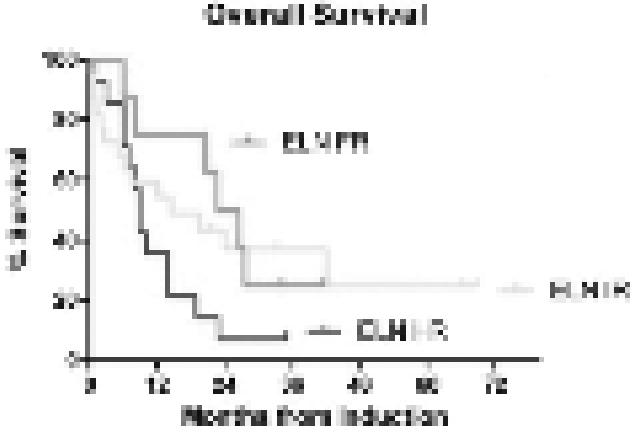

Figure 1.

Summary and Conclusions: Our results indicate that while the prognosis of elderly AML patients is poor, selected eligible patients might benefit from intensive treatment aiming for the achievement of CR. ECOG status before treatment rather than conventional prognostic markers should be used to triage elderly patients for intensive chemotherapy. While the role of post remission therapy in the elderly is still a matter of debate, RIC allo-HCT for patients who achieve CR should be considered.

PB1483

A PROPOSAL FOR MINIMAL DIAGNOSTIC PROCEDURES BASED DIAGNOSTIC ALGORITHM FOR ACUTE MYELOID LEUKEMIA (AML): SINGLE CENTER EXPERIENCE

I Panovska-Stavridis[1,*], L Cevreska[1], S Trajkova[1], M Ivanovski[1], M Popova[1], D Dukovski[1], L Hadzi-Pecova[1]

[1]University Clinic of Hematology-Skopje, Medical faculty-Skopje, Skopje, Macedonia, The Former Yugoslav Republic of Korea

Background: Modern concept of the individual therapeutic approach for acute myeloid leukemia (AML) cases is based on exact classification and prognosis of the AML subtype at diagnosis. A multimodal diagnostic approach which combines different diagnostic techniques is needed to meet these requirements. The diagnostic process is becoming more demanding with respect to experience, time and costs due to the expansion of methods and algorithms, which guide the diagnostic procedure from basic to more specific methods and which finally lead to results that are essential for modern diagnostics and therapeutic concepts. There are numerous overlaps between different diagnostic methods.

Aims: In order to establish and standardize a diagnostic algorithm based on a

minimal diagnostic procedures and to improve the diagnosis and management of acute leukemia in Republic of Macedonia, we conduct a prospective study at the University Clinic of Hematology-Skopje.
Methods: A total of 67 (>15 years) adult patients with acute leukemia who were consecutively admitted at the Clinic were enrolled in the study. The aim of our study was to establish the correct lineage assignment of the blast cells and to evaluate the incidence of the favorable genetic markers PML/RARa, AML1/ETO, CBFb/MYH11 among the AML cases. Furthermore, the obtained results were correlated with patients' age, comorbidities, and performance status, and consecutively effective treatment strategy for each single acute leukemia patient was selected. The diagnosis of acute leukemia was made by standard morphological examinations and cytochemical analyses of bone marrow smears according to the criteria established by the French-American-British (FAB) Study Group and confirmed by immunophenotyping of bone marrow aspirates and/or peripheral blood samples following the criteria of the European Group for the Immunological Classification of Leukemia's (EGIL) and the British Committee for Standards in Hematology (BCSH).
Results: Morphological and cytochemistry analyses assigned myeloid lineage in 83.6%of the patients, but in 16,4%of cases additional immunological analyses were need for establishment of the lineage assignment. Furthermore, using a reverse transcriptase-polymerase chain reaction (RT- PCR) assay 12 pateints were classified in the prognostic favorable AML group; 5 patients were positive for PML/RARa, 5 patients for AML1/ETO and 2 patients for CBFb/MYH11 fusion trasncripts. The applied multimodal diagnostic approach enabled improved and more precise diagnosis and clinical stratification in 34.3% acute leukemia patients from our study. Moreover, when we correlate those results with the results obtained from the analyses of the ECOG performance status and the incidence of the comborbidities in our study group, an additional 12.5% of the patients were stratified to a different risk adapted therapy.
Summary and Conclusions: Our initial results are consistent with literature data and indicate that our applied multimodal diagnostic approach based on minimal diagnostic procedures enables definition of specific genetic entities of AML and allows further individual clinical stratification in treatment protocols of the patients.

AZACYTIDINE THERAPY IN UNTREATED AML PATIENTS: RETROSPECTIVE MULTICENTRE REGIONAL EXPERIENCE

E De Astis[1,*] F Guolo[1], M Clavio[1], P Minetto[1], T Calzamiglia[2], R Goretti[3], O Racchi[4], D Avenoso[1], F Ballerini[1], M Miglino[1], L Del Corso[5], C Marani[5], G Pastori[5], L Rocchi[2], F Cruciani[5], C Dellepiane[5], D Lovera[5], E Prencipe[6], E Balleari[5], E Arboscello[5], L Mitscheunig[1], RM Lemoli[1], M Gobbi[1]
[1]IRCCS S AOU S.Martino Hospital – IST, Clinical Hematology, Genova, Italy. , Genova , [2]Ospedale Sanremo, Sanremo, [3]Ospedale Santa Corona, Pietra Ligure, [4]Ospedale Villa Scassi, [5]IRCCS S AOU S.Martino Hospital – IST, , Genova, [6]Ospedale rapallo, Rapallo, Italy

Background: In patients with high risk myelodysplastic syndromes DNA methyltransferase inhibitors induce up to 40% responses and azacytidine (AZA) has shown to prolong survival when compared with conventional supportive therapy. AZA is increasingly used in acute myeloid leukaemia patients (AML) with low marrow blast count or considered unfit for intensive chemotherapy.
Aims: Herein we report a retrospective analysis of AML patients treated with AZA therapy in an Italian region (Liguria).
Methods: From June 2010 to December 2013, 34 AML patients received AZA as front line treatment. Median age was 75 years (range 46-89); males were 60%, females 40%. Thirteen patients had de novo (38%) and 26 (62%) secondary AML. Median marrow blastic infiltration was 30% (range 29-90%). Karyotype was available in 16 patients [normal in 12, del (Y) in one, complex in 3]. Relevant comorbidities were present in the majority of patients (70%), mainly diabetes mellitus, heart disease, hypertension, liver or lung diseases. AZA was delivered at a dosage of 75 mg/sqm s.c. with a 5+2 days schedule. Patients were given a median of 4 courses of treatment (range 1-27). Twenty-five patients (75%) received concomitant recombinant alpha erythropoietin therapy (40 000 U once weekly).
Results: Major infections were recorded in 23 patients (67%). Six patients (18%) died early, mainly for infection associated to disease progression. Twenty-eight patients received at least 3 courses of therapy and were evaluated for response. Complete (CR) and partial remission (PR) were achieved in 5 (15%) and 14 (41%) patients, respectively, for an overall response rate of 56% (19/34). Nine patients did not respond (26%). Hematological response was achieved after a median of 3 courses of AZA (range 1-6). A statistically significant reduction of transfusional support was observed in responding patients ($p<0.05$). De novo disease was the only factor that significantly impacted on response rate (all denovo AML patients were responsive to treatment). Disease progression was observed in 12 out of 19 responding patients. At the moment of analysis 19 patients have died (55%), 15 are alive (45%) with a median follow up of 20 months. Overall 12 months and 20 months projected survival was 48.8%, and 39.4%, respectively. Survival was not different in de novo and secondary AML patients. Survival, was significantly worse in older patients, in patients with high marrow blast count (20 months-projected survival was 57.1% and 18.3% in patients with <30% and > 30% marrow blasts, respectively, $p<0.05$) and in patients showing progression under AZA therapy (20 months-projected survival was 36.4% and 85.7% in patients with and without progression under treatment, respectively; $p<0.05$). Two out of five patients aged 65 or less underwent allogeneic BMT (one in PR and one in CR, after 11 and 6 courses of therapy).
Summary and Conclusions: Our data show the efficacy and feasibility of AZA therapy in the common clinical practice, for newly diagnosed AML patients. High marrow blast infiltration at diagnosis, older age and progression under AZA therapy are poor prognostic factors affecting survival in this patient population. Outcome and quality of life of AML patients treated with AZA seem to compare favourably with that of patients receiving conventional intensive chemotherapy or supportive therapy only.

PB1485

CYTOGENETIC PROFILE AND FLT3 MUTATION OF 1OO ADULT DE NOVO ACUTE MYELOID LEUKEMIA PATIENTS FROM SAUDI ARABIA: CORRELATION TO BIOLOGIC FACTORS AND OUTCOME

G Elyamany[1,2,*] H Elghezal[1], O Alsuhaibani[1], K Fadalla[3], M Awad[1], I Ben-Abdallah Bouhajar[1], H Osman[3], Y Elborai[4,5], A Elarja[1], K AL-Fayez[1], A Al-Abulaaly[3]
[1]Dept. of Pathology and Laboratory Medicine, Prince Sultan Military Medical City (PSMMC), Riyadh, Saudi Arabia, [2]Department of Hematology and Blood Bank, Theodor Bilharz Research Institute, Cairo, Egypt, [3]Dept. of Adult Hematology/Oncology, [4]Pediatric Hem/Onc and Stem Cell Transplant, Prince Sultan Military Medical City (PSMMC), Riyadh, Saudi Arabia, [5]Pediatric Hem/Onc and Stem Cell Transplant, National Cancer Institute (NCI), Cairo University, Cairo, Egypt

Background: Diagnostic cytogenetic is regarded as one of the most valuable prognostic indicators in acute leukemia. Clonal chromosome abnormalities can be detected in approximately 55-78% of adult acute myeloid leukemia (AML) and in 78-85% of childhood AML. AML patients are categorized into good, intermediate and poor-risk groups according to cytogenetic changes.
Aims: No sufficient data exist regarding cytogenetic profile in Saudi AML patients. Most of the data reported were from western countries. Our aim was to define the frequencies and subtypes of chromosomal abnormalities among adult AML patients in the Saudi population and to compare the cytogenetic profile with those reported from other populations and did a correlation to other biologic factors.
Methods: From 2004 to 2013, we reviewed all cases with established diagnosis of Adult AML (100 cases). Informed consent was obtained.
Cytogenetic Analysis: Chromosome banding analysis and fluorescence *in situ* hybridization (FISH) were used to detect genetic aberrations. *Analysis of FLT3 mutations:* Bone marrow or blood samples were screened for *FLT3* mutations (internal tandem duplications, ITDs and point mutations, D835) using polymerase chain reaction methods (PCR).
Results: Table 1: Summarizes patient's characteristics and Cytogenetic and molecular findings. Our patients are categorized into good (13), intermediate (58), and poor-risk (29) groups according to cytogenetic changes.
Out of 100 cases, 20 cases were positive for FLT3 mutations with overall frequency of 20% (15/20, ITD and 5/20, D835), the frequency of cytogenetic abnormality in FLT3 positive group 8/20 (40%) while in FLT3 negative group was 34/60 (57%). Successful cytogenetic analysis 80/100 by FISH (80%) and 58/100 by Conventional cytogenetics (58%) showed chromosomal anomalies in 42 out of 80 cases with overall incidence 42/80 (53%). The most frequent cytogenetic abnormality was t(8;21) detected in 7/80 (9%) of successful cases, followed by trisomy 8 in 8/80 (10%) , t(15;17) in 5/80, (6%) , Inv 16 / t (16;16) in 4/80 (5%), and -5, +5, and 11q23/MLL each in 3/80 (4%) . The most frequent numerical abnormality was of chromosome 8, occurring in 9/80 (11%), 8 gain (+8) and one loss (-8) with or without additional abnormalities. This frequency was similar to that seen in most western countries (6–13.9%) but higher than most of Asian countries (3.8-7.1%). The mean age of patients with translocation abnormalities was significantly younger than that of patients with normal, deletion or trisomy anomaly. This study revealed the occurrence of false negative results by conventional cytogenetics analysis and highlighted the complementary nature of FISH in detecting cryptic genetic abnormalities in AML patients [one case in our study, t(15;17)]**.** Our data are in accordance with those published showed that *FLT3*-ITD mutation have a strong bad prognostic factor in AML patients and associated disease progression with high rate of relapse, shorter overall survival; (P=0.036) and event-free survival (EFS) was also worse (P=0.040**)** compared to standard risk group.
Summary and Conclusions: The frequencies of *FLT3* and cytogenetic abnormalities were slightly lower than those reported in the literatures but not reach significant, while its prognostic relevance was similar to those reported population from Asia and western countries. These data confirm that *FLT3* mutation occur in a significant percentage of Saudi AML and had bad prognostic relevance. More cases should be collected to clarify these findings.

PB1486

THE ROLE OF FLOW- CYTOMETRIC IMMUNOPHENOTYPING IN THE EARLY PROGNOSTIC STRATIFICATION OF ACUTE MYELOID LEUKEMIA PATIENTS: SINGLE CENTER EXPERIENCE

D Dukovski[1,*] L Cevreska[1], S Trajkova[1], M Ivanovski[1], M Popova-Simjanovska[1], S Stankovik[1], I Panovska-Stavridis[1]
[1]Hematology, University clinic for Hematology, Skopje, Macedonia, The Former Yugoslav Republic Of

Background: Flow cytometric immunophenotyping (FCI) has a well established role as a diagnostic modality in acute myeloid leukemia, particularly as a tool for assigning lineage and facilitating further pathologic classifications. So far, there is no clear consensus regarding the prognostic implications of FCI in AML in contest of predicting treatment response, induction death or overall survival.
Aims: In this study we evaluate possible role of the leukemia associated immunophenotype in the early prognostic classification of AML regarding the treatment response, especially the rate of early induction remission.
Methods: In our study we evaluate one hundred and fourteen (114) consecutive adult (>14 years) AML patients. Acute promyelocytic leukemia (APL) cases were excluded because they received different treatment. The diagnosis of AML was made by standard morphological examination and cytochemical analyses of peripheral blood/bone marrow samples to the criteria established by FAB Cooperative Study Group and confirmed by immunophenotyping of bone marrow aspirates and/or peripheral blood samples following the criteria of the European group for the immunological Classification of acute leukemia (EGIL).
Results: All patients received anthracycline plus cytarabine-based induction chemotherapy After 42 days from the initiation of the treatment 55.8% of the patients (male: female=29;20; median age 49, 8) achieved complete remission (CR), 17, 7% of the patients experienced early induction dead, and 30, 8% of the patients had residual disease. The expression of CD34 and HLA-DR or a combination of those markers was different between the remission and early induction dead group, with the statistical significance of $p<0,05$ for the CD34 expression. None of the other analyzed panmyloid markers or their combinations, nor the aberrant expression of the lymphoid markers was found to correlate with the induction treatment outcome. Moreover, our analyses showed that CD34 expression was associated with leukocyte count $>100 \times 10^{(9)}$ /l. A further analysis of the succumbed patients showed that risk factors for early induction death are also comorbidity index score ≥3 and age > 65 years.
Summary and Conclusions: Our results showed that results from FCI, especially expression of CD34 and HLA-DR alone, or their coexpression in correlation with age >65 years, and comorbidity score ≥3 can be used as early predictive marker for induction therapy outcome and may facilitate early individual therapeutical stratification of AML patients.

PB1487

ACUTE MYELOID LEUKEMIA IN PREGNANCY: A SINGLE CENTRE EXPERIENCE

N Fracchiolla[1,*] F Guidotti[1], F D'Ambrosi[2], N Orofino[1], C Boschetti[1], M Colombi[1], M W Ossola[3], L Napolitano[4], A Cortelezzi[1]
[1]UOC Oncoematologia, Fondazione IRCCS Ca'Granda - Ospedale Maggiore Policlinico, [2]UOC Ostetricia e Ginecologia, IRCCS Ca'Granda - Ospedale Maggiore Policlinico, [3]UOC Ostetricia e Ginecologia, Fondazione IRCCS Ca'Granda - Ospedale Maggiore Policlinico, [4]UOC Anestesia e Rianimazione, Fondazione IRCCS Ca'Granda - Ospedale Maggiore Policlinico, Milan, Italy

Background: The incidence of acute myeloid leukemia (AML) is estimated to be 1 in 50-70.000 pregnancies. Due to aggressiveness of disease, treatment cannot be delayed indefinitely and balance between chemotherapy (CTx) consequences on both fetus and mother, as well as the effects of postponing treatment must be carefully evaluated. In the 1st trimester the risks of CTx during organogenesis must be considered and discussed carefully. In the 2nd or 3rd trimester CTx with cytarabine and daunorubicin can be administered monitoring fetal cardiac function and growth.
Aims: To describe our experience consisting of 5 cases of AML diagnosed during pregnancy.
Results: -A 31 year old woman, 14 weeks pregnant, presented with severe leucopenia: bone marrow (BM) was consistent with AML. After 5 days of multidisciplinary consulting, the patient (Pt) asked for surgical abortion. Then she underwent induction CTx and consolidation with HSCT. Two years after the women is alive and in CR. A 36 year old woman, 32 weeks pregnant, was admitted with severe anemia, thrombocytopenia and LDH increase. An urgent cesarean section was performed and an healthy female was born. BM revealed AML and the patient received conventional induction and consolidation CTx. Eight months after, because of recurrence, she underwent autologous HSCT. Five years later she is alive and in CR. A 32 year old women, 26 weeks pregnant, presented with severe pancytopenia. US showed normal fetus growth. BM was consistent with RAEB-1. We decided for close monitoring, supportive Tx and betamethasone. Elective cesarean section was performed at 32+2 without complications. Soon after delivery, disease progressed to AML. The Pt received induction and consolidation CTx with HSCT. She is alive and well. A 34 years old woman, 31 weeks pregnant, presented with abdominal pain, asthenia and fever, thrombocytopenia, elevated LDH and D-Dimer with fibrinogen 167 mg/dl. At US examination fetus was still alive. However, an urgent cesarean section lead to extraction of a dead fetus of 1865g. Placenta resulted histologically involved by AML with hematoma and infarcts of surrounding parenchima. BM examination confirmed AML without maturation. She received induction and consolidation therapy and is still in CR. A 39 years old woman, 24 weeks pregnant, was referred to our hospital for management of AML. Blood values showed severe anemia, thrombocytopenia and leukocytosis. Betamethasone was administered and she underwent induction CTx with daunorubicin and cytarabine in continuous infusion (3+7 schedule). At 30 weeks of gestational age a caesarean section extracted a living male of 1495 grams. The Pt died after 4 months for sepsis during consolidation therapy.
Summary and Conclusions: From 2006 to 2012, at our Institution, 5 pregnant women were diagnosed with myeloid malignancies. One Pt had an intrauterine death at diagnosis; one chose surgical abortion before starting CTx, while 3 continued a regular pregnancy and delivered a healthy baby; one of them underwent CTx during pregnancy and died some months after delivery for septic shock in CR. In summary 4 women are currently living in CR and 3 healthy children were born. Our cases indicate that treating AML in pregnancy is demanding, but feasible. The clinical approach must be multidisciplinary: the specialists team must consider the nature of the disease (MDS *vs* AML), must discuss the appropriate timing for any intervention (both delivery and chemotherapy), with a continuous and careful evaluation of both maternal and fetal risk, during all the period of cure.

PB1488

ADDITIONAL CHROMOSOMAL ABNORMALITIES IN ACUTE PROMYELOCYTIC LEUKEMIA: A SINGLE-INSTITUTION EXPERIENCE

N S Fracchiolla[1,*] F Guidotti[1], G Reda[1], N Orofino[1], C Boschetti[1], M Colombi[1], D Vincenti[1], S Guarco[1], E Santambrogio[1], A Cortelezzi[1]
[1]UOC Oncoematologia, Fondazione IRCCS Ca'Granda - Ospedale Maggiore Policlinico, Milan, Italy

Background: Additional cytogenetic abnormalities (ACAs) are reported in 23-39% of acute promyelocytic leukaemia (APL) cases. Even if most studies report no impact on clinical outcomes in patients treated with ATRA and chemotherapy, the prognostic significance of ACAs is still not clearly defined. In particular, recently, Wiernik et al demonstrated, in a cohort of 140 APLs, a reduced ATRA sensitivity in patients with karyotypic evolution, compared to those characterized by t(15;17) alone.

Aims: To describe the incidence and the prognostic value of the presence of ACAs in patients affected by APL referred to our Institution since 2002
Methods: From 2002 until 2013, a total of 27 patients were diagnosed as affected by APL at our Hematologic Unit. There were 13 males and 14 females, with a median age of 43 years (range 13-76 years). Six patients were classifiable as high risk (*i.e.* WBC > $10x10^9$/L), 9 were intermediate risk (PLT<$40x10^9$/L) and the remaining 12 were low risk (PLT > $40x10^9$/l). All the patients were treated with chemotherapy plus ATRA (in the majority of cases as per AIDA 2000 schedule). Only one patient received arsenic trioxide (ATO) plus ATRA as induction therapy followed by maintenance with the same drugs. One patient had clinical characteristics, bone marrow morphology and immunophenotype (HLA-DR+) not consistent with APL, and received ATRA only after cytogenetic results acquisition.
Results: Among the 27 consecutive APL cases (24 de novo, 3 therapy-related) patients, 18 (67%) had t(15;17) as the only chromosomal alteration, 1 (3%) had no metaphases analysable and 8 (30%) had an ACA at the cytogenetic analysis (Table 1).

Table 1.

No statistical differences were observed in the two groups in terms of age, sex or WBC count. Median follow-up was 34 months. We had a total of 5 relapse at a median time from diagnosis of 14 months. Only 1 relapse was observed in patients with ACA: this case carried t(5;21)(q31q22) in combination to t(15;17) in 3 metaphases and only t(5;21) in 17; the aquired , non constitutional nature of the translocation t(5;21) has been confirmed by a cytogenetically normal result of phytohemagglutinin-stimulated blood analysis. The patient obtained molecular remission and a normal karyotype after the first consolidation cycle; however he had a bone marrow molecular relapse with asymptomatic CNS involvement after 3 months maintenance therapy. Three patients of our cohort died: we had two early deaths, both for intracranial hemorrhage, while one patient died for progressive disease after a third relapse treated with familiar HSCT. All these 3 patients had t(15;17) as the only chromosomal alteration. Overall survival seem not to be influenced by the presence of ACA.
Summary and Conclusions: In conclusion, we report an incidence of 30% ACAs in APL, consistently with published studies. We did not observe any chromosome 8 trisomy, described as the most common ACA, and reported an additional balanced translocation, t(5;21), which, to our knowledge, has never been described in APL. This patient had an early cytogenetic relapse with CNS involvement. The analysis of additional cases may help to assess a possible prognostic role for this translocation. In our series, the presence of ACAs did not seem to impact on APL clinical characteristics and outcome.

PB1489

THE EVALUATION OF NO AND LDH SERA LEVEL REGARDING THE FAB SUBTYPES OF AML

N Colovic[1,2,*]D Tomin[3], V Jurisic[4], A Vidovic[5], I Djunic[6], M Colovic[5]
[1]Internal medicine, Medical Faculty University Belgrade, [2]Assi prof.of Internal medicine, Clinic of Hematology Clinical Center Velgrade, [3]Prof.of Internal medicine, Medical Faculty University of Belgrade, [4]Prof.of Internal medicine, Medical Faculty Kragujevac, [5]Prof.of Internal medicine, Medical Faculty University Belgrade, [6]dr in Intensive care unit, Clinic of Hematology Clinical Center Velgrade, Belgrade, Serbia

Background: Nitric oxide (NO) is a multifunctional molecule produced in a variety of cells. There are many other molecules which it can interact, that it is quickly consumed close where it is synthesized. At lower levels NO is associated with vasodilatation and neurotransmission. At higher levels, NO has tumoricidal and bactericidal effects .
Aims: Several lines of evidence indicate that NO has cytotoxic effects on human cell lines from patients with leukemia or lymphoma. We investigated the level of NO and LDH at diagnosis of acute myeloid leukemia and correlated its with FAB subtypes.
Methods: This study included 22 man and 18 woman of AML patients, aged 25 to 68 years (median 50 years). Bone marrow aspirate was analyzed with classic cytochemical staining and immunophenotyping of blast cells by flow cytometry (Becton Dickinson) with monoclonal antibodies. Cytogenetic examination of bone marrow cells revealed a normal karyotype in 20 pts. In 1 pts t(15;17), trisomy 8 in 1, del(9) in 1, hyperploidy in 1, del(16) in 2, inv(16) in 3 and Ph chromosome in 3 patients were found. *NO* analysis was performed with Griess reaction. The level of NO was determined with ELISA spectrophotometer (Behring, ELISA reader, Germany) on wave length 570 nm. LDH activity in sera of AML patients was determined using Ectachem clinical chemistry slides with a multipoint rate slides test (Jonson & Johnson Clinical Diagnositic, USA) on the Ectachem 259 Analyser
Results: Results show that patients with AML have significantly different values of sera NO depending on FAB subtype of AML . The patients with M0 subtype of AML have higher values of NO (27.17 mmol/L) than other subtype of AML which also correlates with other poor clinical and cytological characteristics of undifferentiated type of AML. In comparison to M0, patients with M4 subtype show values of N0 of 5.45 mmol/L, which is statisticaly significantly lower in comparison to M0 (Mann Whitney U test, p=0.009). Sera NO in AML patients with M2 subtype showed values of 14.12 mmol/L which is significantly different in comparison with M4 (Mann Whitney U test, p=0.02), but with no difference in comparison with M1 (Mann Whitney U test, p> 0.05). Lowest values of NO in M4 subtypes correlated with favorable cytogenetic findings (inversion and deletion of chromosome 16) and with good prognosis. Significant positive correlation between NO and LDH was found in this study. AML patients with sera LDH below 300 U/ml show at the same time lowest sera NO and AML patients with elevated LDH (over 1000 U/ml) have elevated sera NO. Correlation between percentage of blast cells in bone marrow and NO was also found. Pearson correlation (p<0.05) shows that increase of blast cells in bone marrow is accompanied with high sera NO level.
Summary and Conclusions: These data indicated that NO is one of indicators of metabolic disturbance in malignant cells and especially of undifferentiated cells types. We conclude that this parameter could be used simultaneously with other prognostic factors for analyses in AML patients.

Chronic lymphocytic leukemia and related disorders - Biology

BENDAMUSTINE USED ALONE OR IN COMBINATION WITH RITUXIMAB MODIFIES THE EXPRESSION OF APOPTOSIS-INVOLVED GENES DEPENDING ON IGVH MUTATIONAL STATUS OF CLL CELLS

E Ziolkowska[1,*] W Fendler[2], E Lech-Maranda[3], D Wolowiec[4], W Mlynarski[2], T Robak[1], A Korycka-Wolowiec[1]
[1]Department of Hematology, [2]Department of Pediatrics, Hematology, Oncology and Diabetes, Medical University of Lodz, Lodz, [3]Department of Hematology, Institute of Hematology and Transfusion Medicine, Warsaw, [4]Department of Hematology, Wroclaw Medical University, Wroclaw, Poland

Background: Bendamustine (BENDA) used either alone or in combination with rituximab (RIT) is effective in the treatment of chronic lymphocytic leukemia (CLL). However, the influence of these drugs on the genes expression profile is still not fully understood and the expression of apoptosis-involved genes depending on IGVH mutational status has not been studied yet.
Aims: The aim of the study was to evaluate the influence of BENDA used alone or jointly with RIT on the apoptotic genes expression of CLL cells *in vitro* and to answer the question if the expression of these genes depends on the IGVH mutational status.
Methods: Peripheral blood samples were collected from 11 newly diagnosed CLL patients (5 F, 9 M) aged 49-81 (mean 66) yrs. All specimens were collected after written consent of patients. The IGVH gene was mutated (IGVH+) in 7, and unmutated (IGVH-) in 4 patients. Peripheral blood CD19+ cells at the concentration of $1.0x10^6$ cells/ml were incubated in RPMI1640 containing 10% fetal calf serum and 10% autologous serum with addition of BENDA (40mg/ml), RIT (10 mg/ml) or BENDA (40 mg/ml)+RIT (10mg/ml), for 48 hours. Control cultures were incubated without the drugs. After standard RNA isolation and cDNA preparation the TaqMan Low Density Array for PCR analysis of 96 gene transcripts (93 examined and 3 housekeeping genes) was used. The results showing the mean expression level at least 100 higher than the remainder were excluded from the microarray analysis. The fold change (RQ) value was defined as the ratio of the gene expression level after incubation of cells with a drug to the expression level in a control culture. RQ <0.5 or >2.0 was considered as significant.
Results: In the IGVH+ group BENDA led to a significant increase of 19 genes expression. Eleven of them encoded proapoptotic proteins, including 7 (*BBC3, BAX, BOK, CARD-9, APAF-1, CASP9, LRDD*) involved in the mitochondrial pathway and 4 (*FAS, CASP10, TNFRSF10, TNFRSF10B)* in the extrinsic pathway. In the IGVH- group BENDA increased the expression of 24 genes: 17 of them *encoding* proapoptotic proteins, including 8 involved in the mitochondrial (*BAK, BAX, BBC3, BNIP3L, BOK, CARD15, DIABLO*, *PYCARD*), and 4 in the extrinsic apoptotic pathway (*CASP14, CASP6, FAS, PYCARD*). The expression of 4 genes (*BAX, BBC3, BOK, FAS)* increased in both IGVH+ and IGVH- groups. In the IGVH+ group RIT significantly increased the expression of 16 genes, 9 of them encoding the proapoptotic proteins. In the IGVH- group RIT modified the expression of 56 genes increasing it in *49* (32 proapoptotic and 13 antiapoptotic), and decreasing it in 7 (6 proapoptotic and 1 antiapoptotic).The expression of 13 genes (*BCL2A1, BCL2L10, BCL2L14, BOK, CASP4, CASP5, CASP7, CRADD, DAPK1, ICEBERG, RIPK1, TNFRSF10B, TNFRSF21*) changed independently of the IGVH mutational status. BENDA+RIT led to an increase of the expression of 34 genes and a decrease of one gene in the IGVH+, and to an increase of 10 genes and a decrease of 3 genes in the IGVH- group. Both groups showed an increase of the expression of 10 genes and a decrease of one gene, 9 of which were proapoptotic (*BAX, BBC3, BOK* involved in the internal pathway; *CASP14, FAS, TNFRSF10B* in the extrinsic pathway and *NFKB1, BCL2L14, CASP5* probably in both the pathways) and 2 antiapoptotic.
Summary and Conclusions: We suggest that BENDA used alone or with RIT induces preferentially the expression of proapoptiotic genes, especially those involved in the intrinsic pathway. This effect seems to depend on the IGVH gene mutational status.
The work was supported by Mundipharma Research LtD grant.

ARRAYCGH ANALYSIS OF CHROMOSOME 13Q DELETIONS IN PATIENTS WITH CHRONIC LYMPHOCYTIC LEUKEMIA

L Kruzova[1,*] M Holzerova[1], M Hruba[2], M Mikesova[1], R Urbanova[1], T Papajik[1], K Indrak[1], M Jarosova[1]
[1]Hemato-oncology, University Hospital, Olomouc, [2]Hemato-oncology, University Hospital, Plzen, Czech Republic

Background: The cytogenetic abnormality most frequently detected by fluorescence *in situ* hybridization (FISH) is deletion of 13q14 present in ~50% of patients with chronic lymphocytic leukemia (CLL). As a single aberration, deletion of 13q14 is associated with favorable prognosis. The prognostic value of other changes such as biallelic deletion of 13q14, monosomy 13 or translocation of chromosome 13 remains controversial. Efforts to clearly determine the extent of the deletion, significant genes located in the deleted region and clinical impact of the changes are still a matter of research.
Aims: To perform arrayCGH analysis of a group of patients with deletion of 13q14, to determine the extent of the deletion and to compare findings in patients with a single aberration, those with deletion of 13q14 and one additional change and those with complex aberrations. Furthermore, to determine the extent of the deleted region and to compare the extent of the deletions with certain clinical parameters.
Methods: A CLL FISH probe panel was used to investigate a group of 671 patients. Of those, 51 patients with detected deletion of 13q were examined with arrayCGH (peripheral blood in 46 pts, bone marrow in 4 pts and a lymph node in 1 pt).
Results: In the group of 671 patients, deletion of 13q14 was determined in 301 (45%) patients. Among those, arrayCGH was used to examine 14 patients with a single aberration of 13q14, 11 patients with two aberrations and 26 patients with complex changes. The subgroup comprised 38 males and 13 females with a median age of 62 years (range, 27–86 years). Seventeen patients had Binet's stage A, 10 patients had stage B and 17 patients had stage C; in 7 patients, the stage was not specified. Unmutated and mutated *IgVH* genes were found in 31 and 11 patients, respectively; in 9 patients, the mutational status was not studied. A total of nine patients died. Ten patients had biallelic deletion of 13q14; this was associated with monoallelic deletion of 13q14 in 8 cases. ArrayCGH determined the smallest deleted region of 850 kb at 13q14.2-13q14.3, containing the *MIR15a, MIR16-1, DLEU1, DLEU2* and *DLEU7* genes. In one patient, deletion of 13q was only determined by arrayCGH at 13q21.1-q21.2 sized 1.1 Mb. Two patients had monosomy 13. Comparison of the detected deletion with certain studied parameters such as *IgVH* mutational status, Binet's stage, type of deletion of 13q and additional chromosomal changes has not confirmed a direct association with the extent of the deletion as yet. Only patients with complex changes tended to have more extensive deletions.
Summary and Conclusions: The arrayCGH analysis of a group of 51 CLL patients with deletion of 13q determined by FISH confirmed a large heterogeneity of the extent of the deletion and tendency of association of large deletion with complex changes. Given the small number of patients in the study, the clinical significance of the investigated deletions of 13q cannot be clearly determined.

***IN VITRO* EFFECTS OF LENALIDOMIDE ON CELL SURFACE ANTIGENS EXPRESSION IN PRIMARY CHRONIC LYMPHOCYTIC LEUKEMIA (CLL) B-CELLS: A QUANTITATIVE FLOW CYTOMETRIC STUDY**

G D'Arena[1,*] V Ruggieri[2], F D'Auria[3], F La Rocca[2], V Simeon[2], T Statuto[3], P Musto[4]
[1]Hematology/Oncology, [2]Laboratory of Preclinical and Translational Research, [3]Laboratory of Clinical and Advanced Diagnostics, [4]Scientific Direction, IRCCS Centro di Riferimento Oncologico della Basilicata, Rionero in Vulture, Italy

Background: B-cells belonging to CLL clones are characterized by low density of CD20 antigen on their surface. Despite this, anti-CD20 monoclonal antibody Rituximab has been proved to be effective in this lymphoid disorder. Moreover, Lenalidomide (Revlimid, CC-5013, Celgene) has been shown to potentiate the therapeutic efficacy of Rituximab in the treatment of CLL (Badoux et al, 2013). Surprisingly, however, it has been reported that, *in vitro*, Lenalidomide induces a down-regulation of CD20 expression on CLL B-cells surface (Lapalombella et al, 2008). Other authors found no antigenic density changes following *in vitro* Lenalidomide treatment (Hernandez-Ilizaturri et al, 2005). In both these studies the expression of CD20 antigen was evaluated by a flow cytometric analysis using the mean fluorescence intensity (MFI).
Aims: We aimed to evaluate the antigenic density of CD20, and that of other surface antigens likely involved in the immunomodulating mechanism(s) of action of Lenalidomide, by means of a different, quantitative flow cytometric approach (QuantiBRITE™, Becton Dickinson), a more accurate technology to estimate the number of antigens expressed per cell as antibody binding capacity (ABC).
Methods: Lenalidomide was provided by Celgene (Summit, NJ) and dissolved in DMSO at a stock concentration of 1 M. Peripheral blood mononuclear cells (PBMC) were collected, after written informed consent, from 8 untreated CLL patients (6 males; 2 females; mean age 74 yrs; range 58-89 yrs). PBMC were cultured at $0,5x10^6$ cell/ml in RPMI 1640 medium supplemented with 10% heat-inactivated human serum, L-glutamine (2 mM) and penicillin–streptomycin (100

U/ml) and treated with three different doses of Lenalidomide (0.1, 0.5 and 2 μM). For each patient, the same number of cells was cultured without Lenalidomide (controls). PE-conjugated monoclonal antibodies anti-CD20, CD44, CD52, CD80, CD86, and CD95 were employed to determine the antigen expression by flow cytometry (FACSCalibur, Becton Dickinson) at different times (24, 48, and 72 hours).

Results: The ABC value of CD20 antigen on B-cells surface, normalized to the relative control and expressed as fold-change, was found to be significantly increased (mean: from 1.13 at 24 hours to 1.2 at 72 hours) after treatment with 2 μM Lenalidomide (Figure). Changes found after 0.1 and 0.5 μM doses were less relevant. Regarding other antigens, a time-related decrease of CD52 expression levels was reported at all doses of treatment. Interestingly, CD44 and CD95 antigens levels showed a characteristic time-related trend. A decreased CD44 expression observed at 24 hours of treatment was in fact followed by an increase at 48 hours and by a new decrease to the basal levels at 72 hours. The CD95 expression trend, on the contrary, was precisely the opposite of the CD44 one. Finally, Lenalidomide augmented the expression levels of CD80 antigen starting from 48 hours of treatment, while the same effect on CD86 expression was observed at 24 hours.

Summary and Conclusions: Differently from previously reported data and using a more precise approach, a positive modulating effect of Lenalidomide on CD20 expression in CLL B-cells was found. The increase of antigen expression occurred at doses that are comparable to those that are effective *in vivo*. Although Lenalidomide is thought to be pleiotropic in modality of action on the CLL microenvironment, an increase in CD20 expression might contribute to explain the synergistic effect of rituximab in CLL when used *in vivo* in combination with Lenalidomide. We are also currently analyzing in detail the possible role of variable changes in expression of other co-stimulatory molecules we found: more mature data in this setting will be presented at the Meeting.

THE SIGNIFICANCE OF KIR GENE POLYMORPHISMS IN CHRONIC LYMPHOCYTIC LEUKEMIA

S Akpinar[1], G Pamuk[1,*] H Tozkir[2], H Gurkan[2], J Duymaz[2], M Demir[1], ON Pamuk[3]

[1]Department of Hematology, [2]Medical Genetics, [3]Department of Rheumatology, Trakya University Medical Faculty, Istanbul, Turkey

Background: Natural killer (NK) cell receptors are polymorphic; and this might cause variations in tumour response among different subjects. The escape of leukemic cells from NK immunity might be possible because of the presence of certain Killer Immunoglobulin-Like Receptor (KIR) genes. KIR receptors might play activating or inhibitory roles depending upon the allelic polymorphism.

Aims: We studied KIR gene polymorphisms in chronic lymphocytic leukemia (CLL). We determined whether KIR polymorphisms had any associations with clinical features like stage, prognosis and survival in CLL patients.

Methods: We included 68 CLL patients (28 females, 40 males, mean age: 64 years) and 64 controls (29 females, 35 males, mean age: 66.6 years). Clinical features, laboratory data, treatment modalities and outcome of CLL patients were recorded from medical records. Ethical committee approval and consent from all subjects were obtained. Peripheral blood was drawn from CLL patients and controls; genomic DNA was extracted. PCR was used to determine KIR gene polymorphisms.

Results: Fifty-two CLL patients (76.5%) had early Rai stage (0, 1, 2) disease, 16 (23.5%) were in advanced stages (III, IV). The inhibitory KIR2DL3 genotype was significantly more frequent in CLL patients (66 patients, 97.1%) than in controls (55 subjects, 86.9%) (OR: 4.78, 95%CI: 1.07-21.3, p=0.02). Other evaluated genotypes (inhibitory KIR2DL1, KIR2DL2, KIR2DL5, KIR3DL1, KIR3DL2, KIR3DL3 and activating KIR2DS1, KIR2DS2 KIR2DS3, KIR2DS4, KIR2DS5, KIR3DS1) were similar in two groups (p values >0.05). Early-stage CLL patients had significantly more frequent KIR2DL5 genotype than the advanced-stage group (57.7% *vs.* 6.3%, p=0.02). The former group had significantly more frequent KIR2DS1 genotype than the latter group (42.3% *vs.*12.5%, p=0.03). KIR2DS3 genotype was significantly more frequent in early-stage CLL patients (40.4% *vs.* 6.3%, p=0.01). Early-stage CLL patients had more frequent KIR3DS1 than advanced-stage patients (50% *vs.* 18.8%,p=0.03). The mean number of activating genes were significantly higher in early-stage CLL patients than in advanced-stage patients (3.1±1.6 *vs.*1.88±1.15,p=0.04).

Summary and Conclusions: The inhibitory KIR2DL3 gene might have suppressed activating signals of NK cells, probably preventing lysis of CLL cells, and contributing to disease pathogenesis. In addition, KIR2DL5, KIR2DS1, KIR2DS3, KIR3DS1 genes which were more frequent in early-stage CLL patients might have played preventive roles in disease progression and acted against more severe disease activity.

PB1495

THE NECESSITY FOR THE PARALLEL APPLICATION OF KARYOTYPE AND FISH ANALYSIS IN CHRONIC LYMPHOCYTIC LEUKEMIA

M Karakosta[1,*] C Panagiotopoulou[1], MI Margariti[1], P Diamantopoulou[1], C Sambani[1], G Pantelias[1], G Kouraklis[2], K N Manola[1]

[1]Cytogenetic, NCSR "DEMOKRITOS", [2]Second Department of Propedeutic Surgery, School of Medicine,University of Athens, Athens, Greece

Background: Conventional and Molecular Cytogenetics is an important prognostic and diagnostic parameter in Chronic Lymphocytic Leukemia (CLL) investigation. Recently, the improvement of cultivation techniques, by using new mitogens, combined with fluorescence *in situ* hybridization (FISH) analysis provide the opportunity of the whole spectrum of CLL aberrations to be revealed that was not possible before due to the low mitotic activity of CLL cells *in vitro*.

Aims: We present a systematic cytogenetic study of 237 B-CLL cases using karyotypic and FISH analysis in order to define the cytogenetic aberrations in CLL and their frequencies in greek population as well as to identify the best method for the investigation of the disease.

Methods: Karyotypic analysis was performed on unstimulated and stimulated with the combination of oligonucleotide DSP30 plus IL-2 bone marrow cells derived from 237 patients, aged 32-88 years. The karyotypic analysis was considered successful when a minimum of 20 metaphases were analyzed. FISH studies were carried out in 126 patients using the commercial CLL set probes: LSI p53/LSI ATM και LSI D13S319/LSI 13q34/CEP12 Multi-Color Probe Sets.

Results: The sex ratio (males/females) was 1.63. The median age of the patients was 64.88 years. Karyotypic analysis was successful in 218 patients (92%). A normal karyotype was found in 82 patients (37.61%) and an abnormal in 136 patients (62.39%). Among the abnormal karyotypes, 43 (31.62%) were complex and 64 (47.06%) carried only one aberration. More than 60 different recurrent chromosomal aberrations were detected in our cohort. The most frequent chromosome aberrations in abnormal karyotypes were: +12 (34.56%), del(13q) (16.91%), -Y (13.24%), translocations of chromosome 14q (10.29%), del(11q) (9.56%), del(6q) (8.82%), -17 (7.35%), translocations of chromosomes 13 and 6 (5.88% each) and add(14q) (5.15%). Other not so frequent but recurrent chromosomal aberrations were also found in 50 patients (36.76%). The most common abnormalities found in karyotypes as sole aberrations were +12 (32.81%), -Y (9.38%), del(13q) (7.81%), del(6q) (6.25%), translocations of 14q (6.25%), and del(11q) (4.69%). FISH analysis was successful in all 126 patients while aberrations were detected in 87 (69.05%) patients. Among the abnormal cases, del(13)(q14.3) was found in 57 (65.52%) patients, +12 in 23 (26.44%), del(17)(p13.1)/p53 in 13 (14.94%), del(11)(q22.3)/ATM in 11 (12.64%) and del(13)(q34.3) in 2 (2.30%) patients. Moreover, a homozygous deletion of 13q14.3 was found in 13 (14.94%) patients.

Summary and Conclusions: Karyotypic analysis in CLL revealed a variety of recurrent chromosomal aberrations, most of which have not been identified as CLL specific abnormalities and consequently have still an unknown prognosis. The frequency of abnormalities found by karyotype and FISH was similar but differences in the number and frequency of specific chromosomal aberrations were detected. Trisomy 12 was the most common abnormality in karyotypes while the submicroscopic del(13)(q14.3) was the most common aberration detected by FISH. These differences can be attributed to the ability of FISH to detect submicroscopic aberrations not always detected in karyotypes and the ability of karyotype to provide an overview of all microscopically visible chromosome

abnormalities through the genome. Therefore, the above indicate the necessity for the parallel application of karyotype and FISH analysis in CLL investigation.

PB1496

INCIDENCE OF SECOND CANCER IN PATIENTS WITH CHRONIC LYMPHOCYTIC LEUKEMIA: 13 YEARS EXPERIENCE FROM SINGLE INSTITUTE

A Gogia[1,*] V Raina[1]
[1]All India Institute of Medical Science, Aiims, New Delhi, India

Background: Chronic lymphocytic leukemia (CLL) is most common malignancy in the west and relatively uncommon in India
Aims: Patients with CLL have a higher incidence of second malignancies (two times) than the general population. Our study aims to present the incidence and predicting factor for second cancer in patients of CLL at our institution.
Methods: We retrospective evaluated 320 patients of CLL registered at All India Institute of Medical Sciences (AIIMS) , New Delhi over a period of 13 years (2000-2012) . A second malignancy was defined as another malignancy at the time of diagnosis or during follow-up
Results: There were 230 males and 90 females. The median age was 59 years (28-90 years). The common presenting features were lymphadenopathy 63%, fatigue 25%, fever 20%, hepatomegaly 40%, splenomegaly 55%. Median total leucocyte count at presentation was $47x10^9$/L. Sixtey percent of patients were early (Rai stage 0 - 10%, stage I - 16%, stage II - 34%) and 40% of cases were in advanced (stage III -20% and stage IV - 20%) stage. Fifty percent of patients received treatment at presentation (one hundred twelve patients (70%) received chlorambucil and 40 patients (25%) received Fludarabine and eight patients received bendamustine based chemotherapy). With a median follow-up of 40 months ,total of 24 cancers were identified (18 hematological and 6 solid tumors) . Seventeen cases were transformation to diffuse B cell lymphoma (richter's syndrome)and rest were myelodysplastic syndrome -1, basal cell carcinoma -1, carcinoma of larynx -1, breast cancer -1, adenocarcinoma of lung -1 and locally advanced urinary bladder cancer -1 case each. According to correlation analysis, young age (<55 years, p=0.015) a high expression of CD38 positivity (>30%, p=0.001) and advanced Rai stage (III & IV, p<0.001) were found to be independent predictors of transformation to richter's syndrome (RS). Median time to progression to RS and overall survival was 26 months and 8 months respectively.
Summary and Conclusions: The incidence of second caner is 7.5 % in our population , richter's transformation is the most common and accounts for 5% of cases . Young age, advanced stage and high expression of CD 38 predict poor outcome

PB1497

CYTOKINE PROFILE IN PATIENTS WITH CHRONIC LYMPHOPROLIFERATIVE DISEASES

N Domnikova[1,*] T Dolgikh[1], Y D'yachkova[1], E Petrusenko[1], E Sholenberg[1], O Reshetnikov[2], S Ryzhikova[3]
[1]Institute of Regional Pathology and Pathomorphology Siberian Branch under the Russian Academy of Medical Sciences, [2]Federal State Budgetary Institution of Internal and Preventive Medicine Siberian Branch under the Russian Academy of Medical Sciences, [3]Joint Stock Company "Vector-Best, Novosibirsk, Russian Federation

Background: Modified cytokine production is especially important in the pathogenesis of hemoblastoses. However, only few studies are available concerning spontaneous and mitogen-stimulated production of pro-, anti-inflammatory cytokines, and colony-stimulating factors in patients with lymphoproliferative diseases.
Aims: Aim of the present study was to evaluate the level of spontaneous and mitogen-stimulated production of pro- and anti-inflammatory cytokines in lymphoproliferative diseases at initial presentation, progression and remission (complete or partial), as a result of chemotherapy.
Methods: Seventy-six patients with lymphoid malignancies: 42 patients (27 men, 15 women, mean age 58.3±9.6 years) with chronic lymphocytic leukemia and small lymphocytic lymphoma; 23 patients (10 men, 13 women, mean age 59.7±8.3 years) with multiple myeloma; 11 patients with diffuse large b-cell lymphoma (6 males, 5 females, mean age 52.0±11.1 years) were included in this study. In order to study spontaneous and mitogen-stimulated cytokine production by blood cells using reagent kit "Cytokine-Stimul-Best", immediately after the punction of the cubital vein 1 ml of blood was added to a vial containing 4 ml of maintenance medium (DMEM), heparin (2.5 U/ml), gentamicin (100 mg/ml) and L-glutamine (0.6 mg/ml). This vial has been used for the study of spontaneous cytokine production. For mitogenic stimulation, 1 ml of resulting diluted blood was transferred to a vial with a mixture of polyclonal activators (lipopolysaccharide, concanavalin A, phytohemagglutinin P and phytohemagglutinin M). Both flasks were incubated during 24 hrs at 37°C, then blood cells were pelleted at 10,000 g for 3 min, the supernatant after separation of the precipitate was frozen and stored at -40 °C until testing of cytokines. The concentration of cytokines in the samples were evaluated using enzyme immunoassay reagent kits manufactured by JSC «Vector-Best" (Novosibirsk). Informed consent to the study was obtained.
Results: Significant increase in the spontaneous production of colony-stimulating factors was shown in the initial presentation and progression phases of lymphoproliferative diseases. Increasing production of IL-18 and VEGF was found to be common for investigated diseases. Decreased secretion of IL-2 in addition to increased levels of cytokines was evidenced in the initial presentation and progression of lymphoproliferative diseases. We found that the remission of lymphoproliferative diseases is accompanied with reducing the level of proinflammatory cytokines (spontaneous production of IL-8, IL-6, IL-2, IL-17, INF-γ, mitogen-stimulated production of TNF-α, IL-6, IL-2) and anti-inflammatory cytokines (spontaneous production of IL-4, IL-10, mitogen-stimulated production of IL-10, IL-1RA). The only exception was an increase in the spontaneous production of GM-CSF that proved to be 4.1-fold (p=0.02) in chronic lymphocytic leukemia and small lymphocytic lymphoma.
Summary and Conclusions: The study has shown that the initial presentation or progression of lymphoproliferative diseases are accompanied with increased level of the majority of pro-inflammatory cytokines and colony-stimulating factors. The remission phase of lymphoproliferative diseases is characterized with reduced level of pro- and antiinflammatory cytokines and increased level of colony-stimulating factors.

PB1498

DOWNREGULATED MIR-181A/B EXPRESSION PREDICTS POOR PROGNOSIS IN CHRONIC LYMPHOCYTIC LEUKEMIA

P Li[1], Z Nan[1,*] X Dahai[1], D Ning[1], L Xiaoliang[1], W Yang[1], Z Xiuxian[1], C Hongli
[1]Emergency Department, First Hospital of Jilin University, changchun, China

Background: Emerging evidence suggests that altered microRNAs (miRNAs) regulation is involved in the pathogenesis of cancers-mainly by regulating the translation of oncogenes and tumor suppressors. Aberrant expression of miRNA has been recently associated with chronic lymphocytic leukemia (CLL) outcome.
Aims: In this study, we aimed to investigate the role of miR-181a/b in Chinese patients of CLL, we assessed the expression of miR-181a/b and their correlation with other prognostic factors, including Binet stages, immunoglobulin heavy chain variable gene (IGHV) mutation status, TP53 mutation status, and CD38 expression level in CLL patients by using real-time polymerase chain reaction methods.
Methods: We assessed the expression of miR-181a/b and their correlation with other prognostic factors, including Binet stages, immunoglobulin heavy chain variable gene (IGHV) mutation status, TP53 mutation status, and CD38 expression level in CLL patients by using real-time polymerase chain reaction methods.
Results: Patients with unmutated IGHV genes had significantly lower expression of miR-181a/b than patients with IGHV mutations. The lower expression level of miR-181a/b was also significantly associated with higher level of CD38 and ZAP-70, and more aggressive Binet stage. Furthermore, the lower expression of miR-181a/b in CLL shows a strong association with shorter overall survival (OS) (p=0.016) as well as with reduced treatment free survival (TFS) (p=0.003). We also observed that miR-181a/b targets BCL-2, Mcl-1, and XIAP protein and that the decrease of its expression inversely correlated with negatively regulated expression of a BCL-2/MCL-1/XIAP 3' untranslated region-based reporter construct.
Summary and Conclusions: Our data suggest that miR-181a/b expression may play an important role in the progression and prognosis of CLL.

PB1499

YOUNG CHRONIC LYMPHOCYTIC LEUKEMIA: A SINGLE CENTRE EXPERIENCE OF 150 CASES

A Gogia[1,*] V Raina[1]
[1]All India Institute of Medical Science, Aiims, New Delhi, India

Background: Chronic lymphocytic leukemia is rare in India and its incidence is 1% of all leukemias
Aims: In this study, the clinical characteristics, survival, and prognostic factors of 150 cases of young (less than 55 years) chronic lymphocytic leukemia (CLL) patients were analysed at IRCH, AIIMS, a large tertiary care centre of Northern India
Methods: Patients records collected from computer database using ICD code (C-91.1) between period of 2000-2013 were retrospectively evaluated
Results: Over a period of 14 years, 360 CLL patients (150 [41.6%]55 years of age) were evaluated. There were similar distribution of sex, lymphadenopathy, organomegaly, and absolute lymphocyte count in both groups At diagnosis, younger patients were less incidentally detected (p =0.01),

more B- symptoms (p=0.01) and advanced Rai stage (p <0.001), than older patients. Response rate and toxicity profile were same in both groups with chlorambucil and fludarabine based chemotherapy. Overall response rate (ORR) seen with chlorambucil and fludarabine was 69% and 88% with complete remission (CR) rate was 3% and 44% respectively. Richter's transformation was significantly higher in younger patients (3.41% v 0.5%; p =0.001). Median follow up period was 39 months. Younger and older patients showed a similar overall median survival but were characterized by a different distribution of causes of deaths. CLL unrelated deaths predominated in the older age group, as one third of patients have different co-morbities like diabetes, hypertension, coronary artery disease e.t.c, whereas the disease related death were prevalent in the younger age group. Multivariate analysis showed that for young CLL patients, advanced clinical stage (Rai III and IV) was associated with poor overall survival [HR 2.22 (95% CI 1.10-4.11) p =0.001].
Summary and Conclusions: Forty one percent our CLL population was young. Young CLL patients presented with more B symptoms and advanced stage (Rai III and IV) than elderly CLL patients.

PB1500

THE PTPN22 R620W POLYMORPHISM IS NOT ASSOCIATED WITH CLINICAL AND MOLECULAR CORRELATES OF CRONIC LYMPHOCYTIC LEUKEMIA (CLL) IN PATIENTS ORIGINATING FROM REPUBLIC OF MACEDONIA

I Panovska-Stavridis[1,*] M Ivanovski[1], A Eftimov[2], S Trajkova[1], L Cevreska[3], D Dukovski[1], M Popova[1], A Dimovski[2]
[1]University Clinic of Hematology-Skopje, Medical faculty-Skopje, [2]Centar for Biomolecular Pharmaceutical Analysis, Faculty of Pharmacy-Skopje, [3]Medical faculty-Skopje, Skopje, Macedonia, The Former Yugoslav Republic of Macedonia

Background: PTPN22 is a protein tyrosine phosphatase that modulates antigen-receptor signaling in T and B cells. A PTPN22 R620W polymorphic allele (C1858T, rs2476601) was associated with a major risk for the development of multiple autoimmune diseases in patients originating from northwestern Europe, whereas this association was less clear in patients originating from southern Europe. A higher frequency of the 620W risk allele has recently been reported in CLL patients originating from northwest Europe. These data adds to the recent findings that PTPN22 is markedly over expressed in the majority of CLL patients and that gene products of PTPN22 is involved in the pathogenesis of the disease by affecting apoptosis/survival of B-lymphocytes.
Aims: In order to extend further those observations we conduct a retrospective study on the frequency of PTPN22 R620W variant in 117 CLL patients and 108 age/sex matched normal controls without a history of malignant disease originating from the Republic of Macedonia (Southeastern Europe), which is a region with low prevalence of the autoimmunity risk variant. Moreover, we analyzed the possible association of the variant with various clinical/molecular correlates of the CLL patients.
Methods: Our study group consisted of 117 adult (>15 years) CLL patients that were diagnosed and followed at the University Clinic of Hematology-Skopje, Republic of Macedonia. Clinical and molecular data from the CLL patients were collected according the internal protocol that was approved by the University Clinic of Hematology Institutional review Board.
Results: Similar allele frequency of the minor T allele (0.06 and 0.063) and genotype distribution (0.88, 0.115 and 0.005 of CC, CT and TT genotypes) was found in CLL patients and normal controls, respectively. Both study groups were in Hardy-Weinberg equilibrium. Also, the PTPN22 R620W variant was not associated with any of the studied parameters in patients such as initial blood counts, Combs test, CD38 expression, IGHV mutation status, incidence of autoimmune disorders and immunoglobulin levels. Our data are comparable with the data reported for CLL patients originated from southeastern European region.
Summary and Conclusions: The PTPN22 R620W variant is not a risk factor for the development or clinical course of CLL in patients originating from the southeastern European region. The differences of our data with the reported findings for CLL patients originating from northwest Europe mirrors the differences observed in patients with various autoimmune diseases, suggesting a possible gene-environmental factor that affects the influence of R620 variant on the lymphocytic homeostasis. Our results are in line with the hypothesis that ethnic variations in the germline composition of the IGHV locus in correlation with environmental factors from particular geographic areas influence development of CLL.

PB1501

NUCLEOPHOSMIN (NPM) AND TELOMERASE (TE) IMMUNOPOSTIVITY IN CLL LYMPHOID CELLS

M Sucic[1,*] N Ljubić[1], D Župani ć[2], T Žanić-Grubišić[3], A Somborac[3], L Perković[1], D Ivanović[1]
[1]Department of Pathology and Cytology, [2]Department of Internal Medicine, Clinical Hospital Sveti Duh (Saint Spirit), [3]Department of Biochemistry and Hematology, Zagreb University Faculty of Pharamacy and Biochemistry, Zagreb, Croatia

Background: Nucleophosmin (NPM) is phosphoprotein that is ubiquitously expressed in tissues, resides in nucleolus and shuttles continuously between nucleus and cytoplasm. Genetic locus of human NPM1 is 5q35.1. The wild-type protein is mainly located in the nucleolus and on the nuclear membrane and in cytoplasm of mitotic cells. Major role of NPM is to mediate nuclear export of ribosome components to the cytoplasm and to control centrosome duplication and it also interacts with oncosupressors p53 and alternate–reading-frame protein (ARF) thus controlling cell proliferation and apoptosis. NPM promotes cell growth by enhancing ribosome biogenesis and transport to the cytoplasm, as its expression increase in response to mitogenic stimuli and above normal amounts are detected in highly proliferating and malignant cell. Telomerase (TE) is an RNA-dependent DNA polymerase that catalyzes the addition of telomeric repeat sequences to chromosome ends, and its genetic locus is 5p15.33. In most human somatic cells, TE activity is undetectable, and telomeres shorten with successive cell divisions. However, telomerase activity is detectable in immortal cells and in many human tumors. It was found that TE is sequestrated within the nucleolus during most of the cell cycle of normal cells and released into the nucleus only just before cell division. TE is not sequestrated in tumor cells and continually interacts with the chromosomes.
Aims: The aim of the study was to analyze NPM and TE immunocytochemical positivity in lymphoid cells and lymphocytes of patients with chronic lymphoid leukemia (CLL).
Methods: Immunocytochemical procedure was performed on cytological bone marrow (BM) specimens of five CLL patients and on effusion sediments in patient with benign reactive effusion lymphocytosis. Cytological specimens collected for immunostaining were obtained in patients at diagnosis, only as a part of standard diagnostic procedure and patients signed informed consent. Cytological specimens were stained with anti-NPM mouse monoclonal antibody (clone FC82291) raised against full length NPM, useful for identification of both wild-type and mutated NPM, and with anti-human goat polyclonal antibody (clone C-20) to TERT (telomerase reverse transcriptase). Immunostaining was further done with LSAB immuno peroxidase technique. NPM and TE nucleus immunopositivity was analyzed by microscope, determined were percentages of immunopositive cells, as well as score values od immunoreaction. Score values of NPM and TE immunopositivity were obtined by rating intensity of 100 cell immunopositivity using a scale of 0 to 4+ and then the number of cells counted in each cell rating is multiplied by the cell rating value and these values were summarized.
Results: Nuclei of almoust all CLL lymphoid cells were strongly NPM immunopostive (percentages median 100%, range 92-100%; score median 257, range 222-375). Telomerase was weakly immunopositive in most of nuclei of CLL lymphoid cells (percenatges median 74%, range 54-93%; score median 110; range 58-150). Opposite, in most of nuclei of reactive effusion lymphoid cells NPM was weakly positive (61%, score 91), and TE was completely negative. NPM and TE immunopostivity pattern in CLL lymphoid cells was different: TE was positive in form of fine small dots, and NPM was mostly positive in form of numerous coarse granules, coarse network or as diffuse coarse immunoreaction. Opposite, in most of benign reactive effusion lymphocytes NPM was weakly immunopositive in form of one fine dot.
Summary and Conclusions: In our five CLL patients most lymphoid cells were NPM and TE immunopositive, but in most of CLL lymphoid cells intensity of TE immunopositivity was weak in comparison to strong NPM immunopositivity. Moreover, benign reactive effusion lymphocytes were negative for telomerase and NPM was weakly immunopostive mostly in form of one fine dot. These results point that telomerase activity is very low and undetectable in benign lymphocytes and that NPM immunopositivity pattern is different in CLL lymphiod cells in comparison to benign reactive effusion lymphocytes. However, the number of analyzed patients is small and further analysis in larger groups of patients with CLL and patients with benign reactive effusion lymphocytes is needed to clearly determine NPM and TE cell immunopositivity differences between CLL lymphoid cells and benign lymphocytes.

PB1502

B CELL LYMPHOPROLIFERATIVE DISORDERS WITH CIRCULATING TETRAPLOID CELLS : FROM CYTOLOGY TO CYTOGENETIC

K Maloum[1,*] C Settegrana[1], E Chapiro[1], M Le Garff-Tavernier[1], A Cosson[2], V Leblond[3], F Davi[1], H Merle-Beral[1], F Nguyen-Khac[1]
[1]Service d'Hématologie Biologique, CHU Pitié-Salpêtrière, [2]UMRS 1138, Centre de Recherche des Cordeliers, [3]Service d'Hématologie Clinique, CHU Pitié-Salpêtrière, Paris, France

Background: Cytogenetic abnormalities are frequent and recurrent in B cell chronic lymphoproliferative disorders (BCLPD). Thus, in chronic lymphocytic leukemia (CLL), the most frequent recurring chromosomal aberrations include

trisomy 12 and deletions of 13q, 11q and 17p, the translocation t(11;14) is closely associated to mantle cell lymphoma (MCL) and t(14;18) is observed very frequently in follicular lymphoma. Some of these cytogenetic abnormalities can be predicted by the morphological aspects of the lymphoid cells, particularly in follicular lymphoma, MCL and CLL with trisomy 12. In MCL, tetraploid clones are more frequently observed in blastoid variant (36%) and pleomorphic variant (80%) (Ott, 1997). In CLL, Quijano et al (2008) showed, by using flow cytometry, DNA hyperdiploidy in 10 out of 180 CLL cases. However no cytogenetic analyses were performed to confirm the flow data. At this time, only few studies reported a correlation between hyperploidy and specific morphological aspects. Pui et al (1990) described a striking morphologic finding with the presence of clumped chromatin and grooved nuclei in acute lymphoblastic leukemia.

Aims: The aim of the study was to relate specific cytologic aspect to tetraploid cells and/or other cytogenetic abnormalities in 9 cases of BCLPD (6 CLL, 2 splenic marginal zone lymphomas (MZL) and 1 unclassified chronic lymphoproliferative syndrome) with peripheral blood circulating tetraploid cells.

Methods: Blood cell counts were performed using XE 2100 or XE 5000 (Sysmex, Japan) and Advia 2120 (Siemens, USA). Total white blood cells (WBC) and basophils are counted in a specific channel in which all WBC except basophils are lysed. Then, resistant cells are counted as basophils. Parallely, corresponding blood smears were performed and stained using the classical method of May Grunwald Giemsa. Microscopic analyses for leucocyte differential count and cytological analysis were performed by 2 different cytologists. Cytogenetic analyses were performed using conventional caryotype and fluorescence *in situ* hybridization (FISH).

Results: Results showed a good correlation between automated hematology analyzers, optical microscopy and cytogenetic studies for detecting tetraploid cells. Results are summarized in the following Table 1.

Summary and Conclusions: In conclusion, this report showed that tetraploidy is associated with a specific morphological aspect that could be suspected by using the hematologic analyzers and well recognized using optical microscopy. In addition, tetraploidy was closely associated with +12, del6q and t(14;19)

Seràgnoli" Bologna, Bologna, [17]UOC di Ematologia di Cosenza, Cosenza, Italy

Background: Recent trials have shown that the combination schedule of rituximab, fludarabine and cyclophosphamide as first-line therapy for chronic lymphocytic leukemia (CLL) patients improved progression free survival (PFS) and overall survival (OS). However, this therapy was associated with increased toxicity: 76% of the patients experienced at least one grade 3 or 4 event. Recently, encouraging clinical results have been obtained using bendamustine in combination with rituximab (R-B) in relapsed and/or refractory, as well as in untreated CLL patients in terms of safety and efficacy.

Aims: We performed a multicentre retrospective study to assess safety and efficacy of R-B in a large group of untreated CLL patients.

Methods: One hundred and eighteen untreated CLL patients satisfying the inclusion criteria were recruited from 11 Italian Institutions and included in the present analysis. The median age was 71 years (range 43–85), with 52% of patients older than 70 years; 51% of cases were male. All patients had active disease as defined by the NCI-WG, and 28% of patients were at Binet stage C at study entry. FISH data, available in 78/118 cases, identified a del(17p) in 6.4% of the patients and del(11q) in 10.3%. Fifty-four patients (46.0%) had a creatinine clearance ≤70 mL/min and 41.5% of the cases showed an elevated lactate dehydrogenase (LDH) value. Fifty-five% of cases showed a WHO performance status (PS) of I-II and 62% a CIRS comorbidity index >0.

Results: Among the 118 patients, 80 cases (68%) received B at the dosage of 90 mg/m^2 on day 1 and 2 every 28 days, the remaining 38 cases received B at the dosage of 70 or 80 mg/m^2. R was administered at the dosage of 375 mg/m^2 on day 1 of all cycles in 59% of cases, while 41% received 375 mg/m^2 on day 1 of first cycle and 500 mg/m^2 on day 1 of the other cycles. A total of 582 cycles were administered with a median number of 4 cycles per patient. Thirteen patients (11%) required early discontinuation of therapy before the sixth cycle for: serious infections (n=6), persistent hematological toxicity (n=3), grade 4 dermatological toxicity (n=2) and withdrawal of consent (n=2). Grade 3 or 4 adverse events for neutropenia, thrombocytopenia, and anemia were documented in 16.1%, 27.1%, and 16.1% of patients, respectively. Grade 3 or 4 severe infections occurred in 6.8% of patients. Out of 93 cases evaluable for response, 64 patients (69%) achieved a complete response (CR), 25 (27%) a partial response (PR) and 4 (4%) a stable disease (SD). Of the clinical and biologic parameters only, age <70 years (P<0.0001), WBC <50x10^9/L (P=0.038) and creatinine clearance >70 ml/min (P<0.0001) were statistically associated with achievement of CR. High-risk FISH (del11q and del17p), as well as PS and CIRS CI >0 did not impact on achievement of CR. After a median follow-up of 8 months, 2-year PFS was 87% and 2-year OS 80% (10 deaths occurred). Five of 10 deaths were CLL-related (infections in 4 cases due to infections and disease progression in 1).

Summary and Conclusions: The clinical practice of the Italian centers taking part in the study confirms that chemoimmunotherapy with R-B was an effective and well-tolerated treatment for untreated CLL patients, producing a remarkably high CR rate and mild toxicity.

PB1504

BENDAMUSTINE-BASED FIRST LINE THERAPY IN CHRONIC LYMPHOCYTIC LEUKEMIA (CLL) IN ROUTINE CLINICAL PRACTICE: INTERIM ANALYSIS OF THE GERMAN NON-INTERVENTIONAL STUDY BE-CELL1ST

HR Bruch[1,*] A Aldaoud[2], M Klausmann[3], R Hansen[4], C Losem[5], M Frank[6], L Strassl[6], K Ruffert[7]
[1]Schwerpunktpraxis Bonn, Bonn, [2]Dr. Aldaoud-Dr. Schwarzer Forschungsgesellschaft mbH, Leipzig, [3]Gemeinschaftspraxis Hämatologie/Onkologie, Aschaffenburg, [4]Onkologische Schwerpunktpraxis, Kaiserslautern, [5]Praxis für Onkologie und Hämatologie, Neuss, [6]iOMEDICO, Freiburg im Breisgau, [7]Eps - early phase solutions GmbH, Poessneck, Germany

Background: Bendamustine is an established treatment option in chronic lymphocytic leukemia (CLL) and frequently used in Germany. Current guidelines recommend a Bendamustine-based therapy in patients (pts) at Binet stage C or at Binet stages A (not covered in product label) and B with symptomatic disease and notably physically non-fit pts. In addition to results from clinical trials Be-CeLL1st reveals treatment modalities and outcome of Bendamustine-based therapy of CLL in daily practice in Germany.
Aims: This trial is conducted to gain further insight into therapy modalities, efficacy and safety of Bendamustine treatment in non-selected patients treated in clinical routine in Germany.
Methods: A total of 400 B-CLL patients are to be enrolled over a period of 43 months at about 70 study centres. Interim results of more than 200 pts are presented. The documentation covers patient demographic and tumor characteristics, treatment modalities, side effects and investigator assessed response evaluation (best response). Main entry criteria are indication for 1st-line therapy with Bendamustine, no pre-treatment with Interferone or Rituximab, unsuitability for Fludarabine-based therapy and absence of contraindications according to the market authorisation for Bendamustine.

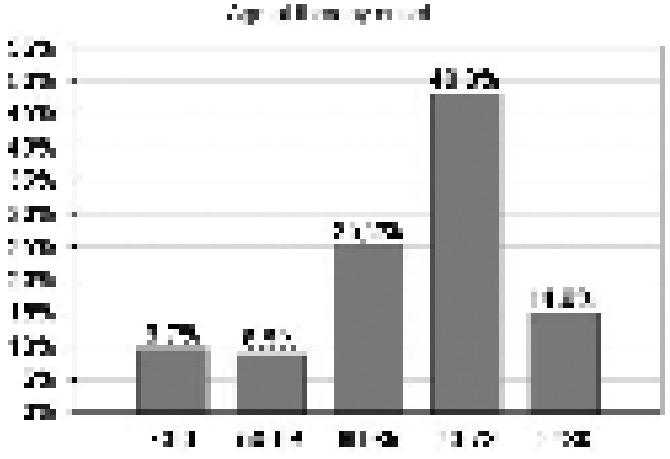

Figure 1.

Results: 264 pts were registered from 10/2011 until 12/2013. 202 pts were enrolled at least 6 months before data cut-off and were analyzed with regard to treatment modalities and efficacy. For safety, data of 253 pts with at least one documented treatment cycle were evaluated. Patients had a median age of 73 years (32-90 years) and performance status ECOG 1. 63% were 70 years or older. 65% of pts were male. 26% of pts presented B-symptoms. Tumor stages were 21% Binet stage A, 44% Binet B and 31% Binet C. CIRS-Score was ≤ 6 in 87% and > 6 in 13% of pts. The majority of pts (90%) was treated with the combination of Bendamustine and Rituximab, complemented by steroids in 3% of these pts. 7% of pts received Bendamustine monotherapy and 3% other combinations. Median time to treatment from primary diagnosis was 25 months. Most pts received Bendamustine on day 1 and 2 of the cycle (83%). In 10% of pts, Bendamustine was administered once per cycle only. The median treatment duration was 6 cycles (Bendamustine monotherapy: 3 cycles). The median dose of Bendamustine was 174 mg/m^2 per cycle. Median dose intensity was 38 mg/m^2 per week. At least one dose modification occurred in 36% of pts. Therapy was delayed at least once in 45% of pts. The most common reasons for therapy modification were side effects and comorbidities. In 16 pts (6%) side effects led to therapy discontinuation. Overall response rate (ORR) for evaluable pts (n=158) was 89% (complete response 38,6%, partial response 50,6%, stable disease 7,6%, progressive disease 3,2%). In 124 of 253 pts (49%) a total of 313 side effects were documented (all grades). Most frequent side effect was neutro-/leukopenia (25%). A total of 61 grade 3/4 adverse events (19%) occurred in 36 pts (14%). Serious adverse reactions occurred in 24 pts (10%). One fatal outcome was reported (sepsis).
Summary and Conclusions: The interim data of Be-CeLL1st shows that Bendamustine (+/- Rituximab) is an effective and safe treatment option for patients with B-CLL in daily clinical routine. These data seems to be in line with efficacy and safety data from recent clinical trials and demonstrates the broad applicability of Bendamustine (+/- Rituximab) in 1st-line CLL also in a wider, non-selected patient population.

PB1505

AN UPDATE ANALYSIS OF RITUXIMAB BASED CHEMOTHERAPY IN CHRONIC LYMPHOCYTIC LEUKAEMIA PATIENTS: AN INDIAN SCENARIO

A Gogia[1,*] V Raina[1]
[1]All India Institute Of Medical Science, Aiims, New Delhi, India

Background: Rituximab (Anti- CD 20) has been reported to be an effective drug for the treatment of chronic lymphocytic leukaemia (CLL) with combination of fludarabine and bendamustine. Its safety and efficacy in Indian patients has not been studied.
Aims: We carried out analysis of 111 patients of CLL who received two different regimen FCR (fludarabine , cyclophosphamide, and rituximab) and BR (bendamustine and rituximab) for treatment of CLL in upfront and relapsed setting at I.R.C.H, AIIMS, New Delhi, India.
Methods: The records of all patients (N=360) with diagnosis of CLL between January 2000 and December 2013 were analysed. Rituximab was used in only 19% of cases (N=70, upfront) in combination ,due to financial constraints. Response evaluation was done as per the National Cancer Institute-Working Group guidelines, in those patients who received at least 3 cycles of chemotherapy. Toxicity was graded as per the common terminology criteria for adverse events, version 3.0. Median event-free survival was obtained using Kaplan-Meier survival analysis. Events were described as relapse, progression and death due to any cause.
Results: One hundred eleven patients (70-upfront/de novo, 41 relapsed) were included in the study and 421 cycles were administered (median: 3 cycles per patient). Fifty five patients received FCR and 55 received BR . Thirty five had treatment delay in FCR and 6 patients in BR subgroup due to prolonged myelosuppression. The complete (CR), partial (PR) and overall response rate (ORR) of FCR and BR was 43%, 43%, 86% and 40%, 50%, 90% respectively those treated upfront . ORR was 50% in those with relapsed disease in both subgroup. Grade 3/4 myelosuppression occurred in 65% with FCR and 20% with BR. One third patients had developed overt tuberculosis during treatment period or subsequent follow-up in patients who received FCR . Four patients died of pneumocystis jiroveci carinii pneumonia (PCP) in FCR group. Median event-free survival for patients treated upfront with FCR was 30 months and BR was not achieved.
Summary and Conclusions: In our patient population, response to FCR and BR is same and similar to that in the published literature but toxicity profile is different. Prolonged myelosuppression (two third of patients leads to treatment delay) and tuberculosis (one third of patients) in FCR regimen. BR is better option to treat CLL patients in our group of population where the prevalence of subclinical tuberculosis is high.

PB1506

LONG-TERM FOLLOW-UP OF A COHORT OF PATIENTS WITH RELAPSED/REFRACTORY CHRONIC LYMPHOCYTIC LEUKEMIA TREATED WITH LOW-DOSE ALEMTUZUMAB

M Sciumè[1], D Vincenti[1], G Reda[1], F Guidotti[1], D Giannarelli[2], A Cortelezzi[1*]
[1]Hematology and Transplantation Unit, Foundation IRCCS Ca' Granda Ospedale Maggiore Policlinico and University of Milan, Italy, Milan, [2]Biostatistics Unit, Regina Elena Institute for Cancer Research and Treatment, Rome, Italy

Background: Chronic lymphocytic leukemia (CLL) is a heterogeneous disease with a variable clinical course. Despite the use of highly effective chemo-immunotherapy, CLL remains incurable. Alemtuzumab has been found to be effective in CLL as both front-line and salvage therapy, also in patients (pts) with worse prognosis carrying 17p deletion and/or TP53 mutations.
Aims: We report long-term results of efficacy and tolerability of low-dose subcutaneous alemtuzumab therapy in pts with relapsed and/or refractory CLL treated at our institution.
Methods: Pts with active relapsed and/or refractory CLL treated with low-dose alemtuzumab were evaluated. Alemtuzumab was administered subcutaneously at the dose of 30 mg weekly for 18 weeks with a maximum cumulative dose of 540 mg.
Results: Sixty-two consecutive pts, treated between January 2003 and June 2013 at our Centre, were included in the analysis. The median age was 68

years (40-83), 26 (42%) pts were older than 70 years. FISH analysis and IGHV mutational status were performed in 52 and 26 pts, respectively. Twelve (23%) pts showed del(11q), while 14 (27%) pts had del(17p); 18 (69%) pts had unmutated IGHV genes. Twenty-six (42%) pts were exposed to fludarabine, single agent or in combination, and 57% of pts were pretreated with at least 2 lines of therapy. Thirty-five (57%) pts concluded the scheduled 18 weeks of treatment; median administered dose was 510 mg. Overall response rate was 62% (95% CI, 49%>73%), with 26% of complete responses. After a median follow-up of 40 months (2-128), median overall survival (OS) was 40.6 months (95% CI, 34.1-52.1) and median progression free survival (PFS) was 16 months (95% CI, 9.8 -22.9). None of prognostic markers or pre-therapeutic parameters was predictive for inferior response. In multivariate analysis, OS was significantly associated only with ZAP-70 expression (p0.004) and PFS with bulky disease (p0.03), CD38 expression (p0.03) and response (p<0.0001). Twenty-two pts of our cohort were fludarabine refractory. These pts had a median OS of 29.5 months (95% CI, 23.8-35.1), 10 obtained at least a PR and 4 are still alive with a survival longer than 36 months. In our analysis, we identified a subset of 34 pts with an OS longer than 36 months from the start of therapy. Their median age was 68 years (40-79). Sixteen (47%) pts were treated with at least 2 lines of therapy and 7 (25%) pts carried del(17p). In multivariate analysis, long-term survival was associated with ZAP-70 expression (p 0.03) and obtained response (p 0.02). Fifteen percent of long-term survivors was pretreated with fludarabine *versus* 39% of no long-term survivors (p 0.03); 6% had lymph-node ≥ 5 cm *versus* 25% (p 0.03); 46% were ZAP-70 positive *versus* 83% (p 0.007); 29% were CD38 positive *versus* 61% (p 0.02); 35% had Binet stage C *versus* 50% (p 0.02). Hematologic toxicities were the most common adverse events. Forty-nine (79%) pts showed peripheral blood cytopenia, but this was grade 3 or greater in 15 (24%) pts. The main non-hematologic adverse effects were CMV reactivation (31%) and non-CMV infections (19%), which together were the main reasons for treatment interruption and/or premature termination. Grades 3 or 4 non-CMV infection occurred in only 4 (7%) pts, while no one had grades 3 or 4 CMV events.

Summary and Conclusions: Low dose subcutaneous alemtuzumab showed a good tolerability and long-term efficacy. We emphasize that alemtuzumab still remains a valid therapeutic option in subsets of relapsed/refractory CLL pts.

PB1507

EXTENDING THE MATUTES' SCORE FOR DIAGNOSIS OF CHRONIC LYMPHOCYTIC LEUKEMIA: THE ROLE OF NEW MARKERS

I Lorand-Metze[1,*] PO Percout[1], FG Pereira-Cunha[2], GB Oliveira-Duarte[2], K Metze[3]
[1]Internal Medicine, [2]Hematology/Hemotherapy Center, [3]Pathology, University of Campinas, Campinas, Brazil

Background: the diagnosis of chronic lypmhocytic leukemia (CLL) is based on data of peripheral blood (PB) counts and immunophenotyping. Due to frequent occurrence of cases with atypical morphology and abnormal phenotypes, the Matutes' score has been established for the differential diagnosis between CLL and other leukemic mature B-cell neoplasms, but even this score takes into account the variability of phenotypic features. So, the utility of new markers have been tested in the last years.
Aims: we examined the relation between the amount of atypical lymphocytes in PB and the occurrence of abnormal phenotypes in CLL. We also tested how the addition of more markers to the Matutes' score could improve the accuracy of the differential diagnosis between CLL and other leukemic mature B-cell neoplasms.
Methods: we examined 75 consecutive cases of PB lymphocytosis entering our Laboratory between june 2012 and November 2013. PB lymphocyte morphology was analyzed. For immunophenotyping, a four color panel of monoclonal antibodies was used. Diagnosis was confirmed by histology of bone marrow or lymph node whenever necessary.
Results: the final diagnosis of CLL was made in 62 cases. Besides, there were 4 cases of mantle cell lymphoma (MCL), 3 cases of lymphoplasmacytic lymphoma (LPL) and 6 cases of splenic marginal zone lymphoma (MZL). For CLL cases, median age: 68 years (45-88); median PB lymphocyte count: $16.9x10^9$/L (5.8-141.6); atypical lymphocytes: median 12% (3-37), prolymphocytes: median: 2% (0-10). Matutes' score was 5 in 14 cases; it was 4 in 31 and 3 in 17 cases. Concerning other markers, expression of CD200 had a median MFI of 129, 163, 7 and 32 respectively for CLL, LPL, MCL and MZL. CD19 had a median MFI 162, 321, 113 and 259 respectively for CLL, LPL, MCL and MZL, and CD20 had a median MFI of 229, 1263, 812 and 1718. In CLL, there was an inverse correlation between the IMF of CD200 and the percentage of atypical lymphocytes (r = -0.34; p=0.003) and prolymphocytes (r = -0.327 p=0.01). In a discriminant analysis using the IMF of CD19 in CLL), CD20 and CD200, the predictive value for CLL x non-CLL was 97%.
Summary and Conclusions: the intensity of expression of CD19, CD20 and CD200 can increase the diagnostic accuracy in atypical cases of CLL.

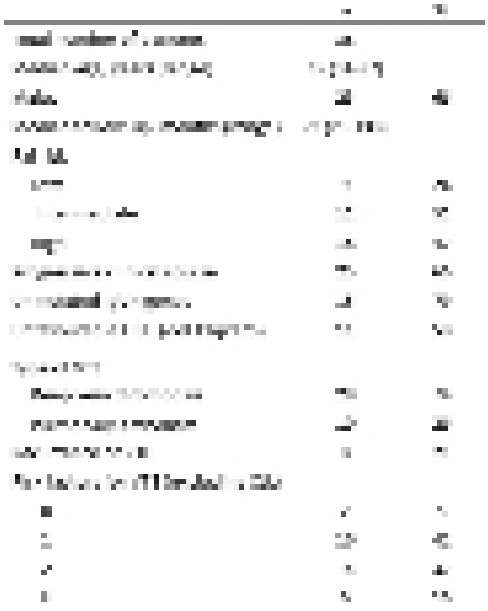
PB1510

VENOUS THROMBEMBOLISM: A FREQUENT COMPLICATION IN CHRONIC LYMPHOCYTIC LEUKEMIA

P Vodarek[1], M Simkovic[1], M Motyckova[1], D Belada[1], L Smolej[1*]
[1]4th Department of Internal Medicine - Hematology, University Hospital and Charles University Faculty of Medicine, Hradec Kralove, Czech Republic

Background: Venous thromboembolism (VTE) is a major cause of morbidity and mortality in patients with malignant tumors. Increased risk of VTE is well described in a variety of hematologic malignancies , especially in myeloproliferative disorders, plasma cell malignancies, and lymphomas. However, data regarding risk of VTE in chronic lymphocytic leukemia (CLL) is very scarce. A recent study (Whittle *et al.*, Leuk Res 2010) reported high incidence of TEN in CLL patients compared with the general population.
Aims: To evaluate the occurrence and risk factors of VTE in patients with CLL.
Methods: We retrospectively analyzed clinical and laboratory data of consecutive patients (pts) with CLL followed up at 4th Department of Internal Medicine – Hematology, University Hospital, Hradec Kralove, diagnosed between 1999 and 2013. In all, 346 patients were analyzed (222 males; median age at diagnosis, 64 years; low/intermediate/ high Rai modified risk in 41/47/12%). Only patients with radiologically confirmed deep vein thrombosis (ultrasonography) or pulmonary embolism (computer tomography) developed after diagnosis of CLL were considered as having VTE.
Results: After a median follow-up of 72 months (range, 26-138), at least one episode of VTE occurred in 38 patients (11%). Basic characteristics are listed in Table 1. VTE developed after with a median of 34 months since CLL diagnosis. There was a high proportion of unfavourable prognostic factors (advanced Rai stages, unmutated IgVH genes, unfavourable cytogenetics). There was no association of VTE with hyperleukocytosis or other parameters of blood count. An apparent precipitating factor for VTE was present in 4 patients (acute infection). The presence of 0/1/2/3 risk factors for VTE was identified in 2/16/14/6 patients. Seventeen pts were previously untreated for CLL; 14 cases of VTE occurred during treatment for CLL and 7 cases after CLL treatment. The most common risk factors for VTE besides age (n=24) were corticosteroid therapy (n=13), other malignancies (n=9) and obesity (n=7). Recurrence of VTE was diagnosed in 8 pts (21%). Overall survival of patients who developed VTE was not different from those without VTE.

Table 1.



Summary and Conclusions: Based on our results, VTE is a relatively frequent complication in patients with CLL. Although most patients had other known risk

factors for VTE including treatment of CLL, 29% had no risk factors or only age≥ 65 years. These findings support the role of CLL in the development of VTE. Updated data will be presented.

PB1511

THE ROLE OF SERUM FREE LIGHT CHAINS IN PROGNOSIS OF CHRONIC LYMPHOCYTIC LEUKEMIA

E Zotina[1,*] T Zagoskina[1], N Panihina[1], T Koryakovtseva[1]
[1]Kirov Research Institute of Hematology and Blood Transfusion, Kirov, Russian Federation

Background: Currently, serum free light chains (sFLC) are considered as an additional factor that can more accurately predict the course of chronic lymphocytic leukemia (CLL) and response to therapy.
Aims: Evaluate the prognostic value of sFLC in patients (pts) with CLL and identify an association with unfavorable prognostic factors.
Methods: The study involved 153 pts with newly diagnosed CLL at the age of 33-75 years (a median age – 59 years). Among the pts were 90 men and 63 women. In 64 (42%) pts stage A was established, in 63 (41%) pts – stage B and 26 (17%) pts – stage C by Binet. Concentration of sFLC (kappa and lambda) was determined by immunoturbidimetric method with the help of reagent kits «Freelite». At the time of diagnosis the expression level of Zap-70 by flow cytometry, was investigated, the cut-off level of the positive expression of ZAP-70 was 20%. The content of serum thymidine kinase (TK) was determined by a radioenzyme method.
Results: In 80 (52%) pts normal sFLC ratio was detected. In 73 (48%) pts abnormal sFLC ratio was revealed due to the predominance of one of the chains, moreover, there were 15 (10%) pts there with an increased production of the set of lambda chain, and in 58 cases (38%) the kappa chain was found. Median follow-up was 32 months. In pts with abnormal sFLC ratio median time from diagnosis to first treatment was significantly shorter than in pts with normal sFLC ratio (3 months *vs.* 26 months, respectively, p<0.001). In this case a correlation of abnormal sFLC ratio with the known unfavorable markers of the course CLL was revealed: positive expression of ZAP-70 (r=0.323; p=0.019) and the level of serum TK ≥ 20 U/L (r=0.386; p=0.027). Furthermore, it is found that the response to immunochemotherapy of FCR (fludarabine, cyclophosphamide, rituximab) depended on the sFLC ratio. Thus, in pts with normal sFLC ratio complete remission (CR) was achieved in 78 (98%) pts, partial remission (CR) – in 2 (2%) pts. Whereas in pts with an abnormal sFLC ratio CR was achieved in 22 (30%) pts, PR – in 41 (56%) pts and 10 (14%) pts were non-responders (p<0.001).
Summary and Conclusions: Production of light chain of kappa or lambda in CLL pts associates with positive expression ZAP-70, high serum TK, rapidly progressive course of the disease and low response to treatment. Determination of sFLC ratio can be used as an additional criterion for prognosis of CLL.

Background: In the last decade, fludarabine+cyclophosphamide+rituximab (FCR) has become the standard first-line treatment for young fit CLL patients, showing great unprecedented efficacy, but also relevant treatment-related toxicities. Though a number of approaches, considering age, comorbidities and organ impairment, have been proposed in clinical trials to define the most appropriate group of patients who can benefit from FCR, none has been specifically validated and little is known on how CLL patients should be managed at best in the daily clinical practice.
Aims: We designed an investigator-driven multicenter retrospective observational non-interventional study in order to collect data on the criteria applied in the clinical practice when selecting first-line treatment for CLL patients and on the outcome in terms of tolerance and toxicities to the initial therapy. The primary objective of the study is to define the most relevant parameters influencing physician's choice and their correlation with treatment tolerance. The most reliable factors will be included in a "Fitness score" that could become the basis for a prospective study aiming at validating its use in day to day clinical practice.
Methods: The study is based on a retrospective data collection from the medical records of consenting patients treated by participating centers. Patients enrolled into the study had previously untreated CLL requiring first-line treatment between January 1st, 2009 and December 31, 2010. The accrual just started and will be completed by Spring 2014, reaching a study target population of 700 subjects.
Results: Thirty-seven Italian sites with long-standing experience in CLL patient management were invited to participate in the study. The main requested clinical information includes anthropologic parameters, global health status, disease information, biological parameters, treatment and follow-up data.
To date, 104 patient records were reported in the dataset. Median age at time of first treatment was 66 years (39-90), 35 were females and 69 males. Reasons for starting treatment were reported as follows: increased lymph nodes (50%), lymphocyte doubling time <6 months (40%), massive splenomegaly (25%), bone marrow failure (27%), autoimmune phenomena not responsive to steroid treatment (3%). The most frequent first line treatment options included: FCR (43%), alkylating agent (22%), alkylating agent+purine analog (15%), alkylating agent+anti-CD20 antibody (13%), other combinations (7%). Thirty-five percent of patients were enrolled in clinical trials. Treatment choice was based on age (relevant parameter in 99% of the cases), comorbidities (98%), functional (82%), performance (80%), and mental (79%) status, need for caregiver (68%) and polypharmacy (65%). Biological factors (*e.g.* IGHV, FISH and CD38) influenced treatment decision in 39%of cases. Thirty-nine percent of patients experienced grade 3-4 adverse events (AEs), with only 1 patient experiencing a fatal AE. The most frequent grade 3-4 AEs were represented by neutropenia (22%), thrombocytopenia (3%), anemia (2%), infusion-related reactions (2%).
Summary and Conclusions: Our study is shedding light on the criteria considered most relevant in the clinical practice and will identify those that more significantly associate with a reduced tolerance to intensive treatments like FCR. This knowledge will allow to develop a comprehensive index of the patient's fitness status towards chemoimmunotherapy, helping the physicians to better stratify patients in order to maximize benefits and avoid potentially harmful overtreatment.

CENTRAL SCREENING ENABLES IDENTIFICATION OF HIGH RISK CLL PATIETNS FOR LENALIDOMIDE MAINTENANCE THERAPY WITHIN THE CLLM1 TRIAL OF THE GERMAN CLL STUDY GROUP

K Loeschcke[1,*] A Fink[1], J Bahlo[1], A Westermann[1], A Zey[1], K Fischer[1], CM Wendtner[1, 2], T Noesslinger[3], P Ghia[4], F Bosch[5], A P Kater[6], KA Kreuzer[1], S Stilgenbauer[7], S Boettcher[8], B Eichhorst[1], M Hallek[1]
[1]Department of Internal Medicine and Center of Integrated Oncology Cologne Bonn, University Hospital , Cologne, [2]Department of Hematology, Oncology, Immunology, Palliative Care, Infectiology and Tropical Medicine, Hospital Munich-Schwabing, Munich, Germany, [3]3rd Department for Hematology and Oncology, Hanusch Hospital, Vienna, Austria, [4]Department of Onco-Hematology, Ospedale San Raffaele and Università Vita-Salute San Raffaele, Milano, Italy, [5]Department of Hematology, University Hospital Vall d'Hebron, Barcelona, Spain, [6]Deptartment of Hematology, Academic Medical Center Amsterdam, Amsterdam, Netherlands, [7]University of Ulm, Ulm , [8]Campus Kiel, 2nd Dept. of Internal Medicine, University of Schleswig-Holstein, Kiel, Germany

Background: Long lasting remissions can be achieved with first-line chemoimmunotherapy (FCR or similar regimens). Research now focuses on the attainment of more durable remissions. In general, a response duration of less than 24 months is regarded as unsatisfactory for patients who received chemoimmunotherapy. Identifying patients with a high likelihood for early relapse after intensive therapy is particularly important since they might be candidates for maintenance and consolidation strategies.
Aims: Based on an analysis of data of the CLL8 trial of the German CLL Study Group a subset of CLL patients was observed with a high risk for early relapse after first-line therapy (median progression free survival of 22 months) and also

a considerably shorter overall survival. These patients can be defined by the presence of minimal residual disease (MRD) levels of ≥10^{-2} or a combination of MRD levels of ≥10^{-4} to <10^{-2} with either an unmutated *IGHV* status, del(17p) or TP53 mutations. CLLM1 is a phase 3, randomized, placebo-controlled study investigating the efficacy and safety of lenalidomide as maintenance therapy for high risk patients with chronic lymphocytic leukemia (CLL) following first-line therapy.
Methods: For identification of high risk patients central screening procedures prior to randomization are performed. Inclusion and exclusion criteria including patients' comorbidities based on the Cumulative Illness Rating Scale, the need of treatment, ECOG performance status and disease stage are centrally reviewed. In addition blood samples are to be sent to the central laboratories to confirm the diagnosis of CLL and to assess cytogenetic aberrations prior to start of first-line therapy. After first-line therapy MRD levels are centrally analyzed. A repeated central review covers the final risk assessment of all risk factors and eligibility, in particular response to first-line therapy and the ability to receive the maintenance treatment. Each patient provided written informed consent before enrolment.
Results: Between July 2012 and February 2014 442 patients were registered. 31 (7.0%) patients were excluded before start of first-line treatment due to other B-cell lymphoma (14/3.2%), withdrawal of consent (4/0.9%), comorbidities (2/0.05%), Hep B infections (2/0.05%) and other reasons (9/2.0%). 72 patients failed to proceed after first-line therapy due to patients' decision (34/47.2%), physicians decision (4/5.6%), non response to first-line (4/5.6%), death (3/4.2%) or other reasons (32/44.4%). A site survey using a questionnaire completed by the treating physicians revealed that the main reasons for patients' withdrawal have been tiredness of treatment, concerns regarding the study drug and frequent visits for maintenance therapy. 171 pts were screened after responding to therapy with FCR (86/ 50.3%), BR (82/ 48.0%) or other (3/1.7%). 130 (76.0%) of them were identified as low risk patients. 36 pts (21.1%) were randomized to receive study drug so far.
Summary and Conclusions: The screening process supports the identification of eligible high risk patients and allows a risk adapted approach to maintenance therapy.

PB1515

EFFICACY OF SPLENECTOMY IN CHRONIC LYMPHOCYTIC LEUKEMIA ASSOCIATED WITH IMMUNE CYTOPENIAS

Y Vyhovska[1,*] Y Yevstakhevych[1], I Yevstakhevych[1], O Vygovska[1], G Diakiv[1], V Loginsky[1]
[1]SI "Institute of Blood Pathology and Transfusion Medicine, NAMS of Ukraine", Lviv, Ukraine

Background: Autoimmune hemolytic anemia (AIHA) and immune thrombocytopenia (ITP) complicate the course of chronic lymphocytic leukemia (CLL) in 15-25% of patients. In case of ineffective steroid-based and chemotherapy and in the presence of overt splenomegaly, splenectomy is performed in such patients.
Aims: To analyze retrospectively the efficacy of splenectomy in patients with CLL associated with AIHA and/or ITP.
Methods: Splenectomy has been undertaken in 40 patients with CLL. In 25 (62.5%) of them, immune cytopenias were diagnosed: AIHA warm type in 10 (25%), ITP in 11 (27.5%), and AIHA + ITP in 4 patients (10%). The patients were under observation during 4-324 months after splenectomy.
Results: In 8 patients with CLL complicated by AIHA, splenectomy proved to be effective. A large tumor mass has been removed, and hemolysis has been ceased. An immediate postoperative death was stated in two patients due to an acute adrenal insufficiency and acute liver impairment, respectively. The median post-splenectomy survival reached 51.2 months. In all 11 patients with CLL and ITP, a normalization of platelet number after splenectomy was noted. One patient died due to disease progression at 2 months following surgery (having a normal platelet count). The median survival in those patients was 113.1 months. In 4 patients, CLL was associated with both AIHA and ITP. Two patients died due to disease progression within a year following splenectomy; one patient had been alive for 21 month; another one has been living 168 more months after surgery. The median survival in that group of patients was 49.1 months.
Summary and Conclusions: Splenectomy is an effective treatment option in CLL associated with overt splenomegaly and immune cytopenias. Presence of AIHA and/or ITP is found to be an additional risk factor of surgical intervention.

PB1516

SECONDARY MALIGNANCIES IN CHRONIC LYMPHOCYTIC LEUKEMIA: OUR EXPERIENCE.

E Madonna[1,*] L Simeone[1], M Raimondo[1], C Cerchione[1], A De Renzo[1], F Chiurazzi[1], F Pane[1]
[1]Division of Hematology, Department of Clinical Medicine, Federico II University, Naples, Italy

Background: There is a general consensus in the literature that the risk of developing a second cancer (SC) is increased in those patients with chronic lymphocytic leukemia (CLL), regardless of treatment. Several mechanism have been discussed for the association between CLL and SC, including disease- and treatment- immunosuppression and shared risk factors.
Aims: We evaluated a small group of patients with diagnosis of CLL and a secondary primary solid neoplasia; we recognized some elements that could be important to make a CLL profile (RAI STAGE, treatment-related immunosuppression) in order to increasing surveillance for an early detection and/or prevention of SC.
Methods: We evaluated at the Division of Hematology of Federico II University in Naples, between 1980 and 2013, n= 476 patients with CLL; 2.7% (F=2 and M= 11) of these, with a median age (yrs) of 64.5 at the diagnosis of CLL, developed a SC. We observed a total of n= 14 SCs (5 non -melanoma skin cancers; 2 gastrointestinal cancers; 3 lung cancers; 1 prostate cancer and 3 bladder cancers): the real incidence was difficult to assess because many patients were lost in follow-up; in 4/13 patients chemotherapy free, we observed 1 lung adenocarcinoma stage IV, 2 urothelial carcinoma G1 and G3, 1 gastric cancer, with a median interval (yrs) between first and second diagnosis of 6.5; 1 patient died 2 months later the diagnosis of lung cancer, at the age of 70 years old. 9/13 patients, on the other hand, received different chemotherapy treatment as first line: fludarabine-based (n=7) and chlorambucil (n=2). Median interval between first and second diagnosis was 5.5 and between the first line treatment and the diagnosis of a SC was 5 years; in this group we observed: 6 skin-cancers (3 basocellular carcinoma, 1 squamous carcinoma, 1 Kaposi's sarcoma), 2 non small cell lung cancer stage IIIA, 1 colorectal cancer stage IIA, 1 urothelial cancer, 1 prostate cancer; one patient presented with the coexistence of 2 different cancer (prostate and skin).
Results: There was an excess in patients with a RAI STAGE IV at diagnosis (43.8% IV, 7.1% III, 14.2% II, 21.4% 0). Smokers in the chemotherapy free group were 15%, and 31% into the other one; 43% of all patients were positive for Hepatitis virus C.
Summary and Conclusions: In our patients with CLL we observed first of all an excess of skin malignancies in the subgroup of treated patients; median interval between first and second diagnosis (5.5 *vs* 6.5 years) was inferior in the treated group, regardless of the histotype of the SC. We observed an increased number of SCs in the subgroup of patients with a RAI STAGE IV, all treated with at least one chemotherapy cycle, and we concluded that there was a very important bias related to a prevalence of advanced stage requiring inevitably a treatment: further research in this area will be necessary to understand the real influence of the chemotherapy. In conclusion, it's important for physicians to be alert to the occurrence of SCs especially whether new symptoms or physical findings arise. This surveillance and a correct cancer screening seems to be important first of all for patients with a RAI STAGE IV at diagnosis.

PB1517

STRATIFICATION MODEL OF PATIENTS WITH CHRONIC LYMPHOCYTIC LEUKEMIA

T Zagoskina[1,*] E Zotina[1], V Shardakov[1]
[1]Kirov Research Institute of Hematology and Blood Transfusion, Kirov, Russian Federation

Background: The pathogenesis of chronic lymphocytic leukemia (CLL) is complex and not completely understood. Currently, interaction aspects of leukemic cells, reflecting their cells' proliferation, survival and resistance to the effects of pro-apoptotic signals play a significant role in it. It is known that the characteristics of the heterogeneous clinical course of CLL depend on a series of prognostic factors, reflecting proliferative activity, apoptosis, and mutation status of tumor cells. The question about the stratification of CLL patients (pts) into risk groups at the time of diagnosis, with a value in predicting the course of the disease and in the selection of program of therapy remains unresolved.
Aims: Develop a model of stratification of CLL pts based on biological markers of tumor cells.
Methods: The study involved 230 pts with a newly diagnosed CLL at the age of 35-79 years (a median age – 59 years). In 81 (35%) pts stage A was established, in 120 (52%) pts – stage B and in 29 (13%) pts – stage C by Binet. Status by ECOG was from 0 to 3 points. At the time of diagnosis the expression level of ZAP-70, Bcl-2 and Ki-67 in tumor cells clone was investigated by flow cytometry. The cut-off level of the positive expression of Zap-70 was 20%. The content of serum thymidine kinase (TK) was determined by a radioenzyme method. Enzyme content which was twice as large as the maximum rate of its normal level (20 U/l) was used as a threshold value of TK.
Results: Depending on the presence of biological markers of tumor cells all CLL pts were divided into 3 risk groups. The low-risk group consisted of pts with negative expression of ZAP-70, Bcl-2 < 30% and Ki-67 < 10% and the level of serum TK < 20 U/l. The intermediate-risk group included pts with positive expression of Zap-70 and the presence of one or two of the following factors:

Bcl-2 ≥ 30% but < 50%, Ki-67 ≥ 10% but < 15%, level of serum TK ≥ 20 U/l. The high-risk group included pts with positive expression of Zap-70, Bcl-2 ≥ 50%, Ki-67 ≥ 15% and the level of serum TK ≥ 20 U/l, *i.e.* with the presence of all four factors. The median of overall survival in the low-risk group was 113 months, in the intermediate-risk group – 73 months and in the high-risk group – 48 months (p=0.027 and p=0.019, respectively). Median time from diagnosis to first treatment was significantly shorter in the high-risk group than in the intermediate and low risk ones (1.4 months *vs.* 11 months, p=0.012; 1.4 months *vs.* 28 months, p=0.004, respectively).

Summary and Conclusions: The results showed that the model stratification of CLL pts, including Zap-70, Ki-67, Bcl-2 and serum TK, predicts the indolent or progressive course of the disease, overall survival that have significance for choosing a therapy program.

PB1518

RISK STRATIFICATION OF CHRONIC LYMPHOCYTIC LEUKEMIA ACCORDING TO THE NUMBER OF FACTORS OF POOR PROGNOSIS

M Alpoim[1,*] C Fernandes[2], T Garrido[1], A Carneiro[1], J Aguiar Andrade[1], JE Guimarães[1]

[1]Hematology Department, [2]Centro Hospitalar de São João, Porto, Portugal

Background: Chronic lymphocytic leukemia (CLL) is one of the most common adult leukemia, presenting a remarkably variable clinical course. The Rai and Binet staging systems have been used to risk-stratify patients; however, for each stage there is still heterogeneity in the clinical evolution. In addition to factors used in clinical staging, several other patient characteristics and laboratory tests have been correlated with overall survival.

Aims: Risk stratification of CLL according to the number of factors of poor prognosis.

Methods: We retrospectively analyzed 178 patients with CLL in a single center between 2000 and 2013. We have considered as factors of poor prognosis: male sex, advanced stage (III-C or IV-C Rai-Binet), absolute lymphocytic count greater than 50 000/µL, elevated serum levels of β-2 microglobulin, elevated serum lactate dehydrogenase (LDH), presence of chromosome abnormalities such as 17p deletion or 11q deletion and expression of ZAP-70 or CD38 by leukemia cells. Patients were divided into 3 groups according to the number of poor prognostic factors: group A (0-1), group B (2-3), group C (>3).

Results: The median age at diagnosis was 69 (range, 30-91) and 64% (n=114) were men. The median follow-up time was 3.6 years (range, 28 days to 12 years). The overall survival (OS) at 3 years was 98.9% in the group A (n=115), 83.4% in the group B (n=54) and 63.5% in the group C (n=9) and these differences were statistically significant (group A *versus* B, p=0.049; A *versus* C, p<0.001; B *versus* C, p=0.026). According to multivariate regression analysis group C presented a risk of death 32.5 times superior than group A (p <0.001, HR 32.5, 95% CI 6.4 - 166.5). The median time from diagnosis to treatment was 2 months for group C, 20 months for group B and 91 months for group C (group A *versus* B, p<0.001; B *versus* C, p=0.03; A *versus* C, p<0.001).

Summary and Conclusions: Accounting for poor prognosis factors allowed us to stratify patients into 3 groups (A, B, C). Mainly, patients with more than 3 poor prognostic factors (group C) had clearly worse OS than patients with 0-3 poor prognosis factors and that determined early treatment.

PB1520

PENTOSTATIN, CYCLOPHOSPHAMIDE AND RITUXIMAB (PCR) IN PATIENTS WITH RELAPSED/REFRACTORY CHRONIC LYMPHOCYTIC LEUKEMIA (CLL)

D Mannina[1,*] A Chiarenza[2], F Di Raimondo[2], M Musso[3], V Bonanno[3], L Nocilli[1], A Sciarrone[1], M Brugiatelli[1]

[1]Hematology, Azienda Ospedaliera Papardo-Piemonte, Messina, [2]Hematology, Ospedale Ferrarotto, AOU Policlinico-OVE, University of Catania, Catania, [3]Oncology, Oncohematology and Bone Marrow Transplantation Unit, La Maddalena, La Maddalena, Palermo, Italy

Background: Three purine nucleoside analogs have shown single-agent efficacy in lymphoid neoplasms: fludarabine, 2-chlorodeoxyadenosine and pentostatin. Their use, however, can be limited by bone marrow suppression and increased risk of infectious complications.

So far, the gold standard in the treatment of fit patients with B-CLL is the combination of rituximab with fludarabine and cyclophosphamide (FCR).

Pentostatin is toxic to lymphocytes as it causes the accumulation of deoxyadenosine-triphosphate and compared to the other purine analogs, it can be less myelosuppressive. We present the results of a retrospective analysis carried out on patients with relapsed/refractory CLL treated with pentostatin, cyclophosphamide, and rituximab (PCR).

Aims: The purpose of this study was to evaluate the toxicity and the efficacy of PCR chemoimmunotherapy in terms of response and survival in unfit and/or relapsed/refractory patients with B-CLL.

Methods: Between February 2008 and December 2010, 29 patients (19 males, 10 females) were treated at 3 italian hematology centers. Their median age was 70 years (range 46-84). Three patients were in 1st line therapy, 12 in 2nd, 8 in 3th and 6 in 4th line. Median number of previous lines was 1. Performance status (PS) was 0 in 4 pts, 1 in 5 pts, 2 in 5 pts, missing in 13 pts. Stage was A/2 in 3 pts, B/2 in 4 pts, B/4 in 1 pt, C/2 in 2 pts, C/3 in 2 pts, C/4 in 5 pts. Cumulative Illness Rating Scale (CIRS) was grade 0 in 15 pts, 1 in 8 pts, 6 in 1 pt. Median peripheral lymphocytosis was 30.8 x 10^9/l (2.6-153.8). Treatment schedule consisted of 4-6 cycles of pentostatin 4 mg/m^2 on day 1, cyclophosphamide 600 mg/m^2 day 1, rituximab 375 mg/m^2 day 1 at the 1st cycle, 500 mg/m^2 for cycles 2-6. The cycle interval was 28 days. Age, gender, stage, performance status, extranodal sites, serum lactate dehydrogenase, B symptoms, bulk, erythrocyte sedimentation rate, serum albumin level, hemoglobin level, white blood cells and platelets count were considered for clinical assessment and prognosis. Responses were classified according to the criteria of the NCI working group. Response and survival durations were calculated according to the method of Kaplan and Meier.

Results: After 3 cycles of PCR, 26 patients were evaluable for response: 9 (31%) were in complete remission (CR), 11 (38%) partial remission (PR), 1 (3%) minimal response (MR), 1 (3%) non-response (NR), with 4 (14%) early death (ED). Overall response rate (ORR) was 69%. The final response was CR in 11 (38%) pts, PR in 7 (24%) pts, stable disease (SD) 1 (3%) with ORR of 62%. More than 50% of patients completed 6 cycles of treatment. Discontinuation of therapy was due to early death in 4 cases , 1 to severe obstructive broncopneumopathy , 1 to an unknown cause. At median time of observation (17 months, range 0.5 to 44), 46% of the patients were alive in CR, overall survival (OS) was 72% and progression free survival (PFS) 67%.

Summary and Conclusions: The PCR regimen showed a good level of response in relapsed or refractory patients, without important side effects, excessive marrow toxicity and/or severe infections. It has shown efficacy in patients pretreated with fludarabine as well. We did not observe the development of myelodysplastic syndromes or acute myeloid leukemias in any of our patients. Despite the encouraging therapeutic advances, CLL remains so far an incurable disorder with many repeated relapses. Therefore, the evidence that, among all other drugs, pentostatin can be successfully and safely used in combination with cyclophosphamide and rituximab in every phase of the disease, even in older or unfit and/or refractory patients, can help to broaden our therapeutic arsenal and further improve our healing potential.

PB1521

SMUDGE CELL ON BLOOD SMEAR IN CHRONIC LYMPHOCYTIC LEUKEMIA PATIENTS: A PROSPECTIVE SINGLE INSTITUTIONAL STUDY FROM INDIA.

A Gogia[1,*] V Raina[1]

[1]All India Institute of Medical Science, Aiims, New Delhi, India

Background: Smudge cells are ruptured lymphocytes seen on routine blood smears of chronic lymphocytic leukemia (CLL) patients

Aims: We evaluated significance of smudge cells percentage on a blood smear in CLL patients.

Methods: We calculated smudge cell percentages (ratio of smudged to intact cells plus smudged lymphocyte) on blood smears of 165 consecutive untreated CLL patients registered at I.R.C.H, AIIMS, New Delhi over a period of 5 years (2006-2010).

Results: There were 125 males and 40 females. The median age was 59 years (30-88). Median absolute lymphocyte count was 40 X10^9/L. Clinical Rai stage distribution was: stage 0 - 5%, stage I - 25%, stage II - 40%, stage III -10% and stage IV - 20%. The median smudge cells percentage was 28% (4% to 76%). There was no correlation of proportion of smudge cells with age, sex, lymphocyte count, lymphocyte doubling time, beta 2 microglobulin , organomegaly, ZAP 70 + or CD 38 + CLL patients, but there was significant correlation with stage of disease. Median smudge cell percentage in stage 0 & I -36% (12-76), stage II-30% (12-61) and stage III&IV-20% (4-51) [p <0.001]. Eighty five patients of early stage (0, I &II) patients required treatment during follow up [65% required treatment with smudge cell<30%, against 35% patients requiring treatment with smudge cells > 30% , p=0.01]. The percentage of smudge cells as a continuous variable correlated with OS [HR 0.96, p< 0.001]. The 5-year survival rate was 51% for patients with 30% or less smudge cells compared with 76% for patients with more than 30% of smudge cells. Median OS was 4.8 years with median follow up period of 3.6 years. Smudge cells percentage (<30% *vs.* >30%) had significant association with OS [HR 0.97, 95%CI (0.62-1.21), p=0.001)].

Summary and Conclusions: Simple and inexpensive detection of smudge cells on blood smears on routine diagnostic test useful in predicting progression free and OS in CLL patients and may be beneficial in countries with limited recourses.

PB1522

SOLUBLE TACI SERUM CONCENTRATIONS AT DIAGNOSIS IS A POWERFULL PROGNOSTIC MARKER IN CLL

MC Kyrtsonis[1,*] K Sarris[1], E Koulieris[1], D Maltezas[1], E Nikolaou[1], MK Angelopoulou[1], V Bartzis[1], T Tzenou[1], M Dimou[1], MP Siakandaris[1], E Vyniou[1], S Sachanas[2], C Kalpadakis[2], GA Pangalis[2], P Panayiotidis[1]
[1]Laikon General Hospital of Athens, University of Athens medical school, [2]Henatology Clinic, Athens Medical Center, Athens, Greece

Background: TACI (transmembrane activator and CAML interactor) is one of the 3 BLyS (BAFF) receptors and is expressed by B and T cells. It can also bind APRIL. Both BLyS and APRIL were shown to regulate B-CLL cells proliferation and survival. Serum BLyS levels were found considerably decreased in CLL patients and their low concentrations related to a shorter time to first treatment (TFT) but not to overall survival (OS). It was suggested that low BLyS levels in aggressive CLL were reflecting its binding to its receptors on B-cell surface, sequestrating it from circulation. TACI can be shed from cells' surface and circulate in its soluble form. Very few studies so far investigated soluble TACI (sTACI) in CLL.
Aims: To investigate the impact of sTACI levels at diagnosis in CLL and to compare them with soluble BLyS levels.
Methods: Sixty CLL patients, followed and treated in our hospital were studied; 58%, 25%, and 17% were in Binet stage A, B and C respectively. Patients' median TFT was 34 months (range 1-157), while median OS was 79 months (range 1.8-174). Frozen sera aliquots drawn at diagnosis were tested for sTACI. Measurements were performed by ELISA (R&D, Quantiquine duo set), according to the manufacturer's instruction. Corresponding soluble BLyS levels ranged from undetectable to 680 pg/ml (median 65) and were statistically significantly lower in patients with a shorter TFT. Statistical analysis was performed by standard methods.
Results: Median serum sTACI levels were 2,52 ng/ml (range undetectable - 17,39) in patients and 0,865 ng/ml in HI (range undetectable - 4,14). sTACI concentrations strongly correlated inversely with soluble BLyS (p=0,000021), while with regard to CLL parameters of disease activity, they correlated with b2-microglobulin (p=0,005), inversely with anemia (p=0,03), thrombocytopenia (p=0,04), Binet stage (p=0,02) and with free light chains ratio (p=0,0003). In addition, serum sTACI values above median were related to a shorter TFT compared to values below median (p=0.007) and, importantly, also to OS (p= 0,048).
Summary and Conclusions: sTACI serum concentrations at diagnosis is a powerfull prognostic marker in CLL, related to parameters of disease activity and stage and more importantly to TFT and OS.

SYSTEMATIC REVIEW OF THE RECENT EVIDENCE OF EFFICACY AND SAFETY OF CHLORAMBUCIL IN PREVIOUSLY UNTREATED PATIENTS WITH CHRONIC LYMPHOCYTIC LEUKEMIA

S Lepretre[1,*] C Dartigeas [2], P Feugier [3], M Marty[4], G Salles[5]
[1]Hématologie, Centre de Lutte contre le cancer H Becquerel, Rouen, [2]Cancérologie Hématologie , CHU Bretenneau, Tours, [3]Pole hématologie, CHU Nancy Brabois, Nancy Les vandoeuvre , [4]Clinical research department, Nukleus , Paris , [5]Hématologie, Centre hospitalier Lyon Sud , Lyon, France

Background: Chlorambucil was historically considered as treatment of choice for previously untreated patients with chronic lymphocytic leukemia (CLL). Emergence of agents as purine analogue (as fludarabine) limited using of chlorambucil to elderly and/or co-morbid patients who may not tolerate aggressive approach due to high risk of unacceptable toxicity.
Aims: Provides recent evidence on efficacy and safety of chlorambucil used alone or in association with other treatment in CLL patients.
Methods: This review attempted to collate all recent empirical evidence that assess efficacy and safety of chlorambucil in CLL. In a systematic research prospective, controlled, randomized, studies on human investigating the benefits and harms of chlorambucil to treat CLL and including at least one group with chlorambucil will be searched (1rst January 2000 to 30 January 2014) in PubMed, Medline databases. Abstracts (less than 2 years) from the 4 main congresses in hematology were also searched (ASCO, ASH, ESH, IWLLC).
Results: Eight studies were identified. Most of studies included co-morbid or unfit patients. In 2 studies all stages of the disease were included (Raï stage I to IV). Each study comprised a group with chlorambucil using alone. Dose (40 mg/m^2 D1, 10 to 12 mg/ m^2 D1 through D7, 0,4 mg/kg to 0,8 mg/kg D1 and D15 each 28 days) and duration (6 to 12 cycles of 28 days) of chlorambucil regimen was very heterogeneous between studies. Two studies included 3 groups of treatment. The comparisons were done either *versus* an association of chlorambucil with fludarabine (1 trial), with ofatumumab (1 trial), with rituximab (1 trial), with obinotuzumab (1 trial) or *versus* a monotherapy: cladribine (1 trial), fludarabine (3 trials), alemtuzumab (1 trial), bendamustin (1 trial). Primary end points were overall survival (OS) (2 trials), progression free survival (PFS) (3 trials), PFS and OS (1 trial), overall response rate (ORR) and PFS (1 trial) and no defined in 1 trial. Median time of follow up ranged from 23 months to 62 months. In chlorambucil groups, ORR ranged from to 31% to 72% and complete response rate (CRR) from to 0% to 10,8% (without steroid) to 12% (with prednisone). Median time for PFS ranged from 8.8 months to 20 months and for OS from 46 months to 78 months. Chlorambucil was used as comparator in 2 more recent RCT assessing efficacy and safety of monoclonal anti-CD20 drugs in association with chlorambucil. In a recent randomized clinical trial (RCT) conducted in advanced age or with co-morbidities untreated CLL patients considered inappropriate for fludarabine-based therapy the median PFS (primary end point) in chlorambucil group was 13.1 months and 22.4 months in ofatumumbab + chlorambucil group (p<0.001). In an another RCT conducted in untreated active CLL with CIRS > 6, the median PFS (primary end point) was 11.1 months in chlorambucil group, 26.7 months in obinotuzumab + chlorambucil group (p<0.001 *vs* chlorambucil) and 16.3 months in rituximab + chlorambucil group (p<0.001 *vs* chlorambucil).
Summary and Conclusions: Recent trials showed that chlorambucil using alone has a low toxicity and acceptable ORR with low level of CR. In unfit patient inappropriate for fludarabine-based therapy, chlorambucil remains the backbone of treatment particularly with the new monoclonal anti-CD20 drugs.

PB1524

PROGNOSTIC SIGNIFICANCE OF IMMUNOPHENOTYPING AND QUANTIFICATION OF CLONAL LYMPHOID CELLS IN PATIENTS WITH CHRONIC LYMPHOCYTIC LEUKEMIA

A Kuvshinov[1], S Voloshin[1], A Schmidt[1,*] V Shuvaev[1], M Fominykh[1], A Garifullin[1], K Abdulkadyrov[1]
[1]Russian Scientific Research Institute of Hematology and Transfusiology, Saint-Petersburg, Russian Federation

Background: With the advent of highly effective treatment options, minimal residual disease (MRD) measurements gained interest as a prognostic marker in chronic lymphocytic leukemia (CLL). With the advent of routine bench-top cytometers capable of simultaneously analyzing ≥ 4 colors and with improved standardization, multicolor flow cytometry (MFC) has become the method of choice for MRD assessments.
Aims: To determine the pretherapeutic immunophenotype and the quantification of clonal lymphoid cells (CLC) and their dynamics after immune-based combination therapies in patients with CLL.
Methods: Thirty-one adult pts (median age 64 years, range 31 - 80; male 20, female 11) with newly diagnosed CLL were included. The diagnosis of CLL was made according to standard diagnostic workup (complete blood count with differential, MFC analysis of blood and bone marrow (BM), lymph node and BM immunohistochemistry (IHC), computered tomography). CLC were prospectively quantified in 31 BM samples based on relative quantity of typical CLL cells (CD5+CD19+CD20+CD23+) and quantity of myelocariocytes. Immunophenotype (IFT) of CLL cells assessed with combinations: CD3/CD19, CD19/CD5, CD19/CD11c, CD19/CD20, CD19/CD22, CD19/CD23, CD19/CD25, CD19/CD38, CD19/CD43, CD19/CD81, CD19/HLA-DR, and CD19/CD5/CD23. We have used NCI revised guidelines (Hallek M, *et al.*, 2008) for treatment initiation and assessment of response after completion of primary therapy with rituximab (RTX)-based regimens (FCR, RB, and RChl). Patients with partial response (PR) and complete response (CR) treated subsequently with RTX maintenance. The quantity of CLC were measured in 6 months (9/17 pts), and in 12 months (5/17) from the start of RTX maintenance.
Results: CD5+CD19+CD23+ cells were detected in 93.5% cases. In cases of CD5-negative CLL (6.5%) assessed with MFC, there were CD5+ slightly positive (IGH) lymph node samples. High expression level of pan-B-cell markers (CD20, CD22) detected with use of MFC (93.5%, and 54.8%, respectively). Elevated expression of CD43 was detected in 90.3%, HLA-DR – 25.8%, CD81 – 22.6%, and CD25 – 6.5% of cases. High expression level of CD38 – 29.0%, CD11c – 25.8%. CLC quantity at diagnosis without indications for treatment was 50.48±10.94x10^9/L (n=9), and 92.27±19.71x10^9/L, when primary therapy was indicated (n=22). The measurement of CLC at the end of induction therapy (n=17) revealed statistically significant differences (*p<.05*): CR (n=10) – .004±.002 x10^9/L, and PR (n=7) - .718±.369 x10^9/L. CLC quantity in 6 months of RTX maintenance - .085±.047x10^9/L, in one year - .002±.002 x10^9/L (*p<.05*). MRD was not detected (<10^{-4} tumor cells) in five (50%) pts at time of CR documentation. IFT of tumor cells at relapse/progression (n=4) did not changed (CLC quantity - 13.9±8.58x10^9/L).
Summary and Conclusions: Detection of IFT and quantification of CLC at diagnosis may help in decision-making process in newly diagnosed CLL patients. RTX maintenance leads to the more complete eradication of tumor clone. It seems that the treatment planning aimed toward achieving long-lasting CRs should include at least one test to assess MRD because the lack of leukemia persistence using these sensitive tests seems to have a strong, positive prognostic impact.

PB1525

EFFICACY OF THE COMBINATION OF BENDAMUSTINE AND RITUXIMAB IN PATIENTS WITH RELAPSED AND REFRACTORY CHRONIC LYMPHOCYTIC LEUKEMIA

T Zagoskina[1,*] E Zotina[1], V Ovsepyan[1], V Shardakov[1]
[1]Kirov Research Institute of Hematology and Blood Transfusion, Kirov, Russian Federation

Background: Currently, one of the treatment's options of relapsed and refractory chronic lymphocytic leukemia (CLL) is the combination of bendamustine and rituximab (BR).
Aims: Evaluate the efficacy and safety of the combination of BR in patients (pts) with relapsed and refractory CLL with regard to the presence of unfavorable prognostic factors.
Methods: Thirty six pts with CLL at the age of 35-72 years (a median age – 56 years) were included in the study. All pts had ECOG status less than 3. Seventeen pts (47%) had B stage and 19 (53%) – stage C by Binet. In 32 (89%) pts a positive expression of ZAP-70 was revealed during the diagnosis and in 24 (67%) pts – positive expression of CD38. In 28 (78%) pts the level of serum thymidine kinase (TK) was ≥ 20 U/l. According to FISH-analysis, 8 (22%) pts had del17p and 15 (42%) pts had del11q. In 14 (39%) pts refractory to prior therapy was registered, 22 (61%) pts had relapsed CLL. The prior therapy included regimens containing fludarabine (FC, FCR and FCMR) and alemtuzumab monotherapy. Median lines of the previous therapy were 2 (from 1 to 4). Pts were treated with BR therapy: bendamustine was administered in a dose of 90 mg/m^2 i.v. on the first and second days, rituximab – in a dose of 375 mg/m^2 i.v. on the first day of course. Therapy BR was carried out every 28 days up to 6 courses. Response to the treatment was assessed according to the criteria IWCLL.
Results: With the combination of BR the overall response rate was 64% (23 pts). Complete remission was achieved in 6 (17%) pts, partial remission – in 17 (47%) pts. Thirteen pts (36%) were non-responders. Response to the treatment was achieved in 6 (43%) pts with refractory CLL and in 18 (82%) pts with relapsed CLL (p=0.040). In pts with refractory CLL more unfavorable prognostic factors were revealed such as del17p, del11q, serum TK ≥ 20 U/L and positive expression of ZAP-70, in comparison with the pts having a relapse (86% *vs.* 45%, p=0.039). With a median follow-up of 27 months median overall survival has not been reached. The median progression free survival (PFS) was 19 months. In the process of a multivariate analysis including age, gender, ECOG status, serum TK, the expression of ZAP-70 and CD38, del11q and del17p, independent prognostic factors for PFS identified serum TK (p=0.031), ZAP-70 (p=0.034) and del17p (p=0.013). Neutropenia, thrombocytopenia, anemia of the 3-4 grade were detected in 8 (22%), 7 (19%) and 5 (14%) pts, respectively. The infection of the 3-4 grade (2 cases of pneumonia, 1 case of sepsis) occurred in 3 (8%) pts.
Summary and Conclusions: Thus, the combination of BR is a safe and effective therapy for pts with relapsed and refractory CLL. The most expressed efficacy was observed in pts with relapses who lacked unfavorable prognostic factors, in comparison with pts with refractory CLL and the presence of unfavorable prognostic factors.

PB1526

PROGRESSION-FREE SURVIVAL AS A SURROGATE ENDPOINT FOR OVERALL SURVIVAL IN RELAPSED-REFRACTORY CHRONIC LYMPHOCYTIC LEUKAEMIA

A Amin[1,*] R Taylor[2], A Alonso[3], C Schwenke[4], M Gaudig[5], S Gaugris[6], H Welten[7], W Erhardt[8], G Roberts[1], M O'Leary[1], M Wasserman[9]
[1]Double Helix Consulting, London, [2]University of Exeter Medical School, Exeter, United Kingdom, [3]Maastricht University, Maastricht, Netherlands, [4]SCO:SSiS, Berlin, [5]EMEA Health Economics and Market Access, Janssen, Neuss, Germany, [6]Outcomes Research, Janssen, High Wycombe, United Kingdom, [7]Health Economics and Market Access, Janssen-Cilag BV, Tilburg, Netherlands, [8]Health Economics and Market Access, Janssen-Cilag GmbH, Neuss, Germany, [9]Double Helix Consulting, Singapore, Singapore

Background: Advancements in treatments for end-stage diseases, specifically in oncology, have made collecting overall survival (OS) as the primary endpoint in clinical trials more challenging. As a result, other endpoints to demonstrate the effectiveness of drugs are becoming increasingly important.
Aims: The purpose of this research is to investigate the potential of progression-free survival (PFS) as a surrogate endpoint predicting overall survival in relapsed and/or refractory (R/R) chronic lymphocytic leukaemia (CLL).
Methods: A systematic literature review was undertaken using MEDLINE and EMBASE, to identify clinical trials investigating the effectiveness of treatments in adult R/R CLL patients. Trials included in the analysis had to report median OS and median PFS. To minimise the risk of attrition bias, studies with substantial loss to follow up (*i.e.* >30%) were excluded. The level of surrogacy was quantified using Pearson and Spearman rank correlation statistics, and weighted least squares (WLS) regression using sample size weights. Correlation statistics were also evaluated within different patient subgroups.
Results: A total of 34 trial arms were analysed from 28 clinical studies. Both correlation analyses demonstrated a strong association between median PFS and median OS in R/R CLL (Spearman=0.891; Pearson=0.877, 95% CI: 0.711 to 0.951). WLS regression also showed positive results (R^2=0.805) with a one month extension of median PFS contributing to 1.42 (95% CI: 1.076 to 1.768) month extension in median OS (p<0.01). The endpoints showed the strongest correlation in trials where the mean age of patients was over 65 (0.922; 95% CI: 0.214 to 0.995), and in trials where patients were treated with a chemo-immunotherapy combination (0.922 95% CI: 0.258 to 0.953).
Summary and Conclusions: These results give convincing evidence about the validity of PFS as a surrogate for OS at the individual level. In fact, our findings demonstrate the potential of the median PFS to predict the median OS in this population of patients. This is necessary in CLL where patients are having increasingly long OS and PFS, justifying the need to establish a suitable surrogate. Further research is necessary to quantify the strength of surrogacy based on treatment effect data (*e.g.* hazard ratio for OS *vs.* hazard ratio PFS) using aggregate or individual patient level data. This research provides the first step in establishing the use of PFS as an acceptable primary clinical endpoint for R/R CLL patients in decision making in the future.

PB1527

RITUXIMAB PLUS BENDAMUSTINE IN ELDERLY PATIENTS AFFECTED BY RELAPSED OR REFRACTORY B-CELL CHRONIC LYMPHOCYTIC LEUKEMIA (CLL)

A Lucania[1,*] MR Villa[1], G Nitrato Izzo[1], S Improta[2], L Mastrullo[1]
[1]UOC Ematologia PO San Gennaro ASL Napoli1 Centro, [2]UOC Ematologia, PO San Gennaro ASL Napoli1 Centro, Naples, Italy

Background: Chronic lymphocytic leukemia (CLL) is characterized by a highly variable clinical course. Among the biological features underlying this heterogeneity, genetic lesions and the mutational status of the immunoglobulin heavy chain variable genes (IGHV) are of importance. Therapeutic options in CLL have been considerably expanded during recent years. The combination of fludarabine, cyclophosphamide and rituximab (FCR) has become gold standard in the first-line treatment of physically fit patients. Bendamustine demonstrated clinical activity in pre-treated hematological malignancies due to its unique mechanism of action distinct from standard alkylating agents.
Aims: We have assessed the efficacy and safety of bendamustine plus rituximab in elderly patients with pre-treated chronic lymphocytic leukaemia.
Methods: In the last 48 months we treated 24 elderly patients (12 F and 12 M, median age: 77 years, r.: 72-88 years) with relapsed/refractory CLL who had been heavily pretreated (more than 4 lines of treatment). Patients received Bendamustine 90 mg/m^2 on days 1 and 2 and Rituximab 375 mg/m^2 on day 3 of a 4-week cycle. A dose escalation of Rituximab to 500 mg/m^2 was performed from second course. 20/24 patients received six cycles, while the remaining two received four cycles.
Results: Overall response rates were 75% (18/24 patients), with clinical complete response rates of 50%. At present (+36 months after the end of treatment), 20/24 patients are alive and show no disease progression. One patient died due to respiratory infection six months after the end of therapy. Thrombocytopenia and gastrointestinal toxicities were more frequent adverse events. Grade ≥ 3 adverse events were infrequent and most commonly included thrombocytopenia (20%), anemia (10%), and infection (10%).
Summary and Conclusions: Our results suggest that bendamustine plus rituximab is effective and well tolerated in the treatment of relapse/refractory CLL in elderly patients. Although further data are required to fully establish the efficacy of this combination therapy in the management of this subset of patients, it appears to be a useful addition to the armamentarium of currently available therapies for this haematological malignancy.

PB1528

ROLE OF PERIPHERAL BENZODIAZEPINE RECEPTOR IN CHRONIC LYMPHOCYTIC LEUKAEMIA

A De Rosa[1,*] MR Villa[2], S Improta[2], L Mastrullo[2], E Cesario[3], A Lombardi[4], M Caraglia[5], P Stiuso[5]
[1]ASL NA3 SUD, [2]UOC Ematologia PO San Gennaro ASL Napoli1 Centro, [3]Medicina Sperimentale Seconda Università di Napoli, [4]Dpt. Biochimica, Biofisica e Patologia Generale Seconda Università di Napoli, [5]Dpt. Biochimica, Biofisica e Patologia Generale Seconda Università di Napoli, Naples, Italy

Background: The peripheral benzodiazepine receptor (PBR) is a critical component of the mitochondrial permeability transition pore (MPTP), a multiprotein complex placed at the contact site between inner and outer mitochondrial membranes, which is intimately involved in the initiation and regulation of apoptosis. PBR is physically associated with the voltage-dependent anion channel (VDAC) and adenosine nucleotide translocase (ANT) that form the

backbone of MPTP. Consistent with its localization in the MPTP, PBR has been involved in the regulation of apoptosis, but also in the regulation of cell proliferation and other related processes. Transfection-enforced overexpression of PBR attenuates apoptosis induced by oxygen radicals or ultraviolet light. Together, these observations led several authors to consider the PBR as a promising drug target, especially in the field of cancer.
Aims: Chronic lymphocytic leukemia (CLL) cells have increased levels of radical oxygen species (ROS). In this prospective study, we have investigated PBR expression in order to use the latter as therapeutic target and prognostic marker.
Methods: We have investigated PBR expression in leukocyte subsets from healthy donors and CLL patients before and after chemo-immunotherapy. Moreover, we evaluated in lymphocytes of healthy donors and CLL patients the levels of toxic aldehydes (MDA) by thiobarbituric acid reactive species (TBARS) assay as expression of oxidative stress.
Results: In 30 CLL patients the CLL cells showed an increased number of PBR receptors normalized for mitochondria expression if compared to normal lymphocytes. Moreover, CLL cells show low levels of TBARS, NO and caspase-3 activity compared to the lymphocytes of healthy donors. After 6 months from the beginning of treatment PBR/mitochondria ratio resembled that one of healthy controls in 24/30 CLL patients. In addition, we evidenced an increase of toxic aldehydes (TBARS assay) and nitric oxide levels, both markers of oxidative stress, and a potentiation of caspase-3 activity in all responder patients. Interestingly, the 6 patients who resulted resistant to treatment displayed also higher PBR levels and lower caspase-3 activity and TBARS levels.
Summary and Conclusions: These data suggest that PBR expression could be a molecular prognostic factor predictive of response in CLL patients. Moreover, PBR could also represent a useful therapeutic target in order to increase treatment activity in CLL patients.

PB1529

BENDAMUSTINE AND RITUXIMAB AS FIRST OR SECOND LINE THERAPY IN ELDERLY PATIENTS WITH CHRONIC LYMPHOCYTIC LEUKEMIA (CLL)
A Gozzetti[1,*] S Ciolli[2], V Candi[1], C Breschi[3], A Fabbri[1], L Schiattone[1], E Cencini[1], G Papini[1], D Raspadori[1], M Defina[1], L Aprile[1], A Bosi[2], M Bocchia[1]
[1]Hematology, Siena, [2]Hematology, Firenze, [3]Oncology, Pistoia, Italy
Background: Current standard therapy for fit young patients with chronic lymphocytic leukemia (CLL) is rituximab, fludarabine, cyclophosphamide (RFC). This therapy is highly effective in standard risk patients with CLL, however in the elderly it can be troublesome since it can give unacceptable myelotoxicity and increase risk of infection. Because median age at diagnosis for CLL patients is now 72, the majority of patients cannot receive RFC, the best therapy available.
Aims: We investigated the safety and efficacy of Bendamustine plus Rituximab (RB) in elderly patients with CLL as second or first line of therapy at three centers in Tuscany, Italy
Methods: Twenty-six patients were treated, 9 at diagnosis and 17 at first relapse. Patients were M/F 14/9, median age was 72 (range 67-80). Six cycles of R-B were planned. Rituximab was given 375 mg/m2 day 3 in the first cycle and then 500 mg/m^2 day 1 of each subsequent cycle. Bendamustine was given 70 mg/m^2 day 1-2 cycle 1 and then day 2-3 in cycles 2-6. Antibiotics prophylaxis was given days 1-10 of each cycle. Biological prognosticators were assessed at diagnosis and at disease relapse. In particular IGHV gene use and mutational status, ZAP-70 protein and CD38 expression by flow cytometry, deletions of 11q22.2, 13q14.1, 17p13.1 loci and chromosome 12 trisomy were determined by fluorescent *in situ* hybridization (FISH) as previously reported.
Results: Results.up is 18 months. Overall response was observed in 22/26 (84%) of the patients, being 6 CR (23%, 4 at diagnosis, 38%), 16 PR (61%). No differences were seen in response and PFS for patients with del 11q , trisomy 12 and del 13q abnormalities; del17p responded less as well as patients with unmutated IGHV. Median PFS for patients treated at diagnosis has not been reached. PFS for patients treated at first relapse is 17 months. Hematologic toxicity was evident but manageable: grade 3-4 in 10/26 (38%) patients, grade 1-2 in 7/26 (27%). Extra hematological toxicity was mild : grade 1 gastrointestinal in 19/26 patients, grade 1 cutaneous in 5/26 patients. Four patients developed pneumonia.
Summary and Conclusions: RB in extremely effective therapy in elderly patients with CLL and particularly at diagnosis. Hematological toxicity is the most important toxicity but can be easily managed with growth factors and antibiotics prophilaxis. These results are important because obtained in a selected aged population of patients.

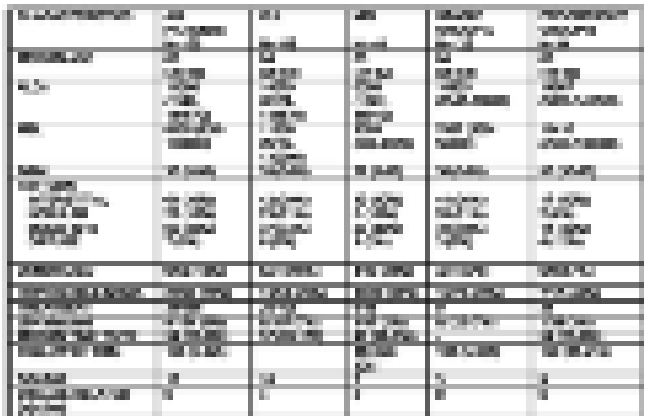
BONE MARROW FINDINGS IN CLL-LIKE MBL AND CLL RAI STAGE 0: CORRELATION WITH MAIN DISEASE FEATURES AND OUTCOME
C Kalpadakis[1,*] G A Pangalis[2], S Kyriakaki[1], M K Angelopoulou[3], S Sachanas[2], P Tsirkinidis[2], P Korkolopoulou[4], F Kontopidou[5], A Dimitrakopoulou[6], E Dimitriadou[3], X Yiakoumis[2], S Kokoris[7], M Moschogiannis[2], M Devetzoglou[1], MC Kyrtsonis[8], D Rontogianni[9], P Panayiotidis[8], P Tsaftaridis[3], H Papadaki[1], T Vassilakopoulos[3]
[1]Haematology, University of Crete, Heraklion, [2]Haematology, Athens Medical Center-Psychikon branch, [3]Haematology, [4]Pathology, University of Athens, [5]Haematology, Ippokrateion General Hospital, [6]Immunology, Laikon General Hospital, [7]Haematology, Attikon General Hospital, [8]1st Department of Propedeutic Internal medicine, University of Athens, [9]Pathology, Evangelismos General Hospital, Athens, Greece

Background: CLL-type MBL and CLL Rai 0 share many clinical and biological similarities. Data on bone marrow histopathology findings in these entities are limited.
Aims: To evaluate the histopathological and immunohistochemical findings of bone marrow biopsies (BMB) in a series of patients with MBL and CLL Rai 0 and to correlate these findings with other disease features.
Methods: 156 pts were included in this study. At diagnosis all pts underwent whole body CT scan and BMB. Evaluation of the extent and the pattern of BM infiltration, the cytology and the immunohistology were performed. Clinical and laboratory data were analyzed.
Results: 48 pts had MBL and 108 CLL Rai 0. The main clinical and laboratory characteristics are shown in table 1. There was significant difference in the extent of BM infiltration between the two groups (p=.003). Furthermore, in MBL cases a mixed (nodular and interstitial) pattern predominated (48%), while in CLL cases the interstitial pattern (39%). The diffuse pattern was uncommon and was correlated with worse outcome. All cases but one exhibited neoplastic infiltration consisting almost exclusively by small lymphocytes. Only one case exhibited plasmacytoid differentiation. All cases presented weak expression of surface immunoglobulin, were CD20, CD79a, CD5 and CD23 positive, were negative for cyclin D1 while most of them were negative for cytoplasmic immunoglobulin. Most cases had preserved hematopoietic reserves, while in 13 cases BMB revealed hyperplasia of erythroid (7 cases) and megakaryocytic (6 cases) series. At a median follow up time of 106 mos (5-325), 122 remained stable (group A) while 34 progressed to CLL requiring therapy (group B). The median lymphocytic infiltration of group A and B was 30% (5-95%) and 50% (30-80%), respectively (p<.001). The nodular pattern was uncommon in group B (6% *vs* 21%). Hypoglobulinemia was evidenced in 22%and 41% of pts in group A and B respectively (p=.18). Unmutated IgVH genes were found in 7% and 67% of group A and B respectively (p<.001).
Summary and Conclusions: BMB evaluation provides important information regarding the tumor load of the disease which usually cannot be identified by the absolute B-cell counts only. BMB evaluation also correlates significantly with other disease features.

Table 1. Clinical characteristcs and BM findings in MBL and CLL Rai O patients.



PB1531

AUTOIMMUNE HEMOLYTIC ANEMIA IN PATIENTS WITH LYMPHOPROLIFERATIVE DISEASES
E Simonovic[1,*] L Macukanovic-Golubovic[2], V Colic[1]
[1]Internal, General Hospital Leskovac, Leskovac, [2]Internal, Clinic of Hematology, Nis, Serbia

Background: Autoimmune haemolytic anaemias (AIHA) are diseases characterized by increased degradation of erythrocytes due to the presence of plasma proteins (globulin) that have character of antibodies' reacting with antigens of erythrocyte membranes of patients. According to the temperature at which the auto-antibodies bind to antigens in erythrocytes, AIHA are divided

into: 1) AIHA caused by warm antibodies. 2) AIHA caused by cold antibodies. 3) Mixed (mixing) type. Depending on the presence or absence of the underlying disease, AIHA are divided into primary and secondary.
Aims: The aim of this study is to monitor the occurrence of secondary AIHA in patients with lymphoproliferative diseases.
Methods: During the period of five years, we followed up 91 patients of both sexes, aged between 18 and 84 years, with the diagnosis of lymphoproliferative disease. The group consisted of 15 patients with acute lymphoblastic leukemia (ALL), 24 patients with chronic lymphocytic leukemia (CLL), 20 patients with Hodgkin's lymphoma, and 32 patients with non-Hodgkin's lymphoma. We used methods of clinical, laboratory and ultrasound examination.
Results: During the monitoring, 18% of patients were reported with autoimmune haemolytic anaemia occurrence. Anaemia is characterized by reticulocytosis, increased levels of lactate dehydrogenase, indirect hyperbilirubinemia, reduced levels of haptoglobin and positive direct Coombs antiglobulin test (DAT). In 80% of patients AIHA was caused by warm antibodies and in 20% of patients with cold antibodies.
We have discovered that the AIHA can occur earlier, together with the occurrence of lymphoproliferative disease, in the course of or after the end of chemotherapy, or as the first sign of disease relapse. The most common occurrence of autoimmune hemolytic anemia was recorded in the group of patients with CLL. Slightly higher incidence was found in the group of patients with Hodgkin's lymphoma, as compared to a group of patients with non-Hodgkin's lymphoma. In patients with CLL, AIHA was usually an early sign of disease relapse. The secondary AIHA is a well known paraneoplastic phenomenon in the lymphoproliferative disorders, closely associated with the development and progression of the disease.
Summary and Conclusions: AIHA may precede the appearance of lymphoproliferative disease, which has great diagnostic significance. AIHA also may be the first, early sign of the disease relapse. Fast definition of the AIHA cause is of great importance for the diagnosis, monitoring and further treatment of lymphoproliferative disease.

Chronic myeloid leukemia - Biology

PB1532

2-HYDROXYPROPYL-B-CYCLODEXTRIN ACTS AS A NOVEL ANTICANCER AGENT

Y Kubota[1,*] M Yokoo[1], K Motoyama[2], T Higashi[2], M Taniyoshi[2], H Tokumaru[2], Y Tabe[3], S Mochinaga[4], A Sato[1], N Sueoka-Aragane[1], E Sueoka[5], H Arima[2], T Irie[2], S Kimura[1]
[1]Division of Hematology and Oncology, Department of Internal Medicine, Saga University, Saga, [2]Graduate School of Pharmaceutical Sciences, Kumamoto University, Kumamoto, [3]Department of Clinical Laboratory Medicine, Juntendo University School of Medicine, Tokyo, [4]Department of Pharmacy, Saga University Hospital, [5]Department of Clinical Laboratory Medicine, Saga University, Saga, Japan

Background: Molecular-targeted drugs have superior anticancer effects compared to those of conventional chemotherapeutic agents, and have less adverse effects. However, resistance to chemotherapy, such as that resulting from point mutations or the existence of cancer stem cells, still hinders the treatment of cancer patients. Thus, alternative therapeutic approaches that enhance neoplastic cell death are required for successful cancer treatment. Cholesterol accumulation and/or dysregulated cholesterol metabolism is reported in various malignancies, including leukemia. Thus, modulation of cholesterol homeostasis might be a rational target for the development of anticancer agents. 2-Hydroxypropyl-β-cyclodextrin (HP-β-CyD) is a cyclic oligosaccharide that is widely used as an enabling excipient in pharmaceutical formulations, but also as a cholesterol modifier. HP-β-CyD has recently been approved for the treatment of Niemann-Pick Type C disease, a lysosomal lipid storage disorder, and is used in clinical practice. However, the potential anticancer activities of HP-β-CyD have not yet been noted.
Aims: We hypothesized that HP-β-CyD itself might have anticancer effects, and investigated anticancer activities of HP-β-CyD using BCR-ABL-induced leukemia models.

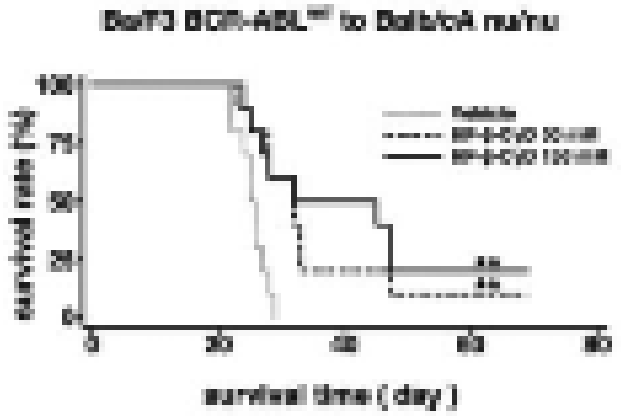


Figure 1. Administration of HP-β-CyD prolongs the survival in mouse model of BCR-ABL-induced leukemia. **P<0.01, compared with vehicle-treated mice.

Results: HP-β-CyD significantly inhibited the growth of mouse pro-B cell Ba/F3 cells expressing wild-type BCR-ABL (Ba/F3 BCR-ABL^{WT}), and BV173 cells, in a dose- and time-dependent manner. The IC_{50} values of 13 leukemic cell lines (Ph^+ leukemia; BV173, K562, KBM-5, KBM-5/STI, KCL22, MYL and MYL-R, AML; HL-60, pre-B cell leukemia; NALM-6, T-cell leukemia; Jurkat and MOLT-4, adult T-cell leukemia; MT1, and MT2) for HP-β-CyD after 72 hours exposure were in the range of 3.86-10.09 mM. Interestingly, HP-β-CyD-induced cell growth inhibition of imatinib-resistant chronic myeloid leukemia (CML) cell lines, such as KBM-5/STI and MYL-R was equivalent to that of respective parental cells. Subsequent *in vitro* analyses demonstrated that HP-β-CyD inhibits the proliferation of leukemic cells by induction of apoptosis and G_2/M cell-cycle arrest. Next, to clarify whether apoptosis induced by HP-β-CyD is related to cholesterol depletion, we evaluated the effect of CyDs on cholesterol efflux from leukemic cells, and revealed that HP-β-CyD treatment increased cholesterol release in a time and dose-dependent manner. In light of the data showing the inhibitory effect of HP-β-CyD on the proliferation of CML cell lines, we were prompted to evaluate HP-β-CyD for their potential to overcome tyrosine kinase inhibitor (TKI) resistance. The IC_{50} of HP-β-CyD against Ba/F3 BCR-ABL^{T315I} cells was comparable to that of the Ba/F3 BCR-ABL^{WT}, and similar results were obtained in cell proliferation assays that used trypan blue staining. These results suggest that HP-β-CyD can inhibit the

proliferation of TKI-resistant cell lines and may be of use against TKI resistance. Importantly, HP-β-CyD also inhibited proliferation of hypoxia-adapted CML cells that have characteristics of leukemic stem cells, and human primary leukemic cell colony formation. Finally, to investigate the *in vivo* efficacy of HP-β-CyD, we generated mouse models of BCR-ABL-induced leukemia, and administered HP-β-CyD. As a result, HP-β-CyD-treated mice survived longer than vehicle-treated mice, and the log-rank test for overall survival showed statistically significant differences between vehicle- and HP-β-CyD-treated recipients (Figure 1). HP-β-CyD treatment also prolonged the survival in human leukemia xenograft model. Systemic administration of HP-β-CyD to mice had no significant adverse effects.
Summary and Conclusions: These data suggest that HP-β-CyD is a promising anticancer agent. This study is the first report to describe the efficacy of HP-β-CyD in BCR-ABL-induced leukemia, including mutated TKI-resistant clones and hypoxia-adapted cells. Early-phase clinical trials are planned to verify the efficacy and safety of HP-β-CyD for treatment of leukemia.

PB1533

PEROXIREDOXIN EXPRESSION COULD BE INVOLVED IN THE INCREASE OF REACTIVE OXYGEN SPECIES AND DRUG RESISTANCE TO TYROSINE-KINASE INHIBITORS IN PATIENTS WITH CHRONIC MYELOID LEUKEMIA

L Woldmar[1], C Mascarenhas[2], K Romanello[1], M B Costa[1], M H de Almeida[3], I Malavazi[1], C De Souza[4], A F Cunha[1]
[1]Departamento de Genética e Evolução, Universidade Federal de São Carlos, São Carlos, [2]Universidade Católica de Brasília, Brasilia, [3]Hemocentro de Campinas, [4]Hemocentro da Universidade Estadual de Campinas, Campinas, Brazil

Background: Peroxiredoxins (Prdx) are a family of multifunctional antioxidant thioredoxin-dependent peroxidases that not only protect cells against oxidative stress but also modulate signaling cascades that apply hydrogen peroxide as a second messenger molecule and regulate cell proliferation. Thereby the Prdx are related to tumorigenesis while acting as cellular antioxidants, regulating cell apoptosis and proliferation, modulating signaling cascades and interacting with oncogene products and molecules related to tumorigenesis. The relation between Prdx and Chronic Myeloid Leukemia (CML) has not been deeply studied up to now; however, there are evidences that the increase of oxidative stress by Reactive Oxygen Species (ROS) could contribute to genomic instability, leading to accumulation of mutations and chromosomal aberrations that could lead to resistance to Tyrosine Kinase Inhibitors (TKI) used to treat the ailment.
Aims: This study aims to correlate gene and protein expression of Peroxiredoxins with oxidative stress, development of Chronic Myeloid Leukemia and the promotion of Tyrosine Kinase Inhibitors (TKI) resistance, allowing better understanding of the disease and helping to develop new targets to improve the treatment for patients with TKI resistance.
Methods: Peroxiredoxin gene and protein expression was evaluated in 17 CML patients in the chronic phase and treated with TKI, and in 8 healthy volunteers. All patients were classified according to criteria of the European Leukemia Net as responsive (6 patients), resistant (6 patients) or with sub-optimal response (5 patients) to TKI. The CML patients were treated with Imatinib 300-800 mg/day, Dasatinib 70-140 mg/day or Nilotinib 800 mg/day. Dasatinib and Nilotinib were used in patients with resistance to Imatinib. All samples were collected at the blood center at the Hematology and Hemoterapy Center at University of Campinas. RNA samples were submitted to the synthesis of cDNA using the kit RevertAid™ HMinus First Strand cDNA Synthesis Kit (Fermentas, Life Sciences). The gene expression was evaluated by quantitative real time PCR using β-Actina as endogenous control, and the results were analyzed using $2^{-\Delta\Delta CT}$; statistical analysis were made by using student's T test. This study was supported by the FAPESP agency.
Results: The results showed that there is a difference in the Peroxiredoxin gene expression between patients with CML and control individuals. The *PRDX 1* expression was significantly reduced in all groups with CML when compared to the healthy volunteers. The *PRDX2* expression was reduced in responsive patients, but did not exhibit significant difference in the other groups. *PRDX6* had a decrease in its expression in responsive and suboptimal response patients. To evaluate the proteins oxidative stress and levels, Western Blot analysis will be made.
Summary and Conclusions: Our results indicate that Peroxiredoxin gene expression is lower in patients with CML when compared to healthy volunteers. Results presented in literature indicated that the increase of ROS in CML leads to an increase of DNA damage, triggering genomic instability and resulting in accumulation of mutations and chromosomal aberrations (Nieborowska-Skorska, Blood, 2012). These alterations could be involved in the mechanism of acquisition of resistance to TKI inhibitors observed in CML patients. The decrease of Peroxiredoxins expression observed, especially in the responsive group, could contribute to this process, since the detoxification of these species are compromising and the effects caused by oxidative stress are even more drastic, leading to mutations that could be followed by TKi resistance.

PB1534

HIGH RESOLUTION MASS SPECTROMETRY OF IMATINIB BIOTRANSFORMATION PRODUCTS

K Mičová[1], D Friedecký[2], E Faber[3], ,*M Hrdá[1], T Adam[2]
[1]Institute of Molecular and Translational Medicine, Faculty of Medicine and Dentistry, Palacky University in Olomouc, [2]Institute of Molecular and Translational Medicine, Laboratory of Inherited Metabolic Disorders and Department of Clinical Chemistry, [3]Department of Hemato-Oncology, Faculty Hospital Olomouc; Faculty of Medicine and Dentistry, Palacky University in Olomouc, Olomouc, Czech Republic

Background: Therapeutic drug monitoring is widely applied useful tool for treatment individualization in order to achieve optimal clinical response and avoid toxicity. Due to drug metabolizing enzymes several bioactive or toxic metabolites may be produced. Therefore determination of not only parent drug but also of metabolites may have clinical relevance and could be helpful for treatment adjustment.
Aims: To assess a detailed profile of imatinib (IMA) metabolites in plasma of patients with chronic myeloid leukemia (CML).
Methods: Before analysis plasma proteins were precipitated by methanol and supernatant was injected. Separation was performed on Phenomenex Kinetex C18 column (100 x 2.1 mm; 1.7 µm) using UltiMate 3000 RS (Thermo Scientific) liquid chromatography. For detection Orbitrap Elite mass spectrometer (Thermo Scientific) based on exact mass measurement was used. Scan range of *m/z* 350 – 1200 was chosen and the resolution was set at 60,000 FWHM. MS/MS data were acquired in data-dependent strategy based on fragmentation of 25 selected exact *m/z* values of potential metabolites. Collision energy for CID was set at 35 eV. Dynamic exclusion duration of 3 s was enabled; mass accuracy was 5 ppm. Data were evaluated using Excalibur 2.2 SP1, MetWorks 1.3 SP3 and Mass Frontier 7.0 software. Eight samples of 7 CML patients with optimal or suboptimal response to treatment were analyzed (age 41-77 years, 400 mg IMA/day; sampling time 20-27 h after IMA ingestion).
Results: Contrary to previously described 14 IMA metabolites in plasma (Rochat B. *et al.* Mass Spectrom. 2008;43:736) we have found 100 potential metabolites in concentration range of 4 orders of magnitude (0.001 – 6.630 %) related to IMA plasma levels (635 – 1360 ng/mL). All metabolites found in plasma were identified on the base of exact *m/z* values and confirmed by MS2 and MS3 fragmentation experiments. Importantly, differences in the profiles of oxidized and dioxidized metabolites in optimally and sub-optimally responding patients were observed.
Summary and Conclusions: The new generation of high resolution mass spectrometry offers sensitive tool for detail study of drug metabolisation in biofluids. IMA is metabolised to many metabolites which have the potential to be diagnostically useful. Further studies should be focused on elucidation of clinical significance of newly discovered metabolites.

IMATINIB AND PLATELET DERIVED GROWTH FACTOR COOPERATE IN INHIBITION OF MESENCHYMAL STEM CELL PROLIFERATION AND SUPPRESSION OF PLATELET DERIVED GROWTH FACTOR RECEPTOR EXPRESSION

F Aerts Kaya[1,*], G Guney[1], G Aydin[1], B Kuskonmaz[2], D Uckan[1,2]
[1]Center for Stem Cell Research and Development, Hacettepe University, [2]Pediatric Hematology Bone Marrow Transplantation Unit, Hacettepe University Ihsan Dogramaci Children's Hospital, Ankara, Turkey

Background: Imatinib is a tyrosine kinase inhibitor (TKI), which is effectively used in the treatment of gastrointestinal stromal tumors (GIST) and chronic myeloid leukemia (CML). Imatinib selectively inhibits Platelet Derived Growth Factor Receptor (PDGF-R), c-kit and BCR-ABL. PDGF/PDGFR Signaling has been shown to be important for tumor progression by modulating the tumor microenvironment through promoting angiogenesis and tumor invasiveness.
Aims: Here, we wanted to assess the effects of Imatinib on proliferation of Mesenchymal Stem Cells (MSCs), the effect on differentiation of MSCs and expression of the PDGF-R.
Methods: Mesenchymal Stem Cells were isolated from healthy donor bone marrow and cultured in complete medium (CM), consisting of 60% MCDB201/40% DMEM-LG basal media, supplemented with 10% heat inactivated fetal calf serum, 1% penicillin/streptomycin and 2 mM L-glutamin. Proliferation was measured for 10 days using the XCelligence Real Time Cell Analyser (Roche, Turkey) using seeding cell doses of 1000-8000 per well in presence of 2,5 – 20 µM Imatinib (Novartis, Turkey). FACS analysis was performed for CD140b (PDGFRb) using a FACSARIA (Becton Dickinson,

Turkey). Adipogenic and osteogenic differentiation was assessed after three weeks of induction in appropriate differentiation media. Cultures were stained with Oil Red O or Alizarin Red S for adipogenic and osteogenic differentiation, respectively. Oil Red O dye extraction and Calcium assays (DICA-500) were performed for quantitation of differentiation. All tests were performed using Passage 3 MSCs.

Results: Imatinib inhibited MSC proliferation at all doses tested, but inhibition was not further increased at doses exceeding 5 μM. Initial seeding cell doses were found to be optimal at 1000 to 2000 cells/well. Increasing cell doses in presence of 5 μM Imatinib, resulted in competition and cell doses of 8000 cells/well in presence of 5 μM Imatinib showed similar proliferation as 2000 MSCs without Imatinib. Unexpectedly, Imatinib aggrevated PDGF induced inhibition of proliferation of MSCs. FACS analysis demonstrated suppression of CD140b after 24 hours of incubation with 5 μM Imatinib from 94.4±6.2% before Imatinib to 77.3±10.5% after Imatinib ($p<0.02$). Addition of 5 or 10 ng/mL PDGF-BB resulted in a further decrease of CD140b expression to 43.9% and 24.9%, respectively. Similar results were obtained after incubations in presence of Imatinib and PDGF for 48 hours or under low serum conditions (2% FCS). Differentiation assays confirmed lack of effect on adipogenic differentiation, but a prominent stimulative effect on osteogenic mineralization.

Summary and Conclusions: Imatinib inhibits PDGF through interference with tyrosine kinases. However, PDGF and Imatinib may reinforce each others actions by simultaneous suppression of the PDGF receptor and interfering with its function. This may result in inhibition of proliferation of MSCs, but may also be the case in GISTs. PDGF has been implicated in regulation of invasiveness of cancers and TKI have been used in the treatment of several types of cancer. Our results suggest that, counterintuitively, combined treatment with Imatinib and PDGF may be even more effective in suppression of cancer growth/invasiveness and may have important implications for future clinical treatment protocols.

PB1536

ADDITIONAL CHROMOSOMAL ABNORMALITIES IN PHILADELPHIA-POSITIVE CHRONIC MYELOID LEUKEMIA PATIENTS APPEARING DURING THERAPY WITH TYROSINE KINASE INHIBITORS

A Bennour[1,*] I Tabka[1], I Ouahchi[1], M Elloumi[2], B Meddeb[3], A Khelif[4], A Saad[1], H Sennana[1]

[1]Cytogenetics, Molecular Genetics and reproductive biology , Cytogenetics, Molecular genetics and reproductive biology laboratory CHU Farhat Hached Hospital, Sousse, [2]Hematology, Hedi Chaker Hospital, Sfax, [3]Hematology, Aziza Othmana Hospital, Tunis, [4]Hematology, Farhat Hached Hospital, Sousse, Tunisia

Background: Clonal cytogenetic aberrations of the Philadelphia chromosome (Ph) positive hematopoiesis most include a second copy of the Ph chromosome, i(17q), trisomy 8 and 19. They are non-random and have been associated with the natural evolution of chronic myeloid leukemia (CML) to advanced disease. Therefore, these aberrations are of clinical and biological importance.

Aims: This study evaluates the frequency of recurrent Ph-positive abnormalities and novel aberrations in Ph-positive metaphases.

Methods: Standard R-banded cytogenetic analysis of metaphases was performed to detect additional chromosomal abnormalities.

Results: Among 600 patients with CML,who were treated with tyrosine kinase inhibitors, 136 (22,66%) developed additional chromosomal aberrations. Of these chromosomal abnormalities, 13,23% include additional copy of the Ph chromosome, 13,23% with trisomy 8, 8,82% with nullisomy Y, 3,67% with isochromosome 17q and 2,94% with monosomy 7. We have also reported novel structural chromosomal aberrations in 52 patients (38,23%), 55,76% of them were isolated with Ph chromosome and 44,23% were associated with other aberrations. They include translocations t(2;12)(p21;p13), t(3;3)(q21;q26), t(3;12)(q21;p13), t(4;9)(q21;p21), t(6;9)(p23;q34), t(7;12)(q11;p13) , t(11;12)(p14;q12), t(12;17)(q14;p13) and rob(14;21)(q10;q10), deletions on chromosomes 3,6,7,9,11,13,14,15,16 and 20, additions on chromosomes 1, 20, 21 and duplication on chromosome 1.

Summary and Conclusions: The presence of additional chromosomal aberrations may reflect genetic instability and, therefore, intrinsic aggressiveness of the disease which will be less amenable to subsequent alternative treatments. Conventional cytogenetic analyses remain mandatory during follow-up of patients with chronic myeloid leukemia under tyrosine kinase inhibitor therapy.

PB1537

RESISTANCE TO TYROSINE KINASE INHIBITORS OF CML PATIENTS MONITORED BY RTQ PCR AND DIRECT SEQUENCING

E Hanusovska[1,2,*] L Majerova[1], R Lukackova[1], K Flimelova[1], K Tothova[1], H Majekova[3], D Danis[3], Z Sninska[4]

[1]Clinical genetics, Medirex, [2]St. Elizabeth University of Health & Social work, [3]Department of cellular and molecular biology of drugs, Faculty of Pharmacy, Comenius University, [4]Clinics of Hematology and Transfusiology, University Hospital, Bratislava, Slovakia

Background: Chronic myeloid leukemia (CML) is monitored by the detection of BCR-ABL1 fusion gene on the molecular level. The protein fusion product BCR-ABL is created by the reciprocal chromosomal translocation t(9;22) and play the role of functional tyrosine kinase, which is constitutively activated by autophosphorylation and drives unchecked cellular signal transduction resulting in excess cellular proliferation. The treatment of the disease is managed by tyrosine kinase inhibitors (TKI). However, primary and secondary resistance is occurred and causes not responding or loss of response to the drug which results in relapse of the disease. Resistance can be caused by many mechanisms (*e.g.* efflux of the drug and it inactivation in plasma, mutations on DNA level). Malignant clones resistant to TKI may be acquired or selected during the treatment by several mutations in kinase domain of BCR-ABL1.

Aims: To monitor CML patients treated by TKI (imatinib in first line) by quantification of BCR-ABL1 transcripts by reverse real time PCR (RTQ PCR) and evaluate optimal and suboptimal response according ELN guidelines. In case of increasing levels of BCR-ABL1-trascripts asses the mutation analysis of the kinase domain of the fusion gene (KD BCR-ABL1) by direct sequencing.

Methods: Whole peripheral blood samples (or bone marrow) from CML patients treated by TKI (n=329) were obtained from 6 hematological clinics in Slovakia with patient´s informed consensus. RNA was extracted after separation of WBC and stabilization in RNAlater solution and cDNA was prepared by using TaqMan reverse transcriptase system. Quantification was performed by real time PCR system using a specific BCR-ABL and ABL TaqMan probes. The quantification of fusion transcripts were evaluated according to ELN guidelines as BCR-ABL/ABL ratio in% IS (international scale). Mutation analysis of KD BCR-ABL1 was assessed on seminested PCR product of fusion gene by direct sequencing using BigDye terminator chemistry for capillary electrophoresis in Genetic analyzer.

Results: Our molecular laboratory of Clinical genetics has assessed quantification of BCR-ABL1-trancripts of TKI-treated patients by real time PCR particularly every 3 months for five years. The suboptimal response (without Major molecular response MMR, or it´s lost) to TKI in 18 month was observed in 26% (77 from 329). In case of inadequate initial response to treatment or any sign of loss of response evaluation of ABL kinase domain mutation of BCR-ABL1 was done. From the cohort of 77 resistant patients mutations were detected in 28 cases (36%) (Figure 1) . Point mutation T315I (highly resistant to TKI) was confirmed 5 times, which is 18% from all detected mutations in resistant clones. In one case the CML patient with T315I mutation has undergone allo-SCT, but in 1 year he relapsed and the resistant clone with T315I reappeared.

Summary and Conclusions: The management of Ph^+, $BCR\text{-}ABL1^+$ CML patients is based on recommendations of European LeukemiaNet (ELN). The response to TKI is the most important prognostic factor. Monitoring of CML patients by RTQ PCR and direct sequencing is an important tool for clinicians, mainly in the case of resistance to TKI and in their choice of alternative doses of the drug or switch on TKI of 2th and 3th generation or undergo allo-SCT.

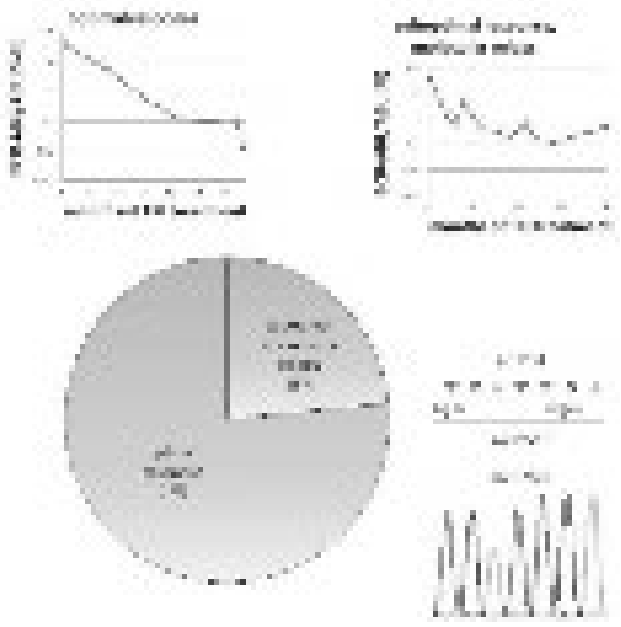

Figure 1.

PB1538

NILOTINIB INDUCES APOPTOSIS THROUGH JAK/STAT PATHWAY MEMBERS STAT5A & STAT5B IN K562 CML CELL MODEL

G Saydam[1,*] T Guliyeva[1], B Tezcanli Kaymaz[2], B Kosova[2], F Sahin[3]
[1]Hematology, Ege University Hospital Internal Medicine, Bornova, [2]Medical Biology, Ege University Hospital, [3]Hematology, Ege University Hospital Internal Medicine, Bornova Izmir, Turkey

Background: Signal transducers and activators of transcription (STAT) proteins function in the JAK/STAT signaling pathway and are activated by phosphorylation. As a result of this signaling event, they affect many cellular processes including cell growth, proliferation, differentiation, and survival. Increases in the expressions of STAT5A and STAT5B play a remarkable role in the development of leukemia in which leukemic cells gain uncontrolled proliferation and angiogenesis ability. Besides, these cells acquire ability to escape from apoptosis and host immune system. For chronic myeloid leukemia (CML) therapy, tyrosine kinase inhibitors are widely being used and one of them is nilotinib.
Aims: In the current study, we aimed to determine transcriptional and translational differences of STAT5A and STAT5B and also apoptosis rates following nilotinib treatment in CML model K562 cells.
Methods: Cell proliferation was assessed by WST assay in order to determine cytotoxicity of nilotinib upon leukemic cells. While mRNA expression levels of STAT5A and STAT5B were analyzed by real time qRT-PCR; protein expressions were detected via western-blot method following nilotinib treatment for duration of 24 – 96 hours also with untreated control group. Apoptosis was performed by "Caspase-3" and "Cell Death Detection" assays following the same treatments with same time intervals. Statistical analyses were done by GraphPad prism software with a significance of $p<0.05$
Results: While number of apoptotic cells were increased by 2.1 fold, 47.36% ($p=0.045$) as a result of measurement of caspase 3 activity; a 1.89 fold, 52.8% increase was detected in apoptosis rate following Cell Death assay ($p=0.0012$) in nilotinib treated group. As for mRNA expression results, while STAT5A expression was significantly decreased by 65.12% [(2.87 fold; $p= 0.0033$)] and by 90.9% [(10.99 fold; $p<0.0001$)] at 72^{th} – 96^{th} hours respectively; STAT5B was downregulated by 80.95% [(5.25 fold; $p= 0.0032$), and 93.36% (15.08 fold; $p<0.0001$)] for 72^{th} and 96^{th} hours in nilotinib treated group compared to control group. As for protein results, both STAT5A and STAT5B protein expression levels were inhibited in a time dependent manner but dramatic suppressions were detected especially at 96^{th} hour for each protein.
Summary and Conclusions: : In conclusion, target genes STATs expressions were suppressed at mRNA and protein levels and also leukemic cell apoptosis was induced following nilotinib treatment of IC_{50} dose. The underlying success mechanism of nilotinib treatment in CML might be due to inhibiting STAT5A & STAT5B transcription and translation. Therefore, targeting JAK/STAT pathway components and evaluating new candidate target genes responsible for CML pathogenesis has an accelerating importance in therapeutic application area.

PB1539

CABOZANTINIB INDUCE ERYTHROID DIFFERENTIATION OF K562 ERYTHROLEUKEMIA CELLS THROUGH DOWN-REGULATING PI3K/AKT SIGNALING PATHWAY

YR Yang[1,*] CY Hu[1], YY Kuo[2], HA Hou[3], CY Chen[3], DL Ou[2], HF Tien[3], LI Lin[1]
[1]Clinical Laboratory Sciences And Medical Biotechnology, [2]Oncology, National Taiwan University, [3]Internal Medicine, National Taiwan University Hospital, Taipei, Taiwan, Republic of China

Background: Chronic myeloid leukemia (CML) is a pluripotent hematopoietic stem cell disease which arises from the *bcr-abl* oncogene. The Bcr-Abl oncoprotein, as a constitutively activated tyrosine kinase, could activate multiple signaling pathways for the malignant transformation. Therefore, specific inhibitors of tyrosine kinases are attractive therapeutic agents. Cabozantinib (XL184, *N*-(4-((6, 7-Dimethoxyquinolin-4-yl) oxy) phenyl)-*N*-(4-fluorophenyl) cyclopropane-1, 1-dicarboxamide), a multiple tyrosine kinase inhibitor, has recently been approved by US FDA for the treatment of medullary thyroid cancer (MTC). The recommended daily dose and the maximum-tolerated dose (MTD) of cabozantinib are 140mg and 175 mg, respectively. Pharmacokinetics study revealed that the steady-state plasma levels were 2.8μM when administrating MTC patients with 175mg daily. In our preliminary results revealed that treating K562 cells harboring *bcr-abl* oncogene with 1μM cabozantinib for 3 days demonstrated an erythroid differentiation phenotype. We wonder that differentiation therapy could be an alternative strategy for treating CML.
Aims: This study was aimed to clarify the therapeutic potency of cabozantinib in CML and speculate its molecular mechanism.
Methods: Human leukemia cell line K562 was used as an *in vitro* model for this study. MTS assay was used to determine the effect of cabozantinib on cell viability. Morphology examination, quantitative real-time PCR, benzidine staining, flow cytometry, and western blotting were used in this study.
Results: Treatment with plasma-reachable dose (1μM) of cabozantinib in K562 leukemia cells for 72 hrs induced erythroid differentiation but not megakaryocytic maturation. We observed a significant population of cells with cytological features of early erythroid differentiation and significantly increased benzidine-positive cells (up to 50%) accompanying with significant accumulation of γ-globin. Expression of transferrin receptor (TfR, CD71) and glycophorin A (GPA, CD235a), both well documented erythroid-specific gene, were induced 3 to 4-fold relative to untreated control cells. Cell cycle analysis revealed that cabozantinib could also result in G_0/G_1 cell cycle arrest without inducing cell death in K562 cells. Signaling pathway analysis revealed that cabozantinib could decrease phosphorylation of ERK, STAT5 and AKT at 6 hours in a dose-dependent manner. Further analysis revealed that cabozantinib treatment could decrease c-Myc with a concomitant induction of p27 and decreased p21, cyclin D and cyclin E in a time- and concentration- dependent manner. Taken together, we proposed that cabozantinib could induce K562 cell differentiation toward erythroid lineage through inhibiting PI3K/AKT pathway, of which Myc, p27, cyclin D and cyclin E were involved (Figure 1).
Summary and Conclusions: We demonstrated cabozantinib with plasma-reachable dose could induce erythroid differentiation. Of note, down-regulating PI3K/AKT signaling pathway may be involved in the molecular mechanisms of cabozantinib-induced erythroid differentiation. This study uncovered the potential of cabozantinib for being a novel differentiation agent for treating patients with CML.

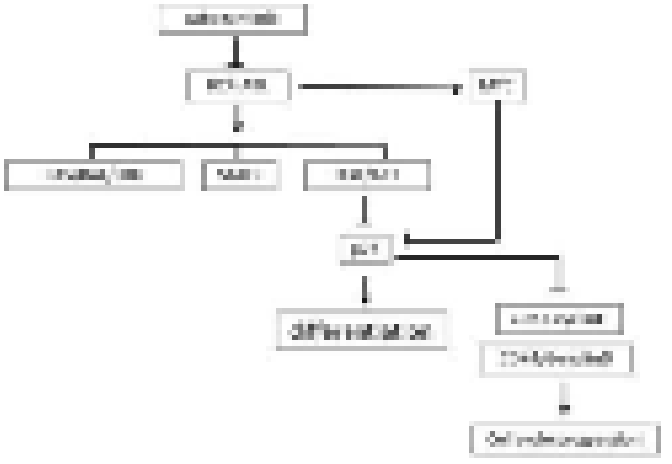

Figure 1.

PB1540

ABL KINASE DOMAIN MUTATIONS IN IMATINIB-TREATED EGYPTIAN PATIENTS WITH CHRONIC MYELOID LEUKEMIA

Y Elnahass[1,*] H K Mahmoud[2]
[1]Clinical Pathology, [2]Medical Oncology, National Cancer Institute/Egypt, Cairo, Egypt

Background: Point mutations within ABL kinase domain (AKD) of the BCR ABL gene are the most common cause of resistance ti Imatinib methylate (IM) treated Chronic Myeloid Leukemia (CML) patients.
Aims: To assess the frequency, type and impact of AKD mutations on prognosis in a cohort of Egyptian CML patients.
Methods: Mutation screening was performed by allele specific oligonucleotide polymerase chain reaction (ASO-PCR) in 76 patients including all 46 non optimal responders; 28 resistant patients, 18 suboptimal responders in addition to 30 patients randomly selected with stable/ decreasing transcript level representing an optimal responder category.
Results: From 16 positive patients, P loop mutations were detected in 9 patients; Q252H in 3 patients (19%), Y253H in 2 patients (12%), Y253F in 2 patients (12%) and E255K in 2 patients (12%). T315I was detected 1/16 patient (6%). Regarding non-p loop mutations; V299L was detected in 1 patient (6%), M351T in 4 patients (25%), F359V in 2 patients (12%). One patient had both Y253H and E255K mutations. Ten/16 (62%) patients carrying mutations experienced disease progression *versus* 1/56 (2%) in non mutation group ($p=0.001$). Median Progression Survival (PFS) and Overall Survival (OS) of the mutation group was 13.5 months and 37.5 months, respectively *versus* 42.6 months in non mutation group ($p=0.001$). The estimated PFS and OS at 49 months in patients with mutations were 37.5% and 56.3% respectively *versus* 98.2% in non mutations carriers ($p<0.001$). Patients harboring P-loop mutations/T315I showed poorer PFS and OS; 14 months (7.5-38) and 10 months (3-40) *versus* 42 months (39-45) and 42 months (9-45) in non P-loop mutations carriers, respectively ($p=0.003$ and $p=0.017$).

Summary and Conclusions: P-loop mutations are significantly associated with advanced CML phases and poorer OS than non P-loop mutations. ASO PCR is a valuable tool for detection of mutations in countries where sequencing facilities are not available.

PB1541

INVESTIGATION OF EFFECTS OF FISETIN, VITEXIN AND HESPERETIN ON CHRONIC MYELOID LEUKEMIA CELLS

A adan gokbulut[1], Y Baran[1*]
[1]Molecular Biology and Genetics, İzmir Institute of Technology, Izmir, Turkey

Background: Chronic Myeloid Leukemia (CML) is characterized by Philadelphia chromosome encoding BCR-ABL1 oncoprotein. Despite therapeutic efficacy of tyrosine kinase inhibitors targeting tyrosine kinase activity of BCR-ABL1 in the clinic, the development of resistance and several side effects are stil challenging problems for most patients. Therefore, alternative therapeutic approaches are required and natural products have been investigated because of their potential in cancer prevention and treatment. Fisetin, viteksin and hesperetin are natural plant flavonoids and commonly found in several fruits and vegetables. Although their anticancer effects has been shown on several cancer types, there is no study related with their effects on K562 CML cells.
Aims: In this study, we aimed to identify the cytotoxic, apoptotic and cytostatic effects of fisetin, vitexin and hesperetin on CML cells.
Methods: K562 CML cells were treated with increasing concentrations (1-200 µM) of fisetin, vitexin and hesperetin and their cytotoxic effects on K562 cells were conducted via MTT cell proliferation assay. Changes in caspase-3 activity of the cells were examined by caspase-3 colorimetric assay kit (BioVision Research Products, USA). The loss of mitochondrial membrane potential (MMP) in response to them was examined by JC-1 Mitochondrial Membrane Potential Detection Kit (Cayman Chemicals, USA). The translocation of phosphatidylserine was determined by Annexin V/PI double staining method. The cell cycle profiles of K562 cells after treatment were analyzed by PI staining by flow cytometry.
Results: The MTT data showed that there were dose- and time- dependent decreases in proliferation of K562 cells. IC_{50} values of fisetin at 48 and 72 h were calculated from cell proliferation plots and were found to be 163- and 120 µM, respectively. On the other hand, IC_{50} values of hesperetin and vitexin were found to be 179- and 162 µM, and 153- and 147 µM at indicated time points, respectively. There were 5.4-, 9.5- ve 11.6 fold increases in percentage of apoptotic K562 cells in response to 50-, 100- and 200 µM fisetin, respectively, as compared to untreated controls. Same hesperetin concentrations resulted in 1.27-, 1.8- ve 4.3- fold changes while there were 1.02-, 1.5- ve 3.6- fold increases in reponse to same concentrations of vitexin. There were 1.03-, 1.25- ve 80-fold increases in loss of MMP in response to 50-, 100- and 200 µM fisetin, respectively. On the other hand, there were 1.7-, 2.4- ve 2.5 fold increases in loss of MMP after hesperetin treatment, and vitexin led to 2.2-, 2.6- ve 2.8 fold increases. There were 1.3-, 1.6- ve 1.8- fold increases in caspase-3 enzyme activity in response to 50, 100- and 200 µM fisetin, respectively, as compared to untreated controls. Hesperetin and vitexin treatment resulted in 2.8- ve 1.4- fold increases in caspase-3 enzyme activity, respectively only at higher concentrations. Hesperetin and vitexin treatment arrested cell cycle at G0/G1 phase.
Summary and Conclusions: All together these findings demonstrated cytotoxic, apoptotic and cytostatic effects of fisetin, hesperetin and vitexin on human K562 CML cells. Fisetin could be evaluated as the most effective flavanoid among others based on these preliminary data. These flavanoids could have therapeutic potentials if supported with *in vivo* studies.

STUDY OF ADDITIONAL GENETIC ABNORMALITIES IN PHILADELPHIA-NEGATIVE CLONES IN CML PATIENTS USING FLUORESCENCE IN SITU HYBRIDIZATION

BR Jeon[1], DH Kang[1], KH Kim[2], YK Lee[1], HS Park[2], S Kim[3*]
[1]Department of Laboratory Medicine and Genetics, Soonchunhyang university hospital, Bucheon, [2]Division of Hematology & Oncology, Soonchunhyang university hospital, Seoul, [3]Division of Hematology & Oncology, Soonchunhyang university hospital, Bucheon, Korea, Republic Of

Background: The Philadelphia chromosome (Ph), the cytogenetic hallmark of chronic myelogenous leukemia (CML), is known to play a central role in the pathogenesis of CML, but other cytogenetic abnormalities have been reported in Ph-negative (Ph-) cells of CML, mostly after treatment. Several mechanisms have also been suggested, such as the possible mutagenic effect of imatinib, the proliferative stress on a small pool of Ph- cells after the eradication of Ph-positive (Ph+) cells by imatinib, and the masking of the presence of concomitant Ph- clonal abnormalities by the presence of a majority of Ph+ cells at the presentation of CML.
Aims: In this study, we tried to detect abnormal cytogenetic abnormalities in Ph- clones in Ph+ CML patients at the time of initial diagnosis using fluorescence *in situ* hybridization (FISH), which is more sensitive than conventional cytogenetic analysis.
Methods: We examined 57 cryopreserved specimens from patients who were newly diagnosed as having BCR/ABL1-positive CML between January 2001 and December 2013. The diagnosis of CML had been established based on peripheral blood and bone marrow examination, supported by conventional chromosomal analysis and FISH to detect the BCR/ABL1 fusion gene.
FISH was performed according to the manufacturer's instructions, using the LSI AML1/ETO Dual Color Dual Fusion Translocation Probe, PML/RARA Dual Color Dual Fusion Translocation Probe, CBFB Dual Color Break Apart Rearrangement Probe, MLL Dual Color Break Apart Rearrangement Probe, and D7S486/CEP7 Dual Color Probe (Vysis/Abbott Molecular, Des Plaines, IL, USA). A minimum of 500 interphase/metaphase nuclei were scored.
Results: With regard to CML diagnosis, one case (1.8%) was in the blast phase, four cases (7.0%) were in the accelerated phase, and 52 cases (91.2%) were in the chronic phase. A total of 47 cases (82.5%) exhibited classical Philadelphia chromosomes, whereas three cases (5.3%) had variant Philadelphia chromosomes, and another four cases (7.0%) had additional chromosome abnormalities at the time of diagnosis. Only one case was classified as positive for abnormality in a Ph- clone in cytogenetic analysis and FISH studies. However, this case was diagnosed as having acute myelogenous leukemia with CML because the blasts were increased (62%) in the bone marrow, and monosomy 7 was positive in the blasts. In that case, BCR/ABL1 rearrangement was positive in 30.0% of the cells. With the exception of this case, the minimum percentage of cases with a positive BCR/ABL1 rearrangement pattern was 89.8%. One case with a three-way translocation as the sole abnormality in a chromosome study exhibited a minor clone with a classical Philadelphia chromosome pattern (1R1G2F) in FISH analysis.
Summary and Conclusions: The results of the present study indicate that the occurrence of masked BCR/ABL1-negative cells with other cytogenetic abnormalities, if present, is rare, particularly in cases with a high BCR/ABL1-positive rate. Larger studies involving more sophisticated methods are needed to fully elucidate this finding.

PB1543

ASSOCIATION OF MDR1 GENE POLYMORPHISM (G2677T) WITH IMATINIB RESPONSE IN EGYPTIAN CHRONIC MYELOID LEUKEMIA PATIENTS

L Ibrahem[1,*] DEL Ghanam[1], E Azmy[2]
[1]clinical pathology department (haematology unit), [2]haematology unit, Mansoura faculty of medicine, mansoura, Egypt

Background: Background:
Despite the excellent efficacy results of IM treatment in CML patients, resistance to IM has emerged as a significant problem. Genetic variations in genes involved in drug transportation might influence the pharmacokinetic and metabolism of IM. The genotype of a patient is increasingly recognized in influencing the response to the treatment.
Aims: to investigate the genotype frequencies of SNPs G2677T in CML patients undergoing IM treatment and to determine whether different genotype pattern of these SNPs have any influence in mediating good response and resistance to IM.
Methods: A total of 96 CML and 30 control samples were analyzed for MDR1 gene (G2677T) polymorphism using PCR- RFLP technique.
Results: Genotype distribution revealed increase in GG, GT (34.4%, 46.9%) and significant decrease in TT (18.8%) genotype frequencies in CML patients compared to controls(p=0.257, 0.326, 0.017 respectively). No significant association of G2677T polymorphism was observed with respect to age and sex (p=0.259, 0.556). Patients in accelerated and blastic phases had higher GT genotype frequency compared to patients in early phases (p<0.001). The distribution of MDR1 2677 genotypes was significantly different among the resistance and sensitivity patients. The resistance incidence correlated with G allele. GG and GT genotypes were higher in CML patients showing imatinib resistance compared to sensitive CML patients (p=0.893, 0.002). Meanwhile TT genotype was shown significantly to be higher among imatinib sensitive group with p<0.001. GT genotype was found to be a significant predictor of IM resistance risk (OR= 4.55; p=0.002). GG genotype was not proved to be significant indicator of resistance risk (OR= 1.06; p=0.893). On the other hand, TT may be a protective factor against imatinib resistance in CML patients (OR= 0.119; P<0.001).
Summary and Conclusions: ABCB1 (MDR1) has been demonstrated to display high affinity for IM and confer IM resistance *in vitro* by extruding IM from hematopoietic cells. The G2677T polymorphism was significantly associated with increased or decreased plasma concentration of P-gp substrates. Carriers of the GT genotype are more at risk of blastic crisis than other individuals. 2677G allele carriers might be at risk for drug resistance. The G allele was reported to have enhanced P-gp expression and was observed to

be associated with increased efflux of P-gp substrates. Since imatinib is one of the P-gp substrate, the present results indicated that G allele was associated with poor response to imatinib in CML patients. Determination of G2677T MDR1 polymorphisms might be useful in response prediction to therapy with Imatinib in patients with CML.

PB1544

THE PROGNOSTIC VALUE OF THE DUAL CD34 AND CD7 EXPRESSION ON MARROW STEM CELLS AMONGE EGYPTIANT CML PATIENTS

H Ellithy[1,*] M Mattar[2], A Lasheen[3], M Elmasry[4]
[1]Internal medicine Dep. Clinical hematology unit, Kasr Al-ainy school of medicine- Cairo university, [2]Internal medicine Dep. Clinical hematology unit, Kasr alainy school of medicine-Cairo university, [3]Clinical pathology departement, [4]Clinical pathology, Kasr Alainy school of medicine- Cairo university, Cairo, Egypt

Background: For various reasons, chronic myeloid leukaemia (CML) is probably one of the most comprehensively studied human malignancies. CML was the first human cancer to be associated with a consistent chromosomal abnormality that responds to molecular target therapy, tyrosine kinase inhibitors (TKIs). The previous observational studies suggesting that the origin of CML clone may occur at 2 levels: The origin of CML from myeloid progenitors cell is supported by several proof such as the presence of a single glucose-6-phosphate dehydrogenase isoenzyme in red cells, neutrophils, eosinophils, basophils, monocytes, and platelets, but not in fibroblasts or other somatic cells in women with CML who are heterozygotes for isoenzymes A and B. Other studies suggesting the primitive pluripotent stem cell origin could be the origin of CML clone, which is supported by detection of the BCR-ABL fusion gene in approximately 25 percent of B lymphocytes in some but not all patients in chronic phase CML. Among CML patients who achieve BCR-ABL transcript-undetectable status; few remain transcript negative after molecular target therapy is stopped while others show re-appearance of transcripts; it may be explained by the variable effect of imatinib on either CML cell origin; Imatinib may eradicate the myeloid progenitors but not the primitive pluripotent stem cell.
Aims: The variant CML stem cell origins may be an explaining factor for the heterogenic course of CML and its effect on survival. The t(9;22) is supposed to occur at either the level of more primitive pluripotent stem cells that express CD7 on CD34+ve cells ; or at the level of more differentiated myeloid progenitors which does not express CD7 on CD 34 +ve cells. We are suggesting that; the more differentiated CML cell origin, the better response to TKIs , TKIs may be capable of total eradication of the more differentiated stem cells origin (CD34+ve, CD7 –ve); however the more primitive stem cells origin (CD34+ve, CD7+ve) are resistance to TKIs, which explain minimal residual disease with an inferior survival. We studied the relation between the expression of early myeloid progenitor marker,CD7, on CD34 +ve bone marrow CML cells and the prognostic Sokal score, to find out if the origin of stem cells is related to this prognostic score or not.
Methods: This study was conducted on a group of 31 Egyptian patients newly diagnosed to have CML in chronic phase who were presented to clinical hematology unit of Kasr Al Ainy teaching hospital. They did not receive TKIs or interferon prior to sampling. Dual culture Epics XL Flucytometry; using dual color FITC for CD34 and PE for CD7 on bone marrow aspirate samples was performed. The dual expression of CD34 and CD7 on bone marrow cells was compared to the Sokal prognostic score.
Results: Patients were catergorized into 3 groups according to Sokal risk score: low risk (19.4%), intermediate risk (38.7%) and high risk (35.5%). Out of thirty one patients; twenty nine patients (94%) have expressed CD34 +ve on bone marrow cells, with mean expression 14.1603%; twenty six patients (86%) have dual CD7 and CD34 expression with mean expression 13.29590%. Dual CD7 and CD34 expression did not correlate with Sokal score. Interestingly, we found CD34 expression is significantly related to Sokal score (p value 0.002).
Summary and Conclusions: The degree of CD34 expression in CML bone marrow cells may have a prognostic value for newly diagnosed CML patients. We are recommending studying CD34 expression on CML bone marrow cells for newly diagnosed patient and correlate it with Sokal risk score among different ethnicity and population, as it may be integrated in Sokal risk score, if it shows a similar significance as in our study.

PB1545

THE EFFECT OF INHIBITING THE SPLICE FACTOR KINASE CLK1 ON ALTERNATIVE SPLICING IN K562 CELLS

H Alabouh[1*]
[1]Faculty of Health & Life Sciences, university west of england, bristol, Bristol, United Kingdom

Background: The alternative splicing of pre-mRNA is a ubiquitous and extremely versatile mechanism controlling the expression of human genes[1]. In humans, 92–94% of multi-exonic genes are alternatively spliced[2]. Alternative splicing provides cells with many protein isoforms with often radically different properties. In leukaemia the preferential expression of anti-apoptotic isoforms promotes the progression of disease[3]. Several receptor tyrosine kinases are involved in the pathogenesis of leukaemia, including RON. RON is alternatively spliced; skipping of exon 11 (DRON) results in a constitutively active isoform in malignancies. RON alternative splicing is altered in acute myeloid leukaemia[4]. The nuclear Cdc2-like protein kinase 1 (Clk1) plays an important role in the regulation of the activity of several splice factors[5], including the oncogenic splice factor SRSF1 known to promote DRON expression. The potential role of Clk1 in the regulation of alternative splicing of RON and of other critically important genes in leukaemia has not yet been investigated.
Aims: To determine whether or not Clk1 might contribute to the regulation of alternative splicing of key genes associated with leukaemia.
Methods: Clk1 was inhibited in K562 cells (CML) with the compound TG003 at 150 μM for 24 hours. Standard RT-PCR was performed to investigate the effect of Clk1 inhibition the expression of splice isoforms of the tyrosine kinase RON, and for comparison of the apoptotic gene caspase 9 and the transcription factor RUNX1 (AML1). The relative intensity of PCR amplicons was quantified using ImagJ software.
Results: The present study demonstrates that the inhibition of the splice factor kinase Clk1 has a significant effect on the alternative splicing of RON, reducing the amount of exon 11 skipping. Ultimately, inhibition of Clk1 would promote the expression of the RON splice isoform in K562 cells.
Summary and Conclusions: Targeting splice factor kinases may offer potential new treatment options. Inhibiting Clk1 cause significant shift in splicing patterns of genes associated to leukaemia.

Chronic myeloid leukemia - Clinical

PB1546

CLINICAL SIGNIFICANCE OF COMBINING BCR-ABL1 TRANSCRIPT LEVELS AT 3 AND 6 MONTHS IN CHRONIC PHASE CHRONIC MYELOID LEUKEMIA PATIENTS TREATED WITH FRONTLINE SECOND-GENERATION TYROSINE KINASE INHIBITORS

SE Lee[1,2,*] SY Choi[2], SH Kim [2], YJ Oh[2], MJ Chae[2], HY Song[2], HL Yoo[2], MY Lee[2], EJ Jang[2], KH Jeong[2], JS Lee[2], DW Kim[1,2]
[1]Department of Hematology, Seoul St. Mary's Hospital, The Catholic University of Korea, [2]Cancer Research Institute, The Catholic University of Korea, Seoul, Korea, Republic Of

Background: The efficacy of frontline second-generation tyrosine kinase inhibitors(2G-TKI) in chronic phase chronic myeloid leukemia (CP CML) has been established. Frontline 2G-TKI threrapy demonstrated faster and deeper responses than imatinib(IM. Recent studies have demonstrated that measurements of BCR-ABL1 transcript levels at 3 and 6 months are able to identify high-risk patients and an achievement of early molecular response (EMR; BCR-ABL1 ≤ 10% at 3 months or BCR-ABL1 ≤ 1% at 6 months) predict overall survival (OS) and progression free survival (PFS).
Aims: The aim of this study was to evaluate clinical significance of combining BCR-ABL1 transcript levels at 3 and 6 months in CML patients treated with frontline 2G-TKI.
Methods: A total of 125 newly diagnosed CP CML patients were treated with radotinib (n=51), nilotinib (n=40), dasatinib (n=21), and bosutinib (n=13) as a frontline therapy. Among them, molecular analysis at 3 and 6 months was conducted in 114 and 106 patients respectively. We classified patients according to their transcript levels at 3 months (lower or higher than 10%) and 6 months (lower or higher than 1%).
Results: 81 men and 44 women were included and th median age was 41 years (range, 18-73). The percentages of patients with low, intermediate and high Sokal risk scores were 39%, 38% and 22%, respectively with unknown risk score in 1%. For 114 patients with molecular data at 3 months, the patients showed BCR-ABL1≤10% (n=106, 93.6%) or >10% (n=8, 6.4%). At 6 months, 8 patients did not yet followed-up. 106 patients with 6-month data showed BCR-ABL1≤1% (n=88, 83%) or >1% (n=18, 17%). A total of 81 patients achieved EMR both at 3 and 6 months; these patients had CI of MMR by 2 year (82.9%), 2 year EFS (75.2%), 2 year FFS (76.4%), and 2 year PFS (98.8%). 5 patients had no EMR on both occasions; these patients had a poor outcomes in terms of 2 year EFS (0%), 2 year FFS (0%), and 2 year PFS (53.3%). 13 patients had EMR at 3 months but no EMR at 6 months; their 2 year EFS, FFS, and PFS were 66.5%, 66.5%, and 92.3%, respectively. Only 2 patients had no EMR at 3 months but EMR at 6 months; until now, they continued frontline 2G-TKI during 9 and 21 months, respectively.
Summary and Conclusions: Our data showed that the patients with no EMR at both time points had poor outcomes. The patients who had EMR at 3 months but no EMR at 6 months showed no difference of EFS, FFS, and PFS, compared to those of patients who had EMR at both time points. It suggested that the combining assessment at 3 and 6 months may apply more prognostic information in CML patients treated with frontline 2G-TKI. However, further clinical investigations in a larger patient population with longer follow-up are needed.

PB1547

CAUSES OF ANEMIA AFTER LONG-TERM TREATMENT WITH IMATINIB IN CHRONIC MYELOID LEUKEMIA

I Lorand-Metze[1,*] M S Moura [1], T C Benevides[1], M T Delamain[2], K B Pagnano[2]
[1]Internal Medicine, [2]Hematology/Hemotherapy Center, University of Campinas, Campinas, Brazil

Background: In the IRIS Study, an incidence of 3% of anemia after 19 months of treatment with imatinib in newly diagnosed chronic myeloid leukemia (CML) (chronic-phase (CP) was reported. This finding was seldom examined by other centers. .
Aims: We evaluated the incidence of anemia after at least two years of imatinib treatment of CML patients in CP and tried to identify other contributing causes of anemia in this population
Methods: consecutive patients with CML, still in CP after completing 2 years of imatinib treatment entered the study. Patients with blast crisis at diagnosis, discontinuation of imatinib before 2 years of treatment or poor adhesion were excluded. Anemia after treatment was defined by the National Cancer Institute (NCI) Common Toxicity Criteria - Version 4.0 (grade 3 - hemoglobin = 6.5 - 8.0 g/dL and grade 4 - hemoglobin <6.5 g/dL). The normal values at diagnosis were considered >12.0 for women and >14.0 for men. Status of cytogenetic and molecular response was also recorded. Besides, renal toxicity and other causes of anemia were investigated.
Results: among 157 patients treated at our Center between 2003 and 2010, 97 fulfilled the inclusion criteria. Median age: 53 years (24-86), 54 male and 43 females. Comorbidities were found in 60 patients. Sokal score was low risk in 39%, intermediate in 36% and high risk in 25% of the patients. Twenty one patients had received interferon and one received bosutinib prior to imatinib. Eighty seven patients achieved complete cytogenetic response (CCR) and 41 had a major molecular response, but at the time of the analysis of anemia, 4 had lost cytogenetic remission and 8 had lost molecular response. After the second year of treatment, 80.8% of the cases presented grade 1, 17.9% grade 2 and 1.3% grade 3 anemia. Of these, no etiological causes for the anemia was found in 52 patients. The etiology of anemia was identified as iron deficiency (n=5), and one of them had simultaneously renal failure. Hypothyroidism was found in 2, B_{12} vitamin deficiency in 2), HIV infection in 1, pulmonary tuberculosis in 1 and renal failure in 1. Twenty-eight patients had normalization of hemoglobin without medical intervention but decrease in hemoglobin persisted in 40 cases. Six patients had resolution of the anemia after switching to a second-generation inhibitor and three showed clinical improvement after treatment of the specific cause. Renal toxicity was observed in 8.9% of patients, most of these patients due to mild TKI toxicity.
Summary and Conclusions: several degrees of anemia may occur in patients with CML on long-term imatinib therapy, most of them not severe. Regular hematological follow-up is required to identify causes not related to CML that can be corrected. In cases related to imatinib toxicity, dose modification or change of TKI is necessary. It should be emphasized the importance of investigating secondary causes for anemia, especially in patients with good adherence to treatment and satisfactory therapeutic response.

PB1548

EARLY COMPLETE CYTOGENETIC RESPONSE (CCGR-6M) CAN PREDICT LONG TERM OUTCOME IN CHRONIC MYELOID LEUKEMIA PATIENTS TREATED BY IMATINIB ACCORDING TO EUROPEAN LEUKEMIA NET RECOMMENDATIONS (ELN2006/2009)

A Bogdanovic[1,*] V Djordjevic[2], V Milosevic[2], D Lekovic[2], J Jovanovic[2], M Dencic Fekete[2]
[1]Outpatient&Diagnostic Dept, Clin Hematology CCS, Faculty of Medicine, Unv Belgrade, [2]Outpatient&Diagnostic Dept, Clin of Hematology CCS, Belgrade, Serbia

Background: Recent ELN 2013 guidelines changed milestones of response in CML patients treated with TKI, mainly imatinib, from previous ones published in ELN 2006 and 2009 recommendations. Also, recent reports emphasize prognostic value of early molecular response at 3 months (German CML IV trial). It is known that most of patients with CML in chronic phase achieving complete cytogenetic response (CCgR) up to certain time period have excellent long term results. But in some countries, like in Serbia, molecular monitoring was not feasible procedure in all patients, and regularly it was scheduled after achievement of CCgR, measuring depth of residual disease.
Aims: To analyze retrospectively prognostic impact of new optimal response milestone, CCgR at 6m (ELN 2013 recommendations).

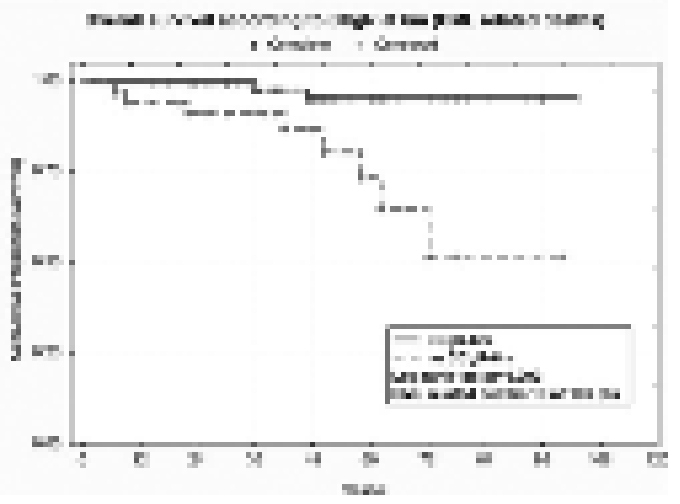

Figure 1.

Methods: Cohort analysis of 110 patients with CML in chronic phase treated with frontline imatinib (IM, Gleevec®) in period of 8 years (2005-2012) in single academic center. Patients were escalated to IM800 in case of suboptimal

response or failure at 6 and 12 months according to ELN 2006&2009 proposals and then subsequently with other TKI (nilotinib). All patients had at least 18 months of follow-up.
Results: Results. From 110 analyzed patients, new 6 month milestone, CCgR-6m was achieved in 72 of them, 64.9%, and others, 35.1% should now be considered as failure or warning (39/110). In that group, 19 patients were escalated to IM800mg due to suboptimal response or failure at 6m (8 pts) or 12m (11 pts) according to ELN 2006&2009 recommendations. Patients not responding to escalated dose of imatinib were switched to nilotinib (5 pts) together with other 5 pts with subsequent loss of response in 2012. In escalated patients, 4 of 8 pts escalated at 6m and 5 of 11 pts escalated at 12m achieved further optimal response (CCgR), comprising roughly 50%. Patients responding to escalated dose had lower Ph+ burden in time of escalation (Ph+ in 40% of mitoses), and many of them were in nowadays defined "warning" area. In our group, 14 pts died, 10 from CML related causes, and 4 from other reasons. Further analysis included only CML related deaths. Overall survival at 5 yrs, OS5y was 87%, but patients achieved CCgR-6m had much better survival, OS5y was 95.5% *vs.* 74.6% (log rank p=0.002). Only two patients achieved CCgR-6m, died due to sudden transformation in 3rd and 4th year from diagnosis. Overall survival at 8 yrs, OS8y was 95.5% for those achieved CCgR-6m but those without CCgR-6m had OS8y 52.3% (log rank p=0.002).
Summary and Conclusions: Even our data are based on small number of patients from single center, new optimal milestone, early complete cytogenetic response at 6 months could also be good and robust prognostic indicator, and therefore could also be used together with other early milestones like bcr-abl/abl<10% at 3 months, especially in circumstances where regular molecular monitoring is not feasible in all patients.

PB1549

METABOLIC SYNDROME AND TKIS TREATMENT IN CHRONIC MYELOID LEUKEMIA

A Iurlo[1],* E Orsi[2], C Bucelli[1], N Orofino[1], V Resi[3], D Zimbalatti[3], D Cattaneo[1], D Consonni[4], A Cortelezzi[1]
[1]Hematology Unit, IRCCS Ca' Granda – Maggiore Policlinico Hospital Foundation and University of Milan, [2]Endocrinology and Diabetes Unit, IRCCS Ca' Granda – Maggiore Policlinico Hospital Foundation and University of Milan, Milan, Italy, [3]Endocrinology and Diabetes Unit, [4]Epidemiology Unit, Department of Preventive Medicine , IRCCS Ca' Granda – Maggiore Policlinico Hospital Foundation and University of Milan, Milan, Italy

Background: Chronic myeloid leukemia (CML) is a myeloproliferative neoplasm characterised by a pathognomonic chromosomal translocation t(9;22)(q34;q11.2). The introduction of Tyrosin-Kinase Inhibitors (TKIs), with the aim of targeting this translocation, has dramatically improved life expectancy of CML patients. First (imatinib) and second generation TKIs (dasatinib and nilotinib) act on various molecular targets and this functional difference could explain the various adverse reactions. Besides non haematological side effects, the three groups of TKIs have different effects on glucose and insulin metabolism (GIM), but no data are available on the prevalence of Metabolic Syndrome (MS). MS is a cluster of interrelated metabolic disorders associated with insulin resistance and increased risk of cardiovascular disease.
Aims: To evaluate the presence of MS defined by the National Institute of Health Cholesterol Education Program-ATP III in a cohort of CML patients treated with the three different classes of TKIs.
Methods: A total of 90 unselected CML patients treated with TKIs and referred to our Hospital were included. Blood samples and other clinical variables were collected for each patient. We evaluated anthropometric parameters to define the presence of MS according to ATP III (≥3 of following abnormalities): waist circumference ≥102 cm in men and ≥88 cm in women, serum tryglicerides level ≥150 mg/dl, HDL cholesterol level <40 mg/dl in men and <50 mg/dl in women, blood pressure ≥130 or ≥85 mmHg, or serum glucose level ≥100 mg/dl. We studied Beta-cell function assessed by HOMA-IR e HOMA-beta to estimate insulin-resistance and insulin-secretion, respectively.
Results: Among our patients, 26 (31%) were confirmed with MS. The nilotinib treated group presented the highest percentage of MS (p<0.01). Adjusting data for sex and age, total (p<0.01) and LDL (p<0.01) cholesterol levels were significantly higher in the nilotinib group when compared to the imatinib and dasatinib groups, while the homocysteine level was significantly higher in the dasatinib treated group (p<0.01) and higher, but not significantly, in the nilotinib treated group, when compared to the imatinib one. The mean levels of HOMA-beta were lower in patients with MS compared to the non-MS patients (p<0.01) in the three groups, while HOMA-IR, weight and BMI were higher (p<0.01).
Summary and Conclusions: In our series MS is highly prevalent and CML patients treated with nilotinib presented a higher cardiovascular risk profile compared to the others. On the basis of our results, when nilotinib is the selected drug, we suggest a multidisciplinary approach with the patient, with the aim to reduce cardiovascular risk and improve long term clinical outcomes.

LABCEUTICS BCR-ABL1 EXTERNAL QUALITY ASSESSMENT STUDY-TWO ENDS OF THE (INTERNATIONAL) SCALE

J Clark[1],* M Griffiths[2], S J Patton[3], A Grossi[4], S D Scott[5], A L Jack[5], E Labourier[6], M Fe Paz[7]
[1]Labceutics, York, [2]West Midlands Regional Genetics Laboratory, Birmingham Women's NHS Foundation Trust, Birmingham, [3]European Molecular Genetics Quality Network, Manchester, United Kingdom, [4]Oncology Unit, Ospedale di Prato, Prato, Italy, [5]UKNEQAS LI, Sheffield , United Kingdom, [6]Asuragen, Austin, United States, [7]Labceutics, Madrid, Spain

Background: Relative quantitative polymerase chain reaction (RQ-PCR) testing for *BCR-ABL1* is the recommended method for monitoring Chronic Myeloid Leukaemia (CML) patients receiving Tyrosine Kinase Inhibitor (TKI) therapy. Current guidelines anchor therapeutic decisions to *BCR-ABL1* levels reported on the International Scale (IS) at specific time points post initiation of therapy. Therefore there is great need to reduce inter-laboratory variation to ensure results are comparable between centres. Recent studies and guidelines have shown the importance of achieving *BCR-ABL1* levels below 10%^{IS} at 3 months as an early indicator of prognosis, whilst at the other end of the scale, many clinical trials are investigating cessation of TKI therapy in patients who demonstrate undetectable disease *e.g.* MR$^{4.5}$.
Aims: Labceutics conducted an EQA modelled study with 15 EU laboratories, investigating the conversion and correction to the international scale. As part of this study laboratory variation was assessed at both ~10%^{IS} and ~0.0032%^{IS}, addressing 2 important and current trends for diagnostic laboratories.
Methods: 15 participating laboratories (enrolled by Labceutics via an open call in EU5) each tested lyophilized cell line dilutions representing 5 levels of *BCR-ABL1* positivity. Five batches of test samples were prepared by the UK National External Quality Assessment Scheme (UKNEQAS) for Leucocyte Immunophenotyping (UK NEQAS LI) and distributed as randomized blinded triplicates (total 15 samples/laboratory) designed to represent clinically relevant *BCR-ABL1/ABL1* ratios between 5% and 0.0005%. Each laboratory extracted and tested the samples using their own laboratory procedures and in addition used the Asuragen ARQ calibrators to report results on the IS. Labceutics coordinated the study, via the CONNECT^{TM} communication portal and double-blinded data analysis was performed by the UKNEQASLI.
Results: Almost half of the laboratories reported at least one sample from batch 1 (consensus median 7.59%^{IS}) to be greater than 10%^{IS}, whilst only 20% of the laboratories reported all of the triplicates to be greater than 10%^{IS}. In total, 35% of samples analysed from this batch were reported as greater than 10%^{IS}, according to the current ELN guidelines this would be defined as a suboptimal response and a change in therapy would be recommended.
5 laboratories detected *BCR-ABL1* at least one of the triplicates from sample batch 5 (consensus median 0.005%^{IS}); of these only 2 laboratories detected *BCR-ABL1* in all of the triplicates, highlighting that routine detection at MR$^{4.5}$ is challenging and further optimisation is needed. When all samples were analysed, one third of the laboratories reported average *ABL1* copy numbers<10,000, with almost half reporting average *ABL1* copy numbers between 10,000 and 32,000 and 2 labs reporting average *ABL1* copy numbers >32,000. Further highlighting the need for assay/procedure optimisation.
Summary and Conclusions: This study has highlighted variability at 2 critical decision making milestones in *BCR-ABL1* monitoring, with the potential to negatively impact on patient management. Further efforts are need to reduce this inter-laboratory variability to facilitate wide spread adoption of clinical guidelines. In order to address the need to improve *BCR-ABL1* testing, specifically at 10%^{IS} and MR$^{4.5}$, Labceutics has initiated CONNECT+ for *BCR-ABL* a network of worldwide laboratories that will work collectively to improve standards in *BCR-ABL1* testing by tackling such topics as pre-analytical variables, physician education and quality indicators for diagnostic services.

PB1551

CML PATIENTS TREATED BY TYROSINE KINASE INHIBITORS IN FIRST CHRONIC PHASE: IMPACT OF MAJOR MOLECULAR RESPONSE ON OVERALL SURVIVAL AND DELAY OF ITS ACHIEVEMENT ON COMPLETE MOLECULAR RESPONSE INCIDENCE

M Michallet[1],* M Sobh[1], S Morisset[1], S Ducastelle[1], L Gilis[1], M Etienne[1], O Le borgne[1], I Tigaud[2], S Hayette[2], X Thomas[1], H Labussière[1], F Barraco[1]
[1]Hematology, [2]Biology, Centre Hospitalier Lyon Sud, PIERRE BENITE CEDEX, France

Background: Most patients with CML treated with Tyrosine Kinase Inhibitors (TKIs) achieve a major molecular response (MMR), that is, the absence of detectable Ph chromosomes. Even after this threshold is achieved, the disease burden continues to progressively decrease with continued treatment. Therefore, more sensitive polymerase chain reaction (PCR)–based molecular methods are required to detect and quantify levels of minimal residual disease

leading to complete molecular response (CMR), especially at long time points after TKI initiation. Low levels of minimal residual disease, as measured by real-time quantitative PCR, have been shown to be an excellent surrogate marker for long-term prognosis.

Aims: The objective of the present study is to describe at a first time the different clinical and therapeutic characteristics of chronic myeloid leukemia (CML) patients consecutively treated in first chronic phase using tyrosine-kinase inhibitors (TKI) as first line treatment, followed at our centre between years 2001 and 2011, and at a second time to assess response to TKI with the incidence of major molecular response (MMR) and then its evolution to reach complete molecular response (CMR).

Methods: We analyzed 183 CML patients, 117 males and 66 females with a median age at diagnosis of 50 years (17-81)]. Among 135 patients evaluated for Sokal score, 41 (30%) were low, 63 (47%) were intermediate and 31 (23%) were high. According to hasford score (125 evaluated), 57 (46)% were low, 61 (49%) intermediate and 7 (5%) were high. First line treatment was imatinib for 161 (88%) patients, dasatinib for 14 (8%) patients and nilotinib for 8 (4%) patients. Overall, 167 (91%) patients obtained MMR [134 (80%) after first line treatment, 26 (16%) after second line and 7 (4%) after third line treatment] within a median time of 13 months (range: 2-88); and 16 (9%) patients never reached MMR. Non-MMR patients, were as follow: 53% had high sokal score 33% intermediate and 14% low; 6% had high hasford score, 47% intermediate and 47% low; they received a median of 3 TKI-based treatment lines during a median follow-up of 37 months; 6 (37.5%) of them died after disease progression and 10 still under treatment.

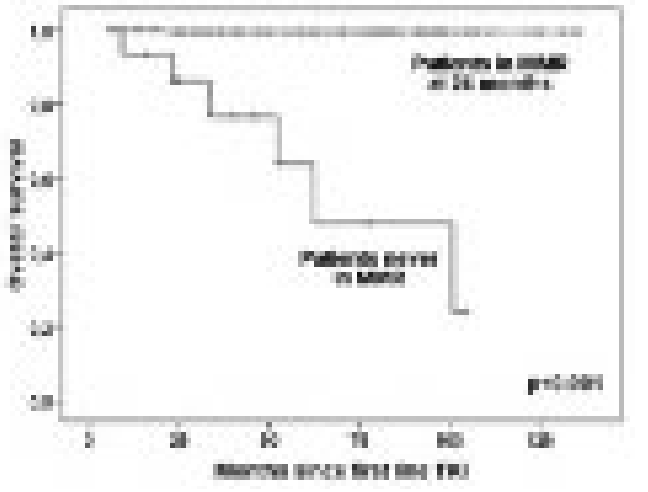

Figure 1.

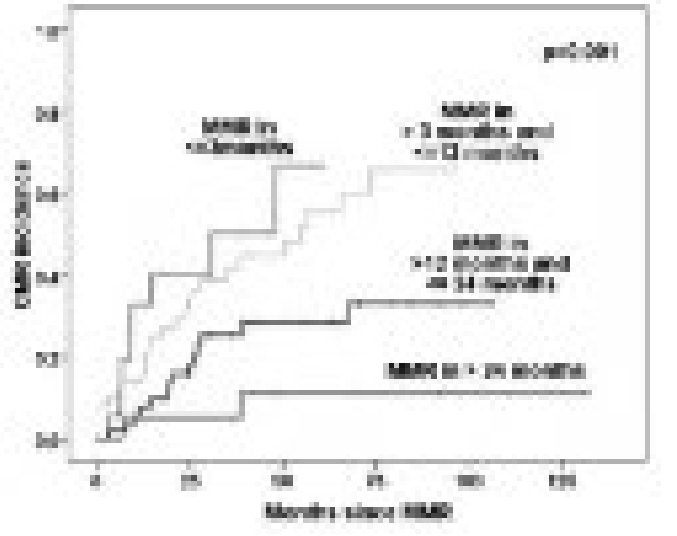

Figure 2.

Results: The median time to obtain MMR was correlated with sokal score: 9 months (range: 2-84) in patients with low score; 13 months (range: 3-78) in patients with intermediate score and 17 months (range: 3-63) in patients with high score, p=0.03, same according to hasford score with 11 months, 13 and 20 months respectively, p=0.05. Among MMR patients, 18 (11%) lost their MMR after a median time of 28 months (range: 3-65) while 57 (34%) achieved a CMR after a median time of 36 months (range: 0-73) from MMR. Interestingly, response enhancement from MMR to CMR was significantly impacted by the time to have a MMR, thus the 5 years incidence of CMR was 67% in patients who had MMR in ≤ 3 months, 56% in patients with MMR > 3 and ≤ 12 months, 28% in patients with MMR > 12 and ≤ 24 months, and 12% in patients with MMR > 24 months, p=0.01 (Figure 1). After a median follow-up of 62 months (range: 6-135), patients who were in MMR at 24 months had 5 years probability of overall survival of 99% compared to 64% for those who did not have it at that time nor later, p <0.001 (Figure 2).

Summary and Conclusions: We showed that patients with low sokal and hasford scores have significant faster time to achieve MMR. CMR incidence was significantly related to shorter time to obtain MMR. Two-years MMR is a significant factor predicting patient overall survival.

Background: Molecular testing for BCR-ABL1 mRNA levels is an essential parameter in treating patients with chronic myeloid leukemia (CML). However, differences in testing methods and control genes have caused inter-laboratories variability, which makes it may limit the clinical utility and comparison of the results of the measurement. In addition, standardization process is complicated and time-consuming.

Aims: Therefore Korean representative university hospitals have agreed with an establishment of centralization of molecular assays including BCR-ABL1 gene quantitation and mutation analysis in a single laboratory.

Methods: Korean molecular test centralization (KoMoC) program has provided complimentary molecular tests including real time quantitative reverse transcriptase polymerase chain reaction (qRT-PCR) and BCR-ABL1 kinase domain mutation assays, and opens to all hospitals caring CML patients. The program covers all of processes from shipping peripheral blood (PB) samples to reporting results through offline or online. We analyzed RNA quality using ABL copy number and BCR-ABL1 transcript level using a standardized international scale (IS).

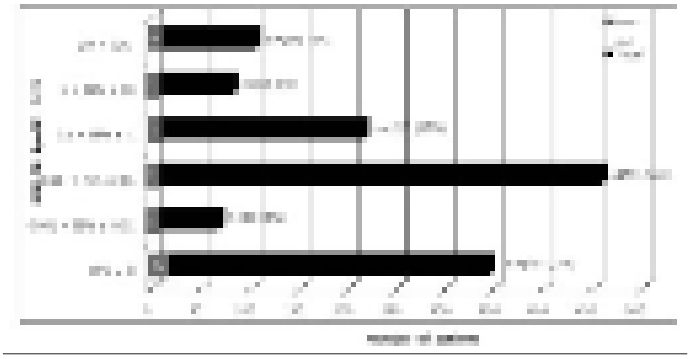

Figure 1. Best molecular response achieving various TKI therapy in KoMoC program.

Results: Between October 2012 and October 2013, a total of 1302 CML patients from 40 university affiliated hospitals have participated in the KoMoC program. Their 2169 PB samples were analyzed using qRT-PCR and 8 samples were requested for Saenger sequencing. Among 2169 PB samples, 2109 samples (98%) had ABL copy over 50,000 and only 17 (1%) samples showed low ABL copy less than 10,000. Using qRT-PCR assay, 888 (68%) out of 1302 CML patients showed BCR-ABL1 transcript<0.1% IS including 345 (27%) patients for undetectable transcript.

Summary and Conclusions: Approximately 70% of Korean CML patients treating with various TKIs are maintaining more than major molecular response and the national-wide centralization program of molecular test have been providing a reliable, high-throughput results in real clinical practice. In addition, KoMoC program can be a part of solution to overcome inter-laboratories variability from lack of standardization. Further analyses with integration of clinical information are now under contemplation.

PB1553

PROGNOSTIC VALUE OF VEGF FOR THE OVERALL SURVIVAL OF PATIENTS WITH CML TREATED WITH IMATINIB

K Kotlyarchuk[1,*], L Lukavetskyy[1], A Lukianova[1], O Danysh[1], O Boyko[1], M Simonova[1], Z Maslyak[1]
[1]SI "Institute of Blood Pathology and Transfusion Medicine, NAMS of Ukraine", Lviv, Ukraine

Background: Early prognosis of optimal response to modern treatment of chronic myeloid leukemia (CML) is among the most discussed issues within hematological community. Particularly, prognostic importance of molecular response at 3 months of treatment with tyrosine kinase inhibitors (TKI) has already been confirmed. However, very little is known about prognostic role of such cytokines as vascular endothelial growth factor (VEGF) in this subset of patients.
Aims: Purpose of this research was to establish prognostic significance of serum level of VEGF in patients with CML determined at different time-points of treatment with imatinib.
Methods: A group of 48 patients with chronic phase CML receiving imatinib either front-line (6 patients) or as subsequent treatment lines (42 patients) were studied. All patients underwent general clinical, laboratory, morphological and cytogenetic investigations. Additionally they were tested for serum levels of VEGF prior to imatinib initiation as well as at 3, 6 and 12 months of this treatment by immunoenzyme assay.
Results: This study comprised 48 patients with chronic phase CML; median observation time was 84,0 months (ranging from 9,5 to 102,2 months). Apart from the standard investigations all patients were tested for serum levels of VEGF at different stages of treatment. Patients were divided into 2 subgroups depending on the level of this cytokine: first included patients with VEGF levels exceeding healthy control group results; second – with levels comparable to the controls. According to the obtained results serum level of VEGF determined before imatinib initiation did not depend on the prior anti-leukemic treatment (median VEGF level in patients starting imatinib front-line was 333,91 pg/mL compared to 340,55 pg/mL in pretreated patients) and was three times higher than the control group. Already after 3 months of imatinib VEGF levels decreased significantly and approached normal values. Subsequently, at 6 and 12 months of treatment they remained relatively stable in the majority of patients. Analysis of the overall survival (OS) was performed in both subgroups depending on their VEGF levels before imatinib initiation and 3, 6, 12 months after its start. Obtained results showed that OS did not depend on the pre-imatinib VEGF levels whereas statistically significant OS advantage was detected for subjects with its normal levels at 3 months compared to those with increased VEGF (81,9% *vs.* 42,9% respectively). Similar but less prominent tendency was detected for VEGF levels at 6 and 12 months of imatinib.
Summary and Conclusions: Results of this study suggest that serum level of VEGF in patients with CML could be considered as an additional prognostic factor for predicting further disease course, response to treatment and overall survival of these patients. According to our data VEGF level at 3 months of imatinib treatment has the most significant potential for this aim. We conclude that after validation in bigger studies this parameter could become an additional prognostic marker for overall survival and achievement of response to treatment with imatinib. Patients with higher levels of VEGF at 3 months could be candidates for closer monitoring and possibly treatment correction especially in case of unavailable or unclear molecular response results at this time-point.

PB1554

EVALUATION OF RUNX1 EXPRESSION IN PATIENTS WITH CHRONIC MYELOID LEUKEMIA (CML) AT DIAGNOSIS AND TREATED WITH ITKS

C Mascarenhas[1,*], A Cunha[2], M Almeida[3], L Aguiar[4], R Pogue[4], K Pagnano[3], C De Souza[3]
[1]Catholic University of Brasilia , BRASILIA, [2]Federal University of Sao Carlos, Sao Carlos, [3]University of Campinas, Campinas, [4]Catholic University of Brasilia, BRASILIA, Brazil

Background: The treatment of chronic myeloid leukemia (CML) with tyrosine kinase inhibitors (TKIs) presents satisfactory response in reducing disease cells and prolonging overall survival in the majority of patients. However, some of CML patients develop resistance to treatment presenting loss of response or disease progression. Although mechanisms underlying the resistance to treatment with TKIs or disease progression are unclear, studies show relation with genomic instability and alterations of key molecules for hematopoiesis, such as *RUNX1.* This gene is one of the subunits of the Core Binding Factor, a transcriptional regulator complex.
Aims: The aim of this study is to analyze *RUNX1* levels at diagnosis and after TKIs treatment of CML patients in all phases and its correlation with cytogenetic and molecular responses.
Methods: *RUNX1* expression was evaluated in 22 newly diagnosed CML patients (pts), 26 pts treated with imatinib 400-600mg in first line and 15 blood donors. Samples were collected from peripheral blood at diagnosis and RNA was obtained from total leucocytes. RNA samples were submitted to the synthesis of cDNA using the kit RevertAid™ HMinus First Strand cDNA Synthesis Kit (Fermentas, Life Sciences). The gene expression was evaluated by qPCR using β-Actina and GAPDH as endogenous control, the results were analyzed using $2^{-\Delta\Delta CT}$. Cytogenetic analysis was performed at diagnosis, 3, 6, 12 and 18 months after starting therapy and then every 12-24 months thereafter if CCR was achieved. BCR-ABL transcripts were measured in peripheral blood at 3-month intervals using qPCR. Results were expressed as BCR-ABL/ABL ratio, with conversion to the international scale (IS). Major molecular response (MMR) was defined as a transcript level ≤ 0.1% IS. All response analysis was based on imatinib start and any patients were classified according to criteria of the European Leukemia Net as responsive, as having a failed/resistant or sub-optimal response to TKIs. The c^2 and Mann-Whitney tests were used to define differences between groups (categorical and continuous variables respectively). $P< 0.05$ was considered significant.
Results: 48 CML pts, 55% male, average age of 52,5 years (20-85) were evaluated, 61% in chronic phase (CP), 28% in accelerated phase (AP) and 11% in blast crisis (BC). The average duration of imatinib treatment was 27 months (1-109) and 85.6% achieved complete hematological response, 69.2% complete cytogenetic response and 59% major or complete molecular response. The analysis showed that higher levels of *RUNX1* were correlated with advanced phases of disease and expression of BCR-ABL transcripts (RQ-PCR <10%) at 3 months analysis. Significant difference in expression between patients that achieved complete cytogenetic response and patients with no cytogenetic response ($p<0.0001$) was observed. Results show statistically significant differences between healthy volunteers and NoCgR patients and between CCgR and NoCgR patients. As well as, the evaluation of pts at diagnosis and pts after treatment with ITK shows that *RUNX1* expression is grown before treatment.
Summary and Conclusions: The expression of *RUNX1* gene was overexpressed in patients in advanced phase of disease when compared with patients who are responding to TKI treatment. *RUNX1* was shown promising, since the occurrence of chromosomal translocations in this gene has been associated with different types of acute leukemia – however, its association with CML is not yet clear. In addition, *RUNX1* can be used as a molecular marker of prognostic and loss of response in CML. Furthermore studies relating the level of expression of this gene with the activation of specific metabolic pathways involved in BCR-ABL can improve the state of the art at therapeutic management in resistant patients.

PB1555

EXPRESSION OF PROTEIN KI-67 BY THE HEMOPOIETIC PERIPHERAL BLOOD AND BONE MARROW CELLS IN THE CML PATIENTS WITH DIFFERENT SOCAL SCORE AND RESPONSE TO TYROSINE KINASE INHIBITORS THERAPY

T Perekhrestenko[1,*], A I Gordienko[2], N N Tretyak[1], Y V Shorop[2], I S Dyagil[3]
[1]blood disease, [2]oncohematology laboratory, State Institution «Institute of Hematology and Transfusiology of NAMS of Ukraine», [3]hematology department, State Institution «National Research Center for Radiation Medicine of NAMS of Ukraine», Kyiv, Ukraine

Background: Pathognomonic feature of CML is the formation of gene BCR-ABL, which products protein with strong tyrosine kinase activity, that stimulates a large number of intracellular signaling pathways and inhibites the action of protein regulators of proliferation and apoptosis. The result of these changes is the increase of the proliferation and tumor cells survival. One of the best known markers of proliferation is the intranuclear protein Ki-67. There are no clear data of expression of Ki-67 protein in patients with CML with different response to TKI therapy. The influence of Ki-67 in the formation of resistance to TKI treatment is unknown. Considering the data on the possible impact of prognostic index Sokal on the efficiency of TKI therapy, we examined the expression of Ki-67 in patients with different risk groups.
Aims: The aim of our study was to compare the proliferative activity of hemopoietic cells of peripheral blood and bone marrow which express protein Ki-67 in patients with CML, belonging to different risk groups Sokal, with the results of cytogenetic monitoring of response to TKI therapy.

Methods: We included 76 patients with CP-CML in study. Median age of patients was 43.3 years (range 19-65). Diagnostics and monitoring of CML were perfomed on the basis of cytogenetic examination of bone marrow cells by G-banding, and also molecular-genetic research of bone marrow and peripheral blood. Expression of protein Ki-67 was determined by flow cytometry in the direct immunofluorescence test using monoclonal antibodies. Socal score was asessed at time of diagnosis before commencing CML treatment by using special formula.
Results: We have found that in patients with low Socal score the number of peripheral blood and bone marrow cells expressing Ki-67 protein was equal to (2.3±0.6)% and (7.5±1.1)% respectively. In the group of patients with intermediate Socal score the number of cells expressing Ki-67 was 3 times higher in PB and twice higher in BM compared with low risk and was (7.1±1.3)% and (15.2±2.2)% respectively. In the group with a high Socal score the number of cells expressing Ki-67 in PB and BM was almost 2 times higher then the number of cells in the group with intermediate risk group and was (14.4±1.6)% and (28.4±2.2)% respectively. In patients with low-risk a little expression of Ki-67 and the optimal response to Imatinib therapy were detected, both 12 and 18 months of treatment. Even there were a some cases where the patients had initially low Socal score, a small number cells with Ki-67 in PB (about 3%) and suboptimal response to therapy after 12 months of treatment. However, at the 18 month of therapy response became optimal. In the case of patients with intermediate-risk the number of hemopoietic cells in PB with co-expression of Ki-67 was 9.5%, and the response to therapy with Imatinib at 12 months of therapy was optimal or suboptimal, but already at the 18 month treatment was ineffective. The patients with high-risk had a large number of Ki-67^{+} cells and after 12 months of Imatinib therapy inefficiency or suboptimal response was marked. However, during next cytogenetic analysis in all patients in this group inefficiency to treatment was determined.
Summary and Conclusions: Studies indicate that there is a relationship between Sokal score and the expression of Ki-67 protein in CML patients treated by Imatinib. The results of TKI therapy were the best for patients with low Socal score and low expression of intranuclear protein Ki-67.

PB1556

POPULATION BASED STUDY OF NON-PHILADELPHIA CYTOGENETIC CHANGES IN PATIENTS WITH CHRONIC MYELOID LEUKAEMIA AND IMPACT ON SURVIVAL.

J Tomlins[1,*] N Telford[2], M Dennis[1], T Somervaille[1], A Bloor[1], J Cavet[1], M Green[2], S Kulkarni[1]
[1]Haematology, [2]Cytogenetics, The Christie NHS Foundation Trust, Manchester, United Kingdom

Background: The diagnosis of patients with chronic myeloid leukaemia (CML) through cytogenetics has been well established. However there are few recent large reports about additional mutations at the time of diagnosis and the impact this has on overall survival is unclear.
Aims: The Cytogenetic laboratory at this hospital provides a regional service as a single facility and 1129 patients were analysed to evaluate if cytogenetic changes should be considered in addition to established risk scoring systems like the Hasford index.
Methods: As this was a population based study, details about the haematological parameters and treatments offered to individual patients were not available. Patients were classified as complex-Philadelphia (Ph) if they had t(9;22)(q34;q11) with additional chromosomal abnormalities. Impact of individual additional abnormalities were analysed and then the effect was stratified according to presence of chromosomal gains, deletions or translocations. There were a few cases with normal cytogenetics on their first sample to this laboratory because they were initially treated elsewhere.
Results: 1129 patients were diagnosed with CML between 1985 and 2013, with 4760 samples analysed. The median age was 52.4 years (4.3-103) with 602 males, 511 females and in 16 gender was not listed. We used 10 year overall survival(OS) as the analysis endpoint. Median follow up was 6.4 years (range: 0-26.8 years; 725/1129(64%) had follow-up more than 10 years). 194/1129 (17.2%) had complex-Ph at diagnosis, 759/1129 (67.2%) had standard Ph, 77/1129 (6.8%) had negative cytogenetics and in 34/1129 (3%) cytogenetic analysis failed at diagnosis. Patients with standard Ph translocation had significantly higher chance of achieving cytogenetic CR than those with complex-Ph (23.4% *vs.* 13.4%, p<0.001). OS was significantly better in patients below the age of 45 (65% *vs* 25% p <0.0001). OS was also better in patients diagnosed after 2000 (67% *vs* 40%, p<0.0001). In univariate analysis, OS was significantly lower with trisomy 8 (10% *vs* 50%, p<0.0001), del(5q) (20% *vs* 50%, p=0.001), other deletions (12% *vs* 48%, p=0.0005), del(17p) (48% *vs.* 0%, p<0.0001), add(21q) (50% *vs.* 0%, p<0.0001), any translocations (50% *vs.* 22%, p<0.0001), additional der(22q) (Ph) or isochromosome 17q (48% *vs.* 10%, p<0.0001), any deletions (50% *vs.* 20%, p<0.0001) and variant Ph translocations (50% *vs* 22%, p=0.004). In multivariate analysis, excluding year of diagnosis, age group (HR 1.93, 95% CI:1.6-2.4 P=<0.0001), complex t(9;22;v) (HR 1.8, 95% CI:1.0-3.1, P=0.035), del(17p) (HR 3.8, 95% CI:1.1-12.6, P=0.033), additional translocations (HR:1.6, 95% CI: 1.1-2.25, p=0.013), trisomy 8 (HR: 1.76, 95% CI: 1.19-2.65, p=0.005), add(21q) (HR: 3.21, 95% CI: 1.65-6.25, p=0.001) and +der(22q) or iso(17q) (HR: 1.57, 95% CI: 1.1-2.25, p=0.013) were independently associated with inferior OS. Number of risk factors in individual patients was used to design a score to evaluate the impact on OS. Patients with 0 risk factors (70% OS at 10 years), 1 risk factor (40% OS at 10 years), 2 risk factors (22% OS at 10 years) or more than 3 risk factors (12% OS at 10 years) had incrementally reduced OS. This was true of patients diagnosed before and after 2000. In the TKI era post year 2000, maimum benefit is seen in patients with standard Ph translocation.
Summary and Conclusions: To our knowledge this is one of the largest population based studies about cytogenetics in CML patients. This analysis suggests that nature of karyotype at diagnosis may add to established risk scoring systems. However these data need to be analysed with a larger patient population including all established risk factors and the effect of therapeutic measures.

PB1557

STANDARD AND HIGH SENSITIVITY MOLECULAR ANALYSIS IN CHRONIC MYELOID LEUKEMIA PATIENTS CANDIDATE TO DISCONTINUATION OF TYROSINE KINASE INHIBITORS

I Dogliotti[1], C Fava[1], E Gottardi[1], F Daraio[1], E Giugliano[1], S Ulisciani[1], G Saglio[1], G Rege-Cambrin[1*]
[1]Division of Hematology and Internal Medicine , University of Turin, San Luigi Hospital, Orbassano, Italy

Background: The introduction of Imatinib and 2nd generation Tyrosine Kinase Inhibitors (TKI) nilotinib and dasatinib has dramatically changed the prognosis of chronic myeloid leukemia (CML). For patients who maintain deep molecular remission for many years, it is now under discussion the possibility to discontinue TKI therapy.
Aims: To identify a subset of patients who achieved deep and durable molecular remission under TKI therapy potentially suitable for future TKI withdrawal, and to assess the real depth of molecular response by Replicate-PCR, a higher sensitivity PCR (up to 10^{-6}) in selected patients willing to discontinue TKI therapy.
Methods: We reviewed molecular data from all chronic phase CML patients (102) followed in our Center in order to identify patients showing either undetectable BCR/ABL transcript (at least MR4) or detectable transcript <0.0032% (MR 4.5) during the last two years (here defined as Complete Molecular Response, CMR). Minimal residual disease was also assessed with a new strategy of Replicate RQ-PCR by using a 82 well plate, each performing an amplification reaction, that demonstrated approximately a 2 log improvement in detection sensitivity limit compared to conventional RQ-PCR (Goh UG et al, Leukemia & Lymphoma 2011). Results from patient samples were compared with 12 normal controls, which resulted in positive amplification in 6 out of 983 total wells with a mean number of positive wells of 0.5 (SD 1.0).
Results: Among the 102 patients we selected a group of 76 patients who were diagnosed after the year 2000 and were treated with TKIs, with a minimum follow-up time of 2 years. At last observation, 43 were treated with Imatinib, 16 with Nilotinib, 14 with Dasatinib, 1 with Bosutinib and 2 were off-treatment. We found that 23 (30.2%) patients met the potential discontinuation criteria we previously described; out of 23 patients, mean age at diagnosis was 52 (28-73), mean time from start of last treatment to CMR was 25 months (3-94), median duration of CMR was 70 months (24-139). 15 patients (65.2%) were receiving Imatinib, 8 (34.8%) were receiving 2nd generation TKIs, in particular 5 Nilotinib (4 as first-line treatment) (21.7%), 2 Dasatinib (1 as first-line treatment) (8.7%) and 1 Bosutinib (4.3%). Among these patients 2 were taking second line therapy and 1 was under third line treatment due to toxicity or resistance. 26% of our selected group had been treated with IFN. Mean time to CMR was 29 mos (4-94) in patients under frontline Imatinib, and 13 mos (6-24) in patients under frontline Nilotinib. Replicate-PCR was performed on 7 of these patients (including 2 patients off-treatment). Samples from 2 other patients already off-treatment who had started therapy before year 2000 were also analyzed. BCR/ABL was undetectable or had a low-level positivity (respectively 1 and 2 positive wells) below the range of normal controls (2.5 = mean +2SD) in 5 patients (2 off and 3 on treatment); in 4 patients (including 2 off-treatment) positive wells were > 2.5 at least in one sample. With these criteria, the 9 patients could be classified as negative (5 cases) or positive (4 cases) at replicate PCR analysis. We are currently expanding the analysis to the other patients.
Summary and Conclusions: In a single center experience, we confirm that a significant percentage of patients treated with TKs (around 30%) may eventually reach criteria for discontinuation. High sensitivity molecular analysis demonstrate that residual transcript is evident in some patients who remain in stable MR4.5, thus indicating that this population of patients is still heterogeneous. The role of replicate PCR (or other highly sensitive molecular techniques) deserve further evaluation.

PB1558

RESULTS OF "REAL-LIFE" FRONTLINE DASATINIB TREATMENT IN UNSELECTED ELDERLY PATIENTS WITH CHRONIC MYELOID LEUKEMIA

R Latagliata[1,*] F Stagno[2], M Annunziata[3], A Iurlo[4], B Scappini[5], A Guarini[6], G Giglio[7], C Fava[8], F Sorà[9], I Capodanno[10], M Crugnola[11], S Leonetti Crescenzi[1,2], S Barsotti[1,3], C Feo[1,4], M Breccia[1,5], P Vigneri[2], G Rege Cambrin[8], A Gozzini[5], G Alimena[1,5]

[1]Cellular Biotechnologies and Hematology, University Sapienza, Rome, [2]Hematology, University of Catania, Catania, [3]Hematology, Cardarelli Hospital, Neaples, [4]Hematology, Foundation IRCCS Ca' Granda Policlinic, Milan, [5]Hematology, University of Florence, Florence, [6]Hematology, Istituto Tumori Giovanni Paolo II, Bari, [7]Hematology, Hospital of Campobasso, Campobasso, [8]Hematology, San Luigi Gonzaga Hospital, Orbassano, [9]Hematology, Catholic University of Sacred Heart, Rome, [10]Hematology, Santa Maria Novella Hospital, Reggio Emilia, [11]Hematology, University of Parma, Parma, [12]Hematology, Sandro Pertini Hospital, Rome, [13]Clinical and Experimental Medicine - Hematology, University of Pisa, Pisa, [14]Hematology, Rummo Hospital, Benevento, [15]Cellular Biotechnology and Hematology, University Sapienza, Rome, Italy

Background: Dasatinib has been very recently licensed for first line treatment of patients with chronic myeloid leukemia (CML). However, there are still no data available as to toxicity and efficacy of dasatinib in elderly unselected CML patients.
Aims: To address this issue, we revised a "real-life" cohort of 29 CML patients in chronic phase aged > 65 years treated with frontline dasatinib in 14 Italian Centers from 6/2012 to 1/2014 as concern toxicity and efficacy data.
Methods: The main clinical features of the patients at diagnosis were as follows: M/F 14/15 (48.3%/51.7%), median age 74.1 years [interquartile range (IQR) 69.3 – 78.1), median Hb 12.2 g/dl (IQR 11.2 – 13.5), median WBC 51.1 x 10^9/l (IQR 27.4 – 83.4), median PLTS 470 x 10^9/l (IQR 243 – 692). According to Sokal risk classification, 1 patient (3.4%) was at low risk, 17 patients (58.6%) were at intermediate risk, 6 (20.7%) at high risk and 5 (17.2%) were not classificable. 13/29 patients (44.8%) had ≥ 2 comorbidities requiring concomitant therapies: according to ECOG scale, performance status at baseline was 0 – 1 in 22 patients (75.9%) and 2 in 7 patients (24.1%).
Results: Median interval from diagnosis to dasatinib start was 23 days (IQR 17 – 33). Starting dose of dasatinib was 140 mg/day in 1 patient (3.4%), 100 mg/day in 21 patients (72.4%) and<100 mg/day in 7 patients (24.1%), respectively. After a median period of treatment of 6.6 months (IQR 2.5 – 14.9) all patients were evaluable for toxicity; on the whole, grade 3 – 4 hematological and extra-hematological toxicities were reported in 3 (10.3%) and 4 (13.8%) patients, respectively. Overall, 6 patients (20.6%) permanently discontinued dasatinib due to toxicity (2 patients in the first 3-month period of treatment and 4 beyond that period). Pleural effusions of all WHO grades occurred in 6 patients (20.6%): in 2 of them the pleural effusion occurred during the first 3-month period of treatment. As to treatment efficacy, 6 patients were considered too early (< 3 months of treatment) and 23 were evaluable for cumulative response; on the whole, 19/23 patients (82.6%) achieved complete cytogenetic response and 14/23 (60.8%) also a major molecular response.
Summary and Conclusions: Present data shows that dasatinib could have a major role in the treatment of unselected patients aged > 65 years; in particular, dasatinib seems very effective and has a favourable safety profile also in elderly subjects with severe comorbidities.

PB1559

EARLY SWITCH THERAPY APPROACH FOR PATIENTS WITH CHRONIC MYELOID LEUKEMIA IN CHRONIC PHASE

O Shukhov[1,*] E Chelysheva[1], G Gusarova[1], A Abdullaev[2], A Sudarikov[2], T Obukhova[2], A Turkina[1]

[1]Scientific and Advisory Department of Chemotherapy of Myeloproliferative Neoplasms, [2]Federal State Budgetary Institution Hematology Research Center of Health Ministry of Russian Federation, Moscow, Russian Federation

Background: New guidelines for chronic myeloid leukemia (CML) 2013 developed by National Society for Hematology in Russian Federation declare prevention of disease progression by early therapeutic interventions at 1st year of therapy, opportunity to use 2nd generation tyrosine kinase inhibitors (TKI2) as 1st line and switch of TKI from 3rd month of therapy in case of failure.
Aims: To evaluate early treatment interventions in CML patients with chronic phase (CP) CML including TKI switch from 3rd month of therapy.
Methods: From August 2012 till February 2014 we included 36 adult patients(pts), 18 men and 18 women, with CP CML approved by cytogenetic and/or molecular analyses. No pretreatment except hydroxyurea was allowed. Median age was 47(19-76) years. Median observation time after starting TKI therapy was 9(0-19) months. Low, intermediate and high Sokal risk score were in 25(69%), 7(19%) and 4(12%) of pts correspondingly. Standard cytogenetic and molecular analyses were done at 3rd, 6th and 12th month of therapy. Cytogenetic analyses were done until complete cytogenetic response (CCyR). FiSH was used in case of non-informative standard cytogenetics. *The optimal response* was considered in case of BCR-ABL≤10% at 3 months, <1% at 6 months and ≤0,1% at 12 months and/or Ph+≤35% at 3 months, Ph+0% since 6th months. The *treatment failure* was if BCR-ABL>10%, Ph+>65% and/or no hematologic response at 3 months; BCR-ABL≥10%, Ph+>35% at 6 months; BCR-ABL≥1%, Ph+>0% at 12 months. The intermediate values were defined as *warning*. For *failure* the therapy was changed, in case of *warning* dose increasing or switching to another TKI was allowed. Assessment of BCR-ABL mutations before switching was performed.
Results: Therapy of 1st line was imatinib 400 mg in 31(86%), nilotinib 600 mg in 4(11%) and dasatinib 100 mg in 1(3%) of newly diagnosed pts. A 3 months evaluation have been performed for 27(75%) pts. *Optimal response* at 3 months was achieved in 21(78%): 16 on imatinib, 4 on nilotinib, 1 on dasatinib. No pts were in *warning* cathegory. *Treatment failure* was in 6(22%) of pts, all on imatinib. CML progression to blast crisis (BC) and death was in 1 of 6 pts. Three pts were switched to nilotinib 800 mg, 2 to dasatinib 100 mg. No BCR-ABL mutations were detected before switching. *Optimal response* at 6 months of therapy was achieved in 16(73%) of 22 evaluated pts: 9 on imatinib, 6 on nilotinib, 1 on dasatinib. *Warning* was applicable for 5(22,5%) of pts. *Treatment failure* still was in 1(4.5%) of pts previously switched to nilotinib 2nd line, it was decided to continue nilotinib for 3 month more. At 12 months of therapy optimal response was marked in 8(57%) of 14 pts who reached this term, 6 (43%) of pts remained in *warning* zone. No *treatment failure* at 12 months was observed, the patient with failure at 6th month moved to *warning*. All 14(100%) of pts had CCyR, 8 of 14 have no less than MMR. Of those 5 pts with treatment failure at 3 months after switching to TKI2 from imatinib 2 of 5 achieved optimal response, 3 of 5 moved to *warning* category during further observation.
Summary and Conclusions: Regular monitoring at the 1st year of treatment of CML CP pts has allocated the groups of pts with optimal response, warning and treatment failure. Switching pts with *treatment failure* at 3 months to more potent TKI allowed to improve therapy results and to overcome the primary resistance. Early treatment intervention approach is a promising strategy of prevention of disease progression in CML. A longer period of observation and more pts should be validated.

PB1560

LONG-TERM SURVIVAL OF PATIENTS WITH CHRONIC PHASE CHRONIC MYELOID LEUKEMIA RECEIVING TYROSINE KINASE INHIBITORS THERAPY AFTER INTERFERON-ALFA FAILURE

O V Lazareva[1,*] G A Gusarova[1], E Y Chelysheva[1], A Bykova[1], O A Shukhov[1], E S Zakharova[1], T I Kolosheinova[2], S V Kuznetsov[2], I A Tishchenko[3], SM Kulikov[3], AG Turkina[1]

[1]Scientific Advisory Department for chemotherapy of myeloproliferative disorders, [2]Polyclinic , [3]Department of Medical Biostatistics, Federal State Budgetary Institution Hematology Research Center, Ministry of Healthcare of Russian Federation, Moscow, Russian Federation

Background: Treatment of patients (pts) with chronic myeloid leukemia (CML) in chronic phase (CP) with very durable disease anamnesis now continues in a routine clinical practice. Those pts in late CP have started tyrosine kinase inhibitors (TKI) therapy after IFN-α and subsequently underwent treatment by various TKI (imatinib, nilotinib, dasatinib, bosutinib). Information about the therapy approaches and effectiveness of TKI in CML CP pts with follow-up over 13 years has not yet been presented.
Aims: To evaluate long term results of treatment in pts in late CP CML including 12-years overall survival (OS) and progression free survival (PFS) and to characterize their current treatment.
Methods: Since July2000- Sept2001 79 pts with Ph-positive CML in CP resistant/intolerant to IFN-α therapy have been included into this non-randomized, open-label study and started therapy by imatinib(IM) 400mg daily. Male/female ratio 41:38, median (Me) age at diagnosis 39 (15-64) years. The Sokal risk groups ratio: 54%/29%/17% for low, intermediate and high score correspondingly. Me time pretreatment by IFN-α 26 (0,5-156) month (mo). Me time from diagnosis to treatment by IM was 35,5 (3-157)mo. Cytogenetic monitoring was done every 6mo at 1st year, after that - as decided by clinician. Molecular monitoring by Real-time PCR was performed since 2005 2-3 times a year. Therapy changes were made according to currently used recommendations and availability of TKI2. Statistical analysis was performed using the SAS 9.3 program.
Results: The 12-year OS of pts receiving TKIs after IFN-α failure was 68%, PFS was 66% (fig1). Me time of life from the start of TKI treatment was 12.2 (0.3-13.5)years. Me follow-up from diagnosis till Feb2014 was 173 (13- 310)mo. Structure of mortality in 25 died pts: 1) progression of CML in 20pts: CP- 3pts; accelerated phase (AP)/ blast crisis (BC) - 17pts 2) comorbidities in3pts 3) unknown reason in 2pts. At the moment of analysis 54pts were alive, 52 of 54 in

CP CML, 2 of 54 in AP. IM therapy continued in 23pts. Me duration of IM therapy was 148(102- 155)mo. Doses of IM: 400mg- 17pts with stable Major Molecular Response (MMR), 600mg-3pts, 800mg-3pts. Totally with IM, complete cytogenetic response (CCyR) and MMR was achieved in 44(55%) and 25(31%)pts, respectively. Me time to CCyR and MMR was 30 (4-91)mo and 87 (48-141)mo, respectively. One patient received IM as a 4th line after the failure of two TKI2. TKI2 received 24 alive pts: nilotinib-15, dasatinib-8, bosutinib-1. Treatment by more than two TKI was in 11pts. Me duration of TKI-2 therapy was 57 (1,5- 95)mo. Me time of switching to the TKI2 was 66,6mo. Active stop of TKI was safely performed in 4pts with complete molecular response (BCR-ABL<0,01%): 2pts- due to toxicity, 2pts- by their own desire. In 2 more pts who stopped therapy progression occurred; among pts who have died due to progression, 3 pts also stopped treatment by themselves. We cannot exclude non-adherence in patients receiving TKI who lost previously achieved CCyR and MMR.

Summary and Conclusions: In 37,5% of CML CP pts with a well performed follow-up for more than 12 years IM therapy continues within persisting MMR. Changing of the TKI in this group was performed mostly at late terms - in 35-84mo after initiation of IM therapy and that was associated with the appearance of TKI2 in clinical practice. It is illustrated that uncontrolled treatment discontinuation can be unsafe for the patients and can lead to disease progression until death.

PB1561

FERTILITY IN MALE PATIENTS WITH (CHRONIC PHASE) CHRONIC MYELOID LEUKEMIA RECEIVING TYROSINE KINASE INHIBITORS AS FIRST LINE OF THERAPY.

M Yassin[1,*] AT Soliman[2], V Desanctis[3]
[1]Hematology /BMT, National Centre for Cancer Care and Research Hamad Medical Corporation, [2]Pediatric endocrinoloy, Hamad medical corporation, doha, Qatar, [3]Pediatric endocrinoloy, Quissana, ferrara, Italy

Background: The introduction of TKIs for the treatment of CML raises the question of whether male fertility is affected and the degree of this affection.
Aims: to evaluate semen parameters and pituitary gonadal function before and 4 months after starting TKIs in patients with CP CML

Methods: We studied prospectively the effect of TKIs' on semen parameters, endocrine functions in 20 euogonadal male patients with CML aged from 35 to 51 years ,were receiving either Imatinib, Dasatinib or Nilotinib as upfront therapy. We studied LH and FSH and testosterone (T) and evaluated sperm parameters before and after four months of using these TKIs.
Results: Four months after starting TKIs there were significant decreases in serum testosterone, LH, FSH concentrations. The total sperm count, total and rapid progressive sperm motility, and% sperms with normal morphology decreased significantly *versus* before treatment. After 4 months of therapy, Dasatinib effects on sperm count (SC), volume(SV), all sperm motilities and% of sperms with normal morphology were significantly less harmful compared to Imatinib and Nilotinib.
Summary and Conclusions: TKIs are associated with significant decrease of sperm parameters and decreased concentrations of serum T, LH, FSH. These potentially toxic effects on spermatogenesis are less prominent in patients treated with Dasatinib compared to Imatinib and Nilotinib. The mechanisms and pathways for these effects need further human and/or experimental studies.

PB1562

LOWER DOSAGE OF IMATINIB (IM) IS SUFFICIENT TO MAINTAIN COMPLETE MOLECULAR RESPONSE (CMR) IN CHRONIC MYELOID LEUKEMIA (CML) PATIENTS WITH LONG-TERM TOXICITY OF THE TREATMENT

E Faber[1,*] I Skoumalová[1], I Marešová[1], M Divoká[1], K Mičová[2], D Friedecký[3], T Adam[3], M Jarošová[1], K Indrák[1]
[1]Department of Hemato-Oncology, Faculty Hospital Olomouc; Faculty of Medicine and Dentistry, Palacky University in Olomouc, [2]Institute of Molecular and Translational Medicine, Faculty of Medicine and Dentistry, Palacky University in Olomouc, [3]Institute of Molecular and Translational Medicine, Laboratory of Inherited Metabolic Disorders, Department of Clinical Chemistry, Faculty Hospital Olomouc; Faculty of Medicine and Dentistry, Palacky University in Olomouc, Olomouc, Czech Republic

Background: Continuation with imatinib (IM) treatment is currently the recommended strategy in all patients with CML and optimal treatment response. However, there is evidence that about 30% of patients may have problems with long-term side-effects symptoms burden. Information about the response in patients with molecularly undetectable leukemia (complete molecular response) CMR after IM in whom the dose should have been reduced in an effort to relieve from long-term toxicity is insufficient.
Aims: Safety and efficacy of IM dose reduction in patients with long-term toxicity and CMR after standard IM dosage was assessed in a retrospective fashion.
Methods: Files of all patients with CML treated with IM at our center were retrospectively analyzed for CMR, toxicity and dosage. 61 (29.8%) of 205 patients treated with first or second line IM with median follow-up 54 and 105 months respectively have achieved CMR. In 19 of them (31.2%; 13 females and 6 males aged 20-71; average m=47 years at diagnosis) the dose of IM was reduced due to toxicity. Sokal score was low in 9, intermediate and high in 4 each and in 2 patients unknown. Patients achieved MMR and CMR after average 13.3 and 27.7 months respectively, 12 of them were pretreated with interferon-alpha. Duration of CMR before dose reduction was 16-123 (m=56.7) months. Reasons for the dose reduction comprised fluid retention, eye-lid swelling, hemorrhage into conjunctiva, hematologic toxicity, muscle cramps, dyspepsia and complications after surgery. Dose reduction was strictly individualized: in 3 patients IM was interrupted, 9 patients received 400mg once to five times a week, 6 patients 300mg three times weekly to daily and one patient was treated with 200mg of IM daily.
Results: After average observation period of 37 (9-84) months CMR has been maintained in 13 (68.4%) patients with lower dose of IM: in three of them with single elevations of BCR-ABL level to MMR. In two other patients the response fluctuates between CMR and MMR while continuation with lower dose. Three patients have lost CMR: one regained it on full-dose IM, two maintain MMR on standard or lower dosage. Only one patient has lost MMR after interruption of treatment: CMR was gained after standard dose of IM and is maintained on lower dose. In all patient, toxicity of the therapy was ameliorated during lower dosage. Even during intermittent treatment patients were able to achieve comparable plasma levels with those achieved on previous standard therapy.
Summary and Conclusions: CMR has been safely and efficiently maintained in 16 (84%) of our patients with CML suffering from long-term toxicity of IM using lower dosage regimens. One patient maintained CMR with full dose and 2 remaining patients have maintained MMR on lower IM dose. Lower or intermittent maintenance treatment with IM have lead to significant reduction of side-effects and cost burden and may serve as an option for the patients who relapse after stopping of IM in CMR. Larger prospective trials are necessary in order to confirm efficacy and safety of this strategy.

PB1563

DIABETES MELLITUS AND TKIS TREATMENT IN CHRONIC MYELOID LEUKEMIA

A Iurlo[1,*] E Orsi[2], N Orofino[1], D Zimbalatti[2], D Cattaneo[1], C Bucelli[1], V Resi[2], D Consonni[3], A Cortelezzi[1]
[1]Hematology Unit, [2]Endocrinology and Diabetes Unit, [3]Epidemiology Unit, Department of Preventive Medicine, IRCCS Ca' Granda – Maggiore Policlinico Hospital Foundation and University of Milan, Milan, Italy

Background: Chronic myeloid leukemia (CML) is a myeloproliferative neoplasm characterised by a pathognomonic chromosomal translocation t(9;22)(q34;q11.2) which results in the oncogenic BCR-ABL1 fusion gene, encoding for a mutant, continuously activated tyrosine kinase. Specific Tyrosin Kinase Inhibitors (TKIs) therapy, having this translocation as a target, dramatically improved life expectancy of CML patients. First (imatinib) and second generation TKIs (dasatinib and nilotinib) act on different molecular targets, leading to varying side effects; several studies have revealed that nilotinib induces hyperglycemia in a subset of non diabetic and diabetic CML patients, whereas imatinib and dasatinib usually do not.
Aims: To evaluate the glico-metabolic assessment of CML patients treated with TKIs.
Methods: A total of 90 unselected CML patients treated with TKIs and referred to our Hospital were included. Blood samples for fasting glycemia, insulin, c-peptide and other clinical variables as anthropometric parameters were collected for each patient. We studied Beta-cell function assessed by HOMA-IR and HOMA-beta with the aim to determine insulin-resistance and insulin-secretion, respectively. The diagnosis of diabetes was performed using criteria (updated 2010) from the American Diabetes Association (ADA).
Results: In our population, DM was diagnosed in 12 patients (13.5%), whereas impaired fasting glucose (IFG) was reported in 22 patients (24.4%). Among the three TKIs, we have not found a significant difference in hyperglycemia and DM presence, although they were both higher in the nilotinib treated group. The same group showed higher basal insulin and c-peptide levels and higher HOMA-IR ($p<0.05$) than the others, without a significant difference in HOMA-beta. In all groups, diabetic patients showed higher HOMA-IR ($p<0.05$), BMI ($p<0.01$), weight ($p<0.01$), age ($p<0.05$) and triglycerids levels ($p<0.01$) than non DM, while HDL cholesterol levels were lower ($p<0.05$).
Summary and Conclusions: Our data confirm the few reports in literature that show higher prevalence of IFG and DM in CML patients. The underlying mechanism is not clear but in our population, diabetic patients showed higher insulin-resistance and BMI, whereas insulin secretion was not reduced.

IMATINIB DISCOTINUATION IN CHRONIC MYELOID LEUKEMIA: A RETROSPECTIVE ANALYSIS ON 28 UNSELECTED PATIENTS

M Cerrano[1,*] C Fava[2], P Pregno[3], V Giai[1], M Nicolosi[3], C Aguzzi[1], I Dogliotti[2], G Rege-Cambrin[2], M Boccadoro[1], U Vitolo[3], G Saglio[2], D Ferrero[1]
[1]Division of Hematology, University of Torino, Torino, [2]Division of Hematology and Internal Medicine, University of Torino, Ospedale San Luigi Gonzaga, Orbassano (To), [3]Division of Hematology II°, Azienda Ospedaliera "Città della Salute e della Scienza", Torino, Italy

Background: Tyrosine kinase inhibitors (TKI) have radically changed the prognosis of chronic myeloid leukemia (CML) patients but current guidelines still recommend to continue a successful therapy indefinitely. However some recent studies proved the safety of imatinib discontinuation and showed the durability of a sustained molecular response in around 40 per cent of the patients without any further therapy.
Aims: The aims of this analysis is to present our experience with imatinib discontinuation.
Methods: We retrospectively analyzed the outcome of patients treated in the Hematology Divisions of Turin and Orbassano (TO) who discontinued imatinib. After discontinuation patients were monitored every 1.5-2 months in the first year and every 3 months thereafter. In case of loss of MMR in one test or loss of MR4 in 2 consecutive analysis, imatinib therapy was restarted immediately.
Results: Twenty-eight patients with chronic phase CML discontinued imatinib. Twenty-two patients (78.6%) had an Undetectable Molecular Disease (UMD) Molecular Response 4.0 log (MR4) at the time of imatinib cessation: in most cases they had an elective discontinuation due to persistent deep molecular response. Three patients had detectable transcript MR4 and 3 were in MMR only: they discontinued because of intolerance or strong patient's desire. Twelve patients had been treated with interferon +/- ARA-C before starting imatinib. Median duration of imatinib treatment was 68 months (range 16-121 months). Median follow up after treatment cessation was 41 months (range 6-104 months). Median duration of MR4 for the 22 patients with UMD at discontinuation was 38 months (range 30-90 months). After discontinuation 17 of them showed a detectable BCR-ABL transcript in at least one occasion (77%,) and 11 in at least 2 consecutive tests (50%). However, only 8 (36%) lost the MR4 and had to restart therapy after a median time from imatinib cessation of 5 months (range 3-11 months). In particular, the reasons for therapy restart were loss of CCYR in 2 cases, loss of MMR for 3 patients and confirmed loss of MR4 in the other 3 cases. All the 6 evaluable patients (with a follow-up of at least 3 months) regained UMD after restarting imatinib, or nilotinib in one case intolerant to imatinib, after a median time of 3 months (range 3-14 months). Patients who received more than 1 year of interferon before stating imatinib treatment were more likely to remain off therapy compared to patients who did not (86% vs 53% p=0.038). Among the 6 patients without UMD at the time of imatinib discontinuation, 2 had to restart treatment (33%) after 3 and 30 months respectively and all regained their previous level of response. On the whole 36% of the patients (10/28) had to restart therapy while 18 patients (64%) remained off treatment, for a median time of 38 months (range 7-104 months). At the last follow up 3 patients had died, all for causes not related to CML and no progression to accelerated or blastic crisis was observed.
Summary and Conclusions: Our experience confirms that treatment discontinuation is feasible and safe for CML patients treated with imatinib, but a close molecular monitoring and a careful selection of candidates is required. Several clinical trials are ongoing to explore the feasibility of treatment discontinuation, also for patients treated with second generation TKI.

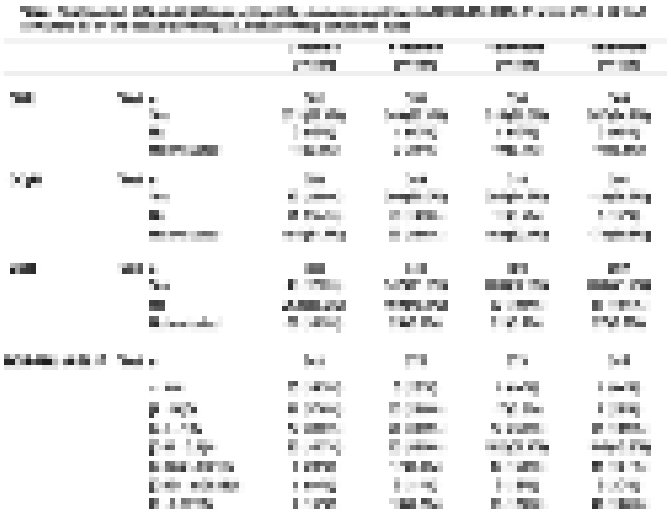
PB1565

EPIDEMIOLOGICAL CROSS-SECTIONNAL SURVEY OF FIRST LINE TREATED PATIENTS WITH CHRONIC MYELOID LEUKEMIA IN CHRONIC PHASE (CML-CP) IN ROUTINE CONSULTATIONS DURING A ONE-MONTH PERIOD: EPIDOR FRENCH SURVEY

G Etienne[1,*] F Huguet[2], A Guerci-Bresler [3], FE Nicolini[4], F Maloisel[5], V Coiteux[6], C Dauriac[7], N Carpentier[8], I Bourdeix[8], M Tulliez[9], P Cony-Makhoul[10]
[1]Service d'Hémato-Oncologie, Institut Bergonié, Centre de lutte contre le cancer de Bordeaux et du Sud-Ouest, Bordeaux, [2]Service d'Hématologie, Centre Hospitalier Universitaire de Toulouse, Hôpital Purpan, Toulouse, [3]Service d'Hématologie et de Médecine Interne, Centre Hospitalier Universitaire de Nancy, Nancy, [4]Service d'Hématologie Clinique, Centre Hospitalier Lyon Sud, Pierre Bénite, [5]Service d'Oncologie-Hématologie, Clinique Sainte-Anne, Strasbourg, [6]Service des Maladies du Sang, Centre Hospitalier Régional Universitaire de Lille, Lille, [7]Clinique Hématologique Jean Dausset, Hôpital de Pontchaillou, Rennes, [8]Novartis Pharma SAS, Rueil-Malmaison, [9]Hématologie, Hôpital Henri Mondor, Créteil, [10]Hématologie Clinique, Centre Hospitalier Annecy Genevois, Metz-Tessy, Pringy, France

Background: 2nd generation TKIs availability and numerous clinical trials assessing their effects, alone or in combination, have extended the range of 1st line therapy options for newly diagnosed CML-CP patients.
Aims: To describe the 1st line therapeutic choices for patients with CML-CP in France and response kinetics.
Methods: Multicentric, national, descriptive, observational, cross-sectional epidemiological survey. 145 physicians were randomly contacted from a list of 1200 specialists; 45 agreed to participate and included all CML-CP pts seen during outpatient routine visits over a rolling 30-day period (Nov-Dec 2013). Primary objective: to describe type of treatment for pts currently receiving 1st line treatment (1st LT). Secondary objectives: to evaluate the proportion of pts still receiving 1st LT and to describe their clinical profile, kinetics of hematologic, cytogenetic and molecular responses at 3, 6, 12 and 18 months (mos), and quality of responses at last available assessment.
Results: 702 CML-CP pts were enrolled, 697 pts (98.9%) analyzable. 62.8% (438) of pts on 1st LT, 37.2% (259) on ≥ 2nd line treatment. Whole population (n=697): Sex ratio M/F: 1.29; Median age was 62 yrs (IQR: 50-72). Median CML history duration was 4 yrs (IQR: 2-9): duration of CML<1yr for 78 pts (11.2%), [1-5[yrs for 271 pts (38.9%); [5-9[yrs for 163 pts (23.4%); [9-14[yrs for 124 pts (17.8%); and ≥14 yrs for 61 pts (8.8%). 1st line population (n=438): Sex ratio M/F: 1.33; Median age was 61 yrs (IQR: 50-72). Median CML history duration was 4 yrs (IQR: 1-9): duration<1yr for 72 pts (16.4%), [1-5[yrs for 195 pts (44.5%); [5-9[yrs for 111 pts (25.3%); [9-14[yrs for 56 pts (12.8%); and ≥14 yrs for 4 pts (0,9%). Sokal score was determined for 78.3% of pts: as assessed by investigators, 42.3% of pts (145/343) had low; 39.7% (136/343) intermediate and 18.1% (62/343) high Sokal score. Bone marrow karyotyping analysis and BCR-ABL1 assessment at diagnosis were performed respectively for 97.5% and 93.1% of pts. Treatment description in 1st line population: 1st LT were (alone or in combination): imatinib (IM) 73.3% (n=321), dasatinib (DAS) 11.9% (n=52), nilotinib (NIL) 11.4% (n=50), interferon (IFN) 4.8% (n=21), ponatinib 0.7% (n=3), bosutinib 0%, others 1.6% (n=7). 29.9% of pts received 1st LT as part of an interventional clinical trial. Treatment combinations consisted in a TKI combined with IFN in 18 pts (4%), the TKI was IM for 11 pts, NIL for 5 and DAS for 2 pts, most often (15/18) as part of clinical trials. Response kinetics in 1st line population: Incidence of CHR, CCyR and MMR at 3, 6, 12 and 18 mos and BCR-ABL1/ABL1^{IS} levels are detailed in the table. At the 12th month assessment, 30.9% (99/320) of patients were not in MMR, and 6.6% (18/273)

had BCR-ABL1/ABL1^{IS} > 1% (respectively new warning and failure definitions according to 2013 ELN guidelines). Quality of response at last available assessment: Described for pts currently receiving 1st LT (median CML history of 4 yrs). Among pts with duration of 1st LT ≥ 12 mos and available data for MMR and Deep Molecular Response (DMR: MR$^{4.0}$ or MR$^{4.5}$): 91.5% (313/342) have achieved MMR, 66.5% (214/322) have achieved DMR.
Summary and Conclusions: Among this unselected real-life population of CML-CP pts seen in a one-month consultations period, 62.8% were still in first line therapy. Focus on pts on 1st line treatment suggests that TKIs induce good molecular response, even outside of clinical trials.



PB1566

IMPORTANCE OF EARLY MOLECULAR RESPONSE IN CHRONIC MIELOID LEUKIMIA (CML) PATIENTS IN CHRONIC PHASE TREATED WITH TIROSINKINASE INHIBITORS (TKI) IN ARGENTINA

Al Varela[1,*], C Pavlovsky[2], M A Perez[3], A Enrico[4], G Bendek[5], R Conti[6], G Ramos Mejia[1], R Mariano[7], E B Moiraghi[1]
[1]Hospital J.M. Ramos Mejia, [2]FUNDALEU, Ciudad Autonoma de Buenos Aires, [3]HIGA Prof. R.Rossiy Sanatorio IPENSA, [4]Hospital Italiano, La Plata, [5]Hospital Centro de Salud Zenon Santillan, San Miguel de Tucuman, [6]Instituto Alexander Fleming, Ciudad Autonoma de Buenos Aires, [7]Hospital San Martin, Parana, Argentina

Background: Early cytogenetic and molecular response are associated with better outcome in CML patients treated with imatinib (IM), dasatinib (DA) or nilotinib (NI). BCR/ABL transcript leve ≤10%IS at 3 months of treatment is associated with higher rates of complete cytogenetic response (CCR), mayor molecular response (MMR), molecular response (MR) 4.5, higher event- free survival (EFS) and progression- free survival (PFS). Evaluation of transcript levels at 3 month is useful to early identify patients with less probability to achieve optimal response.
Aims: To describe clinical cytogenetic and molecular outcome of CML patients treated with TKI in Argentina according to the BCR/ABL transcript levels after 3 months of treatment.

Table 1.

Methods: Cohort observational study . Data of CML patients treated with TKI that had BCR/ABL IS transcript levels measured at 3 was collected retrospectively in 7 centers in Argentina. Frequency of CCR at 6 months, MMR at 12 and 18 months, even free survival, progression free survival and overall survival was calculated in the group with transcripts ≤10%IS and >10% at 3 months.
Results: 76 patients were included with a median follow up of 46 months (IQR: 18-61). Average age was 48 years old (22-74), male 45%(34/76). Sokal risk distribution was: low risk 37%(28/76), intermediate 36%(27/76), high 28%(21/76).Patients with Imatinib treatment 45%(37/76), nilotinib 22% (17/76) and dasatinib 29% (22/76). BCR/ABL transcripts level ≤10% IS at 3 months treatment was found in 86% (65/76) and > 10%IS in 14% (11/76). Regarding the different TKI, the proportion of patients with transcript level ≤10% in treatment with IM was 83% (31/37), with NI 88% (15/17) and with DA 86% (19/22). Characteristics and patients evolution according MR at 3 months were asses. See Table 1.
Summary and Conclusions: Frequency of optimal response at 3 month is high with IM, NI and DA. In the group with BCR/ABL >10%IS, high risk Sokal Score, lower ratio of CCR and MMR was observed. The frequency of events, progression and death was also higher in this group. The analysis is limited by the difference in number of patients in each group, but the results confirm the value of early molecular response assessment to predict outcome in this population.

PB1567

ANALYSIS OF TRANSCRIPTOME IN CHRONIC MYELOID LEUKEMIA REVEALS GENES AND PATHWAYS POTENTIALLY INVOLVED IN THE RESISTANCE TO TKI THERAPY

A Lavrov[1, 2], E Adilgereeva[1], S Smirnikhina[1], E Chelysheva[3], O Shukhov[3], A Turkina[3], S Kutsev[1,2*]
[1]Laboratory of mutagenesis, Federal State Budgetary Institution "Research Centre for Medical Genetics" of the Russian Academy of Medical Sciences , [2]Department of Molecular Genetics and Cytogenetics, Pirogov Russian National Research Medical University, [3]Department of Myeloproliferative Disorders, Hematology Research Center of Ministry Healthcare of the Russian Federation, Moscow, Russian Federation

Background: High efficiency of targeted therapy of chronic myeloid leukemia (CML) by tyrosine kinases inhibitors (TKI) has been confirmed by multiple long term observation studies. However these studies also demonstrate that primary resistance to TKI may develop in part of CML patients. Whole transcriptome expression analysis of cancer cells in CML is thought to detect genes and pathways involved in molecular mechanisms of TKI-resistance. These findings may help to find more effective strategies of CML treatment.
Aims: Our aim was to find particular expression patterns in cancer cells of primary CML patients, who demonstrated sensitivity or resistance to TKI.
Methods: Gene expression profiles were analyzed using Illumina HT-12 Expression Bead Chip. These chips quantitate expression levels of more than 47000 transcripts. According to European Leukemia Net (2013) criteria patients were divided into resistant to TKI therapy – molecular response >10% in 6 months of therapy; and optimal responders with molecular response <1% in 6 months of therapy.
Results: Comparison of expression data with Partek Genome Suite (Partek) revealed 2672 genes differently expressed in responders and non-responders. Selected genes were used for pathway enrichment analysis which identified several molecular networks influenced by these genes (p<0,05): HTLV-1 infection (*FZD10, ADCY1, MYB*); PPAR signaling pathway (*SCD-1, OLR1*); Transcriptional misregulation in cancer (*MPO, CEBPE, ELANE*); Melanogenesis (*ADCY1, FZD10*). Detailed analysis demonstrated that all of the selected genes are overexpressed in cancer cells of patients sensitive to TKI therapy.
Summary and Conclusions: Targeted expression analysis of the selected pathways may help to find other genes involved in clinical features of CML and its susceptibility to TKI treatment. Identified genes may be found as useful molecular markers for prognosis of the TKI therapy efficacy and treatment optimization of CML.

PB1568

A CLINICAL AND LABORATORY STUDY OF CHRONIC MYELOID LEUKEMIA WITH ATYPICAL BCR- ABL FUSION GENE SUBTYPES

J Pan[1], J Zhang[1], S Chen[1], A Sun[1], D Wu[1], H Qiu[1*]
[1]the First Affiliated Hospital of Soochow University, Suzhou, China

Background: The clinical and laboratory features of f chronic myeloid leukemia (CML) with atypical transcripts are unclear.
Aims: To explore the clinical and laboratory features of CML with atypical e14a3and e19a2BCR- ABL fusion gene subtypes.
Methods: We retrospectively analyzed a cohort of CML patients with Ph chromosome positive confirmed by cytogenetic and FISH but classical e13a3(b2a2) e14a2 (b3a2) and e1a2fusion transcripts negative confirmed by conventional realtime quantification RT- PCR RQ- PCR. Further RQ- PCR was done with the forward primer and reverse primer designed to detect rare atypical BCR- ABL fusion genes including e14a3and e19a2transcripts. Direct sequencing analysis was performed on the PCR products and mutations in the BCR- ABL kinase domain were detected. The clinical data of patients were retrospectively analyzed.

Results: Six CML patients were found to have t□9;22□abnormality and BCR- ABL rearrangement confirmed by FISH but classical BCR-ABL fusion genes negative detected by RQ-PCR. Further RQ-PCR and sequencing analysis confirmed the fusion of BCR exon 14 and ABL exon 3 in five CML patients□case1-5□and the fusion of BCR exon19and ABL exon 2 in one CML patient□case6□. E255K and I293T IM-resistant mutation were detected in case1and 2, respectively. Among five cases with e14a3 transcripts, four were CML- CP, one CML-AP. Four patients were male and one was female. The median age was 48 years. The patient (case6) with e19a2 transcripts was 40-year-old female with a diagnosis of CML-CP and PLT count was more than 1000×10^9/L. Imatinib (IM) therapy was started in case 1,2,3,4and hematopoietic stem cell transplantation (HSCT) was undergone in case5after hydroxyurea (Hu) or interferon failure. Case1who had E255K IM resistant mutation, responded poorly to IM and obtained a complete cytogenetic remission (CCyR) after converting IM to dasatinib. Case 2 and 3 achieved CCyR 6 months later after IM treatment and had been maintained well with IM despite I293T mutation in case 2. Case 4 attained CCyR 3 months later after IM treatment but relapsed and died soon. Case 5was still in CCyR after HSCT. Case 6 with e19a2 transcripts got complete hematologic response after Hu treatment. Thereafter, IM was given and CCyR was achieved soon.
Summary and Conclusions: Incidence of CML with atypical transcripts is extremely low. They could benefit from tyrosine kinase inhibitors or HSCT. Rare and atypical BCR-ABL fusion gene subtypes could be missed by conventional RQ-PCR.

PB1569

CLINICO-HEMATOLOGICAL PRESENTATION AND SURVIVAL ANALYSIS IN PEDIATRIC CHRONIC MYELOID LEUKEMIA: A TERTIARY CARE HOSPITAL EXPERIENCE

P Bhatia[1,*] D bansal[1], A trehan[1], N varma[2], R K marwaha[1]
[1]Pediatric Hematology-oncology, [2]PGIMER, chandigarh, India

Background: CML comprises 3% of all pediatric leukemias, with an annual incidence of 1 per million children.
Aims: To highlight the clinical and hematological presenting features and outcome in pediatric CML cases.
Methods: 17 pediatric CML cases (0-12 years), diagnosed over last three years (2010-2013) were selected and clinical and follow up data analyzed from record files.
Results: Male: Female ratio was 1:0.5. All (100%) had massive spleenomegaly and 8 (47%) mild hepatomegaly. 13/17 (76%) were in chronic phase, 3/17 (18%) accelerated phase and 1 (6%) in blast crisis. All had high TLC, with 15/17 (88%) cases having a WBC count more than 100 x 10^9/L. 8/17 (47%) had high platelet count (>450 x 10^9/L) and 2/17 (12%) had low platelet count. High absolute basophil count (> 0.5 x 10^9/L) was seen in 16/17 (94%) cases. 12/17 (70.5%) cases had a low LAP score (<15; normal range 24-120). Cytogenetic analysis revealed t (9; 22) in 14/17 (82%) cases. All (100%) were positive for BCR-ABL transcript (p210 type) by RT-PCR analysis. 15/17 (88%) cases received imatinib treatment, 2/15 (13%) developed relapse, while 1/15 (6%) died and 1/15 (6%) did not respond to treatment. The median duration of remission free interval was 26 months, while the median survival duration for responders was 29 months (Figure 1a & b).
Summary and Conclusions: Our study highlights that pediatric CML presents with high WBC count and massive spleenomegaly and has an improved outcome with imatinib. Pediatric CML though rare, needs to be considered in cases with high TLC and basophil count. BCR-ABL studies are necessary to confirm diagnosis and imatinib is an effective first line treatment modality.

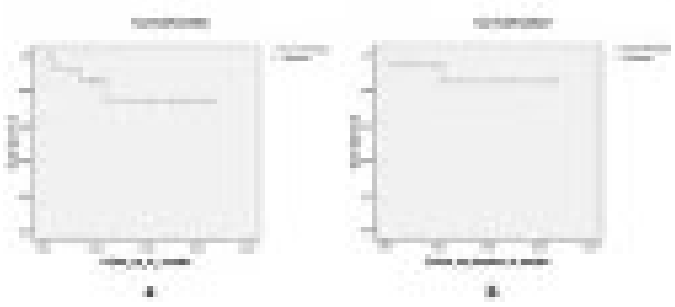


Figure 1. a) Shows remission free interval in months and b) shows over-all survival in rsponders in months.

PB1570

IMMUNOPROFILING OF PATIENTS WITH CHRONIC MYELOID LEUKEMIA IN TREATMENT WITH TYROSINE KINASI INHIBITOR

G Catania[1,*] M Coppo[1], F Monaco[1], M Pini[1], MT Corsetti[1], F Zallio[1], F Salvi[1]
[1]Ospedale San Antonio e Biagio e Cesare Arrigo, Alessandria, Italy

Background: For most patients with chronic myeloid leukemia (CML), the advent of ABL1 tyrosine kinase inhibitor (TKI) therapy has turned their chronic leukemia into a truly indolent medical condition, although only in a small subset of patients may discontinue treatment. In those last patients, it was hypothesized immunogical control of the leukaemia clone. In addition to target BCR-ABL oncoprotein, the TKIs inhibit off-target kinases (such as c-KIT, TEC, SRC), some of which have physiological functions in immune responses. Several studies have documented the influence of TKIs on immunological system, not always clean, some show inhibitions others stimulation.
Aims: The aim of this study was to evaluate the existence of correlation between immunoprofiling and the depth of molecular response.
Methods: Were evaluated patients with CML in chronic phase treated in our institution with TKIs. It were excluded those with less than one year of treatment and/or undergone at allogeneic stem cell transplantation.
We valued on peripheral blood (PB) immunoglobulin levels, electrophoresis and lymphocyte count. Molecular responses were evaluated with RT-Q-PCR in PB. The patients were divided into two groups, “deep molecular” response ($BCR\text{-}ABL^{IS} \leq 0.0032$) and “superficial molecular” response ($BCR.ABL^{IS} > 0.0032$).
Results: 48 patients were considered. The median age of patients was 61 years (range 22-80 years) and 29 (60%) were male. Sixteen patients were in “deep molecular” response (dMR) and thirty-two were in “superficial molecular” response (sMR). A mild hypogammaglobulinemia (IgG > 450 mg/dl) was seen in both groups (56% *vs* 43%) and an increased CD4/CD8 ratio were reported (56% *vs* 44%), without difference between the two groups. (table1 a,b).
Summary and Conclusions: In our study the increase in the CD4/CD8 ratio had demonstrated the activation of immune system,that does not correlate with the a depth of molecular response. To confirm this observation is necessary a higher number of patients.

PB1571

PREDICTIVE VALUE OF PRETREATMENT BCR-ABLIS TRANSCRIPT LEVEL ON RESPONSE TO IMATINIB THERAPY IN EGYPTIAN PATIENTS WITH CHRONIC PHASE CHRONIC MYELOID LEUKEMIA (CPCML)

Y Elnahass[1,*] W Elmetenawy[2], M Mattar[2]
[1]Clinical Pathology, National Cancer Institute/Egypt, [2]Medical Oncology, Faculty of Medicine, Cairo, Egypt

Background: A wide range of responses of patients with CPCML to IM has been reported. Several factors were proposed to predict response including molecular response at 3 and 6 months
Aims: To study the impact of pretreatment BCR -ABL transcript level on molecular response to IM, and to assess the value of the milestone ≤10% transcript at 3 months on PFS and OS.
Methods: Fifty five adult CP-CML patients receiving daily dose of 400 mg IM were subjected to molecular and cytogenetic analysis at diagnosis and at regular time intervals. Median follow up period was 36 months (15-48). Hematologic, cytogenetic, and molecular responses were rated according to ELN.
Results: Two Patient groups were distinguished regarding response to IM therapy. A group of 22/55 patients (40%) having pretreatment BCR-ABLIS level ≤200% and a second patient group 33/55 (60%) having transcript level >200%. The ≤10% milestone was achieved by 15/22 patients (68%) *versus* 7/33 patients (21%) (p=0.04) in favor of the first group. Optimal responders in first group were 14/22 (64%) compared to 13/33 (39%) in second group (p=0.02). Achievement of 10% transcript level significantly correlated with longer PFS. The median BCR-ABLIS transcripts levels in optimal responders at 3, 6 and 18 months was 10%, 2% and 0.1%, respectively compared to 100%, 65% and 10%, in suboptimal/resistant patients p=0.001. Resistance in 11 patients was correlated with identifiable ABL Kinase mutations.
Summary and Conclusions: The Pretreatment 200% cutoff and the 3 month BCR-ABLIS ≤10% transcript levels proved strong predictors of response to IM and significantly correlated with probability of CCyR, MMR and PFS.

Myelodysplastic syndromes - Biology

MOLECULAR PREDICTORS OF RESPONSE TO DECITABINE IN CHRONIC MYELOMONOCYTIC LEUKEMIA

A Rossi[1,*] A Valencia[1], O Abdel-Wahab [2], E Masala[1], F Buchi[1], A Sanna[1], A Bosi[1], A Levis[3], B Allione[4], M Lunghi[5], A Poloni[6], A Terenzi[7], E Angelucci[8], C Finelli[9], F Onida[10], G Rossi[11], V Santini[1]

[1]SODc Ematologia, Università degli Studi di Firenze, Firenze, Italy, [2]Department of Medicine, Memorial Sloan-Kettering Cancer Center, Human Oncology and Pathogenesis Program, and Leukemia Service, New York, United States, [3]Ematologia, AO SS Antonio e Biagio e C.Arrigo, Alessandria, [4]Ematologia, Ospedale S. Giovanni Battista Molinette , Torino, [5]Ematologia, AOU Maggiore della Carità Scav Ematologia, Novara, [6]Ematologia, Ospedali Riuniti, Ancona, [7]Ematologia, Ospedale Santa Maria della Misericordia, Perugia, [8]Ematologia, Ospedale Oncologico A. Businco, Cagliari, [9]Ematologia, Ospedale Sant'Orsola Malpighi, Ematologia Seragnoli, Bologna, [10]Ematologia, Fondazione IRCCS Ca' Granda di Milano, Milano, [11]Ematologia, AO Spedali Civili, Brescia, Italy

Background: The hypomethylating agent 5-aza-2'-deoxycytidine (decitabine, DAC) has been demonstrated to have efficacy in the therapy of chronic myelomonocytic leukemia (CMML). However,response is quite heterogenous with overall response rate ranging from 25-70%(Braun,Blood 2011).Given that no other specific therapy has been identified for CMML,there is a need to identify molecular markers that could support decision making when choosing DAC therapy.DAC is a pyrimidine nucleoside analogue of cytidine,and different studies have demonstrated the importance of the levels of expression of the enzymes involved in nucleoside metabolism and consequently in the resistance/response to this kind of drugs(ie gemcitabine,cytosine arabinoside).In addition,mutations in several genes have been demonstrated to impact survival of CMML patients.
Aims: In this study,we(1)measured expression levels of genes involved in the metabolism of DAC and(2)performed mutational analysis for genes recurrently mutated in CMML in pretreatment samples from CMML patients prospectively treated with DAC as part of a clinical trial.
Methods: DNA and RNA were extracted from marrow mononuclear cells of 39 patients treated with at least six cycles of DAC iv 20mg/m^2/5 days every 28 days. Quantitative real-time PCR was then performed in 22/39 for *hENT1,hENT2,DCTD,hCNT3,CN-II,DCK and CDA*.
Results: The expression of all genes analyzed was compared between responders and non-responders. In addition, samples were sequenced for the 15 genes known to be recurrently mutated in CMML at a mean depth of coverage of 520X(range 169–714x).Of the 39 patients,16 patients were responders and 20 non-responders to DAC,according to the IWG 2006 criteria(3 had response which was non-evaluable).Individually,none of these genes was differentially expressed in responders *versus* non-responders. The mutational frequencies in this cohort were:48.7%SRSF2,43.6% *ASXL1,* 17.9% *NRAS,*12.8% *TET2,*10.3% *RUNX1,* 10.3% *DNMT3A*,*U2AF1* 7.7%,7.7% *TP53,*7.7% *KRAS,*5.1% *JAK2,*2.6% *EZH2,*2.6% *IDH1,*2.6% *IDH2,*2.6% *SF3B1,*2.6% *KIT.*No single genetic alteration was significantly associated with adverse overall survival or resistance to decitabine in this cohort.
Summary and Conclusions: Although the main limit of the study is the small number of cases,our results seem to show that the absence of clinical response to DAC of CMML patients is not strictly correlated with the expression of genes involved in the DAC metabolism or to specific genetic alterations.This finding is not in line with what our group recently demonstrated in MDS cases treated with the nucleoside analog azacitidine,for whom UCK1 expression levels correlated with response.Further studies on larger series of CMML cases are needed to validate these results.

PB1573

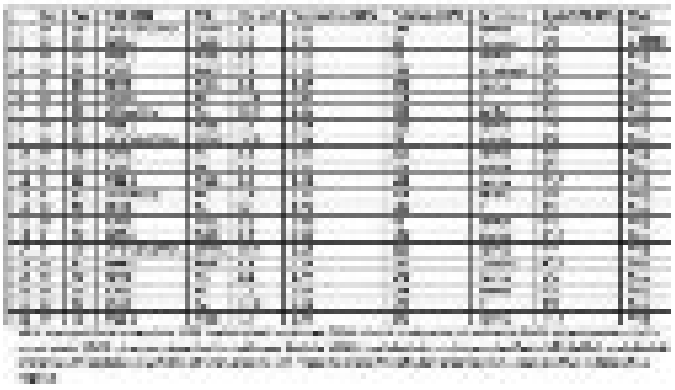
CSF3R POINT MUTATIONS IN A COHORT OF PATIENTS WITH MYELODISPLASTIC SYNDROMES AND NEUTROPENIA AT DIAGNOSIS

C Da Silva[1,*] L Arenillas[1], L Martínez-Avilés[2], MC Vela[2], C Cuéllar[2], D Acemel[1], B Costan[1], C Pedro[3], B Bellosillo[2], L Florensa[1]

[1]Laboratori de Citologia Hematològica. Servei de Patologia, [2]Laboratori de Biologia Molecular. Servei de Patologia, [3]Servei de Hematologia, Hospital del Mar. GRETNHE, IMIM (Hospital del Mar Research Institute), Barcelona, Spain

Background: Granulocyte colony-stimulating factor (GCSF) receptor, also known as CSF3R, plays an essential role in the proliferation and granulocyte differentiation. Two types of *CSF3R* mutations have been described, mutations causing truncations of the cytoplasmatic domain and membrane-proximal point mutations. *CSF3R* truncation mutations have been observed in patients with severe congenital neutropenia (SCN) chronically treated with pharmacologic doses of GCSF. Membrane proximal mutations confer ligand-independent-growth and are the mutations most frequently reported in chronic neutrophilic leukemia (CNL) and atypical chronic myeloid leukemia. Myelodysplastic syndromes (MDS) are acquired clonal hematopoietic disorders, characterized by cytopenias, dysplasia in one or more of the myeloid cell lines and an increased risk of development of acute myeloid leukemia. To our knowledge there is limited information about the incidence of *CSF3R* mutations in MDS. Abnormalities in the signal-transduction pathways for CSF3R may play a role in the pathogenesis and the development of neutropenia in MDS
Aims: The aim of this study was to investigate the presence of *CSF3R* point mutations in patients diagnosed with MDS that presented neutropenia.
Methods: Mutational analysis of the *CSF3R* gene (exons 14-17) was performed by Sanger sequencing using DNA obtained from bone marrow or peripheral blood samples of 22 MDS patients who presented neutropenia <1800/mm^3 at diagnosis. Diagnosis of MDS was made according to the FAB classification. Three out of the 22 patients were diagnosed of chronic myelomonocytic leukaemia according to the 2008 WHO classification. Samples were collected at the time of diagnosis and without any prior therapy.
Results: Median age at diagnosis was 76 years (range 63–86). Fifteen out of the 22 patients (68%) were males and 90% were older than 70 years. Baseline characteristics are shown in Table I. Median overall survival was 47 months (95% CI: 24-70). We identified a *CSF3R* mutation in 1 out of the 22 patients. The mutational analysis showed one missense variant resulting in the substitution of a glutamic acid to a lysine at amino acid position 808 (p.E808K) located at exon 17 of the *CSF3R* gene (G>A coding location 2422, NM_000760.3). This mutation has previously been described in one case of chronic myelomonocytic leukaemia and in one case of CNL, this last one coexisting with the P.T618I mutation. Our patient (#2) was a 73-year old man who was referred to our service for pancytopenia (neutrophils count 1.72 x10^9/L, hemoglobin level 9.6 g/dL, platelets count 69 x10^9/L). Bone marrow was hypercellular with dysplasia involving the three myeloid lineages and 6% of blasts. Conventional cytogenetic analysis on bone marrow cells revealed the following karyotype: 46,XY,-5,del(7)(q11q35),+8,der(17)t(5;17)(p11;p11)[20]. Diagnosis of RAEB-1 was established. The patient developed an acute myeloid leukaemia 16 months later from diagnosis. Overall survival for this patient was 18 months, clearly lower compared to the rest of the patients.
Summary and Conclusions: In our experience, mutations affecting the *CSF3R* gene are an uncommon event in MDS patients. Here we report a rare variant located at exon 17 (p.E808K) in a patient with MDS and neutropenia. The biological and the clinical relevance of this mutation remains unknown. More studies in larger series are required to determine the incidence and role of *CSF3R* mutations in MDS.

Table 1.



PB1574

SIGNIFICANCE OF P53 OVEREXPRESSION IN BONE MARROW BIOPSIES FROM PATIENTS WITH MYELODYSPLASTIC SYNDROME (MDS) AND NON-NEOPLASTIC CONDITIONS ASSOCIATED WITH MYELODYSPLASIA

S U Bozkurt[1,*] H Toper[1], F Pepedil[2], I K Atagunduz[2], K Turkoz[1], T Tuglular[2]

[1]Pathology, [2]Hematology, Marmara University Medical Faculty, istanbul, Turkey

Background: Myelodysplastic syndromes (MDS) are clonal diseases of the bone marrow, characterized by ineffective hematopoiesis causing peripheral blood cytopenias. Apoptosis is suggested in the pathogenesis of MDS. An important controller of this process is p53 tumor supressor gene. Although p53 mutations commonly found in many cancer types, the results of the role of the p53 in MDS are variable in the literatüre.
Aims: To investigate the role of p53 overexpression in the development of Myelodysplastic syndrome (MDS) and to assess their impact on differential diagnosis with myelodysplasia associated with non-neoplastic conditions.
Methods: Bone marrow biopsy samples from 72 patients admitted to the

hospital with cytopenias with preliminary diagnosis of MDS were obtained from archives of Marmara University Pathology Laboratory. Fiftyfour patients were diagnosed as MDS (24 female , 30 male), 18 patients diagnosed as reactive conditions associted with mild dysplasia (10 female, 8 male). MDS group was classified as Refractory anemia (MDS- RA)(n = 10), Refractory anemia with ring sideroblasts (MDS- RARS) (n = 10), Refractory cytopenia with multilineage dysplasia) (MDS- RCMLD) (n = 10),Refractory anemia with excess blasts-I (RAEB-I) (n = 10) , Refractory anemia with excess blast - II(RAEB-II) (n =10), MDS associated with isolated 5q deletion (MDS 5q-) (n = 4) according to the WHO 2008 classification. Patients having preliminary diagnosis as MDS were classified in reactive group composed of patients having mild dysplasia (<%10 dysplasia in myeloid cells) founded in bone marrow biopsies with no detected cytogenetic abnormality, and patients who were evaluated as Paroxysmal nocturnal hemoglobinuria , Idiopathic thrombocytopenic purpura , collagen vascular disease , vitamin B12 deficiency , anemia of chronic disease with subsequent follow-up. The p53 (Leica, concantrated 1/100) staining was evaluated by counting nuclear positivity in all cells at x1000 magnification in "hot spot" area.

Results: In reactive group, no positivity of p53 was detected in their marrow. The p53 positivity was detected in 37(68%) of all patients with MDS . The p53 staining was detected in 3 patients with mean staining 0.3% (% 0-2.9) in MDS-RA group , 8 patients had a mean of 1.75% (% 0-5.3) in RARS group, 6 patients had a mean of 1.9% (% 0-6.1) in RCMLD group , 7 patients had a mean of 7.4% (0-22.4%) RAEB -I group, 10 patients had a mean of 20.7% (6.6-50%)in RAEB -II group, 3 patients had a mean 10.4%(0-23%), in MDS 5q (-) group. The p53 values were found to be statistically significantly between reactive and myelodysplasia groups .(p <0.001) (Kruskal-Wallis test)

The p53 values were found to be statistically significant between the RA group that had the lowest p53 immunoreactivity compared with the reactive group. (p <0.05) (Mann-Whitney test).

Summary and Conclusions: The detection of no expression for p53 immunhistochemistry in bone marrow biopsy from clinically suspicious MDS patients having limited dysplasia in the bone marrow, can favor the reactive condition. The p53 positivity in bone marrow biopsy is a valuable tool in the differential diagnosis of myelodysplaia assaciated with MDS and myelodysplasia associated with non-neoplastic conditions. p53 may also have prognostic importance in MDS patients due to the a higher rate of detection of p53 especially in high risk MDS group (RAEB-I/RAEB-II). The detection of high p53 positivity in patients with MDS with isolated 5Q(-) sydnrome , suggest that p53 activation plays an important role in the development of MDS in Isolated 5Q (-) syndrome

PB1575

POLYMORPHISM OF FOLATE AND METHIONINE METABOLISM GENES IN PATIENTS WITH MYELODYSPLASTIC SYNDROME

Z Sidorova[1],* S Gritsaev[1], K Abdulkadyrov[1], S Kapustin[1]
[1]FSBI "Russian Research Institute of Hematology and Transfusiology of FMBA", Saint-Petersburg, Russian Federation

Background: Epigenetic mechanisms, including aberrant methylation of CpG islands, have an important role in pathogenesis of human neoplasias and are often seen in patients with myelodysplastic syndrome (MDS). Polymorphism of folate and methionine metabolism (FMM) related genes can influence the methylation processes. The role of gene variations in FMM genes in predisposition to MDS is not well known.

Aims: The aim of this study was to assess the peculiarities of alleles and genotypes distributions of the FMM genes in MDS patients.

Methods: Twenty-nine patients with MDS (10 men and 19 women, mean age 63.7 yrs) and 121 healthy controls (HC) were genotyped for the MTHFR C677T, MTHFR A1298C, MTR A2756G, MTRR A66G and MTHFD G1958A polymorphisms by PCR-RFLP technique. The differences in allele and genotype frequencies between patient and HC groups were assessed by Fisher's exact test with computation of odds ratios (OR), their 95% confidence intervals (CI) and p-values.

Results: For all studied genes, the alleles and genotypes distributions in patients were not statistically different from those in HC. The frequency of the MTFR 677CC genotype was slightly decreased in MDS patients when compared to HC group (41.4% *vs.* 52.1%, respectively, p=0.4). At the same time, the MTRR 66GG variant was present in 10 (34.5%) patients and 28 (23.1%) controls (p=0.24). The simultaneous presence of the MTHFR 677T allele and MTRR 66GG genotype was more often detected in MDS group (24.1% *vs.* 9.1%, OR=3.2, 95%CI: 1.1-9.1, p=0.049). Moreover, the frequency of the MTHFD 1958GG genotype was increased in patients (41.4% *vs.* 24.8%, OR=2.1, 95%CI: 0.9-5.0, p=0.1).

Summary and Conclusions: We conclude that polymorphism of the FMM genes could have an important role in pathogenesis of MDS. The simultaneous presence of the MTHFR 677T allele and MTRR 66GG genotype is a significant risk factor for MDS development.

PB1576

INTRACHROMOSOMAL AMPLIFICATION OF RUNX1 GENE (IAMP21) IN A PATIENT WITH HYPOPLASTIC MYELODYSPLASTIC SYNDROME (MDS): FIRST OBSERVATION

M Parihar[1,*] N Arora[2], D K Mishra[2], A SR[1], A K Yadav[1], R Chitrapur[3], S J Bhave[3], A Chakrapani[3], R Nair[3], M Chandy[3]
[1]Lab Haematology and Cytogenetics, [2]Lab Haematology, [3]Clinical Hematology, Tata Medical Center, Kolkata, India

Background: Most recurrent cytogenetic abnormalities in MDS are unbalanced, with loss of or deletion of parts of chromosome. The intrachromosomal amplification of *RUNX1* gene (iAMP21), defined as three or more extra copies of *RUNX1* gene on a single abnormal chromosome 21 is a distinct clinical entity reported in pediatric acute lymphoblastic leukemia (ALL). Although *RUNX1* mutations are known to occur in MDS, iAMP21 has never been described in MDS. Here, we report a case of iAMP21 associated with intrachromosomal amplification of the MLL gene (iAMPMLL) in a 28 year old patient with hypoplastic MDS and history of chronic exposure to cytotoxic chemicals.

Aims: To document the presence of iAMP21 in hypoplastic MDS highlighting the first ever report of its correlation with cytotoxic exposure.

Methods: Karyotyping and FISH using *ETV6*/*RUNX1* fusion and *MLL* breakapart probes were carried out on bone marrow aspirates cultured overnight using standard protocols.

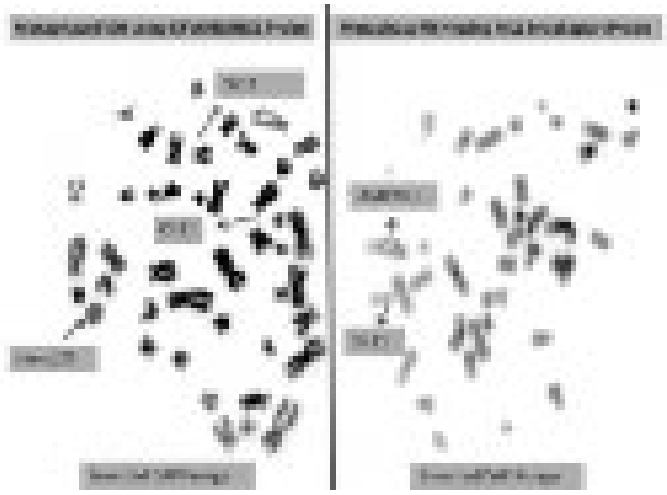


Figure 1.

Results: A 28 year old male presented with history of weakness for two months. He had worked for many years in the leather industry and had nearly 2 decades of exposure to organic solvents, polyurethane and polycholoropene compounds. Clinical examination showed pallor with no other significant findings. Blood counts revealed pancytopenia (Hb 6.6g/dL; total leucocyte count 2.2 × 10^9/L; platelet 5 × 10^9/L) with features of dysgranulopoiesis on peripheral blood smear. Marrow studies indicated hypocellularity (30% cellularity) and florid trilineage dysplasia with 7% blasts and no significant marrow fibrosis. Cytogenetic analysis revealed a complex hypodiploid karyotype with multiple subclones. A deletion 7q and a derivative chromosome 21 were observed in all the cells. In 16 metaphases, a derivative chromosome 15 with an unbalanced translocation was seen. The modal karyotype was 44~46,XY, del(1)(p34.3), t(1;3)(p31;p25), -4, del(5)(q21q33), del(7) (q11.2), add(8)(q24), -9, der(10)t(10;?)(q26;?), -11, ?i(11)(p11), dic(11;12)(q25;p13), der(15)t(15;?)(p11.2;?), -18, +der21?iamp(21), der(21)?iamp(21) [CP20]. A metaphase FISH using the ETV6/RUNX1 fusion probe confirmed the presence of iAMP21.Metaphase FISH using the MLL breakapart probe showed iAMPMLL on the derivative chromosome 15. The patient is planned for a haploidentical allogeneic bone marrow transplant.

Summary and Conclusions: We report a patient with hypoplastic MDS, probably arising from chronic exposure to hazardous chemicals. Cytogenetic analysis showed a complex karyotype with iAMP21 as well as iAMPMLL. iAMP21 is a recognised cytogenetic abnormality in precursor-B ALL and the observation of this abnormality in MDS is unusual. Its co-existence with iAMPMLL suggests a common mechanism of chromosome instability associated with the breakage-fusion-bridge cycle, resulting in amplification and formation of dicentric chromosomes. Since the iAMPMLL was seen in only a subpopulation of iAMP21 positive cells, it is likely that the iAMPMLL arose as a secondary event in this patient. A more detailed molecular study would uncover molecular and cellular mechanisms underlying this clinical phenotype.

PB1577

SRSF2 IN CMML: CORRELATION BETWEEN CLINICAL AND LABORATORY FINDINGS

M Torres Ochando[1,*] N Cruz Cruz[1], MT Gómez Casares[1], G Santana Santana[1], A Lemes Castellano[1], C Rodríguez Medina[1], T Molero Labarta[1]
[1]Department of Hematology and Hemotherapy, Dr. Negrín Hospital, Las Palmas de Gran Canaria, Spain

Background: Chronic Myelomonocytic leukemia (CMML) is a clonal blood disorder that belongs to the Myelodysplastic Syndrome/ Myeloproliferative Neoplasm (MDS / MPN) group of the World Health Organization classification of 2008 (WHO), because it shares clinical and biological data of both entities. Taking in reference the WHO classification, CMML is divided in two groups depending on morphologic features: CMML-1 with fewer than 5% blasts in peripheral blood (PB) or 10 in bone marrow (BM), and CMML-2 with 5-19% blasts in PB or 10-19% in BM. The French-American-British (FAB) classification considered 2 groups of this pathology, dysplastic and proliferative variants, with the cut-off of 13000 leucocytes in PB. At present, the only specific molecular criterion for the diagnosis of this entity is the absence of BCR-ABL1 fusion transcript, but there are not specific cytogenetic or molecular abnormalities described. Although other groups have studied the association of some common mutations in MDS, like the mutation that affects the splicing gene SRSF2. The SRSF2 gene, located on chromosome 17q25.1, encodes the splicing factor 2, rich in serine /arginine, important in this process in which the pre-mRNA into mature mRNA is transformed, essential for the production of proteins. Current literature shows a prevalence of the SRSF2 mutation between 40-50% of patients diagnosed of CMML. These findings make it as a possible factor in the diagnosis of this entity.
Aims: The aim of this study is to analyze the SRSF2 mutation in a series of patients diagnosed of CMML. We included also patients affected of other pathologies to have a relation of the association of this mutation with myeloid pathology in general.
Methods: The study included 40 patients with the following diagnoses: CMML (9) , MDS (4) , MDS / MPN (2) , Acute myeloid leukemia (AML) (10) ,Chronic lymphatic leukemia (CLL- B) (3), monocytosis (1) , metastatic carcinoid tumor in BM (1), immune thrombocytopenic purpura (1), mastocytosis (1).
The method of analysis used is the real-time PCR, obtaining results through High resolution Melting (HRM) with two possibilities (mutated or not mutated). In a second step, positive results have been checked by sequencing.
Results: The results obtained are shown in the Table 1.

Table 1.

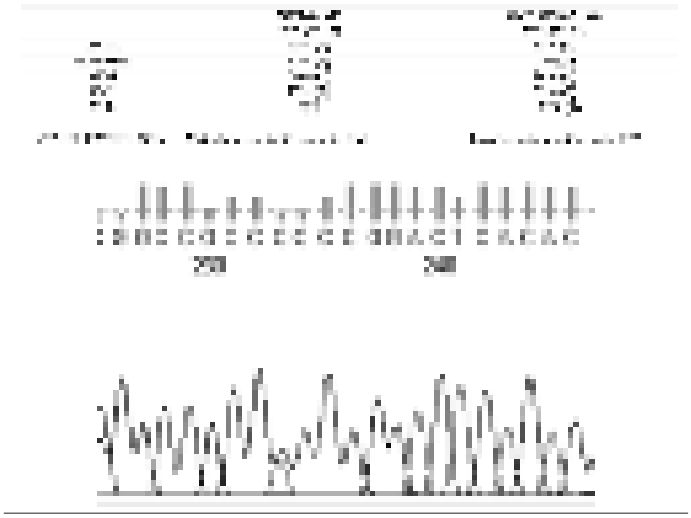

Figure 1.

Summary and Conclusions: The analysis showed a prevalence of 65% of the SRSF2 mutation in patients with a diagnosis of CMML. Although the overall sample size for other diseases is insufficient, we observed that patients with different myeloid pathologies may also have the mutation. We did not find association of the SRSF2 mutation with sex or age. At the beginning of the study we found a relation between the dysplastic variant of the FAB classification and the SRSF2 mutation, but when we expand the sample size, we observed that it was a chance finding. In conclusion, we did not find any relation between the variants of the WHO and FAB classification with the presence or absence of the mutation. More than a half of patients with CMML showed the SRSF2 mutation, for this reason, we concluded, that it could be an important finding to help in the diagnosis of this heterogeneous patholoy.

PB1578

DISTRIBUTION OF CYTOGENETIC ABNORMALITIES IN MYELODYSPLASTIC SYNDROMES IN A SINGLE CENTER IN ALGERIA

T Souad[1,*] B Yamina[1], A M Tayeb[2]
[1]HEMATOLOGY, EHS ELCC CAC, [2]HEMATOLOGY, EHS ELCC CAC Faculty of Medecine University Blida 1, BLIDA, Algeria

Background: The myelodysplastic syndromes (MDS) are a heterogeneous group of hematologic diseases which reflect a clonal hematopoietic stem cell achievement. SBDS are associated with a significant risk of transformation into acute myeloid leukemia (secondary leukemia).Cytogenetics (Karyotype and FISH) became an essential consideration in the management of Myelodysplastic syndromes, as much for the diagnosis, the prognosis and the monitoring of residual disease.The 2008 who classification takes into account the cytogenetic study in order to stratify on the prognostic map myelodysplastic syndromes.Main cytogenetic abnormalities observed in myelodysplastic syndromes are highlighted by the karyotype. Hybridization *in situ* because its sensitivity found a framework of choice for the revelation of targeted abnormalities.
Aims: Our presentation is designed to report the main cytogenetic abnormalities observed in our practice, and their contribution to the diagnosis and prognostic classification
Methods: The study involved 40 patients of average age = 60 years (25-84), sex ratio = 1, 1 .Karyotype and hybridization *in situ* have been made systematically on a bone marrow sample.A culture of 24 hours with synchronization was performed, R banding was adopted with an analysis of at least 20 mitoses.The reading was made by microscope coupled with analysis type Cytovision for software; the FISH probes targeting the most common abnormalities have been used: probe 5 q - (5q31.2; 5q33.2); Probe 5q 33 break; Probe 7 q - (7q 22 q 7, 35); Probe 20 q - (PTPRT20q12 / 20q 11); Probe P53 (17 p 13/SE17)
Results: On 40 completed karyotypes, 30 were informative. Chess are represented by 7 failures of culture because of poor sampling (hypoplastic forms) and 3 failures of karyotyping: difficulty of banding.On 30 informative karyotypes: no abnormality was detected in 17 cases (56.7%) Karyotype with abnormalies in 13 cases (43.3%): A single anomaly in 8 cases, two anomalies in 1 case, ≥ 3 abnormalities in 4 cases.The karyotype abnormalities: Del 5 q / monosomy 5: 4 cases (13.3%), isolated in 2 cases (5%); associated with a complex karyotype in 2 cases; Del7q / monosomy 7: 4 cases (13.3%), isolated in 1 case (2.5%), associated with a complex karyotype in 3 cases; Del 20q: 2 isolated cases (5%). Del 13q (iso 17q): 1 case (2.5%) insulated; Tri 8: 4 cases: secluded in 2 cases, associated in 2 cases .Translocations unbalanced in complex karyotype abnormalities: 4 cases (10%).On 40 FISH carried out there: without abnormalities: 24 (60%); with anomalies: 16 (40%): del 5q : 6 cases: 2 isolated, 4 associated ; del 7q : 5 cases : 1 isolated, 4 associated ; del 20q: 2 cases: all isolated ; del P53: 5 cases : 4 isolated, 1 complex ; other anomalies : duplication of the 20q, the 7 q , the 5q ; t (7; ?); + 17.
Summary and Conclusions: The combination of the Karyotype and FISH allowed to detect abnormalities in 18 patients (45%) and the absence of anomalies in 22 patients (55%).In 10 cases of failure of the karyotype, the FISH has identified 3 abnormalities. In cases where the karyotype was normal, the FISH found targeted anomalies. In 15 cases where the karyotype was normal, the FISH did not reveal targeted anomalies. In 9 cases the abnormalities found in the karyotype were confirmed by the FISH. The karyotype revealed Trisomy 8 isolated or associated in 4 cases, abnormality not targeted by the FISH. The karyotype is the only procedure which revealed complex abnormalities. These data are as those identified in the literature; They also attest to the complementarity of these two procedures.

Myelodysplastic syndromes - Clinical

PB1579

DECITABINE AS COMPARED TO AZACITIDINE THERAPY MAY RESULT IN BETTER OVERALL SURVIVAL BUT NOT QUALITY OF LIFE IN PATIENTS DIAGNOSED WITH CHRONIC MYELOMONOCYTIC LEUKEMIA (CMML): A RETROSPECTIVE, SINGLE I

A Al-Kali[1,*], S Hashmi[1], A Alsahlawi[1], M Patnaik[1], M Elliott[1], A Wolanskyj[1], W Hogan[1], M Siddiqui[1], M Litzow[1]
[1]Hematology, Mayo Clinic, Rochester, United States

Background: CMML is one of the clonal hematopoietic disorders classified under the myelodysplastic/ myeloproliferative overlap category. Hypomethylating agents (HA) (azacitidine [AZA] and decitabine [DAC]) have been approved by the FDA for the treatment of myelodysplastic syndromes (MDS) and CMML, based on MDS studies which included few patients (pts) who received AZA and DAC. To our knowledge, these two therapies have not been compared in either a prospective or retrospective study for the treatment of CMML.
Aims: To compare the clinical and quality of life outcomes in pts on HA for CMML.
Methods: We performed a retrospective chart review of pts diagnosed with CMML at the Mayo Clinic between 1994 to 2011. Overall response (OR) was categorized as complete remission (CR), partial remission (PR), marrow remission (MR) or hematological improvement (HI), based on the modified International Working group (IWG) criteria in MDS (Cheson B et al Blood 2006). IRB approval was obtained in accordance with the Helsinki declaration. Comparison between the two groups was done using the Wilcoxon test, while survival estimates were calculated using Kaplan-Meier estimates via JMP software v.9. For the cost-effectiveness analysis, Incremental cost-effectiveness ratios (ICER) were calculated (cost difference /quality adjusted life years [QALY]). Only direct costs were included due to absence of the indirect costs, and the drug prices for both AZA and DAC were obtained from the Pharmacy Red Book 2010.

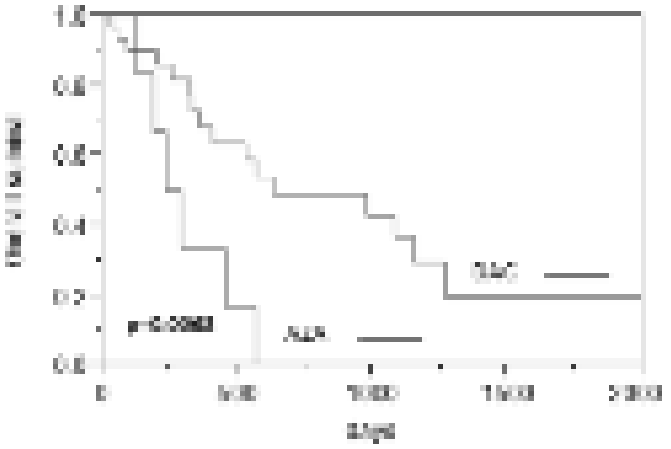

Figure 1.

Results: A total 268 pts with CMML were identified and of these, 36 pts (13%) were treated with HA: 29 (81%) received DAC (group, (Gp 1)) and 7 (19%) received AZA (Gp 2). No significant baseline differences in median age (70 *vs* 73 years), hemoglobin (11 *vs* 10 g/dl), WBC (14 *vs* 9 x10^9/L), platelets (74 *vs* 40 x10^9/L), monocyte (18% *vs* 26%), Peripheral blood (PB) or BM blast (0% and 4%) was found between Gp 1 and Gp 2, respectively. In Gp 1 cytogenetics were diploid in 62% *vs* 100% in Gp 2 (p=0.016). There was no significant difference in the median number of cycles (5 [range 1-22] cycles of DAC compared to 3 [range of 1-9] of AZA) and median follow up in days between both groups (409 for Gp 1 *vs* 239 for Gp 2). Differences in OR for Gp 1 *vs* Gp 2 were not significant: OR 41% *vs* 29% (p=0.5), CR 20% *vs* 0 (p=0.09), MR 17% *vs* 0 (p=0.13), HI 3 *vs* 29% (p=0.059) as was transformation to AML, 28% *vs* 14% (p=0.4). Median overall survival (OS) was significantly higher for Gp1 *vs* Gp 2 (634 *vs* 266 days, respectively, (p=0.0068)). When limiting analysis to pts with BM blast >4%, median OS was 531 *vs* 292 days, respectively (p=0.13) compared to pts with BM blast <5%, 979 *vs* 266 days, respectively (p=0.023). On multivariate analysis, platelets (p=0.04) and HA type of therapy (DAC *vs* AZA) (p=0.048) were significant for OS, but not age, hemoglobin, WBC, monocyte count, PB or BM blasts. For ICER, a difference of US$4727 for dominance of DAC was found, which is insufficient to recommend a meaningful difference between the two drugs from a societal or a third party payor perspective as far as QALY's is concerned.
Summary and Conclusions: In a single institution retrospective study DAC was used more frequently compared to AZA for CMML. OS was significantly better for patients on DAC (in particular if BM blast <5%). Only type of HA therapy and platelet count remained significant on multivariate analysis. Our findings suggest the DAC as compared to AZA may result in better OS in CMML and require confirmation in prospective studies.

PB1580

A PHASE 4, OPEN-LABEL, SINGLE-ARM STUDY TO EVALUATE THE EFFICACY, SAFETY, AND PHARMACOKINETICS OF SUBCUTANEOUS AZACITIDINE IN ADULT TAIWANESE SUBJECTS WITH HIGHER-RISK MYELODYSPLASTIC SYNDROMES

WC Chou[1,*], SP Yeh[2], LT Hsiao[3], SF Lin[4], YC Chen[5], TY Chen[6], JY Wang[7], A Galettis[8], Q Dong[8], S Songer[8], C Beach[8]
[1]National Taiwan University Hospital, Taipei, [2]China Medical University Hospital, Taichung, [3]Division of Hematology/Oncology, Taipei Veterans General Hospital, Taipei, [4]Kaohsiung Medical University Hospital, Kaohsiung, [5]Division of Hematology/Oncology, Tri-Service General Hospital, National Defense Medical Center, Taipei, [6]National Cheng-Kung University Hospital, Tainan, [7]Hualien Tzu Chi Medical Center, Buddhist Tzu Chi General Hospital, Hualien, Taiwan, Republic of China, [8]Celgene Corporation, Summit, United States

Background: Subcutaneous (SC) azacitidine (AZA) significantly improved overall survival (OS) and hematologic improvement (HI) in Western patients (pts) with higher-risk MDS (HR-MDS) (Fenaux *et al*, 2009). Hematologic response with AZA was evaluated in small studies in Japanese and Korean pts with HR-MDS (Kim *et al*, 2011; Uchida *et al*, 2011). Variation in gene polymorphisms among Asian populations (Kurose *et al*, 2012) may influence AZA clinical outcomes. The PK parameters of SC AZA in Taiwanese pts (n=12) from this study were comparable to those in North American pts (Laille *et al*, 2013; Garcia-Manero *et al*, 2011). To our knowledge, the treatment effects of AZA in Taiwanese pts with HR-MDS have not previously been evaluated.
Aims: This study evaluated the safety and efficacy of AZA in Taiwanese pts with HR-MDS.
Methods: This multicenter open-label, single-arm, phase 4 study enrolled Taiwanese pts aged ≥18 years, with IPSS HR-MDS (Intermediate-2 [Int-2] or High risk), a diagnosis of RAEB, RAEB-T, or CMML (10-29% bone marrow [BM] blasts), and an ECOG PS of 0-2. All pts received SC AZA 75 mg/m^2/day x 7 days/28-day cycle for up to 6 cycles. BM aspirates were assessed by central review. Investigator-determined complete and partial remission (CR, PR), and HI and transfusion independence (TI), were defined per IWG 2000 criteria. Pts must have had a BM assessment at baseline (BL) and at cycle 6 to be evaluable for CR or PR. TI was assessed in pts who were transfusion-dependent (TD) at BL (≥1 RBC/platelet transfusion over 56 days before receiving AZA). Safety was assessed by frequency and severity of treatment-emergent adverse events (TEAEs) occurring between the first AZA dose and 28 days after last AZA dose (NCI-CTCAE v.4.0).
Results: In all, 44 pts had a median (range) age of 64 (36-90) years. Most were male (n=27, 61%). Forty-two pts were classified as having IPSS Int-2 (n=16, 36%) or High (n=26, 59%) risk MDS. Two pts (5%) had IPSS Int-1 risk MDS. Most pts had RAEB (n=32, 73%) or RAEB-T (n=9, 20.5%) disease, 2 had CMML (5%), and 1 had AML (2%). Median number of treatment cycles was 6 (range 1-6), with 68% (n=30) receiving ≥4 cycles. Eleven pts were not evaluable for CR or PR. Reasons for discontinuation were TEAEs (n=6, 14%); death (n=4, 9%); disease progression (n=3, 7%), withdrawal of consent (n=3, 7%), or other reasons (n=3, 7%). No evaluable pt had a CR or PR but 64% (n=28) of pts maintained stable disease. Additionally, 50% (n=22) of pts achieved an HI (HI-E n=14, HI-P n=14, HI-N n=2). Of BL TD pts, 38% (12/32) achieved RBC TI, and 39% (7/18) achieved platelet TI. The most common Grade 3/4 TEAEs were neutropenia (52%); leukopenia (39%); and anemia, febrile neutropenia, and thrombocytopenia (36% each). One or more serious TEAEs were reported by 14 pts, including febrile neutropenia (16%); neutropenia (7%); and pneumonia, pyrexia, and thrombocytopenia (5% each). Three TEAEs resulted in death (pneumonia n=2, hepatic/respiratory failure) that were suspected to be related to study drug.
Summary and Conclusions: These data confirm the efficacy and safety of SC AZA in Taiwanese pts with HR-MDS. AZA reduced transfusion burden in more than one-third of treated pts and 50% achieved HI. HI has been associated with improved OS in HR-MDS (Gore *et al*, 2013). Outcomes in Taiwanese pts were comparable to those reported in a primarily Caucasian population in the pivotal phase 3 AZA-001 study (Fenaux *et al*, 2009). The safety of AZA in Taiwanese pts was consistent with the known safety profile of AZA in Western pts.

PB1581

CLINICAL EVOLUTION OF PATIENTS WITH NEWLY DIAGNOSED CHRONIC MYELOMONOCYTIC LEUKEMIA DEPENDING ON INITIAL TREATMENT STRATEGY. A REPORT FROM ERASME STUDY

J Montoro[1,*] D Valcárcel[1], M Arnan[2], T Bernal[3], R Coll[4], M Calbacho[5], M Rafel[6], R García[7]

[1]Department of Hematology and Oncology, Hospital Vall d'Hebrón, [2]Department of Hematology, Hospital Duran y Reynals, Barcelona, [3]Department of Hematology, Hospital Universitario Central de Asturias, Oviedo, [4]Department of Hematology, Hospital Universitario Dr. Josep Trueta de Girona (ICO Girona), Girona, [5]Department of Hematology, Hospital Ramón y Cajal, [6]Medical Affairs Department, Celgene S.L., Madrid, [7]Department of hematology, Hospital Clínico Virgen de la Victoria, Málaga, Spain

Background: Chronic myelomonocytic leukemia (CMML) is a clonal hematopoietic stem cell disorder characterized by a heterogeneous clinical and morphological expression that shares features of both myelodysplastic syndromes (MDS) and chronic myeloproliferative disorders. In the last years some new treatments have been included in the clinical practice, but data from the general population on how these treatments are being used and their impact on the evolution remain scarce.
Aims: The aim of the study is to describe the "real world" management of CMML patients and to analyze the impact of the time to therapy initiation from diagnosis and the therapeutic strategy chosen on the clinical outcomes.
Methods: The ERASME (CEL-SMD-2012-01) study is an observational, post-authorization, prospective, multicentre study that will include a total of 600 newly diagnosed MDS and CMML patients and follow them during three years or until death. We present here the results of an intermediate analysis with data of the first 21 CMML patients enrolled into the ERASME study. The primary endpoint of this study is to describe the disease progression in routine clinical practice, analyzing the impact of time to therapy initiation from diagnosis and the initial therapeutic strategy chosen. The initial management of the patients is classified in three groups: Observation & support (SP) (including growth factors), active therapy (AT) (chemotherapy, azacitidine, etc) and allogenic hematopoietic cell transplant (HCT). In addition to disease-specific data, we will also collect data related to comorbidities, quality of life and healthcare resource utilization. Data from the pre-specified interim analysis are presented.
Results: A total of 21 CMML patients (38% women) with a median age of 75 years (range 51-91 years) have been recruited between January and October 2013. The median follow-up time was 3.8 months in CMML patients. Morphological subtypes according WHO classification were CMML-1 (blasts count <10%) in 15 patients (71%) and CMML-2 (blasts count 10% to 19%) in 5 (24%). According to FAB criteria, 17 patients (81%) had CMML-MD depending on absolute leukocyte count at diagnosis (WBC ≤13x109/L) and 4 (19%) had CMML-MP (WBC >13x10^9/L). Karyotype was normal in 15 patients (83%). Three patients displayed cytogenetic abnormalities, 2 patients with trisomy 8 (isolated or with one additional abnormality) and 1 patient with complex karyotype (a finding of ≥3 chromosome abnormalities) and thus the CMML-GESMD cytogenetic risk classification was low/intermediate/high risk in 62%/19%/10% of patients, respectively. The CPSS was low/int-1/int-2/high in 29%/33%/24%/5% of patients, respectively. Seven out of 21 patients were transfusion dependent at diagnosis. After diagnosis, 16, 4 and 1 of CMML patients were considered candidate to SP, AT and HCT strategy, respectively and median time to AT initiation from diagnosis was 7.1 weeks. The reasons for observation just after diagnosis (SP group; n=16) were the risk-disease, symptomatology of pathology, patient's age, and comorbidities. Of those patients considered candidate for AT (n=4), 3 received other low-dose chemotherapy and 1 other therapy (erythropoietin and azacitidine), respectively. Only one patient was considered candidate for HCT and received azacitidine prior the transplant. In the last follow-up, 3 patients have died (14%) after a median of 1.7 months and 1 patient developed AML after 2.9 months.
Summary and Conclusions: CMML patients were treated on an individualized therapy strategy after diagnostic evaluation and prognosis assessment. More data on disease progression in routine clinical practice may be useful in characterizing the newly diagnosed CMML patients.

PB1582

EXPERIENCES WITH 10-COLOR FLOW CYTOMETRY IN MDS DIAGNOSTICS

S Vormisto[1,*] F Ebeling[1], S Siitonen[2]

[1]Department of Hematology, [2]HUSLAB (Laboratory Services), Helsinki University Central Hospital, Helsinki, Finland

Background: Peripheral blood cytopenias of unknown etiology are a significant cause of referrals to hematology units. In some cases, where the diagnostic golden standard, cytomorphology (CM), reveals only minimal dysplasia not sufficient for a definitive diagnosis of MDS or no dysplasia at all, MDS can be verified by cytogenetics (CG) or by molecular abnormalities. In a significant proportion of cases, additional diagnostic approaches are needed to diagnose or rule out MDS. Multiparameter flow cytometry (MFC) has been shown to be able to increase the diagnostic yield, and its inclusion to the standard diagnostic work-up has been recommended.
Aims: A pilot study to explore the possibility of increasing MFC sensitivity with a wider array of colors to detect distinct aberrancies in antigen expression using simultaneously altogether 10 antibody conjugates.
Methods: 36 new patients with unclear cytopenia in one or more lineages (median age 69 yrs, range 32-87 yrs) were analyzed in parallel by CM and MFC. CG was performed in cases with clear clinical suspicion of hematologic malignancy. MFC was performed with 10-color flow in 4-5 tubes following ELN recommendations (Westers, Leukemia 2012;26:1730-) in myeloid progenitor cells (MPC), granulocytes, and monocytes. As a modification to the ELN protocol, the novel AML stem cell-associated antigen, C-Type Lectin Molecule-1 (CLL-1) together with CD38 was studied on MPCs. Our analysis also included the robust four parameter flow cytometric score (FCM score) originally reported by Della Porta and ELN (Haematologica 2012;97:1209-). In their study, a FCM score ≥2 was significantly associated with MDS. As MFC controls we had bone marrow samples from six healthy subjects.
Results: On the basis of CM and CG the patients were grouped to: 1) patients with confirmed MDS or CMML (12 pts, 33%), 2) patients with evidence of mild dysplasia not sufficient to diagnose MDS and with normal CG (6 pts, 17%), and 3) patients with no evidence of dysplasia in CM (18 pts, 50%).
MPCs defined as CD34+CD117+ cells or cells of monocytic lineage co-expressed lymphoid markers in 5/12 pts of group 1), in 3/6 pts of group 2), in 0/18 pts in group 3), and in none of the healthy controls. The most common aberrant lymphoid marker was the NK cell antigen CD56. In line with previously published results, the CLL-1 was expressed on 32-45% of CD38+ MPCs of the healthy controls. In one MDS case, it was not expressed at all and in another MDS case it was aberrantly expressed on 85% of CD38dim/neg MPCs.
The FCM score was ≥2 in 10/12 (83%) in group 1), 1/6 (17%) in group 2), 1/18 (6%) in group 3), and in none of the healthy controls.
Summary and Conclusions: We found 10-color flow cytometry feasible in MDS diagnostics. It allows better characterization of small blast populations and analysis of a wider selection of antigens in fewer tubes compared with conventional routine 4-5 color flow. As interesting findings in this pilot analysis still collecting new samples, we found CD56 as the most frequently aberrantly expressed lymphoid antigen, and the aberrant expression of CLL-1, previously described in AML, in two MDS patients.

PB1583

CLINICAL EVOLUTION OF PATIENTS WITH NEWLY DIAGNOSED MYELODYSPLASTIC SYNDROME DEPENDING ON INITIAL TREATMENT STRATEGY. A REPORT FROM ERASME STUDY

R García[1,*] J Montoro[2], B Moreno[3], E Barranco[4], F Ramos[5], M Arnan[6], M Calbacho[7], M Castellanos[8], R Coll[9], M Navarro[10], D Valcárcel[2]

[1]Department of Hematology, Hospital Clínico Virgen de la Victoria, Málaga, [2]Department of Hematology and Oncology, Hospital Vall d'Hebrón, Barcelona, [3]Department of Hematology, Hospital Txagurritxu, Álava, [4]Department of Hematology, Hospital de la Creu i Sant Pau, Barcelona, [5]Department of Hematology, Hospital Universitario de León, León, [6]Department of Hematology, Hospital Duran y Reynalds, Barcelona, [7]Department of Hematology, Hospital Ramón y Cajal, Madrid, [8]Department of Hematology, Hospital Clínico Universitario de Valladolid, Valladolid, [9]Department of Hematology, Hospital Universitario Dr. Josep Trueta de Girona (ICO Girona), Girona, [10]Medical Affairs Department, Celgene S.L., Madrid, Spain

Background: Myelodysplastic syndromes (MDS) are a group of stem cell neoplastic disorders characterized by a very heterogeneous prognosis. New treatments have been included, but data from the general population on how these treatments are being used and their impact on the evolution remain scarce.
Aims: To describe the "real world" management of MDS and Chronic Myelomonocytic Leukemia (CMML) patients and to analyze the impact of the time to therapy initiation from diagnosis and the therapeutic strategy chosen on the clinical outcomes. Here we present an intermediate analysis with the data of the group of MDS patients included in the ERASME study.
Methods: The ERASME (CEL-SMD-2012-01) study is an observational, post-authorization, prospective, multicentre study that will include a total of 600 patients with MDS and CMML and follow them during three years or until death. Primary endpoint is to describe the disease progression, based on the time to therapy initiation from diagnosis and the initial therapeutic strategy chosen. The patients are classified in 1) low/Int-1 IPSS, 2) int-2/high IPSS and 3) CMML. The initial management of the patients is classified in Observation & support (SP) (including growth factors), active therapy (AT) (chemotherapy, azacitidine, lenalidomide, etc) and allogenic hematopoietic cell transplant (HCT). In addition, we will also collect data related to comorbidities, quality of life and healthcare resource utilization. Data from the pre-specified interim analysis are presented.
Results: A total of 120 patients (48% women) with a median age of 76 years (range 37-88 years) have been recruited between January-October 2013. For

MDS patients the diagnosis were refractory cytopenia (RC) 6%, RC with ringed sideroblasts 6%, RC with multi-lineage dysplasia 39%, refractory anemia with excess of blast (RAEB-1) 15%, RAEB-2 27%, MDS with isolated del 5q 3% and unclassifiable MDS 4%. Group-1 included 68 patients (57%) and group-2 52 (43%). The median time to AT initiation from diagnosis was 24 and 11.6 weeks in group-1 (n=10) and group-2 (n=1), respectively. The IPSS-R was very low/low/intermediate/high/very high in 21/12/15/40/12% of MDS patients, respectively. The median follow-up time was 4 months. After diagnosis, 57/31/12% of patients were considered candidate to SP, AT and HCT strategy, respectively; the picture for group-1, group-2 was 87/9/4% and 17/60/23% for SP/AT/HCT strategies, respectively. The reasons for observation after diagnosis (SP; n=68) were the risk-disease in 90% of patients, symptomatology of pathology in 71%, patient's age in 57%, and comorbidities in 46%. Of those patients considered candidate for AT (n=37), 76% and 11% received azacitidine or AML-like chemotherapy/AZA, respectively. Fifteen out of 120 patients (13%) were considered candidate for HCT, moreover 1, 4, and 10 of these HCT patients were considered to receive transplant front line (without prior treatment), after AML-like chemotherapy or after azacitidine, respectively. Six of 15 HCT patients have already received transplant, 2 patients died before transplant and 7 are still waiting for the transplant. In the last follow-up, 19 patients have died (16%) after a median of 4.2 months and 6 patients developed AML after 4.2 months. For the MDS cohort, the leukemia free survival for the SP therapies was 9.03 months and the overall survival for AC/TPH therapies were 7.43/6.60 months, respectively.

Summary and Conclusions: MDS patients were treated on an individualized therapy strategy, risk-adapted basis after diagnostic evaluation and prognosis assessment. Most patients with higher risk MDS were considered candidate for AT while most patients in the lower risk group received supportive therapy.

ICE INDUCTION PLUS AZA MAINTENANCE AS A FIRST LINE THERAPY IN HIGH RISK MDS PATIENTS: CETLAM MDS-09 RESULTS.

J Bargay[1,*] B Xicoy[2], S Brunet[3], M Tormo[4], C Pedro[5], M Talarn[6], R Coll[7], M Nomdedeu[8], J Marti[9], J Borras[1], X Ortin[10], D Valcarcel[11], A Sampol[1,2], V Marco[1,3], E Ramila[1,4], J Sierra[3], J Ribera[2]

[1]Hematology, Hospital Son Llàtzer, Palma de Mallorca, [2]Hematology, Hospital Germans Trias i Pujol, Badalona, [3]Hematology, Hospital Santa Creu i Sant Pau, Barcelona, [4]Hematology, Hospital Clinico, Valencia, [5]Hematology, Hospital del Mar, Barcelona, [6]Hematology, Hospital Joan XIII, Tarragona, [7]Hematology, Hospital Josep Trueta, Girona, [8]Hematology, Hospital Clinico, Barcelona, [9]Hematology, Mutua de Terrasa, Terrasa, [10]Hematology, Hospital Verge de la Cinta, Tortosa, [11]Hematology, Hospital Vall d´Hebrón, Barcelona, [12]Hematology, Hospital Son Espases, Palma de Mallorca, [13]Hematology, Hospital Arnau de Vilanova, Lleida, [14]Hematology, Hospital Parc Taulí, Sabadell, Spain

Background: Myelodysplastyc syndrome is a group of clonal hematologic malignancies that evolves heterogeneously, being transformation to AML and comorbidities related to prolonged cytopeniathe most shocking features.Thus, high-risk MDS patients have an overall survival median of 12 months. What is more, the ALO-HSCT has become the only curative option. Under the CETLAM MDS-09 protocol, different strategies to improve high-risk MDS treatment and outcome were approached, considering the use of polychemotherapy followed by azacitidine for those patients without available donor or no HSCT candidates.

Aims: Assess treatment efficacy in terms of Overall Survival (OS) and Event Free Survival (EFS)in high-risk MDS patients.

Methods: Since May 2009 to date, patients diagnosed with MDS (accordingly to WHO classification, 2008) from 15 CETLAM hospitals have been studied: Patients without comorbidities, good performance status and no HSCT candidates have been stratified according to cytogenetics. Induction with ICE (Idarrubicin 10 mg/m^2 IV days 1, 3 and 5, Cytarabin 100mg/m^{2}IV days 1 to 7, Etoposide 100mg/m^2 IV days 1 to 3) followed by 5-AZA maintenance (5-AZA 75 mg/m^2 x 5 days every 28 days) were administered to those with good karyotype. Eastern Cooperative Oncology Group (ECOG) Performance Status and Hematopoietic Cell Transplant-Comorbidity Index (HCT-CI) were used to assess patient status and the International Prognosis System (IPSS) for MDS to calculate the risk. IBM SPSS© was used for descriptive analysis, performing survival analysis with Kaplan Meyer method.

Results: We have studied 28 patients, 23 men (82.1%) and 5 women (17.9%), with a median age of 66.7 years (40.6-75.9). According to WHO MDS classification, there were 3 RCDM (10.7%), 1 RCDM-RS (3.6%), 1 RAEB-I (3.6%), 10 RAEB-II (35.7%) and 3 MDS-U (3.6%). Also 10 secondary AML (35.7%) were studied (6 of them with a blast count >30%). Following the IPSS, we have 8 high-risk patients (28.6%), 10 intermediate-II (35.7%), 4 intermediate-I (14.3%) and 6 (21.4%) unclassifiable to have a blast count more than 30%. Regarding patient status, 27 (96.4%) had ECOG ≤2 and 23 (82.1%) an HCT-CI score ≤3. The overall survival (OS) median was 17.66 months (CI 95%:11.47-23.85) with a follow up median of 13.83 months (0.99-45.53). The event free survival (EFS) was 11.51 months (CI 95%:4.92-18.09). The median of AZA cycles was 4.5 (0-27). The Overall Response Rate (ORR) achieved after ICE induction was 71.4% and the ORR after 6 cycles of AZA maintenance was 55%. 5 patients (17.9%) had treatment failure after ICE and 2 (7.1%) died during ICE induction, both of them due to infectious events. One patient had Stable disease after ICE (3.6%).

Summary and Conclusions: Despite having a short follow up and a relatively small sample, it seems to be a benefit of receiving ICE induction in terms of prolonging OS in this set of patients.

PB1585

AZACITIDINE IMPROVES SURVIVAL IN PATIENTS WITH MYELODYSPLASTIC SYNDROMES AND ACUTE MYELOID LEUKEMIA WITH MYELODYSPLASIA-RELATED CHANGES WITH 20-30% BONE MARROW BLASTS AND POOR-RISK CYTOGENETIC CATEGOR

J F Falantes[1,*] C Calderón[1], F J Márquez-Malaver[1], E Carrillo[1], R Bernal[1], R Morales[1], R Parody[1], J González[1], I Montero[1], M L Martino[1], I Espigado[1], J A Pérez-Simón[1]

[1]Hematology, Hospital Virgen del Rocío/IBIS, Seville, Spain

Background: Karyotype is a key prognostic factor in MDS and AML. Azacitidine (AZA) has shown survival advantage in high-risk MDS and AML (20%>30% blasts) in a randomized phase III trial. However, data on outcome of MDS and AML (20-30% blasts) with adverse karyotype treated with AZA and compared with conventional regimens are scarce.

Aims: To evaluate the role of AZA in MDS and AML with myelodysplasia-related changes (20-30% blasts) with poor-risk cytogenetic categories in an unselect cohort of patients (pts) treated with AZA or conventional care regimens.

Methods: Forty pts were retrospectively analyzed (MDS, n=32. AML, n=8). Karyotype was reported according to ISCN. Analysis included pts diagnosed from 2000 to 2013 and those with cytogenetic categories of poor (IPSS) or poor/very poor (IPSS-R). Patients were divided into two groups: Those who received AZA (AZA group, from 2009 to present; n=23, including: RCMD=5, RAEB-2=13, AML=5) and those who did not (non-AZA group, ECOG≤2,prior to AZA approval, from 2000 to 2009; n=17. RCMD=6, RAEB-1=4, RAEB-2=4, CMML=2, AML=3).Non-AZA group included intensive chemotherapy and non-intensive approaches (low-dose ARA-C). Response to therapy was defined by IWG MDS 2006 criteria.

Results: There were no differences between both groups in terms of WHO subtype, age, bone marrow (BM) blast% and distribution of pts with chromosome 3 abnormality (abn) or having ≥3 chromosomal abn and pts with monosomal karyotype (MK) *versus* any other adverse category, although a trend to higher BM blast% and chromosome 3 abn/≥3 abn was noticed in the AZA group as compared to non-AZA cohort (14% *vs* 6% and 73% *vs* 53%, respectively). At last follow-up, 10/40 (25%) patients are alive. Median OS was 14 months for AZA pts *vs* 6 months for non-AZA (*P*=0.07). Median OS for responding patients to AZA was 20 months (12.9-27). Overall response rate (CR/marrow CR/PR) was 56% (CR=47%, mCR=8%) in the AZA group. Interestingly, 41% of pts with chromosome 3 abn/≥3 chromosomal abn and 45% of pts with MK achieved CR with AZA, with median OS for responders of 16 and 14 months in each category, respectively. Four pts from each cohort underwent SCT. In the multivariable Cox proportional hazard model including SCT as a time-dependent covariate (Table 1), only treatment with AZA significantly influenced on survival (HR 0.33, 95% CI 0.146-0.973;*P*=0.04). A trend towards a better outcome was also observed in patients treated with IC (P=0.08). Receiving SCT (time-dependent covariate) did not have impact on survival (*P*=0.15). Severe thrombocytopenia (<50x10e^9/L) was associated with a poor outcome (*P*=0.055; HR=0.860, 95% IC: 0.007-1.059).

Table 1.

Parameter	HR (95% CI)	P
SCT	1.08 (0.239-4.883)	0.9
AZA	0.33 (0.146-0.973)	0.04
IC	0.33 (0.96-1.177)	0.08
Abn3/>3 abn	1.06 (0.432-2.616)	0.8
Plat<50x10^9/L	0.33 (0.146-0.973)	0.05

Summary and Conclusions: These data suggests a potential benefit on overall survival for azacitidine in pts with MDS and AML with myelodysplasia-related changes and adverse karyotype. Severity of karyotypic abnormalities did not preclude the possibility of achieving response to AZA. Tolerability and no need for hospital admission may favor the clinical decision whether to offer this approach to pts aged >65 years with MDS or AML (20-30% blasts) with adverse cytogenetics.

PB1586

RISK FACTORS IN MYELODYSPLASTIC SYNDROMES

MR Villa[1,*] A Gagliardi[1], R Cuccurullo[1], S Improta[1], L Mastrullo[1]
[1]UOC Ematologia PO San Gennaro ASL Napoli1 Centro, Naples, Italy

Background: Myelodysplastic Syndromes (MDS) are clonal hematopoietic stem-cell disorders characterized by peripheral-blood cytopenias and risk of progression to acute myeloid leukemia. The clinical, morphological and prognostic heterogeneity is not sufficiently addressed even in current classification systems.
Aims: We investigated the role of WT1 gene expression and its association with the expression of the chemokine receptor CXCR4 on bone marrow CD34+ cells of MDS patients.
Methods: From January 2007 to January 2014 BM samples from 73 MDS patients (according to WHO classification: 22 RA, 12 RCMD, 10 RAEB I, 8 RAEB II, 9 RARS, 10 deletion of 5q, 2 MDS unclass) were tested for WT1 expression at diagnosis and every 6 months. WT1 gene expression was evaluated by methods of real-time quantitative PCR (RQ-PCR). Surface CXCR4 expression were measured flow cytometrically.
Results: At diagnosis, 29 BM samples (10 RA, 7 RCMD, 6 RAEB I, 4 RAEB II, 1 RARS, 1 MDS unclass) expressed WT1 transcript amounts greater than the ranges level. The degree of WT1 expression was highly correlated with the type of MDS, was much higher in RAEB I and II compared with RA, and other types, and increased during disease progression. A significant correlation was found between WT1 expression levels, blast cell percentage and CXCR4 over-expression on blast cells (as defined by CXCR4 mean fluorescence intensity ratio thresholds of more than 5). After 6 months, 9 patients (2 RA, 5 RAEB I, 2 RAEB II) converted to AML. All of these patients showed at diagnosis an high WT1 and CXCR4 expression and a further elevation of WT1 expression level after 6 months.
Summary and Conclusions: WT1 expression has been previously reported to be increased also in myelodysplastic syndromes. In this study, the data obtained show that in most MDS, including a large percentage of RA and almost the total number of RAEB I and II, WT1 is expressed above the range observed in normal controls in BM and that its expression is directly correlated with the type of MDS. A strong association is present between the level of WT1 expression and the blast percentage and the CXCR4 over-expression. The identification of a molecular marker so able to establish the tendency of MDS to progression can be of great help in decision making for MDS patients. Our results justify further investigation into the role of CXCR4 in MDS and suggest that WT1 and CXCR4 should be incorporated into the risk assessment of MDS patients.

Background: Little is known about the incidence and epidemiological patterns of Myelodysplastic Syndromes (MDS) in Latin American region. The requirement of high quality exchangeable data has become a priority all over the world.
Aims: To register MDS cases reported in our region, to review and analyze the data.
Methods: From January 2007 through February 2014, fourteen Argentine Hematology Centers reported 479 adult patients (pts). FAB and WHO classification were taken into account, as well as IPSS, WPSS, and IPSS-R. Informed Consent was required.
Results: Median age was 71 (range: 17-94), women 206 (43%), M/F ratio: 1.3, primary MDS (p-MDS) 425 (89%). FAB (422 evaluable pts), subtypes: RA 56%, RARS 7%, RAEB 17%, RAEB-T 6% and CMML 15% (Proliferative CMML 34%). WHO (355 pts): RCUD/RS 9%, 5q- 4%, RCMD 61%, RAEB-1 10%, and RAEB-2 16%. Median follow-up: 17 months, median OS: 43 months; deaths: 182 (40%), and Acute Myeloid Leukemia progression: 93 (19%).

Prognostic Scoring Systems	Results
IPSS (n=352)	L (43%), Int-1 (40%), Int-2 (12%), H (5%)
WPSS (n=308)	VL (29%), L (41%), I (22%), H + VH (8%)
IPSS-R (n=345)	VL (29%), L (40%), I (11%), H (11%), VH (8%)

Cytogenetic in p-MDS according to IPSS-R (377 pts) showed: VL 3%, L 76%, IM 13%, H 4% and VH 4%, and the percentage of altered cytogenetic studies in secondary MDS (s-MDS) was 46%. Myelofibrosis (MF) was evaluated in 374 pts: MF0+MF1 (88%) and MF2+MF3 (12%), with a median survival of 47 and 16 months, respectively (*p=0,004*). Treatment reported: EPO (43%), iron chelation (4%), hypometilanting agents (27%), and Bone Marrow Transplant (3%).
Summary and Conclusions: Although Argentine Registry is young with a relatively short follow-up, we were able to observe a high incidence of RA, CMML and a predominance of lower risk groups. There was a good correlation among different Scoring Systems, MDS subtypes and time to AML progression. In s-MDS, the number of altered cytogenetic studies was relatively low. The presence of Myelofibrosis was useful to predict survival. Erythropoietin and Hypomethylating agents were frequently used.

PB1588

COMPARATIVE ANALYSIS OF CLINICOPATHOLOGIC FEATURES IN HYPOPLASTIC MYELODYSPLASTIC SYNDROME AND APLASTIC ANEMIA: COULD THE TWO REPRESENT THE SAME DISEASE ENTITY?

E Wang[1,*] Y Shi[1], C Rehder[1]
[1]Pathology, Duke University Medical Center, Durham, United States

Background: Hypoplastic myelodysplastic syndrome (hMDS) has clinical and morphologic manifestations overlapped with those of aplastic anemia (AA). In the majority of cases, diagnostic distinction between hMDS and AA is difficult, and often impossible. Overt MDS or acute myeloid leukemia (AML) has been seen in patients treated for AA. The pathogenesis is currently unclear.
Aims: To investigate the clinicopathologic distinction between hMDS and AA.
Methods: Eighteen cases of hMDS and 9 cases of MDS/AML secondary to AA (sMDS/AML) were identified in our databases from 2002-2012, and were retrospectively analyzed for clinical presentations and pathologic features, in comparison with 59 cases of AA.

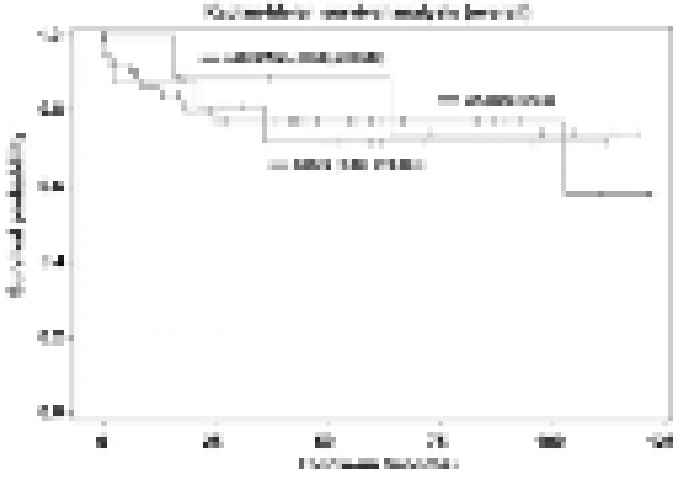

Figure 1.

Results: At diagnosis, the median age was 49.5 years (range, 5-87) for hMDS, 47 years (16-72) for sMDS/AML and 41 years (2-99) for AA. The male/female ratios were 1:1, 2:1 and 3:2, respectively, for the 3 groups. Among the 3 groups, the clinical presentations were similar with the majority manifesting anemia-related symptoms and laboratory evidence of moderate-severe pancytopenia. The morphologic features of initial marrow biopsies were indistinguishable among the three, all showing markedly decreased cellularity with hematopoietic hypoplasia. Cytogenetic study was performed in 17/18 hMDSs, 8/9 sMDS/AMLs and 48/59 AAs. Clonal cytogenetic abnormalities were detected in 16/17 (94.1%) hMDSs, while all cases of AA showed no abnormal changes. All the 8 cases of sMDS/AML demonstrated no cytogenetic abnormalities, and were initially diagnosed as AA. Due to similar clinical presentations, all the patients received conservative therapy at the beginning, primarily with immunosuppressive therapy (IST), until confirmed refractoriness and worsening

pancytopenia, when nonmyeloablative stem cell transplant (SCT) was considered. Eventually, SCT was given to 17/55 (30.9%) patients in AA, 7/18 (38.9%) in hMDS and 3/9 (33.3%) in sMDS/AML. For 9 patients who later developed sMDS/AML, the median interval between the diagnoses of AA and sMDS was 27.5 months (8-77), and the one between AA and sAML was 12 months (12-16). Interestingly, -7/-7q constituted 55.6% (5/9) of cytogenetic abnormalities in sMDS/AML, the proportion similar to that in hMDS (8/17 [47.1%]). After further treatment, 2/9 (22.2%) patients died in sMDS/AML group, with median follow-up of 37 months (6-86), compared to 4/14 (28.6%) in hMDS (median follow-up of 36 months [0.5-112]) and 12/55 (21.8%) of AA (median follow-up of 26 months [0.23-122]). Survival analysis demonstrated no significant difference between AA and hMDS as well as between hMDS and sMDS/AML (Figure 1).

Summary and Conclusions: Because of no distinguishable clinical and morphologic features between hMDS from AA, the diagnosis of hMDS is largely relied on cytogenetic analysis. About 50% of diagnostic hMDS harbor -7/-7q, the feature distinct from other de novo MDS. AA (13.4% in our series) may transform to overt MDS/AML 1-6 years after the diagnosis. While the role of treatment in the transformation is currently unclear, it may be a natural course of AA given a similar composition of cytogenetic abnormalities in sMDS/AML and hMDS. Due to the significantly overlapped pathologic features and similar clinical outcome, AA and hMDS may represent the same disease entity with the majority manifesting indolently with IST and a minority evolved to an aggressive course. While close monitoring of "AA" with cytogenetic study may be justifiable at this time, an early distinction between the two in many cases need identifying additional clonal markers because of the limitation of cytogenetic analysis, particularly in this disease group.

PB1589

BIOSIMILAR EPOETIN IN ELDERLY PATIENTS WITH LOW-RISK/INTERMEDIATE 1 MYELODYSPLASTIC SYNDROMES IMPROVES ANEMIA, QUALITY OF LIFE AND BRAIN FUNCTION

R Castelli[1,*] G Lambertenghi Deliliers[2], R Colombo[3], P Gallipoli[4], G Pantaleo[5]
[1]Department of Pathophysiology and Transplantation, Internal Medicine Section, University of Milan, and Department of Haematology IRCCS Ca' Granda Policlinico, Milan, Italy, Department of Pathophysiology and Transplantation, Internal Medicine Section, University of Milan, and Department of Haematology IRCCS Ca' Granda Policlinico, Milan, Italy, [2]Fondazione Mattarelli, [3]Fondazione Ospedale Maggiore Policlinico and University of Milan, Milan, Italy, [4]Hematology, Addenbrooke's Hospital, Cambridge University Hospitals NHS Trust, Cambridge, UK., Cambridge, United Kingdom, [5]Faculty of Psychology, Vita-Salute San Raffaele University of Milan, Italy, Faculty of Psychology, Vita-Salute San Raffaele University of Milan, Italy, Milan , Italy

Background: Myelodysplastic syndromes (MDS) are a group of clonal myeloid disorders characterized by ineffective hematopoiesis with progressive cytopenia and a variable risk of transformation to acute myeloid leukemia (AML). MDS primarily affects elderly patients and its annual incidence is 5 cases per 100,000. Cytopenia and its complications (fatigue, infections, bleeding), the risk of disease progression, and patients' age and co-morbidities can all affect patients' physical and psychological status. Quality of life in MDS is compromised by functional and disease-specific components and has been found to be associated with hemoglobin (Hb) levels and with transfusion dependency. Transfusion dependence is associated with reduced survival in patients with lower-risk MDS due to iron overload, cardiac failure, and progression to myeloid leukemia. Erythroid-stimulating agents (ESAs) have two potentially useful actions in the treatment of anaemia in the setting of MDS syndromes: correcting anaemia to improve QOL and avoiding/reducing the need for transfusions. However, some MDS patients are refractory to this treatment and little is known about the exact molecular mechanisms underlying the effect of ESAs in these subjects. A biosimilar epoetin α was approved by the European Medicines Agency (EMA) in 2007, and is marketed as Binocrit®. Binocrit was developed using Eprex/Erypo (the Janssen Cilag recombinant erythropoietin α authorized in the EU in 1994) as the reference product. Comparable efficacy was confirmed in treatment of anemia by administration of intravenous Binocrit in 478 chronic renal failure patients receiving hemodialysis . Emerging data suggest that Binocrit is effective and safe for the treatment of patients with cancer and chemotherapy-induced anaemia.

Aims: To evaluate the effectiveness of a biosimilar epoetin α (Binocrit) for the treatment of anemia in low/intermediate 1 risk MDS patients and to evaluate the impact of ESAs on QOL.

Methods: we studied a group of 24 consecutive MDS patients aged over 65 years and treated with Bio similar epoetin α (40,000 IU once a week). 14 patients were male and 10 patients were female. The average age was 72 years (range 65- 84 years). Criteria for eligibility consisted of adult age, newly diagnosed MDS, International Prognostic Scoring System (IPSS) score<2 and at least one cytopenia. 15 patients had refractory anemia (RA), 5 refractory cytopenia with multilineage dysplasia with or without ringed sideroblasts (RCMD±RS), 1 patient had refractory anemia with excess of blasts type I (RAEB I), and 3 patients had refractory anemia with ringed sideroblasts (RARS). All patients received biosimilar epoetin α at a fixed dose of 40,000 IU once a week subcutaneously for a minimum of 12 weeks. Responsive patients continued with 40,000 IU/week for further 12 weeks. Changes in QOL were assessed by the Functional Assessment of Cancer Therapy-Anemia (FACT-An). Cognitive function was assessed using a psychometric test, the mini-mental state examination (MMSE).

Results: All patients completed 12 weeks of therapy. Sixteen patients (66.67%) achieved an erythroid response (ER), 14 patients (58.33%) achieved a major response, while two patients had a minor response (8.33%). Briefly, in order to classify groups of patients according to international response criteria, patients'response was defined as "major" when Hb increased more than 2 g/dL for patients with pretreatment Hb values smaller than 11 g/dL or, in red blood transfusion-dependent patients, when they reached transfusion independence. By contrast, response was defined as "minor", when Hb increased 1 to 2 g/dL in patients with pretreatment Hb values smaller than 11 g/dL and, for red blood cell transfusion-dependent patients, when transfusion requirements decreased by a rate of 50% [21]. Non-responders were considered patients who achieved neither major or minor response Eight patients were non-responders (33%), of whom 5 patients were low risk and 3 intermediate I risk. Six responders were low risk, and 10 were intermediate-1 risk. Mean hemoglobin (Hb) values were significantly higher after treatment in both responders ($p<.001$) and non-responders ($p_s<.03$). ER was maintained after 24 weeks. Statistically significant positive correlations between improvement in Hb and variations in patients' mini-mental (Spearman's Rho = .54 $p<.01$) and FACT-An scores (Spearman's Rho = .59, $p<.003$) were demonstrated

Summary and Conclusions: our study gives preliminary encouraging data showing that Biosimilar epoetin α has comparable efficacy to that of other ESAs in the treatment of anaemia in MDS patients. These data should be confirmed with studies enrolling a larger number of patients, and with a direct comparison with originator ESA. Use of biosimilar ESAs can provide savings in hospital budgets, expand access to ESA treatment, and provide physicians with the latitude to treat anaemia earlier (in accordance with current labels and guidelines) Patient responding to Biosimilar epoetin α have similar clinic characteristics to MDS patients who respond to originator products, and similarly they could maintain sustained responses to treatment

ACUTE MYELOID LEUKEMIA PROGRESSION IN MYELODYSPLASTIC SYNDROMES, RESULTS FROM THE ARGENTINE REGISTRY

A Enrico[1,*] L Kornblihtt[2], J Milone[3], J Arbelbide[4], D Fantl[5], G Alfonso[6], M Iastrebner[7], M Flores[8], W Correa[3], P Negri Aranguren[9], L Celebrin[10], M Agra[10], N Watman[11], A Basquiera[12], Y Bestach[13], R Bengio[13], I Larripa[13], C Belli[13]
[1]Hematolology, Hospital Italiano de La Plata, La Plata, [2]Hematolology, Hospital de Clinicas Universidad de Buenos Aires, Ciudad de Buenos Aires, [3]Hematolology, Hospital Italiano La Plata, La Plata, [4]Hematolology, Hospita Italiano De Buenos Aires, [5]Hematolology, Hospital Italiano de Buenos Aires, [6]Hematolology, Hospital Posadas, [7]Hematolology, Centro Medico OSECAC, [8]Hematolology, Hospital Duran, Ciudad de Buenos Aires, [9]Hematolology, Hospital San Roque, Parana Entre Rios, [10]Hematolology, Hospital Tornu, [11]Hematolology, Hospital Ramos Mejia, Ciudad de Buenos Aires, [12]Hematolology, Hospital Privado Centro Medico de Cordoba, Cordoba, [13]Hematolology, Academia Nacional de Medicina, Ciudad de Buenos Aires, Argentina

Background: At least, one third of patients with Myelodysplastic Syndromes (MDS) develops Acute Myeloid Leukemia (AML) at any time of the follow-up. This subgroup of patients depict clinical and laboratory features, specific MDS subtype, and especially poor prognosis.

Aims: To describe and analyze clinical features of adult MDS patients that had progressed to AML

Methods: This is a multicenter retrospective study of 197 (23%) adult MDS patients that progressed to secondary AML (s-AML), from a database of 840 patients diagnosed from 1981 to 2013. Data belong to the MDS Registry sponsored by the Argentinean Society of Hematology and to a previous multicenter study. Informed Consent was required. Patients were classified following FAB and WHO criteria and 13 patients presented with secondary MDS. The median age was 64 (17-89) years with 74% above 60 years, a male/female (123/74) ratio of 1.7. During the follow-up, with a median overall survival of 14.3 months, 173 (88%) died. BM transplanted patients were censored till the moment of the procedure. Using a log-rank test and *Kaplan-Meier*, we performed a univariate analysis to examine the effects of age at MDS diagnosis (limit of 70 years), gender, haematological parameters and, IPSS, WPSS and IPSS-R scores on time to Leukemia transformation (TTL) and on the overall survival (OS).

Results: FAB classification was evaluable in 184 patients distributed into: RA 37 (20%), RARS 7 (4%), RAEB 71 (39%), RAEB-T 39 (21%), CMML 30 (16%).

WHO classification was evaluable in 134 patients: RCUD/5q- 10 (7%), RCMD 34 (25%), RAEB-1 33 (25%), and RAEB-2 57 (43%). Age (limit of 70 years), percentage of bone marrow blast (0-<5, 5-10, 11-20, >20), hemoglobin level (limit of 10 g/dL), platelets (limit of 100000 /µL) and neutrophil count (limit of 800 /µL), LDH level, cytogenetic group of risk (according to the IPSS-R), and red blood cell transfusion requirements were significant predictive variables for prognosis (Kaplan-Meier and Long-Rank test, p<0.05). According to our database, most patients received supportive care with vitaminotherapy; erytroid and neutrophil stimulating factors, and 158 required red blood cells transfusion support. Chemotherapy was administered once the leukemic phase of the disease was diagnosed (68 patients) or for stem cell transplant (14 patients), hypomethylating agents were administered in 66 patients, and 2 lenalidomide.
Summary and Conclusions: Our multicenter Argentinean cohort showed a rate of 23.4% of patients who progress to s-AML, similar to previous reports. Clinical parameters, age, classifications and the applied scoring systems were useful tools to evaluate prognosis in our series. As expected, we observed a higher gender ratio, a lower median age and an increased incidence of higher risk groups, but the shorter time to AML in lower risk group will be matter of future studies.

Table 1.

PB1591

EFFICACY OF PSYCHOLOGICAL NURSING ON MYELODYSPLASTIC SYNDROME

X Dahai[1], Z Nan[1], P Li[1], L Xiaoliang[1], W Yang[1], Z Xiuxian[1], C Hongli[1*]
[1]Emergency Department, First Hospital of Jilin University, Changchun, China

Background: Patients with myelodysplastic syndrome always have much anxiety.Anxiety can affect the therapeutic efficacy.Psychological nursing is needed on the baisis of traditional nursing.Psychological nursing supplies patients with psychological intervention to alleviate anxiety.Patients with less anxiety can have a good therapeutic alliance.
Aims: To analyze the efficacy of psychological nursing on myelodysplastic syndrome.
Methods: 192 myelodysplastic syndrome patients were divided randomly into 2 groups:psychological nursing group(A group) 85 cases and control group(B group) 97 cases.A group accepted routine nursing combinating with psychological nursing.B group accepted routine nursing. Analyze HAMA scores of each group respectively between prior treatment and aftrer 10 days of treatment and compare HAMS scores of two groups prior treatment and aftrer 10 days of treatment.
Results: Prior treatment,HAMA score of A group 19.37±6.73 points and HAMA score of B group 18.33±5.64 points,had no significant differences.After 10 days of treatment,HAMA score of A group 11.19±3.63 points and HAMA score of B group 14.52±4.10 points,had signicant differences.A group and B group both had significant differences between prior treatment and posttreatment.
Summary and Conclusions: Psychological nursing can ameliorate anxiety of myelodysplastic syndrome patients and should be advocated.

PB1592

HEAVY SMOKERS HAVE HIGHER FREQUENCY OF LEUKEMIC TRANSFORMATION THAN LIGHT SMOKERS IN PATIENTS DIAGNOSED WITH CHRONIC MYELOMONOCYTIC LEUKEMIA (CMML)

A Alsahlawi[1,*] M Litzow[1], M Patnaik[1], D Alfakara[1], K Begna[1], E Michelle[1], W Hogan[1], A Al-Kali[1]
[1]Hematology, Mayo Clinic, Rochester, United States

Background: Chronic myelomonocytic leukemia (CMML) is a clonal hematological disorder that is classified by the World Health Organization (WHO) as one of the myelodysplastic (MDS)/ myeloproliferative (MPN) overlap diseases. Smoking has been found to cause damage to somatic and germ cells, and in some studies smoking was defined as a risk factor to develop MDS. Even more recently, smoking appeared to have negative impact on overall survival (OS) in patients (pts) with low-risk MDS, but its impact in CMML is still unknown.
Aims: To study the effect of smoking on clinical outcome for patients diagnosed with CMML.
Methods: A single institution, retrospective study through chart review of all cases diagnosed with CMML at Mayo Clinic Rochester between 1994 to 2011 was performed. Smoking was classified into never/ ever smoker patients, all demographic information were obtained from the patients' medical records. Appropriate IRB approval was obtained in accordance with the Helsinki declaration. Comparison between groups' medians was done using Wilcoxon test, while survival estimates were calculated using Kaplan-Meier curves using JMP V9.
Results: Two-hundred and thirty five pts (out of 270) were found to be eligible, of which 53% (124 pts) were identified as ever-smoker (103 (44%) former smoker, 21(9%) current). Median age was 72 years, 68% of which were males. Median hemoglobin was 11 gm/dL, white blood cells (WBC) 12 x 10^9/L, platelets were 88 x 10^9/L, peripheral blood (PB) blasts 0, and bone marrow (BM) blasts 3%. Sixty five percent (148 patients) had diploid cytogenetics (CG). CMML2 was seen in 10% of group. Leukemic transformation (LT) to acute myeloid leukemia was documented in 32 pts (14%). Median OS was 534 days with a median follow-up was 311 days. No statistical difference was found upon comparison of never-smoker pts (group 1) to ever-smoker pts (group 2): Median age was 72 *vs* 71 years, hemoglobin 11 *vs* 10 gm/dL, WBC 12 x 10^9/L (both groups), platelets 95 *vs* 84 x10^9/L, PB blasts 0 (both groups), and BM blasts were 4% *vs* 3%, respectively. CG was diploid in 65% *vs* 35%, respectively. Males were more frequent in group 2 *vs* 1 (81% *vs* 53%, p <0.0001). Median overall survival (OS) was found to be similar in both groups (515 day *vs* 565 days, respectively (p=0.8)). There was no statistically significant difference for LT between group 1 *vs* 2 (16% *vs* 11%). On multivariate analysis, smoking (in addition to PB and BM blast) did not affect mOS, while (age, hemoglobin, and platelets) did impact mOS. Among the 124 ever-smoker pts, heavy smokers (HS) (≥ 1 pack/day) were found in 65% (33 pts), while light smokers (LS) (< 1 pack/day) were found in 35% (18 pts). LT was significantly higher in HS *vs* LS (21% *vs* 0, p=0.01), but mOS was not different (480 *vs* 534 days, p=0.8).
Summary and Conclusions: Smoking was found in about half pts diagnosed with CMML (53%), with more males being smokers than females. However, smoking did not affect pts characteristics and did not impact overall survival compared to never-smoker. Upon comparison with light smokers, heavy smokers had higher frequency of LT but did not affect mOS. More studies are needed to study effect of smoking on leukemic pts.

PB1593

PHARMACOKINETICS AND PRECLINICAL ACTIVITIES OF PRACINOSTAT AND ACTIVE METABOLITE SB991

W Levin[1,*] O Moreno[1]
[1]MEI Pharma, Inc., San Diego, United States

Background: Pracinostat (SB939) is an orally available histone deacetylase (HDAC) inhibitor being developed for hematologic malignancies including myelodysplatic syndrome (MDS) and acute myeloid leukemia (AML). SB991, an N-de-ethylation of Pracinostat, was shown to form as the primary metabolite following Pracinostat incubation with human, dog, rat and mouse microsomes.
Aims: To compare the exposure between Pracinostat and SB991 following oral Pracinostat administration in humans and dogs as well as the *in vitro* bioactivity of each compound.
Methods: Dogs received Pracinostat (10 mg/kg) via oral gavage, and PK samples were obtained 5 min, 15min, 30min, 1h, 2h, 4h, 6h, 8h, and 24h. Plasma was analyzed for Pracinostat and SB991 using an HPLC bioanalytical method. The HDAC inhibitory activities of Pracinostat and SB991 were measured *in vitro* using purified recombinant HDAC 1, 2, 3, 4, 5, 6, 7, 8, 9, 10 and 11 enzymes. Functional HDAC inhibition was assessed by measuring DNMT1 protein (a measure of HDAC1 activity) and acetylated alpha-tubulin (a measure of HDAC6 activity) in MDA-MB-231 (human breast adenocarcinoma) cells by western blot. Humans (healthy volunteers) received Pracinostat 60 mg orally following an overnight fast, and PK samples were collected pre-dose and at 0.25, 0.5, 1, 1.25, 1.5, 2, 2.5, 3, 4, 6, 8, 12, 16, 24, 36, and 48 hours postdose. Plasma samples were analyzed for Pracinostat and SB991 using a validated bioanalytical method.
Results: SB991 displayed greater inhibitory activity than Pracinostat against all HDACs tested (Table 1). In addition, SB991 displayed greater bioactivity in MDA-MB-231 cells than Pracinostat as measured by a decrease in DNMT1 protein levels and increase in acetylated alpha-tubulin by western blot. Analysis of dog plasma samples showed SB991 to be formed by metabolism of Pracinostat after oral administration (Figure1). Non-compartmental pharmacokinetic analyses indicated an $AUC_{0\text{-}inf}$ of 6,900 ng*h/ml for Pracinostat and 13,700 ng*h/ml for SB991. C_{max} was 2,200 ng/ml for Pracinostat and 3,000 ng/ml for SB991. The human healthy volunteer study is currently underway and results will be reported.

Table 1. IC50 of Pracinostat and SB991 against a panel of HDACs.

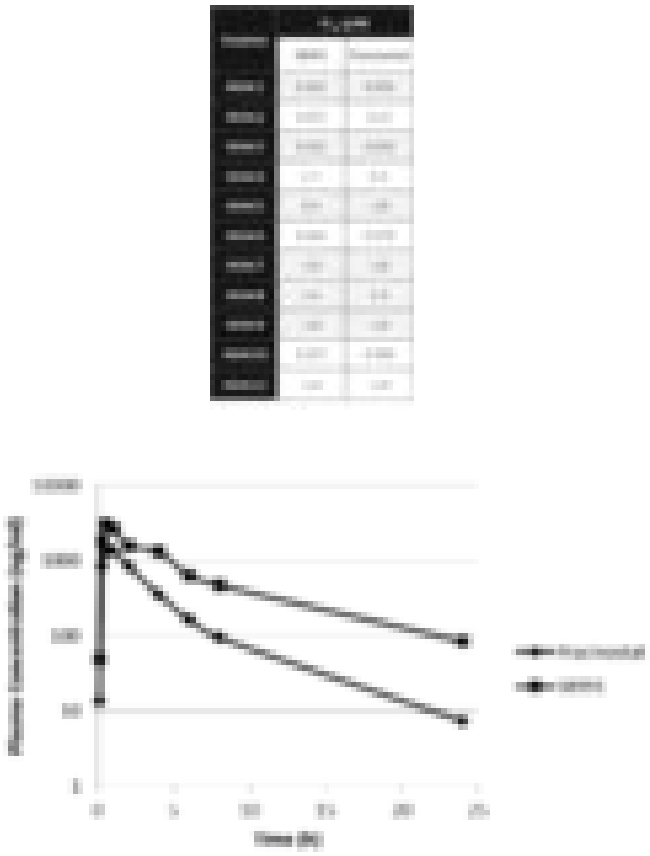

Figure 1. Plot of plasma concentration *vs* time for Pracinostat and SB991 after oral administration of 10 mg/kg Pracinostat to beagle dogs.

Summary and Conclusions: SB991 is a more potent HDACi than Pracinostat. In addition, the combined *in vivo* levels of Pracinostat and SB991 in dogs indicated a much greater exposure to HDACi than would be expected based on levels of Pracinostat alone. This increased exposure may distinguish Pracinostat from other HDACi under development. Thus, when considering the potential clinical efficacy of Pracinostat as a function of potency and exposure, it is valuable to consider the combined exposures to Pracinostat and SB991, rather than exposure to Pracinostat alone.

PB1594

DETECTION OF NUCLEOPHOSMIN 1 (NPM1) MUTATIONS IN MYELODYSPLASTIC SYNDROMES AND MYELODYSPLASTIC/MYELOPROLIFERATIVE NEOPLASMS: STILL A DIAGNOSTIC DILEMMA

F Forghieri[1,*] A Paolini[1], M Morselli[1], L Potenza[1], S Bigliardi[1], G Leonardi[1], V Coluccio[1], M Maccaferri[1], V Fantuzzi[1], L Faglioni[1], E Colaci[1], F Soci[1], V Nasillo[1], A Messerotti[1], G Bonacorsi[1], P Zaldini[1], P Zucchini[1], E Zanetti[1], C Quadrelli[1], G Corradini[1], F Giacobbi[1], D Vallerini[1], G Riva[1], P Barozzi[1], I Lagreca[1], R Marasca[1], F Narni[1], C Mecucci[2], B Falini[2], M Luppi[1]
[1]Medical and Surgical Sciences, University of Modena and Reggio Emilia, Policlinico di Modena, Modena, [2]Department of Clinical and Experimental Medicine, University of Perugia, Perugia, Italy

Background: De novo acute myeloid leukemia (AML) carrying mutations of the nucleophosmin 1 (NPM1) gene account for about 30% of all cases, 50-60% of AML cases with normal karyotype (NK), whereas NPM1 mutations are less frequently observed in secondary AML, arising from either myelodysplastic syndromes (MDS) or myelodysplastic/myeloproliferative neoplasms (MDS/MPN), ranging from 8% to 17% of the cases. Furthermore, NPM1 mutations are rarely found in patients diagnosed with either MDS or MDS/MPN (2%>4% of the cases), but scanty information is reported about immunohistochemical (IHC) examination for NPM1 in this clinico-pathologic setting.
Aims: We describe two cases observed at our Institution, with peripheral blood and bone marrow (BM) myeloid blast count <20%. Patient 1, a 57-year old woman, was initially diagnosed with atypical chronic myeloid leukemia, BCR-ABL negative, with NK. Patient 2, a 47-year old woman, was initially diagnosed with MDS/MPN-unclassifiable, with NK. Surprisingly, in both patients NPM1 mutation was documented by PCR analysis, in the absence of any other molecular abnormality. The IHC examination of BM trephine biopsy documented cytoplasmic NPM1 (NPMc+) staining in more than 20% of cells, so that, in both patients, AML with mutated NPM1 was finally diagnosed and treated with intensive chemotherapy, obtaining complete remission and subsequent favorable outcome. Based upon these observations, we have retrospectively analyzed 175 further adults with either MDS or MDS/MPN, consecutively observed over a period of 6 years (2008-2013). Overall, BM aspirate samples were available for molecular analysis to investigate the presence of NPM1 mutations in 135 cases (76.3%). For patients with NPM1 mutations, subcellular localization of NPM1 was investigated by IHC analysis, performed on BM trephine biopsy.
Results: A total of 177 patients, namely 140 MDS and 37 MDS/MPN (29 CMML) cases, 109 males and 68 females, of median age 77 years (range 47-93 years) were analyzed. BM aspirate and trephine biopsy morphologic examinations were available for 167 (94.4%) and 136 (76.8%) cases, respectively. Cytogenetic analyses were performed in 151 patients and showed NK in 79 cases (52.3%), while chromosomal abnormalities were documented in 71 cases (47.7%). Including patients 1 and 2, NPM1 mutations were observed in 4 out the 135 (3%) BM aspirates available for the molecular analysis. The IHC examinations, retrospectively performed on BM trephine biopsies from the two further elderly patients with RAEB-2 (patients 3 and 4, observed in 2010 and 2012, respectively), in whom NPM1 mutation was observed, documented NPMc+ staining in more than 20% of cells, suggesting AML with mutated NPM1. Of note, patient 3, a 79-year old man, developed AML after having received 6 cycle of 5-azacytidine, whereas patient 4, a 85-year old woman with pancytopenia, received best supportive care only.
Summary and Conclusions: According to Falini *et al.* (Blood 2007;109:874-85), caution is needed when defining a case as NPM1-mutated MDS, since NPMc+ AML frequently shows multilineage involvement and dysplastic features. Moreover, MDS and MDS/MPN cases with NPM1 mutation frequently progress to AML, within 0.5 to 14 months since diagnosis. The results of our study suggest that in the rare cases of either MDS or MDS/MPN with a blast count invariably <20%, but with NPM1 mutation on molecular analysis, AML may be under-diagnosed. IHC examination may be the method of choice to precisely evaluate the percentage of BM cells with NPMc+ staining, thus reaching a definite NPMc+ AML diagnosis.

PB1595

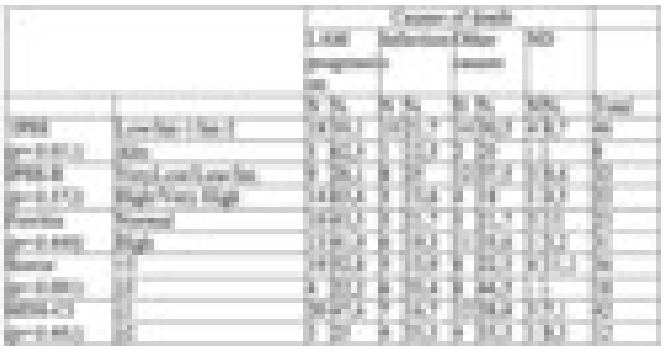
ASSESSMENT OF MORTALITY EVENTS IN MYELODYSPLASTIC SYNDROME (MDS): EXPERIENCE IN A SPANISH FACILITY.

P Romero[1,*] JB Borras[1], I Vazquez[1], M Mascaro[1], R Del Campo[1], A Cladera[1], JM Guerra[1], D Gomez[1], E Gonzalez[1], J Bargay[1]
[1]Hematology, Hospital Son Llàtzer, Palma de Mallorca, Spain

Background: MDS is a haematological malignant disorder characterized by a low life expectancy and high morbidity and mortality rates. Disease evolution and intensive chemotherapy strategies can lead to prolonged immunosuppression status that increase death related to infectious events. What is more, high-risk MDS patients have a high leukemia transformation rate.
Aims: Our goal is to assess different mortality events in MDS patients at our department.
Methods: From January 2002 to October 2013, data of all patients diagnosed with MDS in Son Llàtzer Hospital were collected. We used SPSS v.19 © statistics for descriptive statistical analysis (c^2 test to determine statistical relationships between main variables) and Kaplan -Meier for survival analysis. Different overall mortality causes were analysed according to prognostic groups IPSS and IPSS-R, comorbidity indexes (Sorror, MDS-CI) and ferritin levels.
Results: Of 112 patients, 96 were eligible for analysis: 57 men (59.4%) and 39 women (40.6%) with a median age of 77 years (33-94). Median follow-up was 28.3 months (1.3 to 120.9). The median overall survival was 41.8 months (95% CI: 34.39-49.22). The cumulative incidence of death at 3 years was 40% and 67% at 5 years. At the time of analysis 54 deaths (56.3%) were reported. The most common cause of death was LAM progression in 42.6% of cases (23 patients), with time to transformation median of 28.8 months. Secondly, infections in 20.4% (11 patients) followed by bleeding in 7.5% (3 patients had CNS haemorrhage and 1 patient had gastrointestinal bleeding secondary to angiodysplasia). The other causes were heart disease 9.3% (5 patients), other causes 9.3% (5 patients: 2 had liver disease with HCV positive serology, one had lower limb gangrene, 1 severe chronic obstructive pulmonary disease (COPD) and 1 bladder cancer) and toxicity procedure-related in 3.7% (2 patients who underwent allogeneic transplant). Regarding infectious events, 2 cases were bacterial sepsis (*Escherichia coli* and polymicrobial), one was fungal infection by *Aspergillus sp.* and no microbiologically documented infections in 8 patients. A statistically significant relationship between death causes in relation to prognosis IPSS groups (p=0.011) was observed and nearly significant regarding SORROR index (p=0.091). Moreover, no statistically

significant differences between the IPSS-R (p=0.372), MDS-CI (p=0.461) prognostic groups and ferritin levels (p=0.446) were observed (Table 1).

Table 1.



Summary and Conclusions: The most common death cause in our series was AML progression, followed by infections. Although the number of patients is small, it appears to be a tendency to die due AML transformation in adverse prognostic patients. In better prognosis subgroups it was observed an increased mortality related to infections, mainly secondary to immunosuppression or other comorbidities.

PB1596

SAFETY PROFILE OF AZACITIDINE IN THE TREATMENT OF THERAPY-RELATED MYELODYSPLASTIC SYNDROMES/ACUTE MYELOID LEUKAEMIA

C Minoia[1,*] N Sgherza[1], G Greco[2], C Buquicchio[3], G Loseto[1], V de Fazio[1], A Iacobazzi[1], A Rana[1], F Merchionne[1], G Tarantini[3], V Pavone[2], A Guarini[1]
[1]Haematology Unit, National Cancer Research Centre "Giovanni Paolo II" , Bari, [2]Haematology Unit, Ospedale G. Panico, Tricase (Lecce), [3]Haematology Unit, Ospedale "Dimiccoli", Barletta (BAT), Italy

Background: The improvement of chemotherapeutic treatments for solid and haematological malignancies is leading to the observation of an ever-increasing number of therapy-related Myelodysplastic syndromes/Acute myeloid leukaemia (t-MDS/AML). A few recent studies have documented the efficacy of 5-azacytidine (AZA) in patients with t-MDS/AML. A comparable overall response rate has been reported between t-MDS/AML and *de novo* MDS/AML, but the former leads to inferior overall survival.
Aims: The aim of the present study was to supply data on the safety profile of AZA in t-MDS/AML.
Methods: We retrospectively collected clinical data from consecutive patients (aged ≥ 18 years old) with t-MDS/AML treated with AZA at 3 Hematology Centers. Patients received at least 2 cycles of AZA.
Results: Seventeen patients with t-MDS (n.13)/AML (n.4) (median age 68, range 44-79, M/F 7/10) were retrospectively selected from August 2006. Previous diagnosis was of solid malignancy for 10 patients, hematologic malignancy for 6 (non-Hodgkin lymphoma n.5, Chronic myelomonocytic leukaemia n.1) and amyloidosis for 1 patient. The median number of chemotherapy courses was 1 (range 1-5); four patients received high dose chemotherapy and autologous stem cell transplant; five patients also received radiotherapy. Underlying malignancy was still active in 5 patients when AZA was started. Eight patients (47%) were transfusion-dependent. The cytogenetic risk, known for 14 patients, was: good for 6 (42.8%), intermediate for 1 (7.1%), poor for 7 (50%). AZA was administered subcutaneously at the dosing of 75 mg/m^2/day for 7 days (schedule 5-2-2) every 28 days. The median number of administered cycles was 5 (range 2-22). None of the patients underwent allogeneic stem cell transplant. AZA was discontinued due to progression of the solid tumor (n.2, 11.7%), treatment failure (n.3, 17.6%), AE (infection) (n.5, 29.4%), death due to ischemic events (n.2, 11.7%) or respiratory failure (n.1, 5.8%). AZA is ongoing in 4 patients (23.5%). Hemoglobin reduction ≥ 1g/dL from baseline and not imputable to disease activity was reported in 58.8% of patients and was observed mainly in the first cycles (1-4). ANC reduction was present in 70.5% (G4 41.1%). 5/17 patients (29.4%) experienced a severe infection, which for 4/5 was fatal: 3/5 presented progressive MDS (1 also with active CLL); 1 with refractory amyloidosis previously treated with autologous SCT; 2/5 died in complete remission, 1 of them had received high dose chemotherapy and autologous SCT. Platelet reduction was observed in 52.9%. A grade 2 bleeding occurred in 2 patients (11.7%). Gastrointestinal toxicity (nausea, constipation, diarrhea) grade 1-2 occurred in 4 patients (23.5%). At the intermediate evaluation (4-6 months), response assessment was possible in 13 patients (76.4%) and we observed: 2 CR (15.3%), 3 PR (23%), 3 SD (23%), and 5 failure (38.4%). The median overall survival was 6 months (range 3-24).
Summary and Conclusions: Hematological and extra-hematological toxicity was comparable to that described in phase III studies for *de novo* MDS. The life-threatening infections mostly occurred in patients who failed to respond to AZA or were heavily pre-treated for a primary malignancy. Our OS resulted inferior in comparison to other reports, possibly due to the inclusion of patients with active primary malignancy. AZA could be a reasonable choice for the treatment of these patients, but larger studies are desirable.

PB1597

REAL LIFE EXPERIENCE OF AZACITIDINE USE FOR A VARIOUS MYELODYSPLASTIC SYNDROMES AND ACUTE MYELOID LEUKEMIA IN A COMMUNITY HOSPITAL. A UK SINGLE CENTRE RETROSPECTIVE STUDY

V Shah[1,*] D S Gillett[2], R F Gale[3], R T Dowse[3], S MB Rassam[4], E M Dimitriadou[1]
[1]Department of Haematology, Maidstone and Tunbridge Wells Hospital Trust, Maidstone, [2]Department of Haematology, Maidstone and Tunbridge Wells Hospital Trust, Tunbridge Wells, [3]Department of Haematology , Maidstone and Tunbridge Wells NHS Trust, [4]Department of Haematology, Maidstone and Tunbridge Wells Hospital, Maidstone, United Kingdom

Background: The real life practicality of using Azacitidine has been poorly reported.
Aims: The aim of this study was to analyse efficacy and practicality of Azacitadine in 41 patients with MDS Intermediate 1 and 2 /high risk, AML with 20-30% blasts, AML in complete remission post intensive chemotherapy (n=2), myeloid sarcoma (n=2), MDS/MPD (n=3) and CMML 2 (n=3).
Methods: Patient's baseline characteristics and outcomes were retrospectively analysed.
Results: Of the 41 patients, 26 were male and 15 were female; median age was 74.69 (range 36-89). Median performance status was 1. 13 patients had poor risk cytogenetics and 20 had >15% blasts. A median of 6 cycles of Azacitidine was administered (range 1-20). Patients were supported throughout their treatment with GCSF, antifungal and antiviral prophylaxis. Treatment continued until progression, transplant or death. Overall 25 patients had a haematological response, and 13 achieved complete remission (CR). Median overall survival was 399 days. There was a significant survival difference between patients with poor risk cytogenetics and those with normal or intermediate genetic abnormalities (median survival 267 *vs* 628 days, p=0.02). There was no significant difference in survival between late *vs* early responders although it should be noted that most responders (21/25) showed signs of haematological recovery within 1 cycle. In terms of toxicity 14 patients required hospitalisation at least once due to infections but mostly at the start of treatment. Three patients had mild self limiting GI toxicity. No patients refused treatment due to toxicity or quality of life issues. 36 patients received Azacitidine with a schedule of 5 + 2 + 2. Two patients received the 5-day regime as maintenance treatment post intensive chemotherapy. One of them received it for 7 cycles but failed to achieve haematological response, remained transfusion dependent and relapsed 2 years later. The other patient underwent allogeneic transplantation and died due to post transplant lymphoproliferative disorder with no evidence of relapsed AML. One patient was changed from the 5+2+2 schedule to a 6 weekly regimen due to prolonged cytopenias and is still in CR. In another patient with AML and 30% blasts who developed cytopenias during treatment with azacytidine, treatment cycle was reduced to 5 days. The patient is still in CR with regards to the bone marrow blast count. One patient went into complete remission from CMML 2 without any other prior therapy and was transplanted. He remains in CR. One patient had a remarkable complete response to Azacitidine from myeloid sarcoma of the bowel on histology.
Summary and Conclusions: Due to the above toxicities and cytopenias experienced by a significant number of patients, the cycle length of Azacitidine can be altered from the 5+2+2. Although Azacitidine treatment is regarded as well tolerated and "non-intensive" it is intensive in terms of timing, cycle length and supportive care especially within the first cycles. Our data suggest that Azacytidine is a safe option in elderly patients with co-morbidities but supportive care is of paramount importance for safe clinical practice maximizing the chance of the best possible response. Not recovering counts does not always signify lack of response as patients might have variable disease kinetics. More data is needed to support and justify altering the administration accordance to response.

PB1598

POLISH EXPERIENCE OF LENALIDOMIDE IN THE TREATMENT OF LOWER RISK MYELODYSPLASTIC SYNDROME WITH ISOLATED DEL(5Q) - A RETROSPECTIVE ANALYSIS

[1]Dept. of Hematology, Blood Neoplasms and Bone Marrow Transplantation, Wroclaw Medical University, Wroclaw, [2]Institute of Hematology and Transfusion Medicine, Warsaw, [3]Carpathian Oncology Centre, Brzozow, [4]Medical University of Gdansk, Gdansk, [5]Warsaw Medical University, Warsaw, [6]Silesian Medical University, Katowice, [7]Provincial Specialist Hospital, Olsztyn, [8]University Hospital, Bydgoszcz, Bydgoszcz, [9]Regional Hospital in Rzeszow, Rzeszow, [10]Regional Hospital, Suwalki, [11]Military Institiute of Medicine, Warsaw, [12]Provincial Hospital, , Zielona Gora, [13]The Nicolas Copernicus State Hospital, Koszalin, [14]Wroclaw Medical University, Wroclaw, Poland

Background: Lenalidomide has been approved for the treatment of lower-risk myelodysplastic syndrome (MDS) with 5q deletion (del(5q)). We present retrospective analysis of low-risk MDS with isolated del5q treated with lenalidomide, outside the clinical trials.
Aims: To analyse efficacy and toxicity of lenalidomide treatment in transfusion-dependent low-risk myelodysplastic syndrome with isolated del(5q) patients.
Methods: 36 red blood cell (RBC) transfusion-dependent patients have been included into the study. Patients received lenalidomide 10 mg/day on days 1-21 of 28-day cycles.
Results: 91.7% of patients responded to lenalidomide treatment: 72.2% has achieved erythroid response, 19.4% achieved minor erythroid response, 8.4% of patients did not respond to treatment. Response depended on number of previous treatment lines (p=0.0101), International Prognostic System Score (IPSS; p=0.0067) and RBC transfusion frequency (p=0.0139). Median duration of response was 16 months (range 6-60 months). Treatment was well tolerated. We observed hematological toxicity (grade 3 and 4): neutropenia - in 16 (44.4%) patients, and thrombocytopenia in 9 (25%) patients. Two patients (5.5%) progressed to high-risk MDS, and two subsequent progressed to acute myeloid leukemia. The overall survival of patients (60 months) in the study group was 79.0±8.8% (Figure 1).

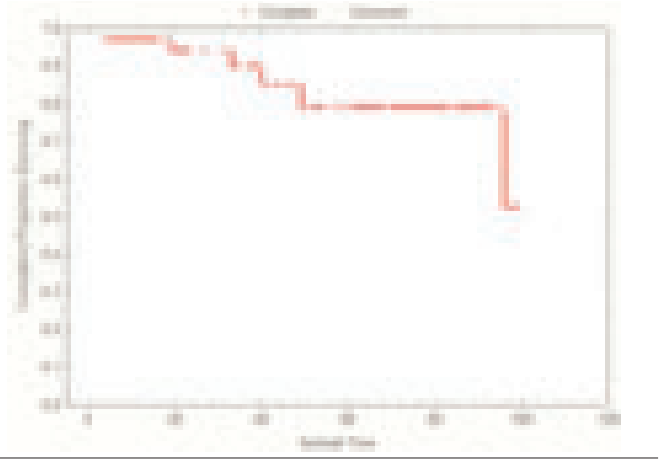

Figure 1.

Summary and Conclusions: Lenalidomide in this group of patients was beneficial for the treatment of RBC transfusion-dependency with well known safety profile.

PB1599

ADHERENCE TO GUIDELINES IN PRESCRIBING IRON CHELATION THERAPY IN MDS PATIENTS

E Ravano[1,*], M Riva[1], A Molteni[1], M Della Porta[2], AM Pelizzari[3], L Borin[4], A Freyrie[5], M Bernardi[6], G Quaresmini[7], M Jacopo[8], F Gigli[9], C Landoni[10], E Morra[1]
[1]Hematology, Niguarda Ca' Granda, Milan, [2]Hematology, Policlinico S. Matteo, Pavia, [3]Hematology, Spedali Civili, Brescia, [4]Hematology, AO San Gerardo, Monza, [5]Hematology, Ospedale Maggiore Policlinico, Mangiagalli e Regina Elena , [6]Hematology, Ospedale San Raffaele, Milan, [7]Hematology, Ospedali Riuniti, Bergamo, [8]Transfusion Medicine, AO Caravaggio, Treviglio, [9]Hematology, Istituto Europeo Oncologia, Milan, [10]Oncology, Ospedale Circolo , Busto Arsizio, Italy

Background: Iron chelation therapy, according to the current guidelines, should be applied to all cases of transfusion dependent patients (pts) with a long life expectancy, after exposure to more than 20 RBC units or with ferritin levels above 1000 ng/dL.
Aims: To verify the appropriateness of iron chelation prescription in Myelodisplastic Syndomes (MDS) patients in Lombardia region.
Methods: The REL ("Rete Ematologica Lombarda") MDS Disease Registry was consulted after 2 years of activity (1 July 2011 - 30 June 2013) and the recorded data were analyzed.
Results: The Registry, at time of extraction, contained data of 218 pts from 10 centers in Lombardia region: 165 primary MDS, 29 t-related MDS and 24 MDS/MPN cases. Concerning primary MDS pts, IPSS was distributed as follow: low in 41 cases, int-1 in 75, int-2 in 27, high in 5, not valuable in 17. At the time of diagnosis the average hemoglobin level was 10.2 g/dl. In 20 patients it was below 8 g/dL. The average value of serum ferritin was 290 ng/mL. In 14 pts it was over 1000 ng/mL. Fourty-one pts were transfusion-dependent. In 45 patients was found an heart disease, with arrhythmia in 6 of them. During the follow-up 73 pts developed anemia with hemoglobin degree under 10 g/dL; of them 39 under 9 g/dL and 25 under 8 g/dL. Transfusional support was started in 63 cases. In 18 cases ferritin levels arise over 1000 ng/dL: of them, it raised over 2000 in 2 cases and over 3000 in one case. Heart disease was developed in one patient more. Iron chelation was started in 12 cases, and in 8 of them was on going at the end of the observation period. In the 4 cases in which the therapy was withdrawn, median time of treatment was of 228 days.
Summary and Conclusions: About half of pts was transfusion dependent after the period of observation. Ferritin levels above 1000 ng/mL were found in about 15% of pts. Assuming that one third of them had an int-2 or high IPSS risk (*i.e.* a bad life-expectancy), we can deduce that about the 10% of this of this population would had benefit by iron chelation. Actually, in only 6% of pts iron chelation therapy was started. We may conclude that in Lombardia region iron chelation therapy is under-prescribed respect to the indication of current guidelines.

PB1600

VERY POOR OUTCOME OF ACUTE MYELOID LEUKEMIA SECONDARY TO MYELODYSPLASTIC SYNDROME AFTER AZACITIDINE FAILURE IN A DAILY-LIFE SETTING

P Niscola[1,*], A Tendas[1], L Cupelli[1], B Neri[1], D Piccioni[1], L Morino[1], L Scaramucci[1], M Giovannini[1], T Dentamaro[1], A Perrotti[1], G Del Poeta[1], P de Fabritiis[1]
[1]Hematology, Sant'Eugenio Hospital, Rome, Italy

Background: In the last decade, azacitidine has represented a major breakthrough in the setting of myelodysplastic syndromes (MDS), allowing to favorably alter the course of disease and to achieve survival benefits and improvement of quality of life. However, no curative effect is provided and acute myeloid leukemia (AML) transformation remains the most probable trend in this setting. Several studies have reported a poor outcome of AML arising from MDS after azacitidine failure, since no suitable therapeutic option is available. Moreover, the clinical presentation of AML in this setting may be rapidly aggressive and particularly devastating, reflecting a probable selection of a more aggressive malignant clone, despite the clinical responses previously achieved by azacitidine.
Aims: From our MDS database, we retrieved 26 patients (7 female) with a median age of 72 (32 – 82) years. At the primary diagnosis, 19 (73%) patients had refractory anemia with excess blasts, 6 (23%) myelodysplastic type-2 chronic myelomonocytic leukemia (CMML-2) and 1 (4%) refractory cytopenia with multilineage dysplasia. The IPSS at the primary MDS diagnosis was low, Int-1, Int-2 and high in 3 (12%), 8 (30%), 14 (54%) and 1(4%) patients, respectively. According to the approved indications in Europe, low and Int-1 patients were treated only after progression, at a median of 2.5 (0.5- 94.2) months from the primary MDS diagnosis; so that, at the start of azacitidine, IPSS was Int-2 and high in 22 (85%) and 4 (15%) patients respectively. Among them, 7 (27%) patients presented an abnormal karyotype. In 5 (19%), 5 (19%) and 4 (16%) of the 26 patients treated with azacitidine, partial response, complete response (CR) and hematological improvement (HI) were achieved (overall response: 54%).
Results: AML transformation occurred 9 (2-40) cycles and 12 (2-49) months after the starting of azacitidine; at the AML onset, a WBC count higher than 50.000/uL was observed in 50% of patients; moreover, 4 (15%) cases progressed to an oligoblastic (20 to 30% bone marrow blasts) AML. One patient presented a myelomonoblastic sarcoma of the anterior chest wall at the time of AML transformation. Cytogenetic analysis was available for 22 (84%) patients; 9 (41%) presented an abnormal karyotype. Given the advanced age, the poor performance status and the particularly devastating disease onset of AML in most patients, only 8 (31%) were suitable for high-dose cytarabine (HDAC)-based regimen and 2 (8%) underwent allogeneic hematopoietic stem cell transplantation (allo-SCT). No patients treated with HDAC-based regimen achieved a CR; moreover, among the two allo-SCT patients, one died because of early AML relapse and the other of transplant-related complications. Of the four patients who progressed to oligoblastic AML and continued to receive azacitidine, all achieved HI. With a median follow-up of 2 months (0-32) from transformation to AML, 6 (23%) patients are still alive, all of them with active disease. The median overall survival was 2 months (56 days) and the 6-months survival was 23% (Figure 1).

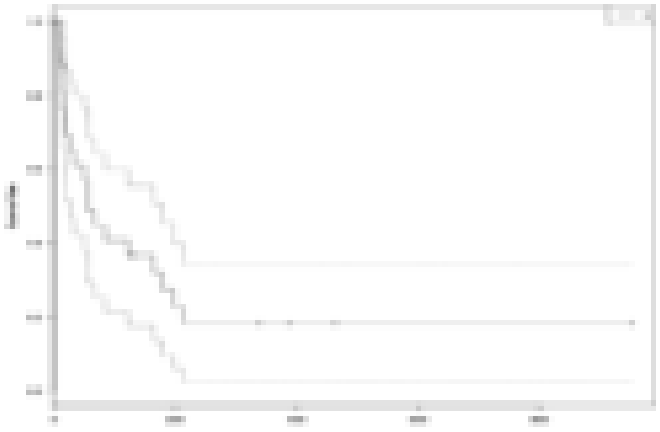

Figure 1. Overall survival: Kaplan-Meier survival curve with 95% confidence limits from AML progression for the 26 patients (time in days).

Summary and Conclusions: Our findings confirm the very poor outcome of these high risk leukemic patients with the current standard of care, including HDAC-based regimens and allo-SCT. Efforts aimed at the development of novel agents and effective AML treatments, including the association of azacidine with innovative agents, are urgently needed.

PB1601

MDS CLEAR PATH: A WEB-BASED EDUCATIONAL ALGORITHM FOR THE DIAGNOSIS AND MANAGEMENT OF PATIENTS WITH MYELODYSPLASTIC SYNDROMES

H A Leitch[1,*] H J Olney[2], A Shamy[3], R A Wells[4]
[1]Hematology, St. Paul's Hospital, University of British Columbia, Vancouver, [2]Hematology, Centre Hospitalier de l'Universite de Montreal, [3]Hematology, Sir Mortimer B. Davis Jewish General Hospital, McGill University, Montreal, [4]Hematology, Sunnybrook Health Sciences Centre, Odette Cancer Centre, University of Toronto, Toronto, Canada

Background: MDS has significant implications for patients, including transfusion dependence, an increased risk of acute myeloid leukemia (AML) transformation and decreased survival. Therapeutic options are available that may reduce transfusion dependence, delay AML transformation, improve survival and improve quality of life. In 2011 the Canadian Consortium on MDS set out to develop Canadian recommendations for the management of MDS, termed MDS Clear Path.
Aims: Objectives were to develop a comprehensive tool for the management of MDS. Key decision points are identified, evidence provided and areas where data are lacking are identified.
Methods: A draft algorithm was developed by the steering committee and presented to a group of hematologists from across Canada in October 2011. Input was obtained from over 60 hematologists through nine regional meetings held between November 2011 and May 2012. Feedback was incorporated at a review in March 2013. The final steering committee review was completed in September 2013.
Results: The algorithm provides a step by step opportunity to diagnose, manage and treat MDS patients from any risk group and at any point in their course. It details investigations required, prognostic scores and management recommendations and features a prognostic calculator for all scoring systems. Information on therapeutic options (erythropoiesis stimulating agents, lenalidomide, azacytidine, immunosuppressive therapy, supportive care, iron chelation therapy, investigational agents and clinical trials with links to trial websites) is provided, including expected response, side effects and their management, and provincial reimbursement. Many points incorporated into the algorithm were by consensus built via input from the regional meetings. Where data from the literature are lacking but practical advice needed, the steering committee incorporated recommendations into the algorithm. The algorithm treatment wizard mode guides the user through a series of questions resulting in a treatment recommendation while the self-directed mode presents the therapeutic algorithm. All reference and supportive data are contained within the algorithm with information panels provided as appropriate. There is an option to search by words of interest. The algorithm is available in English or French at www.MDSClearPath.org and as an app that can be downloaded onto an ipad from the website or the Apple store.
Summary and Conclusions: Through a collaborative effort of Canadian hematologists, an internet/app based algorithm is currently available to support qualified health care providers in the diagnosis and management of MDS patients. Recommendations from the algorithm should assist in standardization of MDS care across the country. The algorithm includes indications and regimens which are not currently approved in Canada; product monographs contain complete indication and safety information. Content will be regularly updated to reflect advances made in the care of MDS patients. Ipads will be available during the poster session to enable conference participants to navigate the MDS Clear Path algorithm. This program was supported by an unrestricted educational grant from Celgene Inc.

AZACYTIDINE THERAPY FOR MDS PATIENTS: RETROSPECTIVE MULTICENTRE REGIONAL EXPERIENCE IN PATIENTS REPORTED IN THE LIGURIAN MDS REGISTRY

P Minetto[1,*] L Mitscheunig[1], M Clavio[1], F Guolo[1], E De Astis[1], D Avenoso[1], M Bergamaschi[1], L Giannoni[1], L Del Corso[2], E Balleari[2], E Arboscello[2], G Pastori[1], T Calzamiglia[3], M Cavaliere[4], C Marani[1], R Goretti[5], O Racchi[6], F Cruciani[1], D Lovera[1], G Beltrami[7], F Ballerini[1], M Miglino[1], R M Lemoli[1], R Ghio[8], M Gobbi[1]
[1]Clinical Hematology, [2]Clinical Internal Medicine, IRCCS AOU San Martino Hospital-IST, Genova, [3]Internal Medicine , Sanremo Hospital , Sanremo, [4]Internal Medicine , San Paolo Hospital, Savona, [5]Internal Medicine , Santa Corona Hospital, Pietra Ligure, [6]Oncology and Hematology, Villa Scassi Hospital, [7]Hematology 1, [8]Internal Medicine , IRCCS AOU San Martino Hospital-IST, Genova, Italy

Background: In high-risk patients with myelodysplastic syndromes (MDS), the DNA methyltransferase inhibitors produce responses in up to 40% patients. Moreover Azacytidine (AZA) has shown a survival advantage when compared with conventional therapies. In clinical trials AZA is also used in low-risk patients failing to respond to recombinant human erythropoietin.
Aims: We retrospectively reviewed the clinical outcome of MDS patients treated with AZA according to common clinical practice in an Italian region (Liguria). MDS patients are registered in the Ligurian MDS registry which is affiliated to the FISM (Italian Foundation for Myelodysplastic Syndromes).
Methods: Herein we report the results of 56 patients treated with AZA in the last five years of whom complete haematological, cytogenetic and clinical informations are available. Median age was 71 years (range 41-85); male/female ratio was 30/26. MDS patients had RA or RARS (n.7, 12%), AREB-1 (n. 18, 32%), AREB 2 (n. 21, 37%), other subtypes (n. 10, 17%). Karyotype was normal in 37 patients (65%), complex in 7 (13%); 2 patients had trisomy 8 (4%) and 10 other alterations (18%). IPSS was intermediate-1 in 28 patients (50%), intermediate-2 in 23 (41%) and high in 5 (9%). The median follow up was 36 months. Forty-six patients had a transfusion-dependent anaemia. All low and int-1 risk MDS patients had a transfusion-dependent anaemia that was unresponsive to r-EPO.
Results: AZA was given at 75 mg/sqm with the "5+2" schedule every 28 days. Patients were delivered a median of 8 courses of treatment (range 3-44). Thirty-nine patients (69%) received concomitant recombinant alpha erythropoietin therapy (40 000 U once weekly). Major infections during therapy were recorded in 13 patients (23%), with no infection-related deaths. Forty-two patients (75%) achieved a hematological response, that was complete in 12 patients (21%) and partial in 25 (44%). Five patients had a hematologic improvement and 14 patients (25%) did not respond. A statistically significant reduction of transfusional support was observed in responding patients ($p<0.05$). Response was achieved after a median of 3 (range 2-12) and 5 (range 1-12) AZA courses in low/int-1 risk and int-2 / high risk MDS patients, respectively. Response lasted a median of 16 months (range 4-40). Leukaemia free survival (LFS) was affected by IPSS risk (36 months projected LFS was 56.9% and 20.4% in patients with intermediate-1 and intermediate-2/ high risk, respectively, p: <0.01) and WHO diagnosis ($p<0.01$). Projected overall survival (OS) was 89.9% at 12 months, 62,6% at 36 months and 45,6% at 60 months (median survival 51 months). OS was mainly affected by response to AZA (60 months projected OS was 60% and 26% in patients achieving at least a PR and in unresponsive patients, respectively; $p<0.01$), IPSS ($p<0.05$), age and WHO diagnosis ($p<0.05$).
Summary and Conclusions: These preliminary data confirm that AZA therapy is well tolerated and effective in the common clinical practice in all age and all risk MDS patients and can significantly reduce transfusional support. LFS and OS are mainly affected by IPSS risk, age and response to AZA.

PB1603

AZACITIDINE IN 'REAL LIFE' PATIENTS WITH CHRONIC MYELOMONOCYTIC LEUKEMIA (CMML): A SINGLE CENTRE EXPERIENCE

A Tendas[1,*] L Cupelli[1], D Piccioni[1], T Caravita[2], A Siniscalchi[1], G Del Poeta[1], L Scaramucci[1], M Giovannini[1], T Dentamaro[1], A Perrotti[3], S Fratoni[4], P de Fabritiis[1], P Niscola[1]
[1]Hematology, Sant'Eugenio Hospital, [2]Hematology, Sant'Eugenio, [3]Hematology,

San'Eugenio Hospital, [4]Pathology Department, Sant'Eugenio Hospital, Rome, Italy

Background: CMML is a clinically heterogeneous disease for which, according to recently reported experiences, hypomethylating therapies have provided significant clinical benefits.
Aims: Herein, we present the outcome of 11 patients (pts) who fulfilled the WHO 2008 criteria for CMML (CMML-2 in 7, CMML-1 in 2) or CMML-related acute myeloid leukemia (AML) with <30% bone marrow blast (2 pts) and have been treated with azacitidine (aza) at our institution between 2010 and 2014 after informed consent has been obtained.
Results: Median age at diagnosis was 76 years (range 62–86). Five pts had proliferative CMML. Four pts were transfusion dependent at some time point of disease course. Two out of 11 pts had abnormal kariotype (46,XY,Inv12 and 45,Y,-X, respectively). Two pts had secondary CMML; one to a 7-years lasting myelodysplastic syndrome (refractory anemia), whereas the other, who has undergone radio-chemotherapy for a solid tumor 3 years before, presented a likely therapy-related CMML. Prior therapies included cytoreductive therapy and erythroid stimulating agents. The MDAPS was low, Int-1, Int-2 and high in 1,2,4 and 2 CMML pts, respectively. Pts were treated with azacitidine, 75 mg/m^2 x 7 days, 5+2+2 schedule, every four weeks, subcoutaneously). Supportive care was given as required. Bone marrow (BM) response was assessed in 10 pts (following the sixth cycle in 9 pts and the fourth in 1); response was not assessed in 1 pt only, due to death (multiorgan failure) occurrence after second cycle. Responses were classified according to the modified IWG criteria; 5/9 evaluable pts achieved complete remission (CR) and 3 partial remissions (PR) with an overall response rate (CR+PR) of 73%; 2 pts maintained stable disease. No progressing pts continued the treatment. Two pts progressed to AML following the sixth and the fourteenth cycle respectively, after having obtained CR. With a median follow-up of 13 (2 – 31) months, 4 pts are alive and all of them continue to receive the treatment; six pts have died, 3 of AML, 2 of sudden cardiac death (with stable CMML), 1 of multiorgan failure (before response assessment); 1 patients was lost at follow up; median survival from therapy start was 15 months. Treatment was well-tolerated and no remarkable side effects were recorded.
Summary and Conclusions: In conclusion, despine the limited number of cases, our experience was encouraging; indeed, the use of aza in our hands achieved good responses in more than 70% of the treated pts, despite their high risk of disease and unfavorable prognostic profile.

PB1604

CYTOGENETIC ANALYSIS IN MYELODYSPLASTIC SYNDROME: AUDIT OF THE CURRENT PRACTICE IN A HAEMATOLOGICAL MALIGNANCY DIAGNOSTIC CENTRE. WHAT IS THERE TO BE LEARNT?

A Tsoulkani[1,*] K E Hodgson[1], L M Barton[1]
[1]Haematology, Leicester Royal Infirmary, University Hospitals of Leicester NHS Trust, Leicester, United Kingdom

Background: Identification of a clonal cytogenetic abnormality is essential for prognostic assessment of patients with Myelodysplastic Syndrome (MDS) (Revised International Prognostic Scoring System (IPPS-R)) and necessary for informing treatment decisions. According to the British Committee for Standards in Haematology (BCSH) guidelines (2013), cytogenetic analysis should be performed on all patients with suspected MDS having a bone marrow examination. Cytogenetic analysis is costly however, so it is crucial to ensure that the test is performed on appropriate samples. In many centres samples are cultured initially and subsequently analysed where needed. As significant numbers of these specimens are not analysed, we have implemented a procedure of immediate morphological screening of bone marrow aspirate samples prior to sending for cytogenetic culture.
Aims: We audited our current laboratory practice of immediate morphological screening of bone marrow aspirate samples before requesting cytogenetic analysis when investigating patients with possible MDS.
Methods: Using the Haematological Malignancy Diagnostic Links (HMDL) database, we reviewed 603 bone marrow samples received from the University Hospitals of Leicester NHS Trust, Kettering General Hospital NHS Foundation Trust and Northampton General Hospital NHS Trust over a 6 month period (March-August 2013). The key words 'myelodysplasia', 'uni-, bi-, pan-cytopenia', were used to select cases where MDS was suspected by the clinician. 116 bone marrows that met the criteria were assessed. Cytogenetic findings were reported in accordance with the International System for Human Cytogenetic Nomenclature Recommendations.
Results: Of the 116 samples, 52 were consistent with MDS according to the World Health Organisation (WHO) Revised Classification 2008 but only 29 of these were a new diagnosis and so appropriate for prognostic cytogenetic analysis. 14 samples were screened as possible MDS but this was not confirmed on detailed morphological reporting and in 7 of these cases cytogenetics were not subsequently analysed. As a result of bone marrow screening, 33 samples requested by clinicians were not sent for cytogenetic processing, as there was no evidence of dysplasia.
Of the 29 suitable cases cytogenetics could not be performed and as a result, the IPPS-R score could not be calculated for 5 new patients. For 3 of these no sample was received and in one case cytogenetic analysis failed. However, in 1 case the sample was rejected at the screening process resulting in the need for a repeat aspirate sample. Out of the 25 available reports, 10 showed an abnormal karyotype (40%). 10 cases were deemed intermediate or high risk by IPSS-R criteria and were considered for treatment with the nucleoside analogue, Azacitidine as per the TA218 National Institute for Health and Care Excellence (NICE) recommendations and the BCSH guidelines.
Summary and Conclusions: Immediate morphological screening of bone marrows referred as possible MDS has prevented the inappropriate processing of 43% of samples. This represents a significant cost saving. The audit has led to the introduction of a check procedure to ensure samples are not inappropriately rejected at screening.

PB1605

ASSISTED ADMINISTRATION OF SUBCUTANEOUS 5-AZACYTIDINE TO THE PATIENT'S HOME IS SAFE AND COST-EFFECTIVE

F Iuliano[1,*] A Perricelli[1], E Iuliano[2], A Pomillo[1], G Cervo[1], F Corea[3], D Gammuto[1], M Rella[1], C Salerno[1]
[1]Internal Medicine, U.O. di Onco-Ematologia S.O. "N.Giannettasio" ASP1 Cosenza, Rossano (CS), [2]Internal Medicine, Magna Grecia University S.Venuta Campus, Catanzaro, [3]Tor Vergata University , Rome, Italy

Background: Administration of azacitidine is planned in-patient daily, there is no experience of its administration to the patient's home.
Aims: The aim of this work was to evalute the feasibility of a program of home administration of azacitidine capable of reducing the cost-of-illness, to increase adherence to treatment while maintaining the same safety of the therapy given in the hospital.
Methods: Between Jan 2005 and Dec 2012, 22 consecutive patents, (MDSs, n= 15; CMML, n= 4; AML, n= 3), were enrolled in the study.The pharmaco-economic analysis included assessment of direct costs (hospital inpatient, physician inpatient,physician outpatient, emergency department , nursing home care, specialists' and other health professionals' care,diagnostic tests, prescription drugs and drug sundries, and medical supplies),indirect costs incurred by care recipients and unpaid caregivers, induding time, productivity and travel cost.
Results: Azacitidine 75 mg/m2 day was administered as a subcutaneous injection for 7 consecutive days every 4 weeks.Median age of the patients was 71 years (range, 65-83. Median number of courses delivered to each patient was 9 (range, 3-31) Hematologic responses (CR/PR/mCR) were induced in 6 patients {27%} Median number of treatment courses to achieve any response was 2 (range 1 -6) Adverse events were evaluated for the first 6 courses for all patients, for a total of 124 courses. Major adverse events were cytopenia and cytopenia-related infection. Grade 3 or higher neutropenia was 64.4%) but incidence of febrile episode requiring intravenous antibiotics was 8,4% slightly lower than reported from the pivotal clinical study. Grade 3 or higher non-hematologic toxicities were infrequent. Injection site reaction 0.4 and site pain 0% Median follow-up duration of surviving patients was 46.9 months (range, 11.8-55-5). Of the 14 patients who where RBC transfusion dependent at baseline, 48.0% became RBC transfusion independent during the treatment period. Adherence to treatment was 100%>
Summary and Conclusions: In our experience, despite the high percentage of elderly patients of whom 36% living in rural area, it was possible to give treatment to all patients with total adherence. There has been a reduction in direct medical costs due to less use of hospitalization, a reduction of indirect costs by 63% due to the lower number of working days lost and a drastic reduction of travel costs with the same efficacy and safety of administration.

PB1606

MYELODYSPLASTIC SYNDROMES MANAGEMENT AND TREATMENT: A CONCEPTUAL FRAMEWORK

T Bentley[1,*] M Broder[1], A DeCristofaro[1], S Megaffin[2], M Petrone[2], T McKearn[2], S Kurtin[3], C Cogle[4]
[1]Partnership for Health Services Research, Beverly Hills, CA, [2]Onconova Therapeutics, Inc, Newtown, PA, [3]University of Arizona Cancer Center, Tuscon, AZ, [4]Division of Hematology & Oncology, University of Florida College of Medicine, Gainesville, FL, United States

Background: First-line treatment of myelodysplastic syndrome (MDS) patients with hypomethylating agents (HMAs) has been demonstrated in clinical trials to improve survival and/or delay progression to acute myelogenous leukemia (AML). However, most patients eventually relapse and, unless eligible for allogeneic hematopoietic cell transplant (HCT), face limited treatment options

and survival of only months. Despite the anticipated growth in the MDS population, little is known about the diagnostic and treatment decision-making undertaken by clinicians who treat non-transplantable MDS patients.
Aims: We sought to better understand MDS patient management and unmet needs by identifying clinicians' approaches for determining MDS: diagnosis; risk; progression; and treatment, particularly among higher-risk patients and after initial treatment failure.
Methods: We conducted in-depth, semi-structured interviews with nine hematology and/or oncology specialists (8 physicians; 1 nurse practitioner) in the US experienced in diagnosing and managing MDS patients.
Results: Diagnostic processes were consistent across providers and included blood work, physical examination, and often tests to rule out potential alternative diagnoses. Bone marrow biopsies (BMBs) were always performed to confirm the diagnosis. Providers calculated International Prognostic Scoring System (IPSS) and/or revised IPSS (IPSS-R) scores for almost all treatment-naïve patients. Some providers used just one system, while others used both due to specific trial protocol requirements and the limited real-world evidence regarding IPSS-R use in guiding treatment decisions. Initial treatment decision-making was driven by risk score, symptoms, transfusion dependency and, in some cases, performance status. Providers' management approaches were generally consistent for very low-risk (*e.g.*, active monitoring) and very high-risk (*e.g.*, HMA; HCT, if eligible) patients. There was substantial variation in response criteria (*e.g.*, change in BMB results, worsening cytopenias) used to determine progression from lower- to higher-risk MDS; several providers cited the need for a validated metric to address this inconsistency. Two-thirds of providers treated indefinitely with HMAs regardless of treatment response and given an absence of treatment-related adverse effects, citing long term or cyclical HMA benefits and lack of second-line options. Differences existed in methods used to determine HMA response, with the most common being periodic blood counts and/or BMBs. Providers noted that patients receiving HMAs either fail to respond or respond for some period of time and eventually experience treatment failure and MDS progression. Providers agreed that there is a significant unmet medical need for treating these second-line, non-HCT eligible MDS patients. Described as "limited," second-line treatments included clinical trials, cytotoxic induction chemotherapy, and supportive care. All providers stated that prognosis is poor regardless of approach.
Summary and Conclusions: The lack of treatment options for MDS patients, especially high-risk patients who do not respond to HMAs or have initial treatment failure, is an issue of profound importance. Providers use different approaches for these patients but agree that none offer significantly improved prognoses, leaving a considerable unmet need for second-line options. More research is required in determining optimal strategies for treating higher-risk and second-line MDS; assessing disease response in treated patients; and defining treatment failure.

PROGNOSTIC SIGNIFICANCE OF CYTOGENETIC CATEGORIES IN MYELODYSPLASTIC SYNDROMES: SINGLE CENTRE STUDY FROM OMAN
N Fawaz[1,*] S Alkindi[1], M Huneini[1], K Al Farsi[1], M Al Khabori[1], A Al Riyami[1], D Dennison[1], A Udayakumar[2], V Panjwani[1], A Pathare[1]
[1]Department of Haematology, [2]Genetics Department, Sultan Qaboos University, Muscat, Oman

Background: Myelodysplastic syndromes (MDS) are clonal disorders of hematopoietic stem cells characterized by ineffective hematopoiesis, peripheral cytopenias and a variable risk of leukemic transformation. Chromosomal abnormalities play an important role in the underlying disease biology, predicting prognosis.
Aims: To investigate and compare IPSS-R prognostic stratification in MDS patients with the outcomes.
Methods: This retrospective study assessed 50 MDS patients (median age-60; range 1-86 years) with IPSS-R poor and very poor (n=5), intermediate (n=7) and good and very good (n=38) prognostic stratification. The median follow up was for 39.5months (range 1-70).They were analyzed for overall survival, leukemic progression, and according to the MDS associated cytogenetic abnormalities.
Results: 31 patients (62%) had normal cytogenetics. Amongst the MDS related abnormalities described, 4 (8%) had monosomy 7, 4 (8%) had trisomy 8 and one each had isochromosome 17q, del (11q) and del (5q). 14 had single abnormality, 3 showed double abnormalities, whereas one each had a complex abnormality and balanced translocation (t(5:12)). In the IPSS-R cytogenetic groups, the median survival was 34months for the good risk, 32 months for the intermediate group but 15.5 months for the poor risk subgroups($p<0.05$, chi square test). Although the overall mortality was 26%, it was 22%, 29% and 36% in the IPSS-R good, intermediate and poor subgroups respectively. Leukemic transformation was seen in 22% patients with an overall mortality of 55%. However, leukemic transformation occurred in 3%, 43% and 55% in the IPSS-R good, intermediate and poor subgroups respectively (Figure 1).

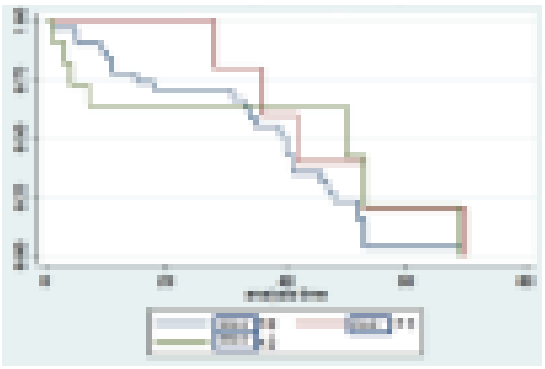

Figure 1. Kaplan-Meier survival estimates.

Summary and Conclusions: The IPSS-R can effectively stratify the prognosis of MDS based on cytogenetics even in a small single centre study of 50 patients with the three Kaplan Meier curves can be seen to diverge initially. However, with effective therapy like BMT, it was seen that progressively the lower curve superimposes with the first indicating the better long term outcomes.

PB1608

PEDIATRIC MYELODYSPLASTIC SYNDROMES: HOW DO THEY DIFFER FROM ADULTS?
N Fawaz[1,*] A Al Rawas[2], W Bashir[2], I Beshlawi[2], M El Shinawi[2], M Zachariah[2], Y Wali[2], D Dennison[1], S Alkindi[1], A Udayakumar[3], A Pathare[1]
[1]Department of Haematology, [2]Child Health, [3]Genetics, Sultan Qaboos University, Muscat, Oman

Background: Although uncommon, pediatric myelodysplastic syndromes [MDS] are not rare but its incidence is underestimated. Furthermore, unlike adults, it frequently presents as bone marrow failure syndrome in contrast to refractory cytopenias, and *per se* there is considerable difficulty in assigning the overlapping morphological features seen with bone marrow failure syndromes.
Aims: To study the clinical presentation, overall survival and correlate WHO 2008 Classification of MDS cytogenetic changes in childhood MDS *versus* Adults.
Methods: This retrospective study assessed 14 pediatric MDS patients (Median Age-11.5; range 1-16 years) and compared them with 39 adult MDS patients (Median age-65, range 23-86 years) from a single tertiary institution in Oman. Pediatric MDS patients were analyzed for initial presentation, type of progression, leukemic transformation and overall survival as well as according to the MDS related cytogenetic abnormalities. The median follow up was for 43 months (range 1-69).
Results: The commonest presentation was refractory cytopenia of childhood [RCC] in 43%, followed by RAEB-T [29%], RAEB [21%] and JMML [7%]. Seven patients (54%) had normal cytogenetics. Amongst the MDS related abnormalities described, four (31%) had monosomy 7 whereas, one each (8%) had trisomy 8 and trisomy21 with del (10q). Overall mortality in the pediatric MDS patients was 29%. Six patients [43%] demonstrated leukemic transformation with 50% mortality. Seven patients [50%] underwent Bone marrow transplantation (BMT) with six long term survivors [85%] (Figure 1).

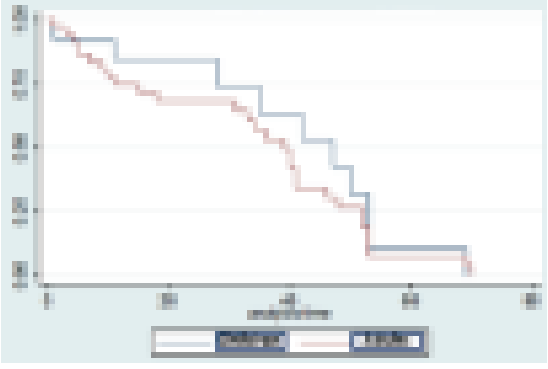

Figure 1. Kaplan-Meier survival estimates.

Summary and Conclusions: Although there are several fundamental differences between childhood and adult MDS patients, the overall survival in these MDS cohorts did not show any statistically significant differences in the

Kaplan Meier survival analysis. Early treatment with BMT is likely to result in good long term prognosis in spite of the poor cytogenetic features.

PB1609

HYPOALBUMINEMIA IS AN INDEPENDENT ADVERSE PROGNOSTIC FACTOR FOR OVERALL SURVIVAL IN MYELODYSPLASTIC SYNDROMES

A Melero-Amor[1,*] EJ Salido[1], JM Moraleda[1]
[1]Hematology, University Clinical Hospital Virgen de la Arrixaca, Murcia, Spain

Background: Low serum albumin level is known to be an adverse prognostic factor in patients with malignances such as multiple myeloma. The negative prognostic value of low serum albumin has been reported by the Moffitt Cancer Center group in a large series of 767 patients (Komrokji *et al.* Am. J. Hematol. 2012;87:1006-1009).
Aims: The aim of this study is to confirm the prognostic value of serum albumin in different MDS risks groups and cytogenetic groups (Schanz *et al.* J. Clin Oncol. 2012;30:820-829).
Methods: Patient's data were obtained from our MDS database. The primary objective was to check the prognostic value of serum albumin for overall survival (OS). Patients were divided into 2 groups according to the levels of serum albumin at diagnosis (< 4 gr/dl y > 4 gr/dl). We used Kaplan-Meier analysis to estimate OS and the log-rank test to compare survival estimates between the two groups. Cox-proportional hazards regression was used for multivariate analysis.
Results: We analyzed data from 53 patients diagnosed of MDS between January 2012 and January 2014. The median age was 69 years. The median of serum albumin was 4,1 gr/dl. MDS were classified in low risk (IPSS low and intermediate-1 or WPSS very low, low and intermediate) 68%, and high risk 32%. Baseline characteristics of the patients in the two groups were:

Table 1.

The median OS for all patients was 25 months (95% CI: 13,2-38). Age (< 60 *vs.* ≥ 60 years) and the MDS cytogenetic subgroups (Very good/Good *vs* Intermediate/Poor/Very poor) did not reach prognostic value. However, the IPSS-WPSS MDS subgroup risk [mean OS 13,6 (95% CI: 7,7-19,5) *vs* 31,8 months (95% CI: 13,3-50,3), p=0,019)] and the albumin levels(< 4 *vs* ≥ 4 gr/dl) [mean OS 9,2 (95% CI: 2,9-15,4) vs 31 months (95% CI: 14,9-47,1), p<=0,0001), see figure] showed statistically significant prognostic value in the univariate analysis. After adjustment for MDS subgroup risk, OS was statistically significantly different among MDS patients with serum albumin<4 gr/dl [Hazard Ratio = 0,112 (95% CI: 0,03-0,4); p=0,001] (Figure 1).

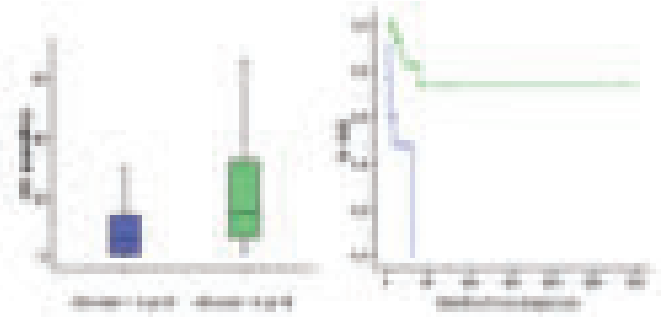

Figure 1.

Summary and Conclusions: In this retrospective analysis patients with serum albumin less than 4 gr/dl at diagnosis have significantly reduced OS, and showed its value as an independent prognostic factor for OS after adjustment for MDS IPSS-WPSS subgroups risk and cytogenetics. Serum albumin should be taken into account as a new prognostic factor in MDS and might be studied as a surrogate factor of performance status and co-morbidities.

PB1610

ORIGINATOR ERYTHROPOIETIN ALPHA *VS* BIOSIMILAR ERYTHROPOIETIN ALPHA *VS* ERYTHROPOIETIN ZED PLUS LIPOFER AND B12 AND FOLATES IN PATIENTS WITH REFRACTORY ANEMIA. FIVE CENTER RETROSPECTIVE STUDY

G Giordano[1,*] T Rosa[2], M Patrizia[3], C Bruno[4], G Berardi[5]
[1]oncology, Foundation "J. Paul II" - Campobasso - Italy, Campobasso, [2]oncology, pascale hospital, naples, [3]oncology, g. martino hospital, messina, [4]oncology, cardarelli hospital, [5]general medicine, asrem, Campobasso, Italy

Background: Biosimilar drugs, including erythropoirtin zed, have a similar, but usually not inferior although not hidentical effects of originator drugs. Safety is hidentical to originator drugs.
Aims: Aim of this study is to verify if in MDS patient with refractory anemia biosimilar erythropoietin alpha and erythropoietin zed, are not inferior to erythropoietin alpha in terms of safety, efficacy and costs.
Methods: This study is a retrospective study.Between july 2008 and december 2013, 101 patients affected by refractory anemia were studied.Median follow-up was 16 months (R10-28).Patients received in group A erythropoietin alpha 40000 IU sc/weekly.In group B patient received biosimilar erythropoietin alpha 40000 IU sc/weekly.In group C patient received biosimilar erythropoietin alpha 40000 IU sc/weekly.In all three arms patients received lipofer 14 mg 2 tablets orally/day calcium levofolinate 7.5 mg/day orally + Vitamin B12: 400 mg/day orally.In group A median age was 70 years (R63-73), M/F: 15/28.In group B median age was 64 years (R60-70), M/F: 24/19.In group C median age was 68 years (R62-73), M/F: 10/5.IPSS was low in 30 patients and int-1 in 12 patients, karyotype showed –Y in two patient, del 20q in one patient, trisomy 8 in two patients in group A.IPSS was low in 32 patients and int-1 in 10 patients, karyotype showed –Y in one patients, del 20q in one patient in group B.IPSS was low in 11 patients and int-1 in 4 patients, karyotype was normal in 9 patients and not evaluable in 6 patients.Patients with 5q- were excluded from this study.Median level of haemoglobin was 9 g/dl in group A (R8-11), 8.7 g/dl (R8.5-10.5) in group B and 8.5 in group C. Cost of every month of erythropoietinic therapy was calculed dividing for each patient the sum of complete erythropoietic therapy for each month of follow-up, then in each group of patients median cost of erythropoietic therapy was calculed.
Results: Group A patients increased Hb level of 1 g/dl after a median time of 5 weeks (R4-9), after a median time of 3.5 weeks (R3-8) in group B and after a memedian time of 4 weeks in group C. No relevant side effects were observed in all three groups groups . Erythropoietin alpha was reduced in group A because Hb achieved a level > 12g/dl after a median of 12 weeks (R 4-18).Biosimilar erythropoietin alpha was reduced in group B because Hb achieved a level > 12g/dl after a median of 10 weeks (R 3-16).Erythropoietin zed was reduced in group C because Hb achieved a level > 12g/dl after a median of 9.5 weeks (R 3-15).In group A maintenance dose was administered with a median of every two weeks (2-4), in group B maintenance dose was administered with a median of every three weeks (2-5), in group C maintenance dose was administered with a median of every three weeks (2-4).Median cost for every month of erythropoietic therapy was 1536 euros/month (R1240-1850) in group A , 1354 euros/month (R954-1550) in group B, 1300 euros/month (R1300-1380) in group C. Five patients need transfusion support in group A,6 patients need transfusion support in group B and 5 in group C.
Summary and Conclusions: Biosimilar erythropoietin alpha and erythropoietin zed plus lipofer and B12 and folates support seems to be safe, feasible, probably equally cost-effective and substantially not inferior to originator erythropoietin alpha support in patients affected by refractory anemia. This study needs confifrmation on a larger cohort of patients.

PB1611

PEDIATRIC MYELODYSPLASTIC SYNDROMES: PROGNOSIS, MANAGEMENT AND EVALUATION

A Contento-Gonzalo[1,*] P Galera-Martin[2], K Hurst[1], AI Rodriguez-Jimenez[1], A Pascual-Martinez[1], AI Heiniger-Mazo[1]
[1]Hematology, [2]Paediatric, Malaga Regional Hospital, Malaga, Spain

Background: Myelodysplastic syndromes (MDS) are a rare disease in children, accounting for less than 5% of all hematological malignancies. The definition and classification of childhood MDS child can be confusing, due to frequent overlapping between forms of MDS and myeloproliferative disorders (MPD). MDS may occur as a previous phase to the development of acute myeloid leukemia, whose progression is usually rapid and fatal if not treated early.
Aims: To analyze clinical characteristics, prognostic factors and outcome of pediatric patients diagnosed with MDS at our center
Methods: We studied 10 patients diagnosed at our center with childhood MDS

(7 juvenile myelomonocytic leukemia (JMML), 1 amegakaryocytic thrombocytopenia, 1 Refractory cytopenia with multilineage dysplasia (RCMD), 1 Refractory anemia with excess blasts-1 (RAEB-1)), with a minimum follow-up of 120 days. Qualitative variables were analyzed using chi -square and nonparametric tests were used for quantitative variables.
Results: The mean age was 4 years (r, 1-13) . Median leukocyte count at diagnosis was 42.61 x10^9/L (r, 3.67-233) with a median fetal hemoglobin of 16%(r, 1-55). One patient presented with unfavorable cytogenetics (monosomy 7) and the remaining nine with an intermediate prognosis. Seven patients (70%) underwent allogeneic HSCT. All donors were HLA- identical, 5 of which were unrelated donors. Bone marrow was used in 4 cases and umbilical cord in 3. The conditioning regimen was myeloablative in 100% of patients. Thymoglobulin+cyclosporine+methotrexate was used in all cases as GVHD prophylaxis . Four patients (57%) developed acute GVHD, grade II – IV in two cases. No chronic GVHD was observed in the analyzed series. Six (60%) presented hepatomegaly at diagnosis, observing 83% (5) of exitus in these patients. Nine patients (90%) developed splenomegaly, splenectomy prior to HSCT was performed in only one (13%), with no affect on mortality. We observed 6 (60%) deaths, 4 of these in patients with JMML. Of the 7 patients that underwent HSCT, 57% (4) are still alive, while 100% (3) of those that didn't receive HSCT have died.
Summary and Conclusions: Pediatric patients with MDS have a fatal evolution as described in the literature. In our series leukocyte count at diagnosis and the presence of hepatomegaly were identified as prognostic factors. The longest survival rates were achieved after HSCT, which should be considered as the first therapeutic option, as it is the only treatment with proven healing capacity in these patients.

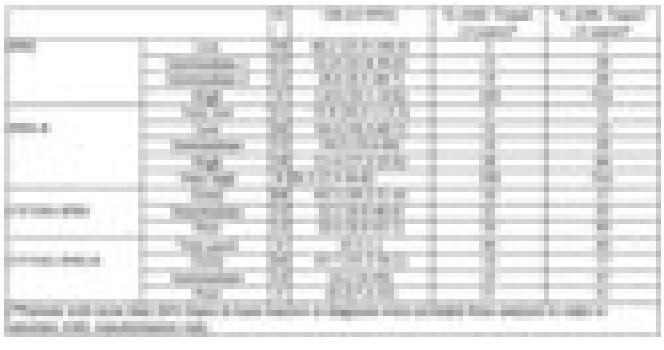
PB1612

VALIDATION OF DIFFERENT PROGNOSTIC CLASSIFICATIONS IN PATIENTS DIAGNOSED WITH MYELODYSPLASTIC SYNDROME (MDS) IN THE NEW MILLENIUM

I Vazquez[1,*] J B Borras[1], M Mascaro[1], P Romero[1], R Del Campo[1], A Cladera[1], JM Guerra[1], D Gomez[1], E Gonzalez[1], F Serra[1], J Bargay[1]
[1]Hematology, Hospital Son Llàtzer, Palma de Mallorca, Spain

Background: To determine a proper therapeutic approach is essential for MDS, due to the wide heterogeneity of disease presentation at diagnosis. For that purpose, we have studied different prognostic classifications: IPSS, IPSS-R and WPSS.
Aims: The aim of our study was to assess the adaptation of these classifications to the results obtained in our patient series.
Methods: Data of all patients diagnosed with MDS at Son Llàtzer Hospital were prospectively collected from January 2002 to February 2014. We used SPSS statistics v.19 © for descriptive and univariate statistical analysis, using Kaplan-Meier for survival analysis and log-rank test to compare the curves.
Results: Of 112 patients, 96 were eligible for analysis: 57 men (59.4%) and 39 women (40.6%) with a median age of 77 years (33-94). According to FAB: RA was 26 (27.1%), 20 RARS (20.8%), 30 RAEB (31.3%), 6 RAEB-t (6%) and 14 CMML (14.6), while according to WHO, 7 were RA (7.3%), 6 RARS (6.3%), 16 RCMD (16.7%), 9 RCMD-RS (4%), 12 RAEB-1 (12.5%), 13 RAEB-2 (13.5%), 5 RCUD (5.2%), 5-5q MDS (5.2%), 15 MDS / MPD (15.6%), 1 SMDI (1%) and 1 was not available. Six patients (6.3%) were diagnosed with secondary AML. The median overall survival (OS) was 41.81 months (95% CI 34.4-49.21) with a median of follow up of 31.38 months. The overall rate of transformation to leukemia after 5 years was 29%. Statistically significant differences were observed in OS according to IPSS (p=*0.000*) and IPSS-R (p=*0.000*). Moreover, no significant differences were found based on WPSS (p=*0.312*), Sorror comorbidities index (p=*0.532*) or according to ferritin levels groups (p=*0.167*) in terms of OS (Table 1).

Table 1.



Summary and Conclusions: In our series, IPSS and IPSS-R rating have been useful for predicting the prognosis in terms of OS as well as the risk to AML transformation. However, some groups of cytogenetic risk at IPSS-R required a larger sample since we have not observed concordance respect to risk of transformation to AML as it appears in the rest of the literature

PB1613

THE ASSESSMENT OF PATIENTS WITH MYELODYSPLASTIC SYNDROME ACCORDING TO REVISED INTERNATIONAL PROGNOSTIC SCORING SYSTEM

AZ Bolaman[1,*] I Yavaşoğlu[2], VG Kadıköylü[2], G Pektaş[2]
[1]hematology, Adnan menderes university medicine faculty, [2]hematoloji, Adnan menderes üniversitesi tıp fakültesi, aydın, Turkey

Background: Myelodysplastic syndrome (MDS) is a heterogeneous myeloid clonal disease. Prognosis can be determined by international prognostic scoring system (IPSS) which is based on both chromosomal abnormalities and blast ratio in bone marrow. Prognosis may be also specified by World Health Organization prognostic scoring system (W-IPSS) which consists of chromosomal abnormalities, blast ratio in bone marrow and the requirement for blood transfusion. Revised international prognostic scoring system (R-IPSS) has been defined recently. This system refers to cytopenia for each blood cell and the blast ratios of<2% or 2-5% as separate categories. Risk groups have been described as very low, low, intermediate, high and very high.
Aims: In this study, we aimed to compare the IPSS with R-IPSS.
Methods: This is a retrospective evaluation of 130 patients (65 men and 65 women) who were diagnosed with MDS at the Department of Hematology in Adnan Menderes University Medical Faculty Hospital between 2008 and 2012. The IPSS and R-IPSS criteria were used for this evaluation. Fifty patients had MDS RA whereas RAEB-2 existed in 17 patients. The mean patient age was 69±12 years while the median overall survival was 41±13 months (Figure 1).
Results: Both IPSS and R-IPSS were found to be statistically similar when they were compared by one way analysis of variance and two-paired t-test.

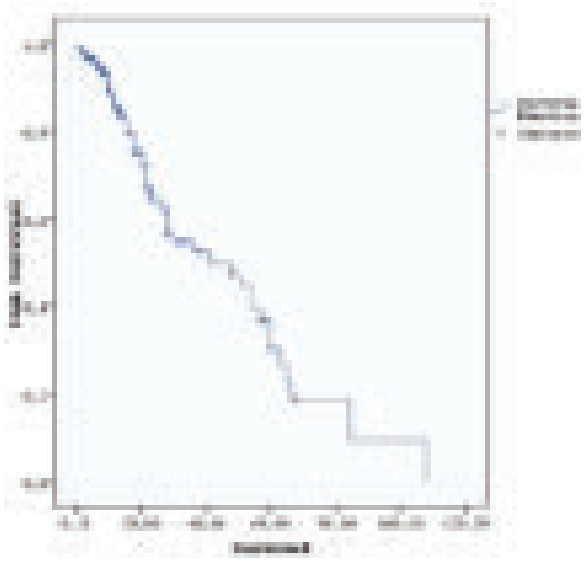


Figure 1.

Summary and Conclusions: Literature indicates superiority of R-IPSS in prognostic evaluation of patient with MSD. However, the present study has been unable to point out an advantage of R-IPSS over IPSS. Such discrepancy may be attributed to the relatively small cohort size and the differences in treatment regimens. Large-scale studies are needed to confirm the validity of these findings.

PB1614

AZACYTIDINE THERAPY FOR MDS, AML AND CMML: TOLERABILITY, EFFICACY AND SURVIVAL. A SINGLE CENTRE EXPERIENCE

A Martín[1], S Lakhwani[1,*] C de Bonis[1], JM Raya[1], T Martín-Santos[1], R Díaz-Rodríguez[1], MT Hernández[1], L Hernández-Nieto[1], B González[1]
[1]Hematology, Hospital Universitario de Canarias, Santa Cruz de Tenerife, Spain

Background: Azacytine (AZA) is a first-in-class hypomethylating drug with documented activity mainly in MDS, but also in AML and CMML.

Aims: We report the results of the treatment with AZA in our Centre in patients with high and low risk MDS, AML and CMML. We evaluate 1) tolerability, 2) efficacy and 3) survival data.
Methods: We reviewed 54 patients (29 males/25 females) with high-risk MDS (n=23), low-risk MDS (n=8), AML (n=19) and CMML (n=4) treated with AZA with at least 2 courses of therapy. Median age of the group was 69.5 years (29-84). Thirty-two patients (59.2%) had a transfusion-dependent anemia, eleven (20.3%) a transfusion-dependent thrombocytopenia, twenty-two (40.7%) a neutrophil count below 500/mm3 and seven (12.9%) a leucocyte count above 10.000/mm3.
Five days AZA dosing schedule was used in 26 (48,1%) patients and seven days in 23 (42.6%). Five patients (9.3%) alternated both schedules. AML and high-risk MDS patients received 7.9 (2-25) and 10.1 (3-47) median number of AZA cycles respectively.
According to the IPSS score at the time of AZA treatment onset, MDS patients (n=31) were classified as low (4), intermediate-1 (12), intermediate-2 (11) and high (4) According to IPSS-R they were low (7), intermediate (3), high (10) and very high (11).
Among high-risk MDS, AZA was the frontline treatment in 22 and second line in 1 patient. In AML patients, AZA was the frontline treatment in 7, second or third line in 10 and maintenance treatment in 2.
Results: 1) Regarding tolerability: overall, AZA was very well tolerated. Dose reduction was needed only in 4 patients: 3 due to hematologic toxicity and 1 due to non-hematologic toxicity.
2) In terms of efficacy: 25 patients (46.3%) achieved haematological improvement: 5 in AML (CR 1, PR 4), 14 in high-risk MDS, 3 in low-risk MDS and 3 in CMML. Transfusion independence was achieved in 13 patients (24.1%): 3 in AML, 8 in high-risk MDS, 1 in low-risk MDS and 1 in CMML. Bone marrow blast reduction was observed in 5 AML patients (26.3%) and in 4 (17.4%) with high-risk MDS.
3) Median overall survival was 11.8 months (1-49): 9 months in AML pts (1-24), 12.2 months in high-risk MDS (4-49), 18.1 months in low-risk MDS (4-43) and 9.7 months in CMML (5-17). In high-risk MDS as well as AML, we could not find any statistically significant association between survival and the following parameters: Sorror comorbidity index, transfusion-dependent anemia, transfusion-dependent thrombocytopenia, neutrophil count below 500/mm3 and prior chemotherapy treatment.
Summary and Conclusions: Data from the use of AZA in our Institution shows: 1) An excellent tolerance to the treatment with a high grade of compliance. 2) Good efficacy rates, with nearly half of patients achieving haematological improvement and nearly a quarter achieving transfusion independence. This benefit was seen in all subgroups of patients. 3) Sorror comorbidity index, transfusion-dependent anemia, transfusion-dependent thrombocytopenia, neutrophil count below 500/mm3 and prior chemotherapy treatment were not related to survival.

Bone marrow failure syndromes incl. PNH - Clinical

DIAMOND-BLACKFAN ANEMIA IN A KOREAN INSTITUTE: GENOTYPING AND LONG-TERM OUTCOME

H Kook[1,*] HJ Baek[1], DK Han[1], JH Cho[1], HI Jang[1], HJ Kim[2], TJ Hwang[1]
[1]Pediatrics, [2]Hematology, Chonnam National University Hwasun Hospital, Hwasun-gun, Korea, Republic Of

Background: Diamond-Blackfan anemia (DBA) is characterized by a rare congenital red cell aplasia, often in association with physical anomalies, short stature, and a predisposition to cancer. DBA is a disorder of aberrant ribosome biogenesis and function. Mutations in more than 10 ribosomal proteins have been identified.
Aims: This study was aimed to characterize Korean patients with DBA. Clinical and hematological manifestations, genotyping and phenotypic correlation, treatment response to steroids, long-term outcome and the effect of L-leucine supplementation were evaluated.
Methods: Medical records of 10 patients who were diagnosed of DBA at Chonnam National University Hospital between 1992 and 2013 were retrospectively reviewed.
Results: Four patients were males. The median age at diagnosis was 3 months (range, 1 to 18 months). Median initial hemoglobin level was 5.9 g/dL (range, 1.9 – 9.4 g/dL). Heart defects were seen in 4, and polydactyly in 3. Among 9 patients tested, 7 had mutations (77%): *RPS19*, 4; *RPL5*, 2; *RPS26*, 1. All patients initially responded to steroids, having hemoglobin level ≥ 9 g/dL with the median of 10 days (range, 7-32 days). Three patients are currently off steroid therapy. Minimum dose of oral prednisolone (≤ 0.2 mg/kg/day) was required to maintain hemoglobin ≥ 9 g/dL in 6 cases. L-leucine at 2,000mg/m^2/day was supplemented in 2 patients who were short and had required transfusions despite steroid treatment. At 6 months both patients showed improvement of appetite and growth spurt as well as the increase of hemoglobin. With the median follow-up of 10 years, no malignancy has been identified. Three patients had short stature.
Summary and Conclusions: The majority of Korean DBA patients had mutations, but genotype-phenotype association was not apparent in our study. Thirty percent of patients achieved a remission, but still many patients are on steroid treatment. L-leucine as a translation enhancer seems to be beneficial without significant side effects. Further studies are warranted to closely monitor steroid side effects and the development of malignancy. The potential role of L-leucine should be validated in trials incorporating more DBA patients.

PB1616

CLINICAL AND IMMUNOLOGICAL ASPECTS OF MYCOPHENOLIC ACID TREATMENT OF PATIENTS WITH APLASTIC ANEMIA

E Shilova[1,*] O Rozanova[2], S Gritsaev[1], J Chubukina[2], T Glazanova[2], K Abdulkadyrov[1]
[1]department of hematology, [2]laboratory of immunohematology, Research Institute of hematology and transfusiology, Saint-Petersburg, Russian Federation

Background: Aplastic anaemia (AA) can be successfully treated with immunosuppressive therapies (IST) with response rates 70% and good long-term survival. Future progress may be achieved by using of new regimens and new agents for the treatment of patients with AA. One of the additional immunosuppressive agents to standard anti-thymocyte globulin/cyclosporin (ATG/CsA) schemes is mycophenolic acid (MFA) which may improve the response rate and survival of patients with AA. Scientific data show, that despite a strong theoretical rationale for its use, MFA-therapy did not result in the improvement of response when compared with historical standard ATG/CsA treatment.
Aims: To demonstrate the results of treatment of AA patients with MFA drug products.
Methods: 14 patients with AA (9-severe AA; 5-non-severe AA) were treated with MFA between 2008 and 2013 at the Russian Institute of Hematology and Transfusiology. Immune cell parameters were evaluated using multi-color flow cytometry.
Results: Positive clinical and hematological effect was observed in 10 patients. MFA therapy was effective in patients who had shown good results after the initial standard IST with inability to continue it due to adverse effects of CsA. Analysis of peripheral blood lymphoid subsets of patients with AA receiving MFA-regimens have revealed the same tendencies as for “traditional” immunosuppresive therapy: decrease of CD3+ T-cells from 87,7% to 72,6%, increase of NK-cells (CD16/56+) from 7,7% to 13,1%, decrease of activated NKT (CD16+/3+) cells from 13,1% to 9,1%, and normalization of CD19+ B-cells. Positive dynamics of the main immune parameters correlated with clinical

efficacy evidencing the influence of MFA products on the key mechanisms of AA pathogenesis, mediated via T-cell immunity. Good tolerability has been shown for two types of MFA products: Cellsept and Myfortic without any significant adverse effects, even with long duration of treatment (up to 40 months).
Summary and Conclusions: Our findings suggest the possibility of using mycophenolic acid products in the second or third line treatment of patients with AA, in which there is no possibility of standard IST with full doses.

PB1617

WOLMAN DISEASE PRESENTING AS FAMILIAL HEMOPHAGOCYTIC LYMOPHOHISTOCYTOSIS

S Elsayed[1,*] E Elsobky[1], A Tantawy[2], I Ragab[2], V Grandin [3], M Gil[3], G de Saint Basile [3]
[1]Genetics Unit, [2]Pediatrics, Children's Hospital, Ain Shams University, Cairo, Egypt, [3]CEDI, Hôpital Necker Enfants Malades, 75015, Paris, France

Background: Familial hemophagocytic lymphohistiocytosis (FHL) is a rare, autosomal recessive disease that is usually evident in the first few months or years of life. Major signs and symptoms include hepatomegaly, splenomegaly , anaemia, leucopenia or thrombocytopenias. These manifestations resemble many inborn errors of metabolism and lysosomal storage diseases in which hemophagocytic lymphohistiocytosis have been reported as a secondary association.
Aims: Molecular characteristics of the Egyptian patients with Wolman disease presenting as FHL.
Methods: The study included patients presented to the Medical Genetics Center for genetic counseling with clinical and laboratory criteria consistent with FHL and no mutation found in known FHLH genes. Molecular diagnosis was done by sequencing of LIPA gene.
Results: Two out of 20 patients (10%) were found to have mutations in LIPA gene consistent with Wolman disease. The first is a 2 month old boy with homozygous mutation G929A (W130X) and the second is a 3 month girl with c.398delC (S133X) mutation. The absence of prominent fever, the huge hepatomegaly and the severe failure to thrive were characteristics of these patients.
Summary and Conclusions: LIPA gene should be excluded in patients with clinical and laboratory characteristics of FHL and negative molecular testing especially if not associated with prominent fever and have huge hepatomegaly or severe failure to thrive .

PB1618

THE PRESENCE OF PNH CLONE IN APLASTIC ANEMIA PATIENTS IS A PROGNOSTIC FACTOR OF GOOD ANSWER ON IMMUNOSUPPRESSIVE THERAPY

Z Fidarova[1,*] E Mikhaylova[1], I Galtseva[1], G Kliasova[1], S Lugovskaya[2], E Naumova[2], V Troitskaya[1], E Ustinova[1], N Tsyba[1], E Parovichnikova[1], V Savchenko[1]
[1]National Research Center for Hematology Russian Ministry of Health, [2]Department of Clinical and Laboratory Diagnostic RMAPE, Moscow, Russian Federation

Background: The immunosuppressive therapy (IST) increases treatment efficacy of patients with aplastic anemia (AA) significantly but 20-30% of them are still refractory. According to international research data the detected PNH clone in AA patients can be a determining factor of good response to IST.
Aims: The main purpose was both detection and monitoring of PNH clone in AA patients and evaluation of its importance for IST effectiveness.
Methods: From May 2011 till November 2013 38 de novo AA patients were studied, the follow-up median (Me) was 12 months, and the median age was 26 years. The patients were divided into two groups: the 1st one consisted from patients with PNH clone (>0,01%), and the 2d one from patients without PNH clone. All patients underwent IST (ATG and cyclosporine). The treatment response was evaluated as hematological improvement (HI) in case if hemoglobin>80 g/l, granulocyte>1,0x10^9/l (for SAA>0,5 x10^9/l), Tr>30x10^9/l). PNH clone was detected by flow cytometry following ICCS guideline with sensitivity 0,01% on granulocytes.
Results: Before IST the PNH clone was detected in 55,2% of patients: Me RBC – 0,1%, Gr – 0,76%, Mon – 5%. HI had been reached by 3 months at 47,4% of patients, 77,8% of them were from 1st group. Among the patients who had not achieved HI (52,6%) by 3 month after therapy started many of them were from 2d group (65%). Other 35% of not HI patients were from 1st group and their difference was only 5,8% PNH clone on monocytes *versus* 0,7% in HI positive patients from 1st group. When the final analysis was made 73,7% of patients had reached HI: 47,4% from 1st group and 26,3% from 2d group in which six patients showed PNH clone appearance and persistence during IST. In patients from 1st group with HI some changes in PNH clone size were observed: in one patient PNH clone disappeared or became less 0,01% and 3 of them showed an increase of the clone size with clinical intravascular hemolysis.
Summary and Conclusions: Positive response was more achieved in the group of patients with initially detected PNH clone. We had observed the appearance and persistence of PNH clone in patients with positive IST response initially negative by PNH clone.

EVALUATION OF SPECIMEN STABILITY FOR DIAGNOSIS OF PAROXYSMAL NOCTURNAL HEMOGLOBINURIA (PNH) USING FLOW CYTOMETRIC MEASUREMENT OF MONOCYTIC CD55/CD59

D An[1,*] H Shim[1], CJ Park[2]
[1]Laboratory Medicine, Seegene Medical Foundation, [2]Laboratory Medicine, University of Ulsan College of Medicine and Asan Medical Center, Seoul, Korea, Republic Of

Background: Flow cytometric analysis of glycophosphatidyl-inositol (GPI)-linked proteins, CD55/CD59 expressed on the surface of neutrophils and monocytes is a fast, inexpensive method for diagnosis of Paroxysmal nocturnal hemoglobinuria (PNH). Although CD55/CD59 analysis of neutrophils is the most sensitive method, it has limitations that flow cytometric analysis should be performed within 4 hours after the collection of specimens. In cases of referred specimens from other laboratories, it is practically impossible to proceed the test within 4 hours.
Aims: In this study, we analyzed the CD55/CD59 expression on the surface of monocytes which are relatively stable than red blood cells and granulocytes, and we compared the effect of time after specimens were prepared.
Methods: Specimens from 53 patients who were suspected as PNH were included in the flow cytometric analysis of CD55, CD59 expression on the surface of red blood cells, neutrophils and monocytes. In order to examine the effects of time, three PNH- negative specimens were analyzed for the measurement of CD55, CD59 in three types of cells at time of 0, 4, 8, 24, 48, 72 hour after the specimens were prepared.
Results: 24 specimens among 50 samples showed positive results in PNH study with less than 95% expression of CD55 or CD59. The remaining 29 specimens were negative in PNH study with more than 95% expression of both CD55 and CD59. CD55/CD59 positivity rate of the 24 specimens was 76.2%/80.9%, 90.5%/90.5%, 81.9%/90.5% for red blood cells, neutrophils and monocytes, respectively. There was no effect in results measured on three types of cells at different time periods.
Summary and Conclusions: : In patients with PNH-positive results, the positivity rate of CD55/CD59 in monocytes was higher than that in red blood cells, wheras that of CD59 was similar in neutrophils. The measurement of CD55/CD59 in monocytes is useful for the diagnosis of PNH when CD55/CD59 is negative in red blood cells but positive in neutrophils. Previous studies have recommended that CD55/CD59 analysis in neutrophils should be done within 4 hours of specimen collection. However, we have demonstrated that three types of cells including red blood cells and monocytes were all stable 72 hours after the specimen collection.

CD137 LIGAND SIGNALING INDUCES OF PROLIFERATION AND SURVIVAL OF MULTIPLE MYELOMA CELL

Z Fu[1,*] H Liu[1], J Wang[2], L Ma[1], S Ju[3], D Wu[1]
[1]the First Affiliated Hospital of Soochow University, [2]the Jiulong Hospital, [3]Soochow University, Suzhou, China

Background: CD137 ligand (CD137L) is mainly expressed by antigen presenting cells, including mature dendritic cells, monocytes /macrophages and B cells. While, the new studies have testified that the CD137L is expressed by various carcinoma cells too. However, the expression of CD137L and the function on multiple myeloma cells is unknown.
Aims: To explore the expression of CD137L and the function on multiple myeloma cells.
Methods: We identified the constitutive expression of CD137L by flow cytometry on U266, RPMI 8226, LP1, MY5 and KMS-11 of Multiple myeloma (MM) cell lines as high as 96%, 97.5%, 89%, 93% and 94%.But, CD137 expressed on the cell surface was low as 4%, 5%, 1%, 2%, 5% respectively. Now that, CD137L was expressed very strongly on MM cell lines, next, we investigated CD137L expression on primary MM cells from 126 BM samples of patients diagnosed of active multiple MM. We found CD137L protein was expressed by a select group of CD45-CD38++CD138+cells (n=126), but not as higher as MM cell lines. Separating those cases in different grouping according to osteolytic bone disease and plasmacytoma, we found highest expression of CD137L in cases with no osteolytic bone disease or no plasmacytoma and the lowest levels of CD137L in cases with more osteolytic bone disease(*P*=0.012). However, CD137L expression was not or hardly detectable on normal plasma cells confirmed by CD45+CD38++CD138+ CD56- CD19+.
Results: *in vitro* study, U266 cells were cultured in 24-well plates or in 96-well plate pre-coated with mAb 1F1 or irrelevant mouse IgG. The proliferation and survival of U266 was enhanced by stimulating- CD137L mAb (1F1) than those induced by control mouse IgG by cell counting and CFSE assay at incubation for 48h. In addition, the cell cycle analysis showed that CD137L induces proliferation and increases the number of cells in the S phase from 36.1% to 42.5% after 72h incubation. Apoptosis was assessed by the externalization of phosphatidylserine, assayed by the Annexin V and PI apoptosis detection. The U266 cells were stained at incubation for 48h and analyzed by flow cytometry. The percentage of apoptosis cells was 19.6% *VS* 21.2% with no statistical significance. We surveyed the cytokine profiles during the incubation of U266 cells cultured for 2 days with different stimuli with mAb 1F1 compared with the control group. Intracellular cytokine staining showed that treatment of cells with 1F1 increased the production of IL-6 from 3.8% to 63.9% by Flow cytometry. When neutralizing anti-IL-6 mAb was added to the culture medium, the cells were cultured for 48 h in pure medium or plus Fc or CD137–Fc protein and the cell proliferation measured by WST-8 was 0.79 *VS* 0.80 *VS* 0.72, the average of 6-well plates absorbance.1F1-induced cell proliferation was effectively inhibited. An increase of these cytokines might explain why CD137L expression could stimulate the proliferation of U266. Finally, the U266 cells were treated with bortezomib and the growth of cells was analyzed by WST-8 assay. It demonstrated that bortezomib could inhibit the function of 1F1 and the inhibition ratio of bortezomib was 22%, 51% and 58% at 24h, 48h and 72h.
Summary and Conclusions: In our study, CD137L is a promoting proliferation factor. This suggests the possibility that its expression on MM cells may be directly target for immunomodulatory therapy for MM.

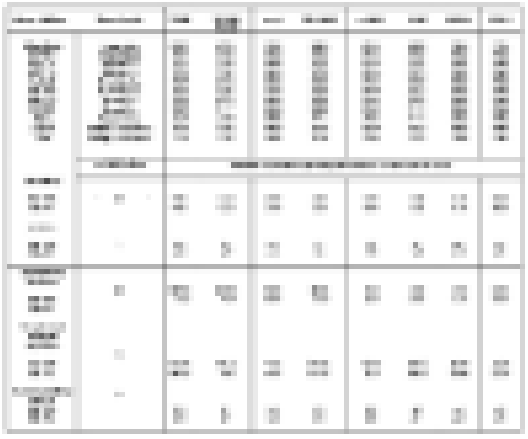
PB1621

EXPRESSION OF ANGIOGENIC FACTORS AND MATRIX-METALLO PROTEINASES IN BONE MARROW AND PERIPHERAL BLOOD PLASMA CELLS OF MULTIPLE

MC Rapanotti[1,*] L Franceschini[1], TM Suarez Viguria[1], L Tonialini[2], S Vaccarini[2], C Ialongo[1], M Rizzo[2], L Cicconi[2], A Zizzari[2], L Gianni[2], L Pupo[2], M Cantonetti[2], M Postorino[2], F Lo Coco[2]
[1]Laboratory Medicine, [2]Department of Biomedicine and Prevention-Haematology , Policlico "Tor Vergata" University of Rome, Rome, Italy

Background: Bone Marrow (BM) angiogenesis is involved in the pathogenesis and progression of multiple myeloma (MM). Moreover, studies on BM biopsies indicate that changes in BM composition from benign conditions such as M-GUS to early stage multiple myeloma (smoldering myeloma, SMM) and to advanced multiple myeloma (MM) follow a precise pattern, including an increase in the degree of angiogenesis and secretion of matrix-metalloproteinase-degrading enzymes (MMP) (1).
Aims: We compared the angiogenic potential and MMPs gene expression in BM and peripheral blood plasma cells from M-GUS, SM and active MM patients.
Methods: Among the pro-angiogenic factors and the MMP enzymes, we analysed by PCR the expression of VEGF, Ang-2, MUC18/MCAM, bFGF, and MMP-2 and MMP-9. e-CADH (epithelial cadherin) and the VE–CADH (vascular endothelial cadherin) genes. Epithelial and MM cell lines were used as controls. PC were separated from BM and PB specimen with antibodies against CD138 as described by manufacturer (Voden-Stem Cell Technology Inc., Milan, Italy) from patients with the following diagnoses: 7 M-GUS, 20 SMM, 20 MM, (4 of the were extramedullary MM). After total cellular RNA extraction, we performed oligo- $d(T)_{16}$-RT and primer-specific-PCR. Primer sequences were designed in house. The house-keeping b-2-microglobulin gene was used as internal control.
Results: Molecular expression of angiogenic factors and metallo-proteinases is summarized in the Table 1 below. BM-PC expression pattern of angiogenic factors and MMP was more restricted compared to PB-PC. Expression was constantly absent in M-GUS PC with exception for a weak MMPs positivity for PB-PC. No angiogenic markers were expressed alone, but always in association with others including VEGF+MUC18/MCAM+Ang2 (particularly in SMM) or bFGF and the MMPs (particularly, in 5 SMM and the symptomatic MM). Similarly to M-GUS, 7 out of 20 SMM did not co-express angiogenic factors, while the remaining 13 co-expressed several markers. We detected e-CADH expression in 100% of BM-PC (16/16) and in 87.5% (14/16) of symptomatic MM and in 5 SSM which shared a similar expression pattern of angiogenic factors. No e-CADH expression was detected in extra medullary BM-PC and in the PB-PC of MM.

Table 1.



Summary and Conclusions: Our preliminary data indicate that increasing angiogenic factors expression follows the disease *spectrum* from M-GUS to MM. In particular, early markers of angiogenesis such as VEGF, Ang2 and MUC 18/MCAM seem to be expressed on SMM while the co-expression of all the above markers together with bFGF and the MMPs is associated with the active disease. Our data on e-CADH, an epithelial cell adhesion molecule, found to be expressed by MM-PC represent a novel unexpected finding deserving further investigation.

LIGHT INVOLVEMENT IN MULTIPLE MYELOMA-OSTEOLYTIC BONE DISEASE

G Brunetti[1,*] R Rizzi[2], I Gigante[1], A Oranger[1], G Mori[3], C Carbone[1], T Mongelli[1], S Scardino[2], B Daraia[2], P Curci[2], A Mestice[2], A Zallone[1], S Colucci[1], G Specchia[2], M Grano[1]
[1]Department of Basic and Medical Sciences, Neurosciences and Sense Organs, section of Human Anatomy and Histology, [2]Department of Emergency and Organ Transplantation, Section of Hematology with Transplantation, University of Bari, Bari, [3]Clinical and Experimental Medicine, University of Foggia, Foggia, Italy

Background: Multiple myeloma (MM)-osteolytic bone disease occurs in about 70% of newly diagnosed patients, and up to 90% at relapse. It is characterized by an unbalanced bone remodelling, due to increased osteoclast (OC) activity and impaired osteoblast repair. Osteoclastogenesis is regulated by members

of TNF superfamily. Among these, there is LIGHT/TNFSF14 recently implicated in the pathogenesis of joint diseases with increased bone resorption, as the rheumatoid arthritis. LIGHT is expressed by activated T-cells, monocytes, granulocytes, spleen cells, and immature dendritic cells, and it is described as a potent T-cell co-stimulatory molecule.
Aims: Here, we purposed to investigate a possible role of LIGHT in the mechanisms of the enhanced osteoclastogenesis occurring in MM-osteolytic bone disease.
Methods: Peripheral blood (PB) and bone marrow (BM) aspirates were obtained from 40 patients (23M/17F, median age: 64 years), newly diagnosed as having symptomatic MM with or without osteolytic bone disease, smoldering MM (sMM) or Monoclonal Gammopathy of Undetermined Significance (M.G.U.S.). Osteolytic lesions were detected by skeleton standard radiography, and in some cases also by spine and pelvis nuclear magnetic resonance. The control group included PB and BM aspirates from 15 patients with non-neoplastic disease without any skeletal involvement as well as PB from 25 healthy donors matching for age and sex with the patients' group. Patients and controls gave their written informed consent to the study, approved by the local Ethical Committee and performed according to the Declaration of Helsinki. By means of flow cytometry, Western Blotting and real-time PCR, LIGHT expression was evaluated in freshly purified CD14+ monocytes, CD2+ T-cells and neutrophils from PB and BM aspirates of patients and controls. OCs were obtained from unfractionated PB mononuclear cells (PBMCs) cultured in the presence or in the absence of an anti-LIGHT neutralizing monoclonal antibody (mAb). Mature OCs were identified as multinucleated tartrate-resistant acid phosphatase (TRAP) positive cells.
Results: In the CD14+ monocytes, $CD2^+$ T-cells and neutrophils isolated from PB and BM of patients with MM-osteolytic bone disease, at both protein and mRNA levels LIGHT was found more expressed than in the cells isolated from the patients with symptomatic MM without bone disease, sMM, M.G.U.S, non-neoplastic disease without any skeletal involvement, and healthy donors. The *in vitro* effect of the anti-LIGHT mAb on osteoclastogenesis resulted in a significant reduction of the OC formation ($p<0.001$).
Summary and Conclusions: Our findings support a possible involvement of LIGHT in the mechanisms of the osteoclastogenesis occurring in MM-osteolytic bone disease.

PB1623

BORTEZOMIB INDUCED EXPRESSION OF HEME OXYGENASE 1 VIA ENDOPLASMIC RETICULUM STRESS

V Di Martina[1,*] D Tibullo[1], I Barbagallo[2], C Conticello[1], C Giallongo[1], P La Cava[1], N Parrinello[1], G Rizzo[1], M Cavalli[1], A La Fauci[1], ML Consoli[1], A Romano[1], S Saccone[3], G Li Volti[2], F Di Raimondo[1]
[1]Clinical and Molecular Biomedicine, section of Hematology - Ferrarotto Hospital, [2]Clinical and Molecular Biomedicine, [3]Department of Biological, Geological and Environmental Sciences, University of Catania, Catania, Italy

Background: The proteasome inhibitor Bortezomib (BO) is one of the most effective drugs in the treatment of Multiple Myeloma (MM) but eventually patients became refractory to this drug. Heme Oxygenase 1 (HO-1) is a cytoprotective microsomal enzyme that catalyzes the degradation of heme into to carbon monoxide, biliverdin and ferrous iron. It plays a pivotal role in inflammation, oxidation and apoptosis and it is increased by endoplasmic reticulum (ER) stress. It has been also recently described that Bortezomib is able to increase HO-1 expression (Barrera, Cell Cycle 2012).
Aims: We have investigated the effect of BO on 2 MM cell lines (U266, SKM-M1). As expected, we observed that BO induced apoptosis after 24h of incubation. We have studied the ability of BO to induce endoplasmic reticulum (ER) stress and we have used as positive control the effect of Thapsigargin, a known inducer of ER stress.
Methods: Apoptosis was evaluated by cytometric analysis (annexin V). Using western blot, we assessed HO-1 and protein markers of ER stress. The compartimentation of HO1 was observed in myeloma cell lines by confocal microscope
Results: Similarly to Thapsigargin, BO was able to induce the expressionof Bip, IRE1alfa , Ero1, PERK and CHOP (some proteins involved in the activation of ER stress) in multiple myeloma cells after 6 h with a peak after 24 h of treatment. Noteworthy, the increased expression of CHOP has to be considered as an index of ER-stress-induced apoptosis, suggesting that induction of apoptosis in multiple myeloma cells by BO can be attributed also by triggering ER stress. Both BO and thapsigargin were also able to induce a significant increase in mRNA levels of HO-1 after 3 hours (h) of treatment with a maximum peak after 6h.All these effects were reverted by adding the chemical chaperone 4-Phenylbutyric acid (4 – PBA). Moreover, flow cytometry analysis revealed that the levels of reactive species of Oxygen (ROS) were increased after 1h of BO treatment with a peak after 3h. By confocal microscope we observed that HO-1 is localized both in the cytoplasm and also in the nucleus of MM cell line and that blockage of HO 1 nuclear translocation, with a selective inhibitor of the protein cleavage, E64, induces this MM cell line to become more sensitive to the cytotoxic effect of BO.
Summary and Conclusions: Our data suggest that BO- induction of HO1 is probably due to the ability of bortezomib to induce ER stress. We hypothesize that HO-1 induction may be involved in the mechanisms of MM drug resistance and that the cytotoxic effect of bortezomib can be potentiated when HO-1 is inhibited to translocate into the nucleus of MM cells.

PB1624

SPHINGOSINE 1-PHOSPHATE AS A THERAPEUTIC TARGET IN MULTIPLE MYELOMA CELLS

Y Tanaka[1,*] S Okabe[1], T Tauchi[1], Y Ito [1], T Umezu[2], JH Ohyashiki[2], K Ohyashiki[1]
[1]First department of internal medicine, [2]Department of Molecular Science, Tokyo medical university, Shinjuku-ku, Japan

Background: Multiple myeloma (MM) is one of the common hematological malignancies and is a uniformly fatal disorder of B cells characterized by accumulation of abnormal plasma cells in the bone marrow. Clinical outcomes for patients of MM have improved with the treatment, including the proteasome inhibitor. However many patients have a relapse of disease and develop drug resistance. Since the prognosis remains poor for patients with refractory disease, the new therapeutic strategies are required to treat against refractory MM patients. Sphingosine-1-phosphate (S1P) is a potent bioactive sphingolipid. Two isoforms of sphingosine kinases (SphKs), SK1 and SK2, catalyze the formation of the S1P in mammalian cells. SphK has also been shown to be up-regulated in the variety of cancer types.
Aims: S1P is involved with cell proliferation, angiogenesis, cell transformation, oncogenesis and cell survival in malignancies such as multiple myeloma. One of the S1P analogue, fingolimod (FTY720), which is an orally active immunomodulatory drug and developed for the treatment of multiple sclerosis. SKI-I, which is a non-lipid pan-SphK inhibitor and ABC294640, which is selective inhibitor of SK2, is currently being investigated in a pivotal phase 1 clinical trial against solid tumors. Therefore S1P and SphKs may present attractive targets for MM treatment.
Methods: In this study we investigated the efficacy of fingolimod, SKI-I and ABC294640 by the use of MM cell lines, which is RPMI8226, MM1.S, MM1.R, and primary MM patients samples.
Results: 72 h treatment of fingolimod exhibits cell growth inhibition of MM cell lines in a dose dependent manner. Treatment of SKI-I and ABC294640 also exhibits cell growth inhibition in a dose dependent manner. Because S1P is the ligand for a family of five G-protein-coupled receptors with distinct signaling pathways that regulate angiogenesis and chemotaxis, we next evaluated the chemotactic response of human umbilical vein endothelial cells (HUVEC). We determined the S1P receptors expression profiles of HUVECs by RT-PCR. Our results indicated that at least S1P1 and S1P3 were expressed in HUVECs. We found that 4 h treatment of S1P significantly induced the migration of HUVECs. Treatment of HUVECs with fingolimod inhibited S1P-stimulated chemotaxis. We also found that S1P-induced chemotaxis of HUVECs was abolished by the SKI-I and ABC294640. These facts suggested that intracellular SK1 and SK2 may play the important role in S1P induced chemotaxis of HUVEC. We next investigated the S1P concentrations in MM patients by enzyme-linked immune sorbent assay (ELISA) because S1P may be a potent tumorigenic growth factor that releases from tumor cells. We found that plasma concentrations of S1P were significantly higher in patients with MM compared with normal samples. We also found that conditioned medium from MM cell line had chemotactic activity for HUVECs.
Summary and Conclusions: These results implicate that S1P may be a novel biomarker for early stage of MM and S1P might be an important bioactive sphingolipid involved in angiogenesis. In this study, we also demonstrate that fingolimod, SKI-I and ABC294640 have potent preclinical anti-tumor activity in MM and also inhibit the angiogenesis. These facts offer unique opportunities for novel therapeutic strategies for the treatment of multiple myeloma.

PB1625

MAST CELL DENSITY IN BONE MARROW CORRELATES WITH BOTH ANGIOGENIC AND PROLIFERATIVE ACTIVITY IN MULTIPLE MYELOMA

G Tsirakis[1,*] A Boula[2], A Kolovou[3], E Stavroulaki[2], M Tzimou[3], S Kyriakaki[1], A Papadopoulou[4], C Pappa[2], M Alexandrakis[1]
[1]Hematology, University Hospital of Heraklion, [2]Hematology, Venizelion Hospital, Heraklion, [3]Hematology, General Hospital of Chania, Chania, [4]Hematology Laboratory, University Hospital of Heraklion, Heraklion, Greece

Background: There is increased mast cell density (MCD) in multiple myeloma (MM) bone marrow (BM), being correlated with the disease stage. Mast cells produce various mediators, promoting MM growth in multiple manners.
Aims: The purpose of this study was to estimate whether BM MCD correlates with markers of disease activity, such as levels of LDH, BM Ki-67 proliferation index, and with the angiogenic potential, estimated by BM microvascular density (MVD) in MM.
Methods: We studied in 42 newly diagnosed active MM patients (19 male,

mean age 66.5±10.1 years, 26 IgG, 12 IgA, 4 light chain, ISS: 12 stage I, 14 II and 16 III), and in 22 healthy controls the immunohistochemical expression of CD31, mast cell thryptase, Ki-67 and CD38, in order to estimate MVD, MCD, Ki-67 proliferation index (Ki-67 PI) and infiltration by plasma cells respectively, as well serum levels of LDH.
Results: All values were higher in active MM patients compared to healthy population ($p<0.001$ for all cases). They also were in parallel with ISS stage ($p<0.003$ for infiltration, $p<0.004$ for LDH and $p<0.001$ for the other cases). Moreover, BM MCD correlated positively with Ki-67 PI ($r=0.537$ $p<0.0001$), BM infiltration ($r=0.431$ $p<0.004$) and MVD ($r=0.360$ $p<0.02$).
Summary and Conclusions: Mast cells are inflammatory cells, increased in MM BM, participating in many aspects of the disease. They may release various mediators, increasing directly and indirectly myeloma growth. They may also contribute to increased angiogenesis, through various mechanisms. Overall, mast cells seem to be important cells in MM biology, rendering them alluring targets for therapy.

PB1626

MYELOID AND LYMPHOID IMPAIRMENT IN MONOCLONAL GAMMOPATHY: AN IMMUNOPHENOTYPE STUDY
N L Parrinello[1], A Romano[1,2,*] C Conticello[1], M Cavalli[1], C Vetro[1], A Triolo[1], A Chiarenza[1], A La Fauci[1], M Consoli[1], G Rizzo[1], G A Palumbo[1], F Di Raimondo[1]
[1]Department of Clinical and Molecular Biomedicine, Haematology Section, University of Catania, Catania, [2]Fondazione Veronesi, Roma, Italy

Background: In Multiple Myeloma (MM), but not in the monoclonal gammopathy of unknown significance (MGUS), the immune function is impaired as consequence of an immunologically hostile microenvironment and cellular defects, including reduction of immuno-surveillance and T-cell immunoparesis. Myeloid-derived suppressor cells (MDSC) are a heterogeneous population of myeloid cells with peculiar immunosuppressive properties against T-cells, well described in solid tumors and recently evaluated in MM.
Aims: We hypothesized immune suppression, detectable at the same time in both myeloid and lymphoid arms can play a role in favoring MM progression and its clinical presentation.
Methods: We evaluated by flow cytometry main suppressive subpopulations investigable in peripheral blood within lymphoid (T-reg, CD62L T cells) and myeloid arm (three phenotypes of MDSC: mo-MDSC, G-MDSC, CD34+-MDSC) in 30 newly diagnosed MM patients treated upfront with lenalidomide compared with 30 MGUS and 30 healthy subjects matched for sex and age.
Results: We found that MM patients exhibit an increased levels of percentage of circulating G-MDSC ($p<0.001$) and mo-MDSC ($p=0.029$) and absolute number of CD34+MDSC ($p=0.009$), with the concomitant down-regulation of CD62L expression on CD8+T-lymphocytes ($p<0.0001$) and an increased percentage of T-reg ($p=0.01$). All patients except 3 obtained at least a partial remission (reduction of more than 50% of monoclonal component present at baseline). After induction therapy, all MDSC subtypes evaluated were significantly reduced ($p=0.003$). None of the immunological parameters at baseline was predictive of the response quality achievable or of progression free survival (PFS), except percentage of G-MDSC. Patients with G-MDSC>60% had a longer PFS than those with less than 60% (13.9 *versus* 42.6 months, $p=0.028$). G-MDSC percentage was independent from any clinical variable at diagnosis except the neutrophils to lymphocyte ratio (r square 0.60, $p<0.0001$). T-reg cells progressively reduced from the first to the last administered cycle (respectively, $p<0.001$).
Summary and Conclusions: Taken together our data suggest that MM expansion needs immunoparesis involving T-reg and MDSC cells in order to maintain poor tumor-specific immune response, phenomenon that can be overcome by new drugs, such as lenalidomide.

IMMUNOHISTOCHEMICAL EXPRESSION OF ENDOGLIN ESTIMATES BONE MARROW NEOANGIOGENESIS IN MULTIPLE MYELOMA
G Tsirakis[1,*] A Kolovou[2], A Boula[3], M Tzimou[2], E Stavroulaki[3], M Devetzoglou[1], A Papadopoulou[4], P Kanellou[1], M Alexandrakis[1]
[1]Hematology, University Hospital of Heraklion, Heraklion, [2]Hematology, General Hospital of Chania, Chania, [3]Hematology, Venizelion General Hospital, [4]Hematology Laboratory, University Hospital of Heraklion, Heraklion, Greece

Background: Bone marrow (BM) microvascular density (MVD), represents the angiogenic process and is prognostic in multiple myeloma (MM). Endoglin (CD105) is highly expressed on endothelial cells in sites of active neoangiogenesis but not when they are in rest. The estimation of CD105-MVD seems to be prognostic in several solid tumors.
Aims: The purpose of the study was to estimate if endoglin is a reliable marker of BM neoangiogenesis in MM.
Methods: We measured in 47 patients with active MM (24 male, mean age 67.4±10.4 years, 29 IgG, 14 IgA, 4 light chain, ISS: 10 stage I, 17 II and 20 III), in 19 of them who responded to bortezomib-based therapy (8 in CR, 11 in VGPR), and in 20 controls: serum levels of soluble CD105 and basic-fibroblast growth factor. We also estimated immunohistochemically BM MVD using both CD31 (being an established marker) and CD105.
Results: All values were higher in active MM, in parallel with ISS stage and decreased after effective treatment. CD105-MVD estimation was lower than CD31-MVD both in the entire group of active MM patients and in each stage separately ($p<0.001$ for all cases), but not in remission patients. CD105-MVD correlated with all angiogenic markers.
Summary and Conclusions: CD105-MVD is following the known behavior of CD31-MVD in MM, suggesting that it is a reliable marker of BM neoangiogenesis in MM. Its prognostic impact remains to be proven.

PB1629

CIRCULATING LEVELS OF SOLUBLE FAS LIGAND IN MULTIPLE MYELOMA
A Kolovou[1,*] G Tsirakis[2], M Tzimou[1], S Kyriakaki[2], Z Haroniti[3], G Metohianakis[3], N Androulakis[3], P Spatharaki[3], M Alexandrakis[2]
[1]Hematology, General Hospital of Chania, Chania, [2]Hematology, [3]Hematology Laboratory, University Hospital of Heraklion, Heraklion, Greece

Background: Multiple myeloma (MM) plasma cells seem to be apoptosis-resistant. Therefore, the system of Fas/FasL may possess other properties.
Aims: The purpose of the study was to correlate serum levels of soluble Fas ligand (Fas-L) in MM patients with markers of disease activity.
Methods: We studied 57 newly diagnosed patients with active MM (28 male, median age 67 years, range 54-83 years, with paraprotein: IgG in 33, IgA in 18 and light chain disease in 6 patients, concerning staging: 13 in ISS I, 22 in II and 22 in III) and 22 age and sex-matched, healthy controls. Values of beta-2 microglobulin (B2M) and C-reactive protein (CRP) were measured on routine examination. Serum levels of soluble Fas-L and interleukin-6 (IL-6) were measured by ELISA, whereas bone marrow infiltration by malignant plasma cells was estimated immunohistochemically using CD38 as marker (routine examination).
Results: Serum levels of measured parameters were higher in active MM patients compared to controls ($p<0.001$ for all cases). All values were also increasing in parallel with the disease ISS stage ($p<0.001$ for all cases). Significant positive correlations were found between serum levels of soluble Fas-L with IL-6 ($r=0.460$), percentage of BM infiltration ($r=0.490$ $p<0.001$ for both cases) and LDH ($r=0.271$ $p<0.04$), but not with values of CRP and B2M.
Summary and Conclusions: It seems that serum levels of soluble Fas-L are in parallel with disease activity. This observation suggests that the system of Fas/Fas-L may not induce apoptosis in MM cells but, on the contrary, may promote tumor growth, using other, non-apoptotic pathways. The non steady correlation with all markers of disease activity suggests an indirect manner on promotion of MM growth. By these means, activation of Fas/Fas-L system in MM bone marrow microenvironment may up-regulate invasion-related genes, may promote recruitment of pro-inflammatory cells and moreover may possess immunosuppressive role against T cell mediate cytotoxicity.

PB1630

ANTINEOPLASTIC EFFECTS OF VARIOUS TARGETED DRUGS ON PRIMARY MYELOMA CELLS AND FIVE DEFINED MYELOMA CELL LINES
K Blatt[1,*] H Herrmann[2], B Peter[1,2], G Stefanzl[1], D Berger[1], P Valent[1,2]
[1]Department of Internal Medicine I, Division of Hematology & Hemostaseology, [2]Ludwig Boltzmann Cluster Oncology, Medical University of Vienna, Vienna, Austria

Background: Multiple Myeloma (MM) is a plasma cell malignancy characterized by monoclonal paraproteinemia, bone marrow plasmocytosis, and osteopathy. During the past few years, novel effective treatment strategies have been developed, but MM is still a clinical challenge and many patients relapse. Therefore, several attempts have been made to identify new effective agents in MM.
Aims: We examined the effects of 15 targeted drugs on growth and survival of five defined MM cell lines (MM1.S, NCI-H929, OPM-2, RPMI8226, U266).
Methods: Apoptosis was measured by morphology evaluation and microscopy as well as by Annexin/PI-staining and Caspase-3-staining by flow cytometry and proliferation was determined by ^{3}H-thymidine uptake. In consecutive experiments, we examined the effects of the most potent drugs on apoptosis

and proliferation of primary neoplastic cells obtained from patients with MM
Results: Of all drugs tested, the PI3-kinase blocker NVP-BEZ235, the pan-Bcl-2 inhibitor obatoclax, the Hsp90-inhibitor 17AAG, and the PLK-1 blocker BI2536 showed major growth-inhibitory and apoptosis-inducing effects (IC50<1μM) in all cell lines tested. All four compounds were found to inhibit the *in vitro* proliferation of MM cells at pharmacologically meaningful concentrations (IC50 <1 μM). Growth-inhibitory drug effects were accompanied by signs of apoptosis. Apoptosis-inducing effects of 17AAG, BI2536 and NVP-BEZ235 were seen in primary bone marrow-derived myeloma cells as well as in the CD20+/CD27+/CD138- subfraction of putative myeloma stem cells. Next, we examined cooperative antineoplastic effects of these drugs. Major cooperative effects on proliferation of MM cell lines were obtained with the following combinations: 17AAG+NVP-BEZ235 (MM1.S, OPM2, RPMI8226, U266), 17AAG+BI2536 (MM1.S, OPM2, RPMI8226, U266), 17AAG+obatoclax (MM1.S, NCI-H929, OPM2, RPMI8226), BI2536+NVP-BEZ235 (MM1.S, NCI-H929, OPM2, RPMI8226), BI2536+obatoclax (MM1.S, OPM2, RPMI8226), and NVP-BEZ235+obatoclax (MM1.S, RPMI8226).
Summary and Conclusions: In conclusion, several different targeted drugs induce anti-proliferative and apoptosis-inducing effects on human MM cells. Whether these effects also occur *in vivo* in MM patients remains so far unknown.

SERUM LEVELS OF INTERLEUKIN-22 CORRELATE WITH MYELOMA ACTIVITY

G Tsirakis[1,*] A Kolovou[2], C Pappa[3], A Boula[3], E Stavroulaki[3], I Konsolas[4], M Tzimou[2], M Devetzoglou[1], M Kokonozaki[5], R Vyzoukaki[5], M Alexandrakis[1]
[1]Hematology, University Hospital of Heraklion, Heraklion, [2]Hematology, General Hospital of Chania, Chania, [3]Hematology, Venizelion Hospital, Heraklion, [4]Hematology, General Hospital of Rhodes, Rhodes, [5]Hematology Laboratory, University Hospital of Heraklion, Heraklion, Greece

Background: Interleukin-22 (IL-22) is a pro-inflammatory cytokine, participating in several aspects of diseases.
Aims: The purpose of the study is to estimate the participation of IL-22 in the inflammatory process of multiple myeloma (MM).
Methods: We studied 51 newly diagnosed active MM patients (25 male, mean age 69.4±13.2 y, 25 IgG, 14 IgA, 2 light chain, ISS: 14 stage I, 16 II and 21 III), 22 of them after effective treatment (CR and VGPR) and 18 controls. We measured serum levels of IL-22, IL-1beta, B2microglobulin (B2M) and paraprotein, as well the degree of bone marrow infiltration.
Results: Serum levels of IL-22, IL-1beta and B2M were significantly higher in active MM patients (p<0.001 for all cases). All values were increasing in parallel with ISS stage (p=0.025 for paraprotein, p<0.001 for the other cases). Serum levels of IL-22 correlated positively with IL-1beta (r=0.614), B2M (r=0.631) and infiltration (r=0.566, p<0.0001 for all cases), but not with paraprotein level. All values decreased significantly in the responders (p<0.001 for all cases). It is remarkable that pre-treatment values of IL-22 were, not significantly, lower in responders compared to entire group. Furthermore, post-treatment values of IL-22 were significantly higher in responders compared to controls (p<0.001).
Summary and Conclusions: IL-22 follows MM activity, suggesting an important participation in its biology. This increased occurrence of IL-22 in bone marrow microenvironment may enhance myeloma proliferation and growth, and moreover, may participate in the mechanisms of immune deregulation of the disease. It seems to be part of the inflammatory process, which remains active even after remission.

PB1632

SERUM LEVELS OF SELECTED PARAMETERS OF BONE MICROENVIRONMENT PREDICT OVERALL SURVIVAL IN MULTIPLE MYELOMA PATIENTS REGARDLESS OF TREATMENT REGIMEN USED

J Minarik[1,*] Z Golova[2], P Petrova[3], J Bacovsky[1], T Pika[1], J Zapletalova[4], V Scudla[1]
[1]Department of Internal Medicine III, University Hospital and Palacky University Olomouc, [2]Medical Faculty of Palacky University Olomouc, [3]Department of Clinical Biochemistry, [4]Department of Medical Biophysics and Statistics, University Hospital and Palacky University Olomouc, Olomouc, Czech Republic

Background: Several cytokines have been identified as potent inductors of myeloma bone disease (MBD) or growth factors in multiple myeloma (MM). Their serum levels often correlate with the extent or aggressiveness of the disease, and, even with prognosis of MM.
Aims: Our aim was to assess serum levels of selected parameters of bone marrow microenvironment with respect to survival functions.
Methods: We have assessed serum levels of 6 selected parameters of bone marrow microenvironment – hepacyte growth factor (HGF), syndecan-1 (SYN), osteopontin (OPN), macrophage inhibitory protein 1α and 1β (MIP-1α, MIP-1β), osteoprotegerin (OPG) and endostatin (END) in a cohort of 52 patients with MM with regard to overall survival (OS), progression free survival (PFS), time to progression (TTP) and duration of response (DOR) after induction treatment line. The patients were treated using biological based regimens (*i.e.* with thalidomide, bortezomib and lenalidomide) or with high-dosed chemotherapy with support of autologous stem cell transplantation. For statistical estimation we used Mann-Whitney U test, ROC analysis, Kaplan-Meier analysis, Cox regression and log rank test at p<0,05.
Results: Out of the 6 evaluated parameters, we found significant correlation with OS in HGF (p=0,042), OPN (p=0,006) and OPG (p=0,029), the other parameters did not have significant differences. Based on these results we constructed ROC curves to find optimal cut-off value with the best discriminatory potential. For HGF the optimal cut-off value was 1919 ng/l with 70% sensitivity and 68% specificity. Patients with HGF<1919ng/l had significantly longer OS than patients with HGF ≥ 1919ng/l (M 6,6 *vs* 3,1 years, p=0,001). In the case of OPN, the optimal cut-off level was 97 ug/l with 68% sensitivity and 84% specificity, dividing the cohort into a group of patients with good prognosis with OPN<97 ug/l and poor prognosis with OPN ≥ 97 ug/l (M 8,0 *vs* 2,9 years, p<0,0001). The optimal cut-off level for OPG was 5,2 pmol/l with 69% sensitivity and 64% specificity. Patients with OPG<5,2 pmol/l had a benefit in survival with respect to patients with OPG ≥ 5,2 pmol/l (M 6,1 *vs* 3,6 years, p=0,015). There were no significant differences between any of the selected parameters with respect to induction treatment line, *i.e.* to PFS, TTP and DOR. Using the logistic regression and Cox regression analysis we constructed a model for short survival. Significant predictors of short survival were OPN ≥ 101 ug/l and OPG ≥ 5,2 pmol/l. OPN ≥ 101 ug/l significantly increased the risk of poor prognosis 5,3 times (95%CI: 1,4 - 19,9; p=0,013). OPG ≥ 5,2 pmol/l significantly increased the risk of poor prognosis 4,3 times (95%CI: 1,2 - 16,2; p=0,030).
Summary and Conclusions: Analysis of serum levels of the parameters of bone microenvironment contributes to closer understanding of biological mechanisms occuring in MM. Our analysis revealed three parameters with prognostic potential in multiple myeloma. Patients with high serum levels of hepatocyte growth factor, osteopontin and osteoprotegerin had significantly shorter overall survival regardless of treatment modality used. There were, however, no differences in PFS, TTP and DOR after the first line treatment suggesting long term outcomes of bone microenvironment processes rather than short term influence of the tumor burden.

PB1633

ROLE OF MONOCLONAL AND POLYCLONAL COMPONENTS IN THE EVALUATION OF K/L RATIO IN PATIENTS WITH MONOCLONAL GAMMOPATHY OF UNDETERMINED SIGNIFICANCE (MGUS)

M Pizzuti[1,*] A Santagostino[2], G Smaldore[3], A Matturro[1], I Chitarrelli[4], A Girardi[3], R Penitente[3], I Attolico[1], M Cimminiello[1], A Amendola[1], N Filardi[1], D Vertone[1], S Coluzzi[1], R Nuccorini[1], SP Pascale[1]
[1]Hematology, San Carlo, Potenza, [2]Onco-Hematology, Sant'Andrea, Vercelli, [3]Clinical Pathology, San Carlo, Potenza, [4]Immuno Hematology, Ospedale Civile, Lagonegro, Italy

Background: In a previous study we observed a significant correlation between immunoparesis and abnormal K/L ratio in patients with MGUS. We confirmed these results after an updated analysis of 123 cases. In patients with immunoparesis (n-64) K/L ratio is abnormal in 43 (67,1%), in those without immunoparesis (n-59) it is abnormal in 23 (38,9%) (P<0,001). K/L ratio can be altered due to the monoclonal chain levels increase or to polyclonal chain levels decrease. The first phenomenon is related to the burden disease, while the second is caused by a physiological loss of immune response.
Aims: Aim of this study was to investigate if both the phenomena are present in MGUS patients and to verify which one is a stronger predictor of progressive disease.
Methods: Patients were stratified in five groups (according to the polyclonal light chain value): 0 when the value was below the lower limit, 5 when it was above the upper limit and 1, 2, 3 and 4 according to the quartile in the normal range. We then correlated polyclonal light chain levels decrease (groups 0,1,2) with K/L ratio and with the presence of immunoparesis. Monoclonal light chain levels increase could be another cause of abnormal K/ L ratio so we correlated monoclonal light chain increase beyond the upper limit of normal range with K/L ratio.
Results: In patients with normal K/L ratio (n-57), polyclonal chain levels are decreased in 28 (49,1%). In those with abnormal K/L ratio (n-66), they are decreased in 54 (81,8%). P<0,0001. In patients without immunoparesis (n-59) polyclonal chain levels are decreased in 34 (57,6%), while in those with immunoparesis (n-64), they are decreased in 49 (76,5%). P=0,034. In patients with normal K/L ratio (n-57) the monoclonal chain levels are upper normal range in 22 (38,5%). In those with abnormal K/L ratio (n-66%) it is upper normal range in 60 (90,9%). P<0,0001. We could not stratify patients according to the monoclonal component (IgG *vs* IgA) because of the limited number of cases included in this study.

Summary and Conclusions: These data suggest that an abnormal K/L ratio could be related either to a reduced activity of immune system with a lower production of polyclonal light chains either to a higher production of monoclonal chains due to the burden disease. We need a longer follow up and a larger number of patients to clarify the role of these two factors in predicting the risk of progression.

THE ROLE OF ADIPOCYTOKINES IN MONOCLONAL GAMMOPATHIES – A PRELIMINARY STUDY

L Oliveira[1], AC Gonçalves[1,2,3], C Geraldes[3,4,5], AS Pais[1,6], E Cortesão[3,4,5], P Matafome[7,8], R Seiça[7,8], L Ribeiro[3,4], JM Nascimento-Costa[3,9,10], AB Sarmento-Ribeiro[1,2,3,4,*]

[1]Applied Molecular Biology and University Clinic of Hematology, Faculty of Medicine, University of Coimbra, [2]Center for Neuroscience and Cell Biology, [3]CIMAGO – Center of Investigation on Environment Genetics and Oncobiology, Faculty of Medicine University of Coimbra, [4]Clinical Hematology Service, Centro Hospitalar e Universitário de Coimbra (CHUC), [5]University Clinic of Hematology, Faculty of Medicine University of Coimbra, [6]Centro Hospitalar e Universitário de Coimbra (CHUC), [7]IBILI, [8]Fisiology, [9]Oncology and Paliative Care, Faculty of Medicine University of Coimbra, [10]Medicine Department, Centro Hospitalar e Universitário de Coimbra (CHUC), Coimbra, Portugal

Background: Multiple myeloma (MM) is a neoplastic disease characterized by the growth of malignant plasma cells in the bone marrow (BM) with a subsequent overproduction of a monoclonal protein and development of bone lesions and soft-tissue masses. This malignancy starts with a monoclonal gammopathy of undetermined significance (MGUS). In the transition from MGUS to MM, the BM microenvironment is believed to have a central role by producing cytokines as Interleukin-6, Interleukin-1b and tumor necrosis factor, that are correlated with the induction of angiogenesis and suppression of cell-mediated immunity, which are important factors for the progression to MM. Adipocytokines are a group of hormones produced by the adipose tissue that play an important role in energy homeostasis, hematopoiesis, immunity, inflammation and angiogenesis. Moreover, adipocytokines can exhibit pro-inflammatory (*e.g.* leptin) or anti-inflammatory (*e.g.* adiponectin) properties. There are studies that have shown that adipocytokines may have a role in the pathogenesis of some cancers such as colon and breast cancer and even hematological malignancies such as acute myeloid leukemia. Recent evidence showing that increased body mass index has a positive association with both mortality and incidence of MM, suggests that adipocytokines may have a role in the pathogenesis of MM.
Aims: This work aim to explore the role of adipocytokines, namely adiponectin, leptin, resistin, MCP-1 and TNF-α in the pathogenesis of Monoclonal Gammopathies and correlate these adipocytokines levels with patient's clinical characteristics.
Methods: A total of 34 monoclonal gammopathies patients (15 MGUS and 19 MM patients, those 3 with smoldering MM and 16 with symptomatic MM) and 37 healthy individuals were included in this study, after informed consent. MGUS patients had an average age of 70,9 years (ranged between 41 and 90 years), 60% female and 40% male. MM patients age ranged between 56 and 86 years (average of 73,5years), being 52,6% female and 47,4% male. Adiponectin, leptin, resistin, MCP-1 and TNF-α levels were quantified on the peripheral blood (PB) and BM using ELISA commercial kits.
Results: Our preliminary results have shown higher levels of resistin in PB of patients with monoclonal gammophaty (15,65±13,96 ng/mL) and MM (18,90±16,78 ng/mL) compared to controls (9,22±5,33 ng/mL). Besides that, resistin levels in PB are higher in symptomatic MM patients (20,91±17,61 ng/mL) when compared with controls (9,22±5,33 ng/mL) and with smoldering MM patients (8,17±1,79 ng/mL). The adiponectin levels were lower in symptomatic MM patients (6,93±5,70 µg/mL) compared with patients presenting smoldering MM (14,84±3,23 µg/mL). However, adiponectin was higher in smoldering MM patients (14,84±3,23 µg/mL) than those with MGUS (8,60±4,86 µg/mL). Furthermore, symptomatic MM patients that exhibit an IgG monoclonal component, had higher levels of MCP-1 in both PB (194,05±93,36 ng/mL) and BM (484,35±323,48 ng/mL). On the other hand, those who overproduce κ light chains show higher levels of MCP-1 in PB (242,25±155,39 ng/mL). According to ISS classification, stage 3 patients, also show higher levels of MCP-1 in PB than those on stage 1 (stage 3: 200,97±88,18 ng/mL; stage 1: 109,59±3,97 ng/mL).
Summary and Conclusions: Our study suggests that adipocytokines may be envolved in the pathogenesis of MM by creating a pro-inflammatory state in the BM that contributes to the carcinogenesis process. These findings might contribute to a better understanding of this malignancy, may allow the development of new treatment approaches and to improve the prognosis classification.

18F-FDG PET/CT AND 99MTC-MIBI SCINTIGRAPHY LOCALIZE ACTIVE MYELOMA LESIONS AND CORRELATE WITH INCREASED SERUM LEVELS OF THYMIDINE KINASE DETECTED BY NOVEL METHOD DIVITUM™

J Bacovsky[1,*] M Myslivecek[2], J Minarik[1], V Scudla[1], T Pika[1], J Zapletalova[3], T Adam[4], SJ Gronowitz[5], P Petrova[6], M Bartkova[6]

[1]Department of Internal Medicine III – Nephrology, Rheumatology and Endocrinology, [2]Department of Nuclear Medicine, Faculty of Medicine and Dentistry, Palacky Olomouc, Czech Republic, [3]Department of Medical Biophysics and Institute of Molecular and Translational Medicine, Faculty of Medicine and Dentistry, Palacky, [4]Department of Clinical Biochemistry, Faculty of Medicine and Dentistry, Palacky Olomouc, Czech Republic, Olomouc, Czech Republic, [5]Biovica AB, Uppsala Science Park, Uppsala, Sweden, [6]Department of Clinical Biochemistry, Faculty of Medicine and Dentistry, Palacky, Olomouc, Czech Republic

Background: Cell proliferation activity is a central independent prognostic factor and one of the targets for personalized and risk-adapted treatment in multiple myeloma (MM). Increased activity of thymidine kinase (TK) in serum is associated with higher proliferation rates in hematological malignancies. Imaging methods such as 99mTc-MIBI scintigraphy or 18F-FDG PET/CT can visualize active myeloma lesions and their positivity is a negative prognostic factor.
Aims: The study aimed at comparing two methods for evaluating thymidinekinase TK in serum – an older RIA method and novel DiviTum™ – in patients with MM and MGUS, and also comparing them with biochemical markers and degree of activity evaluated by imaging methods 99mTc-MIBI scintigraphy and 18F-FDG PET/CT.
Methods: Serum thymidinekinase TK levels were evaluated by DiviTum™ and an RIA method (TK REA kit by Immunotech);The study analyzed correlation of TK activity in serum with biochemical markers reflecting activity of MM: β2-m, LDH, the ratio of kappa to lambda (κ/λ) free light chains and percentage of bone marrow plasma cells (BMPC). 99mTc-MIBI scintigraphy and 18F-FDG PET/CT were performed at the time of diagnosis. The degree of activity was expressed semiquantitatively. Scans were classified as 0 (normal activity), 1 (diffuse positivity) or 2 (focal positivity).
Results: We found a strong positive correlation between TK in serum evaluated by DiviTum™ and by TK REA.. The DiviTum™ analytic method extended the detection range and was able to detect higher levels of TK than the RIA method. DiviTum™ technique found positive correlation with β2-m (r = 0.497) and LDH (r = 0.502) and moderate positive correlation with BMPC (r = 0.368). Significantly higher TK values measured by TK REA and DiviTum™ in the group of patients with MM (stages I, II or III) than in those with MGUS. Increased TK levels were observed in MIBI- or PET/CT-positive patients. Analysis of repeated measurements of TK in serum during treatment of MM patients found a correlation between change in TK measured by DiviTum™ and LDH during treatment.
Summary and Conclusions: Analysis revealed a significant correlation between TK in serum and LDH, β2-m and BMPC. Increased levels of TK in serum were observed in MIBI- or PET/CT-positive patients. Combination of positivity of imaging methods which can localize active tumor lesions and increased levels of TK in serum can have an impact on decision-making and optimization of the therapeutic approach.

PLASMA LEVELS OF MACROPHAGE CHEMOTACTIC PROTEIN-1 IN ASSOCIATION WITH PARAMETERS OF TUMOR BURDEN AND OTHER HUMORAL PROGNOSTIC FACTORS IN NEWLY DIAGNOSED MULTIPLE MYELOMA PATIENTS

T Valković[1,*] E Babarović[2], M Aralica[3], A Načinović-Duletić[1], D Petranović[1], I Host[1], T Juranović[1], I Seili-Bekafigo[4], K Lučin[2], N Jonjić[2]

[1]Department of Hematology, Clinical Hospital Center Rijeka, [2]Department of Pathology, Medical School Rijeka, University of Rijeka, [3]Department of Laboratory diagnostic, [4]Center for Cytology , Clinical Hospital Center Rijeka, Rijeka, Croatia

Background: The underlying role in pathogenesis of multiple myeloma (MM) and clinical relevance of the chemokine Macrophage chemotactic protein-1 (MCP-1) has not yet been fully elucidated. However, previous data suggest it's contribution in the homing of malignant plasma cells in bone marrow and angiogenesis.
Aims: The aim of this preliminary retrospective study was to determine potential association between pretreatment MCP-1 plasma levels, parameters of tumor burden (Durie-Salmon Stage- DSS and International Staging System- ISS) and some humoral prognostic factors, such as plasma levels of Vascular enothelial growth factor (VEGF), osteopontin (OPN), C-reactive protein (CRP) and lactate dehydrogenase (LDH). The association of plasma MCP-1 levels and patient survival was also evaluated.

Methods: diagnoses were established at the Department of Hematology, Clinical Center Rijeka, during the period from 2010 to 2012, according to the International Myeloma Working Group Criteria. Plasma levels of MCP-1, VEGF and OPN were measured by ELISA method in 45 untreated patients with MM (22 male and 23 female, median age 69 years, range 44-86) and 24 healthy controls (12 male i 12 female, median age 67 years, range 35-83). The values of LDH, CRP, as well as DSS and ISS are obtained from patient's medical records. The association of plasma MCP-1 concentration with patient survival was evaluated using Kaplan-Meier method, and differences between groups (high *vs.* low plasma levels) were tested by the log-rank test.
Results: certain amounts of MCP-1 were detected in plasma samples from all patients and controls. The median plasma level of MCP-1 in MM patients was 109.5 pg/ml (range 8.3 - 289.5 pg/ml) while median level for healthy controls was 104.9 pg/ml (range 69.5 – 234.5 pg/ml). There was no statistically significant difference in the values of MCP-1 between MM patients and control group ($p<0.949$). A significant positive correlation between plasma MCP-1 concentration and plasma OPN level ($r=0.418$; $p=0.006$) was determined, while there was a negative correlation between plasma MCP-1 and CRP levels ($r=-0.339$; $p=0.05$). However, no statistical differences were observed between plasma levels of MCP-1 and different stages of DSS ($p=0.276$) and ISS ($p=0.434$). Also there was no statistically significant association between MCP-1 plasma levels and VEGF ($p=0.745$), LDH ($p=0.268$) or patient surrvival ($p=0.638$).
Summary and Conclusions: in present pilot study the possitive associtaion between plasma levels of MCP-1 and OPN was established which can sugest the potential role of this chemokine in the pathogenesis of bone disease and angiogenesis. Furthermore, this association can implicate possible involvement of MCP-1 in the regulation of OPN secretion. Because of negative association between MCP-1 and CRP, which is surrogate measure of IL-6 and tumor aggressiveness, the pathogenetic and prognostic role of this chemokine should be clarified in the further prospective analysis of a large group of myeloma patients.

PB1637

CLINICAL CHARACTERISTICS AND PROGNOSTIC FACTORS IN PATIENTS WITH MULTIPLE MYELOMA FROM NORTH-EAST BRAZIL: A SINGLE CENTER STUDY

C Minnicelli[1,*] J F Maciel[2], PR L Machado[1], TM AM Lemos[1], R Hassan[3]
[1]Universidade Federal do Rio Grande do Norte, [2]Liga Norteriograndense contra o câncer, [3]Instituto Nacional do Câncer, Natal, Brazil

Background: Multiple myeloma (MM) is an incurable plasma cell neoplasm, characterized by genetic heterogeneity and particular immune deficits. The anti-inflammatory interleukin-10 (IL-10) production is under the influence of gene promoter functional single nucleotide polymorphisms (SNP) that can interfere with clinical outcome.
Aims: To describe clinical characteristics in a MM patient series diagnosed from 2001 to 2013 in a public single center from Natal, north-eastern Brazil, and to explore clinical impact of IL-10 proximal promoter SNPs (-1082A/G, -819C/T, -592C/A) genotypes and haplotypes.
Methods: *IL10* SNPs were genotyped with three experimental haplotyping-PCRs. Associations between gene polymorphisms and clinical/laboratory data were assessed by χ^2 and Fisher tests. Overall (OS) and progression free (PFS) survival analysis were performed by Kaplan Meier method and log rank tests.
Results: From the 38 patients enrolled in the study, 60.5% were female (sex ratio= 1.5). Median age at diagnosis was 62.5y (35-79). IgG/kappa was the most common type of MM (68.4%). Most of the patients were in Durie and Salmon stage IIIA (68.4%). Patients were equally distributed between stages I, II and III (36.8%, 21.1% and 31.6%, respectively) of the International Staging System. BM plasma cell ranged from 12 to 82% (median=20%). Plasmacytoma was observed in 44.7% of patients, being the thoracic curve of the vertebral column the most frequent site (N=6/17, 35.3%). Infections and paresthesia affected 39.5% and 28.9% of cases, respectively. Treatment was performed according to CTD protocol in 60.5%, MPT in 23.7%, Tal/Dexa in 10.5% and VAD in 5.3% of cases. According to the International Myeloma Working Group (IMWG), 15.8% of patients achieved complete response (CR), 23.7% very good partial response (VGPR), 37.1% partial response (PR), 7.9% stable disease (SD) and 10.5% progressive disease (PD). Eight patients were eligible for autologous stem cell transplantation (A-SCT). *IL10* (-1082A/G) genotype frequencies were 51.6% (AA), 32.3% (AG) and 16.1% (GG), and 45.2% (CC), 41.9% (CA) and 12.9% (AA) for *IL10* (-592C/A) SNP. Both SNPs were in Hardy Weinberg equilibrium At diagnosis, women exhibited lower ISS (ISS I= 54.5%; ISS II=22.5%; ISS III=22.5%) compared to men (ISS I= 16.7%; ISS II=25%; ISS III=58.3%, p=0.06). Most women achieved VGPR or PR (18/21, 85.7%, p=0.017), compared to men (4/14, 28.6%). OS was 86.5% and PFS was 69.4% in a follow up time of 125 months. *IL10* (-1082A/G) genotypes defined different OS: 93.8% (AA), 77.8% (AG), 80% (GG), p=0.001, Figure 1; and PFS: 80% (AA), 55.6% (AG), 75% (GG), p=0.042. The CTD-treated group had OS of 90.9% and PFS of 78.3%. In this group, patients underwent A-SCT had longer OS (0/6; 100% *vs* 2/16; 87.5%, p= 0.039) and carriers of the GCC *IL10* haplotype exhibited a worse OS compared to non carries (1/9, 88.9% *vs* 1/11, 90.9%; p= 0.046). Conversely, carriers of the -1082A allele had a better OS (1/16, 93.8% *vs* 1/4, 75%; p= 0.046). The MPT-treated group had OS of 77.8% and PFS of 62.5%.

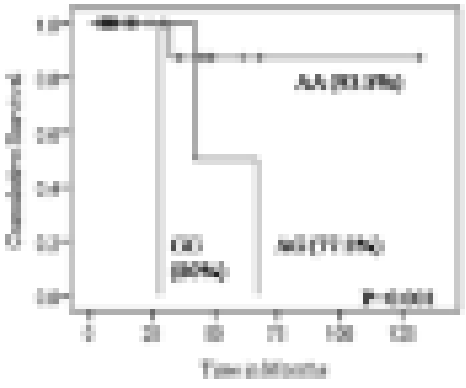

Figure 1.

Summary and Conclusions: Clinical presentation and response to treatment revealed gender-related differences not found worldwide, with women being diagnosed at early disease stages and achieving better responses. The causes of this (either related to bias in referral, or social and/or biological characteristics of the population) are not evident and warrant further research. IL10 SNPs were associated with differential survival; carriers of the -1082G allele exhibited a worse OS and PFS, while the -1082A allele was associated to a better survival.

PB1638

INTERACTION BETWEEN MONOCYTES AND BONE MARROW MICROENVIRONMENT IN PATHOGENESIS OF MULTIPLE MYELOMA

H Ikeda[1,*] T Igarashi[1], T Hayashi[1], T Ishida[1], Y Shinomura[1]
[1]First Department of Internal Medicine, Sapporo Medical University, Sapporo, Japan

Background: Multiple myeloma (MM) is an incurable haematological malignancy characterized by the clonal proliferation of malignant plasma cells within the bone marrow. The current data on MM disease progression indicate that bone marrow microenvironment plays crucial role in pathogenesis of MM. Myeloma cells contacts with bone marrow stromal cells (BMSCs), which secrete factors/cytokines, promoting tumor cell growth and survival. Paracrine secretion of cytokines, such as IL-6, insulin-like growth factor-1, inflammatory protein-1a in BMSCs promotes MM cell proliferation and protects against drug-induced cytotoxicity.MM lytic bone disease is caused by osteoclast activation and osteoblast inhibition. Disease-related bone complications result in significant morbidity due to pain, pathologic fractures and spinal cord compression. The bone microenvironment creates a supportive niche for MM progression. Osteoclasts and BMSCs, along with extracellular matrix and cytokines stimulate myeloma cell proliferation and confer chemoresistance. Therefore, the reciprocal interactions among tumor cells, osteoclasts, osteoblasts, and bone marrow stromal cells impact both the establishment and progression of MM.In current study, monocyte can directly promote osteogenic differentiation of mesenchymal stem cells through cell contact interactions and production of osteogenic factors. This mechanism is mediated by the activation of STAT3 signaling pathway in the mesechymal stem cells that leads to the upregulation of osteoblasts-associated genes such as Runx2 and alkaline phosphatase (ALP), and the downregulation of osteoblast inhibitors such as DKK1 to drive the differentiation of mesechymal stem cells into osteoblasts.
Aims: We revealed the role of monocyte, a component of bone marrow microenvironment, in the MM progression.
Methods: We investigated the proliferation of MM cell lines cultured alone or co-cultured with BM stromal cells, monocytes, or a combination of BM stromal cells and monocytes.The growth inhibitory effect of MM cell lines, monocytes and BMSCs was assessed by measuring 3-(4,5-dimethylthiazol-2-yl)-2,5-diphenyl tetra-sodium bromide (MTT; Chemicon International, Temecula, CA) dye absorbance.To evaluate growth stimulation and signaling in MM cells, MM cells were cultured in BMSC coated 96-well plates in the presence or absence of monocyte. DNA synthesis was measured by [3H]-thymidine uptake, with [3H]-thymidine added during the last 8 h of 48 h cultures. All experiments were performed in quadruplicate.
Results: We observed increased proliferation of MM cell lines in the presence of either BM stromal cells or monocytes compared to cell line-only control. Furthermore,the co-culture of BM stromal cells plus monocytes induced the greatest degree of proliferation of myeloma cells. In addition to increased proliferation, BMSCs and monocytes decreased the rate of apoptosis of

myeloma cells. Our results therefore suggest that highlights the role of monocyte as an important component of the BM microenvironment.
Summary and Conclusions: Our results therefore suggest that highlights the role of monocyte as an important component of the BM microenvironment.

PB1639

THE IMPACT OF SINGLE NUCLEOTIDE POLYMORPHISMS OF INTERLEUKINS ON PAIN RELIEF AND ANALGESIC CONSUMPTION IN THE TREATMENT OF MULTIPLE MYELOMA PATIENTS WITH PAINFUL BONE DESTRUCTIONS BY RADIOTHERAPY

M Rudzianskiene[1,*] A Inciura[1], R Gerbutavicius[1], E Juozaityte[1], R Ugenskiene[1], D Raulinaityte[1], V Rudzianskas[1], G E Kiavialaitis[2]
[1]Oncology Institute, Lithuanian University of Health Sciences , Kaunas, Lithuania, [2]Anesthesiology, University Hospital Aachen, Aachen, Germany

Background: Multiple myeloma (MM) cells interact with bone marrow stromal cells stimulating transcription and secretion of proinflammatory cytokines like IL-6 and IL-10, which are implicated in the progression and dissemination of MM. IL-6 is one of the most important cytokines that contributes to MM cells survival and proliferation, while IL-10 is not only the most potent factor for B-Cell differentiation, but it stimulates MM cell growth as well. Regulation of cytokines secretion is under genetic control through genetic polymorphisms in their coding and promoter sequences. It seems that single nucleotide polymorphism (SNP) in the promoter region of various genes may regulate the plasma concentrations of cytokines. Cytokines could be also hypothesized to function as pain modulators as peripheral nociceptors are sensitized by proinflammatory cytokines.
Aims: To determine if the SNP of IL-6 and IL-10 cytokines could influence the analgesic response of radiotherapy in the treatment of painful bone destructions in MM patients.
Methods: From 2012 until 2013, 30 patients (19 women and 11 men, median age: 67 years) with multiple myeloma and painful bone destructions were enrolled in the study. Patients with painful bone destructions were treated with palliative radiotherapy. Pain was evaluated according to the visual analogue scale with score endpoints ranging from 0 (no pain at all) to 10 (worst imaginable pain). A pain score ≤ 4 was classified as mild, 5 – 7 as moderate and ≥ 8 as severe. Pain score and analgesics usage were measured prior to radiotherapy as well as 4, 12 and 24 weeks afterward. Opioid analgesics were converted to the morphine-equivalent daily dose (mg/day). Genomic DNA was extracted from peripheral blood leukocytes and IL-6 and Il-10 gene promoter polymorphisms were analyzed with polymerase chain reaction-restriction.
Results: 60% (18/30) of the patients reported severe pain prior to radiotherapy, which decreased to 13% (4/30) at the first follow up visit (p <0.001). The Mean Morphine Equivalent Daily Dose (MEDD) on admission to the hospital was 75 mg/day (range 10 – 260 mg/day) which decreased to 46 mg/day (range 0 – 140 mg/day) at the first follow up visit after radiotherapy (p=0.033). A significant parameter in pain relief was: age<65 years (p=0.029). We analyzed 3 SNPs (-597G/A, -572G/C, -174G/C) in IL-6 gene promoter region and 3 SNPs (-592A/C, -819C/T, -1082A/G) in IL-10 gene promoter and their association with pain severity and analgesic consumption. Due to the small sample size we did not find significant relations, but there was a borderline association for patients who are IL6 -597A/A and G/G carriers assumed to be at higher risk for severe pain prior to radiotherapy (p=0.07) while for patients who are IL10 -1082A/A carries: the median pain score decreased faster (p=0.08). Patients with genotypes IL6 -597A/A and IL6 -174C/C required a smaller dose of opioids (p=0.06). Patients who are IL10 -1082A/G carriers are prone to respond better to radiotherapy than other patients (p<0.05).
Summary and Conclusions: SNP of IL-6 and IL-10 cytokines can influence the analgesic response of radiotherapy. Patients with genotype Il-10 -1082A/G respond better to radiotherapy.

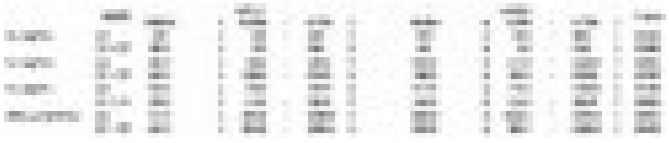
PB1640

BLOOD CONCENTRATION OF LENALIDOMIDE WOULD CHANGE WITH THE EXISTENCE OF CLARITHROMYCIN

N Takezako[1,*] N Sekiguchi[1], A Nagata[1], M Miura[2], T Niioka[2], S Shida[3], T Kobayashi[3], M Abumiya [2], N Takahashi[3]
[1]Hematology, Disaster medical center of Japan, Tachikawa, [2]Pharmacology, Akita University Hospital, [3]Hematology, Nephrology, and Rheumatology, Akita University Graduate School of Medicine, Akita, Japan

Background: Multiple myeloma is still lethal disease. However, the prognosis of this disease has been improving according to the administration of novel agents. Among of these novel agents, lenalidomide is confirmed the validity of consolidation-maintenance setting by a randomized controlled study. Recently, the combination of clarithromycin, lenalidomide, and dexamethasone (BiRd) was evaluated as therapy for treatment-naive symptomatic multiple myeloma (MM), with overall response at 2 years of 90%. However, mechanism of clarithromycin against myeloma cells is not still clear. It was reported that single-agent clarithromycin to have no efficacy in a phase 2 pilot study of 23 patients. However, some investigators argued that the addition of clarithromycin to weekly dexamethasone enhances the corticosteroid effect and may therefore increase both the overall response rate and toxicity. As known, lenalidomide is a weak substrate of P-glycoprotein, a membrane efflux transporter ubiquitously expressed in human tissues, such as the small intestine, whose activity could decrease the bioavailability of lenalidomide. Clarithromycin is known as inhibitor of P-glycoprotein in the intestinal wall. Therefore, we examined whether blood concentration of lenalidomide would change with the existence of clarithromycin.1
Aims: To investigate whether blood concentration of lenalidomide would change with the existence of clarithromycin.
Methods: Lenalidomide 15 mg (Revlimid; Celgene Corporation, Tokyo, Japan) was orally administered once daily at 08:00 hours according to the recommendations (day 1-21) of a 28-day cycle. Dexamethasone (20mg) was administrated on day 1,8,15, and 22. Orally, from day 8 to 21, Clarithromycin 400mg was administrated twice daily. On day 7and 14 of Bird therapy, whole-blood samples were collected just before oral lenalidomide administration, and at 1, 2, 4, and 6 hours thereafter. Pharmacokinetic analysis of lenalidomide was carried out using the standard non-compartmental method using WinNonlin (version 5.2; Pharsight Co, Mountain View, CA). The elimination half-life was calculated from the log-linear regression of the terminal phase of the concentration–time curve using at least 3 sampling points (elimination half-life = ln2/ke; ke = elimination rate constant). The total AUC was calculated using the linear trapezoidal rule.1
Results: Fifteen patients were enrolled in this study from April 2012 to February 2013. In some patients, blood concentration of lenalidomide increased administration of clarithromycin. These patients had wild type of ATP-binding Cassette Sub-family B Member 1 (ABCB1) C3435T genotype (C/C) (6 patients). The other patients who were not affect to clarithromycin administration were mutated types (C/T(6 patients) or T/T (3 patients)). The significant association between gingival overgrowth and the 3435TT genotype was confirmed by logistic regression analysis (p<0.046) (Table 1).

Table 1.



Summary and Conclusions: In patients who had wild type of ABCB1 genotype (C/C), blood concentration of lenalidomide significantly increased with the existence of clarithromycin. We need to do further examination whether blood concentration and an ORR are related.

PB1641

SERUM LEVELS OF FLT3 LIGAND ARE ASSOCIATED WITH MYELOMA ACTIVITY

A Xekalou[1], G Tsirakis[2,*] A Kolovou[3], A Boula[4], R Vyzoukaki[5], M Kokonozaki[5], A Papadopoulou[5], E Fasoulaki[5], M Alexandrakis[2]
[1]Pathology, [2]Hematology, University Hospital of Heraklion, Heraklion, [3]Hematology, General Hospital of Chania, Chania, [4]Hematology, Venizelion Hospital of Heraklion, [5]Hematology Laboratory, University Hospital of Heraklion, Heraklion, Greece

Background: FLT3 ligand (FLT3L) and its receptor FLT3 participate in the normal development of lymphocytes.
Aims: The aim of the study is to measure serum levels of FLT3L in active MM patients and to estimate if they are associated with known factor of disease activity.
Methods: We studied 58 patients with active MM (33 male; 30 with IgG, 19 with IgA, 9 with light chain paraprotein; 17 stage I, 19 stage II, 22 stage III, according to ISS) and 30 age and sex-matched, healthy controls. We measured serum levels of FLT3L and interleukin-6 (IL-6) by ELISA. We also recorded serum values of CRP, LDH and beta2 microglobulin (B2M), being measured routinely.
Results: Serum levels of FLT3L and the other parameters, were higher in active MM patients (p<0.001 in all cases). They all were, also increasing in parallel with ISS disease stage (p<0.001 in all cases). Moreover, serum levels of FLT3L correlated positively with values of IL-6 (r=0.400 p<0.002), CRP (r=0.489 p<0.0001) and LDH (r=0.434 p<0.001).
Summary and Conclusions: Serum levels of FLT3L reflect MM disease activity. Therefore, they could be useful markers, justifying both a more in-depth study of its participation in MM biology and the rational for potential use as a therapeutic target.

PB1642

DEK EXPRESSION IN NORMAL AND MALIGNANT PLASMA CELLS

T Çakar[1,*] A Özdilek[1], A S Kim[2], Ö Doğan[3], A Bosompem[2], B Saka[4], A Kandilci[1]
[1]Molecular Biology and Genetics, Gebze Institute of Technology, Gebze, Kocaeli, Turkey, [2]Pathology, Microbiology and Immunology, Vanderbilt University School of Medicine, Nashville, United States, [3]Department of Pathology, [4]Internal medicine, Istanbul University, Istanbul, Turkey

Background: Copy number variations are between the most frequent chromosomal abnormalities found in multiple myeloma (MM), a plasma cell neoplasm. *DEK*, which locates on chromosome 6p22.3, was initially identified in acute myeloid leukemia as a partner of abnormal *DEK-CAN* fusion. Increased expression of *DEK* provides proliferative advantage to epithelial cells whereas it enhances differentiation of myeloid cells. Increased copy number of chromosome 6p22.3 was correlated with upregulation of *DEK* expression in melanoma, urinary bladder cancer and retinoblastoma. Although amplification of 6p22.3 region where *DEK* locates was detected in about 20% of MM patients, whether this variation affects the expression of *DEK* in MM remains elusive.
Aims: We aimed to determine the expression level and copy number of *DEK* in multiple myeloma patients.
Methods: We isolated CD138^{positive} and CD138^{negative} cells from frozen or fresh bone marrow cells using the EasySep™ CD138 positive selection kit (Stem Cell Technologies, Vancouver, BC). Purity of the CD138^{positive} population was confirmed by flow cytometry. We analyzed the expression level of *DEK* mRNA in CD138^{positive} and CD138^{negative} cells from MM patients (n=41) and controls (pooled 3 bone marrow samples) using reverse transcription quantitative PCR (RT-qPCR). The copy number of *DEK* was determined in the same set of samples (CD138^{positive} MM cells and controls) using quantitative PCR (qPCR). In addition, DEK and CD138 expression was analyzed in formalin-fixed paraffin embedded (FFPE) bone marrow samples from 56 MM cases, 12 cases of monoclonal gammopathy of undetermined significance (MGUS), and 8 controls samples using immunohistochemistry (IHC).
Results: Immunohistochemical stains demonstrated moderate to high level of expression in the myeloid and erythroid cells, while DEK protein was not detectable in both normal and neoplastic CD138^{positive} plasma cells using FFPE bone marrow samples of MGUS, MM and controls. Immunohistochemical analysis of lymph nodes used as a positive control showed DEK expression in all lymphocytes, more extensively in the germinal center cells, but not in CD138 ^{positive} plasma cells. Accordingly, RT-qPCR results showed that *DEK* mRNA expression was significantly lower in CD138^{positive} MM cells compared to both CD138^{negative} cells (predominantly myeloid and erythroid cells) (P<0.0001) or control bone marrows (P<0.0009). There was a continuum of expression of *DEK* mRNA in the plasma cells without separation into a clear population of *DEK* overexpressors. By contrast, copy number of *DEK* was increased (between 1.5-2 fold) in 4 out of 41 MM samples by qPCR, but was not correlated with the expression level of *DEK* mRNA in these samples. In this limited number of cases, the percentage of samples showing *DEK* amplification (10%, 4/41) was slightly lower than the previously reported percentage of 20%.
Summary and Conclusions: Our results suggest that DEK expression level is downregulated in normal and malignant plasma cells which is independent of the copy number of *DEK*. Lack of detectable DEK protein might serve as an additional useful immunohistochemical marker for the diagnosis of MM.

Myeloma and other monoclonal gammopathies - Clinical

PB1643

RONEPARSTAT, A NOVEL HEPARANASE INHIBITOR AS A POTENTIAL TOOL FOR MULTIPLE MYELOMA THERAPY

A Rambaldi[1,*] P Barbieri[2], M Galli[1], M Leiba[3], A Naggi[4], R Sanderson[5], A Nagler[3], I Vlodavsky[6]
[1]Hematology and Bone Marrow Transplant Unit, Azienda Ospedaliera Papa Giovanni XXIII, Bergamo, Italy, [2]Clinical Development, sigma tau Research Switzerland S.A., Mendrisio, Switzerland, [3]Division of Hematology, Chaim Sheba Medical Center, Tel Hashomer, Israel, [4]Istituto di Ricerche Chimiche e Biochimiche "G. Ronzoni", Milano, Italy, [5]University of Alabama, Birmingham, AL, United States, [6]Rappaport Faculty of Medicine, Technion, Haifa, Israel

Background: Heparanase (HPSE), an enzyme that cleaves heparan sulfate chains, has been associated with aggressive growth of several tumor types. HPSE activity upregulates expression of genes that support tumor growth and also remodels the extracellular matrix within the tumor microenvironment thereby facilitating cell invasion associated with cancer growth, angiogenesis and inflammation. This makes HPSE a promising new and unexploited therapeutic target with multiple potential applications, including cancer and other diseases (*e.g.*, diabetes, inflammatory diseases). Roneparstat (SST0001), a 100% N-acetylated glycol split heparin(1), is a potent HPSE inhibitor devoid of any significant anticoagulant effect. In preclinical testing, Roneparstat significantly inhibited subcutaneous (sc) growth of tumor xenografts utilizing multiple myeloma (MM) cell lines RPMI-8226, MM1.S, CAG and KMS-11. In the myeloma tumors, Roneparstat inhibited angiogenesis and diminished levels of HGF, VEGF and MMP-9(2). Roneparstat also diminished HPSE induced shedding of syndecan-1, a heparan sulfate proteoglycan known to be a potent promoter of myeloma growth(3). In addition Roneparstat had an anti-metastatic effect in models of breast, pancreatic and melanoma cancers.
Aims: Although new therapies over the last decade have improved treatment of patients with MM, essentially all patients eventually develop resistance to drugs and succumb to the disease. Thus, the identification of innovative and effective treatments for MM is needed. In a model of MM using drug resistant MM.1R cells, the combination of Roneparstat with dexamethasone significantly inhibited tumor growth(2). This prompted evaluation of Roneparstat in MM patients, in combination with dexamethasone.
Methods: A First in Man, multicentre, international, phase I clinical study is currently ongoing in advanced heavily pre-treated refractory MM patients who have exhausted all available anti-MM therapies. Roneparstat is administered sc, with a starting flat dose of 25 mg defined according to ICH S9 guidelines. Dose escalation is combined with an escalation in the number of days of treatment (from DX5Q28D to DX5QW1,W2 Q28D); in absence of relevant toxicity, the dose levels are escalated in a doubling fashion, otherwise the dose escalation is based upon the type and severity of toxicity seen. Each cohort plans 3 + 3 patients. aPTT is used as a surrogate measurement of Roneparstat plasma concentration in pharmacokinetic studies. The pharmacodynamic effect of the drug on the coagulation cascade and any antitumor effect are also evaluated.
Results: The study is ongoing with 8 patients enrolled to date. Two patients received 1 cycle of therapy, three patients 2 cycles, one 4 cycles, one 5 cycles and one is not evaluable. No DLTs were observed. Roneparstat so far has been well tolerated both systemically and locally.
Summary and Conclusions: Nonclinical pharmacology studies suggested Roneparstat activity against hematological malignancies, in particular multiple myeloma, with an additive or synergistic effect with dexamethasone. The currently ongoing study will permit evaluation of the Maximum Tolerated Dose and will establish the Recommended Dose for further Roneparstat development as combination therapy in MM.

A PHASE TWO STUDY OF LENALIDOMIDE, METRONOMIC DOSES OF CYCLOPHOSPHAMIDE AND PREDNISONE IN THE TREATMENT OF NEWLY DIAGNOSED MULTIPLE MYELOMA PATIENTS OLDER THAN 75 YO

G Ramirez[1,*] F J Capote[2], M Casanova[3], E Rios[4], J L Guzmán[5], A Alcalá[6], J Ruiz[7], C Montalbán[8], A F Jurado[9]

[1]Hematology, Hospital Universitario Virgen de la Victoria, Málaga, [2]Hospital Puerta del Mar, Cadiz, [3]Hospital Costa del Sol, Marbella (Spain), [4]Hospital de Valme, Seville, [5]Hospital de Jerez de la Frontera, Cadiz, [6]Hospital de Jaen, Jaen, [7]Hospital de Antequera, Antequera, [8]Hospital Ramón y Cajal, Madrid, [9]Hospital Juan Ramón Jimenez, Huelva, Spain

Background: Multiple Mieloma (MM) remains incurable. There is an increasing interest in the treatment of the oldest MM patients (75yo or older) due to increasing of life expectancy. The current challenge is to incorporate the new drugs in tolerable schedules that may improve treatment-results without compromising the quality of life of such population of patients.
Aims: Our aim was to assess the response rate according to the International Myeloma Working Group (IMWG) criteria with the combination of lenalidomide, prednisone, and metronomic doses of cyclophosphamide in newly diagnosed MM patients older than 75 years-old.
Methods: This is an open-label, multicenter, single-arm, phase II study in patients older than 75 years with newly diagnosed MM. After signing the informed consents, patients were treated with lenalidomide, cyclophosphamide and prednisone combined during 21 days in 28-day cycles (lenalidomide10, 15 and 25 mg/day in the first three cycles respectively; cyclophosphamide 50 mg/every other day; prednisone 50 mg/every other day). Treatment was administered until disease progression or unacceptable toxicity. The primary endpoint of this study was to assess the response rate according to the IMWG criteria. Response rates were assessed at the end of each 3 cycles. Secondary endpoints were: time to progression (TTP), overall survival (OS), progression free survival (PFS), early mortality, treatment regimen tolerability and treatment regimen toxicity.
Results: A total of 21 patients (57,1% women) with a median age of 80,6 years (range 76,1 – 90,4 years) were recruited between June 2009 and June 2011.The ISS at diagnosis was I for 2 patient (9,5%), II for 5 patients (23,8%), III for 13 patients (61,9%) and non available for 1 patient (4,8%). The overall median time to treatment initiation from diagnosis was 17 days. Overall response rate in the study was 71,5% (sCR 0%, CR 14,3%, VGPR 14,3%, PR 38,1%, SD 4,8%). Median time to response was 91 days (CI 95% 88,5 – 96,3). Median response duration was 365 days (CI 95% 343,8 – 386,2). Median TTP was 460 days (CI 95% 333,3– 586,3). The mean overall survival was 728 days (CI 95% 616 – 841). A total of 58 adverse events were related to the study medication. The most frequent related adverse events were diarrhea and neutropenia. Serious adverse events were reported in 11 patients but only 5 of them were considered as treatment-related.
Summary and Conclusions: The results of the study provide evidence that the combination of lenalidomide, cyclophosphamide and prednisone were effective and well-tolerated in patients older than 75 yo with newly diagnose of MM. A larger prospective trial is required in this special population for a better knowledge of this combination or others.

PB1645

IMPACT OF COMORBIDITY INDICES ON TREATMENT RESPONSE AND SURVIVAL IN MULTIPLE MYELOMA

B Öneç[1,*] H Okutan[1], M Albayrak[1], E Sarıbacak Can[1], V Aslan[1]
[1]Hematology, Dışkapı Yıldırım Beyazıt Education and Research Hospital, Ankara, Turkey

Background: Multiple myeloma (MM) is a heterogeneous disease with 20% of patients having a survival period of less than 2 years, but more than 15% of patients have more than a 10 year survival period. Therefore it is important to identify disease features and prognostic factors that may allow better tailored therapeutic intervention. Because it is a disease involving a relatively older population with a median age of diagnosis at 69 years, besides advanced age and poor performance status, comorbidities are also empirically used as prognostic factors in treatment determination. As not all comorbidities may affect the outcome, weighted comorbidity measurements are frequently used in older patients but it is not well known which of them are really prominent at MM.
Aims: The purpose of this study was to assess whether and which comorbidity indices predict survival in a real life population of MM. We calculated the Charlson Comorbidity Index (CCI), CCI-age combined index, Hematopoietic cell transplantation-specific comorbidity index (HCT-CI) and Freiburger comorbidity index (FCI) retrospectively for 66 MM patients and compared their impact on treatment responses and overall survival.
Methods: The mean age of the 66 MM patients who varied between 34-90 years of age was 66.55 (±12.149) and nearly 60% (n=40) of the patients were men and 40% were women (n=26). As a result of the assessment (n=66) the mean and median survivals were determined to be 32.87 and 39.01 months respectively with no significant difference between genders. In order to compare the comobidity scores the patients were separated into the three risk groups of low, medium and high in accordance with literature.
Results: When the patients were separated into two groups taking the median age 67 as reference it was observed that the average survival period in the advanced age group (age≥67) is 27 months and 37 months in the younger group (age<67). However this was not found to be statistically significant (p=0.172). In the performed assessment the relation of calcium, albumin, beta-2 micro globulin, ISS and Durie-Salmon staging, ECOG and Karnofsky performance scales with survival were statistically significant (p<0.05). The ISS staging (p=0.006) and ECOG performance state were the factors that have a significant impact on treatment response. When the response to treatment is examined the response to treatment are found to be meaningfully worse (p=0.042, p=0,016, p=0,03 respectively) in CCI, CCI-age, HCT-CI high risk groups while FCI's response to treatment effect was not significant. When survival is examined while there is no meaningful relation with CCI, CCI-age and HCT-CI indices, it is observed that survival is 40.7 months, 38.5 months and 21.2 months respectively in the FCI-CI low, medium and high risk groups (p=0,006). When the factors comprising the FCI scoring were each examined individually it was observed that pulmonary and renal comorbidity scores do not have a significant impact on survival on their own but the Karnofsky performance state has a significant relation with survival on its own when coded as under and over 70 (p<0.001).
Summary and Conclusions: In light of these findings the conclusion can be made that during the initial assessment of patients the presentation of performance state and comorbidity in addition to staging is an important tool in predicting the prognosis of patients. In the assessment of comorbidities with different scores it has been presented that the FCI developed in MM patients is the only index with a significant effect on overall survival however, contrary to other indices, its relation with response to treatment has been found not to be signicant.

PB1646

A SINGLE CENTRE CLINICAL EXPERIENCE OF THE EFFICACY AN SAFETY PROFILE OF SUBCUTANEOUS VERSUS INTRAVENOUS BORTEZOMIB

K Randall[1,*] I Qureshi[1], S Bokhari[1]
[1]Department of Haematology, University Hospitals Coventry and Warwickshire NHS Trust , Coventry, United Kingdom

Background: Bortezomib plays a key role in the management of patients with multiple myeloma and has traditionally been administered intravenously. Subcutaneous administration is an alternative with a study by Moreau et al in 2011 demonstrating similar efficacy to intravenous use with an improved safety profile. The European Medicines Agency approved its subcutaneous administration in 2012 however there is little published data on its use in clinical practice.
Aims: Our hospital changed to subcutaneous use in April 2012. This study aimed to compare our experience of patients treated with subcutaneous *versus* intravenous bortezomib.
Methods: Patients treated with bortezomib between January 2011 and September 2013 were identified and their records retrospectively reviewed. Demographic details, side effects experienced, remission duration and survival data was collected. Statistical analysis was performed using GraphPad Prism©.
Results: 54 patients were treated with bortezomib; 28 by intravenous and 26 by subcutaneous route. The median age was 70.5 years. The majority of patients had received at least 1 prior treatment (89% subcutaneous; 90% intravenous) with 81% and 75% having received a previous IMiD. Patients received a median of 5.5 cycles in both groups with a similar cumulative dose administered (23.5mg/m^2 subcutaneous; 23.3 mg/m^2 intravenous group). 75% in the intravenous arm were treated with bortezomib alone or in combination with dexamethasone compared to 35% in subcutaneous arm where the remainder received a combination of bortezomib, cyclophosphamide and dexamethasone (VCD 54%) or bortezomib, adriamycin and dexamethasone (PAD 11%). 12% of subcutaneous group underwent autologous stem cell transplant *versus* 4% in intravenous group. The overall response rate (CR+VGPR+PR) was similar between the subcutaneous and intravenous groups (80% *versus* 71% respectively) with a median time to best response of 4 cycles in both (range 1-7). The median follow up was 12 and 24 months in subcutaneous and intravenous groups respectively with no significant difference in overall survival (1 year survival 84% and 78%, p=0.78) or relapse-free survival (median 13 and 6 months, p=0.28). The trend towards improved relapse-free survival may be due a higher number receiving autologous stem cell transplants in the subcutaneous arm. There were 50 adverse events recorded in the subcutaneous group compared with 43 in intravenous group with 10(20%) and 7(16%) grade 3-4 adverse events respectively. Of interest 50% of adverse events in the subcutaneous group occurred in those who received VCD therapy. 14% of adverse events required discontinuation of Bortezomib in both groups with 22% and 16% needing dose reductions in subcutaneous and intravenous groups respectively. 16 patients in both groups developed peripheral neuropathy (62% and 57%, p=0.84) with 3 (12%) *versus* 5 (18%) patients developing Grade 3-4 in the subcutaneous and intravenous groups. There were more Grade 3-4 haematological toxicities in the subcutaneous group (19% and 2%), however 4 of the 5 patients in the subcutaneous group were being treated with VCD or PAD
Summary and Conclusions: Our study demonstrated no significant difference

in outcomes between subcutaneous and intravenous bortezomib. We did not find the significant reduction in peripheral neuropathy with subcutaneous administration seen in previous studies however the safety profile was equivalent. Subcutaneous administration has obvious advantages in terms of patient experience and potential cost savings and should be considered a viable alternative to intravenous bortezomib.

PB1647

SMOLDERING AND SYMPTOMATIC MULTIPLE MYELOMA. EPIDEMIOLOGY IN THE NORTH AREA OF SANTA CRUZ DE TENERIFE: 1990-2009

M Fernandez-González[1,*] M Tapia[2], J García-Talavera[3], S Lakhwani[1], JM Raya[1], S E Iraheta[1], L Hernández-Nieto[1], C Stoica[1], T Martín-Santos[1], A Martín-Martín[1], JL García[4], MT Hernández[1]
[1]Hematology, Hospital Universitario de Canarias, La Laguna, [2]Hematology, Hospital General de La Palma, La Palma, [3]Hematology, Hospital universitario Nuestra Señora de la Candelaria, Santa Cruz de Tenerife, [4]Medical Director at Celgene, Celgene, Madrid, Spain

Background: Multiple myeloma (MM) is the second most common hematological malignance (after lymphoma), and constitutes 1% of all cancers. The incidence rate for MM is 5.8 per 100,000 per year.
Aims: Due to the high number of patients diagnosed with MM in Tenerife, and especially in La Palma, we wonder whether the incidence in our study area would be greater than that reported in the literature
Methods: We retrospectively reviewed the cases of all patients diagnosed with MM (smoldering and symptomatic) in our reference area, which includes the north of the island of Tenerife and the entire island of La Palma, (patients should have lived in this areas at least 2 years before of the diagnosis) between 1990 and 2009. We collected demographic data, laboratory variables, and treatment and response. We separate the cases according to the municipality, type of myeloma and year of diagnosis. We use the annual census of each municipality to estimate incidence.
Results: Of 409 patients (203 men and 206 women), 313 were symptomatic and 96 were smoldering (SMM) (29 low risk and 49 high-risk cases with 18 unclassified). The mean age was 68.4 years (± 0.568), with a range between 32 and 92 years. 62% of patients were> 65 years. The incidence of the total area in the last 15 years (more reliable data) is 5.6 cases per 100,000 citizens / year with an incidence of 7,53 in La Palma island and 5,14 in Tenerife island (p=0.0012). The highest incidence in Tenerife was in 2008 (8.29) and in 2002 in La Palma (15.99), although both islands the incidence trend is ever upward for decades (Figure 1A). Within the island of Tenerife, the towns of La Laguna and Tegueste have the highest incidence (8.64 and 5.10, respectively), while on the island of La Palma are Barlovento (12,05), Villa de Mazo (10,37) and Garafía (10,21). The latest available incidence obtained from the last five years is of 6.36; in Tenerife 5,89 and 8.39 in La Palma (p=0.0612). The median overall survival from diagnosis (OS) was 3.75 years±0.37 years and the median overall survival from treatment (OS_T) was 2.78 years±0.29 years. The median progression-free survival after treatment (SLP_T) was 1.35 years±0.10 years. The median time of progression to symptomatic MM from low risk SMM was 4.02 years±0.68 years, while for high risk SMM was 1.21 years±0.25 years. The OS_T of high risk SMM was not different from the symptomatic MM´s of novo (p=0.117). Multivariate analyses were performed using Cox's regression. Were clinically significant the following factors: A) At diagnosis: Durie-Salmon (Figure 1B), ISS, LDH, comorbidities and percent of plasma cell B) Related to treatment: response to the first line (Figure 1C) , transplantation and maintenance.

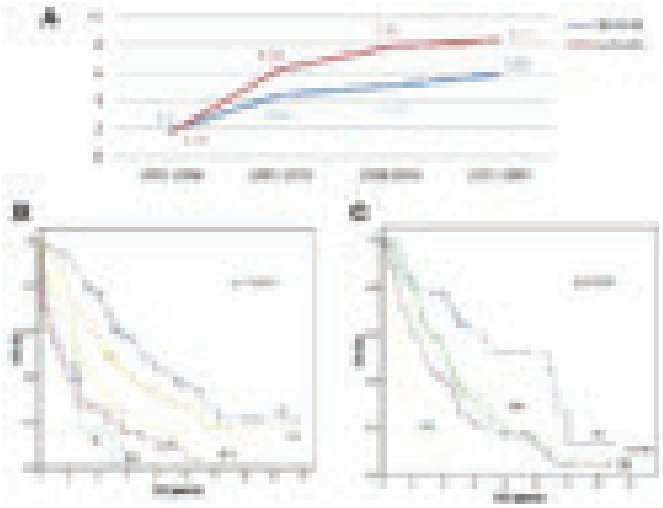

Figure 1.

Summary and Conclusions: The incidence of MM in our area is high, especially on La Palma island. The causes of this high incidence in some towns in the province should be studied in more detail. The high risk SMM evolves much faster to symptomatic MM and the survival, once treated, is similar to symptomatic. This finding suggests that high-risk smoldering myeloma should be assimilated in terms of prognosis to symptomatic myeloma.

PB1648

PHASE II TRIAL TO INVESTIGATE EFFICACY AND SAFETY OF BENDAMUSTINE, DEXAMETHASONE AND THALIDOMIDE IN RELAPSED OR REFRACTORY MULTIPLE MYELOMA PATIENTS AFTER TREATMENT WITH LENALIDOMIDE AND BORTEZOMIB

M Mian[1,*] N Pescosta[2], S Luminari[3], S Badiali[3], L Marcheselli[3], F Patriarca[4], R Zambello[5], P Mondello[6], A Pascarella[7], V Pitini[6], S Cortelazzo[8]
[1]Hematology & CBMT, [2]Hospital of Bolzano, Bolzano, [3]Department of Oncology and Hematology, University of Modena and Reggio Emilia, Modena, [4]Azienda Ospedaliera-Universitaria, Udine, [5]Padua University School of Medicine, Padova, [6]University of Messina, Messina, [7]Ospedaledell'Angelo, Venezia-Mestre, Mestre, [8]Humanitas/Gavazzeni Cancer Center, Bergamo, Italy

Background: Despite the introduction of new and efficient drugs for multiple myeloma (MM) treatment, mainly bortezomib-based multidrug regimens, most patients relapse and lenalidomide based also provide only a temporary disease free state. After the third relapse the prognosis is usually dismal and new therapeutic approaches are needed.
Aims: The aim of this trial is to assess the tolerability and efficacy of bendamustine in association with dexamethasone and thalidomide (BDT) in relapsed/refractory patients after lenalidomide and bortezomib or who are ineligible to these drugs.
Methods: The primary endpoints of this multicenter phase II trial were the assessment of efficacy, in an intention to treat analysis, and toxicity. Treatment consisted of bendamustine (60mg/m2, d 1, 8, 15), dexamethasone (20mg, d 1, 8, 15, 22) and thalidomide (100mg, d1-28) repeated every 28 days for 6 cycles.
Results: Up to now 18 of the planned 30 patients were enrolled and completed at least the first therapy cycle. They underwent a median of 2 previous treatment lines (range 1-6). Median age was 60 years and most patients presented with an ISS-1 (61%), a good performance status (50%) and had a IgG kappa monoclonal component (33%). 4 patients completed the planned treatment and another 4 underwent ≥4 treatment cycles. Treatment was usually well-tolerated and overall only 4 patients experienced grade 3/4 hematologic toxicity. During 53 cycles, 5 treatment related serious adverse events (9%) were recorded (3 cases of pneumonia, 1 cerebral hemorrhage, 1 deep vein thrombosis and 1 pulmonary embolism), leading to death in 2 patients (4%). Of note note, no grade 3/4 neurologic toxicity has been observed. Up to now the ORR was 5/9 (55%): 3 very good partial remissions and 2 partial remissions. Other 2 patients had stable disease and 2 progressed during treatment after 2 and 4 treatment cycles, respectively and died (Figure 1).

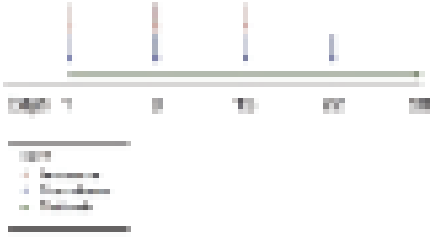

Figure 1.

Summary and Conclusions: In this interim analysis, BDT demonstrated to be an effective regimen for relapsed/refractory MM patients. The toxicity, as expected, in these heavily pretreated patients was not negligible, but manageable and no grade 3/4 neurologic side effect was observed.

PB1649

INTER-LABORATORY DISCORDANCE OF BETA-2 MICROGLOBULIN RESULTS: IMPACT ON THE VALIDITY OF THE INTERNATIONAL STAGING SYSTEM FOR MULTIPLE MYELOMA

PL Fedele[1], KW Choy[2], JC Doery[2,3], J Shortt[1,4], G Grigoriadis[1,5,*] ZX Lu[3,6]
[1]Clinical Haematology, [2]Pathology Department, Monash Health, Melbourne, [3]Medicine, Monash University, Clayton, [4]Division of Research, Peter MacCallum Cancer Centre, Melbourne, [5]Medicine, Southern Clinical School, Monash University, Clayton, [6]Pathology, Monash Health, Melbourne, Australia
Background: Multiple myeloma prognostication is largely defined by the International Staging System (ISS)[1] using serum beta-2 microglobulin (β2M)

and albumin results. Local external quality assurance data showed substantial, method-dependant variations in β2M results.
Aims: We determined the variability of different β2M methods using patient samples, and whether this influences ISS prognostic scores.
Methods: β2M stability after freeze-thawing was established first. Specimens (n=21) were then sent frozen to four laboratories using different methods/instruments for β2M: Lab1, nephelometric (Beckman Coulter Immage); Lab2, chemiluminescent (Immulite 2000); Lab3, turbidimetric (Roche Cobas c502) and Lab 4 turbidimetric (Abbott Architect c16200). All laboratories use the same albumin method (bromocresol purple).
Results: Lab1 produced β2M results consistently higher than other laboratories (Figure 1): mean difference +1.55 mg/L (28.5%) (95%CI: 1.02 – 2.09, p<0.0001) compared to Lab2; +1.09 mg/L (20.1%) (95% CI: 0.78 – 1.41, p<0.0001) to Lab3; and +0.51 mg/L (9.3%) (95% CI: 0.29 – 0.73, p<0.0001) to Lab4. Compared to Lab1, ISS scores were classified one stage lower in 7, 5 and 3 patients by Lab2, Lab3 and Lab4, respectively. One patient could have been classified either stage I, II or III depending on which laboratory performed the tests. Albumin methods aligned well and had minimal impact on ISS score.
Summary and Conclusions: Results from different β2M methods are highly variable and harmonisation is required. This study has important implications on the validity of ISS staging for myeloma.

PB1650

EFFICACY OF LENALIDOMIDE-BASED AND BORTEZOMIB-BASED REGIMENS IN THE FIRST RELAPSE OF 144 MULTIPLE MYELOMA PATIENTS: A SINGLE CENTRE EXPERIENCE
M Krejci[1,*] Z Adam[1], L Pour[1], A Krivanova[1], E Sevcikova[1], J Pelcova[1], J Mayer[1]
[1]Department of Internal Medicine, Hematology and Oncology, University Hospital Brno, Brno, Czech Republic

Background: The introduction of novel agents, such as proteasome inhibitors and immunomodulatory drugs, has substantially changed the treatment paradigm of multiple myeloma (MM). It is not yet clear whether some of the novel agents are significantly better than others for the first relapse of MM.
Aims: In this retrospective study, we have analyzed the outcomes of patients (pts) with the first relapse of MM treated with lenalidomide-based (L) regimens (n=72) or bortezomib-based (B) regimens (n=72) with aims to compare the efficacy of these therapies. Both treatment groups are comparable in baseline clinical parameters including age, clinical stages according to ISS and DS staging systems, the type of M-protein, presence of renal impairment and in the first-line therapy of MM.
Methods: Clinical stages according to ISS were the following: stage 1 in 32% of pts (46/144), stage 2 in 43% of pts (62/144) and stage 3 in 25% of pts (36/144). Renal insufficiency was presented in 19% of pts (27/144). Median age was 69 years (range: 49-83). Median follow-up from start of treatment was 32 months. Lenalidomide-based (L) regimens were used in 72 pts; lenalidomide+alkylating agent+ dexamethasone: 54 cases (75%), lenalidomide + dexamethasone: 15 cases (21%), alone lenalidomide: 3 cases (4%). Patients were treated with lenalidomide 25 mg daily (day 1-21, repeating of cycle on day +28); in cases with renal impairment the dose was 10 mg daily. Bortezomib-based (B) regimens were used in 72 pts; bortezomib+alkylating agent+ dexamethasone: 58 cases (81%), bortezomib+dexamethasone: 11 cases (15%), alone bortezomib: 3 cases (4%). Bortezomib was used in standard dose 1.3 mg/m^2 subcutaneously on days 1, 4, 8, 15. The cycle repeated on day 21-28 for up to 9 cycles or until progression. Median of L and B treament cycles was 5, range 1-9.
Results: In the lenalidomide-based group, overall response rate (ORR) was 56%, 10% of pts achieved the complete response (CR), 21% of pts were in very good partial response (VGPR), 25% of pts in partial response (PR), 8% of pts had minimal response (MR) or stable disease (SD) and 35% of pts had progression of disease. Median time to progression (TTP) from the start of relapse treatment was 18.4 months, median overall survival (OS) was 38.3 months. In the bortezomib-based group, overall response rate (ORR) was 51%, 13% of pts were in CR, VGPR was achieved in 16% of pts, PR in 22% of pts, MR or SD in 16% of pts, progression was observed in 33% of pts. Median TTP and OS from start of bortezomib treatment were 18.2 and 40.8 months, respectively.
Summary and Conclusions: The lenalidomide-based and bortezomib-based regimens are effective in treatment of the first relapse MM with ORR 51-56%. Medians of TTP and OS are similar for both treatment groups. According to our findings, there are no significant differences between treatment regimens containing either lenalidomide or bortezomib for the first relapse of MM.

PB1651

COMBINED USE OF HLC AND FLC IN MULTIPLE MYELOMA AND MONOCLONAL GAMMOPATHIES PATIENTS
A Gagliardi[1,*] A Russo[2], C Carbone[2], S Improta[1], L Mastrullo[1]
[1]UOC Ematologia PO San Gennaro ASL Napoli1 Centro, [2]UOC Patologia Clinica PO San Gennaro ASL Napoli1 Centro, Naples, Italy
Background: International Myeloma Working Group guidelines recommend serum protein electrophoresis (SPEP) and serum free light chain (FLC) immunoassays with derived kappa/lambda ratios for diagnosis, prognosis and monitoring in multiple myeloma and monoclonal gammopathies. Heavy light chain (HLC) immunoassay can be used in screening, monitoring and risk stratifying of multiple myeloma and monoclonal gammopathies patients.
Aims: We have effected FLC plus HLC assays at diagnosis and after at regular intervals for monitoring of multiple myeloma disease or monoclonal gammopathies.
Methods: Beginning from July 2012 we have observed 150 patients in our Haematology Unit selected by the presence of monoclonal component at SPEP. We have evaluated HLC and FLC ratios on the basis of patients disease (Multiple Myeloma (MM), smouldering myeloma, Monoclonal Gammopathy (MGUS), Waldenström disease (MW).
Results: In many patients combined evaluation of HLC and FLC is useful for identification of CR an MDR in course of multiple myeloma monitoring. In several cases both tests are needed to exclude presence of minimal amounts of M-Ig. Persistent disease was indicated by an abnormal HLC ratio in 10/43 patients who achieved CR with normal FLC ratios. Somewhat contradictory is the observation of a normal HLC ratio in 15/48 IFE-positive patients achieving nCR or VGPR. Also we have observed several cases of double M-component in course of therapy for multiple myeloma with normal FLC ratio.
Summary and Conclusions: Combined evaluaton of HLC and FLC is useful for diagnosis, prognosis and monitoring of Multiple Myeloma and Monoclonal Gammopathies.

PB1652

THE COMPARISON OF BORTEZOMIB-CONTAING REGIMEN AND THALIDOMIDE-CONTAINING REGIMEN; SUPERIORITY OF BORTEZOMIB, DOXORUBICIN, AND DEXAMETHASONE THERAYPY IN NEWLY DIAGNOSED MYELOMA WITH RENAL IMPAIRMENT
N Sekiguchi[1,*] N Takezako[1], A Nagata[1], K Youngil [2,3], HJ Lee[3,4], SS Yoon[2,3]
[1]Divison of Hematology, National Hospital Organization Disaster Medical Center, Tokyo, Japan, [2]Department of Internal Medicine, Division of Hematology/Medical Oncology, Seoul National University Hospital, [3]Cancer Research Institute, Seoul National University College of Medicine, Seoul, [4]Department of Internal Medicine, Dongguk University Ilsan Medical Center, Goyang, Korea, Republic Of

Background: Multiple Myeloma (MM) with renal impairment (RI) has had poor prognosis so far. Bortezomib-containing regimen (Bor-R) and thalidomide-containing regimen (Thal-R) have already been proven to be safe and effective in MM with RI. Bor-R such as bortezomib and dexamethasone (BD) therapies, and combination regimens of bortezomib with other agents are recommended in a consensus statement of International Myeloma Working Group (IMWG) for patients of MM with RI. However, only a limited number of reports are available regarding the comparative studies among Bor-R, Thal-R, and lenalidomide-containing regimen. Furthermore, the best Bor-R combination has not been demonstrated yet.
Aims: To clarify the best regimen for newly diagnosed MM with RI, we compared the recovery of renal function, response of MM, and toxicities between Bor-R and Thal-R.
Methods: Newly diagnosed MM with RI from January 2004 to December 2013 in National Hospital Organization Disaster Medical Center in Japan and Seoul National University Hospital in South Korea were enrolled in this study. Patients, MM characteristics, regimen, renal response, and MM response were obtained from medical charts. As for an initial therapy, Bor-R including BD therapy, Bor, doxorubicin, and dexamethasone (PAD, Takezako N, *et al.*, 14th IMW abstract P220), and Bor, melphalan, and prednisone (VMP), and Thal-R were enrolled. Supportive care including hydration and administration of bisphosphonates were allowed. Renal functions were measured by the simplified Modification of Diet in Renal Disease formula to identify RI in MM patients with stabilized serum creatinine levels, and best renal response was evaluated according to a consensus statement of IMWG for patients of MM with RI. Major renal response means either CR or PR. Best myeloma response during initial induction treatment was assessed according to IMWG response criteria.
Results: Sixty-three patients were enrolled in this study. Median age was 68 years-old, and Male/Female was 41/22. Of 63 patients, 56 cases were ISS >2. As for an initial therapy, 45 received Bor-R (BD=23, PAD=11, VMP=11), and 18 received Thal-R. Compared to Bor-R, younger age, better PS were statistically more common in Thal-R. Overall renal response and major renal response rate was 34/45 (75.6%), and 25/45 (55.6%) in Bor-R, and 10/18 (55.5%), and 7/18 (38.9%) in Thal-R (statistically not significant). However, day to best renal response of Bor-R was 14 days, whereas, it was 50.5 days in Thal-R (P=0.01). None of 2 in Thal-R, 3 of 5 in Bor-R who required dialysis became independent of the procedure. Myeloma response was not statistically significant between the 2 groups. Among Bor-R, younger age in PAD, better PS in VMP were statistically more common. Major renal response rate was superior in PAD (P<0.01), and days to best renal response of BD, PAD, and VMP were

14, 10, and 19 days, respectively. Furthermore, PAD was superior in myeloma response among Bor-R (P<0.01). On the other hand, hematologic toxicities were statistically severer in PAD. Regimen, sex, hypercalcemia, and myeloma response affected renal response in univariate analysis. On the other hand, multivariate analysis demonstrated regimen (P=0.01), and myeloma response (P=0.04) contributed to major renal response.
Summary and Conclusions: Bor-R, and Thal-R were effective in MM with RI. However, Bor-R might have earlier renal response. Furthermore, PAD was considered as best regimen among Bor-R from the view of higher renal response rate, earlier renal response, and myeloma response in newly diagnosed MM with RI.

PB1653

NOVEL MARINE COMPOUNDS WITH ANTI-MYELOMA ACTIVITY IN VITRO AND *IN VIVO*

N Steiner[1,2,*]G Untergasser[1], J Kern[1,3], K Joehrer[3], A Seeber[3], M Aracil[4], W Willenbacher[2], G Gastl[2], E Gunsilius[1,2,3]
[1]Laboratory of Tumor Biology and Angiogenesis, [2]Department of Internal Medicine V (Hematology and Oncology, Innsbruck Medical University (IMU), [3]Tyrolean Cancer Research Institute (TCRI), Innsbruck, Austria, [4]PharmaMar (Zeltia Group), Colmenar Viejo, Madrid, Spain

Background: The prognosis of patients with multiple myeloma (MM) has substantially improved during the last years- due to implementation of novel drugs into the treatment.
Aims: However, MM is still incurable and novel treatment strategies are needed.
Methods: Here, we tested novel substances for their anti-myeloma activities *in vitro* and *in vivo*. 11 new marine compounds with unknown activity against MM were applied in different concentrations to the MM cell lines OPM-2, NCI, U-266 and on primary multiple myeloma cells *in vitro*. Apoptosis was determined by FACS using annexin V FITC/ 7AAD-staining and GFP-ELISA. The compounds effective *in vitro* were tested further on PBMC's and on GFP-transgenic MM cell lines *in vitro* and *in vivo* (CAM assay).
Results: 6/11 compounds showed anti-myeloma effects *in vitro*. IC50 was <10[nM] for 4/6 effective substances, suggesting activity similar to Bortezomib. These compounds were also effective against purified human MM cells *in vitro* and exhibited anti-myeloma effects on GFP- transgenic OPM-2 cells *in vivo*.
Summary and Conclusions: New compounds with potential anti-myeloma effects *in vitro* and *in vivo* were identified.

PB1654

HEMODIALYSIS WITH HIGH CUT-OFF FILTERS AND CHEMOTHERAPY FOR MULTIPLE MYELOMA PATIENTS WITH ACUTE RENAL FAILURE

N Alkadi[1,*] V Dourdil[1], E Bonafonte[1], L Arango[1], D Leza[1], MJ Escobar[1], LL Romero[1], MT Olave[1], L Palomera[1]
[1]Department of Hematology, Hospital Clínico Universitario Lozano Blesa, Zaragoza, Spain

Background: Acute renal failure (ARF) in multiple myeloma (MM) is present in about 10-15% of the cases, and the patient's survival depends on the recovery of their renal function. Cast nephropathy, caused by intratubular precipitation of circulating free light chains (FLC), is the most common cause. To avoid this, the early introduction of anti-myeloma treatment is necessary. One coadjuvant measure is the elimination of FLC by hemodialysis with high cut-off filters (HCO) (Theralite), which removes a huge amount of FLC.
Aims: This study assessed the combination of chemotherapy and hemodialysis with HCO on amount of free light chains, renal recovery and hematologic response in patients with MM and ARF.
Methods: We report 9 cases (8 M/ 1 F) of ARF and MM treated with this procedure. Average age was 60 years (42-71). Types: Bence -Jones MM: 6 (4 κ and 2 λ), IgG: λ: 2 and IgG: κ: 1. Average level of serum creatinine was 6,9 mg / dL (2,9-12,1). Average creatinine clearance (MDRD -6) was 9,9 mL/min/1,73m2 (4,51-22,3). Average proteinuria was 14,9 g /24 h (1-35). Average serum FLC (Binding -Site) was 7845 mg / L (1130-20200). Time between the onset of renal failure and the start of the hemodialysis with HCO was 38 days (5-90). FLC measures at the beginning and at end of treatment were conducted. The antiMM treatment was: 7 patients on Velcade (Bortezomib) - Dexamethasone, 1 patient on Velcade - Revlimid (Lenalidomide) - Dexamethasone, 1 patient on Velcade - Thalidomide - Dexamethasone and Revlimid - Dexamethasone.
Results: Average of hemodialysis with HCO was 12 (6-27). Average serum FLC after the procedure was 287 mg / L (17-790). Average final serum creatinine was 2,62 mg/dL (0,82 to 5,9), and creatinine clearance was 44,64 mL/min/1, 73m2 (9,54 to 95,4). Renal response was complete in 3 patients, partial in 3, minimum in 1 and failure in 2. Seven patients were dialysis independent. The hematologic response was: 4 RC, 1 VGPR, 2 PR, 2 MR. Two patients died of MM. Patients who did not recover renal function or only partially, had an average start of hemodialysis of 56 days, an average FLC level of 10067 mg/L, and a dialysis average of 16,7. Meanwhile, patients who achieved response had an average start of hemodialysis of 20 days, FLC level of 6056 mg/L, and a dialysis average of 7,3.
Summary and Conclusions: In our experience the combination of hemodialysis treatment with HCO combined with an antiMM treatment provides a satisfactory result (66% of the responses) in patients with MM and ARF. The predictive factors of response where the amount of serum FLC and the early introduction of hemodialysis with HCO.

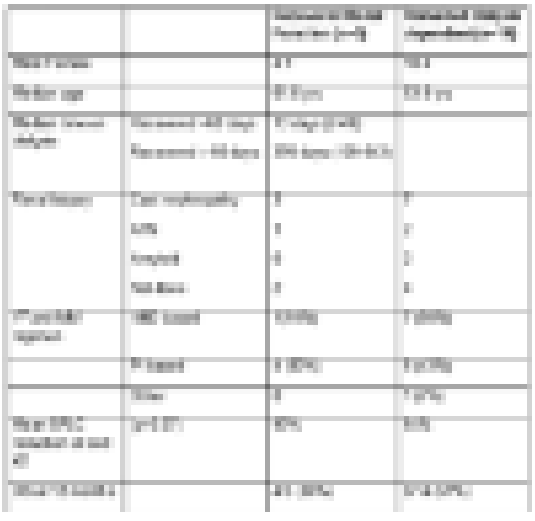
PB1655

FACTORS PREDICTING RENAL RECOVERY IN MYELOMA PATIENTS PRESENTING WITH DIALYSIS DEPENDENT ACUTE KIDNEY INJURY

C Pawlyn[1,*] S Jain[2], E Masters[1], A Hunt[2], D Makanjuola[2], S C Stern[1]
[1]Haematology, [2]Renal Unit, St Helier Hospital, Sutton, United Kingdom

Background: Renal failure is a common complication of myeloma (MM) caused by toxic effects of high monoclonal free light chains along with other contributory factors. Up to 10% of MM patients present with dialysis dependent acute kidney injury (AKI). Early and sustained reduction in light chains leads to improved renal recovery, translating into improved survival and quality of life. The use of novel agents developed over the last decade has made this a realistic aim and the advent of serum free light chain (SFLC) monitoring has enabled the rapid assessment of disease response to treatment given their significantly shorter half-life than whole M-protein.
Aims: To identify factors associated with renal recovery in patients presenting with MM and dialysis dependent AKI.
Methods: Data were collected retrospectively for patients presenting to our centre, a district general hospital with a tertiary referral renal unit. We analysed those patients with a new diagnosis of MM presenting with AKI requiring dialysis. Adequate data were available for 19 patients presenting between 2010 and 2012.
Results: All patients had SFLC at diagnosis of >1000 mg/l (mean 8655mg/l, range 1200-34600, 74% kappa, 26% lambda). 8 patients had light chain only disease whilst the other 11 patients also had a paraprotein (IgG in all cases). Median age was 63 years, 14 male *vs* 5 female. Where recorded all patients were ISS Stage 3. 3 patients died within 60 days of diagnosis (16%). 4 patients underwent ASCT, two whilst still receiving dialysis but with a reduced dose of melphalan (140mg/m^2). 3/19 patients demonstrated renal recovery by 3 months (median time on dialysis 13 days, range 2-49). These patients all had a mean reduction in their SFLC of >90% by the end of cycle 2 of therapy (mean reduction 96% *vs* 64% for those who did not go on to recover renal function). 2 additional patients went on to recover renal function later. They had a reduction in SFLC levels by the end of cycle 2 of 92% and 89%, in one patient this was after a change in therapy from a thalidomide based regimen to bortezomib following deterioration of disease markers. Further comparison is made in Table 1. Patients who recovered renal function had a longer overall survival (OS) than those who did not (median NR *vs* 385 days, p=0.25). The OS in all patients at 12 months of 68% (13/19) compares favourably to a historical cohort from our centre who presented between 2000 and 2005 which had a 12 month OS of 45%.

Table 1.



Summary and Conclusions: Our "real life" data in an unselected group of

patients suggests that the use of proteasome inhibitors as the first anti-MM treatment and the speed of reduction in SFLCs predicts for renal recovery in MM patients presenting with AKI. However, this study was not sufficiently powered to determine whether these factors are significant or independent. We suggest that clinicians should undertake frequent monitoring of SFLC and consider a change in therapy if response does not occur quickly.
Overall survival at our centre in this patient cohort has improved with the advent of novel agents in comparison to historical studies.

Background: AL amyloidosis is a monoclonal plasma cell disorder associated with progressive end-organ dysfunction and poor survival outcomes. Bortezomib combination chemotherapy is rapidly active in AL amyloidosis with high rates of hematologic and organ responses.
Aims: We aimed to determine the efficacy and toxicity of bortezomib, melphalan, and prednisolone (VMP) as first-line chemotherapy in patients with AL amyloidosis who were ineligible for autologous stem cell transplant (ASCT).
Methods: We conducted a retrospective review of patients with newly diagnosed AL amyloidosis with or without multiple myeloma who were initially received a VMP regimen between 2011 and 2013 at a single center.
Results: For 19 patients included, the median age was 65 years (range, 42-74 years) and in 90% of patients had two or more organs; heart and kidneys were affected in 18 (95%) and 6 (32%) patients, respectively. Most of the patients was advanced stage AL amyloidosis (84% in 2004 Mayo Stage III and 92% in 2012 Mayo Stage III or IV). Sixteen (84%) patients had a hematologic response, including 7 (37%) complete response, within a median time to response of 1 month (range, 1-3 months). Cardiac and renal responses were seen in 44% and 40% of patients, respectively. At median follow-up of 8 months (range, 1-32 months) months, median progression-free survival and overall survival was 8 and 11 months, respectively. The most frequent grade 3-4 adverse events were thrombocytopenia, diarrhea, and pneumonia.
Summary and Conclusions: Our results suggest that VMP seems to be highly effective treatment for AL amyloidosis as a first-line treatment. Further investigation of VMP as treatment for AL amyloidosis is needed.

Background: Renal impairment (RI) is a common complication at diagnosis in patients with multiple myeloma (MM). The presence of renal impairment is associated with an increased risk of early death.
Aims: This study examined the prognostic factors for survival outcomes in patients with MM presenting with RI.
Methods: Retrospective data for 104 patients who presented RI at diagnosis were analyzed. RI was defined as an estimated glomerular filtration rate (eGFR) ≤ 60 ml/min/1.73 m^2 using the simplified Modification of Diet in Renal Disease formula.
Results: Baseline median eGFR was 39.0 ml/min (range 5.1-59.8). Achievement of renal complete response (renalCR) was observed in 37.1% of patients. Predictors of overall survival were evaluated using logistic regression analysis which included age (> 65), eGFR<30ml/min, oliguria (< 500 ml/day), thrombocytopenia (platelet<100,000/mm^3) , achievement of renalCR, myeloma response (≥ partial response) and performance of autologous stem cell transplantation (ASCT). On multivariate analysis, oliguria at diagnosis (hazard ratio [HR]= 4.493, p=0.001), thrombocytopenia at diagnosis (HR= 2.666, p=0.003), and performance of ASCT (HR = 0.456, p=0.039) were significantly associated with overall survival.
Summary and Conclusions: In conclusion, an oliguria and thrombocytopenia at diagnosis were important predictors for poor survival in MM patients with RI.

THE IMPACT OF HYPERGLYCEMIA ON RISK OF SEVERE INFECTIONS DURING EARLY PERIOD OF INDUCTION THERAPY IN PATIENTS WITH NEWLY DIAGNOSED MULTIPLE MYELOMA

DH Yang[1,*] JS Ahn[1], SH Jung[1], YK Kim[1], HJ Kim[1], JJ Lee[1]
[1]Hematology-Oncology, Chonnam National University Hwasun Hospital, Hwasun, Korea, Republic Of

Background: The association with hyperglycemia and infections during induction chemotherapy has been reported in a number of hematologic disorders.
Aims: We evaluated the incidence of hyperglycemia and its association to development of severe infection during early period of initial chemotherapy in patients with multiple myeloma (MM).
Methods: The records of 176 patients were retrospectively analyzed. Patients were stratified into three groups by World Health Organization criteria: eugylcemia, mild hyperglycemia and overt hyperglycemia.
Results: A total of 35 (19.9%) patients developed overt hyperglycemia (≥ 200 mg/dl) during induction therapy. Serious infections occurred in 32 (18.2%) of 176 patients and infection-related mortality within 2 months after treatment was 2.3% (4 patients). In a univariate analysis, overt hyperglycemia, poor performance status (≥ 2), International Stage System III, lymphopenia (< 500/μL), and elevated serum creatinine (≥ 2 mg/dL) were associated with serious infections. In multivariate analysis, only overt hyperglycemia (OR 5.188, 95% CI 2.046-13.155, p=0.001) and poor performance status (OR 4.105, 95% CI 1.588-10.611, p=0.004) remained significant. Furthermore, patients in the overt hyperglycemic group showed increased mortality compared to that in patients in the other groups (38.6 *vs.* 56.8 months, p=0.046).
Summary and Conclusions: This study demonstrates an association between hyperglycemia and serious infections during induction therapy in patients with MM.

PERIPHERAL BLOOD ABSOLUTE MONOCYTE COUNT AS PREDICTOR OF OVERALL SURVIVAL IN MULTIPLE MYELOMA

E Piro[1], G Carillio[1], M Kropp[1], M Lentini[1], L Levato[1], D Magro[1], S Molica[1,*]
[1]Dipartimento Ematoncologia, Azienda Ospedaliera Pugliese-Ciaccio, Catanzaro, Italy

Background: The tumor microenvironment, including tumor-infiltrating lymphocytes and myeloid-derived cells, is an important factor in the pathogenesis and clinical behavior of different neoplasms.
Aims: However, the prognostic significance of peripheral monocytes in multiple myeloma (MM) was never assessed thus far.
Methods: In a retrospective unselected cohort including 120 patients diagnosed as having active MM at our institution over a 10-year period (2000-2010) we evaluated the prognostic impact of absolute monocyte count (AMC), absolute lymphocyte count (ALC) and lymphocyte/monocyte ratio (LMR).
Results: Median age of patients was 69 years (range, 41-86 years) and there were 64 males and 56 females. Patient distribution according to ISS was as follows: ISS 1, 75 cases; ISS 2-3, 45 cases. After a median follow-up time of 39 months (range, 2-160 months)53 patients died while median OS was 52 months. Looking at the prognostic impact of ALC,AMC and LMR different thresholds were set. While ALC or LMR failed to demonstrate any impact on clinical outcome of MMpatients in terms of overall survival (OS), a cut-off value of 0.450 x 109 for AMC, corresponding to 75th percentile, was strongly associated with OS. Survival curve according to AMC is presented below. As shown, median survival of patients with AMC<0.450 x 109 at the time of diagnosis was 91 months therefore significantly longer than median survival of patients with AMC ≥0.450 x 109 (34 moths) [HR, 2.67 (95% CI, 2.12-3.22); P=0.004]. No correlation could be found between AMC and ISS score (P=0.719), response to therapy (P=0.966) and comordidity index as assessed by ACE-27 score (P=0.135). In contrast, an inverse correlation between patient age and AMC characterized our cohort (P=0.04) (Figure 1).

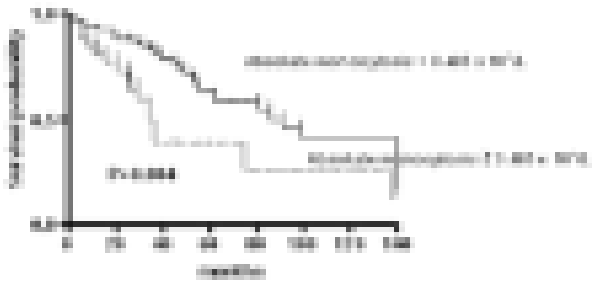

Figure 1.

Summary and Conclusions: In summary, AMC at diagnosis, as a simple index which reflects tumor microenvironment, predicts clinical outcome in MM patients.AMC isan objective, reproducibleand cost effective test, which can easily be obtained from standardblood count. Additional studies on AMC are warranted in MM patients to better understand the roles of monocytes in this disease.

Background: Waldenström macroglobulinemia (WM) was defined as a distinct clinicopathologic entity characterized by bone marrow infiltration by lymphoplasmacytic lymphoma (LPL) and IgM monoclonal gammopathy. WM is very rare hematologic malignancy which has an overall incidence of approximately 3 per million persons per year, accounting for approximately 1% to 2% of hematologic cancers in USA. The incidence rates of WM are lower in South Korea than those in USA, which were documented about 0.3 per 1000,000 person-years according to data of National Cancer Information Center in South Koea. However, many reported studies presented the superior efficacy of chemotherapy combined novel agents including rituximab, bendamustine, fludarabine, bortezomib, lenalidomide, and thalidomide than that of conventional chemotherapy. But novel agents combined chemotherapy for patients with WM have been used restrictively in Asia and south Korea because of very low incidence and limitation of insurance. So until now, there were a few reports about clinical features, epidemiology, and cytogenetics of WM in Asia including south Korea. Moreover, there is no study about treatment outcomes in patients with WM treated by novel agents combined chemotherapy.
Aims: This unique study was planned for investigation of clinical features and comparision of treatment outcomes between novel agents and conventional chemotherapy.
